67

68 **Summary**

69 This study aims to describe the modification in epithelial cells populations during the first and the  
70 last month of milking in Holstein Friesian cows that have undergone different management during  
71 the dry period. We report the differential expression of CD49f<sup>+</sup> and cytokeratin18<sup>+</sup> cell  
72 subpopulations managed in overstocking during the dry period (from 21 ± 3 d to the expected  
73 calving until calving). Twenty six cows were randomly divided into 2 groups (13 animals each),  
74 balanced for the number of lactations, body condition score, and expected date of calving. Cows in  
75 the far-off phase of the dry period (from 60 to 21 d before the expected calving date) were housed  
76 together in a bedded pack. Then, animals (from 21 ± 3 d before the expected calving) until calving  
77 were housed in pens with the same size but under different crowding conditions due to the  
78 introduction of heifers (interference animals) into the pen. The control condition (CTR) had 2  
79 animals per pen with 12.0 m<sup>2</sup> each, whereas the overstocked condition (OS) had 3 interference  
80 animals in the same pen with 4.8 m<sup>2</sup> for each animal. Cells collected from milk samples were  
81 directly analyzed for: CD45, CD49f, cytokeratin 14, cytokeratin 18 and cell viability. Milk samples  
82 were collected in two different periods of lactation: early lactation (EL = d 0–30) and late lactation  
83 (LL = 270–300). We observed a differential expression with a reduction in CD49f<sup>+</sup> (p<0.01) and  
84 cytokeratin 18<sup>+</sup> (p<0.05) cells in EL. These observations suggest that mammary epithelial cell  
85 immunophenotypes could be associated to different animal management in dry period and we  
86 hypothesize they may have a role as biomarkers for mammary gland function in dairy cows.

87 **Introduction**

88 Increased stocking density is a common practice among dairy producers. One of the main tools to  
89 evaluate the effect of such management is to determine the threshold of stressful situation that  
90 triggers a number of changes such as activation of the sympathetic nervous system and  
91 hypothalamic-pituitary-adrenal axis that have been considered a well-known source of biomarkers  
92 for animal welfare (Prunier *et al.*, 2013). Very recently it has been demonstrated that overstocking  
93 during the dry period in Holstein Friesian dairy cow is associated with changes also in DHEA  
94 (Fustini *et al.*, 2017).

95 However, the determination of hormonal pattern to evaluate stressful situation presents some  
96 difficulties for the sampling and comparison of hormone levels in a given time interval. Also it  
97 would be interesting to include the ability to insert other physiological parameters that are to some  
98 extent related to the animal's well being. We have reported the expression of epithelial precursors  
99 and fully differentiated cells in bovine milk, highlighting possible variations in the number and  
100 features of mammary epithelial cells (MEC) subsets in dairy cows (Baratta *et al.*, 2015). MEC are  
101 found in milk, caused by shedding during the lactation phase, but the range of cell frequency differ  
102 from total somatic cell count (SCC) if only the live cell fraction is analyzed. The total amount of  
103 somatic cells in milk is affected by different factors, such as species, breeds, lactation phase, milk  
104 yield, individual animal differences, and management practices (Rupp *et al.*, 2000). A specific  
105 pattern of epithelial cell types has been found in the milk according to the stage of lactation. Cell  
106 types include an inner layer of cytokeratin 18 (K18)<sup>+</sup> luminal cells and an outer layer of cytokeratin  
107 14 (K14)<sup>+</sup> myoepithelial cells while CD49f<sup>+</sup> cells are probably derived from a more primitive stage  
108 of cell differentiation (Martignani *et al.*, 2015). In this study we show different mammary epithelial  
109 cell types present in milk of dairy cows that have been undergone overstocking during the dry  
110 period and hypothesize that specific cell types variations may be related to stressful management.

111

112 **Materials and Methods**

113 *Animals, housing and diet*

114 Twenty six Holstein dairy cows were enrolled in this experiment. All animals were housed at the  
115 farm of the University of Bologna (Ozzano Emilia, Italy) and used according to EEC animal care  
116 guidelines. The experimental procedures had been approved by the Ethical Committee of Bologna  
117 University. Animals were randomly divided into two groups (13 animals each), balanced for

118 number of lactations, BCS (body condition score) and expected date of calving. Cows in the far-off  
119 phase of the dry period (from 60 to 21 days before the expected calving date) were housed together  
120 in a bedded-pack and received water and grass hay ad libitum. From 21±3 days until calving  
121 animals were housed in two bedded-pack groups where they had ad libitum access to water and  
122 were fed daily using total mixed ration. After calving cows were housed together in a bedded pack  
123 area for the first 2 weeks of lactation and then moved to a free-stall pen for the rest of lactation. The  
124 total mixed rations (TMR) were fed approximately at 7 am for lactating cows and 9 am for dry  
125 cows.

126

### 127 *Experimental design, blood sampling and hormone assays*

128 Animals, dried off 8 weeks before the expected calving, were housed in pens with the same size  
129 (22,5 m<sup>2</sup> in total with 13,5 m<sup>2</sup> of resting area and 9 m<sup>2</sup> of feeding area) but in different crowding  
130 conditions due to the introduction in the pen of heifers (interference animals) having a body weight  
131 of 450-550 Kg. Control condition (CTR) had 2 animals per pen (one animal of the study with an  
132 interference animal) with 11 m<sup>2</sup> each, while the overstocked condition (OS) had three interference  
133 animals in the same pen with 5 m<sup>2</sup> for each animal. Cow were allocated to CTR or OS group based  
134 on parity, at 21 days before expected calving dates. The resting area is a deep-bedded pack with  
135 straw added twice a day. On days -30, -21, -7 before and 4, 10, 30, 60 relative to calving blood  
136 samples were collected from each cow for the determination of plasma DHEA and cortisol (C)  
137 concentrations by RIA..

138

### 139 *Flow Cytometry Analysis: Sample Processing*

140 Quarter foremilk samples were obtained in accordance with the Veterinary Services Standards of  
141 the Italian National Health Service, branch of the Ministry of Health. Before morning milking, teats  
142 were scrubbed with 70% ethanol and the first 2 strips of milk were discarded. Aliquots of 200 mL  
143 of milk per udder were collected aseptically.. Cells were collected and analyzed according to  
144 previously reported (Baratta *et al.*, 2015). Briefly, the determination of epithelial subpopulations in  
145 milk was carried out utilizing a 6-color flow cytometry assay. Anti-CD45 antibody (VMRD Inc.,  
146 Pullman, WA) was used to gate immune cells, anti-human- CD49f-FITC antibody (anti-h- $\alpha$ -  
147 integrin-6-FITC, Novus Biological, Littleton, CO), monoclonal anti-CK peptide 18 antibody (clone  
148 KS-B17.2, Sigma, St. Louis, MO), and anti-CK14 antibody (Covance, Life Technology, Thermo  
149 Fisher).. Stained samples were analyzed using an Attune Acoustic Focusing Cytometer (Life

iris-AperTO

150 Technologies). Cells without antibody labeling served as a negative control and were regarded to be  
151 a measure for background fluorescence. Fluorescence Minus One (FMO) controls were used to  
152 identify data spread due to the multiple fluorescent signals (2000; Bayer *et al.*, 2007). Epithelial  
153 cells were identified and counted in the total living CD45<sup>-</sup> cell population.

154

#### 155 *Statistical Analysis*

156 The two groups of cows (13 animals each) were compared on the following variables: living cells,  
157 CD49f<sup>+</sup>, K14<sup>+</sup>, K18<sup>+</sup>, and K14<sup>+</sup>K18<sup>+</sup>; values were collected at the beginning and in the last month of  
158 lactation. Considering that all variables were frequencies, non-parametric test were performed for  
159 all the analyses. In particular, Mann-Whitney U test was chosen and, firstly, variables were  
160 compared between the groups of cows at the first month of lactation. Secondly, the same analyses  
161 were repeated for measures collected in the last month of lactation, in order to explore for  
162 differences in significant results. Results were considered significant when associated at least to  
163  $p < 0.05$  for all the comparisons.

164

## 165 **Results**

### 166 *Hormones concentrations*

167 In overstocking group (OS) significantly ( $P < 0.01$ ) DHEA significantly increased compared to CTR  
168 group at day -7 ( $2.13 \pm 0.63$  vs  $1.47 \pm 0.46$  pmol/ml) while C did not differ between CTR and OS  
169 group (see supplementary data).

170

### 171 *Frequency of epithelial subpopulations during the first month of lactation*

172 Figure 1a shows total living cells (ranging from 66% to 78%) detected in the somatic cell  
173 population, identified as CD45<sup>-</sup> cells, in Holstein Friesian cows in response to stress induced by  
174 overstocking (OS) or not (CTR) during the dry period. A significant difference between the two  
175 groups was observed in CD49f<sup>+</sup> cells ( $p < 0.01$ ) with a decrease in OS group of frequency from 20 to  
176 5%. Interestingly, we observed a significant difference ( $p < 0.05$ ) in the level of luminal cells (K18<sup>+</sup>)  
177 with a decrease in OS group. Finally, no differences were detected in myoepithelial (K14<sup>+</sup>) and  
178 CK14<sup>+</sup>/CK18<sup>+</sup> cells.

179

### 180 *Frequency of epithelial subpopulations during the last month of lactation*

181 Figure 1b shows total living cells ranging from 63% to 75% detected in the somatic cell population,  
182 identified as CD45<sup>-</sup> cells, in cows that were exposed to stress during the dry period induced by  
183 overstocking (OS). A tendency to a decrease in OS group was observed without reaching a  
184 statistical difference was ( $p= 0.066$ ). Luminal cell (K18<sup>+</sup>) were present at low frequency in both  
185 group (2-3 %) while myoepithelial cells (K14<sup>+</sup>) still showed a greater concentration ranging from  
186 18 to 21%. Finally, no differences were detected in myoepithelial, luminal and CK14<sup>+</sup>/CK18<sup>+</sup> cells  
187 between the two groups.

188

#### 189 *Milk yield in response to treatment over transition period*

190 Mean milk yield (kg/d) in response to treatment over the transition period was not different among  
191 treatments (Table 1). Among cows, treatment did not differ regarding previous lactation 305-d  
192 mature- equivalent milk yield (CTR =  $10.1 \pm 215.1$  kg, OS =  $9.5 \pm 187,7$  kg;  $P = 0.35$ ).

193

#### 194 **Discussion**

195 It has recently been reported that DHEA secretion is affected in response to overstocking during the  
196 dry period in Holstein Friesian cows (Fustini *et al.*, 2017). We reported that DHEA concentrations  
197 were affected only during the dry period, when the stressful stimulus was applied, while no  
198 differences in DHEA secretion were observed during the first two months of lactation. Since the  
199 placenta seems the most important DHEA source in the late pregnant cow (Gabai *et al.*, 2004), it is  
200 possible that overstocking stimulates the release of DHEA from the maternal-foetal units through a  
201 still unknown mechanism. In the present work we cannot investigate on the source of this  
202 metabolite; however, we can confirm that in dairy cow DHEA plasma levels are affected during the  
203 last part of pregnancy by stressful management like overstocking that usually occurring during the  
204 dry period.

205 We mainly focused our attention on the frequency and differential expression of epithelial cells  
206 subpopulations in milk. We have previously reported the expression of epithelial precursors and  
207 fully differentiated cells according to the phase of lactation (Baratta *et al.*, 2015). We report now a  
208 further information that lead us to consider the hypothesis that different distributions of MEC  
209 subpopulations may provide more detailed information on the physiology of the mammary gland  
210 during lactation in dairy cows. In particular, our data suggest that stressful situations can affect the  
211 somatic cell subpopulations. We considered the first and the last month of lactation period that

212 received or not the stressful experience of overstocking monitored by the change of DHEA during  
213 the last days of dry period. We observed a different pattern of expression between the two groups of  
214 animal in the first month of lactation but not at the end of the physiological period indicating that  
215 the stressful-experienced cows showed a lower expression in CD49f<sup>+</sup> and K18<sup>+</sup> cell populations.  
216 We were interested on CD49f population evaluation since they belong to more primitive MEC  
217 (mammary precursors). They appear to decrease during the decline of lactation and in this way may  
218 exert a role in the reduction of the mammary secretory function, which adjusts the number of active  
219 secretory cells. We hypothesize that this subpopulation may be considered the signal of a reduction  
220 in mammary efficiency. The presence of CD49f positive cells, even if in a low number, may be  
221 related also to the reduction in the myoepithelial compartment that indicated the modification of the  
222 myoepithelial genetic program (Garbe *et al.*, 2012). This integrin has been shown to be a  
223 component of a feedback circuit that regulates the myoepithelial phenotype in mammary epithelial  
224 cells from humans and mice (Deugnier *et al.*, 1999; LaBarge *et al.*, 2009) suggesting that the basal  
225 regulatory machinery may be disrupted in myoepithelial cells and inappropriately engaged in  
226 luminal epithelial cells, maybe during the aging process. We did not observe a significant difference  
227 in K14/K18 double positive cells, in term of activation of regenerative functional tissue of  
228 mammary gland, in particular during the final phase of lactation. On the contrary, we have observed  
229 a difference in K18<sup>+</sup> cells with a decrease in OS group during the first month of lactation. This  
230 subpopulation are specifically linked to the secreting cells since they are referred as luminal cells.  
231 We would expect this difference to be associated with a reduction in milk yield during the period of  
232 milking, although we did not observed any decrease in milk production. The exposure to stressful  
233 conditions might influence the numerical relationship between luminal cells that produce milk in  
234 the mammary gland and epithelial cells that are shed in milk. One aspect that deserves to be  
235 thoroughly investigated is the number of functional cells found in milk needed to detect an effect on  
236 milk production.

237

## 238 **Conclusions**

239 In conclusion, we report the expression of epithelial precursors and fully differentiated cells during  
240 the first month of lactation in dairy cows that were overstocked during the previous dry period,  
241 highlighting variations in the number and features of MEC subsets in milk. Although we were not  
242 able to detect a correlation with milk production, it remains interesting to observe that overstocking  
243 associated with hormonal pattern during dry period shows different modulation of somatic cells

---

iris-AperTO

244 during the lactation. Further studies are necessary to determine if different distributions of MEC  
245 subpopulations may provide more detailed information on the physiology of the mammary gland  
246 during lactation in dairy cows and, potentially, have an application to evaluate mammary gland  
247 functionality as biomarkers.
