19 **KEYWORDS:** renal cancer; proteomics; tumor markers; immunohistochemistry;
20 Reticulocalbin 1.

21 **Abbreviations:** RCC, renal cell carcinoma; IHC, immunohistochemistry; RCN1,
22 Reticulocalbin 1; WB, Western Blotting; DAB, 3,3'-diaminobenzidine.

23 **ABSTRACT**

24 Renal cell carcinoma (RCC) biomarkers are necessary for diagnosis and prognosis. They
25 serve to monitor therapy response and follow-up, as drug targets, and therapy predictors in
26 personalized treatments. Proteomics is a suitable method for biomarker discovery. Here we
27 investigate differential protein expression in RCC, and we evaluate Reticulocalbin 1 (RCN1)
28 use as a new potential marker. Neoplastic and healthy tissue samples were collected from 24
29 RCC patients during radical nephrectomy. Seven specimens were firstly processed by
30 proteomic analysis (2-DE and MALDI-TOF) and 18 differentially expressed proteins from
31 neoplastic and healthy renal tissues were identified. Among them, RCN1 was over-expressed
32 in all cancer specimens analyzed by proteomics. Consequently RCN1 use as a potential
33 marker was further evaluated in all 24 donors. RCN1 expression was verified by Western
34 Blotting (WB) and immunohistochemistry. WB analysis confirmed RCN1 over-expression in
35 21 out of 24 tumor specimens, whereas immunohistochemistry displayed focal or diffuse
36 expression of RCN1 in all 24 RCC tissues. Thus RCN1 appears as a potential marker for
37 clinical approaches. A larger histopathological trial will clarify the prognostic value of RCN1
38 in RCC.

39

40 **1. Introduction**

41 Renal cell cancer (RCC) is the most frequent neoplasm of the kidney. This disease accounts
42 for approximately 2–3% of all cancers. RCC is a heterogeneous disease, comprised of
43 different histological variants with a distinct clinical course, genetic changes and response to
44 systemic treatment. The categorization of RCC includes different subtypes based on
45 morphology, including clear cell, papillary, chromophobe, granular, spindle cell, cyst-
46 associated, translocation and collecting-duct carcinomas. The most common subtype is clear
47 cell carcinoma, accounting for 75% of cases, papillary follows with 10%, chromophobe 5%
48 and undifferentiated represent approximately 10% of cases [1]. RCC incidence varies
49 substantially worldwide [2]. Nonetheless, several studies have shown evidence of an
50 increasing number of RCC cases. Apparently, this was associated with a larger number of
51 early-stage diagnoses - presumably due to improved use of imaging techniques - but also with
52 an increasing incidence of late-stage tumors [3]. Even though imaging examination such as
53 ultrasonography represents a major tool for diagnosis and screening of renal masses,
54 complementary research methods should not be neglected, and several authors have recently
55 suggested new potential RCC markers [4-7].

56 Indeed, RCC biomarkers are useful not only in diagnosis but also to determine the prognosis,
57 function as drug targets, monitor follow-up and therapy response, and choose therapy in
58 personalized treatments [4-7]. To date, a quite large number of molecules (including
59 cytokeratins, vimentin, PAX2, PAX8, CD10, E-cadherin, kidney-specific cadherin,
60 parvalbumin, claudin-7, claudin-8, α -methylacyl coenzyme A racemase, CD117, TFE3,
61 thrombomodulin, uroplakin III, p63, CD57, and carbonic anhydrase IX) are under evaluation
62 as RCC markers, and some of them are used in pathological diagnosis through
63 immunohistochemical (IHC) techniques [8]. Some major issues calling for IHC include
64 differential diagnosis of renal *versus* non-renal neoplasms, histologic sub-typing of RCC,

65 diagnosis of renal neoplasms in small core-biopsy specimens, diagnosis of possible metastatic
66 renal carcinomas, and less frequently, molecular prognostic prediction [8-9]. Notable,
67 proteomics is a major approach used for biomarker discovery, since it allows examination of
68 either biological fluids or tissues [10] and comparison of protein expression between cancer
69 patients and normal subjects [11].

70 In this study, we investigated the presence of abnormally expressed proteins in RCC tissues
71 from a small cohort of patients, through an already described proteomic approach [12]. The
72 most significantly differentially expressed protein was Reticulocalbin 1 (RCN1), which
73 underwent additional investigation through IHC and Western Blotting (WB), in order to
74 confirm data from proteomics and support its putative use as RCC biomarker.

75

76 **2. Materials and methods**

77

78 *2.1 Materials*

79 Unless otherwise stated, all materials were from Sigma-Aldrich, Milano, Italy. TissueLyser
80 was from Qiagen, Milano, Italy; Standard RNA Releaser was from Nurex S.r.l., Sassari, Italy;
81 DC Protein Assay Kit, IPG strip gels, Protean IEF cell apparatus, Bio-Rad XI cell, PDQuest
82 software (version 7.2), Immun-Star HRP chemiluminescence kit, and Mini Protean system
83 were from Bio-Rad, Segrate (MI), Italy; Immobilon-P Transfer Membranes were from Merck
84 Millipore, Milano, Italy; anti-RCN1 rabbit polyclonal antibodies (only for WB use) were from
85 Bethyl Laboratories, Montgomery, TX, USA; EnVision system and 3,3'-diaminobenzidine
86 (DAB) were from DakoCytomation, Glostrup, Denmark.

87

88 *2.2 Tissue collection*

89 From October 2010 to February 2012, patients with a renal mass were enrolled in this study

90 before undergoing radical nephrectomy; patients with a histological diagnosis other than RCC
91 were subsequently excluded. The study was approved by the local research Ethical Committee
92 and was conducted according to Helsinki Declaration principles. All subjects included in the
93 protocol signed a declaration of informed consent. The specimens of RCC and
94 macroscopically normal tissue distant from tumor mass were obtained from 24 RCC patients
95 (Table 1). Renal tissue cold sections were obtained during radical nephrectomy, immediately
96 after kidney removal. Almost 5-10 mg of both malignant and normal tissues were collected .
97 Tissue specimens were immediately frozen in liquid nitrogen and stored at -80 °C before use.

98

99 *2.3 Protein extraction*

100 Neoplastic and normal renal tissues were disrupted through TissueLyser in 1 ml of Standard
101 RNA Releaser, followed by the addition of 0.1 ml of chloroform and proteins were extracted
102 as previously described [12]. Briefly, the homogenate was kept for 5 min in wet ice and then
103 was centrifuged (12,000 g for 15 min). The upper aqueous phase was discarded, then 0.3 ml
104 of 100% ethanol was added to the lower organic phase for DNA precipitation. After
105 centrifugation (2000 g at 4 °C for 5 min), the supernatant was used for protein purification by
106 adding 1 ml of isopropanol. The mixture was incubated for 5 to 10 min at room temperature
107 and was centrifuged (12,000 g for 10 min). The pellet was washed twice for 20 min at room
108 temperature in 0.3 M guanidine hydrochloride (dissolved in 95% of ethanol). After
109 centrifugation (7500 g at 4 °C for 5 min), 2 ml of ethanol were added to the protein pellets
110 and samples were incubated overnight at -20 °C. After discarding the ethanol, the protein
111 pellets were suspended in solubilization buffer (8 M urea, 2% [w/v] Chaps, 40 mM Tris, 1
112 mM PMSF, 1 mM EDTA), then sonicated for 10 min in a water bath, and incubated at 4°C for
113 24 h. After protein centrifugation, the supernatants were collected and stored at -20 °C before
114 use. Protein concentration was quantified through a DC Protein Assay Kit, using bovine

115 serum albumin as a standard, according to manufacturer's instructions.

116 *2.4 Two-dimensional polyacrylamide gel electrophoresis*

117 2-DE was performed using IPG strip gels (17 cm IPG strips, pH 3–10NL). Each protein
118 sample (1.2 mg) was loaded onto an IPG gel through overnight in-gel rehydration. Isoelectric
119 focusing was carried out in a Protean IEF cell apparatus as previously described [12]. Briefly,
120 focusing commenced at 50 V, and the voltage was increased to 9000 V until a maximum of
121 60,000 V/h was reached. Focusing was performed at 18 °C with a limit of 50 A per strip. The
122 IPG strips were equilibrated under continuous shaking for 15 min in equilibration buffer no. 1
123 (6 M urea, 3% [w/v] SDS, 0.375 M Tris–HCl [pH 8.8], 30% [v/v] glycerol, 1% [w/v]
124 dithiothreitol) and for 12 min in equilibration buffer no. 2 (6 M urea, 3% [w/v] SDS, 0.375 M
125 Tris–HCl [pH 8.8], 30% [v/v] glycerol, 2.5% [w/v] iodoacetamide). For the second dimension
126 protein separation, 12% acrylamide gels were run on a Bio-Rad XI cell.

127 *2.5 Gel staining and image analysis*

128 Gels were stained with colloidal Coomassie (18% [v/v] ethanol, 15% [w/v] ammonium
129 sulfate, 2% [v/v] phosphoric acid, 0.2% [w/v] Coomassie G-250) for 48 h and destained with
130 water. Gel images were obtained by scanning through a Chemidoc MP Bio-Rad. 2-DE image
131 analysis was performed using PDQuest software (version 7.2) according to manufacturer's
132 instructions. Normalization of each individual spot was performed according to total quantity
133 of the valid spots in each gel, after subtraction of background values. Spot volume was used
134 as an analytical parameter to quantify protein expression.

135 *2.6 Sample preparation for mass spectrometry analysis*

136 Coomassie G-stained spots underwent excision from 2-DE gels, and proteins were digested
137 with trypsin. Each spot was destained with 100 µl of 50% (v/v) acetonitrile in 5 mM
138 ammonium bicarbonate and dried with 100 µl of acetonitrile. Each dried gel piece was
139 rehydrated for 40 min at 4 °C in 10 µl of digestion buffer (5 mM ammonium bicarbonate; 10

140 ng/l trypsin). Digestion was allowed to proceed overnight at 37 °C, and peptide mixtures were
141 stored at 4 °C before use.

142

143 *2.7 MALDI-MS and peptide mass Fingerprinting*

144 MS analysis of peptides was performed using a MALDI-TOF spectrometer (MALDI micro
145 MX) equipped with a delayed extraction unit, according to manufacturer's tuning procedures,
146 operating on reflectron mode as previously described [13]. Briefly, samples were loaded onto
147 the MALDI target using 1.5 µl of the tryptic digest mixed 1:1 with a saturated α-
148 cyanohydroxycinnamic acid (10 mg/ml) solution in 40% v/v acetonitrile, 60% v/v
149 trifluoroacetic acid 0.1%. The MALDI-TOF was calibrated with a mix of PEG (PEG 1000, 2000
150 and 3000 with the ratio 1:1:2) and mass spectra were acquired in the positive-ion mode. Peak lists
151 were generated by ProteinLynx Global Server 2.2.5 (Waters, Milford, MA, USA) data
152 preparation using the following parameters: external calibration with lock mass using a mass
153 of 2465.1989 Da for ACTH (adrenocorticotropic hormone), background subtract type
154 adaptive combining all scans, and deisotoping with a threshold of 1%. The 25 most intense
155 masses were used for database searches against SWISSPROT database (Release 2011_12 of 14-
156 Dec-11) using free search program MASCOT 2.3.02 (<http://www.matrixscience.com>). The
157 following parameters were used in the searches: taxa Homo sapiens, trypsin digest, one
158 missed cleavage by trypsin, carbamidomethylation of cysteine as fixed modification,
159 methionine oxidation as variable modifications and 100 ppm as maximum error allowed.
160 Only proteins with a Mascot score > 56 were considered.

161

162 *2.8 Western Blotting*

163 After adding Laemmli buffer [14], samples were boiled for 5 min, and 30 µg of each protein

165 sample were run on 10% SDS-polyacrylamide gel on a Mini Protean system. Proteins
166 resolved by electrophoresis were blotted onto Immobilon™-P polyvinylidene fluoride
167 membranes. After blotting, membranes were probed using anti-RCN1 rabbit polyclonal
168 antibodies (diluted 1:3000 in PBS-TWEEN 1% non-fat dry milk) and anti-β-actin mouse
169 monoclonal antibodies (diluted 1:500 in PBS 1% BSA) for 1 h. After washing, they were
170 incubated for 1 h with horseradish-peroxidase-labeled anti-rabbit (diluted 1:10000 in PBS-
171 TWEEN 1% BSA) or anti-mouse (diluted 1:10000 in PBS-TWEEN 1% non-fat dry milk)
172 antibodies. The immunoreactivity was detected by using a Immun-Star HRP
173 chemiluminescence kit. Densitometric analysis of the bands was performed using free ImageJ
174 software (version 1.44).

174

175 *2.9 Immunohistochemistry*

176 Formalin-fixed paraffin-embedded selected blocks from 24 RCC specimens were cut into 4
177 μm thick sections and collected onto charged slides for IHC staining. After de-paraffination
178 and rehydration through graded alcohols and PBS (pH 7.5), the endogenous peroxidase
179 activity was blocked by incubation with absolute methanol and 0.3% hydrogen peroxide for
180 15 minutes. Antigen retrieval was performed by sterilizing the section in 10 mmol/L citrate
181 buffer (pH 6.0) at 98 °C for 40 minutes. Sections were incubated at the optimal conditions
182 with anti-RCN1 rabbit polyclonal antibodies (1:1000). Immunoreaction was revealed by a
183 dextran-chain (biotin-free) detection system (EnVision), using DAB as a chromogen. The
184 sections were lightly counterstained with hematoxylin. Negative control reactions were
185 obtained by omitting primary antibodies, whereas neuroblastoma cell line blocks were used as
186 positive control. A pathologist (LD) interpreted the results from immunohistochemical
187 analysis unaware of the concurrent results obtained from investigation by histopathology and
188 proteomics.

190 *2.10 Statistical analysis*

191 Statistical significance, calculated by a two-sided Student's *t* test, a chi-square test and
192 ANOVA was set at *p* values < 0.05. In 2-DE experiments, proteins were classified as
193 differentially expressed when spot intensity ratios between neoplastic and normal tissues were
194 greater than 1.5-fold (over-expressed proteins) or lower than 0.5-fold (down-expressed
195 proteins). The relationship among TNM staging, Fuhrman grading, histotype and RCN1
196 expression (both by WB and IHC) were also explored.

197

198 **3. Results**

199

200 *3.1 Renal tissue proteomic analysis*

201 Seven tissue specimens of RCC and corresponding normal tissue distant from neoplastic
202 lesion were comparatively analyzed. Figure 1 shows two representative 2-DE gel images of
203 normal and neoplastic renal tissues stained by colloidal Comassie. Table 2 shows MS
204 identification of differentially expressed proteins listed by frequency. For each identified
205 protein, the average ratios of protein expression in cancer *versus* normal tissues and
206 corresponding *p* values are also shown. Results showed 18 differentially expressed proteins in
207 neoplastic tissues. Seven of them (corresponding to spots 1-9) were found over-expressed in
208 neoplastic specimens. In particular, spot 1 (corresponding to RCN1) was over-expressed in all
209 analyzed neoplastic tissues.

210

211 *3.2 RCN1 expression analysis by WB in RCC and normal tissues*

212 Since RCN1 was over-expressed in all RCC tissues analyzed by MS, results were validated by
213 performing anti-RCN1 WB and subsequent densitometry on a larger cohort of patients (24

214 RCC patients, including the seven cases previously analyzed by proteomics). RCN1 protein
was over-expressed in 21 out of 24 RCC tissues. Among these 21 cases, RCN1 was found to
216 be induced *de novo* in 9 neoplastic tissues, whereas in the remaining 12 patients RCN1
217 protein levels from RCC tissues were significantly enhanced compared to normal renal
218 tissues. Such an enhancement was measured by calculating densitometric RCN1 protein ratios
219 between RCC and normal tissues (mean value \pm SD: 3.28 ± 2.76 , $p < 0.01$). Eight RCC tissues
220 appeared weakly enhanced (mean value \pm SD: 1.57 ± 0.35 , $p < 0.001$), whereas 4 RCC tissues
221 were intensely enhanced (mean value \pm SD: 6.70 ± 2.07 , $p < 0.05$). Figure 2 shows a
222 representative blot obtained from three RCN1-positive RCC patients in which RCN1 was
223 induced *de novo* or intensely/weakly enhanced. As already showed by Cooper et al. [15] two
224 bands are detected by the antibody and both are RCN1. The analysis of histopathological data
225 and WB results did not show any statistically significant relationship between RCN1
226 expression and tumor stage (TNM) and grade (G).

227

228 *3.3 RCN1 expression analysis by IHC in RCC and normal tissues*

229 All 24 RCC/normal tissues, including those displaying low RCN1 expression after WB
230 analysis, were additionally tested for RCN1 protein levels by IHC. Normal renal tissues
231 adjacent to lesions showed a positive and uniform staining of the tubules but not of the
232 glomerulus (Figure 3, Panel A). On the contrary, all RCC specimens displayed either focal or
233 diffuse expression of RCN1 protein, with stain intensity varying from weak to strong
234 depending on patients. Figure 3 shows a representative IHC image from 2 RCC patients out of
235 24 analyzed in which RCN1 was weakly or intensely expressed. The degree of expression did
236 not appear to correlate to stage (TNM) and grade in a statistically significant manner, even
237 though most of the low T stage cancers had a weak staining while most of the high T stage
238 cers had a strong degree ($p=0,19$).

can

240 **4. Discussion**

241 Molecular biomarkers are relevant for a large kaleidoscope of applications in clinical practice,
242 including diagnosis, outcome prediction, drug targeting, monitoring of response to therapy,
243 and development of personalized treatments. In recent years, proteome analysis revealed itself
244 as a useful approach to identify differentially expressed proteins as possible new biomarkers.
245 Therefore, the present work aimed at finding new biomarkers for RCC - a life-threatening
246 disease characterized by high incidence in Western countries - by performing differential
247 proteomic analysis of neoplastic and normal renal tissues obtained from a small cohort of
248 RCC patients (n=7).

249 Results showed 18 differentially expressed proteins in RCC tissues. Seven proteins were over-
250 expressed in RCC tissues in comparison with healthy tissues, whereas 11 proteins appeared
251 down-regulated. Over-expressed proteins included molecules related to glucose metabolism
252 (α -enolase, phosphoglycerate kinase 1 and triose phosphate isomerase), carrier proteins
253 (transthyretin and retinol binding protein-4), a member of the small heat shock protein family
254 (α -crystallin B) and a calcium-binding protein (RCN1). Down-regulated proteins included
255 molecules related to metabolism (ATP synthase, NADH dehydrogenase flavoprotein 2,
256 electron-transfer-flavoprotein, alcohol dehydrogenase, inorganic pyrophosphatase) or signal
257 transduction (WD40-repeat-containing gene 25, phosphatidylethanolamine-binding protein 1),
258 stress proteins (HSP β -1 and Protein DJ-1) and ion binding proteins (myosin and ester
259 hydrolase C11orf54).

260 Interestingly, some of the identified proteins have been previously associated to renal cancer
261 (α -enolase, triosephosphate isomerase, α -crystallin B, RCN1, HSP beta-1, ATP synthase,
262 phosphatidylethanolamine-binding protein 1) [11, 16-19] or to other renal diseases (retinol-
263 binding protein-4) [20]. A possible role for HSP beta-1 and triosephosphate isomerase as
264 prognostic/diagnostic markers was validated by Valera and colleagues by IHC [17]. However,

265 any data confirming the possible use of these proteins in clinical practice is not available to
266 date.

267 Notable, our results from proteomic analysis showed a significant over-expression of RCN1
268 protein in all RCC tissues. RCN1 is a Ca(2+)-binding protein discovered two decades ago and
269 shown to be stored in endoplasmic reticulum [21]; a recent study displayed RCN1 additional
270 localization at the surface of bone endothelial cells and prostate cancer cells [22]. Moreover,
271 RCN1 is a component of CREC molecules (acronym for: Cab45, Reticulocalbin, ERC-45,
272 Calumenin), a family of multiple (up to seven) EF-hand proteins involved in secretory
273 pathways of mammalian cells and associated with pathological activities such as malignant
274 cell transformation, mediation of the effects of snake venom toxins and putative participation
275 in amyloid formation. Nevertheless, the role of RCN1 in malignant transformation is largely
276 unknown. In some tissues, RCN1 was observed to interact with SEC63p, a protein related to
277 autosomal polycystic liver and kidney disease, that should operate in protein translocation and
278 quality control pathways in the endoplasmic reticulum [23, 24]. It was also proposed that loss
279 of the RCN1 gene might compromise cell survival [25].

280 According to literature data, broad expression of RCN1 was found by IHC analysis in a large
281 number of endocrine and exocrine organs, apart from thyroid gland cells. However, RCN1
282 expression appears heterogeneous, depending on which specialized cells of different organs it
283 belongs to. Increased RCN1 expression concurrent with inflammation was observed both in
284 epithelial and non-epithelial cells [26]. Notable, epithelial cells generally display strong RCN1
285 staining, except for squamous cells; on the other hand, strong staining is also found in non-
286 epithelial cells, including testicular germ, neuronal, vascular endothelial, follicular dendritic
287 and plasma cells [25]. Up-regulation of RCN1 protein or gene was detected also in a number
288 of cancerous cell lines, including breast [27], colorectal [28] and liver [29]. In non-small cell

289 lung cancer patients, RCN1 was proposed as a prognostic factor to identify post-operative
290 adjuvant chemotherapy responders [30].

291 To validate our proteomic data, and to confirm the involvement of RCN1 in renal cancer, we
292 set up a small pilot study by collecting surgical samples from a more extensive cohort of RCC
293 patients, and RCN1 protein levels were evaluated by WB and IHC. Interestingly, IHC
294 confirmed RCN1 over-expression in RCC tissues of all examined patients, displaying weak
295 protein expression in healthy renal tissues only in correspondence to the renal tubule section.
296 On the other hand, WB analysis showed over-expressed RCN1 protein in 21 RCC patients out
297 of 24. This data indicates a possible use of RCN1 as a new marker in renal cancer and
298 indicates the proximal convoluted renal tubule as a putative origin point for RCC. This
299 evidence is consistent with results by Fukuda and colleagues [25], suggesting that RCN1 may
300 be helpful in establishing cellular origin of neoplasms in some organs. Therefore, IHC for
301 RCN1 could be employed in clinical practice in order to distinguish between RCC and other
302 tumors not originating from renal tubule, provided that a number of different histological
303 types of renal cancer will be tested in order to confirm it. Since IHC staining displayed
304 different grades of intensity in tested tissues, RCN1 could also be employed as a prognostic
305 marker or as a response predictor for RCC-targeted therapy. The analysis of correlation of
306 IHC staining and TNM stage, grade and histotype did not show any statistically significant
307 results because of the small population of the study. Nevertheless, a correlation trend between
308 tumor staining degree and T stage was observed ($p=0,19$). As far as histotype is concerned,
309 only three non-clear cell cancers were included (1 chromophobe and 2 papillary) and we
310 cannot formulate any hypothesis on different RCN1 expression in different histotypes, even
311 though one can expect that a different kind of RCC could have a larger or smaller
312 involvement of RCN1 molecular paths. To test the correlation of IHC staining with TNM
313 stage, Fuhrman grade, histotype, response to therapy and survival, a larger retrospective trial

314 on paraffin-embedded tissues obtained from radical or partial nephrectomy of RCC patients is
315 planned to be performed by our group.

316 In conclusion, in the present study a preliminary proteomic approach, performed on a small
317 cohort of 7 RCC patients, identified 18 differentially expressed proteins. Among them, RCN1
318 was significantly over-expressed in all seven samples. Further investigation on RCN1 protein
319 expression performed either by IHC or by WB on a larger cohort (24 patients) confirmed
320 previous results from proteomics. Therefore, data from the present pilot study supports the
321 potential use of RCN1 as a new marker in renal cancer, encouraging future large-scale studies
322 to be performed.

323

417 **FIGURE LEGENDS**

418 **Fig. 1 - 2-DE proteomic analysis of differentially expressed proteins in RCC tissue.**

419 Neoplastic and normal tissues from 7 RCC patients were analyzed by 2-DE proteomics. Data
420 are shown as representative gels obtained from one patient out of seven showing almost
421 consistent results (Panel A: normal Tissue; Panel B: RCC tissue). Black circled spots indicate
422 the position of identified proteins (listed in Table 2) differentially expressed in RCC and
423 normal tissues.

424 **Fig. 2 - RCN1 protein is over-expressed in RCC tissues: WB analysis.**

425 Paired biopsies of neoplastic and normal tissues (30 μ g proteins for each tested sample) from
426 24 RCC patients were analyzed for RCN1 protein expression by WB. Results are shown as a
427 representative blot (upper Panel) of RCN1 protein levels in normal (lanes A, C, E) and
428 neoplastic (lanes B, D, F) renal tissues from three of 21 RCC patients in the cohort identified
429 as RCN1-positive. House-keeping β -actin protein levels are also shown (lower Panel).

430 **Fig. 3 - RCN1 protein is over-expressed in RCC tissues: IHC analysis.**

431 Paired biopsies of neoplastic and normal tissues from 24 RCC patients underwent
432 hematoxylin/eosin staining and IHC reaction with anti-RCN1 antibodies. Results are shown
433 as representative IHC images (20X magnification, all Panels) from 2 RCC patients out of 24
434 analyzed. Panel A: IHC reaction with anti-RCN1 antibodies on normal renal tissue; Panels B-
435 C: hematoxylin/eosin staining (B) and IHC reaction with anti-RCN1 antibodies (C) on weakly
436 RCN1-positive neoplastic renal tissue; Panels D-E: hematoxylin/eosin staining (D) and IHC
437 reaction with anti-RCN1 antibodies (E) on strongly RCN1-positive neoplastic renal tissue.

Table 1 - Summary of clinicopathological features of the renal cancer patients

Characteristic	
Patients, no.	24
Age, years, mean (range)	63.17 (42-79)
Sex, no., male/female	13/11
Kidney cancer histology, no. (%)	
Clear cell (cRCC)	21 (87,5%)
Papillary (pRCC)	2 (8,33%)
Chromophobe (chRCC)	1 (4,17%)
Pathological T stage no. (%)	
T1a	3 (12.50%)
T1b	7 (29.17 %)
T2a	1 (4.17%)
T2b	2 (8.33%)
T3a	6 (25.00%)
T3b	5 (20.83%)
Pathological N stage no. (%)	
N0	14 (58.33%)
Nx	9 (37.5%)
N+	1 (4.17%)
Pathological M stage no. (%)	
M0	4 (16.17%)
Mx	18 (75.00%)
M+	2 (8.33%)
Pathological G stage no. (%)	
G1	1 (4.17%)
G2	12 (50.00%)
G3	6 (25.00%)
G4	5 (20.83%)

Table 2

Table 2 - List of identified differentially expressed proteins sorted by frequency between normal and RCC tissues obtained after 2-DE coupled with MALDI-TOF mass spectrometry analysis. ^aFrequency: number of samples in which a protein is altered more than 1.5-fold (over-expressed proteins) or less than 0.5-fold (down-expressed proteins) in RCC tissues. Total 7 samples. ^bSpots numbers relative to Figure 1, B. ^cAverage ratio of differential expression (≥ 1.5 -fold increase or ≤ 0.5 -fold decrease) between RCC and normal tissues. ^d*p* values corresponding to average ratios.

Frequency ^a	Spot No. ^b	Protein name	Accession No.	matched/unmatched peptides	coverage	MASCOT score	Average Ca/N ratio ^c	Ca/N <i>p</i> value ^d
7	1	Reticulocalbin-1 [Precursor]	Q15293	10/25	33%	102	2.92	<0.05
6	2	Alpha-enolase	P06733	10/25	28%	100	3.11	<0.01
5	3	Phosphoglycerate kinase 1	P00558	7/25	26%	62	2.82	<0.01
3	4	Phosphoglycerate kinase 1	P00558	9/25	26%	67	2.40	<0.001
4	5	Transthyretin [Precursor]	P02766	5/25	48%	73	1.94	<0.001
3	6	Retinol-binding protein 4 [Precursor]	P02753	8/25	40%	96	2.19	<0.01
3	7	Triosephosphate isomerase	P60174	12/25	66%	171	2.23	<0.01
3	8	Alpha-crystallin B chain	P02511	7/25	40%	77	2.86	<0.01
3	9	Alpha-crystallin B chain	P02511	9/25	52%	125	2.41	<0.01
4	10	Heat shock protein beta-1	P04792	7/25	32%	86	0.45	<0.001
4	11	Myosin light polypeptide 6	P60660	10/25	47%	115	0.35	<0.001
4	12	ATP synthase subunit d, mitochondrial	O75947	8/25	46%	98	0.41	<0.001
4	13	Ester hydrolase C11orf54	Q9H0W9	10/25	26%	77	0.30	<0.001
4	14	NADH dehydrogenase [ubiquinone] flavoprotein 2, mitochondrial [Precursor]	P19404	8/25	32%	66	0.40	<0.001
4	15	Protein DJ-1	Q99497	7/25	37%	70	0.45	<0.001
4	16	WD repeat-containing protein 25	Q64LD2	7/25	23%	72	0.46	<0.01
5	17	Inorganic pyrophosphatase	Q15181	12/25	44%	156	0.33	<0.001
5	18	Electron transfer flavoprotein subunit alpha, mitochondrial [Precursor]	P13804	9/25	43%	104	0.39	<0.001
5	19	Phosphatidylethanolamine-binding protein 1	P30086	9/25	54%	131	0.13	<0.001
6	20	Phosphatidylethanolamine-binding protein 1	P30086	10/25	54%	132	0.37	<0.001
