19 Abstract

Background In the current SARS-Coronavirus-2 (SARS-CoV-2) pandemic little is known about
 SARS-CoV-2 in human milk. It is important to discover if breast milk is a vehicle of infection.

Objective Our aim was to look for the presence of SARS-CoV-2 RNA in the milk of a group of
 SARS-CoV-2 positive mothers from North-West Italy.

- Methods This is a prospective collaborative observational study where samples of human milk from 14 breastfeeding mothers positive for SARS-CoV-2 were collected. A search of viral RNA in breast milk samples was performed by RT-PCR (Real-Time reverse-transcriptase-Polymerase-Chain-Reaction) methodology tested for human milk. All the newborns underwent a clinical follow up during the first month of life or until the finding of two sequential negative swabs.
- Results In thirteen cases the search for SARS-CoV-2 RNA in milk samples resulted negative and in one case it was positive. Thirteen of the fourteen newborns were exclusively breastfed and closely monitored in the first month of life. Clinical outcome was uneventful. Four newborns tested positive for SARS-CoV-2 and were all detected in the first 48 hours of life, after the onset of maternal symptoms. Also the clinical course of these 4 infants, including the one who received mother's milk positive for SARS-CoV-2, was uneventful, and all of them became SARS-CoV-2 negative within 6 weeks of life.
- Conclusion Our study supports the view that SARS-CoV-2 positive mothers do not expose their
 newborns to an additional risk of infection by breastfeeding.

38 **1 Introduction:**

- 39 In the current SARS-Coronavirus-2 (SARS-CoV-2) pandemic it is important to identify every
- 40 possible route of transmission to prevent the spread of the disease. To date, all reports suggest that
- 41 lack of evidence for vertical transmission of SARS-CoV-2 is unlikely [1-6]. However, the possible
- 42 transmission of the virus via breastfeeding is still under debate. Providing reliable data on this issue
- 43 may have significant practical implications for the management of the SARS-CoV-2 positive

mother-infant dyad and breastfeeding support. Based on current knowledge from clinical studies, it
appears unlikely that the virus is transmitted through breast milk. [1-2, 4, 7-11]. However the data on
the detection of SARS-CoV-2 in breast milk available in the literature, have a low sample size
[13-15] and in most cases methodological limitations [16].

Here, we report the results of a prospective collaborative observational study whose primary aim 48 was to look for the presence of SARS-CoV-2 RNA in the milk of a group of SARS-CoV-2 positive 49 mothers from North-West Italy, an area with a very high incidence for Coronavirus disease 19 (COVID-50 19) at the time of sample collection. The study was specifically designed to analyze human milk, with 51 the adoption of a real-time PCR method tested to effectively detect SARS-COV-2 nucleic acid in 52 human milk, a fluid that is difficult to analyze due to its complex composition. The secondary aim of 53 the study was to evaluate clinical outcome during the first month of life in infants exclusively 54 55 breastfed by their positive mothers.

56 **2 Methods**:

57 2.1 Study design

This is a prospective collaborative observational study coordinated by the Neonatal Care Unit and
the Laboratory of Molecular Virology of the University of Turin, Italy.

60 The study was approved by the local Ethical Committee (protocol number 0039684), and informed61 consent to participate in the study was obtained from each mother.

The study centers were located in North-West Italy. From April 1st 2020 to July 31st 2020, these
centers collected samples of milk from 14 breastfeeding mothers diagnosed with Covid-19.

64 All the mothers were diagnosed with COVID-19 by real-time reverse-transcriptase-polymerase-

65 chain-reaction (RT-PCR) assays of nasal and pharyngeal swabs, in accordance with WHO guidance

66 [17]. We collected clinical records, breastfeeding history, and laboratory findings related to SARS-

67 CoV-2 of 14 mothers and their infants during hospital stay and in the six weeks after discharge.

Newborn follow up was performed during the first month of life or until the finding of two sequentialnegative swabs.

70 2.2 Sample Collection

Milk collection was performed with a dedicated breast-pump in ten of the mothers and in four with 71 manual expression. All mothers were advised to follow strict hygienic rules according to 72 international recommendations [18,19]. For milk expression mothers wore a disposable surgical face 73 mask, washed their hands with water and soap for at least 20 seconds, cleaned their breast with warm 74 water and soap and then dried it with a clean paper towel. Immediately after breast milk was collected 75 76 and transferred in sterile single-use plastic containers and stored in a freezer at -20°C. Eight mothers 77 expressed their milk in the hospital (cases 4, 6, 8, 9,11,12,13,14), five mothers expressed it at home (cases 1, 2, 5, 7, 10), and one mother (case 3) expressed the first two samples in the hospital and the 78 79 following four samples at home.

80 2.3 Detection Methods of SARS-CoV-2 in human milk by rt-PCR

Analysis of the milk samples was carried out by the Laboratory of Clinical Microbiology at the 81 San Luigi Gonzaga Hospital, Orbassano, Italy. Positivity to SARS-CoV-2 in milk samples from Case 82 83 3 was confirmed by the Microbiology and Virology Unit at City of Health and Science of Turin, Italy. Before analyzing milk samples, the analytical methods were tested for use in milk. To this aim, 84 the SARS-CoV-2 positive control plasmid provided by the manufacturer of the analytical kits, was 85 added to a milk sample collected in February 2019 from an Italian woman, almost one year before the 86 onset of the COVID-19 outbreak in Italy and therefore surely negative for SARS-CoV-2. In both 87 laboratories the positive control was properly detected by RT-PCR generating a standard 88 amplification curve and a threshold cycle similar to that obtained when the analytical methods were 89 used in routine diagnostic procedures. At the San Luigi Gonzaga Hospital RNA was extracted from 90 milk specimens using the BD MAXTM ExKTM TNA-3 and determined by rRT-PCR targeting the 91 SARS-CoV-2 S gene by using the VIASURE SARS-CoV-2 Real Time PCR Detection Kit (CertTest, 92

Zaragoza, Spain). Real-time qPCR reactions were performed on BD MAX RT-PCR apparatus
(Becton Dickinson). At the Microbiology and Virology Unit of City of Health and Science of
Turin, extraction was carried out with the QIAsymphony DSP Virus/Pathogen Midi Kit (Qiagen)
and amplification with the Seegene AllplexTM 2019-nCoV Assay (target genes: E, N, RdRp).

97 **3 Results:**

98 The main clinical characteristics of our population and the results of SARS-CoV-2 search in milk
99 samples are summarized in Table 1.

Eleven out of fourteen mothers were symptomatic at the moment of the test for SARS-CoV-2, performed in eight cases just before delivery and in three cases after delivery and presented at least one of following signs: fever, myalgia, rhinitis, cough, dyspnea, sore throat, conjunctivitis, diarrhea, chest pain, anosmia, ageusia. In three asymptomatic mothers (cases 9, 11, 14), the nasopharyngeal swab for SARS-CoV-2 was performed as a routine test at hospital admission (required in two centers). In thirteen cases the assays were negative for SARS-CoV-2 RNA and in one case it was positive (Case 3).

107 **3.1 Neonatal Outcome**

In our population, four newborns tested positive for SARS-CoV-2 (cases 1, 3, 7, 9 in Table 1), and were all detected in the first 48 hours of life, after the onset of maternal symptoms and the positivity of her swab test. The clinical course of these four infants was carefully monitored and was uneventful and all of them became negative by six weeks of life. All of them received exclusive breastfeeding during the observational period.

113 The other ten infants tested negative for SARS-CoV-2. Nine of them were breastfed, and one received 114 artificial formula from fourth day of life (the breast milk sample was collected previously). None of 115 them turned out to be positive and/or symptomatic during the first month of life.

116 **3.2 Case 3 report**

117 Case 3 resulted positive for SARS-CoV-2 at the first two milk collections, based on two different

samples collected with manual expression with one-hour interval at day five after delivery. Further 118 119 samples were collected at day 18, 28, 31, and 36 after delivery. Of these samples, only the one collected at 28 days resulted weakly positive for SARS-CoV-2 (Figure 1). The mother and her infant 120 were kept together immediately after delivery and practiced rooming-in in the first two days of life 121 without any specific precautions, until the first clinical signs of COVID-19 appeared in the mother 122 (fever, cough, ageusia, anosmia) one day after delivery. A maternal nasopharyngeal swab was 123 performed and resulted positive for SARS-CoV-2. The day after a nasopharyngeal swab was 124 performed in the newborn, with a positive result for SARS-CoV-2 as well. Maternal fever and 125 coughing disappeared in one week, with residual anosmia and ageusia still persisting after one month. 126 127 The newborn was exclusively breastfed for the first month of life, closely monitored during this period 128 and the clinical outcome was uneventful. The newborn was found negative for SARS-CoV-2 at two consecutive nasopharyngeal swabs at 16 and 26. One more swab was performed and resulted negative 129 at 38 days of life (because the mother was again positive at day 26). 130

131 4 Discussion

In this case series we found that milk samples of 13 out of 14 SARS-CoV-2 positive mothers were 132 negative for the virus. In one case the milk samples tested positive. Thirteen out of the fourteen 133 newborns were exclusively breastfed during the observation period, and clinical outcome in all of 134 them was carefully monitored and was uneventful. Thus, we have no evidence to consider 135 breastfeeding in SARS-CoV-2 positive mothers as unsafe for their newborns. A recent cohort study 136 [11] concerning breastfed infants of SARS-CoV-2 positive mothers in the first month of life, revealed 137 that they remained SARS-CoV-2 negative on nasopharyngeal swab. However, the presence of the 138 139 virus in human milk was not evaluated. Recently the presence of SARS-CoV-2 in breastmilk was evaluated in 18 infected women from delivery to 19 months, with only one sample found positive 140 [12]. These data are in accordance with our results. 141

We suppose that in the four newborns who tested positive for SARS-CoV-2, the virus passed from themother to the infant through intrapartum or airborne exposure. The four infants remained

144 asymptomatic during the observation period including case 3, in whom, irrespective of the reason for 145 milk positivity, careful monitoring did not reveal any clinical symptoms. Of particular interest is that 146 this infant at 16 and 26 days tested negative although the mother was positive again at 26 days and 147 the milk was again positive at 27 days (Figure 1). This supports the view that breast milk, even when 148 positive, is not a route of contagion.

A recently published letter [13] describes a case where milk samples of a mother with COVID-19 were 149 positive for SARS- CoV-2, and the newborn after discharge was re-hospitalized with icterus and 150 respiratory symptoms. As this newborn tested positive for both Respiratory Syncytial Virus (RSV) 151 152 and SARS-CoV-2, it is possible that the symptoms for re-hospitalization were due to RSV and not to SARS-CoV-2, being the former a common cause of bronchiolitis. However, even if the newborn 153 symptoms were Covid-19 related, this does not mean that the oral route of transmission poses an 154 155 additional risk respect to the respiratory route. In our study, we hypothesize three possible explanations for the positivity of SARS-CoV-2 in breast milk of case 3. 156

The first is that the virus could have shed in the milk of the infected mother during lactation. The argument supporting this hypothesis is that the virus was consistently detected in samples from three independent collections (Figure 1).

160 Furthermore, the pattern of positivity in milk samples was consistent with that of the mother's swabs. On the basis of the literature available so far, including this report, the presence of SARS-CoV-2 in 161 162 human milk is a rare event. Indeed, up to now there is no evidence of shedding, apart from a case 163 of SARS-CoV-2 in human milk that was detected, but not confirmed when retested two days after [3] and three cases in which it was consistently found positive [13-15]. Data on other human 164 coronaviruses do not shed light on this issue. A single case report failed to detect SARS-CoV in the 165 166 milk of a SARS positive mother [20], while no data are available on MERS-CoV. A study on the human coronavirus NL63, causing common cold, provided limited evidence of vertical transmission 167 and did not investigate the presence of viral RNA in milk samples [21]. 168

The second hypothesis is that milk samples were contaminated in the laboratory during the assay procedures. This possibility is highly unlikely since the virus was found in three samples from the same mother analyzed independently.

The third hypothesis is that milk was contaminated due an inadequate compliance with hygienemeasures in expressing the milk.

Finally, detection of SARS-CoV-2 RNA does not necessarily imply the presence of an infectious and
active virus that can be transmitted via breastfeeding and to infect the infant [12].

176 In conclusion, our study supports the view that SARS-CoV-2 positive mothers do not expose their newborns to an additional risk of infection by breastfeeding. This is an important message that should 177 be given to mothers and healthcare providers in this moment of uncertainty. This information is useful 178 179 also for all mothers living in areas with high prevalence of COVID-19 infection. In fact, our results support the view that they should breastfeed, irrespective of swab test results, considering the 180 immunological and anti-infective properties of mother's milk. Clearly, the recommended hygiene 181 measures for the control of airborne exposure, for direct breastfeeding, as well as for milk expression 182 when a mother and her infant need to be separated, must be carefully followed. 183

184 Findings from our study are limited by small samples size and self-collection of milk samples so185 future studies are needed to confirm our results.
