The article aimed to assess the relationship between personality metatraits and managerial competencies demonstrated in AC simulations while taking into consideration managers' age, which was used as a moderator variable. According to our hypotheses, positive personality metatraits should be linked with a higher level of managerial competencies, while negative personality metatraits should be related to a lower level of managerial competencies. The results showed that Plasticity (Beta-plus) was positively related to openness to change, problem-solving, and employee development. Integration (Gamma-plus) correlated positively with problem-solving, openness to change, and employee development. On the other hand, Passiveness (Beta-minus) and Disharmony (Gamma-minus) had a negative relationship with all managerial competencies. Thus, we could conclude that only three out of the eight measured personality metatraits played an important role in this relationship. We should highlight that although these correlations were significant, they were not very strong, so the results should be interpreted with caution, albeit similar findings were reported in other studies that measured these constructs (e.g. Meriac et al., 2008; Klehe et al., 2012; Simonenko et al., 2013).

A person's performance in the AC may be influenced by the level of individual characteristics and context. Managerial competencies were assessed by observing behavior in four AC simulations grouped into strong and weak VUCA, so in the second step, we wanted to check whether personality metatraits predicted AC performance in strong and weak VUCA simulations. We found that Passiveness (Beta-minus) was a negative predictor of (1) social skills in strong but not in weak VUCA, (2) problem-solving in strong and weak VUCA. Summarizing, the dark characteristics of personality like apathy and submissiveness in interpersonal relations can be perceived as individual barriers to demonstrating social skills (e.g. effective communication, assertiveness, and teamwork) and problem-solving (e.g. ability to analyze a situation and seek the best solution to these problems), which are crucial in managers' work environment. Interestingly, no relationships were found

between positive personality metatraits and managerial competencies, so we could conclude that the bright sides of our personality are neutral in this relationship and only the dark sides can disturb the demonstration of managerial competencies.

The performance of a person during the AC may be influenced by the level of individual characteristics, the context, and managers' age; so in the next step, we wanted to check whether personality metatraits predicted AC performance in various age groups. The results showed that Disharmony (Gamma-minus) was a negative predictor of AC performance in the youngest group of managers, while Passiveness (Beta-minus) was a negative predictor of AC performance in the middle-aged group of managers. No significant regression coefficients were observed in the oldest group of managers, so we could conclude that dark personality metatraits could be considered blockers in demonstrating managerial competencies among the youngest and middle-aged managers. A possible explanation of our results could be that personality plays a more important role among younger managers than among older ones, whereas older managers' performance relies more on their competencies.

Oral presentation OP30

PerspectivesTM PsyCap Potential - The critical psychological capabilities underpinning leadership potential in a VUCA world

Nicola Adcock, Peoplewise - Head of Leadership and Development; Belinda Board, Peoplewise - CEO

science&practice

Research goals

PeopleWise sought to understand what differentiates successful leaders, and the critical psychological variables that predict leadership potential to enable organisations to identify, develop & retain their critical talent to build robust leadership pipelines for the future.

Theoretical background

Grounding the model in positive psychology, PeopleWise drew on existing literature, including the work of Judge et al. (1997) on core self-evaluations, the psychology of performance, motivation, leadership & interpersonal effectiveness, as well as research conducted by PeopleWise practitioners in leadership, organisational behaviour & psychological capabilities. Insights were also drawn from the research on corporate psychopathy & disordered personalities in the workplace (Board and Fritzon, 2005) and the extensive experience working with many organisations and thousands of leaders globally over the last two decades.

Methodology

The model was first conceptualised in the early 2000s, with a global client to profile & develop high potential leaders within their organisation. The client wanted to use psychometrics with strong predictive validity for leadership potential, but that also could be developed through micro-interventions such as development centres & programmes. A substantial gap in the literature and the market was identified, with a lack of an integrative theory of state-like measures that could also predict performance & potential at work. This project was the springboard for the development of the Perspectives TM PsyCap Potential model.

PeopleWise identified criteria for sifting through leadership theory to produce an integrative taxonomy of psychological capabilities in the workplace. PeopleWise reviewed the literature using key criteria and constructed the first draft of the PsyCap model, known as the Potential Evaluation Profile (PEP). Initially, as three higher-order capabilities, which later expanded to become the PsyCap Potential assessment of five critical psychological capabilities. Extensive reliability and validity studies were conducted with focus on criterion-referenced validity, to ensure the constructs were associated with key organisational outcomes linked to leadership potential and performance. This was key to defining its utility for selection and development.

Results

In pursuing which capabilities define leadership potential, PeopleWise identified five higher-order psychological capabilities defining the Perspectives TM PsyCap Potential model: Mental Agility, Emotional Agility, Confidence, Resilience & Drive. Within each of the five capabilities are three lower-order sub-capabilities. This has resulted in the development of a single comprehensive, rigorous assessment measuring the five critical psychological capabilities consistently shown to be associated with leadership performance, leadership potential & marginal risk. This is demonstrated through

significant relationships established with job performance, success on work-related training courses, 180 performance ratings, assessment centre performance ratings (and 12 month post-centre potential rating), annual performance ratings, leadership success, academic performance, number of promotions, organisational Citizenship Behaviours (OCBs).

Limitations

May be beneficial to conduct a global longitudinal study, to validate the psychological capabilities against other organisational outcomes.

Implications

The model provides organisations and practitioners with an assessment tool for selection and development to not only know their talent but also grow their talent based on a well-researched and globally validated model of potential. PeopleWise has received strong client and candidate feedback on the assessment tool as a number of clients have applied the model within their organisations. The tool has been described as revolutionary and an essential part of the HR toolkit providing new and useful insights into top talent. Clients have integrated the assessment into several different leadership development programmes, both as part of the entry process as well as a tool to inform development across the programmes. The tool has also been integrated into selection processes to aid in recruitment decisions at various different leadership levels across the business from individual contributors to senior leaders.

In addition to the Perspectives TM PsyCap Potential model, the behavioural capabilities linked to each psychological capability have also been developed. This provides organisations with a single, comprehensive & integrated model to assess and develop both leadership potential (through psychological capabilities) but also leadership performance (through behavioural capabilities).

Value

Researching a less traditional methodology of assessing personality through a holistic approach to defining, measuring and developing state-based personality through capabilities which are developable and positively associated with organisational outcomes.

Keywords: Perspectives, PsyCap Potential, Psychometric

Oral presentation OP84

Physical absence makes the heart grow fonder? The motivational implications of digital communication during a work-at-home day

Elke Van de Wiele, Sophie De Winne, Marijke Verbruggen, Anja Van den Broeck & Elfi Baillien | KU Leuven

science

Ever since the pandemic, we have witnessed a major shift in how jobs are conducted, with a significant increase of telecommuting in a range of organizations and occupations. A rising practice in this respect has been telework from home (TWFH; Vleeshouwers et al., 2022) in which the employee adheres to telecommunication technologies for performing their work-related tasks from home (Rudolph et al., 2021). The subject of TWFH had already fueled scholarly interest before, with researchers investigating its effects on both the employee and the work environment (e.g., organizational culture and turnover intention; Bloom, Liang, Roberts & Ying, 2013). Their studies were predominantly conducted along the lines of work stress theory (Ingusci et al., 2021) and social identity theory (Thatcher &Zhu, 2006; Fonner & Roloff; 2012).Applying these perspectives specifically, they found that TWFH caused feelings of professional isolation, an increase in working hours (i.e., working overtime), blurred work-family boundaries, and work to home conflict (Delanoeije, Verbruggen & Germeys, 2019). Alternatively, some studies also pointed at higher focus and productivity from TWFH (Vleeshouwers et al., 2022); indicating that TWFH does not seem to be "all that bad". However, to date, there is little insight of the more positive effects of TWFH. Therefore, in this study, we aim to adopt a more positive angle towards TWFH by looking at how this practice may contribute to the employee's motivation. More specifically, we investigate to what extent and how TWFH relates to the employee's basic needs satisfaction – i.e., frustration versus fulfillment of the needs of autonomy, relatedness and competence - as defined in Self Determination Theory (SDT; Van den Broeck et al., 2016). Indeed, abundant research has attested the importance of the fulfilment of these needs for desired outcomes such as well-being (Peters, Calvo & Ryan, 2018). The frustration of these needs is associated with higher levels of work-related stress and leads to ill-being (Olafsen, Niemiec, Halvari, Deci & Williams, 2017).

In applying a motivational lens to TWFH, we orient ourselves towards a highly important feature of TWFH days as we have seen from the more recent approaches to such days ever since the pandemic: we specifically look at computer mediated communication (CMC) when teleworking from home. That is, employees are now increasingly using CMC to do their work and socially connect to their supervisor and co-workers. In this study we want to investigate why such CMC during a working day at home could fuel versus challenge needs satisfaction. CMC is approached as a scale, measuring the extent of work related communication via e-mail, audioconference, videoconference and instant messaging during the work hours.

Next, drawing on the literature, we identified three features of CMC important for a work setting specifically: techno-workload (Liu, Du, Choi & Li, 2022), social support (Barnett, Martin & Garza, 2019), and interruptions (Sonnentag, Reinecke, Mata & Vorderer, 2018). We expect the use of CMC to fulfill the need for autonomy. Additionally, CMC will fulfill the need for relatedness and immediate CMC is likely to lead to the satisfaction for the need for competence, in contrast to delayed communication which likely is frustrating. So we expect CMC with colleagues during a day TWFH to have an impact on the daily motivation through different topics. In all, this study contributes to science by being the first to explicitly investigate TWFH, and more precisely CMC during a TWFH day, from a motivational perspective.

To test our hypotheses, we used an event-based diary study in which we examined the impact of CMC during a TWFH day on employee basic needs satisfaction through techno-workload, social support and interruptions. Data were collected over two periods of 10 consecutive workdays (in May and September 2022), and participants were invited to complete a survey at the end of each TWFH day. We collected a total of 591 TWFH observations. We are now in the process of analyzing the data using multilevel analysis, which will be completed by the beginning of 2023. We will discuss our findings and their implications during our oral presentation.

Oral presentation OP87

Placing data analytics into the HRM tool kit: A view to improve organizational effectiveness

Vincent Cassar, University of Malta; Frank Bezzina, University of Malta; Suzanne Rank , Mainz University of Applied Science, Germany; Stephanie Fabri, University of Malta; Sylwia Przytula, Wroclaw University of Science and Technology

science&practice

This study evaluates how HRM practitioners make sense of the strategic relevance of HRM Data Analytics (HRMDA). We conducted in-depth interviews amongst 48 HRM practitioners from three European countries working in diverse organizations with the aim of highlighting their concerns, beliefs and expectations associated to the use and adoption of data analytics. We utilised Diffusion of Innovation Theory to inform our thinking and focused on the contextualisation of data analytics, their potential role in HRM practice, the required skills needed to support their adoption and the degree of trust associated with accepting HRMDAs. Overall, participants acknowledged the importance of HRMDAs but were still generally sceptical whether it can substitute traditional HRM and tended to rate it as reinforcing HRM rather than substituting it. Research on HRMDAs, from the point of view of practitioners, is scarce and research is required to explore how analytics will re-shape the professional landscape of HRM in a changing world of work.

Oral presentation OP138

Positive team climate and emotional intelligence of both team leaders and followers as resources for high job flourishing and performance

Rizqi A'yuninnisa, Celeste Wilderom & Lara Carminati | University of Twente

science

Research goals and rationale

How can workers' well-being and productivity be promoted at the same time? Answering this age-old question has been a focus in positive occupational health psychology. To help reach the optimal level of both desirable outcomes, scholars and practitioners alike must better understand their dynamic antecedents. Despite a few controversial issues inherent to measuring emotional intelligence (EI), empirical findings have consistently demonstrated the positive impact of a leader's EI on followers' well-being and job performance. However, little is known about why and how these effects occur and what the added value is of the predominantly positive (contagious) emotions within their team. Our empirical study aims to find out how a leader's EI can enhance his/her followers' job flourishing and performance, and how a positive emotional climate within the team may moderate these links.

Theoretical background

According to the multi-level model of emotion at work (Ashkanasy, 2003), effective team leaders are expected to have a high level of EI since they are required to co-manage their followers' emotions well. These leaders' emotions are likely to be communicated and reflected by their EI, which is an important job resource that can influence followers' EI levels through emotional contagion. We argue that this interactive process particularly occurs when the emotional climate within the team is positive. Indeed, according to the job demands-resources (JD-R) theory (Bakker & Demerouti, 2017), EI is a personal resource that might affect job flourishing and performance. Furthermore, despite the generally known positive influence of a leader's EI on followers' work outcomes, not every team member may display a high level of EI as a result of a high level of leader EI. Thus, a contextual factor such as team climate can be another resource for team members (or followers) EI. When developing our multilevel research model, we expected that the perceived leader's EI would help to promote individual follower's job flourishing and performance via an enhanced level of follower EI, particularly when there is a high positive team climate.

Design

To test our hypothesized multilevel model, a two-wave survey design was invoked while collecting data from 1,227 primary school teachers in Indonesia and their 169 leaders.

Results

The results suggest that a team leader's EI plays a key role in promoting job flourishing directly ($B = 0.17$, $p < 0.001$), or indirectly via enhanced EI ($B = 0.11$, $p < 0.001$), particularly when the positive team emotional climate is high ($B = 0.17$, $p < 0.01$). Moreover, the leader's EI also has a direct effect on job performance (leader-rated $B = 0.046$, $p < 0.05$; self-rated $B = 0.180$, $p < 0.001$). It is evident, thus, that a team leader's EI contributes to followers' job flourishing and performance. This dynamic is likely to occur due to emotional contagion processes from the leaders to followers, which appears to be also facilitated by a positive emotional climate within the team. Meanwhile, individual follower

EI serves prominently as a crucial mediating mechanism or personal resource for promoting self-rated job performance ($B = 0.34$, $p < 0.001$).

Limitations

Despite the multiple waves of multilevel data collection, we did not control for common method variance or bias which is also prone to reverse causation in the relationships among the variables in our model. Additionally, the follower and leader ratings of job performance differed significantly, implying a need to take more objective and multi-stakeholder performance measures over time.

Conclusions

After implementing the conceptual assumptions of the JD-R and the multi-level emotions model in an organization, we shed light on the supervisory, team and non-managerial worker dynamics associated with high follower job flourishing and performance. As a theoretical implication, we highlight the role of a leader's EI as a job resource to promote individual follower EI, thereby ultimately affecting both followers' job flourishing and performance. In addition, team positive emotional climate serves as an extra resource to facilitate the contagion process of positive emotions and to enhance the levels of job flourishing and performance. These results illuminate the multi-level perspectives of the two theories which we used to hypothesize and examine the dynamics of high job flourishing and performance.

Relevance to the Congress Theme

The changing world of work has posed emotionally demanding situations for work-floor personnel in which, one would assume, emotional stability is required; this study examined a set of related factors. To stay agile and mentally healthy in current day organizations, certain personal and job resources are needed. High leader emotional intelligence and a positive emotional team climate are suggested to bring out latently available personal resources from the workers for both their own wellbeing and their job performance.

Keywords: Leader/Follower emotional intelligence, team climate, job flourishing/performance

Pragmatic solutions for implementing stress prevention in small enterprises? Process evaluation of a combined web-based intervention 'System P'

Miriam Engels, Department of Work and Organisational Psychology, Faculty of Psychology, Open University of the Netherlands; Judith Engels, Chair of Business Administration, in particular Work, Human Resource Management and Organization Studies, Faculty of Business Administration and Economics, Heinrich-Heine- University Dusseldorf, Germany

science&practice

Research goals

Micro and small-sized enterprises (MSE) often lack of resources for occupational stress prevention. The goal of this work was to evaluate the implementation of a pragmatic web-based intervention for stress prevention in MSE.

Background

Despite evidence regarding the effectiveness of workplace-based interventions in preventing work stress, the implementation of respective interventions in micro and small-sized enterprises (MSE) remains scarce [1]. Addressing common barriers for implementation of such interventions (e.g. high costs and complex procedures), we adapted existing web-based interventions at individual and organizational level (online stress management training and psychosocial risk assessment) and integrated them into one platform specifically developed for MSE – called System P. The study aims to evaluate the implementation of System P in terms of acceptance, usage and effectiveness in the target group.

Methodology

The implementation of System P is evaluated in a pragmatic mixed methods pre-post design with outcome measurements at baseline (T1) and 6-months follow-up (T2). Indicators for a successful implementation process include acceptability, adoption, feasibility, reach, dose, and fidelity [2] which are measured with repeated questionnaires and semi-structured interviews (n=10). We also track and analyse usage data collected directly within the web-based platform between T1 and T2. Effectiveness of the intervention is analysed by comparing individual mental health outcomes like depressive symptoms and perceived stress as well as organizational health outcomes like psychosocial safety climate at T1 und T2.

Results

Recruitment for the study started in November 2021 and ended in September 2022, with 40 participating MSE. So far, 75 participants filled out the questionnaire at T1 (25 owners and 50 employees) and 2 participants have completed data collection at T2. Despite of high acceptability in terms of self-ratings and interviews answers, the process outcomes for adoption, reach, dose and fidelity were below expectations. Preliminary analysis show that the majority of active users of System P tend to have prior experience with stress prevention and a high psychosocial safety climate. At the conference, we will present the final results for the implementation process and effectiveness outcomes.

Limitations

Due to the heterogeneity of MSE, the study was set up without a control group and limited information about non-adopters and their reasons is available. Although multiple communication strategies were used (via intercorporate stakeholders, social media, conference presentations), recruitment was slower than expected.

Conclusions

Preliminary results indicate that implementation via a web-based platform can only reach a small part of the target group. The sample in this study was highly informed about and showed high engagement in occupational stress prevention actions. Different strategies have to be tested in order to reach those with less knowledge and experience with occupational stress prevention. Furthermore, interviews underline that MSE often have limited time and resources to implement interventions. One possible way to address these barriers in the future may be to involve third party disseminators with more expertise to deliver System P to multiple MSE.

Relevance to the Congress Theme „The Future is Now: the changing world of work"

This study aimed to test innovative approaches of occupational stress prevention strategies by using a purely digital intervention approach that fit to the increasingly digitalized life of micro and small enterprises and their workforce.

Relevant UN SDGs

This study primarily contributes to the UN Sustainable Development Goal of Good health and well-being as the workplace displays a promising setting for health prevention.

Acknowledgement

This study is funded by the German Federal Ministry of Education and Research (BMBF) within the Framework Concept "Future of work" (fund number 02L16D020 to 02L16D023) and managed by the Project Management Agency Forschungszentrum Karlsruhe, Production and Manufacturing Technologies Division (PTKA).

Oral presentation OP83

Preferential Differences for Transactional vs. Transformational Leadership in a Student and Working Population

Sophie-Claire Lusser, University of Göttingen; Andreas Prof. Dr. Mojzisch, University of Hildesheim; Stefan Prof. Dr. Schulz-Hardt, University of Göttingen

science&practice

Research Questions: Do Preferences for Transformational vs Transactional Leadership change with experience and age i.e., differ between students and the working population? Can differential preferences be predicted by Big-5 Personality, business-focused personality and/ or work orientation? (Exploratory)

Background: According to Path Goal Theory (House, 1971) followers' responses to leadership (styles) are dependent on individual needs, goals and preferences and should thus differ between individuals. In a similar vein, Shamir et al.'s (1993) Self-Concept based theory of charismatic leadership postulates, that in order for a charismatic relationship between leader and follower to develop, the leader's message must be congruent with followers' values and identity, indicating that individuals' reactions to one and the same leader might be dependent on personal attributes such as work orientation and personality. Since individual (job related) needs and goals as well work-orientations and values are prone to change with experience and age, I postulate that preferences for different types of leadership might differ between individuals at different stages of their career.

Following the process-view of leadership, I am interested in examining which leadership style followers prefer: The transformational leadership style which is said to raise the level of motivation and morality of followers by engaging with them and creating a connection, or the transactional leadership style, which is more concerned with the clarification of roles and task-requirements? And further, to examine whether the distribution of preferences differs between individuals at different stages of their career.

Methodology: In the proposed study, I examine preference distributions for transactional and transformational leadership in two different samples: University students and a working population. In an online-experiment using vignettes of leaders scoring high on either transformational or transactional leadership, I will measure individual preferences for either leadership style. Leader gender and order of presentation of the vignettes will be balanced between subjects. Measured variables are leader preference (transformational vs transactional leader) as well as Big-Five Personality as measured by the Big-5 Inventory (BFI-2; Danner et al., 2016); Business-focused Personality as measured by the Business-focused Personality inventory (BIP-6F; Hossiep, 2022) and work orientation as measured by the Work Orientation Questionnaire (Willner et al., 2020).

Expected Results: I expect students to strive for ideals, team-work and self-actualization and thus prefer the transformational leader, while the working population should strive for clarity regarding requirements and goals and thus prefer the transactional leader. In an exploratory analysis I want to further investigate whether leader preferences can be predicted by Big-5 and business-focused personality factors as well as work orientation.

Current state of the project: So far, using a mixed sample (university students and working population) I have validated the transactional and transformational leader vignettes using the German version of the Mulitfactor Leadership Questionnaire (MLQ; Felfe, 2006), while also obtaining a first assessment of the distribution of preferences for the transformational compared to the

transactional leader. I found that subjects' preferences for the transformational or transactional leadership style did not differ significantly, indicating that within the mixed population, preferences for either style are distributed evenly. I am currently in the process of Preregistering the proposed study and hope to start data collection at the beginning of October.

Limitations: While the use of vignettes offers a clean and easy research design, it is unclear whether follower responses are applicable to the real world. Further, the question of differential effects of leadership style on productivity remains unanswered and should be examined in future research.

Conclusions: So far, I have found that subjects differ in their preferences for transactional vs transformational leadership, indicating that "one-size" does not fit all. Under the assumption that attraction to a leader affects satisfaction as well as performance under that leader, leaders should consider individual needs and preferences when deciding on how to approach prospective followers. Knowledge of differential leadership style preferences in early and late career stage employees can help leaders adapt their leadership style accordingly.

Relevance to the Congress theme: In order to change the future for the better, we need effective leaders that engage their followers by adapting their style to individual needs and preferences. Knowledge about preferential differences between early and late career stage employees might help leaders adapt accordingly, providing a more satisfactory and productive environment for all.

Keywords: Transformational Leadership, Follower Preference, Personality

Oral presentation OP292

Preliminary data from VASSIP: A gamified assessment for personnel selection

Pedro Ramos-Villagrasa, Elena Fernández-del-Río & Ramón Hermoso | University of Zaragoza

science

Recent reviews point out that technology is the future of personnel selection. Game-related assessments (GRA) are one of the topics related to this issue. GRA has the potential to become an additional valid method among those used in personnel selection, but further evidence is needed regarding the different kinds of GRA and their actual functioning. The present study introduces VASSIP, a theory-driven gamified assessment tool (i.e., a traditional assessment which includes game elements) developed to assess cognitive ability and Big Five personality in the organizational context. VASSIP incorporates three elements from games: (1) a game fiction situated in the far future; (2) immersion , incorporating multimedia resources; (3) conflict , because the player must make decisions and solve problems throughout the story. Our research goals are to investigate its content and predictive validity, its applicant reactions compared with traditional assessments, and the possible existence of gender differences. A sample of 100 students (57.7% are women, 44% are at least part-time workers) was part of the study. Participants answered an online questionnaire with the original forms of the cognitive ability and personality measures, and a self-reported job performance scale. Then they played VASSIP. Analyses (reliability, descriptive statistics, correlations, hierarchical regression, mean comparisons) were performed with SPSS. Results have shown that original and gamified versions of the assessment are highly associated (Mr = 0.76), as expected. Hierarchical models have shown that personality measured with VASSIP is able to predict task performance (R 2 = .31), contextual performance (R 2 = .25), and counterproductive behaviors (R 2 = .21). Regarding applicant behaviors, original assessment has significantly higher scores regarding organizational fit (M original = 17.60; M VASSIP = 17.40), whilst the gamified assessment has higher scores in organizational attractiveness (M original = 18.41; M VASSIP = 21.45). Lastly, we found differences in VASSIP scores and applicant reactions related to gender: women achieve higher scores in neuroticism (M men = 14.30; M women = 16.59) and conscientiousness (M men = 24.07; M women = 25.42), an expected result according to previous literature, but also a better applicant reaction in terms of perception of predictive validity (M men = 7.94; M women = 8.79) and organizational fit (M men = 16.37; M women = 18.00). Together, these results provide promising initial support for the use of VASSIP, and additional evidence for the use of gamified assessments in general. The results regarding gender differences contradict the stereotype regarding games, suggesting that women have higher positive reactions to gamified evaluations. Besides that, the present study is, to the best of our knowledge, the first study that considered counterproductive work behaviors in the GRA literature. Nevertheless, our study has significant limitations that should be noted, namely the use of students as participants and self-reports of job performance. However, given that the study of GRA is still in its infancy, our results may be useful to guide further research.

Keywords: game-based assessment; personnel selection; job performance

Oral presentation OP213

Preventing turnover intentions: the role of meaningful work and basic psychological need satisfaction

Georgina Csordás, Semmelweis University; Tamás Martos, University of Szeged; Viola Sallay, University of Szeged; Balázs Matuszka, Pázmány Péter Catholic University

science

Positive psychological approaches in the workplace are becoming more and more popular, due to the fact that well-being in the workplace affects work engagement and productivity not only at the level of the employee but also at the level of the employer. Our research investigated possible preventive factors for turnover intentions. We explored the relationship between the fulfillment of basic psychological needs (autonomy, competence and relatedness), meaningful work and job satisfaction in connection with turnover intention among Hungarian white-collar workers. The aim of the study is to develop a theoretical model in which basic psychological needs contribute to both meaningful work and job satisfaction, which in turn leads to lower turnover intentions. The analysis was conducted using path modelling on a sample of 1,842 white collar workers from different fields (eg. education, administration, finance). To assess the previously mentioned constructs we used the Basic Psychological Needs Scale (La Guardia et al., 2000; Kardos et al., 2020), the Work and Meaning Inventory (Steger et al., 2021; Csordás et al., 2020) and the Satisfaction With Work Scale (Fényszárosi et al., 2018; Csordás et al., 2020). According to our path model, the fulfilment of all three basic psychological needs in the workplace affects work satisfaction (ß ranged from .088 to .454), while autonomy (ß = .231) and competence (ß = .413) predicted meaningful work. The perceived higher sense of meaningful work (ß = -.124) and work satisfaction (ß = -.481) predicted lower turnover intentions overall (R2 = .310). The fit indices of the final model predicted good fit (RMSEA = .048, SRMR = .01, CFI = .995). These findings confirm the relevance of meaningful work as a potential factor in preventing turnover intentions, and also the vital role of the fulfilment of basic psychological needs in the workplace in relation to work satisfaction. Strengthening these factors in the workplace can be an affordable yet very effective way of improving employee well-being.

Keywords: meaningful work, turnover intentions, work satisfaction

Oral presentation OP155

Proactive behaviors towards a sustainable career across the school-to-work transition

Sjoerd Gerritsen, Radboud University & Rotterdam University of Applied Sciences; Beatrice van der Heijden, Radboud University; Jos Akkermans, Vrije Universiteit Amsterdam; Karen Pak, Tilburg University; Maral Darouei, Vrije Universitei

science&practice

Theoretical Background & Research goals and why the work was worth doing: In today's school-to-work transition (STWT), young professionals must adapt to continuous change and complexity, making their careers less defined and predictable than ever before (Akkermans et al., 2021; De Vos et al., 2019). However, despite this change to continuous learning, research in this area has predominantly focused on the STWT as a major one-off transition moment that emerging adults need to adapt to and navigate effectively (Hirschi, 2010; Johnston, 2016; Koen et al., 2012).

However, adaptability is only one piece of the puzzle. Recent research suggests that emerging adults should be proactive in their careers (Akkermans et al., 2013; Akkermans & Tims, 2017; Blokker et al., 2019) to enhance their career success (Akkermans & Tims, 2017). As such, proactive behaviors might be the key for them to lay the foundation for a sustainable career (De Vos et al., 2020; Van der Heijden et al., 2020) characterized by happiness, health, and productivity (Van der Heijden, 2005). With this study, we aim to understand how emerging adults' proactive behaviors may help them to achieve career sustainability during the STWT, and what hinders and enables those behaviors.

Methodology: To capture how the behaviors of emerging adults develop during the STWT, we employed a longitudinal qualitative design. We interviewed 44 graduating students at a Dutch University of Applied Sciences twice, interviewing them six months before (T1, N = 44) and six months (T2, N = 36) after graduation. Additionally, we triangulated these data with nine focus groups (N = 56) and four interviews (N = 6) with stakeholders (i.e., parents, faculty/staff, potential employers, the ministry of education, etc.) to include a broader life context.

The interviews at T1 tapped into the students' proactive behaviors and career aspirations and explored the potential enabling and hindering factors toward a sustainable career. The T2 interviews focused on the development of health, happiness, and productivity during the STWT and what behaviors, motivations, and influences played an enabling or hindering role. The stakeholder focus groups and interviews allowed for a more nuanced and holistic understanding of the data that emerged from the T1 and T2 interviews. At this point, we have completed the data collection, transcribing, and coding. We aim to finish the analyses before the end of 2022.

Results obtained and expected: Preliminary results suggest that, next to proactive behaviors, career competencies (Akkermans & Tims, 2017) seem to play an important role during emerging adults' STWT. Interestingly, these competencies are not solely applied to their work and careers, but also to their private lives in general. This adds a broader perspective to the usage of career competencies. Concerning proactive behavior, we find that emerging adults report an increase in change-oriented behavior over time. Regarding the enabling and hindering factors, we see how family, the university itself, job/society pressure, and Covid-19 all influence emerging adults' proactive behavior. For example, the university and its educational structures are considered one of the biggest hindrances toward proactive behavior due to its rigidity and the inherent (job)pressures it provides for emerging adults.

Limitations: Due to research taking place within an Applied Sciences University, the findings might limit themselves to this specific population. That said, an effort has been made to use purposive sampling to have a qualitative representative sample herewith trying to maximize its generalizability. We consider the qualitative nature and in-depth approach a strength and are already eyeing possible quantitative future research possibilities.

Research/practical implications: This study will provide new insights into how proactive behaviors can help emerging adults to lay a foundation for a sustainable career, and the role of key enablers and barriers in this process. Until now, STWT research has primarily focused on how competencies and behaviors influence one's work and career. However, our results encourage a broader life perspective that includes one's private life as well. These insights can be used to develop interventions to help students develop proactive behaviors toward a career in which they can remain happy, healthy, and productive.

Originality/Value: This study is among the first to provide empirical evidence based on the conceptual model of sustainable careers described by De Vos et al. (2020). Moreover, we do so at a crucial career stage: the initial transition into work. Our findings will shed light on the interaction between individual and contextual factors that can shape school-to-work transitions in the contemporary career.

Relevance to congress theme: As this research focuses on the abilities of the future labor force, it is critical they start their careers in a sustainable manner.

Keywords: Sustainable careers, proactive behaviors, school-to-work transition.

Oral presentation OP28

Probing Leader Resource-Seeking: The Differential Effect of Asking for Advice versus Help on Perceived Leader Humility and Leadership Effectiveness

Julia Rieg, Kühne Logistics University; José Keating, CIPSI, Escola de Psicologia, University of Minho, Braga, Portugal; Prisca Brosi & Niels Van Quaquebeke | Kühne Logistics University

science&practice

Given the frequently attested potency of leader humility for leadership effectiveness, we focus on a key behavioural antecedent of perceived leader humility: leaders' question asking (also referred to as inquiry). With the present paper, we provide critical nuance to the questions-as-information research that suggests that, in general, genuine leader inquiry for resources leads to a humility premium. Extending the general theoretical notion, we argue that two forms of seemingly similar resource inquiry—namely, asking for advice and asking for help—send very different signals regarding self-orientation versus other-orientation; as a result, they differentially influence perceptions of leaders' humility and, ultimately, effectiveness. The results of a behavioural experiment, a vignette study, and a two-wave field survey support our theorising that asking for advice is considered humbler than asking for help because of the comparatively higher other-orientation that is signalled, with downstream positive consequences for leadership effectiveness.

Keywords: resource-seeking, questions, leadership

Oral presentation OP37

Productivity of communication in organization: approach and application

Anna Kiseleva & Petr Vlasov | Institute of Applied Psychology "Humanitarian center" Kharkov, Ukraine

science&practice

Problem: The significance of communication rises simultaneously with the increase in the level of environment uncertainty. Organizations constantly reduce uncertainty, make efforts for sensemaking. Communication problems are caused by growing complexity, significance of social/economic results. It demands creation of special structure of communication on different hierarchical levels of complexity. Objectives: To analyze the structure of productive communication "man-text" in situation of uncertainty, to research sensemaking structure, elements, results in communication process. Method: method of intertextual questions for collecting data, and semantic classification of sensemaking reactions for processing data (in summary, 1500 sensemaking questions to 3 texts consisting of 15-50 sentences). Results: we discovered hierarchical structure of sensemaking: formal level (associated not with content but with its expression form); static (aimed at participants, objects, their attribution); dynamic (aimed at action dimensions); logical questions (establish connection between objects, participants, actions); inferences (synthesizing conclusions, fix content parts comprehension). Regularity of hierarchical level appropriateness is discovered between level of content and level of sensemaking as the requirement of openness and adequacy of communication, it is needed for quality of sensemaking. Connection between sensemaking levels is discovered: interaction on lower level blocks it on higher ones. Personifying effect (subjective involvedness) mediates sensemaking quality. The higher the demands to sensemaking, the more personifying effect attributes are required: novelty, reference in reality, utterances' explanatory power, target function in sentence, elements' validity and conditionality.

Oral presentation OP490

Professionalisation of the occupational clinician: towards a competence profil

Céline Leclercq & Isabelle Hansez | University of Liege

science&practice

In 2020, Belgian figures show 470,000 people were on long-term incapacity. This is twice as much long-term incapacity as 15 years ago. Moreover, considering also short-term incapacities, the cost, estimated in 2010 at 4.7 billion euros, rose to 8.6 billion euros in 2019, i.e. an increase of 7% each year. Indeed, a survey conducted by a Belgian mutual insurance company (2021) [1] among 5 602 people shows 56% of respondents consider their work is (partially) responsible for their incapacity. Among those, 36.8% attribute their incapacity to burnout or mental illness, such as depression or anxiety. These figures highlight work-mental disorders constitute a major issue. This is confirmed by health professionals who reported more patients expressing work suffering. They are facing new disorders requiring new skills.

We aim to explore an innovative competence profile in the area of occupational health psychology, and especially in the diagnosis and follow-up of burnout or other work-related psychological disorders. This Belgian project launched in 2019 [2] was funded by the Minister of Social Affairs and Public Health as part of the new burnout initiatives, more particularly that related to the creation of a training program and networking device in occupational clinic.

The competence profile was developed according to the needs identified among health professionals:

The first need is being able, as occupational clinicians, to self-evaluate and identify the necessary relevant training for their own formation. The second one is checking if their practices are appropriate in the area of occupational health psychology. The next one refers to having a guide to create a training program for both first-line prevention actors (i.e, occupational physicians, general practitioners, prevention counsellors) and second-line health professionals (i.e, occupational clinicians). The fourth need was enhancing recognition of the role of the occupational clinician and to protect the activities involved in occupational clinic.

Regarding the methodology, 12 focus groups were conducted by 2 animators and transcribed by 2 observers. 19 practitioners were divided into 3 groups of 6-7 practitioners and each group took part in 4 sessions. The objective was to highlight the behaviours implemented in critical situations (e.g. through a clinical case). In order to collect the behaviours, we chose different methods as the nominal group, the SPC (Sens-Process-Content) method and the focus group method with the critical incident technique.

Concerning the results, we first realized a qualitative analysis, based on the SPC method, which give us 521 behaviours. Secondly, a categorization of these behaviours was carried out with a group of 5-6 occupational clinicians. Finally, based on this categorization, a coordinator and a researcher realized the competence profile. The validation of the profile was based on an iteration process of reviews conducted by all the experts including in this project (project coordinators, psycho-pedagogue, occupational clinicians, scientific committee with representatives of different Belgian universities, pilot committee).

This competence profile includes seven skills: therapeutic setting (e.g. legitimacy, professional confidentiality), communication (e.g. with the worker, the health professionals, the prevention

actors), network (e.g. how to develop and mobilise the network), diagnosis (e.g. anamnesis, tools, differential diagnosis), follow-up (e.g. work on resources, on demands), return-to-work (e.g. preparation for the return-to-work or for a professional transition) and sensitization (e.g. of the worker, of the hierarchical line). Furthermore, according to the competence profile for occupational psychologists (Wopsy, 2019), these skills are divided into some objectives that include behaviours and abilities. Then, the competence profile was linked to a variety of resources.

We also focus on the reflections in terms of practical and pedagogical scopes, the ethical and deontic position of occupational clinicians and the relevance of our competence profile as a guideline for health professionals practising or not yet as occupational clinicians.

This presentation will be relevant for the congress due to its contributions concerning the continuing professional development, skills training, the mental health at work and therapeutic interventions, among other things.

Oral presentation OP230

Profiles of Career Self-Management Behaviours and Their Motivational Correlates

Francisco Wilhelm, University of Bern; Andreas Hirschi, University of Bern / Deakin Business School

science

Research Goals. Career self-management (CSM) is a multidimensional construct involving the utilization of various CSM behaviours. The most common way to examine CSM and its associated career behaviours is to take a variable-centred perspective and examine the relation of one or multiple CSM behaviours to correlates across an entire sample. However, according to theory, persons selectively use various CSM behaviours in accordance with their motivation and resources. This suggests that subgroups of individuals exhibit distinct combinations of CSM behaviours. These subgroups may deviate from the findings of variable-centred studies, which focus on average behaviours across an entire sample. Therefore, we aimed to give a profile-centred perspective on CSM by uncovering different theorized combinations of CSM behaviours and validating these combinations through examination of their relation to motivational resources (i.e., self-efficacy, boundaryless career orientation, and career motives).

Theoretical background. Drawing on career development theories that acknowledge that different career capitals, such as human capital and social capital, may be of varying importance to different persons and preceding qualitative studies, we identified different plausible combinations of CSM behaviours. We expected that CSM behaviour combinations differ among three axes: (a) the general extent of CSM, (b) the focus on building human or social capital, and (c) the extent of career exploration and mobility-oriented behaviours. Furthermore, we expected that profiles differ in their motivational correlates. Because self-efficacy is a motivator of behaviour in general, we hypothesized that it is related to the general extent of CSM. A boundaryless career orientation includes the willingness to be mobile, and we hypothesized that it related to profiles focused on career exploration and mobility-oriented behaviour. As growth career motives entail the motive to develop knowledge and skills, we hypothesized that they are related to human capital-focused profiles. Self-enhancement motives entail motives to attain traditional markers of career success and we hypothesized that they are related to a focus on social capital as a crucial capital for 'getting ahead'.

Approach. Self-report data was collected from a sample of N = 529 German employees. CSM behaviours were measured at Time 1, and, to reduce common method variance, motivational correlates were measured two weeks later at Time 2. CSM behaviours were assessed using a multidimensional scale that measures eight different CSM behaviours. We operationalized the combinations of CSM behaviour as profiles in a latent profile analysis. The profiles were based on the factor scores derived from a bifactor confirmatory factor analysis model to disentangle shape and level differences among profiles better. Differences in profile correlates were examined using the BCH procedure.

Results . A five-profile solution was selected based on good fit and theoretical parsimony. The profiles were partially in line with our expected three axes and were labelled: 1. Disengaged, 2. Self-exploring, 3. Medium social focus, 4. High social focus, 5. Mobility-oriented. Supporting our hypotheses regarding the motivational correlates of profiles, CSM self-efficacy distinguished between profiles high or low in CSM. Boundaryless career orientation was highest in the mobility-oriented profile. Self-enhancement strivings were highest in the high social focus profile. Contrary to our hypotheses, there was no profile focusing on human capital; hence we did not find support for a relation between growth strivings and such a profile.

Limitations . We focused only on three motivational correlates. It is likely that more correlates proposed by models of proactive motivation are relevant for CSM behaviour, such as career affect. Furthermore, our findings are based on a single sample of German employees. Future studies should validate our profile solution and its correlates in new samples, possibly from multiple cultural contexts.

Conclusions . Our study shows that CSM behaviours can be validly understood from a person-centred lens as multiple distinct combinations of CSM behaviours which are related to different motivational resources and motives.

Relevance to the Congress Theme. Today's workforce increasingly needs to engage in complex and multi-faceted responses to navigate the changing world of work. A better understanding of the different typical combinations of CSM behaviours and their motivational basis that employees use will allow researchers and practitioners to get a better understanding of how individuals develop their careers and their underlying motivations.

Relevant UN SDGs. Addressing these issues may enable practitioners in fields such as career counselling and HRM to better support their client's careers and working lives, including their capability to attain UN SDG goals of 'Quality education' and 'Decent work'.

Keywords: career management, latent profile analysis, boundaryless career

Oral presentation OP183

Promoting Collaborative Innovation Through Multiculturalism: A Longitudinal Experimental Intervention

Jonali Baruah, Tarleton State University

science

Research goals and rationale

The process of globalization is causing organizations to become increasingly diverse and virtual. Now COVID-19 has further caused a sudden urgency to rely on virtual communication, which has worsened issues of social equity (Pikoos et al., 2021; Wang et al., 2019). For example, women of color receive less speaking time during team meetings and are more likely to be interrupted (Karpowitz et al., 2012). In addition, virtual teams are not likely immune to members' subjective categorizations (Garrison et al., 2010). Multicultural virtual teams are less likely to focus on potential gains at the task when experiencing micro-conflicts (Paletz & Miron-Spektor, 2018).

Globalization has also increased diversity in educational institutions. Today's college graduates are expected to learn not only the content of a discipline but also to develop 'generic' abilities suitable for a wide range of work and life contexts (Pithers & Soden, 2000). A common practice at schools is that students of different cultural backgrounds should assimilate to be accepted by the dominant culture (Daniel, 2008). As opposed to this superordinate identity approach of intergroup contact focusing on commonalities and ignoring differences (commonality approach), a focus on the uniqueness of cultures, simultaneously considering the contradictory thoughts processes, placing them in juxtaposition (paradoxical approach) to enhance critical thinking is a more viable approach (Leung & Chiu, 2010; Miron-Spektor et al., 2011).

The current research aims to develop an intervention that would allow elaboration and evaluation of the problems using the uniqueness of multicultural groups, which can result in enhanced critical thinking and collaborative innovation. We predict that groups trained with paradoxical frames will demonstrate higher creativity and ethnocentric empathy than groups with common identity frames or control groups.

Theoretical background

A multicultural setting often gives rise to contradictory thought processes due to the occurrence of conflicting ideas. The mental templates that encourage individuals to recognize and embrace contradictory viewpoints are termed paradoxical frames (Smith & Tushman, 2005). The presence of paradoxical frames triggers a sense of cognitive conflict due to contradicting thought processes. To adapt, one is likely to become more sensitive to complementary relationships between contradicting thought processes (Fong, 2006; Schwartz & Bless, 1991). Studies report that recognizing and embracing contradictory thoughts is particularly conducive to creative thinking in individuals (Leung et al., 2018; Patil & Tetlock, 2014), although no studies have used this approach as an intervention using a longitudinal study.

Methodology

In this 3-week longitudinal experimental intervention, 23 groups of 3 to 4 participants (n = 72) completed the pretest, experimental intervention, and post-test session. The pretest included a demographic survey and a creativity task for baseline measure (3 days). In the intervention (2 weeks) session, groups engaged in collaborative problem-solving, group discussions, and intergroup contact

exercises focused on either paradoxical (9 groups) or commonality (9 groups) interventions. In the posttest period (4 days), all groups completed posttest surveys measuring creativity and ethnocentric empathy. A control group with no intervention served as a baseline condition for the whole period.

A 2(Sessions) x 3(Intervention type) mixed factorial ANOVA revealed a significant main effect of the type of training, $F(1, 19) = 7.145$, $p = 0.005$). The contrast test revealed that the paradoxical training groups generated more original ideas than the control group ($p < .005$), but the difference was marginally significant between the commonality and the control group ($p = .06$). Moreover, the paradoxical perspective groups generated the most original ideas in the posttest session, $F(2,19)=5.69$, $p < 0.01$.

The ethnocultural empathy at the post-test session was higher for all groups compared to the pretest session, $F(1, 19) = 24.95$, $p < 0.001$, $\eta^2=.27$. However, the paradoxical perspective groups demonstrated the highest ethnocultural empathy in the posttest session, $F(2, 19) = 4.40$, $p = 0.02$ followed by commonality and the control groups.

Conclusion

research proposes an innovative pedagogical strategy to optimize critical thinking in the college curriculum, which prepares students for future work. This intervention provides ways to apply the differences and contradictions of multicultural groups in a meaningful way, thereby enhancing collaborative creativity. A limitation of the study was that, due to attrition, the control group had a small sample of 5 groups. A novel contribution of this study is that it offers a virtual intervention that will help employers facilitate creative thinking by exploiting inequalities in diverse workgroups,

Oral presentation OP133

Promoting Pro-environmental Engagement through Social Identification: An Investigation of Multiple Social Identities

Melissa Hehnen, LMU Center for Leadership and People Management; Martin Fladerer, TUM School of Management / Technical University of Munich, Germany

science&practice

There is not much time left to limit global warming to 1.5°C. However, greenhouse gas emissions continue to rise. One promising psychological approach to answering the question of how to reduce this "public inactivity" is the Social Identity Approach (SIA) (e.g., Fielding & Hornsey, 2016). Growing research is studying the auspicious impact of global identification on pro-environmental intentions and behaviors (e.g., Loy et al., 2021; Loy & Spence, 2020; Reese, 2016). However, most of these studies don't consider the variety of social identities in people's everyday life (Gaither, 2018) and examine the influence of a global identity in isolation. This research doesn't take into account that people identify themselves with many groups and that closer social identities are more likely to be salient and influential when it comes to behavior change than abstract group identities (Masson & Fritsche, 2021). Thus, looking only at people's global identification gives us a limited understanding of its relevance vis-à-vis closer social identities. In the present research, we investigate the impact of global identification in a multiple-identity-setting by analyzing whether a salient global identity still guides pro-environmental commitment when a regional identity is salient at the same time. Our goal is to identify the group (level) that can best influence people's behavior.

Our hypotheses are the following:

People whose regional identity is salient or whose regional identity is salient in combination with a salient global identity, show more support for regional than global environmental commitment than people with only a salient global identity.

People whose regional identity is salient or whose regional identity is salient in combination with a salient global identity, significantly more often decide to donate money to an organization that is committed to regional climate protection than people with a salient global identity.

People whose regional identity is salient or whose regional identity is salient in combination with a salient global identity, decide significantly more often not to receive information on how they can contribute to global climate protection than people with a salient global identity.

In an experimental design with three groups (1. primed regional identity, 2. primed global identity, 3. primed global and regional identity) we measure pro-environmental intentions as well as concrete behaviors (donations and information seeking behavior) as indicators for environmental commitment. We prime social identification by asking participants to imagine looking the earth from above and to describe what unites all people, what we all have in common and / or to describe what unites the people who live in the region of the participants.

Data collection is ongoing and is expected to be completed in January 2023. Our study is pre-registered on the OSF: https://osf.io/dapwm/?view_only=c5d9a3fdc1ae4c2f9cf0621f2f5540e6

The biggest crises we are currently facing are collective crisis and require cooperation. Research shows that a shared social identity can motivate people to engage in collective action (e.g., Van Zomeren et al., 2008). It is therefore all the more important to consider people's everyday lives and to identify the groups that can best motivate people's behavior.

Keywords: Climate Crisis, Social Identity, Global Identity

Oral presentation OP217

Promoting reflection and new understanding in online clinical group supervision

Mikko Pohjola & Virpi-Liisa Kykyri | University of Jyväskylä, Finland; Risto Puutio, Metanoia Institute, Finland

science&practice

Clinical group supervision is a common practice in social and health services. In clinical group supervision, the participating professionals reflect on their practice together. Such exchange enables creation of new understanding and development of participants' professional skills.

In recent reviews on clinical supervision research, scholars have called for research on the components of supervision. Our study contributes to bridging this gap by exploring supervisor's interactional practices in trying to promote the ideals of supervision.

While the goals of online supervision are same as in face-to-face supervision, the participants must adapt their communication to differences and challenges related to online environment. In our study, by analysing authentic video-recordings of online supervision conversations, we aim to illustrate what kind of interactional practices the supervisors use to promote shared reflection in the face of these challenges.

In our study, we have following specific research questions: 1) What kinds of interactional practices supervisors use to promote shared reflection and creation of new understanding in online supervision meetings, 2) how the supervisees answer to these interactional practices? and 3) what kind of new understanding supervisees display in episodes under study?

We approach supervision meetings from a social constructionist perspective, which entails that social realities and meanings are co-constructed by interlocutors in conversations. By using methods and concepts from discursive approaches and conversation analysis we have focused specifically on how new meanings are generated through social interaction that unfolds turn-by-turn.

Our study is part of the project Reducing strain and increasing gain of remote work group meetings with physiological indicators (PhInGain) that is funded by the Finnish Work Environment Fund. The study data comprise video recordings of 24 authentic supervision sessions and their written transcripts, questionnaires on working alliance and the useful and the stressful moments in the sessions, and participants' physiological activation (HR) measured with a finger pulse oximeter To answer our research questions we focused our analysis on two (of the total 70) topical episodes. We selected these two episodes for detailed analyses because in the questionnaire, supervisees had named these as particularly useful for them and reported that during those episodes they had gained learning on their work.

In our analysis, we identified five supervisor's interactional practices that contributed to promotion of shared reflection and to creation of new meanings. These were 1) inviting the supervisees to orient toward each other, 2) inviting the supervisees to share their own experiences and ideas, 3) using his own expertise as discursive resource and 4) challenging the supervisee to look at the problem from different viewpoint by shifting the focus of conversation and 5) giving feedback.

In the studied episodes, the supervisees answered to the abovementioned supervisor's interactional practices by joining shared reflection. They displayed new understanding on their everyday working experience, on the possible reasons for their clients' behavior and on their challenges in working with some of their clients.

By focusing solely on the episodes where new understanding was generated, we may have missed other possible instances where the supervisor used the similar kinds of interactional practices to invite supervisees into reflexive space without success. In this study, we focused mainly on verbal exchange. In the future, we will include nonverbal interactions, which could be important in the creation of reflexive space, as well as psychophysiological responses into our analyses.

To our knowledge, there is no previous research that has identified interactional practices that the supervisors use in promoting reflection and new understanding in online clinical group supervision. By identifying some of these practices our study contributes to the practices and development of online clinical group supervision. By adding to understanding on online learning and work group dynamics our study is also relevant for other fields such as education and organization development.

Keywords: clinical supervision, videoconferencing, learning

Oral presentation OP772

PsyCap and Mindfulness as Mediators, not Antecedents, in the Job Demands-Resources Model

Sebastian Moder & Marco Furtner | University of Liechtenstein

science

Research Goals

Workplaces are the most commonly reported individual stressor (American Psychological Association, 2019, 2021). Notably, some individuals thrive amidst high demands while others burn out. The prevalent job demands-resources model (JD-R) does not consider the role of individual differences. This study answers recent calls for further elucidation (Bakker &Demerouti, 2017; Schaufeli & Taris, 2014) by examining whether personal resources play an antecedent or mediating role in the relationship between job characteristics and employee burnout, engagement, and flourishing.

Theory

According to the JD-R (Demerouti et al., 2001; Schaufeli & Bakker, 2004) job demands lead to burnout, and job resources lead to engagement and reduce the development of burnout. Yet, different individuals are affected differently by the same environment, which can be explained by differences in personal resources (Hobfoll, 1989; Hobfoll et al., 2003). One such resource is psychological capital (PsyCap), an individual's "positive appraisal of circumstances and probability for success based on motivated effort and perseverance" (Luthans, Avolio, Avey, et al., 2007, p. 550). Another such resource is mindfulness, an individual's likelihood of being non-judgmentally aware of present-moment experiences (Baer, 2003; Kabat-Zinn, 1990). Meta-analytic findings attest to desirable workplace-related outcomes for both PsyCap (see Avey et al., 2011) and mindfulness (see Mesmer-Magnus et al., 2017).Highly demanding workplaces depleted employees' personal resources (Xanthopoulou et al., 2007). Lower job demands may facilitate PsyCap by enabling expectations of successful outcomes. Further, environmental characteristics like on-task attentional pull or off-task attentional demands can facilitate or impede mindfulness (Reina & Kudesia, 2020).Hypothesis 1: Personal resources mediate the relationship between job demands and well-being.Inversely, resourceful employees may be able to create a resourceful work environment. PsyCap refers to an individual's belief in their abilities to surmount obstacles. Therefore, individuals high in PsyCap may perceive their workplace to be less demanding (e.g., Grover et al., 2018). Further, mindfulness entails a non-judgmental attitude, which may enable more mindful individuals to be less fixated on the difficult characteristics of their workplace.Hypothesis 2: Job demands mediate the relationship between personal resources and well-being.

Methodology

The study was conducted on a sample of N = 138 employees (76% female) at a non-profit organization providing child protection and care. Data was collected via an internet survey using the following measures: personal resources included mindfulness (Brown & Ryan, 2003) and psychological capital (Luthans, Avolio, & Avey, 2007); job demands included quantitative, cognitive, and emotional demands (Burr et al., 2019); well-being included burnout (Schaufeli et al., 2020), engagement (Schaufeli & Bakker, 2010) and flourishing (Butler & Kern, 2016).

Results

Path models were computed using R and the lavaan package. The model on an antecedent role of personal resources included direct relationships between two personal resources and three job demands, and between three job demands and three outcome variables; it displayed unsatisfactory fit ($\chi 2 = 124.631$, $df = 6$, $p < .001$, CFI = .628, SRMR = .168, RMSEA = .379). In the model on a mediating role, the positions of personal resources and job demands were switched; it displayed better and satisfactory fit ($\chi 2 = 43.763$, $df = 9$, $p < .001$, CFI = .891, SRMR = .089, RMSEA = .167), lending support for Hypothesis 1.

Limitations

The study was conducted inside a single organization to ensure that actual job demands are comparable across participants, which may have impeded external validity. Besides, data was obtained via self-report questionnaires, subjecting the findings to single-source and common-method bias (see Baumeister et al., 2007).

Conclusions

Theoretically, findings on the role of personal resources in the JD R diverge substantially. This study was conducted within a stable environment, ensuring consistency in objective job demands across participants. Practically, by focusing on developable personal resources, this study aimed to equip employees with tools that help them thrive, enabling them to surmount their demands instead of being surmounted by them; further, it aims to inform human resource management to consider investments in training employees' personal resources.

Relevance to Congress Theme

While workplaces are required to safeguard the health of their employees, stress-related diseases are on the rise. Until more effective policies and practices related to mental health education, supervision, and prevention are in place, individuals must assume agency over their experience and develop their mental fitness to be able to create a future worth living in.

Keywords: Mindfulness, Psychological Capital, Job Demands

Oral presentation OP186

PSYCHOLOGICAL PREDICTORS OF INTERPERSONAL CONFLICT MANAGEMENT AT WORK

Emilio Sánchez Santa-Bárbara, Universidad de Granada; Nancy Guzmán Raya, Universidad de Alicante

science

Introduction

Interpersonal conflict is inherent to human beings. Conflicts occur when one person or group tries to maximize their advantage at the expense of others or when incompatible activities take place. Since people differ in personality, values, beliefs, and needs, sooner or later conflict will arise.

This study focuses on identifying psychosocial predictors of the strategies that employees use to deal with conflicts in the organizational context. Rahim and Bonoma's (1979) model includes two dimensions that condition employee behavior in a conflict: self-interest (the degree to which a person attempts to satisfy his or her own interests) and concern for others (the degree to which a person facilitates that others satisfy their interests). It is assumed that these dimensions reflect the motivational structure of the person to face conflicts. Five conflict management strategies emerge from the combination of these two dimensions: integrating (high self, high others), obliging (low self, high others), dominating (high self, low others), avoiding (low self, low others), and compromising (medium self, medium others).

Personal values operate as motivational guides and can explain behaviors and attitudes. Values will be explored as predictors of a person's behavior in the face of conflict. Schwartz's (2001) model of values establishes two bipolar dimensions: a) transcending personal interests in favour of a collective good and treating others as equals (“Self-transcendence”) versus the “Self-promotion” of those who put their own interests, success and personal mastery first. b) The “Conservation” dimension reflects why some people value tradition, security and order versus the “Openness to Change” dimension, which explains the behavior of those who value freedom of action and thought and independence .

Personality has a considerable impact on our thoughts, emotions and behaviors. The ”Big Five” model was used (Extraversion, Agreeableness, Openness to experience, Conscientiousness and Stability).

Method

In this correlational and cross-sectional study, questionnaire data from a sample of 958 employed workers (454 men, 500 women and 4 did not provide this information) with an average age of 35.23 years (range between 18 and 65) were used. . The measurement instruments were the ROCI-II for conflict management styles, the PVQ for personal values and the TIPI for the measurement of the Big Five personality traits. Correlation analyses between conflict management styles, values and personality factors were performed, followed by regression analysis.

Results

As hypothesized, employees’ values and personality are good predictors of conflict management styles at work. The Integrating style can be predicted in 23.1% by the values of self-transcendence, self-promotion and openness to change and by the personality traits of conscientiousness and affability. The Compromise style can be predicted in 19.2% by the same variables and with a different weight. The Dominating style is predicted in 16.2% by values of self-promotion and conservation, and

personality traits as openness to experience and (negatively) with agreeableness. The Avoiding style is predicted by values of conservation and openness to experience, and agreeableness as personality traits. The Obliging style is predicted by the values of conservation, self-promotion, self-transcendence and the personality trait of conscientiousness.

Discussion

In the integrating style, open-mindedness stands out both in values and in personality, the sense of transcending oneself while seeking personal gain, as well as affability and awareness or responsibility to reach agreements.

It is worth mentioning that the values are more important than personality traits to predict one's behaviour in a conflict situation.The values with the higher weight to predict all five conflict management styles are those hypothesized: Self-transcendence for Integrating and Compromise; Self-promotion for Dominating, and Conservation for Avoiding and Obliging.

Keywords: Conflict, values, personality

Oral presentation OP281

Psychological Safety at Work - Tales From the Field

Pär Löfstrand, Mid Sweden University; Ulrik Terp, Karlstad University

science

This study exposes results from five small studies regarding psychological safety and work. The data consists of semi-structured interviews, focus groups interviews and questionnaires with people working as Human resource (HR) managers, schoolteachers, hospital staff, care assistants and firefighters in rescue service. One sub study also consists quantitative data. Each partial study penetrates different aspects of psychological safety.

Previous research has revealed psychological safety as an important factor for individuals to perform well together with others at workplaces. A psychological safe condition is defined as a condition when one feels included, safe to learn, safe to contribute and safe to challenge the status quo without fear of being embarrassed, marginalized or punished in some way (Edmondson, 1999). Previous research has also revealed that psychological safety affects learning and efficiency at a workplace positively, (Edmondson & Lei, 2014). Psychological safety as also been found to have positive correlations with work engagement (May et al., 2004; Nembhard & Edmondson, 2006; Chinelato et al., 2020; Lee & Ok, 2014). Other studies have revealed that psychological safety indirectly has effects for workplace conditions. Rothmann and Rothmann, 2010, revealed that psychological safety might be seen as a mediator as it has a positive effect on supervisor relations as in turn has a positive effect on work engagement.

Research on psychological safety has been predominantly quantitative. There is a pent-up need for qualitative research with the aim of studying how people in different contexts experience psychological safety. This study consists of five different sub studies that has explored psychological safety in different contexts. Four of them has a qualitative design.

Methodology

Four studies with a qualitative design were conducted. Each included persons with different occupational categories and had slightly different framing of questions. The Fifth (study II, had a quantitative approach. However, all of them had an overall focus on psychological safety, (Edmondson, 1999).

Thirty-six interviews with human resource managers, fire fighters, hospital health care staff and elder care staff was conducted. Furthermore, 63 teachers answered a questionnaire with questions concerning psychological safety, work engagement and hope.

Each sub study had its own design and data were collected through in-depth interviews, semi-structured interviews or focus group interviews or questionnaires. The meta-analysis was conducted with a qualitative approach and aimed to find common denominators linked to psychological safety in the five sub studies.

Study I, Semi-structured interviews with six Human Resource managers. The purpose of this sub-study was to gain an in-depth understanding of how HR strategists discuss the various components within psychological safety, how these are connected, and which are handled, and which need to be elucidated more deeply in the HR strategic work.

Study II, sixty-three secondary upper schoolteachers answered a questionnaire with questions of how they experienced psychological safety, work engagement and hope at work. The goal with the study was to explore how the three factors were related to each other.

Study III, semi structured interviews with medical doctors and nurses working at a hospital. The aim in this study was to explore how external factors such as working conditions, budget issues and leadership philosophies might have implications for psychological safety.

Study IV, focus group interviews and interviews with nurses and people working with elder care. The study also involved an interview with a first line manager. In this study, the theoretical starting point was linked to social psychological aspects such how, for example, stereotypes risk affecting the psychological safety in a work group.

Study V, semi-structured interviews with eight persons working as firefighters in rescue service teams. The purpose with his sub-study was to gain a deeper understanding of how firefighters experience psychological safety in critical and get a better understanding of how psychological safety emerge in groups and if affects perception of results, cooperation and risk-taking.

Preliminary results

The results will be finalized at latest in January 2023, when the analyse of the results for study III-V are finished. The results from the first two sub studies are done. The results of study I reveal that what is perceived as most central to create psychological safety rests on first-line managers. However, to achieve this requires strategies at central level (HR) and continues training of the managers. The results from study II revealed that hope had a significant positive correlation with work engagement while psychological safety did not have that. This indicates that interventions aimed at increasing teachers' hope could be associated with an improvement in their work engagement.

Oral presentation OP207

Psychometric Properties of Work-related Acceptance and Action Questionnaire (WAAQ) in Italian context

Angela Russo, University of Catania; Rita Zarbo, University Kore of Enna; Andrea Zammitti, University of Catania

science

Psychological flexibility – as a fundamental aspect of personal and social functioning (Kashdan & Rottenberg, 2010) – can help people to manage themselves in the uncertain and unpredictable world of work, where sudden or continuous change is the norm rather than the exception. Psychological flexibility is a construct that emerges from Acceptance and Commitment Therapy (ACT; Hayes, Strosahl & Wilson, 1999), a variant of third-generation cognitive behavioral therapy, and it refers to "the ability to contact the present moment more fully as a conscious human being, and to change or persist in behavior when doing so serves valued ends" (Hayes et al., 2006, p. 7). Psychological flexibility is both the core process of ACT and the mediational process of change in ACT (e.g., Ciarrochi et al., 2010) and has been largely demonstrated as a robust and complex set of skills that can improve well-being and performance in work settings (i.e., Flaxman et al., 2013; Moran et al., 2015; Bond et al., 2016).

ACT framework (Hayes et al., 1999, 2006) suggests that the process of psychological flexibility is contextually controlled so that it can vary across different contexts due to variations in levels of awareness, the relevance of one's values in a given context and interaction between the two. Therefore, measuring psychological flexibility with a specific tool for the work context can help to evaluate the personal resources of workers more accurately.

The present research aimed to develop and examine the psychometric properties of the Work-related Acceptance and Action Questionnaire (W-AAQ; Bond et al., 2013) in the Italian context. Four studies were conducted: (1) the exploratory factor analysis, which confirmed the one-factor structure of W-AAQ; (2) the confirmatory factor analysis, to test the fit of the one-factor W-AAQ; (3) concurrent validity, to test the relative associations of the W-AAQ to various criteria, such us to the most widely used measure of psychological inflexibility (AAQ-II), life satisfaction (SWLS), flourishing (FS) and work-engagement (UWES-9); and (4) the stability of W-AAQ using the test-retest method after a 3-weeks.

The study presented shows that the W-AAQ scale is a reliable and valid instrument for researchers and practitioners who wants to evaluate work-related psychological flexibility in the Italian context. This result must be considered with the main limitation of the research, e.g., the convenience sampling used in all four studies. This study contributes to the literature (e.g., Bond et al., 2013) that confirms that work-related psychological flexibility is more related to organizational variables - such as work engagement - than general psychological flexibility, suggesting that future research should use contextual measurement tools of psychological variables. Contextually measuring psychological processes can be an essential action in prevention and treatment paths that aim to ensure healthy lives and promote well-being for all at all ages (SDG3; Good Health and Well-Being; United Nations, 2015).

Oral presentation OP367

Public promotion processes and ethical governance: An analysis of the competencies, gender and job performance

Antonio L. Garcia-Izquierdo & Monica Zuazua | University of Oviedo (Spain); Ana Castaño, University of La Rioja (Spain)

science&practice

Objective: To analyze the competencies (hard and soft) and job performance (task, contextual and counterproductive –in the form of pro-organizational unethical behaviours, UPOB–) of public managers in order to shed light on what are the criteria for promotion. Moreover, we want to know if promotion criteria are in line with the objectives of ethical governance.

Theoretical background: This analysis was carried out within the framework of organizational justice theory and competency-based assessment models and their relationship to job performance from a gender perspective.

Design/Methodology/Approach/Intervention: A quantitative cross-sectional post hoc study was conducted, using a questionnaire of 412 public incumbent managers at high and low levels of responsibility. Pearson and Point-Biserial correlations, hierarchical logistic regression, and comparison of means via t- tests were carried out using bootstrapping analyses.

Results: The likelihood of reaching the rank with greater responsibility increases with tenure and gender (being a man). Moreover, the competency of Innovation Orientation and the UPOB are the main factors determining promotion to positions of higher responsibility. In addition, when taking gender into account, UPOB may have a greater influence on the promotion of men. Innovation Orientation and Contextual Performance were found to be higher for women than for men in positions of greater responsibility.

Limitations: Besides the difficulties to establish causal relationships between the variables analyzed, the results may also be affected by common variance bias, given that managerial competencies and job performance were self-assessed.

Conclusions – research and or practical implications/Originality/Value: This study points to the need for a review of Spanish public administration promotion processes, and proposes the implementation of an alternative competency-based management model to achieve a fairer and more ethical promotion procedure. Specifically, results serve to reinforce the urgent need of Spanish public administration to modernize promotion.processes by increasing the presence of competencies. The originality of the study is based on the fact that we carried out analyses of management levels in Spanish public administration that consider gender impact on management skills and the role of the relevant but scarcely studied topic of unethical counterproductive performance.

Keywords: Public Management Competencies and Job Performance, Gender, Ethical Governance

Oral presentation OP47

Purpose: From theory to practice

Leigh Ann Jones Khosla & Jorge F.S. Gomes | ISEG - Lisbon School of Economics and Management

science&practice

Research goals : While there is abundant discussion in business journals on the 'how to' of purpose to achieve social good beyond profitability, academic research addressing the theoretical and practical impact of purpose is limited. Some management scholars claim that organizations that are not purpose-driven and fail to consider the needs of their relevant stakeholders will not be able to create long term value for their companies. Purpose is a complex word lacking a concise definition and can be interpreted in many ways depending on the context in which it is used. The need for purpose can be considered a defining characteristic of human beings craved by individuals as a fundamental component of life. Organizations as well are experiencing a fundamental shift where purpose is considered a key factor driving how they relate to stakeholders and their ability to work beyond profitability to provide social benefit and long-term value creation for their shareholders. To determine whether purpose impacts the long-term value creation of organizations, this research examined a deeper understanding of the meaning of purpose from both individual and organizational perspectives.

Theoretical background: To understand purpose in an organizational context, there is a need to first clarify what purpose means and its importance to individuals. This research explored the various meanings of purpose and determined that it is generally agreed to be a human attribute which requires intention, consciousness, creativity, and expression. Academic scholars have related purpose to the wellness of individuals with links the occupational and spiritual dimensions as of human existence. With clarity on individual purpose as the ability for humans to consciously set their intentions to achieve good, organizational purpose can be considered as the conscious intentions of individuals to work towards social good beyond the singular goal of profitability. Given the current shift of organizations that previously sought to deliver solely on shareholder value maximization to a more inclusive stakeholder approach, purpose is considered by many academic scholars and business practitioners as the fundamental reason for organizations to exist and is a critical component for the creation of long-term value for shareholders.

Design/methodology: Building on the theoretical understanding of purpose, this research proposes a practical approach to measure the impact of purpose using a Stakeholder Purpose Framework which aims to demonstrate the link between purpose and long-term value creation. This framework aligns an organization's purpose with their stakeholders and measures the outcomes of relevant environmental, social, and governance (ESG) metrics. While there are various ESG metrics available to organizations today, the Stakeholder Purpose Framework proposes to utilize the World Economic Forum (WEF) Stakeholder Capitalism Metrics (SCM) which aligns around the four themes of Principles of Governance, People, Planet, and Prosperity. Future metrics, like the International Sustainability Standards Board (ISSB) will introduce globally standardized metrics that can also be considered within the framework. Activating this framework will provide analytical data supporting whether (or not) purpose does impact an organization's ability to create long-term value.

Limitations: Although metrics are available that allow for the reporting of an organization's ESG initiatives, limited empirical studies have considered the role of purpose in driving those initiatives and whether that purpose is contributing to the long-term value creation of the organization. There is also currently a lack of standardized metrics used globally which could challenge consistency in

academic research. In addition, although voluntary reporting on ESG metrics is increasing globally, the unregulated nature of these metrics could impact on reporting from one organization to another.

Conclusions: Purpose, a word full of complexity and meanings, is considered a driving force in the lives of individuals and organizations. While much literature focuses on the 'how to' of finding and implementing purpose, this research aims to find a deeper understanding of purpose and how it can be measured to show its impact on organizational long-term value creation.

Relevance to Congress Theme/UN SDGs: There is tremendous change happening in the world of work and the impact of that change is felt globally. Issues that were once considered the role of government are now considered achievable only with the cooperation of organizations. Organizations driven by purpose to work beyond profitability will play an active role in addressing the imminent issues of climate change, sustainability, and social justice. This research is looking not only at the role of purpose-driven entities to address these critical issues, but how working with purpose is vital for an organization's ability to create long-term value.

Keywords: Purpose, stakeholders, long-term value creation

Oral presentation OP232

RADICAL IMPROVISATION VERSUS INCREMENTAL IMPROVISATION: AN ANALYSIS WITHIN AN AMATEUR CYCLISTS' TEAM

Arnaud Feral & Narjes Sassi | ISG International Business School

science&practice

Team improvisation is associated with intuition, spontaneity, creativity, and with coordination and communication (Vera & Crossan, 2005). It is characterized by the temporal convergence between the actions' planification and implementation.

An improvisation's process begins with an event – endogenous/exogenous - that disrupts the tasks, the strategy imagined, or the team members' roles. Some researchers try to identify the processes that lead to improvisation (Cunha, et al., 1999). For Adrot (2010), temporal compression is an important characteristic of improvisation explaining the spontaneity that action requires. For this author, it implies (1) a recombination of resources; (2) in a creative way; (3) in a short time between decision and action; (4) allowing an adaptation of a collective work; (5) through an innovation. For authors such as Moorman and Miner (1995), improvisation follows a continuum in which spontaneous and impulsive actions are found at its upper limit and thoughtful and planned actions at its lower limit. Weick (1998) establishes a four-level hierarchy to qualify the stages of improvisation as a function of temporal pressure and the environment uncertainty.

Research on this field enlighten the management situations that require improvisation but provide little information about the processes explaining the intensity and variety of improvisation situations. The objective of this paper is therefore to identify the factors that lead to improvisational situations and to highlight the interacting parameters leading either to incremental improvisation (slight transformation of the initial strategy) or to radical improvisation (total transformation of the initial strategy).

Improvisation is a phenomenon that can only be truly appreciated in motion, as close as possible to its implementation. We therefore used an autoethnography (Akehurst & Scott, 2021) to qualify the compositions of variables that explain the improvisation processes. The first author kept a diary describing ten cycling races in which he participated. He expresses his perceptions, his experience of the disruptive events and describes the events and the improvisational choices that he and his team made. Cycling race is a collective sport where we can find similarities with a traditional work team: collective objectives, strategies, roles, resources, competencies…

A reflexive analysis of these data allowed us to establish a chronology of events (timeline) and a qualification of the variables in interaction that explain incremental improvisation and radical improvisation situations. Our results reveal four configurations of interactions between variables to distinguish improvisation choice during the races. These variables are mainly: the nature, intensity and duration of the disturbing event, its impact on the initial strategy, the team members roles' change, the confidence, and beliefs on the competences of team members, the previous similar experiences, and the facility or difficulty of communication. We specifically find that the nature and intensity of the disturbing event can't only explain either the improvisation will be incremental or radical. Finally, our results demonstrate the importance of coordination and communication in order to create routines, mental patterns and decision heuristics that is common to team members and help them improvise successfully. Strengthening the links between team members and developing improvisational skills seem necessary in this context.

This research contributes to the literature as it identifies the main variables in interaction that explain the different situation of team improvisation: four variables interactions' configurations. This research contributes also to managerial literature as it highlights the processes leading to radical and/or incremental improvisation. Although many precautions were taken during data collection and analysis, this research could be improved by integrating the race's narratives of different team members to ensure better ecological validity.

Keywords: Improvisation, team strategy, autoethnography

Oral presentation OP391

Real Leaders Emerge from Crisis: A Study on Female and Male Governors' Charisma in Times of the COVID-19 Crisis

Stefanie Franziska Krügl, South Westphalia University of Applied Sciences; Rafael Wilms, Vrije Universiteit Amsterdam; Helena Marie Hüster, South Westphalia University of Applied Sciences

science

Research Goals

Nowadays, one crisis chases the other, and that calls for strong leadership. But do leaders become more charismatic in times of crisis? Many scholars theorized crisis as an antecedent for leader charisma (e.g., Shamir, House, & Arthur, 1993; Shamir & Howell 1999). Bligh et al. (2004) demonstrated that U.S. President George W. Bush increased his charismatic rhetoric after 9/11, and classified it into eight "charismatic themes" (See Shamir et al., 1994).

Bastardoz et al. (2022) expanded their results: They showed that a crisis does not only foster "charismatic themes" (Shamir et al., 1994), but also the amount of charismatic leadership tactics (CLTs) (Antonakis et al., 2011) in presidential speeches. They used a Regression Discontinuity in Time (RDiT) design to identify the causal effects. They extended generalizability, by examining the speeches of French President François Hollande after the 2015 Paris attacks. However, both studies focused on terrorist attacks, sampled few speakers and focused solely on male leaders.

Our study analyzes the rhetoric of 9 female and 9 male U.S. governors 3 months before and after the onset of the COVID-19 pandemic. We thereby extend previous insights of charisma and crises literature in at least three ways: Firstly, we explore leader gender as a moderator of the relationship between crisis and leader charisma. Secondly, we explore the nature of a different crises (e.g., terror attacks vs. pandemic). Thirdly, we sampled more speakers.

Theoretical Background

Antonakis et al. (2016, p. 304) defined charisma as "values-based, symbolic, and emotion-laden leader signaling". We suggest: (H1) crisis will increase the amount of verbal CLTs used by political leaders.

According to role congruity theory (Eagly & Karau, 2002), we suggest that women (1) often do not fit the leader stereotype and (2) are criticized for not behaving like women when acting as agentic leaders. Consequently, female and male leaders could also craft their speeches to match gender stereotypes. Hence, we explore:

RQ1: Do female and male political leaders use different CLTs?

RQ2: Does the use of CLTs change as a function of politicians' gender and crisis?

Study Design (Data collection finished by April 2023)

We selected 9 female U.S. governors and utilized a propensity score matching to find 9 statistically identical male U.S. governors. Following Bastardoz et al. (2022), we used a RDiT approach, and centered our assignment variable on 15 March 2020 where the "Declaration of a National Emergency" marked the onset of the crisis in the USA (measurement period: December 15, 2019 - June 15, 2020). We are collecting a sample of 14 speeches (7 before / 7 after the assignment variable) for each governor (n=252). Speeches are assigned to variable treatment based on time (i.e.,

assignment variable) and declaration of state of emergency (i.e., discontinuity). The sum of CLTs and the individual tactics within a speech represent the dependent variables. We examine the influence of gender as a moderator and control for both the total number of words and sentences within a speech (data analysis ongoing).

Results expected

We anticipate that the crisis will increase the use of CLTs. In addition, we do not expect significant gender differences in the frequency of CLT use, but for the type of CLTs used.

Limitations

Since more female governors are Democrats, our sample is unbalanced between the parties. Democratic states had stricter Corona regulations than Republican states, which has an impact on the rhetoric and perceptions of the Corona crisis.

Future research could conduct a more nuanced analysis of gender differences in the use of agency and community tactics with a more balanced sample.

Implications

Our research expands knowledge on how crises affect charisma signaling, which is crucial for responsible political leaders' communication in the face of rising global crises.

We also show whether women use the same amount and types of CLTs as men and examine the impact of gender stereotypes in crisis communication.

Congress Theme

Crises exist in all areas - both global crises (e.g., climate change) and organizational crises (e.g., corporate restructuring) - and will challenge future leaders. Analyzing the rhetoric of female and male leaders during crises can help to improve future crisis communication in all fields.

Keywords: Charismatic leadership tactics, Crisis, Gender

Oral presentation OP462

Recovery from interpersonal conflict at work: A stressor – detachment model approach

Vera Lazanaki, Athens University of Economics and Business

science

Research goals and why the work was worth doing

This study explores the impact of psychological detachment on the relationship between interpersonal conflict as a stressor and emotional exhaustion as a strain based on the Stressor-Detachment model (Sonnentag, 2011). Interpersonal conflict is a well-studied stressor at work which has not been examined so far in association with SDM model, however it is worth studying this construct because as a stressor it has a great negative impact on the employee's emotional exhaustion. Recovering from work has been recognized as a mechanism that buffers the negative impact of interpersonal conflict on mental health, such as emotional exhaustion. Thus, this study aims to cover these gaps regarding the relationships among interpersonal conflict, psychological detachment and emotional exhaustion.

Theoretical background

This research will be based on the theoretical framework of the model „Stressor - Detachment", which examines the effect of stressors on the mental health of employees through their detachment from work when they are off the job. Interpersonal conflicts are observed daily in the workplace and are represented by the degree to which employees have negative social interactions with their co-workers. Interpersonal conflict is positively related to burnout (DeDreu, 2002). Emotional exhaustion is the core of burnout and due to this fact it was selected in this study. Emotional exhaustion is an indicator of work-related strain, emotional tension and fatigue. It is suggested that on days that employees have an interpersonal conflict, they will feel increased emotional exhaustion. Psychological detachment, however, entails buffering of work-related thoughts and job stressors, allowing the employee to recover and to rebuild psychological resources (increasing well-being and reducing strain). There is extensive literature implying that recovery helps individuals to have reduced emotional exhaustion. The reason for this is that individuals who detach from work can refill their energy reservoir, which has been depleted during work (due to the expenditure of effort). Once the energy reservoir is replenished, people are more likely to feel energized at work. In addition, people who have refilled their energy tank through psychological detachment will be better equipped to cope with the daily stressors of work. Once the employee has recovered, the work stressor, in this case interpersonal conflict, will be perceived as a challenge through which an individual can learn and be developed. However, when individuals have not found opportunities to detach psychologically from work and reduce their normal energy, work pressure is likely to lead to psychological exhaustion. As a result, psychological detachment should weaken the positive relationship between job stressors and strain. It is suggested that psychological detachment from work is a useful strategy that prevents the negative effects of stressful situations at work, such as interpersonal conflict.

Methodology

A daily diary study was conducted with 67 employees from a multinational company in sales sector. Participants responded two times each day to questionnaires for five consecutive workdays. Data was collected after the end of work (a) and in the morning before work (b). After the end of the

work, they reported their level of interpersonal conflict and emotional exhaustion. In the morning before work, they reported their level of psychological detachment.

Results obtained

The analysis demonstrated that on days that employees that have an interpersonal conflict, feel emotional exhaustion. Moreover, psychological detachment negative moderates the positive relationship between employees' interpersonal conflict and emotional exhaustion.

Limitations

The researcher have used only self-reports (which increase the risk of common method bias), but we collected data at different time. Another limitation is that single-item measures were used, which are easier and take less time to complete (an important fact of diary studies), but are usually more sensitive to errors than multi-item measures.

Conclusions

Research will benefit from results to extend the stressor-detachment model regarding interpersonal conflict. Since psychological detachment from work during off-job time proved significant regarding the reduction of strain , employees should be encouraged to mentally switch off after work. To the best of our knowledge, this is the first empirical study on interpersonal conflict as a part of stressor – detachment model. This study seeks to fill this gap by adding interpersonal conflict as a stressor.

Relevance to the Congress Theme

Throughout Covid, many workplace interpersonal conflicts have increased, often fueled by pandemic-driven changes to working lives. Thus, it is important for the congress to examine all these issues of conflict, in order to overcome organizations obstacles associated with emotional exhaustion.

Keywords: Interpersonal conflict, emotional exhaustion, psychological detachment

Oral presentation OP723

Reducing Evaluative Bias in a Big Five Psychometric and the Impact on the Big Five Structure

Jonathan Cannon & Stewart Desson | Lumina Learning

science&practice

Research Goals

The research to be presented was conducted as part of doctoral research at the University of Westminster (Desson, 2017), which involved the development of an integrated adaptive and maladaptive personality model for measuring the Big Five, termed Lumina Spark.

Two goals of this research will be presented:

1) How to reduce evaluative bias in personality psychometrics

2) How to measure adaptive and maladaptive personality traits in an integrated assessment

These goals address two issues existent in most traditional measures of the Big Five:

1) Inherent biases found where certain traits are valued more than others. For example, where Extraverted behaviours are conceptualised more positively than Introverted, thus contributing to negative connotations associated with Introversion. This research explores how to value diversity in terms of personality.

2) Many assessments of maladaptive personality tend to stand alone and have their roots in a subclinical form of the DSM framework. Their use in conjunction with measures of adaptive personality is, therefore, more complex, where an integrated measure would allow for a holistic understanding of an individual's personality in terms of preferences and behaviours, both adaptive and maladaptive.

If these issues are addressed, there is a potential improvement in user validity (MacIver et al. , 2014).

Theoretical Background

The research to be presented builds on previous research into the Big Five model of personality, informing the basic structure of the model including its factors and facets. Based on the five-factor model, Lumina Spark bifurcates each factor into their opposite polarities, treating each as an independently measurable scale, with facets sitting under each of the ten scales. These qualities are assessed in terms of adaptive and maladaptive manifestations of associated preferences and behaviours.

Lumina Spark also builds on research conducted by Backstrom, Bjorklund and Larsson (2014), who reported the existence of evaluative bias in many Big Five models, which was also researched by Peabody (1967). However, there has been limited application in practice of these important personality psychometric ideas.

Two questions informed the development with regards to reducing evaluative bias:

1) Has the construct been measured in a comprehensive and non-biased way?

2) How does the user feel about reading about aspects of their personality in a biased and unbalanced personalised report?

By developing a measure of personality with reduced bias and a balanced conceptualisation of the whole spectrum of personality, this research addresses a problem identified by Pettersson et al. (2014) regarding the initial development of the Big Five by Goldberg (1992):

"When an evaluatively unbalanced set of descriptors such as the Big Five adjectival markers (Goldberg, 1992) is subjected to a simple structure rotation algorithm, the resulting factors almost invariably end up contrasting positive versus negative descriptors (Goldberg, 1992)."

Design and Methodology

Participants were invited to complete a range of personality measures including Lumina Spark (n=2,506), the IPIP-NEO (Johnson, 2014) (n=234), the Trait Descriptive Adjectives (Goldberg, 1992) (n=420), and also measures of levels of social desirability of each.

The factor structure of Lumina Spark was established through confirmatory factor analysis; this was also achieved through the mapping of facets to the periodic table of personality (Woods and Anderson, 2016). Results from measures of social desirability and evaluative bias were compared in order to ascertain differential levels of bias inherent in each instrument.

Results

CFA highlighted the robust structure of Lumina Spark, with the structure of the Big Five evident, with further support from the placement of facets onto the periodic table of personality.

Analyses of social desirability showed a significant reduction in evaluative bias of Lumina Spark when compared to the IPIP-NEO (Johnson, 2014) and the TDA (Goldberg, 1992).

Limitations

Limitations include the use of a convenient sample, comprised mostly of western white-collar professionals, and the relatively small sample size for analyses of evaluative bias.

Practical and Research Implications

There is a need for cross-validation of findings on a separate and larger sample, and also exploration of the effects of maladaptive traits on performance.

Practically, the developed model allows for the use of a balanced and unbiased psychometric for use in developmental and recruitment contexts, with the benefits of reduced adverse impact and improved user experience and recognition of diversity.

Originality and Value

This research applies Peabody's (1967) methodology in new and innovative ways, with the benefit of valuing diversity of all personalities and supporting inclusivity interventions.

Keywords: Lumina Spark, Evaluative Bias, Big Five

Oral Session OP693

Reflections on the use of artificial intelligence in nursing from the perspective of humanistic psychology

Thomas Kühn, IPU Berlin

science

In this presentatoon, the significance of artificial intelligence (AI) for nursing will be examined from the perspective of humanistic psychology. A particular focus is placed on the seminal work of Erich Fromm.

By way of introduction, it will be shown why the topic of AI in nursing is relevant from both a nursing science and psychological perspective. The term artificial intelligence (AI) refers to applications in which patterns are recognized by means of algorithms and these recognition processes are intended to lead to the most optimized problem solution possible and to the formation of judgments and decisions linked to it. Technical assistance systems in care are already indispensable today. These include applications such as emergency recognition and notification, support in organizing everyday life, for example when it comes to the right time and the right amount of medication to take, but also assistance in rehabilitation processes, such as exercises to increase or regain one's own mobility.

This makes it all the more urgent to reflect on what significance AI can and should play in care and nursing from the perspective of humanistic ethics. After all, not everything that can be possible must also be good for people and society: Not everything that is technically feasible is ethically unobjectionable. This involves both a discussion of the possibilities and limits of technology, which are constantly changing with advances in research, and a reflection on the question of what actually constitutes and distinguishes what is human. Therefore, it is important to address the opportunities and risks of further development and to actively incorporate the insights gained into ongoing decision-making processes.

In the presentation, critical perspectives will first be elaborated that address the dangers of the increased use of AI for care, nursing and society. Possible negative consequences for nursing such as a change in normative standards and increasing de-humanization will be pointed out. The larger the scope of possible AI-supported activities in nursing, the higher the pressure could become to perform them within certain narrowly defined time frames. This could be associated with increasing de-humanization if the opportunities for time-consuming interpersonal encounters in care were increasingly reduced as a result. In Fromm's sense, it could lead to increasing bureaucratization in such a way that processes in care become more and more standardized so that they can be measured and potentially made more efficient. One risk, therefore, is that the parts of care associated with AI will become increasingly socially valorized at the expense of the purely interpersonal, bodily-mental part of care, ultimately also changing the character of the field of care in such a way that spontaneous encounters between people lose value.

However, AI can also be seen as a beacon of hope and provide support for people's lifelong identity work. Opportunities and risks for identity work are discussed in terms of the dimensions of authenticity, belonging and control in the model developed by Thomas Kühn, "the normative abc of identity". AI can support maintaining a sense of one's own personal integrity and dignity, provide feelings of participation in social change, lead to a reduction in feelings of loneliness, provide a basic sense of security, and counteract feelings of being at the mercy of others.

Finally, a short summary is drawn, emphasizing the importance of bringing social science-based knowledge into political discourses and technology development. For the discussion of technological progress, this means that it must not be a matter of primarily striving to contain possible dangers associated with technical innovations such as AI systems as best as possible out of a rather resigned basic attitude and a projective idealization of a world imagined as "natural," but rather of developing a vision that is linked to the hope of even better interpersonal interaction in societies.

At the same time, hope must not be associated with carelessness, naivety and closing one's eyes to fundamental dangers. In this sense, it would be illusory to understand the field of care in isolation from social development. However, the more societies are characterized by growing social inequalities, centralization of power, acceleration, and a one-sided glorification of technology and measurable data, the greater the dangers described in this presentation that the increasing use of AI can also lead to de-humanization, further bureaucratization in nursing, and seriously endanger the quality of interpersonal relationships in this field.

Oral presentation OP433

Regulatory emotional self-efficacy and work self-efficacy as protective factors of stressful challenges

Lorenzo Filosa, Guido Alessandri, Valentina Sommovigo & Valentina Rosa | Sapienza, University of Rome

science&practice

Research goals. This research aimed to explore to what extent and how regulatory emotional self-efficacy beliefs in managing negative emotions (RESE-NE) would predict changes in psychophysiological states related to the process of occupational stress. Specifically, this study investigated changes in the following three main cortisol parameters: the Cortisol Awakening Response (CAR); the Diurnal Cortisol Slope (DCS), and the Area Under the Curve with respect to the ground (AUGg). A further purpose of this study was to examine whether work self-efficacy (WSE) would mediate the relationship between RESE-NE and different cortisol parameters.

Theoretical background. RESE-NE at work refers to the perceived ability to effectively manage one's interpersonal relations in the workplace, recover from one's negative emotional states elicited by adversities and avoid being overwhelmed by one's negative emotions, which are all protective factors against stress (Alessandri et al., 2018). Workers who feel able to regulate their emotions can better manage and respond flexibly to stressful events at work, minimizing the impact of such events on their own functioning and environment. Thus, high RESE-NE promotes an individual's perception of control over work stressors (Bandura, 1997). WSE, instead, reflects workers' perceived ability to meet the requests of their job, cope with challenging job demands and adapt to demanding work contexts. As RESE-NE, high WSE promotes a sense of control over work stressors, while low WSE is related to maladjustment (Alessandri, 2018). Literature suggests that RESE-NE beliefs foster WSE beliefs over time (Alessandri et al., 2021). Individuals who perceive themselves as able to manage their emotions refer to be more confident in their work abilities and have more cognitive resources to devote to task performance. To extend this line of research, this study investigates the psychophysiological outcomes of RESE-NE and WSE. To this aim, we fitted a multilevel mediational model where RESE-NE was posited as an indirect predictor which impacted cortisol parameters through the mediation of WSE, specified as a proxy predictor of cortisol parameters.

Design. Intensive longitudinal data were collected on 162 workers during two consecutive workdays. Workers were assessed on their RESE-NE and WSE at the beginning of the study. Then, they provided saliva samples five times a day over two working days.

Results . We fitted three multilevel mediational models, each with one of the three cortisol parameters (i.e., CAR, DCS, or AUCg) modeled as level-1 indicators allowed to randomly change over the two study days. RESE-NE and WSE were included as level-2 variables. We controlled for important dynamic (i.e., caffeine and nicotine use, time since awakening) and static (Body Mass Index) covariates, usually related to cortisol changes all over the days. Results from these analyses revealed a significant direct prediction of AUCg by WSE, and a significant indirect prediction of AUCg by RESE-NE through WSE. No significant prediction of CAR or DCS was found by RESE-NE or WSE.

Limitations. RESE-NE and WSE were assessed as static, between-individual variables. Future studies could consider collecting dynamic measures of these constructs over days or weeks.

Conclusions. This research contributes to the existing literature on self-efficacy and well-being in the workplace by showing that RESE-NE and WSE represent protective factors warding off negative

physiological consequences of stress. These constructs were indeed associated with an index of the overall cortisol accumulation over two workdays. Most importantly, the relationships of RESE-NE and WSE with AUCg support our theoretical predictions (Alessandri et al., 2021). From a practical standpoint, organizations could provide their employees with emotion management and coping effectiveness training programs. Training techniques could embrace the use of case studies, role-playing, and simulation to allow employees to experiment with their capabilities in protected settings and then enhance their self-efficacy beliefs through mastery and modelling experiences. Moreover, managers could conduct sharing and debriefing sessions where employees are stimulated to openly share their emotional experiences with their colleagues to relieve negative emotions and build mutually supportive relationships. Supervisors could also support their collaborators through regular communication and mentoring sessions aimed at facilitating positive reappraisal of potentially stressful job-related situations.

Relevance to the Congress Theme. This study extends the wellbeing topic by establishing a firm link between workers' self-efficacy beliefs and daily physiological functioning, shedding new light on the distinctive roles of RESE-NE and WSE in protecting against psychological strain states.

Relevant UN SDGs . Personal beliefs at work and wellbeing

Audience . Both practitioners and academics

Oral presentation OP745

RESET Fitbit Study: Validation of The Caen Chronotype Questionnaire (CCQ)

Robert Hickman, King's College London & Maudsley Biomedical Research Centre (BRC); Dr Teresa D'Oliveira, King's College London

science&practice

BACKGROUND

Chronotype refers to an individual's preference to perform activities at certain times of the day. Circadian preference has an important role in a number of health-related outcomes; these include general wellbeing, mental health, risk of psychiatric disorder, sleep, metabolic function and cardiovascular risk (Partonen, 2015). Individuals with an evening chronotype ("owls"), for example, show increase incidence of obesity, type 2 diabetes, depression, sleep disturbances and irregular sleep-wake schedules (Taylor & Hasler, 2018; Kivelä et al. 2018; Jones et al., 2019; Fabbian et al., 2016). Chronotype also has implications for working time arrangements; employees with shift patterns and work schedules more closely aligned with their individual chronotype, demonstrate improved sleep (Vetter et al. 2015), task performance, job satisfaction, and function more effectively at work (Kühnel et al., 2018).

The Caen Chronotype Questionnaire (CCQ) is a self-reporting measure of circadian rhythms which captures both chronotype (i.e., morningness or eveningness, 'CCQ-ME') and an amplitude dimension known as 'distinctness' (i.e., variations in individual functioning across the day, 'CCQ-A') (Dosseville et al., 2013; Laborde et al., 2018).

The CCQ has been validated in six languages including Arabic, Dutch, German, Italian, Portuguese and Spanish. An English version of the CCQ has so far not been fully validated. This oral presentation reports findings from a UK validation study of the CCQ (N = 600) and a subsample (N=30) of participants who wore an actigraph device for 7 consecutive days.

METHODOLOGY

The sample (N = 600) was reflective of the demographic characteristics of the UK and included full-time workers (aged 18-65) who had English as their main language. Online questionnaires were completed on Qualtrics with detailed information on job characteristics, work schedules, demographics, sleep routine, mood, lifestyle items and two chronotype measures; the Caen Chronotype Questionnaire (CCQ) and Morningness-Eveningness Questionnaire (MEQ).

A subset of participants (N = 30) wore an 'actigraph' (Fitbit Charge 4 device) for one week. The Fitbit Charge 4 is a multi-sensor commercial device with a 3-axis accelerometer and altimeter (e.g. to collect movement and activity data) and optical heart-rate monitor (e.g. to record beats per minute signals). Various sleep parameters (e.g. sleep stage trends and total sleep time) are estimated using Fitbit propriety scoring algorithms (Haghayegh et al. 2019; Nissen et al. 2022).

RESULTS

A confirmatory factor analysis (CFA) confirmed a two-factor model of the Caen Chronotype Questionnaire (CCQ) with dimensions of chronotype (morningness and eveningness; CCQ-ME) and amplitude (distinctiveness; CCQ-A). The convergent validity of both dimensions, CCQ construct validity, and discriminant validity were also evaluated. Full results will be available in January 2023,

including validation data of actigraphy markers against chronotype (CCQ-ME) and amplitude (CCQ-A) dimensions.

LIMITATIONS

The test-retest reliability of the English CCQ version was not evaluated, as in previous multilanguage validations of the questionnaire (Laborde et al., 2018). To better assess circadian typology and distinguish between work and non-work days, future research could extend wrist-worn actigraphy for ≥2-weeks and record daily sleep logs or physiological markers (e.g. dim light melatonin) (Zucconi & Ferri, 2014).

CONCLUSIONS

This is the first study to (1) validate an English version of the Caen Chronotype Questionnaire (CCQ) and (2) incorporate actigraphy data to objectively assess self-reported sleep, activity, and CCQ chronotype estimation. This oral presentation will highlight the importance of studying the 'amplitude' of chronotype as proposed by the CCQ; organisations may better promote employee wellbeing, performance, and productivity, by adopting flexible work-hours that align with an individual's chronotype and circadian preference.

Oral presentation OP461

Resilience and supportive climate as determinants of the influence of supportive leadership on dedication at work

Pedro Antonio Díaz-Fúnez, University of Almería; Leady Viky Fajardo-Castro, University of Valencia; Miguel Ángel Mañas-Rodríguez, University of Almería

science&practice

The World Health Organization -WHO- (2021) has recognized that the world is facing an unprecedented health crisis. For this reason, the Society of Industrial and Organizational Psychology -SIOP- (2022) has marked a research trend within this specialty, the study of mental health and employee engagement.

The engagement or emotional attachment of the employee is one of the factors that most affect their well-being and high levels of job success (Rich et al., 2010; Walumbwa et al., 2010). However, the results of the investigations have shown that its dimensions are not affected in the same way by the elements that make up the organizational context. Authors such as Rothmann and Jordaan (2006) and Abdelrazek (2016) showed that labor resources such as organization support and growth opportunities have a statistically significant positive relationship with the dimension of dedication above the rest of the elements that make up this variable.

But the impact of leadership on the employee's dedication is not a direct effect. This way must influence previously the employee's perception/assessment of their work context. Models such as the one developed by Bakker and Demerouti (2017) propose the existence of intermediate variables in this relationship of influence. In this sense, research has shown the importance of the perception of the organizational climate (Parry, 2002). From an individual level, personal resources such as psychological capital are decisive when the employee forms an image appropriate to the context (Parker et al., 2003).

The objective of this study is to analyze a model of individual development through increased dedication, starting from the influence the support of the leader has on this dimension of engagement. In this model, we suggest the mediating role of the supporting climate between the support of the leader and dedication and the participation of resilience as a moderating variable between the support of the leader and the perception of the supporting climate.

A total of 418 employees from 15 companies belonging to the VML holding, linked to the service sector, responded to the measurement protocol, although only 396 questionnaires were valid.

The results of the moderation model on the mediating variable (support climate) show the leader's support was a significant predictor of the supporting climate (B:.20; p:.001). At the same time, the interaction between leader support and resilience shows a significant impact index on the supporting climate (B:.10; p: .001). This result indicates that the sum of the effect of resilience to the support of the leader increases the capacity of the latter to influence the perception of the supporting climate of the employee, going from a positive and significant influence of .12 (p: .001) with low levels of resilience, to a positive influence of .33 (p:.001) when the employee has high levels of resilience.

On the other hand, the results of the moderate mediation model show how the total effect of the leader's support on work dedication was significant (t = 6.12, SE = .03, p .000). This model shows that the supportive climate (mediator) was also a significant predictor of work dedication when this variable included in the regression analysis (B:.22; p:.001). The moderated mediation indices indicate

an increase in the indirect effect of leader support on dedication at work through the supportive climate that goes from .02 to .07 depending on the levels of the moderating variable (resilience), showing all of them a significant effect. Finally, the results showed an overall moderate mediation index, with a value of .024 (SE = .107 95% BC CI from .004 to .045).

In conclusion, the relevant role of resilience can be drawn as a determinant factor in the process that improves the perception of support due to the support of leaders. This finally up having a positive effect on employee dedication. The findings of this research help organizations and leaders in their efforts to develop and implement successful human resource strategies.

Revenge bedtime procrastination: Using text mining approach to explore why people choose to delay their bedtime

Nanxi Yan, University of Groningen; Anne-Kathrin Kleine, Ludwig Maximilian University of Munich

science

Revenge bedtime procrastination: Using text mining approach to explore why people choose to delay their bedtime

Research Goals and Why the Work was Worth Doing

In our achievement society (Han & Butler, 2015) we live and work under pressure of always aiming high and achieving our goals in a limited amount of time. The associated mixing of work and private life makes poor sleep a prevalent issue among working-age adults (Robbins et al., 2019; Watson et al., 2015). Insufficient sleep leads to poor job performance (Feddock et al., 2007) and impaired health (Kecklund & Axelsson, 2016). One phenomenon responsible for this sleep deprivation is called bedtime procrastination—people going to bed later than intended because of self-regulation failures (Kroese et al., 2014; Kroese et al., 2016).

A phenomenon that obtained increased attention in popular media is called "revenge bedtime procrastination", which refers to deliberately giving up part of one's sleeping time to engage in leisure activities (Liang, 2020). Although its name attributes this behavior to procrastination, this form of postponing bedtime may be more accurately characterized as purposeful bedtime delay (Nauts et al., 2019). This is because there is no intention-behavior gap in purposeful bedtime delay (as people simply want to sleep later) and this delay is not mainly caused by self-regulation failures, which are two key features of procrastination (Steel, 2007).

Following the conservation of resources theory (COR, Hobfoll, 1989, 2002), while bedtime procrastination is related to resource depletion/loss, purposeful bedtime delay might set a resource generation or resource gain process in motion, meaning that people invest resources (e.g., time) to obtain, retain, and protect resources reservoirs (Chen et al., 2015). Nevertheless, current research mainly focuses on the negative consequences of bedtime procrastination. However, it is possible that purposeful bedtime delay might represent a neglected adaptive side of this behavior (i.e., to gain resources). The current research aims to bridge the gap by exploring how people perceive revenge bedtime procrastination and the outcomes related to it. Based on COR, the results of our analyses offer starting points for a theory on individual motives for, and positive and negative consequences of revenge bedtime procrastination. We conducted preliminary analyses on the obtained data. The final results will be presented at the conference.

Method

The current study investigates the content of recently published newspaper articles uses through natural language processing (NLP) techniques (e.g., topic modeling, sentimental analysis) and thematic analysis (Braun & Clarke, 2006), with the goal of uncovering expressed positive and negative attitudes and experiences regarding revenge bedtime procrastination. We use online archival data (NexisUni and twitter) because revenge bedtime procrastination is a young phenomenon predominantly discussed in online blogposts and news articles rather than in scientific literature (Liang, 2020). Applying NLP on online sources discussing bedtime procrastination allows us

to throw an impartial and holistic view on this new phenomenon, thus providing a starting point for future theory development.

Expected Results

In preliminary analyses, we identified multiple different topics that are discussed in the context of revenge bedtime procrastination, namely “work and professional motives”, “the pandemic”, “health risks”, “gaining control”, and “bedtime habits”. Positive aspects of revenge bedtime procrastination pertain to gaining time for the family and leisure activities, gaining control and freedom, and following personal passions. Negative aspects of revenge bedtime procrastination mostly relate to physical and mental problems.

Limitations

The main limitation of the study pertains to the data selection process. The data used in the study was gathered from only two sources, necessarily limiting the generalization to individuals not falling into the user group of these news sources.

Implications and Relevance to the Conference Theme

Sleep deprivation is a relevant health risk. Based on COR, the current study highlights both positive and negative aspects of revenge bedtime procrastination to potentially enrich our understanding of how to foster healthy and limit unhealthy bedtime procrastination behavior.

SDG Goals : Studying the sleeping issue is relevant to the Goal 3 of UN SDG: Good health and well-being.

Keywords: sleep, conservation of resources theory, topic modeling

Oral presentation OP565

Role of workplace telepressure on employees' commitment and job involvement in digitalised work culture

Akhilesh Singh & Vijyendra Pandey | Central University of Karnataka

science&practice

The increased dependence on ICT devices (information and communication) has pressured employees to stay connected with work online. It has expanded the chances of immediate response expectations and permanent availability for work requests. The sudden imposition of work from home during the lockdown has digitalised the working style of the employees and evolved a new work culture. Although people are now moving towards hybrid or traditional working modes, digital communication has mostly taken the place of face-to-face interactions. It has led to a pressure known as workplace telepressure. Workplace telepressure (WT) is a preoccupation with thoughts and an urge to respond immediately to work-related messages during personal or working hours. Studies have reported that people have started giving importance to digital information over and above face-to-face interactions. According to the job-demand resource (JD-R) model, job demands are those aspects of work that need to be done and require physical, mental and emotional exertion. Now, along with job demands, work culture also includes social demands (maintaining social relationships via ICT communication), which is more stressful for employees. WT is a type of ICT demand. It encourages employees to stay connected with other members and work constantly. Messages at the right time can be helpful for task completion and reducing the ambiguity of the work, which has positive results. In contrast, unwanted messages work as an interruption in the task that leads to distractions. Some employees pretend to be constantly connected with work and use this to create an impression on their supervisor as they are hardworking and dedicated to work. Immediately reply to messages or emails late at night to show how hard they work. It may not always be accurate. Therefore, the present paper aims to study the relationship between WT, organisational commitment and employee job involvement. Furthermore, the researcher has studied this relationship in the presence of power distance as a mediator to study the cultural effect. Data collection was done using the online survey method with the help of structured questionnaires. A total of 250 employees were selected for the final study, of which 26.4 per cent are female, and 73.6 per cent are male. The mean age of the participant is 28.01, and S.D. is 4.574. All the participants are full-time employees working in private firms for at least one year. Statistical analysis was done using software SPSS and AMOS v. 25. The study's findings have shown a positive relationship between WT and job involvement but not organisational commitment. It shows that although employees are involved in their work, they lack commitment towards the organisation. Furthermore, there is no direct effect of WT on organizational commitment, but power distance acts as a mediator in their relationship. It shows that India's high power distance culture influences the employees' behaviour. It can be why employees immediately respond to emails or messages when they receive from their seniors or supervisors. They feel obliged and responsible for replying as soon as possible. However, there is a direct effect of WT on job involvement, but there is no mediating effect of power distance. Moreover, differences based on gender, age and marital status were not found in the study. In conclusion, WT can be suitable for employees for job involvement but not for increasing commitment towards the organisation. Therefore, management needs to realise that staying connected with work through ICT devices will not make their employees productive. They should not judge their employee based on online availability. Instead, management needs to prioritise increasing organisational commitment among employees. Lack of organisational commitment can lead to low job satisfaction and high turnover intention, which is not advantageous for any

organisation in the long run. The study's outcome would contribute to theoretical and application aspects for the organisation. The study's findings may be utilised by management as they can train their employees to use technological devices productively. WT is related to the use of mobile phones and computers. Findings would help understand the influence of the use of technology in the workplace and how to implement technology in such a way that can be helpful for work performance, organisational effectiveness and society so that there are fewer negative consequences of the use of technology. The organisation can make policies related to using mobile phones at the workplace. It is essential to provide proper breaks in between work if employees continuously work on computers. Also, employees need to understand the importance of maintaining the boundary between work and family space. It could be helpful for employees to increase work performance which would eventually lead to increased organisational performance and effectiveness.

Keywords: Workplace telepressure, Organizational commitment, Job involvement, Power distance

Oral presentation OP767

Romanian Version of the Career Crafting Assessment: Psychometric Properties

Bogdan Oprea, University of Bucharest; Raluca Ioana Chifor, University of Amsterdam

science

The notion of career is no longer understood as a progressive advancement within the same organization, but rather as a lifelong dynamic transition between multiple jobs. Lee et al. (2021) developed Career Crafting Assessment (CCA) as a means of identifying the proactive behaviors that people engage in when transitioning from one job to another. Career crafting represents "a set of proactive behaviors that create or expand task, relational, and cognitive resources with the goal of supporting individuals' efforts toward achieving congruence between their career and their needs, values, and interests" (Lee et al., 2021). The dimensions of career crafting were derived from the domains of job crafting: changing relational boundaries, utilizing relational resources, reflecting positive career meaning, and expanding task boundaries.

The objective of the current research was to analyze the psychometric properties of the Romanian version of the CCA. We achieved this goal through three studies. In the first study (N = 938), we conducted a confirmatory factor analysis on a sample of Romanian participants, we investigated the measurement invariance of the scale across gender and generations, and we evaluated the internal consistency of the scale and the correlations between career crafting factors. In the second study (N = 344), we tested the convergent validity of the scale by correlating career crafting scores with those obtained for similar constructs (organizational career management and job crafting). In the third study (N = 213), we tested the criterion validity of the scale by correlating its scores with a series of plausible consequences (work engagement, meaningfulness of work, and person-job fit).

Lee et al. (2021) developed the CCA on a sample of participants from both Canada and the USA. However, those two cultures might be fairly similar since they are both categorized as strongly individualistic according to Hofstede's model (Hofstede, 2011). This raises the question of whether the concept of career crafting can also be applied to predominantly collectivist cultures, such as Romania (Hofstede, 2011). The validation of the instrument for different languages can allow the assessment of measurement invariance across cultures. The validation of the instrument for several countries allows comparisons related to the way people craft their career in different cultures. Results obtained with the CCA could be used to improve both coaching and vocational counseling services in Romania. Also, the instrument can be used to test the effectiveness of career crafting interventions.

Participants completed an online questionnaire. Our data was collected from a convenience sample consisting of Romanian employees, who have been recruited using the snowball method. We selected participants based on a number of eligibility criteria similar to those imposed by Lee et al. (2021). In addition, freelancers and company owners have also been excluded from the final sample. The statistical analyses were conducted using SPSS Statistics Version 25 (2020) and Mplus version 7 (Muthén & Muthén, 1988-2012).

Overall, the results indicate adequate psychometric properties for the Romanian version of CCA. Results from the confirmatory factor analysis indicated a good fit between our data and the four-factor model proposed by Lee et al. (2021). Measurement invariance across genders was supported by data. However, measurement invariance across age groups was not supported and the data collected from Gen X participants presented only a marginal fit with the theoretical model. The instrument presents a good internal consistency. Our results supported both the convergent validity

and the criterion validity of the scale. In support of convergent validity, we found significant positive correlations between career crafting and two similar constructs (job crafting and organizational career management). Criterion validity was supported by significant positive correlations between career crafting and performance, work engagement, meaningfulness of work, and person-job fit.

Our study presents a number of limitations. First, our research design was cross-sectional, which means that it is impossible to draw any conclusions about the reliability of our results over time, as well as the predictive validity of the scale. Second, we have examined only a limited number of relationships between career crafting and other variables. A third limit of our study concerns the exclusion of freelances and entrepreneurs from the final sample.

The psychometric properties of the Romanian version of CCA are similar to those of its American counterpart. Our results are in line with the findings of Lee et al. (2021) and suggest that the Romanian version of the instrument is valid.

Understanding career crafting is important because it offers us solutions through which employees can adapt to the changing world of work and through which they can have access to decent work.

Oral presentation OP704

See Something, Say Something: A Meta-Analytic Examination of Safety Voice

Erin Newkirk, Florida International University; Jessica Mesmer-Magnus, University of North Carolina Wilmington; Archana Tedone, The University of Baltimore

science

Safety voice is defined as the change-oriented communication about workplace safety concerns or issues, and is a critical component of proactive safety models and successful safety systems. Given the (1) volume of research on safety voice, (2) the diversity of disciplines in which results have been published, and (3) the criticality of safety voice for successful workplace safety systems, this study aims to take stock of the current knowledge on safety voice in the workplace.

At its roots, safety voice can be thought of as a form of extra-role or organizational citizenship behavior (OCB), given that while engaging in voice behavior is beneficial, it is not usually a requirement of a job.

Sufficient research has accumulated to begin to understand the unique role of safety voice in safety performance, and despite the potential for other interfering influences, it is likely safety voice is at least somewhat positively predictive of safety behavior.

Hypothesis 1: Safety voice is positively associated with safety behavior. (Supported)

Given the natural similarity and probable reciprocity between the motivational bases of the safety voice and safety citizenship performance constructs, it is likely safety voice is more strongly predictive of safety citizenship performance than safety compliance performance.

Hypothesis 2: Safety voice is more strongly associated with a) safety citizenship behavior than with b) safety compliance behavior. (Supported)

Speaking up about safety issues requires a keen knowledge of safety regulations and policies as well as a motivation to protect the health and safety of the workplace. Research supports the notion that increasing workers' knowledge about safety policies and initiatives increases safe work behaviors and contributes to safety-supportive workplaces. Employees who are motivated to create safer workplaces are more likely to weigh in favor of voicing safety concerns rather than remaining silent, particularly when they feel safe and supported.

Hypothesis 3: Safety voice explains incremental variance in safety behavior above and beyond safety knowledge and safety motivation.

Models of workplace safety often depict safety knowledge and motivation as reciprocally-reinforcing constructs that are promoted by safety-supportive environments, and which together predict safety behavior. However, the mechanism by which knowledge and motivation result in safety behavior remains unclear. Some action must result from the knowledge and motivation in order to yield safety behavior. Could safety voice be a missing link?

Hypothesis 4: Safety motivation and safety knowledge indirectly affect safety behavior through the mechanism of safety voice.

Our meta-analytic database is composed of fifty independent studies reported in 45 manuscripts (total N 50,956) reporting 158 unique effect size relationships relevant to the nomological net of safety voice. To ensure a comprehensive search, we canvassed the relevant literature. Next, we

performed a reverse-citation search of articles that referenced foundational publications in the area of safety voice. Third, we conducted a reverse-citation search for articles that referenced scales commonly used to measure safety voice. Articles that met criteria for inclusion in the meta-analytic database were independently coded by two of this manuscript's authors. Inter-coder reliability was very high (99%) likely due to the objective nature of the coding content.

We ran a series of meta-analyses to test H1-H4. Significant results were obtained from the analyses, providing support for each of our hypotheses.

Proactive safety systems actively promote health and prioritize safety by preventing accidents and injuries before they occur. A critical component of such safety systems is safety voice. Results of this meta-analysis suggest that safety voice is related to critical individual safety factors such as safety motivation and knowledge and plays an important role in predicting safety behavior.

This paper contributes to the UN SDGs of good health and wellbeing, as well as peace, justice, and strong institutions. First, working in an environment in which workers feel comfortable about expressing their concerns about safety issues contributes to psychological health and wellbeing, as well as physical safety by preventing safety issues from resulting in adverse safety outcomes. Building such a climate also promotes strong institutions in which workers feel happy, healthy, and psychologically safe.

Keywords: safety voice, safety citizenship behaviors, meta-analysis

Oral presentation OP145

Seeing the wood and the trees: A study to understand the office worker experience of well-being when taking their work outdoors

Sarah Holland, Kerrie Unsworth & Matthew Davis | Leeds University Business School

science&practice

We have seen a resurgence in people spending more time outdoors, we are also witnessing people choosing to take their work outdoors but with very little understanding of the experience of this for people. From prior research, we know that experiencing outdoor nature is an aid for mental recovery through passive undirected attention. Yet an uncertainty arises as people choose to work outdoors: do they still gain the associated restorative benefits of being outdoors while maintaining directed attention and focus for working? Currently, we understand very little about the mechanisms which may allow these two things to happen at once. We propose that the primary causal mechanism between a combination of nature and work lies within people's memories of previous nature awe experiences. By integrating the concepts of affordances of space from the workspace literature (e.g., Gibson, 1979), liminality from the architecture literature (e.g., Dale & Burrell, 2008) and awe from the positive psychology literature (e.g., Keltner & Haidt, 2003), we suggest that as people experience a heightened in the moment focus, they continually loop in and out of soft fascination related to nature and directed attention towards work focus.

To date, research has examined how nature provides restoration. Stress Reduction Theory (SRT; Ulrich et al., 1991) argues that nature can trigger a positive physiological response in humans (e.g., reduced heartrate) . Attention Restoration Theory (ART; Kaplan & Kaplan, 1989) explains that the nature element of soft fascination is most likely to affect such well-being, in that we don't have to interact with nature resulting in depleted directed attention being restored.

Thus, currently we can understand how outdoor space at the workplace and at home is useful for short restorative breaks. However, this study looks to understand longer periods of time spent working outdoors. What happens when an employee takes their work outside? The theory of affordances of space (Gibson, 1979) understands that a workforce may require 'office items' (such as desks and chairs) in an outdoor space to legitimise its' use before employees can begin to explore how they may both work there and experience well-being. Can an outdoor workplace provide such legitimisation?

An in-depth inductive study was run from May–October 2022 using employees from the University of Leeds using a qualitative methodology of participant audio diaries and photo-elicitation, and unstructured and semi-structured interviews. This approach has been taken to reflect the philosophical stance of the researcher along with using Interpretative Phenomenological Analysis (Smith et al., 2009) to gain in-depth understanding of how people individually experience well-being while taking work outdoors. Participants recorded short audio diaries when they took their work outdoors on campus to a place of their choosing to capture details which may otherwise have been lost. Participants were also asked to take photographs of nature elements which they felt were important to them when working outside. Due to the duration of the study a mid-point unstructured interview took place followed by a final semi-structured interview.

Initial results suggest that the experience of taking work outdoors is related to well-being by way of feelings of awe, senses being activated, and memories of time spent in nature. The surprising result thus far has been the ability to focus on work tasks in the outdoor space where working in the outdoors allows for the ability to distance oneself from interruptions. A further 60 interviews are

taking place towards the end of 2022 using Prolific to recruit participants globally who have taken their office work outdoors, because of the sample size I will be bricolaging the data analysis by using thematic analysis to understand this cohort's experience of well-being.

One of the key limitations for this study has been participation. This has been led by both the potential participants but also a key area of concern has been with regards to managerial acceptance of people legitimately taking their work outdoors.

This research contributes to the conversation around third workspaces which includes being outside in nature. By integrating concepts across related literatures, we can provide a platform for future workplace research. Moreover, there are practical implications of an alternative outdoor workspace in an age of pandemics which adds to the research with regards to employee well-being.

This research is relevant to the congress theme of well-being at work and in particular well-being at work and thriving at work. Additionally, this research is also relevant to the UN SDGs of good health and well-being due to the primary research question of understanding how people experience well-being while taking work outdoors.

Keywords: Outdoor, nature, workspace

Oral presentation OP749

Self-Sacrifice at Work: A Synthesized Definition and A Social Identity-Based Framework

Hannah Berkers, Hogeschool van Amsterdam; Yifeng Fan, Fairfield University

science

Sacrifice at work made headlines across the world during the global pandemic. Healthcare employees sacrificed their health, or even their lives, due to higher risks of COVID-19 infection. More essential employees made personal sacrifices by continuing their work without adequate resources and support. Elsewhere, the issue of sacrifice increasingly lays bare in modern-day workplaces, with employees being encouraged and pressured to dedicate more of their lives to work and fit the 'ideal worker' image, even in times of a global pandemic. Particularly, when organizations enlarge employees' responsibilities by turning extra-role behaviors into in-role tasks, employees may be expected to routinely perform extra tasks at potentially steep personal and professional costs. As highlighted by the pandemic, these sacrifices, and the associated antecedents and ramifications, deserve more scholarly and practical attention. If we envision the future of work as more humane and meaningful for average employees, then we should have a deeper conversation about the role of sacrifice at work.

Scholarly inquiries into self-sacrifice, however, have been scattered across research streams which hindered its conceptualization. Moreover, sacrifice is also (implicitly) mentioned in related constructs, often without a clear conceptualization as to what sacrifice actually means. Despite the frequent reference to self-sacrifice, there has been no consensus on its definition as a standalone construct across research streams. This lack of agreement severely impedes the examination of fundamental research questions around self-sacrifice (e.g., its drivers, consequences, and boundary conditions).

Therefore, we first define self-sacrifice at work as a voluntary act of forgoing one's self-interest for others that carries a significant cost. We propose that voluntarily foregoing self-interest and significant cost are key defining features of sacrifice and help distinguish sacrifice from other related constructs such as OCB, workaholism, presenteeism, etc.

Then, we propose a framework (see Figure 1 below) using the lens of social identity. Following Social Identity Theory (SIT), it is possible to explain why employees would sacrifice their self-interests and bring (or risk bringing) harm to themselves and are willing to act in favor of a collective. When individuals see themselves as members of a social category and internalize the goals and values of that social category as their own (i.e., identification), their behavior is likely to be shaped by group membership. Because individuals are motivated to behave consistently with their self-concept and uphold and enhance their social identities, they may sacrifice themselves for those social entities they hold dear, such as their organization or profession.

We focus on employees' identification with different foci. We argue that individuals are motivated to make sacrifices at work when an entity becomes a significant part of their identity. We identify four such categories of identification foci: 1) relational, 2) organizational, 3) professional, and 4) societal causes (e.g., justice or climate change). Following previous work on the dynamic of identification (Kreiner & Ashforth, 2004), we propose four main identification outcomes out of the verification process: increased identification, decreased identification, disidentification, and ambivalent identification. Particularly, employees may feel two distinctly negative feelings toward the identification target, namely decreased identification and disidentification.

The implications of this paper are twofold. First, by defining self-sacrifice at work, we create a foundation for future systematic research on sacrifice in organizational psychology. Moreover, we synthesize these existing insights and highlight their uniqueness and similarities compared to related concepts in the nomological network. Second, in proposing a framework to examine self-sacrifice through the lens of SIT, we create a theoretical foundation upon which future research examining self-sacrifice can advance.

Finally, on the theme of the future of work, crystalizing the concept and examining it along the theoretical framework may also help address the ethical issues in promoting sacrifice at work. It is telling that, in management and organizational literature, attention seems to focus on how organizations can nudge or stimulate employees to go above and beyond their self-interest than how organizations also need to protect those who harm their self-interest. This is important because self-sacrificing behavior may not have an equal pay-off for individuals and organizations. Whereas organizations are able to predominately reap the benefits of this behavior, the focal person making the sacrifice is expected to bear the costs.

Keywords: sacrifice; social identity; wellbeing

Oral presentation OP702

Sexual harassment prevention strategies of Nordic working life actors in tourism and hospitality workspaces

Olga Gjerald & Tone Therese Linge | University of Stavanger, Norway; Tara Duncan, Maria Thulemark & Eleonora Rossi| Dalarne University, Sweden; Kai Victor Myrnes-Hansen & Åse Helene Bakkevig Dagsland | University of Stavanger, Norway; Magnfríður Júlíusdóttir, University of Iceland; Trude Furunes, University of Stavanger, Norway

science&practice

The prevalence of sexual harassment in the tourism and hospitality sector is alarmingly high compared to other sectors and workers in tourism and hospitality are more exposed to workplace-related mistreatment and violence than in other sectors. Taking the tourism and hospitality sector as a lens, this interdisciplinary project initiates collaborative activities between working life actors (specifically unions, employer associations, and tripartite organizations representing employees, employers, and government) and researchers in Iceland, Norway, and Sweden. This research aims to contribute to trans-Nordic knowledge about issues of sexual harassment in tourism and hospitality workspaces. We ask three key questions:

How have working life actors worked on preventing sexual harassment in tourism and hospitality workplaces?

What are definitions of sexual harassment in the tourism and hospitality sector across different Nordic contexts and what impacts do these definitions have on the acceptance of behaviours that may be perceived or understood as forms of sexual harassment?

How can understanding past and current trans-Nordic approaches to sexual harassment provide opportunities for future collaboration, exchange of best practices, and other initiatives that lead to active prevention strategies for sexual harassment in tourism and hospitality workplaces?

Theoretical background

The UN Women (2021) recent report highlights concerns about what sexual harassment 'is' as well as difficulties in the definition that contribute to the under-reporting of this issue. Even as sexual harassment can be defined as "a situation where any form of unwanted verbal, non-verbal or physical conduct of a sexual nature occurs, with the purpose or effect of violating the dignity of a person, in particular when creating an intimidating, hostile, degrading, humiliating or offensive environment (Equal Treatment Amendment Directive 2002/73/EC), questions arise as to whether formal definitions of sexual harassment relate to how such harassment is experienced, perceived and understood in practice. Taking an intersectional approach addresses issues of discrimination and subservience connected to belonging to more than one identity category simultaneously. Here, we see that the intersection of gender and race, skin colour, ethnicity, nationality, class, sexuality, age, and impairment can capture the multiple and complex relationships that construct personal identity and hierarchical social locations. However, while research has pointed out the pervasive nature of sexual harassment in the workplace, intersectional approaches are largely lacking in the literature on work-life and sexual harassment (Brassel et al., 2020) and in hospitality research (Morgan & Pritchard, 2019).

Design/methodology

The study design consists of three stages: stocktaking activities (collating existing material, in-depth interviews with key working life actors, and a broad literature review), workshops (in-country and trans-Nordic), and knowledge consolidation and dissemination (trans-Nordic). The study adopts a qualitative approach to gain in-depth knowledge. The focus is on three main methods:

Content analysis of texts written in campaigns, information brochures, and on webpages connected to the stakeholders in the Nordic tourism and hospitality industry.

In-depth interviews with key stakeholders (unions, employer associations, and tripartite organizations representing employees, employers, and government).

Workshops with key stakeholders and researchers.

Results obtained or expected

This is an ongoing study where the data collection is still under process. The workshops are planned to be conducted in November 2022 and February 2023.

Limitations

The limited amount of participants makes it difficult to generalize the findings.

Conclusions

Using an intersectional lens when focusing on the key issues in our research questions of prevention, definition and future proactive strategies will allow this project to gather, collate and disseminate scientific evidence that will provide practice-based, relevant knowledge that will be useful across the Nordic countries and have wider application across service-based industry sectors.

Relevance to the Congress Theme

The hospitality and tourism industry has up until now largely neglected to focus on sustainable outcomes in relation to employment and workforce issues (Baum, 2018). Such topics are integral to the concepts of decent work and well-being in light of changing work conditions, and there is a need for more research that addresses sexual harassment prevention strategies in the context of the hospitality and tourism sector.

Relevant UN SDGs

This study is grounded in the UN's sustainability goal 8, which promotes inclusive and sustainable economic growth, employment, and decent work for all; and goal 17, which aims at strengthening the means of implementation and revitalizing the global partnership for the goals.

Keywords: Sexual harassment, hospitality, tourism

Oral presentation OP274

Shaping well-being at work through tailored physiotherapeutic training among employees working in a prolonged sitting position

Dorota Molek-Winiarska, University of Economics and Business; Adam Paluszak, Wroclaw University of Health and Sport Sciences; Barbara Chomątowska, University of Economics and Business

science&practice

Background As a result of the Covid-19 pandemic, many office workers had to change office workstations into remote or hybrid work. Only a small percentage of organisations equipped employees who switched to remote work with appropriate ergonomic tools (chairs, screens, desks), and even fewer took care of healthy habits at work, both physical and psychosocial. Additionally, numerous restrictions in the last years meant that employees stopped or significantly reduced their physical activity. It increased the risk of skeletal muscle ailments, which are already common among office workers, as well as a decrease in well-being and work efficiency. The problem of presentism may also get worse.

The aim of this project was to assess the effectiveness of tailored physiotherapeutic training among employees performing administrative work and spending their working time in a sitting position. The study consisted of an intervention study in which tailored physical activity training was conducted. It is assumed that physical activity might reduce musculoskeletal ailments and presenteeism and improve well-being and engagement.

Two hypotheses were stated:

H1: Tailored training will increase the level of well-being and engagement and reduce the level of presenteeism

H2: Tailored training will reduce musculoskeletal alignment and experienced level of pain

Methods

45 participants selected from the administrative staff were divided into intervention (N=22) and comparison (N=23) groups. The following inclusion criteria for the groups were considered: (1) age 30-50 years old; (2) minimum 2 years of work in a sitting position. The exclusion criteria were: (1) serious health problems; (2) certified degree of disability.

The intervention lasted 4 weeks; training was conducted 3 times a week, 45 minutes for each session, in groups of 11. The selected exercises were to reduce tension and fatigue of muscles used during a long-term sitting position (trapezius, back extensor in the thoracic and lumbar region). The subjects performed exercises under the supervision of a physiotherapist. They also received oral instruction on how to perform a given exercise and why it is important to perform it (how it affects a particular muscle).

Well-being at work, presenteeism and engagement at work were measured using standardised and tailored research questionnaires such as Well-BQ (NIOSH, 2021); SPS-6 (Koopman et al., 2002) and UWES (Schaufeli et al., 2006). The level of musculoskeletal complaints was assessed by NMQ (Kuorinka et al., 1987), specifying the location and the level of pain caused by the ailments.

All measurements were carried out two times – before the intervention (training), and after its completion. Participants received personalised links to fill in online questionnaires.

Statistical analyses were conducted using t-test for comparison between groups as well as between variables before and after the interventions. Correlation coefficients were also conducted.

Results

Analyses didn't show differences in the level of engagement as well as most of the aspects of well-being. However, we found some changes in perceived safety in the organisation as a part of the well-being assessment. Participants in the intervention group experienced a decreased feeling of safety and being cared for by an organisation ($t=2.73$; $p<.01$) . On the other hand, they assessed higher their physical health ($t=3.07$; $p< .01$) and lowered their concentration on work problems ($t=-5.01$; $p<.01$) . They also experience fewer insomnia problems ($t=2.22$; $p<.05$).

Presenteeism was reduced significantly after the training (2.69; $p<.05$), while there were no changes in the comparison group between two-time measurements. Significant differences were also noted in the level of experienced pain resulting from musculoskeletal problems. They were related to the neck (2.77; $p<.01$), arms (2.76; $p<.01$), wrists (3.14; $p<.01$) and lower trunk (2.69; $p<.05$). Both hypotheses were partly confirmed.

Conclusions

Even if many interventions were conducted to prove that physical activity positively affects well-being and the musculoskeletal system, there are still many gaps and ambiguities in this research area. Further and in-depth research is needed in the following areas: (1) relations between mental and physical health issues and different interventions at work (2) optimal frequency and duration of the exercises, the importance of their supervision (3) evidence-based examples with intervention and comparison groups etc.

This article meets these needs. The main findings of this study are that adequately selected, supervised physical exercise can effectively reduce musculoskeletal discomfort, especially neck, arms and lumbar pain. There are also links between the intervention and specific aspects of well-being and presenteeism. The obtained results can support work organisers and occupational health and safety specialists in developing MSD prevention programs in the office work environment.

Keywords: well-being, MSD, intervention

Oral presentation OP254

Sharing Mental Models: Helicopter Pilots' Communication Based Information Gathering

Nejc Sedlar, Amelia Hunt & Amy Irwin | University of Aberdeen

science

The goal of the present study was to explore the ways in which internal communication was used by helicopter pilots to gather and share information within their environment in order to aid in their situation awareness. Specifically, we wished to explore the differences in types of communication and their perceived purpose in the sharing/gathering of relevant information, as well as identify the factors affecting the type of communication used.

Situation awareness is considered a core non-technical skill essential for the safe operation of an aircraft. Deficiencies in situational awareness have been noted as one of the foremost hazards to flight operations. While extensive research does exist on situation awareness within aviation, this research has predominantly focused on fixed wing operations. Due to a myriad of operational differences, helicopter specific research is essential for an accurate understanding of the contextual conditions and strategies employed by the crews facing these. With helicopter crews consisting of two pilots (pilot flying and pilot monitoring), as well as a rear/technical crew in some operations, effective communication is an essential non-technical skill which enhances situation awareness by extending an individual's perceptual field to include that of someone else. Clarity, efficiency, and adaptability of communication are therefore essential for the overall helicopter crews' situation awareness within such dynamic and information rich environments.

Semi-structured interviews were conducted with 21 helicopter pilots across 4 general operational backgrounds: Helicopter Emergency Medical Service (HEMS), Military, Offshore Transport (OT), and Search and Rescue (SAR). The focus of the interview was to explore the ways in which helicopter pilots gather information for the purposes of landing and to investigate the factors which may affect these strategies. Within the present paper we will focus specifically on the information gathering that was said to occur through the communication between the crew. Inductive content analysis was used to identify types of communication that the pilots engaged in throughout the flight, as well as the factors which were said to have affected this interaction.

The general aim of all communication within the cockpit was said to be the creation of a shared mental model. When information was shared by one pilot, this was seen to serve three general functions – 1) improving the situational awareness of the receiving pilot in situations when they were not aware of the information beforehand, 2) a confirmation to oneself that the other person is now aware of this information, and 3) a confirmation to the other person that you yourself are aware of this information, as well as that you are alert. In essence, the sharing of raw information serves the purpose of increasing the other pilot's awareness of the situation, while also acting as a tool for informing the communicators of one another's mental model – which in turn guides subsequent communications. The type and amount of communication used was said to be highly dependent on a number of both internal and external factors. The most notable of these were the experience of the crew, type of operations being flown, presence of rear crew, and the complexity of the landing being conducted. Significant individual differences between pilots and crews were also reported, particularly regarding the amount of communication deemed necessary.

The present data relies on self-reported experiences of communication and general information gathering rather than observations of real-world operations. While useful for understanding the

participants' reasoning for their reported actions, we are not able to confirm whether the types of communications are in fact used, or how often.

The reported individual differences between different crews on the amount and type of communication used warrant further investigation. Identification and classification of distinct communicator types (e.g. quiet, listener, talkative) may be carried out with subsequent enquiry into whether these affect the way that pilots approach general information gathering (e.g. do they substitute knowledge from one source with another?).

The helicopter sector within aviation has historically been lagging behind its fixed wing counterpart with respect to human factors research. Though notable differences exist between the two types of operations, findings from the latter were often used to inform procedures of the former. The present study represents another piece of data specifically relevant to that of helicopter operations and builds on the already established research on helicopter specific non-technical skills research.

Keywords: situation awareness, communication, mental models

Oral presentation OP489

Shift work: An analysis of the consequences on employees' health and wellbeing

Emilio Sánchez Santa-Bárbara & Esperanza Pérez Méndez | Universidad de Granada; Nancy Guzmán Raya, Universidad de Alicante

science

Introduction

Work (what it consists of, under what conditions it is carried out, etc.) as well as not having it or having a precarious job has repercussions on health, mood and interpersonal relationships. Thus, unemployment, under-employment, labour inactivity, changes in working conditions or even its temporary organization can produce certain physical and psychological disorders, as explained from the vitamin model of Warr (1987) or the deprivation model of Jahoda (1982).

Shift work is a potentially negative psychosocial factor due to the implications on the psychological well-being of those who perform it (INSHT, 2006). This shift work system requires an adaptive response from employees as it interferes with the biological rhythms of sleep and wakefulness, with their family and social life outside of working hours or with eating habits. Research has found significant associations between shift work and the negative impact on physical and mental health, the development of daily activities, family and social relationships, thus reducing the time available for domestic, cultural or leisure activities.

Method

A cross-sectional correlational study was carried out to identify the consequences of shift work on the physical and mental health of a sample of employees. An intentional sample of 137 workers (58.4% men) was used, 70 with conventional hours (age: M= 45.58 years, sd= 10.94) and 67 on rotating shifts (age: M= 39.34 years, sd= 9.86). The instruments used were, among others, the Survey Of Shiftworkers (SOS) by Barton et al. (1995), to measure the impact of shift work on the health and well-being of workers.

Results

Mean contrasts were made in the dimensions of SOS between the group with conventional hours and the group working in shifts, not finding statistically significant differences in flexibility in sleep habits or in circadian typology. Statistically significant differences were observed in Sleep Quality ($t= 2.474$, $df= 133$, $p=0.015$), in the Interference with social activities ($t= -3.525$, $df= 133$, $p=0.001$), in the Interference with family and domestic life ($t= -2.770$, $df= 135$, $p=0.006$) and in musculoskeletal disorders ($t= -2.253$, $df= 125$, $p=0.026$). No differences were found between the conventional schedule group and the shift work group in Neuroticism, Digestive Disorders, Cardiovascular Disorders or Mental Health.

A multivariate linear regression analysis was run to predict the severity of musculoskeletal pain. This physical disorder can be predicted in 29.1% with the type of working schedule (conventional vs. rotating), sex, alterations in sleep quality and interference with their balance work-family life, and with a high pace of work and workload and length of service.

Limitations

The number of participants was limited and a convenience sample was used, and it is a cross-sectional study, what reduces the generalizability of these results. In addition, further developments

of this research would study the consequences in health and well-being for workers with conventional hours (e.g., weaker decrease in well-being) and workers on rotating shifts (e.g., stronger decrease in well-being), for instance, during the weeks following a vacation time.

Conclusions

The exposure of workers to this rotating schedule system manifests itself in the medium term in greater alterations in the rhythms of sleep and wakefulness, as well as in the balance of work and personal life and also in the frequency and severity of minor physical health disorders. In the longer term, the negative impact on mental health and other types of disorders (digestive, coronary, etc.) in workers is foreseeable.

It is worth mentioning that working in a rotating system (i.e. with alterations in their sleep and interference in their lives), in a high pace of work and workload predicts the severity of musculoskeletal pain. Females and working in that rotating schedule increases the vulnerability or employes to pain and other musculoskeletal disorders, what reflects a gender issue.

Keywords: Shift work, physical disorders, wellbeing.

Oral presentation OP438

Shifting from on-site to hybrid working: Testing the JD-R Model and SDT on job satisfaction, work engagement, and burnout of hybrid workers

Luuk van Iperen, Maastricht University / Eindhoven University of Technology

science

Research goals

The rise of remote working due to COVID-19 imposed rapid individual and organizational adaptations and resulted in new working patterns, which diverged from on-site working and previous remote working arrangements (Wang et al., 2020). Many employees now work completely remotely or utilizing hybrid arrangements. To understand what enables optimal hybrid conditions, a re-evaluation of established and popular frameworks can prove useful. Accordingly, the aim of this research is to compare the Job Demands-Resources Model (JD-R) and Self-Determination Theory (SDT) in their ability to explain the job satisfaction, work engagement, and burnout of hybrid workers. Investigating their mechanisms and key components can boost our understanding and – in turn –guide future studies and interventions. Moreover, it provides an implicit test of whether their effectiveness remains in contexts that diverge from where they were originally conceived.

Theoretical background

Understanding employee motivation and well-being have been among the key goals of the JD-R and SDT. The JD-R outlines how job characteristics (i.e., demands and resources) affect employee outcomes and how proactive job redesign behaviors, including job crafting, can affect this relation. In contrast, the SDT focuses on psychological needs (i.e., autonomy, competence, and relatedness), and has been linked with harmonious and obsessive passion.

Our first goal, given that both prior frameworks originate from on-site working, is to provide a comprehensive view of the individual value of both frameworks in their association with job satisfaction, burnout, and work engagement of hybrid workers. Our second goal, as both frameworks have also been simultaneously employed (e.g., van Wingerden et al., 2018), is to evaluate their combined utility in the context of hybrid working. Our third and final goal is to exploratively determine the commonality and relative importance of the key components within each framework, which can provide implications for optimized usage of scales. This data-driven approach is then connected back to their respective theoretical frameworks in providing implications.

Study design

We utilized an exploratory cross-sectional survey study design, focusing on hybrid workers who worked at least 4 days/week in total, of which at least 2 days/week remotely. A sample was gathered in 2021 (N = 299; 43% female / 57% male; M age = 44.4 +/- 13.0; 76% Dutch). The self-reported survey included demographics; a selection of demands, resources, and job crafting scales; measures for autonomy, competence, relatedness, as well as obsessive and harmonious passion; and scales for job satisfaction, burnout, and engagement. A variety of regression analyses were employed (including SEM, Automatic Linear Modelling, and commonality analysis).

Results

Preliminary results show that among our sample of hybrid workers, the extended JD-R explained the most variance in job satisfaction (38%), engagement (32%), and finally burnout (25%). The extended

SDT explained more variance in the same order (i.e., 58%, 49%, and 35%, respectively). Predictably, combining both frameworks explained more but differences were marginal given the increase in items. Commonality analyses revealed strong overlap between predictors in both frameworks, and the highest overall contribution came from obsessive and harmonious passion, with these two scales explaining 50%, 42%, and 25% of variance, respectively.

Limitations

The cross-sectional nature prevents inferring temporal or causal order.

Conclusions

Preliminary findings indicate that the JD-R and SDT frameworks explain considerable variance among our outcomes of job satisfaction, engagement and burnout. Thereby, this study did not find evidence that their application to hybrid workers is compromised. The SDT explained more variance, and obsessive and harmonious passion were the most important contributors overall. Framed differently, given the cross-sectional nature, these constructs may show considerable conceptual overlap with certain outcomes (see also Smith et al., 2022).

This study borrows its relevance from the – apparently permanent – shift to hybrid and remote working as well as the resurgence of COVID-19 at the time of writing, which is likely to sustain this shift. Moreover, it sets out to compare two frameworks as opposed to building on a single one, providing a critical evaluation of the frameworks we utilize to investigate remote working and guide future studies.

Relevance to the Congress Theme

Contemporary developments call for a deeper understanding and evaluation of established frameworks in the context of hybrid working.

Relevant UN SDGs

Understanding correlates of healthy hybrid working practices allow us to contribute to “Health and Well-Being” and “Decent Work”.

Keywords: Job Demands-Resources, Self-Determination Theory, Hybrid working

Oral presentation OP375

Silver Linings in the Covid-19 pandemic: How resilience promotes personal growth in adversity

Amélia Monteiro & Pedro Neves | Nova School of Business and Economics

science

Research goals and why the work was worth doing: The COVID-19 pandemic is both a universal health calamity and a global economic and social crisis. It impacted workers and workplaces around the world in a dramatic manner (Kniffin et al., 2020). The fact is that "the world of work may change forever" (BBC, 2020). Taking into account the unknown unknowns of this pandemic, COVID-19 context is a crucial moment to find and comprehend mechanisms that are important but not noticeable during normal times (Kniffin et al., 2020), since it is the first attempt to deal with this virus.

Theoretical background: Resilience is a fundamental coping capability, since resilient people search for the positive side, look for creative solutions to overcome hurdles and are focused on recovering faced losses (Bonanno, 2004; Tugade and Fredrickson, 2007). We leverage conservation of resources theory (Hobfoll, 1989) to examine the extent to which resilience mitigates the consequences of COVID-19 pandemic. Resilient individuals are less likely to experience the pandemic's negative impact in their work and personal lives (Shoss et al., 2018). Since resilient people try to adapt in face of negative circumstances, we propose that resilience may be able to buffer the negative impact of COVID-19 and boost the use of personal resources. In these demanding times, resilient individuals have the capacity to control and influence their changing work environment in a successful way (Windle, 2011).

Design/Methodology: We conducted a time-lagged study with a sample of 156 employees from multiple organizations that completed three surveys (t1, t2, t3) separated by a week's time lag. The period of data collection happened during the first wave of the SARS-CoV-2 infection. Several countries were in a state of emergency and lockdown. Our study examines the relationship between resilience, proactive behavior (job crafting) and personal growth, moderated by the COVID-19 pandemic.

Results obtained: We found that more resilient people, faced with a threat, are the ones who engage more in proactive behaviors such as job crafting and are also the ones who grow (referring to a constant and positive change in the way of self-improvement (Robitschek, 1998). On the other hand, less resilient people lack the resources to deal with a perceived threat, and are unable to activate job crafting behaviors nor grow.

Limitations: Our mortality rate between t1-t2 and t2-t3 was rather high (66% and 76%) and the study used self-report measures, which may have caused an overestimation of the relationship between the variables and a potential overlap with other constructs.

Research/Practical Implications: In times of uncertainty and growing insecurity, employees' personal growth initiative is a very important factor to guarantee the success of any contemporary organization (Grant and Ashford, 2008; Parker and Collins, 2010; Srivastava et al., 2020). This study advances the conservation of resources theory by including resilience as an important resource to deal with crises. It also tries to contribute to resilience studies, a topic that is increasingly important nowadays, despite there being very little empirical evidence in the workplace (from what we tend to „assume" is true). The COVID-19 global health crisis, with its human and economic consequences, has skyrocketed the interest in the concept of resilience (Vera et al., 2020). Additionally, it is very

important to understand the actual context and the new ways of working, since it is something that will perpetuate through time.

Originality/Value: In times of uncertainty and growing insecurity, employees' personal growth initiative is a very important factor to guarantee the success of any contemporary organization (Grant and Ashford, 2008; Parker and Collins, 2010; Srivastava et al., 2020). This study advances the conservation of resources theory by including resilience as an important resource to deal with crises. It also tries to contribute to resilience studies, a topic that is increasingly important nowadays, despite there being very little empirical evidence in the workplace (from what we tend to „assume" is true). The COVID-19 global health crisis, with its human and economic consequences, has skyrocketed the interest in the concept of resilience (Vera et al., 2020). Additionally, it is very important to understand the actual context and the new ways of working, since it is something that will perpetuate through time.

Intended audience: more for academics, taking into account the advances in conservation of resources and resilience literature, but also for practice, since it is a global health crisis.

Keywords: Resilience, Growth, Covid-19

Oral presentation OP807

Sleep deprivation and negotiation

Emma Halfmann & Jan A. Häusser | JLU Giessen Germany; Nadira S. Faber, University of Exeter; Joachim Hüffmeier, TU Dortmund

science&practice

Negotiations are often used as conflict resolution in a society that is increasingly sleep-deprived. Yet, not much is known about how sleep deprivation affects negotiations. We presented a theoretical framework for understanding and investigating the effects of sleep deprivation on various negotiation processes and outcomes, particularly joint economic outcomes, individual economic outcomes, social perceptions and emotions, and impasses (Häusser et al., 2022). Focusing on integrative negotiations, we identified cognitive capacities and epistemic motivation to be highly relevant psychological processes, affected by sleep deprivation in negotiation. These impairments deteriorate effective information exchange and hamper information processing, which reduces the quality of (integrative) agreements.

In four quantitative studies and one qualitative study, the hypothesized effect of sleep deprivation on the quality of negotiation agreements in terms of joint economic outcomes was tested. Three experiments employed one-factorial between-subjects designs with individuals performing the tasks either sleep-deprived or well-rested. Study 1 (n = 80) and Study 2 (n = 174) manipulated sleep deprivation with one night of total sleep deprivation (min. 26 hours without sleep, cf. Barnes et al., 2015; Häusser et al., 2016), and Study 3 (n = 144) used a protocol for which individual's sleep was restricted to 50% of habitual sleep duration for two nights (Swann et al., 2006). In Studies 1 and 2 individuals performed an integrative negotiation in dyads (Hüffmeier et al, 2019; Thompson & Hastie, 1990). The central dependent measure was the joint economic outcome. In Study 3 (online) participants observed an integrative negotiation (Thompson et al., 1996) and their suggested optimal contract for both parties depicted the dependent measure. Contrary to theoretical predictions, in all three studies, there was no substantial effect of sleep deprivation on agreement quality. Even though small effects could have been undetected, Bayesian meta-analysis across all three studies provide support that the data are in favor of the null hypothesis relative to the postulated alternative hypothesis. In Study 4 (n = 152) we described the procedure of Study 2 and disclosed the exact joint outcome the well-rested dyads reached on average. Laypersons' expectations fall in line with our theoretical predictions. However, in Studies 2 and 3 there was an indication of an increase in compensatory effort for the sleep-deprived individuals that could account for the absence of a substantial negative effect of sleep deprivation. To gain further insights, qualitative interviews with 22 German elected politicians were conducted (including heads of state and federal ministers) who are experienced in negotiations under sleep deprivation (Study 5). Their responses (coded following the Qualitative Content Analysis by two independent coders) shed light on the nature of compensatory strategies that might help to cope with sleep deprivation in real-life negotiations. These strategies include prerequisites and preparations in advance, as well as actions that individuals and groups can take to counteract the negative effects of sleep deprivation (e.g. active participation, group monitoring). Our mixed-method approach provides first-time insights into negotiations under sleep deprivation. The results of three experimental studies, laypeople's beliefs, and expert interviews suggest that sleep deprivation does not impair negotiators' joint economic outcomes as we (and laypeople) expected. Instead, we suggest that compensatory effort might occur and suppress the emergence of negative consequences of negotiation outcomes.

Our research contributes to the UN Sustainable Development Goals by addressing a prevalent contextual factor (sleep deprivation) known to impair individual states predictive of negotiation success.

Keywords: negotiation,sleep deprivation

Smart working, job demands/resources, and cortisol to DHEA(S) ratio: A longitudinal investigation during the COVID-19 pandemic

Alessandra Falco & Damiano Girardi | FISPPA Section of Applied Psychology, University of Padua, Italy; Tanja Peric, Department of Agricultural, Food, Environmental and Animal Sciences, University of Udine

science&practice

Research goals : This study aimed to investigate the association over time between perceived characteristics of the work environment, smart working (i.e., a flexible work arrangement characterized by the absence of time/space restrictions and an organization by phases, cycles, and objectives), and possible biomarkers of stress, namely cortisol and dehydroepiandrosterone-sulphate – or DHEA(S) – in the hair, during the COVID-19 pandemic.

Theoretical background : Work-related stress (WRS) can be seen as the process by which psychosocial, physical, or organizational aspects of the job (i.e., job demands/resources), by interacting with employees' individual characteristics, trigger psychological, physiological, and behavioural responses in the individual over time. Therefore, the WRS risk assessment benefits from the integration of different measurement methods in a longitudinal perspective. In addition, the COVID-19 pandemic has originated several changes in the work (and non-work) domain, including a sharp acceleration in the adoption of smart working (SW) as a way to contain the spread of the new coronavirus (e.g., by reducing face-to-face interactions with colleagues/supervisors). In this perspective, and in line with the Allostatic Load model, in this study we investigated the longitudinal association between perceived workload and job autonomy – as a job demand and a job resource, respectively – and concentrations of cortisol and DHEA(S) in the hair. Specifically, we focused on the ratio between cortisol and DHEA(S), which is considered as a biomarker of adverse chronic stress. We also investigated the association between SW and cortisol/DHEA(S) ratio over time, as well as the moderating role of SW in the relationship between workload/job autonomy and cortisol/DHEA(S) ratio.

Methodology : The study is part of a larger research project about working conditions, biomarkers of stress, and employees' health and well-being during the COVID-19 pandemic. Workers from different organizations in Italy participated in a longitudinal, multi-method study that took place between April and July 2022. Each participant completed a self-report questionnaire at two time points, Time 1 (T1) and Time 2 (T2), with a three-months time-lag. The questionnaire was aimed at determining workload, job autonomy, and work arrangement (in-person vs smart working). Similarly, participants were also asked to provide a hair strand (i.e., approximately three cm) at both time points. Cortisol and DHEA(S) were quantified in the first 3 cm most proximal of the gathered scalp hair from a posterior-to-vertex position, and they were measured using an in-house Enzyme-linked immunosorbent assay (ELISA). The hypothesized associations were tested using moderated multiple regression analysis, controlling for gender and age.

Results obtained : Workload and job autonomy at T1 were not associated with cortisol/DHEA(S) ratio at T2, while SW at T1 was negatively associated with it. Interestingly, an interaction between workload and SW emerged. Simple slope analysis revealed that the longitudinal association between workload and cortisol/DHEA(S) ratio was positive for smart workers, but nonsignificant for in-person workers.

Limitations : Data were collected at only two time points, and – at this stage – the sample size was relatively small.

Conclusions : Overall, results from this study – which clearly warrants further empirical investigation – suggest that cortisol/DHEA(S) ratio is a promising biomarker of WRS. Hence, if replicated by future research, our results suggest that measurement of hair cortisol and DHEA(S) could be beneficial for early detection of employees at risk of WRS, as well as for prevention of more severe, stress-related consequences for workers' health and well-being. This study also suggests that SW can be considered as a double-edged sword. On the one hand, SW was negatively associated with cortisol/DHEA(S) ratio, a possible biomarker of stress, thus suggesting a possible "bright side" of remote working (e.g., SW may reduce the inference between work and private life). On the other hand, workload was positively associated with cortisol/DHEA(S) ratio among smart workers, thus revealing a possible “dark side” of SW. Employees working remotely may face difficulties in managing their workload (e.g., due to technology-related problems, frequent interruptions, high email quantity and poor email quality), which may lead them to invest more physical and mental effort in their work, thus resulting in higher psycho-physiological costs for the individual.

Relevance to the Congress Theme : In the future, hybrid work arrangements that combine office work and smart working will be increasingly common, and research is needed to promote well-being in this context of change. In this perspective, our study focuses on both antecedents and consequences of new, flexible work arrangements.

Keywords: work-related stress, biomarkers, smart working

Oral presentation OP182

SOCIAL CAPITAL AND ORGANIZATIONAL RESILIENCE: THE ROLE OF HIGH-INVOLVEMENT WORK PRACTICES

Qin Zhou, Leeds University; Tinkuma Edafioghor, University of the West of England; Chiahuei Wu, Leeds University

science&practice

Research goals and why the work was worth doing

Although organizational resilience capability is critical to Small- and Medium-sized enterprises (SMEs) in the turbulent business environment, and social capital has been identified as one of the key sources for organizational resilience, the questions of how and when social capital contributes to organizational resilience in SMEs remain unanswered.

Theoretical background

Adler and Kwon's (2002) opportunity-motivation-ability framework of social capital posits that all three sources must be present for social capital to be activated. Accordingly, we propose a moderated mediation model in which external social capital influence organizational resilience indirectly via information sharing, and high involvement work systems (HIWS) moderate the indirect effect of external social capital on organizational resilience via information sharing.

Design/Methodology/Approach

We tested our model using data from 1134 participants (including top management team members, middle-level managers and entry-level employees) from 177 Nigerian SMEs.

Results obtained

The results showed that: 1) knowledge sharing mediates the impact of external social capital on organizational resilience; 2) the relationship between external social capital and knowledge sharing is stronger when HIWS is high rather than low; 3) the indirect effect of external social capital on organizational resilience via knowledge sharing is stronger when HIWS is high rather than low.

Limitations

Our study has some limitations that provide opportunities for future research. First, our study was conducted before the Covid-19 pandemic with SMEs in Nigeria, a relatively dynamic business environment and a fast-developing economy. Hence, the findings can be context-specific, limiting their generalizability to unprecedented disruptions such as the Covid-19 pandemic, other types of organizations, and national contexts. Future research can test our model in larger firms, different types of disruptions, and different national contexts. Second, to test our model, we employed a cross-sectional design. Future research can address this by adopting a longitudinal design to understand the relationships uncovered in our study.

Conclusions

Our research has several important implications. First, while there are clear indications from the literature that internal resources and capabilities, including leadership, internal investments and cash flows, internal social capital, and dynamic capability help build organisational resilience, little is known about how external factors can enhance organizational resilience. Few studies have tried to fill this gap by examining the relationship between external social capital and resilience with a focus

on relationships formed at an organizational level with supplier, our study deviates from this line of enquiry to examine the role of external social capital (i.e., resources rooted in employees' personal network relationships from outside the organization) in promoting organizational resilience capability (i.e., an organization's ability to learn and develop new strategies or growth pathways through disruptive events). Second, our study extends prior research which focuses mainly on direct relationships between dimensions of social capital (internal and/or external) and organizational resilience (with the exception of Ozanne et al., 2022), by showing the process through which employees' external social capital accumulated at the unit-level can influence organizational resilience. Third, our finding that HIWS can moderate the impact of external social capital on knowledge sharing to contribute to organizational resilience provides empirical evidence for the utility of HRM systems as a moderator in fostering organizational resilience, particularly in the SME context. Although previous studies in the strategic HRM research stream primarily focus on proposing HRM systems, such as HIWPs as antecedents to employee and organizational outcomes (see Jiang, Takeuchi, & Lepak, 2013 for a review), our study deviates from this trend to show the interactional role that HIPWs can play in the relationship between external social capital and organizational resilience in the SME context. Hence, we address the need to examine interaction effects of resources for building organizational resilience (Chu, 2015; Tognazzo et al., 2016).

Relevance to the Congress Theme

This research is relevant to the congress theme - the Future is now: the changing world of work shares critical links with employee wellbeing and the key terms of our research - social capital, information sharing, resilience and employee involvement initiatives have been identified through empirical research to substantially improve employee wellbeing (Cooper et al., 2014; Freeman & Kleiner, 2005; Parzefall & Kuppelwieser, 2012)

Relevant UN SDGs

Our research is relevant to good health and wellbeing, and decent work and economic growth

Keywords: organizational resilience, high-involvement work systems, knowledge sharing

Oral presentation OP151

Social Influence of Informal Leaders: A Study Based on Machine Coding of Verbal and Nonverbal Charismatic Signaling

Laetitia Aurelie Renier, University of Lausanne - HEC; Alyson Meister, IMD; Jennifer Jordan, IMD; Marianne Schmid Mast & John Antonakis | University of Lausanne - HEC

science&practice

Research Goal

We aim at testing the effect of charismatic signaling on social influence. We additionally aim at providing evidence of such effects while relying on innovative measures of charismatic signaling.

The study of leadership faces at least two challenges. First, research on leadership tends to focus on its effects rather than on its causes or does not differentiate the two. This makes leadership challenging to grasp but also to train. We thus seek to differentiate the effect (e.g., influencing people) from its causes (e.g., leaders' behaviors).

Second, traditional methods for studying behaviors might lead to biased measures and reduce the possibility of causal claims. We thus adopt new methods to measure as objectively as possible charismatic signaling using both traditional (human-based) and innovative (machine-based) approaches. Our approach to measuring charismatic signaling also enabled us to move completely from perceptual measures to objective markers of verbal charismatic signaling (VCS) and nonverbal charismatic signaling (NVCS). This reduces the risk of human biases and endogeneity issues.

Theoretical background

Leaders can influence others (Antonakis et al., 2016), increase the extent to which people exert effort (Meslec et al., 2020), and reach people from a distance thanks to social media (Tur et a., 2021). Leaders can influence others thanks to charismatic signaling.

Charismatic signaling is defined as "values-based, symbolic, and emotion-laden signaling" (Antonakis et al., 2016, p. 304), and "signaling" refers to the visible things one does partially designed to communicate (Spence, 2002, p. 434). Charismatic signaling thus refers to what is done or communicated by a leader that makes people become their followers, act, or promote their ideas. Charismatic signaling concerns therefore the cause of being followed and not its effect, nor the theory of charismatic leadership.

In this research, we test the effect of charismatic signaling on social influence by differentiating the cause (i.e., VCS and NVCS) from its effect (i.e., social influence). We operationalized charisma as the extent to which the leader uses VCS and NVCS. We also relied on coding, instead of questionnaires, to measure VCS and NVCS. We additionally include key instrumental variables and statistical methods adapted to the risk of endogeneity.

Methodology

We carried out a study using field data (n =769 TED talk videos) where machine coding, alongside human coding, of VCS and NVCS, was used to measure the impact of charismatic signaling on social influence. Concerning NVCS, for example, we used (a) human ratings of the extent to which the speakers were expressive in their face and their body (i.e., human coding) and (b) automatic detection and classification of specific landmarks and their trajectory (e.g., detection of movements of the nose and arms then classified as big or small movements; machine coding). Concerning social

influence, the number of views, automatically extracted from the TED website, was used as a proxy for social influence.

We used instrumental variable Poisson regression models to predict social influence based on VCS and NVCS. We included talk-based material to control for static attractiveness, gender, and other variables to minimize the risk of omitted variable bias.

Results

Our results first show that human coding–and not machine coding–of NVCS is influenced by attractiveness and gender. Second, our main results show that VCS has a positive effect on social influence, above and beyond NVCS.

Limitations

One limitation concerns the operationalization of human vs. machine coding of nonverbal behaviors. Human and machine coding might concern different levels of abstraction (inference vs. motion unit). Still, in the current study, machine coding appears to be an appropriate proxy for nonverbal behaviors because we assumed that people being more expressive would move more.

Conclusions

This research contributes to research and practice by improving our understanding of leadership and how what is said (VCS) or done (NVCS) influences people. Moreover, our use of machine coding enabled us to rely on objective markers of charismatic signaling, not biased by speakers' appearance. Our results provide additional evidence that speakers using more VCS achieve greater social influence.

Relevance to the Congress Theme

This research contributes to the three facets of the 2023 theme: Contribution and Delivery by highlighting how leaders' behaviors influence others and thus, how one might lead the way to change; Urgency by using field data that mirrors current challenges. This research also aims to answer the question " What must we say? How should we say it " by discussing practical implications in terms of training, leadership, and social influence.

Relevant UN SDGs

The implications of this research are transversal to the UN's sustainable goals by addressing ways to federate people and improve social skills training for future leaders.

Keywords: Leadership, Charisma, Verbal and nonverbal behavior

Oral presentation OP445

Solving the puzzle of social class effects on prosocial behaviors – interactions between social class background, current socioeconomic status, and po

Johannes Stark, Niels Van Quaquebeke & Christian Tröster | Kuehne Logistics University

science

Research goals

Prosocial behaviors are crucial for the performance of individuals, teams, and organizations. Recently, research has proliferated around the relationship between social class and prosocial behaviors, reporting largely inconsistent findings, that is, negative effects (Piff et al., 2010), null effects (Stamos et al., 2020), and even positive effects of social class on prosocial behaviors (Andreoni et al., 2021), pointing to yet unexplored moderators. This study aims to reconcile said empirical inconsistencies by introducing two contextual moderators and a mediator that explain when and why social differences in prosocial behaviors occur.

Theoretical background

Previous research suffers from two major shortcomings: First, no distinction has been made between social class background (i.e., parental education and income) and current socioeconomic status (SES), neglecting interaction effects between the two. Specifically, after being born into a particular social class, an individual's SES often changes during their lives, which is experienced differently depending on their original social class (Martin & Côté, 2019). Indeed, research implies that individuals from higher-class backgrounds, but not from lower-class backgrounds, experience ego threat when having a low SES due to a perceived status loss (Phillips et al., 2020), which we will argue leads to an increase in self-concern and thus to lower levels of prosocial behavior.

However, individuals only sometimes act upon their goals and desires, mainly if they are in high power positions (Guinote, 2007). Previous research on social class and prosocial behaviors neglected the confounding effects of power, defined as an individual's ability to control their own and others' outcomes, which is experienced extensively by higher-class individuals but very limited to lower-class individuals (Lareau, 2002). We, therefore, predict that, only in positions of high power, individuals from higher-class backgrounds show less prosocial behaviors than individuals from lower-class backgrounds if their SES is low. Moreover, we predict that only if power is high, self-concern is (negatively) related to prosocial behaviors, mediating the interaction effect between social class background and current SES on prosocial behaviors.

Methodology

To test our hypothesis, we conducted an experimental study (N = 304) and a preregistered direct replication study (N = 410; aspredicted.org/63au2.pdf) in which we manipulated power (high vs. low) as a between-person factor and measured social class background and current SES as between-person covariates. We randomly assigned participants to two conditions. In the high power condition, respondents participated in a dictator game, in which they voluntarily shared part of their bonus payout and thus had complete control over their outcomes (Piff et al., 2010). The low power condition was identical except that their partner could finally suspend the bonus payout for both of them and thus completely controlled their outcomes (i.e., ultimatum game; Nowak et al., 2000). Furthermore, we measured current SES and social class background using combined scores of own

education and income and parental education and income score, respectively, and self-concern with one item (“I am concerned about my own needs and interests.”; De Dreu & Nauta, 2009).

Results

Supporting our hypothesis, we find significant three-way interaction effects between social class background, power, and current SES on prosocial behavior (b = -7.46, p = .014). Specifically, individuals from higher-class backgrounds with low SES (but not those with high SES), who were assigned to the high (but not low) power condition, shared less of their bonus payout with their partner than individuals from lower-class backgrounds (simple effect = -8.04, p = .007). Moreover, in study 2, we successfully replicated these findings and tested the predicted mediation. Specifically, individuals from high-class (but not lower-class) backgrounds with low SES exhibit higher levels of self-concern, which translates into lower levels of prosocial behavior, but only if their power is high (indirect effect = -1.27, p = .040).

Conclusion

With this research, we aim to reconcile empirical inconsistencies in research on social differences in prosocial behavior by diverging from a socialization perspective to a more dynamic social context perspective. By introducing two essential contextual moderators (i.e., current SES and power), we explain when and why higher-class individuals show less prosocial behavior than lower-class individuals.

Relevance to the UN SDGs

The present research is relevant to the UN Sustainable Development Goals revealing how context affects lower- and higher-class individuals, contributing to a better understanding of social differences in behavior.

Keywords: social class, prosocial behavior, social context

Oral presentation OP597

Speaking up in the cockpit: Do crew status differences affect team cognition, processes, and performance?

Andra Toader, The University of Manchester; Meghan Coleman, Moët Hennessy UK

science&practice

Research goals and importance : Human errors, in particular poor team communication and decision-making, have proven to be determinant factors in a multitude of aviation mishaps and several prominent aviation disasters. Research on team communication in aviation crews (e.g., Foushee & Helmreich, 1988; Fisher & Orasanu, 1999; Kanki et al., 1991) shows that crew errors, omissions, and accidents are caused by fear of speaking up in the cockpit. Specifically, lower status roles such as first officers often fail to express concerns or point out mistakes to high status roles such as captains, due to a strict hierarchy and fear or repercussions. This study aims to investigate the role of status differences in impacting team cognition, team processes and coordination, and team safety. This research is critical because accidents and missteps in aviation teams have deleterious consequences, resulting in potential loss of human life (e.g., NTSB, 1986). The findings of this research will foster improvements in team training and will guide adjacent research literatures on safety critical teams.

Theoretical background : Voice behaviour is the direct and explicit communication of observations or concerns regarding the status of the mission or operations that might affect the progress of the mission. Voice behaviour is a key cause of multiple aviation disasters (e.g., Billings & Cheney, 1981). When crew members voice their opinions and concerns, this enables them to form a shared mental model which will facilitate seamless team processes. Poor voice behaviours imply that members do not share their opinions, hence then end up knowing different things (partial mental models). Lack of shared mental models in turn will prevent their seamless interactions during flight, leading to potential fatal delays and missteps (e.g., e.g., Mathisen et al., 2022; Nembhard & Edmonson, 2006).

We expect that the team's mental model will be dominated by high status members as they are more likely to engage freely in voice behaviour, while lower status members are likely to abstain from voice behaviour (e.g., Fisher & Orasanu, 1999). Status differences are predicted to be associated with differences in voice behaviour and psychological safety, in favour of high status members. Voice behaviour should affect shared mental model development and indirectly (via shared mental models) team processes and team effectiveness.

Design/Methodology : We tested our predictions in a quantitative survey-based study on a sample of N = 159 commercial airline pilots in the United Kingdom (M age = 47.34, SD age = 9.28; 151 males, 7 females, 1 non-disclosed; M experience = 23.14, SD experience = 10.11; 72 Captains, 82 First Officers). The following variables were measured: safety voice, voice behaviour, perceived team mental models, perceived team processes, psychological safety, and team performance. We controlled for interpersonal liking and interpersonal similarities.

Results : There were no significant differences between the low and high-status group in voice behaviour and psychological safety. Voice behaviour had a positive association with perceived team mental models. Perceived team mental models had a positive association with team processes. Team processes had a positive association with team performance. The results of the serial mediation were significant: Voice behaviour had an indirect effect on team performance via perceived team mental models and team processes.

Limitations : This study had several limitations, such as: reliance on cross-sectional self-report data; measurement of perceptions of teamwork as opposed to objective (e.g., behavioural) measures; potential recollection biases as participants were asked to reflect on their last flight in answering the questions.

Conclusions : This is one of the few studies to investigate the role of voice behaviour and team mental models in flight crews in a field sample. Its implications are far reaching in demonstrating that status differences in airline pilots in the UK are perceived to be low. Pilots are able to express their opinions and disagreements freely and crucially, draw each other's attention to failures, omissions, and missteps which might have fatal effects on the flight. These findings underline the importance of team training such as crew resource management to foster safe communication and interactions on the team. Further research is needed to understand how status differences operate at the inter-team level (e.g., pilots-engineers; pilots-cabin crew), in other cultures, and in intercultural teams.

Relevance to the Congress Theme : This study is relevant to the congress topic The Future Is Now : Our research aims to show how equality and egalitarian relationships in work in the 21 st century can improve team and organizational outcomes.

Relevant UN SDGs : Decent work and economic growth.

Keywords: teamwork, status differences, team mental models

Oral presentation OP54

Square Pegs in Round Holes: Problems with defining the occupation as the environment in John Holland's P-E fit theory of vocational satisfaction

Joel Warburton, University of Lincoln; Ciara Kelly, University of Sheffield; Eva Selenko & John Arnold | Loughborough University

science&practice

1. This research examined the congruence problem within Holland's Theory of Vocational Choice (1997). The congruence problem is defined as the unexpectedly weak associations between a good Person-Occupation Fit and positive outcomes (Arnold, 2004). In order to shed light on this issue, this research examined the experience of workers who defy fit theory, i.e. those who either assessed a good fit with their occupation but are dissatisfied, or assessed a poor fit, yet are satisfied.

Through this approach, we achieved a more detailed understanding of how workers interact with their environments, and produce findings that inform career guidance practice through improved matching tools and approaches. Given that 47% of UK workers desire career change and 23% regret their current career choice (LSBF, 2015), there are many who could potentially benefit from more informed approaches.

2. Academics, and practitioners alike, use the longstanding Person-Environment Fit approach to compare measurements of individuals and work environments (Badger-Darrow & Behrend, 2017). Good fit (congruence) is associated with positive work outcomes, such as satisfaction and tenure. The concept of fit is intuitive and alluring, supporting a popular logic that it should be possible to place the right person in the right occupation (Kristof-Brown & Guay, 2011). Career guidance theory offers several approaches to matching individuals with suitable vocations. Based on Person-Environment Fit, Holland's (1997) Theory of Vocational Choice claims when workers enter occupations deemed a match with their individual work personalities, positive outcomes follow.

Given the widespread use and influence of this approach (Patton & McMahon, 2006), relationships between congruence and positive outcomes are weaker than one might expect (Toomey et al., 2009). However, there has been little empirical investigation into why this is the case.

3. This research consisted of two phases. Phase 1 of the research measured Work personality (Holland & Messer, 2013) and satisfaction (Cooper et al., 1988), and used occupational data from 253 UK workers. We then identified a subgroup of 39 participants who defied the predictions of Holland's theory. This selective approach yields "information-rich" cases (Patton, 2014, p. 264), and provides a greater focus on the lived experience of those in an anomalous situation than could be achieved with a non-selective sample. Phase 2 used semi-structured interviews to explore these 39 participants' experiences, explanations and circumstances relevant to the congruence problem. Transcriptions were analysed using Thematic Analysis (Braun & Clarke, 2006; 2013). Themes were used to understand why Holland's theory failed to explain these participants' experiences and situations.

4. This presentation focuses on results that demonstrate the difficulties of capturing and using environmental data within the context of PE fit. For example, it highlights inadequacies in the O*NET occupational description that contributes noise to the fit calculation, and more fundamentally, provides evidence to show that occupation itself is no longer sufficient as a measure of environment. It also delivers evidence of other potential contributors to the congruence problem discovered in this research. These will include limitations of vocational fit theory, errors and omissions in fit calculations and coping mechanisms.

5. Although this research includes a comprehensive range of occupations, participant distribution within SOC categories was not wholly representative of the UK working population. Therefore the generalisability of the findings would need to be explored further, including using transferability as a model of generalization (Firestone, 1993).

6. This research raises serious questions about the capability of Holland's Theory of Vocational Choice to determine meaningful predictions in a career guidance context. This also suggests fragility in Person-Occupation fit approaches in research and practice. Through an increased understanding of how workers' experiences are affected, improved approaches are discussed.

7. This presentation is designed for Academics with Vocational and Organisational Psychology interests, as well as practitioners in HR and guidance fields. It Contributes by highlighting that current vocational approaches based on fit are risking vocational misguidance . This is Urgent in that workers subject to misdirection are likely contributing to dissatisfied and underproductive workforces. It Delivers a discussion of additional and alternative approaches that capture some of the missing/mismeasured elements in traditional approaches.

8. Decent work and economic growth & Reduced inequalities

Starting happy to innovate: Mediating effects of newcomers' happiness and job satisfaction between servant leadership and innovative performance

Patrik Fröhlich & Stefan Diestel |University of Wuppertal; Ricarda Rehwaldt & Timo Kortsch | IU International University Erfurt; Elvira Radaca, University of Wuppertal

science

Introduction : In the changing world of work, organizations face a growing competitive environment and must adapt to succeed in the war for talent. Employees nowadays tend to change jobs more often (Gallup, 2016) and their expectations go beyond financial compensation and satisfaction. Aspects such as self-realization, influence, and meaningfulness are just some of the motivations for choosing and staying with a company (Bergmann, cf. 2019). In addition to these drivers, research demonstrates that organizational socialization impacts important financial and organizational outcomes during the first year of employment (Saks & Gruman, 2014). This outlines the need to enable newcomers to have a good and positive start. Addressing factors that make them happy and lead to more than just satisfaction with the job will make newcomers contribute from the very start and help enhance competitiveness. Against this background, the primary interest of our study is to examine differences between satisfactory working conditions and conditions that make newcomers happy. Furthermore, we seek to clarify to what extent servant leadership, which has gained growing interest and been linked to innovation and creativity (Yoshida et al., 2014), promotes satisfaction or happiness and whether this relates to innovative behavior among newcomers. Based on the Job Demands Resources Model (Bakker & Demerouti, 2008), we assume direct and indirect effects of servant leadership on newcomers' innovative performance. We expect happiness factors and job satisfaction to mediate the indirect effects, with a stronger effect via happiness factors.

Method & Results : The sample of our ongoing study consist of 288 recently employed newcomers from a German university. To cover the first year of organizational socialization, participants were asked to fill out seven questionnaires with intervals from 1 to 3 months, starting at 4-6 weeks after organizational entry. We used 1-1-1 multilevel mediation analysis with robust maximum-likelihood estimation and random slopes to test our hypotheses.

Results indicate that servant leadership is positively related to happiness at work dimensions and job satisfaction and has a positive direct influence on innovative performance of newcomers. The positive effect of happiness factors on innovative performance also proves significant, thus proving an indirect effect via happiness at work. Job satisfaction has no significant effect on innovative performance, thus leading to a nonsignificant mediation.

Discussion, Limitations and Implications: To the authors' knowledge, this is the first longitudinal study to examine innovative behavior in the field of organizational socialization and to investigate the differential roles of happiness and job satisfaction. Thus, we contribute to research in organizational socialization and to research on happiness at work and job satisfaction. We show that even organizational newcomers engage in the development, promotion, and implementation of innovative ideas within the organization, thus strengthening competitiveness. This adds to existing literature, transferring insights from group socialization research (Levine et al., 2001, 2003) into the broader context of organizational socialization. Moreover, we contribute to the literature regarding the differences between the constructs of happiness and satisfaction, which are currently not sufficiently differentiated. While doing so, we outline differences in the influence of leadership and in resulting consequences, namely innovative behavior.

Even though the sample was collected in only one organization, the results appear to be transferable because the newcomers had various backgrounds and job types. Additionally, potential moderators, such as newcomers' personal resources, could be included in future analyses to gain more detailed insights into the mechanisms of the effects between servant leadership, the mediators and innovative performance.

For practice, our study gains insights into how to enable a happy start in a new organization. Shifting from uncertainty reduction and satisfaction towards happiness not only helps newcomers generate novel ideas, but also strengthens the attractiveness and competitiveness of organizations. Demonstrating the effects of servant leadership on happiness at work, our study brings good starting points for companies that want to promote New Work and decent work from the very beginning. Simultaneously, companies may improve newcomer innovative behavior by focusing servant leadership.

The changing world of work therefore implies a need for change in the mindset of those responsible for successful and effective socialization: Successful organizations need to provide newcomers with attractive working conditions that make them happy to innovate and maintain competitiveness.

Keywords: happiness at work, job satisfaction, servant leadership

Oral presentation OP624

Starting Out in a Gender-Atypical Occupation: Understanding Negative Work Event Trajectories of Male and Female Tokens and Their Impact on Performance

Sophie Moser, University of Konstanz

science

Research goals

More men in kindergartens, more women on the construction site? Wrong! The gender segregation within the labour market has barely changed in the past 35 years. (FAZ, 2014)

This quote portrays the current workforce situation in many countries where a majority of occupations is extremely gender segregated. In Germany, many technical occupations are practiced almost exclusively by men, while many social occupations are heavily dominated by women. Thus, it is relevant to ask: How do female newcomers in male-dominated occupations and male newcomers in female-dominated occupations experience their workdays? Do they experience negative events at work which prevent them from completing their job tasks or make them wish to drop out of their jobs?

Shedding light to these questions is also relevant theoretically. For several decades, research attention focused on the consequence of being demographically dissimilar to others. With special regard to gender, Kanter's (1977) tokenism theory initiated a stream of research which so far disagrees on whether men and women react in the same way to being a member of a underrepresented social group ("token").

Aim of this study is to analyze whether the effect of newcomers' gender on temporal changes in negative work events depends on the gender composition of their occupation and whether these temporal changes in turn impact performance and withdrawal.

Theoretical Background

Incorporating role congruity theory (Eagly & Karau, 2002) with ego depletion theory (Baumeister & Vohs, 2007), I argue that, in a symmetric way, both men and women are likely to experience an increase in negative work events if their own gender is underrepresented in their occupation. Further drawing from prospect theory (Kahneman & Tversky, 1984), I expect those changes in negative work events to decrease newcomers' performance and to increase their withdrawal in the long run.

Methods

To test the hypotheses, I surveyed employees of German companies in an extensive repeated-measures design on 482 newcomers. The data was matched with official occupation statistics.

To test the interaction of gender and occupational gender share in predicting negative work event changes, I built a two-level random effects model. To test whether negative work event changes predict employee performance and withdrawal, I calculated Bayes Estimates that capture the change in negative work events for every individual and used them to predict performance and withdrawal in single-level regression analyses.

Results

Supporting my theoretical considerations, men working in occupations with a high share of women (44% or higher) were found to experience an increase in negative work events over time. Opposing

my theoretical considerations, women were found to not experience an increase in negative work events, even if the share of men in their occupation was extraordinarily high. Analyses thus revealed that women and men react to their token status in an asymmetric way. Moreover, the increase in negative work events was indeed found to impairs performance and enhances withdrawal in the long run.

Limitations

Besides several strengths, my study suffers from limitations. Respondents participated voluntarily and were not randomly assigned to the study conditions. Additionally, my study exclusively focuses on the gender composition at the occupational level and does not capture whether the actual worksite of a person indeed is gender segregated. However, a supplementary analysis which relied on the work-group token status arrived at non-findings. My incorporation of the extra-organizational level thus provides insights that would have gone unnoticed, if I had assessed the token status at the work-group level exclusively.

Conclusion

With my research, I contribute to tokenism research that has been characterized by mixed evidence by introducing the extra-organizational factor occupational gender composition. My result furthermore offers direct practical implications: Practitioners in occupations with a high share of women must prevent treating male newcomers with a negative bias.

Relevance to Congress Theme

Occupational gender segregation is a phenomenon that, up until today, is evident. Consequently, the probability to be a token is fairly high for members of several social groups. While historically, in an initially male-dominated labour market, especially women were likely to experience tokenism, today, men also find themselves in workplace scenarios dominated by their opposite gender. By addressing the effects of this trend, this study maps onto the Congress Theme.

Relevant UN SDGs

This study contributes to UNSDG #5 to combat gender inequalities. My findings suggest that in order to overcome the reproduction of structural inequality between women and men at all levels of the labour market, political actors, civil society and economic players must work together with the joint goal: More men in kindergartens, more women on the construction site!

Keywords: tokenism, gender dissimilarity, occupational demography

Oral presentation OP615

STRESS AND PERCEIVED HEALTH: THE EFFECTS OF PSYCHOSOCIAL CONDITIONS IN HOTEL HOUSEKEEPERS

Maria Esther García-Buades, Ortiz-Bonnin Silvia, Montañez-Juan Maribel & Blahopoulou Joanna | University of the Balearic Islands (Spain)

science

Research goal

Hotel housekeepers (HH) represent a main occupational group in the Balearic Islands (Spain), a major tourism destination in Europe. This female-dominated job plays an often invisible but essential role in the hospitality sector. It is considered a poor quality job highly exposed to occupational hazards such as chemicals, work overload and hard physical conditions, but also to mentally demanding conditions such as time pressure and emotional demands. In fact, HH report higher than average visits to the doctor and self-prescribed medication to deal with pain and perceived anxiety and stress. To advance our understanding on the mentally demanding aspects of the job, this study analyses the psychosocial work environment for HH and its relationship with stress and perceived health.

Theoretical background

Most research on the HH job has focused on its "physical aspects" and adopted a traditional occupational health perspective (i.e., physical health protection). Recent studies and claims by unions, however, have highlighted and recognized the relevance of psychosocial conditions, and not only the physical conditions, as risk factors for stress and poor health. Building on the Job Demands-Resources (JD-R) model, the psychosocial work environment of HH and its relationship with health outcomes is analysed in this study.

Design/Methodology

Hotel housekeepers (N = 1043; 100% female) in the Balearic Islands (Spain) answered a questionnaire to assess 18 psychosocial factors (Spanish COPSOQ-II), work-related stress and perceived health in the past year (National Health Survey, 2017).

Results

There is high prevalence of risk factors such as work pace, work-life conflict, and emotional demands. Resources rely on role clarity and task meaning as well as social factors such as social support from peers and leaders, and sense of community. Hierarchical regression showed these factors accounted for 35% variance in stress, and 15% perceived health. Health outcomes were mainly predicted by work demands and the quality of leadership. Less important but significant factors were co-worker support and job insecurity.

Limitations

This research relies on a cross-sectional design and self-reports. The generalization of results to other geographical locations and socio-economic and legal conditions is limited.

Conclusion

The health effects of poor quality jobs such as the HH occupation need considering psychosocial factors in the work environment rather than viewing it as an exclusively physically demanding job.

Work demands and quality of leadership are the most important factors in the prediction of stress and perceived health in this context. Hotel managers could improve the work setting and health of their workforce by reducing work demands and improving leadership skills of middle managers in HH departments. Future research should focus on redesigning HH jobs to develop healthier good quality jobs, and evaluating the success of such interventions.

Relevance to the Congress Theme.

This study offers recommendations to change the world of work for HH to become a healthier, more meaningful, and decent occupation.

Relevant UN Sustainable Development Goals.

Promoting decent work (SDG number 8) and good health and wellbeing (SDG number 3).

Keywords: stress, perceived health, psychosocial conditions

Oral presentation OP77

Stress of conscience, burnout, and turnover in healthcare

Mari Herttalampi & Taru Feldt | University of Jyväskylä

science

Goals and contribution: Stress of conscience (SC) occurs when there is a discrepancy between personal moral values and actions taken at work, such as having to lower the quality of care because of a lack of time. There is still some debate about the number and nature of SC dimensions, and a lack of longitudinal research on its predictive factors and consequences. Our aim was to identify a valid, longitudinally invariant factor model for the Stress of Conscience Questionnaire, and to investigate how different SC dimensions develop over time among healthcare personnel. We also examined how SC dimensions associate with burnout and turnover intentions, contributing to healthcare staff's well-being and retention.

Theoretical background: To date, only two studies have investigated how stress of conscience might develop or change over time. In addition, there have been conflicting findings about the psychometric properties and dimensionality of the Stress of Conscience Questionnaire. Thus, there is a pressing need to understand more clearly how SC evolves over time so that more effective ways can be found to intervene in time to prevent harmful SC developments. We focused on burnout and turnover intentions (to change one's organization or profession) as two key indicators of the negative effects that stress of conscience can have on well-being. Both indicators are of major concern to the healthcare sector, manifesting themselves as sickness absences, higher staff turnover, and lower overall quality of care.

Methodology: Using a longitudinal, person-centered survey study design, we examined the SC ratings from 306 healthcare employees, who rated their stress of conscience in 2019 and 2021. This data was used to conduct a latent profile analysis. Using multinomial regression and multivariate analysis of covariance, the SC profiles were compared in terms of burnout and organizational and professional turnover.

Results: The factor analysis resulted in two SC dimensions: hindrance stressors (e.g., not having time to treat people properly) and violation stressors (e.g., having to do something that felt wrong). Five qualitatively different profiles were identified based on these dimensions: (1) hindrance-related stress, (2) violation-related stress, (3) both stress dimensions increasing over time, (4) both high yet decreasing over time, and (5) stable levels of low stress. Increasing SC (profile 3) associated with increased exhaustion, whereas cynicism was highest in profile 4. Employees in these profiles (3 and 4) reported more organizational turnover intentions than employees in the other profiles. Violation-related stress corresponded positively with professional turnover intentions.

Limitations: The two-wave study design did not allow for reliable analysis of any causal relationships or mediation processes. We measured employees' intentions to leave their organization or profession, rather than their actual turnover.

Conclusions: Our main theoretical contribution was that we found two dimensions to underlie stress of conscience: hindrance stressors (being unable to do the right thing) and violation stressors (being forced to do the morally wrong thing). Person-centered analysis enabled us to identify also atypical SC profiles, such as a combination of high levels of both hindrance and violation stressors, which related to employee burnout and turnover intentions. On its own, hindrance-related stress (e.g., lowering one's aspirations for high quality work) is less detrimental to

well-being than when it is combined with violation-related stress (e.g., being forced to do something that feels wrong).

Relevance to the Congress Theme: The Future is now/Contribution: Identifying and mitigating both hindrance and violation stressors at work is a crucial aim for increasing employee attraction and retention in healthcare. Urgency: Despite other competing stressors in healthcare, stress of conscience is a relevant phenomenon to recognize, as it puts healthcare personnel in risk for burnout and turnover. Delivery: Interventions that aim to support employee wellbeing can apply these findings in identifying potential risk profiles of stress of conscience. This will help to target appropriate and effective actions that support wellbeing among healthcare employees.

Relevant UN SDGs: Understanding and mitigating stress of conscience and consequently reducing burnout and turnover in healthcare contributes to the goals of good health and wellbeing, decent work and economic growth (employees should be able to follow their moral values at work despite scarce job resources), reduced inequality (by increasing the ability to follow personal values in one's work), and sustainable communities (by supporting ethical ways of working within work communities).

Keywords: stress of conscience, burnout, turnover intentions

Oral presentation OP26

Stressors from the Macrosocial Sphere of Life: The Missing Pieces of the Mental Health Puzzle in a Professional Context

Jean Cadieux & Nathalie Cadieux | Université de Sherbrooke

science&practice

Theoretical background. Over the past century, many theoretical models have been developed for understanding occupational stress (e.g., Karasek, 1979; Siegrist, 1996). Changes in the labour market and advances in knowledge related to psychological health at work have allowed these models to evolve gradually (e.g., Johnson & Hall, 1988; Karasek & Theorell, 1990). However, several theories, including the structure/agency theory (Archer, 1995; Giddens, 1987) and the social stress theory (Pearlin, 1999), suggest the importance of using broader approaches to understanding the stressors that may influence the psychological health of professionals. These theoretical developments lead to new multidimensional models by expanding the origins of stress (Pearlin, 1999; Marchand et al., 2006), including not just those found within work, but also those found in individual characteristics, in life outside of work, and in society and its structures (the macrosocial sphere) (Marchand et al., 2006). According to Marchand et al. (2006), stressors from the macrosocial sphere come from values that are promoted in society, in the prevailing culture, and in established rules. Despite the relevance of integrating stressors from society to understanding the stress experienced by professionals, these stressors are rarely considered in the empirical studies. This limitation occurs because recent models do not precisely identify the variables that would operationalize the social dimension. However, recent studies suggest that some professions in the knowledge-based economy may be particularly exposed to these types of stressor (Cadieux et al., 2020).

Research goals. Following the multidimensional approach proposed by Marchand et al. (2006) and a mixed method approach, the research aims to: 1) identify stressors that arise from the macrosocial sphere of life, and 2) measure the contribution and impact of these stressors on the psychological distress of regulated professionals, while considering the contribution of the other spheres of life (working conditions, individual characteristics, and family).

Design. From a sample of lawyers, the methodology employs several successive phases by using mixed methods. The first phase consisted of a qualitative exploratory study using semi-directed interviews (n = 22 lawyers) enabling a thematic content analysis that identifies four main social stressors to which professionals are exposed. The second phase involved a pre-test (n = 40 lawyers) designed to confirm the validity of the scales ($\alpha \geq 0.8$) and adjust them as needed. The third and last phase was a quantitative study (n = 2027 lawyers) using an self-reported questionnaire. Aligned with best practices in scale development, EFA and CFA were performed to validate scales to measure social stressors. Finally, multiple and hierarchical regression analyses were performed to isolate the contribution of four stressors from the macrosocial sphere, while considering the effect of work, family, age and sex (n = 1311 lawyers).

Results. Qualitative interviews highlighted four main stressors from society that impact the psychological health of professionals, including accountability-professional obligation, technology, performance-oriented professional culture and valorization of the professional reputation and success. In the quantitative phase, stressors from the macrosocial sphere account for 21,4% of psychological distress (R^2 Adjusted = .214; $p \leq .001$). Even considering the contribution of stressors from the organizational, family and individual spheres, accountability-professional obligation,

technology and valorization of the professional reputation and success remain significant for explaining the psychological distress of the participants.

Limitations. To confirm its results, the study should be replicated in other professional contexts. The cross-sectional design used in the quantitative phase limits the generalizability of the results obtained.

Research/Practical Implications. Results highlighted the contribution of stressors resulting from the practice of a profession in the knowledge-based economy (macrosocial sphere). The significant contribution of these stressors to explaining the psychological distress of professionals suggests the importance of improving theoretical models for a better understanding of psychological health at work. These results should guide the development of future theoretical models for understanding psychological distress at work, particularly in the knowledge-based economy and the regulated professions.

Originality and value . The results of the study provide a better understanding of the stressors in the social sphere and highlighted the changing nature of stressors to which professionals are exposed. This research is in alignment with UN sustainable development goals, to promotes good health and wellbeing.

Intended audience. Academics and practitioners.

Keywords: Stress, profession, lawyers

Oral presentation OP740

Studying Psychological Safety in Contemporary Teams: A Dyadic Approach

Robbe Verresen, KU Leuven

science

Introduction In the changing world of work, team members are often part of multiple teams, scattered across locations, and highly diverse in expertise and task focus. As a result, the traditional concept of teams—stable and bounded entities, all members uniformly involved in reaching a common goal—no longer applies to many contemporary teams. However, team researchers often still start from this traditional team understanding. Based on an a priori assumption of homogeneity, individuals' team perceptions are (given statistical criteria are met) aggregated to the team level, focusing solely on team-level variance and equating the – proportionally large – intra-team variation to measurement error. We argue that this individual variance is conceptually meaningful, indicative of underlying patterns hidden using a traditional approach. Using psychological safety (PS) as an exemplar, we examine its relational micro-foundations and compare them to the dominant referent-shift approach to improve our understanding of how team constructs, in general, and PS manifest in members' underlying relational patterns.

Theoretical background Team psychological safety is the shared belief that a team is safe for interpersonal risk-taking. Its emergence (i.e., the convergence of perceptions) and magnitude (e.g., high vs. low team-level PS) are assumed to result from members' ongoing collective interactions and experiences. However, members also share relationships and interactions with other members outside these whole-team events, potentially resulting in disparities in members' PS perceptions and intra-team variability. While others acknowledged the actuality and relevance of this intra-team variability, adding dispersion indices does not explain where this variation—or lack thereof—comes from. A dyadic lens to PS can reveal underlying relational patterns and identify the source of diversity at its lowest level.

PS in Contemporary Teams We explore how three team characteristics affect the PS relational patterns in teams as they act as an engine pushing team members to interact more (or less), contributing to the rise of dyadic PS relationships (DPS) within teams. First, we hypothesize that team members' task interdependence pushes members to interact more frequently, stimulating the rise of DPS. Similarly, in the context of flexible workplaces and telework, having a joint physically close (assigned) office can nudge team members to interact, indirectly creating safer dyadic PS relationships. Furthermore, based on the similarity-attraction principle, we expect that members sharing more similarities (e.g., language, gender, tenure, function) have a higher likelihood of developing DPS.

Method We administered a cross-sectional relational survey to 740 employees nested within 3680 dyads and 80 highly virtual, dispersed, and diverse teams from one large Belgium service company. Moreover, we used a longitudinal database of employees' office registrations over the past eleven months to construct dyadic colocation, indicating the extent of face-to-face contact opportunities. Data were analyzed using a multilevel Social Relation Model.

Results Findings indicated that the variance in DPS was primarily due to unique relational effects (47,6%), suggesting substantial intra-team variation in how members idiosyncratically perceive others. Additionally, some members consistently felt safer with others (perceiver-variance; 37.9%), while some are consistently perceived as safer by others (target-variance; 7.7%). The remaining variance in DPS was located on the team level (6.8%).

Taking a closer look at which team characteristics affect the rise of dyadically safe interrelationships, we see that task interdependence, being co-assigned to the same office, and similarity in language, function, and tenure stimulate dyadic PS via increased online and face-to-face contact.

Limitations The sample consisted of teams nested within departments of one company in the aftermath of the covid-19-pandemic, potentially distorting the variance components and limiting the generalisability. Furthermore, the research was cross-sectional, inhibiting any causal claims.

Conclusion Our research confirms the relevance of a dyadic lens toward PS as complementary to the dominant shared-belief approach. Even within teams characterized by a shared climate (i.e., sufficient within-team agreement), underlying dyadic PS relationships can reveal diversified patterns. Furthermore, these relationships and the factors influencing them can help improve our understanding of how such relationships contribute to the rise of a shared climate (i.e., emergence).

Relevance Congress Theme In the changing world of work, researchers must change how work is studied. As team researchers' practical contribution is limited to the match between teams-in-theory and teams-in-practice, the field must re-evaluate its conceptual and methodological frameworks to study teams as they exist in reality.

Keywords: psychological safety, dyadic analysis, referent-shift

Oral presentation OP659

Subjective Well-being, Attitudes towards Work-Family Balance and Leadership Performance: Study with leaders of Brazilian Organizations

Amália Perez-Nébra; Francisco Antonio Coelho Junior, University of Brasília / Brazil; Bernadete Cordeiro, UDF Academical Center / Brazil; Stela Gomes Faiad, University of Brasília / Brazil; Pedro Henrique Oliveira Miranda, Ministry of Women, Family and Human Rights / Brazil

science&practice

Contenporary literature, especially in the current pandemic moment, has been demonstrating that attitudes more favorable towards work-family balance have a positive impact on subjective well-being. Both variables have the potential to influence the behavior of leaders, considering their subjective interpretations of the work reality. Attitudes are about readiness to act in the face of pre-existing mental models. Subjective well-being refers to the extent to which people rate happiness in their lives, and how fulfilled they believe they are. We consider here that the leadership performance is influenced by their attitudes towards work-family balance and by subjective well-being. This study aims to investigate the predictive relationship between subjective well-being and performance of Brazilian leaders mediated by attitudes towards work-family balance. Through procedures of systematic literature review and identification of thematic categories, a set of items that composed the three psychological instruments of this research were constructed. All instruments were submitted to validation procedures by judges and semantics along with 36 leaders, chosen for accessibility, who worked in 6 different organizations (public and private) in Brazil. The first instrument was the 'Attitudes Towards the Promotion of Work-Family Balance' (7 items; KMO = 0.74; alpha = 0.775; factor loadings ranging from 0.63 to 0.49). The 'Subjective Well-Being Instrument' had only one factor (3 items; KMO = 0.67; alpha = 0.83; factor loadings ranging from 0.97 to 0.71). Leadership Performance' was measured by self-report about the creation of organizational practices related to work-family balance (7 items, explained variance = 13.28; alpha = 0.880, factor loadings between 0.831 and 0.462). After digitizing the questionnaire, the data collection was made by survey, took place intentionally, for accessibility, at a distance mode. The procedure used to disseminate the instrument was the snowball. Only managers, of any management level, who led a team, could respond to the survey. All ethical procedures were followed. Multiple regression was used for analysis and interpretation of results. The sample obtained consisted of 220 Brazilian managers, with a mean age of 40.69 years (SD = 8.84), men (62.90%), married (66%), with at least 1 child (59.2%) and leading teams made up of three or more people (47.5%). Moderate positive correlations were identified between subjective well-being and attitudes ($r = 0.274$; $p<0.01$), subjective well-being and leadership performance ($r = 0.273$; $p<0.01$) and attitudes and performance ($r = 0.30$; $p<0.01$). The model obtained has a fit r squared ($r2 = 0.116$). Subjective well-being (Beta = 0.233) and attitudes (Beta = 0.203), all significant ($p<0.005$), predicted leadership performance. The results show that subjective well-being, mediated by favorable attitudes towards the promotion of work-family balance, contributed to the performance of leaders. As a limitation, we highlight the little sampling variability, even if leaders from other regions of Brazil were invited to participate in this research. Organizational practices to promote quality of life and well-being at work may be impacted considering the development of positive mental attitudes. Leaders can be trained to promote a healthy organizational environment, based on respect, empathy, trust and reciprocity, promoting well-being at work.

Keywords: employee attitudes, work-life balance, employee welfare

Oral presentation OP152

Supervisory Feedback at Work: An Updated Meta-Analysis

Silvia Dello Russo, Luiss University & ISCTE-IUL; Mariella Miraglia, University of Liverpool

science

Research goals:

The meta-analysis by Kluger and DeNisi (1996) questioned the effectiveness of supervisory feedback, which decreased performance in over one third of the cases. The authors proposed a preliminary theory of feedback intervention to explain the processes at play in the delivery and reception of feedback.

After 25 years, we believe it is time to follow up on Kluger and DeNisi's (1996) controversial results, particularly in light of the growing literature on feedback quality (Elicker et al., 2019).

Theoretical background:

We are interested in investigating whether and how the content (i.e., feedback valence) and delivery (i.e., feedback quality, with its various features) of supervisory feedback can differently impact employees' responses to feedback. We build on Kirkpatrick's model of learning evaluation (Kirkpatrick, 1976, 1996) as well as on Ellis and colleagues' theory of learning from experience (Ellis et al., 2014) to identify three categories of individual response to feedback, which we name "reactions to feedback", "learning from feedback", and "behaviours after feedback". Moreover, scholars have pointed out the lack of research on cultural differences in feedback reactions (Elicker et al., 2019); so, we explored the moderating role of culture using the GLOBE model to fill this gap.

Design/Methodology:

Drawing on 103 samples (K = 33,536) retrieved via both electronic and manual searches of the literature on feedback, we conducted a series of meta-analyses of correlations, using the random effects meta-analytic procedure (Schmidt & Hunter, 2015) and correcting for sampling and measurement errors. The meta-analyses were run separately for content (i.e., feedback valence) and delivery of feedback, as well as for the above-mentioned three categories of individual responses. To limit biased results, sensitivity analyses were conducted to exclude outliers due to incommensurate sample or effect sizes and to exclude/include longitudinal measures of the outcomes; publication bias was also checked. Finally, to test the moderating role of culture, we conducted a One-Stage Meta-Analytic Structural Equation Model (One-Stage MASEM).

Results:

Preliminary results showed that both favourable feedback content and delivery are positively related to the reactions (ρ = .48, K = 19, N = 1,160; ρ = .44, K = 14, N = 4,355), learning (ρ = .29, K = 23, N = 5,231; ρ = .27, K = 24, N = 8,563), and behaviours (ρ = .41, K = 23, N = 7,460; ρ = .24, K = 23, N = 6,027) of feedback recipients. Moreover, negative feedback showed negative meta-analytic correlations with reactions (ρ = -.15, K = 6, N = 1,641); small but positive correlations with behaviours (ρ = .07, K = 14, N = 3,945); and non-significant association with learning (ρ = .01, K = 14, N = 3,761). Meta-analyses were also conducted on the specific features of feedback delivery and on the sub-dimensions of the three categories of individual response to feedback; the results will be described in the oral presentation. The One-Stage MASEM showed that several cultural values, as

captured by the GLOBE model, moderated (either by strengthening or weakening) the association between feedback valence and responses to feedback.

Limitations:

Possible limitations pertain to the use of cross-sectional meta-analytic correlations, the inevitable focus on variables previously studied in the literature, and the possibility that not all the available studies in the field have been retrieved and included in the meta-analysis.

Research/Practical Implications:

We propose and test a model of supervisory feedback that conceptualises the influence of feedback content and delivery on the individual responses to feedback. Moreover, we shed light on the contextual conditions for feedback effectiveness, addressing calls to investigate cultural differences in feedback research.

The meta-analysis offers insightful evidence-based recommendations for managers, HR professionals, and organisations on how to improve their feedback practice. The results have also implications for cross-cultural management.

Originality/Value:

We extend previous meta-analyses (Katz et al., 2021; Kluger & DeNisi, 1996; Pichler et al., 2020) by considering multiple elements of feedback giving simultaneously and a wider array of employees' responses, beyond performance outcomes.

Relevance to the Congress Theme:

The increasing demand of workers for remote working and other flexible work arrangements require that people develop interactions that are instrumental to achieve wellbeing and to successfully carry out their job – regardless of whether these interactions occur face-to-face or virtually. Supervisory feedback is a key element to provide psycho-social and performance-related support; hence our work shows what features are (most) effective in feedback giving so that they are fostered also in the new world of work.

Keywords: Supervisory feedback; employee responses; meta-analysis

Oral presentation OP513

Supporting New Moms at Work: Knowledge-Based Training Improves Attitudes Towards Inclusive Workplaces

Cody Cox & Ahry Green | St. Mary's University

science&practice

Research goals and why the work was worth doing

In the United States, federal legislation requires organizations to provide breastfeeding mothers with adequate breaks and proper locations to breastfeed or pump. However, these programs are not put in place due to lack of knowledge. Research indicates that specific training about breastfeeding accommodations can promote more positive attitudes towards providing those accommodations; however, whether these accommodations can promote more positive attitudes towards accommodations generally has not been explored. Participants (N = 315) in this study viewed either a knowledge-based breastfeeding training or control training. Afterwards, they completed a knowledge posttest and an inbox task. The result show that a short, knowledge-based video can improve people's attitudes towards breastfeeding accommodations. Moreover, the results indicate that the intervention improved attitudes towards other accommodations as well, suggesting that targeted interventions can promote more inclusive workplaces. These findings demonstrate that even a brief workplace training can promote diversity efforts more broadly.

Theoretical background

In the United States, new mothers often do not have access to breastfeeding accommodations. One study of 550 working mothers found that 59% reported having access to reasonable break time to express milk, 45% had access to a private space, but only 40% had access to both mandated accommodations (Kozhimannil, Jou, Gjerdingen, McGovern, 2015). In addition to satisfying legal obligations, breastfeeding support also leads to greater work-life balance which then leads to greater job satisfaction (Jantzer, Anderson, Kuehl, 2018). There is evidence that Seijts and Yip (2008) demonstrated that knowledge of the benefits of breastfeeding can lead to more support for breastfeeding. However, we anticipate that providing this training will improve attitudes towards accommodating policies generally.

Design/Methodology/Approach/Intervention

The study used a between-subjects design. Participants completed measures of personality, knowledge and empathy. The participants then viewed either a video describing the health benefits of breastfeeding or a control video. Both of these trainings lasted approximately 5 minutes. Participants then completed a distractor exercises and finally completed an inbox task. In the task, participants were asked to take the role of a supervisor; in the target scenarios, participants were asked whether they should accommodate an employee's needs.

Results obtained or expected (if not available, it must be made clear when they will be)

We anticipated that the video about breastfeeding accommodations would improve attitudes towards inclusive workplace policies. Participants were more knowledgeable and accommodating for breastfeeding moms after observing the breastfeeding video. In support of our hypotheses, a test of the main effect of condition indicated that participants who witnessed the video promoting breastfeeding accommodation were more accommodating in both the accommodation scenarios than participants witnessing the control video. These results indicate that the brief video not only

improved attitudes towards providing breastfeeding accommodations, but also improved attitudes towards other inclusive practices.

Limitations

The study was cross-sectional, which raises potential common method bias concerns. However, the fact that the differences were found between conditions mitigates these concerns somewhat. Few of the participants had experience in management positions which limits the generalizability of our findings.

Conclusions – research and or practical implications/Originality/Value

Our data instead suggests knowledge-based training about breastfeeding can significantly change attitudes about breastfeeding accommodations in the workplace and promote inclusivity generally. Individuals who viewed the knowledge-based training had more knowledge about breastfeeding at Time 2. Further, individuals viewing the knowledge-based trainings were more accommodating in our inbox tasks. The data also supports the statement that the videos gave the participants more knowledge regarding breastfeeding accommodations and that training on specific workplace accommodations can promote more inclusive workplace policies generally.

Relevance to the Congress Theme

This presentation is most relevant to the theme of Diversity and Inclusion.

Relevant UN SDGs

This presentation is most relevant to Gender Equality.

Oral presentation OP224

Supporting proactive coping in adaptation to work using an evidence-based psychological onboarding training

Katarzyna Ślebarska & Dominik Adamek | University of Silesia in Katowice

science&practice

Research goal: Proactivity has positive effects on work adaptation. This study introduces a professional onboarding program that aims to enhance a critical resource of newcomer adaptation, i.e., proactive coping, by resource accumulation and controllability training for organizational newcomers.

Theoretical Background : The newcomers' process of adapting to the workplace gains crucial importance. In the entry phase, an employee new to an organization must gain orientation in the current expectations regarding their functioning at the workplace at a relatively quick pace. Adapting to new vocational settings is often accompanied by feelings of confusion, uncertainty, and insecurity (Saks & Gruman, 2012). There is a strong intention to change the workplace among newly hired employees (Allen, 2006). 4% of new employees quit after a poorly spent first day on the job, and 22% leave within the first 45 days. One of the reasons for employee rotation is an inappropriate adaptation to a new workplace, resulting in a lack of commitment to work or even the desire to change it. On the one hand, an individual's adjusting to an organization is influenced by the organization, proposing various socializing techniques. On the other hand, new employees actively seek the needed information. The theory of organizational socialization (Bauer et al., 2007) highlights that newcomers' goal is to reduce the uncertainty felt in the entry phase so that their environment becomes more predictable. Such an approach corresponds with the process of adapting to a new workplace. The insecurity may be mitigated, among others, by information acquired from various sources, mainly through social interactions with supervisors and coworkers. Through multiple techniques and channels, employees are provided with information that is necessary to do their job well (role clarification), those concerning possibilities to function well in the face of real requirements of their professional roles, as well as those regarding social relations in the workplace. The settings that are unfavorable to job integration may lead to vocational exclusion. The past view of new employees described them as submissive, passive individuals who adjust to their environment and go with the organization's flow. In contrast, current employees are perceived as active participants, particularly proactive, in their adaptation processes (Griffin, Neal & Parker, 2007). Proactive adaptation is described as newcomers playing an active role by demonstrating initiative in learning. Proactivity appears to be an element that is even more significant than the support received by new employees in an organization, such as, for example, feedback or advice provided by supervisors (Ślebarska, Soucek & Moser, 2019).

Method : Our onboarding program comprises the following aspects: 1) positive assessment of events, 2) identification and accumulation of own resources, 3) strategic planning, 4) action planning, and 5) coping planning. Increasing the number of proactive remedial actions within the work orientation program makes the newly hired employee comfortable in the new organization. It leads to higher satisfaction, which may favor a better understanding of one's professional duties, the organizational hierarchy, and mission.

Results : The effectiveness of the orientation program (e-learning structured training) was assessed in a sample of organizational newcomers within a longitudinal evaluation design (one-pretest double-

posttest design). The training improved proactive coping and enhanced an important proximal adaptation outcome.

Conclusion : Overall, the study demonstrates that increasing proactive coping enhances the adaptation of organizational newcomers or work form changers concerning role clarity and provides a good point for evidence-based onboarding programs.

Keywords: proactive coping, work adaptation, onboarding training

Suppress to Get Along: A Lifespan Account of Social Motives for Suppression

Elissa El Khawli, Radboud University & Susanne Scheibe | University of Groningen; Susan Reh, University of Groningen / University of Exeter; Anita Keller, University of Groningen

science

Suppress to Get Along: A Lifespan Account of Social Motives for Suppression

Research Goals. The goal of this paper is to understand why (i.e., what motives) and when (i.e., at what age) people use expressive suppression to regulate their emotions at work. This is important because expressive suppression, an emotion regulation strategy that entails hiding one's feelings, is commonly used as a reaction to interpersonal stressors, despite its negative association with a myriad of well-being outcomes.

Theoretical Background. Generally, the literature on emotion regulation at work assumes that people regulate their emotions for well-being and hedonic goals (i.e., to feel better and to avoid feeling bad). Yet, people commonly report suppressing their emotions at work, a putatively dysfunctional way to deal with their emotions, especially as a reaction to interpersonal stressors such as experienced interpersonal incivility. Accordingly, emotion regulation at work may be motivated by non-hedonic, instrumental goals. Given the social nature of expressive suppression, we adopt a socially motivated account for suppression use at work to understand which social motives (communion and status motives) are linked with the use of suppression, and whether salience of a given social motive influences the relationship between experienced incivility and suppression use. Furthermore, we investigate whether age is related to the prevalence of communion and status motives at work. Indeed, lifespan theory suggests that aging is accompanied by changes in the way people allocate their resources. As such, younger workers are more likely to allocate their resources towards growth (i.e., reaching for higher levels of functioning), whereas older workers are more likely to allocate their resources towards maintenance (i.e., maintaining stable levels of functioning). In the work context, an untested implication is that these developmental tendencies may shift the prevalence of communion and status motives. Accordingly, age may be linked with social motives through growth/maintenance goal orientations.

Design and Methodology. Using a daily diary study, we investigated the effects of experienced daily incivility, in concert with communion and status motives, in predicting suppression. Additionally, we addressed individual differences in the salience of communion and status motives by investigating how age relates to these motives via two theoretically established developmental goals at work, growth and maintenance. Data were analyzed from 291 participants (3,159 observations) who participated in a daily diary study of three measurements per day for 15 working days.

Results. At the within-level, we found that experienced incivility and communion motives both predicted use of suppression. Status motives did not relate to suppression, nor did both motives interact with experienced incivility to predict suppression. At the between-level, age was indirectly negatively related to status and communion motives via a lower tendency to be growth orientated in one's career.

Limitations. Given the design of our study, we could not investigate any chronic or long-term longitudinal effects of incivility or motives on suppression. Furthermore, the data were collected during the COVID-19 pandemic, and 64% of the observations were records of people working from

home. Therefore, the way people experienced and responded to their social work environment (e.g., instances of incivility, social motives) in the study may have been influenced by teleworking.

Conclusions. All in all, we observe that people are more likely to use suppression to regulate their emotions on days when their communion motives are salient. Both communion and status motives are more salient among people with high career growth orientation, which, in turn, is more likely among younger workers. Our findings offer insight into how daily motives influence emotion regulation strategy choice, as well as how age and higher-order goals relate to these motives at the dispositional level.

Relevance to the Congress Theme. By examining age differences in the salience of higher-order goals and social motives, this presentation provides food for thought on how we may want to change the workforce of the future to equally accommodate workers of all ages.

Relevant UN SDGs. Given the importance of emotion regulation at work for occupational well-being, the presentation is most relevant to the UN Sustainable Development Goal Good Health and Wellbeing.

Keywords: management of emotion, coping and social support, aging workforce

Oral presentation OP753

Survival of democratic enterprises in capitalist economies: A systematic review on organizational and psychological features

Thomas Höge, Wolfgang G. Weber, Severin Hornung & Christine Unterrainer | University of Innsbruck

science

Research goals and why the work was worth doing

Positive effects of organizational democracy on employee outcomes are empirically well-documented. However, the possibility of enduring survival of democratic enterprises (e.g., worker cooperatives) in a capitalist market environment without a degeneration of original democratic principles and practices has long been contested. The goal of this systematic review was to identify organizational and external conditions, organizational practices and psychological phenomena contributing to the degeneration, retention or regeneration of democratic enterprises. Against the ongoing international debate on democratic degeneration, obtained results expand theoretical and practical knowledge about how to make democratic enterprises and their positive effects on individuals and societies more sustainable.

Theoretical background

Organizational democracy refers to ongoing, broad-based, and institutionalized employee participation that is not ad hoc or occasional in nature. Written rules, regulations, and institutionalized boards enable employees to exert substantial influence on tactical and strategic decisions, either directly or through elected representatives. Examples of democratic enterprises are worker cooperatives, employee stock ownership plans (if owned by a majority of workers), democratic reform enterprises, and self-governed worker-owned firms. Since the beginning of research on democratic enterprises in the early 20 th century, scholars have voiced pessimistic views about the viability of democratic enterprises in a capitalist market environment. Prominent examples are the “degeneration thesis” by Webb and Webb (1914) and the “iron law of oligarchy” by Michels (1915), which form the basis for later and more elaborated models, such as the “cooperative’s life cycle model” by Meister (1984). However, the deterministic character of these pessimistic views has been criticized, for example, by the “retention thesis” by Rothschild-Witt (1976) or the “regeneration thesis” by Batstone (1983), which assume that under specific conditions, democratic enterprises can survive and retain their democratic structures, principles and values – or have the potential to regenerate after periods of democratic degeneration.

Design/Methodology/Approach/Intervention

We conducted a systematic review of published journal articles on qualitative research investigating democratic enterprises within the last 50 years. Based on a comprehensive literature search and a set of detailed inclusion and exclusion criteria, we reviewed 77 relevant qualitative studies that examined altogether 83 democratic enterprises (including 15 studies on nine enterprises of the Mondragon Cooperative Cooperation network, which is the largest democratic corporation worldwide).

Results obtained or expected

The majority of enterprises either resisted pressures towards degeneration or regenerated after a period of degeneration (63.5%). Only 9.5% degenerated fully to the level of conventional hierarchical

enterprises, and 27% showed degeneration tendencies but still remained democratic. We were able to identify a large variety of organizational and external conditions, organizational practices and psychological phenomena that contribute to the degeneration, regeneration or retention of democratic enterprises. In this presentation, we will focus on conditions, practices and psychological phenomena contributing to regeneration and retention.

Limitations

The most serious limitation of this systematic review is the heterogeneity of the quality of primary studies, as well as the varying levels of detail of information about the studied enterprises and qualitative research procedures. Another limitation refers to the lack of theoretical elaboration of the identified psychological phenomena. One reason for this shortcoming might be that the primary studies mostly were not conducted by organizational psychologists, but by researchers from other academic disciplines, such as economists, political scientists, and sociologists.

Conclusions – research and or practical implications

The results of this systematic review refute the pessimistic and deterministic views of the "degeneration thesis" and the "iron law of oligarchy". Democratic enterprises clearly have the potential to survive and succeed economically in capitalist market environments without abandoning their democratic structures, principles and values. The identified organizational and psychological features contributing to the retention or regeneration may inform practitioners on how to implement resilient democratic structures and procedures in contemporary organizations.

Relevance to the Congress Theme

Democratic enterprises can be interpreted as "real utopias" that are able to inform us about possibilities and practices for social transformation towards a more democratic, more humanistic, more egalitarian, more sustainable world of work and society – now and in the future.

Keywords: organizational democracy, degeneration, retention

Oral presentation OP80

Sustainability-oriented target groups and the effect of the locus of control on their word-of-mouth communication

Martin Pittner, Fachhochschule Wiener Neustadt GmbH; Gerald Kolar, FHW GmbH

science&practice

Consumers are both receivers and senders of sustainability messages. They can perform their function both as senders in consumer policy discourse, and through proactive sustainable consumption. Sustainability communication, which makes it possible to turn consumers not only into recipients but also into senders of sustainability messages is particularly promising for a change in society. In this form, consumption becomes a political instrument that enforces the normative idea of intra- and intergenerational justice in terms of promoting the conscious consumption of natural resources. The other political instruments are not replaced by strategic consumption, on the contrary, they are supported (Bilharz, 2009). But sustainable consumption cannot replace a system change in ecological economy (Dauvergne & Lister, 2010). Consumers mainly use daily newspapers, above-the-line advertising and personal conversations with friends, acquaintances and relatives as sources of information concerning CSR. The most credible information sources are consumer magazines and test reports, personal conversations with friends, acquaintances and relatives as well as certificates from independent organizations such as Fairtrade. This proves the great value of word of mouth in spreading “green” messages (Mayerhofer et al., 2008). But little is known about the psychological factors that are associated with WOM (Kim et al., 2023).

Lam & Dick (2005) investigated the effect of subjects' control beliefs on brand word-of-mouth (WOM). While subjects with general internal locus of control (LOC) were more likely to talk about brands with "out groups" (people with whom they have a weaker relationship), those with general external LOC were more likely to spread their brand messages to "in groups" (close friends/family). People with internal LOC usually have higher education and higher income and tend to talk about brand innovations with “out groups”. Addressing the latter target group would facilitate the diffusion of "green" innovations or messages.

The aim of this study is to evaluate the influence of personality traits such as competence and control beliefs (FKK, Krampen, 1991) on brand word-of-mouth communication (WOM; Lam & Dick, 2005) of in particularly sustainability-oriented consumers. For this purpose, a standardised online survey (n=709) was conducted among Austrian consumers. WOM was surveyed with questions asking for the preferred dissemination of information about new brands and products.

The results demonstrate that the segment of “proactive“ sustainability-oriented consumers with higher levels of internal control conviction show increased WOM communication with both in- and out-groups. However, this effect cannot be attested for all environmentally conscious consumers. No significant effect of the external control conviction of sustainability-oriented consumers on the WOM communication with in/out groups could be substantiated. In general, the results of the survey group show that with an increasing sustainable lifestyle and increasing consumption of organic products, the WOM communication with both in- and out-groups also increases significantly.

The study indicates that an increasing level of knowledge and understanding of sustainable consumption seems to enhance the diffusion of green messages to all target groups. The influence of LOC on brand WOM needs further studies. It should be noted that the focus of the study is on Natur*pur, an organic private label of the Austrian food retailer Spar.

Keywords: sustainability, locus of control, word of mouth communication

Oral presentation OP618

Sustainable employability, technology acceptance and task performance in Italian workers collaborating with robots: a pilot study

Massimo Miglioretti & Eleonora Picco| University of Milano-Bicocca; Pascale Le Blanc, Eindhoven University of Technology

science&practice

1. Research goals and why the work was worth doing

The world of work is exponentially changed by digitalization and robotics. However, in organizations with an ageing workforce the use of these advanced technologies puts the sustainable employability (SE) of workers-collaborating-with-robots, and, in particular, their task performance at risk. However, we still don't know whether, and if yes how, SE policies can impact workers' task performance in digitalized workplaces. Drawing on the models of SE by van der Klink et al. (2015) and Picco et al. (2022), this study aims to ascertain whether the relationship between SE policies and employee task performance – as a fundamental indicator of SE – is mediated by health and productive capabilities, and whether this indirect effect is moderated by the levels of User Acceptance of Information Technology (UTAUT) main predictors (i.e., performance expectancy, effort expectancy, social influence and facilitating conditions; Venkatesh et al. 2003).

2. Theoretical background

In an aging and rapidly transforming world of work, thinking about organizational policies from a sustainability perspective is needed. In this study, we define SE policies as organizational practices that may improve employee SE (Ybema et al. 2020). Based on scientific literature that highlights the relevance of organizational SE policies (e.g., Nielsen et al. 2017), we first argue that SE policies are positively related with the task performance of workers that collaborate with robots (Hypothesis 1). According to van der Klink and colleagues (2015) and Picco et al. (2022), when talking about SE, it is important to consider employee capabilities. These can be defined as the perception of attainability of aspects such as taking care of health while maintaining the job (health capabilities), or having the right competencies to successfully perform the job (productive capabilities). Based on the Job Demands-Resources Model (JD-R model; Demerouti et al. 2001) and the recent literature on SE interventions (Picco et al. 2022), we consider health and productive capabilities as complex personal resources, and expect these capabilities to have a mediation role in the previously hypothesized relationship between SE policies and employee task performance (Hypothesis 2). Finally, based on the UTAUT model (Venkatesh et al. 2003), we argue that employee levels of UTUAT predictors moderate the hypothesized indirect relationship between SE policies and task performance. In particular, in line with the discrepancy-arousal theory (Capella and Greene 1982, 1984; Kluger and DeNisi 1998), we suggest this indirect effect to be stronger among employees with a low score on these predictors compared to employees with a high score on these predictors (Hypothesis 3).

3. Design/Methodology/Approach/Intervention

Cross-sectional surveys were conducted among workers in an Italian company using collaborative robots in manufacturing processes and in a convenience sample recruited with the help of a company producing collaborative robots. The final sample consisted of 88 employees who are collaborating with robots or are expected to do so in the near future (65% men, with a mean age of 47 years, and 50% secondary education). Descriptive, correlational and moderated mediation analyses were performed by means of the SPSS 28 software package and Hayes process macro.

4. Results obtained or expected (if not available, it must be made clear when they will be)

Our findings indicate that SE policies were positively related to task performance via health and productive capabilities. This indirect effect was moderated by the levels of performance expectancy, effort expectancy, social influence and facilitating conditions, so that it was positive and statistically significant only at low or medium levels of the moderators. Hence, hypotheses 1-3 were confirmed.

5. Limitations

The main limitation to this study is the small sample size. Moreover, only two specific types of SE capabilities have been considered.

6. Conclusions – research and or practical implications/Originality/Value

SE policies contribute to employee health and productive capabilities, and in turn to workers' task performance. The contribution and recognition of employee capabilities is fundamental when employee acceptance levels of cobots are not high yet.

7. Relevance to the Congress Theme

This paper fits the Congress theme by addressing the broader question 'What makes work sustainable in a changing world of work?'

8. Relevant UN SDGs

The present study aims at answering the call for a decent work for all (SDG number 8).

Keywords: sustainable employability, technology acceptance, task performance

Oral presentation OP285

SUSTAINED AND INCLUSIVE INSTITUTIONS FOR ALL: NEURODIVERSITY-FRIENDLY WORK DESIGN.

Joanna Szulc & Michał Tomczak | Gdansk University of Technology

science&practice

Research goals and relevance

Against the backdrop of calls for more theoretical and empirical research on the inclusion of neurodivergent individuals into employment in general and more specifically in non-standard ways of working, we explore the characteristics of the inclusive neurodiversity-friendly job design in the smart-work context (i.e., flexible work arrangement where employees can work outside their office and with a flexible time schedule). Understanding this appears vital since the vast majority of smart, remote, or even traditional workplaces are designed for neurotypicals. Given that approximately one in seven employees is neurodivergent, it appears paradoxical that the neurominority community has been hitherto silenced by job design theorists.

Theoretical background

We apply the job-demands-control-support model of job design as a theoretical lens to see a) what constitutes demands for neurodivergent employees in the smart-work context, b) what particular support is valued by this community, and c) what the perceived impact of the demands, support and control of one's work is on neurodivergents' well-being. We subsequently arrive at a revised version of the theoretical model which captures the unique needs of the neurodivergent community.

Design

This rich qualitative study consists of two phases. First, twenty semi-structured interviews with individuals with personal experience or professional input into the support of neurodivergent employees were conducted. The interviews were followed up with two focus groups. Each focus group consisted of five individuals studying towards the Postgraduate Diploma in 'Neurodiversity at Work' program and had varying levels of neurodivergence experience (the sample included, inter alia, high-rank managers responsible for international neurodivergence programs, neurodivergent employees and entrepreneurs, and neurodiversity champions). The goal of the focus groups was to complement the findings from the study's first phase in more interactive settings allowing for dynamic conversations.

Results

We found that the job experience of neurodivergent individuals is influenced by unique resources and demands. These are often overlooked in traditional job design theories due to their predominant focus on the neurotypical population. Our findings further delineate a number of support mechanisms that could be used in the smart-work context not only to mitigate the negative effects of demands placed on individual employees but also to foster better performance and well-being. Through a theoretically informed discussion of effective smart work design with neurominorities in mind, we offer a conceptual neuro-inclusive smart work model of job design to assist organizations in creating an inclusive remote work environment where both neurominorities and neurotypicals can equally contribute to organizational success.

Limitations

The reported research recruited a small number of participants (n=30). Even though it was inclusive of different neurominorities, it is important not to generalize the reported findings. The suggestions presented in the emerged conceptual model should be now tested further to evaluate the effectiveness of the suggested adjustments, potentially through advanced statistical methods or experimental design.

Conclusions

We answer recent calls for mainstream management research to stop treating employees as an undifferentiated mass and offer novel insights into well-established research on demand-control-support model. By capturing the unique needs of specific groups of employees and in the novel context of smart work, we show that job design can be a potential source of competitive advantage as long as management does not use simplified work as the default approach to designing jobs. Our revised theoretical model of neuro-inclusive job design should enable greater precision in describing existing institutional arrangements, as well as serve as a prerequisite for a fuller debate about the desired nature of inclusive smart-work job design for researchers and practitioners alike. The innovative way of looking at job design we offer is likely to change the way in which it is currently investigated and provide important directions for future research.

Relevance to the Congress Theme

This year's congress theme implies that the world of work is changing and although the idea of neurodiversity has been building since the '90s, it only recently started to shake the foundations of the world of work. The many neurodiversity-friendly initiatives we observed are often described as a real step change that we are all delighted to see happen. However, the onus now lies on the researchers and practitioners to make it branch out into systemic inclusion.

UN SDGs

Our research contributes to the promotion of inclusive employment and decent work by reducing inequalities (see: Goals 8 & 16).

Keywords: neurodiversity, inclusion, job-demands-control-support model

Oral presentation OP750

Talent individual donate their knowledge and are still innovative

Sabina Bogilović & Tatjana Kozjek | University of Ljubljana Faculty of Public Administration

science&practice

Research goals and why the work was worth doing: The purpose of this paper is to extend the current discussion on the drivers of innovative work behavior by examining how awareness of talent status and knowledge donation affect IWB. First, our research contributes to the creativity literature by examining how knowledge donation stimulates the innovation process, answering Anderson et al.'s (2014) call for more in-depth research on knowledge and innovation. Second, we provide evidence that awareness of talent status is related to knowledge donations and innovative work behaviors, thus contributing to the talent management literature by responding to McDonnell, Collings, Mellahi & Schuler's (2017) call for a clear understanding of how talent contributes to organizational performance.

Theoretical background: The ability of employees to continuously innovate is more critical than ever for organizations due to fierce competition in global markets (Anderson et al., 2014; West, 2002; De Jong and Den Hartog, 2010). The social exchange between colleagues is a valuable source of innovative work behavior, while knowledge sharing increases creative problem-solving capacity (Carmeli, Gelbard, Reiter-Palmon, 2013), making diverse knowledge that exists within individuals (Pelled, Eisenhardt, Xin, 1999; Williams & O'Reilly, 1998) a valuable source of innovative work behavior. However, whether individuals share their knowledge with colleagues is not so straightforward (Gilson & Shalley, 2004). Therefore, managers need to encourage innovative work behavior among their employees by stimulating knowledge donation from employees that trigger novel and radical innovations. Based on psychological contract theory and social categorization theory, we hypothesize that employees who are aware of their talent status in the organization will be more likely to engage in knowledge donation because of the psychological contract (e.g., the mutual perceptions and informal commitments between an employer and an employee). We argue that individual talent identification is perceived as a signal „that the employer has fulfilled its contract by choosing to invest in the employee's future career" (Björkman et al., 2013, p.197) and now it is the employee's turn to behave in a way that fulfills the organization's goals and interests (Allen & Meyer, 1990; Lee, Liu, Rousseau, Hui, & Chen, 2011; Wiener, 1982). Thus, we expect that individuals who perceive that they have been identified as talent are more likely to engage in knowledge donation to stimulate innovative work behaviors than those who perceive that they have not been identified.

Design/Methodology: We conducted a field study with professionals in public administration (n=383) and followed standard procedures to examine mediation model using a bootstrap approach (Preacher and Hayes, 2004). To test our hypotheses, we first examined the relationship between talent awareness status and innovative work behaviors (H1) mediated by the use of knowledge donation (H2) by conducting mediation in PROCESS.Results The result showed that talent status awareness was positively related to innovative work behavior. Moreover, mediation model 4 in PROCESS macro showed that knowledge donation mediates the positive relationship between talent status awareness and innovative work behavior, thus supporting hypothesis 2.

Limitations: Our dataset is based on cross-sectional, self-reported data gathering, and although all variables can only be assessed via self-perception, causal relationships could be reversed. Future laboratory or field experiments or three-wave longitudinal studies could address these concerns and

provide clearer evidence for the proposed causal relationships. Another limitation of our research is that we examined the effects of knowledge on innovative work behaviors rather than the different stages of innovation. Although knowledge donation and talent status awareness are critical to innovative work behavior, it would also be beneficial to provide empirical evidence on how the variables used are related to the different stages of the innovation process (idea generation, idea championing, and idea implementation).

Research/Practical Implications: From a managerial perspective, we provide evidence that talent status awareness is essential for innovative work behavior and knowledge donation. Therefore, managers should keep in mind that recognizing talented employees is key to increasing the quality of social exchanges among all colleagues, which can lead to higher innovative performance of the entire organization.

Originality/Value: This study is the first of its kind to empirically examine whether employees with talent status are also more innovative in their work, based on psychological contract theory. In addition, this paper provides evidence that talented employees are more likely to donate knowledge, which in turn increases their own innovative work behavior.

Keywords: Talent status awareness, Innovative work behavior, Knowledge donating

Oral presentation OP504

Teacher Self-Efficacy and Job Satisfaction: A Four-Wave Random-Intercept Cross-Lagged Analysis

Maja Parmac Kovacic, University of Zagreb; Zvjezdan Penezic, Kresimir Jaksic & Irena Buric | University of Zadar

science

Research goals and why the work was worth doing

Although longitudinal associations between self-efficacy and professional wellbeing indicators have been investigated previously, studies that separate stable individual differences in these constructs from changes that occur within individuals over time are still scarce. Therefore, in the present research, we tested the random-intercept cross lagged panel model (RI-CLPM) and investigated the relationship between teacher self-efficacy and job satisfaction at between-person level (by examining whether teachers with higher levels of self-efficacy are in general more satisfied with their job) and within-person level (by examining whether teachers who report higher than typical levels of self-efficacy are also satisfied with their job more than expected at a single time point and across time points). In addition, since teacher self-efficacy is multi-faceted construct (i.e., efficacy for student engagement, efficacy for instructional strategies, and efficacy for classroom management), we tested these relationships for each dimension of teacher self-efficacy separately to examine its possible differentiated effects.

Theoretical background

The shortage of teachers is a problem faced by many countries around the world. Research shows that attrition rates for teachers in the first five years in the profession are as high as 50% (Buchanan et al., 2013; Lindqvist et al., 2014). Strategies aimed at reducing teacher attrition are largely focused at increasing job satisfaction, considering its established relation with the decision to leave the profession (Klassen & Chiu, 2011; Kelly et al., 2019). Teachers' self-efficacy is considered to be one of the most important factors affecting teachers' job satisfaction - teachers with low levels of self-efficacy tend to be dissatisfied with their jobs, which increases the likelihood of leaving the teaching profession (Evans, 2001; Ingersoll, 2001).

Design/Methodology/Approach/Intervention

In total, 1141 teachers (881 females) with an average teaching experience of 15.88 years (SD = 9.13), employed in 73 secondary schools in Croatia, participated in a longitudinal study with a full panel design. Teachers filled out an online questionnaire four times within a school year with a time lag of 2.5 months. Participation in the study was voluntary and anonymous and responses of teachers from different time points were matched based on specially created self-generated codes. To account for nestedness of teachers within schools and possible bias in estimates of standard errors, the RI-CLPM was tested with the TYPE IS COMPLEX option in Mplus.

Results obtained

The results showed that stable parts of all three dimensions of teacher self-efficacy and job satisfaction were positively correlated implying that teachers with higher levels of efficacy for student engagement, instructional strategies, and classroom management also tend to be more satisfied with their job. Regarding the time-specific associations, we found that teachers with higher than expected levels of self-efficacy at a given time point, also reported higher than expected levels of job satisfaction. Finally, we established longitudinal spill-over effects from efficacy for student

engagement and instructional strategies to job satisfaction, showing that teachers with higher than usual levels of self-efficacy at one time point are also more satisfied with their job at subsequent measurement occasion. However, no such effects were found for efficacy for classroom management. In addition, longitudinal effects from job satisfaction to self-efficacy were not established. Our results point to the importance of examining different aspects of teacher self-efficacy separately and highlight the causal predominance of self-efficacy construct over job satisfaction while exploring its dynamic relationship.

Limitations

Common method bias may have occurred given that self-efficacy and job satisfaction were both measured using self-ratings. Also, although large, a convenience sample of participants was used.

Conclusions – research and or practical implications/Originality/Value

Given that higher levels of teacher self-efficacy are related to higher level of job satisfaction, it is necessary to develop and implement different methods and strategies to increase self-efficacy among teachers.

Relevance to the Congress Theme

As the world of work changes, so does the teaching profession. Changes in the teaching profession result in lower job satisfaction and leaving the profession, which is a problem that many countries around the world are facing.

Relevant UN SDGs

UN SDGs relevant to this paper are Good health and well-being, Quality education and Decent work and economic growth.

Keywords: self-efficacy, job satisfaction, teachers

Oral presentation OP104

Team Members Familiarity, Leadership Behaviours, and Psychological Safety as Predictors of Conflicts in Virtual Teams: A Multilevel Pilot Study

Pawel Jurek & Eva Eldridge | University of Gdansk

science&practice

Research aims and why the work was worth doing

Our aim was to identify the relationships between leadership styles, psychological safety and familiarity with conflict (task, relational, process, and status) in VTs. When communication is constrained by technology, psychological safety challenged by lack of familiarity, geographical dispersion highlights the separateness and detachment, what happens to the perception of conflict? The aim for this study was three-fold :

1) To test how a virtual team of members with no previous history of professional or personal familiarity perceives 4 different types of intrateam conflict. We expected that familiarity (IV) is negatively related to conflict perception (DV) H1

2) To test if members' familiarity can moderate leadership behaviours (IV) in relation to members' conflict perception in 4 types of conflict. We expected that familiarity (M) buffers the negative effect of poor leadership behaviors (IV) on conflict perceptions (DV) H2

3) To test the relationship between teams' levels of psychological safety with perception of 4 types of conflict. We expected negative correlation between psychological safety (IV) and conf. perception (DV) H3

Theoretical background

We base our research on Behavioural Complexity in Leadership theory, which states that leaders' effectiveness manifests itself in a diverse set of behaviors in response to complex circumstances. In their interactions leaders impact certain dimensions of influence in order to prevent conflicts in VTs.

The familiarity construct consists of professional familiarity and personal familiarity. When team members do not know each other in person are their relationships solid enough to mitigate conflict in VTs?

Team psychological safety is a shared belief that team space is safe enough to take interpersonal risks. Psychological safety facilitates learning, info sharing, creativity and innovation.

Design and Methodology

Data were collected from 99 employees nested in 20 virtual teams with team size varying from 3 to 12 members (M = 4.95, SD = 2.18). The variables were assessed using Professional and Personal Familiarity Measure in VTs , Leadership Behav. Scale , Psych. Safety Scale , and Intragroup Conflict Scale . All the aforementioned variables were grand-mean centered so that when they predict the random slopes in the model. The hypotheses were tested using multilevel regression analysis with team membership as a grouping variable. The R environment with the corresponding packages was used for all the calculations.

Results

Surprisingly, the analyses revealed no significant relation between team members familiarity and perceived relationship, process, and status conflict in VTs. Significant individual-level effect was observed only for task conflict, suggesting that the better team members' professional familiarity, the less task conflict they reported. However, results revealed interaction effects of professional familiarity and individually experienced leadership behaviours on relationship, process, and status team conflict. In all three types of conflict, the negative relationship between leadership behaviours and the perceived severity of conflict in the virtual team was stronger when employees reported higher team members professional familiarity.

Limitations

While there are a multitude of factors that mitigate or aggravate VTs conflict we only focused on 3 areas. Another limitation is that the study provides a static view of team conflict.

Conclusions: Research/Practical Implications

Since we focus on conflict antecedents, team leaders and managers can utilise our findings to minimize destructive effects of team conflicts and maximize teams' viability. We believe that teams which can early detect and manage factors that predict conflict before it is too late, have much better chance not only to survive but thrive in modern ever-changing organisational environment.

Originality/Value

We extend the intrateam conflict literature by examining the effects of leadership behaviours on VTs conflict as moderated by familiarity and psychological safety. Our research focuses on the antecedents of conflict instead of its effects and does it on a cross-level analysis.

Relevance to the Congress Theme

In-depth understanding of virtual teams is not a concept we may wait to discover in the future. In this particular area of organisational life, the future really "is now".

Relevant UN SDGs

Our research is in line with the 8 th goal of the Sustainable Development Goals of the UN related to promoting productive employment and decent work for all.

Intended audience: Academic, Practitioner

Keywords: virtual team conflict, team familiarity, virtual team psychological safety

Oral presentation OP65

Teams' media capabilities repertoires: Presenting a new construct and instrument

Ignacio Perez Sepulveda, Carolyn Axtell & Jeremy Dawson | Sheffield University

science

Teams' media capabilities repertoires: Presenting a new construct and instrument

Research goals: Due to the COVID-19 pandemic, team members are increasingly using information and communication technologies (ICTs) to interact with each other while working remotely . The term team virtuality has been coined to refer to this phenomenon (Raghuram et al, 2019). However, our understanding of 'virtuality' still needs further work. Specifically, a limitation is that this research has largely assumed an antagonistic view of face-to-face (FtF) versus ICT-mediated interactions. This view neglects the fact that different ICTs present vastly different physical attributes or capabilities (e.g., text-based emails vs. audio-based phone calls), and that some ICTs can offer similar capabilities to FtF interactions (e.g., video calls). Examining these capabilities can offer a nuanced understanding of virtuality and help explaining some of the mixed results in the area (Gibson et al., 2014). Unfortunately, to date, there is a lack of theories addressing how team members use media's capabilities and a lack of instruments to measure them. Accordingly, this study's goals are to present (1) a new construct focused on the use of media capabilities within teams, and (2) the development and validation of an instrument to measure it.

Theoretical background: Media Synchronicity Theory (MST; Dennis et al., 2008) is one of the most recent developments that have systematised the capabilities of media, both ICTs and FtF. MST proposes that media can offer five different capabilities: (1) transmission velocity, (2) parallelism, (3) symbol sets, (4) rehearsability, and (5) reprocessability. However, some authors have questioned deterministic views in which technologies (and media) are argued to have intrinsic structures that shape human actions and interactions without considering the role of people's agency. Technology-in-Practice perspective (Orlikowski, 2000) argues that we must think about structures as emergent from people's use of technology (i.e., enactment) instead of them being embodied into technology. This theory proposes that this enactment emerges from the material properties (e.g., capabilities), but also the context (e.g., norms and protocols) and personal attributes of users (e.g., beliefs, experiences, and knowledge) to articulate a particular situated use of technology. The idea of enactment emphasises that people can use technologies as they were designed, but they can also use them in creative and innovative ways. Considering this, we propose the new construct of teams' media capabilities repertoires as the examination of how team members enact a particular use of the capabilities of the media that they have at their disposal to interact with each other. This construct differs from MST as it focuses on how the capabilities are actually used to support team members' interactions.

Methodology: An instrument to measure teams' media capabilities repertoires was developed and validated following a five-step approach. First, we generated a set of 50 items to measure the use of the five capabilities of MST within teams. Second, six experts reviewed these items to assess their content validity (relevance and clarity). After this, we reduced the initial set to 38 items. Third, we gathered a sample of 95 team members (non-experts) to assess the items' definitional correspondence and distinctiveness (Colquitt et al., 2019). Fourth, we gathered a sample of 301 workers to assess the internal structure validity of the scales at the individual level. Finally, we are collecting a sample of 100 teams to assess the team level internal structure and predictive validity of the instrument.

Results obtained: The experts and non-experts' revisions supported the content validity of the instrument. The subscales' reliability – transmission velocity (α = .89), parallelism (α = .85), natural symbols (α = .81), digital symbols (α = .72), rehearsability (α = .87), reprocessability (α = .84) – and confirmatory factor analysis – χ^2 (233) = 355.42, $p < .01$; CFI = .96; TLI = .95; RMSEA = .04 [.03, .05]; SRMR = .06; factor correlations ranging from .02 to .46 – supported the individual level internal structure validity. The team level internal structure and predictive validity results are pending but will be available for the Conference in May 2023.

Limitations: Due to the cross-sectional nature of the samples, concerns regarding the temporal stability and predictive validity of the scales are raised.

Conclusions: This study expands our understanding of team virtuality by (1) presenting the construct of teams' repertoires of media capabilities which offers a more nuanced understanding of the use of different media within teams, and (2) a scale to measure it.

Relevance to the Congress Theme : This study concerns a relevant topic to understand work team dynamics as after the COVID-19 pandemic team members rely more than ever on ICTs to communicate with each other.

Keywords: team virtuality, information and communication technologies, media capabilities

Oral presentation OP557

Telepresence robot to promote communication between residents and relatives in a nursing home

Hartmut Schulze, Michelle Rüegg & Andreas Urech | University of Applied Sciences and Arts Nothwestern Switzerland

science&practice

1. Research Goals and Theoretical Background

Sufficient contact with family and acquaintances is important for the well-being of older persons in nursing homes (Niemelä et al., 2019). Opportunities to maintain contacts can be expanded through the use of digital systems. Telepresence robots offer a new additional option. A telepresence robot is a freestanding system on wheels that has a camera, speaker, microphone, and LCD screen and can be remotely navigated in a remote environment while providing two-way video and audio transmission. However, widespread use of telepresence robots in old-age and nursing institutions has not yet been established in Switzerland (Seifert & Ackermann, 2020). The introduction of new technologies is hindered e.g. by high acquisition costs or a lack of digital skills. Consequently, there are still only a few practical examples of the use of telepresence robots in nursing institutions for elderly.

2. Method

In the context of the study presented, findings were obtained on the basis of a scientifically accompanied pilot deployment of a telepresence robot in a nursing institution for elderly. For the pilot project, a telepresence robot (model "Beam" from the company GoBe Robots www.gobe-robots.com) was deployed. During the pilot, the telepresence robot could be used by residents and relatives for communication. The company raumCode (www.raumcode.ch) provided the telepresence robot and took responsibility for the technical implementation and support during the pilot. A total of 30 calls were made during the test phase, which lasted approximately 20 minutes on average (M = 19.36min, SD = 9.45min). For evaluation purposes eight semi-structured interviews were conducted, three with residents, three with the respective relatives and two with the home's management and nursing staff. The interviews were conducted by telephone, Zoom or via GoBe "Beam" and recorded. For the analysis of the interviews, the content-structuring qualitative content analysis was chosen.

3. Results

The results show that the use of GoBe "Beam" in the care institution led to a better conversation experience between the relatives and residents and could contribute to a positive mood. Calls that took place via GoBe "Beam" could not replace real contact, but they made relatives and residents feel closer to each other and conversations were experienced as more personal than on the phone. Relatives pointed out that the attention and participation of the residents was higher during the conversation via GoBe "Beam" and the interactions lasted longer than on the phone. Furthermore, the use of a telepresence robot in the care institution did not result in any great additional effort for the administration or for the nursing staff. The demands on the technical know-how of the staff were also low. During the test phase, relatives and residents appreciated the possibility to use the telepresence robot spontaneously. It is important that the relatives are motivated to use GoBe "Beam", as it is they who initiate the contact.

4. Conclusion and Limitations

The pilot study showed that the use of telepresence robots in the context of nursing homes for communication between residents and their relatives is promising. For a long-term use, however, further uncertainties have to be clarified. For example, the question arises which further use cases would be useful, and from this it should be further derived which additional functionalities a telepresence robot should offer. However, the number of users was low during the test run. The competence requirement for the use of the telepresence robot lies in particular on the side of the relatives. They need basic skills in the use of IT tools. For example, software must be downloaded. Furthermore, it should be investigated how the telepresence robot can be integrated into the physical as well as organisational environment without any problems. This includes, for example, dealing with lifts, doors and policies.

5. Relevance to congress theme and relevant UN SDGs

In the study, the UN SDG Goals 9 “Industry, Innovation and Infrastructure” and 16 “peace, justice and strong institutions” are addressed. Developing and introducing useful social robots offers perspecitves for technological as well as market gains. Furthermore, the realization of the potential of such robots depends on the responsible participation of users, technology companies, and the political and social spheres. As well, the topic matches to the EAWOP Topic Area 19) Work patterns and conditions as well as to 16) Technology (Human-Robot-Interaction).

Oral presentation OP388

Temporal Understanding of Meaningfulness: A Cross-Discipline Structured Literature Review and Topic Analysis

Tahereh Maghsoudi & Yih-Teen Lee | Department Managing People in Organizations, IESE Business School, University of Navarra, Barcelona, Spain

science&practice

The concept of work meaningfulness, defined as the perception or experience that one's work is positive and significant (Pratt and Ashforth 2003), has gained traction in both academic (Rosso et al. 2010) and public discourses. Work meaningfulness is associated with positive outcomes for both individuals and organizations, including increased levels of well-being, talent retention, and goal accomplishment (Allan et al. 2019; Rosso et al. 2010). Given these positive outcomes, it is worrying that an increasing number of employees experience low meaningfulness, and that the literature to date cannot yet answer questions as to the temporal dynamics of how meaningfulness may develop, stabilize, decrease, be restored etc.

Researchers have conceptualized meaningfulness as a relatively stable experience, as well as an in-the moment experience with possibly daily fluctuations, and highlighted the role of temporal cognitions in the meaningfulness process (Tommasi et al. 2020). Yet, knowledge on the temporal nature of meaningfulness is limited, in part because discussions take place within disciplinary boundaries in the fields of (cognitive) psychology, organizational behavior, management, sociology, ethics, etc. To address this research gap, we review the literature on temporal aspects of work meaningfulness from various research disciplines to: 1) identify key topics of interest and current trends, 2) achieve an overview of what is known, and unknown, in different fields, and 3) discuss the future of this nascent field of inquiry.

To address these objectives, we combine a structured literature review with citation analysis, a topic modelling approach based on machine learning technique (Blei 2012), and a manual review of articles. The corpus comprised articles indexed in Scopus and Web of Science (WoS). The initial search yielded 30,442 documents, which we will further analyze through an iterative process based on inclusion and exclusion criteria to achieve a final sample.

Initial results indicate a growing interest in the temporal understanding of meaningfulness, highlighting the significance of a review to integrate findings from diverse research fields. In general, researchers in the fields of sociology, organizational behavior, and business ethics have generally focused on work meaningfulness as a steady mindset, while scholars in psychology have also established an episodic/fluctuating conceptualization (Tommasi et al. 2020). More detailed analyses through a topic modeling procedure will further examine latent topics and patterns in published documents and map the distribution of topics over time.

A structured literature research using machine learning technique has the advantage over a traditional literature research that it can cover a wider scope of articles, and automatically detect latent and underlying patterns that are not visible when scanning these articles manually (Hannigan et al. 2019). Similar approaches in related fields (e.g., digital technologies, blockchain) have demonstrated that a structured literature review is beneficial when the field of research is broad and unstructured. These conditions are particularly applicable to the field of work meaningfulness and we envision the results of our work to contribute to the development of the field by integrating the knowledge from different disciplines and outlining opportunities for future research. Ultimately, we hope that increased insights into the temporal nature of work meaningfulness can help the

generation, maintenance, and restoration of work meaningfulness among people in society at large, so as to facilitate general well-being and mental health.

Oral presentation OP626

Testing the effects of an intervention aimed to increase civility in Swedish workplaces

Kristoffer Holm, Josefin Björk, Sandra Jönsson & Rebecka Cowen Forssell | Centre for Work Life and Evaluation Studies, Malmö University

science&practice

Research goals and why the work was worth doing

Over the past two decades, research has demonstrated that workplace incivility is a ubiquitous work environment issue, which can have deleterious consequences for both individuals and organizations (Schilpzand et al., 2016; Cortina et al., 2017). Workplace incivility refers to low-intensity rude behavior in the workplace (Andersson & Pearson, 1999). The effects of incivility can be far-reaching, as it may spread in the workplace (Foulk et al., 2016; Holm et al., 2021).

One promising avenue to address incivility has been the use of civility interventions. Actively promoting civility in the workplace may reduce the risk for incivility, and increase civility and respect (Leiter et al., 2011; 2012). However, recent research has shown less consistent results of civility interventions when applied in other cultural contexts than North America (e.g., Sawada et al., 2021), or in other workplaces than hospitals (e.g., Grantham, 2019). More information is therefore needed on the effects of implementing civility interventions in the workplace, particularly exploring mechanisms and moderators in the intervention process. The aim of the present study is to test the effects of an intervention aimed to increase civility in Swedish workplaces.

Theoretical background

The present study is based on the principles developed in the Civility, Respect and Engagement in the Workplace (CREW) intervention (Osatuke et al., 2013). CREW was developed by the United States Department of Veteran Affairs in 2005. CREW was a culture-based workplace intervention promoting civility in the workplace in the departments' VA-hospitals, with documented successful outcomes (Osatuke et al., 2009). Two research studies tested the effect of the CREW intervention in hospitals in North America, showing both short- and long-term effects of the intervention on workplace behavior, attitudes, and absence (Leiter et al., 2011; 2012). However, little is still known about how civility interventions operate in other contexts than hospitals, and which mechanisms or boundary conditions that influence the impact of civility interventions.

Design/Methodology/Approach/Intervention

The present study has a quasi-experimental waitlist-control design. Participating workplaces are assigned to one of two conditions, an intervention condition or waitlist. The intervention group participates in a series of monthly workshops during the period of September 2022 – January 2023. The workshops address topics such as workplace culture, with the aim to promote workplace civility and reduce the risk of workplace incivility. The waitlist serves as the control group. Pre- and post-surveys are conducted to investigate possible effects of the intervention on measures of workplace (in)civility, norms for civility, social work environment factors, as well as work-related well-being.

Results (expected)

Baseline survey data have currently been gathered from about 200 individuals across 13 workplaces in a Swedish municipality. The intervention group is currently undergoing the workshop series. The follow up post-survey is planned for January of 2023. When post-measures have been completed,

possible change in measures of workplace civility, norms for civility, and workplace incivility will be explored. Change in social work environment factors, as well as work-related well-being, will also be explored. The intervention is expected to result in increased civility and norms for civility, as well as reduced incivility over time.

Limitations

Workplaces were not assigned to the intervention or control condition via cluster randomization. Instead, it was based on practical aspects such as feasibility and scheduling in the participating organizations. Moreover, the follow-up measure is carried out only a few weeks after completion of the final workshop. Possible effects on behavior or well-being may take longer time to develop. Lastly, the measures are self-reported by participants.

Conclusions – research and or practical implications/Originality/Value

Results from the post-measure surveys will be presented at the congress. The originality of the project lies in exploring the effects of an updated version of a civility intervention, in a context outside of hospital settings in North America. The study will also provide information about potential mechanisms and moderators involved in the intervention process. Practically, the knowledge that results from the study could be of use in future attempts to improve the social work environment in workplaces by working with the workplace culture.

Relevance to the Congress Theme

The study is relevant to several of the congress themes, e.g. 6. Group dynamics, 8. Organizational design and development, 15. Stress and dysfunction, and 18. Well-being.

Relevant UN SDGs

Goal 3. Good health and well-being

Goal 8. Decent work and economic growth

Keywords: workplace civility, workplace incivility, intervention

Oral presentation OP317

The activities system of unemployed persons: regulations and deregulations

Ingrid Plivard, Université catholique de l'Ouest

science&practice

In response to the questions raised by the relationship between life at work and life outside of work, the theoretical model of the activity system has been developed in France by Curie & Hajjar. It makes it possible to account for the way in which the individual signifies, objectifies his activities. The system is made up of three subsystems (family; personal and social; professional) which are both autonomous (own goals) and interdependent (exchanges between the subsystems). The regulation between these three subsystems is determined by an interweaving of external and internal elements, which we mean to broach through the activity system inventory.

The activity system inventory (ISA) is a French questionnaire developed by Curie & Hajjar. Within the framework of an action-research with the French work support place, Pôle Emploi (equivalent of jobcentre in the UK or employment agency), the aim of our research is to standardise a version of the ISA adapted to jobseekers in order to understand deregulations and regulations during unemployment. This version of the ISA is based on previous qualitative research with 14 unemployed people (Cimier, 2021). The French employment agency is regionalized. Nine out of the thirteen French region are participating in this study. A total of 158 occupational psychologist from those agencies administered at least 2 questionnaires. Those occupational psychologists assist unemployed people to help them to elaborate a reflection related to their future. Their target population, which is also ours, is long term unemployed people. We collected more than 350 questionnaires through the psychologist cooperation.

In our paper we will present the tool which is composed of three exercises. The first exercise deals with the action model made up of the individual's priority objectives in the different spheres of life. The second exercise allows us to determine the model of life made up of what the individual values most in the different spheres. Finally, the third exercise concerns the activities carried out, suspended, and thwarted, which testify to the activation and inhibition of the overall system. In order to refine the variables of aspirations (exercise 1) and valuations by spheres of life (exercise 2) to formalise this activity system inventory for unemployed people, we use three scales with proven psychometric qualities: the General Health Questionnaire (Goldberg & Hiller, 1979); the Meaning at Work (Arnoux-Nicolas, Sovet, Lhotellier & Bernaud, 2016) and the Locus of Control (Rotter, 1954). The final tool will be made available to occupational psychologists at the Pôle Emploi for coaching purposes. The first results show that imbalances in the life model and the action model lead to a loss of meaning at work and a feeling of poor perceived health. They show that these imbalances are not systematically sources of pathologies of the global system, but can be a sign of future development of activities. We will also present the final developments of our tool.

Keywords: unemployement - activities system

Oral presentation OP95

The association between collective orientation and team flow: the mediation effect of teamwork-related stressors and resources

Vera Hagemann, University of Bremen, Business Psychology; Corinna Peifer, University of Lübeck, Research Group Work and Health; Maik Holtz, Cologne Professional Fire Department, Institute for Security Science and Rescue Technology; Lena Heinemann, University of Bremen, Business Psychology

science&practice

Research Goals

Flow is often experienced under stress-related conditions and associated with improved performance and well-being (Rijavec et al., 2017). Moreover, there is first evidence that flow on the team level is also associated with better performance outcomes (van den Hout et al., 2019). This could be important especially in the firefighting context where teamwork is indispensable and bad performance or failure can have severe consequences. Increasing team flow could enhance the performance in these teams. To do so it is necessary to find out which factors influence flow at the team level. Our study explores the associations between team flow, typical teamwork-related stressors, and resources as well as the role of collective orientation.

Theoretical Background

Team flow has been described as a shared experience of flow within a team that occurs while working on interdependent personal tasks (van den Hout et al., 2019). While different workplace stressors and resources demonstrably affect individual flow (cf. Peifer & Wolters, 2021), research about influencing factors considering the team level is scarce and heterogenous. Firefighters work under extremely challenging conditions and rely on functioning teamwork processes, thereby constituting a promising sample for examining team flow and its contributing factors. Our study explores if the experience of typical teamwork-related stressors and resources experienced during firefighting missions influence the frequency of team flow. Moreover, we examine the role of collective orientation. Highly collectively orientated people pay more attention to their team members and show better coordination processes (Driskell et al., 2010; Hagemann, 2017). Therefore, we wanted to know if collective orientation affects the experience of teamflow, teamwork-related stressors and resources.

Methods

An online questionnaire was implemented in Germany which addressed firefighters from different areas. The frequency of experienced teamwork-related stressors (e.g., delayed disclosure of information), and resources (e.g., knowing mission tactics) during firefighting missions were elevated with a recently developed questionnaire based on expert interviews and a document analysis. Team flow was measured with self-constructed items based on the Flow Short Scale (Rheinberg et al., 2003) and the Team-Flow-Monitor (van den Hout et al., 2019). Collective orientation was also measured (Hagemann, 2017) as a potential predictor of team flow and of teamwork-related stressors and resources. The final sample consisted of 317 experienced firefighters.

Results

Multiple regression analyses showed that the more often firefighters experienced stressors of teamwork (e.g., problems regarding leadership or lacking shared mental models) the less often they

experienced team flow. Conversely, the experience of resources of teamwork (e.g., good communication and shared mental models) was associated with more frequent team flow. Collective orientation was positively associated with team flow. This relationship was mediated by frequency of experienced stressors and resources of teamwork. Here, collective orientation was associated with less frequent experience of teamwork stressors and more frequent experience of resources.

Limitations

Data was collected in a cross-sectional design. Therefore, other directions of action cannot be excluded. For example, the frequent experience of teamwork-related stressors could lead to a lower collective orientation as this attitude is amenable to experience and training. Furthermore, a retrospective survey was used, so that biases due to long professional experience may have occurred.

Conclusion

Our study provides empirical evidence that team flow is affected by the experience of stressors and resources of teamwork, suggesting additional conditions and characteristics in team flow compared to individual flow. Conditions of team flow therefore need further investigation in different contexts. Since team competencies can be trained, the study offers concrete approaches for interventions that strengthen teamwork and thus increase team flow. These can be applied not only to firefighters, but also to teams in other professions. Collective orientation is positively associated with team flow. This relationship is mediated by the experience of resources and stressors. Again, this relationship should be addressed in future research with an experimental setting.

Keywords: Collective Orientation, Team Flow, Teamwork Stressors and Resources

Oral presentation OP158

The association between hospital physicians' working hours and on-call work with wellbeing. A cohort study with survey and register linkage

Kati Karhula, Finnish Institute of Occupational Health; Mikko Härmä , Finnish Institute of Occupational Health; Sampsa Puttonen, University of Tampere; Tuula Oksanen, University of Eastern Finland; Jenni Ervasti, Finnish Institute of Occupational Health

science&practice

Research goal

The aim of this study was to investigate the associations between actual working times and on-call work with sickness absence, occupational injuries, and wellbeing among hospital physicians.

Background

Health care services run at all hours. Hospital physicians are required to be on call at the workplace in addition to normal working hours. Earlier survey research has linked physicians' long working hours to many negative outcomes, such as sleep problems, work-life conflict, and needle-stick injuries. To our knowledge, no prior study had used long-term data on physicians' realized working hours to analyze the associations between working hour characteristics and wellbeing.

Methodology

This study included twelve Finnish hospital districts with working hour data from 14 704 hospital physicians (2005–2019) whereof 2 845 physicians (64% women) had a short sickness absence (1–3 days) and 556 physicians (64% women) an occupational injury in the Finnish Workers´ Compensation Center data. These data were analyzed using case-crossover methods with conditional logistic regression analysis with 28-day exposure and control windows for the short sickness absences, and 7-day windows for the occupational injuries. The cross-sectional survey data on sleep, work-life conflict, and work pace in 2015 included 892 physicians (62% women) from three hospital districts in the Finnish Public Sector study. Survey responses were linked with working hours from preceding 91 days and analyzed with multinomial logistic regression analysis adjusted for age, sex, hospital district, marital status, number of children, stressfulness of the life situation and control over working hours.

Results

Frequent (≥5 vs. none) >12h work shifts (OR 2.54, 95% CI 1.68–3.84), frequent >24h continuous work periods (OR 2.62, 95% CI 1.61–4.27), frequent on-call shifts of any length (OR 2.15, 95% CI 1.44–3.21) and frequent short shift intervals (<11h, OR 12.61, 95% CI 8.88–17.90) were all associated with higher odds of short sickness absence.

Having had 3–4 on-call shifts during the preceding 7 days was associated with higher odds of occupational injury (OR 3.54, 95% CI 2.11–5.92) as well as having had 3–4 long (>12h) work shifts (OR 2.14, 95% CI 1.11–4.09) compared to zero such work shifts. An increasing number of several consecutive workdays was associated with higher probability of occupational injury in a dose-response manner, whereas increasing number of ≤12-hour work shifts associated with reduced likelihood of occupational injury (OR 0.79, 95% CI 0.64–0.98).

Frequent night work (>6 shifts/91 days) was associated with short sleep (≤6.5h, OR 1.87 95% CI 1.23–2.83) compared to no night work. Long weekly working hours (>48h/week) were associated with perceived insufficient sleep (OR 1.78 95% CI 1.15–2.76) compared to short weekly (<40h/week)

working hours. Frequent on-call duties (>12 duties/91 days, OR 2.00 95% CI 1.08–3.72), frequent night work (OR 1.60 95% CI 1.09–2.37), and frequent short shift intervals (≤11 hours; >12 times/3 months, OR 1.65 95% CI 1.01–2.69) were all associated with insufficient sleep compared to having not at all the working hour characteristic in question. Frequent night work associated with increased odds for difficulties in initiating sleep (OR 2.43 95% CI 1.04–5.69) but otherwise sleep difficulties were not associated with the studied working hour characteristics.

Although actual working hours of over 40 or over 48 hours on average per week were not associated with work-life conflict, self-evaluated similar average working hours were associated with having work-life conflict (OR 2.46 95% CI 1.60–3.79 and OR 2.90 95% CI 1.92–4.63, respectively). Self-evaluated >48-hour work weeks were also associated with perceived time pressure at work (OR 2.99 95% CI 1.92–4.63).

Limitations

Register data did not include possible working hours outside the studied hospital districts, whereas the self-estimated working hours included all the work done, including, e.g., the private sector. The register data did not allow analysis between different medical specialties. These results are likely generalizable to other EU countries that comply with the EU Working Time Directive, whereas other countries may have different legislation for maximum working hours and minimum rest periods. Survey response was available from less than 40% of the physicians.

Conclusions

To maintain hospital physicians' wellbeing and occupational safety, long work weeks and long work shifts should be avoided, and amount of short shift intervals and night-time on-call shifts should be reasonable.

Keywords: working hours, sickness absence, occupational injury

Oral presentation OP435

The association between well-being, coping strategies, and thoughts about their career among Hungarian employees

Blanka Balogh & Agota Kun | Department of Ergonomics and Psychology, Faculty of Economic and Social Sciences, Budapest University of Technology and Economics, Hungary

science&practice

The aim of the study is to extend knowledge of the well-being and coping strategies of employees in distinct career stages and indicate further applications and how they identify challenging situations at work.

World Health Organization (2018) defined mental health as a state of well-being in which one can discover one's abilities, is able to cope with the normal level of stress, is productive at work, and adds value to their company. Positive psychology is a useful approach when trying to enhance employee well-being, since it helps us to understand better the „dark" and „bright" side of human behavior, emotions, and cognition (Seligman et al., 2005). There are several theories with different aspects and elements. The current study focuses on multidimensional models of well-being, which highlight the importance of career and work-related success (Seligman, 2011; Rath & Harter, 2010; Marsh et al., 2020). Besides the positive effects of increased well-being, also advanced coping strategies result from positive emotions (Fredrickson & Joiner, 2002) and prevent setbacks (Fava & Ruini, 2003). Just like human behavior, neither well-being nor coping with stress and challenging situations are black or white. Researchers claim that employees and their preferences may change as they face different development stages during their career, which suggests developing personalized interventions and programs instead of general ones (Veiga, 1983; Darcy et al., 2012).

Cross-sectional research was conducted to analyze a) the relationship between well-being, experienced career crisis, actual and desired career stage, and coping strategies, b) how well-being explains the variance of an experienced crisis, c) how coping strategies explain the variance of well-being. The study sample included 457 actively working Hungarian employees. Instruments used in the research were Wellbeing Profile (Marsh et al., 2020) (WB-Pro, 15 items), Brief COPE (Carver, 1997) (28 items), and own items regarding participants' thoughts regarding their career.

Results show weak or moderate relations in the case of correlations. However, regression models mean sufficient evidence to highlight the importance of tailored development of coping strategies and well-being factors to enhance the level of well-being and lower experienced career crises. We developed two models to describe the connections between Well-being components and Coping strategies and Experienced crisis and Actual career stage. Structured Equation Modeling confirmed our models and showed very good fit indicators. In conclusion, our findings have further strengthened our conviction that career and work-related experiences play a vital role in employees' well-being which are consistent with the well-being theories of Seligman (2011) and Rath and Harter (2010).

The research has some limitations. We consider cross-sectional research a good choice for this research to explore whether there are any relations between the variables. However, in the future we aim to use longitudinal design to enhance the reliability of our findings and test whether these connections are stable. Furthermore, the reliability of Brief COPE was not as good as we hoped. This also suggests the use of other coping surveys when conducting further research.

These findings may help practitioners to identify challenging situations at work, elaborate customized programs, and apply targeted interventions instead of using general solutions. On the other hand, our observations have several implications for research into the analysis of career-lifespan, challenges at the workplace, and enhancement of workplace well-being.

This study is the first step towards enhancing our understanding of characteristics of well-being and signature coping strategies among employees in Hungary. Although there is room for further research, these suggestions might be helpful for practitioners and organizations when planning career development, well-being programs, or interventions.

Keywords: employee well-being, work stress, coping strategies

Oral presentation OP712

The Benefits and Boundaries of a Remote Positive Self-leadership Intervention

Hannah Moore, University of Amsterdam; Marianne van Woerkom, Arnold Bakker & Heleen van Mierlo | Erasmus University Rotterdam

science

Goals

At the start of the COVID-19 pandemic, non-essential workers were suddenly forced to work from home and integrate their work and home lives in times of great uncertainty. This accelerated switch to teleworking has led to a new standard of work in which online interaction is ever more important. However, simultaneously managing home and work demands can induce burnout symptoms such as exhaustion, especially among women (Meyer et al., 2021). The aim of this study is to test the effectiveness of an online intervention that combines strengths use with self-leadership in reducing burnout symptoms, compared to a control group. Taking a process-oriented approach, this study also aims to examine whether the intervention effects depended on subjective and objective adherence, including days of participation, how well instructions were followed, effort put into the assignments, and post hoc perceptions of the intervention.

Theoretical background

Self-leadership interventions consist of training cognitive and behavioral strategies with which people positively influence themselves to behave and perform towards the outcomes they desire (Unsworth & Mason, 2012). According to positive psychology and strengths use theory, interventions that encourage proactive behaviors by focusing on positive individual traits and valued subjective experiences can increase well-being and prevent ill-being (Bakker & van Woerkom, 2018). With the capacity to identify and use personal strengths, people can visualize a positive vision of themselves and utilize their strengths to achieve goals that are aligned with that vision. In this study, we integrate strategies of self-leadership with personal strengths to develop and test the first online positive self-leadership intervention. We predict that intervention participation will reduce burnout symptoms compared to nonparticipation, and that intervention effectiveness relates to adherence, effort, and interest.

Design

This study consisted of three measurement points (baseline, posttest, and follow-up) and one intervention week. 187 eligible Dutch workers (54% female, 45% male, 1% unspecified; age 19-77, $M = 42.43$, $SD = 14$) completed the baseline survey, after which the sample was randomly split into experimental and control groups. At baseline, all were asked to provide demographics and respond to scales measuring work and wellbeing-related measures about the past week, including information about their current work situation due to the lockdown. In the following five-day workweek, the experimental group received daily assignments containing positive reflections on their work the current day and a positive goal-setting assignment for the next day. After the intervention week and two weeks later, participants were asked to respond to the baseline survey again, including questions about their experiences participating in the intervention.

Results obtained or expected

The analyses are currently ongoing and expected to be finalized in November 2022. Here, we present preliminary results. A 3x2 repeated measures GLM with time (baseline vs. posttest vs. follow-

up) and group (experimental vs. control) as the predictors and gender as a covariate revealed a significant GROUP * TIME interaction on levels of burnout ($F(2,78) = 3.75$, $p = .028$, $\eta 2 = .09$), such that burnout symptoms decreased in the experimental group after the intervention week whereas no change was detected in the control group, as expected. Furthermore, controlling for baseline differences, intervention adherence positively related to degrees of self-leadership skills ($t(48) = 4.05$, $SE = .13$, $p < .001$) and strengths ($t(48) = 3.20$, $b = .25$, $SE = .08$, $p = .002$) used during the intervention week, and the more interest participants had for the intervention, the more they continued to use their self-leadership skills two weeks later ($t(15) = 3.09$, $b = .22$, $SE = .07$, $p = .009$).

Limitations

Limitations include the use of self-reports, which raises the issue of common method variance, and the fact that we were not able to test long-term effects of the intervention.

Conclusions

The emergence of telework has blurred the boundaries between home and work and caused strain for many teleworkers. These findings provide some support that some strain may be mitigated by an online positive self-leadership intervention, which researchers and practitioners can use to study and encourage positive proactive behaviors among teleworkers.

Relevance to the congress theme

In a changing world of work where teleworking is the new standard, it is crucial to find ways to remotely foster employee well-being and prevent ill-being.

Keywords: Strengths use, self-leadership, burnout

Oral presentation OP301

The boon and bane of perfectionism for employees' goal progress and well-being: Psychological capital as a mediator

Emily Kleszewski, Philipps-University of Marburg; Monique Mohr, University of Technology Chemnitz; Kathleen Otto, Philipps-University of Marburg

science

Research goals and why the work was worth doing :

It is unsurprising that perfectionism is on the rise in a world that is increasingly competitive. The workplace is a domain that is particularly affected by perfectionism, given that this context is predestinated for topics such as goal achievement, performance appraisal, and feedback. A recent meta-analysis and review on perfectionism in the workplace highlight the double-edgedness of this multidimensional personality disposition concerning a wide range of organizational variables. Commonly, researchers distinguish perfectionistic strivings, referring to high-performance standards, and perfectionistic concerns, including the fear of negative evaluation and concern over mistakes. Especially perfectionistic concerns may place employees at risk for high stress and impaired well-being. Perfectionistic strivings, on the contrary, are considered less detrimental and are even discussed in terms of adaptiveness. Comparatively little research has focused on the mechanisms that underlie the different associations of perfectionism and organizational outcomes. Knowledge of these mechanisms, however, is important to advance theory on what renders the dimensions of perfectionism adaptive or maladaptive and to support employees in coping with perfectionism in terms of interventions (i.e., coaching). From the perspective of positive psychology, we propose the generation and availability of resources as such a mechanism. In this study, we investigate whether psychological capital mediates theassociations of employees' perfectionism with goal progress and well-being.

Theoretical background:

According to Hobfoll's conservation of resources (COR) theory, individuals aim to build and protect their resources. Resources are valuable because they facilitate meeting demands and achieving goals and protect individuals from losing resources. Based on COR theory, we expect that employees high in perfectionistic strivings but not those high in perfectionistic concerns are able to manage their resources successfully and thus to meet their high work demands and experience well-being. In addition, employees high in perfectionistic concerns can be assumed to have few resources. Thus, they should be vulnerable to resource loss and impaired well-being. In this study, we focus on psychological capital (PC) as a valuable resource for employees.PC, comprising the four cognitive strengths hope, self-efficacy, resilience, and optimism, is a positive developmental state that emphasizes individual's strengths and facilitates personal growth. We propose that perfectionistic strivings will display a positive indirect effect, whereas perfectionistic concerns will show a negative indirect effect on goal progress and well-being (operationalized as job satisfaction and meaning in life) via PC.

Methodology : Three waves of data, each with a time lag of two months, were collected via the German panel provider Respondi. The data collection was part of a larger project on entrepreneurship; all variables were assessed using self-report measures. For the present study, a subset of 264 employed or self-employed participants was analyzed. About half of them was female (43.6%), with a mean age of 45.34, mean weekly working hours of 35.88 and mean tenure of 10.80

years. The mediation model was tested using Mplus and bootstrapping was employed to test the significance of the indirect effects.

Results: The results from path analysis revealed positive indirect effects of perfectionistic strivings (T1) and negative indirect effects of perfectionistic concerns (T1) on goal progress, job satisfaction and meaning (T3) via PC (T2). Autoregressors of the T3 variables as well as positive and negative affect as control variables were included in the model.

Limitations: With its focus on PC, the present study investigates one specific resource. Future research may extend these findings to other resources and examine their relative predictive validity.

Conclusions: Perfectionism can be considered as 'boon and bane'. Our results indicate the dimensions of perfectionism are differently related to PC as a resource which is relevant for goal progress and well-being. Thus, the lack or availability of resources may be one decisive aspect for the adaptiveness or maladaptiveness of perfectionism. Given that PC is a trainable resource, practitioners may support employees high in perfectionistic concerns in building this resource. Further, our results highlight the urge to reduce perfectionistic concerns.

Relevance to the Congress Theme : Work is changing and so are employees: Perfectionism is on the rise among young adults. Consequently, organizations will inevitably face the assets and drawbacks of this disposition and have to consider how to deal with it.

Relevant UN SDGs: Our study aims to identify mechanisms that are decisive for health and well-being of employees, as well as for their productivity (goal progress) and, thus, economic growth.

Keywords: perfectionism, psychological capital, well-being

Oral presentation OP247

The boundaries of agile work: Longitudinal effects of work intensity and agility on sleep and next-day performance

Matej Černe, Miha Škerlavaj, Mojca Marc & Amadeja Lamovšek | School of Economics and Business University of Ljubljana

science

Research goals and why the work was worth doing:

The basic aim of this paper is to rigorously examine how occurrences at work in the agile/innovative setting affect sleep, and vice versa. Length, quality and consistency of sleep represent crucial factors in human energy restoration and subsequently a key predisposition to normal functioning for individuals at work, and away from it. Individuals sleep and work approximately two thirds of our lives, and sleep has important implications for workplace performance, collaboration and general well-being. The '24/7-on' society with a high emphasis on high intensity workload, the need for adaptability and responsiveness to change, and the innovation imperative at workplaces have made these issues even more highlighted. Our lives, and thus sleep patterns, are 'now more complicated than they were', leaving people disrupted and disorientated, with crucial effects on how individuals behave at work. We posed the following research question: What is the relationship between sleep and workplace occurrences (perceptions and performance), and vice versa, in the context of agile work?

Theoretical background:

Recent meta-analyses and systematic review articles on this matter are insightful, however, several crucial shortcomings related to research linking sleep and work are identified:

1) Previous reviews were predominantly based on cross-sectional studies and consequently do not allow for causal inferences.

2) The body of literature focused on the relationship between work and sleep usually focuses on only one aspect of a potentially reciprocal relationship between the two; only examining work as an antecedent of sleep, or vice versa, but not both simultaneously.

3) Methodologically, there is a clear dearth of research on work and sleep association that would be applying objective measures of sleep, especially in a natural sleep environment, and do so in connection with real-life work phenomena.

4) Theoretically/content-wise, while studies have addressed the relationship between sleep and workplace performance and vice versa, there is an important thematic gap in the literature related to assessing workplace performance in the context of agile, creative, innovative knowledge work.

Design/Methodology/Approach/Intervention:

We used objective measures for sleep (via clinically-validated devices, i.e., Dreem bands) in a natural sleep environment, combining them with daily (morning and afternoon) experience-sampling-method(ESM)-based perceptions and participants' experiences in a real-life work setting (14 days and nights per participant). We implemented this research design on a sample of 67 employees that experience agile and innovative ways of working in six service companies based in Slovenia. Data were analyzed with longitudinal (multi-level) modeling using MLmed.

Results obtained or expected:

Preliminary data analyses indicate that work intensity and required agility predict higher levels of strain and stress, and cause lower levels of sleep efficiency, REM and deep sleep. However, we could not found effects on next-day creativity, individual innovation, work focus or work performance. This might indicate that important boundary conditions of the work and sleep relationship unfolding over time in this context might play a role, such as employee personal characteristics (e.g., proactivity, resilience) and job/contextual characteristics (e.g., autonomy, task interdependence, social support, skill variety, psychological safety).

Limitations:

Self-reported and shortened measures in the ESM part of the data collection with daily surveys. Possibility of stronger effects in more extreme cases of agile work.

Conclusions – research and or practical implications:

The main contribution is in treating the relationship between sleep and work in a reciprocal, possibly recursive manner. Using objective measures for sleep, combining them with daily experience-sampling-based perceptions and participants' experiences in a real-life work setting over time, we capture the causality in the basic relationship between sleep and work. Our research addresses the paradox that agile work was set up to foster innovative work and beneficial outcomes, yet previously underexplored adverse effects related to individuals' strain, stress, burnout and negative outcomes. This contributes theoretically and empirically by enhancing our understanding of the true nature of the work-sleep relationship, practically allowing for managers and organisations to the organisational context in a way that improves the potential for high-quality sleep of individuals with different sleep patterns and profiles, maximising their well-being on the one hand, and work outcomes on the other.

Relevance to the Congress Theme:

Our study provides a valuable insight on one’s coping with work demands and well-being in the changing world of work that tends to be increasingly agile and requires creativity and innovation.

Keywords: sleep, agility, performance

Oral presentation OP683

THE BURNOUT EXPERIENCE OF UNIVERSITY TEACHERS

Emilio Sánchez Santa-Bárbara, Elías García García, Antonio Delgado Padial & José María González González | Universidad de Granada

science

Introduction

The job of a university teacher has suffered important changes in the last few decades. Many lecturers have to devote part of their working hours to prepare their classes, to do research in a very competitive way ("publish or perish"), to be in charge of multiple administrative tasks and, in some cases, also to do managerial functions at their department, faculty or university or at their research group.

Traditionally, it was economically recognized profession and had social prestige. It was a healthy job as it was free from both ergonomic and psychosocial risks at work. Recently it has changed to become highly competitive, its social status has diminished and for many lecturers and researchers the working conditions now include precariousness, instability, insecurity, among other psychosocial risks. Those higher demands and lower compensations are responsible for the high levels of stress and burnout.

Burnout can be defined as a state of emotional and physical exhaustion. It can happen when the employee experiences long-term stress in their job or when the job itself is physically or emotionally draining for a long time. Thus, burnout appears as a prolonged response to chronic interpersonal stressors on the job. In our context, university teachers may feel overwhelmed, helpless, cynical about the people they work with or negative about their own achievements. Maslach (1982) defined burnout as a psychological syndrome involving emotional exhaustion, depersonalization, and a diminished sense of personal accomplishment that occurred to professionals who work with other people in challenging situations.

Our aim is to identify the psychosocial factors and other variables to predict the severity of burnout in university teachers and researchers. The theoretical framework consists of "demand-control-social support" (Karasek, Theorell and Johnson, 1990) and the "effort rewards" model (Siegrist, 2002). According to that, the psychosocial risks of university teachers in a University at the south of Spain (University of Granada) have been analyzed. A multiple regression analysis was run to predict the severity of university teachers' burnout.

Method

The questionnaire COPSQ-ISTAS 21 was administered to a convenience sample of 1735 teachers and researchers from the University of Granada (Spain), 769 females and 953 males (13 did not report their sex). 1537 were teachers and researchers, 109 only teachers and 89 only researchers. 275 were up to 31 years old, 471 were between 31 and 45 and 984 were older than 45.

The main psychosocial risks suffered by university teachers in Spain are the insecurity about their working conditions (M=3.731), insecurity about employment (M=3.505), quantitative demands (M=3.378), double presence (M=3.212), role conflict (M=3.158), demands to hide emotions (M=3.083). The rest of the dimensions scored lower than 3 in a 5-points scale.

Mean contrast analyses were run between each of the 15 dimensions of COPSOQ-ISTAS21 and sex, age and type of function, and those statistically significant were included in the multiple regression analysis (stepwise). The result was the burnout was predicted in a 49.6% by a set of variables as double presence, emotional demands, sex (female), age (younger), pace of work, support from superiors, role conflict. Other variables act in a protective way against burnout as group feeling, meaningful work and influence.

Limitations

The number of participants was limited and a convenience sample was used, and it is a cross-sectional study, what reduces the generalizability of these results. In addition, further developments of this research would study the consequences in health and well-being for workers with conventional hours (e.g., weaker decrease in well-being) and workers on rotating shifts (e.g., stronger decrease in well-being), for instance, during the weeks following a vacation time.

Conclusion

Currently, the job itself of a university teacher as it is conceived in most universities reflects a wrong organization that causes burnout in many professionals. Psychosocial factors related to the job itself can be identified. In many cases teachers must cover simultaneous demands from work and family, with a feeling of failure in one or both demands, the need not to express their own opinions at work, the high pace of work because quite often the deadlines are too short or they have to do many different tasks (teaching and research…) at the time. This situation is more severe when there is lack of support from superiors, and when there is a role conflict (how much energy is put either in teaching and research or in their family life) . This burnout experience is worse for females and younger teachers, what reflects a gender issue. On the other side, other factors may protect the teacher from burnout, such as the feeling of belonging to a group, considering that one's work is meaningful and useful and the capacity to make decisions about the content of the job.

Keywords: Burnout, university, psychosocial risks

Oral presentation OP695

The case of the WOP-P mentorship program: an organizational intervention to reduce acculturative stress in international education.

Kristin Wassmuth, Martina Tasca, Natalia Beatriz Silva Morillo, Natasha Sutherland, Mariana Kortišová, Noa Münster | University of Valencia

practice

1. Research goals and why the work was worth doing

In this paper, we analyse the case of the "WOP-P Peer Mentorship Program", a program designed and developed by master students[NMM1] . The program is oriented at providing peer support (practical, social, emotional) and alleviate feelings of acculturative stress and anxiety among international first-year master students. Herein, incoming students ("Mentees") are partnered with a volunteering second-year student ("Mentors") who provide support through regular meetups and social events. The main goal of the program is to provide guidance and support for [NMM2] first-year students from their peers in the second year. Furthermore, mentors can provide tacit academic knowledge and detailed practical advice that allow mentees to develop essential competencies and social skills in their new environment. In fact, peer mentorship programs have been shown to improve student academic performance, which is one of the expected results. [NMM3]

2. Theoretical background

International university students face several personal and social challenges when moving away from their home country. [NMM4] Such transition may be associated with feelings of anxiety, homesickness, or depression, which have been conceptualized as acculturative stress. Ultimately, this may exacerbate the mental and physical health of the students. And indeed, international students seem more vulnerable for negative effects on mental health and wellbeing compared to domestic students. Previous literature suggests that a strong social support system can help to navigate stress associated with such transition. Mentees of the peer mentorship program will have the chance to experience a series of psychosocial benefits through friendships, role modelling, identity development, socialization, and academic advice from their mentors.

3. Design/Methodology/Approach/Intervention

Previously, mentors were trained in mentoring competitions.

A mixed-method approach was used to assess the efficacy of the program. Questionnaires were passed and interviews were conducted with the participating mentees (N= 26) before, during and at the end of the first academic year. Their level of acculturative stress was assessed using the Acculturative Stress Scale for International Students with 36-items. Their perceived social support was assessed using the Index of Sojourner Social Support Scale (ISSS) with 18 items.

Additionally, interviews were conducted go uncover pros and cons of the mentorship program.

4. Results obtained or expected

Although the quantitative data did not show significant differences between the three measurements, the interviews conducted showed a positive assessment of the program and its contribution to the adjustment of the mentored students towards the new international academic environment. In addition, the program contributed to the development of professional competencies

of the mentors. Lastly, the mentorship program helped creating an international social network between 1 st and 2 nd year students, that was beyond the goals of the program.

5. Limitations

In the present study, the Number of participants was limited to the scope of the program. Further, the support for the effectiveness is limited to qualitative data. Future efforts in assessing the program could exploit qualitative data methods (e.g. focus groups) to explore the contributions of the program. Further, a control group would have provided further support for the efficacy but was disregarded out of ethical reasons.

6.Conclusions – research and or practical implications/Originality/Value

The case study shows the potential of support systems (peer mentoring) to improve the well-being of international students; an initiative that was taken by students who changed the narrative from a problem-focused approach towards a positive approach by focusing on the members' potentials. It also contributes to the improvement of mentors' competences and through fostering networking opens the possibility for the construction of a professional support network. Such systems, through accumulating knowledge and ideas, may increasingly adapt to the needs and opportunities of the context and develop continuously. Additionally, peer-to-peer support programs reduce the burden on the coordinative and administrative staff of the master.

7.Relevance to the Congress Theme and Relevant UN SDGs

Well-being & health. The result of this programme can be a valuable case study for providing support to international students/workers that have to face the move between culturally different countries.

Keywords: Peer to peer support, acculturative stress, international students

Oral presentation OP234

The co-construction of transparency and accountability in teams: the mediating use of digital project management tools

Yibin Fabricius Zhang, Aarhus University

science

Research goal

The goal of this study is to examine how transparency and accountability are co-constructed using mediating technologies in the context of project management. It is relevant for understanding the dynamic relationship between transparency and accountability, and how this relationship is shaped by the current virtual work context.

Background

Accountability is a social relation, where one party has the obligation of giving accounts of their conduct to another party that has the power of imposing rewards or sanctions (Bovens, 2007), and as such, accountability is central to project management (Leong, 1991). Burga and Rezania (2017) show that accountability in project management is enacted by dynamic processes involving not only people, but also artifacts (e.g., the building under construction, and digital communication tools) that disclose information about the progress of the project.

In recent years, it has become a common approach for organizations to use digital technologies to disclose information about organizations' inner workings, thereby creating transparency to achieve positive accountability (e.g., Bertot et al., 2012). Some scholars (e.g., Hansen & Flyverbom, 2015) criticize this approach for ignoring the role of technologies in allowing the selection and manipulation of information and shaping the production of transparency. Moreover, Heimstädt and Dobusch (2020) highlight the limitation of using transparency and accountability as analytic concepts with predefined meaning and make a call for empirically examining "what is at stake when people claim and contest transparency and accountability" (p.7).

The use of digital project management tools (DPMTs), such as Jira and Trello, can be seen as examples of transparency-creating initiatives in the context of project management. These tools are developed to display tasks and project status and log every change that has been made. Since both clients and project teams can access DPMTs regardless of their location and time once given permission, DPMTs provide a way for project teams to make their work visible to clients, and for clients to monitor the progress of projects (Vanzin et al., 2006). Because of the centrality of demonstrating accountability in project management (Leong, 1991), the use of DPMTs affords an interesting opportunity to answer the call of Heimstädt and Dobusch (2020) and empirically examine how transparency and accountability are practically co-constructed by the mediating DPMTs.

Methodology

Ethnography is chosen since it provides a situated perspective on practices (Hammersley & Atkinson, 2007; Jarzabkowski et al., 2014), which makes it possible for the researcher to investigate how DPMTs are used to co-construct transparency and accountability, and the related consequences. Specifically, I followed five project teams from a Scandinavian software consultancy company over nine months in 2022 using participant observation and interviews (Spradley, 1979, 2011) and analyzed the data using thematic analysis (Braun & Clarke, 2006).

Preliminary findings

The preliminary findings show that there is a dynamic relationship between accountability, transparency, and digital technologies, which on the one hand allows the construction of transparency and related claims of accountability, while on the other hand ties the project teams and their clients to their past transparency and keeps them continuously and mutually accountable.

Specifically, the accountability demands of clients urge project teams to make their work transparent using DPMTs, which can provide them with a historically documented justification of their conduct of work. Since project teams are themselves responsible for updating their DPMTs, they can to some extent control the produced transparency and related claims of accountability. However, this freedom of co-construction is far from unlimited. Since what is made transparent cannot be quietly changed later due to system logging, the use of DPMTs holds both clients and project teams accountable for their past conduct.

Limitations

This study focused primarily on the perspective of project teams, and how they understand and work with their accountability relationships with their clients. However, this does not necessarily reflect clients' understanding of the same relationship, which could be explored by future studies.

Conclusions

This study demonstrates that transparency and accountability are co-constructed by means of DPMTs. The DPMTs' specific logging holds an important role in structuring this dynamic relationship by settling the possibilities and limitations of the visible and accountable.

Contribution to the congress theme

This study contributes to the congress theme by providing an understanding of how project management has changed with the introduction of new technologies, and the potential consequences involved for transparency and accountability.

Keywords: Computer Supported Cooperative Work, project management, accountability

Oral presentation OP40

The Conceptualization and Development of the Employee Ambassadorship Scale

Marthe Rys, Greet Van Hoye, Eveline Schollaert, Bert Weijters | Ghent University

science&practice

Organizations worldwide are competing to acquire talent, as human capital is the main source of competitive advantage (Pandita & Ray, 2018). Due to shortages in the labour market, acquiring and retaining talent has not been evident. Researchers have proposed employer branding as an efficient strategy to create a sustainable workforce (Alves et al., 2020). This strategy focuses on building an employer image and transfer this image to stakeholders. Employees can play an influential role in this process as they can resonate the employer image to employees and applicants, and become ambassadors (Sengupta et al., 2015).

Despite the influential role of employee ambassadorship for the organization, this concept has received limited attention in research, which is in sharp contrast with the organizational environment. Employee ambassadorship programs are exponentially implemented (Andersson, 2019). However, their policy is not based on research and can hold negative implications for organizations (Gill, 2018). Therefore, to encourage scientific insight in this research field, we aim to create a common understanding of this concept and developing an employee ambassadorship scale.

Based on Hinkin (1995) and Podsakoff et al. (2012), we developed a five-phase methodology. First, we conceptualized employee ambassadorship based on the tripartite model of Hilgard (1980). As such, we constructed a five-dimension model of employee ambassadorship: Employer Brand Knowledge, Employer Brand Relevance, Employer Brand Affective Connection, Employer Brand Consistent Behavior, and Employer Brand Citizenship Behavior. Subsequently, we interviewed 6 actors related to employee ambassadorship and finetuned our theoretical model and definitions based on these interviews. Once we finalized our model, we began to generate items from literature, existing scales, and the interview input. Next, we represented them to the interviewees and ask them to give their opinion.

Afterward, we assessed this model and items in the second phase. To assess the content validity of the items, we conducted an item sorting exercise. To determine the factor structure, an EFA (N = 238) was conducted. Based on eigenvalues > 1 and parallel analysis, a 5-factor solution was suggested. In the third phase, the CFA confirmed the 5-factor structure (N = 257). We also investigated the tendency to respond “socially desirable”. Only the moralistic response scale correlated higher than .20 and a good internal consistency was observed (α >.85; AVE > .55, CR >.80). In the fourth and fifth phase, we will assess construct, nomological, and concurrent validity by collecting a sample of 250 employees. We intend to have these results in December ‘22.

This study has scientific and practical implications. First, we contribute to the literature on employee ambassadorship by providing a conceptualization of employee ambassadorship. Furthermore, a validated measure of employee ambassadorship is constituted, drawing on five dimensions. This will give researchers the opportunity to shed light on this highly relevant but under-researched topic through future studies. Regarding the practical implications, organizations can take interventions to encourage ambassadorship among their employees. By measuring the five dimensions of employee ambassadorship, they can gain insights into how much knowledge, employees have regarding employer brand or how willingly they want to behave like an employee ambassador. As such, HR managers can analyse which of the five dimensions need attention and determine a plan of action.

Lastly, due to the scale, organizations will be more able to recognize employees who want to become an ambassador, which ultimately assists in attracting and retaining talent.

When developing a scale, there are limitations. First, the employee ambassadorship scale has been developed as a self-reported measure, however, by validating this scale with objective measures and control for social desirability, we counter these effects. Secondly, the samples largely included well-educated English-speaking participants, which raises a concern about the generalizability of the scale beyond these occupations. Therefore, the next step could be to validate this scale in more diverse samples and languages.

As there are shortages in the labour market and high turnover, organizations are urged to adopt strategies to attract and retain employees. As a result, organizations are encouraging employees to promote the employer image to stakeholders, which assists in attracting applicants and fosters economic growth and success. However, organizations are not supporting their policy on research, as employee ambassadorship is unexplored research field. By conducting this research, we aim to change the way organizations work regarding employee ambassadorship, support practitioners in creating an evidence-based policy for employee ambassadorship, and encourage researchers to study this topic.

Oral presentation OP347

The COVID-19 Pandemic for University Students: How Resilience and Social Support Help in Dealing with a Career Shock

Stephanie Meyer, Simone Kauffeld & Britta Wittner | Technische Universität Braunschweig - Arbeits-, Organisations- und Sozialpsychologie

science

As a global crisis, the COVID-19 pandemic had a massive impact on the daily as well as career-related lives of individuals (Elmer et al., 2020). Consequently, it forced society to take drastic measures to reduce infection rates. Young people – being in crucial stages of their development at the beginning of social distancing – suffered from its consequences. Career planning, which is already a difficult task under normal circumstances, became even more difficult during the COVID-19 pandemic. First, young people were more preoccupied with the crisis and its consequences. Second, important experiences in relation with career planning were not always possible due to the pandemic: e.g. internships had to be cancelled. Therefore, adolescents and young adults might be less certain about their career choices.

According to Akkermans and colleagues (2021), the COVID-19 pandemic can be categorized as career shock. Career shocks are disruptive and extra-ordinary events that are, at least partly, outside the individual's control, and trigger a conscious thought process concerning one's career (Akkermans et al., 2018). The thought process triggered by the career shock and the deliberation one one's career can have a major impact on career trajectories. For example, 69% of school and college students in a study by Bright et al. (2005) indicated that chance events influenced their career decision making process. Students who aim to become teachers after their study programme (prospect teachers) might be especially influenced by the COVID-19 pandemic. On the one hand, they are influenced by the consequences of the distance learning and the decreased social contacts with their peers and professors. On the other hand, they also experience the drastic change of their future work environment in a way that they were not prepared for in their studies. Thus, it seems important to investigate how those students are affected by the COVID-19 pandemic and the career deliberation process triggered by it.

Resources could play an important role in alleviating the consequences of the career deliberation process on the confidence in the vocational choice of those prospect teachers. According to Conservation of Resources Theory (COR Theory), individuals with higher resources are less affected by challenges and career shocks. Especially resilience and support in their social networks are important resources in crises, as they help in dealing with challenges and setbacks.

Our study followed a group of German bachelor students (N=790) in a teaching degree at three time points: in January 2020, during the first period of social distancing in April 2020, when distance learning started in the universities, and afterwards in June 2020, during a period of less restrictions. We assume that students with high resilience and social support experience less career reflection processes due to the COVID-19 pandemic and are thus more likely to remain confident in their career choice.

The findings align with those assumptions: more resilient students worried less about their career as consequence of the COVID-19 pandemic. Furthermore, the thought process triggered by the COVID-19 pandemic also led to less confidence in their vocational choice. Students who worried more about their career were less confident in their chosen field of study at a later point in time. Resources –

namely social support and resilience – were also positively related to confidence in vocational choice over medium-term.

These results, underline the importance of resources in dealing with career shocks and crisis in alliance with COR Theory,. Furthermore, it shows that that thought processes triggered by career shocks have a direct influence on confidence in vocational choice, possibly influencing the career path of individuals. Since both resilience and social networks can be influenced, we recommend different measures for universities, students, and the society.

Regarding to the UN sustainable development goals, the current study shows the importance of quality education for the career paths of young adults. Young adults can profit from counselling programmes to strengthen their resilience and helping them rebuild their social networks after the COVID-19 pandemic.

The COVID-19 pandemic showed one aspect of the changing world of work: People had to quickly exchange their workplace for a home office, students and pupils had to get used to digital learning environments and the whole system had to be converted to digital solutions. That individuals' career paths are strongly influenced by this shock seems unsurprising. This also affects young people who are still at the beginning of their careers, figuring out what they want to achieve. In this context, the study can help to better understand the effects of and how to deal with career shocks. In this context, measures can possibly be taken to support young people in their career planning and career development in the face of crises.

Keywords: career shocks, resources, COVID-19

The Dark Side of Stardom: The Negative Implications of Star Centrality on Shared Leadership

Ahsan Ali, School of Economics and Management, Zhejiang Sci-Tech University; Hongwei Wang, School of Economics and Management, Tongji University; Janet A. Boekhorst, Conrad School of Entrepreneurship and Business, University of Waterloo

practice

1. Research goals and why the work was worth doing

Stars employees are often highly sought after by organizations because they are believed to offer significant and disproportionate contributions. Star employees are known for their disproportionately high and prolonged performance, strong internal and external visibility, and social capital. Without much surprise, star employees garner significant attention and resources given that they often perform key roles in their team. Thus, star employees often take on informal leadership roles within teams. This raises important questions with respect to the leading-following dynamics within these teams: If star employees often take on leadership roles, how does this affect nonstars' perceptions of their own team role? How does this affect shared leadership in the team?

2. Theoretical background

According to adaptive leadership theory, employees participate in mutual reciprocation of leading-following interactions that influence the formation of team role identities, which affects the shared leadership structure. Drawing from this lens, star members who are central to the team workflow (i.e., star centrality) affect their leading-following interactions with nonstars. Importantly, stars and nonstars are unlikely to equally participate in these leading-following actions. Thus, star members who occupy central network positions are likely to claim leadership roles that are granted by nonstars who claim followership roles that are reinforced by these central stars. Adaptive leadership theory suggests that these leading-following interactions facilitate the social construction of leader and follower identities that inherently provides self-relevant social information to nonstars. This invites a social comparison, which reflects thinking about information about one or more other people in relation to the self. Social comparison research suggests that nonstars make an upward comparison to central stars, given that stars are superior on at least one dimension (e.g., performance, social capital, visibility). Through this social comparison process, nonstars acknowledge that central stars are superior because they provide more inputs to others, making nonstars believe that their team members have doubts about their leadership capabilities. In turn, these leadership (underdog) expectations are associated with a decrease in the leadership claims of nonstars, hindering shared leadership within the team. Lastly, team diversity can affect these leading-following interactions and we investigate the moderating role of team cognitive diversity given that diversity affects interpersonal interactions, including the claiming and granting of leadership and followership roles.

3. Design/Methodology/Approach/Intervention

Using time-separated, multisource field data collected from 517 members, 87 teams to test these team-level hypotheses.

4. Results obtained

We find that star centrality has a negative direct effect on shared leadership and a negative indirect effect via leadership (underdog) expectations of nonstars. Furthermore, these direct and indirect

effects are strengthened under conditions of low team cognitive diversity, suggesting that star centrality has a stronger effect when there is little team cognitive diversity.

5. Limitations

First, despite strong theoretical underpinnings for the hypothesized relationships, the data does not permit causal inferences. Future studies should employ scenario experiments to facilitate causal inferences.

Second, although our conceptualization of stars was in accordance with the stars literature, the results may not apply to other conceptualizations of stars, such as “relational stars”. Future research should investigate the effects of alternative conceptualizations of stars.

6. Conclusions – research and or practical implications/Originality/Value

Organizations are in a constant state of competition, which has placed significant focus on the need to attract highly skilled talent. Although star employees can offer significant contributions to organizations, little research has investigated how star centrality can affect team dynamics within the leadership context. Our research shows that the central position of star members is negatively associated with shared leadership via leadership (underdog) expectations of nonstars, which is exacerbated when there is little cognitive diversity within the team. Thus, organizations must start to recognize that stars can have an important effect on nonstars, ultimately affecting leading-following team dynamics.

7. Relevance to the Congress Theme

Star employees are highly valuable in current changing work environment. Therefore, understanding how they affect other employees is of significant value to complete in dynamic work context.

8. Relevant UN SDGs

Decent work and economic growth

Partnerships for the goals

Reduced inequalities

Keywords: Star employees, shared leadership, underdog expectations

Oral presentation OP392

The Detrimental Effects of Financial Worry on Customer-Directed Counterproductive Performance

Imke Dirkx & Bert Schreurs | Vrije Universiteit Brussel

science

Research goals

Chances are that we all experience financial worries at some point during our careers. Financial worries can stem from a number of causes (e.g., unexpected expenses, getting a divorce). The COVID-19 pandemic and the associated job loss have spotlighted the topic of financial worry. The emotional and psychological consequences of financial worry are well documented, but there is a dearth of research on its organizational consequences. Moreover, research has ignored the possibility that financial worry fluctuates over time. A negative event (e.g., unexpected expenses) can cause financial worry even among people who generally have low levels of financial worry, and once these expenses disappear their financial worries will simmer away. This study addresses both knowledge gaps. We investigate the extent to which financial worry fluctuates over time, and to what extent within-person variations in financial worry associate with within-person variations in counterproductive performance among service personnel. Due to the nature of service-related jobs, employees are more likely to direct their counterproductive performance towards customers. Accordingly, we focus on customer-directed counterproductive performance.

Theoretical Background

Building on the stressor-emotion model of counterproductive performance, we argue that the experience of financial worry leads to higher levels of experienced negative affect and increased customer-directed counterproductive performance. This model predicts what happens to individuals when they experience stress and is therefore suited for developing hypotheses about the within-person associations between financial worry and counterproductive performance. One of the predictions is that stressors cause individuals to experience negative affect which in turn triggers negative behavior. Accordingly, we hypothesize negative affect to mediate the within-person association between financial worry and customer-directed counterproductive performance. Another prediction that follows from the model is that control mitigates the impact of stressors on negative emotions. Hence, we test whether the strength of the within-person association between financial worry and negative affect depends on individuals' personal involvement with money. Finally, we propose a conditional indirect effect, in that the within-person indirect association is moderated by personal involvement with money.

Methodology

We conducted a weekly diary study among 129 employees in service jobs. Participants completed a questionnaire assessing their personal involvement with money (Level-2). One week later, participants received the first of five weekly diary surveys measuring weekly financial worry, customer-directed counterproductive performance, and negative affect (Level-1).

Results

Financial worry was positively related to negative affect (b =0.14; 95% CI[0.04, 0.25]) but not to customer-directed counterproductive performance. We found a cross-level interaction between financial worry and personal involvement with money: the positive Level-1 relationship between financial worry and negative affect was moderated by Level-2 personal involvement with money (b

=-0.08; 95% CI[-0.16, -0.01]). Financial worry was only related to negative affect for employees with low (b =0.24, p <.001) and average levels of personal involvement (b =0.14, p <.05). Results further showed that negative affect was positively related to customer-directed counterproductive performance (b =0.07, 95% CI[0.00, 0.13]). Unexpectedly, negative affect did not mediate the relationship between financial worry and customer-directed counterproductive performance.

Limitations

Since all data was gathered through self-reports the results should be interpreted with caution.

Implications

This study provides evidence for the stressor-emotion model of counterproductive performance in the context of financial worries and shows that worrying about one's financial situation elicits negative affect, especially among employees who are generally less involved with money issues. Organizations could develop interventions to teach employees to be more involved with their personal finances, enabling them to cope with their worries more efficiently and refrain from working out their frustrations on customers.

Originality

To our knowledge, no other study investigated the consequences of financial worry on customer-directed counterproductive performance. From the study we learn that financial worry-induced negative affect can be effectively managed by actively taking control over one's finances. Finally, this study is a first attempt to investigate the within-person variability of financial worry.

Relevance Congress Theme

The current research specifies the effect financial worries have on service employees in order to formulate strong interventions for prevention in the future.

Keywords: Financial worry, customer-oriented counterproductive performance, multilevel

Oral presentation OP777

The development of the Embodied, Dynamic and Inclusive (EDI) model of self-confidence; a conceptual model for use in executive coaching

Anna Kane, Zest Psychology; Joanna Yarker & Rachel Lewis | Birkbeck and Affinity Health at Work

science&practice

Research goals and why the work was worth doing: The goal of this research was to develop a model of self-confidence for use in executive coaching. Self-confidence is an important coaching topic, yet our understanding of what it is and how it can be developed is limited to narrower concepts of self-efficacy and self-esteem. The aim was to address shortcomings in the literature, including those identified in this systematic review (a conceptual and methodological review of measures of self-confidence, self-efficacy and self-esteem in workplace settings).

Theoretical background: This paper explores the development of the Embodied, Dynamic and Inclusive (EDI) model of self-confidence at work. It was in response to findings from a systematic literature review (SLR) of measures of self-confidence, self-efficacy and self-esteem. It was evident further qualitative work was required to define self-confidence. This paper discusses the embodied and inclusive methodology, which overcame some of the limitations of existing measures, as discovered in the SLR.

Methodology: The methodology employed in this study sought to address various limitations noted in past research. The research team ensured to recruit a diverse participant pool and ensure the credibility of the approach. This diverse sample of 27 employees included a range of genders, ethnicities, sexualities, socio-economic statuses, ages, professions and industries. Having completed the interviews, we thought it would be interesting to report the participants' neurodiversity as well as mental and physical disability. A survey was emailed to collect this data.

We used an embodied interview approach. This extended through to the analysis, where the researcher listened carefully to her whole mind-body to guide her thematic analysis. The researcher expanded the analysis approach to include mind-mapping, percolating data and plugging one text into another.

Results obtained: The Embodied, Dynamic and Inclusive (EDI) Model of Self-Confidence emerged. It contains the components of Authenticity, Competence and Connectedness. The EDI Model is unique in that it captures the dynamics of Loss of Confidence and building a Confident Performance and identifies the role Mindset plays.

We sought to identify a broader model yet identify the risk that the conceptualisation can be too broad, and factors might not relate to a higher-order core construct.

Limitations: It is possible that we have found a cluster of constructs that only have minimal relation. Other limitations noted are that while our research focused on diversity and inclusion to overcome limitations in existing research, we acknowledge that neither interviewers were male, BAME, nor had disabilities and they reported as neurotypical. It is possible this influenced and limited our research findings.

Research and Practical implications: This research has enhanced our understanding of self-confidence in five ways because it:

Responds to the need for a dynamic model

Moves beyond cognitive and emotional concepts to the embodiment

Reflects workplace diversity

Identifies the role of mindset

Conceptualises self-confidence as a broad factor

Recommendations for coaching include a focus on certain topics for building confidence such as the art of giving and receiving feedback, giving, and receiving support from colleagues and leaders creating inclusive environments where a range of individuals feel secure being themselves and have a sense of belonging.

Relevance to the Congress Theme:

Contribution: The EDI model of self-competence shows us it is about competence, connectedness and authenticity. Contributing to the now by building confidence across a range of professions to lead the way.

Urgency: The EDI model was partly developed to address the criticism that existing research focused on white, young, American undergrads. To solve the complex problems of the world, we need diverse experiences, thinking and leadership. The EDI model is already supporting the development of people from a range of diverse backgrounds, enabling the confidence building of not just the established elite and privileged few who have historically created the problems that now need solving.

Delivery: Change is inevitable. The focus of the EDI model is to enable the development of confidence among the most diverse and vibrant group of people. We plan to deliver this transformation through the implementation of our Authentic Confidence Program.

Relevant UN SDGs:

Our research has shown that there is a link between self-confidence and well-being at work. Our substantial coaching experience using the model shows us that it is best to improve health and well-being before working on self-confidence. Once confidence has been mastered (it is a skill to develop rather than a purely innate quality), then individuals and teams are equipped to produce decent work and generate economic growth.

Keywords: Self-confidence, Coaching, Inclusive

Oral presentation OP509

The Direct Intercultural Effectiveness Simulation Instrument

Delphine Van Muylem; Stijn Schelfhout & Eva Derous | Ghent University, Faculty of Psychology and Educational Sciences, Department of Work, Organisation and Society

science&practice

Research goals

The present research is rooted in a regionwide Flemish project that aims to address the problem of ethnic discrimination towards ethnic minorities, spanning four domains that are anchored into the constitution: education, health care, housing and work. To this extent, the project is developing digital tools to make domain professionals (e.g., teachers, healthcare workers, brokers and employment counselors) aware of their biases towards ethnic minorities and to train these professionals so that their intercultural interactions contribute to reduce ethnic inequality in these four domains. The present research aims to contribute to this practical goal by introducing the DIES (direct intercultural effectiveness simulation) instrument. The DIES instrument measures to which extent professionals know and tend to display intercultural effectiveness (IE) in (future) intercultural interactions. In practice, the participant results and subsequent feedback can be used both as standalone interventions towards more awareness of personal behavior as well as in combination with other interventions towards training.

Theoretical background

An implicit trait policy (ITP) is a known construct that represents the interaction between the personality (amongst other factors) of an individual and the individual's beliefs (often called general domain knowledge) towards which behavior is effective in specific situations. For instance, if an individual is convinced empathic behavior is effective to solve work conflicts, an empathic person will endorse or perform more empathic behavior in conflict situations. As literature already shows that empathic behavior enhances effectiveness, measuring an ITP can predict future behavior. ITPs are normally used in SJTs to measure future effectiveness in work situations. However, IE literature does not yet report an instrument that measures an ITP directly, which can predict future behavior. Such an instrument can help in addressing important issues in intercultural interaction like ethnic discrimination.

Design and Methodology

In a series of three empirical studies (N = 993), DIES directly simulates an ITP on IE by presenting future professionals with a series of four scenarios and ten responses to each scenario. Participants have to rate the effectiveness and/or the chance they would act like the response in future interactions (score of 0 to 100). The ITP is calculated using the principles of the accentuation effect by subtracting the average score of the ineffective items from the average score of the effective items. As effective and ineffective items are compared against each other, we expect to observe a clear difference between effective and ineffective items. The reliability of the DIES is obtained over items and over scenarios. The construct validity of DIES is assessed using structural equation modeling (SEM), not only including a confirmatory CFA, but also a full structural framework of IE including measures of intercultural traits, attitudes, capabilities and real life behavioral measures like the intensity of intercultural contacts. The DIES results are also correlated with a nomological network containing about twenty related measures like modern racism, social dominance orientation and right wing authoritarianism to establish convergent and divergent validity.

Results obtained

Results show that participants can distinguish and intend to use effective over ineffective intercultural behavior. This effect was found and replicated across three studies. These findings are in line with literature on the accentuation effect, general domain knowledge and ITPs. DIES shows reliability measures of about $\alpha = .80$, while showing positive correlations with scales like open mindedness and cultural intelligence and negative correlations with scales like modern racism, social dominance orientation and right wing authoritarianism. SEM analyses show that the ITP measure functions as the bridge between cultural intelligence and actual behavior.

Limitations

Present research was conducted on future professionals. Future research will target actual domain professionals.

Conclusions – research and or practical implications/Originality/Value

Theoretically, the present research provides literature with an instrument capable of measuring an ITP on IE. Practically, the DIES instrument can be used as a proxy for actual behavior to tackle important problems like ethnic discrimination.

Relevance to the Congress Theme

DIES contributes to developing IE in (future) professionals in domains of education, healthcare, housing and work. DIES is urgent as intercultural interactions are becoming the norm. DIES delivers as the instrument is able to measure if people have the knowledge and the intent to interact effectively in intercultural situations.

Relevant UN SDGsReduced inequalities

Oral presentation OP29

The Double-Edged Sword of Leaders' Resource-Seeking: Divergent Curvilinear Effects on Leaders' Perceived Humility, Competence, and Effectiveness

Julia Rieg, Prisca Brosi & Niels Van Quaquebeke | Kühne Logistics University

science&practice

The extant literature on the consequences of leaders' resource seeking has produced inconsistent results on whether it helps or hurts leaders' humility, competence, and ultimately effectiveness perceptions. We resolve these by proposing that the frequency with which leaders ask their followers for resources plays a crucial role. In contrast to previous literature, which has predominantly focused on linear effects, we argue for a too-much-of-a-good-thing logic and emphasise that leaders who seek resources too infrequently or too frequently are appraised as less effective. We explain this nonmonotonic relationship using a competitive mediation model where perceived leader humility and competence act as two mediators with opposite curvilinear directionalities of influence. Results of a vignette study and a two-wave field survey support our theorising that humility premiums mediate a positive relationship between resource seeking and perceived leadership effectiveness at low to medium levels of frequency, while competence penalties mediate a negative relationship when frequency exceeds medium levels. In consequence, our study offers integration for prior empirical inconsistencies and allows for better advice to practitioners, who often are rightfully wary of the double-edged sword of asking followers for resources.

Keywords: double-edged, resource-seeking, curvilinear

Oral presentation OP647

The effect of organizational justice on knowledge hiding among self-initiated expatriates (SIEs) and host country nationals (HCNs)

Alexandra Henderson, Yi Zhang & Taiba Hussain | Zayed University

science

Research goals

In this study, we draw upon social exchange theory to examine the effects of distributive, procedural, and interactional justice on knowledge hiding. We also examine the potential moderating effects of employment type (SIE versus HCN) and culture (high versus low collectivism). This research has several theoretical and practical contributions. First, we examine a theoretically plausible antecedent to knowledge hiding. Second, we examine two theoretically plausible moderators (employment type and collectivism) of the relationship between justice and knowledge hiding that are highly relevant to the increasing globalization of organizations. Together, we advance our theoretical understanding of what causes and exacerbates knowledge hiding in organizations, which will provide researchers with a more complete framework for future research and provide practitioners with guidance for reducing knowledge hiding in organizations.

Theoretical background

Perceptions of low distributive justice (fairness of outcomes), low procedural justice (fairness of the formal processes or polices by which outcomes are allocated), or low interactional justice (fairness of the interpersonal treatment they receive from organizational decision makers, Cropanzano et al., 2002) should signal an imbalance in the exchange of resources such that employees believe they should have received more outcomes, different procedures, or better interpersonal treatment for what they have provided as employees. In line with social exchange theory, this imbalance should subsequently encourage employees to retaliate in such a way that will rebalance the exchange relationship. Knowledge hiding would effectively harm the organization and restore the balance in the exchange of resources.

The resources invested by self-initiated expatriates (SIEs) in order to work at a foreign organization are considerably high, especially compared to host country nationals (HCNs). Thus, SIEs should perceive low justice as a failure to reciprocate, not only to the contributions they have made to the organization, but to the sacrifices they have made to be an expatriate. HCNs, on the other hand, would only perceive low justice as a failure to reciprocate to their organizational contributions. As such, the greater social exchange imbalance for SIEs' in a low justice environment should result in a more exaggerated retaliatory response (knowledge hiding) in the exchange relationship.

Finally, collectivists place greater value on social resources, such as interdependence (Thomas et al., 2003), loyalty and cohesiveness (House et al., 2004) and norms of reciprocity (Van Dyne et al., 2000). All three forms of justice relate to these social resources. Thus, SIEs from collectivist cultures may perceive low justice as a greater threat to resources, as they place a higher value on these threatened resources, and will subsequently be more inclined to retaliate (knowledge hiding) and bring balance back to the exchange relationship.

Methodology

Data was collected in two public organizations in the United Arab Emirates. 462 employees completed the time 1 survey, which included organizational justice (distributive, procedural,

interactional) and demographic information (age, gender, tenure, nationality). 390 employees completed the time 2 survey, which included collectivism and knowledge hiding.

Results and Conclusion

Our results showed that all three types of justice were negatively related to knowledge hiding. However, in line with our hypotheses, we found that the relationship between procedural justice and knowledge hiding and the relationship between interactional justice and knowledge hiding were both stronger among SIEs. We also found that the relationship between procedural justice and knowledge hiding was stronger among SIEs with high collectivism. This research highlights the importance of organizational justice in ensuring effective knowledge management and identifies specific groups (SIEs, especially those with high collectivism) that are more susceptible to knowledge hiding following injustice.

Limitations

First, we collected data from organizations in the UAE, which is a highly diverse context (90% expatriates from over 209 countries). This diversity may limit the generalizability of our results to organizations or labor forces with fewer expatriates. Second, our variables were measured via self-report methods. However, we mitigated potential issues of common method variance by separating the collection time of our variables.

Keywords: justice, knowledge sharing

Oral presentation OP162

The effect of public value and transformational leadership on flow-experience: An investigation in the context of public administration

Jessica Bardeli, Dr. Arend Oetker Chair of Business Psychology and Leadership, HHL Leipzig Graduate School of Management, Germany;

Timo Meynhardt, Dr. Arend Oetker Chair of Business Psychology and Leadership, HHL Leipzig Graduate School of Management,

science&practice

Content: Given the past years' challenges and the organisations' requirement to adapt rapidly to new environmental and working conditions, leadership issues and motivational factors enabling cohesion and adaptation among employees have come even more into focus. On a societal level, public value contribution of organisations' was identified to provide an important contribution to cohesion in society (Bozeman, 2007; Moore, 1995). More recent research, however, also indicates that the individual in the working environment may benefit from the public value orientation of organisations (Grubert et al., 2022; Meynhardt et al., 2018). Building upon this research, the goal of the present study is to investigate the relationship between public value and the psychological construct flow as well as the spillover effect on life satisfaction at the employee level. Moreover, this study examines the moderating role of transformational leadership and mediating role of professional self-efficacy. In addition, this study wants to show that the organisational public value is an essential aspect in the current work environment and contributes to offering managers ways to increase the public value of their organisation and consequently raise motivational processes among their employees. The present study is based on Meynhardt´s public value approach (2009), which demonstrates the organisation's contribution to the common good and builds on the cognitive-experiential self-theory by Epstein (2003). This study aims to make an important contribution to ensuring that the topics public value and leadership and their impact on different levels within an organisation, in particular at the employee level, increase in relevance. The contribution of the present research is two-fold: First, it contributes to the public value literature by showing that the public value contribution of organisations translates into motivational effects on the individual level. Second, it contributes to the flow literature by showing that the public value contribution provides an important antecedent of the flow state.

Design/Methodology: The study is tested on data collected in 2022 within an online survey at the public administration organisation (German Federal Employment Agency). The sample in study 1 consists of 3,326 respondents. Respondents' ages ranged between 18 and over 60 years, and 70.4% of the respondents were female, 17.0% held a leadership position, and 68.4% worked full-time. A second study will occur end of 2022 in the same participating institutions.

Results: Study findings suggest that organisational public value is positively related to flow-experience at the individual level and that this relationship is partially mediated by professional self-efficacy. Results further show that the indirect effect of organisational public value on flow-experience via professional self-efficacy is moderated by transformational leadership such that they are stronger at higher transformational leadership levels. The results of the second study are expected in January 2023, enabling us to provide causal inferences and further analyses.

Limitations: All data were collected through self-reports.

Research/Practical Implications: The underlying results provide important implications for management practice, particularly in public administration. The management should focus more on public value creation within and outside the organisation. As mentioned, the perception of individuals plays an important role in the context of the working environment. When public institutions focus their efforts on creating public value and even engage in public value entrepreneurship (Meynhardt and Diefenbach, 2012; Kearney and Meynhardt, 2016), they can contribute to positive work outcomes as well as well-being of employees.

Originality/Value: This study provides first results on the relationship between public value and flow-experience at the level of employee in the context of public administration. The underpinning research design reveal a moderated mediation.

Relevance to the Congress Theme and Relevant UN SDGs: Perfectly in line with the congress topic, the present study shows the importance of employee perceptions and needs in a changing world of work. The contribution of companies to the common good has come more into focus due to events such as the pandemic, that led to the need to adapt future-oriented working conditions. Moreover, this study contributes to the UN SDGs by showing that a perceived public value contribution of a company by the employee leads to a better flow-experience and thus also to life satisfaction and, consequently, well-being. In addition, the study takes place in the context of public administration and visualises the important aspect that the perceived public value contributes to a balanced functioning system and peace in the society. This represents the public administration as a form of a strong institution, especially within times of crisis.

Keywords: Public value, flow-experience, transformational leadership

Oral presentation OP426

The effect of talent management on motivation, commitment and citizenship behavior of talented employees: examining the role of organizational support

Daniel Gajda, Milena Gojny-Zbierowska & Przemysław Zbierowski | University of Economics in Katowice

science

Research goals

Contemporary economic realities, characterised by intense market competition, high dynamics of changes in the organizations' environment and declining demand due to the recent lockdowns caused by the COVID-19 pandemic, have led to a significant increase in risk and uncertainty in managing the organization. These tendencies have contributed to the weakening of bonds between employees and employers who, facing difficult market conditions, are unable to provide their staff with stable, long-term employment. This, in turn, evokes in employees growing dissatisfaction with their work and willingness to change the job. In response to the economic challenges of the 21 st century, organizational decision-makers implements the talent management (TM) programs to mitigate the loss of talented employees and meet the company's current and future competency needs (Seopa et al. , 2015).

Despite the ongoing discussion on TM over the past few decades the question that still remains unanswered is: How TM affects employees' attitudes and behavior? Whereas some studies (e.g. Barkhuizen et al. , 2014; Mensah, 2016) find positive effects of TM on work-related attitudes and behavior, others report that talent pool members demonstrate negative reactions to TM, that is feeling of stress and insecurity (Dries & Pepermans, 2008) or identity struggles at work (Tansley & Tietze, 2013). This tension makes managers lack a scientific ground for taking decisions related to the talented employees. Therefore, the purpose of our study is to identify the consequences of TM practices for talented employees. Specifically, following the theoretical model of strategic TM (Collings & Mellahi, 2009), as part of these consequences we examine motivation to work, organizational commitment and organizational citizenship behavior (OCB) of talented employees, as attitudes and behaviors associated with organizational performance in previous research. Moreover, to better understand employees' reactions to TM, we explored the psychological process that is involved in shaping attitudes and behavior of talent pool members.

Theoretical background

We apply social exchange theory (Blau, 1994) to explain how the employees' reactions to TM are formed. Based on literature review we argue that the perception of TM practices has a positive impact on their motivation to work, organizational commitment and OCB. It was also expected that perceived organizational support (POS) constitute a transmission mechanism through which TM practices affects employees' attitudes and behavior.

Method

We surveyed 730 participants of TM programs from 33 large companies operating in Poland. At least 22 correctly and completely completed questionnaires were obtained in each of the examined organization. A series of hierarchical multilevel regression analyses and structural equation models were performed to test our hypotheses.

Results

The results reveal that intended TM practices significantly predict perceived TM practices, and these, in turn, have a direct and indirect positive impact on talent pool members' motivation to work, organizational commitment and OCB. We also found that POS mediates the relationship between perceived TM practices and examined attitudes and behavior of talented employees.

Limitations

The study is limited in some ways. First, all the data for the study were gathered at a single point in time, raising concerns about common method bias (CMB). However, the post-hoc test indicated that CMB is not a threat to our results. Second, our study had a cross-sectional design. There is thus a possibility for reverse causality such that individuals who are seen to exhibit attitudes and behavior examined in the study are more likely than others to be included in talent pools.

Research and practical implications

The study expands the academic understanding of employees' reactions to TM and, in consequence, verifies the assumption that TM practices positively affects motivation to work, commitment, and OCB of talent pool members. It also provides a profound insight into the underlying psychological process that is involved in shaping employees' attitudes and behavior. The results obtained are valuable for organizational decision-makers who invest increasing amounts of money into TM initiatives without confidence whether these are successful in achieving the TM objectives.

Relevance to the Congress theme

The study is particularly relevant in the light of changing world of work because when the financial capital becomes widely accessible, and product or process innovations can be easily imitated, the talent that is rare and difficult to imitate, may be a source of a sustainable competitive advantage.

Relevance to the UN SDGs

The results of our research show that TM contribute to a more positive working experience and elicit discretionary behavior, which leads to strengthening interpersonal relations and building social capital. This may results in achieving UN SDG, such as well-being.

Keywords: talent management, perceived organizational support, employee attitudes

The effect of Workplace Health Promotion Programs (WHPP) on the well-being of blue-collar workers within the Transport & Logistic sector

Sarah Detaille, HAN University of Applied Sciences; Annet de Lange, Open University of the Netherlands; Josephine Engels, HAN University of Applied Sciences; Adela Reig-Botella, Universidad de A Coruña; Bouwine Carlier, University of Applied Sciences

science&practice

Purpose:

Transport workers are highly at risk of developing overweight and obesity (Naug et al., 2016; STL, 2016 Arbouw, 2010; Goetzel et al., 2010). A recent study has shown that 73% of the transport and logistic workers is overweight (STL, 2021). Excessive body weight is associated with increased mortality and morbidity and has a negative impact on health and work ability , like for example the incidence of chronic diseases such as low back pain, diabetes type II or cardiovascular disorders (Burdorf et. Al, 2016). Overweight and obesity are also related to a decrease of work ability of the individual [Damen et al., 2022]. A few companies in the Netherlands in the Transport & Logistic sector offer Worksite Health Promotion Programs (WHPP's) with the aim of improving the health, vitality and work ability of workers. There is until now little insight into the effect of WHPP's and which factors influence the effectivity of WHPP's.

Design:

An experimental design has been used with a 12-month follow-up (intervention group= 159, control group n=1378) (Blue collar workers within the transport en logistic sector). The health promotion interventions of the Transport and Logistic Sector have been evaluated on process and effect outcomes. The primary effect outcomes were Work-Ability (Ilmarinen, 1999), Vitality, Physical and Mental Health (SF-12), Work-engagement (Schaufeli, 2014) and relationship with management (VBBA). The secondary effect-outcome variables were weight and healthy behavior. Furthermore, qualitative data was analyzed to evaluate the implementation of the intervention. This project used the RE-AIM model framework (Glasgow et al., 1999), combined with the validated framework of Steckler & Linnan (2002). The data has been collected through interviews with different stakeholders as well as a longitudinal survey study.

Results:

The linear regression shows that the following variables: work engagement, relationship with management and perceived health (physical and mental), have improved significantly after the intervention. However, no significant effects on lifestyle outcomes have been observed after the intervention. The control group (no intervention) goes significantly

backwards on most variables after 12 months. This indicates that following an intervention not only can have a stimulating effect on wellbeing but can also prevent health deterioration and demotivation of the target group.

Oral presentation OP297

The Effects of Authentic Leadership on Employee Well-Being: The Mediating Role of Psychological Empowerment, Psychological Capital and Work Engagement

Elli Tsitouri & Olivia Kyriakidou | The American College of Greece, Athens, Greece

science

Purpose: The purpose of the current study was to examine the relationship between authentic leadership and employee wellbeing and specifically to shed light on the underlying mechanisms that are at play in the association between authentic leadership and employee wellbeing. Employee wellbeing is becoming an increasingly relevant and important consideration in the modern workplace environment, especially in the post-Covid era. Prior research has revealed that employee wellbeing is affected not only by the physical work environment, but also the psychosocial work environment. Specifically, the management style at work is considered to be one of the most fundamental organizational factors that can influence the welfare of employees. Currently, one of the increasingly important explanatory models of leadership, is the model of authentic leadership, drawing from the positive organizational psychology field. Our paper takes a look at leadership through this positive lens.

However, even though authentic leadership has for long been proposed as a ' pathway to positive health' and various studies have substantiated the fundamental role of authenticity in wellbeing, there seems to be limited research involving the relationship between authentic leadership and employee wellbeing. In light of recent calls made by researchers (Hildenbrand et al., 2021; Rahimnia & Sharifrad, 2015) who contend that additional empirical research is needed in order to better understand the process through which authentic leadership affects employee wellbeing, the current study seeks to address this gap in the literature by exploring two underlying mechanisms and more specifically the mediating role of psychological empowerment, psychological capital and work engagement.

Theoretical Background: In order to explore the dynamic interplay between job resources and personal resources that lay the foundation for employee wellbeing, two conceptual frameworks were utilized: the Job Demands-Resources Model and Conservation of Resources Theory. Accordingly, authentic leadership was conceptualized as a job resource given its potential of leveraging healthier, happier and more productive workplaces. Psychological empowerment and PsyCap were viewed as personal resources that mediated the relationship between job resources (i.e., authentic leadership) and employee wellbeing. Finally, work engagement was construed as an intervening mechanism that connects psychological empowerment and PsyCap, respectively, to employee wellbeing.

Design/Methodology: Non-probability convenience sampling was employed, using a sample of 213 employees (N =213) working in various public, private and non-profit organizations. The study is grounded on two serial double mediation models. In the first mediation model, authentic leadership is predicted to result in employee wellbeing through the mediating effects of psychological empowerment and work engagement. While, in the second mediation model, authentic leadership is predicted to result in employee wellbeing through the mediating effects of psychological capital and work engagement.

Results: Multiple hierarchical regression analyses along with Process Macro, utilizing bootstrapping, confirmed all of the hypotheses. Authentic leadership was found to result in greater employee wellbeing, with the results validating both mediation models, thereby confirming the mediating role

of psychological empowerment, PsyCap and work engagement in the relation between authentic leadership and employee wellbeing.

Limitations: Conclusions are limited by the cross-sectional design of the study, the use of single, self-report data and the lack of examination of moderating variables.

Research/Practical Implications: The study fills a research gap, by shedding light and expanding our current knowledge and understanding of the relationship between authentic leadership and employee wellbeing. At the same time, it also offers important guidance to organizations, supervisors and human resource practitioners on how to foster authentic leadership at work in order to promote greater employee wellbeing. As such, authentic leadership represents an extremely valuable health-promotion tool that organizations can and should leverage in order to maintain a healthy workforce.

Originality/Value: To our knowledge, no empirical research has examined the combined effect of psychological empowerment, psychological capital and work engagement in the relation between authentic leadership and employee wellbeing. This study is among the first to examine these important variables in conjunction, helping us to obtain a more nuanced understanding of the underlying processes that are involved in the relationship between authentic leadership and employee wellbeing.

Relevance to the Congress Theme: The study is relevant to the congress theme as it tries to identify mechanisms to lead our way towards a future of work with more wellbeing for all.

Keywords: employee well-being, authentic leadership, psychological capital

Oral presentation OP56

The effects of career adaptability on perceived future employability and career motivation: Employed vs. Unemployed fresh university graduates

Alia Azalea, Sunway University; Michelle Chin Chin Lee, Massey University; Mei-Hua Lin & Pek Kei Lim | Sunway University

science&practice

The changing economy and work environment due to the COVID-19 pandemic has made the transition to the labour market more complex for fresh university graduates. Derived from Rudolph et al. (2017) model and career construction theory by Savickas (2017), career adaptability, defined as individual's attitude and behaviours that they adopt in fitting themselves into careers that are suitable for them (Savickas, 2005), was identified as an essential factor to help individuals adapt and cope with challenges. This career adaptation is expected to result in higher perceived future employability (PFE) and career motivation (CM), an outcome not considered by Rudolph et al. Thus, we aim to fill in this research gap. In addition, we also compared the effects of career adaptability on the adaptation results (CM and PFE) between employed and unemployed fresh university graduates, which could help individuals strategise their career.

We utilised a cross-sectional method where 457 (257 employed, 200 unemployed; 64.1 women; 58.6% private universities graduates) Malaysian fresh university graduates from various public and private universities participated. Graduates of tertiary education were chosen as they have the ability to impact their community the most compared to others, especially with income obtained from their employment (Gagnon, 2022). Data were collected between May to September 2022. Participants completed a set of demographic questions and the Career Adapt-Abilities Scale – USA form (CAAS-USA), Career Motivation Scale and The Perceived Future Employability Scale to assessed their career adaptability, career motivation, and employability in their future-self, respectively. All measurements were tested using Structural Equation Modelling and shown a good fit.

The structural model showed an acceptable fit and we found differences in the effects of CA dimensions on CM and PFE dimensions between employed and unemployed Malaysian fresh university graduates. The CA–concern and control dimensions were negatively associated with PFE dimensions for unemployed participants, but positively associated for employed participants. The CA–curiosity dimension negatively affected PFE and CM dimensions for both groups of participants, with a stronger effect for employed participants on PFE and for unemployed participants on CM. The CA–confidence dimension positively affected PFE and CM for both groups, with a stronger effect for unemployed participants.

There were a few limitations to our study. Firstly, we utilised a self-reported survey method which are usually subjected to social desirability bias despite the assured anonymity of participants. Future research should take social desirability bias into consideration, and implement strategies that could overcome this bias, such as including a social desirability scale which would help to detect respondents who are more prone to this type of bias. Secondly, the contrasting association in the relationship between CA dimensions and perceived future employability between two different groups might indicate the existence of mediators and moderators which were not considered in our study. Therefore, future studies should identify and examine possible variables which could provide a deeper insight into how the association between CA and PFE varies in different situations.

We validated parts of Rudolph et al. (2017) model on a Malaysian population by supporting how adaptability resources (career adaptability) lead to adaptation results. We also compared the CA of

the employed and unemployed Malaysian fresh university graduates who are transitioning from academic to employment and shown the importance of career adaptability on career outcomes (i.e., PFE, CM – resiliency). Higher educational institutions should focus on improving CA of their graduates by providing training that enable them to better cope and adapt to the changing labour market, thus, increasing their chances to obtained full-time employment upon graduation.

Our study is relevant to the congress theme as the working environment experienced a profound change due to COVID-19 pandemic and career adaptability become an even more important quality for fresh university graduates to transitioned successfully from academic to the work environment. It is particularly relevant to Subtopic 1 as we examine the effect of career adaptability on career outcomes between employed and unemployed individuals.

Our study is relevant to UN SDG Goal 8, as we found that career adaptability leads to resilience and that employed individuals has higher career resilience than the unemployed. This could indicate that more adaptable individuals are more resilient and productive, thus, are more likely to be employed. Therefore, it is important to develop policies that support productive activities to facilitate employment for all individuals, especially the new generations of young people joining the workforce.

Keywords: Career adaptability, Career motivation, Perceived future employability

Oral presentation OP214

The Effects of Islamic Work Ethic Rules on Employees Perception of Wellbeing in a Cross-Cultural Context

Zeynep Mercan, Yuksel Ekinci, Zarah Vernham & Darren Van Laar | University of Portsmouth

Research Goals

The first aim of the current research project was to evaluate the influence of Islamic Work Ethic (IWE) values on perceptions of work characteristics for religious British and Turkish employees. The second aim was to compare the influence of IWE values on Christian-majority British participants' and Muslim-majority Turkish workers' perceptions of work characteristics.

Theoretical background

Quality of working life (QoWL) theory is an increasingly popular component of the quality of life of employees; its conceptualization includes all workplace-related factors that may affect an individual's wellbeing as well as the impact of work on an employee's quality of life. As the QoWL concept investigates an individual's subjective perspective of the quality of their working life, it has also been shown to be especially affected by an individual's religious beliefs. Thus, the impact of religiosity on the QoWL is likely to be an important factor to consider in employee wellbeing and satisfaction. Islam is the second-largest religion in the world, as well as in the UK (that is, the emigration of Muslims due to refugee crises has increased the number of Muslims working and living in western countries such as the U.K.). One of the most measured effects of religiosity on work is through the corresponding work ethic value. Although Western-based work ethic scales (e.g. the Protestant work ethic) have been investigated in non-Western countries, in Muslim-majority countries, and in cross-cultural research, no such research investigates the role of Islamic Work Ethic values in Western contexts.

Design/Methodology

This study's data analysis was based on correlational statistical methods. The study compared a cohort of highly religious Turkish Muslim participants (n=241) with a cohort of British Christian religious participants (n=237) on their scores for Islamic Work Ethic (IWE) and Work-related Quality of Life (WRQoL). The WRQoL scale comprised 6 sub-scales, including Work-life Balance (WLB), Job career satisfaction (JCS), General Wellbeing (GWB), and working conditions (WCS). A correlational method design was used and structural equation modelling (SEM) was conducted to analyse the hypothesized measurement model.

Results obtained

Results of the SEM analysis supported the full mediation model. The results showed that scores on IWE significantly predicted JCS and WLB for both Turkish and British religious employees, with these factors also mediating the relationship between IWE values and WCS. The Turkish employee's GWB was indirectly affected by IWE through the sequential mediation of WLB and WCS, while the British employees' GWB was affected through the sequential mediation of JCS and WCS. This difference between countries could be a result of their overall culture. Turkey is a collectivistic country as well as Islam encourages collectivism. For Turkish employees to have WLB as the initial mediator between IWE and GWB, might be due to the emphasis Islam and culture put on the family. On the other hand, the individualistic nature of UK employees would mean that the influence of IWE on their GWB is more dependent on perceived individualistic job satisfaction.

Limitations

The current research project was performed in two separate parts: the Turkish data were collected before the COVID-19 pandemic while the British data were collected after the COVID-19 pandemic. It is acknowledged that this could have potentially created some invariance between the groups; to overcome this, the researcher applied scales and metric invariance tests to ensure the data were comparable.

Research/Practical implications

In terms of the implications of the findings, some of the IWE rules (e.g., Good work benefits both oneself and others; Producing more than enough to meet one's personal needs contributes to the prosperity of society as a whole) could be applied to Christian workers as well as Muslim workers and therefore they are likely to similarly affect the wellbeing of both these types of religious employees. Organizations and practitioners could develop organizational policies that incorporate such religious values, for the mutual benefit of both Christian and Muslim employees.

Originality

This paper contributes to the literature and highlights the importance of religious cultures on work behavior and job satisfaction. It demonstrates that although religious values affect employees' perceptions of their work and life, the perceived effects of these values are likely to be dependent on the cultural background of an employee's country of origin.

Oral presentation OP399

The Effects of Self-Compassion and Leader-Compassion on Affect and Thriving: A Multilevel Experimental Study

Vince Pelzer, University of Amsterdam

science

Title of oral presentation. The Effects of Self-Compassion and Leader-Compassion on Affect and Thriving: A Multilevel Experimental Study.

Research goals. Many employees suffer from work-related mental health problems due to structural job demands, such as high workload. To mitigate these issues, it may be beneficial to focus not only on building resilience on the individual level, but also to investigate the role of the leader in strengthening employee well-being. On the individual level, self-compassion is a promising personal resource for employees to maintain employee well-being at work (Ferrari et al., 2019. In addition, leader-compassion may have added benefits for the self-compassion of their employees. The goal of the current study was to examine the direct and interaction effects of leader-compassion and individual-level self-compassion on individual affect and thriving.

Theoretical background. According to the Job Demands-Resources Model (JDR-model; Bakker & Demerouti, 2007), individuals may use their personal resources to deal with job demands. Personal resources are defined as psychological characteristics or aspects of the individual, which relate to one's resilience and to one's ability to successfully influence the work environment or shape the environment to one's own control (Hobfoll, 1989; Xanthopoulou et al., 2007). We investigate self-compassion as an important personal resource that may help individuals deal with job demands and improve their well-being (i.e., affect, thriving). Self-compassion consists of three aspects that can help employees through negative self-relevant experience (e.g., failure, negative feedback): self-kindness, common-humanity, and mindfulness (Neff, 2011). Moreover, taking a multilevel approach (Martin et al., 2016), we examine whether leader compassion might strengthen the effects of individual self-compassion on thriving and affect. First of all, we expect that a positive direct effect of leader compassion as well as self-compassion on thriving and affect. Secondly, we expect that leader compassion moderates the effect of self-compassion on thriving and affect, such that high levels of leader compassion will lead to a larger effect of self-compassion on thriving and affect.

Methodology. Participants (N = 176 students) were randomly assigned in a 2 (leader compassion: neutral vs. compassionate) x 2 (self-compassion: neutral vs. self-compassion) between-subjects design. Participants first completed an online marketing task, after which they received either neutral or compassionate feedback on the task from a vignette supervisor (Manipulation 1). Subsequently, participants reflected on the feedback either with self-compassion, using a self-guided writing exercise (cf. Kreemers et al., 2020), or by freely writing about the feedback (Manipulation 2).

Results. Factorial ANOVAs showed support for the direct effects of the (individual-level) self-compassion intervention on state self-compassion (manipulation-check) and negative affect, but not on positive affect and thriving as compared to the freely writing condition.

Furthermore, results indicate no direct effect of leader compassion (compared to the neutral feedback condition) on state self-compassion and positive affect , but a (marginally) effect on negative affect, and thriving.

Lastly, no support was found for the interaction effects of leader compassion and self-compassion on negative affect, positive affect , and thriving.

Limitations. Even though the use of an experimental design allows us to establish causality, the use of students who received fictional feedback limits the generalizability to actual employees in organizational contexts. Future research can shed a light on this by observing leadership behaviors and their impact on follower self-compassion in a sample of employees.

Conclusions. This study suggests that self-compassion and leader-compassion are effective resources for improving well-being. However, no interaction effects of self-compassion and leader compassion were found on thriving and affect. The findings of this study contribute to the (self-)compassion intervention literature by showing the additional benefits of leader-compassion beyond individuals' self-compassion. In a broader perspective, this study shows how self-compassion and leader-compassion can contribute to employee well-being.

Relevance to the Congress Theme. This study shows that self-compassion may be an important personal resource that is malleable and offers benefits for employee well-being. By demonstrating the added effects of leader-compassion, we contribute to creating healthy workplaces for the future.

Relevant UN SDGs. We strive to contribute to creating healthy workplaces by showing how self-compassion and leader-compassion can increase individual mental health and well-being.

Keywords: Self-compassion, intervention, leadership

Oral presentation OP799

The Emotions and Entrepreneurial Passions of Tech and Digital Entrepreneurs During Their Start-up Journey

James Brook & Almuth McDowall | Birkbeck University of London

science

Research goals

Entrepreneurial ventures in the Tech and Digital sectors form an increasingly important part of the UK and European economies. One of the critical factors determining the success of entrepreneurs is how they deal with their emotions and remain passionate and motivated during the start-up phase on their venture, when challenges, setbacks, failures, and frustrations are common. However, there is still a shortfall of research on the lived emotional experiences of entrepreneurs owing to a historical positivist bias in entrepreneurial research that endures to this day. This longitudinal, qualitative research aims to bridge this gap by examining how UK Tech-Digital entrepreneurs experience emotions and passions as their venture unfolds and how these shape both the founder and their venture.

Theoretical background

Entrepreneurship has long been regarded as an emotional endeavour. It has metaphorically been described as a rollercoaster ride involving stronger and faster changing negative and positive emotions than most other professions and occupations (De Cock, Denoo, Clarysse, 2019). Although the role of emotions in entrepreneurship is receiving increased focus as a topic of research (Baron, 2008; Delgado et al., 2015; Fodor & Pintea, 2017), it remains under-researched. Most academic research into entrepreneurship has been positivist and temporal in nature, so very little is known about how entrepreneurs experience the process as it evolves (Schindehutte et al., 2006). Entrepreneurial passion (EP), or intense positive feelings toward entrepreneurial activities and roles that are meaningful to the entrepreneur (Cardon et al., 2009) has emerged as a particularly popular emotional and motivational construct among researchers seeking to better understand entrepreneurial behaviour and processes. This interest reflects a growing acceptance that entrepreneurship is an intensely emotional experience requiring high levels of energy, enthusiasm, and motivation to succeed. Yet EP is still poorly understood. Most studies assume a positivist paradigm, are survey-based, and measure EP at a single point in time. There is also no agreed definition on what EP is, how it emerges and is experienced by different entrepreneurs, and how it shapes both the entrepreneur and the venture creation process.

Method

Employing purposive sampling and a longitudinal research method, data were collected from a diverse group of 12 Tech-Digital business founders over a 12–18-month period. Seven of the participants were female and 5 were male. The researcher used three c.45-minute semi-structured interviews together with a short questionnaire before the second and third interviews. Each interview was transcribed and coded using NVivo. Within-case narrative analysis was used to examine unique variations in entrepreneurs' emotional experiences and EP. Template analysis was then applied to investigate common themes within the sample.

Results

The results of the study will be available by April 2023, although publication of the final thesis is planned for September 2023.

Limitations

Given the qualitative nature of this research and intention to provide a rich, contextualized account of entrepreneurs' evolving emotions and passions, the results are not generalizable to UK Tech-Digital entrepreneurs or entrepreneurs in other sectors. Another potential limitation is that the researcher has significant expererience in Tech-Digital entrepreneurship, having founded two HRTech businesses. As pointed out by Berger (2015), even with critical self-reflection and reflexivity, this may lead the researcher to unconsciously project their own experiences in the way they observe and interpret participants' narratives.

Conclusions

This research enriches the body of research and literature on the role of emotions and EP in venture creation by providing insights into how entrepreneurs experience the inevitable highs and lows of their start-up journey. Moreover, it highlights the unique emotional experiences and sense-making of each entrepreneur in response to unfolding events, including how this shapes their motivation, behaviour, and self-identity. This is particularly salient for the design of training curricula offered by universities, start-up accelerators, and other entrepreneur training organizations in future. The research will also enable entrepreneurs to gain a better understanding of how their emotions and EP shape their identity, motivation and how the venture emerges.

Relevance to the congress theme

Entrepreneurship is becoming increasingly common in a fast-changing world of work, with more people of working age turning to Tech-Digital entrepreneurship as an alternative to traditional corporate roles. In this fast-changing context, it is important we conduct more research to augment our understanding of entrepreneurial processes and behaviours, including how emotions and EP emerge, are experienced, and impact an entrepreneur's start-up journey.

Keywords: Entrepreneurship, Passion, Emotions

Oral presentation OP401

The employee's sense of influence on the organisation: its dimensions and importance in fostering motivation and commitment

Justyna Pawlak & Małgorzata Adamska-Chudzińska | Cracow University of Economics

science

An important determinant of the quality of human capital is an organisation's ability to attract and retain talented employees. One way to achieve this is to strengthen their autonomous motivation. Especially in job positions where employee has to deal with sometimes uninteresting tasks requiring disciplined commitment (what is very often the case in work reality) it is the autonomous extrinsic motivation that can lead to the most effective performance. Identifying and implementing effective solutions to support employee autonomous motivation is therefore an important task for researchers and managers.

From the perspective proposed by self-determination theory, autonomous motivation includes intrinsic motivation and well internalised extrinsic motivation. Being autonomously motivated thus means that one is motivated by one's own interest in an activity (intrinsic motivation) and/or that the values and regulations associated with that activity have been integrated into the person (integrated extrinsic motivation). Autonomous motivation is therefore characterised by a sense of choice and freedom, whereas controlled motivation is based on a sense of pressure and the need to engage in a certain behaviour. The experience of autonomy at work is one of the main dimensions of the sense of influence on organisational reality, which in turn can determines the readiness for a proactive response on the part of the employee.

The present research attempts to find an answer to the question of whether and to what extent a sense of influence is a factor with such a level of attractiveness for employees that it will result in a high level of organisation commitment. Identifying the type and degree of this relationship can be a guideline for the design of motivational systems that will strengthen employees' willingness to bind themselves to the organisation for the long term and allow verification of some of the actions taken by management practitioner.

In our research we distinguish two manifestations of the sense of influence on organisational reality. The first emanates from the leader and manifests itself as enabling the employee to experience autonomy in their roles and is an invitation to the employee to take on the responsibility that comes with that autonomy. The second comes from the employee and manifests itself in his or her initiative and readiness to innovate. It requires, in turn, openness from the leader and willingness to support the proposed solutions. Based on the survey results, we develop a model of the employee's sense of influence in the organisation and organisational commitment.

The study was conducted on a sample of 541 employees and it used the author's Employee's Sense of Influence questionnaire and the organisational commitment model proposed by Mayer and Allen. The results showed that providing employees with a sense of influence has a positive impact on their affective and normative organisational commitment.

These findings provide insights and suggestions for managers, as they indicate how leaders can develop organisational commitment among their employees by adopting effective human resource practices that could lead to organisational competitiveness and increased productivity. The essence of any such action is the treatment of employees as subjects, which, depending on their position,

professional and personality predispositions and needs, might involve different forms of taking interest in the employees and creating space for independent actions.

Keywords: sense of influence, organisational commitment, autonomy

Oral presentation OP406

The future is subtractive

Georgios Fraros, Bernard Nijstad, Diana Rus & Eric Rietzschel | University of Groningen

science

Research goals

The discourse on sustainable innovation is dominated by a „more is more" mindset that focuses on additive transformations (e.g., adding new technologies). Ironically, this often leads the benefits of energy technologies to be canceled out by the further expansion of energy demands (Jevons Paradox). Thus, the sustainability transition will also require subtractive solutions guided by a „less is more" mindset (e.g., eliminating certain technologies, products or processes). The aim of this project, therefore, is to examine factors that mitigate the additive bias (i.e., the tendency to solve problems by adding elements to the existing situation) and foster the implementation of subtractive innovations, hence leading to a better balance between additive and subtractive change. In the present work, we are investigating potential cognitive factors that may favor or hinder the creation of subtractive solutions to problems.

Theoretical background

Recent research shows that people are more likely to make additive changes (adding elements to an existing situation) than subtractive changes (removing elements to transform a situation). However, the mechanisms behind this bias are not completely clear. As a first step in this project, we focus on a cognitive explanation, specifically by addressing the role of cognitive demands and construal level. Previous research has shown that instruction cues towards subtraction can weaken participants' additive bias, especially when people are under low cognitive load. This suggests that subtractive changes are more cognitively demanding (even when cued); however, this has not been directly tested yet. Furthermore, according to construal level theory, we suggest that subtractive changes might be less cognitively demanding under a high construal level, because construal level is positively associated with cognitive flexibility and creativity. As such, a high construal level could serve as a way to diminish the additive bias without incurring cognitive costs.

Methodology

In two experimental studies, participants will be asked to come up with creative solutions in a transformation task. In Study 1, we will replicate existing work on the additive bias, assigning participants either to a control condition or a condition with a subtraction cue. Moreover, we will include measurements of cognitive depletion and (exploratively) construal level. In Study 2, we will use the same transformation task as in Study 1, manipulating construal level (through temporal distance) by assigning participants to a high construal or low construal condition and measure their cognitive depletion as in Study 1.

Results expected

We are currently in the process of setting up the two studies and plan to run them this winter. The results are expected in early spring 2023. In Study 1, we expect participants to predominantly make additive choices in the control condition, but less so in the cue condition. Cues may help reduce the additive bias, but at the cost of cognitive depletion; therefore we expect cognitive depletion to be higher in the cue condition than in the control condition. In Study 2, we expect that under a high construal level, participants will make more subtractive changes than under low construal level;

however, in contrast to the cue effect in Study 1, we do not expect this increase in subtraction to be associated with higher cognitive depletion.

Limitations

The current study is a first step in a larger project and only addresses additive bias on the level of the individual change agent. In our future studies we aspire to explore additional determinants of additive bias, as well as the interplay between macro-environmental and organizational-level factors that affect top management and employee receptiveness to and implementation of subtractive ideas.

Relevance to the Congress Theme

By understanding the conditions under which subtractive innovations may occur, this research project contributes to the development of new competences that can help lead the way towards a sustainable future. It aims to understand how people think about problems and how their thinking may be influenced in order to consider subtractive transformations more seriously. This “new way of thinking” may eventually help to address urgent socio-ecological problems, by helping us to avoid falling into the trap of renewed overconsumption.

Relevant UN SDGs

It is widely agreed that addressing the world's pressing socio-ecological problems requires effective and innovative solutions. Sustainable innovation is the main focus of this project, which aims to create viable solutions to problems, such as the depletion of natural resources and the tendency towards excessive consumption and irresponsible production.

Keywords: sustainable innovation, additive bias, subtractive transformations

Oral presentation OP165

The Gender Bias Scale for Women Leaders: Gender bias and women's motivation to lead

Mona Algner, Universität Potsdam; Timo Lorenz, MSB Medical School Berlin; Doris Fay, Universität Potsdam

science

Research goals and why the work was worth doing

Despite efforts to achieve gender equality, women are still underrepresented in elite leadership roles. This might be due to bias and gendered barriers keeping women from entering and succeeding in leadership positions. Our aim was twofold: first, we wanted to translate and validate the Gender Bias Scale for Women Leaders (GBSWL; Diehl et al., 2020) in German and Spanish. The GBSWL is a heterogeneous instrument assessing a broad range of gender biases and has originally been developed for women leaders in the US. Second, we aimed to investigate the impact of gender bias on women's motivation to lead.

Theoretical background

We use role congruity theory (RCT; Eagly, 1987) and the theory of motivation to lead (Chan & Drasgow, 2001) as our overarching frameworks. RCT posits that the perceived incongruity between the (self-)ascribed female gender role and leadership roles lead to two forms of prejudice: 1) women are evaluated as less favorable compared to men as potential occupants of leadership roles and 2) women who exercise leadership behaviors experience backlash (i.e., evaluating women more negatively when acting as leader compared to men). This is because male and leader stereotypes contain more agentic, that is assertive or dominant, qualities (e.g., "think manager, think male"; Schein, 1973) than women, who ought to be warm, sensitive and helpful (i.e., present more communal qualities). Furthermore, recent meta-analytic results (Badura et al., 2020) suggest a small, but consistent gender difference in affective-identity motivation to lead, the facet that reflects mostly agentic qualities. We argue that gender biases are negatively related to women's affective-identity motivation to lead.

Design/Methodology/Approach/Intervention

In this study, we translated and validated the Gender Bias Scale for Women Leaders (Diehl et al., 2020) in German and Spanish samples of women with (n = 470) and without leadership responsibility (n = 400). We performed confirmatory factor analyses to establish factorial validity and conducted measurement invariance analyses between both the two countries and two leadership responsibilities.

We further ran ordinary least square regression analyses, controlling for relevant variables, to examine the influence of specific gender bias facets (i.e., male culture, unequal standards, constrained communication and lack of sponsorship) on women's motivation to lead.

Results

Confirmatory factor analyses (CFA) exhibited good model fit for an adapted version of the scale (CFI range = [.93 – 1.00], RMSEA range = [.000 - .098], SRMR range = [.013 - .060]). Results of the multi-group CFAs revealed at least metric invariance between all groups. We further found that specific gender bias facets, especially those pertaining to leadership identity and agentic qualities, have a statistically significant negative association with women's motivation to lead.

Limitations

Our study is not free from limitations. First, some items of the Gender Bias Scale for Women Leaders exhibited low standardized factor loadings and low reliabilities. Second, construct validation of the German and Spanish versions has only been tested in Germany and Spain, respectively, but not in other German or Spanish speaking countries. Thus, we advise scholars to be careful, when using the scale in German or Spanish speaking samples not from Germany or Spain, since nuances in terms of use of language might affect the meaning of items and thus validity of the instrument.

Conclusions

The adapted version of the Gender Bias Scale for Women Leaders can be used to assess the degree of gender bias experienced by women with and without leadership responsibilities in Germany and Spain. Thus, it can help to shed light on what keeps women from entering as well as succeeding in leadership positions. This knowledge can potentially be used to develop specific interventions on either organisational or individual level to foster gender equality at the workplace. We furthermore showed how women's motivation to lead is impacted by several forms of gender bias.

Relevance to the Congress Theme

To tackle the persisting gender inequality at work, change is imperative. We present German and Spanish versions of a scale to assess the degree of gender bias at work. Our hope is that scholars will use the scale to enhance the understanding of the gendered barriers women face at work, as well as develop and evaluate specific interventions to enable organisational change towards an equal future.

Keywords: women and leadership, motivation to lead, construct validation

Oral presentation OP566

The good, the bad and the... so what? A review of the "double-edge sword effect" in organizational research

Michael Clinton, King's College London; Jaqueline García Cordero, King's College London & Universidad Nacional Autónoma de México

science

Research goals and why the work was worth doing

The research sought to review the recent organizational literature to examine the treatment of the "double-edged sword effect" to evaluate its potential for describing aspects of organizational life. A double-edged sword effect reflects a pattern of results where a variable has both positive and negative effects concurrently, which can often appear paradoxical. At present, the examination of double-edged sword effects is popular with a seemingly growing number of concepts being identified as having these mixed outcomes (e.g. team diversity, occupational callings, citizenship behavior, HR practices) and can be seen in numerous reviews of the "dark sides" of concepts. So, against the background of a growing appreciation that many concepts within the field can be constructed as being a "double edge sword", we seek to 1) describe how the field is currently theorising and researching these effects, to 2) categorise double-edged sword effects into a more nuanced set of relationship patterns, to 3) differentiate them from other related-phenomenon within the field (e.g. too much of a good thing effects, multi-dimensionality), and then 4) develop good practice for researchers studying "double-edged sword effects" in relation to any variable in the wider field.

Theoretical background

While we believe that this work will have widespread practical and theoretical utility, we develop an example based within the area of employee wellbeing and careers. Accordingly, we draw on theory relating to occupational calling (Bunderson & Thompson, 2005), goal systems (Kruglanski, 2003) and eudaimonic wellbeing (Ryan & Deci, 2001).

Design/Methodology/Approach/Intervention

We conducted a review of all CABS-rated 3, 4 and 4* rated journals in the areas of general management, human resource management, organization studies and organisational studies for articles using the terms "double-edge sword" and "mixed blessing" in the five-year period between 2017-2021. We identified 333 articles that used these terms, of which just over 200 we identified as having directly examined a "double edged sword effect" either empirically or theoretically. We then sought to content analyse these articles to form the basis of the review.

Results obtained or expected (if not available, it must be made clear when they will be)

Early results are available, but will be developed further. They show that even over a five-year period, a sizeable increase in the use of the two search terms has occurred. Concerningly, they indicate many common misapplications of the term which is mistakenly used to describe a range of other effects, including moderated relationships, nonlinear relationships, and positive and negative dimensions of a construct. It is also common for studies to only examine one side of the double-edged sword (e.g. the dark side). The detection of a "double edged sword effect" (and labelling as such) is often the end point of a research study, with consideration of deep implications being offered by only a few studies. The examination of mechanisms (mediators) to explain a concept's relationship with contrasting findings is very rare.

Several “good practices” are generated from the review and then applied together to the topic of occupational callings and worker wellbeing, as a worked model.

Limitations

Given that researchers will use a variety of terms to describe these kinds of effects, it is possible that we did not review all relevant studies through our keyword search.

Conclusions – research and or practical implications/Originality/Value

The research clearly conceptualises what a double-edged sword effect is, what it is not, and how researchers can generate more insightful theoretical and empirical implications when studying concepts that are likely to have a set of positive and negative effects.

Relevance to the Congress Theme

The review seeks to directly address the greater complexity that will characterise the future and changing world of work.

Relevant UN SDGs

The research could relate to all, but the presentation will be particularly focused on good health and wellbeing.

Keywords: double-edge sword, wellbeing, calling

Oral presentation OP412

The impact of burnout symptoms on coping and appraisal of acute stressors: An event-based approach among Dutch riot police trainees

Liselotte Eikenhout, Open Universiteit / TNO; Joris Van Ruysseveldt, Open Universiteit; Wim Kamphuis, TNO; Roos Delahaij, TNO; Inge Hulshof, Open Universiteit

science

Police officers are exposed to acute stress situations while on duty, such as arrests, violent suspects, use of firearm, situations of human suffering (Abdollahi, 2002; Violanti et al., 2017). Ineffective or lacking coping with stressors increases risks of developing stress-related psychological issues, such as acute stress disorder or PTSD (Benight & Bandura, 2004; McLean & Clauw, 2004). Further, accumulation of stress can lead to burnout symptoms, reduced job performance and outflow of police officers (Anshel, 2000; Burke, 1993). To maintain psychological wellbeing effective coping is required, which depends on an individual's appraisal of the situation and the availability of coping resources (Hobfoll, 1989; Delahaij & Van Dam, 2017). Stressors can be appraised as both threatening and challenging and elicit specific emotions (appraisal theory; Lazarus, 1993), which trigger psychological and physiological responses (Crawford et al., 2010; Delahaij & Van Dam, 2017).

Theory and research generally focus on either the acute stress process, involving appraisal and coping processes in acute stress situations, or the chronic stress process, which involves accumulation of residual need for recovery (NFR) and burnout symptoms as a result of chronic work demands. To our knowledge, no studies incorporated measures of chronic strain in the appraisal and coping of acute stress situations, especially using an event-based approach. The goal of this study is to investigate these two processes as intertwined. Therefore, we examined the impact of burnout symptoms on the appraisal and coping of acute stress situations.

Drawing on theories of appraisal, COR, and efficacy beliefs, we test a model in which burnout symptoms moderate the relationships between coping self-efficacy (CSE) and appraisal emotions, and between appraisal emotions and NFR. On a sample of Dutch riot police (Mobiele Eenheid; ME) trainees (n=47) we used an event-based approach, that is we look at the effects of pre-measured variables on event-triggered variables. The ME is a national unit that consists of regular police officers who are trained for this additional role. During their regular working hours and spare time, the ME can be summoned for deployment at large events and riots, where they perform under varying, sometimes extreme circumstances that constitute acute stress events. ME-trainees are all subject to fixed acute stress events at the same stages in their training in the form of stressful exercises. As a result, it is possible to compare whether individuals react differently to the same event and what the effect of differences in their levels of pre-existing strain is.

Pre-existing strain (BAT-12; Schaufeli et al, 2019) and CSE (Police Resilience Monitor; Kamphuis et al., 2017) were measured at baseline, appraisal emotions (Stress Questionnaire; Delahaij & Van Dam, 2017; Folkman & Lazarus, 1985) and NFR (Need for Recovery Scale; Van Veldhoven & Meijman, 1994) were measured after the stressful event. After 16 days of training, participants were subjected to the acute stress event.

Moderated mediation analysis (Hayes' Process macro, model 58, 10.000 resamples; Hayes, 2018) showed that individuals with high levels of CSE experienced high challenge emotions, which then negatively affected NFR after the event. More importantly, the results indicated that for individuals who have high levels of burnout symptoms, low levels of CSE were associated with high threat emotions, while high levels of CSE were associated with low threat emotions. CSE, especially in

exhausted individuals, proved to play a key role in preventing negative experiences from stressful situations. Further research into the intertwinement of chronic and acute stress, also on larger samples, is needed to prevent negative outcomes for police officers and to make clear recommendations for future deployment.

We demonstrated that initial levels of burnout symptoms moderate the effect of CSE on threat emotions. We assume this process is relevant because NFR, following an acute stress event, could build up and be predictive of future burnout symptoms. Limitations of the study are low sample size, use of a healthy police officer sample, and generalizability to the general (riot) police population as only one acute stress event in a training setting was measured. This study demonstrates whether and how an event-based approach can be used to extend research on the combination of chronic and acute stress processes. Future research could focus on multiple events. Ultimately, results may lead to new insights into training and adaptive deployment of riot police and regular police personnel.

Our study relates to the congress theme The Future is Now: the changing world of work and the UN SDGs Good health and wellbeing and Decent work and economic growth, as we aim to gain insight into the possibilities of adaptive deployment and positive wellbeing for sustainable employment of police officers.

Keywords: burnout symptoms, acute stress process, police personnel

Oral presentation OP421

The Impact of Gender Norms on Gender Gap in Leadership: Focusing on Voice Pitch Analysis

Myung Jin Chung, University of Cambridge Judge Business School

science

We examine to what extent gender norms affect the voice patterns of women in leadership positions by analysing voice pitch. Motivated by studies that show links between women's vocal behaviours and gender stereotypes, we investigate whether gender inequalities are related to the gender gap in voice pitch. We hypothesize that women from countries with traditional gender norms will speak in higher-pitched voices than men and that the gender gap in voice pitch will be more pronounced compared to countries with less restrictive gender norms. Using 578 voice samples from 58 countries from 2019 to 2020, we find statistically robust patterns that the gender gap in average voice pitch increases in countries with less gender equality. These results provide suggestive evidence that gender norms play a critical role in the gender disparity of social leadership.

Considering the biological differences between the sexes – with a woman's average voice pitch being about an octave higher than a man's average pitch -– voice pitch can be a contributing factor to the smaller number of females in leadership positions. People with higher-pitched voices are often regarded as insecure, less qualified, and less dependable. This suggests that because women, in general, have higher-pitched voices than men, the voice pitch could contribute to fewer women holding leadership positions than men. Thus, we hypothesize that women in countries with strong gender norms use higher-pitched voices than women in countries with more flexible gender norms.

We compile a cross-country dataset of 58 countries containing 578 voice samples from 68 broadcasting programs between 2019 and 2020. We use an open-source phonetics software called Praat (ver. 6.1.38) to calculate average, minimum, and maximum voice pitches for each speaker. Our dataset also includes information on the speaker's gender, the date of the broadcast, and the type of program. Using the 2020 Global Gender Gap Index (GGI) from the Global Gender Gap Report published by the World Economic Forum, we measure the overall level of gender disparity among countries. We then divide countries into three equally sized groups by GGI, resulting in the top, middle, and bottom gender equality groups. Using an ordinary least squares (OLS) model, we measure the gender differences in average, minimum, and maximum voice pitches across these three gender equality groups while controlling for the month, year, program type, and country fixed effects.

Consistent with our assumption, we find that the gender gap in the average voice pitch decreases by 12 to 18 Hz for the top and middle gender equality groups in comparison to the bottom gender equality group. For example, in our sample, the average voice pitch in the bottom gender equality group is 145 Hz for men and 219 Hz for women, which creates a gender gap of 74 Hz. However, the gap decreases to 56 Hz in the middle group and 62 Hz in the top group. These differences translate to a 24% decrease in the voice pitch gender gap between male and female speakers in countries with average gender equality and a 16% decrease in countries with the highest gender equality. Even after controlling for detailed characteristics, including the time of the broadcast, program type, and country, the estimated coefficients for the gender gap in average voice pitch are robust and significant at the 1% level. These results provide suggestive evidence that gender norms play a critical role in the gender disparity of social leadership.

There are a few important caveats to these conclusions. First, we cannot completely rule out the possibility that voice pitch may be correlated with certain socioeconomic traits of an individual that

we cannot measure in this study. Also, some argue that the vocal behaviours of media professionals are heavily conditioned by the gender norms of society. Therefore, such trained speech patterns may not accurately represent the common language patterns of the public. Additionally, due to data limitations, our study only focuses on the pitch, a single acoustic parameter of voice.

This research examines the impact of gender norms on women's speech patterns in assuming leadership. Our focus on the voice pitch stems from numerous studies that show how the social construction of gender bias accounts for gender differences in vocalization. Using an OLS regression, we find that the gender gap in average voice pitch is wider in the countries with higher gender inequality compared to the countries with lower gender inequality. This paper contributes to the literature by being the first to conduct a cross-country analysis of the gender gap in voice pitch and to show a significant effect of gender norms on the vocal behaviour of women. These results are consistent with empirical patterns observed in previous studies. Our findings support the importance of gender parity for greater representation of women in the world of leadership.

Keywords: gender gap, leadership, voice pitch

Oral presentation OP439

The impact of managers' role-modelling on the leadership behaviours of their subordinate supervisors

Martin Grill, Pernilla Larsman | University of Gothenburg

science&practice

Research goals and why the work was worth doing

The construction industry is heavily affected by occupational accidents; in the year 2019 it accounted for more than 20% of all occupational fatalities in Europe. Leadership behaviours on construction sites, both generic and safety-specific, have been found to be associated with employees' safety-related behaviours, and safety-related behaviours have been identified as important antecedents of workplace accidents and injuries. The overall aim of the present study was to investigate how safety-leadership behaviours are fostered within the construction industry through managerial role modelling.

Theoretical background

One of the pathways through which senior managers' safety-leadership may influence workplace safety is through its influence on their junior managers' safety-leadership behaviours, via the mechanism of role modelling and imitation. Sims and Manz (1982) argue that modelling and imitation occurs regularly within organizations and are central to organizational functioning. Modelling may establish new behaviours and increase the frequency of existing behaviours.

Design/Methodology/Approach/Intervention

A two-wave longitudinal cohort study with 4 months between measurement occasions was conducted among construction site supervisors in Sweden (n = 51). Supervisors' ratings of their site managers' as well as their own generic and safety-specific contingent reward leadership behaviours were obtained by means of questionnaires. Cross-lagged panel models were tested within a path model framework to test the hypothesis that site managers' leadership behaviours prospectively influence supervisors' leadership behaviours.

Results obtained or expected (if not available, it must be made clear when they will be)

Site managers' contingent reward behaviours prospectively influenced supervisors' contingent reward behaviours, both generic contingent reward behaviours ($\beta = .29$, $p = .01$) and safety-specific contingent reward behaviours ($\beta = .22$, $p = .04$). For safety-specific contingent reward behaviours, a reversed effect ($\beta = .26$, $p = .03$) was also found; implying that supervisors' behaviours also prospectively influenced site managers' behaviours when it comes to safety leadership.

Limitations

All data included in the present analyses were obtained from a single source (i.e., the supervisors) using a single method of data collection (i.e., questionnaire data). This may lead to common-methods-variance, potentially inflating the associations between the study variables.

Conclusions – research and or practical implications/Originality/Value

The results of the present study indicate that senior leaders may improve workplace safety through their influence on junior leaders, via the mechanism of role modelling. This finding imply that senior

leaders can use role-modelling as a way of influencing the safety-leadership behaviours of junior leaders and thereby the occupational safety performance.

Relevance to the Congress Theme

Safety-leadership is a key component for organizations to maintain high occupational safety in a changing world of work. Understanding how safety-leadership behaviours can be transferred from senior to junior leaders is therefore urgent.

Relevant UN SDGs

Maintaining efficient safety-leadership in the construction industry is a prerequisite for good health and well-being of employees as well as decent work and economic growth.

Keywords: role-modelling, leadership, occupational safety

Oral presentation OP101

The Impact of Personality on Candidate Reactions to Selection Processes

Katy Welsh, Civil Service

science&practice

Research goals

With the continuing 'War for Talent' and the recent 'Great Resignation', it is clear that competition for talented employees is increasing. The selection process is often a key point of contact between individuals and organisations and there can be significant negative impacts of a poorly received selection process for both parties. Therefore, a better understanding of how selection processes may be perceived by individuals with different traits could help inform the design of processes which are viewed more positively and appeal to more diverse talent pools.

While there is a large body of research regarding the reactions of candidates to different types of selection processes, far less is known about the role personality plays in candidate reactions. Further, the majority of research in the field of candidate reactions has been with students and junior populations using traditional selection methods. This field study provided a unique opportunity to investigate the reactions of senior candidates internal to the organisation using newer, technology-enabled selection processes.

Theoretical background

The study was based on Gilliland's (1993) model of distributive and procedural justice, which identified a number of 'rules' which a selection process must follow in order to be perceived as just and fair by candidates. In addition, a recent review by Woods et al. (2020) on selection in the digital age concluded that practice has moved faster than research and that a more comprehensive evidence base is needed to support the application of technology in selection, in particular noting the need to review the changing nature of procedural justice in the digital age.

Methodology

A cross-sectional survey design was employed. An adaptation of Bauer et al.'s (2001) Selection Procedural Justice Scale was used to measure candidate reactions to the selection process and items from the IPIP were used to measure the Big Five Factors of personality.

Participants were applicants to a selection process for talent development schemes in the UK Civil Service. These prestigious development schemes attract a large number of applicants each year and are targeted at senior managers and leaders in the organisation. The selection process comprises two stages, stage one was the focus of the current study. In stage one, candidates were asked to complete two questionnaires, a candidate statement, and a situational judgement test. Following completion of these exercises, candidates were invited to complete the reactions questionnaire and the personality test. 625 participants completed the study.

Results

The responses were investigated through correlational analysis and significant relationships were investigated further using hierarchical multiple regression. The results of the study showed that Conscientious, Agreeableness and Neuroticism had small but significant relationships which candidate reactions, with Conscientiousness explaining the largest proportion of variance. Hypothesised relationships with Extraversion and Openness to Experience were not supported. The

relationships between personality factors and candidate reactions varied depending on the exercise investigated.

Socio-demographic factors were also investigated as control variables, with differences in some aspects of the reactions questionnaire found for Gender and Ethnicity.

Limitations

The study was carried out with internal candidates for selection onto development schemes, meaning that the findings may not generalise to other selection settings. However, the candidates were from a large variety of professional backgrounds and the schemes represent a significant career development step, therefore there are similarities with other high-stakes selection processes.

Implications

The study expanded the evidence base into the factors driving candidate reactions. By investigating a multimethod selection process it was possible to compare reactions to a range of commonly used, but under-researched selection methods in the same sample. The research also investigated a population who have been given limited attention to date.

The research highlighted that a combination of selection exercises and personality factors play a role in candidate reactions. Practitioners would benefit from considering how their selection process will be perceived by potential candidates with traits that are desirable to the job role in question, and should consider using selection methods which comprise different exercises in a single early stage in order to maximise their chances of attracting the broadest pool of potential talent.

Relevance to the Congress Theme

This research responds to the theme of the changing world of work by testing well-established concepts with newer technology-enabled selection methods and investigates current populations of interest in the current economic climate of the 'Great Resignation'.

Keywords: selection, personality, technology

Oral presentation OP376

The Impact of Telecommuting on Psychological Distress: A Cross-Lagged Study during the COVID-19 Pandemic

Tinne Vander Elst, Tilburg University & IDEWE Group; Lode Godderis, Isabelle Boets & Sofie Vandenbroeck | KU Leuven & IDEWE Group

science

Telecommuting is "a work practice that involves members of an organization substituting a portion of their typical work hours to work away from a central workplace—typically principally from home—using technology to interact with others as needed to conduct work tasks" (Allen & Golden, 2015). Since the beginning of the COVID-19 pandemic, many governments have encouraged or mandated telecommuting to contain the spread of the virus. This massive switch to telework may have an important impact on workers' mental health. Research from before the pandemic is mainly cross-sectional and yields inconsistent findings on the effect of telecommuting on health. Thereby, clear insights into the explanatory mechanisms of this effect are lacking. We aim to enhance our understanding of the impact of telecommuting on psychological distress during the COVID-19 pandemic by simultaneously investigating four explanatory mechanisms. In doing so, we use four-wave longitudinal data, examining these processes within individuals.

Building on the Job Demands-Resources model and extensions adding the effect of organizational context factors to the model, we predict that telecommuting acts as an HRM practice affecting employees' well-being through changes in their perceived work characteristics. Indeed, telecommuting was first introduced by companies as an important HRM practice to save costs and create advantages for employees (e.g. less travel costs, more flexibility, better work-home balance). In this regard, it can be conceived as an organizational resource that positively affects well-being through individual job resources. However, during the COVID-19 pandemic, many employees were forced to work from home exclusively, which came with some challenges. First, extensive telework might have blurred the boundaries between work and personal life and make detachment from work at home more difficult, thus increasing work-home interference (WHI). Second, telecommuting might have increased home-work interference (HWI), especially as many employees had to combine telework with homeschooling and taking care of their child(ren). Finally, telework could have decreased the interactions with colleagues, lowering social support by colleagues and increasing feelings of loneliness. Hence, in this study, we predicted telecommuting to act as an organizational demand increasing workers' psychological distress through these individual (job) demands.

Data were collected in a heterogenous sample of 5959 Belgian workers, who participated in at least one of four online surveys during the initial lockdown and a period of initial relaxations of the COVID-19 measures (April-June 2020, time lag of four weeks between measurements). Random Intercept Cross-Lagged Panel Modeling using MPlus 8.7 was conducted to investigate within-person processes over time and to test hypotheses.

Within-person level results show that the effects of telecommuting on HWI, social support and loneliness depended on the time of measurement. While telecommuting positively affected HWI at the peak of the COVID-19 wave when schools and daycare centers were closed (from T1 to T2), it was only related to a decrease of social support and an increase in loneliness at the end of the study when people could slowly return to their workplaces (from T3 to T4). There was no direct effect of telecommuting on WHI and psychological distress. Next, loneliness positively predicted psychological distress earlier in the study (from T1 to T2 and from T2 to T3), social support negatively predicted

psychological distress from T2 to T3 and from T3 to T4, and WHI and HWI affected psychological distress only from T3 to T4. No indirect effects from telecommuting to psychological distress via the mediators were found.

Study limitations are the use of self-reports to measure our study variables and the finding that several lagged effects were found to be unstable across measurement points.

This study contributes to our knowledge of the explanations of the effects of telecommuting on mental health. We found that the effects of telecommuting on HWI, social support and loneliness differed depending on the stage in the first wave of the COVID-19 pandemic. This suggests that the context presents certain challenges to teleworkers that may or may not make telecommuting challenging in terms of HWI, social support and loneliness. Customized support is recommended depending on the stage in the pandemic (e.g. attention to HWI when schools and daycare centers close, attention to social contact when the pandemic lasts longer and there are opportunities to return to the workplace again).

This study best fits within the '8. Organisational design and development' EAWOP topic area. It also contributes to the UN Sustainable Development Goals of 'Good health and wellbeing' and 'Decent work and economic growth', as it investigates the impact of telecommuting on employee well-being and addresses ways to protect the welfare of home workers.

Keywords: Telework, Employee well-being, Work-life conflict

Oral presentation OP404

The impact of the COVID-19 pandemic on the prevalence of physicians' burnout, depression, and sickness absence

Emma Brulin, Karolinska Institutet; Ulrik Lidwall, The Swedish Social Insurance Agency and Karolinska Institutet; Anna Nyberg, Uppsala University; Alexander Wilczek, Karolinska Institutet; Kerstin Ekberg, Linköping University; Bodil J. Landstad, Mid Sweden University

science

The unprecedented demands on clinical practice and the disruptions caused by the COVID-19 pandemic have contributed to physicians' experience of higher levels of burnout, psychological distress, anxiety, insomnia, and depression with variations across workplaces and specialties. A few longitudinal studies indicate that the level of mental health problems increased among, especially, front-line physicians during the pandemic. However, knowledge is limited due to methodological shortcomings or restricted samples. To summarise, many studies focus on one single clinic or hospital or only physicians at the frontline leaving out a large share of physicians. Moreover, many studies have small samples and short follow-up times. This study uses a nationally representative sample of physicians from various medical specialties and positions (physicians in training, specialists, and consultants) to expand current knowledge.

This study aims to investigate the impact of the COVID-19 pandemic on physicians' mental health problems by assessing changes in the level of burnout and depression between 2021 and 2022 among physicians in Sweden. Also, we will investigate whether burnout and depression in 2021 predict the prevalence of sickness absence. Differences across genders, hierarchical positions, and specialties will additionally be explored.

We will draw on data from the Longitudinal Occupational Health survey for HealthCare professionals in Sweden (LOHHCS). A questionnaire was distributed to a representative sample of physicians in the Swedish occupational register from February to May 2021 (T1). A follow-up questionnaire was distributed from March to June 2022 (T2). A total of 1575 physicians answered the questionnaire at both times. The Burnout Assessment Tool 12 (BAT) was used to assess burnout, and the Symptom Check List 6 (SCL) was used to assess depression. Data on sickness absence derives from Swedish Social Insurance registers and covers all the number of days on sick leaves, exceeding 14 days until June 2022.

The full results are yet to be compiled. Preliminary results show that the mean value of burnout measured with the BAT score has increased in the total sample of physicians from 1.80 to 1.91. For female physicians, the mean level on the BAT score in 2021 was 1.86 and 1.99 in 2022. For male physicians mean score in 2021 was 1.71 and in 2022 1.81. The prevalence of depression was 3.7% in 2021 and 5.5% in 2022. The prevalence of depression among female physicians increased from 4.1% in 2021 to 6.4% in 2022 and among male physicians from 3.1% to 4.3%. Further analyses will be carried out to determine if there are significant differences between 2021 and 2022 across groups of physicians in Sweden. Also, logistic regressions will be carried out to determine if burnout and depression in 2021 predict sickness absence.

A limitation of this study is that no data was collected before the start of the pandemic. That would have given us the opportunity to monitor the full impact of the pandemic.

Based on these preliminary results, we conclude that mental health problems have increased in Swedish physicians between 2021 and 2022.

Relevant to this study are the UN Sustainable Development Goals ‘Decent work and economic growth' and ‘Good health and well-being’. Furthermore, this study is relevant to the congress theme by emphasising the urgent need to explore organisational shortcomings that drive and maintain ill health among healthcare workers. This study has relevance for theme 18 well-being and theme 15.

Keywords: burnout, sickness absence, physicians

Oral presentation OP34

The impact of transformational and transactional leadership on employee engagement in the context of the COVID 19 pandemic

Michael Stadler & Frithjof Müller | School of Management and Law, ZHAW

science

Research goals

The primary aim of this study is to investigate whether and what relationships exist between transformational and transactional leadership styles and employee engagement in the context of the COVID 19 pandemic.

Theoretical background

The outbreak of COVID-19 confronted many companies with new challenges (Aditama & Riyanto 2020). Managers play a central role in reducing the discomfort of employees in this exceptional situation and ensuring that the employee engagement of the workforce is maintained (Aditama & Riyanto 2020).

In general, leadership can be considered a substantial driver of employee engagement (Bedarkar & Pandita, 2014). Both transformational and transactional leadership can be used to influence employee engagement (Breevaart et al., 2014). Transformational leadership, as opposed to the transactional method, motivates employees to not only meet but exceed the expectations of the respective leader (Bass, 1996, p. 2). Although elements of both styles may trigger additional effort from employees, transformational leadership produces better results in terms of effectiveness (Bass, 1990). Nevertheless, transformational leadership is not a substitute for transactional leadership, but a complement to that style (Bass, 1999).

Due to the pandemic and its impact on the world of work, it is now necessary to review how leadership styles influenced employee engagement. Measures that have been taken in organizations to contain the virus, such as social distancing regulations, influenced the relationship between superiors and subordinates and led accordingly, to certain changes in leadership (Chen & Sriphon, 2021).

In the past, the linkage between the two research areas of leadership and employee engagement has been pointed out and studied in different countries (cf. e.g., Li, Sun, Taris, Xing & Peeters, 2020). The specific use of transactional and transformational leadership has also been considered in combination with employee engagement (see, e.g., Breevaart et al., 2014). However, under the current external circumstance, specifically the global pandemic, little[HVE(1] has been conducted in this regard. Initial research has been completed in which either the area of leadership or employee engagement has been analyzed in the context of COVID-19. For example, it was found that in this exceptional situation, it is significant for employees to report to a leader who has a clear vision of the future for the team (Tiwari & Singh, 2021). In this regard, the presence of an inspiring vision resonates with transformational leadership (Bass, 1999). However, because the consequences of the virus were not felt in many parts of the world until the spring of 2020, there are generally few publications in which there is an exploration of leadership or employee engagement. There has been no[HVE(2] consideration of transformational and transactional leadership, employee engagement, or COVID-19. Consequently, it is unknown whether the insights generated in this regard are also valid

under the current pandemic conditions. Furthermore, the consequences triggered by the virus, such as short-time work, have not yet been included in the research.

Methodology

An online survey with 280 participants was conducted applying the validated German version of the Multiple Leadership Questionnaire (Felfe, 2006) for assessing transactional and transformational leadership and employee engagement was measured by the survey of Rich et al. (2010).

Results

The study found that transformational leadership style has a positive relationship with employee engagement. Also, each of the four associated sub-elements (Idealized Influence, Inspirational Motivation, Intellectual Stimulation, Individualized Consideration) has positive relationships with Employee Engagement. In the case of transactional leadership, a positive (Contingent Reward), a non-significant (Management by Exception: active) and a negative (Management by Exception: passive) relationship to employee engagement was found for the three components. Overall, transformational leadership is used more frequently than the transactional approach.

Limitations

As the current study focused on the two theoretically and practically established leadership constructs no statements with respect to other up to date leadership approaches can be made.

Conclusions

Through the findings of this work, the previous research results can also be largely confirmed in the context of the COVID-19 pandemic. Consequently, even under the current circumstances, it is recommended that transformational leadership style is primarily used and transactional leadership style should be used as a supplement in order to be able to generate an optimal basis for high employee engagement.

Relevance

In the context of the changing world of work – there is more remote work than ever before - it is important to learn more about how organizations are able to effectively manage these situations by applying efficient leadership styles.

Keywords: Leadership, Employee Engagement, COVID-19

Oral presentation OP19

The impact of transformational leadership on workers' personal resources: Latent profile analysis and links with physical and psychological health

Daniel Cortés-Denia, University of Jaén; Esther Lopez-Zafra, University of Jaén; Janine Bosak, Dublin City University; Manuel Pulido-Martos, University of Jaén

science

Research goals: This study aims to i) identify latent 'resources' profiles among two samples combining vigor at work, work engagement, and vigorous, moderate, and walking physical activity levels; ii) examine the link between the identified profiles and indicators of psychological and physical health; and iii) test whether different levels of transformational leadership determine the probability of belonging to a particular profile.

Theoretical background: Several studies have examined the impact of leadership on employee wellbeing and health, and their underlying pathways. Yet, this research has focused on a variable-centred approach. In contrast, we adopted a person-centred approach; it allowed us to identify different groups of employees to know the implications that transformational leadership has on them, and which results to expect at the employee well-being level. Thus, the combination of vigor at work, physical activity and work engagement could help to better understand their jointly effects addressed in worker´s profiles, following job demands-resources theory.

Design/Methodology: Two samples of workers (N Sample 1 = 354; N Sample 2 = 158) completed a cross-sectional survey before their annual medical examination at a company for health surveillance and control in Spain.

Results: For Sample 1, results from latent profile analysis yielded three profiles: Spiritless , Spirited and High-Spirited . Both High-Spirited and Spirited profiles showed a positive relationship with mental health, whereas Spiritless showed a negative relationship. For Sample 2, two profiles (Spirited and Spiritless) were replicated with similar effects on mental health to those found in Sample 1, but none of them was found to be related to total cholesterol biomarker values. In both samples, transformational leadership determined the probability of belonging to favourable profiles regarding to resources.

Limitations: Although we carried out two latent profile analysis in two samples to enrich the analyses, the results and the findings of the study, the reduced number of participants with biomarkers is likely to have affected the number of profiles in Sample 2. Moreover, workers´ data were mainly obtained through self-report measures, except for the cholesterol biomarker.

Conclusions – research and or practical implications/Originality/Value: Transformational leadership was an important variable that increased the probability of pertaining to a more positive profile (High-Spirited/Spirited vs. Spiritless) and consecutively with better mental health. This research can provide to the health practitioners a guide to categorize the workers into different profiles and to boost changes in profile membership by fostering transformational leadership.

Relevance to the Congress Theme: The relevance of this study derives from the fact that the world of work and the types of workers are changing year by year. For that reason, we used a person-centred approach, analysing how variables fluctuate within people.

Relevant UN SDGs: This study contributes to the third goal (good health and well-being) of the Sustainable Development Goals.

Keywords: personal resources, physical/psychological health, transformational leadership

Oral presentation OP223

The impact of workplace stress, organizational commitment, and self-efficacy on burnout among Croatian workers

Natalija Smrtić, LUSH manufaktura d.o.o.; Mirta Mandarić, PEVEX d.d.

science

Research goals and why the work paid off : The goal of this study is to examine the contribution of psychological demands and job control as variables of workplace stress and affective, instrumental, and normative organizational commitment in explaining disengagement and exhaustion as burnout dimensions among employees in Croatia. Additionally, the aim is to examine the mediating role of self-efficacy between psychological demands and job control as variables of workplace stress and disengagement and exhaustion as variables of burnout. This research represents a valuable contribution to explaining the effects of work and personal resources on mental health. The obtained results can contribute to the increase in the awareness of organizations about the importance of the mental health of employees, planning interventions for the prevention of negative health outcomes of employees, building resilience, and increasing commitment to the organization.

Theoretical background : The desire to achieve the best results combined with a busy lifestyle often leads to burnout symptoms in the workplace. This disrupts daily functioning and reduces professional efficiency. Burnout syndrome is the result of chronic workplace stress that has not been successfully managed (WHO, 2019). Research shows that workplace stress contributes to burnout (Khamisa et al., 2017; Varjačić, 2013). Individual health outcomes are also related to work attitudes, with organizational commitment being both a risk and a protective factor for burnout (Enginyurt et al., 2015; Sarisik et al., 2019). Furthermore, personal beliefs have a huge role in an individual's well-being and mental health. According to Yao et al. (2018) self-efficacy has the most important protective role in job-related burnout. It is a personal resource that can be used to cope as it is one's belief that one can achieve the goals one sets (eg. Schwarzer et al. 1995). Self-efficacy can mitigate the negative effect of stressors on burnout and prevent burnout (Makara-Studzińska, 2021).

Design/Methodology/Approach/Intervention: 135 employees (51 men and 84 women) from different industries participated in the research. 8.15 % of participants belong to the age range from 18 to 25 years, from 26 to 30 years 38.52 %, from 31 to 40 years 43.70 %, from 41 to 50 years 6.67 %, and from 51 up to 60 years 2.96 % of participants. The measuring instruments were the Job Content Questionnaire - JCQ (Scale of Psychological Demands and Job Control), the Three-Component Organisational Commitment Scale, the General Self-Efficacy Scale, and the Oldenburg Burnout Inventory. The participants received an online questionnaire via e-mail or social networks.

Obtained results: Two hierarchical regression analyses were conducted with dimensions of burnout as criteria. Demographic variables were included as predictors in the first step, dimensions of workplace stress in the second, and dimensions of organizational commitment in the third step. Affective commitment is obtained as a negative predictor and instrumental commitment as a positive predictor of disengagement. Job control and affective commitment are negative predictors, and psychological demands are shown to be positive predictors of exhaustion. In the relationship between the dimensions of workplace stress and burnout, self-efficacy is not a mediator in the dimension of disengagement. However, partial mediation was achieved between job control and exhaustion, while there was no mediation effect for psychological demands.

Limitations: The research was conducted on a small sample, and the respondents were not divided by industries, which can differ significantly in working conditions and job requirements. Also, some

authors point out three dimensions of burnout - emotional exhaustion, depersonalization/cynicism, and feeling of insufficient achievement, while in this research only two were measured.

Conclusions – research and/or practical implications/Originality/Value: Lower affective commitment and higher instrumental commitment predict disengagement. Lower job control, higher job demands, and lower affective commitment predict exhaustion. Self-efficacy is a partial mediator in the relationship between job control and exhaustion. The results contribute to the design of interventions aimed at strengthening self-efficacy as a protective factor. Interventions can be designed with a focus on leadership academies aimed at creating psychologically safe and positive working environments.

Relevance to the theme of the Congress: Unlike traditional organizations, today more employers recognize the importance of workplace well-being. The future of work is the well-being of employees. It is our duty to promote general health, the happiness of employees, and a supportive workplace.

Relevant UN SDGs: Our research is relevant to the goal Good health and well-being. We provide insight into the contribution of organizational and personal factors to well-being.

Keywords: burnout, stress, organizational commitment

Oral presentation OP633

The importance of a discrepancy between preferred and actual proportion of remote working in predicting intention to leave

John Hackston, The Myers-Briggs Company

science&practice

Purpose and goals

Organizations seek to reduce staff turnover. Previous research has shown intention to leave one's job can relate to factors such as managerial support, job satisfaction and work-life balance. However, now many organizations are planning a post-COVID return to the office, those who now remote or hybrid working may seek a new job. As part of a study into attitudes to remote, hybrid and non-remote work, this paper investigates factors underlying workers' intentions to leave their job. This is relevant to organizations considering a mandated return to the office, and for workers wishing to influence how such policies may be applied.

Theoretical background

Many enjoy working from home and may not wish to return to the office full-time. Where there is a mismatch between preferred amount of time in the office and how much time actually spent there, workers may consider leaving their job; the larger the difference, the more likely this is.

Personality differences exist between remote and non-remote workers, and these are likely important in understanding why individuals do or do not wish to return to the office, and in guiding organizations to shape effective strategy. Research using the Myers-Briggs (MBTI) model show that those with an Intuitive (N) and/or a Perceiving (P) personality preference are more likely to be looking to leave their jobs than those with a Sensing (S) and/or a Judging (J) preference.

Methodology

Data was collected online from participants who had previously completed the MBTI assessment. 405 people took part, representing a wide range of industries, job types and occupational levels. They were asked for their MBTI type, their views about their job, and both for the percentage of time they actually worked remotely and the percentage they would prefer to do so, in each case choosing one of 12 categories scored from 1 (0% remote working) and 2 (11-20%) up to 12 (100%) The difference between preferred and actual working was calculated (preferred category score – actual category score), resulting in a score from -11 (preferred remote working much greater than actual) to 11 (actual remote working much greater than preferred).

Other possible predictors of intention to leave included job satisfaction, feeling valued and included, work-related stress, managerial support and personality type.

Results

Fewer respondents wanted to work entirely remotely, or entirely non-remotely, than actually did so. 42% would like to work remotely more than they do now, 27% matched their preference, and 31% would like to work in the office more often.

Respondents with a mismatch between remote working preference and actuality were more likely to say they were looking for a new job, especially those working remotely much less than they

wanted. 57% of those with a (preference-actual) score of -11 to -6 agreed or strongly agreed that they were looking for a new job, compared with 20% of those with a score of 6 to 11.

Intention to leave correlated -.553 with job satisfaction, -.472 with feeling valued and included, .195 with work-related stress and -.440 with managerial support (all sig at the 0.01% level)

Those Intuition preferences were more likely to be looking for a new job than those with Sensing (chi-square 9.953, sig at the 5% level). There was no significant relationship with Judging-Perceiving or other MBTI dimensions.

A univariate ANOVA showed that both the discrepancy between preferred and actual amount of remote working and the Sensing-Intuition dimension showed a significant effect, though not as strong as job satisfaction, feeling valued and included, and managerial support. Work-related stress did not show a significant effect. A univariate ANOVA omitting work-related stress showed a Rsquare of .494 and adjusted Rsquare of .429.

Limitations

Due to survey space, some possibly relevant factors were not included, such as salary and work-life balance.

The data was self-report and correlational.

Conclusions

The discrepancy between preference and actuality in remote working accounted for unique variance in intention to leave, over and above job satisfaction, feeling valued and included, and managerial support. Those working remotely much less than their preferred level were more likely to say that they were looking for a new job. If an organization mandates that all employees return to the office, this could result in an increase in intention to leave and losing valuable employees. Organizations and individual managers avoid blanket back-to-office policies without very good reasons.

Relevance to Congress theme

Following COVID, many organizations opined that large-scale remote and hybrid working was temporary and showed an interest in reverting back to an office-based workforce. This is relevant to the congress theme of “The Future is Now: the changing world of work”.

Keywords: intention to leave, remote working, retention

Oral presentation OP305

The importance of being available: the consequences of working flexibly on team processes and team outcomes

Sabina Hodzic, University of Graz; Martina Hartner-Tiefenthaler, TU Wien; Bettina Kubicek, University of Graz

science&practice

Research goals

Working from home has become an everyday reality for many employees. Although there is now a wide range of research on the advantages and disadvantages of flexible forms of work, these almost exclusively consider individual effects. The effects of flexible work on team processes and team outcomes have received little attention so far.

The point of connection between teams and flexible working arrangements usually occurs in the domain of virtual teams research. However, studies on flexible work and virtual teams have so far been two largely unconnected research streams. The aim of this work is, therefore, to connect these two research streams and to take the team level into account in flexible work. Specifically, we explore the effects of flexibility on team processes and team outcomes among teams who work flexibly. We operationalize flexibility through team members place and time overlap and through perceived team members' availability.

Theoretical background

Leaning on the adaptation of the Input-Process-Output (IPO) Model (Dulebohn & Hoch, 2017), we focused on the team level for input, process and output factors. With regard to input factors, we considered the composition of the team in terms of time and place overlap, as well as the perceived availability of other team members. To capture the team processes of teams working flexibly, we focus on team communication, team planning and coordination. Finally, we considered group outcome perceptions and team performance as relevant output factors. This model has been specifically adapted for studying virtual teams because it includes aspects relevant for virtual teams and their effectiveness and therefore allows us to identify factors that we consider important for success in teams that work flexibly.

Methodology

In total 94 teams (that work flexibly to some extent) and their team leaders answered the survey between May 2020 and February 2022. Teams ranged in size between 3 and 22 team members (M = 5.6 team members, SD = 2.47; team response rate 66.75%).

Team members' place and time overlap was assessed asking respondents to rate how often they usually worked at the same place and time with other team members and then aggregating these scores for each team. Aggregate team scores were also obtained for perceived availability of team members, three dimensions of team communication, team coordination and team planning. Managers' evaluations were obtained for group outcome perceptions and team performance.

Regression analyses were performed using SPSS PROCESS 4.1 Macro (Hayes, 2013) to test hypothesized mediations with team overlap and perceived team availability as independent variables, team communication (knowledge sharing, communication quality and spontaneous communication), coordination and planning as mediators and team outcome perception and team

performance (both assessed on the manager level) as dependent variables. Mediation analysis were performed for each mediator separately, because of their high bi-variate correlations which could cause problems of multicollinearity.

Results obtained

Results revealed no effect of team members' place nor time overlap on the team outcome nor the team processes. Perceived team member availability, on the other hand, predicted managers' outcome perceptions through team coordination (b=.23, 95% CI, .089 to .401), team planning (b=.15, 95% CI, .065 to .253), knowledge sharing (b=.16, 95% CI, .008 to .329) and communication quality (b=.18, 95% CI, .027 to .337), as well as team performance through team planning (b=.13, 95% CI, .006 to .249). All indirect effects represented full mediation.

Limitations

Even though we collected data on both employee and manager level, the data is still cross-sectional, and no objective indicator of performance was used. Furthermore, the question remains whether the conceptualization of team overlap adequately reflects team flexibility or whether a different way of measuring team members objective flexibility should be applied.

Conclusions

The main contribution of our work is to merge two separate research streams – flexible work and virtual teams (Raghuram et al., 2019) – and provide new insight into the effects of workplace flexibility among teams. Our results showed that perceived availability, but not time and place flexibility, are related to team processes and team results. It seems that for efficient teamwork, it is less important whether team members work flexibly but whether they are easily reachable and responsive to each other. Therefore, our main take home message for practitioners is to establish clear, uniform rules for availability/reachability among teams that work flexibly. Moreover, we contribute to the literature on teams by introducing a new team communication scale suitable to use for all teams but especially in the context of flexible teams.

Keywords: flexible work, teams, availability

Oral presentation OP560

The importance of servant leadership features towards creating a conducive diverse climate: A dominance analysis

Sean McCallaghan, Optentia Research Focus Area North-West University, Vanderbijlpark Campus

science&practice

Research goals and research importance: Leadership plays an integral role in creating positive perceptions towards diversity. Unfortunately, minimal research has been conducted to determine how leadership and primary features of servant leadership could enhance a conducive diversity climate. Consequently, the objectives of this research were twofold. The first objective was to examine the impact of servant leadership on diversity climate, and secondly, to determine which characteristic of servant leadership would contribute the most towards a conducive diversity climate.

Theoretical background: With workforces becoming more diverse, leadership and diversity will remain an important and relevant topic for any organisation. Servant leadership can be integral in organisations experiencing change due to increased diversity. One should keep in mind that a diverse organisation is a culmination of different races, cultures, nationalities, religions and even sexual orientations, which require specialist managerial knowledge.

In essence, servant leadership is a service to followers. Servant leaders would typically display behaviours of interpersonal support, building community, altruism, egalitarianism and moral integrity. In terms of diversity climate, organisations manage diversity through policies and practices concerning diversity to create an inclusive and diverse-friendly environment. Employees form perceptions of these managerial involvements and are known as diversity climate. Diversity climate is an essential facet for any organisation, mainly due to the associated benefits for both employees and organizations and therefore, organisations will strive to stimulate a conducive diversity climate.

Employees and managers in diverse organisations will require knowledge and skills to manage and lead heterogeneous work teams and groups. Servant leadership will be an essential leadership style due to its high emphasis on morality and contributing towards a sense of interactional justice, optimistic attitude and commitment to change. Although previous examinations have found positive relationships between servant leadership and inclusion, there seems to be a research opportunity to examine servant leadership and diversity climate.

Methodology: The quantitative cross-sectional study collected 230 responses from a convenience sample. Respondents from the South African financial, retail and manufacturing sectors completed measures for servant leadership, including characteristics of servant leadership (interpersonal support, building community, altruism, egalitarianism and moral integrity) and diversity climate. The statistical analysis included descriptive and reliability statistics, a confirmatory factor analysis, correlation analysis, standardised regressions and a dominance analysis to determine which feature of servant leadership would contribute the most towards a conducive diversity climate. A dominance analysis can demonstrate the relevant importance of each predictor (servant leadership characteristics) in a specific model.

Results: The results found evidence of a reliable (interpersonal support, $\alpha = 0.92$; building community, $\alpha = 0.86$; altruism, $\alpha = 0.91$; egalitarianism, $\alpha = 0.89$; moral integrity, $\alpha = 0.92$) and valid model ($\chi 2 = 22.64$; $df = 5$; $p < 0.001$; TLI = 0.96; CFI = 0.98; RMSEA = 0.01). The correlation analysis further revealed all features of servant leadership were significant and positively related to diversity climate. The results from the standardized regressions found an improvement in servant

leadership characteristics will result in an improvement in diversity climate. The dominance analysis further showed moral integrity to dominate as a predictor (41%) followed by building community (31%), altruism (11%), interpersonal support (10%) and Egalitarianism (7%).

Limitations: The research approach and design do not allow causality conclusions, while the sampling technique restricts conclusions to the sample group. Data were collected from South Africa, and future studies should consider including a wider audience with a longitudinal research design in order to examine the impact of possible interventions.

Research/Practical Implications: Organisations who wish to enhance a diversity climate with limited resources can adopt a focused strategy, emphasising developing moral integrity and a sense of building community.

Value: A study of similar nature does not yet exist. Therefore the findings contribute to the body of knowledge for servant leadership and diversity climate. The information can also be used to train managers tasked with managing diversity in organisations.

Relevance to congress themes: A conducive diversity climate is manifested in how well an organisation is able to manage diversity and create an inclusive environment. Knowledge of servant leadership features that can contribute towards a conducive diversity climate is beneficial towards both practitioners and scholars.

Keywords: Diversity climate, servant leadership, dominance analysis.

Oral presentation OP498

The importance of working models in the relationship between green tape and psychological safety

Bárbara Posse, University of Coimbra

science&practice

The study has the main objective to test how green tape and psychological safety are positively related by the working models.

It was used the concept of psychological safety, as defined by Edmondson (1999), as well the working model that the workers have been adopting, namely regarding it being an in-person, fully remote or hybrid model, and asses the effect that the effectiveness of the rules of an organization (green tape) has in this relationship.

The data was collected from a convenience sample of workers that were employed by the time of the collection of the data. The collection happened between January and February 2022.

The sample was composed by 360 workers with different academic backgrounds, from Germany, Portugal, and Brazil, and aged between 20 and 69 years. The participants were from the different activities sectors.

The used protocol was formed by four questionnaires: sociodemographic questionnaire, working model questionnaire, green tape questionnaire developed by De-Hart Davis (2008) and the psychological safety questionnaire developed by Edmondson (1999), all of them validated in English and Portuguese.

Relatable to the hypothesis, were stablished the follows:

H1: There is a positive and significant correlation between green tape and psychological safety.

H1a: There is a positive and significant correlation between green tape and psychological safety for workers in an in-person working model.

H1b: There is a positive and significant correlation between green tape and psychological safety for workers in a remote working model.

H1c: There is a positive and significant correlation between green tape and psychological safety for workers in a hybrid working model.

H2a: There is a positive relation between green tape and psychological safety in an in-person working model.

H2b: There is a positive relation between green tape and psychological safety in a remote working model.

H2c: There is a positive relation between green tape and psychological safety in a hybrid working model.

H3: There are significant differences between the working models and green tape.

H4: There are significant differences between working models and psychological safety.

The main conclusion drowned from the study was that green tape always exists, regardless of the type of working model used, so if the requirements defined by DeHart-Davis (1999) are met, there will always be rule effectiveness.

Initially, was expected that the effectiveness of the rules would always be higher when it came to in-person work context, than a remote or hybrid. That didn't happen, the green tape, exist in an equal way, regardless the working model. Such results can be explained by the timing of this research, post-Covid-19 pandemic. During the Covid-19 pandemic the world was forced to "shut-down" due to the rapid spread of the new deadly virus (Hatipoglu, 2020). This resulted in a needed of adaptation of the world of work (Moens et al., 2012).

To test the first hypothesis established, it was essential to try to understand if the effectiveness of the rules (green tape) and psychological safety were correlated, something which was proved, so when exist green tape, exist psychological safety.

Then the need arose to test these two variables in relation to each type of working models and it was concluded that there were no differences between the effectiveness of the rules and psychological safety, regardless of the model of work. It is important to note that the correlation with the highest value was for remote work, which goes against all the previous covid ideas, that's prove my first thought about the theme.

There were differences between the various working models, but these was not statistically significant, this may be due the fact that the sample was not large enough to reflect larger differences. But the bottom line is that there were no differences, in this study, in the relationship between rule effectiveness and psychological safety, regardless of the working model.

The team work, only needs the five theoretical attributes of green tape to achieve a good and health environmental in the workplace: accountability and legitimate authority (promoted by written rules), the wise use of public resources (advanced by valid relationships between rule means and ends), managerial efficiency (facilitated by the optimal control), fairness in the distribution of the public resources (assisted by consistent rule application), and transparency (furthered by stakeholder understanding of rule purposes) (DeHart-Davis, 2008). That ends in a work design that provides proficiency and stakeholders acceptability.

With the use of an ANOVA, it was possible to prove that there really are no differences between the working models and the green tape, what emphasizes what was written in the forward paragraph.

Relatable to the differences between the working models and psychological safety, the same test, that was conducted before, showed that there existed differences between psychological safety and working models. The model that most proved to influence positively psychology safety was the hybrid model. With that was possible to verify that the workers that were working in-person tends to have lower levels of psychological safety. To reinforce this idea, a T-Test for independent samples was carried out in which in-person work and technological working models (hybrid and remote) were tested. The results showed that the working models mediated by technology have a greater impact on psychological safety than the in-person model.

This leaded me to reflect on the fact that workers need to feel safe sharing their ideas and opinions and contributing more effectively to the organization (Edmondson, 1999) when they feel that have more flexibility choosing and adjusting the working model to their personal and work needs.

Subsequently, others, equally interesting conclusions were reached. I was able to understand that the closer the green tape questionnaire was to the optimal response point, the greater the feeling of

effectiveness of the rules. The same happened when I studied the perspective of effectiveness of the rules independently of the working model. So, if the workers feel that the rules of organizations are adapted to their needs, and are effective, the workers tend to feel happier in the workplace.

Finally, it was concluded that neither nationality, age, organizational tenure, job tenure nor gender, influences the way workers perceive the effectiveness of the rules. With this I can conclude that doesn't matter what kind of sociodemographic variable I have, if the five theoretical requirements exist, green tape and effective rules, will exist.

This study has some rich and interesting information, even more so when the world is about to change. The human being's life, for the most part, is tied up with work. I have long argued that if a worker feels happy, connected to his/her organization, and fulfilled, there is a high probability that he/she will feel happiness and motivation in his/her life.

The biggest conclusion I can draw from the study is that there is always green tape when all the requirements about the rules are fulfilled, which reinforces the idea of De-Hart Davis (2008).

With this study it was also possible to realize that psychological safety tends to exist when green tape exists. In other words, a feeling of efficacy of the rules leads to sharing and greater participation, as well as the security to do so on the part of the workers. These variables translate into a healthier working environment and sharing, which leads to greater growth at a personal and organizational level.

The fact that the study was conducted after a pandemic, which forced an abysmal development of the world of work, proves that this world depends on all the surrounding variables and that organizations must have the ability to adapt and seek stability to survive. This also, I think, leads to changes in paradigms and to the recognition that all kinds of work are possible, in remote or hybrid conditions, and that this does not change the perspective of the effectiveness of the rules.

Keywords: Green tape, Psychological safety, Working models

Oral presentation OP529

The influence of Authentic Leadership and Organisational Justice on Commitment

Francisco D. Bretones, Juan Manuel Fernandez-Millan & Alejandro Gonzalez-Canovas | University of Granada

science

This paper delves into the relationship between Authentic Leadership and Affective Commitment of workers as well as the mediating influence of the perception of Organisational Justice, aspects linked to the competence of management policies. The notion of employer/worker reciprocity is a subject that has been raised by certain authors (Alfes et al., 2013; Leroy et al., 2012) who, based on the Social Exchange Theory designed by Blau (1964), suggest that relationships between workers and their leaders are characterised by dynamic interactions that seek reciprocal behaviour and trust that lead to mutual commitment. Hence when employees perceive these values from their leaders, they feel in debt, a sentiment which raises their commitment to the organisation (Xiong, Lin, Li, and Wang, 2016).The style of leadership in the development of attitudes of commitment among workers plays a major role from the perspective of morals and values. Furthermore, their perception of justice is another key element in the development of organisational commitment. This study therefore analyses the relationship between leadership style and the perception of organisational justice on the commitment of workers towards the organisation that employs them.To verify these relationships, this study sampled 302 employees of Spanish companies with the following three tools: the Authentic Leadership Questionnaire designed by Avolio, Gardner, Walumbwa, Luthans and May (2004), the Scale of Organisational Commitment of Meyer and Allen (1997) and the Organisational Justice Perception Scale of Niehoff and Moornan (1993). The results gleaned from different regression and mediation models confirm both the direct relationship of Authentic Leadership and the role of justice with Affective Commitment. In addition, the SEM analyses certified the goodness of the model for the three variables. Our results offer evidence of the relationships between the study variables and allow delving into each of the four working hypotheses.One of these is the influence of supervisor leadership style on worker commitment. The leader is a concrete, non-abstract incarnation of the image of an organisation that is key to the link between employees and the organisation. In this sense, the leader/follower relationship is crucial to grasp the influence of supervisors on employee organisational commitment (anonymized, 2018; Wallace, De Chernatony and Buil, 2013).The findings of this study also allow delving into the role of the perception of Organisational Justice as a mediating variable between leadership and commitment. OJ plays a pivotal role in worker management in that the relevance of the perception of OJ is a factor that affects their behaviour and performance and thus can have an impact on company success (Swalhi, Zgoulli, and Hofaidhllaoui, 2017).A limitation of this study is its number of participants which should in future work be expanded to go deeper into the conclusions. Another limitation is the influence of authentic leadership style over the other variables. It is true that there are different models and leadership styles that could result in redundancies (Banks et al., 2016). Hence a future line of research should independently analyse the influence that other styles (transformational leadership, empowerment, etc.) can wield over OJ and AC.Finally, we believe that the current study forms part of recent literature on the influence and significance of relations of social exchange between leaders and followers as well as on the perception and attitude of employees in the labour framework (Malmrud, et al., 2020; Van Knippenberg et al., 2015) as it offers strategies to administrators and supervisors to carry out optimal management of organisational human resources.

Oral presentation OP251

The Influence Of Multitasking While Videoconferencing On Videoconference Fatigue. An Experimental Approach.

Yannick Frontzkowski, Jörg Felfe & Annika Krick | Helmut-Schmidt-University

science

Introduction

Since the Covid-19-pandemic, employees had to work from home and were forced to use new communication technology to adapt to the new challenges. Employees started to report a massive raise in the use of videoconferences for work related tasks. In 2020 public media reported that employees and leaders were increasingly fatigued after workdays with multiple videoconferences (i.e., zoom fatigue). This expression describes symptoms of exhaustion and fatigue encompassing social, emotional, motivational, and physical aspects (Fauville et al., 2021). Meanwhile “zoom fatigue” has been replaced by the term “videoconference fatigue”.

Research question

Studies showed a connection between the use of videoconferences and videoconference fatigue (Bennett et al., 2021; Lestari et al., 2021). It is theorized that videoconference fatigue results from a higher cognitive effort to compensate for communication difficulties such as missing nonverbal cues or body language and eye contact (Bailenson, 2021). Companies reported that employees tend to multitask during videoconferences more frequently compared to face-to-face (f2f) meetings (Cao et al., 2021). In comparison to f2f meetings, working with remote meeting software entices the participants to engage in multiple tasks during the meeting (e.g., responding to e-mails, browsing the web, or working on other tasks). Persons who multitask often think, they are more productive (Cao et al., 2021), however there are less studies examining a relationship between multitasking and performance, especially not with an experimental design. Multitasking has been examined in traditional work context, but research on multitasking during videoconferences and a potential relationship to videoconference fatigue is rare. Therefore, we analyzed the effects of multitasking on videoconference fatigue and task performance.

Based on the Job Demands-Resources Model (JD-R; Bakker & Demerouti, 2007), multitasking behavior as a job demand can negatively influence work outcomes such as task performance or videoconference fatigue, as multitasking behavior might increase cognitive load which depletes cognitive capacities. Based on previous findings and the JD-R model, we expected the following hypothesis: Multitasking during videoconferences increases videoconference fatigue (a) and reduces task performance (b).

Design

To test the hypotheses, a two factorial (mt vs no mt) experimental pre post design had been chosen with a convenience sample of N = 98 German students with work experience between 20 and 34 years. After filling out a first questionnaire (pre), participants were randomly assigned to the experimental or control group. Participants had to imaging being an employee of a marketing company. Both groups watched a 20-minute prerecorded online meeting of the company which they were told it would be a life conference in a company in which they had to take notes for their team leader (task 1a). The experimental group was simultaneously instructed to correct a text from a new colleague (task 1b). After the videoconference both groups were told to correct another text from a

new colleague (task 2). After 20 minutes they had to stop correcting the text. After completing task 2, all participants completed a second questionnaire (post).

Results

Regarding H1, a repeated measures ANOVA showed an increase of videoconference fatigue from pre to post for the experimental group but not for the control group. To test H2, we compared task performance (i.e., corrections made in text) of the experimental group in task 1b with the control group in task 2. Results showed a decreased task performance for the experimental group with multitasking in comparison to the control group. H1 and H2 are supported, indicating a negative effect of multitasking for videoconference fatigue and performance.

Limitations

The generalizability is limited due to the experimental setting. Future studies should test samples in the work context to extend the generalizability. Nevertheless, due to the experimental design of the study our data provides strong evidence for the direction of the hypothesized relationships.

Implications

This research contributes to the literature of videoconference fatigue, multitasking and performance by revealing their relationship. Future studies should focus on technological drivers of videoconference fatigue, such as software design and advanced technologies, such as virtual reality. Knowledge of effects of multitasking during videoconferences is important for organizations and researchers to find ways to minimize negative effects of multitasking (e.g., training, self-management).

The topic and results of this study contribute to the congress theme “The Future is Now: the changing world of work” as it reflects current problems with telecommunication technology use and problems with telecommunication technology itself and suggests further research to examine opportunities of new upcoming technology.

Oral presentation OP106

The interplay between protean and boundaryless career orientations: a person-centred approach

Ricardo Rodrigues, King's Business School; Teresa Oliveira, University of Coimbra, School of Economics; David Guest, King's Business School

science

Aims

Protean and boundaryless career orientations (PCO, BCO) have been largely discussed and empirically explored separately in the literature, leaving us with a partial and biased perspective about contemporary career preferences. We address this limitation by adopting a person-centred approach to exploring the interplay between both orientations and offer a more nuanced approach to capturing the nature of contemporary careers.

Theoretical background

Over the last 25 years a burgeoning body of writing and research has furthered our understanding of PCO and BCO and extensively explored their key correlates. However, this line of inquiry also conveys a rather fragmented and incomplete perspective of contemporary careers and their implications for individuals and organizations. Both metaphors are constructive and capture potentially salient elements of careers that depart from the prototypical organizational career. Taken together they depict a career that is dynamic and fluid, driven by psychological proactivity, independence from any one organization and potentially involving multidirectional moves. However, in practice both metaphors have been used interchangeably in the literature and empirical research has explored their correlates in isolation producing a limited account of the way people make sense of and enact careers in the contemporary world.

We argue that protean and boundaryless careers should be seen two sides of the same coin – the former capturing aspects associated with the internal career and the latter describing more observable career patterns. We explore the interplay between PCO and BCO adopting a person-centred approach allowing us to capture additional complexity and nuances of careers that break away from the traditional organizational career model. Our paper has three aims.

First, we discuss and empirically explore new career orientations profiles among a sample of workers in different organizations. Second, we explore how key individual (self-efficacy, gender, age, education) and work experience factors (tenure, employment contract, salary) are associated with membership in different profiles. We therefore address calls to explore the role of more visible individual differences and aspects of the work experience in shaping career preferences. Finally, we contribute to the ongoing discussion about the implications of new career orientations for employers and explore the extent to which high-commitment HRM is associated with employee well-being and task performance across new career orientations profiles.

Method

Data were collected through a questionnaire of a sample of 1050 workers and respective supervisors in 28 SMEs in Portugal. Data were analysed using latent profile analysis.

Results

A four-profile solution fits the data best. Individuals in the first profile (76% of participants) have average levels of PCO and BCO and were labelled traditional careerists. Participants in profile 2 (3%

of participants) report lower levels of PCO and high levels of BCO and were labelled opportunistic. The third profile (17% of participants) is comprised of individuals who are self-directed but prefer a career within their organizations and were labelled proactive organizational citizens. The final profile (4% of participants) aggregates individuals who are high on PCO and BCO and were labelled new careerist.

Results confirmed significant differences in profile membership. For instance, in comparison with traditional careerists, new careerists report higher self-efficacy and are more likely to be younger. New careerists also report lower employer tenure and higher earnings when compared with individuals in other profiles.

Finally, results indicate that HR practices are associated with performance and wellbeing among traditional and new careerists. Investment in HRM does not seem to elicit desired outcomes among opportunists and proactive organizational citizens.

Limitations

The cross-sectional nature of our study limits our ability to discuss causality in profile membership and outcomes.

Conclusions

Our study shows diversity in the way people relate to key features of PCO and BCO. Moreover, it shows that most people still relate to the ideal-type of a traditional organizational career and that only 4% of participants seek to enact a self-driven and independent career. In addition, it shows the added value of considering profiles of new career orientations in understanding their impact on individual and organizational outcomes.

Relevance to the Congress Theme

Our paper shows diversity and complexity in the way people construe and enact their careers. Those interested in the future of work necessarily need to consider that change in work and career-related values is far from being consistent and wide-ranging and that organizations seeking to engage and retain talent need to understand and address this complexity.

Relevance UN SDGs

The study addresses concerns about balancing performance and employee well-being.

Keywords: New career orientations, HRM, latent profile analysis

Oral presentation OP503

The latent functions of work and unemployment

Bernad Batinic, Johannes Kepler University Linz; Matthias Collischon & Sebastian Bähr| Institute for Employment Research (IAB) Nuremberg, Germany

science

According to Marie Jahoda, paid work, in addition to its manifest function (monetary returns), also fulfills numerous latent functions (e.g., social contacts). Empirical studies have examined the relationship between latent functions and unemployment. However, these studies often face shortcomings, such as small sample sizes, crude definitions of employment status groups, or survey data based on non-random samples. The goal of this paper is to empirically test the key assumptions of Jahoda's model using a representative sample. We analyze 2020 data from the Household Panel Study "Labor Market and Social Security" (PASS, N 10,210 individuals from 7,547 households), a survey investigating labor market and poverty in Germany (Trappmann et al., 2019). Compared to previous studies a large sample allows us a detailed analysis of the presumed effects.

Keywords: latent functions of employment, Jahoda, labor market,unemployment

Oral presentation OP295

The lived experience of autistic adults in employment

David Thorpe, Heriot-Watt University

science&practice

Background:

In 2020 it was found that while 52.1% of disabled people in the UK are employed, only 21.7% of autistic people are employed (Office for National Statistics, 2021). This is despite having a positive perception from employers who have worked with them, and have perceptions of being trustworthy, reliable, efficient, and honest (Baldwin, 2014; Richards, 2012).

Objectives:

This research presents an exploration the employment experience for autistic adults, it does so by identifying the key themes and experiences an autistic adult has within employment. Additionally, it will provide a discussion of the implications this may have in both research and practice.

Methods:

A series of semi-structured interviews were conducted with 18 autistic individuals in full or part time employment. These interviews were analysed using a form Interpretative phenomenological analysis (Smith & Osborn, 2003), and provides a thorough analysis of what themes and experiences are key to the autistic working experience.

Results:

Three emergent themes have been identified: Navigating the Social Experience; Doing the job; your 'self' and the workplace. In addition to broad themes, key experiences have been highlighted such as consequences of manager changeover, disclosure makes you vulnerable, and being exploited at work.

Conclusions:

Taking these themes and key experiences we can learn better ways to improve the working experience. This research has large implications on practice as it provides insight on to how to create a positive working experience, and additionally has implications on research as it explores a growing method of exploring employment for autistic adults.

Oral presentation OP361

The longitudinal impact of work-life interference on burnout among male and female physicians in Sweden during the COVID-19 pandemic

Britta Gynning, Emma Brulin, Filip Christansen & Ulrik Lidwall | Karolinska Institutet

science

In the aftermath of the COVID-19 pandemic, sick leave due to stress and exhaustion has increased in Sweden, especially among women (1) and particularly with a focus on healthcare workers (2–4). Besides the exasperated workload and increased number of work hours for healthcare workers during the pandemic, many also experienced increased levels of interference between work and private life (5). The theoretical background of this paper is the psychosocial model of work-life interference which can work as an explanation for this ongoing trend of ill health (6,7). Interference comprises of two directions work interfering on life (WLC) and life interfering on work (LWC) (8). It is based on the idea of an interrole conflict that can occur when demands from work and private life are incompatible creating strain and stress increasing the risk for exhaustion and burnout (9). Interference tends to negatively affect physicians' mental health (2,10–15) which in turn has the risk to negatively affect the quality of care and safety for their patients (3,16,17). Yet, in Sweden interference, especially in relation to gender and burnout among physicians, is an under researched area. Considering the context of Sweden with norms of dual-earners alongside a still predominant view of women being the primary homemaker (11) the goal of this paper was to study changes in work-life interference among physicians in Sweden in relation to their mental health between the years 2021 to 2022 as well as to explore possible gender differences affecting this relation. With regards to the COVID-19 pandemic the aim was also to explore if and how work-life interference has been affected by working with COVID-patients.

The study apply data from the Longitudinal Occupational Health Survey for HealthCare professionals in Sweden (LOHHCS) study. Questionnaires was distributed 2021 and 2022 to a representative sample of physicians working in Sweden. The study-sample included 1573 individuals. The main measurements used were WLC and LWC (8) adjusted for different life and work factors. Burnout was assessed through the Burnout Assessment Tool (BAT). Different statistical methods were used ranging from descriptive summary statistics to logistics regression.

The results are yet to be compiled and are expected in the end of November 2022. However, initial analysis indicates increase of interference and burnout between 2021 and 2022 among all physicians. Considering previous literature and findings of physicians having an increased risk for exhaustion and burnout in relation to interference, this study, set in a Swedish context with data including rank and gender, opens for a more specific analysis. Thus, there is the possibility to highlight more specific intersection of Swedish physicians and how their relation of interference and burnout differentiates from each other pinpointing if one group might be more exposed than the other.

Limitations include non-responses both external and internal for both data extractions. Another limitation, regarding the papers focus on physicians work with COVID-patients, is that no data was collected before the pandemic. Lastly, although the study has two points of extraction, they might be too close in time. Meaning that it might be hard to establish causal relations between interference and burnout.

The study has especial relevance to the 18th EAWOP topic "Well-being– work-life balance". Regarding the papers focus on mental health and gender differences in relation to interference

among physicians it is also relevant to the UN SDGs of good health and wellbeing, gender equality, and decent work and economic growth.

Oral presentation OP582

The moderating role of age and seniority on nurses' emotional dissonance and perceived health

Francesco Pace, Francesca Sinatra, Giulia Sciotto & Naomi Alexia Randazzo | Università degli studi di Palermo

science

The emotional impact of working closely with suffering is an aspect that cannot be overlooked in studies that explore the stressors of the health sector (Happel et al., 2013). The emotional load is linked to the concept of emotional dissonance, i.e., the constant need to maintain an emotional state that is consonant with the situation, but not experienced as natural (Brotheridge & Lee, 2003). Furthermore, increasing importance is given to the evaluation of the different ways in which nurses face the burden of this complex profession in the different phases of their careers (Ryan et al., 2017). Therefore, the aim of the study is to evaluate the weight of surface acting (being forced to show an expression that is not consonant with one's emotions) in the relationship between emotional load and well-being and to evaluate the moderating effects of age and seniority on a sample of 359 nurses operating in public and private facilities throughout Italy.

The PROCESS macro (Hayes, 2018) of SPSS was used to test the moderated mediation model. We computed emotional load as the independent variable, perceived health as the dependent variable, surface acting as mediating variable, and age and length of service as the moderators. The model was tested twice, alternating moderators. The bootstrap method with 5,000 replications and 95% confidence intervals was used to verify the significance of indirect effects. Limitations of the study stem from the cross-sectional design, the use of self-report measures only, and the smallness of the sample.

The results show that the emotional load has a negative effect on perceived health both directly and indirectly, through the effect of surface acting. Moreover, both age and seniority have moderating effects so that in conditions of high emotional load, older and more experienced nurses show higher levels of surface acting, and in conditions of high surface acting, younger and less experienced nurses show lower levels of perceived health. The results suggest that nurses do not get used to the burden of emotional demands over time, making it necessary to resort to the surface acting to respond to the dissonance between felt and displayed emotions. On the other hand, over time the implementation of this strategy seems to be less and less connected to states of discomfort.

In conclusion, it would seem that the weight of the emotional load increases with age and seniority, while the effect of surface acting on well-being is more detrimental for younger nurses with fewer years in the role. Each result highlights the importance of providing emotional regulation skills training and supportive strategies to reduce the psychological impact of emotional demands on workers who have to deal with them on a daily basis.

Considering the variables taken into consideration, this study is in line with more than one Congress Theme, as it deals with workplace emotions, job demands, and work-related stress, but also the safeguarding and protection of workers. It also responds to Goal no. 3 of the UN SDGs, which promotes well-being at all ages.

Keywords: Nurses, age, emotional dissonance

Oral presentation OP551

The moderating role of team psychological safety climate in the relationships between career ambition, job- and career crafting and thriving

Elias Janssen, Ghent University & Radboud University; Mieke Audenaert, Ghent University; Jeroen de Jong & Beatrice van der Heijden | Radboud University

science

Co-workers play a crucial role in shaping job and career crafting behaviours and its outcomes. In this study, we take an interactionist perspective on job and career crafting behaviours in teams and examine the moderating role of team psychological safety climate on the relationships (1) between career ambition and job and career crafting and (2) between job and career crafting and thriving at work.

Career ambition is an individual trait that comprises a consistent striving towards attaining success and accomplishment in one's career. We argue that career ambition may be expressed through engaging in job and career crafting, as these behaviours can serve to realize career ambition. Trait-activation theory suggests that the extent to which individual traits are actually expressed through behaviours is dependent upon contextual factors, like team climate. Team climate refers to the shared perceptions in a team regarding policies, procedures and practices. Hence, we expect that a supportive team climate in which challenging the status quo is perceived to be safe (i.e. team psychological safety climate) will weaken the positive relationship between career ambition and job and career crafting. This hypothesis may seem counterintuitive. However, we argue that ambitious individuals tend to engage in job and career crafting regardless of situational constraints, meaning that being ambitious will likely become more salient for these behaviours in the context of a psychologically unsafe climate. Team psychological safety climate may therefore play a compensatory role for career ambition in predicting job and career crafting.

Furthermore, we expect that team psychological safety climate strengthens the relationship between job and career crafting and thriving. Thriving comprises vitality and learning, respectively the affective and cognitive component of the experience of personal growth. Individuals can craft their job and career in such a way that enables them to thrive in their work. Social information processing theory infers that the affective outcomes of crafting behaviours are likely to be influenced by positive or negative reactions from co-workers. When taking risks is in general welcomed and perceived as safe, co-workers are likely to respond in a supportive way to crafting behaviours, strengthening the relationship between job and career crafting and thriving.

To test our model, we are going to collect two-wave survey data among teaching staff in education teams in the Dutch secondary vocational education sector. Each education team is responsible for providing one specific education program and these teams have considerable autonomy over how they divide their work tasks, making this an especially interesting study context to study job and career crafting. We strive for a level 2 sample size of 100 education teams, with an average level 1 sample size of 10 teachers per team. Data will be analysed using multilevel regression analysis. As job and career crafting may be hindered by rules and regulations and by one's leader, we will control for job control and team leader empowerment. We plan to collect this data in November and December 2022 and expect to have our results in March 2023, in time to present the results at the EAWOP 2023 congress.

With our study, we aim to add to the sparse research on the role of co-workers in shaping job and career crafting and its outcomes, answering calls for research on this topic. By studying the role of

team climate in job and career crafting, we aim to generate insights on how teams and their leaders can create an environment in which taking initiative is welcomed, thereby supporting job and career crafting and potentially optimizing its outcomes.

Oral presentation OP787

The Overlap between Occupational Burnout and Major Depressive Disorders in the Colaus|PsyColaus Cohort

Yara Shoman, Center of primary care and public health (Unisanté), University of Lausanne, Switzerland; Martin Preisig , Department of Psychiatry, Center for research in psychiatric epidemiology and psychopathology, Lausanne University

science&practice

Research goals: We aimed to investigate the relationship between occupational burnout and Major Depressive Disorders (MDD) in the population-based cohort Colaus|PsyColaus.

Theoretical background: There is no international consensus about how to assess or treat occupational burnout. World Health Organization (WHO) classified burnout as a factor influencing health in the eleventh edition of the International Classification of Diseases (ICD-11) and not as a health condition or disease. However, some researchers have shown that burnout could reflect a depressive state and not a distinctive entity. Additionally, the prescription of antidepressants is common for workers with “severe burnout”. Nevertheless, the issue of burnout–depression overlap remains unsolved. We, therefore, aimed to investigate the relationship between burnout and major depressive disorder (MDD) in a population-based cohort.

Methods: Data stemmed from CoLaus|PsyCoLaus, a prospective population-based cohort including a random sample of participants selected from the general population of Lausanne (Switzerland). After the baseline investigation between 2003 and 2007, the cohort was followed-up for approximately five (follow-up (FU) 1), 9 (FU2), and 13 years (FU3). From FU2 on, current workers and participants without occupational activity for one year or less were invited to fill in the Maslach Burnout Inventory-General Survey (MBI-GS) during the psychiatric evaluation. Diagnostic information and demographic characteristics were elicited through the semi-structured Diagnostic Instrument for Genetic Studies (DIGS). MDD diagnosis was assigned according to the DSM-IV. We defined MDD as current if the criteria for this diagnosis were met at the time of the MBI-GS assessment. Participants were included in the analysis if they replied to the MBI-GS either at FU2 or FU3 and were active workers at the time of the MBI-GS assessment. Due to the lack of valid and reliable cut-offs of MBI-GS, we decided to use the scores of the three dimensions (i.e., exhaustion, cynicism, and professional efficacy) of the MBI-GS separately instead of using a dichotomized outcome of burnout. We performed one logistic regression model with current MDD as an outcome and the three dimensions of burnout as predictors while controlling for age, sex, and the type of occupational activity.

Results: A total of 1299 participants (mean (SD) age: 56.20 (0.16) years; 49% men) completed at least once MBI-GS and were active workers. Among them, 8.4% (101/1299) people reported a current diagnosis of MDD. The scores of exhaustion and cynicism were higher in participants with a current diagnosis of MDD compared to participants with no current diagnosis of MDD (mean (SD) 2.86 (1.53) vs. 1.44 (1.16), p=0.00, and 2.68 (1.65) vs. 1.69 (1.34), p=0.00 respectively). The score of professional efficacy was higher in participants without a current diagnosis of MDD compared to participants with a current diagnosis of MDD ((4.60 (0.94)) vs. 4.40 (0.87), p=0.01). The logistic regression results showed that higher exhaustion increased the risk of current MDD (OR=2.00, 95%CI=1.65, 2.43).

Limitations: The self-reported measurement of burnout may be considered a limitation of this study. Future research may benefit from the use of hetero-assessment tools to measure burnout.

Conclusions: The results of this study show that only the exhaustion dimension of occupational burnout is associated with MDD. Based on the findings of this study, cynicism and professional efficacy are not associated with MDD.

Originality/Value: The need for studies investigating the relationship between burnout and MDD was highlighted in the literature. This study is the first Swiss study to use data from a large population-based cohort to illustrate the relationship between burnout and MDD where MDD was measured using semi-structured diagnostic interviews.

Relevance to the Congress Theme: Dissemination of the results of this study may be of interest to researchers and practitioners attending the congress. Additionally, the congress will provide an opportunity to discuss these results and receive valuable feedback.

Keywords: Burnout; Depression; Regression

Oral presentation OP357

The pro-endogroup bias in the binarity vs. non-binarity challenge: trough the perception of a CV sorting performed by a human vs. an algorithm

Alan HASSELBERGER & Pascal TISSERANT | Psychologie Ergonomique et Sociale pour l'Éxpérience utilisateurs (PErSEUs) Université de Lorraine

science

The aim of the present study is 1/ to examine the perception of the selection of a binary vs. non-binary candidate by a human vs. an algorithm and 2/ to identify or not a pro-endogroup bias in the justifications of participants concerning this perception.

The pro-endogroup bias consists for individuals to favour the members of their respective categories to the detriment of others. In the context of recruitment, it leads recruiters to discriminate against candidates on the basis of criteria such as gender and ethnic origin (Petit et al., 2020). To tackle this subjectivity, algorithms have been developed (Amadieu & Roy, 2019). Are they perceived in this way? For some authors, they are effective (Lacroux & Martin-Lacroux, 2021) but not for others (Peña et al., 2020). Chen et al. (2018), for example, found that automatic CV sorting removed direct, but not indirect, discrimination that would relate information about an applicant to those of a category. Indicators such as hobbies (Delroisse, 2011) included in a CV can give information about belonging to a gender category. What then happens when that membership is ambiguous, such as non-binarity? Dovidio and Gartner (2000) suggest that this ambiguity is a source of discrimination. This raises the question of whether this pro-group bias is present in the perception of a decision about a CV sorting made by a human vs. an algorithm when heterosexual vs. LGBTQIA+ respondents give their opinions. It is hypothesized that binary/heterosexual vs. LGBTQIA+ respondents will agree more with a decision selecting the candidate of their group affiliation, when the CV sorting is performed by a human, rather than an algorithm. To deepen the understanding of the choices, it is relevant to look at the justifications given by respondents to explain a CV sorting decision. Indeed, as justification is at the heart of discrimination (Delroisse, 2011), it seems appropriate to study the content of the explanations provided in order to identify possible indirect forms of discrimination and therefore of pro-endogroup bias. For instance, a passive position in a sentence indicates an indirect discrimination and the individuals are perceived as enduring the action unlike ones in a subject position (N'Dobo & Gardair, 2006). In addition, it is expected that the content of the justifications will put the binary candidate in a more favourable position when produced by heterosexual/binary respondents than when produced by LGBTQIA+ respondents.

98 heterosexual/binary and 84 LGBTQIA+ individuals were presented vignettes relating a story of a CV sorting, performed by an algorithm vs. a human, involving a non-binary vs. binary candidate. Participants were asked to indicate on a 5-point scale their level of agreement vs. disagreement with the CV sorting performed by the algorithm vs. human. Then, they had to justify it in 100 words.

The data processed using non-parametric tests. They show that the heterosexual binary respondents agree more with a CV sorting selecting the binary candidate rather than the non-binary one, only when the CV sorting is performed by a human ($p=.03$). LGBTQIA+ respondents do not make a difference. Explanations processed using the TROPES software (version 8.5). They indicate that heterosexual/binary ($\chi2(N=80) =9.49$; $p=.02$; $V=0.20$) and LGBTQIA+ ($\chi2 (N=75) =4.25$, $p=.04$; $V=0.23$) respondents place the non-binary candidate in a passive position in the sentence more than the binary one, when the CV sorting is performed by a human or an algorithm.

Thus, heterosexual/binary respondents seem to agree more with a decision selecting the binary candidate over the non-binary one when a human conducts the CV sorting. This result appears to show the existence of a pro-endogroup bias. In contrast, the justifications indicate an indirect discrimination against the non-binary candidate, by all respondents, when the CV sorting is conducted by a human and an algorithm. This evidence may indicate that algorithms are perceived as addressing direct but not indirect discrimination, against non-binary candidates. Thus, these data do not support the results of the study by Hasselberger & Agnoletti (2022). This suggests differences in the CV sorting processes underlying sexual orientation and gender identity discrimination. This is the originality of our work.

Although the small number of participants seems to be a limitation of this study, it offers interesting perspectives to be communicated during this congress by exploring the perception of the use of algorithms in the face of crucial social changes: diversity management. This presentation is at the centre of new social concerns for companies, hoping to provide ideas to contribute to an egalitarian recruitment of non-binary candidates.

Oral presentation OP85

The psychologist profession in Europe – legal regulations, scope of practice, mobility potential, and working context diversity

Ole Tunold, EFPA

practice

Background

There is a widespread belief that the title 'psychologist' describes a homogeneous and relatively unambiguous profession in European countries. But that is not the case.

In 2013–2016, the EU implemented a large-scale mutual evaluation of regulated professions. The purpose was through deregulation in the labour market and thereby increased mobility for the professions to create new jobs and economic growth. The evaluation revealed a huge variation both in terms of regulations, educational structure (from 3 to 11 years) and the scope of psychologists' practice. The evaluation avoided the question of whether the individual countries' regulations are related to the role of psychologists in the various fields of parctice. Unfortunately. Because then one would have found the explanation for these large variations. It is imperative to secure that the professional standards are fit to cover the tasks and responsibilities entrusted to the profession in a given country.

A paramount question to address when settling the framework for mobility: Is it meaningful to establish a universal professional standard when the role of a psychologist could be so different across borders? In 2020, an EFPA project set out to gather information about legal regulations of the profession, mobility opportunities, bordering professions and professional context diversity in Europe.

Objective

The overarching goal of the project is to have an up to date, complete and objective overview of the psychologist profession in Europe. The overview should be on display and subject to amendments and corrections from the MAs.

Four sub goals are identified:

A model of legal regulation for Member Associations in whose country 'Psychologist' is not yet a regulated profession or will be revised (MODEL).

Identified mobility options (professional migration) in Europe (MOBILITY).

Identified boundaries and communalities between the profession of psychologists and that of psychotherapists, to demonstrate and promote the uniqueness of the psychologist profession (SCOPE).

A basis for development of the psychology profession to optimally serve society and psychologists in the national contexts (CONTEXT).

Method

Data are drawn from 4-6 available data bases. Data are compiled and displayed for each country in a sufficiently condensed format to make it accessible.

Each Member Association is invited to make amendments and corrections. Once the Member Associations have approved the overviews, they will go on display on a designated page at EFPA's website, to be regularly updated.

Results

Preliminary results and experiences from the project work will be presented.

Keywords: Professional context diversity

Oral presentation OP17

The psychology of cycling to work: Joy, well-being, and behaviour change

Alan Redman, Birkbeck College, University of London

science&practice

The daily commute to work is an extension of the working day that has significant implications for healthy and sustainable ways of working. Motorised modes of transport are used for 84% of commuting journeys and create 93% of carbon emissions. The daily commute in its present form contributes to critical contemporary problems affecting health and sustainability: Environmental harm, congestion, poor public health, lack of exercise and adverse impacts on well-being at work.

The benefits of cycle commuting appear self-evident, with evidence of positive contributions to personal health, well-being, public health, and decreases in emissions and carbon. However, a recent systematic review identified that research examining the benefits of cycle commuting overlooked the psychological processes and individual differences that determine commuting mode choice.

Theoretical background:

This session describes the results of a systematic literature review, which identified the dearth of psychological research into what engages and sustains cycle-commuting behaviours. The review identified 456 papers using search terms relating to cycle-commuting. Papers were excluded on the basis of systematic criteria, and duplicates removed, leaving 24 studies for review. The synthesis of these papers identified 5 physical/objective determinants (Infrastructure, Environment, Trip qualities, Facilities/incentives, and Group membership) forming the basis of the research findings. Only a single psychological determinant, Attitude, was examined across the papers identified by the review. This review informed subsequent research to specifically investigate the wider psychological factors around riding to work, which explored the determinants of cycle commuting using a sample of UK cycle commuters using an inductive exploratory thematic analysis.

Results obtained:

The research identified themes that articulated the determinants that influence choices, decisions, habits, and perceived benefits associated with cycle commuting. The research identified core psychological themes relating to well-being, health, exercise, perceived control, and social attitudes relating to cycle commuting. The themes identified were I feel fantastic; I can do this; I belong here. Each theme included a cluster of sub-themes to provide greater clarity and meaning. These included Cost and environmental savings; Health & fitness; Wellbeing; Pleasure/ enjoyment; Maximising utility; Commuting strategies; Bloody-mindedness & grit; In-group-attitudes; and Out-group behaviours.

Limitations:

The results of this study were based on a small group of cycle commuters in the city of Brighton. While broadly representative of other urban centres in the UK, appropriate caution should be applied before generalising the results to other contexts. This study explored the experiences of people already engaged in a regular cycle commuting habit. It does not therefore explore the determinants of this mode choice in the context of commuters who use alternative commuting modes. While this was an exploratory qualitative study, its outcomes both corroborate and extend previous research in this area and resulted in the development of an initial model demonstrating the psychological

determinants of cycle commuting. This model could serve as the basis from which to test this empirically on a larger population in a quantitative study.

Research/Practical Implications:

This study describes the key determinants of cycle commuting based on the experiences of cycle commuters in the UK. This adds to current theory by developing our understanding of the interaction between objective/physical determinants and psychological determinants. The study developed a psychological model that can be used as a basis for subsequent actions and research to encourage uptake of cycle-commuting. From this study, recommendations can be made for behavioural change interventions relating to the COM-B model from three levels: Policy (local and central government), organisations, and individuals considering mode-switch.

Originality/Value:

The research is a novel contribution to our understanding of commuting choices, which can be used to inform the design of behaviour-change interventions to increase well-being and sustainability at work. This presentation will present an initial explanatory model describing the interaction between psychological determinants and physical/objective factors such as infrastructure that drives the behaviour change process away from motorised commuting modes to the healthier and more sustainable alternatives of cycling. The session will discuss potential change-actions for individuals, organisations and policymakers who want to foster healthy and sustainable workplaces, as well as directions for future research.

Intended audience:

Both Academic and Practitioner. The presenter is a practitioner with over 25-years of experience. The content is drawn from his doctoral research.

Keywords: active travel, cycle-commuting, behaviour change

The Psychosocial Risks of University Teachers: A bettersweet job

Emilio Sánchez Santa-Bárbara, José María González González & Antonio Delgado Padial | University of Granada (Spain)

science&practice

The working requirements, demands and conditions of university teachers in Spain have changed significantly over the last few years to adapt to the teaching quality demands, research competitiveness and management efficiency that arise from the society. As a result, this prestigious and socially-and-economically-recognized profession, which offered great and reasonable possibilities of career development and was healthy from a psychosocial point of view, has become, in a short period of time, a highly-competitive profession that has lost certain social status, its working conditions have clearly worsened (precariousness, instability, insecurity, etc.) and the academic, teaching, scientific and management demands have increased quantitatively and qualitatively, which causes high level of work stress and a large number of psychosocial risks.

Thus, taking as theoretical framework The Stress General Theory integrated by the conceptual models: "demand-control-social support" (Karasek, Theorell and Johnson, 1990), "effort-rewards" (Siegrist, 2002); and the transactional, mediational and interactional model of stress (Lazarus and Folkman, 1984, 1986); the pychosocial risks of university teachers in a University at the south of Spain (University of Granada) have been analyzed. For this purpose, The Psychosocial Risks Evaluation Methodology COPSQ-ISTAS 21 was administrated to a sample of teachers from University of Granada (Spain) 756 and a series of semi-structured interviews have been also conducted with a sample of 30 teachers from the former Spanish public university.

The main psychosocial risks suffered by university teachers in Spain are to work in a very fast way; emotional job demands; role strain and conflicts, bureaucratic fatigue; being constantly subject to external evaluation as a method of control; suffering career stabilization or development processes that are increasingly demanding and competitive; the tensions rising between teaching, management and research demands; increased psycho-pedagogical and teaching demands as a consequence of the adaptation to the European Higher Education Area (EHEA); challenges that they have to face during the internationalization processes of the Spanish public university system; the effort-reward imbalance in research; the taking on of management tasks without training or authority; the presence of some medieval hierarchical culture in the Spanish university noticeable in the criteria of "status and seniority" when taking decisions that together with the paternalistic and mentoring culture between mentors and students foster "invisible bonds" between the different groups of teachers and some sectarianism stemming from the relations of in-group favoritism and out-group discrimination and; finally, the demagogic promotion of the student discourse "customer-king".

The final result is a feeling of ambivalence where an expecting, exciting and motivating idealization of the academic-scientific world contrasts with a pragmatic, frustrating and demanding social and labor reality that encourages disillusionment and lack of interest among a group increasingly oppressed and in worse working conditions that also has serious consequences for the mental health of university teachers.

Keywords: Psychosocial Risks, Stress, Precariousness

Oral presentation OP681

The Quality at Work Tool (AQ@workT_S) to assess the quality of life at work in university staff

Vincenza Capone, Università degli Studi di Napoli Federico II; Fulvio Signore, Università del Salento; Emanuela Ingusci, Università del Salento; Dina Guglielmi, Università di Bologna; Francesco Pace, Università degli studi di Palermo; Paola Spagnoli, Università degli Studi della Campania; Silvia Platania, Università di Catania; Alessandra Falco, Università di Padova; Damiano Girardi, Università di Padova; Amelia Manuti, Università degli studi "A. Moro" Bari; Carmela Buono, Università degli Studi della Campania; Andreina Bruno, Università di Genova; Giuseppina Dell'Aversana, Università Bicocca Milano; Massimo Miglioretti, Università Bicocca Milano; Daniela Converso, Università di Torino; Maria Luisa Giancaspro, Università degli studi "A. Moro" Bari; Silvia Gilardi, Università di Milano; Margherita Brondino, Università di Verona; Michela Cortini, UNIVERSITA' DEGLI STUDI G. D'ANNUNZIO DI CHIETI - PESCARA

science&practice

Theoretical background. The rapid changes that academics have experienced over recent years are resulting in several challenges for those who work in the University. These changes, which transversely affect all university workers, result in more significant work intensification, which may have adverse outcomes. On the topic, the JD-R model provides a simple but complete heuristic framework linking a wide variety of characteristics related to job content and a wide range of job results. This model was developed to provide a comprehensive framework to understand the factors that may challenge or enhance workers' physical, mental, and psychological well-being. The present study provides evidence for a valid and reliable tool, the Quality at Work Tool (Brondino et al., 2022) staff version (AQ@workT_S), grounded in the job demands-resources model. The tool aims to investigate the quality of life at work in technical and administrative staff within the university sector. Methodology. The AQ@workT_S was developed by the QoL@Work research team, namely a group of expert academics in the field of work and organizational psychology affiliated with the Italian Association of Psychologists. The psychometric properties were assessed in a study comprising a wide sample of Italian university staff, and analyses were carried out on a sample of 1820 technical-administrative staff workers. After appropriately calculating asymmetry and kurtosis indices, aggregate confirmatory analyses were proposed for demands, resources, mediators/moderators and output of the questionnaire constructs, according to the distinction arising from the Job Demands-Job Resources theoretical model. Missing data less than 10% were estimated by means of the FIML algorithm, while scales with missings greater than that percentage were processed keeping only the present ones. Results. Reliability and content, and construct validity were supported, as well as measurement invariance across gender and seniority of service. The results suggest that job resources (superiors and colleagues support, job autonomy, organisational identification, environment quality, distributive justice, organisational work-family support, meaning of work), demands (work intensity, workload, Conflict, work-family balance, out-of-hours demands), mediators/moderators (workaholism) and outcomes (work engagement, burnout, technostress) present acceptable fit indices, according to the criteria proposed by Kline (2016, CFI > .90, RMSEA < .08, SRMR <.08). Construct validity was finally measured by means of correlation analysis between the variables and revealed polarities and intensities consistent with the literature. Invariance was then subsequently tested for university, seniority, and gender. Future studies, such as longitudinal tests of the AQ@workT_S, should test predictive validity among the variables in the tool. Limitations. Self-report questionnaire, convenience sampling strategy, and social desirability bias. Practical Implications. Evidence from the present study shows that the AQ@workT_S represents a useful and reliable tool to assist university management in enhancing the quality of life, managing work-related

stress, and mitigating the potential for harm to technical and administrative staff, which also takes into account techno-stress and post-pandemic re-organization. Recommendations are offered for management on how academic staff can be maintained and supported to achieve well-being at work.

Keywords: University workers, psychometric tool, JD-R

Oral presentation OP116

The relationship between emotion inertia and burnout

Tim Vantilborgh, Jesse Vullinghs, Sara De Gieter, Safâa Achnak & Valentina Sagmeister | Vrije Universiteit Brussel

science

Research goals and why the work was worth doing

The goal of this study was to examine whether emotion inertia—i.e., the extent to which one's current emotional state can be predicted by past emotional state (Kuppens et al., 2012)—relates to burnout. Past research has demonstrated that high emotion inertia is maladaptive and relates to the development of depression (Kuppens et al., 2012). However, how emotion inertia links to burnout has not been explored to date.

Theoretical background

Burnout can be considered a syndrome consisting of core (exhaustion, mental distance, cognitive impairment, emotional impairment) and secondary dimensions (psychological complaints, psychosomatic complaints) (Schaufeli et al., 2020). While several personal and environmental factors have been linked to the development of burnout (Crawford et al., 2010), it remains unclear how ones emotional experiences may predispose them to burning out. In this study, we address this gap by focusing on emotion inertia, which captures a dynamic characteristic of emotional experiences. Emotion inertia is defined as the extent to which past emotions tend to persist over time, and high inertia—meaning that emotions change slowly—has been theorized to be maladaptive (Kuppens et al., 2012). The main reason for this is that high emotion inertia signals that individuals are unable to regulate their emotions in response to external and internal influences. Empirical studies confirm that emotion inertia positively relates to depression and negatively to self-esteem (Kuppens et al., 2012). Likewise, our central research questions is therefore whether a positive relationship exists for emotion inertia and burnout.

Design/Methodology/Approach/Intervention

We used an experience sampling design to collect data from 220 participants. Each participant first completed a general survey, measuring burnout with the Burnout Assessment Tool (Schaufeli et al., 2020). Next, participants completed 84 short ESM surveys measuring positive and negative discrete emotions (12 measurement moments per day for 7 days). We used a multilevel autoregressive model to estimate emotion inertia (for each discrete emotion) from the ESM data (de Haan-Rietdijk et al., 2016). Emotion inertia was then used to predict burnout dimension scores using multiple regression analysis. We explored whether the effect of emotion inertia was moderated by the average level of affect.

Results

No significant direct effects of emotion inertia on any of the burnout dimensions were found. However, we did find that the effect of emotion inertia depends on the average level of affect. This interaction effect mainly emerged for the discrete emotion of sadness. In particular, high emotion inertia in sadness was positively related to exhaustion, mental distance, emotional impairment, and cognitive impairment, if the average level of sadness was low.

Limitations

As burnout was only measured once, we cannot relate emotion inertia to change in burnout or to the onset of burnout. Moreover, other emotion dynamics may relate to burnout and need to be explored.

Conclusions

We draw attention to the relationship between emotion dynamics and burnout. In particular, we reveal how individuals who generally do not experience high levels of sadness yet experience an episode of persistent sadness over time tend to report higher levels of burnout. This may help in early detection of burnout, as maladaptive emotion regulation may act as an early warning signal.

Relevance to the Congress Theme

This presentation is relevant to the congress theme, as burnout has been called an epidemic and affects around 10% of the European workforce according to recent figures.

Relevant UN SDGs

This presentation is relevant for the “Good health and wellbeing” and the “Decent work and economic growth” UN SDGs.

Keywords: burnout; emotion inertia; experience sampling method

Oral presentation OP423

The relationship between organization's internal ethical context and subjective well-being – the role of socially responsible HRM and ethical leadersh

Eduardo Simões, Ana Patrícia Duarte & Raquel Dias |Iscte - Instituto Universitário de Lisboa, BRU-IUL

science&practice

Research goals and why the work was worth doing: This study sought to understand how organizations' internal ethical context (IEC) relates to employees' subjective well-being (SWB) and satisfaction with life (Diener, 2012). Two potential mediating variables were examined, namely socially responsible HRM (SRHRM) and ethical leadership. The study contributes to increase current understanding of the effects of IEC on employees' SWB, a neglected research topic (Schwepker et al., 2021).

Theoretical background : Organizations' IEC is part of the "ethical infrastructure" (Tenbrunsel et al., 2003) which includes formal and informal ethical systems (Kish-Gephart et al., 2010; Treviño & Weaver, 2001). One way to communicate formal norms is having an ethical program that presents the expected conduct, reward, and sanctioning system.

Ethics programs' dynamics are extremely important in impacting individual ethical awareness and, consequently, their ethical behavior (Kaptein, 2015). Previous research suggests that organizations' IEC is relevant to employees' well-being, being associated to diminishing levels of distress (Schwepker et al., 2021). Organizations with strong IEC strive to treat employees with justice (Vitell & Singhapakdi, 2007), which influences their job satisfaction (Valentine & Fleischman,2007) and quality of life (Kim et al.,2017). Satisfaction with work is an important consequent of ethical context as well as an important predictor of employees' happiness with life in general (Lee et al., 2015). So, the first hypothesis (H1) is that organization's IEC will be positively related to employees' levels of SWB.

IEC's impact on SWB might be explained by how organizations manage their members. Specifically, it is proposed that a stronger IEC is associated with a firmer adoption of SRHRM practices, i.e., HRM guidelines involving concerns for corporate social responsibility practices focused in promoting employees' quality of life (Sancho et al., 2018). The investment in such practices increases employees' SWB (Zhang et al., 2021). Accordingly, we posit that SRHRM mediates the relationship between IEC and employees' SWB (H2).

Ethical leadership might also help explaining how IEC promotes employees' SWB. Leaders can translate organization's ethical concerns into workers' daily lives, serving as role models, by giving salience to ethical issues, rewarding and sanctioning (un)ethical behaviors. Since ethical leaders contribute to higher job satisfaction (e.g., Sarwar et al., 2020), we predicted that ethical leadership mediates the relationship between IEC and SWB (H3).

The existence of a strong SRHRM system can enhance stronger ethical leadership. As SRHRM improves employees' behaviors and adherence to ethical practices (Podgorodnichenko et al., 2021), it is also expected to foster ethicality of leaders' behaviors. Leaders might serve as ambassadors of ethical and socially responsible practices in the workplace, communicating and promoting those practices (Brown & Treviño, 2006). Therefore, we propose that SRHRM and ethical leadership sequentially mediate the relationship between IEC and SWB (H4).

Design/Methodology/Approach/Intervention : A quantitative correlational, survey-based study was developed with 315 workers. It included instruments selected from the relevant literature (e.g.,

Brown et al., 2005; Diener et al., 1985; Kaptein, 2015; Sancho et al., 2018). The data were analyzed using multiple regression analysis using PROCESS macro.

Results obtained or expected : Three mediation models were examined, one for each SWB indicator. The results indicated significant total effects of IEC (measured by the scope of the ethics program) on positive and negative affects but not satisfaction with life, partially supporting H1. Furthermore, SRHRM mediates the relationship between IEC and the three indicators of SWB, supporting H2. H3 did not received support as ethical leadership does not mediates any of the relationships. Finally, findings provide support to H4, with the sequential mediation being significant for all SWB indicators.

Limitations : The convenience sample limits the results' generalizability. Common method bias is a potential threat given the study's cross-sectional, single source use.

Conclusions : Literature had previously confirmed the effect of IEC in the reduction of unethical behaviors. This study has look to the IEC with a different lens, examining its effect on employees' SWB and satisfaction with life. The findings indicate that a stronger IEC, promotes employees' SWB both directly and indirectly by fostering SRHRM, and, subsequentially, enhancing ethical leadership.

Relevance to the Congress Theme : Promoting people's well-being inside and outside work is a key challenge of today's organizations. This study shows how organizations' IEC can contribute for this endeavor by fostering SRHRM and ethical leadership.

Keywords: internal ethical context, subjective well-being, socially responsible human resource management

Oral presentation OP610

The relationship between organizational factors and mental health stigma at the workplace

Anja Lehmann, University of Zurich

science

Research goals: The aim of this study is to investigate the role of organizational factors on mental health stigma at the workplace.

Theoretical background: The high prevalence of mental health issues among the working population leads to severe challenges for many OECD countries since it creates costs, lowers well-being and harms employment. Although people with a mental health issue are both able and willing to work, empirical evidence indicate these people are more likely to be un- and underemployed compared to people without a mental health issue. One important reason concerning the issues of work participation among people with mental health issues is stigma. Stigma is a devaluation of a group of persons often part of a minority group leading to their exclusion and discrimination. Although there is empirical evidence of the severity of mental health stigma at the workplace, up to now, there is lack of research that has investigated the role of organizational factors (such as organizational culture, leadership and the working conditions) to address mental health stigma.

Design: Data from the general working population from Switzerland, Austria and Germany will be collected (expected sample size: N = 700) in November 2022. Participants will be recruited via Respondi (respondi.com) a high-quality panel provider based in Germany. It should be emphasized that the sample from the online panel is highly representative in terms of demographic factors, such as gender, age or level of education. Respondents will be randomly presented with two of four vignettes. These vignettes will show a person with a mental health issue (depression, burnout, schizophrenia, and alcohol addiction) who has been treated in a clinic and wants to return to work. After presenting the vignettes, the respondents will answer an online questionnaire with regard to stigma-related attitudes and organizational factors (i.e. organizational culture, leadership and the working conditions)

Results: We don't have the results yet but we will able to present the results at the conference.

Limitations: Although we consider four different mental health issues, we are not able to cover the whole spectrum of different diagnoses. Moreover, our study was limited by self-reported information.

Conclusions: This project gives a novel, different perspective on how mental health stigma at the workplace could be addressed by improving organizational and contextual conditions. This would be a first important step to adapt existing and to develop new stigma interventions suited to workplace-related contexts. This, in turn, has an important public and organizational health impact since tackling mental health stigma could reduce societal and organizational costs, prevent turnover and promote healthy and productive workplaces.

Relevance to the Congress Theme: This research fits the congress theme "The Future is Now: the changing world of work" as it addresses societal and work-related challenges due to the high prevalence of mental health issues. To prevent further social inequalities, we need knowledge about how workplaces should be designed to support employees with mental health issues.

Keywords: mental health stigma, occupational health, organizational design

Oral presentation OP680

The Relationship between Psychological Contract, Work-life Conflict and Burnout: The moderating role of Mindfulness

João Fontes_da_Costa, Ana Dias & Ana Junça | Polythecnic Institute of Tomar

science

Research goals and why the work was worth doing

This research tested (i) the mediating role of work-life conflict (WLC) in the relationship between Psychological Contract breaches (PCB) and Burnout (B) and (ii) the moderating role of Mindfulness (M) in the same conceptual relation.

Theoretical background

The PC is an implicit relationship between the Worker and the Employer tending to align expectations on both sides of the work relationship, assuming a regulatory dimension (Kotter, 1973, Argyris, 1962; Rousseau, 1989; Rousseau, 1995). It consists of a set of individual beliefs about the terms and conditions of a reciprocal exchange. The PC breach occurs when workers consider that the organization has failed to fulfill its obligations (Coyle-Shapiro & Kessler, 2000; Robinson, 1996; Rousseau, 1995). When this happens, individuals experience a feeling of violation; that is, an emotionally strong response (Morrison & Robinson, 1997; Zhao et al., 2007).

The concept of burnout as a chronic occupational stress syndrome, occurs when workers are unable to effectively manage the demands of their work (Dormann and Zapf, 2004). Freudenberger (1975) associated burnout with emotional exhaustion that materializes symptomatically with emotional changes that materialize in physical impacts.

Greenhaus and Beutell (1985) defined WLC as an incompatibility of social roles with responsibilities in opposite dimensions. WLC arises from permeable barriers between the family and organizational spheres (Barnett, et al., 1992).

Mindfulness has been studied as a strategy to increase productivity, manage stress levels, and assist workers in management efforts to balance work and family (Morganson, et al., 2015; Miller, et al., 1995). Mindfulness allows the individual to face the context with greater positivity (McCraty, et al., 2003), positively influencing job satisfaction, and negatively influencing stress, burnout and emotional exhaustion (Hülsheger, et al., 2013). At work, where change prevails, mindfulness can be a resource for the individual as it can help to manage and accept emotions (Troy, et al. 2013). Thus, mindfulness can be a condition that facilitates positive attitudes towards adverse events or conditions (e.g., Junça-Silva, et al., 2021). There is theoretical and empirical support for mindfulness as a personal resource. Resource conservation theory (Hobfoll, 1989) suggests that individuals strive to maintain and acquire more resources as a strategy to deal with negative working conditions and consequent work demands, such as PCB and WLC (Hobfoll, et al., 2018).

Design/Methodology

The present study was based on the Job Demand-Control (Support) Model and the Job-Demands and Resource Model. To this end a daily study was developed over five consecutive days with 67 workers (N=67*5=335).

Results obtained

Results showed: (1) that the breach of the psychological contract negatively influenced the work-family conflict and this, in turn, presented a positive relationship with burnout at the intra-individual level; (2) that the work-family conflict was a mediator of the relationship between the psychological contract breach and burnout also at the intra-individual level. In addition, results showed that this relationship seems to be conditional on the levels of mindfulness, since it proved to be a moderator of the previous mediation relationship, in a unexpected form, that is, the indirect effect of the psychological contract breach and burnout via work-family conflict was shown to be stronger for those individuals with lower levels of mindfulness (versus more mindful individuals).

Conclusions – research and or practical implications/Originality/Value

The conclusions allow us to delineate preventive strategies (on the breach of the psychological contract) and intervention (to reduce signs of emotional exhaustion) in organizations. Furthermore, these findings open the door to future studies that focus on the explanatory mechanisms of the relationship between the psychological contract and the development of burnout, as well as the analysis of the role of mindfulness in this relationship.

Relevance to the Congress Theme

Changes in the world of work introduce potential alterations in the psychological contract that thus deserve to be revisited in the light of the work-life conflict. Potential coping mechanisms should be studied preventively in order to guide future study and action.

Keywords: Psychological Contract; Work-Life Conflict; Mindfulness

Oral presentation OP379

The relationships of cobot operators' core self-evaluations and PsyCap with human-cobot interaction fluency. The role of emotional wellbeing

Mateusz Paliga, Institute of Psychology, Faculty of Social Sciences, University of Silesia in Katowice

science

In recent years, rapid changes fueled by the Fourth Industrial Revolution have led to the creation of Industry 4.0. A principal aspect of this transformation is the emphasis on advanced robotics and human-robot interaction (HRI). In fact, HRI, with a human-centered approach, has become an essential resource in Industry 4.0. Human centrality allows for a paradigm shift from automated and independent human activities to human–automation symbiosis characterized by the cooperation of machines with humans, therefore enabling new means to increase competitiveness. In light of these changes, the deployment of collaborative robots (cobots) has changed the game in modern factories. Cobots are devices supporting mutual and direct interactions with human operators while actively cooperating with them in the shared workspace, production activities, and working time. Because cobots are designed to be more co-workers than tools, fluent interaction between the operators and their robotic counterparts is critical for employees' task accomplishment and high performance. As a quality of interaction, fluency in joint action refers to a highly coordinated cooperation between the human and the robot who form a well-synchronized synergy-driven team, adapt to each other, and perform together to complete the task. Continuous fluent interaction requires the team members to jointly understand the capabilities of the others and is necessary to perform shared tasks.

In light of the human-centered approach to HRI, the current study investigates the dispositional and state-like human factors of fluency in human-robot interaction. Therefore, the first aim is to verify the relationships of operators' core self-evaluations (as a personality trait that pertains to one's worthiness, effectiveness, and capability) and psychological capital (as a state-like personal capacity encompassing self-efficacy, hope, optimism, and resilience) with four perspectives of human-robot interaction fluency (i.e., the human emotions-oriented, the human contribution-oriented, the robot-oriented, and the team-oriented fluency). It is hypothesized that both trait-like core self-evaluations and positive state-like Psychological Capital will be positively related to human-robot interaction fluency. The second aim of the study is to answer why personality and personal state-like factors might relate to fluency in HRI. Based on the broaden-and-built theory of positive emotions, the mediating role of operators' job-related affective well-being (i.e., positive and negative emotions) at work with cobots is investigated. Here, it is assumed that core self-evaluations and Psychological Capital are associated with human-robot fluency due to their relationship with positive job-related affective well-being, which in turn relates to HRI fluency.

The structural equation modeling performed on data from 200 male and female cobot operators working on the shop floor showed that the model fit the data well ($X2 = 18,80$ ($df = 17$; $p = 0,34$); CFI = 0,99; NNFI = 0,99; RMSEA = 0,02). Obtained results suggest that core self-evaluations positively correlate with robot-oriented fluency. Among the capacities of psychological capital, hope is positively related to human contribution-oriented and team-oriented fluency. The analyses also revealed that positive and negative emotions mediate the relationships between several human operators' dispositions and state-like capacities and their fluency in interacting with cobots.

The results of the study will be discussed within the theoretical framework of the human-centric approach to automation and the broaden-and-built theory of positive emotions. For a human-robot interaction to be successful, positive emotions are crucial. However, until recently, not enough

attention has been given to human emotions in the research on the human-machine system. Therefore, this study also adopts the perspective of hedonomics - focused on the enjoyable aspects of human-technology interaction - in order to explore how emotional states are involved in the process between the cobot operator's dispositions, state-like capacities, and HRI fluency. Suggestions of implications for the design of human-robot interaction stations will be given.

Keywords: human-robot interaction fluency, cobot, personality

Oral presentation OP686

The Right To Do Wrong: Compulsory citizenship behavior and unethical pro-organizational behavior: the role of psychological entitlement

Cemre Çınar, Sabanci University; Gergely Czukor, Istanbul Bilgi University

science

This study is testing a moderated mediation model linking Compulsory Citizenship Behavior (CCB) and Unethical pro-organizational Behavior (UPB) through the underlying mechanism of Psychological Entitlement, considering the role of moral licensing as a moderator. Previous studies focused on organizational identification, ethical leadership, and social exchange relationships to understand the driving forces of UPB. However, research on moral regulation as an alternative process explaining UPB is still in a nascent stage. Drawing on moral licensing theory, we test whether employees engaging in CCB are more likely to conduct UPB via a psychological entitlement mechanism, and whether this mediated relationship is moderated by perceptions of moral credit. Based on the attribution theory, psychologically entitled individuals are more likely to commit unethical acts as it is characterized as an inflated sense of self-deservingness and seeking special treatment. As individuals may offset or balance the previous good deeds with future unethical behavior, we hypothesized that the relationship between CCB and UPB mediated by PE is stronger for individuals with high moral credits. We conducted an experimental study manipulating CCB as focal predictor. The results based on 200 full-time white collaremployees from Istanbul, Turkey, supported the moderated mediation relationship. The findings indicate that the strength of indirect effects varies depending on employees' moral credits. As there are several corporate greenwashing scandals, including Volkswagen, Nestle, Starbucks, and Ikea, against sustainable production and consumption is a crucial term for executing United Nations (UN) Sustainable Development Goals in the organizational context . As part of UPB, employees may deceive the public by misrepresenting data causing environmental harm to the customers and stakeholders, financial fraud, or selling medicine that can be dangerous to health. Poor population is especially vulnerable to the consequences of UPB as people from poorer countries may be subjected to products that do not meet the quality standards of Western countries. This increases the gap between the quality of life of the poor populations and the richer ones. Overall, it is crucial to analyze the antecedents of UPB as it creates a competitive advantage for organizations to make more profit by deceiving the public. This deception may harm vulnerable populations and the environment that accentuates the inequalities among people. The theoretical and practical implications of these findings are discussed further.

Keywords: psychological entitlement, moral credits, unethical pro-organizational behavior

Oral presentation OP400

The road to inclusion: Which factors contribute to feeling included in the workplace and what good does it bring?

Ellen Delvaux, 1. IDEWE, External Service for Prevention and Protection at Work, 2. Center for Social and Cultural Psychology, KU Leuven; Lode Godderis, 1. IDEWE, External Service for Prevention and Protection at Work; 2. Center for Environment and Health, KU Leuven

science

INTRODUCTION : Our world today is characterised by globalisation and changes, which are accompanied with great complexities and many insecurities. This is no different in the labour market. The complexities in the workplace call for different perspectives and talents. In addition, an ageing population challenges the labour market with a shortage of workers. These challenges make it important to strive for an inclusive workplace where there is room for everyone, regardless of gender, age, skin colour, disability, etc., where everyone feels welcome and where anyone can bring in their unique perspective. In this study, we aim to gain insights into predictors of workers' feeling of inclusion, as well as its outcomes in terms of work-related well-being. Such insights may inform policy makers on the different actions they can take to improve workers' feeling of inclusion and well-being at work.

THEORY : In the organisational literature on diversity and inclusion, there has been a recent shift from diversity to inclusion (e.g., Ikeije & Lekan-Akomolafe, 2015; Shore et al., 2011, 2018). Although the potential of a diverse workplace to foster organisations' productivity and innovativeness has been recognized by scholars, the empirical results are mixed: A diverse workplace does not always lead to positive (organisational) outcomes (e.g., Williams & O'Reilly, 1998). Just bringing in diverse profiles does not seem to be enough. And this is where the idea of inclusion comes in. In order to flourish, workers need to feel welcome in the organisation and need to feel they can make a unique contribution to the whole (Shore et al, 2011).

The job demands-resources (Bakker & Demerouti, 2007) model posits that workers' well-being depends on job characteristics that motivate and energize them (job resources) or that demotivate them and take away energy (job demands). In the current study, we aimed to investigate how different aspects of the organisational culture (both job resources and demands) may predict workers' feeling of inclusion, which in turn may benefit well-being outcomes at the individual and organisational level. Following the logic of positive psychology, studying how growth can be achieved by nourishing positive experiences (Fredrickson, 2001), we focus mainly on positive organisational culture characteristics.

HYPOTHESES : As such, we hypothesize that positive organisational culture characteristics (participation in decision making, communication, supervisor involvement, supervisor diversity competence, diversity climate and diversity management) are positively associated with positive job outcomes (job involvement, extra-role behaviour, net promotor score, performance, innovative behaviour and intention to stay) and negatively with negative job outcomes (job stress). We expect the reverse associations between conflicts at work and the different job outcomes.

METHOD & (PRELIMINARY) RESULTS : We investigated work characteristics and job outcomes in relation to feeling included in the workplace in a three-wave online survey study. At this moment, the data collection is ongoing. In the first wave, 1342 Belgian workers completed the questionnaire. Respondents were recruited independently of their employer. Consequently, they hold different positions in their organisation (blue-collar workers: 5.2%; white-collar workers: 72.7%; managers:

22.1%) and worked in various sectors (care: 29.4%; public sector: 14.9%; offices: 13.4%; education: 13.1%; and industry: 9.5% as most common sectors). Overall, there were many highly educated respondents (77.0%), and only 2.7% labelled themselves as a member of a minority group.

Preliminary analyses from the first wave provide evidence for the hypothesized associations. We will use cross-lagged path analysis on the three waves to examine the predicted associations over time and to test for the directionality of the effects.

DISCUSSION : Although we aimed to recruit a heterogeneous sample for this study, participants were relatively homogeneous in terms of level of education and ethnic minority. Future research may investigate whether the same patterns hold true in a sample with more variation on these factors.

Our findings contribute to the scientific knowledge on inclusion in the workplace and inform policy makers about strategies to improve inclusion at work.

In order to deal with the complexities and challenges that go along with this changing world, we need all people to join forces and to work together in an inclusive way, counting on the individual strengths of everyone.

Oral presentation OP64

The Role of Country-Level Individualism in Strategic Career Behaviours in Flexible Working Arrangements

Kiall Hildred, Joana Carneiro Pinto & Claudia Simao | Universidade Católica Portuguesa

science

The recent covid-19 pandemic has put teleworking into the spotlight. Yet, minimal focus has been placed on teleworkers in previous studies on strategic career behaviours. Furthermore, cultural differences, particularly levels of individualism vs collectivism, can play an important role in the effects that the isolation of teleworking can have on the career development of individuals. This study extends work developing a model of the antecedents and consequences of SCB using the Kaleidoscope Career Model (KCM), which has shown to interact with the career-relevant constructs of perceived self-efficacy (PSE), desire for career control (DCC) perceived organizational support (POS), perceived career control (PCC), objective and subjective career success (OCS; SCS), and career satisfaction (SAT). The present study extends this work by investigating these variables in a European sample and comparing country-level differences in these outcomes based on Hofstede's Individualism/Collectivism scale (IDV). A total of 739 employees (Male=442, 59.8%), with a mean age of 27.64 years (SD=8.48; Range=[18, 70]), working mostly full-time (N=398, 53.9%) and with 46.35% of their work being done remotely, completed a questionnaire on a number of demographic variables and SCB and on the career-relevant variables. Participants were included if they were both resident in and working for a company in continental Europe, including the UK, Turkey and Cyprus, but excluding Russia, and were split into two groups based on their residence country's score on Hofstede's Individualism/Collectivism scale (Low[<50]=286, 38.7%; Range=[27, 89]). Correlation and regression analysis tested the antecedents PSE, DCC and POS as predictors of SCB, and tested SCB as predictors of the consequences PCC, OBC, SCS and SAT. Mediation analysis tested the SCB as a mediator between the antecedents and consequences. T-tests compared the low and high IDV groups for significance of differences on variables in the model. Results indicated that OCS was not related to the antecedent variables or SCB and hence was removed from the model. For both low and high IDV countries: PSE and DCC were good predictors of the use of SCB, but POS was not; SCB were reasonable predictors of PCC, and very strong predictors of SCS and SAT; PSE had a direct effect on the consequent variables; POS had a significant effect on PCC and SAT, but not on SCS; and DCC had a significant effect on SCS but not on PCC, and only for high IDV countries on SAT. Significant differences were found between the groups' mean scores on PSE, DCC, SCB, SCS and SAT, but not POS or PCC. Although this study was intended to include a wider European sample, the majority (57.9%, N=428) resided in either Portugal or Poland. This may indicate a limitation in the methodology of using paid online questionnaires and limits the generalisability of the findings to other European countries. However, this suggests the need for further research that includes a larger sample more representative of remote workers on the European continent and further analysis to make pairwise comparisons between countries. The significant shift to teleworking and other location-flexible work arrangements will be important factors in the changing world of work. The results of this study will contribute to the UN SDG of decent work and economic growth by supporting the development of career management programs for employees to manage their career goals, accounting for advantages and difficulties specific to teleworking, while also catering for possible cultural differences that may play a role in the impact telework has on career management.

The role of educational-job match in the relationship between career adaptability and career success

Jesús Yeves, Universidad Diego Portales, Chile. Millennium Nucleus on the Evolution of Work, Chile; Mariana Bargsted, Universidad Adolfo Ibáñez, Chile. Millennium Nucleus on the Evolution of Work, Chile; Cristián Torres-Ochoa, Millennium Nucleus on the Evolution of Work, Chile

science

Purpose

The aim of this study is to analyze the relationship between career adaptability on career success (objective and subjective), through the match between the educational level obtained and educational level required by the job (vertical match) and the relationship between graduates' field of studies and job (horizontal match).

Theoretical background

In a context characterized by faster changes in the labor market, career adaptability has emerged as a personal resource that helps individuals effectively manage career-related tasks throughout their working lives. Although empirical studies have demonstrated the positive relationship between career adaptability and career success, there are mechanisms mediating this relationship that have been little explored, such as the educational-job match, both horizontal and vertical.

Design/methodology/approach

An online survey was answered by 984 Chilean graduates from a large non-selective higher education institution that enrolls a significant number of first generation, and lower socio-economic background students. Structural equation modeling was used to examine the mediating role of educational-job match.

Findings

The results of structural equation modeling showed that career adaptability was positively related to objective and subjective career success. Also, the results showed that both vertical and horizontal match partially mediate the relationship between career adaptability and objective and subjective career success.

Originality/value

This study contributes to improving the understanding about how different resources, such as career adaptability and education-job match influence career success. Testing the utility of these relationships on a group that has been underrepresented in career development studies is also relevant, particularly, the use of the gain spiral concept from Conservation of Resources theory.

Research limitation

The study made use of a cross-sectional design, which hinders the identification of causal direction.

Practical implications

Universities, organizations, and career counselors might need to focus on career adaptability to promote career success. Moreover, considering that resources do not exist in isolation, but act in

caravans and influence each other, it is important to consider other resources such as education-job match.

Relevance to the congress theme

Nowadays, careers and work itself are radically changing, due to the transformation of the work context. This implies, more than ever, the need to study personal and organizational resources that can promote the development of satisfactory careers. In that vein, this research contributes by analyzing the role that personal resources, such as career adaptability, and organizational resources, such as educational-job match, in enhancing the favorable perception of career achievements that contribute to work and general well-being.

Relevance UN SDGs

Career research is facing new challenges, particularly, when looking for new contexts in which to test these relationships, in order to identify potential resources in specific social groups, such as first-generation professionals. This group of professionals has developed their careers with certain disadvantages, such as lack of social capital and family support. This social group represents, on average, 75% of all the graduates from OECD countries (OECD, 2017). Therefore, a better understanding regarding the role of educational-job match to improve career success could help educational centers and organizations to develop policies and practices to promote this match.

Oral presentation OP136

The role of implicit leadership and followership theories in abusive supervision perceptions and outcomes

Maria João Velez, ISCTE-IUL

science

The role of employees' individual leadership schemas in shaping their perceptions of supervisory behavior has been acknowledged by many organizational scholars (e.g., Foti & Lord, 1987; Lord, 1985; Lord, Foti, & De Vader, 1984; Lord & Maher, 1993). However, little research attention has been devoted to employees' implicit leadership theories as an antecedent of abusive supervsion perceptions. Specifically, we suggest that the prototypic dimensions (sensitivity, intelligence, motivation, and dynamism) are positively related to abusive supervision perceptions, contrary to the antiprototypic dimensions (tyranny and masculinity). Additionally, we suggest that implicit followership theories act as a moderator in the relationship between abusive supervision and deviant behaviors, since beliefs about followers' personal attributes and characteristics affect the way subordinates behave, even when they are victims of supervisory abusive behaviors. Thus, we propose that prototypic followers are less prone to retaliate directely against abusive supervisors, however, they retaliate indirectly through turnover intentions.

Participantes were 367 supervisor-subordinate dyads from different organizational settings. Bootstrapping results indicate that the prototypic dimensions are significantly related to abusive supervision perceptions and that abusive supervision is significantly related to deviant behaviors when prototypical or positive second order IFTs factor was low ($t = 3.15$; $p < .05$), but not when it was high ($t = -.52$; $p > .05$). Contrary, abusive supervision is significantly related to turnover intentions when prototypical or positive second order IFTs factor was high ($t = 4.22$; $p < 05$), but not when it was low ($t = -.34$; $p > .05$).

Research results indicate that employees' prior expectations and cognitive prototypes influence not only abusive supervision perceptions, but also abusive supervision outcomes. Specifically, the current study provides support for Lord and Maher's (1993) suggestions that employees use implicit leadership theories as an uncertainty reduction mechanism and compare their actual supervisior with their implicit profile in order to evaluate his/her behavior (Epitropaki & Martin, 2005).

One limitation is related to common method bias, since employees provided ratings of implicit leadership theories, abusive supervision, implicit followership theories and turnover intentions. Because our design is cross-sectional, we cannot infer causality.

This research makes several contributions for theory and practice. Firstly, it expands the content domain of abusive supervision research and highlights the relevance of employees' schema to abusive supervision perceptions and consequences. Secondly, it is useful for managers to know that abusive supervision may affect employees differentially, depending on employees' prior expectations and schema.

This research contributes to the better understanding of abusive supervision, mainly by shedding some light concerning abusive supervision antecedents and individual factors that could buffer or exacerbate the negative effects of abusive supervision on organizational functioning.

Keywords: implicit leadership theories; implicit followership theories; abusive supervision

Oral presentation OP596

The Role of Job Insecurity in Predicting Multiple Jobholding

Claudia Rossetti, Himani Singh | University of Mannheim

science

This study looks at how perceived job insecurity (JI), representing the level of perceived threat to the continuity of one's job or employment, affects employees' likelihood of taking on more than one paid job, i.e., entering multiple jobholding (MJ). MJ has had longstanding importance in advanced economies thanks to the growing prevalence of work flexibility, platform technologies, and gig work. MJ is now an increasingly touted way to generate additional income, learn skills, and enlarge one's professional network. Thus, research in economics theorizes MJ as a hedging strategy allowing employees to distribute risks, including those associated with JI, across jobs. We challenge this notion by arguing that MJ represents a double-edged sword for job-insecure employees. Though these employees can benefit in certain ways from taking on additional jobs, the potential gains come at the cost of significant resource investments. Accordingly, our paper offers a longitudinal investigation of how JI impacts the propensity to enter MJ.

Drawing from conservation of resources (COR), we develop competing hypotheses that link JI and MJ. JI poses a threat to the resources associated with one's job, such as income and status. First, relying on the "resource conservation" tenet of the theory, we argue that perceived JI can reduce the likelihood of MJ entry (Hypothesis 1a). Based on this tenet, employees faced with high levels of JI may adopt a defensive orientation to protect against the threat of net resource loss and thus strive to conserve existing resources. Accordingly, they may avoid taking on side jobs to preserve resources such as time and energy and safeguard resources derived from the primary job. Second, based on the "resource acquisition" tenet, we posit that perceived JI increases the likelihood of MJ entry (Hypothesis 1b). Based on this tenet, employees may invest resources to acquire resources to buffer against the threat of resource loss. Thereby, they may enter MJ to acquire additional resources, such as income, knowledge, and networking opportunities, that replenish the ones at risk because of the threat of losing the primary job.

We use secondary data from 1999 to 2019 included in the German Socio-Economic Panel, a longitudinal survey of German individuals. The survey collects individuals' perceptions of JI and details on both primary and secondary jobs, among other information . Our sample consists of 3,140 job spells for 819 German individuals (50.92% female, 49.08% male) and 106 MJ entries. We use Cox proportional hazards models to estimate how perceived JI affects the likelihood of an employee who hitherto does not have additional jobs to enter MJ. Supporting Hypothesis 1a, higher levels of perceived JI significantly reduce individuals' propensity to enter MJ ($b = -.105$, $p = .019$; hazard ratio: 0.90). Thus, a one-unit change in perceived JI decreases the likelihood of entering MJ by 10.00%. Our results are robust to several alternative specifications. Plus, we examine potential moderators of this relationship.

We use COR theory instead of other common perspectives in JI research (such as social exchange theory) to offer a more comprehensive theoretical explanation for how JI might impact the propensity to take on work outside of the primary job. So far, scholars have theorized a positive link between precarious workers and MJ, and findings have been equivocal. We expand this research by developing a framework that, by including conservation and acquisition mechanisms from COR theory, holistically explains how JI relates to MJ while answering the call to simultaneously theorize about competing mechanisms that relate JI to its outcomes. Our findings are important given that we

longitudinally investigate individuals' actual entry behaviors in response to perceived JI (as opposed to entry intentions or purely cross-sectional analyses typically used in existing research). Moreover, we add to the studies in the field of JI that have started to examine how JI affects "extra-organizational behaviors", revealing that increasing levels of perceived JI limit MJ entries.

The changing world of work is creating new pressures and opportunities when it comes to employment conditions. Employment is becoming more precarious due to pandemics, economic crises, automation, among others. At the same time, new forms of work arrangements are on the rise thanks to the growing influence of gig work and remote working technologies. Our paper brings together both issues by investigating how JI affects workers' chances of entering MJ. Accordingly, our research is relevant to a broad audience, including individuals, organizations, and policymakers, and to the UN SDG of promoting full employment and decent work for all.

Oral presentation OP113

The role of online platforms as sources of daily social support for gig workers' in- and extra-role performance

Vera M. Schweitzer & Fabiola H. Gerpott | WHU - Otto Beisheim School of Management; Wladislaw Rivkin, Trinity College Dublin

science

Research Goals

Due to the advancement of platform economies as well as the growing desire for "on demand" work, the number of gig workers has increased drastically in recent years (Sessions et al., 2021). Gig workers are independent workers contracting directly with customers for a short-term gig, for example, via online platforms (Ashford et al., 2018). Extant research has proclaimed that gig workers – especially those on crowdworking platforms such as MTurk – suffer from a lack of social support by others (e.g., co-workers, supervisors) as these gig workers are not part of a "real" organization but instead work alone at home (Watson et al., 2021). We challenge this notion by arguing that theory on traditional OB phenomena (such as social support) needs to be updated to incorporate new forms of social exchange. Specifically, we focus on informal online platforms (i.e., Turkerview) as a potential point of contact that gig workers can consult, and argue that seeking social support from other gig workers on such platforms can help to deal with the inherent daily challenges of gig work (i.e., emotional and cognitive demands of flexible work) in order to stabilize their in- and extra-role performance.

Theoretical Background

We integrate the transactional stress theory with the social support literature to propose that gig workers engage in emotion- and problem-focused coping in reaction to daily gig work-specific demands by seeking social support on informal online platforms. Specifically, we propose that daily gig work-specific cognitive and emotional demands predict gig workers' emotional and instrumental support seeking as situational (i.e., within-level) and dispositional (i.e., between-level) coping mechanisms that stabilize gig workers' effectiveness (i.e., the money they earn on MTurk) and allow them to engage in extra-role behaviors.

Study Design

We first conducted a pilot study with 102 MTurkers to collect qualitative descriptions of social support on online forums. We categorized the responses and identified four specific forms of emotional (e.g., seeking motivation) and instrumental support seeking (e.g., seeking advice on problems with specific HITS), respectively. We used the insights for the development of items to capture these constructs during a workday. Study 1 served as a first test of our research model with regard to gig work-specific demands, social support seeking, and extra-role behaviors. Study 2 further examined downstream consequences on gig workers' monetary performance. Moreover, in Study 2, we could disentangle rather stable between-person effects from daily within-person effects.

Results

In Study 1, we found that gig-specific emotional demands predicted emotional support seeking on informal online platforms. Moreover, gig-specific cognitive demands predicted both emotional and instrumental support seeking. Subsequently, emotional support seeking was positively associated

with emotional support providing. Similarly, instrumental support seeking was positively related to instrumental support providing as well as OCB-O towards the crowd working platform.

Study 2 explored our research model on both the within- and between-person level. With regards to the between-level, we replicated the between-person findings from Study 1 showing that emotional demands predict emotional support seeking and cognitive demands predict instrumental support seeking. We further found again that emotional support seeking is associated with emotional support providing and instrumental support seeking is related to instrumental support providing and OCB-O towards MTurk. However, Study 2 does not find that cognitive demands lead to more emotional support seeking. Instead, we found that instrumental support seeking is additionally associated with emotional support providing and that emotional support seeking is also related to OCB-O towards MTurk on the between-level. Further, we do not find an effect of emotional and instrumental support seeking on monetary performance between persons.

Limitations

We rely on self-reported data and cannot claim causality of our model. In the future, within-person field experiments redirecting participants to specific MTurk-related forums and asking them to engage in social support seeking could address these limitations.

Implications

Our research challenges previous assumptions regarding the loneliness of gig workers (Caza et al., 2022) by demonstrating that gig workers can receive social support related to their work. We also expand the transactional stress theory (Lazarus & Folkman, 1984) by suggesting that emotional and instrumental support seeking reflect forms of emotion- and problem-focused coping in the gig context.

Congress theme

Gig work is a phenomenon of the 21 st century, with MTurk being founded only in 2005 and growing ever since. Thus, studying the work experiences of people working on MTurk is of inherent relevance to the congress theme.

UN SDG

Decent work and economic growth

Oral presentation OP140

The Role of Working Conditions in the Emergence of Technostress Among Legal Professionals

Audrée Bethsa Camille, Pierre-Luc Fournier & Nathalie Cadieux | University of Sherbrooke

science

Recent technological advances and applications have transformed professional practices in transmitting and processing information. However, the widespread implementation of these technologies presents a paradox: increased flexibility and accessibility lead to an intensified pace and workload to reduce the professionals' performance. The challenge resides in organizations' inadequacy in adapting professional working conditions to these technological environments. Furthermore, these advances and their implementation have been linked to psychological risk factors for wellness, such as technostress. Technostress refers to the stress experienced by an individual due to information and communication technologies (ICT) usage to perform their work. This phenomenon is widely observed among knowledge workers, including legal professionals, university professors, and librarians. These professionals have a symbiotic relationship with their organization; their wellness at work, the evolution of their careers and their organization's progress are entwined.

Technostress has given rise to multidisciplinary attention, providing various paradigms and measurements to advance the technostress literature. To that extent, occupational stress theories have provided a solid theoretical background for emerging studies on technostress. Our research draws on the transactional stress and coping (TSC) theory and the job demands-resources (JDR) model propositions. The TSC theory states that job risk factors result from a disturbed person-environment equilibrium. The JDR model argues that each profession may have specific risk factors associated with occupational health, i.e., job stressors. In doing so, it provides an investigation framework to examine the influence of these risk factors on stress reactions, such as burnout. Therefore, our research model is grounded in that framework to explore the working conditions, demands and resources associated with the experience of technostress.

The context of abundant information transfer requires knowledge workers, such as lawyers, to acquire new techniques to process knowledge in their expertise. Through a mixed-method approach (interviews and surveys), prior research found technostress prevalent among lawyers. Interview analyses reported that 32% of statements regarding sources of stress are related to the difficulty of adapting to ICT in an organizational setting. Their results indicated that technostress dimensions (technostressors) are significantly associated with increased psychological distress and burnout. The acceleration of the pace of work induced by ICT, the information and communication overload, and the replacement by artificial intelligence are just a few examples of technostressors that affect lawyers. However, this prior research has not examined the association between working conditions and technostress.

Our research aims to understand the relationship between psychological working conditions and the experience of technostress among legal professionals, using a secondary analysis of data obtained through a survey distributed to Canadian legal professionals in 2021 after the third COVID-19 wave. The data subset includes 3,850 completed and useable responses from lawyers, notaries, and paralegals. A hierarchical analysis is carried out, using the enter method, to reveal the effect of working conditions on technostress. The results reveal three models sequencing the interaction of job demands (entered first) and job resources (entered second) while controlling for age and gender. The analysis consistently shows that quantitative psychological demands, lack of resources, and emotional demands significantly exacerbate technostress. Additionally, consistency of values and

social support from colleagues are significantly associated with technostress mitigation. The presentation will detail which working conditions exacerbate and mitigate the experience of technostress.

Legal professionals whose work has seen many changes through ICT usage are a group of knowledge workers in the grip of technostress. Examining working conditions is a worthwhile approach to ensure technostress prevention. This research contributes to the technostress literature and the study of knowledge workers' wellness by highlighting the decisive role of demands and resources in the experience of technostress and therefore provide insight for recommendations. The study's limitations stem from the cross-sectional design of the survey. In addition, the dataset was collected during the COVID-19 pandemic, a period characterized by massive transitions toward teleworking and ICT. In alignment with UN sustainable development goals, adjusting professional work settings and job characteristics promotes good health and wellness, preventing professional burnout (the third goal). A well-rounded ICT implementation process that considers technostress prevention also ensures sustainable performance expectations (the eighth goal).

Keywords: working conditions, technostress, legal professionals

Oral presentation OP248

The State of a Nation: The Prevalence and Correlates of Employee Anxiety in the UK

Neil Conway, Royal Holloway; Martin Edwards, UQ Business School; Michael Clinton, King's College London

science

Research goals and why worth doing

We examine the prevalence and correlates of employee anxiety during the 2008-2011 recessionary period in the UK following the 2008 Global Financial Crisis using an authoritative nationally representative multilevel dataset.

Countries throughout Europe have been profoundly challenged by major crises in the last 15 years (Global Financial Crisis 2008; COVID19; Ukraine war 2022). These and other events have led researchers to claim we live in an age of anxiety. Our focus here is employee anxiety, which has been under-researched and is worth studying because of its implications for employee health and workplace behaviour (Cheng & McCarthy, 2018). Our focus on the recession following the 2008 financial crisis offer insights into more recent crises.

Theoretical background

While there are many organizational studies on stress and negative affect, and on anxiety in the broader psychology literature, there has been a neglect of research on workplace anxiety (Cheng & McCarthy, 2018). We develop a wide-ranging model of antecedents to and consequences of workplace anxiety drawing on Cheng and McCarthy's Theory of Workplace Anxiety (2018) and Kensbock, Alkaersig and Lomberg's (2022) social contagion model of anxiety.

Method

We use the authoritative Workplace Employment Relations Survey (WERS, 2011), consisting of a large-scale UK nationally representative dataset of 14,804 full-time employees nested within 1,752 workplaces. The publicly funded survey is designed to cover a broad range of employee and workplace issues and includes items measuring institutional factors (e.g., governance structures), organizational factors (e.g., HR practices), employment contract types, job characteristics, work attitudes, affective wellbeing,, and performance outcomes.

Anxiety was measured using the three negatively worded items from Warr's (1990) measure of anxiety–contentment (i.e., 'tense', 'worried', 'uneasy'). Antecedents to workplace anxiety drew on items capturing demographic differences (e.g., gender), perceived competence, job security, job characteristics (e.g., autonomy, demands), and a series of items capturing how the recession affected employees' jobs. Measures of consequences to workplace anxiety included attitudes (e.g., job satisfaction) and behaviours (e.g., overtime hours). The role of anxiety will be contrasted with depression (three item measure: 'depressed', 'gloomy', 'miserable') to examine the unique effects of workplace anxiety.

Results obtained

The dataset is publicly available and therefore already obtained. About 15% of the sample reported feeling anxious most or all of the time. Preliminary regression analyses show support for the Theory of Workplace Anxiety and the social contagion model where, for example, anxiety was strongly associated with antecedents including disability, workload increases attributed to the recession, job

insecurity, high job demands and low manager support; anxiety associated with the outcomes of lowered job satisfaction, decreased organizational commitment, and working more overtime hours. The strongest effects of all were found for social contagion where the employee with the highest anxiety within the work unit were found to be the carrier of anxiety, with the line manager being a carrier to a lesser extent.

Limitations

Cross-sectional and self-report data. WERS is a broad purpose survey and therefore necessarily uses short-item scales (ranging mostly between single to five item measures).

Conclusions – research & practical implications/Originality

There is limited research on anxiety in organizations (Cheng & McCarthy, 2018), and we offer one of the first studies to investigate the incidence and correlates of employee anxiety at the national UK-level. We test a wide range of explanations that suggest implications for interventions at the level of organizational practices and social policy.

Relevance to Congress Theme

We examine one of the most important crises in recent history, namely, the recession following 2008 Global Financial Crisis. Our discussion will contextualize our findings alongside other national studies of anxiety and other global crises (e.g., COVID19).

Relevant UN SDG

Our study of employee anxiety provides national level evidence relevant to the SDGs of 'Good health and wellbeing' and 'Decent work and economic growth'.

Keywords: employee anxiety; recession

Oral presentation OP515

Three pillars of onboarding – conceptualization and measurement proposal

Przemysław Zbierowski & Krzysztof Wąsek | University of Economics in Katowice

science

Research goal

Onboarding process becomes increasingly important in modern HRM due to accelerating employee turnover (Semenza et al., 2020) and a great need for employee development (Karambelkar & Bhattacharya, 2017). Organizations design more suitable implementation programs so that new employees are ready to fully function in their work positions without loss of time (Becker & Bish, 2019). Yet, up to date, onboarding has not received a lot of scientific attention. We believe that one of the reasons behind it is the lack of reliable measures that would enable the study of cognitive and behavioural consequences of onboarding, such as psychological capital or organizational citizenship behaviour. The purpose of the paper is to develop such measure.

Theoretical background

The current research on onboarding is focused mostly on the levels of implementation that an employee can achieve after completing the program (Bauer, 2010). Moreover, the only measure of onboarding is a short scale consisting of three open-ended questions which reliability has not been thoroughly tested (Meyer, Bartels, Lynn, 2017). The literature however suggests that three factors matter in onboarding process: interactivity, proactivity and community.

Interactivity is the response of HRM departments to the needs of young generations of employees who are used to acquire knowledge and experience through movies, websites and other interactive formats. It has already been established that interactive solutions have a greater impact on young generations (Ferri-Red, 2013). Interactivity also gains imporatance in post-pandemic reality and with the increase of remote work with considerable share of onboarding taking place online.

Proactivity plays a key role in smooth and comprehensive implementation. Previous research emphasizes the importance of the proactive attitude of managers responsible for onboarding (Saks et al., 2011; Jeske & Olson, 2021). Dekas (2013) highlights that managers, characterized by a proactive approach to sharing knowledge, increase the chances of success of the process.

Community brings together all the people, their competences and skills used in the implementation of onboarding. Bradt and Vonnegut (2009) emphasize the special role played by mentors who are an extremely helpful source of information and support for new employees (McKimm et al., 2007) and buddies who can be described as friends of newly hired. Also others (Karambelkar & Bhattacharya, 2017; Caldwell & Peters, 2018; Bhakta & Medina, 2021) stress the fact that assigning a patron is an excellent idea to support individualized forms of implementation. Graybill and colleagues (2013) include mentors and buddies among the necessary components of any onboarding.

Method

We follow the literature to propose a three-dimensional measure of onboarding that will enable to explore the psychological effects of onboarding process and, in consequence, create more effective implementation programs. The first stage of the research was to find items categorized into three pillars of onboarding in the process of literature review of over 100 peer-reviewed journal articles.

In the next stage, 23 interviews were conducted with people holding middle and senior managerial positions in the HR area. During the interviews, experts were asked what activities they would classify under each of the pillars. The comparison of the results from the two stages of the procedure made it possible to compare the most common activities. In the next stage, the three-dimensional measure of onboarding with 31 items (11 for interactivity, 10 for proactivity and 10 for community) was tested on a group of 556 employees using factor and reliability analyses.

Results

In factor analysis the number of items was reduced to 3 (interactivity, α=.801), 4 (proactivity, α=.867) and 3 (community, α=.708) to form 10-item scale. Confirmatory factor analysis produced the RMSEA value of .071 which indicates that the models falls between close and acceptable fit (Pituch & Stevens, 2016). The values of CFI (.967) and TLI (.954) indicate a very good fit (Schumaker & Lomax, 2016). Also the value of SRMR (.039) indicates a close fit (Pituch & Stevens, 2016). For comparison we tested the fit of one-dimensional model which is significantly lower (RMSEA .110, CFI .915, TLI .890, SRMR .050).

Implications

The effect of the described work is a research tool covering the area of the 3 pillars of onboarding. The developed tool can be used by both the scientific community to study psychological consequences of onboarding and managers to create onboarding programs and improve existing implementation programs.

Relevance to the Congress Theme

With increasing importance of onboarding, our study contributes to potential positive change in the world of work reducing inequalities between employees and increasing their performance and satisfaction with work.

Keywords: onboarding, interactivity, proactivity

Oral presentation OP265

Time to CHAT? A concise risk assessment tool for workplace bullying and harassment

Elfi Baillien, KU Leuven; Guy Notelaers, University of Bergen; Hans De Witte, KU Leuven

science&practice

Purpose

While scholars and practitioners have repeatedly underscored the importance of a thorough risk assessment foreffective prevention of workplace bullying and harassment (WBH), the current status regarding such assessmentsshows some obvious gaps. First, from a scientific perspective, most of these instruments are developed byinstances (e.g., consultancy firms) applying a more commercial angle to the assessment. Consequently, many of the tools at hand lack a sound underpinning in terms of their psychometric qualities. Most of them lack a validationprocedure and some of them even fail to adhere to item-theory standards. And, many tools apply outdated or inadequate statistical methods, therefore providing inaccurate feedback for risk prevention. Moreover, many of the existing tools miss out on crucial risk factors because they were not developed based on a scientific research protocol.Notably, also, they predominantly look at risk factors within the job or organization, missing out on the interpersonal, social context displayed in personal relationships between team members. Consequently, the instruments tend to explain rather low variance in WBH. Second, from a practical perspective, the tools that do aim to respect psychometric and statistical requirements are often lengthy, time consuming, and costly. Moreover, they can often onlyprovide feedback after weeks to months, which challenges a swift prevention program from assessment towardsinterventions. In reply, we developed CHAT (i.e., Combat Harassment tool) that is (1) valid and (2) short, (3) includes the interpersonal aspect of WBH, (4) applies adequate statistics and (5) provides direct feedback.

Methodology

First, potential risk factors of WBH and its measurements were identified based on a thorough review of the current literature, including more recent publications tapping more social and interpersonal factors. Second, apilot study (N = 354) was conducted to assess the psychometric properties of the preliminary questionnaire (EFA, CFA, reliability). Then, atwo-wave data collection (N = 77648) was used to identify the prominent risk factors WBH using regression analyses.Through ROC-analyses we calculated their cut-off points in terms of primary prevention (i.e., incivility) and secondary prevention (i.e., LCA-determined victims). We collected input from practitioners' stakeholders as to develop the online tool and support (N = 27).

Results

CHAT entails seven risk factors, being role conflict, workload, task-related conflicts, personal conflicts, laissez-faire leadership, quantitative job insecurity, and qualitative job insecurity. It also includes measurements for experiencing and witnessing bullying, sexual harassment, and violence as well as who enacted these behaviors. Finally, it also assesses burnout. The Cronbach's Alfa of the scales reached between .75 and .93. From the ROC-analyses we established green, orange, and red zones for each of the risk factors. An online tool was programmed allowing organizations to log in and distribute the CHAT questionnaire among pre-defined groups of employees. After finishing the survey, they can directly upload the results to start 'chatting' about what is going on.

Limitations

The longitudinal study was carried out during the pandemic. Therefore, we are following up the data collected currently through the CHAT surveys as to recalculate potential shifts in the green, orange, and red zones.

Conclusion

The results allow determining the relative importance of work-related antecedents of WBH. This fosters thedevelopment of adequate interventions for the prevention of WBH. In all, CHAT aims to be the first of its kind risk assessment for WBH specifically, by combining current voids from both a scientific as a practical angle.

Relevance

This presentation suits the congress theme in terms of contributing to science-based practice, applying an innovative approach as an online tool to support practitioners in WBH prevention. WBH are notable issues in our workplaces, and through CHAT we can deliver direct insight in the situation allowing organizations to act in urgence .

Keywords: bullying, risk assessment, evidence-based tool

Oral presentation OP348

Title Scratching the Glass Ceiling in Academia by Rebranding Top Positions' Identity Discourses

Barbara Germann, Selina Weber & Prof. Dr. Dörte Resch | FHNW University of Applied Sciences and Arts Northwestern Switzerland

science&practice

Research goals and why the work was worth doing

The goal is to increase the proportion of women in top positions at a university of applied sciences in Switzerland. The research question was: Which obstacles stand in the way of women attaining professor and leadership positions and how can these professions be rebranded so that they are attractive for all genders?

This research is important to provide equal opportunities and to counteract the skilled labor shortage.

Theoretical background

The goal is to increase the proportion of women in top positions at a university of applied sciences in Switzerland. The research question was: Which obstacles stand in the way of women attaining professor and leadership positions and how can these professions be rebranded so that they are attractive for all genders?

This research is important to provide equal opportunities and to counteract the skilled labor shortage.

Theoretical background

One reason why women are progressively lost from senior positions in academia is the role that socio-cultural constructions play in the development of scientific careers (Avolio et al., 2020). Scientific careers are strongly associated with men (Miller et al., 2015) which influences women's perceived fit (Heilman, 1983) and consequently their scientific self-concepts, their self-efficacy and ultimately their science career choices (Deemer & Thoman, 2014; Ertl et al., 2017; Ramaci et al., 2017). So far, too little has been done to analyze how these gender-stereotypes can be dissolved. One approach that can be used to frame the often-unconscious images as gender inclusive is branding (Lundkvist, 2015). To date, the focus of branding was on the organization, but branding theory can also be applied to study courses or professions (e.g. Resch et al. (2020) used this approach to rebrand the image of ICT study programs and increased the proportion of women by 73%).

Methodology

To identify (gendered) identity constructs about academic top positions, a qualitative approach based on a social constructionist perspective was used. Data were collected through document analysis (career site of the university, LinkedIn profiles of professors, internal HR documents), problem-centered interviews (Witzel, 2000) with HR managers and institute/university directors (n=25) and nine group discussions among professors (n=37). A discourse analysis was performed. Based on the identified discourses, professor and leadership professions were rebranded in a way that enables all individuals to identify with them more strongly.

Results

The following discourses were identified:

The university of applied sciences is unique in its function as it operates at the interface between universities and industry.

Gender and profession are identity-creating features, which means that no one can escape its effects.

The job profile of a university of applied science professor is much unknown.

The requirements that applicants must meet are very high.

The job of a professor is characterized by creative freedom and interdisciplinary exchange.

These interpretative repertoires are used as explanations why women drop out on the way up: male dominated cultures, skepticism about equality policies, assumption that women do not want to occupy high positions, viewing gender inequalities as a societal problem.

Based on these discourses a reconstruction was developed forming a more inclusive brand identity.

Limitations

This qualitative study was focused on producing insides in a specific context. More research is needed to evaluate the implementation.

Conclusions

Overall, the unique combination of a discourse analysis with branding theory achieves novel results. Based on the identified discourses academic top positions could be rebranded to make them more attractive for all genders, therefore enforcing a more diverse image of “a professor”. The next step is to launch the new brand in the form of revising job websites and job advertisements, offering courses about gender-sensitive recruiting and promoting the new professional brand to target groups (e.g., through career events).

Especially interesting is the discourse about gender. Many respondents were reasoning that the agency solely lies with women or society in general. The strong association of scientific careers with men (Miller et al., 2015) did not get reflected. So, if universities want to attract a more diverse workforce they have to actively counter gender stereotypes of the profession. Furthermore, the role of internal stakeholders concerning these matters should not be underestimated since it addresses identity-forming aspects relevant to them.

Relevance to the Congress Theme

As an institution, one must be aware of the impact one has on society and take effective steps to fulfill this responsibility. By actively addressing gender stereotypes, universities contribute to supporting gender diversity.

Relevant UN SDGs

The research project aims to improve gender equality at universities top positions.

Keywords: gender stereotypes, branding, discourse analysis

Oral presentation OP111

To be or not to be a perfect parent? How the striving for perfect parenting harms employed parents

Monique Mohr, Chemnitz University of Technology; Sabine Sonnentag, University of Mannheim

science&practice

Managing multiple roles in the work and in the family domain can be difficult, especially for employed parents. Nowadays, managing one's roles as an employee and a parent has become even more demanding as more and more employees aim to be perfect parents. In line with this notion, parenting perfectionism (i.e., striving to achieve extremely high standards for one's performance as a parent coupled with a tendency to overly criticize one's parenting abilities) has recently received increasing attention in the media. However, despite this growing public interest and obvious need to understand perfectionism in the parenting role and its implications, this phenomenon is – from a research perspective – not well understood to date. Therefore, our study addresses this issue. Specifically, we investigated how employees' parenting perfectionism relates to overprotection in their role as a parent (i.e., an inappropriate, excessive provision of protection that involves smothering and constant worries about child welfare) and whether this overprotection, in turn, relates to conflict between family and work life as well as to co-parenting conflicts with their intimate partners. Moreover, we examined possible implications for employees' own and their partners' well-being and satisfaction.

Toward this aim, we drew on theoretical approaches stemming from family-work and perfectionism research. That is, we integrated the conflict perspective and the principle of resource drain stemming from family-work research with the Expanded Social Disconnection Model stemming from perfectionism research to develop a comprehensive conceptual model that considers intraindividual, interindividual, and domain-crossing (i.e., from the family to the work domain) processes driven by perfectionism in the parenting role. To test our hypotheses, we used multi-wave (T0, T1 = one year later, T2 = two years later) survey data collected via interviews of 541 employed couples with parental obligation participating in The German Family Panel pairfam. In line with our hypotheses, path analytic results showed that parenting perfectionism was indirectly related to a decrease in employees' well-being and partnership satisfaction from T0 to T2 via overprotection at T0 and family-work conflict at T1. As expected, parenting perfectionism was also indirectly related to a decrease in partners' well-being and partnership satisfaction via overprotection and co-parenting conflicts. Contrary to expectations, parenting perfectionism did not relate to a decrease in job satisfaction from T0 to T2 via overprotection and family-work conflict.

Our study has some limitations that need to be considered. First, albeit being conceptualized as a multidimensional construct, parenting perfectionism was assessed with a shortened overall measure that did not differentiate between its various dimensions. Second, (co-)parenting and related conflicts might also be affected by partners' personality and ways of parenting. Unfortunately, these constructs were not assessed from partners. Third, because most of the couples in our study represent the "traditional" family type (i.e., heterosexual, married, cohabitating with two children), it is unclear whether our results are transferable to other family types.

Our results highlight the impact parenting perfectionism can have: It might not only ultimately impair one's own and others' well-being and satisfaction but can also permeate boundaries between family and work life. Consequently, scholars should consider perfectionism's intra- and interindividual as well as domain-crossing effects in the future. We conclude that parenting

perfectionism is a problematic phenomenon that is on the rise among employed parents. Accordingly, it is important to examine parenting perfectionism more closely and to find ways how employees and organizations can effectively handle it. For instance, organizations might support perfectionistic parents by providing flexible work arrangements, high-quality corporate day-care centres and kindergartens, homework supervision, tutoring, or supervised leisure time activities.

Our study is of special relevance to next year's congress theme "The future is now" as it deals with a recently arising and likely further increasing phenomenon that has the potential to deeply affect many employees – now and in the future. Accordingly, the time has come to discuss whether increasing perfectionism in employed parents is a desirable change or not. Furthermore, our study aligns well with the UN SDG of "Good health and wellbeing" as it points out processes that might impair long-term wellbeing.

Keywords: perfectionism, family-work conflict, parenting

Oral presentation OP279

Too Vulnerable to Engage at Work: The Individual Differences in Vulnerability to Diseases, Rumination, and Work Engagement

Jian Shi, Vrije Universiteit Amsterdam

science&practice

Too Vulnerable to Engage at Work: The Individual Differences in Vulnerability to Diseases, Rumination, and Work Engagement

The COVID-19 pandemic poses a serious and prolonged global health threat, dramatically affecting working patterns worldwide and changing people's work experiences fundamentally. In line with recommendations from the World Health Organization, various key health measures to protect against COVID-19 have been applied at workplace to avoid contracting and spreading infection in organizations. However, it is yet unclear to what extent employees have complied with these tighter rules and regulations on their initiative, especially whether they vary in coping with those health threats at workplaces regarding their dispositions. More importantly, the psychological impacts of COVID-19 on their work engagement are still underappreciated, which has been acknowledged as the most significant indicator of desirable work outcomes. Furthermore, managers are always expected to effectively navigate the crisis. Nevertheless, it is unknown if managers who are always expected to have prototypical qualities can effectively cope with the downsides of health threats. Top amongst those is the directive and dominant instead of prestigious leaders, which have been evidenced as one of the most effective roles in the crisis, but we do know little of these leadership qualities in the nascent health crisis.

In the present research, we argue that a fundamental factor in the way employees cope with the health crisis is the extent to which they perceive themselves to be vulnerable to infectious disease threats, that is perceived infectability. Accordingly, we aim to examine whether employees with a high vulnerability have experienced lower levels of work engagement during the pandemic, and how they adaptively respond to these diseases at workplaces. Moreover, we further investigate if the dominant versus prestigious leadership of the supervisor mitigates the negative impacts of infectability.

Theoretically, the behavioral immune system (BIS, Schaller & Park, 2011) provides an appropriate theoretical framework, arguing that individuals, besides the physiological immune system, have evolved psychological mechanisms enabling them to detect infectious pathogen threats in their social environment, and these mechanisms trigger a suite of adaptive responses that prevent them from getting infected. Besides, a specific feature of the BIS argues that BIS is supposed to react in accordance with these individual and contextual factors. Drawing upon BIS, we propose that during the pandemic employees who believe they are especially vulnerable to getting infected are more concerned about work-related rumination, resulting in lower levels of work engagement. Furthermore, we explore whether the negative impacts of infectability on engagement are buffered by a particular leadership style from their supervisors.

We conducted a multi-wave field study early in the pandemic to test the hypotheses. We adopted a three-wave field survey with one-week intervals collecting data from 260 UK-based employees. The results support the primary assertation that perceived infectability of employees was negatively associated with their work engagement on a time-lag basis. We also examined the processes of disease-avoidance activation and revealed that employees high in infectability were more concerned with work-related rumination, in turn decreased their work engagement. Last, results revealed that

the impact of infectability on work engagement would be less pronounced among employees who perceived their supervisor as prestigious rather than dominant.

Our research makes three theoretical contributions. First, by linking individual differences in infectability to work-related outcomes, we focus on a factor that has been neglected in past research by adopting an evolutionary approach but has come to the fore since the COVID-19 crisis. Second, we reveal that perceived infectability can be a crucial indicator of employees work engagement and suggest that a lower work engagement may be an adaptive avoidance response. Lastly, we contribute to COVID-19 workplace research by investigating the important role of dominant leaders who navigate the health crisis less effectively than expectations in other economic and political crises, but prestigious ones matter. Our research also offers timely practical implications. Organizations would acknowledge the role of individual differences in infectability to help understand why some employees have fared worse than others during the pandemic. Moreover, managers should consider how their leadership style can worsen employees outcomes. Obviously, there are also several limitations. First, given the correlational nature of our research, we are unable to completely erase the common method bias. Second, we focus on lower work engagement as an adaptive disease-avoidance response, but other types of responses also warrant attention. Third, it would be a significant extension to evaluate how employees high in infectability are managing after the crisis.

Keywords: perceived infectability, work engagement, rumination

Oral presentation OP63

Towards promoting detachment: insights from a four-arm randomized control trial

Dorota Reis & Malte Friese | Saarland University; Dirk Lehr, Leuphana University Lueneburg; Kai Krautter & Alexander Hart | Saarland University

science

Research goals and why the work was worth doing: Blurred work-life boundaries contribute to increasing difficulties in „switching off" after work, and separating work from leisure seems even more challenging when job demands are high. Psychological detachment–the ability to mentally disengage from work during non-work times–is crucial for counterbalancing employees' reactions to job demands, thereby maintaining employee well-being and health. Acknowledging the importance of psychological detachment for critical work-related outcomes, several interventions aimed at improving psychological detachment have been developed in recent years. However, these interventions exhibit considerable heterogeneity in their effectiveness. It is also unclear which within-person processes contribute to improved detachment. Therefore, the present study aimed to compare the effectiveness of two six-week interventions directly. In addition, to examine changes in within-person processes, we combined a pre-post-follow-up design with phases of experience sampling (measurement burst design).

Theoretical background: By applying interventions based on the DRAMMA model (Newman et al., 2014) and mindfulness-based approaches (Goldberg, 2022), the study contributes to a better understanding of the dynamic processes suggested in the stressor-detachment model (Sonnentag & Fritz, 2015).

Design/Methodology/Approach/Intervention: We conducted a four-armed randomized control trial. In our sample (N = 393, 76% female, 24% male, N = 2 did not disclose their gender; M_age = 40.56; SD_age = 10.93), the majority of the participants were teachers or employed in other areas of public service.

Results: Based on latent change models, we found substantial pre-post improvements in detachment in both intervention groups (d = 1.06 and 1.33) that were maintained at follow-up (d = 1.21 and 1.39). Notably, in line with recent meta-analytical findings showing substantial measurement reactivity effects in experience sampling studies, our control group also reported considerable improvements in detachment (d = 0.72). Applying multilevel structural equation models, we elucidated the role of daily negative activation as a factor linking daily job demands with (low) detachment and how its detrimental effect of prolonging the adverse effects of job demands into leisure time could be modified through training.

Limitations: All data were self-reported.

Conclusions/Research & Practical Implications: Both interventions provide a valuable approach for organizations that wish to promote employee detachment.

Originality/Value: The study is one of the first to directly compare the effectiveness of two interventions focusing on promoting detachment. In addition, due to the measurement burst design, the study provides unique insights into both short-term fluctuations and long-term changes in detachment.

Keywords: detachment, intervention, measurement burst design,

Oral presentation OP548

Tracking individual trajectories of perceived shared mental models: A 12-week longitudinal study

Catarina M. Santos, Maastricht University School of Business and Economics; Jia Li, Vlerick Business School; Simon B. de Jong, Maastricht University School of Business and Economics

science

Drawing on the shared mental model literature and interdependence theory, this study aims to analyse whether individuals perceive similar or distinct trajectories of shared mental models over time and test whether those trajectories relate to different individual antecedents and outcomes. This study questions the common (implicit) assumption that individuals perceive and develop shared mental models uniformly.

Successful teamwork is crucial to solve many of today's key problems. Yet, to effectively perform the tasks assigned to the team, team members have to build and be aware of a shared mental model (i.e., a shared understanding about who does what, when, and with whom) successfully and in a timely manner. Within the shared mental model literature, the idea that each individual team member can perceive the shared mental model that consists of several dimensions has taken root in recent years. The state-of-the-science is that there are five dimensions of perceived shared mental models, namely equipment, execution, composition, interaction, and temporal. However, most research has focused on one or a few of these dimensions and has focused on aggregated (team-level) conceptualizations of shared mental models. Therefore, research has overlooked the possibility that individuals might have different perceptions of the various shared mental model dimensions. Furthermore, individual-level longitudinal studies on shared mental models have never been attempted. Therefore, it is currently unknown whether and how individual perceptions of shared mental models change over time, and whether the development of perceived shared mental models is similar or dissimilar for the five dimensions.

We collected data across six-time points from more than 300 participants who assessed their perceived shared mental models in their first 12 weeks of working in a new project team. Initial latent class analyses showed there are distinct trajectories for each of the shared mental model dimensions. This showed, for instance, that individuals can have different starting points as well as ending points and that those can differ per shared mental model dimensions. Moreover, the temporal process between these starting and ending points also had different shapes, as, for instance, some lines stayed uniformly high or low, whilst others grew or declined and then stabilized, whilst yet other lines first raised and then fell down again. We will analyse the antecedents and outcomes of the trajectories and share the updated results during the EAWOP 2023 Congress.

Although individual beliefs and perceptions are the foundation of shared mental models, in this study we focus only on the individual trajectories of perceived mental models, and not on the trajectories within teams. Overall, this study advances the shared mental model literature, as our analysis of the individual trajectories of perceived shared mental models show that the common assumption that individuals develop shared mental models uniformly needs to be revisited. Thus, our work provides a starting point to develop new theoretical and empirical knowledge on how the different dimensions of shared mental models start and develop by taking a more fine-grained look at the individual level of analysis.

Overall, this study is relevant to the Congress Theme "The future is now: The changing world of work" and to the UN SDG "Decent work and economic growth", as this study contributes to the development of a sustainable workforce from a bottom-up micro perspective by providing managers,

team members, and team leaders – as well as consultants and other decision-makers – with knowledge and competences that aim to increase cooperation and collaboration, which ultimately contributes to individual and team effectiveness.

Keywords: teams, shared mental models, longitudinal study

Oral presentation OP798

Transformational Leadership and Followers' Narrow Personality Traits

Hallvard Føllesdal, BI Norwegian Business School

science&practice

Research Goals

The present study examines how followers' narrow personality traits are associated with subdimensions of transformational leadership behavior.

Theoretical Background

Wang et al. (2019) conducted a meta-analysis and found that followers' overall ratings of TFL were associated with their scores on the Big Five. Moreover, Wang et al. (2019) also showed that followers' personality may influence both the perceptions of, and the actual behavior of their leader, using an overall score of transformational leadership. The present study, however, will assess whether followers' personality is differentially related to their ratings of subdimensions of transformational leadership. Previous studies have found that subdimensions of transformational leadership are differentially associated with various antecedents and outcomes of transformational leadership. For instance, Deinert et al. (2015) found that subdimension of transformational leadership were differentially related to leaders' personality. Moreover, Arnold (2017) suggested that future research should investigate subdimensions of transformational leadership as they might be differentially related to followers' well-being. When it comes to personality, recent research suggests that narrow personality traits may outperform the broad Big Five domains in predicting various outcomes. Thus, to better understand the influence of followers' personality on ratings of transformational leadership, we need to investigate subdimensions of transformational leadership and narrow personality traits.

Methodology

In an ongoing data collection, Norwegian executives (N=187) rated their transformational leadership behavior (MLQ-5X) toward two of their immediate subordinates (N=371). They also rated each of these follower's personality, using the BFI-2. The BFI-2 measures the Big Five and fifteen narrow personality traits. Moreover, 92 of the executives were rated by an average of 2.9 followers (n = 267) on transformational leadership. The same followers also completed the BFI-2-S. The scores were analyzed with Mplus in a multilevel framework.

Results

The results revealed that leaders' ratings of followers' transformational leadership behavior were significantly associated with their ratings of the same followers' personality traits. Ongoing analyses will assess how followers' ratings of transformational leadership are associated with followers' self-rated personality traits. To the extent that the pattern of findings converges, they will shed light on to the extent to which followers' personality traits might influence leaders' transformational leadership behavior. The data collection is ongoing, and data will be further analyzed, and results will be presented and discussed.

Limitations

The leaders selected two subordinates and rated their own transformational leadership behavior toward each of the subordinates, along with ratings of the same subordinate's personality traits.

These ratings, however, were not matched with followers who provided ratings of transformational leadership and their own personality.

Conclusion

Followers' personality traits seem to play a role in ratings of transformational leadership, and the present study sheds light on which facets are important. It is important to know to what extent different ratings of leadership are due to perceptual differences or occur because leaders behave differently toward followers with different personalities. The present study provides new knowledge regarding which personality facets are important.

Keywords

Transformational leadership; personality; broad versus narrow traits

Oral presentation OP419

Transportation safety and organizational demands: the role of recovery on reducing distractions while commuting

Mattia Zene, Università di Verona

science&practice

Research goals and why the work was worth doing: The increasing availability of social media and technological devices provides people continuous stimuli for distractions while commuting (e.g., posting on social media, messaging, checking work notifications etc.), making the associated risks for the user significantly greater. Beyond knowledge about individual dimensions (e.g., risk perception), such distractions may be related to work. On the one hand, people may use distractions to recover from work when commuting to home. On the other hand, engaged individuals may start focusing on their even during their commuting. The present study aims to provide empirical knowledge on the relationship between recovery, sleep quality, exhaustion, and work engagement and the assumption of distracting behaviors while commuting.

Theoretical background: According to the literature, there is a strong association between recovery and JD-R dimensions, with recovery as an antecedent of positive effects on work engagement and negative effects on exhaustion. Nevertheless, the literature around commuting and recovery is still sparse. Although there is a relationship between exhaustion and cell phone use as a form of recovery strategy, the literature lacks evidence about the association between work engagement and smartphone use while commuting.

Design: The study hypothesis were tested using a diary study design. Daily diary data were collected for five consecutive workdays, twice a day: one for commuting from home to work and one for commuting from work to home. Accidental non-probability method was used to recruit employed individuals. In the questionnaire administered after work-home commuting, recovery from the previous workday and sleep quality were investigated. In the questionnaire administered after work-home commuting, dimensions of JD-R (i.e., job demands, job resources), and their outcomes (i.e., work engagement, work exhaustion) were investigated. In both questionnaires, information was collected regarding the intake of distracting behaviours while commuting (i.e., posting on social media, messaging, checking work notifications) and information regarding the means of transport used while commuting (i.e., by feet, by car, by bicycle, public transport). total 148 Italian employees who commuted to and from work completed the diary study.

Results obtained or expected: Recovery, specifically psychological detachment and relaxation, had a negative correlation with exhaustion and a positive correlation with work engagement. Mastery also had a positive correlation with work engagement. Work engagement had a positive correlation with daily mobile phone use while commuting from work to home, particularly with text messaging, talking on the phone, and using social media. In contrast, exhaustion had a positive correlation only with using social media while commuting from work to home.

Limitations : One of the main limitations is the use of self-reported measures to assess the study variables. Also, The possible individual difference in terms of „distractibility" or otherwise any form of propensity to use technological devices that, if used while commuting, can become risk factors was not considered at the time of data collection. In addition, to make the data collected more generalizable, it is necessary to repeat the study with a larger sample. Future studies should also consider replicating the present research model in different socio-cultural and socio-economic

contexts, in order to consider the influence given by risk perception and different program of transportation safety.

Conclusions – research and or practical implications: The results provide valuable insights into the relationship between recovery, work engagement, and distractions while commuting, and could help identify factors that contribute to distraction-related accidents during home/work and work/home commuting. The study highlights the importance of managing the relationship between resources and work demands at work and its role in the risks of accidents while driving.

Relevance to the Congress Theme: The present research is situated within the themes of well-being and health. Indeed, aspects of well-being in the workplace are highlighted, as well as the consequences that work has on well-being outside of it. Safety, psychological and physical, are the focus of interest in this research.

Relevant UN SDGs: Good health and wellbeing

Keywords: Recovery, Commuting, JD-R

Oral presentation OP766

Trauma-informed Compassionate Leader Behaviors: Compassion in the workplace for traumatized employees

Nicole Alonso, University of St. Gallen; Jennifer Bragger, Montclair State University; Vincent Ng, University of Houston; Caitlin Porter, University of Memphis

science&practice

Research Goals:

The present study sought to develop a measure of Trauma-informed Compassionate Leader Behaviors (TICLB). Specifically, we identify the positive behaviors leaders can enact when dealing with employees—especially following trauma—to ensure employee well-being. Additionally, we demonstrate the relationship between TICLB and important employee outcomes such as psychological safety, well-being, and post-traumatic growth.

Theoretical Background:

The vast majority of people experience some form of trauma during their working years (e.g., death of a family member, divorce), a fact exacerbated by the COVID-19 pandemic (Duane et al., 2020). To mitigate the effects of trauma on employee outcomes such as well-being, perceptions of workplace, and performance, leaders may extend compassion to those who have suffered trauma. Indeed, experiencing compassion in the workplace following a hardship reduces anxiety (Lilius et al., 2008), and encourages psychological healing (Bento, 1994). Despite the benefits of compassion at work, research has yet to identify how leaders can demonstrate compassion to their employees (Way & Tracy, 2012). Furthermore, compassion research (e.g., Lilius et al., 2008) has failed to incorporate a trauma-informed approach, which is unfortunate given the success of trauma-informed approaches used by service providers for traumatized clients in other fields (Ward-Lasher et al., 2017). Integrating the literature on compassion and trauma-informed care is a fundamental starting point to better understand the positive behaviors leaders can enact to mitigate the disproportionate influence trauma has on employees .

Design:

In Study 1, semi-structured interviews were used with 22 employees who live and work in the U.S. and have experienced severe trauma (e.g., combat, human trafficking) to discover what trauma-informed compassionate leader behaviors were. Items were created based on content from interviews. In Studies 2 and 3, data were collected via online survey from two groups, 21 graduate students attending U.S. universities and five subject matter experts (SMEs). To provide evidence of content validity, students rated how well the items measured TICLB (Hinken &Tracey, 1999) while the SMEs rated how essential items were to measure TICLB (Lawshe, 1975). In study 4, data were collected at two time points via online survey from 1000 participants who live and work in the U.S. to investigate factor structure, convergent/discriminant validity, and predictive validity.

Results:

Content analysis in Study 1 produced 51 items that capture TICLB. In Study 2, the item set was reduced to 30 items; items were then edited for clarity and one new item was written. In Study 3, SMEs reduced the item set to 17 items. The EFA in study 4 revealed a two-factor structure after 3 items with cross-loadings were removed. The CFA provided evidence for a bifactor model structure with two subfactors and one general factor. Regression analysis showed that TICLB predicts

employee well-being (self-compassion, psychological well-being, and posttraumatic growth), psychological safety, and job performance. Multiple regression analysis suggests that TICLB predicts these outcomes above and beyond general compassion and compassionate leader behaviors.

Limitations:

Sample sizes for studies 1-3 were relatively small, however, this is not uncommon when investigating difficult to reach/recruit populations (Ellard-Gray, 2015). Additionally, all participants lived and worked/studied within the U.S. which may limit the generalizability of the results to other cultures. Data were also collected at least 6 months after the most recent traumatic event, which could limit participants' recall of helpful/harmful leader behaviors.

Conclusions:

Given the current state of the world it is imperative that leaders understand how to best interact with and support employees, especially when they are dealing with trauma. By merging a well-known tactic used in clinical services (trauma-informed care) with a well-known concept in the business industry (compassion), this study enables conversations about the role leaders can play in supporting employees through trauma.

Congress Theme:

It is no longer enough for leaders to simply manage employees' work and productivity. A major concern for organizations now, and moving forward, is employee mental health and well-being (SHRM, 2022); however, many leaders may not be equipped to support employees' mental health and well-being. This project begins the conversation about the behaviors leaders can adopt to help traumatized employees experience posttraumatic growth and well-being as organizational priorities shift.

UN SDGs:

This project aligns with UN SDG 3, health and well-being. The purpose of this project was to identify leader behaviors that positively impact employee well-being, especially after trauma.

Keywords: Leadership, Well-being, Trauma-informed Compassion

Oral presentation OP120

Trends in the Study of Paternity Leave: a State of the Art using a Systematic Literature Review

Jon Pizarro & Leire Gartzia | Deusto Business School, University of Deusto

science&practice

Research goals. The current study aims at clarifying past, current and future directions of research regarding paternity leaves, using a Systematic Literature Review (SLR).In particular, we analyze the trends in the study of paternity leave over time, the main thematic areas and the extraction of primary conclusions, putting together existing knowledge into a common framework that can inform future research in this area.

Theoretical background. Inequalities and resistances to successfully implement actions to promote gender equality are still common. Remaining challenges behind these trends are the domestic division of labor and women´s greater dedication to care work and education of underage sons and daughters, as well as care for people who are in situation of dependency (Eagly & Carli, 2007; Doucet & McKay, 2020).

Among the measures that have been implemented internationally to overcome the domestic division of labor, policies and legislation around absence care leaves is common, and in particular paternity leaves (ILO, 2014; EIGE, 2021).

Scholars and policymakers have underscored the necessity of going deeper into the design of specific leaves for fathers internationally, in order to generate more egalitarian workplaces and promote greater assumption of caregiving functions by men and fathers (ILO, 2014; EIGE; 2021; Lammi-Taksula, 2008). Therefore, it is necessary to better understand current approaches, categorizations and dissimilarities in parental and paternity leave research, in an attempt to capture the unique key elements of paternity leave policies and current challenges.

Methodology We carried out our SLR search in ISI Web of Knowledge, including its related databases, Elsevier Scopus and PsycInfo databases.

The search was restricted to peer-reviewed articles in English or Spanish containing the words “paternity leave”, either in the title, abstract or author keyword section. No restriction was placed on year of publication.

Once all possible studies had been identified, we conducted a second screening to assess eligibility against inclusion criteria and then full text articles were retrieved for those that met the inclusion criteria. These criteria required that the published peer-reviewed article meet all of the following three specifications: (i) be in the English or Spanish language; (ii) be an empirical study or a literature review (i.e., not an essay, book review, letter, editorial, opinion, journalistic article); and (iii) discuss paternity leaves as the central element.

Results. Once the corpus of study was defined, a process of analysis and synthesis was envisaged that was based on keywords. Keywords were uploaded into an ad hoc database and categorised into thematic groups. This inductive process was iterated three times, until the final categories for study emerged. In total, seven areas of research have been identified and the principal conclusions of each of them have been collated.

Several descriptive data about the sample were extracted and commented concerning, among others, the geographical dispersion of the papers, the method of analysis or the type of sample.

Limitations. The analysis presented is the result of exploiting the data obtained solely through references available online and corresponding to scientific articles indexed in the indicated databases.

Regarding the origin of the references, a geographical bias towards studies centred on North America and Europe was identified.

Conclusions. The current research evidences the growing interest of academics in the topic of parental leave and in particular fathers´ use of domestic measures at work. Furthermore, a framework is presented that aggregates previous findings and clarifies the main research areas within paternity leaves, as well as the methodologies used, providing a comprehensive compilation for future studies. Finally, the study provides a systematic review with practical information for policymakers and employers willing to more effective develop paternity leave policies, identifying the elements they should be take into consideration. Futures lines of research, in particular concerning several challenges for the implementation of policies in organizations, are also identified.

Originality/Value. The study contributes to the methodology for conducting Systematic Literature Reviews in the field of organizational psychology, specifically in the design and implementation of paternity leave policies. It presents an effective method for the mapping and classification of existing knowledge and the identification of emerging trends.

Relevance to the Congress Theme. The changing nature of the work environment cannot be analyzed without understanding the new demands of workers for reconciliation, as well as the existing gender differences in this work-life balance policies and the impact that these differences can originate on the organizations of the future and their adaptability.

Keywords: paternity leaves, domestic work, systematic literature review

Oral presentation OP68

Trickle-Down Effects of Organizational Dehumanization: A Social Information Processing Perspective

Constantin Lagios & Gaëtane Caesens | Université catholique de Louvain; Simon Restubog, University of Illinois Urbana-Champaign

science

Research Goals

In exploring the dark side of the employee-organization relationship, scholars (e.g., Nguyen et al., 2021) have recently begun to pay attention to the concept of organizational dehumanization (OD), defined as the experience of an employee who feels treated like a tool or instrument for the organization's ends (Bell & Khoury, 2011). While there exists converging evidence that OD has negative consequences for employees' well-being, attitudes and behaviors (Brison et al., 2022), it is still unclear whether employees' interpersonal relationships at work may also be impacted. Interestingly, research on trickle-down effects (Wo et al., 2019) showed that a treatment from the organization as perceived by a supervisor can in turn influence the treatment that the supervisor provides to their subordinate, thereby affecting their interpersonal relationships.

Integrating trickle-down effects with the OD literature, this research investigates the extent to which supervisors who feel dehumanized by their organization will engage in dehumanizing behaviors toward their subordinates who will, in turn, display lower levels of in-role and extra-role performance and creativity.

Background

To explain these relationships, we draw upon social information processing theory (SIP; Salancik & Pfeffer, 1978), which holds that employees' behaviors cannot be separated from the larger social context in which they take place. Specifically, SIP posits that "individuals, as adaptive organisms, adapt [their] attitudes, behavior, and beliefs to their social context and to the reality of their own past and present behavior and situation" (Salancik & Pfeffer, 1978, p.226). Stated differently, individuals use social cues from their environment to interpret events and develop expectations about the appropriateness and consequences of their behaviors (Salancik & Pfeffer, 1978).

In the context of our research, we argue that OD acts as a social cue that shapes how supervisors interact with their subordinates. Precisely, when supervisors are dehumanized by their organization, they may perceive that dehumanizing treatments are normative and expected in the organization, which would eventually lead them to adopt dehumanizing behaviors directed toward their subordinates. We further hypothesize that dehumanizing behaviors from supervisors will detrimentally affect subordinates' work behaviors. Indeed, because being treated as a tool or instrument used for the supervisors' ends is likely to engender a loss of resources for the subordinates, we expect them to display lower levels of in-role and extra-role performance and creativity. Overall, we hypothesize that dehumanizing organizational treatments trickle down to influence subordinates through their effects on supervisors.

Design

Our hypothesized predictions were tested across two studies involving supervisor-subordinate dyads (N Study1 =211; N Study2 =199). Supervisors reported their perceptions of OD and rated their

subordinates' levels of in-role and extra-role performance and creativity. Conversely, subordinates reported their perceptions of dehumanizing behaviors from their supervisors.

Results

The results of SEM and latent bootstrap analyses of both studies indicated that OD trickles down to affect subordinates' performance and creativity. Precisely, the results showed that dehumanizing organizational treatments were positively associated with supervisors' dehumanizing behaviors toward their subordinates. In turn, supervisors' dehumanizing behaviors were negatively related to the subordinates' in-role and extra-role performance and creativity.

Limitations

Both studies adopted cross-sectional designs and causal relations among the variables cannot be drawn. Data were also collected among samples of Belgian employees, which may limit the generalizability of the findings.

Implications

By demonstrating that dehumanizing organizational treatments can detrimentally impact subordinates' performance and creativity through dehumanizing supervisory treatments, our work meaningfully extends previous work by showing that (1) OD influences how supervisors and subordinates interact and (2) the consequences of OD go beyond the focal actor (i.e., the supervisor) who feels dehumanized by their organization.

Originality

Using matched supervisor-subordinate data, our research is the first to examine the trickle-down consequences of OD.

Congress Theme Relevance

OD is of particular interest for this year's congress, which focuses on a better understanding of the future of work. Indeed, as the COVID-19 pandemic forced organizations worldwide to adopt cost-cutting policies and/or rely on new technologies, employees "face a substantial risk of being brought closer to the status of instruments and further away from humanity" (Brison et al., 2022, p.1). Thus, OD is more relevant than ever, and will be even more so in the (near) future. Therefore, having a broad overview of the consequences of OD warrants empirical attention.

Trust and Reciprocity within Workplace Relationships: A Dyadic and Longitudinal Study of Top Management Teams

Finian Buckley, Colette Real, Finian Buckley & Lisa van der Werff | Dublin City University

science

Research goals and why the work was worth doing

Trust is generally recognised as a reciprocal process between two parties leading to mutually beneficial outcomes such as interpersonal cooperation and is critical to the success of organisations. However, the examination of both parties in a trust relationship is uncommon in empirical studies. Ignoring this relational context can lead to an incomplete understanding of the nature of interpersonal trust and can result in misunderstanding the true impact of trust in practice. Recent trust reviews have called for more examination of the dynamic nature of trust and the reciprocal interplay between two parties simultaneously (Dirks & de Jong, 2022; Korsgaard, 2018; Möllering, 2019). This study considers both parties in a dyadic work relationship and examines how the trustworthiness perceptions and trust intentions of each party influences the other over time.

Theoretical background

Interpersonal trust is commonly conceptualised as a psychological state within an individual directed at a specific trust referent (Rousseau et al., 1998). It occurs within a relationship where both parties engage in an ongoing interactive process of trusting and being trusted. This is frequently explained by social exchange theory (Blau, 1964), the norm of reciprocity (Gouldner, 1960), and to a lesser extent, interdependence theory (Kelley & Thibaut, 1978). However, a dyadic level of analysis remains relatively uncommon in organisational research (Tse & Ashkanasy, 2015) and in trust research (Korsgaard et al., 2015; Krasikova & LeBreton, 2012).While it has long been acknowledged that trust elicits trust reciprocity and that trust can change over time (e.g., Lewicki et al., 2006), the dyadic patterns of reciprocity and change are not well understood. Korsgaard et al. (2018) suggest that three key facets of reciprocal trust over time remain unclear. Explanations for the direction of trust spirals (increases or decreases) over time, understanding the strength of relationships between variables over time, and understanding the rate of change over time all require further research attention. In addition, while it has been found that dyadic trust levels can assume a variety of configurations involving high to low levels of convergence or asymmetry (Tomlinson et al., 2009), a better understanding is needed of the patterns of dispersion within a trust dyad and the resulting behavioural impact.

Design/Methodology

Participants were members of the top management team of small and medium sized enterprises who attended a 6-month executive development programme. Five waves of data were collected using quantitative self-report survey methods. The final sample consisted of 90 firms and 230 dyadic relationships. Structural equation modelling was chosen for data analysis based on the sample characteristics and the nature of the hypotheses.

Results

Results provides evidence for reciprocal influences between the two parties by modelling the bidirectional patterns of influence of distinct trustworthiness components (ability, benevolence, integrity) and distinct trust components (reliance, disclosure), and their subsequent impact on

person- and task-focused interpersonal citizenship behaviour. In particular, the results draw attention to the reciprocal influence between benevolence and disclosure, and between reliance and interpersonal helping (both task-focused and person-focused). The results also provide evidence of the development of trust over time and the impact of trust incongruence within the dyad.

Limitations

As the sample of this study consisted of top management team members of small and medium sized enterprises in one country, the results might not generalise to other types of work relationships, larger organisations, or other cultures. Further insight could be gained by collecting objective performance data and examining how dyadic trust patterns are related to individual and organisational performance.

Conclusions – research and or practical implications/Originality/Value

This research extends the current understanding of trust within organisational relationships by taking a dyadic and longitudinal approach, which is relatively uncommon. The results of this study provide evidence for reciprocal influences between the two parties and provide a more nuanced understanding of the components and dynamics of interpersonal trust.

Relevance to the Congress Theme

This research highlights how encouraging and developing mutual trust relationships is valuable for both task performance and for promoting social connection and support within the workplace. In the current era of knowledge-based work characterised by high levels of role interdependence, the promotion of positive work relationships with high levels of mutual trust is fundamental for organisations and individuals seeking to benefit from enduring cooperative behaviours within the workplace.

Keywords: trust, interpersonal, quantitative

Oral presentation OP602

Unconsciously Paying People Based on their Gender? The Relationship Between Implicit Stereotypes and the Gender Pay Bias

Maria Hällfritzsch, Leipzig University

science

Research Goals: In 2022, men still make more money than women (Destatis, 2021; Proctor et al., 2016). In addition to structural factors—job choice, part-time work, parental leave—the gender pay gap is caused by women achieving worse outcomes in salary negotiations than men (Mazei et al., 2015). The negotiation discrepancy might be due to gender differences in candidates' behaviour or recruiters' implicit gender negotiation stereotypes (GNS). This study aimed to reduce the influence of males' implicit GNS on the gender pay bias (GPB) by providing participants with feedback on their implicit GNS.

Theoretical Background: Following social role theory (Eagly, 1987), females ought to show behaviours (e.g., caring about others) that are inconsistent with effective negotiation strategies (e.g., assertiveness). Therefore, we expect women to receive lower offers in a salary negotiation. Related to the expectations tied to social roles, stereotypes are overgeneralised and socially shared assumptions about members of social groups (Greenwald & Banaji, 1995). They influence our actions towards other individuals (Major & O'Brien, 2005), even while being unaware of these stereotypes (Greenwald & Banaji, 1995). Previous studies show the negative relationship between males' implicit GNS and females' negotiation outcomes (Pardal et al., 2020). Hence, we suggest that males' implicit GNS partly explain the GPB. Lastly, drawing on the idea that people must become aware of their attitudes to adjust their behaviour, the intervention groups completed an implicit association test and received feedback on their implicit GNS. Here, we suggest that males in the intervention group will be less affected by their stereotype and therefore exhibit a smaller GPB.

Design/Methodology/Approach/Intervention: This preregistered online study (N = 359) investigated the effect of males' implicit GNS on the GPB in a 2 (candidate's gender : male vs. female) x 3 (intervention : control vs. IAT vs. IAT+feedback) design. Males in the intervention groups completed an implicit association test measuring their GNS resulting in a D- score similar to a Cohen's D (Greenwald et al., 2003; A score above 0 indicates associating men more than women with successful negotiating and vice versa for a score below 0). Then, everyone obtained identical information regarding education and work experience of an either male or female candidate and received an identical non-numerical envisioned salary of the candidate on a visual sliding scale (no currency and industry effects). We measured the GPB by comparing participants' counteroffers and maximum willingness to pay to male and female candidates. Lastly, they completed additional measures including explicit sexist beliefs, and explicit GNS as well as competence ratings and the likelihood to hire the candidate. This enabled us to obtain a clearer picture of the relevance of implicit GNS above and beyond explicit measures.

Results: The results revealed a partly reversed GPB (i.e., male participants offered female candidates higher salaries than male candidates). However, moderation analyses underscored the importance of implicit GNS; IAT scores 1 SD below the mean (d = 0.13), and at the mean (d = 0.51) predicted a significant GPB favoring women (not significant for participants with IAT scores 1 SD above the mean [d = 0.90]). The intervention had no effect on the GPB. Additionally, females were rated as significantly more competent and more likely to be hired. This resulted in a sequential

mediation of the candidate's gender on the GPB via perceived candidate competence and likelihood to hire. Explicit measures related to sexist beliefs did not play a role.

Limitations : Possible limitations include the potentially unrealistic computerised design and missing personal information about the candidate. These features of the study might limit the generalisability to real negotiation settings, but they eliminated variance due to factors such as attractiveness and likeability of the candidate.

Conclusion and Implications : Males with low to medium implicit GNS favouring men exhibited a GPB favouring female candidates. Additionally, the results are in line with research showing that females are increasingly associated with competence (Eagly et al., 2020). Lastly, implicit stereotypes measured in this study affected participants' explicit behaviour which challenges the understanding that implicit attitudes mainly affect subtle, as opposed to explicit behaviours (Quillian, 2006).

Relevance to the Congress Theme : This study fits to the congress topic of diversity and inclusion. Especially the areas of sexual and gender identities and unconscious bias are covered by advancing the understanding of gender roles and by elucidating the role of implicit stereotypes in the GPB.

Relevance UN SDG: By providing insights on the influence of implicit GNS on the GPB, this study tried to advance decent work and gender equality (while reducing inequalities).

Keywords: gender pay bias, gender stereotypes, implicit stereotypes

Oral presentation OP491

Under what circumstances does leadership training work?

Anders Pousette & Martin Grill | University of Gothenburg

science

Research goals and why the work was worth doing

There is a need for knowledge about what constitutes effective leadership training. Intervention researchers have pointed out the importance of going beyond effect studies by broadening the perspective to examine the context and process of the interventions being studied. The purpose of the current study was to examine variation in outcomes among managers who undergo leadership training.

Theoretical background

Leadership training can be viewed as an organizational intervention. Nielsen and Randall (2013) proposed a framework for examination of organizational interventions with three perspectives. We used this framework to analyse the variation in outcome of a leadership training intervention. The first aim was to investigate which contextual circumstances facilitate or hinder the development of leadership behaviour and performance. The second aim was to investigate the importance of the managers mental models for the development of leadership behaviour and performance. The third aim was to identify implementation elements of importance for development of leadership behaviour and performance.

Design/Methodology/Approach/Intervention

Managers in local government municipalities (n=59) participated in managerial behaviour training consisting of six 90 minutes training sessions during a period of six months. Leadership behaviour and performance were assessed by subordinates of these managers before (n=406) and after (n=377) the training period. The participating managers reported on contextual information and their mental models before the training started by means of an online questionnaire. Data on implementation was collected at the end of each of the six training-sessions; participating managers as well as the trainers independently assessed properties of the session. Outcome data from the employees were nested withing the managers that underwent training; hence, multilevel modelling (MLM) was used for the analysis.

Results obtained

The results showed that several context variables and the manager’s readiness for change were important, but we could not find evidence of a moderating effect of the intervention implementation variables. The leadership training was facilitated when the managers had favourable resources in terms of support from their superior management and from managerial colleagues. The leadership training was hindered by taxing job demands in term of role stressors. The participating managers mental models in terms of readiness for change had a moderating effect on leader performance but not on behaviour. Participants' and supervisors' assessments of the process showed that the training worked very well throughout; that is, the average ratings of the process variables were very high. Thus, there was no opportunity to detect any impact of specific process elements.

Limitations

The study was conducted on municipal managers in a few municipalities in Sweden, which may restrict the generalizability of the results. The participating managers were also highly motivated to participate, which may also restrict generalizability. There were conditions that may have limited the ability to detect the effects of context and process elements on intervention outcomes.

Conclusions – research and or practical implications/Originality/Value

The study shows the importance of managers' working conditions for them to have good opportunities to develop as leaders. Organizations wanting to increase the competence of their leaders by offering leadership training need to be aware of what is required to achieve favourable results. Senior managers who provide good and genuine support are one such prerequisite. Managers who are going to train their leadership also need to have reasonable working conditions without too much stress; they also need to have a willingness to enter into a process of change. Overall, organizations need to create favourable conditions for leaders' change and development.

Relevance to the Congress Theme

Leadership is a key process for organizations in a changing world of work. The development of leadership skills is therefore an urgent task.

Relevant UN SDGs

Leadership training aims at better functioning leaders which can be expected to lead to good health and well-being of employees as well as to decent work and economic growth.

Keywords: leadership training, context, process evaluation

oral session OP81

Understanding hybrid work: Quantitative diary study as the gold standard for research purposes and organizations - with examples

Ferdinando Toscano, Salvatore Zappala | University of Bologna

science&practice

Research goals and why the work was worth doing

This contribute aims to present the potential of the diary study as a key tool for analysing hybrid work, both for research and organizational purposes. Its specific objectives are to: 1) present some research evidence carried out found through quantitative diary studies; 2) provide examples of diary applications as a tool for organizational diagnosis.

The highlighting of this dual capacity and the presentation of concrete examples from both the science and practitioner perspectives constitute important elements of this study.

Theoretical background

Recent times have increased the interest of researchers and practitioners in remote ways of working. As a result of this, on the one hand, researchers have produced a large body of papers on the subject, and on the other hand, practitioners have worked copiously with organizations interested in processes for diagnosing the well-being of telecommuters and making remote work more efficient. For both research and practical purposes, the one-shot survey technique was the preferred one. It is a very advantageous tool in terms of study feasibility, cost, and descriptive power of the processes studied.

On the other hand, remote work today is mostly hybrid work, i.e., taking place partly on the site and partly in the worker's home or other places. Therefore, it is necessary to broaden the investigative power of our action of diagnosis and inference and, to avoid confusion in workers' memories and responses, it is crucial to identify assessment strategies that accurately distinguish what happens when working in the workplace and what happens when working outside. This is what the diary study does. This is what both research (e.g., Anderson et al., 2015; Charalampous et al., 2019) and companies interested in high-level consulting are asking for. This is the motive behind this contribution intended for researchers and practitioners.

Methodology

Adopting data collected in 2021 and 2022, this study will provide some examples where diary study is used for research and practical purposes. The diary studies that will be shown were conducted for Italian organizations in administration periods of 5-10 consecutive working days.

Through these diary studies, both strictly work- and task-related variables (e.g., hours worked, task autonomy, task performance etc.) and personal perceptions (e.g., perceived self-efficacy, engagement, family-work conflict) were measured. All diary measures refer to data referring to the day of compilation, that is, they are daily-centred. In some cases, one-shot questionnaires enriched the data collection, capturing variables not changing day by day. The discriminant variable for the analysis of the responses received was in each case whether workers were working in the office or outside in each day, to appreciate the differences between the perceptions received in the two contexts (on-site and outside) investigated.

Results

A selection of research results will be presented. They will mainly compare the positive and negative processes involved in working in the office and working at home, highlighting pros and cons of each work arrangement. We will also present some examples of analyses and reports provided to organizations, for organizational consulting purposes.

Limitations

For the multi-objective purposes of this study, the psychological mechanisms found through diary studies will be described only superficially, and more emphasis will be given to presenting the method of investigation applied to hybrid work, in the dual perspective of scientists and practitioners.

Conclusions

From a theoretical perspective, this study adds knowledge about hybrid work as a still understudied work arrangement, by punctually distinguishing employee perceptions when working on-site our outside. From a practical point of view, this contribution promotes the use of diary study as a powerful, albeit complex, organizational diagnostic tool, so that consultants can provide their clients with tools to optimize hybrid work, punctually understanding the situations it generates in the office and other places where employees work.

Relevance to the Congress Theme

This study provides some research results and practical examples related to hybrid work. This is a way to know more about this work arrangement, a work arrangement between present and future, as the theme of the congress recalls.

Keywords: hybrid work, diary study, telework

Oral presentation OP153

Understanding the next talent wave: Career expectations of graduates in turbulent times

Valérie Legrand, Sarah Quataert, Koen Dewettinck & Dirk Buyens | Vlerick Business School

science&practice

Young graduates are the talent of the future, and they will become an important group in organisations in the next decennial. Whilst the inflow of graduates in the European labour market is increasing yearly (Green & Henseke, 2021), recent years have been characterised by economic uncertainty. The recession caused by the COVID-19 pandemic had a temporary yet detrimental effect on the labour market (Lee et al., 2020), and the question arises whether this led graduate students to lower their career expectations or whether the imprint of this generation is so strong that their expectations remain high. To gain more insight into how organisations can attract, develop and retain graduates according to their current needs, our study examines the impact of economic uncertainty on the career expectations of graduates.

Contextual forces such as globalisation, technology, organisational restructuring, and the growth of services have altered the way we look at careers and challenge what older generations have taken for granted (Barley et al., 2017; Dries et al., 2008; Rousseau, 1990). We also know contextual influences are likely to have a stronger impact than the generational cohort to which one belongs (Deal, 2007; Wong et al., 2008). To our specific interest is the impact of the COVID-19 recession on individual factors influencing the psychological contract beliefs that precede the employment relationship, i.e., the anticipatory psychological contract (APC) (De Vos et al., 2009; Rousseau, 2001). One considers this as the lens through which graduates view their future employment relationship and could be seen as the foundation for the development of their future psychological contract. Our study elaborates on three types of individual factors that are expected to impact their anticipatory psychological contract expectations: optimism, careerism and the desire for future job security (De Vos et al., 2009; Rousseau, 2001).

We report data from three matched samples of advanced master students surveyed a few weeks before graduation. Sample 1 (N = 110) was surveyed in June 2017, whilst sample 2 (N = 125) and sample 3 (N = 97) were surveyed in June 2020 and 2022 respectively. Data were obtained using self-assessment questionnaires measuring optimism (De Hauw & De Vos, 2009), careerism (Rousseau, 1990), and expectations about employer inducements (job security). All responses were provided using five-point Likert scales.

One-way ANOVA analyses and post-hoc comparisons reveal significantly lower levels of optimism concerning the economic situation in graduates from 2020 compared to those graduating in 2017 and 2022. However, in comparison to previous graduate cohorts, each new cohort reports significantly higher levels of optimism concerning the jobs available given their skills and diploma. Our findings for careerism partially support the literature that this is rather a stable individual factor, not so much influenced by the socioeconomic situation (De Hauw & De Vos, 2009; Rousseau, 1990). Only when comparing graduates from 2020 and 2022, significant lower levels of careerism are reported by the latter. Lastly, master students graduating in 2020 attach more importance to job security than the ones graduating three years ago and in 2022.

These findings demonstrate the impact of contextual factors on the career expectations of graduates. Students graduating in a period of recession report lower levels of economic optimism and a higher preference for job security than students graduating in a period of economic growth. The research presented adds to the existing literature on what new cohorts of graduates expect from

their future career and employer. In terms of practical relevance, our aim is to contribute to the research on the expectations and intentions of graduates towards their future employment relationship as it can provide important information for the development and implementation of effective human resources (HR)-practices towards new employees. As such, the intended audience can be both academics and practitioners.

In conclusion, we hope to contribute to the 'Decent work and economic growth' Sustainable Development Goal as described by the United Nations with this research.

Keywords: anticipatory psychological contract, career expectations, career management

Oral presentation OP383

Uneventful days? A cautionary tale about the underestimated role of triggering events in employee silence research

Dominik Dilba & Bertolt Meyer | TU Chemnitz

science

Research goals, relevance, and background

Employee silence, i.e. withholding work-related information that could be relevant or useful (suggestions, ideas, concerns; Morrison, 2014), is connected to a multitude of important organizational phenomena, from learning and error management (Li & Tangirala, 2021; Morrison & Milliken, 2000) to individual well-being and burnout (Sherf et al., 2021).

A core tenet of silence research is that employees must have relevant input to share (Morrison, 2014), i.e. they must have encountered some form of triggering event, e.g. coming up with an idea, experiencing conflicts, observing inefficacies, or encountering injustice (Brinsfield, 2013; Milliken et al., 2003; Pinder & Harlos, 2001). We argue that this central role of triggering events in silence research is not reflected in empirical studies:

First, studies are often conducted with survey instruments (cf. Sherf et al., 2021), which do not measure the presence of preceding events. If such information is available (e.g. Knoll et al., 2019, 2021), up to 60 percent of participants did not encounter relevant situations to speak up or remain silent about.

Second, the aforementioned events affect the same outcomes that are attributed to silence. For instance, there is a positive association between silence and burnout (Sherf et al., 2021), and between perceived injustice and burnout (Robbins et al., 2012). Given that cases of injustice can be triggers of silence (Pinder & Harlos, 2001), studying silence effects without controlling for event effects is prone to confounding.

Methodological approach and results

Study 1 is a re-analysis of a cross-cultural dataset (N = 8222 from 35 samples; Knoll et al., 2021). We use this data to highlight the large number of persons who do not encounter events to remain silent about at work, and their highly ambiguous answer patterns: For instance, 40.9 % of participants who did not encounter relevant events in the past six months still said that they remained silent about them. They also stated different motives for remaining silent, despite claiming that they did not encounter situations where they could have remained silent.

Study 2 is another re-analysis of data from two large German organizations (energy provider, N = 675, 75 work groups; public administration, N = 894, 107 work groups; Zill et al., 2020). Using multilevel models, we first tested whether the frequency of silence predicted an outcome of interest (exhaustion), which it did in both samples (standardized b = 0.22, se = 0.05, 95 % bootstrap CI: 0.13, 0.31 and b = 0.22, se = 0.04, CI: 0.15, 0.29). However, adding the frequency of events to remain silent about as a predictor weakened the relationship between silence and exhaustion (b = 0.15, se = 0.05, CI: 0.05, 0.24 and b = 0.13, se = 0.04, CI: 0.05, 0.20). Removing persons who never encountered events to remain silent about reduced the estimated effects further (b = 0.11, se = 0.06, CI: -0.01, 0.22 and b = 0.11, se = 0.04, CI: 0.02, 0.19), which would be compatible with a null effect in sample 1.

In Study 3, we simulated data where the effect of silence on an outcome variable was held constant. We then varied the frequency of events to remain silent about, the frequency of silence itself, the correlation between event frequency and silence frequency, and the size of the sample. When event frequency and silence both had an effect on the outcome variable, but only the silence effect was estimated in a linear regression model, the estimated coefficient for the silence effect could be severely overestimated due to confounding. In the worst scenario we tested, the estimated effect of silence was three times as large as the true parameter value (unstandardized b = 0.31 vs. 0.10).

Limitations and conclusion

The samples re-analyzed in Studies 1 and 2 provide only limited information outside the event frequency (e.g. content, severity etc. are unknown). Study 3, as a simulation study, requires many decisions about parameter values, model choices etc., introducing researcher degrees of freedom (to limit this issue, we derived most parameters from Studies 1 and 2).

Methodologically, the implications of these results are troubling: Many questionnaire studies on employee silence do not include the information we have available here, i.e. it is unclear if participants encountered events to remain silent about at all; and how strongly these events affect the outcomes attributed to silence. Based on our simulations, published silence effects without control of preceding events are likely to be overestimated. An important implication is therefore to adapt the way survey studies on silence are done, e.g. by measuring and controlling for the frequency of preceding events. However, our results also open up interesting new possibilities for theories about the consequences of silence, e.g. developing a framework that explicitly models the interplay of workplace events and remaining silent about them.

Keywords: employee voice and silence, psychological well-being, simulation study

Oral presentation OP824

Unfolding presenteeism – applying the Health-Performance Framework of Presenteeism in practice

Marie Louise Kirkegaard, Technical University of Denmark; Caroline Biron, Université Laval; Valérie Hervieux , Université Laval; Kasper Edwards, Technical University of Denmark; Christine Ipsen, Technical University of Denmark; Maria Karanika-Murray, University of Leicester

Goals. By applying the 'Health-Performance Framework of Presenteeism' (HPFP) to practice, we seek to unfold context-specific practices that influence presenteeism with a focus on the presentee.

Background. Presenteeism is a neutral but adaptive purposeful behavior that employees do because they expect its benefits will outweigh its costs (Lohaus et al., 2021; Ruhle et al., 2019). The HPFP describes the health and performance of the individual presentee and has four categories. Therapeutic presenteeism with optimal health and poor performance, functional presenteeism with optimal health and performance, overachieving presenteeism with poor health and optimal performance, and dysfunctional presenteeism with poor health and performance (Karanika-Murray and Biron, 2020; Kirkegaard et al., Under review).

Methodology. We explored presenteeism among blue-collar employees in food-processing facilities. The employees work in production lines that make up the workgroups. The employees experience physical demands and time pressure, which is correlated with presenteeism (Miraglia and Johns, 2016). We conducted 47 semi-structured interviews with employees, administrators, and managers from six slaughterhouses, asking about attendance behavior and occupational health and safety. We applied the HPFP as a coding framework in a deductive thematical analysis and ordered the results using the Individual, group, leader, and organization (IGLO) model (Nielsen et al., 2017).

Results. Individual: The employees found individual strategies like exercising to eliminate pain and obtain functional presenteeism." It depends on how you maintain your body […] if you just return home and lay on the couch, you will be worn down quickly."

Group: The groups would help each other job-craft to achieve therapeutic presenteeism by temporarily limiting performance demands by switching the presentee to less straining tasks in the group or finishing a colleague's task.

Leader: Managers can move employees temporarily, allowing for therapeutic presenteeism. A manager on the strategic level said, "I know that there is an expense with a guy […] who isn't productive, but I am completely convinced that the period will be shorter, " referring to the period of poor health. Sometimes, a manager would relocate a presentee permanently, letting the presentee perform different tasks optimally without straining their health, thereby enacting functional presenteeism.

Organization: The organization had set up procedures for employees returning after long-term sickness absences. The slaughterhouses would start the employees with fewer working hours in a short period to reduce the performance needed, supporting therapeutic presenteeism. Some slaughterhouses had a physical therapist employed to treat the employees and give them exercises to maintain their health while keeping up their work, who had "[…] exceptional abilities to heal people .

The employees, groups, managers, and the organization had strong financial incentives for employees to practice presenteeism by working in pain, when slightly ill, or with minor injuries. Dysfunctional presenteeism was unfeasible because the employees worked in production lines with

complete intragroup dependence on pace and quality. In cases where the employees, groups, managers, and organizations could not or were not willing to successfully install changes, the employees would try to keep up with the performance to the detriment of their health, stating, "A butcher does not get sick. He dies."

Limitations. The results primarily pertain to blue-collar work.

Implications. The study presents a clear case for understanding presenteeism by combining context awareness with a focus on the presentee. It shows that context-specific practices on an individual, group, leader, and organizational level influence how employees enact presenteeism. For work to be sustainable, it needs to support the employees on different organizational levels in maintaining their health while upholding performance.

Keywords: Blue-collar workers, presenteeism, flexible work resources

Oral presentation OP484

Unpacking Emotional and cognitive responses to feedback in teams

Catherine Gabelica, c.gabelica@ieseg.fr; Vitaliy Popov, University of Michigan

science

A small but growing body of literature suggests that providing teams with feedback about their performance is a powerful intervention to steer, motivate, and support future behaviour. However, although team scholars and practitioners seem to agree that feedback processing is crucial to understand its effectiveness, it has largely remained a black box. Very few scholars have zoomed in on the processes occurring after team feedback delivery. Importantly, team members' emotions can hamper cognitive processing of feedback. Despite widespread recognition that emotions play a significant role in learning and performance, emotional and cognitive processing of feedback are still insufficiently explored in individual situations, and research is even scarcer in team contexts. Understanding and specifying emotions, cognitions, and behaviours following team feedback reception is hence crucial to extend our knowledge about why not all feedback is beneficial in teams. The aim of the present paper is to explore the extent to which members of high vs. low performing teams express (a) (de)activating positive or negative emotions and (b) feedback processing behaviours (i.e., reflective statements and formulation of a general vs. specific focus and/or a general vs. specific strategy) when prompted to react to team-level feedback.

The participants (N = 111) were last-year business students working in units of a fictitious company over three days. On day 2, they received feedback from customers about their team products. We used microanalytic protocols, a type of structured interview, to access team members' emotional and cognitive responses to this team-level feedback.

Q1: You have just received customers' feedback on the product that your team has been crafting for the last two days. What was your immediate reaction to this feedback?

Q2: Moving forward, how will you use this feedback to improve your team performance? Please be as specific as possible).

To understand how team members perceived their team feedback, meaningful units of analysis were coded using two coding schemes to affective and cognitive dimensions of feedback perception: team reflexivity coding scheme from Gabelica et al. (2014), and the taxonomy of academic emotions from Pekrun (2006).

Each team members' response to Q1 was coded as 0 (absence of reflective behaviour), 1 (evaluating), 2 (looking for alternatives), 3 (making decisions).

Each response to Q1 was also coded as depicting: (1) positive activating, (2) negative activating, (3) positive deactivating, (4) negative deactivating, or (5) mixed emotions (when emotions of opposing valence were expressed by the same subject).

Finally, we examined 'feed-forward'. Team members' response to Q2 were coded using Cleary et al. (2012) and Cleary and Zimmerman (2001) microanalytic self-regulation coding schemes. We coded responses as expressing (a) a general focus, (b) a specific focus, (c) a general strategy, (d) a specific strategy.

The results of our explorative study reveal that members of high-performing teams predominantly express activating positive emotions. Additionally, they provide little evidence of initial team

reflection in the first place (Q1). However, it seems that when they are asked to think about how to use their team feedback for enhancement purposes, they start processing it cognitively. When prompted to strategic planning, they predominantly state (general) strategies to act on feedback. Low-performing teams show more complex patterns of feedback processing. Half of those teams express positive, activating emotions. There are no teams that express team reflexivity statements and negative emotions. Further, team reflexivity rather occurs in teams that have most members expressing positive emotions. Half of those teams already engage in cognitive thinking/processing of feedback at the first stage (Q1). However, after Q2, even teams expressing deactivating negative emotions state a focus and a strategy. Half of those teams even express a specific focus for their next team task. It appears that members of those teams resolved their negative emotions and moved on to cognitively assessing and integrating data from their feedback.

In sum, our study shows that there seems to be a complex interplay between feedback valence and affective and cognitive reactions to team feedback, while team feedback research has mainly focused on the dimensions of feedback interventions. Sheding light on the receivers' reactions would allow to better tailor feedback interventions to increase the chances of constructive uptake of feedback by each member.

The limitations of the study are the limited sample size (and the number of teams in each feedback valence group) and the use of graduate student teams.

Keywords: teams, feedback, emotions

Oral presentation OP694

Unpacking the Employability Paradox: Commitment Systems, Employability and Sustainable Work

Yvonne G.T. van Rossenberg, Sofija Pajic & Beatrice I.J.M. van der Heijden | Institute for Management Research, Radboud Universiteit, Nijmegen, The Netherlands

science

The debate around the employability paradox is recurring. Particularly with tight labor markets, it is key to find out if investment in workers' employability is a worthy organizational investment. Is it true that organizational investment in employability leads to knowledgeable employees leaving as soon as they see better chances elsewhere? The so-called management paradox (De Cuyper & De Witte, 2011) or the employability paradox (De Cuyper et al., 2011) refers to the (potential) trade-off effect between employability investment and increased turnover (Benson, 2006). The overarching goal of this study is to systematically unpack the theoretical grounding of the employability paradox and to assess the conditions under which this phenomenon is more likely to occur.

On the one hand, human capital theory (Becker, 1962) and conservation of resources theory (Hobfoll, 2001) highlight that employability, i.e., the continuous fulfilling, acquiring or creating of work through the optimal use of competences (Van der Heijde & Van der Heijden, 2006, p. 453), contributes to employees being fit for the external labor market, which comes at the cost of commitment to the current organization (Philippaers et al., 2016). Consistently, employability has been related to increased marketability (Nelissen et al., 2017) and turnover intentions (De Cuyper et al., 2011). On the other hand, organizational investment in employability is likely to be part of the reciprocal social exchange process between the employee and the organization, which is likely to result in increased commitment (De Cuyper & De Witte, 2011). Accordingly, it has been related to a variety of organizationally beneficial attitudes and behaviors, principally to the increased performance and intention to stay (Stanley et al., 2013). In sum, the current theoretical grounding and empirical evidence of the employability paradox are inconclusive (Nelissen et al., 2017).

To provide deeper analysis of these differences we perform systematic literature review and a meta-analysis which jointly aim to provide three main contributions. First, the study offers an integration of the existing evidence against the dominant theoretical frameworks providing more general conclusions about how and why of the employability paradox. Second, through meta-analysis, the study provides critical evaluation of the strength of the evidence pro and contra employability paradox. Finally. comparing the findings from multiple primary studies and examining moderators, the study contributes to explaining the current inconsistencies.

To identify the primary studies to be included in the current systematic literature review and meta-analysis, we conducted a comprehensive search for relevant publications across different databases (i.e., PsycINFO, Web of Science, Business Source Premier). We used combinations of keywords pertinent to the employability, commitment and turnover. Next, we scanned the studies against the set of inclusion criteria, coded the information in a standardized coding scheme, and performed qualitative and quantitative analyses of the key relationships.

Here, we outline the main preliminary results from both systematic literature review and meta-analysis. First, the systematic literature review provides deeper insight into the theoretical underpinnings of the employability paradox, and the preliminary results show: (1) a severe lack of theoretical diversity (mainly social exchange theory), (2) a lack of insight into the "how" of the theoretical framework, the actual social exchange has rarely been examined, (3) neglect of theorizing of the paradox, including theory missing or misfit to the paradox, (4) both employability

and commitment are measured inconsistently, and (5) studies relate employability to commitment to the organization, while commitment to the profession and/or career are neglected. Second, preliminary results of the meta-analysis of the relationships between employability, commitment, and turnover intention shows little evidence for the employability paradox. Specifically, the positive, instead of a negative, effect of employability on commitment is substantiated by empirical evidence, while no significant relationship is found with turnover intention. The results do substantially vary across studies depending on the specific conceptualization of employability, measurement, and commitment target.

In conclusion, we unpack the employability paradox increasing insight into the complexity of the organizational investment in employability. From the societal standpoint, this is relevant because organizations are in the position to stimulate or prohibit workers from a broader development by making them skill-dependent, which might inhibit their contributions to resolving societal issues. With the current labor shortage in key societal sectors (healthcare, education, social work), societies need workers to develop beyond organizational boundaries.

Keywords: Commitment, Employability, Sustainable Work

Oral presentation OP222

Unravelling the Interplay of Innovation Culture Elements With a Paradox Lens

Nora Varesco Kager & Gudela Grote | ETH Zurich, Switzerland; Jennifer L. Sparr, University of Zurich, Switzerland

science&practice

Goals: Organizational culture (OC) is a powerful context variable, playing a key role in companies' innovation efforts. However, OC is a multidimensional phenomenon and our understanding of the dynamics within the OC is still limited. We apply a paradox lens to investigate the persistent contradictions and interrelations between cultural elements to better understand how culture affects innovation.

Theoretical background : OC research calls to go beyond the predominant focus on OC's effects on organizational outcomes. Instead, we need to better understand how OC itself operates, surfacing how multiple cultural elements interplay to jointly impact outcomes such as innovation. This configurational perspective might be particularly relevant for innovation culture, since innovation is characterized by tensions between contradictory yet interrelated elements (e.g., exploration-exploitation, passion-discipline). For instance, research considers a culture that hosts dual value combinations (e.g., values encouraging flexibility and clear structures) as helpful to integrate exploration and exploitation. As paradox theory suggests, focusing on only one element of these tensions might stifle innovation, while embracing them with a both/and approach sparks innovation. Further, recent paradox research points out that multiple tensions may be interrelated ("knotted"). Since the paradox lens allows for a deeper understanding of complex relationships, it might be particularly helpful to enhance our understanding of how multiple culture elements jointly affect innovation.

Methods: Within a family-owned Swiss engineering company, we conducted 54 semi-structured interviews with employees in innovation-related roles (e.g., executive board, senior managers, R&D heads, specialists). Mean interview length was 43.6 minutes (std=8.3). We asked about interviewees' innovation definition, innovation examples and related learnings about corporate's culture, values, tensions, and suggestions for innovation culture development. We transcribed the recorded interviews verbatim and analyzed the data following Gioia et al. (2013). We created first-order categories capturing interviewees' descriptions, which we combined into more abstract themes by iterating between data and literature. We then developed propositions regarding cultural elements' interplay.

Results: In this particular company, we identified three cultural dimensions containing six dominant cultural elements. The first cultural dimension characterized the company's identity (who are we?: one good family; diverse family), while the second dimension captured valued working modes (how do we function?: discovery; discipline and endurance). The third dimension summarized cultural drivers (why do we do it?: higher purpose; business relevance). These paradoxical cultural element sets resemble organizational tensions between unity and diversity, creativity and discipline, purpose and profit, which are already established in the literature. For instance, the company's higher purpose stimulated innovations whose market success was not guaranteed, contradicting the need for solutions with business relevance. Further, employees belonged to different units with their own approaches and perspectives (diverse family), which competed with the felt need to stick together as one good family. We provide propositions for how cultural elements interrelate with each other in an intensifying and/or alleviating way across these innovation-related tensions, such as: " purpose

enables identification with the company, uniting diverse family parts under one good family "– where a cultural element from one tension helps integrating both cultural elements from another tension; "acting as one good family inhibits discovery (i.e., by tediously involving everyone) and stimulates discovery (i.e., by leveraging trust and openness)"–exemplifying polarizing effects from one cultural element to another across tensions.

Limitations: Our work is based on a single case with its historically built cultural elements. Future studies might investigate non-family or non-profit organizations to investigate the transferability of our findings.

Conclusions: With our work, we unravel how cultural elements work together to affect innovation. Specifically, our findings suggest that cultural elements reflect typical innovation-related tensions and are knotted to each other across them, unfolding their combined power on innovation by fueling and easing entangled tensions. Thereby, we contribute to a better understanding of how an innovation culture operates. From a practical view, considering the competing and interrelating relationships across cultural elements might help managers to understand innovation culture as a system of interacting elements.

Relevance to Congress Theme: Our insights on tensions in OC add to our understanding of the increasing complexity of our world of work and what to consider when attempting to navigate it.

Keywords: organizational culture, innovation culture, tensions

Oral presentation OP661

Using VR-Avatar Videos to support Business Process Understanding and Learning Motivation of Employees in the Context of Digital Transformation

Sarah Depenbusch, Paderborn University; Jan-Philip Schumacher, Osnabrück University; Niclas Schaper, Paderborn University

science

Research goals: Digital transformation requires employees to constantly adapt to new business processes. Currently, business processes are mainly communicated by means of paper-based process models using modeling grammars that are difficult to understand for employees due to their abstract and context-free nature (Poehler & Teuteberg, 2021). Thus, there is a strong need for new instructional methods presenting business processes in a more comprehensible way (Aysolmaz & Reijers, 2021). Virtual Reality (VR) arises as a possible answer to this challenge as it allows creating realistic and context-based visualizations of business processes and work environments. However, the use of VR relates to high costs (e.g., quantity of hardware required for broad communication). Instructional videos can function as a more (cost-) effective medium for broad application while still offering the ability of shifting learning environments from theoretical to practical (e.g., Köse et al., 2021). When it comes to choose the appropriate visual presentation format (e.g. animation vs. static pictures), current research provides a rather scattered picture (Hattermann et al., 2021). In the context of business process training, animated VR-avatars have found to be an effective format for communicating business processes providing high representational fidelity (e.g., Leyer et al., 2021). Additionally, VR-based visualizations increase learning motivation (Huang et al., 2022), which can mediate learning by increasing or decreasing learners' cognitive engagement (affective mediation hypothesis, Mayer, 2014). Against this background, the potential of VR-avatar-videos to support employees' business process understanding and learning motivation is investigated in comparison to voice-over-slides-videos using abstract and static pictures. In addition, it is explored whether learning motivation in turn affects learning outcomes and whether employees' prior content knowledge may function as a moderator in this context.

Theoretical background: Referring to the cognitive theory of multimedia learning (CTML; Mayer, 2005) and cognitive affective theory of learning with media (CATLM; Moreno, 2005), we hypothesize that VR-avatar-videos will be more effective in supporting business process understanding and learning motivation than voice-over-slides-videos. According to CTML, VR-avatar-animation provides dynamic and thus more explicit information about the execution of working steps which may facilitate process understanding. According to CATLM, VR-avatar-animation appears more appealing and thus can increase learning motivation (Mayer, 2014).

Methodology: We carry out an online experiment (N = approx. 150 participants, power analysis suggesting a total sample size of at least 129 participants) using a between-subject design. Participants are randomly assigned to the VR-avatar-video group or the voice-over-slides-video group. Both videos show the same business process. After watching the video, participants answer knowledge questions and assess their learning motivation based on the instructional materials motivation survey (IMMS; Keller, 2010). Group differences concerning business process understanding and learning motivation are investigated using one-way ANOVA. The effects of learning motivation and demographic variables on business process understanding are calculated with regression-based analysis using PROCESS.

Expected Results: Data analysis will be completed in March 2023. We expect that the VR-avatar-video leads to better process understanding and higher learning motivation than the voice-over-slides-video. Further, we expect that motivation has a positive effect on business process understanding and thus mediates the effect of instructional video design on process understanding. Finally, we assume that employees' prior knowledge functions as a moderator in this context.

Limitations: Instead of a real learning environment, a fictional experimental setting is applied. Further, a convenience sample is used which mainly contains students.

Conclusion: This study contributes to research by providing first empirical results concerning the effectiveness of VR-avatar- videos to enhance employees' business process understanding in the context of digital transformation. These insights support organizations in preparing effective instructional methods and instruments for prospective business process training.

Relevance to the Congress Theme: This study takes up the central congress theme "the changing world of work" and provides new scientific and practical insights with regard to the effectiveness of video-based process trainings.

Relevant UN SDGs: Our study addresses the UN SDGs of supporting inclusive, equitable and quality education and of promoting lifelong learning opportunities for everyone.

Keywords: VR-based learning, instructional video, business process understanding

Oral presentation OP676

Validity Evidences of the Brazilian Leaders Competencies Scale Aimed to Promoting Work-Family Balance

Amália Perez-Nébra; Francisco Antonio Coelho Junior, University of Brasília / Brazil; Samantha Albano Amorim Cardoso, Ministry of Women, Family and Human Rights / Brazil; Ianne Oliveira Lima, University of Brasília / Brazil; Júlia Louise Medeiros, University of Brasília / Brazil

science

During the COVID-19 pandemic, leaders had to learn to deal with the unforeseen and impactful consequences that the new virus caused across the planet. Understanding which competencies can contribute to balance and adaptation to the new scenario imposed by the pandemic has became very relevant. The personal space at home has become the same professional space at work. Conflicts in both family and work were very common, considering the invasion of one over the other. Many leaders lacked certain competencies, especially those related to promoting work-family balance. These competencies had to be quickly developed because of the compulsory home office, considering the social isolation. There has never been so much need for clever leaders, developing capacity of planning and support actions considering the dynamics dyad between work and family. This research aims to present evidence of validity of the Brazilian scale of leaders' competences aimed at promoting work-family balance. The first version of this scale was built based on a systematic survey considering the existing literature. The main theoretical categories related to the topic were identified by the research team. Afterwards, 4 focus groups were carried out (N=21 Brazilian leaders), in addition to 3 individual in-depth interviews with other Brazilian representative leaders. The focus group and interviews aimed to map the strategies of action of leaders in the leadership of their teams during the pandemic. We also identify what type of leaders' competencies they developed during the pandemic period. All leaders who participated in the qualitative step were intentionally chosen for accessibility and convenience. Semantic and judges validation procedures were also performed (N = 12). After the qualitative step, and before the exploratory factorial validation, the instrument has had 17 leadership competencies oriented by work-family balance. These competencies were evaluated in terms of their domain considering the report by leaders about how much they impacted their performance. After digitizing the questionnaire, the data collection was made by survey and took place intentionally, for accessibility, at a distance mode. The procedure used to disseminate the instrument was the snowball. Only managers, of any management level, who led a team, could respond to the survey. All ethical procedures were followed. Exploratory factor analysis was used for the analysis and interpretation of results. The sample obtained consisted of 220 Brazilian managers, with a mean age of 40.69 years (SD = 8.84), men (62.90%), married (66%), with at least 1 child (59.2%) and leading teams made up of three or more people (47.5%). The results showed a factorable empirical structure (KMO = 0.898), with three factors: ‘Technical Competencies for Managing and Planning the Work of the People Led’ (7 items, explained variance = 37.96; eigenvalue = 6.45, alpha = 0.815, factor loadings between 0.776 and 0.398), ‘Competences to Promote Organizational Culture Practices Oriented to Balance Work and Family’ (7 items, explained variance = 13.28; eigenvalue = 2.26, alpha = 0.880, factor loadings between 0.831 and 0.462) and ‘Authentic Leadership and Socio-Emotional Competencies for Work and Family Integration (3 items, explained variance = 7.01; eigenvalue = 1.19, alpha = 0.755, factor loadings between 0.465 and 0.383). The psychometric indicators obtained in this first version were very satisfactory. As a limitation, we highlight the little sampling variability, even if leaders from other regions of Brazil were invited to participate in this research. The scale is unprecedented and original, allowing identified leadership styles used in the compulsory home office during the

pandemic. Training actions can be better directed to develop the needs of leaders, working to promote the well-being and quality of life of their subordinates, reducing injustices in their actions and promoting the work-life balance.

Keywords: leadership competencies, authentic leadership, statistical methods

Oral presentation OP479

Values and innovation at work: the relationship between Person-Organization value (In)congruence, eudaimonia and innovation.

Theresa Schweizer, Núria Tordera & Ana Hernández | IDOCAL. Universitat de València

science

Research goals and why the work was worth doing

Innovation is a crucial asset for an organization's success. Thus, it is of interest to investigate the role of individual and organizational factors contributing to innovative behaviors at work (IWB) and the mechanisms that explain these relationships. Personal values, such as stimulation and self-direction, are considered to promote IWB. However, individuals are also influenced by organizational values and culture, which not always are aligned with individual personal values. Thus, the fit between personal and organizational (P-O) values might play an additional role in the promotion of IWB. Although most part of the research considers P-O congruence to be positively related to individual outcomes (e.g. well-being), the relationship with innovative behaviors and the pathways to their development remains highly unexplored. Some evidence has been found for the relationship between value congruence and creativity. It is important to consider other key factors embodied by IWB such as idea promotion and implementation. Thus, the aim of this research is to analyze the relationship between P-O value congruence (stimulation and self-direction) and IWB and the mediating role of eudaimonic well-being in this relationship. In addition, we investigate whether gender moderates the relationship between P-O value congruence and eudaimonic well-being, and thus has a differential indirect effect on IWB.

Theoretical background

The theoretical background of the research is based on Schwartz's basic values theory (1992, 2012), and P-O fit congruence and social exchange theory (Blau, 1968). Schwartz's theory suggests that certain values, namely stimulation, and self-direction, are of particular interest to IWB. P-O congruence and social exchange theory suggest that the congruence in values could contribute to IWB by its effects on individuals' well-being. We also build on the happy-productive-worker model (e.g. Wright & Cropanzano, 2007)

Design/Methodology

Data came from 306 employees from six organizations in Spain who responded to an online questionnaire implemented in Limesurvey. The questionnaire was accessible via a link sent to participants' work email addresses. Traditionally, value congruence has been measured with difference scores. However, this approach is flawed as it discards information and is conceptually ambiguous. To overcome these problems, the moderated effects of value congruence on well-being were analyzed by means of hierarchical polynomial regression and response surface methodologies (Edwards, 2007). The relationship between well-being and IWB was tested by means of regression. In all cases, we controlled for the organization. We tested the hypothesized (conditional) indirect effects by means of bootstrapping

Results

Results showed a constant increase in IWB for congruence in stimulation. Congruence in low stimulation exceeded any incongruence. Regarding self-direction, we found O-P congruence to be related to increasing eudaimonia, however, incongruence with high personal self-direction was

pivotal. Eudaimonia mediated the relationship between congruence in self-direction and IWB. Gender did not play a moderating role in the proposed model.

Limitations

A methodological limitation is the cross-sectional nature of the study precluding causality and reciprocal causality between eudaimonia and IWB. Further experimental studies or cross-lagged panel correlation designs are recommended.

Conclusions -research and or practical implications

The contributions of P-O value congruence and eudaimonia can be decisive factor in predicting innovation and, subsequently, determine the competitiveness and success of organizations. Our research acts as an initial advance in disentangling relationships between value congruence, eudaimonia, and IWB. Collectively, the results regarding innovation and eudaimonia contribute to the rising discussion of the joint optimization of performance and well-being in organizational studies. Relevance to the Congress Theme 9

In the changing world of work, research focusing on innovative behaviors and personal growth and development contributes to the development of sustainable societies and workplaces. Our results state that adjustment between organizations and individuals can be a relevant drive to individuals' well-being and innovation. However, organizations pursuing innovation might also benefit from those individual values that challenge organizational values to some extent.

Relevant UNSDGs

SDG 8. Decent work and economic growth. Promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all.

Our results offer guidance for the promotion of innovative behavior at work and eudaimonic well-being. Thus, they can contribute to more sustainable workplaces and higher quality work.

Keywords: Innovative work behavior, Value congruence, Eudaimonic well-being

Videoconference fatigue: validation of the Italian translated Zoom Exhaustion and Fatigue Scale

Giulia Paganin, Department of Medical and Surgical Science-University of Bologna; Silvia Simbula, Department of Psychology, University of Milan-Bicocca; Monica Molino, Department of Psychology, University of Turin

science

Research goals and why the work was worth doing

The present study aims to investigate the psychometric properties of the Italian translation of the Zoom Exhaustion and Fatigue Scale (ZEFS). Additionally, it seeks to evaluate this construct's relationship with technostress creators, sleep problems, work engagement, and job satisfaction.

Theoretical background

In the last few years, using video conferencing has become a necessity worldwide due to the Covid-19 pandemic. Indeed, many employees started to attend meetings virtually using technologies such as Zoom or Microsoft Teams, instead of meeting face-to-face. The Zoom platform's widespread use in video conferences has become generic, with many individuals substituting "Zoom" for "video conferencing." Recent research has found that using videoconferencing programs might leave you feeling exhausted, stressed, or depleted. Therefore, a new term -"Zoom Fatigue"- emerged because of overusing video conferencing technologies. Zoom fatigue is the state of being worn out after using a video conferencing platform for a meeting. Recently, a diagnostic tool (i.e., ZEFS) was implemented to identify zoom fatigue arising from excessive screen time (Fauville et al., 2021). However, as far as we know, a validation of the ZEF scale is unavailable in the Italian language; moreover, little is known about the psychological consequences of the recently increased utilization of videoconferencing.

Design/Methodology/Approach/Intervention

An online survey was administered to a sample of 360 Italian workers (56% male, M age =38.6±11.96). Besides the Italian translation of the ZEFS (15 items) used to assess Zoom Fatigue, the survey was composed of questionnaires (including validated measures) focused on sociodemographic and job-related information, technostress creators, work engagement, job satisfaction and sleep problems. The psychometric properties of the ZEFS were evaluated through exploratory and confirmatory factor analyses, as well as Cronbach's alpha and corrected-item correlation. Correlation and regression analyses were conducted to examine the associations between Zoom Fatigue and all the other variables.

Results obtained or expected (if not available, it must be made clear when they will be)

Preliminary analyses showed adequate reliability and validity of the ZEFS as well as favourable goodness-of-fit indexes and fit indices (CFI=0.961; TLI=0.95; RMSEA=0.076). ZEF scores were significantly and positively associated with technostress creators (techno-overload, techno-invasion, and techno-complexity) and sleep problems. In contrast, they were negatively associated with job satisfaction and work engagement, supporting the scale's concurrent validity.

Limitations

This study used a cross-sectional design that merely relied on self-report measures. Therefore, the current research did not allow for testing relationships among these variables across time nor to

assess all types of validity or reliability, such as test-retest reliability. Moreover, future work could also explore how contextual and individual differences may impact the experience of Zoom fatigue.

Conclusions – research and or practical implications/Originality/Value

The results indicated that ZEFS is a valid and reliable tool for assessing the psychological effects of videoconferencing in the Italian context. Moreover, by showing the relationships of Zoom exhaustion and fatigue with technostress creators, sleep problems, job satisfaction, and work engagement, the present study identified prospective directions that could be taken to protect the well-being of workers who use videoconferencing on a regular basis.

Relevance to the Congress Theme

The nature of work has changed considerably over the last few years, involving a progressive use of videoconferencing programs as a consequence of remote working. This raised attention to a specific form of fatigue, namely Zoom Fatigue. This complex situation needs to be addressed at different levels, and scholars need valid and reliable tools to understand this phenomenon.

Keywords: zoom fatigue; italian validation; well-being

Virtual, Hybrid, and Co-located Team Members' Well-being. A Systematic Comparison of Antecedents

Jaroslaw Grobelny, Adam Mickiewicz University in Poznan, Poland

science&practice

Research goals and why the work was worth doing

The pandemic has brought significant changes in many professions, forcing employees to work remotely. After restrictions were withdrawn in many countries, some workers opted to work from home permanently, causing a rise in the number of hybrid teams. This has prompted the need to provide evidence-based guidance on managing this type of teams and maintaining their members' well-being. While there are studies on employee well-being antecedents, no systematic comparison of what specifically contributes to the well-being of employees from virtual, hybrid, and co-located teams has yet been provided. The goal of this exploratory study was to address this issue.

Theoretical background

Employees' well-being was defined in accordance with the hedonic perspectives (i.e., the presence of positive job-specific evaluations and the experience of positive job-related emotions). Working in each of the three types of teams results in specific demands experienced by team members. Therefore, I drew from the JD-R model and existing evidence on well-being antecedents to select factors that could be relevant to each team member's well-being. On this basis, factors from the following areas were selected: personal resources, such as emotional intelligence and home environment & individual factors; workplace resources, such as workstation environment, team communication, flexible work schedule, and leader-member exchange; and job demands, such as workload and team conflicts.

Methodology

A cross-sectional study was conducted with 1264 participants. They were recruited through direct invitations on social and professional networking sites. About half of the sample came from the US (n = 613) and about the same amount from Poland (n = 598). The proportion of participants from co-located, hybrid, and remote teams were more or less equal (n 1 = 384, n 2 = 425, n 3 = 371). Participants completed the survey with the Job Descriptive Index, Jon-related Affective Well-being Scale, Schutte Emotional Intelligence Test, Demand Control Support Questionnaire, Work Group Characteristics Measure, Leader-Member Exchange 7 Questionnaire, and rating scales to measure lifestyle, household, workstation, and flexible schedule factors.

Results obtained

Multiple linear regression and Johnson's Relative Weights Analysis were employed to analyze the results. Predictors accounted for 45% of all participants' well-being variability ($F(27, 1236) = 37.46$; $p < 0.001$). Coefficients of determination were slightly dispersed between different team types (56% for co-located, 49% for hybrid, and 45% for virtual). The analysis showed substantial differences in how the variables contributed to predicting the well-being of team members. For example, EI impacted only co-located team members' well-being. Having children driven hybrid team members' well-being while living alone in the household was significant only for virtual team members. Workstation quality seemed to be significant only for workers in stationary teams. Working in the same room with other people lowered only virtual team members' well-being, while affective conflict

was significant only for the hybrid teams. A flexible work schedule was particularly important for hybrid teams as well. There were factors impacting all team members' well-being, e.g., distraction at work or LMX. Also, such factors as physical exercise, having dedicated working space, workload, and informal chat opportunities do not contribute to the employees' well-being.

Limitations

The study's limitations are due to its cross-sectional design. The results should be confirmed in a longitudinal study to have more confidence in the robustness of the conclusions. In addition, a follow-up study with a random and larger sample would allow inferences about differences in well-being magnitude between members of each team type.

Research and practical implications

The study's results showed considerable differences in the strength and significance of the antecedents of well-being between groups of people working in different team types. This suggests that theoretical models describing well-being at work should consider the team factor and the specific demands of working in each team type. From a practical perspective, the study's findings will allow the development of evidence-based policies to enhance and maintain the employees' well-being in a way that fits their work mode and team composition.

Relevance to the Congress Theme

The presentation is related to the Urgency facet of the Congress Theme, as it addresses a recent and widespread change in the work organization practice.

Relevant UN SDGs

The study is relevant to the "Good health and well-being" goal, as it addresses the antecedents of these constructs, allowing to develop an evidence-based policy to enhance it.

Keywords: well-being, hybrid teams, remote work

Oral presentation OP444

Visionary leadership and team performance: The role of team potency and resource sufficiency

Pierre-Marc Leblanc, Université de Montréal; Jean-François Harvey, HEC Montréal; Vincent Rousseau, Université de Montréal

science

THEORETICAL BACKGROUND AND HYPOTHESES

Articulating an aspiring vision is at the heart of effective leadership (Venus et al., 2019). According to Stam and al. (2014), visionary leadership mobilizes team members toward achieving a common future by triggering the emergence of collective possible selves. When leaders craft a strong vision for their team (e.g., to become the leading team regarding patient's satisfaction), they express confidence in the team's ability to become a new and improved version of itself, which may influence how the team evaluates its own ability to change (van Knippenberg et al., 2004). Drawing on social cognitive theory (Bandura, 1986), we first argue that visionary leadership positively and indirectly affects team performance via increased team potency, that is the team's general belief that it can be effective across tasks and contexts (Schaubroeck et al., 2011).

Yet, a leader's vision can also be threatening (Dent & Goldberg, 1999). It may raise the team's awareness of surrounding constraints and challenges (Rafferty & Griffin, 2004), thereby sowing doubt in team members' mind as to their collective ability to achieve the vision (Shamir et al., 1998). When the leader's vision is deemed unrealistic, team members may even start questioning the leader's judgement, which can further compromise the realization of team's future perspectives (Ashford et al., 2018). In this study, we challenge the unconditional positive perspective on visionary leadership and argue that resource sufficiency (e.g., time, information, and equipment) is a key boundary condition. Especially, we suggest that visionary leadership stimulates team performance via increased team potency when resource sufficiency is high, but not when it is low.

METHOD

In this time-lagged multisource study, we used a sample of 69 functional teams and their immediate supervisor working in a Canadian hospital (T1 = 422 members; T2 = 336 members). The response scale ranged from 1 (strongly disagree) to 7 (strongly agree). We adapted the three highest loading items from House (1998) to assess visionary leadership (T1; α = .97) by replacing the words organization and unit with the word team . We slightly modified Amabile's (1995) six-items scale to assess resource sufficiency (T1; α = .82). We measured team potency (T2; α = .90) with Guzzo's (1993) eight-items scale. Immediate supervisors assessed team performance (T3; α = .81) with the three positively worded items (out of four) developed by Edmondson (1999). We controlled for team size, team interdependence, and team leader's level of education.

RESULTS AND DISCUSSION

We aggregated individual scores at the team level for all variables: visionary leadership (r_{wg} = .70; F = 4.10, $p < .001$; ICC(1) = .34; ICC(2) = .76), resources sufficiency (r_{wg} = .81; F = 1.92, $p<.001$; ICC(1) = .13; ICC(2) = .48), and team potency (r_{wg} = .95; F = 1.39, p = .035; ICC(1) = .08; ICC(2) = .28).

We used parcels to assess the distinctiveness between our measures (Little et al., 2002). Results of the four-factor model that included all the latent variables showed a satisfactory structure (χ 2 =

99.665, df = 59, p = .001; CFI = .942; TLI = .923; SRMR = .0796), which is superior to best alternative model (Δc 2 = 72.626, p < .001).

We tested our hypotheses with PROCESS (Hayes, 2019) on 5,000 bootstrap samples at a 95% confidence interval. Our first hypothesis stated that visionary leadership increases team performance via team potency. Results show that visionary leadership is positively related with team potency (b = .10, SE = .05, p = .03), which is in turn positively related with team performance (b = .48, SE = .19, p = .02). Results from bootstrapping analyses support this hypothesis (indirect effect = .05, BootSE = .03, CI = [.004, .11]).

Our second hypothesis stated that resource sufficiency moderates the indirect relationship between visionary leadership and team performance via increased team potency, which is also supported (index of moderated mediation = .06, BootSE = .03, CI = [.001, .12]). We plotted the simple slopes of this indirect relationship at 1 SD above and 1 SD below the mean of resource sufficiency . Results show that this indirect effect is significant when resource sufficiency is high (indirect effect = .08, BootSE = .04, CI = [.01, .16]), but not when it is moderate (indirect effect = .04, BootSE = .03, CI = [-.007, .10]) and low (indirect effect = .003, BootSE = .03, CI = [-.06, .06]).

We advance research on visionary leadership in the team domain in very important ways. Pushing SCT to the team-level, we suggest that to create the conditions for team performance, visionary leaders should make resources salient to team members. In future research, we encourage scholars to use a longitudinal design to clarify the temporal sequence linking visionary leadership to team performance, and to examine whether certain team attributes (e.g., team power distance) modulate the influence of visionary leadership.

Keywords: visionary leadership, team potency, resources sufficiency

Oral presentation OP699

Well-being and heart rate variability in everyday life of managers in care facilities

Regina Schmid & Joachim Thomas | Catholic University of Eichstaett-Ingolstadt; Jean-Pierre Harder, Caritasverband Eichstaett; Paula Gasser, Catholic University of Eichstaett-Ingolstadt

science&practice

Research Goals: The nursing sector has been of great public interest not only since the start of the Covid-19 pandemic. A growing need for nursing care coupled with an increasing shortage of personnel characterizes the critical situation in Germany, which was further exacerbated by the pandemic. As a result, nursing facilities are facing major challenges that place a considerable burden on their employees. While health-related working conditions of nursing staff have already been investigated in numerous studies, there is a lack of research on their leader's health. Leaders, however, bear the great responsibility of having to meet these challenges under high pressure and constantly changing working conditions. The planned study is intended to close this research gap.

Theoretical Background: According to the job demands-resources (JD-R) model, strain reactions are based on the level of health-impairing job demands and stress-buffering resources. The present study aims to contribute to work and organizational research by integrating subjective and objective health-related outcomes into the JD-R framework while studying a rarely researched population.

Methodology: Using a sample of nursing managers and directors, we conducted an ambulatory assessment study to investigate measures of well-being and heart rate variability (HRV) in association with current situational aspects. Participants wore an electrocardiogram device on two working days and rated their level of job demands (e.g., overload and rumination), job resources (e.g., self-efficacy and role identification), and well-being (e.g., positive affect) five times a day. Data collection is currently still ongoing and is expected to be completed by the end of 2023. Based on the preliminary data, multilevel models were calculated for a total of 27 managers and 347 situations predicting affective valence and 5-minute state HRV.

Results: A preliminary result is that, in line with the health-impairment process, situations with high overload and rumination were associated with temporarily decreased positive affect, but not with HRV. Furthermore, consistent with the stress-buffering hypothesis, momentary self-efficacy and role identification significantly buffered the negative effects of work overload on positive affect and marginally on HRV. That is, overloading situations in which managers were self-efficacious and identified with their current role were associated with fewer impairments in affect and HRV than overloading situations in which these resources were unavailable. Further analyses are planned once the data collection is completed.

Conclusion: Contributing to psychophysiological ambulatory research in occupational health psychology, the present study provides insights into the detrimental concomitants of overload among nursing managing staff, while emphasizing the importance of increasing self-efficacy and role aspects as protective and stress-buffering resources.

Strengths and Limitations: Identified limitations of the study are the small sample size, the cross-sectional design, and the focus on only a few selected demands and resources, while many other variables of the work environment remained unconsidered. On the other hand, the multi-methodological approach provides insights into new, psychophysiological relationships within and between managers and offers a holistic view of real-life occupational health.

Relevance to the Congress Theme: The study focuses on an occupational group that has been confronted with a constantly changing working environment over the last few years. Not only the pandemic brought great dynamics into this professional field, but also new reforms and laws, advancing digitalizations and the increasing demand for care due to demographic developments. With innovative measurement methods in the form of smartphone- and sensor-based technologies, we wanted to capture these new challenges in an equally contemporary way.

Relevant UN SDGs: The present study contributes to the UN SDG “Good health and well-being” by offering insights into psychophysiological aspects of strain and by providing practical recommendations for promoting health and well-being at the workplace.

Oral presentation OP199

Well-being and job search during unemployment

George Michaelides & Zografia Bika | University of East Anglia

science

Research goals

We aim to understand the role of well-being in job seeking behaviour and how potentially well-being can mediate the effect of key factors that can promote job seeking behaviour including, job search efficacy, social support, and social capital. This is important as it will provide a deeper understanding of the underlying mechanisms that govern job seeking behaviours.

Theoretical background

Job seeking behaviour and potentially reemployment depends on a number of individual and situational factors including job seeker's personality traits, human and social capital, and support mechanisms available to individuals (Kanfer et al., 2001; Wanberg et al., 2002). However, unemployment can have detrimental effects on well-being with the potential to diminish individual's engagement with job seeking (McKee-Ryan, et al, 2005).

To understand this process, we examine how psychological well-being can mediate the relationship between job search self-efficacy, social support and social capital with job search activities and hypothesised two moderators of the mediation paths. First, we suggest that selective optimization with compensation (SOC) can strengthen the positive effects of our predictors on well-being. SOC is a self-regulation strategy that has been developed in life-span developmental psychology (Baltes and Dickson, 2001) and emphasizes the maximization of gains and minimization of losses associated with situational contexts such as the loss of employment. Second, we hypothesise that the positive association between well-being and job search activities is moderated by job search self-efficacy. Self-efficacy, which captures individual's belief in their capacity and ability to carry out tasks is instrumental in motivation and goal commitment. Thus, we expect that those with high job search self- efficacy are more likely to persist and commit to their job search even when they experience diminished psychological well-being.

Design and Methodology

We evaluated our hypotheses using Bayesian analysis and data from 292 unemployed participants. Participants resided in 14 locations in the UK and France and therefore a multilevel model was used to account for potential contextual differences between them.

Results

Preliminary results revealed that job search self-efficacy, social capital and social support have positive associations with psychological well-being. Moreover, the moderating effect of SOC was significant only for social capital indicating a stronger positive effect when individuals utilise SOC strategies. For job search activities, we found direct positive effects for job search self-efficacy, SOC and social capital but not for social support. Unexpectedly, there was no main effect for psychological well-being on job search, but the effect was conditional on job search self-efficacy. Specifically, well-being was positively associated with job search activities when job search self-efficacy is high and negatively when low. This was propagated to the indirect effects of SOC, social

support, and social capital so that the indirect effects were positive when job search self-efficacy is high and negative when low.

A key limitation of the study is that the data are cross-sectional and therefore the relationships identified cannot be interpreted as causal.

Conclusions

Our results make several contributions. First, we embellish our understanding of the mechanisms behind job search and the role of well-being in future job search and reemployment. Second, we show the instrumental role of SOC and job search self-efficacy in enabling individuals to engage with job search activities. Finally, our results have implications for practitioners and policy makers as they can inform the design of interventions for job seekers.

Relevance to the congress theme

Changing the world of work, should encompass a clearer understanding of job seeking behaviours. This study makes is relevant in this regard as it provides insights on how individuals can escape the vicious cycle of unemployment, poor well-being and disengagement from job search.

Relevant UN SDGs

Good health and well-being; decent work and economic growth

Wellbeing at work of the intellectually gifted

Patricia van Casteren, Tilburg School of Social and Behavioural Sciences, Tranzo, Tilburg, The Netherlands/ Lifeworks; Jac van der Klink, Tilburg School of Social and Behavioural Sciences, Tranzo, Tilburg, The Netherlands / North West University of South Africa

science

Purpose & theoretical background

Neurodiversity can be both a blessing and a curse in the workplace. Recent research shows that people with for example ADHD and ASS can increase their wellbeing at work by benefitting from certain workplace adaptations. As a result they feel better, have less intent to leave and are able to positively contribute to their organizations.(Khalifa et al., 2020; Patton, 2022)

There is relatively little known about the factors that impact the wellbeing at work of another group of neurodiverse workers: the intellectually gifted. Such knowledge is necessary to design solid interventions and improve counselling for this group. This current research project aims to expand this body of knowledge and thus contribute to the wellbeing at work of the intellectually gifted.

This study is a quantitative follow up to an earlier qualitative study, that showed that the gifted have specific hurdles to tackle at work e.g. an intolerance for perceived injustice, a need to be intellectually challenged and difficulties connecting with co-workers (van Casteren et al., 2021) . In this study we aim to learn more about the factors that are associated with experienced wellbeing at work by exploring the aspects of work that people really value and to what extend they are enabled and able to achieve said values. We also included concepts like autonomy, authenticity, leadership styles and intellectual humility to our questionnaire, in order to learn more about factors that are associated with wellbeing at work of gifted workers. By looking at factors connected to the gifted workers themselves as well as to the role of the occupational context, we aim to paint as complete a picture as possible.

Methods

The current study consists of a cross-sectional questionnaire study among members of Mensa in the Netherlands with an income from paid employment or from entrepreneurship. Mensa is an international society for gifted people from all walks of life which requires proof of an IQ score in the 98 th percentile of an approved intelligence test to become a member. We strive for N>00.

The work related values of gifted workers are identified by presenting them the capability set for work, a validated questionnaire in line with the value based approach of sustainable employability and wellbeing at work (Abma et al., 2016) (Gürbüz et al., 2022). Our questionnaire further encompasses themes questions about autonomy, person-job fit, preferred leadership styles, intellectual humility, and proactive personality. These topics were derived from earlier research into wellbeing at work in general and specifically for the intellectually gifted.

Results:

We expect to be able to report the first results and analyses from our study in the first quarter of 2023.

Limitations

The sample is not representative for all intellectually gifted workers due to the sampling method used.

Conclusion

More knowledge about the factors influencing wellbeing at work of gifted adults is needed to better identify threats and opportunities for the enhancement of the work experiences of this group. The results of this study will provide input for the development of interventions and improve counseling, especially around topics like career counseling and burn out prevention.

Relevance for congress

This research is relevant to the congress theme as it focusses on the UN Sustainable Development Goal 'Good health and Wellbeing'. The findings of the current study can help to inform future research and interventions which can create a more inclusive work environment. In a more inclusive work environment, fitting accommodations will be available and intellectual giftedness will no longer be an obstacle for experiencing wellbeing at work.

Keywords: Giftedness, neurodiversity, wellbeing

Oral presentation OP761

Wellbeing, sleep and health assessments in remote due to Covid pandemic workers depending on social support and hours worked

Irena Iskra-Golec, SWPS University of Social Sciences and Humanities, Faculty in Poznan, Poland; Patrycja Siemiginowska, Institute of Applied Psychology, Jagiellonian University, Krakow, Poland

science

The aim of this study was to examine the impact of remote due to pandemic working arrangements on wellbeing, sleep problems, and physical health perception in a representative sample of remote workers in Poland. The outbreak of Covid -19 pandemic resulting in implementation of remote work on a larger scale than earlier has a potential of creating new work stressors as well as stress outcomes. The systematic reviews and meta analyses show negative impact of remote working during pandemic on wellbeing, sleep and health (Patel, Robertson, Kwong, Griffith, Willan, Green, et al. 20220). There is some evidence on a positive role of social support in alleviating these negative effects (Grey, Arora, Thomas, Saneh, Tohme, Abi-Habib, 2020). The participants (n=635; women=438; men=197) aged 19 to 70 years (M=37,24; SD=11,02 years) filled in an online survey. They were divided into 6 groups on the basis of hours worked per week (below 40h, 40h, more than 40h) and social support (low (LSS), high (HSS)). The groups were as follows: (1) LSS >40h per week (N=77, M=38,60 years; SD=13,24 years), (2) LSS and 40h (N=144, M=36,21 years, SD=8,94 years, 67%), (3) LSS and <40h (N=123, M=36,23 years; SD=8,96 years), (4) HSS and >40hours per week (N=73, M=39,48 years, SD=14,29 years), (5) HSS and 40h (N=118, M=36,31 years, SD=10,98 years), (6) HSS and <40h (N= 100, M=38,39 ears, SD=11,30 years,). Social support was measured by Multidimensional Scale of Perceived Social Support (Zimet, Zimet, Farley, 2017), well-being was assessed by WHO-5 Well-being Index (WHO, 1998), sleep problems were evaluated by usage of Athens Insomnia Scale (Soldatos, Dikeos, Paparrigopoulos, 2000), and subjective health was assessed by questions derived from Short form Health Survey SF-36 (Ware, Sherbourne, 1992). Two factorial analysis of variance was performed on the data (the factors: a number of hours worked per week and social support). Interactive effect of hours worked per week and social support was found on wellbeing ($F(5.629)=12.23$, $p=.000$). Employees with HSS working less than 40 hours per week ($x=18.20$, $SD=.03$) and those working full time ($x=18.41$, $SD=.43$) assessed their wellbeing higher than those with lower social support regardless of hours worked per week ($x=16.29$, $SD=.53$; $x=15,26$, $SD=.29$; $x=14,49$, $SD=.42$, respectively). Significant effect of interaction of hours worked per week and social support was found for assessment of sleep problems ($F(5,629)=8,072$; $p<0,001$). Employees with HSS working less than 40h per week ($x=18.45$, $SD=.76$) and those working full time ($x=19,03$, $SD=.59$) reported less sleep problems than those working more than 40h per week irrespective of social support (LSS: $x=23.03$,$SD=.58$;HSS: $x=22,46$, $SD=.65$). Significant interaction of hours worked per week and social support on physical health assessment was found ($F(5,629)=2,787$, $p=.017$). Physical health assessment was higher in workers with higher social support in all groups of working hours ($x=3.47$, $SD=.09$; $x=3.47$, $SD=.08$; $x=3.32$, $SD=.08$, respectively) when compared to those with low social support ($x=3.22$, $SD=.09$; $x=3.22$, $SD=.07$; $x=3.15$, $SD=.07$, respectively) with the lowest assessment in the group of low social support working overtime. The limitation of this study is too small amount of men when compared to women in the studied group. There is a high relevance to the subject of Congress theme because working remotely full time may create new work stressors, which may create a risk for health and wellbeing of the workers. Practical implications of the research is showing that social support seems to be a crucial factor for wellbeing, sleep quality and health perception in pandemic situation. Moreover, health, sleep and well-being problems were experienced more often by employees working overtime, therefore no more than 40 hours of

remote work should be recommended. This research stressed the importance of social support as well as working remotely no more than full time to maintain wellbeing, sleep, and subjective health. By indicating these this presentation contributes to SDGs (Good health and wellbeing).

Keywords: well-being, social support, remote work

Oral presentation OP122

What difference does it make? An experimental study on the effectiveness of health-oriented leadership on-site compared to the digital working context

Jörg Felfe & Laura Klebe | Helmut-Schmidt-University

science

Research goal: Leadership represents an important workplace resource for employees. However, as opportunities to work from home increased in the past years, the question may be raised on whether leadership is more or less effective in digital working contexts compared to working on-site with regular face-to-face contact. The current research therefore investigates, whether the effectiveness of health-oriented leadership in terms of staff care (i.e., the extent to which leaders value, are aware of and promote employees' health at work) differs for employees in an experimental study.

Theoretical background: Due to containment measures during the pandemic, many employees immediately needed to shift to working from home. Since then, working from home opportunities have become established in many organizations. Working from home may pose a chance, but also a risk for employees' health and their work-related attitudes. In order to reduce risks and to promote employee health in the working context, there is a growing interest in health-oriented leadership, which specifically accounts for leader and employee health. While health-oriented leadership plays a crucial role for employees when working on-site, the role of health-oriented leadership in digital working environments yet remains unknown. It is an open question, whether health-oriented leadership in terms of staff care is more or less effective for employees when leaders and followers solely communicate via digital media compared to direct face-to-face contact.

Method: In a laboratory experiment with N = 60 participants, a moderating effect of the working context on the relationship between staff care and employee health as well as work-related attitudes was tested. We utilized a between-subjects design with a systematic variation of the the working context (on-site vs. digital working context). A professional actor, who was intensively trained before the experiment, portrayed a health-oriented leader, who either worked and communicated about 30 minutes with his employees (i.e., the participants) on-site with direct face-to-face contact or digitally via video call. As dependant variables, employees' physical and mental health, job satisfaction and engagement were measured by objective health measures (i.e., heart rate and heart rate variability) and self-ratings (exhaustion, engagement and job satisfaction). The experiment took about 45 minutes per participant.

Results: Data were analyzed by conducting mixed RM-ANOVAs. Results uncovered positive effects of staff care on employees' health and work-related attitudes. Moreover, results revealed that the effects of staff care on employees' engagement and job satisfaction were stronger, when the leader and employees were working on-site with direct face-to-face contact compared to the digital working condition.

Limitations: This study initially shows positive effects of staff care on employee health and work-related attitudes in a laboratory experiment. However, we cannot rule out deficits in the stability of the experimental conditions, as conversations between the leader and employees may have slightly differed from each other. Moreover, the limited time period might have been too short to uncover leadership effects which usually develop over weeks or months.

Conclusion: In line with previous research, the findings confirm that staff care has positive effects on employees' health and their work-related attitudes. Moreover, effects of staff care on employees may be stronger on-site with face-to-face contact than in the digital working context. Organizations should make leaders aware of their responsibilities for their own and their followers' health, and should invest in leadership trainings specifically for staff care in digital working environments. Moreover, it seems to be important for leaders to also maintain regular face-to-face contact, so that staff care can unfold its full effectiveness.

Relevance to the congress theme: This study is the first to compare the effectiveness of health-oriented leadership in the digital working context to more 'traditional' working contexts with regular face-to-face contact. Regarding the congress theme ' Changing the world of work ', the study thus contributes to a deeper understanding of situational contingencies of health-oriented leadership in digital working environments which are likely to remain in the future. The study has important implications for leadership effects on employee health and wellbeing during the proceeding digitization.

Relevant UN SDGs: Good health and wellbeing

Keywords: health-oriented leadership, working from home, well-being

Oral presentation OP620

What do we know about entrepreneurial potential?

Frej Sørensen & Ann-Louise Holten | University of Copenhagen

science

Research goals

The current economic crisis and ageing population raise questions of how the entrepreneurial development in Europe can be strengthened, for example through generational change and continued entrepreneurial development.

By coining the term entrepreneurial potential (Krueger & Brazeal, 1994), a new scientific field has recently manifested itself. The knowledge developed within this field, may further our understanding of the concept and processes of entrepreneurial potential and its potential for solving imminent societal challenges. With this purpose, we review the literature on entrepreneurial potential and develop a wider theoretical model of entrepreneurial potential.

Theoretical background

Focusing the review on literature on developmental-competence actualization of human potential, we apply the Aristotelian distinction between potentiality and actuality (Aristotle, 2017) as a guiding, theoretical framework for the review.

Methodology

As the purpose of the review was to identify and understand all the relevant research traditions and approaches to entrepreneurial potential and to synthesize this into an overall theoretical model, we applied a semi-systematic review methodology (Wong et al, 2013). The literature search was performed in Scopus and Web of Science, resulting in 356 (Scopus) and 303 hits (Web of Science) using the phrase search “entrepreneurial potential”, supported by backward snowballing (Jalali & Wohlin, 2012)

Results

The literature review reveals that this nascent field studying entrepreneurial potential is not yet clearly outlined and delimitated, neither in terms of theorization, construct definition, nor operationalization.

Theorization/ The main theoretical lenses applied in the emerging field are socialisation and/or personality theories. Using social learning theory (Bandura, 1977), social cognitive theory (Bandura, 1986), and theory of planned behavior (Ajzen, 1991), entrepreneurial potential is theorized to develop through role modelling, implicit learning, or other intangibles, often studied through a family business background (Chen et al, 1998; Wang et al, 2018; Hahn et al, 2021).

Construct/ Most publications do not define the phenomenon of entrepreneurial potential but frequently use proxy phenomena as indicators of entrepreneurial potential (Chen et al., 1998, Wang et al, 2018). Entrepreneurial potential is most commonly defined as a precursor for and preparedness to engage in entrepreneurial activities (Krueger & Brazeal, 1994; Santos et al, 2013; Veljkovic et al, 2019).

Operationalization/ Our review finds a great variety of operationalisations and approaches in the few available empirical studies (Chen et al, 1998; Hahn et al, 2021). Also the operationalisations

apply proxy-measurements, such as entrepreneurial intentions, risk-taking propensities, locus of control, personality traits, etc. Some studies seek to operationalize entrepreneurial potential as a fixed set of specific competencies (Raab et al, 2005; Santos et al, 2013), while others as more general characteristics (Krueger & Brazeal, 1994; Veljkovic et al, 2019)

Gender/ The review reveals important gender differences in the development, state, and actualization of entrepreneurial potential. Some empirical studies suggest that women need higher degrees of self-efficacy than men to engage in entrepreneurial acts (Wilson et al, 2007, 2009). Knowledge in gendered entrepreneurial potential is underrepresented.

With the purpose of synthesizing the available knowledge on entrepreneurial potential, we develop a theoretical model based on Aristoteles' broader conception of potentiality. The model will depict entrepreneurial potential as a teleological process, through which entrepreneurial potential develops (becoming/potentiality), is self-efficacious (state of being), and manifests itself (doing/actuality).

Limitations

The scope of the review is limited by the selection of search words and inclusion/exclusion criteria and is, as a semi-structured review, intended to explore and synthesize, rather than be exhaustive.

Conclusions

Mapping the literature review onto our theoretical model, we find that research is needed to offer a generally applicable definition of entrepreneurial potential, to develop and interrelate knowledge on both the potentiality and actuality, and to further the understanding of enabling and inhibiting conditions. Furthermore, specific knowledge on the development and application of female entrepreneurial potential is highly needed.

Relevance to Congress Theme

The paper is relevant to the congress theme, as it highlights important and emerging research on entrepreneurial potential. Entrepreneurial potential is not exclusively relevant for business start-up or take-over, but may also unfold and actualize in a wider world of work, which is defined by complexity and diversity.

Relevant UN SDGs

- Gender equality
- Decent work and economic growth
- Reduced inequalities

Keywords: entrepreneurial potential, entrepreneurship, literature review

Oral presentation OP132

What do Workers Want? Individual Differences in Reward Preference.

Liliana Pitacho, Instituto Politécnico de Setúbal - Escola Superior de Ciências Empresariais; Pedro Correira, Universidade de Coimbra - Faculdade de Direito; Patrícia da Palma, Universidade de Lisboa - Instituto Superior de Ciências Sociais e Políticas

science

Rewards have been considered vital elements of the relationship between organizations and collaborators, and they are central to the attraction, motivation, performance, and retention of key employees of the organization. However, extensive research has shown that this relationship between the reward system and the attitudes and behaviors of individuals in the work context is anything but linear and easy to predict. According to the theory of expectance, the rewards contain different instrumental values, and each individual can attribute the same reward to a different value. As such, the higher the value attributed to the given reward, the more significant effort the individual is willing to apply according to it. Therefore, the higher the value attributed by the individual to this reward, the more significant the impact of the same on their attitudes and behaviors in the work context. It is then essential to realize that characteristics lead individuals to value a specific type of reward more than others.

This investigation proposes that the preference for a given type of reward may vary depending on the psychological meaning that individuals attribute to work. For example, the work orientation construct conceptualizes different psychological meanings that individuals can attribute to professional activity. Simultaneously, it makes us know what each one seeks to draw from professional activity.The tripartite model of work orientation conceptualizes the existence of three orientations, job, career, and calling. Individuals with job orientation establish a transactional relationship with their work, only performing their tasks and waiting for their salary. Work is not an end but a means to achieve monetary rewards. Concerning career orientation, it is found that individuals work essentially motivated by career ascent but also by the ambition of recognition and status, both professional and social. Finally, individuals with a calling, almost as opposed to employment guidance, demonstrate an internal motivation for working exercise, which reflects a personal passion, and creates a predisposition to make sacrifices at various levels, including monetary and career.Given these differences, the present study proposes that work orientation may explain the different values attributed by individuals to rewards. As such, it can be crucial in explaining the inconsistencies in the relationship between reward systems and employee behavior. Thus, this study aims to verify whether people with different work orientations also value different rewards.

This study was based on the post-positivist paradigm and the hypothetical-deductive logic, using the quantitative methodology to assess the veracity of the hypotheses posed a priori. This study had 959 participants, 59.7% female, and 40.3% male, with a mean age of 40.65 years (SD=9.54).

Regarding results, participants generally valued, in order of preference, opportunities for development and progression, intrinsic rewards, fixed financial rewards, variable financial rewards, and status symbols. Additionally, reward preferences vary depending on the work orientation, except for the fixed financial rewards that are valued by all equally regardless of their work orientation. Workers with career orientation significantly value development and progression opportunities and status symbols more than other workers. Moreover, they value fixed and variable financial rewards more than workers with calling orientation. In turn, workers with a calling orientation significantly

value intrinsic rewards more than career workers. Finally, workers with job orientation are the ones who value the most fixed financial rewards. However, contrary to what is expected, this difference is not significant, and in addition, the rewards that value the most are the intrinsic rewards.

In conclusion, work orientation contributes, even modestly, to understanding individual differences in the appreciation of rewards. This study contributes both to the literature on work orientation and rewards literature. Regarding, then, its contribution to the literature on work orientation seems to us that this study reinforces the idea that this is a relevant variable for understanding the attitudes and behaviors of individuals in the work context. Nevertheless, as we were able to determine and save better analysis, it was a pioneering study relating work orientation directly with the rewards. In addition, it also contributes to the literature with a piece of knowledge about individuals' preferences about rewards.About organizational practice, these results point to the importance of increasing the spectrums of the diversity of rewards they should make available to their employees. Additionally, reinforce the relevance of organizations investing in total reward systems and preparing them for the worker's measure. For example, within a certain fixed amount of budget and rules, employees select their rewards.

Oral presentation OP459

What Does it Mean to be Entrepreneurial? Factor Structure of a Facet-level Framework for Entrepreneurial Personality

Zixuan Qi & Gorkan Ahmetoglu | University College London

science&practice

Theoretical background

Entrepreneurial individuals are imperative for economic growth. Grounded in the dispositional trait theory, Ahmetoglu and Chamorro-Premuzic (2017) postulated a succinct four-factor framework for conceptualizing and measuring individual differences in entrepreneurial personality traits. This theory asserts that people vary in their tendencies and abilities to engage in critical entrepreneurial activities such as opportunity identification and exploitation, innovation, and value creation (Ahmetoglu, 2015; Shane, 2000). Its operational measure (Measure of Entrepreneurial Tendencies and Abilities, META; Ahmetoglu et al., 2011) constitutes four enduring psychological and behavioural traits labelled as Opportunism, Proactivity, Vision, and Creativity. META has provided a new framework for conceptualizing entrepreneurial traits and measuring entrepreneurial personality that is not limited to entrepreneurs (Ahmetoglu & Chamorro-Premuzic, 2017). META has been empirically validated such that it has been demonstrated to predict a wide range of critical entrepreneurial output (e.g., patents registered) and various organizational performances including engagement and job performance (e.g., Ahmetoglu et al., 2019; Akhtar & Kang, 2016; Almeida et al., 2014; Leutner et al., 2014). Nevertheless, to better identify and support entrepreneurial individuals, this paper argues that it is imperative to examine the traits that subsume under (aka “facets”) the four factors of the META framework.

The four-factor META framework has several limitations. Personality traits occur in hierarchies (Eysenck, 1990); higher-order traits (aka “factors”) are located near the top of the hierarchy subsuming more specific traits called facets. We postulate that the existing four-factor META framework holds non-trivial deficiencies that calls for the need of facets. First, higher-order traits are broader, more general, and come with less fidelity (Cronbach & Gleser, 1957). In simple terms, broad traits are like the microscope lens that has low resolution but a broad field of view, whereas narrow traits have a smaller field of view but high-resolution. The narrow lens, in relation to entrepreneurial personality, would allow us to see specific behavioural, cognitive, or affective patterns of entrepreneurial individuals with more granular details. Second, relying solely on factors may gloss over potentially important variations within the same domain (e.g., Danner et al., 2020), which means loss of information that captures individual differences in entrepreneurial personality. Third, ample evidence supports that narrow traits such as facets have stronger theoretical and empirical relationships with the criteria (e.g., Anglim & Grant, 2014; Anglim & Grant, 2016). In organizational settings, for instance, META factors may not be able to pinpoint which specific trait is a more important factor regarding innovation performance, yet facets could do so while offering in-depth explanation regarding trait-performance relationships.

Research goals

The research aims to extend the four-factor META framework and address the above issues by providing a facet-level META framework. Derived from literature reviews, we propose a twelve-facet META framework. This paper empirically tests its dimensionality and factorial structure, as well as its nomological validity, criterion validity, and incremental validity over several commonly researched

personality traits in entrepreneurship (i.e., entrepreneurial alertness, grit, creativity, transformational leadership).

Method

We ran two survey studies (N = 1471) to validate the META-facet measure - a self-report inventory that uses a five-point Likert scale. Study 1 examined the factor structure using Exploratory and Confirmatory Factor Analysis; study 2 investigated the nomological, criterion, and incremental validity of META facets in relation to the four established personality traits. Responses were collected via Prolific (www.Prolific.co).

Results

We expect to complete the analyses by March 2023.

Limitations

Future research should incorporate experimental designs to compensate for the limitations of self-report data in this research.

Conclusions

This research enriches the entrepreneurship literature by focusing on specific traits in entrepreneurial competences. Organizations could benefit from this research to identify and develop entrepreneurial employees that could facilitate collaboration and improve organizations' competitiveness (Rauch et al., 2009). Entrepreneurs may benefit from improved understanding of their own entrepreneurial tendencies and develop their behaviors when engaging in entrepreneurial processes.

Relevance

This work is relevant to the 'decent work and economic growth' UNSDG and the congress theme. We aim to introduce an in-depth comprehensive personality framework to deliver desired changes for productive employment and new entrepreneurial ventures to promote economic growth.

Keywords: Entrepreneurial personality, narrow traits, psychometric assessment

Oral presentation OP273

What doesn't kill us makes us stronger? The use of active trust strategies by managers and employees during challenging timesmes

Lisa van der Werff, Sian Kelly, Lisa van der Werff & Yseult Freeney | Dublin City University

science&practice

Research goals & worth:

The aim of the present research is to extend current knowledge regarding how individuals within a manager-employee dyad actively support the development and maintenance of trust . Such insights make several worthy contributions to theory and practice, including but not limited to; offering an empirical understanding and framework of active trust strategies that can be employed across trust development and maintenance processes, and developing new theory regarding the use of active trust strategies in manager-employee trusting relationships during both routine and non routine times.

Theoretical background:

Seminal models of trust development depict trust to evolve over time as trustors make a judgement of trustees trustworthiness during repeated interactions (Lewicki & Bunker, 1996). Research has since disputed this passive process of trust development and points to the more intentional and agentic role individuals adopt to build trust (Möllering, 2006; Nikolova et al., 2015), however only a small body of literature has examined this idea and our understanding is curtailed. Another factor that has stalled our understanding of the intentional role individuals play in trusting relationships is the assumption that trust is maintained simply in the absence of violations (Williams & Belkin, 2016).

Notwithstanding these barriers to knowledge, some research accurately portrays trusting as an active process, akin to the concept of active trust, conceptualising trust as an ongoing accomplishment that requires continuous work by actors, even once established (Möllering, 2006, 2013). Existing research highlights certain behaviours that support active trust development (Child & Mollering, 2003; Hughes & Saunders, 2021; Six et al., 2010; Williams, 2007) and active trust maintenance (Gustafsson et al., 2020; Williams & Belkin, 2016). That said, there is a lack of continuity within this stream of literature as a consequence of varied foci in terms of both trust processes and referents. Thus current theory does not offer a clear conceptualisation of the intentional role individuals can adopt in trust processes.

Design:

This study adopts a qualitative method of inquiry (Van Maanen, 1998). Data is elicited from both parties in the trusting relationship via semi-structured, open-ended, in-depth, conversational interviews with 27 manager-employee dyads (54 interviews). To guide analysis, thematic analysis is applied as a methodological lens (Braun & Clarke, 2006).

Results:

Preliminary results support the proposition that individuals engage in active trust strategies to support the development of trust within manager-employee dyads. With regard to trust development, trustworthiness signalling, creating vulnerability, intentional supportive behaviour and identification are the recurring strategies employed in dyads that reported trusting relationships.

An interesting finding is that individuals employ different strategies to maintain trust depending on whether they are operating in routine or non routine times. In routine times, a continuation of the same behaviours seems to be important to maintain trust. Whereas when dyads face some form of non-routine, relational threat that threatens to destabilise their trusting relationship a divergence in strategies appears to be necessary to maintain trust. In such times, creating a shared understanding, negotiation and future focused problem solving , are the recurring strategies employed in dyads that report sustained trusting relationships.

Limitations:

The main limitation is the cross sectional nature of the research giving way to potential recall bias of participants. To address this, participants in relationships of various tenure were purposefully recruited (Lincoln & Guba, 1985).

Conclusions:

This research extends our empirical understanding of the concept of active trust and supports the development of new theory regarding the use of active trust strategies. Such empirical insight will also offer tangible outputs and will address a call for trust research to provide “practical, actionable insights for managers and organisations” (Dirks & de Jong, 2022, p. 23).

Relevance to the Congress Theme & UN SDGs:

At a macro level, the world we currently live in is an uncertain and, for many, a scary place . When we narrow our lens to consider the world of work, the same applies. Today's organisations are operating in complex landscapes, placing organisational actors in highly vulnerable positions. In such times, trust is more important than ever, particularly in relationships as crucial to organisational success as manager and employee. Although this research will focus at the micro interpersonal level, it will uncover strategies that are also applicable to the wider organisational and societal level. The findings will consequently support the UN goals of wellbeing, to which peoples' wellness at work plays an undeniably important role, and peace, justice and strong institutions.

Keywords: Trust, active trust strategies, manager-employee dyads

Oral presentation OP118

What happens to Health-oriented Leadership from leaders' and employees' perspective when working from home?

Katharina Schuebbe, Jörg Felfe & Dorothee Tautz | Helmut-Schmidt-University

science

The Covid-19 crisis provoked changes in the world of working. Both leaders and employees were forced to switch from office work to work from home (WFH). WFH has brought benefits, but also presents challenges to employees' health such as isolation or the expectation of constant availability. Previous studies have shown that leadership is an important resource for enhancing employees' health in the traditional office setting.

A leadership style that specifically focuses on employees' health is Health-oriented Leadership (HoL) (Franke et al., 2014). HoL encompasses (1) StaffCare (SC) describing the importance of employees' health for leaders (value), the perception of employees' warning signals (awareness), and leaders' active promotion of employees' health (behavior), (2) leaders' SelfCare, and (3) employees' SelfCare. Previous literature showed positive effects of SC on employees' health. However, it is unclear whether SC can be transferred to the digital work context and whether health-oriented leaders still are able to unfold their effectiveness on employees' health when not working on site and rarely meet the team in presence. Due to digital communication and the lack of direct contact, positive effects of SC might be limited. We assume that leaders less prioritize employees' health (value), as they might feel distanced by less contact. WFH might also challenge awareness through limited nonverbal communication via digital media, making it harder for leaders to recognize signs of overload. Moreover, leaders may also see fewer possibilities in their specific health-oriented behavior to influence working conditions at home, potentially leading to less action to promote employees' health.

As highlighted by Rudolph et al. (2020), less is known about contextual conditions of HoL. Following their framework model for healthy leadership, we investigated the feasibility and conditions for the feasibility and effectiveness of HoL in terms of SC when WFH from both leaders' and employees' perspective considering value , awareness , and behavior . We used a) quantitative data from a standardized survey with $n = 18$ employees and $n = 23$ leaders. Participants worked at least one day per week from home. To assess SC, we used items from the HoL instrument by Pundt and Felfe (2017). Employees were asked to rate their leaders' SC and leaders rated their own SC from a self-perspective. Both groups rated SC for the traditional work setting (office) and when WFH on a five-point likert scale from 1 (not at all) to 5 (completely true). Mean scores of the sub facets of SC were calculated and values for office and WFH were compared. Furthermore, we assessed b) qualitative data with semi-structured interviews in these both groups. After the general assessment of SC for office and WFH, they were asked to explain their ratings and elaborate on potential differences of SC when working in the office and when WFH. Interviews were analyzed and interpreted using qualitative content analysis after Mayring (2022).

Results of the quantitative data showed that SC was rated lower when WFH than for the office, both from leaders' and employees' perspective. Only in SC behavior no substantial differences were found from employees' perspective. Qualitative data showed that leaders feel less responsible (value) for employees' health due to limited control over their work environment, and instead ask for more individual initiative. Both leaders and employees experienced reduced communication and interaction during WFH, leading to less SC awareness . In addition, leaders find that digital

conversations are lacking in trust and prefer face-to-face interactions to detect early warning signals. From both perspectives, leaders display less health-promoting behavior when WFH compared to the office. Leaders feel limited in their ability to positively impact employees' health during WFH.

Our study provides several strengths and limitations. A strength is the use of a mixed methods approach and collection of quantitative and qualitative data to gain a comprehensive understanding of HoL SC when WFH. The interviewed leaders and employees did not work together in dyads, we therefore could not match the data. It would be interesting to compare the perceptions of leaders with the perceptions of their direct employees.

Our study contributes to the congress theme “The Future is Now: the changing world of work” and to the UN SDG “Good health and well-being”, as our research was novel in exploring specific challenges for leaders regarding the feasibility of HoL SC during WFH and understanding the underlying mechanisms. WFH immensely increased due to the Covid-19 crisis and is going to remain a part of the future world of work. Therefore, challenges for HoL as well as potential recommendations and practical implications for leaders and HR practitioners need to be addressed.

Oral presentation OP675

What I do not know does not exist. The challenge of digitalization for the inclusive employment of people with intellectual disability

Carolina Moliner, Leady V. Fajardo-Castro & Jose Ramos | IDOCAL.University of Valencia; Eva Lira, University of Zaragoza; Alexander Plavšić, IDOCAL.University of Valenencia

science

In recent decades, a change in focus began in the area of disability. It goes on to put the person first, instead of the disability. Disability is associated with the person but within a specific environment. This change indicates that interventions must be directed at the environment. From this perspective, it is understood that if a supportive environment is generated, social inclusion improves, given that if there is support in the environment, it is easier to participate in it. Based on the self-determination theory, it is reasonable to expect that supportive environments promoting self-determination will improve autonomy and well-being.

Although this was crucial progress, it was not enough to achieve the inclusion of people with intellectual disabilities (people with limited intellectual and adaptive functioning originating before the age of 18, Shalock et al, 2010). If there are supports that make it easier to do things even if you have an intellectual disability, but you don't have the opportunity to do it in “natural” environments, the objective of social inclusion is not fully achieved. Digitalization is a new challenge that can limit or facilitate the social inclusion of people with intellectual disabilities in regular workplaces (an important natural environment).

This paper analyzed the challenges of digitalization for the employment of people with intellectual disabilities in ordinary organizations. The types of work carried out by people with disabilities in ordinary organizations may be affected by digitization, so that tasks they carried out may be performed by artificial systems, given that they carry out low-skilled manual activities. The challenge is to achieve a technological transition that respects the inclusion of people with intellectual disabilities into the world of work. It is necessary to prevent a setback from occurring in social inclusion, preventing the creation of a digitalization process that separates people with intellectual disabilities from regular workplaces.

This work was based on the semi-structured interview methodology with triangulation of informants, which allows us to analyze the information by combining the perspectives of different types of participants. Three technology experts linked to the intellectual disability sector, three people with intellectual disabilities who were working in ordinary organizations and three team supervisors were interviewed. It was based on a script of questions that addresses the fundamental questions of analysis: tasks performed by people with ID in ordinary organizations, use of technologies, skills that this people will be required in the future in a context of change technology, technology opportunities, and supports for the worker with ID.

With the information obtained from the interviews, a content analysis was carried out (Burnard et al., 2008; Tuthill et al., 2020). For this, the transcription of the interviews was carried out. Subsequently, it was coded identifying the different swallowed aspects. From that base, another different researcher carried out an independent analysis having to reach an agreement with the initial one, resulting in a list of codes that integrate to arrive at a reduced list of manageable sub-categories. Finally, the final categories were discussed, making the adjustments and illustrating them with significant phrases from each category.

The results provided with information that allows the design of professional profiles for people with ID in which non-routine tasks and high social interaction that are difficult to automate are considered. It is also considered that technology can act as a facilitator. Finally, it will be important throughout the redesign process not to forget the objective of the autonomy of the person with an intellectual disability as a priority objective.

One of the most effective ways of achieving social inclusion for people with ID is through employment in ordinary organizations, but the difficulties remain. Due to its own characteristics, the work carried out by people with ID in ordinary organizations can be particularly affected by digitalization. The future of work, as well as its effects, will depend on the choices that we humans make. An important challenge is to achieve a technological transition that avoids the exclusion of people with intellectual disabilities. The present work supposes an advance in this sense from a socio-technical approach (e.g., Walker et al, 2008), contributing to the knowledge of the satisfactory and viable relationship between technology linked to digitalization and inclusive employment.

The theme of the congress is included in the objectives of this work. Dealing with digitalization represents an opportunity for people with intellectual disabilities. If we seek a society where the full social inclusion of this group is a reality, our look must change, and with it the strategies linked to their incorporation in natural environments.

Keywords: People with intelectual disabilities, Digitalization, inclusive employment

Oral presentation OP594

What inhibits successful job mobility? The hiring bias towards applicants with atypical work experience.

Xinhui Jing, Marijke Verbruggen | KU Leuven

science&practice

The Covid-19 pandemic has strengthened the need for cross-occupational job mobility. Due to the digital automation accelerated by this pandemic, it is estimated that up to 25 percent of the people worldwide will need to switch occupations by 2030 (McKinsey, 2021). In addition, the pandemic triggered people to reflect on their career, resulting in many people desiring an occupational change since the pandemic (The Brussels Times, 2021). However, realizing this wanted and much-needed increase in job mobility is highly challenging, since organizations tend to avoid hiring "atypical" profiles - such as job seekers who lack industry or occupational experience (Wechtler et al., 2021), although many organizations face an increase in vacancies and are struggling to find personnel (McKinsey, 2022). This continued focus among hiring professionals on the 'right' occupational and industry expertise is surprising since research has shown that pre-hire experience is of little value in predicting subsequent job performance (e.g., Van Iddekinge et al., 2019). Despite the necessity for organizations to (at least occasionally) hire people with atypical work experience, current academic efforts so far have failed to uncover why such hiring bias towards atypical candidates still occurs and when it is more likely to happen.

Research Aim and Theory

This research aims to address these questions by examining which inertial forces (Verbruggen & De Vos, 2020) underlie the hiring decision process among HR selection professionals and by exploring factors that could strengthen or weaken these inertial forces. To this end, we build on the inaction theory (Verbruggen & De Vos, 2020).

Methodology

This research consists of two steps. Firstly, we conducted 11 inductive interviews in Fall 2022 with hiring professionals in China and Belgium to explore their hiring decision process towards job applicants with atypical work experience. During the interviews, interviewees shared their own recruiting experience with atypical candidates and evaluated four manipulated resumes. Next, we intend to conduct experimental vignette studies in Winter 2022/2023 to examine the effects of inertial forces and the moderating factors drawn from the exploratory interviews on the hiring likelihood of atypical candidates. Vignette studies are a powerful tool for causal investigations of respondent judgements (Aguinis & Bradley, 2014).

Results

Based on the inductive interviews, we have identified several inertial forces that may inhibit employers from hiring candidates with atypical work experience. For instance, recruiters were often reluctant to hire strong atypical candidates out of fear due to uncertainty and risk (e.g., 'We will face enormous uncertainty on if she is capable of or adapted to taking such huge responsibility although I admit she is potential for this position. We will bear the loss and I have to take accountability if she makes mistakes or quits in the early stage…'). In addition, we also found some factors that could influence the strength of the inertial forces and, thereby, affect the likelihood of hiring atypical candidates – such as whether the new hire would work in a team or alone and how the relationship

was between hiring professionals and line managers (trusty partner/operational sourcer). Also the time perspective (i.e., focus on immediate fit versus focus on long-term potential) had an impact.

Limitation

One concern of experiments is the low external validity. We, therefore, plan to conduct a large-scale field study in Fall 2023.

Conclusions

By uncovering why hiring bias towards atypical candidates occurs and when it is more likely to happen, this research could extend our knowledge of personnel selection. Practically, understanding this bias better and designing interventions based on the factors that could lower the inertial forces among hiring professionals are of critical importance since more openness toward candidates with an atypical profile is considered as one of the key ways to address the increasing workforce shortage in organizations and the needed labor mobility in the society.

Relevance to the Congress Theme

Most organizations today focus on the short-term person-job fit with an overrated attention on applicants' skills and work experience, while the skills and experience that are useful for today's tasks may not be applicable for the jobs in the future. Thus, our research proposes a new perspective to understand the person-organization fit in the long-run, which could help employers establish a more sustainable personnel selection process to hire the potential ones for tomorrow – and help people achieve a smooth occupational transition.

Relevant UN SDGs

By helping increase the openness towards people with atypical work experience in the hiring practice, this project will benefit the problem of workforce shortage in organizations and the unemployment issue in the society, which could contribute to a sustainable economic growth.

Keywords: hiring bias, occupational transition, labor mobility

What is the meaning of paid work for the wellbeing of autistic adults? A focus group study comparing views between people with and without paid work

Evelien Brouwers & Jeroen Dewinter | Tilburg University; Sarah Detaille, HAN University of applied sciences; Jaap Van Weeghel & Michel Bergijk | Tilburg University

science&practice

What is the meaning of paid employment for the wellbeing of autistic adults? A focus group study on differences and similarities in views between autistic adults with and without paid employment.

Research goals and theoretical background

Worldwide, employment rates of people with autism are poor, which is problematic. In the prevailing medical model, the condition was seen as the primary reason for work disability, and consequently, the role of the work environment, strengths, talents and values of the (potential) worker were overlooked. In the current study, the meaning of competitive employment for wellbeing of autistic adults with and without paid work was evaluated. Research questions were: (1) What is the meaning/value of paid employment for autistic adults' wellbeing?; (2) What are differences and similarities between autistic adults with and without paid employment, in what having paid employment means for their wellbeing?

Methods

A total of 8 focus groups were conducted, including a total of 64 participants: 4 groups with and 4 groups without paid employment. All meetings were transcribed verbatim and analyzed separately for the groups with and without employment, using ATLAS.ti 9.

Results

In both the groups with and without employment, participants viewed having paid employment as highly important for their wellbeing, and the results showed more similarities than differences between the groups. Regarding the meaning of paid employment for wellbeing, three main themes were found from the data. The first theme was: Paid employment provides a variety of major benefits for wellbeing, with subthemes: 'purpose', 'social contacts', 'growth and use of talents', 'structure and calmness' and 'income and freedom'. The second theme was: Not having paid employment was associated with lacking societal recognition, and low self-esteem. This major theme was addressed in both groups but especially emerged from the group without paid employment and was not just the opposite of the first theme. Here, participants often reported to feel guilty, ashamed, socially excluded by society, and this was associated with feelings of low self-esteem and low self-worth, even if they had voluntary work. Moreover, participants receiving disability benefits talked about the 'benefits trap' they found themselves in, referring to being glad their current financial stress had been solved, but fear of losing those benefits also stood in the way of their wishes for future re-employment. The third theme was: (3) Work can seriously damage health and wellbeing . Both groups emphasized that work can be very damaging to health, and in both groups many participants had experienced burnouts. In the groups without employment, the severe health damage resulting from previous negative employment experiences sometimes was reported as a reason why participants did not envision themselves ever working again, although even then they often could still talk about the positive sides of employment and elaborate on what their ideal job would look like.

Limitations

The study is exploratory, for which reason no causal relationships can be established. Moreover, the study included participants in the two types of groups based on actual employment status, not taking into account factors like previous employment duration or employment success. Also, the study population was relatively highly educated.

Conclusions

In conclusion, the findings from both groups strongly highlight the importance of paid employment for the wellbeing of autistic adults. Not only did paid employment show many benefits for wellbeing, the absence of paid work made participants feel socially excluded, looked down upon by society and ashamed. However, most participants agreed that competitive work can be harmful to health and wellbeing. Future research should focus on how to improve employment success for autistic adults, how to lower their life and occupational stress levels and to prevent autistic burnout, and on how healthy jobs can be created where autistic adults get positive energy and increased wellbeing.

Relevance for congress theme and UN SDGs With current shortages in workers, it is essential workplaces become more inclusive. Many autistic adults want to have paid employment and have their individual talents, but work should not be harmful to their health. This study aligns with the UN SDG's 'No poverty', 'Good health and well-being', and 'Reduced inequalities'.

Keywords: autism, meaning of work, wellbeing

What makes coaching work? A longitudinal process study into the active ingredients of coaching

Lara Solms, University of Amsterdam & Erasmus Medical Center; Matthijs de Hoog, Erasmus Medical Center; Anne P.J. de Pagter, Erasmus Medical Center; Barbara Nevicka, University of Amsterdam; Jessie Koen, Netherlands Organization for Applied Scientific Research

science&practice

Research goals and why the work was worth doing

The aim of this study is to examine the psychological mechanisms underlying successful coaching. With growing attention to individual well-being and thriving in the past two decades, professional coaching has become a popular intervention at both the workplace and the private domain. While the benefits of professional coaching for both well-being and functioning have been demonstrated in various settings, little is known about how and under which circumstances these positive coaching outcomes are attained. Unraveling the factors that make coaching work will inform both theory and practice of coaching.

Theoretical background

Research on the effects of coaching supports its popularity: studies have repeatedly demonstrated the positive effects of coaching on both well-being and performance outcomes. Yet, little is known about the coaching process itself: 'what is actually happening in the session, what coach and client do in the coaching interaction', and the process factors that help or hinder successful coaching.

In this longitudinal study, we aim to investigate important process factors that facilitate positive coaching outcomes . Specifically, we are interested in the techniques and methods that coaches are using, that is specific coach behaviors, such as stimulating self-reflection, showing empathy, or promoting active coping behavior, that might facilitate positive client change (e.g., increased self-awareness, goal attainment, improved well-being). Additionally, we are taking into account 'classic' process factors of coaching, such as the working alliance, and trust between coach and client. In linking these process factors to coaching outcomes, this study can provide important input into the 'active ingredients' of coaching to both coaching researchers and practitioners.

Design/Methodology/Approach/Intervention

Participants in this study will be following a 10-month long coaching intervention that consists of 6 individual face-to-face coaching sessions with a professional coach. The coaching program is voluntary and offered to medical specialists and residents from several hospitals in the Netherlands. Based on the Job Demands – Resources Model, we assess job demands (e.g., workload), job resources (e.g., social support), and personal resources (i.e., psychological capital), as well as burnout and work engagement before the intervention (T1), shortly after the intervention (T3), and at 6-month follow-up (T4). Coaching behaviors will be assessed after coaching is finished (T3). Additionally, we measure process variables of coaching (e.g., working alliance) at both the client- and the coach-level halfway through coaching (i.e., T2; after the 3 rd coaching session).

Results obtained or expected

Given the hierarchical structure of our data (i.e., observations nested in clients (1), and clients nested within coaches (2), we will use a multilevel approach to analyze our data. We expect that positive coaching outcomes (at T3 and T4) will be impacted by specific coach behaviors (i.e., the

techniques/behaviors that the coach is showing during coaching). More so, we expect that positive coaching outcomes will be influenced by classic process factors, such as the quality of the working alliance between coach and client. The results of these analyses are expected in winter 2022.

Limitations

Our study will be limited by issues relating to missing data points and drop out. Another limitation is that we cannot capture the coaching process in all its complexity but that we need to resort to self-reports of clients and coaches to characterize the coaching process.

Conclusions - Research/Practical Implications

From a theoretical perspective, this study will provide insight into the 'active ingredients' of coaching, helping to provide a richer scientific foundation to the practice of coaching. Second, understanding the coaching process – how it unfolds over time in presence or absence of relevant process factors – can inform coaching practitioners about their own share in generating coaching success, and how to intervene in their coaching practice.

Relevance to the Congress Theme

This study can provide evidence about understudied coach- and client process factors that play a key role in successful coaching. It will also shed light on the relevance of process factors that have been argued to be decisive for coaching success (e.g., the working alliance), yet have rarely been empirically examined. With coaching being a popular change methodology at the workplace across professions, this study helps to uncover how successful coaching can be promoted, and as such, how people can best be supported in ‘the changing world of work’.

Relevant UN SDGs

Coaching is used to promote employee well-being, personal growth, and development. As such, this research is clearly linked to the UN SDG of 'good health and wellbeing'.

Keywords: coaching; professional development; self-development

What makes nurses flourish at work? Intrinsic motivation in the Job Demands-Resource model

Dorothea Kohnen, Research Group Work, Organizational, and Psychology, KU Leuven, Leuven, Belgium; Walter Sermeus, KU Leuven Institute for Healthcare Policy, KU Leuven, Leuven, Belgium; Luk Bruyneel, KU Leuven Institute for Healthcare Policy, KU Leuven, Leuven, Belgium; Hans De Witte, Research Group Work, Organizational, and Psychology, KU Leuven, Leuven, Belgium; Wilmar Schaufeli, Research Group Work, Organizational, and Psychology, KU Leuven, Leuven, Belgium

science&practice

Research goals and why the work was worth doing

This study was designed to deepen our understanding of the boundary conditions and underlying processes by which characteristics present in the clinical environment influence nurses' well-being.

Theoretical background

A large body of evidence supports the stress as well as motivational process as postulated in the JD-R model, however, the processes underlying the stressor-resource-strain relationship remain rather understudied. It has been argued that not all employees perceive job demands and resources in the same way and that this is mainly influenced by their personal resources (Sonnentag & Frese, 2012). In the present study we posit that intrinsic motivation functions as personal resource as it is believed to influence the way in which employees allocate and balance their resources (Kanfer et al., 2017). Drawing on the postulates of SDT (Ryan & Deci, 2000), the aim was to investigate the mediating role of intrinsic motivation in the JD-R model (Demerouti et al., 2001). To validate and extent existing research on the JD-R and earlier job stress models such as Karasek's JDC model (Karasek, 1979), we further examined if job resources moderate the relationship of job demands with a) intrinsic motivation (activation hypothesis) and b) burnout (strain hypothesis).

Methodology

This study used a cross-sectional data set of direct care nurses (n=1729) from general acute care hospitals (n = 14) in Belgium. The data collection took place by means of online questionnaires between October 2020 and July 2021. The level of data collection, theory and statistical analysis is at the individual level. In a first step, CFA was conducted. Second, mediation and moderation analyses by means of SEM were computed, using Mplus software. Job characteristics included a set of different job demands and job resources (Dallner et al., 2000; Van Veldhoven et al., 2002). Intrinsic motivation was measured with the Work Extrinsic and Intrinsic Motivation Scale (WEIMS, 3-items; Tremblay et al., 2009). Work engagement was assessed using the 3-item version of the Utrecht Work Engagement Scale (UWES, Schaufeli et al., 2019). To measure burnout, a short version (12-items) of the Burnout Assessment Tool (BAT), a novel self-report questionnaire, was used (Schaufeli et al., 2020).

Preliminary Results

Job resources appeared to be a crucial factor for nurses' health as they influence their work motivation (β = .513), engagement (β = .462) but also their feelings of burnout (β = -.216). Job demands remained an essential factor that harms psychological health, increasing burnout (β = .489). Our results confirmed that job resources – via intrinsic motivation – led to increased work engagement (β = .170) and decreased burnout (β = -.135). In addition, job resources moderated the relationship of job demands with burnout (β = -.039). In line with the strain hypothesis, low job

resources exacerbated the adverse impact of high demands on burnout. Against our expectations, we found no associations between job demands and intrinsic motivation nor a moderation effect of job resources on the respective relationship (activation hypothesis).

Limitations

First, due to its cross-sectional nature of our research, we are unable to determine any causal connections between the measures included in the study. Second, by focusing on registered nurses working in general acute care hospitals in Belgium, we put a narrow focus on culture and professional field in our study. This represents a limitation on the generalization of our findings. Third, concepts measured in this study were obtained through self-reports. As such, the strength of the effects reported here may have been biased due to common-method variance.

Implications

The clinical environment can be a source of significant stress which may put nurses' health at severe risk. On the other hand, it can also be a place where they experience joy, pleasure and fulfilment, promoting their motivation and engagement. Specifically, our findings indicate that nurses who perceive sufficient job resources such as feedback, autonomy and opportunities for growth and development, are likely to feel intrinsically motivated at work which seem to be beneficial in two ways: first, it will foster their work engagement and second, it will prevent them from burning out.

Originality/Value

The study contributes to research on nurses' well-being by uncovering the processes of how work motivation acts on employee functioning and the role it plays in both the motivational and energetic processes of the JD-R. Another originality of this study lies in its focus on both, the strain and activation hypothesis (as postulated by earlier stress models) in relation to burnout and work motivation.

Relevance to the Congress Theme

In order to sustain a healthy workforce and to meet challenging demands also in the future, hospitals need to create work conditions that promote workers' work motivation and well-being while preventing burnout.

What matters more for daily well- and ill-being? The dual pathways of daily need satisfaction and frustration

Leoni van der Vaart, Optentia Research Unit, North-West University, South Africa; Bert Schreurs, Faculty of Social Sciences and Solvay Business School, Vrije Universiteit Brussel, Belgium; Sebastiaan Rothmann, Optentia Research Unit, North-West University, South Africa

science

Research goals, value add, and theoretical background

The self-determination theory denotes that employees' basic psychological needs should be fulfilled for employees to experience optimal growth and functioning. However, these needs may also be thwarted, often resulting in less favourable outcomes such as ill-being. Positive effects result from the 'bright pathway' initiated by need satisfaction, whereas adverse outcomes result from the 'dark pathway' initiated by need frustration. The former pathway includes need satisfaction being associated with more optimal forms of motivation (and consequently optimal functioning), whereas the latter pathway includes need frustration being associated with less optimal forms of motivation. The needs are also context-responsive; therefore, it can be argued that they (and their mechanisms and outcomes) vary daily. Although need satisfaction has been widely researched, need frustration has been less explored.

Furthermore, these pathways (or mechanisms) are more often investigated on the between-person level rather than on the within-person level. These shortcomings are unfortunate as it leaves several questions unanswered. Does need satisfaction lead to positive outcomes but not to adverse outcomes? Is the opposite then true for need frustration? Or are both need satisfaction and frustration related to positive and negative outcomes but differ in strength? To answer these questions, this study aimed to understand the dual pathways (to well- and ill-being) of daily need satisfaction and frustration through the different motivational regulations. We also aimed to compare the strength of the indirect effects; that is if daily need satisfaction relates more strongly to positive outcomes than need frustration and if need frustration is more strongly associated with adverse outcomes.

Design/Methodology

An intensive longitudinal quantitative research design with a multilevel approach was used. Employees in small and medium enterprises were asked to complete daily surveys for ten working days (N = 68 / n = 557). Data were analysed using multilevel structural equation modelling.

Results

The results revealed that both daily need satisfaction and frustration had an indirect influence on work engagement and exhaustion via intrinsic motivation. At the same time, the other motivational regulations did not play a mediating role. However, daily need satisfaction's indirect effect on work engagement was more substantial than need frustration. Similarly, daily need frustration's path to exhaustion via intrinsic motivation was more substantial than need satisfaction.

Limitations

First, the study's design did not allow for causal inferences to be drawn, as there was no temporal separation of the variables. Second, the study relied on self-report measures, which may raise

questions about measurement bias. Last, daily basic psychological need satisfaction and frustration were aggregated to reduce the number of items participants had to respond to.

Conclusion

These findings suggest that daily need satisfaction and frustration relate differently to the same outcomes, but that need satisfaction plays a more significant role in enhancing positive outcomes, whereas need frustration plays a more substantial role in improving adverse outcomes. The implications of this are that management can benefit from actively making efforts to support employees' daily needs and reduce their daily need frustration. Theoretically, it is important that researchers include both need satisfaction and frustration to account for the dual pathways to employee outcomes. It is also important to investigate the relationships on a within-person level as results differ from those on the between-person.

Relevance for the congress

Employee motivation and well-being, especially in under-resourced small business, remains a relevant topic in the changing world of work and in recovering economies.

Keywords: motivation, diary study, self-determination theory

Oral presentation OP447

What psychological mechanisms can explain the link between episodic interpersonal conflict at work and diurnal cortisol patterns? A diary study

Valentina Sommovigo, Guido Alessandri, Valentina Rosa & Lorenzo Filosa | Sapienza, University of Rome, Department of Psychology

science&practice

Research goals. Research has disregarded how episodes of conflict at work alter daily temporal fluctuations of physiological strain states. Shedding light into how employees physiologically react to daily social stressors is nonetheless vital to formulate measures that prevent employees' psycho-physical malaise in response to common daily stressors. This study examines how within-person episodic changes in response to interpersonal conflicts can affect daily patterns of negative affect and then daily diurnal cortisol patterns, namely biological indicators of strain states. Precisely, this study investigates how interpersonal conflict at work may impact three indices of cortisol: cortisol awakening responses (CAR; the rise in cortisol shortly after awakening, which is optimal when moderate), overall cortisol output (AUC; total cortisol produced across the day, which is optimal when low or moderate) and diurnal cortisol slopes (DCS; the decline in cortisol across the day, which is optimal when low and steep).

Theoretical background. Cortisol follows a diurnal rhythm, with a healthy diurnal rhythm that peaks within an hour of awakening and slowly decreases across the day. Literature shows that acute social stressors impact the diurnal cortisol rhythm, and lead to flattened cortisol slopes (Shrout et al., 2022), greater AUC (Zeiders et al., 2018), and altered CAR (Armstrong-Carter et al., 2021). By altering the cortisol cycle, conflict-related stress may compromise immune function, ultimately raising morbidity risks (Adam et al., 2017). Most studies linking cortisol parameters to conflict occurrence have been conducted in romantic couples, clinical or adolescent samples, and laboratory settings. Instead, the few studies on strain reactions using real-life stressor events have focused on work-family conflict, showing that workers have greater dysregulation in their DCS on days when they experience high work-family conflict (Almeida et al., 2016), or react differently to conflict, especially in terms of affective response (French & Allen, 2019). However, these studies did not consider naturally occurring conflicts, such as daily conflict at work. This suggests the importance of using "in vivo" methodologies for investigating the psychobiological correlates of real work conflicts. In this regard, prior diary studies on negative emotions suggest a link between the experience of a conflict at work and a subsequent rise in workers' negative emotions. Thus, one may wonder if it is the mere conflict occurrence to compromise the workers' cortisol cycle, or if the subsequent lasting and momentary alterations in resulting negative emotions play any relevant roles.

Design. Intensive longitudinal data were collected on 162 workers during two consecutive workdays. Research participants provided momentary reports on interpersonal conflict at work and negative affect, ten times a day for two days, and saliva samples five times a day.

Results . The results of latent growth curve piecewise multilevel models revealed associations between episodic interpersonal conflict at work, negative affect, and diurnal cortisol patterns. The simple occurrence of a conflict at work introduced significant variations in cortisol indices except for CAR. Indices of negative emotion dynamics predicted DCS and AUCg, controlling for conflict occurrence and other relevant covariates.

Limitations. Unmeasured moderating variables might intervene in the analysed link.

Conclusions. By integrating a daily diary design with multiple objective measures of strain, this study answers the call for investigating more short-term effects of social stressors and overcomes methodological issues related to self-report. In doing so, this study moves a step forward in the stress and conflict literature, as it is the first to identify day-to-day within-person fluctuations in negative affect as dynamic psychological mechanisms connecting episodic interpersonal conflict at work and daily cortisol patterns. Thus, this research clarifies "what happens" as conflict episodes unfold in real-time and real-life work settings. Thus, our findings suggest that companies could provide their staff with training on effective conflict management skills, and emotion regulation strategies. Companies could also consider introducing conflict resolution measures and psychological support services to support staff.

Relevance to the Congress Theme. This study extends the well-being topic by establishing a firm link between episodic interpersonal conflict at work and daily patterns of AUC and disclosing the psychological mechanisms through which this occurs.

Relevant UN SDGs . Good health and well-being.

Audience. Both practitioners and academics

Keywords: interpersonal conflict, negative emotions, cortisol

What the press reveals about the unemployed : a lexicometric analysis of 12 996 articles from the French written newspapers from 2005 to 2022

Charly Marie & David Bourguignon | Université de Lorraine (Metz, France)

science

Why the work was worth doing : Unemployed people are perceived in a very negative way (Norlander et al., 2020; Seghouat et al., 2021). This harmful stereotype and the associated stigma has four main consequences for the unemployed, who:

Are discriminated against in access to employment (Kroft et al., 2013), depending on the length of time spent unemployed (Ghayad, 2013) ;

Exhibit poorer social inclusion, self-esteem and psychological well-being (Bourguignon et al., 2022; Brand, 2015; Wanberg, 2012) ;

Experience a deterioration of their physical and mental health, in part due to the effects of stigmatization (Andler et al., 2020; McKee-Ryan et al., 2005; Paul & Moser, 2009) ;

Do not take-up their unemployment insurance for 1 in every 3 eligible people in France (Hentzgen et al., 2022);

Research goals : Considering these effects, it is therefore crucial to better understand the origin and the nature of the stereotypes about the unemployed . We investigate their coverage in the French press by analyzing 12 929 articles published from 2005 to 2022.

Theoretical background : Three major ways of analysing media production are agenda-setting and news framing (Scheufele & Tewksbury, 2007).

Agenda-setting refers to the capacity of newspapers, newsrooms, political parties or public figures to determine which topic is newsworthy;

Framing, or the way a piece of information is presented, has consequences for the understanding of that information and then for the behaviours that result from it;

Priming states that it is easier for a person to process a target-word if it is presented after a related prime. For this study, the used words in a news article can be thought of as cognitive associations between targets and primers;

Methodology : We use the "Reinert" unsupervised exploratory lexicometric method, which enables themes or frames to emerge from the data by statistically studying the co-occurrences of full words in a text (Ratinaud, 2014, 2018; Reinert, 1990). The analysis is based on a series of bi-partitions using a top-down hierarchical classification and uncovers classes that are the most specific in terms of their vocabulary, yet the most distinct from each other. Each class groups together associated text segments, reflecting the framings that structure our corpus (see Masciantonio et al., 2021; Ratinaud, 2018; and Schonhardt-Bailey, 2005, for an in-depth description of the method).

Results : The first of our findings concerns the lack of visibility of the unemployed in the media treatment, representing 0.027% of the published articles over the studied period (compared to 1.78% for football).

Then, our work classifies 97.36% of our data into 6 frames :

The administrative and economic accounting of unemployment and the unemployed (18.8%) ;

Political visions and treatments of unemployment and the unemployed, debates on ideas and policies to be pursued (17.6 %) ;

The implementation of these political visions through legislation and decrees (17.9 %);

Territorial and associative support for the unemployed, territorial application of policies (23.6%) ;

Being unemployed: living, talking about and suffering from the experience of unemployment (15.5%) ;

Collective actions, associations and demonstrations by the unemployed (6.7%) ;

The newspapers coverage of the unemployed reflects their very low visibility, from which they are largely absent. The unemployed are hardly ever put on the agenda, if not mostly as a statistical and political issue rather than as people and experiences. This low visibility of their feelings, stories and visions could reflect a lack of empathy that is typical of people whose stigma is considered controllable (Decety et al., 2010; Weiner et al., 1988).

This invisibility can "be coupled, for the individual and collective actors who are victims of it, with a feeling of social inexistence, of contempt and negation of their very existence (Voirol, 2005, p. 117).

Limitations : The first limitation is our method, as other methods could nuance and complete our work. The second limitation is that we had to start our analysis on the 26th of October 2005, which left out several previous years of the newspapers coverage of the unemployed.

Conclusions and implications : To conclude, the unemployed carry a highly toxic social identity, with numerous consequences for their social and professional integration, psychological well-being and physical and mental health. A better understanding of the stereotype of the unemployed and its spread in the media allows for a better understanding of the channels through which the unemployed are exposed to this stereotype.

Relevance to the Congress Theme : The view of the unemployed, and its toxic and deleterious consequences, leads to a set of highly negative consequences for them and for society at large. This stigma needs to change in order to build a more inclusive future for the 13 million unemployed in the European Union (EuroStat, 2022).

Keywords: Stereotypes, Stigma, Political communication

Oral presentation OP255

What Works When You Work From Home: The Preferences of Employees On Working from Home

Alexandra Kirienko, London School of Economics and Political Science; Marie Briguglio, University of Malta

science&practice

Research goals

The research examines to what extent the conditions of the work-from-home set up of the employee affect her preferences around working from home (WFH). Additionally the self-reported quality of work when working from home was examined. The factors taken into account include having a dedicated desk, work chair, high speed internet, private space for work, as well as demographic factors including gender and presence of children under the age of 18 in the household. The research provides an increased understanding on ways to optimise hybrid working schedules to cater to both the employee preference as well as maximise the quality of work produced. The results point at ways that organisations can reassess their approach to supporting employees in hybrid work.

Theoretical background

The restrictions associated with the Covid-19 pandemic have contributed to the creation of the idea of a “new normal” way of working (Bonacini et al., 2021). As restrictions lifted, companies began to consider the impact on WFH on their businesses (Fayard et al., 2021). Organisations are now increasing their plans for remote hiring going forward (Ozimek, 2020).

Several studies point to the relationship between office-like workstations at home and productivity (Karakolis & Callaghan, 2014; David et al., 2020). An important aspect of working from home is internet connection, as for many working remotely involves being in regular communication with their team and using internet as part of the job (Anandarajan et al., 2000).

The presence of children at home is a significant factor that influences the life-work balance of the employee (European Foundation for the Improvement of Living and Working Conditions, 2012). The findings by Powell and Craig (2015) indicate that women are more likely to work from home on a given day than men, and that the time fragmentation and scheduling also differ significantly by gender.

Data

The data which lies at the foundation of the analysis has been collected by the Malta Business Bureau. It relates to the period of time when the first round of coronavirus restrictions in Malta has been lifted. The survey asked employees to reflect on working from home during this time across a range of topics. The raw dataset has the survey results for 347 respondents who include employees and business owners in Malta.

Research Methodology:

Linear and ordinal logistic regressions are run, withthe number of WFH hours the employee would like to have relative to their current number of WFH hours and self-reported quality of work as dependent variables respectively.

Results

The results were surprising in that the majority of WFH set up factors including high-speed internet, dedicated desk and chair were not significant in the regressions. However, demographic variables such as gender and the presence of children under the age of 18 in the household were highly significant (to 1%) in both the linear and ordinal logistic regressions. The interaction variable created for employees of different genders and different number of children at home also showed informative coefficient values: the direction of the coefficient changes based on whether the employee identified as male or female, and the size of the coefficient changes to reflect the different number of children present in the household.

The study contrinbutes to the Future of Work literature and can provide new avenues of thinking to organisations looking to implement hybrid working models on aspects of working from home that are of particular importance to employees.

Limitations

The main limitation of the study is the Malta-based dataset which might have limited external validity depending on other geographies in question. The size of the dataset also does not allow to capture convincingly large subsets for each of the interaction variable values.

Conclusions

The results of the analysis are novel and informative both within academia and industry. The impact of factors on employees' preferences around WFH are to date underresearched making the insights from the research highly valuable. It is highly advisable that practitioners take into accounts the findings of this study as they make decisions around hybrid working arrangements. In particular, the limited role of factors such as providing workstation hardware can lead to cost savings for organisations. The difference in preferences between men and women in the organisations should be emphasised, with additional childcare facilities provision one of the suggestions the authors would like to put forward.

Relevance to the Congress Theme

The world of work is changing, and we believe that our research brings insights to the new emerging ways of working, hybrid working and WFH in particular.

Relevant UN SDGs

The two main sustainable developments goals addressed by this research are Good Health and Wellbeing, and Gender Equality.

Keywords: hybrid working, work from home, gender

Oral presentation OP742

When and why employees who experience family-to-work conflict are ostracized at work?

Paulina Idziak & Małgorzata Gamian-Wilk | SWPS University of Social Sciences and Humanity; Cong Liu, Department of Psychology, Hofstra University; Amanda Staniszewska-Celer, SWPS University of Social Sciences and Humanity

science

Research goals: The present series of studies examines the relationship between family-supportive supervision and family-to-work conflict as potential sources of workplace ostracism. The purpose of the present research was to identify reasons of ostracising co-workers who experienced family-to-work conflicts.

Theoretical background: Workplace ostracism, that is a failure to engage another when it is socially appropriate to do so (Robinson et al., 2013), is a damaging process connected with severe individual and organizational costs (Gamian-Wilk & Madeja-Bien, 2019; Howard et al., 2020; Liu & Ma, 2021 for review). One of the streams of research on workplace ostracism concentrates on workplace ostracism antecedents (environmental factors, e.g., Ferris et al., 2016; Howard et al., 2020). The present research focuses on lack of family-supportive supervision (FSS, the perception of the degree to which employees consider their supervisors as supportive of their family role demands, Kossek et al., 2007; 2011) and experiencing family-to-work conflict as potential ostracism antecedents. Our previous findings indicated that the lack of family-supportive supervision occurred not to be linked with being excluded or rejected six or twelve weeks later. Additionally, the family-to-work conflict mediated the relationship between the lack of family-supportive supervision and workplace ostracism (Gamian-Wilk et al., 2022). In the present research we examined possible reasons why employees who experience family-to-work conflict are ostracised at work. We considered negative perceptions as mediators in the relationship between the lack of family supportive supervision, experiencing family-to-work conflict and being ostracised. Co-workers may attribute procrastination and laziness to employees suffering from family duties overload and strains.

Methodology: A series of three experimental studies (N1=295, N2=232, N3=420) in a 2 (a scenario of a target having vs not having FSS at work) × 2 (a target experiencing vs not experiencing family-to-work conflict) between subject design, with the tendency to ostracise a target as a dependent variable was conducted among employees in an on-line survey. In the second and third studies target's perceived conscientiousness and tendency to procrastinate as mediators were also measured. In the third study we also manipulated the target's gender in the scenario.

Results: The results indicate a strong main effect of target's experiencing family-to-work conflict on excluding the target. Surprisingly, the tendency to ostracise the target was stronger when the FSS was high. Moreover, perceived target's procrastination and low conscientiousness mediated the relation between target presented as experiencing family-to-work conflict and ostracizing them.

Limitations: The manipulation used in the studies are based on hypothetical scenarios. Future studies should include employees responses to co-workers experiencing family-to-work conflicts in the workplace setting. The lack of multi-source data (coming from both ostracised and ostracising employees) call for caution in interpreting the results.

Conclusions: The findings of the present studies propose an explanation why employees who perceive their co-workers as experiencing family-to-work conflicts ostracise them. Our research extend literature on the integrative model of the work-family interface and on workplace ostracism.

Identifying negative perceptions as mechanism leading to excluding certain groups of employees suffering from family strains invites for preparing specified interventions focused on increasing family supportive supervision.

Relevance to the Congress Theme: Our topic is relevant to theme No4: Diversity and Inclusion and theme No14: Stress and Disfunctions

Relevant UN SDGs: Our research concentrates on such UN Sustainable Development Goals as Good health and wellbeing at workplace and Reduced inequalities at workplace.

Keywords: workplace ostracism, family-to-work conflict, family supportive supervision

Oral presentation OP742

When and why employees who experience family-to-work conflict are ostracized at work?

Paulina Idziak, SWPS University of Social Sciences and Humanities; Cong Liu, Hofstra University; Amanda Staniszewska, Konrad Smolak, Małgorzata Gamian-Wilk | SWPS University of Social Sciences and Humanities

science

1. Research goals and why the work was worth doing: The present series of studiesexamines the relationship between family-supportive supervision and family-to-workconflict as potential sources of workplace ostracism. The purpose of the present researchwas to identify reasons of ostracising co-workers who experienced family-to-workconflicts.

2. Theoretical background: Workplace ostracism, that is a failure to engage another whenit is socially appropriate to do so (Robinson et al., 2013), is a damaging processconnected with severe individual and organizational costs (Gamian-Wilk & Madeja-Bien,2019; Howard et al., 2020; Liu & Ma, 2021 for review). One of the streams of researchon workplace ostracism concentrates on workplace ostracism antecedents (environmentalfactors, e.g., Ferris et al., 2016; Howard et al., 2020). The present research focuses onlack of family-supportive supervision (FSS, the perception of the degree to whichemployees consider their supervisors as supportive of their family role demands, Kosseket al., 2007; 2011) and experiencing family-to-work conflict as potential ostracismantecedents. Our previous findings indicated that the lack of family-supportivesupervision occurred not to be linked with being excluded or rejected six or twelve weekslater. Additionally, the family-to-work conflict mediated the relationship between thelack of family-supportive supervision and workplace ostracism (Gamian-Wilk et al.,2022). In the present research we examined possible reasons why employees whoexperience family-to-work conflict are ostracised at work. We considered negativeperceptions as mediators in the relationship between the lack of family supportivesupervision, experiencing family-to-work conflict and being ostracised. Co-workers mayattribute procrastination and laziness to employees suffering from family duties overloadand strains.

3. Design/Methodology/Approach/Intervention: A series of three experimental studies(N1=295, N2=232, N3=420) in a 2 (a scenario of a target having vs not having FSS atwork) × 2 (a target experiencing vs not experiencing family-to-work conflict) betweensubject design, with the tendency to ostracise a target as a dependent variable wasconducted among employees in an on-line survey. In the second and third studies target'sperceived conscientiousness and tendency to procrastinate as mediators were alsomeasured. In the third study we also manipulated the target's gender in the scenario.

4. Results: The results indicate a strong main effect of target's experiencing family-to-workconflict on excluding the target. Surprisingly, the tendency to ostracise the target wasstronger when the FSS was high. Moreover, perceived target's procrastination and lowconscientiousness mediated the relation between target presented as experiencing family-to-work conflict and ostracizing them.

5. Limitations: The manipulation used in the studies are based on hypothetical scenarios.Future studies should include employees responses to co-workers experiencing family-to-work conflicts in the workplace setting. The lack of multi-source data (coming from bothostracised and ostracising employees) call for caution in interpreting the results.

6. Conclusions – research and or practical implications/Originality/Value: The findingsof the present studies propose an explanation why employees who perceive their co-workers as experiencing family-to-work conflicts ostracise them. Our research extendliterature on the integrative model of the work-family interface and on workplaceostracism. Identifying negative perceptions as mechanism leading to excluding certaingroups of employees suffering from family strains invites for preparing specifiedinterventions focused on increasing family supportive supervision.

7. Relevance to the Congress Theme: Our topic is relevant to theme No4: Diversity andInclusion and theme No14: Stress and Disfunctions

8. Relevant UN SDGs : Our research concentrates on such UN Sustainable DevelopmentGoals as Good health and wellbeing at workplace and Reduced inequalities at workplace.

Keywords: workplace ostracism, family to work conflict, work-life balance

Oral presentation OP460

When do challenging demands unfold their performance-enhancing potential? A daily diary study using objectively-measured information processing speed

Johanna Perzl, Joachim Thomas & Elisabeth Maria Riedl | Catholic University of Eichstätt-Ingolstadt

science

Research Goals: According to the Challenge-Hindrance Framework, challenging job demands can have resource-depleting as well as stimulating and motivating effects on job performance. As former research was either relying on self-reported outcomes or conducted in the laboratory, little is known about the performance-enhancing potential of challenging job stressors on job performance in occupational realities. Therefore, in this study, we shed light on the stimulating effect of the challenging job demand workload on objectively measured performance (i.e., information processing speed) across the workday. In particular, we investigated under which circumstances the performance-enhancing potential of challenging job demands becomes evident. Theoretical Background: According to the Challenge-Hindrance Framework, workload is a typical challenge stressor that has resource-depleting and stimulating features. Based on this assumption, we hypothesised that high workload in the morning would have positive stimulating effects on information processing speed before the lunch break. As job demands are interrupted during the break, the length of the break is important for post break information processing. We assumed that only on days with a break duration shorter than usual, morning workload would still have a stimulating effect on the information processing speed after the lunch break. Longer lunch breaks, however, provide greater opportunities to restore resources as supposed by the Effort Recovery Model. As increased effort can only be shown if a sufficient amount of resources is available, we hypothesised that information processing speed at the end of the workday would only be stimulated by afternoon workload on days with an above-average lunch break duration. Methodology: To test these hypotheses, service providers (N = 64) answered smartphone questionnaires repeatedly over two weeks. The questionnaires were presented three times a day at the workplace: before and after the lunch break as well as at the end of the workday, providing a total of 1244 valid measurements. Information processing speed was measured with a smartphone-based 90-second digit symbol modalities test that was included in the questionnaire. Results: Multilevel models revealed that workload in the morning correlated positively with information processing speed before the lunch break. There was no significant main effect of morning workload on information processing speed after the lunch break which was also not significantly moderated by the break duration. In line with our hypotheses, post break workload was only positively associated with information processing speed at the end of the workday on days with an expanded lunch break duration. Conclusion: One possible conclusion is that high workload can have a positive stimulating effect on cognitive performance if sufficient resources are available. Thus, lunch breaks seem to play a crucial role: Even though they may temporarily interrupt the stimulating effect of challenging demands as supposed by the Challenge-Hindrance Framework, they still may ensure the resources necessary to invest in more efficient information processing in the long term as assumed by the Effort Recovery Model. For this reason, lunch breaks can be seen as a key resource to sustainably ensure afternoon performance - especially on days with a high workload. Strengths and Limitations: A particular strength of the study is the repeated assessment of objective performance in a real-life occupational setting outside the laboratory. However, it was not examined to what extent increased information processing speed manifests itself in job-specific performance. Furthermore, individual challenge and hindrance appraisals have not been taken into consideration. Nevertheless, these results provide new insights into the stimulating effects of momentary workload and lunch break recovery on cognitive

performance in the occupational context that should be further investigated. Relevance to the Congress Theme: The use of smartphone-based objective measurements in the workplace shows that psychological research is moving with the times, deriving benefits from new technologies and not being left behind by other disciplines. Furthermore, information processing can be seen as a key feature in the changing world of work, especially with regard to modern knowledge work, as it is a fundamental premise for the performance of employees in many occupational fields. Relevant UN SDGs: The present study provides insights into the role of lunch breaks for the effect of challenging demands on individual strain. Such occupational research findings are the first step towards lunch breaks organized in a way that enables employees to make efficient and sustainable use of their individual capacities during work, without overburdening their available resources, to ensure employee health and well-being.

Keywords: information processing speed, work breaks, workload

Oral presentation OP220

When do employees seek social resources? The role of identity leadership for job crafting behaviors

Magdalena Marszałek, SWPS University of Social Sciences and Humanities, Sopot Campus, Poland; Marta Roczniewska, SWPS University of Social Sciences and Humanities, Sopot Campus, Poland / Karolinska Istitutet, LIME Department, Stokholm, Sweden

science&practice

Research goals and why the work was worth doing

The aim of this project is to investigate the conditions which facilitate job crafting among employees. Namely, we will investigate how Identity Leadership (IL) determines job crafting (JC) behaviors, with specific focus on increasing social resources. We will also investigate a mediating role of team identification in this relationship.

Theoretical background

JC describes job's modifications that employees make to achieve a better fit between their personal needs or abilities and their job (Wrześniewski & Dutton, 2001; Tims & Bakker, 2010). According to Tims & Bakker (2010) there are four types of JC: increasing structural resources, increasing social resources, increasing challenging demands and decreasing hindering demands. Researchers emphasize that JC is beneficial for employees and organizations (see Rudolph et al., 2017). Thus, it is important to investigate the predictors which facilitate JC among employees. One such relevant predictor is leadership, since leaders are the ones shaping the work environment and affecting employee motivation. For instance, Wang and colleagues (2017) showed that one Transformational Leadership can facilitate JC. However, this relationship was weaker when employees had a high level of organizational identification. This means that organizational/team identification—which is an important part of IL—could be a crucial factor for JC. The IL also is a positive leadership style. And—what is worth to emphasize—IL is based on shared social identity ("sense of we and us"). Research suggests that a shared social identity is an important factor related to the employees' well-being (Steffens et al., 2014; van Dick et al., 2018). For instance, van Dick and colleagues (2018) showed that IL is positively related to team identification, trust, job satisfaction and innovation. Although past research has shown that a range of positive leadership styles facilitate employee proactivity (Tummers & Bakker, 2021; Wang, 2017), according to our best knowledge, the relationship between IL and JC has not been investigated. We argue that investigating relationships and mechanisms between IL and JC is important for at least several reasons. First, increasing social resources is a less frequently used type of JC (compared to increasing structural resources and increasing challenges; Rudolph et al., 2017). Thus, it would be important to find conditions that strengthen this type of JC behavior. At the same time, we assume that IL will be a key factor predicting increasing social resources. It is because a fundamental component of IL—"sense of we and us"—seems to be crucial for employees' proactive changes that are based on relations with colleagues.

Design/Methodology/Approach/Intervention

The study will test the relationship between three aspects of IL (identity advancement, identity entrepreneurship and identity impresarioship), team identification as a mediator and increasing social resources using time-lagged correlational design (expected sample N = 850). We will also control for transformational leadership. There will be two measurement points separated by 6-8 weeks. At each measurement point we will use the following scales: Identity Leadership Scale (van

Dick et al. 2018), Job Crafting Behavior Scale (Petrou et al., 2012), Team Identification Scale (Doosje et al., 1995), and A short measure of Transformational Leadership (Carless et al., 2000). To test our hypotheses, we will perform structural equation modeling.

Results obtained or expected (if not available, it must be made clear when they will be)

We hypothesize that (a) identity advancement, (b) identity entrepreneurship, and (c) identity impresarioship are positively related to increasing social resources and these relationships are mediated by increased team identification. Moreover, we assume that these relationships remain significant when transformational leadership is controlled.

The first data collection of this study will be performed in January 2023, and the second measurement point will be conducted after 6-8 weeks. The results will be available by March/April 2023.

Limitations

We will apply a time-lagged cross-sectional research design and use self-reports to measure focal variables. Thus, our data may be subject to common method bias.

Con clusions - Research/Practical Implications/ Originality/Value

If our hypotheses are supported, we will identify which leadership behaviors motivate employees to introduce proactive changes in their work. Namely, these findings will enable us to explain what conditions lead to increasing social resources and can help leaders and organizations shape a positive work environment that facilitates employee proactivity.

Keywords: job crafting, identity leadership, team identification

Oral presentation OP410

When Does Creativity Lead to Innovation? The Moderating Role of Work Standardisation and Rewarding Innovation

Bart Verwaeren, Aarhus BSS; Bernard Nijstad, University of Groningen

science

1. Research goals

Creativity and innovation are obviously connected – all innovation starts with a novel and useful idea – but they are also clearly separate. In fact, it has been firmly established that creative ideas often fail to be realized and live up to their potential (Sarooghi et al., 2015). In this paper, we examine the surprising effects of work standardisation as a facilitator of the creativity – innovation relationship, as well as how the social context (i.e., rewards for innovation) further conditions this relationship.

2. Theoretical background

Moving from a creative idea to an implemented innovation requires the deployment of a wide array of resources (Baer, 2012; Garud, et al., 2013). In this paper, we examine the role of task standardisation and rewards for innovation in bolstering the creativity – innovation link for small work groups, through resource conservation and allocation. We try to expand our understanding of the effect of work standardisation (standardisation of habitual work processes, not directly focused at creative or innovative activities), a relatively understudied form of standardisation, especially in relation to creativity and innovation, given its prevalence (Vogus & Welbourne, 2003).

The effect of standardisation on creativity and innovation is the subject of some debate, with both positive and negative effects found in various contexts, types of DVs, and types of standardisation in scope (Damadzic et al., 2021; Acar et al., 2019). On the one hand, innovative behaviour implies deviating from standard working routines, suggesting a negative relationship between standardisation and innovation. On the other hand, because standardisation and routinization save time, energy, or other, more tangible resources, especially in workgroups it could be argued that standardisation will stimulate innovative outcomes. We adopt this resource conservation logic to predict that work standardisation will positively moderate the relationship between creativity and innovation (hypothesis 1), given the particular need for resource deployment at this stage of the creative/innovation process (e.g., Garud et al, 2013).

Furthermore, we propose that standardisation of routine task may free up cognitive and time resources (Ohly et al. 2006), but that these resources are not necessarily allocated to innovation processes. Drawing from a resource allocation perspective (Kanfer & Ackerman, 1989) and from expectancy theory (Vroom, 1964), we suggest that the benefits of standardisation for the innovation process will depend on the motivation to allocate the freed resources to innovation. Thus, we propose a resource conservation and allocation model, suggesting that the degree to which innovation is explicitly valued and rewarded acts as a boundary condition for the positive moderation effect of standardisation on the creativity – innovation relationship (hypothesis 2, two-way interaction, and 3, three-way interaction).

3. Methodology

We examine our model using a multisource and multilevel data set, containing input from team leaders, team members, and senior managers from 24 SMEs in the Netherlands. The final sample contains 109 teams. Mixed effects regression analyses are used to test the hypotheses.

4. Results

Regarding our study hypotheses, we did not find a significant moderation effect of work standardisation and team creativity on team innovation (H1), but we did find a positive moderation effect for rewards for innovation (H2). Consistent with our resource conservation and allocation logic, we find support for a three-way interaction of team creativity, standardisation, and rewards for creativity (H3). This result suggests that team creativity is most strongly (positively) related to team innovation when both work standardisation and rewards for innovation are high.

5. Limitations

Our empirical approach is limited in the degree it allows to make causal claims, particularly with regards to the mechanism. Although our results certainly are consistent with resource allocation being part of the answer, we can only infer this trough theory and are not able to show the nuance ways in which this process may unfold. Further investigations could employ an experimental approach to overcome such limitations.

6. Conclusions

The results support a model that emphasizes that the separate and interactive effects of creativity, resource conservation and allocation should be considered when making predictions about the effects of work standardisation.

7. Relevance to the congress theme

The changing world of work implies a focus on both creativity and innovation and on work design. This study contributes to a nuanced way of making decisions about an important work design parameter (standardisation) and its relationship with creativity and innovation.

Keywords: Creativity, Innovation, standardisation

Oral presentation OP3

WHEN EMPLOYEE GENDER DIVERSITY BENEFITS FIRM PERFORMANCE: THE IMPORTANCE OF FEMALE REPRESENTATION IN THE TMT

Hun Whee Lee, The Ohio State University; Jin Nam Choi, Seoul National University; Maria Triana, Vanderbilt University; Jooyoung Kim, Deakin University

science

Organizations have slowly become more gender-diverse. The vast majority of countries in the United Nations have enacted sex discrimination legislation related to employment and promoted gender equity as a sustainable development goal (United Nations, 2015). The increasing trends in women's employment are encouraging in terms of achieving egalitarian societal values, but contemporary organizations face challenges to harness the potential of gender-diverse employees. Indeed, having a gender-diverse workforce involves challenges such as interpersonal conflict, the formation of subgroups, and gender-based stereotypes, thereby potentially damaging social integration and organizational productivity.

Inconsistent results from extant research studying the relationship between gender diversity in the workforce and organizational outcomes reflect such difficulties. For example, existing studies found null, positive, negative, or curvilinear effects of employee gender diversity on organizational performance. Thus, scholars have investigated various boundary conditions such as human resource management investment, work-family programs, organizational life-cycle stage, and institutional and industrial contexts. Taken together, the current body of research suggests that addressing challenges in a gender-diverse workforce is critical for maximizing its value.

The purpose of our study is to provide new insights into how firms can successfully integrate gender-diverse members and harness potential benefits of employee gender diversity for firm performance. We identify female representation in top management teams (TMTs) as a powerful contingency factor that shapes the successful coordination and effectiveness of gender diversity in organizations. Specifically, we suggest that gender-diverse employees can successfully work together to contribute to firm performance when there is greater female representation in the TMT. Indeed, gender composition at the top of the organization is highly visible to employees. Drawing from signaling theory and a symbolic perspective of TMTs (Broome & Krawiec, 2008; Hambrick & Pettigrew, 2001; Spence, 1974), we suggest that female representation in TMTs signals to employees that their firms emphasize gender equity, thereby enabling gender-diverse employees to cooperate with one another at their highest capability. Thus, female representation in a TMT can be a powerful asset that integrates gender-diverse members, which ultimately enhances the overall success of the firm.

We contribute to the literatures on gender diversity, strategic human resource management (HRM), and firm performance by highlighting the importance of the co-existence of employee gender diversity and female representation in the TMT. Our research highlights an integrative view on gender diversity at various levels of the organization. Prior works have largely been divided into employee-focused and TMT-focused research, with each stream of research focusing on examining gender composition either at the employee level or the TMT level. We provide theoretical reasoning and empirical evidence on how and why the potential synergistic interactions across the different levels of gender composition in the organization may occur. Specifically, we capture relational coordination as a measure of social and task-related integration among gender-diverse employees and suggest that female representation in the TMT will help successfully integrate gender-diverse employees, which leads to higher firm performance. Our identification of female representation in

the TMT as a critical boundary condition is noteworthy because it speaks to the importance of improving the gender inequality that still remains at the upper levels of contemporary organizations. Due to significant underrepresentation of women at the top level, female representation in the TMT can send a powerful signal to employees regarding a firm's commitment to gender equity.

In sum, our research identifies a way to maximize the benefits of gender diversity in the workplace: promoting female representation in the TMT to create a context where gender-diverse employees contribute to firm performance. We test our theory using panel data from South Korea (Study 1: 1,017 observations from 306 Korean firms across eight years) and an online experiment in the United States (Study 2: 483 working adults) and find general support for our predictions. In doing so, we believe that our research is well aligned with the Congress Theme and UN SDGs as our research seeks to contribute to gender equality.

Keywords: TMT GENDER DIVERSITY, EMPLOYEE GENDER DIVERSITY, FIRM PERFORMANCE

Oral presentation OP794

When follower performance violates leader performance expectations: Evidence for a causal mechanism of destructive leadership

Monika Thiel, Rudolf Kerschreiter & Daniel May | Freie Universität Berlin

science

Research goals and why the work was worth doing: We examine how follower performance that substantially exceeds or falls below the leader's performance expectations can trigger abusive supervision, a specific form of destructive leadership. Destructive leadership has extensive negative consequences for employees and organizations (e.g., Mackey et al., 2017). The examination of its antecedents is essential for the development of future interventions.

Theoretical background: Previous evidence suggests that both high and low follower performance can trigger destructive leadership (e.g., Tepper et al., 2011; Tariq et al. 2019). However, an integrative explanation for why leaders show destructive behavior towards low- or high-performing followers is still lacking. To address this issue, we developed a theoretical framework building on expectation states theory (Correll & Ridgeway, 2003) and leadership identity construction theory (DeRue & Ashford, 2010). We hypothesize that when followers diverge substantially from leaders' performance expectations both positively or negatively, this can threaten the leaders' leader identity , as they may perceive the followers' performance behavior as a denial to their claim of leadership. We further assume that this leader identity threat can result in destructive leader behavior as a means to remove the threat (cf. Epitropaki et al., 2017). Drawing on the folk-conceptual theory of action explanation (Malle, 1999, 2911), we hypothesize that leaders differ in the degree of identity threat based on the perceived intention behind the follower performance behavior: the threat should be particularly high when the leader suspects an egoistic intention of the follower.

Design/Methodology/Approach/Intervention: To test our hypotheses, we conducted an online confederate study in a 2x5 between-subject design, implementing a face-to-face interaction between a follower (confederate) and a leader (participant). The follower's intention (prosocial vs. egoistic) was manipulated using a video message shown to participants (N =226) before the face-to-face interaction. Participants then took part in a video conference where they were tasked to discuss the execution of a personnel selection task with the follower. Here, the follower's (confederate's) task performance was manipulated (performance well below expectations vs. performance below expectations vs. performance fulfilling expectations vs. performance above expectations vs. performance well above expectations). Participants were then asked to rate their leader identity threat and their intention to show abusive supervision (Tepper, 2000). As a further measure of destructive leadership, independent raters assessed the leader's behavior during the video conference.

Results obtained: We found significant main effects of follower performance and follower intention on abusive supervision intentions, all in the expected directions. We did not find a significant interaction term. A multi-categorical moderated mediation model (Hayes, 2018) showed that most indirect effects linking follower performance to abusive supervision intentions via leader identity threat were significant. We did not find significant moderation effects of follower intention on the follower performance – identity threat paths. We found similar results for the independent ratings destructive leader behavior. Our results generally support our theoretical assumptions that leader identity threat mediates the relationship between follower performance and abusive supervision.

Limitations: Only a small part of the participants held an actual leadership position (22.6 %), limiting our results' ecological validity.

Conclusions – research and/or practical Implications: We developed and tested an integrative framework explaining why leaders engage in destructive behavior when working with low- or high-performing followers, contributing to the growing body of research on destructive leadership. Future research should investigate the described model in the field with participants in actual leader and follower positions. Organizations could apply the findings in leadership development for leader self-reflection and awareness methods to prevent destructive leadership.

Relevance to the Congress Theme: Our contribution is relevant to the congress theme insofar as destructive leader behavior is likely to remain a commonplace occurrence in work environments, despite growing efforts to curb it. Creating awareness among HR professionals, leaders, and followers alike that unexpectedly high and low follower performance can cause destructive leadership is crucial for reducing its negative impact.

Relevant UN SDGs: Focusing on how destructive leadership is triggered, our research fits the goal of "decent work & economic growth." Our research is helpful for the development of interventions to avoid destructive leadership in the future, which helps to create decent work environments.

Keywords: follower performance, leader identity threat, abusive supervision

Oral presentation OP231

When team mindfulness creates value from diversity in values – A two-stage moderated mediation model linking cognitive diversity to team performance

Alexander Goetmann, Lucerne School of Business ; Myriam Bechtoldt, EBS University

science

Organizations largely integrate team-based structures to fuel the value of their workforce. As these teams become more heterogeneous due to demographic changes in the workforce composition, growing employee mobility, and higher task specializations, organizations have to increasingly deal with a multitude of values, beliefs, attitudes, and opinions among their teams. While research on the adverse effects of cognitive diversity (e.g., differences in beliefs and values among team members) has proliferated in the past, much less is known about how challenges associated with cognitive diversity in teams can be attenuated to positively influence team performance.

Our research addresses this gap. In the present research, we develop and test a two-stage moderated meditation model in a longitudinal study with 104 teams from three countries to argue that team mindfulness attenuates the adverse effects of cognitive diversity on relationship conflicts. Team mindfulness is particularly beneficial to teams with high task interdependence where the task requires members to work closely together; team mindfulness leads these teams to experience less relational conflict, which in turn predicts higher team performance.

Our study makes several contributions to theory and practice. We add to the ongoing scholarly debate on the diversity-performance link by generating novel insights on when and how cognitive diversity influences team performance. This endeavor benefits the theoretical and practical conversation on the pitfalls of team diversity and offers empirical evidence on how to overcome these. Second, our research responds to the call for more empirical research on mindfulness as a team-level construct. More specifically, we provide an attempt to investigate the role of team mindfulness for team performance in a longitudinal, international field study.

We focus on cognitive diversity, which has been shown to partly relate to negative effects in teams because people are drawn to and seek collaboration with those they perceive as similar. They tend to stick to their own perspectives and reject the opinions of those they perceive as dissimilar, which frequently results in disagreements. More than that, teams characterized by high cognitive diversity in terms of beliefs, opinions, and values are more likely to experience lower cohesion and higher levels of conflicts. If cognitive diversity leads to more relationship conflicts among team members, an essential question for organizational scholars and practitioners alike is how to attenuate these effects to avoid adverse effects on team performance. We suggest that team mindfulness - a form of shared believes among group members that interactions are characterized by awareness and non-judgment - constitutes a promising psychological construct to influence the relationship between cognitive diversity and relationship conflicts.

We used a longitudinal design and assessed individual and collective-level variables at four different time points with 104 teams from three different countries. Teams worked together for a certain period (average= 2.6 weeks, max=10 weeks) on graded group assignments necessary to finalize the course successfully. The graded group work consisted of team presentations. Team performance was measured using third-party judgments of the course instructors who were blind to the study hypotheses.

We find evidence for an attenuation effect of team mindfulness in the relationship between cognitive diversity and relationship conflict, suggesting that teams high in mindfulness are less prone to personal conflicts resulting from cognitive diversity. This is particularly beneficial to teams whose task requires members to work closely together, as relational conflict predicts lower team performance, especially among them.

Despite the strength of the present research, our work has some limitations that warrant further directions for research. First, we integrated a previously validated measure of cognitive diversity that is relatively concise and was shortened for economic reasons. The used scale for cognitive diversity is not able to capture more complex dynamics of emergent states in team diversity. Second, we applied a correlational design to investigate our theoretical model. The concern of reverse causality in our study is unwarranted, as cognitive diversity was measured as the group work started and relationship conflicts with three measurement points over several weeks. However, we acknowledge that further research should integrate experimental methods to allow for even more robust causal inferences.

This paper adds to our understanding of the diversity-performance relationship and suggests that mindfulness as a collective-level construct can positively influence team performance by reducing relationship conflicts in diverse teams. We hope to stimulate further research on mitigating and attenuating factors of the adverse effects of cognitive diversity on team performance.

Keywords: diversity, team mindfulness, team performance

Oral presentation OP360

When work aligns with values: an intervention study to strengthen the wellbeing, health, and employability in healthcare professionals

Margot Joosen, Evelien Brouwers & Kim Janssens | Tilburg University, Tilburg School of Social and Behavioral Sciences, department Tranzo

science&practice

Research goals :

With the healthcare sector facing high sickness absence levels, turnover and growing shortages of health-care workers, it becomes important to pay attention to retention of healthcare professionals. The scarcity of qualified healthcare professionals is even more problematic since the Covid-19 pandemic, where the multitude of work-related stressors that these professionals face put their well-being, health and employability at serious risk. In light of these stressors, there is often little attention for positive aspects in the daily work, such as personal values that drive them in work (e.g., helping others, making a meaningful contribution). For protecting healthcare professionals and promoting wellbeing and health, value-based approaches hold an enormous potential. For this reason, the 'Work Values' intervention was developed which aims to provide health-care professionals with opportunities to realize their work values.

This study aims to investigate (1) the barriers and facilitators for implementing the Work Values intervention in a hospital care setting, and (2) the effect of the Work Values intervention on wellbeing, health and team cohesion of a team of healthcare professionals of a hospital unit.

Background :

The emerging scientific field of positive psychology has stressed the hidden potential of focusing on positive aspects in life such as values, strengths, and positive experiences. Applications of positive psychology to work have, however, mainly focused on interventions at the individual level that are detached from the immediate work environment. Less is known about positive approaches that enable the achievement of personally meaningful work values in which both the individual level and organizational level are involved.

A promising model to foster meaningful work values is the idea of value-based work, is the capability approach. Applied to the work context, the capability approach recognizes that employees value work for different reasons, such as opportunities for personal growth or for contributing to something meaningful. To date, however, employee values are rarely discussed explicitly at work. Especially, when the pressure is high or when problems arise, there usually is a strong emphasis on coping with pressure (e.g., through better time management) and fixing the problem (e.g., working on one's deficits). However, especially in challenging times, it may be crucial to focus on the value and meaning that people derive from their work to help them cope.

Based on the capability approach, the 'Work Values' intervention was developed in which teams were provided with opportunities to realize work values that are most important to them. The intervention aims to help team leaders and -members identify (a) the aspects that employees/teams value in their work; (b) work context factors that play to these values; and (c) individual/team actions that contribute to realizing these values.

Design and methods :

In this field experiment and pilot study, the ‘Work Values’ intervention, was tested and evaluated in nursing units of a Dutch non-university hospital. Pre-, post-, and follow-up questionnaires were distributed among team leaders and team members (i.e. nurses). Besides demographic data, Health (SF-1), wellbeing (UBOS), work engagement (UBES), Team climate (Team Climate inventory), supervisory support (POS) and employability self-efficacy were measured. Also face-to-face interviews with team leaders and team members were conducted to investigate barriers and facilitators for implementation and to study the perceived impact on work-related well-being, team cohesion and employability.

Results :

Results will be available end of 2022. The first preliminary findings show that the intervention is feasible for the hospital care setting and teamleaders and teammembers are highly satisfied with the intervention.

Conclusion:

This study will contribute to the understanding of what is needed for health-care professionals to stay motivated, engaged, and healthy at work and how sustainable employability can be promoted within the healthcare sector. Especially in challenging times (such the ongoing transformation in healthcare) strengthening the wellbeing, health and employability of healthcare professionals is essential for society. Value-based approaches to work hold an enormous potential for protecting healthcare professionals but are scarcely used in practice or researched. The ‘Work Values’ intervention is one of the few positive psychology interventions to enable personally meaningful work values. Since this is a pilot study, no control condition was included. Therefore the effects of the intervention can not be compared with care as usual.

Keywords: Healthcare, valuable work, workers’ wellbeing

Oral presentation OP20

When work hurts – Mental health challenges upon returning to work post-COVID-19 pandemic restrictions within the South African public service

Willie Chinyamurindi, University of Fort Hare

science

The COVID-19 pandemic has affected the world of work immensely. Pre-existing socio-economic challenges compound this impact in South Africa before the pandemic. In managing the challenges posed by the COVID-19 pandemic, the South African government introduced measures to minimize the spread of the pandemic. These measures affected not just individuals but also covered the organizations in which they operated. Calls exist to understand challenges faced as part of the new normal and post the COVID-19 pandemic restrictions. This research narrows the focus on understanding the experiences of a sample of 12 employees over a year in narrating their experience of work post-COVID-19 pandemic restrictions. Multiple interviews were used, including a web-based diary entry, to collect participant experiences given the research aim. A qualitative approach relying on narrative inquiry was utilized to understand the participant's experiences. Three main findings existed. First, the participant narrated challenges upon returning to work post-COVID-19. These challenges were compounded by a level of anxiety and uncertainty related to the employees' job security. Subsequently, this led to mental strain. Second, concerning organizational functioning, the participants also expressed the challenge of operating within organizational structures unable to support the post-COVID-19 setting. This also included questioning why it was still necessary to come to the physical office space. Third, as a result of the two findings, participants expressed a desire to leave the workplace for “greener pastures” or more conducive workspaces that support mental health ideals. Based on the findings, strategies can be put in place that inform the promotion of mental health in the South African public service. These include the need for support services to promote mental health to address individual and organizational issues that impede the pathway of such interventions. The findings proffer useful precursors to interventions that address the challenge of mental health.

Keywords: mental health, work, employees, public service, well-being, narratives

Oral presentation OP452

Which factor most affects unethical behavior at work? The influence of ethical culture, ethical culture strength and collective moral identity

Marilia Mesquita Resende, University of Brasilia; Francisco Gracia, University of Valencia; Juliana Porto, University of Brasilia

science&practice

Ethics in the workplace is an important phenomenon that has a critical impact on organizations and societies. Ethical scandals, such as those in business and politics, have called attention to the need to create policies and other mechanisms that can undermine unethical acts. Hence, contextual factors such as ethical culture stand out as crucial because they can play a pivotal role in enhancing or diminishing unethical acts. Ethical culture is a subset of the concept of organizational culture and corresponds to the interplay between formal and informal systems that boost ethical behavior or prevent unethical conduct. Regarding individuals, moral identity has been one of the most studied constructs related to moral behavior. Moral identity is defined as a self-concept around a set of moral traits. Past research suggests that ethical culture and moral identity positively impact ethical behavior in organizations. However, research has yet to consider if collective moral identity interacts with ethical culture to predict ethical behavior and how ethical culture strength has a role in this relationship.

The purpose of this study was to investigate the effect of ethical culture, ethical culture strength, and collective moral identity on unit-level observed unethical behavior and unethical pro-organizational behavior while examining their moderating effects.

We tested our model with 1942 employees from 96 units of ten organizations in Brazil. Of the ten organizations, three were public institutions, and seven were private. We applied the Corporate Ethical Virtues Scale (CEV), the moral identity scale, the Observed Unethical Behavior in Organizations Scale, and the Unethical Pro-Organizational Behavior Scale. The within-unit agreement was estimated for all variables and provided evidence of agreement within units for all the variables, except for the ethical culture's sanctionability dimension. To model the relations between the variables, we employed an SEM.

The results showed no statistically significant associations between the collective moral identity and both unethical behavior measures. We found negative, statistically significant correlations between both measures of unethical behavior and the dimensions of ethical culture, except for the feasibility dimension. The results also showed that ethical culture strength among members of the work units was significantly related to a lower shared perception of observed unethical behavior and a lower shared perception of unethical pro-organizational behavior. Since collective moral identity was not a significant predictor of the dependent variables, the interaction models of moral identity and ethical culture were also non-significant.

Our findings point out that ethical culture and ethical culture strength have a strong effect on unethical behavior, but that collective moral identity has no impact. The research on moral hypocrisy can explain this, which means appearing moral to others while avoiding the cost of actually being moral. Additionally, we must consider the cultural context in which this data was collected. Brazil has a phenomenon known as the Brazilian jeitinho , which refers to a social mechanism used by Brazilian citizens to deal with difficult situations that arise in daily life and for troubleshooting.

There are some limitations in our study. The first limitation is that the data is cross-sectional, which unviable causal inferences about the model. Second, all the measures used in this study were self-reported surveys, which have issues related to common method bias. Third, we measured only moral identity using the classic self-report scale from Aquino and Reed (2002).

Regardless of these limitations, this study provides a clear contribution to our understanding of ethical culture on unethical behavior. First, we contribute to the ethical culture literature by introducing the concept of ethical culture strength and showing that it has a significant negative effect on unethical behavior. Second, we demonstrate that ethical culture has a significant association with unethical pro-organizational behavior, even though it has a weaker effect.

We also contribute to the literature by demonstrating that moral identity may not always be a good predictor for ethical behavior - this effect may vary depending on the context. Regarding practical implications, our research highlights the potential effect of ethical culture on unethical behavior. Hence, our research points out that organizations that invest in ethical norms and values can positively affect the company.

This study is relevant to the Congress Theme “The Future is Now: the changing world of work” because it investigates how can we enhance a desirable competence in the future world – specifically ethical behavior – by making changes in the work context related to ethical culture and by promoting group dynamics that could help increase ethical behavior and diminish unethical acts.

Keywords: ethical culture, collective moral identity, unethical behavior

Oral presentation OP170

Who is first? The effect of trustworthiness on the decision to hire first employees in new businesses

Theresa U. Zimmer, Cornelius J. König & Nida ul Habib Bajwa | Saarland University

science

Research goals: The goal of this study is to examine a first step to business growth from a psychological perspective: Who is hired as the first employee? Given that the first employment involves taking considerable risk, we suggest early-stage entrepreneurs' intention to hire should be influenced by the trustworthiness of potential future employees. Therefore, this study explores whether an adapted version of a well-established model of trust can be used to understand early-stage entrepreneurs' hiring decisions.

Theoretical background: Although many studies have examined entrepreneurial growth, it remains unclear how entrepreneurs acquire human capital, and what characteristics of new employees explain successful business growth. Hiring a first employee could be a strategy to obtain human capital, but such a hiring decision is risky for entrepreneurs, which makes trust research highly relevant for this topic. According to a standard trust model (Mayer et al. 1995), risk-taking in relationships depends on trust, which evolves from the interplay of the trustors´ propensity to trust and the trustworthiness of the trustee. Furthermore, Mayer et al. differentiate between of three different trustworthiness facets: benevolence, integrity, and ability. We therefore, suggest that early-stage entrepreneurs hire candidates if they are high in benevolence and high in integrity. In addition, we propose to adapt the ability component to the start-up context: In entrepreneurship situations, it might be less candidates' amount of ability, but rather the breadth of their ability that matters (i.e., broad but smaller expertise in diverse fields vs. specific expertise in one field). The broader the scope of abilities (given the same overall ability), the higher should be the likelihood that someone is hired as a first employee.

Design/Methodology: 195 Pakistani entrepreneurs were randomly assigned to four groups. All were asked to imagine a critical situation of a start-up with numerous, overwhelming tasks to be accomplished. They read that the entrepreneur in this scenario decided to hire an employee. Subsequently, two potential candidates were described with different ability characteristics (i.e., one participant with average expertise in diverse fields and one participant with high specific expertise in one field but low expertise in others) and then rated by the participants. In each of the four groups, both candidates were either high (or low) in benevolence (or in integrity). Therefore, benevolence and integrity were between-subject experimental factors and breadth of ability a within-subject factor.

Results obtained: An ANOVA revealed that the within-participants effect was significant (i.e., participants intended to hire the candidate with a broad scope of abilities and not the expert), but between-participants effects were not. Thus, our data suggests that entrepreneurs care mostly about the breath of expertise when hiring, whereas the trustworthiness factors benevolence and integrity of first employees seem less relevant for entrepreneurs' hiring intentions.

Limitations: The study was conducted in Pakistan and needs replication in other countries to claim generalizability.

Conclusions: Our study broadened the scope of trust research, differentiating the trustworthiness factor ability. In addition, we bridge research about HRM and entrepreneurial growth, applying a

well-supported theoretical model to the situation of early-stage entrepreneurs who face the decision to hire first employees.

Relevance to the Congress Theme: Entrepreneurship has been considered by many governments as a crucial strategy to move countries forward and to foster innovations. However, this strategy can only be beneficial if new businesses survive and grow.

Relevant UN SDGs: SDG 8, decent work and economic growth.

Keywords: Entrepreneurship, busines growth

Oral presentation OP137

Who is in control? Understanding different patterns of leadership entrainment processes with a video-based observational study

Lioba A. Gierke, WHU - Otto Beisheim School of Management; Niels van Quaquebeke, Kühne Logistics University; Florian Klonek, Curtin University; Fabiola H. Gerpott, WHU - Otto Beisheim School of Management

science

Research Goals

Meetings are a ubiquitous characteristic of work life. Managers and their employees spend a great deal of their time in meetings with each other, and while ideally both parties align and learn through such conversations, this is often not the case. This increasingly becomes a problem as – in contrast to the traditional view of leadership as something that a single person owns through their position of authority – leadership is more and more seen as something that should be brought about by all participants taking part in leadership activities, which entails that leadership is not a one-way street, but that ideally, a manager and their employee provide each other with new perspectives. Yet, how exactly does this look like? Surprisingly, we do not know much about different conversational patterns that characterize how managers and employees try to influence each other in the form of claiming and granting leadership in meetings. However, it is intuitively appealing that there is considerable variability in how a manager and an employee jointly shape the flow of the conversation, and that how such a conversation unfolds has downstream consequences for how a meeting is perceived. The goal of our research was thus to identify different types of manager-employee interaction patterns and explore how these different types relate to perceived mutual learning (i.e., the employees' perception of reciprocal learning between themselves and the manager).

Theory

The key argument regarding leadership claiming (i.e., verbal behaviors that signal the willingness to offer a direction and to exhibit social influence) and granting (i.e., verbal behaviors that accept another person's influence attempts) is that leadership control can be exhibited not only by managers but also by employees (DeRue & Ashford, 2010; Cashman et al., 1976). This constitutes a dynamic process which can be more or less aligned. Accordingly, we expect that a manager and an employee can show different patterns of alignment of their claiming and granting behavior over the course of a meeting. Drawing from entrainment theory (Ancona & Chong, 1999), we describe a high alignment of the behaviors of the manager and the employee (e.g., manager claims leadership, employee grants leadership) as high entrainment, and divergent behaviors (e.g., manager claims leadership, employee shows neutral behavior) as low entrainment.

Design & Methodology

We collected video-recorded one-on-one meetings from 103 manager-employee dyads. Using these videos, we coded the verbal behaviors (claiming, granting, neutral) of both interaction partners and developed a temporal index that visualizes claiming and granting behaviors from leaders (and followers) over time. We graphed these indices for each dyad and qualitatively analyzed these graphs to identify clusters that illustrate similar interaction patterns. Employees also self-reported their mutual learning after the meeting.

Results

We identified five entrainment types that we labelled “Traditional Dancing”, “Modern Dancing”, “Irish Dancing”, “Late Bloomers” and “Single Dancing”. We chose the analogy with dancing because when people are dancing together, they also align their movements by synchronizing their steps, creating an entrainment pattern.

Three of these types (i.e., “Traditional Dancing”, k = 23; “Modern Dancing” k = 25; “Irish Dancing”, k = 24;) represent high entrainment, that is, both parties show an aligned pattern of behaviors (i.e., they act in sync). The other two types (“Late Bloomers”, k = 13; “Single Dancing”, k = 18) represent low entrainment (i.e., both parties do not show synchronized behaviors).

Meetings characterized by high entrainment were positively associated with employees perceived mutual learning, whereas the “Late Bloomers” type was negatively associated with mutual learning.

Limitations

Two limitations concern (1) the lack of knowledge about the meeting content and (2) the sole focus on verbal behaviors. Future research could utilize a thematic coding scheme and also capture nonverbal behaviors (e.g., gestures) to explore whether entrainment patterns also generalize to different meeting foci and communication channels.

Conclusion

In our mixed-method study, we investigated the actual behaviors shown in dyadic manager-employee meetings and developed a typology of entrainment patterns. In doing so, we shed light into the “black box” of meeting interactions and unravel the dynamics between managers and employees. We also provide first insights into the implications of different dynamics for mutual learning, which is a crucial outcome in the knowledge economy.

Relevance to the Congress Theme

The paper is relevant to the theme as it develops theory for a future that is already there, namely that leadership and followership are increasingly merging, and that alignment between both parties in meetings is crucial in a globalized world with hybrid and virtual work arrangements.

Keywords: dynamics, leadership, relational control

Oral presentation OP76

Who is Successful in Career Development? A Person-Centered Approach to the Study of Career Orientation Profiles

Nicolas Bazine, Université de Bordeaux

science

This research examined the presence of career orientation profiles by investigating how young workers combined protean career orientation attitudes, motivation to learn to develop one's career, and an optimistic future perspective on their career. Further, it explored how workers differentiated endorsement of these attitudes and motivation (i.e., career orientation profiles) were associated with the adoption of multiple career enhancing behaviors, namely proactive career behaviors (i.e., career planning, networking, and skill development) and learning behaviors with technologies. Latent profile analysis was conducted among individuals in early career (N=767) and found four distinct profiles. A first profile revealed that 28.4% of workers in early career were displaying high levels of protean career orientation, motivation to learn, and optimistic future time perspective (profile 4). Two differentiated profiles showed either high levels of protean career attitudes and low levels of motivation to learn (profile 3) or low levels of protean career attitudes and high levels of motivation to learn (profile 2). These profiles presented average level of future time perspective and represented 13.8% and 40.6% of the sample. Finally, 17.2% of the sample showed low levels on all these variables (profile 1). Only workers who showed high levels on all these indicators also presented high levels of proactive behaviors and learning with technologies. The other three profiles were associated with suboptimal levels on these outcomes. Taken together, these results offer new insights on the psychological state of mind most adapted to success in a modern career.

Keywords: career orientation profiles; career development; protean career orientation

Oral presentation OP202

Why can't I get out? Development of a career inaction scale.

Paulien D'Huyvetter, Marijke Verbuggen | Department of Work and Organisation Studies, KU Leuven

science

Context & aim

Although many western governments strive to stimulate job transitions as a way of addressing the mismatch in the labour market and of improving career sustainability (De Vos et al., 2020; Joint Employment Report, 2021), job mobility rates remain low in many countries. Similarly, many people who feel unsatisfied with or stuck in their careers, do not change jobs (e.g., Watson et al., 2021). The phenomenon of "career inaction" offers one potential explanation for these apparent contradictions. Career inaction refers to the phenomenon that people desire or need a change in their career but fail to take sufficient action to realize that change (Verbruggen & De Vos, 2020). Verbruggen and De Vos (2020) theorize that career inaction holds considerable risks for both employees and organizations, such as poorer health, lower well-being, increased stress, and lowered productivity. Yet, to date, little is known about the actual outcomes or correlates of career inaction, partly due to the lack of a measurement instrument to assess this phenomenon. We aim to address this gap by developing and testing a scale that captures the psychological concept of feeling stuck in your career.

Approach

We started by reading the Theory of Career Inaction (Verbruggen & De Vos, 2020) and related research (e.g., Rogiers et al., 2022). Based on this reading, we formulated an initial set of items. We collected input on these items from 7 expert scholars and 10 laymen on the clarity, and content and face validity of these items. In a next step, we tested the scale in a data set with 264 Belgian employees. We ran an explorative factor analysis on our scale and assessed its reliability. Third, we evaluated the scale in a longitudinal survey with Belgian employees who applied for career counseling vouchers. We already ran reliability and correlation analyses on data from wave 1 (N=794) and wave 2 (N=477). We also plan to perform a confirmatory factor analysis using this dataset.

Results

Results from study 1 indicate that our 9 items reliably measure one underlying factor (α= .94); namely, not being able to undertake sufficient action despite the desire for change. Results from the second study indicate a significant ($p<.00$), moderately to highly positive correlation of all 9 items for both waves 1 and 2. Preliminary results showed again that our scale reliably (α= .88 for wave 1 and .92 for wave 2) reflects career inaction as one factor.

Limitations

First, since research on career inaction is still in a nascent stage, the item generation was mainly based on the conceptualization by Verbruggen and De Vos (2020). Yet, a recent qualitative study on the lived experience of 43 Belgian employees in career inaction (Rogiers et al., 2022) provided further inspiration for our initial items. Second, our scale was formulated and tested in Dutch given our Belgian research context. However, in collaboration with 6 expert career scholars and 3 laymen, we now generated an English version of our scale to increase its usefulness in future, international studies.

Conclusion and contribution

This scale development is of value to both scholars and practitioners in the career field. So far, career inaction could only be measured indirectly, i.e., by targeting people who fail to realize the desired or needed change in their careers. Our scale allows scholars to directly pinpoint the specific situation of not succeeding to take sufficient action on a desired or needed career change. In doing so, it can facilitate more empirical insights into the prevalence, antecedents, and potential effects of career inaction. Additionally, it can support career coaches in clearly identifying whether or not clients find themselves in career inaction and selecting appropriate counseling actions accordingly.

Relevance to the Congress Theme and relevant UN SDGs

In the changing world of work, career decisions and transitions become more and more complex for many employees. (measuring) Career inaction – and its potential risks – therefore seamlessly connects to the topic of "the future of work". This topical phenomenon reflects how thinking about future jobs or other career desires can put people in a psychological state of career inaction with unwanted negative consequences (e.g., regret in the long run or a higher risk of burnout). Raising awareness of career inaction can help to reduce those negative consequences and, perhaps, even guide people out of their 'stuckness'. As such, we also hope to contribute to the UN SDG of stimulating and guarding employees' good health and well-being.

Oral presentation OP261

Why do some autistic adults have paid work whereas others do not? An exploratory focus group study comparing autistic adults with and without work

Evelien Brouwers & Jeroen Dewinter | Tilburg University; Sarah Detaille, HAN University of Applied Sciences; Jaap Van Weeghel & Michel Bergijk | Tilburg University

science&practice

Research goals and theoretical background

Globally, sustainable employment rates of people with autism are very low, indicating difficulties in both finding and keeping competitive employment. Due to the biomedical model, much previous research assumed this is due to the 'condition'. Recently however, awareness is growing that other factors hamper work participation, such as an unwelcoming work environment. In this exploratory focus group study, we evaluated what autistic people with and without paid employment reported as barriers and facilitators to sustainable, paid employment. Research questions were: (1) What barriers and facilitators do autistic adults report in finding and keeping competitive employment?; and (2) What are differences and similarities between autistic adults with and without paid employment regarding the barriers and facilitators they report for sustainable employment?

Methods

A total of 8 focus groups were conducted, including a total of 64 participants: 4 groups with and 4 groups without paid employment. All meetings were transcribed verbatim and analyzed separately for the groups with and without employment (inductive thematic content analysis), using ATLAS.ti 9.

Results

In both groups, major themes were: ‘workplace atmosphere’, ‘supervisor skills and attitudes’, ‘work tasks and work environment’, ‘work that is enjoyable and aligns with talents’, ‘getting adequate support’, ‘self-insight’, ‘self-esteem’, and ‘communication’. A theme only found in those with employment was ‘proactivity’. A theme only found in groups without work was ‘disability pension takes away stress’.

Important barriers in both groups were supervisors’ and coworkers’ lack of knowledge about autism and their unwillingness to adapt themselves or the workplace to the autistic worker. Over- and underestimation of skills and not being able to do work that is enjoyable or fitting talents was common in both groups. Both groups reported needing support (e.g. job coaching) but not receiving it, and those without work even often reported inadequate support. In both groups participants showed difficulties with self-insight/self knowledge regarding personal boundaries, talents and career preferences, especially prior to the diagnosis. The group without work seemed to have had more damaging experiences as a result, e.g. by working too hard and not respecting their boundaries, often resulting in burnout. They also showed lower self-esteem and more distrust. Receiving disability benefits relieved stress in this group.

Important facilitators were a positive and inclusive work environment and supervisor, who creates calmness, has an eye for wellbeing and talent, and who communicates well. The groups without work emphasized the importance of having a place to retract oneself socially if needed and to be able to work without pressure. In the groups with employment, higher self-esteem was found, and these participants seemed less affected by prior negative experiences in work or school (e.g. bullying, rejection). Finally, in the groups with paid work, assertiveness in general, as well as assertive

communication about workplace needs were found. Finally, only in the group with work, proactivity was found as theme, e.g. regarding personal career goals, finding creative solutions and through thorough preparation of job applications.

Limitations

The study is exploratory, for which reason no causal relationships can be established. Moreover, the study included participants in the two types of groups based on actual employment status, not taking into account factors like previous employment duration or employment success. Also, the study population was relatively highly educated.

Conclusions A large variety of factors are involved in successful occupational outcomes for autistic adults. Findings suggest that interventions should focus both on the side of the work environment, and the worker. Employers need to become more inclusive in attitude and behavior and eradicate hiring discrimination. Moreover, they need to become more flexible willing to make tailored workplace adjustments favoring individual workers' needs and talents. Interventions targeting autistic adults should enhance self-insight/self-knowledge (e.g. concerning healthy boundaries, talents or preferences), improve assertive communication skills regarding needs and boundaries, and improve self-esteem and empowerment.

Relevance for congress theme and UN SDGs With current shortages in workers, it is essential workplaces become more inclusive. Many autistic adults want to have paid employment and have their own talents, but work should not be harmful to their health. This study aligns with the UN SDG's 'No poverty', 'Good health and well-being', and 'Reduced inequalities'.

Keywords: autism, barriers and facilitators, focus group

Oral presentation OP159

Why do they leave? Factors associated with young managers' propensity to leave or not to leave their position

Robert Lundmark, Susanne Tafvelin, Hanna Irehill & Erik Lundkvist | Umeå University

science

Research goals and why the work was worth doing

The aim of this research is to find out more about why young managers' leave or intend to leave their managerial position. Given the high dropout rate, and problems of recruiting young people to managerial positions, this work will identifying factors that are associated with young managers wanting to leave or remain in their position. Thus, the work contributes to giving recommendations and guidance for future intervention studies looking to support young managers.

Theoretical background

A lifespan perspective on managerial development suggests that young managers may be confronted with extra challenges, and thus in need of special attention and support in their transition into the role and identity as a manager (Liu et al., 2021). Furthermore, entering a new role, for which a young age can be seen as nonprototypical, may be considered an extra demanding challenge. Thus, from a stress theory perspective (e.g. Conservation of Resources; Hobfoll, 1989), building up and making available (the right kind of) resources may facilitate a more healthy transition into the identity as a manager.

Design/Methodology/Approach/Intervention

We will analyze survey data from approximately 600 young managers (i.e., 19-29 years of age), from different sectors who have worked or are working in a managerial role. We will conduct comparative analyses between those who have left their position and those remaining in their managerial role. We will also study and compare the strength of relations between a variety of contextual factors (e.g., role clarity, support, span of control) and turnover intentions among those still working as managers.

Results obtained or expected (if not available, it must be made clear when they will be)

The data analysis will be conducted at the end of 2022. We expect to find a range of work and demographic factors that contribute to young mangers propensity to leave their managerial role, but also factors that may contribute to lower turnover rates.

Limitations

The data used in this research is cross-sectional. Although this may pose less of a problem for the analysis based on register data, we cannot be certain about the direction of the relations between studied work environment factors, nor that common-method bias inflate strength of relations. However, given the lack of studies on young managers' propensity to leave the results can be used as a starting point for future explorations.

Conclusions – research and or practical implications/Originality/Value

This study will be among the first to focus on young managers propensity to leave the managerial role at an early stage. The results will clarify what factors contribute to them leaving or intending to leave as managers. Thus, the research will shed light on potential risk factors and supportive factors

to consider if organizations want to create beneficial conditions for their young mangers to thrive and develop in their managerial role.

Relevance to the Congress Theme

Managers' play an important role for employee wellbeing and performance. Making sure that the upcoming generations of managers have sufficient resources to develop their managerial skills and be fit to lead the way is an important part of creating a sustainable future working life.

Relevant UN SDGs

Supportive managerial behaviors are vital for achieving good workers' health and wellbeing, as well as decent work and economic growth in organizations. To increase chances of reaching these goals, managers' prerequisites and possibilities to thrive and develop into their managerial role is an important precondition.

Keywords: Managers, Work environment, Age

Oral presentation OP464

Will you lend me your strength? Development and evaluation of an interpersonal strengths-use intervention.

Piet van Gool & Ishani Sewnarain Sukul | Eindhoven University of Technology

science

Research goal

Using your own strengths at work has been shown to positively affect well-being and performance. But can you also proactively make use of other people's strengths, and how does that affect either partner involved? As our jobs become increasingly interdependent, these questions become more salient. In this study, we (1) introduce the concept of interpersonal strengths-use as a proactive strategy in which employees try to use other people's strengths for their own benefit and (2) develop and test an interpersonal strengths-use intervention to examine its effects on both interaction partners.

Theoretical background

We hypothesized that employees who proactively try to use their coworker's strengths, positively affect the dyadic relational energy they experience when interacting with that coworker, as well as their own individual performance. The rationale is that the coworker's strengths function as a job resource for the employee who tries to use the coworker's strengths. Moreover, we hypothesized that the coworker that is the target of interpersonal strengths-use would also benefit from this behavior in terms of dyadic relational energy and individual performance because it would allow this target to capitalize on their own strengths.

Design

We developed an interpersonal strengths-use intervention and tested its effects using a waiting list-control group design. We built the intervention around identifying, developing, and using strengths as is a best-practice in individual-level strength-use interventions (Meyers & Van Woerkom, 2017) but changed the focus to the strengths of the other participants. Using a round-robin survey, we collected dyadic data before and after the intervention among direct colleagues in 9 teams from an IT consultancy company in the Netherlands. This yielded a total of 508 dyadic measurements, including pre- and post-measurements of both the experimental and control group. We adapted the individual strengths-use measure to reflect interpersonal strengths-use. Participants rated their (own) strengths use, their interpersonal strengths use, and their relational energy in the interactions with all their team colleagues. All measures were adapted for dyadic use. Additionally, the team leaders rated everybody's performance. We extended used the Multilevel Social Relations Model (Snijders & Kenny, 1999) to be able to split team, actor, partner, and dyadic effects. The multi-level structure allowed us to extend the social relations model to include measurements over time (i.e., the pre- and post-measures).

Results

Our results showed that our intervention stimulated interpersonal strengths-use. Moreover, interpersonal strengths-use energizes those who seek out strengths in others. We did, however, not find significant effects of interpersonal strengths-use on either the strengths-use or relational energy of the target of interpersonal strengths-use. We also found no significant impact on the performance of either side of the dyad.

Limitations

Due to a relatively limited sample size, we were not able to properly examine the effects of interpersonal strengths-use on the individual or team level.

Conclusions

Interpersonal strengths-use seems to be a promising new positive, proactive strategy that employees can use to benefit their well-being by creating more energizing interactions with colleagues. More research is needed to explore the boundary conditions under which interpersonal strengths-use may also help the target of this behavior. Both practitioners and researchers can use the intervention we developed to stimulate interpersonal strengths-use and increase employees' well-being.

Relevance to the Congress Theme

Employees are increasingly dependent on others in their work. Interpersonal strengths-use can help employees make optimal use of their social environment in their job.

Relevant UN SDGs

Good relationships at work are an essential factor in employees' well-being. Our intervention helps employees to proactively create more energizing interactions with their colleagues.

Keywords: strengths use, intervention, dyads

Oral presentation OP611

Win or lose: Rivalry, risk-taking, and relative performance

Himani Singh, himani.singh@uni-mannheim.de

science

Competition is an essential component of organizational life. While some competitive situations can be defined purely in structural terms, a subset are characterized by the relational significance of the competition to the competing parties, and these latter types of competition are encapsulated by the construct of relational rivalry (Kilduff et al., 2010; Kilduff, 2014, 2019). Rivalry, in this context, is defined as an intense competitive relationship with heightened psychological stakes associated with the competition. Thus, relational rivals are competitors who have an enduring, historically-embedded competitive relationship that lends them much greater subjective importance, compared to other competitors who pose equal threat.

Prior research shows that rivalry can have powerful motivational effects, which prompt both rational and irrational responses, including increased motivation to outperform competitors, greater risk-taking, eager decision-making, pronounced legacy concerns, and unethical behavior. These studies demonstrate that the motivation to win and defeat the competitor increases in a contest against a rival. However, while multiple inferences can be made from the existing literature about the motivation to succeed against a rival, not much can be said about the actual implications of success or failure against a rival. This paper thus examines the implications of relative performance for the relationship between rivalry and risk-taking.

Drawing on arguments from social comparison theory and the literature on social aspirations, this paper proposes that relative performance against a rival impacts the extent to which rivalry affects risk-taking and performance. Underperformance relative to a rival is likely to have a special psychological salience that magnifies its significance and may serve as an unambiguous indicator of performance below aspiration levels. Accordingly, this paper hypothesizes that risk-taking is higher when underperforming against a rival compared to overperforming against a rival, as well as when underperforming against a rival compared to underperforming against other competitors.

To test the proposed relationships, this paper uses archival play-by-play and game level data from the National Football League (NFL) in the USA, since clear rivalries can be identified in the NFL, along with clearly-identifiable performance objectives and empirically established measures for both performance and risk-taking. Linear and logistic regressions are used to test the hypotheses. Initial analyses suggest the presence of a significant interaction between relative performance and rivalry when it comes to predicting risk-taking. Fine-grained results will be available by early next year. We will further examine the role played by the magnitude and significance of the relative performance differential.

This paper will seek to build on rivalry, risk taking, and performance improvement literature. First, this paper will attempt to contribute to rivalry theory by investigating an important boundary condition for the known effects of rivalry. Investigating this is especially relevant because real-life competitions are hardly ever one-off interactions, and performance feedback is often available at various points in the prolonged competitive relationship. Second, this paper will contribute to the literature on performance feedback and social aspirations. Prior work has argued that social aspirations are less consequential for performance feedback due to their scarcity and interpretational ambiguity. In contrast, the present paper points toward one type of social

performance feedback that is likely to be interpreted as a relatively clear and unambiguous indicator of the failure to achieve social aspirations: relative performance with respect to one's rival.

The findings of this paper have important implications for how individuals and organizations cope with the changing world of work, since risk preferences and attitudes are an integral part of managerial and organizational decision-making. Calculated risk-taking will play a significant role in how individuals, teams, and organizations prepare for the future and respond to changing economic, social, and political pressures. Furthering our understanding of the drivers of risk-taking will contribute to the ability to make decisions that lead to greater benefits and fewer adverse outcomes for employees, organizations, and society at large.

Keywords: rivalry, risk taking, relative performance

Oral presentation OP103

Witnessing Workplace Ostracism: The Role of Organizational Dehumanization

Noémie Brison & Gaëtane Caesens | Université catholique de Louvain

science

Research goals

To date, workplace ostracism (i.e., employees' perceptions of being ignored or excluded by others at work; Ferris et al.,2008) has exclusively been examined from the victims' perspective (i.e., experienced workplace ostracism). It was found to negatively influence victims' well-being, attitudes and behaviors (Howard et al.,2020). Recently, scholars suggested that workplace ostracism might also be detrimental to employees who witness ostracizing phenomena (Sharma & Dhar,2020), notably by damaging their employee-organization relationship (Wilkerson & Meyer,2019). Although investigating how witnessed workplace ostracism (WWO) affects observers' organizational perceptions might be necessary to build a full picture of the construct (Mao et al.,2017), no research examined the influence of WWO on observers' organizational dehumanization (OD) perceptions (i.e., employees' perceptions to be treated like tools by their organization; Bell & Khoury,2011). This research aims to explore the relationship between WWO and OD, its boundary conditions (i.e., employees' entitativity) and subsequent consequences (i.e., employees' life satisfaction, affective commitment, and strike intentions).

Theoretical background

On the one hand, WWO is argued to negatively affect observers as they feel the victims' pain as their own (Harvey et al.,2018). Additionally, witnessing workplace incivility entails negative consequences for observers beyond experienced mistreatment (Miner & Cortina,2007). For instance, it is negatively linked to observers' life satisfaction (Glomb et al.,1997), affective commitment (Dupré et al.,2014), and is thought to increase witnesses' strike intentions (Skarlicki & Kulik,2005).

On the other hand, OD impairs employees' psychological strains (Taskin et al.,2019), affective commitment (Stinglhamber et al.,2021) and is thought to promote strike intentions (Brison et al.,2022) as it thwarts employees' socioemotional needs.

Interestingly, scholars suggested that observers of workplace ostracism are likely to blame their organization for fostering a hostile work environment (Wilkerson & Meyer,2019) where their need to belong can be threatened (Dhanani & LaPalme,2019). Hence, we hypothesize that, when controlling for experienced workplace ostracism, WWO positively relates to OD (H1). Since both WWO and OD affect employees' well-being, attitudes and behaviors (Caesens et al.,2017; Sharma & Dhar,2020), we further hypothesize that, when controlling for experienced workplace ostracism, OD mediates the relationships between WWO and observers' decreased life satisfaction (H2a), decreased affective commitment (H2b), and increased strike intentions (H2c).

Additionally, observers are more likely to blame organizations for a member's wrongdoing (e.g., ostracism) when they perceive organizational members as highly entitative (i.e., as a single entity rather than multiple individuals) (Effron et al.,2021). Hence, we hypothesize that the relationship between WWO and OD is stronger when employees' entitativity is high (H3). We also hypothesize that the effect of WWO on observers' decreased life satisfaction (H4a), decreased affective commitment (H4b), and increased strike intentions (H4c) via OD will be stronger when entitativity is high.

Methodology

The hypotheses were tested in two cross-sectional studies using online questionnaires distributed to employees from various organizations. In Study 1 (N =204), H1 and H2a-c were tested. Study 2 (N =345) replicates and extends Study 1 by testing all hypotheses. All variables were measured using original or adapted validated scales (e.g., WWO was measured using an adapted version of Ferris et al.'s (2008) experienced workplace ostracism scale).

Results

In both studies, results of SEM and latent bootstrap analyses provided support for all hypotheses. Yet, the interactive effect between WWO and entitativity surprisingly showed at low levels of WWO.

Limitations

This research relies on self-reported measures, which rises concerns about common method variance bias. Additionally, the cross-sectional design of both studies makes it difficult to draw conclusions regarding causality.

Conclusions/Implications

On top of operationalizing WWO for the first time, this research contributes to the workplace ostracism literature by showing that it affects every employee, not solely victims. This research also adds to the OD literature by extending its nomological network.

Relevance to the Congress Theme

Because OD relates to decreased life satisfaction and affective commitment, and increased strike intentions, it is of utmost importance to implement changes to reduce these perceptions. By showing that WWO is a predictor of OD, this research provides organizations with an avenue to achieve this goal.

Relevant UN SDGs

By focusing on predictors of employees' life satisfaction, this research identifies leverages to improve employees' wellbeing, thereby being relevant to the Good health and wellbeing SDG.

Keywords: witnessed workplace ostracism, organizational dehumanization, entitativity

Oral presentation OP688

Women in aerospace: Perspectives from the lenses of HR specialists

Marta Pinto, Quasar Human Capital, Unipessoal Lda Lisboa, Portugal; Miriam Rosa, Instituto Universitário de Lisboa (ISCTE-IUL), CIS-IUL, Lisboa, Portugal

science&practice

The aerospace sector represents a great economic contribution; however, it faces the challenge of attracting and retaining qualified workers, especially women. STEM (science, technology, engineering, and mathematics) fields experience, in general, gender occupational segregation, which contributes to shortages of workers and their skills, consequently undermining the future of work and workers. This is even more visible in aerospace, being, thus, important to understand why this sector pulls girls and women away.

Several theoretical approaches were proposed in the literature to answer this question. There is a so-called leaky pipeline going from early stages of socialization and education until the first career stages, progressively losing women for STEM jobs. Besides biological gender differences, psychosocial aspects play an important role in those leaks. For instance, gender stereotypes regarding both women (expected to be caring and choosing communal-oriented careers) and STEM jobs (perceived as being agency and problem-solving oriented, which are considered masculine attributes) inform a socialization that matches these stereotypes from parents and teachers, while also create among girls a mismatch in interests. Lack of self-efficacy in STEM courses (e.g. maths) has also been considered. The consequential low representation of women in STEM makes female role-models scarce, which reinforces stereotypes.

This is a complex phenomenon requiring perspectives from multiple stakeholders. An overlooked perspective is that of HR professionals in charge of recruiting, and training workers, and promoting jobs in aerospace among students. This research presents a case study of QSR, a HR consultancy firm in social sciences operating in the aerospace sector. It aims to understand the experiences of women in aerospace as well as the work developed by them on female representation. For this purpose, two qualitative ressources were available in QSR: 1) perspectives from HR specialists and 2) documents. Thus, individual in-depth interview to all (N=9) HR specialists were conducted, as well as a document analysis of the five Research and Development (R&D) projects in which QSR was a team member. The analyses of the collected data were carried out with IRaMuTeQ software, which allowed the mining and visualization of the emerging main themes/classes.

In the individual interviews, after an iterative process of category creation and allocation of excerpts, the software showed six classes in textual analysis: 1) expertise in aerospace, 2) perspectives on gender equality (e.g., role of women in male-dominated fields), 3) interpersonal context in women experiences (e.g. discrimination experiences and support from others); 4) intrapersonal aspects (e.g. voicing and allowing discrimination); 5) QSR and HR professionals' mission, and 6) the influential role of school and teaching. Among these insights, we highlight that low work-life balance was the most mentioned barrier for women to enter and thrive in aerospace (e.g. a field hostile to motherhood), and assertiveness was the most referenced strategy they perceive women use to overcome barriers. Some gender-blindness was also pointed as a strategy used by HR professionals to avoid discrimination.

The documental analysis showed words associated with the inclusion of women in aerospace appearing only in one R&D project. Analysing this report in detail, the following classes were

suggested: historical context of women entering aerospace (e.g. war); organizational facilitators (e.g. mentors); workplace barriers (e.g. pay-gap); and academic barriers (e.g. interest).

In spite of limitations such as focusing in only one company with few workers, thus restricting generalization, these studies provide important messages. They provide insights from the lenses of HR specialists, which is novel (to our knowledge, the perspective of girls and women themselves, teachers and/or parents is more often taken). They highlight initiatives that, in the perspective of these professionals, are crucial to increase women representation in aerospace: networking actions, contact with role-models, and top-down organizational inclusion measures. However, these HR specialists might adopt gender-blind approaches in their practice, which are well-intended and can increase confidence in women, but disregard the effects of past experiences in access to opportunities. In the spirit of EAWOP 2023 conference, this case study highlights that the future of work in aerospace needs skilled profiles that are more out of reach for women due to sexism, and HR specialists need to be part of the dialogue with other stakeholders and disciplines for, together, developing competences and facilitating the attainment of UN sustainable development goals 5 (gender equality) and 8 (decent work and economic growth), given the importance of aerospace for economically prosperous careers and societies.

Oral presentation OP747

Women leaders in family firms: challenges and opportunities

Cristina Alvarado, KU Leuven/Universitat Autònoma de Barcelona; Martin Euwema, KU Leuven; Ana B. Garcia, Loyola University Andalusia

science

Research goals: The majority of businesses worldwide are family firms. Many organizations, and family firms face challenges in inclusiveness and equity when it comes to the role of women, especially in leadership positions. Although family firms are well positioned to enable women to access leadership positions, research on their leadership and the unique challenges they face is still underdeveloped (Maseda et al., 2021). The aim of this study is twofold. First, to understand the main challenges women leaders of family businesses face, and how they cope with and overcome these challenges. Especially regarding career development, specific leadership styles and how they manage intrapersonal, interpersonal and group conflict. Second, increasing our understanding of how women leaders deal with family and business demands would help to empower current and future women leaders in family businesses.

Theoretical background: Becoming influential leaders of their family firms imply women must overcome several challenges related to enhancing their self-confidence and self-efficacy, authenticity, and having legitimacy (McAdam et al., 2020). Being part of a business family might offer women potential easier access to leadership however, there is also the risk of experiencing the "impostor phenomenon" (Shanine et al., 2020), given gender stereotypes and the influence of family ties to be appointed as leaders. Literature reports the advantages of the presence of women in leadership (e.g., emotional strengths, constructive conflict behaviour), which could be extra salient in family firms given their positive impact both family and business (Kubiceck & Machek, 2019). Exploring specific leadership styles (e.g., servant leadership, authentic leadership, autocratic leadership) could advance our understanding of how family context shapes business leadership and how leadership could promote or hinder constructive conflict management (Alvarado-Alvarez et al., 2020; Obi et al., 2020).

Research design: This study adopted a qualitative approach. The participants (n=25) were recruited on purpose from a database of women leaders of Spanish SMEs family firms created for the researchers. Data was collected through in-depth interviews varying from 1,5 to 2 hours of length). A thematic analysis will be used to extract the salient themes related to imposter feelings, leadership development, and conflict management.

Results expected: We expect to obtain themes regarding career development, imposter feelings and cognitions, styles of leadership, and conflict management (e.g., types of conflict, family conflict). A comparative analysis will inform about the differences and similarities across these dimensions considering the age of the participants, the company's size, and the industry or sector. We also expect to draw a rich and complex structure of relationships between the dimensions.

Limitations: The use of purposive sampling gives space to the researcher's bias and the self-motivated willingness of the participants to take part in the study. The specific context (e.g., women leaders, Spain, and family SMEs) motivates further studies in other contexts (e.g., other countries) or comparing groups of women and men.

Conclusions: Understanding how women leaders in family firms develop their career as leaders facing unique challenges because of the intersection of family, management, and ownership roles

contribute to contextualizing leadership and conflict management theories. This study is also relevant for practice because brings empirical evidence for developing mentoring and coaching programs for career development and well-being under a gender perspective.

Relevance to the Congress Theme: This research responds to the call for urgent actions addressed to reduce the gender gap in organizations as family firms by bringing more visibility to the contributions of women leaders and the unique challenges they face.

Keywords: women, leadership, family firms

Oral presentation OP107

Women's Attraction to Top Level Positions: A field study among female government executives in the public sector

Eva Derous & Aylin Kocak | Ghent University

science&practice

Research goals. Women are underrepresented at top levels in organizations (European Comission, 2019), despite research showing that men and women are equally effective in these leadership positions (Eagly et al., 1995). Scholars tried to comprehend this glass ceiling by studying gender biases during selection (Bosak & Sczesny, 2011). However, female candidates can also be prone to biases when deciding (not) to take on a higher role, e.g., because of gender biases in job advertisements. Studies found that gendered language in job ads leads to lower application intention/behavior among women (Born & Taris, 2010; Derous & Wille, 2018). The present study expands this research line in an applied field setting: among government executives.

Background. Building on the theory of symbolic attraction (Highhouse et al., 2007), we investigated whether role, behavioral, and technical requirements (positively or negatively metastereotyped) in existing job ads and their wording (dispositional or situational) withheld female government executives from applying for top management positions. Female executives may believe that others perceive them as less qualified leaders due to their gender (metastereotypes; Vorauer et al., 1998). Hence, ads that require leadership competences might refrain instead of attract female executives to apply. We expected job attraction (H1) and application behavior (H2) to be lower for role (H1a/H1a), behavioral (H1b/H2b) and technical (H1c/2c) requirements that female candidates hold negative metastereotypes about. Building on the linguistic category model (Semin & Fiedler, 1991) we further expected effects on job attraction (H3) and application behavior (H4) to be stronger if role (H3a/H4a), behavioral (H3b/H4b) and technical (H3c/4c) requirements were worded in a dispositional rather than a situational way.

Design & Method. A field experiment with a 2x2 within subjects design investigated effects of metastereotyped requirements (negative versus positive) and their wording (dispositional or behavioral) on job attraction/application behavior of female government executives (N =129). Negative and positive gender metastereotypes regarding the requirements were selected/tested based on a literature review and pilot studies.

Results. Manipulation checks were successful. Mixed Model Analysis showed that, even when controlling for qualifications on the requirements, a negatively metastereotyped requirement in an ad was perceived as less attractive than a positively metastereotyped requirement for the role and technical requirements but not for the behavioral requirements (H1a/H1c supported, H1b unsupported). There was no interaction between type of requirement and wording on attraction for role and technical requirements (H3a/H3c unsupported). For the behavioral requirements, there was a significant interaction between type of requirement and wording, such that type of requirement had no effect on attraction when the wording was behavioral, yet when a dispositional wording was used, a negatively metastereotyped requirement was significantly less attractive than a positive one (H3b supported). Generalized Estimating Equation analysis showed that, when controlling for qualifications on the requirements, application behavior was higher when the job ad contained positive compared to negative role and technical requirements (H2a/H2c supported), but not for behavioral requirements (H2b unsupported). No interactions were found between type of requirement and wording for role and technical requirements (H4a/H4c unsupported), but there was

an interaction between type of behavioral requirement and wording such that a negative metastereotype only led to lower application if worded in a dispositional way (H4b supported).

Limitations. Although participants were executives of a wide variety of departments in the government organization, this study only focused on one government organization. Future research could also include other (private) organizations.

Conclusions. Findings are in line with the theory of symbolic attraction (Highhouse et al., 2007) and findings from Wille and Derous (2018) and indicate that effects of metastereotypes in ads hold in a field setting. For behavioral requirements, results supported the linguistic category model and showed that a dispositional wording can have negative effects on attraction and application behavior. Organizations that wish to obtain more women on top level positions should carefully consider which words to use in job ads and avoid dispositional wording of person requirements.

Conference theme. This study aims to uncover early barriers in women's promotion to top level positions by studying metastereotypes in existing job ads from a large government organizations. This way, we can make tailored recommendations to this government organization on how to better formulate job ads to gain more women at top level positions.

Oral presentation OP568

Women's Careers in Policing: factors supporting and hindering career progression and what the police can do about it

Laura Longstaff, Northumbria University; Jo Nelson, Large UK Police Force; Catherine Stephens, Large UK Police Force; Jo Faichney, Newcastle University; Andrew Clements, Aston University; Vicki Elsey, Northumbria University

science&practice

The current research, conducted in partnership between academics and practitioners from a large UK Police Force, aims to understand the factors which support and hinder women's career progression in the Force, and explores the ways in which the research findings have informed practice. This research provides contextual information which can support the career progression of women by understanding; in their own words, the barriers that they face. In addition, our data explored rank, race, sexual orientation, gender identity and caring responsibilities in line with recommendations to explore intersectionality and factors other than oversimplifications made by gender alone (Sharheim, 2019).

Women's career progression has been made prominent by #metoo, pay gap reporting and the motherhood penalty (Morgan, 2015). In policing, research has observed gender differences in the promotion process in Australia (Drew & Saunders, 2020), gender and culture challenges in Canada (Murray, 2021), implications of police transformation for women officers in the UK (Brown & Silvestri, 2019), as well as understanding how women have successfully navigated their careers in policing in the USA (Morabito & Shelley, 2018). At a recent US summit, barriers to promotion for women in policing were discussed and ranged from lack of confidence to pervasive 'masculine' culture (Sharheim, 2019).

In the UK, policing is by consent (Home Office, 2018) with a key goal to ensure that the 'police are the public and the public are the police' ensuring appropriate representation within forces (Boag-Munro, 2017). The theory of representative bureaucracy explains the importance of diversity in public organisations (Bradbury & Kellough, 2010). In the UK in 2020, women were 31% police officers, 33% police constables, 22.5% Chief Superintendent and 29.4% Chief Officer. The Force involved in this study has diversity and inclusion and improving community representation as a strategic priority.

Women in policing face multiple career challenges, partly due to the pervasive view that promotions are positive discrimination, therefore even when women are promoted, believing this was because of gender and not ability (Archbold & Moses Shultz, 2008). Women also experience reduced confidence coupled with 'second shift' or family responsibilities and a lack of resources making promotion seem like an impossible feat (Archbold & Hassell, 2009; Benard, 2008; Gale, 2013; Dugan & Barnes-Farrell, 2020; Trappe et al, 2015). The 'ideal worker' and 'ideal parent' model help explain women's career progression, often epitomised by part-time work and gaps following parental leave, in contrast to the 'ideal police worker' who is full time with continuous and unbroken service (Silvester, 2017).

An online qualitative survey was distributed to women in the force in Spring 2020. Participants responded to free text questions about their expected and desired rank, their feelings about their career and availability of support. There were 166 completed questionnaires (125 with demographic data). Our sample was primarily white (82%), Police Constable (50%), with children under 16 (36%) or no caring responsibilities (28%), heterosexual (72%), with an undergraduate degree or similar (42%). Data was analysed using inductive content analysis.

Results were categorised into three broad themes of:

Culture : masculinity, face fitting, tokenism and individual responsibility for career development.

Family considerations : the gendered nature of work, role flexibility and the importance of good manager relationships.

Promotion process : challenges finding time to study, the recruitment process for promotion, mentoring and the desire not to move away from front line policing into management.

Further analysis of these headline themes is currently underway and will be presented at the conference. Additionally, we will share how this information was triangulated with exit interviews and coaching feedback to inform practice and policy in the force.

Our initial study aimed to look at the intersection between race and gender, yet representation of BAME individuals was low. This led the researchers to question how to reach BAME individuals and encourage participation in research. The sample here was predominantly white and therefore further research is needed to ensure we reach (and receive the trust of) a diverse audience.

The academic/practitioner partnership is unique and enabled an evidence-based approach to support the force to identify strategies to understand and enhance the career progression of women. Insights were offered into common challenges such as how to communicate regarding equality, diversity and inclusion, e.g., the difference between positive action and positive discrimination. In context findings add to the research literature which can be utilised by other forces around the world to understand the perceptions, barriers and facilitators to women's career progression.

Keywords: Womens Careers, Barriers, Facilitators

Oral presentation OP307

Work Adaptability Among Older Workers – A Review and Research Agenda

Sarah Darlene Mullen & Andreas Hirschi | University of Bern

science&practice

Aim and objectives Workers aged 55 to 64 are increasing and are set to equal one-quarter of the global workforce by 2030 (Harasty & Ostermeier, 2020). Accordingly, it is crucial to advance the understanding of what factors help older workers to adapt effectively to their working conditions. The current review aims to generate new knowledge through a critical and systematic review of the existing literature on career adaptability among older workers. By identifying findings and perspectives from a broad range of empirical studies, the review highlights commonalities, and differences by depicting the antecedents, processes, conceptualization, and outcomes of older workers' career adaptability.

Theoretical background Career adaptability is an important resource in coping with changing work conditions, such as managing career-related tasks, transitions, and work traumas (Savickas, 2005). Given its relevance for favorable work outcomes such as e.g., career performance (Rudolph et al., 2017), research lacks an understanding of how and why career adaptability plays a crucial role in the careers of older workers. While it is conceivable that age-related losses restrict, and age-related gains foster, older workers' ability to deal with the challenges in their careers (Fasbender et al., 2019), career adaptability may vary as a function of age. In addition, because individuals allocate their resources for the regulation of age-related losses (Baltes et al., 2006), there is a need for a clearer understanding of critical factors associated with how older workers regulate career adaptability resources to ensure proper functioning.

Method The systematic review included peer-reviewed articles, cross-sectional and longitudinal data, and intervention studies. The search terms were as follows: career adaptability, work adaptability, work adjustment, older workers, older employees, career construction, retirement, work behaviors, aging workforce, late-career planning.

Results The results reveal that career adaptability is an essential construct among older workers, which might facilitate their late career development and transition to retirement. We also outline several avenues for future research to advance the understanding of career adaptability in the late career.

Limitations The current review focused on empirical peer-reviewed papers, which are identified with the used keywords in the selected research fields. More general research on aging and life adjustment was not the focus of this work.

Conclusion The article concludes by demonstrating knowledge and understanding of the role of career adaptability among older workers and offering several suggestions for future research, highlighting the theoretical, practical, and empirical contributions that future work in this domain could make.

Relevance to the Congress Theme Contemporary workplaces require individuals to construct their careers and acquire career adaptability more actively, yet the convergence of changing global demography brings challenges for companies and individuals alike. The role of career adaptability may address the challenges associated with an aging workforce on an individual and broader contextual level.

Relevant UN SDGs Age-related losses across the lifespan are unavoidable and age discrimination are still common in the workplace today. By incorporating findings to specify the questions of the core theories, processes, antecedents, and outcomes of career adaptability among older workers, the current review addresses the inequalities of older workers in the workplace by providing a greater understanding of age and adaptation, i.e., how older workers better engage in work which allows for maximizing older workers' advantage. This contributes to the UN SDGs of "decent work and economic growth" and "reduced inequalities."

Keywords: Career adaptability, Older workers, Aging workforce

Oral presentation OP642

Work Design, availability of psychological resources during work, and health

Alice Nöh, Wuppertaler Institut für Unternehmensforschung und Organisationspsychologie (WIFOP) of the Bergische Universität Wuppertal

science&practice

Research Goals. In a fast changing work environment, it is vital to identify key factors of work affecting employees' well-being and their ability to focus. By that, creating a health promoting and skill enhancing work environment and tasks will be possible, even if circumstances change quickly (e.g. introducing home office during and after pandemic). The goal of this research was to see how work design on the one hand and regulation hindrances on the other hand affect well-being at work and how that affects employees' mental health.

Theoretical background. Three key factors of psychological work design are being researched: task demands, scope of action and regulation hindrances. Tasks that present different levels of cognitive challenge, as well as the opportunity to decide for oneself which tasks to do and how, are signs of complete work assignments (Hacker & Sachse, 2014). Regulation hindrances, however, can be seen as risk factors: they interrupt or hinder the flow of work, disrupt concentration and create uncertainty and frustration, e. g. in the form of unclear work assignments or lack of feedback, forcing employees to spend time and resources they actually need to perform their tasks on resolving these obstacles (Zapf & Semmer, 2004). While well-designed work situations enable employees to access and use more of the psychophysical resources required for task completion, monotonous, tightly predetermined and often interrupted unclear tasks take away positive mental and motivational states (e.g. attention, concentration) and reinforce negative emotional and physical states (e.g. nervousness, physical discomfort; Wieland, 2013). These momentary states reflecting resource availability during work in turn affect long-term health: the more effort required to reach a state where one is able to perform a task, the more exhausted one is (Bakker & Demerouti, 2007). However, psychophysical health problems are rarer when positive states predominate (Hammes, 2015). The ability to manage one's own health can make it easier to cope with poorly designed work conditions (Hammes & Wieland, 2012b). Based on the five-by-five effect model (Wieland & Hammes, 2014), the state of resource availability during work is expected to mediate the influence of task design (*hypothesis 1*) and regulation hindrances (*hypothesis 2*) on the frequency of psychophysical health problems. Individual health competence is expected to moderate the influence of task design (*hypothesis 3*) and regulation hindrances (*hypothesis 4*) on the state of resource availability during work.

Methodology. Data was collected in twelve different production and service companies as a cross-sectional study within the framework of workplace health promotion projects online and by means of paper questionnaires (N = 2 488). Data analysis was conducted using two moderated mediation analyses.

Results. The better the tasks were designed (predictor 1), the more psychophysical resources were available during work and the less frequently psychophysical health problems occurred. The direct correlation of task design with health impairments disappeared when the mediator resource availability was added. The correlation of task design and health problems was mediated by resource availability but not moderated by health competence (*hypothesis 3*). The more regulation hindrances were present (predictor 2), the fewer psychophysical resources were available during work, leading to more frequent psychophysical health problems. Although there was a direct correlation between

regulation hindrances and psychophysical health problems, this was mediated by resource availability. The relationship between regulation hindrances and resource availability was slightly moderated by individual health competence. High individual health competence could buffer the negative influence of regulation hindrances on resource availability during work, especially if many regulation hindrances are present (*hypothesis 4*).

Limitations. As this is a cross-sectional study, caution should be exercised when interpreting causal relationships. Only German companies participated in this study.

Conclusions. Both health-promoting and health-impairing effects of working conditions can essentially be attributed to the indication that they either strengthen or weaken the state of resource availability during work, which points to a predictive role of the quality of work design and supports important correlations within the five-by-five effect model. While varied task demands and scope of action are to be promoted to an appropriate extent, regulation hindrances are to be reduced as much as possible. An additional strengthening of individual health competence should make it easier to deal with “unavoidable” regulation hindrances that often accompany major changes in companies. This research links science to practise, as the used model is also applied in psychosocial risk assessment in companies.

Keywords: task design, regulation hindrances, psychophysical resources

Oral presentation OP362

Work engagement in healthcare workers during the COVID-19 pandemic in the Netherlands

Margot Joosen, Tilburg University, Tilburg School of Social and Behavioral Sciences, department Tranzo; Steven Kilroy, Trinity College Dublin; Karen Keijsers, Jeroen Bosch Hospital, Den Bosch, The Netherlands; Lena Horn, Tilburg University, School of Social and Behavioral Sciences

science&practice

Research goals :

The COVID-19 pandemic has placed great pressure on healthcare systems and societies around the globe. Intense and extended stress responses during crises like these can have short and long-term effects. The ability of healthcare workers to effectively cope with stressors is vital for their patients, their families, and themselves. It is of importance to improve the mental health and resilience of healthcare professionals, to combat the aftermath of the COVID-19 crisis and possible future crises.

This study explores the impact of the COVID-19 pandemic on healthcare workers' wellbeing and engagement at work and to provide recommendations to healthcare workers and hospital managers to maintain or improve the health and wellbeing at work. Specific research aims are: 1) to examine the levels of work engagement experienced by hospital employees in the Netherlands at 2 time-points during the COVID-19 outbreak, 2) to explore differences in work engagement levels between medical and non-medical employees (and the different occupational groups within each) at both waves, and 3) to examine potential predictors of work engagement among all hospital employees during the COVID-19 outbreak.

Background :

The COVID-19 pandemic has been linked to a great deal of anxiety, exacerbation of mental illnesses, social isolation, and feelings of helplessness among individuals (Sahebi et al., 2021). For healthcare workers these outcomes are believed to be even more severe, due to the high vulnerability of healthcare workers working with COVID-19 patients and increased work stress and workload (Badahdah et al., 2020; Cao et al., 2020). Despite the emerging research on the impact of COVID-19 on the well-being of healthcare workers, two important issues remain understudied. First, little emphasis has been given to the potential impact of the Covid-19 pandemic on non-medical workers in healthcare settings (e.g. cleaning- and logistic staff, lab workers, managers). Second, insight into potential positive effects and positive outcomes (e.g. engagement and team support) is less profound. Yet, these positive effects are interesting to explore since they can play an important role in helping healthcare workers cope better when confronted with difficult situations (e.g. the COVID-19 pandemic).

Design and methods :

A cross-sectional study was conducted using data from two cohorts; at two time-points (COVID-wave 1 cohort in June 2020 and COVID-wave 2 cohort in November 2020), a survey was conducted among all ~6000 hospital employees of a non-university hospital in the Netherlands.

Main outcome measurement was work engagement (UWES). Furthermore, potential prognostic variables were work pressure (Job Content Questionnaire), co-worker support (VBBA) and preparedness for traumatic events (Bank et al, 2018). To explain the key outcomes among the different occupational groups, employees were divided into medical employees (doctor, nurse

specialist/physician assistant, allied health professional and trainee) and non-medical employees (manager, staff, supporting staff with patient contact, and supporting staff without patient contact).

Analysis of variance (ANOVA) tests will be used to compare the outcomes for various job types while controlling for age and gender. To examine which employee outcomes are prognostic factors for work engagement, multivariable regression analysis will be conducted.

Results :

In total, N=1980 hospital employees were included in the COVID-wave 1 cohort and n=1261 hospital employees in the COVID-wave 2 cohort. Preliminary results show that the overall levels of work engagement were considered average for both cohorts (COVID-wave 1: M = 3.92, SD = 0.82; COVID-wave 2: M = 3.88, SD = .95) for both job types (medical vs. non-medical) compared to Dutch norms (Schaufeli & Bakker, 2004). Further results concerning potential significant differences between mean scores of engagement (subscales) across job types and prognostic employee factors for engagement will be available end of 2022.

Conclusion:

Although the cross-sectional nature of the study and inability to match respondents from time 1 and time 2 should be recognised as a limitation, this study provides relevant insight into what factors are paramount for ensuring that healthcare workers remain healthy at work and how resilience can be improved. Knowledge of this nature will assist healthcare managers and policy makers in taking care of their staff during the aftermath of COVID-19. These results can also inform managers in preparing healthcare workers for the ongoing transformation in healthcare where healthcare demands are rising and resources are becoming increasingly scarce.

Keywords: Health care, Covid-19, workers' engagement

Oral presentation OP454

Work interrupted: The dual nature of daily work interruptions and the moderating role of daily perceived overqualification

Barbara Körner, Leeds University Business School; Martin Kleinmann, University of Zurich; Maike E. Debus, University of Neuchâtel

science

Research goals: Currently, there is a consensus in the literature that interruptions are largely harmful (e.g., Puranik et al., 2020). This theoretical perspective considers interruptions during the workday as hindering task completion, thereby eliciting negative outcomes later in the day such as negative affective states, reduced well-being, and reduced performance (e.g., Puranik et al., 2020). Yet, a more recent perspective challenges the above ideas, putting forward the notion that work interruptions might at times also have beneficial aspects due to the fact that they may provide key information that can boost interrupted employees' goal progress, thus leading to positive outcomes for employees (Puranik et al., 2020; Sonnentag et al., 2018). Thus far, these perspectives have been considered rather separately in the literature, leaving open how interruptions can trigger employee reactions that are more ambivalent in nature. In the present study, we unite both pathways – thereby drawing on cognitive appraisal theory that provides a suitable theoretical basis to examine work stressors that might cause ambivalent reactions.

Theoretical background: Following cognitive appraisal theory, we posited that daily work interruptions are comprised of both threat (i.e., increased daily negative affect) and challenge (i.e., increased daily work goal progress) aspects, thus leading to opposing effects on outcomes (i.e., daily job satisfaction, daily creative process engagement, and daily work-private life conflict). We further proposed that if an employee perceives themselves to be overqualified for that day's work, this will constitute a resource surplus that buffers the threat aspects and amplifies the challenge aspects of daily work interruptions.

Research Design: We collected daily diary data over 10 workdays from 213 employees.

Results: Results showed that daily work interruptions were positively related to daily negative affect and positively related to daily work goal progress. Moreover, results showed significant indirect effects of daily work interruptions on daily job satisfaction and daily work-private life conflict via daily negative affect as well as significant indirect effects of daily work interruptions on daily job satisfaction and daily creative progress engagement via daily work goal progress, Further, higher levels of daily perceived overqualification than on average buffered the positive relationship between daily interruptions and daily negative affect.

Limitations: Although daily diary designs provide strengths, there are some limitations. For example, despite separating the measurements of study variables across two daily surveys to address common-method bias, we cannot claim causal effects. Furthermore, data from the two different daily diary surveys came from the same sources and therefore, common-source bias might have affected our study results.

Conclusion - Research and Practical Implications : Our study advances theory on the stressor-strain relationship by emphasizing the need to specify how different stressors can activate functionally different psychological pathways. Results further highlight that daily work interruptions are ambivalent in their nature. Moreover, we showed that perceptions of overqualification vary between days and that daily perceived overqualification acts as a resource when dealing with work

interruptions. By adding this micro perspective to research on perceived overqualification, our study provides evidence on potentially beneficial aspects of perceived overqualification. Lastly, companies should offer trainings for employees that detail positive and negative aspects of interruptions as well as related consequences. In doing so, employees may acquire the knowledge to decide on a case-by-case or day-by-day basis how to deal with interruptions. Moreover, companies should find ways to facilitate the informal exchange of information between colleagues and supervisors/employees that comes with interruptions and which can bolster work goal progress.

Relevance to the Congress Theme ： Within a changing and evermore interconnected world of work, work interruptions are one of the most pertinent task-related stressors (e.g., Puranik et al., 2020; Sonnentag & Frese, 2013). Thus, it is crucial to understand how employees are affected by interruptions and how they can effectively cope with being interrupted to navigate the changing world of work.

Relevant UN SDGs: This work is relevant to the ‘ Good health and wellbeing ’ UN SDG goal, as it addresses how employees can cope with interruptions at work as one of the most pertinent work stressors in modern day work. Moreover, this research is related to the ‘ Decent work and economic growth ’ UN SDG goal as it relates to the question how demands of a growing and changing economy impact employees’ working conditions.

Keywords: stress, work interruptions, perceived overqualification

Oral presentation OP22

Work well, sleep well? The complex relationships between person-job fit and sleep

Olga Kombeiz & Zsofia Zab | Loughborough University

science&practice

Research goals and why the work was worth doing. In the present study, we examined the interplay between person-job fit and self-efficacy on job stress and indirectly on sleep quality. Theoretical perspectives and previous empirical findings suggest that a holistic approach is needed when examining the relation between key factors at work and sleep quality. Therefore, we focused on person-job fit, an approach that considers the fit between individual abilities and characteristics of the jobs' tasks that are performed at work. Building on previous research surrounding the negative relationship between job stress and sleep quality, we also took job stress into account and examined it as an underlying mechanism between person-job/self-efficacy interaction and sleep quality.

Theoretical background. Poor sleep quality has been shown to have negative consequences for individuals and organisations such as poor job performance, counterproductive work behaviour and accidents. Thus, in order to improve well-being of employees and the performance of organisations, there is a need to identify key factors at work that can lead to impaired sleep. Previous research provides mixed findings around relation between job characteristics and sleep quality, indicating a) a need for a holistic approach and b) existence of moderating variables. Person-job fit considers the match between the job tasks and individual abilities and/or preferences, providing thus a broader focus than just looking at job characteristics. Self-efficacy is individual's confidence about their own abilities to compete specific tasks and has previously been shown to influence the perception of job situiations. In present study, we expect self efficacy to moderate the relation between person-job fit and job stress such that it will strengthen the negative relationship and in turn influence the sleep quality.

Design/Methodology. In a cross-sectional field study (N = 177) the complex relationships between person-job fit, self-efficacy, job stress and sleep were examined. Participants aged between 18 and 65 years filled in an online questionnaire, assessing their current work situation, self-efficacy, stress perception and the sleep quality.

Results. The results revelated that the interactive effects of person-job fit with self-efficacy on job stress and in turn on sleep quality were significant. As expected, good person job fit led to less job stress and better sleep quality only for employees with high self-efficacy.

Limitations. The study was conducted within a cross-sectional design; thus, the causality of the effects remains uncertain. Future research could examine whether the results can be replicated with a larger sample and in a more controlled setting, for example as a laboratory study, obtaining internally valid findings or within a time-lagged design.

Research/Practical Implications/ Originality/Value. The present research investigated how the interaction between person-job fit and self-efficacy impacts sleep quality via job stress. We obtained externally valid (field study) findings and demonstrated that a combination of a good person-job fit and a high self-efficacy can be a key to less job stress and good sleep quality. These findings supplement previous research by creating a new approach to the discourse surrounding how person job fit might impact sleep. The present study can also be the basis of further research that allows for practical implications in development and training of employees regarding their self-efficacy.

Relevance to the Congress Theme. In order to promote success of organisations, we need to focus more on employees' needs. Present research demonstrates that development of specific competencies such as self-efficacy, might increase the sleep quality of employees, which has previously been shown to be related to many positive work outcomes.

Relevance to UN SDGs: Present research is relevant to promotion of goals of wellbeing and health, as well as decent work and economic growth.

Keywords: Person-job fit, self-efficacy, sleep quality

Oral presentation OP536

Work Well-Being in Expatriates: Investigating Developmental Trajectories of Exhaustion and Vigor

Tania Biswas, Samu Kemppinen, Liisa Mäkelä | University of Vaasa

science&practice

The world of work is continuously changing, forcing organizations to recognize the importance of a global workforce. Discussions around managing this international mobility of highly skilled people and accessing the availability of human capital have generated debates of great magnitude across the world. Multinational organizations benefit from highly skilled expatriates, as they bring competitive advantages to the employers and the potential of international economic exchange and cross-cultural development. The work well-being of these global talents is an essential antecedent for their productivity and ability to perform well, and therefore novel knowledge about expatriates' work well-being is needed. Expatriates operate in a unique and challenging environment, where a great deal of demands and stress are imposed on them daily. Research has shown that job exhaustion (negative indicator) and vigor (positive indicator) are the most essential dimensions of job burnout and work engagement - elements of work wellbeing. Job exhaustion and vigor are often studied in domestic work well-being literature and have also been found to be relevant when studying expatriates. Expatriates are likely to experience both engagement and burnout simultaneously, because of the constant new challenges and requirements they face. Under these unique working conditions, it is possible to find expatriates who are highly engaged in their work, but at the same time experience exhaustion due to work demands. However, identifications of simultaneous profiles of work engagement and burnout are rare overall, and nonexistent in expatriate literature.

Experiences from expatriation work affect work well-being. Even though studies have highlighted that working abroad has transformative influence on individuals, providing a possibility to explore the meaning of their expatriation experiences and changing their perception of identity, little is known how these kinds of experiences link to their work well-being. In this study, we focus on the meaningfulness of expatriate work, in particular, the perceptions of meaning making(MM) that their work abroad provides for expatriates personally, and how it links to their work well-being in terms of exhaustion and vigor. MM is an appropriate job resource in the context of expatriation as it has been found to involve several positive elements, such as learning and development opportunities on a professional and personal level, interesting tasks involving wider responsibilities than occur in the home country, and some studies show evidence that these kinds of issues are related to positive outcomes such as career success.

Following Conservation of Resources (COR) theory,we perform latent profile analyses (LPA) on a three-wave longitudinal dataset from 416 Finnish expatriates to identify the configurations of exhaustion and vigor among an expatriate population, for example, subgroups of the sample experiencing high levels of vigor coupled with high levels of exhaustion, or subgroups experiencing low exhaustion along with high vigor, etc. This approach helps to provide a holistic understanding of work well-being among the studied group. We identified the existence of three exhaustion-vigor profiles; profile 1, labeled "Stable" (n = 240, 58%), indicated stable low levels of exhaustion and stable high levels of vigor; profile 2, labeled "Unenergized" (n = 43, 10%), presented stable medium levels of exhaustion and vigor and finally, profile 3, labeled "Risky" (n = 133, 32%), indicated a stable high level of exhaustion and decreasing high level of vigor.Further we demonstrated that meaning making (MM) through work predicts the developmental profile membership in exhaustion-vigor continuum. Expatriates with higher levels of MM were more likely to display characteristics from

either stable or risky profile of exhaustion-vigor continua rather than the unenergized profile.Results showed high proportion of expatriates belonged to a risky group, experiencing both high exhaustion and high vigor. This particular group of expatriates are simultaneously exhausted and vigorous all while experiencing meaning of life through their work. However, their levels of vigor have found to be dropping overtime thus indicating that such state of being exhausted and vigorous at the same time could be risky and unstainable in the long run even though they have a meaningful job.

Our contribution is threefolds: first, we examine exhaustion and vigor utilizing a person-centered approach, examining the development of workplace well-being among individuals, particularly in the international work context. Second, the profiles of exhaustion and vigor are studied simultaneously, which provides naturally occurring longitudinal subgroup combinations of expatriate population. Third, we contribute to the knowledge of how perceptions of meaning making through expatriate work are associated with different longitudinal exhaustion-vigor profiles.

Keywords: Expatriates, meaningful work, latent profile analysis

Oral presentation OP242

Worker Safety and Health Training in Relation to the United Nations Sustainable Development Goals

Michael Burke, Tulane University

science&practice

The purpose of this presentation is to discuss how key research contributions and best practices regarding worker safety and health training can assist others in making progress toward the accomplishment of select United Nations Sustainable Development Goals. This presentation will be organized around the goals and targets associated with GOOD HEALTH AND WELL-BEING (Goal 3) and DECENT WORK AND ECONOMIC GROWTH (Goal 8), as research and practice on worker safety and health training relates directly to these goals and specific objectives. For each target, the presentation will emphasize exemplary research and practice efforts regarding safety and health training as indicated below.

Goal 3: GOOD HEALTH AND WELL-BEING: Ensure healthy lives and promote well-being for all at all ages.

3.4 By 2030, reduce by one third premature mortality from non-communicable diseases through prevention and treatment and promote mental health and well-being.

This discussion will highlight how training programs can be developing and implemented for both workers and supervisors to assist them in adapting well (i.e. preventing mental health problems) in the face of adversity, trauma, tragedy, or sources of stress. As an example, an application and evaluation of a disaster worker resiliency training program developed by the U.S.'s National Institute of Environmental Health Sciences and the Substance Abuse and Mental Health Services Administration will be provided.

3.5 Strengthen the prevention and treatment of substance abuse, including narcotic drug abuse and harmful use of alcohol.

Given worldwide concerns associated with the opioid crisis, this discussion will focus on current research and ongoing worker awareness training programs that focus on primary prevention and empowerment of workers to take care of themselves and their co-workers in regard to opiate use. A safety training example from the construction industry, which has been hit particularly hard by the opioid crisis, will be provided.

3.6 By 2020, halve the number of global deaths and injuries from road traffic accidents.

Globally, the number of road traffic deaths continues to rise steadily, with the problem being particularly severe in low and middle-income countries and with respect to incidents involving professional truck drivers. This discussion will highlight how safety training for truck drivers is being conducted to teach defensive driving strategies to avoid collisions. The discussion will also note how work psychologists are advancing practice through safety climate research to enhance the positive transfer of safety training for professional truck drivers.

3.9 By 2030, substantially reduce the number of deaths and illnesses from hazardous chemicals and air, water and soil pollution and contamination.

This discussion will focus on how work psychologists have defined the domain of safety performance for hazardous waste workers and emergency responders and how their research has identified best

practices for training these workers. In addition, this aspect of the presentation will point out that hazardous waste worker training is a critical element for preparing workers to deal with climate-related hazards and natural disasters. Thus, the discussion will also be tied to how work psychologists' contributions can be employed to assist others in achieving United Nations Sustainable Development Goal 13 on CLIMATE ACTION (i.e., Take urgent action to combat climate change and its impacts) and Target 13.1 "Strengthen resilience and adaptive capacity to climate-related hazards and natural disasters in all countries."

Goal 8: DECENT WORK AND ECONOMIC GROWTH: Promote inclusive and sustainable economic growth, employment and decent work for all.

8.8 Protect labour rights and promote safe and secure working environments for all workers, including migrant workers, in particular women migrants, and those in precarious employment.

On a worldwide basis, researchers and practitioners have stressed that there are often considerable barriers to the acquisition and use of safety knowledge for minorities, immigrants, and indigenous peoples in safety-critical work. The discussion here, using an example of workforce preparation for cleaning up the Deepwater Horizon Oil Spill, will indicate how researchers and practitioners designed and delivered training to remove such barriers and promote the safety and health of all workers (i.e., Asian (Vietnamese), Blacks, Hispanics, Isleños, and Whites). Notably, this discussion will provide examples for how government policy makers can incorporate findings from behavioral research on safety and health training into guidance documents for worker safety training.

Oral presentation OP684

Workers' age and their contribution to innovation in organisations

Reidar J. Mykletun, University of Stavanger Business School

science&practice

Organisations are in constant need for innovations (Rosenbusch et al., 2011). However, the workforce is ageing and there are wide-spread beliefs that the ability to innovate and the openness to changes decline with increasing age (Appelbaum et al, 2016; Harris et al, 2017; Ng & Feldman, 2013). Norwegian time series studies show that between 55 and 65 % of the leaders prefer involving younger workers when new technologies and methods are to be introduced (Ljunggren et al., 2021). Thus, through this practice of age discrimination , older workers might become marginalised in innovation processes, impairing their motivation, competence development, and employability, and the organisations must rely on decreasing numbers of individuals for their needed innovations. Against this backdrop, this research aims at revealing the role of workers' age in organisational innovations. The study report on relationships between innovation and workers' age, taking into consideration the effect of organisational leadership, autonomy, predictability, innovation climate, age of teammates, age discrimination, engagement, openness, and satisfaction with own performance.

Theoretical background

Innovation is here defined as idea development, support for co-workers' ideas, and participation in idea implementations (Jansson, 2000), operationalised accordingly, and briefly named innovative behaviour . A worker's leeway for innovative contributions depends on organisational, team level, and individual factors (Amabile et al., 2016; Blomberg et al., 2017; Rietzschel et al., 2016). Research has found positive (Ng & Feldman, 2013), negative (e.g., Lehman, 1943; 1960) or no relationships (e.g., Fischer et al., 2019; Liu et al., 2016) between age and innovation. Methodological weaknesses exist (Frosch, 2011), most studies have been on workforce in one or a few companies, and few studies are conducted on representative samples of workforce populations. The present study expected workers' age to relate positively to innovative behaviour due to older workers' accumulated insight in their work processes and own organisation. Further, the study expected several factors perceived as being on organisational, team, and individual levels, as listed above, to predict innovative behaviour in organisations.

Design/Methodology

Data were collected in 2021 by questionnaires to a representative sample of Norwegian workers aged 20 – 74 years (N=1531). Innovation was measured by nine items (Janssens, 2000; Van der Vegt & Janssens, 2003). Three items measured idea development (α=.84), support for co-workers' ideas (α=.89), and participation in implementations of ideas (α=.88), respectively. Leadership was measured by an LMX-scale (Glasø et al., 2015). QPS-Nordic ADW (Pakin et al., 2008) was used to measure Autonomy (α=.76), Predictability (α=.80), Openness (α=.81), Satisfaction with own performance (α=.73), and Work ability (α=.77). Innovation climate was measured by The Organizational Climate Measure (OCM)" (Patterson et al., 2005), (α=.89). Age discrimination was measured by NADS (Furunes & Mykletun, 2010), (α=.82), Engagement by UWES-3 (Schaufeli et al., 2019), (α=.81). Data were analysed by correlations and multiple hierarchical regression, entering age in the final step.

Results

Idea development, support for co-workers' ideas, and implementations of ideas were strongly correlated (r=.68 - .81). Workers' age was unrelated to these innovation behaviour variables but correlated to all predictor variables except LMX and Work ability. Idea development was predicted by Autonomy (β=.18), Predictability (β=.07), Innovation climate (β=15), Age discrimination (β=.08), Engagement (β=.10), Openness (.19), Satisfaction with own performance (β=.13), and weekly working hours (β=.07). S upport for co-workers' ideas was predicted by LMX (β=.07), (Autonomy (β=.19), Innovation climate (β=22), Engagement (β=.12), and Openness (.22). Implementations of ideas was predicted by Autonomy (β=.21), Predictability (β=.07), Innovation climate (β=21), Age discrimination (β=.07), Engagement (β=.09), Openness (.16), Satisfaction with own performance (β=.08), and weekly working hours (β=.08). The models accounted for 24 % of the Idea development variance, 34% of the Support for co-workers' ideas variance, and .31 % of the S upport for co-workers' ideas variance .

Limitations

The findings rely on self-reports and the same method of measurement.

Conclusions

Workers' age is unrelated to innovative behaviour in the Norwegian working population. Instead, innovative behaviour is predicted by autonomy, predictability, positive leader-member interaction, and innovation climate as perceived contextual factors, and openness, satisfaction with own performance and engagement as individual factors. Organisations might profit from including workers of all ages in innovation processes.

Relevance to the Congress Theme

The study addresses the core of the congress theme – change.

Keywords: Ageing workers, innovation, age discrimination

Oral presentation OP82

Work-family conciliation practices and supervisor support: a weekly study

Daniela Geraldes, Vânia Sofia Carvalho & Maria José Chambel | Faculty of Psychology of University of Lisbon (Portugal)

science

Given the prevalence and continued growth of work-life balance as a theoretical and empirical concept, strategies such as work-family practices, created to improve the relationship between work and family/personal life domains (e.g., flexibility policies, dependent care support, leave arrangements, etc.) had been implemented. However, despite some organizations offering the possibility to use these practices, the actual use by employees is dependent on different organizational context' variables, namely the support and acceptance of supervisors to their utilization. Accordingly, and given the already-known importance of work-family culture support and, therefore, the positive impact of these factors on individual and organizational outcomes, this study has as its main objective the understanding of the supervisors' impact on the actual use of work-family policies, along with the impact on boundaries management and employees' well-being. To explore this interconnection more fully, this tests a weekly study for four weeks as a methodological approach to understand if having different levels of supervisor support along the weeks impacts the employees' use of work-family policies differently and, therefore, the boundaries management and consequent well-being. Specifically, with a sample of employees from a Portuguese bank institution (participant number to be defined), until the middle of 2023 and, through quantitative and statistical methods, we aim to determine: (i) whether there is an explanatory role of supervisor support in the employee's use of work-family practices; (ii) if there is an explanatory role of supervisor support in the employee's boundary management behaviours (i.e., work-family boundary control and work-family segmentation behaviours) and (iii) understand how this interconnection is related to well-being at work (i.e., burnout and engagement) and beyond work (i.e., satisfaction with life and satisfaction with family life). Despite the homogeneous sample as a possible limitation, this study contributes theoretically and empirically to the work-life framework. Firstly, it is important to point out the methodological and innovative contribution of a weekly study regarding work-family practices and supervisor support. Moreover, it extends the existing literature on the above-mentioned relationship, considering its effect and possible variations on boundary management and well-being over four weeks. Hence, taking these variables together, this study can bring important implications for future research and human resources departments, especially in what concerns the implementation and use of work-family conciliation practices at a time when organizations and employees are bringing the work-life balance concept to the table. Accordingly, this study gives an important contribution to the theme of the changing world of work , specifically regarding well-being and work-life balance. Likewise, it contributes to the UN Sustainable Development Goals, namely decent work, economic growth, good health, and well-being.

Keywords: work-life balance, work-family conciliation practices, well-being

Oral presentation OP780

Work-family relationship and social support among remote employees with regard to sex and hours worked per week - longitudital approach

Patrycja Siemiginowska, Jagiellonian University, Krakow, Poland; Irena Iskra-Golec, SWPS University of Social Sciences and Humanities, Faculty in Poznan, Poland

science

The goal of this study was to examine the work-family relationship and social support among remote employees who have been working remotely for at least three months and then reexamine work-family relationship and social support in four months. This longitudinal approach gave an opportunity to compare work-family relationship and social support levels with regard to sex and hours worked per week.

Holmes et al. (2020) pointed out that psychological and social aspects of the COVID-19 pandemic need to be researched (among other aspects). When the coronavirus pandemic started a lot of enterprises implemented remote work where it was possible. Although remote work has been known for decades now, the sudden implementation of it in various work environments has been introduced without a proper preparation. This caused extra stress for the employees already worried about their health and their loved ones' wellbeing.

635 workers aged 19 to 70 years old (M=37,24 years, SD=11,02 years) took part in the online study. They had to have been working remotely for at least three months. 4 months later of those employees 477 (75,12% of the original sample) completed the follow-up study. There were 311 women (65%) and 166 men (35%). They were either working less than 40 hours per week (N=113, 23,7%), full time (40 hours per week, N=205, 43%) or more than 40 hours per week (overtime, N=159, 33,3%). Workers were split into six groups: (1) women working less than 40 hours per week (N=67, aged 21-68, M=36,63 years; SD=11,11 years), (2) women working full time (40 hours per week; N=133, aged:21-63, M=37,23 years, SD=9,54 years), (3) women working overtime (more than 40 hours per week; N=111; aged: 22-69 years, M=39,86 years; SD=10,48 years), (4) men working less than 40 hours per week (N=46; aged: 21-70 years, M=45,21 years, SD=13,50 years), (5) men working full time (N=72, aged: 23-71 years, M=40,32 years, SD=10,42 years), (6) men working overtime (N= 48, aged: 24-63 years, M=39,54 ears, SD=9,17 years).

Work-family interface was measured by 12-item scale comprising of four subscales: work-family facilitation, work-family conflict, family-work facilitation, family-work conflict. Social Support was measured by Polish adaptation of Multidimensional Scale of Perceived Social Support developed by Zimet and coworkers (Buszman, Przybyła-Basista, 2017). Repeated measures ANOVA's with between-subjects factors (6 groups described above) were applied.

None statistically significant results were obtained with regard to work-family relationship. However, post-hoc analysis revealed that regardless of the time that passed between measurments women working overtime when compared to men working less than 40 hours per week had lower levels of work-family facilitation (p=0,015).

Statistically significant differences in perceived social support results were revealed between the first time and the second time participants were researched (F(1,471)=4,396; p=0,037). Regardless of the sex or hours worked per week employees perceived a lower level of social support after four months since the first measurement was taken. To further investigate this matter repeated measures ANOVA's with between subjects factors were performed with regard to perceived social support

obtained from significant other, family, and from friends. The only significant differences were observed in perceived social support from friends. The participants reported less support from them in time ($F(1,471)=8,327$; $p=0,004$).

The work-family relationship remained fairly stable in remote workers during the pandemic. This research showed that men working less than 40 hours per week when compared to women working overtime report higher levels of work-family facilitation. It could imply that men working remotely could observe more benefits from their work to their family domain than women who were working overtime. Also, this research can provide some insight into the role of social support as a potential stress buffer. Unfortunately, the study showed that in time remote workers perceive lower levels of social support, especially lovwer level of support from their friends. Pandemic as a chronic stressor might deplete workers' social support reservoirs.

It is important to note that perceived social support levels from significant other and family remained unchanged during those 4 months that passed between measurements. It is worth considering to investigate work-family relationship and social support over the time as the COVID-19 pandemic time being a huge stressor causing psychological distress is proven to be detrimental to mental health (Patel et al., 2022). Resources to provide social support to friends might deplete with time, perhaps providing it to the significant other and family might decrease too - a longer perspective is needed to investigate this effect in the future.

Relevant UN SDG of this research is 'good health and wellbeing'.

Keywords: work-family relationship, social support, telework

Oral presentation OP793

Working on the "coronacoaster": A netnographic study exploring the navigation to working from home in the Covid 19 pandemic

Karen Maher, Aston University; Nicola Bateman, University of Leicester; Gail Kinman, Birkbeck, University of London; Cheryl Travers, Loughborough University

science&practice

Research goals/Theoretical Background: Few studies have examined the impact of working from home during the Covid 19 pandemic on employee wellbeing. Within the available research many factors identified as influencing homeworkers' wellbeing, (e.g., isolation and difficulty detaching from work), are not unique to lockdown (Wood et al 2021), but the strength of their effects and way they shape wellbeing may have altered during this time. Whilst survey design can capture a 'snapshot' in time and identify relationships between variables, insight into the underlying mechanisms is limited. The inability to capture pre-pandemic data limits the application of survey findings for informing recommendations and shaping interventions.

Interview studies exploring the construction of work-life borders have identified employees' desire for flexibility across four distinct areas: time, space, evaluation and compensation (Cowan and Hoffman, 2007). However, individual circumstances and preferences influence how individuals integrate/segregate their work and non-work lives (Kossek et al 2012). Interviews capture prevailing thoughts and meaning-making for participants relying on accuracy of recall when asking for reflections on past experiences. As such, their potential for identifying strategies to manage work-life borders and understand the ebb and flow of homeworking over time is limited.

The Job Demands-Resources model (Bakker and Demerouti 2007;2016) provides a framework to understand how people craft balance between their work/non-work demands and resources. With evidence that factors specific to the pandemic have had a more indirect than direct impact on wellbeing (Wood et al 2021), this period allowed us to capture the evolving social narrative around the navigation of work and non-work life, the experience of work/non-work demands, and resources people utilise to manage borders between different life domains.

Design/method: A netnographic approach was employed (Kozinets, 2015) which allowed us to draw on the strengths of other methods in a single data collection tool. A closed group was created on a popular social media platform in April 2020, following the BPS ethical guidelines for internet mediated research (BPS, 2017). Participants were initially invited to participate through our personal networks, followed by snowballing. Informed consent was gained through entry to the group via agreement to group rules and participation. 203 participants, mostly based within the UK, representing a range of occupational groups required to work from home took part. Participants were free to post comments, pictures, gifs, videos and weblinks both unprompted and in response to discussion points posted by the research team and other participants.

Data were analysed through an inductive approach to identify themes and patterns within participants' experiences of the initial transition to homeworking and as the situation evolved over time.

Findings obtained: Much like a diary method, we were able to capture personal challenges and experiences from early on in the pandemic; the "Coronacoaster" as it became known within the group. The sharing of comments and posts enabled an understanding of individual perspectives and social narrative, much like a focus group, but occurring in a more naturalistic way. We were also able

to gather visual data as participants 'invited us into their homes' with pictures facilitating richer insight into participants' experiences and aiding a deeper level of interpretation. Broad themes include; Contradictions and transitions; implications for wellbeing and performance; the homeworking environment; and sharing space with others.

Limitations: The self-organising nature of the group is both a strength and a limitation. It allowed us to capture the process of sense making as participants shared thoughts as they arose and considered meaningful. Due to the nature of the social media group, we were unable to collect demographic and work-related data, such as whether they worked from home pre-pandemic, so cannot comment on whether this had an impact on participants' experiences of boundary construction.

Conclusions: Our study highlights the value of netnography for gathering rich data on the unfolding social narratives of work. Moreover, it captured reactions to an ongoing debate within the business community around the longer-term plans for returning to offices, permanent homeworking, or adopting a flexible hybrid approach. Our findings will inform interventions or strategies to assist workers navigating homeworking as part of routine working environments beyond Covid-19 and help organisations support them in doing so. Through using netnography to explore social narratives around work, a deeper understanding of employee experiences and sense-making can be achieved. The routine use of work-based social platforms, such as MSTeams, offer opportunities for narrative research of organisational phenomena

Keywords: Home-working, Netnography, work/non-work interaction

Work-life balance in the armed forces - In times of uncertainty

Johan Österberg, Swedish Defence University; Emanuela Rizzo, Military Academy at the ETH Zurich; Jacques Robert, Military Academy at the ETH Zurich; Tibor Szvircsev Tresch, Military Academy at the ETH Zurich; Irina Goldenberg , Canadian Department of National Defence

science&practice

Introduction

Work-life balance is a well-established concept that has been studied comprehensively. Overall, work-life balance considerations help to explain how well employees feel that they manage to combine their work and non-work roles (Casper et al., 2018). The perception of balance is based on a subjective experience, which means that individuals' commitment to each role must be proportional to how they value these roles. In contrast, work-life conflict emerges when role expectations between work life and non-work life are incompatible in some respect (Greenhaus & Beutell, 1985). The conflict can be bidirectional, which means that work life can interfere with non-work life and life outside work can interfere with work life.In recent years, interest in the different ways in which military employment affects individuals' work-life balance has grown. Military personnel face unique challenges in balancing their military commitments and home-related responsibilities, and sometimes have to act in demanding and stressful situations with little or no advance notice. Finding an appropriate balance between work and non-work is particularly complex during military training and deployments that require lengthy periods away from home. Throughout their career, military personnel are likely to face repeated separation from home, family, and friends while participating in training and deployments. Furthermore, military personnel's perceptions of work-life balance are likely to influence their job satisfaction and future career intentions (Sachau et al., 2012). Research shows that after serving abroad, personnel report lower satisfaction with their personal relationships and an increased desire to leave the armed forces (Andres et al., 2012). However, the offer of organizational support, and thus being better equipped to handle the conflicting demands from work and non-work life, has a positive impact on work-life balance (Anderson & Goldenberg, 2019; Sachau et al., 2018).

Work-life balance in a military context is a highly relevant issue that calls for further attention, and interest in the different ways in which military employment affects individuals' work-life balance has grown. Military members are facing unique challenges in balancing their military commitments and home-related responsibilities, and sometimes to act in demanding and stressful situations with little or no advance notice. Finding an appropriate balance between work and non-work is particularly complex challenge in all phases of military employment, including throughout military training and deployments that require lengthy periods away from home. Throughout their career, military members are likely to face repeated separations from home, family, and friends while participating in training and deployments. Moreover, military personnel's perceptions of work-life balance are likely to influence their job satisfaction and turnover intentions (Sachau et al., 2012).. Research shows that after serving abroad, employees report lower satisfaction with their personal relationships and an increased desire to leave the armed forces (Andres et al., 2012). Being offered organizational support and thus being better equipped to handle the conflicting demands from work and other life, however, has a positive impact on work-life balance (Johnson & Goldenberg, 2019; Sachau et al., 2018).

Aim and method

The aim of this study is to investigate how work-life balance and different work-related demands and resources affect well-being, job satisfaction, commitment to the organization, and willingness to remain in the organization among military personnel.

A comparative approach was used wherein questionnaire study was carried out in Sweden, Finland, Norway, Denmark, Switzerland, Canada and the Netherlands. The questionnaire was translated into each country's native language. Denmark used an English version. The questionnaire was constructed drawing in the work from Netemeyer et al (1996), Osipow & spokane (1982), Spector (1985), Eisenberger et al (1986), Baruch-Feldman et al (2002), Sinclair & Wallston (2004) and Mowdat, Steers & Porter (1979).

Results

Results are at the time of this abstracts writing, under construction, but will be completed during the fall of 2022. Initial results from the Nordic countries show that between 30-45 % of the personnell frequently think of quitting their job, that work-life balance predict retention and that the Nordic countries face considerable challenges in the years ahead when there will be huge retirements from their armed forces.

Discussion/conclusion

Recognition of the importance of work-life balance has increased in recent years, particularly given changes in the nature of work more broadly, and as many military organizations are growing after many years of downsizing. As many armed forces are characterized of organizational growth, the issue of retention is of outmost importance.

Oral presentation OP356

Workplace bullying in a group context: Are victim reports of working conditions representative for others at the workplace?

Michael Rosander, Linköping University; Morten Birkeland Nielsen, University of Bergen

science

Research goals: Previous research on psychosocial working conditions as risk factors of workplace bullying is based on the underlying, but rarely discussed, assumption that the targets' subjective reports of their psychosocial working conditions are shared by their non-bullied colleagues at the same workplace. We argue that this assumption is problematic since previous studies have shown that exposure to bullying influence the targets' view of the workplace and that the targets thereby have a more negative view of the working environment compared to non-bullied colleagues. The majority of previous research on antecedents to workplace bullying have applied an approach where associations between risk factors and bullying has been reported at the individual level. Hence, strictly speaking, most previous studies have really investigated whether the individual perceptions of one's work environment correlate with one's own exposure to bullying behaviours. The present study investigates differences in perception of such conditions by comparing the ratings from targets of bullying behaviours, witnesses, and non-witnesses in groups with at least one target, and groups free from bullying. As a further test, we examined if known psychosocial risk factors could predict bullying using a group level estimate of bullying behaviours even with the identified targets excluded from the analyses.

Design/methodology/approach: Data included 2215 employees in 195 work groups (112 groups free from bullying and 83 with at least one target) from three different work sectors in Sweden. We employed a new strategy to get a relevant group level estimate of the level of exposure to bullying behaviours. Previous group estimates have been based on group means or percentage of witnesses to bullying in each group. Both may be problematic. Using reports from witnesses alone may be problematic as such an approach is dependent on the openness of the bullying. For instance, it is more likely that colleagues will observe verbal attacks than more indirect behaviours such as ostracism. Using the group mean of exposure to bullying behaviours as a group level assessment of workplace bullying is also problematic in that bullying as a phenomenon is highly skewed with vast majority of group members experiencing no or very low levels of bullying behaviours. By using an estimate based on the most exposed individual in each group, we overcame these difficulties and were able to get an overall estimate for each work group that allowed differentation of severity and inclusion of more than merely observable kinds of bullying behaviours. It also allowed exclusion of different categories of participants — targets and witnesses — when investigating associations between potential risk factors and bullying.

Results: The results showed that targets of bullying behaviours perceived the psychosocial working conditions as more negative compared to non-exposed colleagues. However, in support of the work environment hypothesis even those unaware of bullying in their own work group reported more negative working conditions than those working in groups free from bullying. The reports by witnesses were in-between the targets and non-witnesses, perceiving a significantly worse work environment than non-witnesses, but a significantly better one compared to targets. As a further support for the work environment hypotheses the associations between the examined working conditions and group level exposure to bullying behaviours were significant even when the targets were excluded from the analyses, albeit less strong. The results indicate that the examined working

conditions are risk factors of workplace bullying, but that previous studies may have overestimated the associations.

Limitations: The data were self-report measures susceptible to social desirability and common method variance. However, as the data collection was part of the participating organizations' regular work environment survey, the answers meant something more to the participants than merely contributing to research—something that may help improve the accuracy of the responses.

Conclusions: The present study found that the way bullied employees view their work environment is not shared by other members of the same work group. This suggest that target reports of working conditions alone cannot be used as valid indicator of work-related risk factors to bullying. Nonetheless, supplementing this finding, we have also shown that even those not witnessing bullying in work groups where bullying is present perceive the working conditions more negatively than employees in work groups free from bullying. This implies work environment deficits are related to the occurrence of bullying, but that the actual working conditions may not be as negative as the target reports would indicate. It is therefore important for future research to take the differences between targets, witnesses and non-witnesses into account.

Oral presentation OP634

Workplace loneliness trajectories in the changing world of work: The effects of leadership behavior and exhaustion

Timo Walz, Maastricht University; Florian Kunze, University of Konstanz; Simon de Jong, Maastricht University; Julia Kensbock, University of Bremen

science&practice

Research goals and theoretical considerations

Loneliness is on the rise (Valtorta et al., 2016), and the COVID-19 pandemic has further accelerated this trend (Li & Wang, 2020). Still, less is known about the longer-term and dynamic effects of the increase in remote work and its impact on workplace loneliness. Such insights are important because the working environment has likely changed permanently with increased home-working arrangements posing significant opportunities and challenges for organizations (Kunze et al., 2020). In general, workplace loneliness is still an understudied phenomenon, and scholars know relatively little about what drives and what prevents workplace loneliness (Ozcelik & Barsade, 2018).

Exhaustion has been found to be a possible consequence of workplace loneliness (Anand & Mishra, 2021). Using the Conservation of Resources Theory (Hobfoll et al., 2000), we suggest that it can also be an antecedent by limiting resources, thus making people less likely to engage in social communications and activities at work or decreasing the quality of interactions, increasing workplace loneliness. This difference is important and relevant to study because it would mean that the process of workplace loneliness could be even more varied than assumed (Wright & Silard, 2020).

We also suggest leadership behavior, namely initiating structure, and consideration (Lambert et al, 2012) as a possible remedy to boost resources reducing employee workplace loneliness. It is important to find factors for mitigating workplace loneliness, both to advance workplace loneliness research on reliable mediators and moderators (Wright & Silard, 2021) but also on a practical level, since leadership behavior could be an effective and relatively cheap way for organizations to positively influence employee work-related outcomes (Lambert et al, 2012).

Methodological Approach

To investigate the dynamic of workplace loneliness, we used a large sample of 699 German employees from different sectors followed over 4 measurements times in 2020 and 2021. We use latent growth modeling (LGM) to investigate: (a) Trajectories of loneliness and exhaustion over time, (b) how exhaustion relates to loneliness over time, and (c) how two leadership behaviors (initiating structure and consideration) affect loneliness both initially and over time. We used established scales to measure all constructs.

Results

Overall, our model indicates a general decline in workplace loneliness. Conditional growth curve models were estimated to examine the effects of each of the major predictors on workplace loneliness trajectories. Exhaustion at each time point had a positive effect on the workplace loneliness trajectory above and beyond the underlying growth process. Negative significant results were obtained for the longitudinal effects of leadership consideration, but not leadership structure.

Limitations

We tried to address issues of endogeneity by including controls that could theoretically be associated with loneliness, among others, relationship status, number of kids, remote working experience and percentage. We tried to address reverse causality by looking at crossed-lagged effects and found some evidence for these, but more experimental or natural experimental designs are needed to establish proper causality inferences.

Conclusions

Our study further shows the importance of leadership behavior as possible interventions to mitigate workplace loneliness over time in a remote setting. Employees whose leaders showed high consideration experienced a significant decline in workplace loneliness levels, whereas leadership structure had no significant influence. Leaders thus need to be supportive and encourage relationships at work and must be careful to not overburden employees with tasks and structures in the new hybrid world of work.

Exhaustion increased workplace loneliness at every time point despite the overall downward trend. For organizations and leaders this means that job demands in the new hybrid working environment need to be kept in check as to not exhaust employees fostering workplace loneliness. Overall, our study emphasizes the importance of continuously paying special attention to the ongoing challenges of workplace loneliness while designing changes in the new hybrid and remote work environment.

Relevance to the Congress Theme

Our study directly addresses the congress theme of “changing the world of work” because it looks at the understudied phenomenon of workplace loneliness in a remote and hybrid working setting, which is here to stay bringing about significant opportunities and challenges (Kniffin et al., 2020). We try to explore how leaders can mitigate some negative effects of workplace loneliness. Hence this work also addresses the UN-SDGs of “decent work and economic growth” and “good health and wellbeing” by suggesting possible interventions for improved employee well-being.

Keywords: workplace loneliness, remote work, leadership

Workplace mental health disclosure, sustainable employability, and wellbeing at work: a cross-sectional study among military personnel.

Rebecca Bogaers, Tilburg University & the Dutch Ministry of Defence; Nicolas Rüsch, University of Ulm and BKH Günzburg; Dike van de Mheen, Tilburg University; Fenna Leijten, the Dutch Ministry of Defence; Andrea Rozema, Tilburg University

science

Purpose & theoretical background

The importance of wellbeing at work for sustainable employability and mental health has increasingly gained attention. Due to the aging working population in Western countries, and the current labor shortage in many industries, this is likely to increase even further in the coming decades and has made the topic of how employers can invest in workers' health and wellbeing, a relevant topic. This is even more important for workers with mental illness, including substance abuse, as illness is a threat to sustainable employability itself.

A crucial decision for workers with mental illness, is the decision to disclose mental illness to a supervisor or not. This decision is a dilemma, as disclosure can have positive (e.g. supervisor support and work accommodations) and negative consequences (e.g. stigma and discrimination). The decision to disclose or not is expected to be an even more prominent dilemma in high-risk occupations, such as the military, as military personnel are expected to be strong, and not to show weakness. However, research on the direct association between disclosure and sustainable employability and wellbeing at work is scarce, and completely lacking within the military. The aim of this study was to investigate the association between the disclosure decision, experiences with the decision and sustainable employment and wellbeing at work among military personnel with mental illness.

Method

A cross-sectional questionnaire study was conducted among military personnel with mental illness (N=323). The questionnaire included questions on demographics, the decision to disclose mental illness to a supervisor (yes/no), the general disclosure experience (positive/negative), specific disclosure experiences, and several measures of sustainable employability and wellbeing at work.

To examine the association between disclosure decision, disclosure experience and sustainable employability and wellbeing at work, linear and ordinal regression analyses were performed. To examine the disclosure decisions and experiences, descriptive analyses were performed. Comparisons were made between those with positive and negative disclosure experiences.

Results

Disclosure decision (yes/no) was not significantly associated with any of the measures of sustainable employability and wellbeing at work. However, positive disclosure experiences were significantly associated with higher scores on almost all measures of sustainable employability and wellbeing at work.

Of those who had disclosed (N=245), 86.9% was positive about their decision. Those with negative disclosure experiences reported significantly more shame ($M_{pos} = 2.42$, $M_{neg} = 2.78$, $p<.05$) and discrimination ($M_{pos} = 1.70$, $M_{neg} = 2.84$, $p <.001$). Those with a positive disclosure experience,

reported significantly more supervisor support (M pos = 3.20, M neg = 1.94, p <.001). Of those who had not disclosed (N=78), 84.6% was positive about their decision. The most mentioned reasons for a positive experience were the preference to solve one's own problems (self-management) (89.4%).

Limitations

First, the current study used a cross-sectional design, meaning that no conclusions about causality in the association between disclosure experiences and sustainable employability and wellbeing at work can be drawn. Future research should examine this association longitudinally. Second, an important limitation of the current study is that it only included active-duty military personnel. This means that those who had left the military, possibly after mental illness and disclosing, were not included in this study. Those with the most negative consequences of disclosure, such as loss of employment, were not represented in this study.

Conclusions

We did not find evidence that the disclosure decision itself is related to measures of sustainable employment and wellbeing at work. In contrast, how participants had experienced their (non-)disclosure decision was significantly related to almost all measures. This emphasizes the importance of the work environments reactions to disclosure and mental illness in the workplace. Future research and interventions should focus on increasing the likelihood of positive disclosure experiences through creating a more inclusive work environment, with more supervisor support and less stigma.

Relevance for congress

This research is relevant to the congress theme as it focusses on the UN Sustainable Development Goal 'Good health and Wellbeing'. The findings of the current study can help to inform future research and interventions which can create a more inclusive work environment. In a more inclusive work environment, disclosure of mental illness is possible, creating opportunities for supervisor support and work accommodations, which contribute to good health and wellbeing.

Oral presentation OP168

Workplace Ostracism: The case of the Sultanate of Oman

Nidaa Al-Barwani, The University of Leeds & Sultan Qaboos University, Samuel Farley, Desmond Leach

science

Research goals: Workplace ostracism (WO) is defined as the omission of taking actions by an individual or a group to engage another individual or a group when it's socially appropriate to do so (Robinson et al., 2013). Research on WO has grown since the inception of the construct in social psychology. However, most of this work has been conducted in Western contexts, with a limited examination of how WO occurs in other cultural contexts. Therefore, the aim of this study concerns the role of culture in understanding the phenomenon of WO in a non-Western context. More specifically, this research examines how Omani workers experience WO to determine whether existing knowledge on the antecedents, nature and outcomes is relevant to the Middle-East by cross-cultural inquiry.

Theoretical background: Ferris (2019) found that social pain resulting from being excluded, rejected, and ostracised is similar to physical pain experienced by being injured. As a result, WO promotes paradoxical pragmatic consequences. On the one hand, it can lead to deviant workplace behaviours such as anti-social and counterproductive behaviours. On the other hand, it could lead to pro-social behaviours such as organisational citizenship behaviour to strengthen interpersonal relationships or increase performance (Robinson et al., 2013). Although research indicates that culture affects WO perceptions and coping strategies (Rudert & Greifeneder, 2019), much work is still needed to examine cross-cultural differences.

Methodology: A thematic narrative interviewing methodology was adopted in semi-structured interviews with 15 full-time Omanis who had experienced workplace ostracism in some form. The sample was aged 29-50, worked in various occupations and held a range of different positions, including managerial roles.

Results: The analysis of ostracism cases within the Omani context revealed that the behaviours underlying the construct are largely the same as in western workplaces. However, key differences were observed in relation to religious and cultural norms. For instance, conflict avoidance was one primary antecedent leading to WO in the Omani context due to the cultural effect of highly respecting seniority, age, status, etc. Because the only religion embraced by Omanis is Islam, Islamic values and practices directly affected coping mechanisms such as remembrance of God & Prophet's sayings.

Limitations: Memory bias and access to only a single source of information, the participants' narratives, are the major limitations.

Originality & practical implication: Methodologically, this research is among the first to evaluate the impact of culture on ostracism in work settings cross-culturally using narrative research. Theoretically, it is among the first to discuss the role of religious beliefs in the way people perceive and cope with WO. Islam avoids conflict by seeking mutual participation in decision-making and encourages harmony and forgiveness (Ali, 2009). Therefore, the research provides implications for practitioners. For example, findings are expected to help practitioners find the most effective policies and practices for dealing with WO in line with cultural norms, such as encouraging employees to accept desirable conflict, develop strategies to deal with it, and seek professional support when

ostracised. Also, the research would provide scholars insights into further investigating the impact of religious belief and culture on WO to better understand WO from a religious and cultural lens.

Relevance to the Congress Theme: Desirable changes in reducing the occurrence of WO in workplaces for a better future entail collaboration between academics and practitioners. That collaboration is only attainable when research is conducted, well communicated to practitioners and issues are clearly addressed. Then, essential changes and practical strategies are expected to take place for healthier work environments. Hence, the research will contribute to identifying the competencies and social and professional interpersonal and leadership skills needed when designing organisational development and training programs to help combat the negative effect of WO and its antecedents.

Relevance UN SDGs: The phenomenon of WO deprives an individual of the necessary visibility, promotion, or from being heard and appreciated. Consequently, WO increases employees' feelings of invisibility and unworthiness, leading to inequality, negative well-being, and a perception of injustice. Therefore, addressing the issue of WO is necessary to create awareness of the phenomenon, improve employees' overall health, develop practices to defeat it, and build strong institutional cultures.

Keywords: Workplace Ostracism, Culture, Religion

Oral presentation OP309

Workplace youngism: A scoping review

Susana Schmitz, Instituto Universitário de Lisboa (Iscte-IUL), CIS-IUL; Católica Lisbon School of Business & Economics; João Mariano, Católica Lisbon School of Business & Economics; Christin-Melanie Vauclair, Instituto Universitário de Lisboa

science&practice

The objective of this work is to systematically examine the literature about ageism (age-based negative attitudes) towards younger workers, also called workplace youngism. The questions addressed in this scoping review include main methodologies, theories and ageism dimensions used to investigate workplace youngism; the age categories and terminology most often used to define younger workers; and the main antecedents and consequences of workplace youngism.

The importance of further investigating workplace youngism has been emphasized by different scholars. The ageing population in many countries and the consequent changes in the workforce composition have not only increased pressure on older workers, but also on younger ones, who are often underpaid and report not feeling valued or being perceived as competent. Whereas previous literature reviews have focused predominantly on ageism against older workers, workplace youngism remains comparatively overlooked.

As scoping reviews aim at identifying research gaps in emerging areas of evidence, this was considered the most appropriate approach. Before initiating our literature search, a protocol was registered in Open Science Framework (OSF), in November 17, 2021. The methodology followed included five key phases: 1) formulating the research questions, 2) identifying relevant studies, 3) selecting among the studies, 4) charting the data, and 5) collating, summarizing, and reporting the results. The following databases were searched: Web of Science, Scopus, and EBSCO host (including Academic Search Complete, Business Source Complete, APA PsycArticles, APA PsycInfo, Psychology and Behavioral Sciences Collection). The search string used was: ageism OR agism OR "age discrimination" OR "age stereotypes" OR “age prejudice” OR "age bias" OR “age attitudes” AND work OR workplace OR "human resources" OR employment OR organi?ation* AND young* OR Millennials OR “Generation Y” OR “Generation Z”. Empirical studies published after 1969, in English and in peer-reviewed articles, which examined workplace youngism were eligible. Titles and abstracts, and then full-text of selected studies were screened by two independent reviewers. At both stages, disagreements were resolved resorting to a third reviewer.

Phases 1 to 4 are completed, and phase 5 is underway. In total, 699 records were identified in the database search. After removing duplicates, 356 records were screened. Of these, 124 full-text articles met the criteria for eligibility and 32 additional records were identified through references. After excluding 48 full-text articles, the remaining 108 articles went through extraction and synthesis. These originated from 21 countries, with the largest number of studies conducted in the USA (42.6%), UK (11.3%), and Germany (8.5%). When specified, samples were mostly composed of workers (57.1%) and students (24%).

Preliminary results show that, in terms of methodological approaches, most studies were experimental (49%) and cross-sectional (24.5%), followed by qualitative (14.7%), mixed methods (7.7%) and longitudinal (2.8%).

Regarding the main ageism dimensions used to investigate workplace ageism, among the quantitative studies, 70% include the cognitive dimension (stereotypes), 65.5% the behavioural dimension (discrimination) and 18.2% the affective dimension (prejudice).

In terms of the age range used to categorize younger workers, the lower age limit varies from 16 to 30 years old, with 18 being the most used. The upper age limit varies from 21 to 49 years old, with 35 as the most frequently adopted. In 91.6% of the studies, younger workers were specified as "young" or "younger", though some studies referred to them as "millennials" or "generation Y" (3,7%).

Additional analyses will be completed in December 2022, to answer questions regarding the main theories used to investigate workplace youngism, its antecedents, consequences, gaps and future research directions for the field.

In terms of limitations, we consider that by having included only peer-reviewed papers in English in our search, we might have missed research published in other languages and/or from other sources that could have added value.

Nevertheless, by summarizing the existing evidence in the important, yet understudied area of workplace youngism, this scoping review can contribute to the advancement of research in this area, to best management and HR practices regarding younger workers and age-diverse workforces, and to policy directed at reducing age discrimination in the workplace.

This research is relevant to the Congress Theme "The Future is Now: the changing world of work" and to UN SDGs, in particular SDG 8 (decent work and economic growth) and SDG 10 (reduced inequalities). In order to build the prosper socioeconomic future we desire, we need different generations effectively collaborating and feeling fairly treated at work. Advancing research on workplace youngism can contribute to these objectives.

Keywords: scoping review, workplace youngism, younger workers.

Oral presentation OP313

Work-related rumination declines with age but not by gender

Mark Cropley, Olga Chelidoni & Lucie Ollis | University of Surrey; Leif Rydstedt, Inland Norway University

science

Research goals and why the work was worth doing

Persistent failure to mentally switch off and unwind from work—known as work-related rumination—wears down the body's physiological restorative system, and is very detrimental to health. Work-related rumination has been associated with a range of serious psychological and physical health symptoms including: negative mood, fatigue, insomnia, and cardiovascular disease/risk.

As life expectancy increases, the age at which people can start receiving state pension is predicted to rise in most OECD countries, and as the need to continue working longer into later life takes effect, it has become vital to understand how working life affects health and wellbeing.

Given there is a growing body of literature linking the physical aspects of work to the health and wellbeing of the aging workforce, there is a notable lack of studies specifically aimed to examine how older workers disengage and mentally switch off from work. The present study aimed to explore the association between age, gender and two different types of work-related rumination (affective rumination, and problem-solving pondering).

Theoretical background

In order to assess rumination, we drew upon the conceptual model of Cropley & Zijlstra (2011) and examined two types of post-work thinking called 'affective rumination, and problem-solving pondering'. Affective rumination is a negative valanced form of thinking characterised by the experience of intrusive, pervasive, recurrent thoughts, about work. Individuals who regularly engage in affective work-related rumination demonstrate high levels of fatigue, poorer psychological and physical well-being. Problem-solving pondering is a form of thinking that may be characterized by prolonged mental scrutiny of a specific problem or an evaluation of previous work to see how it can be improved, but it does not involve the emotional process that sustains arousal as in affective rumination (Cropley & Zijlstra, 2011). People may ponder about work related problems because they find the act of thinking about work issues interesting. In such situations, people keep thinking about their work during their leisure time because they enjoy their work, and it helps them to solve issues that they are faced with, and there is no problem with being 'switched-on'.

Design

The present study aimed to explore the association between age, gender and two different types of work-related rumination utilising a cross-sectional sample of 3991 full-time employees (classified as working 30 or more hours per week). Age was stratified into five age bands (18-25, 26-35, 36-45, 46-55, 56-65 yrs.).

Results

Affective rumination was found to significantly decline in the older age groups (46+ yrs.), but this finding was moderated by gender. Males reported lower work-related rumination over the entire age range, but the greatest difference between males and females was observed in the 56-65 age

category. The results for problem-solving pondering mirrored those of affective rumination but with the only exception that there was no significant difference in gender between those aged 18-25 years. Qualitative interviews suggested why there are differences between genders and rumination.

Limitations

It is not possible within the present dataset to definitely conclude that the findings represent a true ageing effect—one that is independent of time—or whether the findings are specific for this particular period of time (i.e., a cohort effect). Further studies using longitudinal designs that track the same individuals across time, are needed.

Conclusions – research and or practical implications

Given the significance of promoting healthy lives for older adults, very little research has been undertaken to investigate the effects working later life has on quality of life and mental wellbeing, among older people. The present study adds to our understanding of how workers across the age span switch off mentally outside of work and the findings may serve to stimulate future investigations on age, gender and recovery from work. As differences in work-related rumination between men and women appears to increase with age, this suggests that future interventions are particularly needed to promote recovery activities in older women.

Keywords: Rumination, age, gender

Oral presentation OP147

Workspace at home and the office: a longitudinal study of their joint effects on performance, well-being and satisfaction

David Holman & Masakatsu Ono | Alliance Manchester Business School; Maximiliano Escaffi Schwarz, Universidad Adolfo Ibáñez; Matthew Davis, Leeds University Business School

science

Research goals

Greater numbers of employees now combine office working with home working. But how do these hybrid workspaces affect employees? In this paper, we test how the design of workspaces at work and at home affects employee satisfaction, engagement and performance.

Background

Theories of activity-based workspaces assert that the supply of workspaces support key work activities (e.g., for concentration, interaction, recovery) should result in better outcomes, such as satisfaction, well-being and performance (Engelen et al., 2019; Wohlers et al., 2017). For example Wohlers et al. (2019) showed the supply of work spaces that support concentration and interaction to be correlated with positive job attitudes. But increasingly, employees work in hybrid work spaces that straddle home and office and such hybrid workspaces have not been considered in research on workspace design. As such, we introduce a model of Hybrid Activity-Based Work Spaces (HAWKS) and test the joint and simultaneous effects of office and home workspace supply on employee outcomes.

Design

A longitudinal in a UK organisation generated a sample of 269 participants. We measured office workspace supply of spaces for concentration, interaction and recovery, and home workspace supply of spaces for concentration, interaction and recovery. We measured the following employee outcomes: office space satisfaction, home space satisfaction, engagement and performance. Data were analysed using cross-lagged path models (Edwards 2007, Su et al., 2019). Controls included gender, role, job design and time spent in office.

Results

We found that office workspaces supporting interaction at Time 1 to be positively related to performance and satisfaction at Time 2, and that home work spaces supporting interaction at Time 1 to be positively related to performance at Time 2. We found that home workspaces that support concentration at Time 1 to be positively related to engagement at Time 2,

There were also some reverse lagged effects. For example, we found that performance, engagement and satisfaction at Time 1 were associated with increases in home workspaces that support concentration.

Limitations

The main limitations are the use of self-report data, that the effects were only over a three month period, and that mechanisms were no addressed.

Conclusions

Our findings show the importance of activity-based workspaces in the office and at home such that spaces should be available for work requiring concentration and social interaction. We did not find any long term effects of supply of spaces for recovery activities, although such effects may be detected using different timeframes of measurement.

Our paper makes a number of theoretical and empirical contributions by i) introducing and testing the HAWKS model which extends models of activity based workspaces to include hybrid workspaces, i.e., home and office workspaces ii) providing longitudinal evidence to support activity based models of workspace design.

Relevance to the Congress Theme & UN SDGs

This paper addresses an important but little studied aspect (i.e., workspace design) of a key change occurring now across many workplaces, namely the shift towards hybrid work. The paper contributes to the UN SDGs by aiding our understanding of how workspace design can contribute to 'Decent Work'.

Keywords: workspace, hybrid working, longitudinal

oral session OP779

YOU DO NOT BELONG HERE: EXPERIENCES OF MICROAGRESSION AMONG INDIAN WOMEN ENGINEERS

Pooja Purang, Sailee Biwalkar & Archita Dutta | IIT BOmbay

science

The present study aims to understand the different micro aggressions faced by Indian women engineers. The engineering profession has a masculine culture with subtle sexist practices that create a chilly climate and resulting in low representation of women. Further research in the Indian context, in contrast to the west, provides that social context and patrifocality are reasons for the gender gap in engineering versus womenâ€™s weaker abilities in science and math. Therefore, the types of micro aggressions experienced by Indian women maybe different from other cultural contexts. Additionally, gendered micro aggression has been studied widely within academic engineering contexts but not within organisations. Therefore, the present study attempts to understand how different micro aggressions unfold and are maintained within the organisational context. Examining different implicit biases that act as barriers to retaining women would provide insights for meaningful diversity initiatives

The theoretical background used in this study is of Social role theory, Gendered microagression theory and Benevolent sexism theory. Social role theory indicates how women are expected to be nurturant and people oriented. Therefore, they should be engaged in disciplines that are congruent to their gender roles like teaching and nursing rather than in professions like engineering which value masculine social norms of competitiveness, agency and decision making. Gendered microagression theory describes subtle sexist acts that are disrespectful and belittles womenâ€™s abilities. These acts are often expressed unconsciously, in everyday behaviour through verbal and non-verbal gestures creating psychological discomfort for women. Benevolent sexism is a part of ambivalent sexist theory that describes how men propagate sexism by communicating that women are dependent on men and need their protection thereby justifying menâ€™s social power over women. Using these theoretical lenses, we examine how sexist practices create hindrances for Indian women employed in engineering professions.

The study was conducted using a qualitative research design by using semi-structured interviews. 20 female engineers were interviewed for the present study using purposive sampling with a mean age of 40.2 years and thematic analysis was used to analyse data.

The results of the present study showed following themes: â€Letâ€™s not hire them: Implicit Hiring Biasesâ€™, â€Nudges towards occupational segregation: Role Assignmentâ€™, â€Disregarding womenâ€™s accomplishments, competence and contributionâ€™, â€Environmental Barriers at Work: Unabling Infrastructureâ€™, â€Be a woman: Donâ€™t Exercise Voiceâ€™ and â€Encountering Benevolent Sexism: Protecting and Unablingâ€™. Â The traditional gender role ideas have led women to encounter different forms of microagression within engineering organisational context. â€Assumptions of traditional gender rolesâ€™ manifested through different biased hiring practices and occupational segregation in the form of pushing women engineers towards non-technical and people-oriented roles. â€Assumption of inferiorityâ€™ is indicated in assumptions regarding womenâ€™s inability to manage senior roles because of their focus on familial responsibilities. Or inability to carry out physically laborious part of engineering work despite intellectual competence. Further, womenâ€™s contributions are often ignored and invalidated by men indirectly through jokes and slights about leaving work early or using affirmative action policies

for promotions. Additionally, women engineers have faced the micro aggression of being considered as a â€second class citizenâ€™ as they had to put in extra effort to let their voice be known. They have also been silenced or ignored implying unimportance of their contribution. Apart from hostile micro aggressive practices, women engineers have encountered benevolent sexism whereby they have been perceived as a â€mother figureâ€™ and therefore viewed only in terms of their nurturant roles. Instances of women needing to be escorted by male colleagues for meetings with external vendor indicated the belief women needed protection. However, this handicaps women engineersâ€™ growth and advancement within engineering workplaces and reinforces sexist beliefs within organisations. Finally, the environmental macroaggression that deny women of infrastructural facilities like having separate washrooms communicate that women do not belong.

The results of the study indicate how engineering as a profession needs to overcome unconscious and subtle sexist practices to make it inclusive. Moreover, the employers need to think beyond the Indian cultural stereotypes of women and value their technical abilities and contribution.

The methodology and sample size is one limitation. Menâ€™s perspectives about different hiring practices, policies and organisational culture and effectiveness of specific diversity initiatives and affirmative policies were not considered.Â

You Keep Me Searching: An Exploration of Career Shock Event Types and Event Features Using Text Mining Techniques

Stefan Mol, University of Amsterdam; Jos Akkermans, Vrije Universiteit Amsterdam; Scott Seibert, Rutgers University; Vladimer Kobayashi, University of the Philippines Mindanao

science&practice

The current study set out to examine whether the text mining of interview transcripts on the subject of career shocks can inform our understanding of whether and if so, when and how context (as opposed to individual agency) plays a role in determining both objective and subjective career success outcomes. Akkermans et al. (2018) have characterized career shocks as being disruptive and extraordinary events that instigate rumination about the career. This characterization is compatible with Event System Theory (EST; Morgeson et al., 2015) which proposes that event novelty, disruptiveness, and criticality jointly constitute event strength and that it is event strength that determines whether a particular event commands attention and ultimately results in action. Our specific objectives in carrying out this study were to: i) Perform text mining to extract different shocks (or shock categories) from text data about careers; ii) perform text mining to see whether it is possible to recover novelty, disruptiveness, criticality, and/or other relevant dimensions of the career shocks so identified; and iii) characterize the career shocks so recovered.

Data were collected in an introductory research methods course, in which students were tasked with carrying out, transcribing, and analyzing two interviews each on the topic of career shocks. From the 2017-2018 academic year until the 2021-2022 academic year around 1340 interview transcripts, and matched survey responses pertaining to demographics and career outcomes, were collected.

In order to address our objectives we aim to perform the following analyses:

On the pre-processed and transformed text data, and the interview transcripts, we will first carry out two topic modelling techniques in an effort to achieve the objectives, namely, structural topic model (STM) and supervised Latent Dirichlet Allocation model (sLDA). We will sample 70% of the data for the training of the model and use 30% as validation data set. Using STM we can incorporate covariates (e.g., demographics) and temporal-based features (e.g., the timing of career-defining shocks in the construction of topics. The constructed topics will then be examined and interpreted by 5 subject matter experts. Each topic will be labeled as to whether or not it comprises a career shock and on the three EST dimensions, namely, novelty, disruptiveness, and/or criticality. The EST dimension may be expanded to include other emergent dimensions. Once the topics have been labelled, we will use sLDA to create a model that can automatically identify career shocks and score them on the identified dimensions for each individual in the dataset.

The results of these analyses will be available by the time of the EAWOP conference. In conclusion, we feel that new data analytic techniques deriving from the field of text mining may offer novel opportunities to inform and/or generate theory. Our submission is relevant to the conference theme “The Future is now: the changing world of work” in that it sets out to redress the limited attention that relatively unpredictable features of context (as opposed to the agentic person) has received using a relatively large sample qualitative data set. Some limitations of our abductive approach may be that it is quite exploratory and that any findings will likely need to be verified using more confirmatory approaches.

Oral presentation OP149

Young managers' identity work; A multicase interview study

Hanna Irehill, Oscar Rantatalo, Robert Lundmark & Susanne Tafvelin | Umeå University

science&practice

Research goals

Age is an important dimension to consider in management research because young managers face specific challenges due to their age and lack of experience. Thus, to claim and be granted the managerial position, young managers need to handle age-based stereotypes. The study seek to answer how young managers (i.e., 19-29 years old) experience being nonprototypical in terms of their relation to the managerial role and how their identity work is enacted to respond to these age stereotypes.

Theoretical background

This article is based on the identity work (Caza et al., 2018) and implicit leadership theory (ILT; Lord et al., 2020). The concept of identity work has been fruitful in broadly capturing subjective identification processes in organizations, However, as the identity process of young managers depends on previously and currently established self-perceptions and expectations from the surrounding context, ILT can further aid in our understanding by its focus on the process (Lord et al., 2020).

Design/Methodology

This qualitative multicase interview study targets young managers experiences of nonprototypicality. We examined young managers' identity work in three business sectors: construction, information technology (IT), and service. In total, interviews (N = 38) and workshops (N=6) was conducted with young managers (n = 17), senior managers (n = 8), subordinates (n = 5), and support functions (n = 8). Two workshops were organized with each organization to present our results, validate our interpretations and facilitate dialogue. We grounded our comparative analysis inspired by Gioia (2013) and worked abductively as data collection, developing theory and interpretation took place in parallell. We used data structures to create a comprehensive process model based on cross-case categories.

Results

The process model illustrates how the identity work of young managers is conditioned by interpersonal dynamics in the organizational context. It reveals how young managers are confronted with rites of passage, where the discrepancies between the individual and the manager role are tested and explicated. Young managers violate age stereotypes regarding management, and thereby embody contradictory or incommensurable positions. Furthermore, young managers strive to transcend their position and enact management in their identity work. The analysis also reveal thresholds narratives describing how young managers' emerge as managers through their identity work.

Limitations

Our sample did not specify management level, which naturally led to a sample in which first-line managers were most frequently represented. Because age is closely related to experience, most young managers hold positions at first-line management levels.

Conclusions and practical implications

Our findings reveal that young managers face specific challenges and are put to test (i.e. rites of passage). Young managers used different strategies to handle their position and to enact management. Implicit theories of leadership in conjunction with interpersonal dynamics influenced how the identity work process developed, highlighting the importance of considering age in leadership research and providing young managers with support. Given the difficulty to extinguish stereotypes, enhanced awareness and strengthening of young managers, is important to motivate young managers to continue in this carrier choice.

Relevance to the Congress Theme and UN Sustainable Development Goals (2015)

Young managers are future leaders of working life. Because of the impact that managers have in organizations (employee wellbeing, performance etc.) knowledge about what our future managers need in order to develop into their role is central, both for them, their employees and organizations. Thus, the present study is relevant in relation to UN SDGs goal due to its focus on prerequisites for young managers and sustainable development in the managerial role.

Symposia

symposium S001

A shut mouth catches no flies: New perspectives on knowledge hiding between co-workers

Laura Venz, Leuphana University Lüneburg, Germany; Johannes F. W. Arendt, Ludwig-Maximilians-Universität München

science

In times in which the asset of many organizations largely consists of the expertise of their employees, the exchange of knowledge between co-workers is a crucial factor for organizational success. Accordingly, research on the antecedents, boundary conditions, and consequences of

knowledge sharing receives unbroken research attention. More recently, scholars have increasingly focused on the other side of the coin: Knowledge hiding, defined as the intentional withholding of knowledge that someone has requested. Since the construct was introduced into organizational research by Connelly and colleagues a decade ago, a steadily increasing number of studies has examined the antecedents and effects of knowledge hiding at work. This research, however, is relatively limited in its methodological scope and perspective on knowledge hiding, often relying on cross-sectional survey studies and variable-centred analysis approaches comparing employees' self-reported levels of general knowledge hiding. This restrains our understanding of the complex inter- and intrapersonal mechanisms behind knowledge hiding in its various facets, what in turn limits possible approaches to prevent its occurrence. From this point of view, the present symposium combines four studies that pursue new approaches to look at knowledge hiding. The first presentation takes a person-centred approach to investigate unique patterns of knowledge exchange behaviour – considering both knowledge sharing and hiding – and to examine person characteristics that explain who is prone to share, to hide, or both. The second and third presentation also focus on the person of the hider, but still take very different perspectives on knowledge hiding. Specifically, the second contribution considers knowledge hiding as an adaptive behaviour to deal with demands, examining it as a buffer (i.e., moderator) of the detrimental longitudinal effects of supplementary work on job performance. The third presentation adds another layer to studying knowledge hiding by considering that there are not only differences between but also within people in knowledge hiding (i.e., that knowledge hiding fluctuates within person over time). From this perspective, the study shedslight on the role of guilt in the context of knowledge hiding enactment by examining and comparing reciprocal relationships of different specific knowledge hiding behaviours and guilt within person (weekly) and between persons (over two months). Finally, considering that knowledge hiding is an interpersonal behaviour that not only affects the hider but also the person knowledge is hidden from, the last study shifts the focus to the targets of knowledge hiding: Using an experimental vignette design, it examines the role of situational and target-related personal factors in the interpersonal effects of knowledge hiding. The symposium will be completed by Catherine Connelly, one of the leading scholars in research on knowledge hiding in organizations, who will discuss implications of the presented research and facilitate Q&A.

Relevance to the Congress Theme

With the growing need to respond to rapid change and ever new crises, organizations must rely on their employees and that they exchange and not withhold knowledge–today more than ever. However, it is evident that knowledge hiding in organizations exists. At the same time, research long took a rather simple perspective on knowledge hiding in organizations, considering it as uniformly negative and using methods that do not do the complexity of knowledge hiding justice. This symposium helps overcome these limitations, enabling evidence-based practice to help organizations to successfully tackle the challenges of the future of work.

Implications

This symposium brings important implications for both research and practice. Considering theoretical and methodological implications, the four studies of this symposium show in a variety of ways that the prevalent perspective on knowledge hiding as a clearly defined, unambiguously negative, immoral behaviour does not adequately reflect its complexity and may lead to incorrect or at least insufficient conclusions being drawn. With considerably broadening the spectrum of research methods and perspectives applied on knowledge hiding, this symposium promotes better evidence-based practice in terms of organizational knowledge management.

Overall Conclusions

Taking novel research approaches and perspectives on knowledge hiding, considering intrapersonal antecedents and (positive and negative) consequences of knowledge hiding for both hiders and targets, this symposium enables a nuanced understanding of who hides knowledge when and why and of how targets react to this behaviour. The four presentations of this symposium together with the discussion lead by Catherine Connelly provide new insights into knowledge hiding in organizations. This symposium contributes to the UN SDG of decent work and economic growth, amongst others.

Paper 1

Knowledge sharing AND hiding: Insights from latent profile analysis

Catherine E. Connelly, DeGroote School of Business, McMaster University, Canada, Ofer Arazy, The University of Haifa, Israel; Ian R. Gellatly, Alberta School of Business, University of Alberta, Canada

Research goals and why the work was worth doing

Organizations invest significant resources to persuade their employees to share knowledge, to increase organizational productivity and performance. However, there is growing awareness that some employees deliberately hide knowledge from coworkers. Rather than study the effects of sharing and hiding as separate variables, we examine whether employees can be classified according to their unique pattern of knowledge exchange behaviour, and whether membership in these cohorts is predictable from motivational states.

Theoretical background

Given the "riskiness" of an employee's decision to share or hide knowledge, we apply regulatory focus theory (RFT), which asserts that two motives underlie human behaviour: individuals either self-regulate towards goals that prevent negative outcomes, or self-regulate towards goals that promote an "ideal" state. When prevention-oriented motives are strong, individuals focus on minimizing risk (personal losses), meeting their responsibilities, and achieving safety and security goals. When promotion-oriented motives are strong, individuals focus on advancement, growth, or achievement.

We hypothesized that when prevention-oriented self-regulatory focus is strong, the tendency to engage in risky self-serving behaviour (i.e., knowledge hiding) will be muted with more effort devoted to satisfying collective interests (i.e., knowledge sharing). Thus, the likelihood of the sharing-only pattern should be greater when prevention focus is strong. In contrast, individuals with a strong promotion focus should exhibit greater response flexibility as they optimize self-interests. We thus expect promotion-focused individuals to share or hide knowledge, as needed. Increased promotion focus should reduce the likelihood of the sharing-only and hiding-only patterns.

Design/Methodology/Approach/Intervention

We tested our hypotheses with two samples (N = 697; N = 1103) of working adults drawn from a variety of geographic locations and industries. Knowledge sharing and hiding tendencies were subjected to latent profile analysis.

Results obtained

Three distinct cohorts of individuals emerged: a sharing-dominant pattern, a hiding-dominant pattern, and a novel pattern that implied behavioural ambidexterity (individuals who engaged frequently in both kinds of behaviours). We also found that membership in the three cohorts was predicted by demographic characteristics (sex, age, organizational tenure) and by the self-regulatory focus (prevention- and promotion-oriented): We found that respondents with a strong prevention focus were almost three (2.68) times more likely to belong to the sharing-dominant profile than the ambidextrous profile. Respondents who reported stronger promotion-oriented regulatory focus were 71% and 64% less likely to belong, respectively, to the sharing dominant and hiding dominant profiles than they were to the ambidextrous profile.

Limitations

While it is appropriate to assess individuals' knowledge hiding and sharing tendencies using self-reports, perceptual biases might have increased the likelihood of certain profile configurations. However, if there was a group of individuals who responded in a socially-desirable manner, we would have captured these individuals within a single profile. We expect that the sharing-dominant pattern would be more socially desirable than the hiding-dominant or the ambidextrouspatterns, and thus social desirability bias would not have altered our findings.

Conclusions: Research/Practical Implications

Beyond our observation that most employees tend to either share or hide knowledge – an insight unique to our analytic strategy – we found that about 10% of employees will frequently share and hide, and we uncover reasons why people pursue this knowledge exchange strategy. Our findings have implications for organizational knowledge management initiatives that are designed to limit knowledge hiding and encourage knowledge sharing.

Our results suggest that in any population of working adults there will be cohorts who exhibit a response pattern of sharing and hiding tendencies. Namely, in addition to groups who demonstrate a proclivity to share or hide, we demonstrate that there will also be a sub-population characterized by an ambidextrous response pattern.

Studying prototypical patterns that combine knowledge sharing and hiding extends theories where these behaviours are viewed as distinct phenomena that co-vary with other variables within a population of interest. A person-oriented analytic strategy explains how information-exchange behaviours might naturally combine, and whether cohorts of individuals within a population share a similar approach when responding to information requests.

Relevance to the Congress Theme

As workplaces continue to change and evolve, employees and organizations must continue to adapt to new pressures. Whereas many organizations implicitly expect employees to share all their knowledge with each other, this expectation is frequently unrealistic. Our more nuanced approach recognizes the tensions inherent in knowledge sharing and hiding, and how employees can strategically maintain productive relationships and their own interests.

Paper 2

A longitudinal analysis

Matej Černe, School of Economics and Business, University of Ljubljana, Slovenia; Sut I Wong, BI Norwegian Business School, Norway; Aldijana Bunjak, University of St Gallen, Switzerland; Robert Buch, Oslo Metropolitan University, Norway; Dominique Kost, Oslo Metropolitan University, Norway; Darija Aleksić, School of Economics and Business, University of Ljubljana, Slovenia

Research goals and why the work was worth doing

The challenging situation created by COVID-19 changed the nature of work and employee behaviours. The main objective of this study was to enhance our understanding of employees' adaptive behaviours during an exceptionally challenging and demanding situation such as the pandemic. Research has shown that employees working remotely are more likely to blur the boundary between work and private lives and work longer and more irregular hours, but the phenomenon of supplemental work remains underexplored. Building on the job demand–control model, we examined two specific adaptive mechanisms, creative bootlegging and knowledge hiding, and the role they play in the relationship between supplemental work and performance. We aim to enhance our understanding of employees' behavioural adaptations during the COVID-19 crisis, thereby complementing existing research on distributed work and work behaviours during the pandemic. Moreover, we intend to contribute to increasingly relevant research on supplemental work by exploring the underlying mechanisms and boundary conditions related to irregular adaptive secrecy behaviours.

Theoretical background

Recent studies show the COVID-19–associated changes in the ways of organizing work (e.g., home–office work environment, digitized team processes, and virtual connection) represent a challenging work context that affects employee performance. In particular, employees have been exposed to increased work pressure, an unfavorable physical environment, and emotionally demanding interactions, which have significantly increased job demands on employees. Thus, when employees engage in supplemental work as an attempt to cope with increased job demands, it can backfire, so that employees who mobilize extra resources, such as working hours, to compensate for fatigue through mental effort become exhausted and fail to perform well due to a reduction in energy resources:

H1: Supplemental work is negatively related to performance.

Knowledge hiding and creative bootlegging (i.e., an unofficial way of pursuing innovative activities without formal support) act as discretionary adaptive behaviours that allow employees to regain a sense of job control and to regulate professional and personal demands. We argue that these discretionary adaptive behaviours interplay in interfering with the relationship between supplemental work and performance:

H2: Knowledge hiding moderates the relationship between supplemental work and performance, mediated by creative bootlegging. For high levels of knowledge hiding, the mediated relationship is positive, whereas for low levels of knowledge hiding, it is negative.

Design/Methodology/Approach/Intervention

We conducted a four-wave (February, March, April and May 2020), longitudinal, web-based questionnaire study with data from 198 employees working across a wide range of industries collected before, during, and after the first wave of COVID-19 emergency in Slovenia, applying quota-based sampling representative for the Slovene workforce.

Results obtained

Across-time effects revealed a negative and significant direct effect of supplemental work on employee performance, supporting Hypothesis 1. The results provide partial support for Hypothesis 2: for low levels of knowledge hiding, the mediated relationship was negative, whereas for high levels of knowledge hiding, it was positive, but it was insignificant.

Limitations

As our research was designed before the pandemic outbreak, with the aim of longitudinally examining adaptive behaviour and performance in the work-from-home context, we did not control for different flexibility arrangements among employees before the COVID-19 pandemic occurred and other contractual agreements concerning overtime work.

Conclusions: Research/practical implications

The results indicated that supplemental work generally had a negative effect on performance, and that knowledge hiding and creative bootlegging serve as important employee adaptive behaviours in this relationship. It is important for managers, organizations, and societies to gain insight into supplemental work's influence on other, more proximal, employee behaviours and organizationally relevant outcomes, such as how well the employees perform over time. Our findings provide implications on whether supplemental work needs to be regulated but also give insight into how this could be done in a post-pandemic work environment.

Relevance to the Congress Theme

Our study provides a valuable insight on one's adaptive behaviours in the time of COVID-19, with implications for other challenging situations in the changing world of work. Along with new technology changing the workplaces, the COVID-19 pandemic altered individual reality and created "the new normal" work conditions.

Paper 3

Once is not once? An examination of the role of guilt in employees' knowledge hiding

Laura Venz, Institute for Management and Organization, Leuphana University Lüneburg, Germany; Sebastian Hofreiter, Hochschule für angewandtes Management; Thomas Steiner, Friedrich-Alexander-Universität Erlangen-Nürnberg, Germany; Florian Offergelt, Privatuniversität Schloss Seeburg, Austria

Research goals and why the work was worth doing

This study examines the role of feelings of guilt in the context of enacting knowledge-hiding behaviours of evasive hiding(giving incomplete/incorrect information), playing dumb (pretending not to possess the knowledge), and rationalized hiding (explaining why one does not share the knowledge). Recent research suggests that the within-person (i.e., relating to one-time incidences of knowledge hiding) and between-person (i.e., relating to more chronic knowledge hiding) intrapersonal effects of knowledge hiding might differ. Considering this, we aim to advance the understanding of the intrapersonal moral consequences of knowledge hiding for hiders by examining both within-person and between-person effects in one study. This is an important undertaking because different prevention approaches would need to be considered depending on whether knowledge hiding has or has not intrapersonal detrimental consequences if enacted only once. Further, considering that guilt is not a dead-end state but likely triggers further behavioural responses, we add the consideration of guilt as a potential predictor of knowledge hiding to this stream of research, testing guilt as part of a knowledge hiding spiral.

Theoretical background

Drawing on moral self-regulation theory, we examine the relationships between employees' enactment of knowledge hiding, their subsequent feelings of guilt, and their subsequent engagement in knowledge hiding. We hypothesize that knowledge hiding is positively related to guilt and that guilt, serving a compensatory function, reduces subsequent knowledge hiding. Whereas we expect this relationship pattern to show on the between-person level of analysis, we pose the research question whether these relationships also show within person, or whether 'once is only once' in the context of knowledge hiding.

Design/Methodology/Approach/Intervention

We conducted a weekly survey study covering six consecutive workweeks framed by two general surveys, one week before the first weekly survey (t1) and one week after the last weekly survey (t2; two months after t1). Weekly surveys were administered at the end of the workweek. We assessed knowledge-hiding behaviours (i.e., evasive hiding, playing dumb, rationalized hiding) referring to the past two months in the general surveys and referring to the past week in the weekly surveys. We assessed state guilt referring to the end of the workweek in the weekly surveys. A total of 224 employees (=between-person level) responded to 998 weekly surveys (=within-person level). We used multilevel structural equation modelling to analyse (a) the within-person relationship of weekly knowledge hiding with end-of-week guilt with next-week knowledge hiding and (b) the between-person relationship of t1 knowledge hiding with aggregated weekly guilt (i.e., person mean) with t2 knowledge hiding (controlling for t1 values).

Results obtained

On the within-person level, none of the knowledge-hiding behaviours was significantly related to guilt. Also, guilt was unrelated to all three knowledge-hiding behaviours in the following week. On the between-person level, however, t1 evasive hiding was positively related to weekly guilt and playing dumb showed a marginally significant effect, while rationalized hiding was unrelated to guilt. Guilt in turn was positively related to t2 evasive hiding and playing dumb, but unrelated to rationalized hiding.

Limitations

All measures rely on self-reports what might have caused biased relationships. Further, despite temporal separation of most measures, no causality can be implied.

Conclusions: Research/Practical Implications

Our results indicate that regarding knowledge hiding, 'once is not once', as, within person, week-specific knowledge-hiding behaviours were unrelated to state guilt; state guilt was, moreover, unrelated to subsequent knowledge hiding. On the between-person level, however, evasive hiding and by trend playing dumb were longitudinally positively related to guilt, indicating that knowledge hiding may have persisting negative intrapersonal consequences when shown regularly. Further, surprisingly, between-person guilt (i.e., the person mean aggregated over six weeks) was related to *enhanced* evasive hiding and playing dumb. This finding challenges the idea that guilt triggers compensatory behaviours, indicating that guilt might in fact cause the opposite – maybe to reduce cognitive or emotional dissonance. This finding bears implications for organizations as they cannot rely on that knowledge hiding will somehow cure itself.

Relevance to the Congress Theme

In a constantly changing world of work, intra-organizational knowledge exchange is a key element to ensure organization's survival and economic growth. At the same time, however, knowledge hiding between co-workers does happen. Without understanding the intrapersonal processes underlying individual employees' decision to hide knowledge this behaviour cannot be stopped, leaving organizations unfit for the future of work.

Relevant UN SDGs

Paper 4

Interpersonal consequences of knowledge hiding between co-workers: Boundary conditions and moderators

Johannes F. W. Arendt, Ludwig-Maximilians-Universität München, Germany; Laura Venz, Leuphana University Lüneburg, Germany

Research goals and why the work was worth doing

This experimental vignette study aims to shed light on different boundary conditions that determine the direction and magnitude of the interpersonal effects of knowledge hiding, focusing on targets' emotional and behavioural reactions. A vignette study is especially suited to study the effects of knowledge hiding on targets given that the prevalence of knowledge hiding is often comparatively low in field studies and that this behaviour might often go unnoticed by its targets, what makes it difficult to study its interpersonal consequences in the field. Using experimental vignette methodology, we can "simulate" situations in which a co-worker engages in perceptible knowledge hiding.

Theoretical background

Although it seems evident that knowledge hiding has negative interpersonal effects, studies from related research areas suggest that whether uncooperative behaviours result in negative effects or not depends on numerous boundary conditions. Against this background, we argue that the interpersonal consequences of knowledge hiding are not always "the same" but rather depend on contextual factors of the knowledge-hiding situation, for example stressors that the hider experiences, and on personal characteristics of the individuals involved, for example targets' personality.

Design/Methodology/Approach/Intervention

We constructed a set of scenarios (i.e., vignettes) in which the participants are or are not targets of knowledge hiding (specifically playing dumb) in co-worker interactions and in which we additionally manipulate two contextual variables that we hypothesize to play a role in targets' evaluation of and response to knowledge hiding, namely time pressure of the hider and complexity of the knowledge requested. In a pilot study with N = 238 participants, we successfully tested the functionality of the vignettes and the manipulations and choose the best-working vignette for our main study.

We will test our hypotheses based on data that we are just collecting with a two-wave experimental vignette study with working participants. At t1, we assess individual personality characteristics and past own knowledge hiding of the participants with self-reports. At t2, we present the different variations of the pre-tested vignette in a randomized between-person manner. As target responses, we examine participants' expected reactions to the presented scenario, for example emotional reactions as well as expected future behaviour towards the hider including knowledge hiding. We plan to collect data until end of October 2022 (current N = 252); the results will be available at the time of the conference.

Results obtained and expected

The pilot study revealed that all developed vignettes successfully manipulated participants' perception of knowledge hiding (especially playing dumb), time pressure of the hider, and complexity of the knowledge requested.

For the main study, we expect that the interpersonal effects of playing dumb on targets depend both on individual tendencies of the target to interpret and react to behaviour of others and on situational contextual factors against whose background knowledge hiding is perceived. Accordingly, we assume that knowledge hiding does not have the same and equally strong effects, respectively, on targets across situations (as manipulate in the vignette) and individuals (as measured via self-report).

Limitations

The use of experimental vignette methodology entails that no actual behaviour and no reactions to real experiences are assessed but only imagined reactions to imagined scenarios are reported.

Conclusions: Research/Practical Implications

Our study is intended to enrich research on knowledge hiding by enabling a more nuanced picture of the impact of knowledge hiding on social relationships in the workplace, focusing on effects on targets. Our study will provide insights into whether and to what extent situational context and personal target characteristics play a role with respect to the interpersonal effects of knowledge hiding among co-workers. Additionally, we see a welcome side effect in the construction of a set of scenario vignettes on knowledge hiding that could be used in future studies by other authors.

Relevance to the Congress Theme

In times of dynamic and knowledge-intense work environments, the exchange of knowledge between co-workers is an essential prerequisite for organizational success. Against this background, a deeper understanding of the phenomenon of knowledge hiding is important for both scientists and practitioners.

Symposium S002

Leadership and wellbeing part 1: Remote, hybrid, and challenges

Birgit Schyns, Neoma Business School; Iris Gauglitz, University of Bamberg, Germany

science

This symposium forms part 1 of a double symposium on leadership and well-being. Part one focuses specifically on new forms of work, that is, remote or hybrid work, as well as job demands and resources and its effects on employee well-being, both in terms of followers and leaders. The symposium comprises of five contributions and a discussion lead by the moderators.

The first two contributions specifically use samples of leaders and followers working in remote contexts. Neidlinger et al. investigate leader well-being when working from home. They argue that leaders' well-being when working from home depends on their core self-evaluations, with those low in core self-evaluations differing more in their well-being depending on where they work than those high in core self-evaluations.

Investigating followers rather than leaders, Tautz and Felfe conducted research into transformational leadership and examined its role in the context of remote work and information and communication technical stressors. They found that even in remote contexts transformational leadership has positive effects on followers but that stressors relayed to the use of information and communication technologies reduce this positive effect.

Rather than emphasising remote work, Lagowska et al. take into account where people work during the week, that is, the sample they drew is from employees working in hybrid contexts. Place of work can be relevant when looking at the effects of abusive supervision on follower well-being. They argue that there is a positive path between abusive supervision and follower well-being that is mediated by adaptive rumination and influenced by cognitive sharing mode with colleagues as well as a negative one running via maladaptive rumination and influenced by affective sharing mode with colleagues. Further, these paths are influenced by where the employee works on a specific day, that is, at home or in the office.

More broadly focusing on outcomes of the pandemic in the workplace, Kiefer et al. argue that changes due to the pandemic affected followers' motivational needs, that is, autonomy, a sense of competence, and relatedness and that ambidextrous leadership, which has been shown to be effective in disruptive context, can help followers maintain their well-being in this context. They found that indeed the pandemic has influenced follower motivational needs and that leader opening but not their closing behaviours help supporting followers' well-being.

The final contribution aims at establishing a new instrument to assess leadership which is more adapted to job demands and resources. Van Rossum et al. suggest that when dealing with job demands and resources, followers might benefit from particular leader behaviours aimed at regulating those demands and resources. While they suggest to construct a general instrument, in the context of this symposium, we will also discuss how leader behaviours might have to differ depending on where leader and followers work.

The symposium includes contributions using different methods and designs, such as survey field studies, scale construction, and a diary study showing the breadth of methods used in the research on leadership and well-being.

The symposium contributes to the congress theme “The Future is Now: the changing world of work” by including news working modes such as remote and hybrid work in their design, sampling, and theoretical framework. It also contributed to the UN SDG “Good health and well-being” by focusing on well-being in the work context both of leaders and followers.

Keywords: Leadership, well-being, new forms of work

Paper 1

Should I Stay or Should I Go (to the Office)? – The Moderating Role of Core-Self Evaluations on Leader Health and Thriving in Remote Work Settings

Joerg Felfe, Katharina Schuebbe & Stephanie Neidlinger | Helmut Schmidt University Hamburg, Germany

Research goals and why the work was worth doing

Working from home increases the opportunities to save time on commute, spend more time with families or leisure, and incorporate more exercise. Although the overall role of working from home as a resource for employees is widely accepted, it is unknown whether positive effects also hold true for those in leading positions. We examined working from home as a resource for leader health and thriving and aim to enrich the literature on working from home by examining the role of leader personality and shedding light on who benefits from working from home.

Theoretical background

Leadership roles are characterized by unique demands and resources. Working from home may provide specific resources and improve leaders' overall health and thriving. When allowed to work from home, leaders may benefit from increased autonomy, reduced interruptions, and reduced complexity of their environment.

We draw on Job-Demands-Resources (JDR) model to conceptualize working from home as an organizational resource for leaders and hypothesize overall positive direct effects of working from home on leader health and thriving. However, it has yet not been shown whether leaders – with their specific demands – benefit from WfH. Since no study has yet examined a sample of leaders, it is of interest to examine not only direct effects of working from home on leader outcomes but also address potential moderators.

The personality concept of Core-Self Evaluations (CSE) has shown relevance for leader outcomes. High CSE constitute a personal resource and are positively related to health. Low CSE on the other hand represent the absence of a resource: people with low CSE have been found to experience poor health and increased stress and strain.

We argue that CSE may be the resource driving whether and to what extent leaders benefit from remote work. Individuals with high CSE and thus high personal resources tend to show positive outcomes at home as well as in the office and compensate the risk of a less favourable context. If resources are high, successful mastery of demands becomes more likely. If CSE however is low, leaders may depend more on a favourable context.

Design

We recruited a sample of 367 leaders from various occupational backgrounds and used a design with two measurements spaced five months apart to capture both direct and interaction effects of working from home and CSE on three outcomes related to thriving. We focused on health, well-being, and work-live balance to capture both general health-related and specific thriving-related outcomes.

Results

Results showed a moderating effect of CSE on all three outcomes, indicating that leaders with low CSE benefitted more from WfH in terms of health, well-being, and work- life balance. Conditional effects for low CSE were significant for all three outcomes. Leaders with high CSE had overall higher levels of health, well-being, and work- life balance regardless of where they worked.

Limitations

We used simple moderation analyses to test all hypotheses. For future studies, a longitudinal design with three or more measurements could enrich analyses by allowing hierarchical linear modelling. Effects were small, potentially to great heterogeneity within the sample. Recruiting a more homogenous sample in terms of i.e., number of followers, might be beneficial.

Conclusions – research and or practical implications

The study contributes to the literature in multiple ways. First, we focused on a sample of leaders, which constitute a high demand subgroup of the employee population. By allowing leaders with low CSE to work from home, positive outcomes for those leaders might be increased. Second, we added to the growing body of research on remote work, extending previous studies by adding leader personality as a moderating construct to shed some light on who benefits from remote work. Results can aid professionals in organizations to adapt current work-design practices to support health and thriving.

Relevance to the Congress Theme & Relevant UN SDGs

Our study contributes to the congress theme and to the UN SDG by shedding light on leader thriving under new working conditions. Understanding who benefits in terms of health, well-being and work life balance will be essential for the future of work.

Keywords: Leadership, remote work, core self-evaluations

Paper 2

Working at home: Challenges for the effectiveness of transformational leadership on employees' well-being

Joerg Felfe & Dorothee Tautz | Helmut Schmidt University Hamburg, Germany

Due to the Covid-19 crisis many employees and their supervisors were forced to relocate their working place from the office to their homes. As many employees benefit from working from home it can be assumed that it remains a huge part of the future world of work. However, working from home also brings challenges, especially to employees' well-being, which need to be considered and addressed. Prior research has found that the well-being of employees working from home might decrease due to limited social connectedness, limited organizational support and family conflicts. However, there is barely any research looking into the role of leadership on employees' well-being in the remote context. While we know from the traditional office context that transformational leaders are able to promote employees' well-being and buffer the negative effects of job stressors, it is unclear whether transformational leadership (TFL) does also unfold its effectiveness in the remote setting. Further we do not know, whether the use of information and communication technologies (ICTs) and the job stressors that come along with it buffer the effectiveness of TFL on employees' well-being. Therefore, in our study we aim to investigate the relationship between TFL and well-being during working from home and the moderating effects of the following ICT-related job stressors: technical problems, high workload, constant availability and communication difficulties. This study advances current literature by shedding new light into the role of TFL in the remote context and the moderating role of ICT demands. Further our purpose is to develop recommendations for organizations and HR practitioners to support effective leadership during working from home.

Literature regarding the effectiveness of TFL in the remote setting is scarce and inconsistent. While some studies provide evidence for the positive effects on employees' performance and satisfaction, others report the opposite. Also, to date we are not aware of any studies investigating the impact of TFL on well-being during working from home. We assume that TFL still works as a job resource in the remote context and positively affects employees' well-being as transformational leaders consider the individual needs of their employees, offer support and create a strong bonding. But in line with the Job-Demands-Resources Model we assume that job stressors related with the use of ICTs negatively influence the relationship between TFL and well-being.

To check our assumptions and answer the research questions we collected longitudinal data from N = 763 employees at two measuring points (July and September 2021). The employees work in different organizations in Germany from various industries, they are all employed and report to a direct supervisor. The participants worked at least one day a week from home and were asked about their subjective perspective on TFL, ICT demands and their well-being during working from home. We analyzed the data using moderation analysis.

The results confirm that even in the remote context with less interaction and communication TFL unfolds its effectiveness on employees' well-being. However, technical problems, high workload and communication difficulties have a buffering effect on this relationship. In contrast constant availability does not impair the effectiveness for employees' well-being. Our study extends previous research by explicitly examining the effectiveness of TFL on well-being when working remotely and supported the assumptions that TFL is still effective but gets weaker under the influence of ICT-

related job stressors. Therefore, organizations and HR practitioners need to make sure that employees are provided with adequate technical equipment. Also, trainings or workshops need to be offered for leaders to recognize and manage workload and decreased well-being of their employees over distance.

Although our study has strengths as the longitudinal design with allows to conclude causal relationships, it also has some limitations. First we only asked employees for their subjective perspective. Future research should extend our research by using physiological measures for employees' well-being or health status and should include leaders' perspective. Also, further research should expand the investigation of job demands during working from home. Our research is limited to four specific ICT-related job demands. However, there might be other stressors that also have an influence on employees' well-being.

Our study contributes to the congress theme "The Future is Now: the changing world of work" and to the UN SDG "Good health and well-being" as we investigated and shed new light into the well-being of employees during working from home. Flexible working arrangement like working from home immensely increased due to the Covid-19 crisis and are going to remain a part of the future world of work. Therefore, challenges for employees need to be addressed and investigated.

Keywords: Leadership, remote work, well-being

Paper 3

Daily abusive supervision, rumination, and follower well-being: The buffering and facilitating effects of co-worker social support and working regime

Birgit Schyns, Dongkyu Kim & Urszula Lagowska | Neoma Business School, France

The goal of this study was to examine the mediating effects of adaptive and maladaptive rumination that underlie the relationship between daily changes in abusive supervision and employee well-being. Further, we assessed the moderating effects of co-worker social support and working regime on these relationships in order to contribute to a better understanding of the consequences of hybrid working regime and the effects of social support (cognitive and affective sharing mode) on the outcomes of abusive supervision.

Over the last two decades, research on negative forms of leadership and notably the concept of abusive supervision (Tepper, 2000) has gained a lot of interest. It is clear that those followers who work under abusive supervisor suffer negative consequences such as lower job and supervisor satisfaction, lower commitment, and also lower general wellbeing (Schyns & Schilling, 2013). At the same time, research also acknowledges that followers might experience more or less of abusive supervision each day (Vogel & Mitchell, 2017), which means also the consequences for followers might vary in reaction to the variations in the leadership they are exposed to.

In the present research, we build on the Job Demand Resources theory (Bakker & Demerouti, 2017) to investigate in how far daily variations in abusive supervision (job demands) are linked to daily variations in indicators of follower wellbeing, such as sleep quality and quantity after exposure to abusive supervision during the day and in burnout the morning after (Rath et al., 2010).

Further, we investigate processes underlying the effects of abusive supervision. Adaptive rumination refers to problem-focused rumination, maladaptive rumination refers to affective rumination (Joormann et al., 2006). Based on prior studies (Eisma et al., 2015), we assume that adaptive rumination, which can act as a resource, should result in lower negative wellbeing after being exposed to abusive supervision. Contrastingly, there is a positive path via maladaptive rumination, which can act as an additional demand, and thus should increase negative wellbeing after being exposed to abusive supervision.

Finally, we explore buffering effects on these relationships. In line with recent trends on the labour market, we investigate in how far working regime can act as a buffer. Since the Covid-19 pandemic, the number of employees working remotely and in hybrid mode has increased (McGregor, 2022). Thus, we investigated if not being directly exposed to an abusive supervisor might act as a buffer for followers' wellbeing, so that after remote working days, wellbeing is less affected than after on-site days. In addition, we assessed moderating effects of social support, understood as cognitive or affective sharing mode (Tremmel & Sonnentag, 2018). We argue that that if followers are encouraged by their colleagues to rethink in a constructive way their experiences of abusive supervision, this acts as a resource, they would ruminate in a more adaptive way, which in turn would positively affect their wellbeing. However, if the support serves as an outlet to emotions, this will lead to more maladaptive rumination.

To assess our predictions, we conducted an online diary study with UK employees from diverse industries. Over the period of 10 working days, participants filled in three online surveys per day (at the end of the workday, at bedtime, and the next morning) which were accessible via computer and

smartphone. Data will be analyzed using multi-level modelling in Mplus and multi-level panel data analysis in STATA.

We expect to find that abusive supervision experienced during the day is positively related to both employee a) adaptive and b) maladaptive rumination during the recovery, and that while adaptive rumination is negatively related to negative employee well-being the next day, the relationship between maladaptive rumination and the well-being is positive. Further, we expect that cognitive sharing enhances the indirect relationship between abusive supervision and wellbeing through adaptive rumination whereas affective sharing mode enhances the indirect relationship between abusive supervision and well-being through maladaptive rumination. Finally, when working from home, the direct effect of abusive supervision on well-being should be weaker than when working on site.

Our study contributes to the congress theme “The Future is Now: the changing world of work” and to the UN SDG “Good health and well-being” as we explore the consequences of abusive supervision on employee sleep quality and burnout depending on the working regime. We assess how new forms of work change the perception of bad leadership and, in turn, affect the health of individuals in organizations.

Keywords: Leadership, well-being, hybrid work

Paper 4

Understanding the role of ambidextrous leadership behaviours for employee wellbeing during the Pandemic

Matt Chennells, Warwick Business School, UK; Laurie Barclay, University of Guelph, Canada; Tina Kiefer, Warwick Business School, UK

Research goals and why the work was worth doing:

The Covid-19 pandemic has presented most employees with a significantly different working context. This meant, similar to other radical organisational change contexts, employees and leaders needed to navigate these new experiences of work. The pandemic has raised attention to questions such flexibility and work-life-balance, the meaning of work, effectiveness at work, and an increased workload. Employee wellbeing was a focus during the Pandemic given these factors are all known to affect employee wellbeing.Leaders were called upon to support and guide employees through the changes that the pandemic presented, while at the same time dealing with and adapting to the same changes. This research firstly aims to understand how the changes to the experience of work triggered by the pandemic affected employee wellbeing; and secondly, how leader behaviours affects both positive and negative employee wellbeing.

We make three main contributions of theoretical and practical significance: Firstly, we apply self-determination theory to understand how and why the shifts in employee experience during the pandemic affected wellbeing; secondly, we extend ambidextrous leadership theory to demonstrate the importance of leader supporting behaviours for employee wellbeing, and thirdly, we focus specifically in on leader behaviours that foster a sense of belonging and connection.

Theoretical background: We draw on self-determination theory to argue that the pandemic has affected the experience of the three core motivational needs, autonomy, a sense of competence, and relatedness. We argue that shifts in all three components are likely to affect employee wellbeing. In order to understand the role of leadership in employee wellbeing, we draw on ambidextrous leadership (AL) theory (Rosing et al., 2011) because it focuses on both on leader opening behaviours (triggering explorative follower behaviours) and closing behaviours (triggering exploitative behaviours in followers). Leader opening and closing behaviours are well suited to lead employees through disruptive change, by allowing and encouraging new ways of doing things as well as focusing on establishing new routines and provide guidance through unstructured contexts. Though very little is known about the impact of AL behaviours on employee wellbeing, we argue that opening and closing behaviours affect competence and autonomy in different ways. However, AL theory does not consider leader behaviours directed towards enhancing relatedness. We introduce leader supporting behaviours as a complementary AL dimension and argue that supporting behaviours are a relevant mechanism by which AL behaviours affect positive and negative employee wellbeing.

Design/Methodology: This is a two-wave survey study of employees and leaders in a multi-national financial services company, conducted during the second half of the Covid-19 pandemic. The survey uses self-report measures due to the nature of the research questions.

Results: Results indicate that leader opening behaviours have a positive indirect effect on both positive and negative wellbeing via competence, and on positive wellbeing via autonomy. Relatedness does not predict positive wellbeing, but is negatively related to negative wellbeing.

Results further suggest that Leader closing behaviours restrict autonomy, but that the relationship is moderated by leader supporting behaviours. When leader supporting behaviours are high, then the relationship between leader closing behaviours and autonomy is positive, while the relationship is negative, when leader closing behaviours are low. We found the same moderation effect of leader supporting behaviours on the relationship of leader closing behaviours on relatedness.

Limitations: Ideally, we would have linked team member perceptions and their supervisors perceptions to predict employee wellbeing. However, restrictions impacted by company decisions related to data protection regulations did not allow us to do so. Further, we chose to use the original validated measure for Leader opening behaviours. However, the some of the wording of the items carry a negative connotations, which may have obscured the role of leader opening behaviours. The next step in our research project aims to address this concern.

Conclusions: Our findings suggest that the Covid-19 pandemic has affected the core needs of autonomy, competence and relatedness and that leader opening behaviours in particular, were supporting employees to adapt to change and maintain their wellbeing. Leader closing behaviours could have a negative effect (i.e. on autonomy), which however was mitigated by leader supporting behaviours. This demonstrates the importance of understanding leadership behaviours beyond the traditional opening and closing behaviours.

Relevance to the Congress Theme and UNSDGs: Our research speaks directly to the EAWOP theme by addressing how the world of work has changed during the pandemic how those changes affect wellbeing. It hence also speaks to the UNSDG's goal 3 on fostering wellbeing and goal 8, which promotes decent work.

Keywords: Leadership, well-being. ambidextrous leadership

Paper 5

Effective leaders regulate employees' job demands and resources

Arnold Bakker, Kimberley Breevaart & Anne van Rossum | Erasmus University Rotterdam, The Netherlands

Research goals and theoretical background: Leaders have a significant influence on employees' well-being and performance, either positive or negative (Skakon, Nielsen, Borg & Guzman, 2010). In our research into effective leadership behavior, we build upon Job Demands and Resources theory (JD-R theory; Demerouti, Bakker, Nachreiner & Schaufeli, 2001). JD-R theory has gained traction in the past decades as it has significantly improved our understanding of employee well-being, behaviors, and performance. According to the theory, job resources and challenging demands positively influence employee work engagement, whereas hindrance demands increase employee levels of stress. Consequently, work engagement improves our job performance, while stress negatively affects our job performance (Bakker & Demerouti, 2017). In the present research, we therefore argue that leadership behavior aimed at regulating employees' job demands and resources will lead to enriched jobs and better employee functioning. We aim to develop and validate a scale that explicitly measures leaders' capabilities to regulate their employees' JD-R's.

Methodology: To develop this scale, we first determined the dimensions to be used as the foundation, based on the JD-R model. The three scale dimensions are regulating employee job resources, regulating employee challenging demands and regulating employee hindrance demands. We invited leadership experts to develop items pertaining to each dimension. We collected approximately 60 items per dimension from eight leadership experts. Based on a set of scale development criteria (Cortina et al., 2020), we rated these items on their suitability. The final scale consisted of 36 items and were tested among a leader and an employee sample. At the time of writing, the researchers are collecting data. Data will be collected until the end of 2022 with an estimate of 300 completed questionnaires, after which studies will be conducted for further scale validation in the first quarter of 2023.

Limitations: Adequate validation of the scale is dependent on a significant number of survey responses. At the time of writing, the researchers are still in the process of gathering this data.

Conclusion - Research/Practical implications: The validated scale may provide a foundation to explore the nomological net surrounding leaders' regulation of employees' demands and resources. The scale and sequential new insights may thereby help leaders to create healthier and more constructive working environments.

Relevance to the Congress Theme: Our research is highly relevant to the EAWOP Congress theme "The future is now: the changing world of work". There is an enormous challenge and opportunity for leaders to shape the changing world of work. New insights from our research will help leaders to positively involve their employees in their contribution to todays and the future's urgent problems.

Relevant UN SDG's: Our research is relevant to the UN Sustainable Development Goals "Good health and well-being" and "Decent work and economic growth". High levels of motivation and low levels of stress are preconditions for decent work and well-being in the workplace. This way, leaders and their employees will be engaged in their jobs, thereby indirectly positioning them to contribute to any of the other UN Sustainable Development Goals.

Keywords: Leadership, well-being, job demand resource model

Symposium S003

To work or not to work? Attitudes and activities fostering well-being and job search during unemployment

Greet Van Hoye, Ghent University; Edwin van Hooft, University of Amsterdam

science

What will be covered and why

Individuals are faced with the transition between non-work and work multiple times during their careers: after graduation, after job loss, or after a period of inactivity (e.g., burnout). Prior research revealed that work serves both manifest (i.e., income) and latent (i.e., time structure, status, social contact, collective purpose, personal status and identity, activity) functions that contribute to our well-being (e.g., Jahoda, 1981). Consequentially, people who are not working generally display lower levels of well-being than their employed counterparts (McKee-Ryan et al., 2005; Paul & Moser, 2009). However, the consequences of not working might not be the same for all individuals (Van Hoye & Lootens, 2013). In addition, although job search can be challenging for mental health, engaging in job search behaviour relates positively to finding employment (Van Hooft et al., 2021), which subsequently can restore the negative effects of not being at work. Therefore, we need to know what determines the well-being of non-working people and how it can be improved. Moreover, as sustainable employment might be the best long-term solution for improving well-being, we need to understand how the job search process can be stimulated.

This symposium features the latest research addressing these key questions. The symposium includes four empirical papers, with researchers from different countries (i.e., Belgium and The Netherlands) and disciplines (i.e., work and organizational psychology, clinical psychology, business economics), applying various theoretical perspectives (i.e., self-discrepancy theory, latent deprivation model, broaden-and-build theory, self-regulation theory), taking samples from multiple relevant populations (i.e., unemployed, inactive, job seekers), and using diverse rigorous methods allowing for causal conclusions (i.e., multiple time wave design, daily diary design, and field experiment).

The first paper applies latent profile analysis to develop profiles of normative attitudes towards work and non-work within the unemployed and inactive populations, and relates those profiles to well-being. The results of a two-wave survey will shed light on whether more positive attitudes towards non-work may help to improve the well-being of non-working individuals. The second paper builds further on these ideas by investigating in a 5-day diary study whether engagement in various non-work activities can support mental health (i.e., mitigate reactions of complicated grief and depression) after involuntarily job loss. The final two papers investigate interventions aimed at facilitating the job search and reemployment process as well as the mechanisms that may explain their effectiveness. The third paper tests in a randomized-controlled trial whether a positive psychology intervention, the Three Good Job Search Things, can improve job seekers' metacognitive activities by stimulating their positive affect. The fourth paper applies a field experimental design to examine if and how a job search training can facilitate older job seekers' reemployment process and whether this effect is contingent on their orientations towards future development (i.e., learning orientation and future time perspective).

Relevance to the Congress Theme

The world of work is changing, but not everybody belongs to the working population. Some may decide not to work or are not able to work, others have lost their job or are yet to find their first job

after graduating. Given the important and central role of work in our society, not being at work can have substantial consequences for individuals' well-being, as demonstrated in prior research. Therefore it is crucial to understand which attitudes and activities can foster well-being while not at work, and how the job search process leading people to (re)employment can be facilitated. By addressing these research questions, this symposium contributes to the UN Sustainable Development Goals of "Good health and well-being" and "Decent work and economic growth".

Research/Practical implications

By drawing together the perspectives and insights of these four papers, this symposium will contribute to a thorough and integrated understanding of how the well-being and job search of non-working individuals can be fostered. In addition to the theoretical added value, this symposium aims to contribute to practice by identifying ideas for the development of well-being and job search interventions and guidelines for employment, career, and mental health counselling.

Overall conclusions

Job loss and unemployment negatively impact people's well-being. The present symposium first uncovers attitudes and activities for inactive and unemployed individuals to improve their mental health. Second, because reemployment is generally the best way to restore well-being, the symposium addresses activities that improve the quality of the job search process and increase reemployment success.

Keywords: Careers, well-being, unemployment

Paper 1

Can or should you (not) work? Normative attitudes towards work and non-work within the unemployed and inactive population: A latent profile analysis

Sophie Cuinen, KU Leuven; Nele De Cuyper, KU Leuven; Anneleen Forrier, KU Leuven; Ilke Grosemans, Open University

Research goals: The aim of this study is (1) to develop profiles of normative attitudes towards work and non-work within the unemployed (i.e., actively looking for work and available for work; Benes & Walsh, 2018) and inactive (i.e., persons not looking for work, and/or not available for work; Benes & Walsh, 2018) population, and (2) to relate those profiles to well-being. Addressing those aims could help to see that the population of those who are currently not at work is heterogeneous (beyond any objective indicator), and that this heterogeneity could explain why some individuals have better well-being than others.

Theoretical background: To address our research goal, we conceptualized normative attitudes towards both work and non-work. Normative attitudes towards work are defined as the extent to which a person sees work as a right or duty of people in society. Normative attitudes towards non-work are defined as the extent to which non-work is seen as a renunciation of the duty to work or as a right of every individual. We will investigate whether profiles of these attitudes across the unemployed and inactive population can be identified.

Our conceptualization of normative attitudes contributes to the literature in two ways. First, research to date typically focuses on work-related attitudes (e.g., work ethic), but less on non-work attitudes. This is unfortunate, as our conception of work is not inversely related to our conception of non-work (Fryer, 1986). Accordingly, we include normative attitudes towards both work and non-work. Second, there seems to be a strong belief that unemployment is overall negative. Nevertheless, research shows heterogeneity with regard to well-being (e.g., Buffel et al., 2017; De Witte et al., 2010). Our focus upon normative attitudes advances a more complex connection with well-being. To illustrate, those who conceive work mainly as a duty to society may be particularly unhappy when not at work, while those who conceive non-work as a right, might feel relatively well during unemployment.

To understand the connection between these profiles and well-being, we use insights from self-discrepancy theory (Higgins, 1987). Self-discrepancy theory states that the greater the discrepancy between a person's selves, the poorer well-being will be. Within this research, we consider the normative attitudes as expressions of the ought self, and the current non-working situation as the actual self. Thus, we expect that profiles who experience a large discrepancy between their normative attitudes and their current situation will experience poorer well-being; and, conversely, that profiles whose normative attitudes fit well with their current situation will experience higher well-being.

Methodology: This research is carried out by means of a two-wave survey within the unemployed and inactive population in Flanders (Dutch-speaking part of Belgium). We developed a measure to capture the normative attitudes towards work and non-work. We will perform a latent profile analysis to identify profiles of these attitudes, and will explore the relation with well-being in a second step.

Results: At present, the first wave of data collection is ongoing. We expect to have collected all data and completed the analyses by the conference in May 2023. Confirmatory analyses of our measure based on the current response showed that the four-factor model fits the data best.

Limitations: The sample is heterogeneous but not representative. Also, we cannot exclude language barriers: the survey is only presented to the respondents in Dutch, although attention was paid to avoiding difficult words and sentence structures.

Research / practical implications: The study extends existing research on attitudes among the inactive and unemployed population, by conceptualizing normative attitudes towards both work and non-work. Identifying profiles of these attitudes across the unemployed and inactive population allows us to enrich existing, objective classifications. Additionally, we study how these profiles of normative attitudes relate to well-being.

Relevance to the congress theme: We examine the connection between normative attitudes and well-being within groups that are traditionally less discussed when talking about work and careers, namely the unemployed and inactive population.

Relevant UN SDGs: good health and wellbeing, decent work and economic growth

Paper 2

Reactions of complicated grief and depression after job loss: Can engagement in non-work activities bring relief?

Janske van Eersel, Utrecht University; Toon Taris, Utrecht University; Paul Boelen, Utrecht University, ARQ National Psychotrauma Centre

Objective.

The present study aimed to examine whether day-level engagement in various non-work activities can mitigate reactions of complicated grief and depression after involuntarily job loss.

Background.

From the perspective of the latent deprivation model of Jahoda, it can be hypothesised that unfulfilled basic needs (e.g., the need for time structure, affiliation and purpose in life) play a role in the development and maintenance of job loss related complicated grief reactions. That is, the intensity of these reactions has been found to be related to the disruption in a person's day-to-day life, access to valuable activities, meaningful interactions, social relationships, loss of identity, and low self-esteem. Therefore, we hypothesised that engaging in non-work activities (e.g., meeting others, exercising, or conducting household chores) can fulfil these five basic needs and that fulfilment of these needs mitigates reactions of complicated grief as well as depression following involuntarily job loss.

Method.

A diary study was conducted on five consecutive days among 236 participants who had involuntarily lost their job, yielding 1,046 daily measures of the time spent on activities, the evaluation of these activities, and emotional distress. Participants were on average 52.4 years old (SD = 8.4 years), and the sample consisted of 44 males (21%) and 166 females (79%).

Results.

The results showed a negative relation between the fulfilment of most basic needs and job loss-related complicated grief reactions. Similar results were found for the fulfilment of most basic needs and depressive reactions. Overall, out of the 30 associations between activities and need fulfilment that were considered, 11 (i.e., 37%) provided statistically significant support for the notion that the time spent on a particular activity is related to the degree to which the five basic needs are fulfilled. These relationships can be negative (e.g., the higher the involvement in relaxing activities, the lower the need fulfilment) or positive (more involvement in meaningful, social and – to some degree – high-duty and physical activities, is associated with higher need fulfilment). Furthermore, when participants found the time invested in a particular activity useful, they were likely to report higher levels of need fulfilment. Unfortunately, the mediation of the basic needs between daily activities on the one hand and reactions of job loss-related complicated grief and depression on the other hand could not be confirmed as the effect sizes were too small.

Limitations.

We did not consider intrapersonal and contextual factors that might have affected the engagement in activities and symptom levels observed in this study. It seems likely that the baseline level for JLCG and depressive symptoms on which a person starts the study, can affect the daily fluctuations of

emotional distress, as well as what type of activities someone undertakes. For example, depressed participants may be relatively inactive, making it difficult to detect effects of daily activities on emotional distress due to restriction of the range of the time spent on these activities.

Conclusions.

In general, the current results suggest that in terms of their impact on the fulfilment of basic needs and levels of emotional distress, the perceived utility of daily activities is more important than the time invested in these activities. For unemployed individuals this implies that to dampen the adverse effect of their job loss, they must undertake activities which they consider useful. Mental health professionals seeking to alleviate reactions of job loss-related complicated grief or depression after job loss need to consider carefully which type of activities are suitable for individual clients.

Relevance Congress Theme.

The current study seems to be best reflect topic '18. Well-being' of the Congress. Since the emphasis is on whether fulfilment of basics needs (Jahoda) and engagement in daily non-work activities can dampen the adverse effects of job loss.

Relevance UN Sustainable Development Goals.

The current study results are related to the UN SDGs 'Good health and well-being'. The study results highlight the significance of tailor-made behavioural interventions as well as preventive measures, where the evaluation of an activity by a participant must be decisive rather than general guidelines about which activities are supportive for persons with high levels of job loss-related complicated grief or depression symptoms after involuntary job loss.

Keywords: Well-being, job loss, grief

Paper 3

Fostering metacognitive activities during job search: The Three Good Job Search Things intervention

Jolien Stremersch & Greet Van Hoye | Ghent University

Research goals

The aim of this study is to (1) test whether conducting the Three Good Job Search Things (3GJST) intervention can increase metacognitive activities, as well as positive affect, during the job search process, (2) check whether positive affect (i.e., activated and deactivated) serves as a mediating mechanism for the effect of the intervention on metacognitive activities.

Theoretical background

Apart from the growing interest in self-regulation, we still know very little about interventions that can help shape the self-regulation processes during job search while simultaneously fostering mental health. We build on principles from positive psychology (Seligman & Csikszentmihalyi, 2000), and the broaden-and-build theory (Fredrickson, 2001) to hypothesize how metacognitive activities can be fostered with an online positive reflection intervention based on the Three Good Things (3GT) exercise (Seligman et al., 2005). Further, we identify positive affect as a possible mediating mechanism between the Three Good Job Search Things intervention and metacognitive activities.

Methodology

We designed a randomized control-group pretest posttest experimental study with three conditions (i.e., 3GJST, active control, and passive control). Our sample consisted of Flemish (Dutch-speaking Belgians) recent job seekers who were actively looking for a job for less than a month. The final sample with T1 (posttest) data consisted of 117 respondents (54% women, M_{age} = 42.57, SD = 14.39).

Results

First, a one-way ANCOVA was conducted to compare the effectiveness of the intervention with the control groups, controlling for pretest (T0) metacognitive activities. There was a significant difference in metacognitive activities [$F_{(2,117)} = 5.50$, $p = .002$] between the conditions. Post hoc tests showed there was a significant difference between the active intervention group and the passive control group ($p = .01$). Comparing the estimated marginal means showed that the highest amount of metacognitive activities was obtained in the 3GJST intervention group ($M = 3.85$, $SD = .67$) compared to passive control group ($M = 3.72$, $SD = .89$). The active control group did not differ from the other two groups.

Second, we tested whether the effect of the intervention on job seekers' metacognitive activities was mediated by activated and deactivated positive affect. We examined these indirect effects using the PROCESS mediation macro in SPSS (Hayes, 2022). We did not observe a significant indirect effect of the intervention condition on metacognitive activities through activated positive affect ($B = .00$, 95% CI [-.03, .05]), nor through deactivated positive affect ($B = .01$, 95% CI [-.03, .05]).

Limitations

First, the majority of our sample was higher educated with a college or university degree, threatening the generalizability of our study. Second, positive affect was only measured at two points in time. Thus, it was not possible to investigate intermediate fluctuations of affect. Lastly, the response rate in our study was an issue across all three groups in our study.

Research / practical implications

The 3GJST can function as a starting point for job seekers to gain more insight into their job search process. This reflection exercise can assist job seekers in increasing their self-regulatory strategies. In addition, we describe a low-cost intervention that can be widely administered with little incremental cost per job seeker regardless of a job seeker's time or geographic restrictions.

Relevance to the congress theme

With this study we tried to contribute to the future of job seekers by adopting a positive psychology approach to study their job search behaviour and well-being. We hereby focus on the positive influences in job seekers' lives, instead of trying to fix what is 'wrong'.

Relevant UN SDGs

Good health and wellbeing, decent work and economic growth

Paper 4

Unique and Joint Effects of Job Search Training and Older Job Seekers' Future Development Orientation on Job Search Behaviour and Reemployment Success

Sarah van den Hee &Edwin van Hooft | University of Amsterdam; Greet Van Hoye, Ghent University

Research goals and why the work was worth doing

Older job seekers are confronted with unique challenges during their job search and are less likely to find reemployment than younger job seekers (Wanberg et al., 2016). Given the negative health-related and financial consequences of unemployment, it is crucial to examine what can help older unemployed individuals to find reemployment. Although there are only few studies among older job seekers, meta-analytic evidence suggests that job search interventions enhance reemployment success in this group (Liu et al., 2014). However, less is known about the mechanisms that explain why interventions may enhance reemployment success among older job seekers. Moreover, some older job seekers may benefit more from job search interventions than others, depending on their orientations towards future development. Therefore, the aim of this study was to examine if and how a job search training facilitates older job seekers' job search process and whether this effect is contingent on individual characteristics (i.e., future time perspective and learning goal orientation).

Theoretical background

We build on self-regulatory frameworks of job search and the attribute-treatment interaction approach to explain why and when a job search training may benefit older job seekers. Based on a self-regulatory perspective (Kanfer et al., 2001; Van Hooft et al., 2013), job search interventions that focus on improving job search skills and self-efficacy likely promote the job search process. Increasing job search skills and self-efficacy may be specifically important for older job seekers, as they often have less experience with contemporary job search methods and are confronted with setbacks and obstacles that may negatively impact their confidence. Greater knowledge about how to search for jobs and higher confidence in how to approach the job search likely facilitate job search behaviour, and subsequent reemployment success.

The attribute-treatment interaction approach (Gully & Chen, 2010) suggests that individual characteristics influence training effects. Despite age-related mechanisms that trigger the motivation to learn, there are individual differences in how future development opportunities are perceived. Two personal characteristics that have strong motivational properties and are relevant in the context of aging are future time perspective and learning goal orientation. We expect that older job seekers with a more expansive future time perspective and a higher learning goal orientation will benefit stronger from job search training, as they are more open to development opportunities and set goals that promote learning and development.

Design/Methodology/Approach/Intervention

The study population consisted of unemployed job seekers (aged above 50) who received unemployment benefits from the Dutch national Employee Insurance Agency. Job seekers were randomly assigned to the experimental (76%; n = 3331) or control group (24%; n = 1035). The training program lasted twelve weeks and consisted of ten group meetings. Central themes in the meetings concerned profiling, networking, and applying. Self-report surveys were sent to the experimental and control group three weeks before the training (T0; including future time

perspective and learning goal orientation), twenty weeks after T0 (T1; including job search self-efficacy, job search knowledge, and job search quantity and quality), and eighteen weeks after T1 (T2; including reemployment status).

Results expected

To formally test the hypothesized paths and model we will perform path analyses using Mplus. The results will be discussed in our presentation.

Limitations

Participation in the job search training was compulsory, which may have affected the training motivation of the participants. Training motivation plays an important role in facilitating learning outcomes and training transfer (Colquitt et al., 2000). However, research findings in a job search context suggest that the compulsory nature of interventions may not have an adverse effect on learning outcomes as long as participants perceive the intervention to be useful for their job search (Koen et al., 2015).

Research/Practical Implications

The study findings add in understanding how job search interventions for older job seekers affect reemployment success and individual orientations towards future development influence training effectiveness. These insights can be used for designing interventions for older job seekers and for tailoring interventions to their specific needs and characteristics.

Relevance to the Congress Theme

Not only the content of work has changed drastically in the past years, but also how individuals search for and find (re)employment. These changes ask for better insight into how specific groups with a distance to the labour market can be supported.

Relevant UN SDGs

This study is relevant to UN SDG 8: Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all.

Keywords: Careers, age, training

Symposium S004

The HEXACO Model in Organizational Contexts: Current Applications and Future Directions

Janneke Oostrom, Vrije Universiteit Amsterdam; Djurre Holtrop, Tilburg University

science_practice

What will be covered and why?: Researchers as well as practitioners have long been interested in measuring personality traits and examining associations between personality traits and attitudes and behaviors in organizational contexts. Although the Big Five model remains the most predominant model, studies adopting an alternative personality model known as the HEXACO model have been increasing in the past decades. The current symposium provides an overview of current and innovative measurements and applications of the HEXACO model and provides evidence for its utility in organizational contexts.

The first (theoretical) presentation will provide an overview of the literature on the HEXACO model and its measurement and application in organizational contexts. The second presentation will offer insights into the development and validation of an innovative technique to measure HEXACO personality traits, i.e., an algorithm that automatically assesses these traits based on asynchronous video interviews. The third and fourth presentation will zoom in on the organizational outcomes of person-environment fit in terms of the HEXACO personality traits. Specifically, the third presentation will focus on the development of a dedicated scale to measure organizational preferences in terms of Honesty-Humility and the validity of this new scale for predicting work attitudes and motivations. The fourth presentation will provide insights into how leader-follower HEXACO personality fit contributes to or hinders followers' work engagement.

Finally, Reinout E. de Vries will discuss these four papers and offer a number of suggestions for how future research can continue to refine the measurement and application of the HEXACO model in organizational contexts.

Relevance to the Congress Theme: Recent societal and organizational developments have brought new challenges for employee selection and assessment. Specifically, technological advancements, globalization, immigration, and changes in the labor market and the way work is organized require that organizations reconsider and refine their current procedures. The HEXACO personality traits are among the most important predictors of organizational attraction (e.g., perceived fit) as well employees' attitudes (e.g., job satisfaction, job stress, turnover intentions) and behaviors (e.g., turnover, job performance) at work. Hence, more insights into how to refine the measurement and application of the HEXACO model, for example, by using new technology and by focusing on person-environment fit, can help organizations deal with today's societal and organizational challenges. As such, our symposium relates to the UN's Sustainable Development Goals (SDGs) of creating good health and wellbeing among employees, offering decent work and economic growth, and reducing inequalities.

Research/Practical implications: All four presentations offer a number of important and unique implications pertaining to the use of the HEXACO model in organizational contexts. Specifically, this symposium will assist researchers in developing their own research agenda when using the HEXACO model, whereas practitioners will benefit through the introduction of new approaches and suggestions for applying the HEXACO model in their everyday work.

Overall conclusions: This symposium integrates and discusses research on the measurement of the HEXACO personality traits and the associations between these personality traits and important

attitudes and behaviors (e.g., job satisfaction, job stress, organizational identification, turnover intentions, job performance, leadership, and work engagement). Importantly, two innovative measurement techniques (i.e., an algorithm-based assessments of HEXACO personality traits and a dedicated scale to measure organizational preferences in terms of Honesty-Humility) as well as two new types of person-environment fit based on the HEXACO personality traits (i.e., the attraction of people low in Honesty-Humility to hazardous organizations and leader-follower HEXACO personality fit) are introduced. Overall, this symposium offers important new insights into the utility of the HEXACO model in organizational contexts.

Paper 1

Automatic Personality Assessment in Online Mock Video Job Interviews

Janneke Oostro, Reinout de Vries & Ward van Breda | Vrije Universiteit Amsterdam; Djurre Holtrop, Tilburg University; Sina Ghassemi & Antonis Koutsoumpis | Vrije Universiteit Amsterdam

Research goals and theoretical background : With the advent of new technology, the traditional job interview process has been supplemented with asynchronous video interviews (AVI). AVIs are one-way interactions where candidates record video responses to interview questions and share them with employers. A recent development in AVIs is the automatic assessment of candidates' responses with algorithms, trained (typically using machine learning techniques) to identify personality traits that are of interest to employers. The advantage of automatic assessment of AVIs is the sheer amount of information that computers can process as compared to humans, something that reduces costs and speeds up the selection process. Large companies are steadily embracing algorithmic assessment and AVI options, but the research on whether this type of automatic assessment complies to the reliability and validity standards which characterize more traditional assessment methods (e.g., personality questionnaires) is lacking.

To this end, the main goal of the present study was to use state-of-the-art methods in machine learning to develop an algorithm that automatically assesses the HEXACO personality traits of individuals who have taken an online AVI (analyzing their verbal and non-verbal behavior). Other goals of the present study were to test whether the type of interview questions affect the accuracy (i.e., explained variance) of HEXACO personality assessment, whether automatic personality assessment has incremental validity over self- and observer reports in predicting hireability scores (assessed by HR consultants), and, finally, explore the effect of four common workplace biases (age, gender, attractiveness, first impressions).

Methodology and results : 710 participants (recruited through Prolific or through a snowball procedure) took an online AVI responding to 8 questions specifically developed to activate the traits of Extraversion and Conscientiousness. Participants completed personality self-reports (HEXACO-60) and, later, their personality traits were assessed by judges. We also collected hireability, attractiveness, and first impression ratings (e.g., attire, quiet environment). We automatically extracted the words, facial expressions, and voice characteristics from the videos and applied state-of-the-art machine learning approaches to automatically predict personality traits and hireability scores. Our algorithm explained a significant proportion of personality variance in Extraversion and Conscientiousness (for self-reports, average R^2 = 6.1%; observer reports average R^2 = 32.5%) and hireability (R^2 = 42.4%). Furthermore, we found that the explained variance increased when participants responded to trait-relevant, compared to trait irrelevant questions. A few months after data collection, a sub-sample of the participants (n- = 154) took the AVI again, and the test-retest reliability was on average r = .27 for self-reported Extraversion and Conscientiousness (and r = .53 for observer reports).

Limitations : An inherent limitation of any type of machine learning assessment is that the output accuracy can never exceed the input. For instance, if the ground truth is based on personality self-reports, the accuracy of the algorithm will never surpass this ground truth. Furthermore, machine learning techniques perform to their full extent when trained on big data. The sample size of the present study was typical for psychology research, but sub-optimal for machine learning approaches.

Conclusions - Research/Practical implications : On the theoretical side, we show that the explained variance of algorithmic personality assessment increases when participants respond to trait-relevant questions. This finding provides support to the Trait Activation Theory, postulating that it is easier to observe a trait that has been previously activated. The practical implication is that AVIs might benefit from the development of trait-relevant interview questions. Furthermore, even though we have not yet finalized data analysis (expected to have finished by end October, 2022), the present results will test whether hiring recommendations made by HR consultants can be accurately predicted by our algorithm, whether algorithmic prediction of hireability offers incremental validity over self- and observer reports of personality traits, as well as whether predicted scores show group differences (i.e., age, gender, attractiveness, first impressions).

Relevance to the Congress Theme: Companies are already using AVIs and automatic personality assessment methods to pre-screen their candidates. However, little is known about the accuracy of such methods, especially when personality is measured under the HEXACO model. The present study addresses this lack of research on the construct validity and reliability of algorithmic personality assessment. Furthermore, we explore whether algorithmic personality assessment from AVIs is affected by four common workplace biases.

Relevant UN SDGs: In the present work, we study the possible effect of some common workplace biases (age, gender, attractiveness, first impressions). Hence, the present work aligns with the 'Gender equality' and 'Reduced inequalities' themes of the UN's SDGs.

Keywords: HEXACO, automatic personality assessment, asynchronous video interviews

Paper 2

HOT and Attractive? The Hazardous Organization Tool as an Instrument to Avoid Attracting People Low in Honesty-Humility

Reinout de Vries, Wendy Andrews & Bo Wang | Vrije Universiteit Amsterdam

Research goals and theoretical background: Honesty-Humility from the HEXACO model is an important trait to be considered in hiring decisions. Employees high in Honesty-Humility are more likely to show beneficial organizational behaviors (e.g., organizational citizenship behavior; Pletzer et al., 2021), while employees low in this trait are more likely to engage in detrimental organizational behaviors (e.g., workplace deviance; Pletzer et al., 2019). However, the organizational preferences of people low in Honesty-Humility are insufficiently understood. The situation activation mechanism from the situation, trait, and outcome activation (STOA) model suggests that people are attracted to situations that match their traits (De Vries et al., 2016). Furthermore, the attraction-selection-attrition model of Schneider et al. (1995, p.749) suggests that "people find organizations differentially attractive as a function of their implicit judgments of the congruence between those organizations' goals (and structures, processes, and culture as manifestations of those goals) and their own personalities." In the current study, we argue that people low in Honesty-Humility (Ashton et al., 2004; De Vries, 2018) are more likely to be attracted to hazardous organizations in which managers and/or employees are more tolerant of sexual misconduct, support power inequality, are strongly motivated by monetary incentives, disregard ethical standards, and hide knowledge.

Methodology: The main goal of the current study is to construct and validate an instrument—Hazardous Organization Tool (HOT) that is descriptive of hazardous organizations attractive to people low rather than high in Honesty-Humility. We (a) developed an initial item pool to describe hazardous organizations, (b) iteratively selected items from this initial item pool to construct the HOT, and (c) examined its validity as a tool to measure people's willingness to work for hazardous organizations. Therefore, we based the factor analysis and item selection on people's ratings of the attractiveness of the HOT items (the Hazardous Organization Tool-Attractiveness, HOT-A), and used these ratings for most of the validity assessments. However, we also used the HOT items to measure the extent to which people perceive an organization as hazardous (the Hazardous Organization Tool-Perception, HOT-P). Some validity assessments were based on this second potential use of the HOT items.

To examine the HOT's convergent and divergent validity, we correlated HOT-A to HEXACO traits, dark traits, organizational culture preferences, and work motivations. To examine the predictive validity of the HOT, we correlated HOT-P to work attitudes and motivations. We also assessed the predictive validity of the HOT by investigating the effects on work attitudes and motivations of the fit between attractiveness of hazardous organizations and the perception of the organization as hazardous. Based on the outcome activation mechanism of the STOA model, fit should lead to desirable individual outcomes (De Vries et al., 2016).

Results: The validity of the scale was tested in three samples (N =952). Scores on the HOT-A had a moderate negative correlation with Honesty-Humility, moderate to strong positive correlations with dark traits, weak to moderate correlations with organizational culture preferences for Integrity, Collaborative, Adaptability, and Results-Oriented, weak to moderate correlations with work motivations, and weaker correlations with theoretically unrelated constructs as hypothesized (e.g., HEXACO traits other than Honesty-Humility), thus demonstrating convergent and divergent validity.

The predictive validity of the HOT was supported by significant correlations of the HOT-P with work attitudes and motivations, and by the finding that the fit between the HOT-A and HOT-P was associated with desirable work attitudes and motivations.

Limitations: The current study used a cross-sectional survey. Further experimental or longitudinal studies are needed to determine the causal relations between the hazardous organizational characteristics, organizational attractiveness, and job application.

Conclusions - Research/Practical implications: Together these findings suggest that organizations that are perceived as hazardous are not only more attractive to applicants low rather than high in Honesty-Humility but also more likely to repel employees low in attractiveness to hazardous organizations (who are more likely to be high in Honesty-Humility). Organizations can utilize this tool to know whether they are at risk of attracting and retaining people low in Honesty-Humility and in what ways they might be able to avoid this.

Relevance to the Congress Theme: The current study introduced a new instrument (i.e., the HOT) to measure people's willingness to work for hazardous organizations and the extent to which people perceive an organization as hazardous, with potential to inform both research and management practice, and thereby changing the world of work.

Relevant UN SDGs: The presentation relates to the UN's SDGs of offering decent work and economic growth and reducing inequalities.

Keywords: Hazardous Organization Tool, Honesty-Humility, organizational attractiveness

Paper 3

Follower-Leader HEXACO Personality Fit and Follower Work Engagement

Jan Pletzer & Kimberley Breevaart | Erasmus University Rotterdam

Research goals and theoretical background: Drawing on the person-environment fit literature (Kristof-Brown et al., 2005), research shows that employees who craft their resources and demands in such a way that they better fit their needs, for example by asking others for advice or by getting involved in a new project, are able to increase their engagement in their work. In the current study, we build on the idea that employees will become more engaged in their work when they experience a better fit between themselves and the environment they work in. Specifically, we extend existing knowledge on antecedents of employee engagement by examining how person-supervisor (in this paper referred to as follower-leader) personality fit contributes to or hinders followers' engagement in their work. We hypothesize that follower-leader discrepancy in the HEXACO trait Emotionality is positively related to followers' work engagement, whereas follower-leader discrepancy in Openness to Experience is negatively related to followers' work engagement. Studying how follower-leader fit in terms of their personality affects followers' work engagement is important because leaders have a major influence on how followers' feel and behave at work (e.g., Skakon et al., 2010). Moreover, personality is a relatively stable, dispositional characteristic, meaning that it is unlikely that personality will change much across time (Costa et al., 2019). As such, both followers' and leaders' personality fit may have a long-lasting influence on followers' work engagement. Our study extends the nomological network surrounding work engagement by focusing on (1) dispositional characteristics related to work engagement and (Young et al., 2018), and (2) follower-leader personality fit as an antecedent of followers' work engagement.

Methodology: Both followers and leaders rated their own personality on the 100 item HEXACO personality measure (Ashton & Lee, 2018). Followers then also rated their own work engagement. In total, 130 unique leader-follower dyads completed our online questionnaires.

Results: To test our hypotheses, we used polynomial regression analyses (Edwards, 1994) with response surface analysis (Box & Draper, 1987). Although we tested the fit in follower-leader personality dimensions for all HEXACO dimensions, we focused on the findings for the hypothesized dimensions Emotionality and Openness to Experience. First, the results show that the higher the discrepancy between follower-leader Emotionality, the more engaged followers are in their work. Surprisingly, the direction of this discrepancy did not matter. This means that followers are more engaged in their work when they are higher in Emotionality compared to their leader, which support our first hypothesis, but also when followers are lower in Emotionality compared to their leader. Next, we found that the higher the discrepancy between follower-leader Openness to Experience, the less engaged followers were in their work. That is, when followers are more open to new experiences compared to their leader, followers are less engaged in their work. Additionally, when followers score lower on Openness to Experience compared to their leader, followers are also less engaged in their work. Follower-leader fit on the other four HEXACO traits did not relate significantly to followers' work engagement.

Limitations: First, the current study is only focused on personality traits, but not on the behavioral manifestations of those traits. Although we argue that, for example, increased task-oriented leadership behavior of leaders low in Emotionality could be responsible for the increased levels of work engagement among followers scoring high on Emotionality, we did not formally test this

proposed mechanism. In addition, it would be interesting to investigate if the current findings also hold for perceived rather than actual differences in personality.

Conclusions - Research/Practical implications : Organizations should gather and use information about the personality traits of their leaders and followers when creating new follower-leader dyads. Another possibility could be to recruit both leaders and followers based on their Emotionality and Openness to Experience scores, and to subsequently match dyads in ways that promote levels of work engagement among followers.

Relevance to the Congress Theme: Most research either holds that leaders exert significant influence on followers' work-related well-being or that employees' individual differences predict their own well-being. Combining these two approaches, we demonstrated that it is crucial to examine the incongruence between leaders' and followers' personality traits. These insights contribute to increasing the well-being of employees as well as the overall productivity of organizations.

Relevant UN SDGs: The presentation relates to the UN's SDGs of creating good health and wellbeing among employees and offering decent work and economic growth.

Keywords: leadership, personality, work engagement

Symposium S005

Erring Outside the Box – (Learning from) Errors in Organisations and Beyond

Alexander Klamar, Federal University of Applied Administrative Sciences; Dorothee Horvath, Technical University of Darmstadt

science

The world of work is ever changing. Errors are a natural by-product of any change, particularly when the direction of change is not known a-priori. In our work environment that is characterized by an increase in tasks and communication, the question of how to deal with occurring errors becomes increasingly important.

Errors can lead to disastrous consequences (e.g., economic damage; loss of lives). It is thus not surprising that organisations usually try to prevent errors from happening, which is denoted as error prevention or avoidance approach. However, one must acknowledge that despite best efforts, it is impossible to be completely error-free. Organisations fare better if they adopt practices and procedures aimed at constructively dealing with errors after they have occurred, that is, an error management approach.

Error management has become a buzzword. Error management aims at minimizing negative error consequences and puts emphasis on maximizing potential positive ones, such as long-term learning and innovation. Supporting this idea, research has shown that error management is linked to a number of desirable individual, team and organisational outcomes such as learning, team performance, firm profitability, safety, and innovativeness.

The topic of errors in organisations has gained increasing attention: In academia, two influential journals in the field of Work and Organisational Psychology have published special issues on this topic (Academy of Management Discoveries , late 2021; the call for papers for Frontiers in Psychology, section Organizational Psychology has ended in 09/22). In practice, the idea that errors can be a rich source of learning is increasingly acknowledged. Probably the most prominent example is the proliferation of so-called “F*ck up nights”. In these, employees from different organisations and entrepreneurs alike share their errors to a broad audience so that everyone can learn from them.

Our symposium deals specifically with the connection between error management and learning: learning from errors is vital for individuals, teams, organisations, and society alike. In our symposium, the presentations focus on different levels of analysis. We aim to widen the focus of research in order to gain a deeper understanding of how approaches towards errors on levels interact.

On the individual level, Tabea Scheel addresses the relation between error orientation, intrinsic motivation, and procrastination. Intrinsic motivation can be a relevant facilitator of learning, whereas the tendency to procrastinate may inhibit learning. Her study shows that a negative orientation towards errors (i.e., stress and strain caused by errors, covering up errors) is positively related to procrastination.

On the organisational level, Wioleta Kucharska summarises findings from a Polish-US cross-country study including over 2.000 knowledge workers from different industries. Her research reveals that the accepting errors as part of a learning culture positively affects knowledge sharing. This boosts intellectual capital and innovativeness. Alexander Klamar presents an ongoing research project which addresses the question to what extent organisations’ “mission statements” that are in line

with error management principles, as expression of organisational (error management) culture, predict firm success in contrast to mission statements that are in line with error avoidant principles.

By and large, research has either focused on the role of errors for individual learning (e.g., by experimentally testing error management training against typical step-by-step instruction approaches) or has taken a team or organisational perspective (e.g., by investigating processes of team error management culture or climate, or organisational outcomes such as profitability or safety). Questions of the interconnectedness between the levels of analysis or of the problems research may face when attempting to measure one concept on different levels (i.e., individual, team/organisational, societal) have largely been neglected. Michael Frese' s presentation sheds light on the latter – from the questions of what constitutes the concepts on different levels to what meaningful outcomes can be in the focus of interest. On the micro-level, outcomes include individual learning from errors, reduced negative affect following errors, and more innovative ideas. On the meso-level, error management culture has been linked to improved profitability of companies. Particularly on the macro level, measuring societal error culture is not a trivial issue.

With the help of our discussant, Sebastian Fischer , who has profound expertise in the areas of error management and its relations with attitudes towards errors at work, innovation, and performance, we attempt to bridge the gap between the different foci and measurement levels of the symposium's presentations. Thereby, we aim to facilitate the discussion with and encourage questions from the audience.

discussant: Sebastian Fischer, Hamm-Lippstadt University of A

Paper 1

The Relationship between Error Orientation, Intrinsic Motivation and Procrastination at the Workplace

Tineke Sondag & Tabea Scheel | Europa-Universität Flensburg

Research goals and why the work was worth doing

The present study aims to investigate the relationship between employee's error orientation and procrastination at the workplace. Furthermore, autonomous motivation was considered as a mediator of this relationship. Error orientation is an important determinant of positive, motivated job attitudes. Deficits in motivation may foster procrastination, which in turn can lead to individual suffering, reduced performance and economic loss. This is the first study investigating the relationship between error orientation and procrastination at the workplace, which also underlines the relevance of error management in organisations.

Theoretical background

The error orientation of employees is related to error management in the organisation and thus, is part of the organisational culture. A positive error orientation (e.g., communicating about errors) is regarded as an indicator for better performance, increased learning, proactive action, and job satisfaction. A negative error orientation, which is associated with an error prevention strategy in the organisation, has the opposite effect. An aversive attitude towards mistakes favours stress and negative emotions as well as reduced work performance. Previous research provides support for an association of individual error orientation and self-efficacy as well as self-regulatory competencies. These, in turn, play an important role concerning procrastination. At least in the context of academic procrastination, correlations with autonomous motivation have been shown.

In sum, employee's positive error orientation should be related to lower procrastination (H1), and the negative error orientation should be related to higher procrastination (H2). Autonomous motivation was hypothesized to mediate both relationships between error orientation and procrastination (H3a,b).

Method

A sample of 104 German employees participated in a cross-sectional online questionnaire. Established and validated scales were used, that is, the Error Orientation Questionnaire (EOQ, Rybowiak et al., 1999; eight subscales falling in two dimensions), the Multidimensional Work Motivation Scale (MWMS, Gagné et al., 2014; two subscales identified regulation, intrinsic motivation) and a short version of the General Procrastination Scale (GPS-K, Klingsieck & Fries, 2018). Reliabilities ranged between Cronbach's $\alpha = .79$ and $\alpha = 96$. Sex was included as a control variable. Regression and mediation analyses were conducted with SPSS and PROCESS.

Results obtained

Positive error orientation was not related to procrastination (H1 not supported); however, negative error orientation was related to higher procrastination (H2 supported). A mediation of both relationships by autonomous motivation was not found (H3a,b not supported). However, positive error orientation was related to higher autonomous motivation. As a side note, men procrastinated more than women.

Limitations

The cross-sectional self-report data may suffer from common method bias. Also, no causal relationships can be inferred; that is, higher procrastination could also lead to a negative error orientation. Additionally, mediation analyses in cross-sectional samples should be avoided. The sample size was small, however, sufficient when compared with the precalculated optimal sample size of N = 71.

Conclusion – Research/Practical implications

For causal conclusions, longitudinal data should be assessed. Further mechanisms beyond motivation are worth considering, for instance, self-regulation capacities or self-efficacy could mediate the relation between error orientation and procrastination. Furthermore, motivation might be a moderator rather than a mediator (these additional results will be presented).

For organisations, the differentiation between a positive and a negative facet of error orientation seems to be reasonable. While an error management approach may foster positive error orientation and thus, autonomous motivation, an error prevention culture may increase negative error orientation and abet procrastination tendencies.

Relevance to the congress theme

The changing world of work is accompanied by increasing responsibility on employee's side, higher complexity of tasks and lack of work structures. Thus, errors are more likely and opportunities for procrastination are increasing.

Relevant UN SDGs

As procrastination at work is related to individual suffering and decreasing performance, our study about error orientation, motivation and procrastination refers to two SDGs, that is, to good health and well-being as well as to decent work and economic growth.

Keywords: error orientation, procrastination, autonomous motivation

Paper 2

Influence of Mistakes Acceptance Component of Learning Culture on Tacit Knowledge Acquisition among Knowledge Workers

Wioleta Kucharska, Gdansk University of Technology

Aim

My presentation purpose is to give a comprehensive summary of the research project entitled "The Influence of Tacit Knowledge Sharing on Innovativeness: A Sector Analysis," financed by the National Science Center of Poland (NCN) that briefly summarizes the project's findings that expand the knowledge about the meaning of the mistake's acceptance component of a constant learning culture for organisational innovativeness.

Theory

The presented findings refer to the Social Learning Theory (Bandura, 1971) by exposing that the sensitive issue of knowledgeable employee learning from mistakes is tremendous for the entire organisation's learning.

Method

The given synthesis of empirical research and implications is based on the Polish-US cross-country study analysis of 2,168 knowledge workers from the healthcare, IT, and construction sectors. The presented synthesis is justified by five structural equation modeling (SEM) models.

Findings

The project revealed that the mistake acceptance component of a constant learning culture significantly affects knowledge sharing and hiding. This way also affects human-related components of intellectual capital that are tremendous for innovativeness and sustainability. These findings create an interesting perspective for the discussion about the future changes in the world of work planned for the EAWOP2023 Congress. Altogether, the designed synthesis exposes the other vital facets of the meaning of knowledge workers' ability to learn from errors for organisations next to such important and broadly discussed in the scientific literature facets of organisational functioning, such as error management, safety assurance, performance improvement, or failure prevention.

Practical implications

Knowledge workers are the main knowledge creators today and, in this way, their collective ability to reveal, acquire and transform tacit knowledge into explicit main make their minds a focal source of value in the knowledge-driven economy. The constant learning culture with its mistake's acceptance component facilitates the knowledge workers' ability to gain tacit knowledge from mistakes and avoids such knowledge hiding. Therefore, from the practical point of view, implementing the mistakes acceptance component of learning culture fosters intellectual capital and innovativeness development thanks to smooth tacit knowledge flow among knowledge workers. So, workplaces with a mistakes acceptance component implemented are workplaces that are needed to achieve sustainability.

Limitation

The limitation of the presented synthesis is that it bases on a cross-country study of two countries only. Moreover, the US men's sample is affected by a bit of bias concerning such variables as internal and external innovations and knowledge, learning, and collaboration (KLC)-cultures.

Conclusion

By facilitating learning from mistakes among knowledge workers: specialists, team leaders, managers, and CEOs, we strengthen the innovativeness of not only processes but also business models that are significant for sustainability. But such learning might be problematic because of the existing common belief that "bosses never make mistakes."

Relevance

EAWOP Congress 2023 focuses on the needed changes in the work environment that matters today for tomorrow's better future. I aim to contribute to this topic by exposing the meaning of the mistake's acceptance component of a constant learning culture for gaining tacit knowledge from knowledgeable employees' mistakes. My synthesis leads to the conclusion that the existing mental convention that "bosses never make mistakes" can be an obstacle for bosses learning from mistakes. EAWOP23 gives a perfect opportunity to discuss it.

Keywords: innovations, knowledge workers, constant learning culture

Paper 3

The Tip of the Iceberg – Can a Positive View on Errors in Mission Statements as Expression of Organisational Error Culture Predict Firm Success?

Alexander Klamar, Federal University of Applied Administrative Sciences; Nina Keith & Dorothee Horvath | Technical University of Darmstadt

Following Schein's Iceberg model, much of organisational culture is left in the dark. Only the tip of the iceberg is visible; usually, this includes "hard facts" such as Key Performance Indicators (KPIs) or symbols such as logos. So-called "mission statements" aim to shed light on some aspects of the iceberg that are usually under the surface: an organisation's values. Mission statements can be helpful to differentiate oneself from competitors, for example by explicitly stating one's unique selling proposition (USP). Moreover, in the ongoing war for talents, mission statements can also be used as an employer branding tool as they convey how supervisors understand their (leadership) role and what atmosphere prevails in the workplace. In that sense, mission statements are typically a combination of, on the one hand, the description of the status quo and, on the other hand, express a desired state. Mission statements are among the most commonly used and most important management tools in the business world.

One aspect of an organisational culture is the understanding of how errors are considered within an organisation and what is the "correct" and desired approach of dealing with errors. Previous research on organisational error management culture has typically focused on questionnaire studies with questionnaires administered to individual organisational members. However, the aspect of the organisation's self-expression has largely been neglected.

Our study aims at investigating how addressing errors in company mission statements may benefit firm success. Research has shown that mission statements can have a significant impact on both employee and company performance. In line with previous research that indicates that error management culture is beneficial for firm success, we assume that organisations that explicitly and positively address errors in their mission statements will show more firm success than organisations that explicitly and negatively address errors in their mission statements, or do not address errors at all.

Method

We collected mission statements of companies (approx. 825 before data cleaning) that were publicly available on their websites. Two rater blind to the study's objectives independently rated the mission statements as to whether they explicitly address the issue of errors and error management with a positive view on errors (errors positive), whether they explicitly address the issue of errors and error prevention with a negative view on errors (errors negative), whether they include error-related topics but without direct reference to errors (e.g., innovation, risk-taking; errors indirect), or whether they are neutral as to the topic of errors (neutral). Cases of disagreement were reviewed and resolved by a third blind rater. Currently, we are in the process of data cleaning and of assessing firm success indicators using publicly available data bases that list various yearly measures of firm success (e.g., return on investment) such as the German Bisnode database.

Expected results

In line with previous research indicating that error management culture predicts firm success, we expect a significant difference in firm success in that firm success is higher in the errors positive group than in the errors negative group or other groups. The effect should remain stable when controlling for company size and line of industry. In a second step, we plan to parallelize both groups with direct reference to errors (i.e., errors positive and errors negative) based on company attributes (e.g., size or line of industry) and re-analyse the data. We expect to have our results in the beginning of 2023.

Limitations

As described above, mission statements always contain a component that expresses how an organisation strives to be. Thus, one critical question is to what extent the view on errors described in the mission statements reflects the actual values and behaviour in the organisations.

Conclusion – Research/Practical implications

Proving error management to be a valuable error handling strategy for organisations may promote the importance and usefulness of this strategy and may motivate organisations to adopt error management in their daily routine and explicitly address errors in their mission statements.

Relevance to the congress theme

Organisational error culture has a great impact on organisational members; it may determine whether one is fired for an error or rewarded for the knowledge the organisation has gained through it. By demonstrating the beneficial effect of a positive error culture, we strive to change negative perspectives on errors in organisations that may still prevail.

Relevant UN SDGs

The topic of organisational error culture is relevant for the UN SDG “Decent work and economic growth”.

Keywords: error management culture, mission statements, organisational performance

Paper 4

Error Management for Individuals, Teams, Companies and Societies: Important for Safety, Performance, and Innovation

Steven Brieger, University of Sussex; Michael Frese, Asia School of Business

Errors are a central topic in philosophy of science (falsificationism), biology (mutations), medicine (medical errors), and in psychology ever since Freud. Errors relate to safety, reliability, quality, performance, innovation, and learning. Surprisingly, in spite of its importance whenever there are actions to be done, there is no scientific work in the area of errors and error management as a cultural issue. The only exception is the analysis of culture by Festinger (cultural development as overcoming errors) (Festinger, 1983). However, there is no empirical study that examines the way errors are treated in the society.

Fortunately, it is possible to use an item from the GLOBE study – a study that is encompassing different dimensions and that is an important improvement to Hofstede's famous IBM study that was not originally intended to be a cross-cultural study.

Error management can be distinguished from error prevention as it happens after an error has occurred but it also attempts to reduce potential negative consequences of errors. Error management clearly differentiates between an error and error consequences. Error management is about reducing negative error consequences but not necessarily about preventing errors from occurring. In contrast, error prevention attempts to reduce the errors per se; there is good evidence in the study of human errors that full error prevention is not possible (Frese & Keith, 2015). One negative effect of a strong error prevention approach is that there is a negative effect on the actor who made an error. Error management attempts not just to reduce the negative error consequences, but also to maximize positive consequences of errors, such as exploration, innovation, and learning.

There may be, however, important differences in the effectiveness of error management depend on which level error management is measured:

1) Individual level: error management leads to improved learning from errors and it has other positive effects on individuals, e.g., less strain, more innovation, more communication about errors. Many of these studies are causal experimental studies.

2) On the level of teams and small companies: Error management culture is related to high profitability in companies and error management culture is related to higher innovativeness and better communication on errors. In the last analysis, errors are better managed and, therefore, there are fewer accidents in those companies.

3) Up to this point, all studies have looked at small to medium sized firms and not to whole societies. Thus, the current focus of my talk is on societal error tolerance (not exactly the same as error management): Here the relationships are very different to those of smaller organisations (e.g., below 1000 employees). Our new study (not yet published) shows that error tolerance is negatively related to a number of positive features of a society, such as societal wealth, road safety and accidents and health. Thus, these results are much more negative in contrast to the above individual and smaller organisation level studies. The only exception to this negative picture of societal culture of error tolerance is entrepreneurship – at least new entrepreneurship is related to error tolerance.

Limitations

The national culture study is based on limited data per country and the relationships are not to be interpreted as causal.

Practical conclusions

The naïve extension that national culture should be changed into the direction of error management (which is often suggested by consultancy firms that – based on our studies – propagate general advantages of error management even for large organisations and societies) needs to be qualified – at least until we have better data and more sophisticated measures of cultural measures.

Keywords: error management, national error culture, levels of analysis

Symposium S006

Playful Work Design: New Insights and Developments

Yuri S. Scharp, Tilburg University, The Netherlands

science_practice

What will be covered and why

Imagine an Uber driver who makes a game out of steering as smoothly as possible. How does this affect their driving experience? What happens when an accountant imagines an amusing narrative that explains the items on an invoice? What about a security officer in a retail shop who tries to predict where a customer will walk next? Play is an integral part of being human. Throughout our lives, we engage in play. These workers exemplify that the work context is no exception. However, playing is a phenomenon rarely examined in the context of work. We contend that play does not constitute a specific set of activities but constitutes approaching and performing activities with humor and imagination, and as challenges and competitions. In this symposium, we focus on playful work design (PWD), which refers to the proactive cognitive-behavioral orientation aimed at designing fun and challenge during existing work activities. Initiating play during work activities exemplifies a proactive strategy by employees that does not change work activities. Instead, this strategy changes one's relationship with existing work activities.

Previous research suggests that PWD represents an important source of well-being and driver of performance for individuals in a variety of occupations. However, various questions remain unanswered. What are the antecedents of PWD? While various studies have shown that PWD relates to well-being and performance, less is known about when PWD occurs. Similarly, although play and learning are considered to be closely related, does this apply to PWD? How does PWD relate to knowledge and learning behaviors? Another important question concerns to what degree PWD extends beyond the work domain. Building on the proposition that play concerns a way of approaching and performing activities, does self-initiated play also occur in the home domain? Finally, is PWD malleable? That is, can we teach individuals to design fun and competition during work activities? In this symposium, we present the efforts of four scholars from several countries (Germany, the UK, and The Netherlands) that aim to answer these questions.

In the first presentation, Scharp builds on the model of proactive motivation to formulate hypotheses regarding who initiates play during work activities and when.The experience sampling study demonstrates under which conditions PWD especially occurs and how this helps employees stay engaged with work.In the second presentation, Junker conceptualizes and develops the measurement of knowledge integration and knowledge specialization.This daily diary study reveals how knowledge behaviors interact with PWD to predict radical creativity and task performance.Importantly, Junker demonstrates that PWD may inhibit performance.In the third presentation, Rofcanin builds on the work-home resources model to investigate how PWD relates to boredom and playful home design.Additionally, this 10-day daily diary study identifies boundary conditions that modulate the cross-over process from work to the home domain.Finally, in the fourth presentation, Gerpott presents findings derived from a randomized, placebo-controlled theory-based field experiment that compared three interventions (ludic work design, agonistic work design, and cognitive biases) in PWD and autonomous motivation.In addition, Gerpott uses qualitative analyses to understand the findings further.

Relevance to the Congress Theme

Professionals in various occupations are creating our future. Their ability to shape the future depends partly on regulating their resources. Our research identifies PWD as a worthwhile strategy for managing resources. Hence, PWD may support professionals in shaping the future.

Research/ Practical Implications

The symposium has several important implications. First, playful tendencies manifest when individuals have a reason to and feel energized to design fun and competition. Second, while designing fun bolsters the association between knowledge specialization and radical creativity, designing fun inhibits its association with task performance. Third, PWD extends to self-initiated play in the home domain. Personal and contextual resources modulate this cross-over mechanism. Finally, the tendency to use PWD appears to be malleable. The findings highlight that PWD is malleable and facilitates resource management, but that boundary conditions are important to consider. Taken together, this symposium calls for tailored interventions.

Overall conclusions

This symposium aims to introduce PWD to scholars and practitioners. PWD constitutes a novel proactive strategy that individuals use to improve their affective and cognitive experiences during work activities. We hope the symposium inspires colleagues and practitioners to use PWD and further advance our understanding of PWD.

Paper 1

Predicting Playful Work Design and Work Engagement: Investigating Who, When, and Why

Yuri S. Scharp, Tilburg University, The Netherlands; Arnold B. Bakker & Kimberley Breevaart | Erasmus University Rotterdam, The Netherlands

Research goals and why the work was worth doing

Play is a naturally occurring phenomenon—also during work activities. A flight attendant may perform flight safety as a rap; a professor may imagine delivering an inspiring speech while writing; an office worker may aim to outperform their previous record of answering e-mails within 15 minutes; and, a delivery worker may "race" other cyclists while biking. They proactively play during their work activities. Indeed, the nascent literature on playful work design (PWD) indicates that various employees naturally initiate play during work activities to design fun and design competition. Moreover, findings thus far suggest that PWD benefits both employees and organizations in terms of well-being and performance outcomes. Yet, research on the antecedents of PWD remains scant. Existing research on the potential antecedents of PWD is mainly cross-sectional. This is problematic because PWD is a dynamic phenomenon. Hence, our understanding of the nature of play during work activities remains limited. Why and when do people initiate play during work activities? We aim to answer this question by investigating who initiates PWD as well as when and why.

Theoretical background

Playful work design constitutes a proactive cognitive-behavioral orientation characterized by volition, cognitive categorization of work activities as opportunities for play, interactive involvement in terms of seeking, finding, and resolving surprises and complexities, momentary focus, and an autotelic focus (i.e., behavior for the sake of fun and/or competition). The conceptualization of playful work design integrates the literature on proactivity and play. Therefore, to investigate the antecedents of playful work design, we draw on the tenets of the model of proactive motivation to contextualize the literature on play at work. The model of proactive motivation suggests proactivity especially occurs when individuals feel they are capable of successfully performing the proactive behavior (can do), have a reason to be proactive (reason to), and feel energized to (energized to). Similarly, the literature on play suggests that individuals with certain cognitive meta-skills will play to regulate their activation level. That is, playful individuals may use play to (a) maintain or (b) up-regulate their activation levels. Therefore, we expect that individuals who have the tendency to use PWD will express this tendency when they either experience activation or deactivation in terms of personal resources and situational characteristics.

Research methodology

A heterogeneous sample of 201 employees filled out a general survey one week before the daily surveys (i.e., trait PWD, demographics). The daily surveys were sent before work, at noon, and in the afternoon. To minimize retrospective bias and overlap, we programmed questionnaires to stop recording responses when the next questionnaire was administered or stay open for a limited time. Specifically, they received a questionnaire in the morning about vigor before work (7:00-12:00; N = 706), during noon about work conditions in the morning (12:00-16:00; N = 706), and after work about PWD and work engagement in the afternoon (16:00-23:59; N = 583) for five consecutive days.

Results obtained

The results partially supported our hypotheses. The largest differences between playful workers (high PWD tendency) and non-playful workers (low PWD tendency) in PWD and work engagement occurred on days characterized by high vigor and high situational activation (motive for maintenance) as well as low vigor and low situational activation (motive for up-regulation). These differences indirectly promoted work engagement. In contrast, the differences in PWD and work engagement between playful and non-playful workers were relatively small on days characterized by low-high and high-low combinations of vigor and situational activation.

Limitations

First, while the antecedents were temporally separated in time, we cannot make claims of causality. Second, we measured all constructs with self-reports, which may increase concerns regarding bias associated with common method variance. However, we partially remedied this issue by separating most measures in time.

Conclusions

The findings suggest that individuals with the tendency to use PWD especially differed from their less playful counterparts in the use of play to maintain or up-regulate activation levels. This suggests that we may conceptualize PWD as a proactive self-regulation strategy that is idiosyncratic.

Relevance to the Congress Theme

In virtually every occupation, work is becoming more dynamic. Complementary to proper top-down job design, This calls for the regulation of resources. The present findings highlight that employees may use PWD for this purpose.

Paper 2

Approaching Knowledge-Work in a Playful Way: Implications for Task Performance and Radical Creativity

Tom L. Junker, Erasmus University Rotterdam, The Netherlands

Research goals and why the work was worth doing

The present study aims to make three contributions to the literature. First, we develop a new scale that captures the day-to-day tradeoff in allocating time to specializing versus integrating knowledge. Second, we test a contingency model that outlines which playful work design strategies benefit task performance and radical creativity during knowledge work. Third, we contribute to organizational scholarship by bringing the topic of play to the serious domain of knowledge work.

Theoretical background

A classic distinction in organizational theory is that firms need both specialized and integrative functions in order to compete in knowledge-intensive industries (Lawrence & Lorsch, 1967). Although the distinction between specialization and integration is prominent in macro-oriented organizational scholarship (e.g., Ghosh & Wu, 2021), this distinction is rarely considered in the study of day-to-day behaviors of knowledge workers. We propose that knowledge-workers face a tradeoff in their daily activities in terms of allocating time to developing specialized knowledge (e.g., reading a scientific paper) versus integrating their knowledge with others (e.g., discussing in a meeting). Given their complementary nature, we hypothesize that knowledge specialization and integration explain unique variance in daily task performance and radical creativity.

Beyond making daily decisions regarding whether to focus on specializing or integrating knowledge, employees can approach their activities in different ways to enhance their task performance and radical creativity. The present study investigates whether a playful approach to knowledge work behaviors is functional for performance and creativity. According to Scharp et al. (2022) employees can approach their work in a playful way by designing elements of fun in their activities (e.g., using humor) and by designing activities in a competitive way to create challenge (e.g., setting time limits to tasks). Building on theories of creative performance (Nijstad et al., 2010), we hypothesize that designing fun when enacting knowledge work behaviors promotes radical creativity, whereas a designing competition benefits task performance. In sum, we propose that workers can optimize their daily functioning by utilizing different playful work design strategies to facilitate the benefits of knowledge specialization and integration.

Research methodology

We conducted a one-week daily diary study to validate the Knowledge Integration-Specialization Scale (KISS) and test the proposed model. Data were collected by three student assistants in their social networks to reach a heterogeneous sample of 151 employees. Most participants came from the Netherlands (44%), followed by Germany (25%), Greece (23%), and other nationalities (8%). We analyzed the data of participants who completed at least three daily diary surveys ($N = 46$ employees, $n = 236$ observations).

Results obtained

Multilevel CFAs supported the two-factor structure of the KISS. While knowledge-integration and specialization were positively correlated at the between-person level, their association was non-significant at the within-person level – supporting the temporal tradeoff perspective. Results of multilevel regression analyses showed that on days when employees engaged in more knowledge-specialization than usual, they reported higher levels of task performance and radical creativity. Main effects of knowledge-integration were not significant. Similarly, only designing fun (but not designing competition) significantly predicted daily task performance and radical creativity. Finally, designing fun strengthened the relationship between knowledge-specialization and daily radical creativity, as hypothesized. Unexpectedly, designing fun weakened the relationship between knowledge-specialization and daily task performance. None of the other interactions reached statistical significance.

Limitations

Current results are limited by the small sample size, which made it harder to detect significant interaction effects. Future research may test the proposed model with more statistical power and also examine mediating mechanisms.

Conclusions

The main empirical findings of this study are as follows. First, it appears that employees face a daily tradeoff in terms of allocating time to specialized versus integrative knowledge work activities. Second, by approaching knowledge-specialization activities in a fun way, employees may enhance their radical creativity but appear to simultaneously undermine their task performance on the given day.

Relevance to the congress theme

Knowledge-based work is becoming even more prevalent in future of work. As such, a better understanding is needed regarding how knowledge workers can take charge of their creativity and performance. The present study investigates this question from the angle of playful work design.

Relevant UN SDGs

The study would be relevant for the UN SDGs: “Good health and wellbeing”, “Decent work and economic growth”, as well as “Industry, Innovation and Infrastructure”.

Keywords: Creativity; Performance; Knowledge

Paper 3

Playful Work Design or Playful Distraction? The Consequences of a Ludic and Agonistic Playful Work Design Intervention in a Rigid Work Environment

Carl Marcus Wallenburg & Fabiola H. Gerpott | WHU – Otto Beisheim School of Management, Düsseldorf, Germany

Research goals and why the work was worth doing

Increasing employees' autonomous motivation at work – i.e., the inner drive to act because it is perceived to be consistent with intrinsic goals – is crucial because it positively relates to employees' psychological well-being, knowledge sharing, and ultimately also their commitment and performance. Against this backdrop, scholars have long studied how work can be (re-)designed to increase autonomous motivation through job enrichment and enlargement activities. However, such work design interventions are often not feasible in rigid or bureaucratic organizations due to legal requirements and a lack of resources. Furthermore, a high degree of bureaucratic rigidity also makes job crafting – i.e., the self-initiated change of job characteristics within set boundaries without the involvement of the management – difficult. A promising approach to still increase motivation in such rigid work environments is Playful Work Design, which refers to the proactive cognitive-behavioral orientation that employees engage in to incorporate play into their work activities to promote fun (ludic work design, LWD) and challenge (agonistic work design, AWD). Both forms of Playful Work Design are possible in rigid work environments because they represent self-initiated bottom-up approaches that are grounded in a person's attitude toward a job while not changing its characteristics or design.

Theoretical background

The emerging research stream on Playful Work Design has indicated that LWD (e.g., the application of humor, fantasy, or entertainment to work activities) and AWD (e.g., creating competitions, (self-)challenges, or (small) goals to stretch skills) differentially relate to relevant outcomes. Yet, there is a lack of causal evidence on whether both forms of Playful Work Design can be increased through interventions targeting employees. Consequently, important questions remain unanswered: Theory would suggest that interventions addressing LWD and AWD, respectively, may impact employees' LWD and AWD and the subsequently implemented Playful Work Design strategies differently – is this true? If yes, do these different interventions have potentially unique downstream effects on employees' autonomous motivation in a rigid work environment? How long would it take to see improvements in AWD or LWD and accompanying motivation levels after the intervention? Do such interventions work equally well for all employees?

Research methodology

227 employees working for different departments in a German district government (that exemplifies a bureaucratic organization) voluntarily signed up for our field experiment. Employees were randomly assigned to one of three theory-based intervention workshops (AWD, LWD, and a control workshop on cognitive biases) and participated in a two-hour training. Two weeks before, and two, four, and eight weeks after the intervention workshops, we captured participants' Playful Work Design with six items each for LWD and AWD, as well as their autonomous motivation via a survey that also included open-ended qualitative questions.

Results obtained

We found no significant increase in LWD in the ludic treatment group at all measurement points after the intervention. In contrast, participants in the agonistic treatment group reported higher AWD four weeks after the intervention. This finding is similar to previous intervention research that found that the target behavioral variable increased after a “flux phase”. Moreover, the increase in AWD four weeks after the intervention was positively associated with an increase in autonomous motivation eight weeks after the intervention.

To understand whether participants in the different treatment groups also developed different PWD strategies, we analyzed their qualitative responses through automized theme detection and subsequent manual coding. We found that employees indeed developed different strategies depending on whether they were in the LWD or AWD treatment group. By analyzing all strategies with respect to their treatment group, we found that strategies can be sorted into a 2x2 matrix to classify strategies that were (1) related to work activities, (2) outside of work activities, (3) self-focused, and (4) other-focused.

Limitations

Our data collection is limited to rigid work environments; thus, the generalizability to different work settings still needs to be tested.

Conclusions

The AWD intervention constitutes a promising workshop for increasing employees’ autonomous motivation in a rigid work environment. Contrarily, participants in the LWD treatment mainly created strategies outside of work activities that could be argued to distract them from their job.

Relevance to the congress theme

In a changing working world, it is essential to equip employees with competencies that allow them to rethink work positively. Our test of theory-based intervention workshops helps organizations to make evidence-based decisions about how and whom to train in which form of Playful Work Design.

Symposium S007

Job Insecurity – Symposium 1: How do employees and leaders react to job insecurity?

Lixin Jiang, University of Auckland; Hans De Witte, Research Group Work, Organizational and Personnel Psychology, KU Leuven, Belgium & Optentia Research Unit, North-West University, South Africa

science_practice

What will be covered: Significant changes in the business, economic, political, and technological backdrops surrounding work have led to fundamental changes to the nature of work. Consequently, workers around the world are experiencing increased uncertainty, and are unsure how much longer they can stay in their current employment or maintain desirable job features.

In the literature, quantitative job insecurity refers to the threat of job loss, while qualitative job insecurity refers to the threat of losing valued job features. We present two symposia with ten papers on job insecurity. In this first symposium, we include five papers focus on employee behaviour or behavioural intentions when facing job insecurity, while the second symposium including additional five papers focuses on attitudinal and well-being outcomes of job insecurity and their reciprocal relationships.

Liang et al. examine the moderating role of technology-induced insecurity in the positive associations of quantitative job insecurity with ego-depletion and turnover intentions with a two-wave sample of IT engineers from China. They find that the positive relationship between job insecurity and turnover intentions is only significant for those with low technology-induced insecurity. However, technology-induced insecurity does not significantly impact the positive relationship between job insecurity and ego-depletion.

The following three papers investigate employee qualitative job insecurity. Lazauskaitė-Zabielskė et al. propose that perceived justice and participative decision-making can attenuate the adverse effects of qualitative job insecurity on in-role performance, extra-role performance, and innovative work behaviours. With data from Belgium, Lithuania, and Switzerland, perceived justice and participative decision-making, unexpectedly, exacerbate the negative effects of job insecurity on these three types of performance.

Huang et al. examine the mediating role of the desire for job control in the relationship between qualitative job insecurity and voice, and the moderating role of employee regulatory focus in the indirect relationship between qualitative job insecurity and voice via desire for control. With three-wave data from China, they confirm that: 1) desire for control mediates the relationship between qualitative job insecurity and voice, and 2) prevention focus strengthens the indirect relationship.

Although the above papers examine the linear effects of job insecurity, the final two papers explore the curvlinear outcomes of job insecurity. Jiang et al. examine whether the curvilinear relationships of qualitative job insecurity with issue selling and skill development depend on masculine orientation and uncertainty avoidance. With two-wave data from Australia, Chile, New Zealand, and the U.S., they show a U-shaped relationship between qualitative job insecurity and issue selling for those reporting low masculine orientation, and a U-shaped relationship between qualitative job insecurity and skill development for those reporting high uncertainty avoidance orientation.

Finally, Wang et al. takes a different perspective by investigating leader job insecurity and their the behavioural reactions to job insecurity. With 95 leaders from China, they find that leader job

insecurity has an inverted U-shaped relationship with their abusive supervision towards subordinates, but U-shaped relationships with their task-oriented and relation-oriented behaviours.

Relevance to the Theme: Job insecurity has become ever-present in the modern world of work. By focusing on how employees and leaders may react to job insecurity, this symposium contributes to our understanding of how people across eight countries (i.e., Australia, Belgium, Chile, China, Lithuania, New Zealand, Switzerland, the U.S.) may behave in the face of the changing world of work featuring job insecurity.

Implications: The symposium contributes to our understanding of employee and leader behavioural reactions to job insecurity. Practically, organisations may create resourceful conditions to minimize job insecurity and/or attenuate the negative behavioural outcomes of job insecurity.

Overall conclusions: Papers in this symposium: 1) reveal moderators that may alter how employees may react to job insecurity (i.e., technology-induced insecurity, perceived justice, participative decision-making, regulatory focus, cultural value orientations), 2) demonstrate a underlying mechanism that may explain employee reactions to job insecurity (i.e., the desire for job control), 3) showcase whether job insecurity may linearly or nonlinearly relate to employee performance, and 4) highlight how leaders who experience job insecurity may interact with their employees. Thus, the symposium deepens our understanding of behavioural reactions to job insecurity by focusing on its moderators, a mediator, linear and curvilinear relationships, and employees and leaders with diverse samples from eight countries.

Keywords: Job Insecurity, performance, stress

Paper 1

Job insecurity and performance in academia: the role of perceived justice and participative decision-making

Hans De Witte, KU Leuven & North-West University; Ieva Urbanavičiūtė, Vilnius University & University of Lausanne; Jurgita Lazauskaitė-Zabielskė, Vilnius University

Research goals and theoretical background. Over the recent decades, the way academic life has been organised has witnessed substantial shifts. Technological, organisational, and managerial changes, pressure to redefine and broaden the role of academia in society (Alexander & Manolchev, 2020; Shin & Jung, 2014), as well as the need to be highly adaptive to unexpected shocks, such as the global COVID-19 pandemic (Savic, 2020) have taken their toll on employees in academia and affected their attitudes, performance, and health. Furthermore, increased job demands and obstacles to gaining promotion and precarious job contracts indicate the prevalence of job insecurity (e.g., Biron et al., 2008; Bryson, 2004; Kinman & Court, 2010). As job insecurity poses a critical risk to employees' performance and well-being (e.g. Jiang & Lavaysse, 2018), considerable research efforts have been directed at finding the preventing or buffering factors for the negative correlates of job insecurity. However, as existing studies usually focus on attitudinal outcomes, more research is needed on the effect of job insecurity on performance, considering the equivocal results on their relationship (e.g., Rosen et al., 2010).

Building upon Fairness Heuristic (Lind, 2001; Van den Bos, Lind, & Wilke, 2001) and Uncertainty Management (UMT, Lind & Van den Bos, 2002) theories and research that suggest equity practices (Kjeldal et al., 2005), academic freedom and participation in decision-making (Silvernail et al., 2021) might be the deciding factors in the way academic employees respond to their career challenges, we investigate the role of perceived overall justice and participative decision-making in the relationship between job insecurity and performance. We expect perceived justice and participative decision-making to alleviate the adverse effects of qualitative job insecurity on three forms of performance, i.e. in-role and extra-role performance and innovative work behaviours.

Design/Methodology/Approach/Intervention. The overall sample consisted of 1444 higher education employees in Belgium, Lithuania, and Switzerland. 68.7% of the participants were female. The mean age was 40.24 (SD = 11.06) years, and the mean tenure was 10.13 (SD = 9.21) years. 28.7% of the participants held temporary contracts. Regarding the occupational position, the sample consisted of three staff categories: administrative employees (n =400), senior academic staff (n = 507), and junior academic staff (n = 366). We tested our hypotheses using moderation analyses.

Results obtained. Roughly half of the tested moderation effects were significant. More precisely, perceived justice and participative decision-making moderated the relationship between qualitative job insecurity and three performance forms. Although higher perceived justice and participative decision-making were related to lower levels of job insecurity, the pattern of moderation effects appeared to be contrary to our expectations. Perceived justice and participative decision-making exacerbated the adverse effects of job insecurity. The negative relationship between job insecurity and performance forms was stronger under high levels of fairness and participation in decision-making. After testing moderations across different staff categories (administrative employees, senior academic staff, and junior academic staff), we found the moderation effect slightly depending on the staff category.

Limitations. Although the results are based on quite a large sample among three countries, the analyses are based on cross-sectional data.

Conclusions. Job insecurity, a significant stressor, is apparently an unfavourable experience, implying adverse outcomes. In fair academic institutions and under participative leadership, job insecurity is experienced as particularly stressful because it contradicts the idea of fair academia, which may drain employees' energetic resources when coping with it.

Relevant UN SDGs: Peace, justice, and strong institutions

Keywords: job insecurity, performance, academia

Paper 2

The moderating roles of cultural value orientations in the curvilinear relationships of qualitative job insecurity with issue selling and skill development

Lixin Jiang, University of Auckland; Xiaohong Xu, University of Texas at San Antonio; Hai-Jiang Wang, Huazhong University of Science and Technology; Marius Stander, North-West University; Lara Roll, KU Leuven & North-West University; Laura Petitta, Sapienza University of Rome; Sergio Lopez-Bohle, Universidad de Santiago de Chile; Xiaowen Hu, Queensland University of Technology; Maike Debus, Université de Neuchâtel

Research goal : A recent meta-analysis has identified the non-linear relationships of job insecurity with task performance, organizational citizenship behaviors towards individuals and organizations, and creative performance (Jiang et al., 2022). Building on and extending upon these findings, we aim to examine whether there are curvilinear relationships between qualitative job insecurity (QJI) and proactive behaviors. We specifically focus on two types of proactive behaviors: issue selling, or calling an organization's attention to key trends, developments, and events that have implications for its performance (Morrison & Phelps, 1990), and skill development activities, or starting initiatives that lead to mastery of the various tasks involved in one's occupation (Claes & Ruiz-Quintanilla, 1998) as it is unknown how job-insecure employees may display these two types of proactive behaviors. Because employees with different cultural value orientations may react to QJI differently, we further examine how cultural value orientations (i.e., individual differences in masculine and uncertainty avoidance orientations) may alter the non-linear relationships between QJI and proactivity.

Theoretical background : Consistent with Jiang et al. (2022), we propose U-shaped relationships of QJI with issue selling and skill development activities. On the one hand, based on social exchange theory (Cropanzano & Mitchell, 2005), individuals reciprocate what they receive from a given relationship. Thus, as job insecurity increases from low to medium levels, it may prompt employee reciprocation motivation to get back at the organization, thereby reducing their issue selling and skill development activities, both of which can benefit the organizations. On the other hand, the job-preservation perspective (Shoss, 2017) argues that to preserve their important job features, highly job-insecure employees may engage in behaviors that benefit the organization and their career development. Such preservation motivation is particularly pronounced when QJI increases from moderate to high levels when the threat of job change becomes more salient, imminent, and vivid. Thus, integrating social exchange theory with job preservation motivation, we propose that the negative relationships of QJI with issue selling and skill development activities turn positive after inflection points.

We further explore whether masculine orientation and uncertainty avoidance orientation may alter the U-shaped relationships of QJI with proactive behaviors. Masculine orientation is the degree to which individuals are assertive, ambitious, and competitive, and strive for material success, while uncertainty avoidance orientation is the extent to which ambiguous situations are felt as threatening (Hofstede, 2001). Individuals with low (vs. high) masculine orientation and those with high (vs. low) uncertainty-avoidance orientation are more likely to perceive the possibility of job loss as threatening. Thus, we propose that for those with low masculine orientation and those with high uncertainty avoidance orientation, the U-shaped relationships of QJI with issue selling and skill development activities are more pronounced.

Method : Two-wave 1,263 employee data were collected in four countries: Australia, Chile, New Zealand, and the United States. We assessed QJI (Låstad et al., 2015) as well as collectivism, power distance, masculine, long-term, and uncertainty-avoidance orientations (Yoo et al., 2011) at Time 1, and issue selling (Morrison & Phelps, 1999) and skill development activities (Claes & Ruiz-Quintanilla, 1998) at Time 2. Collectivism, power distance, and long-term orientations were included as controls.

Results : Using hierarchical multiple regression analyses, we found that there was a significant moderating effect of masculine orientation on the relationship between QJI and issue selling where we observed a U-shaped relationship between QJI and issue selling for those reporting low masculine orientation. There was also a significant moderating role of uncertainty avoidance orientation in the relationship between QJI and skill development where we observed shows a U-shaped relationship between QJI and employee skill development among those with high uncertainty avoidance orientation. Other significant relationships were not detected.

Limitations: This study relied on self-reports, which may introduce common method bias. We used a cross-lagged design, which undermines our ability to make casual inference. We did not examine the mechanisms proposed by the integrated theoretical frameworks.

Conclusions : We conclude that the U-shaped relationships of QJI with proactive behaviors (issue selling and skill development) depend on one's cultural value orientation. The U-shaped relationship of job insecurity with issue selling only exists for those with low masculine, while the U-shaped relationship of job insecurity with skill development only exists for those with high uncertainty avoidance.

Relevance to the Congress Theme : The changing world of work inevitably involves undesirable changes to one's employment — QJI. Our findings reveal how employees with different cultural value orientations may react to QJI.

Relevant UN SDGs : decent work and economic growth.

Keywords: job insecurity, curvilinear, proactivity

Paper 3

Job insecurity and (un)sustainable well-being: A study of within-person effects among working adults in Switzerland

Ieva Urbanaviciute & Massoudi Koorosh | Swiss National Centre of Competence in Research LIVES, University of Lausanne, Switzerland; De Witte Hans, Research Group Work, Organizational and Personnel Psychology (WOPP-O2L), KU Leuven, Belgium

Goals

In the contemporary labour market, a threat of job loss represents a major occupational hazard that has significant repercussions for workers' health and well-being (Eurofound, 2021). Within the stressor-strain literature, existing research (e.g., Cheng & Chan, 2008; De Witte et al., 2016) points to a host of potentially detrimental effects resulting from individual strain responses to (perceived) job insecurity that still need to be better understood. In the current study, we aim to contribute to this understanding in two ways. First, we focus on within-person relationships, seeking to unravel intraindividual dynamics of job insecurity. In so doing, the present study meaningfully adds to the current knowledge on the topic that is still largely based on the interindividual differences approach. Second, we adopt a cross-domain perspective that includes testing both work-related (i.e., job satisfaction, work strain) and life outcomes (i.e., life satisfaction, health complaints). This is necessary in order to better understand how job insecurity threatens sustainable well-being, because the notion of sustainability implies thriving in different areas of life.

Theoretical background

Drawing on conservation of resources theory, employment is conceptualized as an important "conditions" resource that provides status and identity for the individual (Hobfoll, 1989; Hobfoll et al., 2018). Job insecurity represents a threat of losing these benefits, which is perceived as stressful and may trigger a range of strain reactions. Therefore, we hypothesized prospective negative relationships between job insecurity and well-being and expected them to occur at the within-person level after controlling for between-person differences on these variables. Moreover, resource loss and strain are thought to be reciprocally intertwined, forming a so-called loss cycle (Halbesleben et al., 2014). For this reason, we also tested the possibility of reversed pathways linking (a lack of) well-being to job insecurity.

Method

To test the hypotheses, we used longitudinal data from the "Career Paths" panel survey based on seven yearly measurements. The survey was carried out within the framework of the Swiss National Centre of Competence in Research—Overcoming Vulnerabilities: Life Course Perspectives (LIVES) and includes a large sample that is representative of the German- and French-speaking population in Switzerland. Our analytic sample consisted of 1134 professionally active adults (49% women, mean age at T1 = 42.34, SD = 8.41). Data analyses were conducted with Mplus v8.8, applying recent extensions to the cross-lagged panel modelling that allow to inspect reciprocal relations at the within-person level (Hamaker et al., 2015; Usami et al., 2019).

Results

According to the results, job insecurity had a significant (yearly) cross-lagged effect on job satisfaction and mental health at the within-person level, which was detectable after controlling for

the corresponding between-person effects. As expected, higher than usual individual job insecurity resulted in lower than usual job satisfaction and more expressed deterioration of health for that individual, highlighting the lasting setbacks people may be subject to when confronted with job-insecure situations. Interestingly, and contrary to prior findings based on the between-person approach, we found only limited support for the reciprocal relationship between job insecurity and well-being. Mental health complaints but not other outcome variables showed a bidirectional pathway, which points to mental health as a potential vulnerability factor that may predispose the person to higher job insecurity and may as well be escalated by it.

Limitations

The present study only included quantitative job insecurity (fear of losing the job), which is somewhat less salient in the general population than qualitative job insecurity (fear of losing valued job features). Moreover, our analyses were based on yearly time lags, which may be suboptimal for capturing more immediate effects.

Conclusion

Our findings showcase the risks to employees' sustainable well-being associated with job insecurity, especially highlighting the intra-individual dynamics of job satisfaction and mental health.

Relevance

The current study fits well to the conference theme because job insecurity is a prevalent and worrisome attribute of the changing world of work. Empirical research aimed at expanding the knowledge about its accompanying risks is crucial for promoting employee health and well-being (thus addressing UN SDG #3) and decent work for all (thus addressing UN SDG #8).

Keywords: Work stressors, employee well-being, within-person analyses

Paper 4

The reciprocal associations between job insecurity, job satisfaction, and perceived stress. A cross-lagged panel analysis on the moderating role of or

Lo Presti Alessandro, Università degli studi della Campania "Luigi Vanvitelli" – Caserta (Italy); Callea Antonino' LUMSA University, Rome, Italy; De Rosa Assunta, Università degli studi della Campania "Luigi Vanvitelli" – Caserta (Italy); Urbini Flavio, LUMSA University, Rome, Italy; Chirumbolo Antonio, Sapienza University of Rome, Italy

Research goals and why the work was worth doing

Job insecurity remains a significant stressor to many workers, with short- and medium- term consequences on their job attitudes and, above all, health. Evidence about the negative effects of job insecurity on job satisfaction and health is consolidated (Lee et al., 2018), however much little is known about the reciprocal effects of these outcomes on job insecurity over time. In fact, among the available longitudinal studies on the effects of job insecurity, only a limited amount included a test of reversed or reciprocal causation (De Witte et al., 2016).

Based on these considerations, we will examine the cross-lagged associations over time between quantitative job insecurity, job satisfaction, and perceived stress, also including organizational identification as a moderator of these associations as, based on the premises of the social identity theory, it could act either as a buffer because identification towards the organization could be a protective factor or as an amplifier of negative effects because of the threat to the organizational membership deriving from job insecurity.

Theoretical background

Consistently with the theoretical model by Sverke et al. (2002), we differentiated, on an individual-level basis, between job satisfaction as a proximal, attitudinal, outcome, and perceived stress as a distal, health-related, outcome. Moreover, we referred to the social identity theory (Tajfel & Turner, 1979) to explain the influence of social aspects on the experience and effects of job insecurity (Selenko et al., 2017), as it can be helpful in explaining the potential moderating role of organizational identification. This latter could amplify the negative association between job insecurity and job satisfaction as well as weaken the negative association between job satisfaction and health.

Design/Methodology

A cross-lagged panel study was carried out over a period of six months in 2020 in the midst of the Covid-19 pandemic: t1 (March 2020), t2 (June 2020), and t3 (September 2020). 539 Italian employees filled an online questionnaire (due to pandemic restrictions). At the t3, 347 valid questionnaires were returned (attrition rate = 35.62%). Before estimating structural models (contrasting normal, reversed, and reciprocal causation) by means of structural equation modelling with latent variables, we estimated alternative measurement models to test for common method variance and we also tested for measurement invariance. Moderation was tested by means of the Process macro for SPSS (5000 subsamples).

Results obtained

First, we tested for alternative measurement models finding support to the distinctiveness between our study variables. Then, we tested for measurement invariance finding support for configural, metric, and scalar invariance. As for the alternative structural models, we found that the reversed causation one fitted best the data. As for the associations between variables we found that stress t1 positively predicted job insecurity t2 and job satisfaction t2. Analogously, stress t2 positively predicted job insecurity t3 and job satisfaction t3. Finally, we tested for the moderating effect of organizational identification, finding that it weakened the negative association between stress and job satisfaction, while it amplified the positive association between stress and job insecurity.

Limitations

The sample was heterogeneous and recruited through a convenience sampling. Future studies could include additional short- and medium-term outcomes as well as differentiate between different kinds of job insecurity (e.g., cognitive vs. affective). The use of objective measures for health (e.g., psychophysiological indicators) could provide additional insights.

Conclusions – research implications

Opposite to our expectations, quantitative job insecurity did not predict neither job satisfaction nor job stress. In fact, job stress positively predicted job insecurity and negatively predicted job satisfaction. It could be argued that job stress does not measure a health outcome but a transient stress state that, consistently with the Appraisal Theory of Stress (Lazarus & Folkman, 1984), impacts on job satisfaction. As for the impact on job insecurity, it may be argued that stressed employees may be more nervous, irritable, and inefficient and this may lead to several intermediate outcomes (e.g., conflicts with supervisors and colleagues, poor performance) that impair their position within their current organization and increase feelings of job insecurity. Moreover, we found that organizational identification is a protective factor of the negative effects of job stress on job satisfaction, while it amplifies its positive effects on job insecurity. As for this latter result, the sense of oneness with an organization could arouse expectations influencing perceived stress and concerns about own job continuity.

Relevance to the Congress Theme

CAREERS AND THE LABOUR MARKET – subtheme: job insecurity

Paper 5

Subtle cutback management and employee exhaustion: the role of qualitative job insecurity as a mediator

Akkermans Yvette & Stynen Dave |Faculty of Management, Open Universiteit, Heerlen, the Netherlands

Research goals and why the work was worth doing

As an answer to crises like COVID-19 organizations implemented more subtle forms of cutback measures like wage moderation, loan sacrifice and recruitment freezes aimed at maintaining a financially healthy organization. In this study the association between subtle cutback management and employee exhaustion is studied, and it investigated whether this potential linkage can be explained by employee perceptions of increased qualitative job insecurity or the fear that valued features of the job will decrease in the future. This research thereby extends prior research on the consequences of cutback management as well as regarding the antecedents of qualitative job insecurity.

Theoretical background

In this study associations are explained by relying on Psychological Contract Theory and organizational change literature on the one hand and the Job Demands-Resources model on the other hand.

Design/Methodology/Approach/Intervention

A cross-sectional online survey study was conducted on a sample of Dutch workers (N=218) active in various organizations in the Netherlands. Regression analysis was applied to test hypotheses. Mediation was investigated by means of Hayes PROCESS macro (SPSS).

Results obtained or expected (if not available, it must be made clear when they will be)

The results of the study indicate that there is no direct relationship between subtle cutback measures deployed at the workplace and employee exhaustion. However, the analyses further revealed that subtle cutback measures were positively related to the experience of qualitative job insecurity in workers and that enhanced qualitative job insecurity was positively related to employee exhaustion. Qualitative job insecurity fully mediated the relationship between subtle cutback measures and employee exhaustion.

Limitations

Because of the cross-sectional design of the study cause-effect relationships cannot be inferred. Sampling was done through 'self-selection,' thereby limiting the generalizability of findings. The measurement of subtle cutback management may not have been exhaustive to capture all forms.

Conclusions – research and or practical implications

This study connects organizational change and well-being literature by adding the insight that the implementation of subtle forms of cutback measures, a form of organizational change, may indirectly relate to more employee exhaustion through increased concerns about the quality of one's job in the near future. This study can contribute to the mitigation of a core facet of burnout, i.e. employee exhaustion, which is regarded as an important precursor of sickness absenteeism and diminished

work participation. This study provides leads for organizations to either turn away from unsustainable practices like the implementation of well-intended cutback measures or to better intervene in the prevention of associated feelings of job insecurity.

Relevance to the Congress Theme (The future is now: The changing world of work")

To respond to turbulent times organizations implement subtle forms of cutback management with the intent to remain a financially healthy organization and avoid lay-offs. Yet, such practices may have unintended negative health effects for employees, and hence trigger downward spirals. As such, this study addresses one of the dilemmas that organizations are facing these days as part of an open, rapidly changing society.

Relevant UN SDGs (https://sdgs.un.org/goals)

Relevant UN SDGs are Goal 3 Ensure healthy lives and promote well-being for all at all age and Goal 8 Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all.

Paper 6

Job insecurity as a societal belief? On the mutual relationship between trust in the government and job insecurity

Eva Selenko, Loughborough University, UK; Van Hootegem Anahi, WOPP-O2L, FPPW, KU Leuven, Belgium; Shoss Mindy, University of Central Florida, US; De Witte Hans, WOPP-O2L, FPPW, KU Leuven, Belgium

Research goals and why the work was worth doing

In current times of political and economic turbulence, an increase in job insecurity seems to go hand in hand with a simultaneous decrease in trust in core political institutions (such as the government). This research wants to establish whether these two processes could be mutually related, explore the societal relevance of work and establish the political risks of job insecurity.

Work is a core social institution: It generates income, is part of people's identity and allows for participation in society, which is a fundamental social right. The workplace is also where people interact with others in society, outside their private family and friendship circle.

Job insecurity threatens all of these aspects, and has been found to have devastating health and work-behavioral effects. Given the centrality of work for people's role in society, could job insecurity also have wider political consequences and undermine the trustworthiness of a government?

Theoretical background

This study borrows from literature on corporate citizenship (e.g. Matten & Crane, 2005), and Jahoda's (1988) conceptual ideas which propose that work is a social institution, and organisations provide employees with the means of participating in society, thereby enabling them to exert an important social citizenship right. The governments' role is to protect citizen's rights and core social institutions.

Job insecurity could hence be understood as a threat to the institution of work and the social right to partaking in society. This can reflect badly on the government as protector of people's rights and plausibly undermines the level of trust citizens have in the government. Low trust in the government in turn will also have an effect: It can render people more insecure about their protection of social rights and social institutions, such as partaking in work.

Previous empirical studies already evidence that a relationship between work and political attitudes is plausible (e.g., De Witte & Selenko, 2021; Shoss et al., 2022; Stanojevic, 2021; Van Hootegem et al., 2021). This study hypothesizes that job insecurity undermines people's trust in their government, and vice versa, as the government protects the social institution of work and the social right to partake in society.

Methodology

A three-wave survey study among 1641 Belgian professionals was conducted to test these assumptions. Standardised instruments were used to measure quantitative job insecurity (Vander Elst et al., 2014), and trust in the organisation (Robinson, 1996), which was included as control variable. Trust in the government was measured by adapting Robinson's 1996 scale, the scale showed good factorial qualities.

Results

To inspect within-person changes in job insecurity and see whether they affect the trust in the government, we used a partly time-invariant, random-intercept cross-lagged panel model. The results confirm the hypothesis by showing a reciprocal relationship between quantitative job insecurity and trust in government, and strangely no effect with trust in one's organisation. Not only did people who experienced increases in job insecurity showed subsequent decrease in trust in the government; also people who reported decreases in trust in the government, experienced increases in job insecurity. This shows that job insecurity is informed by the trustworthiness of the government, which stands for the protection of individual's social rights, of which participating in work is an important element. A government who is not trusted, will not be trusted to ensure that people can access their social right of work.

Limitations

Our study focussed on trust in the government only, it did not assess perceived social right violations, nor did it measure to which degree people saw the government as being responsible for the protection of their social rights or the social institution of work. This renders the core elements of the theoretical assumptions as yet untested.

Conclusions – research and or practical implications

The study makes a substantial contribution to the work and organisational psychological literature by evidencing the effect of job insecurity on political attitudes, but also by showing that job insecurity is informed by an assessment of the wider political climate in a country. By recognising the societal context of work, this study highlights the responsibility of work and organisational psychology to solve wider socially significant problems.

Relevance to the congress theme

The future of (good) work relies on trustworthy governments.

Keywords: job insecurity, political trust, longitudinal

Symposium S008

Blurred Lines – Empirical evidence on the importance of studying distinct forms of how work can enter nonwork roles and vice versa

Nina M. Junker, University of Oslo; Stefanie Marx-Fleck, Goethe University Frankfurt

science

1. What will be covered and why:

The lines between work and nonwork roles get increasingly blurred due to changes in how and where we work. As such, technology enables employees to work anytime and anywhere and organizations support the integration of work and nonwork roles through various practices. Yet, individuals not only differ in their preferences to integrate (i.e., to create thin and permeable role boundaries) or segment (i.e., to create thick and impermeable role boundaries; Ashforth et al., 2000) but also in how they integrate such roles (Allen et al., 2014; Capitano et al., 2019). Yet, to date, when studying how individuals navigate their work and nonwork roles, the majority of studies have focused on overall degrees of role integration (or segmentation). In this symposium, we take a more differentiated perspective and zoom in on distinct ways of how work can enter nonwork roles and how nonwork roles can enter the work role. The first presentation by Humps et al. focuses on workplace friendship as a form of people integration and studies how individuals' integration preferences affect workplace friendships and what its consequences for organizational citizenship behaviors are. The next three contributions study work-related rumination as a specific form of cognitively integrating the work role into a nonwork role. In a longitudinal three-wave study, Marx-Fleck et al. show how affective rumination prolongs the consequences of defensive decision-making to chronically deplete individuals – and how chronic resource depletion affects future decision-making. In a daily diary study, Mackenbach et al. study the relevance of such cognitive role integration as a mechanism in how characteristics of the work role affect dream content. In another daily diary study, Heimrich et al. show whether and how affective rumination prolongs the consequences of work experiences (here, workplace incivility) to affect well-being and next-day work behaviors. Finally, Willemen et al. present findings from a study on how being a dog owner affects employees 'well-being when teleworking (i.e., physically integrating work and nonwork roles)

2. Relevance to the congress theme:

This symposium directly speaks to the congress theme as the potential for integrating work and nonwork roles is a direct consequence of the future of work. Particularly since the COVID-19 pandemic, employers have been increasingly discussing teleworking offers, thus supporting the integration of the work role into nonwork roles. At the same time, employers have been increasingly offering options to similarly integrate nonwork roles into the work role, for instance, through on-side childcare opportunities or joint sports activities

3. Research/Practical Implications:

Jointly, the five contributions in this symposium provide crucial research implications, supporting the need for a more differentiated perspective on studying role integration and expanding role integration to other roles than the family role. Likewise, this symposium helps in raising employees' and employers' awareness of the many forms of how the work role can enter nonwork roles and vice versa. The results of these five studies can help employees better navigate their boundaries between work and nonwork roles and support employers in building a healthy future of work.

45. Overall conclusions:

Overall, the five presentations in this symposium help provide a more fine-grained perspective on multiple-role integration, which is increasingly common in nowadays working lives.

Keywords: boundary management, well-being, work-nonwork interface

Paper 1

Special treatments for my friend: The centrality of workplace friendships on organizational citizenship behaviour

Nina M. Junker, University of Oslo; Anna Deuster, Goethe University Frankfurt; Sophia E. M. Humps, University of Oslo

1. Research goals and why the work was worth doing

Extending beyond formal role descriptions is essential to organisational citizenship behaviour and workplace friendships. Through organisational citizenship behaviour (OCB), employees go beyond what is formally expected of them to benefit the organisation in general (OCBO) and indirectly through benefits directed to specific individuals (OCBI; Organ, 2018). At the same time, workplace friendship extends beyond the formal role description of co-workers by including the role of a friend in the working relationship (Pillemer & Rothbard, 2018). Both concepts blur the lines of what is formally asked of employees and impact organisational behaviour and outcomes. This study aims to identify individual factors that predict when employees go beyond the formal work relationship using Boundary Management Theory (BMT) and examines the subsequent consequences for OCB.

2. Theoretical background

Following the research on BMT in the work-family domain, particularly two factors influence whether individuals integrate or keep their roles segmented. First, role centrality describes the priority and value individuals place on a specific role (Kossek et al., 2012). Regarding workplace friendships, role centrality determines how meaningful friendships at work are compared to friendships outside work. When individuals prioritise their workplace friendships over other friendships, they invest more into those relationships and probably maintain more workplace friendships than those who prioritise friendships outside of work. Second, individual differences exist in the general preferences of integrating or segmenting different roles (Rothbard et al., 2005). Individuals with high integration preferences prefer blurring their personal and professional life and might therefore be more likely to engage in workplace friendships that are inherently blurred.

The prevalence of workplace friendships has profound implications for an organisation. Previous studies attested to the positive effect of workplace friendships on organisational outcomes through more job satisfaction, greater productivity, and greater trust among befriended employees(Morrison & Cooper-Thomas, 2016). As a result, employees with more workplace friendships might display higher OCBO to benefit the organisation. Additionally, through friends' support on a dyadic level, friendships benefit single individuals and, subsequently, the organisation (OCBI).

Drawing on the boundary management literature in the work-family context and research on workplace friendships, we expected that a higher role centrality of workplace friends increases organisational citizenship behaviour (both OCBI and OCBO) through a higher friendship prevalence at work and that this association would be stronger for individuals with stronger integration preferences.

3. Design/Methodology/Approach/Intervention

We conducted a time-lagged survey with German-speaking employees and analysed the data using moderated mediation models.

4. Results obtained or expected

We found no direct associations between role centrality and both OCB dimensions. However, supporting our assumptions, we found an indirect positive association between role centrality and OCBI via more friendship prevalence. Individuals who prioritised workplace friendships over other friendships showed a higher friendship prevalence at work, which in turn was associated with more organisational extra-role behaviour benefitting specific individuals. We did not find this indirect association for OCBO. Moreover, integration preferences did not moderate these associations. However, stronger integration preferences related to more friendship prevalence at work.

5. Limitations

The present results are based on individuals' self-reports, facing the risk of common-method bias. Considering the nature of friendships and the effect of OCB on the individual level, it might be important to capture these on a dyadic level. To observe more objective consequences of workplace friendships for OCB, supervisor ratings may better capture OCB outcomes.

6. Conclusions – research and/or practical implications

The present study contributes to understanding workplace friendships as multiple-role relationships and uses BMT to examine the individualistic determinants that foster these work relationships. Our findings suggest that emphasising workplace friendships over non-work friendships relates to more friendship prevalence at work, in turn, positively relating to OCBI but not OCBO.

7. Relevance to the Congress Theme

In the changing world of work, a rising number of organisations blur the line between what was formerly considered purely professional and personal aspects of life by integrating leisure activities and social events in the workplace and thus fostering employee friendships. Using BMT allows us to study the unique dual-nature friendships present in today's companies.

8. Relevant UN SDGs

In an integrating world of work, employee behaviour often exceeds expected behaviour. As organisations foster employee friendships, they enable social relationships contributing to employees' decent working conditions. At the same time, as our research showed, the effects of friendship go beyond the social relationship by benefitting the effectiveness of organisations through OCBI, fostering economic growth.

Keywords: boundary management, workplace friendship, organizational citizenship behaviors

Paper 2

Affective rumination as a cognitive integration of individual's work role into their non-work role

Nina M. Junker, University of Oslo; Rolf van Dick & Stefanie Marx-Fleck | Goethe University Frankfurt

1. Research goals and why the work was worth doing

Defensive decision making aims at protecting one's resources by choosing a personally safer yet organizationally inferior option (Artinger et al., 2019). However, deliberately opting for a second-best option might threaten one's self-integrity as a personal resource, thus keeping the decision salient. We argue that this cognitive preoccupation causes employees to ruminate about their decision affectively even if they have physically left the workplace, impairing well-being and increasing work-family conflicts (Junker et al., 2021). This study aimed to test if deciding defensively (mirroring stressors within the work domain) enters the non-work domain via affective rumination, draining resources and ultimately resulting in exhaustion.

2. Theoretical background

Allen et al. (2014) distinguish multiple ways of integrating work into the home domain. However, if the individual's work role interferes with the non-work role, this bears the risk of conflicts between the two domains (Ashforth et al., 2000). Individuals strive to see themselves as coherent and stable (Cross et al., 2003). Therefore, inconsistent behavior at work threatens a positive view of the self and impairs employees' well-being (Brief et al., 2001; Kammeyer-Mueller et al., 2012). Integrating these two perspectives, we propose that the behavioral inconsistency evoked by defensive decisions induces individuals to ruminate affectively about those decisions. If they fail in mentally distancing themselves from their work role after the end of work, those ruminative thoughts might serve as one mechanism through which the work domain interferes with the non-work domain, resulting in exhaustion. Thus, affective rumination represents one way of cognitively integrating the work role into a nonwork role, extending the (here, draining) consequences of work.

3. Design/Methodology/Approach/Intervention

We conducted a three-wave study with 6-week intervals between measurement points to test our model. We measured all constructs at each measurement point. To assess defensive decision making, we used an adapted version of Artinger et al. (2019). Affective rumination was measured with the five items developed by Cropley et al. (2012), adapted to relate to the time after making a defensive decision. Emotional exhaustion was assessed with the nine items from the Maslach Burnout Inventory (Maslach & Jackson, 1981).

4. Results obtained or expected

We found that affective rumination mediated the relationship between defensive decision making and emotional exhaustion, illustrating that individuals who are not able to stop thinking about work drain their cognitive resources even when they physically leave their workplace, resulting in the perception of prolonged exposure to the stressor. We further found support for reciprocal associations: whereas one-time defensive decision making did not inevitably result in feelings of emotional exhaustion, exhausted employees tended to decide more defensively in the future.

5. Limitations

We relied on self-reports, which may be subject to social desirability and common-method bias. Furthermore, we relied on participants' ability to recall situations in which they decide defensively accurately, which might be subject to individual differences. Besides, our research design did not allow us to make strong causal inferences.

6. Conclusions – research and/or practical implications

The results show that employees who aim to protect their resources by deciding defensively mentally take this decision home, thus lacking resources to spend in their nonwork roles. Instead of replenishing their resources, they further drain these, ultimately experiencing exhaustion. By strengthening boundaries between work and home, organizations can enable employees to leave their work physically and mentally behind.

7. Relevance to the Congress Theme

This study highlights the need to carefully consider the psychological permeation between the work and non-work domains to sustain employees' mental health.

8. Relevant UN SDGs

Defensive decision making is not limited to a particular domain. Thus, it is relevant for promoting sustainable, climate-friendly organizational decision-making.

Keywords: defensive decision making, burnout, affective rumination

Paper 3

The effects of challenge and hindrance demands on dream content and valence - a daily diary study

Jan A. Häusser, Sascha Abdel Hadi, Janina Janurek & Anna Luca Mackenbach | Justus-Liebig-Universität Gießen

1. Research goals and why the work was worth doing

The purpose of this study was to explore if challenge and hindrance demands are related to dreaming (i.e., dream affect and work-relatedness of dream content) and if this relationship is mediated by work-related rumination before going to sleep. This research contributes to the emerging research of work influences on sleep, with broadening the scope to dreaming.

2. Theoretical background

Previous research has shown that work stressors are related to perseverative cognition which in turn has a negative influence on various sleep parameters, such as sleep efficiency or number of awakenings (e.g., van Laethem et al., 2016; van Laethem et al., 2018). Barnes and colleagues (2021) initially investigated the involvement of dreaming in the relationship between work stressors and sleep, and found that day-specific job demands are related to day-specific dream affect via day-specific work-related rumination.

Building on these findings, we investigated the effects of challenge and hindrance demands on dream content. Specifically, we hypothesized that daily challenge and hindrance demands predict work-related dream content at the successive night, and tested work-related rumination as a potential mediator of this relationship.

3. Design/Methodology/Approach/Intervention

We conducted a daily diary study with 263 employees working from home over the course of 14 consecutive days. Day-specific challenge and hindrance demands were assessed directly after work and day-specific pre-sleep rumination, dream affect and work-relatedness of dream content were assessed the following morning. 82 out of the 263 participants reported to have remembered their dreams at least once during the two-week assessment. Therefore, a total of 149 dreams from these 82 participants could be analysed.

4. Results obtained or expected

Multilevel analyses indicated no significant indirect effect of work-related rumination before going to sleep for the relationship between challenge and hindrance demands and dream affect, neither on the between-person nor on the within-person level. Nevertheless, we found a direct effect of hindrance demands on dream affect on the within-person level: Higher hindrance demands were associated with more negative dream affect. Regarding work-relatedness of dream content as an outcome, no significant indirect effect of work-related rumination at night was found on the within-person level. We did, however, find the predicted indirect effect linking high hindrance (but not challenge) demands to more work-related dreams via more work-related rumination on the between-person level.

5. Limitations

Common method bias might be an issue since all variables were measured via self-report.

6. Conclusions – research and/or practical implications

Our study shows that strain reactions caused by work stressors are prone to be prolonged in the form of work-related rumination in the evening and can even invade the night in the form of work-related dreams. Furthermore, our results support the idea that challenge versus hindrance demands are differently related to rumination and dreaming as we only found an indirect effect linking hindrance demands, but not challenge demands, to work-relatedness of dream content via work-related rumination. Based on our findings, we recommend that organisations contribute to healthy work environments by reducing hindrance demands. This will prevent employees from developing rumination routines and, as a result, from continuing to experience work stressors in the form of work-related dreams.

7. Relevance to the Congress Theme

In our study, we collected data from employees who exclusively worked from home. Since the start of the COVID-19 pandemic, remote work has become increasingly important. With home and work being at the same place, the boundary between the two has become more blurred, making it harder to mentally switch off during non-work time. Due to this, it has become even more crucial to identify the specific causes and consequences of work-related rumination during non-work hours in order to improve employees' well-being and health in the long run.

8. Relevant UN SDGs

By investigating the work-related antecedents of impaired sleep, our study contributes to the UN Sustainable Development Goal of good health and well-being. Sleep is crucial for recovery, and maintaining optimal functioning. Poor sleep is associated with a broad range of health problems, such as cardiovascular diseases, burnout, depression or neurodegenerative diseases. The investigation of dream affect and work-relatedness of dream content provides insight into a largely unknown aspect of sleep quality and its relationship with job stressors, and could help to improve employees sleep quality in the future.

Keywords: challenge demands, hindrance demands, dreams

Paper 4

The relevance of workplace incivility and work-related rumination for reattachment and sleep quality

Nina M. Junker, University of Oslo; Thomas Rigotti, Johannes-Gutenberg University Mainz & Leibniz Institute for Resilience Research; Jan A. Häusser, Justus-Liebig-Universität Gießen; Julia Heimrich, Goethe University Frankfurt

1. Research goals and why the work was worth doing

Workplace incivility can be defined as a mistreatment behavior at work, characterized by low intensity and ambiguous intent to harm the target (Andersson & Pearson, 1999). Due to its ubiquity, workplace incivility is an important topic in organizational research. Although a lot is known about its antecedents and consequences (Han et al., 2021), the underlying mechanisms have received substantially less attention. We introduce affective rumination (Cropley & Zijlstra, 2011) as one such mechanism through which experienced workplace incivility indirectly affects sleep quality and reattachment the next morning. We further study how instigated incivility (targets' own uncivil behavior) moderates these associations. By studying potential spillover effects of experienced workplace incivility to the home domain and back to work and instigated incivility as a contingency factor, we aim to contribute to a better understanding of this widespread phenomenon.

2. Theoretical background

Drawing on the Effort Recovery Model (Meijman & Mulder, 1998), affective rumination may inhibit recovery from the resource loss caused by experienced workplace incivility. That is, employees may not be able to replenish their resources during non-work time. Instead, by cognitively integrating their work experiences into their nonwork roles, they continue to deplete these, impeding their recovery from work (through worse sleep quality). According to Sonnentag et al. (2002), reattachment is goal-directed and relates to positive affect. Therefore, we further expected affective rumination to impair this positive mental reconnection. We assume that instigating incivility may foster a belief of retaliation and compensate for the experienced injustice, so that such behavior might buffer the adverse consequences of experienced incivility.

3. Design/Methodology/Approach/Intervention

We conducted a 10-day diary study (N = 133) with three daily measurement points to test our assumptions, whereby we used data from the morning and the afternoon survey. In the afternoon survey, participants gave information about their experienced instigated incivility behavior and momentary rumination. In the morning survey, we assessed participants' sleep quality and morning reattachment.

4. Results obtained or expected

Overall, we found limited support for our assumptions. In particular, although workplace incivility was positively associated with affective rumination, there were no downstream consequences on individuals' sleep quality. Moreover, we found an unexpected positive indirect association between experienced workplace incivility and reattachment the next morning via affective rumination. Instigated incivility did not moderate any of the obtained associations

5. Limitations

We did not differentiate between different sources of workplace incivility (e. g., supervisor, co-worker) and cannot make inferences on employees living alone as we exclusively sampled couples and individuals with children living at home. Finally, the average of experienced incivility and incivility towards others were low, which might explain why we found limited support for our assumptions.

6. Conclusions – research and/or practical implications

Our results cautiously implicate that experienced incivility may not have immediate health-related consequences. The unexpected positive indirect association between experienced incivility and next-day reattachment via affective rumination might hint that experiencing incivility may have even positive effects. However, it is important to emphasize the crucial role of detaching from work through transitioning to nonwork roles during leisure time for effective recovery. Future research should therefore further study the influence of affective rumination on, not only the transition from work to home, but also the reconnection back to the work role and how this association influences the workday. Organizations should not only focus on reducing factors leading to adverse work-related thoughts at home but also encourage employees' goal-related reattachment.

7. Relevance to the Congress Theme

The blurred lines due to ruminating about work during nonwork time may lead to a vicious circle impacting the work and non-work role as well as health and well-being of employees. For the future world of work, it is essential to draw attention on the transitions between work and nonwork. Especially as the Covid-19 pandemic has led to the increased use of teleworking, boundary management between work and home may be more difficult and work topics may increasingly find their way into the home-domain.

8. Relevant UN SDGs

Our study shows the importance of reducing incivility as this impact affective rumination, resulting in severe negative health and well-being outcomes.

Keywords: workplace incivility, affective rumination, well-being

Paper 5

Teleworking in the presence of your dog: how your dog impacts your teleworking experience

Joni Delanoeije, Marijke Verbruggen & Emma Willemen | KU Leuven

1. Research goals and why the work was worth doing

Since an increasing number of employees own a dog (FEDIAF EuropeanPetFood, 2022), companies may benefit from offering practices that facilitate employees' care for their dogs as this allows them to both attract and retain employees in an increasingly tight labour market. One such practice is teleworking. However, our current understanding of how dog characteristics and dog-related activities influence employee outcomes while teleworking is limited. This is surprising as various studies in the field of human-dog interaction have highlighted the need for including dog and people characteristics, as well as features of their interactions, to understand the impact of dogs on human outcomes (Barcelos et al., 2020). Therefore, we aim to evaluate to which extent characteristics of the dog (i.e., behaviour) and dog-related activities (i.e., walking with the dog, playing with the dog, petting the dog) impact employee job performance outcomes (e.g., concentration) and well-being outcomes (e.g., stress, positive and negative affect, social support) while teleworking in the presence of a dog.

2. Theoretical background

Teleworking can have specific benefits for dog owners. Firstly, the work-home combination, including the care for the dog, is facilitated through telework (Maharaj & Haney, 2015). Secondly, as dogs are sensitive to the duration of time left alone (Rehn & Keeling, 2010), telework enables dog owners to reduce this alone time. Finally, dog-owning teleworkers may experience more well-being benefits from telework thanks to their dogs through a healthy amount of physical activity, welcoming breaks, and social interactions (Hoffman, 2021; Westgarth et al., 2019).

However, the benefits of telework for dog owners may not always be realized as they may depend on dog characteristics (e.g., dog behaviour) and dog-related activities (e.g., walking with the dog). Certain dog behaviours, like barking, can create distractions during the workday (Hoffman, 2021), which may lower the well-being and performance benefits of having a dog at home while teleworking. This expectation is in line with research on the harmful impacts of work interruptions (e.g., Delanoeije et al., 2019; Wilkes et al., 2017). In addition, since several of the expected benefits of having a dog while teleworking assume that the dog owner engages in interactions with the dog (Barcelos et al., 2020), it is likely to assume that the benefits will be lower on days the dog owner had less dog-related activities while teleworking.

3. Design/Methodology/Approach/Intervention

We conducted a daily dairy study in a sample of 302 dog-owning employees who worked at home regularly. They filled out a background survey and, three weeks later, daily surveys at the end of the evening during ten consecutive working days. The background survey included demographics and questions about personality and psychological closeness to the dog. The daily surveys included measures of dog behaviour, dog-related activities, job performance, and well-being during that day. Data will be analysed using multilevel modelling.

4. Results obtained or expected

Results will be available at the beginning of 2023.

5. Limitations

We collected data during COVID restrictions. Besides, we did not take into account the presence of other companion animals while teleworking.

6. Conclusions – research and or practical implications

Our findings will shed light on which dog characteristics and dog-related activities influence employee outcomes while teleworking. As we know little about the factors related to the presence of a dog that determine the beneficial or harmful effects on employee outcomes, elucidating this will improve our understanding of the effects of teleworking in the presence of a dog on employee job performance and well-being outcomes.

7. Relevance to the Congress Theme

This research fits within the conference theme 'The changing world of work', as teleworking, even after the pandemic, will stay to exist and both owning a dog and teleworking impacts employee well-being and performance (Barcelos et al., 2020; Delanoeije & Verbruggen, 2020; Hoffman, 2021).

Symposium S009

Predicting Leadership, Negotiation, Aggression, and Faking: With Implicit Measures

Malte Runge, Oslo Metropolitan University; Jonas Lang, Exeter University

science_practice

What will be covered and why?

Implicit personality constructs are typically described as nonconscious thoughts affecting behavior, affect, needs, cognition, or attitudes (Uhlmann et al., 2012). Prominent examples are implicit motives describing stable preferences for classes of affectively charged incentives such as need for achievement, power, affiliation, or aggression (McClelland, 1987). Implicit personality constructs are commonly measured through indirect means, such as picture story exercises, conditional reasoning tests, or implicit association tests because they are not accessible through introspection. Researchers have long been interested to study the effect of implicit personality on people's work life. Earlier research found that implicit personality assessed using indirect measures are promising and predict outcomes like performance (Lang et al., 2012), career success (Spangler, 1992; Winter et al., 1998), entrepreneurial success (Rauch & Frese, 2007; Wainer & Rubin, 1969), or counterproductive work behavior (Galić & Ružojčić, 2017; Runge et al., 2020). However, the use of implicit measures is still relatively rare compared to the use of simple self-report measures. What can the field potentially gain from adopting implicit measures more widely and how do different implicit measurement approaches work? This symposium seeks to answers questions of this type.

All five presentations contribute to the understanding of implicit personality constructs as individual differences covering central aspects of employees in organizations.

The first presentation (Galić et al.) links leaders' implicit and explicit achievement and power motives with entrepreneurial and managerial performance in a sample of CEOs. Galic et al. rely on a conditional reasoning approach to measure implicit motives and measure CEO performance using follower ratings.

The second presentation (Amory et al.) studies implicit motives as basis for moral leadership. Amory et al. rely on the Motive Self Categorization test to study implicit motives as drivers of moral leadership.

The third presentation (Moeller) studies the link between the implicit motive to aggress and deficits in correctly interpreting social situations. Moeller's study is motivated by recent issues with police violence and situations in which police officers social perceptions were flawed.

The fourth presentation (Bakac et al.) reports three studies on the role of explicit and implicit motives in negotiations. Organizational researchers have long tried to understand predictors of negotiation performance and Bakac and colleagues identified agentic motives as predictors.

Finally, the fifth presentation (Spruyt & Altenburg) investigates the usefulness of an adapted version of the Relational Responding Task—an implicit autobiographical test—in detecting untruthful questionnaire responding.

The symposium includes empirical studies relying on three different implicit measurement approaches: Conditional reasoning (Galić et al., Moeller), fantasy-based operant measurement (Amory et al., Bakac et al.), and relational responding (Spruyt & Altenburg) and thus provides attendees a good overview of different measurement paradigms in this area while also providing a

basis for animated discussion between experts and attendees. The symposium also includes studies that focus on a number of highly important outcomes and issues within work and organizational psychology such as leadership (Galić et al., Amory et al.), transgressions/faking (Moeller, Spruyt &Altenberg), and negotiation (Bakac et al.) and thus gives a good impression what the field can potentially gain from the wider adoption of implicit measurement approaches.

Relevance to the Congress Theme

This symposium fits the "the future is now" congress theme well. The symposium includes research on a variety of timely topics such as virtual negotiation which becomes more and more important in an increasingly virtual work environment; startup leadership in a business world in which entrepreneurial activities are essential; moral leadership in times of #metoo and corporate scandals, and police force, which is an important issue in today's world.

Research/Practical Implications

Overall, this symposium presents new findings in research on implicit personality constructs in WOP expanding existing literature on leadership, perception of social situations, and negotiation. Additionally to those theoretical contributions, the symposium has a high value for practitioners who are interested in implementing implicit measures in personnel selection.

Overall Conclusion

Measuring (explicit) personality is already standard practice in many organizational settings such as hiring and personnel development. This symposium proposal aims to present recent advancements and findings in research on implicit personality constructs, with a focus on how these findings can be used in practice to complement existing explicit personality approaches.

Keywords: implicit motives, implicit measurement, selection

Paper 1

Implicit power and achievement motives as predictors of entrepreneurial leadership: The conditional reasoning approach

Nikola Erceg, Mitja Ružojčić & Zvonimir Galić | University of Zagreb

Research goals

The purpose of this study was to explore usefulness of one of the most prominent methods of implicit personality assessment: the conditional reasoning approach (James & LeBreton, 2012) for understanding success in entrepreneurial leadership. Using a sample of CEOs/owners of small businesses, we compared validity of the Conditional Reasoning Test for Power motive (CRT-P), and the Conditional Reasoning Test for Achievement motive (CRT-Ach) in explaining subordinates' perceptions of CEO's leadership style/effectiveness and general entrepreneurial performance. We decided to focus on those two motivational traits because they were shown to be differentially predictive for success in entrepreneurial (achievement) and managerial (power motive) jobs.

Theoretical background

The trend of resurgence of interest in unconscious/ automatic/implicit psychological processes has already reflected in organizational psychology/organizational behavior (OP/OB) literature (Uhlmann et al., 2012). The use of the implicit measures in the leadership field is "quite rare" (Chong, Djurdjevic, & Johnson, 2017, p. 14), and in the nascent field of entrepreneurial leadership (Leitch & Harrison, 2018) virtually non-existing. New measures have a potential to resolve conflicting findings about importance of entrepreneur's personality for entrepreneurial activity and venture success.

Design/Methodology

The participants supposed to satisfy the following criteria: (a) are owners and CEOs of companies with more than two but less than 50 employees; (b) have been occupying their current position for over a year. We asked the CEOs to provide contact information for 3 to 5 of their subordinates. The only requirement for inclusion was that subordinates had worked in the company for at least 6-months (in order to have sufficient opportunities to observe leader/entrepreneur across a broad range of situations). A research associate visited each CEO in the company's offices to collect the data, and contacted subordinates directly to give them rating forms and envelopes with a prepaid response. The subordinates were instructed to fill the form at their homes and send them back to the researchers.

In total, we collected the data from 53 small business owners and 157 of their subordinates. CEO's implicit power and achievement motives were captured with the CRT-P and CRT-Ach. We also assessed CEO's explicit power and achievement motives with self-report scales taken from the Unified Motive Scales (Schönbrodt et al., 2012) Subordinates reported about leadership style and effectiveness using the Multifactor Leadership Questionnaire (MLQ). We also collected employees' ratings of CEO's entrepreneurial performance by asking subordinates about their employer's effectiveness on a set of job tasks defining entrepreneurial job such as searching for opportunities, creating new products or raising funds.

Results

Data aggregated at CEO's level showed that implicit achievement motive was significantly related to employee's ratings of active leadership style and perceived success in the leadership role. Additionally, CRT-Ach was significantly correlated with the employees' ratings of CEO's overall entrepreneurial performance. The obtained effects were moderate in size (the correlations ranged between .33 and .42). Neither CRT-P nor self-reported achievement and power motive measures were related to the outcomes.

Limitations

Our study was conducted on a relatively small sample of managers/organizations. Moreover, our sample comes from a specific cultural context that may limit generalizability of the findings.

Research/Practical Implications

Leadership is a crucial factor in the success or failure of small businesses because they are characterized by non-formalized structures where leaders' personality has a potential to play important role. Our study points that CEOs'/business owners' implicit achievement motive is a significant determinant of their entrepreneurial leadership success. Though their jobs include managerial activities, managers of small businesses are foremost entrepreneurs and that reflects in psychological determinants of their performance. Our findings suggest that CRT-Ach might be used to identify individuals who are more likely to succeed in entrepreneurial activity.

Originality/Value

Entrepreneurial leadership is a field that exists at the intersection of entrepreneurship and leadership. Within that context, little is known about psychological determinants of entrepreneurial leaders' success. Our study indicates that scientifically valid and practically convenient psychological instruments that measure implicit motivational traits, such as conditional reasoning tests, have a potential to advance both current research and practice in the field.

Relevance to the Congress Theme

The rapidly changing world of work includes moving away from classical, large hierarchical organization structures toward more entrepreneurial endeavours. With our study we want to contribute to understanding of psychological determinants of successful leadership in such organizations.

Relevant UN SDGs

Decent work and economic growth

Keywords: entrepreneurial leadership, achievement and power motive, conditional reasoning tests

Paper 2

What Drives Leaders to Be Moral? An Investigation of the Explicit and Implicit Motives of Servant, Ethical, Humble, and Authentic Leaders

Malte Runge, Oslo Metropolitan University; Bart Wille & Justine Amory | Ghent University

Research goals and why the work was worth doing

Despite a surge in interest in moral (i.e., ethical, authentic, servant, and humble) leadership styles over the past two decades, it is still unclear what drives leaders to behave morally. Existing research on the antecedents of moral leadership has typically focused on explicit traits and operationalized these with the Big Five framework. As a result, two potentially important antecedents have remained unexplored: the role of more subconscious motivations (i.e., implicit motives) and the explicit trait "honesty/humility".

Theoretical background

Past research has shown that leaders do not only differ based on their expressed personality (i.e., explicit motives) but also on what inherently motivates them (i.e., implicit motives): a high desire for power (control, impact, and influence on other people), affiliation (close and warm connections with others) or achievement (accomplishment, excellence, and success). According to the channeling hypothesis, these explicit and implicit motives work together to influence behavior and should therefore be studied jointly. This is especially relevant for morality, as moral action manifests itself in both deliberated (e.g., moral dilemmas, decisions under high accountability) and spontaneous (impulsive urges, decisions under low accountability) processes, which are best captured by explicit and implicit measures respectively (Perugini & Leone, 2009).

Design/Methodology/Approach/Intervention

This research uses subordinate-supervisor dyads (N = 127, we aim to collect a total of 200 dyads by the end of January) to examine the relationship between leaders' implicit and explicit motives and their subordinate ratings on four moral leadership styles (i.e., ethical, servant, authentic, and humble leadership). More specifically, this study uses multiple regression analyses to investigate whether 1) implicit motives predict moral leadership styles above and beyond explicit motives, 2) implicit and explicit motives interact to predict moral leadership styles, and 3) associations are similar across the four moral leadership styles (i.e., if there are common antecedents of moral leadership). To address these questions, we rely on recent theoretical (Lemoine et al., 2019) and methodological (e.g., the motive self-categorization test; Runge & Lang, 2019) advances, as well as the HEXACO framework (Ashton & Lee, 2007).

Results obtained or expected (if not available, it must be made clear when they will be)

Contrary to our expectations, implicit motives did not provide incremental validity over — nor interacted with — explicit motives to predict moral leadership. Surprisingly, the trait honesty/humility did not significantly predict any of the four moral leadership styles. Instead, emotionality appeared as the only important antecedent of moral leadership and was significantly associated with three of the four (i.e., authentic, servant, humble) moral leadership styles.

Limitations

One limitation of this study is its cross-sectional design. Although implicit and explicit motives are typically considered early antecedents of leadership behavior, the possibility of a causal link in the opposite direction (unfolding over a longer period of time) cannot be excluded. Another limitation is that, due to our current sample size, this study is likely underpowered to find the hypothesized effects.

Conclusions – research and or practical implications

Results of this study suggest that moral leadership is best predicted with explicit rather than implicit measures. A possible explanation is that leaders are highly accountable in nature, and therefore generally rely on conscious rather than unconscious processes when adopting moral behavior. In general, the current study sheds light on the antecedents of moral leadership and can be particularly relevant for leadership selection and development.

Relevance to the Congress Theme

Corporate scandals and vivid public debate (e.g., #MeToo Movement) have recently increased awareness about the importance of workplace morality. As a result, expectations towards leaders are likely to have changed, leading moral leaders to be more relevant, efficient, and competitive than in the past.

Relevant UN SDGs

Moral leadership styles have in common that they promote broad positive behaviors such as openness, fairness, trustworthiness, integrity, and consideration. More specifically, research shows that moral leaders are concerned with sustainability (e.g., Kalshoven et al., 2011), are gender-integrative (e.g., Reynolds 2011), and generate high justice perceptions among their subordinates (e.g., Xu et al., 2016). Therefore, we believe this research works toward three main UN Sustainable Development Goals : 1) Peace, justice, and strong institutions, 2) Responsible consumption and production, and 3) Gender inequality.

Keywords: implicit motives, personality, moral leadership

Paper 3

The Implicit Motive to Aggress and Deficits in Mentalizing: An Initial Investigation

Amanda Moeller, Penn State University

Research Goals: Police misconduct is a troubling issue that has received much attention in recent years. Police officers are entrusted with protecting and serving the public, but incidents involving police officers using excessive force or committing acts of inappropriate aggression continue to be a concern. Police officers undergo rigorous testing prior to employment, but police misconduct persists. This begs the question of how systems used to select police officers could be updated to better "select out" candidates that are most likely to engage in acts of excessive aggression.

Police officers must frequently make decisions about what others are thinking and feeling and respond appropriately. In many cases of unwarranted police aggression, officers misread the social situation, citing that a non-threatening person posed a threat to the officer or to others, necessitating the use of force. This indicates potential impairments in mentalizing, which describes the ability to understand what others are thinking and feeling and to accurately read social situations and react appropriately.

The current research represents the first step in understanding the relationship between the implicit motive to aggress and deficits in mentalizing. The implicit motive to aggress describes a person's implicit, or unconscious, preparedness to harm others (James et al., 2005; James & LeBreton, 2010).

The relationship between the implicit motive to aggress and deficits in mentalizing is tested here using a sample of undergraduates. However, plans are underway to conduct this research among a sample of police officers. If such a relationship is found, a case can be made for the measurement of the implicit motive to aggress to be used in police selection systems.

Theoretical Background:

Within applied psychology, the implicit motive to aggress is typically studied under the conditional reasoning theory of personality, which posits that individuals with an implicit motive to aggress are likely to adopt cognitive biases, called justification mechanisms, that allow them to rationalize, justify, and legitimize behavior intended to harm or injure others (James, 1998; James & LeBreton, 2010; 2012). Justification mechanisms shape a person's reasoning and thought processes in a way that enhances the rational appeal of aggressive behavior.

Design & Methodology:

The sample consisted of n=108 undergraduate students. Participants completed an online test battery including the Reading the Mind in the Eyes Test (RME; Baron-Cohen et al., 2001), a measure of mentalizing ability, and the Conditional Reasoning Test for Aggression (CRT-A; James & LeBreton, 2010), a measure of the implicit motive to aggress. The relationship between the constructs was tested using linear regression.

Results:

The implicit motive to aggress was significantly related to the misperception of neutral facial expressions as negative ($r=0.19$, $p=0.05$). In other words, individuals with a higher implicit motive to aggress were more likely to view images of faces displaying neutral emotional expressions (e.g.,

bored, calm) and incorrectly indicate that they were displaying negative emotional expressions (e.g., hostile, angry).

Limitations:

One limitation of the research concerns the format of the RME, which requires respondents to view images of eye regions and select one word from a bank of four words that best describes what the person in each image is feeling. For each image on the RME, there is not always a positive, neutral, and negative word available to select from, limiting respondents' ability to demonstrate the errors of interest.

Conclusions:

This research suggests that the implicit motive to aggress is related to the misperception of neutral faces as negative. Thus, the measurement of the implicit motive to aggress could be useful to organizations hiring individuals into positions, such as policing, where it is particularly beneficial for individuals to accurately appraise the mental states of others.

Relevance to the Congress Theme:

We cannot wait any longer to address the issue of inappropriate excessive force in policing. If we are to enhance human rights when it comes to policing, we must do more to prevent individuals who are more likely to see non-threatening individuals as threatening from being hired into these critical roles. Social change in this area is urgently needed, and the field of organizational psychology can play a pivotal role in addressing the issue of police excessive force.

Relevant UN SDGs:

This research most closely contributes to SDG VIII: Peace, justice, and strong institutions. Peace entails freedom from harm. Justice concerns fair treatment. The goal of this research is to improve the selection practices of police organizations in order to diminish the occurrence of inappropriate police aggression, and therefore, to increase peace, reduce conflict, and ensure fair behavior and treatment of citizens by police officers.

Keywords: implicit motives, personality, aggression

Paper 4

Linking Implicit Motives and Explicit Motives with Negotiation Outcomes

Jonas Lang, University of Exeter; Hugo Kehr & Cafer Bakac | Technical University of Munich

Research goals

Negotiation researchers have recently called for revival of research on individual differences in negotiation outcomes (e.g. Elfenbein, 2015; Sharma et al., 2018). Recently, especially after this call, a number of studies have appeared in this area (e.g., Kugler et al., 2018; Volkema et al., 2013). However, these studies have exclusively relied on trait characteristics as antecedents of negotiation outcomes and ignored motivational perspectives of personality. Next to trait measures of personality, motivational perspectives to personality has traditionally been the second source of individual differences (see Winter et al., 1998). The purpose of this study is to examine the role of implicit motives on negotiation performance.

Theoretical background

Implicit motives are generally referred to as "motivational dispositions that operate outside of a person's conscious awareness and are aimed at the attainment of specific classes of incentives and the avoidance of specific classes of disincentives" (Schultheiss & Brunstein, 2010, p. 603) while explicit motives are termed as conscious intentions and strivings (Sheldon et al., 2004). Implicit and explicit motives represent different motive systems, do not typically correlate and predict different behaviors (e.g., McClelland et al., 1989). Furthermore, implicit motives are activated by task-inherent incentives and explicit motives are activated by explicit incentives such as experimenter instructions, money or praises. As motivation scenarios generally include at least two parties negotiating over scarce resources, individual with high implicit motives could find such situations (un)pleasurable and (not) engage in negotiation behaviors. Building on McClelland's (1987) motives framework, achievement motives, affiliation motives and power motives are characterized by the need for improving one's standards of excellence and skills, building and maintaining positive relationships with other individuals, and having influence and control over others or environments respectively. Based on these, we hypothesized that individuals with high implicit achievement and power motives have a high self-reported negotiation performance and concede at high points in a negotiation task. However, individuals with high implicit affiliation motives have low self-reported negotiation performance and concede at low points in a negotiation task.

Design/Methodology

To test these hypotheses, in study 1, we collected data from 241 individuals using an adapted self-reported negotiation performance measure (Sharma et al., 2018). We used the Motive Self Categorization Test (Runge & Lang, 2019) and the Unified Motive Scales (Schönbrodt et al., 2012) to measure implicit and explicit motives respectively. In study 2 and 3, we adopted a validated virtual mixed-motive negotiation experiment (e.g., De Dreu & Van Kleef, 2004) and collected data from 84 and 147 participants. In study 2 and 3, we used the Motive Self Categorization Test (Runge & Lang, 2019) to measure implicit motives. Furthermore, we used Personality Research Form (Jackson, 1984) in study 2 and the Unified Motive Scales (Schönbrodt et al., 2012) in study 3 to explicit motives.

Results

Overall, results showed that implicit achievement and power motives were positively related to self-reported negotiation performance (ß = .17 and ß = .15, ps < .05 respectively) and objective negotiation performance measured through the negotiation task (study 2: ß = .29 and ß = .24, ps < .05 respectively and study 3 : ß = .19 and ß = .25, ps < .05 respectively).

Limitations

Possible limitations of our research include the usage of a virtual negotiation task and the cross-sectional nature of the study. Future studies should replicate our findings in real life negotiation scenarios or in the lab.

Research/Practical Implications

From a theoretical view, we strengthen the claim that motives are important personality constructs next to trait measures and add to the literature using implicit and explicit motives as predictors of negotiation performance. A practical implication of our study is that understanding individuals' motives might help practitioners in addressing the conflict that arises as a result of salary or overall negotiations at organizations.

Relevance to the Congress Theme

We measured objective measure of negotiation performance through a virtual negotiation task, where participants engaged in a negotiation scenario with another counterpart online. The cover story told that the work interactions get increasingly online and we are interested in how individuals interact online. This clearly fits the congress theme, where the focus is on the "changing world of work".

Relevant UN SDGs

Our research contribute to UN's peace, justice, and strong institutions SDG. By understanding the possible antecedents of conflict in organizations, practitioners can facilitate peace in institutions and organizations.

Keywords: Implicit motives, explicit motives, negotiation performance

Paper 5

Lying About Lies: Using the Autobiographical Relational Responding Task to Detect Fraudulent Survey Responses

Daria Altenburg & Adriaan Spruyt | Ghent University

Research goals and why the work was worth doing

Every single day, thousands of (managerial) decisions are based on the answers people give to questionnaires. The aim of the present research was to develop a new implicit measure capable of detecting fraudulent survey responses.

Theoretical background

After 25 years of academic research into (the use of) implicit measures, these 'innovative assessment tools' are only rarely, if ever, used in applied settings. We argue that for implicit measures to be useful outside the laboratory, it is key (a) to establish their potential to alleviate real-life problems, (b) to focus research efforts on fields of application in which the correspondence between implicit measures and self-report measures is low by definition, and (c) to engage in a careful analysis of their sensitivity and specificity as a function of the diagnostic goals that one is attempting to achieve. The reported research meets these requirements.

Design/Methodology/Approach/Intervention

In each of four (online) experiments (total N = 600), respondents first completed a short questionnaire. In Experiments 1-3, this questionnaire probed simple autobiographical facts (e.g., country of origin). In Experiment 4, the 'Honesty – Humility' scale of the HEXACO-PI-R was used. In each experiment, one group of respondents was asked to respond truthfully and one group was asked to provide false information. Next, both groups completed an adaptation of the Relational Responding Task aimed at detecting fraudulent survey responses (i.e., autobiographical Relational Responding Task, or a-RRT). To evaluate the sensitivity and specificity of the a-RRT, Receiver Operating Characteristic (ROC) curves were computed for all experiments (and conditions, in the case of Experiment 2).

Results obtained

Results showed that the accuracy of the a-RRT is quite good, with AUC-values ranging between 86.72% (Experiment 2) and 95.28% (i.e., Experiment 1). Second, the internal consistency of the a-RRT was relatively high in comparison to other implicit measures, with Rsb values ranging between .59 (i.e., Experiment 3) and .88 (i.e., Experiment 2). Third, using the theoretical zero point of the measurement scale, the true negative rate (or specificity) was perfect (i.e., 100%) both in Experiment 1 and Experiment 3

Limitations

The current experimental setting was atypical in the sense that there were no real-life consequences of being exposed as a person who provided false information. We are thus unable to rule out the possibility that respondents might do a much better job at manipulating their a-RRT results if the stakes are high. In addition, it remains an open question to what extent the a-RRT enables the detection of survey fraud when respondents provide a mix of truthful and untruthful answers, a scenario that is more likely than the one implemented in the current set of experiments.

Conclusions: Research/Practical Implications

Our findings suggest that the a-RRT might be useful in increasing the validity of classic survey data. The observation that the true negative rate was perfect (i.e., 100%) in two out of four experiments is particularly interesting from an applied point of view, as it implies that one can place a great deal of confidence in cases marked as 'positive', even at the level of the individual test taker.

Relevance to the Congress Theme

This research is relevant to the theme of the conference in that it aims to integrate recent innovations in the domain of cognitive-experimental psychology into the HR domain with the aim of improving the validity of classic survey instruments (i.e. "The future is now. Contribution").

Relevant UN SDG's

This research is primarily relevant to UN SDG 8 (i.e., "promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all") as it will help increase economic productivity through optimizing HR assessment practices.

New working environments

Sandra J. Diller, LMU Center for Leadership and People Management at LMU Munich & Private University Seeburg Castle; Irmgard Mausz, LMU Center for Leadership and People Management at LMU Munich

science_practice

Especially during the Corona pandemic, it became apparent that new working environments and digitalisation are playing an increasingly important role. On the one hand, this can mean spatial changes such as working from home or in coworking spaces. On the other hand, it could also change how we work with each other and which tools we use in our work. The current symposium therefore integrates research providing different perspectives on new work environments.

Specifically, the contributions zoom in on spatial changes in the workplace, such as working from home (Contribution #1) and working in coworking spaces (Contribution #2). Additionally, the contributions address challenges and implications for how we work with each other by providing meta-analytic insight into the consequences of agile project management (Contribution #3). New working environments are increasingly associated with the use of AI-enabled systems. Accordingly, Contributions #4 and #5 offer an implementation perspective by shedding light on the factors that influence the implementation and use of AI recommendations and tools in the workplace.

The symposium offers an integrative and holistic perspective on various challenges and chances of transformations in new work environments.

Paper 1

The Influence of Working From Home in 2021 on Organisational Measures and the Power of Mindfulness

Sandra J. Diller, LMU Center for Leadership and People Management at LMU Munich & Private University Seeburg Castle; Andrea Kübler, Julius Maximilian University of Würzburg; Magdalena Weber, Private University Seeburg Castle

Due to Covid-19, working from home became part of many people's everyday working lives. While working from home (WFH) can have positive consequences, it could also negatively affect organisational measures. The present research (N = 463 working people) investigated whether WFH negatively influenced organisational measures. As mindfulness can positively affect organisational measures, the research further explores the effect of mindfulness while WFH. The sample consisted of working people with different percentages WFH in 2021 during the second year of the Covid pandemic. The results show that WFH increased feelings of fatigue, sadness, and distress as well as decreased feelings of social integration, organisational identification, and organisational commitment. In contrast, mindfulness positively affected all organisational measures, including the decrease of negative work-related emotions and distress as well as the increase of positive work-related emotions, organisational integration, organisational identification, organisational commitment, job satisfaction, and even work performance. However, mindfulness did not moderate the relationship between WFH and organisational measures. Theoretical and practical implications are discussed.

Paper 2

The Emergence of Transactive Memory Systems in Coworking Spaces

Simon Hensellek & Jonah Weißwange | Technical University of Dortmund

The concept of transactive memory systems (TMSs), a mechanism that allows teams to collectively encode, store, and retrieve knowledge, has sparked vivid interest in work and organisational psychology. It positively influences team performance and innovation. However, TMS research beyond work teams remains scarce. Our research aims to investigate the development of TMSs within loosely affiliated work groups, i.e. coworking spaces (CWSs). CWSs enjoy surging popularity among knowledge workers by providing affordable office space and serving as a supportive community of knowledge exchange and networking. Using data from coworkers from German CWSs, we investigate the emergence of TMSs inside CWSs also taking into account the potential moderating effects of CWS offerings, amenities, and their hosts.

Keywords: Coworking spaces, coworking, transactive memory systems

Paper 3

The Affective, Behavioral, and Cognitive Outcomes of Agile Project Management: A Systematic Review and Preliminary Meta-Analysis

Carsten C. Schermuly, Ivana Drazic & Jan Koch | SRH Berlin University of Applied Sciences

Agile project management (APM) refers to a set of project management frameworks that are increasingly common in a range of industries. In this meta-analysis, we examine the effects of APM on affective, behavioural, and cognitive outcomes based on K = 40 records (with k = 41 independent studies, N = 73,825). Our analyses indicate the beneficial effects of APM across outcomes: For the affective outcomes of job satisfaction, affective strain, and organisational commitment, the effect sizes were, on average, small. The effect sizes were medium to large for the behavioural outcomes of performance and innovative behaviour. For the cognitive outcome of psychological empowerment, the results of our meta-analysis suggest a medium effect. Compared to studies conducted with software developers, the effect sizes are stronger in other occupations. Moreover, stronger effect sizes are found in published than in unpublished records.

Keywords: Agile project management, meta-analysis, review

Paper 4

The Effect of Explainable Artificial Intelligence on People's Decision-Making in an HR Task

Susanne Gaube, LMU Center for Leadership and People Management at LMU Munich & University Hospital Regensburg; Eva Lermer, LMU Center for Leadership and People Management at LMU Munich & University of Applied Sciences Augsburg; Matthias Hudecek, University of Regensburg; Julia Cecil, LMU Center for Leadership and People Management at LMU Munich

Despite the increasing use of AI-based decision support systems in personnel selection, recruiters' understanding of the technology's underlying processes is often limited, leading to low user acceptance and trust. Explainable AI-based systems have the potential to reduce this discrepancy. In our study with N = 300 participants, we examined the effect of type of advice (no advice vs. AI advice without explanation vs. AI advice with visualised explanation) and accuracy of advice (80% correct advice) on the decision performance, perceived quality of the advice and confidence in one's decision in a personnel selection task. Receiving correct advice had a significant positive effect on performance, quality, and confidence, whereas explainable advice resulted in non-significant effects.

Keywords: Explainable AI, HR, personnel selection

Paper 5

The Implementation of AI-Enabled Medical Support Systems: A Systematic Review and Meta-Analysis Based on the Universal Theory of Acceptance and Use of

Susanne Gaube, LMU Center for Leadership and People Management at LMU Munich & University Hospital Regensburg; Eva Lermer, LMU Center for Leadership and People Management at LMU Munich & University of Applied Sciences Augsburg; Anne Kleine, LMU Center for Leadership and People Management at LMU Munich

Artificial intelligence (AI) enabled clinical decision support systems (CDSS) may help clinicians diagnose diseases and forecast disease courses, select appropriate treatment regimens, and predict treatment outcomes. The use of AI tools has become widespread in some healthcare areas. At the same time, healthcare practitioners often do not adopt available tools due to a general reluctance to base decisions on algorithms, data privacy concerns, or the belief that these tools do not offer any benefits for their care. Based on the unified theory of acceptance and use of technology (UTAUT), the current meta-analysis examines the predictors and boundary conditions of the intention to use AI-enabled CDSS. The meta-analytic insight may provide means to ease the adoption of AI-enabled CDSS, thus enhancing efficiency and effectiveness in healthcare.

Keywords: UTAUT, clinical decision support systems, meta-analysis

Symposium S011

Leadership and wellbeing part 2: Forms of wellbeing, negative leadership and a meta-analysis

Tina Kiefer, Warwick Business School; Urszula Lagowska, NEOMA

science

This symposium forms part 2 of a double symposium on leadership and well-being. Part two focuses specifically on the role of different leader behaviours in follower well-being as well as negative leadership events and how they affect follower well-being. The symposium comprises of five contributions and a discussion lead by the moderators.

The first contribution by Knight et al. presents a meta-analysis on different types of leadership behaviours and their relationship to employee well-being. The authors examine this relationship taking into account work design issues such as motivational job characteristics. Seen how work changes (see part 1 of the symposium) this is highly relevant, particular as it highlights the broader role of leaders not only in directly shaping follower affect and well-being but also in shaping the environment people work in.

Acknowledging that work place conditions, including frequent changes can be stressful and lead to organisational cynicism. Schilling suggests a new theoretical model, looking at the relationship between organizational cynicism and well-being, arguing the traditional positive relationship might not capture the full spectrum of the effects of cynicism. Indeed, Schilling proposes that cynicism can foster solidarity and relatedness between employees who share their negative experiences on their employer with each other. In that sense, this contribution continues the discussion on support by colleagues in difficult work situations (see also Lagowska et al. in part 1 of this symposium).

Extending the work on negative aspects of leadership which often focuses on the leader exclusively, Gauglitz et al. examine the dyadic effects of leader and follower narcissism on well-being. Similar to other studies in part 1 of this symposium they take into account not only follower but also leader well-being by incorporating both leader and follower job satisfaction as a well-being indicator. They propose leader and follower narcissism to be related both to the actor's job satisfaction (due to a frustration of narcissistic needs) and the partner's job satisfaction (due to aggressive tendencies of narcissists).

Breevaart et al. remind us of the importance of an in depth investigation of how victims perceive abusive supervisory relationships and why leaving such a relationship can be so difficult. Interviewing former victims of abusive supervision, they derive barriers that keep victims from leaving abusive supervisory relationships. These insights can be used to develop meaningful support mechanisms on individual, organisational, and societal levels.

Finally, Castanheira and Neves shed light on the dark side of usefulness of technology to work, an argument often used by leaders to facilitate engagement with technological tools. When technostress and perceived usefulness of technology are high, an addictive spiral is initiated (i.e., uncontrollable compulsion to use ICTs), with consequences for their ability to work (i.e., heightened production deviant behaviors).

The contributions to this symposium employ different designs, such as meta-analyses, theoretical frameworks, actor-partner approaches, qualitative interviews and thus highlight the breadth of possibilities to conduct research on leadership and well-being.

The symposium contributes to the congress theme “The Future is Now: the changing world of work” by including highlighting the role of leader behaviour in well-being and the dangers of negative work events and suggesting ways forward for organisations but also the wider society to protect employees. It also contributed to the UN SDG “Good health and well-being” by focusing on well-being in the work context of followers.

Keywords: leadership, wellbeing

Paper 1

Why Leadership Behavior Relates to Employee Well-being: A Meta-analysis of the Specific Role of Motivational Job Characteristics

Sharon Parker, Centre for Transformative Work Design, Curtin University, Perth, Western Australia; Maximiliano Escaffi-Schwarz Escuela de Psicología, Universidad Adolfo Ibáñez, Santiago, Chile; David Holman, Organisational Psychology Group, Alliance Manchester Business School, Manchester, UK; Olga Epitropaki, Management & Marketing Department, Durham University Business School, Durham, UK; Anja van den Broeck, Department of Work and Organization Studies, KU Leuven, Belgium; Daniela Andrei & Caroline Knight | Centre for Transformative Work Design, Curtin University, Perth, Western Australia

Research goals and value

Leadership and motivational work design have both been extensively examined as influences on employee wellbeing. Theory suggests that leadership can affect employee well-being partly through shaping work design. However, empirical research on this possibility is scattered and poorly integrated, with studies focusing on a limited set of leader behaviors, and with diverse conceptualizations of work design. In this meta-analysis, we synthesize evidence on whether and how relational-oriented, task-oriented, and change-oriented leadership styles affect well-being outcomes through five core work characteristics: autonomy, variety, task identity, task significance, and feedback. Our study spurs theoretical integration of leadership and work design literature, and suggests integrated practical interventions to boost worker wellbeing.

Theoretical background

Work design refers to the tasks, activities, relationships, and roles involved in a worker's job (Parker, 2014). The Job Characteristics Model (Hackman & Oldham, 1976) identified five key work characteristics that foster motivation and wellbeing, which are the focus of this research. Multiple reviews and meta-analyses have shown how these work characteristics affect employee wellbeing (e.g., Humphrey et al., 2006). Theory suggests that leaders can shape the work design of followers objectively, by changing task allocations, policies or procedures, or subjectively, by influencing how work is perceived and how meaningful it is (Parker et al., 2017). This suggests that shaping work design is one important way that leaders can positively impact wellbeing.

Adopting the tripartite leadership behaviours taxonomy (Yukl et al., 2002; DeRue et al., 2011), we focus on three constructive leader behaviours which are linked to positive wellbeing. Change-oriented leadership behaviours inspire and motivate change, relational-oriented behaviours foster follower respect and welfare, and task-oriented behaviours promote role expectations and performance standards. We propose 9 hypotheses about how these types of leadership differentially affect work design and hence wellbeing.

Methodology

A systematic literature search for published studies measuring at least one of our three focal leadership styles and one of our five key work characteristics was conducted in three key databases. We included all field study designs involving working participants, both cross-sectional and longitudinal. Hunter and Schmidt (2004) meta-analytic techniques were applied to identify relationships between leadership styles and work characteristics. Studies which also measured either

positive or negative wellbeing were involved in metaSEM, to determine the role of work characteristics as mediators between leadership styles and wellbeing. We also conducted a relative weights analysis and tested for heterogeneity and publication bias.

Results

Direct effects from meta-analytic results involving 144 independent samples showed that relational and change oriented leadership positively affected all core work characteristics, whereas task-oriented leadership predicted all but autonomy and variety. Relative weights analysis showed that change leadership was the strongest predictor of all work characteristics, except for task significance, which was most strongly predicted by relational leadership. Mediation analyses revealed a more nuanced picture: relational and change-oriented leadership improved well-being outcomes through significantly enhancing autonomy, variety, and task significance, while task-oriented leadership had a negative impact due to indirect negative paths through all core motivational characteristics except for feedback.

Limitations

Our results are based on cross-sectional data due to the limited amount of longitudinal data available, limiting causal conclusions. Sample sizes were small for some analyses, however, tests for publication bias suggest they are robust.

Conclusions

We show that different leadership styles affect well-being differentially through work design. It is likely that leaders who display characteristics of both change and relational-oriented leadership will have the most optimal impact on wellbeing through positively shaping employee's work design. Practitioners can use this knowledge for leadership development and training programmes.

Relevance to congress theme & UN SDGs

The nature of work is shifting rapidly. Work is increasingly flexible, more reliant on technology, and demanding, with psychological distress high (Knight et al., 2022). Many are re-evaluating their career goals and values, and choosing to leave jobs amidst the "great resignation" (Newman at al., 2022). This means leaders are tasked with managing and motivating employees in an unpredictable world. Good work design is motivational, and leaders design jobs, yet we have very little evidence as to whether and which leadership behaviours positively shape which follower work characteristics, and how this impacts wellbeing. For organisations to remain adaptable in this fast changing world of work, it is imperative that we understand how leaders can actively shape work design for optimal outcomes.

Relevant UN SDGs are "Good health and wellbeing", and "Decent work and economic growth". We identify how leaders can shape work design and promote optimal wellbeing so that every employee has the opportunity to reap the rewards of "decent work".

Keywords: Leadership, Wellbeing, job characteristics

Paper 2

The relation between Leader and Follower Narcissism with Job Satisfaction of both parties

Astrid Schütz, Marco J. Held & Iris K. Gauglitz | University of Bamberg

Research goals and why the work was worth doing:

The goal of this research was to examine actor and partner effects of leader and follower narcissism on leader and follower job satisfaction. This research expands prior research by examining if leader and follower personality reciprocally predict job satisfaction of both dyad members.

Theoretical background:

In the last decades, narcissism has been studied intensely in organizational psychology research. Previous research showed that narcissism is related to important workplace criteria, such as job satisfaction.

One line of research has examined the relationship between employees' narcissism and their job satisfaction. Narcissistic individuals are preoccupied with grandiose fantasies and have an intense desire for admiration and respect. Therefore, they tend to think that there are and that they deserve better jobs than they currently have. Furthermore, narcissists have inflated self-views. For instance, they think they perform better than others do, when in fact they do not. Thus, it is likely that narcissistic employees receive feedback at work, which is more negative than they expected - and this might negatively impact their job satisfaction. Accordingly, research has shown that employee narcissism is associated with reduced job satisfaction.

Another line of research has examined if leader narcissism is associated with their followers' job satisfaction. This research builds on findings, which show that narcissism is associated with a lack of empathy, aggression, and superficial relationships. Accordingly, it was shown that leader narcissism is associated with reduced follower job satisfaction.

Yet, recently a shift in focus has occurred and increasing attention has been paid to leaders' well-being and how their followers affect it. We assume that follower narcissism is negatively related to leaders' job satisfaction because narcissistic followers may act egoistically, aggressively, and show little empathy for their leaders.

Accordingly, with the current research we expand previous research and examine the relationship of leader and follower narcissism with their own and with the other party's job satisfaction. We assume that leader and follower narcissism will be negatively associated with their own job satisfaction, as these individuals would think they deserve a better job or that they do not receive the admiration and respect at work that they deserve. Furthermore, we assume that leader and follower narcissism is negatively associated with the other party's level of job satisfaction in each dyad, because narcissists tend to behave in unempathetic and aggressive ways. However, we suggest that the assumed negative association between leader narcissism and follower job satisfaction will be stronger than the negative association between follower narcissism and leader job satisfaction, because followers are more dependent on their leaders than the other way around.

Design/Methodology/Approach/Intervention:

We conducted an online field study with leader-follower dyads from diverse industries across two measurement points (one month apart). At the first measurement, leader and follower narcissism

were assessed via self-reports. At the second measurement, leaders and followers reported their level of job satisfaction.

Data will be analyzed using an Actor-Partner Interdependence model using structural equation modelling in Mplus.

Results obtained or expected:

Data are currently gathered, expected end date of data collection is December 2022.

Limitations:

Even though we collected data across two measurement points, we cannot draw causal conclusions. Future research should employ longitudinal research designs and experimental studies in order to be able to support causal interpretations.Conclusions – research and or practical implications:

As we do not have study results yet, we cannot yet derive specific theoretical and practical implications already. As for now, we hope to gain a more holistic understanding of the relationship between leader and follower narcissism and leader with follower job satisfaction. Furthermore, knowing if and how leader and follower narcissism is related to leader and follower job satisfaction is an important prerequisite to derive practical implications and to ensure that leaders and followers are satisfied with their jobs.

Relevance to the Congress Theme:

Our research highlights the fact that it is important to foster well-being in both leaders and followers (i.e., in terms of their job satisfaction) and shows how leaders and followers reciprocally influence each other in that respect.

Relevant UN SDGs:

This research aims at promoting good health and wellbeing of leaders and followers at work.

Keywords: Leadership, Narcissism, job satisfaction

Paper 3

Abusive Supervisory Relationships: Insight from Former Victims

Birgit Schyns, NEOMA; Barbara Wisse, Groningen University, the Netherlands; Kimberley Breevaart, Erasmus University Rotterdam, the Netherlands

Research goals and theoretical background: While abusive supervision refers to the sustained display of hostile verbal and non-verbal behaviors (Tepper, 2000) such as invading employees' privacy, isolating employees from important others and blaming employees for something they did not do, not much is known about the duration of abusive supervision. We therefore lack critical knowledge about one of the most fundamental aspects of abusive supervision. In The Barriers Model of Abusive Supervision (Breevaart, Wisse, & Schyns, 2022), we explain the longevity of abusive supervision by outlining the barriers that make it difficult for victims of abusive supervision to escape. Specifically, we argue that employees may experience a range of barriers at the societal level (e.g., lack of awareness for the problem), the organizational level (e.g., lack of policies regarding unacceptable behavior), the supervisor-employee relationship level (e.g., being brainwashed), and the individual level (e.g., being highly agreeable) that make it difficult to break the abusive supervisory relationship. In the current study, we ran the first empirical test of The Barriers Model of Abusive Supervision in a sample of former victims of abusive supervisors.

Methodology: 121 self-labelled former victims of abusive supervision filled out the questionnaire in which we asked them to indicate the duration of the relationship, the reasons why the relationship ended, what help they received and what help they missed.

Results: Participants were mostly female (N = 77) and came from a variety of countries and industries. The average age was 41.26 (SD = 14.25). The preliminary result showed that on average, the abusive supervisory relationship lasted 2.67 years (SD = 3.97). In the majority of cases, the relationship ended because the victim left (50%). Other reasons were that the victim got transferred to a different department (8.3%), the leader left (8.3%) or the victim got fired (6.7%). The relationship duration was significantly lower for those reported they got help from friends (M = 1.765) versus those who did not report receiving help from friends (M = 3.029). Many reported to have missed help from important stakeholders in the organizations such as higher management, HR, and confidants. More results will be available by the end of 2022.

Limitations: The data is mostly qualitative data and future research is needed to collect additional quantitative data.

Conclusions - Research/Practical implications : The study shows preliminary support for The Barriers Model of Abusive Supervision. Interestingly, former victims of abusive supervision seem to have suffered for a long time and indicated that they could not rely on their organization to help them. This shows that there is much work to be done for organizations to better protect their employees from abusive supervisors.

Relevance to the Congress Theme: While awareness for psychological abuse in intimate and family relationships is raising, this awareness is still lacking when it comes to workplace abuse. Too often, organizations fail to protect their employees from abusive supervisors because they do not hold supervisors accountable for the abuse (Courtright et al., 2016). Research among former victims of abusive supervision is needed to learn how long abusive supervisory relationship generally last and we as scientists, but also as organizations can do to break these relationships.

Relevant UN SDGs. The presentation relates to the UN's SDGs of creating good health and wellbeing among employees and offering decent work and economic growth.

Keywords: Leadership, Abusive supervision, victims

Paper 4

Technostress and addiction to technology: The augmenting effect of perceived usefulness of technology

Pedro Neves, Pedro Neves & Filipa Castanheira | Nova School of Business and Economics, Portugal

Research goals

We contend that the ability of ICT use to act as a reinforcer of addictive patterns may be heightened by the perceived usefulness of that technology to work. That is, the interplay between technostress and perceived usefulness should trigger an addictive process. We also argue that these individuals may be at a particular risk by stepping into an uncontrolled spiral of resource loss (Hobfoll, 1988). Thus, we predict that as mobile technologies become more invasive and overburdening, individuals develop an addiction to those technologies, especially when they believe that these are extremely helpful in dealing with work, with consequences for organizational deviance. When perceived usefulness is low, the lack of the cognitive reinforcing element of addiction should lead individuals to engage in the typical response to stressors and disengage from ICT use to the point where they are no longer at risk of developing an addictive usage pattern.

Theoretical background

There is more to Information and Communication Technologies (ICTs) at work than designing, purchasing or simply applying technologies. On the one side, there is an assumption that the use of technology is predominantly positive (Davis, 1986). On the other side, there is evidence demonstrating that the overuse of technology may be sapping individuals' well-being and performance (Tarafdar, Gupta, & Turel, 2015), and creating a maladaptive and obsessive dependencies (Tarafdar, Maier, Laumer, & Weitzel, 2020). According to the stress literature (Lazarus & Folkman, 1984), the latter is a rather counter-intuitive response: individuals suffering from technostress, rather than disconnecting from the ICT stressor, continue using it, often developing an addiction to that same stressor. Addiction to technology often includes inducing and reinforcing features that may contribute to the promotion of addictive tendencies (Griffiths, 1995) and usually includes an uncontrollable compulsion to use ICTs 'everywhere and anytime'.

The present research makes several contributions: a) by analyzing the potential interplay between technostress and perceived usefulness on the development of addictive behaviors, we enrich the scope of TAM (Davis, 1986); b) we demonstrate the addictive potential of ICTs at work, moving beyond contexts such as social networking sites, sampling teenagers and young adults (Griffiths, 1995; Kuss & Griffiths, 2017); and c) we show how this process contributes to deviance as a coping response to workplace stress (Henle & Blanchard 2008; Weatherbee 2010).

Design/Methodology/Approach/Intervention

We tested our hypotheses with a sample of 230 employees and their respective supervisor. The subordinate measures provided acceptable reliabilities: techno-invasion (Ragu-Nathan et al., 2008; α = .68), techno-overload (Ragu-Nathan et al., 2008; α = .84), perceived usefulness of technology (Davis, 1989; α = .93), and addiction to mobile technology (Turel, Serenko & Bontis, 2011; α = .81). Supervisors assessed the subordinate's production deviance (Robinson & Bennett, 1995; α = .89).

Results

To analyze our data, we used the bootstrapping PROCESS macro (Preacher et al., 2007). Techno-invasion was significantly related to addiction, while techno-overload was not. Both interaction effects with perceived usefulness on addiction were significant: when perceived usefulness was high, both techno-invasion and techno-overload were positively related to addiction to mobile technology; when it was low, techno-invasion was still significantly related to addiction, albeit less strongly, while techno-overload was not related to addiction. We also found a significant moderated mediation for techno-overload. As techno-overload increased, so did production deviance via addiction to mobile technologies, but only when perceived usefulness was high; when it was low, the effect was not significant.

Limitations

The design is cross-sectional (although it relies on two sources of information).

Conclusions

Taken together, our findings show that the impact of techno-invasion and techno-overload on addiction to mobile technology (and production deviance) depends on the perceived usefulness of technology. By doing so, we unveil the interplay between usefulness of technology and technostress, demonstrating that the negative impact of technostress is particularly pervasive when workers perceive the technology to be useful. This is important given that organizations often provide a context where the usefulness argument is very salient. We hope our findings raise awareness and contribute to the discussion of the potential addictive side of ICTs and its unintended consequences.

Relevance to the Congress Theme

The changing world of work is signaling the use of technology does not only carry positive effects and is demanding solutions to help organizations, especially those that rely on the usefulness of technology as an argument to promote behavioral change.

Relevant UN SDGs

Good health and well-being (3); Decent work and economic growth (8).

Keywords: Stress, technology

Symposium S013

Making diversity work better for employees: Valuable top-down and bottom-up approaches

Sonja Rispens, Eindhoven University of Technology, Netherlands; Huatian Wang, Lingnan University, Hong Kong

science_practice

What will be covered and why: Workplace diversity is described as differences based on any characteristic on which employees differ or perceive themselves to be different from their co-workers (Guillaume et al., 2017). Managing and utilizing diversity (e.g., diversity in generation, ethnicity, education, and functional background) is creating incomparable challenges for leaders and employees over the world. While organizations promote diversity anticipating higher productivity and innovation, diversity is found to strain interpersonal trust, integration and undermine well-being. Therefore, the critical question remains on how contemporary organizations can make the best of diversity in the workplace, unlocking its potential and overcoming its risks. Incorporating both the management level (a top-down perspective) and employee level (a bottom-up perspective), this symposium aims to provide some valuable insights into this issue. Five empirical papers in the symposium will add to our understanding of (1) how organizational climate (e.g., diversity and inclusion policy, synergy climate, intergenerational climate) can help to increase the level of diversity in organizations and employee outcomes; (2) how inclusive leadership can play a beneficial role in enhancing employee work states (e.g., engagement) and behaviors (e.g., customer orientation behavior, helping behaviors, resources-seeking behaviors) in a diverse workplace; (3) how employees themselves engage in proactive, self-customized strategies (e.g., job crafting) to gain necessary job resources and optimize job demands presented by a diverse work environment. This symposium will present an integrated understanding of what organizations, leaders, and employees can do to unlock more potential of diversity.

Relevance to the Congress Theme: Contemporary workplace is more diverse than it used to be. It is now no longer possible to ignore the pervading influence of diversity in organizations. The concept of diversity has transformed from being a governmental or legal obligation to a strategic priority. The aim of attaining sustainable competitive advantage has instigated organizations worldwide to embrace the concept of diversity.

Research/Practical Implications: Our symposium aims to make several theoretical and practical implications. First, we add to the diversity management literature by presenting recent work on both top-down and bottom-up approaches of diversity management. We suggest that organizational climate, diversity-oriented leadership, and employee self-initiated behaviors are three important inputs that can bring out the benefits of diversity. Therefore, effective diversity management tools should be multilevel and multidimensional. Second, this symposium particularly focused on the effects of diversity on employees, which shifts the attention from the team-level (Hentschel et al., 2013; Roberge & van Dick, 2010; van Dijk, 2022) and organizational-level (Cunningham, 2009; Mohr & Puck, 2005; Van De Ven et al., 2008) to the individual-level. This angle is largely overlooked but equally important because employees are the main actors of an organization and the most important assets for an organization. Teams and organizations might not gain the benefits of diversity if we fail to understand what diversity means to individuals and how individuals enact in a diverse workplace. Employee-level outcomes (e.g., engagement, well-being, career development) should not be neglected because employees have the need for self-development and self-actualization and highly performed and engaged employees can make a significant difference to organizations.

This symposium also provides valuable practical implications. First, we suggest that organizations should foster a higher level of synergy climate and intergenerational climate as these types of organizational climates are helpful to release the benefits of diversity and make employees feel psychologically safer and more justice. Second, we suggest that leaders engage in more inclusive leadership in order to manage diverse employees and create a more inclusive and cohesive work group. Thus, training on inclusive leadership is essential. Third, we suggest that organizations and leaders should also not ignore the capabilities of employees themselves in terms of utilizing diversity in the workplace. Organizations should give employees more autonomy to craft their own job conditions in a diverse work environment. As such, employees can fully reflect upon their own interests, preferences, and goals to engage in the most appropriate strategies to navigate and grow up in a diverse workplace.

Conclusions: Diversity is a double-edged sword for organizations and employees. To maximize the potential of diversity, organizations should initiate more synergy and intergenerational climate, leaders should be more inclusive, and employees should be allowed to craft their own job conditions in a diverse work environment.

Keywords: diversity management; inclusive climate and leadership; employee proactive behavior

Paper 1

The Art of Diversity: Creating Cultural Organizations That Are Diverse in Their Personnel, Public, Program, and Partners

Chenhao Zhou, Utrecht University, Netherlands; Brian Doornenbal, Leiden University Medical Center, The Netherlands; Hans van Dijk, Tilburg University, The Netherlands

Research goals: This paper aims to uncover the role of Diversity & Inclusion (D&I) policies, diversity climate, and inclusive leadership in creating diverse cultural organizations on the four Ps: Personnel, Program, Public (i.e., audience), and Partners. We propose a moderated mediation model in which inclusive leadership moderates the relationship between D&I policies and diversity climate (i.e., fairness and synergy), and the diversity climate mediates the association between D&I policies and diversity on the four Ps.

Theoretical background: Research indicates that setting goals and targets helps to increase personnel diversity (Klettner et al., 2016). Whereas prior research mostly speaks to how such policies enhance diversity in organizations' personnel, goal-setting theory suggests that any outcome is more likely to be achieved when specific goals and targets are set, and responsibilities and budgets are assigned to those goals (Locke & Latham, 2006). We therefore expect that the overall D&I policies will foster diversity on all four Ps (H1a). Furthermore, because goal-setting theory suggests that specific goals direct attention and effort towards those specific (and not other) goals (Wright & Kacmar, 1994), we argue that the D&I policies that target a specific P relate more to diversity outcomes on that specific P than diversity outcomes on the other Ps (H1b). In addition, we argue that the setting and implementation of D&I policies will indirectly contribute to diversity outcomes via an organization's diversity climate. Diversity climate refers to "employees' perceptions about the extent to which their organization values diversity" including the fairness and synergy components (Dwertmann et al., 2016, p. 1137). Signal theory (Connelly et al., 2011) suggests that employees are likely to interpret policies aimed at improving diversity as signals that the organization values diversity. As such, D&I policies are likely to contribute to diversity in the four Ps through a diversity climate in which employees experience that the organization values diversity (H2). For the experience of a diversity climate, especially inclusive leadership is likely to shape employees' understanding of the value of diverse perspectives (van Knippenberg & van Ginkel, 2021). We therefore also hypothesize that inclusive leadership strengthens the relationship between D&I policies and diversity climate, such that the relationship between D&I policies and diversity climate is more positive for higher levels of inclusive leadership (H3).

Methodology: This study used the data from an online D&I scan for organizations in the Dutch cultural sector. The scan, built by two of our authors, functions as an instrument to improve policies on diversity and inclusion. We tested the hypotheses based on data from 295 unique organizations.

Results obtained: In line with H1a, we found a positive association between the overall D&I Policy and overall diversity outcomes ($\beta = .61$, $SE = .05$, $t\ (295) = 13.08$, $p < 0.001$; model fit: $F\ (1, 293) = 170.99$, $p < .001$, $R\ 2$ adjusted $= .37$. Our results showed that D&I policies that target a specific P (e.g., personnel) are stronger related to that specific type of diversity (e.g., personnel) than to other types of diversity (e.g., public) by comparing their standardized coefficients and effect size (H1b). Unexpectedly, parallel mediation analysis did not support H2 that the fairness and/or synergy component of diversity climate mediated the relationship between the overall D&I policies and diversity in the four Ps. Partially supporting H3, we found that inclusive leadership strengthened the

positive relationship between D&I policies and the fairness component (β = 0.65, SE = 0.04, t (291) = 2.40, p = 0.017) but not the synergy climate (β = 0.20, SE = 0.03, t (291) = 1.00, p = 0.317) of a diversity climate.

Limitations: This study is a cross-sectional survey study. Whereas the use of multiple respondents per organization minimized the risk of single source bias, the ability to infer causality is still limited (Setia, 2016).

Research and practical implications: This study increases the understanding of the impact of D&I policies on diversity. We found support for an important principle of Goal Setting Theory within enhancing organizational diversity at multiple aspects of diversity. We demonstrate that D&I policies should be targeted at specific diversity types, and we are the first to suggest distinguishing diversity into four Ps. We also found that inclusive leadership is essential in strengthening a fair climate. Overall, this study further adds to the pile of evidence regarding the roles of diversity climate and inclusive leadership in creating more diverse and inclusive organizations.

Relevance to the Congress Theme: This paper highlights the contribution aspect of the theme "the future is now." We tried to uncover the mechanism to achieve four P's diversity in cultural organizations by investigating the roles of HR Policies, diversity climate, and inclusive leadership.

Relevant UN SDGs: this study contributes to "gender equality goal (SDG.5)" as it concerns the equality among underrepresented populations by investigating the fairness component of a diversity climate in the cultural organizations. This study also contributes to "decent work and economic growth goal (SDG.8)" by creating a diverse and inclusive working environment that is helpful for both employees' and organizations' health and growth.

Keywords: Diversity and inclusion, Workplace climate, Inclusive leadership

Paper 2

Enhancing employee sustainable career in the age-diverse workplace: The role of intergenerational climate

Anqi Chen, Hai-jiang Wang & Jian-Qiao Liao | Huazhong University of Science and Technology, China; Beatrice Van der Heijden, Radboud University, the Netherlands

Research goals : The present study aims to reveal the beneficial role of workplace intergenerational climate (WICS; King & Bryant, 2016) in influencing the sustainable career of older employees under an increasing age diversity context. We explore how and when WICS can enhance employee sustainable career development. Specifically, we examine how meaning at work plays a mediating role and how occupational future time perspective (OFTP; Zacher & Frese, 2009) plays a moderating role in the relationship between intergenerational climate and individual sustainable careers (Van der Heijde & Van der Heijden, 2006) in terms of career satisfaction, employability, and health among older workers.

Theoretical background : We employ the Social-emotional Selectivity theory (SST; Carstensen, Isaacowitz, & Charles, 1999) to understand the relationship between WICS and sustainable careers. First, we argue that positive WICS has a positive influence on sustainable career outcomes (i.e., career satisfaction, employability, and general health; H1a, H1b and H1c). Based on SST, people prioritize the meaning of interactions as their future time perspective begins to become limited. In positive WICS, they suffer less discrimination and may have a better social experience, therefore contributes to their satisfaction, well-being as well as employability. In addition, older workers enhance the meaningfulness of their work during intergenerational interactions through generative striving (Carstensen, 2002) or knowledge transfer (Erikson, 1963). In a positive WICS, elderly employees are more likely to support future generations actively, leading to higher meaning at work (H2). Deriving meaning from individuals' professional activities contributes to their career sustainability (Van der Heijden, 2005), research on ageing has shown that meaningful work provides richer, more satisfying, and more productive employment for individuals (Steger et al., 2013). Subsequently, we hypothesize meaning at work mediates the relationship between WICS and their sustainable career (H3a, H3b and H3c). However, the above inferences are based on the core assumption of SST that older workers have more limited perspective of the future. Conversely, if the OFTP is more positive, the relationship we assume will be weakened. We hypothesize OFTP negatively moderates the positive relationship between WICS and meaning at work (H4) as well as the overall moderated mediating model (H5a, H5b, H5c).

Methodology : A longitudinal survey was conducted among a sample of older workers over 45 years from 13 different industries and 77 companies participated in China. We used structured questionnaires across three waves with a time lag of two weeks, resulting in a sample size of 267 participants. All the instruments used in the study had acceptable reliability and validity. Our hypotheses were verified by a moderated mediating structural equation model with MPLUS version 8.3.

Results obtained : The direct effect of WICS on general health ($\beta = .20$, $p < .001$) was significant while on the other dimension were not, supporting H1c. It also positively influence meaning at work ($\beta = .36$, $p < .001$), H2 was supported. Moreover, we found significant effects of meaning at work on employability ($\beta = .18$, $p < .05$) as well as general health ($\beta = .30$, $p < .001$).The results suggested WICS had significant indirect effect on both employability ($b = .03$, $t = .01$, CI [.004, .060]) and

general health (b = .09, t = .03, CI [.035, .152]) but had no significant effect on career satisfaction, thus, H3b and H3c were supported. In addition, the interaction term of intergenerational climate and OFTP with respect to predicting perceived meaning at work was significant (β = -.18, p < .001), H4 was supported. Finally, the analysis of the conditional indirect effect indicated the differences between indirect effects at low levels of OFTP and at high levels of OFTP were significant with regard to employability (Δ b = -.02, t = .01, CI [-.057, -.004]) and general health (Δ b = -.07, t = .03, CI [-.143, -.025]), supporting H5b and H5c.

Concluding Remarks : This study found that intergenerational climate, as a top-down approach to managing age diversity in the workplace, was associated with sustainable career outcomes. We contributed to intergenerational climate and sustainable career literature through revealing a contextual antecedent to predict career outcomes.

Relevance to the Congress Theme : We highlight the urgency aspect of “The future is now!”. We expect to contribute to the sustainability of workforce in the context of the increasing global trend of ageing.

Relevant UN SDGs : This study contributes to “Decent Work and Economic Growth” (SDG.8) since inclusive leadership is not only a moral imperative but also has a business argument to it.

Keywords: age diversity; intergenerational climate; employee sustainable career

Paper 3

Inclusive leadership and customer orientation: The mediating role of employee engagement and moderating role of perceived organizational support

Ayfer Veli Korkmaz, Tilburg University; Lena Knappert, Vrije University of Amsterdam; Robin Bauwens, Tilburg University; René Schalk, Tilburg University; Marloes van Engen, Radboud University

Research goals: This study wishes to understand the influence of inclusive leadership (IL) on customer orientation (CO), considering the mediating role of employee engagement (EE) and moderating role of perceived organizational support (POS). IL enables employees to show inclusive behaviours to their customers. These inclusive behaviours contribute to building relationships between employees and their customers; to an inclusive society as diverse customers' daily life experiences improve; to organizations' competitive advantage as they become preferrable suppliers for diverse profiles; to improving the optimal service delivery which is relevant for organizations' business success. Lastly, by doing this research, we contribute to the inclusion literature with a novel validated IL scale.

Theoretical background: Customer-oriented employees show a set of behaviours ensuring a good service (Brown et al., 2002) towards their internal and external customers. Based on social learning theory (Bandura, 1977), we suggest inclusive leaders, who give attention to employees' uniqueness, belongingness, feeling of being appreciated and organizations' efforts (Veli Korkmaz et al., 2022), will be role modelling inclusive behaviours to their employees. Accordingly, we suggest IL will influence employees' customer-oriented behaviours positively (H1). Secondly, based on self-determination theory, we suggest employees' engagement, experience of vigour, dedication, and absorption at work (Schaufeli, 2022), will play a mediating role between IL and CO. This is because IL will contribute to employees' innate needs of autonomy, competence, and relatedness as proposed by self-determination theory (Deci and Ryan, 1985) which will promote their engagement (H2). Next, based on broaden-build-theory, we suggest that high level of engagement will be reflected in employees' customer-oriented behaviours (Frederickson, 2001) which results in engagement's mediating role (H3). Lastly, we include POS, employees' perception of organizations' treatment (Eisenberger et al, 1986), to the equity. Organizational support theory suggests POS as a resource for employees which will strengthen the relationship between IL and engagement (H4a) and between IL and CO (H4b).

Methodology: The quantitative data was collected from a financial sector company located in Europe (N=271) from various teams in the organization using following surveys: Customer Orientation Scale (Susskind et al., 2003); UWES-3 (Schaufeli et al., 2019); Perceived Organizational Support (Eisenberger et al., 1997) and Inclusive Leadership scale developed for this research. After assessing the construct validity of the new scale and controlling the statistical adequacy of the measurement model, we analysed the hypotheses using multilevel regression in R with support of packages lavaan (Rosseel, 2012), nlme (Pinheiro et al.,2017), and mediation (Tingley et al., 2014).

Results obtained: IL had a significant effect on both CO (H1) ($\beta = 0.19$, $p < 0.001$) and engagement ($\beta = 0.26$, $p < 0.05$) (H2). Contrary to expectations engagement had no significant effect on CO ($\beta = 0.02$, $p = 0.42$). Thus, no significant indirect effect was observed (0.01 [-0.01, 0.03], $p = 0.41$) (H3). Additionally, while POS did not moderate the relationship between IL and engagement ($\beta = -0.03$, $p = 0.64$) (H4a), it did moderate the direct relationship between IL and CO ($\beta = 0.09$, $p <; 0.01$) (H4b).

Limitations: Adopting a cross-sectional design and conducting the research in a limited field (financial sector, Europe context) were two of the methodological limitations. Moreover, using the same conceptualization of CO both for internal and external CO; and not focusing on variables' dimensions separately (e.g., three dimensions of EE) might have limited our understanding of the respective relationships.

Research and practical implications: Future research can investigate how focusing on customer orientation influences the relationship between employees as they are internal customers for each other; the impact organizations have on their external customers' daily-life experiences; the suggested relationships in an experimental and longitudinal setting to understand the over-time impact of inclusive leadership. Considering its impact, organizations should invest in IL by, for instance, providing training to the managers. Furthermore, improving employees' POS (e.g., by offering individualized benefits, Eisenberger & Malone, 2016) will help strengthen IL's impact on CO.

Relevance to the Congress Theme: We highlight the Delivery aspect of "The future is now?". We suggest attention to CO should persist while considering leadership styles that are needed in today's diverse workplaces to facilitate CO. This can be done by focusing on what inclusive leadership entails and how it can be fostered.

Relevant UN SDGs: This study contributes to "Decent Work and Economic Growth" (SDG.8) since inclusive leadership is not only a moral imperative but also has a business argument to it.

Keywords: Inclusive leadership, customer orientation, employee engagement

Paper 4

Uncovering the link between inclusive leadership and employee outcomes. The explanatory role of prosocial and proactive employee behaviors

Sonja Rispens, Eindhoven University of Technology; Huatian Wang, Lingnan University, Hong Kong; Evangelia Demerouti & Janna Behnke | Eindhoven University of Technology

Research goals and why the work was worth doing: This research examines employees' resource-seeking and helping behavior as possible mechanisms that explain the influence of inclusive leadership (IL) on work engagement (WE) and task performance (TP). While scholars acknowledge IL as essential in managing workforce diversity, we cannot assume that leaders' behaviors affect employees in a vacuum. Our research efforts follow the belief that employees and leaders simultaneously create inclusive work climates, but research neglects the role of employees (Nishii & Leroy, 2022).

Theoretical background: One possibility for STEM (science, technology, engineering, and mathematics) organizations to benefit from workforce diversity is to implement IL and boost employees' inclusion experiences (Shore et al., 2018). Randel and colleagues (2018, p.192) conceptualize IL as "leader behaviors that respond to group members' needs for belongingness and uniqueness within a workgroup." IL links to various positive outcomes (Veli Korkmaz et al., 2022). However, research lacks insight into the collective impact of employee and leader behaviors on employee outcomes in the context of diversity and inclusion (e.g., Ashikali et al., 2020; Homan et al., 2020). Based on the social learning theory (Bandura, 1971), we argue that IL sends information about desired behaviors and values, which will stimulate the employees to engage in prosocial/proactive behaviors at work (i.e., seeking resources from leaders and helping colleagues). While contributing to a more inclusive and social workplace, employees will be more engaged and productive at work (Shore et al., 2018). Additionally, diversity displays a crucial contextual aspect of IL (Nishii & Leroy, 2022). We thus assume that the relationships between IL and employee outcomes will be stronger in more diverse work groups.

Methodology: We collected survey data from 153 employees and their supervisors at Dutch and German STEM organizations. Employees shared their perceptions of IL (Zheng et al., 2017), their seeking-resources behavior (Tims et al., 2012), as well as their WE (Schaufeli et al., 2006). Leaders indicated the extent to which the employee engaged in helping behavior (MacKenzie et al., 1991) and TP (Williams and Anderson, 1991). Employees and leaders reported their perceptions of workforce diversity (Van Dick et al., 2008). We tested the hypotheses by utilizing the structural equation modeling (SEM) approach using SmartPLS 3.0.

Results obtained: In line with our hypotheses, IL related positively to TP ($b = 0.269$; $p \leq 0.01$) and WE (dedication: $b = 0.245$; $p \leq 0.01$; vigor: $b = 0.301$; $p \leq .01$; and absorption: $b = 0.215$; $p \leq 0.01$). Moreover, IL was positively related to TP through helping behavior ($b = 0.153$, $p \leq 0.01$, CI = [0.065, 0.256]) and resources-seeking behavior ($b = 0.063$, $p \leq 0.05$, CI = [0.003, 0.127]). Nevertheless, IL was not significantly related to WE through helping behavior ($b = 0.019$, $p = 0.375$, CI = [-0.024, 0.065] for vigor; $b = 0.031$, $p = 0.137$, CI = [-0.010, 0.080] for dedication; $b = 0.024$, $p = 0.339$, CI = [-0.022, 0.077] for absorption) and only the indirect effect through resources-seeking behavior on dedication was significant (one dimension of WE; $b = 0.115$, $p \leq 0.05$, CI = [0.016, 0.222]). Finally, IL was only positively related to TP when workplace diversity was high ($b = 0.236$, $p \leq 0.05$) compared to when it was low ($b = 0.074$, $p = 0.100$), highlighting the important contextual role of workforce diversity.

Limitations: The cross-sectional data limits the possibility of concluding causality. Moreover, the study did not consider possible confounds, such as frequency of contact between employees and leaders or value congruence, which might impact how leaders and employees rated each other's behaviors.

Research and practical implications: Future longitudinal and experimental research should investigate the directionality of the relationship between IL, prosocial/proactive behaviors, and employee outcomes. Studies could also include the role of and the impact on a team.

Relevance to the Congress Theme: Our research contributes to the urgency aspect of "The future is now!" theme. Diversification of the workforce in STEM displays a reality and ethical imperative for organizations that they need to manage "now." By examining inclusive leadership and specific prosocial/proactive employee behaviors, we offer insights into how organizations and their members can jointly facilitate more inclusive workplaces in which employees feel engaged and productive.

Relevant UN SDGs: This study applies to the UN SDG "Decent work and economic growth." Our research shows that leaders who manage their diverse workforce more inclusively stimulate employees' prosocial/proactive behaviors and enhance employee functioning and well-being, especially in diverse workplaces.

Keywords: Inclusive leadership, helping behavior, resource-seeking behavior

Paper 5

Successfully navigating informational diverse work environments: The important roles of job crafting and emotional intelligence

Sonja Rispens, Eindhoven University of Technology; Huatian Wang, Lingnan University, Hong Kong; Evangelia Demerouti, Eindhoven University of Technology

Research goals: Many employees work in an informationally diverse work environment, which is characterized by increased variations in type, source, or category of relevant information, knowledge, and perspectives in the workplace (Allen et al., 2008). While informational diversity is found to be beneficial, such as facilitating task completion (Bell et al., 2011), making high-quality decisions (Van Knippenberg et al., 2004), enhancing group creativity (Zhang, 2016), and keeping competitive advantages with other competitors (Cox & Blake, 2013), these findings largely concentrated on the team, organizational level. On the individual level, we know little about whether and how employees themselves could engage in customized, ongoing actions to profit from informational diversity, and then optimize their own work. Following the job redesign (Oldham & Fried, 2016) and job demands-resources (JD-R) (Bakker & Demerouti, 2017) perspectives, this study investigates the roles of employees' job crafting behaviors and emotional intelligence.

Theoretical background: Job crafting refers to the self-initiated adjustments of one's work conditions, including job resources and job demands (Tims et al., 2013). Based on the JD-R perspective, job crafting involves a motivating process whereby individuals make micro-adjustments based on their own needs, preferences, and unique job conditions. Thus, via job crafting behaviors, employees could actively mobilize valuable job resources they need from informational-diverse work environments, respond to challenging demands, and consequently, improves their work outcomes. Emotional intelligence (EI) refers to the ability to effectively manage one's emotions as well as intentionally harness and use emotions and emotional information (Mayer et al., 1997). The diversity literature indicates that when working in a diverse setting (e.g., exchanging information, ideas, and resources with people of different backgrounds), individuals likely feel more stressed and anxious and may cause discord and conflict (Clark & Polesello, 2017; Gardenswartz et al., 2010). Based on the JD-R perspective, EI is seen as a vital personal resource. We argue that high EI employees could better understand, process, and use different information presented by different people, and thus more likely take appropriate strategies for responding to complex environments.

Methodology: We conducted a weekly diary design over four consecutive weeks. Our sample consisted of employees from three medium-sized hospitals located in China. A total of 254 individuals, including nurses, medical specialists, and admin personnel out of 359 (71% participation rate), completed a general questionnaire and four weekly questionnaires (1,016 observations). In the general questionnaire, we measured perceived diversity, emotional intelligence, and demographic variables. In the subsequent four-weeks diaries, we measured employees' job crafting behaviors, work engagement and performance (self-rated) by the end of each week. To examine the mediation and moderated mediation effects, we conducted 2-1-1 model using Mplus. Specifically, we drew the model of the mediation and moderated mediation on Level 2 but also drew a model of the relationship between weekly job crafting and weekly employee outcomes on Level 1.

Results: Our results showed that perceived informational diversity indirectly improves employees' work outcomes (e.g., work performance and work engagement) via engaging in job crafting behaviors. Moreover, this indirect effect was stronger for employees with high levels of EI.

Limitations: Our constructs were self-reported, and our sample was from a single industry and a single country setting, which may raise the issue of generalizability.

Research/Practical implications: First, we add to the workplace diversity literature by highlighting the beneficial role of job crafting in informational diverse workplaces. Traditionally, studies focused on how informational diversity can be managed through top-down approaches (e.g., inclusive HRM practices, organizational justice and equality policies) (Blouch & Azeem, 2019; Jaiswal & Dyaram, 2020; Singh et al., 2013) and/or how these top-down approaches lead to higher team-level outcomes (e.g., team creativity, team productivity) (Bell et al., 2011; Kearney & Gebert, 2009). Our study uncovers a bottom-up means by which employees benefit from the heterogeneity in resources presented by an informational diverse work environment. Second, we contribute to the workplace diversity and job redesign literatures by highlighting the moderating role of EI. We highlight that EI is a vital ability to help employees to take appropriate strategies to process emotional demands presented by an informational diverse work environment. Third, we enrich job demands-resources and job crafting literature by pointing out that informational diversity offers both job resources and job demands and could be a vital antecedent of job crafting.

We suggest that organizations empower employees with more autonomy to take bottom-up approaches to manage informational diversity at work. The job crafting scholars have developed several job crafting intervention programs, which yield numerous beneficial outcomes (Dubbelt et al., 2019; Gordon et al., 2018). Management practitioners may want to use these intervention programs to boost employees' job crafting behaviors or other proactive behaviors at work, and then achieve desirable work outcomes.

Relevance to the Congress Theme: The diverse workplace makes today's work uncertain and dynamic. This study aims to highlight the important role of informational diversity at work and how job crafting, and emotional intelligence can help employees to adapt to the diverse, changing, and uncertain work environment.

Relevant UN SDGs: Good health and wellbeing; Decent work and economic growth; Peace, justice, and strong institutions

Keywords: workplace informational diversity; employee job crafting; emotional intelligence

Symposium S016

Harnessing motivation and self-regulation via interventions: Implications for work-related well-being

Anna Steidle, University of Applied Sciences Ludwigsburg

science

What will be covered and why: The future of work is likely to see a much greater percentage of workers engaged in remote work or blended forms of work, resulting in more flexible working patterns, poorer boundaries between work and home, and a greater need for workers to be able to motivate themselves and self-manage their work. Although individual level interventions often implicitly train workers to change something (about themselves, their environment) and thus, inherently require motivation and self-regulation, few studies to date have formally investigated the potential of interventions to promote self-regulation and motivation. In this symposium, we discuss five studies which do just this. The first paper (Althammer, Wöhrmann & Michel) examines a comprehensive six week self-regulation intervention for flexible workers, demonstrating that it increases self-regulation, well-being and work-life balance compared to a control group. The second paper (Michel et al.) focuses on how we can design interventions to help employees create better boundaries between work and home life. It contrasts two interventions, namely mindfulness as a cognitive-emotional segmentation strategy with an intervention based on different types of segmentation strategies and transitions rituals (with a control) to see which one is more effective for work-life balance and well-being. The third paper (O'Shea et al.) specifically focuses on the emotional mechanisms via which trait mindfulness and situationally induced mindfulness unfold their beneficial influence on cognitive resources. The final two papers present particularly novel methodologies and interventions. Pogrebtsova and González-Morales use appreciative inquiry to conduct a process evaluation of a job crafting intervention, highlighting how participants experience better alignment between their needs, strengths and values. Finally, Lennefer, Reis, Lopper and Hoppe combine the psychological and physical to show how the use of an activity tracker combined with an online coach can lead to increased movement and decreased strain and negative affect.

Relevance to the Congress Theme: This symposium has relevance to the conference theme as it is focused on issues pertaining to the changing nature of work and specifically on the delivery of necessary interventions to support employees in developing self-regulation skills so organisations can deliver desired changes.

Research/Practical Implications: These five studies target different aspects of self-regulation (e.g., awareness, monitoring, behaviour change, reflection) and motivational resources (impact, affect, needs, values), demonstrating that there is much potential in harnessing such approaches via interventions to improve various facets of well-being and aiding workers in managing more flexible working arrangements. Collectively they demonstrate that although such interventions can take a variety of approaches they have important implications for employees.

Overall conclusions: Combined, the research in this symposium suggests that there is scope to further explore the added value of individual-level interventions specifically targeting self-regulation and motivational resources. As the world moves into the future of work, with greater emphasis on flexible working and hybrid workplaces, employee's ability to develop their own skills and strategies to self-manage and motivate themselves will be particularly important.

Keywords: intervention, well-being, self-regulation

Paper 1

Comparing Online and Blended Training - Effects on Psychological Detachment, Work-Life Balance, and Well-Being

Sarah E. Althammer, Alexandra Michel & Anne M. Wöhrmann | Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany

Research goals and why the work was worth doing: In the changing world of work, an increasing share of workers has at least some temporal and spatial flexibility (i.e., autonomy in choosing their work times and locations). Flexible work designs (FWD) such as flexitime and telework can have benefits for employees (e.g., reduced commuting times, balancing work and private life). However, they come with specific challenges such as blurring boundaries between work and private life, prolonged working hours and insufficient recovery. This can negatively affect well-being and work-life balance. Hence, we developed an online training to help workers cope with these challenges. To address shortcomings of online interventions such as high dropout and feelings of isolation, we also developed a blended training intervention in which members attended three group sessions in addition to the online training. This study evaluates the effectiveness of the training approach to improve recovery, work-life balance, and well-being, and compares whether a blended training format can address the shortcomings of an online training format.

Theoretical background: Self-determination theory proposes that people possess intrinsic motivation to engage in a particular behaviour, facilitated by the satisfaction of basic psychological needs (competence, autonomy, relatedness). Moreover, based on social identity theory, the sense of belonging to a group and group interactions can strengthen social support. Thus, group sessions may increase intrinsic motivation to engage in the training and social support, thus improving training effectiveness.

Design & Intervention: To evaluate the training, we conducted a randomized controlled trial with four measurement points (pre-intervention, post-intervention, four-week follow-up and six-month follow up). Participants who completed the baseline questionnaire (n = 575) were randomly assigned to an intervention group that received the online training (IG-ON), an intervention group that received the blended training (IG-BL), or the control group (CG). The control group received the intervention after the four-week follow-up. The final sample at T2 included 340 participants (n IG-BL = 119, n IG-ON = 84, n CG = 137). The six-week online training “FlexAbility” consists of six weekly modules and short daily tasks. The training provides participants with several strategies to address the specific challenges of FWD. They learn segmentation strategies that help them manage boundaries between work and private life. They learn respite strategies that help them recover during work breaks and after work. Further, they learn strategies that help them organize their workday. Blended training participants participated in three supplementary three-hour videoconference group sessions designed to promote group interactions and social support and consolidate learnings and exercises from the online training.

Results: In line with our hypothesis, multilevel analyses revealed that both training formats improved psychological detachment, satisfaction with work-life balance, and well-being compared to the control group. Unexpectedly, blended training participants did not profit more from the intervention than online training participants did. However, blended training participants reported more social exchange with others (that is, sharing of experiential knowledge and emotional support)

and were more likely to be compliant (i.e., engage with modules, practice daily tasks, attend group meetings).

Limitations: Women and participants with high education were over-represented because they were self-selected. We assessed compliance via self-report due to data protection requirements.

Research/Practical Implications: Both the online and the blended training can be helpful tools in supporting workers to cope with the specific challenges of FWD. This is important as the share of workers with FWD is expected to remain at a high level in the future. The study contributes to research comparing the effectiveness of training formats in the work context. Moreover, providing an empirical test for the theoretical assumption based on social identity theory and self-determination theory, group sessions accompanying the online training can promote social exchange and increase the likelihood that participants actively participate in training. Thus, practitioners should encourage group interactions accompanying online trainings to increase training adherence. Employees who participate in online trainings can share their experiences and goals with others to increase their own commitment.

Relevance to the Congress Theme: This study contributes to the congress topic “The Future is Now: the changing world of work” as the intervention was designed specifically for workers with FWD, which is increasingly important in the changing world of work. The possibilities of digitalization and ICT use promote FWD, and the COVID-19-pandemic further increased the number of workers with temporal and spatial flexibility. This research can provide guidance how to design FWD optimally.

Relevant UN SDGs: This research contributes to the goal of achieving good health and well-being.

Keywords: flexible working conditions, intervention, self-regulation

Paper 2

Effects of an online-self-regulation intervention on self-regulation, occupational self-efficacy and negative affect

Alexandra Michel, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany / Heidelberg University, Heidelberg, Germany; Anne M. Wöhrmann, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany; Sarah E. Althammer, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany / Heidelberg University, Heidelberg, Germany; Lucia M. E. Piehl, Heidelberg University, Heidelberg, Germany

Research goals and why the work was worth doing: Aim of this study was to evaluate the effectiveness of an online self-regulation intervention teaching different self-regulation strategies to promote self-regulation, occupational self-efficacy and to reduce negative affect. Being able to self-regulate and self-organize one's working life becomes more and more important due to higher work flexibility. Flexible work designs (FWD) such as flexitime and telework can be beneficial for employees. However, they come with specific challenges such as organizing one's own working day including goal setting, self-monitoring and rewarding one's success. Hence, we developed an online training to help workers cope with these challenges.

Theoretical background: Self-regulation theory proposes that "self-regulation refers to self-generated thoughts, feelings, and actions that are planned and cyclically adapted to attainment of personal goals" (Zimmermann, 2000, p. 14). Thus, an online self-regulation training may increase self-regulated work behaviour, improve occupational self-efficacy and reduced negative affect.

Design & Intervention: To evaluate the training, we conducted a randomized controlled trial with four measurement points (pre-intervention, post-intervention, two-week follow-up and six-week follow-up). Participants who completed the baseline questionnaire were randomly assigned to an intervention group (N=32) that received the online training or to a waiting control group (N=55). The control group received the intervention after the six-week follow-up. The training provides participants with different self-regulation strategies.

Results: In line with the hypotheses, analyses revealed that self-regulation and occupational self-efficacy were increased and negative affect was reduced for the experimental group in comparison to the control group at post and follow-up measurement points.

Limitations: All data were self-reported.

Research/Practical Implications: Our study results show that an online self-regulation intervention is effective in promoting self-regulation, occupational self-efficacy and well-being.

Relevance to the Congress Theme : This study contributes to the congress topic "The Future is Now: the changing world of work" as the intervention was designed and conducted in the context of an increase of flexible work designs triggered by the COVID-19 pandemic. Thus, results are helpful in designing future interventions for a flexible workforce.

Relevant UN SDGs : This research contributes to the goal of achieving good health and well-being.

Keywords: intervention, self-regulation, affect

Paper 3

Examining the impact of mindfulness on daily well-being and performance

Deirdre O'Shea, Kemmy Business School / University of Limerick, Ireland; Anna Steidle, Department of Management and Law, University of Applied Sciences Ludwigsburg, Germany; Annekatrin Hoppe, Department of Psychology, Humboldt Universität zu Berlin, Germany; Alexandra Michel, Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany / Heidelberg University, Heidelberg, Germany; M. Gloria Gonzalez-Morales, Division of Behavioral & Organizational Sciences, Claremont Graduate University, USA; Agustin Molina, Escuela de Psicología., Pontificia Universidad Católica de Chile, Chile

Research goals: Drawing on theories of mindfulness-to-meaning (Garland, Farb, Goldin, & Fredrickson, 2015b), we investigate the ways in which mindfulness (trait and induced) has its effects on daily outcomes. We propose the trait mindfulness operates via the mechanism of affect and is associated with higher daily positive affect which is in turn related to higher daily concentration and lower fatigue.

Theoretical background: Mindfulness has been defined as a state where one is "attentive and aware of what is taking place in the present" (Brown & Ryan, 2003; p. 822). Although typically defined as a state, research has also shown that individuals differ in their propensity to be mindful, and this individual difference is termed trait mindfulness, referring to the duration, frequency and intensity with which an individual tends to engage in mindfulness (Hülsheger, Alberts, Feinholdt, & Lang, 2013; Jamieson & Tuckey, 2017). State mindfulness can be induced through mindfulness-based interventions, which if practiced regularly and over time will cultivate higher levels of trait mindfulness (Hülsheger et al., 2013; Jamieson & Tuckey, 2017). In this research, we investigated the impact of both trait mindfulness and state mindfulness (induced via intervention).

Intervention: The mindfulness intervention drew on Garland and colleagues (2015a) mindfulness-to-meaning theory, and on the previous work of Michel, Bosch and Rexroth (2014) who demonstrated that mindfulness can be used as a cognitive-emotional segmentation strategy. In order to develop the necessary skills, our mindfulness intervention followed a self-regulation process where we first enabled participants to become aware of their emotions, then to recognize their emotions, and accept them. We contrasted this with a stringent active control condition.

Design/Method: 237 (28.2%) employees from an Irish organisation volunteered to take part in the research. The cluster randomization resulted in 173 participants in the mindfulness condition and 63 in the active control (AC) condition. Following drop-out, the final sample consisted of 1242 daily observations nested in 186 participants (n AC = 54; n Mind = 132). After completing the baseline survey, participants were provided with training on the intervention activities. Over four weeks, they were sent a link via e-mail on a daily basis which provided them with access to the intervention activities in an online platform.

Results: The intervention moderated the indirect effect from trait mindfulness to daily concentration and fatigue via daily positive affect. This study demonstrates that completing a daily mindful emotion regulation intervention provides the opportunity for trait mindfulness to positively influence daily concentration and fatigue via daily positive affect, which is boosted by engaging in daily mindfulness practice, when compared to an active control intervention that does not facilitate this process.

Research/Practical Implications: These findings provide some insights into the mechanisms through which mindfulness has its effects on daily well-being and performance. Furthermore, it highlights interesting findings with regard to the way in which interventions may facilitate personal strengths to unfold their beneficial impact. Our findings suggest that relatively low dose interventions work as self-regulatory prompts for those with already developed mindfulness skills. Thus, our research contributes to our current understanding of how and for whom mindfulness is beneficial in workplace settings.

Originality/Value : Our study contributes to the literature by examining the interplay of a daily mindfulness intervention and trait mindfulness in terms of how they impact daily outcomes. We extend past research demonstrating that mindfulness and mindful reappraisal are associated with growth in daily positive affect (Pogrebtsova, Craig, Chris, O'Shea, & Gonzalez-Morales, 2018), and by demonstrating that positive affect is a mediating mechanism through which mindfulness influences daily concentration and fatigue.

Relevance to the Congress Theme: This study contributes to the congress topic “The Future is Now: the changing world of work” as the it demonstrates how trait mindfulness and a daily mindfulness intervention can help workers to improve their daily concentration and well-being. As the changing world of work, and the possibilities of digitalization and ICT use promote hybrid and flexible working opportunities, this research provides guidance on daily strategies to help workers focus and maintain their energy through the day.

Relevant UN SDGs: This research contributes to the goal of achieving good health and well-being.

Keywords: mindfulness, intervention, daily

Paper 4

A step away from impaired well-being: An activity tracker intervention among low active employees of a logistics company

Annekatrin Hoppe & Elisa Lopper | Humboldt-Universität zu Berlin, Germany; Dorota Reis, Department of Psychology, Saarland University, Germany; Thomas Lennefer, Humboldt-Universität zu Berlin, Germany

Research goals and why the work was worth doing: The aim of the present study was to evaluate the effectiveness of a workplace intervention combining activity trackers with an online coach in order to increase employees' number of steps (i.e. their physical activity) and decrease emotional strain and negative affect (i.e. their impaired well-being). Moreover, we investigated the moderating role of work-related and personal resources (i.e., job control and self-efficacy) on the intervention's effectiveness.

Theoretical background: Building on self-determination theory and (Ryan & Deci, 2002) and the Health Action Process Approach (Schwarzer, 2008) the study combines a behavioural (activity tracker) and cognitive (online coach) intervention approach.

Design/Methodology: 108 mainly low active employees of a large company participated in the intervention over the course of three weeks. Data were collected at six measurement points and analysed with latent growth curve modelling.

Results: The results revealed that employees increased their number of steps until the second intervention week. Moreover, the intervention was effective in decreasing emotional strain and negative affect over the course of the intervention. Job control and self-efficacy did not moderate intervention effectiveness.

Limitations: The study does not provide a control group. Furthermore, moderating effects of job characteristics that promote or hinder the intervention effectiveness need to be further explored.

Research/Practical Implications: The intervention provides a useful person-focused approach for organizations that wish to promote physical activity and employee well-being.

Originality/Value: By applying latent growth curve modelling, we could link the growth of one variable (e.g., employees' number of steps) to the growth of another variable (e.g., employees' impaired well-being) and, thus, provide information about the relationship between the variables. Accordingly, analyses revealed that increase in number of steps was related to the decrease in negative affect, whereas no such association was found for the increase in number of steps and the decrease in emotional strain.

Relevance to the Congress Theme: This study contributes to the congress topic "The Future is Now: the changing world of work" as it successfully integrates new technologies into health-promoting interventions at work. It furthermore addresses an underserved population of blue-collar workers who should receive more attention in I/O psychology research in the future so that the needs of all workers are addressed.

Relevant UN SDGs: This research contributes to the goal of achieving good health and well-being.

Keywords: Physical activity, intervention, well-being

Symposium S017

PSYCHOLOGICAL SAFETY AT WORK: CONTRIBUTIONS TO DECENT WORK, PERFORMANCE AND EMPLOYEE WELLBEING

Sanna Malinen, University of Canterbury, NZ

science_practice

Psychological safety is a widely researched topic. Research repeatedly highlights the critical role of psychological safety in the workplace and its contribution to learning and improvement efforts (Carmeli et al., 2009; Carmeli & Gittell, 2009; Edmondson, 1999; Hirak et al., 2012; Liu et al., 2014; Nembhard & Edmondson, 2006; Wong et al., 2010), creativity (Carmeli et al., 2010; Kark & Carmeli, 2009), innovation (Andersson et al., 2020), performance (Andersson et al., 2020; Baer & Frese, 2003; Hirak et al., 2012; Schaubroeck et al., 2011), and voice behaviour (Erkutlu & Chafra, 2015a; Erkutlu & Chafra, 2015b; Detert & Burris, 2017; Lee et al., 2021; Sherf et al., 2021).The topic has similarly attracted significant media attention. Most notably, reports such as Google's Project Aristotle (Duhigg, 2016; Rozovsky, 2015) have stressed the need for psychological safety in order to develop effective, high-performing teams.

Psychological safety (PS) is defined as a belief that an employee is safe to take interpersonal risks, including a sense of confidence that the team will not reject, embarrass, or punish their colleagues for speaking up (Edmondson, 1999).

While PS is considered key to effective team work, employee engagement and wellbeing, many questions remain. This symposium includes five presentations on psychological safety, including the construct's measurement (Cottrell, Malinen), how to foster it (Clarke, Wong) and psychological safety's role in an occupational safety framework (Teperi). The presentations come from various contexts and industries (health, law, governance) and are likely of interest to both scholars and practitioners. Overall, the presentations hope to advance the decent work agenda, by promoting safe workplaces that support employee wellbeing, inclusion and reduce inequalities.

Cottrell et al. will discuss the importance of psychological safety in the context of team decision making. In addition to psychological safety, her study includes measures of belongingness, inclusion and independent thinking, and investigates how these factors enable effective team-level decision making.

Clarke's presentation focuses on speaking up at work and how leaders can improve employee experience and their wellbeing through psychological safety. Clarke focused specifically on ethical leadership behaviours in the context of law firms, and found compelling evidence for the role that psychological safety climate plays in key employee outcomes.

Malinen's presentation focuses on the measurement of psychological safety. She will discuss considerations for scholars wanting to advance psychological safety measurement, and provides recommendations for those wanting to measure psychological safety.

Wong's presentation is in the context of innovation in healthcare. Her study investigates how a climate of psychological safety can promote the uptake of medical technology by health providers, specifically a low-cost diabetes solution.

Finally, Teperi will present a theoretical framework and a practical model, Human Oriented Occupational Safety (HOS), for improving work and safety from the psychological viewpoint. The HOS

has been developed from an integrative perspective that combines lessons learnt from past safety paradigms and the current views on Human Factors and safety management.

Relevance to the Congress Theme

Psychological safety climate is an essential characteristic of effective and healthy teams and organisations. Amidst ongoing global challenges, being able to bring one's whole self to work is not only key for promoting equity and inclusion, it is crucial for organisational performance. Psychological safety at work also promotes the decent work agenda, economic growth, and contributes to employee wellbeing and reducing inequalities.

Research/Practical Implications

This symposium's presentations provide noteworthy implications for both scholars and practitioners. For practitioners, we show various ways through which psychological safety can be promoted and provide evidence for the psychological safety's importance for performance and employee wellbeing. With the chronic skill shortages and fierce competition, promoting psychological safety climate enhances both the employee experience and organisations' competitive advantage. For scholars, we provide a critical lens through which psychological safety measurement can be improved and provide potential avenues for advancing this field further.

Overall conclusions

This symposium presents cutting edge research on psychological safety, showing its power in promoting positive employee and organisational outcomes, while also highlighting areas in need of further research and scrutiny. We hope to provide stimulating presentations and discussion on psychological safety, and its implications for research and practice.

Keywords: Psychological safety, inclusion, team work

Paper 1

Effective team decision-making: Exploring the role of psychological safety

Lloyd Mander, Diversity of Thought; Sanna Malinen, Katharina Näswall & Story Dealy Cottrell | University of Canterbury, NZ

Research goals and why the work was worth doing:

This exploratory study aims to understand factors that contribute to effective team decision-making by examining work teams that engage in complex decision-making. High-functioning teams with effective team work and decision-making are essential for organisational performance (Jones & Roelofma, 2000; Kim, Lee, Connerton, 2020). The essence of management and success in competitive environments depends on the quality of decisions made despite information overload and several alternatives in both solutions and outcomes (Albar & Jetter, 2009). Therefore, importance is placed on creating a climate that supports sharing thoughts openly in the team. By promoting psychological safety within a team, individuals can examine issues from various angles and see implications of their decisions from different perspectives. In addition to psychological safety, individual's perceptions of inclusion, belongingness, and independent thinking, are likely to contribute to effective group decision-making. This research investigates how psychological safety, inclusion, belongingness and independent thinking relate to each other and contribute to effective group decision-making.

Theoretical Background:

Teams are often employed in decision-making as they can bring increased knowledge and resources to a problem beyond that of an individual, thereby increasing the probability that a group decision is of higher quality than an individual decision (Brodbeck, Kerschreiter, Mojzish, Frey & Schulz-Hardt, 2002). Psychological safety, understood as feeling safe to take interpersonal risks in a team context, is critical for effective team performance (Edmondson, 1999). Group members within a psychologically safe environment, can look at a problem from diverse perspectives and employ their expertise allowing specific insights and increasing their collective capability. Therefore a climate that allows members to share thoughts and discuss options is imperative. Teams are essential; they create opportunities to make decisions, the conditions with which decisions are made are essential to their success, and psychological safety is a necessary condition.

Design/Methodology/Approach/Intervention:

This is a cross-sectional study design employing an online survey to identify relationships between the variables; psychological safety, inclusion, independent thinking, belongingness, and group decision-making. The requirement for each participating team was more than two people, and that team members actively engage in decision-making while at work. Team leaders distributed the survey link to team members for completion and took 10-15 minutes to complete.

Results Obtained or Expected:

Data is currently being analysed, predicted findings are likely to discover that heightened psychological safety, inclusion, and belongingness within a team will enhance sharing of independent thoughts and strengthen group decision-making. There are likely to be positive relationships between the variables, and they will be clear predictors of enhanced group decision-making.

Survey results will be assessed through regressions to understand relationships between the variables and how they impact effective group decision-making. The data will be analysed at the team level, accounting for within-team perceptions of predictors using multilevel modelling with individuals (level 1) in teams (level 2). Given that psychological safety, inclusion, belongingness, and independent thinking are similar constructs, the items will likely be highly correlated, relative weights will be used to unpack the highly correlated predictors, address multicollinearity issues and calculate the importance rank of variables.

Limitations:

The first limitation is the use of a cross-sectional design, which restricts the determination of causal relationships among the variables. The second limitation related to the survey instructions, although clarity was intended, some participants from the same team reported different team sizes which impacts the option to do analyses involving team size. The final limitation was that the research used only a survey approach. Future research may improve this study by utilising a mixed-method approach that includes both quantitative and qualitative data collection.

Conclusion - research or practical implications

It is important for employees and leaders to understand the impact of psychological safety, inclusion, independent thinking, and belongingness on outcomes such as team decision-making.

Feeling psychologically safe is important as it decreases barriers to engagement and the benefit of having an engaged workforce is enhanced employee performance, which is important for team functioning and decision-making (Wanless, 2016; Markos & Sridrevi, 2010). Teamwork and decision-making are important components of organisational performance. Therefore, it is vital for employees and organisations to understand how fostering psychological safety can improve team performance. This research could have implications for leaders by indicating what a team climate needs in order to be more effective in their decision-making processes.

Relevance to the Congress Theme: The future is now: the changing world of work

The research presents relevance to this theme given that teamwork is prominent in all workplaces and with the acceleration of remote working there is a need to create a safe place for teams to allow effective decision-making. When online, it is harder to gauge emotional stances from other team members. If the team climate and practices are positive for the team, there will be enhanced performance, teamwork and decision-making.

Relevant UD SDGs:

By understanding what team climates promote effective decision-making, this research contributes to the UD SDG's by enhancing wellbeing and equity in the workplace.

Keywords: Teams, decision making, inclusion

Paper 2

Feeling safe to speak up: leaders improving employee wellbeing outcomes through psychologically safety

Emma Clarke, Sanna Malinen & Katharina Näswall | University of Canterbury, NZ

Research goals and why the work was worth doing:

Wellbeing at work is an important area of research because of the impact it can have on people's professional and personal lives. Employees who experience high wellbeing perform better and are better organisational citizens (Diener & Seligman, 2004; Krieger & Sheldon, 2015). Further, employee wellbeing has a significant impact on organisational success by influencing the costs related to illness, absenteeism, job performance and turnover (Grant et al., 2007; Sears et al., 2013).

Wellbeing can be nurtured in organisations through developing psychological safety, and a key driver of psychological safety in organisations is the behaviour of leaders (Edmondson, 1999; Nembhard & Edmondson, 2006). Ethical leaders have been found to promote psychologically safe practices in the workplace (Bedi et al., 2016; Brown et al., 2005), however further research is needed across cultures and different professions, to provide more empirical evidence of this relationship.

While this research examined the broader wellbeing outcomes of ethical leadership, the primary focus of this study was to explore psychological safety as a mechanism through which ethical leadership influences employee wellbeing.

Theoretical background:

Social Learning Theory was used in this study to illuminate the relationship between leadership behaviour and psychological safety. Conservation of Resources (COR) Theory, was also chosen as a theoretical framework for the study as it helps to explain the relationship between ethical leadership and wellbeing as well as the role that psychological safety has in this relationship (Hobfoll, 2011).

Method:

For this study, the New Zealand (NZ) legal profession was chosen as a context to investigate the key constructs. Law firms are often hierarchical in nature, creating potentially inequitable power dynamics between employees. These power differences can prevent employees from speaking up.

Participants were sourced through Human Resources (HR) departments within large corporate law firms and Senior Management within small and mid-sized NZ law firms. In addition, members of NZ law societies and associations were also invited to participate.

Lawyers and partners completed two online surveys in 2021 via Qualtrics, four weeks apart. Of the 320 participants that registered their interest in participating, 234 completed the first survey and 132 completed the second survey. The participants were 75% female and 25% male with a mean age of 35.4 (SD = 11.27).

Results:

All hypotheses were tested using regression analysis in SPSS. Results showed that ethical leadership was positively related to psychological safety four weeks later, and that ethical leadership influenced six of the seven outcomes (general wellbeing, intrapersonal wellbeing, job satisfaction, performance, incivility, and burnout) through psychological safety. That is, when employees are working in an

environment with high psychological safety they experience higher levels of wellbeing, performance and job satisfaction. We also found that ethical leadership was directly related to lower levels of incivility in the workplace and an increase in interpersonal wellbeing and performance.

Limitations:

To test for mediation, the key constructs were measured with the same participants at two timepoints four weeks apart. The timeframe for when these constructs influence each other is unknown and this could provide different results based on the timeframe chosen between timepoints. Future research might consider measuring the key constructs across three timepoints using different periods of time between each timepoint.

Conclusions and Practical Implications:

These findings add to the accumulating evidence that psychological safety is critical to employee wellbeing as well as organisational success. By improving employee wellbeing, through the development of psychologically safe work environments, ethical leadership can make a significant impact on an organisation's bottom-line. High wellbeing not only leads to better performance, it also leads to higher retention (Bartels et al., 2019), which helps reduce costs associated with employee turnover.

This research advances the field of organisational psychology by progressing literature on psychological safety in the workplace and by illuminating ways in which workplaces can enhance employee wellbeing. In addition, this research will provide further understanding as to how leaders can shape a psychological safe working environment in order to increase employee wellbeing, performance and job satisfaction while reducing burnout and turnover.

Relevance to the Congress theme:

As the workplace evolves and becomes more digitised, leaders and organisations need to ensure they are providing employees with an environment that allows them to bring their whole selves to work, to feel safe sharing new ideas and to flourish. By providing a supportive and psychologically safe working environment to minimise any negative impact on wellbeing, leaders can help employees adapt to the rapidly changing world of work.

Relevant UN SDG's:

Having greater understanding of the pathways that impact employee wellbeing will contribute to the United Nations SDG's of providing fair and decent work to employees and ensuring healthy lives for all.

Paper 3

Review of Psychological Safety measurement scales: Recommendations and future directions

Sanna Malinen, Katharina Näswall & Lena Chernoglazova | University of Canterbury, NZ

Theoretical background

Psychological safety research is gaining in popularity, likely due to the phenomenon's significant impact on various individual, team, and organisational outcomes. Many definitions and operationalisations of psychological safety have emerged, resulting in an array of quantitative measures being developed and used across the literature. These measures differ in number of items, context, and level of analysis, and are often tailored to the research setting and population. Currently, Edmondson's (1999) scale dominates the psychological safety literature, with one review calling for researchers to use this in preference to other measures due to its high degree of reliability and predictive validity (Newman et al., 2017). However, researchers using Edmondson's (1999) scale have often adapted the measure (Newman et al., 2017), and Edmondson has also been involved in the development of multiple other psychological safety scales (Edmondson & Mogelof, 2005; Edmondson & Woolley, 2003; Garvin et al., 2008; Nembhard & Edmondson, 2006). These adaptations of Edmondson's (1999) scale suggest that improvements can and already have been made to the original measure. New and adapted scales therefore continue to emerge, indicating a lack of consensus on how best to measure psychological safety.

The proliferation of scales has the potential to impede future research into psychological safety. Such a large variety of measures can create difficulties for researchers striving to find the best scale to suit their purpose and lead to inconsistencies in research findings due to different operationalisations. The quality of psychological safety research will vary depending on the quality of the researchers' chosen measure. A review of psychological safety measure will improve understanding of the suitability of different measures to various research contexts, providing researchers with valuable information and aiding them in identifying the most suitable scale for their chosen setting. This will, in turn, improve the validity of future research into psychological safety.

This presentation will identify, compare, and provide a critical review of currently available measures of psychological safety. The goal of this presentation is to provide guidance for researchers in terms of the measures that they could choose to investigate psychological safety in organisations. A number of recommendations are put forth for both scale developers and researchers using existing measures.

New Perspectives/Contributions

This presentation will include several key recommendations for both scale development and measure selection purposes. These recommendations will focus on four key areas: 1. Referent and Level of Analysis (what is a team? What to do in case of multiple teams?); 2. Scale Length and Coverage (trade-off between validity and reliability); 3 . Item Wording (removing jargon, ambiguous terms); and 4. Greater Transparency in reporting (validity evidence, item wording).

This presentation will conclude with discussing future directions for measurement of psychological safety, including a) change over time, b) defining a team, and c) considering the cultural context.

Conclusions – research and or practical implications

This presentation addresses a substantial gap in the research by providing a measurement-focused review and critique of psychological safety. There remains a lack of consensus surrounding best practice in psychological safety measurement, and while it may not be possible to establish a consensus, it is important to address these issues so that they may be resolved in future research. By reviewing and evaluating currently available psychological safety measures, we hope to advance the field of psychological safety measurement both for practical and scholarly purposes.

Relevance to the Congress Theme

Promoting psychological safety at work has multitude of benefits. Understanding psychological safety, how best to measure and research the construct, is key to advancing the agenda of workplaces that both promote better decision making, inclusion and employee wellbeing.

Relevant UN SDGs

Promoting decent work is a way through which various SDGs can be advanced, including providing safe working conditions and work, where people can bring their whole selves to work. Psychological safety is an important element is promoting inclusive workplaces, where processes, such as creativity and effective team work, can be promoted through employee wellbeing.

Keywords: Measurement, review, scale development

Paper 4

Crossing the medtech chasm: A mix method study of psychological safety and innovation uptake in Aotearoa New Zealand healthcare workplaces

Jennifer Wong, Sanna Malinen, Geoff Chase & Katharina Näswall | University of Canterbury, NZ; Grace Walker, Think Analytic

Research goal and why the work is worth doing:

Medical technological innovation is a nearly trillion-dollar per annual industry with tangible individual and societal impacts (Statistica, 2018; Factors, 2021). Continuous advancements in medical technologies are vital for improving the capacity of the health system to deliver health and wellbeing benefits. Despite these investments, patients are reported to benefit from only 30-60% of new healthcare technologies (Grol, 2001; Schuster, McGlynn, Brook, 2005). This disappointing rate suggests almost half of clinically validated innovations fail to be adopt successfully in healthcare workplaces. The goal of this research project is to explore the role a culture of psychological safety plays in fostering innovation uptake in healthcare workplaces.

Theoretical background:

While there is a clear priority for healthcare innovation, there is an imbalance of what is prioritised during its development and implementation—the technology itself, rather than the individuals using it (Chase et al., 2008). Research and best practice point to co-designing medical technology with end-users for it to be accepted and useful to both patients and healthcare staff (Chen et al., 2021; Greenhalgh et al., 2019). Co-designing technology with healthcare staff requires a distinct approach that acknowledges staff members as both users and providers of the technology (Papoutsi et al., 2021), and operate as professionals within organisational and regulatory systems. Within these systems, there are social, organisational, and societal barriers to the uptake of novel healthcare technologies that when removed can increase the likelihood that medical technologies can be successfully adopted in healthcare workplaces (Wong et al., 2022). What is currently unknown is how psychological safety relates to these barriers to technology uptake and the overall innovation climate in the context of healthcare workplaces.

Methodology:

In this presentation I will be sharing findings from a research project on the factors that impact the uptake and acceptance of a novel, low-cost, diabetes solution for health providers in Aotearoa New Zealand. Both surveys and interviews will be conducted with health providers to provide insights on the barriers of medical technology adoption. Enablers of adoption will also be explored, specifically the structures and practices that support a climate of innovation and psychological safety.

Results expected:

The findings shared in this presentation are from the first phase (Nov 2022-April 2023) of a larger multidisciplinary project that explores the impact of co-design on overcoming medical technology barriers for Māori, tangata whenua (indigenous people) of Aotearoa New Zealand, living with diabetes and their health providers. I expect the survey and interviews to revealed that a history of psychologically safe practices and structures in health providers would lead to more positive perspectives towards adopting the novel diabetes solution. My reflections, as the social science lead,

on the initial stages of co-designing with medical professionals and collaborating with the multidisciplinary team will also be shared during this presentation.

Limitations:

As a case study within the context of Aotearoa New Zealand, findings is unique to the studies context and may not be readily generalisable to healthcare workplaces in other countries. I will be discussing the boundaries of generalisability in the presentation.

Conclusions:

The social and economic costs of diabetes are projected to double over the next 10-20 years in Aotearoa New Zealand (PWC, 2021). These harms are multiplied by genetic, socio-cultural, and socio-economical differences for Māori (Perry, 2021), creating significant inequity in access to care and quality outcomes. The findings of this project can have significant cultural, social, and economical impact for Māori living with diabetes, their whānau (community of families) caregivers through supporting their health providers in adopting low-cost medical technologies. Maximising innovation uptake in healthcare organisations that provide services to Māori is crucial to providing equal opportunities at best care for individuals living with diabetes in Aotearoa New Zealand.

Relevance to Congress Theme and UN SDGs:

EAWOP 2023 Congress theme considers the changing nature of work to become an increasingly transdisciplinary effort that targets the world's current challenges. This presentation and greater research project support both the Congress theme and several UN Sustainable Development Goals: Through in-depth collaboration with engineers, cultural advisors, and end-users, the goals of good health and wellbeing can become more equitable. Told through the lens of an organisational psychology scientist, the importance of social sciences in solving the world's challenges will be emphasized throughout the presentation.

Keywords: technology adoption, healthcare, innovation uptake

Paper 5

Human-oriented occupational safety as an approach to psychological safety

Anna-Maria Teperi, Finnish Institute of Occupational Health

Aim

In this paper, we present our theoretical framework and practical model, Human Oriented Occupational Safety (HOS), for improving work and safety from the psychological viewpoint. We have developed HOS from an integrative perspective that combines lessons learnt from past safety paradigms and the current views on Human Factors (HF) and safety management.

Theoretical background

The traditional reason for the need to implement the HF approach has been that HF contribute to the majority of workplace events and incidents. However, there are also other reasons for taking human contribution into account. First, our functional environment is becoming increasingly complex, dynamic, uncertain, and fragmented, with contributing and interrelating megatrends of climate change, globalisation, and technological innovations. This turbulence affects the way in which work is performed, organised, and led. The more complicated our functional environment, the more mutual collaboration and distributed knowledge among organisations and teams is needed, to proactively tackle potential risks. We need broader, systemic models and networks to anticipate and cope with risks. Second, future safety threats may concern aspects of 'mental or psychological safety', although physical risks still emerge in traditional industrial fields. Today's increasingly overheating work life is challenging people through continuous change, new competence demands and the need to balance different areas of life. A resilient, 'mentally healthy organisation' more effectively mitigates safety risks. Third, in several safety-critical fields such as the transport sector and energy production, safety management systems are mandatory, including requirements for applying HF. These fields need continuous mastery of HF to maintain their operation licences. Fourth, workplaces and professional fields are constantly striving for safety improvements, for which they need practical solutions and concrete facilitation.

Approach

The HOS is conducted by a multiprofessional team consisting of seven members with specialised competences from cognitive ergonomics, group dynamics, work and organisational development, resilience, and pedagogics, to engineering and system design. The main theoretical framework and practical tool for HOS implementation has been the HF Tool, which describes the levels and details of human contribution as a four-leaf model. The model has been applied for the last 20 years in the transport sector, nuclear industry, and the public sector, to increase awareness of HF and to take HF into account as part of safety practices. The three elements of successfully applying HOS have been a systemic, holistic view to HF, a participative manner of applying HF at all organisational levels, and a solution-based, positive view of people.

Results

HOS research and development projects have shown several benefits. Increased awareness of the relevance of and competence in HOS has improved the capability of organisations to create a just, fair culture. Organisations have more deeply and openly learnt to analyse the contributing factors of operative events, also from a positive viewpoint, thus leading to more accurate corrective actions

and sharing lessons learnt. Workplaces have established new HF-focused procedures for improving recruitment and occupational health care processes and colleague-to-colleague mental first aid, fostering recovery from post-incident reactions. HF thinking and the toolkit have provided ways to have open discussions at the workplace. For example, managers are better able to have constructive discussions on safety with their employees. HF projects have made it easier to motivate and commit people to the development of safety by offering a positive starting point. However, clear boundaries can also increase the sense of safety: abuse or arrogant actions that undermine safety must result in appropriate sanctions. Bad practices can be identified and delimited.

Limitations

The HF Tool has been evaluated using Reason's (2008) six criteria on what a proper accident investigation tool should consist of. According to these criteria, the HF Tool fits the users' knowledge and understanding and helps make sense of situations. It is easy to communicate and share. However, it is not able to find all possible latent factors or anticipate future events or the functionality of processes. Moreover, the study conducted in the nuclear industry has shown that the strength of the HF Tool is its applicability, despite limitations in tackling the systemic nature of complex intertwined systems. Thus, it is best combined with other models or methods.

Relevance to Congress Theme

This study creates new theory and practice for industry and academia, to improve safety by considering human contribution. It utilises knowledge of individual, work and organisational psychology combined with engineering and pedagogics.

Relevant UN SDGs

Our SDGs are safety, health, and well-being. We believe that our study findings will facilitate workplaces' future climate actions.

Keywords: Human factors, occupational safety, safety management

Symposium S018

Proactivity in the context of time

Shereen Fatimah, Singapore Management University, Singapore; Anita Starzyk, NEOMA Business School, France

science

Introduction. Workplace proactivity is a process in which employees create a positive change by identifying and taking action on opportunities or problems in the work environment (Frese & Fay, 2001; Parker, Bindl, & Strauss, 2010); which in turn has far-reaching implications for the reputation and competitive advantage of the organization (Jacob, Frese, Krauss, & Friedrich, 2019). However, as these proactive behaviors also challenge the status quo at work, employees' attempts to be proactive may not be uniform across time. Specifically, the obstacles that employees encounter (e.g., managerial resistance to voice) or benefits that they accrue across time (e.g., authenticity) may amplify or curtail their efforts to be proactive. Importantly, these proactive trajectories (or silence) across time in turn has implications for organizations' ability to adapt to changes and opportunities in the work environment. Thus, in this symposium, we explore the temporal dynamics that underlie employees' proactive behaviors and how it unfolds across time.

Research and Practical Implications. This symposium which spans different proactive behaviors, time frames (short-term vs. long-term processes), and methodologies, offers new theoretical and practical insights:

Zhang et al integrate research on work design and career theory to develop strategies to improve employees' career progress. Through a multi-wave study, they find that employees' growth career mindset influences their job crafting strategies (strength vs. interest focused) which impact their career satisfaction and employability.

Fay & Strauss explore voice behaviors as an avenue for employees to express their authentic self in the workplace. Across two experience sampling studies, they find that daily promotive voice leads to daily authenticity which in turn has implications for employees' daily motivation and life satisfaction.

Anita Starzyk takes a qualitative and longitudinal approach to unpacking when and why employees persist to voice ideas despite initial pushback from managers. The preliminary findings indicate that employees' decision to persist in their voice efforts is contingent on the issue and past experiences of managerial neglect.

Weiss and Zacher apply social identity theory to explain the dark side of employee silence. In a longitudinal study, they find that over time, employees' silence lowers their organizational identification and heightens incivility towards others.

Michael Frese reviews the research on voice and personal initiative and puts forth future directions for the literature. In this review, he highlights the need to explore the recursive influences of personal initiative and voice and the contextual conditions that facilitate these reciprocal relationships across time.

Relevance to Congress. This symposium contributes new knowledge to ways in which employees, managers, and organizations may adapt to the 'changing world of work'. By paying close attention to how employees' proactive behaviors unfold across time, this research unpacks the intra-individual, inter-personal, and contextual mechanisms that enable employees and managers to facilitate

positive consequences for change-oriented behaviors and adapt to the changing demands in the workplace.

Overall Conclusions. Through a focus on temporal dynamics, this symposium sheds light on the nuances through which the trajectories of proactive behaviors and its consequences may take shape. By contributing new knowledge on when and why proactive behaviors may be strengthened or weakened across time and the dark side of these trajectories, the symposium also identifies practical strategies for employees and managers to adapt to the future of work.

Paper 1

Job crafting in the career context: How growth career mindset relates to career satisfaction and employability via different job crafting strategies.

Sharon Parker, Curtin University, Australia; Zhen Wang, Renmin University of China, China; Zijun Cai, Beijing Normal University, China; Fangfang Zhang, Curtin University, Australia

Research Goals and Theoretical Background. Due to the increased career mobility and flexibility, individuals are supposed to take more responsibility to manage their job and career. It has been indicated that employees can engage in proactive behaviours that promote self-management at both the job and the career level. An important form of proactive behaviour focused on the job level is job crafting, which has been shown positive effects on both individuals' jobs and career. However, existing job crafting research predominantly focused on the changes to one's job (e.g., changes to tasks and relations, or changes to job resources and demands) and omitted personal goals or motives in the job crafting process. Research has indicated that individuals could have different goals in job crafting: crafting to better utilize one's strengths (job crafting towards strengths, JC-strengths) or crafting to better match one's interests (job crafting towards interests, JC-interests). Research has shown that the two different job crafting strategies lead to different outcomes and has called for more investigation into their distinct effects. The purpose of this study is to bring together work design and career theory in the examination of how individuals' growth career mindset stimulates two job crafting strategies (i.e., JC-strengths and JC-interests), and the distinct effects of the two job crafting strategies on employee subjective career success reflected by career satisfaction, internal marketability, and external marketability.

Design. Two-wave data were collected from a company located in Eastern China. Demographics and growth career mindset were measured at the first wave. Job crafting and career outcomes were measured at each wave. 302 participants completed surveys at both waves. Path analysis was conducted using MPlus 8.3 to examine the proposed research model and hypotheses. We controlled for T1 career outcomes to improve the robustness of our results. We controlled for the demographic variables (i.e., gender, age, education, and job tenure) as these factors may affect career outcomes. These demographic control variables did not change our results; thus, for the purpose of parsimony, demographic variables were not included in our final model.

Results. T1 growth career mindset was positively related to T2 JC-strengths ($\beta = .29$, $p < .001$) and T2 JC-interests ($\beta = .23$, $p < .001$). Both T2 JC-strengths ($\beta = .28$, $p < .001$) and T2 JC-interests ($\beta = .15$, $p = .04$) were positively related to employee T2 career satisfaction. T2 JC-strengths was only positively related to T2 internal marketability ($\beta = .33$, $p < .001$) while T2 JC-interests was only positively related to T2 external marketability ($\beta = .30$, $p < .001$). JC-strengths mediated the positive relationship between growth career mindset and career satisfaction ($\beta = .09$, 95% CI [.04, .16]), and the relationship between growth career mindset and internal marketability ($\beta = .12$, 95% CI [.05, .20]). JC-interests mediated the positive relationship between growth career mindset and external marketability ($\beta = .08$, 95% CI [.03, .16]). However, the indirect effect of growth career mindset and career satisfaction via JC-interests were nonsignificant ($\beta = .04$, 95% CI [.00, .09]).

Limitations. The main limitation of this study is that we cannot draw causal conclusions of our findings due to the research design. Moreover, situational factors may interact with personal characteristics to affect individuals' job crafting behaviours, which we did not investigate in this study.

Research and Practical Implications. This study advances research on both work design theory and career theory by explaining how career mindset shapes individuals' job crafting behaviours, which in turn leads to distinct effects on their career satisfaction and employability. Moreover, this research provides significant insights and guides for individuals and organizations to improve employees' career satisfaction and employability via crafting one's job to better use one's strengths and match one's interests.

Relevance to Congress Theme. This study is relevant to the Congress Theme as it addressed one of the major challenges that employees are facing in today's changing world and in future work, that is how to proactively maintain their employment and achieve a successful career.

Relevant UN SDGs. This study is relevant to SDG 8 "Decent work and economic growth". It helps to address unemployment and boost productivity by enhancing employees' employability. It also helps to improve employees' job quality via job crafting.

Keywords: Job crafting, Growth Mindset, Career Success

Paper 2

Letting my true self speak: How daily promotive voice fosters authenticity and satisfaction with life

Doris Fay, University of Potsdam, Germany; Karoline Strauss, ESSEC Business School, France

Research Goals. Authenticity, defined as the "the sense or feeling that one is currently in alignment with one's true or genuine self, that one is being his or her real self" (Sedikides et al., 2017, p. 521), is an important and positive experience for human beings. Studies show that employees' experience of authenticity benefits both individuals and organizations. Accordingly, research has investigated how organizations can encourage authenticity, focusing on how leaders can promote the experience of authenticity in their followers, or how authenticity can be fostered through work design, organizational climate or culture. However, employees are not only passive respondents to the organizational context. Instead, they may find avenues to align their behavior with their true self and express their authentic values at work through their discretionary behavior. The aim of our paper is thus to explore the active role of individuals in their experience of authenticity.

Theoretical Background. We propose that voice behavior, employees' discretionary communication of suggestions or concerns aimed at affecting change in the organization is an important avenue through which individuals express their "true self" at work. Voice may enhance the experience of authenticity because it entails the two key conditions necessary for authenticity to emerge. First, the experience of authenticity requires to have the sense that the behavior is self-authored (Ryan & Ryan, 2019, p. 99). Voice behavior involves employees going above and beyond the expectations of their job role, providing an opportunity to experience one's behavior as self-authored. Second individuals need to have "the subjective experience of alignment between one's internal experiences and external expressions" (Roberts et al., 2009, p. 151). Speaking out about work-related improvements and concerns provides an organizationally sanctioned avenue for employees to leave the path of prescribed work behaviors and instead align their behavior, i.e., their verbal expressions, with their thoughts, feelings, and values. We furthermore expect the effect of promotive voice on authenticity to be stronger than the effect of prohibitive voice, because the former (advancing suggestions for improvement) allows for more self-expression than the latter (flagging up work problems). We finally propose that the experience of authenticity entails beneficial consequences for individual well-being. Drawing on previous research on the well-being implications of authenticity (e.g., Kernis & Goldman, 2006; Wood et al., 2008) and a recent integration of the authenticity literature (Cha et al., 2019), we propose that authenticity results in higher satisfaction with life, and that effect of authenticity on life satisfaction is mediated by the satisfaction of psychological needs and personal resources. Thus, our model implies a serial mediation in which the expression of voice positively affects the experience of authenticity, which in turn enhances need satisfaction (autonomy, relatedness, competence) and contributes to personal resources (self-esteem), which finally contribute to satisfaction with life.

Design. We tested our model with two daily diary studies (each n gt 100, k gt 400). Study 1 was conducted with full-time employees whom we recruited via an online access panel. Participants completed one day-level survey at the end of each workday over four consecutive workdays. Study 2 participants (service sector employees) completed four surveys each day (morning, noon, afternoon, evening) over five consecutive workdays.

Results. We analyzed the data with multilevel structural equation modeling. Findings of Study 1 indicate that daily promotive, but not prohibitive voice, is positively associated with daily

authenticity. This effect reached through to daily satisfaction with life, mediated by autonomy need satisfaction and self-esteem. Study 2 replicates the findings. Daily morning promotive voice but not prohibitive voice is positively associated with afternoon authenticity. This effect reached through to end-of-day life satisfaction, mediated by afternoon autonomy need satisfaction and afternoon self-esteem.

Limitations. Even though in Study 2 the measures were obtained in the temporal order implied in our model, we must be careful with conclusions regarding causality. Future research may obtain ratings of voice from differences sources (e.g., supervisors, peers).

Conclusions. Our research highlights the active role that individuals have in their experience of authenticity at work.

Relevance to the Congress Theme. Organizations operating in the present and in the future will rely on organizational members' input in form of voice; therefore, we need to fully understand its consequences.

Relevant UN SDGs. Findings relevant to understand workers' well-being at work.

Keywords: Voice, Authenticity, Life Satisfaction

Paper 3

To speak out again or not? A qualitative exploration of how employees make decisions after unheeded voice attempts

Anita Starzyk, NEOMA Business School, France

Research goals. Employee voice is not always welcome. Managers can resist or disregard when employees speak about work-related concerns or ideas for improvement (Burris et al., 2017; Lam et al., 2019). The dominant perspective is that employees will turn silent when managers neglect their voices (Bashshur & Oc, 2015; Morrison, 2014). In contrast, some researchers have suggested that employees can endure managerial neglect and sustain their voice (King et al., 2019; Lam et al., 2018). However, the question remains when and why employees choose to speak out again, even after initial pushback. I aim to support employees in shaping their voice attempts to become more effective and sustainable in bringing about positive change at work.

Theoretical background. The research on employee voice, silence, and issue selling has focused on employees' initial decisions, general motivations, and the means of how they speak out or remain silent (e.g., Milliken et al., 2003; Morrison, 2011; Dutton et al., 2001). By weighing up the implications of voice versus silence for themselves and others, they decide whether speaking out or remaining silent is fruitful and advantageous. However, employees must question and re-evaluate their previous decisions when their initial attempt at voicing an issue has failed. Consequently, I focused on how employees re-engage with this decision-making process and which factors they emphasized when managers rebuffed employees' initial aspirations and expectations.

Approach. I interviewed 19 employees monthly over three months following a semi-structured qualitative protocol. I chose this approach because experiences of managerial neglect are common but not frequent, and the process of speaking out again unfolds over several weeks. In the first semi-structured interviews, I identified issues that had fallen on deaf ears or that employees had struggled to implement. In the two follow-up interviews, I enquired whether and why employees had opted to (not) speak out about those issues again. In total, I conducted 57 interviews, on average of 83 minutes at the first meeting, 45 minutes at the second, and 43 minutes at the third. The 19 interviewed employees worked in various positions and industries. They were 21 to 68 years old, and six had managerial responsibilities.

Findings. Managerial neglect often triggered a re-evaluation. Adapting to the given circumstances, employees re-evaluated the relevance of the issue and the implications of (not) voicing it again. The preliminary thematic analyses indicated that their re-evaluation was impacted by two significant aspects: (1) different time frames and (2) various stakeholders. Regarding time aspects, employees focused mainly on the present but also took into account short-term and longer-term perspectives. Depending on the issue, employees identified themselves, their relations, their managers, their colleagues and co-workers, and the organization as relevant stakeholders. Importantly, employees did not consider all aspects thoroughly. The salient aspects depended on the employee, the issue, and the manager. Finally, their decision-making could further generalize from this particular issue to impacting similarly themed issues or their future voice and silence more broadly.

Limitations. This approach captures accessible cognitive processes that employees can reflect on and verbalize. Future studies could complement this research with experimental approaches to investigate implicit and subconscious processes.

Conclusions. Employees do not immediately turn silent. Their decision to (not) speak out again depends on the time frames and stakeholders they consider in the decision-making process. Adopting a changed time frame and taking more or other stakeholders into account impacts how they re-evaluate the importance and the consequences of not following up on the rebuffed issue. These differences in decision-making may explain why some employees believe in getting heard and continue striving for change.

Relevance to the Congress Theme. Most employees reflect on how they can continue to have a voice, which issues they should address, and how they should broach them. I contribute to empowering employee voices further. This study proposes an extended decision basis for employees to consider after initial setbacks: Which time frames and stakeholders are relevant in the context of the particular issue? Is the managerial neglect relevant only for this issue or, more broadly, for similarly-themed issues and their overall voice? This extended decision basis can enable employees to be better heard and sustain their motivation to speak out again.

Relevant UN SDGs. This study fits within the goals of (1) enabling decent work and organizational growth and (2) promoting the good health and well-being of employees. The findings can support employees to continue pushing organizations to change continuously for the better while maintaining their engagement and well-being.

Keywords: Voice, Managerial Reactions, Qualitative

Paper 4

Still waters run deep – and may be dangerous: How employee silence affects workplace incivility over time.

Mona Weiss, Freie Universität Berlin, School of Business and Economics; Hannes Zacher, Leipzig University, School of Psychology

Research Goals. Employee silence—the conscious withholding of potentially important information, suggestions, or concerns by employees—is a widespread phenomenon in organizations and can have detrimental consequences for organizational functioning and employee well-being. Even though it has been shown that silent employees often psychologically withdraw from their workplace, scholars have so far neglected the possibility that this withdrawal, over time, could make employees more prone to engage in negative workplace behavior. Thus, we aimed to expand our theoretical understanding of silence by investigating whether silence, over time, could also lead employees to harm other people at work.

Theoretical Background. Drawing on social identity theory, we propose that silence that is motivated by fear and resignation (i.e., quiescent and acquiescent silence) relates to lower subsequent organizational identification, which, in turn, relates to higher instigated incivility over time. This is because employees who are silent are likely to feel that their own personal goals and identity cannot be aligned with their organization. This should lower their feeling of "oneness" and identification with their organization. Thus, we hypothesize:

H1a: Acquiescent silence is related to lower subsequent organizational identification.

H1b: Quiescent silence is related to lower subsequent organizational identification.

H2: Organizational identification is related to lower subsequent instigated incivility.

H3a: Acquiescent silence has a positive indirect effect on subsequent instigated incivility through lower organizational identification.

H3b: Quiescent silence has a positive indirect effect on subsequent instigated incivility through lower organizational identification.

Design. We tested our model using five waves of longitudinal data across four months from 609 employees working in different industries. We analyzed our longitudinal data using a RI-CLPM. In contrast to the traditional CLPM, which confounds between- and within-person effects, the RI-CLPM allows for decomposing between- and within-person variance. Moreover, the RI-CLPM provides an assessment of the stability of the variables over time (by including auto-regressive paths), as well as a simultaneous test both of the hypothesized effects of silence on organizational identification, and on instigated incivility respectively, and of the reverse causal effect of instigated incivility on organizational identification, and silence.

Results. Supporting H1a, results showed that acquiescent silence related to lower subsequent organizational identification (B = -.106, SE = .035 p = .003). Moreover, as predicted by H2, lower organizational identification was related to increased instigated incivility at the subsequent measurement point (B = -.042, SE = .018 p = .023). The predicted indirect effect (H3a) was significant at B = .004; 95%CI = .001 to .011. Contrary to predictions (H1b & H3b), no significant effect of quiescent silence on organizational identification emerged (B = .001, SE = .039, p = .978).

Limitations. Because our measures rely on self-report data future research should obtain data on silence and instigated incivility from other sources, such as co-workers (silence), or supervisors (incivility).

Research and Practical Implications. Overall, this study expands the literature on employee silence, organizational identification, and workplace incivility. Our study is the first to demonstrate that employees who do not speak up because they feel that their input is futile may subsequently dissociate from their organization and harm other people at work. We also extend previous research on workplace incivility that has focused on more apparent predictors such as trait anger or conflict management styles. Thus, organizations should identify and target chronic patterns of silence among employees.

Relevance to the Congress Theme. Workplace change is stimulated by employees who speak up and halted or even impaired when they remain silent. Our findings offer important insights into the motives of silence and their longer-term implications for employees and their organizations.

Relevance to UN SDGs. One important goal laid out by the UN SDGs is to promote socially sustainable and inclusive workplaces. This includes identifying patterns and sources of maladaptive workplace behaviors such as instigated incivility that could harm interpersonal relationships and individual well-being.

Keywords: Silence, Organizational Identification, Incivility

Symposium S019

The within- and between-person dynamics of proactive behavior

Alina Gerlach, Department of Management, Technology, and Economics, ETH Zurich, Zurich, Switzerland; Zitong Sheng, Future of Work Institute, Faculty of Business and Law, Curtin University, Perth, Australia

science

What will be covered and why. In today's world of work, employees need to cope with increasing amounts of complexity and uncertainty. For doing this successfully, proactivity, defined as "making things happen" (p. 828; Parker et al., 2010), has been highlighted as a crucial competence. Individuals differ in their propensity for proactivity, but proactive behavior is also influenced by and shapes individuals' social context. By studying within- and between-person processes of proactivity, a fuller understanding can be gained of how supportive environments for proactivity can be created. The four studies in the symposium cover different kinds of proactive behavior (e.g., feedback seeking, job crafting, personal initiative) and investigate different avenues of how to conceptualize individual proactivity dynamics (e.g., emotional regulation, goal striving) both from within- and between person perspectives. Four contributions are being made by research teams from the Netherlands, Switzerland, Australia, New Zealand, and the United Kingdom. Yashan and colleagues study the reverse relationship from proactivity to emotions in a daily diary design by investigating the effects of personal initiative on intraindividual emotional exhaustion via a dual-pathway model that integrates a resource-gaining and resource-depleting mechanism and proactive personality. Gerlach and Grote develop a theoretical model of how within-person emotional responses to different degrees of uncertainty at work trigger feedback seeking and discuss implications for studying the dynamics of feedback seeking on a daily and weekly level. Keller and colleagues take a work design and goal theory perspective in a weekly survey on how feedback availability (from the job versus others) – which eases enacting proactive behavior - helps employees to adapt and regain clarity about their work tasks during change processes and show that it positively influences task proficiency. Klonek and colleagues highlight possible negative effects of proactivity, which individuals engaging in proactive behaviors should also be aware of: In an experimental study they find negative affective reactions and antagonistic reactions by coworkers (e.g., uncivil behavior, gossiping) towards job crafters. The symposium's discussant Uta Bindl, a distinguished proactivity scholar, accentuates the theoretical, methodological, and practical challenges and implications from the presented research.

Relevance to the congress theme. As today's workplaces shift constantly, organizations call their employees to be proactive and engage in self-managing their work experiences more than ever. Proactivity is a key requirement for employees to manage the challenges well as the changes coming with new models of work and emerging economic, societal, and technological changes. The symposium helps to integrate what we know about processes of self-regulation and of relevant social processes involved in effective proactive behavior.

Research and practical implications. This symposium suggests that within-person approaches are relevant to understand employees' internal mechanisms that spark or hinder the positive effects of proactive behavior on stress, well-being, and performance. The symposium also advances our theoretical understanding of how within- and between-person processes may interact. Practice can benefit from this understanding of when and why employees self-initiate proactivity and what outcomes stem from it to tailor organizational support to cultivating successful proactive behaviors.

Overall conclusions. This symposium sheds light on processes of proactivity that relate to within- (e.g., emotions and goal-related processes) and between-person dynamics (e.g., through other individuals at work), and highlights processes that can buffer uncertainty or emotional exhaustion and can endorse individual well-being, motivation, and performance.

discussant: Uta K. Bindl, King's Business School

Keywords: proactivity, self-regulation, research design

Paper 1

The effect of daily personal initiative on emotional exhaustion: Integrating resource-gaining and resource-depleting mechanisms

Daryna Yashan & Lixin Jiang | School of Psychology, University of Auckland, New Zealand; Zitong Sheng, Future of Work Institute, Faculty of Business and Law, Curtin University, Perth, Australia

Research goals and theoretical background. Proactive behaviour overall and personal initiative in particular have become desired characteristics of modern employees. Despite the amount of research on proactive behaviour, its effects on well-being outcomes vary. Scholars have discussed its benefits as well as adverse consequences. This study draws upon Cangiano and Parker's (2015) dual-pathway theoretical model and integrates the resource-gaining and resource-depleting mechanisms of daily proactive behaviour. Specifically, the resource-gaining path characterises the positive spiral of well-being benefits stimulated by proactive behaviour. In contrast, the resource-depleting path suggests that individuals' engagement in proactive behaviour consumes energy and as a result, they experience more adverse outcomes such as increased emotional strain and role overload. We further suggest that one's disposition to be proactive in nature (i.e., proactive personality) influences which mechanism is more dominant. To the best of our knowledge, this study is the first to integrate the two conflicting streams of research by investigating the distinct daily resource-gaining and resource-depleting mechanisms of proactive behaviour.

Design and methodology. This study focused on one specific type of proactive behaviour, personal initiative. Utilising a daily diary design, we analysed the effect of daily personal initiative behaviour at work on one's experienced emotional exhaustion at the end of the working day. We hypothesised that daily personal initiative activated a resource-gaining path through positively influencing one's daily work goals progress (H1), which in turn reduces end-of-day emotional exhaustion due to boosting employees' resources (H2). On the other hand, daily personal initiative was also proposed to activate a resource-depleting path, such that one's engagement in daily personal initiative behaviour directly drains resources and increases the end-of-day emotional exhaustion (H3). In addition, we also proposed the moderating role of proactive personality in enhancing the effects of the resource-gaining path (H4) and weakening the effect of the resource-depleting path (H5).

Results and conclusions. Using daily diary survey data of 156 New Zealand employees across five working days, this study found support for the resource-gaining path but not the resource-depleting one. Specifically, daily personal initiative behaviour was found to significantly and negatively affect the end-of-day emotional exhaustion both directly ($\gamma = -.18$, $p < .001$) and via the mediator of daily work goals progress ($\gamma = -.09$, $p < .001$; 95% CI = [-.13, -.05]). Our findings therefore suggest that engaging in initiative behaviour in the morning reduces the level of emotional exhaustion at the end of the working day by helping one make more progress on one's work goals. In addition, engaging in personal initiative also directly reduces end-of-day emotional exhaustion. These findings together indicate that employees' engaging in proactive behaviour has immediate well-being benefits on a daily basis.

Additionally, proactive personality only significantly moderated the negative direct effect of daily personal initiative on the end-of-day emotional exhaustion ($\gamma = -.14$, $p < .01$), but not the indirect effect via daily work goal progress ($\gamma = .07$, $p > .05$). The higher one's proactive personality is, the more strongly that daily engagement in personal initiative behaviour lowers emotional exhaustion. This result suggests that proactive behaviour engenders more well-being benefits for people who are

proactive by nature. In comparison, proactive personality did not significantly moderate the effect of daily personal initiative on daily goals progress, indicating that personal initiative helps people make better progress on work goals irrespective of one's proactive personality. In other words, this result suggests that the benefits of daily engagement in proactive behaviour on work goals progress is more universal – showing personal initiative in the morning increases one's work goals progress at the end of the workday, whether the person is proactive by nature or not.

Relevance to the congress theme/UN SDGs. Theoretically, this study emphasises the immediate benefits of daily engagement in proactive behaviour by examining the dynamic relationship between morning personal initiative and end-of-day emotional exhaustion. Our study also makes a methodological contribution by utilising a daily diary design, which provides strong empirical evidence on the focal relationships. This study aligns with the congress theme of "The Future is Now: the changing world of work". Proactive behaviour by nature is future-oriented and focuses strongly on "making things happen" (Parker et al., 2010; p. 828), findings of the current study further highlight the value of such behaviour—proactively striving to bring about change in the environment and oneself to achieve a different future has immediate well-being benefits for employees themselves. The positive effect of employee proactive behaviour is also closely connected to the UN Sustainable Development Goal of promoting good worker health and well-being.

Keywords: daily initiative, emotional exhaustion, dual-pathway model

Paper 2

The role of emotional states and perceptions of uncertainty in feedback seeking behavior

Alina Gerlach & Gudela Grote | Department of Management, Technology, and Economics, ETH Zurich, Zurich, Switzerland

Theoretical background. Due to its importance in navigating the high levels of uncertainty in current organizations, proactive behavior such as feedback seeking has attracted increasing attention. Individuals who seek feedback proactively aim to acquire more information about their goal attainment and work performance to align their efforts with the requirements of their surroundings. Feedback seeking is conceptually closely tied to uncertainty, but within-person approaches on how daily-level changes in uncertainty perceptions address changes in feedback seeking behavior remain scarce. This theoretical contribution intends to examine the connections between individual perceptions of uncertainty and different types of feedback by establishing the role that emotional states play in the feedback seeking process. We draw upon current frameworks of uncertainty self-regulation as well as proactivity and emotions to outline a contingent model of how these components interact. By discerning different types of uncertainty and the emotional responses they engender, we can observe that individuals could seek feedback in different ways to learn and develop themselves professionally at work.

New perspectives/Contributions. Research on feedback seeking behavior is moving away from the understanding that feedback seeking is mainly motivated by an uncertainty reduction motive, as uncertainty itself does not always lead to feedback seeking. The underlying idea is that individuals are averse to feeling uncertain at work, and when they do, they seek for feedback to reduce it. However, feedback does not always reduce uncertainty, and research has revealed numerous other motivational states that influence feedback seeking. Given that asking other workplace members (e.g., supervisors, peers) is a perquisite for active feedback seeking, one major source of uncertainty is the social context of work. This social context is likely producing other perceptions of uncertainty than task-related uncertainty, which gives less room for perceptions of self-threat to one's identity. In this research we propose a novel lens on this context by investigating the intraindividual processes that drive these relationships. We further propose that one main mechanism that links feelings of uncertainty and feedback seeking on a micro-level are individuals emotional states at work. Drawing from theory on proactivity and emotions, we propose that if individuals experience uncertainty about themselves that stems from the task versus the self, it will set off different emotional responses (positive, ambivalent, negative), which influences feedback seeking. We further give reason to the fact that not all individuals encounter uncertainty daily. Given that some extent of uncertainty is needed so that individuals can develop professionally and learn at work, we argue that, under conditions of certainty, individuals will engage in different types of proactive feedback seeking to arouse some extend of self-uncertainty with the goal of favoring professional development and learning. We discuss this proposition for states of task-related and social certainty.

Conclusion. With this research, we aim to establish relevance of emotional states in feedback seeking and integrate the interactive effects of perceived uncertainty and emotional responses. Our research advances theory of within-person processes driving feedback seeking by conceptualizing the role of perceived uncertainty about the self as a driver of emotional states at work. Given that it is yet unclear whether intra-individual processes of feedback seeking are happening on a weekly- or daily-level we will discuss initial results from a pilot study in relation to the proposed theoretical contribution. We inform practice of intraindividual dynamics that should be accounted for when

designing workplaces and leadership processes by proposing different influences of uncertainty on emotional states and feedback seeking.

Relevance to congress theme. Given that the world of work is already changing, our study emphasizes the significance of different perceptions of uncertainty at work and their impact on behavior such as feedback seeking in today's workplace. We provide a theoretic solution to inconsistencies in feedback seeking research about its relation to uncertainty while contributing with a conceptional framework that aims to better understand individual emotional responses to uncertainty.

UN SDGs. This research is related to the UN Sustainable Development Goals of ensuring good health and well-being for individuals who experience uncertainty at work, along with decent working conditions.

Keywords: feedback seeking, emotions, uncertainty self-regulation

Paper 3

Am I on the right track? The role of feedback availability during change processes

Anita C. Keller, Department of Psychology, University of Groningen, The Netherlands; Sharon K. Parker & Caroline Knight | Centre for Transformative Work Design, Future of Work Institute, Faculty of Business and Law, Curtin University, Perth, Australia

Research goals. Many employees started working from home, without any preparation or prior experience, due to COVID-19 lockdown measures. Feedback availability supports employees to cope with new, challenging situations as it helps them to understand their tasks and roles within the company, which in turn allows them to set relevant goals. Typically, the literature distinguishes two sources of feedback availability, that is, feedback from the job and feedback from others. In this study, we investigate the different temporal patterns of feedback from the job versus others, and their dynamic relationship with motivational states and task proficiency, to understand how employees adapt and regain clarity about their work tasks during change processes.

We contribute to the literature in three ways. First, work design is dynamic and changes regularly. Accounting for such changes potentially offers insights into how employees manage to successfully adapt. Second, the work design literature typically does not compare the functioning of feedback from job versus others. Although feedback from others serves similar functions as feedback from job (i.e., goal setting), it can also contain a social message about one's current and future standing in the organization. Third, we focus on procrastination as a transmitting process between feedback and proficiency. Procrastination refers to delaying work despite knowing that the delay is costly and can signal a state of feeling overwhelmed and a lack of motivation. Feedback might be well suited to help employees overcome procrastination as it provides clarity what needs to be done at what quality and speed.

Theoretical background. Drawing from work design and goal theories, we propose that feedback has beneficial effects on proficiency via decreased procrastination. Feedback from the job gives employees cues if they are making progress in the right direction to achieve their work goals which decreases procrastination. Similarly, feedback from others is thought to have decreasing effects on procrastination as the feedback signals accountability and can include constructive help to solve arising challenges. However, once employees experience increases in proficiency, they will have learned which cues from the task to look for and have adapted to the changes in their environment. These experiences increase feedback from the job subsequently. In contrast, we assume continued feedback from others to take away attention from proficiently executing the tasks and once employees understand their role, they no longer require feedback from others, indicated by a subsequent decrease in feedback from others.

Methods. We collected data from 444 full-time employees working from home during the early stages of the pandemic. Participants were invited to complete a weekly questionnaire for four weeks. Participants were 41.6 years old (SD = 10.9), 70% were female, worked 36.1 hours per week over the four weeks of observations (ranging from 25.1 to 36.9, average SD = 13.1), worked for 6.1 years with their current organization, and held diverse occupations. We used validated scales to assess feedback from job, feedback from others, procrastination, and proficiency.

Results. After establishing measurement invariance, we estimated random intercept cross-lagged panel models to test the reciprocal assumptions over time. At the within-person level, increases in

feedback from both sources led to subsequent increases in proficiency directly (job: b = .10, p <.05; others: b = .08, p < .05) and via increases in procrastination (job: b = -.17, p <.05, b = -.13, p < .05; others: b = -.10, p <.05, b = -.11, p < .05). In addition, increases in proficiency led to subsequent increases in feedback from the job (b = .25, p < .01), but there was no lagged effect on procrastination or feedback from others.

Conclusions. By focusing on the temporal patterns of the two types of feedback, we illustrate the different functioning of feedback availability during change processes. Although both types of feedback increase proficiency directly and indirectly via procrastination, we only found reciprocal relationships for feedback from the job. Employees may have learned how to interpret cues from their tasks to understand if they make progress in the right direction. Presumably, feedback from others signals a clear discrepancy between expected and delivered proficiency. Our results indicate that employees need feedback from others to adapt to fundamental changes in their work environment as it may provide opportunities to discuss action plans.

Limitations of our study include lack of information on the quality of feedback (e.g., valence) and use of self-report for proficiency.

Relevance to congress theme/UN SDGs. Understanding how employees adapt to changes in their work not only fosters understanding of proficiency, but also contributes to the UN Sustainable Development Goal of promoting employee well-being.

Keywords: feedback availability; change processes; procrastination

Paper 4

The dark side of crafting: How does job crafting affect coworker reactions?

Florian Klonek & Sharon K. Parker | Centre for Transformative Work Design, Future of Work Institute, Faculty of Business and Law, Curtin University, Perth, Australia; Maria Tims, Department of Management and Organisation, School of Business and Economics, Vrije Universiteit Amsterdam, The Netherlands

Research goals. The research goal of this research project is to shed light on the consequences of individual crafting within interdependent contexts and its impact on coworkers. Job crafting is a form of proactive behaviour that entails employees' self-initiated alterations of job design and task features to match them with individual needs. Examples are taking on new tasks that suit their skills better or taking the lead in a project so that they are more in control of their work environment. Although much research has indicated benefits of job crafting regarding individual outcomes, more recent perspectives have highlighted that job crafting might also result in negative consequences since alterations of job boundaries can impact colleagues and coworkers.

Theoretical background. Job crafting refers to employees' self-initiated alterations of their job design and task features. While research has suggested that crafting has positive consequences for job incumbents, many tasks and roles are embedded within a collaborative or team environment. Hence, alterations of tasks, workload, and social relationships may elicit negative emotional reactions in proximal coworkers that work closely on interdependent tasks. Thus, we need a better understanding of the potential negative consequences of crafting with respect to affective and behavioural reactions. We hypothesized that certain job crafting behaviors (decreasing hindering job demands, increasing challenging job demands, and increasing structural resources) are associated with negative affective responses and antagonistic reactions in coworkers. With respect to antagonistic coworker behaviours, we focus on uncivil behaviors (low-intensity deviant behaviours with an ambiguous intent to harm) and gossiping (informal and negative evaluative talk about a person who is not present) about the job crafting coworker.

Design and methodology. We developed an experiment in which we manipulated job crafting behaviors from a fictional coworker. In the experimental simulation, participants are engaging in an immersive email collaboration task. In this task, participants are randomly assigned to a coworker who engages in four different types of job crafting (and a non-crafting control condition in which the fictional coworker did not craft and adhered to the requirements of the job descriptions). The job crafting manipulations were validated in a pilot study with N = 70 participants. In the main experiment, we sampled N = 197 participants. We present how the experiment allowed us to measure the extent to which participants engage in antagonistic coworker behaviors (i.e., uncivil communication towards the fictional coworker) and gossiping about the coworker. We measured affective reactions towards the job crafting coworker using self-report measures of affective resistance.

Results. Analysis of variance showed significant differences between crafting conditions on affective resistance towards the crafter, gossiping about the crafter, and uncivil behaviors towards the crafting coworkers. Contrasting crafting conditions with the control condition revealed that decreasing hindering demands crafting (and increasing structural demands) elicited affective resistance in comparison to coworkers from the control condition (who did not craft). Furthermore, decreasing hindering demands (and increasing structural demands) also elicited antagonistic

coworker reactiosn (i.e., gossiping) in comparison to the control condition. Crafting in the form of decreasing hindering demands and increasing challenge demands was significantly associated with uncivil behaviors from the participants. We discuss the initial results of this experiment and clarify a better understanding the affective and relational consequences of job crafting.

Limitations. One limitation is that the data were collected from a sample of undergraduate students, thus having limitations with respect to external validity.

Conclusions. We found that some job crafting forms can elicit antagonistic reactions and affective resistance towards the crafter. Thus, our study helps towards a better understanding of how crafting can harm coworker relationships. A practical implication is that employees should be carefully advised that only some forms of job crafting (e.g., increasing social resources) are helpful, while others could elicit negative coworkers' reactions. Future research could explore how context (e.g., high task interdependence) or attributions of the coworker (e.g., prosocial motives) might further worsen negative crafting effects.

Relevance to the congress theme. Research on job crafting is highly relevant to the congress theme "The Future is Now: the changing world of work." The changing nature of work means that workers are not only experiencing top-down changes with respect to when and how they work but also that jobs increasingly have more fuzzy boundaries that allow proactive behaviours like job crafting behaviours (i.e., employees make self-initiated changes to their jobs).

UN SDGs. The consequences of proactive employee behaviour (such as job crafting) are closely connected to the UN Sustainable Development Goal of promoting good worker health and well-being.

Keywords: job crafting, coworker reactions, affective responses

Symposium S020

Recent Developments on Mindsets and Cognitions at work

Federico Magni & Alina Gerlach | ETH Zürich

science

Content: This symposium will cover current research on mindsets in the work and organizational domains. Mindsets are defined as the beliefs people hold about specific characteristics—mostly about such characteristics being fixed or malleable—and have been studied in relation to several individual characteristics and other factors, including personality, intelligence, creativity, and stress. Since the groundbreaking work of Dweck and colleagues, mindset research has enjoyed high popularity because it combines theoretical contributions and tangible impact, often achieved through interventions. The research projects featured in this symposium extend the current literature on mindsets by looking at previously understudied mindsets, such as those related to uncertainty, socioemotional attributes, culture, and technological ability, and by linking mindsets to other fundamental cognitive processes. Specifically, Magni and colleagues develop and validate a measure of uncertainty mindset as a new and important construct with two dimensions (threat/opportunity and fixed/malleable) and relations to relevant work outcomes. Howe compares mindsets about cognitive and socioemotional attributes, finding in a multi-nation, large sample that people tend to have more fixed mindsets about the latter (e.g., empathy, emotional intelligence) than the former (e.g., intelligence). Chao and Lam look at how a growth cultural mindset can facilitate one's sense of competence in intercultural contexts by reducing intercultural rejection sensitivity, and test whether an environment supportive to intercultural learning amplifies this effect. Wong and colleagues study implicit beliefs about technological ability, and specifically how employees' growth digital mindset is impacted by their leaders' own digital mindset. Richner and colleagues take a neuroscientific perspective and not only study cognitive processes such as the ability to update one' knowledge and to inhibit automatized thinking as important predictors of ambidextrous behaviors, but also design an intervention aimed at improving these cognitive and meta-cognitive skills.

Relevance to the Congress Theme: The world is an increasingly complicated place and mindsets are not only a prevalent tool that we use to make sense of what is happening around us, but also a promising area of intervention for making people better able to cope with the challenges of the future of work. Specifically, uncertainty (in a post-Covid world), socioemotional skills (in a world where humans collaborate with AI and need to contribute what machines still cannot), and the ability to successfully manage intercultural exchanges and digitalization are critical factors for workers, managers, and organizations to thrive. Moreover, behaviors that allow people to cope with fast-changing and uncertain situations (e.g., ambidextrous behaviors) will be more and more necessary, and it is critical to understand how to foster the enactment of such behaviors via cognitive mechanisms, such as mindsets and cognitive flexibility.

Research and Practical Implications: This symposium highlights the relevance of mindsets and related cognitions in impacting relevant work outcomes in a rapidly changing social environment. It situates mindsets withing a wide nomological network, looking at antecedents of mindsets (e.g., leaders' mindsets, cognitive skills), comparing mindsets with each other (e.g., cognitive vs. socio-emotional, threat/opportunity vs fixed/malleable), and evidencing relevant consequences of mindsets (e.g., cultural adaptation, wellbeing, feedback seeking, creativity, ambidexterity). It also establishes the relevance of previously understudied mindsets, for instance those related to uncertainty, socio-emotional attributes, culture, and digital technology, as well as of how cognitive

flexibility works with mindsets in leadership trainings. Through the recruitment of large samples and the development of interventions, the research featured in this symposium not only provides relevant theoretical advancements to the mindset literature, but also offers important practical implications.

Conclusions: Overall, this symposium shows that mindsets and cognitions are critical for thriving in the current, complex organizational context, and it highlights the broad implications of mindsets and related cognitions at work. This stream of research combines solid theoretical grounding with practical impact and relevance, highlighting its potential for not only advancing knowledge, but also improving people's life and work thanks to this knowledge, often through interventions and by better understanding mindsets and their consequences. In addition, mindsets can support a more human-centered approach in the current organizational context by putting beliefs and attitudes center-stage.

Paper 1

Uncertainty mindset: scale development and nomological network of a new construct

Federico Magni, Laura Elaine Strittmatter & Gudela Grote | ETH Zürich; Sara Zaniboni , Università di Bologna; Julian Pfrombeck, Columbia University; Alina Gerlach, ETH Zürich

Research goals: Envisioning uncertainty mindset as a key predictor of people's attitudes and behaviors towards uncertainty, we conceptualize uncertainty mindset as a new construct, develop scales to measure its subdimensions, and test its convergent and divergent validity in comparison to other uncertainty-related constructs and other mindsets, as well as examine its nomological network. Our goal is to show that seeing uncertainty as malleable and as an opportunity positively relates to desirable work- and life-related outcomes.

Theoretical background: Research on uncertainty regulation is moving away from the conceptualization of uncertainty as something negative to avoid and minimize towards a more encompassing view of uncertainty as something that can be regulated in both directions—i.e., increasing and decreasing it. As people decide whether to reduce or increase uncertainty by comparing their uncertainty preferences with their perceived level of uncertainty around them, we advance uncertainty mindsets as a key predictor of uncertainty preferences. We build on existing mindset research (e.g., on growth mindset and stress mindset) and conceptualize two dimensions of uncertainty mindsets: uncertainty as threat vs opportunity, and uncertainty as fixed vs malleable. We expect people to generally hold relatively threat and fixed uncertainty mindsets and aim to link opportunity and malleable uncertainty mindsets to desirable states, attitudes, and behaviors, including wellbeing, reduced stress, creativity, feedback seeking, and proactivity.

Design/methodology: We developed scales to measure the four facets of uncertainty mindsets (threat, opportunity, fixed, malleable) through discussions within the research team as well as thanks to external expert feedback, including a scale development workshop. This resulted in 14 pairs of items (6 pairs for fixed/malleable and 8 for threat/opportunity). In a pilot study, we collected data on 141 employed participants to conduct EFA on this initial pool of items. Subsequently, we collected two-wave data from 679 employed participants to conduct CFA on the retained items, as well as test convergent and divergent validity, and the nomological network of the new scales in two domains (general life and work).

Results obtained: The results of the pilot study led us to exclude one pair of items from the fixed/malleable scale and two pairs from the threat/opportunity scale, leaving us with 5 and 6 pairs of items, respectively. The factor structure suggested that threat and opportunity mindsets were two separate constructs, whereas fixed and malleable mindsets were two ends of the same continuum. In addition, we found the fixed/malleable mindset to be different in the work domain and in the general life domain, whereas the threat and opportunity mindsets were both domain general.

Study 1 results confirmed the factor structure from the pilot study, with all items loading on the respective factor, and suggesting the following constructs as distinct: fixed/malleable mindset in life, fixed/malleable mindset at work, threat mindset, and opportunity mindset. Moreover, we found these mindsets to be distinct from both other mindsets (e.g., growth mindset, stress mindset, creativity mindset, ageing mindset) as well as from other uncertainty-related constructs both in life and at work specifically. Finally, threat and fixed mindsets were negatively linked, while opportunity

and malleable mindsets were positively linked to desirable outcomes, such as satisfaction, learning goal orientation, reduced stress, creativity, feedback seeking, career planning, and expansive agency.

Limitations: Our studies were conducted on convenience and online samples, so we need to collect data in real organizational contexts to enhance the generalizability of our findings. In addition, we need to complement our current work with experimental evidence to test the causality of the proposed relations.

Conclusions: We establish uncertainty mindset as a relevant and distinct construct, and we also evidence its dimensionality in terms of the threat-opportunity and fixed-malleable dimensions in life and at work. We create and validate item scales to measure these dimensions of the uncertainty mindset and showcase the links of these dimensions to relevant work and general life outcomes.

Relevance to the Congress Theme: In the recent years with pandemics, wars, globalization, and fast-paced technological advances, uncertainty is skyrocketing. This generates negative consequences for many people, threatening wellbeing and productivity. By proposing uncertainty mindset as a new construct, we not only want to show the relevance of such mindset on relevant work and life outcomes, but also set the basis for intervening on this mindset, with the goal of putting individuals in a position to benefit from uncertainty, for example by fostering lifelong learning, new career opportunities, and creativity.

Relevant UN SDGs: #3 Good Health and Well-Being, #4 Quality Education, #8 Decent Work and Economic Growth, #16 Peace, Justice, and Strong Institutions

Keywords: mindset, uncertainty, construct development

Paper 2

Fixed mindsets about socioemotional attributes versus cognitive attributes: A global study in 35 countries

Lauren Howe & Jochen Menges | University of Zürich; Laura M. Giurge, London School of Economics

Research goals: Empirical evidence demonstrates that empathy and emotional intelligence can be learned and developed. Meta-analyses find that both trainings on emotional intelligence and empathy induce increases. Yet we theorized that individuals may not broadly endorse the view empathy and emotional intelligence are trainable skills. Our research thus set out to examine whether working adults across the globe might hold more fixed mindsets about socioemotional attributes (i.e., believing they are static, difficult to develop) relative to cognitive attributes.

Theoretical background: Theories often describe empathy as innate and depict emotional intelligence as a disposition that is heritable to the same degree as personality traits. There is a general lack of measures that can be used at scale to reliably mark progress on the development of these attributes, which may give the impression that they are difficult to systematically develop. Reflecting this more fixed view of socioemotional skills, experts refer to such skills as "tough-to-teach intangibles." Given a large body of evidence illustrating that holding a more fixed mindset about attributes prevents individuals from developing them further, more fixed mindsets about these attributes could present a barrier to embracing these skills at scale for the future of work.

Design/methodology: We embedded an experiment in an online survey fielded to 18,605 working adults across 35 countries. Each participant completed a scale assessing fixed mindsets about one of four attributes (e.g., "People have a certain amount of _____, and they can't really do much to change it"). We randomly assigned each participant to complete the scale about either one of two socioemotional attributes (empathy, emotional intelligence) or one of two cognitive attributes (intelligence, programming aptitude). We also examined participants' valuation of socioemotional skills in the future of work via participants' ratings of the anticipated actual importance and desired importance of socioemotional versus technical skills in the future of work.

Results obtained: Across the globe, working adults viewed the socioemotional attributes (i.e., empathy and emotional intelligence) as more difficult to develop than the cognitive attributes (i.e., programming aptitude and intelligence). Fixed mindsets about empathy were particularly pronounced; it was seen as more fixed relative to emotional intelligence. Illustrating these differences, most working adults (55.5%) endorsed a fixed mindset about empathy and 50.8% of working adults endorsed a fixed mindset about emotional intelligence. In contrast, a minority of working adults endorsed a fixed mindset about intelligence (44.7%) and programming aptitude (43.4%). Participants with more fixed mindsets about socioemotional attributes predicted that these skills would be less valuable in the future of work relative to technical skills and also said that these skills should be less valued in the future of work.

Limitations: We found an association between mindsets about socioemotional attributes and future prioritization of these skills; further evidence is needed to determine causality. We assessed fixed rather than growth mindsets, but did so because this can minimize socially desirable responding.

Conclusions: To create a more human-centered future of work that complements technical expertise with fundamentally human skills like empathy and emotional intelligence, people may first need to be encouraged that these skills can be learned. Promoting empathy for the future of work may present a challenge, given that this attribute was seen as the most fixed of those examined. Institutions may need to take steps to promote growth mindsets about socioemotional skills in education and work experiences, such as presenting evidence that these skills can indeed be increased through trainings. As socioemotional learning programs proliferate in education, they could address such beliefs. Societal dialogues about socioemotional skills may need to be shifted to dispel the myth that such skills are set in stone.

Relevance to the Congress Theme: Socioemotional skills, and in particular empathy and emotional intelligence, are increasingly cited as key for the future of work. The World Economic Forum placed emotional intelligence on its list of the top ten skills employees need to remain employable and labeled empathy as a "must-have" for future leaders and organizations. Academic research also illustrates the importance of socioemotional skills in the future of work, suggesting that automation will result in increased jobs where these skills are valued. Yet our results suggest that to encourage individuals to train socioemotional skills to prepare for the future of work, society may need to address widespread fundamental misbeliefs about the nature of these attributes.

Keywords: mindsets, socioemotional attributes, cognitive attributes

Paper 3

From mindset to cultural competence: Understanding the effects of intervention and its boundary conditions

Melody Manchi Chao, Hong Kong University of Science and Technology; Elia Q.Y. Lam, University of Toronto

Research goals: The increasingly multicultural society presents challenges to organizations, from serving culturally diverse clients, building effective multicultural teams, to enhancing employee adjustment. Cultural competence, also known as cultural intelligence, refers to the ability of individuals to work effectively in culturally diverse settings. Although it is suggested to be a learnable attribute, little is known about whether and how cultural competence can be enhanced, and, more importantly, when it would flourish. This research draws on the literature on mindset to address these issues.

Theoretical background: Cultural mindset refers to the beliefs that attributes and knowledge about cultural groups are malleable or fixed. In intercultural interaction contexts, there are often uncertainties involved that might result in misunderstanding and setback. Having a malleable cultural mindset has been shown to be important in enabling sojourners to adjust to foreign cultures and promoting more positive intercultural negotiation outcomes. In short, becoming culturally competent often involves trial-and-error in learning how to deal with unfamiliar others in new environments. Therefore, a malleable cultural mindset can play an important role in developing cultural competence. Past studies have shown that anxious anticipation over potential rejection due to cultural group membership can be particularly salient in intercultural contexts. In order to enhance cultural competence, we argue that it is important to impart individuals with malleable mindsets to reduce their discomforts in and concerns toward intercultural interactions, enabling individuals to see potentially challenging intercultural situations as important learning experiences. Specifically, a malleable mindset reduces intercultural rejection sensitivity, which then increases their sense of competence in intercultural contexts (Hypothesis 1). Furthermore, the effect of mindsets would be contingent on the intercultural context. The literature on cultural intelligence is typically quiet about the impact of the cultural environment, as the environment is often assumed to be open to intercultural learning. We argue that, however, the positive effects of mindsets would only materialized in an environment that would support intercultural learning (Hypothesis 2). We examined these two hypotheses through two field experiments (Studies 1 and 2) and an online experiment (Study 3).

Design/methodology: Study 1 recruited 232 international exchange students to participate in a 2-part study. Before their departure (Time 1), participants completed baseline measures of their mindsets, intercultural rejection sensitivity, and cultural intelligence. During their overseas exchange (Time 2), the participants either received a malleable mindset intervention or no intervention. They then completed the same measures as in Time 1. Study 2 recruited 148 international exchange students. Before their departure (Time 1), participants either received a malleable mindset intervention or no intervention. They then completed measures of their mindsets, intercultural rejection sensitivity, and cultural intelligence. During their exchange overseas (Time 2), they completed measures that assessed their general, social, and academic adjustment experiences. Study 3 is an ongoing project in which we aim to recruit at least 950 participants online to complete a scenario study, which involves either a friendly or a hostile foreign cultural environment. Participants are randomly assigned to either the mindset intervention or no intervention. The study invovles a 2

(Environment: Friendly vs. Hostile) X 2 (Intervention: Yes vs. No) design. After the manipulations, their intercultural rejection sensitivity, and their perceptions and reactions toward the other culture would be assessed.

Results obtained: Structural equation modeling showed that across Studies 1 and 2, the mindset intervention was related higher sense of cultural competence through reducing rejection sensitivity. Study 2 further showed that the pre-departure intervention effect carried over to enhance cultural adjustment experiences when the students were overseas. As note, Study 3 is an ongoing project. We expect to find that the effect of the mindset intervention would only be effective when there is environmental affordance.

Limitations: This project represents an initial step toward enhancing intercultural effectiveness through mindset interventions. It mainly examines self-perceptions and attitude toward the other culture. Future studies could examine whether mindset interventions would influence interpersonal interactions in the long run.

Conclusions: This research suggests that intercultural competence can be learned through shaping mindsets.

Relevance to the Congress Theme:

In this rapidly changing world of work, it is important to impart our future workforce with the mindset to learn and adjust now to prepare them for the every changing future.

Paper 4

Spillover Effects of Leaders' Mindset About Technological Ability on Employees' Mindset in Contexts of Technology Induced Change

Katarzyna Adamska, BI Norwegian Business School; Laura Traavik, Kristiania University College; Elizabeth Solberg, Institute for Energy Technology; Sut I Wong, BI Norwegian Business School

Research goals: Digitalization, whether to increase workplace efficiency or to drive innovation, often requires implementing changes within the organization at various levels. Managing the changes needed to realize the potential benefits of digitalization can be challenging. The success of these changes could depend on the extent to which leaders and their employees believe in their own and other's ability to learn and adapt to new technology. In particular, people's implicit beliefs about the nature of technological ability and the extent to which it can be developed through dedicated effort, are held to constitute an important part of their "digital mindset." Like mindsets held about human ability in general, beliefs about the nature of technological ability frame people's way of seeing and interpreting digitalization initiatives, and shape their responses to the changes that digitalization requires.

Theoretical background: Extensive research shows that having a growth mindset —the belief that human ability is malleable and can be improved through effort—is advantageous across a range of achievement contexts. On the other, a fixed mindset —the belief that human ability is fixed and cannot be improved—is disadvantageous across a range of achievement contexts. However, little is known regarding the influence that having a growth or a fixed mindset about technological ability has on outcomes important for the success of digitalization initiatives. Notably, research has not addressed if leaders' mindset about technological ability (growth or fixed) can have a spillover effect on their employees' own mindsets about technological ability. Answering this research question is important, because a leader's ability to promote a growth mindset about technological ability among their employees is likely relevant for the success of digitalization initiatives.

Design/methodology: To address this research question, we conducted a vignette-based experimental study with 372 participants. The vignette in our study described an organization that was undergoing large digital changes, where the employees were expected to use some new technological tools in their daily work. Thus, the vignette refers to a situation that is both highly realistic and relevant for today's organizations and their employees, as the majority of them are experiencing or will experience considerable digitalization. Study participants were asked to place themselves in the position of an employee working in the organization described. We manipulated the digital mindset of the leader that study participants worked for in this organization. Specifically, participants were randomly assigned to work under (condition 1) a leader with fixed mindset about technological ability; (condition 2) a leader with growth mindset about technological ability; or (condition 3) a control condition with no indication of leader's mindset about technological ability. After reading the respective vignette, they were asked to complete measured of their fixed and growth mindset about technological ability and their demographics.

Results obtained: The results showed statistically significant differences in study participant's growth mindsets about technological ability across the three conditions. The mean score of participant's growth mindset about technological ability in the condition with the growth mindset leader ($M = 3.95$, $SD = .60$) was significantly higher ($p < .01$) than that of those in the condition with the fixed mindset leader ($M = 3.29$, $SD = 1.05$). Further, the mean score of participant's growth

mindset about technological ability in the control condition with no indication of leader's mindset (M = 3.91, SD = .67) was significantly higher ($p < .01$) than that of those in the condition with the fixed mindset leader. However, growth mindset scores between the control condition and the growth mindset leader condition were not significantly different.

Conclusions: The results of this study extend research on the digital mindset concept, and on the influence that implicit beliefs about the nature of technological ability have in workplace digitalization contexts, by contributing support for the notion that a leader's mindset about technological ability can influence the mindsets held by their employees. In exploring whether a spillover effect exists between leaders' and employees' mindset about technological ability, we bring forth an increased understanding of variation in leaders' success with implementing digital changes. Just as having a growth mindset about general ability is shown to be beneficial in several achievement settings, our research indicates that having a growth mindset about technological ability is beneficial in the context of digital changes in organizations, because it promotes a mindset in the organization that is better oriented to support digitalization efforts and the changes they require.

Relevant UN SDGs: #8 Decent work and economic growth

Keywords: mindset, technological ability, spillover effect

Paper 5

Cognitive Foundations of Ambidexterity - An Experimental Training Intervention

Jan Richner & Daniella Laureiro-Martinez | ETH Zürich

Research Goals: The last couple of years have made more evident the worlds' constant change. Events such as the COVID-19 pandemic, the war in eastern Europe, mass migration, resources shortage, and inflation have shown that societies and leaders' adaptability are and probably will continue to be tested. As adaptability is so important, we want to better understand, how cognitive flexibility predicts a leader's ability to be adaptive—i.e., to switch between exploration and exploitation at the right moment ("ambidexterity"). Cognitive flexibility has already been linked to organizational ambidexterity and we know from extensive empirical evidence that ambidextrous leaders favor the success and survival of their organizations. However, we do not yet know how to train ambidexterity in organizational leaders. With this research we intend to change this.

Theoretical Background: At its core, cognitive flexibility is defined as the "mental ability to switch between thinking about two different concepts according to the context of a situation". Cognitive flexibility is based on five antecedents, or executive functions. These are salience detection, sustained attention, updating, inhibition and switching. Salience detection is our ability to identify changing stimuli in the environment; sustained attention is the ability to maintain focus on a task at hand; updating is the ability to process and manipulate information; inhibition is the ability to stop automatized thinking or behavior; switching is the ability to disengage from an irrelevant task set and engage a relevant task set.

Methodology: To achieve the first of the two research goals, we conducted a survey study using behavioral task and self-report questionnaires with 198 officer cadets of the Swiss Armed Forces. We included leadership performance evaluations, being conducted by military instructors across several months in officer school and practical service. As a next step, in Spring 2023 we will implement a training intervention with a pre-test–training–post-test experimental design allowing to differentiate training effects between (study/control group) and within (before/after training) participants. This training intervention will be based on cognitive enhancement therapy (CET), defined as "a behavioural training-based intervention that aims to improve cognitive processes … with the goal of durability and generalization". Core elements of the CET are the use of cognitive exercises and teaching of meta-cognitive strategies.

Results: The antecedents of cognitive flexibility predict 9.5 % of variance in ambidextrous decision-making in the lab, while sustained attention and updating are the strongest predictors. In the field, inhibition is most predictive for leadership performance. Cognitive flexibility itself predicts 14 % of variance in the cadets' leadership ability. Equally exploitation, and especially exploration, are highly predictive for leadership performance in the field. We expect that our training intervention will improve ambidextrous decision-making in the treatment group.

Limitations : The main limitation of our current results lies in the fact that our survey design does not allow to establish causality. The planned training intervention shall allow to do this. Moreover, our research context marked by strong routines and regulations might have influenced the answer behavior of our participants and might also affect the results of the training intervention.

Conclusions: Our empirical evidence shows that the antecedents of cognitive flexibility and cognitive flexibility itself are promising for the training of ambidexterity and leadership performance.

This foundation allows the development of an ambidexterity training intervention. During the EAWOP symposium, we will be able to present the here outlined results as well as initial findings from the training intervention starting in Spring 2023.

Relevance to the Congress Theme: This work will contribute by investigating a better way of training organizational leaders. The experimental training intervention answers the call for urgency by being taught to military leaders who have important roles in addressing our societies challenges—whether regarding pandemics, mass migration or war itself. We address delivery by developing an intervention that trains organizational leaders to balance stability (exploitation) and change (exploration). Our research project improves the way in which the Swiss Armed Forces select and train their leaders.

Relevant UN SGD's: Most directly, our training intervention addresses the UN SGD "Quality Education". Still, considerable empirical evidence shows that ambidextrous leaders are particularly well equipped to manage organizations, which are the most central entity in the achievement of all UN SGD's.

Keywords: cognitive flexibility, ambidexterity, intervention

Symposium S021

Recent developments in employability research among working and non-working populations

Alessandro Lo Presti, Università degli studi della Campania "Luigi Vanvitelli"

science

As the growing turbulence and unpredictability of the labour market pose additional challenges to individuals, scholars are increasingly interested in those characteristics, skills, attitudes, resources, and behaviours that may support individuals in better coping with occupational transitions. These, in turn, have the potential to enhance individuals' employability, foster their career success, and even promote their well-being. The augmented emphasis on individuals' proactivity in the labour market is a priority to both employees and those who have not entered the labour market yet but are close to this transition, namely students, and in particular university students. While employees need to continuously maintain their employability in uncertain organizational career contexts, university students require employability resources for a successful university-to-work transition. Hence, employability as a research and practical topic attracts the attention of both vocational and organizational psychologists (as well human resource specialists, higher education experts, and others) depending on the examined population (i.e., students vs employees), and consequently on the context under scrutiny (e.g., university-to-work transition vs inter-organizational mobility).

Based on this scenario, the four studies that will be presented during this symposium aim to provide an articulated and diversified picture of the recent developments in employability research: the first two studies examine university students samples, and the remaining two examine employee samples. The contributions examine vital aspects of employability and its antecedents and outcomes, including the relation of employability to well-being from a Conservation of Resources Theory perspective, the role of traits and adaptability resources for employability from a Career Adaptation Model perspective, and the relation of career self-management behaviours to facets of employability from the perspective of content-models of career self-management.

The study by Petruzziello, Chiesa, Guglielmi, van der Heijden, de Jong, and Mariani examined the reciprocal association between self-perceived employability and psychological well-being on a sample of 376 Italian university students and recent graduates by means of a three-wave cross-lagged panel research design. Consistently with the Conservation of Resources Theory, and in particular with the gain spiral idea, they found that self-perceived employability and psychological well-being influenced each other over time.

The study by Gamboa and Lo Presti examined the associations of career decision-making tolerance to ambiguity on one side, and job search behaviours and perceived employability on the other side, also considering the mediating effect of career adaptability on a sample of 235 Portuguese undergraduate students via a cross-sectional research design. The hypothesized direct and indirect effects were confirmed, providing further support to the Career Adaptation model.

The study by Wilhelm, Hirschi, and Schläpfer examined the associations between different facets of career self-management behaviours and employability operationalized in terms of movement capital dimensions through a two-wave time-lagged research design on a sample of 536 German employees. They found that career self-management behaviours (as well as a unitary higher-level construct) were uniquely related to the four dimensions of movement capital, providing additional evidence about the differential predictive role of career self-management behaviours.

The study by Lo Presti and De Rosa examined the reciprocal associations between resource-based employability and psychological well-being indicators (i.e., vigour, emotional exhaustion), also taking into account the mediating roles of objective and subjective career success by means of a three-wave cross-lagged panel research design on a sample of 381 Italian employees. They found that employability positively predicted vigour as well as subjective and objective career success. Moreover, in line with the resource caravan idea, they found that subjective career success mediated its effect on emotional exhaustion, and that vigour mediated the relationship between employability and vigour over time.

Overall, apart from the significant empirical contributions and the theoretical and practical implications drawn from these four studies in terms of antecedents and outcomes of employability, the evidence provided is consistent with some relevant UN Sustainable Development Goals. Indeed, the results suggest ways to reach the goals of Decent Work and Economic Growth, Quality Education, Good Health and Wellbeing, Reduced inequalities, and Partnerships for the Goals.

Paper 1

Reciprocal Association Between Self-Perceived Employability and Psychological Well-Being: Evidence for Gain Spirals Among Italian Students

Gerardo Petruzziello, Department of Psychology "Renzo Canestrari", University of Bologna, Italy; Marco Giovanni Mariani, Department of Psychology "Renzo Canestrari", University of Bologna, Italy; Jeroen de Jong , Strategic Human Resource Management, Radboud University; Beatrice I. J. M. van der Heijden, Strategic Human Resource Management, Radboud University; Dina Guglielmi, Department of Education "Giovanni Maria Bertin", University of Bologna; Rita Chiesa, Department of Psychology "Renzo Canestrari", University of Bologna, Italy

Research goal

This study aimed to test the reciprocal associations between Self-perceived Employability (SPE) and Psychological Well-being (PWB) among Italian students and graduates. Testing such relationships can add valuably to SPE literature. Indeed, using a longitudinal cross-lagged design advances and deepens the understanding of the nature and direction of the SPE-PWB relationship, offering more robust results compared to previous studies. Moreover, findings may expand the theorising of SPE in early careers, including PWB as an antecedent. This, in turn, generates valuable suggestions for practice.

Theoretical background

Research incorporates SPE within the Conservation of Resources (COR) theory framework as a personal resource that labour market entrants may invest not only in effective career behaviours and towards valuable transition outcomes. It also functions as a coping resource against the threats of career entry, thus allowing people to deactivate the resource-consuming loss spiral and invest in gain spirals to foster their mental health and increase PWB. We hypothesised a cross-lagged positive effect of SPE on PWB over time (Hypothesis 1). PWB can also be seen as a resource, in the form of energy to invest in coping with challenging circumstances and incurring positive resource acquisition spirals. Feeling well predisposes people to use broader thinking and action patterns. This could drive them to perform more effectively in life domains, interact with their environment to identify opportunities, and accumulate resources to overcome challenging transition events, herewith promoting more positive appraisals of SPE. We hypothesised a cross-lagged positive effect of PWB on SPE over time (Hypothesis 2). COR theory suggests that both the normal and reversed relationship between SPE and PWB are simultaneously plausible through a process of resource gain where initial resource acquisition stimulates an upward movement. That creates pools of correlated resources following a spiralling trend, meaning that resources create a dynamic synergy, influencing each other over time. SPE can increase PWB over time and, in turn, PWB can exert a positive effect on SPE. PWB can also be the initiator of this process. We hypothesised that SPE and PWB have a positive and reciprocal effect over time (Hypothesis 3).

Methodology

We adopted a three-wave cross-lagged research design in which PWB and SPE were measured at each time, starting from November 2019. We invited last-year university students and graduates to complete an online questionnaire three times, with a three-month time lag. They were assured confidentiality and acknowledged the right to participate upon informed consent and withdraw at any time. The final sample comprised 376 participants with a mean age of 25.79 years (SD = 4.21), mostly Women (89.4%).

Results

Using the AMOS software, the structural equation modelling approach allowed us to test the hypotheses. We achieved a good fit of the measurement models at each time and measurement invariance across time. Results confirmed our hypotheses. SPE and PWB affect each other reciprocally over time, meaning they can be both initiators of an upward positive gain spiral.

Limitations

Longer time lags and a more representative sample may generate more robust results. Moreover, our study did not account for the perceptions of the labour market conditions, which may affect the hypothesised relationships, especially given the impact of the pandemic.

Research and practical implications

Our study advances the empirical understanding of the SPE concept. It corroborates the beneficial effect of SPE on PWB among entrants with a more robust design. The reverse effect of PWB on SPE offers an empirical basis to inform an extension of the SPE theory, expanding its nomological network and suggesting future research to account for the predicting role of PWB. The three-wave cross-lagged design represents a more reliable solution to support the existence of a gain spiral. In a practical sense, results suggest that SPE and PWB are both building blocks of the path towards sustainability and that they should be fostered with integrated and systemic interventions.

Relevance to the Congress Theme

Our study remarks on the need for personal resources to achieve sustainability throughout the transition-to-work stage. We argue that a multidisciplinary, integrated, and targeted approach involving policy-makers and stakeholders of youth employment fosters different personal resources and facilitates a sustainable transition to work.

Paper 2

How Do Employees Stay Employable? Career Self-Management Behaviours and Their Relation to Movement Capital

Francisco Wilhelm, Dawa Schläpfer & Andreas Hirschi | University of Bern

Research goals and why the work was worth doing

Career self-management (CSM) is a multidimensional construct involving various behaviours that individuals use to achieve their career goals, such as staying employable in a rapidly changing career environment. Although CSM has been linked to employability and theories acknowledge the role of CSM in enhancing and maintaining employability, it remains unclear how different CSM behaviours are uniquely related to various facets of employability. This is a significant omission that obstructs our understanding of the specific ways in which individuals shape their employability through various CSM behaviours. Therefore, in the present study, we sought to clarify how CSM behaviour is related to various facets of employability.

Theoretical background

We conceptualize employability through the movement capital framework, which defines the various personal resources that facilitate career mobility. Movement capital has four dimensions: human capital, social capital, self-awareness, and adaptability. We propose that CSM behavior must be understood as a hierarchical construct with a general level, referring to the extent to which one generally engages in CSM, and multiple specific behaviors. Drawing on career development theories such as the intelligent career framework, we hypothesize that (a) human capital development is uniquely related to human capital operationalized as occupational expertise, (b) building social contacts is uniquely related to social capital operationalized as the breadth of internal and external networks, (c) career goal setting and planning is uniquely related to self-awareness operationalized as career goal clarity, (d) mobility-oriented behavior is uniquely linked to adaptability operationalized as job market knowledge. Furthermore, we hypothesize that (e) the general level of CSM is positively related to all dimensions of movement capital.

Design/Methodology/Approach/Intervention

Self-report data were collected from a sample of N = 536 German employees. CSM behaviours were measured at Time 1. To reduce common method variance, movement capital variables were measured two weeks later at Time 2. CSM behaviours were modelled using bifactor confirmatory factor analysis to distinguish between the general and specific CSM behaviour dimensions. Hypotheses were tested using a series of structural equation models.

Results

We found that the hypothesized specific CSM behaviours are uniquely related to the four dimensions of movement capital, while the general level of CSM was also related to all four dimensions of movement capital. Furthermore, we found that mobility-oriented behaviour was negatively related to career goal clarity, while building social contacts was positively related to job market knowledge.

Limitations

Our findings are based on a single sample of German employees and should be replicated in other populations. Furthermore, longitudinal studies are needed to investigate the extent to which CSM behaviours maintain and enhance movement capital and the extent to which movement capital facilitates engaging in these CSM behaviours.

Conclusions

We contribute to the employability literature by clarifying how CSM behaviors are linked to central facets of employability. Specifically, this extends the movement capital framework, which has acknowledged the role that CSM may play in maintaining and enhancing employability but does not specify the specific relations among CSM behaviors and different dimensions of movement capital. Hence, our examination of the role of CSM behaviors in predicting movement capital enables a better understanding of how persons develop and enact their employability through behavioral processes.

Relevance to the congress theme

In a changing world of work, individuals today increasingly need to become proactive and manage their employability through CSM. As such, the present study advances our understanding of how individuals become agents of their careers in a changing world of work.

Relevant UN SDGs

The issues addressed in this study may ultimately enable practitioners in fields such as career counselling and HRM to better support their client's careers and working lives, thereby contributing to the UN SDGs 'decent work and economic growth' and 'quality education'.

Keywords: employability, career behaviour, proactivity

Paper 3

Employable, successful, and healthy, or vice versa? A three-wave cross-lagged analysis

Alessandro Lo Presti & Assunta De Rosa | Università degli studi della Campania "Luigi Vanvitelli"

Research goals and why the work was worth doing

This study aimed to examine the positive associations between employability and psychological well-being as mediated by objective and subjective career success through a three-wave cross-lagged research design. Previous studies showed that the association between employability and work-related well-being relies largely on cross-sectional studies (Kinnunen et al., 2011), with the most recent longitudinal studies encompassing two-time lags (Vanhercke et al., 2015) or more time lags with a limited array of well-being indicators and/or without the examination of potential mediators (De Cuyper et al., 2010; Kirves et al., 2014). Furthermore, the mediating roles of subjective and objective career success (hereafter, SCS and OCS) with respect to the association between employability and work-related well-being have been largely overlooked. Consequently, this study aims to go beyond these gaps present in the employability framework.

Theoretical background

The study is grounded on the CoR theory (Hobfoll, 1989) and on the resource-based model of Lo Presti and Pluviano (2016), which defined employability as a personal resource that can protect individuals from stressful events (e.g., inadequate working conditions, underemployment) and promote their well-being (Vanhercke et al., 2016) through the intervening role of career success. Based on this theoretical background, we argue that employability, career success, and work-related well-being are personal resources, pertaining to the work domain, that individuals try to develop and accumulate, as they can be conceived as desirable states that people strive to attain.

Design/Methodology

We sampled 381 Italian employees (response rate = 38.52%; initial N = 989) on all the study variables across three time points over a period of eight months. Associations between variables (considering one outcome at a time) were examined through structural equation modelling testing for direct causation, reversed causation, and reciprocal causation.

Results

We found that employability positively predicted vigour, subjective and objective career success, showing that the availability of resources may spark individuals' energy and lead to favorable outcomes providing additional evidence about the novel resource-based conceptualization of employability (Lo Presti & Pluviano, 2016) and its association with work-related well-being variables. SCS mediated the negative association between employability and emotional exhaustion; in other words, a resource caravan exists linking employability, SCS and emotional exhaustion so that employable individuals will perceive their career as more satisfactory and consequently will feel less exhausted. Lastly, vigour mediated the relationship between employability and vigour over time which showed that, consistently with the resource caravan idea, highly employable individuals will also show higher vigour at work because they could count on resources that will increase their energy at work.

Limitations

This study has some limitations. First, the drop-out analysis showed that employees who were older, had a longer general tenure and worked less hours a week were more likely to fill the three study questionnaires. Nevertheless, our analysis highlighted no evidence regarding significant differences in the study variables. Second, our data were collected through self-report measures which may rise biases due to common method variance. However, to cope with it, based on Podsakoff et al., (2003), we applied different scale endpoints and formats for the variables to reduce biases caused by commonalities in scale endpoints and anchoring effects; moreover, we randomly inserted items into the questionnaire and scales were graphically separated from each other Third, our study used CLPM (cross-lagged panel model) analysis focusing on the prospective effect of individual differences in a construct on change in individual differences in another construct.

Conclusions and Practical Implications

This study brings evidence for the differentiated impact of employability on subjective and objective career success and indicators of work-related well-being. In particular, resource caravans were found in regards to emotional exhaustion and vigour, providing the literature with a more exhaustive and empirically solid examination of the longitudinal effects of employability, as a personal resource. From a practical standpoint, organizations may encourage a stronger employability culture (Nauta et al., 2009), invest in opportunities for competency development (De Vos et al., 2011), or broaden the set of developmental human resources practices (van Harten et al., 2020), while, career success may be also fostered by providing clearer career paths (Lo Presti & Elia, 2020) or through career counseling and training interventions (Glerum & Judge, 2021).

Relevance to the Congress Theme

As employability is increasingly recognized as a personal resource that can facilitate the entering and permanence into the labour market, our study contributed to shedding light on its longitudinal associations with career success and psychological well-being, consistently with the sustainable career idea.

Relevant UN SDGs

Good health and well-being – decent work and economic growth.

Keywords: employability, career success, psychological well-being

Symposium S023

What Happens When You Say Something: Individual-, Dyad-, and Team-level Outcomes of Employee Voice

Mona Weiss, Freie Universität Berlin; Tina Davidson, Erasmus University

science

What will be covered and why

Employee voice behavior refers to employees' discretionary communication of ideas, opinions, and work-related concerns to improve team and organizational functioning. Whereas employee voice behavior is intended to bring about positive change in the organization, there remains much to be learned about the type of outcomes voice may affect (incl. those at different levels), and by what mechanism(s) and under which circumstances such change is likely to take effect. With this symposium, our aim is to contribute to the emerging conversation in this area by exploring novel perspectives on the nature and level of impact voice can affect (e.g., future voice behavior, leader empowering behavior, team performance), as well as by providing a systematic understanding of the processes and conditions under which such impact can occur.

This symposium comprises five papers explaining when (i.e., moderators) and why (i.e., mediators) voice impacts a range of novel outcomes at the team-, dyad-, and individual level. Isaakyan et al. investigate how voice can affect team coordination and performance and find differentiated effects of private voice (i.e., directed at few team members) and public voice (i.e., directed at all team members). Androulidaki et al. ask when and why employee voice can develop leaders in terms of the extent to which they empower their employees and whether leader self-reflection can strengthen such developmental value of employee voice. Herrmann et al. look at how supervisor's perceptions of employee warmth and competence determine whether they recognize and give credit to employees' taking charge behavior (i.e., conceptually related to voice). At the individual level, Weiss & Zacher explore whether voice can result in an "initiative penalty" (i.e., being tasked with taking care of voiced suggestions and concerns) and how this affects subsequent voice episodes by drawing on longitudinal data from a diverse sample of employees. Finally, Davidson et al. examine how voice can be a lever for leader identity development for women (vs. men) and further investigate perceived leadership effectiveness as a downstream consequence of such leader identity development.

Collectively, this symposium advances research on voice by introducing new voice outcomes at different levels within the organization (i.e., team, interpersonal, and individual level) and delineates processes by and circumstances under which voice can be helpful (vs. harmful) in these areas.

Relevance to the Congress Theme

Understanding more about the consequences of employee voice is crucial in the changing world of work as voice is a main driver of change and innovativeness. Only when employees engage in voice, and are heard by their supervisors, co-workers, and teams, change is likely to occur and sustain. Voice is also critical in how we deal with change. Because our work context is now subject to various profound changes (e.g., digitalization, gig economy, demographic change, climate change), it is not only imperative that people critically respond to these transformations and speak up with their concerns but that others respond to their input in most effective ways.

Research/Practical Implications

This symposium presents a new research agenda on consequences of voice and expands theoretical knowledge on important moderating conditions at different levels of analysis. Moreover, we provide important practical implications for leaders, teams, and HR practitioners to help reap the benefits of employee voice in organizations.

Overall conclusions

Against the backdrop of today's ever-changing world and workplaces, this symposium presents new theoretical developments regarding when and how employee voice can initiate and facilitate change in individuals' work experiences (e.g., well-being), their self-views (e.g., leader identity), as well as well as affect leader behavior (e.g., leader empowering behavior) and team functioning (e.g., team coordination and performance.

Keywords: employee voice; proactivity; outcomes

Paper 1

Distinguishing Public and Private Voice in Teams Diverse in Regulatory Mode: Its Effects on Team Coordination and Performance

Sofya Isaakyan, Erasmus University; Subra Tangirala, University of Maryland; Elad Sherf, University of North Carolina

Research Goals and Why the Work Was Worth Doing

One of the key functions of voice, or the expression of work-related ideas, opinions, or concerns by team members (LePine & Van Dyne, 1998), is to help members effectively coordinate—integrate and align ideas, actions, and efforts to accomplish tasks. Yet, we know relatively little about when voice is more or less likely to benefit team coordination processes which are essential for effective team performance (Marks et al., 2001).

Theoretical Background

We make a distinction between public team voice (i.e., instances in which members voice in the presence of all other members) and private team voice (instances in which members voice only to some of their peers) and drawing from the regulatory mode theory (Higgins et al., 2003), argue that public team voice contributes to coordination processes in teams composed of members who are diverse in how they analyze the task (i.e., assessment mode) and act on the task (i.e., locomotion mode). Importantly, we do not expect similar benefits for private team voice. We then argue that team coordination positively affects team performance and that the relationship is stronger when team diversity in assessment and locomotion mode is higher.

Design & Methodology

To test our conceptual model, we collected data over two years using a sample of 171 student teams (13 teams had 3 members, 158 teams had 4 members) with 671 participants (M age = 18.62, 54% female) as part of the Organizational Behavior course in a business school in the Netherlands. At the start of the team project (Time 1), we measured members assessment and locomotion modes (Higgins et al., 2003). Halfway through the project (Time 2), members reported how often other members engaged in public and private voice using 1-item round robin measures. At the end of the project (Time 3), they rated their team coordination (Mathieu et al., 2020). Finally, we collected objective data on performance (i.e., grades on team projects) (Time 4).

Results

Results showed that public team voice was positively related to team coordination and interacted with diversity in assessment mode such that the relationship was positive when diversity in assessment was higher and not significant when diversity in assessment was lower. Similarly, public team voice interacted with diversity in locomotion mode such that the relationship was positive when diversity in locomotion was higher but not significant when diversity in locomotion was lower. Private team voice was not related to team coordination and interaction effects between private team voice and team diversity in assessment mode as well as between private team voice and team diversity in locomotion mode were not significant either. Results also showed that team coordination interacted with diversity in assessment mode such that coordination was positively related to team performance when diversity in assessment mode was higher but not when diversity in assessment mode was lower. The indirect effect of public voice on team performance via team coordination was

positive when diversity in assessment mode was higher but not significant when it was lower. The interaction between coordination and diversity in locomotion mode was not significant.

Limitations

While we employed a lagged field study design to establish causality, we still encourage scholars to replicate our research using a controlled experimental set-up to provide better evidence for causality.

Conclusions

Our research contributes to the voice literature by underscoring how voice might lead to different team outcomes depending on (a) whether it is enacted in the presence of all other team members or only in the presence of some of the peers and (b) whether team members are diverse in how they analyze and act on the task. Moreover, we challenge the predominant negative view on public voice (Detert & Edmondson, 2011; Isaakyan et al., 2021) by demonstrating that when teams high in regulatory mode diversity do not utilize public forums, and, instead, keep voice in private one-on-one settings, they encounter unique coordination pitfalls that can hamper effective team functioning.

Relevance to the Congress Theme

This research highlights how teams can best utilize their members voice to effectively address rising opportunities and potential threats in today's complex and changing world of work.

Relevant UN SDGs

Voice behavior contributes to a more inclusive environment and thus is indirectly relevant to the United Nations sustainable development goal on reducing inequalities (SDG 10).

Keywords: voice; teams; coordination

Paper 2

Investigating the effects of supervisors' social judgements of employees on recognising employee proactivity

Schaefer, S., Bindl, U.K., & Reich, T.

Research Goals and Why the Work Was Worth Doing

Proactive behaviour, that is employees' self-initiated and future-oriented action to bring about change (Parker et al., 2006), is increasingly expected by organisations. However, outcomes of proactivity are mixed; for example, findings on how supervisors respond to proactive behaviour of their direct reports is somewhat inconsistent (Grant et al., 2009). One potential explanation lies in employee proactive behaviour not always being recognised by the organisation. It is therefore important to develop our understanding of factors that influence supervisors' recognition of employee proactive behaviour, to ensure this important behaviour will be rewarded in organisations.

Theoretical Background

We draw on the Stereotype Content Model (SCM; Fiske et al., 2002) to argue how supervisors' social judgement influence their perception of their direct report's engagement in proactive behaviour. According to SCM, social judgement of others' behaviour depends on a combination of two fundamental dimensions: warmth and competence. Warmth refers to social judgments that another person has a concern for others, whereas competence refers to perceptions another person has high ability, intelligence, agency, and skills. We argue that warmth and competence judgements will influence whether supervisors recognise employees' proactive behaviour (taking charge) in comparison to a more affiliative type of extra-role behaviour (helping). Taking charge at work is understood as a display of dominance and assertiveness. In contrast, helping others is more likely to be prompted by close relationships, directed toward benefiting others (Van Dyne & LePine, 1998). Because interpretations of an employee's behaviour may depend on social evaluations by others, we argue that general perceptions of the direct report as warm vs competent will influence supervisors' perceptions of employee proactivity (vs. helping) such that behaviour that aligns with a supervisor's overall expectation of the direct report will make that behaviour more salient and will lead to greater recognition of the behaviour in the form of higher performance ratings for proactivity (vs. helping).

Design & Methodology

We tested our hypotheses in a sample of matched supervisor-direct report dyads (N =214) across a wide range of occupations and organisations in the USA via an online survey panel provider (www.studyresponse.net). We used established and validated scales to assess supervisors' perceptions of direct report's overall warmth and competence, as well as of employees' engagement in, vs. supervisors' performance ratings of, taking charge and helping at work.

Results

We used multiple hierarchal regression analysis in SPSS, using Hayes' Process Macro Model. In support of our theorising, the relationship between employees' self-reported engagement in taking charge behaviour and supervisor ratings of taking charge performance was stronger for employees who were perceived to be high (vs. low) in competence as well as low (vs. high) in warmth. However, we did not find support for the expected interaction between supervisor warmth or competence perceptions for helping behaviour.

Limitations

Although our findings account for a wide range of occupations and organisations and therefore allow for overarching insights into how employee proactivity is perceived by supervisors' contingent on their social perceptions of their direct reports, future research would benefit from considering the importance of warmth vs. competence perceptions in specific organisational settings, such as those with a distinct organisational culture and norms/expectations on proactivity at work.

Conclusions

The presented study expands the discussion on the conditions necessary for employees to receive credit from supervisors for their proactive behaviour. Our findings suggest employees will receive better proactive performance ratings if they are perceived by their supervisor to be 'the type of person' who fits with the values associated with proactivity at work. Supervisors may need to be encouraged to be more aware of and to recognise performance that may not fit with their overall perceptions of their direct reports. In addition, organisations aiming to promote proactivity in staff may benefit from providing training or additional feedback to these employees already motivated to engage in proactivity on how to enact it in ways that will be seen and recognised by their supervisor.

Relevance to the Congress Theme

This study contributes to addressing the 21 st EAWOP Congress call-to-action focusing on employee proactivity. In particular, we advance understanding of a largely overlooked but valuable topic of the consequences of supervisors' social judgement for direct reports' behaviour. Thus, we develop insights into the conditions necessary for employees to be recognised for their proactive behaviour.

Relevant UN SDGs

This study has relevance for SDG8, that is inclusion and equality at work, by contributing to our understanding of the consequences of supervisors' social judgement. With this, we highlight training potentials (SDG4) to promote proactivity.

Keywords: voice; supervisor judgments; warmth and competence

Paper 3

Why Don't YOU Just Take Care of This? Longitudinal Relationships between Voice and Perceived Voice Penalty

Mona Weiss, Freie Universität Berlin; Hannes Zacher, Leipzig University

Research Goals and Why the Work Was Worth Doing

Previous research has shown that when employees engage in voice, that is, the discretionary communication of suggestions, ideas, and work-related problems, they can contribute to organizational and team effectiveness and increase their own occupational well-being. However, past research on voice has rarely considered the fact that voice is often a process that necessitates several voice episodes over time. Within this voice process, it is likely that superiors and colleagues may react in a defensive manner as they feel bothered or threatened by the voiced input. In this project, we propose that voice might not only lead to positive or negative reactions from others, but also to a "voice penalty." This perceived penalty for voice might result in additional task load for the voicing employee, which can then affect subsequent voice episodes.

Theoretical Background

On the basis of the literature on upward communication, we propose that voice leads to a higher propensity to receive additional task load because voicers challenge the status quo in an organization. As voice may entail proposing an alternative course of action or raising a work-related issue, co-workers and superiors may view such input as threatening and, consequently, react defensively and re-direct the issue to the individual speaking up. Thus, engaging in voice may cause employees to be tasked with solving and managing the issue on their own (i.e., perceived voice penalty), which may affect their willingness to engage in future voice episodes as well as their occupational well-being. Drawing from conservation of resources theory, we propose that voicers who experience a voice penalty will be less likely to engage in subsequent voice behavior in order to protect their resources.

Design & Methodology

Using three waves of monthly longitudinal data from a highly diverse sample of working adults (N =368), we assessed voice and positive and negative voice reactions over time. To assess the extent to which individuals perceive negative reactions to their voiced input in the form of additional task load and individual responsibility, we developed an 8-item measure of perceived voice penalty (e.g., "When I spoke up with work-related issues, I was often tasked with taking care of the problem on my own"). We applied Random-Intercept Cross Lagged Panel Modeling (RI-CLPM) to investigate within-person relationships between voice and voice reactions over time.

Results

Preliminary results suggest that, at the between-person level, a perceived voice penalty results in more subsequent voice behavior. Within-person relationships suggest differential relationships with promotive (i.e., suggestion-focused) and prohibitive (problem-focused) voice.

Limitations

Even though this research is based on longitudinal data and we are able to separate within- from between-person relationships over time, self-presentation issues as well as common method variance remain a concern that should be addressed in future research.

Conclusions

Our research fits with emerging conceptualizations of voice as a process that may entail positive and negative reactions and consequently affect future voice episodes.

Relevance to the Congress Theme

Initiating positive change and improvement to one's workplace has been considered as a central motive within the voice literature. As such, our research is highly relevant with regard to the question of when individuals are likely to sustain their efforts to induce change at work and how such change is managed.

Relevant UN SDGs

One essential UN SDG is the promotion of well-being. We contend that a better understanding of voice and the consequences of inducing positive change at work has implications for both of these overarching goals. Individuals thrive at work when they can exert control over important aspects of their job. Voice is means by which individuals can enact control but we have yet to understand the role of others' reactions in the voice process.

Keywords: voice; perceived voice penalty; longitudinal relationships

Paper 4

Enact It till You Become It: How Voice Behavior Affects Leader Identity Development for Women

Tina Davidson & Hannes Leroy | Erasmus University; Ronit Kark, Bar-Ilan University; Sofya Isaakyan, Erasmus University

Research goals and why the work was worth doing

Implicit societal biases and expectations still suggest an incompatibility between a leader role and the female gender role. As a result, women often experience conflicted thoughts and attitudes when contemplating their leadership potential, which renders embracing a leader identity particularly challenging for women. Because leader identity is an important antecedent to leadership emergence, effectiveness, and development, this research explores how women can develop their leader identity despite prevailing societal biases assuming a misfit between their gender role and aspired leader role.

Theoretical background

We draw on the behavioral theory of identity construction (Ashforth & Schinoff, 2016) which posits that behaviors which are self-initiated , public, and prototypical for a particular identity are most likely to lead to internalization of this identity. Applying this theoretical premise, we argue that voice behavior —the voluntary expression of constructive change-oriented ideas, suggestions, and opinions with an intent to improve organizational functioning (Morrison, 2011)—represents such self-initiated public behavior prototypical for leader identity which can support leader identity development. Moreover, drawing on the behavioral theory of identity construction, we propose that women will benefit more from engaging in voice behavior than men as they are more likely to be attentive to cues regarding whether they fit the leader prototype. We further propose that individuals who internalize a leader identity are also more likely to be perceived by others as effective in their leadership. Specifically, conceiving of oneself as a leader (i.e., strong leader identity) urges individuals to more frequently practice and display leadership across domains and situations. Hence, we expect that individuals with a strong leader identity are more likely to be viewed as effective leaders. Taken together, we propose that gender moderates the indirect effect of voice behavior on perceived leadership effectiveness via leader identity, such that the indirect effect is stronger (vs. weaker) for women (vs. men). In other words, by behaving leader-like—in the form of voice behavior—women can effectively undo some of the biases they encounter when taking up a leader role, and the process by which this happens is through strengthening their leader identity.

Design & Methodology

We tested our conceptual model across two studies. Study 1 employs a between-person time-lagged design (n = 247) and Study 2 employs a within-person repeated-measures design (n between = 134, n within = 450). Voice and perceived leadership effectiveness were peer-rated using a round-robin design. Leader identity was self-rated.

Results obtained

Across two studies, we found support for our conceptual model. In particular, engagement in voice behavior interacted with gender such that voice was positively related to leader identity for women but not for men. Furthermore, leader identity was positively related to perceived leadership effectiveness. Finally, the indirect effect of voice on perceived leadership effectiveness via leader

identity was moderated by gender, such that engagement in voice behavior was positively related to perceived leadership effectiveness via leader identity development for women, but not for men.

Limitations

While this research finds general support for our conceptual model across multiple samples, using multiple sources, and research set-ups, future research should still do well to replicate and extend this work by using a controlled experimental set-up to provide more conclusive evidence for causality.

Conclusions

This research expands emerging work in the realms of gender, leadership, and voice. Specifically, it underscores how leadership development is experienced and carried out differently by men and women and how—for women—engaging in voice behavior can debias perceived leadership effectiveness via the intrapersonal route of leader identity development.

Relevance to the Congress Theme

This presentation urges us to exchange ideas and forge future work on gender and leadership vis-à-vis our changing world of work. As more gender-diverse (vs. homogenous) leadership teams do better in turbulent and complex environments, how then can we create more of a level-playing field in leadership? Our presentation puts forward one strategy to address this challenge, as well as stimulates future research in this area.

Relevant UN SDGs

With its focus on building women (internal) resources for leading (i.e., leader identity) as well as interpersonal recognition of their effectiveness (i.e., perceived leadership effectiveness), this presentation is of relevance to UN SDG 5 on Gender Equality.

Keywords: voice; leader identity development; women leaders

Symposium S024

Asynchronous Video Interviews: Applicant reactions, performance and validity

Ottilie Tilston, Department of Organisational Behaviour, University of Lausanne, Switzerland

science_practice

In today's hiring landscape, interviews are increasingly conducted online in the form of Asynchronous Video Interviews (AVIs). In AVIs the applicant logs onto a platform to record video responses to questions, and the recorded responses are evaluated later. AVIs offer numerous benefits to the hiring process and are already in widespread use. Despite this, research suggests that applicants do not react well to them. Relatively little is known regarding the mechanisms that lie behind these negative interview experiences, and how and why they are related to applicant perceptions, behaviour and performance. This symposium brings together five papers from controlled laboratory and high-stakes settings to shed light on several issues specific to the AVI context.

One defining aspect of AVIs is the lack of synchronous communication between applicant and recruiter. This makes AVIs fundamentally different from other types of interviews, so research is required to understand how it impacts interview outcomes. In the first paper, Germanier et al. compare applicants' responses to past-behaviour questions in the AVI vs. face-to-face context. They also investigate how interview performance is related to job performance, providing one of the first investigations into the criterion-validity of AVI evaluations.

Another defining aspect of AVIs is that they vary widely in the way they are designed. Specific design features are likely to have an important impact on applicant reactions. Research suggests that organisations using AVIs often retain the default settings for many design features, but in doing so they may be missing out on opportunities to improve applicant reactions. Two papers in this symposium investigate this. Using a basic psychological needs theoretical lens, Dunlop et al. experimentally investigate whether allowing applicants to choose the order they answer questions improves reactions. They found no effect of choosing question order on perceptions of need support, fairness or overall candidate experience. Tilston et al. analyse a large dataset to investigate how applicants react to certain design features, in one of the first such investigations with real applicants, and how this relationship is moderated by applicants' demographic characteristics. They found that certain design features improved applicant reactions to AVIs and that this was moderated by age, with younger and older applicants preferring different AVI options, but not gender.

A final defining aspect of AVIs investigated in this symposium is the possibility to integrate artificially intelligent (AI) algorithms for evaluation. Langer et al. investigate whether applicant suitability affects the preference for human versus automated evaluators. While no effect was found for applicant suitability, they found that automated systems were perceived as more consistent and less biased. Nonetheless, participants rated the human decision-maker to be fairer and perceived more possibility to influence the human decision-maker. Finally, Lukacik and Bourdage investigate AI in the context of faking. Participants completed AVIs to examine the effects of type of evaluator (AI or human) and consequences for faking (identification vs. disqualification warnings) on applicant behaviour, reactions and outcomes. Results indicated more honest self-promotion and ingratiation were directed towards A.I. compared to human evaluators. Interview performance was not significantly influenced by evaluator type or warnings.

Overall, these five studies have numerous implications for research and practice. Obtaining a better understanding of the differences between face-to-face interviews and AVIs can contribute to

reducing the potential for bias and unfairness associated with digital technologies (Germanier et al.). Investigating whether all applicants react uniformly negatively to AVIs (Tilston et al.), and whether certain design features can potentially improve applicant reactions (Dunlop et al.) can help organisations design AVIs in a more candidate-friendly way. Organisations using automated evaluation as part of their AVIs need to be aware that applicants prefer human decision-makers (Langer et al.). Taking into consideration how applicants faking behaviour changes when they believe they are being evaluated by AI has clear implications for validity (Lukacik et al.).

This symposium is closely tied to all three facets of this year's congress theme: "The Future is Now". Firstly, AVIs are a novel technology that are transforming the hiring landscape, and the incorporation of AI pushes this even further. As organisational psychologists we must contribute our expertise to effectively implement these selection processes in real-world contexts. Secondly, the use of AVIs has already accelerated as a result of the pandemic, so it is urgent that we understand them better. Thirdly, our papers deliver evidence-based conclusions that can be applied to improve hiring technology in the future.

Keywords: Asynchronous video interviews, Applicant reactions, AI evaluation

Paper 1

Effect of face-to-face and asynchronous video interviews on applicant responses to past-behaviour questions, interview performance and job performance

Elisabeth Germanier, Institute of Work and Organisational Psychology, University of Neuchâtel, Switzerland; Marianne Schmid Mast & Laetitia A. Renier | Department of Organisational Behaviour, University of Lausanne, Switzerland; Mutian He & Philip N. Garner | Idiap Research Institute, Switzerland; Adrian Bangerter & Koralie Tchango Orji | Institute of Work and Organisational Psychology, University of Neuchâtel, Switzerland

Research goals: Past-behaviour questions (e.g., Can you tell me about an occasion where you had to deal with an angry client?) require applicants to respond by telling a story about their actions in a past work situation. They are valid predictors of job performance. But it is unclear what is measured (poor construct validity). The first goal of this study is to investigate how (1) storytelling responses to past-behaviour questions and (2) interview performance are related to job performance.

Selection interviews are increasingly conducted online. In AVIs, applicants record themselves answering questions through their computer and webcam. Little is known about how the medium and lack of a human interviewer affects their responses to past-behaviour questions. The second goal of this study is thus to compare storytelling responses to past-behaviour questions and interview performance in face-to-face interviews and AVIs.

Theoretical background: Past-behaviour questions require applicants to tell a story about a past job-related situation (I was working as a client relations manager. One day I got a call…). Recruiters score them using behaviourally-anchored rating scales (BARS) to measure applicants' mastery of a competency. Although recruiters rate applicants who produce stories better, applicants struggle with storytelling (Bangerter et al., 2014). In addition, despite the high criterion validity of past-behaviour questions (Huffcutt & Arthur, 1994), little is known about whether they actually measure the competency they are supposed to measure (construct validity).

In technology-mediated interviews, applicants often perform poorly (Blacksmith et al., 2014) and give shorter responses (Langer et al., 2017). AVIs in particular are not well accepted by applicants (Basch & Melchers, 2020). Nonetheless, the processes behind these differences are unknown. AVIs typically feature an impoverished communication situation where participants must manage technological affordances, including videorecording themselves and where rapport with an interviewer is absent. Moreover, the criterion validity of AVI is unknown.

This experiment compared mock job interviews in two conditions (face-to-face interview vs AVI, between-subjects) organized in two sessions. In the first session, participants completed a work sample to measure communication skills (job performance measure). In the second session, they participated in either a face-to-face interview or an AVI where they responded to a past-behaviour question asking them about their actions in the work sample. We correlate different facets of the work sample performance and the interview performance to investigate criterion and construct validity, and we also compare face-to-face interviews and AVIs in terms of storytelling and interview performance.

Methodology: 254 undergraduates participated. In the first session, participants completed a work sample. This consisted of two successive role-plays in which participants played the role of a manager whose task was to lay off two different employees. Each role-play was videotaped and

participants' performance was scored using a standardized checklist (our measure of job performance). One week later, in the second session, participants completed a mock selection interview in either the face-to-face or AVI condition. They answered three past-behaviour questions, including one where they were asked to describe what happened in one of the role-plays. Interview performance is determined by rating responses to the past-behaviour questions using BARS. The presence or absence of storytelling and thematic elements of stories (describing situations, tasks, actions or results) were coded.

Results obtained: Coding of job performance, interview performance and storytelling is currently under way. At the conference, we will present results on (1) the effect of face-to-face interviews vs AVIs on storytelling and interview performance and (2) the relation between different facets of job performance and interview performance (construct and criterion validity).

Limitations: One limitation is the experimental nature of the study: the interviews and work samples are not real-life situations. Furthermore, the layoff task is not a recurrent situation in undergraduates' life. Their performance might differ from the work performance of real managers.

Conclusions – research and or practical implications: Results contribute to our understanding of participants' responses to past-behaviour questions in face-to-face and virtual interview settings. They also enable a more detailed understanding of how job performance is related to responses to past-behaviour questions.

Relevance to the Congress Theme: The study's focus on a technological innovation (AVIs) is relevant to the congress theme.

Relevant UN SDGs: Digital technologies carry the potential for bias and unfairness. Our study contributes to a better understanding of potential differences between face-to-face interviews and AVIs, which may contribute to reducing bias.

Keywords: Asynchronous video interviews, storytelling, interview performance

Paper 2

Improving Asynchronous Video Interview experiences through autonomy-supportive design: Choose your question sequence

Patrick D. Dunlop & Marylène Gagné | Future of Work Institute, Curtin University, Australia; Djurre Holtrop, Department of Social Psychology, Tilburg School of Social and Behavioral Sciences, The Netherlands; Hayley I. Moore, Future of Work Institute, Curtin University, Australia

Research goals and theoretical background: Although asynchronous video interviews (AVIs) are growing in use (Dunlop et al., 2022; Lukacik et al., 2022), some research has suggested that the assessment format is not well-liked by candidates (Langer et al., 2017). In this experimental study, we adopted Basic Psychological Needs Theory (BPTN) as a lens through which to design an improved AVI experience. Briefly, BPTN proposes that the satisfaction of three psychological needs, autonomy, relatedness, and competence is essential for individuals' adjustment, flourishing, and wellbeing (Deci et al., 2017; Vansteenkiste et al., 2020). The need for autonomy describes the need to experience volition and control over one's behaviours, as opposed to coercion or pressure (Deci & Ryan, 2000). In the context of completing an assessment for a job application, this need may be supported by features that grant flexibility, offer meaningful choice, and have a clear rationale. The need for competence describes the need to experience effectiveness and mastery and can be satisfied by engaging in activities that allow the use and development of skills. Assessments that afford maximal opportunities to demonstrate competence may better support this need than those that do not (Deci et al., 1994; Gilliland, 1993)AVIs typically present interview questions in a pre-determined order, meaning candidates have no opportunity to craft their own AVI experience, and that some may encounter more challenging (competence-threatening) questions early on during the interview. Here, we invited participants in the experimental condition to specify the order in which they would receive the interview questions. We expected these participants to perceive greater support for the autonomy need (attributable to the affordance of meaningful choice; H1), and competence (attributed to the opportunity to start the interview with easier questions; H2), perceive the interview as fairer (H3), and report a more positive candidate experience (H4) compared to those who could not choose the order of questions.

Methodology: Using Prolific, we invited anyone aged 18-30 years and were willing to be recorded on video and received useable responses from 278 participants (65% Female, 33% male, 2% other, Mage = 24.9 years, SD = 3.5 years). Participants were presented with a job advertisement and asked to imagine that they had applied for the role and were subsequently invited to complete a "one-way digital interview". Those in the control condition were informed that they would next be asked to respond to three interview questions on the topics "conflict management", "time management", and "integrity", presented in a randomly determined order. Those in the experimental condition were shown the same three topics, but were then invited to organize the questions in the order they would like to respond to them. Participants then responded to three interview questions in AVI format, in the order determined during the previous session. Finally, participants were redirected to the post-interview questionnaire. Participants responded to 12 items developed in another similar project that measured perceptions of support for autonomy, relatedness, and competence, 4 items apiece (alpha = .79, .90, and .89 respectively). General fairness was assessed via three items from Langer et al 2017 (alpha = .86), and a single item "How would you describe your experience of the selection process at CSA?" with a 7-point extremely negative to extremely positive response scale captured a global candidate experience indicator.

Results: To test all Hypotheses, we performed two-tailed independent samples t-tests. Overall, the differences between the need-support and control conditions were close to zero, with the largest effect size point estimate being Cohen's d = 0.15. All t-tests were non-significant, with p -values generally well above 0.05.

Limitations and conclusions: Although we expected that providing participants with the opportunity to pre-determine the order in which AVI questions could be answered would improve perceptions of need support and of the fairness and candidate experience, the results did not support these expectations. We suggest that alternative approaches be considered if seeking to design AVIs that are more candidate-friendly. A limitation of this research is that participants were asked to imagine a job application, however a review of the responses to the questions suggested many participants took the exercise very seriously.

Relevance to the Congress Theme: This research is focused on a relatively new piece of technology that is increasingly being used for selection purposes.

Relevant UN SDGs: This research seeks to improve the experiences of individuals in the work context, specifically during job applications (SDGs 8 and 10).

Keywords: Asynchronous video interviews, Applicant reactions, Autonomy

Paper 3

Improving applicant reactions to AVIs: The role of AVI design features and applicant demographics

Ottilie Tilston, Department of Organisational Behaviour, University of Lausanne, Switzerland; Nino Sziedell, AON, Brunswick, GA, United States; Joshua S. Bourdage, Department of Psychology, University of Calgary, Canada; Nicolas Roulin, Department of Psychology, Saint Mary's University, Canada; Franciska Krings, Department of Organisational Behaviour, University of Lausanne, Switzerland

Research goals: Despite the numerous benefits that Asynchronous Video Interviews (AVIs) provide to the hiring process, research suggests that applicants do not react well to them (Langer et al., 2017). These negative reactions are likely related to certain design features, as AVIs differ widely in how they are designed (Lukacik et al., 2022). Research is only starting to document how design features are used in practice (Dunlop et al., 2022), and how applicants react to them. In the current hiring landscape, it is important for organisations to establish recruitment procedures that applicants experience positively in order to avoid driving away potential candidates (Carpentier & Van Hoye, 2021).

Theoretical background: Lukacik et al.'s (2022) model proposes that increased preparation time, response time and opportunity to re-record a response may benefit applicant reactions by reducing interview anxiety and improving fairness perceptions. It also proposes that including video questions in an AVI may improve applicant reactions by enhancing social presence and media richness (Lukacik et al., 2022). The current study tests this model on a large field dataset and extends it by further investigating the effect of number and type of questions (with a focus on past behavioural questions). We also propose that applicants' age and gender may moderate the relationships between design features and applicant reactions. In terms of age, older applicants perceive AVIs to be less fair and useful compared to synchronous interviews (Basch & Melchers, 2019), whereas younger applicants who have grown up with computer-mediated communication may be more at ease with the asynchronous video format. Gender may also moderate applicant reactions to AVI design features due to gender-related differences in appearance anxiety (Fauville et al., 2021).

Methodology: Data are fitted with linear mixed-effects models. We examine data provided to us by an AVI vendor comprised of 27,809 candidates, 32% female, mean age 25.9, SD = 7.3, ranging from 16 - 66 years. Data were collected in eleven different countries, 69.3% of them in the anglophone countries of UK, Ireland, USA, and Australia, from 33 clients and relating to 72 unique job positions. Country, client, and job position are included as random effects to account for the nested nature of the data. The data was primarily collected post-March 2020, so can be considered representative of attitudes towards technology-mediated interviewing since the onset of the pandemic.

Results obtained: A first model focused on design elements showed that preparation time and opportunity to re-record were positively related to applicant reactions, and number of questions was negatively related to applicant reactions. The remaining design features (response time, video questions, proportion of past behavioural questions) were not. A second model showed that age moderated the positive relationship between preparation time and applicant reactions, and the negative relationship between number of questions and applicant reactions, meaning older applicants preferred more preparation time and fewer questions. Age also moderated the relationship between response time and applicant reactions (older applicants prefer shorter, not longer, response times). A third model showed that gender did not have any moderating effect.

Limitations: Our data are limited by the use of a single item response variable, and future studies should include a broader range of reaction measures.

Conclusions – research and or practical implications: Our results show that certain design features can potentially improve applicant reactions to AVIs. In addition, not all applicants react uniformly (negatively) to AVIs, but younger and older applicants prefer different AVI options. This could enable AVI vendors and organisations to design these interviews in a more inclusive way.

Relevance to the Congress Theme: AVIs are relevant to the congress theme “The future is now” as they are a new selection technology that is transforming the hiring landscape.

Relevant UN SDGs: This paper is relevant to the UN SDG’s of “Gender Equality” and “Reduced Inequalities”. By establishing how AVIs may be experienced differently by diverse groups of applicants, AVI design can be improved in order to prevent additional obstacles in the recruitment process for certain applicants. This also relates to “Decent work and economic growth” for all.

Keywords: Asynchronous video interviews, Applicant reactions, Diversity and inclusion

Paper 4

Does applicant suitability affect applicant reactions to automated systems in personnel selection?

Markus Langer, Philipps-University of Marburg, Germany; Markus Kramp & Cornelius J. König | Saarland University, Germany

Research goals: As automated systems become increasingly prevalent to support decision-making in management, assessing individuals' reactions to automated systems as decision-makers becomes increasingly important. Whereas there is mounting evidence that applicants react negatively to highly-automated decisions in personnel selection, research unveiling the reasons for the preference for human decision-making still remains scarce. With this study, we contribute to understanding possible reasons why decision-recipients prefer the involvement of humans in consequential decision-making (i.e. decision-making contexts that may influence the decision-recipients' future).

Theoretical background: Research showed that applicants prefer human decision-makers over automated systems in interview-based personnel selection (Langer & Landers, 2021). We hypothesise that applicant suitability may affect the preference for human versus automated decision-making. Specifically, especially unsuitable applicants may prefer human decision-makers because they may believe that for human decision-makers they can hope for luck or biased decisions to their own favor. This hypothesis is informed by research showing that people expect humans to have more variance in their decision-making than automated systems (Dietvorst et al., 2020), and by research indicating that people believe systems to be less biased and more consistent in their decision-making processes than human decision-makers (Bigman et al., 2020; Bonezzi et al., 2022).

Methodology: In a randomized 2 (recruiting agent: human vs. automated system) x 2 (suitability: suitable, applicant characteristics match the job requirements vs. unsuitable, applicant characteristics do not match job requirements) between-subjects design, participants (N = 172; 72% students, median age = 24) had to imagine being a suitable (unsuitable) applicant for a job opening, and they were informed that they were invited to conduct an asynchronous video interview as selection tool. They were further informed that a human (an automated system) will assess their interview performance. Participants responded to applicant reaction measures (e.g., perceived fairness, opportunity to perform) and to items assessing how strongly participants believe that different applicant characteristics (e.g. qualifications, gender, attractiveness) affect the selection decision.

Results: Participants perceived automated systems as more consistent, less biased, and assumed that they are less influenced by immutable, and partly protected, applicant characteristics (e.g., gender, age, ethnicity). For job-relevant characteristics (e.g., job experience, grades, education), we found no difference between the human and the system condition, and even tendencies that participants expect that this information will more strongly influence system outputs than it influences human decision-makers' decisions. However, the preference for human decision-makers prevailed: participants rated the human decision-maker to be fairer and perceived more possibility to influence the human decision-maker. In contrast to our hypotheses, we found no interaction effect between applicant suitability and the nature of the recruiting agent regarding applicant reactions.

Limitations: Most participants were students. Also, participants had to imagine being a suitable or unsuitable applicant, so results may differ if participants would actually have to imagine being in a selection situation where their individual characteristics will be assessed.

Conclusions – research and or practical implications: Our results imply that the preference for human decision-makers in comparison to fully-automated decisions prevails despite the fact that our participants assumed human decision-making to be influenced by potentially irrelevant, immutable, and protected applicant characteristics. Additionally, our study contributes to emerging evidence showing that people seem to expect automated systems to be more consistent, less biased, and less influenced by sociodemographic attributes when producing decisions about individuals. From a practical perspective, companies using automated selection tools need to be aware that applicants may believe that systems are less biased than human decision-makers but those applicants might still prefer human decision-makers, possibly because they believe they can more likely exert a positive influence over their outcomes with human decision-makers.

Relevance to the Congress Theme: Fuelled by advances in machine learning, automated systems in personnel selection spread across the globe. This is consequently a topic where “The future is now”, where we as IO psychologists need to contribute our expertise to shape the human-centered implementation of these systems into real-world selection processes.

Relevant UN SDGs: This study has relevance regarding the UN SDGs “Gender Equality” and “Reduced Inequalities” because it examines bias-related reactions to automated selection tools. Expectations regarding less bias and more consistency when using automated systems in selection may be warranted in case providers of such tools invest to optimize their tools in this regard. However, it can also be dangerous to assume that automated tools produce less biased decisions than human decision-makers (e.g., because biased decisions will less likely be revealed).

Keywords: AI evaluation, Applicant reactions, Fairness

Paper 5

We're/It's Watching – You've Been Warned! The Effects of Evaluator Type and Warnings on Asynchronous Video Interview Outcomes

Joshua S. Bourdage & Eden-Raye Lukacik | Department of Psychology, University of Calgary, Canada

Research Goals: The proliferation of asynchronous video interviews (AVIs) (Dunlop et al., 2022; Hirevue, 2022) necessitates the investigation of behaviour and reactions to this novel modality. AVI design (the features used when creating and formatting the AVI) can affect applicants' impression management (IM) behaviour and perceptions, such as justice (Lukacik et al., 2022).

Theoretical Background: Drawing on faking likelihood theory (Levashina & Campion, 2006), AVI designs that increase applicants' willingness to use deceptive IM (i.e., faking), may negatively impact interview validity (Barrick et al., 2009; Ingold et al., 2015).

Design: This experiment (N = 297) had undergraduates complete an AVI to examine the effects of two design features on interview behaviour (i.e., honest and deceptive IM), reactions (i.e., perceptions of justice, technology, difficulty, organizational attraction), and outcomes (performance, subjective perceptions of fit, competence, hireability, likeability, professionalism, seriousness). Top performers could get a bonus. First, we manipulated the type of interview evaluator who would be engaging in deception detection. Mock-applicants were told either an A.I. trained algorithm, or a human evaluator would review their performance. Second, we manipulated the consequences for being caught deceiving (i.e., a faking warning was used) by telling applicants that they could be identified (deception detection was used, but no punishment) or that deception detection meant disqualification (disqualification from bonus).

Results: Willingness to engage in deceptive behavior did not significantly differ between the conditions, however, there was some evidence from ANOVA that those presented with a disqualification warning engaged in less extensive image creation (fabricating experience and lying), engaged in more honest ingratiation (truthful expressions of how their values and opinions aligned with the organization), and were overall more honest in their responses. More honest self-promotion and ingratiation were directed towards A.I. evaluators compared to human evaluators. Counter to expectations, evaluator type did not affect technology acceptance, privacy concerns, or perceptions of social justice. Faking warnings were associated with lower privacy, however structural justice perceptions (beliefs about job relevance, information provided, chance to perform, reconsideration and feedback opportunity) were higher for those who were told that deception would be punished (i.e., no chance for a reward). Interview performance was not significantly influenced by the evaluator type or warnings, except for the overall subjective rating of applicant (higher on average for those in the disqualification conditions). These findings should be interpreted with caution, as controlling for number of tests reduced the significance of effects.

Limitations: The sample was completing an interview for a position they may not have chosen to apply for but were incentivized to perform their best regardless.

Conclusions: This research contributes to our understanding of applicant behaviour in AVIs where there is no dynamic human interaction, and specifically how applicants use honest and deceptive IM in this context. This research also speaks to how deceptive behaviour can be mitigated in AVIs and how applicants react to faking-related AVI design decisions. The findings suggest that faking warnings

may function for AVIs as they have for other assessments (Burns et al., 2015; Dwight & Donovan, 2003; Law et al., 2016; McFarland, 2003).

Relevance to congress theme: AVIs themselves are a novel technology that is changing the hiring landscape, and the incorporation of other technology into AVIs, such as artificially intelligent algorithms, pushes this boundary even further. As such, this work is well-aligned with the theme of the changing world of work. Our contribution to the future is examining the direct effect AVIs have on organizations and work through selection. Our competencies will have to expand to implement AVIs reliably and effectively. It is urgent that new selection modalities follow best practices even in times of economic crisis, and we want to deliver evidence-based conclusions to improve hiring technology in the future.

Relevance to UN SDGs: This work is relevant to the UN SDGs of having decent work and economic growth for all, and to promote industry innovation and infrastructure. The UN notes that two impediments to global economic recovery are labour market challenges and COVID-19. Under the right design conditions, AVIs could be a valuable tool for addressing these issues. AVIs allow for remote and safe selection and can tap international labour markets to screen applicants worldwide. Further, the UN notes that higher technology industries are more resilient in a crisis than lower technology industries. Further investigation is needed to determine best practices, but AVIs are one technological innovation that may help organizations meet recruitment and selection demands.

Symposium S025

Demographic Change is Now: Four Approaches to Bolster the Ability, Motivation, and Well-being of an Aging Workforce

Julian Pfrombeck, Columbia University; Sara Zaniboni, University of Bologna

science

What will be covered and why (including the contribution of any discussant)

Many European countries experience demographic shifts toward an aging population due to higher life expectancies and lower birth rates over the past decades. Because of these developments, traditional views of careers and retirement systems have become increasingly outdated. In the present and even more so in the future, individuals will be expected to engage in extended working lives and change their careers in alignment with their motivation, ability, and needs. This symposium consists of four contributions from research teams across Australia, Italy, Ireland, Germany, Switzerland, and the United States presenting a variety of approaches to bolster the ability, motivation, and well-being of an aging workforce. McCarthy, Brady, Truxillo, and O'Shea present the results of their meta-analysis on work ability interventions. Work ability captures a person's ability, or perception of their ability, to meet the demands of their current role interventions. Gioaba and Andrei take a self-regulatory perspective to examine the consequences of subtle age discrimination on older workers' well-being in a longitudinal field study. The last two presentations focus on how people's mindsets (i.e., their subjective sense-making of aging and uncertainty) shape their occupational future time perspective and motivation to continue working. Weiss, Weiss, and Zacher explore the role of essentialist beliefs about aging on older workers' motivation to continue working beyond retirement age in a field study and an experiment. Pfrombeck, Zaniboni, Magni, Gerlach, Strittmatter, and Grote develop the concept of uncertainty mindsets and demonstrate how uncertainty mindsets shape employees' occupational future time perspective through engagement in opening behaviors. Together, these contributions highlight an array of innovative approaches to promoting the ability, motivation, and well-being of an aging workforce. Our discussant, Mo Wang, emphasizes the theoretical and practical implications of the symposium contributions and provides constructive suggestions to enhance these and future research efforts.

Relevance to the Congress Theme

The Congress theme – the future is now: the changing world of work – highlights the urgency to act now to address ongoing changes and to deliver solutions to current problems. The age composition of the workforce is one way in which the world of work is already changing right now. Due to different developments, populations and workforces are aging in many developed countries requiring organizations and policy makers to act. The ability, motivation, and well-being of older employees represent key aspects for successful aging at work.

Research/Practical Implications

The symposium advances our understanding of important psychological experiences and structural interventions relevant to an aging workforce. A better understanding of older individuals' experience of subtle age discrimination and the effectiveness of work ability interventions informs organizations about potential structural steps to curtail organizational measures to an aging workforce. Mindset interventions that address essentialist beliefs about aging or uncertainty regulation enable older individuals to maintain and enhance motivation, ability, and well-being in their late career stage.

Overall conclusions

This symposium highlights how different psychological and structural approaches can help bolster the ability, motivation, and well-being of an aging workforce.

Keywords: Aging workforce; demographic change; intervention

Paper 1

The Effectiveness of Workplace Interventions on Employee' Work Ability: A Meta-Analysis

Deirdre O'Shea & Donald Truxillo | University of Limerick; Grant Brady, California State University, East Bay; Gemma McCarthy, University of Limerick

Background

Over the past few decades, there has been an increase in life expectancy around the world (Woolf & Schoomaker, 2019). Moreover, the demographic shifts of an aging population and declining birth rates are leading to a new reality in which relatively fewer younger workers are available to support the aging population (Osterman et al., 2021; Ritchie & Roser, 2019), which is putting increased pressures on retirement systems. To understand how we might extend working lives, there has been a growth in research on work ability, which is defined as a person's ability, or perception of their ability, to meet the demands of their current role (Ilmarinen et al., 1991). Given that work ability has been found to predict important work outcomes, including retirement (Von Bonsdorff et al., 2009), turnover intentions (Derycke et al., 2012), and job satisfaction (Wagenaar et al., 2015), there has been an increase in the number of intervention studies aimed at improving employee work ability. However, it is not yet known what type of interventions, if any, lead to improvements in work ability? The present study will systematically evaluate the efficacy of work ability intervention studies conducted to date.

Research goals and why the work was worth doing

This research aims to investigate the efficacy of work ability interventions, specifically by meta-analysing the findings from past intervention research on work ability. There has been a significant increase in workplace interventions aiming to improve work ability in recent years. Some studies have shown a positive effect of workplace interventions on increasing work ability, while other interventions did not impact work ability.

Design/Methodology/Approach/Intervention

Building on previous research conducted by Brady et al. (2018), we searched PsychInfo and PubMed for additional work ability intervention studies published between 2015 and 2021. We also included additional articles in scoping reviews that were not found in our search.

Results expected

A total of 111 empirical studies are included in our analysis. To date, we have coded a portion (k=48) of the total studies. Preliminary analysis of the coded sample suggests that work ability interventions are effective (d = .25, 95% CI [.17, .32]); however, we have yet to determine which types of interventions work best. The intervention types include, but are not limited to, ergonomic interventions, physical exercise, job design, and educational training. We are also coding for factors such as intervention length and whether the intervention is online or in-person. The final results will be presented at the EAWOP conference.

Limitations

Many of the interventions are multimodal which will make it difficult to draw conclusions about what specific components of the interventions are effective at increasing work ability.

Conclusions – research and or practical implications

Identifying which types of interventions are most effective at improving work ability will allow researchers and practitioners to develop more focused interventions to promote work ability.

Relevance to the Congress Theme

As the workforce continues to age, future efforts to encourage longer working lives will be crucial. Given the ever-changing nature of work, it is vital to be able to monitor the alignment between a worker's abilities and the demands of their job. Furthermore, when work ability is low, it is important to identify ways to improve one's ability to meet their work demands.

Relevant UN SDGs

This research is closely related to goal 3 (to ensure healthy lives and promote well-being for all at all ages) as it aims to identify ways of supporting employee work ability, which has been found to decline with age (Brady et al., 2020). Furthermore, given that work ability has been shown to be a good predictor of labour force outcomes, our research project aligns with UN SDG 8, which aims to promote sustained, inclusive, and sustainable economic growth, full and productive employment, and decent work for all.

Keywords: work ability; intervention

Paper 2

The Role of Uncertainty Mindsets in Extending Occupational Future Time Perspective

Pfrombeck Julian, Columbia University; Zaniboni Sara, University of Bologna; Magni Federico, Gerlach Alina, Strittmatter Laura Elaine & Grote Gudela, ETH Zurich

Research goals

Demographic trends in many European countries require a longer active engagement of older individuals in the labor market. Occupational future time perspective is a key variable in predicting older employees' work engagement and motivation to continue working. With increasing chronological age, employees' occupational future time perspective becomes more limited. The aim of this research is to examine whether changing employees' uncertainty mindsets is one way to enhance their occupational future time perspective. An uncertainty mindset can be conceptualized as the extent to which people hold the belief that uncertainty entails threats versus opportunities and is fixed versus malleable.

Theoretical background

Managing uncertainty is an important part of our lives. This has become particularly salient during the Covid-19 pandemic. But also under less severe circumstances, managing uncertainty is an inextricable part of people's future career and work life planning by the mere fact that the future is not entirely predictable. Uncertainty to date has not been explicitly included in theories of aging and lifespan research. Drawing on theories of uncertainty regulation, we argue that by proactively regulating the amount of uncertainty one is exposed to, individuals' future time perspective can be altered. Specifically, we predict that a positive uncertainty mindset (i.e., people experience uncertainty as malleable and a source of opportunities) is positively related to employees' engagement in opening behaviors (i.e., exploration strategies and career planning). By engaging in these opening behaviors, employees unfold new opportunities and perspectives, which positively affect their occupational future time perspective.

Design and Methodology

First, we established the concept of uncertainty mindsets, and we developed a scale to measure multiple dimensions of uncertainty mindsets (i.e., threat, opportunity, fixed, malleable). A pilot study with 141 employees has been conducted to establish the validity and reliability of the new measure. Then, a time-lagged study among 679 employees from different industries has been conducted to test our hypotheses. We measured employees' uncertainty mindset at T1, and opening behaviors (i.e., exploration strategies and career planning) and occupational future time perspective at T2.

Results

The results of the pilot study confirmed convergent and divergent validity of uncertainty mindsets. The developed uncertainty mindset measure also demonstrated high internal consistency. In Study 2, we found that individuals with an opportunity and malleability uncertainty mindset engaged in more exploratory strategies and career planning, which in turn, had positive effects on occupational future time perspective. Uncertainty mindsets could explain unique variance in opening behaviors and in occupational future time perspective above and beyond established predictors, such as age, aging mindsets (whether aging is fixed or malleable), work experience, proactive personality, and other personality traits.

Limitations

The design of Study 2 focuses on between-person differences in uncertainty mindsets. It precludes us from examining the effect of within-person change over time and the causal effect of uncertainty mindsets on opening behaviors and a more extended occupational future time perspective.

Conclusions

With this research, we established the concept of uncertainty mindsets and demonstrated its practical relevance in shaping employees' occupational future time perspective. Our research advances motivational theories in aging and lifespan research by theorizing and empirically testing the role of uncertainty regulation in extending occupational future time perspective.

Relevance to congress theme

Our research embraces the congress theme of the changing world of work in several ways. First, our research is relevant to addressing the challenges of a changing demographic landscape in the labor market with an increasing share of older individuals. Second, our research is relevant to addressing the many uncertainties that come with changes in the world of work. Our research offers a more balanced view of uncertainty, one that acknowledges its threats and also its opportunities. We demonstrate that the experience of uncertainties can be successfully managed by adopting a mindset that allows for volitional uncertainty regulation.

Relevance to UN SDGs

This research contributes to two UN Sustainable Development Goals. First, our research identified uncertainty mindsets as a critical factor to enhance occupational future time perspective, which contributes to creating inclusive and sustainable economic growth by addressing demographic changes and an aging population. Second, our research addresses the goal to promote good health and well-being because occupational future time perspective is not only related to engagement and motivation to continue working but also well-being and healthy aging at work.

Keywords: Uncertainty mindset; opening behaviors; exploration

Paper 3

Subtle Discrimination Experiences of Mature Workers and Their Effect on Workplace Wellbeing

Daniela Andrei, Curtin University; Irina Gioaba, Kean University

Research goals

The last few decades have witnessed a tremendous increase in workforce participation among the older segment of the population (Toossi & Torpey, 2017). Despite these recent trends, bias and discrimination against mature workers is a common phenomenon, documented by both field and experimental evidence (Gioaba & Krings, 2017; Krings et al., 2021; Lahey, 2008; Neumark et al., 2015). However, most of this evidence focuses on formal and overt forms of discrimination, leaving the subdomain of subtle, interpersonal discrimination largely understudied (Jones et al., 2016). The goal of this research is to investigate the effects of subtle age discrimination on older workers on workplace wellbeing, with an additional emphasis on understanding which mature workers are more affected.

Theoretical background

Subtle discrimination refers to negative and ambivalent demeanor and/or treatment enacted toward social minorities that is not necessarily conscious and is likely to convey ambiguous intent (Jones et al., 2016). Unlike overt forms of discrimination, subtle discrimination is less likely to be unlawful and readily apparent, being often regarded "everyday discrimination" due to its seemingly natural, normal, and harmless nature (Deitch et al., 2003). It can take various shapes from harassment, incivility, malicious remarks, jokes, to nonverbal behaviors such as avoiding gaze, reduced smiling, or larger interpersonal distance (Cortina, 2008; Hebl et al., 2002; Van Laer & Janssens, 2011). While less harmful in appearance, this form of discrimination has been shown to be just as (if not more) detrimental, relative to overt discrimination (Dhanani et al., 2018; Jones et al., 2016). Given that the intent is less clear, targets are more likely to expand cognitive resources to understand if discrimination has actually occurred. To better understand the effects of subtle discrimination on mature workers, we draw upon self-regulation theory (Baumeister et al., 1998; Muraven & Baumeister, 2000) to investigate how daily incivility exposure can affect two important indicators of workplace wellbeing: job satisfaction and work engagement. According to this theory, individuals have a limited pool of self- regulatory resources at any given time, and the regulation of one's thoughts, actions, and emotions exerts self-control, therefore reducing the reserve of available resources needed for subsequent tasks. Empirical evidence supports these assumptions, showing that individuals who experienced subtle discrimination performed worse on subsequent tasks due to depletion of their cognitive resources and reported reduced self-control strength which led to poorer emotional outcomes the next day (Park et al., 2021; Walker et al., 2021).

Methodology

Using a 4-wave longitudinal study of mature employees (N =673, 51.6% male) in Australia, we measure incivility experiences, self-regulatory resource depletion, job satisfaction and work engagement.

Results

Preliminary results from the first wave support our predictions that incivility has a negative impact on job satisfaction (B = -.39, SE =.05, p <.001) and work engagement (B = -.30, SE =.04, p <.001).

The rest of the data will be collected by December 2022 and we expect to present final results in May 2023.

Limitations

Although our four-wave longitudinal study has distinct advantages, especially compared to typical cross-sectional research designs, we are concerned that the longer time intervals between measurements might be insufficient for capturing subtle discrimination experiences. Therefore, we plan on conducting a second study using an experience-sampling methodology which will allow us to examine within-person fluctuations in emotions and behaviors as they occur naturally, in their spontaneous context (Bolger et al., 2003). This design is commonly used in studying short- and long-term effects of subtle forms of discrimination (e.g., Jones et al., 2020).

Conclusions

This research expands our understanding of the contexts and consequences of subtle bias against mature workers. It is important that organizations understand the ramifications of age discrimination and are aware of the negative impact of such displays and take steps to curtail the occurrence of subtle discrimination.

Relevance to the Congress Theme

This research is highly relevant to the theme of the congress as it examines an underrepresented yet growing proportion of the workforce. It is estimated that by 2030 the number of individuals aged 55+ will increase by more than 15% (Van der Heijden et al., 2008). Therefore, accommodating and managing the increasingly age-diverse workforce is of utmost priority for the future of work.

Relevant UN SDGs

This research contributes to a better understanding of the workplace experiences of mature employees and responds to the United Nations Sustainable Goal of reducing inequalities.

Keywords: age discrimination; age diversity; wellbeing

Paper 4

All Set in Stone? How Essentialist Beliefs about Aging Affect Older Workers' Motivation to Continue Working Beyond Retirement Age

Hannes Zacher, Leipzig University; David Weiss, Martin-Luther University of Halle-Wittenberg; Mona Weiss, Freie Universität Berlin

Research goals

Although population aging requires that employees increasingly work beyond traditional retirement ages, negative age stereotypes often portray older workers as unwilling or unable to work longer. However, recent lifespan developmental research suggests that there are significant individual differences in how fixed versus malleable individuals perceive the aging process, which may possibly affect how they envision their occupational future.

Theoretical background

In this paper, we develop and test a new theoretical model on the role of essentialist beliefs about aging (EBA) in affecting retirement decisions. EBA refer to the extent to which people believe that aging is an immutable, genetically determined vs. a flexible and malleable process. EBA as recently developed construct have been shown to affect how people deal with aging-related changes and master cognitive tasks. We hypothesized that older workers (40–65 years) who more strongly endorse essentialist beliefs about aging will be less motivated to continue working beyond retirement age, because they have a more constrained occupational future time perspective (OFTP).

Design and Methodology

To test our hypotheses, we conducted two studies that encompassed a three-wave longitudinal study (Study 1; N = 631) and an experiment (Study 2; N = 358) using two heterogeneous samples of working adults aged 40 to 77 years. In Study 1, we tested an autoregressive panel model assessing EBA at T1, OFTP at T2 and motivation to continue working using at T3 while controlling for the autoregressions. In Study 2, we manipulated EBA and assessed its subsequent effects on OFTP and motivation to continue working.

Results

Across both studies, we find evidence for our proposed indirect effect model, above and beyond previously established control variables (e.g., age, income, health, and age stereotypes). In Study 1, we find that EBA are negatively related to motivation to continue working and that this relationship is mediated by a more constrained OFTP. In Study 2, we largely replicate the results of Study 1 and demonstrate a significant indirect effect of EBA on motivation to continue working through OFTP.

Limitations

In Study 1, we focused on between-person differences rather than on within-person change over time. Thus, future research is needed to investigate how EBA, OFTP, and motivation to continue working might change and affect each other (possibly also reciprocally) over time. Another limitation pertaining to both studies is that we did not include potential contextual moderators (e.g. organizational support) that may also impact individuals' motivation to continue working.

Conclusions

Our findings advance theorizing on work motivation and retirement in later adulthood by pointing to the important but so far neglected role of EBA. On this basis, our findings also offer important practical implications by showing that EBA can be targeted through interventions in order to motivate older individuals to work longer.

Relevance to congress theme

Our research speaks to the profound workplace changes due to population aging. The share of older individuals is steadily increasing, which also means that there are fewer younger individuals available who could replace older workers. Thus, policymakers and organizations need to gain more insight into the psychological preconditions that enable older workers to work longer. One possibility is to increase options for partial retirement schemes that enable extended work lives while also supporting those who wish to retire due to health-related reasons.

Relevance to UN SDGs

Our work contributes most to UN Sustainable Development goal to create sustained and inclusive economic growth. Such growth is only possible if we understand how population aging and age diversity can be best managed in the upcoming years and decades. At the broader societal level, we need to also critically reflect on our images of aging that may often lead to age discrimination. Negative representations and beliefs about aging may suggest that older workers are not as capable and competent as younger workers, which, in turn, may undermine older workers' beliefs in their ability to work longer. Thus, to promote age-friendly workplaces, we need to promote and be inclusive to all age groups.

Keywords: beliefs about aging; experiment

symposium S026

Leadership and Aging I: Impact of Leadership style and Organisational Practices

Franziska Jungmann, International School of Management, Berlin, Germany; Eva Zellman, Curtin University, Perth, Australia

science_practice

What will be covered and why: Demographic change is altering the age-composition of the workforce, resulting in more older workers and increasingly age diverse teams (e.g., Boehm & Dwertmann, 2015; Czaja, 2020; Truxillo et al, 2015). The demographic change signals the need for leaders and organisations to create a work environment that aligns with age-related needs and preferences, fosters wellbeing, as well as creating decent work opportunities regardless of age. For example, to mitigate against age biases and discrimination, and leverage the distinct knowledge and perspectives that workers of different ages offer, organisations need to have effective organisational practices in place. However, organisations have been slow to implement policies and practices to support an older and more age diverse workforce (Perron, 2020; Truxillo et al, 2015).

Leaders are well positioned to shape the experience of aging and age diverse employees because they have the opportunity to influence important team processes and most aspects of followers' experience, wellbeing, and performance at work (Kunze & Bruch, 2010; Kearney & Gebert, 2009). Studies show that leader attitudes and behaviours can have an important influence on employees` performance and well-being (e.g., Ilmarinen & Tempel, 2002).

Yet, it is unclear which particular types or styles of leadership are most effective to achieve positive outcomes for age diverse employees. Are established leadership styles such as LMX or supportive leadership sufficient? Is there a need for specific age-oriented or age-inclusive leadership? What are the impacts of HR practices and an age-friendly workplace climate? What other factors enable leaders to consider age and effectively manage age diversity?

In this two-part symposium we aim to find answers to these questions by incorporating a range of empirical and conceptual contributions including intervention studies focusing on how to close the research-to-practice gap.

This first part of the proposed two-part symposium, Aging and Leadership I: Impact of leadership style and organisational practices , explores the interaction between followers' age and leadership in the workplace, and will examine the impact of different leadership styles on aging and age diverse workers. It is followed by a second symposium, Aging and Leadership II: Impact of leader characteristics and training , that builds upon the first symposium by investigating the effects of leaders' attributes and characteristics, and presents practical organisational interventions to improve the work environment of age diverse workers.

The first study sets the stage by providing a systemic review on the impact of different leadership styles on team processes and employee outcomes. The authors review the relevant literature and discuss whether certain leadership styles are more beneficial for different age groups and outcomes. The second study looks how workers' employability can be enhanced across the work lifespan by examining leader-member-exchange as a crucial leadership style. The third study tackles age stereotypes and technology usage. The authors propose two processes in which age and technology usage and acceptance are related, and furthermore test digital leadership as a potential moderator. The objective of the fourth study is to analyse how supportive leadership can counteract the possible negative age biases in the field of STEM and thus reduce turnover and career withdrawal. The fifth

study complements the previous studies in considering the congruence of leaders' and employees' perceptions of age-friendly HR practices. The authors analyse the impact of an (mis)aligned perspective on employee's well-being.

Relevance to the Congress Theme: An aging and more age diverse workforce is an accelerating trend in in the European Union as well as in most other developed countries (Boehm & Dwertmann, 2015). Hence, this is something organisations and leaders need to manage now, and not push towards the future. Identifying the effectiveness and impact of different leader behaviours and organisational practices will not only provide benefits in terms of wellbeing and decent employment for workers of all ages, but also more resilient and successful organisations.

Overall conclusions and research/practical implications: The proposed two-part symposium addresses leadership as an important mechanism to overcome ageing and age diversity challenges. The studies reveal the beneficial effects of several leadership styles on follower outcomes and highlight the potential value of an age-oriented leadership style. Moreover, the studies demonstrate the importance of leader characteristics and provide guidelines on evidence based organizational interventions. Despite the diverse contributions to this symposium, more research is needed to explain, for example how age-oriented leadership exerts its effect on employees of different age groups and across industries.

Keywords: Age diversity, Leadership, HR interventions

Paper 1

Leading an Age Diverse Workforce: A Systematic Review of Leadership Styles and Their Impact on Ageing and Age Diverse Employees

Eva Zellman, Sharon Parker & Daniela Andrei, Curtin University, Perth, Australia

Research goals and why the work was worth doing: Due to changes in population demographics, the workforce is aging and becoming more age diverse (Truxillo et al., 2015). This trend requires organisations to effectively mitigate against age biases, ensure the workplace enables sustained employability of older workers, and leverage the potential performance and innovation advantages associated with age diversity (Gürbüz et al., 2022; van Knippenberg et al., 2004). Leaders are well positioned to help achieve such goals as they are responsible for managing each worker individually, as well as leading the team as a whole, and can substantially influence most aspects of subordinates' experience, wellbeing and performance (Kunze & Bruch, 2010).

Against this background, our goal is to conduct a systematic review to understand how different styles of leadership influence individuals of different ages, and affect individual and team level processes relevant to an age-diverse workforce. The impact of many different leadership styles, such as supportive, transformational and inclusive leadership, on employees of different ages have been discussed in the literature the last 30-40 years (e.g. Gürbüz et al., 2022; Kunze & Bruch, 2010; Profili et al., 2016). However, it is not clear for what age groups, and in what way, different styles of leadership have positive impact. For example, we don't know if a particular style of leadership is more beneficial for older or younger workers, or the distinct types of impact the different styles may have (e.g. enhancing engagement or reducing bias). Integrating the literature to understand this gap in the literature will help progress research, as well as provide insights from a practitioner perspective.

Research methodology: In this systematic review we identified and screened 8599 abstracts from peer reviewed publications since 1980 by searching 4 different databases using keywords associated with "leader", "age" and "workplace". Three hundred and twenty-nine full text articles were reviewed, with 158 meeting the inclusion criteria. These were coded based on leadership styles, variables measured and methodological characteristics. The data is yet to be summarised, itemised and analysed.

Results expected: While the full data analysis is yet to be conducted, our initial analysis indicates that the vast majority of studies use quantitative methods with a cross sectional research design. With regards to representation of age of followers, about a third of the studies use 'generations', with the remainder using age groups or age as a continuum. In terms of leadership styles researched, supportive, transformational and leader-member exchange are the most studied leadership styles. Preliminary results suggest that older workers may benefit more from a supportive style of leadership, while leader-member exchange seems somewhat more important for younger workers.

Limitations: Publication and language bias are two key limitations in this study as we only included peer reviewed publications written in the English language in our search.

Conclusions: Conclusions will be drawn once the full data analysis has been completed.

Relevance to the congress theme: The demographic changes with an aging and more age diverse workforce are experienced in most developed countries, and is expected to accelerate further

(Boehm & Dwertmann, 2015; Temple & Wilcon, 2021). It is therefore important to have leaders who are well equipped to deal with the challenges and opportunities a more age diverse workforce presents now and in the future.

Relevant UN SDGs: This research is relevant to the UN SDGs “Decent work and economic growth” as well as “Reduced inequalities”. Understanding how leaders best can manage ageing and age diverse employees partly involve leaders reducing inequalities driven by ageism, as well as enhancing inclusion that makes employees thrive and enables sustainable employment.

Keywords: Leadership styles, Age, Systematic review

Paper 2

How supervisor's life-span related HRM practices relate to work-related flow and employability: The role of leader-member exchange

Beatrice Van der Heijden, Radboud University Nijmegen, Netherlands; Adelien Decramer, Vincent Goossens, Elias Janssen & Mieke Audenaert | Ghent University, Ghent, Belgium

Many organizations are challenged by demographic changes that require attention in order to safeguard all workers' sustainable employability. Supervisor's Life-Span related HRM (SL-HRM) practices may be a way to cope with issues related to these demographic changes. This study aims to increase our understanding of how SL-HRM practices are linked to workers' employability via work-related flow, and to examine whether LMX quality moderates this relationship. SEM analyses among 698 respondents in 51 educational institutions across the Netherlands reveal that SL-HRM practices are positively related to several dimensions of employability, through work-related flow, and that LMX quality serves as a lens through which these HRM practices are interpreted. Our findings suggest that such practices can indeed make a difference in workers' employability, but that its effectiveness depends on the LMX quality.

Relevance to the congress theme: By focusing on the role of the employee's supervisor, and the exchange relationship between the two parties can play with regard to protecting workers' well-being and prosperity at work, we add to the scholarly knowledge. In particular, our research contributes to a better understanding of which measures may enhance opportunities to cope with the changing world of work.

Relevant UN SDGs: Promote sustained, inclusive and sustainable economic growth, full and productive employment and decent work for all.

Keywords: SL-HRM practices, Employability, LMX

Paper 3

A Dual Pathway Model of Age and Technology Acceptance: Highlighting the Impact of Digital Leadership

Ulrike Fasbender & Laura Rinker | University of Hohenheim, Stuttgart, Germany; Fabiola Gerpott, WHU - Otto Beisheim School of Management, Düsseldorf, Germany

Research goals and why the work was worth doing: Rapid technological advancements and global workforce aging shape the future of work. To date, we know very little about how employees' age is shaping technology acceptance at work. A meta-analysis revealed that age is negatively related to employees' perceived ease of use, perceived usefulness, and intention to use a technology (Hauk et al., 2018). While these findings seem to support stereotypical views that technology is less popular with increasing age, the processes behind these findings remain unknown. Against this background, our study aims to connect the literature on aging with the research on technology acceptance in organizations.

Moreover, while employees' technology acceptance is certainly determined by different person factors, including their aging experience and technology motivation, we argue that employees' work environment also matters. Specifically, we focus on digital leadership, which refers to favorable supervisor behavior and attitudes toward digitalization, including up-to-date digital knowledge and enthusiasm about the digital transformation at work (Zeike et al., 2019). Relying on the notion that supervisors high in digital leadership motivate and develop technology-related capabilities in their employees (Larson & DeChurch, 2020), we explore digital leadership as a potential moderator in this study.

Theoretical background: Our conceptual model is based on the technology acceptance model (Davis, 1985, 1989) and states that the two components perceived usefulness (i.e., the expectation that using a technology improves one's productivity) and perceived ease of use (i.e., the perception that using a technology is simple) determine employees' attitude toward new technology (i.e., the positive or negative evaluation of a technology that has been newly introduced to an employee; Davis et al., 1989). To untangle the complex relation between employee age and attitude toward new technology, we develop a dual pathway model consisting of a motivational and a capability pathway. In a nutshell, the motivational pathway captures perceived usefulness as the motivational force, while the capability pathway captures perceived ease of use as the capability-related force driving the attitude toward a new technology. We further derive aging-related mechanisms that match the motivational and the capability-related forces. On the motivational side, we consider the two dimensions of future time perspective, namely future opportunities and remaining time that inform perceived usefulness. On the capability side, we consider two cognitive constraints, namely processing speed difficulties and organization difficulties that inform perceived ease of use. Furthermore, we extend the model by considering digital leadership as a potential moderator of the effects of employee age on future time perspective and cognitive constraints, and its subsequent indirect effects on attitude toward new technology.

Research methodology: We pre-registered our hypotheses at the Open Science Framework (https://osf.io/z2vjd/?view_only=b70b7d4240cc435cae0a4994bb1363f8). We tested our hypotheses using three-wave data of 643 employees. We applied structural equation modelling in Mplus 8.4. We used the XWITH command to test the interaction effects between age and digital leadership. Since bootstrapping is not available when using the XWITH command in conjunction with MLR estimation

in Mplus, we applied Monte Carlo-simulation of confidence intervals for the indirect and conditional indirect paths in R.

Results obtained: Our findings support our hypotheses for the motivational pathway showing that age is negatively linked to attitude toward new technology via future time perspective, and subsequent perceived usefulness and perceived ease of use. Digital leadership buffered the negative indirect effects of age on attitude toward new technology. For the capability pathway, the results were opposite to what we expected. Specifically, age was negatively related to organization difficulties, which in turn were negatively linked to attitude toward technology via perceived ease of use and perceived usefulness.

Limitations: First, we used a self-report survey approach to collect the data, potentially raising concerns of common-method-bias or that participants may be subject to positive illusions when asked to report on undesirable developments such as cognitive constraints. Second, although we utilized a time-lagged design, more fine-grained and long-term temporal relations of employee age and attitude toward new technology remain unclear.

Conclusions: Together, our findings put the link between age and technology acceptance into a more positive light than previous research and suggest that motivational and capability-related forces are interwoven in predicting attitude toward new technology.

Relevance to the congress theme: Workforce aging and digitalization are two mega trends in business and society that we address with our research. Moreover, by pointing to the moderating role of digital leadership we provide some concrete solutions (that can be applied right now!) to the problems of the changing world of work.

Relevant UN SDGs: Decent work and economic growth

Keywords: Digital leadership, Age, Attitude towards technology

Paper 4

A multi-sample study of the role of age, supportive leadership, and perceived age bias on withdrawal in STEM

Lucinda Iles, Curtin University, Perth, Australia; Sharon Parker & Daniela Andrei | Curtin University, Perth, Australia

Theoretical background and research goals: The importance of a strong science, technology, engineering, and mathematics (STEM) industry has never been clearer than in recent years. However, organizations that employ STEM professionals are facing serious workforce shortages as modelling predicts approximately one million unfilled jobs in the coming decade (Iammartino et al., 2016). Given the additional challenges presented by population aging, it is important that STEM organizations retain and engage employees across the lifespan. Therefore, this study aims to explore the relationship between age and two indicators of withdrawal, turnover intentions and career disengagement in STEM workers.

We situate our study within Zacher and Froidevaux's (2021) framework which integrates ageing theories with career outcomes and argues that personal and contextual age-related factors can interact to influence career behavior. We identify age bias as an important mediating factor in the relationship between age and withdrawal, which is likely to be a particular risk in the STEM context. Highly prevalent STEM job-related stereotypes related to modernity, innovation, and technology make older workers particularly vulnerable to bias because they contrast with common older worker stereotypes (Perry et al., 1996; Posthuma & Campion, 2009). Leadership behavior has been recognized as a factor that may help reduce the experience of age bias and may counteract the negative effects of the STEM context (Homan et al., 2020). We hypothesize that supportive leadership, defined as "when leaders express concern for, and take account of, followers' needs and preferences" (Rafferty & Griffin, 2006, p. 39) should be especially important for older workers, who tend to show a greater preference for meaningful social interactions (Rudolph & Zacher, 2017).

Design and methodology: We used three samples to test our hypotheses. Study 1 tested the effect of age on turnover intentions and career disengagement via perceived age bias, moderated by supportive leadership in a cross-sectional sample of 256 employees from an Australian engineering firm. In Study 2, we focused on the role of supportive leadership by testing the indirect effect of leadership on withdrawal via age bias across a 6-month period in 2020 for 102 older STEM workers (aged 45 and over). Finally, we tested our assumption that these processes were especially important for STEM workers. Using large panel survey design (N=1970), we tested a three-way interaction between age, supportive leadership, and STEM work on age bias, as well as the indirect effect on withdrawal.

Results: Study 1 found that supportive leadership moderated the effect of age on bias, with a significant negative relationship when leadership was high. Also, the indirect effect of age on both turnover intentions and career disengagement was positive and significant when leadership was low.

Study 2 tested the indirect effect of supportive leadership on withdrawal outcomes over time. We found a significant negative indirect effect of leadership at time one on career disengagement at time 2 (controlling for values at time 1). We did not find evidence of this longitudinal effect on turnover intentions however we note that the coronavirus pandemic may have played a role in this.

In study 3 we found support for our hypothesized three-way interaction. The association between age and age bias was negative and strongest for STEM workers with highly supportive leaders. Consistent with Study 1, the indirect effects of age on turnover intentions and career disengagement were positive when supportive leadership was low and negative when leadership was high. As expected, these effects were stronger for STEM workers.

Limitations: Our research relies on three separate self-report datasets, with participation restricted to Australian workers only. Study 2 focuses solely on older workers, limiting our ability to compare with younger workers. Studies 1 and 3 are each limited in their reliance on cross-sectional data, limiting the ability to make causal claims.

Conclusions and relevance to congress theme: Our study highlights the importance of supportive leadership for older workers, particularly those in STEM and contributes to a growing body of evidence on the potential value of an age differentiated approach to leadership (Wegge et al., 2012). The research contributes to the conference theme through the examination of the aging workforce, a phenomenon that will continue to change the demographics of our organizations. The research's focus on reducing turnover and career disengagement contributes to the UN SDG theme "Decent Work and Economic Growth" and "Reduced Inequality" as it identifies supportive leadership as a means through which STEM organizations can retain the wisdom of older workers by reducing the experience of age bias.

Keywords: Supportive leadership, Age bias, Work withdrawal

Paper 5

The Role of Perceptual Congruence of Age-Friendly Organizational Practices Between Leaders and Older Employees and Impact on Wellbeing

Julia Finsel, Leuphana University of Lüneburg, Lüneburg, Germany; Laura Venz, Leuphana University of Lüneburg, Lüneburg, Germany; Anne Wöhrmann , Federal Institute for Occupational Safety and Health (BAuA), Dortmund, Germany; Max Wilckens, Leuphana University of Lüneburg, Lüneburg, Germany; Jürgen Deller, Leuphana University of Lüneburg, Lüneburg, Germany

Research goals: In times of demographic change and aging workforces, organizational strategies on how to retain and improve older employees' well-being become increasingly important. Research so far has tended to focus on older employees' perceptions of age-friendly organizational practices. We extend this research by also considering other organizational stakeholders' perceptions. Prior research suggests that leaders' perceptions, in particular the similarity of perceptions held by employees and leaders (i.e., perceptual congruence), are related to employee work outcomes like their job satisfaction and performance. In our study, we applied the concept of leader-employee perceptual (in)congruence to the context of aging workforces and assessed whether leader-employee perceptual (in)congruence on age-friendly organizational practices regarding organizational climate, management, and work design plays a role for older employees' well-being.

Theoretical background: Drawing on perceptual (in)congruence and psychological contract theory, we hypothesize that older employees' well-being will be higher when older employees and leaders align at high levels of perceived age-friendly organizational practices compared to when they align at low levels. Moreover, we hypothesize that older employees' well-being will be lower when leaders evaluate the perceived age-friendly organizational practices higher than older employees (i.e., leaders' overestimation) compared to when they evaluate them lower (i.e., leaders' underestimation).

Method: We collected dyadic data from 484 older employees and their direct leaders from 100 organizations. We applied polynomial regression and response surface analyses to test our hypotheses. Because of the nested data, we applied a multilevel random-slope random-intercept model using the organization as a grouping variable.

Results: Older employees' perceptions of all three age-friendly organizational practices were positively related to their well-being. There was no direct relationship between leaders' perceptions and older employees' well-being. Our results widely support the proposed role of leader-employee perceptual (in)congruence, though. Older employees' well-being was highest when both older employees and leaders rated their organization's work design to be very age-friendly (i.e., congruence at high levels). For age-friendly organizational climate and management, congruence did not play a role. For the case of perceptual incongruence, results indicated a directional incongruence effect for all three age-friendly organizational practices: Older employees' well-being was lowest when leaders overestimated the age-friendliness compared to their older employees.

Limitations: Since we applied a cross-sectional design, causal relations cannot be analyzed in this study. Additionally, we recruited a convenience sample. The research might have mainly appealed to organizations that have an interest in the topic of aging workforces and age-friendly organizational practices, which might have caused a selection bias. However, descriptive results indicate considerable variance regarding the perception of the age-friendly practices between organizations.

Conclusions: Our study revealed significant discrepancies between older employees' and leaders' perceptions of age-friendly organizational practices. Further, this leader-employee perceptual (in)congruence matters for older employees' well-being beyond older employees' individual perceptions alone. The findings emphasize the need to consider the perceptions of different organizational stakeholders. Moreover, theoretical advancements and longitudinal studies are needed to shed light on the underlying processes that transfer the effects of perceptual (in)congruence on employee outcomes. Human resource managers and leaders should aim to close potential gaps in the perception of organizational practices to generate better employee outcomes. Furthermore, both leaders and older employees should be included in the implementation process of new organizational practices to prevent the emergence of perceptual incongruence.

Relevance to the Congress Theme: Demographic change is happening in most Western countries. Challenges emerging from this trend (e.g., increasing pressure on social security systems or a shortage of skilled workers) will intensify for both societies and organizations, highlighting the need to take action. With our study, we demonstrate how researchers and practitioners can contribute to creating and implementing an age-friendly work environment.

Relevant UN SDGs: Related to the SDGs "Good health and wellbeing" as well as "Decent work and economic growth", we highlight how older employees' well-being can be retained through different age-friendly organizational practices and strategies in order to foster employees' continued and healthy employment in later life.

Keywords: Aging workforce, Leadership, Organizational climate

Symposium S027

Leadership and Aging II: Impact of Leader Characteristics and Training

Eva Zellman, Curtin University, Perth, Australia; Franziska Jungmann, International School of Management, Berlin, Germany

science_practice

What will be covered and why: Demographic change is altering the age-composition of the workforce, resulting in more older workers and increasingly age diverse teams (e.g., Boehm & Dwertmann, 2015; Czaja, 2020; Truxillo et al, 2015). The demographic change signals the need for leaders and organisations to create a work environment that aligns with age-related needs and preferences, fosters wellbeing, as well as creating decent work opportunities regardless of age. For example, to mitigate against age biases and discrimination, and leverage the distinct knowledge and perspectives that workers of different ages offer, organisations need to have effective organisational practices in place. However, organisations have been slow to implement policies and practices to support an older and more age diverse workforce (Perron, 2020; Truxillo et al, 2015).

Leaders are well positioned to shape the experience of aging and age diverse employees because they have the opportunity to influence important team processes and most aspects of followers' experience, wellbeing, and performance at work (Kunze & Bruch, 2010; Kearney & Gebert, 2009). Studies show that leader attitudes and behaviours can have an important influence on employees` performance and well-being (e.g., Ilmarinen & Tempel, 2002).

Yet, it is unclear which particular types or styles of leadership are most effective to achieve positive outcomes for age diverse employees. Are established leadership styles such as LMX or supportive leadership sufficient? Is there a need for specific age-oriented or age-inclusive leadership? What are the impacts of HR practices and an age-friendly workplace climate? What other factors enable leaders to consider age and effectively manage age diversity?

In this two-part symposium we aim to find answers to these questions by incorporating a range of empirical and conceptual contributions including intervention studies focusing on how to close the research-to-practice gap.

Following the first symposium, Aging and Leadership I: Impact of leadership style and organisational practices , which explored the effects of leadership styles on ageing and age diverse employees, this subsequent second symposium, Aging and Leadership II: Impact of leader characteristics and training , addresses the impact of leader attributes on the leader-employee relationship and leadership behaviors, with leaders' age and attitudes being the main focus. To overcome the research-to-practice gap, this symposium also provides practical interventions to support leaders of aging and age diverse workers.

The first two studies focus on how leaders' age impacts the leader-subordinate relationship. The authors of the first study look at leaders' age and the related warmth and competence, and how this relates to perceptions of leaders' conflict involvement. The second study presents and tests a newly developed scale to measure age-related negative attitudes towards younger leaders with older followers. The objective of the third study is to determine what individual and contextual factors contribute to leaders adopting an age-oriented leadership style. The fourth and fifth studies put research into practice and present results from intervention studies addressing aging and leadership in the workplace. The fourth study evaluates the effect of a age-related leadership training, while the

author of study five gives insights into four projects designed to protect older employees' health and safety as well as cultivate age-inclusive workplaces.

Relevance to the Congress Theme: An aging and more age diverse workforce is an accelerating trend in in the European Union as well as in most other developed countries (Boehm & Dwertmann, 2015). Hence, this is something organisations and leaders need to manage now, and not push towards the future. Identifying the effectiveness and impact of different leader characteristics and practical workplace interventions will not only provide benefits in terms of wellbeing and decent employment for workers of all ages, but also more resilient and successful organisations.

Overall conclusions and research/practical implications: The proposed two-part symposium address leadership as an important mechanism to overcome ageing and age diversity challenges. The studies in this symposium reveal the beneficial effects of several leadership styles on follower outcomes and highlight the potential value of an age-oriented leadership style. Moreover, the studies demonstrate the importance of leader characteristics and provide guidelines on evidence based organizational interventions. Despite the diverse contributions to this symposium, more research is needed to explain, for example how age-oriented leadership exerts its effect on employees of different age groups and across industries

Keywords: Age diversity, Leadership, HR interventions

Paper 1

Less conflict with my older leader: Evidence of a competence-warmth halo effect

Kyriaki Fousiani, Georgios Michelakis & Susanne Scheibe | University of Groningen, Groningen, Netherlands

Research goals and theoretical background: In recent decades, one of the most profound macro-level changes in the workplace has been the increase in age diversity. As the average age of employees increases, so, too, does the age of leaders (Korunka et al., 2003). Yet, there is limited empirical research on the role of leader age in the organizational literature (Zacher , Rosing, Henning, et al., 2011; see also Walter & Scheibe, 2013 for a review). This is a significant gap, given that older, middle-aged and younger leaders form different kinds of relationships with their employees, which then influence employees' attitudes and behaviors toward their leaders (Truxillo & Burlacu, 2015).

In this study, we propose that leader age influences the relationship between leader qualities (i.e., competence) and follower involvement in conflict with leaders. Based on the halo effect theory (Abele & Bruckmüller, 2011), we hypothesized that more competent leaders are more likely to be perceived as warm by their followers, especially when they are older. Warmth, in turn, was expected to predict lower conflict involvement of followers with their leaders.

Method: We conducted three studies to investigate our hypotheses. Study 1 was a dyadic field study where leaders reported on their followers' conflict involvement and followers reported on their leaders' competence. Study 2 was a two-week time-lagged study among organizational employees. Study 3 was a scenario experiment with employee participants.

Results: Study 1 showed that leader age strengthens the negative effect of leader competence on conflict involvement. Studies 2 and 3 showed that perceived warmth of the leader mediates the effect of leader competence on conflict involvement. Study 2 further showed that age moderates the indirect effect of leader competence on conflict involvement. Further exploratory analyses showed that leader generativity (Studies 2 and 3) and leader construal of power as responsibility (Study2) might be more relevant mediators than warmth perceptions in the hypothesized relationships given their closer theoretical relevance with leadership phenomena.

Limitations: Notably, all of the studies relied on global self-reports of follower conflict involvement. Future studies should strive to replicate our findings with more objective and/or immediate measures of conflict engagement. Moreover, it would be insightful to match followers' perceptions of leaders with said leaders' perceptions of their own positive qualities. This would illuminate whether the identified halo effects are grounded in reality or merely exist in the eye of the beholder.

Conclusions: Competent leaders are more likely to be seen as warm, responsible, and generative by their followers when they are older rather than younger, which may help explain why older leaders elicit less conflict from their followers. These insights add to a growing body of literature documenting the emotional benefits of age in the workplace in particular contexts, such as leader-follower interactions. By way of halo effects, older leaders who are equipped with certain positive qualities (competence) are also ascribed other positive qualities (warmth, generativity), which trickles down to followers' conflict behavior. These insights enhance our understanding of both the role of age in leadership and the antecedents of interpersonal conflict in organizations. Overall, we suggest that older competent leaders may be particularly suited to intervene in internal organizational conflicts.

Relevance to the Congress Theme: Ageing is a universal phenomenon. The proportion of the global population aged 60 years or above rose from 8.5% in 1980 to 12.7% in 2017 and it is expected to accelerate in the coming decades reaching 21.3% in 2050 (United Nations, 2017). The demographic change towards an aging workforce signals the need to change how leaders and employees are viewed in the workplace for a more sustainable work environment in the future.

Relevant UN SDGs: Among other values, the UN SDGs point out the importance of employment and decent work for all and at all ages. This research is in line with the UN SDGs as it forwards the idea that older persons are a valuable resource, making significant contributions to the economy.

Keywords: Older leaders, Conflict involvement, Halo effect

Paper 2

Measuring attitudes within young-leads-old relationships: The scale development of three attitude measures

Paulina Bilinska, Rhenus Logistics, Düsseldorf, Germany; Johannes Wendsche, Technische Universität, Dresden, Germany and Federal Institute of Occupational Safety and Health, Germany; Jurgen Wegge, Technische Universität, Dresden, Germany

Research goals and why the work was worth doing: Leadership constellations in which a leader is younger than his or her followers are broadly considered to be norm-violating because for many decades leadership was reserved for workers with high tenure and extensive work- and life-experience. The consequences of norm-violating age differences between leaders and subordinates have been widely considered to be negative – whether for the younger leader (Collins, Harris, & Rocco, 2009) or the older subordinate (Rocco & O´Hair,2009). However, related research findings are mixed. We further argue that the theoretical assumptions underlying these statements have never been tested rigorously because adequate measurement instruments for critical attitudes involved in these constellations are missing. Moreover, negative consequences are also commonly anticipated within HR practice and various "emerging leadership" programs on the training and coaching market focus on norm-violating leadership constellations. Taken together, the topic gains increasing interest in both the scientific and the business community and this motivates our goal of a better construct definition and measurement of central attitudes involved in such constellations.

Theoretical background: Two theories have been widely used in this context: 1) Relational demography, referring to the extent in which coworkers of one work unit differ from each other in regard to various demographic (visible and non-visible) attributes, investigating their influence on work related individual and higher level outcomes (Tsui & O´Reilly, 1989), and 2) Career Timetable Theory (Lawrence, 1984, 1988) suggesting that humans evaluate their professional success by comparing themselves to significant and salient others in the workplace in order to find out if they are on or behind schedule, based on age norms for the attainment of certain positions within an organization.

Design/Methodology/Approach/Intervention: In this study, we introduce three new attitude/ stereotype concepts within the "young(er) leads old(er)" constellation and their measurement: 1. Negative attitudes towards younger leaders (NAYL) from the perspective of the follower, 2. Negative attitudes towards older followers (NAOF) from the perspective of the leader, and 3. leadership age stereotypes (LAS), measuring the degree to which desirable attributes are associated with older or younger leaders. Because in leadership dyads always two levels are involved, we conceptualize negative attitudes held by leaders and followers separately (i.e., NAYL and NAOF). Moreover, we examine which characteristics and behaviors are associated with older and younger leaders by using most cited stereotypes towards older, younger, and leaders in general (i.e., LAS). With a total of four studies (N = 1.075), we developed these three new scales to measure the constructs, investigate their psychometric properties, as well as establishing discriminant and convergent validity by examining its linkages with existing measures. Finally, we also examine the association with leadership and follower outcomes considering individual-level as well as team-level effects.

Results obtained or expected: All new measures were found to be reliable (>.8 for Cronbach´s alpha), valid (discriminant and convergent validity) and useful (e.g., explaining variance for important outcomes beyond existing measures).

Limitations: There are several limitations of our study: First, we mainly relied on data from questionnaires and have no objective outcome measures . Second, although data from various industries has been collected, the findings show that scale means in the nursing population are much lower. Future research should account for the role of type of industry and sector-related cultures and consider collecting data from more traditional and hierarchical industries (e.g., automobile, production, banking etc.)

Conclusions – research and or practical implications: Our findings lead to the following central implication: Leadership evaluations in age norm violating constellations are biased by several age stereotypes (NAYL; NAOF; LAS) and our new scales can be used both in research and practice to manage potential negative consequences of such constellations: ,

Relevance to the Congress Theme: One highly relevant and salient aspect of changing work environments is the demographical change on the management floors all over the world. The rise of younger workers (age cohort 25-34) in management positions over the past ten years has increased from 2.57 million in 2011 to 3.28 million in 2020. (U.S. Bureau of Labor Statistics). Already today, one third of U.S. workers have a younger boss, 15% of workers have a boss at least 10 years younger than them (Lorenz, 2012).

Relevant UN SDGs: Our research supports goal number 3 (Ensure healthy lives and promote well-being for all at all ages) as it sheds light on the widely neglected phenomenon of age discrimination towards younger persons in the workplace (Bratt, Abrams, Swift, Vauclair, & Marques, 2018 found that the highest levels of age discrimination was reported by younger respondents).

Keywords: Scale development, Young-leads-old, Attitudes

Paper 3

Effects of a training promoting age-differentiated leadership on employee`s health: A multi-level analysis

Anne Kemter, Jurgen Wegge | Technische Universität Dresden, Dresden, Germany; Franziska Jungmann, International School of Management, Germany

Research goals: The main goal of this research project was the improvement of health, innovation and effectiveness in age-diverse teams by promoting age-differentiated leadership. This form of leadership is conceptualized as an important team resource for improving health and team climate for all age groups. The first training program for age-diverse teams was developed by Jungmann et al. (2020) and evaluated in the administration sector.

It imparts knowledge about demographic change, the negative consequences of salience of age-differences, stereotypes, age-differentiated leadership, work design and communication techniques in two modules within two days. Several methods (e.g., presentations, behavior modeling) are used to attain the planned affective, cognitive and behavioral change. To promote learning transfer a half-day booster training took place four months later (Jungmann & Wegge, 2015; Jungmann et al., 2020). Here, we present a new evaluation of the training in production.

Theoretical background: Age-diversity is faced by organizations worldwide (Farndale et al., 2015). Research results on the effects of team-diversity differ. While several empirical studies have reported a negative effect of age-diversity on performance (Bell et al., 2011; Joshi & Roh, 2009; van Dijk et al., 2012), others results indicate a positive relationship (Wegge et al., 2008). The inconsistency in these findings can be explained by two different social processes. On one hand, social categorization theory suggests that people tend to categorize themselves and others into groups by characteristics as age if such categories become salient. Further they prefer their own ingroup (Tajfel & Turner, 1986). This can result in negative team climate and performance as reported above. On the other hand, information elaboration of diverse team members can improve problem solving within groups (Kerschreiter et al., 2003). Both theories were integrated by van Knippenberg et al. (2004) in the categorization-elaboration model emphasizing the possibility of both positive and negative outcomes for diverse teams. Consistent with this reasoning, a more specific model focusing on age-diverse teams, the so called ADIGU model was developed (e. g., Liebermann et al., 2013; Ries et al., 2013; Wegge & Meyer, 2020). The model includes several moderators which influence the likelihood of observing more positive or negative effects of age-diversity. It was tested and confirmed in different work samples in Germany (Fritzsche et al., 2014; Ries et al., 2013; Wegge & Jungmann, 2015; Wegge et al., 2012). Based on these results the main moderating factors of the model informed the contents of the training.

Design: Approximately 90 teams and their 135 leaders participated over a 2-year-time span in this research project. Three month after the first survey to assess the current status of indicators such as health, team climate, age-differentiated leadership, the training group took part in the intervention. For month later, all blue-collar workers filled out the second survey. One year after the training group the waiting control group was trained. A final survey was conducted four months later. The evaluation framework by Kirckpatrick (1959) was used to assess training effectiveness (Jungmann et al., 2016). Here, we analyze how the training affects the health of employees of the trained supervisor by taking into account the hierarchical data structure by using a multilevel approach for the longitudinal data (N1 = 989, N2 = 838, N3 = 937; N1-3 = 463).

Results: First results indicate a training effect for some health indicators. For example, physical complaints decrease immediately (n.s.) after the training. These effects seem to disappear fast and 16 months after the training physical complaints are significant higher than before the training in all groups. Significant intraclass correlation coefficients (ICC 1 = 0.67; ICC2 = 0.81) on person and on team level (ICC1 = 0.12; ICC2 = 0.60) imply the need for further multilevel analyses. It is expected that at least some health outcomes will be better in the two trained groups than in the non-trained group.

Limitations: The training was just conducted in one large organization. In addition, just 463 blue collar workers participated more than once in the surveys.

Conclusions: Based on earlier research, age-differentiated leadership has a positive effect on health related outcomes. The results of this study will show how far this can be generalized to production work.

Relevance for the congress: Demographic change is an issue, which will affect society, work and family in the next decades. In the work context, qualified workforce decreases. As a consequence, organizations need to obtain young workers and need to keep older workers healthy and committed to the company. Age-differentiated leadership is probable a promising approach to solve the challenges linked to these developments.

Keywords: Age-differentiated leadership, Health, Training

Paper 4

What's a Leader to Do? Developing Tools and Resources for Managing an Aging Workforce

Gretchen Petery, National Institute for Occupational Safety and Health, Centers for Disease Control and Prevention, Cincinnati, OH, USA

Background: Population aging is a global trend with far reaching societal implications, including maintaining sufficient numbers of qualified workers (Czaja, 2020). One response to the aging phenomenon is developing strategies to encourage and support extending workers' labor force participation. At the national level, countries have raised the qualifying age for receiving government-sponsored retirement-related benefits (e.g., U.S. Social Security) or offered incentives to companies who hire and retain older workers. Yet, employers have been slow to implement organizational policies and practices to support an older workforce (Perron, 2020).

Recognizing the critical need to protect older workers' safety and health in the workforce, in 2015 the U.S. National Institute for Occupational Safety and Health established the National Center for Productive Aging and Work (NCPAW). NCPAW researchers strive to understand physical and psychosocial aspects of work that contribute to a productive aging workforce and thus are mutually beneficial to workers and employers alike. The theoretical approach of productive aging focuses on the positive aspects of aging and emphasizes the important contributions older individuals can continue to make in their workplaces (Grosch et al., 2019). Productive aging at work is characterized by a work environment that is safe and healthy and gives workers of all ages the power to be successful and thrive in their jobs (Grosch, 2020). To facilitate its work in support of productive workforce aging, NCPAW regularly collaborates with the academic community to conduct original research, and to translate and disseminate research to the public, including employers and health and safety professionals.

New contributions: Whilst researchers have recently begun to develop and test various strategic frameworks related to productive workforce aging, such as the 3i model (e.g., Parker & Andrei, 2020) and the Later Life Workforce Index (Wilckens et al., 2021), scientific-based guidance developed for use by organizational leaders is lacking. To address the research-to-practice gap, the NCPAW research team is working on several projects aimed at educating employers and business leaders on ways to create an age friendly workplace and support productive aging. Many of NCPAW's practice-focused projects involve partnering with academic-based researchers to produce scientifically rigorous, empirically supported resources for public dissemination. These partnerships hold promise for meeting the needs of the employers, employees, and the broader scientific community. This presentation will provide an overview of four current NCPAW projects in diverse industry sectors that involve developing and disseminating promising strategies that employers can use to address the health and safety needs of their older workers.

NCPAW is creating an online tool that managers and safety and health professionals within manufacturing companies can use to assess the age friendliness of their workplace. Using the work ability framework (Gould et al., 2008), the tool will assess four areas: the physical work environment, organization and leadership policies and practices, professional development, and individual health resources. A similar project is developing an ageing workforce module for the Small Business Safety and Handbook jointly published by the U. S. Occupational Safety and Health Administration (OSHA) and NIOSH (2021). In a third project NCPAW is developing a training intervention for hotel managers and supervisors that provides guidance and practical strategies for designing an age-inclusive

workplace to support hotel housekeeping employees, a working population that tends to be older than the national average. Lastly, NCPAW is developing general educational and guidance materials for employers and business leaders on psychosocial factors in the workplace that are associated with productive aging at work.

Conclusions – research and/or practical implications: Providing employers with theoretically sound and empirically supported organizational policies and practices is critical for confronting the challenges that come with an aging workforce. Research collaborations to assess the aging workforce is necessary to mitigate a labor shortage and ensure the health and safety of this group. Broad dissemination of theoretically grounded and empirically supported findings to employers is equally as important to ensure best practices are implemented in the workplace. NCPAW leverages collaborations with the academic community to move the field of workforce aging forward and bridge the research to practice gap.

Relevance to the Congress theme "The future is now : the changing world of work". Workforce aging is no longer something that will happen in the future – it is happening now. Creating resources designed for and freely available to employers is important toward communicating much needed guidance on effective strategies and important considerations for managing an aging workforce.

Relevant United Nations Sustainable Development Goals: Decent work and economic growth.

Paper 5

What does it take? Antecedents of age-oriented leadership

Franziska Jungmann , International School of Management, Berlin, Germany; Juergen Wegge , Technische Universität Dresden, Dresden, Germany

Research goals and theoretical background: The demographic developments in most industrialized countries lead to an increased proportion of older employees and age-diversity in the workforce, and this trend will continue over the coming decades (Czaja, 2020; Schlick et al., 2013; Truxillo et al., 2015). Offering age-oriented human resource management practices might help promoting health and performance of workers across the working life. Several researchers have identified leadership behavior as a key factor for enhancing performance and work ability of older workers and age-diverse workforces (e.g. Ilmarinen & Tempel, 2002; Wegge, Jungmann, et al., 2012; Wegge, Schmidt, et al., 2012).

Age-oriented leadership (AOL) can be characterized as leadership behaviors that promote health, satisfaction, and performance by accounting for age-related skills, needs and motives of aging employees and that leverage the potential of age-diverse teams (Braedel-Kühner & van Elst, 2012; Jungmann et al., 2015; Kunze et al., 2011; Wegge, Schmidt, et al., 2012). Though AOL provides a useful tool, many organizations and leaders report not to be prepared for challenges associated with the demographic change (Bruch & Kunze, 2007; Müller et al., 2014). In this vein, most often the terms 'demographic change', 'age diversity' or 'aging' itself are too abstract (Bendig et al., 2011) and might delude leaders to underestimate their impact. Despite knowing that employees' age is an important factor, leaders only adapt their leadership behavior to a small, limited amount (Muecke, 2008).

Given the positive effects of AOL, this is quite surprising. What is missing from the literature is an understanding of the processes through which AOL-behavior emerges. Therefore, we aim at identifying important antecedents contributing to leaders' engagement in AOL. Based on the literature, we propose and test a new model of potential antecedents comprising leaders' individual characteristics (e.g., attitudes towards own aging process) as well as contextual factors (e.g., age composition of the team they lead). We further hypothesize that attitudes towards own aging process and knowledge on aging are important moderators of the effects of age on AOL.

Design and research methodology: We used to samples to test our hypotheses. In study 1 we surveyed 576 leaders of a German pharmaceutical company in a cross-sectional sample. We conducted multiple regression analyses to examine the impact of individual attributes and contextual factors predicting leaders engaging in AOL. Furthermore, we tested a three-way interaction between age, knowledge on aging and attitudes towards aging on AOL. In study 2, we collected data of 90 leaders and their respective subordinates from a German car manufacturing company across a 4-month period. Correlational analyses and multiple hierarchical regression analyses will be conducted.

Results obtained: In study 1 we found that older leaders, leaders with a more positive attitude towards their own aging, and leaders with a high span of leadership are more likely to engage in AOL. Moreover, we found age-based differences among the antecedents and a three-way interaction showing different patterns in the interaction of knowledge and attitudes towards aging for younger and older leaders. Preliminary results for study 2 highlight the importance of leaders' age stereotypes and appreciation of age-diverse teamwork for engaging in AOL. Further results will be presented

Limitations: Both studies used self-report survey data, which might be subject to social desirability biases. Study 1 is solely based on leaders reports, whereas study 2 incorporates data from leaders and their subordinates. Study 1 is based on cross-sectional data and thus, limited in the ability to make causal claims. Data in both samples was gathered predominantly among blue-collar workers, which might limit generalizability to white-collar jobs.

Conclusions and implications: Our study highlights the importance of individual as well as contextual factors that increase the likelihood of leaders engaging in AOL.

The results suggest that age-related knowledge and attitudes are interwoven in predicting AOL. Hence, both should be addressed in leadership training on AOL. At the same time, organisations should create conditions (e.g., time for leadership) that enable leaders to engage in AOL.

Relevance to the congress theme: Our research contributes to the conference theme through enabling leaders to consider age in their leadership behavior and, thereby, making use of the additional value of AOL for aging and age-diverse workforces.

Relevant UN SDGs: Good health and wellbeing; Decent work and economic growth.

symposium S028

Career and Work Role Transitions Across Different Career Stages: Insights From Europe

Wehrle Katja, Justus-Liebig-University Giessen; Annabelle Hofer, University of Cologne

science

What will be Covered and Why

Scholarship emphasizes the changing nature of modern careers as careers grow more complex and new career forms and trajectories emerge. The resulting career landscape confronts workers with increasing demands for intra- and inter-organizational mobility and career self-management. While people's career moves typically occurred in organizations and through a series of jobs, these moves gradually make way for transitions between organizations, sectors, and occupations. While the reasons for career transitions are diverse, people generally face professional and personal change as they build, modify, or exit their earlier careers and work roles to enter new ones. Career transitions happen throughout people's career journeys – from work entry to retirement – and they bring about changes in people's work-role requirements and contexts, and in the collective, relational, and personal aspects that constitute how people understand themselves, their work, and their careers.

To date, career research has focused on internal labor market transitions, particularly on the mechanisms related to workers' career progression and barriers to future employment. Yet, research still lacks insights into the transition processes and into how people experience the movements between different career stages and situations. More insights are needed on what shapes and influences people's career transitions and on how people experience career transitions and adapt to new career phases and work roles. These insights are critical, as they would enable us to offer solutions that can support people during transitions.

This symposium addresses these gaps by combining in-depth qualitative and longitudinal quantitative research from diverse European countries on the factors shaping and the experiences unfolding in people's careers at different stages and situations. For this, the contributions cover diverse samples ranging from pupils to professionals in their early careers to those reentering work and seeking to gain leadership positions. We begin with two studies focusing on people's earliest career transition – the school-to-work transition. Using a longitudinal design across 18 months via three time points, the first study examines the development of adolescents' career preparedness including career preparedness transition outcomes from 9th grade until the transition to a vocational and educational training in Switzerland. Next, the second study applies a longitudinal quantitative design to assess the role of internships in helping young people who struggle to transition from school to work decide on their future career. The study integrates four data time points from young people not in employment, education, or training, who took part in a one-year vocational preparation program in Germany. We then shift perspective to two interview studies that unravel employed persons' lived experience in crucial work role transitions. Drawing on two data sets of medical residents with versus without prior paramedical experiences in Germany, the third study generates a grounded theory on how an established professional identity influences the development of a new professional identity in an intra-institutional work role transition. The fourth study moves on to mothers at managerial levels seeking to progress to leadership positions in European companies. Via an inductive thematic analysis, the study reveals the embeddedness of the ideal-worker-norm in organizational practices and structures, and how this norm can influence mothers' career progression. Finally, our discussant, who is an expert on career transitions and career development, offers an in-depth discussion of the studies' findings and their implications.

Overall, we offer new insights into modern career topics and developments and new solutions that facilitate career and work role transitions.

Relevance to the Congress Theme

This symposium highlights how workers transition through their careers at different parts of their career journeys. We illustrate how modern work developments gradually change the nature of careers and workplaces, creating a new world of work that is characterized by high demands for worker mobility.

Implications

The symposium illustrates the complexity and the factors shaping career and work role transitions. We extend career research and foster theory development by studying topical issues relating to career transitions. We inform counseling, intervention, work design, and HRM practices.

Overall Conclusions

The contributions reveal the importance of a right person-job fit and a clear vocational self-concept for people's career progression. We show how internal (e.g., decisional self-efficacy) and external factors (e.g., internships) facilitate transitions and how people's former work roles influence their continuing careers. We illuminate how workplace structures can foster identity tensions, perpetuate gender inequality, and depict career barriers.

discussant: Jos Akkermans, Vrije Universiteit Amsterdam

Paper 1

School-To-Work: Social Cognitive Influences on Career Construction Responses

Julian Marciniak & Andreas Hirschi | University of Bern

Research Goals and Why the Work was Worth Doing

Research into school-to-work transitions do not test the development of career preparedness longitudinally, and even fewer assess actual career preparedness transition outcomes (Marciniak et al., 2020). In this study, we investigated the development of career preparedness of adolescents in 9 th grade until the transition from school to vocational and educational training (VET). Specifically, we investigated the impact of decisional self-efficacy and outcome expectations on the transition outcomes of job satisfaction, occupational commitment, and person-job fit, 18 months later during VET. We furthermore postulate that this relationship is mediated by four career construction adapting responses. Our goal is to enrich the theoretical literature by (a) investigating the mediating role of adapting responses, and (b) by combing the theoretical assertions of the career construction theory and the social cognitive career theory.

Theoretical Background

We are drawing on the social cognitive career theory (e.g., Lent et al., 2002, 2016), which posits that self-efficacy and outcome expectations are central predictors of subsequent career behaviors. For career behaviors, we draw on the career construction theory (Savickas, 2002, 2005) which defines adapting responses (Rudolph et al., 2017) as distinct outcomes of the career construction sequence. Recently Savickas and colleagues (2018) have defined a specific measurement of career adapting responses in adolescents, namely crystallizing a vocational self-concept, exploring occupations, making a decision, and preparing for the transition.

Methods

Our sample consists of 598 students (48.2% female) from the German-speaking parts of Switzerland with the mean age of 14.49 (SD =1.04). We used a longitudinal design across 18 months, with three time points. We first collected self-efficacy and outcome expectations at the beginning of grade nine, we then collected adapting responses at T2 four months before the transition to VET (N =594), and collected outcome variables roughly one year later at T3 (N =222).

Results

The results show that decisional self-efficacy is positive and significant predictor of all four career adapting responses. However, outcome expectations was only found to be a significant and positive predictor of crystallizing a vocational self-concept (b =.16, p <.001). We found no direct effects of career decisional self-efficacy and outcome expectations on the outcomes of job satisfaction, occupational commitment, and person-job fit 18 months later. Still, a mediation analysis showed an indirect effect of decisional self-efficacy via crystallizing a vocational self-concept towards a person-job fit during VET with an unstandardized estimate of .07 (95% CI [.01;13]). For job satisfaction and occupational commitment, we found no significant indirect effects.

Limitations

The biggest limitation is the attrition rate towards T3, where we lost more than 50% of our sample, which can be attributed to two factors: (1) instead of doing the last data collection within the context

of a class room, we now had to do individual follow-ups and (2) the COVID-19 pandemic just started at T3, which led to a decreased response. Next, an additional data collection at the beginning of VET could have provided more insight into the development of outcomes of the school-to-work transition.

Implications

Our results are fairly surprising, as only decisional self-efficacy and crystallizing a vocational self-concept seemed to be the only significant predictors of find the correct person-job. These results support the older but still very relevant notions of finding the right person-job fit (e.g., Holland, 1997). Additionally, future research should investigate whether the other adapting responses might have more immediate impact on other transitional outcomes. Practitioners may use these results to inform their career counselling practice, by make sure that adolescents develop a clear vocational self-concept during school. They may use exercises that bolster decisional self-efficacy in order to improve their self-concept, which then may lead to an increased person-job fit.

Relevance to the Congress Theme

Given that the career transitions become increasingly unpredictable (Lent, 2018), research needs to investigate which factors significantly benefit individuals when facing a career transition. This is especially true for the first career transition, the school-to-work transition. Hence, this research is getting a glimpse at a pivotal career decision while living in an increasingly changing world of work.

Paper 2

Setting Sails for Your Harbor: Examining the Relationship Between Career Decidedness and Internships in NEETs

Gloria Willhardt, Miriam Schäfer & Ute-Christine Klehe | Justus-Liebig-University Giessen

Research Goals and Why the Work was Worth Doing

Early unemployment bears the risk of lasting effects such as long-term unemployment and associated individual strain and societal costs (Scarpetta et al., 2010). To prevent such a spiraling effect of unemployment in young years, we follow youths across a one-year early career program aimed at helping them prepare for and decide on their future career trajectory. The present study aimed to shed light on the situation of unemployed youths and to identify mechanisms that can lead to a positive job outcome in the context of such a program.

Theoretical Background

Career decidedness, the certainty one has over one's occupational course (Jaffe, 1998; Lounsbury et al., 2004), has long been the focus of early-career research (see Gordon, 1998). Decidedness towards one's career can have beneficial effects on several psychological variables. Developing career decidedness thus is a crucial developmental task for teenagers and young adults (Super, 1981) in preparing for the transition from school to work (e.g., Marciniak et al., 2022).

Successful school-to-work transitions result in adequate integration in the labor market and psychosocial networks and set the first building block for a promising career (Akkermans et al., 2021; Steiner et al., 2022). However, some young people struggle with this transition, with far-reaching consequences (e.g., Burgess et al., 2003). One way to enhance people's decidedness status about their occupational future could be the increased employment of internships. Typically used for soon-to-be graduates in universities or schools, internships provide some sort of orientation about certain occupations and might offer insight into typical workdays and tasks in said jobs. This can either lead to adoption of more decidedness for a specific field or job or less, when people realize that the work is not what they thought it would be (Brooks et al., 1995). Additionally, some sort of work experience additional to a degree has proven beneficial for entry in the labor market (Ebner et al., 2021).

The current study employed a sample of 264 NEETs – young people not in employment, education, or training – and followed their development over the course of a one-year early career program. NEETs are at high risk for long-term consequences such as reduced earnings (Mroz & Savage, 2006), diminished job satisfaction, happiness, and health (Scarpetta et al., 2010), and often face higher risks for long-term unemployment (Carcillo et al., 2015).

Methods

We assessed NEETs self-described career decidedness at four measurement points, as well as the internships they completed over the course of the program. Using a random intercept cross-lagged panel model, we were able to estimate the development of career decidedness, self-efficacy beliefs concerning their search and the influence of the internships over the program course on an employment outcome.

Results

Results so far indicate that career decidedness, number, and length of internships were positively associated with NEETs' outcomes, that is, the more decided they felt at program completion, and the more and longer internships they completed, the higher was their chance to go back to school for a degree or find employment.

Limitations

The current study employs a convenience sample, that is, all students who, at a given point, were enrolled in a government-directed early career preparation program. We cannot make any statement about the voluntary motivation to participate. Furthermore, not all participants completed the program; the dropout rate over the four waves was about 62%.

Implications

With this study, we shed light on the role of internships in helping young people with otherwise bleak outlook decide on their future career. Practical implications include advice for program design targeted specifically to younger people.

Relevance to the Congress Theme

Bringing young people in decent, sustainable work must be a top priority, especially after recent years with youth unemployment on the rise in certain countries (ILO, 2020).

Relevant UN SDGs

No poverty; good health and wellbeing; quality education; decent work and economic growth

Keywords: school-to-work transition, vocational education, youth unemployment

Paper 3

Medical Residents' Identity Baggage: Dynamics Between an Established and Emerging Professional Identity in an Intra-Institutional Work Role Transition

Katja Wehrle & Ute-Christine Klehe | Justus-Liebig-University Giessen; Mari Kira, University of Michigan

Research Goals and Why the Work was Worth Doing

In contemporary working life, people frequently transition between jobs, professions, and careers, thus moving away from one professional identity towards a new one (Ibarra & Barbulescu, 2010). Professional identity research has addressed professional identity construction and development along people's unfolding careers (Pratt et al., 2006) and, reflecting the transitions in people's careers, recent research has alluded to the role of people's lingering 'identity baggage' in the construction of new professional identities (Wittman, 2019). Identity baggage refers to the idea that pre-existing professional and personal identities influence the formation and enactment of a new professional identity. Yet, we lack empirical insights into how people construct new professional identities when their role transition happens within the same institutional settings and identity construction happens on the foundation of a relevant pre-existing professional identity. Such intra-institutional transitions are further complicated when they elevate a person's hierarchical status and, thereby, require them to navigate impressions of belonging to two different status groups. Seeking to build theory around how an established professional identity influences the development of a new professional identity in an intra-institutional work role transition, we ask: How does an existing paramedic identity influence the development of a physician identity?

Theoretical Background

Identities are self-referential cognitive and meaning structures that form as people take on new roles, supporting them in making sense of themselves and their surroundings (Gecas, 1982; Tajfel & Turner, 1986). As people transition into new positions within, across, or beyond organizational boundaries, their work-related roles change and, with them, the collective, relational, and personal aspects that have defined their work-related role identities (George et al., 2022). Consequently, people adapt their identities to meet the new role's expectations; they, e.g., cognitively restructure existing identities or abandon them (Petriglieri, 2011). Yet, people may also seek to retain established identities, particularly when these are central to them and enable the expression of their authentic self (Wittman, 2019). People's understanding and crafting of a meaningful professional self may thus be colored by the sustained identification with a former role, and so people may construct a new identity in interplay with former ones.

Methods

This inductive qualitative study adopts a grounded theory approach (Gioia et al., 2013) to generate a theoretical model of how an established identity influences professionals' identity development. For this, we, first, analyze the identity development among 36 medical residents with a prior professional paramedic training in Germany to then, second, contrast the findings with the data of 33 medical residents without a professional paramedic training to explore how physicians' identity development differs between the groups.

The German medical school context offers a rich opportunity to address our research question. The medical profession constitutes the prototype of a profession (Hughes, 1956), and medical residency is a crucial, practice-focused period for construction of a physician identity (Pratt et al., 2006). In addition, due to competitive admissions to physician training programs, many applicants apply several times, bridging the time between medical school applications with other professional training in healthcare.

Results

Holding an established paramedic identity uniquely influenced medical residents' identity development; it shaped their framing of the physician work and role. Participants experienced identity tensions between their paramedical and physician identities, as they recognized changed relationships to patients, conflicts between work activity priorities, a hostility of their former in-group, and a longing for the "old". Nevertheless, they managed to cope, e.g., by aggregating their paramedical and physician identities: (1) They formed a salience hierarchy between them (e.g., recognizing and prioritizing changed responsibilities, while occasionally adopting former work activities) and (2) developed integrity towards a physician identity (e.g., stressing the relevance of their unique interdisciplinary competence). Established health-care-related identity resources facilitated identity aggregation (i.e., knowledge of the care system and clinical skills, experience with patient care and other worker groups, and personal maturity).

Limitations

This study bases on cross-sectional data.

Implications

We decipher how an established professional identity influences the development of a new professional identity in an intra-institutional work role transition. Theoretically, we contribute to career and work role transition, identity work, and socialization research. Practically, we inform medical studies' curricula and clinics' work design, and highlight the relevance of interdisciplinary competence in physicians' work.

Relevance to the Congress Theme

This study focuses on how former identities shape emerging identities in intra-institutional work role transitions among professionals whose career model is gradually changing.

Relevant UN SDGs

By revealing medical residents' various role conflicts and the severe institutionalized restraints that impede them in performing their work as desired, we inform on the SDGs of 'good health and wellbeing', 'decent work and economic growth', and 'quality education' in the healthcare sector.

Keywords: lingering identities, role identities, work role transition

Paper 4

Organizational Enablers and Barriers to Mothers' Career Progression

America Harris & Ulrike Fasbender | University of Hohenheim

Research Goals and Why the Work was Worth Doing

Despite improvements for women in the labor market, mothers continue to experience lower earnings, labor market participation, and progression to leadership than child-free women and fathers. The "motherhood penalty," which is the financial and career disadvantages of motherhood, perpetuates gender inequality. Most research on motherhood penalties takes individual-level and familial-level approaches, while organizational factors contributing to the motherhood penalty have been scantly addressed (Fuller & Hirsh, 2019). However, the organizational-level approach is vital to providing a holistic understanding of career barriers within organizations, as gender inequality comes in multi-leveled forms. Drawing on systemic intersectionality theory (Acker, 2006) and the concept of the "ideal worker" (Acker, 1990), this study investigates the embeddedness of the ideal-worker-norm within organizational practices, policies, job criteria, and reward systems and how this may help or hinder mothers' career progression.

Theoretical Background

Systemic intersectionality theory foregrounds the organizational context and workplace structures, which may provide further understanding of the career progression barriers mothers face because it can help to identify organizational factors that act as systemic barriers. Systemic intersectionality posits that social categories, such as gender and motherhood, interlock and affect each other interdependently at the macro-level of organizations, social structures, and cultural ideologies (Castro & Holvino, 2016).

Research indicates gendered assumptions underlie workplace structures and culture, disadvantaging mothers (Acker, 2012; Kmec et al., 2014). The concept of the ideal worker is a framework for the social construction of gender that could help identify organizational barriers that hinder mothers' career progression. The ideal worker is an unencumbered worker who is devoted to work and assumes the ability to work long hours, continuously full-time, without family interference. Studies find that the ideal worker image and norm privileges men, marginalizes women, and penalizes mothers who navigate between work and family roles, which maintains gender segregation and reinforces gender inequality in the workplace (Deming, 2022; Zanhour & Sumpter, 2022). Moreover, studies indicate mothers' uptake of flexible work arrangements are incongruent with ideal worker norms (Cech & Blair-Loy, 2014; Kmec et al., 2014). While studies refer to the pervasiveness of the ideal worker norm within work cultures, few investigate the embeddedness of the ideal-worker-norm in workplace structures.

Methods

This study explores the following research questions: 1) How do organizational factors shape mothers' career progression? 2) How are ideal-worker-norms embedded into work structures? We adopt a qualitative approach to facilitate understanding of participants' subjective experiences of workplace structures, which are then examined against the ideal worker framework to reveal career enablers and barriers. We will conduct fifty semi-structured interviews with mothers at managerial levels seeking to progress to high-status/leadership positions within European companies. Eight of

the fifty interviews have been completed, with the remaining to be completed by April 2023. Data will be analyzed using inductive thematic analysis.

Results

Interim results indicate that the ideal-worker-norm is embedded in European organizational cultures, practices, policies, and job requirements in informal ways, which disadvantages mothers who cannot perform according to the ideal worker norm. While formal workplace structures embody neutral and gender-free characteristics, their informal operationalizations are embedded with the ideal-worker-norm. Preliminary findings reveal three themes: “Invisible penalties of flexible-work,” “Unencumbered male-typed job criteria,” and “Part-time work equals non-promotable work,” which hinder mothers’ career progression.

Limitations

An inherent limitation of qualitative research is that its aim is not to achieve generalizability as the results are relevant to a segment of the population. However, theoretical generalizability will enable linking individuals’ experiences in the findings with extant literature. Additionally, casual conclusions cannot be drawn from the results.

Implications

This study will make several contributions to academic and practitioner knowledge. It is one of few studies investigating organizational factors contributing to mothers’ career progression, thus expanding theoretical understanding of how workplace structures are implicated in perpetuating gender inequality and contributing to motherhood penalty, human resource management (HRM), and career literature. This study carries significant practical implications for HRM practitioners. By advancing knowledge on gender inequalities embedded within work structures, this study can offer interventions to deconstruct ideal worker norms within HRM practices and redesign HRM practices/policies to foster diversity at leadership levels, thus improving labor market outcomes for mothers.

Relevance to the Congress Theme

The future of work is diverse; as such, organizations are increasingly challenged to improve diversity, equality, and inclusion within their workforce. This study carries practical implications for improving gender equality within organizations.

Relevant UN SDGs

The study’s aim of identifying career enablers and barriers to mothers’ career progression is relevant to the UN SDG of gender equality.

Keywords: career progression, ideal worker, motherhood penalty

Symposium S030

The future is (almost) now: Changing the world of analysing time in occupational health psychology research (Part 1)

Christian Dormann, University of Mainz, Germay

science

What will be covered and why

This is Part I of a symposium that covers a range of empirical studies applying continuous time structural equation modelling (CTSEM) to investigate propositions derived by the job demands-resources (JD-R) model. Since its introduction a decade ago, CTSEM has continuously gained popularity. It represents the state-of-the-art method of analysis because it accommodates more restricted methods of analysis such as growth curve modelling, latent change score analysis, or discrete time SEM. In general, CTSEM probably is the best tool to analyse repeated measures gathered in field studies and could provide the best insight into work and organizational psychology phenomena. Part I of the symposium provides a brief introduction into the principles of ctsem, followed by two presentations dealing with possible reciprocal relations among stressors and burnout, and it ends with some room for questions and answers. In Part II of the symposium, more complex CTSEM analysis of job stress studies are presented.

In the introduction, Dormann briefly introduces CTSEM and its strengths, so that researchers familiar with structural equation modelling or multi-level lineal modelling get an understanding of this relatively new technique. Four strengths are (a) dealing with varying time intervals within and between individuals, (b) separation of unexplained variance in structural equations and measurement error even with single item measures, (c) accounting for unobserved heterogeneity by modelling random intercepts (i.e., random intercept cross-lagged panel modelling; RI-CLPM), and (d) aggregation of effects across different studies by means of continuous time meta-analysis (CoTiMA).

The second contribution to Part I is the study by Che Mat and colleagues . This study investigates possible reversed causal effects among role conflict, student social stressors, and emotional demands and mental exhaustion and mental distance among teachers. The authors conducted a 3-wave study which huge within and between person variations in time intervals. Whereas they could not find a significant cross-lagged effect between any of the three stressors and exhaustion at the between-person level, several (reciprocal) effects emerged at the within person level. Most importantly, role conflict and emotional demands had cross-lagged effects on mental exhaustion and mental distance. Also, some positive as well as some negative 'strain-effects' of exhaustion and distance on stressors were found, suggesting some vicious circles of increasingly more strain on the one hand and some 'homeostatic' circles on the other, by which stressor and strain levels are kept within boundaries.

The third contribution to Part I of the symposium is a paper by Mueller and Guthier , which deals with reciprocal relations among illegitimate tasks and burnout. The concept of illegitimate tasks has gained much attention since the millennium. However, no single study has been published reporting possible reciprocal relations with burnout. The authors found that reciprocal effects between illegitimate tasks and burnout indeed exist. The strain effect of burnout on illegitimate tasks was significantly stronger than the stressor effect of illegitimate tasks on burnout. With their findings, the authors contribute to the increasing evidence of the importance of strain effects.

Relevance to the Congress Theme:

The world of work is changing, and so is the work of researchers, who constantly face the challenges brought by new statistical methods. Longitudinal studies that frequently spanned years and sometime even decades cannot cover the pace of changes in work anymore. Furthermore, new designs such as diary designs, experience sampling methods, or shortitudinal studies challenge the usefulness of established statistical methods. As researchers, we should change our own work, i.e., the way we used to analyse data.

Research/Practical Implications:

Overall conclusions:

Future research should use time intervals within a range of days to a few weeks, and they could vary time intervals within and between participants. Further, if the three or time points are available, RI-CTSEM models allow for analysing reciprocal within person effects, thus accommodating the strengths of several other methods to analyse repeatedly measured variables.

Paper 2

The competing effect of within-person vs between-person of three types of job stressors on burnout

Nurhema binti Che Mat & Mohd Awang Idris | University Malaya, Kuala Lumpur, Malaysia; Christian Dormann, Johannes Gutenberg-University, Mainz, Germany

Research goals and why the work was worth doing

Studies on the cross-lagged effect of job stressors and burnout provide insights on the development of burnout over time. While a plethora of longitudinal research empirically provides meaningful support on burnout as a prolonged phenomenon, it remains unclear whether different types of job stressors develop burnout in different time gaps (e.g., short, medium, and long). Thus, it is important to examine if different kinds of job stressors lead to burnout and how this relation unfolds over different time intervals.

Theoretical background:

Based on the job demands-resources (JD-R) model, we examine how three competing job stressors namely role conflict (RC), student social stressors (SSS), and emotional demands (ED) lead to mental exhaustion and mental distance among employees. More specifically, we used within-person and between-person analysis and investigated if there are any differences of job stressors' reactions on burnout. The present study adds to the literature because previous studies mainly missed taking possible reciprocal relations at the within-person level into account, which challenges the common interpretation that stressors cause burnout (cf. Guthier et al., 2020).

Design/Methodology:

Leveraging on the benefits of unequal time intervals in the continuous time method (Voelkle et al.,2018), we collected data amongst teachers in Malaysia (N = 80) three times within a year at various time intervals to reflect different time gaps (short term and long term). Participants were informed that they will be getting reminders to do their second questionnaire on the fifth day upon completion of the first questionnaires and subsequent reminders on monthly basic will be sent out to motivate them to participate in the third questionnaires. Once the third questionnaires completed, the researcher did not follow up for any participation anymore. In any stages of study, participants were informed that they may opt to leave or continue the study voluntarily.

Participants responded to the questionnaire at a time point on their own choice. As a result, the time intervals for the second data collection ranged from 5 days to 8 months, and for the third data collection they ranged from 1 month to 12 months from the first data collection. Since the nature of study involves the different time intervals within and between persons, we used continuous time structural equation modelling (CTSEM) as the state-of-the-art method for analysing data with varying time intervals.

Results:

Using the R-package CTSEM, we found that the effect of three competing job stressors on mental exhaustion and mental distance are different to each other, especially when comparing within-person and between-person effects. At the between-person level, there was neither a significant cross-lagged effect between job stressors on mental exhaustion nor mental distance. On the

contrary, within-person cross-lagged effects were found for two job stressors. Role conflict significantly increased both mental exhaustion and mental distance. We also found that mental exhaustion reduced role conflict, and mental distance increased role conflict. Cross-lagged effects were also observed for emotional demands and mental distance. Results revealed that emotional demands increased mental distance, but mental distance reduced emotional demands. However, neither was there a cross-lagged effect of emotional demands on mental exhaustion. SSS has no cross-lagged effect on neither mental exhaustion nor on mental distance.

Limitation & Conclusions:

There are a few limitations of this study. First, our participants are specifically in a teaching profession, thus should not generalise to the other occupations. However, as our main research is to investigate psychological process for experiencing student related stressor, role conflict and emotional demands, our participants selection was appropriate. Second, the study was conducted during covid-19 pandemic, whereby teachers had to change their teaching method from physical classroom to online classroom, and they also worked from home rather than engaging their students in physical presence, there are some other stressors perhaps confounding our result. In addition, since the data collection approach involves several times intervals, it is difficult to keep participants remain engage in the study. Although we were able to get 148 participants involvement in the first data collection, but only 80 participants completed all three data collections in a year. In general, the study reveals on how job stressors are important factor that able explain fluctuation and prolong effect of burnout symptom.

Keywords: ctsem, job stress, teachers

Paper 3

Longitudinal moderation effects of personality on reciprocal relations between burnout and illegitimate tasks

Annika Müller, Christina Guthier | Johannes Gutenberg University of Mainz, Germany

Research goals and why the work was worth doing:

The effect of stressors on burnout has been studied many times. Interestingly, a longitudinal meta-analysis found that the reverse 'strain effect' of burnout on stressors is twice as large as the 'stressor effect' of stressors on burnout (Guthier et al., 2020). Thus far, the strain effect burnout on stressors has been rarely studied so far, and possible moderators of the strain effects have not been investigated yet. Since such moderator effects are important as they could mitigate the vicious circle of stressors and burnout, our study fills in this gap. In particular, we investigate personality as a potential moderator of the stressor effect and the strain effect between illegitimate tasks and burnout.

Theoretical background:

Illegitimate tasks are perceived as unnecessary or unreasonable (Semmer et al., 2010). Illegitimate tasks can threaten one's identity (Semmer et al., 2015). According to the Stress-as-Offense-to-Self (SOS) framework, illegitimate tasks as a stressor result from a task associated with a negative social message that can result in a threat to the positive self-image (Semmer et al., 2015). Any kind of threat (e.g., social, emotional, physical) causes stress reactions. To deal with stress, a person can become exhausted, and this can lead to burnout in the long run. There is also the possibility that burnout increases the perception of stressors like illegitimate tasks. Since the perception of illegitimate tasks highly depends on personal role expectations and subjective perceptions of the appropriateness of the tasks, this perception should change due to altered emotional information processing when suffering from burnout. Therefore, we expect that both illegitimate tasks increase burnout and burnout increases illegitimate tasks. Since illegitimate tasks are highly subjective, we assume that the reciprocal effects will differ between people and that certain personality traits will buffer the reciprocal effects. For example, given that extroverted people consciously select positive aspects of stress and tend to seek more social support (Hemenover et al., 1996), we assumed that an extroverted exhausted person is less likely to perceive tasks as illegitimate due to support or social contact and the more positive view. Thus, a reducing moderation effect of extraversion can be assumed.

Design/Methodology:

We conducted a two-wave panel study. The average time interval was ten days, but there was variation across employees so that continuous time analysis was the method of choice. Data were collected by using online surveys for employees who were at least 50% employed. A total of 1.111 completed questionnaires and longitudinal data from N = 192 participants were available. The Bern Illegitimate Tasks Scale (Semmer et al., 2010), the German version of the Maslach Burnout Inventory-Student Survey (MBI-SS; Schaufeli et al., 2002), and the MRS-30 to measure the Big 5 personality dimensions (Schallberger et al., 1999) were applied to measure the Big Five personality dimensions. Data were analyzed with moderated structural equation modeling.

Results

Both reciprocal effects between illegitimate tasks and burnout were significant with the strain effect of burnout on illegitimate tasks being stronger than the stressor effect of illegitimate tasks on burnout. Moderator analysis showed that conscientiousness significantly decreased the strain effect of illegitimate tasks on burnout. No significant moderation effects were found for the other personality dimensions.

Limitation & Conclusions:

The results confirm the meta-analytical established reciprocal effect of stressors and burnout and further confirm a stronger strain effect than stressor effects. Strain effects should therefore be considered in theoretical models and future studies to better understand how they emerge. Further, conscientiousness moderates the strain effect, by which the vicious reciprocal cycle between stressors and burnout gets weaker. Again, there is a need to better understand how exactly this moderating effect emerges, and future studies should investigate this effect in more detail.

Keywords: ctsem, job stress, illegitimate tasks

Symposium S031

The future is (almost) now: Changing the world of analysing time in occupational health psychology research (Part II)

Christian Dormann, University of Mainz

science

What will be covered and why

This is Part II of a symposium that covers a range of empirical studies applying continuous time structural equation modelling (CTSEM) to investigate propositions derived by the job demands-resources (JD-R) model. In Part I of the symposium, an introduction into ctsem and two typical job stress studies analysed with ctsem are presented. In this second part, some complex studies are presented involving a moderated ctsem analysis of the effects of job resources, and a random intercept continuous time meta-analysis (RI-CoTiMA) of the effects of job resources in diary studies, and a RI-COTiMA of reciprocal relations among job demands and burnout. Finally, Laurenz Meier as invited discussant provides a critical evaluation of both parts of the symposium.

The first contribution to Part II of the symposium is a paper by Loh and colleagues. They proposed that a psychologically healthy workplace with abundant task-level resources is beneficial for improving workplace creativity. Specifically, they aim to understand how psychosocial safety climate (PSC) interacts with job resources (i.e., supervisor support and co-worker support) to influence employee creativity. Loh et al. applied a multi-wave quantitative diary design and collected data from 35 engineers, and they analysed their data with CTSEM. Their main findings are that that co-worker support predicted future creativity, and this effect was even stronger in a high PSC context. Supervisor support predicted future creativity only when employees were in a high PSC context, emphasizing that a psychosocially sustainable work environment, i.e., a high PSC context, supports employee creativity.

The second study presented in Part II of this symposium is study by Plueckhahn and colleagues. This study represents the first meta-analysis of possible reciprocal relations conducted with diary data. In particular, the authors investigate reciprocal relations between relational resources at work and negative affect using RI-CoTiMA. They found the strain effect of negative affect on relational resources to be stronger than the effect of resources on affect. By this, the authors provide first empirical evidence that strain effects are important to be modelled in diary studies. They also found that both cross-lagged effects reached their maximum after only about 2.5 hours, suggesting the absence of a carryover effect on the next day. Further, the authors also conducted analyses of statistical power suggesting that future diary studies should sample much more participants than done in previous studies to achieve an adequate probability to find truly existing effects.

The third paper by Dormann and Driver extends a recently published CoTiMA of k=48 longitudinal studies (Guthier et al., 2020; N = 26319) on the reciprocal relations among workload/time pressure and burnout by using RI-CoTiMA. The CoTiMA results by Guthier et al. could be challenged because they did not account for possible bias due to stable interpersonal differences (i.e., unmeasured traits). The present CoTiMA did so by including random intercepts. Still, the results largely confirm the results by Guthier et al. and show that workload is less likely to cause burnout than burnout is likely to cause increased (perceptions of) workload. In neither of the different models tested, workload/time pressure significantly increased burnout.

This discussant (Laurenz Meier) will critically discuss the results present in Part I and in Part II of the symposium. He is an internationally recognized expert of the analysis of longitudinal and quantitative diary data using advanced statistical methods, and he will provide critical remarks as well as suggestions for further research.

Relevance to the Congress Theme:

The world of work is changing, and so is the work of researchers, who constantly face the challenges brought by new statistical methods. Longitudinal studies that frequently spanned years and sometime even decades cannot cover the pace of changes in work anymore. Furthermore, new designs such as diary designs, experience sampling methods, or shortitudinal studies challenge the usefulness of established statistical methods. As researchers, we should change our own work, i.e., the way we analyse our data.

Research/Practical Implications

Overall conclusions:

Future research should use time intervals within a range of days to a few weeks, and they could vary time intervals within and between participants. Further, if the three or time points are available, RI-CTSEM models allow for analysing reciprocal within person effects, thus accommodating the strengths of several other methods to analyse repeatedly measured variables.

discussant: Laurenz Meier, University of Neuchâtel

Paper 1

Psychosocial safety climate and workplace creativity: A continuous-time modelling approach

Authors:

May Young Loh, Psychosocial Safety Climate Observatory, University of South Australia, Adelaide, may.loh@unisa.edu.au

Maureen Dollard, Psychosocial Safety Climate Observatory, University of South Australia, Adelaide, maureen.dollard@unisa.edu.au

Amy Zadow, Psychosocial Safety Climate Observatory, University of South Australia, Adelaide; & School of Psychology, University of Adelaide, Adelaide, amy.zadow@unisa.edu.au

Research goals and why the work was worth doing:

Working in a positive organizational context is essential for employee creativity. Employees' ability to create novel products and solve problems with innovative solutions improves corporate growth and effectiveness. Being creative also has value in shaping an employee's stress appraisal and enhancing their well-being. Given the importance of creativity, organizational researchers have devoted much effort to understanding the factors of boosting and cultivating creativity in workplaces. To improve our understanding of workplace creativity, there is a need for more attention to be given to the contextual effect and to how it interplays with other factors to influence creativity.

Theoretical background:

In the current study, we proposed that a psychologically healthy workplace with abundant task-level resources is beneficial for improving workplace creativity. Specifically, we aim to understand how psychosocial safety climate (PSC) interacts with job resources (i.e., supervisor support and co-worker support) to influence employee creativity. As posited by the Job Demands-Resources (JD-R) model, job resources, such as social support are key determinants of employees' performance, motivation, well-being, and creativity. The effect of job resources could be boosted if a positive work context such as a high PSC exists. Psychosocial safety climate (PSC) is a facet-specific organisational climate that reflects the organisational policies, practices, and procedures related to employee psychological health. A high PSC workplace consists of abundant resources and signals that employees are free and secure to use these resources. However, the interactive link between PSC, job resources, and workplace creativity has not yet been investigated; neither have been possible reciprocal effects. In addition, most of the longitudinal studies between job resources, organisational climate and creativity have ignored the influence of time intervals. This is unfortunate because this may reduce the validity and generalizability of results. We used continuous time structural equation modelling (CTSEM) to test our hypothesis to overcome this issue.

Design/Methodology:

A multi-wave quantitative diary design was included in this study. We collected data from 35 engineers from an Australian engineering firm. After omitting respondents with less than two observations, a total of 123 observations were included in the analysis. We analysed the data with CTSEM using the R package ctsem.

Results:

CTSEM results suggested that job resources, particularly co-worker support, predicted future creativity. Higher co-worker support was related to higher creativity (5.0012, lower level [LL] = 3.6307; upper level [UL] = 6.3778, 95% confidence interval [CI]). The effect was even stronger when being in a high PSC context (1.4424, LL = 0.7237; UL = 2.1547). Supervisor support predicted future creativity only within high PSC contexts (0.3286; LL = 0.1703; 0.4852). Unexpectedly, the findings revealed a negative reversed effect of creativity on supervisor support (-20.0859; LL = -25.5958; UL = -14.6843) and co-worker support (-66.4920; LL = -96.8514; UL = -35.5602), indicating that the more creative a person is, the less likely they are to receive supervisor and co-worker social support. This negative effect is slightly reduced by PSC (-0.0890; LL = -0.1106; UL = -0.0672).

Limitations:

Our study is limited with a small sample size from a single occupation and types of job resources (we only examined social support in the current study). Future research should include a larger sample and examine other resources, such as opportunities for learning and rewards. Even so, our study is the first attempt to understand the interplay of a psychologically healthy workplace and job design on creativity. We propose that high PSC is a significant element for creating a creative organizational environment and a protective factor for creative people.

Conclusions – research and or practical implications:

From the findings, we suggest that a high PSC work context is the key to boosting the impact of job resources and improving employees' creativity. In addition, we argue that building a high PSC is good for enhancing creativity and creating a friendly working environment for creative people.

Relevant UN SDGs:

Building a psychologically healthy and humane workplace is one of the global agendas in this changing world of work, as recognised by the International Labor Organization and the United Nations. Our study answers the call to promote decent work and economic growth in the latest UN SDGs.

Keywords: Psychosocial safety climate, creativity, ctsem

Paper 2

Challenging Unidirectionality. A Continuous Time Meta-Analysis of Short-Term Reciprocal Effects of Relational Resources and Negative Affect.

Wiebke Plückhahn & Thomas Rigotti | Johannes Gutenberg-University Mainz; Verena C. Haun, Julius-Maximilians-University Würzburg

Research goals and why the work was worth doing:

Prevention of long-term health-impairment processes is essential, especially when considering potentially harmful changes at the modern workplace. Recently, the reciprocal interplay of employee well-being and work characteristics has gained attention. Focusing on social relationships at work, we conducted a meta-analysis of time-lagged bidirectional effects between relational resources and negative affect. We provide insights into fundamentals of the dynamic relationships by analysing shortitudinal effects that might result in long-term build-up processes.

Theoretical background: The study of work characteristics has shaped research in work and organizational psychology during the recent decades. This is for good reason, as a variety of studies has linked work characteristics to positive as well as negative personal and organizational outcomes. Some longitudinal research papers and meta-analyses, however, also refer to strain effects, pointing out that employee well-being in turn seems to impact the experience of work, too. Drawing on that and Job Demands-Resources (JD-R) theory, we investigate reciprocal effects of relational resources at work and negative affect. Relational resources emerge from connections and bonds with colleagues and supervisors. When studying health outcomes, they have been shown to prevent depressive states and long-term health constraints. As past work focused on medium- to long-term effects, we examine daily diary data to understand fundamentals of dynamic processes and provide fine-grained insights into effects within a workweek. First, we investigate whether bidirectional effects already occur during this short time span. We then test whether resource and strain effects are of equal magnitude. Furthermore, we inspect the respective time lag after which the effects are largest.

Design/Methodology/Approach/Intervention: We conducted a documented literature research, including studies being published within the past 5 years from German speaking samples. The final sample consisted of 8 studies with a total of 1291 working individuals providing 6546 data points. We estimated cross-lagged effects using the usual cross-lagged panel model (CLPM) implemented in time continuous meta-analytical modelling (CoTiMA), and we extended the analysis by including random intercepts to identify pure within person effects (RI-CoTiMA). Further, we tested for equality of cross-lagged effects, and conducted power analyses to determine minimum sample sizes.

Results:

Overall, we found evidence for both the resource effect from social resources on negative affect, as well as the reversed effect from negative affect on social resources on the within-person and between-person level. On the latter, cross-lagged effects were equally strong and reached the biggest effect size after approximately 1.5 days, whereafter they slightly decreased. Remarkably, on the within-person level the strain effect of negative affect on relational resources was even stronger than the effect of resources on affect, meaning that short-term negative affect reduced relational resources more strongly than relational resources decreased negative affect reported shortly thereafter. Both cross-lagged effects reached their maximum after only about 2.5 hours before they almost completely decayed after only one day. Additionally, power analyses revealed large minimum

sample sizes to reliably detect short-term effects at between-person level. Within-person models clearly seem to be more economical, however, only when examining time lags of less than one day.

Limitations:

The sample includes only German-language data and relatively few studies. Therefore, our results are not entirely generalizable. Furthermore, it is unclear whether we surveyed resources themselves, as job characteristics usually are fairly stable, and it is questionable to what extent they actually fluctuate at an hourly level. It is more likely that, implicitly, the appraisal of resources was examined.

Conclusions:

Short-term negative affect influenced relational resources at least as much as vice versa, underlining the importance of considering reciprocal relationships of job characteristics and affect in future research designs. Especially the rapidly decaying within-person spikes should be further examined. Future studies should also pursue the question of how these microlevel effects build up into long-term burnout and/or depression. Here, our power analyses provide guidance on necessary sample sizes.

Relevance to the Congress Theme:

The short-term dynamic relationships of job characteristics and employee affect are important to understand in the rapidly changing world of work. Since we investigate very recent studies in this meta-analysis, the results show the pattern of effects at modern workplaces.

Relevant UN SDGs:

This study refers to the sustainable development goals of good health and wellbeing, as well as decent work and economic growth.

Paper 3

Traits Out – Stress Gone? A Random Intercept Continuous Time Meta-Analysis (RI-CoTiMA) of Workload-Burnout Relations

Christian Dormann, University of South Australia & University of Mainz, Germany; Charles Driver, University of Zuerich, Switzerland

Research goals and why the work was worth doing:

The effect of workload on burnout has been investigated many times and workload has been regarded as one of the major causes of burnout. Surprisingly, a recent continuous-time meta-analysis (CoTiMA) of longitudinal studies found that the reverse 'strain effect' of burnout on stressors is twice as large as the 'stressor effect' of stressors on burnout (Guthier et al., 2020). The CoTiMA by Guthier and colleagues applied the common cross-lagged panel model (CLPM), which has been criticized because cross-lagged effects could be biased, and they represent a blend of within and between person effects. Therefore, a random intercept alternative (RI-CLPM) has been proposed by Hamaker (2015), which eliminates trait variance and yields within person effects, which researchers are usually interested in. Since Guthier et al.'s finding – stress effects are smaller than strain effects – is extremely challenging for job stress researchers, and since it could well be possible that their finding relates to the problems of CLPM to yield unbiased within person effects, we used the same set of k = 48 longitudinal studies and analysed them with a new CoTiMA using random intercepts (RI-CoTiMA).

Theoretical background:

All job stress models propose that stressors cause strain (stressor effect), but virtually no model proposes that strain causes stressors (strain effect). However, some longitudinal studies found strain effects, and in these instances most researchers explained them post hoc by proposing mechanisms such as the stressor perception effect, the stressor creation effect, or the drift effect by which employees suffering from strain drift to more stressful jobs/tasks in the future. Until the recent meta-analysis by Guthier et al. (2020), however, there were few systematic investigations of possible reciprocal relations among stressors and strains such as workload and burnout. Unfortunately, interpreting the strain effect the authors found is difficult because it represents a blend of within and between person effects. For both theory building as well as for worksite interventions it is important to know if strain effects are not caused by personality characteristics (i.e., traits) and instead represent within person processes. Therefore, the present study proposes that stressor effect of workload and the strain effects of burnout exist at the within person level, and that the strain effect is larger than the stressor effect.

Design/Methodology:

We used the same set of k = 48 longitudinal studies included in the recent CoTiMA by Guthier et al. (2020). Among these were 6 studies with 3 or more waves, which were required to estimate random intercepts. Estimating random intercepts, however, was not limited to these 6 primary studies. Rather, the subset of these 6 studies enabled estimating random intercepts for the whole set of k = 48 studies.

Results:

A RI-CoTiMA of subset of k=6 studies with three of more waves yielded a continuous time significant stressor effect with negative (sic) sign (-.5623), whereas the strain effect was significant and positive as expected (1.8475). When extending the analysis and including all available k=48 studies, the stressor effects was positive and significant as expected (.9748), and the strain effect was significant and larger (1.8546), as expected. All analyses suggest that stressor effect and strain effects have their largest magnitude across time intervals of around 1 month, which is much shorter than the interval of 27 month reported by Guthier et al. (2020).

Limitation & Conclusions

The results confirm the previously meta-analytical established reciprocal effect of stressors and burnout and further confirm a stronger strain effect than stressor effects. Strain effects should therefore be considered in theoretical models and future studies to better understand how they emerge. We still do not know why the subset of k=6 studies with three or more waves yielded a negative stressor effect suggesting the workload might decrease burnout, and we will test some possible study-level moderators as possible explanations later. Still, there is a need to better understand how exactly strain effects moderating effect emerges, and future studies should investigate this effect in more detail. Since the largest effects emerged across time intervals as short as 1month, future studies should take this into account, too.

Keywords: stress, burnout, continuous time meta-analysis

Symposium S032

Applying Socio-Technical Systems Thinking to the Changing World of Work

Matthew Davis, University of Leeds; Patrick Waterson, Loughborough University

science

Overview:

The world of work is changing rapidly, for example, with the emergence and introduction of new technologies, advanced machine learning and artificial intelligence (AI), flexible work patterns and shifting ideas of what it means to "go to work" following the COVID-19 pandemic. Our symposium brings together three presentations that each applies Socio-Technical Systems principles (Cherns, 1979; Clegg, 2000) and tools to demonstrate how this thinking can be used to tackle specific challenges posed by changing world of work. The presentations share a common view that the changes that we are witnessing are not neatly attributable to or solvable by a single discipline. They are complex problems and to adequately understand and address them requires recognising the interaction between human behaviour, technology, infrastructure and management practices – in other words, taking a systems perspective.

In presentation one, Waterson describes a computer program capable of identifying factors contributing to harm during pregnancy and birth and explains how this can be used to design specific ways to improve maternal care for Black ethnic mothers. Waterson explains the complex set of factors that contribute to maternal harm. The example is used to illustrate the opportunity to use socio-technical systems principles to inform the design of healthcare systems. Waterson sets out an agenda for the use of machine learning in other healthcare contexts (e.g., the design of effective integrated care health pathways) and guidance for the application of the framework and principles laid down by Clegg (2000).

In presentation two, Grote, considers how work and organizational psychologists can help stakeholders to co-create and co-design AI. Grote describes how the development of AI raise fundamental questions about the distribution of control and accountability in socio-technical systems. AI is becoming increasingly capable of acting autonomously – this has profound implications for humans working alongside or accountable for such technologies. Grote and colleagues propose a design theory for the accountable design and use of AI, supporting practitioner decision-making on developing and using AI.

In presentation three, Davis considers how socio-technical systems tools and principles can be used to inform the design of the future workplace and examines how socio-technical systems thinking itself needs to be extended to better reflect the new world of work. A study by Davis and colleagues using the systems scenarios tool (SST) provides insights into how different office designs, organizational policies and building management practices interact to affect occupants. Davis considers how competing individual needs can be supported within contemporary office design.

The symposium concludes with an interactive discussion that challenges participants to consider new applications for socio-technical systems thinking to contemporary organizational problems and to identify barriers (and solutions) to use.

New Perspectives/Contributions

Our symposium provides three different illustrations as to the application socio-technical systems thinking to current challenges relating to the changing world of work. We provide work and

organizational psychologists with illustrations as to how principles, frameworks and tools can be applied to help understand and address these and offer a new design theory to help guide AI design. We present new empirical and conceptual research.

Relevance to the Congress Theme

We directly contribute to the congress theme demonstrating how socio-technical principles, tools and methods can be applied to: 1. help understand the impact of new technologies, work processes, physical work environments and work patterns, and; 2. equip work and organizational psychologists to take an active role to design, shape and improve the changing world of work.

Relevant UN SDGs

We directly address a number of SDGs, most notably "decent work and economic growth", "good health and well-being", “reduce inequalities” and "industry, innovation, and infrastructure".

Research/Practical Implications:

The symposium will help extend both research and practice by providing worked examples of how socio-technical systems principles, methods and tools can be applied. The discussion will prompt reflection around extensions and refinements to existing theory and further application areas.

Keywords: socio-technical systems, artificial intelligence, hybrid work

Paper 1

New Directions for Sociotechnical Systems – the use of Machine Learning to improve the investigation of patient harm

Patrick Waterson, Human Factors and Complex Systems Group, Loughborough University, UK

Theoretical Background

The field of sociotechnical systems (STS) has always been an eclectic one. Over the course of the last 70 years or so new fields and disciplines have been added to the list of collaborators that STS researchers work with. One of the latest collaborations is with colleagues working in the area of machine learning, artificial intelligence and data science. This paper will describe some work which has begun with the aim of applying machine learning to a large number of investigation reports covering patient safety with maternity in the UK NHS. In particular, the focus is on harm caused to patients from Black communities, as well as other ethnic minorities. Black women are five times more likely to die in the UK as a result of complications in their pregnancy than White women. Women of Black heritage are around 83% more likely to suffer a 'near miss' in childbirth. Research also found that Black children have a 121% increased risk of stillbirth and a 50% increased risk of neonatal death. At the moment, we do not have an accurate picture of the causes contributing to these statistics. Research points to biological factors (e.g., obesity or the birth history of mothers) as one cause of poor outcomes in maternity. Similarly, social and economic factors (e.g., language barriers, unemployment) are thought to play a role. Finally, the quality of care (e.g., poor communication with the mother, lack of knowledge on health issues) given to Black mothers and families is likely to be a factor.

One challenge is to provide an objective assessment of how these factors interact and influence each other. The Healthcare Safety Investigation Branch (HSIB) has carried out more than 2000 investigations over the last few years into things that go wrong during pregnancy and birth. Approximately 10% of these investigations involve Black mothers and families. One of the challenges HSIB faces is identifying patterns and trends within and across all of this data and using these to influence national bodies (e.g., CQC, NHS Improvement) and established and emerging campaigns (e.g., the NHS Maternity Transformation Programme, the NHS Long Term Plan).

Method

We will describe in our presentation a computer program that is capable of analysing the investigation reports and extracting data based on a set of codes for identifying factors contributing to harm during pregnancy and birth. The computer program uses machine learning to probe deeper into how different factors (e.g., regional, biological, clinical, care quality) interact, influence one another and lead to harm. The computer program also allows us to design specific ways in which maternal care for Black ethnic mothers and families can be improved.

New Perspectives/Contributions

Part of the presentation will be given over to a demonstration of how the computer program works and the codes that are learnt by the machine learning algorithm. These codes cover factors which contribute to maternal harm. Some of these are care-related (e.g., lack of escalation, delays in treatment) and some are related to background physiological factors (e.g., eclampsia, high levels of BMI). Part of the presentation will also be given over to discussing our collaboration with maternity

groups drawn from Black and ethnic minority groups (e.g., Five X More). We will also set out an agenda for the use of machine learning in other healthcare contexts (e.g., the design of effective integrated care health pathways). The work we describe is grounded in the framework and principles laid down by Clegg (2000) and we will describe how our work fits in and complements this earlier research. The research we will describe is funded by the UK Health Foundation.

Relevance to the Congress Theme

We directly contribute to the congress theme, addressing the positive role of new technology (artificial intelligence and machine learning) in understanding differences in outcomes from a work system (maternal healthcare providers).

Relevant UN SDGs

We address a number of SDGs, principally "good health and well-being", “reduce inequalities" and "industry, innovation, and infrastructure".

Keywords: socio-technical systems, artificial intelligence, patient safety

Paper 2

Organizing AI: A design theory for making decisions about learning algorithms in networks of accountability

Gudela Grote, ETH Zürich, Switzerland; Kevin Crowston, Syracuse University, New York, USA; Sharon Parker, Curtin University, Australia

Theoretical background

Information systems researchers have long bemoaned the lack of interest from management scholars in the role of technology for organizations and organizing. The recent transformative opportunities for autonomated decision-making based on learning algorithms and artificial intelligence (AI)-based technologies more broadly have dramatically changed this state of indifference. Many authors have expressed strong concerns regarding profound negative consequences of AI. Often, the predictions seem to draw on the paradigm of technological determinism, where technology is assumed to have foreseeable effects because users have no choice but to integrate it into their work in predefined ways. We argue that management research, and in particular research in work and organizational psychology, needs to develop a more proactive stance towards these new technologies in order to better support organizations and employees in managing both emerging threats and opportunities. The envisioned changes brought about by AI, defined as "algorithmic processes that learn from data in an automated or semi-automated manner" (NIST, 2022), are massive and raise fundamental questions about the distribution of control and accountability in socio-technical systems. As technologies' capabilities for autonomous action are rapidly growing, human actors find themselves in the uncomfortable situation of being held to account for actions they barely understand and have no control over. Rather than accept such developments as inevitable, stakeholders need to be empowered and enabled to co-create and co-direct accountable design and use of AI with the aim to align control and accountability for all parties involved.

New Perspectives/Contributions

We propose a design theory for creating and governing networks of accountability to foster accountable AI design and use based on accountability negotiations. Our theory and the testable design propositions derived from it are meant to guide prospective research on the impact of emerging AI technologies, but also to provide immediate support for organizational strategists in their attempts to harness the benefits of these technologies. We argue that decisions about technology development and implementation should be founded in a concern about "how things ought to be" (Simon, 1996) rather than in explanatory science about how things are. In a similar vein, Aguinis et al. (2022) have emphasized the need to convert exploratory and explanatory research in organizational behavior and human resource management to prescriptive and normative research.

In our theory, we propose that multiple stakeholders have to be brought together in networks of accountability rather than relying on the decisions of single actors at different stages of system development and implementation. Borrowing from risk theory, we postulate that stakeholders need to be enabled to conduct accountability negotiations across prospective, real-time and retrospective modes of organizing in an AI cycle and to consider and integrate rationalist and constructivist perspectives on accountable AI. We formulate four sets of design propositions concerning (1) the set-up of networks of accountability as preconditions for (2) defining transition mechanisms in the AI

cycle, which in turn are necessary prerequisites for the governance of networks of accountability both in terms of (3) adequate consideration of rationalist and constructivist perspectives and (4) handling of conflicts. Assumed outcomes of successfully creating and governing networks of accountability are alignment between control and accountability for all stakeholders, effective performance of the socio-technical systems in which AI is developed and used, and employee well-being.

Conclusions – research and practical implications

By proposing a design theory for the accountable design and use of AI, we expand the existing literature on AI in management towards prospective and normative research. Our design propositions map out avenues for future research, but also support practitioner decision-making on developing and using AI. By outlining the workings of networks of accountability, we shed light on how the intricate relation between technology, work, and organization can be managed, taking both rationalist and constructivist prespectives into account. Furthermore, we outline how risk should be considered more systematically and fundamentally in technology management, encompassing economic, physical and psychosocial risks.

Relevance to the Congress Theme

We directly contribute to the congress theme, as the impact of new technologies on work is imminent and work and organizational psychology should play a stronger role in shaping this impact. Our theory provides a framework for such more proactive research.

Relevant UN SDGs

By linking technological innovation with work design, we address a number of SDGs, foremost "good health and well-being", "decent work and economic growth" and "industry, innovation, and infrastructure".

Keywords: socio-technical systems, artificial intelligence, design theory

Paper 3

Applying socio-technical systems principles to the design of the future workplace

Matthew Davis, University of Leeds; Hannah Collis, University of Exeter; Linhao Fang, Emma Gritt, Simon Rees & Helen Hughes | University of Leeds

Background

COVID-19 changed where we work. Hybrid working (working from multiple workspaces e.g., office, client sites, home, third spaces) has become main stream. This work arrangement is preferred by office-based employees in the UK and across the EU (e.g., Davis et al., 2022; Eurostat, 2022). In this presentation we target academic impact by addressing the knowledge gap this shift to hybrid and more flexible forms of working creates, specifically in terms of the changing experience of work itself and how the future workplace needs to be adapted. Existing management and organizational psychology literatures have examined psychological and organizational implications of remote or home working, but more dynamic forms of working, such as hybrid working, remain underspecified and poorly understood. We demonstrate the value of applying socio-technical systems principles (e.g., Cherns, 1979; Clegg, 2000) to inform the design of the future workplace and examine how socio-technical systems thinking itself needs extending to better reflect the features of dynamic work environments.

Method

We employed the socio-technical Systems Scenarios Tool (SST) methodology (see: Hughes et al, 2017) to: 1. Identify the socio-technical factors influencing the employee experience of current workplaces that had been retrofitted to accommodate hybrid working practices; 2. Identify criteria for success and performance outcomes in future workplaces between different organisational stakeholders; 3. Explore participant generated future workplace scenarios (e.g., alternative physical designs, technology, process and management configurations) with trade-offs and contingencies identified. We worked with three UK based case study organizations (a private sector financial services firm, a public sector research organisation, and a private sector global engineering firm), each predominantly employing knowledge workers within traditional office environments. We followed the SST approach by first gathering contextual information via company documentation, floor plans, meetings with management and conducting employee interviews (n=46). This information informed the design of the workshop materials to guide participants through discussion and evaluation of their workplace design and ways of working in both the current and future scenarios. Four workshops were conducted within these organisations, each lasting four hours and involving 73 participants drawn from across departments, roles, seniority and tenures.

Findings and Conclusions

The workshop data was analysed by applying a socio-technical systems framework (Davis et al., 2014) using a template approach (Hughes et al., 2017; Clegg, et al., 2017). This approach generates key findings from integrating diverse data to map the trade-offs and inter-dependencies inherent in the design of future workplaces. Our analysis provides insights into how occupants are affected when different office designs, organizational policies and building management practices interact. We use these findings to explicitly consider how competing needs (e.g., individual vs team, working preferences, job characteristics) can be supported within a contemporary workplace context. Discussion will reflect on how the application of socio-technical systems principles, frameworks and

tools can help inform the design of future workplaces so they can both support the employee experience and promote organizational performance. Discussion will also consider the opportunity to extend existing socio-technical principles (see Davis, 2019) so they reflect the rapidly changing nature of work post COVID-19. Our discussion builds upon the developing discourse within the work and organizational psychology domain (e.g., Ayoko & Ashkanasy, 2020; Davis et al., 2019; Ward & Parker, 2020), regarding the opportunity to explicitly consider the physical work context within work design theory. We conclude by noting the practical implications and opportunities that this rapid shift to hybrid working presents for organizations and organizational psychology practitioners, to both inform and facilitate this change.

Relevance to the Congress Theme

We directly contribute to the congress theme, as the impact of changing work patterns, new technologies and physical work environments are rapidly changing the experience of work. We present insights and methods to aid work and organizational psychologists take an active role in designing and improving the future workplace.

Relevant UN SDGs

We directly address a number of SDGs, most notably "decent work and economic growth" and "industry, innovation, and infrastructure".

Keywords: socio-technical systems, physical workplace, hybrid work

Symposium S033

The Challenges We Face: What Can Work and Organizational Psychologists Learn from Entrepreneurs and How can Psychology Help Entrepreneurs?

Constanze Eib, Uppsala University

science

What will be covered and why

Despite the importance of entrepreneurs for innovation and job creation, as well as the sizable percentage of self-employed in the European labor market, Work and Organizational Psychologists (WOP) still seem to not regard entrepreneurs as central population to study. With this symposium, we aim to change this view. Entrepreneurs, self-employed, giggers, freelancers are a heterogenous group of the working population. Some are in precarious situations, some lonely, some feel inadequate, some are passionate and some playful and creative. Studying entrepreneurs can provide answers to multiple challenges of our world. In this symposium, we approach these challenges: an aging population, gender inequality, future ways of work including a lack of a clear organizational support network and gamification.

The symposium presents a collection of new and exciting studies using psychological theory on different types of entrepreneurs:

Chadwick & Dawson present two quantitative studies (cross-sectional, longitudinal) with entrepreneurs operating in the US. Based on the imposter phenomenon (a psychological bias, leading capable people to feel inadequate in the face of success) and gender-role incongruity theory (Eagly &Karau, 2002), they investigate predictors of women entrepreneurs experiencing imposter perceptions. Also, they study the consequences of feeling like an imposter and the moderating effects of social support and psychological resilience.

Purc & Laguna explore older entrepreneurs' reasons and motives to continue working at retirement age. Using a qualitative approach with entrepreneurs operating in Poland, they find that older entrepreneurs experienced a variety of motives to continue running a business apart from financial reasons. Also, they explored older entrepreneurs' views on their age and their well-being while working.

Wach et al. examine solo self-employed in Germany during the COVID-19 pandemic. Lacking an organizational safety net, solo self-employed were hit hard by the pandemic and faced many stressors and challenges. Building on transactional stress theory (Lazarus & Folkman, 1984) and using a mixed method design, the authors find specific coping strategies and recovery activities that helped this precarious group of entrepreneurs to maintain their well-being.

Eib et al. examine the impact of others (i.e., stakeholders) in shaping entrepreneurs' work environment. They suggest that entrepreneurs operate within a network of people and institutions that are sources of entrepreneurs' fairness perceptions. Data on solo self-employed operating in Sweden are analyzed with latent profile analysis. Findings reveal that entrepreneurs view treatment from various stakeholders differently, and these different profiles vary in work outcomes and well-being.

Mukerjee et al. conclude the symposium with three survey studies on the development of two play at work scales, using data from SME owners in France. They propose that play and entrepreneurship are both processes that share similarities; however, a lack of a reliable and valid measure on play at

work hinders progress on this topic. As the practice of play at work is rising (Mainemalis & Ronson, 2006), especially with the millennial workforce bringing in a 'play and game culture' to their workplace, the study of play is arguably of interest to all WOP.

Relevance to the Congress Theme

In this symposium, we tackle several challenges we are all facing right now in this changed world of work. Chadwick & Dawson confront gender inequality in entrepreneurship and the challenge of highly competent people feeling inadequate. Purc & Laguna approach the challenge of an aging population in Europe with unsustainable pension systems. They study motives that help prolong an entrepreneurial career as well as age-related experiences. Wach et al. study coping and recovery of entrepreneurs during the pandemic to learn how to build resilience against future crises. Eib et al. grapple with the challenge of how workers, who work outside of an organizational support network, are affected by external institutions and people. Mukerjee et al. provide us with ideas on how play, creativity and gamification may change our future way of work.

Research/Practical Implications

The collection of studies is designed to give new thoughts and ideas to WOP, entrepreneurs, and policy-makers. We develop insights into: what entrepreneurs need to create a sustainable career, how institutions can support entrepreneurs, and how to reduce gender inequalities in entrepreneurship. We also contribute to the entrepreneurial well-being literature, alike we introduce psychological theories into entrepreneurship.

Overall conclusions

To solve the big challenges of our times, we as WOP need to be present in all businesses, no matter how small or large. Entrepreneurial businesses will change our future – the question is: how can We help entrepreneurs do that best.

Keywords: entrepreneurs, self-employed, well-being

Paper 1

The Complex Role of the Imposter Phenomenon Among Women Entrepreneurs

Alexandra Dawson & Ingrid Chadwick | Concordia University

Research goals and why the work was worth doing

In line with gender-role incongruity theory (Eagly & Karau, 2002), women tend to experience competing social expectations of what it means to be a woman versus a working professional, making them more susceptible to feel like imposters (Sandford et al., 2015). This paints a bleak picture for women entrepreneurs in the male-dominated context of entrepreneurship. Scholars have accordingly argued that women entrepreneurs are more likely to experience imposter fears than men, and that this may help explain why fewer women become entrepreneurs and why, once they do, they tend to be less likely to succeed (Ladge et al., 2019).

The goal of this research is therefore two-fold. First, grounded in the literatures on the imposter phenomenon (Clance & Imes, 1978) and gender-role incongruity theory (Eagly & Karau, 2002), we seek to better understand the extent to which women entrepreneurs experience the imposter phenomenon, and whether certain women are more or less likely to do so. Second, we aim to explore both business and personal outcomes of experiencing the imposter phenomenon in entrepreneurship for women relative to men, and whether there are critical factors that can alleviate its negative effects (or possibly enhance positive effects).

Theoretical background

The imposter phenomenon is a psychological bias, leading highly capable and intelligent individuals to attribute their success to external factors such as hard work or luck, feel inadequate and fraudulent, even in the face of success, and believe others overestimate their abilities (Clance & Imes, 1978; Tewfik, 2022). Not surprisingly, feeling like an 'imposter' is associated with negative outcomes such as anxiety, low self-efficacy, and maladaptive behaviours including self-denigration (Ferrari & Thompson, 2006).

The imposter phenomenon is often triggered in high achievement contexts, leading to its prevalence among people of all backgrounds and demographics in today's complex and competitive working world (Badawy et al., 2018). However, research suggests that high-achieving women in male-dominated contexts, such as entrepreneurship, may be exceptionally affected due to gendered expectations for success in such domains (Kets de Vries, 2005; Ladge et al., 2019).

Despite claims about the potential harmful impact of the imposter phenomenon for women's entrepreneurship, there are scarce empirical investigations available to date. This is an important oversight as women are entering entrepreneurship at increasing rates across the globe (Elam et al., 2019). Hence, we need to better understand the prevalence and implications of women experiencing imposter fears, but above and beyond that, we need to investigate the role of different factors that may help these women avoid or at least overcome this bias.

Methods

We are conducting two complementary studies using validated measures (to be completed by March 2023). Study 1 is a survey of 150 women entrepreneurs in Canada who are asked to report on their experiences of the imposter phenomenon (using Clance's (1985) scale), and offer demographic,

business, and industry information to shed light on what types of women are more or less likely to feel like imposters in entrepreneurship. This study also incorporates measures of a potential identity conflict respondents may experience as women and entrepreneurs (a potential antecedent to the imposter phenomenon), including their gender evaluation (Luhtanen & Crocker, 1992).

Study 2 is a time-lagged survey of 100 men and 100 women entrepreneurs, in which respondents are asked about the imposter phenomenon at time 1, followed by individual (e.g., wellbeing) and business (e.g., performance) outcomes at time 2. Moderating factors such as social support and psychological resilience will also be measured to investigate ways to mitigate any harmful effects that the imposter phenomenon may produce, including differences in results for men versus women.

Preliminary results

Preliminary results from Study 1 suggest the imposter phenomenon does not affect all women entrepreneurs equally, depending on demographics and gender evaluations. Furthermore, the implications of feeling like an imposter may not be as clear cut as the literature suggests, encouraging more research on this important topic.

Limitations

It may be fruitful to study women entrepreneurs in other countries to replicate the findings.

Research/Practical Implications

Our research seeks to test and extend theory on the role of the imposter phenomenon for women entrepreneurs, and to ultimately contribute insights that enable more women to thrive in entrepreneurship.

Relevance to the Congress Theme

We contribute to improving the changing world of work by focusing on reducing gender inequalities. The imposter phenomenon may be one factor that can explain the gender inequality in entrepreneurship.

Paper 2

Do You Want to Work Forever? Reasons to Continue Running a Business From the Perspective of Entrepreneurs at the Retirement Age

Mariola Laguna & Ewelina Purc | The John Paul II Catholic University of Lublin

Research goals and why the work was worth doing

Due to the population aging, visible especially in developed countries, people, including entrepreneurs, often have to work longer than it used to be (Herrador-Alcaide et al., 2021; Noone et al., 2021; Vignoli et al., 2021). There is a growing research interest in startup activities by older individuals (e.g., Halvorsen & Morrow-Howell, 2017). However, little is known about specific motivations and perceptions of entrepreneurs who continue running their businesses even when they could be retired. Hence, a qualitative study was conducted to explore older entrepreneurs' reasons for continuing to operate a company at retirement age. Moreover, age-related difficulties and perceptions of the work situation of such entrepreneurs were investigated.

Theoretical background

Age matters when starting and/or operating a business. In general, younger people recognize more opportunities to start a business (Bohlmann et al., 2017), and indeed are more likely to start a business (Levesque et al., 2006). However, older people, over the course of their lives, have acquired more knowledge and experience relevant for business operations (Small, 2012; Kautonen, 2013; Stirzaker et al., 2014; Fachinger, 2019). Moreover, research has shown that the human and social capital of older people contributes to reducing business failure rates (Wainwright & Kibler, 2014). In addition, due to retirement benefits, older entrepreneurs have a steady income (Fachinger, 2019), with the result that the financial risk of running a business is lower. However, when they invest their savings into the business and the business does not survive, they have much less time to rebuild their position and raise funds than young entrepreneurs (Wainwright & Kibler, 2014). All these premises suggest that there are specific motivations and factors responsible for continuing running businesses at the retirement age.

Design/Method

The data used in the study were collected in qualitative semi-structured interviews. Participants were 50 Polish entrepreneurs (34% women) aged 60-83 years, running their businesses for 25.3 years on average. In Poland, the retirement age is 60 for women and 65 for men. Participants were asked about (1) reasons to continue running a business, (2) age-related difficulties, and (3) perceptions of older entrepreneurs' work situation. Data were analyzed with a thematic analysis approach.

Results obtained

Results show that reasons why older entrepreneurs continue to run a business were to satisfy financial needs, the need to be active, out of passion, and perceiving running a business as a mission. Surprisingly, few participants experienced age-related difficulties. Some entrepreneurs indicated difficulties related to their worsening health and psychophysical capacity and due to their limited ability to use new technology. However, despite these few age-related difficulties, older entrepreneurs perceived their vast experience as an advantage over younger entrepreneurs. As for their perception of the overall situation of older entrepreneurs, many believed that running a business was an obligation – participants were convinced that as long as health and other factors

allowed it, one should continue working even after reaching the retirement age. It is consistent with the theory of continuity of aging (Atchley, 1989), which assumes that older people have higher psychological well-being when they maintain similar lifestyles and activities as when they were younger.

Limitations

Entrepreneurs were selected on the basis of their availability; the sample is thus not representative. Due to restrictions involving the COVID-19 pandemic, some entrepreneurs were interviewed face-to-face and others by phone. Future studies may combine qualitative and quantitative methodological approaches to further study the relationship between quality of life and running a business at retirement age.

Research/Practical Implications

The study results provide relevant insights into older entrepreneurs' work situation, which can be used by scholars and policymakers in supporting their valuable activity. Reasons for continuing to operate a company at retirement age and age-related difficulties were identified. It should be emphasized that older entrepreneurs have a great potential to contribute to countries' economic development.

Relevance to the Congress Theme

Better understanding the changing world of work has to include the issue of population aging in developed countries. Research shows that the older the population in a country, the lower the rate of overall entrepreneurship is (Liang et al., 2014). Considering the societal and economic importance of creating and maintaining businesses, it is vital to get insights into factors stimulating older entrepreneurs to continue running a business and into the difficulties they face.

Relevant UN SDGs

The topic is related to UN sustainable development goals concerning poverty reduction, decent work and economic growth.

Keywords: retirement, aging, entrepreneurs

Paper 3

How do the solo-self-employed safeguard their wellbeing during a crisis? Insights into stress, coping and recovery during the Covid-19 pandemic

Martina Pieperhoff, TU Dresden; Ute Stephan, King's College London; Dominika Wach, TU Dresden

Research goals and relevance

The current study integrates stressor coping research with insights from the recovery literature to explore, first, what stressors the solo-self-employed experience during the Covid-19 pandemic and, second, how they deploy problem- and emotion-oriented coping alongside recovery as mechanisms to maintain their life satisfaction and prevent vital exhaustion. Our current mixed-method study contributes insights to the growing research on entrepreneurial well-being (e.g. Stephan, 2018), and in particular, to coping and recovery as potential solution to entrepreneurial ill-being that help entrepreneurs to sustain their wellbeing whilst navigating their intensely stressful work.

Theoretical background

Based on a Lazarus and Folkman's transactional stress and coping theory (1984) as well as stressor detachment model (Sonnentag & Fritz, 2015), we explore in what ways the COVID-19-pandemic was experienced as threatening for solo-self-employed and their businesses. In response to stressors such as uncertainty, loneliness, or financial pressures, we expected solo-self-employed to engage in problem-focused coping, for instance, via exploration and testing novel business ideas, as well as in emotion- oriented coping to reduce their psychological distress. We view recovery as emotion-oriented coping strategy that promotes psychological well-being (Van Harreveld, Van der Pligt, Claassen, & Van Dijk, 2007).

Design/Method

We conducted 22 in-depth qualitative interviews with German solo-self-employed from two sectors in Saxony during March 2021. We explored COVID-19 related stressors experienced by the participants as well as their coping strategies including recovery from work in their leisure time and during the workday. We analyzed the data drawing on Mayring's summarizing content analysis (2015) and used MaxQda software to code the interviews and calculate interrater reliability. Prior to this study we conducted online survey to collect data on participants' well-being, resilience, and socio-demographic data, including information regarding the negative impact of COVID-19-crisis on their business.

Results

The main themes regarding "stressors" related to financial problems, uncertainty and lack of social contacts. Typical "coping strategies" were mindfulness, maintaining a positive outlook, and taking advantage of the pandemic to engage in personal professional development. Interestingly, most participants recognized and implemented new business opportunities as a way of coping, while hiking, walking and exercise were typical "recovery" strategies. In regard to well-being, solo-self-employed reported moderate life satisfaction and vital exhaustion. We also gained valuable insight about how certain coping strategies were preferred by solo-self-employed to deal with specific stressors, and identified different types of participants based on their profiles of utilization of particular coping and recovery mechanisms.

Limitations

Our findings showed moderate interrater-reliability (Kappa = 0.56) calculated based on eight randomly selected interviews that were coded by an independent research assistant blind to our research questions. Our sample was rather small and homogenous which prevent us from deriving more general conclusions.

Research/Practical Implications

Investigating stressors, coping strategies and well-being in vulnerable groups such as solo-self-employed, who were particularly strongly hit by the pandemic, has the potential to offer insights that could be valuable in future crises. Transactional stress theory seems very well suited in the context of the COVID-19-pademic and self-employment. It highlights the relevance of social support as coping strategy and suggests that solo-self-employed should actively search for networking opportunities to better deal with crises. On the more negative site, professional coaching and counselling should address entrepreneurs' negative emotions such as anger and fears, to help alleviate their distress.

Attempts to provide coaching tailored to the needs of solo-self-employed in crises may orientate on existing coaching as proposed and evaluated by Schermuly et al. (2021).

Relevance to the Congress Theme

Our contribution is of high relevance for the congress theme "The Future is Now: the changing world of work". At a time when systemic health and climate crises (e.g. flooding, fires) are becoming more

frequent, it is paramount that we have a robust understanding of how entrepreneurs cope with crises to be able to support them. This is also important as solo-self-employed account for 54.4% of all self-employed in Germany being its "economic backbone". To build a resilient economy, research is needed to predict how entrepreneurs overcome a crisis (i.e., their businesses survive) and how they may even thrive in times of crisis by recognizing new opportunities and innovation.

Relevant UN SDGs

Good health and wellbeing (SDG3)

Decent work (SDG9)

Paper 4

Not so alone after all? From where do entrepreneurs get fair treatment at work – and does it matter for their well-being?

Constanze Eib, Uppsala University; Claudia Bernhard-Oettel & Franziska Müller | Stockholm University

Research goals and why the work was worth doing:

The aim of this study is to investigate sources of fairness perceptions for entrepreneurs. With this, we make a theoretical contribution to the entrepreneurship literature by proposing that entrepreneurs indeed have a support network, even though it is different from the organizational support net employees have. We suggest that entrepreneurs operate within a network of people and institutions that shape entrepreneurs' work environment in fundamental ways. Moreover, we make a theoretical contribution to the justice literature by looking at sources of fairness perceptions outside of an organizational support network.

Theoretical background:

Research on the importance of the work environment of entrepreneurs has been increasing in recent years. Entrepreneurs are seen as independent creators of their work environment, balancing high workload, loneliness, financial insecurities with high autonomy and meaningful work. One of the aspects missing from this literature is the consideration of stakeholders in shaping entrepreneurs' work environment.

From research on employees, we know that fairness perceptions are an important psychosocial work environment factor with substantial associations to work outcomes, well-being and health. The fairness literature is vast but limited in at least one important way – research is mostly conducted within organizations, with employees being the primary target of interest. One reason may be that fairness perceptions stem from interactions with so-called sources. The source of fair or unfair treatment that informs employees' fairness perceptions is the immediate supervisor or organizational representatives. Entrepreneurs, however, lack both supervisor and organizational representatives. Thus, entrepreneurs are an interesting population to study to determine whether fairness extends beyond organizational boundaries. Previously, it has been suggested that entrepreneurs also have fairness perceptions, and that these may be informed by the treatment they receive from their different stakeholders, like state agencies, banks, clients, etc. However, there is no empirical work that studied sources of entrepreneurs' fairness perceptions.

In this study, we investigate fairness perceptions in relation to different stakeholders of entrepreneurs. Using a person-centered approach, we explore whether stakeholder justice perceptions form distinct profiles. Profiles are validated with demographics, business variables as well as work and well-being outcomes.

Methodology

Data from 453 solo self-employed operating in Sweden were collected. Stakeholder fairness perceptions were assessed with five items. Each question started with "To what extent do you feel fairly treated…?", ending with "by governmental agencies and municipalities", "by clients", "by bankers or financiers", "by unions", by "unemployment fund". Importantly, in the Swedish context, entrepreneurs are, in part, integrated into unions and unemployment funds.

Results obtained:

Generally, fairness perceptions were highest for treatment by clients, medium for banks, government agencies, unions, and lowest regarding the unemployment fund. Latent profile analysis extracted distinct profiles of stakeholder justice, which not only differed in level but also in shape. Profiles significantly differed in performance, job and career satisfaction, as well as in well-being and health. In terms of covariates that differentiated between profiles, demographic variables made mostly no difference. Instead, variables concerned with security factors (e.g., income security, impact of COVID-19, lack of clients) differentiated between profiles.

These results suggest that justice perceptions of entrepreneurs may stem from various stakeholders, and that it makes a difference for entrepreneurs' work and well-being outcomes how they perceive treatment from these stakeholders.

Limitations:

Cross-sectional data, the limited number of stakeholders investigated, and the specificity of the sample may limit drawing wide-ranging conclusions.

Research/Practical Implications:

The study of justice perceptions within entrepreneurs is a new area of research and very little theoretical or empirical work has been done. The idea that stakeholders impact the work environment of entrepreneurs, which in turn, affects entrepreneurs' work and well-being outcomes, has theoretical implications that needs to be explored further.

The Swedish welfare system is built around employees' needs. Anecdotal evidence suggests that many entrepreneurs feel that they do not get their fair share out while paying into the system (e.g., parental leave, sick pay, pension rights). Thus, studying how entrepreneurs perceive fairness from various stakeholders may provide insights into what policy changes are needed to foster greater interest in becoming an entrepreneur in Sweden as well as provide a sustainable and positive entrepreneurship climate for current entrepreneurs.

Relevance to the Congress Theme

As entrepreneurs are an increasing force in the labor market, it is important to study the work environment they face. Understanding how fairness is perceived by entrepreneurs, and how different stakeholders impact entrepreneurs may help to make being an entrepreneur a more sustainable career choice.

Paper 5

"Playing the fool or playing to be serious"? Development of play scales for work organizations

Olivier Torres, University of Montpellier; Roy Thurik, Erasmus University; Annelot Wismans, Erasmus University; Jinia Mukerjee, Montpellier Business School

science

Research goals and why the work is worth doing

Play is a phenomenon as old as civilization. As put by Huizinga "play is older than culture" (2014: 1). In the field of management however, play has traditionally been seen as opposite of work. This was unequivocally stated by Frederick Taylor: "It is a matter of ordinary common sense to plan working hours so that the workers can really "work while they work" and "play while they play," and not mix the two" (Taylor, 1911: 126). Play has always been present in work organizations though, notwithstanding surreptitiously, away from the managerial gaze (Roy, 1959). In the last two decades, many organizations have institutionalized play with the belief that it has positive consequences, both on workers' motivation, well-being, performance, as well as on the organizations (Mainemelis & Ronson, 2006).

An attempt to forge a synthesis between the view that work and play are opposite has been put forth by studies arguing that work, especially creative work, can become a kind of play (Starbuck & Webster, 1991; Schrage, 2000). Playing with work tasks to increase productivity called 'serious play' – in the form of prototyping, brainstorming, etc., – has become common in many organizations (Schrage, 2000). On the other hand, 'diversionary play', that is play unrelated to work tasks but enjoyable, undertaken often to recharge and replenish from work, always present in work organizations (Roy, 1959), is now openly carried out by workers, often encouraged by managers. Such play can take many different forms, e.g., socializing, jokes and humor, or games (Dumas & Rothbard, 2013; Abramis, 1990; Filipowicz, 2002).

Despite growing interest and recognition among management scholars that play is omnipresent in work organizations most empirical work on play are case studies or ethnographic studies that have zoomed into one (or two) organization(s) (Hunter et al., 2010; Sørensen & Spoelstra, 2011; Nath, 2016; Mukerjee & Metiu, 2022). These studies have been essential to understand and theorize about the phenomenon of play at work, and helped us gain a deeper understanding of the ways in which play unfolds in work organization and benefits work. Recently, scholars have studied and created a scale to measure playful work design initiated by employees at work (Scharp et al., 2022).

However, with the changing nature of work, especially with the rise of the millennial workforce (Wey Smola & Sutton, 2002) who grew up in a gaming culture, and demand freedom at work, play is becoming more and more pervasive in organizations (Mukerjee & Metiu, 2022). Therefore, investigating play in organizations, through a theory-based measure is now timely. As a part of a larger research project, in this paper we develop measurement scales for two types of play documented in work organizations: diversionary and serious play. We do this by testing our scales on entrepreneurs.

Our motivation to focus on entrepreneurs is driven by two principal reasons. Entrepreneurship can be seen 'as becoming in the moment of life where initiative, spontaneity, imagination and immediacy emerges' (Hjorth & Steyaert, 1999), a process that shares stark similarity with play. Surprisingly, while the popular press has often alluded that creating a company demands playful imagination, and

entrepreneurs are people who ‘work hard and play hard’, the entrepreneurship literature has remained surprisingly silent about the role of play in the entrepreneurial process.

Secondly, unlike employees/managers working in large organizations, entrepreneurs, especially small to medium business owners, have the freedom to create and shape their firm’s environment (Kauannui et al., 2010), and are often the creator and gatekeepers of the firm’s culture. Thus, entrepreneurs are a good proxy for measuring the extent of play present in their enterprise.

Theoretical background

We draw on anthropological theories of play (Bateson,1972; Huizinga, 1955) as well as existing works on play in organizations (Mainemelis & Ronson, 2006; see Petelczyc et al., 2018 for a review) to conceptualize the dimensions of diversionary and serious play.

Design/methods

For creating the scales for diversionary and serious play, we will follow three stages: item development, scale development, and scale evaluation (Boateng et al., 2018). We will use three datasets solely consisting of French SME owners (N=80, N=250, N=250). Data collection is expected to finish until December 2022. Other measures used for checking validity are available upon request from authors.

Expected results

Preliminary data are available and suggest that play can be assessed with a reliable and valid scale.

Limitations

We aim to contact samples representative for SME owners in France, though the sample may be biased as we are dependent on voluntary participation.

Research/Practical Implications

Organizational life is no longer narrowly defined as being just about work. The notion of organizational life now represents “a site for the search for ‘personal wellness’, a place and time where ‘well-being’ is defined and self-expression actively encouraged, where ‘happiness’ is sought through a proliferation of techniques celebrating the self” (Costea, Crump, and Holm, 2005: 141). As a result, play at work has started to receive increasing interest. Furthermore, with the millennials’ desire to balance work with play and freedom, play is progressively becoming an organizational reality that begs for serious research enquiry.

Relevance to the Congress theme

By developing scales to measure the two most frequent types of play studied in work organizations, our study contributes to one of the central research agenda of organizational studies – understanding the changing context and nature of work (Barley et al., 2017).

Relevant UN SDGs

Decent work and economic growth; good health and wellbeing

Keywords: play, scale development, entrepreneurs

Symposium S034

On Sleep and its Many Faces: Portraying the Manifold Relations of Sleep and Work

Jette Völker, Department of Psychology, University of Mannheim, Germany

science

Employees spend about one third of the day asleep and about one third of the day at work. Specifically, humans seem to sleep even one hour longer than the usual employee spends working per day. This makes sleep and work two vastly important domains that structure employees' everyday lives. Importantly, both sleep and work can mutually affect each other. On the one hand, sleeping long and well can restore energetic resources needed to function effectively at work, for example, to experience work engagement or perform well. On the other hand, work can impair sleep, for example, due to time constraints or ruminative processes.

Different aspects can characterise sleep. While sleep duration refers to the amount of time spent sleeping, sleep quality, efficiency, and fragmentation describe experiencing restorative sleep such as not having trouble falling and staying asleep. Also, the timing of sleep matters as social sleep lag describes a discrepancy between employees' biologically preferred and actual sleep times. All these sleep characteristics can differentially relate to employees' work experiences and behaviour. However, research on the interplay of sleep and work is still in its infancy – with many studies only investigating sleep quality as a control variable for other daily relationships.

The presentations in this symposium portray the manifold ways sleep and work can be related. In the first presentation, the authors investigate state and trait workaholism as predictors of employees' sleep quality depending on their after-work recovery experiences. In the second presentation, the authors examine the bidirectional relationship between emotions experienced at work and objectively assessed sleep characteristics of nurses involved in shift work systems. In the third presentation, the authors investigate how workload and job control predict latent profiles of sleep characteristics (sleep duration, bedtime, wake time, sleep quality, and sleep fragmentation) that are, in turn, related to fatigue and burnout. The fourth presentation demonstrates how sleep quality (subjectively and objectively assessed) affects creativity at work via mindfulness. Finally, the last presentation introduces employees' daily social sleep lag as a boundary condition for after-work recovery processes.

Thus, the presentations in this symposium combine views on sleep as an outcome of work-related processes, as a predictor for experiences and behaviour at work, as well as a boundary condition for after-work recovery processes, highlighting the various ways sleep is relevant in everyday working life. At the same time, the presentations illustrate the many faces of sleep by differentially investigating various sleep characteristics and combining different methodological approaches (objectively vs. subjectively assessed sleep characteristics, person- vs. variable-centred approaches to data analysis). Thereby, this symposium helps to paint a clearer picture of the complex interplay of sleep and work as two major domains in employees' everyday lives.

To sum up, this symposium seeks to inspire future research on how to sustainably budget resources to achieve both - good sleep and favourable work experiences. Understanding these processes is also highly relevant for practitioners to prevent vicious circles of impaired sleep and poor work behaviour. The changing world of work poses many challenges but also opportunities for employees' sleep. On the one hand, increased flexibility to work from home, as we observed during the peaks of the COVID-19 pandemic, can be associated with favourable sleep outcomes. Working from home can enable employees to follow their biologically preferred sleep-wake rhythms and sleep longer due to

missing commuting. On the other hand, increased workload and demands pose challenges to employees' sleep. Time constraints as well as limited recovery can thwart maintaining good and long enough sleep. Overall, enabling employees to sleep long, well, and at the right time is crucial to achieving the UN Sustainable Development Goal of good health and well-being. At the same time, sleep is also a key element when aiming to achieve the UN Sustainable Development Goal of decent work and economic growth by providing employees with resources to be sustainably productive at work. This symposium thus emphasises the relevance of considering sleep in organisational research by portraying the manifold ways that sleep and work can be related.

Keywords: sleep, well-being, work behaviour and experiences

Paper 1

Daily Fluctuations in State Workaholism, Sleep Quality, and Recovery Experiences: Does Workaholism Act as an Internal Stressor?

Luca Menghini, Department of Psychology and Cognitive Science, University of Trento, Italy;
Cristian Balducci, Department for Life Quality Studies, University of Bologna, Italy

Research Goals. This pre-registered study aimed at empirically evaluating the conceptualisation of workaholism as a multilevel construct, exhibiting both differences between individuals (trait workaholism) and within-individual fluctuations (state workaholism). More specifically, it focuses on perceived sleep disturbances as a primary strain outcome by investigating the within-individual relationship between state workaholism and sleep quality, controlling for the corresponding association at the between-individual level. Moreover, moving from the hypothesis that workaholism acts as an internally generated demand or stressor, we investigated whether its within-individual relationship with sleep quality was buffered by the daily level of recovery experiences.

Theoretical Background. Over the last decade or so, workaholism has caught increasing attention both inside and outside the academia, also due to the rising awareness on the health and well-being implications of work intensification. It has been most widely conceptualized as a dysfunctional tendency to work excessively and compulsively; a stable trait implying unsustainable effort and time spent at work. Indeed, at the between-individual level, trait workaholism has been shown to act as an internal job-related demand leading to strain responses such as sleep disturbances (Clark et al., 2016). Only in the last two years, a few studies provided initial evidence of within-individual fluctuations in state workaholism and their potential short-terms consequences. Here, we built from the Effort-Recovery (Meijman & Mulder, 1998) and the Stressor-Detachment model (Sonnentag & Fritz, 2015) to investigate the straining effects of state workaholism on sleep quality and the potential buffering role of recovery experiences. Considering the Perseverative Cognition Hypothesis (Brosschot et al., 2006), we expected that higher-than-usual state workaholism could lead to prolonged activation in the evening due to job-related compulsive and perseverative thoughts, eventually compromising sleep quality. However, we expected such relationship to be weakened in those working days with higher-than-usual levels of job detachment and relaxation.

Design. The study involved a sample 114 full-time workers (51% women) from several job sectors that participated in a daily diary protocol over two workweeks. Each day, participants reported their state workaholism (diary 1: end of the working day), after-work recovery experiences (diary 2: bedtime), and sleep quality (diary 3: next morning), using seven-point adaptations of widely used and validated scales (i.e., Dutch Work Addiction Scale, Recovery Experience Questionnaire, Mini Sleep Questionnaire). Specifically, the six-item workaholism measure exhibited satisfactory reliability at both within- and between-individual level, with multilevel confirmatory factor analysis supporting the cross-level invariance of factor loadings, a critical condition for conceptualizing multilevel constructs.

Results. Multilevel modelling conducted on 725 complete observations indicated that sleep quality was negatively related to both trait and state workaholism, controlling for recovery experiences and gender. Moreover, we found evidence of within-individual interactions between state workaholism and recovery experiences, with the former becoming unrelated to sleep quality in those days characterised by higher-than-usual levels of detachment and relaxation.

Limitations. The limitations of this study include the relatively small convenience sample (i.e., between-level statistical units) and the sole use of self-report measures.

Conclusions. Accounting for such limitations, this is to our knowledge the first study investigating the within-individual relationships between workaholism, recovery, and sleep quality, the first investigation of state workaholism that temporally separated predictor and outcome measures, and the first pre-registered study on workaholism, implying stronger methodological rigour than previous research. Our results provide convincing support to the conceptualisation of workaholism as a multilevel construct exhibiting cross-level isomorphism and homologous relationships with sleep quality across levels. Moreover, our findings corroborate the idea that workaholism acts as an internal job-related stressor triggering strain responses, particularly when not accompanied by adequate recovery. While this study contributes to the advancement of workaholism research by enriching its conceptualisation and nomological network, it is also informative for planning interventions aiming at reducing the related short-term strain responses. Indeed, such innovative within-person approach to workaholism research can help organisations preventing job-related triggers of state workaholism before it manifests as more stable signs of work addiction.

Relevance to the Congress Theme. This study contributed to advancing the knowledge and prevention of a problematic and prevalent phenomenon that is particularly peculiar of the demanding and competitive modern workplaces. Based on our and previous findings, there is an urgent need to change the increasingly spreading long work-hour culture to promote healthier working conditions.

Relevant UN SDGs. Good health and well-being; Decent work and economic growth.

Keywords: State workaholism, Sleep quality, Recovery experiences

Paper 2

Shift Work in the NHS: Sleep and Emotional Wellbeing of UK Nurses

Teresa C. D'Oliveira, King's College London, United Kingdom; Robert Hickman, King's College London, United Kingdom / NIHR Maudsley Biomedical Research Centre (BRC), United Kingdom

Research Goals. Primary research objectives were to explore the directional interplay of shift work, sleep, and emotions among NHS nurses in the UK. A focus was on daily affective events and momentary ratings of mood, wellbeing, and alertness. Secondary outcomes expand on existing research to identify potential differences between nurses working standard and non-standard shift patterns and their impact on natural sleep cycles, daily rhythms and cognitive performance. Factors which might protect NHS nurses or improve toleration of shift work (e.g., chronotype, post-shift recovery activities) were also considered.

Theoretical Background. Shift work is especially common among health and social work professionals, with 1 in 3 involved in a shift work system. Long-term shift work (especially at night) poses a significant risk for chronic sleep and circadian disruption. Poor sleep can have numerous adverse outcomes: increased medical errors, impaired decision making and attention, cognitive performance, diagnostic ability, poorer mood, emotional reactivity, wellbeing and greater psychosocial stress (Farquhar, 2017; Mansukhani, Kolla, Surani, Varon, & Ramar, 2012; Rosa et al., 2019; Zohar, Tzischinsky, Epstein, & Lavie, 2005). Although sleep and emotions are closely linked, prior studies have largely been cross-sectional, relied on subjective sleep data, and lacked ecological validity. Few studies have considered the role of daily mood and emotions experienced within natural or 'real world' settings (e.g., in the workplace) and their impact on the amount and quality of sleep obtained (Ashkanasy & Humphrey, 2011; Weiss Howard & Beal Daniel, 2005; Zohar et al., 2005). This project aimed to address these limitations to assess sleep-emotion dyads among healthcare staff through daily diaries, experiencing sampling (ESM) and actigraphy.

Design / Methodology / Approach. Nurses with standard and non-standard shift schedules wore an actigraph continuously for 2 weeks. In line with prior studies with healthcare professionals, variable shift types, patterns, lengths and nursing activities were considered. ActiGraph wGT3X-BT devices were worn daily and combined with sleep diaries to track acute and chronic sleep disturbances. Smartphone-based experience sampling (ESM) recorded momentary measures of affect, emotional wellbeing, and alertness each day. Nurses also completed daily emotional diaries and perceived workload post-shift. During the study, participants completed a short battery of cognitive tasks and online questionnaires; these included detailed information on nursing speciality, shift schedules, perceived work schedule control and recovery activities.

Expected Results. Full results will be available in January 2023 and presented at the EAWOP Congress (May 24–27, 2023).

Limitations. Completing multiple and repeated daily assessments can be burdensome. The high workload and nature of on-shift nursing activities may result in missing data responses. However, smartphone ESM push-notifications are personalised for each nurse according to their daily shift schedule, with real-time reminders. Adherence and compliance to the study protocol has also been high so far.

Conclusions – Research and/or Practical Implications. This research addresses limitations in the literature by integrating non-invasive, ambulatory markers to explore the bidirectional relationship of

sleep, mood, and emotions in healthcare staff. The study aims to identify the potential adverse impacts of sleep loss and fatigue arising from diverse shift patterns and work schedules.

Relevance to the Congress Theme. Demand for a 24-hour healthcare system has resulted in long, often widely unregulated working hours (Greig & Snow, 2017; M. R. Smith & Eastman, 2012). Schedules with short recovery times between shifts (<11 hours) are associated with increased insomnia, sleepiness, and fatigue (Eldevik, Flo, Moen, Pallesen, & Bjorvatn, 2013; Foster, 2020). As a result, there is an urgent need to address the negative impacts of sleep and circadian disruption in healthcare and elucidate how best nurses can recover and recuperate from work-demands on intervening days.

Paper 3

Sweet Dreams are Made of This: Estimating Workers' Latent Sleep Profiles as a Mechanism of Fatigue Accumulation

Eka Gatari, Faculty of Psychology and Neuroscience, Maastricht University, Netherlands; Bram P. I. Fleuren | Faculty of Psychology and Neuroscience, Maastricht University, Netherlands; Faculty of Psychology, Universitas Indonesia, Indonesia; Fred R. H. Zijlstra, Maastricht University; Ute R. Hülsheger, Maastricht University

Research Goals . Sleep is a central part of the recovery process that enables workers after a day of effort expenditure to function well again the next day. Previous studies show the importance of sleep as a recovery mechanism, but they typically rely on variable-centred approaches (e.g., Hülsheger, 2016; Rook &Zijlstra, 2006; Weigelt et al., 2021). Such studies show independent effects of different sleep dimensions on mental and physical health outcomes, but insufficiently address how the combination of levels and intraindividual variability of sleep dimensions across the week can affect fatigue accumulation (Matricciani et al., 2018). Using a person-centred approach in the form of latent profile analysis (LPA) on daily diary data, this study aims to identify subgroups with different sleep patterns over the week and their predictors and outcomes. By doing so, the study highlights how person-centred can help in theory development on how sleep predicts fatigue.

Theoretical Background . The two-process model of sleep (Borbély, 1982) is used to select relevant and important sleep indicators, namely sleep duration, bedtime, wake time, quality, and fragmentation. The study uses the average levels and the intraindividual variability within a week of aforementioned sleep dimensions as the basis of the sleep profiles. Based on the Effort-Recovery model (Meijman & Mulder, 1998), the profiles are expected to predict possible indications of fatigue accumulation (i.e., prolonged fatigue and burnout). Furthermore, this study draws on the Job Demands-Control model (Karasek, 1989) to identify potential predictors of sleep profiles membership, that is, workload, job control, and the interaction between the two.

Design/Methodology . This study uses one-week daily dairy data with a follow-up questionnaire three weeks later. 316 Indonesian employees filled out three different kinds of online questionnaires: A baseline survey for the predictors, daily surveys for the sleep indicators, and one final survey for the outcome variables. LPA in MPlus 8 was used to identify profiles of co-occurring sleep levels and variability over one week. These profiles were then included in an R3STEP (i.e., multinomial regression) analysis to identify their potential predictors. Finally, we performed direct inclusion into the LPA model to understand the sleep subgroups' outcomes.

Results Obtained . The LPA identified four profiles: 'Average Sleepers', 'Deep Owls,' 'Short Sleep Compensators', and 'Restless, Erratic Sleepers'. Moreover, R3STEP revealed that workload, job control, and their interaction did not predict profile membership. Compared to the 'Average Sleepers', 'Restless, Erratic Sleepers' had higher prolonged fatigue, 'Deep Owls' had some higher cognitive impairment, and both profiles tended to have higher mental distance and burnout secondary symptoms.

Conclusions . The findings firstly identify a novel set of sleep profiles that naturally occur in workers. Moreover, the results highlight the importance of person-centred approaches by illustrating how combinations of sleep averages and their intraindividual variability across a week can predict prolonged fatigue and burnout dimensions. Practically, the results offer a more fine-grained

understanding of alarming sleep patterns and highlight the importance of sleep compensation in preventing adverse states of accumulated fatigue.

Limitations . A potential limitation of this study results from its relatively small sample size for conducting LPA. Ideally, larger samples are used for this analysis, but nonetheless, we are able to estimate a working model with this limited sample. A second limitation might relate to the generalisability of our findings because of its specific Indonesian sample. A third potential limitation is that we relied on subjective measurements for our sleep indicators while objective sleep indicators could also be considered. Given these limitations, future studies with larger samples in different contexts that include objective sleep indicators seem useful to solidify our results.

Relevance to the Congress Theme . Our study relates to the changing world of work in various ways. Its emphasis on well-being and recovery matches the increased interest in these topics within the global workforce. Moreover, by moving from a variable-centred to a person-centred approach, the study connects to the emerging trend of looking beyond variables alone to understand employee functioning.

Relevant UN SDGs . This study is relevant to the SDGs related to health and well-being and decent work as it connects to promoting the well-being of workers.

Keywords: latent sleep profiles, fatigue accumulation, job demands and control

Paper 4

How Sleep Helps to Solve Daily Problems – The Relevance of Sleep Quality and Mindfulness for Creativity at Work

Tabea Maier, Department of Occupational, Economic and Social Psychology, Faculty of Psychology, University of Vienna, Austria; Ronald Bledow, EDHEC Business School, France; Stefan Diestel , Department of Work, Organizational and Economic Psychology, Schumpeter School of Business and Economics, University of Wuppertal, Germany; Jana Kühnel, Department of Occupational, Economic and Social Psychology, Faculty of Psychology, University of Vienna, Austria

Research Goals. Studies have shed light on the relevance of mindfulness for psychological well-being and cognitive performance (e.g., Carson & Langer, 2006; Henrikson et al., 2020; Sedlmeier et al., 2012). According to these studies, trait mindfulness as well as mindfulness training foster creativity (Carson & Langer, 2006; Lebuda et al., 2016). Researchers assume that the individual state of mindfulness (Suelmann et al., 2018) as well as individuals' creative performance (Kamp et al, 2022) vary across situations and time. However, research has scarcely examined the relationship between mindfulness and creativity on the level of daily processes and has not addressed the question of whether a mindful start of a workday matters for creativity at work (Kamp et al., 2022). Further, research has not yet investigated the role of sleep for whether mindfulness occurs at the beginning of the workday. We therefore focus on high-quality sleep as a recovery process that may restore regulatory resources and hence facilitate states of mindfulness. To provide first evidence for our prediction, the current study investigated the indirect effect of day-specific sleep quality on creativity at work via day-specific mindfulness.

Theoretical Background. Drawing on resource-based theories of self-regulation (Ridder & Wit, 2006; Vohs & Baumeister, 2016), we argue that self-regulatory resources are necessary to shift attention on the current moment in a non-judgmental way and to achieve a state of high mindfulness (Vago & Silbersweig, 2012). Thus, the restoration of self-regulatory resources during high-quality sleep at night (Barnes et al., 2011; Kühnel et al., 2016) should support experiencing mindfulness in the morning. Next, we argue that mindfulness should support radical and incremental creativity during the workday. A non-judgmental state of mind helps to detach from usual thoughts and being aware of upcoming unusual thoughts should support generating novel and original ideas and solutions to everyday problems (Henrikson et al., 2020; Prabhu et al., 2008). In conclusion, we hypothesised that after nights with higher-quality sleep compared to days with lower-quality sleep employees are more mindful the next morning and therefore experience more radical and incremental creativity during the workday.

Design. To test our hypotheses, we conducted a daily diary study with 136 employees. Participants completed two questionnaires each day over the course of two workweeks: the first questionnaire assessed sleep quality (with the single item of the PSQI by Buysse et al., 1989) and mindfulness (with the MAAS by Brown & Ryan, 2003; modified by Höfling et al., 2011) before work (t1), the second questionnaire assessed radical and incremental creativity (with the scale of Madjar et al., 2011) after work (t2). Further, participants wore actigraphy devices (ActiGraph® wGT3X-BT) that capture indicators of sleep quality (sleep efficiency).

Results. Results from multilevel analyses showed that previous night's sleep quality and sleep efficiency positively relate to employees' state mindfulness. On days with a higher level of mindfulness participants reported more radical creativity throughout the workday. Our findings also

revealed positive indirect effects of sleep quality and sleep efficiency on radical creativity via mindfulness. However, mindfulness did not significantly predict incremental creativity, resulting in non-significant indirect effects of sleep quality and sleep efficiency on incremental creativity via mindfulness. Results including day-specific control variables will be discussed.

Limitations. According to potential limitations, subjective sleep quality and mindfulness were measured at the same time point. Having obtained an indicator of sleep quality assessed with the help of actigraphy, however, is a strength of this study that mitigates this limitation. In addition, we did not examine moderators, such as individual differences that may alter the effects of sleep and mindfulness on creativity.

Conclusions. This is the first study that sheds light on the relationship between sleep quality, mindfulness, and creativity on a within-person level. Our findings suggest that different day-specific processes seem to operate regarding radical creativity and incremental creativity. Further research might want to examine these differences. To facilitate employees' radical creativity, we recommend fostering mindfulness as well as sleep quality. To achieve this, organisations could provide interventions addressing sleep hygiene and mindfulness and take care that employees' sleep is not endangered by excessive workload and work-related extended availability.

Relevance to the Congress Theme & Relevant UN SDGs. Interventions targeting employees' sleep and mindfulness contribute to ensuring employees' health and well-being, and thus to the sustainable development goals of the UN.

Keywords: sleep quality, mindfulness, creativity

Paper 5

Mind the Misalignment: Daily Social Sleep Lag as Boundary Condition for Employees' Recovery

Jette Völker, Sabine Sonnentag, Monika Wiegelmann & Theresa J. S. Koch | Department of Psychology, University of Mannheim, Germany

Research Goals. Even though studies demonstrated that circadian misalignment between actual and biologically preferred sleeping times matters for employees at work and circadian perspectives on recovery were suggested, these perspectives have not yet arrived in empirical recovery research. We thus embed the concept of circadian misalignment into the recovery literature by investigating employees' daily social sleep lag (i.e., the discrepancy between employees' actual and biologically preferred sleep-wake times) as a boundary condition for their recovery processes.

Theoretical Background. Building on the stressor-detachment model (Sonnentag & Fritz, 2015), we propose that low recovery experiences (i.e., relaxation and mastery) explain the relationship between job stressors (i.e., interpersonal conflicts at work) and low next-morning well-being (i.e., vigour). Introducing the circadian perspective (Zijlstra et al., 2014), we portray recovery as a process regulating arousal throughout the day. As daily social sleep lag increases the discrepancy between actual (determined by biological preferences) and required (determined by work) arousal levels, we suggest that it can change the occurrence (i.e., if and how employees recover after stressful workdays) and the effectiveness (i.e., how well employees benefit from recovery) of daily recovery experiences. Specifically, we propose that daily social sleep lag strengthens the negative relationship of interpersonal conflicts and recovery experiences. In addition, we suggest that daily social sleep lag strengthens the relationship of relaxation (i.e., low-arousal recovery experience) and next-morning vigour but weakens the relationship of mastery (i.e., high-arousal recovery experience) and next-morning vigour. In contrast to previous research focusing on stable between-person differences in circadian misalignment, we focus on within-person fluctuations in social sleep lag to account for the dynamic nature of sleep.

Design/Methods. To test our hypotheses, we conducted a daily diary study with 305 employees who responded to daily surveys throughout two workweeks (Monday to Friday), providing data on 2,040 days.

Results. Analysing the data using two-level path models in Mplus 8.7, we found that low mastery experiences, but not relaxation, explained the negative association between interpersonal conflicts and next-morning vigour. Social sleep lag served as a boundary condition such that mastery experiences translated less to next-morning vigour on days with high (vs. low) social sleep lag. Additional analyses demonstrated that daily social sleep lag was a relevant boundary condition for this relationship over and above other frequently studied sleep variables (i.e., sleep quality, sleep duration), underlining the relevance of the timing of sleep.

Limitations. Limitations of our study are that we relied on self-report measures and retrospectively assessed recovery experiences in the next morning, raising concerns about common-method bias.

Implications. Adding to previous research on the role of circadian misalignment for employees at work, our study thus demonstrated the relevance of circadian misalignment for employees after work, namely for their recovery processes. Likewise, these results indicate that recovery experiences are not equally effective on any given day: Experiencing mastery was only related to next-morning vigour on days when social sleep lag was low. Furthermore, our study emphasises the need to take a

day-level perspective on social sleep lag because neglecting within-person fluctuations underestimates the dynamic nature of sleep and the circadian system during the week. We encourage future research to transfer our results to other recovery opportunities, for example, breaks during the workday. At the same time, scholars might investigate the temporal sequence of employees' recovery experiences in greater detail, for example, to disentangle whether especially increasing mastery experiences (i.e., high activation) shortly before sleep do not translate to vigour.

Relevance to the Congress Theme. Our results imply that employees should try to not engage in challenging activities offering mastery experiences (e.g., physical activity, creative activities) on days with higher social sleep lag but instead reschedule those activities to days with lower social sleep lag to fully benefit from them. At the same time, increased flexibility to work from home in the changing world of work can enable employees to reduce their circadian misalignment and better follow their biological preferences during the workweek.

Relevant UN SDGs. Taken together, by demonstrating daily social sleep lag as a boundary condition for employees' after-work recovery processes, our study bridges the gap between research on recovery from work and circadian misalignment. Combining these two streams of research can help determine under which circumstances employees recover from work best, highlighting the need to take circadian processes into account in recovery research. Thereby, our study provides relevant insights into how to achieve the UN Sustainable Development Goal of good health and wellbeing .

Addicted to work: Towards a better characterization of the organizational and clinical implications of workaholism

Cristian Balducci, Department of Psychology, University of Bologna, Bologna (Italy); Pawel Atroszko, Institute of Psychology, University of Gdańsk, Gdańsk (Poland)

science

What will be covered: In the last decade or so, there has been increasing attention towards the phenomenon of workaholism or work addiction, a dysfunctional form of heavy work investment with potentially strong negative implications for workers well-being and organizational vitality. Such a trend may, at least in part, be explained by a higher prevalence of certain working conditions (e.g., intensification and digitalization) that have accentuated the need to invest heavily at work, creating a context in which workaholic tendencies may be strengthened. Indeed, it has been noted that the widespread use of ICT, which allow people to work anytime and anywhere, may lead to both work intensification and to the need (real or perceived) to be virtually always available. This could lead to addiction to ICT, working long hours, and stress. In such circumstances, the belief that being available 24/7 is a sign of success may easily develop, no matter the associated costs for health and well-being.

Thus, there is a need to further document the correlates and impact of workaholism. Unfortunately, the quality of the available research has been still recently defined as ''low', since most studies in the field have adopted small-scale cross-sectional designs. Such evidence may be less useful as the basis to develop credible interventions and persuade organizational leaders on the noxious nature of workaholism. With this symposium, which benefits from a multidisciplinary (WOP and clinical psychology) approach, we aim to improve the characterization of workaholism and strengthen the evidence on its negative implications. The symposium includes two WOP longitudinal studies. The first study (Balducci et al.) adopts a daily diary approach and investigates whether daily fluctuations in workaholism explain stress reactions as indicated by blood pressure and end-of-day emotional exhaustion. The second study (Avanzi et al.) aims at construct clarification by focusing on the similarities and differences between workaholism and overcommitment, including how they might be differentiated and related together and with health outcomes (i.e., burnout). Two additional studies adopt a clinical focus. One (Kun et al.) is a large-scale survey examining the hypothesis that addictive workers might use psychoactive substances in order to cope with their negative mood states. The other (Atroszko et al.), also based on a very large sample of workers, aims at both identifying different profiles of work-addicted individuals and their clinical correlates, such as attention deficit hyperactivity disorder, obsessive-compulsive disorder, anxiety, and depression. A fifth study (Buczny & Oostrom) focuses on workaholism measurement and presents a new situational judgment test to assess workaholic tendencies. Together, the studies will contribute to advance our understanding of the peculiarities of workaholism and to strengthen a recently launched international collaboration aimed at raising further awareness on the phenomenon: https://workaddiction.org/

Relevance to the congress theme: Excessive and dysfunctional work investment is prevalent in the modern world of work, often fueled by the so-called long work-hour culture. This – which may have increased during the recent pandemic – may be responsible for up to 775.000 deaths for CVD due to overwork each year, according to a recent study. Importantly, such a culture and its associated phenomena, such as workaholism, are not inevitable results of contemporary realities such as global competition and technological change, but of managerial decision and discretion. Thus, there is a need to document the impact of workaholism to promote a general change towards a more balanced

work-life relationship, which may act as an important protective factor for health, well-being, and performance in contemporary and future working life.

Research/Practical Implications : To remain healthy and competitive, organizations need motivated and engaged individuals, not work addicted. Altogether, the studies included in the present symposium will strengthen the quality of the available evidence on workaholism. They will further document why workaholics constitute a significant problem rather than an important resource for organizations and society, and highlight some potential avenues for prevention. Integrating WOP and clinical psychology frameworks may also allow us to address the problem better and align with the World Health Organization's plan for improving mental health in the workplace.

Overall conclusions: Workaholism is a significant and prevalent problem affecting workers' health, while at the same time having no added value for job performance. The present symposium will contribute to advance our understanding of the far-reaching health and well-being implications of the phenomenon.

Keywords: workaholism, work addiction, well-being at work

Paper 1

A daily diary investigation on the relationship between day-level workaholism, blood pressure, and emotional exhaustion

Cristian Balducci, Department of Psychology, University of Bologna (Italy); Luca Menghini, Department of General Psychology, University of Padova (Italy)

Research goals : Most research on workaholism has been based on the idea that workaholism is an enduring personal characteristic, a trait-like phenomenon. Such an approach, however, overlooks the potential within-individual variance in workaholism, the study of which may be very useful for revealing micro (e.g., day-level) processes related to the health impairment effects of workaholism. Thus, the objectives of the present study were to investigate whether workaholism may fluctuate from day to day and whether such fluctuations are consequential in terms of job strain as indicated by systolic and diastolic blood pressure and emotional exhaustion.

Theoretical background : Based on the ideas of Whole Trait Theory of personality, according to which a trait or stable disposition may be seen as a distribution of momentary states – which may vary even across short intervals of time – we hypothesised that workaholism, similar to other enduring personal dispositions, shows significant variation within individuals from day to day. Additionally, given that workaholism acts as an uncontrollable internal pressure or demand, leading to a high effort expenditure at work and thus to the experience of high levels of job strain, we also hypothesised that workers report more accentuated stress reactions in days associated with higher levels of workaholic symptoms than usual. In line with allostatic load theory, postulating that primary stress reactions may involve both physiological and psychological indicators, we expected that day-level workaholism is positively and significantly related with day-level blood pressure and day-level exhaustion.

Design/Methodology: We conducted a mobile-based daily diary study by surveying participants (N=135; 51.1% females) multiple times per day for a period of one to two weeks (i.e., a maximum of ten consecutive working days). Before the daily surveys, which were administered in the morning (1st) afternoon (2nd) and at bedtime (3rd), participants measured their blood pressure by using a validated wrist blood pressure monitor device. We also measured a variety of constructs, including the ones focused by the present investigation. Workaholism was measured in the afternoon by asking participants whether they experienced common workaholic symptoms during the day, while emotional exhaustion was measured at bedtime. The adopted scales provided adequate psychometric properties at both between and within-individual level. To test the proposed hypotheses, we implemented multilevel linear regression models. Results are preliminary since further analyses are in progress.

Results: In line with some previous studies, day-level workaholism showed significant variance both at the between and the within levels (ICC = 0.61), indicating that all days are not created equal as far as the experience of workaholic cognition and behavior is concerned. Multilevel models revealed that daily workaholism levels were positively and significantly related at the within level, with daily systolic and diastolic blood pressure measured in the afternoon ($b=1.28$ mmHg, $SE= 0.38$, $t = 3.36$, $p < .001$; and $b=1.05$ mmHg, $SE= 0.32$, $t = 3.29$, $p < .01$, respectively), and with emotional exhaustion as reported at bed time ($b=0.16$, $SE= 0.04$, $t = 3.66$, $p < .001$). The results generally supported the formulated hypotheses, highlighting some day-level mechanisms with which workaholism may potentially affect health and well-being in the longer run.

Limitations: The most important limitation is the convenience sample obtained, including participants from different occupations and sectors Additionally, the relatively low number of participants (i.e., level-2 units) may constitute a further study limitation.

Conclusion: Day-level (or state) workaholism may produce significant negative perturbations to health and well-being, which may perhaps explain the longer-term consequences of workaholism such as accentuated cardiovascular risk or mental health problems including depressive symptoms. Organizations should seriously consider discouraging workaholic behavior among their employees with the aim of protecting job-related well-being and, consequently, job performance. This may be done, for example, by allocating manageable workloads, discouraging excessive competition and reward practices of the type 'one wins all', and by promoting disconnection from work and the adoption of a 'balanced' work-life interface. Health promotion interventions aiming at training employees on stress management strategies such as mindfulness may also be helpful to facilitate unwinding from the work tension and fatigue associated to workaholism.

Relevance to the congress theme: Work may be killing individuals or make them sick not only by exposing them to noxious conditions such as high strain work situations, but also by promoting – in interaction with personal characteristics – certain unhealthy work styles such as workaholism. There is an urgent need to change the currently spreading long-work-hour culture for contributing to better and healthier working conditions.

Relevant UN SDGs: Good health and well-being; decent work and economic growth.

Keywords: workaholism, blood pressure, diary study

Paper 2

The relationship between workaholism, overcommitment, and burnout: The moderating role of job satisfaction

Lorenzo Avanzi, Department of Psychology and Cognitive Science, University of Trento (Italy); Cristian Balducci, Department of Psychology, University of Bologna (Italy); Nina M. Junker, Department of Psychology, University of Oslo (Norway); Michela Vignoli & Enrico Perinelli , Department of Psychology and Cognitive Science, University of Trento (Italy)

Research goals : Both workaholism and overcommitment have been defined as an irrational or obsessive attachment to work. These two constructs are often considered similar, yet they are conceptualized in quite different ways, and they in fact could represent different aspects or "moments" of work addiction. The aim of this study was to longitudinally test a model in which workaholism increases overcommitment, especially for stronger satisfied employees, and overcommitment, in turn, increases job burnout over time.

Theoretical background : Both workaholic and overcommitted employees are characterized by an excessive attachment to their job, with negative consequences for their health. However, the relation between these two constructs is not well explored until now. In particular, we hypothesized that overcommitment is more related to external stimuli and conditions (such as job satisfaction and job demands) than workaholism. Neuroticism should be the root of overcommitment, while conscientiousness should be the root of workaholism. Furthermore, we expect that workaholism could be a more distal antecedent of job burnout, whereas overcommitment should be the more proximal one. In particular, in this study, we hypothesized that overcommitment mediates the relation between workaholism and burnout. Moreover, we hypothesized that the more employees are satisfied, the stronger will be the relation between workaholism and overcommitment over time.

Design/Methodology: We conducted a three-wave (time-lag = 1 month) longitudinal design in a sample of Italian workers. We used well-validated scales that provided adequate psychometric properties. At the first administration, 501 employees answered our questionnaire, while the final longitudinal sample at T3 was 89. At T1, we used partial correlations to disentangle the actual relation between workaholism and overcommitment on the one hand, and the other constructs on the other. MPlus was used to test our longitudinal moderated mediation model. We controlled for job burnout and overcommitment measured at T1, and we controlled for personal (i.e., gender, neuroticism, and conscientiousness) and contextual (i.e., job demands) factors.

Results: As expected at T1, by using partial correlations, overcommitment ($r = .50$, $p < .001$), but not workaholism ($r = .06$, $p > .05$), was significantly and positively related to job burnout. Again, overcommitment was positively and significantly related to neuroticism ($r = .34$, $p < .001$), but not conscientiousness, while workaholism was positively related to conscientiousness ($r = .13$, $p < .01$) but not neuroticism. Interestingly, overcommitment was negatively related to job satisfaction ($r = -.24$, $p < .001$), whereas workaholism was positively related ($r = .19$, $p < .001$). Contrary to our expectations, both constructs were significantly and positively related to job demands. Regarding the main longitudinal analyses, the results supported our hypotheses outlining that overcommitment at T2 fully mediated the relation between workaholism at T1 and job burnout at T3. Furthermore, job satisfaction was a significant moderator of the first path, meaning that workaholism increased overcommitment over time, especially for more satisfied employees. Results were robust and remained significant even when taking the control variables into account.

Limitations: The final sample was small. Only self-report measures were used. Future studies could use other-report measures or objective ones.

Conclusion: From a theoretical point of view, our findings may help researchers to clarify some inconsistencies found in the workaholism literature, better redefining its conceptualization. Workaholics may be driven to hardly and compulsively work mainly by internal pressure rather than external rewards, and this hard work could be associated with fugacious positive feelings. On the contrary, overcommitted employees are more sensitive to external factors and rewards, likely because they are characterized by extreme impatience, irritability, and focus on negative emotional states. While workaholism seems to be a root of overcommitment over time, the latter is the more proximal precursor of employees' job burnout and ill-health. From a practical point of view, organizations could prevent negative consequences for employees' well-being by acting in terms of fair rewards or avoiding reinforcing an overwork climate. Our results also highlight that this work addiction dynamic plays a stronger negative effect for more satisfied employees. In this sense, like individuals affected by other addictions, experiencing work enjoyment could "paradoxically" reinforce these maladaptive job strategies.

Relevance to the congress theme: Nowadays, job demands are increasing and organizations request an increasingly stronger commitment to work. However, an excessive and not adequate attachment, such as work addiction, could become detrimental to both employees' health and performance.

Relevant UN SDGs: Good health and well-being.

Keywords: workaholism, overcommitment, burnout

Paper 3

Work addiction and psychoactive substance use

Bernadette Kun, Institute of Psychology, ELTE Eötvös Loránd University, Budapest (Hungary); Zsolt Demetrovics, Centre of Excellence in Responsible Gaming, University of Gibraltar, Gibraltar (Gibraltar); Borbála Paksi, Institute of Education, ELTE Eötvös Loránd University, Budapest (Hungary); Andrea Eisinger & Anna Magi | Institute of Psychology, ELTE Eötvös Loránd University, Budapest (Hungary)

Research goals: The current study aims to explore the associations between work addiction and psychoactive substance use. Since individuals affected by work addiction show specific characteristics and symptoms that might motivate them to manage their internal states with psychoactive substances, we investigated the characteristics of this relationship in a general population study.

Theoretical background : Work addiction is a syndrome characterized by excessive and obsessive overwork that disturbs the individual's physical, mental, and social health (Oates, 1971). Work addiction is also defined as a behavioral addiction showing the seven main components (salience, tolerance, withdrawal, mood modification, conflicts, relapse, and problems) identified in other addictive disorders (Griffiths & Karanika-Murray, 2012). It is well documented that individuals affected by work addiction show a higher level of neuroticism, negative affectivity, anxiety, and obsessiveness and they have poorer self-esteem than healthy workers (Kun et al., 2020). These people are always in a rush, want to perform better than others (high perfectionism), and spend their free time with work (Clark et al., 2010; Robinson, 1998). They are motivated to overwork to avoid their negative feelings, frustrations, and rumination (Stoeber et al., 2013; Kun et al., 2021). It is also found that emotional discharge as a maladaptive coping strategy mediates between work addiction and psychological and physical complaints (Shimazu et al., 2010). Based on the above, it can be presumed that individuals with work addiction might use psychoactive substances in order to cope with their negative states. Stimulants can help them to keep more awake and perform better and to experience higher self-esteem (Lasco, 2014, Lende et al., 2007), while depressants might be used to mitigate their elevated level of stress and anxiety (Grant el al., 2009), and to help them to fall asleep (Roehrs & Roth, 2001). Therefore, we hypothesized that individuals with work addiction will show a higher prevalence of both stimulant (i.e., nicotine, caffeine, illicit stimulants) use, and legal depressant (i.e., alcohol and prescription tranquillizer/sedative) use.

Methodology: Data from the first wave of the Budapest Longitudinal Study (BLS) was analyzed. The BLS follows young adults for five years because this age group is in a sensitive period in terms of development of different behavioral addictions. Stratified sampling method was used to have a representative sample in terms of district of residence and age of young adults (aged between 18-35 years) living in Budapest. The total sample size was N = 3,076 (females = 50.3%, M age = SD = 4.34), and only those individuals were involved in the analyses who had a current, full-time job. Work addiction was assessed by the Bergen Work Addiction Scale (BWAS; Andreassen et al., 2012; Orosz et al., 2016), and questions were used to measure lifetime (LTP), last year (LYP), and last month prevalence (LMP) of the following licit and illicit substances: nicotine, caffeine (coffee and energy drinks), ecstasy, amphetamine, cocaine, crack, new psychoactive stimulants (NPS), alcohol, and prescription sedatives/tranquillizers. All the variables for smoking and illicit stimulant use habits were dichotomous categorical variables, namely, the participants could choose between the answers 'yes' or 'no' (e.g., Did you use ecstasy in your life / during the last year / last month/?). Regarding coffee and energy drink consumptions, we asked the number of cups of coffee / cans of energy drink

consumed during a weekday/weekend day in the last 30 days. First, we performed a Latent Profile Analysis (LPA) based on the seven items of the BWAS, then we compared the worker profiles in the substance use habits (LTP, LYP, and LMP) by using $\chi 2$ statistics (for dichotomous variables) and BHC method (for continuous variables).

Results: As a result of LPA, we found a three-profile solution that classified individuals based on their work addiction symptoms. While "Non-problematic workers" (N = 2,238; 70.92%) did not show any symptoms of work addiction, „Excessive workers" (N = 609; 19.29%) showed moderate level of work addiction symptoms. Individuals in Profile 3 ("Addictive workers"; N = 309; 9.79%) showed the highest risk of work addiction. We found that "Addictive workers" showed the highest prevalence rates of cigarette, e-cigarette, amphetamine, cocaine, crack, NPS, alcohol, and prescription sedatives/tranquillizer use. Contrary to our assumptions "Addictive workers" drink significantly less amount of coffee than „Non-problematic workers", however, addictive workers drink significantly more energy drinks on a regular weekday than excessive workers do.

Limitations: The cross-sectional design of the study does not allow us to conclude any causal relationship between work addiction and substance use. We used self-report questionnaire for assessing work addiction and it might cause bias in the self-perception of the participants. Questions regarding substance use habits are very sensitive, therefore some of the respondents might hide their real frequency of substance use.

Conclusion: Previous studies showed that individuals affected by work addiction show more psychopathological symptoms (e.g., obsessive-compulsiveness, depression, ADHD) than healthy workers (Andreassen et al., 2016; Atroszko et al., 2017). It is clear now that work addiction is not a "positive addiction", and our current findings also show the maladaptive pattern of this syndrome. We can assume that an increased level of stimulant use serves as an enhancer for addictive workers: it helps them to stay awake, to be more energized and to feel more comfortable. At the same time, depressants, such as alcohol and prescription drugs can have a stress management function for these workers because they cannot easily relax after a long day and have sleeping issues too (Salanova et al., 2016).

Relevance: The prevention of work addiction is crucial for organizations because of the several negative health consequences of the syndrome. Organizational health promotion programs should emphasize the importance of work-life balance, and they should help employees to develop more adaptive and effective stress management and time management strategies.

Relevant UN SDGs: Good health and well-being.

Paper 4

Latent profiles of work addiction and components of attention deficit hyperactivity disorder: Potential risk factors and consequences

Paweł A. Atroszko, Institute of Psychology, University of Gdańsk, Gdańsk (Poland); Ståle Pallesen, Department of Psychosocial Science, Psychology Faculty, University of Bergen, Bergen (Norway); Edyta Charzyńska, Faculty of Social Sciences, University of Silesia in Katowice, Katowice (Poland)

Research goals: The study aims to investigate the profiles of work addiction and attention deficit hyperactivity disorder (ADHD) and analyze their potential antecedents and consequences in individuals showing symptoms of work addiction based on screening in the general population of working adults in Norway. Identifying specific patterns of co-occurrence of work addiction and ADHD may allow for a better understanding of their relationship and its consequences for diagnosis of work addiction, its risk factors, and related harm, as well as provide guidelines for clinical management and organizational solutions.

Theoretical background : Work addiction and attention deficit hyperactivity disorder (ADHD) show consistent and considerable associations across studies and countries. Work addiction was previously suggested to be a compensatory mechanism for ADHD in some individuals. Moreover, non-ADHD-related work addiction type was suggested based on the studies and theoretical considerations concerning the relationships of work addiction with perfectionism, obsessive-compulsive personality disorder, eating disorders, particularly anorexia nervosa, and conscientiousness. This type is rather associated with excessive controlling behaviors and perfectionism than impulsiveness and behavioral disinhibition.

In the current study, we expected to identify two main profiles. The first profile would group individuals with high levels of work addiction and high levels of ADHD components of inattention, motor hyperactivity, and verbal hyperactivity. The second profile would consist of individuals with high levels of work addiction but low/average levels of ADHD components. Intermediate profiles are feasible; however, no specific predictions based on previous studies can be reliably made. Different profiles of work addiction and ADHD co-occurrence may have somewhat specific risk factors and different potential consequences. It can be hypothesized that individuals with high levels of work addiction and ADHD components would have higher symptoms of OCD, anxiety, and depression than individuals with high levels of work addiction and low/average levels of ADHD symptoms because comorbidity is generally related to worse outcomes, management, and prognosis. Moreover, members of the former profile were expected to be younger than members of the latter profile because ADHD symptoms were previously found to be lower in older age groups.

Methodology : Data were collected from the Norwegian population (n = 16,426; women = 63.8%, M age = 37.3 years, SD = 11.4, min. = 16, max. = 75) via convenience sampling. A wide range of professions was included. Latent profile analysis was conducted on a subsample (7.8% of the total sample) of individuals meeting the polythetic cut-off score that identifies those at the highest risk of work addiction (n = 1,287; women = 67.8%, M age = 34.0 years, SD = 10.5, min. 16, max. 71). Work addiction was assessed with the Bergen Work Addiction Scale (BWAS), ADHD components of inattention, hyperactivity motor and hyperactivity verbal were assessed with the Adult Attention Deficit Hyperactivity Disorder Self-Report Scale (ASRS 1.1). Potential antecedents included gender, age, managerial status, and OCD measured with the Obsessive-Compulsive Inventory-Revised (OCI-R), whereas potential consequences included anxiety and depression measured with the Hospital

Anxiety and Depression scale. First, we performed a latent profile analysis (LPA) based on BWAS and three ADHD components. After identifying the profiles, we explored the associations between latent profile membership and its potential predictors and consequences. All calculations were performed using the MPlus, version 8.

Results : Three basic profiles of work addiction types were identified, including (1) those with high levels of work addiction and low levels of ADHD symptoms (34.5%), (2) those with high levels of work addiction and elevated levels of ADHD symptoms (54.6%), and (3) those with the highest levels of work addiction and ADHD symptoms (10.9%). Members of the first profile were older and exhibited fewer symptoms of OCD than members of the two remaining profiles. Moreover, individuals with the highest levels of work addiction and ADHD had the highest levels of anxiety and depression; individuals with high levels of work addiction and elevated levels of ADHD symptoms had higher levels of anxiety and depression than individuals with high levels of work addiction and low levels of ADHD symptoms. Additional validation data (currently still gathered) from the Polish sample will be discussed during the conference.

Limitations : The study's cross-sectional design does not allow us to conclude any causal relationship between profiles and their potential antecedents and consequences. We used self-report questionnaires for assessing work addiction and ADHD symptoms, as well as for potential antecedents and consequences, which are related to potential bias typically identified for such methodology.

Conclusion : Work addiction and ADHD are closely associated and often co-occurring. In the current study, the most severe cases of work addiction were related to the highest symptoms of inattention and hyperactivity. These individuals showed the highest levels of potential harm, including depression and anxiety. However, the profile with high levels of work addiction and low/average levels of ADHD symptoms was also identified, which shows that work addiction is not always associated with this psychopathology. These profiles notably differed in potential risk factors, such that the members of the profile with the highest levels of ADHD were younger and exhibited more OCD than those with high levels of work addiction but low/average levels of ADHD symptoms. The results show that there is a profile of work addiction which is most severe and comorbid with a wide range of psychopathology, including ADHD, OCD, anxiety, and depression. This profile constitutes about 10% of those with the highest scores on BWAS, which roughly translates to about 1% of the general population of working adults in Norway.

Relevance : Work addiction is a relatively frequent and serious organizational problem. It is comorbid with various mental health problems, including ADHD, depression, anxiety, and OCD. It should be systematically addressed by proper prevention programs. Most importantly, raising awareness about its nature, causes and consequences should be the first step to developing effective and systematic solutions.

Relevant UN SDGs : Good health and well-being; decent work and economic growth.

Paper 5

A workaholism situational judgment test (WSJT)

Jacek Buczny, Department of Experimental and Applied Psychology, Vrije Universiteit Amsterdam (The Netherlands); Janneke Oostrom, Department of Management and Organization, Vrije Universiteit Amsterdam (The Netherlands)

Research goals: The current instruments applied to measure workaholism are based on simple self-report items arranged into questionnaires. As such instruments are prone to various biases, the current research was carried out to address these limitations and, thus, develop and validate a new instrument: a situational judgment test. Based on the Work Craving Theory, we created a series of items describing a plethora of work-related situations and tested whether the situations were relevant to measure workaholism.

Theoretical background: Workaholism has been more consistently defined as a pathological phenomenon: a chronic pattern of high work investment involving an uncontrollable obsession and concern with work. Work addiction has been linked to many negative outcomes: reduced psychological well-being, perceived health, and psychiatric disorders, such as depression and anxiety. Workaholism may increase turnover intention and negatively impact job satisfaction and performance; ultimately, workaholism may harm business growth. Due to the lack of a unanimous conceptualization of workaholism, researchers have struggled to create an accurate operationalization of this construct. Still, they use self-report to measure workaholism regardless definition of the construct. Such measures generally are susceptible to various biases, require the ability and motivation to use introspection, and are susceptible to faking. To increase the validity of the self-report instrument, the researchers contextualize instruments. Situational judgment tests (SJTs) are contextualized measures as they present a detailed description of work-related situations with a set of responses representing various options to choose from. Such options represent higher or lower levels of the measured construct. Respondents are typically asked to select the answer option that best represents how they would respond in that situation. There is substantial evidence for the criterion and predictive validity of SJTs. Importantly, SJTs are generally well-accepted by candidates and display lower levels of adverse impact.

Compared to self-report measures, SJTs are less prone to faking. Additionally, SJTs are less susceptible to measurement contamination because they can help avoid measuring unintended constructs. Contextualization of workaholism instruments is justified as the previous research suggests that situational factors can modify workaholism levels over time.

The Work Craving Theory suggests that workaholics experience an overpowering craving for work, leading them to engage in intense working behavior to fulfill their self-imposed unrealistic standards of work performance. Work craving comprises three components and four dimensions: the cognitive component: Neurotic Perfectionism; the behavioral dimension: Obsessive-Compulsive Desire for Work; and the hedonic component: Anticipation of Self-Worth Compensatory Incentives, and Anticipation of Reduction of Negative Affect (Relief) and Withdrawal Symptoms. As a result, workaholics experience positive reinforcements, such as increased self-acceptance and self-worth, and negative reinforcements, such as reduced negative affect. In short, workaholics pursue rewards by engaging in compulsive work and acquiring neurotic performance standards.

Design/Methodology: We created a set of 56 SJT items of the Workaholism Situational Judgment Test (WSJT). Five experts evaluated each item based on three criteria: complexity, relevance, and content contamination. Then, each item was corrected, and after an additional evaluation, we selected 48 of the best items (12 per dimension) for further validation. As the items were prepared in English, we utilized the help of a professional English proofreader (native speaker) to correct the items. We conducted a study (N = 960) in the US and UK Prolific samples. We measured various constructs to assess convergent (work craving; the WCS), criterion (self-esteem, depression symptoms, perceived stress, burnout), and divergent validity (working hours, organizational commitment). All the SJT items were rotated. The order of all the used instruments also was rotated. After reading an informed consent, the participants provided their responses to the questionnaires, then gave their demographics, read a debrief, and were thanked. The monetary compensation was 7 euros per hour; every participant received 3 euros on average.

Results: Employing confirmatory factor analyses, we tested whether the hypothesized four-factor model of the WSJT fitted the data. The result showed a moderate fit, CFI = 0.721, RMSEA = 0.042, 95% CI [0.040, 0.044], $p < .001$; SRMR = 0.050. The average correlations between the SJTs dimension and: (1) work craving were higher than $r = .40$, (2) self-esteem were lower than $r = –.15$, (3) depression symptoms higher than $r = 0.25$, (4) emotional exhaustion were higher than $r = .20$, (5) perceived work stress were higher than $r = .25$, (6) working hours were lower than $r = .10$, and (7) continuance and affective organizational commitment were lower than $r = .09$. An MTMM analysis indicated that the convergent validity was substantially higher than divergent validity. The reliability of the measurement of WSJT varied from .42 to .72.

Limitations: The current set of the WSTJ items needs to be reduced following a detailed item analysis to increase the model's fit and reliability. We plan to delete bad items (2 per dimension, 8 in total) and then collect data on a large sample (minimum N = 1500), including sampling from companies not only based on the Prolific participant pool. In addition, we want to address low reliability in the current study by carrying out a test-retest measurement. Lastly, in future studies, it is necessary to test whether the WSJT is less susceptible to faking than the equivalent self-report instrument.

Conclusion: The correlational analyses suggested that the WSJT is moderately related to the WCS, supporting its convergent validity and providing a potential indication that the WSJT may also have incremental validity over the WCS. Overall, the validation of WSJT showed its good psychometric qualities with room for a few substantial improvements.

Relevance to the congress theme: The presence of work-related disorders is one of the most important indicators of reduced well-being in the workplace. Improvements in the measurement of workaholism are one of the essential steps to adequately identify the employee who may display pathological work behaviors but, for various reasons, are not able or willing to disclose their symptoms while filling out self-report questionnaires. Organizations should be able to tackle the problem of workaholism before it becomes severe and even consider selecting out candidates that display workaholic tendencies.

Relevant UN SDGs: Good health and well-being; decent work and economic growth.

Symposium S037

Novel perspectives on interventions to increase workers' well-being and performance during times of change

Renée Boesten, Eindhoven University of Technology

science_practice

Description

Workers must deal with changes towards an intensified working life characterized by globalization, rapid technological developments, and leisure scarcity. These changes significantly impact workers' well-being and performance, meaning that workers need to find new ways to remain engaged, motivated, and healthy. This development has increased the search for alternative ways to arrange work and workers' work and non-work balance. This symposium contributes to work sustainability by developing interventions that may help workers be better prepared to deal with future changes and challenges. In five presentations, we discuss new insights, possible bottom-up adjustments to the work environment, corresponding interventions, and delivery methods to change both the work and the work-non-work perspective of workers.

Interventions are essential to increase workers' well-being and performance. By creating creative and playful work interventions that simultaneously foster agility, workers can be better prepared to deal with a changing environment. Literature shows that job crafting interventions may provide opportunities for workers to optimize their functioning in terms of well-being and performance, which is highly relevant given the progressively increasing complexity and independency of work. Jenny et al. (presentation 1) are developing a way to promote job crafting with the digital "Crafting Playbook". They are studying how "crafting plays" can help workers reflect on their strengths, work activities, and relationships at work, creating a balance between their demands and resources, which is crucial for their well-being. Creating a playful environment can help workers to be more engaged. Another way to foster such a playful work environment is by making work activities more fun and challenging. Verelst et al. (presentation 2) looked into an electronic playful work design micro-intervention to combine the state-of-the-art knowledge of playful work design, electronic intervention research, and micro-intervention research. In doing so, they aim to develop a hands-on method to boost workers' well-being and performance.

Another way to deal with changing work environments is to increase workers' resilience. Resilience is defined as successfully adapting to difficult or challenging life events. Methods to increase this resilience can help workers deal better with changing work environments. Therefore, Boesten et al. (presentation 3) developed an intervention to increase the resilience of entrepreneurs by focusing on enhancing their business resources and demands, network, creativity, and work-nonwork balance. Boesten et al. expect an increase in well-being, performance, and resilience by not only looking at their business but also outside their business (e.g., non-work).

Another way to complete the cycle of transitions between the work and non-work domains and improve daily work experience is psychological reattach to work in the morning. To study the effect of psychological reattachment on workers' daily work experiences, Schleupner et al. (presentation 4) developed an intervention to actively take care of their work experience and well-being, receiving information on the links between recovery after work, including psychological detachment, on employing psychological reattachment to get into a better workflow, on building mindful morning and evening routines, and on transitioning between work roles and non-work roles. Moreover, changing the worker's work hours can also change the worker's non-work perception. De Bloom et

al. (presentation 5) investigated the effects of an intervention on an unlimited leave policy. In other words, workers in this intervention did not have a restriction on the number of days they wanted to take a day off. By changing the number of days off, workers can take agency over their work, increasing their autonomy and well-being. Their results showed increased engagement, a better work-non-work balance, and more job satisfaction.

Relevance to the Congress Theme

Workers have to handle changing work environments due to globalization, rapid technological developments, and leisure scarcity. These societal changes trigger a need for developing new types of interventions. The (online) interventions we present in our symposium can be considered a starting point.

Research/Practical Implications and overall conclusions

This symposium shows different aspects workers may consider while dealing with impactful changes in the work environment. By focusing on different possible intervention types that include both the work and non-work domains, we tried to elaborate on the many options employees have to effectively deal with these changes. We bring together five presentations from four countries that provide unique insight into interventions that can help deal with the changing work context by including characteristics for leisure time to maintain workers' well-being and performance.

Paper 1

The Crafting Playbook: a playful way to more balance and meaning at work

Gregor Jenny, Georg Bauer & Philipp Kerksieck | University of Zurich

Theoretical Background

New ways of working are being experimented with, and this experimentation is not just in the hands of organizations: individuals too must ask themselves how their work should be designed in the future. Hereby the approach of job crafting offers guidance. Crafting means reflecting on one's own strengths, work activities and relationships at work. On this basis, one tries to strengthen resources at work: Aspects such as support, participation and development opportunities increase motivation and protect against the potentially negative consequences of high demands at work. A good balance of resources and demands is therefore crucial for well-being (Jenny et al., 2020). Likewise, meaning at work is experienced when one is productive, feels a sense of belonging, develops competencies and can strengthen one's own identity (Rosso et al., 2010).

New Perspectives

We aim to promote job crafting with the digital “Crafting Playbook”, into which “Crafting Plays” are implemented. Plays are short activities concerning balance and meaning at work. For example, users can learn more about the interplay of job resources and demands in a mini-game or chat with a program about meaning at work. The Plays are structured in such a way that the users internalize a positive story of work as resourceful and meaningful (“Story Plays”), reflect on themselves and their work (“Reflection Plays”) and plan and implement changes in everyday life (“Action Plays”). The target audience is the general working population, whereby Plays can also be applied collectively in teams (“multi-player option”). To make the Plays attractive and effective, they combine expert knowledge with creative and experimental elements. They are developed by researchers and students together with the private sector, administrations and education: these join together to form the “Crafting Circle” and establish the processes for funding and expanding the Playbook in an agile way. Finally, the decision for the terminology of the “Playbook” and the “Plays” is on the one hand based on the wish to differentiate from the field of coaching applications, because these are often closely linked to face-to-face coaching. On the other hand, it is a desire to emphasise the creative, experimental and also playful with this terminology: In work and organizational psychology, the influence of positive psychology is increasing and concepts such as “Playful Work Design” have been introduced: This involves giving work activities a playful touch from time to time by encouraging humorous interactions or challenging oneself in a playful way, and studies have shown that this is positively related to engagement at work (Scharp et al., 2022).

Conclusions

Developing digital solutions is a challenge for researchers that should not be underestimated (Arigo et al., 2019). The demands on technology, user interaction (UI) and experience (UX) are high and the costs considerable. With the Crafting Circle we aim to establish an agile format for both development and financing the Playbook. In addition, individual and collective change processes usually require a lot of energy. Thus the Playbook is built of Plays that attract users with little initial effort and without having to get involved with extra services or experts. Health promotion is increasingly using this format in the classic areas of exercise, nutrition and relaxation: Many applications offer short daily units of 5-10 minutes to build up the desired behaviors - depending on the nomenclature, these are

“Daily Challenges” or “Micro Activities”, which are designed to guide people into new routines in small steps (Cobb & Poirier, 2014). And last, the role of eliciting positive emotions through the Plays is crucial, not only to trigger learning and development processes (Fredrickson, 2013), but also to support adherence, i.e. the use of an application as intended by the developers (Ludden et al., 2015).

Relevance to the congress themes

This contribution highlights how “new work” also needs “new interventions” (Jenny & Bauer, under review): We need to make targeted use of digitalisation to offer experimental, creative and also playful interventions, and simultaneously adapt our interventions in an agile way to the ongoing change processes in the new working world.

Relevant UN SDGs

This work is relevant for the SDG (8) “Decent work and economic growth” and (3) “Good health and well-being”.

Keywords: Job crafting, Playful Work Design, Digital Solutions

Paper 2

The development and validation of an electronic micro-intervention for enhancing playful work design

Lorenz Verelst, Katholieke Universiteit Leuven; Marianne van Woerkom, Marijke Verbruggen & Rein De Cooman | KU Leuven

Research goals

While some people find their job activating and fun, between 15% and 87% of employees feel bored at work (van Hooff et al., 2017). Playful work design (hereafter PWD) is often put forward to tackle this problem. During work, workers may engage in playful work design actions to make their work activities more fun and challenging. Besides tackling work boredom, these PWD actions have been linked to several well-being (e.g., work engagement) and performance outcomes (Scharp et al., 2019). Given the potential benefits of PWD, this study aims to develop and validate an electronic PWD micro-intervention. In developing this intervention, we combine the state-of-the-art knowledge of PWD, electronic intervention research, and micro-intervention research. To validate the effectiveness of the intervention, we quantitatively and qualitatively investigate its direct effect on PWD and indirect effect on workers' well-being and performance.

Theoretical background

A common drawback of electronic interventions targeted at fostering behaviour and well-being is the substantial attrition rate. That is why we rely on nudging theory to make an easy-to-use, attractive, and time-efficient intervention. Further, the content of the intervention is based on goal-setting theory, stating that specific and measurable goals are essential to foster change. Accordingly, PWD actions can be stimulated by setting achievable PWD goals.

Methodology

The research project was conducted in Flanders, Belgium, and targeted white-collar employees, working at least 80% on a full-time contract. The electronic PWD intervention consisted of two steps, namely a short video explaining the concept of PWD and how PWD can be applied in a work context, and a self-guided exercise in which participants had to develop two PWD goals based on the provided instructions. Participants were given two weeks to attain these goals.

To validate the effectiveness of the PWD intervention, we applied a quasi-experimental design with a pre-test (i.e., right before the intervention) and two post-test measurement(s) (i.e., two weeks and six weeks after the intervention). The experimental group received the intervention, while the waiting-list control group received access to the intervention after the study.

Results

We are currently analysing the data. Results will be presented during the conference.

Limitations

One limitation pertains to our passive control group, thereby limiting our possibility to state that the content of the PWD intervention was the component responsible to foster change. Another limitation might be that the intervention was 'too micro', failing to directly foster PWD and indirectly well-being and performance.

Conclusions and practical implications

We can conclude that an electronic PWD micro-intervention is fruitful to investigate as a possible way to foster PWD and, as such, indirectly tackle work boredom and boost well-being and/or performance. Given its potential benefits, we see high practical value for individual workers, managers, and organizations.

Relevance to the Congress Theme : The changing world of work demands personal initiative and self-management from individual employees. Our electronic PWD micro-intervention aims to boost such personal initiatives among workers. At the same time, it might help managers and organizations to facilitate the shift towards more agency of their employees.

Paper 3

Resilient entrepreneurship: An online intervention study

Renée Boesten, Evangelia Demerouti, Pascale Le Blanc & Keri Pekaar | Eindhoven University of Technology

Research goals

Being resilient has often been proposed as helpful for entrepreneurs in dealing with changing work environments. Resilience is indispensable for entrepreneurs to continue functioning throughout disruptive events (e.g., crises) and is defined as being capable of going back to the original state of your business (Hedner et al., 2017). Resilient entrepreneurs create change and opportunities with the resources available at the time, which can even make them thrive in the face of adversity. They bounce back more easily after setbacks, are more aware of opportunities within their work environment, and deal better with (unexpected) changes (Kuckertz et al., 2020). However, it is still unclear if entrepreneurs can be taught to become more resilient. Therefore, we developed a six-day online training intervention providing participants with behavioural strategies aimed at enhancing their resilience through enhancing their business resources and demands, network, creativity, and work-life balance.

Theoretical background

The online six-day intervention we developed aims to enhance entrepreneurs' resilience by stimulating the participants to combine their available internal resources, call upon external resources and understand their business demands to be more resilient. We plan on doing this by focusing on the business demands and resources, developing the network, enhancing creativity, and focusing on leisure activities. To accomplish this, the first three days of the intervention focus on the available business demands and resources and how the participants can change these business demands and resources (crafting behaviour). Crafting behaviour helps entrepreneurs to deal successfully with a crisis because it allows them to mobilize the necessary resources to remain healthy and prosperous during turbulent times (Boesten et al., 2022). The topic of the fourth day is the network of entrepreneurs. Entrepreneurs extensively develop and use their networks during their careers. A more diverse network can help them better to call upon these external resources. Our intervention teaches them how to develop their external resources by developing their network and, at the same time, increasing their diversity. On day five, the intervention elaborates on creativity. To develop innovations, entrepreneurs must be creative. Innovative businesses anticipate and adjust to changing environments constantly and continuously. Our training stimulates entrepreneurs to identify new business opportunities and thus enhance their creativity. Moreover, although many entrepreneurs initially started their businesses to create a better work-life balance (i.e., an equilibrium of both work and private life demands), most of them eventually end up with extended workdays, especially during times of high work-related stress. Therefore, the last day of the intervention focuses on leisure activities, as leisure time after work is essential to stay engaged and perform well.

Methodology

The intervention consists of a daily short (3-5 minutes) theoretical and instruction video, followed by practical assignments the participants have to work on during that specific day. By comparing pre- and post-intervention scores on our key study variables of entrepreneurs who participated in the

training with those of a control group, we will study the effects of the intervention on entrepreneurs' use the behavioural strategies: business crafting, network development, enhancing creativity, leisure activities after work to augment entrepreneurs' resilience through higher personal well-being, better performance, idea implementation (i.e., innovations), and less work-life interference.

Results

The online intervention was launched in October '22, and data are currently being collected. We will be able to present the first results during the EAOHP 2023 conference. We aim to train at least 50 entrepreneurs.

Limitations

With an online intervention, there is always a risk of high dropout rates and decreased interest in the intervention. In addition, we cannot track if the participants actually apply their mentioned strategies during the day. However, they have to evaluate the next day what they did and how they did it.

Research/practical implications

This research evaluates the effectiveness of a hands-on intervention that teaches entrepreneurs behavioural strategies to remain or become more resilient, which may help them better deal with changing work conditions (e.g., crises). With this training, we offer a holistic approach to how entrepreneurs can increase their resilience.

Relevance to Congress theme

Work is changing nowadays, especially for entrepreneurs. Crises are often detrimental, but they may also be a trigger to look for opportunities. By developing a tool that may help entrepreneurs to increase their resilience, we contribute to the viability of their businesses by making them better prepared to deal with future changes.

UN SDGs

This work is relevant for the SDGs „good health and well-being" and „decent work and economic growth".

Keywords: Resilience, Business Strategies, Work-Home Interference

Paper 4

Start your day right: Fostering day-specific proactivity, work engagement, and self-efficacy through a training aimed at psychological reattachment

Ricarda Schleupner, Jana Kühnel | University of Vienna

Research goals and why the work was worth doing

There is empirical evidence on the benefits of psychological reattachment to work in the morning for employees' anticipatory task focus, goal activation, positive affect, and work engagement throughout their workday (Sonnentag & Kühnel, 2016; Sonnentag et al., 2019). Thus, psychological reattachment should be encouraged and trained among employees. With the current study, we aimed to develop a short intervention targeting psychological reattachment and investigate its effects on employees' daily work experiences. Moreover, we investigated effects of psychological reattachment on day-specific self-efficacy, proactivity, and work engagement.

Theoretical background

Psychological reattachment to work in the morning is the process of mentally preparing for work, anticipating demands and tasks, and transitioning from nonwork life to work life (Sonnentag & Kühnel, 2016). It is the phenomenon complementary to psychological detachment after work in the evening, the two forming a cycle that ideally takes place every workday (Fritz & Taylor, 2019).

In previous studies, psychological detachment and psychological reattachment have turned out to bear multiple positive effects on employees' health, well-being, and performance

(Fritz & Taylor, 2019). Interventions aiming at psychological detachment have already been conducted successfully. Equivalently, we were interested in whether reattachment's benefits may become accessible for employees who learned about it in a training. In the training, employees are empowered to actively take care of their own work-nonwork balance, receiving information on the links between recovery after work including psychological detachment, on employing psychological reattachment to get into a better workflow, on building mindful morning and evening routines, and on transitioning between work roles and nonwork roles. We hypothesized that employees who participated in the training should psychologically reattach more before work compared to participants who did not participate in the training. Furthermore, employees who employ psychological reattachment to work in the morning should experience more day-specific self-efficacy and work engagement and show more day-specific proactive behavior. The effect of the reattachment training on day- specific self-efficacy, work engagement, and proactivity should unfold via psychological reattachment.

Design/Methodology/Approach/Intervention

Our study is an experimental daily diary study. After filling in a pre-survey, participants were randomly separated into two groups (experimental group and waitlist control group); both groups received daily surveys (one at the beginning and one at the end of the workday, 5 minutes each) for two consecutive workweeks. After the first week, the experimental group participated in the short training. Thus, the first week serves as a baseline to identify effects of the training during the second week. The training contained a 2-hour live zoom session, an interactive presentation, self-reflective exercises, take-home material, and the opportunity to ask questions and exchange with other

participants. After the two weeks, the waiting list control group had the opportunity to voluntarily participate in the training.

Results obtained

We collected data from 148 persons (Level 2) on 1068 days (Level 1). We analyzed the training effect by calculating a cross-level moderation analysis, time (week 1 vs. week 2) being the level- 1 predictor and group (experimental vs. waitlist control group) being the level-2 moderator. The training did show a significant and positive effect on day-specific psychological reattachment. Day-specific psychological reattachment was positively related to day-specific work engagement, proactivity, and self-efficacy. We tested for conditional indirect effects within our multilevel model to investigate possible training effects for day- specific work experience via psychological reattachment. However, we did not find evidence for our hypothesis that day-specific work engagement, proactivity, and self-efficacy increased due to an increase in psychological reattachment due to the training.

Limitations

We did not add a follow-up measurement point to our data collection, so we did not measure long-term training effects. We chose to cover complex topics within a 2-hour short training. On the other hand, our approach is economic, easily applicable for organizations of all sizes, practicable for all kinds of settings (group trainings and individual trainings, synchronous and asynchronous setting, online or in-person trainings). The effect of the training was rather small, implying that the training may still be improved.

Research/Practical Implications

We obtained new insights on as well as further empirical support for benefits of psychological reattachment, namely, the positive effect on day-specific work engagement, proactivity, and self-efficacy. We provide a ready-to-use, economic training for organizations, setting the basis for a more extensive, e.g., whole-day training for employees on the topic of work-nonwork interface.

Originality/Value

This is the first project that tested whether psychological reattachment can be improved with the help of a field intervention. It is also the first study connecting psychological reattachment to day-specific proactivity and self-efficacy.

Keywords: Field Intervention, Psychological Reattachment, Work-Nonwork Interface

Paper 5

Temptation Island – A multi-source cluster-randomized controlled trial on the effects and mechanisms of an Unlimited Paid Time Off Policy

Jessica de Bloom, University of Groningen; Christine Syrek, Hochschule Bonn-Rhein-Sieg; Tim Vahle-Hinz, Psychologische Hochschule Berlin; Jana Kühnel, University of Vienna

Research goals

Changes towards an intensified working life characterized by globalization, rapid technological developments, and leisure scarcity have led to a renewed interest in alternative and more flexible working time arrangements. Unlimited paid time off policies are widely discussed by HR professionals around the globe. Would employees continue working and remain productive if they could instead enjoy free time while being paid their regular salary? We conducted a multi-source cluster-randomized controlled trial to examine this question by testing the effects and underlying processes of an unlimited paid time off policy which was introduced in a large company in the financial sector in the Netherlands

Theoretical background

We propose two pathways through which effects of UPTO´s unfold: autonomy need satisfaction and social exchange. In abandoning a fixed amount of leave, companies aim to establish a culture of trust and psychological ownership. UPTO enables employees to take agency over their work and this autonomy is considered the core mechanism which can bring about positive effects of UPTO. At the same time, UPTO may create a social obligation towards the employer following social exchange theory. Taking advantage of UPTO may lead to a feeling of obligation or even guilt towards the employer. In return for UPTO, the organization may expect the employee to be an ideal worker who is willing and able to “walk the extra mile” and UPTO becomes a part of a psychological contract.

Design

An experimental group (N = 290) received an infinite amount of paid leave days for an entire year, while the control group (N = 293) kept working under the company´s regular leave policy.

At the beginning and the end of the intervention year, we measured work engagement, job satisfaction, and work-nonwork balance via self-report questionnaires and received company-registered data on supervisor-rated performance and sickness absence rate. On a monthly basis, we assessed self-reported autonomy regarding leave taking and social pressure and received company-registered data on monthly leave hours. We also conducted semi-structured interviews four times per year in a subsample of twenty employees in the EG.

Results

Access to unlimited leave (i.e., EG versus CG) was related to taking more leave and a greater variability in leave taking, higher work engagement, a better work-nonwork balance, and more job satisfaction. However, unlimited leave also increased social pressure and, unexpectedly, lowered autonomy regarding leave taking. Furthermore, it appears in an inconsistent mediation pattern that lowered autonomy regarding leave taking impedes the positive effects of the unlimited leave policy. Concerning company-registered outcomes, unlimited leave was not related to task performance,

organizational citizenship behavior and sickness absence rates. Employees with unlimited leave displayed higher supervisor-rated stretch ambition compared to the control group.

Through the interviews, we observed how the new policy impacts trust, perceptions of workload and responsibility, and reciprocity norms among teams. Leave turns from an individual commodity into a collective good, amplifies pre-existing relationships, lays bare power struggles, and shifts roles and responsibilities. It also leads employees to reexamine the purpose of leave taking from hedonic to utilitarian.

Limitations

Limitations of this study relate to reactance/disappointment of being assigned to the control group and greater dropout in the control group (N=209-211). Team leads could decide whether they want to join the research project or not, potentially leading to selective samples. The COVID-19 pandemic during the intervention year affected people´s leave taking behaviors and possibilities to talk and negotiate about leave with their team members.

Conclusions

The influence of and mechanisms behind unlimited leave policies are complex and partly different than expected. Unlimited leave can engender beneficial work outcomes. But employee´s sense of autonomy is at risk: Unlimited leave transforms leave from an individual trading good into a collective good. Autonomy is shifted from managers to teams and individuals, and this requires negotiation and justification towards oneself and one´s team upon leave utilization. Accordingly, unlimited leave constitutes a prime example for rises in collective freedom, and vertical autonomy redistribution which - paradoxically - jeopardize individual freedom. Future working life requires new skills to be developed on the individual level (e.g., self-reflection), on the team-level (e.g., negotiation strategies) as well as organizational support to orchestra the delicate interplay between collective and individual freedom.

Relevance to the Congress Theme

Policies which increase employee´s freedom to organize their own work (in terms of time, place, order of tasks etc.) is an extremely timely topic. Unlimited paid time off is a policy which is reflective of the changing world of work in which organizations shift responsibilities to employees.

symposium S038

Examining the effects of the COVID-19 pandemic, remote work, and the implications on employee well-being

Afshan Iqbal, University of Leeds

science_practice

What will be covered and why

The onset of the COVID-19 pandemic changed our lives in many ways, from how we live to how we work. This symposium aims to discuss two important aspects of the impact of such large-scale events on employee health and well-being. First, we examine how employees were affected by the COVID-19 pandemic, including changes in their job engagement (i.e., occupational well-being) and sickness presence (i.e., health behavior). Second, we investigate the impact of changing work arrangements on employees, with a focus on remote work. Studying these changes is important for maintaining and promoting employee health and well-being in the face of major disruptive events, and for designing resilient future workplaces. Our discussant, Monica Molina, will lead discussions by presenting some of the key trends to have emerged over the last two years around home and hybrid working along with key considerations towards employee well-being.

Overall, this symposium offers a collection of studies focusing on changes in employee behaviour and well-being caused by disruptive environmental events (first part) and how flexible work arrangements can be designed to maintain and foster employee health and well-being when facing such events in the future (second part).

1) Posch et al. examine changes in employees' job engagement caused by two national lockdowns during the pandemic and the moderating role of four job characteristics (i.e., workload, job autonomy, supervisor, and co-worker support). They find the expected declines in job engagement in response to both lockdowns, which were particularly strong after the first event and partially moderated by job characteristics prior to event onset.

2) Dietz considers changes in employees' health behaviour in the working context (i.e., sickness presence) during the COVID-19 pandemic and investigates potential differences in these changes depending on spatial working arrangements. She finds an unexpected decrease in sickness presence before the lockdown depending on spatial working arrangements and no support for changes during the lockdown.

3) The study by Straus et al. investigates the fit between organisational and employee values and how it affects the well-being of remote workers. Results show that a congruence of values is not crucial for engagement but that the values' content matters, deviating from the widespread value congruence theory and research.

4) Iqbal et al. will draw upon the presence of technostress amongst remote workers and how this can lead to work-family conflict, with employees struggling to detach from work outside of regular working hours. The findings revealed that the volume of virtual meetings interrupting daily workflow was a significant antecedent of technostress. Peer support was a significant moderator, buffering the relationship between virtual meeting interruptions and techno-invasion.

Relevance to the Congress Theme

We address the first facet of the congress theme (The future is now.) by using rigorous empirical longitudinal methods to contribute to the understanding of changes in the world of work due to disruptive environmental events. Addressing the second facet (The future is now!), we provide urgent knowledge on how employees have adapted to unique circumstances, with little warning or careful planning, and discuss how we can maintain and promote employee health and well-being in such situations. Finally, we contribute to the last facet of the congress theme (The future is now?) by discussing how and where we should work, challenging the status quo of traditional working practices, and highlighting the importance of actively shaping the future of work. We seek to address questions around how workplaces can not only adapt to sudden economic, environmental, and societal changes, but also keep the maintenance of employee well-being at its core.

Research & Practical Implications

This symposium presents four longitudinal studies that provide comprehensive insight into the impact of sudden, disruptive external challenges on employee's job satisfaction, job engagement and work behaviours related to well-being. The synergies emerging from these studies enhance our understanding of current working practices and discuss how work design can promote and maintain employee well-being, particularly for remote workers. We pose questions for further research on employee well-being and the future world of work.

Conclusions

The studies in this symposium and our discussant reflect on the changes that have occurred in the last two years, as well as the impact of emerging trends we are seeing with regards to the changing world of work. Through the research presented, we aim to discuss the changes we would like to see in the future workplace that support employee well-being and the issues researchers and practitioners need to address to ensure a happy, healthy, and productive workforce.

discussant: Monica Molino, University of Turin

Paper 1

Reacting and Adapting to Disruptive Environmental Events: Interactive Effects of Events and Job Characteristics on Job Engagement

Melina Posch & Hannes Zacher | Leipzig University; Cort W. Rudolph, Saint Louis University; Richard Janzen & Oliver Weigelt | Leipzig University

Research Goals

This study examines the impact of disruptive environmental events on employees' job engagement. We investigate the effects of two national lockdowns in Germany during the COVID-19 pandemic and explore the influence of event novelty as well as the potential moderating role of four job characteristics (i.e., workload, job autonomy, supervisor and co-worker support). Our study extends theory and research on transitions and adaptation processes and is relevant to practitioners who want to address the negative effects of disruptive environmental events on employees.

Theoretical Background

Job engagement is an affective-motivational construct that refers to employees' simultaneous investment of physical, cognitive, and emotional energy in their work role (Rich et al., 2010) and is also described as an energized form of occupational well-being (Inceoglu & Warr, 2011). Based on Event System Theory (EST; Morgeson et al., 2015) and the transition-adaptation framework by Bliese et al. (2017), we investigate the effects of two disruptive environmental events (i.e., national lockdowns during the COVID-19 pandemic) on employees' job engagement. We expect declines in job engagement due to both disruptive environmental events and a less pronounced effect of the second, less novel event. Following both events, we expect gradual increases in employees' job engagement due to adaptation. Regarding the role of job characteristics, we expect that a high (vs. low) workload amplifies the declines in job engagement due to the disruptive environmental events, whereas high (vs. low) levels of job autonomy and social support mitigate these declines.

Design &Methodology

To test our hypotheses, we analyzed longitudinal data with 20 measurement waves, collected between December 2019 and September 2021. The sample consisted of 652 full-time employees in Germany from a variety of professions. Job engagement and job characteristics were assessed using reliable and valid self-report measures. We used discontinuous growth curve models (Bliese et al., 2017) to analyze the development of job engagement over time and the changes related to the onsets of the first (March 2020) and second (December 2020) national lockdown in Germany.

Results

Our analyses revealed a decline in all three facets of job engagement at the beginning of the first disruptive environmental event and only negligible changes due to the second event. In particular, declines in physical and cognitive engagement were stronger for the first event compared to the second event. Our hypotheses regarding the moderating role of job characteristics were only partially supported. For example, higher levels of workload strengthened the decline in physical and cognitive engagement due to the first occurrence of the event, whereas lower co-worker support was associated with a stronger decrease in emotional engagement due to the second event.

Limitations

We assessed job engagement and job characteristics using self-report measures, which could reduce validity due to method biases. While repeated measurements help address this issue, future studies should also incorporate objective measures. Furthermore, future research could investigate the specific mechanisms through which disruptive environmental events impact employees, such as information processing requirements or the changing of routines.

Research & Practical Implications

This study advances theory and research on transitions and adaptation processes, as it examines employees' repeated exposure to disruptive events in their broader environment. By investigating potential moderators of these effects at the job level, we integrate event-oriented approaches with work design research. In more general terms, our research may contribute to research on the meta-concept of resilience (e.g., Hartmann et al., 2020; Infurna & Jayawickreme, 2019). Regarding practical implications, our results illustrate that disruptive environmental events can have severe and long-lasting effects on employees' job engagement that are important to address. To help employees adapt to such events, it may be promising to promote certain job characteristics, such as job autonomy and co-worker support.

Relevance to the Congress Theme

Changes in the world of work may originate within, but also outside the work context. The present study advances knowledge on how employees' job engagement changes due to disruptive events in their broader environment. Our research findings provide insight into how work may be designed to support employees' adaptation and resilient reactions to such changes.

Relevant UN SDGs

The findings of our study may help to ensure decent working conditions and employee well-being, even when employees are confronted with disruptive, often unexpected, environmental events (UN SDGs #3 and #8). Understanding the impact of such events on employee experiences and supporting employees' adaptation and resilient reactions to these events has the potential to contribute to employees' long-term health and well-being (UN SDG #3).

Keywords: Event System Theory, Job Engagement, Job Characteristics

Paper 2

Sickness Presence during a Pandemic: The Role of Governmental Pandemic Guidelines and Telework

Carolin Dietz, University of Technology Chemnitz

Research Goals

Sickness presence is defined as working while in a state of ill-health (Ruhle et al., 2020) and is a risk for individual and public health, especially during a pandemic (Kinman & Grant, 2020). This study examines the impact of governmental pandemic guidelines on employees' sickness presence. Specifically, I investigate the development of sickness presence in Germany during the early COVID-19 pandemic and explore the influence of a national lockdown as well as the potential moderating role of telework. The study contributes to the literature on antecedents of sickness presence and has practical implications for the development of strategies preventing pandemics.

Theoretical Background

Based on situational strength theory (Meyer et al., 2010), the study investigates the effects of situational strength (i.e., a national lockdown) on employees' sickness presence. Situational strength is defined as "implicit or explicit cues provided by external entities regarding the desirability of potential behaviours" (Meyer et al., 2010, p. 122). During the pandemic, people in Germany were asked by the government to follow the AHA-guidelines, standing for distancing, hygiene, and masks. Sickness presence may be relatively stable when governmental guidelines are relaxed (low situational strength). However, sickness presence may decrease due to strict governmental guidelines during a national lockdown (high situational strength). Regarding the role of telework, exclusively working on site may exacerbate the decrease in sickness presence during a lockdown compared to working arrangements allowing to work from home.

Design & Methodology

Longitudinal data was collected at seven measurement waves between June 2020 and December 2020. Participants respond to an online questionnaire at the first week of each month. The sample consisted of 634 employees working full-time in a variety of industries. To test my assumptions, I applied a piecewise growth model in Mplus. The model examines the development of average sickness presence days per month before the national lockdown in Germany (May to October 2020) and during the lockdown (October to December 2020) depending on spatial working arrangements (remote work vs. non-remote work).

Results

Controlling for health and job demands, results show an unexpected decline in sickness presence between May 2020 and September 2020. In addition, there was no support for changes in sickness presence between September 2020 and December 2020 during the national lockdown. The hypothesis regarding the moderating role of telework was partially supported.

Limitations

Sickness presence was assessed asking employees to report the number of days they worked in a state of ill-health in the last month, which could reduce reliability due to recall biases. In addition,

future studies may examine employees' perceptions of situational strength regarding governmental pandemic guidelines.

Research & Practical Implications

The results of this study contribute to our knowledge on antecedents of sickness presence at the societal level by giving insights into the development of employees' sickness presence during a pandemic and changes in this behaviour due to governmental restrictions. Furthermore, this study contributes to work design research by investigating a spatial working arrangement, namely telework as a potential moderator of these effects. Results have practical implications for the development of strategies to prevent pandemics. Telework may be helpful in containing the spreading of contagious diseases but seems to be less effective in preventing virtual sickness presence (Ruhle & Schmoll, 2021).

Relevance to the Congress Theme

Major societal events such as the Covid-19 pandemic can influence and change the world of work. The results of this study provide insights into the development of health behaviour in the working context during a pandemic. The study advances knowledge on the consequences of a work arrangement becoming more frequent, namely telework and its effects on employees' health behaviour.

Relevant UN SDGs

This study may contribute to the design of strategies to prevent the spreading of contagious disease during pandemics and therefore, to maintain public health (UN sustainable development goal 3 & 16). Findings further give insights into the consequences of spatial flexibility for employees' well-being and health (UN sustainable development goal 3 & 8).

Keywords: Sickness Presence, Telework, COVID-19 pandemic

Paper 3

Remote worker's values and well-being: Is it irrelevant what employees strive for as long as they fit the organizations' values?

Eva Straus & Christian Korunka | University of Vienna; Jeffrey R. Edward , University of North Carolina; Anja Van den Broeck, KU Leuven; Arabella Mühl, University of Vienna

Research Goals

"We need employees that fit our values." is a statement manager often use to select candidates. For Human Resources (HR) departments a fit between the company's values and the applicant's values is often crucial for hiring candidates (Adkins et al., 1994; Cable & Judge, 1995, 1997; Chatman, 1989; Kristof-Brown, 2000). Given that organizations decide to hire a candidate based on their values, positive and negative effects of value congruence should be examined in great detail.

Theoretical Background

Theories of value that focus on congruence assume that congruence between individual and organizational values is universally associated with positive outcomes (Greguras & Diefendorff, 2009; Kristof-Brown et al., 2005). However, other research on values that focus on the content of values show that different contents of values lead to different outcomes. For instance, the self-determination theory (SDT) suggests to differentiate between intrinsic values (e.g. contribution to the society) and extrinsic values (e.g. financial success) leading to either positive or negative individual and organizational outcomes, respectively (Kasser & Ryan, 2001; Van den Broeck et al., 2019; Vansteenkiste et al., 2007). While striving for intrinsic values leads to well-being and life satisfaction, extrinsic aspirations lead to high turnover intentions and emotional exhaustion (Vansteenkiste et al., 2008). So, is it really irrelevant what employees strive for as long as they fit the company's values?

Drawing on these two contrasting perspectives, the aim of the present study is to reveal whether a fit or the content of values (intrinsic vs. extrinsic values) is crucial for well-being (measured with items of engagement) and emotional exhaustion.

Design &Methodology

This longitudinal study consists of three measurements with four weeks between each measurement. A questionnaire had to be filled out at every measurement. The first questionnaire included personal values and sociodemographic items. Four weeks later, participants filled out a questionnaire containing organizational values. Eight weeks after the first questionnaire, the dependent variables were measured. Participants received the appropriate links via e-mail. The sample size of this longitudinal study was 740 (421 women; 319 men) participants.

To analyze our data, we calculated non-linear regression coefficients (polynomial regressions: $Z = b_0 + b_1 X + b_2 Y + b_3 X^2 + b_4 XY + b_5 Y^2 + e$), which we tested using the bootstrap. In line with Edwards and Parry (1993), we used response surface methodology to analyze the shape of each surface along the Y = X and Y = -X lines and the location of the first principal axis.

Results

Our results show that a congruence of values is not crucial for engagement but that the values' content matters, deviating from the widespread value congruence theory and research. More

specifically, we disclose that engagement is high as soon as organizations support intrinsic values, independently of a person's individual aspirations. Extrinsic values are even associated with emotional exhaustion.

Limitations

We used self-reported data that is prone to common method bias and consistency effects (Podsakoff et al., 2003). Also, we worked with a panel provider whose pool of participants may represent a biased sample such as different demographic and employment characteristics relative to other traditional sampling techniques (Behrend et al., 2011).

Research & Practical Implications

This longitudinal study combines the empirical work on value congruence with research on the content of values. It reveals that the content of values has main effects on well-being and emotional exhaustion, even in case of a congruence with the environment. Considering the negative consequences of extrinsic value congruence, this study underlines the importance for organizations to promote intrinsic values such as social responsibility and personality development instead of power and wealth to have satisfied employees.

Relevance to the Congress Theme

Recent global events have major influences on our personal values: In times of crises, such as the COVID-19 pandemic, people are more prone to extrinsic values. As our study reveals that extrinsic values, even the congruence of extrinsic values, can have negative consequences for companies, we underline the importance for organizations to promote intrinsic values such as social responsibility instead of power and wealth to have engaged employees and to cope with times of crises (Organ et al., 2006).

Relevant UN SDGs

This study contributes to the 17 Sustainable Development Goals (SDGs) by investigating well-being and exhaustion of employees. By examining values at work, we provide guidelines how to improve employees' well-being and prevent exhaustion at work.

Keywords: Organizational Values, Engagement, Emotional Exhaustion

Paper 4

Working from home or living at work? Understanding the role of technostress on work-family conflict

Afshan Iqbal, Mark Robinson & Matthew Davis | University of Leeds

Research Goals

The traditional 9-5 working day has long been questioned. Greater workplace flexibility allows employees to balance their work and personal demands (Kossek et al, 2015). Where organisations enable flexible and home working, employees have higher levels of job satisfaction, productivity, and organisational commitment (Gajendran & Harrison, 2007; Fonner & Roloff, 2010; Charalampous et al, 2019). Flexible working also improves employee well-being and reduces burnout through better work-life balance (Dizaho et al, 2017). Such flexibility has been enabled by sophisticated technologies, allowing people to work anytime, anywhere (Gonsalves, 2020).

During 2019, only 5% of the UK workforce worked mainly from home, whereas by April 2020 almost half (47%) of the UK working population did, due to the pandemic (ONS, 2020). Almost overnight, people adapted to a new way of working, using new technologies to work and communicate with colleagues (Unsworth, 2020).

It is therefore necessary to understand how people adjusted to working in a new environment, as their personal and professional lives collide. Are there particular personal circumstances that are more conducive to successful homeworking than other circumstance? This research aims to inform academic and practitioner understanding on shaping an efficient, productive, and healthy future workplace, especially since returning to the office full-time now seems unlikely.

Theoretical Background

Technology has undeniably revolutionised the way we work, by providing communication options, both synchronous and asynchronous, enabling organisations to streamline operations (Leung & Wang, 2015). The technostress perspective argues that technology can be overwhelming, and people thus struggle to adapt healthily (Ragu-Nathan et al, 2008). Technology can trigger stressors, which in turn influence the strain individuals experience at work (Tarafdar et al, 2011). Thus, a perceived discrepancy between individual ability and work demands leads to some distress (Suh and Lee, 2017).

Drawing on the technostress model, this study investigates the adaptation to remote working. In particular, we explore the influences of technostress (specifically techno-overload, techno-invasion and techno-complexity) on work-family conflict. Hyper-connectivity can overwhelm people when they constantly react to noise and struggle to detach from work (Tarafdar et al, 2011). At what point does flexible work become inescapable work?

Design & Methodology

A three-wave longitudinal study was conducted between July 2020 and 2021 in line with the UK Government's National Lockdown strategies. A final matched sample consisted of 202 employees working from home full-time, across the UK, from a variety of professions. The sample consisted of 51% male, 44% female and 5% other. Majority of the participants were aged between 25 and 39 years (75%) and only one-third had some experience of working from home, prior to the pandemic.

Structural equation modelling was the method of analysis, testing for direct, indirect, and moderating relationships.

Results

The findings show that virtual meetings as interruptions to workflow significantly predicts technostress (techno-overload; $\beta = .49$, $p<.001$, techno-invasion; $\beta = .27$, $p<.001$, and techno-complexity; $\beta = .18$, $p<.001$). When testing for the indirect relationships between virtual meetings as interruptions and work-family conflict, the analysis revealed that techno-overload ($\beta = .09$, $p<.05$) and techno-invasion ($\beta = .09$, $p<.05$) significantly mediated this relationship. However, techno-complexity did not ($\beta = -.01$, $p=.56$). Peer support significantly moderated the relationship between virtual meetings as interruptions and techno-invasion only ($\beta= -.18$, $p<.05$). The findings therefore demonstrate the need to take a more nuanced view of technostress and peoples' experiences of working from home.

Limitations

This study relies on participants recalling their experiences retrospectively, both in the survey and interview responses, which may not be entirely accurate. Future research could also use diary studies for participants to capture their experiences in real-time, rather than solely relying on memory.

Research & Practical Implications

This paper helps advance our conceptual understanding of technostress and what this means for work-family conflict and well-being when working from home. The findings can help inform academic research by posing new questions about employee experiences of working from home as well as adapting to a new hybrid work model. It should also encourage further academic discussions around work design, well-being, and productivity. Furthermore, the findings may provide practical guidance for human resource management (HRM) and employment law policies.

Relevance to congress themes

Recent global events, such as the pandemic have shown that changes experienced in the world of work is not always influenced by people or events associated with the workplace. Indeed, external events have a significant influence and consequently radically changed the way in which we work. The present study investigates how employees adapted to new ways of working and how we can further support employee well-being and productivity in alternative work environments.

Relevant UN SDGs

The findings from this research align with the UN SDGs 3 (Good Health & Well-being) and 8 (Decent Work & Economic Growth). Our study provides insights into employee well-being and productivity during unexpected, disruptive environmental circumstances.

Keywords: Technostress, Remote Work, Work-Family Conflict

Symposium S039

Recovery and Behaviors after Work: New Developments

Wilken Wehrt, Maastricht University

science

In this symposium, we present five empirical papers that concern research on recovery and behaviors after work by following different methodological and theoretical angles. The motivations behind these papers are manifold, but they unite in their aim to improve research on recovery and behaviors after work. The presented works improve recovery-related research by (1) focusing on neglected aspects to improve our theoretical understanding of recovery processes (e.g., activity characteristics, implicit theories), (2) considering recent developments and interesting phenomena affecting successful recovery (e.g., telework, being in nature), or by (3) extending the range of behaviors that may deserve attention next to recovery activities after work.

Concerning the studies that focus on neglected aspects that can improve our understanding of recovery processes, Alameer et al. takes a step back systematically disentangling recovery activities and experiences. Via a latent profile approach and a large diary study sample of 345 persons, the presented study enquires if characteristics of recovery activities (e.g., physical, social, creative, mental, spiritual, virtual, and outdoor) cluster together to form recovery activity profiles that further can predict recovery experiences and well-being the next workday.

Also Seibel and Haun aim to foster our theoretical understanding of recovery processes and in particular energy management by introducing a questionnaire to assess employees' implicit theories about energy resource gains and losses during work and non-working time (ITERGL). In two online surveys, the authors evaluate discriminant and construct validity (Survey 1, N = ca. 380), and predictive and re-test reliability (Survey 2, N = ca. 300). With this questionnaire, the authors aim to challenge the assumption that energy investment at work and energy replenishment after work via recovery are the sole processes explaining how employees manage their energy. In their view, employees' thoughts on these processes (i.e., their implicit theories) may further explain how employees manage their energy resources, e.g., by affecting the decision to engage in recovery activities even after exhausting working days.

Two studies consider recent developments and interesting phenomena that may affect successful recovery. Venz et al. takes up new developments for more telework and looks at the issue of increasingly blurred boundaries between work and home. Using a diary design with data from 232 persons on 1540 workdays, their study poses the question if telework impairs recovery via people's perceived expectation to be available for work matters during one's free time.

The second study on recent developments and interesting phenomena by Kühnel et al. looks at one specific activity that did not receive much attention yet. "Shinrin-Yoku" or "Forest bathing" describes to immerse oneself into nature in a mindful manner with a focus on one's senses. In order to examine the effectiveness of forest bathing, the authors conducted a randomized field intervention with 107 participants over three weeks. Participants in the intervention group were instructed to spend time in the forest focusing on their five senses. "Forest bathing" may not only be good for recovery, but also help to decrease strain, and enable a higher sense of coherence at work.

The last presented study by Wehrt et al. extends the range of behaviors that deserve attention besides recovery activities after work. In a preregistered diary study with 137 participants, the authors aim to gain a better understanding on how and via which mechanisms work demands may

translate into self-control failures at home. In particular, they examine the role of different work demands for a wide range of self-control failures at home (i.e., overeating, media overconsumption, neglecting household and social duties) via different processes namely depletion, motivation, desires for self-reward, and desires for self-direction. The authors draw upon several recent theoretical developments stemming from social psychology to illuminate self-control processes at the work-home interface.

Together, these five papers demonstrate that research on recovery is manifold and still offers many fruitful routes to walk and explore. The perspectives provided hopefully stimulate further extension, differentiation and integration of recovery research with research on the work-home interface, and inspire further methodological flourishing in the field.

Paper 1

Examining the Profiles of Daily Recovery Activity Characteristics

Khalid M. Alameer, Ute R. Hülsheger & Sjir Uitdewilligen | Maastricht University

Research goals

Alameer, Uitdewilligen, and Hülsheger (2022) introduced a dimensional approach, called recovery activity characteristics, to study how people recover from work stress. The dimensional approach poses that recovery activities can be characterized by multiple continuous dimensions (e.g., physical, social, creative, mental, spiritual, virtual, and outdoor). In the present study, we aim to examine whether these activity characteristics cluster together into distinguishable profiles on a daily basis. Moreover, we will investigate whether individuals may vary on such profiles from one day to the other. Finally, we aim to explore whether these profiles predict recovery experiences and well-being outcomes in the evening and during the subsequent workday.

Theoretical background

Active participation in recovery activities is an essential strategy to enhance recovery from work stress (Sonnentag et al., 2022). However, research is still inconclusive about the activities that enhance recovery mainly because recovery activities have been assessed with broad categories (e.g., physical, social, low-effort activities; Sonnentag, 2001; Sonnentag & Zijlstra, 2006). However, in this category based approach, a broad range of activities are joined together that may conceptually be different (e.g. both walking and playing a team sports fall under the physical category). Moreover, the category-based approach provides limited insights into the underlying mechanisms driving the effects on recovery. Each specific activity can have multiple underlying characteristics. For example, playing football can be physically effortful and social, while dancing is physically effortful and creative.

To overcome the shortcomings of the category-based approach, Alameer, Uitdewilligen, and Hülsheger (2022) introduced a dimensional approach. This approach allows for studying recovery activities using a comprehensive multidimensional approach to assessing recovery activities rather than using very broad categories to classify activities. Yet, it is likely that specific activity dimensions may systematically cluster together into activity profiles (for instance high physical and high social). The identification of such profiles provides insight into which activity characteristics naturally occur together and enable an assessment the conjoint effects of these activities on recovery outcomes.

Study Design/ Methodology

The project consisted of an online 10-day diary study involving two measurements per day targeting adults who work at least 19 hours and had regular daytime working hours. In the evening survey, participants answered the recovery activity characteristics questionnaire (Alameer et al., 2022), the recovery experiences questionnaire (Sonnentag & Fritz, 2007), and items to assess emotional exhaustion (Halbesleben & Demerouti, 2005) while in the morning surveys, participants answered items that assess vigor and exhaustion (Schaufeli, Bakker, Salanova, 2006; Halbesleben & Demerouti, 2005). Participants were recruited using research assistants' personal networks and the snowball sampling technique. A total of 345 employees participated in this study.

Results

We plan to run Multilevel Latent Profile Analysis (MLPA) to identify profiles of daily activity characteristics and to assess whether one profile differs significantly from other profiles on each outcome. But before doing this, we ran null models using Mplus decomposing between- and within-person variance in each variable. Results indicate that 27% to 66% of the variance in our constructs was within-person, supporting our use of MLPA.

Limitations

One limitation is that we focus only on evening activities, whereas recovery occurs in many settings (such as work breaks, weekends, and vacations). Nevertheless, the psychological mechanisms underlying recovery seem to be alike across these settings (Sonnetag et al, 2017).

Conclusion

Rather than examine one or two activity/activity characteristics in isolation, we examine daily recovery activity characteristics in conjunction. This allows us to identify the active ingredients of generally occurring combinations of recovery activities and provides practical recommendations to employees to help them recover from work stress.

Relevance to the congress theme

The new way of working (i.e. working from home, and the 24/7 access to telecommunication device) intervene in employees' personal life and make recovery from work stress much more difficult. When we think of the future of work, we need to take the importance of recovery into account. We need to push employees to engage in activities that make them recover. We need to create interventions and redesign jobs to reinforce participation in recovery activities. However, we first need to know better which activities make them recover.

Relevant UN SDGs:

The Study is relevant to the UN Sustainable Development goals, specifically “good health and wellbeing” and “Decent work and economic growth” goals. Stress has been shown to harm individuals, society, and the economy (Ganster & Rosen, 2013; Nixon et al., 2011). Understanding how people recover from work stress is vital to eliminate the detrimental impact of stress on individual health and wellbeing and on society and the economy.

Keywords: recovery activity characteristics, latent profile analysis, well-being

Paper 2

Implicit Theories of Energy Resource Gains and Losses during Work and Nonwork Time

Sebastian Seibel & Verena C. Haun | University of Wuerzburg

Research goals and why the work was worth doing: Previous research demonstrated that the implicit theories individuals have (e.g., about willpower) influence their cognitions and behaviours. Building on this notion, we expect that the implicit beliefs about energy resource gains and losses during work and nonwork time might explain differential behaviours and experiences during work (e.g., investing effort at work) and during nonwork time (e.g., engaging in recovery activities) above and beyond work and nonwork characteristics. As a first step to enable future research in this field, we aim to develop and validate a survey to assess implicit theories about energy resource gains and losses during work and nonwork time (ITERGL) by examining its discriminant, concurrent and predictive validity.

Theoretical Background: Based on the notion that both work and nonwork time can have energy draining as well as energy replenishing aspects, we developed a 20-items survey with four dimensions and demonstrated its four-factor structure in an initial study: (1) Implicit theories about energy resource losses during work time (ITERLoss_w), (2) energy resource gains during work time (ITERGain_w), (3) energy resource gains during nonwork time (ITERGain_nw), and (4) energy resource losses during nonwork time (ITERLoss_nw). To demonstrate discriminant validity, we suggested that ITERGL are different from implicit theories of willpower (Job et al., 2010), a work-related theory (i.e., stress mindset; Crum et al., 2013), and a non-work-related theory [i.e., recovery-related self-efficacy (RRSE); Sonnentag & Kruel, 2006]. Thus, we propose that a seven-factor model should fit the data best. To show concurrent validity, we investigate the relationship between ITERGL and job satisfaction (Judge et al., 1998), nonwork time satisfaction (adapted from Judge et al., 1998), nonwork time anticipation (Seibel et al., 2020), work prospection (Rutten et al., 2022), and level of energy during working and nonwork time (Weigelt et al., 2022). We expect that the work time-related dimensions of ITERGL show higher correlations with work-related than with the nonwork-related constructs and vice versa. Regarding predictive validity (four weeks later), we propose that ITERGL relate to work engagement (Schaufeli et al., 2006), job engagement (Rich et al., 2010), morning recovery (Sonnentag, 2001), fatigue (McNair et al., 1992), need for recovery (van Veldhoven & Broersen, 2003), and energy during work and during nonwork time (Weigelt et al., 2022). We expect that, for instance, ITERGain_w positively relate to work engagement, ITERGain_nw positively relate to morning recovery, and ITERLoss_w correlate positively with the need for recovery.

Design/Methodology/Approach/Intervention: Our study consists of two online surveys at intervals of four weeks. Survey 1 (N = 347) included the variables to evaluate discriminant and concurrent validity. Survey 2 will be used to assess predictive validity and re-test reliability. Data collection of Survey 2 will be completed in November 2022.

Results obtained or expected: Confirmatory factor analyses showed that the expected seven-factor model fits the data best, supporting discriminant validity. Regarding concurrent validity, correlations were in the expected directions, and work-related ITERGL correlated stronger with work-related than nonwork-related variables and vice versa, supporting the concurrent validity of the ITERGL questionnaire. However, RRSE was only related to work-related ITERGL, and energy during nonwork time was not related to any ITERGL. Results on predictive validity and re-test reliability will be available in November 2022.

Limitations: Because we focused on employees' self-reported cognitions during work and nonwork time, we cannot draw conclusions on whether ITERGL change employees' behaviours (e.g., invest more effort at work) and decisions (e.g., engage in leisure activities).

Conclusions: In sum, we demonstrate the validity of the ITERGL questionnaire and thus provide a parsimonious survey to study implicit theories in future research endeavours.

Relevance to the Congress Theme: The world of work is changing, and as work intensifies, employees' energy management at work and home becomes more and more important for their long-term health and productivity. Knowledge about ITERGL can be used to sensitize employees to a more sustainable energy management.

Relevant UN SDGs: Because recovery interventions have been only based on the idea that work time consumes energy resources, understanding employees' ITERGLs might contribute to developing sustainable interventions by identifying potential implicit sources for energy resource gains and losses in both the work and nonwork life domains. Therefore, our research on ITERGL might help promote psychological well-being and contribute to a healthy life.

Keywords: implicit theories, energy resources, scale development

Paper 3

How Working From Home Impairs Recovery From Work: Anticipated Availability as a Cognitive Process in the Stressor-Detachment Model

Laura Venz, Leuphana University Lüneburg; Dana Unger, UiT The Arctic University of Norway; Anne M. Wöhrmann, Leuphana University Lüneburg & Federal Institute for Occupational Safety in Health (BAuA)

Research goals and why the work was worth doing

During the COVID-19 pandemic, many employees who shifted to regular work from home (i.e., telework) found that their recovery from work was impaired under these work circumstances. We subjected this anecdotal evidence to an empirical test and examined why telework might impair recovery (in terms of lacking psychological detachment in the evening and poor well-being in the next morning), studying anticipated availability (i.e., the expectation of having to be available and/or be contacted for work matters during one's free time) as a cognitive explanatory mechanism. Considering that telework arrangements are here to stay, it is important to understand how this work practice might interfere with successful employee recovery.

Theoretical background

We base our research on the stressor-detachment model (Sonnentag & Fritz, 2015), according to which job demands impair successful recovery, especially psychological detachment (i.e., being mentally away from work) and subsequent well-being. Under the umbrella of information communication technology research in work and organizational psychology (Hu et al., 2021), we combined the stressor-detachment model with theorizing on anticipated stressors (e.g., Casper & Sonnentag, 2020) and examined anticipated availability as a cognitive mechanism underlying the stressor-detachment relationship. The stressor-detachment model reveals a "paradox" (Sonnentag, 2018): Detachment is most needed when stressors are high but most difficult to achieve on such days. We argue that this paradoxical situation applies to classical stressors, such as workload, but also to telework which places numerous demands on employees (e.g., blurred work-home boundaries). We suggest that when working from home, employees perceive higher availability expectations for their off-work time than when working on-site and that this higher anticipated availability explains why employees detach worse on telework days, which will contribute to higher exhaustion the next morning. We suggest the same process to also explain why high workload impairs recovery.

Design/Methodology/Approach/Intervention

With a quantitative daily diary study with three daily measurement points, we collected data from 232 persons over 1540 workdays. Participants indicated if they had worked from home that day (no/yes), their day-specific workload, and anticipated availability for their off-work time at the end of work. We obtained data on participants' actual availability and psychological detachment in the evening and on state exhaustion the next morning. We tested our hypotheses with a two-level path analysis for 1-1-1 mediation with fixed slopes.

Results obtained

On the day level, both workload and telework positively predicted anticipated availability but were unrelated to actual availability. Anticipated and actual availability negatively predicted psychological

detachment beyond each other. Workload and telework were negatively indirectly related to psychological detachment via anticipated availability. Detachment was negatively related to next-morning exhaustion. Anticipated availability was not significantly related to psychological detachment on the person level.

Limitations

From a methodological viewpoint, this study is limited due to the exclusive use of self-report measures and some of the variables being measured at the same timepoint, which might result in overestimated relationships. From a content viewpoint, our research does not include moderators (e.g., segmentation preferences and norms) that could explain for whom telework, workload, or anticipated availability does not impair recovery.

Conclusions – research and or practical implications

We extend the stressor-detachment model, showing that beyond encountered stressors (at work and at home) also anticipated stressors can impair recovery. Indeed, anticipated stressors can function as a cognitive process that underlies the stressor-detachment relationship. Specifically, anticipation of availability for one's free time explains how high workload and telework encroach upon peoples' home life and impair recovery – no matter if people were actually contacted or not. From a practical perspective, this means that it is not enough to not contact people in their free time, but that clear expectations and norms about non-availability must be set, especially when workload is high and when people work from home.

Relevance to the Congress Theme

As telework and hybrid work arrangements are becoming the norm, the future of work brings new demands for many employees, including external and internal pressures to be always available. Our research helps understand specific challenges that the changing world of work brings for employee recovery and well-being. Only with this understanding can we create a sustainable world of work, now and in the future.

Relevant UN SDGs:

This research is relevant to the UN SDGs 3, Good Health and Well-being, and 8, Decent Work and Economic Growth.

Keywords: psychological detachment, anticipated availability, telework

Paper 4

The Power of "Shinrin-Yoku": A Field Intervention Study Showing Benefits of "Forest Bathing" for Employee Well-Being

Jana Kühnel, University of Vienna; Jochen Reb, Singapore Management University; Livia Erber & Benedikt Baier | University of Vienna

The Japanese term "shinrin-yoku", coined by Tomohide Akiyama of the Japanese Ministry of Agriculture, Forestry, and Fisheries in 1982, can be translated as "forest bathing." Shinrin-yoku is defined as immersing oneself in nature, while mindfully paying attention to one's senses (Kotera, Richardson, Sheffield, 2020). Since the introduction of the term, the interest in shinrin-yoku increased both among those living in our modern-day society who look for a relief from stress by being in a nature environment as well as among scientists who aim to better understand shinrin-yoku's beneficial effects for health (e.g., Tsunetsugu, Park, Miyazaki, 2009).

Building on research in public health and environmental psychology, the current field intervention study is among the first to examine the benefits of forest bathing for employees and on work-related outcome variables. From the theoretical lens of stress reduction theory (Ulrich et al., 1991) and the effort-recovery model (Meijman & Mulder, 1998), we propose that being in and focusing on an unthreatening natural environment enables relief from job stressors and thus reduces strain. Moreover, we extend previous research by investigating whether benefits of forest bathing spill-over into how employees experience their work. Specifically, we propose that forest bathing should strengthen employees' work-related sense of coherence (i.e., employees' perception of their work as being comprehensible, manageable, and meaningful; Eberz, Becker, Antoni, 2011).

We conducted a randomized field intervention study with 107 participants working in diverse industries, with 55 participants randomly assigned to the intervention group and 52 participants to the delayed treatment control group. Over the course of three work weeks, all participants were asked to answer a paper-and-pencil questionnaire at the end of each work week assessing strain, psychological detachment from work, and work-related sense of coherence. Participants in the intervention group received the forest bathing instructions after filling in the first questionnaire, the participants in the waitlist-control group received the forest bathing instructions after filling in the second questionnaire. Participants who received the forest bathing instructions were asked to spend as much time as feasible in the forest, and they were given detailed instructions on how to focus on their five senses while in the forest.

In line with our hypotheses, results from repeated measures ANOVAs showed significant group (intervention vs. delayed treatment control group) × time interactions: Strain decreased, whereas psychological detachment from work and work-related sense of coherence increased, from the first to the second week in the intervention group and from the second to the third week in the delayed treatment control group. For the intervention group, strain remained on the lower, and psychological detachment and sense of coherence on the higher, level during the third week, showing that benefits of the forest bathing intervention lasted for more than a week.

This is the first study that sheds light on positive spill-over effects of a forest bathing intervention for employees. A limitation of our study in terms of generalizability of results is that only those people who had access to a forest could take part in the study. Thus, future studies may want to examine whether a walk in a park can have similar effects for people who do not have a forest nearby. To

facilitate employees' relief from stress, we recommend forest bathing as an exercise. To achieve this, organizations should provide work schedules that are compatible with spending time in a forest during daylight hours, for example by offering the opportunity to take a longer break from work so that employees can engage in forest bathing or "park bathing" on a regular basis. Those interventions contribute to ensuring employees' health and wellbeing, and thus to the sustainable development goals of the UN.

Keywords: forest bathing, sense of coherence, randomized control trial

Paper 5

How Work Translates into Self-Control Failure at Home. A Preregistered Diary Study

Wilken Wehrt. Maastricht University; Hadar Nesher Shoshan & Leon Többen | University of Mannheim

Research goals

The aim of this diary study is to understand how and via which mechanisms work translates into self-control failures at home. We examine incivility, aversive tasks and self-control effort at work in the morning and the afternoon as predictors of self-control failures at home. As potential mediators, we examine self-control depletion, desire to reward oneself, desire for self-direction and self-control motivation (specific for each examined self-control failure) at home. For the outcomes, we look at two forms of self-control failures at home: (1) behaviors that represent failures when exerted excessively (i.e., overeating, media overconsumption); (2) behaviors that represent failures when not exerted (i.e., neglecting household and social duties).

Theoretical background

Previous research on the work-home interface has focused on recovery (Sonnentag et al., 2022), and work-private life boundary dynamics (Allen et al., 2014). These perspectives inform how to manage work-life boundaries and handle work demands. However, handling work demands also implies preventing that work translates into self-control failure at home. Despite a vast literature on self-control (De Ridder et al., 2012), self-control failures at home as consequences of work have been only considered in the domain of eating, sports or sleep (Headrick & Park, 2022, Sonnentag & Jelden, 2009). It is worthwhile to extend the range of self-control failures studied at home.

In addition, research in work psychology strongly relies on the ego-depletion perspective to explain self-control failure (Wehrt et al., 2020). This is surprising, because the ego-depletion perspective has been challenged fundamentally (Friese et al., 2019), and alternative motivational accounts explaining self-control failure have been proposed (e.g. Vaghef et al., 2021). Responding to these issues, this study examines a broader range of self-control failures at home, and tests competing mechanisms explaining why they occur.

Study Design/ Methodology

The study was preregistered (https://osf.io/qbypu). Data was collected with the help of undergraduate students via their social networks. The study consisted of a two work-week diary (Monday to Friday) with a midday, end-of-work and a prior-to-sleep survey. Incivility, aversive tasks and self-control effort at work were assessed in the midday and end-of-work survey. Depletion, desire for self-reward, desire for self-direction and self-control motivation at home were assessed in the end-of-work survey. Self-control failures at home were assessed in the prior-to-sleep survey. The final sample consists of 137 participants (n = 962).

Results

All analyses and results reported are preliminary. We conducted multi-level confirmatory factor analyses, yielding overall good fits and supporting the adequacy and construct validity of our models. To test hypotheses, we specified four multi-level path models, one for each specific self-control failure at home including only the specific self-control motivation. This means, we specified one

model for the self-control failure overeating, one for media overconsumption, one for neglecting household and one for neglecting social duties.

Results concerning the work-related predictors show that only afternoon aversive tasks relate to depletion and desire for self-reward at the end of work. Contrary to hypotheses, afternoon self-control effort at work related positively to motivation to avoid overeating. Results concerning the mediators predicting self-control failures were as follows: All self-control motivations predicted the respective self-control failure at home (e.g., motivation to avoid overeating predicted less overeating). Depletion at the end of work predicted neglecting social duties, but not the other self-control failures. Accordingly, there was an indirect effect from afternoon aversive tasks on neglecting social duties via depletion. Desire for self-reward at the end of work predicted overeating and neglecting household duties. Desire for self-direction predicted media overconsumption.

Limitations

First, we assess depletion via self-report, whereas it is not clear if people can reliably report on their current self-control capacity. Second, we do not test affect as a mediating mechanism although it has been proposed in the literature (Sonnentag, Pundt, & Venz, 2017). Third, we focus only a set of work-related predictors that may overlook other important work-related aspects, such as other social stressors or indicators of workload.

Conclusion

Results indicate that self-control motivation matters for self-control failures at home. Further, results indicate that different mechanisms beyond depletion are important for different self-control failures after work. Thus, understanding self-control processes after work requires considering specific behaviors and alternative explanations.

Relevance to the congress theme and the UN SDGs

The study is relevant for the congress theme because work-home boundaries become increasingly blurred. Thus, it is important to identify how work may undermine private life in order to find strategies to prevent and cope with such processes, on the individual and organizational level (e.g., job redesign). The study is relevant to the UN Sustainable Development goals, specifically “good health and wellbeing” and “decent work and economic growth” goals.

Symposium S040

Understanding the Psychological and Social Processes Affecting Unethical Behavior

Roberta Fida, Norwich Business School, University of East Anglia; Rosalind Searle, Adam Smith Business School, Glasgow University

science

What will be covered and why . Research in the industrial and organizational psychology have highlighted that unethical behavior are not the prerogative of "bad apples", instead, research shows that under certain conditions, "good apples" may also engage in unethical behavior (Bandura, 2016; Moore & Gino, 2013; Newman et al., 2020). Research has started to identify the key social and psychological determinants (Belschak et al., 2018; Chugh & Kern, 2016; Fida et al., 2015; Griep & Vantilborgh, 2018; Moore & Gino, 2013; Searle & Rice, 2020) however there is still the need to further understand how organizational and social processes contribute to the enactment of these behavior and their routinization (Fida et al., 2018; Welsh et al., 2015). The papers in the proposed symposium present more complex approaches to understand this relevant topic.

Relevance to the Congress Theme. Unethical behaviors are a widespread phenomenon in the workplace. Research indicates that almost 41% of employees have witness some form of an unethical conduct in their working context (Ethics Resource Center - ERC, 2013). The enactment of unethical behavior can have negative and devastating consequences for organizations, the individuals as well as the broader society (Spector & Fox, 2005).

Research/Practical Implications. The first and second paper of the proposed session focused on the psychosocial mechanisms which can explain engagement in unethical pro-organizational behavior (Umphress & Bingham, 2011). The first paper extends in particular our understanding of moral disengagement (Bandura, 2016). While most of the research focused on the personal disengagement of moral standards, the authors explore the role of the collective moral disengagement. This paper demonstrates that while personal moral disengagement is a stronger predictor of counterproductive work behavior, collective moral disengagement is a much stronger predictor of unethical pro-organizational behaviors. The second paper focuses on the social exchange mechanisms which can explain the enactment of unethical behavior in the workplace. The author presents a conceptual paper which unpacks the role psychological contract and in particular the role of the perceived obligation to fulfil as a motivational force underlying unethical behavior. The paper presents a theoretical model exploring the specific conditions enabling the fulfillment of psychological contract obligation through moral disengagement mechanisms. The third paper explores how organizations themselves can contribute to unethical behavior through examining three cases of insider threat in a high security context. Drawing also on socio-cognitive theory, and adding conservation of resources theory (Hobfoll, 1989) we review the paradoxical balance a distrusting organization has to achieve, and how their organizationally-initiated changes can upset this balance creating unintended processes and consequences for individuals, teams and the organization as a whole. Using event mapping for these events, we use the insights to propose ways to reduce and deter these incidents in the future. The fourth paper focuses on the effect of vicarious experiences of interpersonal deviance on self-serving behaviors. In particular the authors explored the mediational role of communion striving and the moderation of both relational identification and susceptibility to emotional contagion.

Overall conclusions. Overall, the papers presented in the symposium advance our understanding of important processes that underlie engagement in unethical behavior in the workplace, and advance our knowledge of how to prevent them.
