Figure 4. Multiparameter FC analysis from FNA specimen in case no. 12, contaminated from peripheral blood. The gate performed on the lymphocytes-monocytes region (P1 in upper left dot plot) evidenced the presence of CD19 positive B-cells with highly increased FSC (P3, in blue) compared with small B cells (P2, in red) and T-lymphocytes (CD3 positive, in the upper right plot). Small B-cells displayed a polyclonal pattern, large B cells did not express surface immunoglobulins and were CD5 and CD10 negative by multicolor analysis.
