6	
7	ABSTRACT
8	
9	Purpose: to report early and mid-term results of post aortic dissection (AD) thoraco-abdominal
10	aneurysms (pD-TAAA) treated by complex endografting in three high-volume centres.
11	
12	Materials and methods: a review of all patients with pD-TAAA unfit for open surgery treated with
13	complex endovascular repair from 2012 to 2018 was performed. Simple thoracic endografts
14	(TEVAR) were excluded. Staged procedures in case of extensive aortic coverage were always
15	planned.
16	
17	Results: 21 patients (16 male, mean age 63±10 years) with pD-TAAA underwent aortic repair by
18	fenestrated or branched thoraco-abdominal endografts for visceral vessels. Mean TAAA diameter
19	was 62 mm (range 55-83). Spinal cord drainage was performed in all patients. A staged approach
20	was used in 12 (57%) cases. Technical success was achieved in 18 patients. No in-hospital deaths
21	occurred. Two patients (9.5%) experienced transient post-procedural spinal cord ischemia. At 30
22	days, six type II endoleaks (28.5%), two type Ic endoleak (9.5%) and one type IIIc endoleak (4.7%)
23	were reported. At a mean follow-up of 23 ± 13 months, no late aortic-related deaths occurred. Three
24	patients underwent reintervention for type Ic and IIIc endoleaks. No visceral vessel occlusion was
25	observed. Estimated freedom from reintervention at 12 and 24 months was 85.7±7%. In 13 cases
26	TAAA diameter decreased at least 5 mm, while in only one case there was a volume increase.

...

. .

1 1

.

27	Complete false lumen thrombosis was noted in 18 patients (86%).
28	Conclusion: complex endografting for pD-TAAA showed favourable results. Staged procedures
29	and careful planning allow to treat safely with excessive risk in case of open repair.

40	TEXT
41 42	Introduction

Uncomplicated type B aortic dissection (TBAD) at the time of the diagnosis requires a strict 43 44 blood pressure control combined with strict radiological follow-up [1-2]. Different studies, however, reported a 30-day mortality of 6-10% even in presence of optimal blood pressure control 45 [3-4]. Long term survival is negatively affected by the disease, with only 50-70% of patients alive 46 at five years [5-7]. Approximately 30% of patients with uncomplicated TBAD will ultimately 47 48 present a post-dissection thoracoabdominal aortic aneurysm (pD-TAAA) [8]. Such evolution in the 49 descending aorta may also occur in patients successfully treated for a type A aortic dissection by 50 ascending aorta and/or aortic arch replacement.

In case of pD-TAAA open surgery is the treatment option of choice, even if it represents an
extremely demanding procedure both for the patient and the physician.

In the recent literature, few selected centers proposed total endovascular aortic repair of pD-TAAA with fenestrated and branched endografts as a valuable alternative to open surgery [9-11]. Endovascular treatment of such a complex entity is extremely challenging due to the anatomic variability between different patients, in terms of visceral vessels' origin from the true lumen (TL) or false lumen (FL), the narrowness of the TL and the possible involvement of the iliac arteries in the dissection.

With this multicentric study we aim to analyze early and mid-term outcomes of total endovascular
pD-TAAA repair in three centers with experience in complex endografting of atherosclerotic
aneurysms.

62

63 Materials & Methods

64 *Study design and preoperative evaluation*

65 A retrospective analysis of all information regarding consecutive patients with pD-TAAA deemed unfit for open surgery and treated with complex fenestrated/branched thoraco-abdominal 66 67 endovascular aortic repair (F/B-TEVAR) in three Italian centres between 2012 and 2018 was 68 conducted. Inclusion criteria were: pD-TAAA with maximum aortic diameter >60 mm, rapidly 69 growing aneurysms (> 10 mm in 12 months) with <60 mm diameter, or symptomatic/ruptured 70 TAAA. Surgical indication was discussed with a multidisciplinary team involving vascular and 71 cardiac surgeons, anaesthesiologists, cardiologists and radiologists. All patients with chronic aortic 72 dissections treated with simple TEVAR were not included in the present study. Primary outcomes 73 were: technical and clinical success of the procedure and overall survival rates. Secondary 74 outcomes were: FL thrombosis, freedom from reintervention and TAAA diameter decrease.

Technical success was defined as complete coverage of primary entry tear, target vessels patency
and absence of type I or III endoleaks (EL). Clinical success was defined as the absence of death,
type I or III EL, infection, significant aneurysm expansion (≥ 5 mm), rupture or complete FL
thrombosis [12-13].

All patients underwent pre-operative computed tomography angiography (CTA) to define aortic
diameter, identify the origin of visceral vessels from the TL or FL and proximal and distal landing
zones and evaluate integrity of the vascular accesses.

Patients have been consented for personal data collection and data use for scientific purposes at the
time of surgery. This present study was designed as a retrospective analysis of those prospectively
collected information, therefore ethical committee approval was waived.

85

86 Endovascular procedures

All endografts were designed to be deployed in the true lumen. When the pre-operative 87 88 planning included a coverage of more than 10 cm of thoracic aorta a stage procedure was performed: the first step was an exclusion of the proximal thoracic entry tears, followed by a second 89 stage with the F/B-TEVAR, with an average delay of one month. The proximal landing zone was 90 91 planned to be either the native non-dissected aorta or a previous surgical graft or endograft with a 92 standard oversizing between 15-20% and a length of at least 25 mm for the native aorta and 40 mm 93 when landing in an endograft or frozen elephant trunk (FET). When landing in Ishimaru zones Z1 94 or Z2 a supra-aortic trunks revascularization was required, the surgery was always performed 95 within the 48 hours before the first endovascular stage to reduce the risks of neurologic complications [2, 14-16]. Preservation of hypogastric artery direct flow was attempted in all 96 97 feasible cases during the F/B-TEVAR stage. Fenestrated endografts were preferred in case of 98 narrow true lumen and when antegrade access for the eventual B-TEVAR was unfavourable as in 99 most of the cases with previous arch replacement. A minimal graft lumen diameter of 18 mm was 100 designed in all cases with narrow a rtic true lumen at the level of visceral arteries. In case of < 18101 mm true lumen, a double diameter-reducing wire was planned for constraint before full deployment 102 [17].

A Cook F/B-TEVAR (Cook Medical, Brisbane Australia) was used in all cases, except for one
 pD-TAAA contained rupture for which a four fenestrations physician-modified Medtronic Navion

105 (Medtronic Vascular, Santa Rosa, CA) endograft was required [18]. Off-the-shelf Zenith t-Branch
106 thoraco-abdominal stent graft (Cook Medical, Birsbane Australia) was used when anatomically
107 suitable.

108 Branched grafts had always straight outer directional branches. Visceral stent-grafts in different 109 configurations (balloon expandable or self-expanding stent-grafts, eventually re-enforced by bare 110 metal stents) were chosen in each dingle case depending on the vessel anatomy. Usually balloon 111 expandable stent-graft was used for fenestrations (Advanta V12, Getinge; BeGraft, Bentley 112 InnoMed) and self-expanding stent was used for branches (Fluency, Bard) [19]. Target vessels were engaged from a femoral access in case of fenestrations, while a brachial approach was used for 113 114 branches. When endovascular fenestration of the lamella was required, this was performed with a progressive non-compliant balloon dilatation over a guidewire displaced across the two lumens at 115 116 the level of a pre-existing tear or through a neo-fenestration. All procedures were performed in 117 hybrid operating room under general anaesthesia.

118 Cerebrospinal fluid (CSF) drainage was placed in all cases during the F/B-TEVAR intervention and 119 maintained for 48/72 hours, with a target spinal cord pressure < 12 mmHg [20]. Other peri-120 operative monitoring included: clinical control in intensive care unit (ICU) for at least 48 hours, 121 strict arterial pressure control with a mean arterial pressure target > 85 mmHg, haemo-transfusion 122 when haemoglobin < 10 g/dl [21-22].</p>

123 Due to the complexity of the treatment, all procedures were performed by a multidisciplinary team 124 consisting of Vascular and Endovascular Surgeons and Radiologists, with the presence of at least 125 one of the most experienced endovascular operators in all cases (FV, CF, GP).

126

127 Post-operative and Follow-up

During the hospital stay, patients were evaluated with clinical and laboratory examinations.
Doppler ultrasound (DUS) control of the vascular accesses and the visceral vessels was performed

along with a CTA before discharge within 30 days from surgery, which represented the first follow-up time-point.

All patients received acetilsalicilic acid 100 mg/daily and prophylactic regimen low molecular
weight heparin (LMWH). Dual antiplatelet therapy was started after CSF drainage removal and
continued lifelong if well tolerated or at least for six months.

Follow-up consisted of clinical evaluation and CTA imaging at 6 months and yearly thereafter, in
absence of complications. Parameters evaluated at follow-up were aneurysm diameter, FL patency,
target vessel patency, presence and characterization of ELs, reinterventions, complications and
mortality.

- 139
- 140 *Statistical analysis*

141 Continuous variables are expressed as mean and standard deviation or range. Categorical 142 variables are presented as percentage. Kaplan-Meier survival estimates were calculated to assess 143 overall mortality, aortic-related mortality and freedom from re-intervention. Curves are displayed as 144 a solid line up to a value of standard error (SE) < .10; dotted lines refer to estimates with a SE \geq .10. 145 Statistical significance was set at p <.05 All statistical analyses were conducted with R version 146 3.6.2. (R foundation for statistical computing, Wien, Austria)

- 147
- 148 **Results**

A total of 21 patients (16 male, mean age 63±10 years) with pD-TAAA were enrolled in the study. Mean aortic diameter at time of indication for F/B-TEVAR was 61±6.2mm. Patients demographics are shown in Table 1. TBAD was the initial presenting disease in 11 (52.3%) cases, the rest presented originally with a type A aortic dissection and had underwent successful proximal aortic surgery. Two patients (9.5%) were affected by connective tissue disorders. Five patients (24%) presented a Crawford type I TAAA, 15 (71.3%) a Crawford type II and one patient (4.7%) Crawford type III TAAA. Endovascular treatment was needed after a mean of 47 months (3 – 120) from the disease onset. Previous TEVAR was already in place in 3 (14%) cases, while two patients
(9.5%) presented FET with Thoraflex (Terumo Aortic, Sunrise). A staged approach was used in 12
cases (57%) with mean interval between the first and second procedure of 58 days.

159

160 *Procedure details and technical success*

161 Custom made fenestrated and branched devices were used for 18 patients (86%) patients; 2 cases 162 (9.4%) were treated with off the shelf Zenith t-branch thoraco-abdominal stent graft (Cook Australia, Brisbane, Australia); in one case (4.7%), due to urgent setting characterised by contained 163 164 thoracic rupture after the first stage of TEVAR in a symptomatic patient, a physician-modified 165 endograft was used. Due to an inadequate proximal landing zone four patients (19%) underwent a 166 carotid-carotid-subclavian bypass, while in three cases a carotid-subclavian bypass (14%) was 167 performed. Common iliac arteries were generally used as distal landing zone with the exception of 168 2 cases (9%) of unilateral external iliac landing zone and hypogastric occlusion (patients 1 and 6), one case (5%) of IBD (patient 6) and 2 cases (9%) where distal abdominal aorta was used as 169 170 landing zone (patients 5 and 21).

171 Overall 84 visceral vessels were successfully targeted (20 coeliac trunks, 21 superior mesenteric

arteries, 42 renal arteries, 1 accessory renal artery; one coeliac trunk was chronically occluded).

173 Seventy-two (85.7%) vessels were targeted with fenestrations and 12 (14.3%) with downward

branches. Seven target vessels (8%) originated from the FL: in 5 cases an endovascular fenestration

175 was necessary to reach the target vessel, while in the remaining 2 cases a branch configuration close

to a large tear of the lamella was used for the revascularization. Previous renal artery stent and

177 celiac artery stent were present in three and two cases respectively (6% of target vessels; Fig. 1).

178 Misalignment between fenestration and target vessel impeding visceral stent grafting did not occur.

179 Data from each procedure are shown in Table 2.

180 Technical success was achieved in 18 patients (86%), with two cases of type Ic EL and one case of
181 type IIIc EL left untreated [23]. One patient underwent early reintervention due to access

182 complication (brachial pseudo-aneurysm). Two patients (9.5%) experienced post-procedural spinal 183 cord ischemia, both resolved within one-month follow-up. At 30 days no type Ia or Ib EL were 184 reported, but there were six type II EL (28.5%), two type Ic EL (9.5%) and one type IIIc EL (4.7%). 185 Type Ic and IIIc EL were treated with visceral vessel stent-graft relining; a successful treatment was 186 achieved in two patients, while a minimal residual type IIIc EL following the procedure was left 187 untreated. Estimated freedom from reintervention at 12 and 24 months was $85.9 \pm 7\%$ (Fig. 2).

188

189

190 *Follow-up and clinical success*

Mean follow-up was 23 ± 13 months, without any loss at follow-up. No late aortic-related deaths occurred; one death at 21 months from the procedure due to acute cardiac failure after myocardial infarction was reported. Overall survival curve is depicted in Fig. 3. No cerebral ischemic complications or visceral vessel loss were reported. In 13 cases TAAA diameter decreased at least 5 mm, with only one TAAA diameter increase. Complete FL thrombosis was obtained in 18 patients, reaching a clinical success of 86%. The reason for a residual FL perfusion was a type II EL in two cases (left untreated due to the absence of aneurysm growth) and a type IIIc EL in one case.

198

199 Discussion

200 Patients with uncomplicated acute TBAD are typically managed medically with 201 antihypertensive drug therapy. However, during chronic phase, these patients are at higher risk for 202 aneurysmal dilatation and rupture of the affected aorta [24]. The estimated aortic growth after 203 TBAD ranges from 1 mm to 7.1mm/year as reported by Blount et al. [25]. Open repair of PD-204 TAAA has always been considered the gold standard despite a not negligible mortality and 205 morbidity rates [26-28]. Analyses of volume-related outcomes over a wide range of hospitals reveal 206 the "real world" picture, with overall mortality reaching 22.3% and postoperative complication rate 207 exceeding 55% [29].

The encouraging results obtained with the use of endovascular repairs for TAAAs, have led to the evaluation of the feasibility of such treatment in pD-TAAAs, at least for high risk patients [7-8]. The presence of re-entry tear in the abdominal aorta reduces the possibilities of a complete FL thrombosis with simple TEVAR. For this reason, different techniques have been used to increase technical success: F/B-TEVAR, FL embolization with coils and plugs, the knickerbocker technique, the Petticoat technique and the STABILISE technique [30-33].

Compared with other techniques, F/B-TEVAR is burdened by an increased complexity in planning due to the difficulties in sizing the TL (often compressed by the FL), the extreme variability in the origin of the visceral vessels from the TL or FL, the narrowness of the TL and the possible involvement of the iliac arteries in the dissection.

219 For these reasons, only high-volume centers with experience in complex endografting were the first 220 to use such approach for pD-TAAA with encouraging results at least in the short term. Early and 221 mid-term outcomes of our study are similar to those present in literature in terms of technical 222 success and early and mid-term mortality, with favorable outcomes considering the complexity of 223 the pathology and the high prevalence of comorbidities of the patients enrolled [9-11, 34-36]. 224 Interestingly, results of the published literature came from very few, selected centers highly devoted 225 to complex endografting, while in the present experience, similar results have been obtained in 226 centers with low annual incidence of pD-TAAA, but well experienced in complex endografting. 227 In the present study two cases of transient SCI were reported (9.5%), which is in average with the 228 data reported in literature, with a range 0-15% [9-10, 34-36]. This evidence seems to support the 229 idea where there is a higher possibility of recovery after SCI in patients undergoing pD-TAAA

endovascular treatment rather than after open repair, however further comparative studies are

231 needed [9, 31].

232 In the cases observed reintervention was required exclusively for visceral stents endoleak

complications, while no occlusions were reported. This observation may be due to the fact that the

visceral vessels were rarely atherosclerotic and the stent graft used were usually rather short due tothe narrow gap between the aortic endograft and the target vessel.

The reason for a not negligible incidence of type Ic and IIIc ELs is not clear, but as suggested by Oikonomu et al, it may be due to the excessive caution during sizing and deployment, along with the insufficient flaring of the bridging in order to avoid a visceral dissection when dealing with the extremely fragile aortic walls and narrow TL [10].

The only residual type IIIc EL despite relining, occurred in our experience with the case of physician-modified endograft. Considering the lack of aneurysm sac growth and patient's frailty it was decided to postpone eventual further treatment. The fenestrations have been designed too large to reduce the risk of misalignment and failure to cannulate, but insufficient flaring of the mating stent graft was then not able to cope with the gap between the aortic and the visceral components. The procedure was however successful in promote thrombosis of the FL in the thoracic portion of the fissured TAAA with survival of the patient.

False lumen thrombosis occurred in 86% of the present experience, a rate similar to others reported 247 248 in literature, with aneurysm sac shrinkage in 62% of cases and no aortic-related deaths [10, 34-36]. 249 This suggests that, although burdened by a higher risk of reintervention, F/B-TEVARmay obtain a 250 stable seal of the aortic wall and the false lumen, representing a potentially valid solution for pD-251 TAAA. Relative motion of the visceral stent-grafts and the aortic component may be less pronounced in pD-TAAA if compared to atherosclerotic TAAA, perhaps reducing the long-term 252 253 risks of secondary ELs. However a situation of particular risk may be the use of longer stents to 254 reach vessels taking off from aneurysmal FL, unless the presence of a rigid lamella may sustain the 255 stent in position.

Study limitations are: the experience suffers from small number of treated patients, low event rates and short follow-up. The multi-center nature of the study may introduce biases regarding different patients and material selection, although most of the operators shared a common training in the same University Center of Perugia.

262 Conclusion

263	Complex endografting for pD-TAAA is a feasible therapeutic solution with favourable mid-term
264	results when performed in highly experienced centres. Staged procedures and careful planning of
265	adjuvant techniques are compulsory in order to perform endovascular repair in patients often
266	evaluated with high surgical risk in case of open repair. Larger multi-center experiences with longer
267	follow-up are suggested for definitive answers regarding the role of endovascular treatment
268	compared to open surgery in post-dissection thoraco-abdominal aneurysms.

409 TABLES

410 Table 1 Patients demographics and risk factors

Comorbidities and risk factors	N (%)
Age	63±10 years
Male gender	16 (71%)
Hypertension	20 (95%)
Diabetes	3 (14%)
Smoking	7 (33%)
Chronic obstructive pulmonary disease	4 (19%)
Chronic renal insufficiency	2 (9.5%)
Coronary artery disease	9 (43%)
Severe obesity*	1 (4.7%)
Marfan or connettive tissue disorders	2 (9.5%)
Original Type B aortic dissection	11 (52.3%)

411

412 *severe obesity evaluated as Body Mass Index >35

413
