#### Abstract

Veblenite, ideally $\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$, is a new mineral with no natural or synthetic analogues. The mineral occurs at Ten Mile Lake, Seal Lake area, Newfoundland and Labrador (Canada), in a band of paragneiss consisting chiefly of albite and arfvedsonite. Veblenite occurs as red brown single laths and fibres included in feldspar. Associated minerals are niobophyllite, albite, arfvedsonite, aegirine-augite, barylite, eudidymite, neptunite, Mn-rich pectolite, pyrochlore, sphalerite and galena. Veblenite has perfect cleavage on $\{001\}$ and splintery fracture. Its calculated density is $3.046 \mathrm{~g} \mathrm{~cm}^{-3}$. Veblenite is biaxial negative with $\alpha 1.676(2), \beta 1.688(2), \gamma 1.692(2)(\lambda 590 \mathrm{~nm}), 2 V_{\text {meas }}=65(1)^{\circ}, 2 V_{\text {calc }}=59.6^{\circ}$, with no discernible dispersion. It is pleochroic in the following pattern: $X=$ black, $Y=$ black, $Z=$ orange-brown. The mineral is red-brown with a vitreous, translucent luster and very pale brown streak. It does not fluoresce under short and long-wave UV-light. Veblenite is triclicnic, space group $P \overline{1}$, a 5.3761(3), b 27.5062(11), c 18.6972(9) $\AA$, a 140.301(3), $\beta$ 93.033(3), y 95.664(3) ${ }^{\circ}$, $V=1720.96(14) \AA^{3}$. The strongest lines in the $X$-ray powder diffraction pattern $[d(\AA)(I)(h k l)]$ are: $16.894(100)(010), 18.204(23)(0 \overline{1} 1), 4.271(9)(1 \overline{4} 1,040,120), 11.661(8)(001), 2.721(3)(1 \overline{9} 5)$, 4.404(3)( $\overline{132}, 1 \overline{4} 2), 4.056(3)(031,1 \overline{1} 2,1 \overline{5} 2, \overline{1} \overline{4} 3), 3.891(2)(003)$.

The chemical composition of veblenite from a combination of electron microprobe analysis and structural determination for $\mathrm{H}_{2} \mathrm{O}$ and the $\mathrm{Fe}^{2+} / \mathrm{Fe}^{3+}$ ratio is $\mathrm{Nb}_{2} \mathrm{O}_{5} 11.69, \mathrm{TiO}_{2} 2.26$, $\mathrm{SiO}_{2} 35.71, \mathrm{Al}_{2} \mathrm{O}_{3} 0.60, \mathrm{Fe}_{2} \mathrm{O}_{3} 10.40, \mathrm{FeO} 11.58, \mathrm{MnO} 12.84, \mathrm{ZnO} 0.36, \mathrm{MgO} 0.08, \mathrm{BaO} 1.31$, $\mathrm{SrO} 0.09, \mathrm{CaO} 1.49, \mathrm{Cs}_{2} \mathrm{O} 0.30, \mathrm{~K}_{2} \mathrm{O} 1.78, \mathrm{Na}_{2} \mathrm{O} 0.68, \mathrm{H}_{2} \mathrm{O} 4.39, \mathrm{~F} 0.22, \mathrm{O}=\mathrm{F}-0.09$, sum 95.69 wt. \%. The empirical formula [based on 20 (Al+Si) p.f.u. $\left(\mathrm{K}_{0.53} \mathrm{Ba}_{0.28} \mathrm{Sr}_{0.03} \square_{0.16}\right)_{\Sigma 1}$ $\left(\mathrm{K}_{0.72} \mathrm{Cs}_{0.07} \square_{1.21}\right)_{\Sigma 2}\left(\mathrm{Na}_{0.72} \mathrm{Ca}_{0.17} \square_{1.11}\right)_{\Sigma 2}\left(\mathrm{Fe}^{2+}{ }_{5.32} \mathrm{Fe}^{3+}{ }_{4.13} \mathrm{Mn}^{2+}{ }_{5.97} \mathrm{Ca}_{0.70} \mathrm{Zn}_{0.15} \mathrm{Mg}_{0.07} \square_{0.66}\right)_{\Sigma 17}\left(\mathrm{Nb}_{2.90}\right.$ $\left.\mathrm{Ti}_{0.93} \mathrm{Fe}^{3+}{ }_{0.17}\right)_{\Sigma 4}\left(\mathrm{Si}_{19.61} \mathrm{Al}_{0.39}\right)_{\Sigma 20} \mathrm{O}_{77.01} \mathrm{H}_{16.08} \mathrm{~F}_{0.38}$. The simplified formula is $(\mathrm{K}, \mathrm{Ba}, \square)_{3}(\square, \mathrm{Na})_{2}\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}(\mathrm{Nb}, \mathrm{Ti})_{4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$. The infrared spectrum of the mineral contains the following bands $\left(\mathrm{cm}^{-1}\right): 453,531,550,654$ and 958 , with

shoulders at 1070, 1031 and 908. A broad absorption was observed between ca 3610 and 3300 with a maximum at ca 3525 . The crystal structure was solved by direct methods and refined to an $R_{1}$ index of $9.1 \%$. In veblenite, the main structural unit is an HOH layer, which consists of the octahedral $(\mathrm{O})$ and two heteropolyhedral $(\mathrm{H})$ sheets. The H sheet is composed of $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups, veblenite $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbons and Nb -dominant D octahedra. This is the first occurrence of an eightmembered $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbon in a mineral crystal structure. In the O sheet, $\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)$ octahedra share common edges to form a modulated O sheet parallel to (001). HOH layers connect via common vertices of $D$ octahedra and cations at the interstitial $A(1,2)$ and $B$ sites. In the intermediate space between two adjacent HOH layers, the $A(1)$ site is occupied mainly by K ; the $A(2)$ site is partly occupied by K and $\mathrm{H}_{2} \mathrm{O}$ groups, the $B$ site is partly occupied by Na . The crystal structure of veblenite is related to several HOH structures: jinshanjiangite, niobophyllite (astrophyllite group) and nafertisite. The mineral is named in honour of David Veblen in recognition of his outstanding contributions to the field of mineralogy and crystallography.

Keywords: veblenite, new mineral, Seal Lake, Newfoundland and Labrador, Canada, electronmicroprobe analysis, crystal structure, veblenite ribbon, nafertisite, niobophyllite, jinshanjiangite.

## Introduction

During a recent work on astrophylite-group minerals (Cámara et al., 2010), the holotype sample of niobophyllite \#M26148 (Royal Ontario Museum, Toronto, Canada) was studied and in that sample we observed red brown single laths included in albite. The shape suggested that these laths were a distinct phase. A test on the diffractometer on one of the longer laths (<200 $\mu \mathrm{m}$ ) gave unit-cell dimensions unknown for HOH heterophyllosilicates (Ferraris et al., 1996; Ferraris, 2008). Heterophyllosilicates are related to TOT silicates: in heterophyllosilicates, five- to sixcoordinated $\mathrm{Ti}(\mathrm{Nb})$ periodically substitute a row of silicate tetrahedra in the tetrahedral (T) sheets of a TOT layer, producing a heteropolyhedral $(\mathrm{H})$ sheet, while the octahedral O sheet is maintained the same. In heterophyllosilicates, HOH layers can link directly or contain interstitial atoms between HOH layers. A single crystal X-ray diffraction study revealed that this is a new structure type with no analogues. Here we describe the properties and the structure of this new mineral.

The name is in honour of David Veblen (b. 1947, Minneapolis, MN, USA) in recognition of his outstanding contributions to the fields of mineralogy and crystallography. He has established himself as one of the foremost experts of TEM in geology and has made a significant contribution to the polysomatic approach in mineralogy. The new mineral species and its name have been approved by the Commission on New Minerals, Nomenclature and Classification of the International Mineralogical Association (IMA 2010-050). The holotype specimen of veblenite (the same as that of niobophyllite) is under catalogue number \#M26148 at the Royal Ontario Museum, 100 Queen's Park, Toronto, Ontario M5S 2C6.

## Occurrence and associated minerals

The mineral occurs at Ten Mile Lake, Seal Lake area, Newfoundland and Labrador (Canada) (latitude $54^{\circ} 12^{\prime} \mathrm{N}$ Longitude: $62^{\circ} 30^{\prime} \mathrm{W}$ ). It occurs as red brown single laths and fibres included in feldspar, in a band of paragneiss consisting chiefly of albite and arfvedsonite. The geology of
the area has been interpreted in terms of a series of interbedded volcanic rocks and gneisses intruded by an alkaline syenite. Associated minerals are niobophyllite, albite, arfvedsonite, aegirine-augite, barylite, eudidymite, neptunite, Mn-rich pectolite, pyrochlore, sphalerite and galena (Nickel et al., 1964 and references therein).

## Physical and optical properties

The main properties of veblenite are presented in Table 1, where they are compared to those of jinshanjiangite, niobophyllite, and nafertisite. The mineral forms laths and fibers; laths are hundreds of microns long and less than tens microns thick and wide (Fig. 1). Veblenite is redbrown, with a very pale brown streak and a vitreous lustre. The mineral is translucent. It has a perfect $\{001\}$ cleavage, with splintery fracture. No parting was observed. It is not fluorescent under 240-400 nm ultraviolet radiation. The density of the mineral and the Mohs hardness could not be measured owing to the very small thickness of the flakes. Its calculated density (using the empirical formula) is $3.041 \mathrm{~g} \mathrm{~cm}^{-3}$. The mineral is biaxial negative with $\alpha 1.676, \beta 1.688, \gamma$ $1.692(\lambda 590 \mathrm{~nm})$, all $\pm 0.002,2 V$ (meas. $)=65.3(1.2)^{\circ}, 2 V($ calc. $)=59.6^{\circ}$, with no determined dispersion. Optical orientation is

|  | a | $\boldsymbol{b}$ | $\boldsymbol{c}$ |
| :---: | :---: | :---: | :---: |
| $X$ | $87.8^{\circ}$ | $92.3^{\circ}$ | $126.7^{\circ}$ |
| $Y$ | $96.0^{\circ}$ | $168.2^{\circ}$ | $36.9^{\circ}$ |
| $Z$ | $173.6^{\circ}$ | $78.5^{\circ}$ | $93.0^{\circ}$ |

It is pleochroic with $X=$ black, $Y=$ black, $Z=$ orange-brown. A Gladston-Dale compatibility index of 0.025 is rated as excellent.

The infrared powder absorption spectrum was recorded with a Nicolet FTIR 740 spectrophotometer in the range $4000-400 \mathrm{~cm}^{-1}$ (Fig. 2). In the principal OH -stretching region (3800-3000 $\mathrm{cm}^{-1}$ ), the spectrum shows a broad absorption between $\sim 3610$ and $\sim 3300 \mathrm{~cm}^{-1}$ with a maximum at $\sim 3525 \mathrm{~cm}^{-1}$ in accord with the presence of several OH and $\mathrm{H}_{2} \mathrm{O}$ groups in the
structure. Several weak bands between 3000 and $2000 \mathrm{~cm}^{-1}$ and weak bands at 1480 and 1377 $\mathrm{cm}^{-1}$ are due to glue that was used during transport of the crystals and subsequently could not be completely removed from the very delicate crystals. There is a band at $1637 \mathrm{~cm}^{-1}$ due to the $\mathrm{H}-\mathrm{O}-\mathrm{H}$ bend of $\mathrm{H}_{2} \mathrm{O}$ groups in the structure. There is a sharp intense band at 958 with shoulders at 1070, 1031 and $908 \mathrm{~cm}^{-1}$ due to the various stretching modes of the $\mathrm{SiO}_{4}$ group, and weaker bands at $654,550,531$ and $453 \mathrm{~cm}^{-1}$ due to complex lattice modes involving the octahedra and coupled motions between the various polyhedra.

## Chemical composition

The chemical composition of veblenite was determined with a Cameca SX-100 electronmicroprobe in wavelength-dispersion mode with an accelerating voltage of 15 kV , a specimen current of 20 nA , a beam size of $10 \mu \mathrm{~m}$ and count times on peak and background of 20 and 10 s , respectively. The following standards were used: $\mathrm{Ba}_{2} \mathrm{NaNb}_{5} \mathrm{O}_{15}(\mathrm{Ba}, \mathrm{Nb}), \mathrm{SrTiO}_{3}(\mathrm{Sr})$, titanite (Ti), diopside ( $\mathrm{Si}, \mathrm{Ca}$ ), andalusite ( Al ), fayalite ( Fe ), spessartine $(\mathrm{Mn})$, forsterite $(\mathrm{Mg})$, gahnite $(\mathrm{Zn})$ orthoclase (K), albite (Na), pollucite (Cs) and F-bearing riebeckite (F). $\mathrm{Sn}, \mathrm{Zr}, \mathrm{Ta}, \mathrm{Pb}$ and Rb were sought but not detected; Li and Be were sought by LA-ICP-MS but not detected. Data were reduced using the PAP procedure of Pouchou and Pichoir (1985). $\mathrm{H}_{2} \mathrm{O}$ and the $\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}$ ratio were calculated from structure refinement. The low total of $\sim 91 \mathrm{wt} \%$ is due to the thinness of the crystal. We did not have material sufficient for direct determination of $\mathrm{H}_{2} \mathrm{O}$, but the presence of $\mathrm{H}_{2} \mathrm{O}$ was confirmed by infrared spectroscopy (see above). The chemical composition of veblenite is given in Table 2. The empirical formula (based on $\mathrm{Si}+\mathrm{Al}=20$ atoms p.f.u. $)$ is $\left(\mathrm{K}_{0.53} \mathrm{Ba}_{0.28} \mathrm{Sr}_{0.03} \square_{0.16}\right)_{\Sigma 1}\left(\mathrm{~K}_{0.72} \mathrm{Cs}_{0.07} \square_{1.21}\right)_{\Sigma 2}\left(\mathrm{Na}_{0.72} \mathrm{Ca}_{0.17} \square_{1.11}\right)_{\Sigma 2}$ $\left(\mathrm{Fe}^{2+}{ }_{5.32} \mathrm{Fe}^{3+}{ }_{4.13} \mathrm{Mn}^{2+}{ }_{5.97} \mathrm{Ca}_{0.70} \mathrm{Zn}_{0.15} \mathrm{Mg}_{0.07} \square_{0.66}\right)_{\Sigma 17}\left(\mathrm{Nb}_{2.90} \mathrm{Ti}_{0.93} \mathrm{Fe}^{3+}{ }_{0.17}\right)_{\Sigma 4}\left(\mathrm{Si}_{19.61} \mathrm{Al}_{0.39}\right)_{\Sigma 20} \mathrm{O}_{77.01} \mathrm{H}_{16.08}$ $F_{0.38}, Z=1$.

## X-ray powder diffraction

The powder-diffraction pattern for veblenite was recorded at the Canadian Museum of Nature using a Bruker D8 Discover micro-powder diffractometer with a Hi-Star multi-wire 2D detector at 12 cm, calibrated following Rowe (2009) and using a psudogandolfi approach. Table 3 shows the X-ray powder-diffraction data (for CuKa, $\lambda=1.54178 \AA$; $40 \mathrm{kV} / 40 \mathrm{~mA}$ ) with refined unit-cell dimensions; the latter are in close agreement with corresponding values determined by singlecrystal diffraction (Table 4).

## Crystal structure

$X$-ray data collection and structure refinement
X-ray diffraction data for the single crystal of veblenite were collected with a Bruker P4 diffractometer with a CCD 4K Smart detector (MoKa radiation) using the largest crystal found in the sample included in a feldspar grain, extracted using a razor blade to open the grain; the crystal came off nicely clean or matrix (no additional spots were observed in the diffraction images). The intensities of 25883 reflections using $0.2^{\circ}$ frame and an integration time of 60 s , of which 15845 are unique ( $R_{\text {int }}=9.47 \%$ ). An empirical absorption correction (SADABS, Sheldrick, 2008) was applied. Only reflections with $-5<h<5,-30<k<30,-20<1<20$, i.e., $46^{\circ} 2 \theta$, corresponding to 4777 unique reflections $R_{\text {int }}=6.66 \%$ were used for refinement. The refined unit-cell parameters were obtained from 7614 reflections with I > 10бI (Table 4). The crystal structure of veblenite was solved in space group $P \overline{1}$ by direct methods using SHELXS (Sheldrick, 2008) and refined with the Bruker SHELXTL Version 5.1 system of programs (Sheldrick, 2008). The crystal structure contains 3 groups of cation sites: D and $\operatorname{Si}$ sites of the H sheet, $M$ sites of the $O$ sheet, and interstitial $A$ and $B$ sites; site labeling is in accord with TSblock minerals (Sokolova, 2006) and astrophyllite-group minerals (Sokolova, 2012). Because of the small size of the single crystal, it was not possible to collect enough reflections for a full
anisotropic refinement. Therefore displacement parameters were refined anisotropically only for atoms of the O sheet, D and Si atoms of H sheets, and interstitial atoms. The occupancies of cations at the $M(1)-M(6)$ sites were fixed (scattering curve of Fe ) while those at the $D(1 \mathrm{~A})-D(2 \mathrm{~B})$ and $M(7)-M(9)$ sites were refined. The observed scattering at the $M(7)-M(9)$ sites was held fixed in the last cycles of refinement (scattering curve of Mn ). Occupancies of atoms were also refined for the interstitial $A(1)$ site (scattering curve of $B a$ ), $A(2 A)-A(2 D)$ sites (scattering curve of K ), $B$ site (scattering curve of Na ), and for anion sites $[W(1)-W(5)]$, corresponding to interstitial $\mathrm{H}_{2} \mathrm{O}$ groups, with $\mathrm{U}_{\text {iso }}$ fixed at $0.05 \AA^{2}$. The structure model was refined to an $R_{1}$ value of $9.05 \%$.

At the last stages of the refinement, 3 peaks with magnitudes of ca. 1.5 el were found as satellites of the $M(1), M(6)$ and $M(9)$ sites. Occupancies of atoms at these subsidiary peaks were refined with the scattering curves of $\mathrm{Fe}, \mathrm{Fe}$ and Mn , respectively, and with $\mathrm{U}_{\text {iso }}$ fixed at $0.01 \AA^{2}$. Refined occupancies of these subsidiary peaks vary from 2 to $5 \%$. Scattering curves for neutral atoms were taken from International Tables for Crystallography (Wilson, 1992). The unusual cell setting chosen for the structure (Tables 1,3 and 4) is obtained from the reduced cell $a=5.3761(3), b=17.7419(10), c=18.6972(11) \AA, \alpha=97.991(1), \beta=93.032(2), \gamma=$ $102.050(1)^{\circ}$ via the transformation $(1,0,0|0,1,-1| 0,0,1)$. The chosen setting with a large $\alpha$ is preferred in order to compare the structure topology of veblenite to those of jinshajiangite and niobophyllite. Details of data collection and structure refinement are given in Table 4, final atom parameters are given in Table 5, selected interatomic distances in Table 6, refined sitescattering values and assigned populations for selected cation sites are given in Table 7, and bond valences in Table 8 (bond-valence parameters from Brown, 1981). Tables of structure factors and anisotropic displacement parameters for several atoms have been deposited with the Principal Editor of Mineralogical Magazine and are available from www.minersoc.org/pages/e journals/dep mat.html.

Site-population assignment

As we did not have enough material to determine the $\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}$ ratio directly by Mössbauer spectroscopy, the $\mathrm{Fe}^{3+} / \mathrm{Fe}^{2+}$ ratio was calculated from the $\mathrm{M}-\mathrm{O}$ distances of the $\mathrm{M}(1-9)$ octahedra of the O sheet; minor $\mathrm{Fe}^{3+}$ was added to fill ( $\mathrm{Nb}, \mathrm{Ti}$ )-dominant $D$ sites. Consider first the two $(\mathrm{Nb}, \mathrm{Ti})$-dominant $D(1,2)$ sites in the H sheet. Each $D$ site is split in two sites: $D(1 \mathrm{~A})$ and $D(1 \mathrm{~B})$, and $D(2 \mathrm{~A})$ and $D(2 \mathrm{~B})$. We assign cations to these sites assuming $50 \%$ occupancy for each split site. The split site is related to a different charge arrangement: $D(1 \mathrm{~A})$ and $D 2(B)$ sites are closer to the O sheet and have a lower charge, while $D(1 \mathrm{~B})$ and $D(2 \mathrm{~A})$ sites are further from the O sheet and are almost fully occupied by Nb . Total $\mathrm{Nb}+\mathrm{Ti}$ is $<4$ a.p.f.u. Thus we assign $\mathrm{Fe}^{3+}$ to achieve $100 \%$-occupancy of the $D$ sites. The resulting calculated site-scattering is significantly lower than the aggregate refined scattering at these sites (141.19 versus 153.42 e.p.f.u., Table 7), indicating heavier atom composition, although the chemical analyses confirmed the absence of Sn and Ta . We assign Si with minor Al to ten tetrahedral Si sites, with <Si-O> = $1.615 \AA$.

Consider next the octahedral sites in the O sheet. There are nine independent [6]coordinated $M$ sites [M(1-9)], with size of a corresponding octahedron increasing from $M(1)$ to $M(9)$; the $M(1-9)$ sites can accommodate up to 17 a.p.f.u. Site scattering for the $M$ sites varies from 20 to 26 electrons per site (e.p.s.), with the lowest values observed at the $M(7-9)$ sites. Total refined scattering at the $M$ sites is 413.5 e.p.f.u., which agrees well with the calculated site-scattering from the remaining $\mathrm{Fe}^{3+}$ plus $\left(\mathrm{Fe}^{2+}+\mathrm{Mn}^{2+}+\mathrm{Ca}+\mathrm{Zn}+\mathrm{Mg}\right)$, with a vacancy of 0.66 p.f.u. On the basis of observed bond distances and incident bond-valence at these sites (Table 8), we assign $2 / 3$ of $\mathrm{Fe}^{3+}$ and $1 / 3$ of $\mathrm{Fe}^{2+}$ to each $M(1), M(2)$ and $M(3)$ site (see above) (Table 7). We allocate the remaining $\mathrm{Fe}^{3+}$ equally to the $M(4)$ and $M(5)$ sites, plus an equal quantity of $\mathrm{Mn}^{2+}$ to account for the larger size of these two octahedra. The $\mathrm{M}(6)$ octahedron is larger and we assign the remaining $\mathrm{Fe}^{2+}$ and $\mathrm{Mn}^{2+}$. The larger $M(7)-M(9)$ sites give different refined scattering values, being higher for the $M(8)$ site, with the $M(8)$ octahedron being slightly smaller than the $M(7,9)$ octahedra. Therefore we assign all the $\mathrm{Zn}+\mathrm{Mg}$ to the $M(8)$ site, while

Ca is distributed equally among the $M(7)$ and $M(9)$ sites, leaving a $15 \%$ vacancy at the latter two sites in agreement with the refined site-scattering at these sites (Table 7). Thus we have three $\mathrm{Fe}^{3+}$-dominant $M(1,2,3)$ sites $[<\mathrm{M}-\varphi>=2.06 \AA$ (where $\varphi=\mathrm{O}, \mathrm{OH})$ ]; three $\mathrm{Fe}^{2+}$-dominant $M(4,5,6)$ sites $\left[\langle M-\varphi\rangle=2.14 \AA\right.$ ] and three $\mathrm{Mn}^{2+}$-dominant $M(7,8,9)$ sites $\left.[<M-\varphi\rangle=2.21 \AA\right]$.

Consider the interstitial $A(1,2)$ and $B$ sites, with refined site-scattering values of 26.89, 17.53 and 11.32 e.p.f.u., respectively (Table 7). The cations to be assigned to these sites are $\mathrm{Na}, \mathrm{Ba}, \mathrm{Sr}, \mathrm{K}$ and Cs , with a total scattering of 55.74 e.p.f.u. (Table 7). $A(2)$ is split into four sites: $A(2 \mathrm{~A}), A(2 \mathrm{~B}), A(2 \mathrm{C})$ and $A(2 \mathrm{D})$. The $\mathrm{A}(1)$ and $\mathrm{A}(2 \mathrm{~A}-2 \mathrm{D})$ polyhedra are larger (mean bond distances of 3.17 and $3.26 \AA$, respectively), while the $B$ polyhedron is smaller, with $\langle B-\varphi\rangle=2.72$ $A$, and $B$ has lower scattering than the $A$ sites. Therefore, we allocate all the available Na as well as the remaining Ca to the $B$ site, which yields 11.32 e.p.f.u. in good agreement with the refined value of 11.3(4) e.p.f.u. Vacancy is therefore dominant at the $B$ site (Table 7). The higher refined scattering at the $A(1)$ site forces us to assign all the $\mathrm{Ba}+\mathrm{Sr}$ from the analysis to that site. Cs is the largest cation left to be assigned and we consequently allocate it to the $A(2 A-$ 2D) sites. The remaining $K$ was distributed so that the best agreement with the refined sitescattering was obtained (Table 7). The $A(1)$ site is K dominant, while the $A(2)$ sites are vacancy dominant.

## General topology of the crystal structure

The crystal structure of veblenite consists of HOH layers stacked along $\mathbf{c}$ (Fig. 3): two H sheets and an O sheet constitute an HOH layer, with a new topology that has not been found in any other HOH structures. M octahedra share common edges to form a modulated trioctahedral close-packed (O) sheet parallel to (001) (Fig. 3). The H sheet is composed of $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups, $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbons and [6]-coordinated Nb -dominant D octahedra (Fig. $4 b$ ). Two H sheets of the HOH layer are identical. This is the first occurrence of a $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbon in a mineral structure, and we call it the veblenite ribbon. This is also the first occurrence of the H sheets of the
composition $\left[\mathrm{Nb}_{3} \mathrm{Ti}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2}\right]^{15-}$. H sheets link to the central O sheet via common anions of $M$ octahedra and Si and D polyhedra. The $t_{1}$ repeat of $\sim 5.5 \AA$ is common to Ti-disilicates (Sokolova, 2006) and astrophyllite-group minerals (Sokolova, 2012). The HOH layers are stacked along [001] and show a lateral shift along [010], which allows linkage via common anions of $D$ polyhedra of the $H$ sheets. This type of linkage yields two types of channels running along [100]: wide and narrow channels that alternate in both [010] and [001] directions (Fig. 5a). Along [100], interstitial $B$ sites are partly occupied by Na (Fig. 5a). Within the narrow [100] channels, $A(1)$ interstitial sites are almost fully occupied by K (Fig. 5a), while at the narrower sides of the wide [001] channels, there are interstitial $K$ cations in partially occupied $A(2 A-D)$ split positions. In the central part of the wide channels, $\mathrm{H}_{2} \mathrm{O}$ groups coordinate K at the $A(2)$ sites (Fig. 5a).

The crystal structure of veblenite is closely related to the structure of nafertisite, ideally $(\mathrm{Na}, \mathrm{K})_{2}\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \text { प }\right)_{10}\left[\mathrm{Ti}_{2}\left(\mathrm{Si}^{2}, \mathrm{Fe}^{3+}, \mathrm{Al}\right)_{12} \mathrm{O}_{37}\right](\mathrm{OH}, \mathrm{O})_{6}$ (Ferraris et al., 1996), niobophyllite, ideally $\mathrm{K}_{2} \mathrm{NaFe}^{2+}{ }_{7}\left(\mathrm{Nb}, \mathrm{Ti}_{2}\right)_{2}\left(\mathrm{Si}_{4} \mathrm{O}_{12}\right)_{2} \mathrm{O}_{2}(\mathrm{OH})_{4}(\mathrm{O}, \mathrm{OH})$ (Cámara et al., 2010), an astrophyllite-group mineral, and jinshaijangite, ideally $\mathrm{NaBaFe}^{2+}{ }_{4} \mathrm{Ti}_{2}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2} \mathrm{O}_{2}(\mathrm{OH})_{2} \mathrm{~F}$ (Sokolova et al., 2009), a TS-block mineral of Group II (Sokolova, 2006). The topology of the veblenite structure was generated by Hawthorne (2012) who used a structure-generating function for polysomatic TOT and HOH structures.

## Description of cation and anion sites

## Cation sites

The crystal structure contains 3 groups of cation sites: $D$ and $S i$ sites of the $H$ sheet, $M$ sites of the $O$ sheet, and interstitial $A$ and $B$ sites (see above).

O sheet

There are nine cation sites in the O sheet: the $\mathrm{Fe}^{3+}$-dominant $M(1,2,3)$ sites, the $\mathrm{Fe}^{2+}$ dominant $M(4,5,6)$ sites and $\mathrm{Mn}^{2+}$-dominant $M(7,8,9)$ sites (Fig. 4a). Fe ${ }^{3+}$ occurs only at the $M(1-6)$ sites and vacancies are present at the $M(7,8,9)$ sites. The $M(1,2,3)$ sites are occupied by $2 / 3 \mathrm{Fe}^{3+}$ and $1 / 3 \mathrm{Fe}^{2+}$ with $\langle\mathrm{M}(1,2,3)-\varphi\rangle=2.06 \AA$ ( $\varphi=$ unspecified anion), and are coordinated by four O atoms shared with Si atoms and two monovalent $\mathrm{X}_{\mathrm{A}}{ }_{\mathrm{A}}$ anions (see section on Anion sites below) (Tables 6 and 7). The $M(4,5)$ sites are occupied by $0.62 \mathrm{Fe}^{2+}$ a.p.s., 0.19 a.p.s. $\mathrm{Fe}^{3+}$ and $0.19 \mathrm{Mn}^{2+}$ a.p.f. with $\langle\mathrm{M}(4,5)-\varphi\rangle=$ $2.13 \AA$, and are coordinated by three O atoms shared with Si atoms, one O atom at the $X_{D}{ }_{D}$ site (shared with a $D$ atom), and two monovalent $X_{A}^{\circ}$ anions (Tables 6,7 and 8). The $M(6)$ site is occupied only by divalent cations ( 0.61 a.p.s. $\mathrm{Fe}^{2+}$ and 0.19 a.p.f. $\mathrm{Mn}^{2+}$ ) with a $<\mathrm{M}(6)-\varphi>$ distance of $2.15 \AA$ and, like the $M(4,5)$ sites, it is coordinated by three $O$ atoms shared with Si atoms, one $\mathrm{X}^{\mathrm{D}}$ divalent anion occupied by oxygen, and two monovalent $X_{A}{ }_{A}$ anions (Tables 6,7 and 8 ) The $M(7,9)$ sites are occupied by 0.67 a.p.s. $\mathrm{Mn}^{2+}, 0.18$ a.p.s. Ca and 0.15 vacancy and are coordinated by four O atoms shared with Si atoms, one $X^{\circ}{ }_{D}$ divalent anion occupied by oxygen, and one monovalent $X_{A}^{\circ}$ anion, with a $<M(7,9)-\varphi>$ distance of $2.22 \AA$, while the $M(8)$ site is occupied by 0.86 a.p.s. $\mathrm{Mn}^{2+}$, 0.08 a.p.s. Zn and 0.03 a.p.s. Mg and 0.03 vacancy per site and is coordinated by three O atoms shared with Si atoms, one $\mathrm{X}^{\mathrm{O}}$ divalent anion occupied by oxygen, and two monovalent $X_{A}{ }_{A}$ anions, with $\langle M(8)-\varphi\rangle=2.19 \AA$ (Tables 6,7 and 8 ). Cations of the $O$ sheet sum to $\left(\mathrm{Fe}^{2+}{ }_{5.32} \mathrm{Fe}^{3+}{ }_{4.13} \mathrm{Mn}^{2+}{ }_{5.97} \mathrm{Ca}_{0.70} \mathrm{Zn}_{0.15} \mathrm{Mg}_{0.07} \square_{0.66}\right.$ ) a.p.f.u. (Table 7), with ideal and simplified compositions of $\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right)$ and $\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}$ a.p.f.u., respectively.

## $H$ sheets

In the H sheets, there are ten tetrahedrally coordinated sites occupied by Si with a $<\mathrm{Si}-$ O> distance of $1.615 \AA$ (Table 6, Fig. $4 b, c$ ). The longest Si-O distance is usually the one
to the O atom shared with the M atoms in the O sheet. There are two Si tetrahedra that are slightly larger [ $\mathrm{Si}(2)$ and $\mathrm{Si}(8)$, with $<\mathrm{Si}-\mathrm{O}>=1.63 \AA$ ] and the $\operatorname{Si}(2,8)$ sites may therefore host up to $10 \% \mathrm{AI}$. Interestingly, the $\mathrm{Si}(2,8)$ tetrahedra share an oxygen atom with two $\mathrm{Mn}^{2+}$-dominant $\mathrm{M}(7,8)$ octahedra; i.e., two of the largest ones] and a $\mathrm{Fe}^{3+}$ dominant $M(3)$ octahedron], while all other Si tetrahedra share an apex with one $\mathrm{Fe}^{2+}$ dominant, one $\mathrm{Mn}^{2+}$-dominant and one $\mathrm{Fe}^{3+}$-dominant octahedra, and would nominally have less incident bond-valence. In fact, these two tetrahedral sites have the lowest incident bond-valence sums among all the Si sites (Table 8). Sokolova (2012) showed that $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups of the astrophyllite $\left[\mathrm{Si}_{4} \mathrm{O}_{12}\right]$ ribbon have a very restricted range of $\mathrm{Si}-\mathrm{O}-$ Si angles, i.e., $138-143^{\circ}$, compared to the $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups in the Ti-silicate minerals, which show a wider range of $\mathrm{Si}-\mathrm{O}-\mathrm{Si}$ angles: $\sim 134$ to $\sim 206^{\circ}$ (Sokolova, 2006). The $\mathrm{Si}-\mathrm{O}-\mathrm{Si}$ angles in veblenite range from 138 to $143^{\circ}$ (Table 6) as in the astrophyllite-group structures, indicating reduced flexibility of the tetrahedral ribbons to match connectivity with the $O$ sheet.

There are two [6]-coordinated $D(1,2)$ sites that each split into two sites: $D(1 \mathrm{~A}, 1 \mathrm{~B})$ and $D(2 \mathrm{~A}, 2 \mathrm{~B})$. Each of the latter four sites is octahedrally coordinated by six O atoms, with <D-O> $=1.98 \AA$ (Table 6). There are three Nb-dominant sites: $D(1 \mathrm{~A}, 1 \mathrm{~B}, 2 \mathrm{~A})$ and one Ti-dominant $D(2 \mathrm{~B})$ site, with total $\mathrm{Nb}_{2.90} \mathrm{Ti}_{0.93} \mathrm{Fe}^{3+}{ }_{0.17}$, ideally $\mathrm{Nb}_{3}$ Ti a.p.f.u. (Table 7). In veblenite, D octahedra of adjacent HOH layers connect via a bridge oxygen at the $X^{P}{ }_{D}$ site (Fig. 3). Four of six O atoms coordinating each $D$ atom are common to a D octahedron and four Si tetrahedra; one atom is common to a D octahedron and three M octahedra of the $O$ sheet. The $X_{D}^{\circ}(1)$ atom belongs to the $D(1 A, 1 B)$ octahedra and the $X_{D}^{\circ}(2)$ atom belongs to the $D(2 A, 2 B)$ octahedra, and the sixth $O$ atom occurs at the $X_{D}{ }_{D}$ site. The shortest and the longest $\mathrm{D}-\mathrm{X}^{\mathrm{O}}{ }_{\mathrm{M}}$ distances are $1.86 \AA$ and $2.23 \AA$, respectively, while the shortest and the longest $\mathrm{D}-\mathrm{X}^{P}{ }_{\mathrm{D}}$ distances are $1.79 \AA$ and $2.15 \AA$, respectively (Fig. 6). These distances are within the observed distances for Nb and Ti at the $M^{H}$ sites
in the H sheet in Ti-disilicates: e.g., epistolite (Sokolova and Hawthorne, 2004), vuonnemite (Ercit et al., 1998), bornemanite (Cámara and Sokolova, 2007), nechelyustovite (Cámara and Sokolova, 2009) and kazanskyite (Cámara et al., 2012).

However we are left with a question: which two of four $D(1 A-2 B)$ sites can form the $\mathrm{D}-\mathrm{X}^{P_{D}}$-D bridges. To do this, we must consider SRO (Short-range order) arrangements.

Short-range order arrangements of the $D$ sites. The $X^{P}{ }_{D}$ atom receives bondvalence contributions from atoms at four $D$ and two $B$ sites occupied at $50 \%$ mainly by Nb and Na (contributions from the $A(2)$ site occupied by K at ca. $40 \%$ are too small and not considered here) (Table 7). Note that $D(1 A)-D(1 B)$ and $D(2 A)-D(2 B)$ occur at short distances of $\sim 0.33 \AA$ and cannot be locally occupied. Hence, in the structure, the $X^{P}{ }_{D}$ site is [4] coordinated by two $D$ sites and two $B$ sites. The incident bond-valence of 1.92 vu (valence units) at the $X^{P}{ }_{D}$ atom (Table 8) tell us that the $X_{D}{ }_{D}$ site is occupied by an $O$ atom both in a long-range structure and short-range-order arrangements. Consider the short-range-ordered arrangement where all cation sites ( $D$ and $B$ ) are fully occupied, i.e., at $100 \%$. To calculate the bond-valence contributions to the $X_{D}^{P}$ atom from $D$ and $B$ atoms, we must multiply their bond-valence contributions by 2 (corresponding to $50 \%$ occupancy): $0.24 \times 2=0.48 \mathrm{vu}[\mathrm{D}(1 \mathrm{~A})], 1.34 \mathrm{vu}[\mathrm{D}(1 \mathrm{~B})], 1.30 \mathrm{vu}[\mathrm{D}(2 \mathrm{~A})], 0.48 \mathrm{vu}[\mathrm{D}(2 \mathrm{~B})]$ and $0.24 \mathrm{vu}(B \times 2)$. Contributions from $D(1 A), D(2 B)$ and $2 B$ atoms sum to 1.20 vu which is too low for an $O$ atom. Contributions from the $D(1 B), D(2 A)$ and $2 B$ atoms sum to 2.88 vu which is too high for an O atom. We are left with two possible short-rangeordered arrangements: contributions from (1) $[D(1 A), D(2 A)$ and $2 B]$ and (2) $[D(1 B)$, $D(2 B)$ and $2 B$ ] atoms sum to 2.02 and 2.06 vu, respectively, compensating the $2^{-}$charge of an $O$ atom at the $X^{P}{ }_{D}$ site. Hence two types of $D-X^{P}{ }_{D}-D$ bridges can occur in the structure: (SRO-1) $D(1 A)-O-D(2 A)$ and (SRO-2) $D(1 B)-O-D(2 B)$ (Fig. 6). Possible occurrence of these two short-range-ordered arrangements explains the difference in D -
$X^{P}{ }_{D}$ and $D-X_{D}{ }_{D}$ distances. For SRO-1, $D(1 A)-O-D(2 A)$, the $X^{P}{ }_{D}$ anion receives a larger bond-valence contribution from $\mathrm{D}(2 \mathrm{~A})(1.30 \mathrm{vu}$, shorter distance of $1.81 \AA$ ) and needs a smaller contribution from $\mathrm{D}(1 \mathrm{~A})(0.4 \mathrm{vu}$, longer distance of $2.14 \AA$ ). Note that the longer $D(1 A)-X^{P}{ }_{D}$ distance of $2.14 \AA$ corresponds to the shorter $D(1 A)-X^{\circ}{ }_{D}(1)$ distance of $1.88 \AA$ [cf. $D(2 A)-X^{P}{ }_{D}=1.81 \AA$ versus $D(2 A)-X^{\circ}{ }_{D}(2)=2.20 \AA$ ] (Fig. 6). It seems that the order of $M$ cations in the $O$ sheet forces the $D$ atoms to change their positions in order to satisfy the bond-valence requirements at the $\mathrm{X}^{\circ}{ }_{\mathrm{D}}$ anions.

The D cations of two H sheets sum to $\mathrm{Nb}_{2.90} \mathrm{Ti}_{0.93} \mathrm{Fe}^{3+}{ }_{0.17}$ a.p.f.u. (Table 7), with ideal and simplified compositions of $\mathrm{Nb}_{3} \mathrm{Ti}$ and $(\mathrm{Nb}, \mathrm{Ti})_{4}$ a.p.f.u., respectively. We will consider the Si atoms as part of the complex oxyanions (see below).

## Interstitial sites

In veblenite, there are two interstitial sites: $A$ and $B$. There are two $A$ sites: $A(1)$ in the narrow channel and $A(2)$ in the wider channel (Fig. 5a). The $A(1)$ site is [12]-coordinated by the basal oxygen atoms of Si tetrahedra on both sides of the channel. It is almost fully occupied by 0.53 a.p.s. K, 0.28 a.p.s. Ba and 0.03 a.p.s. $S r$ and with $0.16 \square$ per site, and $\langle A(1)-\varphi\rangle=3.17 \AA$ (Table 6). We write the ideal and simplified compositions of the $A(1)$ site as K and $(\mathrm{K}, \mathrm{Ba})$, respectively. The $A(2)$ site is split in 4 mutually exclusive positions with partial occupancy (Table 7), being dominantly vacant (Fig. 5b). These split positions are [9-10]-coordinated by oxygen from the basal planes of tetrahedra of the adjacent H layers and by $\mathrm{H}_{2} \mathrm{O}$ groups at partly occupied $W$ sites (see section on Anion sites below), with $\langle A(2 A, B)-\varphi\rangle=3.19 \AA,\langle A(2 C)-\varphi\rangle=3.12 \AA$, and $\langle A(2 D)-\varphi\rangle=3.26 \AA$. Aggregate composition for the $A(2 A-2 D)$ sites is $0.60 \square$ p.s. +0.36 a.p.s. $K$, and 0.04 a.p.s. Cs. We write the ideal and simplified compositions of the $A(2)$ site as ( $\square \mathrm{K}$ ) and $(\square, K)_{2}$, respectively. The occupancy of $A(2)$ sites is probably related to the $\mathrm{Nb}_{-1} \mathrm{Ti}$ substitution at the adjacent $D$ sites. Therefore, the $A(2)$ composition is constrained by
the relation $\mathrm{A}(2)_{\mathrm{n}}=\mathrm{Nb}_{4-\mathrm{n}} \mathrm{Ti}_{\mathrm{n}}$, although the $\mathrm{Nb}_{-1} \mathrm{Ti}$ substitution could be compensated also by increasing the amount of $\mathrm{Fe}^{3+}$ at the $M(1-3)$ sites.

The $B$ site occurs between four $D$ sites (from adjacent HOH layers, Figs. $5 a, b$ ); they are [10]-coordinated by the basal oxygen atoms of the Si tetrahedra of the adjacent HOH layers and by the oxygen atom shared by two D atoms from different HOH layers, with <B-O> $=2.72 \AA$. The $B$ site is occupied at $45 \%$ by 0.36 a.p.s. Na and 0.09 a.p.s. Ca (Table 7). We write the ideal and simplified compositions of the $B$ site as ( $\square \mathrm{Na}$ ) and $(\square, \mathrm{Na})$, respectively, and the ideal and simplified compositions of the interstitial $A(1) A(2) B$ sites are $\mathrm{K}(\square \mathrm{K})(\square \mathrm{Na})=\mathrm{K}_{2} \square_{2} \mathrm{Na}$ and $(\mathrm{K}, \mathrm{Ba})(\square, \mathrm{K})_{2}(\square, \mathrm{Na})_{2}$, respectively.

We write the cation part of the ideal and simplified formulas the sum of the $M$ sites of the O sheet $+D$ sites of two H sheets + interstitial $A$ and $B$ sites: (1) ideal formula: $\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right)+\mathrm{Nb}_{3} \mathrm{Ti}+\mathrm{K}(\square \mathrm{K})(\square \mathrm{Na})=\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}$, with a total charge of $58^{+}$; $(2)$ simplified formula: $\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}+(\mathrm{Nb}, \mathrm{Ti})_{4}+(\mathrm{K}, \mathrm{Ba})(\square, \mathrm{K})_{2}(\square, \mathrm{Na})_{2}=$ $\left[(\mathrm{K}, \mathrm{Ba}, \square)_{3}(\square, \mathrm{Na})_{2}\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}(\mathrm{Nb}, \mathrm{Ti})_{4}\right]$ a.p.f.u.

## Anion sites

Following the nomenclature of the anion sites by Sokolova (2012), we label the X anions: $2 \mathrm{X}^{\circ}{ }_{\mathrm{D}}$ = anions at common vertices of 3 M and D polyhedra; $5 \mathrm{X}_{\mathrm{A}}^{\mathrm{O}}=$ monovalent anions at common vertices of 3 M polyhedra; $\mathrm{X}_{\mathrm{D}}^{P}=$ apical anion shared by two D cations from two different HOH layers. Additionally, there are 5 interstitial $\mathrm{H}_{2} \mathrm{O}$ groups (with partial occupancy) which we label $W(1-5)$.

There are 29 anion sites, $\mathrm{O}(1-29)$, occupied by O atoms which form the tetrahedral coordination of the Si atoms (Tables 5,6 ). $\mathrm{Si}(1-8)$ and $\mathrm{O}(1-29)$ atoms form two distinct complex oxyanions, $\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}$ and $\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2}$ per formula unit. There are two sites, $X^{\circ}{ }_{D}(1,2)$, which are common anions for the D polyhedra and three octahedra of the O sheet (Tables 5,6 ) and give
$\mathrm{O}_{4}$ p.f.u. These anions receive bond valences of 1.71-1.74 vu (Table 8) and hence are O atoms. The low incident bond-valence is probably due to the split of the $D$ sites. There is one anion, $X^{P}{ }_{D}$, shared by two $D$ atoms of adjacent HOH layers; this anion receives a bond valence of 1.92 vu (Table 8) and hence is an O atom. The $\mathrm{X}_{\mathrm{D}}$ site gives $\mathrm{O}_{2}$ p.f.u. There are five $\mathrm{X}_{\mathrm{A}}{ }_{A}(1-5)$ sites that are common anions for three octahedra of the O sheet. They receive bond valences of $1.20-1.38 \mathrm{vu}$ (Table 8), and hence are monovalent anions ( OH or F ). The chemical analysis gives F 0.38 a.p.f.u. and we need $10-0.38=9.62 \mathrm{OH}$ p.f.u. to fill these five sites. Therefore, we assign $\mathrm{OH}_{9.62} \mathrm{~F}_{0.38}$ to the five $X^{\mathrm{O}}{ }_{\mathrm{A}}(1-5)$ sites. Ideally, the five $X_{\mathrm{A}}{ }^{\text {s sites give }(\mathrm{OH})_{10} \text { p.f.u. There }}$ are $\mathrm{H}_{2} \mathrm{O}$ groups at the five $W(1-5)$ sites, and the O atoms of the $\mathrm{H}_{2} \mathrm{O}$ groups are bonded to the A(2A-D) cations. The $W(1-5)$ sites are partly occupied (Table 5): $W(1)$ and $W(2)$ at 57 and $43 \%$, and $W(3,4,5)$ at 23,17 and $21 \%$, respectively. Local occupancy of both $W(1)$ and $W(2)$ is incompatible as $\mathrm{W}(1)-\mathrm{W}(2)=2.59(5) \AA$. Each $\mathrm{H}_{2} \mathrm{O}$ group at one of these two sites bonds weakly to the basal oxygen atoms of the tetrahedra in the $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbon. Occupancy of the $W(3)$ site cannot be locally associated with occupancy of the $W(4)$ and $W(5)$ sites as $W(3)-W(5)=$ 1.11(12) $\AA$ and $W(3)-W(5)=2.06(15) \AA$. The occupancy of the $W(3-5)$ sites is linked to the occupancy of the $A(2 A-2 D)$ sites. The observed occupancy of the $W(3-5)$ is lower than that at the $A(2 A-2 D)$ sites, probably due to the difficulty in correctly calculating the scattering at split positions with data from such a thin crystal. In veblenite, the $W(1,2)$ and $W(3-5)$ sites give $\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ and $\left[\left(\mathrm{H}_{2} \mathrm{O}\right)_{1.23} \square_{2.77}\right]$ p.f.u., respectively, ideally $\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ p.f.u.

To conclude, we write the anion part of the ideal structural formula as the sum of the complex anions and the simple anions (charge is given in brackets): $\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(12^{-}\right)+\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2}$ $\left(24^{-}\right)+\mathrm{O}_{4}\left[\mathrm{X}_{\mathrm{D}}^{\mathrm{O}}(1,2)\right]\left(8^{-}\right)+\mathrm{O}_{2}\left[\mathrm{X}_{\mathrm{D}}\right]\left(4^{-}\right)+(\mathrm{OH})_{10}\left[\mathrm{X}_{\mathrm{A}}^{\mathrm{O}}(1-5)\right]\left(10^{-}\right)+\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}[\mathrm{~W}(1-5)]=$ $\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$, with a total charge of $58^{\circ}$.

Based on the SREF results and bond-valence calculations, we write the ideal and simplified formulae of veblenite as the sum of the cation and anion components:
$\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}_{( }\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ and $(\mathrm{K}, \mathrm{Ba}, \square)_{3}(\square, \mathrm{Na})_{2}$
$\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}\left(\mathrm{Nb}, \mathrm{Ti}_{4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right.$, respectively, $Z=1$. The validity of the ideal formula is supported by the good agreement between the total charges for cations in the ideal and empirical formulae: $3^{+}\left[\mathrm{K}_{2} \square_{2} \mathrm{Na}\right]+36^{+}\left[\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \mathrm{\square}\right]+19^{+}\left[\mathrm{Nb}_{3} \mathrm{Ti}\right]=58^{+}$versus $3^{+}$ $\left[\square_{2.48} \mathrm{~K}_{1.25} \mathrm{Na}_{0.72} \mathrm{Ba}_{0.28} \mathrm{Ca}_{0.17} \mathrm{Cs}_{0.07} \mathrm{Sr}_{0.03}\right]+36.81^{+}\left[\left(\mathrm{Mn}^{2+}{ }_{5.97} \mathrm{Fe}^{2+}{ }_{5.32} \mathrm{Fe}^{3+}{ }_{4.13} \mathrm{Ca}_{0.70} \square_{0.66} \mathrm{Zn}_{0.15} \mathrm{Mg}_{0.07}\right)\right]$ $+18.73^{+}\left[\left(\mathrm{Nb}_{2.90} \mathrm{Ti}_{0.93} \mathrm{Fe}^{2+}{ }_{0.17}\right)\right]=58.54^{+}$.

## The general structural formula of veblenite

Above, we wrote the ideal formulae of veblenite based on the sum of the cation and anion components: $\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}, \mathrm{Z}=1$. The structural formula has the form $\mathrm{A}_{1} \mathrm{~A}_{2} \mathrm{~B}_{2} \mathrm{M}_{17} \mathrm{D}_{4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{X}^{\mathrm{O}}{ }_{\mathrm{D} 4} \mathrm{X}^{P}{ }_{\mathrm{D} 2} \mathrm{X}^{\mathrm{O}}{ }_{\mathrm{A} 10} \mathrm{~W}_{8}$ where A and B are interstitial cations; $M$ and $D$ are cations of the $O$ and $H$ sheets; $X^{O}$ are anions of the $O$ sheet; $X_{D}{ }_{D}$ are common anions for the D cations and from two adjacent HOH layers; and W are $\mathrm{H}_{2} \mathrm{O}$ groups in the wide channels. The structural formula obtained from chemical analysis (Table 2) is therefore $\left(\mathrm{K}_{0.53} \mathrm{Ba}_{0.28} \mathrm{Sr}_{0.03} \square_{0.16}\right)_{\Sigma 1}\left(\mathrm{~K}_{0.72} \mathrm{Cs}_{0.07} \square_{1.21}\right)_{\Sigma 2}\left(\mathrm{Na}_{0.72} \mathrm{Ca}_{0.18} \square_{1.10}\right)_{\Sigma 2}\left(\mathrm{Fe}^{2+}{ }_{5.32} \mathrm{Fe}^{3+}{ }_{4.13} \mathrm{Mn}^{2+}{ }_{5.97}\right.$ $\left.\mathrm{Ca}_{0.70} \mathrm{Zn}_{0.15} \mathrm{Mg}_{0.07} \square_{0.66}\right)_{\Sigma 17}\left(\mathrm{Nb}_{2.90} \mathrm{Ti}_{0.93} \mathrm{Fe}^{3+}{ }_{0.17}\right)_{\Sigma 4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{7.80} \mathrm{Al}_{0.20} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}\left(\mathrm{OH}_{9.78} \mathrm{~F}_{0.22}\right)_{\Sigma 10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{2}$ $\left[\left(\mathrm{H}_{2} \mathrm{O}\right)_{1.23} \square_{2.77}\right]_{54}$. The ideal formulae of veblenite, $\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}^{( }\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}$ $\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$, requires $\mathrm{Nb}_{2} \mathrm{O}_{5}$ 12.76, $\mathrm{TiO}_{2} 2.56, \mathrm{SiO}_{2} 38.46, \mathrm{Fe}_{2} \mathrm{O}_{3}$ 10.22, MnO 15.89, FeO 11.50, $\mathrm{K}_{2} \mathrm{O} 3.01, \mathrm{Na}_{2} \mathrm{O} 0.99, \mathrm{H}_{2} \mathrm{O} 4.61$; total 100.00 wt . \%. The simplified formula of veblenite is $(\mathrm{K}, \mathrm{Ba}, \square)_{3}(\square, \mathrm{Na})_{2}\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}\left(\mathrm{Nb}, \mathrm{Ti}_{4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}\right.$.

## Summary

Veblenite is a new ( $\mathrm{Nb}, \mathrm{Ti}$ )-silicate mineral with a new structure that has no natural or synthetic analogues. It is triclinic: space group $P \overline{1}, a 5.3761(3), b 27.5062(11), c$ 18.6972(9) $\AA, \alpha$ 140.301(3), $\beta$ 93.033(3), $\gamma 95.664(3)^{\circ}, V=1720.96(14) \AA^{3}$. The structural unit of veblenite is an HOH layer. Dominant cations in the O sheet are $\left(\mathrm{Fe}^{2+}+\mathrm{Fe}^{3+}\right)>\mathrm{Mn}^{2+}$, with $\mathrm{Fe}^{2+}>\mathrm{Fe}^{3+}$. The H
sheet is composed of $(\mathrm{Nb}, \mathrm{Ti})$ octahedra, $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups and the veblenite $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbon, a new type of $\mathrm{Si}-\mathrm{O}$ ribbon. In the structure, the HOH layers connect via common anions of ( $\mathrm{Nb}, \mathrm{Ti}$ ) octahedra. In the interstitial space between two HOH layers, K and Na atoms and $\mathrm{H}_{2} \mathrm{O}$ groups constitute the I block.

We write the ideal and simplified formulae of veblenite $(Z=1)$ as
$\mathrm{K}_{2} \square_{2} \mathrm{Na}\left(\mathrm{Fe}^{2+}{ }_{5} \mathrm{Fe}^{3+}{ }_{4} \mathrm{Mn}^{2+}{ }_{7} \square\right) \mathrm{Nb}_{3} \mathrm{Ti}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ and $(\mathrm{K}, \mathrm{Ba}, \square)_{3}(\square, \mathrm{Na})_{2}\left(\mathrm{Fe}^{2+}, \mathrm{Fe}^{3+}, \mathrm{Mn}^{2+}\right)_{17}(\mathrm{Nb}, \mathrm{Ti})_{4}\left(\mathrm{Si}_{2} \mathrm{O}_{7}\right)_{2}\left(\mathrm{Si}_{8} \mathrm{O}_{22}\right)_{2} \mathrm{O}_{6}(\mathrm{OH})_{10}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$, respectively. Aspects of the crystal chemistry of veblenite will be considered in a later paper.

## Acknowledgements

We thank Jeffrey Post and Ian Grey for reviewing the manuscript. FCH was supported by a Canada Research Chair in Crystallography and Mineralogy, by Discovery and Major Installation grants from the Natural Sciences and Engineering Research Council of Canada, and by Innovation Grants from the Canada Foundation for Innovation. FC also thanks Frank Hawthorne for supporting a visiting research period at Winnipeg.

## Figure captions

FIG. 1. Images of veblenite crystals (marked with arrows) in albite (ab) matrix in probe mounting.

FIG. 2. IR spectrum of veblenite.

FIG. 3. General view of the crystal structure of veblenite. Si tetrahedra are orange, $\mathrm{Fe}^{2+}-\mathrm{Fe}^{3+}-$ and Mn -dominant M octahedra are green, yellow and pink, ( $\mathrm{Nb}, \mathrm{Ti}$ ) D octahedra are pale yellow; K- and Na - dominant $A(1), A(2)$ and $B$ sites are shown as green and blue spheres, respectively; OH and $\mathrm{H}_{2} \mathrm{O}$ groups are shown as small and large red spheres. The unit cell is shown with thin black lines.

FIG. 4. The HOH layer in veblenite (a) The O sheet; $(b)$ The H sheet in veblenite shows two types of $\mathrm{Si}-\mathrm{O}$ radicals: $\mathrm{Si}_{2} \mathrm{O}_{7}$ groups and a new veblenite $\mathrm{Si}_{8} \mathrm{O}_{22}$ ribbon; the repeat of the veblenite ribbon is indicated with a red box; (c) linkage of H and O sheets. Legend as in Fig. 3, Si tetrahedra are orange, ( $\mathrm{Nb}, \mathrm{Ti}$ ) D octahedra are pale yellow. The unit cell is shown with thin black lines; in (c), M octahedra are numbered.

FIG. 5. General view of the narrow and wide [100]-channels in the structure of veblenite, showing the position of $A$ and $B$ sites and OH and $\mathrm{H}_{2} \mathrm{O}$ groups: (a) projection along [100]. (b) projection along [001] (legend as in Fig. 3).

FIG. 6. Fragment of the crystal structure showing details of the linkage of two HOH layers via the bridge $\mathrm{D}-\mathrm{X}^{P}{ }_{\mathrm{D}}-\mathrm{D} . \mathrm{Nb}$ and Na atoms at the $D$ and $B$ sites are shown as yellow and blue spheres, O atoms at the $X^{P}{ }_{\mathrm{D}}$ and $X^{\mathrm{O}}{ }_{\mathrm{D}}$ sites are shown as red spheres, bonds between Nb and

Na atoms and O atoms are shown as solid black lines; $\mathrm{Fe}^{2+}$ - and Mn -dominant octahedra in the O sheet are green and magenta and represent O sheets of different HOH layers.

* Bond-valence parameters are from Brown (1981); coordination numbers are shown for non [4]-coordinated anion; bond-valence values are not calculated from K atoms at the $\mathrm{A}(2 \mathrm{~A}-2 \mathrm{D}$ ) sites ( $\sim 10 \%$ occupancy); $X_{A}^{\circ}(1-5)$ are either $O$ atoms of $O H$ groups or $F$ atoms.
