1

2 **ABSTRACT**

3 **Objectives**

4 The aim of this study was to describe and analyse the performance career trajectories for Italian athletes that  
5 participated in sprint, hurdles, discus throw, and shot-put athletics events.

6 **Design**

7 Retrospective study, data collected between 1994 and 2014.

8 **Method**

9 A total of 5929 athletes (female: n = 2977, 50.2%) were included in the study. The age of entering competition  
10 and personal best performance was identified in the official competition records. Personal best performances  
11 were ranked in percentiles and top-level athletes were considered those in the highest 4% of the performance  
12 distribution.

13 **Results**

14 Overall, when controlling for the age of entering competition, top-level athletes reached their personal best  
15 later (i.e., around 23-25 years old) for all events compare to the rest of the athletes. Moreover, regression  
16 analysis showed that entering competitions later, was linked to better performances during adulthood. Also,  
17 only 17% to 26% [90% CI] of the top-level adult athletes were considered as such when they were 14 to 17  
18 years of age.

19 **Conclusions**

20 Together, these findings suggest that early sport success is not a strong predictor of top-level performance at  
21 senior level. Entering sport-specific competitions later and lengthening the sports career at beyond 23-25 years  
22 of age may be important factors to reach top-level performance in sprint and throwing events.

## 26 **i. Introduction**

27           Recently, in many countries there has been an increased focus on talent identification and development  
28 programmes<sup>1</sup> with the main aim to identify talented athletes and develop them to compete at senior level.<sup>2</sup> In  
29 sports where performance is determined in centimeters, grams, or seconds (CGS) there is a tendency to define  
30 talent based on competitive results at a young age. A comprehensive definition of “sports talent” is lacking,  
31 however, it is accepted that a talented sports-person is an individual whose athletic performances are superior  
32 to his peer/age group and is capable of reaching or has achieved performances at top level in his/her  
33 event/discipline.<sup>3</sup> With this approach, coaching communities have tended to identify talent at a young age  
34 based on performance of physical traits mostly based on Eastern European models. Few authors have argued  
35 the need to consider late developers<sup>4</sup> because of the risks of selecting and nurturing early maturers at early  
36 stages of athletics careers, neglecting children with the real potential to excel at later stages in life.<sup>2</sup>  
37 Furthermore, few studies have suggested to include psychological and learning aspects.<sup>5</sup> In CGS sports, talent  
38 identification and confirmation are usually based on assessing specific physical traits and/or results in  
39 competitions/qualifications in major international events. In athletics, it is relatively simple to track progress  
40 in competitions as nowadays most of the official competitions are recorded with international judging  
41 standards and results are kept in publicly available databases of national and/or international federations (eg.:  
42 <https://www.iaaf.org/home>).

43           Athletic abilities are determined to a certain extent by genetic factors,<sup>6-8</sup> they are affected by growth  
44 and maturation<sup>9,10</sup> and can be improved in the lifespan with training. Recent attempts of database analysis have  
45 presented normative development data of performances in track and field athletes suggesting typical  
46 development pathways in various age groups.<sup>11-14</sup> However, some authors highlighted that sports performance  
47 progression is rarely linear and does not guarantee that someone performing well in development stages as a  
48 youth athlete will perform well as an adult.<sup>15,16</sup> Within track and field athletics, this hypothesis could explain  
49 why, as indicated by Piacentini et al.,<sup>17</sup> success at World Junior Championships is not a good predictor of  
50 success in adult competitions in throwing events. Furthermore, recent literature supports the notion that early  
51 stage success is not a prerequisite for later success. For example, Shibli and Barrett (2011) reported that only  
52 12% of top 20 Under 15 athletes in the United Kingdom retained their ranking when competing as Under 20.  
53 More supportive evidence came from recent study<sup>18</sup> reporting similar findings in sprinting, throwing, jumping  
54 and middle-distance events within the United Kingdom. Outside the United Kingdom, we recently reported

55 that only 12 to 25 % of Italian long and high jumpers were considered top-level when they were younger than  
56 18 years old (yo)<sup>12</sup> However, this study was restricted to jumping events, therefore, more data about sprint,  
57 hurdles and throwing events are needed.

58 Previous research has found differences between elite and non-elite athletes in terms of performance  
59 development and training regimes. For example, few studies found that on CGS sports elite athletes specialized  
60 later than near-elite athletes.<sup>4,19</sup> However, as these studies examined athletes of specific nationalities, their  
61 findings may not be applicable to other contexts. While performance databases cannot be used to understand  
62 training regimens, they can provide important information to study athletes' career development.<sup>12,18</sup> For  
63 example, the age of entering sport-specific competitions and its possible effect on the performance in the  
64 adulthood can be extrapolated from performance databases. This would be useful information for track and  
65 field coaches and sports administrator. Such data could in fact provide better information on youth  
66 competitions, typical development pathways to refer to as well as more evidence to support progressive  
67 specialisation programmes. Furthermore, while it is established that the mean age to reach peak performance  
68 is typically 25-27 years in World-class athletes,<sup>14</sup> more data are needed to understand how their pathway to  
69 excellence looks like and gain a better understanding of the differences in development between elite and non-  
70 elite athletes. Overall, these data could provide coaching communities with realistic progression patterns and  
71 better inform talent development and retention pathways.

72 Therefore, to address the aforementioned gap, we aimed to answer the following three experimental  
73 questions considering speed, hurdles, discus throw and shot-put events. We aimed to determine 1) possible  
74 differences in the age of reaching peak performance between top-level athletes compared to athletes  
75 performing at a lower level; 2) if early appearance on national ranking affected their developed; 3) the  
76 distribution of appearance in the top ranking of senior elite athletes when they were younger than 18 years of  
77 age.

78

## 79 **ii. Methods**

80 All data were collected from the database of FIDAL (Italian Track and Field Federation) and included  
81 the following groups events: 100 m sprint, the 100/110 m hurdles, the discus throw, and the shot put. The  
82 technical rules of these disciplines are reported in the following link <https://www.iaaf.org/about-iaaf/documents/rules-regulations>. Adolescent athletes competed in age categories grouped every two years:

84 12-13 years; 14-15 years; 16-17 years; 18-19 years. Following FIDAL rules, the adolescent competition  
85 formats are scaled-down in relation to the age categories. Indeed, the younger categories competed with shorter  
86 distance (in run events), with shorter distance and lower hurdles height (in hurdles events), or lighter weight  
87 equipment (in throwing events) with respect to adult category. Therefore, it is impossible to calculate the rate  
88 of performance improvement.

89 The athletes ranked in the top 200 official lists in each season were included in the analysis.  
90 Competitive seasons from 1994 to 2014 were analysed. Data about rankings were collected (1) from 12 to 35  
91 yo, (2) or until career termination, (3) or until the 31/12/2014 if the athletes were not retirement. Only results  
92 obtained with legal wind speed ( $\leq 2$  m/s) were included according to IAAF rules. The naturalized Italian  
93 athletes were excluded from the analysis as many appeared on the rankings only at later stages and/or  
94 sporadically. This study was approved by the local ethics committee of the University of Verona and involved  
95 access to publicly available databases. Therefore, no informed consent was sought.

96 Longitudinal data of each athletes were extrapolated from custom-written software in MATLAB  
97 R2015a (Mathworks, Natick, Massachusetts). Separate analyses were performed considering discipline and  
98 gender. Records were included in the analysis only if the correspondent athlete was present in the ranking list  
99 at least for three years, also non-consecutively. Considering each discipline separately, athletes were ranked  
100 on the basis of the percentile of their personal best performance thus generating an “all-time” ranking. Then,  
101 athletes were sub-grouped in 25 groups (i.e. 4 percentiles for each sub-group) according with their personal  
102 best percentiles. Thus, the worst performers were those with a percentile  $\leq 4$ , whereas the best performer (top-  
103 level) were those with a percentile  $\geq 97$ . In order to analyze the athletes’ rank when they were younger than  
104 18 yo, the above-mentioned calculations were also performed for each year of ages lower than 18.

105 Using the age at which each athlete entered official competitions as a covariate, an ANCOVA with  
106 rank as between factor (from 1<sup>st</sup> to 25<sup>th</sup> sub-group of performance) was conducted to test the significant  
107 differences on age of best performance in the different disciplines (i.e., sprint, hurdles, discus throw, and shot  
108 put). A multiple regression was run to predict rank (from 1<sup>st</sup> to 25<sup>th</sup> sub-group of performance) from initial  
109 ages. Finally, the percentages of top-level adult athletes that were considered top-level (i.e., percentiles of  
110 performance  $\geq 97$ ) when they were younger than 18 yo were computed. All the above analyses were performed  
111 separately for male and female athletes. The Statistical Package for Social Sciences (SPSS 24.0 for Windows)  
112 was used for all statistical analyses. Alpha was set at  $P \leq 0.05$ .

113

### 114 **iii. Results**

115 After error and duplication removals a total of 5929 (male:  $n = 2949$ , 49.8%; female:  $n = 2977$ , 50.2%) athletes  
116 were included in the study. Specifically, 2037 athletes (male:  $n = 1012$ , 49.7%; female:  $n = 1025$ , 50.3%) were  
117 sprinters, 1453 were discus throwers (male:  $n = 778$ , 53.5%; female:  $n = 675$ , 46.5%), 873 were hurdlers (male:  
118  $n = 384$ , 44%; female:  $n = 486$ , 56%), 1563 were shot putters (male:  $n = 775$ , 49.6%; female:  $n = 788$ , 50.4%).

119 Table 1 reports the performance thresholds to be considered a top-level athlete in Italian competitions.  
120 Table 1 also reports the descriptive statistics of the age of entering competitions and the age of reaching  
121 personal best performance. Nevertheless, the performance thresholds demarcate the best 20-40 athletes of each  
122 discipline that can be considered top-level in the national context.

123 <Insert Table 1 about here>

124 Figure 1 shows when athletes achieved their personal best performance for each discipline for males  
125 (Figure 1a) and females (Figure 1b), respectively.

126 <Insert Figure 1 about here>

127 Overall, the age of achieving personal best performance of top-level athletes was higher compared to  
128 the rest of the sample (Figure 1). When analyzing male athletes, the one-way ANCOVA yielded significant  
129 main effects of rank in sprint ( $F_{24,986}=8.553$ ,  $P < 0.001$ , partial  $\eta^2 = 0.172$ ), hurdles ( $F_{24,358}=2.306$ ,  $P=0.001$ ,  
130 partial  $\eta^2=0.134$ ), discus ( $F_{24,752}=3.891$ ,  $P < 0.001$ , partial  $\eta^2=0.110$ ) and shot-put disciplines  
131 ( $F_{24,749}=3.324$ ,  $P < 0.001$ , partial  $\eta^2=0.096$ ). Considering female athletes, the one-way ANCOVA yielded  
132 significant main effects of rank in sprint athletes ( $F_{24,999}=13.019$ ,  $P < 0.001$ , partial  $\eta^2=0.238$ ), hurdles  
133 ( $F_{24,463}=7.598$ ,  $P < 0.001$ , partial  $\eta^2=0.283$ ), discus ( $F_{24,679}=6.007$ ,  $P < 0.001$ , partial  $\eta^2=0.182$ ) and shot-put  
134 disciplines ( $F_{24,762}=7.549$ ,  $P < 0.001$ , partial  $\eta^2=0.192$ ).

135 Considering male athletes, the age of entering competition positively correlated with the rank in  
136 hurdles ( $F_{1,382}=7.767$ ,  $R^2= 0.017$ ,  $\beta=0.141$ ,  $P=0.006$ ), discus ( $F_{1,776}=76.146$ ,  $\beta=0.088$ ,  $P < 0.001$ ), and shot put  
137 ( $F_{1,774}=91.015$ ,  $R^2=0.104$ ,  $\beta=0.325$ ,  $P < 0.001$ ), disciplines. Considering female athletes, the age of entering  
138 competition positively correlated with the rank in sprint ( $F_{1,1024}=167.884$ ,  $R^2=0.001$ ,  $\beta = 0.375$ ,  $P < 0.001$ ),  
139 discus ( $F_{1,674}=25.908$ ,  $R^2=0.036$ ,  $\beta=0.193$ ,  $P < 0.001$ ), and shot put ( $F_{1,776}=62.689$ ,  $R^2=0.073$ ,  $\beta=0.272$ ,  
140  $P < 0.001$ ) disciplines. This means that the higher the age of entering competition of a young athletes, the higher  
141 was the level of performance in the adulthood. Differently, no significance was observed in sprint discipline

142 for male ( $F_{1,1011}=0.385$ ,  $R^2=0.001$ ,  $\beta=0.020$ ,  $P<0.535$ ) and hurdles discipline for female athletes  
143 ( $F_{1,488}=0.834$ ,  $R^2=0.001$ ,  $\beta=0.041$ ,  $P<0.362$ ).

144 The percentage of top-level adult athletes considered as top-level athletes too when they were younger  
145 than 18 yo is reported in Table 2. On the contrary, the followings are the amount of top-level adult athletes  
146 that started their competitions later than 18 yo, and thus do not appear in the Table 2: 15 out of 40 male and  
147 12 out of 41 female sprint top-level athletes; 4 out of 39 male and 3 out of 34 female discus-throw top-level  
148 athletes; 3 out of 15 male and 4 out 20 female hurdles top-level athletes; 4 out of 39 male and 4 out of 39  
149 female shot-put top-level athletes.

150 <Insert Table 2 about here>

151

#### 152 **iv. Discussion**

153 The present study tracked the career performance ranking of nearly 6000 Italian athletes that  
154 participated in official athletics competition of 100 m sprint, the 100/110 m hurdles, the discus throw, and the  
155 shot-put events from the 1994 to 2014. We compared the career of those who performed at the highest national  
156 level with the rest of the sample, providing quantitative data about the age of career initiation, the youth  
157 performances, and the age of personal peak performances.

158 The present results showed that senior top-level athletes reached on average their personal best  
159 performance later than the others. Despite this trend was observable in male (Figure 1a) and female athletes  
160 (Figure 1b), the effect was more pronounced in females.<sup>14</sup> Since this statistical analysis was corrected for the  
161 age of entering competition, it is possible to state that the *duration* of someone's sporting career is a key factor  
162 for reaching high performance levels. Indeed, athletes involved in specialised training and competitions  
163 programmes at a young age, are more likely to reach their best performance at a relatively younger age than  
164 their peers supporting the idea that delaying specialisation could be a much better approach to reach elite senior  
165 success.<sup>19-21</sup> Elite performance requires many hours of training and exposure to numerous competitions, thus  
166 it is obvious that the longer the career the greater the possibility to reach high performance level. An athlete's  
167 career can terminate because of many reasons: injuries, lack of motivation, and lack of performance  
168 improvements, can in fact reduce the chances of success.<sup>22</sup> Therefore, the lack of reaching high level  
169 performance may be both the cause and the effect of an early career termination.<sup>23</sup> Whatever the causes of  
170 early career termination, this study suggests that prolonging the athlete's career over 23-25 years of age seems

171 to be essential in order to reach high levels of performance in the athletics events herein analysed. While we  
172 did not know the injury history of the athletes included in this analysis, it is possible to suggest that keeping  
173 them healthy until such age may increase the chances of them reaching their best performance.

174 The peak performance usually occurs quite a few years after biological maturity is reached.<sup>20,21,24</sup> In  
175 fact, previous studies on world-prominent athletes found that athletes reached their peak performance between  
176 24 and 26 years of age for sprint and hurdles disciplines, and around 26-28 years for throwing disciplines.<sup>20,21,24</sup>  
177 In our study, the age of performance of the best national athletes was one to two years earlier than previously  
178 reported for top competitors on the World stage probably due to the difference in performance level.<sup>14</sup> In fact,  
179 only 1% of Italian athletes was present in the top 100 world-ranked in 2014 (<https://www.iaaf.org/home>).

180 Our study also suggests that the peak ages for performance are differ between athletics' events. For  
181 example, endurance events show that personal best performance in 800-1500 m distance runners peaks at about  
182 26-28 yo, whereas longer distance runners peak at 30-35 years of age<sup>25</sup> suggesting that peak age tends to  
183 increase with increase distance. While this is clear in endurance events, data of our study on events lasting less  
184 than 15 s and relying mainly on explosive contractions and anaerobic metabolic contribution suggest a different  
185 pattern and similarities between events.

186 Generally, the age of entering competition positively correlates with the peak performance in the  
187 regression analysis. This result indicates that the later the age of first competition, the higher the level of  
188 performance reached by an athlete in the specific sport event. This is in line with a previous study<sup>26</sup> showing  
189 that elite athletes began competition in their sport later than did near-elites. We did not check for competition  
190 entries in different disciplines in the same athletes, therefore, it was impossible to understand if those who  
191 started their competitive activity earlier, were competing in only one discipline. Hence, it was impossible to  
192 understand when athletes started to specialize, i.e. when started a year-round intense training activity focusing  
193 on a single main sport while excluding others.<sup>27</sup> However, while it is challenging to determine the optimal age  
194 of entering competition, our findings support the idea that early competition may not provide any advantage  
195 for later success. This is in agreement with previous literature suggesting that early sport specialization and  
196 competition does not facilitate the development of peak performance in adulthood.<sup>19</sup> Indeed, previous findings  
197 on CGS sports suggested that elite athletes specialized later than near-elite athletes.<sup>4, 19</sup> This should be  
198 considered when developing competition and training strategies for youngsters, possibly favoring a more  
199 diverse experience in training and competition.

200 Most of the top-level adult athletes were not performing at the top level when they were between 14  
201 and 17 years of age. Only 0-30% of them were at the top-level when they were 15, and this proportion grew  
202 up to 22-50% for the age of 17 (Table 2). The present findings are in line with previous studies on high jump  
203 and long jump<sup>12</sup> and, to some extent, on middle-distance running.<sup>28</sup> Thus, the career of most athletes at top-  
204 level markedly developed, when compared to their peers, after their 18<sup>th</sup> birthday. This agrees with the  
205 possibility that late maturers might be more likely to have a better career as adults in sprints and throwing  
206 events. The 100m was the discipline in which this trend was more pronounced. On the contrary, the discus  
207 throw showed a slightly different trend. It is plausible that the anthropometric characteristics that are  
208 fundamental to compete at high level in throwing events, were already observable in young throwers in the  
209 cohort analysed.

210 When interpreting the current data, the following limitations should be considered. First of all, it should  
211 be recognized that the threshold used to define top-level athletes, as those who performed in the best 4% of  
212 the sample, may have affected the results. We arbitrarily choose this threshold because the performances  
213 identified by this threshold approximately correspond to the performances of the athletes ranked 4<sup>th</sup>/8<sup>th</sup> in the  
214 finals of track and field national championships in the last few years. However, we also tried to run the analysis  
215 by identifying top-level between 5% and 1% of the distribution and the significance of the study did not  
216 substantially change in any these cases. Moreover, no data of injury history or other reasons affecting  
217 competition stop were considered. Finally, as these data refer only to Italian athletes, and in the years of  
218 observation only a small percentage of them was considered '*elite*' in terms of World Ranking, caution should  
219 be applied when using our data as a reference. Future studies in individual countries should assess the typical  
220 development pathways of their athletes in key events. Furthermore, thanks to the access of international online  
221 databases, it should be possible in the near future to track the performance pathways of elite performers not  
222 only to have a better description of typical/a-typical developments but also to implement such approach for the  
223 fight against doping.<sup>29</sup>

224

## 225 **v. Conclusions**

226 The present study suggests that the duration of the competitive career in athletics was a key factor to determine  
227 the ability to reach elite national-level performances in athletes competing in sprint, hurdles, discus throw and  
228 shot-put events. Moreover, we found that only few top-level adult athletes were considered as such when they

229 were younger than 18 yo. Taken together, these findings suggest that early sport success may not transfer to  
230 top-level performance at senior level and therefore caution needs to be applied when deciding upon athletes'  
231 progressions in funded/selection programmes.

232

#### 233 **vi. Practical Implication**

234 ● Being a top-level at a young age is not a prerequisite to become a top-level adult athlete in sprints and  
235 throwing events with the potential bias of early maturation.

236 ● Focusing on results in early event-specific competitions should be considered with caution because it  
237 may blunt future performance in the adulthood.

238 ● Coaches, clubs and governing bodies should aim to lengthen the athletes' sports career in athletics  
239 disciplines instead of focusing on early success.

240

**Table 1. Descriptive statistics of top-level athletes.**

		Disciplines																		
		Sprint				Hurdles				Discus Throw				Shot Put						
Gender	N	Top	Performance			N	Top	Performance			N	Top	Performance			N	Top	Performance		
			threshold (s)	Enter	Best			threshold (s)	Enter	Best			threshold (m)	Enter	Best			threshold (m)	Enter	Best
<b>Males</b>	1012	40	10.45	16.8 ±2.4	23.4±3.3	384	15	14.00	15.3±1.5	24.0±2.1	778	31	51.26	15.6±2.3	24.7±2.5	775	31	15.79	15.4±2.3	23.5±2.9
<b>Females</b>	1025	41	11.83	14.85±1.6	23.6±3.7	486	20	13.83	14.5±0.9	25.3±3.6	675	27	46.35	15.4±2.2	24.7±4.0	788	32	13.24	15.2±1.8	24.5±3.7

Notes: The number of tracked athletes are reported for each discipline and gender (N). The number of identified top-level athletes (Top, those with peak performance higher or equal to the 97<sup>th</sup> percentile) and the performance thresholds (that is the performance associated to the 97<sup>th</sup> percentile) are also reported. For top-level athletes the descriptive statistics of the age of entering competition (Enter) and the age of reaching of best performance (Best) are also reported.

**Table 2. Percentages of top-level adult athletes that were considered top-level when they were younger than 18 yo.**

Disciplines		Age (years)			
		14	15	16	17
Sprint	Males	0	10	7	22
	Females	14	21	29	34
Hurdles	Males	0	0	26	40
	Females	15	30	40	35
Discus throw	Males	2	23	23	38
	Females	14	20	35	50
Shot put	Males	2	12	12	33
	Females	7	23	38	43
90% confidence intervals (for age)		2 – 11	11 – 23	18 – 34	31 – 42
90% confidence intervals (overall)		17 – 26			

*Notes:* For each age from 14 to 17, each cell represents the percentage of the top-level adult athletes who were top-level performer when they were younger than 18 yo.

**Figure 1 – Age of personal best performance for males and females.**

Age of personal best performance (mean±SD) for male (a) and female (b) athletes. The sample was subgrouped on based on the percentiles of the personal best performance (reported in the x axis). The sample consisted of Italian athletes that took part in official athletics competition in sprint (100 m), hurdles (110 m hurdles), discus throw, and shot-put events from the 1994 to 2014. Overall, top-level (percentile  $\geq 97$ ) reached their personal best performance later than the rest of the sample in all disciplines (see results for statistics).
