21 Abstract

22 Quorum sensing (QS) is the ability of some bacteria to detect and to respond to
23 population density through signaling molecules. QS molecules are involved in motility and cell
24 aggregation mechanisms in diseases, such as sepsis. Few biomarkers are currently available to
25 diagnose sepsis, especially in high-risk conditions. The aim of this study was the development of
26 new analytical methods based on liquid chromatography-mass spectrometry for the detection and
27 quantification in biofluids of QS signaling molecules like N-acyl homoserine lactones (AHL)
28 and hydroxyquinolones (HQ). Biological samples used in the study were *Pseudomonas*
29 *aeruginosa* bacterial cultures and plasma from septic patients. We developed two MS analytical
30 methods based on neutral loss (NL) and product ion (PI) experiments to identify and characterize
31 unknown AHL and HQ molecules. Then we settled a multiple-reaction-monitoring (MRM)

method to quantify specific QS compounds. We validated the HPLC-MS based approaches (MRM-NL-PI) and data were in accordance with the validation guidelines. With the NL and PI MS based methods we identify and characterize in biological samples 3 and 13 unknown AHL and HQ compounds respectively. One of the new-found AHL molecules was C12-AHL firstly quantified in *Pseudomonas aeruginosa* bacterial cultures. The MRM quantitation of analytes in plasma from septic patients confirmed the ability of MRM analysis to quantify virulence factors during sepsis.

Keywords

Quorum sensing molecules, Homoserine lactones, Hydroxyquinolones, *Pseudomonas aeruginosa*, Mass Spectrometry, Triple Quadrupole

Abbreviations

3-oxo-C12-AHL: N-(3-oxododecanoyl)-L-homoserine lactone

AHLs: N-acyl homoserine lactones

AI: Autoinducer

C4-AHL: N-butanoyl-L-homoserine lactone

C7 HQ (or PQS): 2-heptyl-3-hydroxy-4(1H)-quinolone

HPLC: High Performance Liquid Chromatography

HPLC-TQ MS: High Performance Liquid Chromatography- Triple Quadrupole Mass Spectrometry

HRMS: High Resolution Mass Spectrometry

HQs: Hydroxyquinolone signaling molecules

IS: Internal Standard

LB: Luria-Bertani

LLOQ: Lower Limit of Quantification

LTQ: Linear Trap Quadrupole

M9: Mineral medium

MOF: Multi Organ Failure

MRM: Multiple Reaction Monitoring

MS: Mass Spectrometry

71 **1. Introduction**

72 Bacteria have the ability to interact each other through a complex language called
73 “Quorum Sensing” (QS) [1-3]. Literally, QS means “detection of the quorum” and it is referred
74 to the ability of bacteria to monitor their density of population and consequently to control their
75 gene expression, through the control of the amount of specific molecules, called autoinducers
76 (AIs), in their living environment [4-6]. AIs are small and diffusible molecules produced by
77 bacteria, released and accumulated in the extra cellular environment. When many AIs are
78 produced and stored, and their concentration gains a threshold level (the quorum), the bacterial
79 population is able to activate or to repress target gene [7]. This mechanism allows the survival of
80 bacterial population in a constantly changing environment (temperature, pH and osmotic
81 concentration variations, and nutrient availability) thanks to the synthesis of new proteins. QS
82 mediated changes are energetically expensive, and they are advantageous only when cells
83 reached high density population [8, 9].

84 Gram-positive and Gram-negative bacteria use different communication-ways [10].
85 Gram-positive bacteria produce oligopeptides as QS autoinducers molecules, while Gram-
86 negative bacteria use others QS signal molecules [11-13]. The most abundant and common are
87 N-acyl homoserine lactones (AHLs) [14, 15]. These molecules are characterized by a γ -lactone
88 cycle which is N-acylated in α position and an acyl-chain (indicated as R-chain in Fig.1). Chain
89 length is the signal specificity factor for bacteria and, generally, the chain contains between 4
90 and 16 carbon atoms. Furthermore, the presence of an -oxo or a -hydroxy group linked to the 3rd
91 carbon atom of the chain is a further element of distinction.

92

Figure 1: N-acyl homoserine lactone generic structure. A: Non-substituted N-acyl homoserine-L-lactone (C_n-HSL) acyl chain; B: N-(3-Hydroxyacylhomoserine)-L-lactone (3-OH-C_n-HSL) acyl chain; C: N-(3-Oxoacylhomoserine)-L-lactone (3-oxo- C_n-HSL) acyl chain. The length is variable, generally n=4-14

In some human opportunistic pathogens, like *Pseudomonas aeruginosa*, the secretion of the most abundant AHLs QS signaling molecules N-(3-oxododecanoyl)-L-homoserine lactone (3-oxo-C₁₂-AHL) and N-butanoyl-L-homoserine lactone (C₄-AHL) depends from the regulatory circuits systems *Las* or *Rhl* [16, 17]. In bacteria, those systems control the expression of different virulence genes in a population density dependent.

In addition to AHLs, Gram-negative bacteria, such as *Pseudomonas aeruginosa*, use a hydroxyquinolone molecule (HQ), the 2-heptyl-3-hydroxy-4(1H)-quinolone (known as PQS or C₇ HQ), as QS signaling compound [18, 19]. The basic structure of quinolone molecules consists in a bicyclic ring. The length of the acyl-chain (marked as R-chain in Fig.2) ranges between 7 and 11 carbon atoms; the presence of a hydroxy- or a carbonyl- group in position 1 of the bicyclic ring is a further element of distinction.

Figure 2: Quinolone signaling molecules generic structure. D: 2-alkyl-4-hydroxyquinolone N-oxide with a chain length variable (C₇-C₉); E: 2-alkyl-4(1H)-quinolone alkyl chain (the length chain is variable, C₇-C₁₁); F: 2-alkyl-3-hydroxy-4(1H)-quinolone.

As described, AHLs and HQs are the most abundant QS signaling molecules produced by Gram negative bacteria. Many studies are present in literature with the aim to describe and quantify well-known or new QS molecules in bacterial culture or human samples [20-35]. There are two main methods to obtain the measurements: biosensors [21-23, 26, 30, 31] and methods

1
2
3 119 based on liquid chromatography coupled to (high resolution) mass spectrometry [20, 23-25, 27-
4 120 29, 32-36]. Biological biosensors reach very low sensitivity, with a pg/mL (fmol) limit of
5 121 detection, and are highly specific for one single QS (AHL or HQ). However, they miss unknown
6 122 molecules and the quantitation shows low accuracy [32]. On the contrary, mass spectrometry
7 123 based methods, both targeted and untargeted, offer accurate quantitation of AHL and HQ
8 124 compounds. During the last years, many LC-MS methods were developed exploiting several
9 125 stationary and mobile phases, and both targeted and untargeted MS approaches. Some studies
10 126 showed a very low limit of quantitation (pg/mL) and a good selectivity optimizing a short liquid
11 127 chromatography separation both for AHLs, furthermore enantiomeric, and for HQs [27-29, 33-
12 128 36]. Other research groups have been developed extended chromatography separation runs to
13 129 provide the quantitation of a higher number of molecules [24] or to identify new AIs molecules
14 130 with untargeted high resolution MS approach [32].

15 131 Summarizing, there is a huge number of QS molecules produced by bacteria and
16 132 identification, characterization and accurate quantitation of peculiar and unknown QS are still
17 133 required.

18 134 The purpose of this work was to develop and validate HPLC-TQ MS chemical class-
19 135 specific methods able to identify and quantify quorum sensing molecules (AHLs and HQs) in
20 136 different matrices, such as bacterial cultures and biological plasma samples. In order to
21 137 characterize and identify unknown AHLs and HQs signaling molecules, the aim of the research
22 138 was the development of MS analytical method based on neutral loss (NL) and product ion (PI)
23 139 experiments. A tandem mass method based on multiple reaction monitoring (MRM) approach
24 140 was developed for the quantitation of AHLs and HQs in bacterial cultures and biological plasma
25 141 samples. To ensure greater reliability of analytical data, fragmentation pathways of analytes of
26 142 interest and exact mass of detected unknown molecules were confirmed by high-resolution mass
27 143 spectrometry (LTQ-Orbitrap). The developed MRM method was firstly applied to quantify the
28 144 QS molecules in *Pseudomonas aeruginosa* cultures obtained from two different strains [37] and
29 145 with our NL and PI methods we aimed to elucidate if other QS molecules were involved in
30 146 protection mechanism used by bacteria. Secondly, the MRM method was applied to pathological
31 147 plasma samples (before and after hemoperfusion) of patients affected by sepsis-related multi-
32 148 organ failure (MOF) pathology, which is associated with high mortality. To our knowledge this

1
2
3 149 study is the first that provide a tandem/mass spectrometry quantitation both of AHLs and HQs in
4
5 150 plasma samples coming from patients with sepsis.

6 7 151 **2. Materials and methods**

8 9 152 *2.1. Chemicals*

10
11 153 Analytical standards (purity>98%) of 2-heptyl-3-hydroxy-4(1H)-quinolone (C7 HQ), N-
12 154 (3-oxododecanoyl)-L-homoserine lactone (3-oxo-C12-AHL), N-hexanoyl-L-homoserine lactone-
13
14 155 D3 (ND3) and N-butanoyl-L-homoserine lactone (C4-AHL) were purchased from Merck KGaA
15
16 156 (Rome, Italy). Stock solutions were prepared with a concentration of 1000 mg/L using methanol
17
18 157 and stored at -4 °C until use. Further dilutions were obtained in 0.1% formic acid in
19
20 158 water/acetonitrile 60:40. All aqueous solutions were prepared with HPLC-grade water from
21
22 159 MilliQ System Academic (Millipore, Milan, Italy). Ethyl acetate for HPLC-MS grade,
23
24 160 acetonitrile and methanol hyper grade for LC-MS, and formic acid were purchased from VWR
25
26 161 International (Milan, Italy).

26 27 162 *2.2. Instrumentation*

28
29 163 Separation and analysis of all analytes and samples were achieved upon a HPLC-TQ MS
30
31 164 platform. HPLC consisted of a Shimadzu Nexera X2 Ultra High Performance Liquid
32
33 165 Chromatography (UHPLC) system (Shimadzu, Kyoto, Japan) coupled for identification and
34
35 166 quantitation to a QTRAP 5500 system (Sciex, Darmstadt, Germany). The triple quadrupole was
36
37 167 equipped with a Turbo V™ Source (ESI mode) which utilized nitrogen and air as sheath and
38
39 168 reagent gas, respectively. Furthermore, to verify the exact mass values, we used the high
40
41 169 resolution mass spectrometer LTQ-Orbitrap (Thermo Scientific, Bremen, Germany) within mass
42
43 170 accuracy of ± 3 ppm and resolution of 30k.

41 42 171 *2.3. HPLC parameters*

43
44 172 To investigate AHL and HQ signaling molecules in biological samples different
45
46 173 chromatographic gradients were carried out. However, HPLC methods had several features in
47
48 174 common. The analytical column used was a Phenomenex Luna C18 reverse-phase (150 × 2.1
49
50 175 mm i.d., 3 μ m particles). Sample injection volume was 10 μ L. Autosampler and oven
51
52 176 temperatures were set at 15 °C and 45 °C respectively for all the duration of the analyses.

52
53 177 For AHLs HPLC-TQ MS analysis eluents were formic acid 0.1% in water (solvent A)
54
55 178 and in acetonitrile (solvent B). Flow rate was set at 200 μ L/min. For bacterial cultures, the
56
57 179 mixture percentage changed from 40% solvent B to 100% solvent B during the first 35 min,

1
2
3 180 maintained for 10 minutes and then the column went back to the starting conditions. For plasma
4
5 181 sample, HPLC run started from 40% solvent B, increased to 100% solvent B in 19 min,
6
7 182 maintained for 10 minutes and then the column went back to the starting conditions. Bacterial
8
9 183 cultures were more complex than plasma samples and required to obtain a satisfactory
10
11 184 chromatographic separation a slower solvent variation during gradient elution (see Electronic
12
13 185 Supplementary Material (ESM) Fig. S1).

14 186 Chromatographic separation for the MRM and PI analysis of C7 HQ in bacterial cultures
15
16 187 and plasma samples was achieved using 2-picolinic acid 2 mM/formic acid 0.1% in water
17
18 188 (solvent C) and acetonitrile 0.1% formic acid (solvent D). 2-picolinic acid acted as a bidentate
19
20 189 chelator preventing peak distortion caused by C7 HQ, an iron chelator molecule [33]. Gradient
21
22 190 started from 20% solvent D, up to 100% solvent D in 12 min; then the column went back to the
23
24 191 starting conditions. Flow rate was 250 μ L/min.

24 192 2.4. MS settings

25
26 193 The LC effluent was delivered to Turbo VTM Source (ESI positive ionization mode) using
27
28 194 nitrogen as sheath (GS1) and curtain (CUR) gas and air as reagent (GS2) gas respectively. The
29
30 195 mass spectrometer parameters were as follow: CUR 26 arbitrary units (arb), GS1 45 arb, GS2 50
31
32 196 arb, ion spray voltage 5.5 kV and ion spray temperature 500 °C.

33 197 Considering all the possible MS experiments developed, each sample was analysed five
34
35 198 times: MRM-NL-PI for AHLs analysis, and MRM-PI for HQs analysis. The MRM, NL and PI
36
37 199 parameters were listed in table 1. For MRM acquisition we selected one qualitative and one
38
39 200 another quantitative (bold in Table 1) transition for each analyte. The instrument parameters
40
41 201 were listed in ESM Tables S1 and S2.

41 202
42 203

Analyte	Precursor ion [M+H] ⁺	Product Ion [M+H] ⁺	Molecule family	MS Mode	Δm (Da)
MRM	3-oxo-C12-AHL	298.2	AHL	NL	101.0
		298.2		PI	102.0
	C4-AHL	172.1	HQ	PI	175.0
		172.1			
	C7 HQ	260.0	188.0

204
205 **Table 1:** Multiple Reaction Monitoring (MRM), Neutral Loss (NL) and Product Ion (PI) scan parameters for AHLs
206 and HQs analysis (bolded transitions were used as quantitative ones).
207
208

209 2.5. Bacterial cultures and biological samples

210 Two *Pseudomonas aeruginosa* strains were selected as representatives of bacterial
211 cultures: wild type PAO1 strain and its isogenic mutant RhII- defective in the synthesis of C4-
212 AHL previously obtained [37, 38].

213 Different *Pseudomonas aeruginosa* PAO1 and RhII bacterial cultures were prepared and
214 analysed: I) wild type bacterial culture grown in Luria-Bertani (LB) broth (rich in nutrients),
215 WT-LB; II) wild type bacterial culture grown in the mineral medium (M9) culture (low in
216 nutrients), WT-M9; III) RhII- mutant bacterial culture grown in the LB broth, RhII-LB; and IV)
217 RhII- mutant bacterial culture grown in the M9 culture, RhII-M9.

218 For the application of the MRM-NL-PI methods developed, we analysed plasma samples
219 belonging to healthy people and patients affected by MOF. All the patients involved in the
220 present study expressed their consent and their will based on their awareness of the proposed
221 research upon their biological fluids, freely deciding whether to accept it or not. All the
222 procedures followed in the work have been carried out in accordance with the ethical standards
223 of our institutional, the national research committee and with the Code of Ethics of the World
224 Medical Association (1964 Helsinki declaration).

225 2.6. Sample preparation and enrichment

226 All the bacteria media were prepared as described by Orlandi et al. [37]. Bacterial
227 cultures were centrifuged for 10 min at 12,000 rpm RT and then the supernatants were collected
228 and filtered (Minisart RC15 Ø 0.20 mm; Sartorius) before extraction (see below).

229 Samples from patients with MOF were taken during a weekly dialysis session, and they
230 were collected before (t_0), after 2 hours (t_{2h}) and 24 hours (t_{24h}) of hemoperfusion, and from
231 healthy people during a draw in the morning. Plasma was separated from blood with an ultra-
232 centrifugation and then stored refrigerated at 4 °C until use. Samples were processed and
233 analysed within two days.

1
2
3 234 Before extracting the analytes from samples, 200 μL of bacterial cultures medium or
4
5 235 plasma were spiked with ND3 internal standard (IS) with a final concentration of 200 $\mu\text{g/L}$. The
6
7 236 internal standard was used to evaluate injection only. All of the analytical validation was done on
8
9 237 the bases of external standard calibration. Successively, samples were extracted twice with 1 mL
10
11 238 of ethyl acetate [39]. After each addition of organic solvent, the sample was centrifuged at 5,000
12
13 239 $g \times 5$ min RT and the organic fractions were collected and dried under a gentle stream of N_2
14
15 240 heating at 40° C. Finally, the residue was reconstituted in 100 μL of 0.1% formic acid in
16
17 241 water/acetonitrile 60:40.

17 242 2.7. HPLC-TQ MS methods validation

18
19 243 The validation procedure was performed upon the HPLC-TQ MS platform, according to
20
21 244 the European Medicine Agency (EMA) and Eurachem guidelines [40, 41]. The calibration
22
23 245 curves were run using a matrix free from quorum sensing molecules (plasma samples from
24
25 246 healthy people) by performing standard addition method. The absence of analytes of interest
26
27 247 within the matrix used (QS-free matrix) for the methods validation was verified through LTQ-
28
29 248 Orbitrap high resolving power platform.

30
31 249 For method validation, different parameters were evaluated: selectivity, recovery, carry-
32
33 250 over, intra-run accuracy and precision, limit of quantitation (LOQ), lower LOQ (LLOQ), upper
34
35 251 LOQ (ULOQ), stability to freeze-thaw cycle and calibration model. The last one, in particular,
36
37 252 was evaluated using a stepwise approach as schematized elsewhere [42] and linearity of
38
39 253 calibration curves using a R routine developed by Desharnais *et al.* [43, 44]: firstly, the
40
41 254 heteroscedasticity of data points was tested performing an F test on the variance of the area ratios
42
43 255 at the lowest and highest calibration levels. The heteroscedasticity study was also integrated with
44
45 256 the Levene test (in the version modified by Brown and Forsythe). Then, a partial F-test was used
46
47 257 to evaluate if the calibration model follows a linear or quadratic trend [45]. The goodness of the
48
49 258 calibration model was finally evaluated by studying the normality of the standardized residuals
50
51 259 (with the Cramer von Mises test) and by performing the back calculation on the averaged signal
52
53 260 from the four replicates [43, 44].

54
55 261 For the validation of AHL molecules, C4-AHL and 3-oxo-C12-AHL were selected as
56
57 262 molecules class representatives. On the contrary, C7 HQ was used as a representative of HQ
58
59 263 molecules. For all the analyses, ND3 was used as injection standard.
60

264 Selectivity (SEL%) was evaluated by comparing the chromatogram of six individual QS-
 265 free matrices and could be below 20%. Recovery (REC%) was evaluated by relating the
 266 responses of analytes in the extracted samples with those solubilized in solvent of injection. The
 267 experiments were conducted at LLOQ and ULOQ concentration, depending on analyte. REC%
 268 was evaluated only for the MRM approach. The carry-over effect (CO%) was studied by
 269 comparing the signal of the molecule of interest in QS-free matrix after the injection of the
 270 highest concentration point of the calibration curve. Values could be below 20% of LLOQ value.
 271 Accuracy (BIAS%) and precision (variation coefficient CV%) of intraday (repeatability) were
 272 calculated in QS-free matrix samples at three different concentration repeated 5 times. Values
 273 could be below 15%. Limit of quantitation (LOQ) was determined by ten times the signal-to-
 274 noise ratio, expressed as the absolute value of analyte concentration. Lower LOQ (LLOQ) and
 275 Upper LOQ (ULOQ) were expressed as experimentally lower and upper measured analyte
 276 concentration. Freeze-thaw stability (STAB%) was valued by comparing freshly prepared
 277 processed samples freezing at -20 °C for three cycles and thawing at RM in order to depict
 278 freeze-thaw stability of the AHLs and HQs standards. The experiments were evaluated at two
 279 concentrations, LLOQ and ULOQ. STAB% could be comprised between 85% and 115%.

3. Results

3.1. Validation results

282 Validation results were summarized in table 2 and presented in ESM Section “2.
 283 Validation tables and results”. All parameters were conformed with those suggested by EMA and
 284 Eurachem guidelines.

Validation parameter	Conc. (µg/L)	3-oxo-C12-AHL			C4-AHL			C7 HQ

Table 2: Validation parameters for 3-oxo-C12-AHL, C4-AHL and C7 HQ obtained in MRM, NL, PI HPLC-MS approaches (n.m. not measured).

288

Selectivity of each MS approach was satisfactory with a value always below 20%, comprised between 0.50 and 16.5%. No isomeric or isobaric interfering compound co-eluted with the analytes and no ion suppression was observed for the AHLs and HQ standard molecules.

The recovery calculated for MRM approach ranged between 34% and 61%. These were presumably correlated with the presence of esterase enzymes in the plasma matrices and quorum sensing molecules, being esters, underwent to a partial hydrolysis. However, using the calibration curves obtained in plasma matrices, we overcame the issue.

Carry-over effect measurements demonstrated, for all MS methods, that in QS-free matrix sample the analytical standards area under the curve (AUC) was lower than 20% of the corresponding LLOQ area.

Precision and accuracy of intra-day run were below 20% for the selected curve calibration points.

LOQ values for analytes ranged between 0.09 to 0.457 $\mu\text{g/L}$, respectively and the MRM method showed the best value of LLOQ (0.4 $\mu\text{g/L}$).

Stability test parameters had always fallen within the acceptable limits and based on the results, average stability % value at each concentration level was in the range between 85% and 117%. Therefore, plasma matrix was stable as at operative conditions temperatures as to freezing and thawing cycles without affecting the concentration of the analyte.

The study of the calibration model provided concordant results for all the analytes. Concerning the study of heteroscedasticity, the F-test and the Levene test provided consistent results for all but two calibration sets, namely C4-AHL-NL and C4-AHL-PI, for which the Levene test suggested a homoscedastic trend (ESM Table S5). In both the cases, a more

1
2
3 312 conservative approach was preferred, and the weight was applied as suggested by the routine
4
5 313 from Desharnais. The weight for the heteroscedasticity was equal to $1/x^2$ in all cases.
6
7 314 Furthermore, all the calibration curves were confirmed to be linear, with p-values for the partial
8
9 315 F-test above the significance limit of 0.05. The goodness of the calibration models was proved
10
11 316 by the good results provided by the Cramer von Mises test (p-values always not significant) and
12
13 317 the back-calculation (deviations far below $\pm 25\%$ for all the models). Finally, also the R-squared
14
15 318 values ($R^2 > 0.990$) demonstrated how our model explained all of the variation in the response
16
17 319 variable around its mean.

3.2. Samples results

With the development of three different MS approaches, we detected and quantified both unknown and known AHLs and HQs molecules in biological samples.

For AHL unknown structures, we used the NL and PI approaches. In NL experiments, precursor and product ions were monitored for the loss of 101 Da which corresponds to 2-amino- γ butyrolactone. In PI mode, Q3 was set to detect only m/z 102 corresponding to the elemental composition of protonated 2-amino- γ butyrolactone (Fig. 3).

For new molecules belonging to the HQs family, we used a PI methodology selecting as product ion the protonated radical ion 2-methyl-3-hydroxyquinolin-4-one with a m/z ratio of 175 (Fig. 3).

Figure 3: TQ MS MS selective acquisition modes. M1 is a generic structural formula of a protonated molecule belonging to N-acyl homoserine lactones (AHLs) family. R varies between 4 and 16 carbon atoms. M2 is the product ion formed after the neutral loss of a 2-amino- γ butyrolactone molecule (MW 101 Da). M2' is the product ion with m/z 102. Analogously, N1 is a general structural formula of compounds belonged to hydroxyquinolone signaling molecule (HQ) family. R varies between 7 and 11 carbon atoms. N2' is the product ion with m/z 175.

Unknown AHL and HQ signaling molecules, identified and characterized in an untargeted approaches using NL and PI modes, were confirmed by the use of HRMS tool (LTQ

orbitrap) and to better describe them we studied the fragmentation pathways of analytical standards (see “Discussion” section).

Two unknown AHL species were detected both in *P. aeruginosa* bacterial cultures and patients’ plasma samples: 3-oxo-C10-AHL ($C_{14}H_{23}NO_4$, m/z 270.1705) and C12-AHL ($C_{16}H_{30}NO_3$, m/z 284.2226). One other, C6-AHL ($C_{10}H_{17}NO_3$, m/z 200.1287), was present in bacterial cultures only (see ESM for chemical and structural formulas, Table S3).

In the bacterial cultures 13 unknown HQ molecules were identified by PI approach and confirmed by HRMS analysis: C2-HQ ($C_{11}H_{11}NO_2$, m/z 190.0868) C3-HQ ($C_{12}H_{13}NO_2$, m/z 204.1024), C4-HQ ($C_{13}H_{15}NO_2$, m/z 218.1181), C5-HQ ($C_{14}H_{17}NO_2$, m/z 232.1337), C6-HQ ($C_{15}H_{19}NO_2$, m/z 246.1494), C6:1-HQ ($C_{15}H_{17}NO_2$, m/z 244.1337), C7:1-HQ ($C_{16}H_{19}NO_2$, m/z 258.1494), C8-HQ ($C_{17}H_{23}NO_2$, m/z 274.1807), C8:1-HQ ($C_{17}H_{21}NO_2$, m/z 272.1650), C9-HQ ($C_{18}H_{25}NO_2$, m/z 288.1936), C9:1-HQ ($C_{18}H_{23}NO_2$, m/z 286.1807), C11-HQ ($C_{20}H_{29}NO_2$, m/z 316.2276) and C11:1-HQ ($C_{20}H_{27}NO_2$, m/z 314.2120) (see ESM for chemical and structural formulas, Table S4).

The detected compounds were then semi-quantified in bacterial cultures using the validated calibration curves of C4-AHL and 3-oxo-C12-AHL, depending on chain length and on hydroxylation grade, to quantify AHLs molecules, and of C7 HQ to quantify HQs compounds. For both quantifications of AHLs and HQs molecules we used the calibration curves obtained with PI MS methods because of their lower LLOQ (1 $\mu\text{g/L}$ for PI vs. 5 $\mu\text{g/L}$ for NL). The results were listed in Tables 3 (AHL) and 4 (HQ).

4. Discussion

4.1. Method validation discussion

The three acquiring techniques showed different LLOQ values and linearity ranges and MRM was the one which allowed the wider calibration range, with a LLOQ equal to $0.4 \mu\text{g/L}$ (for PI and NL LLOQ was $1 \mu\text{g/L}$ and $5 \mu\text{g/L}$, respectively). It is known that the MRM approach has a better sensitivity respect to NL and PI [46], moreover balanced by the better diagnostic possibilities of these different approaches.

Independently from the MS/MS, the class of the targeted molecule and the calibration range, the heteroscedasticity tests showed concordant results. Both the F-test and the Levene test on the variance of the calibration replicates demonstrated the need of a $1/x^2$ weight. The only exceptions are the NL and PI experiments performed for C4-AHL, for which the Levene test suggested a homoscedastic trend. This was discordant with the T-test output and also with the visual inspection of the replicates, by which it is evident a progressively greater variance for replicates of the higher calibration levels. Hence, a more conservative approach was preferred and a weight applied. Furthermore, the verification of the linearity trend by means of a partial F-test confirmed the linearity within the selected calibration range, with all the p-values above the cut-off limit of 0.05. The goodness of the selected calibration model was finally verified by high values of the p-value for the study of the standardised residuals normality and the back calculation at all the calibration levels (ESM Tables S5 and S6).

4.2. Sample results discussion

Before starting with the identification and characterization of unknown AHL and HQ molecules (presented in the section “Sample results” and in ESM Tables S1 and S2), an investigation using HRMS of fragmentation pathways of analytical standards was carried out. As representatives of AHLs class we selected 3-oxo-C12-AHL and C4-AHL, and C7 HQ from HQs family. ND3 as previously described was used as IS. CID MS² fragmentation schemes of C4-AHL, 3-oxo-C12-AHL, C7 HQ and ND3 are presented in Figure 4. As mentioned before, AHLs molecules shared the product ion m/z 102, and C7 HQ showed the peculiar product radical ion m/z 175 common for the HQ family.

Figure 4: MS² fragmentation pathways of, N-(3-oxododecanoyl)-L-homoserine lactone (3-oxo-C12-AHL), N-butanoyl-L-homoserine lactone (C4-AHL), 2-heptyl-3-hydroxy-4(1H)-quinolone (C7 HQ) and N-hexanoyl-L-homoserine lactone-D3 (ND3). Product ion m/z 102 and product radical ion m/z 175 are the characteristic fragmentation products of molecules belonged to AHLs and HQs family respectively.

1
2
3 417 Since the analysis of bacterial cultures and plasma of patients samples were completed
4
5 418 only two days after sampling and handling, and samples were stored refrigerated at -4 °C, no
6
7 419 other pathogens should develop [33]. In this situation, the unknown AHLs and HQs detected
8
9 420 with the developed MS methods resulted from *P. aeruginosa* bacteria or patients with sepsis.

10 421 The chromatographic runs here proposed for AHL molecules were quite longer if
11
12 422 compared with others analytical methods. Ortoni and co-workers [27] used a 2.9 minutes long
13
14 423 separation run to quantify 26 AHLs in bacterial cultures. Readel *et al.* [36] with an acetonitrile
15
16 424 isocratic run of 10 minutes successfully separated six racemic L/D homoserine lactones. Struss
17
18 425 [29] and Hoang [35] teams developed a 17 minutes reverse phase HPLC methods to quantify
19
20 426 AHL in sputum of cystic fibrosis patients and bacterial cultures, respectively. In particular,
21
22 427 Hoang group [35] presented a green analytical method with the use of supercritical-fluid
23
24 428 chromatography (SFC); they performed a profound optimization of the method. Unfortunately,
25
26 429 SFC-TOF is quite expensive technology and requires very skilled operator. Although these
27
28 430 methods showed very low limit of quantitation (pg/mL), good selectivity and robustness, they
29
30 431 quantified well-known molecules belonged to AHL family (using analytical standards) [27, 35,
31
32 432 36] or a limited number of analytes [29].

31 433 When the number of molecules increases and, more significantly, when unknown
32
33 434 compounds should be identified and characterized, the duration of separation run lengthens in
34
35 435 order to obtain no analytes co-elution or ion suppression. The developed chromatographic run
36
37 436 lasted 35 minutes, time comparable with those proposed by Kumari *et al.* [24] for the detection
38
39 437 of ten AHLs. An untargeted high resolution mass spectrometry method for the identification of
40
41 438 novel AHLs in eight different bacterial cultures growth under different condition was proposed
42
43 439 by Patel *et al.* [32]. They used a C18 column and a Q-exactive high resolution mass spectrometer
44
45 440 and within 13 minutes they recognized 23 AHLs, some of them never described in literature.
46
47 441 Their method showed little overlapping and tailing of chromatographic peaks, nevertheless they
48
49 442 achieved very low limit of detection for all analytes and performed the identification of
50
51 443 unexpected AHL molecules using a labelled approach. The MS/MS method for the identification
52
53 444 of AHLs was based, as for our, on peculiar product ion with m/z 102.

51 445 The HQs separation run was shorter than AHLs, and it could be comparable to those
52
53 446 developed by Maurer [28] and Brewer [34] groups. It lasted 12 minutes (Maurer 9' and Brewer
54
55 447 8') and the separation obtained with the use of 2-picolinic acid was satisfactory (ESM Fig. S2).

1
2
3 448 Although Maurer and co-workers [28] used a mixture of acetic anhydride–pyridine to derivatize
4 449 C7-HQ, and Brewer team [34] employed EDTA as mobile aqueous phase, we preferred to follow
5 450 the Turpnenny recommendation [33] in order to obtain a good shape of chromatographic peaks
6 451 and consequently a possible and accurate quantification of the HQ compounds. So, we run the
7 452 chromatographic separation with the use of 2-picolinic acid. Indeed, EDTA molecule is not
8 453 suggested for MS analysis since it is a non-volatile salt and gives ion suppression effect and
9 454 derivatization is not a quantitative operation. On the contrary, 2-picolinic acid is highly volatile
10 455 and a bidentate chelating agent and, as Turpnenny declared, the use of formic acid together with
11 456 2-picolinic acid improved the ESI positive ionization of the studied molecules [33].

12 457 As previously presented, we were able to detect and identify 13 HQs in bacterial cultures
13 458 and plasma samples. Among all the possible QS molecules, the most expressed (high
14 459 concentration) was the C7 HQ. In minimal medium poor in nutrients (W9), the C7 HQ species
15 460 was the only one detected both in the wild type and the RhlI- derivative bacterial cultures. This
16 461 finding could support the hypothesis that the knock-out mutant, unable to produce C4-AHL,
17 462 intensified the production of this signal molecule to bear bacterial cell growth. As for AHLs
18 463 compounds, cells grew in LB broth showed most abundant content of HQs molecules respect to
19 464 M9 medium. The detection of HQ molecules in biological samples is very important because
20 465 their concentration is related to the expression of many virulence factors and to the regulation of
21 466 iron usage inside the cells [47].

22 467 In addition to the importance of a good chromatographic separation, also the developed
23 468 NL and PI MS approaches played a fundamental role in the identification of unknown
24 469 compounds. The unknown species C6-AHL detected in bacterial cultures only, with empirical
25 470 formula $C_{10}H_{17}NO_3$, and accurate m/z 200.1287 (confirmed with LTQ orbitrap system) is in
26 471 agreement with Alayande et al [48]. The authors grew *Pseudomonas aeruginosa* PAO1 in LB
27 472 medium and evaluated the levels of AHL by LC-MS/MS analysis. This work is among the very
28 473 few on *P. aeruginosa* that showed the detection of C6-AHL signal molecule production and the
29 474 only report where C6-AHL was detected in an amount greater than that of 3-oxo-C12-AHL.
30 475 They found for the first time that C4-AHL and C6-AHL among the various signal molecules
31 476 played the most important signaling role in QS system of *P. aeruginosa* PAO1. Moreover, the
32 477 search for C6-AHL showed the presence of three chromatographic peaks presumably
33 478 corresponding to three isomers. Even the known C4-AHL molecule ($C_8H_{13}NO_3$, m/z 172.0974)

1
2
3 479 was detectable as two different isomers when monitored using NL approach. However, the
4
5 480 possibility to discriminate between the isomers would require a more detailed investigation using
6
7 481 for example NMR technique to obtain structural informations. The analysis of HQ molecules
8
9 482 didn't show any isomeric species.

10 483 Also 3-oxo-C10-AHL was recognized in bacterial cultures and its amount was rather
11
12 484 high, especially in RhII-W9 samples. This indicates that in the absence of C4-AHL, bacteria
13
14 485 could use this other molecule to communicate. Similar results were obtained by Patel *et al.* [32]
15
16 486 in *Erwinia carotovora* culture growth in medium rich in nutrients.

17 487 Last but not least, we quantified C12-AHL in bacterial samples, to our knowledge for the
18
19 488 first time. In fact, others research groups discovered novel AHL molecules in bacterial cultures
20
21 489 [27, 32, 35]. For example, Patel and co-workers [32] measured 24 AHLs in eight bacterial
22
23 490 cultures using a high resolution MS approach; they recognized C12-AHL in others cultures, but
24
25 491 not in *Pseudomonas aeruginosa*. The same was for the study of Hoang *et al.* [35] that quantified
26
27 492 C12-AHL in the Gram-negative endophytic bacterium *Paraburkholderia* sp. As previously
28
29 493 underlined, C7 HQ, 3-oxo-C10-AHL and finally C12-AHL could be the alternative controlled
30
31 494 factors expressed by mutant *P. aeruginosa* bacteria responsible of their high tolerance to the
32
33 495 photodynamic therapy and photo-oxidative stress induced by the therapy. These results lay the
34
35 496 foundations for more in-depth studies on the *lasI* and the *rhII* QS signal systems.

36 497 An accurate quantitation of the molecules was achieved for bacterial cultures WT-W9,
37
38 498 WT-LB, RhII-W9 and RhII-LB, and for human plasma samples using the NL and PI validated
39
40 499 MS method. We decided to validate the analytical method in plasma QS free matrix (belonging
41
42 500 to healthy volunteers) because the ultimate goal of the study was to quantify QS molecules in
43
44 501 plasma of patients affected by MOF. Many others research groups validated their analytical
45
46 502 approaches in bacterial cultures [28, 34, 35]. A comprehensive method for QS compounds
47
48 503 quantitation in human samples is lacking [23-25, 29]. Furthermore, we studied the *Pseudomonas*
49
50 504 *aeruginosa* QS molecules production because this is one of the most common bacteria giving
51
52 505 infection in patients with sepsis [49, 50]. Data shown in table 6 evidence that C4-AHL was
53
54 506 detectable in all the samples within a concentration range of 4-7 $\mu\text{g/L}$, 3-oxo-C12-AHL in a
55
56 507 range of 0-0.6 $\mu\text{g/L}$ and finally C7-HQ in a range between 2 and 18 $\mu\text{g/L}$. A general tendency of
57
58 508 QS molecules concentration to decrease was evidenced showing that hemoperfusion of plasma of
59
60 509 patients with MOF was effective in removing of QS compounds. The monitoring of QS

1
2
3 510 analytical standard molecules in hemoperfused plasma samples from MOF patients confirmed
4
5 511 the ability of MRM approach to quantify virulence factors during sepsis with a good sensitivity.

6 7 512 **5. Conclusions**

8
9 513 In conclusion, selective, sensitive and robust HPLC-TQ MS methods were developed and
10
11 514 applied to wild-type and mutant *P. aeruginosa* bacteria cultures and to biological plasma
12
13 515 samples. Thanks to untargeted NL and PI methods and MRM targeted ones different AHLs and
14
15 516 HQs molecules has been identified, characterized and quantified.

16 517 HPLC-TQ MS/MS analytical procedure has been validated in MRM, NL and PI scan
17
18 518 mode. Experimental data indicated that the method was suitable for the detection of low
19
20 519 concentration of AHLs and HQs in bacterial cultures of *Pseudomonas aeruginosa* and biofluids
21
22 520 in early stages of the sepsis-related multi-organ failure illness. Using the NL and PI scan
23
24 521 methods, it was possible to discover new kind of species whose presence within the sample was
25
26 522 not predictable at the beginning of the analysis. The presence of high concentrations of C7 HQ,
27
28 523 3-oxo-C10-AHL and C12-AHL in mutant strains of *P. aeruginosa* knocked for the production of
29
30 524 C4-AHL, could be the starting point for a better understanding of how bacteria exploit the
31
32 525 controlled factors to survive and proliferate. MRM approach was suitable for the detection of
33
34 526 low AHLs and HQs levels within less abundant samples. The comparison between bacteria
35
36 527 cultures and plasma samples highlighted even more why high sensitivity methods are mandatory
37
38 528 for plasma, given the concentration of few $\mu\text{g/L}$ of the molecules of interest within the sample.

39
40 529 The three validated approaches demonstrated to be reproducible, repeatable, robust and
41
42 530 sensitive enough to quantify QS in real biological samples and we think to have evidenced the
43
44 531 possibility to apply them to the solution of practical analytical problems with the known
45
46 532 limitations of sensitivity. LTQ-Orbitrap-HRMS platform has been confirmed as an indispensable
47
48 533 tool to investigate the fragmentation pathways and to confirm the detection of unexpected QS
49
50 534 molecules.

51
52 535 In an on-going study on MOF patients we are going to demonstrate the ability of
53
54 536 hemoperfusion to reduce the QS amount underlining the physiopathological implications of these
55
56 537 findings. Here we presented the usefulness of the studied LC-MS approaches and applied them
57
58 538 to real samples.

13 14 547 *Disclosure of potential conflicts of interest*

15 548 The authors declare that they have no conflict of interest.

16 549

17 18 19 550 *Research involving Human Participants and/or Animals*

20
21 551 As insurance that principles of ethical and professional have been followed in each step
22
23 552 of the present work, the research was approved by the proper university human research ethics
24
25 553 committee (protocol number 0114479 approved the 29th November 2017 at AOU Città della
26
27 554 Salute e della Scienza di Torino). All procedures described in studies were in accordance with
28
29 555 the ethical standards of our institutional and/or national research committee and with the Code of
30
31 556 Ethics of the World Medical Association (1964 Helsinki declaration) and its later amendments or
32
33 557 comparable ethical standards.
34

35 558

36 559 *Informed consent*

37 560 All healthy volunteers and patients who took part in the study gave their written informed
38
39 561 consent before participation. All studies were performed in accordance with the ethical standards
40
41 562 provided in the Declaration of Helsinki. The ethical approval was granted by the Research
42
43 563 Ethical Committee (protocol number 0114479 approved the 29th November 2017 at AOU Città
44
45 564 della Salute e della Scienza di Torino).

1. Figures

Fig. S1 Chromatograms acquired with NL MS approach for AHLs signalling molecules analysis. On the left it was presented the separation of few AHL compounds in a sample of patient plasma. As discussed in the main manuscript, since the sample was poor in AHL detection, the elution gradient was of 48 minutes and no overlapping peaks were observed. On the contrary, the right panel shows the NL AHLs separation in a sample of *Pseudomonas aeruginosa* wild type grown in Luria Bertani (LB) broth. Here, many AHL molecules were detected and the gradient separation was slower compared with plasma sample in order to obtain a satisfactory separation of peaks

Fig. S2 Chromatogram acquired with PI MS approach for HQs signalling molecules analysis using 2-picolinic acid as aqueous mobile phase

2. Validation tables and results

*The acronym AUC means “area under the curve”.

1. Figures

Fig. S1 Chromatograms acquired with NL MS approach for AHLs signalling molecules analysis. On the left it was presented the separation of few AHL compounds in a sample of patient plasma. As discussed in the main manuscript, since the sample was poor in AHL detection, the elution gradient was of 48 minutes and no overlapping peaks were observed. On the contrary, the right panel shows the NL AHLs separation in a sample of *Pseudomonas aeruginosa* wild type grown in Luria Bertani (LB) broth. Here, many AHL molecules were detected and the gradient separation was slower compared with plasma sample in order to obtain a satisfactory separation of peaks

Fig. S2 Chromatogram acquired with PI MS approach for HQs signalling molecules analysis using 2-picolinic acid as aqueous mobile phase
