

## POSTER PRESENTATIONS

anterior tibialis muscle,  $p < 0.05$ ), cross section area of muscle fiber ( $3,944 \pm 536$  vs.  $3,066 \pm 211 \mu\text{m}^2$ ,  $p < 0.05$ ) and muscular protein content ( $211 \pm 10$  mg/g vs.  $151 \pm 9$  mg/g,  $p < 0.05$ ), inhibited myotropic markers expression (MuRF1 and MAFbx,  $p < 0.05$ ), M1 macrophage infiltration ( $p < 0.05$ ), muscular nitrotyrosine concentration ( $229.4 \pm 11$  vs.  $320 \pm 43$  pmol/mg,  $p < 0.05$ ) and normalized myogenic markers expression (MyoD1 and MHC,  $p < 0.05$ ). Moreover, acute thalidomide incubation in TNF- $\alpha$  pretreated C2C12 myoblasts normalized the abnormal expressions of NF $\kappa$ Bp65/iNOS, myotropic and myogenic markers ( $p < 0.05$ ). However, the *in vitro* beneficial effects of thalidomide were reduced by concomitant pre-incubation of amiguanidine.

**Conclusions:** By down-regulating of NF $\kappa$ Bp65-iNOS pathway, chronic thalidomide treatment decreased circulating CD16<sup>+</sup> (inflammatory) monocytes, inhibited muscular macrophage infiltration, suppressed myotropic signals and normalized myogenic signals expression. Taken together, thalidomide is a potential agent for treatment of cirrhotic muscle wasting.

**Background and Aims:** Catecholamines trigger proximal tubular fluid retention and decrease Na<sup>+</sup> and water delivery to the diluting segment of the Henle's loop, thereby reducing renal excretion of solute-free water. In advanced cirrhosis, non-osmotic hypersecretion of vasopressin (ADH) has a role in causing dilutional hyponatremia, but the advantage of ADH V<sub>2</sub> receptor antagonists is still controversial in the treatment of ascites. We meant to test the hypothesis that adrenergic hyperfunction might greatly contribute to water retention in experimental ascitic cirrhosis.

**Methods:** Hormonal status, renal function and tubular free-water reabsorption (TFWR) were assessed in six groups of rats with ascitic cirrhosis: rats with cirrhosis due to 13-week CCl<sub>4</sub> administration (group G1); cirrhotic rats receiving, from 11<sup>th</sup> to 13<sup>th</sup> weeks of CCl<sub>4</sub>, daily diuretics alone (0.5 mg/kg furosemide plus 2 mg/kg K<sup>+</sup>-canrenoate) (G2), or diuretics associated with guanfacine oral prodrug ( $\alpha_2$  adrenergic receptor agonist and sympatholytic agent) 2 (G3), 7 (G4), or 10 mg/kg (G5), or diuretics plus SSP-004240F1 (V<sub>2</sub> receptor antagonist) 1 mg/kg (G6).

**Results:** Natriuresis was lower in G1 than in G2, G4 and G6 (all  $P < 0.05$ ). Low-dose guanfacine, added to diuretics in G3, reduced serum norepinephrine from  $423 \pm 22$  (in G2) to  $211 \pm 41$  ng/L (in G3) ( $P < 0.05$ ), plasma renin activity from  $35 \pm 8$  to  $9 \pm 2$  ng/mL/h (G2 vs. G3) ( $P < 0.05$ ), and TFWR from  $45 \pm 8$  to  $20 \pm 6$  microL/min (G2 vs. G3) ( $P < 0.01$ ). Compared to G1 (untreated ascitic cirrhosis) or G2 (ascitic cirrhosis treated with sole diuretics), TFWR was reduced to the same extent in groups G3 (low-dose guanfacine plus diuretics) and G6 (V<sub>2</sub> antagonist plus diuretics). TFWR correlated only with plasma aldosterone ( $r = 0.51$ ,  $P < 0.01$ ) and urinary potassium excretion ( $r = 0.90$ ,  $P < 0.001$ ).

**Conclusions:** In ascitic cirrhosis, reduced volaemia with secondary aldosteronism and adrenergic hyperfunction, especially when exacerbated by potassium-depleting diuretics (furosemide), contributes to tubular retention of water and dilutional hyponatremia. In this case, suitable doses of sympatholytic agents are as effective as V<sub>2</sub> antagonists when the aquaretic effect is needed.

**Background and Aims:** Muscle wasting is a common feature in cirrhosis. Our aim was to investigate main molecular pathways contributing to muscle wasting in an experimental model of carbon tetrachloride induced liver cirrhosis (CCl<sub>4</sub>).

**Methods:** 12-week old male wild-type (FVB) mice were used. Cirrhosis was induced by intraperitoneal injection, twice a week, of CCl<sub>4</sub> for 12 weeks according to a well-established model. Control animals received intraperitoneal injections of vehicle only (CTR). Twelve weeks after body weight was recorded and mice were sacrificed. Liver histological analysis was performed to confirm cirrhosis. Peripheral muscles were rapidly dissected at the sacrifice and weighed. Contractile properties of extensor digitorum longus (EDL) was studied *in vitro* in both isometric and isotonic conditions. Muscle samples were then rapidly stored for histological and biological analysis. mRNA and proteins were quantified using real time qRT-PCR and immunoblots.

**Results:** Results refer to fourteen mice, 7 CCl<sub>4</sub> and 7 CTR. At the end of 12 weeks, cirrhosis was histologically confirmed in all the CCl<sub>4</sub> treated mice. Compared with CTR, CCl<sub>4</sub> mice had a reduction in skeletal muscle weights, mainly in quadriceps and gastrocnemius. The average cross sectional area (CSA) and the total myofiber number of the quadriceps were significantly reduced in CCl<sub>4</sub> vs CTR. The frequency distribution of muscle fibers' revealed a shift toward a smaller size in CCl<sub>4</sub> treated mice. Muscle atrophy was not associated with a significant modification in muscles' contractile properties. Main molecular pathways involved in muscles atrophy were subsequently investigated. Neither myostatin, AKT and mTOR expressions were modified in CCl<sub>4</sub> vs CTR. Upregulation of proinflammatory cytokines TNF $\alpha$  and IL6, mRNA and protein expressions, were observed in CCl<sub>4</sub> mice. Since TNF- $\alpha$  mediates its effect on muscle by activation of NF- $\kappa$ B, we have also investigated the expression of NF $\kappa$ B which was found to be significantly increased in CCl<sub>4</sub> mice. An upregulation of MuRF-1 expression was also observed confirming activation of NF- $\kappa$ B-mediated gene transcription.

**Conclusions:** Muscle atrophy is a characteristic complication in experimental models of CCl<sub>4</sub> induced cirrhosis. NF- $\kappa$ B overexpression in skeletal muscle is activated by inflammatory cytokines, particularly tumor necrosis factor  $\alpha$  (TNF $\alpha$ ), suggesting that inflammation is an important trigger of muscle atrophy in this model of liver cirrhosis.
