The International Congress "Steroids and Nervous System" held in Torino (Italy) has been held every two years since 2001, for the researcher community in this field of neuroendocrinology (1-8).

The present Special Issue is a collection of some of the lectures presented at the 9th International Meeting on Steroids and the Nervous System, held in February 2017. These reviews provide an update on the state of the art of recent discoveries in three main fields of current research on the role of neuroactive steroids in the brain, with special emphasis on brain development and sexual differentiation, the cellular and molecular mechanisms involved in the action of neuroactive steroids, and clinical implications for the understanding of brain disease and for the potential therapeutic use of these molecules or their analogues.

The Special Issue is opened with a review on the epigenetic and non-epigenetic mechanisms that drive the sexual differentiation of the brain (9). In particular, the mechanisms involving both histone acetylation and DNA methylation in the development of sex differences in the brain and behavior of rodents are discussed, as well as the demonstration that sex differences in the number of neurons of a particular phenotype may be programmed by differences in DNA methylation early in life. The following review discusses improvements in the study of the effects of steroids in the brain by the potential use of human induced pluripotent stem cells (iPSCs) to develop organoids (3D neuronal cultures) to test steroid properties and their therapeutic value (10).
The role of testosterone and the regulation of the enzyme, aromatase, is the theme of the following three papers (11-13). The expression of aromatase (which converts testosterone into estradiol) is regulated by several factors including sex hormones, genes and neurosteroids, therefore these actors may impact on the organizational effects of steroids during development (11). However, testosterone is not only the source for the local synthesis of estradiol, but it may itself regulate the development of sexually differentiated circuits, as revealed by studies in mice with mutations in the androgen receptor (12). Furthermore, androgens (e.g., testosterone and dehydroepiandrosterone) play a crucial role in sex-specific cortical growth during development and adolescence (13).

Also neurosteroids (i.e. brain-derived steroids, such as allopregnanolone) are involved in the regulation of brain development. One of their roles is represented by the regulation of the GABA-A receptor, which is one of the major players in both embryonic and neonatal brain development. Belelli et al. (14) review recent evidence indicating that changes in neurosteroidogenesis substantially influence neonatal GABA-ergic synaptic transmission, and discuss how interference of neurosteroids/GABA-A receptor interaction early in life may contribute to psychiatric conditions later in life. To conclude this part of the Issue dedicated to the role of steroids in brain development and sex differences, Gaignard et al. (15) review their recent findings concerning sex differences in brain mitochondrial function in physiological and pathological conditions, and the influence of endogenous sex steroids.

The second part of this Special Issue is dedicated to cellular and molecular mechanisms of steroid action. It is opened by a review on translocator protein of 18 kDa (TSPO), an ubiquitous mitochondrial protein part of a multiprotein complex involved in cholesterol transport into the mitochondrion. This is the rate-limiting step in steroidogenesis. Recent studies have generated controversy about the role of this protein in steroid synthesis, however recent results using various genetic animal models suggest that TSPO is a unique pharmacological target for diseases that involve increased mitochondrial activity, including steroidogenesis (16).

The three following reviews discuss different aspects of estrogen action in the brain through their receptors. The first is dedicated to the estrogen receptor beta (ERβ), a multifunctional nuclear receptor with a broad range of physiological functions resulting from the activity of several alternatively spliced isoforms of ERβ (17). The second review discusses the tissue,
cellular and subcellular localization in the brain of a recently discovered estrogen receptor coregulator (Proline-, Glutamic acid-, and Leucine-rich Protein 1). Recent evidence from PELP1 forebrain-specific knockout mice demonstrated a critical role of PELP1 in mediating both extranuclear and nuclear ER signaling in the brain, as well as E2-induced neuroprotection, anti-inflammatory effects, and regulation of cognitive function (18). The review of Sheppard et al. (19) examines recent developments in the study of the rapid effects of 17β-estradiol and estrogen receptor (ER) agonists on learning and memory tasks in female rodents, including activation of intracellular signaling cascades and epigenetic processes. The rapid non-genomic modulation of dendritic spinogenesis in rat and mouse hippocampal slices is mediated by sex steroids, including dihydrotestosterone, testosterone, estradiol, and progesterone. These rapid synaptic modulations are mediated by sex steroid receptors including rapid non-genomic effects. In the review of Murakami et al. (20), results from optical imaging of dendritic spines are discussed together with results obtained from other types of imaging techniques, including electron microscopic imaging.

Relationships between spine modulation and modulation of cognition are also discussed. The anti-inflammatory action of neuroactive steroids is discussed in the following two reviews. The review of De Nicola et al. (21) discusses the role of neuroactive steroids in experimental autoimmune encephalomyelitis (EAE), a commonly used model for multiple sclerosis (MS). Data reviewed in this paper suggest that enhanced synthesis of neurosteroids contributes in an auto/paracrine manner to reinforce the neuroprotective and anti-inflammatory effects of exogenous progesterone given to EAE mice. The review of Rizzi et al. (22) illustrates the results obtained by developing a mouse reporter system (the NFkB-luc2 reporter mouse) to understand the anti-inflammatory action of estrogens at the molecular level, in order to evaluate the extent to which the action of this steroid hormone was relevant in models of pathologies characterized by a strong inflammatory component, and to investigate the efficacy of novel, synthetic estrogens endowed with anti-inflammatory activity.

Some transient calcium channels (Transient Receptor Potential Channels, TRPC) are regulated for their tissue- and cell-specific expression in the brain by different neuroactive steroids, including pregnenolone, progesterone and dihydrotestosterone. In the review of Qiu et al. (23) the authors discuss their findings of the depolarizing action of insulin and leptin on proopiomelanocortin neurons of the arcuate nucleus mediated by activation of TRPC5 channels, indicating a potential link among neurosteroids and anorexigenic neuronal systems.
The last paper of this section is an experimental paper describing the properties of BR297 (a new analog of allopregnanolone) that appears to be a potent neuroprotective compound devoid of cell-proliferative activity. These results open promising perspectives for the development of neurosteroid-based selective and effective strategies against neuroendocrine and/or neurodegenerative disorders (24).

The last part of the Special Issue is dedicated to the clinical implications of the action of neuroactive steroids. Moraga-Amaro et al. (25) discuss the current status of Positron Emission Tomography (PET) imaging for studying sex steroid hormones in the brain. This technique has been applied to reveal changes in sex hormone receptor expression, to measure aromatase and to evaluate the effects of hormonal treatment in the brain, and is a useful technique to facilitate the translation of results from animal studies into clinical trials in patients.

Many clinical aspects suggest that sex steroid-nervous system interactions may contribute to the onset and course of symptoms, and the cognitive impairment displayed by men and women with schizophrenia. The review of Owens et al. (26) discusses the relationships between the action of estrogen and testosterone on the brain during adolescent development, and schizophrenia, and presents evidence of potential beneficial, as well as detrimental, effects of both testosterone and estrogen.

Premenstrual dysphoric disorder (PMDD) is characterized by recurrent negative mood symptoms during the luteal phase of the menstrual cycle with a temporal association with circulating progesterone and its metabolite, allopregnanolone. Bixo et al. (27) discuss in their review the results of a randomized, placebo-controlled clinical trial that demonstrates that isoallopregnanolone (an isomer of allopregnanolone) can ameliorate the symptoms of PMDD due to its ability to antagonize the allopregnanolone effect on the GABAa receptor.

In the review of Slowick et al. (28), the authors discuss the most recent findings demonstrating that estrogens selectively suppress the activation of the neuroinflammatory cascade in the brain in acute and chronic brain disease models. In addition, they discuss the presence of an inflammatory component in psychiatric disorders such as depression that could be modulated by estrogen.
In the last review of the issue, the authors (29) discuss how steroids can influence the gut microbiota, and in turn how the gut microbiota can influence hormone levels altering the stress axis and behavior, addressing future research in this new area at the intersection of steroids, stress, gut-brain axis and human health.

Acknowledgements. We want to acknowledge the support of the Fondazione Cavalieri Ottolenghi, the University of Torino, the University of Milano, the Department of Neuroscience, Rita Levi Montalcini (Torino) and the Department of Pharmacological and Biomolecular Sciences (Milano). Finally, we want to thank Wiley and all the staff of Journal of Neuroendocrinology that hosted this special issue.
