[1]*International Agency for Research on Cancer, Lyon/France,* [2]*National Cancer Institute, Rockville/United States of America,* [3]*Leeds Teaching Hospitals, Leeds/United Kingdom,* [4]*University of Manchester, Manchester/United Kingdom*

Background: CT lung cancer screening can be more efficient when risk models are used to determine eligibility. However, detailed risk assessment requires time spent by a healthcare provider and may present a barrier to screening when resources are limited. Here, we developed a tool to identify ever-smokers with low probability of risk-based eligibility. **Method:** We analyzed ever-smokers aged 50-80 in the representative 2015 US National Health Interview Survey. We defined ever-smokers with 6-year risk ≥1.3% by the 12-question PLCOm2012 model as screening-eligible. We considered that detailed risk assessment may be inefficient when the probability of eligibility is less than 5%. Accordingly, we used cross-tabulations of age, cigarettes-per-day, and quit-years to identify groups in whom risk assessment might be avoided. **Result:** There are approximately 44,140,774 U.S. ever-smokers aged 50-80 who could consider detailed risk assessment. However, a simple decision-tree tool identified 22,293,477 ever-smokers (50.5%) who are less than 5% likely to be screening-eligible (Figure). This includes all those who smoke(d) less than 5 cigarettes-per-day. Over 1 year, approximately 103,512 lung cancers were predicted among eligible ever-smokers. If our tool were used, then 1,784 of these eligible cases (1.7%) would not undergo detailed risk assessment or screening.

Conclusion: When resources are limited, a simple decision-tree tool could avoid detailed risk assessment for more than half of U.S. ever smokers aged 50-80, while still identifying 98.3% of eligible cases. Such a tool could be self-administered by patients in the waiting room or applied automatically to electronic health records to optimize use of provider time.

Keywords: low-dose CT screening, risk-based screening, screening eligibility

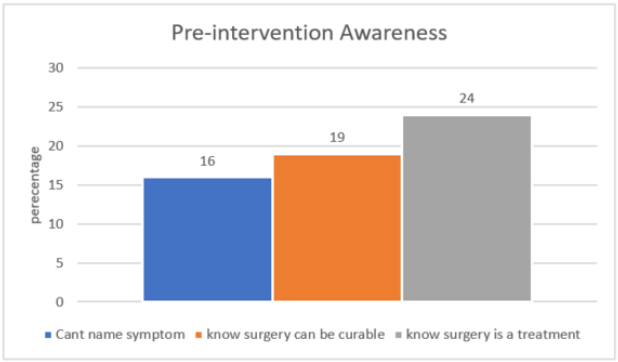
P1.11-37 FACE YOUR FEAR AWARENESS CAMPAIGN

L. Dallas[1], R. Avery[2]

[1]*Roy Castle Lung Cancer Foundation, Glasgow/United Kingdom,* [2]*Roy Castle Lung Cancer Foundation, Liverpool/United Kingdom*

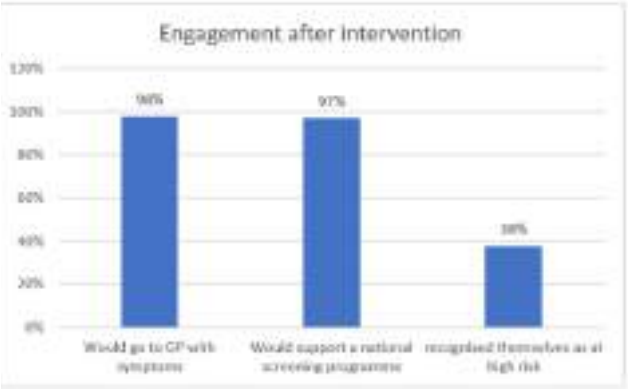
Background: Awareness of lung cancer in the UK is poor. 21% of people could not name a symptom of lung cancer. An Incisive Health study in 2018 indicated that fear stops 1in 4 people going to the doctor with potential cancer symptoms. 1year survival is 37% influenced by late stage at presentation, with 53% diagnosed at stage IV and a further 8% at stage IIIb. The Face your Fear Campaign was a multifaceted digital and community engagement campaign aimed at improving knowledge of symptoms and encouraging earlier presentation, during Awareness Month 2018.This campaign was sponsored by Astra Zeneca UK. **Method:** We filmed case studies featuring patients living well with all stages of lung cancer. We created a virtual reality film highlighting the benefits and consequences of symptom awareness and late stage presentation. A suite of materials, digital and hard copy, including an interactive quiz enabled those at risk to learn more about lung cancer and encourage action. We took an exhibition and VR film to shopping malls across the UK. The roadshow ran in locations with high incidence and poor outcomes. **Result:**

	Pre-intervention
Cant name symptom	16
know surgery can be curable	19
know surgery is a treatment	24



We had over 1.3 million views of our videos. We had an increase in 113% on web traffic and a 234% increase in views of our Signs & Symptoms page compared to the same period in 2017. Our roadshow ran across 11 locations and staff engaged with an average of 18 people per day, reaching 1008 people at risk with direct messages. We distributed over 500 Awareness Packs compared to 287 in 2017.

	After engaging:
Would go to GP with symptoms	98%
Would support a national screening programme	97%
recognised themselves as at high risk	38%



Conclusion: There is a need for accurate, patient centred information on how to diagnose lung cancer early. Public awareness in areas of poor outcomes is poorer than across the country as a whole. Targeted awareness work has a role in generating engagement with health care and increasing early detection.

Keywords: Awareness, diagnosis, Advocacy

P1.11-38 FREQUENCY AND PROGNOSTIC IMPACT OF CONCOMITANT MUTATIONS IN KRAS AND TP53 OR STK11 IN BRAZILIAN LUNG ADENOCARCINOMA PATIENTS

V. De Sa[1], J. Chinoca[1], M. Spina Donadio[1], V. De Lima[2], G. Torrezan[1], D. Carraro[1], H. Freitas[2]

[1]*AC Camargo Cancer Center, SAO PAULO/Brazil,* [2]*AC Camargo Cancer Center, Sao Paulo/Brazil*

Background: Previous studies reported that co-occurring genomic alterations in *KRAS* and *STK11/LKB1* or *TP53* tumor suppressor genes define subgroups of *KRAS*-mutant lung adenocarcinomas (LADC) with distinct biology, therapeutic vulnerabilities, and immune profiles. The impact of concomitant *STK11, TP53 and KRAS* mutations in Brazilian lung cancer patients remains poorly explored. Aims: In our preliminary study, we investigated the frequency of *STK11* and *TP53* in *KRAS* mutant or wild-type LADC. *STK11* and *TP53* mutational status was correlated with clinico-pathological characteristics and overall survival (OS). **Method:** This is a retrospective analysis which included 27 consecutive LADC patients treated with platinum-based chemotherapy and/or immunotherapy. Mutational status analysis was performed using the Illumina TruSight Tumor 26™ panel based on multiplex-PCR. This customized multiple genes panel covers 26 critical oncogenes or tumor supressor genes including: exons 2–4 of *KRAS*, exons 1–9 of *STK11* and 1–11 of *TP53,* specifically considered in the current study. Kaplan-Meier method was used to calculate overall survival and the univariate Cox model was used to compare survival. **Result:** Among the 27 patients included, 23 (85%) were *KRAS* mutant (*KRAS*mut), 15 (55.6%) were *TP53* mutant (*TP53*mut) and 5 (18%) harbored a *STK11* mutation (*STK11*mut). From all mutant cases, 10 (37%) were *KRAS*mut only; 4 (14.8%) *TP53*mut only; 2 (7.4%) *KRAS+STK11;* 8 (29.6%) *KRAS+TP53;* 3 (11%) *KRAS+TP53+STK11.* No associations were observed between *KRAS, TP53* and *STK11* status and clinico-pathological variables. OS was shorter for *TP53mut* compared with wild-type patients in Cox univariate analysis (p=0.006). *KRAS* and *STK11* status did not impact OS and progression-free survival. The co-occurrence of *KRAS* and *TP53* mutations appears to have a detrimental effect in OS (p=0.064). **Conclusion:** In this cohort, *KRAS, TP53,* and *STK11* mutations were not associated with clinico-pathological features. *TP53* mutations may identify a more aggressive molecular subtype of LADC.

Keyword: STK11, P53, KRAS, Lung Adenocarcinoma, molecular diagnosis, overall survival

P1.11-39 LOW-DOSE CT LUNG SCREENING: DATA ANALYSIS OF LUNG CANCER PATIENTS WITH ABOVE 40 YEARS OLD

Y. Jin, N. Wu

Peking Union Medical College/Chinese Academy of Medical Sciences, Cancer Hospital, Beijing/China

Background: LDCT lung cancer screening now being implemented in US and some European countries. However, LDCT lung cancer screening is still under consideration in China due to the epidemiological characteristics, medical system and patient compliance. This study aims of 1) to explore the application value of LDCT lung cancer screening in different age groups in China through analysis the data of clinical, pathology and radiology for LDCT participants, 2) to improve the effectiveness of LDCT lung cancer screening. **Method:** 10033 participants had LDCT lung cancer screening in *Cancer Hospital, Chinese Academy of Medical Sciences* were involved and divided into three groups by age (40-49, 50-59 and ≥ 60years old group). The detection rate was calculated for overall and individual groups. Clinical, pathology and radiology data were also collected and analyzed for group differences. **Result:** Lung cancer detection rate: The overall lung cancer detection rate with LDCT was 0.6% (64 cases) and the detection rate for 40-49, 50-59 and ≥60 years old group was 0.4%, 0.6%, 1.2% respectively. The difference of lung cancer detection rate between age groups was significant (*P*=0.001), and increased with age (*P*=0.002). Stage: In 64 lung cancer cases, the proportion of stage I, II, III, IV were 88%,5%, 5%, 2% respectively, with more advanced lung cancers (stage III or IV) were oberserved in ≥60 years old group than other groups(*P*=0.031). Pathological type: Adenocarcinoma was 61 cases (61/64, 95.3%), and squamous-cell carcinoma, small cell carcinoma and carcinoid was 1 case respectively, no significant differences of pathological types were found among three groups (*P*=0.134). Tumor markers: 9 cases had CEA increase (9/53,17.0%), among which 7 cases were in ≥60 years old group (7/24, 29.2%), higher than other age groups, and the difference was statistically significant (P=0.03). In addition, The odds ratio of CEA abnormally increased in ≥60 years old group was 2.059 (95% CI:0.36-11.91) compared with the 40-49 years old group. Other clinical parameters for all age groups showed no significant difference (*P*>0.05).

Table 1 The clinical, pathology and radiology data of lung cancers detected by LDCT

Characteristics	Number of cases
Age group	
40-49 years old group	15 (23.4%)
50-59 years old group	23 (35.9%)
≥60 years old group	26 (40.6%)
Sex	
Male	29 (45.3%)
Female	35 (54.7%)
History of Smoking	
Yes	18 (28.1%)
No	45 (70.3%)
Unknown	1 (1.6%)
History of Secondhand Smoking	
Yes	61 (95.3%)
No	2 (3.1%)
Unknown	1 (1.6%)
Family history of lung cancer	
Yes	15 (23.4%)
No	40 (62.5%)
Unknown	9 (14.1%)
Lung cancer stage	
Stage I	50 (87.7%)
Stage II	3 (5.3%)
Stage III	3 (5.3%)
Stage IV	1 (1.7%)
Histology	
Adenocarcinoma	61 (95.3%)
Squamous-cell carcinoma	1 (1.6%)
Carcinoid tumour	1 (1.6%)
Small-cell carcinoma	1 (1.6%)
Location	
Right lung	39 (60.9%)
Left lung	25 (39.1%)
CT consistency of lung cancer	
Solid	36 (56.3%)
Part-solid	23 (35.9%)
Non-solid	5 (7.8%)

Conclusion: The LDCT lung cancer detection rate increased significantly with age. 40-49years old group detection rate is lower than overall. ≥60years old group had the highest detection rate but stage III or IV patients proportion rised. Thus, we recommended it LDCT lung cancer screening for ≥50 years old to guarantee more early stage lung cancer cases being detected. LDCT lung cancer screening for ≥60years old could combine with CEA. This study detected 88% stage I lung cancers.

P1.11-40 SYSTEMATIC DEVELOPMENT AND MULTI-COHORT VALIDATION OF A SERUM MIRNA BIOMARKER PANEL FOR DETECTION OF EARLY STAGE NON-SMALL CELL LUNG CANCER

L. Zhou[1], R. Zou[1], L. Ying[2], D. Su[2], J. Tam[3], W. Mao[2], H.-P. Too[3]

[1]*Mirxes Pte Ltd, Singapore/Singapore,* [2]*Cancer Research Institute, Zhe Jiang Cancer Hospital, Hangzhou/China,* [3]*National University of Singapore, Singapore/Singapore*

Background: High mortality from lung cancer is related to the late manifestation of its symptoms. The incidence of non-small cell lung cancer (NSCLC) has been rising over the past several decades. A blood-based biomarker with the ability to detect early stages of NSCLC could significantly improve patient outcomes. Previous attempts have shown promising results of circulating miRNA as potential non-invasive NSCLC biomarker. However, concerns have been raised on several pre-analytical and analytical variables which could confound the performance of these miRNA biomarkers. In this study, we aimed to systematically evaluate and develop a serum miRNA biomarker panel for early detection of NSCLC through a multi-cohort study with well-controlled pre-analytical and analytical parameters. **Method:** This study included a total of 768 NSCLC

and 948 matched control subjects from Singaporean, Chinese and European Cohorts to develop a multi-target miRNA panel. Serum specimen from these subjects were collected and stored with a stringently controlled sample collection and processing protocol that minimized hemolysis, variations in clotting and platelet activation. Using high-throughput, single-plex RT-qPCR, we quantified the absolute expressions of 520 high confidence circulating miRNAs in a discovery cohort of 204 Stage 1 and 2 NSCLC patients, with 220 age, gender, ethnicity and smoking history matched controls. The regulation of candidate miRNA biomarkers in NSCLC patients was then verified in two additional cohorts of 432 Chinese and 218 Caucasians subjects. A panel of miRNA biomarkers was then constructed through multi-variant data analysis. The results were generated with the use of a logistic-regression algorithm. We subsequently validated the performance of this multi-miR panel in three independent Singaporean and Chinese cohorts comprising of 642 Subjects. All participants underwent LDCT independent of the miRNA results. **Result:** Among the 520 high confidence miRNA quantified, 29 were significantly dysregulated in the discovery cohort of 424 subjects. These miRNAs were also found to be scarcely influenced by pre-analytical and analytical variables. We were able to verify the dysregulation of 18 miRNAs in two additional Chinese and Caucasian cohorts and developed a final panel 5-miR biomarkers through a two-fold cross-validation procedure that incorporated a feature selection algorithm and a logistic regression predictive model. This 5-miR panel demonstrated an Area-Under-Curve (AUC) of 0.936 to 0.984 in the discovery cohorts. When validated in the 3 independent cohorts, the 5-miR panel with a fixed algorithm showed AUC of 0.973 (95% CI, 0.950 to 0.986), 0.916 (95% CI, 0.852 to 0.949), and 0.911 (95% CI, 0.822 to 0.963) respectively. We estimated an overall sensitivity of 81.3% (95% CI, 78.2% to 84.1%) at a specificity of 90.7% (95% CI, 88.3% to 92.8%) in the 3 validation cohorts. **Conclusion:** We have systematically evaluated the absolute expression of circulating miRNAs in NSCLC patients and matched controls of both Asian and Caucasian ethnicity. We developed a 5-miR serum miRNA panel that is minimally confounded by pre-analytical and analytical factors and validated its performance in 3 independent cohorts. These biomarkers have the potential to be a useful, non-invasive assay for early detection of NSCLC.

P1.11-41 THE IMPLEMENTATION OF THE LUNG-RADS ™ IN PILOT SILESIAN STUDY WITH LDCT - AN OPPORTUNITY FOR BETTER CONTROL OF OVERDIAGNOSIS

E. Wachula[1], S. Szablowska-Siwik[1], D. Czyzewski[2], M. Adamek[1]

[1]*School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice/Poland,* [2]*School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Zabrze/Poland*

Background: A high percentage of false positive results observed in lung cancer screening (LCS) studies with LDCT was the reason for the modification of radiological assesement methods. Originally, all non-calcified nodules with a dimension ≥ 4 mm were considered as positive, whereas the implementation of the Lung-RADS ™ recommends additional testing only for nodules ≥ 6 mm in categories 3 and 4. This allowed for the reduction of false positive results and avoiding the effect of "overdiagnosis" (unnecessary interventions). **Method:** We retrospectively analyzed 601 of first round LDCT scans, performed in 2010-2012 in asymptomatic volunteers of Pilot Silesian Study of Early Lung Cancer Detection with Low-Dose CT, with a smoking history of at least 20 pack-years, who actively smoked tobacco or quit smoking in the last 15 years. The analysis of non-invasive (additional examinations with contrast CT) and invasive interventions (bronchoscopy, EBUS, biopsies, surgery) done in screening participants was performed, followed by assessment of nodules according to the Lung-RADS ™ system, grouping them to 2, 3, 4A and 4B categories. Then the percentage of interventions that could be avoided using the ACR LungRADS ™ criteria was estimated. **Result:** In total, 1016 nodules of solid, partial-solid and non-solid morphology were identified in 265 participants. In the entire screening cohort 87 interventions were performed, including 58 (66.6%) non-invasive and 29 (33.3%) invasive. Among nodules belonging to category 4A and B, 8 invasive lung cancers were identified, 1lung cancer was overlooked (false negative) and in 1 case metastases from colorectal cancer were diagnosed. With the using of LungRADS ™ criteria, 34.4% of non-invasive and 8% of invasive interventions in categories 2 and 3 could be avoided. **Conclusion:** The LungRADS ACR classification system proved to be a practical tool for assessing lung nodules, which allowed to significantly reduce the effect of "overdiagnosis" especially in category 2 where the probability of lung cancer is low (<1%).

P1.12 SMALL CELL LUNG CANCER/NET
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.12-01 CD81-HOTTIP REGULATING LOOP ENHANCES MYC-MEDIATED CHEMORESISTANCE IN SMALL CELL LUNG CANCER VIA ERK SIGNALING PATHWAY

L. Guo, W. Huang

Pathology, Zhujiang Hospital, Southern Medical University, Guangzhou/China

Background: The majority of small cell lung cancer (SCLC) patients who are treated with platinum-based chemotherapy will eventually develops into drug resistance. Currently, there are no effective durable therapies for patients with resistant recurrent SCLC. High expression of CD81 is associated with SCLC chemoresistance and poor clinical outcome. Here, our goal is to study the underlying mechanism and define a novel signaling pathway controlled by CD81 -modulating SCLC chemotherapy resistance. **Method:** The expression of CD81, HOTTIP, and MYCBP were examined in human SCLC tissues, patient-derived xenograft (PDX) models, cell lines derived xenograft tumor model, and SCLC cell lines. The correlations between CD81 and HOTTIP were also confirmed by RNA immunoprecipitation and luciferase reporter assay. Functional analysis of HOTTIP, MYCBP, and ERK signaling was investigated in SCLC cell lines and xenografts. **Result:** Knockdown CD81 enhanced cell responsiveness to chemotherapeutic drugs in SCLC and decreased the expression of HOTTIP, as well as inhibited the intra-nuclear translocation of MYCBP/MYC complex. Conversely, overexpression of CD81 decreased the chemotherapeutic reactivity and increased the expression of HOTTIP and promoting nuclear translocation of MYCBP/MYC complex. CD81 upregulation of HOTTIP requires the transcription factor TCF4. Further analysis demonstrated that CD81-mediated activation of ERK signaling pathway and inhibition of β-catenin degradation leads to promotion of β-catenin transfer to the nucleus. Nuclear β-catenin enhances transcriptional activity of TCF4 and then promotes the transcription of HOTTIP. Synergistically, HOTTIP could bind and increase the nucleus transduction of the MYCBP, form a HOTTIP/MYCBP/MYC complex in nucleus, resulting in increased MYC levels in nucleus. Nuclear MYC further mediates chemoresistance and promotes CD81 expression, forming a positive feedback regulatory pathway in SCLC. In addition, in vivo experiments showed that inhibitors that target the CD81-HOTTIP feedback regulatory loop combined with chemotherapeutic drugs can reverse the chemotherapeutic resistance of SCLC. **Conclusion:** Our findings suggest a novel feedback regulatory pathway dominated by CD81 and HOTTIP controlling SCLC chemotherapeutic resistance, which could serve as a new therapeutic targets for this devastating disease.

Keywords: chemoresistance, small cell lung cancer (SCLC), CD81-HOTTIP

P1.12-02 NATIONWIDE ASSESSMENT OF THE ROLE OF ADJUVANT SYSTEMIC THERAPY IN HIGH-RISK LUNG CARCINOIDS

M. Kamel, A. Sholi, A. Naik, S. Harrison, B. Lee, B. Stiles, N. Altorki, J. Port

New York Presbyterian Hospital-Weill Cornell Medical College, New York/ United States of America

Background: Carcinoid tumors are often considered indolent tumors. However, a subset of patients develop recurrence after resection, and some even develop disseminated disease. To date, little data exists regarding the role of adjuvant therapy in high-risk carcinoid patients. We sought to assess whether adjuvant systemic therapy provides survival benefit for patients with these tumors. **Method:** The National Cancer Database was queried for patients undergoing resection for carcinoids (2004–2014). Adjusted mortality hazard ratios (aHR) (adjusted for age, gender and stage) were estimated for typical vs. atypical carcinoids and also for node

negative vs. node positive atypical carcinoids. Patients with node positive atypical carcinoids were divided into two groups; adjuvant chemotherapy vs. no adjuvant chemotherapy. Balance between the two groups was obtained by propensity matching (controlling for age, gender, comorbidity, pStage, and number of positive nodes). **Result:** 21820 patients had carcinoid tumors (19560 typical, and 2260 atypical). Carcinoids had a lower mortality (aHR 0.35, CI:0.31-0.39) compared to adenocarcinoma (reference) and squamous cell carcinoma (aHR 1.17, CI:1.14-1.20). Among patients with carcinoid tumors, atypical carcinoids had higher mortality compared to typical carcinoids (aHR 2.16 CI:1.55-3). Among atypical carcinoids only, those with node positive disease had worse survival (aHR 2.42 CI:1.63-3.58). Patients with atypical carcinoids who had lymph node positive disease were propensity matched (1:1, caliper 0.1, n=250) to those who received adjuvant chemotherapy and those who had no adjuvant therapy (Table). There was no difference in 5-year survival between the two groups (67% vs 62%, P=0.67).

	Adjuvant CTH (n=125)	No CTH (n=125)	P value
Age	60 (50.5-69)	61 (52.5-71)	0.389
Gender (M)	90 (72%)	91 (72.8%)	0.887
Charlson Comorbidity Index			
0	80 (64%)	78 (62.4%)	0.963
1	31 (24.8%)	32 (25.6%)	
≥2	14 (11.2%)	15 (12%)	
Path stage			
Stage II	59 (47.2%)	56 (44.8%)	0.703
Stage III	66 (52.8%)	69 (55.2%)	
Number positive nodes	2 (1-3)	2 (1-3)	0.554

CTH, Chemotherapy

Conclusion: Patients with node positive, atypical carcinoid tumors, have a significantly reduced survival compared to other carcinoid patients. However, adjuvant therapy did not confer an improvement in outcome. Novel adjuvant treatments are required for these higher risk patients.

Keywords: carcinoid, adjuvant chemotherapy, Lung cancer

P1.12-03 ANTITUMOR ACTIVITY OF SINGLE AGENT LURBINECTEDIN IN PATIENTS WITH RELAPSED SCLC OCCURRING ≥30 DAYS AFTER LAST PLATINUM DOSE

Background: Lurbinectedin (L) inhibits activated transcription and induces DNA double-strand breaks, leading to apoptosis. **Method:** This multicenter, single agent, phase II Basket trial treated a cohort of 105 SCLC patients (pts) with ECOG PS 0-2 who had received one prior chemotherapy line. L 3.2 mg/m^2 was administered as a 1-hour i.v. infusion on Day 1 q3wk. Primary endpoint, confirmed overall response rate (ORR) by RECIST v.1.1 according to investigator assessment, was met (ORR=35.2%; 95% CI, 26.2-45.2%). A sub-analysis excluding the 21 pts with disease relapse < 30 days after last platinum dose is reported here. **Result:** Median age of 84 evaluated pts was 60 years (range, 41-83), 58.3% were male, ECOG PS 0-1/2 in 96/4%, liver metastasis in 36.9%, history of CNS involvement in 4.8%, prior platinum in 100%, median chemotherapy-free interval (CTFI)=3.9 months (1.1-16.1); prior immunotherapy in 8.3%. A median of 5.5 cycles (range, 1-24) was administered.

ORR, % (95% CI) (confirmed responses) (n=84)	40.5 (29.9-51.7)*
CTFI≥90d (n=60)	45.0 (32.1-58.4)
CTFI 30-89d (n=24)	29.2 (12.6-51.1)
Disease Control Rate at 6 months, % (n=84)	48.8
Median duration of response (months) (95% CI) (n=34)	5.3 (3.5-6.4)
CTFI≥90d (n=27)	6.2 (3.5-7.3)
CTFI 30-89d (n=7)	4.1 (2.6-5.3)
Median overall survival (months) (95% CI) (n=84)**	10.9 (7.8-14.9)
CTFI≥90d (n=60)**	11.9 (9.7-16.2)
CTFI 30-89d (n=24)**	(4.1-7.6)
*4 of 7 pts who failed prior immunotherapy had confirmed response **Preliminary data	

L was well tolerated. Neutropenia was the most common adverse event (AE) (G3:21.5% and G4:25%), whereas febrile neutropenia was reported in 2.4%. Most common non-hematological AEs included fatigue (G3: 7.1%), nausea and vomiting (all G1-2: 32.1% and 16.7%) and transaminase increase (G3:7.2%). There was no death due to treatment related AE. **Conclusion:** L is an active agent for second-line treatment of SCLC. The highest ORR (45.0%) was reported for pts with CTFI≥90d. Notable antitumor activity (ORR=29.2%) was also observed in pts with CTFI 30-89d, for whom no therapy is currently approved. Hence, L is a valuable therapeutic option for SCLC pts with disease relapse after first-line platinum-based therapy. Updated trial results will be presented at the conference.

Keywords: second line, Lurbinectedin, SCLC

P1.12-04 A PHASE I STUDY OF THE ^{177}LU-DOTA^0-TYR^3-OCTREOTATE IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH EXTENSIVE-STAGE SMALL CELL LUNG CANCER

C. Kim[1], D. Subramaniam[1], S. Liu[1], T. Torres[1], G. Esposito[1], G. Giaccone[2]

[1]*Georgetown University, Washington/United States of America,* [2]*Georgetown University, Washington DC/United States of America*

Background: Despite initial sensitivity to systemic treatment, most patients with extensive-stage small cell lung cancer (ES-SCLC) relapse. It has been shown that somatostatin receptors are expressed in SCLC. Lutathera is a ^{177}Lutetium-labeled somatostatin analog approved for treatment of gastroenteropancreatic neuroendocrine tumors (NETs). Nivolumab, an anti-PD-1 antibody, in combination with lutathera may act synergistically to generate anti-tumor immunity. Here we report the final results of the phase I study of this combination in patients with ES-SCLC. **Method:** This is a phase I/II trial of lutathera and nivolumab in patients with ES-SCLC (NCT03325816). For phase I, patients with either relapsed/refractory ES-SCLC or non-progressing ES-SCLC after first-line platinum-based chemotherapy, or advanced grade I-II pulmonary NETs were eligible. The primary objective was to determine the recommended phase 2 dose (RP2D). The phase I portion followed the standard 3+3 design, assessing two dose levels (dose level 1: Lutathera 3.7 GBq Q8W for 4 doses with nivolumab 240 mg Q2W; dose level 2: Lutathera 7.4 GBq Q8W for 4 doses with nivolumab 240 mg Q2W). The DLT period was defined as first 8 weeks after treatment initiation. Adverse events (AEs) were assessed per CTCAE

4.03. **Result:** A total of 9 patients were enrolled. Three patients with ES-SCLC (2 relapsed ES-SCLC, 1 non-progressing ES-SCLC after first-line chemotherapy) were enrolled at dose level 1 and no DLTs were observed. At dose level 2, six patients (3 relapsed/refractory ES-SCLC, 2 metastatic atypical carcinoid, and 1 high-grade NET) were enrolled. One patient with refractory ES-SCLC developed a DLT (grade 3 rash). The most common treatment-related AEs (trAEs) were lymphopenia (n=7), thrombocytopenia (n=4), anemia (n=3), and nausea (n=3). 5 (55.5%) of 9 patients had grade 3 trAEs, but the most common grade 3 trAE was lymphopenia (n=4). Grade 3 anemia, thrombocytopenia, pneumonitis, and rash occurred in one patient each. No grade 4/5 trAEs were reported. Among 7 patients with measurable disease, 1 patient with non-progressing ES-SCLC had a confirmed partial response and 2 patients with metastatic atypical carcinoid had stable disease lasting 6 months. The RP2D was lutathera 7.4 GBq Q8W for 4 doses with nivolumab 240 mg Q2W. **Conclusion:** Evidence from this phase I study of lutathera and nivolumab suggests that the combination has a manageable safety profile and showed initial signs of antitumor activity. The safety and efficacy of the combination may be further explored in phase II as maintenance therapy in patients with ES-SCLC.

Keywords: SCLC, Lutathera, nivolumab

P1.12-05 MICROENVIRONMENT CHARACTERIZATION OF SMALL CELL LUNG CANCER XENOGRAFTS IMPLANTED IN HEMATOPOIETIC HUMANIZED MICE

H. Yu[1], J. Lang[1], J. Kern[2], S. Lueke Pickard[1], C. Rudin[3], C. Rivard[1], F.R. Hirsch[4]

[1]*University of Colorado Anschutz Medical, Aurora/United States of America,* [2]*National Jewish Health, Denver/United States of America,* [3]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [4]*Mount Sinai Cancer, Mount Sinai Health System, NYC/United States of America*

Background: With the high mutational burden seen in small cell lung cancer (SCLC) there is the theoretical potential to improve SCLC outcome through immunotherapy. Recent immunotherapeutic clinical trials in SCLC have demonstrated promising results. However, to better understand the immune response and the potential role of immunotherapy in SCLC, immunocompetent models are needed. To this end, we have applied a hematopoietic humanized mouse model, Hu-CB-BRGS to investigate the mechanisms underlying SCLC immunotherapy and develop novel strategies to improve therapeutic efficacy. **Method:** BALB/c-Rag2nullllll2rynullSIRPαNOD (BRGS) pups were humanized through transplantation of cord blood (CB)-derived CD34+ cells. SCLC flank tumors were initiated in BRGS mice using two characterized SCLC cell lines (CDX) and 1 patient derived xenograft (PDX). Upon verification of human T-cell chimerism in the Hu-CB-BRGS mice, SCLC tumors grown in BRGS mice were engrafted into the flanks of Hu-CB-BRGS mice by trocar transfer. Tumor growth was quantified by twice weekly measurement and harvested on reaching 1200 mm3. At harvest, tumor tissue as well as host immune organs (lymph node, spleen) were collected for immunological assessment. Humanized immune system and tumor were evaluated by flow cytometry and immunohistochemistry (IHC). **Result:** Flank tumors from two CDX tumors (H82 and H187) and one PDX tumor (LX-95) were successfully developed in the Hu-CB-BRGS mice with take rates averaging 82%. SCLC tumor growth rate in Hu-CB-BRGS mice was comparable to that seen in BRGS mice. Although human T cells were well represented in the lymph nodes and spleens of the Hu-CB-BRGS mice, we detected very few tumor infiltrating immune cells in the engrafted SCLC tumors by IHC and flow cytometry as defined by CD45 and CD3, which is consistent with the observations in SCLC patient tumor tissue. Tumor cells, identified by EpCAM expression, expressed low levels of MHC class I, II and PD-L1. PD-1 was expressed by human T cells found in the lymph nodes and spleen of Hu-CB-BRGS mice, while the SCLC xenografts expressed varying levels. **Conclusion:** We demonstrate that both SCLC PDX and CDX tumors can be grown in the context of a humanized immune system within mouse recipients. SCLC Hu-CB-BRGS mice demonstrate persistence of human immune cells, including T cells and B cells in the immune organs. The xenograft tumor microenvironment included variable human immune infiltrates. The SCLC Hu-CB-BRGS mouse model may be a valuable preclinical platform for testing human specific immune-oncology therapeutics for SCLC patients.

Keywords: SCLC, hematopoietic humanized mouse model, Microenvironment

P1.12-06 OZONE-PRIMED NEUTROPHILS PROMOTE EARLY STEPS OF TUMOR CELL METASTASIS TO LUNGS BY ENHANCING THEIR NETS PRODUCTION

N. Rocks[1], C. Vanwinge[1], C. Radermecker[1], S. Blacher[1], C. Gilles[1], R. Marée[1], A. Gillard[1], B. Evrard[1], C. Pequeux[1], T. Marichal[1], A. Noël[1], D. Cataldo[1,2]

[1]*University of Liège, Liège/Belgium,* [2]*CHU Liège and University of Liège, Liège/Belgium*

Background: Air pollution is becoming a major health problem since it is responsible for millions of deaths related to cardiovascular and lung diseases. Particulate matter and gazes such as ozone produced have been shown to increase lung cancer morbidity in industrialized countries. However, no clear link between air quality levels and cancer cell dissemination to lung tissue has yet been established. **Method:** A reliable murine model of concomitant pulmonary O_3 exposure and tumor cell injection was used to evaluate metastatic burden in the lungs after pulmonary ozone exposure. The implication of neutrophils in this process was studied by using anti-Ly6G antibodies to prevent recruitment of neutrophils to the lungs. Additionally, the implication of neutrophil extracellular traps (NETs) in metastatic processes was evaluated using *MRP8cre-Pad4lox/lox* mice or by treating mice with DNase I. **Result:** Pulmonary ozone exposure induces 1) a strong inflammatory response in lung tissues characterized by the recruitment of neutrophils and, 2) colonization of lung tissues by cancer cells and this already at early steps of the metastatic dissemination process. Additionally, an increased production of NETs by ozone-primed neutrophils was observed. Interestingly, neutrophil depletion and inhibition of NET formation greatly diminished the metastatic burden in lungs of mice exposed to ozone. The ability of O_3-primed neutrophils to enhance lung colonization by tumor cells was further confirmed after their adoptive transfer in Balb/c mice unexposed to O_3. **Conclusion:** Pulmonary neutrophils induced by O_3 promote metastatic dissemination to lungs by producing NETs. These findings open new perspectives to improve treatment and prevention strategies in patients affected by metastatic diseases.

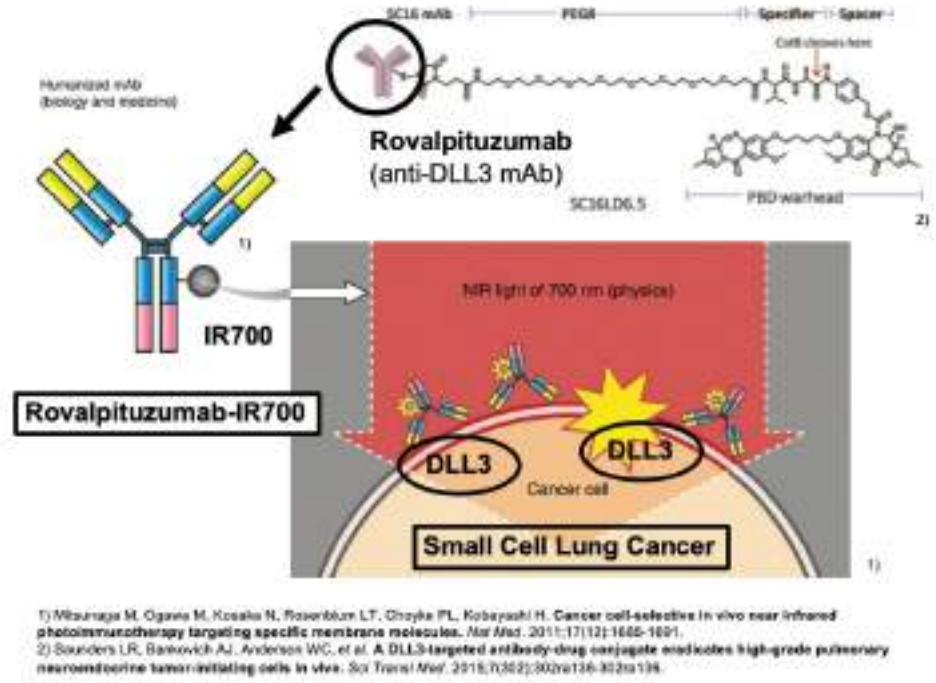
Keywords: NETs, metastasis, ozone pollution

P1.12-07 NEAR INFRARED PHOTOIMMUNOTHERAPY TARGETING DLL3 AGAINST SMALL CELL LUNG CANCER

Y. Isobe[1], K. Sato[2], K. Takahashi[1], S. Taki[1], H. Yasui[1], Y. Nishinaga[1], T. Matsui[3], Y. Hasegawa[1,3]

[1]*Nagoya University Graduate School of Medicine, Nagoya/Japan,* [2]*Nagoya University, Nagoya/Japan,* [3]*Nagoya University Hospital, Nagoya/Japan*

Background: Small cell lung cancer (SCLC) has poor prognosis, and its treatment options are limited. Delta-like protein 3 (DLL3) is a promising treatment target for SCLC, and Rovalpituzumab tesirine (Rova-T) is the first antibody drug conjugate targeting DLL3, which is currently in clinical trials. Although DLL3 is ideal target for SCLC, the result of clinical studies has not reached its primary object. Thus, new approaches are still needed. Near infrared photoimmunotherapy (NIR-PIT) is a new cancer treatment that combines the specificity of intravenously injected antibodies for targeting tumor with the toxicity induced by photosensitizers after exposure to near infrared (NIR) light. This new therapy is now in international Phase III clinical trial against locoregional, recurrent head and neck squamous cell cancer (LUZERA-301). Herein, we exploited NIR-PIT to develop new therapy for SCLC with DLL3 antibody. We preclinically evaluates the efficacy of DLL3-targeted-NIR-PIT.



1) Mitsunaga M, Ogawa M, Kosaka N, Rosenblum LT, Choyke PL, Kobayashi H. **Cancer cell-selective in vivo near infrared photoimmunotherapy targeting specific membrane molecules.** *Nat Med.* 2011;17(12):1685-1691.
2) Saunders LR, Bankovich AJ, Anderson WC, et al. **A DLL3-targeted antibody-drug conjugate eradicates high-grade pulmonary neuroendocrine tumor-initiating cells in vivo.** *Sci Transl Med.* 2015;7(302):302ra136-302ra136.

Method: *In vitro* and *in vivo* experiments were conducted with DLL3, GFP, and luciferase-expressing SCLC cell line and/or mouse fibroblast cell line (SBC5-DLL3-luc-GFP and 3T3-DLL3-luc-GFP). An antibody-photosensitizer conjugate consisting of rovalpituzumab (anti-DLL3 humanized monoclonal antibody) and a phthalocyanine dye, IRDye-700DX, was synthesized (rova-IR700) and cells or tumors were exposed to NIR-light. Serial fluorescence microscopic observation was done before and after NIR-PIT. *In vitro* NIR-PIT cytotoxicity was assessed with dead cell staining by flow cytometry and luciferase activity. *In vivo* NIR-PIT was performed in mice with tumors implanted in the flank and these were assessed by tumor volume, bioluminescence and overall survival. **Result:** After exposure to NIR-light, cellular swelling, bleb formation, rupture of the lysosome and dead cell staining were observed in fluorescence microscope. *In vitro* cytotoxicity of NIR-PIT was light dose dependent. *In vivo* the antitumor effects of NIR-PIT were confirmed by significant reductions in tumor volume ($p < 0.05$), luciferase activity ($p < 0.01$) and overall survival ($p = 0.023$). **Conclusion:** These results suggest that DLL3-targeting-NIR-PIT could be a new promising treatment for SCLC.

Keywords: small cell lung cancer, DLL3, Photoimmunotherapy

P1.12-08 THE IMPACT OF PATIENT AGE AND SOCIOECONOMIC FACTORS ON CLINICAL OUTCOMES IN SMALL CELL LUNG CANCER (SCLC): A NATIONAL STUDY

R. Chen, A.-G. Azzouqa, R. Manochakian, S. Ailawadhi, Y. Lou

Mayo Clinic Florida, Jacksonville/United States of America

Background: SCLC represents one of the most aggressive cancers with limited treatment options. Chemotherapy with or without radiation therapy remain the backbone treatment for this challenging disease. The impact of age and other socioeconomic factors on treatment modalities and clinical outcomes remain largely unknown. This study investigates the demographic, clinical, socioeconomic, and treatment modalities in each age group and the impact of patients' age on survival. **Method:** The National Cancer Database with NSCLC incident cases between 2004-2014 was used. Clinical factors including Charlson-Deyo comorbidity score, TNM staging, tumor histology, and type of treatment, demographic features, socioeconomic status and overall survival (OS) were analyzed by age of diagnosis, accounting for multivariate factors in NCDB. **Result:** A total of 214,096 SCLC patients were included in the analysis. Median age at diagnosis was 67 years old (y/o). OS including all stages is 10.97 months for <60 y/o; 9.43 months for 60-69 y/o; 7.20 months for 70-79 y/o and 3.42 months for ≥ 80 y/o respectively ($p<0.0001$). The impact of age on survival is more prominent in stage I, II and III patients than those in stage IV patients. Patients ≥ 80 y/o are associated with significant smaller tumor size (41 mm vs 50 mm, $p<0.0001$) and more stage I cancer at diagnosis (3.8% vs 6.9%, $p<0.0001$) compared to patients <60 y/o respectively. Patients ≥ 80 y/o are associated with high income, high education and Pacific geographic region. Hispanics, Asians, females, and patients younger than 60 y/o are independently associated with improved OS. Despite comparable comorbidity, patients with ≥ 80 y/o are treated differently and received much less aggressive therapy including radiation therapy and/or chemotherapy at each stage ($p<0.0001$). **Conclusion:** The overall survival of SCLC is significantly impacted by patient's age and socioeconomic factors. In particular, elderly patients are associated with significantly smaller tumor size, more stage I at diagnosis, however, they are under-treated and have worse survival compared to younger patients.

Background: Recent preclinical cell line data presented at World Conference on Lung Cancer 2018 suggest that neuroendocrine (NE) pattern of small cell lung cancer (SCLC) has strong therapeutic relevance. NE high tumors are associated with immune desert and NE low tumors are considered immune oasis phenotype. **Method:** Targeted RNA-sequencing of 2560 genes was performed on 32 matched surgically resected SCLC patients primary tumors and lymph node (LN) metastases. We performed a cluster analysis and heat map to divide patients into NE high and NE low subtypes by using the top NE associated genes. **Result:** Cluster analysis clearly identified SCLC NE subtypes according to primary tumor (NE high vs. low, 20 vs. 12, respectively) and LNs (NE high vs. low, 23 vs. 9, respectively). In case of five patients, a change in NE pattern was observed, suggesting a possible inter-tumor heterogeneity regarding NE differentiation. Moreover, a significant downregulation of NE associated genes CAV1, CAV2 and ANXA3 was found in LN metastases compared to primary tumor. A lower expression of NE associated key RNA genes REST and Myc, and the higher expression of DLL3 in NE high subtype are in accordance with the preclinical findings, and confirms the accuracy of the cluster analysis performed. **Conclusion:** Our data confirm the results of preclinical studies and show NE low and high differentiation clusters in SCLC. NE pattern of the LN metastatic lesions might not reflect the NE phenotype of the primary tumor, consequently, treatment decisions including immunotherapy administration needs to be further investigated.

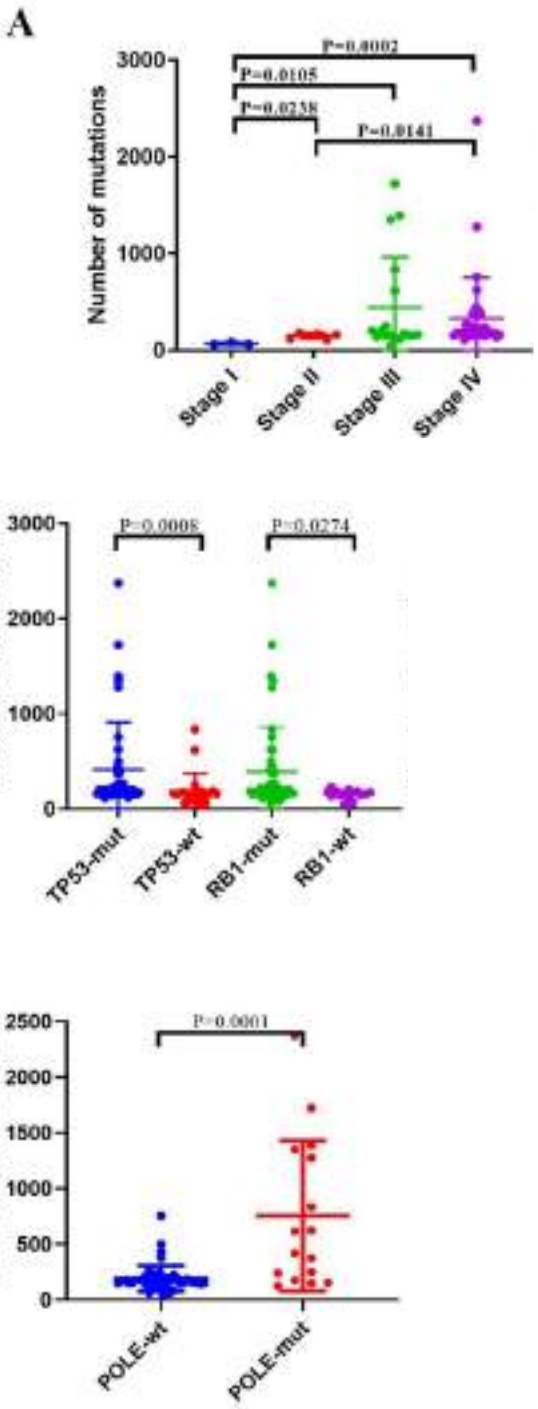
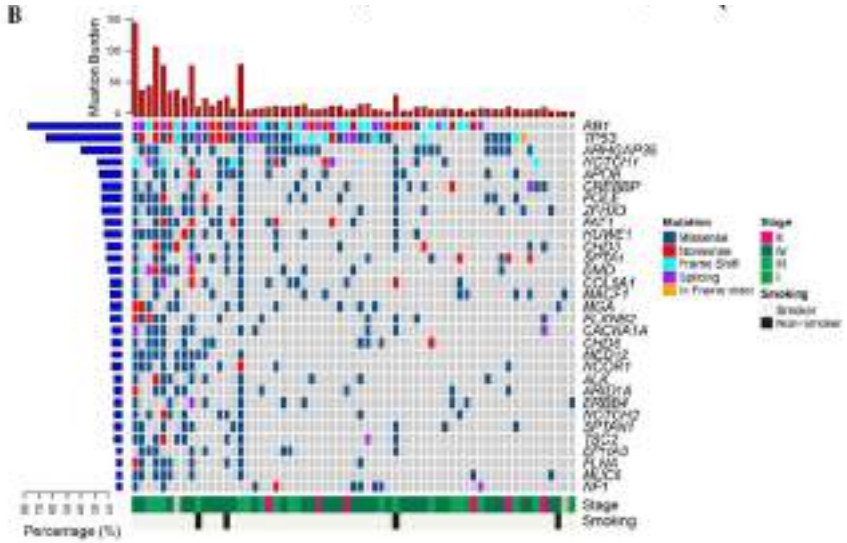
P1.12-10 THE GENOMIC PROFILES OF SMALL CELL LUNG CANCER IN EAST ASIAN

Z.-B. Song[1], X.-F. Wang[2,3], J. Li[3], L.-P. Chang[3], Y.-F. Guan[3], X. Xia[3], X. Yi[3], R. Chen[3]

[1]*Zhejiang Cancer Hospital, Hangzhou/China,* [2]*Xi'an Jiaotong Univercity, Xi'an/China,* [3]*Geneplus-Beijing Institute, Beijing/China*

Background: Small cell lung cancer (SCLC) is an aggressive neuroendocrine malignancy with poor survival, which is initially effective treated by chemotherapy and relapses rapidly. Comprehensive genomic analysis of SCLC contribute to the understanding of drug resistance mechanisms and discerning patients who respond to treatments, especially immunotherapy that has been proved to be efficient in SCLCs harboring high tumor mutational burden (TMB). This study was initiated to investigate the genomic profiles of SCLC in Chinese. **Method:** SCLC specimens were obtained by surgery or biopsy from 64 patients. Whole-exome sequencing (WES) was performed on tumor samples without paired PBMCs. Alterations were confirmed with VAF between 5% and 90%, subsequently filtered by mutated genes above 5% in J.Geroge's and LY. Jiang's researches. Tumor mutational burden was calculated by the number of non-synonymous mutations. The mutations of highly mutated driver genes in SCLC was also determined based on MH. Bailey's study. **Result:** TP53 and RB1 were the most frequently mutated genes in SCLCs, occurred in 87.5% (56/64) tumors, and furthermore related to a higher mutational burden (P = 0.0008 and 0.0274, respectively). Tumor mutational burden after filtered by highly mutated genes in SCLC was 333 non-synonymous mutations per tumor, with high mutation rates exhibited in advanced stage of SCLCs, while the smoking history did not correlate with the number of mutations. Driver genes mutation in high frequency was detected almost in all tumors (63/64), with 17.4 mutations on average (0-144). Tumors with POLE mutation tended to harbor a higher driver genes mutation rates, as well as a higher TMB. Pathway analysis using altered driver genes showed enrichment of PI3K-Akt (adj. P = 8.38e-07), MAPK (adj. P = 1.63e-05), mismatch repair (adj. P = 4.55e-05), cell cycle (adj. P= 0.0016), and Wnt (adj. P= 0.0047) signaling pathways. We did not observe significant correlation of mutations in Wnt signaling pathway with survival, though it has proved to be a mechanism of chemoresistance in SCLCs.





Conclusion: SCLCs exhibited complex genomic features with extensive mutational burden and high numbers of altered driver genes. Various sorts of cancer-related pathways were enriched, highlighted the complicacy of SCLCs.

Keywords: TMB, driver gene, SCLC

P1.12-11 EXPLORING SEX DIFFERENCES IN SMALL CELL LUNG CANCER: IS THIS A HORMONAL ISSUE?

N. Duma[1], T. Ho[1], U. Durani[1], S. Funni[1], J. Inselman[1], H. Paripati[2], A. Adjei[1], J. Molina[1], A. Mansfield[1]

[1]*Mayo Clinic, Rochester/United States of America,* [2]*Mayo Clinic, Scottsdale/United States of America*

Background: Small cell lung cancer (SCLC) accounts for about 10% to 15% of lung cancers among women and men. Though heavily associated with smoking, its incidence in women is rapidly increasing despite a decline in cigarette exposure. Given the changing demographics of SCLC and hormonal factors associated with other forms of lung cancer, we studied differences between sexes in SCLC. **Method:** Utilizing the National Cancer Database, we identified all incident SCLC cases from 2004 to 2014. Patients were classified as limited (LS) or extensive stage (ES). Women were stratified by menopausal status (≥55 years = postmenopausal). Kaplan-Meier method and Cox regression were used for overall survival (OS) and multivariable analysis. **Result:** 161,978 patients were identified. No significant sociodemographic differences were observed between sexes. The majority of patients were non-Hispanic whites (89.1%), followed by non-Hispanic blacks (7.5%). Men were more likely to be diagnosed with ES disease than women (63% vs. 56%). Both sexes initiated treatment within a similar time frame from diagnosis (chemotherapy, median 18 days, IQR 8-32). Women had better median OS compared to men in both LS (15.2 vs. 12.7 months, HR: 0.85, 95% CI 0.83-0.86, p < 0.0001) and ES (6.4 vs. 5.7 months, HR: 0.88, 95% CI 0.87-0.90, p < 0.0001). No racial or ethnic disparities in OS were observed, overall and when examined within sex and disease stage groups. Differences between sexes in OS were also observed when comparing patients within the same racial/ethnic group (women having better OS). When divided by menopausal status, postmenopausal women with LS and ES had worse OS than premenopausal women (14.7 vs. 22 months, HR: 1.50, 95% CI 1.44-1.56; 6.1 vs. 9.8 months, HR: 1.41, 95% CI: 1.37-1.46, respectively). We also observed worse OS in older men when divided by age (<55 years and ≥55 years). In multivariable analysis, older age, postmenopausal status, and Medicaid as primary insurance were associated with worse OS for both LS and ES. **Conclusion:** In this large cohort, women with SCLC had better OS compared to men. Post-menopausal women had worse OS compared to pre-menopausal women. Since older men had a similar trend of worse survival compared to younger men, age might exert a more significant influence on survival than hormonal status in SCLC. Further studies with data on sexual hormone levels are necessary to better understand their role in women with SCLC.

Keywords: small cell lung cancer, hormones, women with lung cancer

P1.12-12 FACTORS AFFECTING THE RISK OF BRAIN METASTASIS IN LIMITED-STAGE SMALL CELL LUNG CANCER AFTER PROPHYLACTIC CRANIAL IRRADIATION

M. Chen, M. Chen, X. Hu

Zhejiang Cancer Hospital, Hangzhou/China

Background: Prophylactic cranial irradiation (PCI) can reduce brain metastases (BM) and improve overall survival (OS) in patients with limited-stage small cell lung cancer (LS-SCLC) after complete response to primary therapy. However, some SCLC patients still suffer from BM after PCI with unknown risk factors.This study conducted to assess the factors affecting the risk of BM in patients with LS-SCLC after PCI and identify characteristics of patients who may not benefit from PCI. **Method:** We identified 550 patients who received chemoradiotherapy at Zhejiang Cancer Hospital in 2002–2017. All patients received PCI. Kaplan–Meier analyses and Cox regression analyses were used to identify factors influencing OS and BM. **Result:** The median survival time for this patient population was 27.9 months, and the 5-year overall survival rate was 31%. Pathologic stage not only correlated with overall survival but also significantly affected the risk of BM. For the whole group, 15.6% (86/550) of the patients had evidence of metastases to brain. The frequency of BM in patients with pathologic stages I, II, and III were 9.3% (4/43), 13.4% (7/52), and 16.5% (75/455), (P=0.026), Having tumors ≥5 cm increased the risk of BM (HR: 1.781 95%CI:1.044-3.039, P=0.034) but not death (HR:1.126 95%CI:0.925-1.663, P=0.182). The median survival time among patients <60 years were significantly higher than patients ≥60 years (34.9 months VS. 24.6 months,P=0.001),however, the difference of the BM risk in two group was not statistically significant. **Conclusion:** PCI remains standard therapy after complete response to chemoradiotherapy for LS-SCLC. However, patients with tumors ≥5 cm may have a higher risk of developing brain metastases after PCI. Further work is warranted to identify patients who may not benefit from PCI.

Keywords: prophylactic cranial irradiation, brain metastasis, small cell lung cancer

P1.12-13 THE PAST, PRESENT, AND FUTURE OF SCLC AND NSCLC INCIDENCE, MORTALITY, AND PREVALENCE IN DENMARK DURING 2006 THROUGH 2030

A. Green[1], K. Olsen[2], G. Persson[3,4], M. Bliddal[2], M. Hornbak[5], H. Christensen[5], E. Jakobsen[2]

[1]*Institute of Applied Economics and Health Research (ApHER), Copenhagen/Denmark,* [2]*Odense University Hospital, Odense/Denmark,* [3]*Herlev-Gentofte Hospital University of Copenhagen, Herlev/Denmark,* [4]*University of Copenhagen, Copenhagen/Denmark,* [5]*AstraZeneca, Copenhagen/Denmark*

Background: Information on the epidemiology of lung cancer and its main subtypes, small-cell lung cancer (SCLC) and non-small-cell lung cancer (NSCLC), is needed to assess the impact of lung cancer subtypes on the current and future health care system. **Method:** Data from Danish nationwide registers were used to describe trends in lung cancer incidence, mortality, and prevalence in Denmark during the study period January 1, 2006 to December 31, 2015. Annual forecast on prevalence of lung cancer in Denmark up till 2030 was developed using projections of incidence rates from NORDCAN (http://www-dep.iarc.fr/NORDCAN/english/frame.asp) combined with forecasted mortality rates in the study patient population. **Result:** A total of 44,291 lung cancer patients were identified in the Danish Cancer Registry during the study period, of which 6,353 (14.3%) had pathologically verified SCLC. Among the remaining cases 'NSCLC+other'; 33,747 (89.0%) had verified NSCLC, 4,038 (10.6%) lacked pathology, and 153 (0.4%) had other pathology than indexed lung cancer. Among SCLC, the annual numbers of new cases and deaths were stable, and at similar levels (Figure 1). As a result, the SCLC prevalence was projected to remain at same stable level until 2030. Among NSCLC+other, the annual numbers of new cases increased gradually. The gap between new cases and deaths became greater during the study period due to slowly steadying number of deaths. Hereby, the observed prevalence of NSCLC +others grew exponentially and was projected to continue so. **Conclusion:** The current and future epidemiological profiles differ according to lung cancer subtype. This finding should be considered when prioritizing and planning for future lung cancer care, particularly in the context of new treatment strategies, where personalized medicine and treatment modalities such as immunotherapy may result in improved prognosis. Further and continuous epidemiological monitoring is recommended to assess the impact of such improvements.

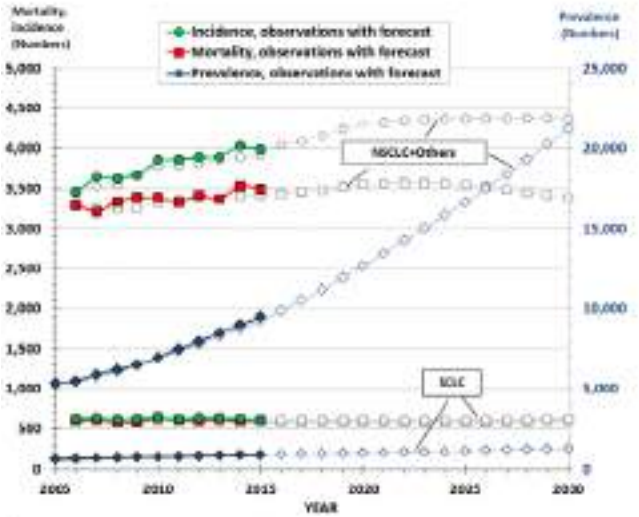


Figure 1 Numbers of annual incidence, mortality, and prevalence in lung cancer stratified by subtypes. Observed during 2005-2015 and predicted during 2016-2030

P1.12-14 PHASE II TRIAL OF APATINIB PLUS CHEMOTHERAPY FOR SECOND-LINE AND ABOVE TREATMENT OF ADVANCED SCLC: FOCUS ON EFFICACY AND SAFETY

K. Ma, Y. Xu, X. Wang, Y. Cai, C. Sun, Y. Guo, S. Qiu

The First Hospital of Jilin University, Chang Chun/China

Background: Small-cell lung cancer (SCLC), which accounts for ~15% of all lung cancers, is characterised by its rapid proliferation. The clinical outcomes of second-line and above treatments are unsatisfactory, resulting in a median progression-free survival (PFS) of less than 3 months. There is currently none targeted drugs or new chemotherapeutic drugs that can achieve breakthroughs in advanced SCLC. This study aims to observe whether apatinib in combination with chemotherapy can be a new choice for second-line and above treatment of advanced SCLC. **Method:** This is a prospective, single-center, single-arm clinical study designed to evaluate the efficacy and safety of apatinib plus chemotherapy for second-line and above treatment of advanced SCLC (ClinicalTrials.gov NCT03547804). Patients received 500mg apatinib qd orally, if the patient has a grade 3/4 adverse reaction during the treatment, it can be reduced to apatinib 250mg qd orally. Chemotherapeutic agents are limited to irinotecan or docetaxel alone. The primary endpoint was the progression-free survival (PFS). The secondary endpoints included overall survival (OS), disease control rate (DCR), objective response rate (ORR), and adverse events (AEs). **Result:** Twenty patients were enrolled from March 2018 to March 2019. Fifteen patients were available for response evaluation. The ORR and DCR were 33.33% (5/15) and 93.33% (14/15), respectively. The predicted median PFS time was 5.8 months (95% confidence interval [CI] 5.1-6.5 months) (SPSS 20.0 software). The most common treatment-related AEs were neutropenia (45.0%), leucopenia(35.0%), abnormal liver function (20%), nausea and vomiting (20%) and thrombocytopenia (20.0%), without any treatment-related deaths. It is worth noting, 12 patients underwent apatinib reduction due to grade 3/4 adverse reactions.

POSTERS

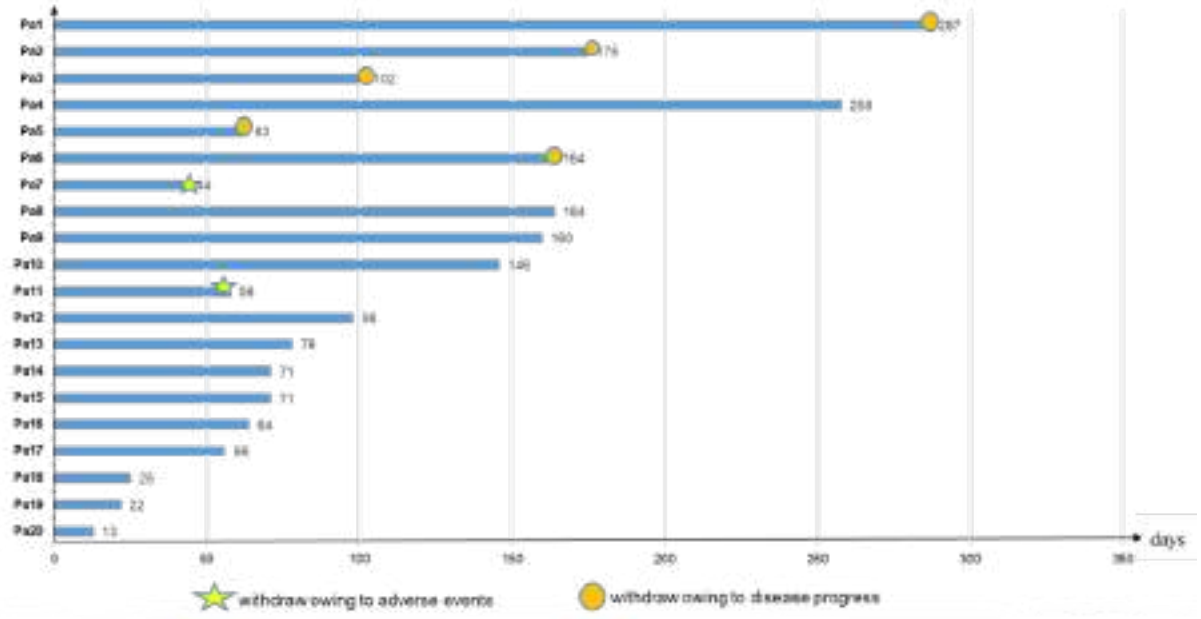

Figure 1. Survival analysis of enrolled patients.

Conclusion: Apatinib plus single agent chemotherapy showed promising efficacy in a patients with advanced SCLC who had failed chemotherapy. And the recommended phase II dose of apatinib as combination therapy was 250 mg qd.

Keywords: small-cell lung cancer, apatinib, phase II

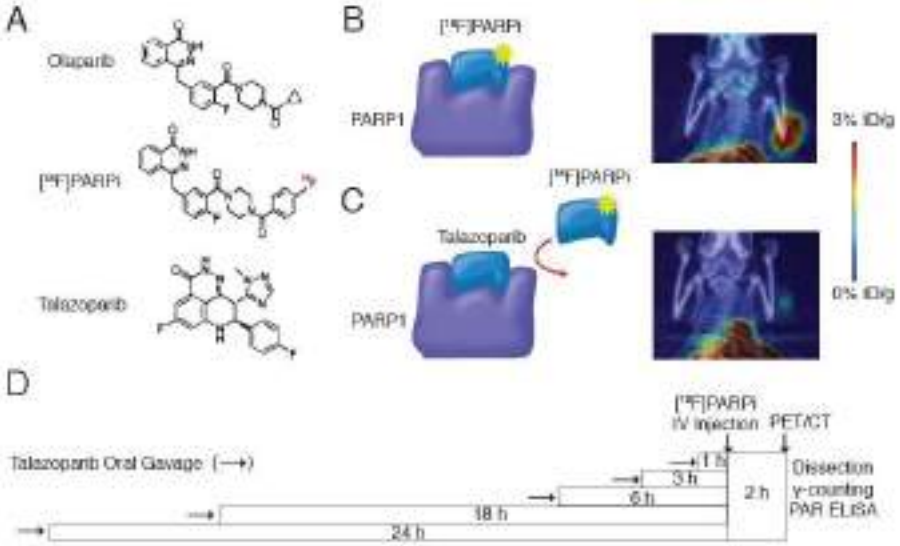
P1.12-15 PET IMAGING OF [^{18}F]PARP INHIBITOR AS A PHARMACODYNAMIC BIOMARKER OF TALAZOPARIB IN SMALL CELL LUNG CANCER PDXS

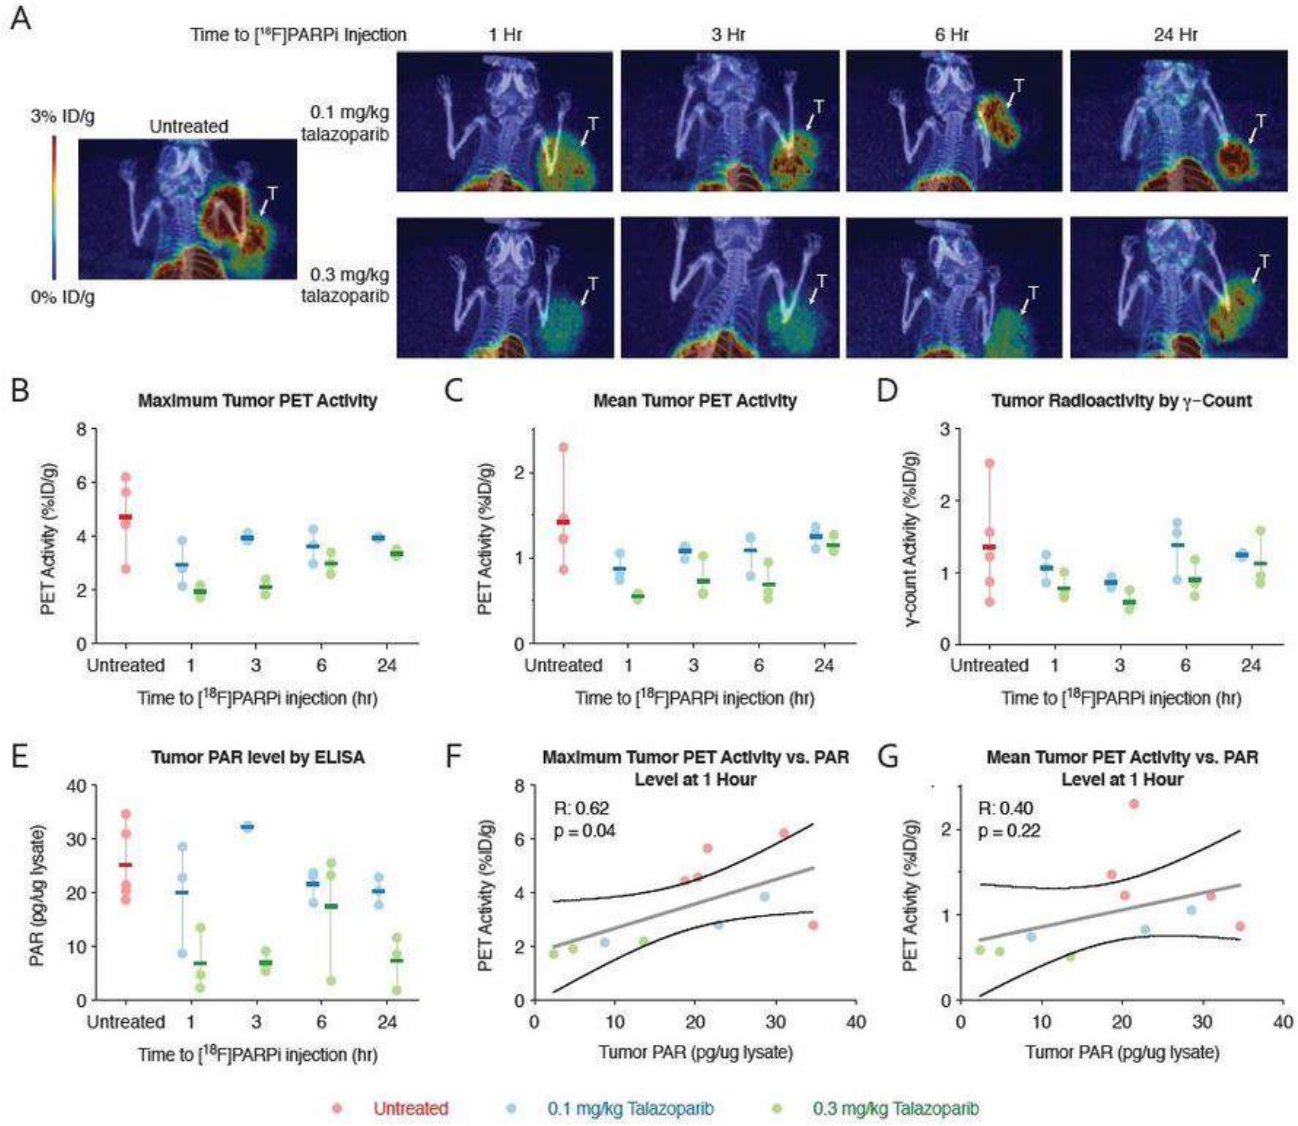
B. Lok[1], J. Laird[2], B. Carney[2], S. Kossatz[2], E. De Stanchina[2], T. Reiner[2], J. Poirier[2], C. Rudin[2]

[1]*Princess Margaret Cancer Centre, Toronto/Canada,* [2]*Memorial Sloan Kettering Cancer Center, New York/United States of America*

Background: Inhibitors of poly-(ADP)-ribose polymerase (PARP) are promising therapeutics for small cell lung cancer (SCLC). We tested whether PARP inhibitor (PARPi) target engagement as measured by a radiolabeled PARP inhibitor ([^{18}F]PARPi) has the potential to predict drug efficacy *in vivo.* **Method:** Tumor growth inhibition during daily talazoparib treatment was evaluated in mice engrafted with SCLC patient-derived xenografts to evaluate talazoparib efficacy at multiple doses. Mice were intravenously injected with [^{18}F]PARPi radiotracer at multiple time points after single doses of oral talazoparib to quantitatively assess the extent to which talazoparib could reduce tumor radiotracer uptake and PET/CT activity.

Result: A dose range of talazoparib with differential therapeutic efficacy was established, with significant delay in time to reach 1000 mm^3 for tumors treated with 0.3 mg/kg (p=0.02) but not 0.1 mg/kg talazoparib. On PET/CT with [^{18}F]PARPi tumor was among the tissues with the highest radioactivity per gram (1.37 ± 0.15 %ID/g), significantly higher than surrounding lung (0.24 ± 0.05 %ID/g, p = 0.007), bone (0.27 ± 0.05 %ID/g, p = 0.007), and muscle (0.24 ± 0.15 %ID/g, p < 0.002). A reduction in [^{18}F]PARPi uptake after talazoparib dosing was consistent with talazoparib clearance, with reduction in PET activity attenuating over 24 hours. Talazoparib target engagement, measured by maximum tumor PET uptake, increased in a dose dependent manner (3.9% vs. 2.1% ID/g for 0.1 and 0.3 mg/kg at 3 hours post-talazoparib, p=0.003) and correlated with PARP enzymatic activity among individual tumors as measured by total tumor PAR (p=0.04, R=0.62 at 1 hour post-talazoparib).





Conclusion: [18F]PARPi PET imaging appears to model PARP inhibitor pharmacokinetics, correlates with PARP inhibitor pharmacodynamics as measured by tumor PAR levels, and differs significantly between therapeutic and subtherapeutic doses of talazoparib. PET imaging using [18F]PARPi has the potential to be a powerful tool in treatment monitoring by assessing PARP inhibitor target engagement in real-time.

Keywords: PARP Inhibitor, [18F]PARPi PET, small cell lung cancer

P1.12-16 LMW HEPARIN ADHERENCE AND EFFECTS ON SURVIVAL WITHIN A RANDOMIZED PHASE III LUNG CANCER TRIAL (RASTEN)

E. Gezelius[1], P.-O. Bendahl[1], K. Gonçalves De Oliveira[1], L. Ek[2], B. Bergman[3], J. Sundberg[1], K. Strandberg[4], R. Kraemer[5], M. Belting[1]

[1]*Lund University, Lund/Sweden,* [2]*Skåne University Hospital, Lund, Lund/Sweden,* [3]*Sahlgrenska University Hospital, Gothenburg/Sweden,* [4]*Lund University, Malmo/Sweden,* [5]*Heidelberg University, Heidelberg/Germany*

Background: Coagulation activation is a hallmark of cancer, and anticoagulants have shown tumor-inhibiting properties. However, recent trials have failed to demonstrate improved survival with low-molecular-weight heparin (LMWH) in cancer populations. This has raised the question of suboptimal adherence as a possible explanation of the lack of benefit. Still, there is no standardized method to directly monitor LMWH in patient plasma. Here, we directly determine LMWH levels in patients using the Heparin Red assay and the anti-factor Xa activity (anti-FXa) assay to objectively assess adherence and how this associates with patient outcome in the RASTEN trial. **Method:** RASTEN is a multi-center, randomized phase-III trial investigating if the addition of LMWH to standard therapy can improve survival in small-cell lung cancer (SCLC). LMWH was measured in plasma (*N*=258) by the Heparin Red assay, and compared with the anti-FXa assay. **Result:** Both methods could differentiate patients in the LMWH from the control arm, and patients receiving therapeutic LMWH due to thrombosis, respectively. ROC analyses yielded adherence rates of 85% for anti-FXa and 68% for Heparin Red. No survival benefits were found in the adherent subgroup compared to the control arm (HR: 1.26; 95% confidence interval (CI) 0.95-1.67; *P*=0.105 and HR: 1.19; 95% CI 0.89-1.60; *P*=0.248 for anti-FXa and Heparin Red, respectively). **Conclusion:** Heparin Red could define patients with high probability of adherence to LMWH treatment, which warrants prospective studies for further validation. Our finding that the LMWH adherent subpopulation did not show improved survival as compared with control patients, excludes that the negative outcome of RASTEN was due to poor adherence. We conclude that LMWH cannot be recommended in the general management of patients with SCLC.

P1.12-17 ASSOCIATION BETWEEN THE PHARMACOKINETICS AND CLINICAL OUTCOME OF AMRUBICIN TREATMENT

S. Fukuda[1], T. Oguri[1], O. Takakuwa[1], Y. Kagawa[1], A. Takeuchi[1], K. Sone[1], K. Fukumitsu[1], Y. Kanemitsu[1], T. Uemura[2], H. Ohkubo[1], M. Takemura[1], K. Maeno[1], Y. Ito[1], A. Niimi[1]

[1]*Nagoya City University Graduate School of Medical Sciences, Nagoya/Japan,* [2]*Aichi Cancer Center Hospital, Nagoya/Japan*

Background: Amrubicin (AMR) is a key agent for small cell lung cancer (SCLC) but involves a high frequency of severe neutropenia. However, the influence of AMR pharmacokinetics (PK) on the clinical outcomes has not been fully elucidated. It was reported that organic cation transporter6 (OCT6) is one of influx transporters, and that single nucleotide polymorphism (SNP) of OCT6 effects clinical outcome of doxorubicin. In this study, we examined the PK parameters of AMR and its active metabolite, amrubicinol (AMR-OH), and whether OCT6 SNP is related to clinical outcome of AMR treatment. **Method:** Seventy-eight lung cancer patients treated with AMR from March 2009 to March 2017 at Nagoya City University hospital were enrolled in this study. Of these 78 patients, 62 were male, 58 were SCLC and 20 were non-small cell lung cancer, and in 35 the dose of AMR were 40mg/m^2 and in 43 were 30 or 35mg/m^2. In 21 patients, blood samples were obtained seven times in a 24-hour after the first AMR administration, and we quantified AMR and AMR-OH concentration by a high-performance liquid chromatography assay and calculated area under curve (AUC) of AMR and AMR-OH by the liner trapezoidal rule from 0 to 24-hour. In 78 all patients, grade of neutropenia and the percent decrease in the absolute neutrophil count (ANC)* in first course of AMR treatment were investigated, and OCT6 SNP (A146G) was genotyped using Taqman genotyping assay. *%decrease ANC= pretreatment ANC – nadir ANC/ pretreatment ANC×100. **Result:** The %decrease ANC was significantly related to the AUC of AMR-OH (r=0.5873, p=0.0051). The AUC of AMR-OH was significantly higher in the patients with grade4 neutropenia (608.9±47.92 ml/min) than in without grade4 neutropenia (383.8±33.75 ml/min) (p=0.0008). Of all 78 patients, classified into OCT6 SNP A146G genotype group, 26 had AA, 43 had AG, and 9 had GG. Among 21 patients examined the PK parameters, 8 had AA and 13 had AG+GG, the AUC of AMR-OH was significantly higher in AA (615.0±51.83 ml/min) than in AG+GG (397.3±35.01 ml/min) (p=0.0019). These results were same as in AMR. The incidence of grade4 neutropenia was significantly higher in patients with AA (15/26) than in patients with AG+GG (12/52) (p=0.0048). **Conclusion:** OCT6 SNP A146G is associated with the AUC of AMR and AMR-OH, as well as affects the emergence of severe neutropenia.

Keywords: OCT6, single nucleotide polymorphism, Amurubicin

P1.12-18 NONCLINICAL SAFETY ASSESSMENT OF AMG 757, A DLL3 BISPECIFIC T CELL ENGAGER, IN THE CYNOMOLGUS MONKEY

E. Lobenhofer[1], J. Werner[1], M. Giffin[1], M. Engwall[1], R. Davies[2], O. Homann[2], M. Lafleur[1], G. Moffat[1]

[1]*Amgen Inc., Thousand Oaks/United States of America,* [2]*Amgen Inc., South San Francisco/United States of America*

Background: Bispecific T-cell engager (BiTE®) antibody constructs, which direct T cell killing of tumor cells by bridging the T cell receptor CD3 subunit and a tumor-associated antigen, are a clinically validated therapeutic modality in hematologic malignancies and have the potential to be effective in solid tumors. Delta-like 3 (DLL3) is overexpressed in small cell lung cancer (SCLC), an aggressive neuroendocrine tumor with a poor prognosis and limited therapeutic options. AMG 757 is a half-life extended BiTE® molecule that binds DLL3 and is in clinical development for the treatment of SCLC. The nonclinical safety assessment of AMG 757 included an evaluation of DLL3 expression and a repeat dose toxicology study in the cynomolgus monkey. **Method:** DLL3 mRNA and protein expression were evaluated in an extensive set of normal cynomolgus monkey and human tissues using RNA sequencing, in situ hybridization, quantitative polymerase chain reaction, Western blot, and immunohistochemistry. In the cynomolgus monkey toxicology study, 3 animals/sex/group received AMG 757 weekly by intravenous infusion at 0, 50, 500, or 4500 μg/kg for 28 days during the dosing phase. An additional 2 animals/sex/group received 0 or 500 μg/kg weekly during the dosing phase and were retained for a 28-day recovery phase. **Result:** The expression data indicate that DLL3 is expressed at low levels only in the pituitary, pancreas, and brain. In an immunohistochemistry assay, immunoreactivity with an anti-DLL3 antibody was cytoplasmic and generally weak in intensity. In the 28-day toxicology study, there were no AMG 757-related changes in clinical signs, body weight, food consumption, ophthalmic examinations, respiration rates, body temperature, neurologic examinations, clinical pathology parameters, cytokines, organ weights, or macroscopic tissue observations. AMG 757-related changes were limited to a transient, slightly higher heart rate at ≥500 μg/kg, a transient, minor decrease in lymphocyte populations at 4500 μg/kg, and a minimal to mild mixed cell infiltrate comprised of lymphocytes and eosinophils in the pituitary at 50 and 500 μg/kg. These changes were considered reversible and the highest non-severely toxic dose was determined to be 4500 μg/kg. **Conclusion:** DLL3 is expressed at low levels in the cytoplasm of a few normal tissues, where it would not be accessible to AMG 757. The nonclinical safety profile of AMG 757 was consistent with this expression pattern and the drug's mechanism of action. These results suggest that limited on-target, off-tumor toxicity is anticipated, and that it may be possible to achieve high clinical exposures that maximize T cell-redirected responses in patients.

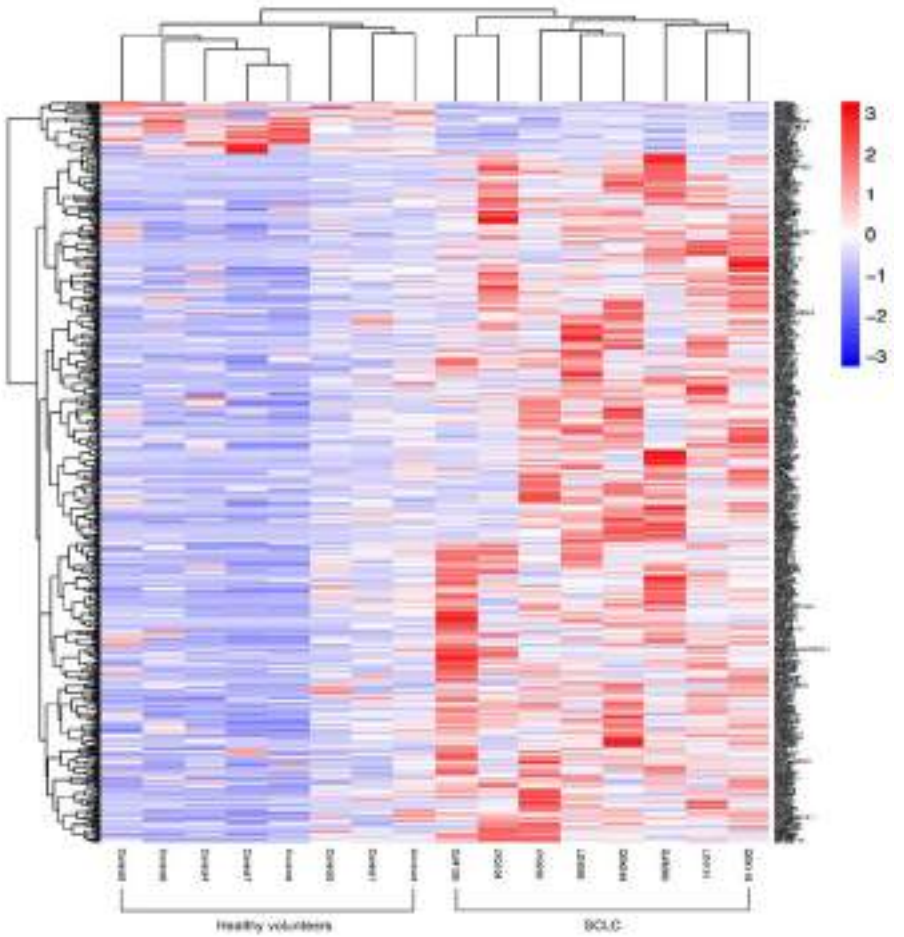
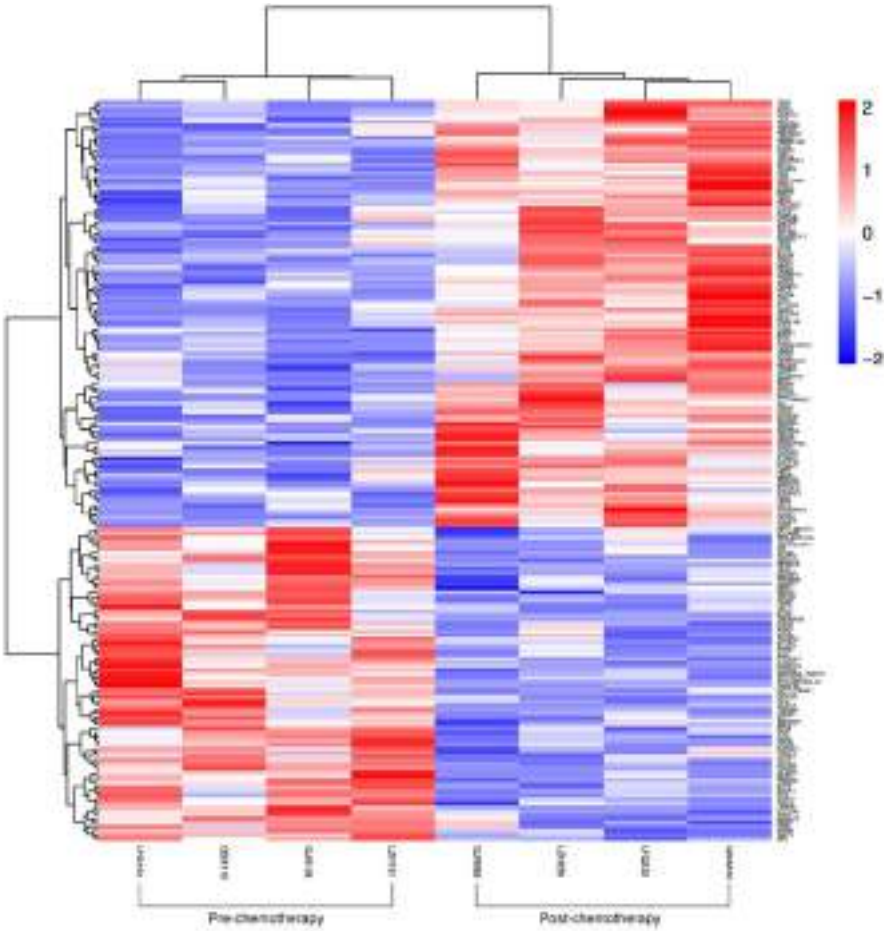
P1.12-19 IDENTIFICATION AND POTENTIAL APPLICATION OF HUMAN BLOOD EXOSOMAL RNA IN SMALL CELL LUNG CANCER

C. Liu[1], J. Wang[1], S. Huang[1], J. Chang[1], H. Yu[1], Z. Zhu[2], M. Fan[1]

[1]*Fudan University Shanghai Cancer Center, Shanghai/China,* [2]*Fudan University, shanghai/China*

Background: Plasma exosomes, which are nanosized endocytic vesicles that have been implicated as non-invasive diagnostic, prognostic sources, contain an abundant cargo of different RNA species that may be used as biomarkers for human cancers. Little research has been done on small cell lung cancer (SCLC) blood exosomal RNA. The aim of this study is to explore SCLC exosomal specific transcriptional profiles and to further predict efficacy of first-line chemotherapy. **Method:** Pre-chemotherapy and paired post-chemotherapy plasma samples (8ml whole blood) from patients with limited or extensive disease SCLC and healthy volunteers were prospectively collected. We used exoRNeasy Serum/Plasma Kit (Qiagen, Hilden, Germany) to purify exosomes and isolate total exosomal RNAs. Exosomal RNA profiling was performed using RNA-seq. RNA-seq libraries were generated using SMART technology (Clontech). We conducted pre-experimental analysis of 8 samples from healthy volunteers and 8 samples of 4 SCLC patients before and after chemotherapy. **Result:** The heat map showed that the exosomal mRNA expression profile of SCLC was significantly up-regulated compared to healthy volunteers and that the mRNA profiles before and after chemotherapy were also significantly different. Compared with healthy volunteers, SCLC had a significant up-regulation of 499 genes including the most differential gene ZNF805 (p=2.82E-05), COPS8 (p=3.20E-05), LRRC47 (p=3.54E-05), FANCE (p=1.02E-04), PGM3 (p=1.47E-04). Before and after chemotherapy, up-regulated genes with the greatest difference included KCNN4, HBB, TRAK2, TMUB2, ELF3; down-regulated genes with the greatest difference included ZBTB7C, LHFP, WNT11, VPS33B, STON1.





Conclusion: This preliminary analysis firstly identified blood exosomal RNA profiles in SCLC and highlighted the potential application of exosomal RNA based non-invasive liquid biopsy in SCLC.

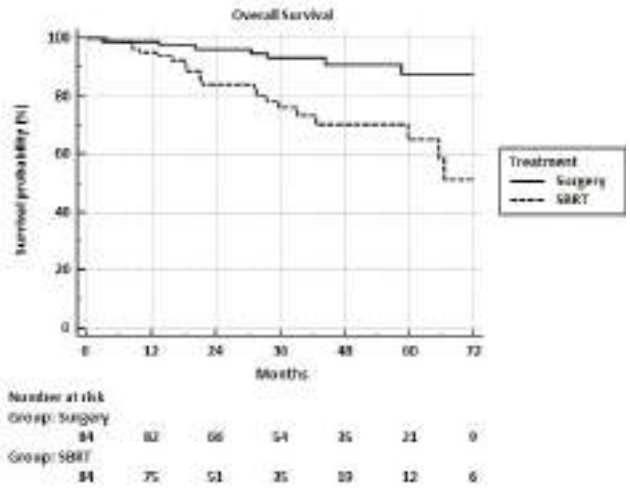
P1.12-20 SURGICAL RESECTION VERSUS STEREOTACTIC BODY RADIATION THERAPY FOR T1-2 N0 TYPICAL BRONCHOPULMONARY CARCINOID TUMORS

R. Wegner, V. Verma, S. Abel, S. Hasan, B. Weksler, A. Colonias

Allegheny Health Network, Pittsburgh/United States of America

Background: There is an ongoing debate of surgical resection versus stereotactic body radiation therapy (SBRT) for early-stage non-small cell lung cancer. However, no study to date has compared these modalities for early-stage bronchopulmonary carcinoid tumors. **Method:** The National Cancer Database was queried for histologically-confirmed T1-2N0M0 typical carcinoid tumors. Additional exclusion criteria were lack of treatment, conventionally-fractionated radiotherapy, or postoperative radiotherapy. Multivariable logistic regression ascertained factors associated with SBRT delivery. Cox proportional hazards modeling examined factors associated with overall survival (OS). Kaplan-Meier OS analysis was performed following propensity matching. **Result:** Of 6,276 patients, 98.7% underwent resection (most commonly bi/lobectomy (67%) or sublobar resection (31%)) and 1.3% underwent SBRT (median dose/fractionation of 50 Gy in 4 fractions). Patients receiving SBRT were older, had greater comorbidities, and lower income (p<0.05 for all). Median follow-up had not been reached. SBRT was associated with poorer OS on Cox multivariate analysis (p<0.001). Following propensity matching, median OS was not reached in either group; respective mean and 5-year OS were 95.6 months and 87%, versus 68.8 months and 79% (p<0.001). Differences between cohorts persisted when removing patients who underwent SBRT specifically owing to surgical contraindications (p<0.001).



Conclusion: Surgical resection should remain the cornerstone of therapy for early-stage bronchopulmonary carcinoid tumors. For inoperable cases, SBRT also produces acceptable survival and should be preferred over conventionally-fractionated radiotherapy. However, because causation cannot be implied in any retrospective comparison of surgery versus SBRT, investigations evaluating cancer-related endpoints are required to corroborate these results.

P1.12-21 IMPACT OF TREATMENT MODALITY ON LONG-TERM SURVIVAL OF SMALL-CELL LUNG CANCER WITH IA STAGE: A COHORT STUDY OF THE US SEER DATABASE

K. Zhu

Fujian Cancer Hospital, fuzhou/China

Background: The purpose of this study is to identify the optimal treatment modality for small-cell lung cancer (SCLC) patients with IA stage (T1N0M0 status). **Method:** The Surveilance, Epidemiology and End Results database was used to identify SCLC patients with IA stage who received surgical resection or chemo-radiotherapy (CRT) between January 2004 and December 2014. Propensity score match analysis is utilized to balance the baseline characteristics. **Result:**

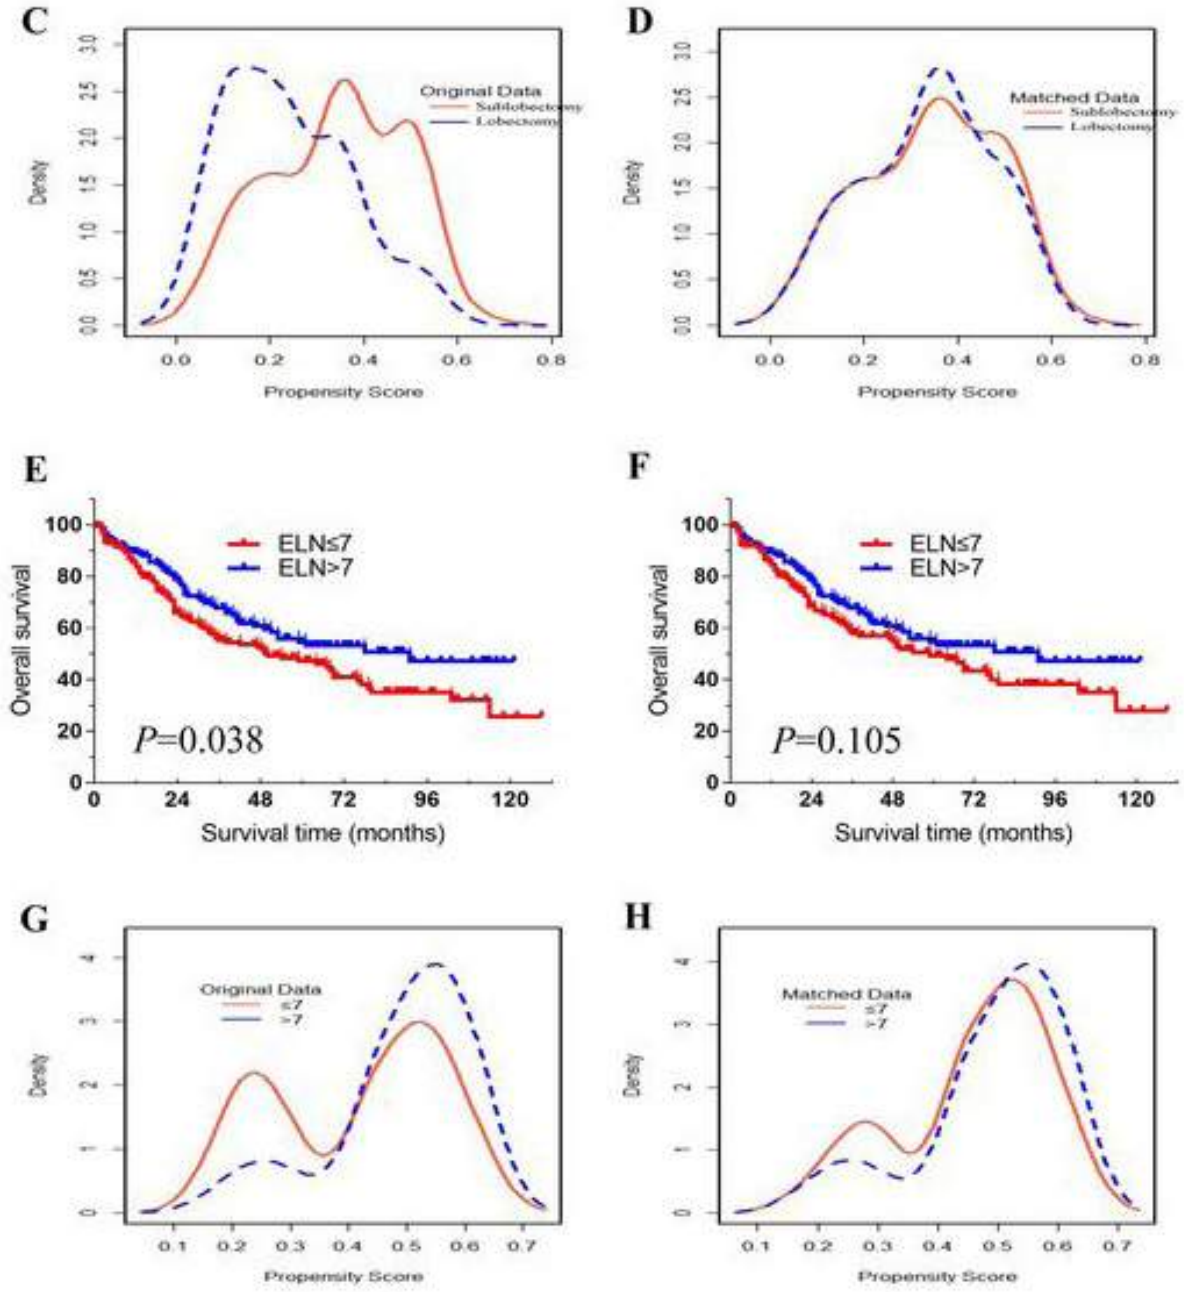
POSTERS



A total of 686 SCLC with IA stage were included (Table 1). Surgery lead to better outcome than CRT alone, with the adjusted hazard ratio (HR) of 0.495. Patients received lobectomy presented longer overall survival (OS) than sublobectomy (crude cohort, median OS, 69 months vs. 38 months; match cohort, median OS, 67 months vs. 38 months); patients with examined lymph nodes (ELN) >7 present longer OS than ELN ≤7 (crude cohort, median OS, 91 months vs. 49 months,; matched cohort, median OS, 91 months vs. 54 months) (Figure 1). The best prognosis was observed in lobectomy plus CRT cohort, with the 5-year survival rate of 73.5% (Table 2). **Conclusion:** Lobectomy plus chemo-radiotherapy as a component of treatment is associated with longer survival and should be considered in the management of IA stage patients with SCLC.

Keywords: small-cell lung cancer, IA stage, surgery

P1.12-22 A PHASE 1B/2 STUDY OF NIRAPARIB PLUS TEMOZOLOMIDE VERSUS STANDARD CARE AS MAINTENANCE THERAPY IN EXTENSIVE-STAGE SMALL CELL LUNG CANCER PATIENTS

A. Cummings[1], E. Garon[2], Z. Wainberg[1], J. Goldman[1]

[1]*David Geffen School of Medicine, University of California, Los Angeles, Los Angeles/United States of America,* [2]*David Geffen School of Medicine at UCLA/Translational Research in Oncology-US Network, Los Angeles/United States of America*

Background: Maintenance therapy is a promising therapeutic approach for extensive-stage small cell lung cancer (ES-SCLC), especially in light of IMpower 133 (Horn NEJM 2018). SCLC models of poly (ADP-ribose) polymerase (PARP) protein 1 and 2 inhibition suggested synergy with temozolomide (TMZ) (Wainberg AACR 2016). Combining PARP inhibition with TMZ after first-line therapy for ES-SCLC may improve disease control. **Method:** This is a phase 1b/2, randomized, open-label study of TMZ plus niraparib, a PARP inhibitor, versus best supportive care (BSC) as maintenance therapy in adult patients with ES-SCLC after completion of platinum-based first-line chemotherapy. The primary outcome for phase 1b is the RP2D of TMZ in combination with niraparib, and for phase 2, progression-free survival (PFS). Secondary endpoints include safety and overall survival. Exploratory endpoints include patient-reported outcomes on health-related quality of life and adverse events which will be collected electronically through a patient portal. Phase 1b participants are required to have an advanced and incurable solid malignancy. An accelerated lead-in of 12 participants will be treated in cohorts of 6 with an initial dose level of niraparib 200 mg po daily in 28-day cycles in addition to low-dose TMZ 40 mg po daily on days 1-5 of each cycle. For phase 2, participants are required to have ES- SCLC with a complete response or partial response per RECIST 1.1 following 4 to 6 cycles of platinum-based chemotherapy and ability to proceed to randomization within 7 weeks after day 1 of the last cycle of prior chemotherapy. Prophylactic WBRT is allowed prior to study. 52 participants will be stratified by a history of brain metastases and randomized 1:1 to RP2D niraparib plus TMZ versus BSC. There will be no cross-over between arms. **Result:** Section not applicable. **Conclusion:** Section not applicable.

Keywords: clinical trial, Extensive-Stage Small Cell Lung Cancer, maintenance therapy

P1.12-23 DLL3 IS A PREDICTIVE MARKER OF SENSITIVITY TO ADJUVANT CHEMOTHERAPY FOR HIGH-GRADE NEUROENDOCRINE TUMORS

H. Ogawa[1], Y. Sakai[2], W. Nishio[1], Y. Fujibayashi[1], M. Nishikubo[1], Y. Nishioka[1], S. Tane[1], Y. Kitamura[1], T. Sudo[1], Y. Sakuma[2], M. Yoshimura[1]

[1]*Hyogo Cancer Center, Akashi City, Hyogo Prefecture/Japan,* [2]*Hyogo Cancer Center, Akashi city, Hyogo prefecture/Japan*

Background: High-grade neuroendocrine carcinomas (HGNECs) include Large-cell neuroendocrine carcinoma (LCNEC) and small-cell lung cancer (SCLC), which represent ~18% of primary lung cancer. The mammalian Notch family ligands delta-like 3 (DLL3) is considered to be a potential therapeutic target for HGNECs. The clinicopathological significance of DLL3 for HGNEC was still unclear. **Method:** We used the prospectively maintained database of Hyogo Cancer Center (Akashi, Japan), and reviewed the medical records of patients who underwent tumor resection and were diagnosed with HGNEC between January 2001 and December 2009. We performed immunohistochemistry for DLL3(E3J5R, monoclonal, 1:300 dilution, CST), and all samples were evaluated by an expert pathologist without knowledge of the patient's outcome. The results were reported as negative (no positive cell) or positive (more than 1% positive cells). We investigated the correlation between the sensitivity of HGNEC to adjuvant chemotherapy and the results of immunohistochemical staining for DLL3. Overall survival (OS) and recurrence-free survival (RFS) was estimated by the Kaplan–Meier method, and differences in distribution were evaluated using the log-rank test. **Result:** We identified 58 patients who underwent complete resection of the primary tumor and who were diagnosed with HGNEC(LCNEC n=39, SCLC n=19). The mean follow-up period was 50.9months. Twenty-one patients (LCNEC n=12, SCLC n=9) received adjuvant chemotherapy. All of them received platinum-based anticancer drugs. DLL3 was positive in 16 (51.7%) LCNEC patients and 14 (73.7 %) SCLC patients. The distribution of pathologic stage in DLL 3 positive and negative patients was stage I in 17 and 14 patients, stage II in 5 and 9 patients, and stage III in 8 and 5 patients. There was no significant difference in OS and RFS between DLL3 positive and negative patients (DLL3 positive vs. negative, 5-year OS: 40.0% vs. 39.3% p=0.79, 5-year RFS: 46.4% vs. 41.5% p=0.87). Amon patients with DLL3 positive tumors, no difference was found in 5-year OS and RFS between patients with adjuvant chemotherapy and those without adjuvant chemotherapy (Adjuvant chemotherapy vs. Surgery alone, 5-year OS: 57.1% vs. 25.0% p=0.28, 5-year RFS: 42.9% vs. 36.5% p=0.92). In contrast, when the tumors were negative for DLL3, a significantly greater 5-year OS and RFS was observed for the patients with adjuvant chemotherapy than for those without adjuvant chemotherapy (Adjuvant chemotherapy vs. Surgery alone: 5-year OS: 100.0% vs. 19.1% p<0.01, 5-year RFS: 85.8% vs. 33.3% p=0.02). **Conclusion:** DLL3 might be a predictive marker of sensitivity to adjuvant chemotherapy for HGNEC.

Keywords: high grade neuroendocrine tumor, adjuvant chemotherapy, surgery

P1.12-24 COMPARISON OF FOUR PROGNOSTIC SCORES FOR PATIENTS WITH BRAIN METASTASES FROM SMALL-CELL LUNG CANCER

L. Zhao, J. Guo, J. Wang, X. Cai, X. Fu

Shanghai Chest Hospital, Shanghai/China

Background: Prognostic indexes are useful to guide tailored treatment strategies for cancer patients with brain metastases(BMs). Primary tumors have different biological behavior justifying separate scoring systems for different tumors. The purpose of this study was to compare four prognostic scores [recursive partitioning analysis(RPA), graded prognostic assessment(GPA), score index for radiosurgery(SIR), and basic score for brain metastases(BSBM)] for patients with BMs from small-cell lung cancer(SCLC). **Method:** Pathological diagnosis of SCLC patients with radiologically confirmed BMs were enrolled except those who received surgery of primary lesion. Clinical data, including age, KPS, primary tumor control, extracranial disease status, number of BMs, systemic disease status, and the largest lesion volume were recorded. The score of RPA, GPA, SIR and BSBM were calculated separately. Overall Survival(OS) was calculated from the date of diagnosis of BMs to the date of death from any case, or the last follow-up. OS was estimated by the Kaplan-Meier method. Cox's regression analysis was performed using a backward elimination approach to determine the best model predicting survival. $P<0.05$ was considered statistically significant. **Result:** From Jan 2011 to Oct 2014, 224 patients were eligible for the study. For the entire cohort, median OS was 9 months (95%CI, 7.7-10.3). The median survival was 10 months for RPA Class I, 9 months for RPA Class II, and 4 months for RPA Class III($P=0.039$). Using the SIR, the median survival was 11, 9, and 6 months for a score of 8-10, 4-7, and 0-3, respectively($P=0.008$). In addition, the median survival was 10 months for GPA Class I, 12 months for GPA Class II, 8 months for GPA Class III, and 6 months for GPA Class IV($P=0.136$). Using the BSBM, the median survival was 10, 8, 9, and 4 months for a score of 3, 2, 1, and 0, respectively($P=0.099$). The backward elimination model in multivariate Cox analysis identified SIR as the only variable significantly associated with survival($P=0.012$).

	Number of patients	OS	P
RPA I	31	10±1.4	
RPA II	184	9±0.7	0.039
RPA III	9	4±0.4	
GPA I	22	10±1.4	
GPA II	30	12±2.2	0.136
GPA III	136	8±0.8	
GPA IV	36	6±1.3	
BSBM 0	6	4±1.2	
BSBM 1	85	9±1.3	
BSBM 2 88		8±0.7	0.099
BSBM 3	45	10±0.7	
SIR I	14	11±2.5	
SIR II	182	9±0.7	0.008
SIR III	28	6±1.3	

POSTERS

Conclusion: The SIR score was more prognostic than the RPA, GPA, and BSBM scores. For patients with BMs from SCLC, SIR was the most accurate for estimating survival. As it was mainly used for radiosurgery in BMs, maybe a new disease-specific prognostic score should be generated in this particular population.

Keywords: small-cell lung cancer, Brain metastases, prognostic scores

P1.13 STAGING
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.13-01 THE IMPORTANCE OF STAGING OF LUNG CANCERS, 30 MM OR LESS, SEPARATELY FOR SUBSOLID AND SOLID NODULES

Y. Wang[1], R. Yip[2], Y. Zhu[2], E. Fevrier[2], T. Ma[3], M. Van Gerwen[4], D. Yankelevitz[2], R. Flores[4], C. Henschke[2]

Background: To determine pathologic results on non-small-cell lung cancers (NSCLCs), 30 mm or less in maximum diameter, separately by tumor consistency (solid, subsolid) on CT scans as we had shown that long-term survival was significantly different by tumor consistency and by type of parenchymal invasion. **Method:** We reviewed all patients enrolled in the Initiative for Early Lung Cancer Research on Treatment (IELCART), a prospective cohort study of patients with first primary T1a-T1c NSCLC between 2016 and 2018 who had surgical resection. Short-axis diameter of N1-N3 lymph node on CT and SUVmax uptake on FDG-PET, if performed, were documented with values ≥ 2.5 defined as PET positive. Pathology reports were reviewed for N1-N3 lymph nodes (LNs) metastases and parenchymal invasion. **Result:**

Table 1

CT tumor size	Total	LN Metastases *		Parenchymal/Pleural Invasion

Total						
Solid	280	5 (1.8%)	14 (5.0%)	104 (37.1%)	40 (14.3%)	22 (7.9%)
Subsolid	67	0 (0.0%)	0 (0.0%)	13 (19.4%)	4 (6.0%)	0 (0.0%)

*N1: lymph node metastases in ipsilateral peribronchial, and/or ipsilateral hilar lymph nodes, and/or intrapulmonary nodes.
N2: lymph node metastases in ipsilateral mediastinal and/or subcarinal lymph nodes.

Among 347 patients, 280 (80.7%) and 67 (19.3%) had solid and subsolid NSCLCs, respectively; all subsolid NSCLCs were adenocarcinoma. There was FDG-PET uptake in 253 (93.3%) with solid NSCLCs and in 55 (91.7%) with subsolid NSCLCs. None of the 67 subsolid NSCLCs had N1 or N2 LN metastases (Table 1). Among the 280 solid NSCLCs, none of the 42 NSCLCs≤ 10 mm had N1 or N2 metastases, while 5 of the 238 solid NSCLCs greater than 10 mm had N2 and 14 had N1 LN metastases. None of the N2 LNs were positive on FDG-PET and only 4(28.6%) of the 14 N1 LNs were positive on FDG-PET. Angiolymphatic invasion was most frequently, followed by pleural and major vascular invasion (Table 1). For solid NSCLCs, invasion increased with increasing tumor diameter. **Conclusion:** No N1-N3 LN metastases were identified in solid NSCLCs ≤ 10 mm; none in subsolid NSCLCs ≤ 30 mm. None with N2 LN metastases were positive on FDG-PET. This suggests that for NSCLCs, 30 mm or less, clinical staging be based on solely tumor size. For pathologic staging, we recommend differentiating staging classification by tumor consistency in line with the latest recommendations for pathologic assessment.

Background: It has been suggested that aortic lymph nodes (stations #5 and #6, aortic-LNs) may have a similar prognostic significance as hilar-LNs (stations #10 and #11). Therefore we compared survival of lung cancer patients with aortic-LNs metastasis to those with N1 disease at the hilar-LNs. **Method:** Between 2008 and 2017, 865 patients with left upper lobe (LUL) lung cancer underwent complete resection in three centers. Overall survival was assessed retrospectively and compared in four groups according to pN status: N0 (n=429, 49.6%), N1 (n=259, 29.9%), $N2^{5,6+}$ (only metastasized to stations 5 and/or 6 with/without N1 disease, n=126, 14.6%), and $N2^{7+}$ (only metastasized to station 7 with/without N1 disease, n=51, 5.9%). pN1 was divided two subgroups according to location; $N1^{peripheral}$ (n=124), $N1^{hilar}$ (n=135). **Result:** Five-year survival rate was significantly better for $N2^{5,6+}$ than $N2^{7+}$ patients (32.7% vs 22.1%) (p=0.05) (Figure 1). Skip metastasis for aortic-LNs (n=39) was a factor of better prognosis as compared to non-skip metastasis (n=87) (42.5% vs. 26.3%) (p=0.03) although five year survival rates were similar for $N2^{single\ (5+\ or\ 6+)}$ (n=96) and $N2^{multiple\ (both\ 5+\ and\ 6+)}$ (n=30) patients (32.8% vs 32.3%, p=0.8). There was no statistically significant difference between the $N2^{5,6+}$ and $N1^{hilar}$ (p=0.4), although $N1^{peripheral}$ had a significantly better survival than $N2^{5,6+}$ (p<0.0001) (Figure 2).

Figure 1. The survival curves of $N2^{5,6+}$ and N^{7+}

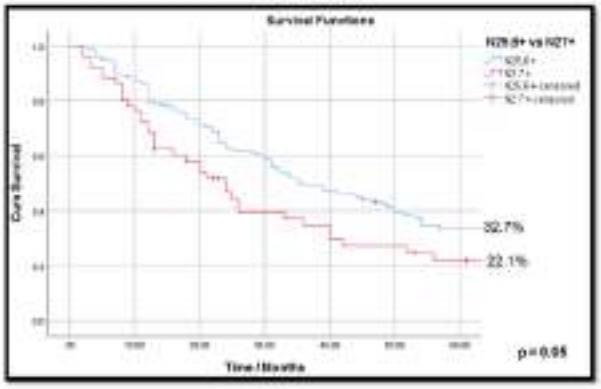

Figure 2. Survival Comparison of $N1^{peripheral}$, $N1^{hilar}$ and $N2^{5,6+}$

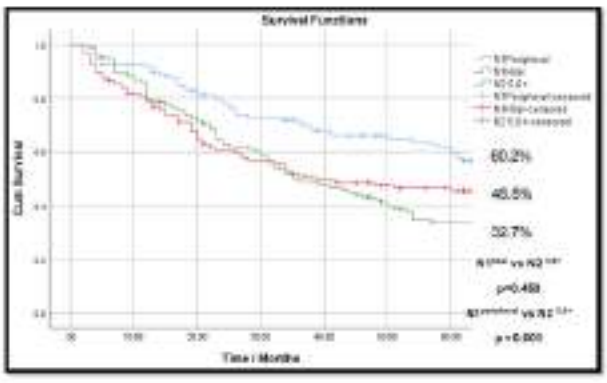

In multivariate analysis, age (p<0.0001), N2 versus N0/1 (p<0.0001), $N1^{hilar}$ versus $N1^{peripheral}$ (p=0.006), $N2^{5,6+}$ versus $N1^{peripheral}$ (p=0.0001), $N2^{7+}$ vs $N2^{5,6+}$ (p=0.05), and $N2^{non\text{-}skip\ 5\ and/or\ 6+}$ vs $N2^{skip\ 5\ and/or\ 6+}$ (p=0.01) were significant independent negative prognostic factors (Table 1).

Conclusion: The prognostic significance of aortic-LNs is similar to hilar-LNs even if LUL tumors with hilar-LNs metastasis is associated with statistically not significant prognosis than aortic-LNs metastasis. In order to generalize this result, it needs to be validated in a bigger database.

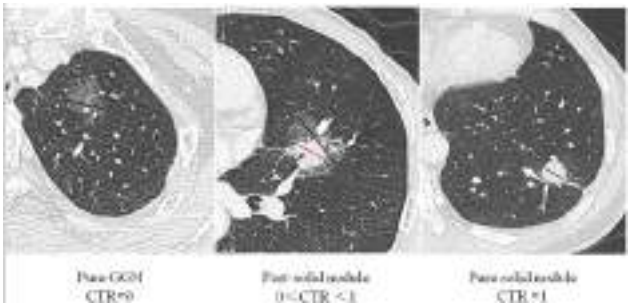
Background: According to guidelines from the Fleischner Society in 2017, subsolid nodules are categorized into pure ground glass nodules (pGGNs) having only a GGO component and part-solid nodules having both GGO and solid components on thin-section computed tomography (TS-CT). Persistent part-solid nodules with solid components ≥ 6mm should be considered highly suspicious. Clinicopathologic features and prognostic predictors of radiological part-solid lung adenocarcinomas were unclear. **Method:** We retrospectively compared clinicopathologic features and survivals of part-solid tumors with those of pure ground glass nodules (pGGNs) and pure solid tumors receiving surgery at Fudan University Shanghai Cancer Center, and evaluated prognostic implications of consolidation-to-tumor ratio (CTR), solid component size and tumor size for part-solid lung adenocarcinomas.



Result: 911 patients and 988 pulmonary nodules (including 329 part-solid nodules (PSNs), 501 pGGNs & 158 pure solid nodules) were analyzed. More female patients (P=0.015) and non-smokers (P=0.003) were seen in PSNs than those in pure solid nodules. Prevalence of lymphatic metastasis was lower in PSNs than that in pure solid tumors (2.2% vs 27%, P=0.000). 5-year lung cancer specific recurrence free survival (LCS-RFS) and overall survival (OS) of PSNs were worse than those of pGGNs (P<0.001; P=0.042), but better than those of pure solid tumors (P<0.001; P<0.0001), respectively. CTR (OR: 12.90; 95% CI: 1.85-90.04), solid component size (OR: 1.45; 95% CI: 1.28-1.64) and tumor size (OR: 1.23; 95% CI: 1.15-1.31) could predict pathologic invasive adenocarcinoma for PSNs. None of them could predict the prognosis. Patients receiving sublobar resection had comparable prognoses with those receiving lobectomy (5-year LCS-RFS: P=0.178; 5-year LCS-OS: P=0.319). Prognostic differences between patients with systemic lymph node dissection (sLND) and those without sLND were statistically insignificant.

P1.13-04 IMPACT OF THE PRESENCE AND PROPORTION OF GGO ON SURVIVAL AND PATHOLOGICAL CHARACTERISTICS IN CLINICAL STAGE I LUNG ADENOCARCINOMA

S. Katsumata[1], K. Aokage[1], G. Ishii[2], S. Nakasone[1], T. Miyoshi[1], K. Tane[1], M. Tsuboi[1]

[1]*National Cancer Center Hospital East, Kashiwa/Japan,* [2]*National Cancer Center, Kashiwa/Japan*

Background: The aim of this study was to investigate a prognostic and clinicopathological impact of ground-glass opacity (GGO) on existing clinical T classification. **Method:** We analyzed 1228 patients with lung adenocarcinoma classified as clinical stage I who underwent complete resection by lobectomy or pneumonectomy from 2003 to 2013. We divided patients into four groups based on the presence and proportion of GGO by using consolidation-to-tumor ratio (CTR), calculated with the maximum solid component diameter divided by the maximum tumor diameter including GGO area on thin-slice computed tomography; A, CTR ≤0.5; B, 0.5< CTR ≤0.75; C, 0.75< CTR ≤1.0 including GGO; D, GGO negative (pure solid). We compared them on overall survival, pathological findings and histological subtypes in each clinical stage of IA1 to IB. **Result:** In all clinical stage, we found no significant differences among group A-C on prognosis and pathological findings. The prognosis of each group of A-C was significantly more favorable than that of group D in clinical stage IA2 and IA3. With respect to the pathological findings, group D had significantly larger positive number of N/ly/v in stage IA2 and that of N/pl/v/STAS in stage IA3 than each group of A-C. Group D had significantly less proportion of lepidic component and consisted with more percentile of solid component than each group of A-C in clinical stage IA2-IB. **Conclusion:** Not proportion but presence of GGO had great impact on prognosis and pathological characteristics. The presence of GGO might as well be included in the next T classification.

Keywords: lung adenocarcinoma, ground-glass opacity, consolidation-to-tumor ratio

P1.13-05 EVALUATION OF PET/CT SCANS TO PREDICT PATHOLOGIC LUNG CANCER STAGING

M. Murthi[1], R. Samannan[2], G. Holt[2]

[1]*Government Mohan Kumaramangalam Medical College, Salem/India,* [2]*University of Miami, Miami/United States of America*

Background: PET/CT scan use prior to biopsy of lesions suspicious for lung cancer is not recommended due to a lack of supporting data. We hypothesize that a PET/CT Scan provides critical information that directly impacts biopsy strategy. **Method:** We retrospectively analyzed all patients referred to the Pulmonary service at the Miami VA Medical Center for abnormal chest imaging concerning for lung cancer from February 12, 2013 to October 1, 2018. **Result:** Of 481 patients, 400(83.2%) underwent PET/CT scanning and 225(46.8%) had lung cancer. Based on PET/CT findings, 74(18.5%) only had a Solitary Pulmonary Nodule(SPN) and went directly to definitive treatment. 51(68.9%) patients underwent surgical resection. However, 1(1.3%) had stage IV pleural disease found during surgery. 3(4%) had invasive disease and 5(6.7%) had lymph node involvement requiring post-operative chemotherapy. 14(18.9%) had stereotactic body radiation therapy, 2(2.7%) had small cell lung cancer without lymph node involvement and 3(4%) were considered inoperable based on comorbidities and were treated with XRT and chemotherapy due to large tumor size. 3(4%) were lost to follow-up. Only one patient (1.3%) was found to have metastatic disease not identified by PET/CT Scan. Of 61(15.2%) patients with a CT scan revealing only an SPN, 30(49.1%) had FDG avid mediastinal lymph nodes positive for cancer in 25 cases (83.3%). 2 were downstaged as the mediastinal lymph nodes were negative on biopsy. One(3.3%) patient was lost to follow-up, 1(3.3%) treated as possible mediastinal disease even though biopsy was negative and 1(3.3%) was stage 4 due to contralateral lung disease. Among the 25 patients, PET/CT missed bone metastasis in 1. Thirty one(50.9%) had extrathoracic lesions on PET/CT with 14(45.1%) proven to have metastatic disease, 11(35.4%) were assumed to have metastatic disease based on imaging, 2(6.4%) had oropharyngeal cancer, 1(3.2%) had a hepatoma and 1(3.2%) had lymphoma. 2 patients (6.4%) were false positives. Among 90 patients with multiple pulmonary nodules on CT, PET/CT found 35(38.8%) had activity in the nodules without mediastinal/extra-thoracic involvement. In these patients, 3(8.6%) had positive mediastinal nodes on biopsy, 21(65.6%) underwent surgery (2 were found to have positive mediastinal lymph nodes at surgery), 7(21.8%) were treated with SBRT, 1(3.1%) had SCLC, 1(3.1%) was treated with chemotherapy/radiation due to size, 1(3.1%) had pleural disease and 1(3.1%) was treated with chemotherapy/radiation for suspected mediastinal disease. Of the remaining 55 patients, 20 had extra thoracic disease, 16 had mediastinal disease and 19 had multiple hypermetabolic nodules with congruence between PET/CT and biopsy in 18(90%), 14(87.5%) and 16(84.3%), respectively. In 225 lung cancer patients, PET/CT accurately predicted pathological stage in 194 patients (86.2%). Compared to CT, PET/CT identified an alternative biopsy location in 16.2% of the patients. Analysis showed SPNs greater than 8mm have 8.2% and 6.5% risk of mediastinal and extra-thoracic disease, respectively. **Conclusion:** Based on our data, we believe use of PET/CT prior to biopsy in patients with chest imaging suspicious for lung cancer will direct a single biopsy that produces the highest stage by least invasive route.

Keywords: PET CT, Lung cancer, Biopsy

P1.13-06 IMPACT OF LYMPH NODE INVOLVEMENT AND TUMOR LOCATION ON SURVIVAL FOLLOWING RESECTION FOR PN1/PN2 NON-SMALL CELL LUNG CANCER

T. Tsitsias, I. Saftic, L. Harling, L. Veres, J. King, K. Harrison-Phipps, T. Routledge, J. Pilling, A. Bille

Guy's & St.Thomas NHS Trust, London/United Kingdom

Background: The aim of this analysis is to validate the proposal for the new N staging system for non-small cell lung cancer and evaluate the impact of cancer location on N disease **Method:** Between January 2011 and December 2015 2,531 anatomical lung cancer resections were performed. Retrospective analysis of the database identified 449 patients with pathological N1 / N2 disease. Patients with N0 disease, carcinoid, small cell lung cancer or secondary cancer were excluded. Patients with M1a (n=5) were excluded as well. **Result:** 449 patients were enrolled in the analysis. Median age was 68 years (range 37 - 87). There were 197(43.9%) female patients. 63.3% (n=284) of the patients were dead at the time of the analysis. Median overall survival of the population was 36.4 months (range 0.4 – 116 months). N1 disease had a median OS of 41.8 months (range 33 -50 months) and N2 26.9 months (range 19 - 34 months) (p=0.004). Dividing single N1 (N1a), multiple N1 (N1b), single N2 with skip metastases (N2a1), single N2 metastasis with N1 disease (N2a2) and multiple N2 (N2b) there was a statistical significant difference in survival (p=0.048): 41.7 months (range 32 - 51), 39.2 months (range 17 - 61), 33.3 months (range 14 - 52), 25 months (range 10 - 39) and 24.6 motnhs (range 19 -30) respectively. Analyzing multiple N2 disease (N2b) with single N1 station involved vs multiple N2 the OS was 18.9 months (range 12-25) vs 31.8 months (range 13-49) respectively. Seventy one patients had skip metastasis, the presence or not of skip metastasis alone did not correlate with OS: 32.2 months (range 16 - 47) vs 37.3 mo (range 32.5 – 42 mo) (p=0.7). Analyzing factors related to the N subclassification sex (p=0.24), side (p=0.17) and histology (p=0.26) were not correlated with the N status. The tumor location was instead related with N status (p=0.05)

Lymph node involvement per tumor location for N1/N2 subgroups

	N1a	N1b	N2a1 ('skip')	N2a2	N2b	Total
Left Hilum	24	0	2	4	5	35
Left upper lobe	63	2	20	23	10	118
Left lower lobe	30	3	6	12	5	56
Right hilum	32	3	2	3	11	51
Right upper lobe	59	6	10	22	15	113
Middle lobe	6	0	3	4	3	16
Right lower lobe	25	4	13	9	9	60

Conclusion: N staging has a significant impact on survival. The new proposed N staging system better stratifies the survival of lung cancer patients with lymph node involvement. Within the N2 category single or multiple N1 and skip N2 metastasis do not have a statistically significant impact on survival.

Keywords: Lung cancer, N2 disease, staging

P1.13-07 COMPARISON OF THE 7TH AND 8TH EDITION OF TNM STAGING FOR NSCLC IN PATIENTS UNDERGOING PULMONARY RESECTION AFTER NEOADJUVANT/ INDUCTION TREATMENT

H. Melek, T. Sevinç, G. Çetinkaya, A. Bayram, A. Deligönül, E. Çubukçu, T. Evrensel, S. Sarıhan, C. Gebitekin

Uludag University, Bursa/Turkey

Background: The new staging system for lung cancer (8thTNM) has been defined and in use since 2017. The aim of this study was to confirm the novel staging system's distinctive ability and prognostic performance in patients with clinic local advanced NSCLC undergoing Neoadjuvant/Induction (N/I) treatment followed by pulmonary resection. **Method:** The patients with locally advanced NSCLC who underwent segmentectomy or larger lung resection after N/I treatment between 2000 and 2017 were prospectively recorded and retrospectively analyzed. ypTNM stages of the patients were recorded using the 7th and 8th TNM staging system. The results were analyzed. **Result:** The study included 449 patients with a mean age of 58.92 ± 8.47, 30 were female and 419 male. Chemotherapy as an N/I was the treatment of choice for 321 (71.5%) patients and chemoradiation in 128 (28.5%) patients. The type of lung resection was segmentectomy in 22 (4.9%), lobectomy in 345 (76.8%) and pneumonectomy in 82 (18.3%). According to the 7th TNM classification; complete response, T0N0, was observed in 78, stage 1a in 83, Ib in 53, IIa in 66, IIb in 45, IIIa in 90, IIIb in 5 and stage IV in 29 patients. However, according to the 8th TNM classification; complete response, T0N0, was observed in 78, Ia1 in 18, Ia2 in 24, Ia3 in 42 patients, Ib in 35, IIa in 21, IIb in 98, IIIa in 88, IIIb in 16, and stage IV in 29 patients. When the long-term survival was analyzed for the 7th and 8th TNM Staging System, significant differences were observed in stages for each edition respectively ($p < 0.001$, $p < 0.001$). **Conclusion:** In patients undergoing surgery after neoadjuvant/induction treatment, a significant number of stage migration was detected between the 7th and 8th staging system. The 8th TNM classification showed no improvement in the ability to differentiate between subgroups compared to the older version, especially for ypStage1. To prove that the 8th TNM classification is a superior method for staging patients with N/I, further studies with larger databases are needed for this group.

P1.13-08 THE MAXIMUM STANDARDIZED UPTAKE VALUES ON POSITRON EMISSION TOMOGRAPHY PREDICT PATHOLOGICAL CHARACTERISTICS OF NON-SMALL CELL LUNG CANCER

T. Koike, Y. Shimizu, T. Goto, S. Sato, S.-I. Toyabe, M. Tsuchida

Niigata University, Niigata/Japan

Background: ^{8}F-fluorodeoxyglucose positron emission tomography/computed tomography (FDG-PET/CT) is widely used in the preoperative staging of non-small cell lung cancer (NSCLC). In this study, we sought to assess the predictive value of maximum standardised uptake value (SUV_{max}) on PET-CT for postoperative pathological metastasis and involvement in clinical stage IA NSCLC patients undergoing curative intent surgical resection. **Method:** In July 2015, FDG-PET/CT was introduced to our institution. We retrospectively reviewed patients with c-stage IA NSCLC diagnosed by FDG-PET/CT at our institution who underwent macroscopic complete pulmonary resection. The pathological metastasis and/or involvement was defined that positive pleural effusion or lavage cytology, pleural involvement, pulmonary metastasis, lymph node metastasis, and/or lymphovascular involvement were identified on pathological examination. To identify predictors for the pathological metastasis and/or involvement, preoperative clinical and radiologic factors (age, sex, smoking index, tumor markers, whole tumor size, solid component size, consolidation/tumor ratio, diseased side, tumor location, tumor histology, and SUV_{max} on FDG-PET/CT) were analyzed by a univariate analysis and multivariate logistic regression analysis. For the significant factors by the multivariate analysis, optimal cutoff points were determined with a receiver operating characteristic (ROC) analysis. **Result:** Of the 179 eligible patients, 103 were male and 76 were female. The median age was 70 years. The median whole tumor size, solid component size, and consolidation/tumor ratio on CT were 2.1 cm (range, 0.3-5.8 cm),1.7 cm (range, 0-3.0 cm),and 87% (range, 0-100%),respectively. The median SUV_{max} on FDG-PET/CT was 4.20 (range, 0.78-28.07). According to the postoperative pathological examination, 147 patients (82%) had adenocarcinoma, 25 (14%) had squamous cell carcinoma, and 7 (4%) had other types of NSCLC. Pleural involvement, pulmonary metastasis, lymph node metastasis, lymphatic permeation, and vascular invasion were identified in 26 (15%), 6 (3%), 15 (8%), 11 (6%), and 19 patients (11%), respectively, and in total, 46 patients (26%) developed the pathological metastasis and/or involvement. The univariate analysis identified SUV_{max}, sex, carcinoembryonic antigen, Sialyl Lewis^{x}-1, whole tumor size, solid component size, consolidation/tumor ratio, diseased side, tumor location, and tumor histology as significant predictors. A multivariate analysis revealed SUV_{max} (OR: 1.197, $p<0.001$) and consolidation/tumor ratio (OR: 1.052, $p = 0.001$) as significant independent predictors. The solid component size and whole tumor size were not identified as significant independent predictors. By the ROC analysis, the optimal cutoff point for SUV_{max} was determined as 6.10. Thirty-seven of the 67 patients (55%) with $\geq$6.10 of SUV_{max} developed the pathological metastasis and/or involvement whereas 9 of the 112 patients (8%) with <6.10 of SUV_{max} developed pathological metastasis and/or involvement. **Conclusion:** Our results suggested the predictive effect of high SUV_{max} on pathological metastasis and involvement in clinical stage IA NSCLC patients. Thus, FDG-PET/CT should be utilized for the preoperative precise evaluation of early stage NSCLC, and we may consider SUV_{max} on FDG-PET/CT to decide surgical procedure for these patients, such as the extent of pulmonary resection and lymphadenectomy.

P1.13-09 UTILITY OF ARTIFICIAL INTELLIGENCE IN ESTIMATION OF THE HISTOLOGIC TYPE OF LUNG CANCER

Y. Kawaguchi, J. Ichinose, Y. Kondo, Y. Matsuura, M. Nakao, S. Okumura, M. Mun

Cancer Institute Hospital of JFCR, Tokyo/Japan

Background: With the development of artificial intelligence (AI), various activities using AI have become able to be performed without specialized knowledge. Computer-aided diagnosis systems using AI have also made great strides in decades. We examined the qualitative diagnostic ability to estimate the histologic type of lung cancer using an image recognition system that can be used online. **Method:** We used 316 computed tomography (CT) images of lung cancer with solid component diameter less than 3 cm resected at our hospital. All images were trimmed at the tumor edge to increase the accuracy of machine learning by AI. Prepared images were classified by pathological diagnosis into adenocarcinoma (AD) group and non-adenocarcinoma (non-AD) group. 159 images were assigned to the training set and 157 were assigned to the test set. IBM watson studio; visual recognition app developed for image recognition was used for machine learning and judgment. The established algorithm by the training set was applied to the test set. The histologic type of which possibility calculated by AI was over 0.5 was defined as the AI answer. **Result:** There were 93 AD and 66 non-AD in the training set and 92 AD and 65 non-AD in the test set. In the AD group, the median of the solid component diameter was 1.5 cm (0 - 2.9 cm). 21 images were pure ground-glass nodules, 122 images were part-solid ground-glass nodules and 42 images were consisted of solid component. In the non-AD group, the median of the solid component diameter was 2.0 cm (0.5 - 3.0 cm) and all images were consisted of solid component. Of the 65 non-AD images in the test set, the AI answer was correct in all images (100%). However, of the 92 AD images in the test set, the AI answer was correct only in 49 images (53%). When the 47 AD images with dominant ground-glass opacity were analyzed, the AI answer was correct in 33 images (70%). **Conclusion:** Although the CT image recognition using AI could accurately estimate the histologic type of lung cancer in tumors with dominant ground-glass

opacity, it was difficult to distinguish solid AD from solid non-AD. The multimodal image analysis including enhanced CT and FDG-PET seems necessary.

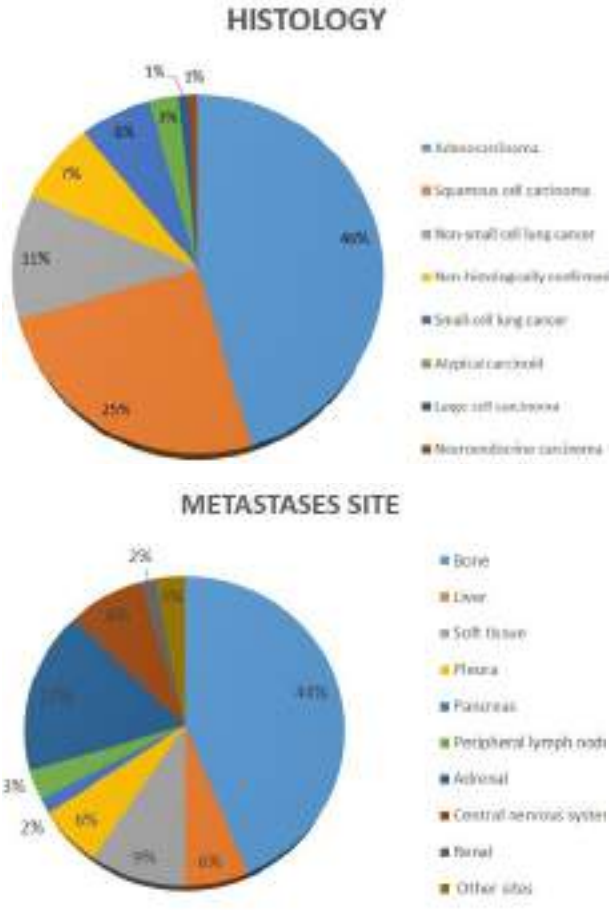
Keyword: AI, image recognition, NSCLC

P1.13-10 INCIDENCE OF HIDDEN EXTRATHORACIC METASTASES AND UNEXPECTED SECOND MALIGNANCIES DETECTED BY PET IN PATIENTS WITH LUNG CANCER

B. García Cabo, C. Caupena Auledas, M. Martinez Palau, T. Pribic, R. Costa Solá, A. Navarro Rolon, A. Hernandez Biette, J. Sanz Santos, J.M. González González, M. Ysamat Marfá

Hospital Mutua de Terrassa, Terrassa/Spain

Background: Recent staging guidelines for lung cancer (LC) staging recommend invasive mediastinal staging regardless of the findings of positron emission tomography (PET). Thus, the role of PET in the staging of LC seems to be increasingly relegated to the detection of hidden extrathoracic metastases. The aim of the study was to determine the incidence of hidden metastasis and second malignancies diagnosed by PET in a cohort of patients with LC and without extrathoracic metastases identified in the initial radiologic work up. **Method:** This is a retrospective study that included patients with a final diagnosis of LC without extrathoracic metastases identified in the initial radiologic work up (thorax and upper abdomen computer tomography). The incidence of hidden metastases and unexpected second malignancies detected by PET were recorded. **Result:** From 2006 to 2018, 343 patients were included (81% male, mean age 68.2 ± 9.6 years) (Table 1). PET detected hidden metastases in 57 (16.6%) patients (Table 2). Fifty-two patients had a single metastasis and 5 had multiple metastases. A total of 64 metastases were detected, the most frequent location was bone (28). Five (1.4%) patients presented an unexpected second malignancy: 2 head and neck, 2 colorectal and one lymphoma.



Conclusion: PET detects hidden metastases in 16% of patients with LC and without extrathoracic metastases identified in the initial radiologic work up. 1.4% patients presented an unexpected second malignancy.

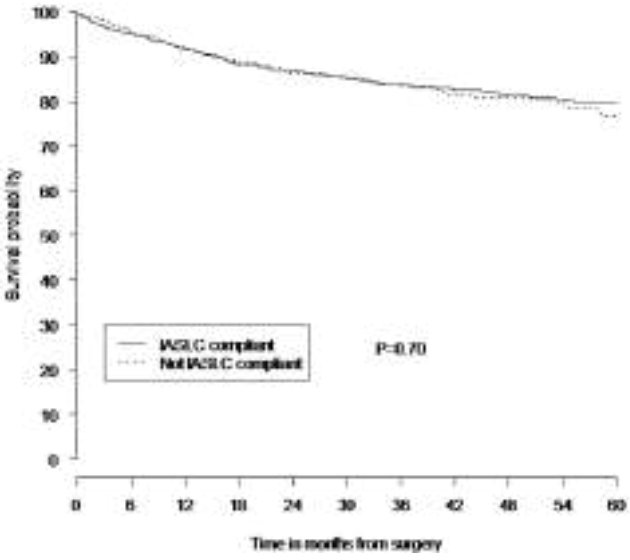
P1.13-11 AN AUDIT ON IASLC COMPLIANCE OF LYMPH NODES DISSECTION AND IMPACT ON SURVIVAL AFTER SURGERY FOR NON-SMALL CELL LUNG CANCER

P. De Sousa, F. Mansour, M. Barbosa, S. Booth, H. Klein, A. Mani, M. Nizami, C. Von Crease, G. Ladas, J. Finch, N. Asadi, E. Beddow, N. Mcgonigle, V. Anikin, S. Begum, S. Jordan, A. Montero-Fernandez, J. Robertus, A. Rice, A. Nicholson, E. Lim

Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom

Background: The IASLC proposed minimal criteria for 6 nodes / stations to ascertain certainty status of complete (R0) resection after lung cancer surgery and in 2017, Edwards et al presented that failure of compliance leading to R0 (un) status was associated with poorer survival. The aims of this audit are to assess compliance of the IASLC recommendations on lymph node staging and determine the impact of R0 (un) status on prognosis in an independent cohort. **Method:** We included patients who underwent lobectomy or pneumonectomy for primary lung cancer. Data was obtained from electronic records and survival status obtained from NHS Spine. **Result:** From January 2010 to December 2017, 2,521 patients underwent lung resection for primary lung cancer staged using TNM7. The mean age (SD) was 67 (10) and 1,235 (49%) were men, the primary diagnoses were either adenocarcinoma or squamous carcinoma in 2,057 (82%). The IASLC compliance with 6 node / stations was 627 (25%) and when sub-carinal station was mandatory it was 608 (24%). After exclusions, we were left with 1,859 patients and on adjustment of T and N category, there was no difference between IASLC non-compliance R0 (un) on overall survival with a hazard ratio of 0.95 (95% CI 0.74 to 1.21; P=0.657) compared to R0 compliant. After adjusting for T and N category there was no significant difference in total lymph nodes stations harvested with a HR 1.01 (0.97 to 1.04, P=0.712) or number of positive stations HR 1.04 (0.92 to 1.16; P=0.543) in survival.



Conclusion: Independent validation of R0 (un) status did not concur with poorer survival. The designation carries uncertainty and likely to be influenced by the extent of N2 dissection. When adjusted for stage, there was no difference on number of stations harvested nor the total number of positive stations on survival.

Keywords: Lung cancer, surgery, lymph node

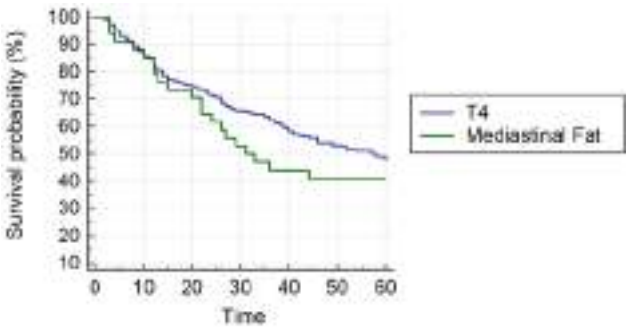
P1.13-12 THE INVASION OF MEDIASTINAL FAT TISSUE SHOULD BE CONSIDERED FOR T4 DESCRIPTION IN THE NEXT TNM CLASSIFICATION OF NSCLC

N. Citak[1], Y. Aksoy[2], O. Isgörücü[1], C. Obuz[2], B. Acikmese[1], S. Büyükkale[3], N. Fener[2], M. Metin[2], A. Sayar[3]

[1]*Bakirkoy Dr.Sadi Konuk Research and Education Hospital, Bakirkoy/Turkey,* [2]*Yedikule Thoracic Surgery and Chest Disease, Istanbul/Turkey,* [3]*Private Memorial Hospital, Istanbul/Turkey*

Background: Mediastinal fat tissue invasion is not included for the T description in the 8th edition of the TNM classification of NSCLC. The present study aimed to compare survival of patients who have

mediastinal fat tissue invasion with patients who are determined as T4 according to the 8th classification of lung cancer. **Method:** Between 2006 and 2016, 2052 patients undergoing pulmonary resection for NSCLC were evaluated. The present study analyzed of 284 cases; of which 36 patients who had been found mediastinal fat tissue invasion by pathological evaluation (Mediastinal Fat group) and 248 cases who had been determined as T4 according to the 8th classification of NSCLC (T4 group; invasion of structures in 78 patients, ipsilateral different lobe satellite pulmonary nodule in 32 patients, and tumor diameter > 7 cm in 138 patients). **Result:** Complete resection (R0) was possible in 255 patients (89.7%). The overall 5-year survival rate was 46.5% (median 54 months). Five-year survival rates for T4 subcategories (invasion of other structures, ipsilateral different lobe pulmonary nodule, and tumor diameter > 7 cm) were 39.4%, 41.9%, and 50.3%, respectively (p=0.109). Mediastinal Fat group survival was found worse better than T4 group (37.6% vs 47.3%, median 31 months vs 57 months), although this difference was not statistically significant (p=0.205, HR=1.325) (Figure 1).



By multivariate analysis, three factors significantly and independently influenced survival: nodal status (N0/1 vs N2; p=0.0001, HR=2.162), complete resection (R0 vs R1; p<0.0001, HR=2.948), and age (<65 vs ≥65; p<0.0001, HR=2.201). As though only N0/1 analyzed for to eliminate the effect of pN2 disease on survival, we observed that the survival of Mediastinal Fat group was worse than T4 group (39.7% vs. 50.8%; p=0.419, HR=1.245). Also, we found that survival of T4 group was better than Mediastinal Fat group when only R0 patients was analyzed (50.9% vs 41.3%, p=0.418, HR=1.237). **Conclusion:** There was no significant difference in survival between patients with mediastinal fat invasion and patients on T4 category for lung cancer. Mediastinal fat invasion should be inclueded as one of a descriptor of T4 in new classification of NSCLC.

Keywords: Nonsmall cell lung cancer, Mediastinal fat invasion, T4 descriptor

P1.13-13 HIGH-RISK CLINICAL STAGE I NON-SMALL CELL LUNG CANCER BASED ON HIGH-RESOLUTION COMPUTED TOMOGRAPHY FINDINGS

Y. Tsutani, A. Kagimoto, Y. Handa, T. Mimae, Y. Miyata, M. Okada

Hiroshima University Hospital, Hiroshima City Minamiku/Japan

Background: Perioperative systemic therapy for stage I non-small cell lung cancer (NSCLC) has not been established. The purpose of this study was to identify the high-risk patients for recurrence in clinical stage I NSCLC who were potentially candidates for systemic therapy in addition to standard lobectomy. **Method:** After excluding patients who underwent sublobar resection, 397 patients with clinical stage I NSCLC who underwent lobectomy with systematic lymph node dissection between April 2007 and March 2016 were analyzed. Solid component size on high-resolution computed tomography (HRCT) was used as tumor size on the basis of the 8th edition of TNM classification. Relapse-free survival (RFS) was estimated using Kaplan-Meier method, and multivariable Cox proportional hazards model was used to identify independent prognostic factors for RFS. **Result:** Five-year RFS of all patients was 73.6%. Multivariable Cox analysis revealed that age (hazard ratio [HR], 1.04 (95% confidence interval [CI], 1.01– 1.06; P = 0.005), solid component size (mm) (HR, 1.06 (95% CI, 1.04–1.09; P <0.001), and pure solid type (HR, 1.79 (95% CI, 1.10–2.91; P = 0.02) were independent prognostic factors for RFS. When patients were divided into high-risk group for recurrence (solid component size of >2 cm or pure solid type) and low-risk group (solid component size of <2 cm and part solid type), there was a significant difference in RFS between high-risk group (n = 298; 5-y RFS, 65.0%) and low-risk group (n = 129; 5-y RFS, 91.0%; P <0.001). Lymphatic invasion (29.5% vs. 9.3%, P <0.001), vascular invasion (36.6% vs. 7.8%, P <0.001), pleural invasion (28.4% vs. 9.3%, P <0.001), and lymph node metastasis (17.9% vs. 1.6%, P <0.001) were more frequent in high-risk group than in low-risk group. **Conclusion:** In clinical stage I NSCLC, patients with solid component size of >2 cm or pure solid type on HRCT were high-risk group for recurrence. These patients may be potential candidates for systemic therapy such as neoadjuvant immunotherapy.

P1.13-14 PROGNOSIS AND CLINICOPATHOLOGIC CHARACTERISTICS OF SKIP N2 METASTASIS IN COMPLETELY RESECTED NON-SMALL CELL LUNG CANCER

T. Tsuboi, D. Eriguchi, D. Nemoto, J. Samejima, T. Nagashima, H. Ito, H. Nakayama

Kanagawa Cancer Center, Yokohama/Japan

Background: In our daily practice of non-small cell lung cancer (NSCLC) surgery, we sometimes encounter cases of pathological stage was up because of unexpected lymph node metastasis. If single-station N2 metastasis without N1 (skip-N2) of the tumor ≤ 5cm was noted postoperatively, it becomes stage IIIA like other N2 disease, and is to be poor prognosis in the current TNM staging system. The aim of this study is to analyze the impact for prognosis and clinicopathologic characteristics of skip-N2 disease. **Method:** We identified 415 patients with <T3 N1-2 NSCLC who underwent anatomical lung resection completely between January 2000 and December 2018. The degree of lymph node metastasis was classified into three; N1, skip-N2 and the other N2 (N2). The prognosis and clinicopathologic characteristics of patients were analyzed comparing skip-N2 with N1 and N2. **Result:** The median follow-up time was 45.7 months. Cases with N1 was 215 (51.8%), skip-N2 was 48 (11.6%) and N2 was 152 (36.6%). Among 48 cases of skip-N2, only 8 cases (16.7%) was diagnosed as N2 preoperatively. 5-year overall survival rate (5y-OS) for N1, Skip-N2 and N2 were 70.9%, 65.7% and 45.3% respectively. 5-year recurrence free survival rate (5y-RFS) for N1, Skip-N2 and N2 were 69.8%, 60.4% and 36.0% respectively. Prognosis of Skip-N2 had similar N1 (5y-OS; p=0.476, 5y-RFS; p=0.534) and had a tendency of better prognosis than N2 (5y-OS; p=0.08, 5y-RFS; p=0.01). As for clinicopathologic characteristics (patients characteristics, tumor marker, tumor size, tumor location, clinical stage and pathological characteristics), there were no significant differences between Skip-N2 disease and the other N1-2 disease. In skip-N2, 98% of cases were found within the extent of lobe specific lymph-node dissection. **Conclusion:** From clinicopathologic factors which can be obtained preoperatively, it is difficult to predict skip-N2. But the possibility of skip N2 among clinical N0 is not high, almost of skip N2 were detectable during surgery; lobe specific lymph node dissection is appropriate for clinical N0. The prognosis of skip N2 showed similar outcome of N1 rather than N2, but the prognosis is not enough; adjuvant chemotherapy is necessary for this population.

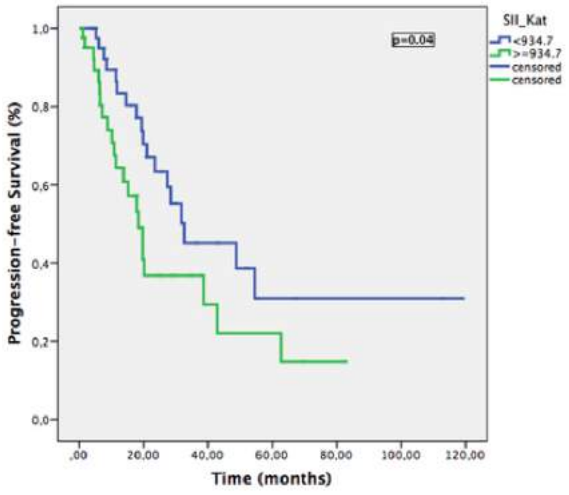
P1.14-01 ARE PRETREATMENT INFLAMMATION-BASED PROGNOSTIC SCORES USEFUL IN PREDICTING THE OUTCOMES OF PATIENTS WITH ALK-POSITIVE NSCLC?

O.F. Olmez[1], A. Bilici[1], P. Gursoy[2], E. Çubukçu[3], O. Yildiz[1], A. Sakin[4], T. Korkmaz[5], I. Cil[6], B. Cakar[2], S. Menekse[7], T. Demir[8], O. Acikgoz[1], J. Hamdard[1]

[1]*Medipol University, Medical Faculty, Istanbul/Turkey,* [2]*Ege University, izmir/Turkey,* [3]*Uludag University, Bursa/Turkey,* [4]*Okmeydanı Education and Resarch Hospital, Istanbul/Turkey,* [5]*Acıbadem University, Istanbul/Turkey,* [6]*Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul/Turkey,* [7]*Bagcilar Education and Research Hospital, Istanbul/Turkey,* [8]*Bezmialem University, Istanbul/Turkey*

Background: Approximately 5% of all diagnosed non-small cell lung cancer (NSCLC) patients harbor a genetic rearrangement between the ALK and EML4 genes, representing a specific molecular and clinical subgroup (ALK+ NSCLC). To date, upfront treatment with ALK-tyrosine-kinase inhibitors (ALK-TKIs) has replaced chemotherapy in the first line setting for this subset of patients with excellent results, but reliable prognostic markers are lacking. An increased systemic inflammatory response has been shown to be associated with a poor prognosis, and some of the parameters used to characterize this response can easily be measured in clinical practice in several tumor types, but have not been analyzed extensively in ALK+ lung cancer in the era of crizotinib. **Method:** We reviewed the medical records of all patients with previously treated advanced ALK-positive NSCLC who received crizotinib between January 2013 and March 2018 outside of a clinical trial. Pre-treatment modified Glasgow prognostic score (mGPS), Prognostic Nutritional Index (PNI) and Systemic immune-inflammation index (SII) were calculated. Multivariable logistic regression and Cox proportional hazards models were used to assess the impact of pretreatment mGPS, PNI and SII on overall survival (OS), progression-free survival (PFS), and overall response rate (ORR). **Result:** 82 patients were treated. Median age was 52.5 years (range; 20–77 years); 42.7% were female. Eighty-four point two percent of patients had an Eastern Cooperative Oncology Group Performance Status (ECOG PS) ≥1; 17.1% had received ≥2 prior systemic therapies. The objective response rate was 77.2% (CR+PR).The optimal cutoff levels were 0.09 for mGPS and PNI, 934.7 for SII by ROC curves analysis. Patients in the SII ≥ 934.7 grous was significantly correlated with worse PFS and OS by univariate analysis (Figure 1).In multivariate analyses, pretreatment prognostic nutritional index (PNI) ≥ 0.09 was independently associated with inferior OS (1 year OS rates, 90.2% vs. 73.7%; HR 2.46, 95% CI 0.88-4.85; p = 0.035). Additionally, we evaluated the effects of these markers on response prediction. The logistic regression analysis of the predictive factors for the response to crizotinib demonstrated that the mGPS and PNI were associated with inferior ORR (OR: 0.1, 95% CI 0.16-1.04; p = 0.009 and OR: 0.16, 95% CI 0.02-0.55; p = 0.035, respectively).



Conclusion: In a cohort of patients with ALK positive NSCLC treated with crizotinib in routine practice,elevated pre-treatment SII was associated with shorter OS and PFS in univariate analysisand PNI was associated with shorter OS in multivariate analyses. Moreover the mGPS and PNI were associated with lower response rates.

P1.14-02 SURVEY OF EGFR MOLECULAR TESTING OF NSCLC IN THE ASIA-PACIFIC REGION

C.K. Liam[1], E. Stone[2], S. Andarini[3]

[1]*Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia,* [2]*Department of Thoracic Medicine, St. Vincent's Hospital, Sydney/Australia,* [3]*Department of Pulmonology and Respiratory Medicine, University of Indonesia-Persahabatan Hospital, Jakarta/Indonesia*

Background: Around 1 million new lung cancer cases occur annually in the Southeast Asian and Western Pacific regions combined, comprising more than half the global new cases each year. In recent years several key oncogenic driver alterations have been identified in non-small cell lung cancer (NSCLC), including epidermal growth factor receptor (*EGFR*) gene mutations, which are detected in up to 60% of adenocarcinoma in Asian patients. *EGFR* mutation testing to optimise therapy and outcomes has become the standard of care in advanced NSCLC. This study aimed to survey the practice of *EGFR* mutation testing in NSCLC across countries in the Asia-Pacific region. **Method:** The survey was circulated as a web-based electronic online survey questionnaire (www.surveymonkey.com) from 18 August to 3 October 2018 to members of the Asian Pacific Society of Respirology. Survey questions sought information on the following aspects of *EGFR* molecular testing: prevalence, methods of testing, funding and cost, type of tissue or sample, time frame for test results, retesting after progression, prevalence of *T790M* testing and use of liquid biopsy. **Result:** Of 121 respondents from 16 countries who treated lung cancer patients, 71 (58.7%) treated <10 lung cancer patients per week, 38 (31.4%) treated 10-30 lung cancer patients per week, and 7 (5.8%) treated >30 lung cancer patients per week. A significantly higher percentage of NSCLC patients was tested for *EGFR* mutation in academic/tertiary centres and public hospitals than in private hospitals [96 of 99 (97.0%)] vs [18 of 22 (81.8%)] (OR, 7.11; 95% CI, 1.47–34.50; p=0.02). The percentage of *EGFR* mutation testing for ≥50% of cases was significantly higher when the number of lung cancer patients treated in the practice was ≥10 per week [40 of 45 (88.9%)] vs [49 of 71 (69.0%)] (OR, 3.56; 95% CI, 1.13–11.17; p=0.023). Testing for molecular aberrations in the initial biopsy was more commonly physician initiated [89 of 121 respondents (73.5%)] than reflex (i.e., ordered by the reporting pathologist based on histopatholgy) [32 respondents (26.4%)]. The percentage of *EGFR* mutation testing for ≥50% of cases was significantly higher when the test was fully reimbursed [46 of 51 (90.2%) compared to otherwise [47 of 70 (67.1%)] (OR, 1.63; 95% CI, 1.25–2.12; p=0.003). The turnaround time (days) was <7 (35.5% of the practices), 7-14 (47.9%) and >14 (12.4%). A significantly higher percentage of respondents would perform tissue rebiopsy in ≥50% of the cases with disease progression while on treatment with 1st- or 2nd-generation *EGFR*-TKIs if osimertinib was accessible for use, 34 of 72 (47.2%) compared to 7 of 49 (14.3%) if otherwise (OR, 5.37; 95% CI, 2.13-13.53; *p*<0.0001). Liquid biopsy for *T790M* mutation detection was performed more frequently in practices where there was access to osimertinib (91.6% vs 28.6%; OR, 27.50, 95% CI, 9.72-77.84; *p*<0.0001). **Conclusion:** It was more likely for ≥50% of NSCLC patients to be tested for *EGFR* mutation by respondents who treated ≥10 lung cancer patients per week and if the test was fully reimbursed. Tissue rebiopsy and liquid biopsy for *T790M* mutation detection was more frequently performed in practices with access to osimertinib.

Moscati Hospital, Avellino/Italy,* [11]*AOU San Luigi, University of Turin, Turin/Italy,* [12]*Santa Maria della Misericordia Hospital, Perugia/Italy,* [13]*ASST Valleolona, PO Saronno, Saronno/Italy*

Background: Lorlatinib, an ALK/ROS1 inhibitor, demonstrated activity in *ROS1+* NSCLC pretreated with crizotinib. However, molecular events predictive for tumor response during lorlatinib treatment are largely unknown. **Method:** PFROST was a prospective phase II trial designed to include *ROS1+* NSCLC refractory to crizotinib. Eligible patients were treated with lorlatinib at the daily dose of 100 mg until disease progression. Primary end point was response rate (RR). For all included patients pre-lorlatinib tumor tissue or blood sample collection was mandatory. At the time of lorlatinib failure liquid biopsy was recommended. The samples were then run with the NEOliquid assay, specifically designed for liquid biopsies, or NEOselect, a panel optimized for formalin-fixed paraffin-embedded (FFPE) tumor tissue, covering 39 cancer related genes. **Result:** From June 2017 to April 2019, 22 *ROS1+* crizotinib refractory lung adenocarcinoma patients were included in 10 Institutions. Median age was 56 years (range 39-82); male/female: 8/14; ECOG PS 0 (N=8; 36.4%), PS1 (N=14; 63,6%); The majority had brain metastases at baseline (N=15; 68.1%), were never smokers (N=13; 59.1%) and received lorlatinib as third line therapy (N=16; 72.7%). In all cases crizotinib was the last therapy line before lorlatinib. At the time of the present analysis, trial completed its accrual and 13 patients are still receiving therapy. A total of 18 patients were evaluable for response and 7 had confirmed complete (N=1) or partial (N=6) responses for an overall RR of 38.8%. In 4 patients, response to therapy was not yet evaluated. A total of 10 tissue biopsies and 20 blood samples obtained after crizotinib and before lorlatinib therapy were collected. For 7 samples analyses are ongoing. Among responders, no patient harbored a secondary *ROS1* mutation. Conversely, no response was observed among patients with secondary *ROS1* mutations (N= 1 *ROS1*^{S1861I}, *N=1 ROS1* ^{V2054A}, N=3 *ROS1*^{G2032R}). All patients harboring the *ROS1*^{G2032R} mutation rapidly progressed and maintained this aberration in liquid biopsy at the time of radiological evidence of lorlatinib failure. **Conclusion:** In our study lorlatinib confirmed its efficacy in crizotinib resistant *ROS1+* NSCLC. Molecular profile of refractory patients suggests reduced efficacy in individuals developing secondary *ROS1* mutations after crizotinib failure.

Background: We hypothesized that young age at lung cancer diagnosis is a clinical characteristic associated with a higher likelihood for having a driver mutation. Our goals were to identify a genomically enriched subtype of lung cancer, facilitate delivery of targeted therapy and lay groundwork for studies of heritable and environmental lung cancer risk factors. **Method:** Eligible subjects had a diagnosis of bronchogenic lung cancer < 40 years old. We included a website to allow for virtual consenting and remote participation from anywhere in the world. An integrated data and biorepository allowed for completion of study activities and routing of specimens. We defined seven genes of interest based on the Lung Cancer Mutational Consortium (LCMC): EGFR, KRAS, HER2, BRAF, ALK, ROS1, RET. We hypothesized that the prevalence of targetable alterations in these genes would be greater in our population compared to the LCMC and powered our study to detect an increase from 35% to 50%. Subjects with advanced adenocarcinoma who were not tested for all seven genes or who were wild type for all seven underwent additional genomic profiling using Foundation Medicine testing. **Result:** We accrued 133 participants from July 2014 to June 2017. Notably, 44% entered the trial via the website. The mean age at diagnosis was 34 (range 16 to 39) and 57% were female; 77% were stage 4 at diagnosis and the majority had adenocarcinoma (86%). Of the 115 patients with adenocarcinoma, 83.5% were stage 4 and the focus of the comparison to the LCMC cohort. A targetable mutation was identified in 85.4%, with 76% harboring a combined ALK (38.5%), EGFR (31.3%), or ROS1 (6.3%) mutation. Of 14 patients who underwent on-protocol testing, a targetable driver was identified in eight (57%), including two with a RET rearrangement, two with ERBB2 mutations, two with MET amplification, one with an ALK rearrangement with a prior negative FISH and one with a novel EGFR-RAD fusion previously tested negative for EGFR. **Conclusion:** We have described a genomically distinct subset of NSCLC in patients < age 40. Those with stage 4 adenocarcinoma must undergo comprehensive genomic testing to identify a targetable driver. The extremely high rate of driver mutations particularly in ALK supports the need for an Epidemiology of YLC study. Additionally, use of remote consenting and the Addario Lung Cancer Foundation's advocacy enabled rapid accrual of this rare cohort (<1%) and has laid the foundation for innovative research partnerships with other rare oncogene-driven patient groups.

P1.14-05 TP53 EXON 8 MUTATION AND PROGNOSIS IN EGFR-MUTATED NSCLC PATIENTS TREATED WITH FIRST-AND-SECOND-GENERATION TKIS

M. Canale[1], E. Petracci[1], L. Crino[1], N. De Luigi[2], V. Ludovini[3], A. Dubini[4], S. Baglivo[3], E. Minenza[3], E. Chiadini[1], L. Landi[5], M. Papi[6], A. Delmonte[1], G. Bronte[1], P. Ulivi[1]

[1]*IRST-IRCCS, Meldola/Italy,* [2]*Ospedale di Stato-Istituto per la Sicurezza Sociale di san Marino, San Marino/San Marino,* [3]*Santa Maria della Misericordia Hospital, Perugia, Italy, Perugia/Italy,* [4]*Ospedale Morgagni-Pierantoni, Forlì/Italy,* [5]*Azienda USL della Romagna, Ravenna/Italy,* [6]*Azienda USL della Romagna, Rimini/Italy*

Background: *TP53* mutation seems to be associated with a worse prognosis in *epidermal growth factor receptor (EGFR)* mutated non-small cell lung cancer (NSCLC) treated with first generation tyrosine kinase inhibitors (TKIs). We previously showed that this was mainly significant for exon 8 *TP53* mutations (Canale M et al, Clin Cancer Res 2017). However, its role on survival, as well as in relation to response to second generation TKIs is not clearly established. **Method:** A retrospective cohort of 270 *EGFR*-mutated NSCLC treated with first- (gefitinib and erlotinib) and second- (afatinib) generation TKIs, in the first line setting, were considered. *TP53* status was evaluated by Sanger Sequencing or Next generation Sequencing. The different mutations were evaluated in relation to disease control rate (DCR), objective response rate (ORR), progression-free survival (PFS), and overall survival (OS). **Result:** One hundred and forty-four patients (53.3%) received a treatment with gefitinib, 84 (31.1%) with erlotinib and 42 (15.7%) with afatinib. In the overall cohort, ORR and DCR were 61.5% and 86.4%, respectively, with about 50% of patients responsive for more than 10 months. Median PFS and OS were of 11.08 (95% CI 9.3-12.6) and 22.9 (95% CI 20.4-27.5) months, respectively. Overall, 79 (30.7%) patients showed a *TP53* mutation. The presence of *TP53* exon 8 mutation was associated with a worse outcome with respect to patients wt or with other *TP53* mutations. In particular, a lower ORR and DCR were observed for patients with *TP53* exon 8 mutation (ORR 94.16% vs 5.84%, p=0.05, and DCR 94.04% vs 5.96%, p<0.001, respectively), together with a worse PFS (HR 1.88 [95% CI 1.20-2.96], p=0.006). These results was even more significant in the subgroup of patients with *EGFR* exon 19 deletion, where *TP53* exon 8 mutation was associated with both worse PFS (HR 4,72 [95% CI 2.31-9.65], p<0,001) and OS (HR 2.60 [95% CI 1.11-6.04], p=0.027). At the multivariable analysis, *EGFR* exon 19 deletion and *TP53* exon

POSTERS

8 mutation remained independently associated with PFS (HR 0.56 [95% CI 0.35-0.89], p=0.014 and HR 1.81 [95% CI 1.13-2.88], p=0.013, respectively). Moreover, *EGFR* exon 19 deletion and age resulted independently associated with OS (HR 0.52 [95% CI 0.26-1.03], p=0.059, and HR 1.02 [95% CI 1.01-1.04], p=0.009, respectively). No other patient and clinical covariate showed an association with PFS and OS in the multivariable models. **Conclusion:** Our results confirm that *TP53* exon 8 mutation confers a worse outcome in patients treated with first and second generation TKIs and that this is particularly evident in patients with *EGFR* exon 19 deletion.

P1.14-06 TISSUE-BASED MOLECULAR AND HISTOLOGIC LANDSCAPE OF ACQUIRED RESISTANCE TO OSIMERTINIB IN PATIENTS WITH EGFR-MUTANT LUNG CANCERS

A. Schoenfeld, J. Chan, H. Rizvi, R. Somwar, D. Kubota, Y. Daneshbod, J. Chang, M. Offin, M. Arcila, D. Pe'Er, M. Kris, N. Rekhtman, G. Riely, M. Ladanyi, H. Yu

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Even though osimertinib (osi) is now the initial treatment for patients with *EGFR*-mutant lung cancers, our knowledge about mechanisms of resistance (MOR) is largely derived from patients who received osi after acquiring EGFR *T790M* on treatment with another EGFR inhibitor. Other studies of osi resistance have mainly reported genotyping of plasma which suboptimally detects lineage plasticity, copy number changes, and chromosomal rearrangements. **Method:** To identify MOR to osi and characterize clinical, molecular and histologic factors associated with duration of response, we identified patients with *EGFR*-mutant lung cancers who had targeted next-generation sequencing (MSK-IMPACT) performed on tumor tissue obtained before treatment and after developing resistance to osi received as either first-line or later line EGFR-TKI. **Result:** From January 2016 to March 2019, we collected paired pre-treatment and resistance specimens from 53 patients (1st line osi: 21. Osi after prior TKI: 32). MOR are summarized in the table. Histologic transformation was identified in 18% of 1st line cases and 17% of all cases. When osi was given as initial treatment, with median follow up of 18 months, early emerging MOR rarely included on-target resistance mechanisms (acquired *EGFR* G724S in 1/21). Other acquired alterations representing potential resistance mechanisms not listed in the table included *CCNE1* and *MYC* amplifications, and mutations in *MTOR A1098S* and *MET H1094Y.*

	First line (n = 21)	Osi after prior TKI (n = 32)	All (n = 53)
Squamous transformation	3	3	6
Neuroendocrine transformation	1	2	3
On target mutation (*EGFR C797X* or other)	1	9	10
Loss of *EGFR T790M* only	-	8	8
Fusions (*ALK, RET, BRAF*)	0	3	3
Amplifications (*HER2, MET, EGFR*)	2	3	4
Off target mutations (*KRAS, BRAF, HER2*)	1	2	3

Conclusion: In this analysis of MOR identified on NGS from tumor tissue, we found a spectrum of resistance mechanisms to osi. By evaluating tissue rather than plasma we provide data on histologic transformation (including squamous cell transformation). Subsequent studies are needed to assess patients with a longer time on initial osi as early progressors may have different MOR, with off-target MOR emerging earlier and on-target resistance mutations later.

P1.14-07 GENOMIC PROFILING OF LIQUID BIOPSIES DURING 2ND/3RD GENERATION ALK INHIBITOR THERAPY TO IDENTIFY NOVEL MECHANISMS OF RESISTANCE

E. Stewart[1], A. Wang[2], J. Huang[2], H. Bao[2], X. Wu[2], D. Patel[1], Z. Chen[1], J. Law[1], P. Bradbury[1], F. Shepherd[1], A. Sacher[1], M. Tsao[1], S. Bratman[1], N. Leighl[1], T. Pugh[1], G. Liu[1]

[1]*University Health Network, Toronto/Canada,* [2]*GeneSeeq, Toronto/Canada*

Background: Second- and third-generation ALK inhibitors each have diverse mechanisms of resistance. Only a fraction of resistance is due to secondary mutations of the ALK gene. Altered bypass tracts are likely the case in some other instances. Genomic alterations of other genes and pathways may be a third mechanism of resistance. Repeat liquid biopsies during the course of patients' treatments can provide a minimally invasive method for sampling cancer-specific genomic information that leads to improved treatment selection. **Method:** In the Lung Cancer Clinic of the Princess Margaret Cancer Centre, serial plasma samples were collected from six lung cancer patients with *ALK* rearrangement at multiple serial clinic visits pre- and post- progression on next-generation ALK inhibitors. We focused on next generation agents, as there has been previous focus on crizotinib resistance mechanisms already. Cell-free DNA (cfDNA) was extracted (median: 50 ng; range: 20-2760 ng) and profiled using a next-generation sequencing (NGS) platform with Geneseeq Prime 425-gene panel at a mean coverage depth of 4747X (and a deduplicated mean coverage depth of 2160X). **Result:** Somatic alterations from plasma cfDNA were detected in all six patients at various time points with three patients having detectable ALK alterations. Systemic progression (2/2 patients) correlated well with the ability of liquid biopsies to detect somatic mutations, while central nervous system (CNS)-predominant progression did not (4/4 patients). One patient, after disease progression on ceritinib, alectinib and brigatinib, exhibited variable allele fractions (AFs) of ALK G1202R mutation in cfDNA. The levels of G1202R decreased and ultimately became undetectable, corresponding to the patient's clinical response to lorlatinib. In a patient who exhibited significant systemic progression, a massive increase in mutation AFs and many newly acquired mutations were detected in the cfDNA, including *NOTCH1, DICER1, BRCA2, TP53, CDKN2A, ERBB3*, and *FAT1*mutations. However, the increase in the number of co-mutations was not related to increases in the amount of extracted cfDNA. **Conclusion:** Broad panel-based NGS of plasma cfDNA enabled noninvasive detection of systemic (but not CNS-predominant) progression during second and subsequent generation ALK inhibitor treatment, and can identify known and putative mechanisms of resistance for treatment decision-making.

P1.14-08 ACTIVITY OF POZIOTINIB AND OTHER 2ND-GEN QUINAZOLINE EGFR TKIS IN ATYPICAL EXON18 AND ACQUIRED OSIMERTINIB RESISTANCE MUTANTS

J. Robichaux, X. Le, Y. Elamin, M. Nilsson, L. Hu, J. He, F. Zhang, A. Poteete, H. Sun, W. Rinsurongkawong, J. Cross, J. Heymach

MD Anderson Cancer Center, Houston/United States of America

Background: In EGFR, exon 18 encodes for the P-loop (L718-V726), and mutations in this region (G719S/A, L718Q/V, G724S) are known to reduce sensitivity to osimertinib and first-generation EGFR TKIs. Osimertinib resistance is associated with a number of acquired mutations in exons 19 and 20 (S784F, L747S, C797S and L792H). We investigated the frequency and drug sensitivity of these and other osimertinib-resistant EGFR mutations **Method:** We generated ~50 different Ba/F3 cell line models expressing classical and/or atypical EGFR mutations (exons 18-21) and evaluated the transforming ability and sensitivity to 14 EGFR TKIs including non-covalent (first-generation), afatinib, dacomitinib, and poziotinib (quinazoline and covalent, second-generation), and covalent T790M-specific (third-generation) inhibitors. Impact of atypical mutations was analyzed by *in silico* modeling. **Result:** We found 3.6% (N=32/895) of EGFR-mutant patients had atypical, exon 18, P-loop mutations in the MD Anderson GEMINI database. Modeling of classical EGFR mutations revealed osimertinib has distinct interactions between the solvent front of osimertinib and residues within the P-loop of EGFR, whereas second-generation quinazoline TKIs, such as poziotinib, extend into the pocket, near T790, lacking these interactions. Mutations in the P-loop were predicted to shift osimertinib out of alignment with V726 and F723, causing resistance to osimertinib but not quinazoline-based TKIs. Atypical exon 18 mutations (G719S/A, L718Q/V, G724S)

had IC_{50} values of 113.6nM, 1.6nM, and 137.5nM for first-, second-, and third-generation TKIs, respectively. Second-generation TKIs inhibited G719S/A-T790M mutations at concentrations 2-fold lower than third-generation TKIs (IC_{50} = 23.4nM and 46nM). Osimertinib-resistance mutations (L747S, S784F, C797S, L792H) co-occurring with classical sensitizing mutations (L858R or ex19del) had IC_{50} values of 56.8nM, 1.4nM, and 996nM to first, second and third-generation inhibitors. Of the second-generation TKIs tested, poziotinib was the most potent for atypical exon 18 P-loop mutations; G719S/A-T790M mutations; and classical mutants with acquired osimertinib-resistance mutations ($IC_{50=}$ 0.4nM, 3.2nM, 0.8nM). **Conclusion:** Exon 18 atypical P-loop mutations and osimertinib-resistance mutations demonstrated high sensitivity to second-generation quinazoline TKIs, compared to first- and third-generation inhibitors. Mutations in the P-loop of EGFR confer resistance to third-generation TKIs by destabilizing solvent front interactions of the molecule, and osimertinib-resistance mutations interfere with covalent binding at C797. Second-generation TKIs, especially poziotinib, are potent inhibitors of these mutations because they have increased hydrophobic interactions at the back of the drug binding cleft that are retained without covalent binding. Together, these data indicate that poziotinib and other second-generation TKIs may be useful for the treatment of NSCLC patients with atypical P-loop and selected osimertinib-resistant EGFR mutations.

P1.14-09 UNVEILING HIDDEN MET-MEDIATED PRIMARY ALECTINIB RESISTANCE IN ALK-POSITIVE NON-SMALL CELL LUNG CANCER

A. Le[1], L. Tyler[1], K. Davies[1], K. Kondo[1], J. Pacheco[1], D. Merrick[1], D. Aisner[2], D.R. Camidge[3], R. Doebele[3]

[1]*University of Colorado-AMC, Aurora/United States of America,* [2]*University of Colorado, Aurora/United States of America,* [3]*University of Colorado Cancer Center, Aurora/United States of America*

Background: Alectinib is an ALK inhibitor that is currently used for the treatment of ALK-positive NSCLC. This next generation ALK inhibitor was initially used as second-line therapy following resistance to crizotinib. More recently, alectinib has superseded crizotinib, an ALK/ROS1/MET inhibitor, as a first-line therapy due to its superiority in phase III trials. Although patients enjoy durable responses to alectinib, they eventually develop resistance. Here we describe four cases of primary resistance to alectinib in which the patients show little to no response to alectinib when administered as first or second-line therapy. **Method:** In order to investigate primary resistance to alectinib, tissue was obtained during re-biopsy and subjected to routine clinical genetic analyses including gene fusion detection and genetic mutation analysis using the Archer FusionPlex and VariantPlex assays, respectively. Concurrently, at the time of biopsy, additional fresh tissue was procured for cell line derivation. The primary cell line was then used to assess ALK and other inhibitors' potency by cell viability assays. Targeted analysis of signaling pathways was performed in the cell lines via western blot analysis and proximity ligation assays to determine resistance mechanisms. **Result:** We present 4 cases of ALK patients with primary resistance to alectinib when used as either first (n=3) or second-line therapy (n=1). In 3 of the 4 cases, routine clinical resistance testing revealed no additional ALK or non-ALK related genetic abnormalities (e.g.; *ALK* kinase domain mutations, other oncogenic gain-of-function mutations, or gene amplification). However, examination of targeted gene expression data indicated elevated RNA transcripts of *MET* alone or combined *MET* and *AXL*. Analysis of the cell lines derived from these 4 patients further implicates MET in alectinib resistance alone or together with AXL or ERBB3. Signaling analysis shows that MET provides a prosurvival effect, signaling through the PI3K/AKT pathway. In the case where MET was the sole identified bypass mechanism of alectinib resistance, the patient also rapidly progressed through brigatinib, but a regimen of crizotinib plus brigatinib resulted in rapid tumor shrinkage. **Conclusion:** Here, we document cases of primary resistance to alectinib therapy using human-derived cell lines to expose novel resistance mechanisms not identified by routine clinical testing. We show that MET is a critical component and serves as a bypass mechanism of alectinib resistance either alone or in combination with AXL or ERBB3. We also demonstrate that crizotinib could overcome MET-mediated ALK resistance in a patient.

Background: *RET* is known as a driver gene which accounts for 1-2% in NSCLC. Recently, RET inhibitors such as LOXO-292 and BLU-667 demonstrated promising efficacy in NSCLC and medullary thyroid cancer. The landscape of *RET* alterations of the Chinese NSCLC population will be explored in this study. **Method:** FFPE tumor and matched blood samples of 3433 Chinese NSCLC patients were collected for performing next-generation sequencing (NGS) based targeted panel sequencing. The genomic variants including single nucleotide variations, indels, copy number alterations and gene rearrangements were analyzed. Tumor mutational burden (TMB) and microsatellite instability (MSI) status were calculated and assessed by NGS algorithms. **Result:** The patients with *RET* alterations, including 61 males and 57 females with a median age of 59.5 years, were identified in approximately 3.4% (118/3433) of the Chinese NSCLC cohort. In this study, 58 out of 118 (1.7%) patients, including 21 males and 37 females with a median age of 58 years, harbored *RET* rearrangements, which is slightly higher than the published data of MSKCC (1.2%). The partner genes of *RET* rearrangements were identified by NGS, including *KIF5B* (38/58), *CCDC6* (6/58), and other genes (14/58). *TP53* was the most common compound gene with *RET* rearrangements. Two co-existing *EGFR* mutations, L858R and L861Q, were identified in 2 *RET* rearrangement patients without previous treatments. Harbored alterations in the cell cycle pathway and in the PI3K/mTOR pathway were found in 15.5% (9/58) and 12.1% (7/58) of patients, respectively. In addition, 8 patients with *RET* rearrangements had no other co-occurring common cancer gene mutations. Meanwhile, 56 (1.6%) patients carried *RET* mutations and 5 (0.2%) patients presented *RET* amplifications. The median TMB of patients with *RET* alteration was 4.6 muts/Mb, which was exactly the same as all the 3433 patients (4.6 muts/Mb). Interestingly, patients with *RET* rearrangements had lower TMB (2.3 muts/Mb, 0-16.2 muts/Mb). All patients with *RET* alternations were microsatellite stable (MSS). **Conclusion:** This is the first study to reveal *RET* genomic profiling in a large Chinese NSCLC cohort. *RET* rearrangements were found in 1.7% of Chinese NSCLC. Besides the most common partner genes, 14 *RET* rearrangements (24%) with uncommon or novel partner genes were identified by NGS. TMB of the patients with *RET* rearrangements was relatively lower.

Keywords: NSCLC, TMB, RET

P1.14-11 A PROSPECTIVE MULTICENTER STUDY OF TARGET-CAPTURE DEEP SEQUENCING IN PAIRED TISSUE AND CTDNA TO GUIDE EGFR-MUTATED LUNG CANCER TREATMENT

Background: TKIs have significantly improved the survival of NSCLC pts carrying sensitive mutations. However, heterozygous responses were observed. We conducted a prospective multicenter clinical trial to explore factors associated with the efficacy of EGFR-TKI,

and assess the mutation and TMB concordance between plasma and tissue NGS. **Method:** Paired tumor and plasma samples were obtained from treatment naïve advanced NSCLC pts whenever applicable. DNA was sequenced by target-capture deep sequencing of 1021 tumor-related genes (pan-cancer panel). PFS was estimated using Kaplan-Meier method and compared using log-rank test. Tissue TMB (tTMB) and plasma TMB (bTMB) analysis interrogated SNVs/Indels with VAF ≥3 % and ≥0.5 %, respectively. TMB-H pts were identified with ≥9 muts/Mb. **Result:** From Feb. 2017 to Jan. 2019, 262 advanced NSCLC pts were enrolled from 12 centers. In 224 pts with paired tumor and plasma samples, 144 had *EGFR* sensitive mutations in tumor samples (L858R, 46%; Ex19Indel, 42%), of whom, 106 (74%) had the identical mutations detected in plasma. The detection rate of tissue *EGFR* mutations in paired plasma was significantly higher in pts with extrathoracic metastasis (81% vs. 61%, p = 0.03). In 38 pts lacking paired samples, 20 pts had *EGFR* sensitive mutations detected. Thus, 164 pts were identified as EGFR positive by either plasma or tissue NGS. One hundred of them were treated EGFR TKIs (ORR: 70%, mPFS: 20 mo). The ORR was affected by *EGFR* subtypes (Ex19Indel vs. L858R: 72% vs. 45%, p = 0.02), concomitant CNV/fusion (with vs. without: 11% vs. 68%, p = 0.002) and *CDKN2A* mutations (with vs. without: 0% vs. 66%, p = 0.007). Mutations in p53 pathway (p = 0.02), CDK12/13 (p = 0.0002), concomitant CNV/fusion (p = 0.003), and high number of alterations (≥ 5) (p = 0.003) significantly shortened mPFS. tTMB was correlated with bTMB ($r_{Pearson}$ = 0.9, p < 0.0001), with a concordance rate of 90% for TMB-H and TMB-L classification. Interestingly, 9.8% of the EGFR positive pts were bTMB-H, and mPFS was shorter in bTMB-H pts (6 mo, 95% CI: 5 - NR) than in bTMB-L pts (NR, 95%: 13 - NR) (p = 0.2). **Conclusion:** Deep sequencing with the pan-cancer panel effectively detected mutations and evaluated TMB in both tissue and plasma with a high consistence. Moreover, the presence of structure variation, high tumor heterogeneity and concomitant mutations in genes such as *CDKN2A* were associated with worse prognosis. Further studies of predictive factors are ongoing (NCT03059641).

P1.14-12 A NOVEL ACTIVATING MAP2K1 IN-FRAME DELETION MEDIATES ACQUIRED RESISTANCE TO ROS1 TKIS IN A PATIENT WITH ROS1 FUSION-POSITIVE NSCLC

H. Sato[1], A. Schoenfeld[1], E. Siau[1], K. Suzawa[1], C. Yue[1], M. Offin[1], A. Drilon[1], M. Davare[2], G. Riely[1], M. Ladanyi[1], R. Somwar[1]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Oregon Health & Science University, portland/United States of America*

Background: *ROS1 tyrosine kinase inhibitors (TKIs) such as crizotinib, entrectinib and lorlatinib* provide significant benefit in non-small cell lung cancer (NSCLC) patients with *ROS1* fusions. As observed with all targeted therapies however, resistance arises. With the widespread adoption of large panel next generation sequencing (NGS) at the time of acquired resistance (AR), our appreciation of novel off-target mechanisms continues to grow. Detecting additional mechanisms of acquired resistance (AR) is crucial to find novel therapies and improve patient outcomes. **Method:** We reviewed targeted large-panel sequencing data (using the MSK-IMPACT assay) of paired pre-treatment and post-progression samples from patients treated with ROS1 TKIs. Genetic alterations hypothesized to confer AR were modeled in a patient-derived cell line (LUAD-0003, expressing *EZR/ROS1*) as well as isogenic human (HBEC) and murine (NIH-3T3) cell lines. *ROS1* fusions were expressed in these cells either by cDNA overexpression (*CD74/ROS1*, *SLC34A2/ROS1*) or CRISPR-Cas9-mediated genomic engineering (*EZR/ROS1*). Using these cell line models, alterations in drug sensitivity and downstream signal pathways were examined. We also explored possible therapeutic strategies to overcome the drug resistance caused by the novel AR mechanisms examined in this study. **Result:** *We identified a patient with NSCLC harboring a MAP2K1 (MEK1) variant encoding an in-frame deletion of amino acids E41-L54 (MEK1del) in a sample taken at the time of resistance to lorlatinib (after 9 months' treatment).* This mutation was not detected in the pre-TKI sample. Induction of ROS1 fusions in HBEC and NIH-3T3 cells increased the sensitivity of these cells to ROS1 TKIs and stimulated activation of MEK/ERK signaling in comparison with AKT signaling, suggesting the importance of the RAS-MAPK pathway in driving ROS1 fusion-positive cancers. Underscoring the importance of the RAS-MAPK pathway in ROS1-mediated tumorigenesis, we identified three patients (pancreatic, salivary, and breast cancer) with a *ROS1* fusion and *NF1* loss-of-function mutation concurrently, in TKI-naïve samples. Expression of MEK1del in HBEC and NIH-3T3 cells harboring ROS1 fusions, and knockdown of *NF1* in LUAD-0003, activated ERK signaling and conferred resistance to ROS1 TKIs. Combined targeting of ROS1 (crizotinib, lorlatinib) and MEK (selumetinib, trametinib) inhibited growth of cells expressing both ROS1 fusion and MEK1del. **Conclusion:** Our results suggest that the activation of the RAS-MAPK pathway plays a critical role in tumorigenesis mediated by *ROS1* fusions, and that activating mutations in this pathway can drive AR to ROS1 TKIs. Combined inhibition of ROS1 and MEK is a potential therapeutic strategy that should be explored clinically.

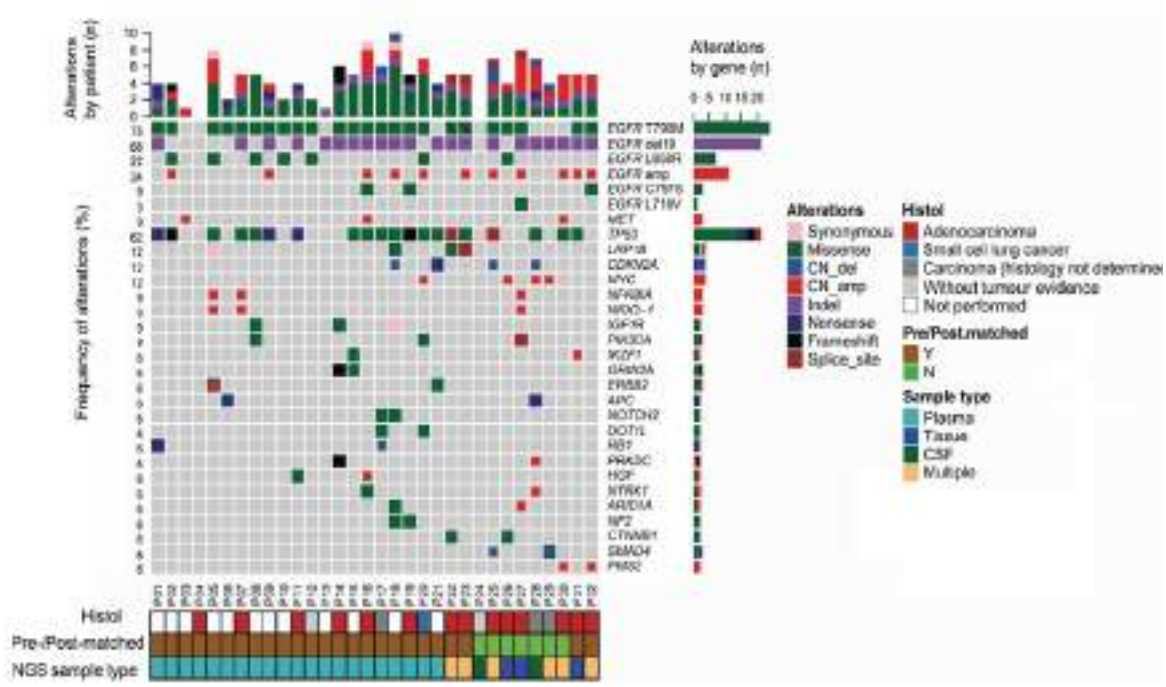
P1.14-13 EGFR AMPLIFICATION MEDIATES RESISTANCE TO THIRD-GENERATION EGFR TKIS AND IN VITRO VALIDATION OF COMBINATION STRATEGIES TO OVERCOME RESISTANCE

Y.-C. Zhang, Q. Zhou, Z. Chen, X.-C. Zhang, J. Su, H. Sun, S.-Y. Liu, Y.-L. Wu

Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: As a concurrent genomic alteration in *EGFR*-mutant NSCLC, whether all detected *EGFR* amplification serve as a driver of resistance to third-generation EGFR-TKIs remains controversial. Furthermore, which subtype of *EGFR* amplification-mediated resistance is actionable has been poorly elucidated. Our study aims to investigate the driver role of *EGFR* amplification in mediating resistance to third-generation EGFR TKIs and potential strategy to overcome resistance mediated by *EGFR* amplification. **Method:** 44 resistance samples from 32 patients who experienced disease progression from to a third-generation EGFR TKI abivertinib in Guangdong Lung Cancer Institute underwent NGS-based genomic profiling (data cutoff: october 30, 2018). FISH analysis of tissue samples from patients with *EGFR* amplification detected by NGS was performed. Different alleles of EGFR over-expressed PC9GR cell line models was established. Cell proliferation assay and western blot were performed to determine the sensitivity of these cell lines to third-generation EGFR TKI abivertinib and osimertinib, and to screen for potential strategies to overcome resistance mediated by *EGFR* amplification. **Result:** Upon abivertinib progression, 27 patients provided plasma samples (six patients also provided paired samples from the progression sites) and five patients only provided samples from the progression sites for NGS. A heterogeneous landscape of resistance to abivertinib was observed with *EGFR* amplification being the most frequent, observed in 11 (34%) patients (Figure 1), and considered a putative resistance mechanism in seven (22%) patients. FISH analysis of 3 patients who had available tissue samples further confirmed the presence of *EGFR* amplification detected by NGS. We established 3 different EGFR-overexpressed PC9GR cell lines by lentivirus transfection of Del 19 *EGFR*, Del19/T790M *EGFR* and wild-type *EGFR*. Among them, introduction of wild-type *EGFR* resulted in significantly loss of cellular sensitivity to abivertinib and osimertinib under EGF stimulation, but retains sensitivity to combination treatment of abivertinib and afatinib. In addition, abivertinib plus nimotuzumab also demonstrated preliminary inhibitory effect on phosphorylation of EGFR downstream pathway in wild-type EGFR overexpressed PC9GR. Finally, abivertinib plus nimotuzumab or afatinib in is effective and tolerable in treating 2 patients who developed *EGFR* amplification-mediated resistance to abivertinib. One of them experienced a long-term benefit from the combination treatments with an overall progression-free survival of 23 months.



Conclusion: Wild-type *EGFR* amplification mediates resistance to third-generation *EGFR* TKIs and could be overcome by combination treatments. Future studies need to more precisely determine the presence of wild-type *EGFR* amplification in third-generation EGFR TKIs resistant setting.

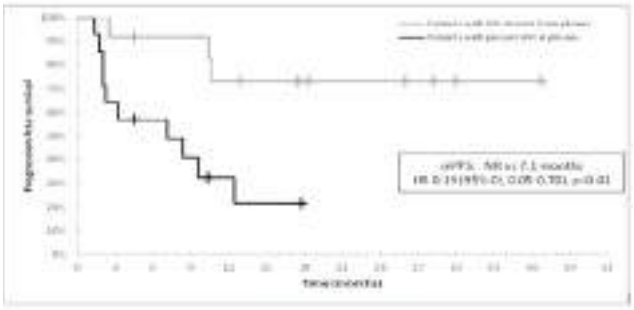
P1.14-14 MONITORING OF EGFR MUTATIONS DURING OSIMERTINIB TREATMENT IN ADVANCE EGFR-MUTANT T790M POSITIVE NSCLC

K. Mohorcic[1], A. Janzic[2], U. Janzic[1], M. Rot[1], I. Kern[1]

[1]*University Clinic Golnik, Golnik/Slovenia,* [2]*JAZMP, Ljubljana/Slovenia*

Background: Genotyping cell free circulating DNA (cfDNA) is a non-invasive method of detecting EGFR mutations (EGFRmu). The aim of our study was to investigate whether changes in the levels of plasma EGFRmu are associated with clinical outcomes of advanced T790M positive EGFRmu patients treated with osimertinib. **Method:** Single centre prospective observational study was performed with plasma being collected from patients with advanced EGFRmu T790M positive NSCLC routinely treated with second line osimertinib. Dynamical monitoring of cfDNA was performed at every scheduled visit (8 weeks) until disease progression. Cobas EGFR Mutation Test v1 and v2 (Roche, USA) was used to detect 42 mutations at EGFR gene in exons 18 to 21, including T790M mutation. Radiological assessment was performed in accordance with RECIST 1.1 criteria. **Result:** Twenty-seven patients were treated with osimertinib from October 2015 until December 2018. At the beginning of osimertinib treatment only 17/27 (63%) patients had detectable T790M mutation in plasma, but almost all patients 26/27 (96%) had detectable plasma EGFR activating mutations (AM). During osimertinib treatment T790M mutation was cleared from plasma in all 17 patients regardless of response to treatment. On the contrary, only 12/26 (45%) patients had AM plasma clearance. Only 3 of them had had progress at median follow up of 17.5 months, what demonstrates significantly longer progression-free survival (PFS) of patients with AM plasma clearance compared to patients without AM clearance (HR 0.19; 95% CI 0.05 – 0.70, p = 0.01) (*Figure 1*). Of the 14 patients that progressed during the observation period all had AM reapperance in cfDNA at the time on progression, while T790M only recurred in one.



Conclusion: Clearance of EGFR AM in plasma during osimertinib treatment is associated with longer PFS, while clearance of T790M has no impact on survival in our small group of patients. Dynamic changes in EGFR AM might be a useful marker of outcome in patients treated with osimertinib, but further studies are needed.

Background: Lorlatinib, a third generation ALK and ROS1 inhibitor, is indicated for the treatment of patients with *ALK+* metastatic NSCLC whose disease has progressed on crizotinib and at least one second-generation ALK inhibitor. The aim of this study is to evaluate the efficacy and safety of lorlatinib in an Expanded Access Program (EAP) in Turkey. **Method:** The EAP was open-label, multicenter, and single-arm. Patients were eligible to receive lorlatinib (100 mg p.o/day) if they had advanced stage *ALK*- or *ROS1*-positive NSCLC and had progressed on crizotinib and/or second generation ALK inhibitors such as ceritinib or alectinib. The primary endpoint was PFS with lorlatinib. Secondary endpoints were objective response rate, overall survival, and safety. **Result:** Between February 2017 and December 2018, a total of 91 patients were admitted to the EAP at 27 oncology centers in Turkey. Eleven patients died before receiving the drug. Four patients were excluded from the EAP because of lost of the follow-up. Of the 76 patients who received drug, 13 were excluded from the analysis due to inability to access patient information. Six of these 13 patients were on lorlatinib treatment at the time of data collection. The median age of patients was 53.5 (17-84) years. Of 63 evaluable patients, 55 (87.3%) had *ALK+* NSCLC and 8 (12.7%) had *ROS1+* NSCLC. All patients had adenocarcinoma histology, and 54% (n=34) had brain metastasis before lorlatinib treatment. Twenty-one patients received lorlatinib as third-line treatment (mostly after chemotherapy and crizotinib). Median follow-up was 9.1 months. Five patients died before the first evaluation of response. In patients who received at least 1 dose of lorlatinib, median PFS was 12.6 months, and 1-year PFS rate was 53%. In *ALK+* patients, median PFS was 14.7 months and 1-year PFS rate was 55%. In *ROS1+* patients, median PFS was 9.1 months and 1-year PFS rate was 47%. In patients who received only crizotinib prior to lorlatinib, median PFS was 14.8 months and 1-year PFS rate was 59%. In patients who received ≥2 ALK inhibitors prior to lorlatinib, median PFS was 5.1 months and 1-year PFS rate was 27%. One-year OS rate was 65%. In response-evaluable patients (n=55), the ORR and DCR were 68.6% and 87.0% all patients. However, ORR and DCR were 69.6% and 87.0% for *ALK+* and 62.5% and 87.5% for *ROS1+* patients. Of response-evaluable 55 patients, the frequency of brain metastasis before lorlatinib was 54.5% (n=30). In only 7 patients (12.7%), brain metastasis developed under lorlatinib treatment. CNS control rate with lorlatinib was 87.3%. Dose reduction occurred in 9 patients (14.3%). Reasons for discontinuation of treatment were disease progression (n=17, 26.8%), adverse events (n=2, 3.2%), death (n=13, 20.6%), and unknown reasons (n=13, 20.6%). **Conclusion:** In this EAP, lorlatinib showed systemic activity in patients with advanced *ALK+* or *ROS1+* NSCLC, regardless of CNS metastases and previous TKI treatment.

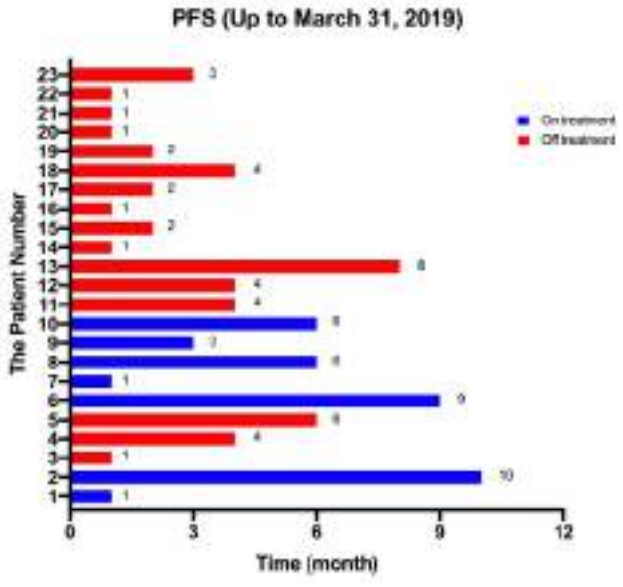
P1.14-16 RESOLVING RESISTANCE TO OSIMERTINIB BY COMBINING APATINIB AND OSIMERTINIB IN EGFR-MUTANT NSCLC PATIENTS

X. Yang[1], J. Zhao[1], L. Liang[2], L. Xu[3]

[1]*Beijing Cancer Hospital, Beijing/China,* [2]*Peking University Third Hospital, Beijing/China,* [3]*Beijing Chest Hospital, Beijing/China*

Background: There are currently limited treatment options after osimertinib resistance.Resistance to epidermal growth factor receptor(EGFR) inhibitors is frequently associated with enhanced vascular endothelial growth factor(VEGF) levels.Dual inhibition of the VEGF receptor(VEGFR) and EGFR signaling pathways has the potential to overcome osimertinib resistance. Apatinib is an oral tyrosine kinase inhibitor(TKI) against VEGFR-2. This study was conducted to evaluate the efficacy of Apatinib plus osimertinib after osimertinib resistance in EGFR-mutant NSCLC patients. **Method:** The study was expected to enroll 30 EGFR-mutant NSCLC patients resistant to osimertinib. Patients received oral apatinib 250mg QD plus osimertinib 80mg qd. Efficacy evaluation was conducted after first month, then every two months once again. The primary endpoint was progression free survival (PFS). **Result:** From March 01, 2018 to February 28, 2019, 23 patients were enrolled. The overall response rate(ORR) and disease control rate(DCR)of apatinib plus osimertinib after osimertinib resistance was 8.7%(2/23) and 73.9%(17/23),respectively.Until the last follow-up(March 31,2019), 17 patients (73.9%,17/23)showed disease progression,the other 6 patients (26.1%,6/23) still received combination therapy,as shown in figure 1.The median PFS was 4.0 months (95% CI 2.4-5.5).Six patients had received at least six-month combination therapy,four of whom were still on treatment.The most common adverse event was hypertension, diarrhea,rash and hand-foot syndrome.What calls for special attention is that one patient achieved partial response, however, stopped the combination therapy due to seriously decreased left ventricular ejection fraction.



Conclusion: Apatinib plus osimertinib might be a choice after osimertinib resistance.For further investigation, large sample and additional clinical trials are warranted.

Keywords: combination therapy, osimertinib resistance, apatinib

Background: *EGFR*-mutant non-small-cell lung cancer (NSCLC) patients inevitably develop drug resistance when treated with EGFR tyrosine kinase inhibitors (TKIs). Clonal and clinical analyses of genetic alterations at baseline and progressive disease (PD), as well as differences between acquired T790M and T790M-negative patients in drug-resistant mechanisms, have not been systematically studied. **Method:** We performed targeted sequencing of pre-treatment and PD tumor samples from 54 *EGFR*-mutant NSCLC patients. Ten additional patients were sequenced using whole exome sequencing to infer the clonal evolution patterns. **Result:** We observed new co-occurring alterations and pathways limiting *EGFR*-inhibitor response, including 9p34.3/19p13.3 (*NOTCH1/STK11)* co-deletion and TGF-beta pathway alterations. Besides acquired T790M mutation, chromosomal instability (CIN) related genes including *AURKA* and *TP53* alterations were the most frequently acquired events. CIN significantly increased with TKI treatment in T790M-negative patients. Transcriptional regulators including *HNF1A*, *ATRX* and *NKX2-1* acquired alterations were enriched in T790M-positive patients, and diverse oncogenic pathway alterations were more common in T790M-negative patients. T790M-positive patients had improved PFS compared to T790M-negative patients. We further identified subgroups within T790M-positive or T790M-negative patients with distinct PFS. Clonal evolution analysis indicated progression of T790M-positive patients depends on competition between T790M and non-T790M resistant subclones. **Conclusion:** Our study is the first attempt to identify co-occurring copy number events to stratify patients resistant to TKI treatment. Besides acquired T790M mutation, chromosomal instability (CIN) related genes were identified as the most frequently acquired events. Clonal evolution analysis indicated indicate that higher competitive advantage of T790M was associated with improved PFS.

P1.14-18 ALK INHIBITOR SEQUENCING AND OUTCOMES AMONG ALK-POSITIVE (ALK+) NSCLC PATIENTS IN THE US COMMUNITY ONCOLOGY SETTING

D. Waterhouse[1], J. Espirito[2], M. Chioda[3], B. Baidoo[2], J. Mardekian[3], N. Robert[2], E. Masters[3]

[1]*1Oncology Hematology Care, Cincinnati/United States of America,* [2]*McKesson Life Sciences, The Woodlands/United States of America,* [3]*Pfizer, New York/United States of America*

Background: Several ALK inhibitors, including 2nd and 3rd generation agents are available for patients with ALK+ NSCLC. Treatment patterns and outcomes with use of multiple sequential ALK inhibitors is limited. **Method:** A retrospective observational cohort study of patients with ALK+ NSCLC treated with 1st generation (crizotinib) and 2nd generation (alectinib, brigatinib, ceritinib) ALK inhibitors from 1 September 2011 to 31 December 2017. Structured data were obtained via programmatic extraction from the iKnowMed EHR database of the US Oncology Network. Patient demographics and treatment sequences were characterized. Index was the start date of the first ALK. Duration of therapy (DOT) from index to end of the last ALK, and overall survival (OS) were assessed using the Kaplan-Meier method. **Result:** A total of 410 ALK+ NSCLC patients were included. Median age at index was 62 years, 54% were female, 78% Caucasian, 87% adenocarcinoma histology, and 54% never smokers. 233 (57%), 144 (35%), and 33 (8%) patients received 1, 2, or 3-4 different ALK inhibitors, respectively. Crizotinib monotherapy (50%) was most common. Among patients that received 2 or more ALK inhibitors (n=177), most were crizotinib-led sequences. In 59% of patients, chemotherapy was given prior to the first ALK (median time from start of chemo to index 6.64 mo), and 53% of patients ended their ALK sequence and received subsequent chemo. Median cumulative ALK DOT in the full study population, regardless of line of therapy or sequence was 16 mo (95% CI 6-19). Median OS from index for the full study population was 28 mo (95% CI 24, 36). Median OS among patients who received 1, 2, or 3-4 ALK inhibitors was 15 mo (95% CI 10, 22), 42 mo (95% CI 38, 60) and 56 mo (95% CI 31, 72). **Conclusion:** Patients received a range of 1 to 4 ALK inhibitors. Crizotinib-led sequences were most common, likely reflecting the approval history of ALK inhibitors during the study period. Longer DOT and OS were observed in patients receiving multiple ALK inhibitors. This study provides an initial view of treatment patterns following the emergence of new ALK inhibitors and suggests feasibility of sequential ALK therapies. Follow-up studies will help improve understanding of outcomes of patients treated with 2nd generation-led sequences.

Background: Non-small cell lung cancer is a dramatic disease. For several years, molecular analyses highlighted several genetic alterations (mutations, gene fusions) enabling use of targeted therapies. Among targetable mutations, the most frequent (11% of lung adenocarcinomas) are *EGFR* mutations spanning from exon 18 to exon 21, except insertion in exon 20 and T790M mutation. In clinical practice, progression free survival under EGFR Tyrosine Kinase Inhibitor is between 12 and 14 months, but some patients rapidly progress in less than 6 months, whereas other patients are treated with EGFR TKI during more than 16 months, and even more in some cases. **Method:** ALCAPONE clinical trial (NCT02281214) included 165 patients with a non-small cell lung cancer divided in 2 different groups: EGFR mutated (n=63) and EGFR wild-type tumors (n=102). All tumors at baseline had an exome analysis performed with SureSelect Human all exon v5 or v6 kit. After adapter trimming and quality check, GATK tools were applied to process the data. After variant calling (Haplotype Caller) and annotation, genetic variations were separated in 3 categories: intron variants, synonymous variants and transcripted variants. Only variants with a general population frequency <1% were conserved for statistical analyses. For the first analysis of the trial, we focused on a training set of 33 EGFR mutated patients homogenously treated by afatinib. We selected 18 extreme responders (10 short responders with PFS<180 days and 8 long responders with PFS>500 days) to select genetic markers predictive of extreme responses and used them to evaluate survival including 15 patients with PFS between 180 and 500 days. **Result:** Thanks to 2 different predictive models, it appeared that 5 genes were able to discriminate short responders from long responders: *AKR1B1, WNK1, IHH*, PLA2G16*, and SMYD3**, whose those with an asterisk selected by the 2 different predictive models. For these genes, the presence of a non-synonymous variant in transcripted (UTR and coding) sequences of the genes was associated with a worse response to afatinib. By studying PFS probability with the 33 EGFR mutated patients of the training set, it appeared that 2 genes discriminated responders from non-responders. Indeed, patients with a variation in *IHH* or in *WNK1* gene had a significant worse PFS than patients with no variation (p=0.0003, median PFS=9 vs 16 months for *IHH* and p=0.0052, median PFS=9 vs 17 months for *WNK1*). Interestingly, in the literature, IHH (Indian HedgeHog) decreased expression are correlated with increased sensitivity to treatment, and WNK1 (With No lysine Kinase 1) activation are linked to cellular migration and epithelial mesenchymal transition in non-small cell lung cancer. **Conclusion:** This first analysis from the ALCAPONE clinical trial identified 2 genes that could discriminate responders from non-responders. As the analysis was performed from 33 EGFR mutated patients, it will be confirmed thanks to a validation set of 30 new EGFR mutated patients treated with afatinib. If these results are confirmed, the analysis of genetic variations on both genes could be

new biomarkers bringing new information to clinicians for the choice of EGFR TKI treatment sequence. ALCAPONE study was supported by Boehringer Ingelheim

P1.14-20 TARLOXOTINIB AS A NOVEL THERAPEUTIC STRATEGY FOR ONCOGENIC ALTERATIONS ACROSS THE ERBB FAMILY OF RECEPTORS

A. Estrada-Bernal[1], Z. Du[2], A. Le[3], A. Patterson[4], J. Smaill[4], V. Tirunagaru[5], A. Vellanki[5], R. Doebele[6], C. Lovly[2]

[1]*University of Colorado, Aurora/United States of America,* [2]*Vanderbilt University Medical Center, Nashville/United States of America,* [3]*University of Colorado-AMC, Aurora/United States of America,* [4]*University of Auckland, Auckland/New Zealand,* [5]*Rain Therapeutics, Newark/United States of America,* [6]*University of Colorado Denver, Aurora/United States of America*

Background: The ErbB family of receptors tyrosine kinases (EGFR, HER2, HER3, and HER4) have been implicated in multiple different tumor types. The implementation of comprehensive next generation sequencing has allowed the identification of diverse gene alterations that function as oncogene drivers in these receptors. Some of the non-common gene alterations identified are resistant to marketed EGFR/HER2 inhibitors. Tarloxotinib is a prodrug that generates a potent and irreversible pan-HER inhibitor (tarloxotinib-E) under hypoxic conditions associated with tumors. In this study we evaluated the effect of tarloxotinib on several types of oncogenic mutations and fusions that involve the ErbB family of receptors. **Method:** cDNAs encoding *EGFR* kinase domain duplications (*EGFR-EGFR*), *EGFR-RAD51* gene fusion, *EGFR-ERBB4*, *ERBB2-GRB7* and *EZR-ERBB4* gene fusion were expressed in Ba/F3 cells. Using spheroid assays we evaluated the proliferation of A172 glioblastoma cell line treated with tarloxotinib, tarloxotinib-E or 1st, 2ndor 3rdgeneration EGFR/HER2 TKIs. We analyze the on target and signaling effects elicited by tarloxotinib-E via immunoblots. Using a nude mice xenograft model of the human derived cell line CUTO17 wi the EGFR exon 20 insertion p.N771_H773dupNPH, we evaluated tumor, tissue and blood drug levels by mass spectrometry and the effect of tarloxotinib on tumor growth. **Result:** Our results demonstrate that tarloxotinib-E inhibits phosphorylation of EGFR with a kinase duplication and inhibits proliferation in a spheroid invasion assay in A172 cells. In the CUTO17 EGFR exon 20 model, treatment with tarloxotinib inhibited tumor growth. Intratumor levels of tarloxotinib-E were ~20 times higher than skin and ~50 times higher than plasma demonstrating selective tumor conversion of tarloxotinib. Cell growth inhibition (EC_{50}) of novel HER family fusions (EGFR-EGFR, EGFR-RAD51, EGFR-ERBB4, ERRB2-GRB7 and EZR-ERBB4) will be presented. **Conclusion:** Tarloxotinib is a potent irreversible inhibitor *in vitro* for cells that harbor oncogenic alterations across the *ERBB* gene family, including EGFR kinase domain duplications, ErbB fusions and exon-20 insertions. Tarloxotinib is selectively activated in hypoxic tumor regions demonstrating a novel mechanism to generate a therapeutic window and avoid on-target EGFR-related toxicities.

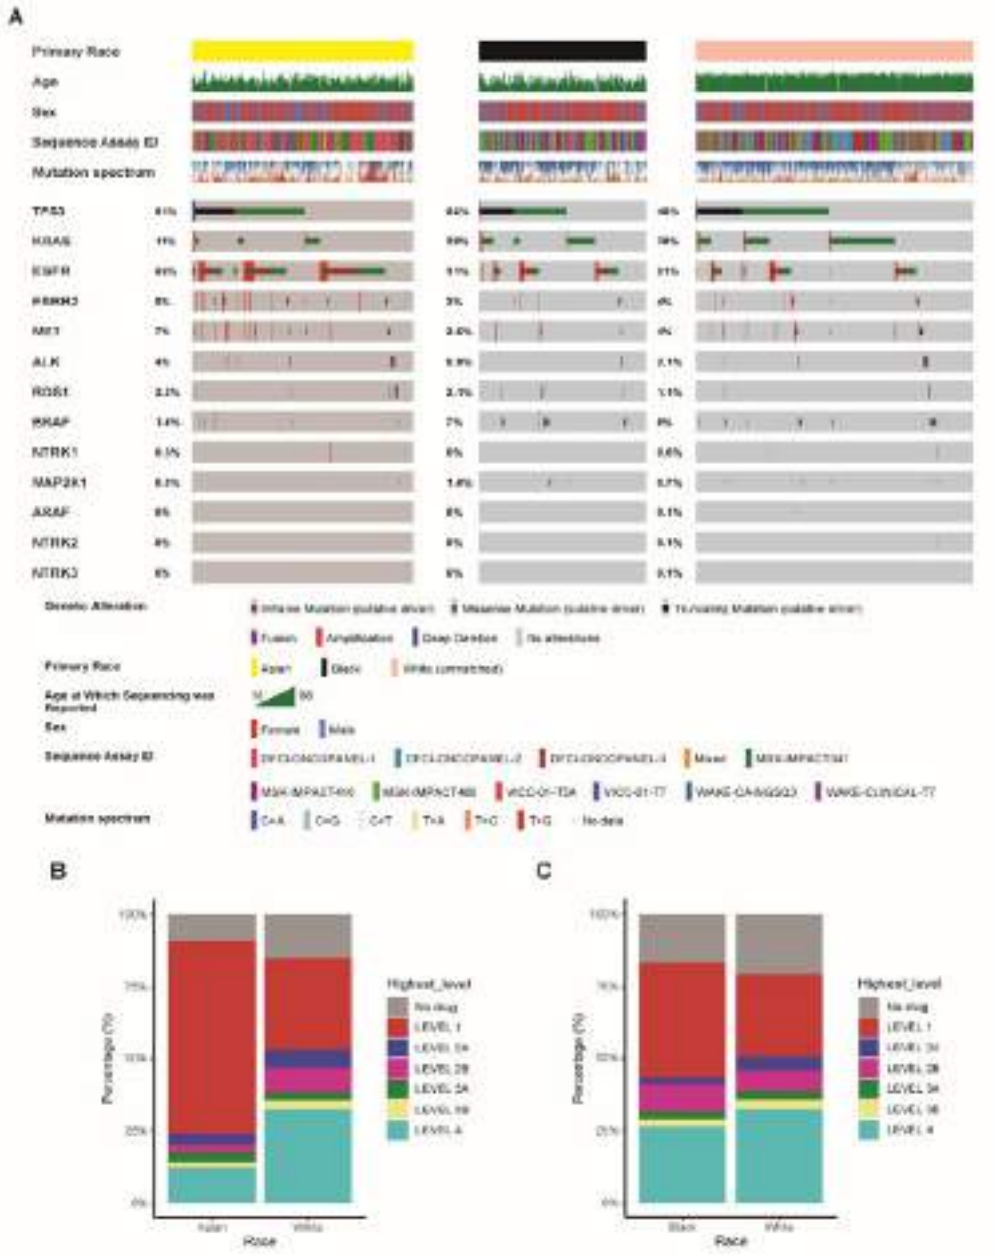
P1.14-21 PROPENSITY-MATCHED GENOMIC PROFILING COMPARISON OF LUNG ADENOCARCINOMAS AMONG 3 RACES, A MULTICENTER STUDY OF 4655 PATIENTS

K. Lan, J. Zhou, F. Yang, J. Wang

Peking University People's Hospital, Beijing/China

Background: The mutation rates of multiple genes are reported to differ among lung adenocarcinoma samples from different races. However, the baseline heterogeneity among different race cohorts may confound the interpretations of the results. This study is the first propensity-matched study designed to determine the genomic and therapeutic actionable disparities among the samples of Asian vs White and Black vs White races. **Method:** Sequencing data from 4 centers with primary races documented as "Asian", "Black", or "White" was accessed from GENIE database. Propensity score analysis (nearest neighbor matching method) was applied to Asian vs White and Black vs White cohorts using age, sex, sample type (primary/metastasis) and enrolling center. Mutation rates, pathway alterations, and therapeutic actionability were compared among the cohorts. Therapeutic actionability was annotated using OncoKB annotator. Fisher's exact test and FDR adjust method were used for comparison. **Result:**



A total of 4655 patients were included before matching (Figure A). 2 pairs of cohorts, 350 Asian vs 1400 White patients and 208 Black vs 832 White patients were identified for study after propensity matching. 11 genes, including *EGFR, KRAS, STK11, KEAP, BRAF, SMARCA4, PIK3CA* et.al. were significantly differentially mutated among Asian and White patients (adjusted P value<0.05), while only *EGFR* mutation rate was significantly different between Black and White cohorts (adjusted P value=0.04). In the analysis of 10 oncogenic pathways, RTK/RAS, cell cycle, hippo, notch, nrf2, wnt pathway alteration rates are different among Asian and White samples (adjusted P value<0.05). The comparison between matched Black and White samples observed no significant difference in pathway alterations. In the therapeutic actionability analysis, 4663 mutations, 974 copy number alterations, 196 fusions were annotated with at least one actionable drug in the whole cohort. 67% of samples from Asian patients embraced at least one genomic alteration corresponding to level 1 drugs, compared to 30% in matched White samples (P<0.001) (Figure B). In the Black vs White group, the rate of coresponding level 1 drugs per sample is 39% vs 29% (P=0.003) (Figure C). **Conclusion:** In this propensity-matched study, samples from Asian LUAD patients displayed significantly different genomic mutation rate, pathway alteration rate, and therapeutic actionability characteristics compared to White patients. Samples from Black patients have a higher rate of EGFR mutations and level 1 therapeutic actionability than white patients. But the difference is more prominent in the Asian vs White group compared to Black vs White group.

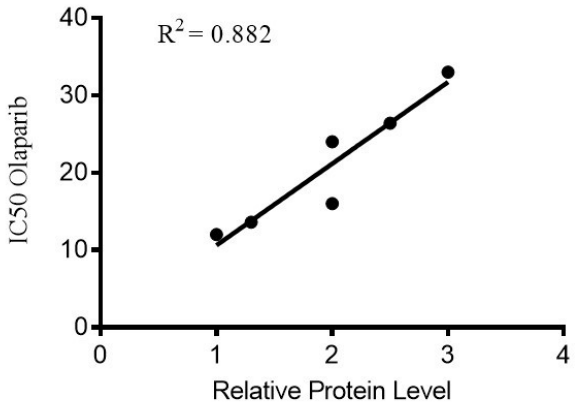
P1.14-22 SASH1, A NOVEL PROGNOSTIC AND PREDICTIVE FACTOR FOR PARP INHIBITORS IN LUNG CANCER

J. Burgess, E. Bolderson, D. Richard, K. O'Byrne

Institute of Health and Biomedical Innovation, Queensland University of Technology Translational Research Institute, WOOLLOONGABBA/Australia

Background: Genomic instability is a universal hallmark of all cancers. Many of the most commonly used chemotherapeutic agents target this genomic instability by directly damaging the DNA, which results in tumour cell death. Our previous work has revealed that loss of SASH1 is associated with impaired apoptosis and increased cellular proliferation. A new generation of drugs have been developed that target the DNA repair enzyme PARP to induce DNA damage and cell death. SASH1 (SAM and SH3 domain containing protein 1) has been described as a tumour suppressor and in support of this SASH1 mRNA levels are decreased in lung, breast, thyroid and colorectal cancers. Our data demonstrates that SASH1 functions in the repair of DNA damage and loss of SASH1 protein expression could be used as a companion diagnostic for PARP inhibitors. **Method:** SASH1 IHC staining of lung cancer was correlated with patient survival. DNA damage repair was assessed following the depleted of SASH1 (siRNA). SASH1 protein levels in cell lines were correlated to PARP inhibitor sensitivity. **Result:** A lung cancer tissue microarray (TMA) of 225 patients was assessed for SASH1 protein level. Low SASH1 levels were associated with an improved patient prognosis in adenocarcinoma on univariate analysis (p = 0.03). Analysis of DNA repair pathways demonstrated that SASH1 plays a role in homologous recombination (HR). Based on this observation, the impact of SASH1 expression on sensitivity to PARP inhibitors was explored. An inverse correlation between SASH1 levels and sensitivity to Olaparib was identified in lung cancer cell lines Figure 1 (R^2 = 0.882). We subsequently analysed Olaparib sensitivity in a panel of SASH1 depleted lung cancer cells that demonstrated increased Olaparib sensitivity.

Figure 1



Conclusion: Our results indicate that SASH1 protein expression is a prognostic factor in lung cancer, high levels being associated with a worse prognosis in adenocarcinoma. Low SASH1 expression is associated with loss of HR and has the potential to be a predictive biomarker for sensitivity to PARP inhibitors in this disease.

Keywords: Biomarker, PARP Inhibitor, NSCLC

P1.14-23 RESISTANCE MECHANISMS TO OSIMERTINIB TREATMENT IN EGFR-MUTATED LUNG CANCER IN A REAL LIFE COHORT

C. Steendam[1,2], P. Atmodimedjo[2], M. Paats[2], C. Van Der Leest[1], J. Von Der Thüsen[2], W. Dinjens[2], R. Van Schaik[2], H. Dubbink[2], J. Aerts[2]

[1]*Amphia Hospital, Breda/Netherlands,* [2]*Erasmus University Medical Center, Rotterdam/Netherlands*

Background: Targeted therapies in Epidermal Growth Factor Receptor (EGFR)-mutated advanced lung cancer are developing rapidly, with registration for third generation EGFR-tyrosine kinase inhibitor (TKI) osimertinib for first line treatment recently. The resistance mechanisms that develop during first line treatment with osimertinib seem to differ from resistance developing during treatment for p.T790M mutation after first- or second generation EGFR-TKI based on current limited knowledge. We investigated the resistance mechanisms at progression on osimertinib treatment in a real life cohort. **Method:** In the START-TKI study, patients with EGFR-mutated lung cancer were pospectively sampled for plasma analysis during TKI treatment. We analysed the included osimertinib cohort until March 1, 2019, which included both first line and second line (based on p.T790M positivity) treated patients. Exclusion criteria were lack of subsequent samples until progression, double gene/TKI treatment or switch to other treatment because of toxicity. Next-generation sequencing (NGS) analysis was performed at progression on plasma and tissue specimens (when available). **Result:** A total of 42 patients was included, which consisted of N=27 in the p.T790M positive (second line treatment) and N=15 in the p.T790M negative (first line treatment) subgroup. We excluded 4 patients in the first, and 5 patients in the second line treatment group. Evaluable progression was reached by N=11 and N=3 patients respectively. In the second line (p.T790M positive) subgroup, resistance mechanisms were identified in 7 patients, and comprised MET amplification (N=2), small-cell transformation (N=2), EGFR p.C797S mutation (N=2) and BRAF mutation (N=1). In the p.T790M negative (first line) subgroup, resistance mechanisms were not identified. **Conclusion:** Tissue specimen can provide important additional information on resistance mechanisms to EGFR-TKI treatment next to plasma analysis due to morphological information and in situ analyses (immunohistochemistry and in situ hybridization). Resistance mechanisms to osimertinib in EGFR-mutated lung cancer are still under investigation, and may differ in a p.T790M positive and p.T790M negative setting. This study was partly funded by a grant from AstraZeneca.

P1.14-24 CHARACTERIZATION OF ACQUIRED RECEPTOR TYROSINE KINASE FUSIONS AS MECHANISMS OF RESISTANCE TO EGFR TYROSINE KINASE INHIBITORS

H. Xu[1,2], Y. Shu[1], H. Jian[3], J. Shen[3], J. Xiang[4], H. Li[4], B. Li[4], T. Zhang[4], L. Zhang[4], X. Mao[4]

[1]*First Affiliated Hospital of Nanjing Medical University, Nanjing/China,* [2]*Kunshan First People's Hospital Affiliated to Jiangsu University, Kunshan/China,* [3]*Shanghai Chest Hospital, Shanghai Jiaotong University, Shanghai/China,* [4]*Burning Rock Biotech, Guangzhou/China*

Background: Responses to *EGFR* targeted therapy are generally temporary due to evitable drug resistance. The prevalence and characteristics of receptor tyrosine kinase (RTK) fusions as acquired resistance to EGFR-TKIs are rarely investigated. **Method:** We retrospectively reviewed genomic profiling data of 3873 *EGFR* (exon 18-21)-mutant lung cancer patients with more than once NGS detection. A total of 16 patients who acquired RTK fusions during EGFR-TKI treatment with paired pre- and post- EGFR-TKI samples were identified. Their treatment history was collected. **Result:** The newly acquired RTK fusions during EGFR-TKI treatment included *RET* (n = 6, 37.5%), *ALK* (n = 5, 31.3%), *NTRK1* (n = 4, 25.0%), *ROS1* (n = 1, 6.3%) and *FGFR3* (n = 1, 6.3%). All the *RET* and *EML4-ALK* fusions were uncommon variants non-*KIF5B-RET* and E2:A20 (V5), respectively. Interestingly, *RET* fusion occurred only after osimertinib treatment, and contributed to drug resistance in 50.0% (6/12) of patients treated with osimertinib, indicating that fusions had different prevalence when functioned as resistance mechanisms to EGFR-TKI. Moreover, we found that in all patients developing drug resistance to EGFR-TKIs due to fusion emergence (n=16), those had treatment history of third-generation EGFR-TKI accounted for 75.0% (n=12). **Conclusion:** We extended the current knowledge of resistance mechanisms to EGFR-TKIs in non-small cell lung cancer. Detection of RTK fusions should be included in genomic profiling panels to uncover potential resistance mechanism of EGFR-TKI which might inform therapeutic strategies such as combination therapy approaches to circumvent tumorigenesis.

Keywords: EGFR-TKI, acquired drug resistance, fusion

P1.14-25 TARGETING NRG1-FUSIONS IN LUNG ADENOCARCINOMA: AFATINIB AS A NOVEL POTENTIAL TREATMENT STRATEGY

M. Duruisseaux[1], J.J. Laskin[2], K. Tolba[3], E. Branden[4], Y. Goto[5], R. Doebele[6], P.K. Cheema[7], J. Cadranel[8], M.R. Jones[9], A. Drilon[10], D. Trombetta[11], L.A. Muscarella[11], A. Cseh[12], F. Solca[12], S. Liu[13]

KG, Vienna/Austria,* [13]*Georgetown University, Washington/United States of America*

Background: Neuregulin 1 (*NRG1*) gene fusions result in activation of ErbB2-/ErbB3-mediated signaling pathways, and may function as oncogenic drivers. *NRG1* fusions have emerged as a potential therapeutic target across multiple tumor types, including non-small-cell lung cancer (NSCLC). Afatinib, a pan-ErbB-family blocker, may be a treatment option for patients with *NRG1+* NSCLC, as supported by preclinical evidence and seven published case reports (Table). **Method:** Here, we report clinico-pathological and molecular characteristics of four new cases of *NRG1* fusion-positive lung adenocarcinoma treated with afatinib. Afatinib activity is reported. **Result:** Case 1 is a 70-year-old, female, never-smoker, diagnosed with pan-wildtype, non-mucinous, adenocarcinoma. She received afatinib in the fifteenth-line setting and experienced a partial response (PR) for 24 months. Following further progression on chemotherapy, *NRG1*-fusion was identified using NanoString analysis (re-biopsy was performed to find an explanation for afatinib efficacy). The patient was re-challenged with afatinib (best response: PR [3 months]), before switching to atezolizumab (best response: progressive disease). Case 2 is a 66-year-old female, never-smoker, diagnosed with metastatic, non-mucinous adenocarcinoma. A *CD74-NRG1* fusion was identified by Oncomine™ Comprehensive Assay, and fifth-line afatinib treatment was initiated. She experienced a PR, ongoing after 14 months of treatment. Case 3 is a 68-year-old male diagnosed with lung adenocarcinoma. A *SDC4-NRG1* fusion was subsequently identified using Next Generation Sequencing and the patient initiated second-line afatinib treatment. He achieved stable disease as best response, lasting for four months. Case 4 is a 43-year-old, female, non-smoker, diagnosed with advanced invasive mucinous adenocarcinoma. A *CD74-NRG1* fusion was subsequently identified by RNA sequencing and the patient initiated third-line afatinib treatment; PR is ongoing. **Conclusion:** These findings add to a growing body of evidence suggesting afatinib activity in *NRG1*-fusion positive NSCLC. Prospective study of a larger cohort of patients with *NRG1*-fusion positive NSCLC treated with afatinib is warranted to better evaluate this potential activity.

Background: Clinical outcomes of ALK positive (ALK+) Non-Small-Cell Lung Cancer (NSCLC) and the identification of the most effective anaplastic lymphoma kinase inhibitor (ALKi) according to the specific ALK fusion variants are not well assessed. We retrospectively characterized fusion variant distribution in a cohort of ALK+ lung adenocarcinomas (ADC) with paired clinical data about treatments and outcomes. **Method:** Diagnostic tumor tissue from advanced ALK+ (by FISH and/or IHC) ADC diagnosed from 2010 to 2018 and treated with single or multiple ALKis were collected (expanded cohort from Gobbini et al. Lung Cancer, 2017). The Oncomine™ Solid Tumor Fusion Transcript Kit on an Ion PGM™ system and the Ion Reporter™ software were used to identify

targeted ALK fusion gene products (ThermoFisher). **Result:** Specific fusion variant transcripts were found in 34/55 (62%) of collected samples. As expected, EML4-ALK fusion transcripts were the most common (31/34 samples, 91%), but HIP-ALK transcripts were also detected (3/34 - 9%). Among EML4-ALK fusions the following variants were detected: V1 (n=11); V2 (n=2); V3a/b (n=12) V5a/b (n=5) and E6A19 (n=1). Patient median age was 60 year [range 36-85], 22 were male and 12 female. Three patients were current, 11 former and 20 never smokers. Crizotinib, alectinib, ceritinib, brigatinib and lorlatinib were the ALKis used. Independently of the therapy line, 12 patients received crizotinib only, while 22 patients received crizotinib followed by one or two other ALKis. Regardless of the type of transcript, those patients who received more than one ALKi had a better median overall survival compared to those receiving crizotinib only, as expected (74 vs 21 months, HR: 5.31; 95%CI: 1.464-19.26, log rank p=0.0006). Furthermore, a significant difference in the mean duration of the different ALKi treatment was found according to the ALK variants (Chi-square p<0.0001), suggesting a private ALKi efficacy profile for specific fusion variants. Finally, the 3 HIP-ALK cases showed a better outcome with respect the EML4-ALK variants (not reached vs 51 months). **Conclusion:** Our analysis suggests that different ALK fusion variant might affect ALKi treatment duration in ALK+ lung ADC.

Keywords: ALK, ALK inhibitor, Fusion variant

P1.14-27 DURATION OF TARGETED THERAPY IN ADVANCED NSCLC (ANSCLC) WITH DRIVERS IDENTIFIED BY CIRCULATING TUMOR DNA (CTDNA) ANALYSIS

C. Baik[1], T. Patil[2], K. Kirtane[1], R. Santana-Davila[1], T. Rich[3], C. Espenschied[3], C. Weipert[3], S. Mach[4], K. Reckamp[4], R. Doebele[5]

[1]*University of Washington, Seattle Cancer Care Alliance, Seattle/United States of America,* [2]*University of Colorado, Aurora/United States of America,* [3]*Guardant Health, Redwood City/United States of America,* [4]*City of Hope, Duarte/United States of America,* [5]*University of Colorado Denver, Aurora/United States of America*

Background: Identifying targetable genomic drivers is critical for optimal first-line treatment planning in aNSCLC. ctDNA testing can aid treatment selection when tissue specimens are inadequate for complete genotyping or when a rapid turnaround time is advantageous. Targeted therapy (TT) outcomes for ctDNA-detected drivers have not been widely reported in the first-line setting given the relatively recent adoption of this technology into clinical practice. **Method:** We conducted a multicenter retrospective review of patients with aNSCLC who received matched TT following identification of a driver on a validated commercial ctDNA assay (Guardant360). Eligible patients were tested per regular clinical care between March 2014-October 2018 and must not have received a TT prior to ctDNA testing (prior chemotherapy or immunotherapy was permitted). Kaplan-Meier analysis was used to estimate median duration of TT (DTT) for both the first and all subsequent sequential targeted therapies where applicable (e.g. osimertinib following erlotinib). Patients still on TT were censored at last follow-up. **Result:** 76 patients met inclusion criteria. Median age of diagnosis of aNSCLC was 64.5 years (range 31-87y), 67% were female, 74% were never smokers, and 97% had adenocarcinoma histology. 21/76 (28%) patients received chemotherapy (n=17), immunotherapy (5), and/or a biologic (4) prior to receiving TT. 41/76 (54%) patients remain on TT at the time of data analysis, 32 of whom are still on their first TT. 38/41 patients still on TT have at least 6 months follow-up. Treatment outcomes are summarized in Table 1.

Table 1. Duration of Targeted Therapy

Driver	Therapy	n, total patients/ discontinued therapy	Median (95% CI) DTT in weeks[1]
EGFR	Erlotinib Osimertinib Afatinib Gefitinib Any EGFR TKI[2]	21 / 19 23 / 6 3 / 2 1 / 1 48 / 20	33 (23-54) NR 3, 13, 93* 63 86 (48-197)
ALK fusion	Alectinib Crizotinib Any ALK TKI[3]	7 / 2 2 / 2 9 / 2	NR 20, 44 NR
BRAF V600E	Dabrafenib + Trametinib	10 / 7	51 (13-88)
MET exon 14 skipping	Crizotinib Investigational	3 / 2 1 / 1	4, 77, 63* 14
ROS1 fusion	Investigational	2 / 1	50, 79*
ERBB2 exon 20 insertion	Ado-trastuzumab emtansine	2 / 1	46, 14*
RET fusion	Investigational	1 / 1	47

1 – individual data rather than median provided for counts <5 2 – includes 15 patients receiving sequential EGFR TKIs 3 – includes 3 patients receiving sequential ALK TKIs * indicates therapy is ongoing for individual data points Abbreviations: NR – not reached; TKI – tyrosine kinase inhibitor

Conclusion: This study provides interim data on targeted therapy outcomes for aNSCLC patients with Guardant360-detected drivers treated in everyday clinical practice. Outcomes are in line with what is expected for tissue-detected drivers in the TT naïve setting and this cohort will continue to be followed. Identification of NSCLC driver mutation using well-validated ctDNA assays can be used for clinical decision-making.

Keywords: ctDNA, Targeted therapy, advanced NCLC

P1.14-28 CORRELATION BETWEEN THE QUALIFICATION FOR THE BEVACIZUMAB USE AND THE SURVIVAL OF NSCLC PATIENTS WITH EGFR MUTATIONS

T. Hakozaki, Y. Okuma, K. Hashimoto, Y. Hosomi

Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan

Background: Previously, the combination of epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs) and bevacizumab (BEV) has been investigated. A subgroup analysis of a phase III trial investigating the combination of atezolizumab, carboplatin, paclitaxel, and bevacizumab (ABCP) demonstrated the benefit of ABCP in patients harboring *EGFR* mutations. This study aims to assess the prognostic significance of the qualification for the BEV use on the survival and proportion of patients who potentially benefit from BEV before and after first-line EGFR-TKIs. **Method:** We retrospectively analyzed the data of 283 patients with advanced or recurrent non-squamous non-small cell lung cancer (NSCLC) harboring *EGFR* mutations who had received EGFR-TKIs. We performed statistical analyzes using the Kaplan–Meier method and Cox regression adjusted for risk factors. **Result:** Of 283 patients, 196 (69%) were eligible to administer BEV ("BEV fit") at the time of EGFR-TKIs initiation. Among "BEV unfit" patients at the baseline (n = 67), 14 (21%) became "BEV fit" at the time of EGFR-TKIs failure. The median overall survival (OS) time of "BEV fit" and "BEV unfit" patients were 25.0 [95% confidence interval (CI): 23.0–29.4] and 18.8 (95% CI: 14.4–22.0) months, respectively (P = 0.0001). The multivariate analysis revealed a marked correlation between survival and the qualification for the BEV use. **Conclusion:** The qualification for the BEV use at the baseline is independently related to the OS. Some patients harboring *EGFR* mutations, including "BEV unfit" at the baseline, could be eligible for the ABCP regimen after the first-line EGFR-TKIs failure.

Background: Genomic alterations drive more than 60% of adenocarcinoma cases of non-small cell lung cancer (NSCLC). About 20% of cases will have an oncogenic driver (EGFR, ALK, ROS1, BRAF, NTRK, etc.) that can be treated with approved targeted therapy drugs, and more (RET, Exon 20 insertions, etc.) have clinical trial options. Patients and caregivers dealing with these cancers have organized globally into oncogene-focused groups ("Groups"—see Table 1) and are building partnerships that seek to provide support, increase awareness and education, accelerate and fund research, and improve access to effective diagnosis and treatment.

Method: We partnered in a variety of ways to accelerate research. While each Group sets its own research priorities, we've found successful collaborative research has the following seven characteristics. It includes patients from the start, in all aspects of the project. It addresses questions meaningful to patients. It develops patient-centered measurements. It accommodates patients' clinical realities. It leverages social media and patient groups. It shares progress with participants frequently. It makes results rapidly and freely available. **Result:** These methods have enabled the Groups to collaborate successfully with clinicians, researchers, advocacy organizations, and industry to generate ideas for next steps in research for their disease, forge new studies and clinical trials for a specific oncogenic driver, create new patient-derived models of oncogene-driven cancers to study acquired resistance, develop registry-based studies to collect real-world data, and guide patients to clinical trials. **Conclusion:** Oncogene-focused patient-caregiver groups are creating new paradigms across the research continuum. They have demonstrated that their partnerships with advocacy organizations, clinicians, researchers, and industry, can increase available patient-derived models, patient data, and specimens among geographically distributed, oncogene-driven cancer populations.

P1.14-30 PHASE I STUDY OF AFATINIB PLUS BEVACIZUMAB IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER HARBORING EGFR MUTATIONS

T. Tokito[1], R. Ko[2], C. Imamura[3], T. Shukuya[2], N. Shimada[2], R. Koyama[2], K. Yamada[1], H. Ishii[1], K. Azuma[1], K. Takahashi[2]

[1]*Kurume University School of Medicine, Kurume/Japan,* [2]*Juntendo University Graduate School of Medicine, Tokyo/Japan,* [3]*Keio University School of Medicine, Tokyo/Japan*

Background: Afatinib, a second-generation epidermal growth factor receptor (*EGFR*) tyrosine kinase inhibitor (TKI), is one of the standard therapies for patients with advanced non-small cell lung cancer (NSCLC) harboring *EGFR* mutations. The first-generation EGFR-TKIs in combination with bevacizumab have been reported to improve progression-free survival (PFS). However, data on afatinib plus bevacizumab are limited. **Method:** In this phase I study, we examined the safety and the efficacy of afatinib plus bevacizumab in patients with advanced non-squamous NSCLC harboring *EGFR* mutations. This study comprised two cohorts. In the dose-finding cohort, eligible patients received afatinib 20, 30, or 40 mg/day (days 1–21) plus bevacizumab 15 mg/kg (day 1) in 21-day cycles. This cohort was designed and conducted in a 3 + 3 manner. In the expansion cohort, the patients were treated with the recommended dose (RD) based on the findings in the dose-finding cohort, and we evaluated the preliminary efficacy of this combination therapy. The serum trough concentration of afatinib was assessed at the steady state. **Result:** Sixteen patients were enrolled in this study (5 patients in the dose-finding cohort and 11 patients in the expansion cohort). No dose-limiting toxicities (DLTs) occurred with afatinib 30 mg/day. With afatinib 40 mg/day, 2 out of 2 patients had DLTs (grade 3 diarrhea) in cycle 1. From these results, afatinib 30 mg/day plus bevacizumab 15 mg/kg was decided as the RD. Additionally, 11 patients in the expansion cohort were treated with RD. Common treatment-emergent adverse events (AEs) with the RD were diarrhea (79%), rash (71%), perionychia (64%), and stomatitis (50%). Grade 3 AEs with the RD were diarrhea (7%), perionychia (7%), and hypertension (7%). There were no grade 4/5 AEs and interstitial lung disease. The response rates and median PFS were 56% and 16.8 months in EGFR-TKI naïve patients, and 0% and 4.9 months in patients pretreated with EGFR-TKIs. The median serum concentration at the steady state was 13.7 ng/mL (range: 8.1–38.1 ng/mL) in the patients treated with the RD. Rebiopsy was conducted in eight patients after disease progression with afatinib plus bevacizumab, and three patients acquired an exon 20 T790M mutation. **Conclusion:** Afatinib 30 mg/day plus bevacizumab 15 mg/kg was well tolerated. Large-scale studies are warranted to evaluate the efficacy of this combination therapy.

Background: BIM deletion polymorphisms are most common in Asian population, with an incidence of 12-16% in lung cancer patients with EGFR mutations. Previous studies showed BIM deletion polymorphisms could predict poor treatment response to EGFR-TKIs, owing to loss function in mediating apoptosis of tumor cells. Recently, available data on BIM is inconsistent on its predictive role and we don't know if NGS could bring us something new. **Method:** Data were pooled from clinical trial CTONG0901 and local database in our hospital (GLCI). 194 and 117 EGFR mutant patients with IIIB-IV NSCLC are enrolled for survival analysis in the two cohorts, respectively. BIM status of all these patients were confirmed by NGS. 28 patients have baseline NGS results with 168 genes panel. **Result:** The incidence of BIM deletion polymorphism in patients with EGFR mutation was 11.3% (22/194) and 17.6% (26/148) in CTONG0901 and GLCI, respectively. In CTONG0901, median PFS of patients treated with erlotinib or gefitinib between BIM deletion polymorphism and BIM wild type is 10.47m versus 11.17m (P=0.59). Median OS is 20.5m versus 20.47m (P=0.82). In GLCI, median PFS between BIM deletion polymorphism and BIM wild type is 10.13m versus 12.87m (P=0.33). Median OS is 58.5m versus 54.97m (P=0.82). No survival differences on PFS and OS present in the two cohorts. 28 patients with baseline NGS were analyzed from two cohorts. Three patients with MET amplification, ALK rearrangement and PD-L1 expression (20%+++) are lower than median PFS (8.63m). Two patients with MET amplification are around median PFS.

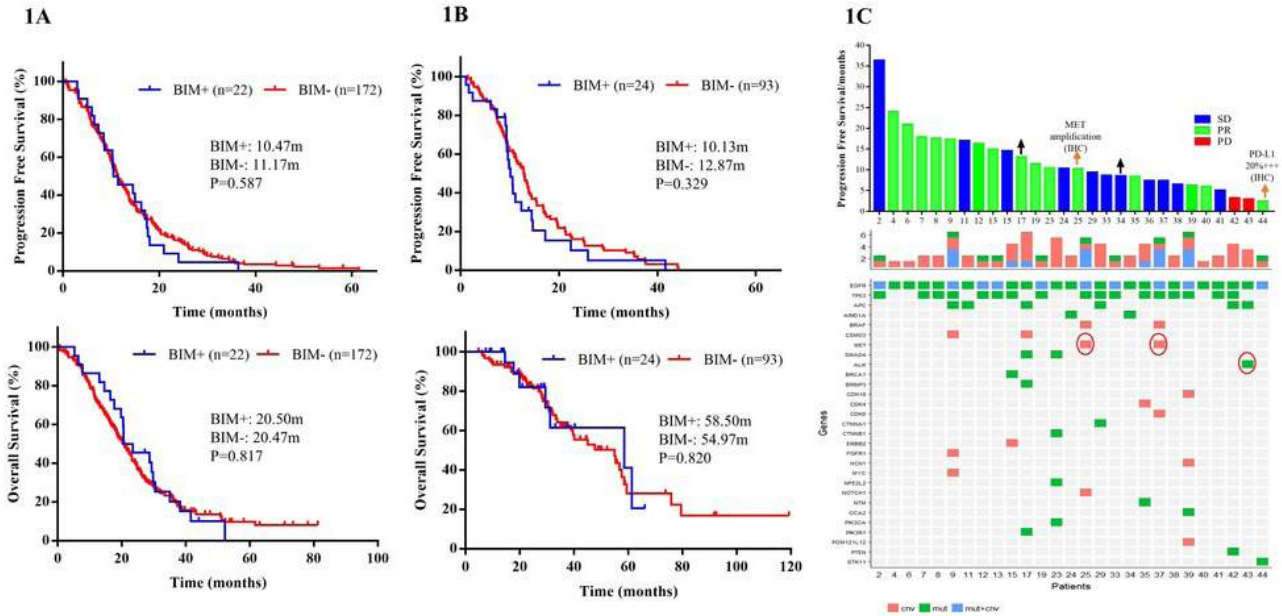

Figure 1A: Survival analysis in CTONG0901 with comparation of PFS and OS between advanced NSCLC patients with BIM deletion polymorphisms and wild type. **Figure 1B:** Survival analysis in local database (GLCI) with comparation of PFS and OS between advanced NSCLC patients with BIM deletion polymorphisms and wild type. **Figure 1C:** Waterfall plot and heatmap of 28 patients with BIM deletion polymorphisms based on the NGS results at baseline. The black up arrows indicates that the PFS has not been reached; the orange up arrows indicates one patient with MET amplification (IHC) and one with PD-L1 20%+++ (IHC); the red circles indicates two patients with MET amplification (NGS) and one with ALK rearrangement (NGS).

Conclusion: In our study, BIM deletion polymorphism has no relationship with the efficacy of EGFR-TKIs in CTONG0901. The result is confirmed in our local database. Outcomes of NGS showed that combined molecular variations, such as MET amplification, ALK rearrangement and PD-L1 expression seems more important to the prediction of EGFR-TKIs on NSCLC patients.

Background: Ensartinib is a potent ALK small molecule tyrosine kinase inhibitor (TKI). In a phase 1/2 study, ensartinib was generally well tolerated and demonstrated good clinical activity in pts with ALK+ non-small cell lung cancer (NSCLC). This post hoc analysis sought to determine the relationship between ensartinib-related rash and clinical benefit. **Method:** Adverse events (AEs) were coded using MedDRA v15.0; severity was assessed by investigators using NCI CTCAE v4.03. Objective response rate (ORR) and median progression-free survival (mPFS) were explored in the efficacy-evaluable population, which included ALK+ pts receiving ensartinib 225 mg QD who had a postbaseline response assessment. **Result:** As of Feb 07, 2019, 80 pts were dosed at the phase 3 dose of 225 mg QD and were efficacy evaluable (13 were ALK TKI naive, 37 had received prior crizotinib only, and 30 had received a prior second-generation ALK TKI). Rash was the most common AE observed in 69% of pts, mostly grade 1/2. The rashes started most frequently (33%) at day 7 or 8. The most common types of rash were general rash, rash maculopapular, and rash erythematous. Rash was primarily managed with topical corticosteroids, with some dose reductions, or no intervention at all and rarely led to discontinuation (2% [n=2]). The median duration of rash was 22 days. The ORR and mPFS were better in pts with rash vs those without (ORR, 53% vs 40%; mPFS, 8.6 vs 5.7 mo; P=.0044) (Table). A multivariate Cox proportional hazards model controlling for baseline factor (eg, age, sex, ECOG PS, and prior ALK TKI) revealed a correlation between rash and PFS (HR=0.556; P=.0755). Pts are still being accrued in this study.

Table. Efficacy in *ALK*+ Pts at 225 mg QD with a Postbaseline Response Assessment

	Evaluable Pts (n=80)[a]	
	Rash (n=55)	**No rash (n=25)**
ORR, n (%)	29 (52.7)	10 (40.0)
mPFS, mo 95% CI	8.6 5.8-11.3	5.7 2.9-7.3
Log-rank *P* value	.0044	

[a]13 *ALK* TKI naive, 37 received prior crizotinib only, and 30 received a prior second-generation ALK TKI.

Conclusion: Ensartinib was associated with mild to moderate rash that was easily managed. Preliminary findings suggest that rash is potentially associated with better clinical benefit with ensartinib.

Keywords: ALK, rash, clinical benefit

P1.14-33 CANAGLIFLOZIN INHIBITS LUNG CANCER SURVIVAL AND ENHANCES ITS RESPONSE TO RADIOTHERAPY; EFFECTIVE BLOCKADE OF MTOR PATHWAY, HIF1A, AND MITOSIS

Background: Non-small cell lung cancer (NSCLC) presents frequently at an advanced stage where standard treatment with radiotherapy (RT) and chemotherapy (CT) provides limited benefit. Driver mutations and alterations of NSCLC cell metabolism contribute to rapid growth, resistance to cytotoxic therapy and survival. In normal cells, these events are controlled by the metabolic stress sensor AMP-activated protein kinase (AMPK), a key regulator of cell metabolism that also responds to cytotoxic therapy. AMPK induces a p53-mediated cycle checkpoint and inhibits the mammalian Target of Rapamycin (mTOR) pathway. Canagliflozin (CANA), a new diabetes agent, was developed to target the renal Na^+-glucose co-transporter 2 and control glycemia through blockade of glucose re-absorption. Earlier, we found that clinically achievable doses of CANA suppress cell survival, mainly through an off-target action, to block complex I of the mitochondria oxidative phosphorylation chain, leading to activation of AMPK. In the present study, we examined the CANA's anti-tumor efficacy in combination with RT. **Method:** Adenocarcinoma (A549, H1299, H1975) and squamous cell carcinoma (SK-MES-1) NSCLC cells were subjected to proliferation, clonogenic survival and metabolic assays after combined CANA (0–30mM) and RT (0–16Gy) treatments. Immunodeficient nude mice were grafted with H1299 cells and treated with Canagliflozin (100 mg/kg/day by oral gavage) and/or RT (10 Gy). Cell and tumor lysates are analyzed with immunoblotting and immunohistochemistry. **Result:** At low micromolar doses achieved routinely in the circulation of diabetic patients, CANA inhibited proliferation and clonogenic survival of NSCLC cells and enhance NSCLC response to RT. In control and irradiated cells, CANA inhibited de novo lipogenesis and abolished histone H3 phosphorylation, an established marker of mitosis. This was associated with the induction of cyclin-dependent kinase inhibitor p27kip1. CANA activated AMPK and mediated effective suppression of the mammalian target of rapamycin (mTOR) pathway, with inhibitory Raptor phosphorylation and blockage of p70S6k and S6 phosphorylation. Importantly, CANA also blocked early signaling events of the Epidermal Growth Factor Receptor (EGFR) pathway such Shc, Gab and PLCg1 phosphorylation and suppressed HIF1a expression. CANA suppressed H1299 tumor growth. On-going experiments analyze tumors proliferation, angiogenesis, cell death, and microenvironment markers. **Conclusion:** Canagliflozin (CANA), an approved and well-tolerated diabetes drug suppresses proliferation, radio-resistance and survival pathways and improves NSCLC response to RT, at doses well within its therapeutic window. This suggests a strong potential for clinical development of CANA in combination with RT for the treatment of NSCLC. Acknowledgments: This work was supported by an RFA grant from Hamilton Health Science and funds from Canadian Institutes for Health Research (CIHR).

P1.14-34 THE LANDSCAPE OF MET ALTERATIONS IN CHINESE NON-SMALL CELL LUNG CANCER PATIENTS

M. Zheng[1], P. Jun[2], S. Wang[3], M. Li[1], N. Mao[3], Y. Liu[4], T. Cheng[5], H. Lan[6], J. Zhao[7], W. Wang[7], J. Hu[7], M. Yao[7], K. Wang[7], Y. Qu[8]

Background: Mesenchymal-to-epithelial transition (*MET*) is a therapeutic target in non-small cell lung cancer (NSCLC), which has a variety of genomic variants. *MET* amplification and *MET* exon 14 skipping (*MET* ex14) have been notable for meaningful clinical response to *MET* inhibitor therapy. However, comprehensive molecular characteristics of *MET* variants of Chinese NSCLC patients are not well understood. **Method:** FFPE tumor and matched blood samples from 3433 Chinese NSCLC patients were collected for targeted next generation sequencing (NGS). Genomic variants including single nucleotide variations (SNV), short/long insertion/deletions (Indel), copy number alterations and gene rearrangements were analyzed. *MET* amplification, *MET* ex14 skipping and gene fusion were defined as *MET* druggable variations. Tumor mutational burden (TMB) was analyzed in all patients. **Result:** In total, *MET* variations were identified in 3.3% (115/3433) of Chinese NSCLC patients. Mutation rates varied in different histological types: 3.3% (N=95) in adenocarcinoma, 1.7% (N=7) in squamous cell carcinoma, 10.1% (N=7) in adenosquamous carcinoma and 15.0% (N=3) in sarcomatoid carcinoma. *MET* druggable variations had been found enriched at an advanced clinical stage accounted for 3.8% of stage IV cases while only 1.2% of cases at earlier stages. Consistent to the previous studies, *MET* amplification and *MET* ex14 skipping were identified in 1.5% and 0.8% of NSCLC patients respectively. *MET* rearrangement was identified in seven patients in this cohort with partner genes as *CD47*, *ST7*, *TMEM168*, *MYTKL* and *FOXP2*. Moreover, 39.5% of *MET* point mutations resulting in pathway activation (D1010, D1228 and H1094) in this cohort could then be potential targets for *MET* inhibitors. Twenty six percent of all *MET* variations co-mutated with *EGFR* sensitive mutations, which may be a resistance mechanism for EGFR-TKI therapy. The median TMB of patients with *MET* variations was 6.1 muts/Mb. Cases with *MET* SNV/Indel alterations had higher median TMB than wild type *MET* (8.1 vs. 4.6 muts/Mb, respectively, $P = 0.03$). In particular, a newly acquired *MET* fusion was detected in a 60-year old female NSCLC patient when disease progressed on TKI against the original *EGFR* L858R-mutant. She achieved a partial response to crizotinib plus osimertinib treatment. **Conclusion:** Our study revealed that *MET* variations occurred in 3.3% of Chinese NSCLC patients. Besides *MET* amplification and *MET* ex14 skipping, *MET* rearrangements and targetable point mutations we identified might be potential therapeutic targets for these patients.

P1.14-35 EPITHELIAL-TO-MESENCHYMAL TRANSITION IS A MECHANISM OF ALK INHIBITOR RESISTANCE IN LUNG CANCER INDEPENDENT OF ALK MUTATION STATUS

K. Fukuda[1], S. Takeuchi[1], S. Arai[1], S. Nanjo[2], R. Katayama[3], K. Takeuchi[4], M. Nishio[5], S. Yano[1]

[1]*Cancer Research Institute Kanazawa University, Kanazawa, Ishikawa/Japan,* [2]*University of California San Francisco, San Francisco/United States of America,* [3]*Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo/Japan,* [4]*The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo/Japan,* [5]*The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/Japan*

Background: *ALK* rearrangement, most commonly *EML4-ALK*, is detected in approximately 3%–5% of NSCLC. ALK tyrosine kinase inhibitor (TKI), shows dramatic clinical efficacy, however, almost all patients acquire resistance over time. The most defined mechanism of crizotinib resistance is secondary *ALK* mutations. A recent study reported that epithelial-to-mesenchymal transition(EMT) and *ALK* resistance mutation were simultaneously detected in a single tumor lesion in patients with *ALK*-rearranged lung cancer who were resistant to ALK-TKIs. However, it is still unknown whether ALK-TKI resistant tumor cells combine mesenchymal phenotype with *ALK* resistance mutation, or each of the mesenchymal type tumor cells and *ALK* resistance mutation–positive cells coexist in a single lesion. In any of these cases, no therapy for EMT-associated targeted drug resistance has yet been established. **Method:** Specimens from a patient with *ALK*-rearranged lung adenocarcinoma who acquired resistance to crizotinib were stained with IHC, and the epithelial regions (ALK$^+$, vimentin$^+$, and E-cadherin$^-$) and the mesenchymal regions (ALK$^+$, vimentin$^-$, and E-cadherin$^+$) were collected by microdissection. The DNA from the each regions were isolated and the *ALK* L1196M mutation was detected by degital PCR analysis. Crizotinib-resistant cell line was developed by continuous treatment with crizotinib in the pleural carcinomatosis mouse model inoculated with the crizotinib-sensitive human lung cancer cell line, A925LPE3, which harbors the *EML4-ALK* gene fusion. The clones were estabilish by limiting dilution and the mechanism of crizotinib resistance was examined by microarray analysis, miRNA array analysis, western blot, and MTT assay. Compounds that overcame crizotinib resistance were screened from a library of 200 kinase inhibitors. **Result:** Digital PCR analyses combined with microdissection after IHC staining for EMT markers revealed that *ALK* L1196M was predominantly detected in epithelial-type tumor cells, indicating that mesenchymal phenotype and *ALK* mutation can coexist as independent mechanisms underlying ALK inhibitor–resistant cancers. Preclinical experiments with crizotinib-resistant lung cancer cells showed that EMT associated with decreased expression of miR-200c and increased expression of ZEB1 caused cross-resistance to new-generation ALK inhibitors alectinib, ceritinib, and lorlatinib. Moreover, pretreatment with the histone deacetylase (HDAC) inhibitor quisinostat overcame this resistance by reverting EMT *in vitro* and *in vivo*. **Conclusion:** These findings indicate that HDAC inhibitor pretreatment followed by a new ALK inhibitor may be useful to circumvent resistance constituted by coexistence of resistance mutations and EMT in the heterogeneous tumor.

Background: Although reports on the use of gefitinib or erlotinib in elderly patients were occasionally found, those on afatinib were rare. According to the analysis of 54 Japanese patients in the LUX-Lung3 study, the dose reduction of afatinib from 40 mg/day was necessary for 76.0% of patients. However, the prolonged administration was possible after a dose reduction to 30 or 20 mg/day, and antitumor effects were maintained with the reduced dose. **Method:** The efficacy and safety of afatinib at 30 mg/day in PS 0-1 patients who were aged 75 years with *EGFR* mutation positive chemotherapy-naïve non-small cell lung cancer were studied. The primary endpoint was the response rate (RR), and the planned number of registered cases was set at 35, with a threshold RR of 50%, an expected RR of 75%, α of 0.05, and β of 0.1. The secondary endpoints were progression-free survival (PFS), overall survival (OS), the incidence rate of adverse events (AEs), QOL survey (FACT-L), and trough plasma concentration of afatinib at steady state (PK, collected between the 8th to 15th day after the start of oral administration). **Result:** The data of 35 patients were collected from May 2015 to August 2017. Patient background was, median age of 79 years (75-92), male/female: 8/27, PS 0/1: 8/27, adenocarcinoma/NSCLC: 30/5, IIIA/IIIB/IV/postoperative recurrence (TNM 7th edition): 2/2/22/9, and exon19del/exon21L858R/exon19del+exon21L858R: 15/19/1. The best overall efficacy was PR/SD/PD/NE: 28/4/1/2, and the RR was 80.0% (95% CI, 63.1-91.6). The median PFS and OS were 16.3 months (95% CI, 11.8-27.0) and not reached, respectively. The main AEs were rash 69%, diarrhea 60%, and paronychia 51%. While the initial afatinib dose was 30 mg, nine (26%) patients continued with

30 mg, 23 (66%) were reduced to 20 mg, and 3 (8%) discontinued due to AEs (2 ILD and 1 stomatitis). Treatment-related death was not observed. There were no significant change of QOL at baseline, after 4, 8, and 12 weeks. PK analyses showed steady state plasma concentration as 22.8 ng/mL which was comparable to reported plasma concentration of 40 mg afatinib in LUX-LUNG3 and 6 (24.3 ng/mL). No obvious PK differences were found according to dose reduction, adverse event, and response. **Conclusion:** Afatinib at 30 mg/day could be an effective treatment option for elderly patients, over 75 years of age, with good PS. (UMIN 0000177050)

Background: Lung cancer among never-smokers is common and increasing [1]. A smoking-independent subgroup of lung adenocarcinoma with certain molecular and clinical features exists [2-3]. In an ongoing project within the Swedish Molecular Initiative against Lung cancer (SMIL) we currently characterize lung cancer in never-smokers for etiological, diagnostic and therapeutic purposes. **Method:** Through the Swedish National Lung Cancer Registry [1], we identified all individuals who underwent surgery for lung cancer in Sweden 2005-2014 and who were registered as never-smokers (n=540). At each study site, clinical data were reviewed by a thoracic oncologist or pulmonologist through patients' medical charts and archived tumor tissues were retrieved and reviewed by a thoracic pathologist. For subsequent studies, we extracted DNA and RNA (using the Qiagen AllPrep kit for FFPE tissue) and constructed tissue microarrays. As first preplanned analyses, we performed fusion gene mapping using an RNA based NanoString nCounter Elements assay and mutational profiling by Next Generation Sequencing (NGS) using a 26-gene exon-focused panel, as previously described [4]. **Result:** Of the 540 never-smokers with surgically resected lung cancer, 69% were females and the majority of cases were adenocarcinomas. The median age at diagnosis was 69 years. In the first 310 analyzed tumor samples, we so far detected 24 fusions involving *ALK* (8%), 10 involving *RET* (3%) and 2 involving *NRG1* (<1%). In addition, *MET* exon 14 skipping was found in 33 samples (11%). Furthermore, among the so far 147 cases where we have completed both the DNA and the RNA analyses, 59 tumors (40%) harbored *EGFR* mutations. In total, targetable alterations were revealed either by NanoString or NGS in 63% of tumors from never-smokers in our study. **Conclusion:** SMIL is an ongoing nation-wide molecular research collaboration on lung cancer where we currently characterize one of the largest never-smoking lung tumor cohorts worldwide. From the first pre-planned analyses, we conclude that, in a population-based cohort of early stage lung cancer from never-smokers, targetable oncogenic fusions and mutations are frequent. Background: Fusions have been described in the fibroblast growth factor receptors (*FGFR*) 1-3 genes with multiple partners in a variety of tumors. Here we focused on the prevalence of *FGFR* fusions in lung cancers for whom might benefit from FGFR inhibitors in clinical development. **Method:** We reviewed *FGFR* alterations in 10833 lung cancer patients (pts) who underwent genetic testing at our institute from 2016 to 2019. Mutation profiles were analyzed using hybridization capture based next-generation sequencing (NGS), which covers all exons of *FGFR1-3* and specific intron regions containing the break points of fusions. All patients were also analyzed for mutations in *EGFR, KRAS, HER2, BRAF, ALK, RET, MET, ROS1*, as well as other oncogenes. **Result:** *FGFR* fusions were identified in 25 lung cancer pts, including 9 adenocarcinoma pts, 4 squamous-cell carcinoma pts, 1 patient with large cell neuroendocrine carcinoma and 11 pts with non-specific pathology. *FGFR3-TACC3* fusion was detected in 72% (18/25) of pts and the remaining were previously unreported fusions (table). Concurrent *EGFR* mutations were identified in 44% (11/25) of pts with *FGFR* fusions (32%, treated with EGFR tyrosine kinase inhibitors (EGFR-TKIs); 12%, not treated with EGFR-TKIs). PI3K-AKT-MTOR signaling pathway was also activated in 28% (7/25) of pts, and cell-cycle gene alterations were also detected in 16% (4/25) of pts.

Table. Frequency of FGFR fusions

Fusions	Fusion region	N (%)
FGFR3-TACC3	EX17:EX11	6 (24%)
	EX18E:EX11	4 (16%)
	EX18E:EX13	2 (8%)
	EX17:EX10	2 (8%)
	others	4 (16%)
FGFR1-chr8:21672159	EX1:chr8:21672159	1 (4%)
FGFR1-MTUS1	EX19E:EX8	1 (4%)
EFHA2-FGFR1	EX2:EX3	1 (4%)
TNRC18-FGFR1	PMT:EX10	1 (4%)
ZMAT4-FGFR1	EX2:EX2	1 (4%)
ZNF696-FGFR1	EX2:EX18E	1 (4%)
OPALIN-FGFR2	EX6E:EX2	1 (4%)
Total		25 (100%)

Conclusion: *FGFR1-3* fusions define a unique molecular subtype of lung cancer. Depending on the concurrent genetic alterations, combined targeted therapy might be an optimal strategy to control tumor growth for these pts.

Keywords: Targeted therapy, Lung cancer, FGFR1-3

P1.14-39 ACQUIRED ALK REARRANGEMENT IN EGFR-MUTANT LUNG ADENOCARCINOMA TREATED WITH EGFR TKIS

Q.-Y. Wang, R.-L. Chen, J. Kang, H.-J. Chen, B.-C. Wang, Z. Wang, Q. Zhou, Y.-L. Wu, J.-J. Yang

Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provicial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: Few studies have been reported on acquired anaplastic lymphoma kinase (*ALK*) rearrangement in epidermal growth factor receptor (*EGFR)*-mutant lung adenocarcinoma patients with EGFR tyrosine kinase inhibitors (TKIs). **Method:** *EGFR*-mutant lung adenocarcinoma patients were screened after resistance to EGFR TKIs from September 2017 to December 2018 at the Guangdong Lung Cancer Institute. Both *EGFR* mutation and *ALK* rearrangement were tested by next-generation sequencing (NGS). Acquired *ALK* rearrangement was defined as positive *ALK* rearrangement after resistance to EGFR TKIs, but negative result detected by NGS at the baseline of EGFR TKI treatments. **Result:** Totally 320 patients were tested by NGS after resistance to EGFR TKIs (175, 42 and 103 with first-, second- and third-generation EGFR-TKIs respectively). Frequency of acquired *ALK* rearrangement was 1.14% (2/175), 2.38% (1/42) and 1.94% (2/103) in patients treated with first-, second- and third-generation EGFR TKIs respectively. The fusion partners of *ALK* were *EML4* in 2 patients, *CLIP4* (1), *NPM1* (1) and *PIBF1* (1). Non-*EML4-ALK* fusion accounted for 60%. One with acquired *EML4-ALK* achieved minor response with osimertinib plus crizotinib. One with acquired *NPM1-ALK* achieved partial response with erlotinib plus crizotinib. Unfortunately, one with acquired *CLIP4-ALK* fusion and *BRAF V600E* mutation did not respond to ensartinib single agent. One with acquired *PIBF1-ALK* had no clinical benefit with osimertinib plus alectinib. Finally, one with acquired *EML4-ALK* died shortly without any treatment due to poor performance status. **Conclusion:** The frequency of acquired *ALK* rearrangement is similar in *EGFR*-mutant lung adenocarcinomas after resistance to the first-, second-, or third-generation EGFR TKIs. The majority of acquired *ALK*-fusion partners are non-*EML4*. Combination of EGFR TKIs and ALK inhibitors might be a strategy to overcome such resistance.

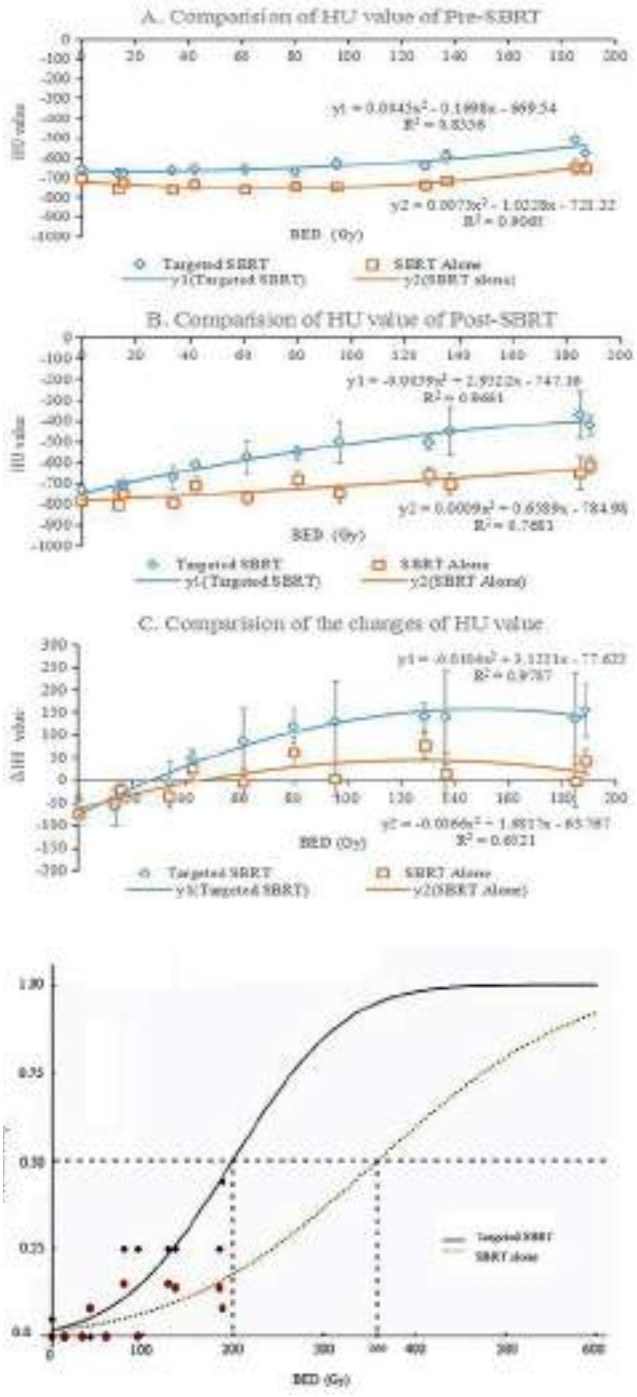
Keywords: ALK rearrangement, EGFR mutation, lung adenocarcinoma

P1.14-40 EGFR-TKIS MAY SENSITIZE RADIATION LUNG DAMAGE IN STEREOTACTIC BODY RADIOTHERAPY BASED ON INTENSITY ANALYZING

X. Tang, Y. Shen, Y. Meng, L. Hou, C. Zhou, C. Yu, W. Wang, H. Yang, F.-M. Kong

Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China

Background: To measure early radiographic changes of acute radiation pneumonitis after stereotactic body radiotherapy (SBRT) and compare the differences between patients treated with and without the epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs). **Method:** Patients with SBRT with 3-month follow-up CT scans were eligible. 20 patients treated with EGFR-TKIs a month before stereotactic body radiotherapy (Target-SBRT group) were formed the primary study population. Another 20 patients received SBRT alone were selected from our SBRT data bank to serve as control, by matching dose prescription, tumor size and location. Pre- and post-SBRT CT scans from these 40 patients were registered to each other and the mean value of CT intensity (Hounsfield unit, HU) were extracted for regions of the lungs receiving the same dose at 10 Gy intervals to generate dose-response curves (DRC). The frequency of density changes>200 HU was modeled depending on the fractionation using a Probit model for different treatments. **Result:** There were significant differences in the DRC of pre-SBRT, post-SBRT and the differences of HU value (△HU) in lung between the SBRT alone and Target SBRT groups (all P<0.050)(Figure 1). The respective dose for a 50% complication risk (TD50) for changes>200HU was 72Gy (95% confidence interval (CI 58-107) in SBRT alone group versus 52Gy (CI 46-59) in targeted SBRT group (Figure 2).



Conclusion: Compared to SBRT alone, targeted SBRT group has a lower TD50 and m value, both suggesting an increased complication probability of normal lung tissue.

P1.14-41 THE COMBINATION OF THE PARP INHIBITOR OLAPARIB AND THE ATR INHIBITOR VE-821 SELECTIVELY TARGETS ATM-DEFICIENT LUNG CANCER CELLS

N. Jette, S. Radhamani, G. Arthur, R. Ye, S. Goutam, A. Boylos, L. Petersen, P. Bose, G. Bebb, S. Lees-Miller

University of Calgary, Calgary/Canada

Background: The driving principle behind precision medicine is to specifically target genetic variations that arise in tumorigenesis while leaving normal cells unaffected. Mutations in Ataxia Telangiectasia Mutated (ATM) may offer such a therapeutic target. ATM is mutated in approximately 12% of lung cancers and up to 40% of lung

POSTERS

adenocarcinoma have been reported to lack ATM protein expression. ATM is an apex signaling kinase that responds to DNA-double strand breaks, playing a direct role in DNA repair as well as the initiation of signaling cascades that can lead to cell cycle arrest and apoptosis. We asked whether ATM-deficient human lung cancer cells are sensitive to the poly-ADP ribose polymerase (PARP) inhibitor olaparib, and investigated the mechanism of action of olaparib in these cells. **Method:** We analyzed drug sensitivity for 61 lung adenocarcinoma cell lines from the Genomics of Drug Sensitivity in Cancer (GDSC) project and deleted ATM from lung adenocarcinoma A549 cells using CRISPR/Cas9. We determined the effects on cell viability using trypan blue exclusion and clonogenic survival assays. To investigate the mechanism of sensitivity of ATM-deficient cells to PARP and ATR inhibitors we used flow cytometry and cell viability assays as above. **Result:** We observed a positive correlation between olaparib IC50 values and ATM mRNA expression. ATM mutant cell lines were more sensitive to olaparib compared to ATM wild-type cell lines or cell lines with amplified ATM. Additionally, ATM-deficient lung cancer cells were sensitive to olaparib, as are lung cancer cells (A549) with CRISPR/Cas9 deletion of ATM. Mechanistically, olaparib caused the temporary and reversible accumulation of G2 phase cells in ATM-deficient cells which manifested as a decrease in proliferation in both the trypan blue exclusion assay and clonogenic survival assay. Olaparib did not induce cell death in ATM-deficient cells, however cell death was induced when olaparib was used in combination with the ATR inhibitor VE-821. **Conclusion:** We show that olaparib acts as a cytostatic agent in ATM-deficient lung cancer cells, inducing a reversible and temporary growth arrest in G2 phase. Only when combined with the ATR inhibitor VE-821 was cell death observed and only in ATM-deficient cells. Our data suggest that patients with ATM-deficient lung cancer could benefit from combinatorial treatment with PARP and ATR inhibitors.

Keyword: Olaparib, VE-821, ATM

P1.14-42 APATINIB COMBINED WITH EGFR - TKI IN TREATING ADVANCED NON-SMALL CELL LUNG CANCER WITH EGFR - TKI RESISTANCE (DATA UPDATED)

R. Tian, X. Song, Y. Guo, X. Zhang, W. Guo, H. Zhu, F. Shen, J. Xu, X. Zhang, R. Wang, X. Ren, J. Li

Shanxi Tumor Hospital, Taiyuan/China

Background: EGFR-TKI has been widely used in patients with EGFR mutations in non-small cell lung cancer (NSCLC) and gained significant benefits.But resistance to EGFR-TKI is inevitable.Previous studies have shown that apatinib (a TKI against VEGFR-2) combined with EGFR-TKI might prevent progression of the disease. We conducted this trial to investigate the efficacy and safety of apatinib combined with EGFR-TKIs(including erlotinib, gefitinib,icotinib,afatinib and osimertinib) compared with traditional chemotherapy for EGFR-TKI resistant NSCLC pts. **Method:** This study enrolled 39 advanced NSCLC pts who acquired resistance to the EGFR-TKI therapy from Mar 2017 to Jan 2019. 25 pts received apatinib combined with EGFR-TKI (apatinib in start dose of 250 mg+prior EGFR-TKI dose),14 pts received chemotherapy (pemetrexed or vinorelbine with platinum). Efficacy was evaluated every 6 weeks based on RECIST 1.1. This study was registered on Chinese Clinical Trail Registry, and the registration number was ChiCTR-OIN-17012051. **Result:** In the apatinib group, 88%(22/25) pts were available evaluated. The objective response rate was 13.6%(3/22) and the disease control rate was 95.5% (21/22). The most common adverse events in the apatinib group were diarrhea (60%,15/25), hypertension (56%,14/25), hand-foot syndrome (40%,10/25), fatigue (30.4%,7/23). Main grade 3 or 4 toxicities were proteinuria (12%, 3/25). Two pts with brain metastases in the apatinib group got metastases lesions decreased. The lesions of two pts who have been taken the dose of 250mg apatinib and progressed had decreased when they change the dose to 500mg. In the chemotherapy group,78.6%(11/14) pts were available evaluated. The objective response rate was 27.3%(3/11) and the disease control rate was 90.9% (10/11).None new adverse event occured. The objective response rate and disease control rate were similar in two group, there were differences in length of treatment. The median length of treatment of apatinib group was 8.7 month,and chemotherapy group was 4.3 month.The longest treatment period in the apatinib group was 24 months. **Conclusion:** Apatinib combined with EGFR-TKI shown a good clinical efficacy in pts with acquired EGFR-TKI(1st 2nd or 3rd generation) resisitance.Patient's quality of life and the compliance of therapy had been increased by oral drugs.Besides,We found that in the patients who were treated with erlotinib, or patients with EGFR 21 mutation, or male, their PFS tended to be prolonged compared to other patients.

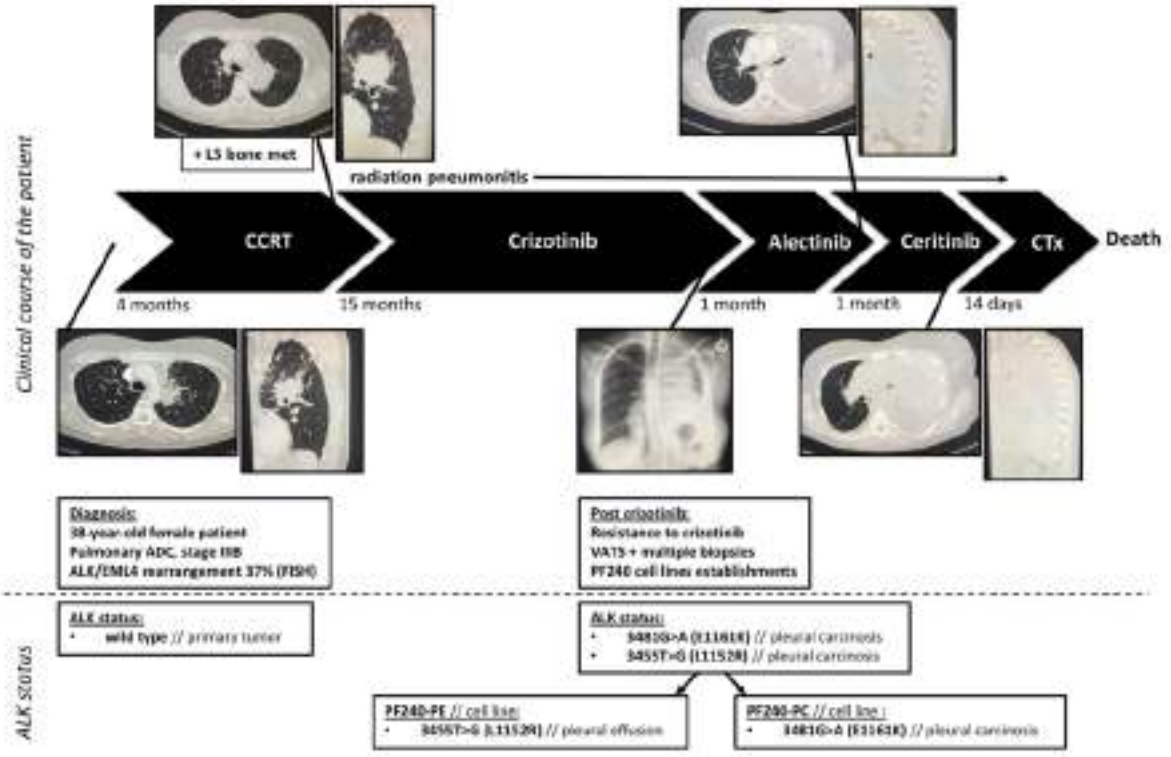
Keywords: apatinib, EGFR-TKI, resistance

P1.14-43 A NOVEL PATIENT DERIVED SYNCHRONOUS CELL PAIR WITH DIFFERENT MUTATIONS IN AN ALK-REARRANGED LUNG ADENOCARCINOMA UNDERLINES TUMOR HETEROGENEITY

P. Stockhammer[1], C.S.L. Ho[2], A. Bankfalvi[3], T. Plönes[4], L. Hegedus[4], M. Schuler[2], C. Aigner[4], A. Schramm[2], B. Hegedus[4]

[1]*Medical University of Vienna, Vienna/Austria,* [2]*West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen/Germany,* [3]*University Clinic Essen, Essen/Germany,* [4]*Ruhrlandklinik, University Hospital Essen, Essen/Germany*

Background: ALK targeted therapy can provide prolonged clinical response rates in ALK-rearranged lung adenocarcinoma (ADC) patients. However, most tumors relapse within a few years of treatment pressure due to a variety of resistance mechanisms, including intratumoral heterogeneity. Understanding these mechanisms is of utmost importance to more precisely tailor future targeted therapies. **Method:** We established a novel synchronous ALK-translocated lung ADC cell pair from the malignant pleural effusion (PF240-PE) and the pleural carcinosis (PF240-PC) of a 38-year-old female patient following sequential ALK targeted therapy. Immunohistochemistry and mutational analyses were executed in pleural carcinosis tissue specimens and in the tumor cell lines. SRB assays were performed for viability testings following different generations ALK inhibitor treatment alone and combined with SAHA, a pan-HDAC inhibitor. As positive control for all treatment lines we used PF521, another newly established ALK-rearranged but treatment naïve lung ADC cell line. In vivo tumorigenicity was evaluated by performing subcutaneous xenografts. **Result:** We identified two distinct resistance mutations in both tissue specimens: a so far non-characterized E1161K and the already described L1152R. Strikingly, PF240-PC harbored E1161K and PF240-PE carried L1152R. Immunohistochemistry showed changes from epithelial/carcinomatous to mesenchymal/sarcomatous differentiation following resistance acquisition. *In vitro* testing revealed that both cell lines were significantly different in morphology and sensitivity to different generation ALK inhibitors including crizotinib, alectinib and lorlatinib. However, the novel tyrosine kinase inhibitor entrectinib was effective in both E1161K and L1152R mutant cells. Importantly, combination treatment of crizotinib or alectinib plus pan-HDAC inhibitor SAHA yielded strong synergism. Of note, both novel cell lines were highly tumorigenic in vivo. In vivo treatment response profiles are currently under evaluation.



Conclusion: This is the first evidence of the synchronous establishment of two highly distinct patient-derived ALK translocated lung ADC cell lines carrying different resistant mutations. This concept supports the paramount significance of spatiotemporal intratumoral heterogeneity under targeted therapy. Furthermore, our findings showed that HDAC inhibition could enhance sensitivity of resistant tumor cells to ALK targeted therapy *in vitro*. Altogether, our findings provide strong evidence for the synchronous emergence of multiple resistance mechanisms and emphasize the importance of multiple site re-biopsies to better identify acquired resistance mechanisms under targeted therapy.

P1.14-44 POSITIVE PD-L1 EXPRESSION IS ASSOCIATED WITH UNFAVORABLE CLINICAL OUTCOME IN EGFR-MUTATED LUNG ADENOCARCINOMAS TREATED WITH EGFR-TKIS

S.H. Lee, M.J. Park, B. Chang

Kyung Hee University Medical Center, Seoul/Korea, Republic of

Background: Clinical implication of programmed death ligand 1 (PD-L1) expression in oncogene-addicted non-small cell lung cancer treated with tyrosine kinase inhibitors (TKIs) is largely unknown. The objective of this study was to determine the frequency of PD-L1 expression and the clinical outcome according to PD-L1 expression in lung adenocarcinomas harboring EGFR mutation and treated with EGFR-TKIs. **Method:** We retrospectively evaluated PD-L1 expression using 22C3 pharmDx assay in lung adenocarcinoma patients with EGFR mutations at two referral hospitals between January 2017 and June 2018. Samples were obtained from surgically resected tumors, small biopsy, or cytologic cell blocks. **Result:** Of all 71 patients analyzed, 44 (58.7%) had PD-L1 tumor proportion score (TPS) of < 1%, 23 (30.7%) had PD-L1 TPS of 1%-49%, and 8 (10.7%) had PD-L1 TPS of ≥ 50%. Of the 37 patients treated with first-line EGFR-TKIs, PD-L1 TPS ≥ 1% was associated with a significantly decreased response rate, compared with PD-L1 TPS < 1% (45.7% vs. 67.3%, p=0.005). Furthermore, PD-L1 TPS ≥ 1% was associated with a significantly shorter median progression free survival, compared with PD-L1 TPS < 1% (9.3 months vs. 14.2 months, p = 0.024). Multivariate analysis showed that PD-L1 TPS ≥1% is independently associated with shorter PFS (hazard ratio 1.32, p=0.012). **Conclusion:** PD-L1 was positive in approximately 40% of patients with EGFR-mutated lung adenocarcinoma. Postive PD-L1 expression may be associated with unfavorable clinical outcome to EGFR-TKIs among those patients group.

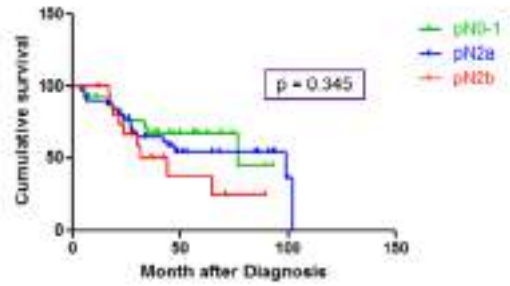
Background: Current staging work-up methodology could not exactly reflect clinical nodal status of aortopulmonary zone (AP zone) without invasive diagnostic tools. The aim of the study is to evaluate the surgical outcome of single zone clinical N2 in AP zone (LN #5 or #6). **Method:** Between 2009 and 2018, a retrospective data of 7488 patients was reviewed. Patients were included when only lymph nodes in AP zone was suspected to be metastasized based on the results of computed tomography (CT), positron

POSTERS

emission tomography (PET-CT) and endobronchial ultrasound transbronchial needle aspiration (EBUS-TBNA). Patients were excluded when metastasis was detected by EBUS-TBNA in other mediastinal lymph node zones. Clinicopathologic variables such as pathologic subtype, differentiation and nodal status were evaluated to identify prognostic factors for survival rate and disease-free survival rate (DFS). **Result:** Ninety-five patients were included, and median duration of follow-up was 35 months (IQR; 20 – 50). Eighty-four patients underwent upfront surgery, and their pathologic nodal staging was pN0 in 20 patients (23.8%), pN1 in 7 (8.3%), pN2a in 40 (47.6%) and pN2b in 17 (20.2%). Overall 5-year survival and 5-year DFS rate was 55.9% 54.5%, respectively. There was no survival difference between patients with pN0-1, pN2a and pN2b (p = 0.345, figure). Neither pathologic N2 nor N2b was not a risk factor for overall survival rate (p = 0.418, 0.159, respectively) and DFS (p = 0.606, 0.650, respectively). In univariate analysis, there was no other significant clinicopathologic factors for survival and DFS. Eleven patients with neoadjuvant treatment showed a similar 5-year survival rate (43.6%) compared with patients with upfront surgery.

Kaplan-Meier survival curves for each nodal stage



Conclusion: Current work-up without invasive tools for cN2a in AP zone showed relatively high false-positive rate (32.1%). However, surgical outcome of cN2a in aortopulmonary zone was comparable. Upfront surgery should be considered in highly selected patients.

P1.14-46 GENOMIC PROFILING OF LARGE CELL NEUROENDOCRINE CARCINOMAS OF LUNG: A PATH TOWARDS INDIVIDUALIZED TREATMENT OPTIONS

N. Ngo, J. Elvin, J.-A. Vergilio, J. Killian, D. Lin, J. Ross

Foundation Medicine, Inc, Cambridge/United States of America

Background: Large cell neuroendocrine carcinomas of lung (LCNEC) are aggressive tumors which straddle the non-small cell / small cell lung carcinoma dichotomy. We performed comprehensive genomic profiling (CGP) to compare genomic alterations (GA) in LCNEC with those in small cell lung carcinoma (SCLC) and lung adenocarcinoma (LUAD). **Method:** FFPE tissue from 657 LCNEC, 2232 SCLC, and 28,052 LUAD underwent hybrid-capture based CGP to evaluate all classes of GA. Tumor mutational burden (TMB) was determined on 1.1 Mb of sequenced DNA and microsatellite instability (MSI) was calculated using 114 loci. **Result:** Genomically, LCNEC's tended to segregate towards either SCLC or LUAD (Table 1). *RB1* and *PTEN* inactivation, hallmarks of SCLC, often co-occurred and were detected in 38% and 10% of LCNEC, respectively. These cases were also enriched for other "SCLC" alterations, including *CCNE1, NOTCH1, SOX2, FGFR1. KRAS, STK11*, and *CDKN2A/B* alterations, hallmarks of LUAD, often co-occurred and were each detected in 15% of LCNEC. These cases were enriched for other "LUAD" alterations, including *SMARCA4, ATM, NKX2-1, KEAP1*. Only 20 of 657 (3%) LCNEC had co-occurring *RB1* and *KRAS* alterations. 20 of 657 (3%) LCNEC carried *EGFR* activating alterations. GA involved other receptor tyrosine kinases (*ALK, ERBB2/3, FGFR1/2/3, KIT, MET, NTRK1/2/3, PDGFRA/B, RET, ROS1*), and *PI3K, MAPK*, and *CCND1* pathway genes. 17% and 49% of LCNEC had TMB of ≥20 and ≥10 mut/Mb, respectively. 0.2% of LCNEC were MSI-High, and 19.4% were PD-L1 positive.

COMPARISON OF GENOMIC PROFILES						
Tumor Type	SCLC		LUAD		LCNEC	
Number of Cases	2232		28,052		657	
TMB ≥ 10 mut/Mb	41.6%		31.5%		48.7%

POSTERS

Conclusion: Treatment for LCNEC is not standardized and often requires choosing between "SCLC" or "NSCLC" chemotherapy regimens based on clinical impression and anecdotal evidence. CGP can help inform these crucial decisions. Identification of actionable GA will enable use of targeted agents as alternatives or adjuncts to chemotherapy (Table 2). Immunotherapy is an important option, as a significant proportion of LCNEC patients have high TMB or PD-L1 positive tumors.

P1.14-47 CTDNA NGS FOR GUIDING CRIZOTINIB TREATMENT IN ALK-REARRANGED ADVANCED NSCLC PATIENTS (PTS)

Y. He[1], J. Zhao[2], C. Liu[3], R. Chen[3], X. Xia[3]

[1]*Daping Hospital, ChongYing/China,* [2]*Beijing Cancer Hospital, Beijing/China,* [3]*Geneplus-Beijing Institute, Beijing/China*

Background: FISH and IHC are commonly used and the golden standard for testing *ALK* rearrangement. However, they provide no information on fusion types or mutation status of other genes, which could be important prognostic factors. In addition, a tissue biopsy is not always applicable/preferred by pts. **Method:** 43 *ALK*-rearranged treatment naïve advanced NSCLC pts were included. *ALK*-rearrangement was confirmed by ctDNA NGS with a panel of 59 tumor-related genes in 25 pts (ctDNA arm) and by IHC/FISH/tissue NGS in 18 pts (control arm). All pts received crizotinib as first-line therapy. PFS was estimated using Kaplan-Meier method and compared using log-rank test. **Result:** On average, Pts in ctDNA arm were significantly older at diagnosis than pts in the control arm (56 vs. 45, p = 0.02), indicating the preferability of ctDNA NGS in elderly pts. Though older, pts in ctDNA arm had a similar mPFS with pts in the control arm (8 vs. 10 mo, p = 0.9). *ALK* fusion types in ctDNA arm and their associated statistics were listed in Table 1. Concomitant mutations were identified in 15 genes in 9 pathways. Frequently mutated pathways include p53 (in 8 pts) and DNA repair pathways (in 3 pts). Mutations in DNA repair pathway (5 vs. 10 mo, p = 0.06), high frequency of *EML4-ALK* (>= 1.5%) (6 mo vs. NR, p = 0.06), and bone metastasis (6 vs. NR, p = 0.05) were associated with shorter mPFS.

Table 1. ALK fusion types and associated statisticss

ALK fusion types	# of pts	(Median) age at diagnosis (year)	(m)PFS (mo)	Average # of mutations per pt
V1	11	52	10	1.5
V3	10	61	6	2.8
V2	1	60	-	1
V5'	1	65	-	1
V7	1	49	3	2
DCTN1-ALK	1	47	-	2

Conclusion: Information on ALK fusion types, concomitant mutations, and mutation frequencies provided by NGS could be valuable prognostic factors and deserves further investigation. ctDNA NGS could be used as an effective alternative to identify *ALK*$^+$ pts, especially for elderly pts, when tissue biopsy is inapplicable or not preferred.

Keywords: crizotinib, ctDNA, ALK

P1.14-48 WHOLE EXOME SEQUENCING (WES) IN NON-SMALL CELL LUNG CARCINOMA (NSCLC): IDENTIFICATION OF NOVEL BIOMARKERS

V. Singh[1], A. Katiyar[2], P. Malik[3], A. Mohan[3], H. Singh[2], D. Jain[1]

[1]*All India Institute of Medical Sciences, new delhi/India,* [2]*Indian Council of Medical Research - All India Institute of Medical Sciences, Computational Genomics Centre, New Delhi/India,* [3]*All India Institute of Medical Sciences, New Delhi/India*

Background: Significant advancement has been made in the treatment of patients with pulmonary adenocarcinoma (ADC) on the basis of the molecular profile. However, no such molecular target exists for squamous cell carcinoma (SCC) or small cell lung cancer (SCLC). WES has been in wide use for the discovery of new genetic markers, which may offer more information for the development of personalized medicine for all subtypes of lung cancer. The aim of the current study is to find out novel genetic markers for NSCLC which can be used as a universal biomarker for the treatment. **Method:** WES of 20 advanced NSCLC patients (10 ADC and 10 SCC) was done on the Illumina HiSeqX10 with paired end 151bp chemistry. The Male: female ratio was 5.6:1 and a median age 56 years. Only 3 patients were non-smoker and in one case smoking history was unknown. 75% of patients were present with co-morbidities, all patients were either in stage III or IV and performance status was either 1 or 2. **Result:**

Table 1: WES data statistics and the total number of variants identified:

S.No	WES data	Numbers

14	Average synonymous SNPs	11607
15	Average variations reported in databases	20269
16	Unknown mutations	659

WES data statistics has been depicted in table 1 including number of variants identified. After excluding common variants (MAF > 0.05), a total of 23 rare variants (0 < MAF < 0.01), *possibly linked to lung carcinoma was identified in the exome. Further stringent filtering showed allele frequencies of mutations in GPRIN2 (G protein-regulated inducer of neurite outgrowth 2), KCNJ18 (potassium voltage-gated channel subfamily J member 18) and TEKT4 (Tektin 4) genes which were present in all the cases.* The variations of amino acid substitutions were i) *TEKT4*: p.A223T and p.A405T (rs75603622); ii) *GPRIN2*: p.V241M (rs9422022), p.V47M (rs3127819); iii) *KCNJ18*: p.L211F (rs1435776313), p.I262S (rs1450551937) **Conclusion:** Although the mechanism of *GPRIN2*, *KCNJ12* and *TEKT4* in tumorigenesis is unclear; our results suggest that these may play a major role in NSCLC and it is worth to be investigated in future. Validation of these genes is under process.

P1.14-49 THE ROLE OF CTDNA DETECTION (LIQUID BIOPSY) IN PATIENTS WITH NSCLC

A. Zhabina[1], F. Moiseenko[2], M. Stepanova[2], V. Moissenko[2], A. Mjslik[2], N. Volkov[2], D. Krylova[2], N. Rysev[2]

[1]*St. Petersburg Clinical Research Center of Specialized Types of Care (Oncology), St. Petersburg/Russian Federation,* [2]*Saint-Petersburg Clinical Research Center of Specialized Types of Medical Care (Oncological), Saint-Petersburg/Russian Federation*

Background: The analysis of the circulating tumor DNA has attracted interest in the last 6-7 years and is being actively introduced into everyday practice. "Liquid biopsy" will eliminate the shortcomings of routine biopsy, accelerate the time of clinical decision-making, to conduct a more comprehensive study of the tumor in terms of personification of treatment and development of resistance. Results of liquid biopsy provide real-time information on the molecular pathologies and morphological features, identify early resistance to treatment and can modify the therapy regimen. **Method:** From 2016 to 2018 year we studied patients with NSCLC. The ctDNA was detected in the baseline plasma samples and then every 2 months after treatment started by RT-PCR. The aim of the study was to assess the relationship between the presence of EGFR positive ctDNA in tumor tissue and blood plasma **Result:** The study was 1050 patients, 462 cases are represented by adenocarcinoma of NSCLC. EGFR mutations was detected in 145/462 cases (31.38%). Among 145 person 109 were women (72.5%) and 36 were men (24.8%). The mean age was 65.18 (35 - 85). The mutational profile was heterogeneous: ex19del – 94/145 (63.8%), L858R – 47/145 (32.4%), others – 4/145 (2.8%). The results of the study demonstrated that analyzing ctDNA from plasma is feasible for the identification of EGFR mutations with mutation status concordance in 79 matched samples of 53.2% (EGFR mutation positive was detected in 42/79 samples). The T790m resistance mutation was detected in the baseline plasma sample in 8/79 cases (10.1%). EGFR-activating mutations were identified in 13/56 (23.3%) plasma samples after 2 months of Gefitinib. Among the 42 patients in whom the CtDNC was detected in the baseline, after 2 months of therapy was determined only in 6/42 (14.2%). Thus, the disappearance of the mutation was observed in 85.71% (36/42). Mediana of PSF for patients who retained ctDNA after 2 months was 16.25 months (CI 95% 11.24 – 19.94), and for patients in whom the mutation disappeared after 2 months was 21.10 (CI 19.21 - 22.98). Currently the study of molecular genetic markers in blood plasma are continuing. The relationship between effectiveness of treatment and ctDNA detection in blood samples will be analyzed. **Conclusion:** This new, minimally invasive method has the potential to change the prognostic and predictive landscape for lung cancer genotyping and patient management, which will improve treatment outcomes

P1.14-50 A PHASE 2 TRIAL OF CABOZANTINIB IN ROS1-REARRANGED LUNG ADENOCARCINOMA

R. Guo[1], I. Preeshagul[1], A. Schoenfeld[1], C. Mccarthy[1], A. Makhnin[1], A. Plodkowski[1], M. Ginsberg[1], M. Davare[2], L. Delasos[3], R. Somwar[1], M. Arcila[1], G. Riely[1,4], N. Rekhtman[1], M. Ladanyi[1], M. Kris[1,4], A. Drilon[1,4]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Oregon Health and Science University, Portland/United States of America,* [3]*UConn Health, Farmington/United States of America,* [4]*Weill Cornell Medical College, New York/United States of America*

Background: To date, no ROS1 inhibitor is approved for the treatment of *ROS1*-rearranged lung cancers after progression on crizotinib. Progression on crizotinib can be mediated by the acquisition of *ROS1* kinase domain mutations (e.g. $ROS1^{G2032R}$ or $ROS1^{D2033N}$). Cabozantinib is a highly potent ROS1 tyrosine kinase inhibitor that has superior activity over lorlatinib against these mutations. We evaluated the activity of cabozantinib in patients with *ROS1*-rearranged lung cancers on a phase 2 trial. **Method:** In this single-center, open-label, Simon two-stage, phase 2 study, eligible patients had *ROS1*-rearranged unresectable/metastatic non-small cell lung cancer, a Karnofsky performance status >70%, and measurable disease. *ROS1* fusion was identified by local testing in a CLIA-compliant environment. Cabozantinib was dosed at 60 mg once daily. The primary endpoint was objective response (RECIST v1.1). In the first stage of this trial, 1 response was required to move to the second stage. Secondary endpoints included safety. **Result:** Six patients received cabozantinib in the ongoing first stage of this study. All patients had ≥1 prior ROS1 inhibitor. The median age was

59 years; all were never smokers. The best response to therapy was: 1 partial response (-92%, confirmed), 1 unconfirmed partial response (-31%), and 4 stable disease. All patients had disease regression (-7 % to -92%); no patients had primary progressive disease. The only patient with a confirmed partial response was a patient whose cancer acquired a $ROS1^{D2033N}$ solvent front mutation after crizotinib. None of the other five ROS1 inhibitor pre-treated patients (who did not have a confirmed response) had a known on-target acquired resistance mutation in their cancer. After progression on cabozantinib (9.1 months after therapy initiation), the patient whose cancer harbored the $ROS1^{D2033N}$ mutation acquired a MET^{D1228N} kinase domain mutation on paired sequencing of pre-cabozantinib and post-progression tumor. The most common grade 3 treatment-related adverse events were hypertension (50%), and mucositis, palmar-plantar erythrodysesthesia, and hypophosphatemia (each in 17%). Most patients (83%) required a dose reduction. **Conclusion:** Cabozantinib can re-establish disease control in *ROS1*-rearranged lung cancers after progression on a prior ROS1 inhibitor. The first stage of this ongoing trial met its prespecified endpoint for efficacy to move into the second stage. Response was only observed in the setting of a known *ROS1* kinase domain resistance mutation.

Keywords: lung adenocarcinoma, cabozantinib, ROS1

P1.14-51 LOC440416 LNCRNA-MEDIATED CELL CYCLE ARREST REGULATED CRIZOTINIB-INDUCED HEPATOTOXICITY

X. Chen

Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, hangzhou/China

Background: To evaluate crizotinib-induced hepatotoxicity in mice and investigate the role of cell cycle arrest mediated by LOC440416lncRNA during liver injury, furthermore, to provide experiment evidence for screening available hepar protector and expending the clinical application of crizotinib. **Method:** The levels of blood serum ALT, AST, LDH were detected using ICR mouse model. Liver samples of mouse fixed were stained with hematoxylin and eosin for histopathological analysis. The cell inhibition rate of primary hepatocytes was detected by MTT assay.Cell cyclin distribution was detected by flow cytometry(FCM) and the expressions of cell cycle protein cyclinB1 and CDK1 were detected with Westblot after mouse primary hepatocytes were treated with 2.5 μM, 5μM, 10 μM crizotinib for 48h. Apoptosis was evaluated by DAPI staining and PI staining for flow cytometry and the expressions of cell apoptosis protein c-PARP and c-caspase-3 were detected with Westblot. LncRNAs regulating hepar cell cycle arrest were screened using Microarray Chip technique after primary hepatocytes were treated with 5μM crizotinib for 24h. The expressions of cell cyclin protein cyclin B1 and CDK1 were tested with Westblot, after siRNA gene silencing technology was used to knock down LOC440416lncRNA. **Result:** The levels of blood serum ALT, AST, LDH elevated significantly in mice after crizotinib treatment.Slices of liver by HE staining for analysis showed cellular swelling of hepatocytes, nucleolus staining deepened and karyokinesis phenomenon with inflammatory cell infiltrate. *In vitro*, MTT assay showed crizotinib-induced hepatotoxicity in mouse primary hepatocytes presented dose-dependented and IC50 value was 4.6μM. DAPI staining exhibited clear chromatin condensation, fragment and apoptotic bodies and FCM showed sub-G1 apoptosis peak was formed after 5μM and10 μM crizotinib treatment. Westblot demonstrated caspase-3 activation and PARP cleavage. All these data revealed that crizotinib-induced hepatotoxicity was through the process of apoptosis. FCM showed the population of G2/M phase elevated, these of G0/G1 phase decreased and G2/M arrested while the concentration of crizotinib was increased. Reduced protein levels of Cyclin B1 and increased protein level of CDK1 were also observed with Westblot. After crizotinib treatment, sixteen elevated or decreased lncRNAs were found more than ten times separately by terms of Microarray Chip technique. LOC440416lncRNA regulating cell cycle arrest was screened by Real-time PCR. The restoration of reduced Cyclin B1, increased CDK1 expressions, even if hepatocytes were treated with crizotinib, after siRNA gene silencing technology was used to knock down LOC440416lncRNA. **Conclusion:** Crizotinib-induced hepatotoxicity was demonstrated by experiment in vivo and *in vitro*. Cell cyclin G_2/M check point arrest accompanied with decreased expression of cyclin B1 protein and increased expression CDK1, mediated by LOC440416 lncRNA, could be the possible mechanism.

P1.14-52 CLINICAL RESPONSE TO OSIMERTINIB IN A PATIENT WITH METASTATIC NSCLC HARBORING EGFR A763_Y764INSFQEA EXON 20 INSERTION MUTATION: A CASE REPORT

G. Bravo Montenegro, C. Kim

Georgetown University Hospital, Washington/United States of America

Background: Epidermal growth factor receptor (*EGFR*) exon 20 insertion mutations represent approximately 4-10% of EGFR-mutant non-small-cell lung cancer (NSCLC). The majority of *EGFR* exon 20 insertion mutations do not respond to approved EGFR tyrosine kinase inhibitors (EGFR-TKIs). Preclinical data suggest that EGFR A763_Y764insFQEA mutation is associated with sensitivity to EGFR-TKI therapy. A few case reports have shown that patients with this rare variant of *EGFR* exon 20 insertion mutation may respond to first- and second-generation EGFR-TKIs. However, efficacy of the third-generation EGFR-TKI osimertinib against the EGFR A763_Y764insFQEA mutation has not been described. Here, we present a patient with metastatic NSCLC harboring EGFR A763_Y764insFQEA alteration treated with osimertinib. **Method:** A 56-year-old never-smoker Asian female presented with complete atelectasis of the left upper lobe, a left circumferential pleural effusion, and diffuse osseous sclerotic lesions. Pathology confirmed the diagnosis of metastatic lung adenocarcinoma. Circulating tumor DNA (ctDNA) assay utilizing InVisionSeq™ Tagged-Amplicon next-generation sequencing (NGS) identified EGFR A763_Y764insFQEA, MET amplification, and TP53 G266*. The patient was started on osimertinib 80 mg once a day. Later, tumor NGS came back positive for EGFR A763_Y764insFQEA, TP53 G266*, and BRCA-2 A2351G. **Result:** The patient's symptoms of cough and shortness of breath started to improve shortly after initiation of osimertinib. A CT scan of the thorax and abdomen obtained 5 weeks after starting osimertinib showed improvement in aeration of the previously collapsed left upper lobe, visualization of a 1.9 x 1.4 cm spiculated left upper lobe lung mass, improved infiltrative soft-tissue in the left hilum, and improved partially loculated left pleural effusion, suggesting response to osimertinib. **Conclusion:** In this patient with the EGFR A763_Y764insFQEA mutation, osimertinib has shown effectiveness as monotherapy, suggesting it could serve a viable therapeutic treatment option in NSCLC with this rare variant of exon 20 insertion mutations. Future studies should validate this finding.

P1.14-53 CO-OCCURRING CDKN2A/2B ALTERATION IS ASSOCIATED WITH POORER SURVIVAL IN ALK-POSITIVE LUNG CANCER

J.Y. Ha, S. Yoon, D.H. Lee, J. Choi, S.-W. Kim

Asan Medical Center, University of Ulsan College of Medicine, Seoul/Korea, Republic of

Background: Anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitors (TKIs) have shown promising clinical outcomes for ALK-positive (ALK+) lung cancer patients. However, clinical outcomes are varied, distinct mechanisms have been suggested for different ALK fusion variants or co-occurring mutations in response to various TKIs. We analyzed whether variants or co-occurring mutations influence the outcome of AKL TKI treatment in ALK+ non-small-cell lung cancer (NSCLC). **Method:** Between March 2017 and October 2018, 489 NSCLC tumor specimens were examined with OncoPanel AMC version3 which is a NGS based assay for the detection of single-nucleotide variants, insertions, deletions, copy number alterations and structural variants across 382 genes. 43 patients were identified as having ALK rearrangement. And 37 patients received ALK TKI treatment. Progression free survival (PFS) and overall survival (OS) were analyzed respectively according to ALK variants and other co-occuring mutations. **Result:** Among 37 patients with ALK+ NSCLC, 32 (86.5%) of patients received crizotinib, and 5 (13.5%) with alectinib as first ALK TKI treatment. The most frequent ALK variant was variant 3a/b in 13 patients (35.1%), followed by variant 1 in 10 patients (27.0%), variant 5 in 4 patients (10.8%), variant 2 in 3 patients (8.1%), and others in 7 patients (18.9%). The similar median PFS was observed in patients ALK variant 3 and non-variant 3 regardless of first ALK TKI treatment strategy (crizotinib, 18.9 vs. 15.2 months, p=0.35; alectinib, both not reached). As a co-occurring mutation, TP53 mutation was detected in 17 (45.9%) patients. And

there was no statistical difference in PFS or OS between the wild type and TP53 mutation group [PFS 18.2 vs 15.3 months, p=0.92; OS 62.1 vs 62.2 months, p=0.44]. CDKN2A/2B alteration was the second most common mutation and observed in 9 (24.3%) patients. Median PFS and OS in ALK-CDKN2A/2B co-mutated patients were lower than wild type patients [PFS 15.3 months (95% CI: 8.1-22.5) versus 18.2 months (95% CI: 13.0–23.4), P=0.064, OS 26.7 months (95% CI: 14.2–39.3) versus not reached, P=0.022]. **Conclusion:** In ALK+ NSCLC, having co-occurring CDKN2A/2B alteration was associated with a poorer OS when treated with an anti-ALK agent.

Keywords: ALK, CDKN2A/2B, TKI

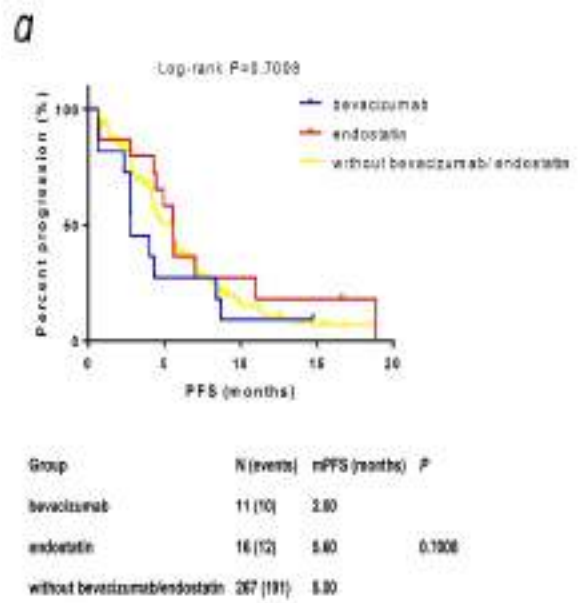
P1.14-54 PREVIOUS THERAPY STRATEGY IMPACT ON EFFICIENCY OF ANLOTINIB HYDROCHLORIDE AS 3RD LINE TREATMENT: A SUBGROUP ANALYSIS OF ALTER0303 TRIAL

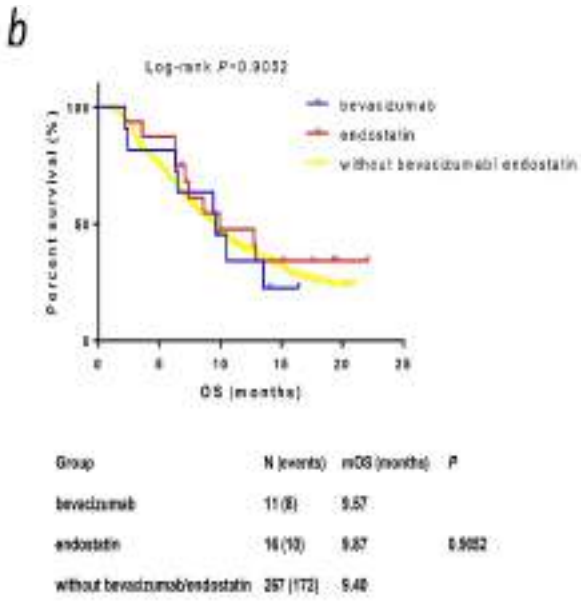
S. Yang, L. Wang, Q. Wang

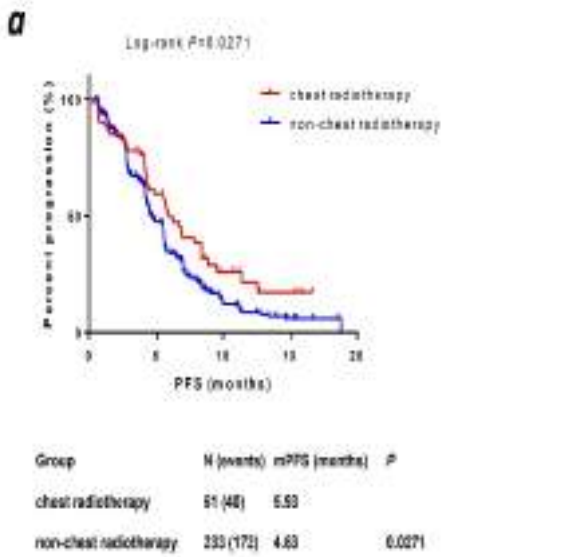
The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China

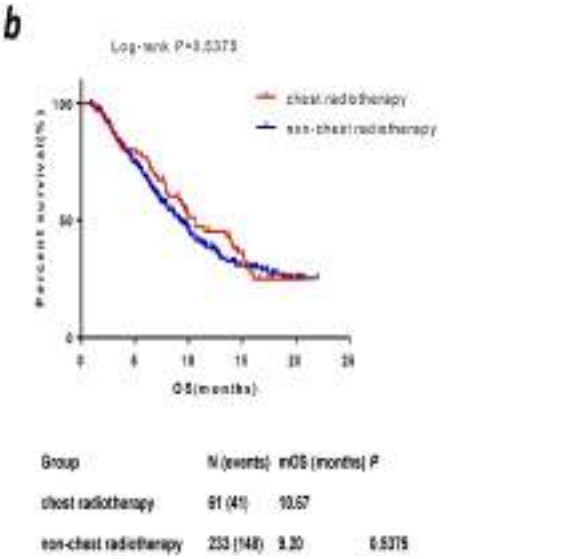
Background: Lung cancer remained one of the deadest cancers throughout worldwide. ALTER0303 trial revealed anlotinib might be used as a third-line or further treatment in non-small-cell lung cancer patients. While previous therapy strategy would have impact on efficiency of anlotinib still remained unknown. **Method:** The subgroup of patients in ALTER0303 were analyzed by using Kaplan-meier estimates, Pearson X^2 or Fisher exact test. **Result:** There is no statistical significance on progression-free survival (PFS) and overall survival (OS) among patients in different previous antiangiogenic treatments groups. Patients in the chest radiotherapy (CRT) group had longer median PFS than non-CRT group (5.93m vs. 4.63m, *P*=0.027). No matter what kind of epidermal growth factor receptor tyrosine kinase inhibitors (EGFR TKI) and chemotherapy regimens used previously, all patients gained longer PFS from anlotinib. While only patients treated with vinorelbine/platinum in EGFR wild type group, pemetrexed/platinum, vinorelbine/platinum and gefitinibin in EGFR mutation group, EGFR TKI used as the first line group could benefit from anlotinib on OS. When the OS was calculated from the time of diagnosis to death, anlotinib may improve about 6 months median OS (33.8m vs.27.8m, *P*<0.001) compared to placebo with HR (95%CI): 0.77 (0.60, 1.00).

Figure 1. Kaplan-Meier estimate of overall and progression-free survival among different previous antiangiogenic therapy subgroup in patients treated with anlotinib.









Conclusion: This study indicated previous bevacizumab or endostatin treatments had no impact on the efficiency of anlotinib. Patients with CRT history benefited more from anlotinib on PFS. EGFR TKI and chemotherapy treatments history had more impact on OS than PFS in patients treated with anlotinib compare to placebo.

Keywords: non-small-cell lung cancer, Anlotinib, antiangiogenic therapy

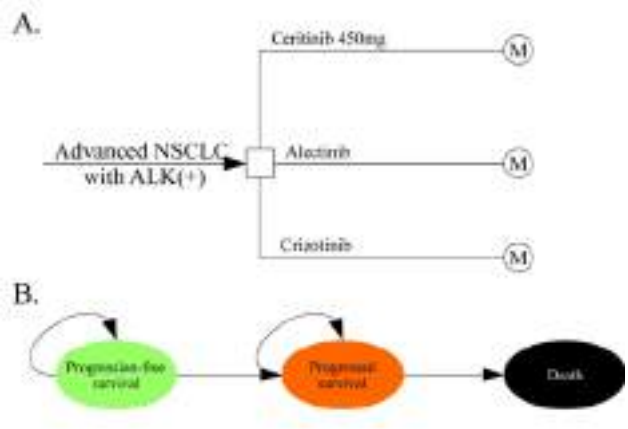
POSTERS

P1.14-55 COST-EFFECTIVENESS OF CERITINIB AND ALECTINIB VS CRIZOTINIB IN FIRST-LINE ANAPLASTIC LYMPHOMA KINASE-POSITIVE ADVANCED NSCLC

B. Wu[1], Y. Xie[2], H. Li[3]

[1]*Ren Ji Hospital, South Campus, School of Medicine, Shanghai Jiaotong University, Shanghai, China, Shanghai/China,* [2]*China Pharmaceutical University, Nanjing/China,* [3]*Analysis Group Inc, Beijing/China*

Background: The recently completed ASCEND and ALEX trials demonstrated that ceritinib and alectinib improved progression-free survival and overall survival in patients with anaplastic lymphoma kinase (ALK) arrangement non-small-cell lung cancer (NSCLC). However, the long-term economic outcomes of using ceritinib and alectinib versus crizotinib is still unclear. The aim of this analysis was to evaluate the cost-effectiveness of ceritinib and alectinib versus crizotinib in the Chinese setting. **Method:** A Markov model was developed to project the economic and health outcomes of treatment of advanced NSCLC with ceritinib, alectinib or crizotinib. The model used the partition survival methods and three health states: progression-free, post-progression, and death. Network meta-analysis was performed to calculate the hazard ratios of ceritinib and alectinib versus crizotinib by pooling published trials. Costs and utility values were obtained from literature. One-way and probabilistic sensitivity analyses were carried out to determine the robustness of the model outcomes. The primary outputs of the model included the total cost, life-years (LYs), quality-adjusted LYs (QALYs), and incremental cost-effectiveness ratio (ICER).



Result: Treatment with ceritinib and alectinib versus crizotinib yielded additional 1.01 and 1.00 QALYs, and incremental costs of US$ 14,217 and 62,168, resulting in an incremental cost-effectiveness ratio of US$14,017 and 62,168/QALY. Drug costs and probabilities of PFS and OS were the main drivers of the model in the one-way sensitivity analysis. From the probabilistic sensitivity analysis, ceritinib and alectinib had a 100% and 0% probability of being cost effective at a willingness-to-pay threshold of US$27,351/ QALY (3× the per capita gross domestic product of China in 2017).

Tab 1. Summary of cost ($) and outcome results in base-case analysis.

Strategy	Cost	Progression-free LYs	Overall LYs	QALYs	Incremental cost per QALY*
Crizotinib	55,204	1.30	4.56	1.99	NA
Alectinib	117,372	2.89	5.45	2.99	62,168
Ceritinib	69,420	3.19	4.94	3.01	14,017

Conclusion: Our results indicate that compared with crizotinib and alectinib, ceritinib is a cost-effective option for treatment-naïve patients with ALK-positive advanced NSCLC.

Keywords: cost-effectiveness, Ceritinib+Alectinib vs Crizotinib, advanced NSCLC

P1.14-56 THE DYNAMIC RANGE OF MUTANT ALLELE FRACTION DETECTED IN CTDNA FROM PATIENTS WITH NSCLC: CLINICAL EXPERIENCE DATA AND CLINICAL IMPLICATIONS

S. Boorgula, J. Mayer, D. Fisher, V. Singh

Biocept, San Diego/United States of America

Background: The detection of both activating and resistance mutations in the circulating tumor DNA (ctDNA) fraction of total cell free DNA (cfDNA) isolated from plasma in patients with NSCLC has gained widespread adoption and clinical practice guideline recommendations. However, the vast majority of cfDNA in blood samples is derived from non-cancerous tissue or white blood cells (WBCs). In patients with NSCLC, ctDNA must be distinguished from cfDNA. Studies have suggested that the contribution of non-tumor genetic material in circulation is greater than 90% whilst the DNA derived from tumor or circulating tumor cells (CTCs) is < 1%. Hence the ability to accurately identify mutations in patients with NSCLC, who would potentially benefit from targeted therapy as well as for monitoring for both emergence of resistance, recurrence and tumor burden, require assays to consistently and reliably detect low level mutations. Additionally, blood collection tubes should maximally stabilize cells to prevent excess breakdown of WBCs that would significantly increase the amount of cell free non-tumor DNA in the plasma fraction leading to potential false negative results for mutations analyzed in patients with NSCLC. **Method:** Patient samples were collected in CEE-Sure™ blood collection tubes to minimize the non-tumor cfDNA content. Plasma was removed from the blood samples and circulating nucleic acid was extracted. The plasma fraction was then used in the highly sensitive EGFR, BRAF, and KRAS Target-Selector™ assays. The Target-Selector™ assays utilize forward and reverse primers and a Target-Selector™ probe to specifically block wild-type amplification of cfDNA, and selectively enrich for mutant sequences (ctDNA). Sanger sequencing of the amplified Target-Selector™ product is used to confirm presence of the mutation. **Result:** A total of 1410 NSCLC patient samples were analyzed for EGFR, 877 for BRAF and 300 for KRAS. Overall mutations were detected in 28% of cases. The dynamic range of the mutant allele frequency (MAF) was 0.05% to 77%. For EGFR mutations, 23% of total mutations per sample were detected at <1% and for individual EGFR alterations (del19, L858R, T790M) within a sample, 74% were detected at <1% MAF. 37% of cases were positive for BRAF and 41% positive for KRAS at <1% MAF. 3% of EGFR mutant NSCLC, 10% of individual EGFR alterations and 11% of BRAF mutations were detected at <0.1% MAF. **Conclusion:** The consistent detection of mutations at a lower MAF of <1% corresponds to previously published biological thresholds of ctDNA in patients with cancer against an excess of non-tumor cfDNA. The ability of an assay to detect mutations consistently at <1% and <0.1% as demonstrated, is an important performance characteristic, as 26%, 47% and 41% of patients with NSCLC harbor mutations at <1% for EGFR, BRAF and KRAS respectively. This has potential clinical implications regarding patient qualification for targeted therapies and monitoring. The blocking of amplification of non-tumor cfDNA component allows for a more sensitive analysis of ctDNA.

P1.14-57 POST-ENSARTINIB OUTCOMES IN REFRACTORY ANAPLASTIC LYMPHOMA KINASE (ALK)-REARRANGED NON-SMALL CELL LUNG CANCER (NSCLC)

H. Kim[1], P. Vu[2], K. Harrow[3], C. Liang[3], G. Selvaggi[3], E. Weihe[2], W. Mitchell[2], L. Bazhenova[4], S. Patel[2]

[1]*UC San Diego, La Jolla/United States of America,* [2]*UC San Diego Moores Cancer Center, La Jolla/United States of America,* [3]*Xcovery Holdings, Inc., Palm Beach Gardens/United States of America,* [4]*University of California San Diego (UCSD) Moores Cancer Center, La Jolla/United States of America*

Background: The effectiveness of the next-generation ALK inhibitor, ensartinib, in refractory ALK-rearranged, advanced NSCLC patients represents a promising therapeutic option. With the advent of novel ALK inhibitors utilized in sequence, the survival of patients with ALK-rearranged tumors has improved dramatically. This case series serves to compare tumor response rates and long-term survival outcomes among four patients treated with ensartinib over the course of four years at our institution. **Method:** We conducted an open-label, first-in-human, IRB approved phase 2 clinical trial using

single-agent ensartinib at a dose of 225 mg once daily. Patients were selected from UC San Diego Moores Cancer Center with ALK-rearranged NSCLC who had previously progressed on crizotinib. Other prior therapies included platinum/pemetrexed chemotherapy (n=3) and pembrolizumab (n=1). Objective response was determined every eight weeks according to RECIST 1.1. Patients were treated until disease progression or unacceptable toxicity. Circulating tumor DNA (ctDNA) sequencing was obtained in 3 patients at baseline and 2 patients at the time of progression. **Result:** Four patients were enrolled (age range, 43-61 years) and all had brain metastases at baseline. All four patients achieved an objective partial response to ensartinib, including one patient with an acquired ALK F1174V crizotinib resistance mutation. Intracranial responses included one partial response, two stable disease, and resolution of a non-target lesion in another patient. The median progression free survival was 12.5 months (range, 8-15 months) and the median decrease in tumor size was 42% (range, 39-48%). Primary sites of disease progression included lung (n=1), brain (n=2), both lung and brain (n=1). No somatic alterations were identified in the two patients who received post-ensartinib ctDNA sequencing. At progression, all patients received brigatinib as subsequent therapy with clinical benefit; one received lorlatinib after brigatinib failure and response is ongoing. Median post-ensartinib survival was 27 months (range, 20-38 months). Two patients remain alive 27 and 95 months after first anti-cancer therapy. The most common adverse events with ensartinib were mild rash, diarrhea, and fatigue that did not require dose reduction. **Conclusion:** Ensartinib is well tolerated and has clinical activity in advanced ALK-rearranged NSCLC patients with brain metastases, despite previously progressing on crizotinib, with durable post-ensartinib survival on subsequent next-generation ALK inhibitors such as brigatinib and lorlatinib. (Trial funded by Xcovery Holdings, Inc.; ClinicalTrials.gov number: NCT01625234)

Keywords: ALK, ensartinib, NSCLC

P1.14-58 A PHASE II STUDY TO EVALUATE NEOADJUVANT OSIMERTINIB FOR SURGICALLY RESECTABLE, EGFR-MUTANT NON-SMALL CELL LUNG CANCER

J. Rotow[1], A. Urisman[1], C. Mccoach[1], T. Jahan[1], T. Bivona[1], K. Jones[1], A. Gupta[1], H. Do[1], J. Riess[2], D. Aisner[3], R. Doebele[4], D. Jablons[1], J. Kratz[1], C. Blakely[1]

[1]*University of California, San Francisco, San Francisco/United States of America,* [2]*UC Davis Comprehensive Cancer Center, Sacramento/United States of America,* [3]*University of Colorado, Aurora/United States of America,* [4]*University of Colorado Denver, Aurora/United States of America*

Background: The third-generation Epidermal Growth Factor Receptor (EGFR) tyrosine kinase inhibitor (TKI) osimertinib is well-tolerated and effective for first-line treatment of metastatic EGFR-mutant non-small cell lung cancer (NSCLC). The efficacy of osimertinib in the treatment of early stage EGFR-mutant NSCLC, however, is unknown, and cytotoxic chemotherapy is considered the standard of care when systemic therapy is necessary for these patients. Neoadjuvant chemotherapy is an established therapeutic modality in locally-advanced NSCLC, in which a major pathologic response is associated with improved survival. Neoadjuvant use of targeted therapies in oncogene-driven NSCLC may offer the dual advantages of increased response rates and of more favorable toxicity profiles compared to cytotoxic chemotherapy, and also provides the opportunity to identify mechanisms underlying tumor cell persistence despite optimal oncogene-targeted therapy. **Method:** This ongoing phase II, multi-institution study aims to enroll 27 patients with surgically resectable stage I-IIIA EGFR-mutant NSCLC. Patients are treated with one to two months of osimertinib 80 mg orally daily followed by surgical resection. The primary endpoint is major pathologic response (mPR) rate, defined as less than 10% residual viable tumor at surgical resection. Secondary endpoints include safety assessment, unanticipated delays to surgery, surgical complication rate, pathological complete response rate (pCR), unconfirmed objective response rate (ORR), rate of lymph node downstaging, disease-free survival, and overall survival. Tumor biopsies are obtained prior to osimertinib treatment in order to permit comparative correlative studies between pre- and post-osimertinib treated tumors. This includes genomic and transcriptomic analyses, evaluation of tumor immune cell infiltrates, and development of patient-derived model systems for functional validation studies. **Result:** As of March 2019, five patients with EGFR-mutant NSCLC (2 stage IIIA, 1 stage IB, 2 Stage IA) have been enrolled and treated with osimertinib for an average of 56 days prior to surgical resection. Restaging imaging prior to surgical resection demonstrated an unconfirmed radiographic partial response in three patients (60% ORR) and stable disease in two patients (100% disease control rate). The mPR rate is 20% (1 of 5). No pCR's were observed. One patient demonstrated lymph node downstaging from N2 to N0. Treatment was well-tolerated without SAEs and all patients proceeded to surgical resection without unscheduled delay or surgical complications. Genomic and immunophenotyping analyses are underway and will be reported. **Conclusion:** Preliminary data from this phase II study indicates that neoadjuvant osimertinib treatment in surgically-resectable, EGFR-mutant NSCLC is well-tolerated and can induce pathological responses and downstaging of disease prior to surgery.

Keywords: Targeted therapy, EGFR, neoadjuvant

P1.14-59 CLINICAL IMPLICATIONS OF THE PHARMACOKINETICS OF DACOMITINIB CO-ADMINISTRATION WITH H2-RECEPTOR ANTAGONISTS IN CANCER PATIENTS

S. Lin, W. Tan

Pfizer, San Diego/United States of America

Background: Dacomitinib (Vizimpro®) is a competitive, irreversible, small-molecule inhibitor of epidermal growth factor receptor (EGFR) and is currently approved for first-line treatment of patients with locally advanced or metastatic non-small cell lung cancer (NSCLC) with EGFR activating mutations. Similar to other EGFR inhibitors, the aqueous solubility of dacomitinib is pH dependent, with its highest solubility observed at acidic pH. Therefore, it is important to evaluate the potential impact of gastric pH-elevating agents on the pharmacokinetics (PK) of dacomitinib. Co-administration of a proton pump inhibitor (rabeprazole 40 mg once daily for 4 days) resulted in approximately a 40-50% decrease in dacomitinib exposure after a single 45-mg dose of dacomitinib. There was no effect on the extent of absorption of dacomitinib during treatment with a short-acting antacid (Maalox Maximum Strength). This report evaluated the effect of co-administration of histamine 2-receptor antagonists (H2RA) on dacomitinib PK based on a retrospective analysis of pooled PK data collected from clinical studies in patients treated with dacomitinib. **Method:** Data were drawn from 11 Phase 1, 2 and 3 clinical studies in advanced NSCLC or solid tumor patients. For each patient, steady-state trough concentrations ($C_{trough,\ ss}$) of dacomitinib after ≥14 days of consecutive dacomitinib dosing at a dose level of 15, 30, 45 or 60 mg once daily were measured at various times during the treatment period. Withinpatient comparison of a 45-mg dose of normalized dacomitinib$C_{trough,\ ss}$ between dacomitinib dosing alone and dacomitinib coadministered with an H2RA (cimetidine, famotidine, nizatidine and ranitidine) consecutively for ≥3 days was performed using a linear mixed effects model with time and treatment as fixed effects and patient within time as a random effect. **Result:** A total of 86 (5.9%) patients from the pooled patient studies received an H2RA. In this analysis, 16 patients had dacomitinib $C_{trough,ss}$ for both dacomitinib dosing alone and dacomitinib co-administered with an H2RA. The adjusted geometric mean ratio of a 45-mg dose of normalized dacomitinib $C_{trough,ss}$ following co-administration with an H2RA was 85.9% (90% confidence interval [CI]: 72.9%, 101.1%) relative to dacomitinib dosing alone. The 90% CI for the ratio includes 100%, suggesting no statistically significant difference between the reference and test groups (P>0.05). **Conclusion:** Co-administration of an H2RA is not expected to have a clinically relevant effect on dacomitinib exposure. In accordance with knowledge derived from other EGFR inhibitors, it is recommended that the time of dacomitinib dosing with an H2RA should be staggered to allow dacomitinib absorption at the time of lowest gastric pH and to minimize any potential impact from the concomitant use of an H2RA.

Keywords: NSCLC, histamine 2-receptor antagonist, dacomitinib

P1.14-60 STATINS OVERCOME RESISTANCE TO TYROSINE KINASE INHIBITORS IN PATIENT-DERIVED, ONCOGENE-DRIVEN NSCLC MODELS

W. Ma[1], E. Tian[1], Q. Li[1], S. Wei[1], C. Zhou[2], K. Yoneda[1], T. Li[1]

[1]*University of California Davis Comprehensive Cancer Center, Sacramento/United States of America,* [2]*University of California Davis, Department of Pathology, Sacramento/United States of America*

Background: Despite the improved efficacy of newer generation targeted TKIs, nearly all patients with EGFR- and ALK-driven NSCLC eventually acquire resistance and succumb to the refractory metastatic disease. Previous studies have shown that simvastatin has more potent antitumor effects compared to other statins. The objective of this study was to determine whether simvastatin could overcome TKI resistance using *in vitro* and *in vivo* NSCLC models. **Method:** Human NSCLC cell lines A549 (*KRAS* G12S), H3255 (*EGFR* L858R), and H1975 (*EGFR* L858R and T790M) were treated with simvastatin either alone or in combination with an TKI. Antitumor effect was measured by growth inhibition by MTS assay and expression of molecular targets by immunoblots. Malignant pleural effusion and biopsied tumors were collected under an IRB-approved protocol and used for primary cell culture and generation of patient-derived xenograft models in NSG mice. Mice implanted with H1975 xenografts were treated with vehicle, simvastatin, osimertinib, or both. Mice engrafted with an ALK-TKI resistant PDX were treated with vehicle simvastatin, brigatinib, or both. Tumor growth was measured every other day for 28 days or the tumor volume reached ~2 cm^3. Tumors were subjected to histomorphological assessment and immune blot analyses. All data are shown as mean ± standard deviation (SD). The two-sample t-test was used for continuous variables. All statistical tests were two-sided and a p-value less than 0.05 was considered statistically significant. **Result:** We found that simvastatin alone had a strong antitumor effect in tested NSCLC cell lines, regardless of tumor genotypes. Simvastatin and osimertinib combination showed synergistic cytotoxic effect in these NSCLC cell lines and several primary culture of patient's pleural effusion. Simvastatin alone reduced the tumor volume by 41% and 57% compared to controls in both the EGFR- and ALK-TKI resistant PDX models. In the H1975 xenograft model, simvastatin and osimertinib combination produced a greater reduction in tumor volume than osimertinib alone ($P < 0.01$). In an ALK TKI-resistant lung PDX model, simvastatin and brigatinib combination resulted in a greater reduction in tumor volume than brigatinib alone ($P < 0.01$) and showed a synergistic effect based on a simple multiplicative model of a fixed dose, two-drug combination. **Conclusion:** Simvastatin displays anti-tumor activity in multiple EGFR and ALK TKI resistant models, and preliminary analysis suggests potential synergism with the two tested TKIs (osimertinib and brigatinib). Further study is needed to characterize the molecular mechanisms responsible for the statin-mediated anti-tumor effect and its interactions with TKIs.

Keywords: statin, oncogene-driven non-small cell lung cancer, resistance

P1.14-61 EGFR INHIBITORS PLUS BEVACIZUMAB ARE SUPERIOR COMPARED TO EGFR INHIBITOR MONOTHERAPY IN ADVANCED EGFR+ NSCLC PATIENTS WITH BIM DELETIONS

A.F. Cardona[1,2,3], O.G. Arrieta[4], A. Ruiz-Patiño[2,3], Z.L. Zatarain Barrón[4], L.L. Rojas[3,5], L. Corrales[6], C. Martin[7], F. Barrón[8], C. Sotelo[3], J. Rodriguez[3], L. Ricaurte[3], J. Ávila[3], D. Mayorga[3], P. Archila[3], J. Otero[1,2,3], H. Freitas[9], V. Cordeiro De Lima[9], L. Mas[10], H. Carranza[1,2,3], C. Vargas[1,2,3], R. Rosell[11]

Background: BIM activation is essential for EGFR-TKIs triggered apoptosis in *EGFR*-mutant Non-small-cell lung cancer (NSCLC). A 2903-bp germline deletion in intron 2 of the BIM gene results in generation of alternatively spliced isoforms that lack the crucial BH3 domain, impairing the apoptotic response to TKIs and conferring NSCLC cells intrinsic resistance to these medications. Patients with both alterations have poor clinical evolution. The current study aimed to investigate the clinical efficacy and tolerability of EGFR-TKIs plus bevacizumab (Bev) versus EGFR-TKIs alone as first-line treatment in advanced NSCLC patients with *EGFR* mutations and BIM deletions (BIM*del*). **Method:** A retrospective analysis was conducted. BIM*del* was detected using polymerase chain reaction (PCR) analysis and direct sequencing of DNA from tumor and peripheral blood cells (PBCs). We also assessed BIM protein expression by immunohistochemistry and BIM mRNA levels by RT-PCR. Clinical characteristics, overall survival (OS), progression-free-survival (PFS), objective response rate (ORR) and treatment-related adverse events were compared in the EGFR-TKIs versus EGFR-TKIs plus Bev groups. **Result:** 32 patients were included; 16 of them received EGFR-TKIs and 18 received EGFR-TKIs plus Bev. The addition of Bev resulted in a significantly higher ORR compared with TKIs alone (94% vs. 44%, p=0.0014). Median PFS was longer with the use of the combination compared with TKIs alone (11.1 vs. 7.77 months; $p < 0.001$). Median OS tended to be longer in the EGFR-TKIs plus Bev group than in TKIs alone (30.9 vs. 25.4 months; $p = 0.06$). EGFR-TKIs plus Bev was associated with more grade >3 hematological and thrombotic adverse events. The expression of BIM by immunohistochemistry did not influence PFS and OS, however when stratifying BIM mRNA levels by the median (≥2.2 vs. <2.1) allowed to find a prognostic trend in favor of those with higher BIM mRNA levels (32.2 vs. 25.2 months respectively; $p = 0.058$). **Conclusion:** EGFR-TKIs plus Bev conferred a significantly higher ORR and PFS in advanced NSCLC patients with *EGFR* mutation and BIM*del*. Further prospective studies are needed to validate these findings.

KG, Vienna/Austria,* [17]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China*

Background: First-line afatinib significantly improved progression-free survival (PFS) compared with platinum-doublet chemotherapy in patients with *EGFR* mutation-positive *(EGFR*m+; including uncommon mutations) NSCLC in two Phase III studies (LUX-Lung 3: median 11.1 vs 6.9 months, hazard ratio [HR]=0.58; p=0.001; LUX-Lung 6: 11.0 vs 5.6 months, HR=0.28; p<0.0001). First-line afatinib also significantly improved PFS compared with gefitinib in the Phase IIb LUX-Lung 7 study (11.0 vs 10.9 months, HR=0.73; p=0.017). However, some patients still receive chemotherapy as a first-line treatment choice in clinical practice. Here, we report a combined analysis of outcomes from two large Phase IIIb studies of afatinib in EGFR TKI-naïve patients treated in a setting similar to real-world practice. **Method:** In both studies, EGFR TKI-naïve, including chemotherapy-pretreated, patients with locally advanced or metastatic *EGFR*m+ NSCLC received 40 mg/day afatinib until progressive disease or lack of tolerability (dose reduction was permitted [minimum: 20 mg/day]). Study 1 enrolled patients across eight European countries, and Russia, Israel and Australia; Study 2 enrolled patients from centres in China, Hong Kong, India, Singapore, and Taiwan. Interim (Study 1; data cut-off: 30 April 2018) and final (Study 2; data cut-off: 06 July 2018) data were used for this combined analysis of time to symptomatic progression (TTSP), PFS, objective response, and safety. **Result:** A total of 1020 patients were treated with afatinib (female: 59%; Asian/White/other: 54%/46%/<1%; median age

[range]: 61 years [25–89]; ECOG PS 0/1/2: 26%/69%/5%; common/uncommon *EGFR* mutations: 82%/18%; treatment line 1st/2nd/≥3rd: 69%/23%/8%; presence of brain metastases: 18%). Overall, median TTSP was 14.6 months (95% confidence interval [CI]: 13.8–15.8 months); median PFS was 12.9 months (95% CI: 11.6–13.7 months). Objective response rate was 52.7%. Adverse events (AEs; all grade/grade ≥3) occurred in 1012/556 (99%/55%) patients; serious AEs were reported in 366 patients (36%). The most common grade ≥3 AEs were diarrhoea (14%) and rash (9%). Any-cause AEs leading to dose reduction were reported in 412 (40%) patients. Treatment discontinuation due to afatinib-related AEs occurred in 54 patients (5%). **Conclusion:** In this combined analysis of two large, prospective 'real-world' afatinib studies in EGFR TKI-naïve patient populations, which included patients treated with afatinib in later lines, patients with ECOG PS 2, patients with brain metastases, and patients with uncommon mutations, safety data were consistent with previous results seen in the LUX-Lung 3, 6, and 7 studies. Efficacy findings are also encouraging, with a median TTSP of 14.6 months.

P1.15 THYMOMA/OTHER THORACIC MALIGNANCIES
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.15-01 PROGNOSTIC FACTORS AND LONG-TERM OUTCOMES AFTER PULMONARY METASTASECTOMY FROM RENAL CELL CARCINOMA

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Treatment of pulmonary metastases from renal cell carcinoma (RCC) remains controversial. However, some studies revealed potential survival benefits of pulmonary metastasectomy (PM) in these patients. We evaluate our experience analyzing surgical results, postoperative outcomes, and prognostic factors in patients receiving PM for RCC. **Method:** Using a prospective database, we retrospectively reviewed data from 133 patients who underwent PM for RCC between 1998 and 2018. There were 93 men (median age, 62 years, range, 29-80). Surgery included 104 wedge/segmentectomies (78.2%), 28 lobectomy/bilobectomy (21.0%), one pneumonectomy (0.8%). Twenty-one patients (15.8%) received a redo-metastasectomy. A single metastasis or 2-3 metastases were removed in 42 patients (31.6%) each; in 91 patients (68.4%) 4 or more metastases were removed. Lymphadenectomy was performed in 84 patients (63.2%): 58/84 (69.1%) were pN0, and 26/84 (30.9%) were pN+. **Result:** Complete resection was achieved in 124 patients (93.2%). Mortality was nil. We had only minor complications occurring in 23 patients (18.0%). After a median follow-up of 2.5 years (range, 0.03-13.3 years), 102 patients (76.7%) were alive. Five and 10-year survival were 57% and 53%, respectively. Disease-free interval was <12 months in 39 patients (29.4%); between 12 and 36 months in 33 (24.8%), and >36 month in 61 (45.8%), respectively. DFI and complete resection did not influence survival rate. Number of resected metastases influenced long-term outcome (60% for less 3 metastases versus 32% for 4 or more, log-rank test: p=.02). Patients with nodal involvement had a poor survival (58% for N0 versus 29% for N+, p=.01). At multivariate analysis, both number of resected metastases and nodal involvement were independent prognostic factors [p=.03 (95% CI: 0,66-8,46) and p=.001 (CI: 0,57-6,35), respectively]. **Conclusion:** PM may be a promising treatment for metastatic RCC allowing a good long-term survival rate. Nodal involvement and a number of resected metastases equal or more than 4 are predictors of poor survival.

Keywords: pulmonary metastasis, renal metastasis

P1.15-02 ROLE OF MTOR INHIBITOR EVEROLIMUS IN THE TREATMENT OF METASTATIC THYMIC EPITHELIAL TUMORS

J. Hellyer[1], S. Padda[1], S. Vali[2], A. Das[3], H. Sikora[3], Z. Husain[3], A. Kumar[3], T. Abbasi[2], H. Wakelee[1]

[1]*Stanford Cancer Institute, Palto Alto/United States of America,* [2]*Cellworks Group, San Jose/United States of America,* [3]*Cellworks Research India Pvt Ltd, Karnataka/India*

Background: Optimal treatment for metastatic thymic epithelial tumors (TETs) after progression on platinum-based chemotherapy has yet to be determined. There is emerging evidence to support the use of mTOR inhibitor everolimus in this setting including the recent phase II study by Zucali et al. However, patient selection and identifying predictors of response remains a challenge. Here, we describe a single-center experience with everolimus in TETs and molecular markers associated with response to therapy using a computational biological model (CBM). **Method:** Data on all patients with advanced TETs who were prescribed everolimus at our institution were retrospectively abstracted from the electronic medical record. Time to treatment failure (TTF) and overall survival (OS) were calculated. Solid Tumor Actionable Mutation Panel (STAMP), a targeted next generation sequencing (NGS) panel, was run on each TET and the results were computationally matched to a cohort of genomically similar TET patients from The Cancer Genome Atlas (TCGA). CBM was used to examine key genomic alterations of TETs correlated with response on everolimus. Responders were defined as having TTF > 6 months. **Result:** Thirteen patients with TETs, including ten thymomas (T) and three thymic carcinomas (TC) treated with everolimus, were included. All patients had been heavily pre-treated with an average of three prior lines of therapy. Three patients discontinued treatment due to adverse events. The average TTF was 10.8 months in T and 2.6 months in TC with median OS of 205 months (T) and 67.8 months (TC). Molecular data was available for 11 of 13 patients and identified mutations in *MAP2K*, *HRAS* and *NF1* as key molecular features associated with a response to everolimus. CBM accurately predicted response in 9 of 11 genomically similar TCGA tumors to our patient cohort. **Conclusion:** Patients with previously treated metastatic TETs appear to benefit from everolimus. Molecular testing of these tumors using targeted NGS panel revealed an association with several key genes, which may help to guide patient selection in the future.

Keywords: thymic epithelial tumors, Everolimus

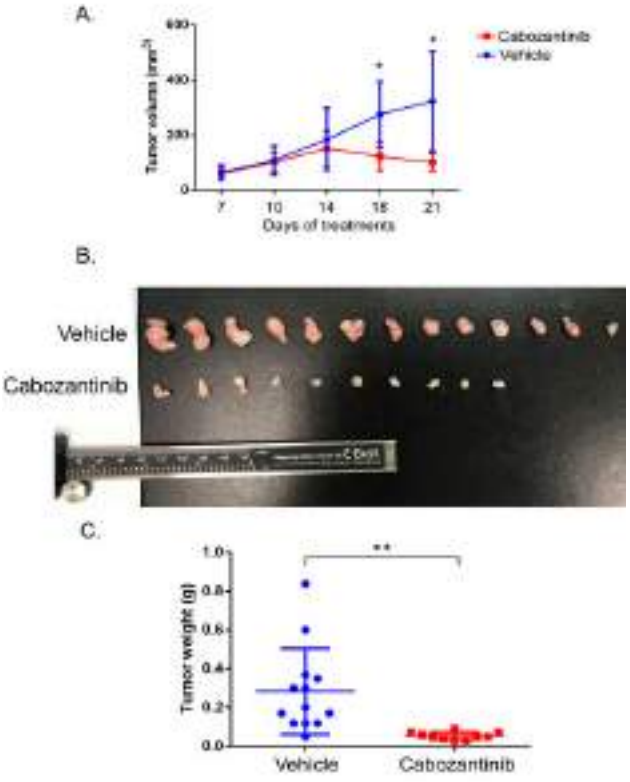
P1.15-03 CABOZANTINIB AND R428 INHIBIT THE GROWTH OF ESOPHAGEAL SQUAMOUS CELL CARCINOMA (ESCC)

P.-W. Yang, J.-M. Lee, M.-S. Hsieh

National Taiwan University Hospital, Taipei City/Taiwan

Background: Esophageal squamous cell carcinoma (ESCC) is a deadly disease for which no effective targeted therapeutic agent has been approved. Both AXL and c-MET have been reported to be independent prognostic factors for ESCC. Thus, inhibitors of AXL/c-MET might have great potential as targeted therapy for ESCC. We evaluated the efficacy of AXL/c-MET selective inhibitors, R428 (BGM324) and cabozantinib (XL184) in ESCC cell and mouse xenograft models. **Method:** The cytotoxicities of R428, BMS-777607 and cabozantinib in CE81T and KYSE-70 cells were determined by MTT survival assay. The effect of each inhibitor on migration activity of ESCC cells was analyzed by wound healing assay. ESCC xenograft models were established by injecting KYSE70 cells with matrigel into the upper back region of NOD-SCID male mice followed by treatment with vehicle control, R428 (50 mg/kg/day), cisplatin (1.0 mg/kg) or cabozantinib (30 mg/kg/day) for the indicated number of days. **Result:** We demonstrated both R428 and cabozantinib significantly inhibit the growth of CE81T and KYSE-70 ESCC cells. R428 but not cabozantinib had a synergistically cytotoxic effect in combination with cisplatin in ESCC cells. Meanwhile, both R428 and cabozantinib inhibited ESCC cell migration by wound-healing assay. In ESCC xenograft models, R428 alone significantly inhibited ESCC tumor growth compared to the vehicle; however, no synergistic effect with cisplatin was observed. Notably, the dramatic efficacy of cabozantinib alone was observed in the mice xenograft model. **Conclusion:** Our study demonstrated that both cabozantinib and R428 inhibit ESCC

growth in cell and xenograft models. The results reveal the great potential of using cabozantinib for targeted therapy of ESCC.



Keywords: esophageal cancer, Targeted therapy, cabozantinib

P1.15-04 CHEST WALL RESECTION AND RECONSTRUCTION FOR THORACIC WALL MALIGNANCIES: INDUCTION THERAPY REDUCES RECURRENCE RATES

M. Sarvan[1], M. Friess[1], I. Inci[2], D. Schneiter[2], W. Weder[1], I. Schmitt-Opitz[1]

[1]*University Hospital Zürich, Zürich/Switzerland,* [2]*University of Zürich, Zürich/Switzerland*

Background: Chest wall resections are associated with significant morbidity. The present analysis reports a the outcome of a large series of chest wall tumor resections. **Method:** Patients with primary and secondary chest wall malignancies undergoing resection and reconstruction were retrieved from our institutional database. Clinical and pathological parameter were correlated with long-term outcome **Result:** The study includes 169 patients, who underwent chest wall resection and reconstruction for primary or secondary chest wall tumors between 1999 and 2018. The median age was 60 (range 10-87) years. 48 (28%) were primary tumors, whereas 121 (72%) were secondary tumors. Primary malignancies were predominantly sarcomas 39 (23%). For secondary malignancies, the largest subgroups were non-small cell lung cancer 65 (38%), breast cancer 24 (14%), and mesothelioma 20 (12%). Resection margins were free in 103 (61%), R1 in 60 (36%), R2 in 4 (2%). Perioperative complications occurred in 67 patients (40%). The 30-days mortality was 4% (n=7). 46 patients (27%) received preoperative chemotherapy, 52 patients (31%) preoperative radiotherapy. The median follow-up time was 21 (range 0-218) months. The median OS was 44 months (95% confidence interval (CI): 33-55 months[SI1]). At the time of last follow-up 71% (n=120) of the patients were recurrent. Local recurrence rate was significantly lower in patients receiving preoperative therapy (16%) compared to patients receiving postoperative therapy (42%) or pre- and postoperative therapy (44%) (p=0.01). In patients receiving a preoperative chemotherapy, a R0 resection was significantly more often achieved (77%) than in patients receiving no preoperative chemotherapy (56%) (p=0.02). Preoperative radiotherapy had no influence on R0 resection (p=0.2). Defect size and resection status had no influence on OS (p=0.4 and p=0.8, respectively). **Conclusion:** Surgical therapy is the cornerstone for the treatment of primary and secondary chest wall malignancies and can be performed with reasonable morbidity. Induction chemo- and/or radiotherapy improves the probability of free resection margin and has positive influence in survival.

P1.15-05 GENOMIC VARIATION LANDSCAPE OF THYMOMA AND THYMIC CARCINOMA IN CHINESE PATIENTS

N. Liang[1], L. Liu[1], H. Liu[1], W. Wang[1], Y. Bi[1], Z. Liang[1], N. Li[2], R. Lin[2], T. Wang[2], S. Li[1]

[1]*Peking Union Medical College Hospital, Beijing/China,* [2]*Hangzhou Repugene Technology Co., Ltd., Hangzhou/China*

Background: Thymoma and thymic carcinoma (TC) are rare diseases of thymus with relatively good prognosis. Though pathological sub-types of thymoma and TC show clear differences on clinical characteristics, morphology, molecular markers, and prognosis, little is known on either the etiology or the molecular mechanism of the two tumor types. **Method:** In this study, 27 thymoma and thymic carcinoma patients with most common thymic epithelial tumor subtypes were enrolled, including 2 type A, 6 type AB, 3 type B1, 1 type B1/B2, 5 type B2, 2 type B2/B3, 5 type B3, and 3 type TC patients in total. The Masaoka stage status of the cohort was 15 stage I, 5 stage II, 3 stage III, and 4 stage IV patients. DNA samples extracted from the frozen tissues were sequenced using a 500-gene NGS panel. **Result:** Forty-seven non-synonymous somatic variants in 38 genes were identified from the sequencing data. The average tumor mutation burden was low (0.83 mut/MB), which was consistent with the previous findings in the TCGA thymic epithelial tumor cohort study (0.48 mut/MB). The KEGG pathway enrichment analysis showed that the function of the mutated genes was closely related to cancer signaling pathways: 15 genes in "pathway in cancer", 9 in "Ras signaling pathway", and 10 in "PI3K-Akt signaling pathway". *GTF2I* L424H mutation was observed in one type A (50% of type A), six type AB (100% of type AB), and four type B (25% of type B) samples. We observed the significantly higher *GTF2I* mutant prevalence on type B samples in our cohort than that in the TCGA cohort (p=0.024). *NF1* and *ATM* were highly mutated genes in our cohort. Three type B samples had *NF1* mutations (D1067V, P1087L, and G1090*). Two type B and one type A samples had *ATM* mutations (S169F, P424H, and R493G). Neither *NF1* nor *ATM* was identified as frequently mutated genes in the TCGA cohort. One *KRAS* (A59del) and one *NRAS* (Q61K) mutations were detected in two type AB samples respectively. No *KIT* or *EGFR* mutation was found. **Conclusion:** This study provided a comprehensive somatic mutation landscape of thymic epithelia tumor in a Chinese cohort. We compared our data to the TCGA cohort, most of which were Caucasian people. We identified higher mutation prevalence of *GTF2I* on type B samples in the Chinese cohort. Moreover, *NF1* and *ATM* mutations were found to be highly mutated in our cohort but not in the TCGA cohort.

Keywords: mutation, thymic epithelial tumor, THYMOMA

P1.15-06 RESECTION OF THORACIC PARAGANGLIOMAS: A MULTICENTER EXPERIENCE

S. Ibarra[1], E. Chan[1], R. Reul[1], M. Kim[1], T. Macgillivray[1], V. Ravi[2], M. Reardon[1]

[1]*Houston Methodist, Houston/United States of America,* [2]*MD Anderson Cancer Center, Houston/United States of America*

Background: Paragangliomas are chromaffin cell tumor arising from the sympathetic ganglia. Approximately 2% of paragangliomas occur in the thoracic cavity. Surgical resection is an effective treatment with most cases being curative. Tumor recurrence and long-term prognosis data remain scarce. We described our 14-year experience of complete resections. **Method:** We analyzed surgical characteristics and outcomes from our multicenter cohort of 17 patients with complete paraganglioma resection. We performed a retrospective review from May 2004 to August 2018 across three institutions. Perioperative data were collected using all available medical records from diagnosis to date. Description of baseline demographics, surgical outcomes, complications and survival rates were included in the analysis. Data are reported as mean ± standard deviation (SD) where applicable. **Result:** A total

of 17 patients underwent resection of thoracic paraganglioma. Baseline demographics, operative characteristics and outcomes are presented in Table 1. Mean age at the time of surgery was 46.8 ± 17.2 with ages ranging from 15 to 76 years. Sixty-five percent of patients were male. Eleven patients (64.7%) had the tumor arising from the left atrium, 3 (17.6%) from the mediastinum, 2 (11.8%) from the aorta, and one (5.9%) from both the left and right atria. Eight (47%) patients underwent cardiac autotransplant technique for a better resection approach. Additionally, 2 patients had a concomitant aortic valve and a pulmonic valve replacement, respectively. Complications included tamponade, right ventricular failure requiring RVAD, left ventricular failure requiring IABP, bi-ventricular failure requiring both RVAD and IABP, junctional bradycardia, tracheostomy, and vocal cord paralysis. Recurrence of the tumor presented in three patients (17.6%). One-year, five-year and ten-year survival was 92.3%, 87.5% and 75%, respectively.

Table 1: Results

Total N=17	n (%)
Age (Mean, years)*	46.8 +/- 17.2
Male Gender	11 (64.7)
Race:	
Caucasian	9 (52.9)
African American	7 (41.2)
Hispanic	1 (5.9)
Preoperative Chemotherapy	1 (5.9)
Tumor location:	
Left atrium	11 (64.7)
Left and right atrium	1 (5.9)
Mediastinum	3 (17.6)
Aorta	2 (11.8)
Surgical Procedure:	
Autotransplant	8 (47)
Valve replacement:	
- Aortic	1 (50)
- Pulmonic	1 (50)
Area of Reconstruction:	
Left Atrium	8 (47)
Left and right atrium	2 (11.8)
Right Ventricle and Pulmonary Artery	1 (5.9)
Aorta	1 (5.9)
Left main coronary artery	1 (5.9)
Postoperative Complications:	
Tamponade	2 (11.8)
Right Ventricular Heart Failure (RVAD)	1 (5.9)
Left Ventricular Heart Failure (IABP)	1 (5.9)
Bi-ventricular Heart Failure	1 (5.9)
Junctional Bradycardia	1 (5.9)
Tracheostomy (ventilator dependence)	1 (5.9)
Vocal cord paralysis	1 (5.9)
Postoperative Outcomes:	
Recurrent tumor	3 (17.6)
Deceased	1 (5.9)

Conclusion: Thoracic paragangliomas are rare and surgically challenging tumors due to their anatomical proximity with surrounding structures. Complete surgical excision is the elective treatment. Surgical mortality is reasonable for this complex disease and long-term outcomes are favorable in patients with complete resection.

P1.15-07 COMBINED AORTIC ARCH RESECTION FOR THYMIC CANCER USING TOTAL REROUTING OF SUPRA-ARCH VESSELS

Y. Shintani, S. Funaki, N. Ose, T. Kanou, E. Fukui, K. Kimura

Osaka Univiersity Graduate School of Medicine, Suita-City, Osaka/Japan

Background: Surgery for aortic arch involvement in thymic cancer cases is challenging, and generally requires provision of extracorporeal circulation with circulatory arrest or use of a cerebral protection technique. With the aim to reduce morbidity, we developed a novel surgical technique that includes total rerouting of supra-arch vessels under a beating heart condition. **Method:** With our technique, the tumor and aortic arch are accessed through a median sternotomy and lateral thoracotomy. The proximal portion of a trifurcation graft is anastomosed to the ascending aorta with a side-clamping technique under a cardiopulmonary bypass, then the 3 distal branches of the graft are sequentially anastomosed to supra-aortic vessels. Next, the ascending aorta distal to the anastomosis of the trifurcated graft and descending aorta are clamped, with perfusion of the heart performed via the femoral and right axillary arteries. Finally, the tumor is resected along with the aortic arch and involved organs, followed by reconstruction of the arch with a tube graft. **Result:** Case 1: A 61-year-old male, diagnosed with cStage III (cT4N0M0) thymic cancer with invasion to the aortic arch, underwent concurrent chemoradiotherapy with carboplatin and paclitaxel, after which complete resection of thymic cancer was performed with total aortic arch replacement and a left lobectomy using our new technique. Operative and CPB times were 738 and 130 minutes, respectively, and blood loss was 4210 ml. The patient was extubated on postoperative day (POD) 1. After an uneventful postoperative course, he was discharged on POD 45 and free of recurrence 8 months later. Case 2: A 45-year-old male diagnosed with cStage IVa (cT4N0M1a) thymic cancer with malignant pericardial effusion underwent chemotherapy with carboplatin and paclitaxel, followed by S-1 administration. Liver dysfunction developed due to chemotherapy and surgery was considered. Thoracoscopic findings ruled out pericardial dissemination, thus complete resection of thymic cancer combined with total aortic arch replacement, a left pneumonectomy, and right pulmonary reconstruction were performed. Operative and CPB times were 958 and 254 minutes, respectively, and blood loss was 7980 ml. Extubation was done on POD 2. After an uneventful postoperative course, the patient was discharged on POD 45 and free of recurrence 2 years later. **Conclusion:** Total arch replacement with total rerouting of the supra-arch vessels under a beating heart condition is effective for thymic cancer patients with aortic involvement. Our novel method has potential to avoid side-effects associated with deep hypothermic circulatory arrest and ischemia-reperfusion injury.

P1.15-08 OUTCOMES OF T4 ESOPHAGEAL CANCER TREATED WITH NEOADJUVANT CHEMORADIATION FOLLOWED BY SURGERY AND DEFINITIVE CHEMORADIATION: A META-ANALYSIS

C.C. Lee[1], Y.Y. Soon[2], J. Tey[2]

[1]*National University Cancer Institute, Singapore, Singapore/Singapore,*
[2]*National University Cancer Institute, Singapore/Singapore*

Background: The optimal treatment approach for T4 esophageal squamous cell carcinoma (SCC) is not well-established. We aim to perform a meta-analysis to determine the outcomes of T4 esophageal SCC treated with two approaches: neoadjuvant chemoradiation followed by surgery (NCRT-S) and definitive chemoradiation (DCRT). **Method:** We searched databases for eligible studies. Studies that evaluated the outcomes of patients with T4 any N M0 esophageal SCC treated with NCRT-S or DCRT were included. Our study outcomes of interests were overall survival (OS), rates of fistula formation and treatment-related death. The pooled estimates of outcomes were calculated using the logistic-normal random effects model. The differences in outcomes between the two treatment groups were examined using the Chi Square test. **Result:** Four prospective and fourteen retrospective studies including 875 patients were identified. The pooled estimates of 1-, 2-, 3-, 4- and 5-year OS were 61% (95% confidence interval (CI), 48%-72%), 38% (95% CI, 26%-51%), 31% (95% CI, 22%-42%), 26% (95% CI, 16%-39%) and 23% (95% CI, 15%-33%) for NCRT-S group and 40% (95% CI, 33%-47%), 23% (95% CI, 15%-32%),

17% (95% CI, 10%-27%), 16% (95% CI, 8%-30%) and 14% (95% CI, 7%-24%) for DCRT group, respectively. The OS of patients treated with NCRT-S were significantly improved compared with those treated with DCRT at 1 year (P= 0.004) and 3 years (P= 0.035). The rate of fistula formation was lower in NCRT-S group compared with DCRT (4% (95% CI, 1%-14%) versus (vs) 12% (95% CI, 7%-19%); P = 0.06). The rates of treatment-related death were similar between NCRT-S and DCRT groups (3% (95% CI, 1%-6%) vs 3% (95% CI, 1%-9%); P= 0.891). **Conclusion:** NCRT-S was associated with improved OS and lower fistula rate in the treatment of T4 esophageal SCC compared with DCRT. The rates of treatment-related death were similarly low in both groups. Randomized controlled trials are warranted to confirm these findings.

P1.15-09 THE IMPACT OF MINIMAL INVASIVE ESOPHAGECTOMY AND NEOADJUVANT CHEMORADIOTHERAPY FOR ESOPHAGEAL MALIGNANCY: A NATIONWIDE DATABASE ANALYSIS

C.-H. How[1], J.-M. Lee[2]

[1]*Far Easter Memorial Hospital, Taipei City/Taiwan,* [2]*National Taiwan University Hospital, Taipei City/Taiwan*

Background: Squamous cell carcinoma is the predominant histologic subtype of esophageal cancer in Asia pacific. Radical surgery provides the most realistic chance of cure from cancer of the esophagus. Multimodality treatment, including radiotherapy, chemotherapy and surgery is superior to surgery alone for patients with resectable adenocarcinoma of the esophagus. Recent advances in thoracoscopic surgery have made it possible to perform esophagectomy via minimal invasive surgery. The objective of this study was to evaluate the survival of esophageal squamous malignancy, received minimally invasive esophagectomy, with or without neoadjuvant chemoradiotherapy. **Method:** From 2010 to 2016, all patients received esophagectomy for esophageal malignancy, in Taiwan, were enrolled into this study. The demographic and outcome data for these patients were retrospectively examined. Logistic regression analysis was used to identify the factors associated with survival. **Result:** Total 3957 patients received esophagectomy, 2946 of these were performed by minimal invasive method. About 56.8% patients received neoadjuvant chemoradiotherapy. The overall five years survival of all stage patients was 35.9%. The patients, who received minimal invasive esophagectomy, had better five years survival of 37.7%. Stage III patients treated with or without adjuvant chemoradiotherapy, the five years survival was 29.2 and 31.8%. Stage IV patients treated with or without adjuvant chemoradiotherapy, the five years survival was 8.8 and 13.4%. **Conclusion:** Minimal invasive esophagectomy had better survival in stage I/II patients. Better survival was also noted in stage III/IV patients, when neoadjuvant chemoradiotherapy was applied.

P1.15-10 TRABECTEDIN HAS LIMITED CLINICAL ACTIVITY IN PRETREATED PATIENTS WITH PLEURAL MESOTHELIOMA

G. Pasquini, L. Petrini, R. Castellana, I. Pecora, C. Vivaldi, M. Lucchesi, A. Chella, A. Falcone

Azienda Ospedaliero Universitaria Pisana, Pisa/Italy

Background: In mesothelioma, chemotherapy with pemetrexed is effective but after progression the options of treatment have limited efficacy. Tumor associated macrophages are necessary for the growth of mesothelial tumors. Trabectedin is a tetrahydroisoquinoline alkaloid used for the treatment of sarcomas and ovarian cancer. Trabectedin interacts with the DNA double helix and interfere with the binding of transcription factors and polymerases, reprogramming gene expression in cancer and microenvironment cells. Therefore, we evaluated the effect of trabectedin in patients with mesothelioma after progression to standard treatments. **Method:** We retrospectively identified 9 patients treated with trabectedin between 2017 and 2019. A continuous infusion of 1.5 mg/m^2 of trabectedin was administrated in 24h every 21 days. According to RECIST criteria, overall survival (OS) and progression free survival (PFS) were calculated using Kaplan-Meier estimation. **Result:** Seven of the 9 patients were male. The median age was 64 years (range 44-77). There were 6 epithelioid, 1 sarcomatoid and 2 biphasic mesotheliomas. The stage at diagnosis was III in 3 patients and IVB in 6 patients. Pleurectomy/decortication was performed in 5 patients, 4 patients received biopsy. The number of previous lines of chemotherapy was 1 in 4 patients, 2 in 2 subjects and 3 in 3 remaining. The median number of cycles was 3 (range 1-6). A grade 2 increase of transaminase was observed in 1 patient and a patient developed an atrial flutter with an heartrate of 180 during treatment. Two patients experienced G3 fatigue and fever. There were not G3-4 hematological toxicities but a G3 increase of creatine kinase was observed in 1 patient. Seven patients experienced a disease progression with a median PFS of 1.8 months (95%CI 1.55-2.05). The median OS was 5 months (95%CI 2.42-7.57). There were not significant differences in PFS and OS in relation to age, histology, sex, performance status, across patients treated with one or more lines of chemotherapy and between those who received pleurectomy **Conclusion:** Trabectedin in pre-treated mesothelioma patients is feasible with a moderate toxicity but there is no meaningful clinical activity for this agent according to the previous report of ATREUS trial.

Keywords: Trabectedin, pre-treated, Mesothelioma

P1.15-11 INTRATHORACIC NEUROGENIC TUMORS: CLINICAL, PATHOLOGICAL, AND LONG-TERM OUTCOMES

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Intrathoracic neurogenic tumors are uncommon neoplasms arising from nerve tissues. We report our single-center experience in treating this rare intrathoracic neurogenic tumors. **Method:** We retrospectively analyzed the clinical, surgical and pathological records of patients receiving the resection of an intrathoracic neurogenic tumor between May 1998 and December 2018. **Result:** There were 82 patients (24 females) with an average age of 53 years (29 to 75 years). Mean diameter was 32 mm, ranging from 12 mm to 68 mm. Histology included 42 benign schwannomas, 7 malignant schwannomas, 15 neurinomas, 14 neurilemmomas, and 4 paragangliomas. 55 were located in the posterior mediastinum, 13 in the thoracic inlet, 7 in the anterior mediastinum, 4 in the lung parenchyma, and 3 in the chest wall. Symptoms were seen in 51 patients (62.2%) and including cough in 23, dyspnea in 15, neurologic symptoms in 11, and wheezing in 2. In 3 patients (3.6%), the tumor showed an intraspinal extension. Tumor resection was made by thoracotomy in 42 (51.2%) cases and thoracoscopy in 40 (48.8%). Resection was complete in 80 patients (97.6%). Postoperative radiotherapy was administerd in 2 cases. Mortality was nil. Morbidity rate occurred in 4 patients (4.8%) and included 2 prolonged air leaks, 1 hemothorax, and 1 chylothorax. Five-year survival was 97% in an average follow-up of 4.9 years. No recurrence occurred during the follow-up period neither for malignant nor for benign tumors. **Conclusion:** The treatment of choice for thoracic neurogenic tumors is complete resection. Long-term prognosis is favorable both for malignant and benign neurogenic tumors.

P1.15-12 A DIFFERENT ASPECT TO TUMOR SIZE DILEMMA IN THYMOMA'S TNM STAGING CLASSIFICATION

A. Kayi Cangir, T. Direk, B. Yenigün, A. Yücemen, G. Kocaman, Y. Kahya, S. Enön, S. Dizbay Sak

Ankara University Faculty of Medicine, Ankara/Turkey

Background: Thymic epithelial tumors including thymomas are relatively rare thoracic neoplasms; though thymomas are the most common tumors of anterior mediastinum in adults. Among the TNM classifications of many solid tumors, tumor size is included in definition of T descriptor and as a key for staging it plays an important role in predicting prognosis and affects clinical decision making. However, TNM or the other classifications of thymomas do not take tumor size into consideration. **Method:** Between 2004 and 2018, 204 consecutive patients with thymic epithelial tumors underwent surgical resection in Department of Thoracic Surgery, Ankara University Medical School. One hundred and forty-three patients with thymoma were included in the study. When survival analysis

was performed, sixteen cases were excluded due to missing datas of either survival and/or tumor diameter. Remaining 127 patients were classified into two groups: a. largest tumor diameter (LTD), b. mean tumor diameter (largest diameter+shortest diameter/2) (MTD). Then each were divided into three subgroups (LTDa/ MTDa ≤5cm; LTDb/ MTDb 5.1-10 cm; LTDc/ MTDc >10 cm). LTDa, LTDb and LTDc subgroups contained 47 (37%), 60 (47.3%) and 20 (15.7%) patients; while MTDa, MTDb and MTDc subgroups had 66 (52%), 56 (44.1%) and 5 (3.9%) patients respectively. **Result:** There were 78 males and 65 females, with a mean age of 49.6 years (10-78). Results of the survival analysis according LTD and MTD subgroups are shown in Table 1. In survival analysis, there were significant differences in the presence of MG, resection status (R0 vs R1), T status and the Masaoka-Koga staging (p=0.018, p=0.001, p=0.015, p = 0.003), respectively. In survival analysis for MTD subgroups, survival decreased as the tumour size increased. In LTD group, the only difference which was close to statistical significance was in R0 group for 10 years OS (p=0.051). Table 1: 10-year survival according to tumor diameter groups

	Largest Tumor Diameter (LTD)			Mean Tumor Diameter* (MTD)		
	≤5cm	5.1-10cm	p value	≤5cm	5.1-10cm	p value
10 years overall survival (%) (LTD:107 (48/59) patients, MTD:122 (66/56))	87.6	80	0.246	91.2	74.8	0.088
10 years disease-free survival (%) (LTD:94 (40/54) patients, MTD:107 (56/51))	75.5	56.5	0.113	82.6	41.9	0.052
10 years overall survival in R0 resection (%) (LTD:91 (37/54) patients, MTD:104 (53/51))	95.2	81.1	0.051	96.8	75.9	0.027
10 years disease-free survival in R0 resection (%) (LTD:82 (34/48) patients, MTD:93 (48/45))	75.2	57.7	0.159	82.4	43.1	0.095

Conclusion: In this study, complete resection was the most powerful prognostic factor for thymoma as reported by Ruffini et al. Though complet resection is associated with better survival, tumor size is an essential factor on decision of complete resection. Therefore, the largest or mean tumor size should be a criterion in the thymoma TNM staging system.

Keywords: Size, staging, THYMOMA

P1.15-13 SUBXIPHOID UNIPORTAL THORACOSCOPIC THYMECTOMY WITHOUT CARBON DIOXIDE INSUFFLATION IN THE PATIENTS WITH THYMOMA

D.K. Kang, M.K. Kang

Haeundae Paik Hospital, College of Medicine, Inje University, Busan/Korea, Republic of

Background: Thymectomy is the most important treatment for anterior mediastinal mass and myasthenia gravis. Until now, different surgical approaches have been described to perform thymectomy, from median sternotomy to robotic thymectomy. But there is no consensus on the best approach of thymectomy. Depending on approach to perform thymectomy, the advantages and disadvantages are different. Currently, the lateral intercostal approach in video-assisted thoracoscopic surgery thymectomy (VATS thymectomy) is the most frequently performed surgical approach for thymectomy. But this approach has difficulty to identify the contralateral phrenic nerve and intercostal nerve impairment. Recently, to overcome shortcomings of VATS thymectomy, subxiphoid single-port thymectomy (SPT) was introduced. We have performed modified subxiphoid SPT using our own manufacturing sternal retractor without carbon dioxide insufflation under one-lung ventilation. We report the initial operative results of modified subxiphoid SPT. **Method:** Subjects of this study were patients who underwent thymectomy or extended thymectomy at Inje University Haeundae Paik Hospital between July 2016 and November 2018. We reviewed the medical records of these patients retrospectively. Indication of thymectomy is anterior mediastinal mass without tumor invasion. In our department, we performed thymectomy for anterior mediastinal mass in the absence of myasthenia gravis. And extended thymectomy, which involves the removal of all adipose tissue involve anterior to the phrenic nerve, was performed for myasthenia gravis. Subxiphoid uniportal thoracoscopic thymectomy was attempted first in July 2016. From this time, thymectomy for anterior mediastinal mass or extended thymectomy for MG were preformed via SPT with sternal retraction. All surgical procedures were performed by a single surgeon. 29 patients who underwent thymectomy or extended thymectomy were enrolled. Information of patient demographics, intraoperative, postoperative data were collected and retrospectively evaluated. **Result:** The patient's demographics and results of operative outcome of subxiphoid SPT are presented in table 1.

Table 1

	Thymectomy	Extended thymectomy
No. of patients	21	8
Age (years)	55.23±13.04	44.62±16.47
Sex (male/female)	10/11	3/5
BMI	24.72±3.60	24.87±3.57
Mass size(cm)	3.85±1.73	2.13±0.38
Operative time (min)	143.57±51.96	184.38±43.30
Blood loss in operation(ml)	246.90±262.76	183.75±147.45
Drain after operation(ml)	488.67±308.05	1506.13±1203.80
Duration of chest tube(day)	2.81±1.12	5.00±2.39
HD after operation (day)	6.05±2.87	8.38±2.39
Conversion to other approach	3	0

Conclusion: The benefit of subxipohid approach with sternal retraction is that it makes it easier to identify the contra-lateral phrenic nerve. Also, our procedure has 3 advantages when compared with carbon dioxide insufflation subxiphoid single-port thymectomy. First, because we do not insufflate carbon dioxide, there is no need to worry about hypotension. Second, we do not use air tight trocar, so we use more instruments and have more flexibility in them. Finally, sternum retraction provides more optimal space for the surgery. Single-port thymectomy through the subxiphoidal incision using sternal retractor under one-lung ventilation without carbon dioxide insufflation was feasible.

Keywords: THYMOMA, Subxiphoidal incision, Without CO2 insufflation

P1.16 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.16-01 COMPLICATIONS ASSOCIATED WITH LUNG BIOPSIES IN PATIENTS WITH LUNG CANCER: A POPULATION BASED ANALYSIS

M. Von Itzstein[1], A. Gupta[1], K. Mara[2], S. Khanna[2], D. Gerber[1]

[1]*UT Southwestern, Dallas/United States of America,* [2]*Mayo Clinic, Rochester/United States of America*

Background: The discovery of molecular biomarkers that guide management of lung cancer has led to increasing frequency and amounts of tissue required for repeat lung biopsies.This has coincided with increased emphasis on patient safety and reporting on adverse events over the past two decades. The safety of repeat lung biopsies in patients with lung cancer has only been studied in small cohorts. We analyzed hospital-acquired adverse events for patients with lung cancer undergoing lung biopsies in the National Hospital Discharge Survey (NHDS) database from 2001- 2010. **Method:** NHDS collects clinical information on patients discharged from non-Federal short-stay United States hospitals. Demographics, diagnoses, procedures, and mortality data were extracted using ICD-9 codes. The Agency for Healthcare Research and Quality (AHRQ) Patient Safety Indicators (PSIs) were utilized to identify hospital-acquired adverse events. Weighted analyses were performed using SAS version 9.4. **Result:** An estimated 540,747 patients with lung cancer underwent lung biopsy during the study period and were included in the analysis; 61% were >65 years, 46% female, 65% white. Biopsy approaches included bronchoscopic (60%), percutaneous (33%), and surgical (7%). The number of lung biopsies increased over the study period, from 51,221 in 2001, to 63,239 in 2010 (P<0.001). Overall, 159,683 (30%) patients suffered ≥1-PSI event during their hospitalization, including an 11% incidence of pneumothorax. Incidence of PSI varied by biopsy type: bronchoscopic (26%), percutaneous (34%), surgical (39%). The proportion of patients experiencing ≥1 PSI event increased from 24% in 2001, to 38% in 2010 (P<0.001). Patients with ≥1 PSI experienced higher in-hospital mortality (14.5% vs 3.2%, adjusted odds ratio, 5.9, 95% CI 3.9 – 8.9; P<0.001), and prolonged length-of-stay (11.6 vs 8.1 days; P<0.001). **Conclusion:** The frequency of lung biopsies performed in lung cancer patients has increased in recent years, as has the rate of documented complications in this selected inpatient cohort. The increased rate of complications may be due to increased attention to and reporting of adverse events in this era focusing on patient safety, which has implications for policy makers and funding authorities. Investigators, sponsors, patients and regulatory authorities should be aware of the risks associated with repeat biopsies as they design, oversee, and analyze clinical trials. Non-invasive assessment of tumor biology, such as cell-free DNA, may help mitigate these risks.

Keyword: patient safety indicator

P1.16-02 THE REAL-WORLD RISK OF BRAIN METASTASES IN STAGE 3 LUNG CANCER PATIENTS IN THE ERA OF PET AND MRI STAGING

R. Ko, K. Therkelsen, R. Von Eyben, J. Neal, B. Loo, S. Nagpal

Stanford Cancer Institute, Stanford/United States of America

Background: Brain metastases (BMs) are a common site of recurrence in Stage 3 NSCLC following definitive chemoradiation. In small-cell lung cancer, prophylactic cranial irradiation (PCI) was historically offered to improve overall survival (OS). Studies of PCI in NSCLC failed to show OS benefit; many were based on a 30% 2-year risk of CNS metastases, using data from the era prior to routine brain imaging at staging. An increasing preference for stereotactic radiosurgery(SRS) over WBRT for BMs may also affect outcomes. The purpose of this study was to review surveillance, incidence, and treatment patterns of BMs in patients with stage 3 NSCLC at our institution. **Method:** In this IRB approved study, we retrospectively reviewed stage 3A/3B NSCLC patients treated at Stanford from 2008-2018. Of 279 patients, 163 received radiation with curative intent, and had complete data regarding pathology, staging, imaging, radiation and follow-up. **Result:** Ninety-seven patients had adenocarcinoma, 54 squamous, and12 other histology (usually large-cell neuro-endocrine). Two patients received PCI; neither developed BMs. For all patients, median survival was 50 months (95%CI:30, 61). Patients with adenocarcinoma had significantly longer survival than squamous (53 v. 24 months, p=0.0119). 37 patients (22.7%) developed BMs, with 2-year cumulative incidence of 17.1% (95%CI:11.6%, 23.5%). Patients with adenocarcinoma had higher cumulative incidence of BM at 2 years, 21.9%, versus squamous 7.9%, and other histology 21.7%(p=0.0295). Of 37 BM patients, 18 presented with one BM, 8 with 2-3, and 11 had >3 BMs. Seventeen patients had asymptomatic BMs discovered at re-staging for systemic recurrence, 3 patients had asymptomatic BMs on surveillance MRI, 14 had BMs on MRI ordered for neurologic symptoms, 3 had symptoms and pre-scheduled surveillance MRI confirmed BM. Twenty-nine patients received SRS for first BM, 3 received WBRT, 5 had no treatment. Time from first BM to death was not different between adeno and squamous histology (21.0 v. 16.5 months, p=0.6050) or symptomatic v. asymptomatic BMs (18 v. 21 months, p=0.8273). **Conclusion:** Patients with stage 3A/3B NSCLC treated at our institution have a lower 2-year incidence of BMs than historically reported, but higher than recently reported in the PACIFIC study (11.8%, 25-month median follow-up). Suspicion for BM should remain high in this population. Our experience suggests imaging at the time of systemic recurrence or neurologic symptoms may capture the majority of brain metastases. Routine surveillance MRI may capture more asymptomatic metastasis, though impact on overall survival remains unclear.

Keywords: Brain metastases, Stage 3 NSCLC, surveillance MRI

P1.16-03 INCIDENCE AND RISK FACTORS OF METACHRONOUS NON-PULMONARY MALIGNANCIES IN RESECTED LUNG ADENOCARCINOMA

P. Kneuertz[1], D. D'Souza[1], M. Richardson[1], M. Abdel-Rasoul[2], S. Moffatt-Bruce[1], R. Merritt[1]

[1]*The Ohio State University Wexner Medical Center, Columbus/United States of America,* [2]*The Ohio State University, Columbus/United States of America*

Background: Patients with non-small cell lung cancers have an increased risk of developing second primary lung cancers (SPLC). However, little is known about the development of non-pulmonary cancers (NPC) in patients with long-term survival after complete resection. We analyzed our experience with resected lung adenocarcinoma patients to assess the incidence and factors associated with metachronous malignancies. **Method:** Surveillance records of 326 patients with primary lung adenocarcinoma who underwent complete staging followed by lobectomy between 2011-2017 at a single center were reviewed. Median follow-up time was 42 months. Metachronous NPCs were distinguished from distant metastases by pathologic correlation of histology and immunohistochemistry. The association of patient/tumor factors and mutation status with NPC was assessed. **Result:** The cohort included 275 (84.4%) smokers, and 51 (15.6%) never smokers, with a median age of 65 years. The majority of patients were pathologic stage-I (72.4%) or stage-II (19.6%). KRAS (38%) and EGFR (17.8%) were the most commonly observed mutations. Metachronous NPC were detected in 30 patients (9.2%) and SPLC in 13 patients (4%), after a median interval of 14 months [IQR: 6.8–44] and 36 months [IQR: 27–60], respectively. Highest incidence of NPCs was seen in patients having EGFR tumor mutations (EGFR+ 17.2% vs. EGFR- 7.5%, p=0.020) and former smokers (former smokers 14.8% vs. never smokers 7.8% vs. active smokers 3.8%, p=0.005). Metachronous breast and GI cancers were frequently seen in patients with EGFR+ lung cancers (Table). Controlling for age, gender, and smoking status, EGFR mutation in resected lung adenocarcinoma was associated with 2.6 times greater odds (95% CI: 1.1-6.3, p=0.028) of metachronous NPC.

POSTERS

Metachronous Non-pulmonary Cancers (NPC) in Resected Lung Adenocarcinoma based on EGFR Mutation Status		
NPC Type	EGFR Positive (N=58)	EGFR Negative (N=268)
Brain	0 (0%)	2 (0.8%)
Head/Neck		
Laryngeal	0 (0%)	1 (0.4%)
Thyroid	0 (0 %)	1 (0.4%)
Breast	4 (6.9%)	5 (1.9%)
GI		
Anal	2 (3.5%)	0 (0.0%)
Colorectal	1 (1.7%)	3 (1.1%)
Hepatocellular Carcinoma	1 (1.7%	1 (0.4%)
GU		
Bladder	0 (0%)	2 (0.8%)
Prostate	0 (0%)	1 (0.4%)
Renal Cell	0 (0 %)	1 (0.4%)
Skin/Soft Tissue Sarcoma		
Skin	1 (1.7%)	2 (0.8%)
Leiomyosarcoma	1 (1.7%)	0 (0.0%)
Liposarcoma	0 (0%)	1 (0.4%)
Total*	10 (17.2%)	20 (7.5%)
*P-value comparing incidence of any NPC's between EGFR groups = 0.020		

Conclusion: Metachronous non-pulmonary malignancies can be frequently detected in patients during active surveillance of resected lung adenocarcinoma. Besides smoking as a known risk factor, patients with EGFR mutated tumors may be at particular risk. Germline mutations of EGFR positive lung adenocarcinoma patients should be further explored.

Keywords: Second Primary, Other Malignancy, EGFR

P1.16-04 REAL WORLD EXPERIENCE OF USING COMPREHENSIVE GENOMIC PROFILING OF PLASMA CIRCULATING TUMOR DNA

Y. Yan[1,2], W. Ma[2], M. Molmen[3], T. Regalo[3], D. Pavlick[3], B. Forcier[3], B. Sawchyn[3], S. Chen[4], J. Gregg[3,5], T. Li[2]

[1]*Department of Oncology, The First Affiliated Hospital of Zhengzhou University, Henan/China,* [2]*University of California Davis Comprehensive Cancer Center, Sacramento/United States of America,* [3]*Foundation Medicine, Cambridge/United States of America,* [4]*University of California Davis, Department of Public Health Sciences, Davis/United States of America,* [5]*University of California Davis Department of Pathology, Sacramento/United States of America*

Background: The clinical application of molecular biomarker assays has revolutionized cancer diagnosis and treatment, enabling the current era of precision lung cancer care. Increasingly, comprehensive genomic profiling (CGP) by next generation sequencing has been used in the clinic. We here summarize our initial experience in using tissue- and blood-based tumor genomic profiling assays. **Method:** This retrospective chart review included consecutive cases from patients with locally advanced or metastatic lung cancer seen at an academic institution between January 2014 and March 2019. A total of 596 archival tumor specimens and 128 blood samples were subjected to tissue- and plasma-based, hybrid capture-based next generation sequencing assays, respectively. Maximum somatic allele frequency (MSAF) was used to quantify the fraction of circulating tumor DNA in the plasma cell free DNA. Survival was calculated by the Kaplan-Meier method. **Result:** We found that plasma cell free DNA (cfDNA) assay significantly reduced the sample acquisition time and test failure rate (Table below). All patients who failed tissue assay due to insufficient tissue or DNA and were willing to undergo liquid biopsy had a successful test result. Reasons for 38 patients who had liquid biopsy only are summarized below. In 117 (19.6%) identified patients with either EGFR-mutant or ALK-rearranged NSCLC tumors, median survival has improved compared to those patients diagnosed before 2014 (N=103) (48.9 vs 30.0 months, hazard ratio 0.43, 95% CI 0.31-0.60; p<0.0001). Furthermore, plasma ctDNA CGP identified suspicious germline mutations in ~16% cases.

Specimen Type	Tumor	Plasma cfDNA	P value
Genomic Assay	FoundationOne or CDx	F-ACT or FoundationOne Liquid	
All cases	596	128	
Sample acquisition time (mean with 95% CI; days)	9.9 (8.79-10.95)	1.3 (0.17-2.49)	<0.0001
Test time (mean with 95% CI; days)	13.0 (12.55-13.53)	14.7 (13.24-16.15)	<0.01
Total test time (mean with 95% CI; days)	22.9 (21.66-24.07)	16.0 (14.19-17.85)	<0.0001
No. (%) Failure cases	114 (19.1%)	4 (3.1%)	
Reasons for liquid biopsy only:		N=38	
Tissue insufficient		11 (29%)	
Resistance evaluation		10 (26%)	
No record		6 (18%)	
Limited panel		7 (16%)	
Refused biopsy or too ill		4 (11%)	

Conclusion: In our experience, the adoption of CGP with subsequent, effective targeted therapy has shown improved median survival in patients with NSCLC. CGP of plasma ctDNA is particularly useful when patients have insufficient tumor specimens and can unveil germline mutations which need further confirmation. A prospective concordance study is planned to compare the FoundationOne CDx and FoundationOne Liquid in patients with advanced NSCLC.

P1.16-05 INCIDENCE AND OUTCOME OF MULTIPLE PRIMARY CANCERS (MPC) IN A SERIES OF LUNG CANCER (LC) PATIENTS

S. Cedres, A. Hernando-Calvo, P. Iranzo, A. Callejo, N. Pardo Aranda, A. Navarro, A. Martinez-Marti, J.D. Assaf, J.M. Miquel, G. Rodriguez, V. Monton, A. Pedrola, C. Viaplana, C. Carbonell, M. Sanso, R. Dienstmann, R. Amat, A. Vivancos, E. Felip

Vall d´Hebron University Hospital and Institute of Oncology (VHIO), barcelona/Spain

Background: The number of cancer survivors has increased as a result of significant progress in prevention, diagnosis and treatment of malignant tumors. The risk of developing a second neoplasm, after treatment of an initial primary cancer, is increasing and indeed lung cancer represents a commonly diagnosed second primary malignancy. This study investigates the co-occurrence of MPC among patients (p) diagnosed with lung cancer (LC). **Method:** Review of clinical data of all consecutive patients with histologically confirmed LC visited at our institution between October 2017 and August 2018 **Result:** Out of 1386 p with LC, two primary cancers occurred in 206 cases (15%), including 41 p (3%) with three primary cancers. Patients with MPC were predominantly males (67%), smokers (88%), statin users (40%) and 28% had known family history. Second cancer was detected in a routine follow-up in 62%, whereas 27% were symptomatic patients. Median age at the first tumor diagnosis was 61 years (27-85). LC occurred as first neoplasm in 34% of the cases, as subsequent neoplasm in 41% and as two consecutive primary

neoplasm in 25%. The most common primary cancer was LC in 34%, followed by breast (16%), colorectal (15%), prostate (9%), bladder (8%) and head and neck (6%). Treatment received for the first cancer included surgery in 80%, chemotherapy in 47% and radiotherapy in 32%. As a second tumor LC represented 41%, followed by bladder (19%), colorectal (10%), prostate (9%) and breast (7%). Surgery was performed in 70% of the cases with a second cancer. Regarding only patients with LC as two primary tumours (first and second tumour), 25 pts (89%) were not metastatic at second tumour, surgery was performed in 82% and 7 pts (24%) developed a third tumour. Overall, median time of diagnosis between the first and the second neoplasm was 4.2 years (CI95% 3.2-5.2), without significant differences if primary tumor was LC or another neoplasm (p=0.82). Smoking was associated with a shorter time of the second neoplasm diagnosis (3.8 years vs 7.9 years for non-smokers, p=0.09), whereas taking statins exhibited longer time of diagnosis of the second neoplasm (5.1 vs 3.3 year, p=0.05). With a median follow up of 7.3 years after diagnosis of the first neoplasm, the 5-year survival rate was 97.2% (94.8-99.7%). **Conclusion:** In our series, the frequency of the MPC co-occurrence among LC p is 15%, indicating that surveillance strategies are recommended. Many p are treated with curative intent. Moreover, smoking and taking statins influences the time interval between tumors

P1.16-06 EARLY CHANGES IN PULMONARY FUNCTION ARE ASSOCIATED WITH DEVELOPMENT OF PNEUMONITIS IN NSCLC PATIENTS RECEIVING IMMUNE CHECKPOINT BLOCKADE

J. Reuss, K. Suresh, K. Psoter, P. Forde, J. Naidoo

Johns Hopkins University School of Medicine, Baltimore/United States of America

Background: Checkpoint inhibitor pneumonitis (CIP) is an immune-related adverse event of immune checkpoint inhibitors (ICI). Pulmonary function test (PFT) changes have been noted in patients receiving drugs such as bleomycin, and PFTs are routinely used to monitor for lung toxicity in such patients. We retrospectively analyzed PFTs in ICI-treated non-small cell lung cancer (NSCLC) patients to identify PFT changes associated with ICI use, and determine whether CIP modified this association. **Method:** The study cohort included NSCLC patients who were treated with PD-(L)1 ICI as standard-of-care or part of a clinical trial at Johns Hopkins from 1/2007 - 7/2017 and had ≥1 PFT in the year preceding and/or following ICI initiation. The primary outcomes of interest were forced expiratory volume in 1 second (FEV1), forced vital capacity (FVC), and FEV1/FVC ratio. Linear regression based on generalized estimating equations (GEE) was used to evaluate changes overall and by CIP status (CIP+: Patients who develop CIP, CIP-: Patients who do not develop CIP). **Result:** A total of 58 patients (43 CIP-, 15 CIP+) were included. Median age was 66y and 96% of patients were current/former smokers. 52% had adenocarcinoma and 45% had squamous histology. 75% had stage III/IV disease at initial diagnosis. Patients received single agent PD-(L)1 ICI (77%), ipilimumab+nivolumab (ipi/nivo) (12%), and novel PD-(L)1 ICI (10%). Compared to CIP- patients, CIP+ patients were more likely to have squamous histology (67% vs. 34%) and receive ipi/nivo (27% vs 7%). In the overall study cohort, ICI initiation was associated with a 0.335L reduction in FEV1 (95% CI: -0.713, 0.042), 0.747L reduction in FVC (-1.21, -0.28), and 0.061 increase in FEV1/FVC (0.006, 0.116) consistent with restrictive lung physiology. Compared to CIP- patients, CIP+ patients had a 0.35L (-0.724, 0.013) lower FEV1 and 0.516L (-1.06, 0.02) lower FVC, while FEV1/FVC did not differ (-0.07, 0.07). The rate of change of FEV1/FVC over time was significantly higher among patients with vs without CIP (p<0.05). **Conclusion:** Our data suggest that initiation of PD-(L)1 ICI is associated with progressively restrictive lung function changes on PFTs (increased FEV1/FVC) irrespective of CIP development. Furthermore, our results indicate that patients who eventually develop CIP may have an altered respiratory physiology prior to ICI initiation, with longitudinal changes in lung function that differ when compared to CIP- patients who receive checkpoint blockade. To further characterize PFT changes associated with CIP, a prospective study assessing serial PFTs in NSCLC patients receiving ICIs is underway.

P1.16-07 REAL WORLD EVIDENCE OF THE IMPACT OF IMMUNOTHERAPY IN PATIENTS WITH ADVANCED LUNG CANCER

C. Pettengell[1], J. Law[2], L. Le[2], M. Sung[2], S. Lau[3], A. Sacher[2], D. Merritt[4], P. Demarco[4], N. Leighl[3]

[1]*Pentavere, Toronto/Canada,* [2]*University Health Network, Toronto/Canada,* [3]*Princess Margaret Cancer Centre, Toronto/Canada,* [4]*Roche Canada, Mississauga/Canada*

Background: PD-1 axis inhibitors have become a standard treatment modality in the management of advanced lung cancer. Novel Natural Language Processing (NLP) and Artificial Intelligence (AI) technology enables automated extraction of real-world data at greater scale than current manual chart abstraction processes, which can be used to further explore the impact of these agents in the general population irrespective of PDL1 tumour expression. **Method:** Patients diagnosed with stage IIIB/IV lung cancer at the Princess Margaret Cancer Centre between 2015 and 2018 were reviewed using the DARWEN™ NLP and AI data abstraction platform developed by Pentavere. Data extracted include patient age, smoking status, ECOG performance status, tumour histology, biomarker status, PDL1 expression, sites of metastases, treatment information and survival. **Result:** Of 615 patients with accessible electronic pathology records, 540 (87.8%) had NSCLC and 280 (51.8%) of those received systemic therapy and were included in the analysis. 86 (30.7%) were EGFR sensitizing mutation positive, 18 (6.4%) ALK rearranged, PDL1>50%/1-49/<1/unknown in 21/8/10/61%. Almost one third (31.7%) of those that received treatment received immunotherapy for any line of therapy (12.1% first-line). Chemotherapy was used first-line in 56.1% and targeted therapy in 36.1% of those receiving systemic therapy Patients that were more likely to receive immunotherapy any line were smokers (OR: 2.7, 95% CI: 1.43-5.10, p=0.002) with a higher number of metastatic sites (OR: 1.23, 95% CI: 1.06-1.43, p=0.005). Those with EGFR sensitizing mutation and ALK rearrangement were less likely to be given immunotherapy (OR: 0.07, 95% CI: 0.03-0.19, p<0.001 and OR: 0.11, 95% CI: 0.01-0.84, p=0.03 respectively). There was no difference in the rates of immunotherapy being given in those with PDL1>50%/1-49/<1 (52/52/44%, p=0.8). Using Cox regression analyses after controlling for ALK, EGFR, PD-L1, age, sex, baseline ECOG, smoking status and number of metastatic sites, patients that received immunotherapy at any point had longer survival (HR: 0.28, 95%CI: 0.12-0.67, p=0.004) in a complete case analysis. **Conclusion:** Novel NLP and AI technologies like DARWEN™ gives clinicians access to previously unavailable information on real world treatment strategies and outcomes. Increasing uptake of immunotherapy may further improve outcomes for patients with this challenging to treat cancer. This study demonstrates that the benefit of immunotherapy seen in clinical trials can be translated into the general advanced lung cancer population. Larger population studies will be needed to further analyze the impact of new treatments in the real world and will be facilitated by automated data abstraction to rapidly generate large datasets.

P1.16-08 INTEGRATION OF DURVALUMAB INTO THE TREATMENT OF STAGE III NON-SMALL CELL LUNG CANCER: REAL-WORLD CONSIDERATIONS

S. Gorgens[1], E. Schreibmann[2], M. Behera[2], C. Steuer[2], R. Pillai[2], T. Owonikoko[2], J. Shelton[2], S. Ramalingam[1], W. Curran[2], K. Higgins[2]

[1]*Emory University School of Medicine, Atlanta/United States of America,* [2]*Winship Cancer Institute, Emory University, Atlanta/United States of America*

Background: In 2017, the PACIFIC study demonstrated improvement in progression free survival, leading to FDA approval for the treatment of unresectable stage III non-small cell lung cancer (NSCLC) that has not progressed following concurrent platinum based chemoradiation (CRT). This study reports on practice patterns during the first year of adaptation of immunotherapy into the treatment paradigm for stage III NSCLC at a NCI designated Comprehensive Cancer Center. **Method:** This retrospective study captured patients (pts) with unresectable NSCLC treated from 09/2017-10/2018 who referred to radiation oncology for definitive treatment. Clinical and treatment characteristics were extracted, including radiation dose parameters and information regarding durvalumab administration. **Result:** 48 pts with locally advanced NSCLC were referred for definitive

POSTERS

radiation therapy. 17% were not eligible for concurrent CRT: of these, 6 received 60 Gy hypofractionated radiation alone, and 2 received 60-64 Gy with conventional fractionation. Forty (83%) received concurrent CRT (80% carboplatin/paclitaxel, 10% cisplatin/etoposide, 10% platinum/pemetrexed). Of the patients undergoing CRT, 32% did not go on to receive durvalumab due to the following factors: 25% due to unresolved grade 3 or higher toxicities, 25% due to relative contraindications to immunotherapy, 17% were lost to follow up, 8% due to disease progression, 8% due to active illicit drug use, 8% due to large tumor and potential risk for pneumonitis, and 8% received nivolumab. Twenty-seven (68% of pts receiving CRT, 56% of all referred pts) went on to receive durvalumab after completion of CRT. For these pts, the radiation dose parameters were as follows: median total dose of 60 Gy (range 60-66 Gy), median lung V20 of 22.7% (range 5.4-31.5%), median lung mean dose of 13.9 Gy (range 5.3-19.5 Gy), and median heart mean dose of 12.9 Gy (range .715 – 29.9 Gy). The median time from completion of radiation to start of durvalumab was 36 days (range 11-84). Restaging imaging with CT chest after completion of CRT was obtained at a median time point of 35 days. The median number of cycles of durvalumab was 5 (range 1-20). Of pts receiving durvalumab, 37% stopped before 1 year; 40% due to disease progression, 50% due to intolerable side effects, and 10% were lost to follow up. **Conclusion:** Conclusions: Durvalumab was successfully integrated in a rapid fashion into the treatment paradigm for stage III NSCLC in this single institution experience, however only 56% of referred pts were ultimately able to receive durvalumab.

Background: Real-world data regarding treatment patterns and clinical outcomes after progression on first-line pembrolizumab (pembro) monotherapy among NSCLC patients are lacking. **Method:** A comprehensive clinicopathological database of 173 consecutive patients with NSCLC and PD-L1>50% treated with first-line pembro in 14 centers in Italy, Spain, Greece and Switzerland was retrospectively created and post-progression patterns and outcomes were recorded. Analysis was performed using the SAS 9.3 software. **Result:** Main clinicopathological features are summarized in Table 1. Median TPS score for PD-L1 expression was 70%. Median duration of pembro treatment was 6.1 months (range: 0.2-20.8). Thirty patients (17.4%) received pembro despite having non-metastatic disease (stage I-IIIC), as deemed medically inoperable or ineligible for definite chemo-radiotherapy. At data cut-off (10th April 2019), 100 patients (58%) had stopped treatment due to disease progression, 9 (5%) due to toxicity, 3 (2%) for other reasons and 61 (35%) were still on treatment. Best response to pembro was CR, PR, SD and PD in 2%, 34%, 20% and 24% respectively, while in 11.6% death occurred in the absence of documented PD. Among patients who progressed (N=100), in 18 cases pembro was continued beyond progression, as considered to confer clinical benefit. Among patients who discontinued pembro (N=94), 47% received any second-line chemotherapy and 53% received no further treatment. Main chemotherapy regimens were carboplatin with either pemetrexed (16%) or gemcitabine (9%) or paclitaxel (7%), cisplatin-pemetrexed (7%) and gemcitabine monotherapy (9%). Best response to chemotherapy was CR, PR, SD and PD in 2%, 30%, 11% and 32% respectively. After a median follow-up of 11.2 months, median OS was 13.5 months (range: 0.16-25.8+). Table 1: Main clinicopathological characteristics of the patient cohort.

		N=173	%

	Unknown	20	11.6

Conclusion: Real-world data in a large retrospective cohort, indirectly compared to Keynote 024, suggest that: 1) Due to it's favorable toxicity profile, pembro is also an option in earlier stages in frail (PS=2 or medically inoperable stage I-III) patients, 2) One in five patients continues pembro beyond progression due to clinical benefit and 3) More than half of patients who progress do not receive any second-line treatment, mainly due to clinical deterioration.

P1.16-10 REAL-WORLD EFFICACY OF FIRST-LINE PEMBROLIZUMAB IN PATIENTS WITH ADVANCED PD-L1 HIGH NON-SMALL CELL LUNG CANCER IN ARGENTINA

A. Kuzminin[1], N. Minatta[2], M. Bluthgen[3], M. Rizzo[4], M. Naveira[5], V. Wainsztein[1], L. Lupinacci[2], M. Rizzi[3], M. Faura[5], A. Perfetti[6], G. Recondo[1]

[1]*Centro de Educación Médica e Investigaciones Clínicas (CEMIC), Buenos Aires/Argentina,* [2]*Hospital Italiano de Buenos Aires, Buenos Aires/Argentina,* [3]*Hospital Aleman de Buenos Aires, Buenos Aires/Argentina,* [4]*Hospital Universitario Austral, Buenos Aires/Argentina,* [5]*Hospital Britanico de Buenos Aires, Buenos Aires/Argentina,* [6]*Hospital Santojanni, Buenos Aires/Argentina*

Background: Pembrolizumab monotherapy is a standard first-line (1L) treatment regimen for patients (pts) with non-small cell lung cancer (NSCLC) and a PD-L1 tumor proportion score (TPS) ≥ 50%. We aimed to study the clinical efficacy and toxicity of this approach in the real-world setting in Argentina. **Method:** We conducted a retrospective, multicenter study. Patients with metastatic NSCLC and a PD-L1 TPS ≥ 50% treated in 1L with at least one dose of pembrolizumab monotherapy, from December 2016 to February 2019, were included. Data was collected from clinical records, overall response rate (ORR), progression-free survival (PFS) and overall survival (OS) were estimated. Cox regression model was performed for uni- and multivariate analysis. **Result:** A total of 53 pts were included. Median age (range) was 68 years (35-88), 33 (62.3%) were male, and 46 pts (86.7%) were smokers. Most tumors were lung adenocarcinoma (N=47, 88.7%), median (IQR) PD-L1 TPS was 79% (60-87.5) and 22 tumors (41.5%) had a TPS ≥ 75%. *EGFR/ALK/ROS1* mutations/fusions were not detected. Brain (N=10; 18.9%), liver (N=5 (9.4%) and bone (N=15; 28.3%) metastasis were present at baseline. Performance status (PS) score was 0-1 in 46 pts (86.8%) and 7 pts (13.2%) had PS 2. Six pts received baseline corticosteroid treatment. The ORR with pembrolizumab was 41.5% (95% CI: 28.1-55.8), median PD-L1 TPS (mTPS) was significantly higher in responders (mTPS 74% vs 67%, P = 0.04). Grade ≥ 3 immune-related adverse events occurred in 7 pts (13.2%) and 10 (18.9%) required systemic therapy with steroids. With a median-follow up of 12.9 months (95% CI: 8.4-17.6), median PFS and median OS were not reached. The estimated percentage of patients alive and without progression at 6 and 12 months was 64.8% and 55.8%. The estimated percentage of patients alive at 6 and 12 months was 77.5% and 69.4%. Median PFS and OS for patients with PS 2 was 2.4 months (95% CI: 1.7-3.1) and 4.5 months (95% CI: 3.1-6.0), respectively. After adjusting for PS, a PDL1 TPS score ≥ 75% was independently associated with improved PFS in multivariate analysis [HR 0.28 (95% CI: 0.09-0.92); P = 0.03) but not with OS. PS score equal to 2 was independently associated with decreased OS [HR 4.52 (95% CI: 1.06-19.28); P = 0.04] in multivariate analysis. **Conclusion:** Pembrolizumab monotherapy is tolerable and confers durable clinical benefit for patients with tumors expressing high levels of PD-L1 in the real world clinical setting. The optimal first-line immunotherapy approach for patients with PS 2 in this setting warrants further studies.

P1.16-11 A DYAD-BASED MINDFULNESS CANCER RECOVERY PROGRAM FOR SURVIVORS AND FAMILY MEMBERS TO REDUCE LUNG CANCER SYMPTOMS

K. Mcdonnell[1], O. Owens[1], D. Gallerani[1], J. Beer[2], J. Hardin[3], A. Bennett[1], L. Webb[1]

[1]*University of South Carolina, Columbia/United States of America,* [2]*University of Georgia, Athens/United States of America,* [3]*Arnold School of Public Health, Columbia/United States of America*

Background: Although the five-year survival rate for individuals with NSCLC stages I-IIIa, is increasing, excessive symptom burden remains a distressing problem that negatively impacts quality of life. Our long-term goal is to improve clinical outcomes for survivors of localized lung cancer (NSCLC; stages I–IIIa). The study objective is to test a tailored intervention, *Breathe Easier*, which encompasses meditation, varying levels of yoga, and breathing exercises to evaluate feasibility and preliminary effects for survivors and family members (dyads). **Method:** A community-based participatory research approach was used to adapt a mindfulness-based cancer recovery program. Using a prospective, one-group, repeated measures, mixed method design, this study collected feasibility and preliminary data to test the hypothesis that survivors and family members (dyads) who receive an 8-week intervention will demonstrate (a) less dyspnea, (b) less fatigue, (c) improved sleep quality and quantity, (d) improved exercise tolerance and (e) less stress immediately after the intervention. The intervention known as *"Breathe Easier"* consisted of breathing exercises, individual and partner sitting, standing and floor yoga movements, meditations and participant interaction.The outcome variables were measured pre and immediately post intervention by the FACIT Dyspnea Short Form (Parts 1 and 2), FACIT Fatigue Scale v.4. Pittsburgh Sleep Quality Index, 6-Minute Walk Test, and the Perceived Stress Scale v.4. Post-intervention qualitative interviews were conducted. Descriptive statistics were obtained for five quantitative feasibility measures (recruitment, retention, intervention dose, adherence, acceptability). Thematic analysis was used to interpret the qualitative data. **Result:** In six iterations of the intervention,164 survivors were reached, and 32 dyads enrolled (62 participants; 20% recruitment and 94% retention rates). Survivors were 44% male and 62% African American. Among all, 74% were not current smokers, 22% used oxygen, and 71% completed a six-minute walk test post-intervention. Adherence was demonstrated by good attendance and exceeding expectations on home assignments for breathing exercises and meditations. All participants practiced gentle movements (yoga), meeting approximately 80% of expectations. Survivors reported completing daily home assignments slightly more than family members. All agreed that the intervention materials were easy to use, learning yoga and breathing exercises helped, and involving a family member was important. For each outcome variable, differences in survivors versus partners were calculated. Survivors had less dyspnea and perceived stress over time. Both groups had improved fatigue and sleep scores. Interview data enriched the understanding of feasibility and preliminary outcome measures. Six themes illustrated participants' experiences: (1) Learning to Breathe Easier, (2) Enhanced Closeness with Committed Partners, (3) Stretching, Releasing Tension, and Feeling Energized, (4) Interacting with Others as Beneficial, (5) Refocused on Living, and (6) Sustainability as a Decision. **Conclusion:** Recruitment, retention, adherence, and acceptability demonstrated strong feasibility. Preliminary outcome data indicate benefits over time for both survivors and family members.

P1.16-12 AN ANALYSIS OF HEALTHCARE USE AND THE COST ASSOCIATED TO END-OF-LIFE CARE OF LUNG CANCER PATIENTS IN A SPANISH HOSPITAL

J.L. Cruz[1], M. Provencio[2], E. Menasalvas[3], C. Parejo[2], F. Martínez-Ruíz[4], J.C. Sánchez-González[2], R. Gómez-Bravo[2], A. Ramos Martín-Vegue[2], A. Royuela[2], A. Rodríguez-González[3]

[1]*Puerta de Hierro University Hospital - Universidad Politécnica de Madrid, Majadahonda/Spain,* [2]*Hospital Puerta de Hierro-Majadahonda, Madrid/Spain,* [3]*Universidad Politécnica de Madrid, Pozuelo de Alarcón/Spain,* [4]*Universidad de Valencia, Valencia/Spain*

Background: Despite various studies have demonstrated that the consumption of healthcare services by cancer patients, and therefore healthcare costs, increases during the end-of-life period, there are insufficient studies which focus specifically on lung cancer. Thus we aim to study the consumption of healthcare services and its cost in end-of-life lung cancer patients attended in the Puerta de Hierro University Hospital, Spain. **Method:** The Cross Industry Standard Process for Data Mining (CRISP-DM) was applied to integrate and analyze activity data extracted from the Electronic Patient Record (EPR) and clinical data of lung cancer patients from a previous study. A cohort of 224 deceased patients, diagnosed between 01/01/2009 and 31/12/2016, was analyzed to determine the use of healthcare services together with the time-related distribution of such use and associated cost during the end-of-life period. **Result:** Overall, 82% of the patients received outpatient care, 68% received emergency service care, 53% experienced some period of hospitalization during the last 30 days of their life, and 38% of the patients died during hospitalization. The cost of hospitalization amounted to 88% of the total (excluding the cost of outpatient administered medication and radiotherapy treatment), with the cost of emergency services and consultations being 2.3% and 9.6%, respectively. In total, 58% of the healthcare assistance cost occurred during the last 6 months of life, and 21% in the last 30 days. The costs during the last 30 days represented 36% of the cost during the last 6 months.

Variable	Total	Variable	Total
Number of patients	224 (100%)	Number of patients	224 (100%)
Gender		Stage at diagnosis	
Male	187 (83.5%)	IA	7 (3.1%)
Female	37 (16.5%)	IB	13 (5.8%)
Age at diagnosis (years)		IIA	12 (5.4%)
Mean (SD)	65.3 (10.0)	IIB	9 (4.0%)
Median (Min.-Max.)	66 (31-92)	IIIA	50 (22.3%)
Race		IIIB	46 (20.5%)
Caucasian	217 (96.9%)	IV	87 (38.8%)
African	4 (1.8%)	With a history of cancer in first degree family	
Latin American	3 (1.3%)	Yes	41 (18.3%)
Tobacco use		No	63 (28.1%)
Ex-smoker (>1 year)	151 (67.4%)	Unknown	120 (53.6%)
Cigarettes per day. Mean (SD)	28.7 (13.4)	Personal history of cancer	
Cigarettes per day. Median (P25-P75)	28 (20-40)	Yes	45 (20.1%)
Active smoker	54 (24.1%)	No	150 (67.0%)
Cigarettes per day. Mean (SD)	27.9 (13.6)	Unknown	29 (12.9%)
Cigarettes per day. Median (P25-P75)	23.5 (20-40)	ECOG-PS at diagnosis	
Never-smoker	17 (7.6%)	0	104 (46.4%)
Unknown	2 (0.9%)	1	87 (38.8%)
Histology		2	24 (10.7%)

P1.16-13 DEVELOPMENT OF A VETERANS AFFAIRS BASED COMPREHENSIVE LUNG CANCER SURVIVORSHIP PROGRAM

S. Shofer[1], A. Hassinger[2], J. Stafford[2], R. Kundich[2], A. Mathews[1], S. Swartzwelder[1]

[1]*Duke University Medical Center, Durham/United States of America,* [2]*Durham VA Medical Center, Durham/United States of America*

Background: Symptoms of depression and poor exercise tolerance are common in patients with lung cancer and negatively impact patients' quality of life and decrease survival[1]. Cardiorespiratory fitness is inversely correlated with survival in lung cancer patients[2], and interventions that improve depression have been shown to increase survival in these patients[1]. We have developed a comprehensive lung cancer survivorship program (LCSP) at the Durham Veterans Administration Medical Center to address symptoms of depression, anxiety, dyspnea, physical debility, and tobacco abuse in veterans with lung cancer. The objective of the program is to alleviate symptoms and improve quality of while potentially impacting longevity through these interventions. **Method:** The LCSP is a 4 part tele-health based program with interventions targeted at depression, tobacco abuse, physical debility, and radiographic surveillance for recurrence. The initial visit is conducted with a mental health PA and an exercise physiologist and consists of a mental health (MH) assessment, depression screen, respiratory symptom, quality of life assessment, 6 min walk, and tobacco use assessment. Medications for depression or COPD may be prescribed or modified and the exercise program is explained and demonstrated to the patient. Patients are followed weekly for 12 weeks with 60 min MH visits and 30 min pulmonary rehabilitation appointments depending which components of the program they are participating in. There is also a video tablet option available for interested patients. At the end of the 12 week program, patients return for an in-person clinic appointment for a final assessment and to complete a repeat set of assessment metrics collected during the initial visit. Patients with ongoing mental health concerns are referred for continued care with a local mental health provider. **Result:** Program enrollment began in January 2019. 71% of referred patients agree to participate. 91% of participants are male, most patients are in the 7thor 8thdecade of life, and 91% are stage I with one stage III non-small lung cancer. All patients are participating in pulmonary rehabilitation, but only 37% have accepted mental health intervention despite 82% of patients carrying a mental health diagnosis (Table 1).

Table 1. Baseline Patient Characteristics

	Number	Percentage
Smoking Status		
Current	2	18
Former	8	82
Never	1	9
Fried Frailty Index		
Non-frail	3	33
Pre-frail	5	45
Frail	1	11
Mental Health Status		
HADS Score $\geq$ 8	6	54
PHQ-9 $\geq$ 5	6	54
Psychiatric Diagnosis	9	82
COPD Status		
No Diagnosis	2	18
Mild	1	9
Moderate	6	54
Severe	2	18

Conclusion: Patients with lung cancer are accepting of home based pulmonary rehabilitation even among elderly patients with poor performance status. Assistance with mental health support is not commonly engaged by this population, despite higher than anticipated rates of depression and post-traumatic stress disorder. Future work will examine the interaction between exercise performance and symptoms of depression.

Keywords: pulmonary rehabilitation, mental health, survivorship

P1.16-14 EFFECTS OF AN ARTIFICIAL INTELLIGENCE (AI) SYSTEM ON CLINICAL TRIAL ENROLLMENT IN LUNG CANCER

K. Leventakos[1], J. Helgeson[1], A. Mansfield[1], E. Deering[1], A. Schwecke[1], A. Adjei[1], J. Molina[1], C. Hocum[1], K. Parikh[1], T. Halfdanarson[1], R. Marks[1], T. Bleeker[1], K. Pomerleau[1], S. Coverdill[2], M. Rammage[3], A. Preininger[3], G. Purcell Jackson[3], T. Haddad[1]

[1]*Mayo Clinic, Rochester/United States of America,* [2]*IBM Watson Health, Caimbridge/United States of America,* [3]*IBM Watson Health, Cambridge/ United States of America*

Background: Clinical trials offer cancer patients access to the latest promising therapies and improve the overall quality and safety of cancer care. However, few patients participate, due in part to the time and effort associated with traditional manual ad hoc screening methods. IBM Watson Health's Clinical Trials Matching (CTM) is an artificial intelligence (AI) system that employs natural language processing to abstract patient and trial data from unstructured sources and machine learning to match patients to trials. This study compared the clinical trial enrollment rates of lung cancer patients before and after deployment of CTM. **Method:** CTM was trained for lung cancer and adopted in an academic outpatient oncology clinic using a phased implementation approach beginning July 2018. Clinical trials included ~42 therapeutic, supportive care, and observational trials. Clinical research coordinators validated Watson-derived clinical trial matches on the day prior to patient clinic visits. Oncologists were provided with a list of potentially eligible trials for each patient to facilitate evaluation at point of care. The average monthly enrollment rates for therapeutic trials were compared 6 months before and after CTM deployment. Average enrollment rates per active clinical trial were reported. **Result:** Clinical trial matches were validated and delivered to lung oncology providers in 69% (1818/2637) of patients' visits during the 6-month phased implementation. Enrollment of patients in lung cancer therapeutic clinical trials occurred at a rate of 3.83 patients/month after CTM deployment, as compared to 1.83 patients/month prior to CTM deployment; a 109% enrollment increase. When adjusted for the average number of active clinical trials before (30) and after (39) CTM implementation, the enrollment was 0.097 patients/trial using CTM, compared to 0.061 patients/trial using traditional methods; a 58.4% enrollment increase. **Conclusion:** Use of IBM Watson Health's Clinical Trials Matching (CTM) system with screening coordinators facilitated an increase in clinical trial enrollment and promoted awareness of clinical trial opportunities within the lung oncology practice.

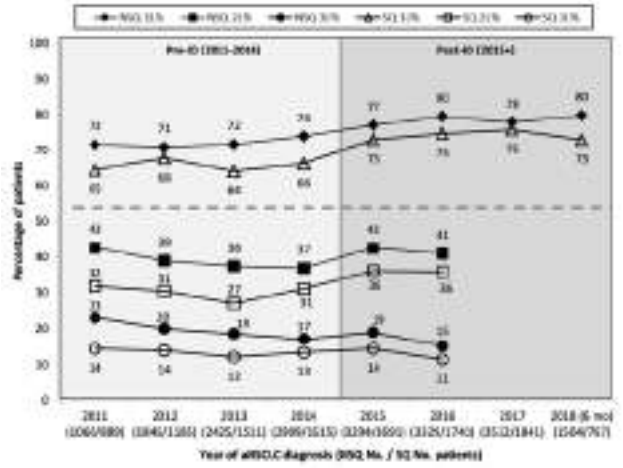
P1.16-15 RATES OF SYSTEMIC ANTICANCER THERAPY (SACT) FOR ADVANCED NON-SMALL CELL LUNG CANCER (ANSCLC) IN THE US, 2011–2018

V. Velcheti[1], S. Chandwani[2], X. Chen[2], B. Piperdi[2], T. Burke[2]

[1]*NYU Langone, Perlmutter Cancer Center, New York/United States of America,* [2]*Merck & Co., Inc., Kenilworth/United States of America*

Background: The SACT options for aNSCLC continue to increase each year with approvals of more effective therapies that improve long-term outcomes, such as immunotherapies (IO). Our aim was to examine trends in SACT rates from 2011-2018 for patients with aNSCLC and no known EGFR/ALK aberrations at US community oncology practices. **Method:** We used the nationwide Flatiron Health EHR-derived database (data cutoff: 31Jan2019), which incorporates oncologist-defined, rule-based lines of therapy. Adults with aNSCLC diagnosis date from Jan2011-Jun2018, inclusive, with recorded EHR activity $\leq$90 days after diagnosis, were eligible. Patients with known EGFR/ALK-positive tumors, or nonsquamous histology (NSQ) with unknown or untested EGFR/ALK status, were excluded. We summarized no-treatment and first-line (1L) SACT rates as a proportion of aNSCLC diagnosed from 2011-2018, while limiting 2L and 3L SACT rates to aNSCLC diagnoses from 2011-2016

in order to have sufficient follow-up. Results were stratified by NSQ and squamous (SQ) histology, as well as by pre-IO and post-IO years of aNSCLC diagnosis, defined broadly as 2011-2014 and 2015+, respectively, based on the earliest IO approval for 2L therapy in Mar2015. **Result:** The figure depicts 1L, 2L, and 3L SACT rates by year of aNSCLC diagnosis for EGFR/ALK-negative NSQ and for SQ. For NSQ, the pre-IO and post-IO no-treatment rates were 28% (2286/8246) and 22% (2520/11,639), respectively. For SQ, the pre-IO and post-IO no-treatment rates were 34% (1781/5200) and 26% (1549/6040).



Conclusion: For both EGFR/ALK-negative NSQ and SQ aNSCLC, 1L SACT rates are trending upward, with no-treatment rates showing substantial drops in the post-IO (versus pre-IO) period. The 2L and 3L SACT rates are variable for both NSQ and SQ; and SACT rates for NSQ tend to be substantially greater than for SQ across all lines of therapy and years of diagnosis.

Keywords: real-world treatment rates, Immunotherapy, advanced NSCLC

P1.16-16 LUNG CANCER CONTROL IN SUB-SAHARAN AFRICA: EXPERIENCE AT AMPATH ONCOLOGY IN WESTERN KENYA

F. Asirwa, L. Atundo, H. Kibet

Ampath_ICI Kenya, ELDORET/Kenya

Background: Objective To find out the cause for the under-diagnosis of Lung Cancer (LC) at AMPATH by using community engagement and high-risk screening at the TB clinics. Methods FGDs with community cough monitors in counties were done due to overlap of LC and TB presentations. **Method:** Consequently through establishing a multinational-lung cancer control program (MLCCP) to improve diagnosis and patient journey for lung cancer patients in our settings, we classified patients with symptomatic lung disease (chest pain, cough, SOB, weight loss, hemoptysis) and negative gene expert/negative sputum for AAFB as high-risk for further evaluation. CT scans were done for anyone with a chest mass/lesion and Image-guided biopsy offered. **Result:** s Jan 2018-Mar 2019, 331 high risk clients were evaluated. 214 with masses CT scans of which 205 were lung and 9 were mediastinal. 131/214 had biopsy, of which 83 (60 LC, 23 secondary mets) while 48 were other conditions.These included: Lung Fibrosis, Aspergillosis, Chronic granulomatous inflammation, TB, Thymoma, viral histiocytosis, Granuloma and unconfirmed diagnosis For the biopsied lung masses-131/214, 60 had confirmed LC. This represented 45.8% of those biopsied. Male to Female ratio was 1:1, median age at diagnosis was 62 with 55-74 age range accounting for 73.2% of LC cases. The mean duration of symptoms was 8 months, range of 1 to 12 months. >50% of the cancer patients made 7-10 hospital visits before diagnosis, with 25% making more than 14 visits. NSCLC accounted for 92.2% of the diagnosis with SCLC 7.8%. Adenocarcinoma was the commonest diagnosed histological sub-type at 66% of NSCLC. Majority of the patients were diagnosed at stage IV, 78.1% with only three patients diagnosed in stage II. 39% (25/64) patients are alive and on follow-up. **Conclusion:** Early detection is key. Poor referral patterns and lack of LC knowledge and diagnostic skills by HC professionals causes late stage at diagnosis. Patients do not present Late. Community engagement and embedding simple protocols for prompt referrals/diagnostic work-up in TB control programs may lead to improved outcomes. Prevention measures should also be rolled out. Cough monitors were essential to improving the LC patient's journey. *MLCCP is a Multi-National Lung Cancer Control Program with Dr. Asirwa the overall PI for Kenya, Tanzania, Swaziland and South Africa. Funding for the program has been provided by Bristol Myers Squib Foundation (BMSF) *MLCCP Team is the Kenyan Team for this Western Kenya Program Component

P1.16-17 GETTING TO KNOW OUR WEAPONS BETTER. ANALYZE FROM REAL LIFE DATA FROM LEÓN, SPAIN

L.F. Sánchez-Cousido, M. Rojas Piedra, M. López Flores, I. Delgado Sillero, A. López González, C. Castañón, B. Nieto Mangudo, M. Pedraza, L. De Sande, S. Medina, Á. Rodriguez, A. García-Palomo, P. Diz Tain

Complejo Asistencial Universitario de León, León/Spain

Background: The way immunotherapy alters the tumor environment is perceived but still not completely known. Although clinical trials revealed good results, data from real life settings is still lacking. We reviewed patients treated with immunotherapy at our center. **Method:** We retrospectively reviewed 83 lung cancer patients treated with immunotherapy at our Hospital between September 2015 and July 2018.75 patientsreceived immunotherapy after previous treatment. Data was obtained from medical records. Primary endpoint was to report immunotherapy efficacy and safety in the 75 pretreated patients with advanced NSCLC of our everyday clinical practice. Secondary aim was to analyze efficacy according to immune related toxicity and other basal features. **Result:** 60 were men, 15 women. Median age 66 years (range 48-84). 50 were former smokers, 23 still smoking, 2 were never smokers. 44 were adenocarcinomas, 26 squamous cell carcinoma, 5 NOS. 18 were stage III, 57 stage IV. 36 had at least one metastatic organ. 11 had liver while 10 had brain metastases. PDL1 was assessed in 12: <1%, 3; 1-49%, 3; >50%, 6. 3 were EGFR-positive, 3 ALK+, 2 KRAS+. Median number of lines was 1 (range=1-5). Best response to any previous treatment was stable disease (SD) 38.7% (n=29); partial response (PR) 36% (n=27); complete response 2.7% (n=2). 71 patients received Nivolumab vs 4 Pembrolizumab. Best response to immunotherapy was PR 21.3% (n=16) with SD 34.7% (n=26). Median number of cycles was 10 (range=1-77). 68 (90.7%) were PS<=1 before immunotherapy while 43 (57.3) still PS<=1 after. Median overall survival (OS) was 18 months (95%CI 7.03-28.69). Median progression free survival (PFS) was 4 months (95%CI 2.52-5.47). OS were higher in former smokers (median OS: 31 months vs 14 p<0.05); in PS<=1 before immunotherapy (median OS: 22 months vs 6 p<0.05) and in those with any grade of toxicity (mean 29 months vs 13 p<0.05). 42.7% (n=32) had any grade of immune-related toxicity (80% <=grade 2). Skin rash and hypothyroidism were the most common toxicities. 32% (n=24) needed corticosteroids to control toxicity. Immunotherapy stopping reasons were progression 47 (62.6%) and toxicity 9 (12%). 33.3% (n=24) received treatment after progression. Best response to treatment after immunotherapy was PR 38.1% (n= 8) with 90.5% disease control rate. 37 (49.3%) patients died at data cut-off. **Conclusion:** Compared with previous publications we had less treatment-related toxicity but the same discontinuation due to it. Best response and PFS is similar while median OS is slightly higher in our center. After immunotherapy we obtained better disease control with chemotherapy. Toxicity was related with better OS as in previous works.

Keywords: NSCLC, Immunotherapy in pretreated patients, Real world data

P1.16-18 PLEURAL MALIGNANT EFFUSION. IS IT POSSIBLE TO PREDICT RECURRENCE AFTER PALLIATIVE PLEURAL PROCEDURE?

F. Abrao[1,2], I. Abreu[1], M. Oliveira[1], G. Viana[1], R. Younes[2], E. Negri[3]

[1]*Hospital Santa Marcelina - Brazil, Sao Paulo/Brazil,* [2]*Hospital Alemão Oswaldo Cruz, SAO PAULO/Brazil,* [3]*Faculdade de Medicina Universidade de São Paulo, São Paulo/Brazil*

Background: Malignant pleural effusion (MPE) accounts for several hospital admissions. MPE recurs rapidly in a considerable number

of patients. Since MPE is associated with poor survival, a detailed prognosis may help to recognize patients with at higher risk of recurrence, aiming to individualize treatment strategies. However, there have been few studies that evaluated factors, including systemic therapy, associated with MPE recurrence. The aim of this study was to recognize risk factors of recurrence in symptomatic patients only, who required a pleural approach. **Method:** A prospectively assembled database was analyzed to search for patients with symptomatic MPE. The obtained data included basic demographics, primary tumor site, performance status, neutrophil/lymphocyte ratio (NLR) and platelets/lymphocyte ratio. Metastatic sites were also evaluated, which was defined as presence of any numbers of metastasis at each organ. Regarding the postoperative period, we analyzed pleural effusion recurrence, the palliative approach used, in addition to the biochemical profile of pleural fluid. Pleural thickening and pulmonary infiltrate were also described. Systemic treatment was evaluated. Patients were classified into three groups at MPE diagnosis: systemic treatment-naïve patients, patients who received first-line systemic treatment and patients receiving second-line systemic treatment or further therapy. The quantitative variables without definite cutoff points were submitted to the ROC (Receiver Operating Characteristic) curve, using a sub-sample of 50% of the recorded cases. Cutoff points were defined as the ones with sensitivity and specificity values >0.80. Univariate and multiple Cox regression models were used to evaluate the risk of recurrence (HR) and their respective 95% confidence intervals (95%CI). **Result:** Of the 288 analyzed patients, the most frequent main procedure was pleurodesis (43.1%). Disease recurrence occurred in 58 patients (20.1%). Recurrence-free survival was 73.3% at 12 months. Patients submitted to the pleurodesis procedure had a longer recurrence-free survival of 84.6%, with HR = 0.33 (95%CI = 0.17 - 0.63) when compared to patients who underwent the pleural drainage. Regarding the chemotherapy lines of treatment, Cox univariate analysis showed that the risk of recurrence for those submitted to the 1st line of palliative CT was HR = 3.19 (95% CI = 1.32 - 7.70) and for the 2nd line of palliative CT, HR = 7.32 (95% CI = 3.34 - 16.07) when compared to the systemic treatment-naïve patients. The independent factors for recurrence-free survival were procedure and chemotherapy lines. Patients who were submitted to pleurodesis had a protective factor for recurrence, with an HR = 0.34 (95% CI = 0.15 - 0.74, p = 0.007). On the other hand, patients submitted to the 1st and 2nd line of palliative CT had, respectively, an HR risk = 2.81 (95% CI = 1.10-7.28, p = 0.034) and HR = 3.23 (95% CI = 1.33 - 7.84, p = 0.010). **Conclusion:** Patients receiving the first or second line of systemic treatment have a higher risk of MPE recurrence when compared to patients who underwent MPE treatment before starting the systemic treatment. The definitive treatment of MPE, such as pleurodesis, was associated with a lower risk of MPE recurrence.

P1.16-19 UNDERSTANDING PHYSICIAN BARRIERS IN THE MANAGEMENT OF LUNG CANCER IN NEPAL. CAN EDUCATIONAL INTERVENTION MAKE A DIFFERENCE?

R. Shilpakar[1], B. Paudel[1], M. Glode[2], A. Shah[1], S. Dulal[1], B. Acharya[1], P. Neupane[3]

[1]*National Academy of Medical Sciences, Bir Hospital, Kathmandu/Nepal,* [2]*University of Colorado Cancer Center, Denver/United States of America,* [3]*University of Kansas Medical Center, Kansas/United States of America*

Background: Lung cancer is the leading cause of cancer morbidity and mortality for both men and women in Nepal. A majority of patients present with advanced or metastatic disease and some patients are never referred to an oncologist for further treatment after diagnosis. Many factors contribute to this, but diagnostic delay, lack of prompt referral and nihilistic attitude towards lung cancer seem to be most important. Potentially, a lack of oncology training and exposure contributes to this. Herein, we evaluated the physician related factors contributing to the current scenario of lung cancer treatment in Nepal and whether oncology education could make a difference. **Method:** A prospective pilot survey among residents and faculty from 10 medical colleges with Internal Medicine programs across Nepal was performed. A structured, self-administered questionnaire focusing on physician's behavior, practice, and attitude towards lung cancer was used. The questionnaire was distributed by e-mail to each site and a printed copy given to participants. **Result:** 74 participants responded to the survey questionnaire. Only 3 out of 10 Internal Medicine programs had a compulsory oncology rotation in their residency program. Multiple factors contributed to delay in diagnosis of lung cancer. 66 participants (91.6%) responded that they gave empirical anti-tubercular drugs(ATT) to patients with a non-resolving consolidative mass before they began evaluation for lung cancer; 22 % deferred CT scan before ATT. Multiple courses of antibiotics was a common practice in 62.5% participants. Misattribution of existing symptoms was common. 83.3% agreed that they treated smokers with respiratory symptoms initially as COPD with no consideration of lung cancer while 72.2% did not consider lung carcinoma in a middle-aged, never-smoker female with non-resolving consolidative mass. A paired t-test was used to analyze the responses among participants with oncology education during their residency with those who did not have an oncology rotation and was statistically significant (p= 0.001). We also discovered that 36.1% of participants don't refer elderly patients with lung cancer to an oncologist because they think lung cancer treatment is usually futile, toxic and does not help the patient. **Conclusion:** Lung cancer remains a neglected disease in Nepal. There is an urgent need to overcome physician related barriers by oncology education for physicians and in training programs for early diagnosis and treatment of lung cancer for potential improvement in survival and quality of life in patients with lung cancers.

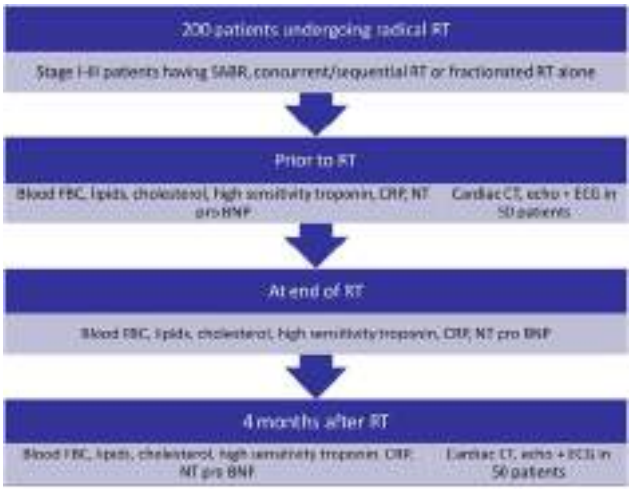
P1.16-20 TRIAL IN PROGRESS: CARDIAC TOXICITY IN PATIENTS UNDERGOING CURATIVE INTENT RADIOTHERAPY FOR LUNG CANCER

K. Banfill[1,2], F. Sun[3], A. Mcwilliam[1,2], A. Abravan[2], J. Lilley[3], B. Wheller[3], M. Schmitt[4], K. Franks[3], M. Van Herk[2], C. Faivre-Finn[1,2]

[1]*Christie NHS Foundation Trust, Manchester/United Kingdom,* [2]*University of Manchester, manchester/United Kingdom,* [3]*Leeds Cancer Centre, Leeds/United Kingdom,* [4]*North West Heart Centre, Manchester/United Kingdom*

Background: The cardiotoxic effects of radiotherapy (RT) in long term survivors of breast cancer or lymphoma are well documented. Post-mortem studies and animal models have shown that RT causes fibrosis of cardiac structures leading to a wide variety of cardiac pathology. RTOG 0617 has highlighted a link between survival and cardiac dose and has led to a number of studies of cardiac toxicity in lung cancer patients. It is difficult to draw conclusions on cardiac dose constraints from available studies due to their retrospective nature and heterogeneity. We present an ongoing multicentre retrospective data mining study and prospective trial of cardiac biomarkers and imaging in patients undergoing radical lung RT, the aim of which is to define cardiac dose contraints leading to cardiac sparing treatment strategies. **Method:** Retrospective Validation Image based data mining results for heart substructures will be validated using a larger cohort. We will obtain data from Public Health England on cardiac risk factors, hospital admissions and cause of death for these patients to conduct a multivariate survival analysis. Clinical Trial (NCT03645317) A prospective study will collect cardiac risk factors (Qrisk 3), detailed cardiac imaging (CT and echocardiogram), ECG and cardiac blood biomarkers to evaluate effect of the radiotherapy on the heart. Figure 1 shows an overview of the clinical trial.



Result: Over 4000 patients treated with curative intent RT from 1/1/2010 to 30/12/206 have been identified. Details on 600 patients have been obtained and will be presented at WCLC 2019. Fifty-two

patients (9%) had cardiac events following RT. The prospective trial is due to open in May 2019 **Conclusion:** Studies of cardiac toxicity in lung RT have so far mainly been heterogeneous and retrospective. We describe a package of work incorporating large retrospective datasets with prospective imaging and blood biomarker collection to define cardiac dose parameters. This will improve the outcomes of lung cancer patients treated with radical radiotherapy by limiting heart dose and reducing cardiac events.

Keywords: cardiac toxicity, cardiac imaging, radiotherapy

P1.16-21 DOES AGE AFFECT WHAT PATIENTS VALUE WHEN CONSIDERING LUNG CANCER TREATMENTS? EVIDENCE FROM A NATIONAL SURVEY

C. Presley[1], S. Janse[1], E. Anderson[2], K. Gallagher[2], A. Ferris[3], E. Janssen[4], U. Basu Roy[3], J. Bridges[1]

[1]*The Ohio State University, Columbus/United States of America,* [2]*Patient Advocate Foundation, Hampton/United States of America,* [3]*LUNGevity Foundation, Bethesda/United States of America,* [4]*ICON PLC, Gaithersburg/United States of America*

Background: Few studies have explored how values vary with patients' lung cancer treatment experience. Due to the rapidly increasing number of treatments for lung cancer, we sought to demonstrate a simple values-elicitation method and explore how values differ across age. **Method:** The values of patients and caregivers with small cell (SCLC) and non-small cell lung cancer (NSCLC) inclusive of all stages were explored using a simple values elicitation exercise developed in partnership with diverse stakeholder advisory boards. Respondents were presented with five treatment characteristics, including progression free survival (PFS), short-term side effects (ST-SE), long-term side effects (LT-SE), and mode of administration. All characteristics and plausible outcomes were described. Values were elicited using a simple three-point Likert scale spanning not important, somewhat important, and very important, which were scored as 0, 5, and 10 respectively. Data came from a national survey completed in partnership with LUNGevity and other partners. Differences in values were explored between patients and caregivers, as well as across patients' self-reported age with two sample t-tests. **Result:** Among 793 eligible respondents, 556 were patients (70%) with 77% NSCLC, 11% SCLC, 12% unknown subtype and 233 were caregivers (30%). The average patient age was 58.4 years (y) (SD = 12.3), with 235 (42%) < 60y and 321 (58%) ≥60y. PFS was the most important attribute for respondents, but was undervalued by caregivers compared to patients (mean score (MS): 8.1 v 8.6, P = 0.014). Caregivers overvalued the importance of ST-SE (MS: 7.0 v 6.1, P < 0.001), LT-SE (MS: 8.4 v 7.6, P = 0.001), and mode of administration (MS: 6.9 v 6.1, P = 0.006). PFS was the most important attribute and valued similarly among younger vs. older patients (MS: 8.7 v 8.6, P = 0.76). However, ST-SE (MS: 6.4 v 5.8, P = 0.042) and LT-SE (MS: 8.0 v 7.4, P = 0.018) were more important among patients < 60y vs. ≥60y, respectively. **Conclusion:** Among patients with lung cancer, progression free survival was highly valued regardless of patient age. Older patients value short term and long term side effects differently as compared to younger patients.

P1.16-22 REDUCED DELAYS IN DIAGNOSTIC PATHWAYS FOR NON-SMALL CELL LUNG CANCER AFTER LOCAL AND NATIONAL INTERVENTIONS

D. Lærum[1], L. Fjellbirkeland[2], O.T. Brustugun[3], F. Gallefoss[1], R. Falk[2], T.-E. Strand[4]

[1]*Sørlandet Hospital Kristiansand, Kristiansand/Norway,* [2]*Oslo University Hospital, Oslo/Norway,* [3]*Drammen Hospital - Vestre Viken Hospital Trust, Drammen/Norway,* [4]*Cancer Registry of Norway, Oslo/Norway*

Background: Patients with non-small cell lung cancer (NSCLC) may experience progression and stage shift due to delays in a complex and time-consuming diagnostic work-up. We have analyzed the impact of both a local and national intervention on total time to treatment (TTT) for a population-based cohort of NSCLC patients. **Method:** All patients diagnosed with NSCLC at a county hospital in Kristiansand, Norway, 2007-2016 were reviewed. The period 2007-12 before the interventions was defined as baseline. Local bottlenecks in the diagnostic pathways were identified and a new, locally developed diagnostic algorithm introduced from 2013. From 2015 National diagnostic cancer pathways were implemented and local adjustments were made accordingly. TTT defined as time from referral of the primary physician to treatment was compared in the three diagnostic time periods; baseline period (2007-12), local initiative (2013-14) and the national initiative (2015-16). Multivariable quantile regression was used to correct for possible confounding factors. **Result:** A total of 780 NSCLC patients were included in the study. The median TTT decreased from 46 days in the first period to 35 days in the last period. Among patients treated with curative intent the median TTT decreased by 21 days, from 64 to 43 days (p<0.001) while the mean number of procedures increased from 3,5 to 3,9. In median regression analysis, the local intervention was associated with a reduction of 7.7 days (95% CI 3.2, 12.3) in TTT, while the national intervention had a reduction of 14.9 days (95% CI 10.2, 19.6) compared to the baseline group. Examining the 75thand 90thpercentile, the last period had 22 days and 27 days shorter TTT than the first period, respectively. Covariates associated with longer TTT were stage I (21.3 days compared to stage IV), use of PET-CT (10.6 days), diagnostic procedure at external hospital (13.0 days), and additional number of diagnostic procedures (5.3 days per procedure). **Conclusion:** Both interventions, the local and national initiatives introduced to this population significantly reduced TTT in NSCLC despite more diagnostic procedures being added to the work-up. The effect was most pronounced among patients with disease available for curative treatment.

P1.16-23 COMPARISON OF ELECTRONIC AND TRADITIONAL THORACIC DRAINAGE SYSTEMS FOR POSTOPERATIVE CHEST TUBE MANAGEMENT AFTER PULMONARY RESECTION

C.F. Wu

Chang Gung Memorial Hospital, Linkou, Taoyuan/Taiwan

Background: The objective of this study was to evaluate whether a electronic thoracic drainage system (ECD) is clinically useful compared with a traditional thoracic drainage system (TTD) in chest tube management following lung lung resection. **Method:** Patients scheduled to undergo wedge, segmentectomy or lobectomy were prospectively randomized before surgery to ECD group or TTD group. A stratification randomization was performed sequentially. The primary end point was the duration of chest tube placement. The secondary endpoint was daily activity of both groups **Result:** No statistically significant differences were found between groups ECD and TTD with regard to the duration of chest tube placement (2.0 vs 3.0 days) and duration of hospitalization in wedge resection sub group, or frequency of postoperative adverse events (1% vs 2%; P=0.361). In subgroup analyses of segemetectoy and lobectomy patients, the duration of chest tube placement(median, 2.5 vs 4.0 days; P=0.045) and duration of hospitalization (median 3.0vs 5.2 days; P=0.048) were significantly different between subgroups. **Conclusion:** The use of a digital thoracic drainage system did not shorten the duration of chest tube placement in comparison to a traditional thoracic drainage system in wedge group. However, in anatomic resection, the chest tube duration and hospitalization was significantly in ECD group

Keyword: VATS, electronic drainage system,daily activity

P1.16-24 DETECTION OF PLASMA T790M MUTATION AFTER THE FIRST GENERATION EGFR-TKI RESISTANCE OF NON-SMALL CELL LUNG CANCER IN THE REAL WORLD

H. Li[1], D. Lv[1], H. Xu[1], M. Ye[2], X. Wu[1], F.-M. Kong[3], H. Yang[3]

[1]*Affiliated Taizhou Hospital at Enze of Wenzhou Medical University, Taizhou/China,* [2]*Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China,* [3]*Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China*

Background: The epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) has shown efficacy in mutation non-small cell lung cancer(NSCLC), but acquired resistance is inevitable. It has been confirmed that the secondary EGFR Thr790Met (T790M) mutation accounted for about 50% at acquired resistance in tumor tissue. The third generation EGFR-TKI had significantly efficacy in T790M positive NSCLC . The purpose of this study was to investigate the

positive rate of plasma T790M mutation and its relationship among the clinical characteristics and the frequency of T790M mutation in acquired resistance after first line EGFR- TKI treatment in the real world. **Method:** Patients were recruited prospective from September 2017 to June 2018.The eligibility criteria of the trial included:1. Older than 18 years, histologically confirmed NSCLC stageIIIB/IV, EGFR mutation positive; 2.Had progressive disease (PD) after first generation EGFR-TKI by RECIST, PFS>3months; 3.excluded patients who had recevied the third generation TKI treatment. All patients take 10 ml of blood, and detected the T790M gene by amplification refractory mutation system(ARMS). The study was approved by the Ethics Committee of Taizhou Hospital, ethical batch number: 201637. **Result:** 189 patients are in the analysis (Table 1). The overall plasma T790M mutation rate was 36.51 % (69/189). The positive rate of T790M mutation after the failure of first generation EGFR-TKI treatment was not correlated with the patient's age, sex and the type of first generation TKI drugs. However, it is related to the mutation type of EGFR in baseline and the mode of progression according to Wu YL et al. reports. The frequency of T790M mutation among patients with initial exon 19 deletion mutation, exon 21 L858R point mutation, and other mutations were 45.44%, 26.19% and 33.33%. The mutation rate of T790M in 19del mutant patients was higher than that of L858R mutation and other mutations (p=0.026). The frequency of T790M mutation in local progression patients was 50% after the first generation EGFR TKI was resistant to drug, when in gradual progression was 26.92%, and in dramatic progression was 38.10%. The frequency of T790M mutation of patients with local progression was significantly higher (p=0.031).

Table 1 Univariate analysis of the association between patients' characteristics and plasma T790M status.

Characteristics	NO.	Plasma T790M mutation states		P value
		Positive (+)	Negative(-)	
Age(yr)				
≤60	64	25(39.1%)	39(60.9%)	P=0.438
>60	125	44(35.2%)	81(64.8%)	
Sex				
Male	64	27(42.19%)	37(57.81%)	P=0.246
Female	125	42(33.6%)	83(66.4%)	
Baseline EGFR mutation status				
19-del	99	45(45.45%)	54(54.55%)	P=0.026
21-L858R	84	22(26.19%)	62(73.91%)	
others	6	2(33.33%)	4(66.67%)	
First generation TKI				
Lcotinib	96	28(29.17%)	68(70.83%)	P=0.074
Gefitinib	90	39(43.33%)	51(56.67%)	
Erlotinib	3	2(66.67%)	1(33.33%)	
Disease progression modes				
Gradual progression	78	21(26.92%)	57(73.08%)	P=0.031
Local progression	48	24(50%)	24(50%)	
Dramatic progression	63	24(38.10%)	39(61.90%)	

Conclusion: The overall plasma T790M mutation rate was 36.51% after first generation of EGFR-TKI acquired resistance of NSCLC in the real world. The frequency of T790M mutation with initial mutation of 19 Del was higher than that of L858R mutation, and local progression was higher than gradual progression and dramatic progression.

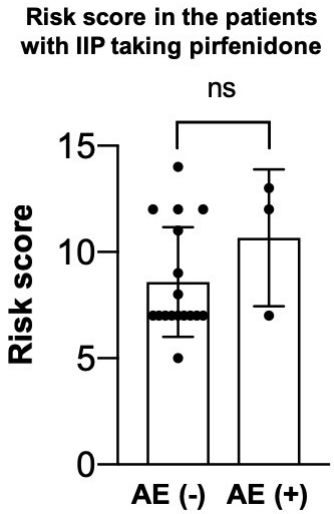
P1.16-25 IMPACT OF PIRFENIDONE ON THE RISK SCORING SYSTEM OF POSTOPERATIVE ACUTE EXACERBATION OF INTERSTITIAL PNEUMONIA IN LUNG CANCER

R. Matsushima, K. Fujino, H. Osumi, K. Ikeda, T. Mori, M. Suzuki

Kumamoto University Hospital, Kumamoto/Japan

Background: Acute exacerbation (AE) of idiopathic interstitial pneumonia (IIP) is a life-threatening complication of lung cancer resection. There has been an increasing number of studies about postoperative AE of IIP in recent years. A few of these have reported that perioperative oral administration of pirfenidone reduces the occurrence of AE in patients with IIP. Furthermore, a large cohort study conducted by the Japanese Association for Chest Surgeons (JACS) proposed risk factors for postoperative AE in IIP patients which can predict the incidence of AE following an operation. JACS risk score included seven factors (sex, history of AE, surgical procedure, usual interstitial pneumonia pattern, steroid use, KL-6, %VC) and classified patients into three groups: low risk (risk score: 0-10), intermediate risk (risk score: 11-14) and high risk (risk score: 15-22). The objective of present study is to investigate the validity of those risk factors for patients with IIP who are taking pirfenidone. **Method:** We retrospectively analyzed 1626 consecutive lung cancer patients who had undergone lung resection at our institution from January 2010 to December 2018. The patients who underwent lung resection since 2016 onward were administered pirfenidone from 4 weeks before operation to 4 weeks after operation. **Result:** Out of 1626 patients, 125 patients (7.7%) had IIP. Twenty patients (16%) took pirfenidone and 105 patients (84%) did not take pirfenidone. Of the patients taking pirfenidone, three patients (15%) contracted AE of IIP after lung resection within 30 postoperative days. No significant difference was identified in JACS risk score between AE (+) group taking pirfenidone and AE (-) group taking pirfenidone (10.7 ± 3.2 versus 8.6 ± 2.6, p = 0.74). In the AE (+) group taking pirfenidone, there were significant higher rates of patients having increased serum levels of KL-6 or having reached pathological stageII-IV (UICC 8th) (p = 0.01, p = 0.04, respectively). Of the patients not taking pirfenidone, seven patients (6.7%) contracted AE of IIP. No significant difference was identified in incidence of postoperative AE between the group of patients taking pirfenidone and the group not taking pirfenidone (p = 0.21).



Conclusion: In the patients taking pirfenidone, there was no significant difference in the risk score between AE (+) group and AE (-) group.

P1.16-26 EPITHELIAL GROWTH FACTOR RECEPTOR MUTATION PATTERN IN NON-SMALL CELL LUNG CANCER OF XUANWEI REGION IN SOUTHWESTERN CHINA

L. Lv[1], Z. Liu[2], Y. Liu[1], W. Zhang[1], L. Jiang[1], W. Liang[3], J. Lin[1]

[1]*The Second Affiliated Hospital of Kunming Medical University, Kunming/China,* [2]*Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China,* [3]*Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center for Respiratory Disease, Guangzhou/China*

Background: The incidence and mortality rate of lung cancer in Xuanwei region are among the highest in China. A previous study reported that non-smoking female lung cancer patients in Xuanwei exhibit different EGFR mutation patterns compared with the patterns seen elsewhere in Asia. A unique environment, ethnic group and certain susceptible population may have certain genetic background. Investigating EGFR mutation distribution of NSCLC patients in Yunnan province especially in Xuanwei region is meaningful. **Method:** A meta-analysis was conducted to identify the distinctive pattern of EGFR mutations in NSCLC patients in Xuanwei. Electronic databases were comprehensively searched and relevant literature with data were retrieved. The odds ratios (OR) for each EGFR mutation between Xuanwei and other regions were calculated, and the absolute incidence of EGFR mutations in Xuanwei was pooled. Subgroup analyses were performed for different EGFR mutation subtypes. **Result:** Five relevant studies with a total of 1,058 NSCLC patients from Yunnan province in southwestern China were conducted. 337 were from Xuanwei and 721 were from other regions; The overall EGFR mutation rate across studies ranged from 34.90% to 55.56%(Table 1). The results revealed a higher incidence of uncommon EGFR mutations (p<0.001), but a lower incidence of common EGFR mutations (p<0.001) in Xuanwei region compared with other regions. The pooled incidence of uncommon and common EGFR mutations in Xuanwei were 62.7% and 37.3%, respectively (Table 2). More specifically, compared with other areas, patients from Xuanwei harbored a higher frequency of exon 20 S768I (P<0.001) and exon 18 G719X + 20 S768I mutations (P<0.05), but had a lower frequency of 19 deletion (p<0.001)(Table 3).

Abbreviations: Retro , Retrospective study ; EGFR, Epidermal growth factor receptor; NA , Not Available; CI, confidence interval.

Conclusion: To summarize, Xuanwei patients carrying EGFR mutations exhibit distinct EGFR mutation spectrum compared with other regions, with higher uncommon mutations but lower common mutations. The Xuanwei pattern provides an important model to study the etiology or risk factor for EGFR uncommon mutations.

Keywords: EGFR mutation, Lung cancer, Xuanwei

P1.16-27 RISK FACTORS ASSOCIATED WITH A SECOND PRIMARY LUNG CANCER (SPLC) IN PATIENTS (PTS) WITH AN INITIAL PRIMARY LUNG CANCER (IPLC)

M. Nagasaka[1,2], D. Farhat[1], K. Belzer[1], S. Kim[1], M.A. Milczuk[1], H. Mamdani[1], A. Sukari[1], A. Wozniak[3]

[1]*Karmanos Cancer Institute, Detroit/United States of America,* [2]*St. Marianna University Graduate School of Medicine, Kawasaki/Japan,* [3]*UPMC Hillman Cancer Center, Pittsburgh/United States of America*

Background: The risk for development of a SPLC after treatment of an IPLC is around 1% to 2% per pt per year. The aim of this study was to characterize the risk factors associated with the development of a SPLC. **Method:** Pts registered in the Karmanos Cancer Institute Tumor Registry diagnosed with an IPLC between 2000 and 2017 were included in this study. Pts with an IPLC who later developed a SPLC were matched for age, histology and stage to pts with an IPLC who did not develop a SPLC. SPLC was defined as a second lung cancer with a different pathology or if the same pathology, anatomically, molecularly, or chronologically distinct. Six variables including: stage at IPLC, histology, family history, surgery as a primary treatment for IPLC, and smoking history (determined by pack years, and continued tobacco use after first diagnosis) were reviewed. Logistic and Cox regression analyses were performed to determine the relationship of these characteristics with the development of a SPLC, and their association with overall survival (OS). **Result:** 121 pts with IPLC who later developed an SPLC were identified and compared to 120 pts with IPLC who did not develop a SPLC. Logistic regression analyses did not show that stage at first diagnosis, histology, family history, smoking history, and continued tobacco use after first diagnosis to be relevant for increased risk of SPLC (Table 1). Pts who were primarily treated with surgical resection had a significantly higher probability of developing a SPLC (Odds Ratio, 0.24; 95% CI, 0.12 to 0.48; p<0.001, see Table 1). Pts who did not have surgical resection as their primary mode of treatment for IPLC had a significantly higher hazard of death than those who received surgical resection (Hazard Ratio, 3.02; 95% CI, 1.99 to 4.57; p<0.001).

Conclusion: Based on our findings, pts who had surgical resection for an IPLC were found to have improved OS and a higher possibility of developing a SPLC. Stage at first diagnosis of IPLC, histology, family history, smoking history and continued use of tobacco after first diagnosis did not correlate with increased risk for SPLC. These results warrant further investigation and if confirmed could have an impact on surveillance recommendations post resection of initial lung cancers.

P1.16-28 THE HUMANISTIC BURDEN OF ALK+ NSCLC: FINDINGS FROM THE ALKCONNECT PATIENT INSIGHT NETWORK AND RESEARCH PLATFORM

H. Lin[1], X. Pan[1], A. Biller[1], K. Covey[2], H. Huang[1], V. Rangel Miller[2], M. Smith[1], H. West[3]

[1]*Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge/United States of America,* [2]*Invitae Corporation, San Francisco/United States of America,* [3]*Swedish Cancer Institute, Seattle/United States of America*

Background: The ALKConnect Patient Insight Network (www.alkconnect.com) is a patient-centered online registry that provides support to and collects information from patients living with Anaplastic Lymphoma Kinase-Positive (ALK+) Non-Small Cell Lung Cancer (NSCLC). The objectives of this study were to: (1) describe the characteristics of patients in ALKConnect; (2) quantify patients' preferences, ALK+ NSCLC symptom burden, and health-related quality of life (HRQoL); and (3) determine whether disease treatment and employment status were associated with HRQoL. **Method:** Study inclusion criteria were US adults (18 years or older) living with ALK+ NSCLC who have internet access, and willingness to answer e-surveys. Cross-sectional 'real-world' data that were collected included demographics, disease history and status, comorbidities, treatments, patient preferences, and HRQoL (MD Anderson Symptom Inventory lung cancer module [MDASI-LC]), reported as symptom severity and interference in activities of daily living (walking, activity, work, relations with others, enjoyment, and mood) caused by symptoms. Data were reported descriptively overall and by subgroups of interest (e.g., treatments, employment status) where sample sizes permitted. Associations between patient treatment history and employment status and HRQoL were analyzed. **Result:** Data for 104 patients were available. Median age was 53.0 years (range 22-90), 67.3% were female, 84.0% were White (n=84), 12.0% were Asian (n=12), and 40.0% (n=40) were employed. Most patients were treated with ALK tyrosine kinase inhibitors (TKIs) (83.7% [n=87] ALK TKI only). Among treatment-associated preferences, preventing disease progression, shrinking tumor size, and maintaining HRQoL were perceived to be the most important treatment attributes. An additional 3-month delay in disease progression was perceived to be meaningful by 57.7% (n=60) of patients. MDASI-LC inventory data (from n=75 patients) showed that the most bothersome patient-reported symptoms were fatigue, sleep disturbance, drowsiness, difficulty remembering, and constipation. Interference on patient HRQoL was greatest for work and activity. Statistically-significant associations were observed between HRQoL and treatment with ALK TKIs (Symptom Severity p=0.0062, Interference p=0.0016), number of prior ALK TKIs (Symptom Severity p=0.1487, Interference p=0.0137), and employment status (Symptom Severity p=0.0201, Interference p=0.0210). **Conclusion:** ALKConnect gathered humanistic burden data directly from patients with ALK+ NSCLC. Participants reported that the most burdensome symptoms were fatigue, sleep disturbance, and drowsiness, and that symptoms interfered most with work and general activity. A 3-month delay in cancer progression and HRQoL were important treatment attributes. Patients' HRQoL was positively associated with ALK TKI treatment and the ability to maintain employment status, suggesting that these aspects may be important for ALK+ NSCLC patients' well-being.

P1.16-29 PROFILING IMMUNE-RELATED ADVERSE EVENTS (IRAES) IN PATIENTS WITH ANTI-PD-1 FOR ADVANCED NON-SMALL CELL LUNG CANCER

Y. Toi, S. Sugawara, M. Aso, K. Tsurumi, K. Ono, J. Sugisaka, H. Shimizu, H. Ono, Y. Domeki, T. Aiba, S. Kawana, R. Saito, K. Terayama, Y. Kawashima, A. Nakamura, S. Yamanda, Y. Kimura, Y. Honda

Sendai Kousei Hospital, Sendai/Japan

Background: Immune-related adverse events (irAEs) are frequently observed during anti-programmed death-1 antibody therapy. We previously reported that patients with irAEs were associated with clinical efficacy. However, little is known about which irAEs are related with clinical efficacy in patients with non-small cell lung cancer (NSCLC). This study aimed to evaluate the correlations between different irAEs and treatment response. **Method:** Patients with advanced NSCLC who received nivolumab or pembrolizumab monotherapy at our hospital (n=154) from January 2016 to April 2018 were included in this study. Subjects were categorized into the irAE-incident group (with irAEs group) or non-irAE-incident group (without irAEs group), specific for each irAE. We evaluated the objective response rate (ORR), time to treatment failure (TTF), progression-free survival (PFS), and overall survival (OS) in each group. **Result:** The categorization of irAEs identified 51 cases of skin reactions (31%), 16 of infusion reactions (10%), 19 of pneumonitis (12%), 21 of thyroid dysfunction (14%), and 10 of hepatitis (6%). In the with/without skin reaction groups, the ORRs were 57% (29 cases)/19% (20 cases) (p<.001), median TTFs (months) were 8.7/2.8 (p<.001), median PFSs were 12.9/3.4 months (p<.001), and median OSs were NR/11.4 months (p<.001), respectively. In the with/without infusion reaction groups, the ORRs were 56% (9 cases)/29% (40 cases) (p=.05), median TTFs were 7.6/3.7 months (p=.11), median PFSs were 11.1/4.1 months (p=.045), and median OSs were NR/14.8 months (p<.001), respectively. In the with/without pneumonitis groups, the ORRs were 63% (12 cases)/27% (37 cases) (p=.004), median TTFs were 4.4/3.7 months (p=.44), median PFSs were 18.9/4.1 months (p=.02), and median OSs were NR/14.8 months (p=.09), respectively. In the with/without thyroid dysfunction groups, the ORRs were 52% (11 cases)/29% (38 cases) (p=.08), median TTFs were 7.4/3.7 months (p=.63), median PFSs were 8.7/4.2 months (p=0.22), and median OSs were 11.8/15.9 months (p=.84), respectively. In the with/without hepatitis groups, the ORRs were 40% (4 cases)/31% (45 cases) (p=.82), median TTFs were 2.7/4.1 months (p=.42), median PFSs were 6.4/4.20 months (p=.70), and median OSs were NR/15.6 months (p=.43). The PFS was significantly longer in patients with skin reactions, infusion reactions, and pneumonitis than that in those without, whereas the OS was significantly longer in patients with skin and infusion reactions than that in those without. **Conclusion:** The development of skin and infusion reactions during nivolumab or pembrolizumab monotherapy for NSCLC might be strongly associated with improved clinical efficacy, and clinical benefits should be validated through large-scale prospective analysis.

P1.16-30 IMPACT OF PATIENT TKI COPAYMENTS ON INSURANCE EXPENDITURE IN ADVANCED EGFR OR ALK POSITIVE NON-SMALL CELL LUNG CANCER (NSCLC)

B. Haddock Lobo Goulart, S. Chennupati, K. Egan, C. Fedorenko, S. Ramsey

Fred Hutchinson Cancer Research Center, Seattle/United States of America

Background: To influence treatment choice and control expenditures, insurance plans impose cost sharing policies for expensive oral tyrosine kinase inhibitors (TKIs). We evaluated the effect of patient TKI copayments on insurance expenditures among patients with EGFR and ALK positive advanced NSCLC receiving TKIs. **Method:** We identified EGFR+ and ALK+ NSCLC patients in the Washington State SEER registry using natural language processing on registry pathology reports, followed by manual confirmation of molecular test results. We linked registry records with commercial and Medicare claims. Eligible patients had stage IV NSCLC diagnosed between 01/01/2010 and 12/31/2016, EGFR exon 19 deletions or L858R mutations, or ALK + by FISH, ≥ 12 months of insurance enrollment, survival of ≥6 months, and ≥ 1 pharmacy claims for EGFR or ALK TKIs with FDA approval in the study period. We estimated monthly TKI copayments by subtracting the drug amount paid from the amount allowed by insurance in pharmacy claims. We used claims to calculate lifetime total and drug costs from the insurance perspective. Covariates included sociodemographic characteristics, insurance type, comorbidity, mutation type, and receipt of chemotherapy and immunotherapy. We used generalized linear models with gamma family and log link to estimate the adjusted effect of TKI copayment of $0 vs. above $0 on insurer expenditures in 2016 US dollars. **Result:** Of 103 eligible patients, median age was 69; 66% were female; 72% were White, median household income was $69,951; 54% had Medicare, 85% were EGFR+, and 51% received chemotherapy or immunotherapy. Mean monthly TKI copayment was $312 (range= $0 to $5,913). Mean total and drug reimbursements were $234,294 and $114,253. Table 1 shows the adjusted effect of TKI copayments on insurance expenditures. **Conclusion:** Higher TKI copayments were not associated with lower insurance expenditures. Eliminating TKI copayments would reduce patient financial burden and not adversely impact insurer spending.

Table 1. Effect of Patient TKI Copayments on Insurance Expenditures, Adjusted for Age, Race, Comorbidity, Insurance Type, Mutation Type, Receipt of Chemotherapy and Immunotherapy (EGFR TKIs: erlotinib, gefitinib, afatinib, osimertinib; ALK TKIs: crizotinib, alectinib, ceritinib, brigatinib).

TKI Copayment (n=103)	Adjusted Mean Total Expenditure (95% CI)	P value	Adjusted Mean Drug Expenditure (95% CI)	P value
$0 (n=82)	$230,989 ($188,958; $273,019)	Ref.	$110,171 ($88,150; $132,194)	Ref.
Above $0 (n=21)	$264,963 ($182,424; $347,502)	0.44	$132,707 ($83,206; $182,208)	0.38

P1.16-31 BODY MASS INDEX RELATING TO PATIENT-REPORTED SYMPTOMS IN FIRST-LINE TREATMENT OF METASTATIC NON-SMALL CELL LUNG CANCER

Q. Shi[1], L. Williams[1], B. El Ferjani[1], M. Hirschmann[1], D. Ponce[1], S. Dibaj[1], S. Chandwani[2], E. Roarty[1], W. Rinsurongkawong[1], J. Lewis[1], T. Burke[2], C. Cleeland[1], J. Lee[1], J. Roth[1], S. Swisher[1], J. Heymach[1], J. Zhang[1], G. Simon[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Merck & Co., Kenilworth/United States of America*

Background: Patient-reported outcomes (PROs) provide information on patient treatment experience. Our aim in this analysis was to assess the longitudinal relationship between body mass index (BMI) with patient-reported symptom severity and interference during treatment. **Method:** Between May 1, 2017 and December 7, 2018, patients with mNSCLC at a single institution were enrolled in a real-world Advanced Non-Small Cell Lung Holistic Registry (ANCHoR) and completed the MDASI-LC prior to start of therapy and at routine clinic visits. MDASI-LC consists of 16 symptom severity and 6 symptom interference items rated on 0-10 scales (0 = no symptom or interference, 10 = worst imaginable symptom or complete interference). BMI was measured at the same schedule as MDASI-LC. Mixed-effects models were used to examine the longitudinal association between BMI and symptom levels during treatment. **Result:** 103 patients completed the MDASI-LC prior to start of therapy and at least 2 follow-up assessments. Mean patient age was 64.3 years (standard deviation = 11.5) and 50% were males. 22% of patients received chemotherapy (CTX), 34% immunotherapy (IM), 23% CTX+IM or angiogenesis inhibitor, and 20% targeted therapy. The median pre-treatment BMI was 25.2 (inter quartile range, 5.2). BMI did not change during treatment and no significant difference was found among treatment groups. Compared with the obese group (BMI≥30), the overweight group (25≤BMI<30) experienced lowest levels of fatigue (estimation(est)=-1.23, standard error (SE)=0.49, p=0.016), disturbed sleep (est=-1.66, SE=0.49, p=0.002), distress (est=-0.90, SE=0.40, p=0.030) and less interference on mood (est=-1.03, SE=0.46, p=0.030) and interference with walking (est=-1.50, SE=0.51, p=0.005). The normal group (BMI<25) demonstrated lower levels of fatigue (est=-1.05, standard error (SE)=0.47, p=0.032) and disturbed sleep (est=-1.15, SE=0.47, p=0.018), compared with the obese group. **Conclusion:** For patients with mNSCLC, obesity was

related with higher symptom burden during active treatment. This analysis provides pilot data for future studies on balanced weight control and patients' wellbeing during cancer treatment.

Keywords: BMI, symptom burden, real-world evidence

P1.16-32 EMPOWERING LUNG CANCER SURVIVORS AND FAMILY MEMBERS TO "BREATHE EASIER": ADAPTATION AND EVALUATION OF A M-HEALTH INTERVENTION

O. Owens[1], K. Mcdonnell[1], J. Beer[2], D. Gallerani[1]

[1]*University of South Carolina, Columbia/United States of America,* [2]*University of Georgia, Athens/United States of America*

Background: Survivors of lung cancer often experience a myriad of symptoms that have devastating effects on their physical and psychological functioning such as dyspnea, fatigue, and stress. To combat these symptoms, the American College of Chest Physicians has recommended the use of complementary therapies. Mindfulness-based Cancer Recovery (MBCR) can empower survivors, and family members who often cope with their own health problems and the stress related to caring for a survivor. Our goal is to deliver a tailored, culturally sensitive, MBCR intervention to survivors and family members via a mHealth app. **Method:** This research was comprised of four phases. Phase I was the development and testing of an 8-week in-person intervention called *Breathe Easier* with survivors and family members (dyads). Phase II adapted *Breathe Easier* into a mHealth app prototype utilizing user-centered design. Phase III was a focus-group evaluation of the usability and acceptance of the mHealth app prototype by survivors and family members. Phase IV was comprised of additional interviews with an African-American subset of survivors and family members to assess the cultural sensitivity of the mHealth app. **Result:** Findings from the in-person intervention (n = 62) showed that all agreed the intervention materials were acceptable, different levels of yoga, breathing exercises, and meditations helped them, and involving a family member was important. Preliminary analyses showed survivors had less dyspnea and perceived stress over time (T1 vs T2). Both groups had improved fatigue and sleep scores. Findings from the mHealth app design and acceptance evaluation were organized into two primary categories: usefulness and ease of use. User-friendly design recommendations included aesthetic appeal, navigation layout, and display of content. Furthermore, potential health outcomes, privacy concerns, and comparison to in-person interventions also influenced app usefulness and acceptance. Lastly, findings from our cultural sensitivity assessment demonstrated that the mHealth app was culturally sensitive for African-Americans, but some changes were recommended. **Conclusion:** MBCR interventions hold great promise for improving the lives of racially diverse survivors of lung cancer and family members. An mHealth app will increase accessibility. However, special consideration of app design is needed to ensure future acceptance and longer-term usage.

P1.16-33 FROM A SYSTEMATIC REVIEW TO REAL WORLD EVIDENCE: INTEGRATING GENDER AS A CLINICAL RISK FACTOR IN NSCLC

N. Alsaadoun[1], K. Kopciuk[1], D. Hao[2], F. Hao[1], A. Elegbede[1], A. Gibson[1], M. Dean[1], R. Tudor[1], G. Bebb[3]

[1]*University of Calgary, Calgary/Canada,* [2]*Tom Baker Cancer Center, Cummings School of Medicine, University of Calgary, Calgary/Canada,* [3]*Alberta Health Services, calgary/Canada*

Background: Gender-based disparities in NSCLC experience have been widely discussed in the literature. The recognition of gender as a confounder in clinical practice remains uncertain. Confirming its impact on prognosis encourages personalized interventions in an effort to improve survival for NSCLC patients. Since best prevention programs are derived from findings established from multiple-evidence based analysis, the influence of gender on the observed disparities in NSCLC was explored using worldwide evidence and single institute experience. A systematic review was initially carried out to synthesize the evidence on a global scale to confirm the influence of gender-discrepancies in NSCLC incidence rates. Findings were compared and contrasted using a single cancer institute to highlight potential trends related to the different data. **Method:** We identified relevant articles published in English using Medline between 1996 and 2016. Pooled standardized-incidence data was analyzed using a semi-parametric longitudinal regression model to estimate changes in NSCLC incidence as a function of time, histology and gender. A heat map was also designed to illustrate the global trend of NSCLC captured in the published articles. Findings of this review were evaluated to confirm the influence of gender on NSCLC trends and outcomes using a single center record. A retrospective analysis was performed using the Glans-Look Database (GLD) for patients diagnosed between 1999 and 2015. The Kaplan-Meier estimator of cumulative survival was conducted to analyze treatment outcomes of patients using SPSS and R. Statistical significance was set at 95% confidence level ($p < 0.05$). **Result:** Our systematic review demonstrated gender-based disparities over time, and the main effect of gender on incidence rates is significant ($p=0.01$). Visualizing global trends of NSCLC's histology confirm that women are prone to develop ADC. GLD data verifies the influence of gender, where women were more prone to develop ADC (49%), and the relative changes of its rate over 15 years increased significantly compared to men (58% vs 32%, $P<0.02$). Survival rates were also predisposed by gender, where female ADC mOS exceeded that of males in overall comparisons (17.6 vs. 12.2, $p=0.047$). **Conclusion:** Our findings serve as a basis to resolve the inherent controversies in the research, and highlight the importance of gender as a clinical risk factor. Therefore, it is important to include gender as a prognostic tool to improve screening programs and promote tailored therapies for better outcomes. Biological, social, or a combination of factors could also influence the differences observed and warrant further investigation.

P1.16-34 ASSOCIATION BETWEEN SKIN REACTIONS AND CLINICAL BENEFIT IN PATIENTS TREATED WITH ANTI-PD-1 TREATMENT FOR ADVANCED NON-SMALL CELL LUNG CANCER

M. Aso, S. Sugawara, Y. Toi, J. Sugisaka, H. Ono, T. Aiba, S. Kawana, R. Saito, K. Tsurumi, K. Ono, H. Shimizu, Y. Domeki, K. Terayama, Y. Kawashima, A. Nakamura, S. Yamanda, Y. Kimura, Y. Honda

Sendai Kosei Hospital, Sendai/Japan

Background: Anti-Programmed death-1 antibody is now standard therapy for advanced non-small cell lung cancer (NSCLC). However, immune-related adverse events (irAEs) including skin reactions are frequently observed. In melanoma, skin reactions and clinical efficacy are reportedly associated. However, little is known about this association in NSCLC. In addition, predictive markers of irAEs remain unknown. This study aimed to evaluate whether skin reactions correlate with clinical efficacy and identify potential clinical biomarkers that may meaningfully and conveniently predict skin reactions following treatment. **Method:** We retrospectively surveyed patients with advanced NSCLC who received nivolumab or pembrolizumab monotherapy at Sendai Kousei Hospital (n=155) between January 2016 and April 2018. The patients were categorized into two groups based on the development of skin reactions during treatment. Treatment efficacy was evaluated in each group, and predictive markers of skin reactions were determined. Furthermore, we also conducted 6-week landmark analysis to assess the association between early skin reactions and clinical benefit. **Result:** In the cohort of 155 patients (median [range] age, 68 [31-88] years; 117 men [75%], 38 women [25%]), skin reactions were observed in 52 (33%) patients. The median duration of onset of skin reactions was 6.4 weeks. The overall response rate (ORR) was significantly higher in patients with skin reactions than that in those without (57% vs. 19%; P<.001). The median progression free survivals (PFSs) were 12.9(95% confidence interval (CI), 8.5–not reached(NR)) and 3.4 (95% CI, 2.5-4.1) (P<.001) months, whereas the median overall survivals (OS) were NR (95% CI, 17.4-NR) and 11.4 months (95% CI, 8.8-15.6) (P<.001) in patients with and without skin reactions, respectively. In 6-week landmark analysis, the ORR was significantly higher in patients with skin reactions than that in those without (28 of 49 patients [57.1%] vs. 20 of 106 patients [18.9%]; P <.001), and the development of skin reactions was significantly associated with increased PFS (with skin reactions median PFS = 10.3 months, 95% CI, 5.6-NR ; without, median PFS = 4.2 months, 95% CI, 3.6-5.9; P=.045). Furthermore, multivariate analysis revealed that pre-existing rheumatoid factor (RF) was an independent predictor of skin reactions (odds ratio, 3.39; 95% CI, 1.56–7.33; P=.003). **Conclusion:** The development of

skin reactions was associated with clinical benefit in patients treated with nivolumab and pembrolizumab for NSCLC. Pre-existing RF also served as an independent predictor of skin reactions. Further studies with large patient samples are necessary to validate these findings.

P1.16-35 THE PROGNOSTIC IMPACT OF SARCOPENIA ON THE CLINICAL OUTCOME OF THORACIC SURGERY FOR NON-SMALL CELL LUNG CANCER IN ELDERLY PATIENTS

A. Miura[1], J. Soh[1,2], S. Miyauchi[1], K. Araki[1], K. Nakata[1], K. Namba[1], K. Suzawa[1], S. Otani[1], H. Yamamoto[1], M. Okazaki[1], S. Sugimoto[1], M. Yamane[1], S. Toyooka[1]

[1]*Okayama University Hospital, Okayama/Japan,* [2]*Kindai University Faculty of Medicine, Osaka-Sayama/Japan*

Background: The elderly patients who undergo surgery for non-small cell lung cancer (NSCLC) is increasing in Japan whereas they are at high risk for surgery because of weakness of physical strength and increased comorbidity. Skeltal muscle depletion, referred to as sarcopenia, has recently been identified as a risk factor of poor clinical outcomes after surgery in the patients with various malignancies including NSCLC. We investigated the impact of sarcopenia on the clinical outcome of thoracic surgery for NSCLC in elderly patients. **Method:** We enrolled 259 patients over 65 years old with NSCLC who underwent pulmonary resection (lobectomy or segmentectomy) without any induction treatment before surgery in our hospital during 2012 to 2015. Sarcopenia was assessed by the psoas muscle mass index (PMI, cm^2/m^2) using the computed tomography imaging at the third lumbar vertebra level before surgery. Postoperative complications, which were observed within 30days after surgery, were classified according to Clavien-Dindo classification. Overall survival (OS) was evaluated by the Kaplan-Meier method with log-rank test (univariate analyses) and by the cox proportional hazard model (multivariate analyses). **Result:** Median age was 73 years old (65 - 92). One hundred fifty-five (60%) patients were male. Two hundred nine (81%) patients were cStage0 or I. Fifty-seven (22%) patients were squamous cell carcinoma (SCC). Postoperative pneumonia, arrhythmia, and delirium were observed in 17 (7%), 35 (14%) and 17 (7%) patients, respectively. Median follow-up was 48.7 months (range 3.0 – 79.6). Using the cutoff values as previously reported, 179 (69%) and 80 (31%) patients were diagnosed as sarcopenic and non-sarcopenic, respectively. Male and ever smoker were significantly more frequent in the sarcopenic patients than the non-sarcopenic patients (P < 0.001 and P = 0.018, respectively). The sarcopenic patients showed the trend of high incidence of Postoperative complications, however, there was no significant difference in OS between the sarcopenic and non-sarcopenic patients. Next, we performed the subgroup analysis to elucidate the prognostic factors only in the elderly sarcopenic patients. Among 179 sarcopenic patients, multivariate analysis including statistically significant factors in the univariate analysis revealed that the patients with restrictive lung disease, advanced cStage, postoperative pneumonia and delirium were inferior in OS [Hazard Ratio, 11.1, 3.6, 5.3 and 4.6; 95% confidence interval, 1.6 to 68.1, 1.1 to 13.0, 1.4 to 20.0 and 1.1 to 16.5; P= 0.011, 0.037, 0.017 and 0.041], suggesting the importance of the intensive perioperative management to avoid complications. **Conclusion:** Perioperative complications are significantly associated with the prognosis of the sarcopenic elderly patients with NSCLC. Intensive perioperative management is mandatory for NSCLC patients with sarcopenia to improve the clinical outcome after thoracic surgery.

P1.16-36 TREATMENT PATTERNS AMONG PATIENTS WITH EGFRM NSCLC TREATED IN THE US COMMUNITY ONCOLOGY SETTING

E. Nadler[1], M. Pavilack[2], J. Clark[3], J. Espirito[3], A. Fernandes[2]

[1]*US Oncology Health Informatics and Internet Technology, Texas Oncology-Baylor Charles A. Sammons Cancer Center, Dallas/United States of America,* [2]*AstraZeneca, Gaithersburg/United States of America,* [3]*McKesson Life Sciences, The Woodlands/United States of America*

Background: Epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) therapy is associated with improved outcomes in patients with EGFR mutation-positive (EGFRm) non-small cell lung cancer (NSCLC). Despite initial responses, most patients develop resistance. Little is known about treatment following first-line (1L) TKIs. This study aimed to understand real world treatment patterns, T790M testing rates, and disposition of EGFRm patients following availability of newer TKIs. **Method:** Adult patients with EGFRm stage IV NSCLC treated between Dec 1, 2015 and Aug 31, 2017, were retrospectively identified from the US Oncology Network's iKnowMed℠ (iKM) electronic health record. Patient characteristics, treatment patterns, and T790M testing data were obtained via programmatic database abstraction and supplemented with chart review. **Result:** 308 patients were identified during the study period. Median age at diagnosis was 69 years, 67% were female, 63% Caucasian, 49% never smokers and 59% with ECOG performance status 0–1. Nearly all patients (n=302; 98%) received treatment with a TKI, 80% (n=246) with a TKI as 1L therapy. The most frequently used TKIs as 1L monotherapy were erlotinib (n=204; 66%), afatinib (n=27; 9%), and gefitinib (n=3; 1%). Combination chemotherapy with or without a TKI was used in 24% of patients. Among all patients treated with a 1L TKI, 19% (n=47) were tested for the T790M mutation after 1L TKI, and 34% (n=16) were positive. The most common 2L therapies in patients who received a 1L TKI (n=44 patients) were pemetrexed-based chemotherapy (n=20; 45%), afatinib (n=7; 16%), and osimertinib (n=7; 16%). Among all patients who received a 1L TKI, 15% (n=41) had died, 18% (n=51) were still alive and on TKI therapy, 12% (n=29) went on to receive subsequent therapy, and 53% (n=149) stopped their TKI and received no subsequent therapy at the end of the follow-up period. **Conclusion:** The majority of patients with EGFRm advanced NSCLC received 1L TKI therapy, most often with erlotinib. Following 1L TKI, less than 20% of patients were tested for T790M, and most did not receive any subsequent therapy following TKI. As understanding of resistance mechanisms in mutation-driven lung cancer is rapidly evolving, and as ongoing studies evaluate optimal treatments, it is imperative to integrate this information into clinical practice.

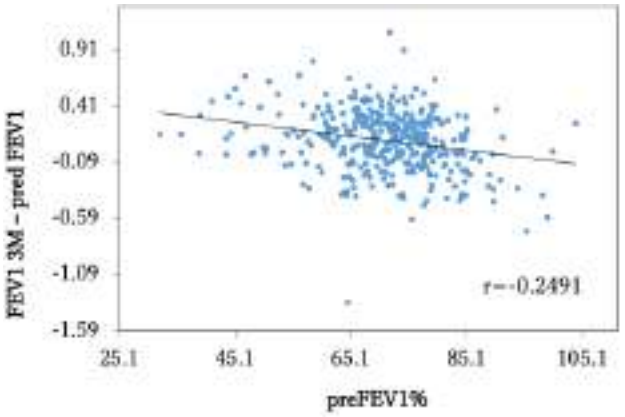
P1.16-37 CORRELATION BETWEEN THE ACTUAL MEASUREMENT VALUE AFTER LUNG LOBECTOMY AND THE PREDICTED VALUE OF FORCED EXPIRATORY VOLUME IN 1 SECOND

T. Hayashi, Y. Sano, H. Shigematsu, R. Sugimoto, N. Sakao, T. Sakaue

Ehime University Hospital, Toon City/Japan

Background: It is important to accurately predict postoperative respiratory function to safely perform lung resection without impairing the postoperative quality of life (QOL), particularly for patients with a significant ventilatory defect. To easily predict the vital capacity (VC) and forced expiratory volume in one second (FEV1), the number of pulmonary segments remaining after lung resection are divided by the total number of pulmonary segments (predicted value of FEV1). **Method:** We performed a retrospective review of 386 consecutive lobectomies performed from June 2011 to December 2018 at the Ehime University Hospital. On the basis of the preoperative values of FEV1%, we made 4 groups: FEV1%< 50% (n=16), FEV1% ≥50% but <60% (n=29), FEV1% ≥60% but <70% (n=109), and FEV1% ≥70% (n=232). We compared the difference between the predicted value of FEV1 and the actual measurement value three months after the lobectomy. **Result:** The scattergram in Fig 1. shows the correlation between the preoperative FEV1% and the predicted value of FEV1 in all cases. A weak but negative correlation (r=-0.2491) was found between them. Furthermore, in the FEV1% <50% group, the actual measurement value of FEV1 three months after the lobectomy was 253.9 mL larger than the predicted value

and was 146.6 mL, 124.8 mL, and 70.4 mL in the FEV1 ≥50% but <60%, FEV1 ≥60% but <70%, and FEV1 ≥70% groups, respectively.



Conclusion: Although this method is convenient and useful in predicting the postoperative respiratory function, it tends to be generally underestimated, especially in patients with a significant ventilatory defect. These results suggest that it is necessary to be careful not to indicate an operable patient as being inoperable on the basis of the predicted FEV1.

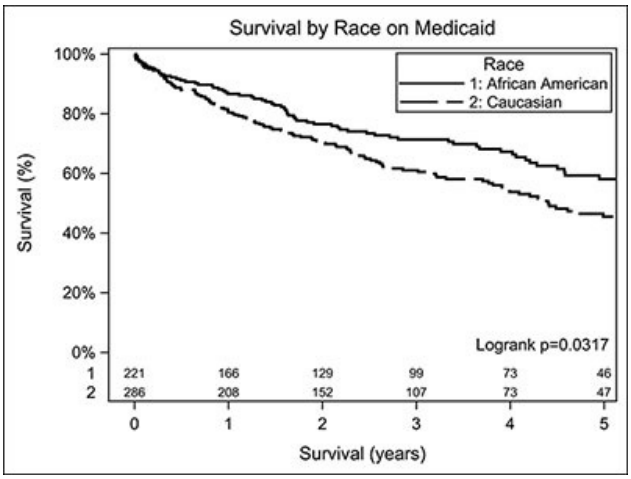
Keywords: actual measurement value three months after the lobectomy, forced expiratory volume in one second, predicted value of FEV1

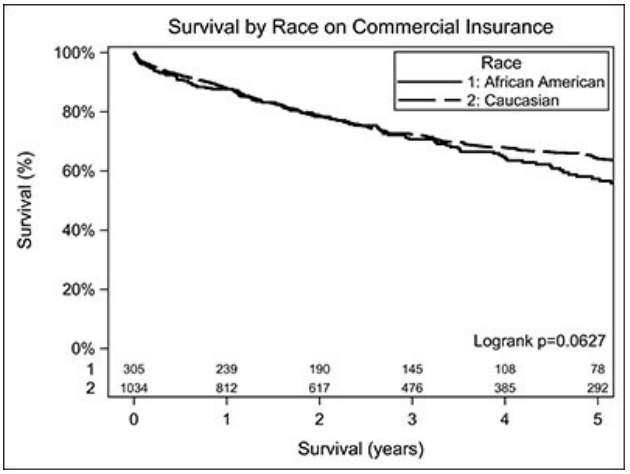
P1.16-38 RACIAL DISPARITIES IN LONG-TERM SURVIVAL AFTER SURGICAL RESECTION IN THE US

M. Taylor[1], M. Smeltzer[1], N. Faris[2], M. Ray[1], C. Fehnel[2], C. Houston-Harris[2], O. Akinbobola[2], P. Ojeabulu[2], R. Osarogiagbon[2]

[1]*University of Memphis, Memphis/United States of America,* [2]*Baptist Cancer Center, Memphis/United States of America*

Background: Racial disparities exist in US lung cancer care, including delayed access, lower use of invasive procedures such as curative-intent surgery, and worse surgical outcomes in African-Americans compared to Caucasians. We investigated if racial disparities persist in non-small cell lung cancer (NSCLC) patients who received curative-intent resection in a population-based cohort. **Method:** We examined all patients from a prospective population-based cohort who underwent curative-intent resections for lung cancer from 12 hospitals across 7 healthcare systems from 2009-2018. We compared overall survival (OS) by race and adjusted for age, sex, smoking status, family history, tumor histology, and clinical stage. We used Chi-square tests, Kaplan-Meier plots, and Cox proportional hazards modeling, reporting unadjusted and adjusted hazard ratios (aHR) with 95% confidence intervals. **Result:** Of the 3,418 patients, 78% were Caucasian, 22% were African-American; 42% had Medicare,15% Medicaid, 39% commercial insurance, and 3% were uninsured. Caucasians were older (mean age 67.8 vs. 64.1; p=<0.0001). African-Americans were more likely to be active smokers (p=0.0017), have adenocarcinoma histology (p=0.0167), and less likely to be clinical stage I (p=0.0453). Median follow-up time in censored patients was 3.4 years. Overall, we found no differences in OS by race (unadjusted HR: 0.97 [0.88-1.08]; aHR: 0.998 [0.87-1.15]). However, stratified by insurance, we found significant differences (p=0.0251). Among patients with Medicaid insurance, African-Americans had significantly better OS (aHR: 0.73 [0.55-0.97]) than Caucasians but among patients with commercial insurance, African-Americans had significantly worse OS (aHR: 1.26 [1.02-1.57]).





Conclusion: When all patients receive curative-intent surgical resection, racial disparities in NSCLC survival may be reduced, but differences in the impact of race on survival by type of insurance suggest residual and complex disparities in both access and quality of care. Further exploration of the interaction between race, socio-economic factors, and the mechanisms of lung cancer outcome disparities is warranted.

Keyword: racial disparities, insurance, survival

P1.16-39 ONCOLOGY EMERGENCIES IN PATIENTS WITH LUNG CANCER: EXPERIENCE OF ONE HOSPITAL

M. Vilaça, É. Cipriano, A. Tavares, A. Soares, F. Estevinho, C. Sottomayor

Hospital Pedro Hispano, Senhora da Hora/Portugal

Background: Oncological emergencies (OE) are common conditions associated with significant morbidity and mortality. Individuals with malignancy may present with a cancer-related emergency; for many, this will be their initial manifestation of cancer (about 23%). Patients with lung cancer are the type of cancer patient who are most often admitted to emergency departments due to OE. The aim of this study was to characterize the OE like superior vena cava syndrome and metastatic spinal cord compression (MSCC) in patients with lung cancer, at our hospital. **Method:** a retrospective review was undertaken to assess the number and the outcomes of patients admitted from 2015 to 2018 with lung cancer who had superior vena cava syndrome and MSCC. **Result:** in this 4-year period there were 455 new patients with the diagnosis of lung cancer, and 31 had an OE: n= 15 (48%) had superior vena cava syndrome and n = 16 (52%) had MSCC. The median age was 66 years old and 90% were man. The histological diagnostics was adenocarcinoma in 48% (n=14), small cell lung cancer in 34% (n=10) and squamous cell carcinoma in 18% (n=4). In 61% (n=19) of the patients the OE was the first manifestation of cancer, and lead to the diagnosis. In the others, the median time between the diagnosis and the emergency was 6 month (0-56 month). Of this, 36% (n=4) were in the first-line chemotherapy, 36%

(n=4) in the second-line chemotherapy and 18% (n=2) in the third-line chemotherapy. MSCC was the most frequent OE with 46% (n=16) of the patients, followed by superior vena cava syndrome (43%; n=15). 63% of the patients with MSCC, when the diagnosis was performed had lost the ability to walk; 50% had paraparesis, 25% paraplegia and only one presented with sphincter incontinence. 69% (n=11) of the patients with MSCC were treated with radiotherapy; 44% (n=7) underwent surgery and/or radiotherapy; 13% (n=2) were treated with steroids in combination with radiotherapy. 14 patients who were presented with superior vena cava syndrome (93%) were treated with radiotherapy. After the OE only 13 patients (37%; n=8 (62%) in superior vena cava syndrome and n=5 (38%) in MSCC) initiated or restarted systemic treatment for lung cancer. In this group disease progression was observed in a median time of 2 month after OE (0-31 months). Only 2 patients with MSCC who had lost the ability to walk regain it. 71% (n=21) of patients were dead 3 months after the OE. Only 4 patients (25%) with MSCC and 6 (40%) with superior vena cava syndrome were alive after 3 months of OE. **Conclusion:** OE causes severe morbidity and compromised survival and can be the initial manifestation of lung cancer. We need to be aware of this situation because the this OE have the potential to progress rapidly; therefore, prompt, accurate diagnosis and institution of appropriate treatment are essential to achieve favorable outcomes.

Keywords: Oncology emergency, superior vena cava syndrome, metastatic spinal cord compression

P1.16-40 REAL-WORLD NEUROCOGNITIVE FUNCTION IN LUNG CANCER: INITIAL RESULTS OF THE PRO-LONG STUDY

L. Van Der Weijst, V. Surmont, W. Schrauwen, Y. Lievens

Ghent University Hospital, Gent/Belgium

Background: Changes in neuro-cognitive function (NCF) as a result of treatment and disease have been repeatedly reported in cancer patients. However, contradictions exist on the prevalence and extent of impairment. Evidence in the lung cancer population is very limited. We here report the initial results of NCF in non-small cell lung (NSCLC) cancer patients receiving radiotherapy and/or systemic therapy in the PRO-Long study. **Method:** PRO-Long is a monocentric, prospective, longitudinal study, investigating the effect of first-line chemotherapy, radiotherapy and/or immunotherapy on patient-reported health-related quality of life (HRQoL), toxicity, functional exercise capacity (6-minute walking test – 6MWT) and NCF in locally-advanced and metastatic NSCLC patients. HRQoL and toxicity data are collected with patient-reported outcome measurements (PROMs). NCF data is collected with the Reys-Osterrieth Complex Figure Test (ROCF), Hopkins Verbal Learning Test-Revidsed (HVLT-R) free recall, delayed recall and recognition; Trail Making Test (TMT) A and B, Controlled Oral Word Association Test (COWA), Wechsler Adult Intelligence Scale (WAIS) digit span and the Stroop Color and Word Test (SCWT). Demographic data are collected at baseline; outcome data (survival, local and loco-regional control and metastatic relapse) during follow-up. NCF data is collected pre-treatment, and 2-3 months, 6 and 12 months after the end of treatment in patients receiving chemo- and/or radiotherapy or after start of immunotherapy. The mixed model approach was applied to determine statistical significance ($p < 0.05$). Meaningful clinical important difference (MCID) in NCF is defined as a decline greater than one standard deviation from baseline. **Result:** Between January 2016 and December 2018, 50 patients (mean age: 63) were recruited. The majority was male (60%), had locally-advanced disease (54%) and received chemotherapy with (50%) or without (24%) radiotherapy. NCF data is available of 49, 28, 16 and 10 patients at baseline, 2-3 months, 6 months and 1 year respectively. So far no significant decline was found in any NCF test. At 2-3 and 6 months after treatment, 42% and 34% of patients had a MCID decline in one or more tests. NCF decline was mostly detected in the HVLT-R free recall test, respectively 15 and 23% at 2-3 and 6 months. **Conclusion:** The initial data suggest that systemic treatment, all or not combined with radiotherapy may result in a clinically meaningful NCF decline in locally-advanced and metastatic NSCLC patients. Particularly, immediate recall seems to be affected. Updated results will be presented.

P1.16-41 TIMING, SITES, AND CORRELATES OF LUNG CANCER RECURRENCE: THE MISSING PIECES IN NATIONAL DATASETS

C. Karacz, J. Yan, H. Zhu, A. Madrigales, D. Gerber

University of Texas Southwestern Medical Center, Dallas/United States of America

Background: Because national datasets do not collect relevant data, few studies have analyzed the timing, sites, and correlates of lung cancer recurrence. We therefore employed an institutional tumor registry to obtain information on this critical, intermediary disease outcome. **Method:** From the UT Southwestern Tumor Registry, we identified cases or primary and/or recurrent lung cancer diagnosed January 1, 2000, to December 31, 2017. For cases with recurrent disease, we recorded site, timing, and case characteristics (including gender, age, race, histology, and primary treatment). Associations between these factors were evaluated using univariable and multivariable random-effect logistic regression models. We estimated time to recurrence using Kaplan-Meier methods. We used univariable and multivariable marginal Cox regression models were to assess the association between time to recurrence and case characteristics. **Result:** A total of 1,619 stage 1-3 lung cancer cases from 1,549 patients were analyzed. Of these, 466 patients (30%) had recurrent lung cancer. In multivariable analyses, both race (P=0.02) and primary treatment (P<0.001) significantly correlated with recurrence. Among recurrent cases, patient age (P=0.02) and TNM staging (P=0.001) significantly correlated with timing of recurrence. The most common type of first recurrence was distant disease, most frequently central nervous system (94/162, 58%). The development of distant recurrent disease was associated with race (P=0.01), histology (P=0.004), and primary treatment (P=0.03). **Conclusion:** In this single-center analysis of early stage and locally advanced in lung cancer, approximately one-third of cases develop recurrent disease, most commonly at distant metastatic sites. Central nervous system was the most frequent site of distant recurrence, accounting for more than half of cases. Race, TNM stage, and primary treatment were associated with the timing and site of recurrent disease. These findings have potential relevance to post-treatment clinical and radiographic surveillance.

Keywords: Recurrence, Clinical surveillance, Single-center analysis

P1.16-42 REAL-WORLD TRENDS IN SYSTEMIC ANTICANCER THERAPY (SACT) FOR SQUAMOUS ADVANCED NSCLC (ANSCLC) IN THE US, 2011–2018

V. Velcheti[1], S. Chandwani[2], X. Chen[2], B. Piperdi[2], T. Burke[2]

[1]*NYU Langone, Perlmutter Cancer Center, New York/United States of America,* [2]*Merck & Co., Inc., Kenilworth/United States of America*

Background: The SACT options for aNSCLC continue to increase each year with approvals of more effective therapies that improve long-term outcomes, as seen with immunotherapies (IO). Our aim was to examine real-world trends in SACT distribution and sequence from first- to second-line (1L-2L) for squamous aNSCLC from 2011-2018 at US community oncology practices. **Method:** This study used the nationwide Flatiron Health de-identified, EHR-derived database (cutoff: 31Jan2019). Eligible patients were adults who initiated 1L SACT from Jan2011-Jun2018 for aNSCLC with squamous histology, excluding patients with known EGFR/ALK-positive tumors. Descriptive analyses included patients receiving ≥1 SACT dose, assigning all SACT regimens to mutually exclusive classes in hierarchical order (combination regimens assigned by highest component), from highest to lowest: (1) PD1/PD-L1 inhibitor (anti-PD1/L1)-based, (2) EGFR/ALK TKI-based, (3) platinum-based chemotherapy combination with vascular endothelial growth factor inhibitor (PBC+VEGF), (4) PBC only, (5) single agent chemotherapy, (6) others. The 2L regimens were examined for patients with 1L SACT initiation only through 2017 to enable sufficient follow-up. Results were stratified by years and by pre-IO and post-IO years of 1L initiation, defined as 2011-2014 and 2015-2018, respectively, based on the earliest IO approval for 2L therapy in Mar2015. **Result:** For 1L therapy, in the pre-IO period, most patients were prescribed PBC (80%), and post-IO, most patients were prescribed PBC (68%) or anti-PD1/L1 (21%). Among patients prescribed 1L therapy, the percentages who received 2L therapy were 44%-53% following 1L PBC and 25%-37% following 1L anti-PD1/L1, with 19% of 2017 1L anti-PD1/L1 starts still on 1L therapy (table).

SACT prescribing for squamous aNSCLC by 1L initiation year, including 1L and three most common 2L regimens overall

1L Regimen	2011 (n=476)	2012 (n=769)	2013 (n=924)	2014 (n=1044)	2015 (n=1240)	2016 (n=1327)	2017 (n=1374)	2018(¼) (n=634)
PBC, n(%)	383(81)	594(77)	756(82)	851(82)	939(76)	939(71)	848(62)	388(61)
Still on 1L[a]	3%	3%	4%	5%	4%	5%	6%	--
Rec'd 2L[a]	50%	49%	44%	45%	52%	52%	53%	--
Anti-PD1/L1[b]	1%	2%	4%	24%	67%	74%	80%	--
PBC[b]	44%	37%	36%	25%	14%	10%	8%	--
Single[b]	31%	38%	39%	32%	11%	9%	8%	--
Anti-PD1/L1, n(%)[c]	0	0	0	2(0)	123(10)	230(17)	394(29)	191(30)
Still on 1L	--	--	--	--	6%	11%	19%	--
Rec'd 2L	--	--	--	--	37%	31%	25%	--
Single	--	--	--	--	37%	35%	24%	--
PBC	--	--	--	--	15%	18%	38%	--
Anti-PD1/L1	--	--	--	--	15%	22%	24%	--
Single, n(%)	44(9)	107(14)	95(10)	104(10)	98(8)	41(3)	41(3)	21(3)
Other, n(%)	23(5)	33(4)	34(4)	45(4)	43(4)	80(6)	69(5)	28(5)
EGFR/ALK, n(%)	13(3)	20(3)	25(3)	26(3)	18(2)	16(1)	9(1)	1(0)
PBC+(EGF, n(%)	10(3)	15(2)	14(2)	16(2)	19(2)	21(2)	13(1)	4(1)

[a]Patients still on 1L or prescribed 2L represent percentages of patients initially prescribed 1L.
[b]Percentages for 2L SACT regimens represent percentages of patients prescribed 2L.
[c]Anti-PD1/L1 regimens included anti-PD1/L1 monotherapy and combination therapy with PBC.

Conclusion: PBC remain the most common 1L SACT prescribed through mid-2018 for patients with squamous aNSCLC at US community oncology practices. Prescribing of PD1/PD-L1 inhibitors as 1L has gradually increased since regulatory approval starting in 2015. Approximately one-half of patients with squamous aNSCLC prescribed 1L PBC are treated with 2L therapy.

Gemelli IRCCS, Roma/Italy,* [7]*Fondazione Policlinico Universitario A. Gemelli, I.R.C.C.S., Università Cattolica del Sacro Cuore, Roma, Roma/Italy*

Background: While weight loss and lean body mass wasting are common hallmarks of non-small-cell lung cancer (NSCLC), their early detection and management are usually overlooked in clinical routine. The present study aimed to explore the prevalence of malnutrition and its correlation with outcome in advance (A)-NSCLC pts. **Method:** A-NSCLC pts treated at AOUI of Verona (2016-2018) received nutritional counseling by a qualified dietitian. Prevalence of malnutrition was assessed by nutritional screening score (NRS). Bilateral psoas major muscles were measured at L3 vertebrae level with routine staging-computed tomography (CT). Changes in psoas muscles observed in subsequent scans were evaluated using Wilcoxon signed-rank test. Clinical, pathological and nutritional data were correlated to progression-free/overall survival (PFS/OS) and response rate (ORR) using a Cox and logistic regression model. Kaplan-Meier curves were compared with Log-Rank. **Result:** Data from 38 pts (20 males [52.6%], 18 females [47.4%]) were gathered (median age 59 years [range 42-82], with a median follow-up of 21 months (range 1-197). At baseline, 18.4% were underweight, 18.4% normal weight, 34.2% overweight and 31.6% obese. The majority (65.8%) were at risk of malnutrition (NRS≥3). At multivariate analysis, stage (HR 4.99, 95% CI 1.05-27.74, *p = 0.04*), performance status (HR 4.99, 95% CI 1.55-16.03, *p = 0.007*) and NRS (HR 7.61, 95% CI 1.52-38.11, *p = 0.01*), were significant independent predictors for PFS. Pts with baseline NRS≤3 had significantly longer 1-year PFS (58.6% vs 16.7%, *p = 0.04*) and 2-year OS (90.6% vs 68.3%, *p = 0.03*) and a better ORR than those with NRS > 3 (66.7% vs 21.4%). Conversely, BMI did not affect PFS/OS. A significant loss in psoas muscle mass was detected in pts treated with both immunotherapy and other therapies (*p = 0.01* and *p=0.002,* respectively). Of interest, in immunotherapy-treated pts (n = 16) loss in psoas muscle mass correlated with worse ORR, PFS and OS, although differences did not reach a statistical significance due to the limited sample. **Conclusion:** Our analysis suggests that malnutrition has a detrimental impact on ORR, PFS and OS in A-NSCLC. Particularly, in pts treated with immunotherapy, muscle mass wasting seems to impact on efficacy outcome, suggesting a potential interaction between immunological and nutritional parameters. Therefore, the introduction in the clinical routine of a comprehensive nutritional profiling and monitoring, beyond body weight and BMI, is highly recommended in A-NSCLC. A comparison between NSCLC pts who underwent a personalized nutritional intervention during therapy and who did not is ongoing, together with a series of biomolecular analysis.

P1.16-44 MULTIPLE PRIMARY CANCERS (MPC) IN A COHORT OF LUNG CANCER (LC) PATIENTS (P): INCIDENCE AND CLINICAL FEATURES

C. Erasun Lecuona, A. Gonzalez, A. Esteve, M. Domenech, E. Felip, M. Cucurull, L. Angelats, S. España, A. Ferrando, A. Plaja, L. Notario, A. Pous, T. Moran, E. Carcereny

Catalan Institute of Oncology-Badalona; Hospital Universitari Germans Trias I Pujol; B-ARGO; IGTP, Badalona/Spain

Background: The prognosis of p with LC has drastically changed during the last decade due to the improvement in prevention, diagnosis and treatment. Therefore, the number of LC survivor ps has significantly increased and subsequently the incidence of MPC is also rising. This study investigates the co-occurrence of MPC among p diagnosed with LC. **Method:** We reviewed of clinical data of patients with histologically confirmed LC visited at our institution between February 2016 and December 2018. **Result:** A total of 492 p out of 777 p, (63.3%) had adenocarcinoma and 223 p (28.7%) had squamous LC. The most frequently related comorbidities were hypertension (42.5%), dyslipidemia (36.2%), COPD (21%), cardiovascular disease (15.7%) and diabetes mellitus (14.5%). Molecular analysis was perform in 402 p (51.7%). EGFR mutation was detected in 77 p (exon 19 in 14% and exon 21 in 5% of p). ALK and ROS1 translocation were diagnosed in 27 and 7 p, respectively. Two primary cancers occurred in 111 cases (14%), including 15 p (1.9%) with three or more primary cancers. Patients with MPC were predominantly males (76.8%), smokers (85%) and 34% had prior family history of MPC. Median age at the first tumor diagnosis was 64 years (57-71). LC occurred as first neoplasm in 8.1% of the cases, 92 p (83%) developed metachronic MPC and 19 p (17%) synchronous MPC. Most common secondary primary cancer were head and neck in 19%, non-melanoma skin cancer in 19%, prostate in 12.6%, bladder and upper urinary tract cancer in 10%, colorectal in 6.3% and breast in 5.4%. First-line treatment for advanced or locally advance LC included chemotherapy in 65.6%, concomitant chemoradiotherapy in 14%, targeted therapy in 4% and immunotherapy in 4%. Overall response rate (ORR) to first-line treatment was 43.7%. Second-line treatment included chemotherapy in 47.6% and immunotherapy in 30.4%, with and ORR of 30%. **Conclusion:** In our series, the frequency of the co-occurrence of MPC among LC p is 14%, suggesting that surveillance strategies are recommended in this population. Most frequent MPC in LC patients are related to smoking. ORR in first and second-line are consistent with the literature.

Keywords: Lung cancer, multiple primary cancers, Real-world data

P1.16-45 CHANGING ATTITUDES REGARDING LUNG CANCER: SHAME, EMBARRASSMENT, AND HOPE

J. Schiller[1], H. Kolkey[2], M. Cox[2], C. Smith[3]

[1]*Inova Schar Cancer Institute, Fairfax/United States of America,* [2]*Genentech, Inc., South San Francisco/United States of America,* [3]*University of Florida, Gainesville/United States of America*

Background: Sriram and colleagues (2015) showed that implicit attitudes (IA) and explicit attitudes (EA) related to shame, embarrassment and hope are more negative toward lung cancer (LC) than breast cancer (BC). The current study used the same measurement procedures as in 2012 to test whether stigma related to LC has decreased in the intervening years. **Method:** To assess EAs, participants (people with cancer [*n*=223], caregivers [*n*=590], healthcare providers [HCPs, *n*=160], and the general public [*n*=637]) were asked to rate their agreement on a six-point scale, with statements about how people with LC and BC "do feel" (descriptive

attitudes). IAs were measured with 3 Implicit Association Tests (IAT) using LC or BC images and categories of good/bad; hope/despair; or suitable/shameful. An IAT *D*-score indicated the strength of bias of LC relative to BC where >0.15 = bias against LC; between -0.15 and +0.15 = no bias, and < -0.15 = bias against BC. **Result:** IAs and EAs were consistently more negative towards LC compared to BC, with the exception of the EA related to embarrassment. When compared to the 2012 data, all IAs and EAs indicate a significant reduction in negativity and stigma of IA and EA toward LC relative to BC, with the exception of IA related to Shame (p=.079). These trends were consistent across caregivers, patients, HCPs, and the public.

	Strain et al., 2015 (Data collected in 2012)	Current data (2019)	p
Explicit			
Ashamed	Mean* = 3.69 40%, 47%, 13%	Mean* = 0.16 28%, 55%, 18%	<.0001
Embarrassed	Mean* = 3.47 32%, 54%, 14%	Mean* = 0.903 19%, 61%, 20%	<.0001
Hopeful	Mean* = 1.08 4%, 41%, 55%	Mean* = -0.67 5%, 56%, 40%	<.0001
Implicit			
Good/Bad	D = 0.42 75%, 17%, 8%	D = 0.32 68%, 24%, 10%	<.0001
Shame/Suitable	D = 0.35 61%, 17%, 18%	D = 0.30 68%, 21%, 13%	.070
Hope/Despair	D = 0.42 74%, 16%, 10%	D = 0.34 78%, 16%, 11%	.003

Percentage order: LC bias%, no bias%, BC bias%; D=mean IAT score; *Means for explicit are difference between scores where positive numbers indicate higher scores for LC than BC.

Conclusion: Compared to data collected in 2012, five of six implicit and explicit attitudes showed a significant reduction in negativity toward lung cancer relative to breast cancer. These findings are especially notable given that current evidence indicates little support for longitudinal shifts in IA at the group level (e.g., Lai et al., 2016; Schmidt & Axt, 2016).

Background: In patients with ALK-positive metastatic non-small cell lung cancer (mNSCLC), the majority of data on ALK inhibitor (ALKi) use and related survival outcomes are from clinical trials; information from community practice is sparse. This study therefore sought to assess ALK testing patterns, treatment characteristics, and overall survival (OS) in patients with mNSCLC treated with ceritinib in routine practice. **Method:** In this retrospective cohort study, medical records for patients with ALK-positive mNSCLC (diagnosed during 2008-2016; aged ≥18 years) were selected from sites in Canada and Europe. Patients were treated with ceritinib in any line for mNSCLC and had at least 8 months of follow-up after ceritinib initiation, except for patients who died sooner than 8 months. Baseline patient characteristics, treatment patterns, and timing of ALK testing relative to start of therapy lines were descriptively assessed. OS was assessed using Kaplan-Meier methods. **Result:** 87 patients were selected (median age: 53 years). Nearly 56% of patients had been tested for ALK mutation before initiating the first-line therapy (1L); 72% were tested before 2L and 77% before 3L. The most common regimens were cisplatin/pemetrexed (25%) in 1L, crizotinib (28%) in 2L, and ceritinib (35%) in 3L. Over two-thirds (68%) received treatment with at least 2 ALKis. The most commonly observed ALKi sequences were crizotinib followed by ceritinib (52%), ceritinib only (23%), and crizotinib followed by ceritinib followed by alectinib (12%). Median OS (95% CI) from mNSCLC diagnosis was 39 (33.1-50.1) months. Median OS (95% CI) from treatment initiation was 36 (28.2-48.9) months for 1L, 29 (22.1-42.8) months for 2L, and 23 (14.0-40.5) months for 3L. **Conclusion:** Only slightly more than half of patients with ALK-positive mNSCLC were tested for ALK mutation before initiating the first-line therapy during the study period. ALKis were the preferred therapies in the second and third lines. Median OS following the first-line therapy initiation was nearly 3 years among the selected study patients.

P1.16-47 EMBEDDING RESEARCH (AND EVIDENCE) IN CANCER HEALTHCARE - ENRICH

B. Brown[1], J. Simes[1], M. Boyer[2], P. Hogg[1], A. Joshua[3], J. Young[1]

[1]*University of Sydney, Camperdown/Australia,* [2]*Chris O'Brien Lifehouse, Camperdown/Australia,* [3]*The Kinghorn Cancer Centre, Darlinghurst/Australia*

Background: In Australia, as in other regions, lung cancer persists as the most common cause of cancer related death and is the leading cause of morbidity and burden of disease. Improvements in lung cancer survival rates are not comparable with improvements for other cancers. The Sydney Catalyst flagship program 'Embedding Research (and evidence) in Cancer Healthcare – EnRICH', is building a program of translational research in lung cancer to develop and extend evidence of effective treatments and to increase the use of clinical care based on existing evidence. Specifically, this prospective clinical cohort of patients with lung cancer (non-small cell and small cell, any histological type, any clinical/pathological stage) will establish a comprehensive data platform, including biological samples (FFPE diagnostic tumour tissue, and serial pre- and post-treatment blood samples) with matched demographic, clinical, biomarker, molecular profile, and outcome data (including quality of care and patient-reported outcomes) to support a range of interconnected research from across the T1 – T3 translational research spectrum, from bench to bedside (and bedside to bench) through to policy and practice. A linked implementation science program will identify methods to promote better integration of research findings and evidence. EnRICH will build on existing collaborations within Sydney Catalyst, across NSW, Australia, and internationally to establish a multidisciplinary program of research in scientific discovery, diagnostic and therapeutic development, clinical trials and implementation science. **Method:** Aim To assemble a patient cohort to: describe the natural history of and patterns of care for lung cancer; identify current gaps in evidence and practice for clinical quality improvement; create a platform for researchers across the T1-T3 translational research spectrum to develop and initiate clinical research and intervention studies to address gaps. Initially lung cancer will be an exemplar. Design Prospective clinical cohort of lung cancer patients including matched demographic, clinical, biomarker, molecular profile, and outcome data (including quality of care and patient-reported outcomes) for current and future research projects. Planned sample size At least 1000 patients. 505 patients enrolled at 31 Jan 2019. Inclusion criteria All patients with lung cancer presenting to defined clinical sites for diagnosis or treatment, including: Patients with a new diagnosis of primary lung cancer (any histological type, any pathological/clinical stage including metastatic) undergoing primary treatment; curative or palliative Patients with first progressive disease, local recurrence or new metastasis after completing previous treatment for non-metastatic disease at the time of initial diagnosis Aged over 18 years Data and biospecimen collection Matched clinical and demographic data will be collected from patient medical records and hospital administrative data sets Archival tissue, for research, will be obtained from routine biopsy specimens. Serial blood samples for research, on average 3 per patient (e.g. prior to commencement of treatment [baseline], and post-treatment [6 and 12 month follow-up]) Patient reported outcomes will be measured through questionnaires Statistical considerations The cohort will enable reliable estimates of outcomes both overall and within histologic and genetic sub-types. **Result:** Section not applicable **Conclusion:** Section not applicable

P1.16-48 EXPERIENCES OF PTS ON 1ST LINE CARE (EP1C): SYMPTOMS AND IMPACTS OF EGFR TKI THERAPY ON REAL-WORLD DAILY LIVES OF NSCLC PTS

I. Elkins[1], R. Bordoni[2], R. Shenolikar[3], A. Ryden[4], M. Martin[5], N. Bakker[6], H. Chung[7], J. Feldman[1]

[1]*Egfr Resisters, Deerfield/United States of America,* [2]*Georgia Cancer Specialists and Northside Hospital Cancer Institute, Sandy Springs/United States of America,* [3]*Us Heor, Astrazeneca, Gaithersburg/United States of America,* [4]*Biopharmaceuticals Medical, Astrazeneca, Gothenburg/Sweden,* [5]*Evidera, Bethesda/United States of America,* [6]*Oncology Business Unit, Medical, Astrazeneca, Cambridge/United Kingdom,* [7]*Biopharmaceuticals Medical, Astrazeneca, Gaithersburg/United States of America*

Background: Approximately one third of patients with NSCLC have tumours harbouring actionable EGFR mutations (Zhang et al. Oncotarget 2016). These patients are routinely treated with EGFR-tyrosine kinase inhibitors (TKIs) that are approved based on their efficacy and safety in clinical trials. Clinical trials do not fully reflect patient experiences as felt and perceived by patients, and in the real world, symptoms related to EGFR-TKIs and impact on patients' daily lives are not well documented or understood. EP1C assessed patients' experience with EGFR-TKIs and their impact on patients' daily lives. Patient insights gained from EP1C can help guide symptom management strategies and improve communication with patients, helping to improve outcomes and quality of life. **Method:** This pilot, non-interventional, US-based, real-world study involved individual interviews with adult patients. Eligible patients were those diagnosed with EGFR-mutated metastatic NSCLC, taking one of three US-approved EGFR-TKIs (erlotinib/afatinib/osimertinib) as first-line treatment. Exclusion criteria included: major surgery or radiation therapy three months before treatment, chemotherapy or other therapy as first-line treatment, a second active cancer, or a cognition or sensory issue. Trained qualitative interviewers used a semi-structured interview guide, and conducted all interviews by telephone. Rating questions were included for the severity and degree of bother caused by their symptoms (0–10 point response scale: 0=not at all severe, 10=extremely severe). All interviews were audio recorded, transcribed and coded (ATLAS.ti software) for analysis of similar themes. **Result:** A total of 19 patients participated in the interviews. The average age was 54.0 years (range 37–76). The sample was 73.7% female (n=14), and 89.5% (n=17) had an education level of college or above. The most frequently reported symptoms were respiratory and gastrointestinal symptoms (n=18; 94.7% each), skin-related sympoms (n=18; 94.7%), discomfort and pain (n=17; 89.5%), hair and nail-related symptoms (n=17; 89.5% each), fatigue and other energy-related symptoms (n=15; 78.9%). Ratings of severity and bothersomeness trended toward the mid-range of the scale (4.0 to 6.0) for most of the more commonly reported symptoms. The higher ratings were seen for very specific symptoms reported by only one or two patients, including constipation (8.0 severity/8.0 bother), armpit rash (7.0/8.0), tightness in throat (8.0/8.0), mouth soreness (8.0/9.0) and stinging/burning in the genital area (10.0/10.0). All 19 patients reported impacts on their daily performance and emotional health. Sleep difficulties were reported by 12 patients (63.2%), and 9 patients (47.4%) reported limitations with inter-personal relationships and social functioning. The impacts on patients' daily activities (work, chores, daily routine; 7.8) and emotions (anxiety, worry, fear and depression; 7.2) were found to be the most difficult to cope with. Several specific impacts, reported by fewer patients, included decreased independence (n=2; 7.0), economic burden (n=6; 7.7), and childcare difficulties (n=2; 8.5). **Conclusion:** In EP1C, real-world interviews allowed patients to express a broader range of symptoms and impacts compared with clinical trials, which mostly focus on symptoms. Some of the traditionally less commonly reported symptoms had a greater impact on patients' daily lives. Clinicians should also consider these when assisting patients in managing their symptoms.

P1.17 TREATMENT OF EARLY STAGE/ LOCALIZED DISEASE
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.17-01 SURGICAL OUTCOME OF EARLY STAGE LUNG CANCER RELATED VS UNRELATED TO HONEYCOMB LESIONS WITH INTERSTITIAL PNEUMONIA

M. Fujiwara[1], Y. Tsutani[2], T. Mimae[2], Y. Miyata[2], M. Okada[2]

[1]*Hiroshima University, Kasumi, Minami-Ku Hiroshima, Japan,/Japan,* [2]*Hiroshima University Hospital, Hiroshima City Minamiku/Japan*

Background: Lung cancer complicated with idiopathic interstitial pneumonia (IIPs) is known to lead to worse prognosis. Recently, it has been reported that the pathological characteristics differ between the lung cancer arising the honeycomb lesion of interstitial pneumonia (H-IIP group) and arising in other lesions (NH-IIP group). In this study, we aimed to assess the clinicopathologic outcome of resected lung cancer in each group. **Method:** From a single center database of 1065 consecutive patients with clinical stage IA non-small cell lung cancer who had undergone preoperative high-resolution computed tomography and F-18-fluorodeoxyglucose positron emission tomography/ computed tomography, 112 patients with a radiologically determined IIP (H-IIPs; n=33, NH-IIP; n=79) were included in this study. Examination of clinicopathological outcomes were performed comparing each group. **Result:** Median solid tumor size of each group were similar (18.4mm vs 18.6mm p=0.928), but median ground gloss opacity rate is significantly higher in NH-IIP group (6.7% vs 21.4% p=0.042). In the histopathological types, H-IIP group had significantly high rate of squamous cell carcinoma (45.5% vs 27.9%) and NH-IIP group had adenocarcinoma (27.3% vs 57.0%). As in previous reports, the proportion of EGFR mutation in adenocarcinomas tended to be high in NH-IIPs and also the high proportion of lepidic predominant. The disease-free survival (DFS) and overall survival (OS) were worse in patients of H-IIP group compared to NH-IIP group (DFS p=0.028, OS p=0.035). In a multivariate analysis, the H-IIP group and lower diffusing capacity for carbon of preoperative pulmonary functional test were significant worse predictors of OS and RFS (P < 0.001, respectively). **Conclusion:** Lung cancer arising the honeycomb lesion of IIP had a great unfavorable impact on the prognosis of NSCLC, because of the worse pathological features.

P1.17-02 THE INVESTIGATION OF INTRAOPERATIVE MARKING BY TRANSBRONCHIAL LOW POWER LASER IRRADIATION IN HUMAN LUNG

K. Ohtani, S. Maehara, K. Imai, H. Furumoto, N. Kajiwara, T. Ohira, N. Ikeda

Tokyo Medical University, Tokyo/Japan

Background: Small lung nodules which appear to be ground glass opacity in peripheral lung are difficult to identify during surgery. In order to identify the site of such lesions, various types of preoperative or intraoperative marking methods have been reported. However, there is no definitive way. Therefore, we have reported a new safe and reliable intraoperative marking method using low power laser light. By irradiating low power laser close to the lesion from a bronchus, the site of the lesion can be identified from the lung surface by looking at the laser light. We conducted an animal experiment and were able to observe the laser light irradiated in bronchus from the lung surface. In this study, we performed laser irradiation to the resected human lung to confirm whether the laser light can actually be observed safely from lung surface. **Method:** The patient was 70-year-old male (40 pack-years ex-smoker). The adenocarcinoma (55×40mm) was located at right S2 area. Immediately after right upper lobectomy, a plastic cylindrical-type laser probe was inserted into peripheral bronchus of the resected lung. The probe was very thin (0.8mm diameter) and flexible. Therefore, it can be inserted into the peripheral lung. It was developed jointly with Keio University. The probe was induced just below the pleura and 70mW low power laser irradiation was performed. We examined whether laser light could be confirmed from lung surface. The effect of laser irradiation to the lung tissue was evaluated pathologically. **Result:** When the probe was guided to just below the pleura, laser light could be clearly observed from the lung surface. After that, the probe was gradually

withdrawn. The laser light could be observed until the depth of 10mm from the pleura. No damage was obtained around the laser irradiated area in pathological findings. The observable depth of laser light was slightly shallow at10mm. The reasons of this were guessed that lung expansion was not sufficiently because harvested lung was used, so the density of lung tissue was increase and pleural thickening and anthracosis were observed in the lung because of his smoking history. **Conclusion:** It might be possible to confirm the localization of small nodules in peripheral lung using low power laser light during surgery.

P1.17-03 INTER-FRACTION VARIABILITY OF 18-FDG PET DURING LUNG SBRT AND THE EFFECT OF SYSTEMIC AND IMMUNOTHERAPY: RESULTS OF A PROSPECTIVE PILOT STUDY

S. Tian[1], J. Switchenko[2], I. Sethi[1], X. Yang[1], A. Da Silva[3], T. Owonikoko[1], D. Schuster[1], W. Curran[1], K. Higgins[1]

[1]*Winship Cancer Institute, Emory University, Atlanta/United States of America,* [2]*Rollins School of Public Health, Atlanta/United States of America,* [3]*RefleXion Medical, Hayward/United States of America*

Background: 18-FDG PET/CT has been used to inform prognosis, response to treatment, adaptive planning, and target volume delineation in NSCLC. Changes in PET characteristics, such as inter-fraction variation of 18-FDG uptake during a course of ablative radiation, and how PET metrics respond to systemic agents during SBRT, are unknown. This study prospectively characterized key metabolic parameters during lung SBRT, an important factor for biology-guided radiotherapy (BgRT). **Method:** Patients treated with lung SBRT of 50Gy in 5 fractions for early-stage NSCLC or lung metastases were eligible. Three PET/CTs were acquired per protocol: within 2 weeks of treatment start (PET1), between fractions 1 and 2 (PET2), and fractions 4 and 5 (PET3). The primary endpoint was inter-fraction variability. FDG-PET parameters including maximum and mean standardized uptake value (SUVmax, SUVmean), metabolic tumor volume (MTV), and derived metrics were extracted and compared longitudinally; where change between PET1 and PET2 is denoted as PET1-2. PET parameters were extracted using a MIMVISTA (v6.8.3) work station. Lesions were segmented with individualized location-based window settings. The effect of co-variates on each static (PET1, PET2, PET3) and change metric (PET1-2, PET2-3, PET1-3) were determined for each PET parameter. Continuous and categorical variables were compared by non-parametric methods with Spearman and Kruskal-Wallis tests. Clinical trial NCT03493789. **Result:** 14 patients who completed treatment as prescribed, with 17 total target lesions, were included. Treatment indications were: 5 (35.7%) medically-inoperable, 2 (14.3%) medically operable, 1 (7.1%) recurrent, 2 (14.3%) metastatic consolidation, 4 (28.6%) metastatic progression. 7 (50%) received prior systemic therapy, 4 (28.6%) received immunotherapy with 2 (14.3%) given concurrently. In aggregate, SUVmax did not significantly change over the SBRT course. Average SUVmax change from PET1 to PET2 (PET1-2) was -8.2% (p=0.51), -7.0% for PET1-3 (p=0.52), and 1.3% for PET2-3 (p=0.92). SUVmean, [SUVmax/SUVmean], and normalized parameters of [SUVmax/liver SUVmean] and [SUVmean/liver SUVmean] were similarly stable over the treatment course. Multiple PET2, PET1-2, and PET2-3 parameters were significantly related to systemic therapy, immunotherapy, and timing of administration. There were no significant interactions between age, sex, number of target lesions, target location, lesions centrality, smoking status, and static and change metrics for each PET parameter.

Table 1. Correlation between treatment variables and median SUVmax for each PET/CT study and each inter-fraction SUVmax change between PET/CTs.

	PET1		PET2		PET3		PET1-2		PET1-3		PET2-3	
Co-variates	Median SUVmax	p-value	Median SUVmax	p-value	Median SUVmax	p-value	SUVmax change	p-value	SUVmax change	p-value	SUVmax change	p-value
Systemic therapy (no vs yes)	7.52 vs 5.76	0.336	8.24 vs 4.91	0.021	6.12 vs 7.26	0.700	0.79 vs -1.46	0.034	0.13 vs -0.40	0.700	-2.46 vs 1.98	0.005
Immunotherapy (no vs yes)	7.46 vs 5.99	0.752	7.92 vs 4.82	0.058	7.26 vs 3.50	0.461	0.65 vs -3.11	0.027	0.14 vs -1.40	0.598	-1.14 vs 0.58	0.073
Concurrent administration (no vs yes)	5.99 vs 10.67	0.365	7.44 vs 6.30	0.821	6.12 vs 10.91	0.308	0.58 vs -4.37	0.024	0.10 vs -1.48	0.428	-0.40 vs 4.38	0.113

Conclusion: Serial 18-FDG PET imaging during lung SBRT demonstrated minimal variability of key parameters. FDG uptake at PET2, change from baseline, and between fractions, were related to systemic therapy, immunotherapy, and timing of administration. Mechanism of PET parameter variability, and its impact of on oncologic outcomes require investigation; prospective evaluation of BgRT is ongoing.

Background: The Japan Clinical Oncology Group (JCOG) conducted a randomized phase III trial (JCOG0707), which compared the survival benefit of tegafur/uracil (UFT) and tegafur/gimeracil/oteracil (S-1) for completely resected pathological stage I (T1>2 cm and T2 in the 6th TNM classification) non-small cell lung cancer (NSCLC). A total of 963 patients were enrolled. Recently, there is a growing concern that those who participated in clinical trials are highly selected and do not represent the "real-world" population. Hereby, we conducted a multicenter observational study of patients excluded from JCOG0707 trial during the study period. **Method:** Patients with completely resected pathological stage I NSCLC, eligible for, but excluded from the JCOG0707 trial during the enrollment period (Nov. 2008– Dec. 2013) were eligible for this study. Physicians from institutions that participated in the JCOG0707 retrospectively assessed the medical records of each patient. The final survival data were collected as of Dec. 2018. **Result:** Of the 48 institutions participating in JCOG0707, 34 participated in this observational study. They had enrolled 917 ("JCOG" cohort) to JCOG0707. To this study, 5004 patients ("All"

cohort), or 85% of those initially considered for JCOG0707 at the 34 institutions, were enrolled. Among them, 2388 (47.7%) were ineligible for the trial and 2616 (52.3%) had not been enrolled to JCOG0707 despite being eligible ("Eligible" cohort). Of the 5004 patients, 1659 (33.2%) received adjuvant chemotherapy, mainly UFT (1550 of 1659, or 93.4% of those received any adjuvant chemotherapy). The 5-year survival rates (5yOS) for All and Eligible cohorts were 83.9% and 89.1%, respectively, versus 89.2% in the JCOG cohort. The 5yOS with UFT adjuvant were 89.4% in Eligible and 88.9% in JCOG cohorts, respectively. UFT administration was a significant prognostic factor in All (adjusted HR=0.66, p<0.0001), but not in Eligible cohort (adjusted HR=0.88, p=0.28). The patients were classified into 3 subgroups, those with tumors without GGA (ground-glass area, non-invasive component; GGA-), with GGA (GGA+) and tumor size < 3 cm, and GGA+ with tumor size > 3cm. 5yOS of 744 patients in the Eligible cohort with GGA+ and tumor size < 3cm were excellent, 96.9%/96.4% with/without UFT. For 416 patients with GGA+ tumor sized > 3cm in Eligible cohort, invasive tumor size in the pathological specimen was prognostic but not predictive for UFT effect. When the invasive tumor size was >3 cm, 5yOS with/without UFT were 90.0/87.8%, whereas when it was <3 cm, 5yOS with/without UFT were 96.2/96.2%. UFT tended to be associated with better prognosis in 1389 patients with GGA- tumor when the tumor size was >3 cm, (5yOS 83.8% vs 77.4%, adjusted HR=0.82, p=0.27), but not when it was <3 cm (5yOS 88.1% vs 88.1%, adjusted HR=0.97, p=0.87). **Conclusion:** Our "real-world" data reproduced the survival outcome of JCOG0707, especially in Eligible cohort. Invasive tumor size was a prognostic factor in GGA+ tumors, suggesting validity of the 8th IASLC TNM classification. GGA+ tumor with invasive tumor size of <3 cm would not require any adjuvant therapy. UFT effect appears to be limited to large GGA- tumor.

P1.17-05 WHAT IS THE OPTIMAL NUMBER OF EXAMINED LYMPH NODE IN STAGE IA NON-SMALL CELL LUNG CANCER?

L. Huang[1], V. Chummun[2], W. Zhang[1], Q. Chu[1], Y. Chen[1]

[1]*Tongji Hospital Tongji Medical College Huazhong University of Science and Tech, Wuhan, China, wuhan/China,* [2]*Victoria Hospital, Mauritius, Mauritius/ Mauritius*

Background: 1.*To find out the optimal number of examined lymph nodes (ELNs) in stage IA non-small cell lung cancer (NSCLC).* 2.To figure out whether there was a turning point beyond which ELNs might have adverse effects on survival. **Method:** Using the Surveillance, Epidemiology, and End Results registry (SEER) database, we selected all NSCLC patients diagnosed with stage IA (T1N0M0) from 1995 to 2015. Cases from 1995 to 2005 were as analytical data set (group 1) and those from 2006-2015 as validation data set (group 2).The overall survival (OS) of patients with different ELNs was compared statistically by SPSS. The optimal cut point of ELNs was calculated by X-Tile and verified by univariable and multivariable analyses. Propensity score matching (PSM) was done by R software 3.5.2. **Result:** In total, we extracted 57481 stage IA NSCLC patients (group 1, n = 20814; group 2, n = 36667). The PSM of Group 1 and Group 2 were balanced based on sex, age and race. In both groups, we divided patients into 3 subgroups, recorded as ELN = 0, 1≤ ELNs < n and ELNs≥ n. ELN = 0 had the highest risk of death in each subgroup (all p < 0.001). From n = 6 to n = 16, OS was significantly different between 1 ≤ ELNs < n, and ELNs ≥ n. But from n = 17 to n = 30, OS was the same between 1 ≤ ELNs < n and ELNs ≥ n. When dividing patients into ELNs = 0, 1-2, 3-5, 6-9, 10-29, ≥ 30,serial improvement in OS was seen with increasing ELNs, up to ELNs = 6-9, and beyond which there was little further incremental survival benefit. The survival curve of ELNs ≥ 30 even had an obvious trend to drop down. **Conclusion:** For stage IA NSCLC, we suggested resecting 6-9 LNs was enough, and no more than 16 LNs. More than 16 ELNs did not improve survival and more than 30 ELNs might have a detrimental effect on survival.

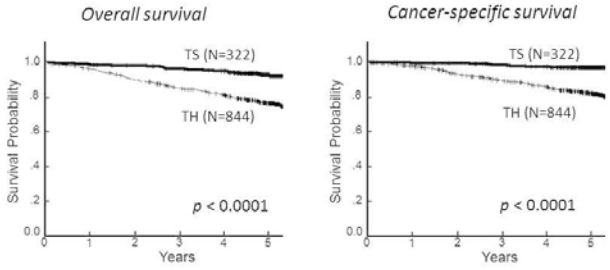
P1.17-06 LONG-TERM ONCOLOGICAL OUTCOME AFTER THORACOSCOPIC LOBECTOMY FOR NON-SMALL CELL LUNG CANCER PATIENTS

M. Nakao, J. Ichinose, Y. Matsuura, S. Okumura, M. Mun

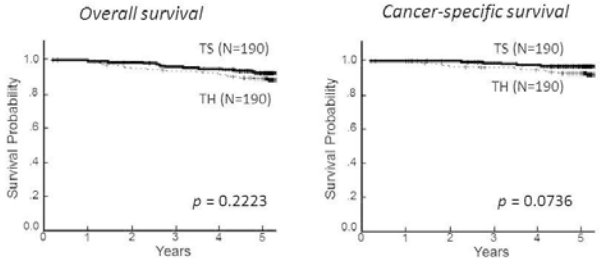
Cancer Institute Hospital, JFCR, Tokyo/Japan

Background: Thoracoscopic surgery (TS) has been used more commonly as a less invasive procedure for early-stage non-small cell lung cancer (NSCLC) than conventional thoracotomy (TH) in Japan. However, limited evidential data are available to compare the treatment efficacy of TS and TH. The purpose of this study was to retrospectively investigate the difference in the long-term outcome and invasiveness of TS and TH. **Method:** Total 1,166 NSCLC patients who underwent surgery between 2005 and 2013 were enrolled. Of these, 844 patients underwent surgery via TH and 322 via TS. We compared several clinicopathological factors and the long-term outcome between the two groups. We performed propensity score matching analysis to minimize differences in the patient background and tumor states. Median follow-up period was 62 months. **Result:** The TS group included more women, non-smokers or light smokers, and healthy patients. In the TS group, the disease states were significantly less aggressive. The TS group had a much better 5-year overall survival (OS) rate and cancer specific survival (CSS) rate than the TH group (p <0.0001, p <0.0001). Using propensity score matching, we extracted 190 patients each from the two groups. No statistical differences were present in the OS and CSS rates of the two matched groups (p =0.2223, p=0.0736), indicating the achievement of adequate balance. For a balanced cohort, intraoperative blood loss was significantly less (44 ± 40ml vs. 100 ± 78ml, p <0.0001), and the duration of postoperative drainage was shorter (2.1 ± 1.7 days vs. 3.5 ± 2.9 days, p <0.0001) in the TS group.

Long-term outcome after thoracoscopic surgery and thoracotomy for non-small cell lung cancer patients; before propensity score matching



Long-term outcome after thoracoscopic surgery and thoracotomy for non-small cell lung cancer patients; after propensity score matching



Conclusion: We reported the excellent long-term oncological outcomes in patients with early-stage NSCLC after TS lobectomy. Although this is a single institutional, retrospective study, we successfully avoided selection bias in the patients and showed comparable treatment outcomes with lower invasiveness of TS as compared to that of TH.

Background: EGFR TKI therapy is standard of care in metastatic EGFR mutant NSCLC, however its role in resectable NSCLC remains unclear. Furthermore, although EGFR TKIs elicit tumor shrinkage in 60% of patients, determinants of response are poorly understood. This was a window-of-opportunity study of neoadjuvant gefitinib prior to surgery for resectable NSCLC with serial plasma and tissue sequencing. **Method:** From Feb 2015 to Nov 2018, stage IA-IIIA EGFRmt NSCLC pts received minimum 4 weeks oral gefitinib 250mg daily before surgery. Biomarkers for TKI sensitivity were correlated with RECIST response, pharmacodynamic changes with serial PET-CT scans and pathologic response. Safety and feasibility were determined. Translational studies included multiregion whole exome sequencing (WES, n=44 sectors total) and RNAseq (n=39 sectors). **Result:** 14 pts were treated, 1 pt withdrew consent prior to surgery without toxicity or progression. Gefitinib (median exposure 1.4 mths) was well tolerated, 1 (8%) pt had ≥G3 AE, with G3 AST/ALT elevation leading to gefitinib cessation. ORR was 62% and DCR was 100%. 13/13 pts underwent resection, 6 (46%) pts had pathological downstaging, 4 (31%) pts had nodal pathCR and 1 (8%) pt had a major pathological response (<10% residual viable tumor cells). There was no correlation between CT response or residual FDG uptake post TKI with % residual viable tumor. WES (up to 370x) showed low tumor purities (median 0.17, range 0.1-0.37) across sectors. Purity correlated with number of coding mutations (r^2=0.29, p<0.01) but not ploidy (r^2=0.04, p=0.2). Compared to a matched treatment naïve cohort (n=18), phylogenetic analysis showed higher proportions of private driver mutations (p=0.04) and sub-clonal copy number variations. The presence of co-occurring truncal drivers did not account for the 5 pts with SD. On RNAseq, all pts had upregulation of immune regulatory and inflammatory response related genes, with significantly higher GEP score (median score; -0.17 vs -1.06, p=0.01) compared to the treatment naive cohort, although with heterogeneity across sectors. EPIC and xCell de-convolution showed high residual FDG uptake may be due to CAFs or infiltrating T-cells. After median 23 mths follow-up, 7/13 pts recurred, median RFS was 20.2 mths. Of 4 evaluable pts re-treated with palliative EGFR TKI, 3 had PR, 1 had PD (leptomeningeal only recurrence). **Conclusion:** Neoadjuvant gefitinib is safe, feasible and effective. Post EGFR TKI treatment samples had low tumor purities influencing genomic and transcriptomic analyses. Percentage residual disease did not correlate with residual FDG uptake or tumor response. There was pervasive upregulation of immune regulatory and inflammatory response genes, indicating infiltration of fibroblasts and T cells, providing unique insight into adaptive response and for the development of rational combination approaches in EGFR mutant NSCLC.

P1.17-08 MRNA EXPRESSION LEVEL OF RECEPTOR TYROSINE KINASES AND NON-RECEPTOR TYROSINE KINASES AS A RECURRENCE RISK IN RESECTED ADENOCARCINOMA OF THE LUNG

M. Ito[1,2,3], M. Serra[4], R. Rami-Porta[4], J. Belda-Sanchis[4], I. Chaib[2], M. Okada[1], N. Karachaliou[3], R. Rosell[5]

[1]*Hiroshima University, Hiroshima/Japan,* [2]*Institute for Health Science Research Germans Trias i Pujol (IGTP), Badalona/Spain,* [3]*Quirón-Dexeus University Institute, Barcelona/Spain,* [4]*University Hospital Mutua de Terrassa, Barcelona/Spain,* [5]*Germans Trias i Pujol Science Inst., Catalan Institute of Oncology (ICO Badalona), Barcelona/Spain*

Background: The profile of receptor tyrosine kinases (RTK) and non-receptor tyrosine kinases (non-RTK) is crucial for tumor genesis and therapeutic strategy in several types of cancer. We previously reported that elevated mRNA expression level of some RTKs/non-RTKs (AXL, CDCP1, STAT3, YAP1) were related to poorer prognosis in lung adenocarcinoma patients receiving EGFR-TKI. The prognostic impact of RTKs/non-RTKs is unclear in early-stage lung cancer. This study aims to explore the usefulness of RTK and non-RTK to detect the risk of recurrence in resected NSCLC, especially in EGFR mutant adenocarcinoma. **Method:** We retrospectively collected pathologic N0-2 adenocarcinoma cases resected in Japanese and Spanish institutions. mRNA expression levels of RTK or non-RTK (STAT3, YAP1, AXL, CDCP1, MET, SHP2, and EGFR) in surgical specimens were evaluated and the impact of expression level on recurrence-free survival (RFS) was compared. The oncological significance on RTK or non-RTK was validated *in vitro*. **Result:** Among enrolled 268 cases, 100 cases (37.3%) harbored EGFR mutation. Forty-five EGFR mutation positive cases recurred and cases with higher mRNA expression level of EGFR showed worse RFS. In addition, higher expression of CDCP1 or SHP2 indicated poorer RFS in EGFR mutation positive cases. *In vitro*, combination of SHP099 (SHP2 inhibitor) and osimertinib showed synergism in EGFR mutation positive cell line (Combination index was 0.62). **Conclusion:** Higher expression of SHP2 and CDCP1 is potential risk of recurrence in EGFR mutant lung adenocarcinoma. The synergism of SHP2 inhibitor plus EGFR-TKI suggests that the expression level of SHP2 is involved in tumorigenesis and is a promising predictor for recurrence in EGFR mutant lung adenocarcinoma.

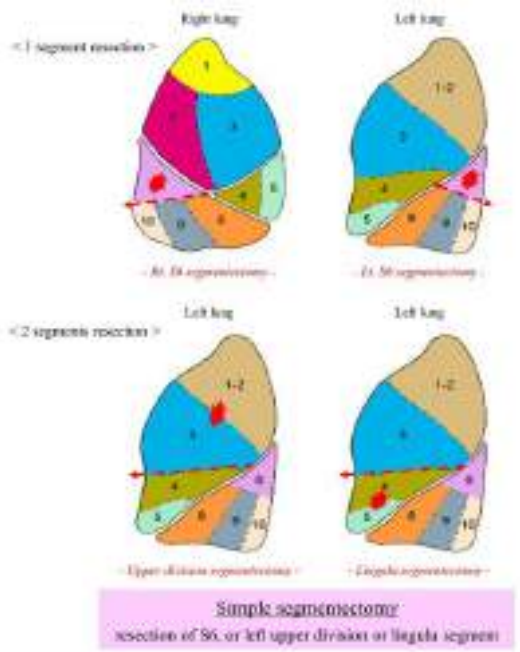
P1.17-09 SURGICAL OUTCOMES OF COMPLEX VERSUS SIMPLE SEGMENTECTOMY FOR STAGE I NON-SMALL CELL LUNG CANCER

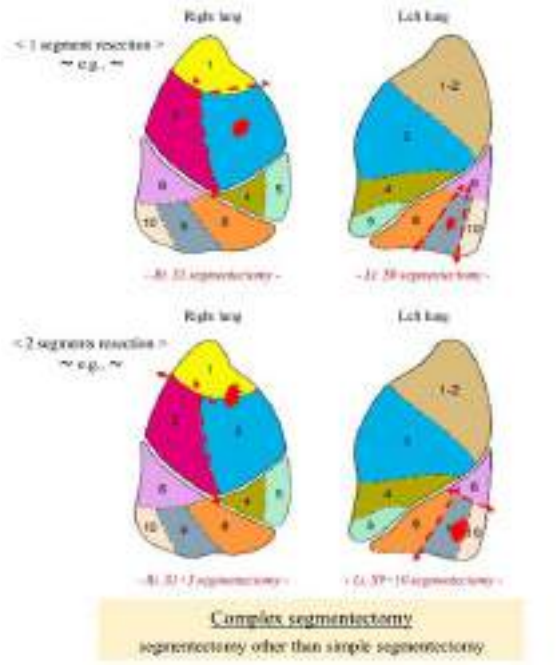
Y. Handa, Y. Tsutani, A. Kagimoto, T. Mimae, Y. Miyata, M. Okada

Hiroshima University Hospital, Hiroshima City Minamiku/Japan

Background: As segmentectomy becomes widely used for lung cancer treatment, "complex segmentectomy," which makes several, intricate intersegmental planes, remains controversial because of procedural complexity and risk of increased complications and incurability. Questions remain regarding mortality, morbidity, surgical margin, lymph nodes dissection, and postoperative pulmonary function. We evaluated operative and postoperative outcomes of complex compared to simple segmentectomy. **Method:** We retrospectively reviewed clinical stage I lung cancer patients who could tolerate lobectomy and underwent complex or simple segmentectomy between April 2007 and March 2017. Clinicopathologic, operative, and postoperative results of the complex (*n* = 117) and simple (*n* = 92) segmentectomy groups were compared.



POSTERS



Result: No significant differences were detected in age, sex, comorbidities, preoperative pulmonary function, tumor histology, and size. Although only median operative time (180 vs. 143.5 minutes; $P < 0.0001$) was significantly longer in the complex group, 30-day mortality (0% vs. 0%), overall complications (24.8% vs. 22.8%), and prolonged air leakage (11.9% vs. 10.9%) were nearly equivalent between the two groups, respectively. The complex group showed comparable results in median surgical margin distance (16.0 vs. 17.5 mm) and number of dissected lymph nodes (6.0 vs. 7.0 nodes). Margin relapse occurred in two patients in the simple group but none occurred in the complex group. Both groups also showed similar postoperative pulmonary functions. **Conclusion:** Complex segmentectomy is a safe option in the treatment of lung cancers with adequate operative outcomes.

Keywords: Operative outcome, Postoperative complication, segmentectomy

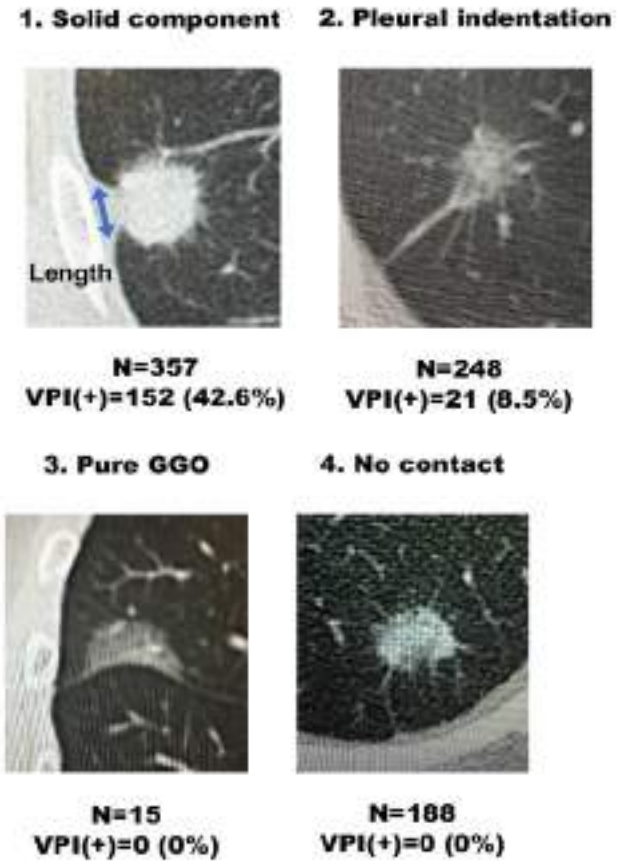
P1.17-10 PREDICTION OF VISCERAL PLEURAL INVASION IN C-N0 NON-SMALL CELL LUNG CANCER

S. Okada[1], A. Hattori[2], T. Matsunaga[2], K. Takamochi[2], S. Oh[2], M. Inoue[1], K. Suzuki[2]

[1]*Kyoto Prefectural University of Medicine, Kyoto/Japan,* [2]*Juntendo University, Tokyo/Japan*

Background: Visceral pleural invasion (VPI) is a tumor invasion pattern and a poor prognostic factor. However, accurate preoperative diagnosis of VPI remains difficult. This study aimed to clarify the clinical and radiological predictors of VPI in patients with c-N0 non-small cell lung cancer (NSCLC). **Method:** A retrospective review was conducted in 808 patients with c-N0 NSCLC who underwent complete resection between 2009 and 2014. VPI included pathological pl1 and pl2. Patients with pl3 were excluded. Radiological findings were evaluated based on thin-section CT and PET. The patients were divided into 4 categories according to the following patterns of pleural contact with tumor: a solid component, pleural indentation, a ground glass opacity (GGO) component, and no pleural contact.

Pattern of pleural contact with tumor



Result: VPI occurred in 173 patients (21.4%), with a significantly higher incidence of pathological nodal involvement than those without VPI (32.9% vs 10.6%, $p<0.001$). Of the 357 patients with pleural contact by a solid component, 248 patients with pleural indentation, and 203 patients with pleural contact by a GGO component/no pleural contact, 152 (42.6%), 21 (8.5%), and none (0%) had VPI, respectively. The length of pleural contact by a solid component was positively correlated to VPI ($p<0.001$). Receiver-operating characteristic curve analysis revealed a cutoff length of 1 mm, indicating the importance of the presence of pleural contact by a solid component. Multivariate logistic regression analysis revealed that pleural contact pattern, pure-solid tumor, SUVmax, and CEA were independent significant predictors of VPI. Adjusted ORs (95%CI) of pleural contact by a solid component and pleural indentation were 181 (11.8–NA) and 40.1 (2.55–633), respectively (in reference to a GGO component/no pleural contact). **Conclusion:** Pleural contact by a solid component was the most relevant predictor of VPI. VPI was reflected by malignant clinical (high CEA) and radiological features (high SUVmax, pure-solid tumor) and a pleural contact pattern (solid component, indentation).

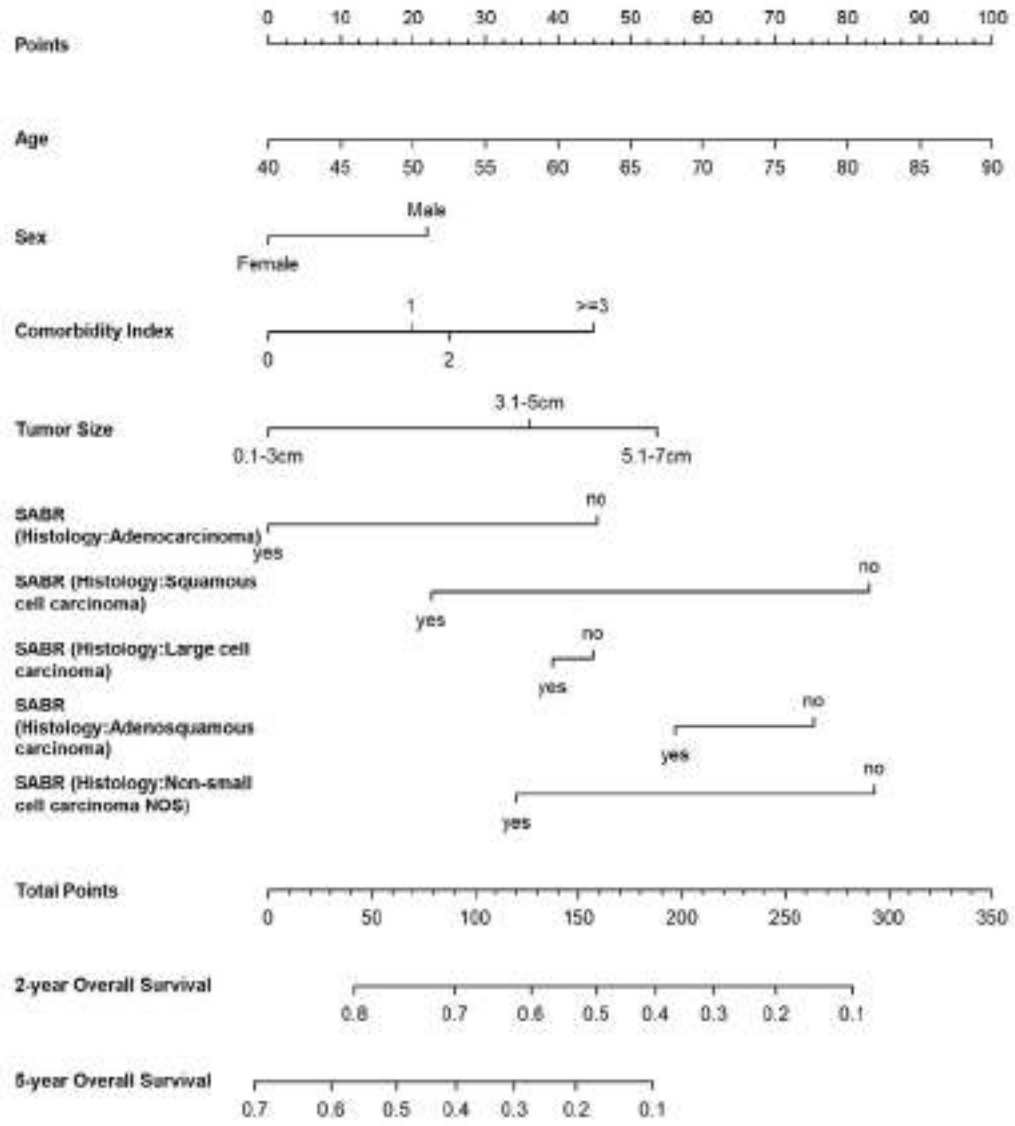
P1.17-11 NOMOGRAM PREDICTING OVERALL SURVIVAL BENEFIT OF STEREOTACTIC ABLATIVE RADIOTHERAPY FOR EARLY STAGE NON-SMALL CELL LUNG CANCER

C. Jacobs, J. Gao, X. Wang, K. Mehta, J. Salama, J. Torok, C. Kelsey

Duke University Medical Center, Durham/United States of America

Background: Stereotactic ablative radiotherapy (SABR) is the preferred treatment for medically inoperable T1-T2N0M0 non-small cell lung cancer (NSCLC). This population is at high risk of mortality from comorbidities precluding surgery. A nomogram to better identify patients most likely to benefit from SABR would be clinically meaningful. **Method:** Adults with T1-T2N0M0 NCSLC (AJCC 7th edition) treated with SABR (30-70 Gy in 1-10 fractions with biologically effective dose ≥100 Gy_{10}) or observation between 2004-2015 in the National Cancer Database were identified. Exclusion criteria included prior malignancy, surgery to the primary tumor, chemotherapy, and no pathologic diagnosis. Propensity score was used to match

SABR and observation cohorts on prognostic demographic and clinicopathologic factors identified by logistic regression. Using backward selection, a multivariable Cox proportional hazards model with Frailty term was identified predicting 2- and 5-year overall survival (OS) via a nomogram. The model prediction accuracy was assessed by the concordance between observed and predicted OS. **Result:** 4,440 matched pairs (total n=8,880) were identified with median age 75, 53% female, 54% Charlson-Deyo comorbidity index of zero, 62% tumor size ≤3 cm, and 50% adenocarcinoma. Factors associated with improved OS on multivariable analysis included younger age (HR 0.824 by decade, p<0.001), female sex (HR 0.809, p<0.001), lower comorbidity index (HR 0.647 for 0 versus ≥3, p<0.001), smaller tumor size (HR 0.595 for ≤3cm versus 5.1-7cm, p<0.001), adenocarcinoma histology (p<0.001), and SABR (p<0.001). Interaction between SABR and histology was significantly associated with OS (p=0.017). Uno's concordance index, evaluating the nomogram's accuracy for predicting OS, was 0.623 (95%CI 0.615–0.631) based on 100 perturbations.



Conclusion: This nomogram predicts the impact of SABR versus observation on 2- and 5-year OS, and may help identify patients with medically inoperable T1-T2N0M0 NSCLC who would benefit most from SABR. Inclusion of other variables, such as performance status, may improve the model prediction accuracy.

P1.17-12 OSTEOGENIC AND BRAIN METASTASES AFTER RESECTION OF NSCLC: IMPLICATIONS FOR THE USE OF FDG-PET AND BRAIN MRI IN POSTOPERATIVE SURVEILLANCE

T. Mizuno, H. Konno, H. Kojima, M. Isaka, Y. Ohde

Shizuoka Cancer Center, Nagaizumi, Shunto-gun, Shizuoka/Japan

Background: In several guidelines for lung cancer treatment, routine use of FDG-PET and brain MRI have not been recommend due to their insufficient evidence of survival benefits for resected NSCLC. In clinical practice, not a small portion of patients experience metastases in osteogenic and/or brain at the initial recurrence after surgery, which routine chest CT hardly diagnose them. In this retrospective study, we aimed to propose the candidates for surveillance using FDG-PET and brain MRI to diagnose OM/BM. **Method:** We retrospectively enrolled 1099 patients who underwent pulmonary resections of lobectomy or more for NSCLC between 2002 and 2013. From medical records, clinicopathological data were collected and reviewed. Surveillance by using FDG-PET and brain MRI were basically performed at patients' complaint of symptoms and/or detection of other metastatic disease. Clinicopathological factors associated with osteogenic metastases (OM) and/ or brain metastases (BM) were investigated by univariate and multivariate analyses. **Result:** We included 1055 patients with lobectomies and 44 patients with pneumonectomies. Nine hundred thirty-three patients (88.4%) received mediastinal and hilar lymphnodes dissection. Seven hundred twenty-one patients had adenocarcinoma histology, 274 had squamous cell carcinoma histology. The prevalence of pStage was as following; pIA: 265 (25.1%), pIB: 348(33.0%), pIIA: 185(17.5%), pIIB: 105 (10.0%), pIIIA: 193 (18.3%), pIIIB: 3 (0.3%) (TNM 7th edition). Postoperative recurrence were identified in 344 patients (32.6%), OM or/and BM were observed in 115 patients (10.9%) as the initial recurrence. OM were diagnosed in 56 patients (5.6%). In the initial year after resection, 41.1% of OM were diagnosed, and 82% in the 2 years. BM were identified as the initial recurrence in 72 patients (6.6%). In the initial year, 44.1% of BM were diagnosed, and 78.9% in the 2 years. Multivariate analyses following univariate analyses revealed higher preoperative serum CEA level than 5ng/ml and presence of pathological nodal metastases were significantly associated with both postoperative OM and BM (p=0.011,<0.001 in OM, p=0.044, <0.001 in BM). Prevalence of OM and/or BM was 24.6% in patients with high serum CEA and nodal metastases. Postrecurrence survival of asymptomatic patients were better than those of symptomatic patients in both OM and BM groups (p=0.009 and 0.29, respectively) **Conclusion:** Preoperative high serum CEA level and pathological nodal spread were closely associated with OM and BM after resection of NSCLC. Most of those events developed in 2 years after resections. Under the patient selections, efficacies of the use of FDG-PET and brain MRI are worthy to be evaluate in respect to earlier detections, maintenance of QOL and survival outcomes.

Keywords: osteogenic metastasis, brain metastasis, postoperative surveillance

P1.17-13 NEXT GENERATION SEQUENCING OF THE CIRCULATING SMALL RNA FROM SERUM IDENTIFIES SMALL RNA-BASED BIOMARKER PANEL FOR STAGE I-II LUNG ADENOCARCINOMA

D. Ueda[1], Y. Tsutani[2], T. Mimae[2], Y. Miyata[2], M. Okada[2], H. Tahara[3]

[1]*Hiroshima University Hospital, Hiroshima/Japan,* [2]*Hiroshima University Hospital, Hiroshima City Minamiku/Japan,* [3]*Hiroshima University, Hiroshima/Japan*

Background: Circulating small RNAs have been reported as biomarkers for cancer diagnosis, including lung cancer. The purpose of this study is to identify the small RNA for the early detection of lung adenocarcinoma. In this study, we used next generation sequencing (NGS) in order to screen and validate expressions of the small RNAs between persons with and without adenocarcinoma and built the RNA-based biomarker panel. **Method:** We used next generation sequencing in all phases (screening set, validation set, and the panel evaluation set) and researched micro RNAs(miR) and transfer RNA fragments(tRF) as small RNAs. We analyzed the RNAs from serum of 21 patients with adenocarcinoma and 20 healthy control for screening and assessed small RNAs from 22 patients with adenocarcinoma and 20 healthy control for validation. Regarding significantly upregulated and downregulated small RNAs, we built RNA-based biomarker panel and evaluated the panel with a different dataset (33 patients with adenocarcinoma and 27 healthy control). **Result:** Based on screening and validation set, four miR and one tRF were upregulated. Tow miR and nine tRF were downregulated. An area under the curve value of each small RNA was 0.65 to 0.85. Among them, nine small RNA were adopted to the biomarker panel by using multiple regression analysis. In the cohort of screening and validation set, the panel showed a sensitivity of 93.0% and specificity of 88.0%, with an area under the curve value of 0.983, which was much larger than that of a single RNA. The panel was evaluated with a different dataset and showed a sensitivity of 90% and specificity of 74.1% when the threshold was 1.8. **Conclusion:** In conclusion, we built the small RNA-based biomarker panel which included nine small RNA and our results showed the diagnostic efficacy of the panel. Further investigation is required to understand the cause for the expression change of each small RNA.

P1.17-14 PROGNOSTIC VALUE OF IMMUNE CELL BIOMARKERS IN SURGICALLY RESECTABLE NON-SMALL CELL LUNG CANCER: A META-ANALYSIS

S. Tuminello, R. Veluswamy, W. Lieberman-Cribbin, S. Gnjatic, F. Petralia, P. Wang, R. Flores, M. Van Gerwen

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Immune cells within the tumor microenvironment (TME) play an important role in the development, progression and outcomes of non-small cell lung cancer (NSCLC). We conducted the first meta-analysis of studies assessing the role of individual immune cells in surgically resected stage I-III NSCLC to evaluate the prognostic value of immune cell biomarkers. **Method:** PubMed was searched to identify eligible studies assessing clinical outcomes of surgically resected stage I-III NSCLC patients according to immune cell subsets: CD3+ T cells, CD4+ T Helper cells, CD8+ T cytotoxic cells, CD20+ B cells, FoxP3+T Regulatory cells, Natural Killer cells (CD56/CD57+), macrophages (CD68+), and Mast Cells. Meta-analysis was performed using a linear mixed-effects model to determine overall survival (OS) and disease free survival (DFS), and was reported according to whether or not the study adjusted for clinical covariates. I^2 was used to assess heterogeneity across studies. **Result:** 42 articles (7,906 patients) were included in this analysis. Higher levels of CD20+ B cells were associated with better OS, while increased FoxP3+ T regulatory cells and Mast Cells were associated with worse OS in unadjusted studies. However, in studies adjusting for clinical variables, CD8+ T cytotoxic cells and Natural Killer cells were also found to be associated with improved OS, while mast cells no longer were significantly detrimental. CD20+ B cells were associated with better DFS in unadjusted studies; in adjusted studies, CD8+ T cytotoxic cells were associated with better survival and FoxP3+ T Regulatory cells were associated with worse survival, with CD20+ B cells no longer significantly associated survival. I2 did not show substantial heterogeneity between studies. Table 1: Meta-Analysis Survival Estimates

HR= Hazard Ratio, CI = Confidence Interval

Conclusion: Immune cell subsets are able to provide prognostic information in early-stage NSCLC undergoing surgical resection. When evaluating these immune biomarkers, adjustment for clinical covariates can have a profound impact on survival estimates.

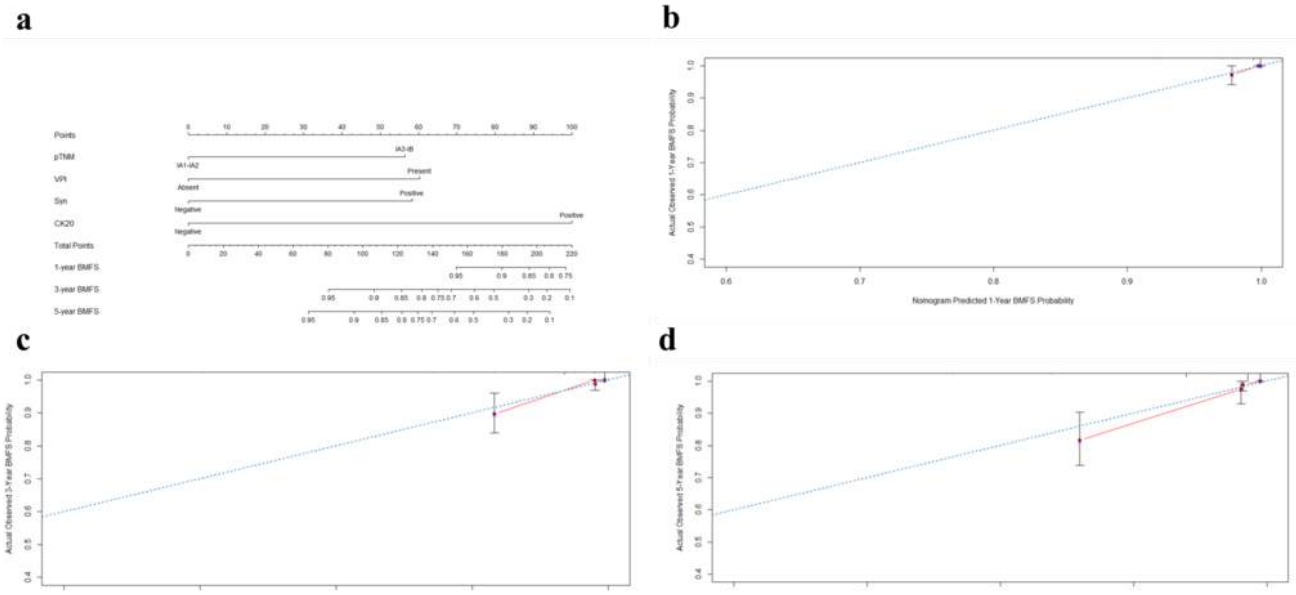
Keywords: Biomarker, Immune Cell

P1.17-15 RISK, PATTERN AND OUTCOME OF BRAIN METASTASES IN COMPLETELY RESECTED STAGE I (AJCC 8TH EDITION) NON-SQUAMOUS NON-SMALL CELL LUNG CANCER

J. Ni, T. Guo, Y. Li, Z. Zhu

Fudan University Shanghai Cancer Center, Shanghai/China

Background: Brain as the first site of recurrence after complete resection in stage I non-squamous non-small cell lung cancer (NSCLC) is occasionally encountered. However, the risk factors and clinical outcomes of this uncommon situation are not fully understood. **Method:** The records of patients who underwent curative surgery at Fudan University Shanghai Cancer Center were reviewed and two cohorts with stage I non-squamous NSCLC were identified. The training cohort consisted of randomly selected patients from January 2013 to December 2017. The validation cohort included consecutive patients from January 2011 to December 2012. Brain metastasis free survival (BMFS) were calculated from the time of surgery to the documentation of brain metastasis (BM). Overall survival (OS) was measured from the documentation of BM to the time of any cause of death. A nomogram was developed based on variables selected in multivariate analysis. **Result:** With a median follow-up of 28 (range, 10-69) months, 16 of the 596 patients in the training cohort had its initial relapse in the brain. The 1-year, 2-year, and 3-year cumulative incidence of BM were 0.7%, 1.9% and 4.2%, respectively. Tumor size≥2cm (HR=5.09, p=0.024), visceral pleural invasion (HR=2.79, p=0.007), expression of Syn (HR=4.24, p=0.007) and expression of CK20 (HR=14.01, p<0.001) were independent risk factors of BM. Afterwards, a nomogram predicting BMFS was developed based on these four factors. Of note, EGFR mutation was not associated with BMFS. Additionally, with a median follow-up of 75 (range, 7-98) months, 18 of the 478 patients in the validation cohort had its initial recurrence in the brain. The nomogram was validated with a concordance index of 0.93 (95%CI, 0.88-0.98) and the calibration curves displayed good agreement between the predicted BMFS and the actual observation. Among the 34 patients with BM, 10 also had extracranial recurrence, 7 were symptomatic and 24 had oligo-metastases in the brain. By the time of data cut-off, 14 patients died with a 5-year OS rate of 24.8%. Positive expression of Syn or CK20 was significantly associated with reduced OS, while upfront local therapy (surgery and/or radiotherapy) after detection of BM tended to prolong OS (p=0.068).



Conclusion: Positive expression of Syn and CK20, but not EGFR mutation, were independent risk factors of BM and reduced survival in curative resected stage I non-squamous NSCLC. The majority of patients developing BM were asymptomatic and initially having oligo-metastases, highlighting the importance of regular brain imaging for patients with high risks.

P1.17-16 NEO-ADJUVANT TARGETED THERAPY IN NON-SMALL CELL LUNG CANCER PATIENTS: A 10-YEAR EXPERIENCE IN A TERTIARY MEDICAL CENTER

H.C. Huang, C.-H. Chiu, C.-L. Chiang, Y.-H. Luo, C.-M. Tsai, Y.-M. Chen

Taipei Veterans General Hospital, Taipei/Taiwan

Background: Epidermal growth factor receptor (EGFR) Tyrosine kinase inhibitor (TKI) or anaplastic lymphoma kinase (ALK) inhibitor had can provide dramatic response in lung adenocarcinoma patients, and have been the first line treatment for stage IV patients with corresponding genes mutations. Recent clinical trials had demonstrated both safety and tolerability in neo-adjuvant settings. However, there are still limited clinical data regarding long-term outcome and additional adjuvant treatment options. Our purpose was to investigate the treatment response and image change of neoadjuvant target therapy in non-small cell lung (NSCLC) cancer patient patients. **Method:** Taipei Veterans General Hospital Lung Cancer Database was used to search for stage I to stage III NSCL patients, who's first line treatment was TKI. Their medical records and chest CT and PET images were reviewed. **Result:** We identified 20 patients in a 10 year period (January 2007 - December 2017) receive neoadjuvant TKI. 2 failed to receive further surgery treatment. One of them was due to disease progression while the other remained non-operable despite tumor sized down. The overall response rate for neoadjuvant TKI was 86%. 17 patients were clinical stage IIIA(AJCC 8th edition), 1 was IIIB, 2B and 1b. One of them received ALK inhibitor while the others received EGFR TKI. The mean duration of neo-adjuvant therapy was 73 days. For 18 patients receiving surgical treatment, 12 experienced down-staging (one got pathological complete response). 13 patients received adjuvant therapy with great variety. 7 patients did not have recurrent disease after surgery, and they all had pathological down staging. The median recurrence-free survival and overall survival was 13.7 months and 6 years, respectively. **Conclusion:** As long-term survival was potentially achievable in such patient group, and with the diverse treatment options, results from randomized clinical trials are needed to give solid conclusion.

Keywords: EGFR, tyrosine kinase inhibitor, Neo-adjuvant

P1.17-17 OUTCOMES FOLLOWING STEREOTACTIC BODY RADIOTHERAPY (SBRT) FOR BIOPSY-CONFIRMED VS. RADIOLOGICALLY-DIAGNOSED PRIMARY LUNG CANCER

T. Koh, W. Ong, T. Leong, C. Lapuz, A. Lim

Oliva Newton John Cancer Research and Wellness Centre, Heidelberg/ Australia

Background: Stereotactic body radiotherapy (SBRT) is increasingly used to treat inoperable non-small cell lung cancer (NSCLC). Obtaining tissue confirmation prior SBRT is not always feasible. We aim to evaluate clinical outcomes in biopsy-confirmed vs. radiologically-diagnosed NSCLC treated with SBRT. **Method:** This is a single-institutional retrospective cohort of NSCLC patients treated with SBRT between February 2014 and October 2018. Differences in baseline characteristics between biopsy-confirmed vs. radiologically-diagnosed NSCLC were compared using chi-squared test for categorical variables and student's t-test for continuous variables. The oncological outcomes of interest were: local failure (LF), distant failure (DF), and overall survival (OS). Probability of LF, DF and OS were estimated using the Kaplan-Meier method. The difference in outcomes between those who had biopsy confirmation vs. no biopsy was evaluated using the log-rank test. **Result:** 63 lesions in 60 patients were treated with SBRT, comprising 35 (58%) men and 25 (42%) women. Mean age was 76.8 years (SD=8.1). 34 (57%) patients were ECOG 0-1 and 26 (43%) were ECOG 2-3. 22 (37%) patients had biopsy-confirmation while 38 (63%) were radiologically-diagnosed. No significant differences in baseline characteristic between the 2 groups. Of the 63 treated lesions, 9 (14%) received 54Gy/3 fractions, 44 (70%) had 48Gy/4 fractions, 7 (11%) had 50Gy/5 fractions, 2 (3%) had 40Gy/5 fractions, and 1 (1%) had 20Gy/1 fraction. The patients were followed-up for a median of 10.6 months (IQR=5.7-14.9). There were 5 cases of LF (4 in biopsy-confirmed, 1 in non-biopsy) observed at a median of 12.8 months post-SBRT. The actuarial 12-month LF-free survival was 95%, with no significant differences between lesions that was biopsied vs. not biopsied (P=0.07). Of the 60 treated patients, 11 developed DF (8 biopsy-confirmed, 3 non-biopsy) at a median of 6.5 months post-SBRT. The 12-month actuarial DF-free survival was 87%, with no difference between patients who had biopsy vs. no biopsy (P=0.3). There were 11 deaths of which only 1 was cancer-specific, reported at a median of 9.6 months post-SBRT. The 12-month OS was 83%. No differences between patients who had biopsy vs. no biopsy (P=0.1). No grade 3 toxicities were observed. **Conclusion:** The LF, DF, and OS did not appear to be affected by

biopsy confirmation in this cohort of NSCLC patients. In situations where biopsy confirmation is not feasible, it is not unreasonable to offer SBRT to patients with presumed NSCLC based on radiological suspicion following multidisciplinary discussions.

Keywords: SBRT, NSCLC

P1.17-18 SURGERY ALONE OR PLUS ADJUVANT RADIOTHERAPY FOR PATIENTS WITH N0 NON-SMALL-CELL LUNG CANCER >5 CM: A POPULATION-BASED STUDY

J. Wen, J. Chen, M. Fan, X. Xu, D. Liu

Fudan University Shanghai Cancer Center, Shanghai/China

Background: According to the eighth edition of the TNM classification for Lung Cancer, T2b (5–7 cm) and T3 (>7 cm) non-small cell lung cancers (NSCLC) should be reclassified as T3 and T4. Here, we evaluated the effect of surgery alone or surgery plus adjuvant radiation (SART) on survival in node-negative patients with NSCLC >5 cm. **Method:** We identified 4557 N0 patients with NSCLC >5 cm from the Surveillance, Epidemiology, and End Results database between 2004 and 2014. Overall survival (OS) and lung cancer-specific survival (LCSS) were compared between patients who underwent surgery alone and those receiving SART. The proportional hazards model was used to evaluate multiple prognostic factors. **Result:** After propensity-score matching, 1042 and 525 patients were included in the surgery alone and SART groups, respectively. OS and LCSS favored surgery alone over SART. In the multivariate analysis, dissection of ≥6 lymph nodes was associated with better OS and LCSS in patients with NSCLC >5 cm, especially in patients treated with surgery alone. Lobectomy was associated with better OS and LCSS in NSCLC 5–7 cm, whereas it was not significantly superior over sublobectomy in NSCLC >7 cm.

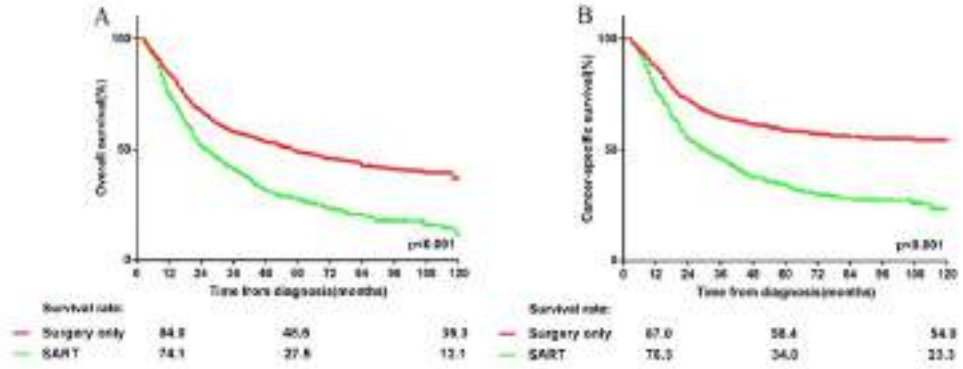

Figure 1 Overall and lung cancer-specific survivals in patients with non-small cell lung cancer (NSCLC) >5 cm who underwent surgery alone or surgery plus adjuvant radiotherapy. SART, surgery plus adjuvant radiotherapy.

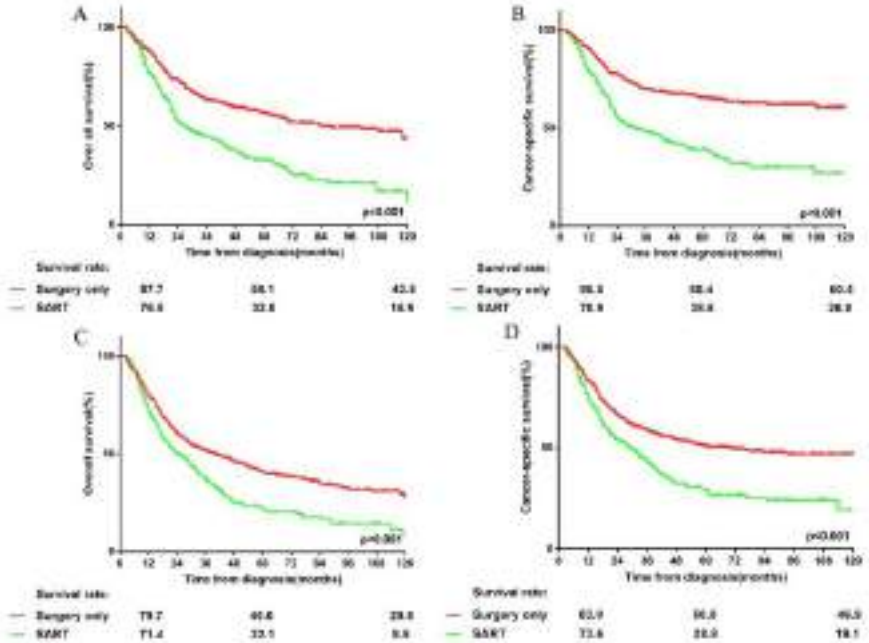

Figure 2 Stratification of overall survival and lung cancer-specific survival in patients with node-negative NSCLC > 5 cm at the cut point of the number of harvested lymph nodes who underwent surgery or surgery plus adjuvant radiotherapy. A and B, overall survival and lung cancer-specific survival in patients with node-negative NSCLC > 5 cm who had more than six lymph nodes dissected.C and D, overall survival and lung cancer-specific survival in patients with node-negative NSCLC > 5 cm who had less than six lymph nodes examined.

Conclusion: Surgery alone with a number of examined lymph nodes greater than six should be recommended as the first choice for patients with NSCLC >5 cm. Lobectomy should be recommended for patients with NSCLC 5-7 cm. For patients with NSCLC >7 cm who do not tolerate lobectomy, sublobectomy might be an alternative surgical procedure.

P1.17-19 LOBE-SPECIFIC LYMPH NODE DISSECTION FOR CLINICAL EARLY-STAGE (CIA) PERIPHERAL NON-SMALL CELL LUNG CANCER PATIENTS: FEASIBLE AND HOW?

H.-Y. Deng[1], Q. Zhou[2]

[1]*West China Hospitial, Sichuan University, Chengdu/China,* [2]*West China Hospital, Sichuan University, Chengdu/China*

Background: Currently, the extent of lobe-specific lymph node (LN) dissection (L-SLND) for early-stage non-small cell lung cancer (NSCLC) in previous literatures remains controversial without well-recognized agreement on exact definition of L-SLND. We aimed to investigate the possible lobe-specific LN metastasis pattern of clinical T1N0M0 peripheral NSCLC and define the extent of L-SLND for them. **Method:** We retrospectively collected clinical data of patients undergoing lobectomy or segmentectomy with systematic lymphadenectomy for early-stage NSCLC from January 2015 to December 2018. The LN metastasis pattern of them was analyzed by tumor lobe location. **Result:** A total of 590 patients were included for analysis. The rate of mediastinal LN metastasis was 9.5% (table 1). For cases in the upper lobes and these in the lower lobes, 8.8% and 6.0% of them respectively metastasized to the upper LN zone (P=0.274). However, cases in the upper lobes hardly metastasized to the subcarinal (0.3%) and lower (0.3%) LN zones while it was 10.2% and 5.4% for cases in the lower lobes, respectively (both P<0.001). When stratified by tumor size, all these cases (100%) metastasizing from lower lobes had a tumor size of 2-3 cm while cases with a tumor size ≤2 cm had no metastasis to upper LN zone. For cases in right middle lobe, none of them metastasized to the lower LN zone. Table 1. Lymph node metastasis pattern among non-small cell lung cancers in different lobes.

Conclusion: A lobe-specific LN metastasis pattern of early-stage peripheral NSCLC was observed and for cases in the upper lobes (≤3cm), there is no need to dissect lower mediastinal LNs and for cases in the lower lobes (≤2cm), there is no need for dissecting upper mediastinal LNs. Otherwise, systematic LN dissection or sampling instead of L-SLND should be recommended.

P1.17-20 EVALUATION OF EFFICACY AND SAFETY OF UNIPORTAL SEGMENTECTOMY IN THE TREATMENT OF LUNG CANCER

C. Zhang, G. Wang, Z. Yu, H. Liu

Liaoning Cancer Hospital & Institute, Shenyang/China

Background: Uniportal segmentectomy is a therapeutic option for early stage lung cancer, but the debate over uniportal segmentectomy still remains. The aim of this study is to evaluate of efficacy and safety of uniportal segmentectomy in the treatment of lung cancer. **Method:** A total of 137 patients who underwent uniportal segmentectomy or subsegmentectomy between January 2017 and April 2019 in Liaoning Cancer Hospital. The clinical data of these patients were retrospectively analyzed, including operation time, number of lymph nodes dissected and postoperative mortality, postoperative complications, postoperative intubation time, and postoperative hospital stay. **Result:** The surgery procedure was anatomical pulmonary segmentectomy or subsegmentectomy. Uniportal segmentectomy was in 133 cases, and subsegmentectomy was in 4 cases. The median operation time was 243 minutes (range, 60-405 minutes), median number of lymph nodes dissected was 14 (range, 0-31), median drainage time was 5 days (range, 1-9 days), median postoperative hospital stay was 8 days (range, 3-19 days). The postoperative complications were pneumonia 2 case (1.5%), fever 12 cases (8.8%), hemoptysis 1 case (0.7%), air leak 2 case (1.5%), atrial fibrillation 1 case (0.7%), and subcutaneous hydrops 2 cases (1.5%). There was no severe postoperative complications, including death, bleeding, reoperation, and bronchopleural fistula. **Conclusion:** Uniportal segmentectomy is a safe and feasible technique for treating early stage lung cancer, with acceptable postoperative complications and mortality.

Keywords: uniportal segmentectomy, subsegmentectomy, Lung cancer

P1.17-21 SAFETY AND EFFECTIVENESS OF STEREOTACTIC ABLATIVE RADIOTHERAPY FOR ULTRA-CENTRAL LUNG LESIONS: A SYSTEMATIC REVIEW

H. Chen, J. Laba, S. Zayed, G. Boldt, D. Palma, A. Louie

London Health Sciences Centre, London/Canada

Background: The safety and effectiveness of stereotactic ablative radiotherapy (SABR) for patients with ultra-central lung tumours is currently unclear. We performed a systematic review to summarize existing data and identify trends in treatment-related toxicity and local control following SABR in patients with ultra-central lung lesions. **Method:** We performed a systematic review using the PRISMA guidelines. The PubMed and Embase databases were queried from dates of inception until September 2018. Studies

in the English language that reported treatment-related toxicity and local control outcomes post-SABR for patients with ultra-central lung lesions were included. Ultra-central lung lesions were defined as lesion whose gross tumour volume (GTV) or planning target volume (PTV) abutted or invaded the proximal tracheo-bronchial tree (PBT) or other mediastinal structures such as the great vessels or esophagus. Guidelines, reviews, non-peer reviewed correspondences, studies focused on re-irradiation and studies with fewer than 5 patients were excluded. **Result:** A total of 446 studies were identified, with 10 meeting all criteria for inclusion. The total sample size from the identified studies was 250 patients with ultra-central lung lesions and all studies were retrospective in design. Six out of the 10 studies included a majority (>50%) of primary lung cancers. Radiotherapy dose and fractionation ranged from 30 to 60 Gy in 3 to 12 fractions, with biologically-effective doses (BED_{10}) ranging from 48 to 138 Gy_{10} (median 78-103 Gy_{10}). Median treatment-related grade ≥3 toxicity was 10% (range: 0-50%). Median treatment-related mortality was 5% (range: 0-22%), most commonly from pulmonary hemorrhage (55%). High-risk indicators for SABR-related mortality included gross endobronchial disease, maximum dose to the proximal bronchial tree (PBT) ≥180 Gy_3 (BED_3, corresponding to 45 Gy in 5 fractions or 55 Gy in 8 fractions), peri-SABR bevacizumab use, and antiplatelet/anticoagulant use. Median 1-year local control rate was 96% (range: 63-100%) and 2-year local control rate was 92% (range: 57-100%). **Conclusion:** SABR for ultra-central lung lesions appears feasible and local control levels are comparable to those found in SABR for central lung lesions. There is a potential for severe toxicity in delivering SABR to ultra-central lung lesions especially in patients receiving high doses to the PBT, patients with endobronchial disease, and patients receiving bevacizumab or anticoagulants around the time of SABR. Prospective studies are required to establish the optimal doses, volumes and normal tissue tolerances for SABR in this patient population.

P1.17-22 DO STATINS IMPROVE OUTCOMES AFTER RADICAL RADIOTHERAPY FOR LUNG CANCER? AN IN-DEPTH ANALYSIS OF OVER 1100 PATIENTS

F. Sun[1], L. Murray[1], J. Lilley[1], K. Banfill[2], B. Wheller[1], A. Mcwilliam[2], A. Abravan[2], M. Van Herk[2], C. Faivre-Finn[3], K. Franks[1]

[1]*Leeds Cancer Centre, Leeds/United Kingdom,* [2]*Univerisity of Manchester, Manchester/United Kingdom,* [3]*The Christie-Univeristy of Manchester, Manchester/United Kingdom*

Background: Statins exhibit anti-cancer activity *in vitro* in addition to cardiovascular protection effects. Trials using statins in lung cancer have shown mixed results. This study investigates statins' impact on patients treated with curative radiotherapy for lung cancer. **Method:** All patients who received radical radiotherapy for lung cancer from 01/01/2010-31/12/2016 at a large cancer centre were included. Individual patient information, including drug history at diagnosis, has been retrieved from hospital electronic database. Pre-existing cardiac conditions, Charlson Co-mobidity index and Qrisk[3] scores were calculated. **Result:** 1181 patients were identified. Patient and treatment demographics are summarised in table 1. Patients in the statin group were older, had more co-morbidities and higher Qrisk[3] scores. For the whole patient population, being on stains at the time of diagnosis was not significantly associated with better Overall Survival (OS) or Progression Free Survival (PFS). A 'High Risk Cohort'(HRC) was identified, which consists of patients with a history of cardiac disease or Qrisk[3] score >40. In HRC, statins significantly improved OS and PFS (p=0.016 and p=0.031 respectively), Graph 1. Table 1

		Total N = 1181	Patients NOT on Statins N = 652	Patients ON statins N = 529
Sex	Male	603	298	305
	Female	578	354	224

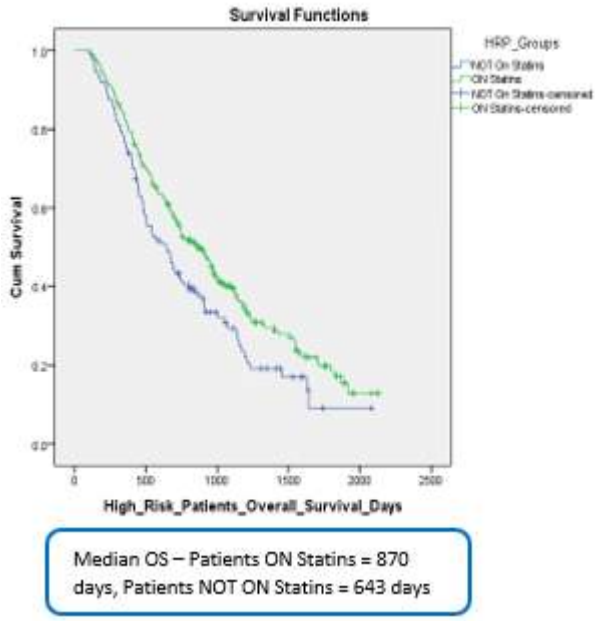
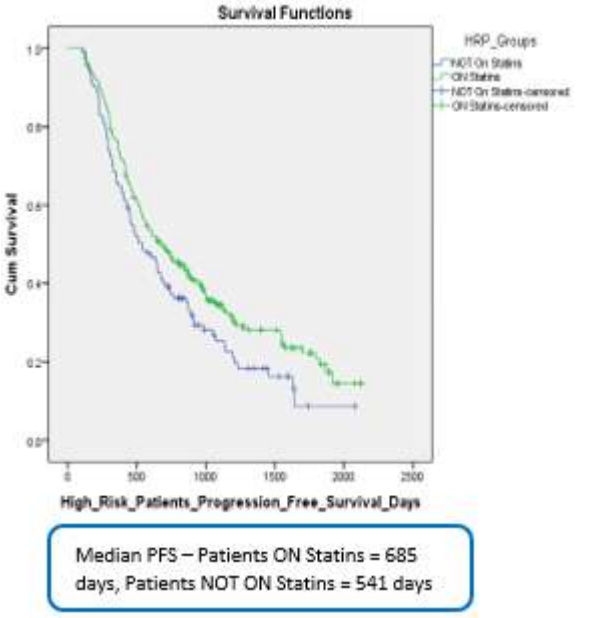
	Radical RT	278	112	166
	Consolidation RT after chemo for stage 4	31	10	21

POSTERS

Graph 1





Conclusion: In this retrospective analysis, patients who were on statins in the HRC had better survival outcomes, despite being older and have more comobidities. Mechanism of action of statins in lung cancer remains unclear and may be different in the post radiotherapy setting. Prospective studies would be useful to evaluate statins in this setting.

P1.17-23 OUTCOME AFTER SURGICAL RESECTION FOR CLINICAL STAGE I NON-SMALL CELL LUNG CANCER ASSOCIATED WITH INTERSTITIAL LUNG DISEASE

T. Koizumi, T. Hirono, T. Watanabe

National Hospital Organization Nishiniigata Chuo Hospital, Niigata/Japan

Background: It has been reported that interstitial lung disease is associated with an increased risk of lung cancer. Several studies have reported surgical results for lung cancer with interstitial lung disease showed poor prognosis. To improve the outcome of surgical treatment for non-small lung cancer with interstitial lung disease, we need to examine the oncological characteristics. **Method:** All of the patients who underwent surgical treatment for clinical stage I non-small cell lung cancer with interstitial lung disease at our institution from January 2004 to December 2016 were reviewed. We retrospectively analyzed the following data; surgical procedure (lobectomy or sublobar resection), clinical and pathological stage, pathological findings, outcomes. **Result:** The 54 patients with interstitial lung disease comprised 52 men and 2 women, with a median age of 73 years (range 55-84 years). 22 patients had UIP and 32 patients had non-UIP. Of the 54 patients, 43 patients had clinical stage IA and 11 had clinical stage IB. The surgical procedures were lobectomy in 25, segmentectomy in 3, wedge resection in 25 and exploratory thoracotomy in 1. Histologically, 30 squamous cell carcinomas, 20 adenocarcinomas, 4 others were noted. Pathological stage (IA/IB/IIA/IIB/IIIA/IV) was as follow; 17/23/2/1/8/3. Pathological upstaging was confirmed in 33 out of 54 after surgical resection. The reasons for pathological upstaging were pleural invasion in 18 patients, nodal metastasis in 9, malignant pleurisy in 3, tumor size in 2 and pulmonary metastasis in 1. Pleural invasion and malignant pleurisy were observed in 21 out of 33 patients. One patient died from acute exacerbation. The median follow-up period was 21.6 months (1.0-103.6 months). The 3-years overall survival rate was 48.8%. Death occurred in 30 (25 from lung cancer, 3 from respiratory failure, 2 from pneumonia). **Conclusion:** Non-small cell lung cancer with interstitial lung disease has a high rate of pleural invasion and pathological upstaging revealing after surgical resection. Regarding the selection of surgical procedure, we should take into consideration the possibility of pleural invasion.

Keywords: Non-Small Cell Lung Cancer, interstitial lung disease, clinical stage I

P1.17-24 TREATMENT OF ULTRACENTRAL LUNG TUMORS WITH HYPOFRACTIONATED RADIATION THERAPY

T. Nsouli, R. Alden, W. Ennis, M. Mix, J. Bogart

SUNY Upstate Medical University, Syracuse/United States of America

Background: The optimal dose schedule for ultracentral (UC) lung lesions remains poorly defined. The aim of this study is to report the efficacy and toxicity of hypofractionated radiation therapy (HFRT) in a single institution experience. **Method:** An IRB approved retrospective review of patients with UC lung lesions treated with HFRT between 2008 and 2015 was performed. UC was defined as gross tumor volume (GTV) abutting the trachea, proximal bronchial tree (PBT), or esophagus. Both primary lung lesions and lung metastases were included. 4D simulation was typically employed, and respiratory management was utilized if appropriate (e.g. tumor motion exceeding 1 cm). Patient characteristics, treatment planning and delivery parameters, patient outcomes, and toxicity were collected. Toxicity was graded using CTCAE 4.03 and statistical analyses were performed using SPSS (Version 25). **Result:** A total of 37 patients, 32 with primary lung tumors and 5 with metastases, were included. Primary lung tumors were stage T1, T2, T3, and T4, in 48%, 42%, 6% and 6% of patients, respectively. 39% had N1 disease and 16% were M1. Median age was 70 (range: 49-89) and 73% were male. The predominant histologies were adenocarcinoma (41%) and squamous cell carcinoma (43%). UC status was due to abutment of PBT in 78% of patients. 32% were treated with three dimensional conformal radiation therapy, and 68% with intensity modulated radiation therapy. 78% (29) of patients were treated in 20 fractions to 60 or 70 Gy, of which, 17 received concurrent weekly carboplatin and paclitaxel. A minority received regimens approximating stereotactic body radiotherapy (SBRT) dosing (60 Gy in 8 fractions in 10% and 50 Gy in 10 fractions in 6%). With a median follow up of 17 months, the crude local failure rate was 8%. Median overall survival was 33 months (range: 0-73 months). There were three grade 3 toxicities consisting of tracheal stenosis, hypoxia, and dysphagia, and no late grade 4/5 events. Notably, two patients receiving 60 and 70 Gy in 20 fractions died during the final week of treatment, after 51 and 60 Gy, respectively. One from sudden massive hemoptysis (hemoptysis to some extent dated back prior to HFRT), and one from complications of lung cancer, with additional details unclear. The GTV abutted/involved multiple critical structures in both cases, and attributability to treatment is uncertain. **Conclusion:** Local tumor control appears promising following treatment with HFRT for UC lung lesions. As with any regimen utilized in this anatomic location, caution is warranted. Additional prospective studies are required to further elucidate optimal dose and fractionation, and how it might compare with the therapeutic index of SBRT.

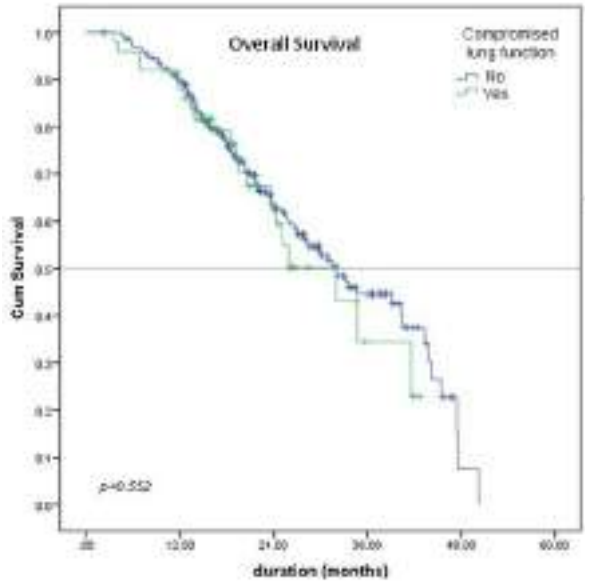
Keywords: ultracentral, hypofractionated radiation therapy

P1.17-25 OUTCOMES OF PRIMARY LUNG CANCER SBRT IN PATIENTS WITH COMPROMISED LUNG FUNCTION

E. Kirby, A. Haridass, A. Pope, M. Mckay, H. Wong

Clatterbridge Cancer Center NHS FT, wirral/United Kingdom

Background: Stereotactic Ablative Body Radiotherapy (SABR) is a standard treatment option for early lung cancer, especially in patients who are not medically fit to undergo surgery. The tolerability and efficacy of this treatment has lead to more comorbid patients being referred for SABR treatment. The objective of this study was to assess outcomes of SABR lung patients treated over a 4 year time frame, with a focus on patients with pre-existing lung fibrosis and/or lung function compromise. This patient group is known to have a poorer survival outcome with conventional radiotherapy due to worsening of their pre existing lung condition.This study was aimed at generating real world data of SABR outomes in this population. **Method:** Data about staging, pathology, lung function, treatment response and follow up in primary early stage lung cancer patients treated with SABR at a tertiary cancer center over a 4 year time frame was gathered retrospectively and analysed for outcomes in survival differences between patients with compromised and non compromised lung function. For the purpose of this abstract compromised lung function was defined as clinical/radiological diagnosis of pulmonary fibrosis and /or a transfer factor for carbon monoxide (TLCO) < 40% predicted. **Result:** The records of 274 patients with a median age of 78 years were analysed. 50(18.2%) patients were found to have compromised lung function as defined. 53% had MRC dypsnoea scores of ≥3 and 75% were current or ex smokers. 80% of the patients had moderate to severe comorbidity. Median overall survival estimate by Kaplan Meir method for patients with compromised lung function undergoing SBRT was 31.9 months(95% CI 22.3 - 41.5) was not significantly different from patients without compromised lung function 32.0 months (95% CI 27.1- 37.0) p=0.552.



Compromised lung function	Median Overall Survival (months)			
	Estimate	Std. Error	95% Confidence Interval	
			Lower Bound	Upper Bound
No	32.033	2.515	27.104	36.963
Yes	31.933	4.892	22.346	41.521
Overall	31.933	2.345	27.336	36.530

Conclusion: SBRT for primary lung cancer appears to be as safe in patients with compromised lung function as those without.

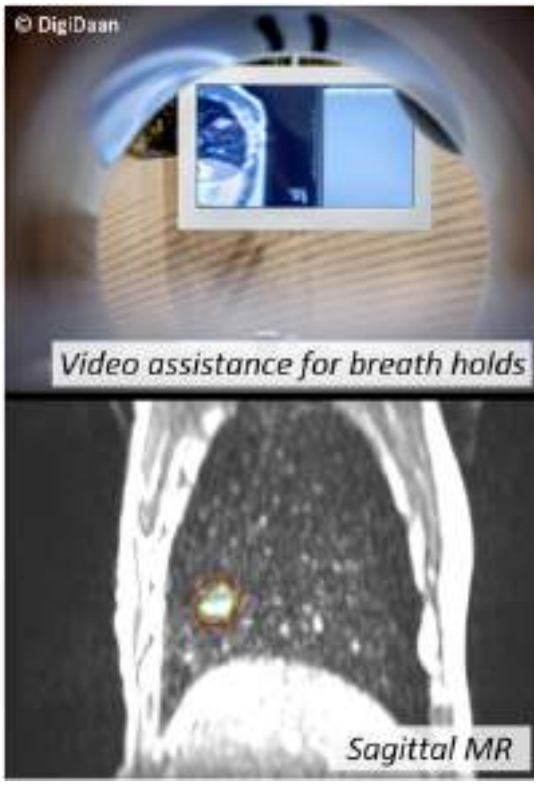
Keyword: SBRT, lung fibrosis, NSCLC

P1.17-26 DELIVERY OF STEREOTACTIC MR-GUIDED ADAPTIVE RADIATION THERAPY FOR PERIPHERAL LUNG TUMORS

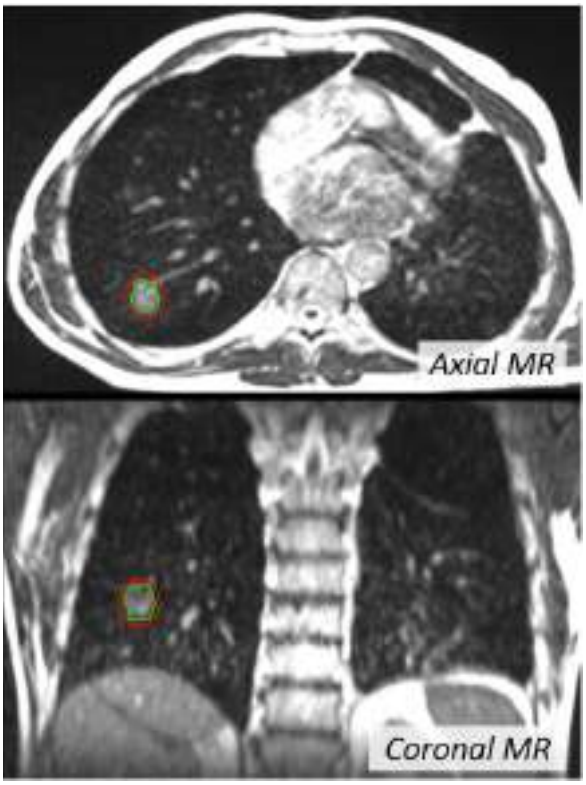
T. Finazzi, M. Palacios, C. Haasbeek, M. Admiraal, F. Spoelstra, A. Bruynzeel, B. Slotman, F. Lagerwaard, S. Senan

Amsterdam University Medical Centers, Location VUmc, Amsterdam/ Netherlands

Background: Stereotactic MR-guided adaptive radiation therapy (SMART) allows delivery of stereotactic ablative radiotherapy (SABR) with high precision (van Sörnsen de Koste JR, 2018). For central lung tumors, SMART with on-table plan adaptation improves target coverage and avoids excessive normal organ doses (Finazzi T, 2019). The benefits of SMART for peripherally located lung tumors are unknown. **Method:** Between 2016-2019, 23 patients (25 peripheral lung tumors) underwent SMART delivered in 3-8 fractions on an MR-Cobalt-60 system or MR-Linac. Before each fraction, a 17-second breath-hold MR scan was acquired, followed by on-table plan adaptation based on the anatomy-of-the-day, using a planning target volume (PTV) margin of 3 or 5 mm. Breath-hold gated delivery was performed under continuous MR-guidance using an in-room monitor (Fig. 1). For 14 patients, a motion-encompassing internal target volume (ITV) was created from a free-breathing 4DCT scan. Benefits of on-table adaptation were studied by comparing 112 «predicted» plans, which are the baseline plans recalculated on the anatomy-of-the-day, with on-table reoptimized plans.



POSTERS



Result: The SMART procedure took a median of 62 minutes on the MR-Cobalt-60 system, and 48 minutes on MR-Linac. Average SMART-PTVs were 15.4 cc (range, [3.1-55.6]). In 14 patients with a 4DCT, SMART-PTVs measured only 53.7% (range, [31.9-75.0]) of PTVs generated from the corresponding 4DCT scans (ITV+5mm). Clinicians chose the reoptimized plan for 91% of fractions. Per fraction, on-table plan adaptation improved prescription dose coverage (V100%) of the PTV from a median of 92.2% in predicted plans, to 95.0% in reoptimized ones, thereby increasing the proportion of fractions delivering a BED_{10Gy} ≥100Gy to 95% of PTV from 90.2% to 100.0%. **Conclusion:** Using SMART for peripheral lung tumors resulted in smaller target volumes, and on-table plan adaptation ensured delivery of ablative doses to the PTV. Despite longer SABR delivery times, our findings suggest that SMART can be beneficial for some peripheral lung tumors.

Keywords: SABR, stereotactic radiotherapy, MR-guided radiotherapy

P1.17-27 STEREOTACTIC RADIOTHERAPY FOR PRIMARY LUNG TUMORS: THE INFLUENCE OF SIZE

I. Rodrigues, T. Figueiredo, J. Gagean, C. Ferreira, A. Laranja, T. Ramos, S. Conde, D. Moreira, L. Carvalho, J. Cardia

Instituto Português de Oncologia do Porto Francisco Gentil, Porto/Portugal

Background: Stereotactic radiotherapy (SBRT) is the main treatment modality for inoperable early-stage lung cancer. Tumor size is commonly associated with higher local and distant relapse rates, but recent studies demonstrate promising results also in larger tumors. **Method:** We retrospectively analysed all patients treated with SBRT for primary lung cancers in our department between 2012 and 2017 and evaluated the influence of size. Survival analysis was carried using the Kaplan-Meier method. **Result:** SBRT was performed in 218 patients (with 233 tumors) with primary lung tumors. Median follow-up was 22 months. Most were males (78.9%), with a median age of 73 (from 51-91). Median maximum diameter was 2.3cm (0.5 to 7.5cm) – 76.4% were T1(≤3cm) and 21.9% were T2(>3 and ≤5cm). A complete local response was observed in 19.3% lesions, a partial response in 22.3% and stable disease in 45.9%. Disease progression was observed locally in 11.5% patients, in the lung in 8.4%, in hilar/mediastinal nodes in 10.7% and a distal progression in 12.1%. In T1 and T2 tumors, overall survival (OS) at 18 months was 74.5%, disease-specific survival (DSS) was 88.8% and local progression-free survival (L-PFS) was 91.3%. At 18 months, a larger tumor size was significantly associated with lower L-PFS (T1-93.6 Vs T2-87.2%, p=0.03) and DSS (T1-91.6 Vs T2-80.8%, p=0.013), but had no impact in OS (p=0.342). There was no significant relationship between size and time of local relapse. **Conclusion:** Lower L-PFS and DSS rates were observed for tumors >3cm, with no impact in OS. Still, the results for T2 lesions are within literature-reported outcomes, with a favourable toxicity profile.

Keywords: SBRT, stereotactic radiotherapy, Early-stage lung cancer

P1.17-28 REFUSAL OF SURGERY FOR EARLY STAGE LUNG CANCER: RISK FACTORS AND SURVIVAL

J. Rapp, S. Tuminello, W. Lieberman-Cribbin, R. Flores, M. Van Gerwen

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: The standard of care for treatment of early stage non-small cell lung cancer (NSCLC) is surgical resection. However, suitable patients refuse surgery for various reasons. We characterize the clinical and sociodemographic predictors of those who refuse recommended surgery for early stage NSCLC cancers and explore the influence of surgical compliance on survival. **Method:** Primary Stage I and II NSCLC cases diagnosed between 2007 and 2014 were selected from the Surveillance, Epidemiology and End Results (SEER) database (n = 36,926). All cases were recommended surgery for treatment. Predictors of surgery refusal were examined using multivariate logistic regression. The likelihood of mortality after refusing surgery and any chemotherapy/radiation and refusing surgery but receiving alternative forms of treatment was performed using a cox proportional hazards model. Propensity-matched survival analysis was then performed between those who received surgery and those who refused surgery. SAS v9.4 was used for statistical analyses. **Result:** The majority of the sample was non-Hispanic White (79%), female (52%), married (57%) and Stage I (83%). Most were between 50-64 years old (31%) or 65-79 years old (55%) and had tumor sizes of 11-20 mm (32%), 21-40 mm (42%), or > 40 mm (20%); 909 cases (2.5%) refused surgical intervention. Of these, 634 (69.7%) cases underwent radiation therapy and 87 (9.6%) received chemotherapeutic treatment. At multivariable analysis, non-Hispanic blacks (OR_{adj} 2.14, 95% CI: 1.76-2.61), increasing age (65-79 years old: OR_{adj} 4.29, 95% CI: 2.02-9.11), increasing tumor size (21-40 mm: OR_{adj} 2.79, 95% CI: 1.73-4.50), and single marital status (OR_{adj} 2.14, 95% CI: 1.85-2.48) were associated with increased odds of surgical refusal. Stage II lung cancer was inversely associated (OR_{adj} 0.75, 95% CI: 0.62-0.92) with surgical refusal. Refusing surgery and having no chemotherapy/radiation (HR_{adj} 4.16, 95% CI: 3.48-4.96) as well as refusing surgery but undergoing alternative forms of treatment (HR_{adj} 2.90, 95% CI: 2.55-3.29) were associated with increased mortality compared to those who received recommended surgery. After propensity matching (n = 1790), refusing surgery was associated with increased likelihood of mortality (HR_{adj} 2.77, 95% CI: 2.22-3.46). **Conclusion:** Identifiable risk factors exist for refusing recommended surgery for Stage I/II NSCLC, and refusal is associated with an increased likelihood of mortality. Recognizing that certain subgroups are more likely to refuse surgery is vital when providing treatment choices and reducing disparities in survival for early stage lung cancer.

Keywords: mortality, Risk Factors, surgery refusal

P1.17-29 8-YEAR EXPERIENCE OF NAVIGATIONAL BRONCHOSCOPY FOR PREOPERATIVE LOCALIZATION OF SUBCENTIMETER LUNG NODULES IN A SMALL COMMUNITY HOSPITAL

C. Galvez-Padilla, P. Craft, K. Baran, S. Gallagher

Berkshire Health Systems, Pittsfield/United States of America

Background: With the advent of lung cancer screening, CT imaging has led to the identification of sub-centimeter nodules that are challenging to localize for both diagnosis and resection. The traditional approaches are problematic because biopsies often have poor diagnostic yield, resulting in repeat attempts at tissue collection, delay in time to treatment, and increased cost. Electromagnetic navigation bronchoscopy (ENB) is a newer technology that allows greater precision in preoperative localization of nodules to obtain tissue for diagnosis and fiducial marker placement. Our institution has adopted a practice that combines simultaneous ENB for nodule localization and video-assisted thoracoscopic surgery (VATS) for resection with single anesthetic administration and operating

room team. We aimed to evaluate changes in time to treatment, time to surgery, and length of stay. **Method:** Retrospective review of all patients who underwent nodule localization and VATS or robotic-assisted VATS (RATS) between (May 2011- March 2019). ENB localization was performed with transbronchial injection of ICG and/or placement of gold fiducial markers. **Result:** A total of 72 patients underwent VATS or RATS. During the first two years of the study period, ENB was performed with portable C-arm fluoroscopic guidance with diagnostic yield of 48%. Surgery was performed on average 29.7 days (4-190 days) after ENB (3 patients had non-diagnostic bronchoscopy and were followed with serial CT scans that resulted in >100 days until surgery). In August 2017 utilization of Cone Beam CT scan began during ENB, which resulted in reduction in time to surgery to average of 20.1 days (1-39 days). After persistent low diagnostic yield with bronchoscopy and demand for expedient diagnosis, in February 2018, ENB and surgical resection were performed simultaneously with single anesthetic administration and OR team. Furthermore, in December 2018 utilization of daVinci Xi robot began for RATS with ICG injection during ENB for intraoperative localization of nodules. The hospital length of stay (LOS) and time to treatment (from the initial identification of a lung nodule to surgery) for Super D bronchoscopy group (SDB) (n=36) is 5.7/63.8 days, SDB-with cone beam technology (n=8) is 4.5/62.8 days, respectively. Transition to simultaneous resection (n=28) resulted in 100% diagnostic yield, further decrease of both hospital LOS and time to treatment, to 3.6 days and 43.7 days, respectively. **Conclusion:** Our data demonstrates that intraoperative ENB lung lesion localization with simultaneous VATS/RATS resection results in decreased hospital length of stay, reduced time to treatment, and 100% diagnostic yield. Both metrics significantly impact patient satisfaction and healthcare costs.

Keywords: ENB, VATS, lung cancer screening

P1.17-30 SEX AND AGE-ASSOCIATED SURVIVAL FOLLOWING RESECTED EARLY STAGE NON-SMALL CELL LUNG CANCER

A. Gibson[1], A. D'Silva[1], M. Dean[1], R. Tudor[1], A. Elegbede[1], S. Otsuka[1], D. Bebb[1,2]

[1]*University of Calgary, Calgary/Canada,* [2]*Alberta Health Services, Calgary/Canada*

Background: Non-small cell lung cancer (NSCLC) is the most common malignant tumour, and a leading cause of mortality worldwide. Rising rates of NSCLC have been observed among females, but nonetheless females also are often observed to possess better prognosis across all stages of disease. We aimed to assess the impact of biological sex along with age at diagnosis on the outcome of NSCLC patients with resected early-stage disease. **Method:** A 15-year population-based retrospective analysis was conducted on *de novo* early stage (AJCC 7th edition, Stage I or II) patients between 1999-2014, whose primary tumor was surgically resected. Demographic, clinical characteristics, treatment modalities and outcome data were extracted from the institutional Glans-Look Lung Cancer Database, and univariate analysis, including Kaplan-Meier survival, alongside multivariate Cox regression was performed to compare outcomes by sex and determine prognostic factors associated with survival. **Result:** 872 early-stage resected NSCLC patients were identified. Median age at diagnosis 65.9 years (IQR: 59.1-72.6), 56% female, 76% 'ever' smokers, 68% Stage I, 91% oncologic resection (9% wedge resection). Median overall survival (mOS) for all early-stage resected cases was 93 months (95% CI: 81.9 – 105.4) with a 5-year survival rate of 62.5%. Females exhibited superior survival outcomes to males (105.4 months vs. 77.5 months, log-rank p=0.002), as did those < 75 years at diagnosis compared to those ≥ 75 years (103.9 vs. 76.2 months, log-rank p <0.001). Best and worst survival outcome was observed in females under age 75, and males over age 75, respectively (mOS 114.3 vs. 64.5 months; 5-year survival: 67.9% vs. 50.5%). No difference in rate of recurrence (overall) or rate of metastatic recurrence between males and females was identified (39% vs. 36%, p=0.214; 19% vs. 16%, p=0.591). After controlling for confounding variables, a reduced risk of mortality was found for females (HR: 0.8, p=0.016), age under 75 years at diagnosis (HR: 0.6, p < 0.001) and stage I presentation (HR: 0.6, p< 0.001). **Conclusion:** Females experience significantly longer mOS, in particularly females under the age of 75 years at diagnosis. After adjusting for confounding factors, we found significantly reduced mortality risk for females aged under 75 years at diagnosis, and Stage I disease. Despite possessing the poorest outcomes among this cohort, males ≥ 75 years still possessed a 5-year survival rate of 50%, suggesting that surgical resection is a highly effective treatment option for suitable NSCLC patients, regardless of age.

Keywords: resected early stage NSCLC, age-based differences in survival, sex-based differences in survival

P1.17-31 VATS SEGMENTECTOMIES ARE AT LEAST AS SAFE AS VATS LOBECTOMIES

T. Marjanski, R. Dziedzic, M. Ostrowski, P. Kanyion, A. Mosiewicz, W. Rzyman

Medical University of Gdansk, Gdańsk/Poland

Background: Video-assisted thoracic surgery (VATS) segmentectomy is a feasible and effective treatment of not only benign lung tumors but also non-small cell lung cancer (NSCLC). Expanding the indications for surgical treatment of early NSCLC in high-risk patients may result in an increased number of complications in the postoperative period. **Method:** Between January 2018 and December 2018 22 VATS segmentectomies were performed in a single center. The postoperative period was recorded and these data were compared to postoperative results of 31 patients who underwent VATS wedge excisions in the relevant period and 438 VATS lobectomies during the VATS program in the department. In order to assess the influence of the type of resection on the number of postoperative complications, multivariable analysis was performed. The selection biases were reduced by the use of propensity-score matched analysis (PSMA; using the nearest neighbor matching method by age, gender, Charlson Comorbidity Index [CCI] and 6-minute walking distance). **Result:** In the multivariable analysis, CCI was the only independent risk factor of increased complications rate (HR 1.321 95%CI 1.009-1.730 p=0.042). Type of resection, gender, and 6-minute walking distance did not influence the risk of complications. The rate of complications in patients who underwent VATS wedge excision was 12.9%, VATS segmentectomies 27.2% and VATS lobectomies 51.5% (OR 2.846 95%CI 1.021-8.298 p=0.026 segmentectomies vs. lobectomies). However, in PSMA analysis, there was a trend towards lower complications rate in patients who underwent VATS segmentectomy comparing to VATS lobectomies (30% vs. 60% OR 0.286 95%CI 0.061-1.263 p=0.057). Postoperative hospital stay did not differ between the study groups 4 vs. 5 days (p=0.170). **Conclusion:** VATS segmentectomy is characterized by similar complications rate and postoperative hospital stay if compared with VATS lobectomy.

Keywords: VATS, lobectomy, segmentectomy

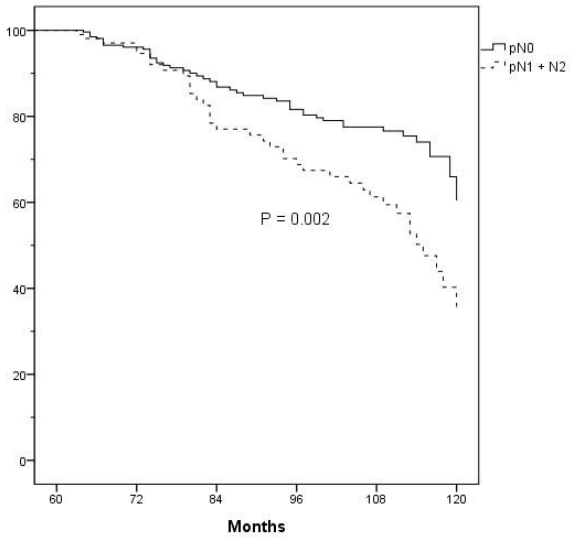
P1.17-32 THE 8TH EDITIONS OF THE AJCC STAGING SYSTEM IN TERMS OF PREDICTING RECURRENCE AND SURVIVAL IN RESECTED NSCLC LONG-TERM SURVIVORS

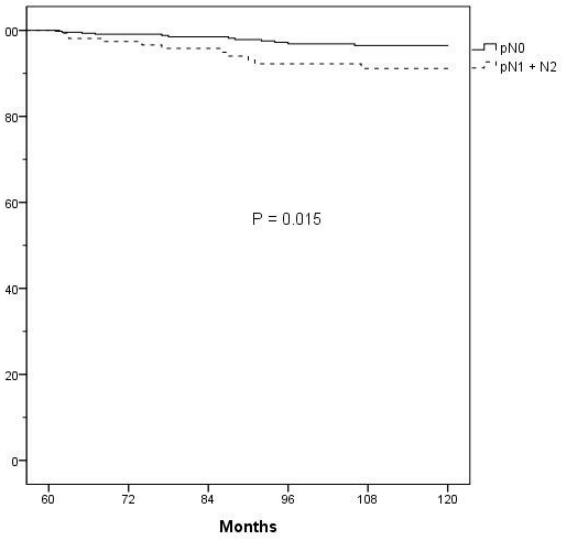
S.H. Song[1], S. Lee[2], J.W. Suh[3], S.Y. Park[3], C.Y. Lee[3], D.J. Kim[3], H.C. Paik[3], K.Y. Chung[3], J.G. Lee[3]

[1]*National Health Insurance Service Ilsan Hospital, Goyang/Korea, Republic of,* [2]*St. Mary's Hospital of the Catholic University, Daejeon/Korea, Republic of,* [3]*College of Medicine, Yonsei University, Seoul/Korea, Republic of*

Background: Lung cancer has a poor prognosis, and the number of long-term survivors (LTSs) is small compared with that of other cancers. There are few studies focusing on late recurrence in long-term survivors with lung cancer. The purpose of this study was to analyze the risk factors for survival and late recurrence in long-term survivors after a disease-free period of 5 years. **Method:** A retrospective analysis of patients with a disease-free survival of at least 5 years after surgical resection for non-small cell lung cancer between January 1998 and December 2009 was conducted. Patients who received neo-adjuvant therapy, had incomplete resection, were of advanced stages according to the AJCC (American Joint Committee on Cancer) 7th edition (stage IIIb and IV), or missing data were excluded. **Result:** A total of 648 (41.7 %) of 1,555 patients were enrolled. The median age was 62.6 (range, 21.3–82.2) years. Pathologic N0 (485 patients, 74.8 %) and stage I (394 patients, 60.8 % in 7th and 363 patients, 56.0 % in 8th edition) were the dominant stage. According to the 7th edition, node-positive (N1+N2) status was an independent risk factor only for disease-free survival (HR, hazard ratio, 2.575; *p*=0.028; CI, confidence interval, 1.107-5.990) on multivariable analysis. By contrast, node-positive was an

independent risk factor for both overall survival (HR, hazard ratio, 1.608; *p*=0.031; CI, confidence interval, 1.043-2.477), and disease-free survival (HR, 2.662; *p*=0.019; CI, 1.175-6.034) in the 8th edition.





Conclusion: Compared to the 7th edition, nodal stage of the 8th edition seems more appropriate as a risk factor for both overall survival and disease-free survival 5 years after surgical treatment in patients with completely resected non-small cell lung cancer.

Keywords: Non-Small Cell Lung Cancer, 5-year disease-free survival, AJCC 8th edition

P1.17-33 SURGICAL TREATMENT STRATEGY FOR LUNG CANCER PATIENTS WITH INTERSTITIAL PNEUMONIA

Jitsuo Usuda

Nippon Medical School Hospital, Tokyo/Japan

Background: In conducting surgical treatment for lung cancer patients with interstitial pneumonia (IP), it is important to conduct oncological radical surgery in consideration of the risk of acute exacerbation. Sato et al. reported risk factors and scores of acute exacerbations of IP in lung cancer (General Thorac Cardiovasc Surg 63; 164-172, 2015), and are being used in daily practice. **Method:** We retrospectively analyzed data from patients with non-small cell lung cancer with a clinical diagnosis of IP who underwent pulmonary resection between 2013 and 2018 at our hospital. **Result:** We analyzed 79 cases, 11.2% of the 701 lung cancer cases in the subject period. 70 men, 9 women, average age 72 years (53-85 years old), average of smoking index of 74 cases excluding 5 cases of never smokers averages 1400 (400-2950). Histological types were adenocarcinoma 29, squamous cell carcinoma 41, large cell carcinoma 4, and 6 others. Surgery was performed with 60 lobectomies, 2 segementectomies, 17 wide wedge resections. The average of acute exacerbation risk scores was 12.3 (5-22), and the incidence rate of acute exacerbations was predicted to be 25% or more in 13 cases. In 13 cases, 6 lobectomy resections, 1 segmentectomy was performed, WWR were 6 cases. There was no case of acute exacerbation in 13 cases, and 3 cases of pirfenidone (lobectomy 1, segmentectomy 1, partial resection 1), nintedanib 1 case (lobectomy), predonine 4 cases (lobectomy 1, partial resections 3). Acute exacerbation onset occurred in 2 cases (2.8%), both risk scores were 11. **Conclusion:** Although there was no correlation between the onset of acute exacerbations and the risk score, it was suggested that oral administration drugs such as pirfenidone was effective.

Keywords: Interstitial pneumonia (IP), acute exacerbation, Lung cancer

P1.17-34 PROGNOSTIC SIGNIFICANCE OF PREOPERATIVE CT-DETERMINED SARCOPENIA AND RADIODENSITY IN RESECTED NON-SMALL CELL LUNG CANCER

E.Y. Kim, K.W. Kim, Y.S. Kim, H.K. Ahn, S.M. Kang

Gachon University Gil Medical Center, Incheon/Korea, Republic of

Background: Sarcopenia, reduced skeletal muscle mass, is associated with poor prognosis in advanced non-small cell lung cancer (NSCLC) patients. The purpose of this study was to evaluate predictive value of CT–determined skeletal muscle area on prognosis after curative resection of NSCLC. **Method:** For a total 272 NSCLC patients (male=164, mean age=63±10 years) that underwent surgery between 2011 and 2016, skeletal muscle (CT Hounsfield unit: −29 to 150 HU) at the level of the third lumbar vertebra (L3) was assessed using preoperative CT images. Sarcopenia was defined as L3 muscle index of <55 cm^2/m^2 for men and of <39 cm^2/m^2 for women. Moreover, skeletal muscle was subsequently classified as abnormal muscle (-29 to <30HU) and normal muscle (30 to 150 HU) by radiodensity. Data on clinical characteristics, disease-free survival (DFS), and overall survival (OS) were retrospectively collected. **Result:** The prevalence of sarcopenia was 22.4% for all study subjects, 32.9% for men, and 6.5% for women. Using a maximal chi-squared method determined optimal cut-off to determine unhealthy muscle (proportion of abnormal muscle >24.5%), the prevalence of patient with unhealthy muscle was 84.2% (78.7% for male and 92.6% for female). There was no significant difference in the prevalence of unhealthy muscle between sarcopenia and non-sarcopenia patients (86.9% vs. 83.4%, p = 0.690). No significant difference was observed between the 3-year DFS rate (77.0% vs 67.0%, *p* = 0.142) or 3-year OS rate (84.8% vs 87.9%, *p* = 0.576) between patients with and without sarcopenia. However, patients with unhealthy muscle tends to have shorter 3-year DFS rate (67.2% vs 79.4%, *p* = 0.094) and 3-year OS rate (86.1% vs 92.6%, *p* = 0.176). In the multivariable analysis, unhealthy muscle was one of independent indicator to predict a 3-year DFS rate (HR, 2.072, p=0.044), along with pathologic T stage (HR, 3.348, p<0.001), pathologic N stage (HR, 3.401, p<0.001), and R1 resection (HR, 3.804, p=0.033). **Conclusion:** Radiodensity based muscle quantification is associated with shorter DFS in resected lung cancer. Further research is warranted to establish whether muscle measures should be integrated into routine practice to improve prognostic accuracy.

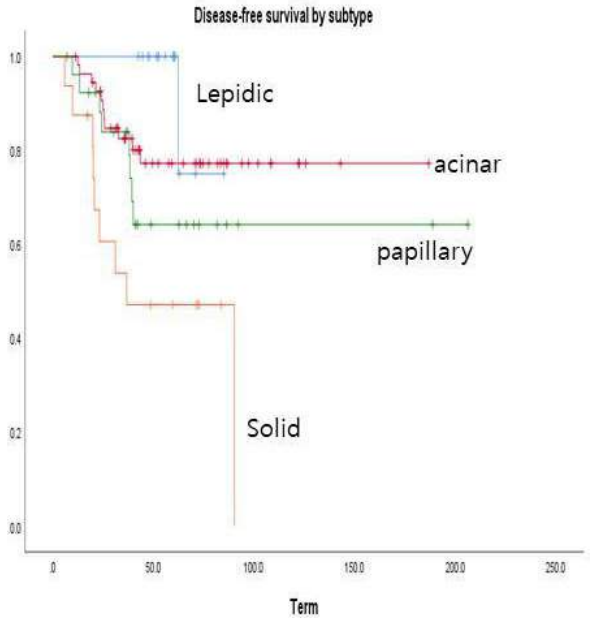
P1.17-35 SOLID PREDOMINANT SUBTYPE IS AN INDEPENDENT RISK FACTOR FOR RECURRENCE IN PATIENTS WITH PATHOLOGIC STAGE I ADENOCARCINOMA

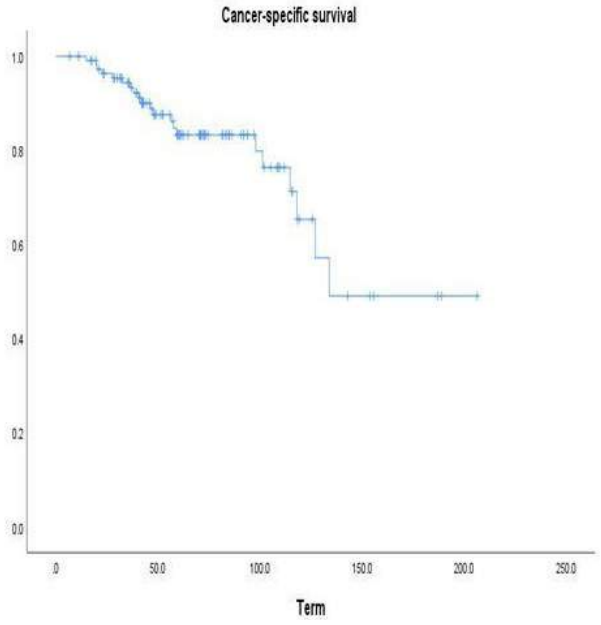
K. Park

DCMC, Daegu/Korea, Republic of

Background: Lobectomy and mediastinal lymph node dissection(MLND) is the standard treatment in patient with stage I non-small cell lung cancer (NSCLC). We expect the high 5-year survival and freedom from recurrence rate in early staged cancer through curative intent. But even in stage I NSCLC, recurrence may occur, which does not fit the expected therapeutic outcome. Therefore, we investigated the risk factors of recurrence and survival outcome in stage I adenocarcinoma. **Method:** We retrospectively

reviewed a total of 114 patients diagnosed with pathologic stage I adenocarcinoma who underwent lobectomy and MLND from June 2001 to July 2017. The risk factors were statistically analyzed using Cox proportional hazard model and the Kaplan meier method for survival. **Result:** The median follow-up period was 59.5months (range 7.0-206.3). Recurrence occurred in 29 of patients (25.4%). Median survival time was 133.9 months. The 5-year cancer specific survival and freedom from recurrence rate were 83.3% and 73.8%, respectively. In univariate analysis, the significant variables for recurrence were ever smoker at the time of surgery, pathologic tumor size, SUVmax in PET-CT, central located tumor, solid predominant histologic subtype. In multivariate analysis, solid predominant subtype(p=0.035, HR=9.70, CI 1.18-79.88) was the independent risk factor for higher probability of recurrence. **Conclusion:** In pathologic stage I NSCLC, the risk factor with higher probability of recurrence was solid pathological subtype. This may be a useful parameter in considering whether adjuvant therapy is needed to reduce recurrence in pathologic stage I adenocarcinoma.





Keywords: adenocarcinoma, solid, Subtype

P1.17-36 ANALYSES OF SEGMENTAL AND INTRAPULMONARY LYMPH NODE METASTASES OF SMALL-SIZED PERIPHERAL SOLID PREDOMINANT NON-SMALL CELL LUNG CANCER (NSCLC)

H. Konno, M. Isaka, T. Mizuno, H. Kojima, Y. Ohde

Shizuoka Cancer Center, Nagaizumi/Japan

Background: Currently, randomized clinical trials to evaluate segmentectomy compared with lobectomy for peripheral small size non-small cell lung cancer (NSCLC) are ongoing, and the results are expected. The extent of lymph node dissection in intentional segmentectomy has not been clarified. The purpose of this study was to retrospectively investigate the pattern of segmental and intrapulmonary metastasis in intentional segmentectomy. **Method:** We reviewed the records of patients who underwent lobectomies and systematic lymph node dissections for small(≦2cm) peripheral solid-predominant and clinical/surgical N0 NSCLC from 2002 to 2018. Among them, a total of 239 patients whose primary nodules was located in the outer third peripheral lung field and consolidation-tumor ratio (CTR) >0.5 on thin-section computed tomography (TSCT); who could be candidates for intentional segmentectomy were enrolled in this study. We analyzed the clinical and radiological factors, which may predict nodal metastases, and the distribution patterns of lymph node metastases. **Result:** Of all patients, 33 (14%) had lymph node metastases (pN1:15, pN2:18). Segmental lymph node metastases (# 13) were observed in 4 cases(1.7%), and there were no metastasis of #13 in adjacent segment. #12 lymph node metastases were in 18 cases (7.5%), and # 11 lymph node metastases in 12 cases (5.0%), respectively. Skip N2 metastases were in 7 cases (2.9%), and all were in the range of regional lymphatic resection. **Conclusion:** Solid-predominant NSCLC may have 14% lymph node metastasisa even with clinical and surgical N0. It may not be necessary to examined outside tumor-bearing segmental lymph nodes. However, there should be adequate lymph node sampling and intraoperative frozen section. In particular, intraoperative sampling of # 11 and # 12 is useful for selection of lobectomy convert cases.

Keywords: Lung cancer, intentional segmentectomy, Lymph node metastasis

P1.17-37 MINIMALLY INVASIVE OPEN SURGERY (MIOS) FOR CLINICAL STAGE I LUNG CANCER: PERIOPERATIVE OUTCOMES IN RECENT 5 YEARS

K. Nakagawa, M. Yotsukura, Y. Yoshida, S. Watanabe

National Cancer Center Hospital, Tokyo/Japan

Background: Many thoracic surgeons have tried to make lung cancer surgery less invasive. Although several minimally invasive procedures for lung cancer surgery have been proposed, it has been controversial which procedure is the most optimal. Since around 2010, minimally invasive open surgery (MIOS) has been adopted for lung cancer surgery at our institute. MIOS was performed with direct vision and thoracoscopic vision through a 2-cm port and a muscle-sparing mini-thoracotomy (incision, 6-8 cm in the fourth or fifth intercostal space at the anterior or posterior axillary line). The objective of this study was to evaluate MIOS in terms of perioperative outcomes in recent 5 years. **Method:** Between 2013 and 2017, 2404 patients underwent pulmonary resection for lung cancer at National Cancer Center Hospital, Tokyo, Japan. Among them, 1930 patients with clinical stage I lung cancer were included in this study. We investigated several perioperative factors according to the type of pulmonary resection: lobectomy, segmentectomy and wedge resection. **Result:** The patients consisted of 993 men (51.5%) and 937 women (48.5%) with a median age of 69 years (range: 32-90 years). Lobectomy was performed in 1288 patients (66.7%), segmentectomy in 397 (20.6%), and wide wedge resection in 245 (12.7%). Median blood loss was 32 ml (range: 1-1489 ml) for lobectomy, 20 ml (range: 1-435 ml) for segmentectomy, and 4 ml (range: 1-177 ml) for wedge resection. Median operative time was 122 min (range: 45-293 min) for lobectomy, 115 min (range: 69-211 min) for segmentectomy, and 66 min (range: 29-177 min) for wedge resection. Median length of post-operative hospital stay was 4 days (range: 1-57 days) for lobectomy, 4 days (range: 2-20 days) for segmentectomy, and 3 days (range: 2-24 days) for wedge resection. There were no operative deaths. The morbidity rate was 11.8% for lobectomy, 7.3% for segmentectomy, and 4.1% for wedge resection. The 30-day mortality rate was 0.16% for lobectomy, 0.25% for segmentectomy, and 0% for wedge

resection. **Conclusion:** MIOS for clinical stage I lung cancer is a technically safe and feasible procedure with a low complication rate and a shorter hospital stay. The oncological outcomes with a longer follow-up need to be investigated.

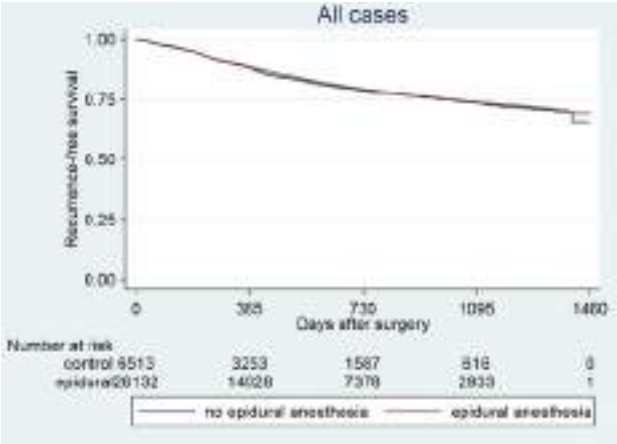
Keywords: minimally invasive surgery, clinical stage I, Lung cancer

P1.17-38 DOES USE OF EPIDURAL ANESTHESIA AFFECTS SURVIVAL OF RESECTABLE NSCLC? ANALYSIS FROM A JAPANESE NATIONWIDE DATABASE

K. Fukumoto, T. Jo, H. Yasunaga, J. Nakajima

The University of Tokyo Graduate School of Medicine, Tokyo/Japan

Background: Several studies have suggested that epidural anesthesia may increase postoperative survival by reducing the cancer recurrence rate. The rationale for this phenomenon is that epidural anesthesia decreases the surgical stress response by suppressing circulating glucocorticoids, catecholamines and inflammatory mediators, and thus reduces transient immunosuppression during cancer surgery. Moreover, epidural anesthesia can reduce the use of opioids, which are generally thought to be immunosuppressive (suppresion of NK cell cytotoxicity, promotion of VEGF-dependent angiogenesis, and activation of EGF pathway). The topic is still controversial, and there are no previous studies related to lung cancer and thoracic epidural anesthesia. Our study aim is to reveal the probable impact of epidural anesthesia during radical lung cancer surgery on long-term postoperative survival and cancer recurrence. **Method:** We used Japanese Diagnosis Procedure Combination database, the national databese which covers 55% of all acute-care hospitalizations in Japan. We retrospectively reviewed the medical records of 34,694 patients who received lobectomy or pneumonectomy for curative intent for non-small cell lung cancer, between July 2010 and March 2016. Propensity score matching and stabilized inverse probability of treatment weighting (IPTW) was used to adjust the patient background. Recurrence-free survival was assessed using Kaplan-Meier curves. **Result:** Among the patients, 27,810 received epidural anesthesia during lung cancer surgery and 6,884 underwent the surgery without epidural anesthesia. Video assisted thoracoscopic surgery (VATS) was performed in about 23,682 (81.2%) in epidural anesthesia patients, and 6,180 (85.5%) in non-epidural anesthesia patients (<0.001). According to the Kaplan-Meier curve after baseline adjusting by using propensity score matching and inverse weighting, there was no stastically significant difference in recurrence-free survival between the groups (p=0.89). Stratification according to the cancer stage revealed no significant difference in recurrence-free survival depending on the type of anesthesia administered at each stage.



Conclusion: Oncological outcome after lung cancer surgery was not affected by the use of epidural anesthesia.

Keywords: surgical outcome, national database, epidural anesthesia

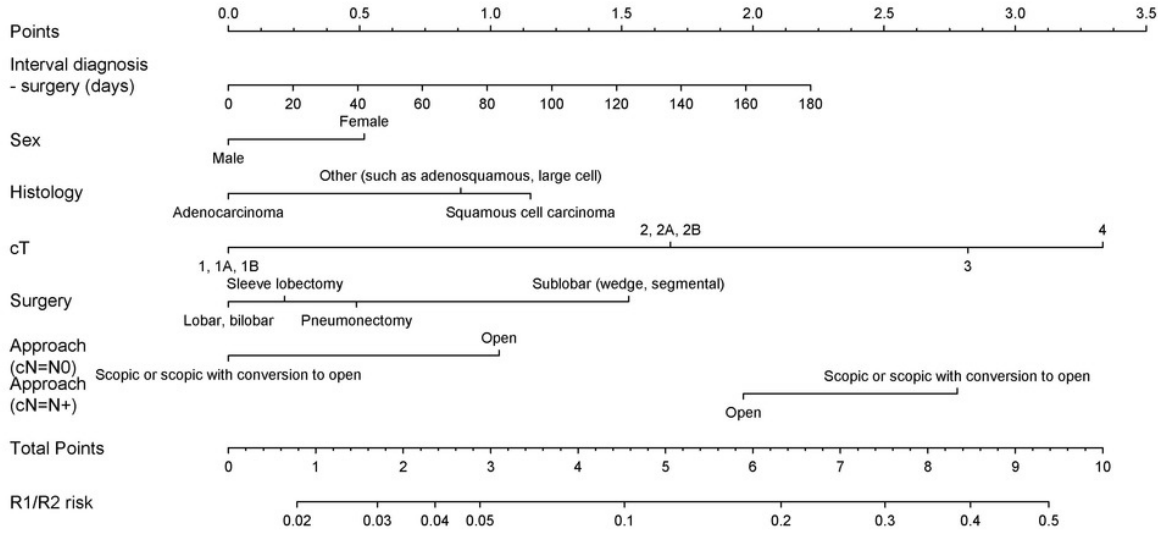
P1.17-39 PREOPERATIVE PREDICTION OF INCOMPLETE RESECTION IN NON-SMALL CELL LUNG CANCER: AN EXTERNALLY VALIDATED CLINICAL NOMOGRAM

M. Rasing[1], M. Peters[1], A. Moreno[2], E. Hofman[3], J. Herder[4], P. Welvaart[4], F. Schramel[3], J. Lodeweges[1], S. Lin[2], J. Verhoeff[1], P. Van Rossum[1]

[1]*University Medical Center Utrecht, Utrecht/Netherlands,* [2]*MD Anderson, Houston/United States of America,* [3]*St. Antonius Hospital, Nieuwegein/ Netherlands,* [4]*Meander Medical Center, Amersfoort/Netherlands*

Background: Patients who are surgically treated for stage I-III non-small cell lung cancer have a worse prognosis after incomplete (R1-R2) resection. Predictive factors for completeness of resection have not satisfactorily been established. Our study aimed to develop, and internally and externally validate a prediction model to estimate the risk of incomplete resection, based on preoperative patient-, tumor-, and treatment-related factors. **Method:** From a Dutch national database (NKR) all consecutive NSCLC patients diagnosed from 2011 to 2014 who had surgery without neoadjuvant therapy were selected. Fifteen possible predictors were analyzed. Multivariable logistic regression analysis with stepwise backward elimination was used to create a prediction model. Discriminatory ability and calibration of the model was determined after internal validation. External validation was applied in an American dataset from the NCDB, whereupon the model was adjusted. The prediction model was presented as a nomogram. **Result:** In the development set of 7,124 patients an incomplete resection was reached in 496 patients (7.0%). Remaining predictors were gender, histology, cT-stage, cN-stage, extent of surgical resection, time interval from diagnosis to surgery, open versus thoracoscopic procedure, and the interaction between procedure and cN-stage. After internal validation, the corrected c-statistic of the resulting nomogram was 0.73. Application of the nomogram to the external dataset of 85,235 patients with R1-R2 resections in 2,485 patients (2.9%) resulted in a c-statistic of 0.70. Calibration revealed good overall fit of the nomogram in both cohorts.

Image 1. Nomogram of prediction model for risk of incomplete resection, for development set. The numbers listed at the upper line of the figure indicate the points to be assigned per variable. By counting up all points, the predicted risk of incomplete resection can be read out by drawing a straight vertical line from the 'Total points' line to the bottom line of the figure.



Conclusion: An internationally validated nomogram is presented providing the ability to predict the individual risk of an incomplete resection in patients with stage I-III NSCLC planned for surgery. In case of a relevant probability of incomplete resection, alternative treatment strategies could be considered, such as a larger extent of surgery, neoadjuvant or definitive chemoradiotherapy. In contrast, with a small predicted probability of incomplete resection, the use of surgery is further supported.

Keywords: NSCLC, incomplete resection, prediction model

P1.17-40 CLINICAL IMPLICATIONS OF USING CIRCULATING TUMOR DNA TO ASSESS MINIMAL RESIDUAL DISEASE (MRD) IN PATIENTS WITH NSCLC AFTER DEFINITIVE TREATMENT

N. Simon[1], Y.K. Chae[2], N. Mohindra[3], V. Villaflor[3]

[1]*Northwestern University Feinberg School of Medicine, Chicago/United States of America,* [2]*Northwestern Medicine Developmental Therapeutics Institute, Chicago/United States of America,* [3]*Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago/United States of America*

Background: Circulating tumor DNA (ctDNA) has been used to identify driver genomic alterations during treatment of metastatic nonsmall cell lung cancer (NSCLC). Recent studies have also demonstrated the role of ctDNA to monitor response to therapy. Here we performed an analysis on a cohort of NSCLC patients (pts) with localized disease who underwent ctDNA testing after definitive treatments to determine whether ctDNA can be used as a marker of MRD. **Method:** Between 2015-2019, 70 pts with localized NSCLC received ctDNA testing. ctDNA testing was done using the next generation sequencing (NGS) panel of 73 genes via digital sequencing technology (Guardant360). Statistical analysis was performed to determine which factors were associated with ctDNA levels and recurrence free survival (RFS). **Result:** Of the 70 pts analyzed, 26 pts had ctDNA testing performed after definitive treatment. Median duration of follow up was 22 months (range: 3 to 36). 26% (n = 7) had stage I disease, 30% (n = 8) had stage II disease, and 42% (n = 11) had stage III disease. 81% (n = 21) were adenocarcinoma while 19% (n = 5) were squamous cell carcinoma. 42% (n = 11) had no recurrence during our observation time, while 58% (n = 15) experienced progression. For definitive treatments, 38% (n = 10) underwent surgery alone, 35% (n = 9) underwent surgery with adjuvant chemotherapy, 15% (n = 4) underwent chemoradiation therapy, 8% (n=2) underwent surgery followed by radiation, and 4% (n=1) under went surgery with adjuvant chemoradiation prior to their ctDNA levels [variant allele frequency (VAF)] being drawn. Of these, 15% (n = 4) tested negative for any ctDNA, while 85% (n = 22) were positive. Only one of the pts with undetectable levels of ctDNA experienced recurrence of cancer 34 months after definitive treatment with surgery followed by chemotherapy. 13 among 22 pts with detectable ctDNA had recurrence (median time to recurrence = 6.3 months). Kaplan-Meir survival analysis revealed a trend toward significant association between the presence of detectable ctDNA and RFS (p = 0.10). **Conclusion:** Our analysis demonstrates that ctDNA could potentially be used as a marker to assess MRD following definitive treatment for localized NSCLC.

P1.17-41 PREOPERATIVE PROGNOSTIC NUTRITIONAL INDEX (PNI) AS A PROGNOSTIC FACTOR IN PATIENTS WITH CLINICAL STAGE I NON-SMALL-CELL LUNG CANCER

M. Matsumoto, K. Hagiwara, H. Komuro, Y. Miyamoto, H. Yamamoto, K. Shirahashi, K. Doi, H. Iwata

Gifu University Hospital, Gifu/Japan

Background: The prognostic nutritional index (PNI) is one of immune nutritional markers. The PNI has reported to predict the risk of postoperative complication or recurrence in various digestive malignancies. In this study, we investigated whether or not PNI be a prognostic factor in clinical stage I non-small-cell lung cancer patients. **Method:** We analyzed 429 patients of clinical stage I lung cancer retrospectively and evaluated the relationship between the preoperative PNI and postoperative outcomes. The PNI was calculated as 10 × preoperative the serum albumin level (g/dL) + 0.005 ×the total lymphocyte count (cells/mm3). We used the cutoff value 48 of PNI referred from K.Migita et al. Ann Surg Oncol (2013) 20:2647-2654. The Prognostic Nutritional Index Predicts Long-term Outcomes of Gastric Cancer Patients Independent of Tumor Stage. Low PNI was less than 48, and high PNI was more than 48. **Result:** In the univariate analysis, the results for low PNI (N=153) and high PNI

(N=276), respectively, were as follows: Age, 72.8±8.6 and 67.5±10.1 years (p<0.001); Sex (Male / Female), 108/45 and 170/106 (p=0.043); FEV1.0, 2102±507 and 2309±596ml (p<0.001); tumor size, 23.0±10.2 and 20.6±8.9 mm (p=0.010); FDG-PET SUV, 5.5±5.3 and 3.5±4.1 (p<0.001); postoperative complication, 56 and 73cases (p=0.030); pathological stage (IA/IB/IIA&IIB/IIIA&IIIB&IV), 87/33/18/15 and 200/32/20/24 (p=0.006); histology (adenocarcinoma/ squamous cell carcinoma/ others), 98/45/10 and 226/36/14cases (p<0.001); pleural invasion (0/1/2/3), 114/23/11/4 and 238/25/8/3cases (p=0.014); intra-tumoral lymphatic vessel invasion (0/1), 94/58 and 184/88cases (p=0.228); intra-tumoral blood vessel invasion (0/1/2), 103/49/1 and 201/71/0cases (p=0.124); 5-year overall survival, 77.4% and 90.2% (log-rank p<0.001) ; disease free survival, 64.8% and 84.2% (log-rank p<0.001); and recurrence free survival, 80.9% and 86.9% (p=0.182). In multivariate analysis, PNI (RR:2.447; 95% CI: 1.113-5.349; p=0.026), FDG-PET SUV (RR:1.067; 95% CI: 1.008-1.128; p=0.025) were independent prognostic factors. **Conclusion:** The low PNI showed inferior outcomes compared to high PNI for clinical stage I lung cancer. Patients with low PNI tended to have more progressive lung cancer stages and higher SUV of FDG-PET than them with high PNI. The preoperative PNI is a useful predictor of all-over survival.

Keyword: PNI lung nutrition

P1.17-42 THE IMPORTANCE OF LYMPHATIC AND VASCULAR INVASION IN STAGE 1 NON-SMALL CELL LUNG CANCER AND DEFINITION OF A TOTALLY CURABLE TUMORS

A. Turna[1], H. Melek[2], I. Sarbay[1], H. Kara[1], C. Gebitekin[2], K. Kaynak[1]

[1]*İstanbul University-Cerrahpaşa Cerrahpasa Medical School, İstanbul/Turkey,* [2]*Uludag University, Bursa/Turkey*

Background: A number of non-anatomic prognostic factors have been reported for resected non-small cell lung carcinoma. Certain histopathologic properties of the tumor such as lymphatic and vascular invasion could help to predict the patients with excellent survival. **Method:** A retrospective study was conducted on 550 surgically resected stage 1 non-small cell lung carcinomas, and the following prognostic factors were evaluated in univariate analysis: age, gender, size of tumor, histologic type of tumor, grade of differentiation, lymphatic invasion, vascular invasion, and perineural invasion. The mean follow-up time was 69 months(range;10 to 181 months). **Result:** Lymphatic vessel invasion, perineural invasion, blood vessel invasion, size of tumor(i.e.,T1a, T1b, T1c) of the tumor were found to be significant prognostic factors (p=0.001, p=0.006, p<0.001 and p=0.029 respectively). According to multivariate analyses, two factors were selected as prognostic indicators: (1) lymphatic invasion (p=0.027;OR:2.27;95%confidence interval:1.097-4.7), (2) vessel invasion (p =0.013;OR:2.021;95%confidence interval:1.16-3.53). By combining these factors we identified a poor and excellent prognostic subgroups of patients with stage I disease. The patients with 1A1 disease without lymphatic or blood vessel invasion had 100% of 5-year survival **Conclusion:** Our study showed that lymphatic vessel and blood vessel invasion of the tumor could be prognostic factors, along with anatomical determinants. The patients with stage 1A1 tumors who had no lymphatic or blood vessel invasion seem to be totally cured by surgical resection.

Keywords: stage 1, lymphatic invasion, blood vessel invasion

P.1.17-43 SUBLOBER RESECTION FOR ADENOCARCINOMA IN SITU DIAGNOSED BY INTRAOPERATIVE FROZEN SECTIONS

T. Shima

Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan

Background: The establishment of sublobar resection procedures for non-small cell lung cancer is expected. Many groups have suggested adenocarcinoma in situ (AIS) to be a potential indication for sublobar resection. **Method:** From 2012 to 2016, 80 patients (23 men and 57 women; median age, 70 years; range 40-86) diagnosed with adenocarcinoma in situ from intraoperative frozen sections, and underwent sublobar resection or lobectomy at our institution. Of these, 74 patients received sublobar resection and 6 patients underwent lobectomy.for adenocarcinoma in situ. We evaluate the predictive value of the intraoperative pathologic examination for AIS diagnosis, and overall survival, disease-free survival, and cancer-specific survival. **Result:** Permanent pathologic examination revealed 61patients had AIS, 17 patients had minimally invasive adnocarcinoma and 2 patients had invasive adnocarcinoma. The predictive value of intraoperative pathologic examination for AIS diagnosis was 79.3%. During a median 48-month follow-up, there were 1 cancer unrelated deaths. The 5-year overall survival rate was 98.8%. The disease-free survival rate and the 5-year cancer-specific survival rate were 100%. **Conclusion:** The results of our retrospective study indicate that an intraoperative pathologic diagnosis of AIS is strongly predictive and allows for an intraoperative decision to perform a sublobar resection in these patients.

P1.18 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.18-01 RELAY EU/US SUBSET: RAMUCIRUMAB PLUS ERLOTINIB IMPROVES PROGRESSION-FREE SURVIVAL IN FIRST-LINE EGFR MUTATION-POSITIVE NSCLC

S. Aix[1], S. Novello[2], E. Garon[3], K. Nakagawa[4], E. Nadal[5], D. Moro-Sibilot[6], M. Alonso Garcia[7], E. Fabre[8], B. Frimodt-Moller[9], A. Zimmermann[10], C. Visseren-Grul[11], M. Reck[12]

[1]*Hospital doce de Octubre Carretera De Andalucia, Madrid/Spain,* [2]*University of Turin, Turin/Italy,* [3]*David Geffen School of Medicine at UCLA/Translational Research in Oncology-US Network, Los Angeles/United States of America,* [4]*Kindai University Faculty of Medicine, Osaka-Sayama/Japan,* [5]*Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona/Spain,* [6]*CHU Grenoble, La Tronche/France,* [7]*Hospital Virgen del Rocío, Sevilla/Spain,* [8]*GHU Paris Ouest, Hôpital Européen Georges-Pompidou Service Oncologie Thoracique, Paris/France,* [9]*Eli Lilly and Company, Herlev/Denmark,* [10]*Eli Lilly and Company, Indianapolis/United States of America,* [11]*Eli Lilly, Utrecht/Netherlands,* [12]*Lung Clinic Grosshansdorf, Airway Research Center North (ARCN), Member of the German Center for Lung Research (DZL), Grosshansdorf/Germany*

Background: Dual blockade of EGFR and VEGFR pathways in *EGFR* mutation-positive NSCLC augments anti-tumor efficacy versus EGFR inhibition alone. The RELAY (NCT02411448) phase 3 study demonstrated a statistically significant and clinically meaningful improvement in progression-free survival (PFS) for erlotinib plus ramucirumab versus erlotinib plus placebo in patients with previously untreated *EGFR* mutation-positive metastatic NSCLC (median PFS 19.4 vs 12.4mo, HR 0.591 (95% CI 0.461–0.760), p<0.0001). Here we report efficacy and safety data of the EU/US subset. **Method:** Eligible patients (untreated, metastatic NSCLC with an *EGFR* exon 19 deletion or exon 21 (L858R) substitution mutation and no CNS metastasis) were randomized (1:1) to receive 150 mg daily oral erlotinib plus 10 mg/kg intravenous ramucirumab (RAM+ERL) or placebo (PL+ERL) Q2W until progressive disease or unacceptable toxicity. Patients were stratified by geographic region (East Asia vs 'other', i.e. EU/US). Primary endpoint was investigator-assessed PFS. Other key objectives included safety, ORR, DoR, PFS2, and OS. **Result:** In the EU/US, 113 (25.2%) of 449 total patients (58 RAM+ERL, 55 PL+ERL) were randomized between Feb 2016-Feb 2018. Baseline characteristics were balanced between treatment arms: ~60% female, ~52% never-smokers and ~66% *Ex19del*. RAM+ERL improved PFS and had a longer DoR (Table). PFS2 and OS data were immature. Grade≥3 TEAEs occurring in >5% of patients included (RAM+ERL vs PL+ERL): hypertension (29.8% vs 7.3%), diarrhea (12.3% vs 1.8%), AST increased (7.0% vs 3.6%), ALT increased (7.0% vs 1.8%), dermatitis acneiform (5.3% vs 9.1%), fatigue (5.3% vs 0%), and rash (0% vs 5.5%).

Abbreviations: CI=confidence interval; DoR=duration of response; ERL=erlotinib; HR=hazard ratio; N=total population; n=total responders; NR=no response; ORR=overall response rate; OS=overall survival; PFS=progression-free survival; PL=placebo; RAM=ramucirumab

	RAM + ERL (N=58)	PL + ERL (N=55)	Unstratified HR (95% CI)	p-value
PFS				
Median, months (95% CI)	20.6 (14.7-26.0)	10.9 (8.3-19.4)	0.605 (0.362-1.010)	0.0523
Censoring rate	52%	38%		
ORR, % (95% CI)	74.1 (62.9-85.4)	76.4 (65.1-87.6)	NA	0.8319
DoR, for responders only	n=43	n=42		
Median, months (95% CI)	18.0 (12.7-22.0)	10.0 (7.1-17.7)	0.527 (0.296-0.939)	0.0274
Censoring rate	54%	33%		
PFS2				
Median, months (95% CI)	NR	NR	0.632 (0.304-1.313)	0.2143
Censoring rate	79%	67%		
OS				
Median, months (95% CI)	NR	NR	1.096 (0.465-2.582)	0.8344
Censoring rate	81%	82%		

Conclusion: The EU/US subset analysis was consistent with the full ITT population where RAM+ERL demonstrated a statistically significant improvement in PFS over PL+ERL. Efficacy and tolerability were similar to that of the overall RELAY study population. Ramucirumab is an effective and safe addition to standard-of-care *EGFR*-TKI for treating *EGFR* mutation-positive metastatic NSCLC.

P1.18-02 THE AEGEAN PHASE 3 TRIAL OF NEOADJUVANT/ADJUVANT DURVALUMAB IN PATIENTS WITH RESECTABLE STAGE II/III NSCLC

J. Heymach[1], J. Taube[2], T. Mitsudomi[3], D. Harpole[4], M. Aperghis[5], L. Trani[5], M. Powell[6], P. Dennis[6], M. Reck[7]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Johns Hopkins University, Baltimore/United States of America,* [3]*Kindai University Faculty of Medicine, Osakasayama/Japan,* [4]*Duke University, Durham/United States of America,* [5]*AstraZeneca, Cambridge/United Kingdom,* [6]*AstraZeneca, Gaithersburg/United States of America,* [7]*Airway Research Center North (ARCN), Großhansdorf/Germany*

Background: For patients (pts) with early stage non-small cell lung cancer (NSCLC) (Stages I–IIIA) surgery is the primary treatment. Adjuvant and neo-adjuvant chemotherapy (CTx) are both accepted approaches for resectable NSCLC, and result in modest but clinically meaningful improvements in overall survival (OS) compared with surgery alone; nevertheless, recurrence rates remain high and improved therapies are needed. Checkpoint inhibitors that block programmed death 1 (PD-1)/PD ligand 1 (PD-L1) have shown benefit as monotherapy and in combination with CTx in NSCLC. Durvalumab (durva), a selective, high-affinity, human IgG1 monoclonal antibody that blocks PD-L1 binding to PD-1 and CD80, significantly improved progression-free survival and OS in pts with unresectable Stage III NSCLC who did not progress following chemoradiotherapy (Antonia et al, NEJM 2017; 2018). The AEGEAN study (NCT03800134) will assess the activity and long-term clinical outcomes of durva plus CTx prior to surgery, as well as further administration of durva post-surgery, in pts with resectable Stages II and III NSCLC. **Method:** The AEGEAN trial is a Phase 3, double-blind, placebo-controlled, multi-center study. Approximately 300 pts with resectable Stage II and III NSCLC will be randomized 1:1 to receive either durva (1500 mg intravenously) or placebo every 3 weeks (wks) alongside platinum-based CTx (4 cycles) prior to surgery, followed by either durva or placebo alone every 4 wks for an additional 12 cycles post-surgery. Pts will be stratified by disease stage and PD-L1 expression levels (<1% vs ≥1%); the number of pts with EGFR/ALK mutations will be capped at 20%. Tumor size (according to RECIST v1.1 criteria) will be evaluated at completion of neo-adjuvant CTx prior to surgery, every 12 wks for the first year; every 24 wks for 2–4 years; then yearly thereafter. The primary endpoint is major pathological response (≤10% residual viable tumor in the resected primary lung tumor after neoadjuvant treatment) in the full analysis set (FAS). Secondary endpoints include safety assessments, a range of efficacy measures including complete pathological response (FAS and PD-L1-TC ≥1%) and OS, pt-reported outcomes, durva pharmacokinetics and immunogenicity. This trial is currently recruiting. **Result:** Section not applicable **Conclusion:** Section not applicable

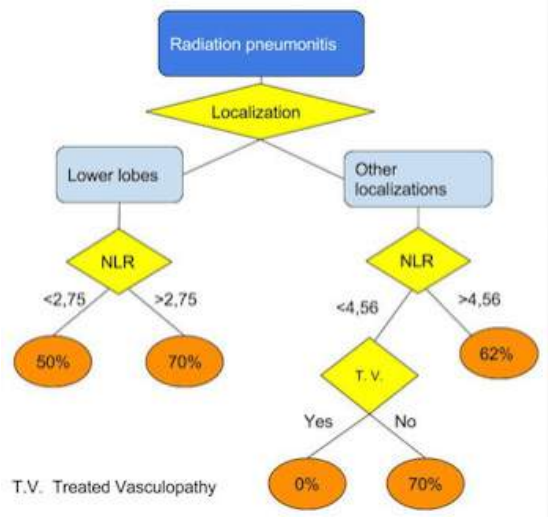
Keywords: durvalumab, NSCLC, Chemotherapy

P1.18-03 HOW TO PREDICT HIGH GRADE RADIATION PNEUMONITIS IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH THORACIC RADIOTHERAPY

J. Bordas-Martinez[1], C. Martin-Cabeza[1], S. Padrones-Sánchez[1], R. Palmero Sánchez[2], E. Nadal[3], V. Navarro-Párez[4], J. Dorca-Sargatal[1], A. Navarro-Martín[5], S. Aso-González[1]

[1]*Department of Pulmonology, Bellvitge Universitary Hospital, L'Hospitalet de Llobregat- Barcelona/Spain,* [2]*Department of Medical Oncology, Catalan Institute of Oncology, L'Hospitalet de Llobregat- Barcelona/Spain,* [3]*Department of Medical Oncology, Catalan Institute of Oncology, Barcelona/Spain,* [4]*Department of Statistics, Catalan Institute of Oncology, L'Hospitalet de Llobregat - Barcelona/Spain,* [5]*Department of Radiation Oncology, Catalan Institute of Oncology, L'Hospitalet de Llobregat- Barcelona/Spain*

Background: Predictive factors of radiation pneumonitis (RP) have been studied without conclusive results. The aim of this retrospective study was to identify clinical, inflammatory or dosimetric factors that could predict the development of high grade RP (HGRP). **Method:** A retrospective analysis was conducted in patients with non-small cell lung cancer (NSCLC) treated with concurrent chemo- radiotherapy, secuential chemo-radiotherapy or radiotherapy (RT) alone at the Catalan Institute of Oncology from 2012 to 2016 who developed symptomatic RP. Collected variables were: anthropometric values, Neutrophil-Lymphocyte Ratio (NLR), Platelet-Lymphocyte Ratio, lung function, tumor features (histology, localization, staging) and treatment characteristics. RP was classified using RTOG scale. Patients were divided in 2 groups (low-grade [G1-G2], and HGRP [G3-G5]). Multivariate and regression tree analysis were performed. **Result:** Sixty-seven patients were identified: 61% had low-grade RP and 39% HGRP. Development of HGRP was only associated with RT total dose (p=0.045). The most relevant predictive factors of HGRP were tumor location in lower lobes, high NLR values and the presence of peripheral vasculopathy. Figure 1 shows, when tumor is located in lower lobes and NLR is > 2.75, the probability of HGRP was 70% vs 50% when NLR <2.75. In other locations with NLR >4.56 the probability to develop a HGRP was 62%. But, when NLR<4.56, the presence of peripheral vasculopathy and its treatment determine the development of HGRP. When vasculopathy was not treated the probability to develop HGRP was 36% vs 0% when it was treated.61% had low-grade RP and 39% HGRP. Development of HGRP was only associated with RT total dose (p=0.045). When cancer is localized in lower lobes and NLR is > 2.75 the probability to develop HGRP was 70% vs 50% when NLR <2.75. In other locations with NLR >4.56 the probability to develop a HGRP was 62%. But, when NLR<4.56, the presence of vasculopathy and its treatment determine the development of HGRP. When vasculopathy was not treated the probability to develop HGRP was 36% vs 0% when it was treated. Figure 1. Probability to develop HGRP (G3 –G5)



Conclusion: The probability of develop HGRP has been associated with RT dose and the association of cancer location, NLR, presence of vasculopathy and its treatment.

[1]*National Cancer Center Hospital East, Kashiwa/Japan,* [2]*Hokkaido University, Sapporo-shi/Japan,* [3]*Osaka City General Hospital, Osaka/Japan,* [4]*Tokyo Metropolitan Cancer and Infectious Diseases Centre, Tokyo/Japan,* [5]*National Hospital Organization Shikoku Cancer Center, Matsuyama/Japan,* [6]*Research Institute for Diseases of the Chest, Graduate School of Medical Sciences, Kyushu University, Fukuoka/Japan,* [7]*Clinical Research Support Office, National Cancer Center Hospital East, Kashiwa/Japan,* [8]*Division of Pathology Exploratory Oncology Research & Clinical Trial Center (EPOC), Kashiwa/Japan*

Background: Ceritinib is a highly selective ALK inhibitor that has been shown potent antitumor activity against ALK-positive non-small cell lung cancer (NSCLC). We conducted a multicenter single-arm phase II study to assess the efficacy and safety of neoadjuvant therapy with ceritinib followed by surgery in patients with ALK-positive resectable locally advanced (LA) NSCLC. **Method:** Three cycles of ceritinib were administered as induction therapy. The drug was administered orally at the dose 750 mg once daily for 28 days per cycle. The primary endpoint was the major pathological response rate (mpRR). This study required 19 patients, with mpRR of 15% considered non-promising and 45% promising (one-side alpha = 0.025; beta = 0.2). Biomarker analyses using pre- and post-ceritinib through next-generation sequencing (NGS) of plasma and tissue is also planned. (Trial Identifier, UMIN000017906). **Result:** A total of 395 patients with LA-NSCLC were screened from March 2015 to March 2018 and 15 patients (4%) were identified as ALK-positive. Only 7 patients were enrolled because of slow accrual. The median age of the patients was 50 years and 71% (n=5) were male. All patients had stage IIIA disease and adenocarcinoma. 6 out of 7 patients completed three cycles of neoadjuvant therapy with ceritinib as planned, 71% (n=5) of patients required dose adjustment. One patient was withdrawn from the study because of hepatitis. The objective clinical response rate was 100%. Surgical resection was performed in 6 patients, and complete (R0) resection was achieved in 5 patients. Among the 7 evaluable patients, the mpRR was 57% (95% CI, 18 to 90); 4 patients achieved mpR and 2 patients achieved pathologic complete response. With a median follow-up of 10 (range 8-33) months, 1 patient died of disease progression and 6 patients remain alive, including 4 patients who are recurrence-free. The most common toxicities were gastrointestinal toxicities. **Conclusion:** Our results showed that neoadjuvant ceritinib is safe and effective, with a high rate of pathologic response, in patients with ALK-positive resectable LA-NSCLC, although the limitation of the data interpretation due to small sample size.

Background: Consolidation PD-1/PD-L1 inhibition following chemoradiation is a new standard of care for patients with stage III NSCLC. 3-year survival rates in patients receiving consolidation PD-1/PD-L1 have not been previously reported. In addition, the response to subsequent chemotherapy or immunotherapy in patients who experienced disease progression following consolidation PD-1/PD-L1 has also not been previously reported. **Method:** This is a phase II, single-arm, multi-center trial of consolidation pembrolizumab 200mg IV every 3 weeks for up to a year following concurrent chemoradiation in patients with unresectable stage III NSCLC. This analysis provides the first-ever report of 3-year overall survival (OS) estimates with consolidation PD-1. In addition, treatment details for patients who experienced progression of disease on or after consolidation pembrolizumab are described. **Result:** Median follow is 31.1 months (range 1.2-42.4). Median OS is 35.8 months (95% CI, 24.2 -not estimable). One, two, and three-year OS estimates are 81.1%, 62%, and 49.5%. Of 37 patients reported to have progressive disease (PD), subsequent treatment data were available for 35. Twenty-four received additional systemic therapy, and 11 received no subsequent systemic treatment. Fifteen experienced PD during pembrolizumab, 18 after pembrolizumab (and 4 had missing data). The best response to any systemic therapy (n=24) was 3 partial responses (PR), 9 stable disease (SD), and 12 PD. Chemotherapy was given to 21 patients and 1 patient each received erlotinib, ponatinib, and an investigational agent. Best response to chemo was 2 PR, 6 SD, and 13 PD. 11 patients received pemetrexed with 2 SD and 9 PD; 6 patients received a single agent taxane with 1 SD and 5 PD. 5 patients received combination therapy with 1 PR, 3 SD, and 1 PD. 3 patients received gemcitabine with 1 PR and 2 PD. 6 of 24 patients received subsequent PD-1 or PD-L1 inhibitors; the best response to immunotherapy was 1 PR and 5 PD. The PR was a patient who had completed pembro consolidation 14 months prior to PD and subsequently was retreated with pembro at the time of biopsy-proven recurrence (PD-L1 TPS was 90%). He responded after 3 cycles of pembro and has maintained this response for 13+ cycles. **Conclusion:** The 3-year OS estimate indicates that nearly half of all patients treated with consolidation pembrolizumab may be long-term survivors. For patients with disease progression after consolidation pembrolizumab, response rates with chemotherapy are similar to what is expected in the 2nd line setting with 38% experiencing disease control for a period of time. Only 1 of 6 patients re-challenged with a checkpoint inhibitor responded, but this patient has maintained a durable response lasting 13+ cycles.

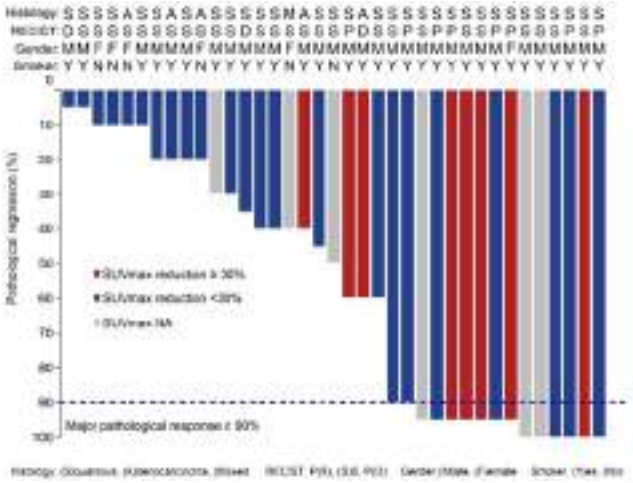
Background: Non-small cell lung cancer (NSCLC) patients with potentially resectable disease most would experience relapse after surgery. New strategy preventing recurrence is in urgent need. In the current study, we first evaluated the efficacy and safety of neoadjuvant sintilimab in Chinese patients with resectable NSCLC. **Method:** Patients with treatment-naïve resectable NSCLC (stage IB-IIIA) received two cycles of sintilimab (200 mg IV) on Day 1 and 22. Surgery was performed between Day 29-43. The tumor imaginations were obtained at baseline and within seven days prior to surgery. The efficacy endpoints include disease free survival, rate of major pathologic response (MPR, ≤10% viable tumor cells) and objective response rate (ORR). Safety and expression of programmed death ligand 1 (PD-L1) in baseline biopsy tissues and surgical samples were investigated. (Registration Number: ChiCTR-OIC-17013726). **Result:** A total of 40 patients with NSCLC were enrolled, among which 32 (80%) were male; 33 (82.5%) had squamous-cell carcinoma; 35 (87.5%) had stage IIA to IIIB disease; and 33 (82.5%) were former or current smokers. As of June 15th, 2019, all of the patients received 2 dose of sintilimab and 37 patients underwent radical resection. Among 37 patients, 8 patients achieved radiological partial response (PR), resulted in an ORR of 21.6% regarding RECIST 1.1. Fifteen (40.5%) patients achieved MPR, and 6 (16.2%) patients had complete pathologic response (cPR) (Figure 1). There's no correlation between baseline characteristics and MPR (Table 1). Maximum standardized uptake values (SUVmax) reduction of primary tumor after sintilimab treatment was significantly corelated with pathological response (correlation coefficient = 0.86, p <0.00001). However, there was no significant correlation between decrease in sum of lesion diameter (SLD) and pathological response (correlation coefficient = 0.21, p = 0.2104). Squamous cell carcinoma showed a better MPR (15/33, 45.5%) compared with adenocarcinoma (0/6 0%). In 18 patients with post-surgery pathologically positive lymph nodes, heterogeneity of response between primary tumor and lymph nodes were found by comparing MPR, change of SUVmax and SLD. Hyperporgression and pseudoprogression were both identified indicating the importance of biomarker selection for neo-adjuvant immunotherapy. Among 40 patients, 18 (45%) patients experienced neoadjuvant treatment-related adverse events (TRAEs). Two (5%) patient experienced grade 3-4 neoadjuvant TRAE. One treatment related surgery delay was reported because of grade 1 hyperthyroidism. None of the patients has confirmed recurrence to date. **Conclusion:** Neoadjuvant sintilimab for Chinese NSCLC patients was well tolerated and the 40.5% MRP rate is encouraging. A SUVmax reduction may be more predictive of pathologic response than decrease in SLD after neoadjuvant PD-1 therapy in NSCLC. Heterogeneity exists between primary tumor and lymph nodes.



Keyword: Sintilimab, neoadjuvant, squamous NSCLC

P1.18-07 POSTOPERATIVE COMPLICATIONS AND LONG-TERM SURVIVAL AMONG OCTOGENARIANS TREATED SURGICALLY FOR NON-SMALL CELL LUNG CANCER

M. Shimomura, H. Tsunezuka, S. Okada, S. Ishihara, N. Ishikawa, S. Ikebe, T. Furuya, K. Kameyama, S. Kitaoka, J. Shimada, M. Inoue

Kyoto Prefectural University of Medicine, Kyoto/Japan

Background: Non-small-cell lung cancer (NSCLC) is a very common disease in the elderly population and its incidence in this particular population is expected to increase further. The purpose of this study is to evaluatesafety and outcome in octogenarians treated surgically for non-small cell lung cancer. **Method:** 225 patients with non-small cell lung cancer have undergone surgical treatment between January 2014 and June 2018. We reviewed 38 (16.9%) consecutive patients over 80 years old. We evaluate safety and postoperative complications of surgical treatment among octogenarians compared to patients under 79 years old. As for long-term survival, we reviewed 69 consecutive octogenarian treated surgically for non-small cell lung cancer (pathological stage IA: 32 cases, IB: 24 cases, over IIA: 12 cases) between January 2007 and June 2014. **Result:** 26 patients (68.4%) have undergone lobectomy and 15 of these patients have undergone mediastinal lymph node dissection. 20 patients (55.6%) were pathological stage IA. As for postoperative complications, 7 cases (18.4%) were prolonged air leak, 1 respiratory failure (emergent thoracotomy due to glottic edema), 1 exacerbation of interstitial pneumonia and 1 chylothorax. There was no significant difference between octogenarians and patients under 79 years old in complications. Five-year survival rate of overall octogenarians, pathological stage IA and stage IB were 55.1%, 67.7% and 43.0%, respectively. 22 cases died in the observation period, and 8 patients died postoperatively due to recurrence of lung cancer. 14 patients (63.6%) died from other diseases without recurrence of lung cancer. **Conclusion:** Surgical treatment for non-small cell lung cancer to octogenarians is a safe modality. assessment of the surgical indication and procedure is the most important because of high mortality due to other diseases.

P1.18-08 SURVIVAL OUTCOMES OF SALVAGE THERAPY FOR LOCOREGIONALLY RECURRENT NON-SMALL CELL LUNG CANCER

S. Moore[1], B. Leung[1], J. Wu[1], C. Ho[1,2]

[1]*BC Cancer, Vancouver/Canada,* [2]*University of British Columbia, BC Cancer, Vancouver/Canada*

Background: Treatment of locally recurrent non-small cell lung cancer (NSCLC) after initial curative therapy may be curative or palliative intent, with options influenced by patient and disease characteristics. We sought to perform a real-world analysis of therapeutic strategies used in locally recurrent NSCLC, and explore the impact of prognostic factors and treatment choice on outcomes. **Method:** A retrospective review was completed of all patients with stage I-III NSCLC who were referred to BC Cancer and received curative intent therapy between 2005 to 2012. Patients were followed to determine if they developed locoregional recurrence. Two cohorts were created: those receiving curative intent treatment at recurrence (surgery, radiotherapy >=50Gy, or stereotactic radiosurgery) and those receiving palliative treatment. Information was collected on known prognostic factors. The primary outcome was overall survival from the date of recurrence. **Result:** During the study period, 1571 patients received curative intent therapy for stage I-III NSCLC. Of these, 187 (12%) developed recurrence; 48% local only, 28% regional nodes, 25% both. 54 (29%) patients were treated with curative intent at recurrence (14 surgery, 40 radiotherapy), and 133 (71%) received palliative treatment due to comorbidities, poor PS, inadequate pulmonary reserve, overlapping radiotherapy fields, or disease distribution. Initial diagnosis characteristics: 30% stage I/24% stage II/47% stage III, 10% never smokers, 46% adenocarcinoma, up front 50% surgery/47% RT/4% both, curative intent chemotherapy 53%. Characteristics at recurrence: median DFS 15.2 m, median age 70, 49% female, 67% ECOG 0-1. Patients receiving curative intent therapy were more likely to have ECOG 0-1 (91% vs 58%), earlier stage at diagnosis (50% stage I vs 22%), no nodal disease at relapse (63% vs 41%), and receive more aggressive staging at recurrence with pathologic confirmation in 76% vs 27%, and PET scan in 72% vs 26%. Overall survival was significantly longer

POSTERS

in the cohort receiving curative intent therapy. Median OS 33.1 m vs 9.7 m and 5 year OS 28.2% vs 3.3%. In a multivariate model incorporating stage at diagnosis, age, sex, histology, smoking status, and ECOG at recurrence, the impact of curative intent vs palliative therapy remained significant (HR for death 2.11 for palliative therapy, p<0.001). **Conclusion:** In this real world population, isolated locoregional recurrences occurred in 12% of patients after curative therapy for NSCLC. Patients who receive curative intent treatment at recurrence have a reasonable chance of achieving long term survival, making aggressive therapy of locoregional recurrences a viable treatment option in selected patients.

P1.18-09 TRIMODAL TREATMENT OF LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER: MODEL-BASED COMPARISON WITH CHEMORADIATION ONLY

M. Strange[1], I. Vogelius[1], L. Nygaard[1], M. Pøhl[1], J. Ravn[1], T. Lacoppidan[1], R. Petersen[1], G. Persson[2]

[1]*Rigshospitalet University of Copenhagen, Copenhagen/Denmark,* [2]*Herlev-Gentofte Hospital University of Copenhagen, Herlev/Denmark*

Background: Standard treatment for patients with locally advanced non-small cell lung cancer (LA-NSCLC) is chemoradiation (CRT). Some patients with minimal N2 disease are offered surgery after CRT (trimodal treatment) but evidence is sparse. In our institution patients were possible candidates for trimodal treatment if they were fit for surgery and had minimal N2 disease or poor local response to CRT. We evaluate the outcome of trimodal treatment compared to CRT alone using a model-based comparison. **Method:** Patients with LA-NSCLC treated with CRT with a radiation dose of 60-66 Gy from 2013-18 were eligible. We registered patient and disease characteristics, treatment outcome and survival. For the trimodal patients we registered complications and postoperative mortality[IRV1] [GP2] . A multivariable model was generated based on data from CRT treated patients to provide an expected survival given the covariables: Age, T- and N-stage, histology, performance status and Charlson Comorbidity Score. The model provided expected survival for trimodality patients and observed outcome was compared to CRT. **Result:** Two-hundred-sixty-six patients were included. Forty-one received trimodal treatment. Patient characteristics are shown in the table. Median time from CRT to surgery was 10 (5-113) weeks. Video assisted thoracic surgery was performed in 36.5% and open surgery in 63.4% of cases. Postoperative complication rate was 51.2%, most commonly infection (29.3%) and bleeding (12,2%). Reoperation rate was 17.1%. 30- and 90-day mortality was 7.3%. Complete pathological response after CRT was seen in 26.8% of cases. In univariate analysis, trimodality patients had improved survival (p=0.01) as compared to CRT. Adjusting for available covariables, the observed survival tended to remain superior to the expected survival if CRT was given (Figure). In the multivariate model thirty-six patients including two cases were excluded as comorbidity score was missing.

Characteristic	*CRT, n (%)*	*Trimodal, n (%)*

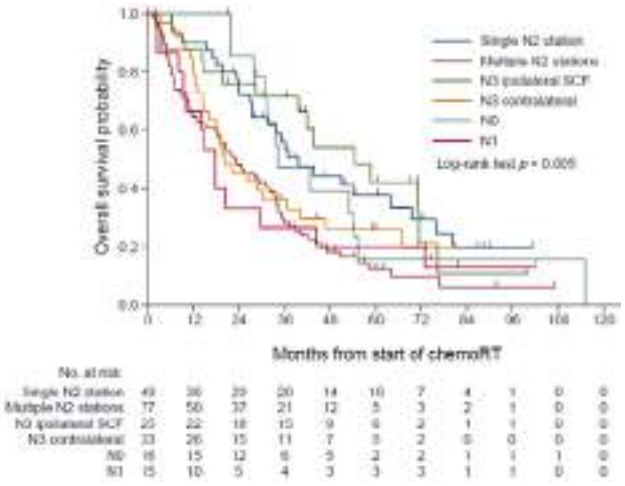
P1.18-10 THE PROGNOSTIC IMPACT OF THE EXTENT OF NODAL INVOLVEMENT IN NSCLC TREATED WITH RADICAL CHEMORADIATION

C. Yip, S.H. Tan, K. Chua, T.R. Siow, A. Thiagarajan, K.W. Fong, S.P. Yap, W.L. Ng, B.S.H. Chia, J. Tan

National Cancer Centre Singapore, Singapore/Singapore

Background: There is inconclusive evidence that single station N2 disease has better prognosis compared to multi-level N2 or N3 involvement in NSCLC. We aimed to evaluate the prognostic impact of the extent and location of nodal involvement in NSCLC treated with radical chemoradiation (CRT). **Method:** We retrospectively evaluated patients treated with radical CRT between 2007-2015 in a single tertiary institution. Nodal staging was based on imaging (CT/PET) and/or endoscopic/surgical evaluation. Nodal involvement was categorised as N0, N1, single station N2 ($N2_{single}$), multi-level N2 ($N2_{multi}$), ipsilateral N3 SCF ($N3_{scf}$) and contralateral mediastinal/SCF N3 ($N3_{contra}$). Single station N2 was further divided into one or >1 nodal deposits. Overall survival (OS) and disease-free survival (DFS) were defined from the date of radiation commencement to the date of death and relapse, respectively. Cox regression and Kaplan-Meier methods were used for survival analysis. **Result:** A total of 207 patients were included, with 165 (80%) treated with concurrent and 42 (20%) with sequential CRT. Most tumours were adenocarcinomas (55%: EGFR+ 26%, EGFR- 49%, unknown 25%) followed by SCC (36%) and other subtypes (9%). Clinical nodal staging was as follows: N0=8%, N1=7%, $N2_{single}$=19%, $N2_{multi}$=37%, $N3_{scf}$=12% and $N3_{contra}$=16%. Conventional AJCC nodal staging was not prognostic of OS (p=0.4) or PFS (p=0.4). However, patients with $N2_{single}$ (median OS=40 months) and $N3_{scf}$ (median OS=55 months) had improved OS compared to $N2_{multi}$ (median OS=23 months) and $N3_{contra}$ (median=20 months) (p=0.005) (Figure 1). In the $N2_{single}$ subset, those with single nodal deposit had longer median OS (44 months) compared to >1 nodal deposits (27 months) but this was not statistically significant, likely due to the small number of patients (p=0.4). There was no significant difference in DFS between nodal groups, although $N2_{single}$ and $N3_{scf}$ showed a trend towards longer PFS compared to $N2_{multi}$ and $N3_{contra}$ (p=0.09). In multivariate analysis, $N2_{multi}$ (HR 1.71, 95% CI 1.08-2.71, p=0.02), T4 (HR 2.02, 95% CI 1.12-3.65, p=0.02) and older age (HR 1.03, 95% CI 1.01-1.05, p=0.003) were associated with inferior OS but not the use of sequential CRT (HR 1.31, 95% CI 0.86-1.99, p=0.2).



Conclusion: In this study, $N2_{single}$ and $N3_{scf}$ stage III NSCLC showed improved overall survival compared to $N2_{multi}$ and $N3_{contra}$ disease after CRT. These findings suggest that nodal distribution, rather than conventional AJCC nodal staging, may have a greater prognostic impact in NSCLC treated with CRT.

Keyword: nodal staging, chemoradiation, prognosis

P1.18-11 DOSE DENSE PACLITAXEL AND CARBOPLATIN AS NEOADJUVANT THERAPY FOR RESECTABLE/ BORDERLINE RESECTABLE NSCLC - A PHASE II TRIAL

A. Mittal[1], P. Malik[1], S. Kumar[1], D. Jain[2], S. Pathy[1]

[1]*All India Institute of Medical Sciences, New Delhi/India,* [2]*All India Institute of Medical Sciences, new delhi/India*

Background: Neoadjuvant chemotherapy in locally advanced NSCLC is controversial. Available data suggest modest benefit and ideal regimen is unknown. Dose dense approach has not yet been tested in neoadjuvant setting. **Method:** This phase II trial tested a novel approach of dose dense paclitaxel at 80mg/m^2on d1, d8, d15 with three weekly carboplatin at AUC-6 for 4 cycles. Only patients with ECOG PS 0-2 with non-bulky N2 (defined as single lymph node < 2cm or multiple LNs or conglomerate, all < 2cm) were included in the study. Response assessment was done after two and four cycles. Primary end point was objective response rate. Relative dose intensity was calculated to define safety and tolerability. Secondary end points included progression free survival (PFS) and recurrence free survival (RFS) for patients who underwent surgery. IEC approved the study and the trial was registered with CTRI (ref no-CTRI/2016/05/006916). **Result:** A total of 33 patients were included in the study. Male to female ratio was 1.75:1. The median age was 54 years (40-78) and majority were smokers (78.8%). Most common histology was squamous cell carcinoma (57.6%) followed by adenocarcinoma (36.4%). Sixteen patients (48.48%) had N2 disease by PET out of which only three were TBNA positive, all were non bulky (<2cm). Around 76% of patients were able to complete the planned 4 cycles of treatment with only one patient having CTCAE ver 5 grade ¾ toxicity. Objective response rate was 61.3%. Relative dose intensity of 80.25% was maintained in patients who completed 4 cycles. Around 58% patients required dose modification, most common reasons included peripheral neuropathy (47%), myalgia (16%), diarrohea (10.5%) and neutropenia (10.5%). A total of 138 grade ½ toxicity events were reported in the study over 12 courses of chemotherapy, with nausea (48.5%), myalgia (42.4%), neutropenia (30.3%), peripheral neuropathy (27.3%) and diarrhea (27.3%) being the most common. Thirteen patients underwent surgery with majority undergoing lobectomy (77%). After a median follow-up time of 19.3 months, median PFS was 11.1 months (95%CI 7.26-18.16) and median overall survival was 26.63 (95% CI 15.03-NR). TNM stage on CT/PET and PET response to NACT significantly correlated with progression free survival on univariate analysis. In patients who underwent surgery, median RFS was 17.36 months (95%CI 6.5-31.86) and 2 year RFS rates were 25%. **Conclusion:** Dose dense therapy with paclitaxel/ carboplatin is feasible, safe and efficacious and can be considered for N2 negative/ low node burden patients.

P1.18-12 PACIFIC-4/RTOG 3515: PHASE III STUDY OF DURVALUMAB FOLLOWING SBRT FOR UNRESECTED STAGE I/II, LYMPH-NODE NEGATIVE NSCLC

C. Robinson[1], C. Hu[2], M. Machtay[3], M. Newton[4], K. Wu[4], K. Barrett[4], P. Dennis[4], J. Bradley[1]

[1]*Washington University in St Louis, St Louis/United States of America,* [2]*The Johns Hopkins University School of Medicine, Baltimore/United States of America,* [3]*University Hospitals Cleveland Medical Center, Cleveland/United States of America,* [4]*AstraZeneca, Gaithersburg/United States of America*

Background: Approximately 20% of non-small-cell lung cancer (NSCLC) patients (pts) present with localized disease and this percentage is expected to increase with routine computerized tomography screening. While surgery remains standard of care (SoC) for operable pts, for unresected pts stereotactic body radiation therapy (SBRT) is now the standard. However, locoregional and distant failures occur in >30% of pts after SBRT, with higher failure rates associated with larger tumors. Durvalumab is a selective high-affinity, human IgG1 monoclonal antibody that blocks PD-L1 binding to PD-1 and CD80. In the Phase 3 PACIFIC trial of durvalumab vs placebo in patients with unresected, Stage III NSCLC without progression on concurrent chemoradiotherapy (cCRT), durvalumab significantly improved both primary endpoints of progression-free survival (PFS) and overall survival (OS) versus placebo and the two treatment arms had similar safety profiles (Antonia et al, NEJM 2017; 2018). Accordingly, the PACIFIC regimen is becoming the SoC for

Stage III NSCLC. Accumulating evidence suggests potential benefit with immunotherapy at early stage NSCLC. PACIFIC-4 will assess the efficacy and safety of durvalumab versus placebo following SBRT in pts with unresected Stage I/II lymph-node negative NSCLC. **Method:** PACIFIC-4 is a Phase 3, randomized, placebo-controlled, double-blind, international study of durvalumab in pts with clinical Stage I/II node-negative (T1 to T3N0M0) NSCLC following definitive SBRT. Approximately 630 pts will be randomized 1:1 to receive durvalumab (1500 mg intravenously) or placebo every 4 weeks for 24 months, or until discontinuation due to disease progression, toxicity or withdrawal of consent. Eligible pts are adults with unresected Stage I/II NSCLC, are node-negative, ECOG PS 0–2, and have completed SoC SBRT. The primary endpoint is PFS using BICR assessments and the key secondary endpoint is OS. Other endpoints include health-related quality of life, lung cancer mortality, pharmacokinetics, immunogenicity, and safety. Recruitment for this trial is ongoing. **Result:** Section not applicable **Conclusion:** Section not applicable

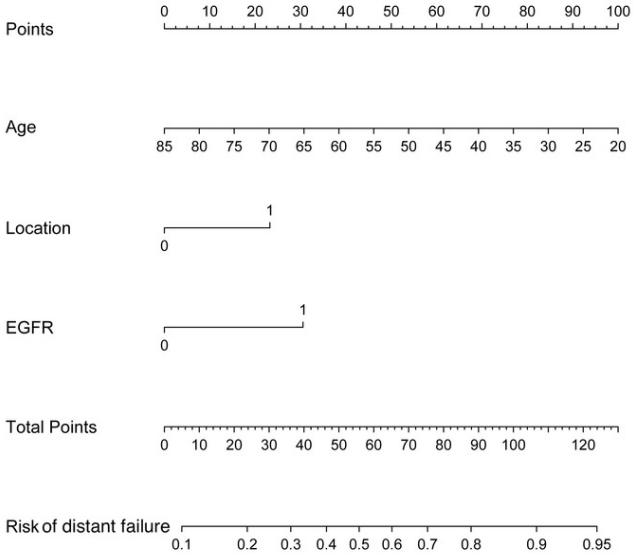
Keywords: durvalumab, NSCLC, SBRT

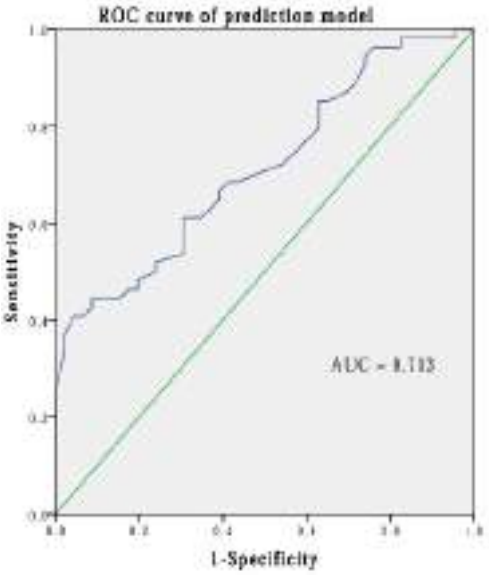
P1.18-13 PREDICTING FAILURE PATTERNS IN PATIENTS WITH INOPERABLE LOCAL ADVANCED NON-SMALL CELL LUNG CANCER RECEIVING DEFINITIVE CHEMORADIOTHERAPY

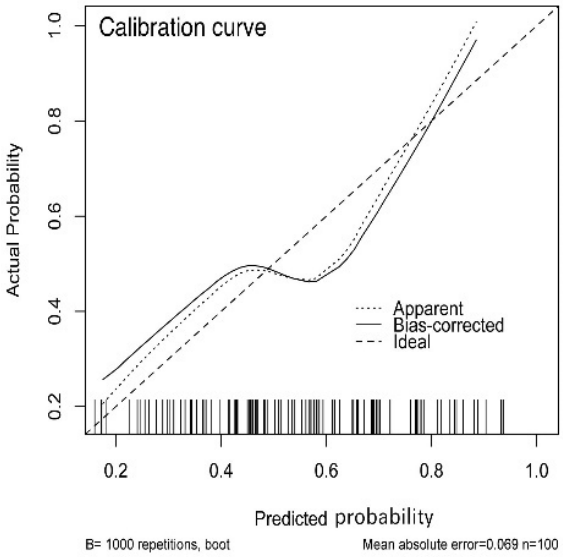
X. Zhu, X. Li, X. Fu

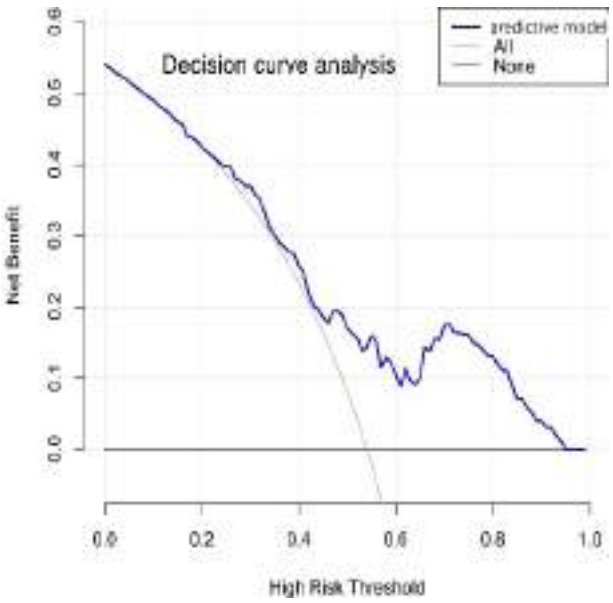
Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: To analyze patterns of failure for patients with local advanced non-small cell lung cancer (LA-NSCLC) receiving definitive chemoradiotherapy and to build a nomogram for predicting the failure patterns in these patients. **Method:** Clinicopathological materials of patients between 2013 and 2016 with LA-NSCLC who receiving definitive chemoradiotherapy and following-up in our hospital were collected. The endpoint was the first failure after definitive chemoradiotherapy. Based on logistic regression, the predictive value of each factor was evaluated and nomogram was built. This model was validated by ROC curve, calibration curve and decision curve analysis (DCA). **Result:** With a median follow-up of 28 month, 100 patients were observed failure. Local failure and distant failure were 46 and 54, respectively. Univariate and multivariate analysis indicated that age (p = 0.016, OR (95%CI): 0.936 (0.887-0.987)), tumor location (p = 0.025, OR (95%CI): 2.732 (1.137-6.567)) and epidermal growth factor receptor (EGFR) mutation status (p = 0.020, OR (95%CI): 3.747 (1.234-11.381)) were independent predictors of distant failure, which were included in the nomogram (Figure 1). ROC curve showed that area under the ROC curve (AUC) of the nomogram was 0.713, which was better than any factors along. Calibration curve revealed a satisfactory consistency between the predicted distant failure and actual observation. DCA showed the majority of the threshold probabilities in this model were with good net benefits (Figure 2).









Conclusion: We concluded that age, tumor location and EGFR mutation status could predict failure pattern in patients with LA-NSCLC receiving definitive chemoradiotherapy. A nomogram was built and validated based on these factors, showing a potential predictive value in clinical practice.

P1.18-14 THE PROGNOSTIC SIGNIFICANCE OF SIGNIFICANT WEIGHT LOSS IN STAGE III NSCLC UNDERGOING DEFINITIVE CRT AFTER FDG-PET STAGING

C. Senko[1], J. Moore[2], K. Hay[3], Z. Lwin[1,3], G. Pratt[3], K. Fong[1], B. Hughes[1,3]

[1]*The Prince Charles Hospital, Brisbane/Australia,* [2]*Princess Alexandra Hospital, Brisbane/Australia,* [3]*Royal Brisbane and Women's Hospital, Brisbane/Australia*

Background: In the pre-PET era, weight loss is a harbinger of occult metastatic disease in patients with stage III NSCLC. Identifying the relationship between weight loss and pattern of relapse (POR), may enable stratification of patients into prognostic groups associated with increased risk of relapse. We sought to identify if weight loss remains a negative independent prognostic factor after FDG-PET staging. **Method:** A retrospective audit (using web-based and electronic databases) was conducted in all patients with stage III NSCLC treated with definitive CRT between 01/07/2013 and 30/06/2018 at the Royal Brisbane and Women's Hospital and The Prince Charles Hospital, Queensland, Australia. A descriptive analysis was applied to describe the primary end-point of PFS and secondary end-points of OS and POR, in relation to the percentage of pre-treatment weight loss (0-10% vs >10-20% vs >20%). A subset analysis looked at other prognostic factors identified in NSCLC to account for potential confounders. **Result:** Of the 127 patients (mean age 65 years, mean weight 76kg, 57% male, 42% current smokers) who commenced treatment during the study period, 24% lost > 10% and 3% lost > 20% weight. Median TTP for the entire cohort was 9 months. Based on multivariable modelling, risk of PD or death was 45% higher with > 10% loss of body weight (p=0.004), and risk of death was 36% higher with > 10% loss of body weight (p=0.05). Of the 54% that died during follow-up, 31 had distant PD, 18 had locoregional PD, 6 had local PD, and 10 had no PD. Males were at increased risk of PD. **Conclusion:** A prognostic link continues to be identified between significant (> 10%) weight loss and risk of progressive disease or death in stage III NSCLC treated with definitive CRT despite pre-treatment FDG-PET. These findings identify a sub-group of patients where weight loss could still be a surrogate for micro-metastases not detected on PET, or other adverse prognostic markers. Other treatment strategies or improved diagnostic strategies are warranted.

Keywords: stage III NSCLC, weight loss, prognostic significance

P1.18-15 DOSIMETRIC AND TOXICITY BENEFITS OF ADAPTIVE IMRT IN PATIENTS WITH STAGE III NON-SMALL CELL LUNG CANCER

Y. Meng, L. Hou, P. Gu, W. Wang, Y. Shen, S. Zhou, F.-M. Kong, H. Yang

Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China

Background: Multiple studies observed anatomical changes or tumor shrinkage during concurrent chemoradiotherapy in patients with non-small cell lung cancer (NSCLC). Mid-treatment CT based adaptive radiotherapy targeting to the shrunken tumor can reduce the dose to adjacent normal tissue or potentially deliver a higher dose to the tumor. We aimed to quantitatively analyze the benefit of intensity-modulated radiotherapy (IMRT) adapting to CT changes at the 20th fraction in stage III NSCLC patients. **Method:** We retrospectively evaluated consecutive patients with unresectable stage III NSCLC treated with adaptive IMRT from November 2017 to August 2018. The eligibility criteria included a mid-treatment CT simulation for replanning at the 20th fraction and a follow-up of at least 6 months. The prescribed dose was 64-66 Gy in 30 fractions unless exceeding the dose limit. Normal tissues were delineated according to RTOG1106 atlas on organs at risk under the supervision of a senior physician. Dose-volume histograms were calculated for the initial plans, composite adaptive plans, and lung isotoxic boost plans. Radiation pneumonitis (RP) and esophagitis (RE) were graded per CTCAE v4.03. Univariate logistic regression was applied to analyze the correlation between dosimetric factors and adverse events. **Result:** 53 patients were eligible in this study. The average GTV shrinkage was -40.9% at the 20th fraction. Comparing the dosimetric factors of the composite adaptive plans to the initial ones, the GTV coverage was found marginally higher (P=0.002). The doses to normal tissues were significantly lower (all Ps<0.001) in heart mean dose by 109.5 cGy, esophagus V60 by 1.53%, cord maximum dose by -272.7 cGy, lung V20 and mean lung dose (MLD) by 1.11% and 79.2 cGy, respectively. The tumor targets could potentially get an average lung isotoxic boost of 481 cGy. Eight patients (15.1%) had grade 2 RP while no grade 3 or higher RP occurred. Twenty-three patients (43.4%) developed grade ≥ 2 RE. MLD was significantly associated with grade 2 RP with an odds ratio of 1.39 per 100 cGy increase (95% CI, 1.01 to 1.91; P=0.042). Esophagus V60 was significantly associated with grade ≥ 2 RE with an odds ratio of 1.15 per 1% increase (95% CI, 1.04 to 1.28; P=0.009). (Table 1)

Factors		Initial Plans	Adaptive Plans	Mean difference	95%CI		P Value
Targets	PGTV (%)	92.96	93.81	0.85	0.33	1.37	0.002
	PTV(%)	94.13	94.54	0.41	0.35	0.80	0.033

Conclusion: By adapting to the changes on CT scans at the 20th fraction, the adaptive IMRT approach provides significant dosimetric benefits and has the potential to lower the risk of symptomatic pneumonitis and esophagitis in stage III NSCLC.

P1.18-16 IS TUMOR SHRINKING DURING CHEMORADIATION FOR LA-NSCLC A BIOMARKER FOR OUTCOME?

S. Ramella, S. Silipigni, M. Fiore, C. Greco, E. Ippolito, P. Zuccoli, B. Santo, R. D'Angelillo

Radiotherapy, Campus Bio-Medico University, Via Alvaro del Portillo (RM)/ Italy

Background: Adaptation of dose distribution to tumor reduction during radiotherapy is an innovative approach. Even if the advantage for lung toxicity is intuitive, some concerns exist about the risk of tumor recurrences in the area of target reduction. Recent data reported no increased local relapse and low pulmonary toxicity so, waiting for the ongoing phase III trial investigating this issue (RTOG 1106-ACRIN 6697), the aims of this study is to compare the long term outcome for patients treated or not with the adaptive approach. **Method:** LA- NSCLC patients enrolled in a prospective study, where they were treated with concomitant chemoradiation and underwent to replanning in case of tumor shrinkage, have been compared with patients without tumor shrinkage treated with the concurrent treatment in the same period. Toxicity was evaluated with the RTOG/ EORTC scale. The differences between groups were compared by Fisher's exact test (two tail) or χ^2 when appropriate. The "time to event" curve was calculated with the Kaplan-Meier method, and log-rank test was used to perform between-group comparisons. **Result:** Patients in the adaptive group (AG) were more likely to receive a total radiation dose equal or higher than 59.4Gy (58% vs 27%, p=0.003). No statistical differences were reported in local recurrences, even if in non-adaptive (NAG) and AG were 48% and 31%, respectively. Distant recurrences were documented in the 55% and 46% of patients. Acute ≥G2 esophageal and pulmonary toxicity was similar, but G3 acute lung toxicity was lower than a third in AG (2% vs 7%) and G3 chronic lung damage reduced by half (7.5% vs 4%). Median follow up for alive patients was 57.8 months. Median OS were 26,6 and 30,5 months and PFS 7,6 and 8.3 months between NAG and AG, respectively. Survival was affected by the rate of shrinking with better result for patients reducing 25-50% of the initial volume (median not reached) in comparison with no-reduction or until 25% patients (median 25 months) (p=0.016). An apparent contra-intuitive result was the lower survival in case of reduction >50% (median 23 months). PFS reflects the same observation with median values of 7,5 and 7,4 months for patients shrinking 0-25% and >50%, respectively and 13,8 months for patients reporting a tumor reduction in the range of 25-50%. **Conclusion:** Waiting for randomized phase III results, adaptive approach confirms its role in escalating dose and reducing toxicity without compromise outcome. The worse outcome in patients with >50% reduction could be explained by high proliferating aggressive tumor behavior. The value of the shrinking rate as a biomarker for survival deserves to be investigated in future trials at the aim to intensify treatment in selected population.

P1.18-17 SURVIVAL AFTER ADJUVANT CHEMOTHERAPY IN COMPLETELY RESECTED N1 NON-SMALL CELL LUNG CANCER

E. Wang[1], É. Bourdages-Pageau[1], H. Gagnon[1], C. Labbe[2], L. Tremblay[1], P. Ugalde[1]

[1]*Institut Universitaire de Cardiologie et Pneumologie de Québec, Québec/ Canada,* [2]*Quebec Heart and Lung Institute Research Center, Quebec/Canada*

Background: Upfront surgery is the standard of care for patients with clinical stage I or II non-small cell lung cancer (NSCLC), but the relapse rate remains high, and 5-year survival is unsatisfactory. Randomized controlled trials, including the International Adjuvant Lung Cancer trial published in 2014, showed that adjuvant chemotherapy (ACT) after surgery increased overall survival at 5 years. However, ACT is seldom well tolerated, and often patients do not complete treatment. The goal of this study was to analyze the effects of adjuvant therapy in patients with N1 disease to better understand the effectiveness of ACT in a real-world surgery series. **Method:** This is a retrospective study from a prospectively maintained database at our institution. Patient with NSCLC were included in the study if they underwent surgery with complete resection (R0) from January 2006 to December 2017 and had pathological N1 NSCLC. **Result:** We identified 207 patients with pN1 NSCLC; their mean age was 64.5 ± 8.9 years. Most (71.2%) had an Eastern Cooperative Oncology Group (ECOG) performance status of 0. Eight patients (3.9%) were never-smokers. Over 50% of the patients had a video-assisted thoracoscopic surgery (VATS) lobectomy. Mean tumor size was 31.6 ± 15.4 mm, and most tumors (70.5%) were adenocarcinomas. Although 139 patients (65.7%) underwent ACT using the BR.10 chemotherapy regimen, only 59 patients (42.4%) completed all cycles of the treatment. Five years after surgery, overall survival was 55±4%, and disease-free survival was 39.3±4%. There was no statistically significant difference in disease-free survival between the patients who received ACT and those who did not (median 4.0 vs 2.8 years, hazard ratio [HR] = 0.74 (95% confidence interval, 0.49, 1.11), p = 0.1463), but there was a trend toward improved overall survival in patients who underwent ACT (median 8.6 vs 5.0 years, HR = 0.66 (0.41, 1.05), p = 0.0763). (Figure 1) **Conclusion:** Adjuvant chemotherapy was completed in only 42% of patients in this single-center, retrospective study. No statistically significant differences in disease-free survival or overall survival as a result of ACT were observed, likely a result of the small cohort. This study highlights the difficulties patients encounter in completing ACT, and the need for alternative ACT regimens to improve survival in patients with pN1 NSCLC after surgery.

P1.18-18 FEASIBILITY OF HYPOFRACTIONATED CHEMORADIATION FOR PATIENTS WITH STAGE III NON-SMALL CELL LUNG CANCER

N. Van Der Voort Van Zyp[1], M. Hashimzadah[1], E. Kouwenhoven[1], K. Maas[1], W. Oosterhuis[1], I. Walraven[2], J. Belderbos[2], M. Mast[1]

[1]*Haaglanden Medisch Centrum, Leidschendam/Netherlands,* [2]*The Netherlands Cancer Institute, Amsterdam/Netherlands*

Background: The standard treatment for fit patients with stage III non-small cell lung cancer (NSCLC) is concurrent chemoradiation often consisting of a platinum doublet and 60-66Gy. In the Netherlands an alternative is mildly hypofractionated radiotherapie (66Gy in 24 fractions of 2.75 Gy) combined with daily low dose Cisplatinum. This schedule aims to improve local tumor controle and overall survival by reducing overall treatment time. We investigated the feasibility of three weekly full dose platinum doublet chemotherapy combined with hypofractionated radiotherapy. The rational for full dose platinum doublet chemotherapy is to reduce the incidence of distant metastases. **Method:** A retrospective observational study was performed including patients with stage III NSCLC (<70 years old, WHO performance score 0-1, estimated length of the oesophagus receiving 66Gy ≤12cm) who were treated with full dose platinum doublet chemotherapy and 66Gy/24 fractions. All patients were staged with a PET-scan and brain MRI. Chemotherapy generally consisted of 1 cycle of Cisplatin/Alimta or Cisplatin/Gemcitabine followed by 2-3 cycles of Cisplatin/Etoposide. Radiotherapy mostly started on day two of the second cycle of chemotherapy. Patients with a single mediastinal lymphnode metastasis who were selected for surgery after chemoradiation are not included in this analysis. Toxicity was scored using the common criteria for adverse events (CTCAE v4.0): acute if it occurred ≤90 days, late >90 days. **Result:** Between 2012-2019, 40 patients were treated with hypofractionated radiotherapy and platinum doublet chemotherapy. The median age was 58 years (SD 8.9), all had a WHO 0-1, and 58% were male. The median follow-up was 3.3 years (IQR 1.7 – 3.9). The median overall survival was 1.6 years (IQR 0.6-3.2). The rate of distant metastases was 30% at two years, and the median progression free survival was 0.9 years. Grade ≥3 acute oesophageal toxicity occurred in 14 patients (35%) and late oesophageal toxicity in 7 patients (17.5%). Five patients died: all due to oesophagus perforation or broncho-oesophageal fistula. **Conclusion:** In selected fit patients with locally advanced stage III NSCLC hypofractionated radiotherapy with concurrent full dose Cisplatin based chemotherapy resulted in an unexpected high rate of severe acute and late esophageal toxicity.

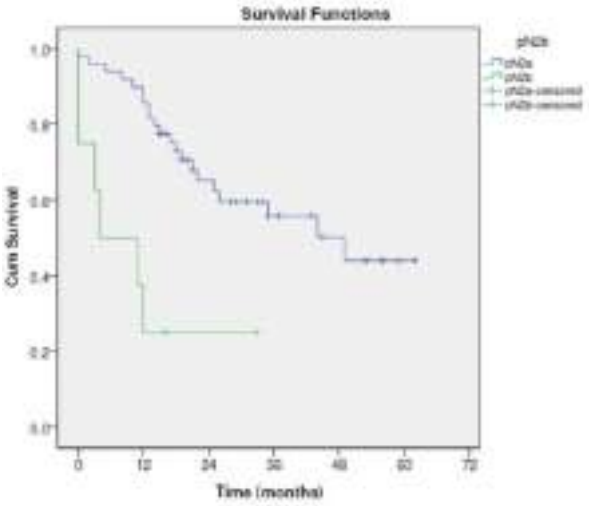
Keyword: NSCLC hypofractionated chemoradiation

P1.18-19 INVASIVE MEDIASTINAL STAGING IS MANDATORY FOR UPFRONT SURGERY FOR N2 DISEASE

A. Selvaraj, K. Lau, G. Sotiropoulos, A.-R. Dhanji, D. Waller

St Bartholomew's Hospital, Barts Health NHS Trust, London/United Kingdom

Background: There is debate about the management of stage IIIA(N2) lung cancer. We evaluated our policy of upfront surgery for limited N2 disease. **Method:** Of 821 resections for primary lung cancer from January 2014 to December 2017, 57(7%) patients [39 male, 19 female, mean age 67.7] had postoperative N2 disease. All patients had standard staging with PET-CT with selective mediastinal biopsy (nine EBUS). We compared the survival of upfront N2 surgery with unexpected pN2 disease. **Result:** Preoperatively 44% had cN2 disease and 56% had cN0/1 with unexpected pN2 disease postoperatively. 23(40.4%) patients had pN2a1, 26(45.6%) pN2a2 and 8(14%) pN2b disease. Majority (63.2%) had adenocarcinoma and lobectomy (94.8%), Unexpected pN2 (cN0-1) had similar overall survival to those with cN2 disease (median survival 49 months vs 44 months, p=0.75). For patients with N2a disease, there was no survival difference between those with pN2a1 and pN2a2 (median survival 49 months vs 44 months p=0.71). Survival was significantly worse with multizone N2b disease than with single-zone N2a disease (figure 1, median survival 49 months vs 4 months, p<0.001) and the effect persisted following multivariate adjustment for age, T-stage and chemotherapy (HR 6.73, p<0.001).



Conclusion: Our data further support the resection of cN2a lung cancer but N2b must be excluded preoperatively.

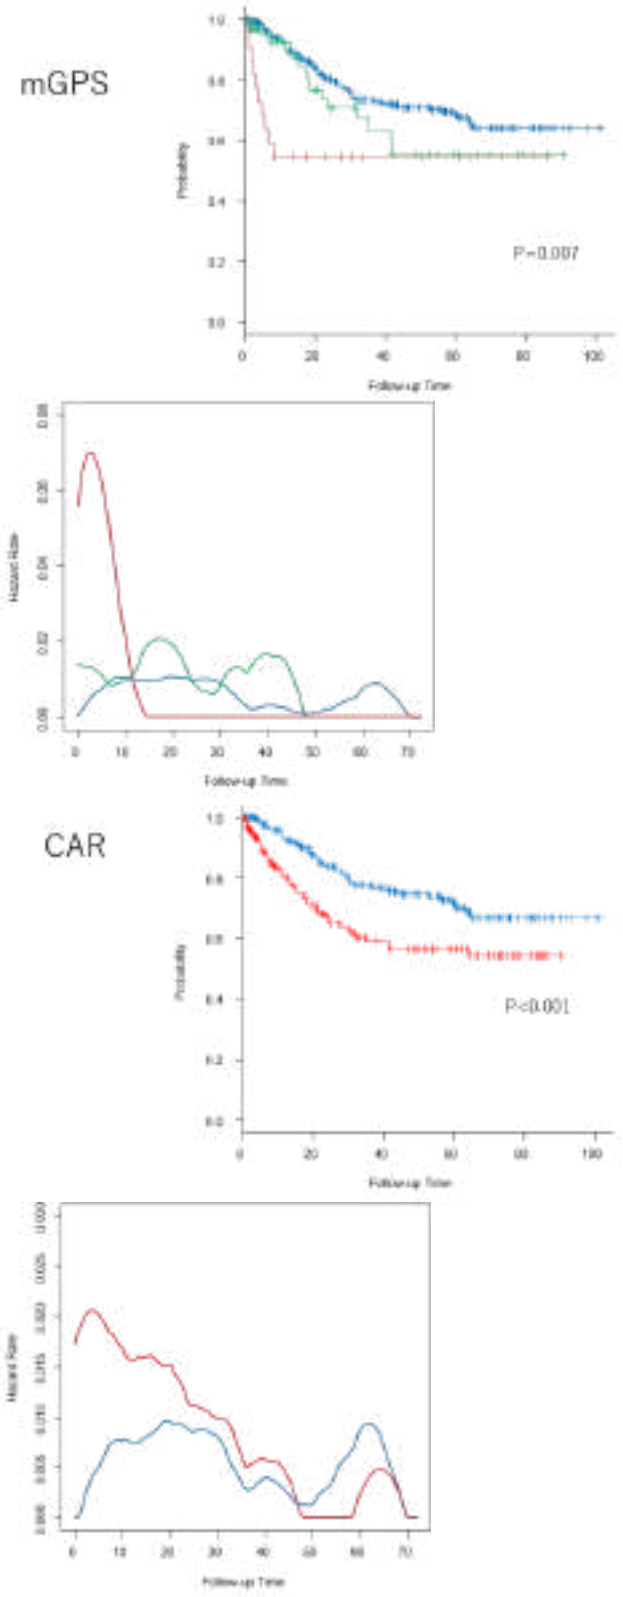
P1.18-20 THE RELATIONSHIP BETWEEN THE RECURRENCE TIMING AND INFLAMMATION-BASED PROGNOSTIC SCORES IN RESECTED NON-SMALL-CELL LUNG CANCER

D. Noma[1,2], K. Watanabe[1,2], M. Masuda[1]

[1]*Yokohama City University School of Medicine, Yokohama/Japan,* [2]*National Yokohama Medical Center, Yokohama/Japan*

Background: Several inflammatory markers are reported to be useful in predicting the surgical outcomes in patients with various cancers. We evaluated the influence of inflammation-based prognostic scores on the postoperative recurrence timing using survival curves and hazard curves for non-small cell lung cancer (NSCLC) patients. **Method:** Total 356 patients with NSCLC who underwent pulmonary resection were retrospectively studied. The study subjects included 217 males and 139 females with a mean age of 70.0 years at the time of the surgery. We divided the population as per the Glasgow prognostic score (GPS), modified GPS, neutrophil-to-lymphocyte ratio (NLR, cut-off: low ≤ 3.75 and high > 3.75), platelet-to-lymphocyte ratio[A1] (low ≤ 200 and high > 200), and C-reactive protein-to-albumin ratio (CAR, low ≤ 0.028 and high > 0.028). Hazard curves and changes in the hazards [A2] over time were evaluated. **Result:** GPS, mGPS, high NLR, and high CAR were significantly associated with poor recurrence-free survival (RFS) in the univariate analysis. Multivariate analysis revealed that only mGPS (Hazard ratio [HR]: 1.569, 95% confidence interval [CI] 1.149–2.144, p = 0.005) and high CAR (HR: 1.751, 95%CI 1.002–3.061, p = 0.049) remained independently associated with RFS. The resulting hazard curves indicated that the recurrence risk pattern correlated with inflammation, with an early sharp peak within a year of surgery for patients with mGPS 2 or a high CAR and some late gentle humps [A1] for patients with mGPS 0 or a low CAR.



Conclusion: Patients with mGPS 2 or a high CAR have a high risk of early recurrence in resected NSCLC. These findings are useful for postoperative follow-up strategy, allowing the identification of patients who would specifically obtain a clinical benefit from intensive surveillance.

P1.18-21 SHORT AND MID-TERM OUTCOMES OF MULTIMODAL TREATMENT FOR LOCALLY-ADVANCED NON SMALL CELL LUNG CANCER IN ELDERLY PATIENTS

S. Bongiolatti[1], F. Mazzoni[2], S. Borgianni[1], A. Gonfiotti[1], A. Salvicchi[1], L. Antonuzzo[2], L. Voltolini[1]

[1]*Thoracic Surgery Unit, florence/Italy,* [2]*Medical Oncology Unit, florence/Italy*

Background: Multimodality treatments are effective for locally advanced non-small cell lung cancer (LA-NSCLC) and have demonstrated clinical benefits in terms of overall (OS) and disease-free survival (DFS), but these options are frequently denied to elderly patients due to the fear of fatal complications. **Method:** The objectives of this retrospective study were: to investigate mortality, morbidity, short and mid-term oncological outcomes of pulmonary resection after induction therapy (IT) for NSCLC in elderly patients (>70 years) treated between June 2014 to December 2018. We divided the study population in two groups based on age at time of the treatment: patients <70 years (group A) and patients >70 years (group B). A multivariable logistic regression was built to identify factors associated with overall morbidity, including a set of variables chosen on clinical relevance. **Result:** 77 patients underwent pulmonary resection after IT; among these, 27 were aged >70 years. Platinum-based chemotherapy was administered to 73 patients and chemoradiation was used more frequently in group A (24% vs 3.7%; p=0.02). Surgical procedures were similar in both groups, although chest wall resections were more frequent in group A (20% vs 11%). Pathological stages and pathological responses were comparable. In-hospital mortality (2% vs 0%) was similar, while the percentage of patients with complication (38% vs 48.1%, p=0.47) and the complication rate (50% vs 77%, p=0.01) were higher in group B, but the severity of complications was comparable between the two groups. The multivariable analysis demonstrated the absence of any significant factors associated with overall morbidity. OS at 3 years and DFS at 2 years were not different between the two groups (61% vs 48.5%, p=0.64; 61.7% vs 44%, p=0.393).

	0	12	24	36	48
Younger	50	43	38	35	36
Elderly	27	23	20	18	

	0	12	24	36
Younger	50	35	34	31
Elderly	27	20	14	

Conclusion: Lung resection for LA-NSCLC after IT can be performed safely in appropriately selected elderly patients with favorable post-operative and mid-term oncological results.

P1.18-22 IMPACT OF USING VOLUMETRIC MODULATED ARC THERAPY ON RADIATION PNEUMONITIS IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER

N. Imano, T. Kimura, T. Kameoka, M. Ochi, Y. Takeuchi, I. Takahashi, I. Nishibuchi, Y. Murakami, D. Kawahara, K. Miki, A. Saito, N. Yasushi

Hiroshima University Hospital, Hirohsima/Japan

Background: The administration of durvalumab after radical chemoradiotherapy has been shown to improve the outcome of locally advanced non-small cell lung cancer (NSCLC); however, it cannot be used when Grade 2 or higher radiation pneumonitis (RP) occurs. Although the use of volumetric modulated arc therapy (VMAT) is widespread, there is concern about the expansion of low doses to the lungs, causing an increase in RP. The concern is stronger for Asians, since RP may be frequent in Asians as with gefitinib-induced pneumonitis. The purpose of this study was to evaluate the impact of using VMAT on lung dose–volume histogram (DVH) and incidence of Grade 2 or higher RP compared with three-dimensional conformal radiotherapy (3D-CRT) in Asians. **Method:** We retrospectively evaluated 63 patients who underwent radical chemoradiotherapy for locally advanced NSCLC at our hospital from 2010 to 2018. RP was evaluated using the common terminology criteria for adverse events version 4.0. Regarding the lung DVH, the mean lung dose (MLD)and V5Gy–V70Gy were analyzed. Student's t test was used to compare the mean value between the two groups and the chi-squared test was used to compare the incidence of toxicities between the two groups. P values < 0.05 were considered statistically significant. **Result:** The total dose was 60–74 Gy/24–35 fractions (median 70 Gy/35 fractions). Thirty-nine patients underwent 3D-CRT (3D-CRT group), and 24 patients underwent VMAT (VMAT group). Of the 63 cases, Grade 2 or higher RP was observed in 41 cases (65.1%). The incidence of Grade 2 or higher RP tended to be lower in the VMAT group, although there was no significant difference (54.2% vs. 74%, p = 0.10). Regarding DVH comparisons between the 3D-CRT and VMAT groups, planning target volumes (PTVs) tended to be large in the VMAT group (451 cc vs. 357 cc, p = 0.14). There were no significant differences in MLD and V10Gy–V50Gy. Lung V5Gy was significantly higher in the VMAT group (49.7% vs. 39.2% p = 0.007), while V60Gy tended to be lower (6.0% vs. 8.5%, p = 0.053) and V70Gy was significantly lower (1.5% vs. 4.0% p = 0.009) in the VMAT group. **Conclusion:** Although VMAT increased the low dose area to the lungs, it could reduce the high dose area and could be performed without increasing RP for relatively larger PTVs in Asians.

Keywords: volumetric modulated arc therapy, Radiation pneumonitis

P1.18-23 USE OF PERFUSION SPECT TO PRESERVE FUNCTIONAL LUNG IN RADIOTHERAPY FOR NON-SMALL-CELL LUNG CANCER (NSCLC) PATIENTS

S. Ramella, C. Greco, E. Ippolito, M. Fiore, S. Gentile, M. Miele, R. D'Angelillo

Radiotherapy, Campus Bio-Medico University, Via Alvaro del Portillo (RM)/Italy

Background: Radiation treatment related pneumonitis (RP), is one of the most common dose-limiting adverse effects of treatment. The rate of G3 or higher pneumonitis was reported in literature in the range of 8%- 11% with the 3D Conformal Radiotherapy (3DCRT). Lung perfusional imaging, such a SPECT, can reflect patient pulmonary function as the perfused areas could coincide with the functional sites. It is possible identify and used different functional regions in treatment planning, using co-registered SPECT images, in order to reduce the radio-induced damage or consent dose escalation. In this study we explore the adaptive approach on organ at risk, using lung functional imaging (SPECT) to guide the dose distribution in lung cancer radiotherapy treatment plans. **Method:** Patients with medically operable stage II-III A-B, undergoing neoadjuvant chemo-radiotherapy from April to December 2017, were included in this dosimetric study. Lung perfusion SPECT images were performed within a week before radiotherapy. The CT and SPECT scans were co-registered. Functional lung volumes were classified in three groups according to their relative tracer uptake in SPECT/CT images: Low Perfusion (LP) (0-40%), Medium Perfusion (MP) (40-70%) and High Perfusion (HP) (70-100%). Two different 3D-conformal plan, with co-planar e non co-planar fields, were generated, in a photon regimen with 6/15 MV nominal energies. The first plan was created without function Lung information (Anatomic Plan, A) the other one using the functional data (Functional Plan, F). Each plan was performed with Varian Eclipse treatment plan System and calculated with Anisotropic Analytical Algorithm (version 10.0.28). To estimate difference between dose coverages, 3 variables were reported, PTV minimum dose, $D_{min,}$ as the minimum dose to the PTV, Conformity Index (CI) as ratio between the volume covered by isodose of 95% and the PTV Homogeneity Index (HI), as the ratio between the maximum dose in the PTV and the prescription dose. Paired t-test was performed to assess differences between groups. **Result:** Eighteen plan were available for analysis (nine patients included). The median volume of PTV was 156 cm^3 (88.8 cm^3- 253.5 cm^3), the median volume of Whole Lung was 3767 cm^3. Most of patients had Low Perfusional areas or perfusion defects in PTV region (64%) or near this area (22%). The functional plans produced a significant reduction of dose in HP areas, in particular the reduction of HPV_{20Gy} values ranging from 15% to 8% (p=0,046), while the $ipsiHPV_{20Gy}$ was reduced by an average of 38% to 22% (p=0,028) and $ipsiHPD_{mean}$ reduction varied between 16Gy and 12Gy (p=0,039). There were no significant differences for Dmean, V38Gy and V42Gy of Heart and Dmean, V35Gy and V50Gy of Esophagus and Dmax of Spinal Canal PTV's Homogeneity and Conformity Index. **Conclusion:** Our results seem to suggest a benefit to use functional imaging in the treatment planning. With Functional Plans, it is possible to avoid HP areas and reduce dose in the HP regions of healthy Lung, especially in homo-lateral lung. This goal is achieved without worsening in OAR irradiation, and with comparable PTV coverage regardless of the technique applied. Further studies are needed in this setting.

P1.18-24 NEOADJUVANT THERAPY VERSUS UPFRONT SURGERY FOR NSCLC PATIENTS WITH CLINICALLY SUSPECTED SUBAORTIC OR PARAAORTIC LYMPH NODES

J. Lee, S. Shin, J.H. Cho, H.K. Kim, Y.S. Choi, J.I. Zo, Y.M. Shim, J. Kim

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: Subaortic lymph nodes (#LN5) and para-aortic lymph nodes (#LN6) cannot be accessed by routine mediastinoscopy and E(B)US-FNA but need additional invasive surgical staging methods such as VATS or anterior mediastinotomy. Therefore, a considerable number of patients with suspected #LN5 or #LN6 receive multimodal treatment or, upfront surgery based on imaging staging only. We investigated survival outcomes of each therapeutic strategy. **Method:** An institutional lung cancer database of consecutive patients between 2007 and 2016 (N=134) was reviewed retrospectively. Eligible patients had pathologically confirmed non-small cell lung cancer with clinically suspected #LN5 or #LN6 involvement by CT or PET-CT without clinical or pathological evidence of other N2 station involvement. Excluded are those with involvement of other N2 stations, unexpected N2, low grade malignancy, and prior history of cancer. Patients in group 1 received neoadjuvant therapy followed by surgery (n=68) and those in group 2 underwent upfront surgery (n=66). **Result:** Group 1 consisted of patients with clinically suspected (n=39, 57%), and biopsy-proven #LN5 or #LN6 (n=29, 43%) by VATS (n=19), anterior mediastinotomy (n=6), or EUS-FNA (n=4). They received preoperative chemoradiation (n=62, 91%) and the rest received chemotherapy (n=6, 9%). Nodal down-staging was occurred in 36 (53%) patients whereas persistent N2 in 32 (47%). On the contrary, group 2 consisted of patients with clinically suspected #LN5 or 6 (n=66). After surgery, 30 (45%) patients were confirmed to have pathologic N0 or N1. The rest 36 (55%) patients were confirmed pathologic N2, and 29 (81%) of them received adjuvant therapy: chemoradiation in 23, and chemotherapy in 6. Overall survival rate at 5-year (5YOS) were 50.5% in group 1 versus 58.9% in group 2 (p=0.55); recurrence-free survival at 5-year (5YRFS) was 42.2% versus 46.7% (p=0.98), respectively. In subgroup, the 5YOS were 44.6% in pathologic N2 in group 2, which were similar to persistent N2 (52.8%, p=0.6), down-staged (49.2%, p=0.89), or biopsy-proven N2 (57.8%, p=0.54) in group 1. The 5YRFS were 26.7% in pathologic N2 in group 2, which were similar to persistent N2 (30.3%, p=0.89) and biopsy-proven N2 (43.9%, p=0.15), but lower than down-staged (53%, p=0.03) in group 1. **Conclusion:** Upfront surgery or omission of invasive mediastinal staging for #LN5 or 6 may not compromise survival outcomes. Each therapeutic strategy is effective in terms of oncologic outcomes.

P1.18-25 THE IMPACT OF RADIATION PNEUMONITIS ON PROGNOSIS OF PATIENTS WITH LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER TREATED WITH CHEMORADIOTHERAPY

T. Akita[1], K. Baba[1], H. Tanaka[1], I. Fujioka[1], S. Suzuki[1], C. Tabe[1], T. Shiratori[1], Y. Ishioka[1], M. Itoga[1], K. Taima[1], J. Yokouchi[2], Y. Hasegawa[2], S. Takanashi[3], S. Tasaka[1]

[1]*Hirosaki University Graduate School of Medicine, Hirosaki/Japan,* [2]*Aomori Prefectural Central Hospital, Aomori/Japan,* [3]*Hirosaki University, Hirosaki/Japan*

Background: Concurrent chemoradiotherapy (CRT) is the standard treatment for patients with locally advanced non-small cell lung cancer (LA-NSCLC). The radiation pneumonitis after CRT is one of the most serious problems in clinical practice. Moreover, the prognosis of the patients with driver mutation who received CRT remains unclear. **Method:** The medical records of LA-NSCLC patients treated with CRT at Hirosaki University Hospital and Aomori Prefectural Central Hospital between January 2008 and June 2018 were reviewed. This study was approved by the ethics committee of Hirosaki University Graduate School of Medicine (No. 2018-1157). **Result:** A total of 257 patients were enrolled. The median age was 67 years (range, 36-84). One hundled six patients (41.2%) had adenocarcinoma, 130 (50.6%) squamous cell carcinoma, and 21 (8.2%) NSCLC not otherwise specified. Response rate was 79.4%. Median progression free survival (PFS) was 13.6 months (95%CI: 11.3-17.8 months) and median overall survival (OS) was 64.2 months (95%CI: 47.5-122.5). There was no difference in PFS between the histological subtypes. Thirteen patients had EGFR mutation. The median PFS after CRT was not significantly different between EGFR mutant and wild type (9.0 vs 11.9 months, p= 0.831). The 2- and 5-yrear OS rate was 66.4% and 47.5%, respectively. Pneumonitis within 42 days after CRT was observed in 84 patients (32.7%), of whom 28 (10.9%) showed grade 3 or over. After 42 days of CRT, 133 patients (51.8%) developed pneumonitis. The patients with radiation pneumonitis within 42 days after CRT had a significantly shorter OS than those who developed pneumonitis after 42 days (38.6 vs 122.5 months, p=.0002). Pulmonary emphysema and fibrosis on baseline CT were correlated with radiation pneumonitis of grade 3 or more. Radiation over 60 Gy significantly prolonged OS than the lower dose (median OS: 64.3 vs 10.1 months, p=0.0002). **Conclusion:** Early pneumonitis after CRT might be suggestive of a poor prognosis, and the EGFR mutation status might not affect PFS after CRT.

P1.18-26 PRETREATMENT RISK FACTORS FOR POSTOPERATIVE PULMONARY COMPLICATION AFTER NEOADJUVANT CONCURRENT CHEMORADIOTHERAPY FOR NSCLC

W.S. Yu[1], J.W. Suh[2], C.Y. Lee[2], J.G. Lee[2], D.J. Kim[2], H.C. Paik[2], K.Y. Chung[2], S.Y. Park[2]

[1]*Ajou University School of Medicine, suwon/Korea, Republic of,* [2]*College of Medicine, Yonsei University, Seoul/Korea, Republic of*

Background: An occurrence of postoperative pulmonary complication (PPC) after neoadjuvant concurrent chemoradiotherapy (CCRT) might be fatal. It is important to stratify the risk of PPCs before the beginning of CCRT to decide treatment plans. This study is performed to investigate characteristics and pretreatment risk factors for PPCs after neoadjuvant CCRT in patients with non-small cell lung cancer (NSCLC). **Method:** We retrospectively reviewed 95 patients who received curative resection after neoadjuvant CCRT for NSCLC from 2007 to May 2018. Data of pulmonary function test and body mass index (BMI) at the time of the beginning of CCRT were used. **Result:** The mean age was 59.6 ± 9.7, and male patients were 69.5%. Twenty-one patients suffered from PPCs more than grade II. Pneumonia/adult respiratory distress syndrome (n=13) is the most common PPCs following bronchopleural fistula (n= 6) and atelectasis (n=4). Patient with PPCs had significantly longer hospital stay (with Vs without PPCs, median 8 days [Interquartile range {IQR}, 6-10] vs. 17 days [IQR, 9.5 – 30.5], p<0001), and more operative mortalities (0 % vs. 38.1 %, p<0.001). In multivariate analysis, Age-adjusted charlson comorbidity index score (CCI) (Odd ratio [OR] = 2.967, p=0.002), lower diffusing capacity for carbon monoxide (DLCO) (%) (OR = 0.939, p=0.017), and lower BMI (OR, 0.612, p = 0.006) were adverse risk factors for PPCs (concordance index 0.897).

Multivariate logistic regression analysis for PPCs

	OR (95 CI)	p value
Male	15.136 (0.059 – 3876.117)	0.337
Age-adjusted CCI	2.967 (1.488 – 5.914)	0.002
Smoking	0.085 (<0.001 – 21.643)	0.383
FEV1 (%)	0.973 (0.930 – 1.019)	0.248
DLCO (%)	0.939 (0.892 – 0.989)	0.017
BMI (kg/m^2)	0.612 (0.433 – 0.867)	0.006
C index	0.897 (0.818 – 0.976)	

Conclusion: Age-adjusted CCI, lower DLCO, and lower BMI were related to PPCs in patients with NSCLC treated neoadjuvant CCRT and surgery. These risk factors should be considered when to decide neoadjuvant CCRT.

P1.18-27 CHEMORADIOTHERAPY OF INOPERABLE NON-SMALL CELL LUNG CANCER (NSCLC) WITH IGRT TECHNIQUE USING TOMOTHERAPY HD

M. Zemanová, S. Hloušek, R. Jirásková, P. Zemanová, J. Končeková, B. Pejchalová, T. Kohlová, L. Petruželka

First Medical Faculty and General University Hospital in Prague, Prague/Czech Republic

Background: Concurrent chemoradiotherapy (CCRT) of locally advanced NSCLC is considered a standard of care last two decades without important improvement except of adjuvant check-point inhibitor therapy. We present one-institutional results of chemoradiotherapy of inoperable NSCLC using daily 3D IGRT with TomoTherapy HD unit. **Method:** A total of 39 patients with inoperable NSCLC staged by UICC7 and treated since April 2015 till September 2018 were included. Clinical data and radiation plans were retrospectively reviewed. Survival was analysed using Kaplan-Meier method, univariate analysis was done using Cox regression model. Our preferential chemotherapy regimen was cisplatin/vinorelbine three-weekly, carboplatin doublet with vinorelbine or paclitaxel was acceptable as well. Standard radiation dose was 66Gy/33fractions/6.5 weeks, daily MVCT was done. Minimal and median follow-up was 7/30 months, respectively. **Result:** Patient characteristics were as follows: mean age 66 years, male 46%, stage II+IIIA/IIIB/locoregional recurrences 44%/33%/23%, respectively. PET/CT was done in 77% of patients. Histology: adenocarcinoma 41%, squamous 38.5%, NOS 20.5%. All patients had chemotherapy, 59% cisplatin-based, 41% carboplatin-based, full radiation dose of 66Gy was delivered to 69% of patients, mean size of PTV was 366ml. CCRT had 69% patients. Subsequently, only one patient passed radical surgery, check-point inhibitors were used in 5 patients as second line palliative therapy. We observed low treatment toxicity, radiation esophagitis grade 1-2 in 64%, grade 3 in one patient. Radiation pneumonitis of grade 1-2 started in 13% of patients. Median survival and median time to progression (TTP) was 35.3 and 22.3 months, 2-year survival and TTP 63% and 44%, respectively. The reason of progression was mainly distant metastases alone (26%) or with locoregional failure (15%). Only locoregional progression occurred in 8% of patients. Univariate analysis did not find any difference in survival or TTP by age, gender, tumour location, regimen and length of chemotherapy, or concurrent treatment delivery. Non-significant trend of better outcome of stage II+IIIA, squamous cancer, higher dose of radiation and shorter interval between chemotherapy and radiotherapy start was observed. Only significant variable was size of PTV. With cut-off 440ml the patients having greater size of PTV had significantly worse survival in compare with those with smaller one (HR 4.209, 95%CI: 1.519;11.665). **Conclusion:** Chemoradiation of inoperable NSCLC with IGRT technique using TomoTherapy HD has excellent results with 77% of durable local control, 63% of 2-year survival and nearly 3-year median survival. Only negative prognostic factor was higher size of PTV.

P1.18-28 SALVAGE SURGERY FOR RESIDUAL LESION/ LOCAL REPROGRESSION AFTER INITIAL MEDICAL TREATMENT IN ADVANCED NON-SMALL CELL LUNG CANCER

K. Nakanishi, H. Kuroda, T. Matsui, S. Shirai, H. Ueno, N. Sakakura

Aichi Cancer Center Hospital, Nagoya/Japan

Background: There is no clear definition of salvage surgery, although the numbers of reports according to salvage surgery in non-small cell lung cancer (NSCLC) have been recently increasing. **Method:** A total of 29 patients underwent lung resection for residual lesion or local reprogression after definitive chemoradiotherapy (median 60Gy) (dCRT) or after systemic chemotherapy (CTx) and/or tyrosine kinase inhibitor (TKI) in our department between January 2005 and March 2019. Among them, the surgeries for small cell lung cancer (6 patients) and post-treatment complications (3 patients) were excluded. We divided the remaining 20 patients into the following two groups: dCRT in 11 patients and CTx/TKI in 9 patients. We evaluated the clinicopathological findings and surgical outcomes in both groups to assess the perioperative safety and survival benefit of these salvage surgeries. **Result:** The median age was 58 years (range, 38-72) in dCRT (male 7, female 4), whereas the median age was 68 years (range, 49-80) in CTx/TKI (male 3, female 6). The majority of clinical stage before initial treatment was stage III in dCRT (91%). In contrast, that was stage IV in CTx/TKI (56%). The median interval between initial treatment and salvage surgery was 20 months (range, 8-119) in dCRT and 31 months (range 4-93) in CTx/TKI (P = 0.94). There was no significant difference in the proportion of lobectomy/pneumonectomy; 8 patients (73%) in dCRT and 5 patients (56%) in CTx/TKI, respectively (P = 0.64). Combined resection with adjacent organ was required more frequently in dCRT than in CTx/TKI (64% vs 0%, P = 0.005). The median operative time was significantly longer in dCRT compared to CTx/TKI (333 min vs 213 min, P = 0.038). The median blood loss was more in dCRT than in CTx/TKI (220 mL vs 90 mL), but the difference was not statistically significant (P = 0.37). Postoperative complications (≧grade II in Clavien-Dindo classification) were significant more frequently observed in dCRT than in CTx/TKI (46% vs 0%, P = 0.038). Perioperative mortality was 0% in both groups. Three-year overall survival was 71% in dCRT and 58% in CTx/TKI (P = 0.38), and 3-year disease-free survival was 62% in dCRT and 39% in CTx/TKI (P = 0.59), respectively. In both groups, 3-year disease-free survival were significantly worse in patients with ypN positive compared to

in patients with ypN negative (in dCRT, 0% vs 76%, $P < 0.001$; in CTx/TKI, 0% vs 53%, $P = 0.017$). **Conclusion:** Although there was limited data, salvage surgery after dCRT or CTx/TKI was associated with acceptable operative mortality and morbidity, and favorable long-term outcomes in highly selected patients. Postoperative N status might potentially be a poor predictive factor for disease-free survival.

Background: Most patients (pts) with non-small cell lung cancer (NSCLC) present with advanced disease at diagnosis. Despite initial response to platinum-based doublet chemotherapy, an established first-line treatment for pts with advanced NSCLC whose tumours do not have *EGFR*, *ALK*, or *ROS 1* mutations, pts often progress and require additional treatment options. In recent years, anti-programmed death-1 (anti–PD-1) therapies have emerged as an effective treatment option for advanced NSCLC, potentially allowing some patients with PD-L1 expression ≥50% to avoid chemotherapy. However, there is currently only one PD-1 inhibitor approved as monotherapy in first-line treatment of NSCLC. In a Phase 1 trial of pts with advanced malignancies, including NSCLC, cemiplimab exhibited anti-tumour activity with a safety profile similar to those described for other anti–PD-1 agents. Cemiplimab-rwlc is the only Food and Drug Administration-approved treatment for patients with advanced cutaneous squamous cell carcinoma. **Method:** This is a randomised (1:1), multicentre, open-label, Phase 3 study of cemiplimab versus platinumbased doublet chemotherapy in systemic treatmentnaïve pts (≥18 years) with stage IIIB, IIIC or IV squamous or nonsquamous NSCLC whose tumours express PDL1 in ≥50% of tumour cells (NCT03088540). Pts will be stratified by histology and geographic region. Pts will receive cemiplimab 350 mg every 3 weeks intravenously (for up to 108 weeks) or 4–6 cycles chemotherapy with (i) paclitaxel + cisplatin or carboplatin, (ii) pemetrexed + cisplatin or carboplatin with or without pemetrexed maintenance, (iii) or gemcitabine + cisplatin or carboplatin. Crossover from chemotherapy to cemiplimab and addition of chemotherapy to cemiplimab at the time of disease progression is allowed. The primary objective is to evaluate progression-free survival (PFS) as determined by blinded independent review committee. Key secondary objectives include assessment of overall survival and objective response rate. An independent data monitoring committee will monitor safety data during study conduct. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Overexpression of interleukin (IL)-1β has been described in solid tumors, including lung. IL-1β can promote angiogenesis, tumor invasiveness, and induces tumor-associated immunosuppression through myeloid-derived suppressor cell (MDSC) accumulation in tumors. Pre-clinical data has shown that IL-1β inhibition reduced tumor growth, by limiting pro-tumorigenic inflammation and polarization of MDSCs into M1 phenotype. Canakinumab is a human monoclonal antibody with high affinity and specificity for IL-1β. Recently, it was found that canakinumab was associated with a significant and dose-dependent reduction in incidence and mortality from lung cancer based on CANTOS study. **Method:** CANOPY-A (NCT03447769) is a phase III, randomized, double-blind, placebo-controlled study designed to evaluate efficacy and safety of adjuvant canakinumab versus placebo in patients with surgically resected NSCLC. This trial will enroll adult patients, with completely resected (R0) AJCC/UICC v.8 stages II-IIIA and IIIB (T >5 cm and N2) NSCLC, who have completed standard-of-care adjuvant treatments, including cisplatin-based chemotherapy and mediastinal radiation therapy (if applicable). Prior treatment with neoadjuvant chemotherapy or neoadjuvant radiotherapy is not permitted. Approximately 1500 patients will be randomized 1:1 to receive canakinumab (200 mg Q3W, s.c) or placebo (Q3W, s.c.) for 18 cycles or until disease recurrence, unacceptable toxicity, treatment discontinuation at the discretion of the investigator or patient, death, or loss to follow-up. Randomization will be stratified by AJCC/UICC v.8 stage, tumor histology, and region. The primary objective is disease-free survival, per investigator assessment. Secondary objectives include overall survival (key secondary objective), lung cancer-specific survival, safety, pharmacokinetics and immunogenicity of canakinumab, and patient-reported outcomes. Enrollment is ongoing.CANOPY-A (NCT03447769) is a phase III, randomized, double-blind, placebo-controlled study designed to evaluate efficacy and safety of adjuvant canakinumab versus placebo in patients with surgically resected NSCLC. P2.01-03 TUMOR TREATING FIELDS PLUS STANDARD OF CARE TREATMENT IN STAGE 4 NON-SMALL CELL LUNG CANCER (NSCLC): PHASE 3 LUNAR STUDY

U. Weinberg, O. Farber, M. Giladi, Z. Bomzon, E. Kirson

Novocure, Haifa/Israel

Background: Tumor Treating Fields (TTFields) are a non-invasive, anti-mitotic treatment that disrupts the formation of the mitotic spindle and dislocation of intracellular constituents. TTFields plus temozolomide significantly extended survival in newly diagnosed glioblastoma. Efficacy of TTFields in NSCLC has been shown in preclinical models. Safety of TTields in combination with pemetrexed has been reported in a phase 2 clinical study. Robust efficacy of concurrent application of TTFields and anti PD-1 therapy has been demonstrated in a mouse model of lung cancer. These data suggest that combining TTFields with anti-PD-1 may achieve tumor control by further enhancing antitumor immunity. In this Phase 3 LUNAR study [NCT02973789], we investigated if the addition of TTFields to immune checkpoint inhibitors or docetaxel increases overall survival (OS). **Method:** Patients (N=534), with squamous or non-squamous NSCLC, are stratified by their selected standard therapy (immune checkpoint inhibitors or docetaxel), histology and geographical region. Key inclusion criteria are disease progression, ECOG 0-2, no electronic medical devices in the upper torso, and absence of brain metastasis. TTFields (150 kHz) are applied to the upper torso for ≥18 hours/day until progression in the thorax and/or liver. The primary endpoint is superiority in OS between patients treated with TTFields in combination with the standard of care treatments versus standard of care treatments alone. Key secondary endpoints compare the OS in patients treated with TTFields and docetaxel versus docetaxel alone, and patients treated with TTFields and immune checkpoint inhibitors vs those treated with immune checkpoint inhibitors alone. An exploratory analysis will test non-inferiority of TTFields with docetaxel compared to checkpoint inhibitors alone. Secondary endpoints include progression-free survival, radiological response rate, quality of life based on the EORTC QLQ C30 questionnaire. The sample size is powered to detect a HR of 0.75 in TTFields-treated patients versus control group. In January 2019, an independent Data Monitoring Committee (DMC) performed a review of the LUNAR trial data collected to that point. The DMC concluded that no unexpected safety issues could be found in patients treated with the combination of immune checkpoint inhibitors and TTFields, and recommended continuation of the LUNAR study as planned. **Result:** “Section not applicable” **Conclusion:** “Section not applicable”

P2.01-04 NCI-NRG ONCOLOGY ALK PROTOCOL (NRG-LU003): A BIOMARKER-DRIVEN PROTOCOL FOR PREVIOUSLY TREATED ALK-POSITIVE NON-SQUAMOUS NSCLC PATIENTS

S. Malik[1], C. Hu[2], A. Shaw[3], E. Korn[1], A. Tsao[4], R. Doebele[5], T. Stinchcombe[6], C. Lovly[7], J. Bradley[8]

[1]*National Cancer Institute/NIH, Rockville/United States of America,* [2]*The Johns Hopkins University School of Medicine, Baltimore/United States of America,* [3]*Massachusetts General Hospital, Boston/United States of America,* [4]*MD Anderson Cancer Center, Houston/United States of America,* [5]*University of Colorado Denver, Aurora/United States of America,* [6]*Duke University, Durham/United States of America,* [7]*Vanderbilt University Medical Center, Nashville/United States of America,* [8]*Washington University School of Medicine, Saint Louis/United States of America*

Background: Currently, the 1st generation ALK inhibitor crizotinib and 2nd generation ALK inhibitors ceritinib, alectinib and brigatinib are FDA-approved for the treatment of advanced ALK-positive NSCLC. The 3rd generation ALK inhibitor *lorlatinib* recently received accelerated approval for patients after failure of a 2nd generation inhibitor. 2nd generation ALK inhibitors are widely used in crizotinib-resistant patients and have recently replaced crizotinib as first-line therapy for newly diagnosed patients. There is an urgent need to define the optimal therapy for patients who have become resistant to a second-generation ALK inhibitor. Pre-clinical data and small case series suggest that the presence/absence of ALK resistance mutations or the specigic ALK mutation may serve as a critical biomarker to guide selection of therapy, particularly in the setting of relapse on a 2nd generation ALK inhibitor when ALK resistance mutations are more common, **Method:** NRG-LU003 proposes to study ALK-positive non-squamous NSCLC patients who develop resistance to a second-generation ALK inhibitor, in order to establish a treatment algorithm for these patients based on resistance mechanisms.Patients will undergo tissue biopsy along with blood sampling for cfDNA analysis. One of the aims of the study is to establish the concordance between tissue and liquid biopsies; liquid biopsy may replace tissue biopsy after the first 200 patients enrolled, depending on the concordance and in consultation with CDRH/FDA. Treatments will be selected based on preclinical and clinical data demonstrating activity of treatment particular inhibitor against the specific ALK mutation or resistance mechanism identified. If no ALK resistance mutations are identified, patients will be randomized to receive either a next-generation ALK inhibitor they have not previously received or pemetrexed-based therapy with cisplatin or carboplatin. Target accrual is 660 patients and primary objective is to assess whether ALK kinase domain mutations (e.g., G1202/C1156/I1171/L1196/V1180/F1174 mutations) associated with drug resistance are predictive of objective response to subsequent ALK inhibitor therapy, to assess whether subsequent pemetrexed based chemotherapy improves objective response compared to ALK inhibitor therapy for patients with no ALK resistance mutations, and to evaluate objective responses of patients with specific genetic alterations (e.g., ALK L1198F, compound mutations, or high-level *MET* amplification) treated with crizotinib.

P2.01-05 MAGELLAN: PHASE 1B STUDY OF DURVALUMAB WITH NOVEL ONCOLOGY THERAPIES, WITH/WITHOUT CHEMOTHERAPY, IN UNTREATED STAGE IV NSCLC

S. Patel[1], Y. Liu[2], E. Grainger[3], Z. Rasheed[2], T. Improta[3]

[1]*UC San Diego Moores Cancer Center, La Jolla/United States of America,* [2]*AstraZeneca, Gaithersburg/United States of America,* [3]*AstraZeneca, Cambridge/United Kingdom*

Background: Immunotherapy with anti-PD-1/PD-L1 antibodies, with or without chemotherapy, is the standard of care in the first-line (1L) treatment for metastatic NSCLC. Despite advances, patients treated with anti-PD-1 directed regimens in metastatic NSCLC have demonstrated median PFS of <1 year. Targeting novel mechanisms in the tumor may improve response rates and survival. For example, danvatirsen is an antisense oligonucleotide that downregulates *STAT3*, a master regulator of immune suppression, and oleclumab is an anti-CD73 monoclonal antibody that alleviates adenosine-mediated immunosuppression. MAGELLAN is a Phase 1B, open-label, multicenter, biomarker-enriched, multicohort study (NCT03819465), designed to assess the safety and efficacy of durvalumab in combination with novel oncology therapies (danvatirsen, oleclumab), with or without chemotherapy, as 1L treatment for patients with Stage IV NSCLC. Additional novel therapies will be added to this study as supportive preclinical/clinical datasets emerge. **Method:** Adult patients with Stage IV NSCLC (histologically/cytologically documented), tumors lacking activating *EGFR* mutations and *ALK* rearrangements, WHO/ECOG PS 0–1, and no prior chemotherapy or systemic therapy for Stage IV NSCLC are eligible. Eligible patients will be assigned to the PD-L1 tumor cell (TC) ≥50% or PD-L1 TC<50% cohorts, as confirmed by the VENTANA PD-L1 (SP263) Assay. Immunohistochemical staining with the SP263 assay is concordant with that for the 22C3 assay, another PD-L1 diagnostic assay. Patients in the PD-L1 TC≥50% cohort will be assigned to durvalumab monotherapy (1500 mg q4w), durvalumab+danvatirsen, or durvalumab+oleclumab. Patients in the PD-L1 TC<50% cohort will be assigned to durvalumab+chemotherapy (1500 mg durvalumab q3w up to 4 cycles [+chemotherapy], then q4w [–chemotherapy]), durvalumab+chemotherapy+danvatirsen, or durvalumab+chemotherapy+oleclumab. All therapy will be administered intravenously until disease progression. Oleclumab (1500 mg starting dose) and danvatirsen (200 mg starting dose) in combination with durvalumab or durvalumab+chemotherapy will be administered using a rolling 6-patient design to evaluate for toxicity. The chemotherapy backbone for use with immunotherapy, per investigator's choice, will be nabpaclitaxel+carboplatin for squamous and non-squamous NSCLC, gemcitabine+cisplatin/carboplatin for squamous NSCLC, and pemetrexed+carboplatin/cisplatin for non-squamous NSCLC. Patients receiving pemetrexed+carboplatin/cisplatin who do not progress after 4 cycles of chemotherapy will receive pemetrexed maintenance therapy and immunotherapy, unless contraindicated. The primary endpoint is safety and tolerability. Secondary endpoints are objective response rate and PFS (both RECIST v1.1), duration of response, OS, and pharmacokinetics and immunogenicity of durvalumab, oleclumab, and danvatirsen. Identification of candidate biomarkers from blood and tissue samples that may correlate the likely clinical benefit with the treatments under investigation will also be explored. Enrollment is ongoing. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Cancer-associated fibroblasts (CAFs) in the tumor microenvironment (TME) inhibit tumor infiltrating lymphocyte activation and are potentially immunosuppressive. Targeting the TME may represent an important synergistic approach in immunotherapy (IO). Combination IO with nivolumab and ipilimumab has proven clinical activity in NSCLC. Nintedanib is an orally available triple kinase inhibitor that is active against NSCLC, inhibits CAFs, and targets VEGFR, FGFR and PDGFR. We report the preliminary results of a phase 1 dose escalation trial evaluating the combination of nintedanib with nivolumab and ipilimumab (N+N+I) in advanced NSCLC pts. **Method:** This is single center, investigational, non-randomized trial of IO naïve or IO pretreated pts with locally advanced or metastatic NSCLC. Primary endpoint is to determine the safety and tolerability of concurrent administration of the proposed regimen. Key secondary endpoints include RR, DOR, OS, PFS. Five dose levels of nintedanib (dose level -1, 0, 1, 2 and 3 with nintedanib given at dose 100 mg once daily,150 mg once daily and 100mg, 150 mg and 200 mg twice daily respectively) are given with fixed dose of nivolumab (3mg/kg every 2 weeks) and ipilimumab (1mg/kg every 6 weeks). Dose escalation was achieved by the 3+3 design. Blood and tumor biopsies are obtained to evaluate potential predictive and resistance mechanisms. **Result:** Enrollment to phase I dose escalation was started on 29th January 2018 and to date 13 patients have been treated on dose level -1 (3), 0 (5) and 1(5). 54% (7) were IO pretreated and 46% (6) were IO naive. Median age is 65 with 62% (8) female patients, ECOG 1 62% (8) and 15% (2) never smoker/ 85% (11) prior or current smokers. Most common AE of any grade were transaminitis and rash in 23% (3). Most G3 AE was transaminitis 8% (1). There were no G4/5 AEs or DLTs. There was no treatment discontinuation due to AEs. PD-L1 expression was < or = 1% in 46% (6), 1-49% in 8% (1) and >/= 50% in 46% (6) pts. Amongst the 12 patients evaluable for confirmed response, 17% (2) had PR, 50% (6) had SD and 33% (4) had PD. In the IO pretreated group, 14% (1) had PR, 57% (4) had SD and 28% (2) had PD. **Conclusion:** The combination of N+N+I was well tolerated. The regimen demonstrates antitumor activity despite progression on prior IO. The updated and mature data of the phase I dose escalation trial will be presented at the meeting. Clinical trial information: NCT03377023.

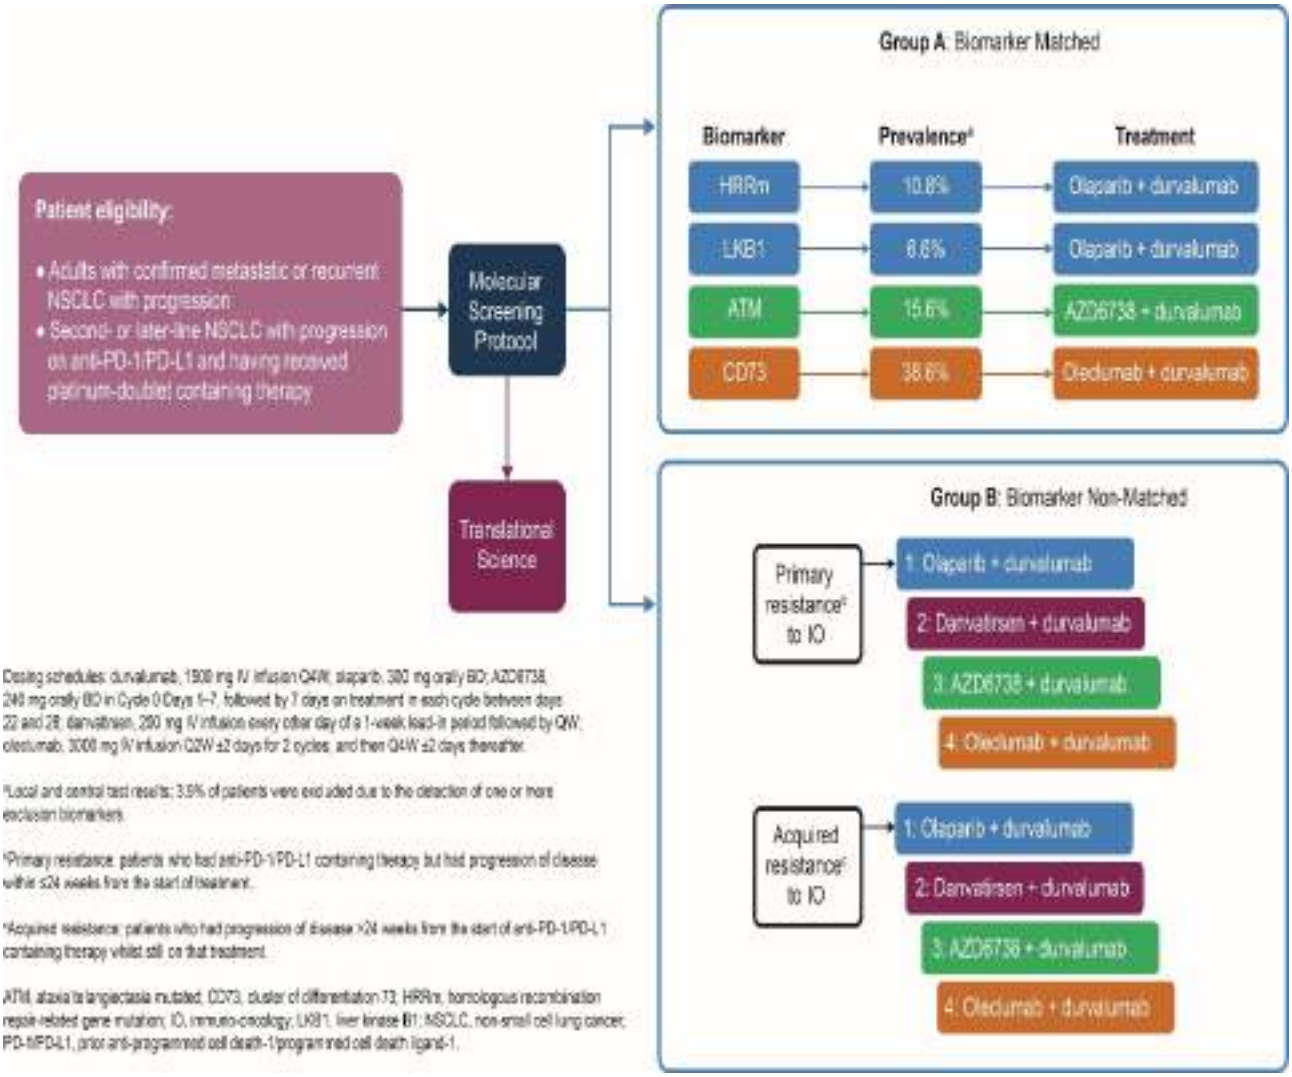
Background: Immune checkpoint inhibitor (ICI)-containing regimens have significantly improved survival outcomes in first- and second-line non-small cell lung cancer (NSCLC). However, few patients have-durable responses to anti-programmed cell death1/ programmed cell death-ligand 1 (anti-PD-[L]1)-containing therapy (primary resistance) or other patients progress during anti-PD-(L)1-containing therapy (acquired resistance). HUDSON addresses the urgent need to identify new treatments and understand ICI resistance for patients who progressed after receiving anti-PD-(L)1-containing therapy. **Method:** HUDSON is a multi-centre, international, multi-arm, platform study (NCT03334617), which will 1) evaluate therapies to reverse ICI resistance and 2) define mechanisms of ICI resistance in patients with NSCLC who have progressed following standard-of-care platinum- and ICI-based therapies. HUDSON consists of biomarker matched and non-matched groups (Figure). Allocation is guided by tumour molecular profile, using a pre-specified algorithm. Pre-existing local next generation sequence (NGS) data enables rapid patient allocation to biomarker-matched groups. Central molecular profiling comprises NGS and immunohistochemistry data. New groups will be added as new translational hypotheses emerge. Translational research will employ serial peripheral blood samples (including ctDNA) and tumour biopsies. Figure. Study design and biomarker prevalence



Dosing schedules: durvalumab, 1500 mg IV infusion Q4W; olaparib, 300 mg orally BID; AZD6738, 240 mg orally BID in Cycle 0 Days 1–7, followed by 7 days on treatment in each cycle between days 22 and 28; danvatirsen, 200 mg IV infusion every other day of a 1-week lead-in period followed by Q2W; oleclumab, 3000 mg IV infusion Q2W ±2 days for 2 cycles, and then Q4W ±2 days thereafter.

*Local and central test results; 3.5% of patients were excluded due to the detection of one or more exclusion biomarkers.

†Primary resistance: patients who had anti-PD-1/PD-L1 containing therapy but had progression of disease within ≤24 weeks from the start of treatment.

‡Acquired resistance: patients who had progression of disease >24 weeks from the start of anti-PD-1/PD-L1 containing therapy whilst still on that treatment.

ATM, ataxia telangiectasia mutated; CD73, cluster of differentiation 73; HRRm, homologous recombination repair-related gene mutation; IO, immuno-oncology; LKB1, liver kinase B1; NSCLC, non-small cell lung cancer; PD-1/PD-L1, prior anti-programmed cell death-1/programmed cell death ligand-1.

Result: Enrolment is ongoing; as of 01 April 2019, patients have been dosed in each of the drug combinations currently open for recruitment. Analyses of tissue and blood samples collected for exploratory research are ongoing, including genomic, transcriptomic and chemistry biomarkers such as tumour mutation burden, human leukocyte antigen status, T-cell receptor repertoire, and peripheral immune activation signatures. **Conclusion:** Specific differences between patients on individual HUDSON arms that inform anti-PD(L)1 resistance mechanisms, plus learnings from the implementation of this innovative and complex platform study will be presented.

[1]*Manchester Cancer Research Centre, Manchester/United Kingdom,* [2]*University of Leeds, Leeds/United Kingdom,* [3]*University of Glasgow, Glasgow/United Kingdom,* [4]*Cancer Research UK Manchester Institute, Manchester/United Kingdom,* [5]*Peter MacCallum Cancer Centre, Melbourne/United Kingdom,* [6]*Newcastle University, Newcastle/United Kingdom,* [7]*Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom,* [8]*Patient Representative, UK/United Kingdom,* [9]*University College London Cancer Centre, London/United Kingdom,* [10]*University of Manchester, Manchester/United Kingdom,* [11]*University of Oxford, Oxford/United Kingdom,* [12]*Velindre Cancer Centre, Cardiff/United Kingdom,* [13]*Queens University Belfast, Belfast/United Kingdom,* [14]*University of Sheffield, Sheffield/United Kingdom*

Background: The majority of patients with locally advanced non-small cell lung cancer (NSCLC) treated with curative intent receive radiotherapy (RT) as part of their treatment. Despite considerable technological advances in RT delivery, the survival of these patients has barely changed over the last 60 years. A major factor in this failure to improve outcomes is the relative radioresistance of NSCLC. Attempts to overcome radioresistance by escalating RT doses have demonstrated inferior outcome likely secondary to normal tissue toxicity. Therefore an alternate approach is to exploit genetic dependencies in the DNA damage response of NSCLC, using biological inhibitors to selectively radiosensitise tumours whilst sparing normal tissues. The CONCORDE study is a multi-arm phase 1B platform study to investigate the combination of radical RT with DNA damage response inhibitors (DDR-i) targeting five different proteins: PARP, ATR, WEE1, ATM, DNA-PK. **Method:** CONCORDE is a hypothesis-driven combination study of novel therapeutics and RT using an innovative adaptive early-phase trial design. The study will address two main research questions: - What are the recommended

phase 2 doses (RP2D) of individual DDR-i in combination with curative RT in patients with stage IIB/III NSCLC? - What are the safety profiles of individual DDR-i combined with curative RT in this population? Key inclusion criteria are stage IIB and III NSCLC planned to receive curative intent RT doses (+/- neoadjuvant chemotherapy) and PS 0-1. Participants will be randomised on a 3:1 basis between DDR-i with RT or RT alone. Patients receiving RT alone will be pooled across the arms to provide contemporary data on toxicity. All patients will receive external beam RT with a planned dose of 60 Gy in 30 fractions. The study will use a Bayesian adaptive model-based approach to dose-escalation, with separate Time-To-Event Continual Reassessment Method (TiTE-CRM) models in each experimental arm. The primary endpoints are dose-limiting toxicities occurring within 12 months of the start of radiotherapy. Secondary endpoints include safety and toxicity (acute and late toxicity up to 2 years including using patient reported outcome (PRO) measures), treatment compliance, and best overall response (using RECIST 1.1, progression-free, and overall survival). Correlative studies will be carried out to identify biomarkers of toxicity and response. We have secured high-level agreement from leading pharmaceutical partners to invest in 5 treatment arms and funding approval from Cancer Research UK is pending. The first participant is estimated to commence treatment in late 2019 **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Immunotherapy is recommended as second-line treatment for advanced Non-Small Cell Lung Cancer (NSCLC) progressing after a platinum doublet treatment. However, response rates remain low and some patients have rapid progression. Novel concepts of synergic action between immunotherapy and chemotherapy have emerged recently. Metronomic oral vinorelbine (MOV) is defined as low-dose and frequent chemotherapy administration. There is no data of the association of immunotherapy and metronomic chemotherapy. The main objective of this trial was to assess safety and efficacy of this combination of MVO and atezolizumab. **Method:** An open label phase 2 trial (NCT 03801304) in two steps. -First step: a safety run-in phase: 12 patients will be enrolled and will receive atezolizumab in combination with MOV (40 mg/day 3 times a week, every week). After 12 patients have received study treatment and completed at least 1 cycle of study treatment (21 days), enrollment will be interrupted and an independent Data Safety Monitoring Board (DSMB) will review the number and percentage of adverse events (AEs). The dose will be considered toxic when Grade ≥ 3 immune-related AEs (>20%) or vinorelbine-related AEs (>20%) occurs. In this case the dose will be decreased to 30 mg, 3 times a week. AEs will be assessed with the same procedure that will be applied to the next 12 patients. - Second step: phase II design as defined by A'hern. The main outcome is PFS rate at 4 months. Minimal efficacy hypothesis (p1) is set at 55% event-free rate of PFS at 4 months, (p0), which would indicate that the strategy is clearly ineffective, is set at 40% PFS at 4 months. With a 5% alpha risk (unilateral perspective) and a 20% beta risk, the number of assessable subjects is set at 71. **Result:** The trial started on 2019 January 24th. 12 patients have been included in 4 centers. The run in step ended at the beginning of April, with no grade 3 or more immune related AEs or vinorelbine related AEs. The DSMB decided to expand the study to the second step, which will start on April, 17th. **Conclusion:** Combination of atezolizumab and MOV appears as a feasible association without major toxicities. The phase 2 is ongoing; complementary results on safety and efficacy will be presented at the meeting.

Background: Cancer is a genomic disease and molecular-targeted therapy plays an increasingly important role in the treatment of advanced NSCLC. The current standard of care (SoC) indication for NSCLC is defined by genomic biomarkers to classify the tumor as a carrier of a therapeutic approved target. However, the current standard of practice for molecular testing in NSCLC in Spain is highly heterogeneous, depending on several factors such as hospital size, resources, laboratory equipment and experience. In addition, there are several other markers and/or genomic signatures which are not determined due to the current lack of scientific evidence, i.e. MSI, TMB, KRAS, BRAF, RET, MET, HER2 and NTKR, which could guide physician second line treatment choice, including clinical trial options. The aim of this study is to evaluate the impact on decision making in the 2nd line treatment using a comprehensive genomic profiling (CGP) in advanced/metastatic NSCLC with adenocarcinoma histology. **Method:** Section not applicable **Result:** Section not applicable **Conclusion:** This is a multicenter, prospective, single-cohort study to describe the clinical management of the 2nd line SoC treatment in patients with locally advanced/metastatic NSCLC with adenocarcinoma histology, when a comprehensive genomic profile based on FoundationOne®CDx or FoundationOne® Liquid test, is provided. 12 academic institutions in Spain were selected and 180 patients were planned to be recruited. The principal objective is to evaluate if there is any change in planned 2nd line treatment decisions after receiving the CGP report. Secondary objectives for this study are:1) to identify non-previously detected actionable molecular aberrations by conventional molecular assays; 2) to evaluate the economic impact in terms of use of healthcare resources of the CGP *vs.* standard diagnostic panels; and 3) to describe each patient's status 2 years after the inclusion of the last patient in the study. Patients will follow usual clinical pathways for biomarker analysis and a comprehensive genomic profiling in the remaining tissue through FoundationOne® CDx, will be conducted or liquid biopsy with FoundationOne® Liquid, if exhausted. To be enrolled in the study, patients must have an ECOG between 0 and 2 and biomarkers ALK, EGFR, ROS1 must have been assayed (negative or unknown results). Enrolment begun on October 2018 and, to date, a total of 110 patients have been included.

P2.01-11 ALKTERNATE: A PROOF OF CONCEPT STUDY IN ALK-REARRANGED NSCLC ALTERNATING LORLATINIB WITH CRIZOTINIB AFTER DISEASE PROGRESSION

M. Itchins[1,2,3], S. Hayes[1,2], A. Hudson[1,2], V. Howell[1,2], S.W.D. Tan[4], S. Clarke[1,2,3], B. Solomon[5], N. Pavlakis[1,2,3]

[1]*University of Sydney, St Leonards/Australia,* [2]*Kolling Institute, St Leonards/Australia,* [3]*Royal North Shore Hospital, St Leonards/Australia,* [4]*National Cancer Centre, Singapore/Singapore,* [5]*Peter MacCallum Cancer Center, Melbourne/Australia*

Background: Standard frontline therapy for patients with advanced *ALK*-NSCLC has rapidly evolved to 2nd generation ALK TKIs based on superior survival. Regardless, resistance to treatment is inevitable. Most will receive multiple lines of TKIs +/- chemotherapy before eventually dying from the disease. Lorlatinib is a 3rd generation ALK TKI active against a broad range of acquired ALK kinase domain (KD) resistance mutations. A recent report demonstrated re-sensitisation to crizotinib by the lorlatinib ALK resistance mutation L1198F.

Increased knowledge of resistance mechanisms is key to overcoming and preventing its emergence. Based on knowledge of the varying patterns of resistance to different ALK TKIs, ALKternate will test the hypothesis that treatment with alternating TKIs will re-equilibrate the selection pressure for enrichment of resistant clones. This hypothesis has been tested preclinically in accompanying abstracts #2072 and #2074. **Method:** ALKternate is a proof of concept open label multi-centre translational study alternating lorlatinib (100mg OD) with crizotinib (250mg BD) (Figure 1. including eligibility). The aim is to identify whether this fixed alternating schedule of ALK TKI is: safe; feasible and active, resulting in prolonged systemic and intracranial disease control via delaying the emergence of ALK TKI resistance. A secondary aim is to investigate whether plasma *ALK*-dependent and independent resistance profiles can be used to monitor therapy effectiveness. The primary outcome measure is time to treatment failure (TTTF) with alternating therapy. Secondary end points include best OR, PK analysis, PFS, DCR (systemic and CNS) after lorlatinib induction and the first cycle of alternating therapy, OS, toxicity, PROs and QOL measures. Plasma ctDNA and proteomic biomarkers will be analysed. Enrolled patients must demonstrate disease control after induction lorlatinib to continue alternating therapy. Imaging occurs more frequently initially (Figure 1.), before 12 weekly after two alternating cycles in those with disease control. Status: Trial in Progress. Enrollment began Q3 2019, ethics approval NSLHD ETH00389.

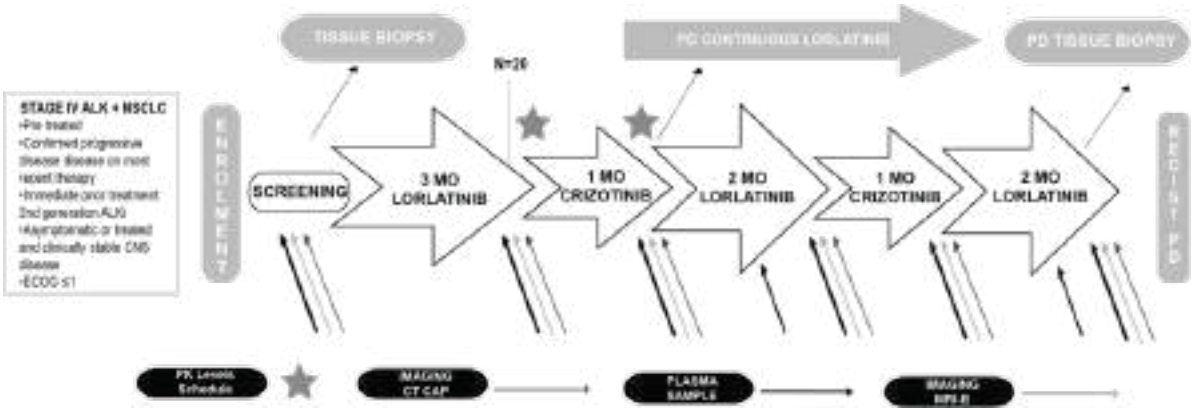

Figure 1. ALKternate trial schema

Background: Immunotherapy has significantly changed the treatment landscape of non-small cell lung cancer (NSCLC) with no driver mutations. However, despite the addition of anti-PD-1/PD-L1 therapies to the clinical armamentarium only a subset of patients derives durable benefit. IO102 is a novel, second generation, HLA-A unrestricted immune modulating T-win® vaccine targeting IDO. IO102 has a dual mode of action; remodulation of the tumour micro-environment through elimination of immune suppressive cells, and induction of CD8 T-cell mediated killing of IDO-expressing tumor cells. Our first-generation IDO vaccine (IO101) has shown promising antitumor activity and a favorable safety in heavily pretreated NSCLC patients (*Iversen, CCR 2013)*. **Method:** Phase I/II, international, multicenter, open-label, randomized trial with two parallel cohorts. Cohort A: IO102 (100µg s.c.) and pembrolizumab (200 mg) (PD-L1 ≥ 50%); Cohort B: IO102, pembrolizumab and carboplatin plus pemetrexed (PD-L1 < 50%). The maximum treatment duration is 35 cycles (app. 2 years). Key eligibility criteria include metastatic NSCLC or non-squamous NSCLC (cohort B) with no prior treatment for metastatic NSCLC and no driver mutations. Phase I is a non-randomized safety run-in with 6 patients per cohort investigating one dose level of the experimental arms. Only one DLT is allowed in each cohort. Phase II is following Sargent's two-stage, three-outcome optimum design (*Sargent, ClinTrial2001*) with a 2:1 randomization in the cohorts. Cohort A: IO102 and pembrolizumab versus pembrolizumab alone; Cohort B: IO102, pembrolizumab and chemotherapy vs. pembrolizumab and chemotherapy. Provision of blood and tumour tissue is required for biomarker studies. The primary endpoint is safety and objective response rate (ORR) per RECIST 1.1 in Phases I and II, respectively. Secondary endpoints include ORR per iRECIST, duration of response, progression free survival, overall survival, and biomarkers including immunoscore in tissue, tumour mutational burden and immunomonitoring in blood. The study is enrolling in Europe. First patient was entered in September 2018 and recruitment is expected to continue throughout 2019: EudraCT Number 2018-000139-28 / IND Number: 018081. **Result:** Section not applicable **Conclusion:** Section not applicable

P2.01-13 THE DAIL TRIAL: DIETETIC ASSESSMENT AND INTERVENTION IN LUNG CANCER

I. Phillips[1], A. Hug[2], L. Allan[2], N. Westran[2], M. Hewish[2], A. Mehta[2], L. Mainsiouw[2], A. Extance[2], B. Smith[2], V. Ezil[2], H. Saxby[2]

[1]*The Edinburgh Cancer Centre, Western General Hospital, Edinburgh/United Kingdom,* [2]*Royal Surrey County Hospital, Guildford/United Kingdom*

Background: Clinical Trial in Progress Lung Cancer related weight loss has a complex aetiology. It includes 3 overlapping but distinct syndromes: cachexia, sarcopenia and malnutrition. ESPEN (European Society for Clinical Nutrition and Metabolism) guidelines suggest that everyone with a new diagnosis of cancer is screened for malnutrition, but there is minimal evidence to support this recommendation. We have opened the DAIL trial to further investigate the proportion of patients with newly diagnosed Non-Small Cell Lung Cancer (NSCLC) who should be referred to a dietitian, and the proportion of patients who had cachexia, sarcopenia and malnutrition. **Method:** Primary objectives are: 1. To identify the proportion of patients diagnosed with NSCLC who are malnourished, cachectic and have sarcopenia before anti-cancer treatment. 2. To identify the proportion of lung cancer patients who would require dietetic review before anti-cancer treatment. Secondary objectives are: 1. To identify whether malnutrition, cachexia or sarcopenia affects overall survival in metastatic NSCLC. 2. To identify whether sarcopenia predicts for a poor outcome in NSCLC. In the study we use patient generated questionnaires, physical assessments and radiological tests to define malnutrition, sarcopenia and cachexia. The specific assessments are: Patient generated subjective global assessment (PG-SGA) G8 EORTC QLQC30 EORTC LC13 Performance status Hand grip strength Spirometry Psoas muscle assessment from diagnostic cross sectional imaging Charlson Co-morbidity Index Inclusion criteria are: Patients >18 years old who are able to consent to entry into a clinical trial Biopsy confirmed Advanced NSCLC (stage IIIb and IV). Patient receiving first line systemic palliative anti-cancer treatment. Exclusion criteria are: Inability to consent to treatment Patient declines anti-cancer treatment **Result:** Section not applicable **Conclusion:** It is anticipated that the results will clarify if a nutritional screening tool such as the PG-SGA can identify patients at risk of malnutrition prior to starting anti-cancer treatment, as well as highlight those who require dietetic intervention. It is hoped that this research will inform a randomised clinical trial of dietetic counselling in lung cancer.

Background: Sitravatinib is a tyrosine kinase inhibitor (TKI) that targets multiple closely-related receptor tyrosine kinases (RTKs), including the split RTKs VEGFR-2 and KIT as well as the TAM (TYRO3, AXL, and MER) RTKs. Inhibition of the split RTKs may reduce immunosuppressive regulatory T (T_{reg}) cells and myeloidderived suppressor cells (MDSCs) within the tumor microenvironment (TME), while inhibition of TAM RTKs may, in addition to promoting depletion of MDSCs, repolarize tumor associated macrophages towards the M1 phenotype that is associated with secretion of pro-inflammatory cytokines. Given these pleiotropic immunestimulating effects, sitravatinib may augment the antitumor immune response of nivolumab in patients (pts) with non-small cell lung cancer (NSCLC). An ongoing Phase 2 study demonstrates clinical activity of this combination in pts with metastatic non-squamous NSCLC after progression on a checkpoint inhibitor (CIT). **Method:** This randomized, open-label, Phase 3 study (N=664) compares the efficacy and safety of sitravatinib in combination with nivolumab vs docetaxel in pts with advanced non-squamous NSCLC who have radiographically documented disease progression on or after platinum-based chemotherapy in combination with CIT. Pts are randomized (1:1) to receive sitravatinib administered orally once daily in continuous 28-day cycles at 120 mg combined with nivolumab IV at 240 mg every 2 weeks or 480 mg every 4 weeks vs treatment with docetaxel 75 mg/m^2 IV every 3 weeks. Patients will be stratified based on duration of previous CIT treatment, ECOG performance status, and presence of brain metastases at baseline. Key eligibility criteria include duration of treatment of CIT for at least 4 months, discontinuation of prior treatment with CIT < 90 days prior to the date of randomization, and absence of symptomatic or uncontrolled brain metastases. The primary endpoint is Overall Survival (OS). Key secondary endpoints include safety and tolerability, ORR, PFS, PROs, and PK. OS will be analyzed using Kaplan-Meier methods and the stratified log-rank test to estimate and compare the median OS between the two treatment arms with 95% CI. An IDMC will be established to review safety at regular intervals and to review efficacy data at the planned interim analysis for futility and possible sample size adjustment based on OS. Recruitment begins May 2019. NCT number NCT03906071 **Result:** Section not applicable **Conclusion:** Section not applicable.

Background: Mesenchymal-Epithelial Transition gene (*MET*) amplification and exon 14 skipping mutations are established oncogenic drivers in non-small cell lung cancer (NSCLC), both occurring in about 4% of cases. In patients with *MET* amplified or mutated lung cancer, oral MET tyrosine kinase inhibitors (TKI) showed promising activity. The American Food and Drug Administration has recently granted crizotinib a breakthrough therapy designation for *MET* exon 14 mutation positive NSCLC. Cabozantinib is a novel oral inhibitor of MET and other receptor tyrosine kinases that has shown preliminary activity in *MET* deregulated NSCLC patients pretreated with crizotinib, although definitive data on its therapeutic role are still missing. **Method:** CABinMET (NCT03911193) is a phase II, single arm, multicenter study assessing the efficacy of cabozantinib in subject with *MET* amplification or *MET* exon 14 skipping mutation pretreated or not with MET inhibitors. The primary endpoint of the trial is overall response rate. Secondary efficacy endpoints are progression free survival, overall survival and disease control rate. Main inclusion criteria include histologically/cytologically confirmed diagnosis of advanced stage NSCLC, presence of *MET* exon 14 skipping mutation or *MET* amplification (MET/CEP7 ratio ≥2.2 on FISH analysis) on archival formalin-fixed paraffin-embedded (FFPE) tumor tissue or circulating tumor DNA, measurable disease, ECOG PS 0-1, at least 1 prior line of standard therapy, adequate organ function. Patients with co-existent driver events or with symptomatic brain metastases are excluded from the trial. Cabozantinib is administered orally at 60 mg once daily until disease progression, patient refusal or unacceptable toxicity. Disease is assessed every 8 weeks. Exploratory biomarker analyses are conducted on archival FFPE tumor tissue and on blood samples collected at baseline, at the time of the first disease assessment and at progression. **Result:** The study is currently running in 9 Italian centers. Recruitment started in September 2018 and 6 of the planned 25 patients have been enrolled. **Conclusion:** Enrollment will be completed in 24 months.

Keywords: NSCLC, MET, cabozantinib

P2.01-16 TACTICAL: A PHASE I/II TRIAL TO ASSESS THE SAFETY AND EFFICACY OF MSCTRAIL IN METASTATIC LUNG ADENOCARCINOMA

A. Davies[1], E. Sage[2], K. Kolluri[1], R. Graham[1], B. Weil[3], R. Rego[3], O. Bain[3], P.S. Patrick[4], K. Champion[5], A. Day[5], B. Popova[5], G. Wheeler[5], D. Fullen[6], T. Kalbur[4], M. Forster[7], M. Lowdell[3], S. Janes[1]

Background: Mesenchymal stromal cells (MSCs) migrate to and incorporate into tumour stroma, acting as vehicles for delivering anti-cancer therapies. TNF-related apoptosis inducing ligand (TRAIL) selectively induces apoptosis in malignant cells, however its short biological half-life has limited therapeutic efficacy. We have transduced MSCs with a lentiviral vector to express TRAIL (MSCTRAIL), demonstrating efficacy *in vitro* using co-culture assays and *in vivo* in orthotopic lung metastasis murine model, showing regression of metastases following treatment with intravenous MSCTRAIL [1] and synergistic activity with other systemic anti-cancer therapies. Given their immune-privileged nature we are now delivering *ex vivo* MSCTRAIL from pooled third party umbilical cord donors without tissue matching or immunosuppression. **Method:** TACTICAL is a phase I/II trial assessing safety and efficacy of MSCTRAIL in combination with first line standard of care (SOC); pemetrexed (500mg/m2) and cisplatin (75mg/m2) and/or pembrolizumab (200mg), in treatment-naive patients with stage IIIB/IV metastatic lung adenocarcinoma. Patients have no actionable driver mutations and ECOG performance status 0-1. Phase I is a dose de-escalation study; patients receive SOC on day 1 and $4x10^8$ MSCTRAIL cells on day 2 of a 21-day cycle for 3 cycles, with a Bayesian adaptive design recommending dose reductions if severe toxicities occur (Fig.1A). Primary outcomes are recommended phase II dose (RP2D), safety and tolerability of MSCTRAIL. In phase II, 46 patients will be randomised (1:1) in a double-blind trial to receive SOC and either RP2D of MSCTRAIL or placebo (Fig.1B). Primary outcome is tumour response rate by RECIST (v1.1) at 12 weeks.

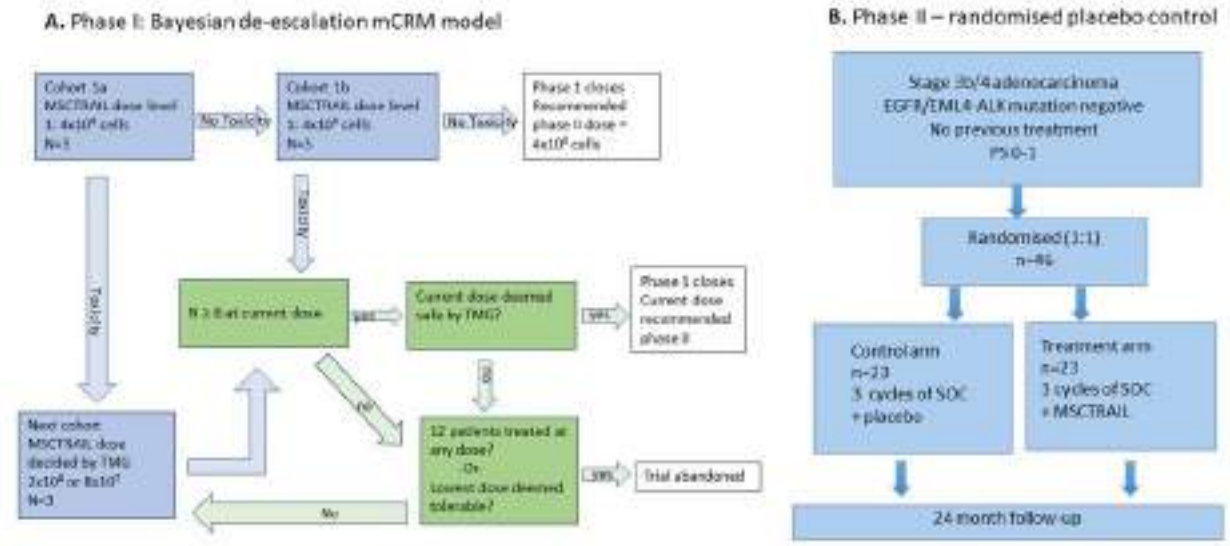

Figure 1: Schematic of TACTICAL Trial
A) Phase I Bayesian de- escalation model. B) Phase II randomised double-blind placebo control

Result: Translational work will include measuring: biomarkers of response; T, B, NK cell function in reaction to allogeneic MSCs; tracking migration of MSCs radiolabelled with ^{89}Zirconium-oxine through serial PET imaging. **Conclusion:** TACTICAL is the first clinical trial of this novel cell and gene therapy and if successful will pave the way for future allogeneic MSC cancer therapies. 1. Loebinger, M.R., et al., *Mesenchymal stem cell delivery of TRAIL can eliminate metastatic cancer.* Cancer Res, 2009. 69(10): p. 4134-42.

Background: Interleukin-1β (IL-1β) inhibition with canakinumab reduced the incidence of and mortality due to lung cancer among patients with atherosclerosis in CANTOS trial. Inhibition of IL-1β driven inflammation may lead to a tumor microenvironment more susceptible to anti-PD-(L)1 therapies. Recent studies have shown that low levels of CRP at baseline or decreased levels over time correlated with improved responses to anti-PD-(L)1 agents, providing rationale for combination of canakinumab and Pembrolizumab (PEM). **Method:** CANOPY-1 (NCT03631199) is a double-blind, randomized, placebo (Pb)-controlled, phase III trial to determine efficacy and safety of PEM + platinum-based chemotherapy (Ctx) ± canakinumab in untreated stage IIIB/IIIC-IV squamous and non-squamous NSCLC pts. It is a 2 part study- In Part 1 [open-label safety run-in with 3 cohorts of ~9 pts each to confirm recommended phase 3 canakinumab regimen], pts will receive canakinumab 200 mg s.c (Q3W) + PEM 200 mg i.v (Q3W) + platinum-based Ctx [Cohort A (non-squamous), carboplatin (CBCDA) + pemetrexed (PTX); Cohort B (non-squamous), cisplatin + PTX; Cohort C (squamous or non-squamous), CBCDA + paclitaxel]. In Part 2 [with ~600 pts) to evaluate efficacy and safety of canakinumab combination], pts will be randomized to receive canakinumab/Pb + PEM + platinum-based Ctx (non-squamous, CBCDA or cisplatin + PTX; squamous, CBCDA + paclitaxel or nab-paclitaxel). PEM and platinum-based Ctx will be administered at their approved doses. Randomization (1:1) will be stratified by PD-L1 status, region and histology. In both parts, pts will receive 4 cycles of induction therapy (canakinumab/Pb + PEM + Ctx) followed by maintenance therapy (PEM + canakinumab/Pb +/- PTX) until progressive disease. Primary objectives: confirm recommended phase 3 regimen for canakinumab combination (Part 1), compare PFS and OS between treatment arms (Part 2). Secondary objectives (Part 1 and 2): ORR, DCR, safety, PK and DOR. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Systemic chemotherapy for first-line (1L) metastatic NSCLC shows mixed outcomes. Results from studies using immunotherapy alone or combined with chemotherapy as 1L treatment in patients (pts) with metastatic NSCLC represent a substantial advance, but further improvement is needed. Increased deoxyribonucleic acid damage triggered by polyadenosine 5'diphosphoribose polymerase inhibition may confer antitumour activity, modify tumour immunogenicity and further sensitise tumours to immune checkpoint inhibition, thus promoting a more durable antitumour response. This Phase 2, randomised, multicentre, double-blind study (NCT03775486) is designed to assess the efficacy and safety of durvalumab+olaparib versus durvalumab alone as maintenance therapy in pts whose stage IV NSCLC has not progressed following 1L platinum-based chemotherapy+durvalumab. **Method:** Adult pts with stage IV NSCLC with tumours lacking activating *EGFR* mutations and *ALK* fusions are eligible. In the initial therapy phase, all pts will receive durvalumab (1500 mg intravenously [IV]) concurrent with platinum-based doublet therapy. Durvalumab+chemotherapy will be administered for 4 cycles for both squamous NSCLC (nanoparticle albumin-bound [nab]-paclitaxel+carboplatin or gemcitabine+carboplatin/cisplatin) and nonsquamous NSCLC (nab-paclitaxel+carboplatin or pemetrexed+carboplatin/cisplatin). Pts whose disease does not progress (complete or partial response [CR/PR] or stable disease [SD]; investigator-assessed RECIST 1.1) will be randomised (1:1) to durvalumab (1500 mg IV, every 4 weeks) + either olaparib (300 mg, oral, twice daily) or its matching placebo until disease progression. Randomisation will be stratified based on objective response to durvalumab+chemotherapy (CR/PR or SD) during the initial therapy phase and histology (squamous or nonsquamous). **Result:** The primary endpoint is progression-free survival (PFS) (investigator-assessed, RECIST 1.1). Secondary endpoints are overall survival, PFS in pts with homologous recombination repair-related gene mutation, objective response rate, duration of response, health-related quality of life, pharmacokinetics and immunogenicity of durvalumab, as well as safety. **Conclusion:** The study start date was 21 December 2018 and patient enrolment is ongoing. All patients will be followed for survival until the end of the study. The estimated primary completion date is 5 October 2020 and the estimated study completion date is 2 June 2022.

P2.01-19 PHASE 2 STUDY OF TELISOTUZUMAB VEDOTIN (TELISO-V) IN PREVIOUSLY TREATED C-MET+ NON-SMALL CELL LUNG CANCER: TRIAL IN PROGRESS

C. Ocampo, J. Wu, J. Dey, Z. Sun, M. Motwani, A. Reddy, A. Parikh, J. Hay, P. Komarnitsky, B. Bach

AbbVie, Inc., North Chicago/United States of America

Background: Telisotuzumab vedotin (ABBV-399; teliso-v), an anti–c-Met antibody-drug conjugate, demonstrated favorable antitumor activity in a phase 1/1b trial (NCT02099058) in patients with non-small cell lung cancer (NSCLC) and c-MET protein overexpression (c-MET+). Evidence from this study supported additional analysis of teliso-v in patients with c-MET+ NSCLC. Herein, we describe the first phase 2 study of teliso-v. The aim of this study is to evaluate the potential activity and safety profile of teliso-v as a later line of therapy in a biomarker-selected population(s) of patients with NSCLC. **Method:** This is a 2-stage (Figure) multicenter, non-randomized, single-arm phase 2 study (NCT03539536) in patients (≥18 years; Eastern Cooperative Oncology Group performance status 0–1) with c-MET+ locally advanced or metastatic histologically confirmed NSCLC. Stage 1 is designed to identify the target c-MET+ NSCLC population(s) best suited for teliso-v therapy in the second- or third-line setting using a novel multifactor Bayesian hierarchical model. In Stage 2, the group(s) that demonstrate promising results during Stage 1 will be expanded in a single-arm cohort to further evaluate teliso-v efficacy in the selected population(s). Teliso-v will be administered intravenously at a dosage of 1.9 mg/kg every 2 weeks until disease progression/intolerable toxicity. The primary endpoint is overall response rate according to Response Evaluation Criteria In Solid Tumors version 1.1. Secondary endpoints include duration of response, disease control rate, duration of disease control, progression-free survival, overall survival, safety, and tolerability. Pharmacokinetic samples will be collected pre-treatment and at specific timepoints during the study. Tumor samples will be collected pre-treatment for biomarker analysis. The trial is active, with the first patient screened on 11/05/2018. As of 3/11/2019, 13 centers in 5 countries have enrolled 3 patients.

P2.01-20 ANLOTINIB VS. DOCETAXEL IN ADVANCED NON-SQUAMOUS NSCLC (EGFR WILD-TYPE) AFTER PROGRESSION ON PLATINUM-BASED CHEMOTHERAPY: A TRIAL PROTOCOL

W. Yao

Sichuan Cancer Hospital, Chengdu/China

Background: Anlotinib, an oral VEGFR, FGFR, PDGFR and c-Kit tyrosine kinase inhibitor, showed significantly longer overall survival in a phase 3 trial. In the multi-center, open-label, randomized controlled ALTER-L023 trial, we compared anlotinib with docetaxel as second-line treatment in patients with advanced non-squamous EGFR wild-type non-small cell lung cancer (NSCLC) previously given platinum-based doublet chemotherapy. **Method:** This multi-center, open-label, randomized controlled ALTER-L023 trial was conducted at 10 hospitals in China. Eligible patients with previously treated non-squamous EGFR wild-type NSCLC were randomly assigned (1:1) to receive anlotinib (12 mg QD from day 1 to 14 of a 21-day cycle) or docetaxel (75mg/m2, on day 1 of a 21-day cycle) till progression or intolerable toxicity. The primary endpoint was progression-free survival (PFS), that was defined as the time from randomization to disease progression or death. The secondary endpoints included objective response rate, disease control rate, duration of response and safety. Based on a two-sided log-rank test at 5% significance level, a power of 80% and a median PFS of 6 months for anlotinib versus 3 months for docetaxel,the simple size was estimated at 77 patients. Allowing for 15% dropouts, the sample size was set at 88 patients (44 patients in both groups). Clinical trial information: NCT03703596 **Result:** Section not applicable **Conclusion:** Section not applicable

P2.01-21 EFFICACY AND SAFETY OF COMBING ANLOTINIB AND ERLOTINIB AS A FIRST-LINE THERAPY IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

B. Han, T. Chu, C. Shi, H. Zhong, W. Zhang, B. Zhang, R. Zhong, X. Zhang

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: As a promising multi-target tyrosine kinase inhibitor (TKI), anlotinib hydrochloride significantly improved overall survival (OS) and progression-free survival (PFS) in advanced NSCLC patients in the phase 3 trial ALTER0303. Antiangiogenesis therapy combined with EGFR-TKI has shown excellent efficacy and survival benefits in patients with EGFR mutations. This is the first trial evaluating anlotinib plus erlotinib in treatment-naive advanced NSCLC patients and is one arm of Phase II anlotinib-based trial (NCT03628521). **Method:** Patients with previously untreated, EGFR mutation–positive (exon 19 deletion or L858R) advanced NSCLC were enrolled. Eligible patients received anlotinib (10 mg QD from day 1 to 14 of a 21-day cycle) combined with erlotinib (at a dose of 150 mg once daily) until disease progression or treatment intolerance. The primary outcome was objective response (ORR) and secondary outcomes were PFS, disease control rate (DCR) and OS. **Result:** Until the 21st March 2019, 26 patients were enrolled. All are under treatment and 17 have received at least one tumor assessment. Among these patients, fifteen of them achieved PR (9 confirmed, the rest waiting for next assessment), two of them achieved SD and no patient developed to disease progression. The objective response rate was 88.2 % while the disease control rate was 100 %.The most common Grade 3 TRAE were rash (15.38 %), oral mucositis (11.54%) and albuminuria (7.69 %), and no grade 4/5 observation. **Conclusion:** The combination of anlotinib and erlotinib showed the promising efficacy for previously untreated, EGFR mutation–positive advanced NSCLC patients with a manageable safety profile. Table 1: Response rates

Response	Assessed
CR	0
PR	15/17(88.2%)
SD	2/17(11.76%)
PD	0
ORR, n/N(%)	15/17 (88.2%)
DCR, n/N(%)	17/17 (100.0%)

Keywords: combination of anlotinib and erlotinib, NSCLC, first-line therapy

Background: Osimertinib is a third-generation, central nervous system (CNS)-active, irreversible epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) that potently and selectively inhibits both EGFR-TKI sensitising mutations (EGFRm) and EGFR T790M. First-line osimertinib has demonstrated superiority in progression-free survival (PFS) compared with first-generation EGFR-TKIs in patients with EGFRm advanced NSCLC (Soria et al, NEJM 2018). The most common resistance mechanisms to first-line osimertinib identified from plasma samples are MET amplification (15%) and EGFR C797S (7%) (Ramalingam et al, Ann Oncol 2018). Further clinical studies are needed to better understand resistance mechanisms and evaluate post-progression targeted treatment options. **Method:** ORCHARD is an open-label, multicentre, biomarker-directed, Phase II platform study evaluating the optimal treatment for individual patients with EGFRm NSCLC depending on their underlying resistance mechanism to first-line osimertinib. Adult patients with EGFRm locally advanced/metastatic NSCLC and radiological progression on first-line osimertinib monotherapy will be eligible. Treatment assignment will be based on molecular characterisation of the tumour at progression from a mandatory tissue biopsy. ORCHARD will comprise of three groups assigned by tumour molecular profile (Figure). An adaptive design allows addition of new treatments based on emerging findings. Tumour assessments (RECIST 1.1) will be performed every 6 weeks for the first 24 weeks and every 9 weeks thereafter until progression. An interim analysis of each cohort will be performed when ≈16 patients have reached the second on-treatment RECIST assessment. Based on preliminary signals, the cohort may be stopped or expanded to 30–40 patients for further evaluation. The primary outcome is investigator-assessed objective response rate; secondary outcomes include PFS, duration of response, overall survival, and pharmacokinetics of each treatment module, evaluated independently. Exploratory outcomes include tumour and plasma biomarker and resistance analyses, and correlation between biomarker profiles and treatment effect. Safety data will also be reported.

P2.01-23 DUBLIN-3, A PHASE (PH) III TRIAL COMPARING THE PLINABULIN (P)/DOCETAXEL(D) COMBINATION WITH D ALONE IN STAGE IIIB/IV NSCLC

R. Mohanlal[1], Y. Sun[2], G. Kloecker[3], T. Feinstein[4], Y. Shi[2], B. Han[5], L. Bazhenova[6], L. Du[7], L. Huang[1]

[1]*BeyondSpring Pharmaceuticals, New York/United States of America,* [2]*Cancer Hospital Chinese Academy of Medical Sciences, Beijing/China,* [3]*University of Louisville Hospital, Louisville/United States of America,* [4]*Peachtree Hemotology-Oncology Consultants, Pc, Atlanta/United States of America,* [5]*Shanghai Chest Hospital, Shanghai/China,* [6]*University of California San Diego (UCSD) Moores Cancer Center, La Jolla/United States of America,* [7]*Wanchun Bulin Pharmaceuticals Limited, Dalian/China*

Background: In 2018, practice patterns changed in untreated metastatic NSCLC, as platinum-based chemotherapy (Chemo) started to be combined with pembrolizumab. Prior to 2018, checkpoint inhibitors (C-I) were given sequentially with Chemo. In C-I refractory metastatic NSCLC, single agent D is standard of care. Although effective, D induces AEs (Neutropenia (N) that may require dose reduction to sub-therapeutic levels. The addition of Plinabulin (P) to D (D+P) reduced D-induced grade 4 (Gr4) N (frequency of 33% vs 5% for D vs D+P; p<0.0003) and thrombocytopenia (P<0.02) vs D alone (Blayney ASH 2018; IASLC 2018) in Ph 2. Importantly, P added to D improved median overall-survival (OS) with 4.6-month, and duration of response (DoR) with 1-year (p<0.05) vs D alone (Mohanlal ASCO-SITC 2017) in pts with a measurable lesion (per RECIST 1.1) located in the lung. P induces Dendritic Cell (DC) maturation and CD40 upregulation and facilitates DC-dependent T-cell proliferation in an antigen (Ag) specific manner (Lloyd AACR 2016). Therefore, P is predicted to be the most effective in a setting that harbors novel Ags, that can stimulate the immune system. Subclonal lung lesions can induce novel Ags (De Bruin Science 2014), but clonal lung lesions can also harbor Ags that can stimulate the immune system, as long as immune tolerance is not yet developed. There is a high concordance in mutation status (thus Ags) between clonal primary and metastatic lesions in NSCLC (Sherwood J Exp & Clin Canc Res 2015), but the distant lesions had more time to induce immune tolerance development. Hence, we required the presence of measurable lesion present in the lung in DUBLIN-3. We combined P with D since D can release Ags which in turn can be presented by P-modulated DCs to cytotoxic CD8 T-cells. **Method:** DUBLIN-3 (NCT02504489), is an ongoing global PhIII study in EGFR wild-type advanced or metastatic NSCLC pts (target n=554) receiving 2nd- or 3rd-line systemic therapy with D+P or D in a 1:1 ratio. The primary endpoint is OS. Key secondary endpoints are incidence of Gr 4 N on day 8 of Cycle 1, D dose modification due to N, QoL (EORTC QLQ-C30), ORR, PFS, and DoR. The study is single-blinded (for pts) to more reliable allow for QoL assessments. Pts must have at least one measurable lesion located in the lung and must have failed a prior platinum-based regimen. Prior PD1/PD-L1 use is allowed. A pre-specified first Interim Analysis (IA) occurred at reaching ~150 events and a second pre-specified IA is to occur at ~ 300 events. **Result:** ~400 patients have been enrolled to date with more than 200 events achieved. Based on the data at the 1st IA, the study will continue, unmodified, to the 2nd IA. **Conclusion:** The D+P combination holds the promise of a novel 2nd or 3rd line treatment option with superior efficacy and safety over D alone. The 2nd IA of DUBLIN-3 is expected to occur later in 2019.

Background: Pembrolizumab, a PD-1 inhibitor combined with platinum-based chemotherapy is standard first-line therapy for eligible patients without a targetable mutation, stage IIIB/IV NSCLC. Currently, there is no data to guide treatment following progression on sequential/concomitant use of platinum-based chemotherapy and PD-1 inhibitors. Activation of inflammation and elevated baseline C-reactive protein (CRP) levels are associated with lower response/resistance to immunotherapies. Canakinumab is a high-affinity anti-IL-1β monoclonal antibody that demonstrated a significant reduction in incidence of fatal and nonfatal lung cancer in patients with increased CRP levels (CANTOS study). **Method:** CANOPY-2 (NCT03626545) is a multicenter, phase 3 study evaluating safety and efficacy of docetaxel ± canakinumab in patients with squamous/non-squamous, stage IIIB-IV NSCLC. This study includes a safety run-in part (part 1 – open label) to confirm recommended phase 3 regimen (RP3R) to be used in randomized phase 3 part (part 2 – double blind, placebo-controlled). Key inclusion criteria: adult patients pretreated with one prior platinum-based chemotherapy and one prior PD-(L)1 inhibitor therapy for locally advanced/metastatic disease, either together/sequentially and then progressed; ECOG PS 0-1. In part 1, ~9 patients will be enrolled to have at least 6 evaluable patients and ~226 patients will be randomized (1:1, stratified by number of prior lines of therapy and histology) in part 2 to docetaxel ± canakinumab. Primary objectives: to confirm RP3R of canakinumab + docetaxel, as determined by incidence of DLTs in first 42 days of administration (part 1) and overall survival (part 2). Secondary objectives are to assess efficacy (overall response rate, disease control rate, duration of response, time to response, progression-free survival by investigator per RECIST v1.1), safety, pharmacokinetics, immunogenicity of canakinumab, and patient reported outcomes. Enrollment is ongoing. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Non Small Cell Lung Cancer (NSCLC) is the leading cause of cancer mortality throughout the world with an incidence exceeding 1.2 million. 70% of NSCLC patients present with incurable disease with treatment aimed at alleviating symptoms, maintaining / improving quality of life as well as prolonging survival. In the last decade there have been dramatic changes in systemic therapy (chemotherapy, immunotherapy, Tyrosine kinase Inhibitors (TKIs)). Despite these advances, many patients suffer from lororegional symptomatic relapse. This may benefit from local radiotherapy in addition to other standards of care such as symptom control. Radiotherapy remains widely used in the management of stage IV NSCLC but strategies vary hugely because the data originates from a series of dose fractionations trials in the 1990s when systemic therapy options were limited. There is therefore limited evidence regarding the use and place of palliative radiotherapy in conjunction with modern systemic treatments and there is a need to assess benefits of advanced radiotherapy techniques in this population. The TOURIST trial aims to establish the utility of palliative thoracic radiotherapy in the primary treatment of stage IV NSCLC. **Method:** This is a phase III platform that currently has 2 study arms, to cover the needs of differing patient populations, defined by the use of first line systemic therapy. Study 1 (PRINCE) Patients receiving first line systemic therapy as standard of care, who have not progressed after 2-4 cycles are randomised 1:1 to either high dose palliative radiotherapy to the thorax, or to no radiotherapy while continuing on their standard systemic therapy. Co-primary endpoints: overall survival, PROMs recorded QOL, with progression free survival and time to next line of therapy, as secondary endpoints. Study 2 (QUARTZ Lung) Asymptomatic patients unsuitable for standard systemic therapy randomised 1:1 to low dose palliative radiotherapy dose to the thorax or no radiotherapy. Telephone follow up will be used for PROMs data collection to measure QOL improvements. Stratification factors for

both studies will include bulk of thoracic disease, use of advanced radiotherapy techniques and performance status. The TOURIST trial intends to recruit 750 patients and is anticipated to open in 2020. **Result:** Section not applicable **Conclusion:** Section not applicable

P2.01-26 EMPOWER-LUNG 3: PHASE 3 STUDY OF COMBINATIONS OF CEMIPLIMAB AND CHEMOTHERAPY IN FIRST-LINE TREATMENT OF ADVANCED NSCLC

M. Gogishvili[1], N. Mobashery[2], T. Makharadze[3], M. Navarro[2], P. Snodgrass[2], H. Chen[2], I. Lowy[2], P. Rietschel[2], S. Lee[4]

[1]*High Technology Medical Centre, University Clinic Ltd, Tbilisi/Georgia,* [2]*Regeneron Pharmaceuticals, Inc., Tarrytown/United States of America,* [3]*LTD High Technology Hospital Medcenter, Batumi/Georgia,* [4]*Regeneron Pharmaceuticals, Inc., Basking Ridge/United States of America*

Background: Most patients (pts) with non-small cell lung cancer (NSCLC) present with advanced disease at the time of diagnosis. Until recently, platinum-based doublet chemotherapy regimens were the standard of care first-line treatment for pts with advanced NSCLC whose tumors lack an *EGFR*, *ALK*, or *ROS1* mutation. Despite chemotherapy, patients with metastatic NSCLC had a median overall survival (OS) of 8 to 12 months and a 5-year survival rate of approximately 18%. With the introduction of programmed cell death-1 (PD-1) inhibitors to NSCLC, this prognosis has improved. Cemiplimab, a human PD-1 monoclonal antibody, has exhibited antitumor activity and safety in a Phase 1 trial of advanced malignancies including NSCLC and was approved recently in the US as cemiplimab-rwlc for advanced cutaneous squamous cell carcinoma (CSCC). Based on their unique modes of action, combining cemiplimab with platinumbased chemotherapy has the potential for a synergistic effect in pts with advanced NSCLC of both histologies and irrespective of PD-L1 expression. **Method:** EMPOWER-lung 3 is a randomised, global, two-part, Phase 3 study of first-line treatment of pts with advanced squamous or non-squamous NSCLC (NCT03409614). Part 1, as previously described (IASLC 19th WCLC; Abstract 13347), is open-label and aims to describe the efficacy and safety of combinations of cemiplimab, ipilimumab, and platinum-based doublet chemotherapy in pts whose tumors express PD-L1 in <50% of the tumor cells. The updated primary endpoint of Part 1 is objective response rate. Here we introduce the recently added Part 2. This part is double-blinded and will compare the efficacy and safety of cemiplimab versus placebo, both in combination with investigator's choice of standard chemotherapy, in all pts irrespective of PD-L1 expression status. Chemotherapy options include: paclitaxel + carboplatin or cisplatin for squamous cell NSCLC and pemetrexed + carboplatin or cisplatin for non-squamous NSCLC. The investigator may choose from one of these regimens provided that it is consistent with the local standard-of-care. Pts will be randomized (2:1) to cemiplimab 350 mg Q3W plus up to four cycles of chemotherapy or placebo Q3W plus up to four cycles of chemotherapy. Pts will be stratified by histology and PD-L1 expression levels. The co-primary endpoints for Part 2 are OS and progression-free survival (PFS). **Result:** Section not applicable **Conclusion:** Section not applicable

Keywords: non-small-cell lung cancer, Anti-PD-1, cemiplimab

P2.01-27 APPARENT DIFFUSION COEFFICIENT (ADC) CHANGE ON REPEATED DIFFUSION-WEIGHTED MRI DURING CHEMOTHERAPY FOR STAGE IV LUNG NSCLC

O. Grundberg[1], M. Skorpil[1], S. Swerkersson[2], K. Kölbeck[1], R. Karimi[1], L. De Petris[1]

[1]*Karolinska University Hospital, stockholm/Sweden,* [2]*St Göran's Hospital, stockholm/Sweden*

Background: Diffusion-weighted magnetic resonance imaging (DWI) depicts the random Brownian movement of water molecules in biological tissues. The net displacement of these molecules diffusing across an area of tissue per second is the apparent diffusion coefficient (ADC). ADC has proven useful in detection, characterization and treatment response monitoring of malignant diseases and is used routinely in the investigation of cancer of the prostate. The role of MRI in the follow up of treated lung cancer remains unclear. Previous publications have suggested that it could function as a biomarker in chemoradiotherapy treated NSCLC. Very little has been published about chemotherapy treated tumours. **Method:** 20 patients with stage IV adenocarcinoma were enrolled between September 2014 and April 2017. They received treatment with carboplatin/placitaxel and bevacizumab (7,5mg/kg) with maintenance bevacizumab if response. Two patients, in whom the lesion proved to be too small to measure (<2ml), were excluded. Characteristics of the remaining 18 patients: 8 f/10m, median age 69 (51 -77), median survival 9 month (1-NR, follow up 60months) and median time to treatment failure 6 month (1-37). DWI was performed at baseline, 2w, 4w and 16w. Four patients did not participate in the full study program. Two examinations were incomplete due to technical problems, and 8 MRI examinations were excluded due to the tumors becoming too small in size (<2ml). A total of 57 MRI examinations were included. **Result:** The ADC value at baseline varied between 950 and 1584mm2/s (median 1228). ADC values both increased and decreased during treatment (% change at week 2 range -11 to 24%, at w4 -14 to 34%, at 16 w -27 to 10%). The evolution of the ADC values at the different timepoints did not show any statistical significant increase or decrease (using Mean Comparison with Student t's test, Prob>Chisq 0,2159). Proportion Hazard analysis did not show any statistical correlation between the baseline ADC value, the change in ADC value and overall survival, nor between ADC values, change in ADC values and time to treatment failure. **Conclusion:** Repeated MRI in lung cancer is feasible. The clinical value of ADC measurements in the follow up of chemotherapy treated lung cancer needs further investigations.

Keywords: MRI, DWI, Bevacizumab

P2.01-28 THE PREDICTIVE FACTOR FOR PROLONGED AIR LEAKAGE OVER 48 HOURS USING LOG DATA OF DIGITAL DRAINAGE SYSTEM

H. Hoshino, K. Aokage, S. Katsumata, S. Nakasone, T. Miyoshi, K. Tane, M. Tsuboi

National Cancer Center Hospital East, Kashiwa/Japan

Background: Air leakage is one of the most common complications after pulmonary resection and many risk factors of air leakage have been reported in the past. However, there are few studies about the objective predictive factors. Digital drainage system (DDS) has enabled us to measure the flow of air leakage after pulmonary resection objectively and quantitatively. We aimed to elucidate the predictive factors of prolonged air leakage (PAL: continuing air leakage over 48 hours) after surgery using the log data of DDS. **Method:** The presence of air leakage was defined as being 20ml/min or more and/or spike in the flow on DDS. Chest tubes were removed at the time of continuing for 8 hours at less than 20ml/min and pleural effusion of less than 300ml/day. The 593 patients underwent pulmonary resection and monitored by DDS postoperatively from May 2016 to January 2018. The 92 patients had air leakage at the time of transferring to intensive care unit or recovery room (postoperative air leakage: POAL). The log data of these 89 patients were analyzed retrospectively and We examined their characteristics using univariate and multivariate manners in logistic regression analysis. **Result:** The median age at the time of pulmonary resection in these 89 patients (72 men and 17 women) was 72 years (range, 40 to 86 years). The 75 patients (84%) had smoking history. The 17 patients (19%) had diabetes mellitus. The 49 patients (55%) had emphysema. Surgical procedures were a lobectomy in 71 patients, a segmentectomy in 4 patients, and a wedge resection in 14 patients. Fibrin glue was used during surgery in 45 patients (51%). The mean flow of POAL was 70.4 ml/min (range, 20.2-1267.9). The mean duration of air leakage was 60 hours (range, 9-257). In univariate analysis, diabetes mellitus (DM, p=0.0284, OR; 3.450), use of fibrin glue (p=0.0452, OR; 0.411), and POAL (p=0.0101) were statistically significant. In the final multivariate model, DM (p=0.0441) and flow of POAL (p=0.0228) were independently associated with PAL. In ROC curve, considering less than 20% false positive rate, the optimal cutoff in patients with DM was 100ml/min (sensitivity; 67%, specificity; 82%). The optimal cutoff in patients without DM was 150ml/min (sensitivity; 53%, specificity; 84%). **Conclusion:** The POAL flow of 150ml/min or more in patients without DM and that of 100 ml/min or more in patients with DM will be likely to develop PAL with high probability. Pleurodesis may be considered earlier for this population.

Keywords: prolonged air leakage, digital drainage system

P2.01-29 THE CORRELATION BETWEEN K-RAS MUTANT SUBSETS WITH TP53 MUTATION AND PD-L1 IN NON-SMALL CELL LUNG CANCER (NSCLC)

N. Abdel Karim[1], C. Onuoha[2], I. Eldesouki[1], I. Ahmad[1], H. Mamdani[3], A. Spira[4], A.R. Naqash[5]

[1]*Augusta University-Georgia Cancer Center, Augusta/United States of America,* [2]*Augusta University, Augusta/United States of America,* [3]*Karmanos Cancer Institute, Detroit/United States of America,* [4]*Virginia Cancer Specialists, Fairfax/United States of America,* [5]*East Carolina University, greenville/United States of America*

Background: Despite its role in non-small cell lung cancer (NSCLC), K-ras gene mutations are considered is a non-targetable with no established predictive value. And so far, programmed death ligand-1 (PD-L1) is the only approved predictive marker for immunotherapy in NSCLC patients and has been associated with smoking, while TP53 mutations has been linked to neoplasms with aggressive nature. Meanwhile, K-ras mutation has been identified with smoking and linked to aggressive NSCLC. Accordingly, we hypothesized that k-ras mutant NSCLC has higher PD-L1 expression which suggests an improved response to immunotherapy in these patients. **Method:** The CARIS database from 2016 - 2018 was queried and patients with NSCLC were identified. PD-L1 antibody 22c3 ≥1% was considered positive. PD-L1 expression as well as k-ras and TP53 mutation status were analyzed and correlation between different variables were identified using ANOVA. **Result:**

Table 1: showing the percentage expression of PD-L1 in each K-ras mutation subtype

K-ras mutation sub-type	PD-L1 negative (n,%)	PD-L1 positive (n,%)	Total (n,%)
G12V	205 (20.8%)	239 (18%)	444 (19.2%)
G12D	142 (14.4%)	194 (14.6%)	336 (14.5%)
G12A	56 (5.7%)	72 (5.4%)	128 (5.5%)
G12C	337 (34.2%)	566 (42.7%)	903(39.1%)
G13C	51 (5.2%)	46 (3.5%)	97 (4.2%)
Q6H	54 (5.5%)	67 (5.1%)	121 (5.2%)
G12R	18 (1.8%)	18 (1.4%)	36 (1.6%)
G12S	18 (1.8%)	16 (1.2%)	34 (1.5%)
Non-Specified	104 (10.6%)	108 (8.1%)	212 (9.2%)
Total	985 (100%)	1326 (100%)	2311 (100%)

We identified 8,471 patients with NSCLC. TP53 mutation was detected in 66% where k-ras mutation in 26.9%. Combined K-ras and TP53 mutations was detected in 12% where 71.48% were PD-L1 positive in this combined category. There was female predominance with a female to male ratio of 1.4:1. We looked for the eight main K-ras mutation subsets and G12C was the most common identified mutation. G12C was associated with a higher occurrence of PD-L1 positivity (42.7%), followed by G12V (18.0%) with a significant difference in PD-L1 expression among K-ras mutations subtypes with P value of 0.004. (table 1). PD-L1 expression in wild type K-ras tumors was 69.4% and although high, wild type K-ras cases showed higher percentage of PD-L1 expression negativity (76.2%). **Conclusion:** Patients with G12C, amongst other k-ras mutation subsets, have higher occurrence of PD-L1 expression which is suggestive of improved response to immunotherapy. The subset of combined K-ras and p-53 mutations showed 71.48% positive PD-L1 expression.

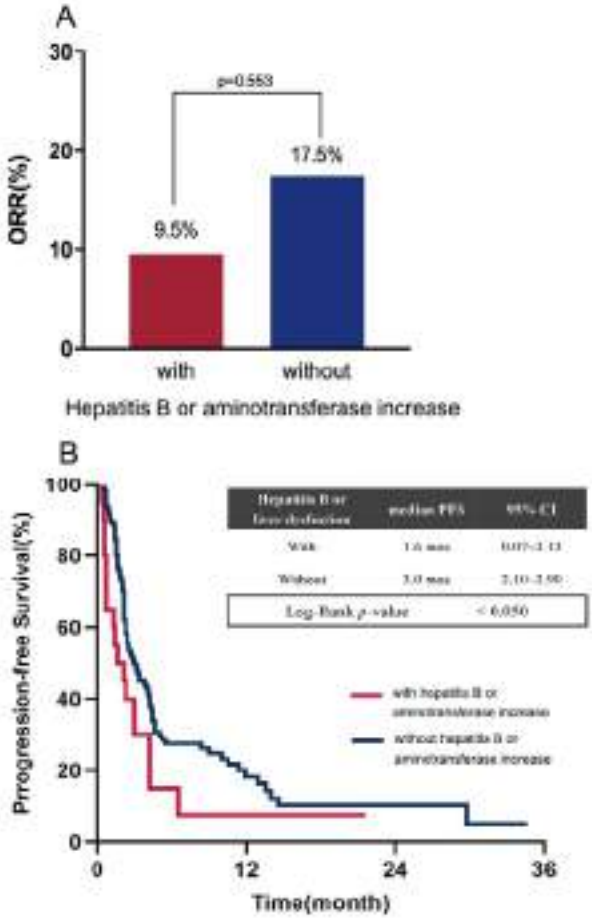
Keywords: PD-L1, NSCLC, K-ras

P2.01-30 HEPATITIS B INFECTION OR AMINOTRANSFERASE INCREASE ASSOCIATE WITH POOR OUTCOME OF ANTI-PD-1 MONOTHERAPY IN PATIENTS WITH ADVANCED NSCLC

Y. Liu, S. Mao, F. Zhou, A. Xiong, B. Chen, J. Yu, F. Wu, Y. He, G. Gao, X. Chen, C. Su, S. Ren, C. Zhou

Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: Previous study demonstrated that the existence of liver metastases at the commencement of immunotherapy was associated with poor response. Since hepatitis B infection and liver dysfunction were higher prevalent in China, this study aimed to investigate the efficacy and safety of PD-1/PD-L1 inhibitor in Chinese NSCLC patients with hepatitis B infection or liver dysfunction. **Method:** We retrospectively collected the patients who were diagnosed with non-small cell lung cancer and received anti-PD-1 monotherapy at Shanghai Pulmonary Hospital, Tongji University School of Medicine, China, from January 2016 to February 2019. Detailed clinicopathologic characteristics, therapeutic outcomes, hepatitis biomarker test and liver function test were collected. **Result:** 135 patients were enrolled with 73(54.1%) aged <65 years old. Among them, 113(83.7%) were male, 84(62.2%) were smoker, 57(42.2%) were squamous, 69(44.4%) received anti-PD-1 monotherapy (Pembolizumab n=28, Nivolumab n=21) as 2nd line setting, 5(3.7%) patients had hepatitis B infection and 17(12.6%) had increased ALT or AST. The baseline characteristics such as age, gender, smoking status, histology, PD-1 mono-antibodies, line of therapy was similar between hepatitis infection or liver dysfunction group vs. normal group. Hepatitis infection or liver dysfunction group had a lower ORR (9.5% vs. 17.5%, p=0.553, Figure A), significantly shorter PFS (1.6 months vs. 3.0 months, p<0.050, Figure B) when compared with these patients without. Out of the 22 patients with hepatitis or increase transaminase, 35.7% deteriorated the grading of alanine or aspartate aminotransferase increased.



Conclusion: NSCLC patients with hepatitis B infection or increased transaminase showed a high incidence of hepatic disfunction and poor outcome to anti-PD-1 monotherapy.

Keywords: Hepatitis B infection, Immunotherapy, aminotransferase increase

P2.01-31 PRELIMINARY RESULTS OF SECOND GENERATION ALK INHIBITOR PLB1003: A PHASE LA STUDY

B. Han, T. Chu, J. Qian, B. Yan, Y. Zhang, Q. Chang

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: ALK rearrangements have been described in approximately 4-5% of patients with non-squamous non-small cell lung cancer (NSCLC). Crizotinib is initially effective in the treatment of ALK-rearranged NSCLC, but the disease eventually progresses. PLB1003, a high-efficiency second generation ALK inhibitor, was developed due to the increased resistance of EML4-ALK fusion genes. Preclinical data show that PLB1003 is safe and effective in cell-based assays and Crizotinib-resistant animal models. This is the ongoing phase Ia study of PLB1003. **Method:** An open-label, multicenter phase I clinical trial was conducted in patients with locally advanced or metastatic NSCLC who had previously failed or were intolerable to Crizotinib or chemotherapy. It consisted of dose-escalation cohorts and dose-expansion cohorts. In the dose-escalation cohorts, patients were orally given 50-500mg/d of PLB1003 at 6 dose levels . In each cohort, patients' plasma were collected for pharmacokinetic evaluation. The safety, tolerability, pharmacokinetics, maximum tolerated dose (MTD), dose limiting toxicities (DLT) and recommended phase 2 dose (RP2D) of PLB1003 were determined. **Result:** A total of 21 patients were enrolled in dose-escalation cohorts as of 31 August 2018. The dose-escalation cohort is ongoing at the dose of 200 and 250 mg BID. A lipase elevation of DLT event was observed at 250 mg BID. MTD has not been reached in this study. Additionally, the most common treatment-emergent adverse events (TEAEs) (>10%) were grade1/2, including: (1) gastrointestinal toxicities: diarrhea (24%), vomiting (14%); (2) hepatotoxicity: increased GGT (g-glutamyltransferase) (48%), increased ALP (33%), elevated ALT (43%) and AST (33%); (3) others: increased blood glucose level (43%), hyperuricemia (24%), increased creatinine (19%), anemia (19%), hypercholesterolemia (14%). All the treatment-related adverse events (TRAEs) were reversible. TRAEs of grade 3, increasing of GGT (-glutamyl transferase) (33%), alkaline phosphatase (10%) and lipase (10%), mostly appeared during 7-13 weeks of initial study. Patients all recovered from TRAEs of grade 3 with symptomatic treatments. Among the 14 evaluable patients in ≥200mg/d cohorts, 10 patients had PR (71%), 2 patients had SD (14%), and the disease control rate (DCR) was 86%. Among the 7 patients who progressed with previous treatment of Crizotinib, 5 patients had PR (71%), 1 patient had SD (14%), and the DCR was 86%. **Conclusion:** PLB1003 is safe, tolerable and has potential clinical benefit to locally advanced or metastatic NSCLC patients with ALK rearrangement mutation and had disease progression or were intolerable to previously treatment of Crizotinib or chemtherapy. (ClinicalTrials.gov number, NCT03130881)

P2.01-32 THE IMPACT OF SEGMENTECTOMY VERSUS LOBECTOMY ON PULMONARY FUNCTION OF PATIENTS WITH NON-SMALL CELL LUNG CANCER: A META-ANALYSIS

G. Qiu[1], Y. Wen[2]

[1]*Guangzhou Medical University, Guangzhou/China,* [2]*The First Affiliated Hospital of Guangzhou Medical University, National Clinical Research Center for Respiratory Disease, China State Key Laboratory of Respiratory Disease, Guangzhou/China*

Background: Lobectomy with lymph node dissection is considered the standard surgical procedure for non-small cell lung cancer (NSCLC). Recently segmentectomy has been regarded as an alternative in early peripheral NSCLC owing to its theoretical advantages of lung function preservation. However, Segmentectomy presents some oncological risk. Thus, we performed a meta-analysis with the aim of evaluating whether segmentectomy offers an advantage in lung function preservation compared with lobectomy. **Method:** We searched and retrieved studies from four databases. Postoperative results and lung functional index and were synthesized. The odds ratio (OR) or Standard Mean Difference (SMD) and its 95% CI were calculated using a random effects model. Subgroup division was conducted according to different time points. Single-arm meta-analysis for lung function of each visit time was conducted. Repeated-measures analysis of variance (ANOVA) was used to compare the lung function between each visit. **Result:** A total of 16 eligible studies including 6,098 patients were recruited. Two groups showed no significant difference based on baseline characteristics before surgery between groups (Segmentectomy and Lobectomy). Segmentectomy correlated with a greater postoperative preserved pulmonary function than Lobectomy in FVC (SMD=0.23, p=0.009) and FEV1 (SMD=0.27, p=0.002), especially within 12 months after surgery. ANOVA showed no difference between FVC (p=0.647) and FEV1 (p=0.468) of the two groups according to visit time. The segmentectomy group showed no significant difference of postoperative complications compared with the Lobectomy groups(OR=0.95, p=0.618) and the recurrence rates were similar between groups (OR=0.90, p=0.644). **Conclusion:** Segmentectomy offers a better short-term but similar long-term lung functional preservation compared with Lobectomy, with similar surgical and oncological safety.

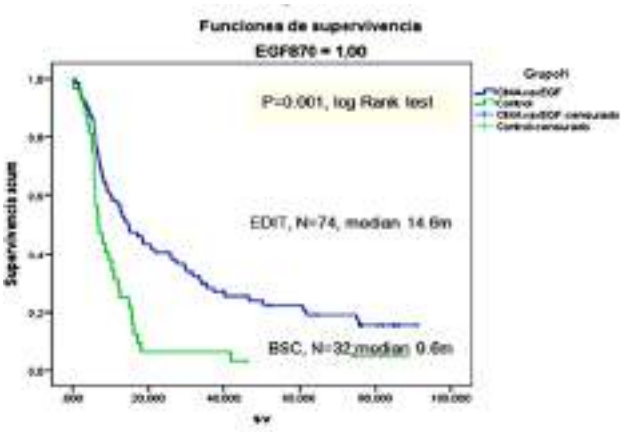
P2.01-33 SURVIVAL BENEFIT OF DEPLETING HIGH SERUM EGF CONCENTRATION IN ADVANCED NSCLC PATIENTS AS SWITCH MAINTENANCE THERAPY

O. Santos Morales[1], E. Neninger[2], R. Carrodeguas[3], P. Luaces[1], P. Rodríguez[1], M. Hernandez[1], C. González[1], T. Crombet[1]

[1]*Center of Molecular Immunology, Havana/Cuba,* [2]*Hermanos Ameijeiras Hospital, Havana/Cuba,* [3]*Celestino Hernández Hospital, Havana/Cuba*

Background: Serum EGF depleting immunotherapy (EDIT) with CIMAvax-EGF has shown to be safe and effective in the treatment of advanced NSCLC patients after first line of treatment with platinum based chemotherapy. The rationale of its use is to create an immune response against circulating serum EGF and by doing this prevent its binding to EGFR. Previous studies have shown that serum EGF levels above 870 pg/mL and response to chemotherapy (at least stable disease) are independent predictors of the response to EDIT. In this study we aimed to better estimate the benefit of this therapy in the population of first line responders with high basal serum EGF concentration **Method:** To know the benefit of EDIT in overall survival compared to Best Support Care in this selected population, we pooled data data from three late stage clinical trials of CIMAvax-EGF in patients with advanced NSCLC (IC RD-EC056, IC RD-EC081, and IC RD-EC0120) after First Line Platinum based chemotherapy. The main outcome was overall survival. **Result:** Out of 523 patients included in the study, 484 were responders (at least stable disease) to FLC. sEGF concentration above 870 pg/mL was measured in 106 patients, (74 and 32 in the EDIT and Control group, respectively). All 106 patients carrying these two protective distinctive features were included in the analyses. A significant benefit in median overall survival was found (14.6 m vs 9.6 m, p=0.001; 5 y survival rate: 22% vs 3%) favouring EDIT therapy.



Conclusion: EGF Depleting Immunotherapy (EDIT) induces a survival benefit as Switch Maintenance in avanced NSCLC patients with high serum EGF concentration.

P2.01-34 ENDOSTAR COMBINED WITH WHOLE BRAIN RADIOTHERAPY IN PATIENTS WITH NSCLC BRAIN METASTASES

L. Chen[1], C. Wei[2], R. Zhang[1], G. Wu[3], X. Dong[1]

[1]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, wuhan/China,* [2]*Huazhong University of Science and Technology, Wuhan/China,* [3]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China*

Background: Brain metastasis (BM) is the leading cause of poor prognosis, recurrence, and death in non-small-cell lung cancer (NSCLC) patients. The effectiveness of whole-brain radiotherapy is unsatisfactory. Endostar was reported as an anti-angiogenic agent, which could promote vascular normalization in tumor. This study is to investigate the influence of endostar combined with cranial radiation to survival, cerebral blood flow, immune status and quality of life of the patients. **Method:** 28 NSCLC patients with multiple brain metastasis(more than four)were randomly divided into two groups. The experimental group (n = 14) received WBRT (30Gy/10F) combined with Endostar (15mg/m2, 7days), and the control group (n=14) received WBRT (30Gy/10F) alone. Tumor progression and survival of the patients were established by certified oncologists based on whole brain MRI scan. Magnetic resonance perfusion imaging was carried out pre- and one month post-radiation to detect regional cerebral blood volume (rCBV), regional cerebral blood flow (rCBF), mean transit time (MTT) and transit time to peak (TTP) of the contrast medium. The changes of blood T lymphocyte subpopulation, the cognitive function and overall healthy level were evaluated pre- and post- radiation every two months against the MMSE, MoCA and EORTC QLQ-C30 scales. **Result:** The median progression free survival (mPFS) was 211 days vs. 84 days (*P*=0.2204), while the median intracranial PFS (miPFS) was 333 days vs. 192 days (*P*=0.1882) and the median extracranial PFS (mePFS) was 311 days vs. 84 days (*P*=0.0873) between the Endostar group vs. the control group, but neither with significant difference, may for the limit of sample size. Moreover, compared with the control group, rCBF of the lesion in the Endostar group decreased more evidently (-69.0286±87.4532 *vs.* -25.3444±233.4, *P*=0.6158), rCBV decreased slightly (-13.1286±389 *vs.* -510.8±800.1, *P*=0.1545), MTT increased (69.0571±1190.7 *vs.* -483.3±1885.1, *P*=0.5108) and TTP increased (156.6±1232.8 *vs.* 102.1±864.1, *P*=0.9185), indicating that endostar group had a better control of the cerebral perfusion and the tumor. The T lymphocyte subpopulation increased in the Endostar group, especially the CD3+CD8+ T lymphocyte but without significant difference compared with the control group(*P*=0.1447). At the same time, after cranial radiation, the cognitive function, physical, role, social and emotional functions improved in the endostar group, while a small fluctuation in the control group with significant difference(*P*<0.05). **Conclusion:** Our study showed that endostar could improve survival of the patients, adjust cerebral perfusion and promote control of lesions, ameliorate the immune status, while improve cognitive function and quality of life of the patients at the same time.

Keywords: Brain metastases, endostar, brain radiotherapy

P2.01-35 ACQUIRED MET-ABERRANCE IS A MECHANISM OF RESISTANCE TO ALK INHIBITORS IN ALK-POSITIVE ADVANCED NON-SMALL-CELL LUNG CANCER

Q.-M. Deng, J. Kang, H.-M. Wang, J.-J. Yang, H.-H. Yan, Z. Wang

Guangdong Lung Cancer Institute (GLCI), Guangdong Provincial People's Hospital (GDPH), Guangzhou/China

Background: Anaplastic lymphoma kinase tyrosine kinase inhibitor (ALK-TKI) is standard of care in *ALK*-positive advanced non-small-cell lung cancer (NSCLC). Unfortunately *ALK*-positive NSCLC patients treated with ALK TKIs inevitably develop resistance mediated by complex mechanisms including *ALK* mutations, *ALK* amplification, or activation of alternative signaling pathways. However, there are few reports about Mesenchymal-epithelial transition factor (MET) signal in NSCLC. **Method:** Totally 136 *ALK*-positive advanced NSCLC patients were screened for *ALK* rearrangement detected by tumor tissue or plasma Next-generation sequencing(NGS) at the Guangdong Lung Cancer Institute from January 2016 to December 2018 .*MET*-aberrance was defined as c-Met overexpression performed by immunohistochemical(IHC) staining method with SP44 antibody and *MET* amplification assessed by tumor tissue or plasma Next-generation sequencing (NGS) or fluorescent in situ hybridization(FISH). **Result:** Totally 5.89% (8/136) of patients were identified with *MET*-aberrance in 136 *ALK*-rearranged cases. Among the 8 patients,there were 6 with *de novo MET*-aberrance and 2 with acquired *MET*-aberrance.The median progression-free survival (PFS) in *ALK*-rearranged patients with *de novo MET*-aberrance was 9.6 months (95% CI 0.0 to 19.2months).The other 2 patients gained *MET*-aberrance after the treatment with alectinib. Both of them received lorlatinib, but the PFS only lasted for 2months. One achieved partial remission with crizotinib, which was originally developed as an inhibitor of the *MET* gene. **Conclusion:** Acquired *MET*-aberrance maybe a mechanism of acquired resistance to the second-generation ALK-TKIs for *ALK*-rearranged advanced NSCLC patients.

P2.01-36 A PILOT STUDY ON CEREBROSPINAL FLUID CELL-FREE DNA SEQUENCING IN LEPTOMENINGEAL METASTASIS FROM NON-SMALL CELL LUNG CANCER

X. Wu[1], J.-L. Li[2]

[1]*Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Peking/China,* [2]*Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center / National Clinical Research Center for Cancer / Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China*

Background: Leptomeningeal metastasis (LM) is a devastating complication of non-small cell lung cancer (NSCLC) with poor prognosis. It is difficult to determine the genomics alternations and assess the therapeutic responses. The purpose of this study was to detect the cell-free DNA (cfDNA) in cerebrospinal fluid (CSF) from NSCLC patients with LM, and to explore the whole genome and chromosomal alterations information of tumors. **Method:** From 2016 October to 2019 February, a total of 40 lung adenocarcinoma patients with LM were enrolled. Paired 10 ml CSF and 10 ml blood samples were collected before intrathecal chemotherapy. Gene mutations of cfDNA in plasma and CSF were detected by second-generation sequencing (NGS). Three cases of NSCLC-LM CSF cfDNA were sequenced by whole genome sequencing (WGS) to screen chromosome instability (CIN). **Result:**

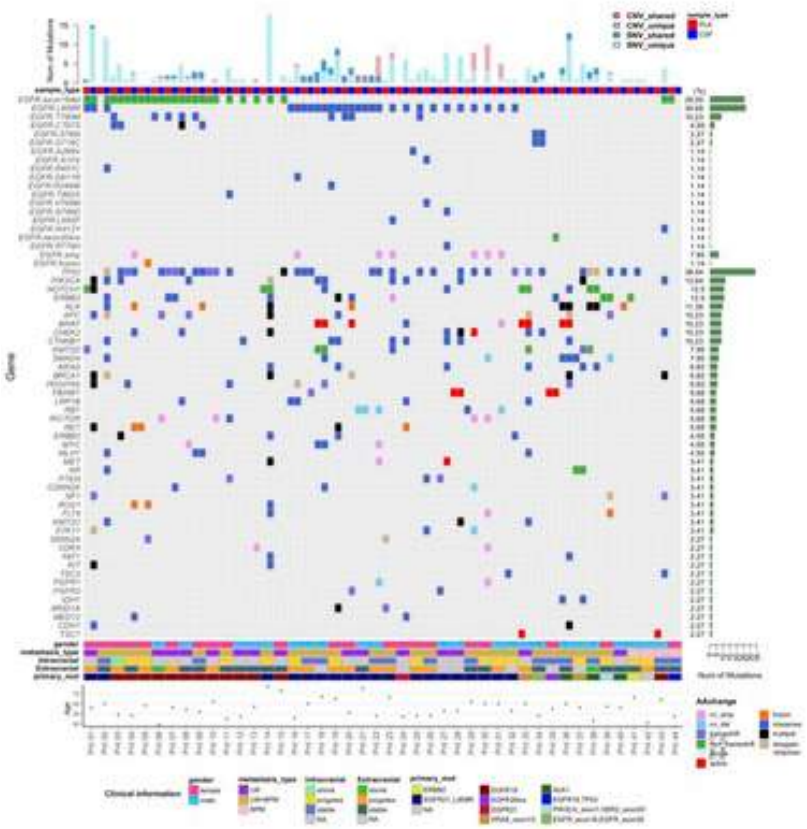

Fig1 Gene mutation landscapes of CSF cfDNA and plasma cfDNA in patients with LM from lung adenocarcinoma

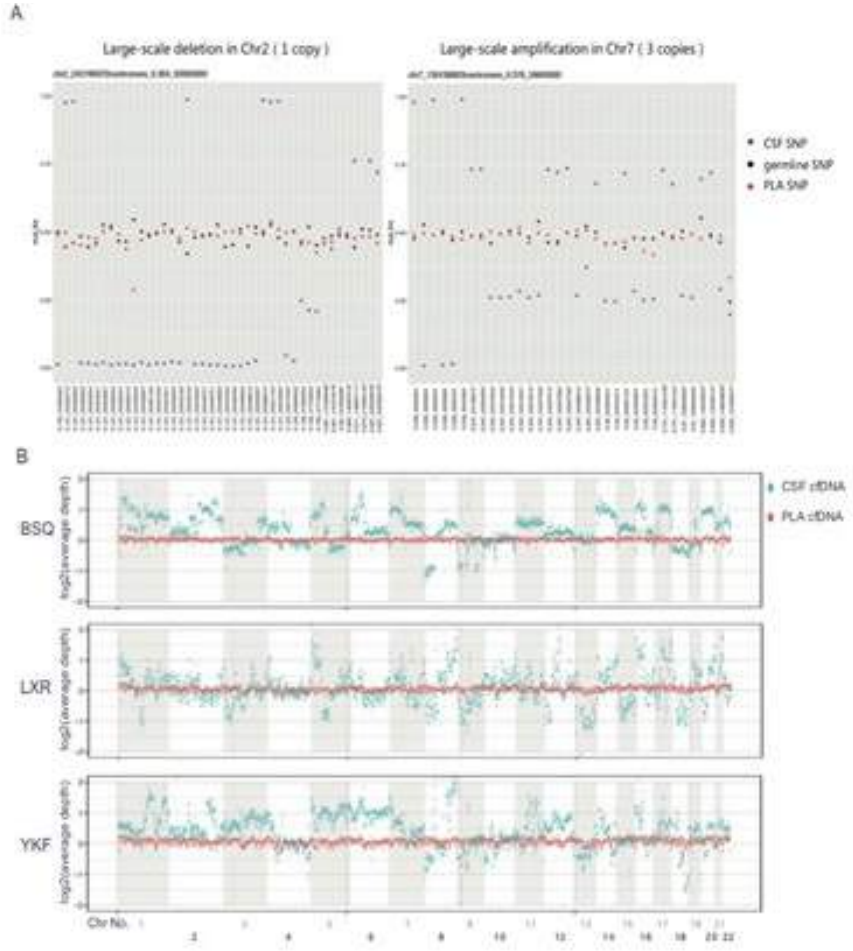

Fig 2 Examples of Chromosome Structural Variation of CSF cfDNA

Among 40 patients with LM from NSCLC, median age was 56 (range, 39-77), 47.8% were female, 85.0% had EGFR mutation, 7.5% ALK rearrangement and 7.5% other activating mutations. Driver genes were detected much higher in CSF cfDNA than plasma cfDNA (100% vs 57.5%). 237 specific genetic mutations were captured in CSF cfDNA, while only 48 specific mutations were detected in plasma. Copy number variations(CNV)were totally identified in CSF cfDNA, however, no CNV was detected in plasma. The three NSCLC-LM CSF cfDNA samples had either short arm deletion on chromosome 8 or short arm amplification on chromosome 5. **Conclusion:** Compared with plasma cfDNA, CSF cfDNA was more sensitive to the detection of LM genomic alterations. We suggest that CSF cfDNA would representative to the LM lesions, it could dynamically monitor the disease progression and guide precision therapies. Whether genome wide doubling (WGD) and CIN can predict overall survival or recurrence risk needs further exploration.

P2.01-37 LOWER RISK OF HYPERCOAGULABILITY IN NON-SMALL CELL LUNG CANCER PATIENTS WITH EGFR MUTATIONS

S. Ohara, K. Suda, T. Takemoto, M. Nishino, M. Chiba, T. Fujino, A. Hamada, T. Koga, J. Soh, T. Misudomi

Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Background: Hypercoagulability is sometimes observed in cancer patients, including non-small cell lung cancer (NSCLC) patients. Plasma levels of fibrinogen or D-dimer are used as markers for hypercoagulability, and several previous studies have reported that upregulation of these markers are poor prognostic factors in NSCLCs. On the other hand, recent studies have highlighted clinical differences between NSCLCs with EGFR mutation and those without. However, there is no data about the difference in hypercoagulability between NSCLCs with EGFR mutation and those without. **Method:** Between January 2007 to December 2016, 270 surgically resected NSCLC patients received EGFR mutation testing and were included in this study. Plasma fibrinogen and D-dimer levels were examined as one of pre-surgical examinations in all patients. We analyzed the correlation between plasma fibrinogen / D-dimer levels and EGFR mutation status. **Result:** Among 270 patients in our cohort, 123 patients had EGFR mutation and 147 patients were wild type (WT) for the EGFR. In our cohort, plasma fibrinogen level was upregulated in 39 patients, while plasma D-dimer level was upregulated in 75 patients. Plasma fibrinogen was upregulated in 9 patients (7%) and in 30 patients (20%) in EGFR mutation group and in WT EGFR group, respectively (p = 0.0017). Plasma D-dimer was upregulated in 27 patients (22%) and in 48 patients (33%) in EGFR mutation group and in WT EGFR group, respectively (p = 0.049). These correlations were still significant after the adjustment with clinical factors including smoking status, age, and histology. In multivariate analysis, odds ratio and 95% CI in EGFR mutation group for upregulated plasma fibrinogen were 0.40 and 0.17 – 0.94, respectively (p = 0.037). On the other hand, odds ratio and 95% CI in EGFR mutation group for upregulated plasma D-dimer were 0.48 and 0.26 – 0.90, respectively (p = 0.022). **Conclusion:** Plasma levels of fibrinogen and D-dimer were significantly lower in NSCLCs with EGFR mutation.

P2.01-38 GENE EXPRESSION PROFILING OF CNS METASTASES IN NON-SMALL CELL LUNG CANCER - MATCHED ANALYSES WITH PRIMARY TUMORS

G. Tsakonas[1], P. Hydbring[2], S. Ekman[1,2]

[1]*Karolinska University Hospital, Stockholm/Sweden,* [2]*Karolinska Institutet, Stockholm/Sweden*

Background: Dissemination of non-small cell lung cancer (NSCLC) in the central nervous system (CNS) is a frequent and challenging clinical problem. Systemic or local therapies rarely prolong survival and have modest activity regarding local control. Alterations in gene expression in brain metastasis (BM) versus primary tumour may increase aggressiveness and could explain the worse prognosis of brain metastatic NSCLC. **Method:** We identified patients with surgically removed BM from NSCLC in two cohorts. The first cohort consisted of 725 patients with surgically removed NSCLC and the second of 280 patients who had received whole brain radiotherapy during the course of their disease. Gene expression analysis with nanoString PanCancer IO 360 panel was performed in BM and primary tumour samples. A minimum of 50 ng of total RNA was used as input for each sample. Identification of differentially expressed genes was conducted on normalized data using the nSolver analysis software. **Result:** 30 patients with surgically removed BM were identified from both cohorts. For 13 of these patients primary tumour samples were available. We compared gene expressions in BM with primary tumour samples and found a statistically significant downregulation of certain genes, especially genes related to immune response and immune cell activation. Gene expression profiles from BM samples displayed a distinct clustering pattern compared to primary tumour samples. Results from KEGG-term analysis on differentially expressed genes revealed a concomitant enrichment of multiple KEGG-terms associated with the immune system. **Conclusion:** We identified a unique gene downregulation pattern in BM samples compared to primary tumour. This finding may explain the lower clinical efficacy of systemic therapy, especially immunotherapy, in BM of NSCLC patients.

P2.01-39 SERIAL PLASMA CTDNA TESTS IDENTIFY GENOMIC ALTERATIONS FOR EARLY PREDICTION OF OSIMERTINIB TREATMENT OUTCOME IN T790M+ NSCLC

B.-C. Liao, W.-H. Hsu, J.-H. Lee, C.-Y. Yang, T.-H. Tsai, W.-Y. Liao, C.-C. Ho, C.-C. Lin, J.-Y. Shih, C.-J. Yu, J. Yang

National Taiwan University Hospital, Taipei/Taiwan

Background: Recent advances in detection of genomic DNA from plasma samples allow us to follow the alteration of shedding tumor DNA in plasma before and after systemic treatment with multiple biopsies. Osimertinib is the standard of care for NSCLC patients with T790M mutations. We plan to use serial plasma cfDNA genomic alteration to predict osimertinib efficacy and search for possible resistance mechanisms. **Method:** We prospectively collected plasma from patients of *EGFR* mutation-positive NSCLC who harbored acquired *EGFR* T790M mutation following prior EGFR-TKI therapy. Plasma samples were collected before starting osimertinib treatment, 4 weeks following osimertinib treatment and upon disease progression. ctDNA were detected by Guardant360 gene panel test. **Result:** Fifteen patients (median age 62 [range 48-77], 53% men, 53% exon 19 deletion and 47% exon 21 L858R mutation) received osimertinib treatment. Acquired T790M mutation was diagnosed by using plasma sample only (Cobas® or digital PCR) (n = 11), tissue or pleural effusion only (n = 2), and both tissue and plasma samples (n = 2). Before starting osimertinib treatment, activating mutations were detected in plasma in all patients, T790M was detected in 93% (n = 14) and *TP53* mutation was detected in 47% (n = 7) of the patients by using Guardant360. After osimertinib treatment, 11 out of the 14 patients had non-detectable plasma T790M at the 4th week. Follow-up CT at least 8 weeks following osimertinib treatment of the 11 patients disclosed decreased tumor size (6 confirmed PR, 1 unconfirmed PR and 5 SD by RECIST criteria). The remaining 3 patients who had detectable plasma T790M (n = 2) or increased activating mutation allele frequency (n = 1) at the 4th week had progressive disease within 16 weeks. The first patient had initial PR but later developed C797S on progression. The second patient developed new liver tumor following prior stable disease. This patient had baseline *TP53* and *CDKN2A* mutations detected in the plasma, and allele frequencies decreased at the 4th week and increased on progression. The last patient had rapid progression on osimertinib treatment, and alterations in *PTEN* and *TP53* were detected on baseline and increased at the 4th week and on progression. In that patient, T790M mutation was not detectable at the 4th week but activating mutation increased in allele frequency at the 4th week and on progression. Regarding patients with baseline *TP53* mutation, 4 (57%) patients who had non-detectable plasma *TP53* mutation at the 4th week achieved disease control, and 2 (29%) patients had detectable or increased *TP53* mutation allele frequency had PD within 16 weeks. **Conclusion:** 4 week plasma ctDNA following osimertinib treatment may predict early progression within 16 weeks.

Keywords: T790M, Osimertinib, ctDNA

P2.01-40 NORMALIZATION OF CARCINOEMBRYONIC ANTIGEN LEVELS IS ASSOCIATED WITH SURVIVAL IMPROVEMENT IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

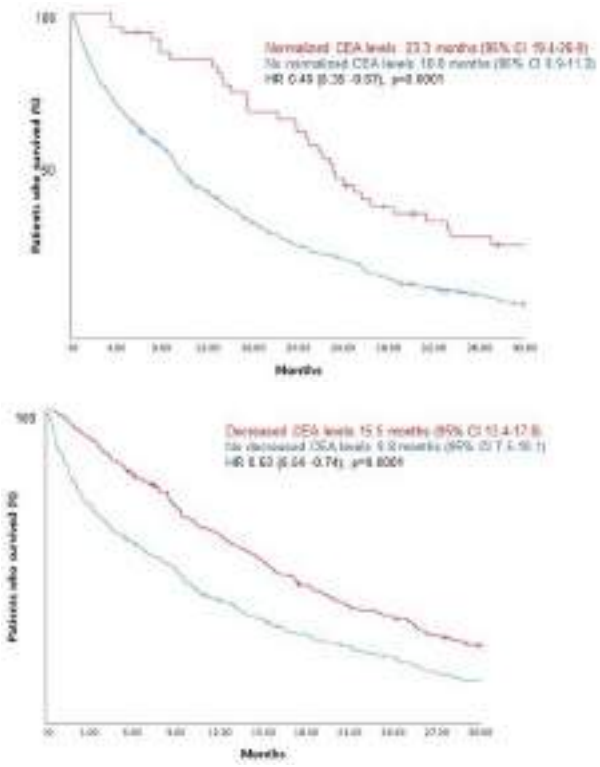
R. Sánchez-Reyes[1,2], E. Varela-Santoyo[3], A. Pereira-García[3], F. Barrón[1], A.F. Cardona[4,5], L. Cabrera-Miranda[1], E. Vergara[1], L. Corrales[6], C. Martin[7], O.G. Arrieta[8]

[1]*Instituto Nacional de Cancerología, Mexico City/Mexico,* [2]*Instituto Nacional de Cancerología, México City/Mexico,* [3]*Médica Sur, CDMX/Mexico,* [4]*FICMAC-Fundación para la Investigación Clínica y Molecular Aplicada al Cáncer, Bogotá/Colombia,* [5]*Clínica del Country, Bogotá/Colombia,* [6]*Hospital San Juan de Dios, San José/Costa Rica,* [7]*Fleming Institute, Buenos Aires/Argentina,* [8]*Instituto Nacional de Cancerologia, Mexico City/Mexico*

Background: Serum carcinoembryonic antigen (CEA) levels are elevated in approximately 65% of the Non-small cell lung cancer (NSCLC) patients with adenocarcinoma histology. Elevated CEA levels are an independent prognostic factor for overall survival (OS) in early and advanced NSCLC stages. Previous reports from our group suggest that the decrease or increase in CEA serum levels

is strongly associated with response and progression to systemic treatment. However, determination of CEA levels is not included in standard guidelines, such as National Comprehensive Cancer Network (NCNN). The aim of this study is to analyze the progression-free survival (PFS) and overall survival (OS) in NSCLC patients with elevated CEA levels at diagnosis and its association with systemic treatment response. **Method:** We performed a retrospective analysis of patients with advanced NSCLC with an elevated serum level baseline of CEA (>20 ng/ml) that received treatment according to international guidelines. The serum CEA levels were measured every two cycles of platinum-based chemotherapy or a tyrosine kinase inhibitor (TKI) treatment. The change in serum CEA levels in response to treatment and the association with overall survival and progression free survival was evaluated. **Result:** Between March 2004 and February 2018, 748 patients with diagnosis of advanced NSCLC and CEA levels >20 ng/mL were included in the analysis. Median age was 60.2 years old, 631 patients (84.4%) had adenocarcinoma histology. From 338 patients evaluated for EGFR mutations, 139 (31.3%) harbored an EGFR mutation. The median OS was 23.3 months (95% CI 19.4-26.9) in patients who completely normalized CEA vs 10.0 months (95% CI 8.9-11.2) in patients who did not achieved CEA normalization, with a HR 0.48 95% CI (0.35 -0.67) p <0.0001. The median OS was 15.5 months (95% CI 13.4-17.6) in patients who showed a decrease in CEA levels vs 8.8 months (95% CI 7.5-10.1) in those who did not. Reduction in CEA levels was associated with better OS, either in patients treated with TKI or platinum-based chemotherapy.

Overall survival according to changes in CEA levels



Conclusion: The normalization or decrease of the serum CEA levels is a biological marker that serves as tool associated with OS. Based on these findings and previous reports, CEA determination should be included in the clinical guidelines for NSCLC as response biomarker. Serum CEA levels should be part of the standard follow-up of NSCLC patients.

P2.01-41 EGFR MUTATION POSITIVE NON-SMALL CELL LUNG CANCER: MANAGEMENT APPROACH AND SURVIVAL OUTCOMES FROM THE HOSPITAL OF LEON

I. Delgado Sillero[1], M. Lopez Flores[1], L.F. Sánchez-Cousido[1], N. Lopetegui Lia[2], M. Rojas Piedra[1], N. Alonso[1], C. Diez Tascon[1], S. Medina[1], M. Pedraza[1], A. López González[1], B. Nieto Mangudo[1], Á. Rodriguez[1], L. De Sande[1], C. Castañón[1], A. García-Palomo[1], P. Diz[1]

[1]*Complejo Asistencial Universitario de León, León/Spain,* [2]*University of Connecticut School of Medicine, Hartford/United States of America*

Background: Approximately 10-16% of non-small cell lung cancer (NSCLC) cases have the EGFR mutation. Studies have shown that EGFR tyrosine kinase inhibitors (TKIs) significantly prolong progression-free survival (PFS) in patients with advanced NSCLC in comparison to those treated with platinum-based chemotherapy doublets. Our aim is to perform a real world analysis of patients treated with TKI as first line therapy at the Hospital of Leon (CAULE). **Method:** We retrospectively reviewed a total of 74 patients diagnosed with EGFR mutation positive NSCLC between March 2011 to June 2018 in the CAULE. Data was obtained from their medical records. The impact of comorbidities and smoking status on the survival rate were evaluated, in addition to the PFS and overall survival (OS) outcomes in patients treated with first line TKI. The follow-up schedule for computed tomography (CT) imaging was realized every 8 to 12 weeks. **Result:** A total of 74 patients were included in the study, out of which 55 were treated with a first line TKI. Exon 19 deletion was the most prevalent mutation subtype accounting for 53% of cases. 67% of patients were women. The average age was 69 years old. 44% had metastasis to more than 2 sites at the time of diagnosis; 6 patients had brain metastasis, 4 of which received prior whole brain radiotherapy, 1 surgical treatment, and 1 didn't receive local treatment. 22% of patients had no medical comorbidities (including cardiovascular, pulmonary, neurological or psychiatric history). Results revealed that the presence of comorbidities had no statistical significance when analyzing its impact on survival outcomes (HR=0.85, 95%CI 0.37-1.83 p=0.64). Similar results were obtained when non-smokers (71%) were compared to smokers or former smokers, suggesting that smoking had no statistical significance when analyzing survival data (HR=0,94 95%CI: 0.43- 2.02 p=0.87). 50% (n= 28) of patients were treated with first line gefitinib, 32% (n=18) with erlotinib and 10% (n= 6) with afatinib. There was no statistical significance in survival rates amongst patients treated with gefitinib vs afatinib or erlotinib (HR=1.6 P=0.56 95%CI 0.84-3.2). When analyzing best response to treatment, 63% of patient had a partial response, 20% demonstrated stable disease and 10% had progression of disease. Median OS was 31 months (95%CI: 20,5-31,4 months) and the PFS was 17 months (95%IC 13,9-20,6 months). 30% were alive at the time of analysis. The main cause of death was disease progression. **Conclusion:** This real-world analysis of the data gathered from the Hospital of Leon confirms that treatment with TKI is beneficial for patients diagnosed with EGFR mutation positive NSCLC. In fact, our OS outcomes are similar than those reported in clinical trials. We have not observed significant differences amongst TKI treatment options, nor was there an impact on global survival rates in patients with underlying medical comorbidities. Given the prevalence of EGFR mutation positive lung cancer, more clinical data is required in order to expand scientific evidence and determine the best driver mutation therapy option based on patient's profile.

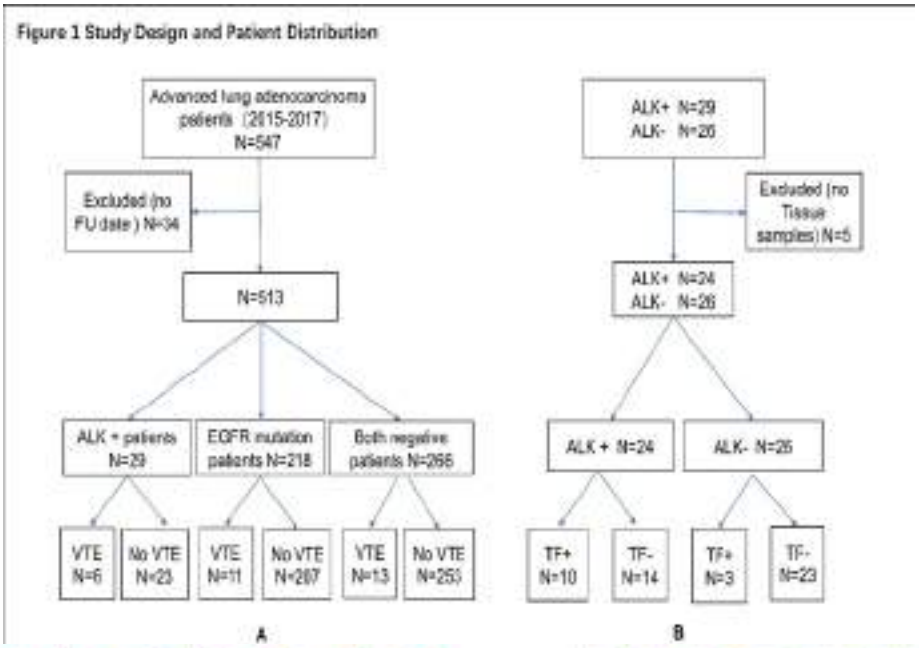
P2.01-42 ALK-REARRANGEMENT MAY PROMOTE VTE BY INCREASING THE EXPRESSION OF TF IN ADVANCED LUNG ADENOCARCINOMA

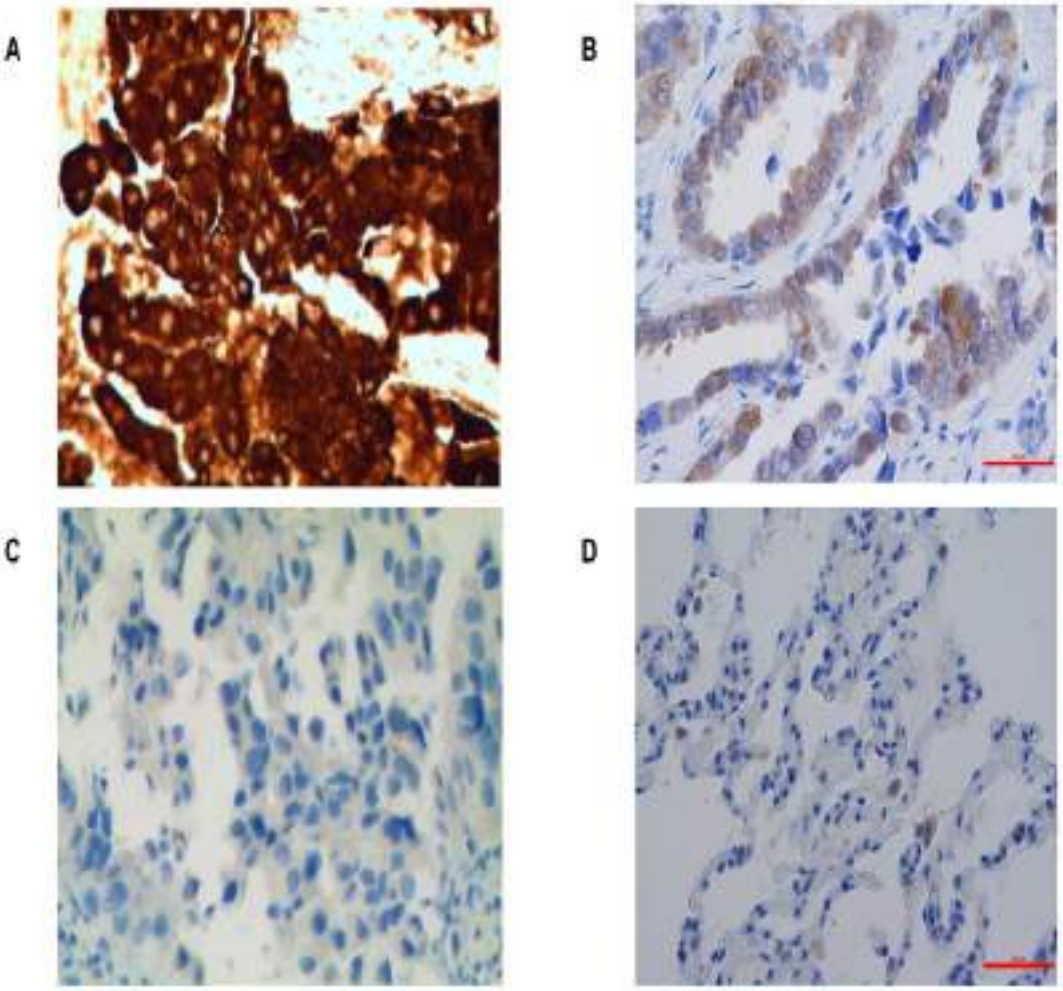
S. Yang, Q. Wang

The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China

Background: Patients with lung cancer are at an increased risk for venous thromboembolism (VTE). About 8% to 15% of patients with advanced none small-cell lung cancer (NSCLC) experience a VTE throughout the course of the disease. However, the incidences of VTE in different molecular subtypes of NSCLC are rarely reported though they have big differentiation in clinical feature and prognosis. Tissue Factor (TF) expressed in many solid tumors could trigger the downstream coagulation cascade and lead to thrombin generation and clot formation. **Method:** Here we extracted retrospective data from electronic medical records at Henan Cancer Hospital

in China between January 2015 and January 2017. Advanced lung adenocarcinoma patients with ALK-rearranged, EGFR mutation and both negative were classified. The incidence of VTE of these patients were calculated. Then we randomly selected ALK-rearranged positive and negative lung adenocarcinoma tissues (N = 29, N = 26, respectively) and detected TF protein expression of the tissues with immunohistochemistry. **Result:** The present study work flow in shown in Figure 1. At a median follow-up of 2.5 years, 5.85% (30 in 513) patients with advanced lung adenocarcinoma experienced VTE. ALK-rearranged patients (Figure 2A) were more likely to occur VTE than EGFR mutation and both negative patients (Figure 2C) (6 in 29, 20.69%; 11 in 218, 5.05%; 13 in 266, 4.89%, respectively *P*=0.018). In ALK-rearranged positive tissues, 41.67% (10 in 24) of them had a high expression of TF protein (Figure 2B) – the incidence was significantly higher than that of ALK-negative tissues' TF protein expression (11.54%, 3 in 26, *P*=0.015) (Figure 2D).





Conclusion: ALK positive NSCLC patients are more likely to occur VTE and this might be due to higher expression of TF in tumor tissues.

POSTERS

P2.01-43 PRE-THERAPEUTIC MARKERS AND SCORES PREDICT RESPONSE AND SURVIVAL IN STAGE IV LUNG CANCER PATIENTS INDEPENDENT OF HISTOLOGY

D. Kauffmann-Guerrero, P. Habisch, J. Götschke, Z. Syunyaeva, P. Mertsch, A. Tufman

Ludwig-Maximilians-University of Munich, Munich/Germany

Background: Lung cancer is the leading cause of death among all cancer entities. Identification of reliable and validated predictive and prognostic markers is important to estimate patients' prognosis. By doing this, planning of treatment and adequate patient guidance would improve. Many studies investigated several predictive and prognostic markers in lung cancer patients. Never the less, most of them describe very selective cohorts. This study aims at investigating histology independent predictive and prognostic markers in stage IV lung cancer patients. **Method:** We retrospectively analyzed 129 stage IV lung cancer patients who had been diagnosed and treated at a German tertiary care lung cancer center between 2015 and 2016. Patients' characteristics in terms of age, gender, performance status, histology, smoking status, treatment modalities and molecular pathological findings were collected from patients' charts. We extracted data sets from electronic patient records and compared anthropometric data, pre-therapeutic blood values as well as clinical scores and performed tests for prediction analysis **Result:** Eight markers and scores could be identified to significantly alter prognosis in univariate analysis. Over the normal cut off elevated values of CRP ($p < 0.001$), LDH ($p < 0.001$), Neutrophil to Lymphocyte ratio (NLR) ($p = 0.018$) and Systemic Inflammation Index (SII) ($p = 0.036$) as well as decreased levels of MCV ($p = 0.025$) and total protein ($p = 0.049$) were significantly associated with reduced overall survival (OS). Furthermore, the higher the Glasgow Prognostic Score (GPS) ($p < 0.001$) or the Lung Prognostic Index (PI-lung) ($p < 0.001$) were the worse was the OS. Failure of first line treatment was significantly predicted by low albumin (p=0.006), lymphocytes ($p = 0.032$) and PNI ($p = 0.001$) levels, whereas low values of CRP ($p < 0.001$), LDH ($p = 0.042$) and Thrombocyte to Lymphocyte ration (TLR) ($p = 0.017$) predict response to first line therapy. Multivariate analysis revealed CRP, PI-lung and GPS as independent prognostic factors regardless histology. **Conclusion:** Simply to obtain blood values and clinical scores provide histology independent markers for response to fist line treatment and survival in stage IV lung cancer patients.

Keywords: Lung cancer, stage IV, prognosis

P2.01-44 PROMOTER POLYMORPHISMS OF TOP2A AND ERCC1 GENES AS PREDICTIVE FACTORS FOR CHEMOTHERAPY IN NON-SMALL CELL LUNG CANCER PATIENTS

A. Grenda[1], J. Błach[1,2], P. Krawczyk[1], M. Nicoś[1], M. Szczyrek[1], B. Kuźnar-Kamińska[3], M. Jakimiec[1], H. Batura-Gabryel[3], M. Sawicki[4], J. Milanowski[1]

[1]*Chair and Department of Pneumonology, Oncology and Allergology, Medical University of Lublin, Lublin/Poland,* [2]*Chair and Department of Clinical Immunology, Medical University of Lublin, Lublin/Poland,* [3]*Department of Pulmonology, Allergology and Respiratory Oncology, University of Medical Sciences in Poznan, Poznań/Poland,* [4]*Chair and Department of Thoracic Surgery, Medical University of Lublin, Lublin/Poland*

Background: TOP2A is an enzyme that control topologic changes in DNA during transcription and replication. ERCC1 is an enzyme takes part in DNA repair processes. Purpose of our studies was to assess predictive role of particular single nucleotide polymorphisms (SNPs) in promoter regions of *TOP2A* and *ERCC1* genes in non-small cell lung cancer patients (NSCLC) treated with chemotherapy. **Method:** We enrolled 116 NSCLC patients qualified to first line chemotherapy. Information on the chemotherapy regimens was available in 106 patients. All chemotherapy regimens were based on platinum compounds. 66 (62%) patients received additionally inhibitors of cell divisions (vinorelbine, taxanes). 40 (38%) patients were treated with nucleoside analogs or antimetabolites (gemcytabine, pemetrexed). DNA was isolated from whole blood with Qiamp DNA Blood Mini kit (Qiagen, Germany) according to the manufacture's instruction. We examined five SNPs: rs11615 (*ERCC1*), rs3212986 (*CD3EAP*), rs13695 (*TOP2A*), rs34300454 (*TOP2A*), rs11540720 (*TOP2A*). Quantitative PCR using TaqMan probe (ThermoFisher, USA) was performed on Eco Illumina Real-Time PCR system device (Illumina Inc., USA). Statistical analysis were performed with MedCalc and Statistica 13.1 softwares. **Result:** In whole group of patients, median of progression free survival (PFS) was 3 months. Patients with CC genotype in rs34300454 had significantly higher median PFS (8 months) compared to patients with CT genotype (4 months, p=0.0026; HR=0.36 with 95% CI: 0,19 to 0,7). We did not detect patients with TT genotype of this SNP. However, the differences in median PFS between patients with different genotypes of the *TOP2A* gene were significant only in the group receiving inhibitors of cell divisions (p=0.011). In second group of patients, we did not observed such significant relationship. Control of disease (response to chemotherapy or stable disease) were observed insignificantly more often in patients with AA genotype in rs11615 of *ERCC1* gene than in patients with AG genotype of this SNP (X^2=3.453, p=0.063). **Conclusion:** Polymorphism of *TOP2A* gene could influence PFS in NSCLC patients treated witch chemotherapy and CC genotype of this polymorphism may be a good predictive factor for chemotherapy regimens containing cell division inhibitors.

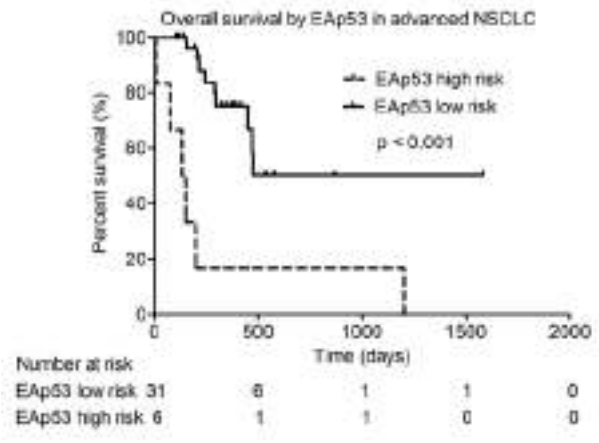
Keywords: NSCLC, TOP2A, ERCC1

P2.01-45 CLINICO-MOLECULAR CHARACTERISTICS AND PROGNOSTIC OUTCOMES OF TP53 MUTATED PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

Z. Song[1], L. Hu[1], Q. Han[1], X. Wang[1], Y. Huo[1], T. Jiao[1], G. Ren[1], K. Wang[1], B. Yin[1], Y. Jia[1], J. Song[1], H. Cheng[2], H. Wang[2], F. Lou[2], S. Cao[2], A. Zang[1]

[1]*Affiliated Hospital of Hebei University., Baoding/China,* [2]*Acornmed Biotechnology Co., Ltd., Beijing/China*

Background: *TP53* mutations are the most common molecular alterations in non-small cell lung cancer (NSCLC), but prognostic role of these mutations remains elusive. The aim of this study was to analyze the clinical and molecular characteristics of *TP53* mutated NSCLC patients and to evaluate a novel approach called evolutionary action (EAp53) to stratify them into high-risk or low-risk groups. **Method:** 85 advanced NSCLC patients were enrolled. Variations of *TP53* and other oncogenic drivers in NSCLC were identified by next-generation sequencing. EAp53 are available at http://mammoth.bcm.tmc.edu/EAp53/. **Result:** Overall, 77 patients (90.6%) exhibited at least one genetic alteration. *TP53* mutations were detected in 51 patients (60.0%) mainly in exons 4, 5, 6, 7, and 8. Notably, *TP53* mutations were not observed in exon 4 when they coexisted with *EGFR* mutations. Mutant allele frequencies (MAFs) of *EGFR* sensitizing mutations (exon 19 deletion or L858R) were significantly higher than those of other *EGFR* mutations in patients harboring *TP53* mutations ($p = 0.012$). Among *TP53* mutated patients, 39.2% of them carried *TP53* truncating mutations (nonsense, splice site, or frameshift), which were correlated with female gender and smokers ($p = 0.026$ and $p = 0.024$, respectively), and were potentially associated with young patients ($p = 0.078$), and were more common in non-DNA-binding domain of *TP53* ($p = 0.033$). Additionally, overall survival time of 37 patients were collected, and patients with high-risk mutations stratified by EAp53 had a significantly worse OS compared to others (HR 23.15; 95% CI 4.30-124.50; $p < 0.001$).



Conclusion: This study is of great significance in understanding the population characteristics of *TP53* mutated NSCLC patients. Furthermore, the data also indicates that evolutionary high risk *TP53* mutations can identify a subset of patients with poor prognosis, suggesting that EAp53 is a novel approach and may be useful in clinical prognosis of NSCLC patients with *TP53* mutations.

P2.01-46 THE EFFICACY AND SAFETY OF 2ND-LINE NIVOLUMAB FOR NON-SMALL CELL LUNG CANCER IN REAL-WORLD PRACTICE WITH EMPHASIS ON HYPERPROGESSION

J.C. Lee, C.-M. Choi, W. Ji, S.H. Kim

Asan Medical Center, Seoul/Korea, Republic of

Background: The efficacy of nivolumab, a PD-1 immune checkpoint inhibitor, has been proven through many clinical trials. However, the data about whether it can be generalized to real-world patients are limited. We investigated the outcomes of non-small cell lung cancer (NSCLC) patients who received nivolumab with emphasis on hyper-progressive disease (HPD). **Method:** This retrospective study enrolled stage IV NSCLC patients who received nivolumab following the progression after previous chemotherapy between July 2016 and June 2018 in single center. HPD was defined as the progression by RECIST at the first evaluation with ≥2-fold increase of the tumor growth rate between the prior and the upon nivolumab period. **Result:** A total of 83 patients with a median age of 60 years were included (Squamous vs non-squamous; 25[30%] vs 58[70%]). Among 59 patients with available PD-L1 level, 17% of patients showed the negative expression of PD-L1 while 20% of them had more than 50% of expression. The response and disease control rate were 7% and 52% while the median PFS and OS were 2.6 (95% confidence interval [CI], 0.82 to 4.31) and 8.6 months (95% CI, 5.56 to 11.59), respectively. The PD-L1 level ≥ 50% group (n=12) showed the superior outcome with the median OS of 18.1 months. Treatment-related adverse events of grade 3 or 4 occurred in 8.4%. HPD developed in 16 (19.2%). The median OS of HPD group was 2.2 months (95% CI, 0.92 to 3.75) whereas that of other progression group was 4.1 months (95% CI, 1.54 to 6.67). Among patients with pleura or pericardium metastasis, increased effusion was seen in 90% of HPD group (n=9/10) whereas 28.6% of other progression group (n=4/14) (p=0.004). There was no other significant HPD-related factor. **Conclusion:** Although the efficacy and safety of nivolumab in real-world patients are comparable to those of clinical trials, clinicians should beware of HPD as it is not uncommon and represents the worst prognosis. The relationship with HPD and effusive metastasis should be further investigated.

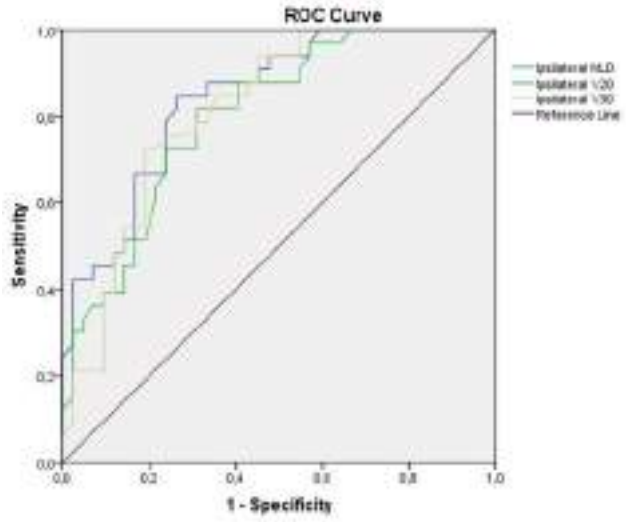
P2.01-47 IPSILATERAL LUNG DOSE CONSTRAINTS PREDICT RADIATION PNEUMONITIS BETTER THAN CONVENTIONAL ONES IN NSCLC PATIENTS TREATED WITH RCT

E. Korkmaz Kıraklı[1], S. Erdem[1], E. Erim[1], D. Yalman[2]

[1]*Dr. Suat Seren Chest Diseases and Research Hospital, İzmir/Turkey,* [2]*Ege University Medical School & Hospital, Izmir/Turkey*

Background: Mean lung dose (MLD) and percent of total lung volume that receive a dose greater than 20 Gy (V_{20}) have been mostly validated parameters in prediction of radiation pneumonitis (RP). But these parameters present mean values of total lung parenchyme and predict the right and the left lung as a unique functional organ unit, not take into account the difference in function, dose density and radiosensitivity between the lungs. Also, there has been very limited data evaluating ipsilateral lung dosimetric constraints in addition to total lung parameters to predict RP in NSCLC-patients treated with radiochemotherapy (RCT). **Method:** Between 2010-2017, clinical-radiological findings of NSCLC-patients treated with RCT were evaluated in terms of RP, retrospectively. The right and the left lung were contoured separately.The total lung was created by extracting PTV. Ipsilateral lung was described as the lung containing more than 50% of PTV and was created by extracting PTV from ipsilateral lung. Pulmonary toxicity was graded according to RTOG/EORTC. Clinicaly important RP was defined as ≥ grade 2 lung morbidity. The primary end point was to asses the relation between ipsilateral lung dose constraints and RP risk.The secondary end-point was to evaluate the predictive value of ipsilateral dose constraints in case of a relationship. **Result:** There were 75 patients.There was ≥ grade 2 RP in 33 cases (%44).Median age at diagnosis was 59.The median follow-up was 21 months.The median RT dose was 63 Gy.There was ≥ grade 2 RP in 33 cases(%44).RP risk was 75% if the tumor was located in upper lobe(p:0.012). Univariate analysis was carried on clinical and dosimetric variables.The most significant ones were;ipsilateral MLD(p<0.001), ipsilateral V_{20}(p<0.001), ipsilateral V_{30}(p<0.001) and total lung V_{30}(p<0.001). Ipsilateral MLDp<0.001(OR:1.34)(%95CI:1.16-1.55) and PTV p:0.039(OR:1.002)(%95CI:1.000-1.004) were found to be the independent risk factors for RP. The diagram of ROC curve analysis is shown in Figure 1.AUC values for ipsilateral MLD, ipsilateralV20, ipsilateralV30, MLD, V20 and V30 were 0.84, 0.80, 0.81, 0.64, 0.69 and 0.77, respectively.Threshold values for ipsilateral MLD, ipsilateral V20 and ipsilateral V30 were selected by ROC curve analysis and was determined as 18 Gy. 35% and 28% respectively.



Conclusion: In NSCLC-patients treated with CRT, MLD, V_{20} and V_{30} values of ipsilateral lung parameters might increase the predictablity of RP risk in addition to total lung parameters or even better. RT plannings might be improved by simply adding ipsilateral dose volume constraints witthout any additional test or effort to the patient

P2.01-48 ENHANCED EXPRESSION OF MIR-204 REDUCES CISPLATIN RESISTANCE IN NSCLC

Z. Cao

The Sixth Affiliated Hospital of Wenzhou Medical University, Lishui/China

Background: Non-small cell lung cancer (NSCLC) is the most common and lethal human malignant tumor worldwide. Platinum-based chemotherapy is still the mainstay treatment for NSCLC. However, long-term chemotherapy usually induces serious drug resistance. Accordingly, it is valuable to develop treatment strategies that could reduce the resistance against platinum-based drugsin NSCLC cells . **Method:** Cisplatin-resistant NSCLC models in A549 and PC9 cell lines (CR-A549 and CR-PC9) were established through long-term exposure to cisplatin. Expression levels of caveolin-1 (CAV-1) and miR-204 in A549, PC9, CR-A549, and CR-PC9 cell lines were detected by western blot and q-PCR, respectively. Regulation of CAV-1 by miR-204 was assessed by bioinformatic analysis, western blot and luciferase reporter assay. The role of the miR-204/CAV-1 axis in regulating cisplatin resistance in NSCLC cells was tested by MTT assay. Interactions with Bcl-2-associated agonist of cell apoptosis (Bad) and Bcl-xl (Bcl-2) were evaluated by co-immunoprecipitation assay. Flow cytometry was used to detect the apoptosis of NSCLC cell lines. **Result:** We observed significant upregulation of CAV-1 expression and a significant decrease of miR-204 expression in CR-A549 and CR-PC9 cells compared to their parental A549 and PC9 cells. Furthermore, we detected down regulation of miR cells. We then found that enforced expression of miR-204 can resensitize CR-A549 and CRPC9 cells to cisplatin treatment through the inhibition of CAV-1 expression. Thus, we declared that recovery of miR-204 expression was able to sensitize the cisplatin-induced mitochondrial apoptosis observed in CR-A549 and CR-PC9 cells through suppression of the caveolin-1/AKT/Bad pathway. **Conclusion:** This study suggested that enhanced expression of miR-204 could increase the sensitivity of cisplatin treatment by suppression of caveolin-1/AKT/Bad pathway, which concluded that overexpression of miR-204 could be a potential approach for enhancing the sensitivity in NSCLC cells with cisplatin resistance.

Keywords: miR-204, Caveolin-1, cisplatin

Background: Silibinin is a bioactive flavonolignan extracted from milk thistle (*Silybum marianum*) and is a direct inhibitor of STAT3 – with high affinity to both the Src homology-2 domain and the DNA-binding domain of STAT3. Pre-clinical data indicate that blocking STAT3 signaling in reactive astrocytes, a major component of the brain metastasis microenvironment, can decrease the number and size of brain metastases (BM). **Method:** We present data on all patients diagnosed with BM from non-small cell lung cancer (NSCLC) from the Cancer Register of the Hospital Universitari Dr. Josep Trueta during 2013–2017. Age, gender, histology, and treatment in patients were recorded. During this period, some patients received compassionate use of Legasil®, a commercially available silibinin-based nutraceutical, in addition to standard oncologic treatment. The data cut-off for survival analysis was 28th March 2019. **Result:** We identified 221 patients with NSCLC and BM. Median age: 62 y (range: 32–88 y); male: 161 (72.9%). Synchronous BM were observed at the diagnosis of primary lung cancer in 133 (60.2%) patients. Differences in median overall survival (mOS) were detected by histology subtype: adenocarcinoma (66.1%)=4.6 m, squamous (17.6%)=1.8 m, not otherwise specified (16.3%)=2.2 m, p=0.000003. Treatment effects on mOS are summarized in Table 1. In the subgroup of patients that received brain radiotherapy in addition to systemic therapy for BM, differences were maintained between patients that received Legasil® (n=15) or not (n=64):28.5 months *vs* 6.3 months (p=0.000052).

Table 1

Treatment	%	mOS (without)	mOS (with treatment)	p-value
Brain radiotherapy	53.8%	1.9 m	5.1 m	< 0.000001
Systemic therapy	52%	1.6 m	6.9 m	< 0.000001
Brain surgery	5%	3.2 m	15.5 m	=0.000127
Silibinin supplementation	8.1%	3.5 m	22.8 m	=0.000001

Conclusion: Our data indicate that silibinin supplementation could contribute to the control of BM in patients with NSCLC. Further evaluation of silibinin, or other STAT3 inhibitors, in clinical trials is warranted in this setting.

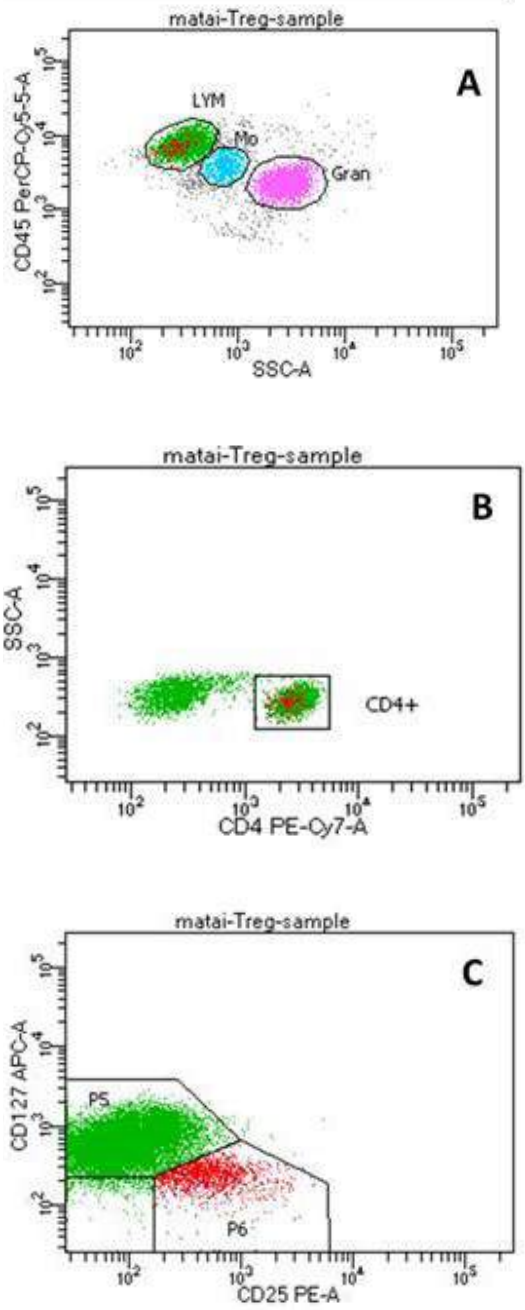
Keywords: silibinin, NSCLC, brain metastasis

P2.01-50 CD 146 A POTENTIAL THERAPEUTIC TARGET FOR LUNG CANCER

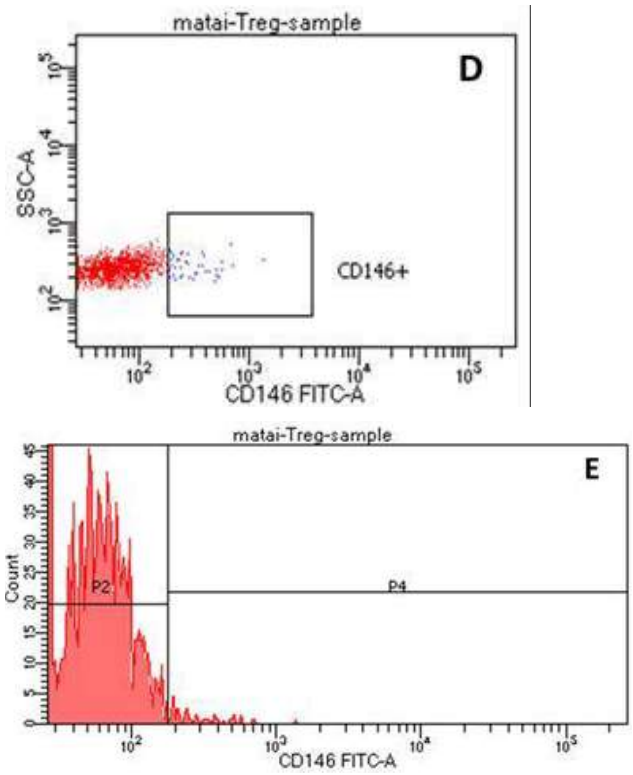
A. Olajuyin[1], A. Olajuyin[2], Z. Xingru[1], Q. Fagyuan[1], W. Zhiti[2], X. Yasi[1], X. Zhang[1], Z. Yaping[1]

[1]*Henan Provincial People Hospital, zhengzhou/China,* [2]*Henan People Provincial People Hospital, Zhengzhou/China*

Background: Non-small-cell lung cancer (NSCLC) patients often exhibit lymphopenia, which has been associated with poor clinical outcomes. However, the mechanisms that lead to lymphopenia have not been fully established. CD 146 is an important glycoprotein found on the integral membrane of the cells. Its ectodomain contains five immunoglobulin-like domains and its cytoplasmic tail contains potential protein kinase C recognition sites and PDZ binding sites indicating possible involvements in cell signaling **Method:** Blood was collected from lung cancer patients and from healthy subjects. The frequency of CD146 cells and the expression of CD 4, CD45, CD 127, CD 25 were determined by flow cytometry. Lymphocytes apoptosis was determined by 7-amino-actinomycin D/Annexin V-APC staining. **Result:** The percentage of CD 146 was significantly higher in patients than in controls. CD 146 expression in whole-blood samples was higher in NSCLC patients than in controls



POSTERS



Conclusion: Increased CD 146 expression on the blood of lung cancer patients may be associated with the underlying mechanisms leading to lymphopenia in NSCLC patients

P2.01-51 NEXT-GENERATION SEQUNCING FOR EFFECTIVE DETECTION OF VARIOUS EGFR EXON 20 INSERTIONS (E20INS) IN NON-SMALL CELL LUNG CANCER (NSCLC)

I. Hwang, S.-W. Kim, S.-M. Chun, S. Yoon, D.H. Lee

Asan Medical Center (AMC), University of Ulsan College of Medicine, Seoul/ Korea, Republic of

Background: Epidermal growth factor receptor (EGFR) E20ins are known as uncommon EGFR mutation and relatively insensitive to current EGFR tyrosine kinase inhibitors (TKIs). However, recent newer TKIs such as poziotinib show good clinical activity against them. Thus, we further explored the rate of EGFR E20ins and their clinical characteristics **Method:** Between March 2017 and October 2018, 488 NSCLC tumor specimens were examined with OncoPanel AMC version3 which is a Next-generation sequencing (NGS) based assay for the detection of single-nucleotide variants, insertions, deletions, copy number alterations and structural variants across 382 genes. Peptide Nucleic Acid (PNA) clamping method version2 is to detect EGFR mutations using allele specific polymerase chain reaction and 6 variants of E20ins could be detected by it. We analyzed those NGS results and they were compared with PNA clamping method results if examined previously. Clinical characteristics were also reviewed. **Result:** Among 488 patients, 143 showed EGFR mutations;16 patients showed wide variety of E20ins, while 59, 54 and 14 patients showing exon 19 deletion, L858R, and other rare EGFR mutations, respectively. Thus, the rate of E20ins was 11.2% of all EGFR mutations. For those 16 patients with E20ins, PNA clamping method failed to detect E20ins EGFR mutation in 8 patients (50%). Male/Female ratio was 7/9. Median age was 57 years (25-76 years). The rate of non-smoking was 68.8%. First-line platinum based regimen were given in 10 patients with 2.5 months of median progression free survival (PFS), while first-line EGFR TKIs were given in 5 patients with 2.3 months of median PFS. Poziotinib was provided to 2 patients later and they showed stable disease and partial remission. **Conclusion:** EGFR E20ins were detected in 11.2% of EGFR-mutant NSCLC by OncoPanel AMC version3, and it was twice the rate by PNA clamping method. Clinically those patients showed lack of response to current EGFR TKIs. Poziotinib is a new EGFR TKI and promising for E20ins EGFR mutation.

P2.01-52 CLINICAL CHARACTERISTICS AND OUTCOMES IN NSCLC PATIENTS ASSOCIATED WITH VERY HIGH PD-L1 EXPRESSION

E. Mcloughlin[1], L. Hanson[1], M. Moore[2], B. Horton[2], R. Gentzler[1], R. Hall[1]

[1]*University of Virginia, Charlottesville/United States of America,* [2]*University of Virginia School of Medicine, Charlottesville/United States of America*

Background: Clinical characteristics and outcomes for patients with non-small cell lung cancer (NSCLC) and very high PD-L1 expression are unknown. We sought to better characterize this subset of patients with PD-L1 ≥90% to determine any differences in clinical presentation or survival. **Method:** We performed a retrospective analysis of patients treated at our institution between 2014 and 2018 with metastatic NSCLC and an available PD-L1 result (any assay). We assessed tumor size, location of metastasis, and presence of mediastinal invasion using continuous PD-L1 values (Wilcoxon Mann-Whitney test) and compared two subgroups based on a PD-L1 cut point of ≥90% (Fisher's exact test). Survival comparisons used Kaplan Meier log-rank methodology. **Result:** A total of 101 patients were included in the analysis; 16.8% had PD-L1 ≥90%. A summary of the patient demographics and clinical characteristics are summarized in Table 1. Higher PD-L1 values were associated with mediastinal invasion (median PD-L1 60% vs 5% without invasion, p=0.0268) and those with PD-L1 ≥90% were more likely to have adrenal metastasis (p=0.0266). There was no correlation between tumor size or other sites of metastasis and PD-L1 expression. OS was not significantly different when compared to those with PD-L1 50-89% or lower PD-L1 subgroups in either immunotherapy alone treatment group (p=0.6358) or for the combination chemotherapy/ immunotherapy group (p=0.2580). Patients receiving immunotherapy alone with PD-L1 expression ≥90% had a median OS of 38.0 months compared to 21.3 months for PD-L1 0-89% (p=0.8480). Table 1:

	PD-L1 status				
	Less than 90% n (% if applicable) n=84	Greater than 90% n (% if applicable) n=17	Total N (%) n=101	P-value (continuous)	P-value (≥90% vs. <90%)
Patient Demographics					
Age (median in years)	63	60	62.5		
Female	42 (50)	9 (53)	51 (51)		
History of Smoking	72 (86)	15 (88)	87 (86)		
Line of treatment with immunotherapy					
First Line	38 (45)	8 (47)	46 (46)		
Second Line or greater	46 (55)	9 (53)	55 (55)		
Immunotherapy alone	57 (68)	13 (77)	70 (69)		
Chemo + IO	27 (32)	4 (24)	31 (31)		
EGFR mutation	0	0	0		
Clinical Characteristics					
Tumor Size (median in cm)	3.6	4.10	3.7	0.0843	0.3598
Evidence of Mediastinal Invasion	13 (16)	4 (24)	17 (17)	0.0268	0.4932
Adrenal Metastasis	10 (12)	6 (35)	16 (16)	0.2067	0.0266
Bone Metastasis	18 (21)	5 (29)	23 (23)	0.8942	0.5316
Brain Metastasis	24 (29)	7 (41)	31 (31)	0.6064	0.3879
Liver Metastasis	15 (18)	2 (12)	15 (15)	0.7518	1.0

Conclusion: Higher PD-L1 expression was associated with mediastinal invasion, and adrenal metastasis were more common in patients with PD-L1 ≥90%. While there were no detectable survival differences in the very high PD-L1 group, differences in clinical characteristics highlight the heterogeneity of this group of patients and need for further characterization that may be predictive of treatment response and help tailor treatments for this group.

P2.01-53 SURGICAL RESECTION OF PRIMARY TUMOR IMPROVE THE PROGNOSIS OF LUNG CANCER PATIENTS WITH BONE METASTASIS

D. Tian[1], X. Zhang[2], X. Ben[1], G. Qiao[1]

[1]*Guangdong Provincial People's Hospital, Guangdong Academy of Medical Sciences, Guangzhou/China,* [2]*Sun Yat-Sen University Cancer Center, Guangzhou/China*

Background: Most of the lung cancer patients are in advanced stage at the time of diagnosis due to occult onset. Bone metastasis is one of the most common sites of hematogenous metastasis of lung cancer. This study used the Surveillance, Epidemiology, and End Results (SEER) database to evaluate the impact of surgical resection of primary tumor on the prognosis of lung cancer patients with bone metastasis. **Method:** We identified 12578 lung patients with only bone metastasis from the Surveillance, Epidemiology, and End Results database. Propensity score matching was used to reduce the selection bias. Cancer–specific survival (CSS) were compared between patients with or without primary tumor resection. The Cox regression model was applied to evaluate multiple prognostic factors. The effects of different surgical extension and lymph node resection on prognosis were also analyzed. **Result:** After propensity matching, a total of 458 patients were selected into survival analysis. There were no statistical differences in age, gender, race, tumor location, histology, T stage and N stage between patients with or without surgical resection of primary tumor. The prognosis of patients undergoing surgical resection of primary tumor was significantly better than that of patients who had not undergone surgery (five-year CSS rate: 2.7% vs. 23.4%, respectively, P<0.001). Multivariable analysis revealed that surgical resection of primary tumor was an independent prognostic factor (HR=0.518, 95% confidence interval [CI] 0.414 to 0.648, P<0.001). In addition, the prognosis of patients undergoing lobectomy/bilobectomy was significantly better than that of others(P<0.001). Furthermore, regional lymph node resection during the operation could significantly improve the prognosis of the patients (P<0.001). **Conclusion:** For lung cancer patients with only bone metastasis, surgical resection of primary tumor could significantly improve the prognosis. Lobectomy/bilobectomy with regional lymph node resection was the best surgical strategy.

P2.01-54 REAL-WORLD PD-L1 TESTING PATTERNS FOR PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER IN GREECE

E. Kokkotou[1], A. Charpidou[1], A. Papaspiliou[1], L. Stournara[1], V. Grammatikou[2], F. Ejzykowicz[3], K. Syrigos[1]

[1]*Athens Medical School, Sotiria General Hospital of Athens, Athens/Greece,* [2]*MSD Greece, Athens/Greece,* [3]*Merck & Co., Inc., New Jersey/United States of America*

Background: Programmed Cell Death Protein-1 (PD-1) and Programmed Death Ligand-1 (PD-L1) inhibitors are important immunotherapy targets for non-small cell lung cancer (NSCLC). This study sought to describe PD-L1 testing for patients with NSCLC in Greece. **Method:** This non-interventional study is based on Sotiria Lung Cancer Registry in Greece recording patients with histologically or cytologically confirmed stage IIIB/IV NSCLC diagnosis, who initiated systemic treatment between August, 15th 2016 and August, 14th 2018. **Result:** A total of 472 patients were included in the registry. Demographic and first-line treatment information are presented in Table 1, along with the respective comparison between patients tested and not tested for PD-L1. Patients with ECOG PS 0-1 are more likely to be tested for PD-L1 status. Among patients tested for PD-L1, Dako 22C3 was the most commonly used testing assay (87.8%). The number of patients tested for PD-L1 increased between the two consecutive time periods (from August, 15th 2016 to August, 14th 2018; Table 2).

Table 1 Demographic characteristics, PD-L1 testing, and first-line treatment patterns.

		Not tested for PD-L1 (N=332)	Tested for PD-L1 (N=140)
Age	≤65	108 (32.5)	45 (32.1)
	>65	224 (67.5)	95 (67.9)
	Mean (sd)	68.4 (8.8)	66.8 (10.0)
Gender	Female	62 (18.7)	36 (25.7)
	Male	270 (81.3)	104 (74.3)
Smoking status	Current	198 (59.6)	78 (55.7)
	Former	106 (31.9)	46 (32.9)
	Non Smoker	14 (4.2)	8 (5.7)
	Unknown	14 (4.2)	8 (5.7)
Stage	IIIB	83 (25.0)	31 (22.1)
	IV	249 (75.0)	109 (77.9)

Hospital Universitario Guadalajara, Guadalajara/Spain,* [6]*Virgen de la Salud Hospital, Toledo/Spain,* [7]*Fundación Jiménez Díaz University Hospital, Madrid/Spain,* [8]*Móstoles University Hospital, Madrid/Spain,* [9]*Fuenlabrada University Hospital, Madrid/Spain,* [10]*Ramón y Cajal University Hospital, Madrid/Spain*

Background: Anti PD-1 and PD-L1 immunotherapies have demonstrated improved survival as second line treatment of patients with advanced lung cancer, and actually, this is a standard of care. In addition, Nintedanib-docetaxel is an option for few patients, and have demonstrated efficacy in second line treatment after platinum-based chemotherapy. The doubt is if immunotherapy could be change efficacy of nintedanib-docetaxel treatment. **Method:** We conducted a retrospective multicenter study, which included all patients with non-small cell lung cancer who received nintedanib with docetaxel in second o third line of treatment. The objective of this study was to determine the efficacy of the nintedanib-docetaxel combination before and after immune checkpoint inhibitors. **Result:** We enrolled 120 patients from 10 different Spanish centers. 72.4% had not received previous immunotherapy, while 27.6% had received it. Of those who had received previous immunotherapy: 10.6% received pembrolizumab, 10.6% received nivolumab and 3,3% received atezolizumab. Receiving previous immunotherapy had no impact on the PFS (4.5 months vs 3.2 months) or on the OS of the patients (25 months vs 20 months). Best response was partial

response in 11 patients, stable disease in 11 patients and progressive disease in 10 patients. After the progression to nintedanib/docetaxel, 21.9% received immunotherapy. 15 patients received nivolumab, 10 patients atezolizumab and 2 patients pembrolizumab. Best response was partial response in 13 patients, stable disease in 5 patients, complete response in 1 patient and progressive disease in 8 patients. Subsequent treatment with immunotherapy was not associated with increased SLP or OS in our study. **Conclusion:** Our experience suggests that the efficacy of nintedanib-docetaxel treatment is not modified by the treatment of previous or subsequent with immunotherapy.

Keyword: non-small cell lung cancer, nintedanib, immunotherapy.

P2.01-56 COPY NUMBER GAINS (CNGS) OF CLINICALLY RELEVANT GENES IN ADVANCED NSCLC PATIENTS

M. Garzón[1], N. Jordana[1], B. García[1], R. Román[1], J. Bertrán-Alamillo[1], S. Rodriguez[1], E. Aldeguer[1], S. Garcia Román[1], S. Viteri[2], A. Aguilar Hernandez[2], M. Gonzalez-Cao[2], M. Fernández-Bruno[3], N. Karachaliou[3], A. Martinez-Bueno[2], I. Moya[4], M.A. Molina-Vila[1], R. Rosell[5], C. Mayo De Las Casas[1]

[1]*Pangaea Oncology, Hospital Universitario Quiron-Dexeus, Barcelona/Spain,* [2]*Instituto Oncologico Dr Rosell. Hospital Universitario Quiron Dexeus, Grupo QuironSalud, Barcelona/Spain,* [3]*Instituto Oncologico Dr Rosell. Background: Somatic copy number variations (CNV; i.e. amplifications and deletions) have been implicated in the origin and development of multiple cancers and some of these aberrations are designated targets for therapies, such as amplified ERBB2 in breast cancer. In the case of NSCLC patients, MET alterations are receiving increasing attention as targets in precision medicine, and several clinical trials of anti-MET agents are ongoing. Routine testing for these potential targets on formalin-fixed paraffin embedded (FFPE) samples is mainly carried out by in-situ hybridization (FISH) approaches covering only a single gene of interest. Although this methodology is still the gold standard of CNV detection, it presents several drawbacks. Here we aimed to determine the potential of next generation sequencing (NGS) to simultaneously determine CNGs across many in FFPE samples **Method:** FFPE biopsies from 140 stage IIIb-IV NSCLC patients (p) of our institution were prospective tested. Of them, 110 corresponded to samples at diagnostic and 30 after progression to targeted therapies. DNA was purified submitted to NGS using the 16-gene QIAact Lung Panel (Genereader®, Qiagen). Coverages for the genes analyzed were normalized using the total coverage of the panel. Cut-off values for CNVs were established as the average normalized coverage for each gene plus two times the standard deviation. Representative samples were analyzed by FISH **Result:** Validation analyses in 8 cell lines showed 100% concordance between FISH and NGS for detection of EGFR, MET and ERBB2 amplifications. Among the 140 NSCLC p, MET was the gene showing a higher frequency of CNGs, followed by PIK3CA, NRAS, EGFR and KRAS (Table 1). In contrast, only one p was found to harbor a ROS1 CNG. Among the 17 samples with MET CNG (12%), 6 corresponded to p progressing to targeted therapies. In addition, 8 of the 17 samples with MET CNGs were submitted to FISH, 6 of them were positive and the remaining 2 samples had copy numbers higher than 3.5 by this technique. In the case of EGFR, CNGs were associated with sensitizing mutations, with 5 samples showing both alterations concomitantly. In contrast, PIK3CA, NRAS, ALK, BRAF, HER2, PDGFRA, KIT and MET CNGs were not associated with mutations (Table 1).

	n CNG	%	n MUTANT
MET	17	12.1	0
PIK3CA	12	8.6	0
NRAS	10	7.1	0
EGFR	10	7.1	5
KRAS	10	7.1	2
ALK	8	5.7	0
BRAF	8	5.7	0
ERBB2	8	5.7	0
PDGFRA	6	4.3	0
KIT	6	4.3	0
ROS1	1	0.7	0

Conclusion: CNGs in clinically relevant genes are present in a significant percentage of advanced NSCLC patients and, except in the case of EGFR, are not associated with driver mutations. Further research is warranted to determine the clinical implications of this finding.

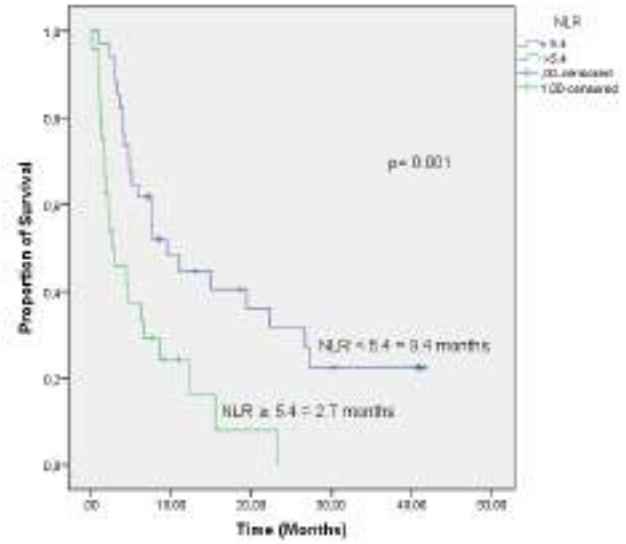
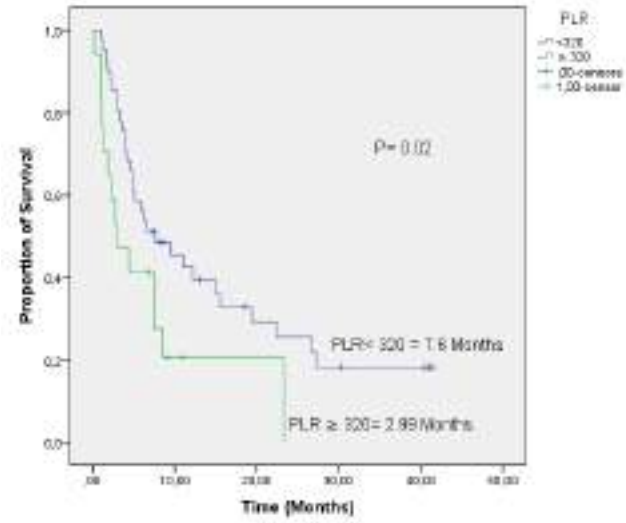
P2.01-57 NEW PROGNOSTIC MARKERS IN PATIENTS WITH LUNG CANCER TREATED WITH IMMUNOTERAPY: NLR AND PLR

S. Gunduz, M. Ozdogan, O. Kırca, M. Çakır, A. Kargı, M. Uysal, V. Kaya, N. Öz, A. Yıldız

Antalya Memorial Hospital, Antalya/Turkey

Background: Immunotherapy has become standard therapy in metastatic lung cancer. The problem for these agents is lack of prognostic and predictive markers which is feasible in clinical practice. On the otherhand up to 30% of patients accelerated progression of tumor early after immune checkpoint blockade(Hyperprogression). Predictive biomarkers of Hyperprogression(HP) have not been emerged. NLR and PLR are established strong prognostic markers associated with worse OS in several tumor types. The aim of our study was to analyse the prognostic impact of NLR and PLR in lung cancer patients treated with immunotherapy. And is there any relationship between these biomarkers and HP. **Method:** NLR was calculated by division of absolute neutrophil and lymphocyte counts measured in peripheral blood before start of immunotherapy. PLR was calculated by division of thrombocytes and lymphocytes accordingly. **Result:** The study included 63 patients who were treated with immunotherapy on metastatic setting. Most of patients (63.4%) had been given at least two line chemotherapy. The after-immunotherapy radiological response; three patients(4.8%) had a complete response, 13 patients(20.6%) had a partial response. Hyperprogression was detected 7(11.1%)patients. Median PFS was 3.2 months (95% CI 2.78 to 3.72), and median OS was 6.5 months (95%CI 4.04 to 9.04) with immunotherapy. Median OS was 9.4 vs 2.7 months in patients with NLR<5.4 vs NLR≥5.4(Log rank p= 0.001). Median OS was 7.6 vs 2.99 months in patients with PLR<320 vs NLR≥320(Log rank p= 0.02). Grade 1-2 hypothroidi was detected in six patients, Grade 3 pneumonia in two patients. No other complications are observed in any other patients.





Conclusion: NLR and PLR are standardized tests and easily used in daily routine. Elevated pre-treatment NLR and PLR are associated with shorter OS in patients with metastatic lung cancer. During the treatment of immunotherapy might be correlated with treatment response and we need larger studies.

Keywords: Immunotherapy, NLR, PLR

P2.01-58 DETECTION OF KRAS MUTATION FROM URINE OF INDONESIAN LUNG CANCER PATIENTS

A. Ridwanuloh[1], F. Fadiyah[1], F. Patria[1], R. Yasril[2], A. Hudoyo[2], J. Zaini[3], S. Andarini[4], N. Masykura[5], A. Utomo[5]

[1]*Indonesian Institute of Sciencies, Bogor/Indonesia,* [2]*Faculty of Medicine Universitas Indonesia, east Jakarta/Indonesia,* [3]*Persahabatan Hospital/ Fakultas Kedokteran Universitas Indonesia, JAKARTA/Indonesia,* [4]*Faculty of Medicine University of Indonesia Persahabatan Hospital, Indonesia, Jakarta/ Indonesia,* [5]*PT Kalbe Farma, Tbk, East Jakarta/Indonesia*

Background: KRAS is one of the most frequently mutated genes in Lung adenocarcinomas and has correlation with smoking history. The prevalence of KRAS mutated genes in Indonesian Lung cancer patients may be very high, because Indonesia is one of country with highest cigarettes consumption in the world. Urine is a potential source of biomarker analysis. In this study we identified KRAS mutation in urine sample from lung adenocarcinoma patients. **Method:** Seventy four urine samples from naive Lung adenocarcinoma patients were collected and extracted to get DNA as material of biomarker analysis. Analysis of KRAS mutation exon 2 was focused on codon 12 and 13 using Restriction Fragment Length Polymorphism (RFLP) and Sanger Sequencing methods. Analytical sensitivity of those methods was evaluated using dilution of DNA from mutant and normal KRAS cell lines. Gender and smoking history of the patients in correspondence with KRAS mutation were also evaluated. **Result:** The analytical sensitivity of the methods was at least 3.125% of mutant DNA using RFLP and at least 25% of mutant DNA by Sanger sequencing. KRAS mutation was detected in 15 of 74 urine patients. Eighty percent (12/15) of them are codon 12 mutation and twenty percent (3/15) are codon 13 mutation. In comparison between man and woman, we found that 7 male patients and 5 female patients have KRAS mutation in codon 12. We also found that 71.43% of KRAS mutation was in male patients with smoking history. **Conclusion:** It is concluded that KRAS mutation was found in urine samples of lung cancer patients and has correlation with smoking history. Urine is a great candidate to be an alternative of lung cancer samples. Comparison using cytological or biopsy samples must be evaluated to determine sensitivity and specificity of urine based KRAS mutation testing.

P2.01-59 PD-L1 VERY HIGH EXPRESSION ASSOCIATED WITH CLINICAL OUTCOME OF PEMBROLIZUMAB MONOTHERAPY OF ADVANCED NSCLC WITH PD-L1 TPS OF 50% OR GREATER

H. Itani, A. Nigi, K. Iwamoto, Y. Ito, M. Tanigawa, S. Kondo

Japanese Red Cross Ise Hospital, Ise/Japan

Background: Programmed cell death ligand 1(PD-L1) pathway-targeted immunotherapy is emerging as a promising therapeutic strategy for non-small-cell lung cancer (NSCLC). Especially, pembrolizumab monotherapy is a standard-of-care regimen for first-line treatment of advanced NSCLC with PD-L1 tumor proportion score(TPS) of 50% or greater. However, progressive disease rate of pembolizumab monotherapy for first-line treatment is 20-30%, and therefore we still need biomarkers in this clinical setting. **Method:** We analyzed data of 41 patients with NSCLC with PD-L1 TPS of 50% or greater treated in Japanese Red Cross Ise Hospital,between March 2017 and January 2019. All patients received pembrolizumab monotherapy. We collected data of patient characteristics, histology, performance status (PS), stage, metastatic sites, smoking history, driver mutation, PD-L1 expression, treatment line from medical records.Progression-free survival(PFS) of pembrolizumab and Overall survival(OS) was calculated using Kaplan-Meier method. We compared PFS according to PD-L1 expression using log rank test and Cox model was used to assess the effect of PD-L1 expression on PFS. Patients were stratified into 2 PD-L1 groups based on PD-L1 expression: medium-high expression(TPS 50-74%), and very high expression(TPS 75-100%). **Result:** The median age was 74 years (range: 43-86) and 15% of patients were women. The metastatic sites were brain(17%), pleural effusion(27%), bone(39%), liver(7%). The 22% of patients previously treated with chemotherapy and 78% of patients was treatment-naive. Median PFS of all patients was 7.0 months (CI95%. 4.2-16 months) and, median OS of all patients was not reached, respectively. In log-lank test, sex, smoking history, brain metastasis, pleural effusion, driver mutation, and PD-L1 expression were associated with PFS. In multivariate analysis using Cox model, only PD-L1 very high expression was associated with good prognosis (HR: 0.37, CI95%: 0.14-1.00). **Conclusion:** Even in cohort of PD-L1 TPS of 50% or greater, PD-L1 very high expression was predictive marker of pembrolizumab monotherapy.

Keywords: PD-L1, NSCLC, Pembrolizumab

P2.01-60 ANALYSIS OF PROGNOSTIC FACTORS ACCORDING TO PERFORMANCE STATUS IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH NIVOLUMAB

Y. Adachi, A. Tamiya, Y. Taniguchi, T. Enomoto, K. Azuma, S. Kouno, N. Saijo, K. Okishio, S. Atagi

National Hospital Organization Kinki-chuo Chest Medical Center, Sakai City, Osaka/Japan

Background: Nivolumab has a promising efficacy for patients with non-small cell lung cancer (NSCLC) as second or later line treatment. Various prognostic factors have been reported in many articles.

Among them, performance status (PS) is often reported as a strong prognostic factor. The aim of this study is to clarify the prognostic factors of good PS group and poor PS group. **Method:** The medical records of 296 patients with NSCLC who were treated with nivolumab at Kinki-chuo Chest Medical Center between December 17, 2015 and December 31, 2018 were collected. We collected clinical data at the time of nivolumab treatment commencement. We investigated the relationship between progression free survival (PFS) and patient characteristics. Furthermore, we analyzed a prognostic value factor according to PS (PS 0-1 or PS 2-4). **Result:** The median age was 70 (range, 40-90) years. 206 patients were male and 224 patients were good PS group (PS 0-1). The median PFS was 3.0 months, 4.6 months, 1.2 months in all patients, good PS group, poor PS group, respectively. Multivariate analysis showed smoking history correlated with longer PFS in both good PS group (Hazard ratio (HR), 0.452; 95% confidence interval (CI), 0.264-0.774; P = .00382) and poor PS group (HR, 0.248; 95% CI, 0.0946-0.6476; P = .00444). Furthermore, steroid use at baseline (HR, 2.341; 95% CI, 1.230-4.457; P = .00962), pleural effusion (HR, 1.516; 95% CI, 1.097-2.222; P = .01343), and liver metastases (HR, 1.732; 95% CI, 1.014-2.958; P = .00444) correlated with shorter PFS in good PS group. On the other hands, high level of advanced lung cancer inflammation index (ALI) (HR, 0.280; 95% CI, 0.109-0.724; P = .00861) and adenocarcinoma (HR, 0.464; 95% CI, 0.219-0.984; P = .0451) correlated with longer PFS in poor PS group. **Conclusion:** Smoking history is independent predictors of nivolumab efficacy in both good PS group and poor PS group. Steroid use at baseline, pleural effusion, and liver metastases are independent prognostic factors in good PS group and ALI and histology are independent prognostic factors in poor PS group.

P2.01-61 MULTIPLE PRIMARY CARCINOMAS (MPC) IN PATIENTS WITH NON SMALL CELL LUNG CANCER (NSCLC)

M. Vaslamatzis, N. Alevizopoulos, T. Tegos, M. Pavlakis, K. Karagiorgou, C. Zoumblios, K. Gioti, V. Nikolaidou, H. Kyriazidou, E. Balis, K. Athanasiadou

Evangelismos General Hospital, Athens/Greece

Background: The improving survival of NSCLC patients, due to: 1. the initial diagnosis in early stages using the newer modern diagnostic tools, 2. the treatment of the disease with new effective antineoplastic drugs, and 3. the remarkable suspicion of the physicians, leads to registry of high incidence ratio of MPC in NSCLC patients. **Method:** The aim of the study was the registration of the number and clinical characteristics of MPC in NSCLC patients. Between 4/1986-3/2019, 1756 patients, 1123 (64%)men, 633 (36%)women, median age 64(33-87)years and ECOG 2(0-3) were consequently admitted in our Unit. Stage <IIIA had 304(17%) and ≥IIIA 1452(83%)patients (groups A, B respectively). Median follow-up was 20+(1+-240+)months. Survival ≥5years observed in 351(20%)patients. According to our protocols, patients stage <IIIA, underwent only follow-up after radical surgery, while patients stage IIIA treated with platinum-based chemotherapy(PBC) adjuvantly or neoadjuvantly±locoregionally radiotherapy. Patients stage ≥IIIB received therapeutically PBC±radiotherapy. **Result:** Eighty-six patients, 78/1123(7%)men, 8/633(1%)women (p<0.001), developed 102 MPC. The median interval time between NSCLC diagnosis and MPC detection, was 58(0-220)months. Two men experienced by four (all metachronous) MPC. One with lung adenocarcinoma(LADC), developed non-AIDS Kaposi-sarcoma of the leg, MDS and squamous-cell lung cancer(SqCLC). The second, with LADC, developed transitional-cell bladder carcinoma(TCBC), prostate adenocarcinoma(PrC), and colon cancer(CC). Five patients(3 men, 2 women) had by three, metachronous, MPC. One had LADC, NHL, CC, the second LADC, TCBC, PrC, and the third SqCLC, CLL and CC. One woman experienced LADC, lymphopenic HL and breast cancer(BC) and the other LADC, CLL, and small-cell lung carcinoma. Other 79 patients developed 79 MPC, 11(14%)median age 63(51-77)years, synchronous and 68(86%)median age 63.5(34-75)years, metachronous The synchronous were LADC/SqCLC in 2, LADC/PrC in 2, LADC/TCBC in 2, SqCLC/head-neck squamous-cell carcinoma(HNSqCC) in 2, and SqCLC/CC in 3 cases. The metachronous MPC were LADC, CLL, TCBC, SqCLC, PrC, CC, HNSqCC, BC, NHL, HL, in 12, 10, 8, 8, 8, 8, 6, 3, 3, 2, cases respectively. Among 351 patients surviving ≥5years, 40(11%) experienced MPC versus 46/1405(3%) with survival <5years(p <0.001). Seventy-five patients diagnosed with metachronous MPC: 10/304(3%) versus 65/1452(4.5%) of group A and B, (p=NS). There was no statistically significance in the location of non-haematological MPC related to the diaphragm (37 upper, 39 lower the diaphragm). **Conclusion:** According to our findings in NSCLC patients: 1. MPC detection is not uncommon, mainly in men. 2. The longer survival enhances the possibility of MPC. This must be considered during the follow-up of those patients. 3. Previous chemoradiotherapy doesn't increase the risk of MPC.

P2.01-62 CIRCULATING TUMOR DNA ASSAY AND SURVIVAL IN PATIENTS WITH METASTATIC, NON-SMALL CELL LUNG CANCER

J. Ersek[1], M. Hosking[1], J. Symanowski[1], E. Green[2], Q. Zhang[1], E. Kim[1]

[1]*Levine Cancer Institute, Atrium Health, Charlotte/United States of America,* [2]*Inivata, Research Triangle Park/United States of America*

Background: Circulating tumor DNA (ctDNA) sampling has emerged as a non-invasive approach to characterizing genomic alterations in blood of patients (pts) with metastatic, non-small cell lung cancer (mNSCLC). ctDNA or 'liquid biopsy' may be used to guide treatment and prognosis. **Method:** This was a prospective pilot study of pts with histologically confirmed mNSCLC. Pts were enrolled prior to initiating a new line of therapy. Tumor and ctDNA specimens were collected prior to treatment and radiology scans were performed at standard intervals; ctDNA collections continued until progression. ctDNA was assessed by Inivata (InvisionFirst) using amplicon-based targeted next generation sequencing with 36-gene panel to detect single nucleotide variants, short insertions/deletions, copy number variations and structural variants. ctDNA features were calculated for each pt and included number of genomic alterations (numGA), number of mutations (numMUT), number of amplifications/fusions (numAMPFUS), sum mutant allele frequency (sumMAF), and maximum mutant allele frequency (maxMAF). Univariate and multivariable Cox proportional hazards models were used to identify ctDNA features associated with progression-free survival (PFS). ctDNA from baseline (T0) to the blood collection closest to progression or censor date (T1) was used to assess change in sumMAF and maxMAF. All models included ctDNA features as continuous variables. **Result:** 27 pts were evaluable. 85.19% were white; 37.04% were male. 85.19% were adenocarcinoma histology; remaining were squamous. 45.83% received prior systemic therapy. Average number of lines of prior therapy was 1.81. 44.44% had prior radiation therapy. 81.48% of pts had at least one genomic alteration detected in ctDNA at baseline. The median numGA, numMUT, and numAMPFUS, maxMAF, sumMAF was 2.00, 2.00, 0.00, 1.61, and 2.34 respectively. TP53, KRAS, and EGFR were the most frequently identified genomic alterations (59.26%, 25.93%, and 22.22%, respectively). EGFR alterations were the most commonly identified genomic alteration in ctDNA. 86.00% of EGFR alterations were actionable. Univariate Cox regression analysis identified numAMPFUS (HR=3.12, p=0.01), sumMAF (HR=1.02, p=0.02), and maxMAF (HR=1.05, p=0.00) to be significantly associated with PFS. Only maxMAF was retained in the final multivariable Cox model. Each percentage point increase in maxMAF from T0 to T1 resulted in a 4% decrease in the risk of progression/death (HR=0.96, p=0.08). **Conclusion:** In this pilot study, pts with higher levels of baseline maxMAF detected in ctDNA were associated with increased risk of progression/death. Following initiation of treatment, results suggest increased change in maxMAF may be associated with a decreased risk of progression/death.

Keywords: Non-Small Cell Lung Cancer, ctDNA, Survival

P2.01-63 RADIOSURGERY FOLLOWED BY TUMOR TREATING FIELDS (TTFIELDS) FOR BRAIN METASTASES (1-10) FROM NSCLC IN THE PHASE 3 METIS TRIAL

M. Mehta[1], V. Gondi[2], M. Ahluwalia[3], P. Brown[4], U. Weinberg[5]

[1]*Miami Medical Center, Miami/United States of America,* [2]*Northwestern Medicine Cancer Center, Warrenville/United States of America,* [3]*Cleveland Clinic, Cleveland/United States of America,* [4]*Mayo Clinic, Rochester/United States of America,* [5]*Novocure, Haifa/Israel*

Background: Tumor Treating Fields (TTFields) are non-invasive, loco-regional, anti-mitotic treatment modality comprising alternating electric fields. TTFields have demonstrated efficacy in preclinical non-small cell lung cancer (NSCLC) models. TTFields

treatment to the brain was safe and extended overall survival in newly-diagnosed glioblastoma. The METIS study [NCT02831959] investigates the efficacy and safety of TTFields in NSCLC patients with brain metastases. **Method:** NSCLC patients (N=270) with 1-10 brain metastases are randomized 1:1 to stereotactic radio surgery (SRS) followed by continuous TTFields ((150 kHz, > 18 hours/day) within 7 days of SRS or supportive care. The TTFields portable device delivers TTFields to the brain using 4 transducer arrays, while patients receive the best standard-of-care for their systemic disease. Patients are followed every two months until second intracranial progression. Key inclusion criteria: KPS ≥70, new diagnosis of 1 inoperable or 2–10 supra- and/or infratentorial brain metastases from NSCLC amenable to SRS; KPS ≥70; and optimal therapy for extracranial disease. Prior WBRT or surgical resection of metastases, a single resectable lesion or recurrent brain metastases were exclusionary. Primary endpoint was time to 1st intracranial progression. Secondary endpoints included time to neurocognitive failure (HVLT, COWAT and TMT), overall survival, radiological response rate (RANO-BM and RECIST V1.1); quality-of-life; adverse events; time to first/second intracranial progression for patients with 1–4 and 5–10 brain metastases; bi-monthly intracranial progression rate from 2–12 months; and time to second intracranial and distant progression. The sample size (N=270) was calculated using a log-rank test (Lakatos 1988 and 2002) with 80% power at a two sided alpha of 0.05 to detect a hazard ratio of 0.57. In August 2018, an independent Data Monitoring Committee (DMC) performed a review of the METIS trial data collected to that point. The DMC concluded that no unexpected safety issues have emerged on the study, and recommended to continue the METIS study as planned. **Result:** "Section not applicable" **Conclusion:** "Section not applicable"

P2.01-64 SYSTEMIC INFLAMMATORY MARKERS AS A PREDICTORS OF RESPONSE TO CRIZOTINIB IN PATIENTS WITH ALK-POSITIVE NON-SMALL-CELL LUNG CANCER

A. Bilici[1], O.F. Olmez[1], P. Gursoy[2], E. Çubukçu[3], O. Yildiz[1], A. Sakin[4], T. Korkmaz[5], I. Cil[6], B. Cakar[2], S. Menekse[7], T. Demir[8], O. Acikgoz[1], J. Hamdard[1]

[1]*Medipol University, Medical Faculty, Istanbul/Turkey,* [2]*Ege University, Medical Faculty, Izmir/Turkey,* [3]*Uludag University, Bursa/Turkey,* [4]*Okmeydanı Education and Resarch Hospital, Istanbul/Turkey,* [5]*Acıbadem University, Istanbul/Turkey,* [6]*Bakirkoy Dr. Sadi Konuk Training and Research Hospital, Istanbul/Turkey,* [7]*Bagcilar Education and Research Hospital, Istanbul/Turkey,* [8]*Bezmialem University, Istanbul/Turkey*

Background: The significance of the presence of a systemic inflammatory response (SIR) in predicting survival has been demonstrated in patients with cancer. Moreover, neutrophil-to-lymphocyte ratio (NLR),lymphocyteratio (NLR), lymphocyte-to-monocyte ratio (LMR) and platelet-to-lymphocyte ratio (PLR) have been also investegated in patients with both early and advanced non-small-cell lung cancer (NSCLC). However, determination of SIR predicting outcomes of patients who are likely to response to crizotinib in ALK-positive NSCLC patients has not been clearly demonstrated. The aim of this study was to investigate the prognostic and predictive value of NLR, LMR and PLR in patients with ALK-positive NSCLC treated with crizotinib. **Method:** Eighty-two patients with ALK-positive NSCLC who were treated with crizotinib were retrospectively analyzed. The cutoff values for NLR, LMR and PLR were defined by the receiver operating characteristic (ROC) curve analysis.Univariate and multivariate analyses were used to evaluate the prognostic significance of NLR, LMR and PLR. Logistic regression analysis was also performed to determine predictive indicators of response to crizotinib. **Result:** Among 82 patients, 35 (42.7%) were male and 47 (57.3%) were female, with a median age of 52.5 years (range; 20–77 years). Crizotinib treatment was administered as a first-line in 26.8% of patients, second-line in 56.1%, third-line in 12.2% and forth-line and later in 4.9%. The objective response rate was 77.2% (CR+PR) and stable disease was obtained in 7.6% of patients. According to the ROC curve, the recommended cutoff values of NLR, LMR and PLR were 3.14, 2.31 and 185,5 respectively. The median follow-up time was 19.3 months. ECOG performance status (PS) (p=0.014) and response to crizotinib (p=0.001) for progression-free survival (PFS) and ECOG PS (p<0.001), response to crizotinib (p<0.001), NLR (p=0.029) and LMR (p=0.028) for overall survival (OS) were found to be prognostic factors by univariate analysis. On the other hand, multivariate analysis showed that only ECOG PS and response to crizotinib were independent prognostic indicators for both PFS and OS.A logistic regression analysis indicated that NLR and LMR was found to bean independent factor for predicting response to crizotinib (p=0.007, OR:0.10 and p=0.044, OR: 0.20, respectively). **Conclusion:** Our findings showed that NLR and LMR are readily feasible and simple and also inexpensive biomarkers predicting response of crizotinib for patients with ALK-positive advanced NSCLC.

P2.01-65 TEMPORAL CHANGES OF RADIATION-INDUCED LUNG INJURY FOLLOWING PROTON THERAPY FOR NON-SMALL CELL LUNG CANCER (NSCLC)

L. Roshkovan[1], A. Lozano[2], A. Hanlon[2], V. Jain[2], K. Cengel[3], C. Simone, Li[4], A. Berman[2], S. Feigenberg[2], S. Katz[1]

[1]*University of Pennsylvania Perelman School of Medicine, Philadelphia/United States of America,* [2]*Perelman School of Medicine, University of Pennsylvania, Philadelphia/United States of America,* [3]*University of Pennsylvania, Philadelphia/United States of America,* [4]*New York Proton Center, New York/ United States of America*

Background: Proton therapy (PT) is increasingly being used in locally advanced non-small cell lung cancer (NSCLC), but is there currently a limited understanding of its radiation-induced lung injury pattern that can cofound radiologic interpretation. Here we characterize imaging of radiation-induced lung injury on CT (computed tomography) and FDG-PET (^{18}F-deoxy-glucose-positon emission tomography) following PT. **Method:** After institutional IRB approval, longitudinal imaging from adult NSCLC patients undergoing PT over a 5-year period at our institution were retrospectively analyzed by two thoracic radiologists. Tumor size and FDG standard uptake value max (SUV_{max}) were recorded. In addition, early (<12 months after PT) and late (>12 months) radiation-induced lung injuries were quantified (0-3 Likert score), including consolidation, ground glass, interlobular septal thickening, bronchiectasis and pleural effusion, on all serial imaging. **Result:**

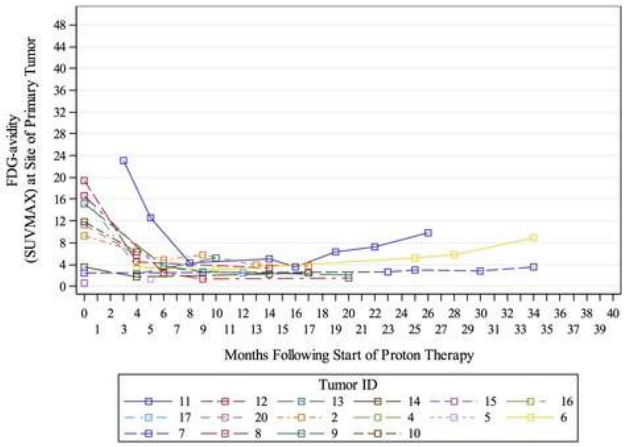

Figure: Temporal changes in FDG avidity in NSCLC following proton therapy. FDG (SUVmax) on PET/CT NSCLC treated with proton therapy exhibits a steady decrease glucose avidity over the first year following therapy.

19 consecutive locally advanced NSCLC patients (mean age 69.3 yrs) had PT during the study period and had serial images available for review. The mean imaging follow-up period from PT start was 30 months. Five patients developed local failure. In the remaining 14 patients, tumor size and FDG avidity steadily decreased over time (mean SUVmax = 10.8 at baseline and 2.5 at 12 months). Ground glass and interlobular septal thickening presented as early changes, increasing through months 6-12 and 9-12 respectively but generally resolved by 24 months. 68% of patients developed a pleural effusion (< 2 years), increasing in severity over the 1st 18 months. Consolidation consistently increased in severity throughout the observation period (max >48 months) Among 11 tumors, 8 achieved maximum severity in late changes of band-like or mass-like consolidation within 24 months and then typically plateaued. Late development of a pleural effusion, mass-like fibrosis, increased tumor caliber and increased FDG avidity were associated with local tumor recurrence. **Conclusion:** Radiation-induced lung injury follows a predictable temporal pattern on CT. Knowledge of expected timeline of the imaging findings may

prevent unnecessary imaging and/or biopsies. We are currently analyzing a larger cohort of 100 NSCLC patients to compare post radiation changes in local recurrence and local control.

P2.01-66 GENOMIC LANDSCAPES OF DNA COPY NUMBER ALTERATIONS IN PRIMARY LUNG CANCERS AND MATCHED BRAIN METASTASES

M. Nicoś[1,2], S. Garnerone[1], L. Harbers[1], A. Kowalczyk[3,4], A. Bożyk[2], R. Peksa[3,4], B. Jarosz[2,4], A. Perdyan[3], M. Sawicki[2], R. Duchnowska[4,5], J. Szumilo[2], W. Biernat[3,4], T. Trojanowski[2,4], J. Milanowski[2], P. Krawczyk[2], J. Jassem[3,4], N. Crosetto[1]

[1]*Karolinska Institutet, Stockholm/Sweden,* [2]*Medical University of Lublin, Lublin/Poland,* [3]*Medical University of Gdansk, Gdansk/Poland,* [4]*Central and East European Oncology Group, Gdansk/Poland,* [5]*Military Institute in Warsaw, Warsaw/Poland*

Background: Lung cancer (LC) is the leading cause of cancer mortality worldwide. The majority of LC patients will develop distant metastases at some point during their disease, and brain is among the most common sites of relapse. However, little is known about the mutational landscape of brain metastases (BM) and their potential inter-tumor heterogeneity. Better knowledge on this subject may pave the way to new therapeutic strategies. Here, we map the DNA copy number alterations (CNAs) by sequencing a cohort of primary LC samples and matched BM. **Method:** The study group included 57 patients (21 females and 36 males, median age 61±8 years; 35 adenocarcinomas, 18 squamous-cell carcinomas, 2 large-cell carcinomas, 1 adenosquamous carcinoma and 1 small-cell lung cancer). From all patients pair-matched tissue samples from primary tumor and corresponding BM were collected, fixed in formalin and embedded in paraffin. All patients were therapy-naïve at the time of primary tumor collection. Genomic DNA was extracted using the QIAamp DNA FFPE Tissue Kit (Qiagen, Germany), followed by NGS library preparation using the NEBNext Ultra II DNA kit (NEB, USA). Samples were sequenced shallowly (average depth 26 Mreads) on the NextSeq 500 system (Illumina, USA). The R package QDNAseq was used to call and visualize DNA copy number levels. The P value of <0.05 (Wilcoxon paired test) was considered statistically significant. **Result:** The median time between primary LC diagnosis and BM occurrence was 13 months range, 0 to 91 months), and synchronous BM were diagnosed in 12% of patients. Overall survival in the entire group was 22.5 months. The number of CNA was significantly higher in BM than in primary tumor, regardless of clinical/demographic data or type of aneuploidy (gains/losses). Primary tumors harbored significantly more gains and almost no losses. In both tumor sites, the most frequent gains affected 1q, 5p, 7p, 8q and 20q, whereas gains of 17q and 19q, and losses of 4p, 4q, 5q, 8p, 9p, 16q, 17p, 18q, 22q were identified only in BM. The fraction of the genome affected by mutational events in BM correlated positively with time to BM development. Three the top altered genes (*IL7R, MLT11, SETDB1*) were identical in both primary lesions and BM. **Conclusion:** Our results indicate that while primary LC lesions harbor frequent amplifications, the CNA landscape of BM is dominated by deletion events. Higher number of CNA harbored by late compared to synchronous BM suggests high levels of genomic instability.

P2.01-67 ARE KRAS MUTATIONS PREDICTIVE OF RESPONSE TO IMMUNOTHERAPY IN NON SMALL-CELL LUNG CANCER? A SINGLE CENTER EXPERIENCE

A. Friedlaender[1], J. Torralvo[2], P.-Y. Dietrich[1], A. Addeo[1]

[1]*Hôpitaux Universitaires de Genève, GENEVA/Switzerland,* [2]*Hôpitaux Universitaires de Genève, Geneva/Switzerland*

Background: Lung cancer is the leading cause of cancer-related mortality. In the last decade, the treatment landscape has evolved for non-small-cell lung cancer (NSCLC), in large part thanks to two therapeutic advances: targeted therapy for oncogene driven tumours and immune checkpoint-inhibitors (ICI). The latter can lead to very long survival, but only in a limited number of patients. Post-hoc analyses and preclinical data suggest KRAS mutated NSCLC may respond better to ICI. **Method:** We retrospectively analysed all stage IV NSCLC patients treated in our center with immunotherapy from January 2016 to December 2017 and compared KRAS mutated to wildtype patients. The clinical outcomes analysed were disease control rate (DCR), partial response (PR), progression free survival (PFS) and overall survival (OS). We performed an exploratory analysis on the impact of KRAS mutation type and concurrent mutations. **Result:** 45 patients treated with ICI. 7 were excluded due to insufficient data. 38 were included. 27 patients (71%) with nivolumab, 9 patients (24%) with pembrolizumab and 2 patients (5%) with atezolizumab. 22 patients (58%) were male and 16 (42%) female. The median age was 63. 21 patients (55%) presented KRAS mutations, of which 4 (19%) had concurrent p53 mutations and 1 (5%) an EGFR mutation. 17 patients (45%) were KRAS wild-type, of which 4 (24%) had EGFR mutations and 1 (6%) had a BRAF V600E mutation. In the KRAS mutated subgroup 59% were male and 41% were female, the median age was 61 years and all patients had PS 0-1. All patients received second line immunotherapy except for 2, one in third line, one fifth line. In the intention to treat population (ITT) the DCR was 71% with 55% PR, PFS was 11.3 months, and OS 17.7 month. In the KRAS wild-type subgroup DCR was 59% with 49% PR, the PFS was 8.4 months and OS 16.8 months. In the KRAS mutated subgroup, DCR was 81%, with 62% PR, PFS was 13.6 months and OS 18.5 months. An exploratory analysis based on KRAS mutation types or co-mutations was performed. The average PFS for G12C, G13C, G12V, G61H and other mutations was 19.1, 7.8, 9.4, 2.2, 13.9 months respectively. PFS for p53 co-mutated KRAS NSCLC was 23.5 months. Further analyses for STK11 co-mutations are ongoing, as these confer resistance to ICI. At the time of analysis 7 patients were still receiving immunotherapy. . **Conclusion:** In our retrospective study, KRAS mutations in NSCLC were predictive of numerically superior response to ICI compared to wildtype patients. Currently, the data is conflicting and larger clinical trials are needed to clarify this hypothesis and ascertain whether and how KRAS should be part of the treatment algorithm for the selection of ICI patients. Furthermore, more research is needed to confirm the potential role of mutation types and clinical impact of co-mutations in KRAS.

P2.01-68 HIGH NLR IS POOR PREDICTIVE BIOMARKER FOR NSCLC TREATED WITH PD-1 INHIBITOR IN REAL WORLD PRACTICE

S.S. Cho[1], S.K. Kim[2], H.S. Park[2], H.J. An[2], K.D. Cho[2], D.G. Cho[2], Y.H. Park[2], J. Yoo[2], S.W. Kim[2], J.M. Ko[2], Y.S. Hwang[2], G.R. Heo[2], C.H. Kim[2], B.Y. Shim[2], E.J. Park[2]

[1]*St. Vincent Hospital, Suwon/Korea, Republic of,* [2]*St. Vincent Hospital, Suwon / Kyunggi-Do/Korea, Republic of*

Background: PD-1 inhibitor in NSCLC is effective treatment option. PD-L1 expression and tumor mutation burden (TMB) is suggested as predictive biomarker for drug efficacy, but especially in the real-world, predictive factors have not been established. Therefore, we evaluated predictive biomarker for NSCLC treated with PD-1 inhibitor in real world practice. **Method:** This study evaluated 73 NSCLC patients treated with PD-1 inhibitor at St. Vincent hospital from April 2016 to January 2019. Following baseline data were recorded at the time of PD-1 inhibitor treatment: Age, Sex, ECOG performance status, PD-1 inhibitor type, line of treatment, lymphopenia, NLR (neutrophil-lymphocyte ratio), hyponatremia, presence of brain, liver and bone metastasis, EGFR status, PD-L1 expression. Progression free survival (PFS) and overall survival (OS) was evaluated and Cox survival analysis was used for these analyses. **Result:** Median age was 66 years old and male was predominant (67.1%). Nivolumab and pembrolizumab was treated in 34 (46.6%) and 39 (53.4%) patients, respectively. Lymphopenia (<1,000/microleter) was 20 (27.4%) and high NLR (≥ 3) was 41 (56.2%). Hyponatremia (135 mEq/L) was noted in 18 (24.7%) and metastasis of brain, liver and bone were 19 (26%), 12 (16.4%) and 28 (38.4%). Median PFS and OS were 84 days and 180 days, respectively. For PFS, ECOG performance status, presence of brain, liver, bone metastasis, PD-L1 (22C3), presence of EGFR mutation, lymphopenia and NLR was significant predictive factors in univariate analysis. As independent factors, presence of liver (Hazard ratio (HR): 3.32, 95% confidence interval (CI): 1.13-9.75, P-value: 0.029), bone metastasis (HR: 2.90, 95% CI: 1.25-6.75, P-value: 0.013), high PD-L1 expression (≥50%) (HR: 0.32, 95% CI: 0.14-0.72, P-value: 0.006) and high NLR (≥ 3) (HR: 2.58, 95% CI: 1.16-5.77, P-value: 0.021) were remained in multivariate analysis. Regarding OS, ECOG performance status, presence of bone metastasis, hyponatremia, lymphopenia and NLR were significant

POSTERS

predictive factor for PD-1 inhibitor. In multivariate analysis, poor ECOG status (2 or 3 compared to 0 or 1) (HR: 2.95, 95% CI 1.54-5.64, P-value: 0.001) and high NLR (≥ 3) (HR: 3.29, 95% CI: 1.68-6.47, P-value: 0.001) were significant predictive factors. **Conclusion:** High NLR is significant predictive biomarker for both PFS and OS in this real world study. Further studies are needed to evaluate these findings.

P2.01-69 NSCLC MUTATION FREQUENCY IN THE CENTRAL AMERICAN AND CARIBBEAN REGION

L. Corrales[1], E. Arauz-Romero[2], M. Lanza[3], L. Bacon[4], L. Homero-Matos[5], C. Vargas-Málaga[6]

[1]*Hospital San Juan de Dios, San José/Costa Rica,* [2]*Instituto Oncológico Nacional, Panama/Panama,* [3]*Honduras Medical Center, Tegucigalpa/Honduras,* [4]*Hospital Metropolitano Vivian Pellas, Managua/Nicaragua,* [5]*Instituto de Oncología "Dr. Heriberto Pieter", Santo Domingo/Dominican Republic,* [6]*AstraZeneca CAMCAR, San José/Costa Rica*

Background: Lung Cancer (LC) constitutes a leading cause of death in the World. Non-small cell lung cancer subtype adenocarcinoma (NSCLC-A) has been associated with epidermal growth factor receptor (EGFR) mutations, which is essential for treatment decisions. The EGFR mutation frequency has been proven to have regional variability in this NSCLC-A population . The current study presents the EGFR mutation incidence and T790M frequency in NSCLC-A cases diagnosed in Central American and Caribbean(CA&C) region. **Method:** A cross-sectional evaluation was performed in patients diagnosed with NSCLC-A between 2016 and 2018 in five CA&C countries. Patients were obtained from Reference Centers in Dominican Republic, Nicaragua, Panama, Honduras and Costa Rica through the AstraZeneca testing program. EGFR mutations were evaluated through Real-Time PCR. **Result:** The research included 972 cases. Mean of age at the diagnosis was 62.79(28.12-90.46) years. Overall distribution of cases by gender was female in 52.37% (509/972) and male in 47.64% (463/972). For the group of antiEGFR TKI naïve patients, tissue samples were processed in 67.83% (601/886). The group of post antiEGFR TKI, patient's plasma samples were processed in 90.70% (78/86). AntiEGFR TKI naïve group, EGFR mutations were present in 26.64% (236 / 886), the mean of age was 63.17 years (28.12-90.46). The frequency of Exon 19 was 53.38% (126/236) and Exon 21 was 27.54%(65/236) and 11.01% (26/236) were complex mutations. T790M mutations in this treatment naïve population was 2.14%(19/886). For the group of post antiEGFR TKI patients the frequency of T790M mutation was 50.00% (43/86) where 78.57% were obtain from plasma samples. **Conclusion:** The frequency of NSCLC EGFR mutation positive patients in the CA&C region was similar to that previously described in other Latin American (LA) countries. In the treatment naïve population, tissue samples remain the most important sample to analyze for EGFR mutations. T790M mutations can be seen in treatment naïve population. For patients that progressed to an antiEGFR TKI, T790M mutations were seen in a similar frequency as describe in previous LA countries. For post antiEGFR TKI patients, plasma samples were the preferred method to evaluate T790M mutations with an adequate sensibility.

P2.01-70 THERAPY WITH OSIMERTINIB IN PATIENTS WITH T790M MUTATION: EXPERIENCE OF A PORTUGUESE ONCOLOGY CENTER

I. Azevedo Pereira, I. Vieira, A. Rodrigues, I. Pousa, J. Oliveira, M. Cassiano, C. Oliveira, A. Rosinha, I. Azevedo, M. Soares

Portuguese Institute of Oncology, Porto/Portugal

Background: Osimertinib, a third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI), was initially approved to treat locally advanced or metastatic non-small cell lung cancer (NSCLC) with T790M acquired resistance and recently for first-line treatment in those with EGFR activating mutations. The aim of the authors was to evaluate the efficacy of osimertinib in a sample of patients followed at a portuguese cancer center who progressed during prior therapy with EGFR-TKI. **Method:** We treated 26 patients with metastatic NSCLC with osimertinib between January 2017 and June 2018. Data was collected from clinical files. Statistical analysis was performed using SPSS software. **Result:** 18 women and 8 men with a median age of 68 (range, 41-81) were included. Median time of follow-up was 13.5 months. The majority (23) were non-smokers and 84.6% had ECOG-PS ≤1. Brain metastasis (BM) was present and stable in 6 patients at the start of therapy. The T790M mutation was diagnosed by liquid biopsy in 61.5%. The disease control rate was 88.5%. Median progression free survival (PFS) was 15 months and was significantly lower in the subgroup with BM (6 months vs. not reached, p = 0.033). The most frequent adverse events were fatigue (46.2%) and thrombocytopenia (38.5%) and one patient had to discontinue treatment for pancytopenia grade ≥3. **Conclusion:** This study revealed similar results to those observed in clinial trials, although with higher PFS. Despite the small sample and limited follow-up time, osimertinib has been shown to be safe and effective in our clinical practice.

P2.01-71 COMPREHENSIVE ANALYSIS OF EGFR T790M-MUTANT ABUNDANCE OF DIFFERENT TECHNOLOGIES AND ITS EFFECT ON EFFICACY OF OSIMERTINIB IN ADVANCED NSCLC

X. Yu[1], Y. Fan[1,2]

[1]*Zhejiang Cancer Hospital, Hangzhou/China,* [2]*Department of Thoracic Medical Oncology, Zhejiang Cancer Hospital, Hangzhou/China*

Background: Osimertinib has been adopted as the standard of care for T790M-mediated acquired epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) resistance. And detecting EGFR T790M mutation can be challenging in routine care, low abundance of the mutation and difficulty for re-biopsy in patients with advanced disease. We aim to compare droplet digital PCR (ddPCR) and next generation sequencing (NGS) in T790M mutation testing, and analyze whether the abundance of T790M mutation is associated with the efficacy of osimertinib in advanced Non–small cell lung cancer (NSCLC). **Method:** We retrospectively studied 132 T790M-positive advanced NSCLC patients who have received osimertinib after acquired TKI resistance from April 2017 to August 2018 at our institution. Treatment response was evaluated and survival data were collected and analyzed. **Result:** Among the 132 patients, 18(13.6%) had adopted amplifcation refractory mutation system (ARMS), 58(43.9%) adopted ddPCR, 43(32.6%) used NGS in T790M testing, and the detection methods of 13(9.9%) patients were unknown. Data of T790M-mutatnt abundance were obtained in 64 patients, 57 of whom were tested by ddPCR in plasma and the other 7 by NGS. The median progression free survival (PFS) was 15 months, median OS was not reached, objective response rate (ORR) was 88%. We found that ARMS, ddPCR, NGS have no difference in T790M testing (p=0.114). Among the 57 ddPCR testing patients with the abundance of T790M, there was no difference in PFS of T790M abundance in the cutoff value of 0.5 (p=0.303). **Conclusion:** Our results suggest that ARMS, ddPCR and NGS are all useful and reliable methods in EGFR T790M mutation detection. And the association between the abundance of T790M mutation using ddPCR in plasma and the efficacy of osimertinib seemed not strong and remained to be explored.

P2.01-72 SAFETY OF PALLIATIVE RADIOTHERAPY AND IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER

M. Tjong[1], M. Ragulojan[2], I. Poon[3], S. Cheng[3], M. Doherty[3], Y. Ung[3], P. Cheung[3], P. Cheema[1]

[1]*University of Toronto, Toronto/Canada,* [2]*McMaster University, Toronto/Canada,* [3]*Sunnybrook Odette Cancer Centre, Toronto/Canada*

Background: Immune checkpoint inhibitors (ICIs) are now widely used as standard of care treatments for metastatic non-small cell lung cancer (m-NSCLC) alongside palliative radiotherapy (RT). Commonly used ICIs have long half-lives, typically between 3-4 weeks, and with reported effect even months after discontinuation. The safety of RT based on timing and biologically effective dose (BED) with respect to ICIs is not yet elucidated. This study

hypothesized that RT use within 3 months interval prior and after ICI does not increase grade ≥2 toxicities from either ICIs or RT. **Method:** This retrospective analysis includes m-NSCLC patients treated with both RT and ICIs at the Sunnybrook Odette Cancer Centre, Toronto from June 2014 to January 2019. Patients were identified by both our chemotherapy computerized physician order entry system, OPIS and radiation database. ICIs and RT-related toxicities after first ICIs dose were graded as per CTCAE v4.0. Based on timing and location, toxicities attributed to either ICIs or RT by clinicians. **Result:** Forty-four m-NSCLC patients treated with ICIs (nivolumab, pembrolizumab, or atezolizumab) and RT were identified. Twenty one (47.7%) were females, median age 67.5 (33.4- 83.2) years, 36 (81.8%) Caucasian, 42 (95.5%) non-squamous histology, 34 (77.3%) previous or current smokers, PD-L1 1-49% in 7 (15.9%) patients and ≥50% in 15 (34.1%), 9 (20.5%) EGFR/ALK positive, 40 (90.9%) ECOG 0-1. Median follow-up was 10.6 (0.7- 54.6) months. Twenty-five patients (group 1) received RT within 3 months prior and after ICIs (60 courses total, 32 (53.3%) extracranial), with median biologically effective dose with α/β= 10 (BED_{10}) 59.5 (14.4-72.0) Gy_{10}, while 19 had no RT in that interval (group 2). Overall, group 1 had 142 RTs (82 outside interval), with median BED_{10} 52.7 (14.4-120) Gy_{10}, while group 2 had 51 RTs, with median BED_{10} 52.8 (10.1-105.6) Gy_{10}. Grade ≥2 toxicities (8 total, 7 ICIs-related, 1 RT-related) occurred in 7 (28.0%) patients from group 1, and in 4 patients (26.3%) in group 2 (6 total all ICIs-related); this was not statistically significant (χ^2 p= 0.60). Five grade 3 toxicities were: pneumonitis (2), hepatitis (1), colitis (1), and nausea (1). No grade 4 or 5 toxicity was reported. **Conclusion:** Palliative RT within 3 months of ICIs did not increase ICIs and RT-induced grade ≥2 toxicities. Proceeding with ICIs while receiving palliative RT for m-NSCLC is likely safe. Further research incorporating larger cohort is planned to verify these safety results.

P2.01-73 OUTCOME DISPARITIES IN AMERICAN INDIAN/ ALASKAN NATIVES WITH ADVANCED STAGE LUNG CANCER

J. Hellyer[1], K. Cunanan[2], H. Wakelee[1], S. Han[2]

[1]*Stanford Cancer Institute, Palto Alto/United States of America,* [2]*Stanford University, Stanford/United States of America*

Background: Although there have been many advances in the treatment of lung cancer, outcomes for American Indian/Alaskan Natives (AI/AN) have remained poor. AI/AN patients present at a younger age, more advanced stage and have higher lung-cancer attributed mortality rates. While disparities in treatment of early stage lung cancer are well described, the pattern of treatment in advanced stage disease and cancer guideline concordance is incompletely understood. **Method:** Data was obtained from the National Cancer Institute SEER database from 2000-2013, which was linked with Medicare enrollment and claims data from the Centers for Medicare and Medicaid Services. Patients were included if they were characterized as AI/AN by either SEER or Medicare databases and diagnosed with stage IIIB/IV lung cancer. Demographic data and clinical characteristics were abstracted. Metrics were developed to assess adherence with lung cancer treatment guidelines. **Result:** Out of 238,439 lung cancer patients, 404 patients had advanced stage disease and were coded as AI/AN in SEER. They were propensity matched by age at diagnosis, year of diagnosis and number of lung cancers to a cohort of white advanced stage patients (N=404). The comparison of the patient characteristics across the two race groups shows that AI/AN patients were more likely to have squamous cell histology, live in smaller urban communities, less likely to be married, and less likely to receive surgery or radiation. Only 20.5% of the advanced lung cancer AI/AN population received appropriate therapy within 90 days of diagnosis compared with 29.5% of the propensity matched white cohort (*p = 0.004*). **Conclusion:** AI/AN patients are less likely to receive cancer-directed care such as surgery or radiation than the matched white cohort and less likely to receive appropriate therapy within 90 days of diagnosis. Work is ongoing to evaluate adherence to other metrics such as receipt of appropriate diagnostics and treatment as well as trends in survival.

Keyword: SEER, AI/AN, disparities

P2.01-74 CLINICAL-PATHOLOGICAL FEATURES AND OUTCOME OF PATIENTS WITH ORAL METASTASES FROM LUNG CANCER: A MULTICENTER RETROSPECTIVE STUDY

M. Tagliamento[1], D. Pignataro[1], P. Bironzo[1], M. Tiseo[2], A.M. Militello[2], G. Banna[3], D. Galetta[4], F. Pesola[4], G. Del Bene[4], M. Lupatelli[5], M. Val[5], E. Olmetto[1], E. Capelletto[1], M. Pentenero[5], S. Novello[1]

[1]*Thoracic Oncology Unit, San Luigi Gonzaga Hospital, Department of Oncology, University of Torino, Orbassano (Torino)/Italy,* [2]*Department of Medicine and Surgery, Medical Oncology, University of Parma, Parma/Italy,* [3]*Division of Medical Oncology, Cannizzaro Hospital, Catania/Italy,* [4]*Medical Thoracic Unit, Cancer Research Center "Giovanni Paolo II", Bari/Italy,* [5]*Oral Medicine and Oral Oncology Unit, Department of Oncology, University of Torino, Orbassano (Torino)/Italy*

Background: Oral metastases are a rare event, accounting to less than 1% of all oral malignancies, sometimes being the first manifestation of a wide-spread disease. Regardless of the site of the primary tumor, patients with oral metastases have a poor prognosis, with a reported median overall survival (mOS) of 6 months. Lung cancer, particularly small cell lung cancer (SCLC) and poorly differentiated carcinoma, represents the main source of oral metastases, even if large datasets still lack. We conducted a multicenter retrospective study investigating incidence, clinical-pathological features and outcome of patients with oral metastases from lung cancer. **Method:** Between January 2014 and December 2018 we collected data from all consecutive patients diagnosed with lung cancer in four oncological Italian centers. Clinical-pathological features of those patients with oral metastases involving jaw or/and soft tissues were described. **Result:** Among 4,082 consecutive lung cancer patients, the incidence of oral cavity metastases was 0.15% (6 out of 4,082 patients,). Patients were more frequently male (5 out of 6, 83%), current or former smokers (5 out of 6, 83%), with a median age at diagnosis of 61 years (range 53-69) [table 1]. Four different histotypes of lung cancer were detected. Five patients (83%) were stage IV *ab initio*, with synchronous histologically confirmed oral metastases. All these patients had distant metastases other than in the oral cavity (median of 5 different metastatic sites). The mOS since the diagnosis of oral metastases was 67 days (range 36-166). Table 1. Patient characteristics

POSTERS

Gender	Age (years)	Smoke	Histotype	N° metastatic sites	Site of oral lesion	Time between stage IV diagnosis and oral lesion occurrence	Local radio-therapy	Median OS from oral lesion occurrence (days)
M	69	Current	Poorly differentiated	4	Jaw	Syncronous	Yes	57
M	61	Current	Sarcomatoid	5	Jaw	Syncronous	Yes	107
M	61	Former	Adenocarcinoma	3	Gum	11 months	Yes	77
M	53	Former	Poorly differentiated	4	Gum	Syncronous	No	44
M	59	Current	SCLC	5	Gum	Syncronous	No	36
F	66	Unknown	Squamous (mut ex 19 EGFR)	5	Gum	Syncronous	No	166

Conclusion: To our knowledge, this is the largest study assessing the incidence of oral metastases in lung cancer patients. Oral involvement, usually diagnosed at an advanced stage, seems to be associated with a very poor prognosis, with a mOS of about 2 months. Further confirmatory datasets are warranted.

Keywords: Lung cancer, oral metastases

P2.01-75 TEMPORAL TRENDS IN TREATMENT PATTERNS FOR ADVANCED/METASTATIC NON-SMALL CELL LUNG CANCER (ANSCLC) IN ROUTINE CLINICAL PRACTICE

V. Stefaniak, K. Winfree, Z. Cui, C. Molife

Eli Lilly and Company, Indianapolis/United States of America

Background: For aNSCLC patients lacking actionable molecular markers, guideline recommendations for first-line treatment include platinum-based chemotherapy or immune checkpoint inhibitors (ICIs) as single agents or in combination with platinum-based chemotherapy (platinum-based chemoimmunotherapy) based on recent clinical trials and FDA approvals. When initial therapy fails, recommendations are for second-line treatment with ICIs (if not given in first-line), single-agent chemotherapy, or ramucirumab+ docetaxel. The objective of this study was to understand the evolution of aNSCLC treatment patterns following the May 2017 FDA approval of platinum-based chemoimmunotherapy in frontline. **Method:** This retrospective observational study analyzed electronic health record data from the Flatiron Health database for adult patients who initiated first-line therapy for aNSCLC between 01/01/2015-12/31/2018. Eligible patients were stratified by first-line treatment initiation time period (before and after May 2017). **Result:** Of the 22,342 eligible patients receiving first-line treatment, 9,482 (42%) initiated second-line systemic therapy, and of those, 3,260 (34%) initiated third-line therapy during the study period. Patient characteristics were generally consistent over time. Overall, there was considerable heterogeneity in the treatment landscape for aNSCLC, with over 200 unique regimens used in each of the three treatment lines evaluated. After May 2017, platinum-based regimens continued to be the standard treatment in first-line (Table), with increasing usage of ICIs as single agents (mostly pembrolizumab) or in combination with platinum-based chemotherapy (mostly pembrolizumab+pemetrexed+platinum), and decreasing use of platinum-based regimens that do not contain an ICI. In second-line, use of ICI monotherapy was consistent and usage of single-agent chemotherapy decreased slightly after May 2017. The use of platinum-based chemotherapy in second-line increased after May 2017, consistent with increased usage among patients receiving first-line ICI monotherapy. Overall, second-line ramucirumab+docetaxel usage increased as ramucirumab+docetaxel has become the most commonly used regimen following first-line platinum-based chemoimmunotherapy. In third-line, the use of ICI monotherapy decreased after May 2017 while usage of single-agent chemotherapy remained consistent over time. Third-line ramucirumab+docetaxel usage also increased after May 2017, in line with increased use of third-line ramucirumab+docetaxel among patients previously treated with sequential platinum-based chemotherapy and ICI monotherapy in first- and second-line.

Table. Trends in Use of Standard Systemic Treatment for aNSCLC

Treatment	Before May 2017	After May 2017	*P*-value[a]
1L Regimen, %[b]			
Any therapy	100 (n = 13,656)	100 (n = 8,686)	
Platinum-based therapy without ICI	66.5	40.3	< 0.001
Platinum + ICI combination therapy	0.1	20.1	< 0.001
ICI monotherapy	12.0	23.5	< 0.001

[a]All p-values are from Pearson's Chi Squared Test.
[b]Percents may not add up to 100% as treatment groups are not mutually exclusive.
[c]Denominator (not shown) is total number of patients treated with 1L regimen of interest.
[d]Denominator (not shown) is total number of patients treated with 1L and 2L sequence of interest.
[e]P-value not computed due to small sample size.

Conclusion: This study illustrates the changing treatment landscape for aNSCLC in real-world clinical practice since May 2017. While usage of aNSCLC treatments continues to be highly variable, the approval and rapid uptake of ICIs in frontline appears to have altered how available post-progression treatment options are prescribed and sequenced. Future studies should evaluate the impact of these changes and treatment heterogeneity on patient outcomes.

P2.01-76 BONE METASTASIS AND PLEURAL DISSEMINATION AS A POTENTIAL MARKER FOR PREDICTING OF T790M MUTATION IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

Y. Mizushina, F. Ohyanagi, M. Nomura, F. Kudo, J. Shiihara, H. Ohta, S. Koyama

Jichi Medical University Saitama Medical Center, Saitama city/Japan

Background: Acquired resistance in epidermal growth factor receptor (EGFR)-mutated non-small-cell lung cancer (NSCLC)-patients after tyrosine kinase inhibitor (TKI)-treatment is a major clinical problem. In the majority of these patients, the T790M-mutation is detected at time of acquired TKI-resistance. However, it is less clear if the location of metastatic site may influence the ability to identify T790M mutation in NSCLC patients. **Method:** We retrospectively screened patients with NSCLC harboring EGFR mutations with progressive disease who were rebiopsied between January 2016 and December 2018. EGFR T790M mutation status after EGFR-TKIs failure was assessed using liquid biopsy or tissue rebiopsy sample. Clinical factors influencing T790M status were evaluated by univariate and multivariate analysis. **Result:** Among 39 rebiopsied patients for whom EGFR mutation status was available, 21 (53.8%) had T790M mutations. Patient characteristics at rebiopsy were not significantly different between T790M-positive and -negative groups, except for bone metastasis. Total duration of EGFR-TKI treatment before rebiopsy, EGFR-TKI treatment history immediately before rebiopsy, progression-free survival after initial TKI treatment, and rebiopsy site (other than fluid samples) significantly influenced T790M status. The incidence of T790M mutation was shown by multivariate analysis to be significantly higher in patients with bone metastasis and pleural dissemination (odds ratio, 26.4; 95% confidence interval (CI), 3.80-184 and odds ratio, 12.1; 95% CI, 1.57-92.4, respectively). **Conclusion:** Bone metastasis and pleural dissemination may represent useful predictive markers for T790M detection. In patients with these clinical factors, rebiopsies may be more recommended to detect T790M mutation.

P2.01-77 PET CT RADIOGENOMIC DEPICTION WITH EGFR AND ALK MOLECULAR ALTERATIONS IN LUNG CANCER AMONG INDIAN POPULATION

A. Jajodia[1], R. Tripathi[1], A. Chaturvedi[1], V. Koyyala[1], A. Chaturvedi[1], S. Pasricha[1], S. Goyal[1], U. Batra[1], A. Mehta[1], H. Prosch[2]

[1]*Rajiv Gandhi Cancer Institute and Research Centre, Delhi/India,* [2]*Medical University of Vienna, Vienna/Austria*

Background: Non small cell lung cancer (NSCLC) represents an area of paramount importance wherein patients undergo testing for targetable genetic alterations. Association between the imaging and molecular phenotypes is vital highlighting the growing importance and unmet need of classifications based on radio genomic characterization. This study was conducted to evaluate the correlations between the radiologic and molecular phenotypes in patients with NSCLC. **Method:** 211 patients with lung cancers during the study period of one year from October 2017 till November 2018 in our institution and undergoing both radiologic (PET-CT) and molecular investigations [Epidermal Growth Factor Receptor (EGFR), Anaplastic lymphoma kinase (ALK)] were included in the study. Both quantitative and qualitative CT findings were evaluated and correlated with the molecular findings. Quantitative data included SUV max obtained from PET component of CT and maximum diameter of lesion according to the RECIST criteria. Qualitative data recorded included location, pleural tail, pleural effusion, pericardial effusion, opacity, margins, calcifications, obstructive changes, pleural nodules, lung nodules, invasion, air bronchogram, emphysema, pulmonary fibrosis, mediastinal lymph nodes and distant metastasis. Statistical analysis was performed to evaluate the association of the qualitative features with the molecular expression. Receiver operating characteristic curves (ROC) were drawn and the corresponding area under curve (AUC) was calculated. *P*-values <0.05 were considered significant. **Result:** Overall, EGFR mutation positivity and ALK rearrangement was observed in 114 and 37 patients, respectively whereas 60 patients had neither of these. SUV max was comparable between the groups with EGFR mutation (11.3±3.9) and ALK rearrangement (12.3±4.0). Correlations were observed between EGFR mutation and ALK rearrangement and location (p-value <0.0001), pleural tail (p-value <0.0001), pleural effusion (p-value <0.0001), obstructive changes (p-value <0.025), pleural nodule (p-value <0.002), lung nodules (p-value <0.002), air bronchogram (p-value <0.002), emphysema (p-value <0.002), mediastinal nodes (p-value <0.002) and distant metastasis (p-value <0.002). EGFR mutation also correlated with invasion (p-value 0.022). In ROC curves, for EGFR mutation and ALK rearrangement prediction based on mediastinal lymph nodes, the AUC was 0.661 and 0.588, respectively. **Conclusion:** The correlation between CT findings and molecular findings highlights the importance of newer radio genomic based characterization for patients with NSCLC for better diagnostic and prognostic approaches.

P2.01-78 A METAANALYSIS AND BIOINFORMATICS EXPLORATION OF THE PROGNOSTIC VALUE OF TP53 CO-MUTATIONS IN EGFR MUTATED NSCLC

R. Jiang[1], F. Wang[1], S. Li[2], X. Wang[1], L. Wang[1], D. Huang[1]

[1]*Tianjin Medical University Cancer Institute & Hospital,National Clinical Research Center for Cancer, Tianjin/China,* [2]*Tianjin Medical University Cancer Institute & Hospital,National Clinical Research Center for Cancer, tianjin/China*

Background: As the leading cancer type for the estimated new cancer cases, lung cancer represents the major cause of cancer related worldwide. Non-small cell lung cancer (NSCLC) accounts for 85% to 90% of primary bronchogenic carcinomas and leads the ranking of cancer-related mortality in the western world. TP53 mutations were recently reported as a useful index in predicting the prognosis of lung cancer. However, the prognostic role of TP53 co-mutations in epidermal growth factor receptor (EGFR)mutated NSCLC remains controversial. **Method:** Relevant literatures were retrieved from PubMed, Embase and Web of Science databases. Meta-analysis was performed using hazard ratio (HR) and 95% confidence intervals (CIs) as effect measures. A total of 1146 patients from 7 studies were finally enrolled in the meta-analysis. Information regarding TP53 and EGFR alterations and patients' survival time in NSCLC was downloaded from the Cancer Genome Atlas Database and The Clinical Lung Cancer Genome Project (CLCGP). Patients were further subdivided into subgroups based on different mutation exons. The distribution of different mutation exon as well as the prognostic value were evaluated. 2660 pieces of data from 2241 NSCLC patient were collected. **Result:** The summary results showed that dual TP53/EGFR mutations predicted poorer overall survival (OS) (HR: 1.38, 95%CI: 1.06–1.81, p < 0.05). Subgroup analysis revealed that dual TP53/EGFR mutations was also associated with poor OS in NSCLC treated by EGFR-TKIs (HR:1.47, 95%CI: 0.88-2.46, P < 0.05). Patients with TP53 mutations in exons 6 and 8 had worse OS compared with patients with TP53 mutations in other exons(HR: 1.22, 95%CI: 0.89–4.33, p < 0.05), especially coexisting with EGFR mutations in exons 20(HR: 1.78, 95%CI:1.13–2.52, p < 0.05). **Conclusion:** In EGFR mutated NSCLC, dual TP53/EGFR mutations suggest poor prognosis, especially in patients treated by EGFR-TKIs. The presence of TP53 mutations in exons 6 and 8 correlated with inferior OS. Larger datasets are required to validate these observations.

P2.01-79 AFATINIB IN EGFR MUTATION-POSITIVE (EGFRM+) NSCLC HARBOURING UNCOMMON MUTATIONS: EXPERIENCE IN 'REAL-WORLD' CLINICAL PRACTICE

W. Brückl[1], E. Laack[2], C. Hoffmann[3], C. Zhou[4], Y.-L. Wu[5]

[1]*Paracelsus Medical University, General Hospital Nuernberg, Nuremberg/Germany,* [2]*Hämato-Onkologie Hamburg, Hamburg/Germany,* [3]*Boehringer Ingelheim International GmbH, Ingelheim am Rhein/Germany,* [4]*Shanghai Pulmonary Hospital, Shanghai/China,* [5]*Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: Approximately 10–12% of patients with *EGFR*m+ NSCLC have tumors harboring uncommon *EGFR* mutations. Preclinical data indicate that the ErbB family blocker, afatinib, has broader inhibitory activity against uncommon mutations, including compound mutations, compared with first-generation EGFR TKIs.[1,2] Post-hoc analysis of the LUX-Lung 2, 3, and 6 trials[3] demonstrated that afatinib is active against certain uncommon *EGFR* mutations. The objective response rate (ORR) with afatinib against G719X (n=18), L861Q (n=16), and S768I (n=8) single/compound mutations was 78%, 56%, and 100%, respectively. Patients with exon 18–21 uncommon mutations had progression-free survival (PFS) and overall survival of 10.7 and 19.4 months, respectively. The aim of this analysis was to explore the sensitivity of uncommon *EGFR* mutations to afatinib in a broader 'real-world' patient population. **Method:** We undertook a pooled analysis of data from an Asian phase IIIB trial (NCT01953913) and a German non-interventional study (NCT02047903) that assessed afatinib in patients with EGFR TKI-naïve *EGFR*m+ NSCLC. Tumour response was based on investigator review, and PFS was calculated by Kaplan–Meier methodology. **Result:** Fifty-four patients were identified with tumours harbouring uncommon mutations, including L861Q (n=13), S768I (n=3), G719X (n=23), and other (n=8); 21 patients had compound mutations. Baseline characteristics were: male, 59%; median age (range), 63.5 (35-79) years; Eastern Cooperative Oncology group performance status 0 or 1/>1, 93%/6%. The combined ORR for evaluable patients with L861Q, S768I, or G719X was 59% (20/34), and the disease control rate was 91% (30/34); ORR and DCR in patients with compound mutations was 47% (9/19) and 89% (17/19), respectively. Overall, median PFS in patients with L861Q, S768I, or G719X was 10.7 months; median PFS in patients with compound mutations was 7.3 months. **Conclusion:** In this 'real-world' cohort of patients with *EGFR*m+ NSCLC, afatinib was active against uncommon mutations known to be less responsive to reversible EGFR TKIs. These data are in line with the LUX-Lung trials and support the use of afatinib in patients with non-resistant *EGFR* mutations.

P2.01-80 CLINICAL OUTCOMES IN ADVANCED EGFR-MUTANT NSCLC PATIENTS TREATED WITH FIRST-GENERATION EGFR TKIS FOLLOWED BY SUBSEQUENT OSIMERTINIB

Y.-H. Yao, J.-T. Cheng, J. Kang, X.-M. Li, H.-J. Chen, Q. Zhou, C. Xu, X.-C. Zhang, J. Su, H.-H. Yan, Y.-L. Wu, J.-J. Yang

Division of Pulmonary Oncology, Cancer Center & Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China

Background: Treatment with first-line epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) plus subsequent osimertinib is standard of care for advanced (*EGFR*)-mutant non-small cell lung cancer (NSCLC) harboring T790M mutation. However, few data are available that have assessed the cumulative survival benefit of sequential EGFR TKIs in patients with *EGFR*-mutant NSCLC with T790M mutations in 'real-world' clinical practice. **Method:** We retrospectively identified advanced *EGFR*-mutant NSCLC patients treated with first-line EGFR TKIs plus subsequent osimertinib between January 27th, 2015 and December 1st, 2018 at our institute. Clinical outcomes were analyzed. Subsequent genetic profiling was performed at the time of progression by next-generation sequencing (NGS). The primary endpoint was overall survival (OS) calculated from first-line treatment start to death or the last follow-up, and the secondary endpoint was progression-free survival (PFS) with osimertinib defined as the time from the first dose of osimertinib to disease progression or death. Primary resistance to osimertinib was defined as PFS≤4 months for T790M-mutant patients treated with osimertinib. The last follow-up time was January 27th, 2019. Median follow-up time was 52.0 months (range, 9.0-108.0 months). **Result:** Among 117 eligible patients treated with first-line EGFR TKIs plus subsequent osimertinib, 96 had T790M mutation and 21 showed negative T790M mutation or unknown status at the baseline of osimertinib treatment,. Median OS was significantly prolonged in T790M-mutant patients than those with negative/unknown T790M mutation (58.0 vs. 28.3 months, p<0.001). However, there was no significant difference in median PFS with osimertinib between the two groups. Furthermore, there was no significant difference in both median OS and PFS with osimertinib between the non-brain metastatic and brain metastatic groups (median OS, 58.0 vs. 54.8 months, p=0.840; median PFS, 11.8 vs. 9.1 months, p=0.145). Median OS was significantly shortened in patients (N=20) with primary resistance to osimertinib than those (N=72) with PFS>4 months (38.2 vs 54.8 months, p=0.027). **Conclusion:** In real-world clinical practice, treatment with first-generation EGFR TKIs plus subsequent osimertinib for T790M-mutant patients can significantly prolong OS than those with negative/unknown T790M mutation. However, survivals are similar between the patients with and without brain metastases at the baseline of osimertinib. OS is significantly shorter in those with primary resistance to osimertinib.

Background: Nintedanib is a triple angiokinase inhibitor that blocks the proangiogenic pathways mediated by vascular endothelial growth factor receptors, platelet-derived growth factor receptors and fibroblast growth factor receptors. Nintedanib in combination with docetaxel is indicated for adults with adenocarcinoma metastatic lung cancer after chemotherapy. Although, as in other antiangiogenic therapies, we do not have a predictive response marker. The aim of this study is to analyze probably factors that influence in the response to the nintedanib-docetaxel scheme. **Method:** We conducted a retrospective multicenter study, which included all patients with non-small cell lung cancer who received nintedanib with docetaxel in second or third line of treatment. Explorative analyses were conducted according to therapy antiangiogenic previous, status PDL1, nintedanib or docetaxel dose adjustment and time to treatment fail in previous line (> 9 months or < 9 months), age, sex and smoking. **Result:** We enrolled 124 patients from 10 different Spanish centers. Progression free-survival was 4,1 months and the overall survival was 26,9 months. Of the factors studied, only the dose adjustment of docetaxel during treatment (5,7 months vs 2,7 months, p<0,05) and the dose adjustment of nintedanib (7,2 months vs 4,7 months, p<0,05) were associated with an increase in PFS. The dose adjustment level of nintedanib (100 mg vs 150 mg twice) did not reach statistical significance. The only factors that achieved statistical significance in overall survival were progression to the first line> 9 month (36,5 months vs 19,3 months, p <0.05) and the dose adjustment of nintedanib (37 months vs 22 months, p < 0.05). Therapy antiangiogenic previous, status PDL1, age, sex and smoking did not increase survival. **Conclusion:** In our study, nintedanib- docetaxel concluded significant OS benefits in adenocarcinoma lung cancer patients with time to relapse to first line >9 months and in patients with dose adjustment during treatment. Further studies are needed to verify this data.

Keyword: non-small cell lung cancer, nintedanib, predictive factors of survival

P2.01-82 LUNG CANCER IN LUNG TRANSPLANT RECIPIENTS

S. Otani, T. Shiotani, K. Suzawa, K. Miyoshi, H. Yamamoto, M. Okazaki, S. Sugimoto, M. Yamane, T. Oto, S. Toyooka

Okayama University Hospital, Okayama/Japan

Background: Long-term immunosuppression is considered to increase the chance of developing malignancy, which is one of the leading causes of death after organ transplantation. Lung cancer in lung transplant recipients can originate from de-novo occurrence, transplanted donor's lung and progression/recurrence of the recipient's lung cancer. We conducted a survey of lung cancer in lung transplant recipients in our institution and report the case series. **Method:** All 189 recipients who underwent lung transplantation (97 brain-dead donor lung transplantation, 90 living donor lobar lung transplantation, 2 hybrid lung transplantation) since October 1998 until December 2018 at Okayama University Hospital were retrospectively reviewed. **Result:** Lung cancer was diagnosed in 4/189 (2.1%) of 16/189 (8.5%) all malignant diseases, in lung transplant recipients with a median follow-up of 4.5 years. Whereas de novo lung cancer occurred in one patient, patient-baring lung cancer was histologically detected in resected lung in three patients, leading to progression after transplantation in the two recipients. One recipient who had a previous history of lung cancer with over 5-year disease free period, experienced no recurrence afterword. All three recipients who had advanced lung cancer died relatively early from the diagnosis of lung cancer, regardless of cancer treatment. Lung cancer in lung transplant recipients could be difficult to detect by radiological screening and biopsy due to severely deteriorated lung condition, especially in idiopathic interstitial pneumonitis. Additionally, recipients with advanced lung cancer seem to have poor prognosis.

Case	Underlying disease	Occurrence	LTx - Lung cancer	Degree of progression	Treatment/Prognosis
#1	LAM	De novo	10 years	Chest wall invasion	Right pneumonectomy (10 months)→chemotherapy (9 months)→death
#2	IIP	Resected recipient's lung	15 months	Mediastinal lymph-nodes	Lymph-node resection (10 months) →death
#3	IIP	Resected recipient's lung	3 months	Pleural Dissemination	chemotherapy (6 months)→death
#4	BO	Resected recipient's lung	nil	nil	nil

LAM: lymphoangioleiomyomatosis IIP: idiopathic interstitial pneumonitis BO: bronchiolitis obliterans LTx: lung transplant

Conclusion: Lung cancer in lung recipients should be screened carefully ever since listing for transplantation.

Keywords: Lung transplantation, Lung cancer

P2.01-83 ROLE OF EXOSOMAL MICRORNAS (MIRNAS) AS PREDICTORS OF RESPONSE TO TREATMENT AND PROGNOSIS IN NON-SMALL CELL LUNG CANCER (NSCLC)

M. Razaq, V. Pareek, A. Srivastava, R. Ramesh

Univ. of Oklahoma HSC, Stephenson Cancer Center, Oklahoma City/United States of America

Background: Exosomes are 30 - 100 nm cellular entities secreted from cells. Exosome contain messenger RNA, miRNAs, DNA and active peptides . Cancer derived exosomes have distinct miRNA profiles. Signature profile of miRNAs can be utilized for disease characterization including response . We are evaluating exosomal miRNAs from urine of NSCLC patients. **Method:** Urine (30-50ml) was collected, before and after treatments in 5 advanced NSCLCs. Exosomes were isolated by differential ultracentrifugation method, miRNA libraries were constructed using 100 ng of total RNA isolated from exosomes and sequenced on the Illumina MiSeq platform. A minimum of 20 million 50base pair sequencing reads were collected and data analyzed using CLC Genomics Workbench Software. miRNAs that was significantly changed (up- or down-regulated) in the matched samples were identified as candidate biomarkers. Target mi RNAs were analyzed with bioinformatics tools. **Result:** miRNA sequencing (RNAseq) showed 111,416 sequence hits for small non-coding RNAs and after aligning with miRBase21, 548 mature miRNAs were identified. The differentially expressed miRNAs clustered separately in pre- and post-treatment samples in all five-patients. Two miRNAs (hsa-miR-6842 and hsa-miR-143) showed marked reduction in post-treatment samples compared to pre-treatment samples. Validation studies by quantitative (q)PCR using miRNA specific primers confirmed the RNAseq results. *In silico* target analysis identified RAS oncogenic family as a prominent target for these miRNAs. Table 1; characteristics of patients, miRNAs changes (fold reduction), response and long term outcomes

Patients	1	2	3	4	5
Age/Sex	42/male	74/female	59/male	81/male	68/male
Stage	4	4	4	4	3 (T1N3)
Pathology	Adenocarcinoma	Squamous cell		Adenocarcinoma	Squamous cell
Tissue Molecular Abnormalities	KRAS G12V, STK11 K62fs*99, NFKBIA amplification, NKX2-1 amplification, TP53 R249W	Not tested	STK11 Y156fs*5, CDKN2A p16IN-K4a E69fs*77 and p14ARF G83fs*51+, MYST3 S1496L, TP53 splice site 919+1G>	Met exon 14 splicing	Not tested
Treatment	Carbo, Permetrexed, Bev X2, f/b carbo/ etoposide with radiation	Carboplatin/ Paclitaxel	Carboplatin/ Paclitaxel	Carboplatin/ Paclitaxel	Carboplatin/ Paclitaxel with radiation
Change in mir-143	-4.371	-1.25	-1.27	-1.139	-15.7
Change in mir-6842	-21.37	-6.27	-4.21	-3.41	-4.57
Treatment Response	PR	PR	SD	SD	CR
Current Status	Alive, 38 months since diagnosis	Died 18 months after diagnosis	Died 6 months after diagnosis	Alive, 38 months since diagnosis	Alive, 32 months since diagnosis

Out of all mi RNAs, miR-143 and miR 6842 showed maximum reduction in value and changes were more pronounced in patients1 and 5. Both patients received radiation with chemo and had very good response and prolonged control of disease with longer survival. Interestingly both of miRNAs are targeting KRAS mRNA. Patient#1 had K ras mutation while Patient#5 was not tested **Conclusion:** Based on our initial experiments we conclude that upon receiving chemo+ radiation combination therapy the miRNA 143 and miRNA 6842 are packaged at lower levels in exosomes by the tumor cells i.e. cells are trying to retain miRNAs within themselves. Since retention of miRNAs will decrease the levels of target miRNA which is KRAS which will result in better treatment outcome. Our study suggests that urine derived exosomal miRNAs 143 and 6842 can be used as prognostic markers to assess treatment response. This is a preliminary data and study is ongoing.

P2.01-84 SERUMAL SERPINE2 AS A POTENTIAL BIOMARKER FOR RADIORESISTANCE IN NSCLC

J. Zhang[1], Q. Wu[1], L. Zhu[2], Y. Zhao[1], S. Xie[1], Y. Wang[1], S. Zhang[1], S. Ma[3]

[1]*Translational Medicine Research Center,Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou/China,* [2]*Radiation Oncology, Hangzhou Cancer Hospital, Hangzhou/China,* [3]*Oncology, Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, hangzhou/China*

Background: Radioresistance is the main reason for the failure of clinical radiotherapy in lung cancer. Among the different tumors, SERPINE2 is a protein with anticoagulant properties which could promote or inhibit solid tumor growth. However, its role in the pathogenesis of lung cancer has not been determined. **Method:** To get radioresistant cell lines A549R and PC9R, A549 and PC9 cells were treated with fractionated irradiation by high energy X-ray. Cell survival fractions were measured by colony formation assay. Furthermore, we performed RNA-SEQ and protein profiling to screen genes differentially expressed in the A549/A549R and PC9/PC9R cells. To elucidate the biological role of SERPINE2 in radioresistance of NSCLC, we conducted SERPINE2 gene overexpression/knockdown experiments using NSCLC cell lines. The aim of this study was to assess serum SERPINE2 concentrations in a group of 26 NSCLC patients with radiation therapy alone in one course of treatment. Blood samples were collected before treatment. Serum SERPINE2 concentration was measured using specific ELISA methods. We analyzed its prognostic significance regarding outcome analysis, as well as its potential biomarker for radiotherapy. **Result:** Two radioresistant lung adenocarcinoma sublines A549R and PC9R were successfully established through dose fractionated irradiation after six months. Results of RNA-SEQ and protein profiling showed the SERPINE2 was higher in A549R and PC9R compared to that in parental cells A549/PC9. We also demonstrated that knockdown of SERPINE2 expression inhibit cell migration and invasion in A549/PC9 cell lines. And the overexpression of SERPINE2 promote cell migration and invasion in H1975/HCC827 cell lines. Knockdown of SERPINE2 expression in the A549R/PC9R by shRNA also reduced significantly cell radiation resistance.The radiobiology parameters, which including SF_2, D_0, D_q and α/β, were significant differences compared with non-silencing shRNA cells. According to response evaluation criteria in solid tumors, the concentrations of SERPINE2 were significantly higher in PD patients compared with SD and PR. **Conclusion:** The preliminary study indicates the SERPINE2 play an important role in the radioresistance of NSCLC and implies the evaluation of SERPINE2 expression in serum may be considered as a potential biomarker in radiotherapy of NSCLC patients. Further research must be explored to clarify the function and mechanism of SERPINE2 in the radioresistance of lung cancer.

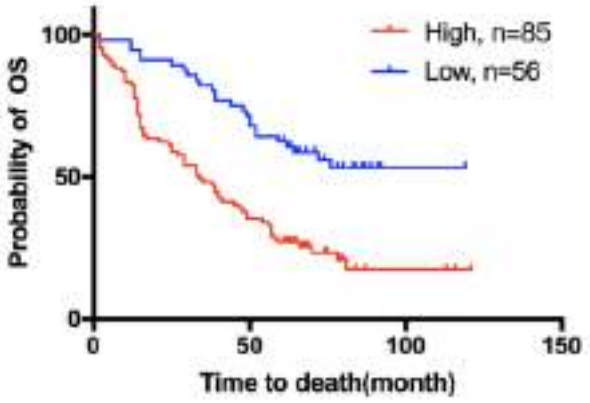
Keywords: SERPINE2, NSCLC, Radioresistance

P2.01-85 SCHWANN CELLS ARE OVEREXPRESSED AND INVERSELY CORRELATED WITH SURVIVAL OF NON-SMALL CELL LUNG CANCER PATIENTS

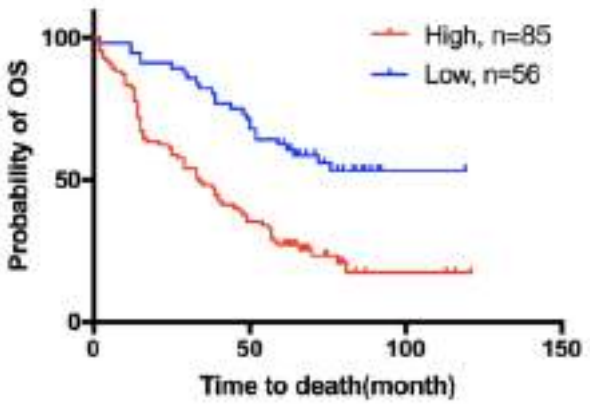
Y. Zhou, H. Zhong, B. Han

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: The lungs are densely innervated by the peripheral nervous system (PNS). We have recently reported the presence of schwann cells(SCs), the principal glial cells of the PNS, in the murine and human lungs and the mechanisms by which tumor–neuroglia interaction affect lung cancer growth and metastasis(Cancer Research. 2018;78(20):5927-39). Nevertheless, the clinical epidemiological characters of the innervation of lung cancer has not been intensively investigated.This study aimed to complement this vacancy by determining the prevalence of SCs expression in NSCLC and analyzing its associations with clinical pathologic parameters and outcome. **Method:** Totally, 141 operated patients at stage I-III NSCLC were enrolled. Formalin-fixed and paraffin-embedded (FFPE) tumour sections were reviewed and stained with glia-specific antibodies S100b, GFAP and P75NTR. The correlations between expression of SCs and clinical pathologic features, overall survival (OS) and recurrence free survival(RFS) were analyzed. **Result:** No significant relationship were found between SCs expression and patients'gender, age, smoking history, subtype or EGFR status. Interestingly, SCs expression was markedly increased in cancer tissues compared with in adjacent tissues. Furthermore, SCs were significantly overexpressed in tumors of stage II-III than in stage I(P<0.01). Kaplan-Meier curve analysis revealed that high expression of SCs was negatively associated with longer RFS (P<0.001) and OS(P<0.001).5 year-RFS were 18.8%(High) and 51.8%(Low) respectively.

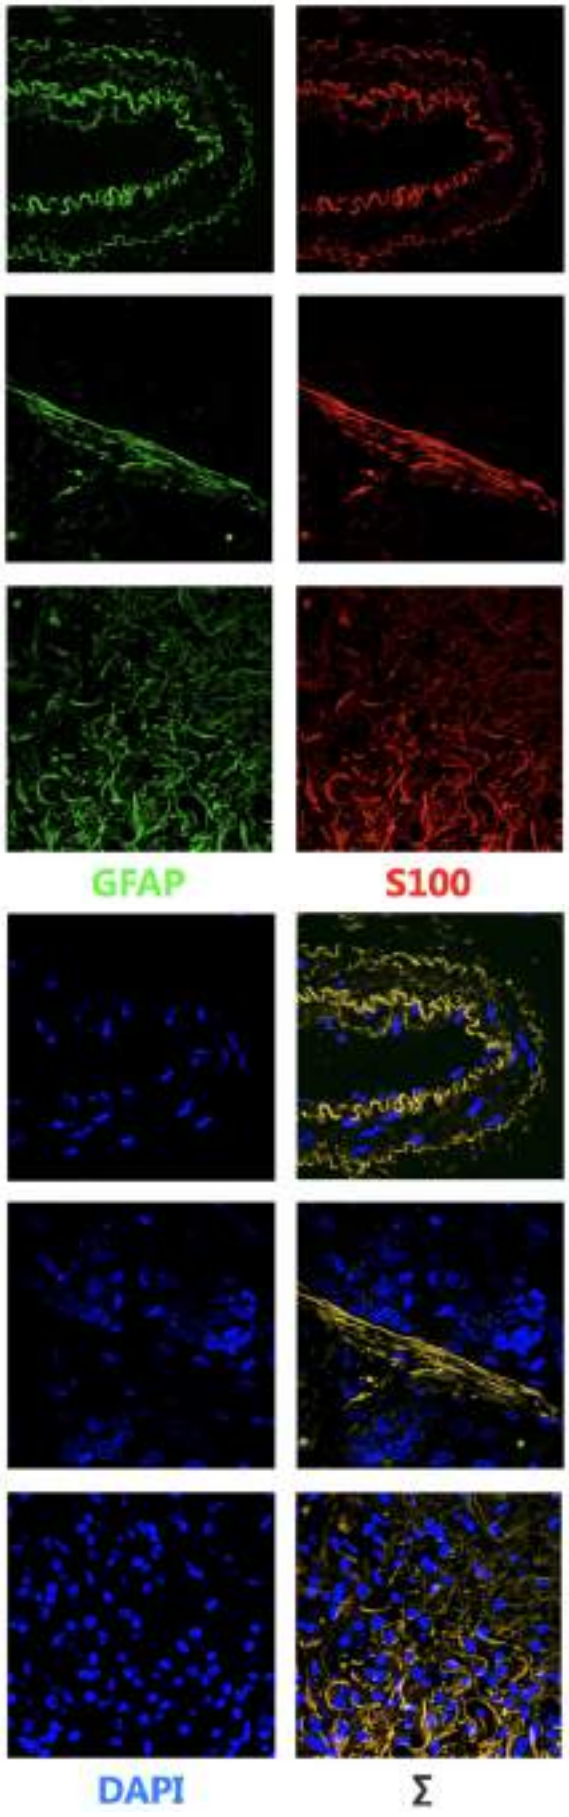


P<0.01,HR=2.706,95%CI:1.794 to 4.082



P<0.01,HR=2.706,95%CI:1.794 to 4.082

POSTERS



Conclusion: High expression of SCs is negatively correlated with tumor stage and survival, indicating its potential diagnostic and therapeutic value for operated NSCLC patients.

P2.01-86 HIGHLY IMMUNOGENIC NEOANTIGENS ENHANCE TUMOR RESPONSE TO IMMUNE CHECKPOINT INHIBITORS IN EGFR-MUTANT NON-SMALL CELL LUNG CANCER (NSCLC)

D. Wu[1], J. Yang[1], Y. Liu[2], X. Hong[1], K. Zhang[1], F. Gu[1], Y. Liu[1], Z. Zhao[2], Y. Hu[1], L. Liu[1]

[1]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China,* [2]*YuceBio, Shenzhen/China*

Background: Immune checkpoint inhibitors have revolutionized the treatment of metastatic non-small cell lung cancer (NSCLC) as significantly extending survival in patients relative to chemotherapy. However evidence to support the role of immune checkpoint inhibitors in *EGFR*-mutant lung cancers remains conflicting. In recent years, neoantigens become promising targets for cancer immunotherapy. Immunogenic neoantigens generated by somatic mutations can be recognized by the host immune system and then tumor clones presenting such neoantigens will be eliminated. **Method:** We report two advanced NSCLC patients with *EGFR* mutations who have both exhibited durable response to PD-1 blockade. We comprehensively analyzed predictive biomarkers and experimentally validated immunogenicity of peptides generated by driver mutations. **Result:** Patient 1 is a 34-year-old male diagnosed with lung adenocarcinoma (IV, cT4N2M1b). *EGFR* exon 19 deletion and *TP53* point mutation (A161T) were identified by next generation sequencing in February 2017 and first line treatment was initiated with Icotinib. He obtained PD within 5 months. After 5 cycles of chemotherapy, brain metastasis was confirmed and *EGFR* T790M mutation was identified by lung biopsy in June 2018. The patient was enrolled in a phase III clinical trial of Nivolumab in July 2018. Patient 2 is a 61-year-old female diagnosed with stage IV lung adenocarcinoma harboring *EGFR* exon 19 deletion identified by next generation sequencing in March 2018. After multilines treatment including TKI therapy, chemotherapy and anti-angiogenic therapy, Nivolumab was given alone to the patient from November 2018. Both patients achieved partial response (PR) to Nivolumab based on imRECIST criteria. The PD-L1 expression level was > 50% and ≥ 5%, respectively in Patient 1 and Patient 2. We performed a target region sequencing which covered 811 cancer genes to determine tumor mutation burden (TMB) and tumor neoantigen burden (TNB). Both patients had moderate level of TMB and TNB. TMB was 6.00 muts/Mb and 4.69 muts/Mb while TNB was 2.67 neos/Mb and 2.68 neos/Mb, respectively in Patient 1 and Patient 2. In order to evaluate the immunogenicity of neoantigens, peptides representing top 7 putative neoantigens were synthesized and tested against PBMC in an IFNγ ELISpot assay. The results revealed tumor-specific T cell immunity targeting neoantigens derived from *EGFR* exon 19 deletion and *TP53* point mutation and the latter exhibited the highest immunogenicity. Strikingly, the patient harboring these mutations achieved partial response for more than 9 months. Additionally, the dynamic changes of TCR profiling during Nivolumab treatment were examined to assess T cell immunity responses. Data shown the maintenance of a majority of high-frequency clonotypes, suggesting the preexisting high-avidity T cells may contribute to antitumor immune response. **Conclusion:** Our study suggests that *EGFR*-mutant NSCLC may still respond to PD-1 blockade. This is the first report on experimentally verifying the highly immunogenic neoantigens derived from *EGFR* driver mutation in patients receiving immunotherapy, which supports potential value of such neoantigens as therapeutic agents. Our study also shows the dynamic monitoring of TCR profiling could help predict T cell immune response.

P2.01-87 β-ADRENERGIC ANTAGONISTS SENSITIZES CHEMORADIATION THERAPY IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER

S. Yan[1], K. Chaudhary[1], B. Halmos[1], T. Wang[1], T. Hei[2], S. Cheng[1]

[1]*Columbia University Medical Center, New York/United States of America,* [2]*Columbia University, New York/United States of America*

Background: Locally advanced non-small cell lung cancer (NSCLC) is highly resistant to chemoradiotherapy, and many cancer patients experience chronic stress. Studies suggest stimulation of β-adrenergic receptor (β-AR) promotes tumor invasion and therapy resistance. We investigated whether β-AR inhibition with beta-blockers acts as a chemotherapy and radiation sensitizer *in vitro* and in patients treated with chemoradiation followed by surgery for locally advanced NSCLC. **Method:** We investigated the effects of the non-selective beta-blocker propranolol on two human lung adenocarcinoma cell lines (PC9, A549) treated with radiation or cisplatin. We retrospectively evaluated 77 patients with Stage IIIA NSCLC who received induction chemoradiation followed by surgery. Pathological and imaging response, metastatic rate and survival were analyzed using SPSSv20 and PrismGraphpad6. **Result:** Propranolol combined with radiation or cisplatin decreased clonogenic survival of PC9 and A549 cells *in vitro* ($p<0.05$). Furthermore, propranolol decreased expression of p-PKA, a β-adrenergic pathway downstream activation target, in both cell lines compared to irradiation or cisplatin alone ($p<0.05$). In patients treated for Stage IIIA NSCLC, 16 took beta-blockers, 61 did not. Beta-blockade is associated with a trend to improved overall survival (OS) at 1 year (81.3% vs 57.4%, p=0.08) and distant metastasis-free survival (DMFS) (2.6 years vs 1.3 years, p=0.16). Although beta-blocker use was associated with decreased distant metastases (risk ratio [RR] 0.19; p=0.03), it did not affect primary tumor pathological response (p=0.40) or imaging response (p=0.36). **Conclusion:** β-AR blockade enhanced radiation and cisplatin sensitivity of human non-small cell lung cancer cells *in vitro*. Beta-blockers use is associated with decreased distant metastases and potentially improved OS and DMFS. Additional studies are warranted to evaluate the role of beta-blockers as a chemoradiation sensitizer in locally advanced NSCLC.

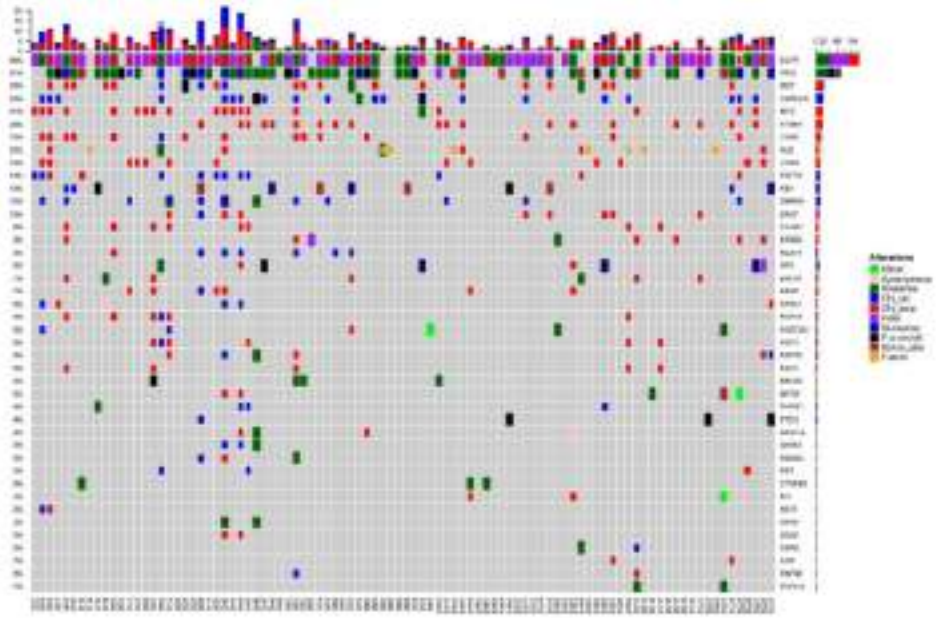
P2.01-88 MOLECULAR ALTERATIONS IN CEREBROSPINAL FLUID PREDICT CLINICAL OUTCOMES OF CENTRAL NERVOUS SYSTEM METASTASES IN LUNG CANCER

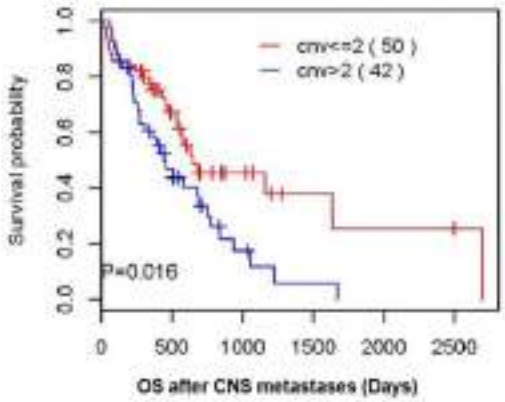
M. Zheng[1,2], Y. Li[1], B. Jiang[1], H. Tu[1], J. Ye[3], J.-J. Yang[1], X.-C. Zhang[4], S. Chuai[3], H. Sun[1], Q. Zhou[1], W.-Z. Zhong[1], Y.-L. Wu[1,2]

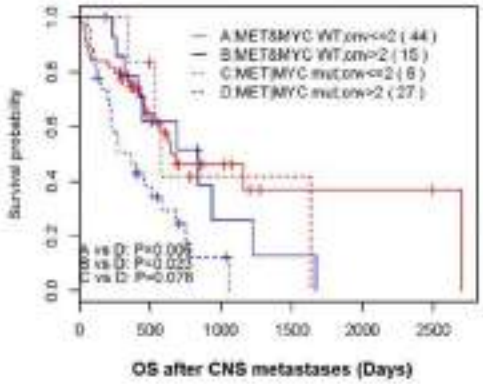
[1]*Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [2]*Guangdong Provincial People's Hospital, School of Medicine, South China University of Technology, Guangzhou/China,* [3]*Burning Rock Biotech, Guangzhou/China,* [4]*Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China*

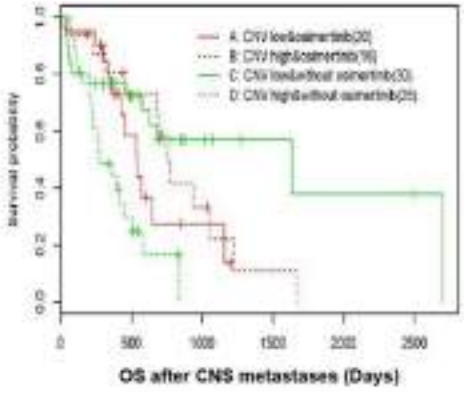
Background: Cerebrospinal fluid (CSF) has been proven as good media for genetic profiling of central nervous system (CNS) metastases. However, the association of genetic alterations in CSF and clinical outcomes remains elusive. **Method:** A total of 94 lung cancer patients with CNS metastases underwent lumbar puncture. Circulating tumor DNA were extracted from CSF and profiled by next-generation sequencing. The effect of genetic alterations in CSF on survival and treatment outcomes were evaluated. **Result:** The most common genes seen in CSF were *EGFR*, *TP53*, *MET*, *CDKN2A*, *MYC*, *NTRK1* and *CDK6*. Kaplan-Meier survival analysis indicated that *CDK4*, *CDK6*, *FGFR1*, *MET* and *MYC* alterations, which were also characterized by more copy number changes, were associated with poor survival. Multivariate analysis found only *MET* (HR, 2.01; 95% CI, 1.15 to 3.52) and *MYC* alterations (HR, 2.31; 95% CI, 1.27 to 4.21) were correlated to poor OS. Forty-two patients harbored high n-CNVs (defined as the number of genes with copy number variations >2) while 50 patients carried low n-CNVs (defined as the number of genes with copy number variations <=2). Median overall survival (OS) of patients with high n-CNVs in CSF was 14.9 months (95% CI, 9.2 to 25.8 months), significantly shorter than those with low n-CNVs (21.6 months, 95% CI, 17.9 months to not reached (NR); HR, 1.9; 95% CI, 1.11 to 3.24; *P*=0.016). Patients with high n-CNVs and *MET* and *MYC* CNVs (copy number variations) were associated with the poorest OS. Osimertinib significantly prolonged OS only among patients with high n-CNVs (with vs. without osimertinib, 25.8 vs. 9.2 months; *P*=0.004). Among *T790M* negative patients, high n-CNVs seemed to positively associate with better response to osimertinib (OS with vs. without osimertinib, 23 vs. 7.8 months; *P*=0.058). Further analysis indicated that *EGFR* and *FGFR1* CNV were the most significant factors associated with OS benefit from osimertinib among the high n-CNVs group (*P*=0.014; *P*=0.02). *TP53*_LOH and Wnt pathway alterations were significantly more prevalent in the high n-CNVs group than in the low n-CNVs group (*P*=0.016, *P*=0.006). With regard to clinical characteristics, higher performance status score (HR, 2.06; 95% CI, 1.38 to 3.07; *P*=0.0004) and occurrence of extracranial metastases (HR, 3.21; 95% CI, 1.25 to 8.24; *P*=0.015) suggested poor OS.

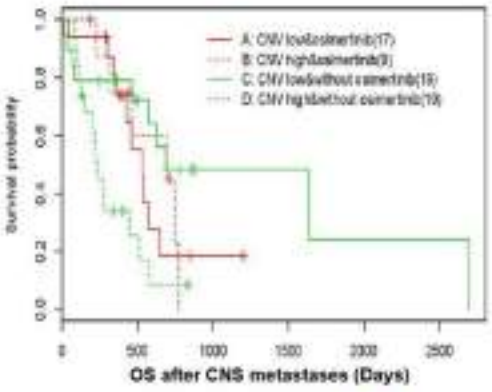
POSTERS

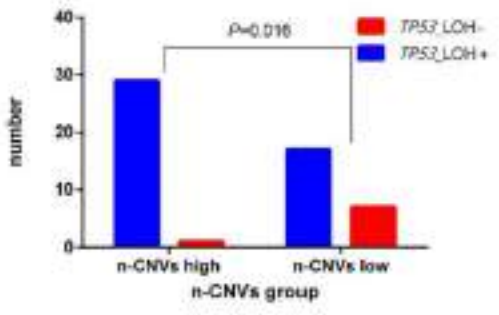


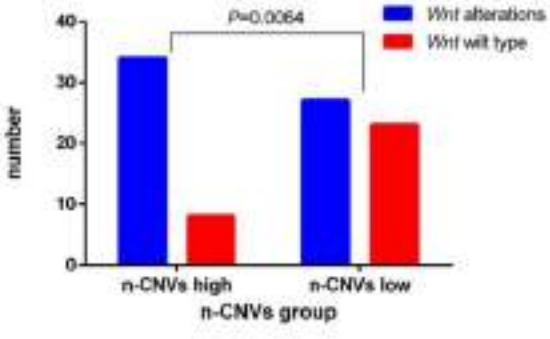












Conclusion: While genetic profiles in CSF, like high n-CNVs as well as *MET* and *MYC* CNV were related to poor prognosis, patients with high n-CNVs, especially those with *EGFR* or *FGFR1* CNV might benefit more from osimertinib, further supporting CSF as liquid biopsy of CNS metastases in lung cancer.

POSTERS

P2.01-89 FEASIBILITY OF INDIVIDUALIZED MULTIDISCIPLINARY TREATMENT FOR LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER BASED ON THE TREATMENT PLANNING

S. Yang, Y. Liu, Y. Ye, Y. Zhu, Q. Xu, Y. Xu

Shanghai Pulmonary Hospital, Shanghai/China

Background: In the individualized multidisciplinary treatment of patients with locally advanced non-small cell lung cancer (LANSCLC), the feasibility of dose escalation to the patients with sequential chemoradiotherapy for increasing tumor control and dose reduction to the patients with concurrent chemoradiotherapy for mitigating the side effects of radiotherapy was analyzed in the aspect of treatment plan optimization. **Method:** Fifty patients with LANSCLC were randomly chosen from Shanghai Pulmonary Hospital and treatment plans were replanned. These patients' PTV was defined as CTV+0.4cm, and CTV was the extravasation of 0.6-0.8cm of GTV, at least 95% volume of the PTV receive 60Gy/30fx, and these plans were called control group. The initial GTV was taken as GTV1, and GTV2 was obtained after GTV irradiated 40Gy; PTV1 was defined as GTV1+0.4cm, and PTV2 was defined as GTV2+0.4cm. With PTV2 dose escalated, the plans with lung remaining the same dose as control group were the Test1 group, and the plans with PTV1 receiving 60Gy and PTV receiving 45Gy were the Test2 group. The feasibility of the treatment regimen for Test1 Group and Test2 Group was analyzed from the perspective of dose drop gradient and the sparing of OARs, respectively. **Result:** By comparing Test1 group with control group, it is found that the dose PTV2 received is affected greatly by the volume ratio, $V_{PTV\text{-}PTV1}/V_{PTV}$, which will escalate when $V_{PTV\text{-}PTV1}/V_{PTV}$ increases. When $V_{PTV\text{-}PTV1}/V_{PTV}$ is in these range, 0.2~0.3, 0.3~0.35, 0.35~0.4, 0.4~0.45, then the dose escalated for PTV2 will be 63Gy, 66Gy, 69Gy and 72Gy. And by comparing Test2 group with control group, it is found that the dose received by OARs will be reduced in Test2 group, for example, V5, V20, V30 and MLD for lung will decrease 2.17%±1.2792%, 1.7148%±1.04733%, 1.9982%±1.165%, 1.299Gy±0.564Gy, respectively; V50 and MHD for heart will decrease 1.9128%±2.1184%, 1.229Gy±0.921Gy, respectively; V60, Dmax and MED for esophagus will decrease 5.41%±5.91%, 4.6296Gy±4.4479Gy, 2.3491Gy±1.3411Gy, respectively, and all the p values are far less than 0.05. **Conclusion:** Individualized radiotherapy can be performed on LANSCLC, and $V_{PTV\text{-}PTV1}/V_{PTV}$ can be used to predict the dose drop gradient. In Test1 group, considering not add additional dose to lung, the larger $V_{PTV\text{-}PTV1}/V_{PTV}$, the higher the PTV2 can escalate. In test2 group, reducing the initial irradiation-field dose significantly decreases the dose OARs received, and it is meaningful that more locally advanced patients can receive concurrent chemoradiotherapy. This study will facilitate the individualized multidisciplinary treatment of patients with LANSCLC, which needs further prospective studies to confirm.

Keywords: individualized multidisciplinary treatment, treatment plan optimization, locally advanced non-small cell lung cancer

P2.01-90 DOSIMETRY PREDICTION OF LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER BASED ON THE TUMOR LOCATION AND THE VOLUME RATIO OF TUMOR TO LUNG

S. Yang, Y. Ye, Y. Zhu, Y. Xu

Shanghai Pulmonary Hospital, Shanghai/China

Background: Based on the tumor location and the volume ratio of tumor to lung, we give a method to predict the lowest dose-volume histogram (DVH) curve for the locally advanced non-small cell lung cancer patients. **Method:** Fifty locally advanced non-small cell lung cancer patients were randomly chosen from Shanghai Pulmonary Hospital, who were treated with radical radiotherapy by intensity modulated radiotherapy(IMRT) technique. The volume of the PTV for these 50 patients range from 44.65cc to 935.36cc, and they were located in different position of the lung. All of the patients received 60Gy total dose in 30 fractions, and at least 95% of the PTV were covered by the prescription dose. All the treatment plans were required to have their optimal results based on the lowest DVH curve of the lung, and the final DVH of the lung were analyzed according to the tumor location and its volume ratio relative to the lung. **Result:** By analyzing the tumor location in lung and the volume ratio of tumor to lung, it is found that the DVH for the lung cancer can be predicted. When the tumors are in the same position, as the volume ratio of tumor to lung increases, the dose volume of the lung will increase proportionally; when the tumors are located in different positions, even if the volume ratio of tumor to lung is the same, the DVH of the lung appears differently; and moreover, it is found that the volume of the lung affects the DVH of the lung much more than the volume ratio of tumor to lung, ie, even though the volume ratio of tumor to lung has a larger value, if the lung has a larger volume, a lower DVH curve of the lung can be obtained. At last, we found that, in any case, if the volume between the 10Gy and 65Gy is in an inverse proportional relationship and the dose received by the other OAR(organ-at-risk) is inside its safe range, then the treatment plan for the patient will be the best. The inflection point (around 6~7 Gy) of the DVH curve for the lung will be obtained, which is the extreme value of the DVH curve. **Conclusion:** By analyzing these 50 patients' treatment plans, the DVH of lung can be predicted for any locally advanced non-small cell lung cancer patient based on the tumor location and the volume ratio of tumor to lung. The lowest DVH curve of the lung can be assessed by its obtained inflection point.

P2.01-91 EXOSOMAL ANALYSIS OF ALK REARRANGEMENTS BY SPIN COLUMN WITH POROUS GLASS FILTER

T. Hatta[1], T. Hase[1], N. Ozawa[1], N. Yogo[1], H. Yukawa[2,3], H. Tanaka[4], D. Onoshima[2], M. Sato[1], M. Hori[4], Y. Baba[2,3], Y. Hasegawa[1]

[1]*Nagoya University Graduate School of Medicine, Nagoya/Japan,* [2]*Institute of Innovation for Future Society, Nagoya University, Nagoya/Japan,* [3]*Graduate School of Engineering, Nagoya University, Nagoya/Japan,* [4]*Center for Low-temperature Plasma Sciences, Nagoya University, Nagoya/Japan*

Background: ALK rearrangements account for about 3-5% of non-small cell lung cancer (NSCLC). ALK-tyrosin kinase inhibitors (TKI) demonstrated robust efficacy compared with cytotoxic chemotherapy in patients with ALK alterations detected in the tumor tissues. Identifying ALK rearrangement was performed using tissue samples, which are not always available. The spin column with porous glass filter has been developed by Nagoya university and AGC Inc, resulting in highly efficient and easy to use exosome isolation. The exosomes contain various molecules of their cell of origin, including proteins and RNA. The purpose of this study was to explore the spin column to capture exosome and detect ALK alterations in exosomal RNA from blood. **Method:** The supernatant of cell culture medium (H3122, H2228) and plasma samples from 3 patients with ALK-positive NSCLC were passed through the filter using a conventional centrifugation. Exosome captured in the filter was lysed with reagent for RNA extraction. The total RNA was retrotranscripted by random primers. The ALK rearrangement in the exosome were determined by RT-qPCR and DNA sequencing. **Result:** EML4-ALK variant 1 and 3 were detected in exosome from 500μL of culture supernatant of H3122 and H2228, respectively. In the analysis of exosome in plasma from patients with EML4-ALK determined by fluorescence *in situ* hybridization and immunohistochemistry, EML4-ALK variant 1 was successfully detected in all cases. **Conclusion:** Exosome remains relatively stable in the blood, making it an attractive target for liquid biopsy. Our preliminary results showed potential capability in the detection of ALK alteration in exosomes from blood. These findings require confirmation in further studies with a larger number of patients with ALK-positive NSCLC.

P2.01-92 CIMAVAX-EGF IN COMBINATION WITH FIRST-LINE CHEMOTHERAPY IN III STAGE NSCLC

E. Neninger[1], H. Caceres[1], K. Camacho[2], M. Hernandez[3], E. Santiesteban[2], C. Del Castillo[1], Y. Menendez[1], B. Gonzalez[4]

[1]*Hermanos Ameijeiras Hospital, Havana/Cuba,* [2]*Jose Ramon Lopez Hospital, Matanzas/Cuba,* [3]*Molecular Immunology Center, Havana/Cuba,* [4]*Ramon Lopez Tabranes Hospital, Matanzas/Cuba*

Background: A Cuban therapeutic cancer vaccine composed by human recombinant Epidermal Growth Factor (EGF) conjugated to a carrier protein, P64K from Neisseria Meningitides (CimaVax-EGF) induces antibodies against self EGF that decrease its concentration and affect EGF-EGFR interaction. Cimavax EGF was registered in Cuba as switch maintenance therapy for advanced

stage NSCLC. Objective: Evaluate the safety an immunogenicity of the combination of cimavax and first-line chemotherapy in patients with inoperable stage IIIa non-small cell lung cancer **Method:** A phase I clinical trial was conducted in two hospitals in Cuba, with the approval of Ethic Committee of each one. Cimavax EGF was administered by intramuscular injection in four sites of administration (4 subdoses of 0.25 ml), every 2 weeks the first 4 doses and after this induction phase monthly reinmunizations were given. First-line platinum-based chemotherapy was administered concomitantly, four to six cycles platinum-based ChT every 21 days. **Result:** Thirty patients entered the study. Most frequently adverse events registered with the combined treatment were: injection-site reaction (7.8 %), cough (7.3%), anemia (6.1%), fever (5.3%), asthenia (4.9%) and anorexia (4.9%). Most of them were classified as grade1 -2 according CTCAE version 3. There were no deaths related to the combined treatment. Antibody response against EGF was repeatedly measured in 24 patients. More than 90% of patients (n = 23; 95,8%) were classified as good antibody responders (GAR). It was observed an inverse correlation between EGF concentrations and anti-EGF antibody titers, as previously Cimavax EGF trials have reported. Anti-EGF antibody titers continue increasing until day 76 during the chemotherapy course and was maintained until the end of the treatment. In fact, there were high anti-EGF antibodies post-chemotherapy than before. The median overall survival (mOS) time for all included patients was 9.4 months. **Conclusion:** Cimavax EGF vaccine in combination with first-line platinum-based chemotherapy was a safe treatment option for NSCLC patients with IIIa stage NSCLC. Immune response was not affected with the administration of chemotherapy. This was the first combined study of Cimavax in locally advanced NSCLC.

Keywords: IIIa NSCLC, immunogenicity, Cimavax Egf vaccine

P2.01-93 DETECTION OF GIANT CANCER-ASSOCIATED MACROPHAGE-LIKE CELLS AFTER CONCURRENT CHEMOIMMUNORADIATION IS ASSOCIATED WITH POOR SURVIVAL IN NSCLC

A. Augustyn[1], D. Adams[2], J. He[1], Y. Qiao[1], T. Xu[1], Z. Liao[1], A. Raghavakaimal[3], K. Gardner[2], C.-M. Tang[2], J. Heymach[1], A. Tsao[1], S. Lin[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*CreatvMicrotech, Inc., Monmouth Junction/United States of America,* [3]*Rutgers University, New Brunswick/United States of America*

Background: Circulating cancer-associated macrophage-like cells (CAMLs) are a recently described stromal cell found in the peripheral blood of cancer patients that have been shown to be associated with disease progression. The presence of giant CAMLs (≥50 μm) was previously reported to be predictive of disease progression in multiple tumor types. In this phase II DETERRED trial of patients with unresectable locally advanced non-small cell lung cancer (NSCLC) treated with atezolizumab (atezo) combined with concurrent chemoradiation, we explored the utility of CAMLs in predicting progression based on blood samples collected throughout treatment and follow up. **Method:** Patients were enrolled between February 2016 and April 2018. Patients were treated with carboplatin/paclitaxel (CP) and conventionally fractionated radiation therapy (60 – 66 Gy) with atezo, followed by CP-atezo, followed by maintenance atezo. Median follow up after the completion of concurrent chemoimmunoradiation (cCIRT) was 13.5 months. CAMLs were collected by obtaining peripheral blood from patients at baseline at the beginning, during, at the end, at first follow up, and final follow up after cCIRT. Blood was filtered using CellSieve™ filtration and CAMLs quantified. CAML size ≤49 μm or ≥50 μm was quantified with the observer blinded to clinical information. Relapse free survival (RFS), distant metastasis free survival (DMFS), progression free survival (PFS), and overall survival (OS) were analyzed at each time point. **Result:** We evaluated 40 patients with unresectable locally advanced NSCLC and obtained a total of 375 samples. CAMLs were identified in 80.5% of samples, averaging 2.5 CAMLs per 7.5 mL sample. Patients with giant CAMLs (≥50 μm) compared to those with smaller CAMLs (≤49 μm) exhibited no difference in RFS, PFS, DMFS, or OS at baseline, during, or immediately after completion of cCIRT. Patients with detectable giant CAMLs at the first follow up (median time 29 days from completion of cCIRT) demonstrated significantly worse RFS (HR=11.79, 95% CI 4.27-32.56, p=0.0021), DMFS (HR=6.48, 95% CI 2.15-19.54, p=0.0009), and PFS (HR=12.47, 95% CI 4.66-33.37, p=0.0014) while OS trended towards statistical significance (HR=5.39 95% CI 1.33-21.81, p=0.071). Long term evaluation of patients with CAML ≥50 μm at first follow up (N=16) revealed 3 patients who converted to CAML<49 μm at last follow up. Patients who converted did not experience any relapses, while all 13 patients who continued to have CAML ≥50 μm experienced progression or death. **Conclusion:** Giant CAMLs at first follow up after completion of concurrent chemoimmunoradiation is predictive of disease progression and death. This may represent an immediate surrogate marker for poor response at the completion of definitive therapy. Long term follow up with maintenance immunotherapy indicates that a subset of patients convert from giant CAMLs to smaller CAMLs, with better outcomes than those that do not, suggesting that these patients may have derived benefit from maintenance immunotherapy. Continued prospective validation of CAMLs as a peripheral blood-based biomarker is needed to validate these findings.

P2.01-94 ADVANCED AGE AND HIGH MODIFIED GLASGOW PROGNOSTIC SCORE ARE ASSOCIATED WITH INCREASED COMPLICATIONS AFTER PNEUMONECTOMY

M. Zaatar[1], T. Stork[1], L. Fangmann[1], A. Martens[1], S. Collaud[1], K. Mardanzai[1], T. Plönes[1], D. Valdivia[1], M. Schuler[1], M. Stuschke[1], K. Darwiche[1], B. Hegedus[2], C. Aigner[2]

[1]*Ruhrlandklinik, Essen/Germany,* [2]*Ruhrlandklinik, University Hospital Essen, Essen/Germany*

Background: Pneumonectomy is associated with increased morbidity and mortality compared to parenchyma sparing anatomic lung resections. The aim of this study was to identify risk factors in lung cancer patients undergoing curative intent pneumonectomy. **Method:** All newly diagnosed non-small cell lung cancer patients undergoing pneumonectomy in curative intent as the primary surgical procedure between 1/2013 and 12/2018 were retrospectively analyzed. We reviewed demographic, clinical, functional and surgical variables. Postoperative complications and 30- as well as 90- day mortality were analyzed to identify risk factors for postoperative morbidity and mortality . **Result:** 103 lung cancer patients (67% male; mean age 62.3 ± 8.5) who underwent pneumonectomy with a curative intent have been identified. 62 patients (60%) received neoadjuvant treatment with chemotherapy (n=20) chemoradiation (n=42). Postoperative complications were registered in 35 (34%) patients (34%), with a major complication rate of 12%. Patients older than 65 years had a significantly higher risk for complications (p=0.0039). There was a strong trend in patients with modified Glasgow Prognostic Score >1 for higher postoperative complications (p=0.0715). There was no increase in postoperative morbidity in patients who underwent neoadjuvant treatment. 30- and 90-day mortality was 2.9% and 2.9%, respectively. **Conclusion:** Pneumonectomy for lung cancer can be done with low postoperative morbidity and mortality. Elderly patients should receive a careful preoperative evaluation. Modified Glasgow Prognostic Score can be considered for risk stratification for this procedure.

P2.01-95 UPDATED DATA OF KRSG 1302 STUDY: NEDAPLATIN AND NAB-PACLITAXEL FOR PATIENTS WITH PREVIOUSLY UNTREATED ADVANCED SQUAMOUS CELL LUNG CANCER

F. Ohyanagi[1], Y. Nagai[2], T. Kasai[2], N. Koyama[2], K. Kobayashi[2], E. Hoshi[2], M. Nakayama[2], K. Mori[2]

[1]*Jichi Medical University Saitama Medical Center, Saitama City/Japan,* [2]*Kanto Respiratory Disease Study Group (KRSG), Utsunomiya/Japan*

Background: Nedaplatin (N) and nab-paclitaxel (nab-P) are efficacious for the treatment of non-small cell lung cancer, especially advanced squamous cell lung cancer. Although a combination of N and nab-P is expected to result in the treatment of squamous cell lung cancer, no sufficient and reliable data have been reported yet. **Method:** Patients and methods: The inclusion criteria were no prior chemotherapy; stage IIIB or stage IV squamous cell lung cancer; a performance status (PS) of 0–1; 75 > patients' age > 20 years; and adequate major organ function. Patients received escalating doses of nab-P under a fixed dose of N (100 mg/m^2, 1st day) every 3 weeks in phase I. The initial dose of nab-P was 100 mg/m^2 on the 1st and 8th

day (level 1), and the next dose was 100 mg/m^2 on the 1st, 8th, and 15th day (level 2). In phase II, the patients received the recommended dose of N/nab-P. The primary endpoint was tumor response, which was measured according to the revised version of response evaluation criteria in solid tumors. **Result:** In this study, 5 patients were enrolled in the phase I. Three patients in level 1 experienced no dose-limiting toxicities (DLTs); whereas, 2 patients in level 2 experienced DLTs. Therefore, level 1 was named the recommended dose. In addition, 23 patients were enrolled in phase II. Three and 23 patients in level 1 and phase II were evaluated, respectively. However, among them, 2 of 26 patients were not assessed due to pneumonia, and 1 of 26 patients was excluded from analysis due to patients' refusal. Partial response, stable disease, and progressive disease were noted in 21, 0, and 2 patients, respectively, yielding a response rate of 91.3% [95% confidence interval (CI): 72.0–98.9]. The median progression-free survival (PFS) was 223 days (95%CI: 144–330), and the median overall survival (OS) was 358 days (95% CI: 255–950). The 1- and 2-year PFS rate were 17.8% and 12.0%. The 1- and 2-year OS rate were 50.0% and 43.8%, respectively. The grade 3 and grade 4 toxicities were manageable and there was no treatment-related death. These data were published in 2018 ESMO. We will report updated efficacy and safety of N/nab-P in KRSG 1302 study. **Conclusion:** Conclusions: A combination of N (100 mg/m^2, 1st day) with nab-P (100 mg/m^2, 1st and 8th day) every 3 weeks demonstrated an effective therapeutic approach. Therefore, N/nab-P administration is to be safe and efficacious for patients with advanced squamous cell lung cancer.

Background: Neuregulin 1 gene (*NRG1*) fusions such as *SLC3A2-NRG1* have been identified in 6,7% of invasive pulmonary mucinous adenocarcinoma (IMA). This fusion leads to ErbB2 and ErbB3 pathway activation. Theoretically a matched targeted therapy may be afatinib, an oral irreversible ErbB-family inhibitor. **Method:** We present the case of a 80 year-old non smoker caucasian female with breathless at rest, bronchorrhea, fever, bilateral ground glass opacities and right lower lobe atelectasia. Body CT scan and PET-scanner revealed hypermetabolic multifocal lung involvement. Cytologic examination of bronchioloalveolar lavage revealed adenocarcinomatous cells compatible with IMA. She received first-line gefitinib 250mg per day, antibiotics and solumedrol. After a clinical improvement of 15 days, cough and hypoxemia worsened and CT scan showed pulmonary opacities progression. A *SLC3A2(e5)-NRG1(e6)* gene fusion was identified with a targeted RNA sequencing performed on cytologic samples (Panel « FusionPlex CTL Kit », ArcherDx). The sample was negative for *EGFR* ex18 to 21, *KRAS, BRAF, PIK3CA, ERBB2, MET* mutations. Afatinib 30mg orally once daily was started. At 8-week follow-up, the patient reported resolution of cough, bronchorrhea, hypoxemia and chest CT showed significant improvement of ground glass opacities in the left lower lobe. The clinical response was sustained to week 16, when her bronchorrea and hypoxemia worsened and CT scan showed progression despite an increasing dosage of afatinib at 40mg once daily. She subsequently received carboplatine- paclitaxel- bevacizumab. A progression eventually occurred after 4 months. We rechallenge afatinib 30mg orally once daily and a clinical and imaging response is still ongoing after 8 weeks. **Result:** The clinical efficacy of afatinib in this case was suggestive of an on target effect of afatinib, with rapid clinical improvement and radiographic response despite a disease control shorter than 16 weeks. **Conclusion:** This report offers some evidence of the activity of afatinib in *NRG1* gene fusion-positive lung cancer.

P2.01-97 ANGIOTENSIN-CONVERTING ENZYME INHIBITOR IS ASSOCIATED WITH DECREASED SURVIVAL IN NSCLC PATIENTS TREATED WITH PD-1 CHECKPOINT BLOCKERS

S. Medjbar[1], C. Richard[1], J.-D. Fumet[1], J. Malo[2], A. Elkrief[2], B. Routy[2], R. Boidot[3], C. Truntzer[3], F. Ghiringhelli[1]

Background: Angiotensin-converting enzyme (ACE) inhibitors are frequently used to treat hypertension and congestive heart failure. Preclinical evidence shows that ACE plays a role on both innate and adaptive immune responses by promoting macrophages and neutrophils function and the stimulation of antigen presentation, thus suggesting the possibility of anti-tumor immunity through an ACE inhibitor-mediated mechanism. Interactions between ACE inhibitors and immune checkpoint blockers (ICB) have not been currently investigated in cancer patients (pts). Our study evaluated the effect of ACE inhibitors on non-small cell lung cancer (NSCLC) pts treated with PD-1/PD-L1 inhibitors. **Method:** We conducted a retrospective multicohort retrospective analysis of pts treated with PD-1/PD-L1 inhibitors for NSCLC at Dijon Cancer Center, and at the University of Montreal Hospital. Clinical data and co-medications were collected. Groups were defined as pts treated with ACE inhibitor or not with at the time of ICB initiation. PFS and OS were compared between both groups. Statistical analyses were performed using the Kaplan-Meier method. Cox regression analyses were performed separately to adjust for standard prognostic factors. RNA sequencing of several tumors were performed and analyzed using CIBERSORT to determine immune cells infiltration. **Result:** Among 283 pts included (177 pts from Dijon, and 106 pts from Montreal), 27 (10%) received ACE inhibitors. Baseline characteristics were equally balanced in both groups. However, the ACE inhibitor group was more frequently treated with statins, beta blockers and metformin. The ACE inhibitor group had shorter median PFS compared to the control group: 2.5 vs. 3.8 months, p= 0.02 (HR=1.7 CI95% 1.1-2.5). The negative impact of ACE inhibitor group was maintained after multivariate analyses adjusting for known risk factors (HR=1.9 CI95% 1.1-3.5 p=0.02 for PFS and HR=2.3 CI95% 1.2-4.4 p=0.01 for OS). RNA sequencing suggested that ACE inhibitor group tumors had lower M1 macrophages, activated mast cells, NK cells and memory activated T cells thus suggesting an immunosuppressed state. **Conclusion:** ACE inhibitor prescription concomitant to the PD-1/PD-L1 inhibitors treatment is associated with impaired outcome in pts with advanced NSCLC pts. This reduction is independent of standard prognostic factors. Biological correlative analyses suggest a tumor immunosuppressed state in ACE inhibitor group. These results should be validated in larger prospective cohorts.

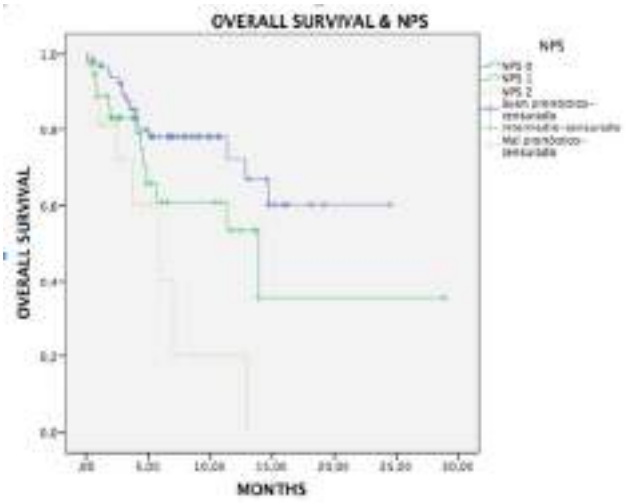
Background: Systemic inflammation response can be characterized by changes of peripheral blood cell amounts. Several blood cell-based scores have been found to have prognostic value in some tumors treated with ICI. Neutrophil-platelet score (NPS) is a systemic

inflammation-based score characterizing 3 prognostic groups: good (0), neutrophils <=7500 and platelets <=400000; intermediate (1), neutrophils >7500 or platelets >400000; poor (2), neutrophils >7500 and platelets >400000). It has never been evaluated as prognostic biomarker in first line treatment setting of non-small-cell lung cancer (NSCLC) patients treated with pembrolizumab. **Method:** This is a multicenter retrospective study with the aim to evaluate prognostic value of NPS in patients with advanced NSCLC and high PD-L1 expression treated with pembrolizumab monotherapy between September 2016 and March 2019. Clinical data were contributed by 12 medical centers in Spain. Primary endpoint was association of NPS with overall survival (OS). **Result:** 121 patients were evaluated. Median age was 68 years (38-88). 90 (74,4%) were male and 90 (74,4%) had PS1. Predominant histologies were adenocarcinoma (68,6%) and squamous-cell carcinoma (23,1%). Median number of cycles was 7 (1-33). Median follow-up: 6,5 months. Most were current or former smokers (95,9%). Only 1 patient had driver mutation (ALK rearrangement). 66,9% had 2 or more metastatic locations, 18,2% had central nervous system (CNS) disease, 17,4% liver metastasis, and 41,3% bone metastasis. Response rate was 40,4% according to RECISTv1.1 criteria. 11% had hyperprogression and 7,2% pseudoprogression. Estimated 12-month-OS was 62% (95%CI: 49.1%-72.5%) and estimated 12-month-PFS was 44.2% (95%CI: 31.1%-56.5%). Higher NPS was associated with poor PFS: NPS1 HR 1,23 (95%CI, 0,61-2,46), p=0,56; NPS2 HR 3,56 (95%CI, 1,61-7,86), p=0,002. NPS was not associated with disease control rate (DCR) or overall response rate (ORR).



Conclusion: NPS predicted OS and PFS in advanced NSCLC patients with high PD-L1 expression treated with first line pembrolizumab monotherapy. NPS2 subgroup has an especially bad prognosis in spite of high PD-L1 expression and frontline treatment with pembrolizumab. These results need to be validated in prospective studies.

Background: The safety and efficacy of afatinib, an orally administered irreversible EGFR TKI, have been demonstrated in patients with *EGFR* mutation-positive (*EGFR*m+) NSCLC in several Phase III clinical trials. However, prospective evidence supporting the clinical benefit of afatinib in the real-world setting is limited. Here, we report final data from a Phase IIIb open-label, multicenter trial evaluating safety and efficacy of afatinib in EGFR TKI-naïve Asian patients with locally advanced/metastatic *EGFR*m+ NSCLC, in a setting similar to real-world practice. **Method:** EGFR TKI-naïve patients with locally advanced/metastatic *EGFR*m+ NSCLC were recruited from 34 sites in China, Hong Kong, India, Singapore, and Taiwan. Patients received 40 mg/day afatinib. Dose reduction to minimum 20 mg/day was permitted. Treatment continued until lack of clinical benefit as determined by the investigator. The primary and secondary safety endpoints were number of patients with serious adverse events (SAEs), and number of patients with drug-related AEs, respectively. The secondary efficacy endpoint was time to symptomatic progression (TTSP). Further endpoints included progression free survival (PFS), objective response, and duration of disease control. **Result:** In total, 541 patients received afatinib. Baseline characteristics were representative of patients with *EGFR*m+ NSCLC (median age, 59 years; female, 52.9%; never smoked, 69.3%; *EGFR* mutations, common [Del19/L858R]/uncommon: 88.2% [48.2%/40.5%]/11.8%; ECOG performance status 0/1, 18.3%/79.7%; brain metastases, 19%). SAEs were reported in 164 patients (30.3%). 34 patients (6.3%) had drug-related SAEs, most commonly (grouped terms): diarrhea (1.8%), stomatitis (0.7%), and vomiting (0.7%). Drug-related AEs (DRAEs) of any grade were reported in 528 patients (97.6%). AEs leading to dose reduction occurred in 154 patients (28.5%); TRAEs leading to treatment discontinuation were reported in 17 patients (3.1%). Three patients experienced DRAEs leading to death (decreased appetite, dyspnea, and respiratory failure). Median TTSP was 14.0 months (95% confidence interval [CI]: 12.9, 15.9) and median PFS was 12.1 months (95% CI: 11.0, 13.6). Objective responses were reported in 312 patients (57.7%) by week 52; the median duration of response was 12.2 months (95% CI: 11.0, 13.5). 483 patients (89.3%) achieved disease control of median duration 13.6 months (95% CI: 12.1, 14.4). **Conclusion:** Safety data for afatinib in this patient population were consistent with previously reported data, with no new safety signals. AEs were manageable and did not lead to discontinuation in most patients. This study also demonstrated the efficacy and clinical benefit of afatinib in Asian patients with locally advanced or metastatic *EGFRm+* NSCLC in a near real-world setting.

P2.01-100 SPECTRUM OF EGFR EXON 20 INSERTION MUTATIONS AND CO-OCCURRING GENETIC ALTERATIONS IN PATIENTS WITH NON-SMALL-CELL LUNG CANCER

G. Bravo Montenegro[1], M. Nagasaka[2], P. Ma[3], A.R. Naqash[4], H. Mamdani[2], A. Spira[5], D. Subramaniam[1], R. Feldman[6], C. Kim[1]

[1]*Georgetown University, Washington/United States of America,* [2]*Karmanos Cancer Institute, Detroit/United States of America,* [3]*West Virginia University, Morgantown/United States of America,* [4]*East Carolina University, greenville/United States of America,* [5]*Virginia Cancer Specialists, Fairfax/United States of America,* [6]*Caris Life Sciences, Phoenix/United States of America*

Background: Epidermal growth factor receptor (*EGFR*) exon 20 insertion mutations are associated with a low response rate to approved EGFR tyrosine kinase inhibitors (EGFR-TKIs) and short progression-free survival. Pre-clinical studies have shown differences in the affinity of *EGFR* exon 20 insertion mutations for EGFR-TKIs, suggesting that the location of the insertion within the C-helix may play an important role in determining EGFR-TKI sensitivity. Several EGFR-TKIs designed to target *EGFR* exon 20 insertion mutations are in clinical development. Comprehensive genomic profiling has allowed for identification of co-occurring genomic alterations, which may help us identify additional pathways that may drive disease progression and

drug resistance. **Method:** Formalin-fixed paraffin-embedded (FFPE) samples from patients with non-small cell lung cancer (NSCLC) were profiled by targeted next-generation sequencing (NGS) using Caris Molecular Intelligence (Caris Life Sciences, Phoenix, AZ). Mutations and copy number variations (CNV) were assessed for each gene included in the NGS panel. Gene amplification (including low amplifications) was defined as gene copy number ≥ 4 and copy number loss as gene copy number < -1.4. **Result:** Among the 1,556 patients with *EGFR* mutations, 104 (6.7%) patients were found to harbor an *EGFR* exon 20 insertion mutation. There were 70 (67.3%) females and 34 (32.7%) males with a mean age 62 (± 11.5 years). 61 (58.7%) samples came from primary lung sites and 43 samples (41.3%) came from metastatic sites. The main histological types were: adenocarcinoma 89 (85.5%), acinar adenocarcinoma 6 (5.7%), papillary adenocarcinoma 5 (4.8%), adenocarcinoma with bronchoalveolar features 1 (1%), squamous cell carcinoma 1 (1%) and carcinoma not otherwise specified 2 (2%). The most common exon 20 insertion mutation was A767_V769dup (25%), followed by S768_D770dup (13%), H773_V774insAH (5%) and H773dup (5%). The most common pathogenic mutations (including presumed pathogenic) included *TP53* (51%), followed by *CTNNB1* (6%), *PIK3CA* (4%), *PTEN* (3%), *SMAD4* (3%), and *CHEK2* (2%). Of the 104 cases, CNVs were available from 54 patients. Among these patients, commonly amplified genes included *CDK4* (11%), *EGFR* (9%), *MDM2* (9%), *FOXA1* (7%), and *HMGA2* (6%). Copy number loss was observed with *CDKN2A* (7%), *CTNNB1* (2%), *ATR* (2%), *BRCA2* (2%), and *FANCL* (2%). **Conclusion:** The diverse spectrum of *EGFR* exon 20 insertion mutations shows molecular heterogeneity of this rare type of *EGFR* mutations. The presence of co-occurring genomic alterations that may promote tumor progression and drug resistance suggests that combination approaches may be necessary to overcome resistance to EGFR-TKI therapy in some patients with an *EGFR* exon 20 insertion mutation.

Keywords: exon 20 insertion mutation, NSCLC, co-occurring genomic alterations

P2.01-101 MULTIPLE CHEMOTHERAPY-BASED COMBINATION THERAPY STRATEGIES FOR ADVANCED LUNG CANCER PATIENTS: A SYSTEMATIC REVIEW AND NETWORK META-ANALYSIS

L. Xiong[1], Y. Bai[1], J. Zhao[1], M. Lanuti[2], H. Tang[1,2]

[1]*Zhongnan Hospital of Wuhan University, Wuhan/China,* [2]*Massachusetts General Hospital, Boston/United States of America*

Background: The treatments for patients with advanced lung cancer focus on chemotherapy, targeted therapy and immunotherapy, or a combination of multiple treatments. This study compares various chemotherapy-based combination therapies to identify the best one for patients with advanced lung cancer. **Method:** A literature search was performed (PubMed, EMBASE and Medline) for randomized controlled trials of advanced lung cancer combination therapy from 2008 to 2018. Primary outcomes were overall survival (OS), progression-free survival (PFS), and objective response rate (ORR), adverse as second outcome indicators. A Bayesian mesh meta-analysis for multiple treatment strategies was implemented. The results of four outcome variables were combined to find the best chemotherapy-based combination therapy strategy. **Result:** The analysis included 43 studies and five combination therapies: Chemotherapy/chemotherapy plus placebo (CT), CT plus one targeted therapy drug (CT+T), CT plus 2 targeted therapy drugs (CT+T+T), chemotherapy combined with immunotherapy (CT+IO) or chemotherapy combined with biotherapy (CT+B) (Figure 1 A-B). Hazard ratios for OS of CT+T, CT+T+T, CT+IO, CT+B compared to CT were 0.92 (CI 0.86, 0.97, p =0.0154), 0.90 (CI 0.74-1.1), 0.82 (CI 0.71-0.93, p =0.0069) and 1.1 (CI 0.77-1.5). And the HRs of CT+T+T, CT+IO compared to CT+T were 0.98 (CI 0.82-1.2), 0.89 (CI 0.77, 1.0). Finally, comparing with CT+T+T, CT+IO had longer survival 0.91 (CI 0.71-1.1). With the same tendency as PFS/ORR and OS (Figure 1 C-H), CT+IO showed the best therapeutic benefits, and its treatment-related adverse reaction rate was the lowest. Among immunotherapy drugs in these studies, pembrolizumab showed superior efficacy. **Conclusion:** Among multiple chemotherapy-based combination therapy strategies, chemotherapy combined with immunotherapy is the best choice for patients with advanced lung cancer. Moreover, the results also showed that the PD-1 inhibitor (pembrolizumab) is superior to the CTLA4 inhibitor (ipilimumab).

P2.01-102 OUTCOME OF PATIENTS WITH EGFR EXON 19 MUTATION IN A PHASE III RANDOMIZED TRIAL COMPARING GEFITINIB TO GEFITINIB WITH CHEMOTHERAPY

K. Prabhash, V. Noronha, V. Patil, A. Joshi, A. Chougule, A. Mahajan, A. Janu, R. Kumar, S. More, S. Goud, N. Kumar, N. Daware, A. Bhattacherjee, S. Shah, A. Yadav, S. Banavali

Tata Memorial Center, Mumbai/India

Background: In patients with EGFR sensitizing mutations, the subtype of the EGFR mutation impacts the clinical outcome and carries both prognostic and predictive value. **Method:** We had conducted a Phase III randomized trial in patients with advanced NSCLC harboring *EGFR* sensitizing mutation, ECOG PS 0 to 2 planned for first-line palliative therapy. The type of sensitizing *EGFR* mutation (exon 19 versus others) was a stratification factor. Randomization was 1:1 to gefitinib 250 mg orally daily (gef) or pemetrexed 500 mg/m^2 and carboplatin AUC 5 IV 3-weekly for 4 cycles, followed by maintenance pemetrexed with gefitinib from day 1 (gef+C). The primary end-point was progression-free survival (PFS); secondary end-points included overall survival (OS), response rate and toxicity. We present the subset analysis of the patients with exon 19 in-frame deletion. **Result:** Between 2016 and 2018, 216 patients with EGFR exon 19 mutation were randomly assigned to gef (n=109) and gef+C (n=107). The median age was 54 years, 51% were males, 20% were PS 2 and 21% had brain metastases. Median follow-up was 17 months (range, 7 to 30). Radiologic response rates were 81% and 75% in gef+C and gef arms respectively, P=0.29. Estimated median PFS was significantly longer with gef+C than gef [17 months, (95% CI, 12.4 to 21.6) versus 8 months (95% CI, 6.8 to 9.3); hazard ratio for disease progression or death, 0.49; 95% CI, 0.35 to 0.69; P<0.001]. Data for OS are immature. Clinically relevant ≥ grade 3 toxicities occurred in 55% and 23% of patients in gef+C and gef arms respectively, P<0.001. **Conclusion:** In patients with exon 19 in-frame deletion, combining pemetrexed and carboplatin chemotherapy with gefitinib led to a significant PFS prolongation, with an increase in clinically relevant severe toxicities.

Keywords: NSCLC, exon 19, EGFR

P2.01-103 REAL-WORLD TREATMENT PATTERNS AND SURVIVAL IN NON-SMALL CELL LUNG CANCER PATIENTS WITH EGFR EXON 20 INSERTION MUTATIONS

M. Dersarkissian[1], R. Bhak[1], H. Lin[2], S. Li[2], M. Cheng[1], A. Lax[1], H. Huang[2], M. Duh[1], S.-H. Ou[3]

[1]*Analysis Group, Inc., Boston/United States of America,* [2]*Millennium Pharmaceuticals Inc., Cambridge/United States of America,* [3]*Chao Family Comprehensive Cancer Center, University of Irvine Healthcare, Orange/United States of America*

Background: Mutations in the epidermal growth factor receptor (EGFR) gene have been identified in 10-50% of patients with non-small cell lung cancer (NSCLC), and 2-10% are exon 20 insertion mutations. This study describes real-world characteristics, treatment patterns, and overall survival (OS) of NSCLC patients with EGFR exon 20 insertions. **Method:** Flatiron Health electronic health record data from 1/2011-4/2018 were used for this retrospective study. Treatment-naïve (TN) and relapsed/refractory (RR) patients with advanced/metastatic NSCLC with EGFR exon 20 insertion mutation aged ≥18 years at treatment initiation were included. Patient characteristics were described, and Kaplan-Meier analyses were used to assess OS for TN and RR patients. **Result:** There were 128 TN and 71 RR patients identified. Median age was 66.5 and 65.0 years for TN and RR patients, respectively, and over half were female (TN: 59.4%, RR: 53.5%). Among 83 TN and 47 RR patients with known ECOG score at advanced diagnosis, most had score 0-1 (TN: 56.3%, RR: 62.0%). Central nervous system metastases were observed in 35.2% of TN and 33.8% of RR patients. 45.3% of TN patients and 23.9% of RR patients received chemotherapy only. Approximately 20% of TN and RR patient were treated with EGFR TKI only. Only 6.3% of TN patients received any immuno-oncologic therapy (IO) or combination, while this was higher in RR patients (29.6%). Overall, median OS was low at 16.2 months for TN patients, and 12.5 months for RR patients. Treatment with any IO was associated with poor survival in TN (6.1 months) and RR (8.0 months) patients.

	TN		RR	
	N (%)	OS Median (IQR), months	N (%)	OS Median (IQR), months
All	28 (100.0)	16.2 (16.9, 27.2)	71 (100.0)	12.5 (5.0, 21.1)
Chemotherapy only	58 (45.3)	18.2 (9.2, 26.5)	17 (23.9)	17.1 (8.7, 30.0)
EGFR TKI only	27 (21.1)	7.1 (2.5, 20.7)	18 (25.4)	15.3 (5.0, 23.5)
IO in any combination	8 (6.3)	6.1 (5.3, -)	21 (29.6)	8.0 (2.0, 10.1)

EGFR TKI = epidermal growth factor receptor tyrosine kinase inhibitor; IO = immuno-oncology therapy; IQR = interquartile range; OS = overall survival; RR = relapsed/refractory; TN = treatment naïve.

Conclusion: OS of patients with EGFR exon 20 NSCLC remains poor. In TN patients, chemotherapy was the most common treatment, followed by EGFR TKIs. Treatment patterns were more diverse in RR patients. This study demonstrated unmet medical need for patients with NSCLC with EGFR exon 20 insertion mutation.

P2.02 ADVOCACY
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.02-01 ALKFUSION AND THE UNMET NEED OF PATIENT-CENTRIC RESEARCH

L. Greco[1], S. Engfer-Triebenach[1], C. Conner Ziegler[2]

[1]*ALKFusion, Wilton/United States of America,* [2]*ALKFusion, North Rose/United States of America*

Background: Approximately four (4) to seven (7) percent of non-small cell lung cancer (NSCLC) is driven by the ALK transfusion. In the United States, approximately 11,000 people are diagnosed with ALK-positive NSCLC every year. There are an array of treatment options for the ALK-positive patient, and these options have improved overall survival rates in this subset of NSCLC patients. Currently, there are five FDA approved tyrosine kinase inhibitors (TKIs) that treat ALK-positive NSCLC: crizotinib, ceritinib, alectinib, brigatinib and lorlatinib. There are other drugs and drug combinations that are currently in clinical trials. Invariably, patients develop acquired resistance to each of these drugs, but the mechanisms of resistance can vary. Better understanding these mechanisms of resistance will provide invaluable information and improve survival outcomes. The development of new drugs, drug combinations, and innovative treatments will significantly impact the survival rate for ALK-positive lung cancer. **Method:** ALKFusion was conceived by a group of seven lung cancer patient advocates with over 30 years of combined patient focused advocacy experience in the lung cancer community. A primary goal of the ALKFusion group is to improve survival for people with ALK-positive NSCLC by accelerating research. Patient collaboration with key shareholders in the lung cancer arena is critical. Further, patients must be educated about their disease in order to make the best treatment decisions. Often, patients lack access to doctors who specialize in ALK-positive lung cancer, as it is a rare subset of NSCLC, so there is a particular need for patients themselves to have the educational resources to discuss with their doctor. **Result:** As a patient-centric organization, ALKFusion is committed to accelerating research to improve the outcomes for ALK-positive lung cancer patients. ALKFusion's vision is twofold; to initiate and support patient-centric research with a focus on collaboration and disease management, and to provide tools to patients so that they can truly be a partner in their care decisions. As patients, the members of ALKFusion are on the frontline of this disease. To aid it in achieving this goal, the group has engaged with a wide range of researchers, clinicians, other lung cancer organizations, and the pharmaceutical industry, with the aim of advancing cutting-edge research and in the treatment of those living with ALK-positive NSCLC. Further, ALKFusion publishes a monthly newsletter titled The ALKFusion Reporter, which provides summaries and links to every recent scientific publication relating to ALK-positive lung cancer. **Conclusion:** ALKFusion is a crucial component of the "patient-first" movement that has been gaining momentum in several oncogene communities. It is a rapidly growing group of educated patient advocates who endeavour to be true partners with the medical community in order to accelerate research for ALK-positive lung cancer.

P2.03-01 MMP1 SECRETED BY CANCER CELLS INDUCES A PRO-TUMORIGENIC SENESCENT PHENOTYPE IN FIBROBLASTS IN LARGE CELL CARCINOMA OF THE LUNG

M. Gabasa[1], R. Ikemori[2], E. Radisky[3], N. Reguart[4], D. Radisky[3], J. Alcaraz[2]

[1]*University of Barcelona, Barcelona/Spain,* [2]*University of Barcelona - Faculty of Medicine, Barcelona/Spain,* [3]*Mayo Clinic, Jacksonville/United States of America,* [4]*Hospital Clinic Barcelona, Barcelona/Spain*

Background: Tumor associated fibroblasts (TAFs) are key effector cells of cancer progression. Senescent TAFs have been reported in a growing list of aggressive cancer subtypes including the aggressive subtype large cell carcinoma (LCC) of the lung. We previously reported that LCC cells induce fibroblast senescence in normal fibroblasts after co-culture, revealing that paracrine signaling must be involved. Moreover, we found that senescent fibroblasts secrete factors that stimulate the growth and invasion of LCC cells beyond the stimulation elicited by non-senescent fibroblasts, supporting that fibroblast senescence may contribute to the aggressive nature of LCC. Whole-genome transcriptional profiling on a panel of non-small cell lung cancer (NSCLC) cell lines, including adenocarcinoma (ADC), squamous cell carcinoma (SCC) and LCC, identified MMP1 as highly overexpressed in LCC cells compared to non-LCC cells. Here we examined the role of MMP1 in LCC cells in the paracrine induction of fibroblast senescence. **Method:** We silenced MMP-1 expression in LCC cancer cell lines by shRNA and analyzed common senescence markers after co-culture with normal fibroblasts, including β-galactosidase staining as well as the expression of common factors of the senescence-associated secretory phenotype (SASP) by qRT-PCR. In addition, the growth and invasion pro-tumorigenic effects elicited by the conditioned medium of fibroblasts co-cultured with shMMP1 or shscramble LCC cells was analyzed. **Result:** Knocking-down MMP1 in LCC cells was sufficient to abrogate fibroblast senescence induction in co-cultures with LCC cells, as well as the growth and invasion enhancement of LCC cells elicited by the conditioned medium of fibroblasts. The addition of active recombinant MMP1 partially rescued the fibroblast senescent phenotype in co-culture, yet it was not sufficient to induce senescence when added to fibroblasts cultured alone. **Conclusion:** Our results unveil a process of "niche construction" by LCC cells that is driven by the overexpression of MMP1, which induces senescence in adjacent fibroblasts. Moreover, our results unveil a novel biological function of MMP1 (i.e. paracrine senescence induction in fibroblasts), that is strikingly different from its well-known collagenolytic function. Our results also show that MMP1 is necessary but not sufficient to induce fibroblast senescence. Moreover, our findings support that the aberrant carcinoma cell-fibroblast crosstalk mediated by MMP1 may be a suitable therapeutic target in LCC.

Keyword: Tumor associated fibroblasts, senescence, MMP1

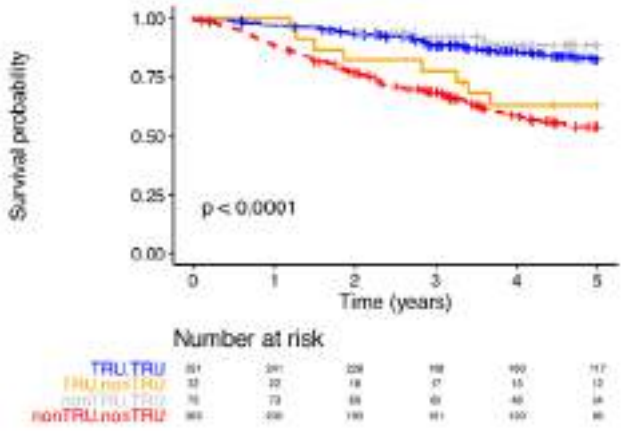
P2.03-02 A SINGLE SAMPLE PREDICTOR OF TRANSCRIPTIONAL LUNG ADENOCARCINOMA SUBTYPES: PREDICTING BIOLOGY AND PROGNOSIS

A. Karlsson, H. Cirenajwis, M. Planck, J. Staaf

Division of Oncology and Pathology, Lund/Sweden

Background: Lung adenocarcinoma accounts for nearly 40% of all lung cancers, thereby representing the major histological subtype. Comprehensive molecular studies have proposed three molecular lung adenocarcinoma subtypes termed the terminal respiratory unit (TRU), proximal-inflammatory (PI), and the proximal-proliferative (PP) subtype based mainly on transcriptional patterns. These subtypes have been linked to molecular characteristics but also to

differences in prognosis, favoring the TRU subtype compared to the PI and PP (combined PI and PP = non-TRU) subtypes. However, the method used (nearest centroid classification=NCC) to classify samples into transcriptional subtypes depends on the cohort composition, consequently struggle with e.g. reproducibility and classification of single samples. In this study, we aimed to derive a single sample predictor (SSP) of these subtypes, capable of predicting single samples irrespective of technical platforms and cohort composition. **Method:** In this study, the gene expression based SSP called "Absolute assignment of breast cancer Intrinsic Molecular Subtype" (AIMS) were trained on a large combined dataset collection (n=1655, 17 datasets) with AC assignment obtained by the NCC method and tested in 5 publicly available gene expression datasets (n=977) with treatment data available. Survival analysis was performed to compare the two classification methods (AIMS vs. NCC) with overall survival (OS) as clinical endpoint. Survival curves were compared using Kaplan-Meier estimates and the log-rank test. **Result:** Using AIMS, a SSP of lung adenocarcinoma transcriptional biology and prognosis was successfully trained and tested in publicly available gene expression datasets. The majority of the samples were assigned equally by the two methods. However, a minor subset (n=97) of samples were given discordant labels. The derived SSP had an accuracy of 85.5% in 977 independent validation samples for TRU vs non-TRU cases, independent of gene expression platform. Interestingly, the patient group consisting of samples classified as TRU by the NCC method and nonTRU by AIMS (TRU.nonTRU, Fig.1, orange line), showed a survival outcome more similar to the nonTRU patient group. The reverse was observed for the nonTRU.TRU patient group (Fig.1, grey line) with a survival pattern resembling that of the TRU group. Thus, on a survival basis, the discordant samples seems to be more accurately classified by the AIMS method.



Conclusion: We present a SSP for proposed transcriptional adenocarcinoma subtypes capable of predicting single samples irrespective of technical platform and cohort composition, thereby overcoming critical limitations in the applicability of gene signatures. The classifier provides refined categorization of patients with respect to prognosis, representing a prognostic predictor in lung adenocarcinoma.

Keywords: adenocarcinoma, single sample predictor, classifier

P2.03-03 LANDSCAPE OF GENE FUSIONS IN LUNG ADENOCARCINOMA PATIENTS WITH MINIMAL CIGARETTE EXPOSURE IDENTIFIED ON MALIGNANT PLEURAL EFFUSIONS

M. Saigi[1,2], E. Pros[1], J. Alburquerque-Béjar[1], I. Català[3], S. Verdura[1], R. Palmero Sánchez[2], M. Jove[2], E. Nadal[4], M. Sanchez-Cespedes[1]

[1]*PEBC-IDIBELL, l'Hospitalet de Llobregat/Spain,* [2]*Institut Català d'Oncologia, L'Hospitalet de Llobregat/Spain,* [3]*Hospital de Bellvitge, L'Hospitalet de Llobregat/Spain,* [4]*Institut Català d'Oncologia, Barcelona/Spain*

Background: Gene fusions in lung adenocarcinoma (LuAD) involving tyrosine kinase receptors such as *ROS1*, *ALK* or *RET* are recurrent oncogenic drivers (~10%), enriched in light or never-smokers. Some of them represent emerging and predictive biomarkers for targeted therapies. Here we report the fusions detected in a cohort of metastatic LuAD patients with low tobacco exposure (never or former-smokers). **Method:** Patient-derived cancer cell lines (PDC) were successfully established from malignant pleural effusions from 11 patients diagnosed with LuAD. We assessed the genetic and molecular profile by whole-exome sequencing (WES) and RNA sequencing (RNA-seq) in each cell line. **Result:** Patients' characteristics: median age, 58 (39-86); 9 were female. Eight of eleven were never-smokers and three, former-smokers. Seven patients were treatment naïve when pleural effusion samples were collected. A cytological examination of pleural fluid was performed by a lung pathologist and all samples were positive for malignant cells. Known driver mutations in lung primary tumours included one *ALK* translocation detected by FISH and three *EGFR* Del19 mutations by targeted sequencing. The three EGFR-mutant LuAD patients progressed to first or second-generation EGFR-TKI and we were able to stablish paired PDC after progressing to tyrosine kinase inhibitors (TKI) in two of them. We identified an acquired *FGFR3-TACC3* fusion in one paired PDC after gefitinib progression (T790M-negative), that led to overexpression of *FGFR3* concurrent with an enrichment of squamous cell lineage transcripts (e.g. *TP63, SOX2*) and MDM2 amplification. Among EGFR wild type (wt) patients, two RET rearrangements, *CCDC6-RET* and *KIF5B-RET*, and one *EML4-ALK* fusion -also detected in the primary tumour- were identified in PDC models. In addition, in two of the samples we discovered novel gene fusions that will be described in detail, involving proteins that are not kinases, and thus, their potential role in cancer is still unknown. **Conclusion:** In this cohort enriched with never-smoking LuAD patients presenting pleural effusions at diagnosis, the presence of known driver fusions during the disease's course detected by RNA-Seq was 36% (4/11), including a *FGFR3-TACC3* fusion as an acquired resistance mechanism to EGFR-TKI. Further study is ongoing in our PDC models to test the functional role of these fusions in order to facilitate precision medicine.

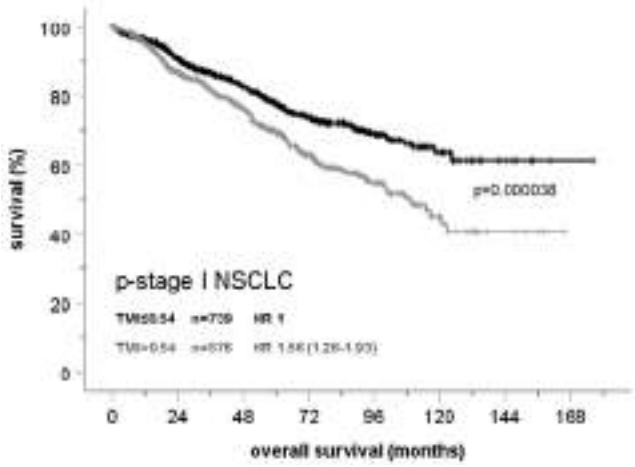
Keywords: Fusions, FGFR3-TACC3, lung adenocarcinoma

P2.03-04 THE PROGNOSTIC VALUE OF SEROLOGICAL TUMOR MARKERS IN LUNG CANCER – ANALYSIS OF 13,373 CASES

T. Muley[1], K. Senghas[1], S. Kobinger[1], M. Meister[1], M. Schneider[1], E. Herpel[2], M. Thomas[1], H. Winter[1], C.-P. Heussel[1], F. Herth[1]

[1]*Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,* [2]*Institute of Pathology, Heidelberg University Hospital, Heidelberg/Germany*

Background: Serological tumor markers such as Carcinoembryonic Antigen (CEA), Cytokeratin 19 Fragments (Cyfra 21-1) and Neuron Specific Enolase (NSE) have been shown to provide prognostic information in lung cancer. We have introduced an algorithm to combine two markers (CEA, Cyfra 21-1) into a new variable the so called tumor marker index (TMI). TMI is defined as the geometric mean of normalized marker values (Muley et al, Anticancer Res 24:1953-56, 2004). **Method:** We have uploaded available routine tumor marker data from various sources (excel sheets, extracts from laboratory IT-systems and from our clinical cancer registry) into the clinical research data warehouse based on i2b2/tranSMART using Talend Open Studio procedures. We extracted selected clinical parameters together with tumor marker data for further analyses with the statistical software package SPSS 25.0 (IBM Deutschland GmbH, Ehningen). Pretherapeutical tumor markers were measured with Roche Elecsys (Roche Diagnostics GmbH, Penzberg). A complete set of tumor marker data for the calculation of TMI1 (CEA, CYFRA21-1) and TMI2 (CEA, CYFRA21-1, NSE) was available in n=13373 and n=13174 cases, respectively. **Result:** The median value (range) for TMI1 and TMI2 was found to be 0.94 (0.01-1311.98) and 1.01 (0.01-201.67), respectively. Besides the validation of our originally published prognostic cut off value of 0.54 for TMI1 (Muley et al, Lung Cancer 2008, 60:408-415) in 1315 p-stage I NSCLC patients (figure), we found additional cut off values for the differentiation of prognostic groups in the data set of all patients. Up to 7 groups with patient number >1800 could be significantly differentiated by both indices (table).



TMI1 cutoff	Patients (n)	Median (mos)	HR	TMI2 cutoff	Patients (n)	Median (mos)	HR
0.42	2,014	62.4	1	0.55	1,989	82.1	1
0.58	1,837	35.3	1.33	0.70	1,774	40.8	1.39
0.79	1,891	26.3	1.61	0.89	1,913	23.5	1.92
1.11	1,913	17.2	2.12	1.15	1,868	16.5	2.49
1.76	1,916	13.3	2.70	1.64	1,871	13.7	3.09
3.54	1,891	10.2	3.44	2.73	1,883	9.4	4.34
>3.54	1,910	6.7	5.00	>2.73	1,871	6.6	5.97

Conclusion: The usefulness of our clinical data warehouse for assembling and structuring of clinical parameters and tumor marker data is warranted. The value of TMIs for the stratification of individual risk groups could be verified in one of the world wide largest series of tumor marker data in lung cancer.

Keywords: prognosis, CYFRA 21-1, CEA

P2.03-05 PHLPP1 EXPRESSION THROUGH AKT AND ERK DUAL SIGNALING PATHWAYS MAY SLOW DOWN THE RESISTANCE TO TKI IN EGFR-MUTATED LUNG ADENOCARCINOMA

W. Wang[1], D. Lv[2], Y. Meng[1], M. Ye[3], S. Zhou[1], F.-M. Kong[1], H. Yang[1]

Background: The epidermal growth factor receptor (EGFR) kinase inhibitors are effective treatments for lung cancers with EGFR activating mutations, but the magnitude of tumor regression varies and drug resistance is unavoidable. Multiple mechanisms of resistance to EGFR-TKIs have been identified, including the occurrence of secondary mutations in the EGFR gene, MET amplification, acquired BRAF rearrangements and activation of bypass pathways. Central to these mechanisms of resistance is the re-activation of AKT and ERK signaling, which enables escape of tumor cells from EGFR inhibitor treatment. However, the mechanisms of reactivation of PI3K-AKT and ERK/MAPK pathway are unclear. Pleckstrin homology (PH) domain leucine-rich repeat protein phosphatase (PHLPP) acts as tumor suppressors in various types of human cancer by suppressing cell survival pathways and promoting apoptosis through inhibiting AKT and ERK pathway activation. Here, we hypothesize that PHLPP is a key regulator of EGFR-TKI resistance in lung cancer and a potential treatment target for overcoming resistance to EGFR-TKI treatment. **Method:** A transcriptomic of PHLPP1 in non-small lung cancer cell according to gefitinib sensitivity obtained from Gene Expression Omnibus (GEO) database under accession number GSE4342 were analysis. The lentivirus-mediated delivery of shRNA was used to generated stable knockdown of PHLPP1 expression lung cancer cells, and retrovirus-mediated delivery was used to generated stable overexpression of PHLPP1 lung cancer cells. Western blotting, real-time PCR (RT-PCR) and immunofluorescence were used to determined PHLPP expression *in vitro*. PHLPP1 expression in clinical sample was determined by Immunohistochemical (IHC) staining. MTT assay was conducted to determine the cell proliferation. Xenografts bearing PHLPP overexpression and control were evaluated EGFR-TKI induced tumor regression. **Result:** PHLPP1 gene expression was higher in gefitinib-sensitive NSCLC cell lines than gefitinib-resistant NSCLC cell lines from a GEO public database. *In vitro*, EGFR mutated NSCLC cell line HCC827 continuously exposing to gefitinib exhibited dramatically reduced expression of PHLPP1 and increased phosphorylation AKT and ERK. Knockdown of PHLPP1 decreased cell death induced by the EGFR-TKI in EGFR-mutant lung cancer cells, overexpression of PHLPP1 enhanced gefitinib-induced apoptosis in gefitinib-resistance EGFR-mutant lung cancer cells. In xenograft model, overexpression of PHLPP showed significantly more tumor regression after gefitinib treatment at 1-week time point compared to control group. In patients, PHLPP1 were highly expressed in tumors with EGFR common mutations pre- and post-development of resistance to EGFR TKIs. PHLPP1 expression were down regulated in the post-relapse tumor samples compared to that of pre-treatment, and patients with higher PHLPP1 expression in pre-treatment had significantly longer progression-free survival (PFS). **Conclusion:** PHLPP loss may be a key molecule contributing to the resistance of EGFR-TKI by activating PI3K-AKT and ERK/MAPK signaling pathway. PHLPP may serve as a potential predictor of EGFR-TKI treatment response in these patients. Up-regulating PHLPP expression may prevent or /and delay the emergence of EGFR-TKI resistance. Further study is warranted to prove PHLPP as an effective strategy.

Background: In advanced disease, circulating tumor (ctDNA) has proven a viable alternative to tissue based molecular testing to identify patients with lung adenocarcinoma (LUAD) eligible for targeted therapies. ctDNA is under investigation for utility in early cancer detection and non-invasive companion diagnostics to allow for identification of targetable biomarkers in patients who may benefit from neoadjuvant targeted therapy. However, in the early stage cancer setting, ctDNA has been limited by reliance on interrogation of genomic alterations alone resulting in low detection rates (13% stage I, 22% stage II, 40% stage III, Abbosh et al, Nature 2017). Herein, we test the ability of the novel ctDNA-based assay to detect ctDNA in patients with early stage LUAD, and secondarily, to identify targetable oncogenes in these patients. **Method:** Eligible patients had stage IA-IIIA LUAD deemed surgically resectable. Following consent, plasma samples were collected prior to surgery or neoadjuvant therapy. Circulating free DNA (cfDNA) was analyzed for ctDNA with the LUNAR assay (Guardant Health), which utilizes an integrated genomic and epigenomic ctDNA assessment at a tumor allelic fraction down to 0.01% to report "ctDNA detected" or "ctDNA not detected". This single blood sample cfDNA assay utilizes a variant filter to distinguish tumor from non-tumor derived cfDNA alterations in the absence of other genomic DNA (e.g. tissue sequencing or peripheral blood mononuclear cells). Molecular analysis of paired FFPE primary tumor specimens was performed using the Illumina TruSight Tumor 26 or ArcherDx VariantPlex Solid Tumor library preparation kits followed by next-generation sequencing (NGS) on the Illumina platform in a CLIA-certified laboratory. Sensitivity for tumor driver mutation detection is evaluated by comparing tumor drivers identified in ctDNA with those identified in corresponding paired primary tumor specimens. **Result:** We enrolled 31 patients with early stage LUAD who ultimately underwent surgical resection,

29 of whom completed LUNAR testing (19 with stage I, 4 with stage II and 6 with stage IIIA). Analysis of tumor tissue identified a driver mutation in 83% (24/29) of cases (*KRAS*=11, *EGFR*=10, *MET*=3, ALK=1). A genomic cancer-associated mutation was identified in 16%, 25% and 67% in stage I, II, and III, respectively. The LUNAR assay demonstrated 100% specificity for *EGFR* and *KRAS* mutations. The incorporation of the epigenomic classifier enhanced pre-operative ctDNA detection to 26% of Stage I, 50% of stage II, and 67% of stage III patients. **Conclusion:** The majority of patients with early stage LUAD had an identifiable oncogene alteration, consistent with data from advanced disease. Utilizing a plasma only, integrated genomic and epigenomic ctDNA assay demonstrated improved performance over tumor informed approaches. The ctDNA detection rate increased with disease stage, consistent with increased tumor burden. With 100% tissue concordance of *EGFR* and *KRAS* alterations identified in ctDNA, ctDNA may prove an option for not only identification of early stage LUAD, but also identifying biomarker positive LUAD eligible for clinical trials utilizing targeted therapy in the neoadjuvant setting.

Keywords: LUNAR, ctDNA, Early stage NSCLC

P2.03-07 FREQUENCY OF DRIVER GENES (EGFR, KRAS, BRAF, ALK, RET AND ROS1) ALTERATIONS IN BRAZILIAN PATIENTS WITH LUNG ADENOCARCINOMA

L. Campanha Novaes, R. Cavagna, F. De Paula, P. De Marchi, M. Zanon Da Silva, A. Evangelista, L. Sussuchi Da Silva, E. Albino Da Silva, L. Leal, R. Reis

Barretos Cancer Hospital, Barretos/Brazil

Background: Lung cancer is the deadliest cancer in the world. Several oncogenic drivers are observed in non-small cell lung cancer (NSCLC) and they have been used as therapeutic targets. The frequency of the major driver genes in lung adenocarcinoma varies based on ethnicity and the impact in the Brazilian admixture population has not been explored. Thus, we aimed to investigate the presence gene mutations of *EGFR, KRAS, and BRAF,* and *ALK, RET* and *ROS1* rearrangements in Brazilian lung adenocarcinoma and to associate the presence of these alterations with clinicopathological characteristics and genetic ancestry. **Method:** We evaluated 444 patients diagnosed with lung adenocarcinoma at Barretos Cancer Hospital. The presence of *EGFR, KRAS* and *BRAF* mutations in hotspot regions were evaluated by direct sequencing. For *EGFR/ KRAS/BRAF* wild-type samples, we investigated the presence of *ALK, RET* and *ROS1* rearrangements by the NanoString platform. Genetic ancestry was assessed by a multiplexed 46-ancestry informative markers panel. Stats: X^2 test and Cox regression model. **Result:** Overall, 232 were male (52%) and 212 female (48%) and the average mean at diagnosis was 61 years. The majority of the patients were self-reported as white (77%), smokers (68%) and most patients were diagnosed at stage IV (74%). The median overall survival in patients at stage IV was 8.8 months. The frequency of *EGFR* mutations was 22.7% (n=101) and they were independently associated with never-smokers and Asian ancestry. *KRAS* mutations were found in 20.4% (n=91) of cases and were independently associated with smoking. The frequency *BRAF* mutations was of 1% (n=4), being all of them non-V600 *BRAF*. The frequency of *ALK* rearrangements was 2.25% (n=10) and was associated with younger age, the presence of metastases and advanced disease stage at diagnosis. *RET* and *ROS1* rearrangements were only observed in 0.2% each (n=1/each) of cases. All the alterations identified in the oncogenic drivers were mutually exclusive. **Conclusion:** The evaluation of the major driver genes for NSCLC, *EGFR, KRAS*, *BRAF, ALK, RET* and *ROS1* can guide better clinical strategies for Brazilian lung adenocarcinoma, and the frequencies observed of these genes are in line with reported in other populations.

Background: The study of the tumor microenvironment is leading to a better understanding of the tumor escape from immunosurveillance and immunotherapy response. Cancer stem cells (CSCs) are targets poorly recognized by the immune surveillance system given that they favor an immunosuppressive microenvironment. The aim of this work is to study the interactions between CSCs and the immune microenvironment in NSCLC. **Method:** Tumor cells from 8 resected NSCLC patients and 12 cell lines were cultured using a sphere forming assay for CSCs enrichment. Adherent cultures were established as differentiated controls. The gene expression of *IL-4*, *IL-10, IL6*, *IL8 LGALS-3* was analyzed by RTqPCR. Gene expression results were validated at a protein level by a sensitivity bead-based multiplex immunoassay using the Millipore kit for Luminex 100/200. The prognostic value of these factors *in silico* was determined in a cohort of 661 patients from The Cancer Genome Atlas (TCGA) cohort. Prognostic value was assessed by Cox regression and Kaplan-Meier curves (long rank-test), considering significant when $p<0.05$. **Result:** Patients' median age was 67 years [57-74], 62% were male, and 62.5% were adenocarcinomas (ADC). Gene expression analysis revealed that lungspheres had significantly higher expression of *LGALS3* compared to differentiated adherent cells. On the contrary, adherent cells had significantly higher expression of *IL6*. In concordance with gene expression levels, we observed significant differences in the secretion of these two soluble factors (IL-6 and Galectin-3) between adherent cells and tumorspheres. Neither expression nor secretion levels of IL-10 and IL-4 were detectable. We had not observed significant results for IL-8. Survival analysis showed that ADC patients with higher *LGALS3* expression had significantly decreased overall survival (OS, 40.49 vs. 87.90 months, p= 0.005) and relapse-free survival (25.28 vs. 41.25 months, p=0.003) than the group with LGALS3 expression below the median. The multivariate analysis showed that *LGALS3* expression can be established as an independent prognostic biomarker for OS [HR=1.75; 95% CI, 1.19-2.59; p=0.004] and for PFS in lung adenocarcinoma [HR=1.68; 95% CI, 1.22-2.32; p= 0.001]. **Conclusion:** Our results suggest that Galectin-3 highly secreted by lung CSCs can be involved in the modulation of the immune microenvironment. Moreover, Galectin-3 is an independent prognostic biomarker for overall survival and relapse-free survival in lung adenocarcinomas. Supported by grants CB16/12/00350, PI18/00266 and PI15-00753 from ISCIII and ACIF/2018/275 from GVA and FSE

P2.03-09 ARF6-RELATED INVASIVE PATHWAY DETERIORATED PATIENTS' PROGNOSIS IN MUTANT EGFR LUNG ADENOCARCINOMA

T. Menju[1], M. Noguchi[1], S. Tamari[1], H. Ishikawa[1], R. Miyata[1], S. Nishikawa[1], K. Takahashi[1], A. Yoshizawa[2], H. Haga[2], H. Date[1]

[1]*Graduate School of Medicine, Kyoto University, Kyoto/Japan,* [2]*Department of Diagnostic Pathology, Kyoto University Hospital, Kyoto/Japan*

Background: Arf6-related pathway has been reported to be activated in the downstream of EGF stimulation and to play pivotal roles in invadopodia formation and integrin recyclying leading to cancer invasion and metastasis. EGFR is well known to be constitutively activated without EGF stimulation in lung cancer harboring the mutations in its kinase domain. Here, we have examined the clinicopathological significance of Arf6-related

pathway especially in mutant EGFR (mEGFR) lung adenocarcinomas. **Method:** Clinical samples were obtained from the 239 cases of resected lung adenocarcinoma which were consecutively operated from January 2001 to December 2007 in Kyoto University Hospital. Then, tissue microarrays (TMAs) were made from all the cases. Using DNA samples extracted from fresh frozen tumors, EGFR mutations were detected by SSCP or direct sequencing methods as previouly published. Immunohistochemical stainings were performed on TMAs against the molecules of Arf6-related pathway: Grb2, GEP100, Arf6, AMAP1, EPB41L5. The positivity of all molecules was judged according to their H-scores: intensities multiplied by percentages. Clinicopathological data were integrated and reviewed. Statistical analyses for overall (OS) or disease-free survival (DFS) were performed by Kaplan-Meirer methods and log-rank tests. Categorical data were analysed by Pearson's test. Cox hazard models were applied for multivariate analyses. P-values less than 0.05 were considered significant. **Result:** Among all cases, mEGFR was found in 113 cases, whereas 118 cases had wild type EGFR (wtEGFR) mutations. Common mutations in EGFR were detected in 104 cases (92.0%). Positivity of each molecule in mEGFR cases was the following: Grb2/ GEP100/ Arf6/ AMAP1/ EPB41L5; 11.9/ 27.7/ 48.2/ 52.7/ 56.3%. Positivity in all molecules showed no significant difference between exon 19 and exon21 mutation cases. Visceral pleural involvments were significantly increased in AMAP1- or EPB41L5-positive groups and lymph node metastases were significantly increased in Grb2- or EPB41L5-positive groups. Univariate analyses showed that 5-year OS rates were significantly low in Grb2 or AMAP1 positive groups specific to mEGFR cases (Grb2-/+: 89.0 vs 69.2%; p=0.0051, AMAP1-/+: 94.1 vs 80.3%; p=0.0057), whereas it was significantly low in EPB41L5 group specific to wtEGFR cases (-/+: 85.1 vs 62.7%; p=0.017). For DFS, all molecules were the significant recurrent factors specific to mEGFR cases (Grb2/ GEP100/ Arf6/ AMAP1/ EPB41L5; p=0.0023/ 0.0033/ 0.0411/ 0.0023/ 0.0263), whereas no molecule was significant specifc to wtEGFR cases. Multivariate analyses specific to mEGFR cases showed that Grb2 and AMAP1 were the independent prognostic factors for OS and Grb2 was the only independent recurrent factor. **Conclusion:** Arf6-related invasive pathway was significantly associated with poor prognosis specific to mEGFR adenocarcinoma. Grb2 and AMAP1 were the strong worsening effectors on the prognosis. Inhibition of this pathway should be a novel targeted therapy in mEGFR lung adenocarcinoma.

Background: Genomic profiling of tumours has become a crucial component of precision cancer medicine. In order to comprehensively characterize molecular alterations in different lung cancer subtypes, we analysed a total number of 327 samples by using Whole-Exome Sequencing (WES) and SNP genotyping arrays. Additionally, we used Targeted Capture Sequencing (TCS) for scanning a selected panel of genes (*n*=52) at high sequencing depth. **Method:** We WES (McGill University Innovation Centre in Montreal) 153 paired tumour-normal samples, with a further 174 paired tumour-normal samples undergoing TCS. Sequencing data were processed and mutations identified using BWA (v.0.7.15), Picard (v.2.17.11), GATK (v.3.7), VarScan (v.2.4.2) and VEP (v. 92) softwares. Illumina OmniExpressExome (v1.6) arrays were used for genotyping all samples and copy number alterations (CNAs) were identified using ASCAT (v.2.5.2), DNACopy (v.1.56.0) and GISTIC (v.2.0) softwares. **Result:** The analysed samples had a tumour content varying from 20 to 90%. The age range of patients was between 28 to 89 years. Out of 159 lung cancer patients, 89 patients had lung adenocarcinoma (LUAD), 36 squamous cell carcinoma (LUSC) and 34 lung neuroendocrine (NET), of which 22 were subclassified as lung carcinoid (LC), 6 small cell carcinoma (LSCLC), 5 large cell carcinoma (LCNEC) and 1 combined NET subtype. *TP53* appeared as the most mutated gene in LUSCs (82%), non-carcinoid NETs (58%) and LUADs (47%), but not in the LC subtype, while the chromatin remodelling gene *ARID1A* was altered across all subtypes (9%). Other mutated genes in LUAD were *KRAS* (31%), *STK11* (22%), *RBM10* (15%), *EGFR* (14%) *and KEAP1* (14%); in LUSC were *PTEN* (26%), *CDKN2A* (21%), *KEAP1* (21%) and *NF1* (15%); in NET, non-carcinoid top mutated genes included *RB1* (42%), *ENPP2* (33%), *ERBB4* and *STK11* (17% for each), while *ARID1A* and *ACKR3* were each present in 9.5 % of LC. In LUADs, mutations in *EGFR* and *KRAS* appeared as mutually-exclusive (*P*=0.007*)*, while gene pairs *NFE2L2 - AKT1* (*P*=0.012) and *STK11-ALK* (*P*=0.029) were co-mutated in LUAD and LUSC, respectively. Deletions in exons 19 and 20 of *EGFR* correlated with longer survival time compared to patients with wild-type *EGFR* (*P*=0.058). In NET, patients with mutated *RB1* showed lower survival time compared to patients with wild-type *RB1* (*P*=0.022). Examination of CNAs showed *TERT* amplifications (5p15.33 cytoband) were commonly found at high frequencies across all subtypes, especially in non-carcinoid NET (71.4%). Other recurrent CNAs included amplifications in *MYC* in 37% of LUAD and 40% of LUSC, and in *EGFR* in 33% of LUAD and 14% of LUSC. Deletions in the *CDKN2A* locus were seen at frequencies of 31% and 28% in LUAD and LUSC, respectively. LC patients showed longer survival time compared to other tumours (*P*=0.015). COSMIC mutational signatures 18 (of unknown aetiology) and 24 (associated with exposure to aflatoxin) were exclusively found in LC. **Conclusion:** The results confirm that lung cancer is a group of heterogenous diseases. In addition to the known effects of *EFGR* mutations, possible therapeutic avenues could be suggested for *TERT* amplifications, for which nucleoside analogues have shown to promote cancer cell death or EZH2 inhibitors for *ARID1A*-mutated cancers.

P2.03-11 IMPACT OF ETHNICITY ON OUTCOME IN NEVER SMOKERS WITH EGFR AND ALK WILDTYPE (EGFR/ALK-WILDTYPE) LUNG ADENOCARCINOMAS

S. Martins-Filho, A. Fares, V. Raghavan, E. Stewart, D. Ravi, K. Perdrizet, J. Weiss, K. Hueniken, D. Patel, N.-A. Pham, A. Sacher, P. Bradbury, N. Leighl, F. Shepherd, M. Tsao, G. Liu

University Health Network, Toronto/Canada

Background: *EGFR*-mutations and *ALK*-rearrangements are frequent in lung adenocarcinoma (LUAD) samples from never smoker patients. Nevertheless, up to a quarter of all LUAD cases in never smokers are *EGFR/ALK*-wildtype: these patients have limited therapeutic options and few well-established clinical and molecular predictors of outcome. Our main objectives here were to investigate the prognostic impact of ethnicity in never smoker patients with *EGFR/ALK*-wildtype LUAD and seek for specific somatic events correlated to ethnical background in these patients. **Method:** We included 85 samples from lifetime never-smoker patients with *EGFR/ALK*-wildtype LUAD collected from surgical resection with curative intent. Stages 1/2/3 were identified in 56 (66%)/15 (18%)/14 (16%) samples. A subset of those samples (n=46), with similar stage distribution, had snap-frozen tumor and paired-adjacent tissue available and were submitted to paired-end whole-exome sequencing. Fisher's exact and Chi-squared tests were used to compare specific mutations between Asians vs non-Asians. Recurrence-free-survival (RFS) was calculated based on the Kaplan-Meier method; Cox modeling was used to generate hazard ratios (HR), adjusted for key clinical features. **Result:** Most patients in the cohort were female (63/85, 74%); the median age was 68 years; median follow-up was 51 months. According to self-reports, 19/85 (22%) and 66/85 (78%) patients identified as Asians and non-Asians, respectively; no major clinical and pathologic differences were identified between these populations. Five-year recurrence free survival was significantly lower for Asians compared to non-Asians (50% vs. 78%, adjusted HR = 2.9; CI = 1.1-7.8, p=0.02), Figure 1. Among somatic events, in-frame deletions in *CNPY3* (Toll-like receptor-specific co-chaperone for HSP90B1) were more frequent in Asians (30%) compared to non-Asians (18%). In contrast, *DDX11* missense mutations (21% vs 0%; nucleic acid binding protein involved in genome stability), *NOTCH2* multi-hits and frame-shift deletions (7% vs 1%), and *KRAS* missense mutations (7% vs 0%) were more frequently altered in non-Asians than in Asians. **Conclusion:** In our cohort of never-smoker patients with *EGFR/ALK*-wildtype LUAD, Asian patients showed higher relapse rates than non-Asians. We identified differentially mutated genes by ethnicity that may partly account for these differences in outcome. (SNMF and AFF contributed equally)

P2.03-12 EPIGENOME-WIDE METHYLATION STUDY FROM BLOOD SAMPLES OF LUNG CANCER PATIENTS AND CONTROLS

H.G. Son[1], J.Y. Hong[2], Y. Hong[3]

[1]*Kangwon National University Hospital, Chuncheon/Korea, Republic of,* [2]*Chuncheon Sacred Heart Hospital, Chuncheon/Korea, Republic of,* [3]*Kangwon National University, Kangwon National University Hospital, Chuncheon/Korea, Republic of*

Background: Despite a concerted effort to find markers for early detection or prognosis prediction, there is no biomarker with clinical application in screening or treatment decision of lung cancer. Early diagnosis using noninvasive biomarkers could play a hopeful role in increasing the survival rate of lung cancer patients. Recently, some evidences were provided that methylation changes in peripheral blood may be predictor of lung cancer mortality and may improve prediction of lung cancer risk. We present the results of an epigenome-wide methylation study from blood of 150 pairs of lung cancer cases and controls from a Korean subjects. **Method:** For this study, we used blood samples obtained from the BioResource Center of Asan Medical Center (Seoul, South Korea) that had been donated by 150 patients who diagnosed to non small cell lung cancer (NSCLC) and 150 normal controls who has undergone a health screening in 2012 to 2014. The normal controls of 150 were selected by frequency matching with the 150 patients with NSCLC on age, sex, smoking status. Genome-wide methylation profiles were obtained by using a MethylationEPIC BeadChip kit, which covers the 850,000bp cytosine-phosphate-guanine (CpG) site. To identify differentially methylated probes (DMPs) in association with NSCLC, a logistic regression model was used with the response variable of NSCLC status and the predictor variable of methylation values. **Result:** The average age was 56 years in patients with NSCLC and control subjects. 72 never, 48 former, and 30 current smokers were included in the both groups. From association analysis, we found 11 suggestive DMPs (p<1.0E-5) associated with NSCLC after adjusting for age, gender, PCA, smoking, and the estimated cell-type proportions. From DMP analyses according to smoking status, we found 58 suggestive DMPs and two significant DMPs (cg12169243 (DPH6), p=4.3E-08 and cg25429010 (IMP3), p=5.2E-08) associated with NSCLC in group of current smokers. To affirm that smoking is associated with NSCLC in our study, as well known, we evaluated significant CpGs associated with current smoking in each groups of NSCLC patients and controls. Cg03636183 (F2RL3) and cg05934812 (AHRR), well known gene site for smoking and NSCLC, were found to be significantly associated with smoking in NSCLC patients group. **Conclusion:** This genome-wide DNA methylation study showed that DNA methylations changes were associated with NSCLC after adjusting for age, gender, PCA, smoking, and the estimated cell-type proportions, independent of smoking status. The DNA methylation changes may be candidate target regions for early detection and prevention in lung cancer.

P2.03-13 ACQUIRED RESISTANCE TO AFATINIB IN NON-SMALL CELL LUNG CANCER WITH EGFR G719X MUTATION

T. Harada, S. Futamura, Y. Inoue, R. Sawada, T. Okuda, K. Kagawa

Fukuchiyama City Hospital, Fukuchiyama/Japan

Background: The frequency of EGFR mutations is said to be relatively high within East Asian population. The most common EGFR mutations such as exon 19 deletions and exon 21 L858R mutation are strong predictors of good response to EGFR-TKIs in non-small-cell lung cancer. Exon 20 T790M mutation which accounts for a large part of 1st and 2nd generation EGFR-TKI resistance, is well known to be detected after failure of prior EGFR-TKI therapy. Furthermore, T790M mutation is a predictor of good response to osimertinib, 3rd generation EGFR-TKI. Meanwhile, other uncommon EGFR mutations are identified, such as exon 18 G719X mutation, exon 20 S768I mutation, and exon 21 L861Q mutation. LUX-Lung study reported afatinib may be effective for these uncommon EGFR mutations, however, their treatments are still controversial and their resistance-gaining mechanisms to EGFR-TKI are also unknown. **Method:** We evaluated the characteristics of patients with G719X single mutation and their effectiveness of afatinib treatment. Furthermore, we analyzed the mechanism of acquired resistance to afatinib from their re-biopsied samples. **Result:** Eighteen patients had G719X single mutation, which include fifteen patients with smoking history. Of all patients with G719X mutation, ten patients were treated with afatinib, which response rate was 40% (4/10). Eight patients of those treated with afatinib underwent re-biopsy after failure of the therapy, and their results revealed that G719X mutation was disappeared in six samples, and T790M mutation was not detected after afatinib treatment. **Conclusion:** As previously reported, the presence of G719X mutation might be used as a predictor of sensitivity to afanitib therapy. Our data suggest that the loss of cancer cells with G719X mutation could be the main mechanism of acquired resistance to afanitib. Furthermore, patients with smoking history were seen frequently in those with G719X mutation. Considering that G719X mutation negative cancer cells may coexist with G719X mutation positive cells in NSCLC patients, smoking might be associated with development of its heterogeneity.

P2.03-14 DEVELOPING AN IMMUNOGENIC MODEL OF NON SMALL CELL LUNG CANCER

S. Laing[1], S. Edwards[1], G. Graham[2], B. Kruspig[1], S. Coffelt[1], D. Strathdee[1], D. Murphy[1]

[1]*Institute of Cancer Sciences, University of Glasgow, Glasgow/United Kingdom,* [2]*University of Glasgow, QQ/United Kingdom*

Background: Lung cancer is the most common form of cancer in the world both in terms of new cases diagnosed and number of deaths, which totals ~1.5 million per annum. Patient prognosis has not improved significantly over the last 40 years, and the 10-year survival rate remains ~5%. Approximately 85% of lung cancers can be classified as non-small cell lung cancer (NSCLC), of which Lung Adenocarcinoma (LuAd) is the most common histological subtype. Specific DNA mutations allow for further molecular characterisation of LuAd, for example, activating mutations in KRAS have been described in one third of cases. The oncogene MYC is a downstream target of KRAS signalling and the two oncogenes have long been known to cooperate to induce tumorigenesis. The gene editing enzyme APOBEC3B has recently been recognised as an important mechanism for fuelling genetic diversity in cancer and has been shown to be upregulated in LuAd. **Method:** The KRas-Myc (KM) mouse model of LuAd combines expression of mutant $Kras^{G12D}$ and modestly overexpressed c-MYC to drive the formation of autochthonous adenocarcinomas. Selective expression of $Kras^{G12D}$ and MYC are induced in the lung epithelium by intranasal inhalation. We have generated the KMA3B model of lung cancer in which APOBEC3B is selectively expressed in the KM model to generate tumours which have a modest overexpression of APOBEC3B. Using immunohistochemistry and FACs analysis we aim to identify the differences occurring in the KM and KMA3B models and investigate the implications of these differences. **Result:** Preliminary results show an increase in $CD8^+$ T cell infiltration has been noted in the KMA3B lungs when compared with their KM counterparts at an 8 week time point. We hypothesize that the presence of APOBEC3B results in an increased number of mutated peptides leading to increased neo-antigen presentation, and a more effective immune response to the tumours. Indeed, survival data indicates that introducing APOBEC3B to the KM genetic background extends survival by 50%. FACs analysis using a panel designed to identify T cells and their activation status indicates differences in the populations of T cells present in KMA3B vs KM tumours. **Conclusion:** We show that the modest overexpression of APOBEC3B in a KM background increases the lifespan of the mice. This increase in survival appears to correlate with an increase in cytotoxic T cell surveillance. The implications and utility of this model will be discussed.

P2.03-15 VALIDATION OF TUMOR ORGANOIDS FROM LUNG ADENOCARCINOMA AS A MODEL OF PRIMARY TUMOR GENOTYPE

C. Seder, A. Arndt, J. Karush, N. Geissen, C. Wakefield, A. Naqib, M. Liptay, C. Frankenberger, J. Borgia

Rush University Medical Center, Chicago/United States of America

Background: Tumor organoids have shown promise as a model to predict clinical treatment response in patients with certain malignancies. However, there is a paucity of data supporting the utility of tumor organoids derived from patients with non-small cell lung cancer (NSCLC). Here, we demonstrate the feasibility of establishing tumor organoids from patients with NSCLC and examine molecular fidelity of tumor organoids derived from early-stage lung adenocarcinomas relative to their primary tumors. **Method:** 140 patients who underwent lung resection for NSCLC were consented for organoid culture. Primary tumor specimens were processed to single cell suspensions and tumor cells were grown in extracellular matrix and chemically defined media. Tumor organoids and their corresponding primary tumors were evaluated by next generation sequencing for copy number and somatic alterations. Overall concordance between primary tumor and organoid was determined by dividing the percentage of overlapping somatic single-nucleotide variant (SNV) alterations by the total somatic SNV alterations present in both tumor and organoid model. **Result:** A subset (n=11) of tumor organoids developed from patients with early-stage lung adenocarcinoma were assessed for molecular concordance as compared to the primary tumor within 12 weeks of establishment (approximately 2-4 passages). The tumor organoids enriched for protein coding SNV somatic mutations with an average of 6.8% overlap of all somatic SNV variants (n=2382) vs 34.8% overlap in coding SNV mutations (n=72); $p<0.001$. Additionally, the overlapping coding SNV mutations are further enriched in the tumor organoid as measured by allelic fraction where on average they are present at 35.3% allelic fraction as compared to 20.9% in the original tumor specimen samples tested. **Conclusion:** Early-stage primary lung adenocarcinoma tumor organoids can be reliably generated and robustly profiled in a clinically compatible time frame. Further investigation into individual driver mutations and tumor mutational burden are underway to support this novel tumor model's stability with sequential passaging and ability to prospectively predict therapeutic response, including strategies targeting immune checkpoint inhibition.

Background: Tyrosine kinase inhibitors (TKIs) are the current standard of care for patients with advanced EGFR-mutant non-small cell lung cancer (NSCLC). However, most patients progressed within 1 to 2 years. The EGFR p.T790M mutation is the most common resistance mechanism to first and second generation EGFR TKIs. The identification of p.T790M mutation is of considerable clinical relevance as osimertinib has demonstrated clinical efficacy in this setting. Guidelines recommend testing for the p.T790M mutation in blood at relapse to TKIs, and re-biopsy only in case of a negative result. Several blood based methodologies for detection of EGFR mutations have been developed in the recent years. However, the number of comparison studies between platforms is very limited. **Method:** This is a multicenter, cross-sectional study (ClinicalTrials.gov Identifier: NCT03363139) performed by the Spanish Lung Cancer Group. Samples from 75 consecutive EGFR mutant NSCLC patients were collected at disease progression to first line TKI treatment. The presence of EGFR mutations in the cfDNA was evaluated in 39 samples by 7 methodologies, namely: Cobas® EGFR Mutation Test v2 (Roche Diagnostics), Therascreen EGFR Plasma RGQ PCR Kit (Qiagen), QuantStudio® 3D Digital PCR System (Thermofisher), a 5'-nuclease real-time PCR (TaqMan®) assay in presence of PNA, OncoBEAM EGFR (Sysmex Inostics), NGS with two different gene panels: Oncomine® (Thermofisher) and Lung Cancer Panel (Qiagen). The agreement between methodologies was assessed using the kappa coefficient (K) and its corresponding 95% confidence

intervals (95% CI). For quantitative variables the concordance correlation coefficient (ccc) was used. **Result:** Complete results are available for 39 patients. Overall, the agreement between all methodologies for the detection of p.T790M mutation as well as the original EGFR sensitizing mutation was good (K=0.669; 95CI: 0.504-0.835 and K=0.750 95CI: 0.599-0.899 respectively). Remarkably, the agreement between FDA-approved methodologies for p.T790M detection was almost perfect (K=0.926; 95CI: 0.712-1) and good for the EGFR sensitizing mutations (K=0.657; 95CI: 0.417-0.902). Similarly, the agreement between NGS-based methodologies for the detection of p.T790M and the EGFR activating mutations was very high (K=0.843; 95CI: 0.567-1 and K=0.872 95CI: 0.595-1 respectively). Moreover, concordance between both technologies for p.T790M and EGFR sensitizing mutation mutant allele frequency was excellent (ccc=0.956; 95CI: 0.906-1 and ccc=0.980 95CI: 0.950-1 respectively). The proportion of samples that were positive for p.T790M detection varied from 28% (PCR based technologies) to 37% depending on the methodology. **Conclusion:** NGS and PCR-based methodologies show a good to excellent agreement for the detection of EGFR mutations, including the p.T790M. Our results support the use of liquid biopsies for non-invasive testing of clinically relevant mutations (Data from the whole cohort will be presented at the meeting).

P2.03-17 OPTIMIZATION OF AN EX-VIVO PRECLINICAL MODEL FOR DRUG TESTING

E. Marin[1,2], P. Duch[2], M. Gabasa[2], E. Urrea[2], R. Ikemori[2], N. Díaz-Valdivia[2], C. Teixido[1], N. Reguart[1], J. Alcaraz[2]

[1]*Hospital Clinic Barcelona, Barcelona/Spain,* [2]*School of Medicine, University of Barcelona, Barcelona/Spain*

Background: Predicting drug response in advanced lung cancer patients remains a major challenge. A promising approach to tackle this challenge is based on testing drugs in an *ex-vivo* preclinical model using cultured precision-cut fresh tumour slices, which maintain not only the tumour itself but also its microenvironment. However, even though different protocols have been reported for *ex-vivo* models with different time-windows in a growing list of cancer types, no standard protocols are currently defined in lung cancer. To address this limitation, we have begun to optimize a protocol for an *ex-vivo* preclinical model for drug testing in lung cancer, using samples from the standard *in vivo* model of bleomycin-induced lung fibrosis, which resembles the fibrotic stroma of non-small cell lung cancers. **Method:** Bleomycin-induced fibrotic and control rat lungs were precision-cut with a tissue-chopper and cultured on cell culture inserts up to 12 days in a sterile setting. Two main variables were tested: the coating of the cell culture insert (bare or collagen-I coated), and the interaction with the culture medium (submerged or floating). Small lung pieces were collected at days 0, 2, 6, 9 and 12 and examined by hematoxylin-eosin staining to assess their integrity and viability. **Result:** Tissue architecture was maintained equally well in all culture conditions up to 12 days. In contrast, cellular content appeared to decline after day 6; since only subsets of cells in the periphery of the explants remained viable at day 9-12. No contamination was detected at any culture time. **Conclusion:** Our preliminary results suggest that our protocols for an ex-vivo preclinical model maintain the integrity and viability of lung cells and their microenvironment up to one week, which is comparable to time-windows previously reported in other cancer types. This time-window is expected to be sufficient to test drug responses, thereby underlying the potential of this preclinical model for drug testing as well as for the study of drug resistance mechanisms.

Background: Recent studies suggest that rare variants, with minor allele frequencies (MAFs) of less than 0.01, exhibit stronger effect sizes than common variants, might play a crucial role in the etiology of complex traits and could account for missing heritability unexplained by common variants. **Method:** Germline DNA from 1059 lung cancer cases and 899 controls from the Transdisciplinary Research in Cancer of the Lung and International Lung Cancer Consortium study were sequenced, utilizing the Agilent SureSelect XT Custom ELID and Whole Exome v5 capture. To unveil the inherited rare causal variants, allelic association analysis of single variant and gene-based collapsing tests of multiple variants were performed, including variants per gene association test, the Kernel-based adaptive cluster test, and SNP-set Kernel association test. Odds ratio (OR), 95% confidence intervals (CIs), and false discovery rate (FDR) adjusted P values were calculated. **Result:**

Table 1. Top rare and deleterious candidates

We identified 32 highly deleterious rare heterozygotes, including 14 rare and 18 novel variants -- absent from prior databases of genetic variation (Table 1). The top candidate substitutions including *NEB*stop gain p.Q7971* (nine cases *versus* zero control carriers, *P* = 0.0056), *OGG1* upstream Chr 3:9816129(11 cases *versus* one control carriers, *P* = 0.0087),*CDKN2B* transcription end site (16 cases *versus* three controls carriers, P = 0.0081), *ATP6V0A2* regulatory Chr 12:124242486 (eight cases *versus* zero control carriers, *P* = 0.0089), *KCNN4* transcription factor binding site (15 cases *versus* two controls carriers, *P* = 0.0044), and *TEX28P1* regulatory rs1445670979 (11 cases *versus* one control carriers, *P* = 0.0087). We also identified candidates in known genes which have been previously implicated in lung cancer risk, i.e., *HLA*, *TP53*, *POT1*, *PTEN, ERC, GPC, RGS17*, and *LAMC1*. Among the candidate genes with multiple rare deleterious SNVs, the top five genes with strong association (FDR adjusted P < 0.01 in burden tests) are *NBPF20* (OR5.69, 95% CI 2.4-13.5), *ERC1* (OR 4.49, 95% CI 2.19-9.23), *LOC440434* (OR 1.85, 95% CI 1.32-2.59), *GPC5* (OR 1.55, 95% CI 1.21-1.99), and *NOTCH2NL*(OR 5.46, 95% CI 1.61-18.5). The KEGG pathway analysis shown the 1st and 4th significant pathways are from small cell and non-small cell lung cancer, respectively. **Conclusion:** Our analyses led to identification of 32 pathogenic germline rare variants associated with lung cancer susceptibility. However, replication in additional populations is necessary to confirm potential genetic differences in lung cancer risk.

P2.03-19 CO-TARGETING PIM KINASE TO OVERCOME MET AMPLIFIED RESISTANCE TO EGFR TKIS IN NSCLC

A. Tranberg Madsen[1], G. Moore[2], N. Simon[2], A. Mahon[2], S. Cuffe[2], S. Finn[2], M. O'Neill[3], B. Sorensen[1], K. Gately[2]

[1]*University Hospital of Aarhus, Aarhus N/Denmark,* [2]*St. James's Hospital/ Trinity College Dublin, Dublin/Ireland,* [3]*Inflection Biosciences Ltd, Dublin/ Ireland*

Background: Currently there are five EGFR tyrosine kinase inhibitors (TKIs) (erlotinib, gefitinib, afatinib, dacomitinib, and osimertinib) available for treatment of EGFR-mutated non-small cell lung cancer (NSCLC). However for virtually all patients, resistance is inevitable, and disease progression occurs within 1 to 2 years of starting a TKI. Efforts to overcome resistance define the landscape of TKI research resulting in the development of second-generation and now third-generation agents and combination regimens. Third-generation agents, such as osimertinib, show improved response rates and extended median overall survival (OS), with potential to overcome previously untreatable resistance mechanisms. However acquired resistance mutations and activation of bypass RTK signalling mechanisms such as MET can mediate primary and secondary resistance to all EGFR TKIs. MET amplification has been observed after prolonged exposure of HCC827 cell lines to third-generation EGFR-TKIs (osimertinib or CNX-2006). We have pinpointed a novel strategic downstream target that plays a key role in MET regulation, cancer progression, drug resistance and immune evasion namely PIM kinase (PIM). The PIM family of serine/ threonine kinases constitute three major isoforms namely PIM-1, 2 and 3 and have been shown to synergise with c-Myc. We have shown that all three PIM isoforms are highly expressed in NSCLC cell lines and patient tumors and hypothesise that co-targeting PIM kinase and EGFR may provide a more durable response to treatment and overcome MET amplified EGFR TKI resistance. **Method:** Quantification & localisation of MET, c-MYC, PIM kinases and downstream substrates were examined by Western blot analysis and high content analysis

(HCA) in EGFR TKI sensitive (HCC827P) and resistant (HCC827ER) cell lines and selected resistant clones (HCC827ER clone 3, HCC827ER clone 10). Efficacy of pan-PIM inhibitor (AZD1208) & novel PI3K/mTOR/PIM inhibitor (IBL-302) alone and in combination with erlotinib were quantified using the CellTiter-Blue, cell viability assay, in all cell lines. Effect of PIM inhibitors on intracellular signalling was quantified by PathScan® Intracellular Signaling Arrays. **Result:** Activation of PIM-1, PIM-3 and c-MYC expression was demonstrated in MET amplified EGFR TKI resistant cells (HCC827ER) and (HCC827ER clone 3) compared to EGFR TKI sensitive cells (HCC827P). Erlotinib resistant clone that had undergone EMT (HCC827ER clone 10) had reduced expression of PIM-1, PIM-3 and c-MYC compared to MET amplified cells (HCC827ER clone 3). HCC827P and HCC827ER cells were both sensitive to AZD1208 (IC50 47.1μM versus 48.2μM). HCC827ER cells and HCC827ER clone3 cells were more sensitive than HCC827P cells to IBL-302 in a dose-response cell viability assay (IC50 0.277μM vs 0.253μM vs 0.351μM). IBL-302 inhibited downstream intracellular signalling at significantly lower concentrations than AZD1208 (250nM versus 2μM respectively). **Conclusion:** We show here for the first time that PIM kinase is activated in MET amplified EGFR TKI resistant cells. Erlotinib resistant HCC827ER cells are sensitive to pan-PIM inhibitor AZD1208 and the novel triple targeted therapy IBL-302. These data demonstrate that PIM kinase is a pivotal mechanism involved in EGFR TKI resistance and is an ideal target for dual inhibition strategies.

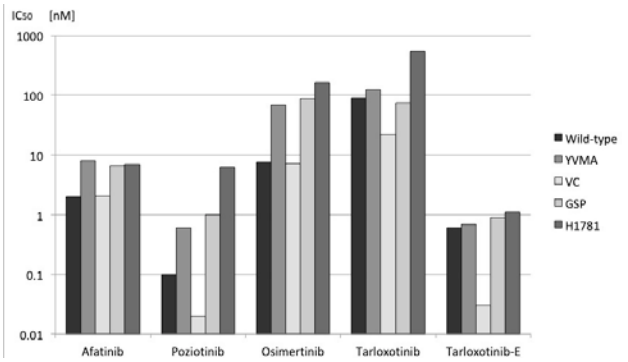
Background: Oncogenic HER2 (*ERBB2*) mutations are present in 2-3% of lung adenocarcinoma. No targeted therapy is currently approved for HER2-mutated lung cancers, and clinical trials using novel irreversible pan-HER inhibitors are underway. However, all of these irreversible pan-HER inhibitors are also active against wild-type (WT) EGFR, resulting in dose limiting toxicities. Tarloxotinib is a novel clinical-stage prodrug that releases a potent, irreversible pan-HER inhibitor (tarloxotinib-E) selectively in pathologically hypoxic regions of tumors. In this study, we evaluated tarloxotinib-E activity against various HER2 exon20 insertion mutations and explored the resistance mechanisms to tarloxotinib-E. **Method:** We introduced WT HER2 or HER2 activating mutations, including A775_G776insYVMA, G776delinsVC, and P780_Y781insGSP into Ba/F3 cells by retroviral transfection. Growth inhibitory assays were performed in these Ba/F3 cells and in H1781 cells (G776delinsVC). Tarloxotinib-E resistant clones were established by exposing these Ba/F3 cells to 200nM of tarloxotinib-E after treatment with N-ethyl-N-nitrosourea. Acquired resistant cells to tarloxotinib-E were also developed from H1781 cells via chronic exposure to increasing concentrations of tarloxotinib-E. HER2 secondary mutations were detected by direct sequencing. **Result:** Tarloxotinib-E displayed potent activity against WT and mutant HER2 Ba/F3 cells and H1781 cells. Furthermore, the IC_{50} of tarloxotinib (prodrug) for wild-type HER2 was > 100 times higher than that of tarloxotinib-E (active drug). So far, we established 12 tarloxotinib-E resistant clones from Ba/F3 models (6 with A775_G776insYVMA and 6 with G776delinsVC), all of which harbored C805S secondary mutation (corresponding to C797S of the EGFR).



Conclusion: Tarloxotinib-E exhibited potent activity for all HER2 exon 20 mutations. We identified secondary HER2 C805S mutation as a common mechanism of acquired resistance, consistent with the covalent binding mode of tarloxotinib via this residue. Additional resistant clones are currently being evaluated.

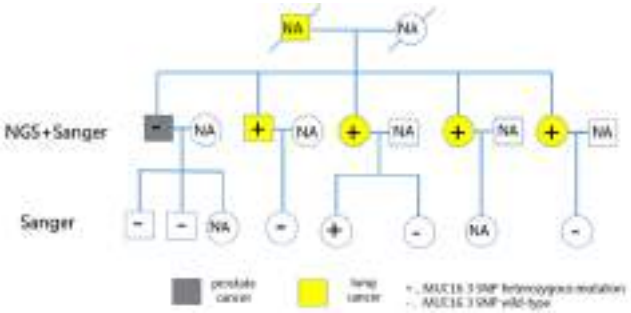
P2.03-21 MUC16 GERMLINE MUTATIONS MAY ASSOCIATE WITH INHERITED LUNG CANCER

T. Wang[1], H. Liu[2], S. Xiao[1], R. Mao[1], R. Lin[1]

[1]*Hangzhou Repuegen Technology Co., Ltd., Hangzhou/China,* [2]*Qingdao Central Hospital, Qingdao/China*

Background: Study of inherited cancer may facilitate the understanding of the molecular mechanism of tumorigenesis. Though sporadic reports have shown that mutations in *EGFR* or *ERBB2* may associate with familial lung cancer, the knowledge of the genetic causes for inherited lung cancer is still limited. **Method:** Genomic DNA (gDNA) from cancer patients or healthy people were extracted from whole blood samples and analyzed using a 500-gene next generation sequencing (NGS) panel. Variants identified by NGS panel were confirmed by Sanger sequencing. **Result:** In November 2017, four siblings in a Chinese family were diagnosed with lung adenocarcinomas. Additionally, the 5th sibling in the family had prostate cancer. A questionnaire for the family did not reveal significant environmental or habitual reasons leading to cancer in the family, suggestive of possible genetic causes. NGS analysis for gDNA samples indicated all 4 siblings with lung cancer had 3 heterozygous alleles of SNPs in *MUC16*, namely rs754254000, rs754856910, and rs746152510. In contrast, the sibling with prostate cancer was wild-type for all of the three alleles (Figure below). The NGS results were then confirmed by Sanger sequencing. The three germline mutations in *MUC16* all had very low population minor allele frequency (below 0.1%). We further analyzed the gDNA of the children in the family, and detected the 3 heterozygous SNPs in a child whose parent had lung cancer, whereas both children of the prostate cancer patient were wild-type for the 3 *MUC16* alleles. Taken together, these results are consistent with a hypothesis that germline mutation of rs754254000, rs754856910, and rs746152510 may predispose the family members to lung cancer. MUC16, also known as CA125, is a biomarker for ovarian cancer, and also shown to be involved in tumorigenesis and metastasis of lung cancer cells. The child with heterozygous SNPs of *MUC16* need be cautious in the future routine check-ups.



Conclusion: In this study, we have demonstrated that germline mutations of *MUC16* may associate with inherited lung adenocarcinomas, which warrants further mechanistic study of *MUC16* gene in lung cancer.

P2.03-22 CHROMATE EXPOSURE INDUCES DNA HYPERMETHYLATION OF THE MISMATCH REPAIR GENE MLH1 IN LUNG CANCER

K. Kondo[1], M. Tsuboi[2], S. Soejima[1], N. Kawakita[2], H. Toba[2], Y. Kawakami[2], M. Yoshida[2], H. Takizawa[1], A. Tangoku[1]

[1]*Graduate School of Biomedical Sciences, Tokushima University, Tokushima/Japan,* [2]*Department of Thoracic, Endocrine Surgery and Oncology, Tokushima/Japan*

Background: Hexavalent chromium is recognized as a human carcinogen. To elucidate the role of chromate on carcinogenesis, we have investigated molecular features of LC from chromate workers (chromate LC). Chromate LC frequently had the microsatellite instability (MSI), and that the MSI was associated with repression of MLH1, which is one of the essential DNA mismatch repair (MMR) proteins. In the present study, we investigated methylation status of the promoter region of *MLH1* determined quantitatively by bisulfite-pyrosequencing in the paired tumorous/ non-tumorous sample sets of chromate and non-chromate LCs. Moreover, we analyzed three DNA double-strand break (DSB) repair genes (*MRE11*, *RAD50*, and *DNA-PKcs*) as possible targets of MSI by fragment length polymorphism analysis. **Method:** Thirty-two lung tumor samples were obtained from chromate workers with LC during surgery or at autopsy at 5 hospitals between August 1975 and October 1997. Thirty-one tumors were obtained from LC patients without chromate exposure during surgery at Tokushima University Hospital as a control group (non-chromate LC). DNA was extracted and bisulfite conversion of DNA was conducted using the EpiTect Bisulfite Kit (QIAGEN). PCR primers and sequencing primer for quantification of methylation level in region -209 nucleotides (nt) to -181 nt from the transcription start site in the *MLH1*. Pyrosequencing of 5 CpG sites in *MLH1* was performed with sequencing primers using a PyroMark 24 Pyrosequencing System, version 2.0.6 (QIAGEN). Regions encompassing mononucleotide repeated sequences of genes were amplified using nested-PCR procedure. Fragments were separated by automated capillary electrophoresis in an ABI Prism 3130/3130xl Genetic Analyzer (Applied Biosystems) and electropherograms were analyzed using the GeneMapper software (Applied Biosystems). **Result:** The mean methylation level of tumorous tissue was 21.1±15.7% and was significantly higher than that of non-tumorous tissue, 10.9±9.4% (P = 0.004) in chromate LC. In non-chromate LC, there was no significant difference between tumorous and non-tumorous tissues: 3.9±5.1% in tumorous tissue versus 4.9±4.1% in non-tumorous tissue. The mean methylation level of tumorous tissues was significantly higher in chromate LC than in non-chromate LC (P < 0.001). The mean methylation level of non-tumorous tissues tended to be higher in the chromate LC than in non-chromate LC (P = 0.062). There was a significant positive correlation between the methylation level and chromate exposure period in tumorous tissue of chromate LC (r = 0.481, P = 0.017). The methylation level was significantly higher in LCs with reduced expression of MLH1 than in LCs with normal expression of MLH1(P = 0.019). The incidence of mutations at mononucleotide repeats was observed in 50.0% of chromate LC and 28.6% of non-chromate LC in *MRE11*, and 17.4% of chromate LC and 0.0% of non-chromate LC in *RAD50*, and in 53.8% of chromate LC and 46.2% of non-chromate LC in *DNA-PKcs*. The incidence of mutation of mononucleotide tended to be higher in chromate LC than in non-chromate LC in *MRE11*. In *RAD50*, the mutation was significantly higher frequency in chromate LC than in non-chromate LC. **Conclusion:** These results suggest that chromate exposure might induce *MLH1* hypermethylation in LC, which is possible cause of carcinogenesis.

P2.03-23 UHRF1 AS A POTENTIAL THERAPEUTIC TARGET FOR KRAS MUTATED NON-SMALL CELL LUNG CANCER

D. Goto[1], M. Kizuki[2], N. Uwatoko[2], K. Kawai[2], M. Koike[2], M. Nakashima[2], A. Miyazawa[1], I. Tanaka[1], T. Hase[1], M. Morise[1], Y. Hasegawa[1], J. Minna[3], M. Sato[2]

[1]*Nagoya University Graduate School of Medicine, Nagoya/Japan,* [2]*Department of Pathophysiological Laboratory Sciences Nagoya University Graduate School of Medicine, Nagoya/Japan,* [3]*University of Texas Southwestern Medical Center, Texas/United States of America*

Background: KRAS mutation occurring in approximately 20% of non-small cell lung cancer (NSCLC) functions as a driver oncogene and it serves as a potential therapeutic target. However, development of *KRAS*-targeted drugs has not been successful primarily because of difficulty in pharmacologically inhibiting a constitutively activated *KRAS* signaling. Activation of several driver oncogenes including mutant *KRAS* in normal cells causes cellular senescence, leading to permanent cell cycle arrest, which is termed oncogene-induced senescence (OIS). Thus, *KRAS* mutated cancers are thought to acquire additional alterations that allow bypassing OIS and such alterations could be good targets for them. With this background, we designed the present study to identify therapeutic targets whose inhibition cause growth suppression in *KRAS* mutated NSCLC through inducing OIS. **Method:** We established *cdk4/hTERT*-immortalized normal human bronchial epithelial cell (HBEC) that expresses mutant *KRAS* upon tetracycline treatment (designated HBEC-RIN). A semi-genome wide shRNA library (DECIPHER) targeting 5,000 genes was transduced in HBEC- RIN. Each shRNA vector is barcoded with unique sequence for quantification. Two weeks after culturing the cells, we extracted genomic DNA from cells at two points: before (point#1) and after (point #2) tetracycline treatment. The barcodes of DNA were sequenced with NGS at a depth of 20 million reads. The effects of senescence-bypass were determined by dividing the normalized barcode abundance at point #2 by that of point#1. The significance of change of each gene was determined by performing *t*-test to compare replicates of shRNA with a given gene with those of luciferase. Senescence was evaluated by senescence associated b-gal staining. Three *KRAS* mutated lung cancer cell lines (A549, H2009, and H460) were used to examine effects of silencing candidates of OIS-bypassing genes. Association between prognosis and expression of candidate genes in NSCLC patients was analyzed with several online datasets. **Result:** We drew a volcano plot from results of a shRNA screen. We selected genes based on significant average suppressive effects. In the present study, we focused on Ubiquitin-like, containing PHD and RING finger domains, 1 (*UHRF1*) because we were able to confirm OIS-bypassing ability of this gene in HBEC-RIN by its transient silencing with synthetic siRNA. Colorimetric growth and colony formation assays showed that *UHRF1* knockdown suppresses cell growth and colony formation in H2009 but not in A549 or H460. Importantly, we found that expression of *UHRF1* mRNA correlated with worse prognosis in patients with NSCLC in multiple independent datasets, suggesting its potential as a prognostic marker. **Conclusion:** These results suggest that *UHRF1* is a potential therapeutic target for *KRAS* mutated NSCLC and that it is a prognostic marker for NSCLC.

Keywords: NSCLC, UHRF1, KRAS

P2.03-24 CONCURRENT ABERRATIONS IN G2/M-PHASE TRANSCRIPTIONAL PROGRAMS AND GENOMIC GATEKEEPERS HIGHLIGHT LUNG CANCER PREDISPOSITION IN COPD PATIENTS

E. Vucic[1], E. Marshall[1], R. Ng[2], S. Lam[1], W. Lam[1]

[1]*BC Cancer Research Centre, Vancouver/Canada,* [2]*University of British Columbia, Vancouver/Canada*

Background: Chronic obstructive pulmonary disease (COPD) is associated with a 7-fold increased risk of lung cancer occurrence. COPD is defined by clinical symptoms and lung function measurement. It is characterized by chronic inflammation, small airway remodelling and loss as well as destruction of alveoli (emphysema). While an important lung cancer risk factor, the molecular overlap between COPD and lung cancer tumorigenesis is relatively understudied. **Method:** In order to examine the commonalities between these two diseases, we first analyzed small airway epithelial gene expression profiles from 127 COPD and 140 non-COPD ever-smoker patients obtained by bronchial brushing. We performed weighted gene correlation network analysis (WGCNA) on these gene expression profiles to discover deregulated gene modules ('metagenes') associated with reduced lung function (Forced Expiratory Volume at 1 second, FEV_1)—a clinical measure of COPD severity most robustly negatively correlated with lung cancer risk. We then assessed the preservation of these modules in two non-small cell lung cancer (NSCLC) tumour/normal data sets (lung adenocarcinoma (LUAD) and squamous cell carcinoma (LUSC), n= 887 tumors total). Airway and tumor patient cohorts were matched for age, gender, tumour stage, and smoking status. **Result:** We discovered 10 distinct small airway expression modules, two of which were significantly negatively correlated ($p < 0.05$) with patient FEV_1. One of these FEV_1 modules was the top overall module preserved in both NSCLC subtypes. This lung cancer-FEV_1 module contained 31 genes solely enriched for two related mitotic functions— G2/M phase transition

(BH-p = 0.02) and mitotic roles of polo-like kinase (BH-p = 0.001, n=31). Of these, 28 genes were significantly overexpressed in both LUAD and LUSC, and mapped to a highly-clustered sub-network of 23 proteins with 465 known and *in silico* predicted protein-protein interactions. When tumours enriched for this lung-cancer-FEV_1 gene signature were further examined, we observed a significant co-occurrence of DNA-level alterations in DNA damage associated checkpoints, specifically mutated *TP53*. **Conclusion:** Coordinated gene expression changes associated with COPD severity measures in small airways and preserved in NSCLC tumors are enriched for G2/M phase transition genes. These genes are further disrupted in tumors, where co-occurring mutations to gate-keeper genes occur. Progression of mitosis during abnormal aneuploidy in lung tissues of COPD patients may confer increased risk of oncogenic transformation in this population, and may underlie the molecular link between COPD and lung cancer.

P2.03-25 ASSESSING THE IMPACT OF CLONAL HEMATOPOIESIS IN DISEASE MONITORING USING TARGETED CELL-FREE DNA (CFDNA) SEQUENCING TECHNOLOGY

S. Yaung[1], L. Xi[1], C. Woestmann[2], C. Ju[3], D. Klass[1], F. Casey[1], B. Hinzmann[2], C.-P. Heussel[4], M. Thomas[4], F. Herth[4], T. Muley[4], B. Wehnl[5], J. Palma[1], X. Ma[1]

[1]*Roche Sequencing Solutions, Inc., Pleasanton/United States of America,* [2]*Roche Sequencing Solutions, Inc., Potsdam/Germany,* [3]*Roche Molecular Systems, Inc, Pleasanton/United States of America,* [4]*Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,* [5]*Roche Diagnostics GmbH, Penzberg/Germany*

Background: Somatic variants found in plasma cell-free DNA (cfDNA) may derive from either solid tumors or clonal hematopoiesis (CH). Little is known about how this may impact plasma-based longitudinal disease monitoring using targeted sequencing of circulating tumor DNA (ctDNA). **Method:** To assess the potential impact of CH in disease monitoring, we evaluated monitoring algorithms by targeted sequencing with and without matched peripheral blood mononuclear cells (PBMC). Samples were collected from a prospective observational study, where 62 late stage lung adenocarcinoma subjects were treated with first-line chemo or chemoradiation therapy. Pre-treatment plasma cfDNA and matched PBMC were analyzed with the AVENIO ctDNA Surveillance Kit (For Research Use Only, not for use in diagnostic procedures), a sequencing panel of 198 kilobases targeting cancer genes. Median input amounts of 25 ng cfDNA and 50 ng PBMC DNA were sequenced to median deduplicated depths of 4582 and 6134, respectively. **Result:** A median of 120 single nucleotide variants were detected per cfDNA sample, with 93.1% of these identified in matched PBMC. Most PBMC-matched cfDNA variants were germline SNPs, with allele frequency (AF) at approximately 50% or 100%. A median of 1 (range 0-5) PBMC-matched cfDNA variants per sample were detected with an AF <10%, consistent with CH. The number of these variants was positively associated with age (p-value = 0.0039) and the most frequently mutated gene was TP53. The remaining somatic variants (i.e., in cfDNA and not PBMC) had an AF range 0.03-40.9%. These PBMC-informed variants (median of 7 per sample) were used in longitudinal monitoring in the first post-treatment plasma sample to assess early response to therapy. Association between ctDNA level and progression-free survival using the same monitoring algorithm yielded nearly identical results on somatic variants derived from filtering approaches independent of matched PBMC (HR 0.32; 95% CI 0.16 - 0.65; log-rank P = 0.0009) and the PBMC-informed method (HR 0.31; 95% CI 0.14 - 0.66; log-rank P = 0.0013). **Conclusion:** A targeted panel focused on solid tumors by design has limited impact from CH. For disease monitoring applications in a non-MRD setting, measuring multiple variants instead of a single variant further enables robust classifiers that can moderate the impact of variants, if any, from CH.

P2.03-26 ELUCIDATING MECHANISMS OF RESISTANCE TO TARGETED THERAPIES IN MUTANT EGFR OR KRAS DRIVEN LUNG ADENOCARCINOMA HARBORING DUAL LOSS OF P53 AND RB1

Y. Inoue[1], R. Somwar[2], M. Ladanyi[2], W. Lockwood[1]

[1]*British Columbia Cancer Research Centre, Vancouver/Canada,* [2]*Memorial Sloan Kettering Cancer Center, New York/United States of America*

Background: Inactivation of the two canonical tumor suppressors, p53 and RB1, is a genetic hallmark of small-cell lung cancer (SCLC). In contrast, lung adenocarcinomas (LUADs) preferentially harbor alterations in the p16 pathway over RB1. Nonetheless, despite being rare, concurrent loss of p53 and RB1 occurs in a subset of LUADs and this is hypothesized to be necessary for the histological transformation of LUAD to SCLC, observed during treatment with tyrosine kinase inhibitors (TKIs). However, whether the dual loss of p53 and RB1 is sufficient for this histological transformation remains unknown. Furthermore, loss of RB1 in LUADs with *EGFR* mutations is associated with poor response to TKIs in the absence of SCLC transformation. Here, we aimed to explore how loss of p53/RB1 affects the biology of p16 pathway-altered LUAD, particularly in the context of acquired resistance mechanisms to targeted therapies. **Method:** Four *TP53*-mutated LUAD cell lines were used: two *EGFR* mutation-positive (PC9 and H1975) and two *KRAS* mutation-positive (H1792 and H358). All these cell lines possess p16 pathway alterations: *p16* (*CDKN2A*) mutations in PC9 and H1975, *CDK4* amplification in H1792, and silenced *p16* in H358. Inactivation of *RB1* was carried out using CRISPR-Cas9 and *RB1* knockout monoclonal cells were established. Cell proliferative and clonogenic abilities were assessed. In addition, osimertinib-resistant (PC9 and H1975) and trametinib-resistant (H1792 and H358) cells were generated (initial high dose and/or stepwise dose escalation methods). Acquired resistance mechanisms were evaluated by MSK-IMPACT profiling. **Result:** Two *RB1* knockout clones were established for each cell line. No advantageous effects were observed for proliferative and clonogenic abilities after *RB1* knockout. Although loss of p53 and RB1 has been reported to result in lineage shift in prostate cancer through the upregulation of SOX2, deregulation of SOX2 expression was not observed upon *RB1* knockout in the *TP53*-mutant LUAD cells. In addition, although loss of RB1 caused a modest reduction in osimertinib and trametinib sensitivities of H1975 and H358 cells, respectively, no effect was observed in PC9 and H1792 cells. After becoming resistant to osimertinib or trametinib, transformation to SCLC was not observed. Individual resistance mechanisms are currently being assessed by MSK-IMPACT. **Conclusion:** Dual loss of p53 and RB1 caused no advantageous effects in *TP53*-mutated and p16 pathway-altered LUAD cells and did not initiate transformation to SCLC as a resistance mechanism to targeted therapies. *TP53*/*RB1* deficiency-related acquired resistance mechanisms to osimertinib or trametinib will be further explored and presented.

Keywords: p53, RB1, Resistance mechanisms

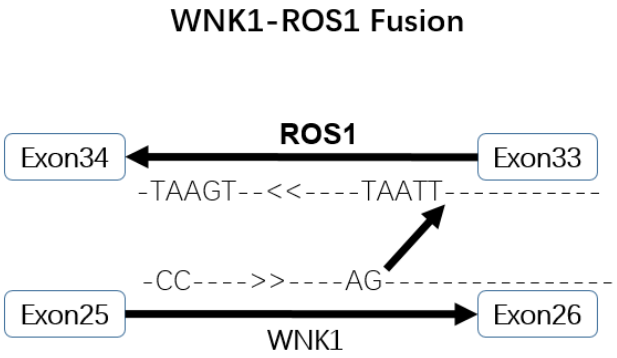
P2.03-27 DISCOVERY OF WNK1-ROS1 FUSION IN A LUNG ADENOCARCINOMA PATIENT AND THE PRECISE GUIDANCE FOR TARGETED THERAPIES

R. Lin[1], T. Liu[2], Y. Liu[3], N. Li[1], Y. Pu[1], T. Wang[1]

[1]*Hangzhou Repuegen Technology Co., Ltd., Hangzhou/China,* [2]*Institute of Hematology & Blood Disease Hospital, Tianjing/China,* [3]*Beijing Key Laboratory of Clinical Study on Anticancer Molecular Targeted Drugs, National Cancer Center/ National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China*

Background: Lung cancer can be driven by activation of tyrosine kinases including *EGFR* mutations, *ALK, ROS1, RET*, or *NTRK* fusions. New partners of gene fusions remain to be identified and their response to targeted therapy need be carefully evaluated in the clinical practice. **Method:** A targeted next-generation sequencing (NGS) panel was used to analyze DNA extracted from tumor tissue and plasma samples from a lung adenocarcinoma patient. The fusion detected by NGS panel was confirmed by Sanger sequencing. **Result:** Using a targeted NGS lung cancer panel, we identified a novel *ROS1* fusion from a 39-year old Chinese female with lung adenocarcinoma. No *EGFR, MET, KRAS, ALK, ROS1* or other driver mutations of lung cancer were detected in the patient. Intron 25 of *WNK1* was translocated to intron 33 of *ROS1* (Figure blow), which resulted in an in-frame fusion transcript of WNK1-ROS1 at the breakpoints of

exon 25 and exon 34, respectively. Sanger sequencing confirmed the fusion and the breakpoints. This novel *WNK1-ROS1* fusion encoded a chimera protein of which the transmembrane and kinase domains of *ROS1* remained intact. The patient received treatment with crizotinib targeting to *ROS1,* and partial response was achieved 3 months later. Resistance to crizotinib occurred at 5 months after the treatment. Analysis of the ctDNA from the patient's plasma sample identified *ROS1* G2032R mutation, a well-known mechanism of *ROS1* resistance to crizotinib. The patient was subsequently treated with TPX-0005, which is effective to *ROS1* G2032R mutant. Decreased CEA level was observed 2 months after TPX-0005 treatment, suggesting the patient was responsive to the targeted therapy.



Conclusion: We identified a lung adenocarcinoma patient with a novel *WNK1-ROS1* fusion who was sensitive to crizotinib and developed crizotinib resistant *ROS1* G2032R mutation at progression but appeared to be responsive to the new generation of TPX-0005 therapy. These results suggest that *WNK1-ROS1* fusion is a new molecular mechanism leading to lung adenocarcinoma and targetable to ROS1 tyrosine kinase inhibitors.

Keywords: ROS1, fusion, crizotinib

P2.03-28 A 500-GENE PANEL TO DETECT TUMOR MUTATION BURDEN OF TISSUE AND PLASMA SAMPLES FROM LUNG CANCER PATIENTS

S. Xiao, R. Mao, R. Lin, T. Wang

Hangzhou Repuegen Technology Co., Ltd., Hangzhou/China

Background: Tumor mutation burden (TMB) from cancer tissue is an FDA approved biomarker for selecting appropriate patients for immunotherapy. However, tissue samples are not readily accessible. Though reports have shown correlation between tissue TMB and plasma based TMB (bTMB), no FDA approved bTMB product is available yet. More assay needs to be evaluated for correlation analysis of TMB and bTMB. **Method:** Matched gDNA, ctDNA, and tumor tissue DNA samples from the same patient with non-small-cell lung cancer (NSCLC) were extracted from blood, plasma, and formalin-fixed paraffin-embedded (FFPE) tissue using Qiagen DNA extraction kits. DNA libraries were prepared using Agilent SureSelectXT HS Reagent Ki and were sequenced by a comprehensive 500-gene NGS cancer panel. After variant calling, non-synonymous variants were included to calculate TMB and bTMB using allele frequency cutoffs at 5% and 0.8%, respectively. An in-house bioinformatics method to get rid of germline mutations were also validated in our dataset. **Result:** To validate the 500-gene panel for TMB and bTMB analysis, we first retrieved TCGA whole exome sequencing (WES) data including 1144 lung cancer patients and about 15500 pan-cancer patients. We then calculated the correlations between the 500-gene panel and WES data on the two datasets and acquired R-square values of 0.93 and 0.94, respectively. Such data demonstrated that our 500-gene is a suitable panel to substitute WES for TMB analysis. We then used the 500-gene panel to analyze 17 NSCLC patients with matched FFPE, ctDNA, and gDNA samples. Using 5% and 0.8% as the allele frequency cutoffs for the variants called from the tissue DNA and ctDNA samples, we found a 0.84 R-square correlation between TMB and bTMB analysis. These results suggest that the bTMB from plasma samples of cancer patients highly correlates to the TMB of the paired tissues using our 500-gene panel. **Conclusion:** We have demonstrated in this study that a 500-gene panel is suitable for TMB analysis of cancer tissues. We further show that bTMB analysis using the 500-gene panel is close and highly correlate to the TMB from paired cancer tissues. Upon further clinical studies, the TMB and bTMB analysis using the 500-gene panel may represent a good biomarker for patient selection using either cancer tissue or plasma samples.

Keywords: bTMB, NGS, TMB

P2.03-29 CIRCULATING LEVELS OF LIGANDS FOR RECEPTOR TYROSINE KINASES MAY CONTRIBUTE TO AN IMMUNOSUPPRESSIVE TUMOR MICROENVIRONMENT

G. Lobato[1], M.J. Fidler[2], J. Fialkoff[1], M. Batus[2], P. Bonomi[2], J. Borgia[1]

Background: Metabolic reprogramming of tumor cells is one of the key mechanisms leading to an immunosuppressive tumor microenvironment (TME) that dampens the therapeutic benefit of immune checkpoint inhibition in subsets of patients. An improved understanding for the role of circulating factors that regulate the tumor's metabolic phenotype may provide insights that will help identify adjunct therapeutic strategies for PD-1/-L1 directed immunotherapy. Metabolic reprogramming in lung adenocarcinoma is predominately regulated at the level of receptor tyrosine kinase (RTK) activation and post-translational modifications (PTM) of intracellular proteins that ultimately regulates the metabolic phenotype of the tumor. In this study we evaluated the impact of circulating ligands for 17 common RTKs for their ability to induce RTK activation and intracellular signaling cascades capable to modulating central metabolism. **Method:** Pretreatment peripheral blood were prepared from either from non-cancer control patients (n=30) from lung cancer screening studies or those with pathologically-confirmed lung adenocarcinoma, consisting of patients with stage I (T1a/bN0M0, n=25); locoregionally progressed (T1-4N1-3M0, n=31) or stage IV disease (n=48). All sera were individually used to screen cultures of A549 lung adenocarcinoma cells for the ability to induce RTK autophosphorylation in a high-throughput manner using Luminex immunobead assays. RTKs evaluated as part of this study included: c-Kit, c-Met/HGFR, EGFR, ErbB2, ErbB3, ErbB4, FLT3, IGF-1R, IR, M-CSFR, PDGFR-α, PDGFRß, Tie1, Tie2, VEGFR1, VEGFR2, VEGFR3, and FGFR1. In parallel, we characterized each patient serum specimen for relevant RTK ligands and decoy receptors also via Luminex. ANOVA with LSD post-hoc was used to assess differences in each group to induce intracellular signaling cascades. **Result:** Patient sera were contrasted based on groupings consisting of the following: a control group from lung cancer screening studies, stage I disease, cases with locoregional progression, and cases with disseminated disease. IGF-1R autophosphorylation was significantly lower (p=0.002) in stage I adenocarcinoma cases relative to control cases lacking a malignancy, which corresponded well with reduced free IGF-1 levels (p=0.011) observed in the stage I group. Any additional stage-based changes in free IGF-1 levels were likely due to ligand sequestration by increased IGFBP-1, IGFBP-3, and IGFBP-5 levels (all p<0.05), but had no impact on IGF-1R activation. Circulating HGF (c-Met ligand) levels were significantly increased in both locoregional metastatic progression and systemic dissemination (both p<0.01), which was accompanied by level-dependent increase in c-Met autophosphorylation (p=0.004). Circulating levels of soluble c-Met are pending analysis. Similarly, metastasis-associated increases in the ligands for VEGFR3 were observed, particularly upon systemic dissemination (p<0.01 for both VEGF-C and VEGF-D), but were accompanied by an unanticipated decrease in RTK autophosphorylation (p=0.002). Other RTKs differentially modulated by sera from the patient groups include c-Kit (locoregionally advanced vs stage IV; p=0.01); Insulin Receptor and PDGFRα (locoregionally advanced vs stage IV; p=0.05) and EGFR (control vs stage IV, p<0.01). **Conclusion:** Stage-dependent differences in circulating ligands for RTKs associated with the modulation of tumoral metabolic phenotype were observed and associated with stage-dependent RTK activation. This study is currently being expanded to provide direct metabolic flux information in conjunction to the RTK data using Seahorse metabolic phenotype assays.

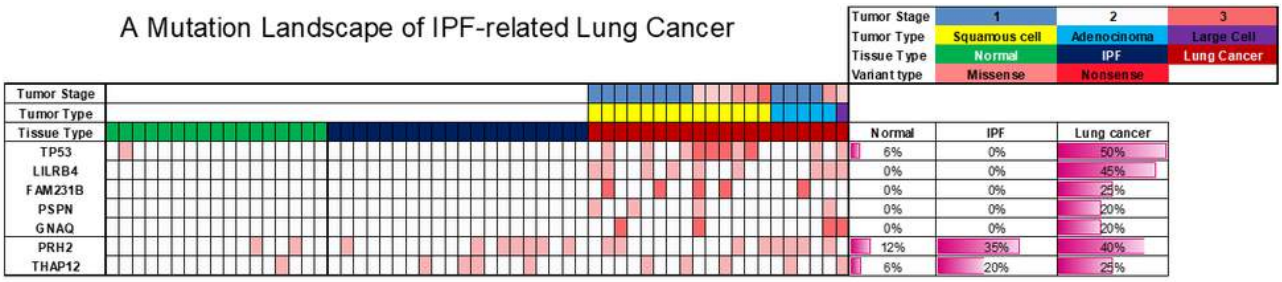
Background: Idiopathic pulmonary fibrosis (IPF) is well known to be associated with lung cancer. However, the genetic alteration contributing to lung cancer development from IPF has not been elucidated. The objective of this study is to investigate the genetic characteristics of IPF-related lung cancer by using next-generation sequencing. **Method:** Patients with IPF who diagnosed lung cancer and underwent pulmonary resection surgery at Seoul National University Bundang Hospital were included. We extracted DNA from three parts of pathologic specimen of the same patient; normal, IPF, and lung cancer tissue. Using the DNA extracted from each tissue, whole exome sequencing was performed. **Result:** Twenty consecutive IPF patients with lung cancer were included. Median age at diagnosis was 72 years, all patients were male and 19 patients (95%) were former or current smokers. Fourteen patients (70%) had squamous cell carcinoma, five patients (25%) had adenocarcinoma, and one (5%) had large cell carcinoma. TP53 (10/20, 50%) was the most frequently identified genetic mutation in lung cancer tissue, followed by LILRB4 (9/20, 45%). These genetic mutations were not observed in IPF tissue of the same patient. The genetic mutations of FAM231B (5/20, 25%), PSPN (4/20, 20%), GNAQ (4/20, 20%) were also observed in lung cancer tissue, but not in IPF tissue. Genetic mutations of PRH2 and THAP12 were identified both IPF and lung cancer tissue. The frequency of mutations was observed to increase in the order of normal, IPF, and lung cancer tissue (PRH2, 12% vs 35% vs 40%; THAP12, 6% vs 20% vs 25%).



Conclusion: Various genetic mutations are associated with the development of lung cancer from IPF. Certain sequential patterns of genetic mutations may be present in IPF-associated lung cancer. Our findings provide insight into the genomic landscape about IPF-related lung cancer.

Background: Activating EGFR mutations in NSCLC confer sensitivity to reversible EGFR TKIs, including gefitinib and erlotinib. Despite promising initial response, acquired resistance develops mediated by the emergence of the secondary T790M mutation or by focal amplification of MET. An epithelialtomesenchymal transition (EMT) is clinically linked to NSCLCs with acquired EGFR TKI resistance. The exact mechanisms of EGFR TKI resistance with EMT phenotype remain elusive. **Method:** We have engineered EGFRmutated NSCLC cell lines with a mesenchymal phenotype by stably depleting ECadherin, overexpressing Snail, or chronically exposing the cells to TGFβ1. The resulting mesenchymal cells are resistant to EGFR TKIs. We employed genomic analyses to identify commonly activated oncogenic drivers that maintain signaling pathways upon EGFR inhibition. We also used EGFRmutated HCC4006 NSCLC cells grown resistant to gefitinib that developed a mesenchymal phenotype (HCC4006GeR). To extend our findings to *in vivo*, we have utilized matched pre- and post-EGFR TKI treatment samples from NSCLC patient and mouse models of acquired EGFR TKI resistance to test if our approach using these cell lines is instructive. **Result:** We discovered that an atypical GPCR, CXC chemokine receptor type 7 (CXCR7), is commonly overexpressed in the cell line models of EGFR TKI resistance with a mesenchymal phenotype. The murine tumors driven by human EGFR exon19 deletion/T790M (TD) with acquired resistance to WZ4002 present mesenchymal phenotype and overexpress CXCR7. 50% of NSCLC patients harboring an EGFR kinase domain mutation who progressed on EGFR inhibitors showed an increase in CXCR7 expression. Using the cell line model of EGFR TKI acquired resistance with a mesenchymal phenotype, we find that CXCR7 activates the MAPK-ERK pathway via b-arrestin. Depletion of CXCR7 abrogates the MAPK pathway and significantly attenuated EGFR TKI resistance in the cells with a mesenchymal phenotype. In the long term, the depletion of CXCR7 resulted in mesenchymal to epithelial transition. Ectopic overexpression of CXCR7 in HCC4006 cells was sufficient in activation of ERK1/2 for the generation of EGFR TKI resistant cells. Furthermore, CXCL12 stimulation resulted in an increase in ERK phosphorylation while EGFR was inhibited in HCC4006Ge-R cells. Similarly, we found we found CXCL12 expression is elevated in patient samples with increased CXCR7 expression. **Conclusion:** Taken together, we discovered that the CXCR7-CXCL12 signaling axis is necessary and sufficient for the maintenance of EGFR TKI resistance with mesenchymal phenotype and CXCR7 inhibition could significantly delay and prevent the emergence of acquired EGFR TKI resistance in EGFR mutant NSCLC.

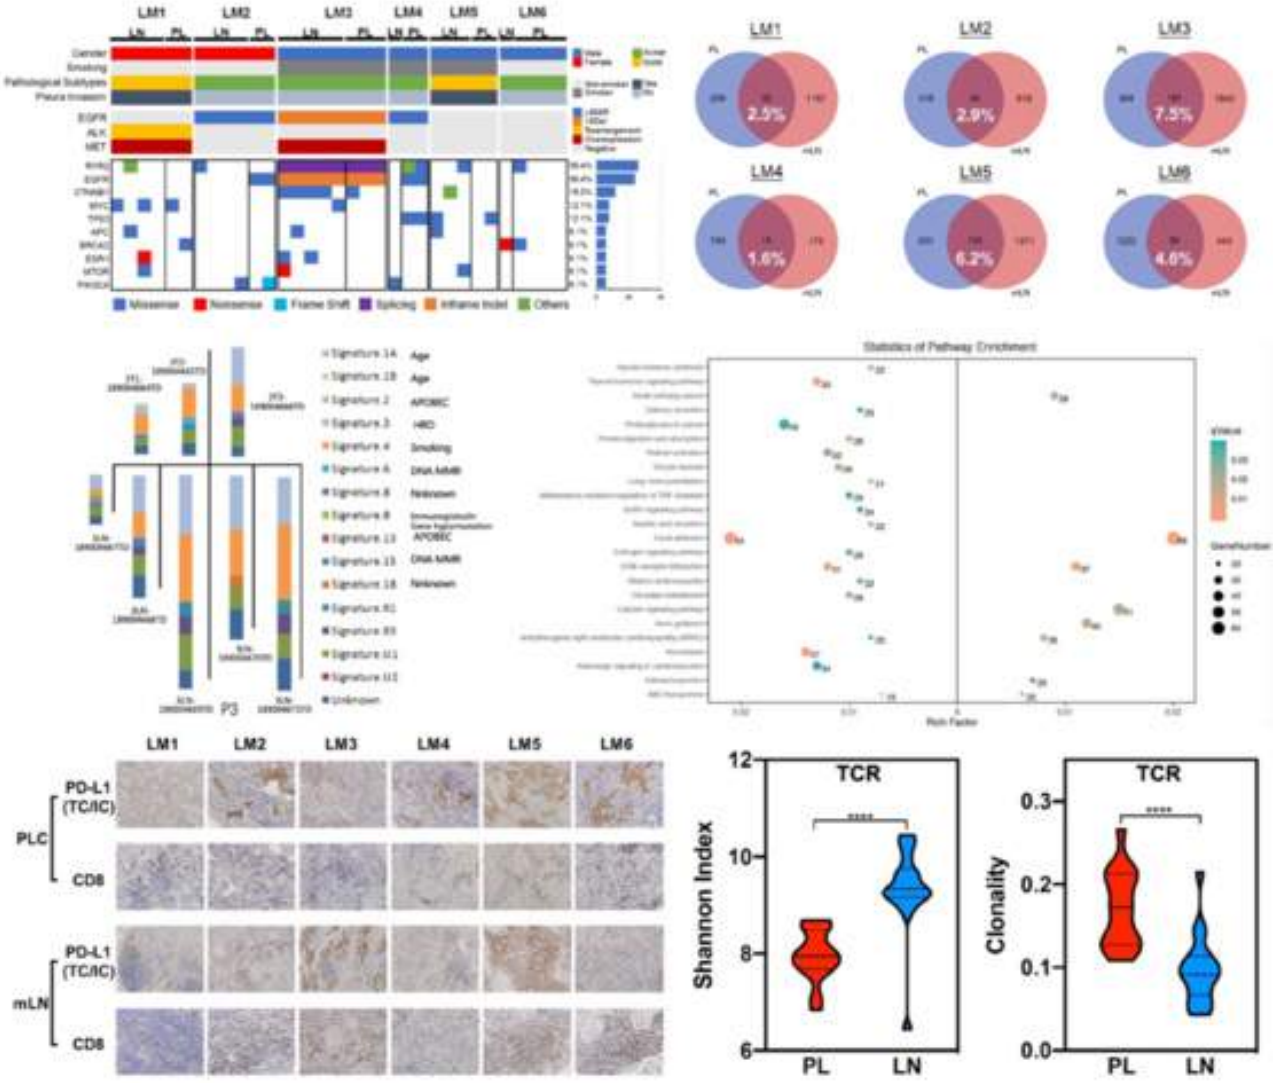
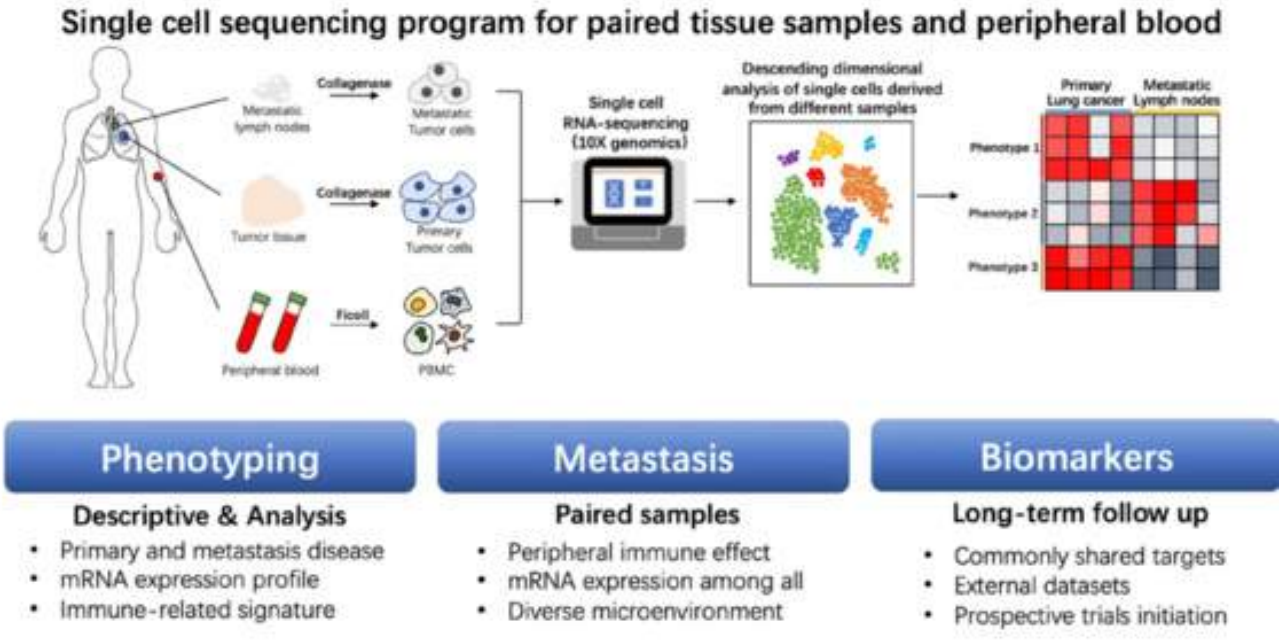
P2.03-32 METASTATIC LYMPH NODES AS HIGH IMMUNOGENICITY MEDIA FOR PERIOPERATIVE IMMUNOTHERAPY IN LOCALLY ADVANCED NSCLC

C. Zhang[1], S.-Y. Liu[1], J. Su[1], X. Gao[2], L.-P. Chang[2], Y.-F. Guan[2], H.-Y. Tu[1], Q. Zhou[1], J.-J. Yang[1], X.-N. Yang[1], X.-C. Zhang[1], Y.-L. Wu[1], W.-Z. Zhong[1]

[1]*Guangdong Lung Cancer Institute, Guangzhou/China,* [2]*Geneplus-Beijing Institute, Beijing/China*

Background: Perioperative chemotherapy showed limited survival benefit and increased toxicities while neoadjuvant immunotherapy achieved great success in early phase trials. Both inter/intra-tumoral heterogeneity (ITH) between primary lesion and metastatic lymph nodes (mLNs), and rationale of superior efficacy for immunotherapy remained poorly explored in locally advanced non-small cell lung cancer (NSCLC). **Method:** We retrospectively collected 6 locally advanced lung adenocarcinoma (LUAD) patients. 15 tissue samples were performed multi-region whole exosome sequencing and TCR repertoire analysis as well as 18 matched metastatic lymph nodes (mLNs). **Result:** 290 somatic mutations in average were identified in primary LUAD (PL) and 441.6 for mLNs. Tumor mutation burden as well as tumor neoantigen burden was significant higher in mLNs than in primary LUAD (median value, 6.6mut/Mb vs. 3.4mut/Mb, P=0.0376; 229.5 neo counts vs. 165 neo counts, P=0.0287). Increased transversion ratio was found in mLNs compared to primary lesions. The genomic concordance between primary lesions and mLNs was 58.4%±12.5% and 33.3% for EGFR-mutation. 87 copy number variants were detected in 14 samples with 3q, 8q and X chromosome as frequently mutated cytobands. Small cell lung cancer functional pathway was enriched in mLNs exclusively. Both expression of PD-L1 and CD8 revealed high level (median value 20% and 40%) and consistence (5/6, 83.3%) between primary and metastatsis lesions. TCR clonality was 17.2% and 9.1% for primary and metastasis lesions, respectively with higher T cell diversity and intra-tumoral heterogeneity of TCR found in mLNs.





Conclusion: Extensive genomic and TCR ITH was found between primary LUAD and mLNs which may lead to mixed response to perioperative treatment. mLNs may serve as a better immunogenicity media for perioperative immunotherapy suggesting a potential adjuvant modality of immunotherapy performing lymph nodes sampling during surgery. Results of an initiated single cell sequencing program including paired samples were pending to further provide insights of diverse immune-microenvironment.

Keywords: locally advanced lung cancer, intra-tumoral heterogeneity, perioperative immunotherapy

P2.03-33 CTDNA LEVELS SIGNIFICANTLY PREDICTS SURVIVAL IN NSCLC PATIENTS WITH AN EGFR ACTIVATING MUTATION

Background: Circulating tumor DNA (ctDNA) have been shown to be useful for non-invasive biomarker testing in non-small cell lung cancer (NSCLC). In addition, there is growing evidence supporting that ctDNA levels can be useful for tumor response to treatment monitoring. Nevertheless, data from large prospective clinical longitudinal studies still limited. **Method:** 300 plasma samples from 100 advanced NSCLC patients, with tumors harboring an EGFR activating mutation and treated with a first line tyrosine Kinase inhibitor were analyzed. Samples were collected before the start of treatment, at first follow up evaluation, at 7 month and at disease progression. ctDNA was analyzed by dPCR. **Result:** Median follow up was 11.3 months. There were not significant differences in progression free survival (PFS) or overall survival (OS) according to treatment (erlotinib, afatinib or gefitinib). Patients harboring a deletion in exon 19 or a mutation in exon 21 exhibited better survival than those with an insertion in exon 20 (P<0.001). dPCR detected EGFR sensitizing mutation in 77% of the pre-treatment samples. ctDNA levels before the start of the treatment did not significantly predict survival, although a tendency was observed, with patients with high levels of ctDNA showing poorer outcome. On the contrary, patients in which the EGFR sensitizing mutation was undetectable at first follow up had a markedly better PFS and OS (HR=2.7; 95IC= 1.4-5.5 and HR= 5.5 95IC: 1.8-17 respectively). In the same way, patients in which the EGFR sensitizing mutation remained negative at 7months had a significantly increased PFS (HR: 2.8; 95IC: 1.2-6.6). None of the patients with undetectable levels at 7 months has deceased. **Conclusion:** ctDNA levels is of prognostic significance in EGFR positive NSCLC patients with advance disease and can be useful to monitor treatment outcome

Keywords: ctDNA levels, EGFR positive NSCLC

P2.03-34 FRACTALKINE ATTENUATE IRRADIATION-INDUCED BRAIN INJURY THROUGH PROMOTING THE M2 POLARIZATION OF MICROGLIA

H. Pan[1], F. Tong[1], H. Li[1], J. Wang[1], C. Wei[1], H. Lu[1], L. Peng[1], Y. Wang[2], X. Dong[2]

[1]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China,* [2]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, wuhan/China*

Background: Radiation-induced brain injury (RIBI) is an unavoidable adverse side-effect induced by cranial radiation therapy. The neuro-inflammation mediated by activated microglia has been proved to be a key role in RIBI by our previous researches. Studies have demonstrated that vascular endothelial cells are damaged by irradiation and Fractalkine (FKN), a crucial mediator modulating the biological activity of microglia, is released. However, the role of FKN in RIBI was poorly understood. The aim of this study was to investigate the effect of FKN on RIBI and its underlying mechanisms. **Method:** Human Umbilical Vein Endothelial Cells (HUVEC) was subjected to 10 Gy or sham irradiation, FKN expression was detected by Western blotting (WB), qRT-PCR and ELISA, γH2AX formation and nuclear translocation of p65 was analyzed by immunocytochemistry (ICC). BV-2 cells received 10-Gy irradiation after being cultured for 3 h with or without FKN (100ng/ml), or co-cultured with HUVEC. Moreover, the CX3CR1 (the receptor of FKN on microglia) wide-type ($CX3CR1^{WT}$) and CX3CR1-knockdown ($CX3CR1^{-/-}$) mice were employed and subjected to lateral ventricular injection (ICV) of 5 μl FKN lentivirus or vector 3 days before 10-Gy whole brain irradiation. The polarization of microglia *in vitro* or in hippocampus and its inflammatory factors release were evaluated through measuring the signature genes, protein and cytokines of M1/M2 phenotype by RT-PCR, WB and ELISA at different time-points after irradiation. Hippocampus neurogenesis was evaluated through detecting the proliferation marker BrdU/nestin and differentiation marker BrdU/NeuN by immunofluorescence (IF) respectively. Neurological function was evaluated by morris water maze (MWM) at 6 weeks after RIBI, and the relationship between microglia and vascular was explored by IF. Then the *in vitro* phagocytosis assays were performed to investigate if FKN could promote BV2' phagocytic function. **Result:** The expression of FKN in HUVEC was increased by 10 Gy irradiation, simultaneously, γH2AX formation and p65 nuclear translocation were observed. FKN regardless from exogenous or secreted by HUVEC could promote the M2 polarization of microglia and inhibit inflammatory response *in vitro*, it also enhanced neurogenesis in hippocampus, and improved function recovery in $CX3CR1^{WT}$ mice, but not in $CX3CR1^{-/-}$mice after RIBI. More interestingly, activated microglia migrated to blood vessels in $CX3CR1^{WT}$ mice was observed *in vivo* by IF. What's more, BV2 cells phagocytized more fluorescent microspheres when treated with FKN. **Conclusion:** The FKN/CX3CR1 axis plays an important role in RIBI, and might be an underlying target for the treatment of radiation-induced cognitive impairment.

Keywords: irradiation-induced brain injury, fractalkine, microglia

P2.03-35 STROMAL TIMP-1 DRIVES TUMOR PROGRESSION IN LUNG ADENOCARCINOMA THROUGH CD63 INTERACTION

P. Duch[1], M. Gabasa[1], R. Ikemori[2], F. Hillberg[3], N. Reguart[4], J. Alcaraz[1]

[1]*University of Barcelona, Barcelona/Spain,* [2]*University of Barcelona - Faculty of Medicine, Barcelona/Spain,* [3]*Boehringer-Ingelheim Inc, Vienna/Austria,* [4]*Hospital Clinic Barcelona, Barcelona/Spain*

Background: Tumor associated fibroblasts (TAFs) are important regulators of tumor growth and resistance to therapies. We have recently shown that TAFs *in vitro* from lung adenocarcinoma (ADC) and squamous cell carcinoma (SCC) respond positively to the antifibrotic drug nintedanib in the former only, thereby mimicking the selective therapeutic effects of nintedanib in ADC reported in the LUME-Lung1 clinical trial. We also showed that the tumor-promoting effects of TAFs are driven by different mechanisms in ADC and SCC. However, it remains to be elucidated the key signaling molecules involved in the aberrant fibroblast-carcinoma crosstalk in ADC. Tissue inhibitor of metalloproteinases 1 (TIMP-1) is a multifunctional protein that has been associated with poor prognosis in lung cancer and other cancer types, and is downregulated by nintedanib in a bleomycin model of pulmonary fibrosis. Moreover, our preliminary analysis revealed that the TIMP-1 cell surface binding protein CD63, is overexpressed in ADC compared to SCC. Therefore, our objective was to study whether the selective tumor-promoting effects of ADC-TAFs are mediated by the interaction of stromal TIMP-1 with epithelial CD63. **Method:** ADC-TAFs and SCC-TAFs were stimulated with TGF-β1 in the presence or absence of nintedanib, and the TIMP-1 content in their conditioned medium was determined by ELISA. TIMP-1 was reduced in ADC-TAFs by siRNA, and the corresponding conditioned medium was used to assess the impact of TIMP-1 on the growth, invasion and survival of the CD63-high ADC cell line H1437. Likewise, CD63 expression in H1437 cells was reduced, by siRNA. In addition we performed immunohistochemical analyses of CD63 in tissue sections from lung cancer patients. **Result:** Our results showed that TIMP-1 secretion induced by TGF-β1 is significantly larger in ADC-TAFs compared to SCC-TAFs. Likewise, nintedanib elicited a larger downregulation of TIMP-1 secretion in ADC-TAFs compared to SCC-TAFs. We also confirmed that CD63 expression is higher in ADC patients than SCC, and revealed that knocking-down CD63 in H1437 ADC cells is sufficient to reduce the growth and invasion elicited by the conditioned medium of activated ADC-TAFs. Likewise, knocking-down TIMP-1 in ADC-TAFs was sufficient to downregulate the growth, invasion and survival of H1437 elicited by the conditioned medium of these TAFs. **Conclusion:** Collectively, our results unveil a novel stroma-carcinoma interaction driven by TIMP-1 and CD63 selectively in lung ADC, and support that such crosstalk is a major regulator of the aberrant tumor-promoting effects of ADC-TAFs that are downregulated selectively by nintedanib.

P2.03-36 TTMB AND BTMB IN EAST ASIAN LUNG CANCER PATIENTS WITH NO TKI-RELATED DRIVER GENE MUTATIONS

Y. He[1], X. Chen[1], B. Chen[1], L. Song[2], X. Li[2], J. Zhang[2], L. Li[2], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China,* [2]*Haplox, Shenzhen/China*

Background: High-level TMB was shown to be correlated with the better response of immunotherapy in lung cancer patients. However, the correlation between tissue tumor mutational burden (tTMB) with the blood tumor mutational burden (bTMB) in lung cancer patients has not been fully defined, and the tTMB and bTMB of East Asian lung cancer patient harboring no TKI-related driver gene mutations remains unexplored. This study aimed to define the tTMB and bTMB in East Asian by whole-exome sequencing (WES) and panel-based sequencing, and interrogate the correlation between gene mutations and TMB in lung cancer patients with no TKI -related driver gene mutations. **Method:** In this cohort study, 122 primary lung cancer patients without TKI-related driver gene (EGFR, ALK, ROS1, RET, BRAF, C-MET, HER2) mutations were included. tTMB and bTMB were determined by whole-exome sequencing (WES) and a targeted 451-gene panel sequencing. The correlation between any two among the WES-tTMB, the panel-tTMB and the panel-bTMB were determined, and the relationship between gene mutations and tTMB were analyzed. Statistics was performed with the SPSS 20 software. **Result:** The mean tTMB measured by WES (WES-tTMB), the 451-gene panel (panel-tTMB) and bTMB measured by the 451-gene panel (panel-bTMB) was 4.5, 7.2 and 6.1 mutations/Mb, respectively. Significant correlation was found between panel-tTMB and WES-tTMB (Pearson r=0.76, P<0.001) or panel-bTMB (Pearson r=0.52, P<0.001), but WES-tTMB showed no correlation with panel-bTMB (Pearson r=0.189, P=0.75). The relationship between gene mutations and WES-tTMB was further explored. Patients with p53, TTN, CSMD3, ZFHX4, RYR2, MUC16, MUC12 and USH2A gene mutations had dramatically higher tTMB (P<0.001), while no significant relationship between CDKN2A or KRAS gene mutations and TMB was identified (p>0.05). In contrast, patients harboring both KRAS and P53 mutations showed significantly higher TMB than those with either gene mutations or no mutations in both genes (P<0.001).

Conclusion: Our study suggested that discrepancies exist in TMB measurement using different NGS-based detecting methods with tissue or blood sample types. The cut-off values should be determined based on detecting methods and samples types. Panel-tTMB was stronger correlation with WES-tTMB and panel-bTMB. Gene mutations were correlated with high TMB might be stronger predictors for TMB status in lung cancer patients without TKI-related driver gene mutations. Our observations provided new insights in TMB determination in East Asian lung cancer patients with NGS-based methods in various samples types and might improve the prediction of therapeutic effect and prognosis in future immunotherapy.

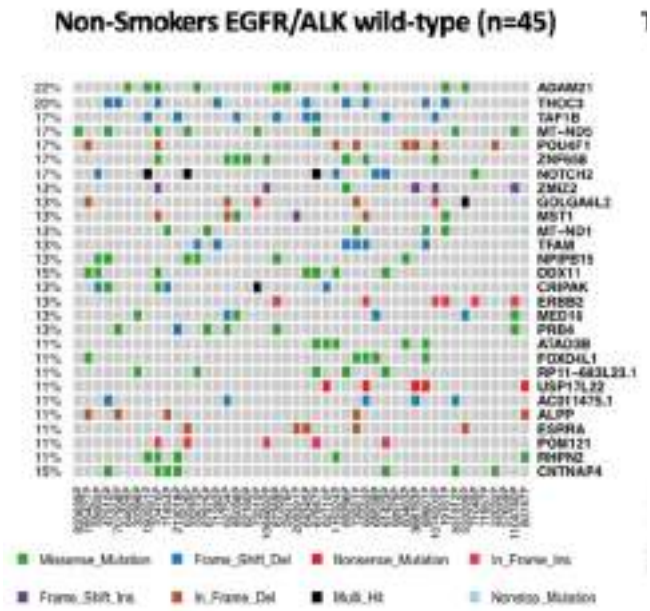
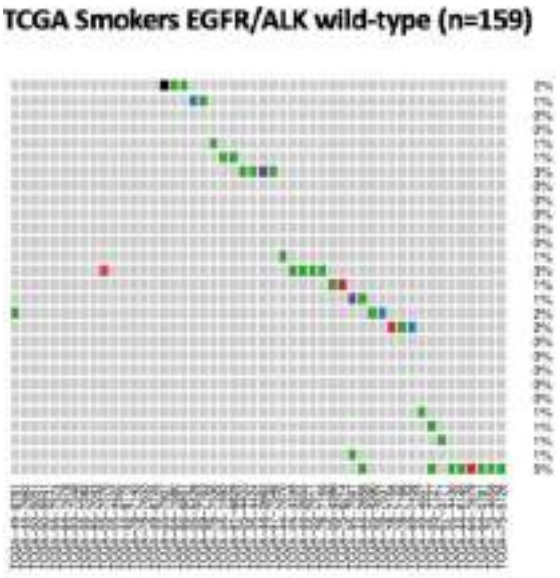
P2.03-37 GENOMIC LANDSCAPE OF EGFR/ALK WILD-TYPE LUNG ADENOCARCINOMAS IN NEVER-SMOKERS AND IMPORTANCE OF EPITHELIAL-MESENCHYMAL-TRANSITION

A. Fares, S. Martins-Filho, V. Raghavan, E. Stewart, D. Ravi, J. Weiss, K. Hueniken, D. Patel, N.-A. Pham, A. Sacher, P. Bradbury, N. Leighl, F. Shepherd, M. Tsao, G. Liu

University Health Network, Toronto/Canada

Background: The molecular landscape of EGFR/ALK wild-type Lung Adenocarcinomas in never-smokers is poorly understood. Never-smokers usually have low PD-L1 expression and low Tumor Mutation Burden, challenging treatment strategies when no known driver-mutations are found. To identify putative driver mutations, we compared whole exome sequencing (WES) results in the EGFR/ALK wild-type Lung Adenocarcinoma in the never smokers Toronto cohort with a corresponding EGFR/ALK wild-type Lung Adenocarcinoma group of smokers from TCGA. **Method:** For never-smokers with resected EGFR/ALK wild-type Lung Adenocarcinomas, frozen tumor and paired-normal-lung were evaluated by WES at a mean coverage of 238x. The paired-end reads were aligned using BWA and were further processed using the standard GATK pipeline. Somatic mutations and indels were identified using MuTect and VarScan, respectively. We compared mutations from our cohort to the TCGA smokers who had EGFR/ALK wild-type Lung Adenocarcinomas from publicly available data (TCGA) to identify genes at least 10% more frequently mutated in never smokers compared to the TCGA cohort. **Result:** In our cohort with 45 never-smoker patients, 80% were females; median age was 70y; 29% were Asians; Stage I/II/III+ were 71%/15%/13%; after a median follow-up of 69 months, 24% had recurred. Median non-synonymous Tumor Mutation Burden was 1.3mut/Mb in never-smokers. We identified 39 genes that were more frequently mutated in never-smokers vs smokers, including some known tumor suppressor genes. The most prevalent genes included ADAM21 missense mutations (21% vs 1%; adj p=0.003), NOTCH2 frame-shift deletions and multi-hit mutations (40% vs 17%; adj p=0.04), MST1 missense mutations and in-frame deletions (13% vs 0%; adj p=0.008), ZMIZ2 frame-shift insertions (13% vs 0%; adj p=0.008) and FOXD4 missense mutations (10% vs 0%; adj p=0.02). Many of these differentially mutated genes have been previously associated to epithelial-mesenchymal-transition signaling pathways. Conversely and as expected, KRAS, TP53, STK11 and KEAP1 were more frequently mutated in the TCGA smokers EGFR/ALK wild-type Lung Adenocarcinomas cohort.





Conclusion: We identified multiple genes, particularly involved in the epithelial-mesenchymal-transition signaling pathways that are over-represented in never-smokers with EGFR/ALK wild-type Lung Adenocarcinomas, when compared to smokers with EGFR/ALK wild-type Lung Adenocarcinomas. This is a novel finding with potential clinical importance. Validation studies, analyzing epithelial-mesenchymal-transition signaling activation pathways on the EGFR/ALK wild-type Lung Adenocarcinomas never smokers population are needed to best identify the actual role in carcinogenesis and metastasis, guiding future treatment strategies. (AFF and SNMF contributed equally).

Background: Synthetic lethality has been defined as the inability of cells to proliferate when co-targeting two genes, with a synergistically superior inhibition than that found for each individual gene. Consistent co-expression of two genes involved in a similar function is a predictor of synthetic lethality, a strategy that is being applied to find out novel cancer vulnerabilities. **Method:** Large-scale bioinformatics analyses across 5 public databases were used to identify genes consistently co-expressed with TMPRSS4, a novel therapeutic target that we have previously identified in NSCLC. Pyrosequencing was used to evaluate methylation levels in patients and cell lines. Functional *in vitro* experiments and animal models were used to assess synthetic lethality of TMPRSS4 and DDR1 in NSCLC. **Result:** Consistent co-expression between TMPRSS4 and DDR1 was found in all NSCLC databases evaluated. Similar to TMPRSS4, DDR1 promoter was hypomethylated in NSCLC in 3 independent cohorts and hypomethylation was an independent prognostic factor of disease-free survival. Treatment with 5-azacitidine increased DDR1 levels in cell lines, suggesting an epigenetic regulation. Cells lacking TMPRSS4 were highly sensitive to the cytotoxic effect of the DDR1 inhibitor dasatinib. TMPRSS4/DDR1 double knock-down cells, but not single knock-out cells suffered a G0/G1 cell cycle arrest with loss of E2F1 and cyclins A and B, increased p21 levels and apoptosis. Moreover, double knock-down cells were highly sensitized to cisplatin, which caused massive apoptosis (~40%). *In vivo* studies demonstrated tumor regression in mice injected with double knock-down-injected cells and lack of 18FDG-uptake by microPET analysis. **Conclusion:** We have identified a novel vulnerability in NSCLC resulting from a synthetic lethal interaction between DDR1 and TMPRSS4. This may help designing therapeutic strategies to impair NSCLC growth by co-targeting both genes.

P2.03-39 SYSTEMATIC EVALUATION OF EGFR VARIANT BIOLOGY IN CANCER

T. Hayes

Dana-Farber Cancer Institute, Boston/United States of America

Background: Lung cancer is the leading cause of cancer related deaths world-wide, with non-small cell lung cancer (NSCLC) accounting for a majority of all cases. Approximately 14% of adenocarcinomas, a NSCLC subtype, are characterized by activating mutations in the epidermal *g*rowth *f*actor *r*eceptor, EGFR. In NSCLC, there are several well-established hotspot mutations in EGFR, such as in-frame deletions in exon 19 and point mutations at residue L858, that have demonstrated dramatic responses to molecularly targeted therapies in subsets of patients. Beyond hotspot mutations, subsets of patients can present with rare EGFR variants at residues G719, L861, or S768, all of which are known to be oncogenic drivers. However, a subset (~5%) of observed EGFR variants remain functionally uncharacterized. Given the increase in targeted panel sequencing of cancer patients, it is feasible that additional EGFR variants will be revealed beyond those already functionally annotated. Additionally, pre-clinical and clinical investigations have revealed that EGFR variants, rare or not, can have differential sensitivity to EGFR TKIs (tyrosine kinase inhibitor), however, the mechanism for this differential sensitivity remains to be elucidated. If we could systematically assess whether

an EGFR variant is a possible driver and determine its TKI sensitivity profile, this could pave the way towards enhanced patient care by providing a catalogue of treatment strategies for specific EGFR variants. **Method:** To systematically evaluate all possible EGFR variants, we employed a high throughput forward genetic screening approach. To generate all possible EGFR variants, we used a saturation mutagenesis strategy, which entailed substituting each amino acid for all other possible amino acids including stop codons, generating a library of approximately 25,000 EGFR variants. We expressed our pooled library in two distinct lung cancer models and assessed the ability of each EGFR variant to grow compared to EGFR WT in the presence of inhibitors using changes to population doublings as a readout for variant functionality. **Result:** Our screens revealed functional information for somatic mutations observed in patients that previously were uncharacterized. Firstly, in both screens, we observed variant enrichment in the kinase domain, which was expected and gives us confidence that our screens have yielded relevant EGFR variant biology. Furthermore, in our oncogenesis screen, we unexpectedly identified variant enrichment in specific EGFR extracellular domains. Conversely, in the second screen, which measured EGFR activity and insensitivity to erlotinib, we observed a distinct variant enrichment pattern in both the EGFR extracellular domain and the transmembrane domain. **Conclusion:** Our strategy is a powerful tool to uncover novel functional information for variants of unknown significance (VUS). Together, our screening results give a comprehensive understanding of the EGFR variant landscape, which has implications for both EGFR biology and patient treatment strategies.

Background: The leading cause of cancer deaths points to lung cancer which tends to exacerbate, especially the cases of never-smokers in East Asian. While environmental exposure to air pollutants-particle matters (PMs) has been reported to increase the risk of lung cancer; the organic or inorganic chemicals absorbed in the surface of particles, including polycyclic aromatic hydrocarbons (PAHs), dioxins or other heavy metals are identified as carcinogens. However, the underlying mechanisms and the extent to which the toxicity of co-exposure to PMs and environmental carcinogens in pulmonary cells remain unclear. **Method:** Here, we used a well-developed murine lung progenitor cell model with the cells primary cultured from neonatal mice and sorted as the OCT4+/CARHi sub-population to expose with fine PMs (urban dust) or ultrafine particles (nano-carbon black, nCB) with/without carcinogens (Benzo[a] pyrene, B[a]P and 2,3,7,8-Tetrachlorodibenzo-p-dioxin, TCDD). High content analysis (HCA) was applied to quantify the progenitor cell population and differentiated alveolar epithelial cells; and the cellular heterogeneity was also examined. The transcriptomics and gene enrichment analysis were also performed to explore the molecular mechanisms via the gene set enrichment analysis with the molecular signatures database. **Result:** We found that co-stimulating the progenitor cells with TCDD and nCB can cause most significantly effects on activating cell proliferation, reducing cell differentiation and remarkably morphological diversity. The potential stemness sub-population of CAR-positive lung progenitor cells was increased following TCDD treatment and forming more significantly colony in the TCDD-nCB co-exposure group; whereas, the population of differentiated pulmonary lung epithelial cells was reduced. Transcriptomic analysis showed that the TCDD-induced genes: AHR, Cyp1A1, COX-2, and TCDD-inducible poly(ADP-ribose) polymerase are significantly up-regulated. The pathway analysis revealed important oncogenic transcriptional factors (TFs): STAT2, IRF1, AHR, BRCA1, and FOS are highly enriched and several key factors on EGFR, RAF, AKT, E2F1, MEK, and LTE2 were identified via the MSigDB oncogenic signatures. Furthermore, the co-exposure of TCDD with nCB also dysregulated the Wnt signaling pathway, cytokine networks (CCLs-CXCLs-CXCRs), antigen processing and presentation, IL-2 receptor signaling, interferon and TNF signaling that are critical on immune homeostasis in the microenvironment. **Conclusion:** In conclusion, co-exposure of ultrafine particles with carcinogens could induce cell proliferation and suppress differentiation in mice lung progenitor cells; and lead to oncogenic and immune-modulatiing gene dysregulation. This study suggests the synergistic effects of the environmental carcinogens and PMs on the initiation of hyperplasia and malignant transformation of the lung progenitor cells via regulating gene expression related to oncogenic TFs, immunity and paracrine niche.

P2.03-41 IDENTIFICATION OF NOVEL BLOOD-BRAIN BARRIER PENETRATING DNA APTAMERS

B.-T. Huang[1], W.-Y. Lai[1], Y.-T. Tseng[1], C.-E. Yeh[1], E. Lin[2], P.-C. Yang[2]

Background: A significant portion of lung cancer patients develops central nervous system (CNS) metastasis at certain time points in their disease courses. The structure of blood-brain barrier (BBB) strictly regulates brain homeostasis and protects the brain from exogenous damage. At the same time, these features impede effective drug delivery in to CNS, including antibody-based molecular probes. Therefore, detection of small CNS lesions and effective drug delivery across the BBB can be very challenging. Aptamers, also known as chemical antibodies, are small synthetic DNA or RNA oligonucleotides. With its inborn nature of low molecular weight, aptamers may possess better tissue penetrating ability comparing to antibodies. The current study aims to develop BBB-penetrating aptamers for CNS metastatic lung tumor targeting. **Method:** In vivo SELEX (Systematic Evolution of Ligands by Exponential enrichment) was used for aptamer identification in the current study. In brief, we established CNS lung cancer mouse models by intra-ventricular inoculation of lung cancer cells. The single-stranded DNA oligonucleotide library was then intraperitoneally injected to the tumor-bearing mice. The mouse was perfused with SELEX buffer and the CNS tissues were carefully isolated. Tissue/tumor-binding oligonucleotide sequences were extracted and amplified by PCR. The procedure was repeated for several rounds and the products of the final SELEX round was subjected for sequencing. **Result:** Our data showed that the CNS lung cancer mouse model was nicely established. The growth of tumors was in vivo monitored by IVIS imaging system and confirmed by immunohistochemistry staining. Through in vivo SELEX using the well-established mouse model, a group of potential BBB-penetrating aptamers was identified. By sequence analyses and secondary structure prediction, we further categorized a subset of aptamers that may possess CNS lung tumors targeting ability. Aptamer signals were in vivo captured by IVIS imaging system and was confirmed by confocal microscopy images showing the colocalization of aptamer and lung cancer cell signals. **Conclusion:** We have identified BBB-penetrating aptamers that may possess CNS lung tumor targeting ability. The aptamers may serve as guiding molecules for drug delivery and/or probes for molecular imaging. Further studies are required to determine their translational potential.

Background: Next-generation sequencing is a genetic analysis platform for multiple analysis and large-scale analysis. Sensitivity is limited by methods for detecting cancer mutations that are contained at low rates in blood. With two highly sensitive detection techniques for genetic alterations, we evaluated their diagnostic value for tumor-derived EGFR mutations in plasma cell-free DNA

(cfDNA) and measured concordance rate of activating EGFR mutations between cfDNA and tumor tissue. **Method:** We conducted this study using FFPE tissue and plasma samples which were donated from NSCLC patients (N=316) between 2011 and 2013 and stored in the Human-derived Biomaterials Bank in Seoul St. Mary's Hospital. Meanwhile, we prospectively collected plasma samples simultaneously when tumor tissue was taken out by surgery. We also collected peripheral blood just before administration of EGFR TKIs and each time imaging study was done during the administration of EGFR TKIs. We analyzed activating EGFR mutations in both cfDNA and tumor tissues using PNAclamping, Cancer panel and Sel-Cap™ Lung Cancer Panel. **Result:** The sensitivity and specificity of three detection techniques, PNAclamp, cancer panel and Sel-Cap™ Lung Cancer Panel NGS for EGFR mutations in tumor tissues were more than 90% in all. In particular, EGFR T790M was found not only in the patients acquiring drug resistance approximately 10-12 months following the administration of 1st or 2nd generation EGFR TKIs, but also in the patients in whom EGFR TKI was continuously maintained over 30 months. The sensitivity of Sel-Cap™ Lung Cancer Panel NGS for EGFR exon19 deletion and exon21 L858R in cfDNA was 76.2% and 61.1%, respectively. In addition, the sensitivity for double mutation of 19del and T790M was about 30% higher compared to that of cancer panel sold domestically (2/20, 10.0% vs. 9/20, 45.0%), suggesting that Sel-Cap™ Lung Cancer Panel NGS enables to detect EGFR mutation up to 0.1% in plasma cfDNA. As a result of tracking of outcomes of EGFR TKIs treatment over time for patients with low frequency of EGFR mutations, we found that 1st or 2nd generation EGFR TKIs were switched into 3rd generation EGFR TKIs on the basis of disease progression on radiologic imaging, when an average of 6.8 months (0.2-25.4 months) elapsed from the first detection time of T790M in cfDNA. The presence of T790M in peripheral blood harvested periodically from patients receiving EGFR TKIs was initially identified about 3-5 months ahead of disease progress assessed by imaging study. **Conclusion:** With regard to the detection of EGFR mutations in lung cancer patients, Sel-Cap™ Lung Cancer Panel NGS platform showed superior sensitivity to conventional NGS-based cancer panels as well as higher concordance rate between tumor tissues and plasma cfDNA. In longitudinal plasma cfDNA samples isolated from periodic liquid biopsies, quantitative changes of EGFR mutation were found to be significantly correlated to tumor response by EGFR TKIs. Our data suggest that Sel-Cap™ Lung Cancer Panel NGS is a highly sensitive diagnostic platform for detection of EGFR T790M induced by long-term administration of EGFR TKIs and for determining when 3rd generation EGFR TKI be begun.

P2.03-43 WTAP ACTIVATES ONCOGENES AND ACCELERATES TUMOR AGGRESSIVENESS THROUGH ADDING M6A RNA MODIFICATION IN NON-SMALL-CELL LUNG CANCER

K. Yoshimura[1], Y. Inoue[1], K. Tsuchiya[1], Y. Iwashita[1], T. Kahyo[1], A. Kawase[1], M. Tanahashi[2], Y. Suzuki[1], M. Karayama[1], H. Ogawa[2], N. Inui[1], K. Funai[1], K. Shinmura[1], H. Niwa[2], T. Suda[1], H. Sugimura[1]

[1]*Hamamatsu University School of Medicine, Hamamatsu/Japan,* [2]*Seirei Mikatahara General Hospital, Hamamatsu/Japan*

Background: N6-methyladenosine (m6A) is one of the RNA modifications affecting multiple cellular processes such as RNA metabolism, stem cell self-renewal, and cell differentiation in eukaryotes. m6A is dynamically regulated by three types of enzymes called writer, eraser, and reader. WT1-associated protein (WTAP) is an important component of the m6A writer complex to which the majority of m6A is attributed. Despite having been revealed in several types of cancers, the relevance and roles of m6A and its modifiers are unclear in non-small cell lung cancer (NSCLC). We here quantified the global m6A levels in NSCLC tissues and associated them with clinical data. In addition, the roles of WTAP in the context of m6A regulation were explored *in vitro*. **Method:** Amounts of global m6A in the purified RNAs extracted from 126 paired tumor and adjacent normal tissues were evaluated using liquid chromatography mass spectrometry/mass spectrometry. The clinicopathological data were retrospectively retrieved. The expression levels of the three major m6A writers (WTAP, METTL3, and METTL14) in lung cancer cell lines (H1299, PC3, and PC9) were assessed using RT-qPCR and western blot. *WTAP* knockdown was carried out using siRNAs and its effects on tumoral activities. Also the changes of global and specific transcripts in WTAP-deprived PC9 cells were evaluated using a microarray analysis and m6A specific RNA immunoprecipitation (RIP) assay. WTAP protein expression levels in 641 resected NSCLC were assessed using immunohistochemistry and their prognostic role was determined. **Result:** The m6A/A was significantly higher in tumor tissues than adjacent normal tissues (P <0.001), and higher m6A/A was significantly associated with worse overall survival (Log-rank, P=0.041). Among the three major writer enzymes assessed, WTAP was identified as the most significant modifier of global m6A. Phenotypically, *WTAP* knockdown reduced proliferation, invasion, and migration. The microarray analysis showed that *WTAP* knockdown was significantly associated with reduction of activities in several important signaling pathways such as EGFR, KRAS, and MYC. Furthermore, the significant decrease of m6A in individual transcripts such as *EGFR, MAPKAPK2,* and *MYC* was confirmed in *WTAP*-deprived PC9 cells. Reporter assays containing wild type or mutant *EGFR*-3'UTR at m6A modification sites indicated that EGFR expression change was mediated by WTAP through its regulation of m6A abundance. Immunohistochemical analysis demonstrated that increased WTAP expression was an independent worse prognostic factor in patients with NSCLC (hazard ratio 1.892; 95% confidence interval 1.356-2.64; P<0.001). **Conclusion:** WTAP accelerates tumor aggressiveness through, in part, adding m6A in several important oncogenic transcripts such as *EGFR* and therefore increasing their expression. Both global m6A abundance and WTAP expression levels are prognostic in patients with NSCLC.

Keywords: m6A, WTAP, NSCLC

P2.03-44 BLU-667 DEMONSTRATES ROBUST ACTIVITY IN RET FUSION-DRIVEN INTRACRANIAL TUMOR MODELS

E. Evans, W. Hu, F. Cao, K. Hoeflich, M. Dorsch

Blueprint Medicines, Cambridge/United States of America

Background: Oncogenic *RET* fusions and mutations have been identified in several cancer types including non-small cell lung cancer (NSCLC), papillary thyroid cancer and medullary thyroid cancer. Current treatment of *RET*-altered cancers is generally limited to multikinase inhibitors (MKIs) designed to target other kinases, and chemotherapy, which often have limited efficacy and carry significant off-target toxicities. BLU-667 is an investigational oral precision therapy that is a potent and highly selective inhibitor of oncogenic *RET* fusions and mutations (IC_{50} = 0.4 nM) and has demonstrated tumor growth inhibition and RET signaling abrogation in numerous subcutaneous models of *RET*-driven disease (Subbiah et al. 2018). Early phase 1 results with BLU-667 have demonstrated promising clinical activity in both *RET* fusion and *RET* mutant-driven tumors. As brain metastases occur in up to half of patients with NSCLC, we developed several preclinical intracranial models of *RET*-driven disease and demonstrate robust activity of BLU-667 in this setting. **Method:** KIF5b-RET-Ba/F3 cells engineered to express luciferase or CCDC6-RET CRC PDX tumors were implanted intracranially in Balb/c nude mice. Efficacy was determined by survival or imaging after luciferin tail vein injection. Pharmacodynamic confirmation of RET kinase inhibition was assessed by immunoblot or qRT-PCR of RET pathway transcriptional markers DUSP6 and SPRY4 in harvested tumors. **Result:** In *RET* fusion-driven intracranial mouse tumor models, oral BLU-667 treatment demonstrated significant survival benefit at well tolerated doses. This benefit occurred with BLU-667 doses (10 or 30 mg/kg BID) also shown to be efficacious in subcutaneous *RET*-driven tumor models and at drug exposures below those achieved at the recommended phase 2 dose in humans (400 mg) established in the BLU-667 phase 1 clinical trial. BLU-667 activity was consistent in both *KIF5b-RET* and *CCDC6-RET* fusions, the most common RET fusions found in NSCLC. Pharmacodynamic analysis of intracranial tumor tissue after BLU-667 treatment confirmed dose dependent inhibition of RET pathway signaling (P-RET, P-SHC) and >90% downregulation DUSP6 and SPRY4, consistent with full pathway inhibition. In intracranial Ba/F3-KIF5b-RET tumors expressing luciferase, imaging analysis established near complete inhibition of tumor growth in mice treated with BLU-667. **Conclusion:** In intracranial tumor models driven by KIF5b-RET or CCDC6-RET fusions, BLU-667 inhibits RET kinase activity and increases survival. These data suggest BLU-667 has promise as an investigational agent for RET fusion NSCLC with or without brain metastasis. As such, BLU-667 is currently being evaluated in a clinical trial for patients with *RET*-driven solid tumors including NSCLC (NCT03037385) with registrational intent.

Background: p21-activated kinase 1 (PAK1) stimulates growth and metastasis in several types of tumors, including non-small cell lung cancer (NSCLC). Protein kinase C iota (PKCi) is an enzyme highly expressed in NSCLC that regulates PAK1 signaling. To understand intrinsic and acquired resistance to different MAPK signaling inhibitors, we explored PKCι-PAK1 signaling in EGFR/KRAS mutant adenocarcinoma or squamous cell carcinoma (SCC) cell lines by combination therapy using PAK1 inhibitor and PKCι inhibitor. **Method:** Three lung cancer cell lines were used: HCC827 and H23 lung adenocarcinoma cells that carries EGFR and KRAS mutations, respectively, and H520 (PAK1 amplified squamous cell carcinoma). Cell viability assays and western blotting were applied to evaluate the effect of IPA-3 (PAK1 inhibitor) plus auranofin (PKCι inhibitor). Since IPA-3 is only for laboratory use, we explored alternative PAK-1 inhibitor and tested combination effect with auranofin. **Result:** IPA-3 plus auranofin was highly synergistic (Combination index was less than 0.4) in EGFR mutant adenocarcinoma (HCC827), KRAS mutant adenocarcinoma (H23) and SCC with PAK1 amplification (H520) cell lines in MTT assay and colony forming assay. We revealed OTSSP167 (a MELK inhibitor in phase I/II trials) inhibits phosphorylated PAK1 and combination of OTSSP167 plus auranofin showed similar synergism in the 3 cell lines. The combination of auranofin with either IPA-3 or OTSSP167 ablated EGFR phosphorylation and downstream signaling pathways: ERK, AKT, STAT3, YAP1 and inhibited the expression of RTKs: AXL, MET, and CDCP1. **Conclusion:** The combination of IPA-3 plus auranofin is promising treatment in different subclasses NSCLC with driver EGFR or KRAS mutations, as well as SCC with PAK1 amplification. OTSSP167 also works as PAK1 inhibitor. The therapeutic effect of PAK-1 inhibitor and PKCι inhibitor was validated using OTSSP167 plus auranofin.

P2.03-46 PI3K/AKT SIGNAL PATHWAY REGULATES MALIGNANT TRANSFORMATION OF MPLC WITH EGFR-SENSITIVE MUTATION

K. Ma, Y. Cai, X. Wang, Y. Xu, Y. Guo, C. Sun, S. Qiu

The First Hospital of Jilin University, Chang Chun/China

Background: Multiple primary lung cancer (MPLC) is a presumed uncommon entity, but its true incidence, ranging from 0.2% to 8%, is increasing as the result of the widespread use of early detection tools. MPLC displays diverse clinical trajectories and genomic profiles. The in-depth study on the mechanism of malignant transformation of MPLC will provide new ideas for the future treatment of MPLC. **Method:** In this study, we analyse the genomic profiles of 25 tumors and 12 adjacent tissues from 10 patients with MPLC who underwent surgical resection through the whole-exome sequencing (WES). **Result:** Ten patients were enrolled in this study, one patient with different evolutional stages of the same disease (AAH, MIA, and IA) and one patient with completely different pathologies (adenocarcinoma and squamous cancer). Eight patients with different driver genes (EGFR exon 19 deletion,exon 21 L858R mutation and exon 21 L861Q mutation) of lung adenocarcinoma. We observed different mutational landscapes between tumors in the same patient by analyzing somatic mutations, copy number variations, clonal structures, and signal transduction pathways. Most tumors showed significant APOBEC mutant patterns, especially C→T transversions (Figure 1). Moreover, we also found that EGFR exon 19 and 21 mutations enrich different signal pathways. The PI3K/AKT signal pathway is often be enriched in tumors with EGFR exon 19 deletion, which is closely related to the early progression of the tumor. While PTEN kinase activation is associated with EGFR exon 21 L858R mutation (Figure 2). MPLCs with EGFR wild-type may be associated with abnormal regulation of signal pathways, including SOS1, JAK-STAT and others.

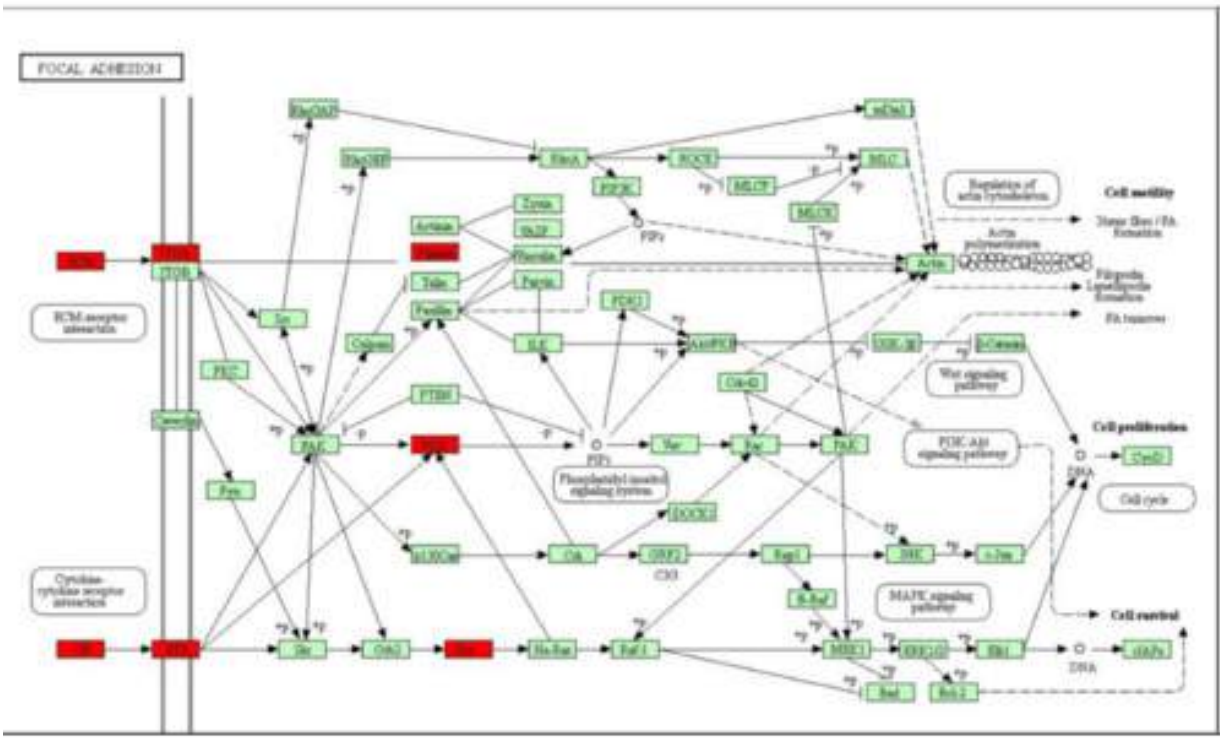
Focal adhesion



L858R

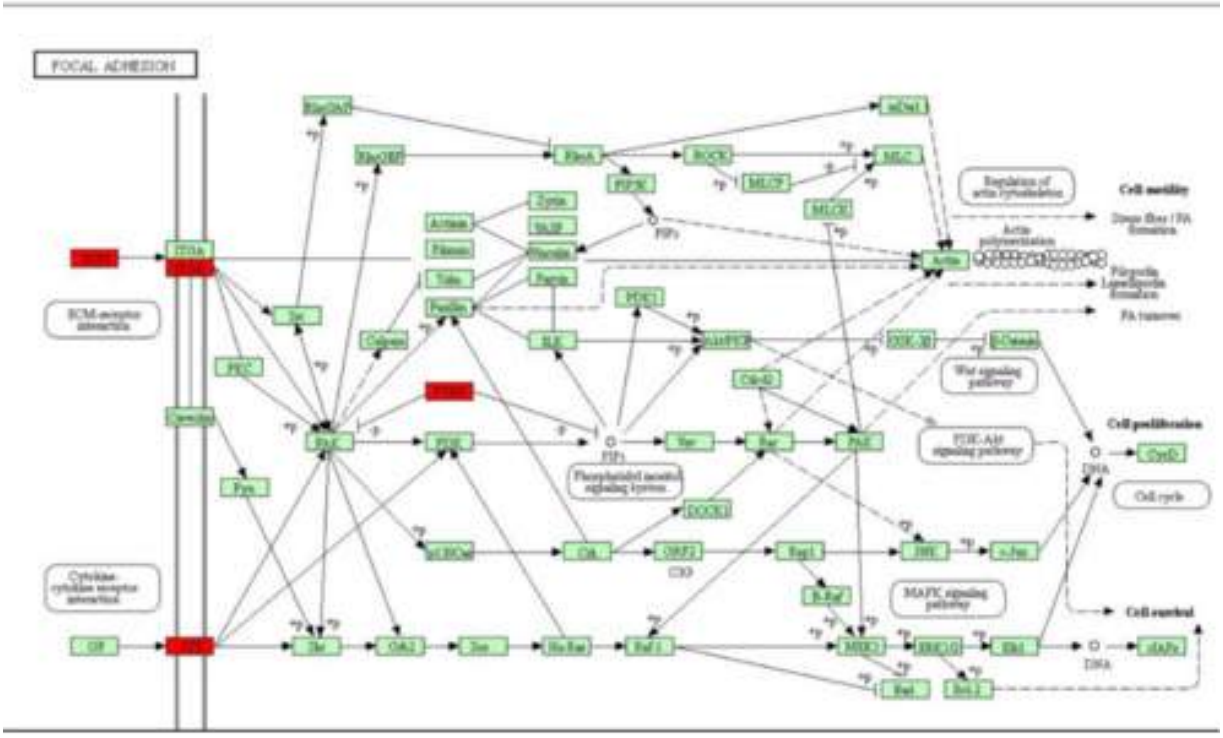


Figure 2. Signal Pathway

Conclusion: This study suggests that the different "gene mutation trajectories" of EGFR exon 19 and 21 mutations are closely related to the genetic heterogeneity of MPLC. Besides that,APOBEC mediated mutations may play an important role in the initial malignant transformation of tumors.

P2.03-47 DEREGULATION OF A NOVEL CIS-ACTING LNCRNA IN NON-SMALL CELL LUNG CANCER MAY CONTROL HMGA1 EXPRESSION

G. Stewart, A. Sage, V. Martinez, K. Enfield, W. Lam

BC Cancer Research Centre, Vancouver/Canada

Background: Since the discovery of long non-coding RNAs (lncRNAs), they have been increasingly implicated in cancer-associated phenotypes. Recently, some lncRNAs have been shown to regulate the expression of neighbouring protein-coding genes, including oncogenes and tumour suppressor genes. High mobility group A1 (HMGA1) is aberrantly expressed in several aggressive cancer types, including non-small cell lung cancer (NSCLC), where high *HMGA1* expression has been associated with poor overall survival and chemotherapy resistance. While *HMGA1* is known to be deregulated in lung cancer, the mechanisms that mediate its expression remain unknown. These lncRNAs, known as *cis*-acting, may represent undiscovered therapeutic action points in cancer driving pathways. Here we investigate the deregulation of a putative *cis*-acting lncRNA in NSCLC, and it's relationship with the oncogene *HMGA1*. **Method:** LncRNA expression was generated from RNA-sequencing data from 36 microdissected tumour and matched non-malignant tissues. Normalized sequence read counts were used to identify transcripts with significantly deregulated expression (Wilcoxon Signed-Rank Test, BH-p<0.05). Validation was performed in sequencing data obtained from The Cancer Genome Atlas (TCGA). SiRNA-mediated knockdown of lncRNA candidates were performed in a non-malignant epithelial lung cell line (BEAS-2B). Quantitative real-time PCR was used to observe the effects of lncRNA knockdown on the expression of neighbouring protein-coding genes. **Result:** Our analyses identified a lncRNA neighbour to *HMGA1*, *RP11.513I15.6*, to be significantly downregulated in 2 cohorts of LUAD samples. Conversely, we found *HMGA1* expression to be significantly overexpressed in LUAD tumours, and was found to be anticorrelated with *RP11.513I15.6.* Additionally while *RP11.513I15.6* decreased with tumour stage, HMGA1 expression increased with stage. *In vitro* experiments demonstrated siRNA-mediated inhibition of *RP11.513I15.6* in immortalized lung epithelial cells resulted in a significant increase in *HMGA1* expression. **Conclusion:** Our results suggest that *RP11.513I15.6* is a novel *cis*-acting lncRNA that negatively regulates HMGA1, and may contribute mechanistically to the maintenance of lung cancer phenotypes. Further characterization of this oncogene regulatory mechanism may uncover a novel therapeutic intervention point for tumours driven by HMGA1.

P2.03-48 TUMOR-DERIVED GRANULOCYTE CHEMOTACTIC PROTEIN 2 COOPERATES WITH PROTEASES TO DRIVE LUNG ADENOCARCINOMA

A.S. Lamort[1], M. Pepe[1], I. Lilis[2], S.A. Weiß[1], K. Arendt[1], G. Ntaliarda[2], M. Spella[2], D. Jenne[1], G. Stathopoulos[2]

[1]*ILBD/CPC Helmholtz Zentrum Munchen, München/Germany,* [2]*University of Patras, Patras/Greece*

Background: Introduction: Lung adenocarcinoma (LADC) commonly arises in the lungs of smokers that are heavily affected by chronic inflammation. Inflammatory signaling from tumor to host cells is critically involved in the pathogenesis of LADC, but the exact mechanisms by which the lung epithelium interacts with the immune system during carcinogenesis are obscure. Objectives: We discovered that murine and human LADC cell lines overexpress the inflammatory and angiogenic CXC chemokine granulocyte chemotactic protein 2 (GCP2, *CXCL6*) compared with normal epithelial cells. GCP2 is processed by immune proteases: neutrophil elastase (NE, *ELANE*), proteinase 3 (PR3, *PRTN3*) and matrix metalloproteinase 9 (MMP9, *MMP9*). We suppose that GCP2 interacts with these proteases to drive LADC and aimed at investigating its function(s). **Method:** GCP2, MMP9 and PR3 expressions were determined by ELISA and immunohistochemistry. Mouse and human microarray data were analyzed using Affymetrix Transcriptome Analysis Console. GCP2 silencing using dedicated shRNA pools (SantaCruz Biotechnology) and NE/PR3 or MMP9 compound knockout mice were used to study GCP2 interaction with immune proteases in LADC progression. **Result:** Murine and human LADC tumors and cell lines overexpress GCP2, MMP9, NE and PR3 at the mRNA and protein levels. GCP2 is sequestered to tumor cells, whereas proteases are produced by tumor-infiltrating immune cells. LADC-secreted GCP2 is incompletely processed and require MMP9, NE or PR3 for full activation and vasoactive effects. Moreover, GCP2-silenced LADC cells injected in mice show a lack in metastasis formation. **Conclusion:** Our results indicate that tumor-originated GCP2 cooperates with immune proteases to drive LADC, providing a paradigm of how the respiratory epithelium coopts the innate immune system during carcinogenesis.

P2.03-49 ROLES OF CENPU IN LUNG ADENOCARCINOMA PROGRESSION AND INVASION

Y. Lou, Y. Zhang, J. Xu, J. Lu, X. Zhang, W. Zhang, H. Wang, B. Han

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Centromere protein U (CENPU), a centromere protein mediating kinetochore-microtubule interaction, is critical for proper cell cycle and mitosis. It has been implicated that CENPU promotes tumorigenesis in variant malignancies. However, roles of CENPU in lung adenocarcinoma progression and underlying mechanisms remain to be elucidated. **Method:** CENPU expression in 90 pair lung adenocarcinoma/adjacent normal lung samples was examined with immunohistochemistry (IHC). Then CENPU expression was inhibited with lentiviral-mediated shRNA strategy in human lung adenocarcinoma cell line H1299 to examine the impact of CENPU knockdown for lung adenocarcinoma progression and metastasis. Cell proliferation, colony formation, cell cycle and cell survival were analyzed by Cellomics cell counting method, colonogenesis assay, PI and Annexin V-APC staining respectively while cellular migration and invasion were determined by cell scratch and transwell test. Furthermore, expression of critical factors involved in epithelial-to-mesenchymal transition (EMT) were determined with western blot. **Result:** CENPU expression was significantly increased in lung adenocarcinomas as compared to adjacent normal lung tissues (fold change=8.54, P<0.0001) (Fig. 1A). Functionl analysis revealed that in human lung adenocarcinoma cell line H1299, CENPU knockdown impaired cell proliferation (Fig. 1B), inhibited colony formation ability (Fig. 1C) and induced cell cycle arrest (Fig. 1D). Additionally, cellular migration and invasion was also inhibited by CENPU knockdown (Fig. 1E-F). It is further shown that E-Cadherin was induced while N-Cadherin and vimentin were inhibited by CENPU knockdown (Fig. 1G), indicating that CENPU was important for EMT process and cancer metastasis.

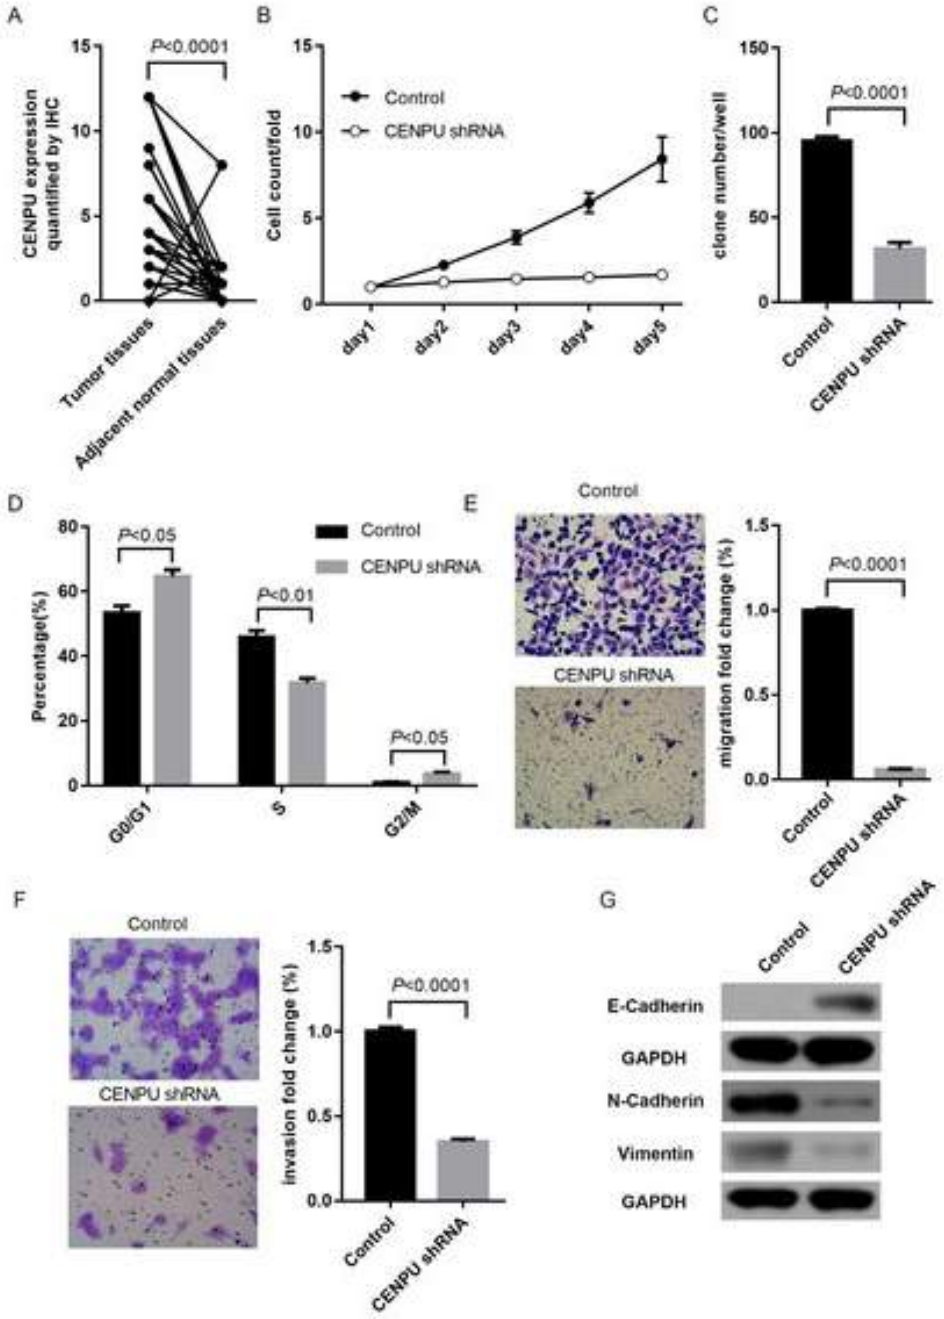

Figure 1 CENPU in lung adenocarcinoma progression and invasion

(A) CENPU status in lung adenocarcinoma and adjacent normal tissues examined through IHC.

(B) Cell proliferation status in H1299 cells with CENPU knockdown.

(C) Colony formation ability in H1299 cells with CENPU knockdown.

(D) Cell cycle status in H1299 cells with CENPU knockdown.

(E) Cell migration ability of H1299 cells with CENPU knockdown examined by transwell assay.

(F) Cell invasion ability of H1299 cells with CENPU knockdown examined by transwell assay (with Matrigel).

Conclusion: It showed that CENPU expression is significantly upregulated lung adenocarcinoma tissue. Functional analysis indicated that CENPU is critical for cell proliferation, survival, migration and metastasis in lung adenocarcinoma cell line H1299. CENPU represents a promising target for lung adenocarcinoma therapy.

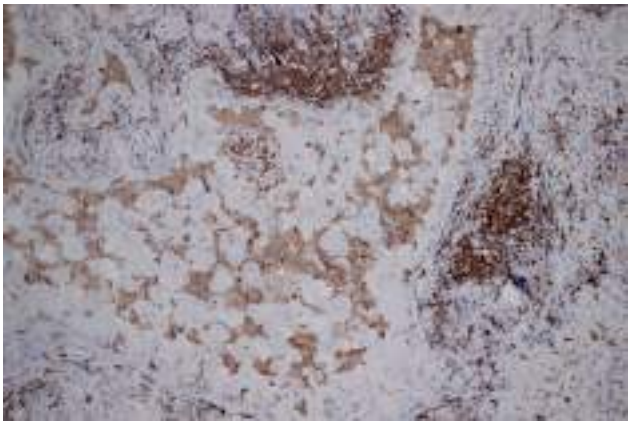
P2.03-50 STROMAL BTK EXPRESSION PREDICTS POOR PROGNOSIS IN NSCLC PATIENTS

W. Liang[1], M. Guo[1], J. He[1], S. Bao[2]

[1]*The 1st Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/China,* [2]*Department of Stem Cell Biology and Regenerative Medicine, Lerner Research Institute, Cleveland/United States of America*

Background: Bruton's tyrosine kinase (BTK) is a kinase that plays a crucial role in B-cell development and widely involves cancer biology. We sought to explore the relationship between BTK expression and NSCLC. **Method:** We firstly used a cohort of 1,249 consecutive NSCLC patients who underwent surgical resection in our center between Apr 2018 and Sep 2018 with fresh tissue to examine the presence of BTK (cohort 1). Another cohort of 681 patients with resected NSCLC between 2009-2014 with stored paraffin sections and survival information were also retrieved to assess the prognostic value of BTK (cohort 2). All samples were stained by IHC for BTK (EPR20445) and PD-L1 (SP142). **Result:** The overall expression rates of BTK expression on tumor and stromal cells were 11.9% and 87.1% respectively in cohort 1, which did not differ across histological types or other clinical features. Both tumoral expression (Chi2=8.84, P<0.01) and stromal expression (Chi2=3.96, P=0.047) of BTK were positively correlated with tumoral PDL1 expression. In cohort 2, we found that the stromal (HR=1.49, P=0.03) but not tumoral (HR=0.74, P=0.20) BTK expression was significantly correlated with poorer prognosis, after adjusting for tumoral PDL1 expression (HR=0.58, P<0.01) and other covariates.



Conclusion: This is the first study showing the presence of BTK expression and its positive correlation with PDL1 expression in NSCLC. Stromal BTK expression predicts poor prognosis in NSCLC patients. This study shed light on the biological effect of BTK-expressing cells and treatment potential of targeting relevant pathways.

P2.03-51 GENE VARIANTS AND EXPRESSIONS OF GALECTIN-3 IS ASSOCIATED WITH NON SMALL CELL LUNG CANCER AND VASCULAR INVASION OF THE TUMOR

S. Terzioglu Usak[1], S. Demirkol[2], C. Horozoglu[3], D. Sönmez[1], İ. Yaylım[1], A. Turna[4]

[1]*Aziz Sancar Institute of Experimental Medicine, Istanbul/Turkey,* [2]*Istanbul Biruni University, Istanbul/Turkey,* [3]*İstanbul Gelisim University, Istanbul/Turkey,* [4]*İstanbul University-Cerrahpaşa, İstanbul/Turkey*

Background: Galectin-3 is a β-galactoside binding protein and known for its deregulation in cancer. In previous studies, correlations between single nucleotide polymorphisms (SNP) and cancer development have been identified in the context of genetic susceptibility to different types of cancer. However, potential phenotypic variations related to galectin-3 SNPs have not yet been evaluated in non-small cell lung cancer (NSCLC). **Method:** In this study, it was aimed to correlate expression levels of gene and protein galectin-3 with genotype and allele distribution of rs4644 and rs4652 SNPs of galectin-3 between NSCLC patients (n=65) and healthy control (n=95) individuals. SNPsrs4644 and rs4652 in galectin-3 were studied using TaqMan Real-Time PCR system. Tissue gene expression levels of galectin-3 for patients was also analysed by Real-Time PCR. Galektin-3 serum levels were measured by ELISA. **Result:** There were no significant differences in genotype and allele distribution of SNPs and galectin-3 gene expression levels between the tumor tissues compared to tumor surrounding tissues (p> 0.05); Mean serum level of galectin-3 was significantly higher in patients (26.05 ± 1.77 ng / ml) than that of controls (11.62 ± 1.30 ng/ml) (p <0.0001). The presence of angiolymphatic invasion was statistically significantly associated with AA genotype (p = 0.04). SNP rs4644 AC/CC genotype was found to be associated with higher serum galectin-3 levels in patients compared to that of controls (p<0.0001) while SNP rs4652 with AA / AC genotype was associated with lower serum galectin-3 levels in controls compared to patients (p<0.0001). Serum galectin-3 level has been shown to be statistically significantly associated with of vascular invasion among patients who had AC genotypes for both SNPs rs4644 and rs4652 (p = 0.03; p = 0.019 respectively). **Conclusion:** Galectin-3 could be defined as a possible biomarker for NSCLC and it plays a role as surrogate marker for vascular invasion in tumors.

P2.03-52 CORRELATION BETWEEN INFLAMMATORY MARKERS AND ONCOLOGICAL OUTCOMES IN SURGICALLY RESECTED NON-SMALL CELL LUNG CANCER

R. Waseda, N. Miyahara, T. Moroga, J.-I. Wakahara, H. Mei, L. Yamamoto, N. Imamura, S. Miyahara, T. Shiraishi, A. Iwasaki

Fukuoka University, Fukuoka/Japan

Background: Various systemic inflammatory factors have been recognized as predictive markers of oncological outcomes in human malignant diseases. Recently, combined scores of inflammatory factors of preoperative peripheral blood have been reported as more sensitive and powerful markers for predicting oncological and survival outcomes in several solid organ malignancies. In the present study, we evaluate the predictive value of various inflammatory parameters for oncologic outcomes in non-small cell lung cancer patients. **Method:** We retrospectively reviewed patients with non-small cell lung cancer undergoing complete resection with pathological nodal evaluation between January 2016 and February 2019 in our department. We assessed the correlation between inflammatory factors including combined parameters from preoperative peripheral blood and pathologic findings expressing oncological invasiveness such as pT3/T4, solid/micropapillary subtype in adenocarcinoma, pleural invasion, lymph node metastasis, and any sort of M factors. The evaluated inflammation-related scores are follows; C-reactive protein (CRP), neutrophils, lymphocytes, albumin, platelets, lactate dehydrogenase (LDH), alkaline phosphatase (ALP), lymphocyte-CRP ratio (LCR), CRP-albumin ratio (CAR), platelet-albumin ratio (PLR), neutrophil-lymphocyte ratio (NLR), lymphocyte-LDH ratio (LLR), albumin-ALP ratio (AAR) and LDH-albumin ratio (LAR). Preoperative carcinoembryonic antigen (CEA) level and maximum standard uptake value (SUV max) of FDG-PET on primary lesions were also evaluated as known predictive markers of oncological outcome in non-small cell lung cancer. **Result:** A total of 306 patients were enrolled in this study. The following data are clinicopathological findings of this cohort; age: 69.5±9.9, gender: male 212, female 94, histology: squamous 64, adeno 230, adenosquamous 4, other 8, solid/micropapillary in adeno 52, pT3/T4 35, positive pleural invasion 75, positive lymph node metastasis 56, positive M factor 1 (dissemination). Results of significant predictive markers are follows (p<0.05, a stronger marker is placed on left side); CRP, CEA, NLR, SUV for pT3/T4, CRP, albumin, LDH, SUV for positive pleural invasion, CRP, CEA, LAR, albumin for pN positive, respectively. No predictive markers were identified regarding histological subtype in adenocarcinoma. **Conclusion:** In non-small cell lung cancer patients, combined inflammatory scores derived from preoperative peripheral blood could predict limited oncological outcomes. Known predictive markers such as CRP, CEA and SUV max on PET-CT reflected the outcomes more strongly.

P2.03-53 IMMUNOPROTEASOME AS A POTENTIAL THERAPEUTIC TARGET IN CISPLATIN-RESISTANT SMALL AND NON-SMALL CELL LUNG CANCER

T. Shoji, E. Kikuchi, J. Kikuchi, M. Maeda, Y. Takashima, M. Furuta, H. Takahashi, I. Kinoshita, H. Dosaka-Akita, J. Sakakibara-Konishi, S. Konno

Hokkaido University, Sapporo-shi/Japan

Background: Cisplatin resistance remains a major problem in the treatment of both non-small (NSCLC) and small cell lung cancer (SCLC). Cisplatin has been reported to cause DNA damages and oxidative stress leading to numerous changes in cell physiology in transcriptional and protein levels. Thus, cisplatin-resistant (CR) cancer cells could alter the proteasome expression to eliminate abnormal proteins induced by cisplatin. Here, we examined the status of proteasomes in CR lung cancer cells and whether proteasomes could be a therapeutic target to overcome cisplatin resistance in lung cancer. **Method:** CR variants were established from three NSCLC cell lines (A549, H1299, and H1975) and two SCLC cell lines (SBC3 and SBC5) in our laboratory. The activity of 20S proteasome core enzyme, the expressions of proteasome subunits, and the sensitivity of immunoproteasome inhibitors, Carfilzomib (CFZ) and PR957, were examined in these CR cells. **Result:** The CR cells showed higher activity of 20S proteasome core enzyme compared with the parent cell counterparts. Quantitative RT-PCR and Western blot analysis revealed that all of the five CR cells had significantly higher expressions of immunoproteasomes, including PSMB8 and PSMB9, while no remarkable changes were observed in the expressions of standard proteasomes. H1299 and SBC3 cells became more sensitive to CFZ and PR957 when acquiring resistance to cisplatin. CFZ induced cell cycle G2/M arrest and apoptosis in CR variants of H1299 and SBC3. **Conclusion:** Immunoproteasome can be a therapeutic target in a portion of cisplatin-resistant both of NSCLC and SCLC.

Keywords: immunoproteasome, proteasome inhibitor, cisplatin

P2.03-54 IMPRINTED GENES PREDICT NON-SMALL CELL LUNG CANCER PROGNOSIS

J. Zhou[1], T. Cheng[2], X. Li[3], X. Wang[3], H. Si[3], P. Zhao[3], R. Yung[4], R. Shen[5], H. Yu[6], S. Lu[7], W. Huang[8], N. Zhou[2], C. Bai[1]

[1]*Zhongshan Hospital/Fudan University, Shanghai/China,* [2]*LiSen Imprinting Diagnostics, Inc., Salt Lake City/United States of America,* [3]*LiSen Imprinting Diagnostics (Wuxi), Inc., Wuxi/China,* [4]*Johns Hopkins University School of Medicine, Baltimore/United States of America,* [5]*Ohio State University Wexner Medical Center, Columbus/United States of America,* [6]*Shanghai Changzheng Hospital, Shanghai/China,* [7]*Zhongshan Hospital, Shanghai/China,* [8]*Nanjing First Hospital, Nanjing/China*

Background: Lung cancer (LC) is the leading cause of cancer mortality worldwide, Significant numbers of stage I/II patients after curative surgery present with recurrent and progressive disease. It is critical to identify additional biomarkers to predict prognosis of early stage NSCLC. In carcinogenesis, epigenetic modifications on imprinted genes are changed and lead to biallelic (loss of imprinting, LOI) and multiallelic (copy number variation, CNV) expression. We present here an epigenetic panel involved in NSCLC prognosis. **Method:** Retrospective study of 123 NSCLC cases with known 5-year survival status. Samples from diagnostic bronchoscopies are subjected to in-situ hybridization targeting non-coding regions to show the expression status of imprinted genes. Total expression (TE), LOI and CNV are counted manually. A statistical model is generated based on the expression status of a 3-imprinting gene epigenetic panel (DCN, PEG10 and SNRPN) to classify the cases. The 5-year survival is used as the only standard for good or poor prognosis. **Result:** The NSCLS cases can be classified into 4 groups by epigenetic panel. In group A with high expression of DCN, 91.2% (31/34) had poor prognosis, including 8 stage I, 6 stage II, 9 stage III and 8 stage IV. In group B with low expression of DCN and high expression of both PEG10 and SNRPN, 75% (6/8) had poor prognosis. In group C with low expression of DCN and low expression of either or both of PEG10 and SNRPN, 39.5% (30/76) had poor prognosis. In group D with no expression of DCN, PEG10 or SNRPN, 100% (5/5) had good prognosis, even when metastatic and recurrent cases are found, their average survival is more than 8 years. **Conclusion:** Imprinting Gene epigenetic panel may provide a quantitative assessment of NSCLC prognosis, and complement standard pathologic staging. This explains the poor prognosis of some early stage ca. The prognostic role may help select individual cases for adjuvant therapies. Further studies with expanded epigenetic panel and larger patient sets are planned to refine the classification algorithm, and identify potential predictive biomarkers for specific therapies to advance personalized lung cancer care.

P2.03-55 HIGH INTEGRIN α3 EXPRESSION IS ASSOCIATED WITH POOR PROGNOSIS IN PATIENTS WITH NSCLC

W. Ma[1], Q. Li[1], E. Tian[1], S. Wei[1], S. Chen[2], C. Zhou[3], T. Wang[3], T. Li[1]

[1]*University of California Davis Comprehensive Cancer Center, Sacramento/United States of America,* [2]*University of California Davis, Department of Public Health Sciences, Davis/United States of America,* [3]*University of California Davis, Department of Pathology, Sacramento/United States of America*

Background: Integrin α3β1 belongs to a family of heterodimeric transmembrane glycoprotein receptors that mediates cell adhesion and cytoskeleton function. We recently showed that integrin α3β1 is a promising novel cancer biomarker and drug target in NSCLC. While the integrin α3 unit (INTA3) mediates the binding to various ligands and substrates, the integrin β1 unit (INTB1) mainly is primarily responsible for the complex biological functions. INTA3 only binds to INTB1 as the binding partner. This study was undertaken to evaluate if INTA3 expression was correlated with clinicopathological parameters and survival in patients with non-small cell lung cancer (NSCLC). **Method:** Tissue microarrays (TMAs) were made from archival formalin-fixed and paraffin-embedded tissue blocks of 161 NSCLC patients, which included 91 adenocarcinoma (LUAD), 46 squamous carcinomas (LUSC), and 24 other histology types. TMA sections were stained for INTA3 expression using anti-integrin α3 antibody (ab131055, dilution 1:100; Abcam) by immunohistochemistry (IHC) stain. Staining intensity was graded as 0 (0-5%, negative), 1+ (6-20%, weak), 2+ (21-50%, moderate), and 3+ (51-100%, strong). Kaplan-Meier curves and log-rank test were used to compare overall survival of IHC score groups. To adjust for covariate imbalance between IHC score groups, propensity-score-weighted Kaplan-Meier curves and weighted Cox models were used. Logistic regression was used to study association between INTA3 expression and patient clinicopathological parameters. **Result:** INTA3 IHC expression was detected in 107/161 (66.5%) of the NSCLC samples. Weak (1+), moderate (2+) and strong (3+) INTA3 expression was detected in 66 (41.0%), 33 (20.5%), and 8 (5.0%) cases, respectively. Kaplan-Meier curves indicated that weak (1+) and strong (3+) INTA3 expression was significantly associated with poor overall survival in NSCLC patients ($p < 0.05$ and $p < 0.001$, respectively). Propensity-score-weighted survival analysis demonstrated that INTA3 IHC expression (1+-3+) was associated with poor prognosis (HR = 1.39, 95% CI: 1.06-1.83, p =0.02) for all NSCLC patients, as well as in subgroups of female patients (HR =1.99, 95% CI: 1.32-3.01, $p < 0.01$), smokers (HR =2.46, 95% CI: 1.66-3.65 $p < 0.01$) and differentiation grade I&II (HR =3.0, 95% CI: 1.91-4.59 $p < 0.01$), but not in LUSC patients (p=0.11), LUAD patients (p=0.07), male patients (p=0.06), non-smokers (p=0.34), differentiation grade III (p=0.98). Logistic regression indicated that high INTA3 expression is associated with no smoke history (OR=2.7, 95% CI:1.3-5.7, p=0.01). **Conclusion:** INTA3 was expressed in the majority of NSCLC by IHC and was associated with poor prognosis. Further study is warranted for targeting integrin α3(β1) in NSCLC.

P2.03-56 POLYMORPHISM ICAM-1 AND BETA-3 INTEGRIN ARE ASSOCIATED WITH THE DEVELOPMENT OF NON-SMALL CELL LUNG CANCER AND THE PROGNOSTIC ROLE OF ICAM-1

H. Fındık Kıyan[1], İ. Yaylım[1], S. Demirkol[2], M. Hakan[1], O. Küçükhüseyin[1], I. Sarbay[3], A. Turna[3]

[1]*Aziz Sancar Institute of Experimental Medicine, Istanbul/Turkey,* [2]*Istanbul Biruni University, Istanbul/Turkey,* [3]*İstanbul University-Cerrahpaşa, İstanbul/Turkey*

Background: Lung cancer is widespread cancer in the worldwide. Non-small cell lung cancer (NSCLC) accounts for 80-85% of all lung cancers. ICAM-1 and β3 integrin have been have been found to be associated with the angiogenesis, tumor growth and metastasis in various tumor types. Our primary aim in this study was to explore gene polymorphisms in ICAM-1 and β3 integrin molecular pathway in NSCLC patients and to clarify whether these values are effective

on the etiopathogenesis and prognosis of the disease. **Method:** Sixty-nine patients with operable (T1-4N0-1M0) NSCLC patients and 120 healthy individuals between January 2012 and June 2018 were included in the study. The tumor samples were taken after resected specimen. Blood samples of the patients were also collected before surgical resection. ICAM-1 and β3 integrin gene polymorphisms were determined by using PCR-RFLP techniques. Also serum ICAM levels were determined by ELISA method. The stages of the tumor were constructed according to 8th staging system. **Result:** There was no statistically significant difference between patient with NSCLC and healthy control groups with regard to β3 Integrin Leu33Pro gene polymorphism(p=0.182). However, in patients with NSCLC, AG genotype frequency and G allele carriers of ICAM K469E variant were found to be higher than the control group and the difference was statistically significant(OR:2,710 95%CI:1,364-5,376; p=0.005). It has been determined that having a G allele increased approximately 2,95 fold the risk of disease and also carrying of AGTC combined genotype increased(OR:2,95 95%CI:1,366-6,373;p=0.049). When patients were evaluated according to tumor stage, serum levels of ICAM-1 gene in early tumor stage was found to be significantly higher than in advanced tumor stage (p=0,013). No significant difference was found between the range of histopathological subtypes and serum ICAM levels (p>0,05). Also, no statistically significant association was found between serum ICAM levels and angiolymphatic invasion (p=0.101, perineural invasion(p=0.054), lymph node metastasis (p=0.585). **Conclusion:** ICAM-1 as an intercellular adhesion molecule seems to play an important role in lung carcinogenesis and it might play a role in the invasiveness of the tumor. However, β-3 integrin was not found to be associated with lung cancer development. The role of ICAM-1 in the genesis of lung cancer as well as immune mechanism should be further investigated.

P2.03-57 THE ROLE OF ARL4C IN THE CARCINOGENESIS PROCESS OF LUNG ADENOCARCINOMA

K. Kimura, S. Matsumoto, E. Fukui, T. Kanou, N. Ose, S. Funaki, Y. Shintani, A. Kikuchi

Osaka Univiersity Graduate School of Medicine, Suita-City, Osaka/Japan

Background: The aberrant activations of EGF / Ras and Wnt / β-catenin signaling are known to be closely involved in carcinogenesis and malignant transformation of various cancers, but the mechanism in carcinogenesis is unknown in detail. The expression of ADP-ribosylation factor (ARF) -like 4c (Arl4c) is induced by the EGF / Ras and the Wnt / β-catenin signalling, and immunohistochemical analyses of tissue specimens obtained from lung adenocarcinoma patients revealed that Arl4c was not observed in non-tumor regions but was strongly expressed at high frequencies in tumor lesions. In addition, the positivity of Arl4c expression was not correlated with the tumor's T grade or N grade. These findings suggest that this protein may be involved in the process of carcinogenesis of lung adenocarcinoma. In this study, we analyzed the role of Arl4c in the carcinogenesis process of lung adenocarcinoma, using immunohistochemical analyses of tissue specimens, and normal human small airway epithelial cell (SAEC) cancer model *in vitro*. **Method:** Using the specimens resected from patients who performed lung resection, Arl4c expression was immunohistochemically examined in Atypical Adenomatous Hyperplasia (AAH), which is a pre-cancerous stage, and relationships between Arl4c expression and clinicopathological characteristics were analyzed. *In vitro*, to establish an immortalized SAEC, we introduced hTERT, CDK4 and DN-p53 to SAEC (SAEC-Triple) with retroviral vector plasmids. Then, we established cell lines stably expressing Arl4c. Using these cells, we assessed the proliferative capacity in a two-dimensional (2D) plastic dish culture and 3D Matrigel culture. In addition, to assess the cell tumorigenic ability, we performed the 2D clonogenic colony formation assay. **Result:** The expression of Arl4c was observed in 22 of 27 patients (81%) with AAH, while Arl4c-positive cells were never observed in the alveolar epithelium of non-AAH region. No significant difference in clinicopathologic characteristics between Arl4c positive and Arl4c negative groups. *In vitro*, Alr4c were transfected into SAEC-Triple and confirmed the expression of these proteins by the western blotting. In 2D culture, there was no significant difference between the cell proliferation capacity of SAEC-Triple with Arl4c and that of SAEC-Triple with control vector. In contrast, when SAEC-Triple were grown in 3D Matrigel, stable expression of Arl4c was remarkably increased sphere areas. In a 2D clonogenic colony formation assay, the number of colonies was much higher in SAEC-Triple with Arl4c compared to SAEC-Triple with control vector ($P < 0.05$). Consistent with these findings, Phosphorylation of Erk1/2 was significantly increased in SAEC-Triple with Arl4c compared with cells expressing control. **Conclusion:** Arl4c expression in AAH lesion indicated that Arl4c involved in the processes of lung carcinogenesis. Arl4c promotes proliferative capacity by activating Phosphorylation of Erk1/2.

P2.03-58 DOUBLE PRIMARY LUNG CANCER AND BREAST CANCER IS A DISTINCT DISEASE ENTITY

E. Lin[1,2], P.-C. Yang[2], Y. Shyr[1]

[1]*Vanderbilt University Medical Center, Nashville/United States of America,* [2]*National Taiwan University Hospital, Taipei/Taiwan*

Background: Double primary lung cancer (LC) and breast cancer (BC) is occasionally observed in clinic. Prior knowledge often attributes increased risks for second primary BC/LC in LC/BC patients to radiation exposure. Our previous study showed that in a 128-patient female Taiwanese double primary LC/BC cohort, 77 (60%) had both cancers diagnosed within 5 years of each other, suggesting the existence of other contributing risk factors. The current study aims to identify characteristics of female double primary LC/BC patients in western-based population. **Method:** The double primary LC/BC cohort was identified from the Vanderbilt BioVU database. Vanderbilt BioVU is a de-identified electronic medical record (EMR)-based biorepository that enables longitudinal EMR study and paired genetic data assessment. **Result:** A total of 65 patients were identified. Among them, 59 (90.8%) were non-Hispanic Caucasians, 5 (7.7%) were African Americans, and one (1.5%) was an Asian. Twelve (18.5%) had their BC and 5 (7.7%) had their LC diagnosed before age 50. Eleven (16.9%) patients were life-long never-smokers, and among them, 4 (36.4%) had their BC and 2 (18.2%) had their LC diagnosed before age 50. Definite disease diagnostic dates were available in 62 patients. Among these, only 18 (29.0%) received radiotherapy for either LC or BC and had two cancers diagnosed beyond 5 years from each other. Among the 50 patients with available data for BC molecular subtypes, 38 (76.0%) were ER/PR-positive and HER2-negative, 4 (8.0%) were ER/PR-positive and HER2-positive, and 6 (12.0%) were triple-negative. All of the HER2-positive patients were never-smokers; one of them had bilateral BC, another had bilateral LC, and the rest two had strong LC family history. Forty-eight (73.9%) patients in this cohort had family cancer history within their first to third-degree relatives. There were BC in 28 (43.1%), LC in 20 (30.8%), colon cancer in 9 (13.9%), hematological malignancies in 9 (13.9%), gynecological cancers in 6 (9.2%), prostate cancer in 5 (7.7%), pancreatic cancer in 4 (6.2%), gastric cancer in 3 (4.7%), esophageal cancer in 2 (3.1%), glioblastoma multiforme in 2 (3.1%) and kidney cancer in 2 (3.1%) patients, respectively. **Conclusion:** Our data showed that female double primary LC/BC is a distinct disease entity, of which hereditary genetic factors may play an important role. In line with our previous study results, radiation exposure may not be the major risk factor for double primary LC/BC. Genomic studies will be of particular importance to unravel the mystery of this unique disease entity.

P2.03-59 THE ROLE OF RADIATION DOSE-DEPENDENT LIPID METABOLISM REPROGRAMMING ON RADIATION SURVIVAL/RESISTANCE IN LUNG CANCER CELLS

X. Zhu, S. Li, L. Wang, Z. Zheng, X. Duan

The Radiation Oncology Department, Nanfang Hospital, Southern Medical University, Guangzhou/China

Background: Radiotherapy plays a more and more important role in the management of lung cancer. However, radioresistance still limits the long-term control of tumors. Exploration of the dynamic changes of metabolic reprogramming in surviving/resistant lung cancer cells exposed to increased doses of radiation is helpful to elucidate the metabolic mechanism of radiation resistance in lung cancer cells, to develop new targets for the clinical intervention and the early detection of radiation resistance. **Method:** Lung cancer cells A549, H520 and H460 were treated *in vitro* with fractionated radiation (2 Gy) to a cumulative total dose of 40Gy, 60Gy or 80Gy.

Cellular radiation sensitivity was verified by colony survival assay and comet experiments. Cell proliferation was determined by EdU assay. Transcriptome sequencing and metabolomic analysis were performed to identify differentially expressed genes and metabolites in radiation-resistant cells and their parental cells. Oil Red O staining was used to detect lipid droplet content. RT-PCR and WB were used to detect the expression of genes related to lipid metabolism. **Result:** Lung cancer cell sublines that had been exposed to 20, 30 or 40 fractions of 2Gy had a significant increase in radioresistance as compared with their parental cells. Furthermore, this radioresistance of cells increased with the increase of previous radiation dose exposure. We found that lipid droplet deposition and the expression of lipid metabolism genes, such as fatty acid oxidation-related genes and glycerol metabolism-related genes, showed an increasing trend with previous radiation dose in surviving/resistant lung cancer cells exposed to radiation. Metabolomic analysis revealed that lipid metabolites such as glycerol and oxaloacetic acid also increased significantly. Inhibition of carnitine palmitoyltransferase 1A (CPT1A) by Etomoxir, a fatty acid oxidation inhibitor, significantly enhanced the radiosensitivity and decreased the DNA repair ability of various surviving/resistant lung cancer cells exposed to radiation. **Conclusion:** The surviving/resistant lung cancer cells generated by sequential irradiation provide models for future investigations of the dose-dependent mechanisms of radioresistance in a preclinical setting. Radiation dose-dependent lipid metabolism reprogramming may contribute to radiation survival/resistance in lung cancer cells. Support: 81572279, 2016J004, LC2016PY016, 2018CR033.

P2.04-01 CHANGES OF BCR REPERTOIRE ARE PREDICTIVE BIOMARKER FOR THE EFFICACY OF IMMUNE CHECKPOINT INHIBITOR IN NSCLC

K. Azuma[1], Y. Nakahara[2], N. Matsuo[1], H. Ishii[1], T. Tokito[1], K. Murotani[3], T. Hoshino[1], T. Sasada[2]

[1]*Kurume University School of Medicine, Kurume/Japan,* [2]*Kanagawa Cancer Center Research Institute, Yokohama/Japan,* [3]*Kurume University School of Medicine, kurume/Japan*

Background: Clonal diversity of T cell receptor (TCR) and/or B cell receptor (BCR) repertoires might play a major role in antitumor immunity in cancer patients. Assessment of TCR and BCR repertoires might enable us to predict the efficacy of immune checkpoint inhibitors (ICI). **Method:** The study population comprised 30 patients with non-small-cell lung cancer (NSCLC), who started treatment with nivolumab (3mg/kg, every two weeks) or pembrolizumab (200mg, every three weeks) between February 2016 and August 2017. Patient blood samples were collected before and four to six weeks after the initiation of treatment. TCR and BCR chain sequences were determined by using the unbiased gene amplification method with Adaptor-Ligation PCR. The diversity of TCR and BCR repertoires was evaluated with inverse Shannon-Weaver index (iSWI). **Result:** We compared the iSWI between before and after treatment. The fold changes of iSWI in BCR repertoire after treatment in patients with PR were significantly higher than those with SD or PD. In contrast, the fold changes of iSWI in TCR repertoire after treatment were not associated with tumor responses. When the cut-off value of fold change of iSWI in BCR repertoire after treatment was determined as 0.85, 25 (83%) and 5 (17%) patients were considered as high and low fold change group, respectively. Progression free survival in the high fold change group was significantly longer compared with that in the low fold change group (182 vs 49 days; 95% confidence interval (CI);99-N.R. vs 31-168 days, respectively; P=0.01). **Conclusion:** Our findings suggest that reduced repertoire diversity in BCR, but not in TCR, might be associated with better clinical outcomes in advanced NSCLC patients treated with ICI. Assessment of the changes of BCR repertoire after treatment might be useful for predicting the efficacy of ICI. The present results require confirmation in a large-scale prospective study.

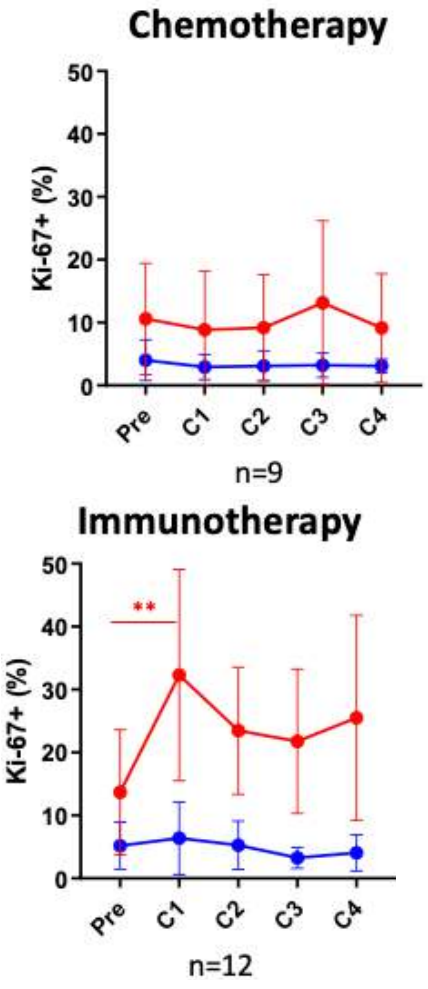
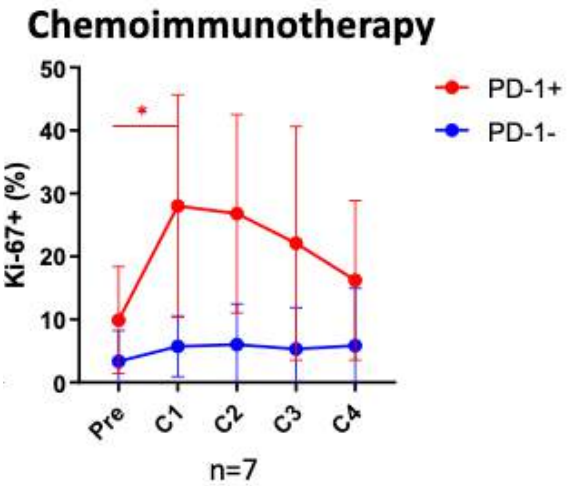
P2.04-02 EFFECT OF CHEMOTHERAPY, CHEMOIMMUNOTHERAPY, AND IMMUNOTHERAPY ON PARAMETERS OF T CELL EXHAUSTION IN METASTATIC NON-SMALL CELL LUNG CANCER

J. Bauml[1], D. Yoon[2], P. Yan[2], S. Katz[3], S. Jeffries[2], C. Davis[4], C. Aggarwal[1], R. Cohen[1], M. Marmarelis[1], A. Singh[1], C. Ciunci[1], E. Wherry[1], S. Albelda[1], C. Langer[1], A. Huang[1]

[1]*Perelman School of Medicine, Philadelphia/United States of America,* [2]*University of Pennsylvania, Philadelphia/United States of America,* [3]*University of Pennsylvania Perelman School of Medicine, Philadelphia/United States of America,* [4]*Perelman School of Medicine, University of Pennsylvania, Philadelphia/United States of America*

Background: The pharmacodynamic immune response to anti-PD-1 immunotherapy can be tracked in the peripheral blood of cancer patients and is associated with response to therapy. However, it is unclear how chemotherapy and chemoimmunotherapy affect T cell activity. Given the established role of these treatments in Non-Small Cell Lung Cancer (NSCLC), we sought to compare the impact of chemotherapy, chemoimmunotherapy, and immunotherapy on T cell immunity. **Method:** We prospectively collected blood samples in pts beginning chemotherapy, chemoimmunotherapy, or immunotherapy for metastatic NSCLC at baseline and with each cycle. Peripheral blood mononuclear cells were stained for immune markers and analyzed using 26 parameter flow cytometry. Immune response was characterized by increased expression of Ki67 on PD-1 expressing CD8 T cells. Statistical analysis was performed using paired t-test or Wilcoxon matched pairs analysis based on normality of data. All patients had CT scans with full RECIST 1.1 and tumor volume measurements. **Result:** We analyzed 28 pts (63% female, median age = 65.5). 9 pts received chemotherapy, 12 pts immunotherapy, and 7 pts chemoimmunotherapy. Both immunotherapy (p = 0.001) and chemoimmunotherapy (p=0.016) resulted in an immune response that peaked at 3 weeks compared to baseline (Figure). No immune response was identified with chemotherapy (p=0.734). Immune response was detected in exhausted T cells (PD1+CD39+ CD8) for both immunotherapy (p =0.007) and chemoimmunotherapy (p =0.031). In addition, chemoimmunotherapy induced activation of CD27+CCR7+ memory CD8 T cells (p=0.0313), not seen with immunotherapy (p= 0.871).





Conclusion: Chemoimmunotherapy and immunotherapy, but not chemotherapy, induced a significant immune response in the peripheral blood, peaking at 3 weeks. While immunotherapy and chemoimmunotherapy both targeted an exhausted population, chemoimmunotherapy induced an immune response in exhausted and memory T cells. We have collected more samples, and at time of the WCLC will present these data, as well as correlation with RECIST responses.

P2.04-03 NIVOLUMAB OUTCOMES IN OCTOGENARIAN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER IN FRENCH REAL-WORLD SETTING

J.-B. Assié[1], F.-E. Cotté[2], M. Giaj Levra[3], C. Calvet[2], R. Jolivel[4], B. Jouaneton[4], A.-F. Gaudin[2], V. Grumberg[5], C. Chouaid[1], R. Corre[6]

[1]*GRC OncoThoParisEst, CHI Créteil, UPEC, Créteil/France,* [2]*Bristol-Myers Squibb France, Rueil-Malmaison/France,* [3]*Centre Hospitalier Universitaire Grenoble Alpes (CHUGA), Grenoble/France,* [4]*HEVA, Lyon/France,* [5]*Grenoble Alpes University, Grenoble/France,* [6]*CHU, Hôpital Ponchaillou, Rennes/France*

Background: Around 10% of patients newly diagnosed non-small cell lung cancer (NSCLC) in France are octogenarian. Knowledge about nivolumab outcomes in such specific population is still limited and real-world data represent a valuable source of information. The aim of this study was to examine use and outcomes of nivolumab in elderly patients aged ≥80 years. **Method:** Based on the National hospitals database (PMSI), we built a retrospective cohort of all NSCLC patients (ICD code: C34*) initiating nivolumab in 2015-2016 in second- or later-line setting and followed them until Dec 2017. Information on patients' baseline characteristics (demographics, comorbidities, treatment history) was retrieved for elderly (≥80 years) and non-elderly (<80 years), and time to treatment discontinuation (TTD) with nivolumab and overall survival (OS) were estimated with Kaplan-Meier methodology. **Result:** Among 10,452 NSCLC patients initiating nivolumab during the inclusion period, 514 (4.9%) were 80 years or over. Mean age at baseline was 82.5 years (±2.4) in elderly and 62.8 years (±8.8) in non-elderly. Compared to non-elderly, patients were more frequently men in elderly group (p<0.001) and had more frequently prevalent hypertension and diabetes (p<0.001). Cerebral metastasis, renal failure, COPD, pulmonary insufficiency and other pulmonary chronic diseases were statistically less frequent in the elderly group (p<0.001). TTD curves showed identical median of treatment duration between both groups (2.8 months). Median OS were found similar between elderly and non-elderly patients (11.5 vs 11.6 months) and, long-term survivals were also comparable with 1-year and 2-year OS rates. Characteristics and outcomes are presented in the table.

Characteristics and outcomes	< 80 years (N=9938)	≥ 80 years (N=514)	p-value
Demographics			
Gender – Male	7019 (70.6%)	401 (78%)	< 0.001
Mean age (±SD)	62.8 y (±8.8)	82.5 y (±2.4)	< 0.001
Median age (Q1-Q3)	64 y (57-69)	82 y (81-84)	< 0.001
Comorbidities			
Hypertension	1844 (18.6%)	142 (27.6%)	< 0.001
Diabetes	871 (8.8%)	63 (12.3%)	< 0.001
Renal failure	460 (4.6 %)	19 (3.7%)	< 0.001
Chronic obstructive pulmonary disease	1298 (13.1%)	50 (9.7%)	< 0.001
Pulmonary insufficiency	149 (1.5%)	4 (0.8%)	< 0.001
Other chronic pulmonary diseases	870 (8.8%)	33 (6.4%)	< 0.001
Cerebral metastasis	1771 (17.8%)	29 (5.6%)	< 0.001
Lung cancer management care			
Diagnosis to nivolumab initiation - Median (Q1–Q3)	12.4 mo (6.7–24.0)	14.2 mo (7.9–29.9)	0.002
Nivolumab TTD - Median (Q1–Q3)	2.8 mo (1.4–6.7)	2.8 mo (1.5–6.5)	N.S.
Nivolumab discontinuation	9120 (91.8%)	473 (92.0%)	N.S.
Subsequent systemic treatment	4908 (53.8%)	210 (44.4%)	< 0.001
Overall survival (OS)			
Median OS (Q1 –Q3)	11.6 mo (4.1-26.2)	11.5 mo (5.0-25.2)	N.S.
1-year OS rate	48.8%	47.5%	N.S.
2-year OS rate	27.3%	25.8%	N.S.
N.S.: non significant ; TTD: time to discontinuation			

Conclusion: A small percentage of patients initiating nivolumab during the study period were aged 80 years or over (<5%). Elderly profile suggests a cautious selection by clinicians, which may also explain similar outcomes than ones in the non-elderly population.

P2.04-04 CITESEQ CHARACTERIZATION IN EARLY STAGE NSCLC PATIENTS IDENTIFIES DISTINCT PATTERNS OF IMMUNE INFILTRATE

A. Leader[1], B. Maier[1], J. Grout[1], C. Chang[1], L. Walker[1], M. Davila[1], A. Lanksy[1], T. Marron[1], R. Flores[1], M.B. Beasley[1], H. Salmon[1], A. Rahman[1], E. Kenigsberg[1], M. Merad[2]

[1]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [2]*Icahn School of Medicine at Mount Sinai, NEW YORK/United States of America*

Background: The success of immunotherapy in late-stage lung cancer patients, together with the need for novel therapies for early-stage disease, mandates an increased understanding of the immune infiltrate in early-stage lesions. Recent advances in sequencing-based single-cell technologies have enabled an unprecedented degree of resolution in the phenotypic characterization of patient tissues. **Method:** Tumor and non-involved lung resection specimens were acquired from 23 early-stage NSCLC patients. Immune cells were isolated and analyzed by single-cell RNAseq (scRNAseq) using the 10X Chromium platform. Resulting expression signatures were clustered using an in-house pipeline. To validate populations and elucidate surface marker staining patterns for transcriptionally-defined cell clusters, we used cellular indexing of transcriptomes and epitopes by sequencing (CITEseq)—using oligonucleotide-conjugated antibodies to simultaneously measure expression of over 50 surface proteins along with transcriptomes of single cells—to analyze tumors from 8 additional patients. To identify T cell phenotypes that were differentially present and clonally expanded within tumor compared to non-involved lung, we paired scRNAseq with T cell receptor repertoire profiling in 3 patients. Finally, to validate the transcriptional phenotypes we detected and to extend our dataset, we incorporated 8 patients from a public dataset, totaling 39 patients included in the study. Immune signatures were correlated with presence of actionable mutations, smoking history, stage, and histology. **Result:** Using these single cell analyses, all major immune cell lineages were identified within tumors, including multiple distinct myeloid and lymphoid subsets, which notably were phenotypically distinct from those isolated from uninvolved lung tissue. Existing databases of ligand-receptor pairs were leveraged to construct an interactome, implicating specific axes of cell-cell communication in driving changes common to tumors. As we hypothesized, correlative analyses across tumor samples revealed a cellular module marked by exhausted T cells, plasma cells, mature dendritic cells, and monocyte-derived macrophages that was enriched in patients with significant smoking histories and *EGFR*^{WT} disease. **Conclusion:** These findings indicate that strong immune differences exist between treatment-naïve lesions, and that these differences stratify with smoking history and smoking-related driver mutations. Given existing literature indicating that positive smoking history confers improved response to immune checkpoint blockade, our data suggests that this disparity may be mediated by set differences in treatment-naïve immune microenvironments. We will now apply this analysis pipeline to tumors treated in the neoadjuvant setting in an ongoing trial (submitted to WCLC in abstract form).

P2.04-05 A RETROSPECTIVE EVALUATION OF PD-L1 EXPRESSION HETEROGENEITY ON PRIMARY NON-SMALL CELL LUNG CANCER AND METASTATIC LYMPH NODES (REPLICA)

A. Bille[1], D. Nonaka[2], P. Taniere[3], E. Willis[4], A. Douiri[5], C. Flach[5], D. Curinga[6], S. Velamuri[6], E. Karapanagiotou[4]

[1]*Guy's Hospital NHS Foundation Trust, London/United Kingdom,* [2]*Guy's Hospital, Rt/United Kingdom,* [3]*University Hospital Birmingham, Birmingham/United Kingdom,* [4]*Guy's Hospital, London/United Kingdom,* [5]*Kings College University, London/United Kingdom,* [6]*MSD UK, London/United Kingdom*

Background: Immunotherapies have changed the treatment landscape in lung cancer. Programmed death ligand (PD-L1) protein which is defined as membranous PD-L1 expression on tumour cells regardless of staining intensity represents a reliable biomarker. The heterogeneity of PD-L1 expression in different sites of disease is unknown; this may have implications on biopsy, staging and potentially treatment choice. The primary objective of this study is to evaluate the relationship between PD-L1 expression in the primary site (lung) and metastatic lymph node LNs N1 and/or N2, in NSCLC. **Method:** Paired samples (lung tumour and hilar/mediastinal LNs) from 300 patients who underwent lung resection and lymphadenectomy for NSCLC, between January 2013 and October 2018, have been collected and analysed for PD-L1 immunohistochemistry expression using the 22C3 pharmDx Agilent assay. PD-L1 stained slides have been reviewed by two pathologists independently, using Tumour Proportion Score in the categories of <1%, 1-49% and >=50%. The agreement between the pathologists was assessed using Kappa statistic, while cross tabulation was used to compare PD-L1 expression and assess association between the primary tumour and involved LNs. **Result:** Of the 300 paired samples 285 have been assessed by pathologist 1 and 300 by pathologist 2. The median age of the patients is 69; 55% were males, 92% had a positive smoking history and 65% had an adenocarcinoma; 50% had hilar involvement only. There was moderate agreement between the two pathologists in PD-L1 assessment in both primary tumour [k=0.40 (95%CI 0.34-0.47)] and LNs [k=0.51(95%CI 0.47-0.59)]. Pathologist 1 and 2 reported 80% and 81% overall agreement between PD-L1 expression classification in the primary tumour and involved LNs respectively. When the primary tumour showed no PD-L1 expression, both pathologists reported no PD-L1 expression in 95% of the paired LNs. When the primary tumour expressed PD-L1 >=50%, pathologist 1 reported 30% of involved LNs showed <1% and 30% showed 1-49% staining, whilst pathologist 2 reported 4 % of involved LN showed PD-L1 <1% and 39% showed 1-49% PD-L1 staining. **Conclusion:** The majority of cases show similar PD-L1 expression between the primary tumour and involved LNs while heterogeneity is present in 20% of cases. Where the PD-L1staining was >=50 in the primary tumour, the majority of involved LNs showed only 1-49% or <1% for PD-L1 expression. These findings may have implications on site of biopsy and management.

P2.04-06 BLOOD-BASED MULTIPLEX KINASE ACTIVITY PROFILING AS A PREDICTIVE MARKER FOR CLINICAL RESPONSE TO CHECKPOINT BLOCKADE IN ADVANCED NSCLC

D. Hurkmans[1], E. Verdegaal[2], R. De Wijn[3], S. Koolen[1], C. Lamers[1], D. Van Den Heuvel[3], J. Groten[3], R. Debets[1], E. Kapiteijn[2], R. Mathijssen[1], S. Van Der Burg[2], J. Aerts[1]

[1]*Erasmus University Medical Center, Rotterdam/Netherlands,* [2]*Leiden University Medical Center, Leiden/Netherlands,* [3]*Pamgene International B.V., 's-Hertogenbosch/Netherlands*

Background: Only a minority of non-small-cell lung cancer (NSCLC) patients benefit from treatment with immune checkpoint inhibitors (ICIs), therefore, there is an urgent need for response prediction. Previously, the potential of using tyrosine kinase activity profiling of baseline peripheral blood mononuclear cells (PBMC) was demonstrated in an analysis with ICI treated advanced melanoma patients [1]. Here, we apply this methodology to evaluate the predictive value for response to ICIs in NSCLC. **Method:** 59 ICI naïve advanced NSCLC patients treated with PD-1 blockade were included in this exploratory analysis of the prospective immuno-monitoring study (MULTOMAB; NTR7015). PBMC were isolated from patient blood samples obtained prior to treatment with ICIs. Kinase phosphorylation signatures of PBMC lysates were measured using a micro-array, comprising of 144 different peptides derived from sites that are substrates for protein tyrosine kinases. Correlation of the profiles with progression free survival (PFS) and overall survival (OS) was analyzed using univariate cox-regression. Predictive multivariate (GLMnet) analysis was performed by binary survival grouping of patients with a cut-off at 140 days for PFS and 365 days for OS. The predictive performance of the models was estimated using cross validation. Multiplex flow cytometry, enumerating 18 immune cell subsets and assessing expression for 28 T cell markers, was performed for a selection of patients to gain additional insight in the immune profile [2]. **Result:** Univariate Cox regression showed significant correlation of phosphorylation signal with PFS for 7 peptides ($p < 0.01$, False Discovery Rate [FDR] = 10%), and with OS for 34 peptides ($p < 0.01$, FDR = 2%). Evaluation of the predictive value of GLMnet models resulted in estimates for the Correct Classification rate (CCR) of 67-70% for PFS and 67-73% for OS. When the cross validated predictions of the models were used to categorize the patients in a *predicted-high-risk* and a *predicted-low-risk group*, this resulted in a significant difference in survival between these groups. The *predicted-low-risk group* displayed significant better median PFS and OS than the *predicted-high-risk group* ([246 vs. 56 days; HR

2.3, 95%CI 1.2-4.7, p=0.02] and [488 vs. 171 days; HR 2.7, 95%CI 1.1-6.6, p=0.03], respectively). **Conclusion:** Similar to melanoma, kinase activity profiles of baseline PBMC samples of advanced NSCLC patients can predict the response to PD-1 blockade. This assay may serve as a predictive biomarker for response to anti-PD-1 therapy. Involvement of immune receptor kinases is being investigated. An independent validation study is underway.

Keywords: NSCLC, kinase activity, immune checkpoint inhibitor

P2.04-07 SURGICAL RESECTION OF ADVANCED LUNG CANCER AFTER A RESPONSE TO EGFR-TKI AND/OR IMMUNOTHERAPY: A SINGLE INSTITUTION EXPERIENCE

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: The usefulness of residual tumor resection after epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) or immunotherapy treatment remains unclear. We describe a single institutional case-series of patients who underwent residual tumor resection after responding to EGFR-TKIs and/or immunotherapy for advanced non-small cell lung cancer (NSCLC) **Method:** Using a prospective database, we reviewed clinical, surgical, pathological, and prognostic data of 15 patients who underwent surgical resection of advanced lung cancer after a response to EGFR-TKI and/or immunotherapy between January 2016 and March 2019. **Result:** There were 10 males and 5 females, all smokers; median age of 58 years (range, 43-72). All patients had T4N2 NSCLC. Five patients received only EGFR-TKI, 6 received EGFR-TKI and immunotherapy, and 4 only immunotherapy. Median time from beginning therapy to surgery was 17 months (range, 6-23). Surgery included 13 lobectomies, one right upper sleeve, and one right pneumonectomy. Lymph node dissection and vascular and bronchial isolation was extremely difficult. Intraoperative morbidity and mortality was nil. Postoperative morbidity was 20% (n=3) and included one bronchopleural fistula, one prolonged air leaks, one atrial fibrillation. Median hospital stay was 6 days (range, 5-15). Pathology showed 6 complete responses (40.0%) (2 after immunotherapy, 4 after EGFR-TKI and immunotherapy) and 9partial responses (60%). Moreover, the area of tumor clearance was characterized by (i) immune activation-dense tumor infiltrating lymphocytes; (ii) massive tumor cell death-cholesterol clefts; and (iii) tissue repair-neovascularization and proliferative fibrosis (each feature enriched in major pathologic responders versus nonresponders, $p<0.05$). With a mean follow-up of 23 months, all patients are alive. **Conclusion:** The timing and validity of a salvage surgery for residual lesions remain unclear when TKIs and/or immunotherapy are offered as first-line therapy to patients with advanced NSCLC. In our cases, surgery was performed with acceptable morbidity. Surgical resection of the residual tumor might contribute to good local control.

P2.04-08 PRELIMINARY EXTERNAL VALIDATION OF THE CLINICAL DEFINITIONS OF RESISTANCE TO IMMUNE CHECKPOINT INHIBITORS IN NON-SMALL CELL LUNG CANCER

E. Gillaspie[1], J. Whisenant[2], L.-C. Huang[1], M. Wharton[1], Y. Shyr[1], L. Horn[2]

[1]*Vanderbilt University Medical Center, Nashville/United States of America,* [2]*Vanderbilt-Ingram Cancer Center, Nashville/United States of America*

Background: Immune checkpoint inhibitors (ICIs) have become an important component of treatment for patients with advanced stage non-small cell lung cancer (NSCLC). Unfortunately, the majority of patients on ICIs will eventually progress. Based on the results from a meta-analysis review of the current ICI literature, Gillaspie et al developed a clinical radiographic response criterion to classify patients as having innate, acquired resistance or durable response to ICIs. The objective of this study was to validate this categorization using prospectively collected clinical data. **Method:** The study population consisted of Stage IIIB and IV, biopsy-proven NSCLC patients from a single institution treated on or off a clinical trial with single agent ICIs in the first, second line or beyond. De-identified tumor data, stage and treatment data long with response to ICIs were collected prospectively into a database. Patients were censored at last date of follow-up if no progression had occurred. Progression-Free survival (PFS) curves and rates were estimated using the Kaplan-Meier method and then compared to the categorization established by the meta-analysis. **Result:** From April 2012 to January 2018, 231 patients met criteria for inclusion and analysis. Median age was 65 years, 61% were male and 92% white. Forty-three (18.6%) received ICI in the first line, while the remaining 188 were treated in the second line or above. Analogous to the meta-analysis, our single center data demonstrated three distinct sub-populations of response. PFS curve slopes were evaluated and compared between the proposed classification and our single center experience (Table 1). The slopes of the curves are similar for the Innate, Adaptive or Acquired Resistance and Durable Response categories established in the meta-analysis. Our single-center experience resulted in a slightly steeper slope in the innate response category compared to the clinical trial literature. This may be explained by our cohort including patients who are treated in the third line or beyond whereas most of the meta-analysis trials restricted populations to either first or second line only. A steeper PFS curve would be expected in a more heavily treated population.

Table 1

	PFS Slope Meta-Analysis	PFS Slope Validation
Innate Resistance	12.9	14.0
Aquired Resistance	3.8	3.4
Durable Response	1.2	1.1

Conclusion: This single center assessment of the proposed classification for resistance to immune checkpoint inhibitors in non-small cell lung cancer confirms the three distinct subgroups of response based on a comparison of the PFS curves. A formal statistical validation will be performed and presented. Future studies are planned to include prospectively collected data from additional comprehensive cancer centers within the validation cohort.

P2.04-09 IMMUNE-RELATED ADVERSE EVENTS IN ADVANCED NON-SQUAMOUS NSCLC PATIENTS TREATED WITH UPFRONT CHECKPOINT INHIBITORS COMBINATION

A. Sultan[1], K. Thein[1], S. Swarup[1], N. Jahan[1], A. Tun[2], S. Meda[1], M. Arevalo[1], T. Naing[3], T. Htut[4], N. D'Cunha[1], S. Awasthi[1], S. Rehman[1], L. Tijani[1], F. Hardwicke[1]

[1]*Texas Tech University Health Science Center, Lubbock/United States of America,* [2]*Brooklyn Hospital Center, New York/United States of America,* [3]*Icahn School of Medicine at Mount Sinai, New York City/United States of America,* [4]*Colchester Hospital University NHS Foundation Trust, UK), Essex/United Kingdom*

Background: Immune-related adverse events (IRAE) are a unique set of adverse events caused by checkpoint inhibitors due to enhanced activation of the immune system. IRAEs can virtually affect any organ system and have been responsible for significant morbidity, treatment delay, treatment discontinuation, and even death. We undertook a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of IRAEs when checkpoint inhibitors were utilized as first-line in combination with chemotherapies in non-squamous non-small cell lung cancer (NSCLC) patients. **Method:** We systematically conducted a literature search using PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019. Phase 3 RCTs that mention IRAEs as adverse effects were incorporated in the analysis. Mantel-Haenszel (MH) method was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q -statistic. Random effects model was applied. **Result:** 2785 patients with advanced non-squamous NSCLC from 5 RCTs (Keynote – 021,189, IMpower – 130, 132 and 150) were eligible. The study arm used standard chemotherapy regimens in combination with pembrolizumab or atezolizumab while control arm utilized only standard chemotherapy regimens. The randomization ratio was 2:1 in IMpower-130 and Keynote-189 studies and 1:1 in other studies. The RR of all-grade side effects were as follows: hypothyroidism, 3.82 (95% CI: 2.14 – 6.80, p < 0.0001); hyperthyroidism, 2.58 (95% CI: 1.32– 5.04; p = 0.005); pneumonitis, 2.62 (95% CI: 1.58– 4.32; p = 0.0002); hepatitis, 3.75 (95% CI: 1.23 – 11.50, p = 0.02); colitis, 4.82 (95% CI: 1.67– 13.90; p = 0.004); and pancreatitis, 2.35 (95% CI: 0.75–7.41; p =0.14). The RR of high-grade side effects were as follows: hypothyroidism, 2.93 (95% CI: 0.62 – 13.74, p = 0.17); hyperthyroidism, 2.32 (95% CI: 0.37– 14.71; p

= 0.37); pneumonitis, 1.65 (95% CI: 0.80– 3.41; p = 0.18); hepatitis, 4.14 (95% CI: 1.05 – 16.33, p = 0.04); colitis, 3.31 (95% CI: 1.02– 10.77; p = 0.05); and pancreatitis, 1.44 (95% CI: 0.29– 7.13; p = 0.65). **Conclusion:** Patients on combined chemoimmunotherapy experienced a significant increase in all grades of hepatitis and colitis with a relative risk of 4.14 for grade 3 and 4 hepatitis. They also contributed to all-grade hypothyroidism, hyperthyroidism and pneumonitis. These toxicities have significant impact on patients' quality of life, ultimately affecting patients' compliance. A timely intervention with proper supportive care is necessary.

Background: PD1/PDL1 treatments have become the main therapy in advanced stages of NSCLC due to its significant increase in overall survival (OS), but recently, combination with chemotherapy in locally advanced stages is showing promising results. Many studies have described peripheral blood immune cells parameters as biomarkers of response to immunotherapy. In our study, we described the effect of neo-adjuvant chemo-immunotherapy treatment in Complete Blood Count (CBC) and Peripheral Blood Mononuclear Cells (PBMCs) phenotype, as well as, the association of these parameters with the degree of pathological response. **Method:** Immune cell populations of 46 resectable stage IIIA NSCLC patients treated with neo-adjuvant chemo-immunotherapy from NADIM clinical trial were analysed. Samples were extracted before initiating the neo-adjuvant treatment with nivolumab plus carboplatin and at the third cycle before patients underwent surgery. We classified patients in 3 subgroups of pathological response assessed in the resection specimen: complete response (pCR), major response (<10% viable tumour) and incomplete response (>10% viable tumour, pIR). Wilcoxon and Mann-Whitney U statistic test were used to evaluate differences between pre and post treatment and between pathological responses groups respectively. **Result:** From 46 patients, 5 patients did not undergo surgery, so they were excluded from the analysis. Absolute numbers of Leucocytes, Eosinophil, Monocytes, Neutrophils, Haemoglobin and Platelets from hemograms were significantly reduced after neo-adjuvant treatment. However, no changes were observed for Lymphocytes, Basophils, LDH levels or the Lung Immune Prognostic Index (LIPI). Additionally, post-treatment Neutrophil-to-Lymphocyte (NLR), Myeloid-to-Lymphoid lineage (M:L) and Platelets-to-Lymphocytes (PLR) ratios were decreased. Remarkably, from all the CBC absolute numbers and ratios, only PLR variation showed differences between pCR and pIR. On the other hand, percentages of PBMCs (T cells, B cells, NK cells and macrophages) did not vary after neo-adjuvant treatment, however activation of CD4 T cells and NK cells as well as PD-1 receptor expression on immune cells were downregulated after neo-adjuvant chemo-immunotherapy. Interestingly, these variations correlate with pCR. **Conclusion:** In our study, PLR, PD-1 expression, CD4 T cells and NK cells activation are predictive biomarkers of response to treatment. Thus, a higher decrease on PLR post neo-adjuvant treatment is associated to pCR. Moreover, a decrease of PD-1 expression in CD4, CD8 and NK cells, as well as, a reduction of CD4 T cells and NK cells activation after neo-adjuvant treatment, are associated to pCR.

Background: Resistance develops in most non-small cell lung (NSCLC) patients treated with anti-PD-1/anti-PD-L1 based immunotherapy. CVA21 is an oncolytic coxsackie virus that targets ICAM over-expressing tumour cells. Pre-clinical models suggest that CVA21-induced tumour lysis may enhance the clinical efficacy of the anti-PD-1 antibody Pembrolizumab by inducing immune cell infiltration in patients that lack an immune cell rich tumour microenvironment. Previously, the Keynote 200 trial of CVA21 combined with Pembrolizumab reported an ORR of 23% in immunotherapy-naive NSCLC. We report the efficacy of Pembrolizumab in combination with CVA21 in a preliminary cohort of eight pre-treated NSCLC patients with secondary resistance to prior anti-PD-1/anti-PD-L1 therapy. **Method:** On progression of prior therapy, IV CVA21 ($1x10^9$ $TCID_{50}$) was administered on days 1, 3, 5, 8, then Q3W for 6 months, in combination with Pembrolizumab (200mg IV from day 8, then Q3W for up to 24 months). Repeat biopsies were mandated prior to cycle 2 of Pembrolizumab. Tumour measurements were calculated using immune-related RECIST. PD-L1 was tested on pre- and post-treatment biopsies using SP-263 (Ventana) and reported using the tumour proportion score (TPS). **Result:** The majority of patients were female (n=7, 88%), median age 65 years (range 55-75), seven (88%) current or former smokers, five (63%) with 3+ lines of prior treatment, and only 1 anti-PD-1/anti-PD-L1 naive. Two patients were KRAS mutant, the remaining were wild type for EGFR, ROS1, ALK and BRAF. Two (25%) partial responses (PR) were observed, both in anti-PD-1/anti-PD-L1 pre-treated patients. Both responders were continuing at data cut-off, 240 and 120 days since commencement. Two achieved SD (overall clinical benefit 50%) and 3 were non-evaluable (1 early non-treatment-related death, 3 awaiting first scan). Early PD at 56 days occurred in the anti-PD-1/anti-PD-L1 naive patient (n=1). In the two PRs, PD-L1 TPS was 25% and 60% respectively. Preliminary IHC staining of paired biopsies showed an increase in PD-L1% in 2 (33%) evaluable patients at 21 days. PD-L1 TPS ranged from <1% to 80% in pre-treatment biopsies, but was not predictive of response or benefit from combination therapy. An increase in PD-L1 was associated with a trend toward longer disease stability (median 147 days). Combination treatment was well-tolerated with no observed G4/5 TRAE's. **Conclusion:** Intravenous CVA21 in combination with pembrolizumab demonstrated encouraging clinical activity in patients who had progressed on prior anti-PD-1/anti-PD-L1 therapy, regardless of PD-L1 levels.

P2.04-12 PH I TRIAL OF CONCURRENT OR SEQUENTIAL IPILIMUMAB, NIVOLUMAB, AND SBRT TO MULTIPLE SITES IN PATIENTS WITH STAGE IV NSCLC

J. Patel, M. Jelinek, C. Bestvina, S. Pitroda, E. Vokes, S. Chmura

University of Chicago, Chicago/United States of America

Background: Despite the promise of immunotherapy for the treatment of advanced NSCLC, only a fraction of patients experience significant benefit from immunotherapy alone. Previous studies have shown that SBRT can stimulate innate and adaptive immunity to potentially augment immunotherapy. In addition, SBRT is used in patients with limited metastatic disease as consolidative approach, showing an improvement overall survival when compared to systemic treatment alone. Combining immunotherapy with ablative therapy is being studied by a number of investigators. While many

of these pre-clinical and clinical studies are promising, timing of immunotherapy with SBRT has not be formally studied. Further, few of these studies have addressed treatment of multiple sites of disease and little is known about what molecular changes occur in the tumor microenvironment immediately after ablative therapy. This trial is designed to evaluate the safety and efficacy of the combination of nivolumab (N) and ipilimumab (I) plus sequential(S) or concurrent(C) SBRT in patients with stage IV NSCLC. **Method:** This is a single-center phase I, open-label, two-arm, randomized platform trial. Eligible patients include those with stage IV NSCLC with ≥2 metastatic lesions that meet criteria for SBRT (0.2 cc to 65 cc of viable tumor, larger tumors able to be partially treated up to 65 cc). Eligible patients are simultaneously accrued on arm I (S) and arm II (C) in a 1:1 ratio. Participants in arm I complete SBRT to 2-4 sites followed by initiation of N/I 1-7 days after completion of SBRT. Participants in arm II are treated with N/I within 24-48 hours of SBRT with required SBRT completion to 2-4 sites within two weeks (prior to the second dose of N). Protocol therapy consists of treatment with N 3mg/kg every 2 weeks and I 1mg/kg every 6 weeks for a maximum of 24 months. The primary endpoint is dose-limiting toxicity defined as a >33% rate of grade ≥3 toxicity. DLT is defined as any grade ≥3 toxicity possibly, likely, or definitely related to SBRT plus N/I (the combination and not the individual components). Secondary endpoints include response rate and progression free survival at 6 months, control rate of treated lesions and non-treated lesions, and comparison of efficacy and toxicity between the arms. Biopsies and blood draws performed pre- and post-SBRT will facilitate molecular correlative studies including investigation of changes in the immune microenvironment induced by the two approaches. **Result:** Current enrollment includes 27 of the 40-80 participants: 15 patients are enrolled on arm 1 (sequential) and 12 patients are enrolled on arm 2 (concurrent). SBRT safety cohorts, to which patients can contribute to more than one, include the following: central lung (n=20), peripheral lung (n=7), abdominal (n=5), osseous (n=9), and liver (n=5). All patients have paired pretreatment and posttreatment biopsies of at least one irradiated lesion. 79% of post-ablative biopsies are suitable for DNA/RNA sequencing. **Conclusion:** Section not applicable

Background: Previous studies have shown that Interleukin-18 (IL-18) suppresses the growth of lung cancer. IL-18 might restore natural killer cell-mediated immunosurveillance against MHC class I-deficient tumors and enhance the therapeutic effects of cancer immunotherapy. However, whether there is a causal influence of higher IL-18 protecting against lung cancer remains unknown. We aim to explore whether genetically predicted circulating level of IL-18 is associated with lung cancer through 2-sample Mendelian randomization (MR) analysis. **Method:** We obtained the summary data for significant single-nucleotide polymorphisms (SNPs, P<5×10−8) associated with serum IL-18 from a genome-wide association study of 8293 healthy adults. Their associations with lung cancer and its histological subtypes were evaluated in the International Lung Cancer Consortium (ILCCO, 11348 lung cancer cases, and 15861 controls) applying Inverse variance–weighted (IVW) meta-analysis, Weighted-median analysis, Mendelian randomization–Egger regression, Simple mode method, and Weighted mode method. We also performed several sensitivity analyses to evaluate the potential violation of MR assumptions. **Result:** Genetically predicted IL-18 level is associated with lower risk of lung cancer (Odds ratio [OR] per 1 standard deviation (SD) increase: 0.824, 95% confidence interval (CI) 0.762-0.890, p<0.001). Similar trends were shown in the histological subtypes of lung cancer: lung adenocarcinoma (OR per 1 SD increase: 0.816, 95%CI 0.708-0.941, p=0.005) and squamous cell lung cancer (OR per 1 SD increase: 0.883, 95%CI 0.787-0.990, p=0.034). Our sensitivity analyses also showed that there was no directional pleiotropy bias and horizontal pleiotropy bias. Table 1. Mendelian randomization estimates of associations of genetically predicted circulating IL-18 and lung cancer and its histological subtypes using different analysis methods.

Variants	Outcome	Method	OR	95%CI	*P* value	Heterogeneity *p*†	MR-Egger intercept *p*‡
IL-18	Lung cancer	IVW	0.824	0.762-0.890	<0.001*	0.868	
		MR Egger	0.964	0.750-1.239	0.787	0.976	0.251
		Weighted median	0.823	0.748-0.906	<0.001*		
		Simple mode	0.826	0.714-0.955	0.042*		
		Weighted mode	0.826	0.727-0.938	0.026*		
IL-18	Lung adeno-carcinoma	IVW	0.816	0.708-0.941	0.005*	0.216	
		MR Egger	1.137	0.752-1.720	0.568	0.372	0.159
		Weighted median	0.840	0.713-0.989	0.036*		
		Simple mode	0.807	0.622-1.046	0.156		
		Weighted mode	0.827	0.663-1.032	0.144

		MR Egger	0.791	0.557-1.123	0.247	0.765	0.545
		Weighted median	0.927	0.803-1.070	0.301		
		Simple mode	0.919	0.736-1.146	0.480		
		Weighted mode	0.939	0.765-1.153	0.572		

*: *P* value < 0.05; IVW: inversevariance weighted; OR: odds ratio; CI: confidence interval.

Conclusion: Genetically predicted higher IL-18 is causally associated with lower lung cancer risk, indicating that IL-18 might have the potential to be used clinically to protect against lung cancer. Additional work is warranted to confirm the causality and underline the potential mechanisms.

Background: Clinical evidence suggests a possible predictive role of Neutrophil-to-Lymphocyte ratio (NLR), derived Neutrophils/(leukocytes minus neutrophils) ratio (dNLR) and Platelet-to-Lymphocyte ratio (PLR) in different tumors, including non-small cell lung cancer (NSCLC) treated with immune checkpoint inhibitors (ICI). **Method:** In this Italian multicenter retrospective trial NLR, dLNR, PRL fluctuations were analyzed in patients with stage IV NSCLC treated with ICI. Those rates were assessed at baseline, before the second, third and fifth cycles. In patients still on treatment, samples were collected also at 1 and at 2 years from ICI start. The primary objective was the relationship between baseline ratios and response to ICI, through the identification of different cut-offs estimated using ROC curves. **Result:** Data of 402 patients receiving ICI (antiPD1 91%, antiPDL1 7% and antiPDL1 plus antiCTLA-4 2%) were analysed: 287 (71%) were males, median age was 65 (39-86 yrs-old), 84 patients (21%) were on first line treatment. The most common histology was adenocarcinoma (62%) and 95% of patients had an ECOG performance status of 0-1. One hundred and eleven (30%) patients were using steroids in permissive doses for ICI. Disease control rate (DCR) was observed in 228 patients (58%) with 95 (24%) reporting an immune objective response. Median progression free survival was 5,3 months and the median overall survival was 9,6 months, after a median follow-up of 9,6 months (range 4,0-13.0). Basal NLR, dNLR and PRL were predictive of response (p=0.0002, p=0.0003 and p=0.0304, respectively). Best response categories were dichotomized in Response (SD + PR + CR) versus no Response (PD). With this classification, the differences were more pronounced and statistically significant for basal NLR and dNLR (p=0,045 and p=0,004, respectively). The cut-off values for basal NLR and dNLR were defined (BLNLR=2,46; BLdNLR=1,61) to identify patients most at risk of "non Response" through the ROC curves. Confounding factors were assessed using logistic regression models (age, gender, smoking). During treatment, an increase in the values was observed at the time of progression, both for NLR (average variation: -1.57) and for dNLR (average variation + 0.32), even if the statistical significance is limited to NLR (p = 0.041). **Conclusion:** NLR, dNLR and PLR are independent factors of response to ICI. Compared to the present literature data, this study highlights that NLR ratio may predict progressive disease earlier than radiological restaging.

P2.04-15 ASSOCIATION BETWEEN OPIOIDS AND OUTCOME OF 1ST LINE IMMUNOTHERAPY IN ADVANCED NSCLC PATIENTS: A RETROSPECTIVE EVALUATION

P. Bironzo[1], D. Pignataro[1], M. Audisio[2], M. Tagliamento[1], C. Paratore[1], F. Tabbò[1], M. Bungaro[1], C. Zichi[1], M. De Filippis[1], S. Rapetti[1], V. Cetoretta[1], S. Carnio[1], A. Mariniello[1], L. Buffoni[1], G. Lacidogna[2], M. Di Maio[2], S. Novello[1]

[1]*University of Turin; San Luigi Gonzaga Hospital, Orbassano/Italy,* [2]*Medical Oncology, Ordine Mauriziano Hospital, Torino/Italy*

Background: Opioids represent the pharmacological backbone of cancer-related pain treatment. However, preclinical studies suggest that opioids can cause immunosuppression. Recently, immune checkpoint inhibitors (ICIs) have become available for treatment of patients with advanced NSCLC. With this study we aimed at retrospectively evaluate the impact of chronic opioid treatment on the outcome of advanced NSCLC (aNSCLC) patients treated with first-line ICIs. **Method:** We retrospectively reviewed the records of aNSCLC patients treated with anti-programmed-death-1 (PD-1) or its ligand (PD-L1) single-agent ICIs in 2 Italian institutions. We included all patients with enough follow-up to have at least one radiological evaluation during ICIs treatment. Patients with rapid clinical progression were included in the analysis. We analyzed response rate (RR), progression-free survival (PFS), and overall survival (OS). Response was evaluated using RECIST v1.1 criteria. **Result:** 75 patients were found, 64 included in the analysis. Mean age at diagnosis was 66.5 years (range 37-84), 65% were male. Histological type were: 76.5% adenocarcinoma, 14% squamous, 9.5% others, most with high PD-L1 expression (90.5% with ≥50% TPS). 58 patients (90.6%) were stage IV at ICIs start, with mean number of metastatic sites 1.8. Most patients were current/former smokers (87.5%); ECOG performance status (PS) at ICI start was: 0 in 34 pts (53.1%), 1 in 25 (39%), 2 in 5 (7.9%). 20 patients were receiving opioids at ICIs start (31.3%), with a mean daily dose equal to 59 mg of oral controlled-release morphine. With a median follow-up of 10.9 months, the median number of ICIs cycles was 7.5 (range 1-26). RR, mPFS and mOS in the whole series were 40.6%, 9.4 months and 17.1 months, respectively. Compared to the others, patients receiving opioids had numerically lower RR (30% vs 45.5%, p=0.24), a shorter PFS (median 12.7 vs 1.7 months, Hazard Ratio [HR] 4.16, 95%CI 2.15-8.05, p<0.001) and OS (median not reached vs 3.2 months, HR 4.68, 95%CI 2.09-10.52, p<0.001). At the multivariate analysis, opioid use continued to be significantly associated with worst PFS (HR 3.19, 95%CI 1.45-7.01, p=0.004) and OS (HR 4.16, 95%CI 1.61-10.76, p=0.003), even when accounting for PS, disease stage and number of metastatic sites. **Conclusion:** Our results suggest a possible detrimental effect of opioids in aNSCLC patients treated with first line single-agent ICIs, even when correcting for other prognostic factors. However, due to the short follow-up, the small number of patients, and the lack of a control group, our results should be considered exploratory.

P2.04-16 NOVEL CT BASED RADIOMIC FEATURES ARE PROGNOSTIC AND PREDICTIVE OF BENEFIT OF CHEMOIMMUNOTHERAPY IN ADVANCED NON-SQUAMOUS NSCLC

P. Patil[1], M. Khorrami[2], A. Zagouras[1], K. Bera[3], P. Fu[3], A. Gupta[3], V. Velcheti[4], N. Pennell[1], A. Madabhushi[3]

[1]*Cleveland Clinic, Cleveland/United States of America,* [2]*Case Western University, Cleveland/United States of America,* [3]*Case Western Reserve University, Cleveland/United States of America,* [4]*NYU Langone Cancer Center, New York/United States of America*

Background: Carboplatin, pemetrexed and pembrolizumab (C/P/P) is currently approved for patients with advanced non-squamous carcinoma of the lung (NS-NSCLC) based on superior survival outcomes noted in KEYNOTE-189. Since clinical benefit was observed across all PD-L1 expression categories, there are currently no robust predictive biomarkers that can identify subsets of patients likely to derive benefit from this regimen. We sought to evaluate whether radiomic features extracted from within and outside the nodule on pre-therapy CT scans could predict response to C/P/P. **Method:** We retrospectively identified 52 patients with stage IV NS-NSCLC who received C/P/P. Of these, 6 were excluded because of non-evaluable thoracic lesions. Lung tumors were contoured on 3D SLICER software by an expert reader. Textural and shape radiomic features were extracted from intra/peritumoral regions using MATLAB® 2018b platform (Mathworks, Natick, MA). The primary endpoint of our study was RECIST response and secondary end point was overall survival (OS). A linear discriminant analysis classifier (LDA) was used to predict response across 100 iterations of threefold cross validation in the dataset. Performance of classifier on response was measured by area under receiver operating characteristic curve (AUC). To build the multivariate radiomic signature for OS, least absolute shrinkage and selection operator (LASSO) Cox regression model was used and a risk score was computed according to a linear combination of selected features. Patients were divided into high-risk or low-risk groups based on median risk score. **Result:** The top five radiomic features (intra/peritumoral textural patterns) predictive of response to C/P/P were identified by mRMR feature selection method. LDA classifier using these features could discriminate responders from non-responders with an AUC of 0.77 ± 0.05. The radiomic risk score was calculated using a linear combination of top six selected features from LASSO with corresponding coefficients. In a multivariate Cox proportional hazards model using a combination of clinicopathologic and radiomic features, the radiomics signature

was found to be significantly associated with OS (averaged on 100 iteration of CV) (HR 10.42; 95% CI: 4.18-26; P = 4.92e-07). Kaplan-Meier survival analyses according to the radiomics signature risk-score showed significantly worse survival in the high risk category. **Conclusion:** Textural features within and outside the nodule on pre-treatment CT images of patients with NS-NSCLC treated with C/P/P were predictive of responses and OS. Additional validation of these quantitative image-based biomarkers in independent cohorts is warranted.

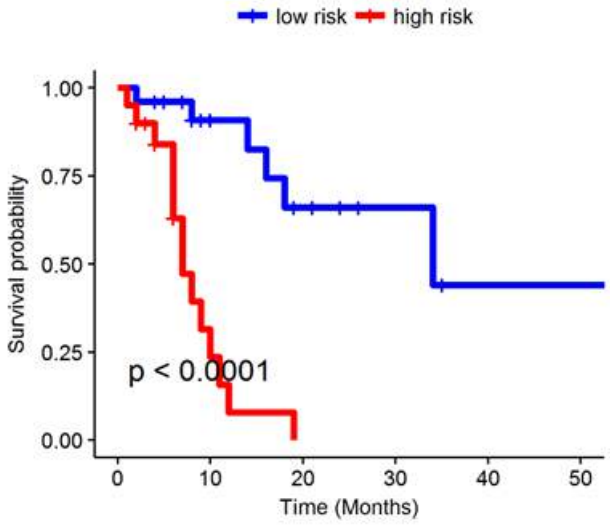

Figure: Kaplan-Meier survival analyses of patients (N = 46) with NS-NSCLC treated with C/P/P using the radiomics signature risk-score.

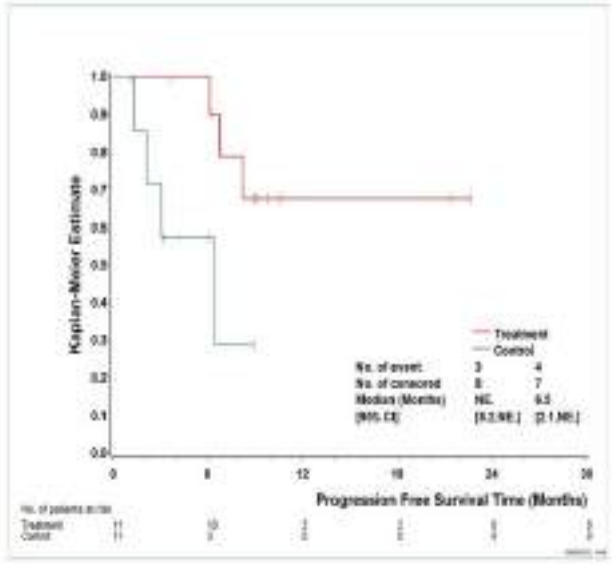
P2.04-17 IMMUNE REPERTOIRE IS A POTENTIAL PREDICTIVE BIOMARKER FOR EVALUATING THE EFFICACY OF MUTANT NEOANTIGEN SPECIFIC T CELL COMBINED WITH PD1 ANTIBODY

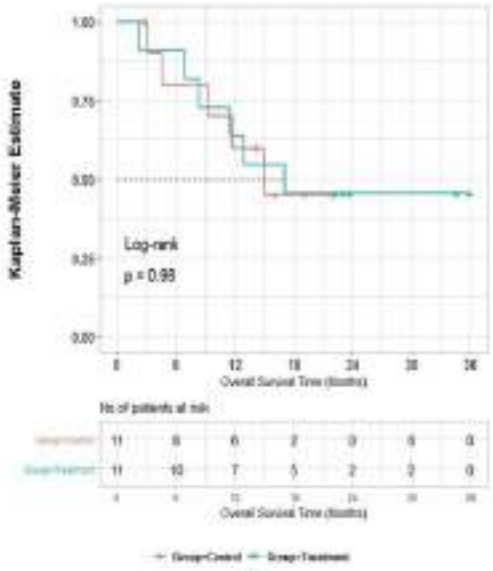
Q. Song[1], J. Li[2], T. Zhang[3], Z. Zhou[3], Y. Song[3], S. Sun[1], B. Qin[1], J. Wang[1], L. Zhang[1], X. Zhang[1], D. Wang[1], M. Chen[1], J. Li[2], S. Jiao[1]

[1]*The General Hospital of People's Liberation Army, Beijing/China,* [2]*Geneplus-Beijing Institute, beijing/China,* [3]*Beijing DCTY Biotech Co.,Ltd., Beijing/China*

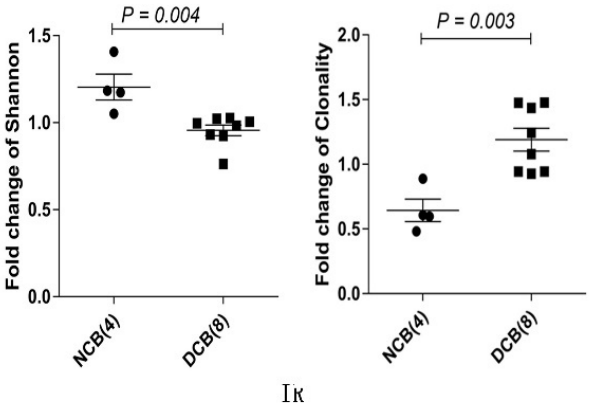
Background: The efficiency of PD1 monoclonal antibody used alone is not satisfactory. The therapeutic method of solid tumor with mutant neoantigen specific T (Nas-T) cell developed in this study is an adoptive cell therapy which is specific for each patient. Our previous research has proved that Nas-T can prolong patients' PFS with a good safety. We aim to further explore the effect of Nas-T on OS and to evaluate the characteristics of immune repertoire (IR) as a predictive biomarker. **Method:** A total number of 12 patients with advanced solid tumors who failed after multiline treatments were recruited. They were treated with Nas-T cells, PD1 antibody and BSC; other 11 patients were treated with PD1 inhibitors and BSC as control. Peripheral blood was collected at baseline and per cycle (21-28d) respectively. Immunosequencing of the CDR3 regions of human TCRβ chains was used to detect IR. T-cell diversity and clonality for each IR was calculated. To quantitatively evaluate the consistency of the infused T-cell repertoires during the therapy, we adopted the Morisita overlap index (MOI), which considers the composition and the abundance of T-cell rearrangements. MOI ranges from 0 to 1, with 1 indicating identical TCR repertoires and 0 indicating completely distinct TCR repertoires between two samples. **Result:**



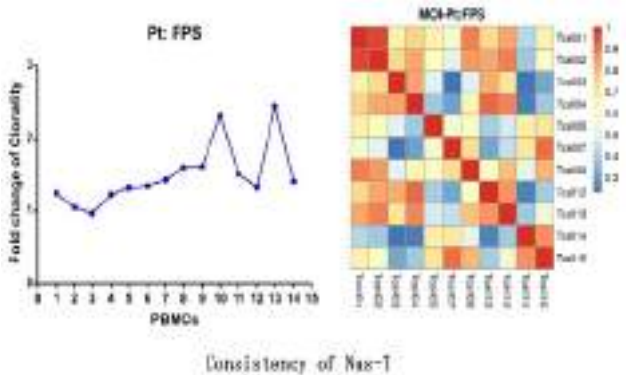
PFS



OS



IR



Updated data showed there was no statistical significance in OS (P>0.05), which may be related to the small sample size and short follow-up time. Compared to baseline, T-cell repertoire of NCB and DCB after 1st cycle displayed significant changes: Shannon 0.96 vs 1.20, P=0.004; Clonality 1.20 vs 0.64, P=0.003. Elevated Clonality may indicate expanded tumor-specific T-cells which could recognize mutant neoantigen specifically. MOI result for one patient, for example, exhibited a good consistency among each batch of infused Nas-T. **Conclusion:** The combined immunotherapy of mutant Nas-T cell and PD1 antibody is more effective than PD1 antibody alone in prolonging PFS, but has no effect on OS. IR Clonality change shows its potential as a predictive biomarker.

P2.04-18 ANALYSIS OF PATIENT MICROBIOME AND ITS CORRELATION TO IMMUNOTHERAPY RESPONSE AND TOXICITY IN LUNG CANCER

J. Chau, M. Yadav, M. Furqan, N. Cady, K. Mercer, E. Eastman, T. Abu-Hejleh, G. Clamon, S. Shahi, Q. Dai, Y. Zakharia, R. Garje, C. Chan, G. Weiner, A. Mangalam, J. Zhang

University of Iowa Hospitals and Clinics, Iowa City/United States of America

Background: In recent years, attention has shifted to modification of tumor responses to immunotherapy, potentially via the host microbiome. The mechanisms of this association, causative or consequential, remain incompletely understood. We seek to explore this further with a longitudinal study of lung cancer patient microbiomes, outcomes and toxicities preceding and during immunotherapy. **Method:** Patients with lung cancer (LC) treated with immunotherapy (anti-PD-1/L1 agents including pembrolizumab, nivolumab, atezolizumab and durvalumab) with or without chemotherapy at the University of Iowa were consented for this ongoing study. Subjects from November 2018 – February 2019 were included in this report. Nasal and buccal swabs, as well as stool samples were obtained prior to therapy in compliance with institutional regulatory guidelines. Patients were treated and monitored per respective disease protocol; responses were recorded per RECIST 1.1 criteria, and toxicities graded per CTCAE 5.0. Samples underwent DNA extraction followed by 16S rRNA metagenomic analysis and taxonomic profiling using Divisive Amplicon Denoising Algorithm (DADA)-2 pipeline. The microbiome from all body sites were compared. LC gut microbiomes were also compared to fecal samples provided by healthy control residents (HC), as well as patients with other malignancies such as renal clear cell (RCC). This project is registered in clinicaltrial.gov (NCT03688347). **Result:** Gut microbiota was significantly different compared to oral and buccal microbiota in all patients. Gut microbiota from 16 LC patients were compared to 8 HC samples. LC patients exhibited drastically different baseline microbiota composition at both the phylum level, including dramatic increases in Firmicutes, Actinobacteria and Verrucomicrobia, and significant decreases in *Bacteroidetes*, *Proteobacteria* and *Cyanobacteria*. We noticed a clear inversion of Firmicutes/Bacteroidetes ratio between HC and LC patients, differences also reflected at the genus level. Interestingly, gut microbiome from 5 RCC patients was strikingly different from HC but exhibit high concordance with those from LC. LC patients who experienced immunotherapy-related toxicities were found to have at baseline markedly more *Anaerostipes* and *Eggerthella* relative to HC, and fewer Lachnospira. **Conclusion:** Our study found promising trends in microbiome constitution whose evaluation will benefit from a larger subject pool as we continue to accrue patients. Compared to HC, we found significant differences in baseline LC gut microbiome at phylum and genus levels, and notable differences when comparing LC patients who suffered immunotherapy-related toxicities to those with none. Our project marks an important first step in a long-term study that could shed new light on the microbiome's influence on immunotherapy treatment outcomes.

Background: Recent success using immune checkpoint blockade (ICB) in the metastatic setting has raised the need to understand the immune microenvironment (IME) in early-stage disease. Moreover, pre-clinical evidence suggests that cytotoxic agents can modulate this IME. A recent study conducted by our group showed that non-small cell lung cancer (NSCLC) patients who received neoadjuvant chemotherapy followed by surgery (NCT), as compared to patients who received upfront surgery (US), had higher densities of $CD3^+$ lymphocytes and $CD68^+$ tumor-associated macrophages (TAMs). $CD3^+CD4^+$ lymphocytes and TAMs also correlated with better clinical outcomes. In this study, we explored the relationships between NCT and the IME by harvesting tumor samples of multiple surgical NSCLC cohorts. **Method:** The PROSPECT microarray database was queried in NCT (n=45) and US (n=200) patients to investigate differentially expressed genes related to immunogenic cell death (ICD), susceptibility to $CD8^+$ T cell and NK cell cytotoxicity, priming of antigen presenting cells, immunosuppressive enzymes and intra-tumoral cytokines. Available data from the ImmunogenomiC prOfiling of NSCLC (ICON) and other surgical NSCLC cohorts was evaluated to determine: 1) differential immune profiling using FACS (NCT=17; US=39) and multiplex IHC imaging (NCT=10; US=72); 2) plasma circulating cytokines (NCT=18; US=73); 3) tumor mutational burden (TMB) (NCT=40; US=61). Participants who received NCT or US were excluded according to these criteria: 1) concurrent treatment in addition to NCT; 2) sarcomatoid and small cell histologies; 3) clinical or pathological TNM Stage 4 disease; 4) synchronous malignancies other than lung. **Result:** PROSPECT NCT patients expressed increased damage-associated molecular pattern (DAMP) genes (HSPA2, HSPA4, HSPE1, and S100A2; $p<0.05$) and T cell-related chemotaxis and antigen presentation genes (CXCR7, CD1A; $p<0.05$). Concordantly, the ICON cohort FACS results showed that NCT patients display increases in: 1) infiltration of $CD8^+$ T cells ($p=0.004$); 2) proliferating $Ki67^+CD8^+$ T cells ($p=0.02$); 3) tissue resident memory $CD8^+CD103^+$ ($p=0.02$) and $CD4^+CD103^+$ non-T_{reg} cells ($p=0.01$). Trends from the ICON multiplex IHC also highlighted increases in $CD8^+$ T cells ($p=0.09$), $CD20^+$ cells ($p=0.08$), as well as $PD\text{-}L1^+$ malignant cells ($p=0.08$) and $PD\text{-}L1^+$ TAMs ($p=0.08$) in NCT patients, the latter finding being supported by increased circulating MCP-1 ($p=0.03$). TMB was similar between NCT and US groups ($p=0.912$). **Conclusion:** Our data provides the first evidence of ICD (i.e., increased DAMP gene expression) following NCT in human early-stage NSCLC. Furthermore, our data highlights the association of NCT with a favorable IME (i.e., increased T cell infiltration), supporting the rationale of NCT and ICB combinations in localized NSCLC.

P2.04-20 TP53/KMT2C CO-MUTATION AS A NOVEL BIOMARKER FOR IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER PATIENTS

Q. Zhou[1], X. Peng[1], W. Wang[2], W. Wang[2], L. Zhang[2], K. Wang[2], S. Zhang[2]

[1]*Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [2]*OrigiMed, Shanghai/China*

Background: Immune checkpoint inhibitors (ICIs) have shown remarkable antitumor effects in non-small cell lung cancer (NSCLC), however only a subset of patients respond. Genomic alterations (GAs) detected by targeted next-generation sequencing (NGS) is increasingly used in clinical practice, but its correlation with recognized immune biomarkers and predictive value for ICIs response in NSCLC is unclear. **Method:** FFPE tumor and matched blood samples of 637 NSCLC patients (84 squamous cell and 553 non-squamous cell) were collected for targeted NGS panel sequencing from December 2017 to January 2019. GAs including single nucleotide variations, short and long insertions/deletions, copy number variations and gene rearrangements were assessed. TMB high (TMB-H) was defined as ≥10 muts/Mb. Positive PD-L1 expression was defined as ≥1% of tumor cells with membranous staining (22C3/28-8, DAKO). Genomic data and ICIs treatment outcome from a 240 NSCLC patient cohort was derived from cBioPortal (MSKCC, J Clin Oncol 2018). **Result:** In 637 NSCLC patients, the prevalence of PD-L1≥1% was 26.5% and the median TMB was 4.6 muts/Mb (IQR, 2.3-10). Recurrent *TP53*, *KRAS*, *LRP1B* and *KEAP1* mutations were significantly correlated with higher TMB (p value). *TP53*, *KRAS* and *KEAP1* mutations were significantly enriched in the TMB-H/PD-L1+ subset while *STK11* mutations were enriched in TMB-H/PD-L1- subset (p value). *KMT2C*, also known as *MLL3*, belongs to the mixed-lineage leukemia (MLL) family of histone methyltransferases and its GAs was found in 5% of our cohort. Tumors with *KMT2C* and *TP53* co-mutations (co-MUT) had a significantly higher TMB (15.1 muts/Mb) than *TP53/KMT2C* single-MUT (8.7 muts/Mb) and *TP53/KMT2C* co-WT (3.1 muts/Mb) tumors. Moreover, TMB-H/PD-L1+ subset was enriched in *KMT2C* and *TP53* co-MUT (25%) comparing to *TP53/KMT2C* single-MUT (14.7%) and *TP53/KMT2C* co-WT (3.3%) tumors. Survival analysis from public clinical trials confirmed that patients with *TP53/KMT2C* co-MUT had remarkable clinical benefit to ICIs in both progression free survival (PFS) and durable clinical benefit (DCB). The median PFS was 7.3, 4.2 and 2.5 months for *TP53/KMT2C* co-MUT, *TP53/KMT2C* single-MUT and *TP53/KMT2C* co-WT patients, respectively (p=0.0032). *TP53/KMT2C* co-MUT was an independent variable of PFS (*TP53/KMT2C* co-MUT vs. *TP53/KMT2C* co-WT, HR: 0.47, 95%CI: 0.25-0.89, p=0.0199). Furthermore, *TP53* with *KMT2C* or *KRAS* co-MUT expanded the patient population benefiting from ICIs (mPFS = 7.2 months, p=0.00042; DCB = 51.2%, p= 0.0195). **Conclusion:** This study provides evidence that *TP53/KMT2C* co-MUT may serve as a predictive biomarker for ICIs in NSCLC. GAs detected by targeted NGS could illuminate insight for immunotherapy.

P2.04-21 SERUM CRP DECREASE HAS PREDICTIVE VALUE FOR LONG-TERM DISEASE CONTROL BY PD-1/ PD-L1 INHIBITORS IN PATIENTS WITH NSCLC

R. Matsuzawa[1], M. Morise[1], I. Tanaka[1], J. Koyama[1], T. Kimura[2], Y. Kondoh[2], T. Hase[1], K. Sakamoto[1], N. Hashimoto[1], Y. Hasegawa[1]

[1]*Nagoya University Hospital, Nagoya/Japan,* [2]*Tosei General Hospital, Seto-City/Japan*

Background: Several studies showed the predictive or prognostic value of systemic inflammatory markers such as C-reactive protein (CRP) in patients with non-small cell lung cancer (NSCLC) treated with PD-1/PD-L1 inhibitors. In OAK study, serum CRP decrease at 6 weeks from baseline was associated with the favorable clinical efficacy of atezolizumab, a PD-L1 inhibitor. However, the result is not validated in the clinical practice setting including patients treated with anti PD-1 antibodies. The aim of this study is to investigate the significance of serum CRP change from baseline as a biomarker in NSCLC patients treated with PD-1/PD-L1 inhibitors. **Method:** The current study is a retrospective cohort study. NSCLC patients treated with anti-PD-1/PD-L1 inhibitors in 2nd or later line setting were reviewed at Nagoya University Hospital and Tosei General Hospital. Patients were divided into two groups by serum CRP change (Group 1; patients with serum CRP decrease at 6 weeks by >= 33% compared to the baseline, and Group 2; the others except Group 1). **Result:** From January 2016 to September 2018, 124 advanced or recurrent NSCLC patients were enrolled. 34 (27.4%) patients were divided into Group 1 and 90 (72.6%) were into group 2, respectively. Group 1 showed statistically significant higher objective response rate compared with Group 2 (38.2% vs 7.0%, p< 0.01), and longer progression-free survival (PFS) (1-year PFS rate: 34.2% vs. 11.7%, HR of group 1 to group 2: 0.63 (95%CI: 0.39-0.98), p=0.04). Multivariate analysis also identified the CRP decrease as an independent favorable factor of PFS (adjusted HR of group 1 to group 2: 0.45 (95%CI: 0.26-0.77), p< 0.01). In contrast, PFS and OS were similar between the patients treated with PD-1 and PD-L1 inhibitors. **Conclusion:** Serum CRP decrease at 6 weeks from baseline would have predictive value for long-term disease control by PD-1/PD-L1 inhibitors for NSCLC in the clinical practice setting.

P2.04-22 PROGRAMMED DEATH 1-MRNA EXPRESSION PREDICTS BENEFIT TO ANTI-PD1 MONOTHERAPY IN A PROSPECTIVE COHORT OF ADVANCED NSCLC

C. Teixido[1], C. Cabrera[1], A. Rodríguez[1], A. Arcocha[1], T. Pascual[1], A. Gimenez-Capitan[2], E. Marin[1], R. Reyes[1], C. Aguado[2], A.I. Martinez-Muñoz[1], N. Viñolas[1], B. Oñate[1], D. Martinez[1], M.A. Molina-Vila[2], A. Prat[1], N. Reguart[1]

[1]*Hospital Clinic Barcelona, Barcelona/Spain,* [2]*Pangaea Oncology, Barcelona/Spain*

Background: Immunotherapy (IO) targeting PD1 or PD-L1 represents a new treatment option for patients (pts) with advanced non-small cell lung cancer (NSCLC). Besides PD-L1 IHC, other predictive biomarkers are being explored as potential predictors of outcomes. Our group has recently described an association between *PD1*-mRNA expression and response to IO in a retrospective multi-tumor dataset (*Annals Oncol 2018*). We aimed to corroborate these results in a prospective cohort of advanced NSCLC. **Method:** We prospectively evaluated the expression of 7 immune-related genes (*CD4, CD8, PD1, PDL1, IFNG, GZMM* and*FOXP3*) and 5 housekeeping genes in formalin-fixed paraffin-embedded tumor samples obtained before anti-PD1 therapy using the nCounter platform (Nanostring Technologies). The study cohort included consecutive pts with advanced NSCLC, ECOG/PS 0-1, no targetable oncogenes, treated in the first or second-line setting with anti-PD1 monotherapy from June 2017 to January 2019. Associations between the expression of *PD1* mRNA (as a continuous variable and using a previously defined pre-specified cutpoint) and response (complete and partial response) were assessed using logistic regression analysis. Kaplan-Meier method was used for survival analysis. PD-L1 IHC tumor cell expression was assessed using the 22C3 clone. Pearson correlation between PD-L1 IHC and *PD1* mRNA was explored. **Result:** A total of 43 pts were included (men 79%; adenocarcinoma 53%; nivolumab 55%; pembrolizumab 45%; first-line 30%; second-line 70%). Response occurred in 23% of pts and was significantly associated with *PD1* (p=0.029) and *FOXP3* (p=0.035) expression. Using the pre-established *PD1* cutoff (*Annals Oncol 2018*), 37% and 63% samples were *PD1*-high and *PD1*-low, respectively. *PD1*-high was significantly associated with increased overall response rate (ORR) (43% *vs* 11%, OR=6.22 [CI=1.31-29.44], p=0.021) and progression-free survival (HR 0.36 [CI= 0.14-0.90], p=0.028) but not with overall survival (p=0.117). PD-L1 IHC expression was available in 35 cases, of which 46% had high (>=50%) expression levels. A moderate concordance (0.49) was observed between PD-L1 IHC and *PD1*-mRNA. In this subset analysis, high PD-L1 IHC was significantly associated with response (50% *vs* 11%, OR=8.50 [CI= 1.45-49.53], p=0.043). Importantly, when combining predefined high/low-sets for both biomarkers (PD-L1 IHC/*PD1*-mRNA), response was significantly increased in PD-L1-high/*PD1*-high compared to PD-L1-low/*PD1*-low (ORR 58% *vs* 0%, p=0.019). **Conclusion:** *PD1*-mRNA expression is associated with response to anti-PD1 monotherapy and can increase the predictive ability of PD-L1 IHC. Further validation of these findings in pivotal clinical trials evaluating IO in advanced NSCLC pts seems warranted.

P2.04-23 TUMOR-STROMA INTERACTIONS PROMOTE CGAS-STING DRIVEN INFLAMMATION IN LUNG TUMOR MICROENVIRONMENT

M. Campisi[1], S. Sundararaman[2], S. Kitajima[2], I. Canadas[2], V. Chiono[1], R. Kamm[3], D. Barbie[2]

[1]*Politecnico di Torino, Torino/Italy,* [2]*Dana-Farber Cancer Institute, Boston/United States of America,* [3]*Massachusetts Institute of Technology, CAMBRIDGE/United States of America*

Background: The tumor stroma is an essential component of the tumor microenvironment (TME) and has critical roles in promoting resistance to immunotherapies. Most anticancer therapies target cancer cells specifically, however, it is important to also study signaling contributions from the TME. The recruitment of immune cells following intratumoral administration of Stimulation of Interferon Genes (STING) agonists in the TME is a critical event in the cGAS-STING-driven antitumor immune response, a pathway with great relevance in the context of cancer immunotherapy. Towards this, the infiltration of immune cells rely on functional vasculature to infiltrate into the tumor tissue. We have previously demonstrated that LKB1 mutation is associated with suppression of tumor cell STING levels due to mitochondrial dysfunction and reduced production of T-cell chemoattractants such as CXCL10 in KRAS-driven non-small cell lung cancer (NSCLC). Consistently, immunohistochemical staining of patient samples showed poor infiltration of CD3, CD4, and CD8 T cells into LKB1 negative versus LKB1 intact cancer epithelium, and instead, retention of T-cells in stroma. **Method:** 3-D microfluidic device was fabricated using cyclic olefin polymer (COP) at AIM BIOTECH. NCI-H1355 cells were cultured for 24h in ultra low-attachment culture plates for spheroid formation. To form the 3D tumor microvascular model, cancer spheroids, human lung fibroblasts (hLFBs) and human umbilical vein endothelial cells (HUVECs) were resuspended in an extracellular matrix-like fibrin/collagen gel and loaded into the central channel and cultured for 7 days and hydrated with culture medium (Vasculife, lifeline). Cytokine profiling (Human Cytokine 40-plex panel) was performed with media collected from 3D culture. **Result:** To examine how LKB1 alters immune cell recruitment, we used a 3-D microfluidic co-culture system to study interactions between vasculature and tumor spheroids derived from a KRAS/LKB1 mutated (KL) cell line with LKB1 reconstitution +/- STING deletion. Co-culturing tumor spheroids and vasculature, we identified changes in morphology, cytokine production, and gene expression that occur during the co-culture. We found that co-culture induced cooperative production of multiple immune cell chemo-attractants such as CXCL10, CCL2, CCL5, and G-CSF (Fig.1b,c). Interestingly, this more physiologic ex vivo tumor model of LKB1 reconstitution revealed particularly strong cooperative production of STING-dependent cytokines such as CXCL10 in the vasculature. Moreover, knocking down STING in the LKB1-reconstituted cancer cells did not significantly attenuate production of CXCL10 and other cytokines in co-culture, suggesting that tumor/vasculature interaction may promote STING activation in the vasculature regardless of cancer cell-intrinsic STING function. Furthermore, although there was no appreciable response after treatment of KL cancer cells with cGAMP based STING agonists, treatment of isolated 3-D vascular networks with cGAMP enhanced vascular permeability and increased production of CXCL10 and CCL5, possibly contributing to defective chemokine gradients that retain T cells near the vasculature. **Conclusion:** Developing these more complex models that incorporate 3-dimensional tumor and self-assembled microvasculature may elucidate important aspects of cGAS-STING biology in KL lung cancer microenvironment, and may ultimately aid further development of effective immunotherapies targeting this signaling pathway.

P2.04-24 TRANSCRIPTIONAL PROFILING OF NEOANTIGEN SPECIFIC T CELLS IN RESECTABLE NSCLC TREATED WITH NEOADJUVANT ANTI-PD-1

J. Caushi[1], Z. Ji[1], J. Zhang[1], M. El Asmar[1], V. Anagnostou[1], T. Cottrell[1], H.Y. Chan[1], H. Guo[1], T. Merghoub[2], J. Wolchok[2], J. Naidoo[1], K. Marrone[1], J. Chaft[2], M. Hellmann[2], E. Gabrielson[1], J. Taube[1], J. Brahmer[1], V. Velculescu[1], N. Zhao[1], P. Forde[1], D. Pardoll[1], H. Ji[1], S. Yegnasubramanian[1], K. Smith[1]

[1]*Johns Hopkins University, Baltimore/United States of America,* [2]*Memorial Sloan Kettering Cancer Center, New York/United States of America*

Background: Neoadjuvant nivolumab has a manageable safety profile and can be effective in patients with resectable non-small cell lung cancer (NSCLC). To characterize the immune response in these patients, we sought to evaluate the existence and dynamics of neoantigen specific tumor-infiltrating T cells and identify their molecular phenotype including co-inhibitory checkpoint expression. **Method:** We evaluated peripheral blood and tumor infiltrating lymphocytes from seven patients treated with nivolumab. To identify neoantigen-specific T cell responses, we used MANAFEST (Mutation Associated Neoantigen Functional Expansion of Specific T cells), an assay we developed that links antigen specificity with unique CD8+ TCR Vβ CDR3 identities. We then carried out single cell TCRseq/RNAseq of tumor infiltrating T lymphocytes (TIL) to enumerate the genome wide digital gene expression and T cell clonotypic identity of each single cell (VDJ+DGE analysis), and particularly those with Vβ CDR3 regions identical to those identified as neoantigen-specific by MANAFEST. **Result:** Neoantigen-specific TCRs were detected in peripheral blood in all 3 patients with major pathologic response (MPR) and in 3 of 4 patients without MPR. Several of these clonotypes were found in the resected tumor and underwent peripheral expansions upon PD-1 blockade. In one notable patient, MD043-011, MANAFEST detected a T cell clonotype specific for a *CARM1* R208W mutation, despite this patient having no evidence of pathologic response. This neoantigen-specific clonotype represented 3.4% of TIL. Two years later, this patient recurred with a solitary brain metastasis. Single cell analyses of TIL in the primary lung lesion and brain metastasis revealed the same neoantigen-specific T cell clonotype was detected in the metastatic lesion. Strikingly, this clonotype exhibited a differential expression profile in the primary and recurrent lesion, with the clonotype in the primary tumor having an enrichment and upregulation of heat shock proteins indicating molecular stress and the clone in the metastatic lesion having an upregulation of checkpoint molecules, including CTLA4, TIM3, and LAG3. T cell cloning and validation experiments, as well as identification of transcriptional programs associated with MPR, are ongoing. **Conclusion:** The coupling of MANAFEST with single cell VDJ+ DGE analysis enabled us to characterize antigen specific clonotypes after differential expansion using the TCR as a molecular barcode. The presence of alternate co-inhibitory immune checkpoints on neoantigen-specific TIL from non-responding tumors suggests a potential driver of resistance to anti-PD-1 in early stage NSCLC. Ultimately, this integrative approach may provide key insights in predicting and understanding clinical response to neoadjuvant PD-1 blockade in NSCLC.

Background: There is a lack in our understanding of pathogenesis and mechanisms accounting for large variability in response to systemic therapy. Recent data suggest that the gut-lung axis regulates systemic immune function. Moreover, in vivo and clinical studies, mainly in melanoma and mixed epithelial tumors, suggest the role of gut bacteria and response to systemic therapy. However, the presence and potential theranostic role of gastrointestinal (GI) mycobiome in lung cancer has not been explored. Here, we aimed to evaluate

the associations of GI bacteria and Candida species in lung cancer patients. **Method:** We included 124 stool samples from 98 lung cancer patients (adenocarcinoma (n=48), squamous cell (n=24), small cell lung cancer (n=15) and other (n=11). Patients underwent lung resection surgery (n=20) or treated with first line chemotherapy CHT (n=78). We analyzed the gut microbiome according clinicopathological variables using Internal transcribed spacer (ITS) and shotgun metagenomic sequencing technique. We performed Spearman correlation between gut microbial species and continuous variables and random forest model (RF) for feature selection. Pathway analysis was done using HUmann2 pipeline, bacterial species annotation was performed with Metaphaln2 pipeline and for fungi ITS, we used PIPITS pipeline. We compared Candida diversity with healthy controls from the Human Microbiome Project. **Result:** We identified Candida species in 65% (71 of 124) of the stool samples. Of these, 48 were baseline 23 were follow-up samples (treatment). 77% of the patients included were diagnosed with advanced stage disease. There were significant differences in Candida abundance in healthy controls vs. cancer patients. In contrast, there were no significant differences in alpha and beta diversity between baseline and follow-up samples (treatment). In total 46 significant species and 140 pathways were significant different and fed into RF. Species belonging to Actinobacteria, Bacteroidetes and Firmicutes phyla are important features in RF and found to be negatively correlated ($r <= -0.3$, and $p < 0.05$) with Candida species. Certain bacteria pathways were significantly different according to the presence of Candida. **Conclusion:** Candida is present in stool samples in the majority of lung cancer patients both at diagnosis and during systemic therapy. There were associations with certain gut bacteria and Candida species that may have potential future therapeutic implications. Further biomarker studies in well-defined homogenous subgroups are ongoing in order to identify the exact biomarker role of the mycobiome in lung cancer.

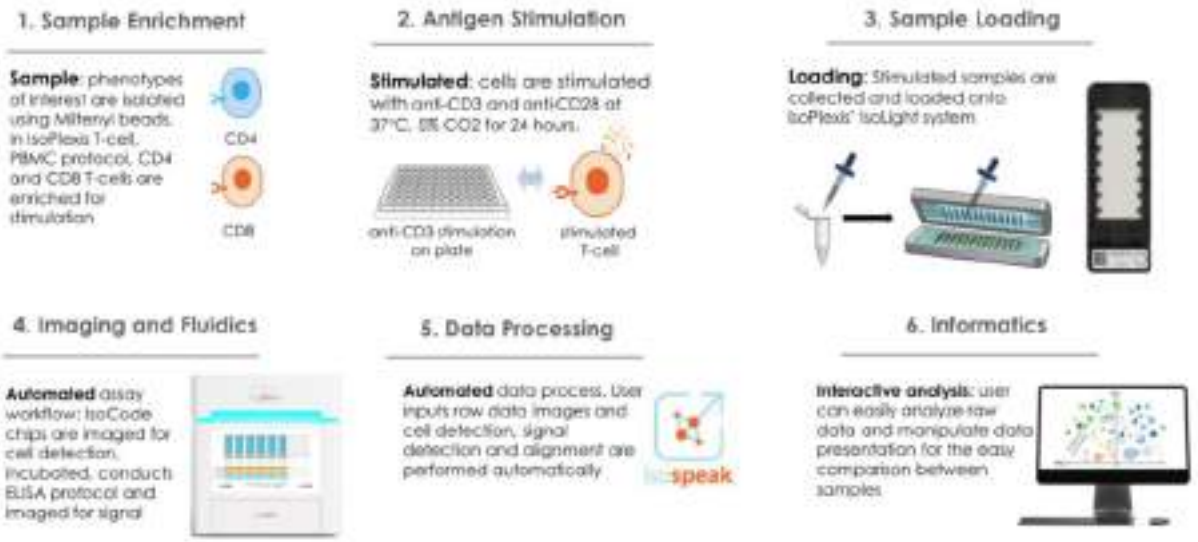
P2.04-26 SINGLE CELL PROTEOMICS PROFILING OF LIVE T-CELLS IN KRAS+ AND MET-AMP NSCLC TO PREDICT IMMUNE CHECKPOINT INHIBITOR RESPONSE

Z.-F. Lim[1], X. Wu[1,2], M. Hafez[3], H. Albandar[3], L. Zhu[1], H. Yang[1], S. Mackay[4], J. Chen[4], J. Zhou[4], P. Ma[1,3]

[1]*WVU Cancer Institute, West Virginia University, Morgantown/United States of America,* [2]*Guizhou Provincial People's Hospital, Guizhou/China,* [3]*Section of Hematology/Oncology, Department of Medicine, West Virginia University, Morgantown/United States of America,* [4]*IsoPlexis, Branford/United States of America*

Background: Immune checkpoint inhibitors (CPI), alone or in combination with chemotherapeutics, have been approved for first-line treatment in non-small cell lung cancers (NSCLCs) and have therapeutic efficacy across many cancer types. While these new cancer immunotherapeutic agents (e.g. pembrolizumab, nivolumab, atezolizumab) represent exciting additions to the treatment paradigm of a large array of genomics-guided precision medicine strategies for oncogene-addicted lung cancers, emerging clinical data raises doubts about the efficacy and the role of immune checkpoint inhibition in oncogene-addicted lung cancers driven by EGFR mutation, ALK-rearrangement, and MET amplification (MET-Amp) or MET exon-14 skipping mutations, regardless of the expression level of PD-L1. Moreover, clinically relevant and reliable predictive biomarkers of CPI response remain inadequate, despite the currently used PD-L1 expression, tumor mutational burden and microsatellite instability (MSI) status. **Method:** We longitudinally profiled more than 32 cytokines released by peripheral T-lymphocytes from patients under CPI therapy using a novel live single-cell microfluidics-based liquid biopsy platform. Paired pretreatment and post-2 cycles of treatment peripheral blood samples from each subject were analyzed to delineate early biomarkers correlative to CPI treatment response in a pilot cohort of four representative patients with advanced NSCLC.



Result: CD8(+) T-cells have stronger polyfunctional response than CD4(+) T-cells in all patients, demonstrating considerable heterogeneity among different patients and different T-cell types [CD4(+) vs. CD8(+)]. To compare overall polyfunctional upregulation by cytokines grouped by function, we adopted a novel polyfunctional strength index (PSI) in our biomarker bioinformatics analysis. Post-treatment CD4(+)/CD8(+) T-cells across patients showed overall higher PSI than pretreatment cells except in one patient. The polyfunctional profiles are largely composed of effector proteins associated with antitumor immunity and, to a lesser extent, chemoattractive and regulatory cytokines in CD8(+) T-cells. Upon anti-CD3/CD28 stimulation, the combinations of secreted cytokines in post-treatment samples are markedly distinct from pretreatment samples in both CD4(+) and CD8(+) cell subsets. The PSI analysis data presented highlight a patient with stage IVB KRAS-mutated (KRAS+)(PD-L1=60%) lung adenocarcinoma and another one with MET-amplified lung adenocarcinoma (PD-L1=85%-95%), who demonstrated excellent tumor response to anti-PD1 CPI, providing an immune single cell proteomics biomarker measure of response in oncogene-addictive tumor treated under CPI. **Conclusion:** Our study nominated an early association between single-cell immune cytokine profiling and CPI clinical treatment outcome in advanced oncogene-driven NSCLC. Further studies with larger cohorts are warranted for validating PSI as predictive biomarker of CPI response, especially in patients with addictive oncogene-driven lung cancer.

P2.04-27 CLINICAL IMPLEMENTATION OF MULTIPLEX IMMUNOFLUORESCENCE TO CHARACTERIZE TUMOR IMMUNE STATUS IN LUNG CANCER PATIENTS

L. Sholl[1], E. Gjini[1], K. Felt[1], P. Kumari[2], J. Lindsay[2], N. Lindeman[1], J. Nowak[1], E. Cerami[2], S. Rodig[1]

[1]*Brigham and Women's Hospital, Boston/United States of America,* [2]*Dana Farber Cancer Institute, Boston/United States of America*

Background: Tumor cell PD-L1 positivity by immunohistochemistry (IHC) enriches for response with PD-(L)1 inhibitors in patients with non-small cell lung carcinoma (NSCLC). However, PD-L1 IHC has limited positive and negative predictive value and does not provide information about the immune effector cell population in the tumor environment. Multiplex immunofluorescence (MIF) can be used to simultaneously characterize checkpoint proteins and immune cell infiltrates on a single tumor slide. MIF is not, however, routinely used in clinical practice. We operationalized and launched prospective MIF for lung cancer patients. **Method:** Patients were consented to an institutional protocol for tumor sequencing and immunoprofiling. Samples were submitted for MIF reflexively following a diagnosis of lung cancer on any in-house core biopsy or resection specimen. Slides were reviewed by a pathologist and imaging scientist to confirm tumor adequacy and three to six representative 20X fields of view that included tumor and tumor-stroma interface were selected for scoring. Automated staining for AE1/AE3, PD-L1, PD-1, CD8, FoxP3 and DAPI was carried out on a Leica BOND RX Autostainer and imaged using the Polaris imaging system (PerkinElmer). Under pathologist supervision, biomarkers were quantified in each region at a single cell level using the Inform Advanced Image Analysis Software (PerkinElmer). An automated reporting system calculated a PD-L1 tumor proportion score (TPS) and immune cell density across the analyzed regions. **Result:** To date, 80 samples have been received for analysis (40% biopsies and 60% resections), of which 78 (98%) were imaged successfully. Average turnaround time from receipt of specimen to complete reporting was 25 days. PD-L1 was considered positive (TPS >50%) in 4 (5%), low positive (1-49%) in 42 (55%), and negative (<1%) in 32 (41%). CD8+/PD1+ density ranged from 0 to >800/mm2 (median 59) and FOXP3+ cells from 2 to >700/mm2 (median 59); both showed a broad standard deviation, consistent with heterogeneity in the tumor and adjacent stroma. Nine (11%) tumors showed a pattern of adaptive immune resistance (so-called "hot" tumors), defined as CD8+/PD1+ density greater than the median and at least low positive PD-L1 TPS. **Conclusion:** Multiplex immunofluorescence and pathologist-guided image analysis of fixed tissue specimens can be integrated into clinical practice with a low rate of failure and acceptable turn-around time to identify unique immunologic subsets of lung cancer. Limitations of data storage and analysis speed require focused field selection, therefore optimization of the scored area(s) is essential to ensure accurate tumor immune classification. Studies to determine the feasibility of use of MIF for selection of patients for immunotherapy are ongoing.

P2.04-28 NEOCOAST: NEOADJUVANT DURVALUMAB ALONE OR WITH NOVEL AGENTS FOR RESECTABLE, EARLY-STAGE (I–IIIA) NONSMALL CELL LUNG CANCER

R. Garcia Campelo[1], P. Forde[2], W. Weder[3], J. Spicer[4], P. He[5], O. Hamid[5], P. Martinez[5], T. Cascone[6]

[1]*University Hospital A Coruña, Coruña/Spain,* [2]*Sidney Kimmel Comprehensive Cancer Center, Baltimore/United States of America,* [3]*University of Zürich, Zürich/Switzerland,* [4]*McGill University, Montreal/Canada,* [5]*AstraZeneca, Gaithersburg/United States of America,* [6]*The University of Texas MD Anderson Cancer Center, Houston/United States of America*

Background: Resectable, earlystage nonsmall cell lung cancer (NSCLC) is a potentially curable disease.The current standard of care is surgery with or without adjuvant or neoadjuvant platinumbased doublet chemotherapy. However, over half of patients eventually relapse after surgery and die from NSCLC. Clinical studies have shown that neoadjuvant programmed cell death-1/programmed cell death ligand-1 (PD-1/PD-L1) checkpoint inhibitors may yield clinically meaningful pathological responses in patients with resectable NSCLC.[1–3] The NeoCOAST trial is a multidrug platform study to assess the PD-L1 checkpoint inhibitor durvalumab alone or in combination with novel agents, with the goal of identifying new treatment strategies to improve clinical outcomes of patients with resectable, early-stage NSCLC. **Method:** NeoCOAST (NCT03794544) is a phase 2, open-label, randomized trial that will initially evaluate the clinical activity and safety of neoadjuvant durvalumab alone or in combination with the novel agents oleclumab (MEDI9447), monalizumab (IPH2201) and danvatirsen (AZD9150), in patients with resectable, stage I (>2 cm) to IIIA NSCLC. New treatment arms evaluating other durvalumab combinations may be added based on emerging preclinical and clinical data. The primary endpoint is major pathological response rate in the resected tumor specimen after treatment with neoadjuvant durvalumab alone or in combination with novel agents. Secondary objectives include feasibility of tumor resection surgery within 14 days of the end of the 4-week treatment period, safety, pathological complete response rate, pharmacokinetics and immunogenicity. Correlative translational analyses include tumor genomics, changes in the tumor microenvironment, and T cell populations. NeoCOAST is open for accrual with an estimated total target enrollment of up to 40 patients per treatment arm. References [1]Forde PM, et al. N Engl J Med. 2018;378:1976–86. [2]Rusch V, et al. Background: Lung cancer is known to be a complex multifactorial disease involving both genetic and environmental factors. The study of different signaling pathways and identification of the genes involved, will contribute to further understanding the pathogenesis of the disease, thus allowing the development of appropriate targeted treatments and even a prevention strategies. The inflammation caused by immune system activation is likely linked to carcinogenesis by promoting angiogenesis and proliferation of tumour cells, according to the cytokine profile in the tumour microenvironment. Previous studies have suggested that key cytokines in inflammation pathways may have an important roles in the etiology of lung cancer. The aim of this study was to investigate whether common inflammation related genes influence lung cancer risk in Moroccan population. **Method:** Single nucleotide polymorphisms (SNPs) in IL-6, IL6-R and IL6-ST, IL6, IL17-A, IL17-F, IL-8, MIF and STAT3 genes were assessed in 150 controls and 150 lung cancer patients. Genotyping was performed with the TaqMan® allelic discrimination technology and RFLP-PCR. Gene expression of cytokines was evaluated in the peripheral blood samples of lung cancer patients and healty controls. Total RNA of the blood cells were extracted and reverse transcribed to cDNA. Screenings of deferentially expressed genes associated with inflammation were performed using real-time PCR. **Result:** Among the studied SNPs, we found a significant association for the IL-6 (rs2069840), IL-6 (rs1800795), IL-6 (rs1800796), IL-17F (rs763780), IL-17F (rs763780), IL-8 and the MIF (rs755622). No significant association was observed for the remaining SNPs of IL-6R (rs2228145) IL-6ST (rs2228044), IL-17A (rs2275913), IL17A (rs7747909) and STAT3 (rs2293152) genes. Cytokines genes expression revealed significant association with lung cancer. Genes expression were increased in lung cancer patients comparing to healty subjects. **Conclusion:** Our results suggest the important role of inflammation related genes in the occurrence of lung cancer and cytokines genes associated may be considered as a genetic marker for predisposition to Lung cancer in Moroccan population.

P2.04-30 SEQ-ING A BETTER WAY TO DETECT PD-L1 IN NSCLC

L. Petersen[1], R. Mcneil[2], M. Dean[1], A. Chan[1], S. Orton[2], O. Kovalchuk[3], D. Bebb[1]

[1]*University of Calgary, Calgary/Canada,* [2]*Mount Royal University, Calgary/Canada,* [3]*University of Lethbridge, Lethbridge/Canada*

Background: Immunotherapies targeted against PD-L1 and PD-1 have caused a paradigm shift in the treatment of NSCLC, and PD-L1 protein expression has emerged as a standard diagnostic biomarker that predicts which patients are more likely to respond to immunotherapy. However, the use of PD-L1 protein expression as a biomarker is complicated by differences in PD-L1 antibodies, immunohistochemistry methods and platforms, pathologist scoring, and positivity cut-points. We propose that using RNA-sequencing (RNA-seq) methodologies will be an equally reliable approach to determine PD-L1 expression within a tumour and will yield a greater depth of biomarker information than PD-L1 IHC alone. **Method:** We performed quantitative immunohistochemistry (qIHC) on 262 resected stage I-III formalin-fixed paraffin-embedded (FFPE) NSCLC patient samples registered in the Glans-Look Lung Cancer Research (GLR) database using the commercially available E1L3N PD-L1 antibody (Cell Signalling Technologies). Staining intensity was quantified and used to establish a positivity threshold that was subsequently used to define positivity cut-points of <1%, 1%-49%, and >50% (as used for determining treatment eligibility for Pembrolizumab). We performed single-end RNA-sequencing on FFPE samples from the same GLR patient cohort. Raw counts were normalized to counts-per-million for use in our analyses. **Result:** We compared the PD-L1 mRNA expression to the PD-L1 protein staining intensity across the tissue core and found a significant correlation (p<0.001, Spearman's rho=0.538). We also found significant correlation between PD-L1 mRNA expression and the percent-positivity score determined by qIHC (p<0.001, Spearman's rho=0.605), which was particularly apparent when comparing PD-L1 mRNA expression between cut-point groups where expression was significantly higher in the 1%-49% and >50% groups. Interestingly, we also found moderate, yet significant correlation between PD-1 mRNA expression and both PD-L1 protein staining intensity and percent positivity (p<0.001, Spearman's rho=0.437 and 0.415 respectively), and we were able to identify several differentially expressed genes between the PD-L1 positive and negative groups. **Conclusion:** Given the high degree of correlation between PD-L1 mRNA expression and PD-L1 protein staining and positivity, RNA-seq can be a viable option for assessing candidacy for immunotherapy. In addition to the wealth of supplementary data on important biomarkers, RNA-seq offers the possibility for using non-invasive procedures such as liquid biopsy to measure PD-L1 levels in a sequential, objective fashion.

P2.04-31 IMMUNE PHENOTYPIC BIOMARKERS IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER TREATED WITH DEFINITIVE CHEMORADIATION AND ATEZOLIZUMAB

E. Cohen, H. Gao, S. Tin, Q. Wu, J. He, Y. Qiao, J. Heymach, A. Tsao, J. Reuben, S. Lin

The University of Texas MD Anderson Cancer Center, Houston/United States of America

Background: Consolidation durvalumab is the current standard of care for locally advanced non-small cell lung cancer (LA-NSCLC) after chemoradiation (CRT). However, predictive and prognostic biomarkers of response to immunotherapy are still poorly characterized. In particular, minimally-invasive blood-based biomarkers that can be sequentially assessed during therapy may prove useful in understanding the characteristics of response and optimal sequencing of therapy. We report serial blood immune-phenotyping of patients undergoing concurrent chemoradiation therapy (CRT) with PD-L1 blockade with atezolizumab. **Method:** Between February 2016 and October 2018, 40 LA-NSCLC patients were evaluated in conjunction with the single-institution DETERRED trial. The first 10 patients were treated with carboplatin/paclitaxel chemotherapy and atezolizumab for two cycles followed by maintenance atezolizumab for 1 year after completing CRT, followed by 30 patients treated with atezolizumab concurrent with CRT followed by chemotherapy/atezolizumab and maintenance atezolizumab. In all, 38 patients were evaluable. Peripheral blood was drawn at the beginning (baseline), midway through CRT (2-4 weeks), and at the end of CRT, with periodic follow up samples for up to two and a half years. Immune phenotyping was performed by flow cytometry on fresh, whole blood within 24 hours of phlebotomy. Cox regression was preformed to assess biomarker correlations with survival. **Result:** At the second blood sample midway through CRT, patients who eventually progressed had a larger increase from baseline in the percentage of peripheral blood CD4 T helper cells expressing PD-1 (p = 0.042) and this change was associated with both progression-free (PFS, p = 0.039) and overall survival (OS, p = 0.042). Progressors had a mean increase of 2.5 percentage points while non-progressors had a mean drop of 1.9. At the first post-CRT follow-up, an increase in the percentage of CD8 cytotoxic T lymphocytes expressing PD-1 was negatively associated with survival (PFS p = 0.0015, OS p = 0.023) as well as the percentage of granulocytic myeloid suppressor cells (PFS p = 0.0089, OS p = 0.034). These comparisons were not significant when corrected for multiple testing. However, the change in CD4 PD1 after 2-4 weeks of CRT was an independent prognostic indicator of PFS in multivariate cox regression analysis including age, stage, and histology (p = 0.02, hazard ratio 1.2, 95% CI 1.03 to 1.4). **Conclusion:** Increases in peripheral blood lymphocytes expressing PD1 and myeloid suppressor cells may be prognostic for locally advanced patients treated with CRT and immune checkpoint blockade but additional studies are needed to verify these markers in immunotherapy resistance.

P2.04-32 COMPARISON OF CLINICOPATHOLOGICAL AND GENOMIC CHARACTERISTICS BETWEEN NSCLCS WITH A PD-L1 TUMOR PROPORTION SCORE OF ≥90% VS <1%

G. Lamberti[1], Y. Li[1,2], L. Spurr[1,2], B. Ricciuti[1], G. Recondo[1], R. Umeton[1], L. Sholl[3], A. Cherniak[1,2], M. Awad[1]

[1]*Dana-Farber Cancer Institute, Boston/United States of America,* [2]*Broad Institute of MIT and Harvard, Boston/United States of America,* [3]*Brigham and Women's Hospital, Boston/United States of America*

Background: Determinants of PD-L1 expression in non-small cell lung cancer (NSCLC) are poorly defined. To identify characteristics associated with high vs. absent PD-L1 expression, we compared clinicopathologic and genomic features of NSCLCs at the two ends of PD-L1 expression spectrum: a PD-L1 tumor proportion score (TPS) of ≥90% or a PD-L1 TPS of <1%. **Method:** We retrospectively collected clinicopathologic and genomic data (via targeted NGS) from consecutive NSCLC patients who had consented to an IRB-approved correlative research study and whose tumor PD-L1 TPS was either ≥90% or <1%. Single nucleotide variations, insertions/deletions, and copy number alterations were compared using Fisher's exact test. Tumor mutational burden (TMB) was compared using Mann-Whitney test. **Result:** 421 NSCLCs with PD-L1 TPS ≥90% (N=133) or <1% (N=288) and successfully performed NGS were identified. There was no difference in age, sex, histology, or stage at diagnosis between the two groups. Patients with a PD-L1 TPS of ≥90% were more likely to be smokers (86.5% vs 76.4%; P=0.02) compared to patients with a PD-L1 TPS of <1%, and tumors in the PD-L1 TPS ≥90% group had higher TMB (10.89 vs 8.47 mutations/megabase; P=0.004) than those in the PD-L1 TPS <1% group. Tumors in the PD-L1 TPS ≥90% group were more likely to have *KRAS* (47.3% vs 31.3%; P=0.002), *MET* exon 14 (9.6% vs 2.1%; P=0.003), and *TP53* mutations (71.0% vs 49.7%; P<0.001) than those in the PD-L1 TPS <1% group. Compared to the PD-L1 TPS ≥90% group, the PD-L1 TPS <1% group was more likely to have *EGFR* (23.6% vs 8.2%; P<0.001) and STK11 (23.4% vs 5.0%; P<0.001) mutations, as well as the absence of known oncogenic driver mutations (35.2% vs 24.8%; P=0.04). Chromosomal gain alterations (amplification or copy number gain) of the 9p24.1 locus, where the *PD-L1*, *PD-L2*, and *JAK2* genes are located, were more common in the PD-L1 TPS ≥90% group than in the PD-L1 TPS <1% group (11.4% vs 2.8%, respectively; P<0.001). Chromosomal loss alterations (copy loss or deletion) of the 9p24.1 locus were more common in the PD-L1 TPS <1% than in the PD-L1 TPS ≥90% group (27.5% vs 3.8%, respectively; P<0.001). A repeated biopsy case showed acquired loss PD-L1 expression (PD-L1 TPS changed from 90% to 0%) with concomitant acquired loss of the 9p24.1 locus. **Conclusion:** High PD-L1 expression in NSCLC is associated with tobacco use, high TMB, gain of the 9p24.1 locus and mutations in *KRAS*, *MET* exon 14, and *TP53*. PD-L1 negativity is associated with never smoking status, low TMB, loss of the 9p24.1 locus, mutations in *EGFR* and *STK11*, and the absence of oncogenic driver mutations.

P2.04-33 SINGLE-AGENT TISLELIZUMAB, AN ANTI-PD-1 ANTIBODY: RESULTS FROM A PHASE 1 EXPANSION COHORT IN NSCLC PATIENTS

P. Barlow[1], M. Jameson[2], C.-C. Lin[3], J. Wu[4], A. Pirzkall[4], J.-S. Lee[5]

[1]*Auckland City Hospital, Auckland/New Zealand,* [2]*Regional Cancer Centre, Waikato Hospital, and the University of Auckland Waikato Clinical Campus, Hamilton/New Zealand,* [3]*National Taiwan University Hospital, Taipei/Taiwan,* [4]*BeiGene USA, Inc., San Mateo/United States of America,* [5]*Seoul National University Bundang Hospital, Seongnam-si, Gyeonggi-do/Korea, Republic of*

Background: Tislelizumab is an investigational monoclonal antibody with high affinity and specificity for PD-1. Tislelizumab was engineered to minimize binding to FcγR on macrophages in order to abrogate antibody-dependent phagocytosis, a mechanism of T-cell clearance and potential resistance to anti-PD-1 therapy. Previous reports from this first-in-human study (NCT02407990), and other early phase studies, suggested tislelizumab was generally well tolerated and had antitumor activity in patients with advanced solid tumors. **Method:** Patients in nine dose-expansion cohorts received tislelizumab administered at a dose of 5 mg/kg Q3W, including a NSCLC cohort. Adverse events (AEs) were assessed per NCI-CTCAE 4.03 and tumor assessments were performed Q9W (RECIST v1.1). PD-L1 was retrospectively assessed with the VENTANA PD-L1 (SP263) assay; PD-L1-positive (PD-L1$^+$) NSCLC was defined as ≥25% tumor cells expressing PD-L1 by immunohistochemistry. **Result:** A total of 49 patients with NSCLC (median age 62 years [39–78]) received tislelizumab. Twenty-three patients were Caucasian and 21 were Asian; 34 patients were current/former smokers. Forty-four patients had received prior systemic chemotherapy (1 line, n=24; 2 lines, n=10; ≥3 lines, n=10). As of 27 Oct 2018, median study follow-up was 11.2 months (0.5–27.7) and 46 patients were evaluable for response. Confirmed partial responses (PRs; n=6) and stable disease (n=23) were observed. The objective response rate was 13% (95% CI: 4.9–26.3) and the disease control rate was 63% (95% CI: 47.6, 76.8). Of the 37 patients with PD-L1 evaluable samples, PRs were seen in three of 16 patients (19%) with PD-L1$^+$ NSCLC and two of 21 patients (10%) with PD-L1$^-$ NSCLC. Across all patients, median overall survival (OS) was 11.5 months (95% CI: 9.3, not reached [NR]). Median OS was 15.1 months (95% CI: 4.2, NR) for patients with PD-L1$^+$ NSCLC and 11.2 months (95% CI: 6.1, NR) for patients with PD-L1$^-$ NSCLC. Hypothyroidism was the most commonly reported treatment-related AE (TRAE; n=6), followed by hyperthyroidism, fatigue, and pneumonitis (n=5 each). Eight grade ≥3 TRAEs were reported in six patients: pneumonitis (n=3), autoimmune colitis, vomiting, elevated ALT, elevated AST, and macular rash (n=1 each). A single treatment-related death due to pneumonitis occurred in a patient with compromised pulmonary capacity at baseline. **Conclusion:** Tislelizumab was generally well tolerated and demonstrated antitumor activity in NSCLC patients. Tislelizumab is being evaluated as a single agent or with chemotherapy in phase 3 studies in NSCLC patients (NCT03358875, NCT03594747, and NCT03663205).

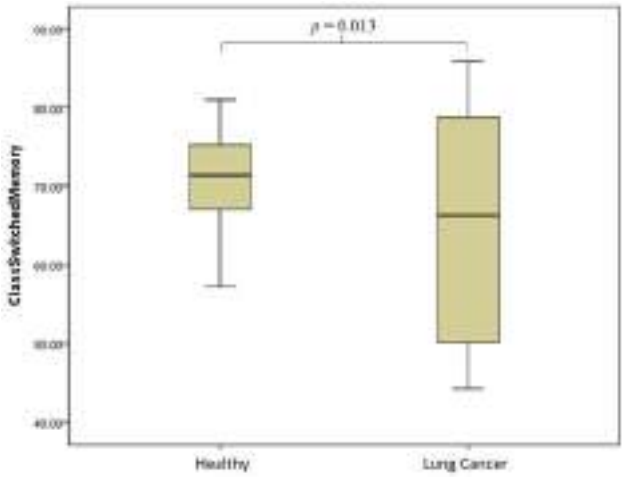
Keywords: tislelizumab, NSCLC, Anti-PD-1

P2.04-34 FCGR2B EXPRESSION AS A REGULATOR OF IMMUNITY IN NON-SMALL CELL LUNG CANCER PATIENTS

Y.-Y. Chen[1], C.-Y. Chen[1], J.-Y. Shih[2], C.-J. Yu[2], P.-C. Yang[2]

[1]*National Taiwan University Hospital Yunlin Branch, Douliou/Taiwan,* [2]*National Taiwan University Hospital, Taipei/Taiwan*

Background: FCGR2B (CD32B), a receptor on the B cell membrane, induces the production of inhibitory messages to maintain the homeostasis of the immune system and prevent excessive activation of B cells to attack their own antigens. Therefore, FCGR2B may cause immune cells to not effectively search and kill for cancer cells.This study examined the level of FCGR2B expression on B cells associated with immunity in non-small cell lung cancer (NSCLC) patients. **Method:** Healthy volunteers and lung cancer patients were recruited. All control donors' and patients' peripheral blood were collected. 200ul blood with appropriate amount of antibody was incubated for 10-15 min at room temperature in the dark and then lysed with 1ml VersaLyse Lysing Solution for 10-15 min at room temperature in the dark. Resuspend in 1ml PBS+ 1% fix solution then were counted by cytoflex flow cytometer (Beckman Coulter). For surface marker analysis, B cells were collected assessing the levels of CD19, CD32, CD21, CD24, CD27, CD38, and IgM/IgD by flow cytometric assay. T cells subtypes including CD3, CD4, CD8, CD27, CD28, CD45, CD45RA, CD57, CCR7 and PD1 were counted by cytoflex flow cytometer. **Result:** In this study, healthy volunteers (n=9) were compared with NSCLC patients (n=17) to detect the expression of FCGR2B on B cell. We found that Class Switched Memory Cell in NSCLC patients had lower performance than healthy subjects (NSCLC patients v.s. healthy subjects: 65.10 ± 15.72 v.s. 70.76 ± 7.26, p = 0.013). Class Switched Memory Cell was significant lower in advanced stage than that in early stage NSCLC patients (advanced stage v.s. early stage: 54.68 ± 27.21 v.s. 77.73 ± 7.12, p = 0.044). The expression of FCGR2B (CD19CD32) in NSCLC patients was slightly lower than that in healthy subjects (NSCLC patients v.s. healthy subjects: 19.68 ± 10.07 v.s. 32.98 ± 23.92, p = 0.099), but did not reach statistically significant differences. The expression of FCGR2B (CD19CD32) was significantly positively correlated with CD4 Naïve T cell (R = 0.789; B = 0.291; p < 0.001) and CD3CD4CD45RA (R = 0.765; B = 0.301; p = 0.001).



Conclusion: NSCLC patients with reduced numbers of Class Switched Memory B Cell are more prone to progress lung cancer disease. The positive correlation between FCGR2 B cells and naive T cells in blood is also observed. Future studies focusing on the presence of these B cell subtypes, antigen specificity and interaction with T cells are necessary to further elucidate in NSCLC patients.

P2.04-35 IMMUNE RELATED ADVERSE EVENTS IN NSCLC PATIENTS TREATED WITH IMMUNE CHECKPOINT THERAPY WHO RECEIVED THE INFLUENZA VACCINATION VS NO VACCINATION

H. Reddy, T. Weis, S. Hough, S. Daignault-Newton, B. Schneider

University of Michigan, Ann Arbor/United States of America

Background: The influenza vaccination is recommended by the CDC for cancer patients to reduce the risk of influenza-related complications. There is concern that the incidence of immune-related adverse events (irAEs) may be greater in vaccinated patients receiving immune checkpoint inhibitors (ICPI). We sought to interrogate if influenza vaccination in patients with NSCLC receiving ICPI therapy had an increased incidence of iRAEs compared to non-vaccinated patients using data from our single-center experience. **Method:** We conducted a single-center retrospective analysis of patients with advanced NSCLC who received PD-1 or PD-L1 inhibitor monotherapy between March 2015 – December 2018. Influenza immunization records from both institutional and state-wide immunization registries were obtained for each patient identified between 2014 -2019. Comparisons of adverse event incidence between flu vaccinated vs control patients were tested using chi-square statistics. **Result:** 117 patients were included in our analysis, 33 patients (28%) were vaccinated during ICPI therapy, 19 (58%) received quadrivalent influenza vaccine, 13 (39%) patients received trivalent influenza vaccine and 1 (3%) was unable to be determined. 22 (67%) of vaccinated patients had an irAE vs 53 (63%) of patients who were not vaccinated during ICPI therapy (p = 0.720). Eight (24%) vaccinated patients had irAE leading to discontinuation of therapy vs 12 (14%) patients who were not vaccinated during ICPI therapy (p = 0.198). The most frequent irAE in both groups was fatigue 16 (48%) vs 28 (33%) (p=0.128). Notable irAEs included colitis (0), pneumonitis (3), hepatitis (1) with vaccination vs. colitis (1), pneumonitis (3), hepatitis (4) without vaccination. There were

no statistically significant differences in baseline demographics between both groups including age, race, gender, tumor histology or ECOG performance status. **Conclusion:** Our retrospective study suggests that in general, irAEs are not significantly increased with vaccination for influenza during treatment with immune checkpoint inhibitors. However, there is a slight trend toward increased incidence of irAE warranting ICPI discontinuation and further investigation is warranted. Limitations of this study include a small sample size and inability to grade irAE retrospectively.

Keywords: Immunotherapy, Immune related adverse events, Influenza Vaccination

P2.04-36 IMMUNE CHECKPOINT INHIBITION FOR NON-SMALL CELL LUNG CANCER (NSCLC) IN PATIENTS WITH PULMONARY TUBERCULOSIS OR HEPATITIS B

G. Chan, Y.Q. Huang, Y. Ang, W.Q. Chong, V. Muthu, A. Wong, R. Soo

National University Cancer Institute, Singapore, Singapore/Singapore

Background: Pulmonary tuberculosis (pTB) and Hepatitis B (HepB) are endemic in Asia. Multiple trials have shown a survival benefit of immune-checkpoint inhibitors (ICI), either as monotherapy or in combination with chemotherapy over chemotherapy in the treatment of NSCLC in first or second-line setting. However, patients with chronic infections are routinely excluded from such studies, and the safety and efficacy of ICI in this population is scarce. **Method:** A retrospective review of clinical records of patients with advanced NSCLC with pTB and/or HepB, treated with ICI from January 2014 to March 2019 at a single Asian centre was conducted. The diagnosis of pTB was based on isolation of m. tuberculosis from sputum culture or nuclei acid amplification. **Result:** 13 patients were analysed. 12 (92.3%) were male, with a median age of 67 years (range 41 – 86) and 10 (76.9%) patients had an Eastern Cooperative Oncology Group performance status of 0-1. Nine (69.2%) patients received anti-PD-1/PD-L1 monotherapy, and four received ICI in combination with chemotherapy. Seven (53.8%) patients were treatment-naïve and six received ICI in the second-line and beyond. Seven patients had a history of pTB and ten patients had HepB. Four patients had a history of both HepB and pTB. The median progression-free survival (PFS) of the entire cohort was 6.7 months (95% CI: 3.3 – 10.2 months). The median overall survival (OS) was 13.3 months (95% CI: 0.0 – 31.2 months). Five patients had an objective response, and nine patients had disease control (complete/partial response or disease control). Immune-related adverse events (irAE) occurred in four patients – one patient each with endocrinopathy (G2), pneumonitis (G3), arthritis (G3) and hepatitis (G3). There were no treatment-related deaths. Four patients had pTB prior to initiation of ICI, and three patients developed pTB after. Two patients received anti-TB therapy on ICI and developed G3 transaminases which resolved after omission of anti-TB therapy. For all the patients who had completed treatment for pTB, none experienced re-activation. Of the 10 patients with HepB, four were chronic carriers (HepB surface-antigen (HBsAg) positive and detectable viral load), and six were previously exposed (HBsAg negative, anti-hepB core-antibody positive). Only one of the patients who had previous exposure to HepB received anti-viral prophylaxis and there were no incidences of re-activation. **Conclusion:** Based on our findings, the risks of ICI therapy do not appear to be increased in patients with pTB or HepB. Further studies identifying those who are at risk of reactivation are essential.

Keywords: Immune-checkpoint inhibitors, Tuberculosis, Hepatitis B

P2.04-37 PHASE I/II TRIAL OF DURVALUMAB AND TREMELIMUMAB WITH CONTINUOUS OR INTERMITTENT MEK INHIBITOR SELUMETINIB IN ADVANCED NSCLC

P.-O. Gaudreau, J. Heymach, D. Gibbons

The University of Texas MD Anderson Cancer Center, Houston/United States of America

Background: Despite therapeutic progress in other molecular subsets of non-small cell lung cancer (NSCLC), little progress has been made for KRAS-mutant NSCLC. Because RAS remains an elusive pharmacological target, agents targeting downstream elements of the MAPK signaling pathway have been developed, including MEK inhibitors. However, substantial benefits have not been achieved due to the development of drug resistance. Current strategies to improve outcomes in this population include MEK inhibitors and PD-1 / PD-L1 immune checkpoint blockade (ICB) combinations (e.g., NCT03225664). On the other hand, combined anti-CTLA-4 and PD-1 / PD-L1 axis ICB improves response rates in melanoma, but similar benefits remain to be seen in NSCLC: MYSTIC trial updates failed to show a progression-free survival (PFS) advantage over standard of care, and CheckMate 227 reported significantly longer PFS with first-line double ICB in the high tumor mutational burden subgroup only. Thus, the objectives of this study are: 1) to determine the safety and efficacy of combined MEK inhibition, anti-PD-L1 and anti-CTLA-4 and; 2) to unveil mechanistic insights for response and resistance. **Method:** This is a single center, Phase I/II study comparing two combination schedules of selumetinib (AZD6244, ARRY-142886), tremelimumab and durvalumab with historical controls in patients with previously treated, unresectable NSCLC. Forty patients will be accrued at the University of Texas MD Anderson Cancer Center. In the first arm, participants receive selumetinib PO BID on days 1-7 and 15-21 and durvalumab IV on day 1. Participants also receive tremelimumab IV on day 1 for courses 1-4 (courses repeat every 28 days in the absence of disease progression or unacceptable toxicity). The second arm differs by the continuous selumetinib schedule: PO BID on days 1-28. Primary objectives include the maximum tolerated dose (MTD; dose-escalation phase) and PFS (dose expansion phase). Standard 3+3 design will be applied to determine the MTD among the three pre-defined dose levels. Estimated PFS will be provided with 95% confidence interval. Secondary objectives include: 1) response rate by RECIST 1.1; 2) disease control rate (complete response + partial response + stable disease); 3) overall survival; 4) safety and; 5) duration of response. Exploratory objectives will assess biomarkers of response and resistance in pre- and on-treatment biopsies as well as peripheral blood using immune profiling, transcriptome and protein readouts. **Result:** Section not applicable (Clinical Trial in Progress) **Conclusion:** The estimated start date for this trial (NCT03581487) is April 15th, 2019, and the estimated study completion is scheduled for April 2021.

P2.04-38 TUMOR-ASSOCIATED NEUTROPHILS AS A POTENTIAL PREDICTOR FOR EARLY RECURRENCE IN RESECTABLE I-IIIA LUNG ADENOCARCINOMA

X.-T. Li[1,2], M.-L. Cheng[1,2], J.-J. Yang[1], Y.-L. Wu[1], X.-C. Zhang[1], J. Hou[2]

[1]*Guangdong Lung Cancer Institute,Guangdong Provincial People's Hospital and Guangdong Academy of Medical Sciences, Guangdong/China,* [2]*School of Medicine,South China University of Technology, Guangzhou/China*

Background: A recurrence of the early-stage non-small cell lung cancer (NSCLC) is usually unpredictable by clinical features alone. It has been appreciated that the high degree of infiltrated neutrophils is significantly associated with poor patient outcome in NSCLC. **Method:** Transcriptional profiles and clinical information of 484 primary lung adenocarcinoma (ADC) subjects were retrieved from Gene Expression Omnibus (GEO). An additional cohort of mRNA expression, somatic mutations, and clinical data of 398 ADC were obtained from The Cancer Genome Atlas (TCGA). CIBERSORT algorithm was employed to infer the relative proportions of 22 sorts of leukocytes in each tumor using gene-expression profiles. Patients were stratified into two groups by the fraction of neutrophils using an optimal cutoff value (0.01) obtained with the "survminer" algorithm in R. We further investigated comprehensively the molecular differences between the high- and low-neutrophils patients. **Result:** A significantly higher rate of 1-year recurrence was found in the high-neutrophils compared with the low-neutrophils group in both training (GEO,19.5% vs 6.1%) and validation (TCGA, 27.3% vs 19.0%) cohorts. However only in training cohort the patients with high neutrophils experienced a poorer recurrence-free survival (HR 1.95, 95% CI 1.47-2.51, P< 0.0001). The two groups were not only distinguished by clinical behaviors, but presented characteristic mutation genes and mutation patterns. *EGFR* and *BRAF* were more frequently mutated in low-neutrophils patients, whereas in high-neutrophils patients the most common mutation was found in *STK11*. Yet such molecular distinction was more pronounced in ADC with high tumor mutation load (TMB >=10). Gene Set Enrichment Analysis (GSEA) suggested that the common mutant genes in high-neutrophils patients were involved in the TP53 signaling, cell cycle pathways or associated with molecular functions including chemokine production and CD4 activation, while the common mutant genes in low-neutrophils patients were linked to RAS signaling pathway. Interestingly, we

POSTERS

observed immune scene accompanied with good prognosis of ADC and concordant with limited infiltration of neutrophils, for instance high infiltration of B memory cells, resting memory CD4+T cells, resting mast cells and CD8+T cells. **Conclusion:** Our findings suggested that local neutrophils are one of important components which are determinant for early recurrence of ADC, and it might serve as a simple predictor. Further research is warranted to identify the molecular mechanisms that neutrophils employed to exert, directly or indirectly, the regulatory effect on ADC progression.

P2.04-39 CLINICAL CHARACTERISTICS OF LONG-TERM SURVIVORS WITH NIVOLUMAB IN PREVIOUSLY TREATED ADVANCED NSCLC FROM REAL WORLD DATA

Y. Watanabe, H. Mizutani, Y. Kato, Y. Yamane, F. Kurimoto, H. Sakai

Saitama Cancer Center, Inamachi/Japan

Background: Nivolumab, a programmed death-1 immune checkpoint inhibitor antibody, has become one of the new standard therapies for previously treated advanced non-small cell lung cancer (NSCLC). However, there is limited information about the long-term survival of real-world patients treated with nivolumab in Japan. **Method:** We performed a retrospective study of previously treated patients with advanced NSCLC who received nivolumab at 3 mg/kg every 2 weeks outside clinical trials from our institution in Saitama (Japan) between January 2016 and February 2017. We used real-world data (RWD) to analyze the clinical characteristics of patients who were alive 2 years after initiating nivolumab treatment. **Result:** A total of 129 patients fulfilled the inclusion criteria. Thirty-eight patients (30%) were alive 2 years after receiving the first dose of nivolumab. The median age at initial nivolumab treatment was 65 years (38–79). Twenty-nine (76%) patients were male, 12 (32%) were never-smokers, 37 (97%) had performance status (PS) 0 and 1, and 30 (79%) had adenocarcinoma histology. Twenty-five (66%) patients received nivolumab as second-line therapy, and 9 (24%) had genetic abnormalities including 7 with epidermal growth factor receptor (*EGFR*) mutations. Thirty-four cases of programmed death-ligand 1 expression in tumor samples were not quantifiable. The best responses to nivolumab per the Response Evaluation Criteria in Solid Tumors version 1.1 included 12 partial responses (32%) and 6 complete responses (16%). Eleven 2-year survivors (29%) received nivolumab for more than two years, three (8%) discontinued nivolumab because of immune-related adverse effects, and four (11%) were retreated. Fourteen 2-year survivors (37%) received only nivolumab without subsequent therapy and did not display evidence of progressive disease at the last follow-up. These survivors exhibited significantly good PS, were male, had a history of smoking, and did not harbour somatic genetic abnormalities. Multivariate analysis identified only good PS as an independent positive predictor of survival of two years or more. **Conclusion:** In our RWD experience, nivolumab resulted in a 2-year survival rate of 30% in previously treated patients with advanced NSCLC. The 2-year survival rate in a real-world clinical setting was slightly lower than that in a Japanese phase II study (ONO4538-05/06 study). Clinical characteristics associated with a positive treatment response were comparable to those observed in previous studies.

P2.04-40 TUMOR MUTATION SCORE IS MORE POWERFUL THAN TUMOR MUTATION BURDEN IN PREDICTING RESPONSE TO IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER

Y. Li[1], Z. Chen[2], L. Wu[1], W. Tao[1]

[1]*Renmin Hospital of Wuhan University, Wuhan/China,* [2]*Tongji Hospital, Huazhong University of Science and Technology, Wuhan/China*

Background: Tumor mutation burden (TMB) and PD-L1 expression are the two important biomarkers for immune checkpoint inhibitors (ICIs) in lung cancer. However, growing evidences are showing that not all mutations, such as EGFR mutation, are favorable factors in predicting clinical outcome of ICIs and the power of TMB, which is unselective, might be attenuated. Therefore, we developed tumor mutation score (TMS) as better biomarker for response of ICIs in non-small cell lung cancer (NSCLC). **Method:** TMS was defined as the number of genes with nonsynonymous somatic mutations. Mutations were detected by targeted next-generation sequencing (NGS) in 240 NSCLC patients treated with anti-PD-(L)1 monotherapy or in combination with anti-CTLA4. Durable clinical benefit (DCB) was defined as complete response (CR)/partial response (PR)/stable disease (SD) that lasted 6 months. TMS, TMB and PD-L1 expression were compared among DCB and no durable benefit (NDB) NSCLC patients. **Result:** The total TMS was significantly correlated with TMB (R=0.98, P<0.001) and performed almost equally to TMB in the analysis. 12 genes and 11 genes (5 sharing genes) were significantly associated with longer progression-free survival (PFS) and response (DCB vs NDB), respectively. The number of mutated genes within these 18 genes were defined as TMS18. In the survival analysis of PFS, the HRs of the high group were TMS19 (HR=0.307, P<0.001), TMB (HR=0.455, P<0.001), and PD-L1 expression (HR= 0.403, P=0.02), separately. Moreover, patients with DCB had significantly higher TMS18 (P<0.001), TMB (P=0.006), and PD-L1 expression (P=0.032). High TMS18 group had highest proportion of CR/PR/SD patients, which was 74.1% (CR/PR/SD: 3/17/20), especially in distinguishing CR patients. Taken together, TMS18 was more powerful than TMB and PD-L1 in predicting response of ICIs in NSCLC. **Conclusion:** Simple transformation from unselective TMB to selective TMS greatly enhanced the power of mutations-based biomarkers. TMS in combination with PD-L1 expression might yield better efficiency in predicting response of ICIs in NSCLC with future validation in larger cohorts.

Background: It is unclear whether factors including clinical and immune microenvironment (IME) are associated with tumor mutation burden (TMB) in patients with non-small cell lung cancer (NSCLC). We aimed to develop a prediction model to identify the association between these factors and TMB in patients with NSCLC. **Method:** We assessed somatic mutation burden in surgical tumor specimens with whole exome sequencing (WES) using an ion torrent proton platform (Thermo Fisher Scientific). The IME profiles including PD-L1 tumor proportion score (TPS), stromal CD8 tumor infiltrating T cell (TIL) density, and stromal Foxp3 TIL were quantified by digital pathology using a machine learning algorithm. To detect factors associated with TMB, factors including clinical and IME were assessed using a multipul regression model. Two hundred NSCLC patients, for whom both WES and clinical data from Project HOPE (High-Tech-Omics-based Patient Evaluation) were available, excluding those with low tumor purity (less than 20%), were assessed in this study. **Result:** Out of 250 NSCLC patients with tumors surgically resected between September 2014 and September 2015, we analyzed tumors from 200 patients. Patient **background:** median age (range) 70 (39-87), male 37.5%, smoker 27.5%, pathological stage (p-stage) (I/ II/ III) 63.5/22.5/14.0% respectively, histological type (Ad/Sq) 77.0/23.0%, primary tumor location (upper/lower) 58.5/41.5%, median standardized uptake value (SUV) 7.5 (0.86-29.8), median serum CEA level (range) 3.4 ng/ml (0.5-144.3), median serum CYFRA 21-1 level 1.2 ng/ml (1.0-38.0), median TMB 2.19/ Mb (0.12-64.38), median PD-L1 TPS 15.1% (0.09-77.4), median stromal CD8 TIL 582.1/mm^2 (120.0-4967.6), and median stromal Foxp3 TIL 183.7/mm^2 (6.3-544.0). In simple regression analysis, gender (male/female), smoking status (yes/no), p-stage (I/II,III,IV), age (< 70, ≥70), primary tumor location (lower/upper), serum CEA level (low [< 5.0ng/ml], high [≥ 5.0 ng/ml]), serum CYFRA level (low [< 3.5ng/ml], high [≥3.5 ng/ml]), and actionable mutation status (Mt+/Mt-) were favorable prognostic factors (p < .0001, p = .0001, p = .072, p = .027, p = .045, p = .002, p = .009, and p = .069 respectively). Multiple regression analysis identified five factors [smoking status:

POSTERS

smoker, age: less than 70, primary tumor location: lower, serum CEA level (greater than 5ng/ml), and serum CYFRA level (greater than 3.5ng/ml)] associated with higher TMB (p = .002, p = .045, p = .03, p = .046 and p = .016 respectively). **Conclusion:** IME factors did not associate with tumor mutation burden. However, along with smoking, lower primary location, elevated CEA and CYFRA level may be independent predictors of high TMB.

Background: The PD-1/PD-L1 pathway contributes to the metabolic reprogramming of immune cells and tumor cells. However, the mechanism by which PD-L1 regulates glycolysis in human cancer and the relationship between PD-L1 expression, glycose metabolism and anti-tumor immune response remain unclear. We addressed these issues in human non-small-cell lung cancer (NSCLC). **Method:** Changes in glycolysis-related molecules and glycolytic activity were evaluated in PD-L1^{low} and PD-L1^{high} NSCLC cells after transfection or knockdown of *PD-L1*, respectively. RNA seq and gene set enrichment analyses (GSEA) was also performed. The association between PD-L1 and immune response-related molecules or glycolysis were analyzed in patients with NSCLC and The Cancer Genome Atlas (TCGA). **Result:** Transfecting *PD-L1* in PD-L1^{low} cells enhanced hexokinase-2 (HK2) expression, lactate production, and extracellular acidification rates, but minimally altered GLUT1 and PKM2 expression and oxygen consumption rates. Consistently, GSEA revealed that the glycolytic pathway was enhanced in PD-L1^{low} cells after PD-L1 transfection. By contrast, knocking-down *PD-L1* in PD-L1^{high} cells decreased HK2 expression and glycolysis by suppressing PI3K/Akt and Erk pathways. Immunohistochemistry revealed that PD-L1 expression was positively correlated with HK2 expression in NSCLC tissues from patients (p<0.001). In TCGA analyses, *HK2* exhibited a positive linear association with *CD274* (PD-L1) expression (p<0.001) but an inverse correlation with the expression of *CD4*, *CD8A*, and T-cell effector function-related genes in the *CD274*^{high} rather than *CD274*^{low} group. Consistent with this, there were fewer CD8$^+$ T-cells in PD-L1^{positive}/HK2^{high} tumors compared to PD-L1^{positive}/HK2^{low} tumors in squamous cell carcinoma. **Conclusion:** PD-L1 enhances glycolysis in NSCLC by upregulating HK2, which might dampen anti-tumor immunity. PD-L1 may contribute to NSCLC oncogenesis by inducing metabolic reprogramming and immune checkpoint pathway.

P2.04-43 HIGH OCCURRENCE OF LINE-1 RETROTRANSPOSITION IS CORRELATED WITH SMOKING HISTORY, LOCAL IMMUNOSUPPRESSION AND POOR PROGNOSIS IN LUSC

J. Yu, R. Zhang, P. Liu, X. Zhang, W. Zhang

Tianjin Medical University Cancer Institute & Hospital, Tianjin/China

Background: Somatic Long Interspersed element-1 (LINE-1) retrotransposition (RT) is a genomic process that relates to gene disruption and tumor occurrence. However, the expression and function of LINE-1 RT in lung squamous cell carcinoma (LUSC) remains unclear. **Method:** We analyzed the transcriptomes of paired LUSC samples in The Cancer Genome Atlas (TCGA), to characterize the most common somatic LINE-1 RTs in LUSC, followed by validation in an independent Chinese LUSC cohort and several cancer cell lines. We also analyzed the association between these LINE-1 RTs and clinico-pathology features, as well as the immunocyte content in local LUSC tumor tissues. **Result:** We observed LINE-1 RT occurred within 90% of tumor samples in TCGA, among which thirteen LINE-1 RTs were filtered for high occurrence in LUSC. In Chinese cohort, the expression of 13 LINE-1 RTs in LUSC tissues was significantly higher than those in matched adjacent normal tissues. Furthermore, 11 of 13 LINE-1 RTs were exclusively detected in LUSC cell lines rather than normal lung epithelial cells. Further analysis showed 3 LINE-1 RTs, including L1-FGGY, L1-ATP8B1 and L1-SVEP1 were correlated with smoking history, large tumor size, central tumor location, and poorer prognosis. The immunohistochemical staining (IHC) analysis showed that less CD3$^+$ T cells, more CD68$^+$ macrophages and CD33$^+$ myeloid-derived suppressive cells (MDSCs) were detected in LINE-1 RT positive tissues which implied that LINE-1 RT might induce significant immunosuppression *in situ*. **Conclusion:** In conclusion, LINE-1 RT is a frequent genomic event that correlates with smoking-related LUSC development and LUSC immune evasion which might be a promising predictive biomarker of poor prognosis in LUSC.

P2.04-44 COMBINED IMMUNE CHECKPOINT BLOCKADE IN MESOTHELIOMA: IN VIVO INVESTIGATION OF IN VITRO DATA

E. Marcq[1], J. Van Audenaerde[1], J. De Waele[1], J. Jacobs[1], J. Van Loenhout[1], P. Pauwels[2], E. Smits[1], J. Van Meerbeeck[2]

[1]*University of Antwerp, Wilrijk/Belgium,* [2]*Antwerp University Hospital, Antwerp/Belgium*

Background: Malignant pleural mesothelioma (MPM) is an aggressive cancer that is causally associated with asbestos exposure. Due to its aggressive nature and despite the effectiveness of conventional anti-cancer treatment, the prognosis of patients diagnosed with MPM remains dismal, highlighting the urgent need for new therapeutic strategies. Our group and others have recently demonstrated PD-1 and PD-L1 expression in MPM patients, providing rationale to evaluate their suitability as immunotherapeutic targets in MPM. **Method:** Tree human cell lines representative for the epithelioid and sarcomatoid subtypes of MPM were placed in allogeneic co-cultures with healthy donor peripheral blood mononuclear cells. The co-cultures were treated with the following immune checkpoint blocking antibodies: anti PD-1 (Nivolumab®, BMS) or anti PD-L1 (Durvalumab®, AstraZeneca) in combination with anti TIM-3 or anti LAG-3. Supernatant was collected and enzyme-linked immunosorbent assays and multiplex electrochemo-luminescence were used to look at the secretion of 7 cytokines, being IFNγ, IL-2/5/6/10, IL-1band TNF-α, as well as the enzyme granzyme B. **Result:** Significant differences were found for the secretion of IFNγ, granzyme B, IL-2, IL-5 and IL-10. Though the differences were not always significant for the 3 MPM cell lines, the same trends were observed among them. Interestingly, highest concentrations of the aforementioned cytokines were all noticed for monotherapy treatment with anti PD-1, anti PD-L1 or or their combination with anti TIM-3. In vivo investigation of PD-1, PD-L1 and TIM-3 blockade, alone or in combination is required for validation of our *in vitro* results and is currently ongoing. **Conclusion:** Our data show that treatment with anti PD-1, anti PD-L1 or their respective combination with anti TIM-3 resulted in the highest secretion of cytokines and granzyme B, suggesting that these treatments stimulate the antitumor response the most. Results of our in vivo validation are awaited in order to confirm our *in vitro* findings.

P2.04-45 A PHASE 1B DOSE-ESCALATION STUDY OF CAROTUXIMAB IN COMBINATION WITH NIVOLUMAB IN PATIENTS WITH METASTATIC NSCLC

F. Robert[1], J.E. Gray[2], A. Trigeiro[3], B. Adams[4], C. Theuer[4]

[1]*University of Alabama at Birmingham, Birmingham/United States of America,* [2]*Lee Moffitt Cancer Center and Research Institute, Tampa/United States of America,* [3]*Tracon Pharmaceutical, San Diego/United States of America,* [4]*Tracon Pharmaceuticals, San Diego/United States of America*

Background: Nivolumab has demostrated clinical benefit in advanced non-small cell lung cancer (NSCLC) patients who have progressed following platinum-based chemotherapy.Carotuximab (TRC105) is an antibody to endoglin, a receptor expressed on

proliferating endothelial cells and myeloid derived suppressor cell (MDSCs), which potently complements the activity of antibody targeting the programmed death receptor (PD-1) in preclinical models. By targeting MDSCs, carotuximab has the potential to complement nivolumab in patients with refractory metastatic NSCLC. **Method:** Patients with refractory metastatic NSCLC were enrolled regardless of baseline PD-L1 tumor expression and treated with 8 mg/kg or 10 mg/kg of carotuximab weekly for four doses and then 15 mg/kg every two weeks, in combination with the approved dose of nivolumab of 240 mg every two weeks using a standard "3+3" dose escalation design. Expansion cohorts were then opened to further assess the safety, tolerability, and preliminary efficacy by iRECIST of the recommended Phase 2 dose (RP2D) of carotuximab with standard dose nivolumab. **Result:** The combination of carotuximab and nivolumab was well-tolerated without dose limiting toxicitiy in 6 patients treated as part of dose escalation. One of these 6 patients, whose archival tumor did not express PD-L1 and who had not received prior PD-1/PD-L1 checkpoint inhibition treatment, developed a partial response and remains on study after 14 months. Two of the other 5 patients, one of whom who progressed following prior nivolumab treatment, achieved stable disease, one of whom remains on study at 7 months. Common adverse events regardless of relationship included low grade headache, vomiting, anemia, dyspnea, fatigue, cutaneous telangectasia, nausea, bleeding gums, diarrhea, and migraine. Target concentrations of carotuximab were achieved in all patients and anti-drug antibody was not detected. Enrollment is continuing in two parallel 12 patient expansion cohorts, one in patients who relapsed following prior PD-1/PD-L1 checkpoint inhibition and one in patients naive to PD-1/PD-L1 checkpoint inhibition. **Conclusion:** Carotuximab at its RP2D of 10 mg/kg weekly x 4 and then 15 mg/kg every 2 weeks was tolerable with nivolumab in patients with NSCLC, and demonstrated preliminary signs of efficacy

Background: Non-small cell lung cancer (NSCLC) accounts for approximately 80% of cases diagnosed with lung cancer. Pembrolizumab is a humanized IgG4 subtype antibody that targets programmed death receptor (PD-1) of lymphocytes. Recent studies have shown that addition of pembrolizumab to traditional chemotherapy regimens improves survival in advanced NSCLC. Nevertheless, there are considerable safety concerns, ultimately leading to significant morbidity affecting patients' quality of life, and treatment discontinuation. We conducted a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of treatment-related adverse events (TRAE) and treatment discontinuation due to TRAE. **Method:** PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019 were queried. RCTs utilizing first-line pembrolizumab chemoimmunotherapy in patients with advanced NSCLC were incorporated in the analysis. The primary meta-analytic approach was a random effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q-test. **Result:** 3 RCTs (Keynote – 021,189 and 407) including 1298 patients with advanced NSCLC were included in the analysis. The study arm used standard chemotherapy regimens in combination with pembrolizumab while control arm utilized only standard chemotherapy regimens. The randomization ratio was 2:1 in Keynote-189 study and 1:1 in other studies. The pooled RR of any-grade TRAE was not significant at 1.01 (95% CI: 0.99–1.02, P = 0.29) and RR of high-grade TRAE was 1.03 (95% CI: 0.95–1.12, P = 0.47). Yet, the relative risk of treatment discontinuation due to any-grade TRAE was statistically significant at 1.75 (95% CI: 1.26–2.45, P = 0.001) and RR of treatment discontinuation due to high-grade TRAE was 1.85 (95% CI: 1.38–2.49, P < 0.0001). Treatment-related deaths were reported as 51 (6.87%) in study arm vs 32 (5.88%) in control arm. The pooled RR was not significant at 1.18 (95% CI: 0.76–1.82, P = 0.46). **Conclusion:** All grades of TRAE and treatment related deaths were not significantly increased in first-line pembrolizumab chemoimmunotherapy. However, patients on the study arm experienced significant drop-out due to TRAE, despite showing survival benefits in the studies. Proper supportive care may reduce unwanted treatment discontinuations and enhance patients' compliance.

Background: A minority of NSCLC patients benefit from anti-PD1 immune checkpoint inhibitor therapy. A rational combination of biomarkers is needed. The value of using a series of mechanism-of-action based parameters was studied for response prediction of immunotherapy: tumor mutational load (TML), $CD8^+$ T cell infiltration, HLA class I expression and the currently used PD-L1 tumor proportion score. **Method:** Patients were prospectively included between April 2016 and August 2017, and retrospectively analyzed. Metastatic NSCLC patients (n=30) with sufficient archival tissue, obtained prior to the first nivolumab administration, were selected. Response was assessed by RECIST v1.1. Progression-free survival (PFS) and overall survival (OS) were analyzed by Kaplan-Meier methodology. TML was determined using a next-genome sequencing panel (409 cancer-related genes). Immunohistochemistry was performed to score PD-L1, total $CD8^+$ T cell infiltration and HLA class I. **Result:** In 30 patients with adenocarcinoma (67%) or squamous cell carcinoma (33%), high TML was significantly associated with better PFS (p=0.004) and OS (p=0.025). Interaction analyses revealed that patients with both high TML and high total $CD8^+$ T cell infiltrate (p=0.023) or no loss of HLA class I (p=0.026), patients with high total $CD8^+$ T cell infiltrate and no loss of HLA class I (p=0.041) or patients with both high PD-L1 and high TML (p=0.003) or no loss of HLA class I (p=0.032) were significantly associated with better PFS. Unsupervised cluster analysis based on the four markers revealed three sub-clusters, of which cluster 1A was overrepresented by patients with progressive disease (15 out of 16), with significant effect on PFS (p=0.007). **Conclusion:** This proof-of-concept study suggests that a combination of PD-L1 expression, TML, $CD8^+$ T cell infiltration and HLA class I expression function as a better predictive biomarker for the response to anti-PD-1 immunotherapy and PFS. Consequently, refinement of this proposed set of biomarkers and validation in a larger set of patients is warranted.

P2.04-48 USE OF IMMUNE CHECKPOINT INHIBITORS IN PATIENTS WITH ADVANCED LUNG CANCER AND PRE-EXISTING AUTOIMMUNE DISEASES

S. Cytryn[1], E. Efuni[1], V. Velcheti[2], S. Sandigursky[1]

[1]*NYU Langone Health, New York/United States of America,* [2]*NYU Langone Cancer Center, New York/United States of America*

Background: The prevalence of autoimmune diseases (AIDs) in patients with lung cancer is approximately 14%. However, patients with pre-existing AIDs have been excluded from trials of immune checkpoint inhibitors (ICIs) known to cause immune activation and lead to immune related adverse events (irAEs) limiting the data on safety and efficacy of these agents. Oncologists are therefore wary to use them in this at-risk population. **Method:** We conducted a single institution IRB-approved retrospective study to evaluate the safety and efficacy of combination and single agent ICI therapy in patients with pre-existing AIDs and concomitant advanced lung cancer that were treated with ICI from 2011 to 2018. Primary endpoints were incidence of irAEs and AID flares. The secondary endpoint was overall survival (OS). **Result:** We evaluated records from 29 patients with

lung cancer of which 17 (59%) had adenocarcinoma, 10 (34%) had squamous cell carcinoma, two (7%) had small cell cancer, and one (3%) had undifferentiated non-small cell lung cancer. AIDs included rheumatic (72%), gastrointestinal (10%), endocrine (10%) and neurologic (7%). 34% of patients experienced an irAE, though only 7% were severe (grade 3-4 colitis and hepatitis). 66% of patients reported no irAEs at all. The most common irAEs were dermatitis (14%) and colitis (10%). 10% of patients had to permanently discontinue ICIs due to an irAE while 17% temporarily held their ICI. 96% of patients with AIDs were either stable or in remission. AID flares were observed in 28% of patients with 24% requiring treatment. None of the AID flares resulted in permanent discontinuation of ICI therapy. 21% of patients were on immunomodulatory therapies at start of ICI treatment. The use of immunomodulatory medications was not associated with an increased incidence of either irAEs or AID flares. Median OS from ICI initiation was 8.5 months and median PFS was 6 months. There was no statistically significant difference for OS or PFS by presence of irAE or presence of immunomodulatory therapy at start of ICI use. **Conclusion:** In this cohort, patients with pre-existing AIDs and advanced lung cancer reported fewer AID flares (28%) than has been cited in the literature (approximately 50%). IrAEs were seen at an incidence similar to that observed in patients without AIDs. In our cohort, the majority of adverse reactions were manageable and did not require permanent discontinuation of ICI therapy. Furthermore, the presence of irAEs did not detrimentally affect patients' OS or PFS. Based on these findings, we would consider ICI therapy as an option in select patients with pre-existing autoimmunity.

Background: Treatment landscape for patients with advanced NSCLC is rapidly evolving, with recent randomized phase III trials demonstrating superiority of chemo-immuno combinations versus chemotherapy alone. Role of chemo-free combinations, including NI, is under investigation with limited available data. Aim of the present trial is to investigate outcome of SqCLC patients when treated with NI or CN. **Method:** SQUINT (NCT03823625) is an open-label, randomized, parallel, non-comparative phase II study designed to assess the efficacy of NI (Arm A) or CN (Arm B) in patients with advanced, metastatic SqCLC. Eligibility requires age ≥ 18 years, histologically confirmed stage IV or recurrent stage IIIB SqCLC, $p63^+$/$p40^+$ and TTF^- tumour tissue, availability of PD-L1 status, no prior systemic therapy, ECOG performance status 0-1, adequate organ functions. Key exclusion criteria include concomitant radiotherapy or chemotherapy, prior treatment with immune checkpoint inhibitors, untreated brain metastases, other serious illness or medical condition potentially interfering with the study or with NI administration. Patients are randomly assigned 1:1 to receive N 360 mg Q3W plus I 1 mg/kg Q6W (Arm A) or plus platinum-based chemotherapy up to 6 cycles plus nivolumab 360 mg Q3W (Arm B), and stratified by PD-L1 expression (<1% versus ≥1%), presence of bone metastases (yes/no) and liver metastases (yes/no). In both arms, immunotherapy is given until disease progression, unacceptable toxicity, patient refusal and in any case for up to 24 months. Primary endpoint is 1-year overall survival (OS) rate in Arm A and B. Secondary endpoints include: response rate (RR), duration of response (DoR), median progression free survival (PFS) and median OS in Arm A and B, and according to predefined stratification factors. Sample size has been calculated assuming for each arm a minimum acceptable 1-year OS rate of 40% and an auspicated 1-year OS rate of 60%, a power of 90% and a one side significant level of 0.05. Based on such premises, the total number of patients required for the study is 112. **Result:** At the time of this analysis a total of 11 Italian Centers are recruiting and 25 subjects have been enrolled. **Conclusion:** We expect to conclude enrolment by January 2020.

P2.04-50 ADVANCED STATISTICAL APPROACH TELLS THE DIFFERENCE: TAYLOR-EXPANSION ADJUSTMENT FOR SURVIVAL ANALYSES IN IMMUNOTHERAPY TRIALS

C.-Y. Hsu, E.P.-Y. Lin, Y. Shyr

Vanderbilt University Medical Center, Nashville/United States of America

Background: The success in immune checkpoint inhibitors (ICIs) has again revolutionized the paradigm in lung cancer therapy, especially among patients without druggable driver mutations. Landmark studies, such as Keynote 010/042 and Checkmate 017/057, showed that patients in the ICI study arm had a better overall survival compared to patients receiving standard chemotherapy. Furthermore, most of the Kaplan-Meier (KM) survival curves crossed within the first 3 to 6 months and the survival curve for ICI study arm showed a long-tail, suggesting the existence of a subgroup that truly respond to ICIs. However, the traditional Cox proportional hazards model does not provide adjustment for treatment responses between true-responders and poor-responders. We hypothesize that hazard ratios (HRs) between the treatments differ from these two subgroups and adjustment is required for survival evaluation in ICI trials. **Method:** Overall survivals in Keynote 010, 042, 189, 407 and Checkmate 017/057 three-year updated data served as the real data illustrations in the current study. The Taylor expansion was applied to the adjustment of HRs derived from the traditional Cox model. Comparisons between the adjusted and the crude HRs were made and the differences in the proportion of patients with long-term survival obtained by the adjustment approach were also inferred. **Result:** Our results showed that when the adjustment approach was applied, the adjusted HRs for the ICI poor-responders compared to the chemotherapy control became statistically non-significant. Furthermore, the proportion of patients with long-term survival differed significantly between ICI true-responders and chemotherapy control. The pattern was observed in all four ICI monotherapy studies with crossing survival curves in the initial 3-6 months (Table 1).

Table 1. Changes in hazard ratio before and after Taylor-expansion adjustment.

ICI Trials	Cox model	Taylor-expansion adjustment	
	Hazard Ratio	Hazard Ratio	Differences in long-tail proportion
Checkmate 017/057 3-yr updated (2018, Annals of Oncology)	**0.70 (0.61, 0.81)**	0.89 (0.77, 1.03)	**0.10 (0.05, 0.15)**
Keynote 010 (2015, NEJM)			
Pembrolizumab 2mg/kg	**0.71 (0.58, 0.88)**	0.95 (0.77, 1.17)	**0.16 (0.04, 0.27)**
Pembrolizumab 10mg/kg	**0.61 (0.49, 0.75)**	0.92 (0.74, 1.13)	**0.23 (0.12, 0.36)**
Keynote 042 (2019, Lancet)			
PD-L1> 50%	**0.69 (0.56, 0.85)**	0.84 (0.68, 1.03)	**0.13 (0.01, 0.25)**
PD-L1> 20%	**0.77 (0.64, 0.92)**	0.88 (0.73, 1.06)	**0.10 (0.01, 0.20)**
PD-L1> 1%	**0.81 (0.71, 0.93)**	0.91 (0.80, 1.05)	**0.09 (0.01, 0.16)**
PD-L1= 1-49%	0.92 (0.77, 1.11)	0.94 (0.79, 1.14)	0.04 (-0.06, 0.13)
Keynote 189 (2018, NEJM)	**0.49 (0.38, 0.64)**	**0.67 (0.52, 0.88)**	**0.20 (0.04, 0.35)**
Keynote 407 (2018, NEJM)	**0.64 (0.49, 0.85)**	**0.71 (0.54, 0.94)**	0.08 (-0.13, 0.27)

Conclusion: The results suggested that the traditional Cox model might not be the optimal method for survival analyses in ICI trials and adjustment is necessary. The differences between the adjusted and the crude HRs may be very significant.

Gemelli IRCCS, Roma/Italy,* [5]*Department of Diagnostics and Public Health, Section of Anatomical Pathology & ARC-Net Research Centre, University and Hospital Trust of Verona, Verona/Italy,* [6]*University and Hospital Trust of Verona, Verona/Italy,* [7]*Università Cattolica del Sacro Cuore; Fondazione Policlinico Agostino Gemelli IRCCS, Rome/Italy*

Background: Genomic abnormalities detected in immune-escape/editing-related genes may promote immunotherapy resistance. In the light of this hypothesis, we designed the PRINCiPe (Predictors of Resistance to Immunotherapy with NIV) study in APNSCLC. **Method:** FFPE-tumor blocks of APNSCLC pts undergone NIV were retrospectively sequenced for Somatic Mutations/Copy Number Variations (SM/CNV) (Ampliseq 17-genes customized panel: *APLNR*, *B2M*, *IFNAR1*, *IFNAR2*, *IFNGR1*, *IFNGR2*, *IRF9*, *JAK1*, *JAK2*, *JAK3*, *PIAS4*, *PTPN2*, *SOCS1*, *STAT1*, *STAT2*, *STAT3*, *TYK2*). End-points of the PRINCiPe study were overall-, progression-free-survival (OS/PFS) and objective response rate (ORR). **Result:** Forty-four APNSCLC pts were gathered (median age 69.5 yrs, median number of previous lines 3 [2-5], 2nd line NIV [75.0%], male/female 77.3/22.7%, squamous/non-squamous 31.8/68.2%, *EGFR* mutant 5 [11.4%], median follow-up 6.8 months [range 1-23], deaths 24 [54.5%]). *JAK3/JAK2* (7/3 pts, 15.9/6.8%) CNV and *IFNAR2* SM (4 pts, 9.1%) were the most frequent (>1 pts) abnormalities. Pts (n=15) with *JAK3*, *PIAS4*, *PTPN2*, *STAT3*, *IFNAR2* SM and/or *JAK2/3* CNV (IGS+) had a significantly lower PFS than those without (IGS-) (median PFS 2.8 vs. 6.6 months; *p=0.006*), while a trend towards significance was observed in terms of OS (median OS 5.1 vs. 13.0 months for IGS+ and IGS-, respectively; *p=0.06* log-rank, *p=0.05* Tarone-Ware). At multivariate analysis, IGS+ was independently associated with a shorter PFS (HR 2.64, 95% CI 1.3-5.4, *p=0.008*). IGS+ pts were significantly more probable to be affected by liver metastases than those without (*p=0.01*). **Conclusion:** The identified IGS appears to select APNSCLC pts with a significant lower chance to benefit from NIV, supporting intrinsic resistance. A prospective larger and external validation is ongoing, as well as the comprehensive transcriptome analysis.

Keywords: signature, genomic analysis, immunotherapy resistance

P2.04-52 IMPACT OF CORTICOSTEROIDS AND ANTIBIOTICS ON EFFICACY OF IMMUNE-CHECKPOINT INHIBITORS IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

M. Riudavets[1], J. Mosquera[2], R. Garcia Campelo[2], J. Serra[1], G. Anguera[1], P. Gallardo[1], I.G. Sullivan[1], A. Barba[1], M. Majem[1]

[1]*Hospital de la Santa Creu i Sant Pau, Barcelona/Spain,* [2]*University Hospital A Coruña, Coruña/Spain*

Background: Immune-checkpoint inhibitors (ICIs) are a standard-of-care in advanced non-small cell lung cancer (NSCLC). Corticosteroids are frequently used in symptomatic advanced NSCLC patients, but their immunosuppressive effect may reduce the efficacy of ICIs. Here we report our experience in patients with NSCLC and the potential impact of on-treatment use of corticosteroids and antibiotics. **Method:** Medical records of 267 patients with advanced NSCLC receiving ICIs from March 2013 to August 2018 were reviewed. Corticosteroid usage at the time of initiation or during ICIs treatment and administration of antibiotics from three months before the initiation of ICIs to 3 months after treatment end were collected. Kaplan Meier and log-rank tests were used to evaluate progression-free (PFS) and overall survival (OS). A multivariable analysis was performed to study the influence of clinical characteristics on treatment efficacy. **Result:** 146 patients (55%) received corticosteroids: 63 (43%) for the treatment of irAEs and 83 (57%) for the management of baseline conditions. Prednisone (40%) and dexamethasone (35%) were the most commonly used types of corticosteroids. Median dose of prednisone equivalent was 50mg daily [5-1250mg], 92% patients received ≥10mg of prednisone equivalent daily. Median duration of corticosteroids was 59 days [0.5-83.0]. OS was longer in the group of patients that did not receive corticosteroids or received <10mg prednisone equivalent daily: 14.7 months (95%CI, 11.1-18.3) vs 8.3 months (95%CI, 6.9-9.8) (p = 0.009). No differences in PFS were observed: 4.6 months (95%CI, 2.9-6.3) vs 4.2 months (95%CI, 2.5-5.9) (p = 0.359). Patients receiving corticosteroids for baseline condition presented shorter median overall survival than the rest of the study population: 6.5 months (95%CI, 4.6-8.3) vs 16.5 months (95%CI, 12.1-20.8) (p <0.001). Multivariable analysis identified corticosteroids usage as an independent variable related to poorer outcomes. 141 patients (52.8%) received antibiotics. Quinolone (37%) and penicillin (33%) were the most commonly used groups of antibiotics. No correlation between the usage of antibiotics and efficacy of ICIs was found, with median OS of 10.2 months (95%CI, 6.4-13.9) vs 12.5 months (95%CI, 9.9-15.0) (p = 0.924). **Conclusion:** In our series, corticosteroid use of ≥10mg of prednisone equivalent daily was associated with significantly poorer outcomes, especially when given for baseline condition. No correlation was found between antibiotics and survival. It is important to underline that the use of

corticosteroids may simply identify a population with higher volume and aggressive tumors. Prudent use of corticosteroids needs to be warranted.

Keywords: corticosteroids, antibiotics, Immune-checkpoint inhibitors

P2.04-53 SERIAL ULTRA-DEEP SEQUENCING OF CTDNA REVEALS THE CLONAL EVOLUTION IN NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH PEMBROLIZUMAB

L. Li, H. Yong

Daping Hospital, Army Medical University, chongqing/China

Background: Immune-therapy with anti-PD1 inhibitors, such as pembrolizumab, is revolutionizing the treatment of non-small cell lung cancers (NSCLC). However, identifying patients for the potential therapeutic response and predicting therapy resistance and early relapse remains a challenge. **Method:** Between 2016 and 2018, 60 patients were treated with pembrolizumab, among who 12 NSCLC patients had both baseline (before treatment) and serial (on treatment) periodical circulating tumor DNA (ctDNA) samples. Those samples were sequenced on a 329 pan cancer-related gene panel. Analyses of tumor burden, blood tumor mutational burden (bTMB), maximum somatic allele frequency (MSAF), and tumor clonal structure were performed in association with clinical response. Resistance mutations involved in relapse and metastases were further investigated. **Result:** ctDNA was detected and mutational profiling was performed for each patient. Those with a high baseline bTMBlevel showed significantly improved progression-freesurvival (PFS) after pembrolizumab treatment. Tumor burden and therapeutic response significantly correlated with the MSAF instead of the bTMB. Clone analysis detected tumor progression about 2-4 months ahead of computedtomography (CT) scan. One mutation in gene *PTCH1* (Protein patched homolog 1) and two acquired anti-PD1 resistance mutations of gene *B2M* (β2 microglobulin) were identified in association with distant metastasis. The evolutionary tree of a representative patient was also described. **Conclusion:** This pilot study showed thatMSAF could be another good indicator of therapeutic response, and clonal analysis could be clinically useful in monitoring clonal dynamics, and detecting resistance and early relapse.

Keywords: Pembrolizumab, ctDNA, maximum somatic allele frequency

P2.04-54 CHARACTERISTIC OF MSI-H LUNG CANCER PATIENTS IDENTIFIED WITH TARGETED NEXT-GENERATION SEQUENCING

W. Lin[1], R. Chen[2], Y. Yi[2], G. Lin[3], J. Zhao[4], M. Yuan[2], Y. Guan[2], X. Xia[2]

[1]*Cancer Hospital of Shantou University Medical College, Shantou/China,* [2]*Geneplus-Beijing Institute, Beijing/China,* [3]*Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou/China,* [4]*Beijing Cancer Hospital, Beijing/China*

Background: MSI-H/dMMR predicts response to immune oncology (IO) agents and is an approved biomarker for pembrolizumab therapy irrespective of histologic diagnosis. In this study, we retrospectively analyzed a large cohort of lung cancer patients using targeted next generation sequencing to examine the prevalence and clinicopathologic associations of MSI-H in lung cancers. **Method:** MSI and TMB status was derived from a 1021 gene targeted next generation sequencing panel. MSI was analyzed using MSIsensor 0.5, that relies on an empirically defined cutoff of MSI score>10%, as MSI-H. TMB analysis interrogated single nucleotide variants, small insertion and deletion, with VAF ≥3 %. TMB-H pts were identified with ≥9 mut/MB (upper quartile of data from geneplus). **Result:** 5592 lung cancer patients were interrogated in the study, with 4753 lung adenocarcinoma, 559 lung squamous cell carcinoma, 112 small cell lung carcinomas (SCLC), and 168 rare lung cancer types including pulmonary sarcomatoid carcinoma, carcinoid and so on. A total of 12 lung tumors were identified as MSI-H (0.21%), and 5 were lung adenocarcinoma (0.1%), 3 were small cell lung cancer (2.7%), 1 was lung squamous cell carcinoma (0.18%), 2 were pulmonary sarcomatoid carcinomas, and 1 was pulmonary carcinoid (1.8%). The incidence was higher in small cell lung cancer and rare lung cancer subtypes. The average diagnosis age of the 12 patients were 53 years (range: 16-74). All the patients were TMB-H, with the TMB averaged 51.23 mut/Mb (range: 10-70 mut/Mb). Two of the 5 lung adenocarcinoma patients carried *EGFR* L858R or 19del mutation. One patient who had both *NRAS* G12V and *EGFR* Ex20 mutation had tried nivolumab (120mg) for one cycle with deteriorating of cough and progression of disease. **Conclusion:** MSI-H is very rare in lung tumors, where it appears to enrich in small cell lung cancer and rare lung cancer subtypes. MSI-H lung cancer patients tend to have a younger diagnosis age. MSI-H may coexist with other driver alterations, including those negatively associated with IO response. Additional investigation is needed to determine efficacy of IO in these patients.

Keywords: MSI-H, TMB-H, Next generation sequencing

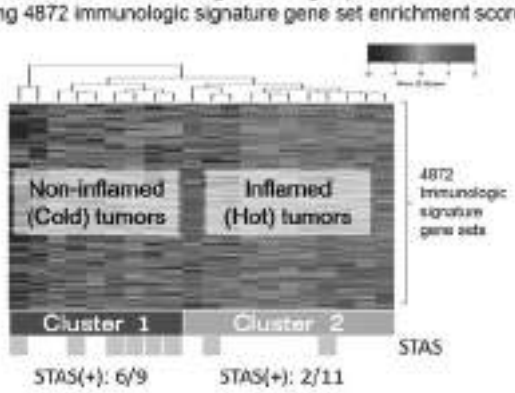
P2.04-55 TUMOR SPREAD THROUGH AIR SPACES IS ASSOCIATED WITH THE NON-INFLAMED IMMUNE MICROENVIRONMENT IN LUNG SQUAMOUS CELL CARCINOMA

T. Karasaki[1,2], Y. Kobayashi[1,2], A. Shinozaki-Ushiku[1], C. Konoeda[1], K. Kitano[1], K. Nagayama[1], M. Sato[1], A. Hosoi[1,2], K. Kakimi[1,2], J. Nakajima[1]

[1]*The University of Tokyo Graduate School of Medicine, Tokyo/Japan,* [2]*RIKEN, Tokyo/Japan*

Background: Tumor spread through air spaces (STAS) is reportedly a poor prognostic factor in non-small cell lung cancer. However, little is known about the molecular background and tumor microenvironment associated with STAS. This study assessed the relationship between STAS and tumor microenvironment in lung squamous cell carcinoma using next generation sequencing data. **Method:** RNA-sequencing and whole-exome sequencing were performed in 20 surgically resected lung squamous cell carcinoma cases. Pathological specimens were reviewed to determine the existence of STAS. Somatic mutations, gene expression and gene set enrichment were analyzed and compared between STAS positive and negative tumors. **Result:** Among 20 patients, nine were pathological stage I, six stage II and five stage III. In all, eight tumors were positive for STAS and 12 were negative. While STAS was not associated with tumor size, all N2 tumors were positive for STAS. Tumor mutational burden was not associated with STAS. Hierarchical clustering using the single sample Gene Set Enrichment Analysis score of 4872 immunologic signature gene sets revealed two clusters (Figure 1). Cluster 1 revealed lower expression of immune-related genes, forming a cluster of non-inflamed (cold) tumors. The cluster of non-inflamed tumors showed a tendency to higher STAS positivity (Cluster 1, 67%; Cluster 2, 18%; p=0.065). Next, we performed Gene Set Enrichment Analysis between STAS positive and negative tumors. Using 50 Hallmark gene sets in the Molecular Signatures Database, gene sets of allograft rejection, IL2-STAT5 signaling, inflammatory response and complement were found to have a significantly lower expression in STAS positive tumors (q <0.05). We further investigated the expression of each immune-related gene and compared them between STAS positive and negative tumors, which showed that PD-L1 gene expression was significantly lower in STAS positive tumors (p=0.023).

Figure1. Hieralchical clustering of 20 lung Squamous cell carcinoma using 4872 immunologic signature gene set enrichment scores



POSTERS

Conclusion: STAS positivity was associated with the non-inflamed tumor-immune microenvironment in lung squamous cell carcinoma. Our findings might partly explain the aggressive behavior of STAS positive tumors. Since the efficacy of immunotherapy might differ between STAS positive and negative tumors, further investigation of immunological and molecular aspects of STAS positive tumors is needed.

P2.04-56 IMPROVED SURVIVAL OF NSCLC FILIPINO PATIENTS GIVEN AUTOLOGOUS DENDRITIC CELL VACCINE: CASE SERIES WITH CTC UPGRADE AND IL15

F.I. Heralde[1,2], M.T. Barzaga[1,3], N. Tan-Liu[1], M.S. Angeles[1], S. Bernal[4]

[1]*Lung Center of the Philippines, Quezon/Philippines,* [2]*University of the Philippines-Manila, Manila/Philippines,* [3]*De La Salle University, Cavite/Philippines,* [4]*The Medical City, Mandaluyong/Philippines*

Background: Lung cancer remains to be a major malignancy among Filipinos with a fatality rate of 19.2 for every 100,000 in 2018. The Molecular Diagnostics and Cellular Therapeutics Laboratory of the Lung Center of the Philippines has developed a complimentary therapy using autologous dendritic cell vaccine for lung adenocarcinoma, the preliminary result of which was reported in this Conference in 2013. From then onwards, a number of modifications has been incorporated in the protocol as part of the continuing research and development program of the Center. Herein, reported is the comparative performance of the vaccination protocol in the period 2009-2013 and 2014-2018 and the modifications introduced that accounted for the improved survival. **Method:** Chart data of sixteen lung adenocarcinoma patients in 2009-2013 and five patients in 2014-2018 who have undergone the immune cell therapy as part of their treatment regimen, were retrieved and compared in terms of their survival in 3, 6 and 9 month timepoints. Protocol for immune cell therapy in the same period were also retrieved and compared. The patients have executed corresponding informed consent and their therapy has undergone ethics review and approval of the Stem Cell Ethics Committee of the Center. **Result:** Patients in 2009-2013 included 1 stage1, 1 stage 2, 6 stage 3 and 8 stage 4, while patients in 2014-2018 included 1 stage 1 and 4 stage 4. For stage 1, there was a 100% survival in the 3, 6 and 9 month timepoints in both periods. For stage 4 there was a 87.5%, 50% and 12.5% survival respectively in the 3, 6 and 9 month timepoints for the 2009-2013 period while a 100%, 75% and75% survival for 2014-2018 period. Protocol evaluation showed an increase in circulating tumor gene targets used for peptide priming (i.e. from 15 to 22 targets) and the use of IL15. The additional targets included were: BRACHURY, CD133, hTERT, p53, NRAS, S100A14, and CA125 **Conclusion:** Although preliminary, the additional targets and the use of IL15 could be attributed to the improved survival rate of patients, especially for stage 4 patients.

Background: Immune checkpoint inhibitors (ICI) have recently emerged as a treatment option for selected patients with advanced non-small-cell lung cancer (NSCLC). However, there is a lack of effective biomarker to predict the treatment response and monitor disease progression. In this prospective observational study, we aimed to investigate the predictive and prognostic value of folate receptor-positive circulating tumor cell (FR+CTC), a well-established lung cancer biomarker, in advanced NSCLC patients treated with ICIs. **Method:** Advanced NSCLC patients with at least one measurable lesion and expected to undergo ICIs treatment were recruited. Peripheral blood samples were collected from each participant at baseline, after each cycle of ICI treatment, and on disease progression. FR+CTCs were enumerated by using negative enrichment and ligand-targeted polymerase chain reaction methods. Treatment efficacy was analyzed according to the iRECIST criteria. The correlation of FR+CTC level and its dynamic changes with radiological responses was evaluated. **Result:** Of the 35 patients, 17 received first-line treatment, 10 received second-line treatment, and 8 received third-line treatment or above. CTCs were detected (≥8.7FU/3ml) in 80.0% of patients at baseline. The baseline CTC of first-line/second-line therapy patients was significantly higher than that of third-line and above therapy patients (median values 16.68 vs 8.36, P=0.017). Meanwhile, there was no significant difference in baseline CTC values between different pathological subtypes and whether PD-L1 was expressed or not. For the radiological responses, after at least two cycles of ICI treatment, PR, SD, and PD were found in 10, 8, and 4 patients, respectively. The CTC count in the PD group at baseline was significant higher than that of the disease control (PR+SD) group (P=0.033). Similarly, the CTC value after two cycles of ICI treatment in PD group (17.84 ± 7.03) was higher than SD/PR group (12.50 ± 4.94), but not statistically significant (P=0.081). However, the changes of CTCs after one or two cycles of immunotherapy were poorly related to the treatment response (P>0.05), perhaps because of the polarization trend of CTC changes in the PR group after treatment. **Conclusion:** In sum, these data confirm the predictive significance of CTCs in advanced NSCLC patients treated with immune checkpoint inhibitors. The baseline CTCs value correlated significantly with radiological response. Further studies are needed to confirm whether CTCs can be used as a prognostic factor for advanced non-small cell lung cancer.

P2.04-58 THE CORRELATION BETWEEN TMB AND CLINICAL FACTORS IN EAST ASIAN LUNG CANCER PATIENTS WITH NO TKI-RELATED DRIVER GENE-MUTATIONS

Y. He[1], X. Chen[1], B. Chen[1], L. Song[2], X. Li[2], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China,* [2]*Haplox, Shenzhen/China*

Background: Clinical factors, such as stage, metastasis, pathological type, age, smoking, gender and tumor mutational burden (TMB), have been reported to correlate with the prognosis of lung cancer (LC). However, it is still unclear how these factors influence the outcomes of patients with no TKI-related driver gene-mutations, and how these factors inter-correlate with each other. The aim of this study was to investigate the inter-correlation of these clinical variables in East Asian LC patients with no TKI-related driver gene-mutations to provide suggestions for patient selection and prognosis prediction. **Method:** 122 primary lung cancer patients without TKI-related driver gene (EGFR, ALK, ROS1, RET, BRAF, C-MET, HER2) mutations were recruited, in which 67 patients were confirmed with stage IV LC. Gene variations were determined in tumor tissue by whole-exome sequencing (WES). SPSS 20 software were used for statistics analysis, and P-values < 0.05 were considered significant. **Result:** In 122 enrolled patients, 110 (90.2%) were male, 87 (71.3%) had smoking history and 95 (77.9%) were older than 60 years old. Significant differences in TMB were observed between male and female (P <0.05), but not between patients with or without smoking history (P >0.05). Patients older than 60 years old had dramatically higher TMB than those younger than 60 (P <0.05). Gender, smoking history, age, lung cancer subtype were not associated with the occurrence of brain or bone metastases (P >0.05). The mean TMB measured by WES was 4.5 mutations/Mb for all lung cancer patients. It was notable that the ratio of patients with TMB ≤4.5 was 68.2% (15/22) and 41.7% (5/12) for bone and brain metastatic patients, respectively. .Although the difference was not significant (P=0.163), the trend suggests that there may be a metastasis-specific difference in TMB. **Conclusion:** Result from this exploratory study confirmed the gender preference in patients without TKI-related driver gene mutations. Male and elder patients with higher TMB may be the population that benefits more in immunotherapy. Although clinical the factors were not found to correlate with metastatic sites in this study, larger cohorts may find significant correlation, which could lead to the identification of novel biomarker for patient stratification or selection in therapies.

P2.04-59 PATIENT SURVIVAL IN NSCLC BASED ON PDL1 EXPRESSION AND TISSUE ORIGIN

S. Khan[1], M. Charalambous[2], M. Khan[2], F. Khalid[2], M. Enver[2], S. Ahmed[2]

[1]*University of Leicester, Leicester/United Kingdom,* [2]*University Hospitals of Leicester, Leicester/United Kingdom*

Background: Patients with NSCLC who have high PDL-1 expression have favourable outcomes when treated with checkpoint blockade compared to those who don't. Here we consider patient outcomes based on the origin of tumour biopsy and PDL-1 expression. This has not been widely considered or published. **Method:** Patient tissues which were assessed for PDL-1 expression between 2013 and 2017 were identified using a central electronic pathology database. In addition, patients who were treated and tested locally between August 2015 and December 2017 were selected using an electronic chemotherapy database. A total of 422 patients were identified. Duplicates and patients who did not have enough cells for analysis (less than 100) were excluded from analysis. Individuals treated on clinical trials were included. Tissues were grouped into lung, lymphoid, pleural or other. Other included sites such as bone, cerebral or adrenal metastasis. Analysis was carried out using SPSS 25. **Result:** Lung tissue: Patients with negative PDL-1 expression (n= 67) median OS was 619 days (95% Confidence Interval 428 -809 days). This included patients who were treated with EGFR and ALK inhibitors. In contrast, those who were PDL-1 positive (n= 106) and exposed to check point blockade, median OS was 511 days (95% Confidence Interval 373- 648 days). Lymph tissue: Patients who had negative PDL-1 expression (n= 21) median OS was 284 days (95% Confidence Interval 196 -361 days), compared to those who had high PDL-1 expression and managed with immunotherapy (n= 46) whose median OS was 546 days (95% Confidence Interval 128 -963 days). Pleural tissue: Tissues which were negative for PDL-1 expression (n= 6) median OS was 90 days (95% Confidence Interval 122- 477 days). Individuals who expressed high levels of PDL-1 (n= 15) median OS was 1253 days (95% Confidence Interval 642- 1864 days) for those who were exposed to immunotherapy. Other: In those with negative PDL-1 expression (n= 8) median OS was 1013 days (95% confidence interval 112- 1913 days). Patients with high PDL-1 expression and treated with immunotherapy had a median OS of 337 days (95% Confidence Interval 12- 661 days). **Conclusion:** OS was highest in patients who had high PDL-1 expression assessed in pleural tissues. In patients where PDL-1 expression was assessed in other tissues the worst outcomes were observed, possibly due to patient and disease factors. Some tissues may be PDL-1 rich or sparse based on origin. This may affect PDL-1 expression and subsequently patient outcomes. This warrants further investigation.

P2.04-60 PEMBROLIZUMAB-BASED REGIMENS ADMINISTERED AT NON-STANDARD FREQUENCY IN NON-SMALL CELL LUNG CANCER (NSCLC)

K. Sehgal, M. Shea, D. Mcdonald, M. Huberman, G. Weiss, P. Vanderlaan, D. Costa, D. Rangachari

Beth Israel Deaconess Medical Center, Boston/United States of America

Background: Pembrolizumab (P) administered every 3 weeks ± chemotherapy is a standard treatment option for advanced NSCLC. However, other than modeling and simulation-based analysis, there have been no post-approval studies to determine the optimal administration frequency or if longer intervals between administrations are effective. **Method:** We retrospectively reviewed medical charts of 81 patients with advanced NSCLC treated with P for at least 4 cycles at a single academic center (02/2016-3/2019). 2 patients groups were selected: those who received 3 or more P-based regimens at non-standard frequency intervals between cycles longer than 3 weeks ± 3 days (group A), or those who received P-based regimens at standard frequency or up to 2 non-standard cycles (group B). Descriptive tables of demographic details, tumor characteristics, treatment details, and immune-related adverse events (irAEs) were generated. Kaplan-Meier survival analysis and Cox proportional hazards model for multivariable regression analysis were utilized. **Result:** Of 81 P-treated patients, 47 (58%) had received at least 4 cycles (group A: 14, B: 33). There were no significant differences between groups in sex, stage at diagnosis, smoking status, driver oncogene mutations, PD-L1 expression, tumor mutation burden, line of therapy, performance status or grade 3 irAEs. Patients in group B were more likely to receive P + chemotherapy (group A: 0%, B: 33.3%, p = 0.02). Patients in group A were more likely to have any grade irAEs (groups A: 78.6%, B: 33.3%, p = 0.024). The reasons for any non-standard cycles in group A were: irAEs (14.3% patients), non-irAE medical issues (35.7% patients) and solely non-medical patient-physician preference (50% patients). Median time to treatment discontinuation (TTD) was significantly longer in group A than group B (24 months vs 5 months, p <0.0001), as was median overall survival (OS) (Not reached vs 14 months, p=0.0029). Patients in group A continued to show significantly longer overall survival when adjusted for confounding variables (Hazard Ratio 5.6, p=0.029). **Conclusion:** Our data, though limited by sample size and single institution design, shows that a significant proportion of patients receive P at extended intervals in routine clinical practice and with no worse outcomes than would be expected for those with advanced NSCLC receiving P at label-specified 3-week intervals. Given the durability of benefit seen in such patients, this requires confirmation in larger datasets and prospective trials so as to maximize patient experience and clinical outcomes while minimizing financial toxicity.

	Group A (≥ 3 Non-standard cycles)	Group B (Standard or ≤ 2 non-standard cycles)	p-value chi-square log-rank test)
	N = 14	N = 33	
Median OS, months (95% CI)	Not reached (14 - not reached)	14 (8 - not reached)	0.0029
Median TTD, months (95% CI)	24 (17 - not reached)	5 (4-6)	<0.0001

P2.04-61 PRELIMINARY REPORT OF A MULTIDISCIPLINARY TASK GROUP FOR THE STUDY OF IMMUNE-MEDIATED PULMONARY TOXICITY

R. Martin-Deleon, M. Sanchez, M. Benegas, C.M. Lucena, C. Cabrera, R. Reyes, D. Martinez, J. Ramirez, R.M. Marrades, N. Viñolas, C. Teixido, C. Agusti, N. Reguart, J. Sellares

Hospital Clinic Barcelona, Barcelona/Spain

Background: Immunotherapy (IO) is now the standard of care for many tumor types. However, it is not free of risks, being pulmonary toxicity one of the most relevant immune-related adverse event due to its severity. Differential diagnosis with other pulmonary complications such as infections or tumor dissemination further complicates its management. **Method:** In order to raise awareness, gather information, and to discuss early management strategies in patients (pts) with immune-related interstitial lung disease (irILD), in 2017 we created a multidisciplinary task group comprised of pneumologists, pathologists, oncologists and radiologists. We herein report the main features of the first series of pts treated with IO who subsequently developed ILD, prospectively identified from a tertiary University Hospital over a period of two years (2017-2019), focusing on clinical presentation, radiological patterns, outcomes and therapeutic intervention. **Result:** We identified a total of 23 pts with suspicion of irILD. Patients mainly received programmed cell death-1 (PD-L1) inhibitors (61%). Main characteristics are summarized in Table 1. ILD occurred more often in males, and former or current smokers (91%), with a median age of 62 years. The most common radiological pattern was the presence of ground-glass opacities (87%), followed by consolidations (61%). Forty-eight percent of the cases had grade 3 severity according to the Common Terminology Criteria for Adverse Events (CTCAE). Thirteen of the patients (57%) underwent a fibrobronchoscopy during the diagnostic period and a specific microorganism was isolated from BAL in three cases (13%) (*Aspergillus fumigatus*, cytomegalovirus and herpes type 1 virus). Ten pts (43%) underwent transbronchial biopsies being focal organizing pneumonia and desquamative changes the most

common pathological patterns observed. Twenty patients (87%) received prednisone (1mg/kg/day) and thirteen of them (57%) also received antibiotic treatment.

		Patients (%)

P2.04-62 TCR REPERTOIRE ANALYSIS OF PERIPHERAL CD8+PD-1+ T CELLS IS EFFECTIVE AS A PREDICTIVE BIOMARKER FOR RESPONSE TO THE IMMUNE CHECKPOINT INHIBITOR

S. Matsumoto[1], T. Matsutani[2], Y. Fujita[1], K. Kitaura[2], Y. Nakamura[2], T. Nakamichi[1], A. Nakamura[1], A. Kuroda[1], M. Hashimoto[1], N. Kondo[1], T. Shini[3], R. Suzuki[2], S. Hasegawa[1]

[1]*Hyogo College of Medicine, Nishinomiya/Japan,* [2]*Repertoire Genesis Incorporation, Osaka/Japan,* [3]*BITS. Co., Ltd, Tokyo/Japan*

Background: Immune checkpoint inhibitors are effective in NSCLC patients. As patient selection is important, many biomarkers have been studied. We developed a method to predict the effect of immune checkpoint inhibitors using peripheral blood. Tumor infiltrating lymphocyte (TIL) sensitizes to neoantigens, some of them migrate to peripheral blood. We measured tumor mutation burden (TMB) of resected specimen and T-cell receptors (TCRs) diversity of peripheral CD8+PD-1+ T cells, examined response rate and prognosis. **Method:** The study included NSCLC patients who relapsed after surgery and chemotherapy failed. Peripheral blood mononuclear cells (PBMC) was collected from patients before 1st administration of nivolumab. CD8+PD-1+ T cells were subjected to FACS sorting, NGS-based TCR repertoire analysis was performed by Repertoire Genesis Inc., and TCR diversity was evaluated statistically. **Result:** There were no differences in the proportion of PD-1+ in CD8+ T cells between responders and non-responders. TCR α diversity based on DE50 was significantly higher among responders than non-responders ($P < 0.01$). TCR β diversity was also significantly higher among responders than non-responders ($P < 0.01$). Progression-free survival (PFS) and Overall survival (OS) were better in TCR diversity high group than that TCR diversity low group (P=0.01). TMB was not significantly different between responder and non-responder. PFS and OS were not significantly different between TMB high (≧10) group and TMB low (<10) group. **Conclusion:** Significant therapeutic effect of nivolumab was observed in NSCLC patients whose peripheral CD8+ PD-1+ T cells had highly diverse TCR. This study suggests the TCR diversity of peripheral CD8+PD-1+ T cells is effective as a predictive biomarker for response to the immune checkpoint inhibitor.

P2.04-63 EVALUATION OF COMBINED BIOMARKERS FOR TUMOR RESPONSE TO IMMUNOTHERAPY (I/O) IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

H. Ramdani[1], M. Falk[2], S. Schatz[2], M. Tiemann[2], L. Heukamp[2], E. Schuuring[3], H. Groen[3], F. Griesinger[4]

[1]*Carl von Ossietzky University Oldenburg, Oldenburg/Germany,* [2]*Hämatopathologie Hamburg, Hamburg/Germany,* [3]*University Medical Center Groningen, Groningen/Netherlands,* [4]*Department of Hematology and Oncology, Pius Hospital, Medical Campus University of Oldenburg, Oldenburg/Germany*

Background: Immune checkpoint inhibitors have revolutionized NSCLC treatment. At present, the only established predictive biomarker for I/O-therapy stratification are PD-L1 expression and MSI status. However, the expression of PD-L1 is limited by heterogeneous expression and even high expressors not always respond to I/O therapy. The aim of the study is to evaluate the value of combinations of positive (Tumor Mutational Burden, PD-L1) and negative (a.o. CD73 expression and inactivating STK11 mutations) predictive markers in patients (pts) with advanced NSCLC on I/O therapy. **Method:** A retrospective study was performed on a cohort of 54 pts with advanced NSCLC that have been treated with I/O between 2015 and 2018. Pts were selected by the availability of tumor tissue and based on tumor response evaluated by RECIST v1.1 criteria: only patients with durable tumor response (CR,PR ≥ 6 months) and patients with no tumor response (PD as best response) were analyzed for biomarkers: hybrid capture NGS assay for TMB (New Oncology) including STK11 mutations and IHC tests for PD-L1, CD73 and VISTA. Adjusted Cox regression and ROC analysis will be performed to evaluate the predictive value of the different biomarkers. **Result:** 43/54 pts received nivolumab, 11/54 pembrolizumab in different therapy lines (from 1st to 5th line). 24 pts were defined as having a durable tumor response (median PFS 20 months, median OS not reached) 30 pts as primary progressors (median PFS 2 months, $p<0.0001$), median OS 12 months, $p<0.0001$). In 30/54 pts enough material was available for TMB testing. The median TMB-value is 11.42 mutations/Mb. In 13 durable responders median TMB-value was 13.28 mutations/Mb versus 11.00 mutations/Mb in 17 primary non-responders. STK11 mutations were observed in 3/17 primary non-responders (10%) vs. 0/13 in durable responders (0%). Additional analyses of PD-L1, CD73, and VISTA will be presented at the meeting as well as correlative data of the parameters analysed. **Conclusion:** Our results suggest that integrating several biomarkers including positive and negative predictive markers may correlate better with responses to I/O than PD-L1 and TMB alone.

P2.04-64 222 NSCLC'S CLASSIFIED BY PAM50: LUMINAL A NSCLC IS A DISTINCT SUBTYPE WITH LOW TMB AND IMMUNE SUPPRESSIVE TME

S. Reddy[1], C. Szeto[2], H. Borghaei[3]

[1]*NantHealth, Culver City/United States of America,* [2]*NantOmics, Culver City/United States of America,* [3]*FCCC, Philadelphia/United States of America*

Background: Breast Cancer (BC) and NSCLC are heterogeneous diseases with distinct disease subtypes. A 50-gene qPCR assay (PAM50) identifies 5 intrinsic biological subtypes: luminal A, luminal B, HER2-enriched, basal-like, and normal-like breast cancer. NSCLC subtypes are often divided by driver oncogene mutations. We assessed the association of genomic and transcriptomic patterns in molecular NSCLC subtypes using a 50-gene breast cancer classifier. **Method:** Retrospective analysis on Whole exome (WES) DNA and deep whole transcriptomic sequencing (RNA-Seq) (~200x10^6 reads per tumor) data from NantHealth was done. BC intrinsic subtype sorting based on RNAseq assay was used to classify breast tumors into luminal A, luminal B, HER2-enriched, basal-like, or normal-like. Immune Checkpoint therapy (ICT) gene expression was measured for PDL1,CTLA4,LAG3, IDO,TIM3,OX40,FOXP3,TIGIT, and PDL2. **Result:**

POSTERS

A total of 222 NSCLC patients were classifiable using RNAseq. The molecular BC subtype distribution was 38.74% Luminal A, 32.88% Luminal B, 14.41% HER2-enriched, 9.46% basal-like, and 4.50% normal-like. Using a TMB cutoff of 200 Non-synonymous variants (Rizvi et al), there was a significant difference between LumA and LumB (OR 0.39, p=0.0014) for TMB high v low, which is similar in BC, with LumA v LumB (OR 0.46, p=0.014). In the TMB low LumA group there was a 23% EGFR mut+ rate, with 0 EGFR mut+ in the LumA TMB high group. ICT gene expression showed no difference in PDL1 expression between subgroups, but TIM3 was significantly higher in LumA and lower in Basal. ICT co-expression patterns in LumA suggest TME suppression via TIM3, IDO, and OX40 expression. Gender difference did not affect subtype classification distribution. **Conclusion:** In this retrospective analysis of NSCLC using PAM50 classification we found similar subtype distributions as BC with both LumA BC and LumA NSCLC subtype as a distinct subgroup characterized by low TMB, and LumA NSCLC with high EGFR mutation frequency, and ICT suppressive TME, suggesting potential uses of the 50 gene BC classifier in NSCLC trial design and treatment for checkpoint inhibitor eligible patients.

Keyword: PAM50, RNAseq, TMB

P2.04-65 PEPTIDE-BASED CANCER VACCINE SHORTENED THE OVERALL SURVIVAL OF A LARGE PORTION, BUT NOT ALL, OF ADVANCED CANCER PATIENTS

K. Yoshiyama[1,2], M. Noguchi[3], M. Terasaki[2], S. Sugawara[4], A. Yamada[3], S. Shichijo[5], S. Takamori[2], Y. Akagi[2], S. Yutani[5], K. Itoh[5]

[1]*Oita Prefecture Saiseikai Hita Hospital, Hita City, Oita/Japan,* [2]*Kurume University School of Medicine, Kurume City, Fukuoka/Japan,* [3]*Kurume University Research Center for Innovative Cancer Therapy, Kurume City, Fukuoka/Japan,* [4]*Sendai Kosei Hospital, Sendai/Japan,* [5]*Kurume University Cancer Vaccine Center, Kurume City, Fukuoka/Japan*

Background: We have been promoting clinical trials of peptide-based cancer vaccination for various cancers, mainly at Kurume University School of Medicine. **Method:** Objective: To determine biomarkers predictive of overall survival (OS) in advanced cancer patients treated with a peptide-based cancer vaccine. Patients: The samples from two randomized, double-blind, placebo-controlled, phase III trials of personalized peptide vaccine (PPV) for advanced prostate cancer patients (n=306) and recurrent glioblastoma (n=88) patients, those from one single arm phase II trial of PPV for various types of advanced cancer patients (n=2588), and those from one randomized placebo-controlled non-personalized phase II trial (n=51) for advanced prostate cancer patients were provided for this retrospective biomarker study. **Result:** No significant differences in clinical benefit (overall survival, OS) were found between the patients receiving PPV and those receiving placebo in each of the two randomized, double-blind, placebo-controlled, phase III trials. The neutrophil or lymphocyte proportion in advanced prostate cancer patients prior to study entry was a biomarker discriminating the PPV patients (70%) who showed significantly shorter OS relative to placebo patients from the remaining PPV patients who showed significantly longer OS relative to placebo patients. The C-C motif chemokine 2 (CCL2) level prior to the study entry in recurrent glioblastoma patients was the other biomarker discriminating the PPV patients (40%) who showed significantly shorter OS relative to placebo patients from the remaining PPV patients who showed significantly longer OS relative to placebo patients. The neutrophil or lymphocyte proportion prior to the phase II study entry (n=2588) was also a biomarker discriminating the PPV patients (60%) with significantly shorter OS from the remaining PPV patients entered in the single arm phase II study in all the advanced cancer patients other than gastric cancer or glioblastoma patients. Notably, the median OS for the 250 of 399 lung cancer patients (62 %) who met either or both the cutoffs of neutrophils ^{3}64% and lymphocytes <26% was significantly shorter than that of the remaining 149 patients (38%) (9.5 month,95% confidence interval: 7.6-11.9 vs 20.0 month,13.0-25.3, p<0.001). The CCL2 level, however, prior to the study entry was not a biomarker in these lung cancer patients receiving PPV. This biomarker was also predictive of OS in a randomized placebo-controlled non-personalized phase II trial of peptide-based vaccine. **Conclusion:** Peptide-based cancer vaccine shortened the OS of a large portion, but not all, of advanced cancer patients with various types of cancer. Prospective clinical studies of peptide-based cancer vaccines using the newly defined prognostic markers may be warranted.

Keywords: peptide-based cancer vaccine, Biomarker, overall survival

P2.04-66 IMMUNOTHERAPY FOR ALL? REPRESENTATION OF MINORITIES AND THE ELDERLY IN LUNG CANCER IMMUNOTHERAPY TRIALS

A. Velazquez[1], L. Seijo[2], N. Duma[3]

[1]*University of California, San Francisco, San Francisco/United States of America,* [2]*Icahn School of Medicine at Mount Sinai Beth Israel, New York/United States of America,* [3]*Mayo Clinic, Rochester/United States of America*

Background: Minority groups have been historically underrepresented in oncology clinical trials (CT). Disparities also exist among patients with lung cancer (LC), with Black males having the highest mortality rates of all subgroups. In 2015 the first immune checkpoint inhibitor was FDA approved for the treatment of LC, since then these agents have become a cornerstone of LC treatment. We aimed to determine the representation of ethnic minorities and elderly patients in immunotherapy LC trials. **Method:** Enrollment data from therapeutic immunotherapy LC trials with published results in ClinicalTrials.gov or individual trial publications from 2008 to 2019 was analyzed. Clinical trials that were terminated early or those that did not report race/ethnicity were excluded. Enrollment fraction (EF) was calculated as the number of trial enrollees divided by the 2015 SEER LC prevalence. **Result:** We identified 29 CT of which 22 (76%) reported race/ethnicity with a total of 11,149 CT enrollees. Majority of CT were phase 3 (54%), international trials (95%), for advanced stage NSCLC (82%). Distribution by sex, age, race/ethnicity and comparison with LC prevalence and US census are described in table 1. Clinical trials participation varied significantly across ethnic groups, Whites (EF 2.4%) and Asians (EF 12.4%) were more likely to be enrolled compared to Blacks (EF 0.46%) and Hispanics (EF 0.85%). Younger patients (<65 years-old) were more likely to be enrolled when compared to older adults, despite the national median age of LC diagnosis being 70 years-old.

	Trial Participants		Enrollment Fraction	Lung Cancer Incidence*‡	Lung Cancer Prevalence*^	2010 US Census
Characteristic	N	%	%	%	%	%
Total	11149		2.1			
Sex						
Male	7275	65.0	3.0	57.2	44.2	49.2
Female	3859	35.0	1.3	42.8	55.8	50.8
Age†						
< 65 years-old	4733	55.2	3.9	4.8	28.2	87.0
≥ 65 years-old	3835	44.8	1.2	95.2	71.8	13.0
Race/Ethnic group						
White	8531	76.5	2.4	68.1	84.5	72.4
Black	209	1.9	0.5	13.4	10.8	12.6
Hispanic	136	1.2	0.9	11.8	3.8	16.3
Asian/Pacific Islander	2027	18.2	14.2	6.0	3.4	5.0
American Indian/ Alaska Native	35	0.3	-‡	0.7	-‡	0.9
Other	163	1.5				6.2
Unknown	132	1.2				

*Age adjusted; ‡Data from 2015 SEER 18; ^Data from 2015 SEER 13; †Subgroup analysis of 15 trials; ‡2015 SEER did not report prevalence for American Indian/Alaskan Native.

Conclusion: Minority and elderly patients were less likely to be enrolled in immunotherapy LC trials from 2008 to 2019. The underrepresentation of these groups leaves knowledge gaps regarding their response and tolerability to immunotherapy, leading to the extrapolation of data from other populations to treat minority and elderly patients. Future CT should take measures to recruit participants that adequately represent our LC population and increase minority recruitment.

Keywords: Immunotherapy, clinical trials, Minorities

P2.04-67 COMPARATIVE ANALYSIS OF TMB AND MUTATIONS BY COMPREHENSIVE GENOMIC PROFILING (TSO500) IN FFPE NSCLC SAMPLES

J. Botling, H. Nord, A. Soderberg, P. Micke, J. Isaksson, P. Smeds, L. Moens

Uppsala University, Uppsala/Sweden

Background: Precision oncology for NSCLC involves an increasing number of targeted drugs and immunotherapy options. Comprehensive genetic profiling has been used in clinical studies to assess predictive biomarkers and mutation patterns, i.e. tumor mutation burden (TMB) associated with checkpoint therapy response. However, limited access to broader sequencing approaches, associated complex bioinformatic pipelines and issues with cross-platform reproducibility remain important hurdles for routine molecular pathology. **Method:** Here we have used the novel TSO500 gene panel (523 genes, 1.95 Mb) on the NextSeq platform (Illumina) to analyze representative surgical FFPE NSCLC specimens (n=50). Detected mutations were evaluated in comparison to matched results from routine diagnostic sequencing based on a custom 18-gene HaloPlex panel (Agilent). Obtained TMB-scores will be compared to data from analysis with the FoundationOne CDx assay (work in progress). **Result:** All 50 samples passed the pre-set QC filters. We found a wide range of TMB-values (0.79 to 610 non-synonymous mutations per Mb) with a median score of 5.6 mut/Mb (Figure 1). EGFR positive cases were found in the lower TMB range, while the remaining adenocarcinoma and squamous cell carcinomas were evenly distributed across the TMB spectrum. All known variants (n=105) from routine sequencing could be detected in the TSO500 data set (Illumina and in-house bioinformatic pipeline) with similar variant allele frequencies (r= 0.76). **Conclusion:** Variant calling with regard to NSCLC hot-spot mutations seems to be robust, but the precision and performance of TSO500 outside clinical hot-spot regions remain to be established. The distribution of TMB scores in our series of NSCLC seems to be consistent with previously published data and concordance to results with FoundationOne CDx will be presented.

P2.04-68 RETROSPECTIVE ANALYSIS OF IMMUNE CHECKPOINT INHIBITORS IN NSCLC: IMMUNE-RELATED ADVERSE EVENTS AND OUTCOMES

A. Lee[1,2], M. Luong[2], D. Ohana[2], M. Forster[1,2], S.M. Lee[1,2]

[1]*University College London, London/United Kingdom,* [2]*University College Hospital, London/United Kingdom*

Background: In the United Kingdom, immune check-point inhibitors (ICPi) including pembrolizumab, atezolizumab and nivolumab are routinely used in advanced NSCLC. These agents are associated with immune-related adverse events (irAE). We present a single centre experience of a tertiary lung cancer centre on the incidence and severity of irAE, with hospitalisation episodes and duration. Patient outcomes were compared with radiological assessment of response, Neutrophil to Lymphocyte ratio (NLR) and Platelet to Lymphocyte ratio (PLR). High NLR and PLR may predict for poorer outcomes following ICPi treatment. **Method:** This was a single-centre retrospective analysis of the electronic records of NSCLC patients who received treatment with an ICPi between January 2017 and December 2018. Patients on clinical trials were excluded. NLR and PLR were derived from the most recent pre-treatment peripheral blood sampling. The subjective response as recorded in radiological reports of cross-sectional imaging was noted. The first response was defined as the response reported in the first scan after initiation of treatment and the best response was defined as best recorded response across all scans following treatment. Kaplan Meier survival analyses were performed. **Result:**

Patient characteristics and response		
Patient Characteristics	**N=46**	**%**
Median age	64.8 (range 48.1 to 81.9)	
Male	28	60.9
Female	18	39.1
Treatment		
Atezolizumab	7	15.2
Pembrolizumab	39	84.8
Line of treatment		
First	20	43.5
Second	20	43.5
Third	6	13
Histology		
Adenocarcinoma	34	73.9
Squamous	8	17.4
Other NSCLC	4	8.7
First response to treatment		
Progressive disease	18	39.1
Stable disease	3	6.5
Partial response	10	21.7
Complete response	1	2.2
Mixed response	10	21.7
Not assessed	4	8.7
Best response to treatment		
Progressive disease	17	37
Stable disease	3	6.5
Partial response	11	23.9
Complete response	2	4.3
Mixed response	9	19.6
Not assessed	4	8.7
irAE and grade (54 events)		
Anorexia, G1-2	2	3.7
Arthritis, G1-2	1	1.9
Arthritis, G3	1	1.9
Diarrhoea, G1-2	4	7.4
Diarrhoea, G3	4	7.4
Diarrhoea, G5	1	1.9
Endocrinopathies, G1-2	6	11.1
Fatigue, G1-2	12	23
Fatigue, G3	3	5.6
Liver dysfunction, G1-2	1	1.9
Nausea/Vomiting, G1-2	6	11.1
Pneumonitis, G3	1	1.9
Pruritus/Rash, G1-2	10	18.5
irAE hospitalisation events	9	19.6
Median length of hospitalisation	8.5 days (range 1 to 19)	
Mean NLR	5.90 (range 0.98 to 28.04)	
Mean PLR	272.02 (range 83.5 to 893.3)	

First recorded radiological response was a predictor of best radiological response and OS, p=0.003. NLR and PLR above mean were predictive factors for decreased OS (HR 3.99, 95% CI 2.01 to 14.35, p=0.0009; HR 2.09, 95% CI 0.84 to 4.87, p=0.119). **Conclusion:** Most patients experienced at least 1 irAE. 1 in 5 had irAE grade 3 or above requiring hospitalisation. The burden of irAE and increased hospitalisation time and costs are likely to increase secondary to the increased use of ICPi in combination with platinum-doublet chemotherapy in the first-line setting for advanced NSCLC. Response at first radiological assessment was a predictor of outcome. NLR and PLR are potential readily measurable predictive biomarkers.

P2.04-69 IMPACT OF ANTIBIOTIC USAGE ON SURVIVAL DURING CHECKPOINT INHIBITOR TREATMENT OF NON-SMALL CELL LUNG CANCER (NSCLC)

C. Hogue[1], T. Kuzel[1], J. Borgia[1], G. Marwaha[1], P. Bonomi[1], M.J. Fidler[2], M. Batus[2], D. Wang[1], P. Barry[1]

[1]*Rush University Medical Center, Chicago/United States of America,* [2]*Rush University Medical Center, chicago/United States of America*

Background: Growing evidence suggests that the gut microbiome influences response to second line checkpoint inhibitor (ICI) therapy. Little has been reported about the influence of antibiotics (ABX) while on ICI. **Method:** This is an IRB approved retrospective study. Patients with advanced (stage IV or relapsed disease) NSCLC that had progressed after platinum based chemotherapy and were subsequently treated with ICIs were identified from an institutional database. Demographics, ABX usage, and survival outcomes were recorded and analyzed. Cox proportional hazard models adjusted for age at diagnosis and sex were performed. **Result:** 161 NSCLC patients met inclusion criteria for this analysis and were treated with ICIs from 2015 to 2019. Median age was 66 years old (range 46-88) and 60% were female. Most patients had prior separate lines of systemic therapy (median 2 lines, range 1-4). Histological subtypes included adenocarcinoma (70%), squamous cell carcinoma (24%) and other histologies (6%). Median ICI treatment length was 2 months. ICIs included Nivolumab and Pembrolizumab. 58 patients (36%) had ABX usage in the 90 days prior to ICI initiation. 33 patients (20%) used ABX during ICI treatment. 71 patients (44%) had no ABX usage prior or during ICI treatment. There were no progression-free survival (PFS) differences for patients receiving antibiotics in the 90 days prior to treatment start (HR 1.024, p=0.92). The use of ABX during ICI therapy was associated with increased PFS (HR 0.597, p=0.02). There were no overall survival (OS) differences for patients receiving ABX in the 90 days prior to the start of ICI therapy (HR 1.122, p=0.64).

The effect of ABX utilization on OS was not significant (HR 0.660, p=0.07). **Conclusion:** Improved PFS and a trend toward improved OS was noted in patients receiving ABX during ICI therapy. This suggests that ABX during ICI therapy may not have a detrimental effect on outcomes. Further studies are needed to determine the regimen, length of ABX treatment and its relation to survival benefits or detriment prior to and during ICI therapy.

P2.04-70 PD-L1 EXPRESSION IN A POPULATION WITH NON-SMALL CELL LUNG CANCER IN A REFERENCE HEALTHCARE CENTER IN LATIN-AMERICA

L. Sua[1,2], J. Lores[1], M. Aguirre[1,2], L. Fernandez-Trujillo[1,2]

[1]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia,* [2]*Universidad Icesi, Cali/Colombia*

Background: Non-small cell lung cancer (NSCLC) is the most common type among malignancies of the lung, and among its histological subtypes, different mutations and protein expressions have been object of study for the past years. Epidermal growth factor receptor (EGFR) mutations and EML4-ALK fusion as driver mutations have been reported to upregulate programmed death-ligand 1 (PD-L1) expression. Despite therapeutic significance of these associations has not been yet completely elucidated, studying the prevalence and correlation of these features becomes more important with time. **Method:** Clinical and mutational features were described in 114 patients diagnosed with NSCLC between 2013 and 2016 at a reference health care center in Colombia. Among the patients in whom PD-L1 expression was tested, we reported its prevalence and distribution in patients positive for EGFR and ALK. **Result:** The mean age was 65±12 years. 72.8%(n=83) were classified as stage IV. Adenocarcinoma was the most frequent (80.7%; n=92). The prevalence for EGFR mutations was 27% (n=30) and for EML4-ALK fusion gene was 15.8% (n=9). PD-L1 expression was tested in 57 patients from which 35% (n=20) came positive, 5 were also positive for EGFR and 4 for ALK. From all PD-L1 positives, 60% (n=12) with high expression. No association was found between gender and PD-L1 expression, and being a non-smoker was associated with a lower expression of the protein. **Conclusion:** The prevalence of EGFR mutations was similar to that reported worldwide, and fusions in the EML4-ALK gene were higher than expected, as well as PD-L1 expression. Smoking has already been reported to be associated with a higher expression of PD-L1, as found in this study. More studies must be done regarding expression of the protein in patients with driver mutations to stablish reliable associations and elucidate the clinical significance of blocking PD-1/PD-L1 in EGFR and ALK-mutant NSCLC treated with TKIs.

P2.04-71 BULLOUS PEMPHIGOID: A RARE IMMUNOMEDIATED EVENT SECONDARY TO IMMUNOTHERAPY IN A PATIENT WITH METASTATIC LUNG CANCER

E. Vissotto, G. Mendes

Hospital Santa Lucia, Brasília/Brazil

Background: Checkpoint Inhibitors (CIs) are already part of the armamentarium in lung cancer treatment, either alone or in combination with chemotherapy. By stimulating the immune system, activation of autoreactive T lymphocytes can lead to development of immune-mediated adverse events. Dermatological toxicities are the most common of these events and may affect up to 50% of patients. The most common are pruritus, rash, dermatitis and bullous dermatitis. We present the case of a patient with metastatic lung adenosquamous carcinoma, using pembrolizumab as a second line treatment who developed pemphigus. **Method:** Case Report **Result:** A 64-year- old female was diagnosed with oligometastatic lung adenosquamous carcinoma (bones). There were no EGFR, BRAF mutations or ALK, ROS translocations. PDL1 expression was 20% (22c3 antibody). Patient received first line treatment with six cycles of carboplatin and paclitaxel, with partial response, but limiting toxicity. Radiotherapy was performed as consolidation in lung and active bone lesion in thoracic spine. There was an early progression in primary lesion, and pembrolizumab was initiated as second line. After five cycles, there was disease progression, and treatment was withheld. Six weeks later, the patient presented with bullous, hyperemic and painful lesions on both feet sole, buttocks, upper limbs, and oral mucosa. Biopsy was performed and revealed superficial and deep perivascular dermatitis with subepidermal blister and numerous eosinophils. The direct immunofluorescence test revealed presence of IgG and C3 deposits, in a linear pattern, in the membrane region. These findings lead to the diagnose of bullous pemphigoid. The lesions regressed completely after topical corticosteroid therapy used for one month. Next Generation Sequence (Foundation One) was performed, a mutation was identified in MET (exon 14) and she is currently receiving crizotinib with partial response and good tolerance. There are no new immunomediated late events. **Conclusion:** Pembrolizumab is a monoclonal antibody (IgG4) which selectively inhibits PD-1 activity in the T cell, activating the immune system but also triggering immune mediated events (IrAE). Cutaneous toxicity are the most common IrAE. The occurrence of bullous pemphigus is extremely rare with only one report in the literature. It may have an early or late onset after treatment iniciation. It is usually preceded by pruritus and nonspecific macular lesions that appear in the trunk and limbs. Histology demonstrates a subepidermal blister with mixed inflammatory infiltrate with eosinophils and immunofluorescence reveals linear deposition of IgG and C3 in the membrane. Management should ideally involve a dermatologist and require the use of systemic or topical corticosteroids, depending on the disease burden. In severe cases, immunotherapy should be discontinued. In our case, dermatologic toxicity had a late but symptomatic onset and a good response was obtained with the use of topical corticosteroids.

P2.04-72 CLINICAL FEATURE AND MANAGEMENT OF ACQUIRED RESISTANCE TO PD-1 INHIBITOR IN ADVANCED NSCLC

S. Okawa[1], H. Udagawa[2], T. Naito[2], K. Kirita[1], T. Ikeda[1], Y. Zenke[2], S. Matsumoto[2], K. Yoh[3], S. Niho[2], K. Goto[2]

[1]*National Cancer Center Hospital East, kashiwa/Japan,* [2]*National Cancer Center Hospital East, Kashiwa/Japan,* [3]*National Cancer Center Hospital, Tokyo/Japan*

Background: Programmed cell death-1(PD-1) inhibitors have emerged as a standard treatment for patients with advanced non-small cell lung cancer (NSCLC). However, the patterns of disease progression (PD) after an initial response (acquired resistance) to a PD-1 inhibitor and the efficacy of continuous PD-1 inhibitor therapy beyond PD remain unclear. **Method:** We retrospectively reviewed medical charts of advanced NSCLC patients treated with nivolumab or pembrolizumab as any line treatment at National Cancer Center Hospital East between January 2016 and October 2017. Acquired resistance was defined as disease progression after 6 months or more of treatment with a PD-1 inhibitor. Isolated disease progression was defined as progression in 1 site or organ, whereas systemic progression involved >1 site or organ. The clinical feature, PD pattern of acquired resistance, subsequent treatment and survival after acquired resistance were investigated. **Result:** Fifty-nine patients were treated with a PD-1 inhibitor for 6 months or more, of whom 27 patients (46%) had acquired resistance. Only 1 patient received a PD-1 inhibitor as fist-line treatment. Twelve patients were diagnosed as adenocarcinoma, 4 as squamous-cell carcinoma and 11 as NSCLC-NOS. The response at 6 months of treatment was partial response in 17 patients (63%) and stable disease in 10 patients (37%). The median time to acquired resistance was 12.2 (95%CI 9.3-17.8) months. Progression in the lesion identified at baseline was observed in 16 patients (59%), new lesions appeared in 4 patients (15%) and both of them occurred in 7 patients (26%). Overall, the most frequent progression site was lung (n=14, 52%), followed by thoracic lymph node (n=7, 26%), pleura (n=6, 22%) and brain (n=4, 15%). The median number of progressed lesions was 2 and 67% of patients had progression limited to one (30%) or two (37%) lesions. Ten patients (37%) had isolated disease progression in lung (n=3), brain (n=3), thoracic lymph node (n=2), neck lymph node (n=1) and adrenal (n=1). In 11 patients, PD-1 inhibitor therapy was continued beyond PD with (n=4) or without local radiotherapy (n=7). The median OS after acquired resistance in patients with or without continuous PD-1 inhibitor therapy beyond PD was 9.9 months and 10.7 months, respectively. **Conclusion:** Our results suggest that the most common pattern of acquired resistance to a PD-1 inhibitor was progression of thoracic lesion identified at baseline. One-third of the patients had isolated disease progression. The efficacy of continuous PD-1 inhibitor therapy beyond PD might be limited.

P2.04-73 MAINTENANCE TREATMENT USING CIMAVAX EGF VACCINE. EXPERIENCE OF SINGLE INSTITUTION

Y. Flores, D. Páramo, S. Alsina, L. Alsina, I. Inguanzo, J. Rodríguez, A. Elejalde, E. Flores, J. Lamadrid, D. Corrales, R. Ropero, E. Gracia, G. Gondori

National Institute of Oncology and Radiobilogy, Havana city/Cuba

Background: In Cuba the lung cancer represented the first cause of mortality for both sex. Approximately 75-85% of non small cell lung cancer (NSCLC) overexpresses the Epidermal grow factor receptor (EGFR) and its ligands. Overexpression of EGFR has been implicated in the process of malignant transformation by promoting cell proliferation, cell survival and motility. EGFR is a well-validated target for patients with NSCLC. CIMAvax-EGF is a therapeutic cancer vaccine composes of human recombinant EGF conjugated to a carrier protein and Montanide ISA51 as adjuvant. The vaccine is intended to induce antibodies against self EGFs that block EGF–EGFR interaction. **Method:** To characterize patients with non-small cell lung cancer treated with CIMAvax-EGF vaccine in maintenance regimen in the real world. Patients Selection: Patients diagnosed from stage IIIB and IV NSCLC at the National Institute of Oncology and Radiobiology in the period from January 2015 to June 2017 and who achieved objective response or stable disease at the end of first line therapy (chemotherapy alone or concomitant chemoradiotherapy). Treatment schedule: After finished first-line treatment, patients who achieved objective response or stabilization start vaccine maintenance regimen as previous described [Rodríguez PC, 2016]. **Result:** A total of 106 patients were treated, 52.8% of the patients were 65 or more years old, 58.5% were male and 48.5% female. The performance status was 1 in 77.4%. 62.3% of the patients were diagnosed from Adenocarcinoma. After started vaccination the 36.8% and 19.8% of patients, kept the objective response or stable disease, at 6 and 12 months respectively. The treatment was well tolerated, more frequents adverse events were pain (27,3 %) and indurations (7.3%) in the site of injection as well as local erithema (10,9%). The median overall survival was 14.6 months IC95% (10.6 -18.6). The overall survival rates were 82.1%, 57.2% and 37.6% at 6, 12 y 24 months, respectively. The median OS for patients less than 65 years old was 16,7 months IC 95% (2.2- 31.1) and for patients with ECOG 0 was 29 months IC 95% (10.4-47.5). The median progression free survival was 8.16 months IC 95%(4.9- 11.3). Progression free survival rates were 55,4%, 36,4% and 19,1% at 6, 12 and 24 months. **Conclusion:** Maintenance treatment using CIMAvax-EGF vaccine shown excellent safety profile. Median PFS and OS were higher than previously reported in phase III clinical trial. Patients less than 65 years old and with ECOG=0 achieved the better overall survival.

P2.04-74 RADIOTHERAPY PRIOR TO IMMUNOTHERAPY IS ASSOCIATED WITH DURABLE DISEASE CONTROL IN ADVANCED NSCLC

Å. Öjlert[1], M. Lund-Iversen[2], R. Åstrøm Ellefsen[1], M. Sprauten[2], O.T. Brustugun[1], V. Flote[2], A.R. Halvorsen[1], Å. Helland[3]

[1]*Oslo University Hospital - The Norwegian Radium Hospital, Oslo/Norway,* [2]*Oslo University Hospital, Oslo/Norway,* [3]*University of Oslo, Oslo/Norway*

Background: In an unselected patient cohort response rates for immune checkpoint inhibitors in advanced NSCLC are around 20 %[1-3]. To enhance this proportion several treatment combinations are under investigation. Radiotherapy combined with immunotherapy has shown promising results in preclinical trials and clinical trials using this combination are in progress, assessing safety and optimal dosage/timing of radiotherapy[4]. **Method:** Between May and September 2015 fifty-seven patients with advanced NSCLC were treated with nivolumab (3 mg/kg every 2nd week) at The Norwegian Radium Hospital in a named-patient-use-program. Clinical information, including dosage and timing of radiotherapy given prior to immunotherapy, has been collected and correlated to clinical outcome.

Result:

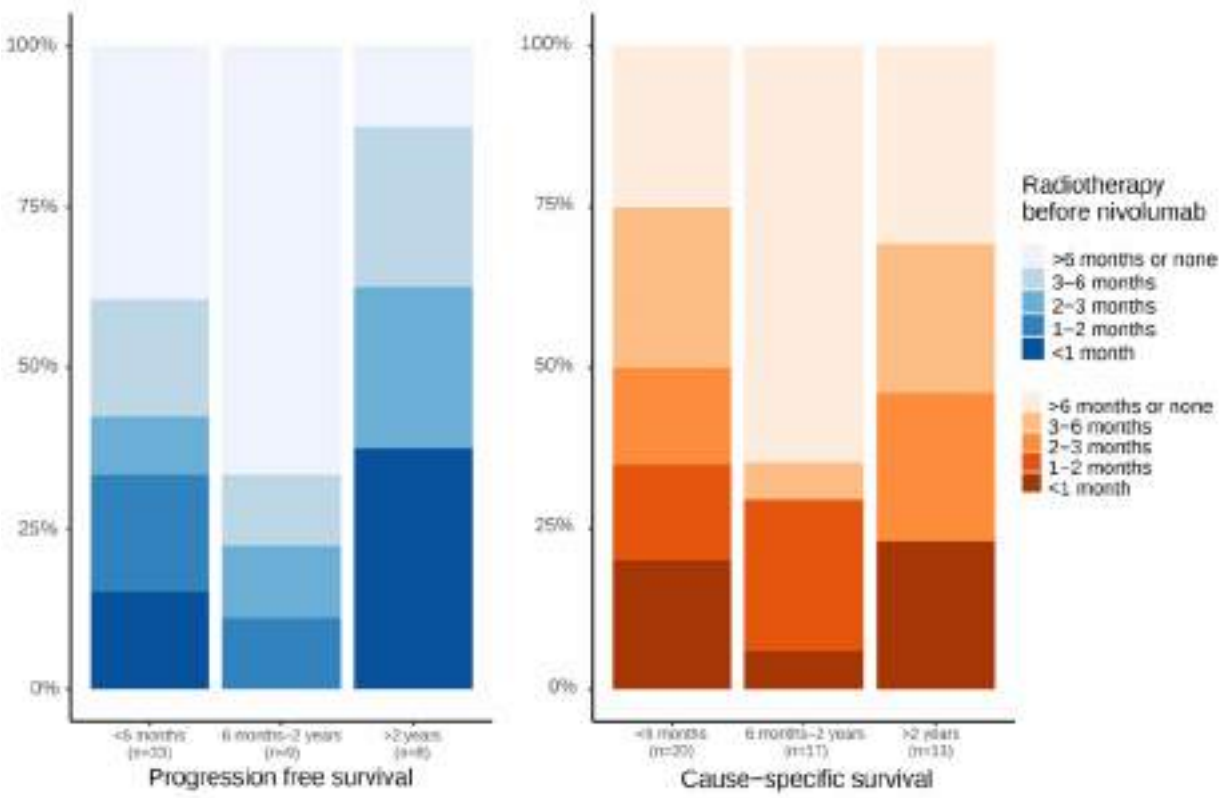

Figure 1. The patients are divided into groups based on time from starting nivolumab to progression and to death from lung cancer, respectively. Patients dead from other causes than lung cancer the first 2 years (n=7) are excluded. The color scales indicate time from last dose of radiotherapy to first dose of nivolumab.

Median follow-up time for those with no event when data was collected was 43.4 months (range 42.4-44.1 months) and overall survival 14%. Eight patients died of other causes than lung cancer. Radiotherapy administered at different time intervals before the first dose of nivolumab was correlated to progression free survival (PFS) and overall survival (OS) using cox regression analysis. We found poor PFS (HR 3.1 p=0.034) and OS (HR 3.7 p=0.015) for those who received radiotherapy between 1-2 months prior to nivolumab. The indication for radiotherapy in late stage lung cancer is most often symptomatic metastases. Hence, recent radiotherapy is usually associated with more advanced disease and poor prognosis. When patients were divided into groups according to prognosis we found that many in the group with short PFS had received radiotherapy shortly before immunotherapy but the proportion was even higher in the group with durable response (figure 1). **Conclusion:** Our findings support the hypothesis that radiotherapy can trigger a tumor-directed immune response which can be enhanced by immunotherapy and result in long-lasting disease control. We will validate our results in an additional cohort and will assess and include PD-L1 expression in our analysis. 1. Brahmer J, Reckamp KL, Baas P, et al. P2.04-75 OVERALL SURVIVAL BY IDO1 AND PD-L1 EXPRESSION IN NSCLC PATIENTS RECEIVING AN IMMUNE CHECKPOINT INHIBITOR (ICI)

M. Moore[1], R. Hall[2], E. Mcloughlin[2], J. Melson[1], B. Horton[1], A. Mills[2], R. Gentzler[2]

[1]*University of Virginia School of Medicine, Charlottesville/United States of America,* [2]*University of Virginia, Charlottesville/United States of America*

Background: Although preliminary data suggest that differential expression of the immunoregulatory enzyme indoleamine-2,3-dioxygenase 1 (IDO1) may modulate clinical response to agents that target the PD-1/PD-L1 axis, little is known about the predictive value of measuring concomitant expression of both markers for patients receiving immune checkpoint inhibitor (ICI) therapy for non-small cell lung cancer (NSCLC). **Method:** We identified patients with stage IV NSCLC who received at least one dose of an ICI alone or in combination with chemotherapy (CTX) at our institution between 2014 and 2018. Immunohistochemistry (IHC) for IDO1 (HPA023072, Sigma Prestige) and PD-L1 (SP142, Abcam) was performed on FFPE tissue. PD-L1 was scored as <1 %, 1-50%, or >50%, and IDO1 was scored as <1% or >1%. Median overall survival (OS) was calculated using proportional hazards model and groups were compared using log-rank test. **Result:** 65 eligible patients were identified. PD-L1 IHC failed in 1 patient. Patient characteristics and IHC results are detailed in Table 1. Patients with IDO1 expression had a numerically longer median OS (37.8 vs. 17.7 months, p=0.16), which was maintained regardless of PDL1 positivity. This effect was more pronounced in the ICI alone cohort (median OS of 34.4 mo vs. 17.7 mo, p=0.0995) than in the CTX+ICI cohort (p=0.92). There was no difference in OS when evaluating IDO and PDL1 expression in 4 subgroups (IDO1+/PD-L1+, +/-, -/+, -/-) using PD-L1 cutoffs of ≥1% (p=0.50) or ≥50% (p=0.49). Table 1:

Characteristic - n, (%)	ICI Alone Cohort n = 48 (73.8%)	ICI + CTX Cohort n = 17 (26.2%)
Patient Demographics		
Age (median in years)	63.5	59

1-49%	25 (53.2)	5 (29.4)
≥50%	13 (27.7)	3 (17.6)
IDO1 IHC		
0%	23 (47.9)	11 (64.7)
≥1%	25 (52.1)	6 (35.3)
PD-L1/IDO1		
<50% / 0%	20 (41.7)	10 (58.8)
<50% / ≥1%	15 (31.2)	4 (23.5)
≥50% / 0%	3 (6.3)	1 (5.9)
≥50% / ≥1%	10 (20.8)	2 (11.8)

Conclusion: In this retrospective study of NSCLC patients receiving an ICI, our results suggest IDO positivity may be predictive of improved OS. Our ability to detect a statistically significant difference may have been limited by small sample size, particularly in the ICI+CTX cohort. Further studies examining the predictive role of IDO1 IHC would be useful to identify patients most likely to benefit from PD-1 or IDO1 inhibition.

P2.04-76 TUMOR MUTATIONAL BURDEN BY TSO500 NEXT GENERATION SEQUENCING PANEL AND CLINICAL OUTCOME IN NON-SMALL CELL LUNG CANCER

K. Cuppens, G. Froyen, B. Cruys, E. Geerdens, R. Achten, M. Vanbockrijck, B. Maes

Jessa Hospital, Hasselt/Belgium

Background: High tumor mutational burden (TMB) can predict durable clinical response to treatment with immunotherapy across cancer types. Gold standard to determine TMB, was whole genome sequencing. TMB by targeted next generation sequencing (NGS) has shown to adequately correlate. We describe, as first to our knowledge, correlation between TMB by TSO500 and outcome in NSCLC patients treated with immunotherapy. **Method:** NSCLC patients treated from 2016 to 2018 with immunotherapy (pembrolizumab or nivolumab in first and further lines) and from whom DNA was readily available after previous routine therapeutic testing, were selected. Finally, 62 patient samples were analyzed with the Illumina TruSight Oncology 500 (TSO500) panel. TMB high was defined as more than 10 mutations/Mb. 22C3 Dako antibody was used for PD-L1 immunohistochemistry. PD-L1 high was defined as 50% or more. Demographic and clinical outcome parameters were collected. A durable response was considered partial or complete response or stable disease for at least 6 months. **Result:** Of 62 analyzed NSCLC patients treated with immunotherapy, 20 were TMB high (32%) and 42 low (68%). 57 patients were evaluated for PD-L1, and 34 (60%) were PD-L1 high and 8 patients were PD-L1 negative (14%). TMB high patients showed more durable responses than TMB low patients although the difference was non-significant [12 of 20 (60%) versus 15 of 42 (36%); p = 0.1012]. Significantly more durable responses were seen in PD-L1 high compared to PD-L1 low NSCLC patients [19 of 34 (56%) versus 5 of 23 (22%); p=0.0143]. Combined TMB and PD-L1 high patients showed significantly more durable responses compared to both TMB and PD-L1 low patients [7 of 10 (70%) versus 1 of 15 (7%) ; p = 0.0017] . A significant longer median duration of response was observed in the combined high group (6 versus 2 months; p = 0.0024) . When PD-L1 cut-off is lowered (1% or more), still a clinical meaningful higher number of responses were seen in TMB high, than TMB low patients [11 of 16 (69%) versus 12 of 33 (36%); p= 0.0654]. **Conclusion:** Patients with high TMB, as determined by TSO500, tend to show more durable responses to immunotherapy, but the difference is not statistically significant. This is probably due to limited sample size. PD-L1 appears a stronger predictor than TMB by TSO500. TMB and PD-L1 combined, is able to identify NSCLC patients likely to respond and also to select patients that will probably lack benefit from immunotherapy. Hence TMB, as assessed by TSO500 in this study, should be considered a valuable part of comprehensive genomic profiling of NSCLC.

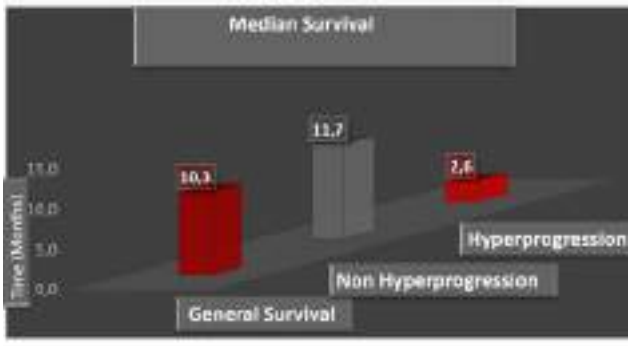
P2.04-77 HYPERPROGRESSION WITH IMMUNOTHERAPY IN METASTATIC NON-SMALL CELL LUNG CANCER: HÔPITAL CHARLES-LEMOYNE EXPERIENCE

L. Galvis Gomez[1,2], D. Gonzalez[3], B. Samson[2], F. De Angelis[2]

[1]*Dr. Everett Chalmers Hospital, Fredericton/Canada,* [2]*Hôpital Charles-LeMoyne, Longueuil/Canada,* [3]*Instituto de Cancerologia Clinica las Americas, Medellin/Colombia*

Background: Immunotherapy has revolutionized cancer treatment and particularly the perspectives of metastatic lung cancer, with durable response rates and overall survival at 5 years of up to 16%. Nevertheless, in addition to the already known immune events related to these new treatments, retrospective studies and case reports describing a rapid progression of the disease related to the beginning of immunotherapy have been published recently, reporting a rate of hyperprogression of 9 to 16%, comparable to the response rate. This phenomenon recently described deserves directed investigations to better characterize, confirm or deny its existence. **Method:** The present study is a retrospective analysis of medical records and medical imaging documents of patients with metastatic lung cancer receiving immunotherapy (nivolumab or pembrolizumab) between July 2015 and July 2017 at Charles-Lemoyne Hospital. Imaging was retrospectively reviewed to categorize patients into 3 groups: hyperprogressors, usual progressors, and non-progressers. Clinical, pathological and molecular characteristics as well as overall survival

data were analyzed according to the 3 groups. The definition by Bouzid, et al[1]. was used to define Hyperprogressive disease as a Tumor Growth Kinetics (TGK) Ratio of 2 or more, with the addition of post progressionTGK and the inclusion of patients with non messurable disease if the time to treatment failure was less than 2 months with an increase of the tumoral burden of 50% or more. [1]Bouzid, et al. Annals of Oncology 28: 1605–1611, 2017 **Result:** A total of 42 files were included with 137 images evaluated. Hyperprogression rates were similar to those reported in the recent literature (14%), and patients with demonstrated hyperprogression had decreased survival. The clinical features analyzed as the presence of recent irradiation, advanced age, and high metastatic burden were not predictive of hyperprogression.



Conclusion: In the era of immunotherapy, the identification of different patterns of progression and the sharing of institutional experiences with unexpected results following a therapy still under development becomes of major importance. This is the experience in our center with hyperprogressive disease to generate hypotheses on the evaluation of the phenomenon, the causes and risk factors. We believe, after constant reports of this finding in retrospective studies, efforts should be done in the prospective trials to actively look for and better characterize this pattern of abnormal progression as it could give us some clues in the resistance to immunotherapy.

P2.04-78 PD-L1 EXPRESSION AS A PROGNOSTIC MARKER FOR NON-SMALL CELL LUNG CANCER IN DISTINCT MUTATIONAL STATUS

N. Trachu[1], S. Oranratnachai[1], N. Iemwimangsa[1], P. Incharoen[1], S. Detarkom[1], P. Sanvarinda[1,2], W. Chantratita[1], T. Reungwetwattana[1]

[1]*Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/Thailand,* [2]*Faculty of Science, Mahidol University, Bangkok/Thailand*

Background: Programmed death-ligand 1 (PD-L1) expression is widely used as the predictive biomarker for immunotherapy treatment in NSCLC whereas their role as a prognostic marker is limited. **Method:** Seventy-nine FFPE tissues (stage I-IV) during 2012-2017 were retrieved for Next Generation Sequencing (NGS) and immunohistochemistry (IHC) staining. PD-L1 expression was performed using 22C3 Ab. Positive-PD-L1 was defined by tumor proportion score (TPS) ≥1%. Targeted mutations and fusion genes were analyzed by Lung Cancer Panel 45 Genes and Targeted RNAscan Panel on NGS, respectively. Variants from NGS with coverage of higher than 1000X, cutoff ≥3% alternate variant frequency were considered positive. The cutoff was validated by Real-time PCR. Clinical data correlation was analyzed. **Result:** Thirty-one patients (39%) had stage I-II and 48 patients (61%) had stage III-IV disease. Mean age was 62.5 years old. Fifty-one patients (65%) were female and 55 patients (70%) were never-smoker. A majority of the patients (83.6%) were negative-PD-L1. All of the 13 PD-L1 positive patients were in stage III-IV, suggesting the increased likelihood of PD-L1 expression in advanced disease (p = 0.014). No difference in age, sex, smoking status, histological subtypes, and mutational status were seen between PD-L1 positive and negative group.However, PD-L1 negative was associated with a trend toward better survival (Table1). Subgroup analysis in stage IV patients with common EGFR mutations revealed PD-L1 positive status as a significant negative prognostic factor with HR of 3.00 (95% CI: 1.17, 7.73; *P*-value=0.023), whereas positive-PD-L1 patients with the other mutations showed a trend of worse survival outcome. Table 1: Cox regression analysis of prognostic factors associated with overall survival of NSCLC patients

POSTERS

Prognostic factors	Follow up time (100 person-month)	Death		Median survival (mo)	Univariate analysis		Multivariate analysis	
		No.	Rate (95% CI)		HR (95% CI)	p-value	Adjusted HR (95% CI)	p-value

Never smoker	24.04	28	1.16 (0.80, 1.69)	76.2	1		1	
Ex-smoker	4.55	10	2.20 (1.18, 4.09)	20.1	1.70 (0.82, 3.52)	0.154	1.02 (0.47, 2.23)	0.962
Current smoker	1.26	8	6.33 (3.17, 12.66)	8.7	3.76 (1.68, 8.41)	0.001	1.70 (0.74, 3.88)	0.208
EGFR						0.825		
Mutation	22.99	35	1.52 (1.09, 2.12)	31.9	0.93 (0.47, 1.83)	0.824	-	
No mutation	6.87	11	1.60 (0.89, 2.89)	33.5	1		-	
ALK						0.869		
Positive	2.28	3	1.32 (0.43, 4.09)	NR	1.11 (0.33, 3.78)	0.867	-	
Negative	16.50	19	1.15 (0.73, 1.81)	76.2	1		-	
KRAS						0.051		
Mutation	13.12	12	0.91 (0.52, 1.61)	NR	0.53 (0.27, 1.03)	0.062	-	
No mutation	16.73	34	2.03 (1.45, 2.84)	31.1	1		-	
Number of co-MT						0.045		
< 1000	11.84	27	2.28 (1.56, 3.33)	22.8	1		1	
≥ 1000	18.02	19	1.05 (0.67, 1.65)	57.6	0.55 (0.30, 0.99)	0.047	1.22 (0.61, 2.41)	0.574

Conclusion: Positive-PD-L1 is significantly associated with advanced disease and a trend toward unfavorable prognosis. The detrimental effect of PD-L1 is significant in stage IV patients with common EGFR mutations. A confirmatory study with a larger sample size would better identify the prognostic benefit of PD-L1 status in vast subsets.

Dexeus Universitary Hospital, Barcelona/Spain,* [10]*Germans Trias i Pujol Science Inst., Catalan Institute of Oncology (ICO Badalona), Barcelona/Spain*

Background: Treatment with anti PD-1/PD-L1 antibodies has demonstrated survival improvement in several malignancies, including non small cell lung cancer (NSCLC), but these therapies are not exempt from risks. Meta-analysis and clinical trials have reported immune related (ir) pneumonitis of any grade in 3-5% of patients treated with anti PD-1/PD-L1 antibodies, including grade 3 or higher in 0.8% to 1.8% of patients. **Method:** We have retrospectively reviewed clinical reports from 125 cancer patients treated at our center with anti PD-1/PD-L1 antibodies (55 were treated with nivolumab, 27 with pembrolizumab, 33 with atezolizumab, 6 with avelumab, and 4 with durvalumab) from January 2016 to January 2019. **Result:** Nineteen patients (15.2%) developed ir pneumonitis. Four (21%) patients had recurrent pneumonitis during tapering corticoesteroid dose after an initial improvement and finally died. Patient characteristics are summarized in Table 1. Median time to pneumonitis was 4 months (m) (range 1m to 9m). Twelve patients (9.6% %) had grade 3-5 and 7 patients (5.6 %) grade 1-2 pneumonitis. Nine (7.2 %) patients died from ir pneumonitis, including 4 patients with no tumor progression (1 had received only one cycle, and 3 patients had ongoing tumor response at 10m+, 12m+ and 30m+). Ir pneumonitis was more frequent with nivolumab (any grade 21.8 %, grade 3 or higher 18.2 %, including 7 fatal cases-12.7%-), while no patient treated with atezolizumab developed pneumonitis (Table 2).

Table 1	
Total	19
Gender Women, n (%)	7 (36,8%)
Age Median (range)	63,4 (51-82)
Cancer type, n (rate) NSCLC Adenoca NS-CLC Squamous SCLC Mesothelioma	13 (68,4 %) 4 (21%) 1 (5,3%) 1 (5,3%)
Line of therapy, n (rate) Adjuvant First line Second or further line	1 (5,2 %) 8 (42,1%) 10 (52,6%)
Tumor Response, n (rate) CR PR SD PD NE	2 (10,5%) 8 (42,1%) 5 (26,3%) 3 (15,8%) 1 (5,2%)

Table 2			
Drug,n patients treated	Any Grade, n (%)	Grade 3-5, n (%)	Grade 5, n (%)
Nivolumab, 55	12 (21,8%)	10 (18,2%)	7 (12,7%)
Pembrolizumab, 27	3 (11,1%)	1 (3,7%)	1 (3,7%)
Atezolizumab, 33	0	0	0
Durvalumab, 4	2 (50%)	0	0
Avelumab, 6	2 (33,3%)	1 (16,7%)	1 (16,7%)
Total, 125	19 (15,2%)	12 (9,6%)	9 (7,2%)

Conclusion: In our experience, ir pneumonitis rate with anti PD-1/PD-L1 antibodies in lung cancer patients was 15.2%, including 7.2% of fatal complications. It suggests that previous clinical trials could have under diagnosed this serious complication. Further studies must be performed in order to specifically assess the rate of pneumonitis in patients treated with anti PD-1 and anti PD-L1 antibodies in lung cancer patients.

P2.04-80 PRETREATMENT NUTRITIONAL STATUS AND RESPONSE TO CHECKPOINT INHIBITORS IN LUNG CANCER

C.-S. Lee[1], R. Sin[1], C. Devoe[2], X. Zhu[2], M.-Y. Lee[2], N. Seetharamu[2]

[1]*St. John's University, Queens/United States of America,* [2]*Northwell Health, New Hyde Park/United States of America*

Background: Immunotherapy has developed as an integral part of the treatment for lung cancer. Obesity has become a pandemic accounting for >20% of the total United States healthcare expenditure. Obesity has been shown to be associated with an increased efficacy of PD-1/PD-L1 blockade. On the other hand, cachectic patients have been shown to not respond as well to immunotherapy. In this study, we aim to assess the pretreatment nutritional status with outcomes of lung cancer patients being treated with immunotherapy. **Method:** An IRB approved retrospective review of lung cancer patients receiving immunotherapy between 2014 and 2017 at the Monter Cancer Center, Northwell Health was conducted. Low nutritional status as defined by either a Body Mass Index (BMI) < 18.5 and/or albumin <3.5 mg/dL prior to immunotherapy treatment. Patients were stratified by BMI: underweight (BMI<18.5), normal weight (BMI of 18.5 to <25), overweight (BMI 25 to 30) and obese (BMI >30). The groups were compared using the log-rank test. Kaplan-Meier was used for overall survival (OS) and progression free survival (PFS) and Cox regression models were used to adjust for potential confounders. **Result:** A total of 116 were included in the analysis, with a median age of 70 (95% CI, 62.5 to 75.5). Patients with a low nutritional status had a median PFS of 2.2 months compared to those who did not of 5.2 months (p<0.00032). Ten (8.6%) were underweight, 44 (37.9%) were normal weight, 32 (27.6%) were overweight, and 30 (25.9%) were obese. PFS was 6.6, 6.0, and 6.9 months for patients in the underweight, normal weight, and overweight/obese groups, respectively. A total of 46 (40%) deceased within the follow up period: 3 (30%), 17 (39%), 11 (34%), and 15 (50%) respectively. BMI classification were not found to be a significant predictor of survival, after adjusting for therapy duration (p=0.44). **Conclusion:** In this single institution retrospective review, lung cancer patients receiving immunotherapy with our defined low nutritional status had a lower PFS. BMI or albumin as individual factors did not have a significant effect on PFS or OS. Additional studies are needed to validate these findings and assess the effects of nutritional status on immunotherapy.

P2.04-81 NON-SMALL CELL LUNG CANCER TREATED WITH IMMUNOTHERAPY: MULTI-INSTITUTIONAL EXPERIENCE FROM ARGENTINA

M. Rizzo[1], M. Bluthgen[2], G. Recondo[3,4], M. Naveira[5], A. Perfetti[6], M. Rizzi[2], M. Cerini[7], A. Kuzminin[4], M. Faura[5], C. Silva[1], L. Lupinacci[7], N. Minatta[7]

[1]*Hospital Universitario Austral, Buenos Aires/Argentina,* [2]*Hospital Aleman de Buenos Aires, Buenos Aires/Argentina,* [3]*Dana-Farber Cancer Institute, Boston/United States of America,* [4]*Centro de Educacion Medica e Investigacion Clinica (CEMIC), Buenos Aires/Argentina,* [5]*Hospital Britanico de Buenos Aires, Buenos Aires/Argentina,* [6]*Hospital Santojanni, Buenos Aires/Argentina,* [7]*Hospital Italiano de Buenos Aires, Buenos Aires/Argentina*

Background: Immunotherapy (IO) has been established as the standard treatment for metastatic non-small cell lung cancer (NSCLC) patients improving survival. It has been approved both in first line and after platinum-treated patients. We aimed to study the efficacy and tolerability of anti PD-(L)1 inhibitors in pts with NSCLC in Argentina providing more evidence about efficacy and toxicity **Method:** Metastatic NSCLC patients (pts) treated with immunotherapy in six hospitals between 11/2013 - 2/2019 were included. Data was collected retrospectively by the investigators. Progression-free survival (PFS) and overall survival (OS) were assessed. Cox-regression model was performed for uni- and multivariate analysis. All pts who received at least one dose of immunotherapy were evaluated for efficacy and toxicity. **Result:** A total of 269 patients were included. Median age (range) was 66 ys (28-88), 164 (61%) were men, 226 (84%) were current/former smokers and 223 (82.9%) had performance status (PS) 0-1. The predominantly histology was non-squamous (N=239; 88.8%), 158 (58.7%) tumors were evaluable for PD-L1 expression and 9 (3.3%) had EGFR mutations. 86 (32%) pts received IO as first-line and 155(57.6%) as second-line therapy. Anti-PD1 antibodies were most commonly administered (83.3%). Baseline brain and liver metastases were present in 50 (18.6%) and 29 (10. 8%) pts, respectively. The

overall response rate was 30.4% (76/256). The most common sites of progression were (N=261) bones 142 (54.4%), lung/lymph nodes 74 (28.4%) and brain 26 (10%), visceral 19 (7.3%). Grade ≥ 3 adverse events occurred in 48 pts (17.8%) and 28 (10.4%) pts discontinued treatment due to toxicity. With a median follow up of 15.88 months (95% CI 12.08-19.68), median PFS was 7.26 (95%CI 5.15-9.38) and OS was 15.18 (95%CI 9.47-20-90). In univariate analysis smoking status (p 0.049), PDL1 (p 0.002), PS (p 0.000), corticoid therapy at beginning of IO (p 0.001), grade≥3 toxicity (p 0.027), first line therapy (p=0.003) and driver mutation (p 0.028) were all associated with PFS. Age (p=0.030), PDL1% (p=0.007), corticoid therapy at beginning of IO (p<0.001), grade≥3 toxicity (p=0.012) and first line therapy (p=0.038) were all associated with OS. In multivariate analysis, PDL1 and PS were independently associated with both, PFS (p=0.011 and p=0.000, respectively) and OS (p=0.036 and p<0.001, respectively). **Conclusion:** Treatment with anti PD-(L)1 inhibitors in the real-world is effective and tolerable, supporting the use of immunotherapy in pts with NSCLC. As previously reported, low PDL1 expression and poor PS confer worst clinical outcomes. Other factors such as age, line of treatment, corticoid use, toxicity and driver mutations may impact treatment response.

P2.04-82 DISCONTINUATION OF ANTI-PD-1/PD-L1 ANTIBODY THERAPY IN THE ABSENCE OF DISEASE PROGRESSION: CLINICAL OUTCOMES IN ADVANCED NSCLC

N. Minatta[1], M. Bluthgen[2], M. Rizzo[3], M. Rizzi[2], A. Kuzminin[4], G. Recondo[5], M. Faura[6], M. Naveira[6], A. Perfetti[7], M. Cerini[1], L. Lupinacci[1]

[1]*Hospital Italiano de Buenos Aires, Buenos Aires/Argentina,* [2]*Hospital Aleman de Buenos Aires, Buenos Aires/Argentina,* [3]*Hospital Universitario Austral, Buenos Aires/Argentina,* [4]*Centro de Educacion Medica e Investigacion Clinica (CEMIC), Buenos Aires/Argentina,* [5]*Lowe Center for Thoracic Oncology, Dana Farber Cancer Institute, Boston/United States of America,* [6]*Hospital Britanico de Buenos Aires, Buenos Aires/Argentina,* [7]*Hospital Santojanni, Buenos Aires/Argentina*

Background: Treatment with anti PD-1/PD-L1 immune checkpoint inhibitors (ICIs) prolongs survival in patients (pts) with advanced non-small cell lung cancer (NSCLC). Treatment discontinuation in the absence of disease progression rises concern on treatment efficacy in patients and providers. We aim to study the outcomes of patients with NSCLC who discontinued treatment with ICIs. **Method:** Retrospective, multicenter descriptive study. Patients diagnosed with advanced NSCLC who discontinued therapy with pembrolizumab, nivolumab or atezolizumab in the absence of disease progression (PD) between 11/2013 - 2/2019 were included. All pts who received at least one dose of immunotherapy were evaluated for efficacy and toxicity. **Result:** A total of 269 patients diagnosed with metastatic NSCLC and treated with anti-PD-1 or anti-PD-L1 antibodies were retrospectively studied. Median follow-up for the entire cohort was 15.8 months (95% CI: 12.08-19.68). Median age 66 ys (r 28-88), 61% men, 83,4% were former or current smokers. Non-squamous NSCLC was the most common histologic subtype (N=239; 89%). Performance status (PS) was 0-1 in 223 pts (83%), 86 pts (32%) received ICIs in first line, 154 pts (57.4%) in second line and 28 pts (10.6%) in third line or beyond. Pembrolizumab was the most common treatment for pts (N= 129; 48%), followed by nivolumab (N= 113; 42%) and atezolizumab (N=27; 10%).Within the entire cohort, 39 pts (14.5%) discontinued treatment with ICIs for reasons other than PD, 35 pts due to toxicity and 4 pts for other reasons. At the time of treatment discontinuation, 3 pts (7.7%) had achieved a complete response (CR), 10 (25.6%) a partial response (PR), 17 pts (43,5%) a stable disease and 9 (23%) had PD. Median duration of response after discontinuation of ICIs was 6 months (range 0.1-27). Of the CR + PR + SD subgroup at the time of analysis 76, 9% remain without PD. If we consider only patients who maintained at least 3 months' therapeutic benefit when discontinuing treatment in the absence of PD, only 3 patients had PD (at 6, 7 and 17 months of discontinuation) and the median duration of response for this group was 8 months (3.74-27). **Conclusion:** Patients who discontinue treatment with ICI in the absence of disease progression can achieve sustainable benefit. Further studies are needed to assess the safety and efficacy of reintroducing ICIs in the event of disease progression in this population.

P2.04-83 LONG-TERM FOLLOW-UP COMPASIONATE USE PROGRAM NIVOLUMAB IN NSCLC

P. Baas, R. Schouten, M. Muller, E. Van Werkhoven

Netherlands Cancer Institute, Amsterdam/Netherlands

Background: From August 2015 until March 2016, patients with NSCLC were treated in the Early Access Program (EAP) or commercially available nivolumab. Here, we report the long term survival figures for this Real Life treatment (early data were presented at WCLC in 2016). Currently, the median follow-up is 3 years for the patients treated in the EAP, and 2.5 years for the patients that have been treated with commercially available nivolumab. We address open questions of the efficacy of nivolumab in real life on special subgroups (brain mets, elderly, ECOG, smoking, platinum sensitivity) with regards to OS. **Method:** A prospective follow up of 248 pts was performed with respect to the above mentioned subgroups using Kaplan Meier curves and Cox proportional hazards regression. **Result:** Median age 63 (29-84); 55% male; 81% (ex)-smoker; 67% adeno, 22% squamous and 11% mixed type carcinoma; PS 0-1: 84%; PS 2-3: 16%; brain mets 23%. Overall survival in the whole group was 17% at 3 years. For the subgroups, the PS 2-3 vs 0-1 showed a HR of 1.77 (p=0.0023); Platinum sensitive vs resistant showed a HR of 0.55 (p=0.00032): (Ex) Smoker vs never smoker showed a HR of 0.62 (p=0.007) and no difference was observed between Squamous vs Non-squamous or for patients who initially presented with or without brain mets. **Conclusion:** These data confirm the activity of nivolumab in second line treatment outside of a reported study. The 17% 3 yrs survival is exactly in line with the pooled data from the Checkmate 017/057 study (Vokes et al. Ann Oncol 32018, 29;9590-65). Long term efficacy of this checkpoint inhibitor is confirmed. Good performance status, smoking, non-squamous carcinoma and platinum sensitive tumors are positive predictive factors.

Keywords: Real life, nivolumab, second line

P2.04-84 NSCLC SURVIVAL EXPECTANCY FOR PATIENTS TREATED WITH DOCETAXEL/NINTEDANIB IN THE SENECA TRIAL AND PREVIOUS IMMUNOTHERAPY

Background: The phase IIb SENECA trial was an Italian real-world experience recently ended, which demonstrated similar progression free survival (PFS) and overall survival (OS) in non-squamous non-small cell lung cancer (nsNSCLC) patients treated with second-line docetaxel/nintedanib, regardless the relapsing-time from end of first-line chemotherapy and the docetaxel schedule employed (weekly or q3wks), with a slightly higher toxicity-trend in the q3wks arm. During accrual period (January 2016-April 2018), no therapeutic alternative to the use of docetaxel was available for patients with recurrent nsNSCLC until April 2017, when the first immune-checkpoint inhibitor was approved and reimbursed in Italy in this setting. At that point, the study was amended allowing enrolment of patients previously treated with immunotherapy (IT). Because of the lack of data about the optimal therapeutic algorithm in this context, aim of the present evaluation is to investigate if survival expectancy of patients treated with docetaxel/nintedanib could positively influenced when previously treated with IT. **Method:** In the SENECA trial, 212 nsNSCLC patients, progressing after first-line chemotherapy, were treated with docetaxel plus continuous oral nintedanib, with the possibility of maintenance in case of stabilization or response. This evaluation

focus on 16 patients previously treated with IT and compares them to the rest of patient population. Survival analysis is performed using Kaplan Meier curves; Hazard Ratios (HR) with 95% Confidence Interval (95%CI) are reported to compare the two groups. **Result:** Patients treated with IT (2 combined with first-line chemotherapy, 14 alone) correspond to 7.5% of the entire study population; they were 9 males and 7 females, with a median age of 62.5 years, mainly current or former-smokers, with an ECOG-performance status 0 in 93.7% of cases. At the cut-off date (December 25th, 2018), after a median follow-up of 35.5 months, no significant differences appear between patients previously treated with IT and the other ones in terms of PFS (5.84 vs 4.31 months, respectively; HR 0.564 [95% CI 0.283-1.122], p-value=0.1029), and OS (9.37 vs 9.02 months, respectively; HR 1.108 [95% CI 0.393-3.123], p-value=0.8456). No significant differences have been observed also in disease-control rates (80.0% vs 66.7%, p-value=0.5436). **Conclusion:** Despite this report does not show a greater survival expectancy for patients treated with docetaxel/nintedanib and previous IT, it's likely that the small sample size may affect this result. The longer PFS and greater disease-control rate are attractive hints for future evaluations with larger sample sizes, supposing a new therapeutic algorithm for recurrent nsNSCLC patients.

P2.04-85 CLINICAL SIGNIFICANCE OF THE PD-L2 EXPRESSION IN PATIENTS WITH NSCLC RECEIVING ANTI-PD-1 INHIBITORS

H. Ishii[1], K. Azuma[1], N. Matsuo[1], T. Tokito[1], K. Yamada[2], T. Hoshino[1]

Background: The programmed cell death 1 (PD-1) receptor–ligand interaction is a major pathway often hijacked by tumors to suppress immune control. Programmed cell death-ligand 1 (PD-L1), a ligand of PD-1, can potentially predict the response to anti-PD-1/PD-L1 inhibitors in patients with non-small cell lung cancer (NSCLC); however, the role of PD-L2, another ligand of PD-1, remains unclear in patients receiving anti-PD-1 inhibitors. This retrospective study aims to determine the significance of the PD-L2 expression in anti-PD-1 inhibitors–treated patients with NSCLC. **Method:** We enrolled 82 patients with advanced or recurrent NSCLC who received anti-PD-1 inhibitors. The PD-L2 expression was assessed by immunohistochemical analysis staining with an antibody of PD-L2 (1:200, clone 176611), and cases with >1% tumor staining of PD-L2 were considered positive. Furthermore, we analyzed correlations between PD-L2 expression and patients' characteristics, efficacy, and immune-related adverse events (irAEs) of anti-PD-1 inhibitors. **Result:** In this study, 59 (72.0%) and 56 (68.3) patients with NSCLC exhibited positive tumor PD-L2 and PD-L1 staining, respectively. Overall, 39 irAEs developed in 36 patients. The PD-L2 expression markedly correlated with the development of irAEs; however, we observed no correlation between PD-L2 expression and the efficacy of anti-PD-1 inhibitors. Other factors, including the PD-L1 expression, age, sex, smoking status, histology, did not correlate with the development of irAEs. **Conclusion:** This study suggests that the PD-L2 expression could be accountable for the development of irAEs in anti-PD-1 inhibitors–treated patients with NSCLC.

Background: Lung cancer is the second most common cancer in both sexes and is the leading cause of cancer mortality in the United States. Combination of checkpoint inhibitors (ipilimumab, nivolumab, pembrolizumab, or atezolizumab) and chemotherapy has shown synergistic anti-tumor activities and has created a fundamental paradigm shift in the management of first-line treatment of advanced lung cancer. We performed a systematic review and meta-analysis of currently available randomized controlled trials (RCTs) to evaluate the efficacy of ipilimumab in combination with chemotherapy for the first-line treatment of advanced lung cancer. **Method:** We systematically conducted a comprehensive literature search using PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019. RCTs utilizing first-line ipilimumab chemoimmunotherapy in patients with advanced lung cancer were incorporated in the analysis. A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for overall survival (OS) and progression-free survival (PFS) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q -statistic. Random effects model was applied. **Result:** A total of 3178 patients with advanced lung cancer from 5 RCTs were included in the analysis. The study arm used standard chemotherapy regimens in combination with ipilimumab while control arm used only standard chemotherapy regimens. The randomization ratio was 1:1 in all studies. Ipilimumab was employed either in phased or concurrent with chemotherapy. The I^2statistic for heterogeneity was 63%, suggesting some heterogeneity among RCTs. The pooled HR for PFS was significant at 0.85 (95% CI: 0.78-0.93; P = 0.0004) when ipilimumab was utilized in phased with chemotherapy. In non-small cell lung cancer population, the pooled HR for PFS was noted at 0.82 (95% CI: 0.68-1.00; P = 0.05), and the pooled HR for OS was 0.92 (95% CI: 0.83- 1.02; P = 0.10). In patients with extensive-stage small cell lung cancer, the pooled HR for PFS was statistically significant at 0.86 (95% CI: 0.77-0.97; P = 0.01), and the pooled HR for OS was 0.92 (95% CI: 0.81-1.06; P = 0.26). **Conclusion:** Our meta-analysis depicted that upfront ipilimumab chemoimmunotherapy significantly improved PFS compared to standard chemotherapy, when ipilimumab was either employed in phased with chemotherapy or in patients with extensive-stage small cell lung cancer.

Background: Standard treatment for patients with locally advanced (LA) non-small cell lung cancer (NSCLC) was concurrent chemoradiotherapy (CRT) with 40-70% of 2-year overall survival (OS). Immune checkpoint inhibitors (ICIs) have been shown efficacy in advanced or recurrent NSCLC and approved on December 2015 in Japan. After that, the ICI durvalumab was approved as maintenance therapy after concurrent CRT even in unresectable LA-NSCLC on July 2018 in Japan. **Method:** To investigate the feasibility of concurrent CRT for LA-NSCLC patients and efficacy of ICI treatment for the relapsed patients after CRT, we assessed consecutive LA-NSCLC patients treated with concurrent CRT between July 2013 and June 2018 (before durvalumab approval), retrospectively. **Result:** 108 eligible patients (81 males and 27 females with median age of 65 years old, including 7 patients with targeted mutations; 2 EGFR, 4 ALK and 1 ROS1) were analyzed. All patients received radical thoracic radiotherapy using 3D planning system and concurrent with platinum-based chemotherapy. 79 (73%) received one or two cycles of consolidation chemotherapy of same regimen. 105 (97%) patients completed planned radiotherapy, and radiation pneumonitis was observed in 93 (85%) patients with median 130 (range, 41-317) days from initiation of radiation to onset. 74 (69%) patients met the PACIFIC criteria and were considered to be eligible for durvalumab. The overall response rate was 64% and the progression free survival was 10.3 (95% CI, 8.4–12.2) months. The OS was 41.8 (95%CI, 20.1-63.5) months and 2-year OS were 63%. Of the 82 patients who relapsed after CRT, 18 patients received ICI treatment (14 nivolumab, 3 pembrolizumab, 1 atezolizumab) in the course of treatment. Patients who received ICI after relapse had significantly better survival than those who did not receive ICI (2-year OS, 87% vs. 41%; p=0.001). **Conclusion:** Concurrent CRT using platinum-based regimen was considered effective treatment with acceptable toxicity for LA-NSCLC patients. The efficacy of ICI treatment has been

shown in patients with relapse after concurrent CRT in LA-NSCLC, and indication with durvalumab maintenance therapy is expected to further improve the prognosis in patients with LA-NSCLC. The optimal use timing of ICI treatment for patients with LA-NSCLC should be considered.

Background: The role of immune checkpoint inhibitors in resectable NSCLC remains undefined. We report the updated safety results of the first multicenter trial assessing neoadjuvant atezolizumab (a PD-L1 inhibitor) for resectable NSCLC. **Method:** Eligible patients with clinical stage IB-IIIB resectable NSCLC received 2 cycles of neoadjuvant atezolizumab (1200 mg, days 1, 22) followed by surgical resection (day 40±10). Pre- and post-treatment PET/CT, pulmonary function tests (PFT), and bio-specimens were obtained. Adverse events (AE) were recorded according to CTCAEv.4.0. Preoperative treatment-related TRAE (preop-TRAE) and postoperative TRAE (postop-TRAE) defined as AE onset on, or after date of surgery, were analyzed. **Result:** Follow-up data to post-surgery visit were analyzed for 101 patients out of planned 180: mean age: 64.6 years; male: 47/101(46.5%); current smokers: 23/101(22.8%); non-squamous histology: 66/101(65.3%); and clinical stages IB(10.9%), IIA(15.8%), IIB(27.7%), IIIA(38.6%), and IIIB(6.9%). Two cycles of atezolizumab were not completed in 5/101(5.0%) patients due to grade 1 or 2 AEs. Surgery was not performed in 11/101(10.9%) patients: 5 demonstrated disease progression, and 6 for 'other' reasons. 6/101(5.9%) patients were deemed unresectable. Surgery was delayed (outside of 10-day window) in 10/90(11.1%) patients by an average of 11(1-39) days. Two of these delays were due to TRAEs (hypothyroidism and pneumonitis), 3 were patient-elected delays, 2 were surgeon-related, and 3 for 'other' reasons. Intraoperative vascular complications occurred in 2/90(2.2%) and extensive hilar fibrosis was noted in 20/90(22.2%) patients. Overall, there was insignificant mean change in the PFTs pre- vs. post-atezolizumab therapy. Only 3/101(3.0%) patients had treatment-related dyspnea, dyspnea on exertion, or pneumonitis. Table 1

Treatment Related Adverse Events (TRAE)	Preoperative TRAE (N = 101)	Postoperative TRAE (N = 90)
All AEs		
Any grade	55 (54.5%)	20 (22.2%)
Grade 1	29 (28.7%)	7 (7.8%)
Grade 2	24 (23.8%)	9 (10.0%)
Grade 3	2 (2.0%)	4 (4.4%)
Grade 4	0	0
Grade 5	0	0
Specific AEs		
Dyspnea	1 (1.0%; grade 2)	3 (3.3%; grade 1)
Dyspnea on exertion	1 (1.0%; grade 1)	0
Myalgia	4 (4.0%; grade 1 or 2)	0
Hyperthyroidism	3 (3.0%; grade 1 or 2)	1 (1.1%; grade 1)
Hypothyroidism	0	1 (1.1%; grade 2)
Pneumonitis	1 (1.0%; grade 3)	3 (3.3%; grade 2 or 3)
Transaminitis (AST or ALT)	8 (7.9%; grade 1 or 2)	3 (3.3%; grade 1 or 2)
Post-atezolizumab Change in Pulmonary Function Tests		
PFT factor	Mean change (95% Confidence Interval)	
FEV1 (N = 72)	-0.6% (-2.6% to 1.3%)	
FVC (N = 72)	0.0% (-1.8% to 1.8%)	
DCLO (N = 64)	-1.2% (-4.1% to 1.7%)	

Conclusion: Treatment with neoadjuvant atezolizumab in resectable stage IB-IIIB NSCLC was well tolerated, with minimal delay to surgery, and few treatment associated AEs. This trial continues to accrue and assess MPR, survival, and other long-term endpoints.

Keyword: neoadjuvant, immuno-oncology, early stage lung cancer

P2.04-89 NEOADJUVANT PEMBROLIZUMAB IN EARLY STAGE NON-SMALL CELL LUNG CANCER (NSCLC): TOXICITY, EFFICACY, AND SURGICAL OUTCOMES

N. Ready[1], B. Tong[1], J. Clarke[1], L. Gu[1], D. Wigle[2], K. Dragnev[3], T. Sporn[1], T. Stinchcombe[1], T. D'Amico[1]

[1]*Duke University, Durham/United States of America,* [2]*Mayo Clinic, Rochester/United States of America,* [3]*Dartmouth Medical Center, Lebanon/United States of America*

Background: Pembrolizumab is a programmed death receptor-1 masking antibody approved for advanced NSCLC in program death receptor ligand-1 high tumors, and in chemotherapy combinations. This trial studies the effect of neoadjuvant pembrolizumab on surgical tolerability (primary endpoint), tumor response, side effects, and immune biomarkers in blood and tumor. **Method:** Baseline PET/CT, brain imaging, histologic diagnosis NSCLC, and surgical consultation were required for eligibility. Patients with stage T > 3 cm and N0, N1, or resectable N2 NSCLC received neoadjuvant pembrolizumab 200 mg every 21 days 2 cycles prior to pre-operative chest CT scan followed by standard surgery. Adjuvant chemotherapy was strongly encouraged but not required. After completion of standard chemotherapy, 4 cycles of adjuvant pembrolizumab 200 mg every 21 days was offered. Blood for immune profiling of circulating immune cells was collected at baseline, after cycle 2 pembrolizumab, after surgery, and after adjuvant pembrolizumab. Excess tumor was disaggregated for tumor infiltrating lymphocytes, regulatory immune cells, and tumor cells, and viably stored for later analysis. We report

clinical outcomes of tumor response and surgical outcomes. **Result:** Study activated 31/1/2017, last enrollment 6/2/2019, and last surgery 19/3/2019. 35 patients signed consent and 30 received at least 1 dose pembrolizumab: 2 withdrew consent, 3 screen failed. Characteristics of 30 treated patients (%): male 16 (53), adenocarcinoma 10 (33), squamous 17 (57), other histology 3 (10), and stages 1B 8 (27), IIA 8 (27), IIB 6 (20), IIIA 8 (27). Planned surgery completed for 25/30 (83%). Reasons for not undergoing surgery: distant metastatic disease (1 brain metastases, 2 pleural metastases), 1 would not tolerate required pneumonectomy, 1 N3 nodal disease. Surgeries performed: video-assisted thoracic surgery (VATS) lobectomy 12, thoracotomy lobectomy 9, VATS pneumonectomy 2, thoracotomy pneumonectomy 1, and VATS bilobectomy and chest wall resection 1. All surgery was performed within range 38-77 days (median 48 days) after cycle 1 day 1 pembrolizumab. Data will be presented for toxicities neoadjuvant pembrolizumab, surgical outcomes, and neoadjuvant pembrolizumab RECIST responses, and pathologic responses. Some major pathologic responses (< 10% viable tumor) and at least 2 pathologic CRs were observed. **Conclusion:** Two doses of neoadjuvant pembrolizumab was tolerable and produced major or complete pathologic responses in some tumors. Neoadjuvant pembrolizumab is tolerable and is an ideal platform to investigate mechanisms of immune resistance and sensitivity in early stage NSCLC.

P2.04-90 NODAL IMMUNE FLARE (NIF) FOLLOWING NEOADJUVANT ANTI-PD-1 AND ANTI-CTLA-4 THERAPY IN NON-SMALL CELL LUNG CANCER

B. Sepesi, M. Godoy, W. William, A. Vaporciyan, H. Lin, C. Leung, J. Lee, K. Mitchell, A. Weissferdt, X. Le, V. Lam, F. Fossella, S. Swisher, J. Heymach, T. Cascone

The University of Texas MD Anderson Cancer Center, Houston/United States of America

Background: Immune checkpoint inhibitors (ICIs) have induced durable responses in selected non-small cell lung cancer (NSCLC) patients. However, ICIs have also shown to induce tumor pseudo-progression in some cases. We report the incidence and consequences of a distinct phenomenon – the apparent radiographic progression of lymph nodes without pathological evidence of tumor – that we define "nodal immune flare" (NIF), following neoadjuvant ICIs in the NEOSTAR phase 2 trial of nivolumab or nivolumab plus ipilimumab for operable NSCLCs. **Method:** NEOSTAR randomized 44 patients with stage I-IIIA (AJCC 7th edition) to nivolumab (3 mg/kg IV, days 1, 15, 29) or nivolumab/ipilimumab (1 mg/kg IV, day 1) with planned surgery between 3-6 weeks after last dose. Computed tomography (CT) and positron emission tomography (PET-CT) were obtained prior to ICIs and prior to resection. Response Evaluation Criteria in Solid Tumors v1.1 were used to evaluate responses. **Result:** 44 patients, median age 66 years (range 43-83), 28 (64%) males, 37 (84%) white were randomized to nivolumab (n=23) or nivolumab/ipilimumab (n=21). 26 (59%) had adenocarcinoma, 17 (39%) squamous cell, 1 (2%) adenosquamous carcinoma. 23 (52%) stage I, 12 (27%) stage II, 9 (20%) stage IIIA. 39 (89%) underwent complete resection, 2 off trial, and 5 (11%) were not resected. NIF occurred in 5/44 (11%) patients, 3 post nivolumab (3/23, 13%) and 2 (2/21, 10%) post nivolumab/ipilimumab. All patients had no evidence of malignancy in nodes of interest prior to ICIs. 2 (2/26, 8%) occurred in adenocarcinoma and 3 (3/17, 18%) in squamous cell. 2 (5%) required additional invasive restaging, 3 (7%) change in surgical plan, 1 (2%) declined surgery, 1 (2%) was thought to have disease progression and was treated with chemotherapy plus ICI prior to resection off study, and 1 (2%) underwent planned resection. Pathologic evaluation of the flared nodes revealed no evidence of cancer in all 5 patients, rather demonstrated noncaseating granulomata. In a previous neoadjuvant trial utilizing platinum-based chemotherapy with nintedanib, we did not observe NIF in 21 patients in absence of pathologic evidence of tumor progression (primary or nodal metastases). **Conclusion:** NIF occurred in 11% of patients following neoadjuvant ICIs and changed treatment plan in 9% of patients. This is the first preliminary report of NIF in operable NSCLCs treated with neoadjuvant single and combined ICIs. Considering the number of ongoing neoadjuvant immunotherapy trials, we highlight the importance of judicious and invasive restaging of sites of suspected progression after neoadjuvant ICIs prior to definitive treatment decisions.

Background: Chimeric antigen receptor (CAR) and T cell receptor (TCR) T cell therapies are innovative 'living drugs' with the potential for transformational benefit to patients. T cell therapies, have so far, shown impressive efficacy in haematological malignancies. However, treatment of solid tumours remains challenging. Unlike CARs, that recognize cell surface proteins, TCRs recognize intracellular targets presented in the context of human leukocyte antigen (HLA). NY-ESO-1 and LAGE-1a are tumour-associated intracellular antigens that generate a shared SLLMWITQC peptide bound to HLA-A*02 and expressed on multiple malignancies, including non-small cell lung cancer (NSCLC). Our TCR T cell product (GSK3377794) consists of autologous, lentivirally (LV) transduced T cells engineered to express an affinity enhanced NY-ESO-1^{c259} TCR recognizing the SLLMWITQC/HLA-A*02 peptide. Cell therapy trials with NY-ESO-1^{c259} TCR T cells have shown the highest objective responses to date to solid cancer in patients with synovial sarcoma, metastatic melanoma and multiple myeloma. Recently a partial response in a patient with advanced lung adenocarcinoma was reported with a another TCR-engineered T cell product targeting NY-ESO-1. The aims of our study were (1) to systematically assess the prevalence of target antigen expression for NY-ESO-1 and LAGE-1a in NSCLC (2) to determine the product-specific threshold of target antigen expression in NSCLC required to induce a specific T cell response, and (3) to explore means to selectively modulate NY-ESO-1/LAGE-1a expression in lung cancer with the aim of increasing patient benefit from TCR T cell treatment. **Method:** We established and characterized a NSCLC tumour biobank consisting of: primary patient tumour tissues, patient derived xenograft (PDX) samples and tumour cell lines. Expression of HLA-A*02 was confirmed by flow cytometry and levels of NY-ESO-1/LAGE-1a were measured via RT-qPCR. GSK3377794 response against these samples was determined by IFN-γ secretion and correlated with NY-ESO-1/LAGE-1a expression levels. **Result:** Expression of NY-ESO-1 and LAGE-1a antigen varied across the NSCLC tumour biobank samples. GSK3377794 activation correlated with NY-ESO-1/LAGE-1a expression levels in NSCLC. The functional readouts identify a product-specific antigen expression threshold for GSK3377794 in NSCLC, which could translate to a potential patient population that may benefit from GSK3377794 treatment. Our experiments further indicate that it is possible to increase NY-ESO-1/LAGE-1a expression in NSCLC cells by use of epigenetic modifiers enhancing specific targeting by GSK3377794. **Conclusion:** To date this is the most comprehensive and systematic analysis that correlates target antigen expression in NSCLC with functional responses of GSK3377794 using a set of clinically relevant sample specimens.

P2.04-92 NEOADJUVANT DURVALUMAB WITH OR WITHOUT SUB-ABLATIVE STEREOTACTIC RADIOTHERAPY (SBRT) IN PATIENTS WITH RESECTABLE NSCLC (NCT02904954)

N. Altorki, A. Borczuk, A. Saxena, J. Port, B. Stiles, B. Lee, N. Sanfilippo, E. Ko, R. Scheff, B. Pua, J. Gruden, P. Christos, C. Spinelli, J. Gakuria, V. Mittal, T. Mcgraw, S. Formenti

Weill Cornell Medicine - New York Presbyterian Hospital, New York/United States of America

Background: Preclinical evidence suggests that sub-ablative doses of radiation may have immunomodulating properties and may result in potent local and systemic anti-tumor immune-responses when combined with immune checkpoint-inhibitors (ICIs). Here we report the preliminary results of an ongoing phase-II trial of neoadjuvant therapy (NT) with Durvalumab alone or SBRT+Durvalumab followed by adjuvant Durvalumab for 12-months. **Method:** Eligible patients were randomized to 2-cycles of Durvalumab (Arm-1) or 3 consecutive doses of SBRT(8GX3) plus 2-cycles of Durvalumab (Arm-2). Surgery was

planned 1-2 weeks after last cycle of Durvalumab. Primary endpoint was DFS for both arms versus historical controls. Secondary endpoints were safety and efficacy determined by clinical/pathological response rates. We compared tumor immunephenotype (IP) in pre- and post-treatment samples by XCell deconvolution of RNAseq transcriptomic data. **Result:** 34 patients were randomized (1/1/17-1/11/19,). Patients in Arm-2 were more frequently ever-smokers and had more PD-L1+ve tumors (Table). All patients completed NT. Grade 3/4 adverse events (AEs) occurred in 4 patients after NT (3 in Arm-1, 1 in Arm-2). One patient (Arm-1) died preoperatively from an unrelated stroke. 32 patients were surgically explored and 30 resected (28R-0:87%). There were no perioperative deaths. Grade 3/4 perioperative AEs occurred in 10/32 patients (31%). In Arm-2, 8/17 (47%) patients had a major pathologic response (MPR: £10% residual tumor) compared to none in Arm-1. Excluding 4 patients with EGFR mutations, MPR occurred in 8/13(61.5%) patients in Arm-2. Relative to Durvalumab alone, SBRT+Durvalumab was associated higher abundance of dendritic cells, myeloid cells and fibroblasts. In Arm-2, tumors with MPR had a higher immunoscore and greater abundance of dendritic cells and higher HLA gene expression. **Conclusion:** In this randomized-trial, neoadjuvant Durvalumab with or without SBRT was well tolerated. The rates of MPR after SBRT+Durvalumab are promising and suggest that sub-ablative doses of radiation may significantly enhance local immune response.

P2.04-93 PERFORMANCE STATUS AND AGE AS PREDICTORS OF IMMUNOTHERAPY OUTCOMES IN ADVANCED NON-SMALL CELL LUNG CANCER

T. Ahmed, T. Lycan, P. Gandhi, J. Miller, B. Levine, M. Farris, J. Ruiz, W.J. Petty

Wake Forest School of Medicine, Winston-Salem/United States of America

Background: Immunotherapy has become a standard of care treatment for patients with advanced non-small cell lung cancer (NSCLC). While a survival advantage has been proven for patients who are medically fit, it is unknown whether a benefit exists for patients with poor performance status (PS). PS has been established as one of the most powerful independent prognostic factors in advanced NSCLC since it is a strong predictor of survival and adverse events. When treated with conventional chemotherapy, patients with poor PS have worse outcomes and higher rates of toxicity which is why they have been excluded from many clinical trials. Standard treatment is generally recommended in patients with PS 0-1, while best supportive care is offered to patients with PS 4. Clinical trials are needed to define the best practices for patients with PS 2 and PS 3. **Method:** We performed a retrospective analysis of NSCLC patients who received immunotherapy in our health system. Patients were identified using drug administration and diagnosis codes. Age and PS at the time of initial immunotherapy administration were assigned based on physician documentation. Radiographic response and date of progression were initially assigned according to the treating physician's assessment and confirmed by the study team. Immune related adverse events (irAE) were extracted from records. All steroid prescriptions and hospitalizations were independently reviewed and attributions assigned. **Result:** We identified 285 NSCLC patients who received immunotherapy between January 2014 and April 2018. In this group, 153 patients (53.7%) had PS 0-1, 114 (40.0%) had PS 2, and 18 (6.3%) had PS 3. Response rates were similar across PS groups with responses in 26.6% for PS 1, 25.2% for PS 2, and 23.1% for PS 3 (p=.95). Survival outcomes varied with pre-treatment PS. For PS 0-1, PS 2, and PS 3, median overall survivals (OS) were 14.7 months, 8.3 months, and 1.5 months (p<0.001), and progression-free survivals (PFS) were 7.4 months, 5.1 months, and 1.3 months (p<0.001). OS and PFS outcomes were not significantly different for older and younger patients. Patients less than 70 years had a lower rate (7.6%) of irAE requiring steroids compared to patients over 70 (15%) (p=0.04). Patients less than 70 had a higher mean number of ICU admissions (p=0.04) and total days in the ICU (p=0.007) compared to patients over 70. **Conclusion:** Patients with poor baseline PS demonstrate similar response rates but inferior PFS and OS compared to medically fit patients. Prospective trials are needed to optimize treatment for this large population. Differences in irAE management and irAE severity according to age warrant further investigation.

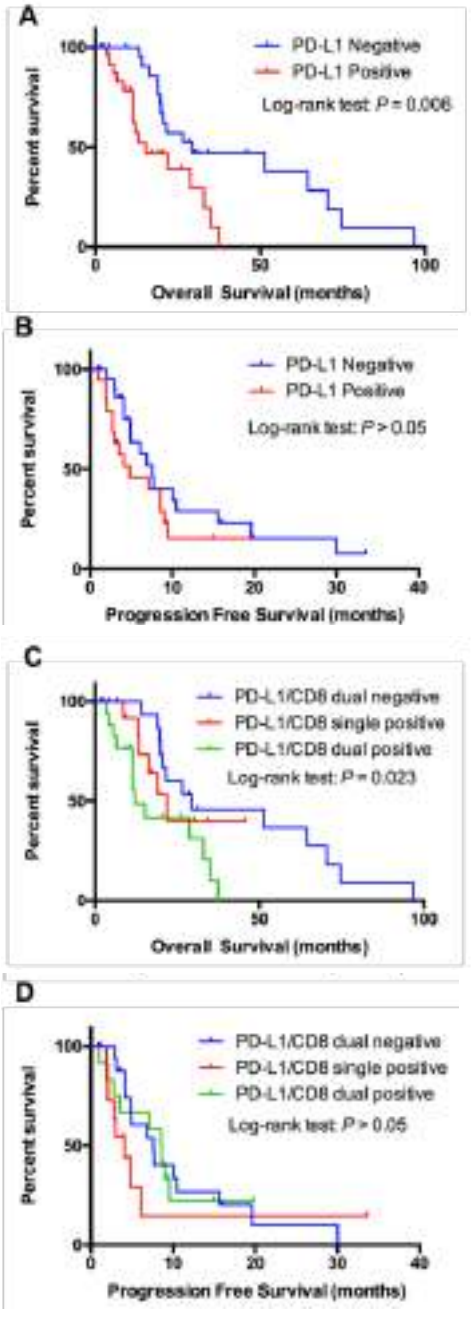
P2.04-94 PD-L1 EXPRESSION IN UNCOMMON EGFR-MUTANT NON-SMALL CELL LUNG CANCER AND ITS RESPONSE TO IMMUNOTHERAPY

K. Chen, Y. Fan

Zhejiang Cancer Hospital, Hangzhou/China

Background: The efficacy of immunotherapy treating EGFR-positive non-small cell lung cancer (NSCLC) patients has been proved to be limited. However, a series of mutant-patients could be benefit from PD-1 blockade. Therefore, this study evaluated the immune microenvironment in NSCLC with uncommon EGFR mutation, and explored the prospect of immunotherapy in this cohort. **Method:** We retrospectively evaluated the expression of PD-L1, CD4 and CD8 in NSCLC patients who harbored uncommon EGFR mutation at Zhejiang Cancer Hospital between April 2016 and September 2017. The association with clinical factors and outcomes were also explored, as well as the effectiveness of immunotherapy in uncommon mutation-positive cases. **Result:**



POSTERS

Among the 600 NSCLC patients with EGFR mutation, we retrospectively collected 49 (8.2%) cases bearing uncommon mutation. In total, 49.0% (24/49) of NSCLC patients showed a strong PD-L1 expression in tumor cells, which was significantly higher than common sensitive (19del and L858R) or negative EGFR mutation (49.0% vs 12.1% vs 26.3%, respectively, $P<0.05$). Furthermore, positive PD-L1 expression was associated with a significantly shortened OS when compared with the negative PD-L1 expression (20.0 vs 44.3 months, $P=0.006$). And PD-L1 positivity was predominantly observed among patients with high CD8 expression rather than low cases (72.0% vs 25.0%, $P=0.001$). Notably, we found PD-L1 and CD8 dual-positive cases demonstrated the worst prognosis (OS: 19.3[dual-positive] vs 31.1[single-positive] vs 44.3[dual-negative] months, $P=0.023$). Additionally, this approach revealed PD-L1 and CD8 positivity were not associated with the response to *EGFR-TKIs*, playing no role in the *de novo* resistance of *EGFR-TKIs* among the uncommon mutated patients. Finally, one patient harboring EGFR G719A mutation with PD-L1 and CD8 dual positivity experienced a favorable response to anti-PD-1 therapy. **Conclusion:** This study revealed the expression of PD-L1, CD4 and CD8 in uncommon EGFR-mutated NSCLC patients. The findings indicated the reshaping of an inflamed immune phenotype characterized by PD-L1 and CD8 dual positivity and suggest potential therapeutic sensitivity to PD-1 blockade.

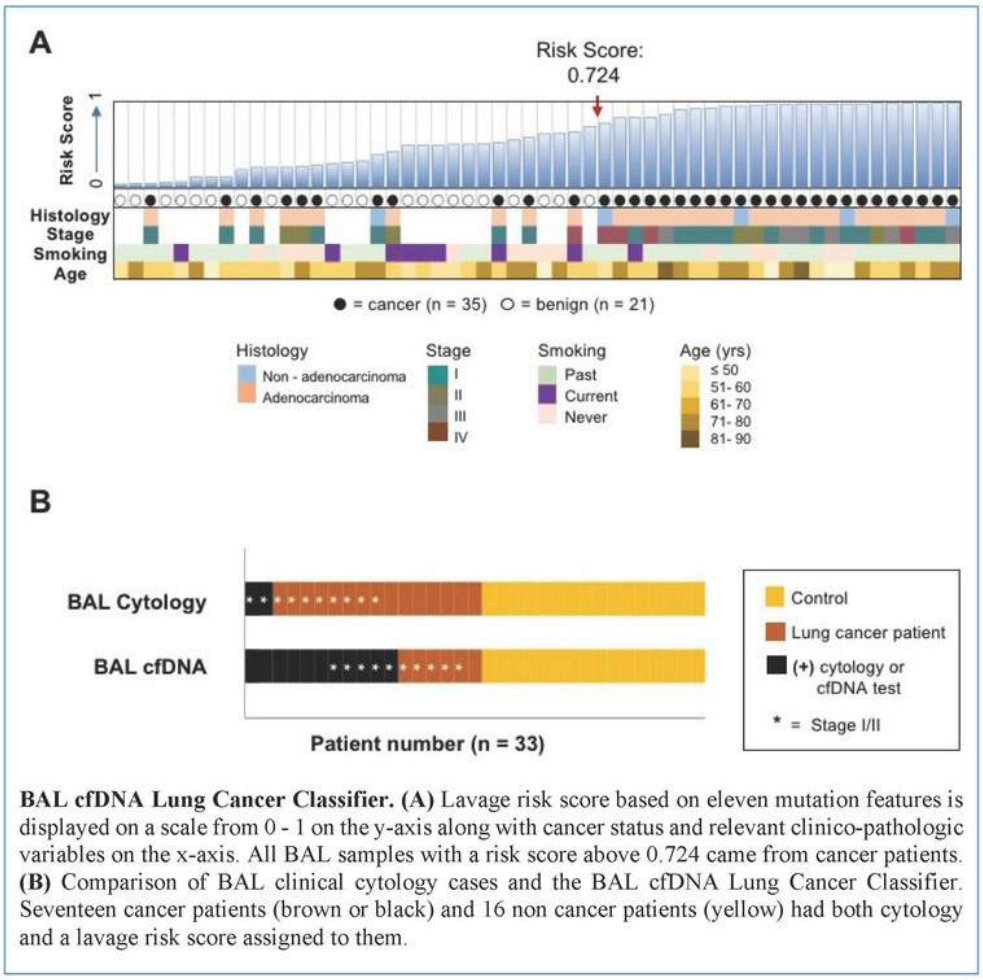
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.05-01 BROAD GENOMIC PROFILING OF BRONCHOALVEOLAR LAVAGE FLUID IN LUNG CANCER

V. Nair[1], A. Bik-Yu Hui[2], J. Chabon[2], M. Esfahani[2], H. Stehr[2], B. Nabet[2], J. Benson[2], A. Chaudhuri[3], L. Zhou[4], K. Ayers[2], H. Bedi[2], M. Ramsey[2], R. Van Wert[2], A. Sung[2], N. Lui[2], L. Backhus[2], M. Berry[2], P. Massion[5], J. Shrager[2], A. Alizadeh[2], M. Diehn[2]

[1]*USF/Moffitt, Tampa/United States of America,* [2]*Stanford University School of Medicine, Stanford/United States of America,* [3]*Washington University, St Louis, St. Louis/United States of America,* [4]*Grail Corp, Menlo Park/United States of America,* [5]*Vanderbilt University School of Medicine, Nashville/United States of America*

Background: We hypothesized that tumor-derived mutations from non-small cell lung cancer (NSCLC) are readily detectable in bronchoalveolar lavage (BAL). To explore our hypothesis, we employed the CAncer Personalized Profiling by deep Sequencing (CAPP-Seq) method to identify somatic mutations in BAL compared to blood. **Method:** We profiled 200 matching lavage, plasma, and PBMC samples from a total of 38 NSCLC patients and 21 controls. We first applied a tumor-informed calling approach to most sensitively detect mutations in BAL and plasma. We then applied a tumor-naïve mutation calling strategy to explore the effect of field cancerization in at risk patients with lung nodules or who smoked. Last, we developed a BAL mutation classifier to differentiate patients with cancer from those without and compared the performance of this classifier to BAL cytology. **Result:** Tumors were primarily lung adenocarcinomas (84%) and mostly early stage disease (I-II 71%; III-IV 29%). We called a median of 4 mutations per tumor. TP53 and KRAS were the most frequently detected variants in tumor (47% and 35% respectively) and lavage cell free (cf) DNA (38% and 26% respectively). Using a tumor-informed approach, we detected significantly more variants in lavage cfDNA than in plasma from cancer patients ($p<0.001$) and variants were more frequently called in lavage cfDNA than in plasma from cancer patients (77% vs. 41%, $p=0.004$). As expected, tumor-naïve calling resulted in fewer variants detected in both sample types when compared to tumor-informed calling but we identified more tumor mutations ($p<0.001$) and more putative cancer driver mutations ($p< 0.003$) in lavage cfDNA than in plasma. Mutations of cancer driver genes at the patient level and average %VAF at the gene level were significantly lower in lavage cfDNA controls compared to cancer patients ($p=0.017$ and $p=0.016$ respectively). Since we also detected mutations in controls, presumably secondary to field cancerization and somatic mosaicism, we developed a risk score of mutation features to classify whether a BAL specimen was likely to come from a cancer patient or control. At a risk score level that identified all non-cancers as benign (A), this BAL classifier of 11 mutation features identified more cancers than cytology for all stages of lung cancer (65% vs 12%, $p=0.001$) and in stage I/II disease (50% vs. 20%, $p=0.25$; B).



BAL cfDNA Lung Cancer Classifier. (A) Lavage risk score based on eleven mutation features is displayed on a scale from 0 - 1 on the y-axis along with cancer status and relevant clinico-pathologic variables on the x-axis. All BAL samples with a risk score above 0.724 came from cancer patients. **(B)** Comparison of BAL clinical cytology cases and the BAL cfDNA Lung Cancer Classifier. Seventeen cancer patients (brown or black) and 16 non cancer patients (yellow) had both cytology and a lavage risk score assigned to them.

Conclusion: We show here that BAL genomic profiling may augment plasma profiling and BAL cytology for diagnosing and profiling NSCLC. Validation studies will be required to confirm our findings.

P2.05-02 ADDED VALUE OF TRANSBRONCHIAL CRYOBIOPSY SAMPLING IN NAVIGATION BRONCHOSCOPY FOR SMALL PULMONARY NODULES

I. Mommers[1], R. Verhoeven[1], K. Grünberg[2], E. Van Der Heijden[1]

[1]*Radboud University Medical Center, Nijmegen/Netherlands,* [2]*Radboudumc, Nijmegen/Netherlands*

Background: There is an increased demand for diagnostic procedures for incidental nodules and suspected early stage lung cancer detected on CT. Endobronchial diagnosis using advanced techniques have been able to increase diagnostic yield when compared to previous (semi-) blind transbronchial biopsy. Yet even when state of the art techniques such as intra-operative cone beam CT imaging (cbCT), radial ultrasound miniprobes and / or electromagnetic navigation technology (EMN) are used, in up to 30% of procedures no final histological diagnosis is made even when these small (<2cm) lesions are reached. In this study we aim to investigate the added value of transbronchial cbCT controlled cryobiopsy for peripheral pulmonary nodule evaluation. **Method:** From a case series of 97 patients who underwent navigation bronchoscopy with histological sampling using either forceps biopsy, cryobiopsy or both were included for analysis. In our routine 6-10 forceps biopsy samples are obtained and when possible followed by a single or repeated cryobiopsy using 3-dimensional cbCT imaging guidance for confirmation for target lesion access during sampling. Retrospective evaluation of specimen quality was performed by a blinded expert pathologist [KG] using a visual analog score for specimen quality classification (range 1-5: very poor to very good). Student T and Pearson chi-square testing were used. **Result:** The mean nodule size was 14 mm (range 4-43mm). In total 37 cryobiopsy specimens were obtained (from n=33 patients). In 31 samples direct comparison of cryobiopsy and forceps biopsy specimens was available from the same target lesions. The cryobiopsy specimens were larger and showed a better quality than the forceps biopsies, with a mean specimen quality score of 4.2 ± 0,2 compared with 2.9 ± 0,2 ($p<0.001$). However, the overall sensitivity to prove malignant or benign origin of nodules using cryobiopsy was 43% (16 out of 37) compared to 78% (76 out of 97) for forceps biopsies ($p<0.001$). **Conclusion:** Navigation bronchoscopy guided cryobiopsy sampling for small peripheral pulmonary nodules is feasible and renders specimens of significantly better quality with less artefacts and larger size. However, the diagnostic yield is still inferior to forceps biopsy. This can likely be attributed to probe stiffness resulting in mis-alignment in these small nodules and to the fact that the complex navigation procedure allows for obtaining only one single cryobiopsy sample in the vast majority of cases.

P2.05-03 TUMOR ATELECTASIS GIVES RISE TO SOLID APPEARANCE IN PULMONARY ADENOCARCINOMAS

F. Ambrosi[1], E. Comans[2], R. Sprengers[3], C. Dickhoff[4], T. Radonic[4], B. Lissenberg-Witte[2], E. Thunnissen[4]

[1]*University of Bologna Medical Center, Bologna/Italy,* [2]*VU Medical Center, Netherlands/Netherlands,* [3]*VU University Medical Centermc, Amsterdam/Netherlands,* [4]*VUmc, Amsterdam/Netherlands*

Background: Ground glass opacities (GGO) on CT scan, if malignant, correlate with adenocarcinoma in situ in histology. Solid appearance on HRCT, either ground glass nodule (GGN) or a solid nodule (SN), is considered to be invasive carcinoma. Histological recognition of invasion in pulmonary adenocarcinoma revealed low kappa scores among expert pathologists. A likely explanation is that morphological collapse is not taken into account in the WHO lung cancer classification. This study aims to compare radiological features in HRCT and histological features of primary adenocarcinomas in resection specimen for the presence of collapse. **Method:** Patients with primary adenocarcinoma in the lung, resected between November 2016 and November 2018, were selected. HRCT scans and CT-PET imaging were evaluated for GGO, GGN, and SN. For pathology diagnosis the 2015 WHO classification was used. Both evaluations were blinded for other information. Lepidic growth pattern with collapse was considered if reduction of air in the histological section was present, while underlying pulmonary architecture was maintained (organoid pattern without invasion). **Result:** In total 47 lesions of 41 patients were evaluated. The number of GGO, GGN and solid nodules was 2, 8 and 37, respectively. Lepidic growth pattern with collapse was present in both GGO lesions, 7 out of 8 (88%) GGN lesions and 24 out of 37 (65%) solid lesions. Remarkably, pre-existing pulmonary architecture with air spaces between alveoli covered with epithelial tumor cells (lepidic pattern) can be detected in over 50% of the adenocarcinomas with solid appearance on HRCT. This can only be explained by tumor related atelectasis (collapse) in vivo. **Conclusion:** Tumor related atelectasis is a frequent finding in pulmonary adenocarcinomas and may be a feature in a solid appearance on HRCT. Therefore, a solid appearance on HRCT cannot be solely attributed to invasion, as has been the assumption until now.

P2.05-04 DEVELOPMENT OF A NEW ENDOBRONCHIAL TREATMENT FOR PERIPHERAL-TYPE LUNG CANCER

J. Usuda

Nippon Medical School Hospital, Sendagi, Bunkyo-ku, Tokyo/Japan

Background: Photodynanic therapy (PDT), is a treatment modality for many cancers, and uses a tumor-specific photosensitizer and laser irradiation. PDT is recommended as a treatment option for centrally located early lung cancer, not for peripheral-type lung cancer. With conventional laser probes, peripheral lung cancer was not an indication for laser therapy, as it was impossible to irradiate the peripheral lung field. Therefore, we have developed a laser probe in this study, we aimed to develop a new endobronchial treatment for peripheral lung cancer using PDT, and we evaluated the feasibility of PDT for peripheral lung cancer. **Method:** This phase I study enrolled 7 patients with peripheral lung cancers (primary tumor< 20 mm, stage IA), which were definitively diagnosed by bronchoscopic modalities such as endobronchial ultrasound-guide sheath (EBUS-GS) and brocnhoscopic navigation system such as electromagnetic navigation bronchoscopy (ENB). We administered NPe6 (40mg/m2) as a photosensitizer intravenously, and 4 hours later we accurately introduced the guide sheath (GS) to the peripheral lung cancer lesions using ENB, and we confirmed the tumor lesions by EBUS. After the confirmation of the tumor location, we inserted the new laser probe by ENB. **Result:** We performed PDT for 3 patients with c-stage IA peripheral lung cancer, using a laser dose (120mW, 50J/cm2), and confirmed the feasibility of the dose. We escalated the laser dose and performed 4 patients using a laser dose (120mW, 100J/cm2). Seven patients met our criteria, and 5 cases were adenocarcinoma and 2 case squamous cell carcinoma. Two weeks and 3 months after NPe6-PDT, complications such as pneumonia and pneumothorax were not found, but one mildly found light skin-photosensitivity. Six months later, we found CR in 3 cases and SD in 4 cases. **Conclusion:** PDT was a feasible and non-invasive treatment for a peripheral type early lung cancer. In the future, for non-invasive adenocarcinoma such as AIS, NPe6-PDT will become a treatment modality. Now, we are planning a physician -initiated clinical trial that conducts PDT for "peripheral small-sized lung cancer patients in whom surgery and radiation therapy are inadequate". For lung cancer cases with interstitial pneumonia combined with low lung function, there are no standard treatments. By expanding the application of PDT to these cases, it is expected to establish a new treatment method that can establish low-cost lung cancer treatment and contribute to improvement of QOL suitable for aging society.

Keywords: photodynamic therapy (PDT), peripheral-type lung cancer, electromagnetic navigation bronchoscopy (ENB)

P2.05-05 AVAILABILITY OF FOUR DIMENSIONAL COMPUTED TOMOGRAPHY (4DCT) FOR LUNG CANCER

H. Arai[1], M. Tajiri[1], Y. Mishina[1], S. Nakamura[1], H. Masuda[1], K. Shiino[1], K. Okudela[2], T. Iwasawa[1], M. Masuda[2]

[1]*Kanagawa Cardiovascular and Respiratory Center, Yokohama/Japan,* [2]*Yokohama City University Graduate School of Medicine, Yokohama/Japan*

Background: Four-dimensional computed tomography (4DCT) imaging is a new form of chest CT that can detect continuous movement of the airways and lungs under free breathing conditions. This method is likely to be used increasingly to evaluate pulmonary function or predict intraoperative adhesion or tumor invasion. **Method:** A total of 31 cases that underwent 4DCT at the Kanagawa Cardiovascular Respiratory Center from October 2017 to February 2019 were reviewed. Dynamic ventilatory scans were performed using a 320-row multi detector CT (Aquilion ONE GENESIS, Canon Medical Systems, Otawara, Tochigi, Japan). The frame rate was 0.25sec/volume and the total estimated radiation exposure was 3.9 mSV. In surgical cases of lung cancer, the 4DCT findings were compared with the intraoperative assessment. We obtained 2 sets (upper lung region and lower region) of 4DCT covering the whole lung. These volume sets were connected and evaluated using imaging processing software. Intrathoracic adhesion and tumor invasion were defined by the differential movement between the tumor and adjacent structures, and laterality of the respiratory motion. **Result:** There were 16 cases of non-neoplastic diseases, such as non-tuberculous mycobacteriosis, giant bulla and lung sequestration. The 15 neoplastic diseases included 2 solitary fibrous tumors and 13 lung cancers. Among them, 12 cases in the lung cancer group underwent surgical procedures and were able to be evaluated. The purposes of the preoperative 4DCT were as follows: evaluation of tumor invasion (n=8), reoperation cases (n=2), medical history of tuberculous mycobacteriosis (n=2) and suspicion of intrathoracic adhesion on chest X-ray (n=1). Adjacent structures were the descending aorta (n=2), pulmonary artery (n=1), subclavian artery (n=1) and chest wall (n=5). The surgical procedures included 10 lobectomies, 1 wedge resection and 1 open lung biopsy. The 4DCT findings were comparable with the intraoperative findings in eleven cases; intraoperative adhesions were noted at the same locations and there were no signs of direct tumor invasion to vital structures, as indicated by 4DCT. In only one case of suspected invasion of the subclavian artery, was unexpected adhesion to the upper mediastinum observed during surgery. As the motion of the apical region was restricted in all cases, we were not able to evaluate apical adhesion. **Conclusion:** The intraoperative findings supported those of 4DCT in 11/12cases. 4DCT of the whole lung was an useful and reliable tool for the preoperative assessment and determination of the surgical indication for lung cancers.

P2.05-06 NEW DOSIMETRIC PARAMETERS ENCOMPASSING HIGH ATTENUATION ENABLES MORE ACCURATE PREDICTION OF RADIATION PNEUMONITIS IN VARIOUS TYPES OF CANCERS

Y. Uchida[1], D. Kinose[1], K. Noma[2], T. Tsugawa[1], K. Aoki[1], H. Nakagawa[1], K. Fukunaga[1], M. Yamaguchi[1], M. Osawa[1], S. Tanaka-Mizuno[1], E. Ogawa[1], Y. Nakano[1]

[1]*Shiga University of Medical Science, Otsu/Japan,* [2]*Shiga University of Medical Science Hospital, Otsu/Japan*

Background: Radiation pneumonits (RP) is an important side effect of radiotherapy, especially symptomatic pneumonitis interferes chemotherapy after radiotherapy. Therefore, prediction and prevention symptomatic radiation pneumonitis is very important. Even if only lung cancer patients, the reported threshold values of dosimetric volume

POSTERS

histogram to predict radiation pneumonitis were ranging among studies . This caused the guidelines of thoracic radiation therapy set ambiguous cut-off values of conventional dosimetric parameters like Mean lung dose (MLD) (20–23Gy) and the percentage of lung volume receiving 20 Gy or more (V20%) (30%–40%) to reduce the risk of RP. We had previously shown that dosimetric parameters calculated using only high attenuation area by excluding emphysematous lesion were better predictors of RP than conventional parameters. Little is known about the threshould value of dosimetric parameters to predict RP among different types of cancers, and if the threshould were closer or same, it will be able to provide a more reliable and versatile . To evaluate if our new dosimetric parameters can predict RP more accurately without changing threshold values among different types of cancers, we compared the performance of our new dosimetric parameters with conventional parameters to predict RT in esophageal cancer patients and lung cancer patients. **Method:** We retrospectively evaluated 77 patients who received radiotherapy for lung cancer and 71 patients for esophageal cancer. RP was graded according to the Common Terminology Criteria for Adverse Events (version 5.0). We quantified high attenuation volume (HAV) using quantitative computed tomography analysis. We compared traditional dosimetric parameters and dosimetric parameters with HAV in both lung cancer and esophageal cancer patients. Finally, the threshold of dosimetric parameters predicted of symptomatic RP and the difference of the threshold of dosimetric parameters between lung cancer patients and esophageal cancer patients were compared. **Result:** The predictive performance of dosimetric parameters for symptomatic RP was compared using AUC. MLD, HAV30% (The percentage of lung with high attenuation volume receiving ≥ 30 Gy), and HAV20% were top three parameters in lung cancer and, HAV10%, HAV5%, and V10% were in esophageal cancer. Comparing difference of the threshold of parameters predicting RP between two cancers, HAV30% revealed same value in both two cancers. In any dosimetric parameters, dosimetric parameters with HAV have smaller difference of the threshold between both cancer patients than in cases of traditional dosimetric parameters. **Conclusion:** Dosimetric parameters with high attenuation area may have higher commonality than traditional dosimetric parameters in any populations.

Keywords: radiation, Radiation pneumonitis, dosimetric parameters

P2.05-07 THE LIVERPOOL "STRAIGHT TO CT" AND "VIRTUAL WORKING" LUNG CANCER PATHWAY – 5 YEARS ON

M. Ledson[1], A. Mciver[2], N. Maddock[2], J. Dunbar[2], S. Sanders[2], C. Smyth[2], M. Walshaw[2]

[1]*Liverpool Heart and Chest Hospital, Liverpool/United Kingdom,* [2]*Liverpool Heart & Chest Hospital & Royal Liverpool Broadgreen University Hospital NHS Trusts., Liverpool/United Kingdom*

Background: Streamlining the diagnosis of lung cancer is pivotal to improving outcomes and thereby the quality of the patient journey. As part of this, in 2014 Liverpool introduced the concepts of "straight to CT" (where patients with suspicious imaging or symptoms have a directly arranged rapid [< 72 hours] CT scan), and also the "virtual assessment" service (where those with scans suggestive of lung cancer are contacted by a lung CNS and the initial clerking and investigation planning is made by telephone) into its lung cancer diagnostic pathway This pathway is now in its 5th year and we report our experience. **Method:** As regards "straight to CT", there has been no increase in the demand for outpatient scan capacity for suspected lung cancer (about 400 scans per year). Patients with scans arranged in primary care without suspicious changes remain in the community, but those with other changes can be referred to a general chest clinic (21%). Of those who enter the virtual assessment pathway, 81% are diagnosed with lung cancer. **Result:** To date, approximately 1200 patients have been through the "virtual assessment" service. Audit has shown that 98% prefer telephone assessment rather than physical clinic attendance, and most wish to be called on the same day as the scan. Patients feel that they had been given correct and timely information and feedback from primary care colleagues is uniformly positive. Lung CNS job satisfaction has improved since skills are now focussed more appropriately. Although the cancer unit diagnoses about 400 cases per year, using the virtual working model means that on average only 7 physical patient clinic attendances per week are necessary to provide the service, thereby greatly reducing resource use, saving 40% of costs overall. Furthermore, the more efficient service easily exceeds the 14 and 62 day cancer targets (99% and 97% respectively). **Conclusion:** Many lung cancer services are now moving towards "straight to CT" and virtual working models. Our experience is positive, and we would recommend its adoption.

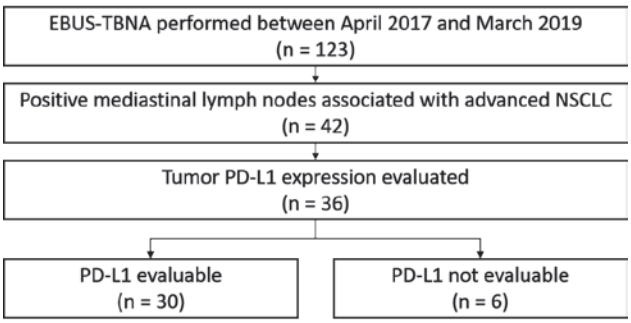
Keywords: virtual, straight to CT

P2.05-08 DIAGNOSTIC YIELD OF EBUS-TBNA IN EVALUATION OF PD-L1 EXPRESSION FOR ADVANCED NON-SMALL CELL LUNG CANCER

K. Mineura, M. Hamaji, S. Tanaka, Y. Yutaka, D. Nakajima, Y. Yamada, A. Ohsumi, T. Menju, T.F. Chen-Yoshikawa, H. Date

Kyoto University Hospital, Kyoto/Japan

Background: Endobronchial ultrasound-transbronchial needle aspiration (EBUS-TBNA) plays a major role in mediastinal staging for advanced non-small cell lung cancer, but the amount of obtained tissue is limited compared to surgical biopsy. The purpose of this study was to assess the diagnostic yield of EBUS-TBNA in evaluating PD-L1 expression in positive mediastinal lymph nodes. **Method:** A retrospective chart review was performed on our prospectively maintained database to identify patients who underwent EBUS-TBNA to evaluate PD-L1 expression in mediastinal lymph nodes associated with advanced non-small cell lung cancer between April 2017 and March 2019. Relevant factors were extracted and compared between those whose PD-L1 expression was able to be evaluated and those whose PD-L1 expression was not. **Result:** Thirty-six patients were identified. The PD-L1 expression was able to be evaluated in 30 (83%) of 36 patients. There were tendencies for a greater diameter (p=0.19) and higher standard uptake value (SUV) in positron emission tomography (p=0.22) of biopsied lymph nodes, and a greater number of biopsies (p=0.28) in those whose PD-L1 expression was be able to be evaluated. Among 30 patients with evaluable PD-1 expression, the degree was high expression (tumor proportion score (TPS) ≧ 50%) in 7 patients (23%), low expression (TPS 1-49%) in 10 patients (33%), and no expression (TPS < 1%) in 13 patients (44%).



Conclusion: Evaluation of PD-L1 expression was feasible in more than 80% patients undergoing EBUS-TBNA for positive mediastinal lymph nodes associated with advanced non-small cell lung cancer. EBUS-TBNA appeared to play an important role in evaluating PD-L1 expression. A larger lymph node, and a lymph node with higher SUV, and a greater number of punctures appeared favorable in evaluation of PD-L1 expression.

Keywords: Non-Small Cell Lung Cancer, EBUS-TBNA, PD-L1

P2.05-09 FDG-PET FOR PREDICTING ACUTE EXACERBATION OF INTERSTITIAL PNEUMONIA AFTER LUNG CANCER SURGERY

K. Shimizu, S. Nakazawa, K. Numajiri, N. Kawabata, K. Obayashi, T. Ibe, T. Yajima, K. Shirabe

Gunma University Hospital, Maebashi/Japan

Background: Acute exacerbation of interstitial pneumonia (IP) is a critical complication after lung cancer resection. Although FDG-PET is commonly used for preoperative assessment of lung cancer, its role for predicting acute exacerbation of IP after lung cancer resection is unclear. **Method:** We retrospectively analyzed data of lung cancer patients that underwent surgical resection at Gunma University Hospital between 2008 and 2016. We analyzed data from

patients with IP based on computed tomography findings (IP group). As control, we also analyzed data in patients with no underlying lung disease (normal group) and with emphysema (emphysema group). Patients with sufficient FDG-PET data were selected and a final of 92 patients in the IP group, 21 patients in the normal group, and 20 patients in the emphysema group were enrolled in analysis. The FDG-PET values were measured at the aorta and the basal lung. Aorta values were used for reference and we calculated the basal/aorta ratio and analyzed correlation with preoperative factors, including acute exacerbation of IP and mortality. **Result:** The basal/aorta ratio was significantly higher in the IP group when compared to normal and emphysema group (both p<0.01). The incidence of acute exacerbation of IP was 10.9%, and the sensitivity and specificity of basal/aorta value for predicting acute exacerbation of IP were 70.0% and 77.2%, respectively (cutoff of basal/aorta ratio at 0.833). Patients were further classified into high basal/aorta ratio group (n=35) and low basal/aorta ratio group (n=57). The incidence of acute exacerbation of IP was significantly higher in the high basal/aorta ratio group (p=0.035). We also compared the value of basal/aorta ratio in comparison to the existing IP acute exacerbation score. Patients were divided into low score (less than 10, n=64) and high score (higher or equal to 11, n=28). The sensitivity and specificity for predicting acute exacerbation of IP was 60.0% and 82.3%, respectively, and there was no significant difference between the high and low score groups (p=0.062). **Conclusion:** The basal/aorta ratio of FDG-PET values showed a significant correlation with the incidence of postoperative acute exacerbation of IP. Since FDG-PET is commonly used for preoperative assessment of lung cancer in Japan, it may be used not only for lung cancer staging but also for surgical indication in IP patients with lung cancer by preoperatively detecting patients at high risk for acute exacerbation.

Keywords: Acute exacerbation of interstitial pneumonia, Lung cancer, FDG-PET

Background: In the management of patient's whit non small cell lung cancer (NSCLC) with EGFR mutations after progression to first and second generation tyrosine kinasa inhibitors (TKI), the mechanism of resistance is very important. Our objective is to analyse the appearance kinetics of the T790M by means of digital PCR techniques in liquid biopsy. **Method:** We conducted a multicenter study with 100 patients with EGFR-mutated NSCLC, treated with first-line TKI therapy. We analyze the ctDNA by dPCR before the start of treatment, at first follow up evaluation, at 6 months and at disease progression. **Result:** We included a total of 100 patients from July 2016 to December of 2017. Seven patients with Exon 20 insertion in EGFR were excluded (final sample 93). The median of follow-up was 12 months. There were not significant differences in progression free survival (PFS) or overall survival (OS) according to treatment (erlotinib, gefitinib or afatinib). dPCR detected EGFR sensitizing mutation in 77% of the pre-treatment samples. Of these cases, EGFR sensitizing mutation was detected in 75% of the patients with stage IVA and 85% in stage IVB respectively, p=0,075. The resistance mutation p.T790M was detected in 52% of the samples collected at disease progression. The probability to detect the resistance mutation p.T790M by liquid biopsy, is greater if the pre-treatment sample was positive for EGFR sensitizing mutation (11% vs 62%) p 0,009. In cases with progression of the disease the percent of detection of p.T790M was 52% and 54% in patients with Exon 19 deletion and L858R mutation respectively. The OS in patients with progression of the disease and p.T790M negative was 85% at 12 months (95%CI: 60%-94%) and 75% with p.T790M positive (95%CI: 49%-88%), p=0,01. **Conclusion:** The burden of disease in patients with NSCLC mutated with EGFR is related to the appearance of sensitivity and resistance mutations in liquid biopsy. The probability to detect the resistance mutation p.T790M in blood, is greater if the pre-treatment sample was positive for EGFR sensitizing mutation.

Keywords: liquid biopsy, EGFR mutation, first-line TKI

P2.05-11 3D CT IS USEFUL FOR SEGMENTECTOMY BUT IS NOT ALWAYS TRUE

T. Mori[1], R. Matsushima[1], H. Hinokuma[1], M. Suzuki[2]

[1]*Japanese Red Cross Kumamoto Hospital, Kumamoto/Japan,* [2]*Kumamoto University, Graduate School of Medical Sciences, Kumamoto/Japan*

Background: Pulmonary vessels and bronchus have a lot of variations. 3D CT is a good guide for segmentectomy, but sometimes shows images different from real anatomy of the lung structures. The aim of this study is to evaluate effectiveness and problems to apply 3D CT for segmentectomy. **Method:** From July 2018 to December 2018, 78 cases underwent chest surgery in our hospital. Using contrast enhanced volume dataset of 64-row CT, pulmonary artery (PA) was separated form pulmonary vein (PV) based on the difference of CT number between them. Image interpretations for surgery were performed by one experienced thoracic surgeon (TM) using axial, sagittal, coronal images, and 3D image containing PA, PV, bronchus, and lobar fissure in this study. **Result:** Of 29 case underwent lobectomy or segmentectomy, 23 cases were performed 3D CT. Failure to discriminate among PA, PV, and other structures were observed in 9 cases: Ascending A2 → branch of V2 in 2 cases; V2t → Ascending A2 in 4 cases; A3a → branch of V3 in 1 case; V3b → branch of A3 in 1 case; V1a → A1 in 1 case; V1 runs dorsal side of A1,3 → part of A1,3 in 1 case; #12l →lower lobe PA in 1 case. Case 7 underwent right S1 segmentectomy. 3D CT showed recurrent A2 runs ventral side of B1, but did not show V1 runs dorsal side of A1,3 which was found during surgery.

Case	true structure	misdrawing to
1	V2t	part of Ascending A2
2	A3a	V3
3	Ascending A2	branch of V2
4	Ascending A2	branch of V2
5	#12l	lower lobe PA
6	V2t	part of Ascending A2
7	V3b	A3
	V1 runs dorsal side of A1,3	part of A1,3
8	V2t	part of Ascending A2
9	V2t	part of Ascending A2
	V1a	part of A1

Conclusion: 3D CT is useful for segmentectomy to understand the lung anatomy, but does not always give us true anatomy. Surgery should be performed keeping the fact in mind.

Keywords: 3D-CT, surgery, segmentectomy

Background: The analysis of biomarkers in lung cancer (LC) is currently one of the most important care needs, given the importance of their presence in the selection of specific treatments. Our objective was to know the implementation degree of these tests in a large cohort of patients in Spain using the Thoracic Tumor Registry (TTR) of the *Grupo Español de Cáncer de Pulmón* (Spanish Lung Cancer Group). **Method:** The TTR is an observational cohort multicenter study of the LC in Spain. Information on patients (p) enrolled from August 2016 to December 2018. The study is conducted according to the Declaration of Helsinki and approved by the institutional review board of each participating institute. The registry was approved by the Spanish Drug Agency as a non-post-authorization, non-interventional study. **Result:** A total of 7,872 patients from 58 Spanish sites were enrolled. Analysis of molecular markers considering all the LC stages: A molecular test, the most frequent being the EGFR test, was performed in 4,456 patients (67.5%). The proportion of biomarker evaluation has varied over time, ranging from 57.9% prior to 2012 up to 73.7% in 2017. Molecular markers in patients with stage IV. Three thousand four hundred forty-six (3,446) patients (52.2%) had a stage IV on diagnosis. The molecular assessment of some biomarkers reached 81.4% of all the patients, there being differences between Regional Communities in regard to the molecular tests made. There was performed some biomarker test in 92% of the 2570 patients with stage IV and adenocarcinoma histology. The analysis of ALK was tested in 79% of the patients, this being in 40% only 2 years ago. ROS was studied in 20% of the cases and EGFR in 92%. **Conclusion:** Although no national plan exists for molecular biomarker analysis in LC in Spain, the implementation of the biomarkers analysis in all the hospitals that contribute to the TTR is high, as close to the maximum as possible. The increase in the ALK analysis in the last period is relevant. As regional differences exist, it would be of interest to go in depth to study its cause

Keywords: biomarkers analysis, EGFR, ROS, ALK

P2.05-13 IMPACT OF DIFFUSING CAPACITY FOR POSTOPERATIVE PULMONARY COMPLICATIONS IN PATIENTS WITHOUT OBSTRUCTIVE PULMONARY DISEASE

Background: This study evaluated the impact of diffusing capacity of the lungs for carbon monoxide (DLco) on postoperative pulmonary complications (PPCs) after lung resection in patients without obstructive pulmonary disease **Method:** We retrospectively reviewed non-small cell lung cancer patients undergoing anatomical lung resection without induction treatment between 2015 and 2016. Of these, 1233 patients without obstructive pulmonary disease were included in the study. We considered the following PPCs as study outcomes: pneumonia, acute respiratory distress syndrome (ARDS), significant atelectasis, empyema, bronchopleural fistula, prolonged air leakage and pneumothorax. The independent effects of DLco on PPCs were evaluated using multivariate logistic regression. Models were adjusted for age, sex, smoking status, comorbidity, histology and type of surgery. **Result:** Twenty three percentage of patients showed the decrement of pred % of DLco less than 80. A total of 104 patients (8.4%) developed at least one PPC. More PPCs were occurred in the patients with impaired DLco (6.2% vs 15.7%, p<0.001). In multivariable-adjusted analyses, risk of PPC in patients with impaired DLco was more than 2 times [the adjusted odds ratio (aOR)=2.44 (1.58,3.77)] compared to those in patients with preserved DLco. Also, with every 10% decreasing in % pred DLco, the risk of developing PPC was gradually increased. [DLco ≥ 80 vs. 70≤DLco<80, aOR=2.07 (1.22, 3.49); 60≤DLco<70, aOR=2.79 (1.45, 5.36); DLco<60, aOR=4.69 (1.72, 12.75), p<0.001] **Conclusion:** Patients with impaired DLco had more risk of PPCs after lung resection even without airflow obstruction. Assessment of DLco is necessary for the prediction of PPCs in lung resection surgery for NSCLC.

P2.05-14 SAFETY AND RISK FACTORS OF CT-GUIDED PERCUTANEOUS TRANSTHORACIC NEEDLE RE-BIOPSY FOR NSCLC

Y. Wang, M. Wang, Z. Zhou

The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China

Background: Re-biopsy of NSCLC after systemic therapy to identify molecular resistance mechanism is very important. CT-guided needle lung re-biopsy has proven feasible. This study aimed to discover the safety of computed tomography (CT)-guided percutaneous transthoracic needle re-biopsy for patients with NSCLC, and its risk factors. **Method:** This was a retrospective, single-institution study. 113 patients who diagnosed as IIIB/IV NSCLC and treated with EGFR-TKIs/chemotherapy from January 2016 to February 2018 in our hospital. Compare the differences incidence of complications between first biopsy and re-biopsy by computed tomography (CT)-guided percutaneous transthoracic needle, and analysis the clinical factors affecting main complications in re-biopsy. **Result:** Success rate of re-biopsy was 88.5% (100/113). The number of patients with complications in first biopsy was 25 (23.9%), and it's 37 (34.5%) in re-biopsy (Table). The main complications were hemorrhage and pneumothorax. Hemorrhage rate in re-biopsy, male was 18.5% (10/54), and female was 3.4% (2/59). Re-biopsy needle size 17G (Angiotech 17G coaxial trocar together with Biopince 18G automatic biopsy needle) was 5.7% (5/87), and needle size 18G (18G Angiotech soft biopsy needle) was 26.9% (7/26). The mean frequency of intraoperative needle adjustment with and without hemorrhage was 3.3±1.8 vs 2.2±1.6. The mean distance (cm) of pleura-to-target in with and without hemorrhage was 3.7±1.5 vs 2.3±1.9. High rate of

pneumothorax for needle through interlobular septal puncture in re-biopsy, 62.5% (5/8). CT-guided percutaneous transthoracic needle re-biopsy of NSCLC was showed in Figure.

First biopsy	Re-biopsy	
Variable	Non-complication	Complication
All complications		
No	60 (53.1%)	28 (24.8%)
Yes	16 (14.2%)	9 (8.0%)
Hemorrhage		
No	94 (83.2%)	11 (9.7%)
Yes	7 (6.2%)	1 (0.9%)
Pneumothorax		
No	78 (69.0%)	19 (16.8%)
Yes	12 (10.6%)	4 (3.5%)
pleural reaction		
No	106 (93.8%)	4 (3.5%)
Yes	3 (2.7%)	0 (0%)

Conclusion: First biopsy and re-biopsy complications were similar. Both of hemorrhage and pneumothorax were acceptable. CT-guided percutaneous transthoracic needle re-biopsy of NSCLC showed safe and feasible.

P2.05-15 RADIAL ENDOBRONCHIAL ULTRASOUND-GUIDED TRANSBRONCHIAL BIOPSY IN PERIPHERAL LUNG LESIONS. WHAT CAN CRYOBIOPSY CONTRIBUTE?

S. Baeza Mena[1], M. Torky[2], C. Centeno Clemente[1], R. Tazi Mezalek[1], I. García Olivé[1], J.L. Mate Sanz[3], R. López Martos[3], P. Lopez De Castro[4], T. Moran[5], E. Carcereny[6], A. Rosell[1], F. Andreo García[1]

[1]*Hospital Universitario Germans Trias i Pujol, Badalona/Spain,* [2]*Tanta University Hospital, Tanta/Egypt,* [3]*Hospital Germans Trias i Pujol, Badalona/Spain,* [4]*Hospital Universitari Germans Trias i Pujol, Badalona/Spain,* [5]*Catalan Institute of Oncology-Badalona; B-ARGO; IGTP, Badalona/Spain,* [6]*Catalan Institute of Oncology-Badalona; Hospital Universitari Germans Trias I Pujol; B-ARGO; IGTP, Badalona/Spain*

Background: Radial probe endobronchial ultrasound (RP-EBUS) is a modern technique for diagnosis of peripheral lung lesions. The addition of transbronchial cryobiopsy (TBCB) could increase the diagnostic value for RP-EBUS. AIM: To evaluate the efficacy of RP-EBUS guided TBCB for diagnosis of peripheral lung lesions. **Method:** We collected 60 patients with peripheral lung diseases. Were excluded 15 patients for not be fit for general anesthesia (necessary for TBCB) or high risk of bleeding. 45 patients were subjected to forceps transbronchial biopsy (forceps TBB) and TBCB guided by RP-EBUS. The diagnostic outcomes including digital assessment for qualitative and quantitative measures of collected samples were detected. Also, the associated complications were recorded. **Result:** The diagnostic yields for forceps TBB versus TBCB is detailed in Table 1. TBCB has achieved higher accuracy than forceps TBB (ROC area of 0.88 versus 0.84 respectively), with no statistical difference between their values (p=0.32). The combination between both techniques has achieved excellent accuracy (ROC area 0.91). In 36 cases were possible the anatomopathological diagnosis with both type of samples, there were significant statistical differences ($p \leq 0.05$) in favour of TBCB when compared to forcep TBB regarding; mean biopsy diameter, mean biopsy surface area, mean biopsy necrosis, percentage and mean biopsy viable tissue area. Only two patients had significant complications (pneumothorax; hypoxemia), and 8 moderate bleeding.

Table 1.

Variable	Forceps TBB	TBCB	Combined
Sensitivity	67.5%	75%	82.5%
Specificity	100%	100%	100%
PPV	100%	100%	100%
NPV	18.8%	23.1%	30%
Accuracy	69.8%	76.7%	83.7%

Conclusion: RP-EBUS guided TBCB is a safe and effective technique for diagnosis of peripheral lung lesions. TBCB could achieve higher diagnostic value than forceps TBB due to better quantity and quality of the samples. *The project was partially funded by SEPAR, grant AEER 2016, grant FUCAP 2017 and Egyptian Ministry of Higher Education.*

P2.05-16 DIAGNOSTIC VALUE OF CONCOMITANT USE OF RADIAL PROBE ENDOBRONCHIAL ULTRASOUND WITH GUIDE SHEATH AND TRANSBRONCHIAL BIOPSY IN LUNG CANCER

S.C. Lee[1], E.Y. Kim[2], M.S. Park[2], J. Chang[2], C.H. Han[1], S.H. Lee[2]

[1]*National Health Insurance Service Ilsan Hospital, Goyang-si, Gyeonggi-do/Korea, Republic of,* [2]*Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of*

Background: Although using radial endobronchial ultrasound with guide sheath (r-EBUS-GS) has shown its diagnostic power in peripheral pulmonary lesion, its actual utility is still low due to variable diagnostic performance. To overcome its limitation, we evaluated the feasibility and efficacy of r-EBUS-GS when combined with transbronchial biopsy (TBB). **Method:** We retrospectively reviewed the medical records of 74 patients with NSCLC who underwent r-EBUS-GS plus TBB or TBB alone as diagnostic methods between 2017 Aug. and 2018 Nov. at the Severance hospital. Subjects were grouped by diagnostic modalities used (r-EBUS-GS plus TBB vs. TBB alone). Each group was matched by age, sex, biopsy location. Chi-square analysis and paired-t test were used to compare the characteristics, and to find the factors which affect to the diagnostic yield. **Result:** In each group, the number of male subjects was 21 and their mean age was 67.5 and 67.3, respectively. Lesion size was statistically smaller in r-EBUS-GS group. Although r-EBUS-GS alone (15/37, 40.5%) showed poor diagnostic yield, combination of r-EBUS-GS and TBB (27/37, 72.9%) showed higher than TBB alone group (23/37, 62.1%). Lung lesion with bronchus sign was revealed significant relationship with higher diagnostic yield (p<0.005).

Table 1. Lesion characteristics of each group			
Lesion characteristics	**r-EBUS-GS+TBB (n=37)**	**TBB only (n=37)**	**P-value**
Location			1.000
- RUL	8 (21.6%)	8 (21.6%)	
- RML	3 (8.1%)	3 (8.1%)	
- RLL	10 (27.0%)	10 (27.0%)	
- LUL	11 (29.7%)	11 (29.7%)	
- LLL	5 (13.5%)	5 (13.5%)	
CT finding			0.193
- Nodule/mass	27 (73.0%)	26 (70.3%)	
- Subsolid GGO	9 (24.3%)	6 (16.2%)	
- GGO or consolidation	1 (2.7%)	5 (13.5%)	
Size	23.6 ± 7.6	34.5 ± 15.5	< 0.001
- < 20	13 (35.1%)	7 (18.9%)	
- 20-30	17 (45.9%)	11 (29.7%)	
- > 30	7 (18.9%)	19 (51.4%)	
Pleural distance	14.8 ± 14.4	10.3 ± 10.5	0.102

Table 2. Comparison of diagnostic yield according to biopsy methods			
Diagnostic yield	r-EBUS-GS+TBB (n=37)		TBB only (n=37)
	r-EBUS-GS only	combined	
- Accuracy	15/37 (40.5%)	27/37 (72.9%)	23/37 (62.1%)

Conclusion: Combination of r-EBUS-GS and TBB has higher diagnostic power than using r-EBUS-GS or TBB alone.

Keywords: Biopsy, Bronchoscopy, Non-Small Cell Lung Cancer

P2.05-17 PREOPERATIVE IDENTIFICATION OF THE LEFT COMMON PULMONARY VEIN FOR SAFE VIDEO-ASSISTED LOBECTOMY

S. Kikuchi, Y. Sekine, K. Sugai, T. Kawamura, T. Yanagihara, Y. Saeki, S. Kitazawa, N. Kobayashi, Y. Goto, M. Onizuka, H. Ichimura, Y. Sato

University of Tsukuba, Tsukuba Ibaraki/Japan

Background: The pulmonary veins (PVs) display many anatomical variations. Some anomalies, especially the common trunk of the left PV, are associated with serious surgical morbidity for patients undergoing lung surgery. Compared with thoracotomy, video-assisted thoracic surgery (VATS) has a limited view of the surgical field, thus thoracic surgeons must be familiar with anatomical variations in the PVs. We aimed to investigate the anatomical variants of the left PVs using three dimensional (3D)- computed tomography (CT) images. **Method:** We reviewed anatomical variations of the left PVs of 156 consecutive patients who had undergone surgical pulmonary resection at our institution, using the multidetector contrast-enhanced CT. The common trunk was defined anatomically as the presence of a single ostium at the point of reflection of the parietal pericardium along the left atrium. **Result:** We identified the common trunk of the left PV in 11 of the 156 patients (7.1%), and the discrete left lingular vein (V4+5) draining near the inferior PV in 2 patients (1.2%). Of which, 5 had the long common trunk; the length of the common trunk outside the pericardium was equal to or longer than 10mm. Of these 11 patients, 5 were men, 4 had hypertension, 3 had valvular disease, 1 had coronary artery disease, 1 had paroxysmal atrial fibrillation (Paf), and the remaining 7 had no hypertension or structural heart disease. Although the anatomical variants of PV have been related to a higher arrhythmogenic potential, only 1 (9%) patient had postoperative complication of Paf. In 11 cases, 3 had incomplete lobulation and 3 had left lingular pulmonary artery arising from pars mediastinalis. The common trunk of the left PV was accompanied by other variant anatomies, that included; 1) right V6 draining into the superior PV in 3 cases; 2) right superior vein passing dorsal to right main pulmonary artery in 1 case; 3) supernumerary bronchus corresponding to left B7 in 2 cases. We encountered three cases demonstrating a common trunk of the left PV during VATS lobectomy. 3D-CT reconstruction was useful for recognizing such anomalies before surgery and allows safe VATS lobectomy. In surgical findings, the common trunk was located in the normal superior pulmonary vein drained into the left atrium. We should expose this vein adequately and dissect peripherally for confirmation of the common trunk. **Conclusion:** We conclude that the common trunk of the left PV is not a very rare anomaly and might be accompanied by other variant anatomies. Careful preoperative radiological evaluation of the pulmonary veins is essential to perform safe VATS lobectomy. 3D-CT can provide detailed information for assessing abnormalities of venous return.

Keywords: a common trunk of the left pulmonary vein, anatomical variations, VATS

P2.05-18 TISSUE SAMPLING AND PROGNOSTIC BIOMARKERS ANALYSIS OF PERIPHERAL LUNG TUMORS USING R-EBUS. SINGLE CENTRE RETROSPECTIVE STUDY

S. Badovinac[1], M. Roglić[1], M. Korsic[1], L. Bitar[1], M. Jakopovic[1], S. Smojver-Ježek[2], M. Samarzija[1]

[1]*University Hospital Centre Zagreb, Zagreb/Croatia,* [2]*University Hospital Centre Zagreb, zagreb/Croatia*

Background: Tissue sampling of peripheral pulmonary neoplasms for patohistology and analysis of prognostic biomarkers can be challenging. Radial endobronchial ultrasound (R-EBUS) is one of sophisticated guiding bronchoscopic modalities used for more precise localisation of the peripheral lesions. Novel therapeutic strategies rely on different prognostic biomarkers status. In this retrospective study we explored sufficiency of specimens for patohistology and prognostic biomarkers analysis obtained by ultra-thin bronchoscope combined with R-EBUS. **Method:** Retrospective analysis of bronchoscopy cases positive on malignancies when R-EBUS was used for visualisation of peripheral tumors and tissue was obtained with commercial sampling kit. **Result:** 80 consecutive cases with pathologic ultrasound pattern found with R-EBUS were analysed. Malignant disease was diagnosed in 49 cases (61%). Mean lesion diameter was 24mm (range 15 to 40mm). The most common histology types were adenocarcinoma, squamous cell carcinoma and small cell carcinoma – 78%, 12% and 4% respectively. Extrathoracic malignancies were diagnosed in 6% of cases. The tissue was sufficient for prognostic biomarker analysis in 91% of the cases – whereas EGFR, ALK, ROS1 and PDL-1 testing was performed for adenocarcinomas and PDL-1 for squamous cell lung carcinomas. In 9% of cases samples were sufficient for histologic typing only. **Conclusion:** Bronchoscopy with R-EBUS is useful diagnostic method for peripheral lung tumours. Obtained samples can be used for histology subtyping and prognostic biomarkers analysis in most cases as well.

Keyword: peripheral tumors, R-EBUS, predictive biomarkers

P2.05-19 THE PATENCY OF RIGHT UPPER LOBE BRONCHUS AFTER Y-STENT PLACEMENT AFFECT OUTCOME ON MALIGNANT TRACHEOBRONCHIAL STENOSIS

S. Mizuguchi, M. Takahama, R. Nakajima, N. Nomura, S. Suzuki, Y. Kanno, R. Yamamoto

Osaka City General Hospital, Miyakojima-ku, Osaka/Japan

Background: Dumon silicone Y-stent is useful for releasing the tracheobronchial stenosis. We often encounter patients with tumors involving the carina between the bronchus to the right upper lobe

and bronchus intermedius. However, there has not been ideal stenting for such cases, especially to maintain the patency of the right upper lobe bronchus. We investigated the clinical outcome in patients with malignant tracheobronchial stenosis, especially focused on the patency of right upper lobe bronchus after Y-stent placement. **Method:** From January 2012 until December 2018, 102 patients who had placed Y-stent on malignant tracheobronchial stenosis in our department were examined retrospectively. This study involved 73 male and 29 female. The mean age was 64 years (range, 30-91 years). Fifty-nine patients had lung cancer, 29 had esophageal cancer, and 14 had other carcinomas. All procedures were carried out in the operating room under general anesthesia, and the stents were implanted via rigid bronchoscopy. The patients were divided into two groups based on the patency of right upper bronchus: patency group (P group, n=73) and stenosis /occlusion group (S group, n=29).The clinicopathological features, clinical course, and the survival after stenting of the groups were compared. **Result:** Stents were implanted and symptoms were resolved in all cases. No operative death occurred. Stent indwelling types were only Y-stent in 69 patients and Y-stent with additional self-expanding metallic stent (SEMS) in 33. Although there was no difference between the two groups in age, gender, preoperative Hugh-Jones classification, hospitalization days, and size of Y-stent, esophageal cancer was significantly more frequent in P group. The total length of placed stent was significantly longer in S group (median 10.5cm) compared to P group (8cm) ($p<0.01$) and the postoperative Hugh-Jones classification (I or II) in S group (47%) was inferior compared to the P group (72%). After stent placement, 67% of the P group could be treated chemotherapy/radiotherapy to primary disease, while only 43% of the S group was received these because of their poor general condition ($p = 0.03$).The median survival time (MST) and 1-year survival rate of the two groups was 7 months and 32% (P group), and 2 months and 17% (S group), respectively ($p<0.01$). **Conclusion:** The patency of right upper lobe bronchus after Y-stent placement affects not only the improvement of postoperative Hugh-Jones classification but also the administration of subsequent treatment to primary disease and associated to their clinical outcome.

Keywords: silicone Y-stent, tracheobronchial stenosis, malignant

P2.06 MESOTHELIOMA
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.06-01 STELLAR TRIAL: RADIOLOGICAL RESPONSE PATTERNS OF TTFIELDS PLUS CHEMOTHERAPY IN FIRST-LINE TREATMENT OF MALIGNANT PLEURAL MESOTHELIOMA

Background: Tumor Treating Fields (TTFields) are an anti-mitotic, regional treatment modality, utilizing low intensity alternating electric fields delivered non-invasively to the tumor using a portable, medical device. TTFields have significantly extended survival of glioblastoma patients. In-vitro, human malignant pleural mesothelioma (MPM) cells were highly susceptible to TTFields. In the STELLAR trial [NCT02397928], patients with unresectable MPM treated with first-line chemotherapy in combination with TTFields had a significantly higher median overall survival compared to historical controls (18.2 Vs. 12.1 months). We analyzed radiological data from STELLAR patients whose tumors responded while receiving the combined therapy. **Method:** The trial accrued 80 patients with unresectable, previously untreated mesothelioma who were treated with continuous 150 kHz TTFields (>18h/day) in combination with pemetrexed and cisplatin or carboplatin (at standard dosing). Inclusion criteria: ECOG PS of 0-1, pathologically proven mesothelioma and at least one measurable lesion according to modified RECIST criteria. Patients were followed q3w (CT scan q6w) until disease progression. Radiological assessments were done at each study site. EOCG status and cancer-related pain were assessed until disease progression using a visual analog scale. **Result:** Partial responses (PRs) were seen in 40.3% of evaluable patients and clinical benefit (PR+SD) was seen in 97.2% of patients. The median time between treatment start and PR was 1.8 (1.4-4.4) months). All patients presenting with PR during the STELLAR study had continuous reduction in the total sum of lesion diameters, suggesting no initial/pseudo-progression. 83% of the patients who responded to the combined therapy finally had disease progression within median response duration of 5.7 (1.4-13) months, per Kaplan-Meier Estimator. One patient did not progress for more than 27 months. Median time to deterioration in performance status was 13.1 months. Average pain score was lower compared to baseline during the first 7 months of treatment and higher later with a median time to a clinical significant 33% increase in pain of 8.4 months. Compliance with TTFields was 68% (16.3 hours/day) during the first 3 months of therapy. No TTFields-related other than expected dermatitis below the arrays were reported. **Conclusion:** The STELLAR study showed significant survival extension in previously untreated MPM patients. Response rates were similar to that of current SOC treatment, but lasted longer with the addition of TTFields. TTFields was not associated with a decrease in performance status or an increase in pain. TTFields in combination with chemotherapy are efficacious in MPM vs chemotherapy alone reported in historical data.

Background: There are currently no approved therapies for the treatment of relapsed mesothelioma. Recent advances in our understanding of inter-patient genomic heterogeneity, identification of potential drivers, and application of high throughput -omic technologies to clinical trial samples, has created opportunities to explore novel treatments in prospectively biomarker-enriched cohorts. **Method:** MiST is a British Lung Foundation funded, University of Leicester sponsored multicentre national clinical trial. Patients (Pts) harbouring either pleural (any histological subtype) or peritoneal mesothelioma are eligible. Pts must have ECOG performance status 1 or 0, received prior standard chemotherapy and progressed from their last treatment (in any line). The study is designed in three stages. Stage 1 comprises prospective molecular profiling of the tumour suppressors BAP1, BRCA1, p16ink4A and the immune checkpoint inhibitor PDL1 (22C3), using automated immunohistochemistry. Stage 2: Patients meeting eligibility criteria are presently stratified into Arm 1: Rucaparib (PARP inhibitor) for BAP1 inactivated (cytoplasmic or loss of expression) /BRCA1 negative mesothelioma. Arm 2: Abemaciclib (CDK4/6 inhibitor) for p16ink4a negative tumour, Arm 3, Pembrolizumab (anti-PD1) and Bemcentinib (AXL) to patients without biomarker specification. Arm 4, Atezolizumab (anti-PDL1) and Avastin (anti-VEGF) for PDL1 positive MM. Further arms are in development. The primary endpoint is 12 week disease control (12wDCR), with the secondary endpoints, 24wDCR, response rate (modified RECIST1.1) and safety/tolerability. 12wDCR>50% will be considered worthy of further investigation. Stage 3: Genome wide somatic copy number analysis and transcriptomic analysis with in-silico deconvolution of immune cell infiltrates will be used to refine molecular correlates of response. Gut microbiome 16RNA sequencing will be conducted in arms 3 and 4. Patients exhibiting a response to treatment who then progress,

will be re-biopsied to facilitate molecular interrogation of acquired resistance mechanisms. MiST is coupled to our laboratory functional genomics programme, aimed at exploring co-clinical trial models, to robustly define or validate mechanisms that underpin drug responses. **Result:** Section not applicable **Conclusion:** In summary, MiST is a new clinical research platform that will support proof-of-concept studies capable of testing biomarker enrichment/efficacy hypotheses, with the aim of advancing personalised therapy for mesothelioma.

P2.06-03 TIMING OF SURGERY AFTER INDUCTION THERAPY FOR MALIGNANT PLEURAL MESOTHELIOMA: A NATIONAL ANALYSIS

S. Voigt, V. Raman, O. Jawitz, C.-F.J. Yang, T. D'Amico, D. Harpole

Duke University, Durham/United States of America

Background: The safe window to offer surgery following induction chemotherapy for malignant pleural mesothelioma (MPM) is unknown. **Method:** The National Cancer Database (NCDB) was queried for patients with cT1-3N0-1M0 MPM undergoing induction chemotherapy followed by definitive surgery. Patients with induction radiation, missing survival data, and time to surgery <1 or >180 days were excluded. Patients were stratified into quartiles based on time from chemotherapy to surgery: Q1 (<85 days), Q2 (85-100 days), Q3 (101-120 days), and Q4 (>120 days). The primary outcome was overall survival, and secondary outcomes were pN2 disease and margin-positive (>R0) resection. Survival was modeled with Kaplan-Meier and Cox Proportional Hazards, and upstaging and >R0 resection with multivariable logistic regression. **Result:** A total of 205 patients were included, with a median time from induction therapy to surgery of 104 days. There was no difference in unadjusted median survival between the groups: 23 (Q1), 25 (Q2), 25 (Q3), and 20 (Q4) months (log-rank p=0.92). In multivariable regression, increasing time to surgery was not associated with survival examined by quartile (Table) or as a continuous variable (adjusted hazard ratio [AHR] 1.00; 95% confidence interval [CI] 0.99-1.01). Increasing time to surgery was also not associated with increased pathologic upstaging to N2 (adjusted odds ratio [AOR] for Q4 vs. Q1: 1.22; 95%CI 0.33-4.65). In a multivariable regression, increased time from chemotherapy to surgery was not associated with >R0 resection (AOR 0.81; 95%CI 0.23-2.87 for Q4 vs. Q1). **Conclusion:** Increased time from induction therapy to surgery for MPM was not associated with worse survival, nodal upstaging, or margin-positive resection in this study. Patients with MPM can be safely offered surgery even three months after induction chemotherapy.

Variable	Adjusted HR	95% CI	P value
Interval (ref:Q1) Q2 Q3 Q4	0.83 0.92 1.08	0.49-1.40 0.55-1.53 0.61-1.92	0.49 0.74 0.79

P2.06-04 TREATMENT PATTERNS AND OUTCOMES OF ADVANCED MALIGNANT PLEURAL MESOTHELIOMA (MPM) PATIENTS IN A COMMUNITY PRACTICE SETTING

D. Waterhouse[1], E. Nwokeji[2], M. Boyd[2], J. Penrod[3], J. Espirito[2], N. Robert[2], M. Daumont[4]

[1]*Oncology Hematology Care, Cincinnati/United States of America,* [2]*McKesson Life Sciences, The Woodlands/United States of America,* [3]*Bristol-Myers Squibb, Princeton/United States of America,* [4]*Bristol-Myers Squibb, Braine-l'Alleud/Belgium*

Background: MPM is an aggressive neoplasm with a poor prognosis and limited therapeutic options. Pemetrexed+platinum is standard of care (SOC) for advanced MPM in the United States with cisplatin doublet as the only approved first-line (1L) treatment by the Food and Drug Administration (FDA). There are no FDA approved treatments in second-line (2L) or later. Understanding how patients are currently treated and the associated outcomes is important to assess the unmet needs in MPM. **Method:** Retrospective data were abstracted from the US Oncology Network's iKnowMed electronic health record (EHR) for patients with advanced MPM receiving systemic therapy between 01-Jan-2008 and 31-Dec-2016, followed through 31-Dec-2017. Eligibility criteria: ≥18 years of age, ≥2 visits, no clinical trial enrollment or other malignancy during study period. Baseline demographic/clinical characteristics, treatment patterns, duration of chemotherapy (DOT) and overall survival (OS) were assessed, using Kaplan-Meier methods for 1L, 2L+ survival. **Result:** 474 advanced MPM patients receiving treatment were identified; median age was 72 years, majority were male (82%) with an Eastern Cooperative Oncology Group (ECOG) score of 0 to 1 (71%). Cisplatin+pemetrexed (n=194; 41%) and carboplatin+pemetrexed (n=175; 37%) were the most frequent 1L regimens, followed by pemetrexed monotherapy (n=51; 11%). Only 108 (23%) patients received 2L and 33 (7%) received 3L. The most common 2L regimens included monotherapies gemcitabine (n=40; 37%), pemetrexed (n=27; 25%), vinorelbine (n=9; 8%), and IO therapy (avelumab, nivolumab or pembrolizumab n=9; 8%). Median DOT was 2.7 months in 1L SOC and 1.7 months in all 2L regimens. Unadjusted median OS in patients 1L SOC was 14.0 months (95%CI, 11.6-17.0) with similar survival observed among cisplatin+pemetrexed (13.7 months; 95%CI, 10.8-18.5) and carboplatin+pemetrexed (14.2 months; 95%CI, 11.1-19.8); OS for 1L pemetrexed monotherapy (10.7 months; 95%CI,6.2-14.3). Unadjusted OS in 2L was 6.4 months (95%CI, 5.1-7.6) ranging from 3.4 months (95%CI, 2.7-6.5) with gemcitabine to 11.8 months (95%CI, 0.3-NR) with immunotherapies. **Conclusion:** This real-world analysis of advanced MPM showed a majority of 1L patients received SOC pemetrexed+platinum based therapy, with carboplatin almost as common as cisplatin. The platinum agent paired with pemetrexed in 1L SOC did not affect unadjusted survival in the community setting. Less than a quarter of 1L patients received a 2L therapy, with gemcitabine as the most common treatment. Overall survival in MPM remains poor and treatment rates in 2L are low, highlighting the need for more effective therapies.

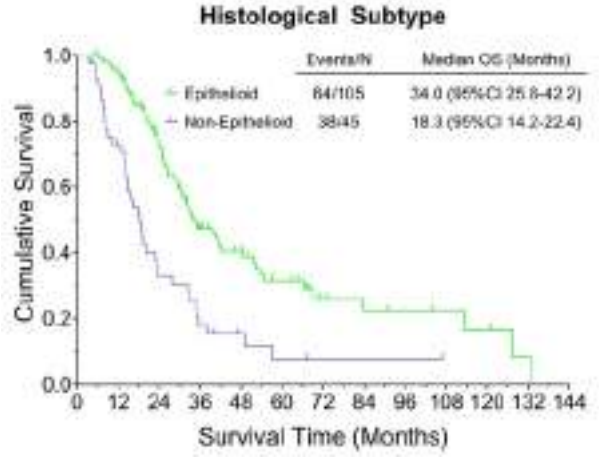
P2.06-05 MULTIMODALITY THERAPY USING TOTAL PLEURECTOMY IN MALIGNANT PLEURAL MESOTHELIOMA: LONG-TERM OUTCOMES IN 150 CONSECUTIVE CASES

L. Lang-Lazdunski[1], Y.Z. Zhang[2], S. Popat[3], M. O'Brien[4], J. Steele[5], T. Newsom-Davis[6], R. Lal[7], A. Nicholson[8]

[1]*Bupa Cromwell Hospital, London/United Kingdom,* [2]*Imperial College London, London/United Kingdom,* [3]*BUPA Cromwell Hospital, London/United Kingdom,* [4]*Royal Marsden, London/United Kingdom,* [5]*Barts Health NHS Trust, London/United Kingdom,* [6]*Chelsea and Westminster Hospital, London/United Kingdom,* [7]*King's Health Partners, London/United Kingdom,* [8]*National Centre for Mesothelioma Research, Imperial College London, London/United Kingdom*

Background: We wished to evaluate the long-term outcomes of patients receiving multimodality therapy including total pleurectomy/decortication, radiotherapy and systemic chemotherapy for malignant pleural mesothelioma. **Method:** Retrospective analysis of patients treated between September 2004 and April 2019 by a specialised thoracic multidisciplinary team. Treatment involved total pleurectomy and decortication of lung, prophylactic radiotherapy (21 Gy in 3 fractions) and systemic chemotherapy based on pemetrexed and platinum. PET-CT was used routinely to diagnose disease recurrence or progression. Second or third-line therapies were administered when appropriate. Survival and prognostic factors were analysed by the Kaplan-Meier method and Cox regression analysis. **Result:** 150 patients had multimodality therapy over a 15-year period. Median age at operation was 62 years (range 32-82) and the male/female ratio was 122/28. Thirty-one patients (20.6%) had received chemotherapy before surgery. Thirty-three patients (22%) had extended resections. Sixty-two patients suffered a postoperative complication and 90-day mortality was nil. Eleven patients (7.3%) had reoperation within 30 days. Histological types were epithelioid in 105 patients and non-epithelioid in 45. Pathological stages were: I:86, II: 9, III: 54, and IV:1 (8th TNM classification). All patients but one received prophylactic radiotherapy. Six patients (4%) did not received systemic chemotherapy. Sixty-five patients (43.3%) received second-line or further systemic therapies. Five patients received stereotactic radiotherapy and three patients had late reoperation for focal tumour recurrence. Median survival was 30.5 months overall (95% CI 25.4-35.6), 34 months for epithelioid type

(95% CI 25.8-42.2) and 18.3 months for non-epithelioid type (95% CI 14.2-22.4). Histological type and macroscopic complete resection were predictive of extended survival in our analysis. **Conclusion:** Total Pleurectomy /Decortication is a safe and well-tolerated procedure associated with no mortality and acceptable morbidity. Most patients can receive prophylactic radiotherapy and systemic chemotherapy in due time. Many can receive second-line or further therapy on progression, resulting in prolonged survival.



Keywords: Mesothelioma, multimodality therapy, surgery

P2.06-06 Y-BOX BINDING PROTEIN-1, A POTENTIAL TARGET IN MALIGNANT PLEURAL MESOTHELIOMA, DRIVES GROWTH THROUGH DISTINCT MECHANISMS

T. Johnson[1,2,3], K. Schelch[4], M. Williams[1], Y.Y. Cheng[1,3], M. Grusch[4], G. Reid[5], A. Burgess[3,6]

[1]*The Asbestos Diseases Research Institute, Sydney, Concord/Australia,* [2]*Sydney Catalyst Translational Cancer Research Centre, Sydney/Australia,* [3]*The University of Sydney, Australia, Sydney/Australia,* [4]*Medical University of Vienna, Vienna/Austria,* [5]*University of Otago, Dunedin/New Zealand,* [6]*ANZAC Research Institute, Sydney/Australia*

Background: Malignant pleural mesothelioma (MPM) is an asbestos-related disease with a fiveyear survival of five percent. Current therapy provides limited success and finding other targetable molecules remains a top priority. We recently identified Y-box binding protein-1 (YB1) as a significantly overexpressed oncogene with prognostic relevance in MPM. YB-1 is a multifunctional transcription and translation factor of the cold-shock protein family. Using siRNAmediated knockdown of YB-1 we showed that silencing YB-1 inhibited the proliferation, migration and invasion of four MPM cells by an unknown mechanism. Here we extend this work to examine how YB-1 regulates MPM growth. **Method:** Functional activity of YB-1 was investigated by siRNA-mediated knockdown in MPM cells followed by TALI apoptosis assays, multi-dimension flow cytometry or live-cell imaging. Transcript expression was determined using reverse transcription qPCR (RT-qPCR) and RNA sequencing (RNAseq) with poly(A) selection. **Result:** Following our previous data demonstrating growth inhibition after YB-1 knockdown, we transfected three MPM cell lines with YB-1 siRNA and conducted multidimension flow cytometry and TALI apoptosis assays to begin understanding how this growth inhibition was occurring. We found that cells underwent either apoptosis or a G0/G1 cell cycle arrest. Using live-cell imaging and single cell fate mapping we found that each cell line undertook a distinct mechanism of growth inhibition. MSTO cells displayed apoptosis during interphase, VMC23 cells showed no death but underwent a G0/G1 cell cycle arrest, while REN cells did not delay during interphase but entered prolonged aberrant mitosis resulting in mitotic catastrophe and cell death. To examine the interphase arrest in MSTO and VMC23 further we analysed the expression of cyclin D1 and Myc, known cell cycle targets of YB-1, in knockdown samples using RT-qPCR. Transcripts of cyclin D1 and Myc were downregulated in both cell lines in response to reducing YB1, partially explaining the growth inhibition observed. To further understand the effects of YB-1 inhibition we have undertaken a global analysis of downstream targets and pathways after YB1 siRNA transfection in all three cell lines using RNAseq analysis. **Conclusion:** This project delves into the complex mechanism underlying YB-1-driven MPM proliferation and found it plays a broader role than expected due to its influence over multiple cancer-promoting genes and pathways. Our study significantly extends our understanding of this important protein in MPM, a disease in dire need of actionable targets.

P2.06-07 PHASE 1 STUDY OF CA-170: FIRST-IN-CLASS SMALL MOLECULE TARGETING VISTA/PD-L1 IN PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA

M. Zauderer[1], J. Brody[2], T. Marron[3], S. Pacey[4], R. Martell[5], H. Wang[5], J. Spicer[6]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Mount Sinai Hospital, New York/United States of America,* [3]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [4]*University of Cambridge, Cambridge/United Kingdom,* [5]*Curis, Inc., Lexington/United States of America,* [6]*King's College London, Guy's Hospital, London/United Kingdom*

Background: In contrast to PD-L1, VISTA is expressed in up to 90% of malignant pleural mesothelioma (MPM) patients with strong expression on infiltrating lymphocytes and on mesothelioma cells. Recent work also found that expression of VISTA in epithelioid MPM is strikingly higher than in other solid tumors. PD-1 and PD-L1 immune checkpoint inhibitors (ICI) have shown modest activity in ≥2nd line MPM which has fueled interest in novel targets, such as VISTA. Many genes associated with VISTA signaling are proliferative and may help drive cancer, providing strong rationale for inhibitors blocking VISTA. VISTA and PD-1 are independent immune checkpoints negatively regulating T-cell function. VISTA is expressed on immune and tumor cells and implicated in resistance to ICI. Preclinical studies show that dual blockade of VISTA and PD-L1 can be synergistic. CA-170, a small molecule inhibitor of VISTA and PD-L1, has demonstrated anti-tumor activity in multiple *in vivo* models including syngeneic models that do not respond to anti-PD-1 treatment. Phase 1/2 trialsof CA-170 monotherapy showed that CA-170 has a favorable safety profile with preliminary signs of anti-tumor activity in PD-1 malignancies. Pharmacological activity, as measured by immune-modulating effects, was observed across a wide dose range. Development of CA-170 is on-going with evaluation of BID doses in VISTA expressing tumors, such as MPM. **Method:** CA-170-101 is a Phase 1 dose finding study in advanced solid tumors and lymphomas. Selected dose levels can be expanded with additional patients in tumor types of interest. Two pharmacologically active doses, 200 and 1200 mg BID, were selected to further expand with MPM patients to better understand CA-170 activity in this high VISTA-expressing tumor type. As of April 2019, 12 patients with MPM have been enrolled; 8 have completed the 21-day safety evaluation period without DLT. Objectives: tolerability and RP2D (primary), anti-tumor activity (PFS and ORR, secondary) and exploratory biomarkers and PD effects. Key eligibility: histologically confirmed epithelioid, ≥1 prior therapy including pemetrexed-platinum doublet, no prior ICI, measurable disease, paired tumor biopsies if medically feasible, ECOG 0-1, life expectancy >3 months, and adequate organ function. Clinical trial: NCT02812875. **Result:** Section not applicable **Conclusion:** Section not applicable

P2.06-08 NIVOLUMAB FOR MALIGNANT MESOTHELIOMA: A REAL-WORLD EXPERIENCE

M. Niki[1,2,3], T. Yokoi[1,2,3], R. Takahashi[1,3], K. Mikami[1,3], E. Shibata[1,3], Y. Nakajima[1,3], Y. Negi[1,3], H. Ishigaki[1,3], A. Tada[1,3], T. Higashiyama[1,3], T. Kamei[1,3], T. Minami[1,3], K. Kuribayashi[1,3], T. Kijima[1,2,3]

[1]*Division of Respiratory Medicine, Department of Internal Medicine, Nishinomiya/Japan,* [2]*Department of Thoracic Oncology, Nishinomiya/Japan,* [3]*Hyogo College of Medicine, Nishinomiya/Japan*

Background: Nivolumab, an anti-PD-1 monoclonal antibody, has beneficial effects against pretreated malignant pleural mesothelioma (MPM). Although this drug is approved in Japan, data on the efficacy and safety of nivolumab in MPM are limited to those from a small number of patients of the MERIT study. Therefore, it is important to accumulate real-world data of nivolumab. **Method:** We retrospectively analyzed all patients with MPM who received

POSTERS

nivolumab at Hyogo College of Medicine Hospital from August 2018 to December 2018. The tumor response was assessed according to RECIST guidelines (version 1.1), and adverse events were evaluated according to the NCI Common Terminology Criteria for Adverse Events (CTCAE), version 4.0. **Result:** A total of 39 patients (31 males and 8 females)were included. There were 29, 6, and 4 patients with a performance status of 0-1, 2, and 3, respectively. There were 34, 4, and 1 patientswith epithelioid, sarcomatoid, and bi-phasic histology, respectively. Nivolumab was given as second-, third-, and ≥fourth-line treatment to 18, 10, and 11 patients, respectively. The response rate (RR)was 20.5% (8/39), and disease control rate (DCR)was 56.4% (22/39). Twelve patients were evaluated asprogressive disease and 5 patientswere not evaluable. The RR and DCR were 11.8% (4/34) and 50.0% (17/34) in the epithelioid-type, and 50.0% (2/4) and 100.0% (4/4)in the sarcomatoid-type.The median progression-free survival was 4.1 months and median overall survival was not reached. Regarding adverse events, fatigue (grade 1–2) was observed in 8, hypothyroidism (grade 1-2) in 4, renal dysfunction (grade 1-2) in 3, loss of appetite (grade 1-2) in 2, pneumonitis (grade 3) in 1, rash (grade 1) in 1and hypopituitarism (grade 2) in 1 patients, respectively. **Conclusion:** The findings of this retrospective study revealed the effectiveness and safety of nivolumab for MPM in the real-world setting. Nivolumab can be used as a standard second-line treatment for MPM.

Keywords: MPM, nivolumab

P2.06-09 DROP THE SCALPEL: LONG-TERM SURVIVAL IN MESOTHELIOMA WITHOUT EXTRAPLEURAL PNEUMONECTOMY OR PLEURECTOMY DECORTICATION

G. Woodard, J. Crockard, A. Anand, V. Ding, K. Jones, M. Gubens, C. Blakely, T. Jahan, D. Jablons

University of California San Francisco, San Francisco/United States of America

Background: Survival times following multimodality treatment with extrapleural pneumonectomy (EPP) and pleurectomy decortication (P/D) for malignant pleural mesothelioma (MPM) are poor with a need to identify factors that predict long-term survival. **Method:** A retrospective single-institution review was performed on all patients who underwent EEP or P/D for histologically confirmed MPM between 1996 and 2015. Patients who underwent a diagnostic biopsy or limited tumor excision were included for survival comparison in a non-operative group (NO). Clinical characteristics, perioperative outcomes, stage, nodal disease, R1 versus R2 resection, treatment modalities, and survival data were collected. The top decile of patients with longest overall survival were studied in subgroup analysis as "long-term survivors." **Result:** A total of 206 patients with MPM underwent any type of operations with a median survival time of 13 months (range, 0-134 months) and a 3-year and 5-year survival rates of 15.9% and 8.1% respectively among all patients. Median survival times following EPP (n=28), P/D (n=102) and NO (n=76) were 14 months, 13 months, and 11 months respectively. Better survival was observed in patients with epithelial histology (16 months, n=146) than biphasic histology (7 months, n=28) or sarcomatoid histology (5 months, n=27) (logrank p<.001). Patients with epithelial histology had the greatest median survival times, EPP (29 months, n=23), P/D (16 months, n=77) and NO (16 months, n=46). Three-year and 5-year overall survival rates among patients with epithelial histology were 34.7%, 14.9% after EPP, 16.7, 10.4% after PD and 25.9%, 8.1% after NO, with the patients in the NO group presenting with the most advanced disease. The top decile of long-term survivors all had epitheliod histology and were treated with a variety of chemotherapy regimens leading to a median survival of 64 months with a mean of 71 months. Patients with disease too advanced for surgical resection in the NO group were equally likely to become long-term survivors (9.2%, median survival 57 months) compared with patients who underwent major surgical resection like EPP or P/D (10.0%, median survival 72 months). **Conclusion:** In this non-randomized retrospective review, patients with MPM too advanced for EPP or PD, who instead underwent palliative limited operations as part of a multimodality treatment regimen had long-term survival rates of approximately 10% that were equivalent to rates of long-term survival following major resections like EPP or P/D. Long-term survival is mesothelioma is therefore more likely determined by outside factors such as disease biology and pace of tumor growth than it is major surgical resection.

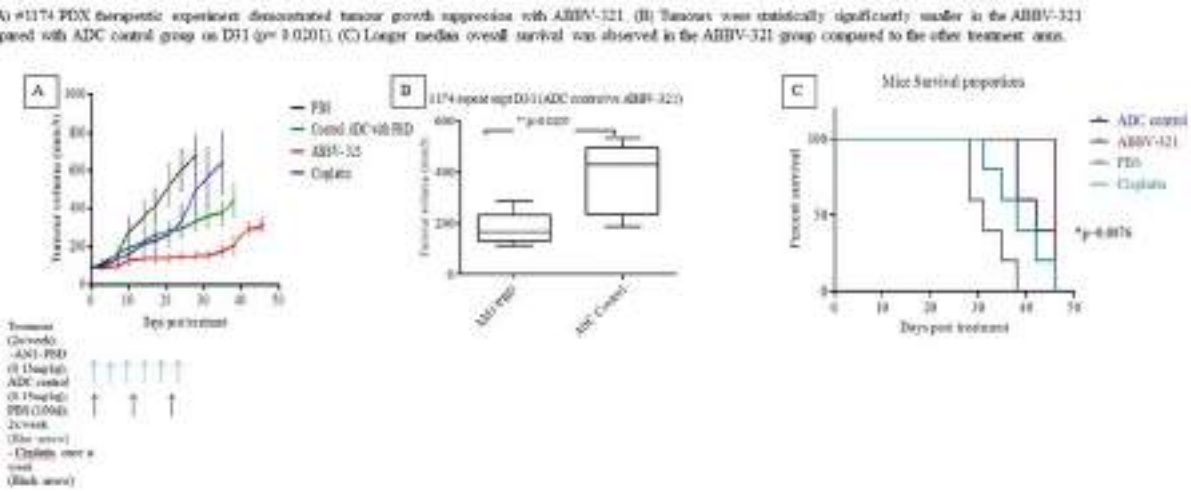
Keywords: pleurectomy/decortication, Mesothelioma, extrapleural pneumonectomy

P2.06-10 ABT-806 DERIVED ANTIBODY DRUG CONJUGATES (ADCS) INHIBIT GROWTH OF MALIGNANT MESOTHELIOMA IN-VIVO

P.L. Chia[1,2,3], D. Cao[1], H. Gan[1,2], E. Reilly[4], A. Phillips[4], T. John[1,2,3,5], A. Scott[1,2,3,5]

[1]*Olivia Newton-John Cancer Research Institute, Melbourne/Australia,* [2]*Austin Health, Heidelberg/Australia,* [3]*University of Melbourne, Melbourne/Australia,* [4]*AbbVie, North Chicago/United States of America,* [5]*LaTrobe University, Bundoora/Australia*

Background: Malignant mesothelioma (MM) is an aggressive malignancy of the pleura with limited therapeutic options, and is associated with a poor prognosis. EGFR is known to be highly over-expressed in mesothelioma with reported EGFR overexpression between 44 to 97%. We have investigated an anti-EGFR antibody (ABT-806), which is tumour specific and robustly inhibits EGFR-expressing tumors. We have previously shown that ABT-806 ADCs demonstrate potent anti-tumor activity in 806 immunohistochemistry (IHC) positive MSTO-211H MM cell line xenograft model. We present data in MM using ABT-806 novel ADCs [ABT-414 (ABT-806- monomethyl auristatin F), ABBV-221 (ABT-806- monomethyl auristatin E), ABBV-322 (ABT-806- pyrrolobenzodiazepine)] and ABBV-321 (Affinity-matured ABT-806- pyrrolobenzodiazepine) in MM patient derived xenografts (PDX). **Method:** We evaluated expression of EGFR and mAb 806 IHC in MM cell lines and PDXs. PDXs were implanted into 5 to 10 NOD-Scid mice per group and treated with control ADC, saline, cisplatin or ABT-806 ADCs and followed longitudinally with caliper measurements. Comparative statistics were performed in Graphpad prism. Quantitative biodistribution and imaging of mAb806 uptake (89Zr-ch806) were performed to allow correlation of mAb806 concentration in MM tumours. **Result:** Three PDX models were selected according to their 806 IHC statuses (2 epithelioid 806 IHC positive, 1 biphasic histology 806 IHC negative). In one epithelioid PDX model, ABBV-322 resulted in significantly reduced tumor growth on day 27 post therapy with median tumour volumes of 180 mm3 (ADC control) compared with 78mm3 (ABBV-322; p=0.0159 two-sided). Moreover, the median survival was also significantly longer in ABBV-322 treated models (p=0.018). In the other epithelioid PDX model, ABBV-321 also resulted in significant responses (median 428mm3 (ADC control) vs 167mm3 (ABBV-321, p= 0.0201) [Figure 1]. In the 806 IHC negative PDX model, the differences in tumor volumes between all groups were found to be non-statistically significant (ADC control vs ABT-414, ADC control vs ABBV-221, ADC-control vs ABBV-321 groups) with p=0.0597 for one-way ANOVA. MSTO211H cell line xenograft model also demonstrated significant anti-tumour response to both ABT-414 and ABBV-221 (p<0.01). Whole-body PET/MR images also confirmed localization of 89Zr-Ch806 to the established MSTO-211H xenograft tumours.



Conclusion: In a disease with limited therapies, ABT-806 targeting ADCs in MM demonstrated significant responses in 806+ PDX and cell lines. These data support clinical expansion of these compounds in 806+ MM patients.

Background: The Mesothelioma evolution: Drugging somatic alterations (MEDUSA) project aims to investigate the genomic evolution and heterogeneity of malignant pleural mesothelioma and identify genomic changes early in mesothelioma evolution that can be targeted by drugs. For 20 malignant pleural mesothelioma patients, we have analysed the exomes of at least four regions of the tumour and paired whole blood. **Method:** Using paired tumour-normal analysis with the software Sequenza, we have called copy number alterations specific to the tumour, and used the software Tumult to reconstruct a phylogeny of the tumour for each of the 20 patients. **Result:** We show that mesothelioma shows extensive heterogeneity in copy number changes, and accumulates typically between 100-200 copy number gains and losses while evolving in a branching pattern. We identify and validate copy number alterations that occur truncally, early in the evolution of the tumour, and are recurrent across patients, including homozygous loss of CDKN2A and MTAP in 4/20 patients, heterozygous loss of MTOR in 6/20 patients and heterozygous loss of BAP1 in 4/20 patients. Losses of these key genes are observed in some other patients, but only in a subset of regions, suggesting that they have occurred later in the evolution of the tumour compared to truncal changes. **Conclusion:** As truncal changes are likely to be present throughout the tumour, identifying them highlights potential Achilles' heels for drug targeting and treatment.

P2.06-12 DYSPHAGIA IN PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA (MPM)

M. Malec[1], A. Desai[2], I. Waxman[1], T. Karrison[1], B. Rose[1], A. Mendoza[1], M. Gadiraju[1], C. Straus[1], J.E. Churpek[1], H. Kindler[1]

[1]*University of Chicago, Chicago/United States of America,* [2]*University of California San Francisco, San Francisco/United States of America*

Background: Dysphagia is common with advanced malignancies but is not well characterized in MPM and is under-recognized as a symptom attributable to this disease. The prevalence of dysphagia in MPM is unknown. Available literature is limited to a few case reports. Dysphagia can lead to nutritional compromise, pain and deterioration of quality of life. It can occur as a result of extrinsic compression of the esophagus by mediastinal lymphadenopathy, intrinsic mechanical obstruction or pseudo-achalasia secondary to infiltration of the esophagus. Palliation is an important goal of therapy and recognizing the underlying etiology will guide selection of interventions. **Method:** We performed a single center, retrospective cohort study of MPM patients who reported dysphagia treated at the University of Chicago between 6/1/2016 and 4/1/2018. 250 consecutive patient records were reviewed for the report of dysphagia and chart extraction was performed. Patient factors collected included patient age at diagnosis, gender and comorbid medical illness. Mesothelioma specific factors included tumor histology, treatment history and overall survival. Dysphagia specific factors including onset of dysphagia relative to diagnosis and patient death, characteristics of dysphagia, findings on imaging and evaluation and interventions performed. **Result:** Eleven patients (4.4%) reported dysphagia. Median age was 72 (range 55-88). 100% male. 8 had right sided, 3 had left sided disease. Tumor histology: 6 epithelioid, 1 sarcomatoid and 4 biphasic. Of these, one patient had dysphagia unrelated to mesothelioma that resolved with surgical intervention. Of the remaining 10 patients, 9 had mediastinal adenopathy and/or esophageal involvement on CT scans. 1 patient had no CT findings to explain dysphagia and EGD revealed extrinsic compression. 3 patients were stented. 2 of 3 required repeat procedures. 1 required a feeding tube. Median time from diagnosis to onset of dysphagia was 18 months (range 0.7-31.7) One patient developed dysphagia 2 months prior to diagnosis. Median time from development of dysphagia to death was 5.7 months (range 2-7.7) One patient remains alive. Median overall survival was 19.8 months (range 4.4-159.7). **Conclusion:** Dysphagia in patients with malignant pleural mesothelioma is most often attributable to the underlying malignancy due to extrinsic compression from mediastinal adenopathy or direct tumor extension. This development is a poor prognostic sign and, in this sample, signaled a median survival just under 6 months. Patients with the shortest interval from diagnosis to onset of dysphagia had the shortest overall survival. A prospective study to further characterize dysphagia in MPM and optimize interventions is ongoing.

P2.06-13 TARGETING RAS SIGNALING IN MALIGNANT MESOTHELIOMA

A. Singh[1], R. Pahwa[1], N. Pruett[1], A. Mahajan[2], J. Madigan[1], D. Schrump[1], C. Hoang[1]

[1]*National Cancer Institute - NIH, Bethesda/United States of America,* [2]*University of Michigan, Ann Arbor/United States of America*

Background: Malignant pleural mesothelioma (MPM) is distinguished by molecular features, such as activated and redundant multiple tyrosine kinases signaling via the Ras pathways. Several pharmacologic strategies have been attempted to disrupt this pathogenic axis, but clinically effective agents remain elusive. We propose to leverage microRNA (miRNA) as a potential therapeutic approach, since miRNA can coherently regulate multiple simultaneous gene targets that comprise critical biologic networks. **Method:** Our prior miRNA profiling results of human MPM (GSE40345) were cross-referenced with TCGA-Meso data to identify prognostic miRNAs. Both MPM cell lines and tissues (tumors and normal pleura) were assessed using quantitative and functional biologic assays that revealed specific molecular mechanisms of relevant miRNA. In silico algorithms identified downstream gene targets that were verified by 3'-UTR luciferase assay. Murine models of MPM xenografts were used to verify *in vitro* observations of miRNA effects. Kaplan-Meier assessed outcomes in vivo. **Result:** Our analyses showed underexpression of miR-206 by 12-fold in MPM tumors compared to normal pleura. TCGA data (n=74 MPM) indicated worse survival in patients with low miR-206 (25-fold decrease) compared to higher miR-206 expression. We confirmed that miR-206 was significantly underexpressed by qRT-PCR analysis of new, randomly selected MPM tumors versus normal pleurae tissues. In MPM cell lines, ectopic re-expression of miR-206 dramatically suppressed cell proliferation, invasiveness, and growth in soft-agar. Interestingly, we noted several MPM-prognostic genes ($p<0.05$) regulated by miR-206: KRAS, CDK4, CCND1, and IGF1R. This signaling axis of KRAS/CDK4/CCND1 is important in MPM as it summates well-known dysregulated tyrosine kinase receptors (EGF, IGF-1, VEGF, MET, etc) that are upstream. The KRAS/CDK4/CCND1 axis is associated with cell cycle progression and survival of cancer cells, but is not an easily druggable target. *In vitro*, miR-206 treatment significantly downregulated KRAS, CDK4 and CCND1 as well upstream target genes such as MET, EGFR, IGF1R and VEGFA. In vivo, miR-206 treatment significantly suppressed MPM tumor growth in subcutaneous and orthotopic xenograft models compared to control. Kaplan-Meier analysis showed that miR-206 treatment improved overall survival. **Conclusion:** miR-206 exerts tumor suppressive effects in MPM via inhibition of KRAS/CDK4/CCND1 signaling, which mimics simultaneous blocking of multiple tyrosine kinases. Loss of miR-206 and concomitant overexpression of KRAS, CDK4 and CCND1 formed a novel poor prognosis signature in MPM. Our results indicate that miR-206 is a rational agent to be developed further in preclinical MPM models as a promising therapeutic.

P2.06-14 BAP1 MUTANT MALIGNANT PLEURAL MESOTHELIOMA (MPM): OUTCOMES WITH CHEMOTHERAPY, ICPI AND PARPI

E. Dudnik[1], J. Bar[2], T. Kuznetsov[2], M. Moskovitz[3], J. Dudnik[4], T. Shochat[5], A. Zer[1], D. Urban[2]

[1]*Davidoff Cancer Center Rabin Medical Center, Petah Tikva/Israel,* [2]*Chaim Sheba Medical Center, Tel HaShomer, Ramat Gan/Israel,* [3]*Rambam Health Care Campus, Haifa, Israel/Israel,* [4]*Soroka University Medical Center, Cancer Institute, Beer-Sheva/Israel,* [5]*Rabin Medical Center, Petah Tikva/Israel*

Background: Little is known regarding the outcomes of systemic treatments (Tx) in BAP1 altered MPM. **Method:** 45 patients (pts) with advanced MPM (Group A: 8 MPM with a BAP1 inactivating mutation/copy number loss (FoundationOne CDx/TEMPUSxT), selected from the electronic databases (eD) of 4 Israeli cancer centers (ICC); Group B: 37 consecutive (years 2016-2018) MPM without a BAP1 alteration/not tested, selected from the eD of 2 ICC) were analyzed for ORR, PFS (mRECIST 1.1) and OS with platinum/pemetrexed+/-bevacizumab/nintedanib (CT, n-28), immune check-point inhibitors (ICPi, n-16) and poly (ADP-ribose) polymerase inhibitors (PARPi, n-4). OS since diagnosis (OSDx) was assessed. **Result:** Pt and Tx characteristics are presented in the Table. There were no differences in ORR, mPFS or mOS with CT between the Groups: ORR-50% in both Groups, mPFS-9.1mo (95%CI, 1.2-16.1) vs 9.2mo (95%CI, 2.9-17.8) (log-rank-0.01, p-0.9), mOS-NR (95%CI, 6.6-NR) vs 18.5mo (95%CI, 5.4-46.3) (log-rank-1.1, p-0.3), in Groups A and B, respectively. There were no differences in ORR, mPFS or mOS with ICPi between the Groups: ORR- 33% vs 50% ($p>0.5$), mPFS-2.5mo (95%CI, 1.4-3.7) vs 3.0mo (95%CI, 0.3-10.5) (log-rank-0.5, p-0.4), mOS-NR (95%CI, 4.0-NR) vs 5.8mo (95%CI, 0.3-13.2) (log-rank-0.1, p-0.7), in Groups A and B, respectively. In Group A, no responses were seen with PARPi; PFS with PARPi was 1.8mo (95%CI, 1.8-1.9). OSDx was NR (95%CI, 9.7-NR) vs 19.5mo (95%CI, 9.7-82.2) in Groups A and B, respectively (log-rank-1.6, p-0.2). In the univariate analysis, sex (p-0.04), histology (p-0.002), ECOG PS (p-0.03), but not BAP1 mutation (p-0.3) correlated with OSDx.

	Group A, n-8	Group B, n-37	p value
Age, y (median, range)	65 (25-76)	70 (30-93)	0.2
Male, %	62	70	0.7
Asbestos exposure, %	25	40	0.4
ECOG PS 0/1, %	87	81	1
Epithelioid histology, %	87	84	0.6
PD-L1 TPS: >50%/1-50%/<1%/NA, %	25/0/12/63	0/11/5/84	0.05
TMB, mut/Mb (median, range)/% tested	3 (0.8-5)/62	1.5 (0-2)/11	0.2
MSI high, n (%)/% tested	0/100	0/16	NA
Tx: CT/ICPi/PARPi, %	100/37/50	54/35/0	NA

Conclusion: Outcomes with CT and ICPi in BAP1 mutant MPM are similar to non-selected MPM. No responses were seen so far with PARPi. According to our data, presence of BAP1 mutation does not affect OS. Additional follow-up is needed.

Keywords: BAP1, immune check-point inhibitors, poly (ADP-ribose) polymerase inhibitors

P2.06-15 CLINICAL VALUE SCORES OF TTFIELDS TREATMENT OF UNRESECTABLE MALIGNANT PLEURAL MESOTHELIOMA USING THE ASCO AND ESMO FRAMEWORK

C. Proescholdt[1], J. Kelly[2], U. Weinberg[3]

[1]*Novocure, Root D/Switzerland,* [2]*Novocure, Portsmouth/United States of America,* [3]*Novocure Ltd, Haifa/Israel*

Background: The effectiveness and safety of TTFields in addition to pemetrexed and cisplatin or carboplatin in unresectable malignant pleural mesothelioma (MPM) was recently shown through the analysis of the phase II single arm EF-23 STELLAR trial. The American Society of Clinical Oncology (ASCO) and the European Society for Medical Oncology (ESMO) have both developed frameworks accounting for the need of physicians and policymakers to objectively and comparably capture the clinical value of new cancer treatments. We quantified the clinical value of the TTFields treatment in MPM by applying ASCO and ESMO frameworks to the comparison of the STELLAR data to historical controls. **Method:** The EF-23 STELLAR trial (n=80) demonstrated that adding TTFields to pemetrexed and cisplatin or carboplatin for malignant pleural mesothelioma patients resulted in overall survival of 18.2 months (95% CI 12.1-25.8) and progression free survival of 7.6 months (95% CI 6.7-8.6). The median time to deterioration in ECOG performance status was 13.1 months. Average pain score was lower compared to baseline during the first 7 months of treatment. The ESMO Magnitude of Clinical Benefit Scale (MCBS) and the ASCO Net Health Benefit (NHB) frameworks were applied to the EF-23 trial data using a historical control as comparator. **Result:** The application of the ASCO framework to the EF-23 data resulted in a NHB score of 52, the first such score reported for MPM. This result is at the higher end of the score range of novel cancer treatments and compares well to the results for nivolumab in NSCLC as reference point. Applying the ESMO framework resulted in MCBS scores of A/5 (adjuvant/advanced) which is also the first MCBS score reported for MPM. The MCBS scores of A/5 are the highest scores achievable in the ESMO framework, and higher then most ESMO MCBS scores reported in the literature for NSCLC treatments. **Conclusion:** Despite differences in their respective concepts, both the ASCO and ESMO frameworks suggest that adding TTFields to Pemetrexed and Cisplatin or Carboplatin in malignant pleural mesothelioma patients may provide a significant clinical benefit. The high scores underline that treatment with TTFields may extended time to deterioration of performance status, progression free and overall survival without additional systemic toxicities.

P2.06-16 RACIAL DISPARITIES IN TREATMENT PATTERNS AND SURVIVAL AMONG SURGICALLY TREATED MALIGNANT PLEURAL MESOTHELIOMA PATIENTS

N. Alpert[1], M. Van Gerwen[1], N. Ohri[2], R. Flores[1], E. Taioli[1]

[1]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [2]*Rutgers Cancer Institute of New Jersey, New Brunswick/United States of America*

Background: Although surgical intervention improves survival for patients with malignant pleural mesothelioma (MPM), black patients are less likely to receive surgery. It is not known what the treatment patterns in MPM surgical patients are according to race. This study sought to examine treatment patterns and survival between black and white surgical patients using a large nationwide cancer database. **Method:** This study used the National Cancer Database (NCDB) to examine the subset of black and white MPM patients who received surgery, defined as pleurectomy/decortication (P/D) or extrapleural pneumonectomy (EPP). Multivariable logistic regressions were used to evaluate the racial differences in the extent of surgery, receipt of additional treatment (chemotherapy and/or radiotherapy), and 30-/90- day mortality, while accounting for clinical and demographic factors. A multivariable Cox proportional hazards model was used to assess the independent associations of race with overall survival. Association between race and survival was also analyzed using a 1:1 propensity score matching with the greedy algorithm. **Result:** There were 2550 MPM patients in the NCDB who received surgery; 2462 white (96.5%) and 88 black (3.5%). Most patients received P/D (77.8%); 63.8% received additional treatment. Black patients were significantly less likely to receive EPP (ORadj: 0.36, 95% CI: 0.17-0.78). There was no significant difference with race in the receipt of additional treatment (ORadj: 0.79, 95% CI: 0.46-1.34); EPP patients were significantly more likely to receive additional treatment (ORadj: 1.34, 95% CI: 1.02-1.74). Black patients tended to have worse 30- and 90- day mortality than white patients (ORadj: 1.52, 95% CI: 0.58-4.01; ORadj: 1.50, 95% CI: 0.75-3.01, respectively). There was no significant difference in overall survival between black and white patients (HRadj: 0.96, 95% CI: 0.72-1.27); patients who had treatment in addition to surgery had significantly better survival (HRadj: 0.71, 95% CI: 0.64-0.80). Results remained similar after propensity matching. **Conclusion:** Among MPM patients receiving surgery, black patients received less extensive surgery, and are less likely to receive additional treatment, indicating less aggressive treatment overall. Although overall survival was similar, black patients tended to have worse short term outcomes after surgery. Racial disparities in treatment and short term outcomes need to be better addressed.

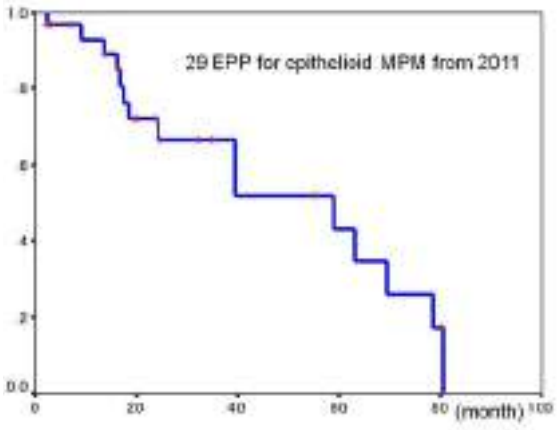
P2.06-17 THE RESULTS OF TRI-MODALITY TREATMENT WITH EXTRAPLEURAL PNEUMONECTOMY, RADIATION, AND CHEMOTHERAPY FOR MALIGNANT PLEURAL MESOTHELIOMA

K. Okabe, H. Inokawa, M. Hayashi, R. Okita, M. Furukawa

Yamaguchi Ube Medical Center, Ube/Japan

Background: Extrapleural pneumonectomy (EPP) or Pleurectomy/Decortication (P/D) is performed for operable malignant pleural mesothelioma (MPM). International Mesothelioma Interest Group (IMIG) guidelines (Rusch V, et al. JTCVS 2013) concluded that EPP or P/D should be selected on the basis of disease distribution, institutional experience, and surgeon preference and experience. Our first choice is EPP followed by radiation and chemotherapy. If EPP is inappropriate, P/D followed by chemotherapy is performed. Our improving results of tri-modality treatment strategy to treat MPM by EPP are reported. **Method:** 58 consecutive EPP for MPM from June 2006 to January 2019 in our hospital were reviewed. We have instituted a trimodality therapy protocol consisting of EPP, adjuvant 45-50.4 Gy hemithoracic radiation, and adjuvant CDDP plus PEM chemotherapy. 48 patients were treated with this protocol. However, 10 patients were given induction chemotherapy, and referred to us. They were scheduled to undergo EPP and adjuvant radiation. Overall survival from the treatment start was calculated using Kaplan-Meier method. The prognosis data were updated in February 2019. **Result:** Median age at EPP was 62 years old (39-74). Female was 11, and male was 47. Right side was 30, and left side was 28. Epithelioid was 39 (67%), biphasic was 14, sarcomatoid was 2, and special variants was 3. Median EPP time was 7 hours 33 minutes (5 h 50 m-12 h 2 m). No blood transfusion during EPP was 20 cases (34%). Mortality was one patient (1.7%) who died due to acute aggravation of interstitial pneumonia. Atrial fibrillation was the most common morbidity, and developed in 20 patients (34%). IMIG pathological stage was IV in 6, III in 31, II in 13, and Ib in 8. Adjuvant 45-50.4 Gy radiation was completed for 49 patients (84%). 11 of 54 patients (20%) could not undergo chemotherapy, and four patients are waiting for chemotherapy. 37 of 54 patients (69%) underwent trimodality therapy, and 4 patients are waiting for chemotherapy. Postoperative median follow-up period was 6 years and 7 months. 5 year survival, 2 year survival, and median survival of all 58 patients were 27%, 53%, and 30 months, and those of 39 epithelioid patients were 32%, 63%, and 37 months, and those of recent 29 epithelioid patients from 2011 were 43%, 72%, and 59 months (Figure).



Conclusion: This tri-modality treatment strategy with EPP, radiation, and chemotherapy for MPM is feasible, and the prognosis has been greatly improved.

P2.06-18 TARGETING POLYAMINES FOR TREATMENT OF MALIGNANT PLEURAL MESOTHELIOMA IN XENOGRAFT MODELS

S.K. Lam, S. Yan, J.C.-M. Ho

The University of Hong Kong, Hong Kong/Hong Kong PRC

Background: Inhaling asbestos fibers is the commonest cause of malignant pleural mesothelioma (MPM). Although the import and use of asbestos have been restricted, the incidence of MPM is still rising due to a long lag time in malignant transformation. In 2004, the US Food and Drug Administration approved a combination of pemetrexed with cisplatin for treatment of unresectable MPM. However, overall prognosis is still extremely poor. As such, development of novel therapeutic options is urgently needed. Ornithine decarboxylase (ODC) is highly expressed in 211H and H226 MPM xenografts and clinical tumor samples. Upregulation of ODC increases polyamine production and enhances tumor growth. a-difluoromethylornithine (DFMO) is a specific ODC inhibitor which can suppress polyamines production. Recent preclinical studies have demonstrated the therapeutic effect of DFMO in colon cancers using xenograft model. However, therapeutic effect of DFMO in MPM has not yet been studied. This study aims to disclose the therapeutic effect of DFMO in MPM xenograft models. The findings from this study will provide scientific foundation for future design of clinical trials of DFMO for therapy for advanced MPM. **Method:** Nude mice were subcutaneous inoculated with tumor cells [211H (biphasic) or H226 (epithelioid)]. Mice were treated with DFMO in drinking water when tumor size reached 50-100 mm3. Mice with tumor size >600mm3 were considered reaching humane endpoint. Spermidine levels, protein expression, cytokines concentrations and apoptosis were investigated by Dot plot, Western blot, ELISA and TUNEL assay respectively. **Result:** DFMO suppressed tumor growth in both xenografts. DFMO increased median survival from 29 days in control arm to 41 days in treatment arm in mice with 211H xenografts (p = 0.0234), while from 30 days to 43.5 days in those with H226 xenografts (p = 0.0050). There was no synergism when combining DFMO (0.5% or 2%) with either cisplatin (1.25 or 2.5 mg/kg) or pemetrexed (75 or 150 mg/kg). The tumor suppressive effect of DFMO was more effective when compared with cisplatin or pemetrexed. Upon DFMO treatment, decrease in spermidine level, increase in nitrotyrosine content, and activation of apoptosis were observed in both xenografts. In addition, increase in nitrosocysteine level, increase in intratumoral IL-6, keratinocyte chemoattractant (KC) and TNF alpha as well as elevation of DNA lesion and downregulation of pAkt were induced by DFMO in H226 xenografts. **Conclusion:** DFMO may have a potential role in treating MPM. Acknowledgment: This research was supported by Hong Kong Pneumoconiosis Compensation Fund Board, HKSAR and YC Chan Scientist Award.

P2.06-19 A META-ANALYSIS OF MESOTHELIN, OSTEOPONTIN, AND FIBULIN-3 AS BIOMARKERS OF MALIGNANT PLEURAL MESOTHELIOMA

C. Gillezeau, M. Van Gerwen, J. Ramos, R. Flores, M. Van Gerwen, E. Taioli

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Malignant Pleural Mesothelioma (MPM) is a rare and aggressive cancer; the use of mesothelin, fibulin-3, and osteopontin as biomarkers has been proposed as a screening tool. The following meta-analysis examines average levels of these biomarkers in blood and pleura in comparison to several control groups. **Method:** A PubMed search was conducted for studies that measured the levels of mesothelin, osteopontin, and fibulin-3 in patients with MPM compared to several control groups (other malignancies, benign lung disease, or healthy participants). **Result:** Thirty two studies with 28 distinct datasets were identified as reporting mesothelin levels. Statistically significant mean differences (MD) were observed between mesothelin in the blood of MPM patients and each of the control groups. The overall MD (95% confidence interval) between MPM and non-MPM controls was 3.88 (2.73-5.05) nM/L (nMPM=455). Statistically significant MDs in pleural levels of mesothelin were also seen between MPM patients and non-MPM cancers and benign lung diseases. The overall MD (95%CI) was 31.45 (23.63-39.27) nM/L (nMPM=571). Twelve articles with 10 distinct datasets reported the mean level of osteopontin in MPM cases and controls. Statistically significant MDs in blood levels of osteopontin were seen between MPM patients and benign lung diseases or healthy controls (overall MD (95% CI) 103.75 (54.77-152.72) ng/mL (nMPM=504)), but not with other cancers. Studies on pleural levels of osteopontin were too scarce to conduct a meta-analysis. Nine articles measured fibulin-3 in blood or pleura of MPM patients compared to controls. There was a statistically significant MD in blood levels of fibulin-3 between MPM and each of the control groups. The overall MD (95%CI) was 46.52 (34.04-59.00) ng/mL (nMPM=330). There was also a statistically significant MD in the pleural levels of fibulin-3 between MPM and the cancer and benign lung disease groups. The overall MD (95% CI) was 385.35 (287.98-482.73)ng/mL (nMPM=137). **Conclusion:** This meta-analysis supports the concept that mesothelin and fibulin-3 in control groups are significantly lower than in MPM, and thus they might be useful as screening biomarkers. Further studies are necessary to better assess the value of these promising biomarkers.

Keywords: Biomarker, Meta-analysis

P2.06-20 CHARACTERIZATION OF CLAUDIN15 AS A NEW DIAGNOSTIC MARKER FOR MALIGNANT PLEURAL MESOTHELIOMAS

M. Watanabe[1], T. Higashi[2], H. Mine[1], H. Takagi[1], Y. Ozaki[1], S. Muto[1], N. Okabe[1], T. Hasegawa[1], Y. Shio[1], K. Sugimoto[2], H. Chiba[2], H. Suzuki[1]

[1]*Fukushima Medical University Department of Chest Surgery, Fukushima/Japan,* [2]*Fukushima Medical University Department of Basic Pathology, Fukushima/Japan*

Background: Malignant pleural mesotheliomas (MPMs) is a fatal disease mainly caused by past exposure to asbestos. MPMs are classified into three main histological subtypes: epithelioid, sarcomatoid, and biphasic type. There have been known several immunopathological markers for diagnosing MPMs, but there are not enough reliable markers, which often makes it difficult to diagnose MPMs correctly. In the present study, we investigated whether Claudin15 serves as a diagnostic and therapeutic target for MPMs. Claudins are four-transmembrane proteins and form a protein family consisting 27 members in humans. Specific combination of claudins are differentially expressed in different organs and form tight junctions with different permeability. Expression of Claudin15 has been known to be increased at mRNA level in MPMs. **Method:** Since 2003 to 2018, 34 patients were diagnosed with MPMs in our hospital. We made a new anti-Claudin15 rat monoclonal antibody, and established a hybridoma clone suitable for IHC. We immunostained 34 tissues with newly established anti-Claudin15 antibody, and compared the staining intensity and occupation with those of Calretinin, a known marker for MPMs. We also immunostained poorly differentiated lung adenocarcinomas, which are sometimes hardly distinguishable with MPMs, with anti-Claudin15 antibody to examine whether Claudin15 staining can distinguish MPMs from adenocarcinomas. **Result:** Of the 34 cases, the epithelial type was 27 cases, the sarcomatoid type was 1 case, and the biphasic type was 6 cases. The overall expression rate was 53% for Claudin15 and 59% for Calretinin. In terms of histology type, Claudin15 was 50% and Calretinin was 65% in the epithelial type, while Claudin15 was 80% and Calretinin was 40% in the biphasic type. There was only one sarcomatoid type, neither was expressed. Poorly differentiated adenocarcinomas showed no or very low-level expression of Claudin15. **Conclusion:** Our results suggest that Claudin15 could be a novel diagnostic marker for MPMs, especially for biphasic type. Greater number of cases and further analyses would be required to establish Claudin15 as a diagnostic impact for MPMs in clinical use.

P2.06-21 EFFICACY AND SAFETY OF TUMOR TREATING FIELDS DELIVERY TO THE THORAX BY COMPUTATIONAL SIMULATIONS

N. Urman, Z. Bomzon, H. Hershkovich, O. Yesharim, A. Naveh, U. Weinberg, E. Kirson, Y. Palti

Novocure Ltd, Haifa/Israel

Background: Tumor Treating Fields (TTFields), an anti-mitotic therapy low intensity, intermediate frequency, alternating electric fields, are approved for glioblastoma. The STELLAR phase 2 registration trial recently demonstrated a significant extension in overall survival in mesothelioma patients treated with TTFields and standard of care chemotherapy vs historical control data on chemotherapy alone. The results highlight the potential benefit of TTFields to treat cancer located in the thorax. Preclinical studies show that efficacy increases with the intensity of the electric field. Optimizing treatment requires a thorough understanding of how TTFields distribute within the body. Simulations can be used to evaluate the treatment safety by assessing tissue heating associated with absorption of the electric field. We present a simulation based study on field distribution and associated heating when delivering TTFields to the thorax. **Method:** We delivered TTFields to the thorax of realistic computational phantoms of a male, female, and obese male (ZMT, Zurich, Switzerland). The field was delivered to the computational phantoms using transducer arrays similar to those used to deliver TTFields to the thorax with the NovoTTF-100L. The field intensities within the lungs of the models were evaluated. Specific Absorption Rate (SAR), a metric for assessing heating due to electromagnetic absorption, was calculated. **Result:** The highest field intensities within the lungs were obtained when the arrays were axially-aligned with the parenchyma as anatomically possible. Field intensities throughout the lungs exceeded the therapeutic threshold of 1 V/cm in all models. Within the internal organs, SAR values were below the allowed level of 10 W/kg set out in the ICNIRP guidelines for occupational exposure. Maximum SAR levels did not exceed 20 W/kg. Occupational exposure standards typically incorporate a safety factor of around 10 when setting basic restrictions, therefore this level of SAR is considered safe and unlikely to lead to heat-related tissue damage. **Conclusion:** TTFields can be delivered to the lungs at therapeutic levels that do not cause damage through tissue heating.

Keywords: Safety, Tumor Treating Fields, Efficacy

P2.06-22 IS LABORATORY PROGNOSTIC INDEX A VALUABLE PROGNOSTIC INDEX FOR MALIGNANT PLEURAL MESOTHELIOMA?

T. Basoglu Tuylu[1], N.C. Demircan[1], R. Arikan[1], T. Akin Telli[1], O. Alan[1], O. Ercelep[2], E. Bozkurtlar[1], D. Kocakaya[1], S. Kaya[2], N. Babacan[2], T. Lacin[1], F. Dane[1], R. Ahiskali[1], H. Batirel[1], P.F. Yumuk[1]

[1]*Marmara University School of Medicine, Marmara University Pendik Training & Research Hospital, Istanbul/Turkey,* [2]*Marmara University Pendik Training & Research Hospital, Istanbul/Turkey*

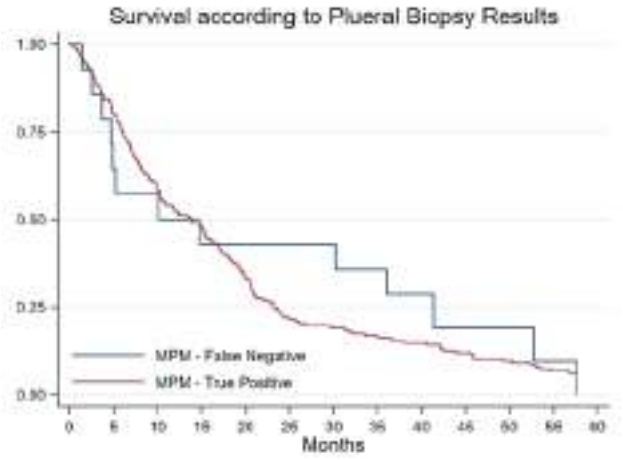
Background: Prognostic significance of Laboratory Prognostic Index (LPI) was demonstrated in non-small cell lung cancer before. We aimed to assess the prognostic value of LPI in patients with malignant pleural mesothelioma (MPM). **Method:** Records of MPM patients were examined retrospectively for serum laboratory results at diagnosis along with demographical and clinicopathological features. LPI is consisted of white blood cell count (>10000/mm3), albumin (<3.5 g/dL), lactate dehydrogenase (>248 U/L), alkalene phosphatase (>120 U/L) and calcium (>10.5 mg/dL) levels; and it is graded according to the number of abnormal parameters: 0 (none), 1 (one) and 2 (two or more). Kaplan-Meier method and stratified log-rank test were used in univariate analysis and a Cox regression model was conducted to determine independent predictors of overall survival (OS). **Result:** Sixty-one patients were included in the study. Median age at diagnosis was 59 (51-66) years. 45 deaths (73.8%) have occurred at the time of final analysis and median OS was 19.5 months. One-year survival rates for patients with LPI 0, 1 and 2, were 82%, 61% and 59%; 2-year survival rates were 75%, 47% and 24%, respectively. Median OS of patients with LPI 0, 1 and 2 were 36.5, 21.7 and 15.6 months, respectively (p=0.007). Age, ECOG performance status, histology, hemoglobin level and LPI were found to effect OS significantly or to have a trend (p<0.1). In multivariate analysis, LPI (p=0.033) and ECOG performance status (p<0.001) were the independent prognostic factors. **Conclusion:** The LPI may be a valuable prognostic factor in mesothelioma as well. Larger studies are needed to confirm this result.

P2.06-23 THE ACCURACY OF VIDEO-ASSISTED THORACIC SURGERY PLEURAL BIOPSY IN PATIENTS WITH SUSPECTED MALIGNANT PLEURAL MESOTHELIOMA: A REAL-LIFE STUDY

F. Guerrera[1], E. Migliore[2], P. Lausi[1], L. Delsedime[3], L. Costardi[1], D. Di Cuonzo[2], P. Lyberis[1], P.L. Filosso[1], M.G. Papotti[3], E. Ruffini[1], D. Mirabelli[2]

[1]*University of Torino, Torino/Italy,* [2]*AOU Città della Salute e della Scienza di Torino and CPO Piemonte, Torino/Italy,* [3]*AOU Città della Salute e della Scienza di Torino and University of Torino, Torino/Italy*

Background: The heritage of occupational and environmental asbestos exposure in Piedmont, Italy, is an enduring epidemic of malignant pleural mesothelioma (MPM). Pleural biopsy (PB) performed *via* thoracoscopy (or video-assisted thoracic surgery (VATS)) remains the diagnostic gold standard for patients with suspected mesothelioma. The aim of our study was to investigate the accuracy of PB *via* VATS and to analyze the diagnostic path of the patients who experienced an initial MPM misdiagnosis. **Method:** Patients who underwent PB by VATS for suspected MPM from 2004 to 2013 were analyzed . The Registry of Malignant Mesothelioma (RMM) records were examined to crosscheck incident cases and to recognize misdiagnosed MPM. Sensitivity and specificity of the initial PB assessment versus the final classification of cases by RMM were evaluated. Overall survival (OS) was estimated using the Kaplan-Meier method and compared using log-rank test. **Result:**



Data of 552 patients were analyzed. Of those, MPM was diagnosed in 178 cases (32%) and no false-positive PBs were observed. Sensitivity and specificity were 93% and 100%, respectively. The number of false-negative PBs was 14 (2%). Of those, 10 (71%) had an initial diagnosis of chronic pleuritis, 3 (28.5%) of atypical mesothelial proliferation and 1 had reactive mesothelial proliferation. All of them reported a history of asbestos exposure and the correct diagnosis was reached after a median of 160 days (interquartile range 86-243) as follow: 9 (64%) after a further PB by VATS, 3 (22%) by cytology examination of a pleural effusion, 1 (7%) by fine-needle biopsy and 1 (7%) by open surgery . The median survival time of the patients with eventual MPM diagnosis was 13.8 months (CI 95%: 10.3-16.6).). One- and 4-year survival were 52% and 10% in MPM PB positive cases and 50% and 19% in false-negative cases (P=0.66) (Figure 1). **Conclusion:** When a history of asbestos exposure is reported and a strong clinical suspicion persists after a negative PB, iterative biopsy attempts should be considered. In high-volume centers, MPM misdiagnosis rate remains small and future advancement in diagnostic technologies could further increase the accuracy of diagnosis.

P2.06-24 MESOTHELIOMA SURVIVAL IN 2 HEALTH CENTRES IN SANTIAGO DE CHILE

J. Fernandez[1,2], T. Alfaro[3], G. Martine<[2], E. Rivera[1], S. Oksenberg[1], J. Pichon[1], M. Fica[1]

[1]*Hospital San José, Santiago/Chile,* [2]*Universidad de Chile, Santiago/Chile,* [3]*Instituto Salud Poblacional, Santiago/Chile*

Background: Malignant pleural mesothelioma (MPM) is a rare but lethal tumour arising in the 5th – 7th decade of life of predominantly male industrial workers of developed countries. The prognosis is dismal because of early spreading and scarcity of therapies. Surgery (extrapleural pneumonectomy or pleurectomy/decortication) has shown some improvement in patient survival, even more important with the addition of radio or chemotherapy. Patients unfit or with advanced disease are treated with palliative chemotherapy or palliative care alone. Some centres (or countries) doesn't have the resources to embark in such aggressive and expensive managements, pondering the idea that in mesothelioma patients, complex therapies are only a futility exercise not worth the investment in herculean surgery or costly and patient-consuming radio or chemotherapy. The question if aggressive therapy is superior to nihilist approaches in terms of survival (SV) is difficult to answer but of critical importance in developing countries **Method:** Consecutive patients pathologically diagnosed with MPM of 2 health centres in the same city and time frame were assessed. Centre A is a public Hospital with an assigned population of 1 million, without thoracic surgeon and oncologic committee, and patients were seldom referred to palliative chemotherapy. Centre B is a terciary, referral academic university Hospital with Thoracic surgeons and oncologic committee. Centre A had 10 patients reviewed and centre B 20. Both cohorts were examined in terms of treatment and SV **Result:** The 2 series were comparable in terms of age (median=61,5) and sex (masculine: 70% for Centre A, 80% for Centre B). Centre A had 30% of patients with presence of metastasis at the time of diagnosis, while centre B had 10%. In centre A 2 of 10 patients received chemotherapy. In centre B: 9 patients had aggressive surgery, 7 patients received chemotherapy and 2 patients received radiotherapy. Kaplan Meier estimate showed 12-month SV of 51% (CI95% 16-79) in centre A and 59% (CI95% 35-77) in centre B, but there were no statistical differences between both groups **Conclusion:** Few patients were diagnosed (30 overall) in line with chilean epidemiology. The 2 centres had radically different resources and approaches to treat this illness, however, even though there is a tendency towards better survival in Centre B, there were no statistically differences between both groups. Differences could appear increasing the follow-up time or including more centres, alternatively, the rarity of this disease could produce oncologic teams with not enough experience dealing with it affecting survival outcomes.

P2.06-25 MESOTHELIOMA UK ARMED FORCES PROJECT: ESTABLISHING A NATIONAL SUPPORT SERVICE FOR VETERANS / ARMED FORCES PERSONNEL WITH MESOTHELIOMA

A. Moylan[1], L. Darlison[2], H. Wilkes[3], L. Booth[4], M. Bhayani[5]

[1]*Portsmouth Hospitals NHS Trust, Portsmouth/United Kingdom,* [2]*Mesothelioma UK, Leicester/United Kingdom,* [3]*University Hospital Southampton, Southampton/United Kingdom,* [4]*HASAG, Southampton/United Kingdom,* [5]*Sandstar Communications, Leicester/United Kingdom*

Background: In 2012 the UK Government announced that fines levied against banks for manipulating the London Inter-Bank Offered rate (LIBOR) rates would be used to support Armed Forces and emergency charities. In 2016 Mesothelioma UK (MUK) applied for a grant from this scheme to support a three year project to develop a specialist service for Armed Forces personnel and veterans affected by mesothelioma – the asbestos related cancer. **Method:** The aim of the project is to increase awareness and support for both serving and ex- military personnel who may have been exposed to asbestos. A work group which included representatives from MUK, patients/carers, advocacy groups and Veterans UK was established by MUK to set the fundamental elements of the project: • Provide a specialist mesothelioma nurse to lead the project • Provide a finance and benefits advisor specifically for Armed Forces personnel and veterans. • Work with multiple organisations and healthcare professionals, responsible for meeting the healthcare needs of Armed Forces personnel and veterans, to raise awareness about mesothelioma and available support. • Develop and deliver a range of information resources to raise awareness of the disease within the Armed Forces and military community. • A Facebook group Armed Forces patients, their family and friends and anyone interested in finding out more. • A comprehensive research programme will collate all available data to quantify and describe the mesothelioma burden among the Armed Forces explore the experience of Armed Forces personnel diagnosed with mesothelioma.• **Result:** The project group developed a range of written information specifically aimed at the Armed Forces community focusing on raising awareness of asbestos exposure within the military. Awareness events proved to be a major factor in the growth of the project providing excellent networking opportunities and resulting in invitations to speak and exhibit at other events. A list of organisations and relevant groups was developed in preparation for the national roll out. A range of social media is used to publicise the project and events. A research project - Military Mesothelioma Experience Study (MiMES) has been developed with University of Sheffield and is recruiting. **Conclusion:** .The development of this service has been very well received by the Armed Forces community and the project continues to gather momentum, widening the range of contacts and links made. We are planning a programme of roll out throughout the UK using the network of MUK funded mesothelioma nurse specialists to facilitate service delivery in their regions.

P2.06-26 THE MILITARY MESOTHELIOMA EXPERIENCE STUDY (MIMES): INITIAL FINDINGS AND IMPLICATIONS FOR PRACTICE

A. Tod[1], L. Darlison[2], S. Ejegi-Memeh[2], B. Taylor[1]

[1]*University of Sheffield, Sheffield/United Kingdom,* [2]*Mesothelioma UK, Leicester/United Kingdom*

Background: Background Mesothelioma is one of the most challenging of cancers; it is incurable, has a long latency period, and is associated with extreme symptom burden. Mesothelioma mostly affects men over 65 years of age; It is linked to exposure to asbestos, normally 15-40 years prior to diagnosis. Its industrial nature diagnosis can mean navigating complex health, legal and welfare systems. Clinical experience and anecdotal evidence from health professionals indicate that this veterans encounter particular challenges in recognising and reporting early symptoms, getting a diagnosis and accessing care and support, including financial help. Little is known about mesothelioma amongst UK military veterans. Research is required to better understand the mesothelioma experience amongst UK military veterans and know how better to meet their needs. **Method:** Methods The Military Mesothelioma Experience Study (MiMES) is a qualitative interview based study that aims to identify the care and support needs of UK military veterans with mesothelioma from the perspective of veterans, family carers, and health professionals and support agency staff. This paper presents findings from the patient and carer data. Semi-structured interviews of up to 15 veterans with mesothelioma and 15 family carers are being conducted. Recruitment is via trusted charitable organisations including Mesothelioma UK and Asbestos Support Groups. Interviews are transcribed and analysed using Framework Analysis techniques. Interviews are being conducted between December 2018 and June 2019. 10 participants have been recruited to date (7 patients and 3 family carers). **Result:** Results The findings provide unique insight into the nature of asbestos exposure whist in the armed forces, as well as participant's diagnostic experience. The impact of military culture on how people respond to the diagnosis and how they navigate services is considered. Valued sources of support included specialist mesothelioma medical and nursing staff as well as mesothelioma/asbestos charities. Participants reported feeling 'in the middle' when it came to understanding legal and financial implications of their disease and asbestos exposure in the military. Being caught between civil and military claim systems and information services could create problems, especially when making a claim was time-pressured. This had an impact on people's quality of life over across the patient pathway. **Conclusion:** Conclusions MiMES is the first study to explore the experiences of UK military veterans with mesothelioma. Implication for practice and collaborative working are considered.

Keywords: Mesothelioma, epidemiology, patient experience

P2.08-01 OUTCOMES FOLLOWING GAMMA KNIFE RADIOSURGERY FOR OLIGOMETASTATIC BRAIN METASTASES IN PATIENTS WITH NSCLC AT LEEDS CANCER CENTRE

R. Samuel, O. Coen, G. Higginbotham, G. Wright, P. Hatfield, K. Franks, P. Jain, M. Snee, K. Clarke

Leeds Cancer Centre, Leeds/United Kingdom

Background: Gamma knife (GK) radiosurgery has increasingly been used for brain metastases from NSCLC in the oligometastatic setting. This study reports outcome results for patients with synchronous brain and new brain metastases from NSCLC at Leeds Cancer Centre (LCC). **Method:** 251 patients, who were treated with GK at LCC from 2009 until 2018 were analysed. Retrospective analysis of notes was performed using electronic patient records. Statistical analysis was performed using SPSS. Kaplan-Meier curves were performed to estimate time to intracranial progression, survival from diagnosis of brain metastases, and overall survival. **Result:** Median age was 65 years (range 33 – 90 years). For patients with new brain metastasis (147 patients), TNM stage at diagnosis was stage I (14 patients), stage II (42 patients), stage IIIA (26 patients) or stage IIIB/IV (65 patients). Histology was majority adenocarcinoma (59%), squamous cell carcinoma (16%) or NSCLC NOS (13%). Radical thoracic treatment (surgery, chemoradiotherapy or stereotactic ablative radiotherapy) was undertaken for 158 patients. 92% completed radical thoracic treatment. Median survival from diagnosis of brain metastases was 382 days (446 days for those with synchronous brain metastases (48 patients), and 325 days for those with new brain metastases (110 patients)). For all patients, median time to intracranial progression after GK was 242 days and overall survival after GK was 293 days. For patients with synchronous brain metastases at presentation (104 patients), median time for overall survival from date of diagnosis was 435 days. For all patients without brain metastases at presentation, median time to intracranial progression from date of diagnosis was 305 days and overall survival was 693 days. **Conclusion:** In conclusion, GK radiosurgery is an effective treatment for brain metastases in NSCLC, providing high rates of local control and improved survival. Beneficial effects are seen in patients with synchronous and new brain metastases, demonstrating its role in a wide subset of patients with advanced NSCLC. Use of GK, in combination with radical thoracic therapy, therefore has the potential to dramatically improve survival in patients who may not have previously been suitable for radical treatment.

Keywords: NSCLC, Brain metastases, oligometastatic disease

P2.08-02 OUTCOMES FOLLOWING STEREOTACTIC RADIOSURGERY FOR SYNCRONOUS BRAIN METASTASES IN NON-SMALL CELL LUNG CANCER

F. Wilson[1], S. Yousif[1], Y. Li[2], N. Bayman[1], C. Chan[1], D. Cobben[1], R. Colaco[1], J. Coote[1], C. Faivre-Finn[3], R. Gattamaneni[1], M. Harris[1], A. Hudson[4], L. Pemberton[1], A. Salem[1], H. Sheikh[1], A. Tran[1], G. Whitfield[1], C. Mcbain[1], D. Woolf[1]

[1]*Christie NHS Foundation Trust, Manchester/United Kingdom,* [2]*University of Manchester, Manchester/United Kingdom,* [3]*The University of Manchester and The Christie NHS Foundation Trust, Manchester/United Kingdom,* [4]*Manchester Cancer Research Centre, Manchester/United Kingdom*

Background: Approximately 10% of non-small cell lung cancer (NSCLC) patients have brain metastases at presentation. The use of stereotactic radiosurgery (SRS) has enabled a proportion of patients with oligometastatic brain disease to be offered a radical treatment in conjunction with SRS. We evaluated the outcomes for patients presenting with synchronous brain metastases who received SRS to determine if radical treatment improves survival. **Method:** 164 patients with NSCLC received SRS for brain metastases between January 2012 and December 2017. This analysis focused on 71 patients who presented synchronously with brain metastases. Electronic patient records were accessed in March 2019 to determine initial extracranial disease treatment and date of death or last follow up. **Result:** 30 patients received radical treatment (18 radiotherapy alone, 11 chemo-radiotherapy and one surgery) and 24 received palliative treatment (17 chemotherapy, four radiotherapy and three tyrosine kinase inhibitor). 17 patients received no treatment following SRS, either due to death, deterioration in performance status or patient choice. Baseline demographics are presented in table 1.

	Radical	Palliative	No treatment
Mean age at diagnosis (+/-SD)	68.3 (8.9)	58.5 (14.5)	61.4 (10.4)
Male (%)	18 (60.0)	10 (41.7)	8 (47.1)
Female (%)	12 (40.0)	14 (58.3)	9 (52.9)
ECOG Performance Status			
0	9 (30.0%)	7 (29.2%)	7 (41.2%)
1	18 (60.0%)	17 (70.8%)	9 (52.9%)
2	3 (10.0%)	0 (0.0%)	1 (5.9%)
Mean number of brain metastases (+/- SD)	1.7 (1.1)	1.9 (1.6)	1.7 (0.9)
T stage			
1	3	5	1
2	14	8	9
3	8	6	4
4	5	5	3
N stage			
0	15	2	4
1	4	3	4
2	8	13	7
3	3	6	2

Table 1 Baseline demographics

Median overall survival for the radical, palliative and no treatment groups were; 7.9 (95% CI 5.5-14.0), 9.4 (6.6-14.4) and 1.4 (1.0-2.9) months, respectively. There was no significant difference in survival between the radical and palliative groups (p=0.43). Kaplan-Meier survival estimates at 12 and 24 months were 30.0% (95% CI 17.4-51.8%) and 10.0% (3.4-29.3%) for the radical and 33.3% (18.9- 58.7%) and 13.0% (4.1-41.4%) in the palliative group, respectively. **Conclusion:** Our results did not demonstrate the benefit for radical treatment, as expected based on published data. Potential reasons for this result include a lack of tools to select patients for radical treatment. Prospective studies are needed to identify the optimal treatment for extracranial disease in this patient group.

Keywords: Brain, synchronous, SRS

P2.08-03 CLINICAL OUTCOME OF PATIENTS WITH RECURRENT NON-SMALL CELL LUNG CANCER AFTER TRIMODALITY THERAPY

K. Suzawa, K. Araki, K. Nakata, S. Miyauchi, A. Miura, K. Namba, S. Otani, H. Yamamoto, M. Okazaki, S. Toyooka

Okayama University Hospital, Okayama/Japan

Background: Trimodality therapy, consisting of induction chemoradiotherapy (CRT) followed by surgery, is a potential treatment option for patients with locally advanced (LA) non-small cell lung cancer (NSCLC), such as N2-3, bulky N1, or T3-4 stage disease. However, even after completing this intensive treatment, postoperative recurrence will develop in a subset of patients. Patients with distant metastatic recurrences are generally considered to have systemic disease, which is regarded as incurable. Nevertheless, some patients have a relatively good prognosis following this treatment, even after postoperative recurrence. **Method:** We analyzed the records of 182 patients with LA-NSCLC who were treated with trimodality therapy between 1999 and 2017 to review the clinical course of those patients and to identify the factors associated with favorable clinical outcome after recurrence. In this study, oligometastasis was defined as one to three metastatic lesions in the brain, or an isolated extracranial metastatic lesion. **Result:** In 182 patients patients who underwent trimodality therapy for LA-NSCLC, the median follow-up period after the beginning of CRT was 50 months, the median age was 61 years (range, 31–78 years), and Recurrence developed after trimodality therapy in 65 patients (35.7%). The median recurrence-free interval, being the period between the administration of trimodality therapy for the primary tumor and initial recurrence, was 11 months (range, 4.1–73.9 months). Of the 62 of these patients able to be assessed retrospectively, The brain was the most frequent location of recurrence (31%), followed by the lung (27%), lymph nodes (24%), and bone (15%). Twenty-eight had oligometastatic recurrence and 30 underwent local treatment with curative intent. Local treatment was most frequently given to patients with oligometastatic recurrence ($P < 0.001$). The median post-recurrence survival (PRS) was 15.1 months, and the 2-year

PRS rate was 57%. Patients who received local treatment showed better PRS (P = 0.004). The presence of liver metastasis (P = 0.003), bone metastasis (P = 0.034), or dissemination (P < 0.0001) were associated with worse PRS. **Conclusion:** The survival of patients who received aggressive local treatment for postoperative recurrence after trimodality therapy for LA-NSCLC was better than that of patients who did not.

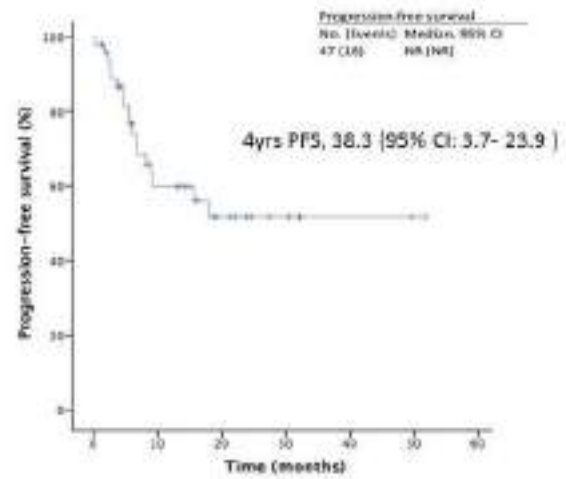
Keywords: induction chemoradiotherapy, local treatment, oligorecurrence

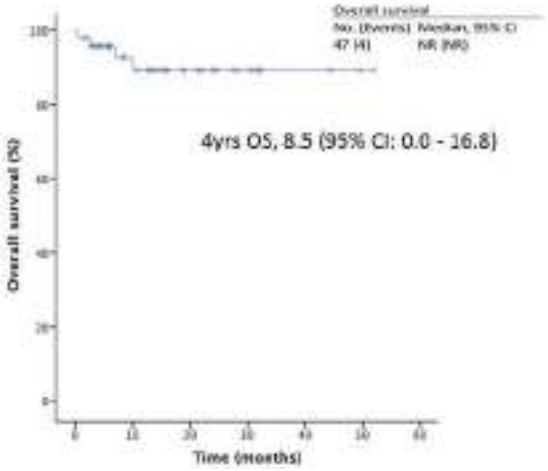
P2.08-04 STEREOTACTIC ABLATIVE RADIATION THERAPY TO LUNG METASTASES ASSOCIATES WITH BETTER OUTCOMES IN OLIGOMETASTATIC LUNG CANCER: PROSPECTIVE STUDY

M. Blake-Cerda[1], F. Lozano Ruiz[2], F. Maldonado Magos[2], D. De La Mata-Moya[3], D.A. Diaz-Garcia[1], L. Ramírez-Tirado[1], M.F. Cuevas Góngora[1], F. Barrón[1], R. Gerson[3], O.G. Arrieta[1]

[1]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [2]*Instituto Nacional de Cancerología, CDMX/Mexico,* [3]*ABC Medical Center, Mexico City/Mexico*

Background: Nearly 7% of stage IV Non-Small cell Lung Cancer (NSCLC) patients present oligometastatic disease at diagnosis. These patients can benefit from definitive treatment to primary tumour and loco-ablation of metastases. The use of stereotactic ablative radiotherapy (SABR) has demonstrated high rates of local control and survival improvement in early disease stage. The aim of this study is to evaluate Progression Free Survival (PFS), Overall survival (OS) and toxicity of patients with oligometastatic NSCLC treated with Stereotactic ablative radiotherapy (SABR) to lung metastases. **Method:** A prospective study was conducted with oligometastatic NSCLC patients. From August 2014 to April 2019, with a median follow up of 13 months, forty-seven patients were enrolled. All patients received systemic therapy according to international guidelines. Then, patients without progression to systemic treatment, received SABR to lung metastases (30-60 Gy in 2-8 fractions) to the thoracic lesion (primary or metastatic) depending on location, size and number of lesions, always keeping BED (Biologically Effective Dose) >100 Gy at isocenter. This study was approved by Ethic and Research comitees at Instituto Nacional de Cancerología (CEI/799)(013/014/ICI). **Result:** Most patients were women (59.6%), with a mean age of 58.9 years. Although two-thirds of patients were ever smokers (66.0%), most of them were light smokers. The most common histology was adenocarcinoma (87.2%). Contralateral lung was the most common metastatic site (40.4%). Half of the patient harbour at least one mutation, EGFR Exon 19 deletion was the most frequent mutation (38.3%). Patients received chemotherapy and EGFR-TKIs as 1st-line treatment in the 61.1% and 38.9%, respectively. All patients received SABR, response to treatment was as follows: disease control rate was 91.5%, partial response 14.9% and complete response 63.8%. Among those with disease progression, median time to systemic progression after SABR treatment was 5.4 months (95% 2.4-8.9 months). PFS since beginning of any treatment was not reached, since only 18 patients (38.3%) had disease progression. Until now only 4 patients (8.5%) had died, thus OS is not reached. Radiographic pneumonitis was observed in 72.2% (13 patients). Grade 1, 2 and 3 pneumonitis were observed in the 69.2% (9/13), 7.7% (1/13) and 23.1 (3/13) of the patients with pneumonitis.





Conclusion: SABR is a suitable and has a moderate toxicity profile. SABR is a therapeutic option for patients with oligometastatic NSCLC. SABR have shown to improve local control and increase progression-free survival. Future clinical trials are required to evaluate SABR against other treatment modalities.

P2.08-05 THE ROLE OF SURGICAL TREATMENT FOR PATIENTS WITH NSCLC DEMONSTRATING LIMITED PLEURAL DISSEMINATION

H. Matsuguma, I. Wakamatsu, R. Nakahara, T. Sugiyama, Y. Nakamura, T. Kasai, Y. Kamiyama, N. Hoshi

Tochigi Cancer Center, Utsunomiya/Japan

Background: Pleural dissemination or malignant pleural effusion confirmed during surgery generally indicates incurable disease and is a contraindication for lung resection. However, recent studies suggested that complete removal of the disseminated nodule in combination with lung resection is associated with long-term survival when dissemination is limited. This study investigated whether there is a curable subgroup of patients with NSCLC exhibiting limited malignant pleural disease (MPD). **Method:** Among 1966 patients who underwent lung surgery for primary lung cancer at our institution between 1986 and 2015, 61 patients were diagnosed with MPD during the operation. Excluding 3 patients who had other active malignancies and 2 patients who were lost to follow-up, we analyzed 59 patients, including 33 who had signs of MPD on preoperative CT. The type of surgery was biopsy only for 26, extrapleural pneumonectomy (EPP) for 17, lobectomy for 13, and wedge resection for 3. Macroscopic complete resection (MCR) was carried out for 24 patients. All but one patient were followed until December 2018 or death, and the follow-up period for surviving patients ranged from 48 to 361 months (median 158 months). **Result:**

Overall and progression-free survival					
Patients group	**Type of surgery**	**Number of patients**	**5yOS/PFS(%)**	**10yOS/PFS(%)**	**15yOS/PFS(%)**
All patients		59	28.1/10.1	18.1/6.7	13.8/6.7
	MCR	24	37.5/25.0	25.0/16.7	20.8/16.7
	EPP	17	41.2/29.4	35.3/23.5	29.4/23.5
No sigh of MPD preoperatively		26	34.6/15.4	19.8/11.5	19.8/11.5
	MCR	11	45.5/36.4	27.3/27.3	27.3/27.3
	EPP	5	60/60	60/60	60/60
Any sign of MPD preoperatively		33	23.1/6.0	13.2/3.0	9.9/3.0
	MCR	13	30.8/15.3	23.1/7.6	15.4/7.6
	EPP	12	33.0/16.6	25.0/8.3	16.7/8.3

Among the 59 patients, 4 patients survived without recurrence for more than 10 years. Furthermore, 3 out of the 4 patients were still alive at 361 months, 300 months, and 211 months, respectively. Among the 4 patients, 3 patients did not exhibit signs of malignant pleural disease preoperatively, and all 4 patients underwent EPP. The overall and progression-free survival rates at 5, 10, and 15 years for all 59 patients, the 26 not exhibiting signs of MPD preoperatively, and the 33 patients with signs of MPD according to the type of surgery are presented in the Table. Prognostic factors significantly associated with longer progression-free survival were early clinical stage, adenocarcinoma histology, absence of pathological mediastinal nodal metastasis, MCR, and EPP. **Conclusion:** A curable subgroup may exist among patients diagnosed with malignant pleural disease during surgery, especially among those without signs of pleural disease preoperatively treated by EPP.

P2.08-06 DEVELOPMENT AND VALIDATION OF A 18F-FDG PET/CT-BASED RADIOMICS MODEL FOR PROGNOSIS PREDICTION IN SYNCHRONOUS OLIGOMETASTATIC NSCLC

X. Zhu[1], Y. Zhang[2], Z. Zheng[1], J. Luo[2]

[1]*The Radiation Oncology Department, Nanfang Hospital, Southern Medical University, Guangzhou/China,* [2]*School of Biomedical Engineering, Southern Medical University, Guangzhou/China*

Background: Oligometastatic non-small cell lung cancer (NSCLC) exists high heterogeneity with distinct outcome, and there is a lack of available biomarkers for patient stratification. In this study, we identified a positron emission tomography (PET)/computed tomography(CT)-based radiomics signature capable of predicting overall survival (OS) in patients with synchronous oligometastatic NSCLC. **Method:** A primary cohort consisted of 46 patients with synchronous oligometastatic NSCLC (≤5 metastases) between January 2012 and December 2017. Clinicopathologic data was acquired from medical records and database. A total of 20648 radiomic features were extracted from pretreatment CT and PET images, which were generated from the same PET/CT scanner. A radiomics signature was built by using the least absolute shrinkage and selection operator (LASSO) regression model. Multivariate Cox regression analysis was performed to establish the predictive model. A prospective internal validation cohort contained 14 patients from January 2018 to December 2018. The performance was evaluated with Harrell' concordance index (C-index). **Result:** 7 radiomics features were selected to build the radiomics signature. Smoking status (P=0.01) was the only independent clinicopathologic risk factor for overall survival prediction. Multivariate analysis indicated that the radiomics signature (P=0.007) was an independent prognostic factor, with a C-index of 0.810 and 0.900 for the primary and validation cohort. **Conclusion:** This study developed a radiomics model for predicting OS in synchronous oligometastatic NSCLC, which may serve as a predictive tool to identify individualized treatment strategy. Further external validation of the model are required. Support: 81572279, 2016J004, LC2016PY016, 2018CR033.

P2.09-01 CHARACTERISTICS OF DRIVER MUTATIONS IN EARLY LUNG ADENOCARCINOMA: FROM PREINVASIVE/ MINIMALLY INVASIVE TO INVASIVE ADENOCARCINOMA

Z. Liu, H. Liang, J. He, W. Liang

Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center for Respiratory Disease, Guangzhou/China

Background: It is still unclear when the gene mutation occurs during the carcinogenetic process, which progresses from preinvasive to invasive adenocarcinoma. We aim to investigate the driver gene alterations profile of adenocarcinoma in situ (AIS), minimally invasive adenocarcinoma (MIA) and invasive adenocarcinoma (IAC). **Method:** A total of 1219 patients with pulmonary nodes smaller than 3 cm were selected for this study. Driver mutation testing was performed with NGS in all resected tumor tissues. The incidence of mutations was calculated and compared among different subtypes. Logistic regression was used to further identify factors that may independently correlate with IAC. **Result:** In all 1219 patients with lung adenocarcinoma, 62 were diagnosed as AIS, 208 as MIA and 949 as IAC. Mutations were found in 809 (66.4%) patients. The frequency of mutations increased with the progression of tumor invasiveness: AIS (32.3%), MIA (45.2%) and IAC (73.2%)(P<0.001 between IAC and AIS, P<0.001 between IAC and MIA). The results (Figure 1) also showed an increasing trend towards more driver mutations from AIS to MIA, and to IAC. Multivariate analysis revealed that driver mutations was a factor associated with IAC (OR: 2.39, P<0.001). Of the genetic factors, EGFR, KRAS and ALK alterations were significant indicators of IAC (all P<0.020), and were found increased in IAC compared with AIS/MIA.

Conclusion: Genetic alterations occurs early in the development of lung adenocarcinoma and can be detected even before tumor have acquired malignant potential. Driver mutations gradually increase in tumorigenesis and progression from AIS to MIA, and finally to overt IAC. A better understanding of carcinogenesis in preinvasive/ minimally invasive cases may allow the development of effective preventive, screening, and treatment strategies.

Background: The aim of this study was to identify an objective way to define a long-term survivors(LTS) and short-term survivors(STS) in patients with surgically resected lung adenocarcinoma (ADK), and secondly to find peculiar clinicopathological features in these two groups of patients. **Method:** all patients who underwent major lung resection for lung ADK from 2000 to 2015 were studied.LTS and STS were extrapolated considering the overall survival(OS) and pathological tumour stage:the first and the fourth quartile of those patients with cancer-related death were considered for statistical analysis. **Result:** from 600 ADK patients we found 79 STS and 77 LTS;clinico-pathologic baseline characteristics are presented in Table 1.Considering STS patients, smoking habit, histotype, tumour necrosis, pleural invasion and pathological stage were significantly associated with OS at univariate analysis (Fig.1). In LTS patients, smoking habit, neoadjuvant chemotherapy, tumour-infiltrated lymphocytes and pathological stage were significantly associated with OS (Fig.2).On multivariate analysis, smoking status, lymphoid infiltrate, pleural invasion and stage remained significantly associated with OS (Table 2).

Table 1

Variable	Full sample[a]	STS (N=79)[a]	LTS (N=77)[a]	p-value
Age at diagnosis (median)	68 (62-74)	68 (61-74)	69 (64-75)	0.301

P2.09-03 PROGNOSTIC VALUE OF MUTATED KRAS IN CIRCULATING TUMOR DNA PRIOR TO THERAPY IN PATIENTS WITH LUNG ADENOCARCINOMA

S.G.F. Wahl[1,2], H.Y. Dai[1,2], E.F. Emdal[1], A.L. Ottestad[2], E. Richardsen[3,4], T.O. Halvorsen[1,2], B.H. Gronberg[1,2]

[1]*St. Olavs Hospital, Trondheim/Norway,* [2]*NTNU, Norwegian University of Technology and Science, Trondheim/Norway,* [3]*UiT, The Arctic University of Norway, Tromso/Norway,* [4]*University Hospital of North Norway, Tromso/Norway*

Background: Studies show an association between total tumor load and the amount of circulating cell-free tumor DNA (ctDNA) in blood, and that detectable ctDNA is a negative prognostic factor. *KRAS* mutations (mut*KRA*S) are the most common oncogenic drivers in lung adenocarcinomas (lungAC) and are found in 25-30 % of the patients. We hypothesized that the concentration of mut*KRAS* in plasma ctDNA is associated with outcomes in patients with lungAC harboring KRAS mutations, and aimed to investigate whether there was an association with disease stage, progression free (PFS) and overall survival (OS). **Method:** Blood samples collected prior to first treatment from 61 lungAC-patients with known mut*KRAS* in tumor DNA were analyzed. Digital droplet PCR was used for detection and quantification of mut*KRAS* in the plasma samples. The false positive rate for each mut*KRAS* assay was determined using cfDNA from healthy donors. A sample was defined as "positive" if the mut*KRAS* level was above the false positive rate. Mann-Whitney U test was used to compare PFS and OS between those with not-detectable and those with detectable mut*KRAS* ctDNA. Log-rank and Cox proportional hazard methods were used for survival analyses. One-way ANOVA was used to compare the concentration of mut*KRAS* between disease stages. **Result:** Median age was 68 years (range 47-83), all patients were former/current smokers, 39.3% were men; 39.3% had stage I, 18.0% stage II, 24.6% stage III and 18.0% stage IV; 55.7% had performance status (PS) 0, 39.3% PS 1, and 4.9% PS 2; 70.5% underwent surgery, 4.9% curative radiochemotherapy and 24.6% palliative treatment. Overall, 26.2% had detectable mutKRAS in ctDNA with a median of 119.68 (range:16.66-1208) copies/ml plasma.The proportion of patients with mutKRAS in plasma ctDNA increased with higher disease stage (stage I: 0%, II: 18%, III: 47%, and IV: 64 %; p=0.006). Patients with plasma mutKRAS had significantly shorter PFS (11.9 vs. 23.5 months; p=0.012) and OS (15.8 vs. 23.5 months; p=.0.010) than those without. The mutKRAS ctDNA concentration was significantly associated with both shorter PFS (HR 1.009, 95% CI 1.004-1.013; p<0.001) and OS (HR 1.007, 95% CI 1.003-1.011; p=0.001).The associations remained statistically significant in the multivariate analyses adjusting for baseline characteristics (gender, age, disease-stage, PS, treatment) for both PFS (HR 1.009, 95% CI 1.003-1.014; p=0.002) and OS (HR 1.008, 95% CI 1.002-1.015; p=0.008). **Conclusion:** The concentration of plasma mut*KRAS* increased with higher disease stage. Patients with detectable plasma mut*KRAS* had worse PFS and OS than patients without. The concentration of mutated *KRAS* was independently associated with worse PFS and OS.

P2.09-04 THE CLINICOPATHOLOGICAL CHARACTERISTICS AND PROGNOSIS OF LUNG CANCER WITH TUMOR SPREAD THROUGH AIR SPACES: A META-ANALYSIS

Y. Wen[1,2], G. Qiu[3], Z. Liu[2], H. Liang[2], J. He[2], W. Liang[3]

[1]*The First Affiliated Hospital of Guangzhou Medical University, National Clinical Research Center for Respiratory Disease, China State Key Laboratory of Respiratory Disease, Guangzhou/China,* [2]*The First Affiliated Hospital of Guangzhou Medical University, Guangzhou 5*[1]*0*[12]*0, China; State Key Laboratory of Respiratory Disease, Guangzhou 5*[1]*0*[12]*0, China; National Clinical Research Center for Respiratory Disease, Guangzhou/China,* [3]*The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center for Respiratory Disease, Guangzhou/China*

Background: The clinicopathological characteristics of lung cancer with tumor spread through air spaces (STAS) has not been clearly characterized yet. Also, it is still not clear whether the presence of STAS correlated with worse prognosis in patients with lung cancer. Thus, we aim to systematically evaluate the clinicopathological characteristics and prognosis of the patients with or without STAS undergoing surgical resection for lung cancer. **Method:** Materials and Methods: A comprehensive search of online databases was performed. Clinicopathological characteristics, 5-year RFS and OS rate were compared between 2 groups. Cumulative meta-analysis was performed to evaluate the temporal trend of pooled outcomes. Specific subgroups according to different types of lung cancer are examined. **Result:** A total of 25 eligible studies including 8494 patients were recruited. STAS occurred in 2881 patients (34%) while non-STAS occurred in 5613 patients (66%). Overall, patients with STAS manifested significantly more aggressive characteristics, including lymphatic invasion (SMD=2.935; P=0.000), pleural invasion (SMD=2.329; P=0.000), vascular invasion (SMD=2.306; P=0.000) as well as lymph node metastasis (OR=3.510; P=0.000). Patients with STAS also correlated with significantly higher pathological stage (OR=2.216; P=0.003), T stage (OR=1.756; P=0.000), N stage (OR=2.395; P=0.000) and larger tumor size (OR=0.275; P=0.001). Meanwhile, the incidence of STAS was significantly associated with the micropapillary (OR=9.792; P=0.000) and solid patterns (OR=2.451; P=0.000). Moreover, the presence of STAS was related to male sex (OR=1.493; P=0.000), smoking history (OR=1.637; P=0.000) and necrosis (OR=2.300; P=0.000). As for the outcomes of the prognosis, patients with STAS linked with significant worse prognosis than those without STAS, including both 5-year RFS (HR=0.585; 95% CI: 0.486–0.684; P=0.000) and 5-year OS rate (HR=0.788; 95% CI: 0.596–0.980; P=0.000). **Conclusion:** The presence of STAS was associated with several invasive pathological characteristics, which might explain the worse prognosis in patients with STAS compared with those without STAS.

[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/Italy,* [2]*Fondazione IRCCS Istituto Nazionale Tumori, Milan/Italy*

Background: Lung Enteric Adenocarcinoma (LEA) is a rare and poorly characterized variant of Lung Adenocarcinoma (LA), defined by an intestinal differentiation in ≥50% of tumor and ≥1 colorectal biomarker at Immunohistochemistry. **Method:** We retrospectively identified the cases of LEA diagnosed at Fondazione IRCCS Istituto Nazionale dei Tumori (INT), Milan, Italy between 01/2013 and 12/2018. Next Generation Sequencing was performed with IonTorrent (ThermoFisher Scientific, Life Technologies) by using the commercial Hot Spot Cancer Panel (HCP) on DNA derived from formalin-fixed paraffin-embedded tissues. ALK and ROS-1 status was assessed with fluorescent *in situ* hybridization. PD-L1 expression was determined with DAKO22C3 assay. Biological data obtained from our cases were compared with those reported in Tumor Cancer Genome Atlas (TCGA) for LA, restricting the comparison only to the genes targeted by HCP. **Result:** We identified 38 LEA cases. Main clinical and biological characteristics of the two populations are detailed in the table.

Variable/ gene mutation	INT LEA (N=38)	TCGA LA (N=660)
	%	%
Gender		
Female	34.1	51.9
Male	65.9	47.9
Unknown	0	0.2
Smoking status		
Former/current	76.3	78.9
Never	15.8	14.1
Unknown	7.9	7.0
Disease stage		
I	2.6	51.6
II	2.6	23.0
III	28.9	16.4
IV	65.9	4.7
Unknown	0	4.3
TP53	52.6	54.1
KRAS	34.2	32.4
STK11	23.7	15.8
CDKN2A	15.8	3.9
APC	7.9	4.8
CTNNB1	7.9	3.8
EGFR	7.9	15.8
KIT	5.3	2.1
PI3KCA	5.3	5.9
SMAD4	5.3	4.1
ATM	2.6	8.9
BRAF	2.6	8.2
FGFR	2.6	0.8
GNAS	2.6	3.8
NRAS	2.6	0.6
PDGFRA	2.6	7.4
RB1	2.6	5.8
SMO	2.6	2.7

Neither ALK nor ROS-1 rearrangements were detected in our case series. PD-L1 was negative in 23 cases, 1-49% in 9 cases, not evaluable in 6 cases. Microsatellite were stable except for 3 cases with low instability and 3 not evaluable cases. **Conclusion:** Our series of LEA was small and differed from TCGA LA for a higher proportions of males and metastatic disease. Given these limitations, our LEA genetic profile showed some difference from that of TCGA LA. In particular, LEA showed a higher incidence of *STK11, CTNNB1, FGFR, NRAS, KIT* and *CDKN2A* mutations, and a lower incidence of *ATM, BRAF, PDGFRA, RB-1* and *EGFR* mutations. PD-L1 expression, ALK and ROS-1 rearrangements were lower than literature data in LA. Most cases were microsatellite stable. In conclusion, further research is needed to understand the biology of LEA, which seems partially different from common LA.

P2.09-06 EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) MUTATION SPECTRUM IN PULMONARY ADENOCARCINOMAS: INDIAN EXPERIENCE

D. Jain[1], V. Singh[1], P. Malik[2], A. Mohan[2]

[1]*All India Institute of Medical Sciences, new delhi/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Incidence of lung cancer is rising in India, which is the major cause of mortality worldwide. The identification of *EGFR* mutations and *ALK* fusions in lung cancer has changed the treatment paradigm. The use of tyrosine kinase inhibitor (TKI) is now well established in clinical practice as it improves treatment outcomes. Molecular testing using tumor tissue is the gold standard for targeted therapies. The aim of the present study is to analyze the exact frequency of *EGFR* activating, rare and coexisting mutations in pulmonary adenocarcinoma (ADC). **Method:** A total of 783 ADC (755 biopsies and 28 cytology aspirate smears) cases were studied. The male: female ratio was 1: 0.3 with age ranging from 20 to 78 years. During grossing, two tumor blocks were made, one for immunohistochemistry studies and other for mutation testing. In high- cellularity, low- tumor fraction cases, tumor enrichment was done by manual microdissection. We used more than one aspirate smears/biopsy blocks in cases with low- cellularity, high- tumor fraction. Probe-based real-time PCR (RT-PCR) technique was used to analyze *EGFR* hotspots mutations (exons 18 to 21). Before proceeding for molecular testing, histo/cytomorphology, tumour content and DNA quality were determined. For checking the quality of DNA, RT-PCR was done using wild type *EGFR* exon 2 primers. **Result:** About 99% cases passed through the quality check of DNA and only 1.02% (8/783) cases failed. Overall, 234 patients (29.8%) were positive for *EGFR* mutations. The distribution of different types of *EGFR* mutations is shown in the Table 1. The common *EGFR* mutations were Exon 19 del and Exon 21 L858R which were equally distributed between both the genders. The *EGFR* mutations were more in non-smokers. T790M was present at baseline in around 3% TKI naive cases and it coexisted mostly with Exon 19 del. Cytological smears also showed *EGFR* mutations in the same pattern as tissue biopsies and a concordance was seen in cases where matched tissue and cytology smears were available. Table1: EGFR mutation spectrum in pulmonary adenocarcinomas

POSTERS

EGFR Exon	Percentage
Single Mutations = 89.7% (210/234)	
EGFR most common mutations	
Exon 19 del	61.5%
Exon 21 L858R	29.1%
EGFR TKI resistant mutation at baseline	
Exon 20 T790M	2.8%
Rare EGFR Single Mutations	
Exon 18 G719X	2.4%
Exon 20 S768I	1.4%
Exon 21 L861Q	1.4%
Exon 20 Ins	1.4%
EGFR double mutations = 10.2% (24/234)	
Common double mutations	
Exon 19 del: Exon 20 T790M	11
Exon 19 del: Exon 21 L858R	5
Rare double mutations	
Exon 18 G719X: exon 20 S768I	2
Exon 21 L858R: exon 20 S768I	2
Exon 20 T790M: Exon 18 G719X	1
Exon 20 T790M: Exon 20 Ins	1
Exon 19 del: Exon 21 L861Q	1
Exon 19 del: Exon 18 G719X	1

Conclusion: With judicious use and triaging of lung cancer diagnostic specimens, it is possible to perform successful mutation testing in >98% cases. *EGFR* mutation was positive in about a third of ADC including rare, TKI resistant and coexisting mutations in approximately 10% cases which may have significant therapeutic implications. In patients with limited amounts of tissue, cytology samples can be used for *EGFR* mutation testing as a promising alternative.

P2.09-07 MULTIPLE IMMUNOHISTOCHEMISTRY OF NON-SMALL CELL LUNG CANCERS REVEALS DISTINCT IMMUNE CONTEXT

B.M. Ku[1], H.A. Jung[2], J.-M. Sun[2], S.-H. Lee[2], J.S. Ahn[2], K. Park[2], M.-J. Ahn[2]

Background: Immune checkpoint blockade improves survival in a subset of patients with non-small cell lung cancer (NSCLC). Though increased tumor infiltrating lymphocytes (TILs) correlate with better outcome in many human cancers, biomarkers that predict response to PD-1 pathway inhibitors remain largely unknown. Therefore, a comprehensive evaluation of the composition and distribution of TILs is necessary to demonstrate their roles. **Method:** To determine the predictive significance of specific immune cells in the tumor microenvironment, we used multiples IHC. Multiplex IHC is a powerful investigative tool which provides objective quantitative data describing the tumor immune context in both immune subset number and location. To evaluate the immune context broadly we used the OPAL staining panel contains CD8, CD4, CD20, CD68, FOXP3, and panCK. **Result:** Pathologic tumor specimens from 101 patients with recurred or metastatic NSCLC were analyzed. Tumors exhibited a high degree of heterogeneity in the immune infiltrate and there was no significant difference when immune infiltrates were compared by tumor histology. Furthermore, there were no significant immune cell differences in EGFR mutant tumors or tumors that did not harbor mutations in adenocarcinoma. We observed increased Tregs (CD4+/FOXP3+) in PD-L1-positive tumors as compared with PD-L1-negative tumors. Our results showed that the infiltration levels of most T-cell subpopulations within tumor did not significantly associated with survival. However, high infiltration of B cells significantly correlated with overall survival. **Conclusion:** Increased infiltration of B cells into tumor regions is an independent predictor of better overall survival in NSCLC. These findings suggest that tumor-infiltrating B cells could act as a clinical factor in anti-PD-1 immunotherapy for NSCLC.

P2.09-08 CORRELATION BETWEEN HORMONE RECEPTOR EXPRESSION AND EGFR GENE MUTATION IN LUNG CANCER PATIENTS WITH SIMULTANEOUS PRIMARY BREAST CANCER

J. Chang, Z. Hu, X. Zou, S. Qin, X. Wu, J. Wang

Fudan University Shanghai Cancer Center, Shanghai/China

Background: Double primary breast cancer (BC) and lung cancer (LC) is not uncommon but research is limited. To decipher the inner pathogenesis, relationship between hormone receptor (HR) protein expression and EGFR gene mutation was explored in the present study. **Method:** Clinicopathological characteristics of 400 female patients with double primary BC and LC were analyzed, while another 114 patients with single LC were compared correspondingly. Tissue samples were obtained from enrolled subjects to detect EGFR mutation status by gene sequencing analysis, and estrogen receptor (ER) and progesterone receptor (PR) expression was determined by immunohistochemistry. **Result:** Among 169 patients, synchronous and metachronous double primary BC-LC cases accounted for 39.1% and 61.0%, respectively. For most female LC patients with simultaneous primary BC, adenocarcinoma was the dominant subtype (95.1%). The positivity rates were 13% for ER and 13% for PR in lung tumor tissues of 200 double BC-LC patients, slightly higher than those in single LC patients. Among BC-LC patients with mutant EGFR, 48.2% were either ER-positive (30.6%) or PR-positive (30.6%). But for those without EGFR mutation, both ER and PR could not be detected in lung tumor tissue samples. $\chi 2$ testfurther confirmed a significantly positive correlation between ER, PR expression and EGFR mutation in lung tumor tissues in double primary patients ($P < 0.05$). However, such relationship could not be similarly observed in single LC cases. Besides, the presence of family tumor history was associated with the onset time of the two primary cancers. **Conclusion:** Double primary BC-LC patients have distinctive clinicopathological features. Expression of HRs (both ER and PR) significantly correlated with EGFR mutation status in their lung tumor tissues.

P2.09-09 EGFR IS HIGHLY MUTATED IN LUNG ADENOCARCINOMA PATIENTS WITH HISTORY OF BREAST CANCER

A. Sakurada, K. Sato, H. Notsuda, H. Oishi, Y. Matsuda, T. Sado, M. Noda, Y. Okada

Institute of Development, Aging and Cancer, Tohoku University, Sendai/Japan

Background: EGFR gene mutation has been reported to be frequent in the patients with specific clinical features such as female, adenocarcinoma, and East-Asian ethnicity. The mutation rate in lung adenocarcinoma is approximately 50% in Japan. Currently, the molecular mechanism which cause EGFR mutation has not been clarified. If the EGFR mutation in lung adenocarcinoma correlates with specific type of malignancy in the other organ, it could be a clue to find a mechanism which promote carcinogenesis of lung adenocarcinoma. In the current study, we focused on breast cancer. **Method:** Patients with lung adenocarcinoma who underwent pulmonary resection in our hospital from January 2011 to December 2018 were analyzed. We retrospectively reviewed clinical information such as past illness, radiological findings, pathological diagnosis, and EGFR mutation status. Correlation was tested by chi-square test and p value of less than 0.05 was regarded as statistically significant. **Result:** A total of 21 patients of lung adenocarcinoma had history of treatment for breast cancer. All patients were female. Among them, EGFR mutation was detected in 20 patients (95%). One patient who were negative for EGFR mutation had history of not only breast cancer but also cervical cancer of uterus and gastrointestinal stromal tumor, and developed angiosarcoma of the skin. Detected EGFR

mutation types in 20 patients were as follows; deletion in exon 19 for 9 patients, L858R for 7 patients G719X for two patients, and L861Q for one patient. One patient showed multiple mutation (G719X and L861). In the same period, among 203 lung adenocarcinoma patients without other organ malignancy, 115 showed EGFR mutation (56.7%). There was significant difference in EGFR mutation rate between breast cancer group and no malignancy group (p=0.00058). **Conclusion:** Patients of lung adenocarcinoma with history of breast cancer showed extremely high positive rate for EGFR mutation in Japan, suggesting underlying common oncogenic molecular mechanism between lung adenocarcinoma and breast cancer. Elucidation of the mechanism may contribute to the diagnosis and treatment of carcinogenesis of breast cancer and lung cancer.

Background: To diagnose small cell lung carcinoma (SCLC), neuroendocrine (NE) phenotype markers such as chromogranin A, synaptophysin and CD56 are helpful. However, because they are dispensable, SCLCs occur without neuroendocrine phenotypes. Insulinoma-associated protein 1 (INSM1) is a transcription factor for neuroendocrine differentiation and has emerged as a single practical marker for SCLC. **Method:** Using the surgical samples of 141 NE tumors (78 SCLCs, 44 large cell neuroendocrine carcinomas (LCNECs), and 19 carcinoids), and 246 non-NE carcinomas, we examined the immunohistochemical expression and prognostic relevance of INSM1 in association with NE phenotype markers in each histologic type. We evaluated its sensitivity and specificity for SCLC diagnosis, as well as its usefulness to diagnose SCLC without NE marker expression and to estimate the prognosis of the subgroups of SCLC stratified by the expression levels of the NE markers. Those of 13 lung cancer cell lines (9 SCLCs and 4 ADCs) were also evaluated. **Result:** INSM1 was expressed in SCLCs (92%, 72/78), LCNECs (68%, 30/44), and carcinoids (95%, 18/19). Additionally, among SCLCs with no expression of NE phenotype markers (n=12), 9 (75%) were positive for INSM1. These data suggest the superiority of INSM1 to the phenotype markers. SCLC with low INSM1 expression (n=28) had a significantly better prognosis (*P*=0.040) than the high-INSM1 group (n=50). Only 7% of adenocarcinomas (9/134) and 4% of squamous cell carcinomas (4/112) were positive for INSM1. In cell lines, most SCLCs were positive for INSM1 (7/9), whereas all ADCs were negative (0/4). **Conclusion:** Our study revealed that INSM1 is highly sensitive to detect SCLC, is positive in most phenotype marker-negative SCLCs and can estimate prognosis. INSM1 will be a promising marker for SCLC.

P2.09-11 GENOMIC PROFILING OF PULMONARY LYMPHOEPITHELIOMA-LIKE CARCINOMA (PLELC)

C. Zhou[1], Z. Xie[1], Y. Qin[1], L. Liu[2], H. Zhang[3], W. Feng[3], X. Xie[1], X. Lin[1], J. Zhang[1], M. Ouyang[1], Y. Gu[1], B. Li[4], H. Han-Zhang[4], A. Lizaso[4], J. Liu[4], S. Mai[4], S. Chen[4], L. Zhang[4]

[1]*State Key Laboratory of Respiratory Disease, National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Health, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China,* [2]*Chronic Airways Diseases Laboratory, Department of Respiratory and Critical Care Medicine, Nanfang Hospital, Southern Medical University, Guangzhou/China,* [3]*The First People's Hospital of Foshan, Foshan/China,* [4]*Burning Rock Biotech, Guangzhou/China*

Background: PLELC, a rare and distinct type of primary lung cancer, is characterized by Epstein-Barr virus (EBV) infection. Histologically, it resembles undifferentiated nasopharyngeal carcinomas (NPC). Only a few hundred cases have been reported since its discovery. Due to the extreme rareness, its genomic landscape remains elusive. **Method:** Tissue samples of 27 PLELC patients (13 males and 14 females) with various stages (Ib to IV) were subjected to targeted sequencing using a panel consisting of 520 cancer-related genes, spanning 1.6Mb of human genome. **Result:** Collectively, we identified 184 somatic mutations spanning 109 genes, including 107 SNVs, 12 insertions or deletions (INDELs) and 65 copy-number amplifications (CNAs). Approximately, 50% of patients had CNAs. One patient had no mutation detected from this panel. Except for 2 patients, 1 with *HER2* amplification and another with *KRAS* mutation, no other classic NSCLC driver genes were detected. The most frequently mutated genes were *CCND1, TP53*, *DAXX* and *NFkBIA*, occurring in 30%, 26%, 22% and 22% of patients, respectively. Interestingly, 78% (21/27) patients had mutations in epigenetic regulators. Of the 184 mutations identified, 51 occurred in epigenetics-related genes. Pathway analysis also revealed an enrichment of genes participating in chromatin remodeling and organization. Next, we compared the genomic profile of PLELC with lung adenocarcinoma and EBV positive NPC. The frequency of *TP53* mutations was significantly higher in lung adenocarcinoma (68% vs 26%, p=0.021). Comparing to NPC, PLELC had significantly more mutations in epigenetic regulators. TMB analysis revealed a median TMB of 1.6/Mb, significantly lowered than lung adenocarcinomas (p<0.01). We also assessed PD-L1expression and revealed that 67% had an overexpression of PD-L1. Interestingly,*TP53*-mutant patients were more likely to associated low PD-L1 expression (p<0.01). **Conclusion:** In this study, we elucidated a distinct genomic landscape associated with PLELC with no classic NSCLC driver mutation but an enrichment of mutations in epigenetic regulators. The observation of high expression of PD-L1 and lack of canonical druggable driver mutation raises the potential of immunocheckpoint blockade therapy for PLELC.

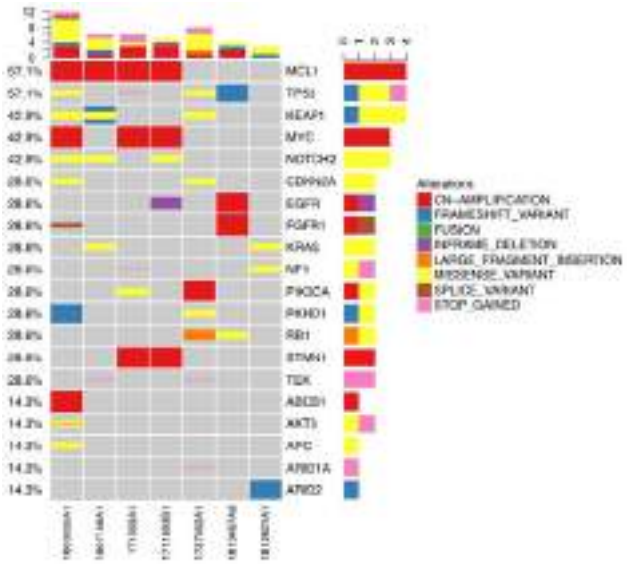
P2.09-12 NEXT-GENERATION SEQUENCING OF 7 CASES WITH DIFFUSELY COEXPRESSED TTF-1 AND P40 REVEALS A NEW MOLECULAR ENTITY IN RESECTED NSCLC

L. Hou, C. Wu

Shanghai Pulmonary Hospital, Shanghai/China

Background: Non-small cell lung cancer (NSCLC) histological and molecular subtypes played a pivotal role in management and treatment of patients. We reported unusual 7 NSCLC cases with diffuse coexpression of TTF-1 and p40 in surgical NSCLC specimens. The clinicopathological features and molecular profile of these cases were investigated in this study. **Method:** NSCLC tumors and paired normal lung tissues were performed targeted next-generation sequencing of 425 cancer genes related to treatment, genetic risks and tumorigenesis. Comprehensive immunohistochemistry and clinical information were analyzed. Genomic data was compared with TCGA database of different lung cancer subtypes. **Result:** In the 7 tumors, the most frequent genomic alterations were MCL1 amplification (confirmed by FISH) and TP53 mutations (57.1%, 4/7), KEAP1 and NOTCH2 mutations (42.9%, 3/7) and MYC amplification (42.9%, 3/7), KRAS and CDKN2A mutations (28.6%, 2/7), and EGFR mutation (14.3%, 1/7). 4 cases with MCL1 amplification were frequently along with NOTCH2 mutations (3 cases) and MYC amplification (3 cases), KRAS (1 case) and EGFR mutation (1 case). Two or three genes amplification co-existed in 4 cases. KRAS mutation was detected to be mutually exclusive from both EGFR and TP53 mutation. 5 cases with tumor mutation burden were more than 10/MB. There was no microsatellite instability found in 7 cases. All tumors were centrally located, with no morphological squamous and glandular differentiation. Diffuse and strong nuclear immunopositivity for TTF-1 (clone 8G7G3/1) and p40 expressed on the same tumor cells and were confirmed by double immunofluorescence. Napsin A was negative in all cases and CK5/6 was positive for 5 cases. 5 of 6 male patients were non-smokers. One was female with no smoking history.



Conclusion: Our results illustrated that poorly differentiated NSCLC with diffuse co-expression of TTF-1 and p40 showed an unique molecular subtype compared with other lung cancer subtypes. Therapies combined with MCL1 inhibitor may be eligible for these MCL1-amplification entities.

P2.09-13 HISTOLOGICAL AND MOLECULAR EVALUATION OF MULTIPLE LUNG CARCINOMA WITH SYNCHRONIC PRESENTATION. SINGLE-CENTER STUDY IN ARGENTINA

M.L. Dalurzo, M. Labanca, N. Minatta, P. De La Iglesia, J. Oliver, C. Franco, F. Jauk

Hospital Italiano Buenos Aires, Buenos Aires/Argentina

Background: The simultaneous presence of more than one tumor nodule in lung cancer patients requires histological assessment to classify them as synchronous or metastatic tumors, allowing correct staging. In certain cases, the distinction based only on histological features is challenging. **Method:** An observational study was performed including 22 lung cancer cases with more than one nodule (17 of them with 2 nodules, 1 with 4 nodules and 2 with more than 4 small nodules). 21 cases corresponded to surgical specimens, and only 1 case corresponded to needle core biopsy. Only 2 nodules per patient were studied, selected according to histological or sizing criteria. Both nodules of each case was assessed histologically according to both WHO 2015 and comprehensive histologic assessment (CHA). Tumors were classified according to both histological criteria into 3 categories: Synchronous, metastatic or undefined. Gene mutations and fusions were assessed using Oncomine Focus Assay (Thermo Fisher) in Ion PGM platform (Thermo Fisher). Cases sharing at least 1 somatic mutation or fusion were considered metastatic tumors. Cases with different somatic mutations/fusions were considered synchronous tumors and those showing no mutations/fusions were classified as undetermined. **Result:** Tumor nodule size in surgical specimens varied between 0,3 and 4 cm, whereas the biopsy case corresponded to an 8-cm mucinous adenocarcinoma. According to the WHO 2015 classification, 20 cases were adenocarcinomas (ADC), 1 was a squamous cell carcinoma and 1 was a large cell carcinoma. On WHO 2015 criteria-based histologic assessment, 10 cases were classified as metastatic (same features), 9 cases were considered synchronous (different features), whereas 3 cases remained undefined. Using CHA criteria, 7 cases were classified as metastatic (same features), 13 cases were considered synchronous (different features), whereas 2 cases remained undefined. Based on molecular testing, we found 6 (27,27%) related and 14 (63,64%) non-related tumors, whereas only 2 cases (9,09%) remained undetermined. Molecular testing was helpful classifying 2 CHA-undefined patients as synchronous, whereas 1 patient could not be re-classified due to the lack of mutations or fusions recognized by our panel. The combination of the WHO, CHA and molecular results helps solving discrepancies in undefined cases. **Conclusion:** The combination of WHO 2015 and CHA criteria improves the accuracy of synchronous or metastatic tumors. The addition of molecular testing is useful to define discrepancies in challenging cases

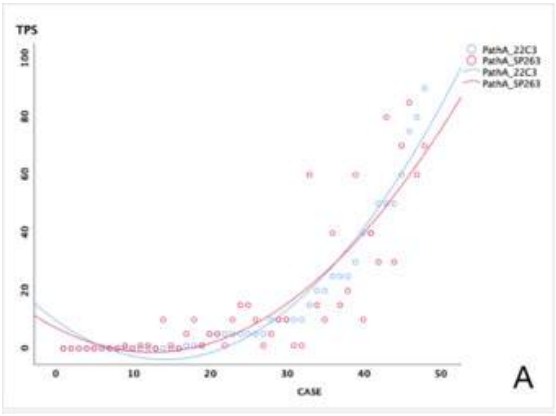
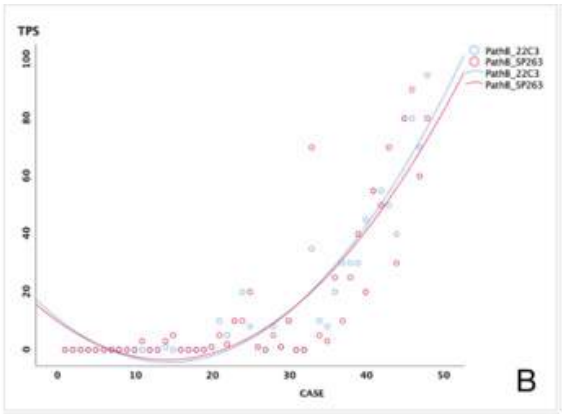
P2.09-14 EVALUATION ON INTER-ASSAY CONSISTENCY AND INTER-READER PRECISION FOR PD-L1 ASSAYS: VENTANA SP263 AND DAKO 22C3 IN NON-SMALL CELL LUNG CANCER

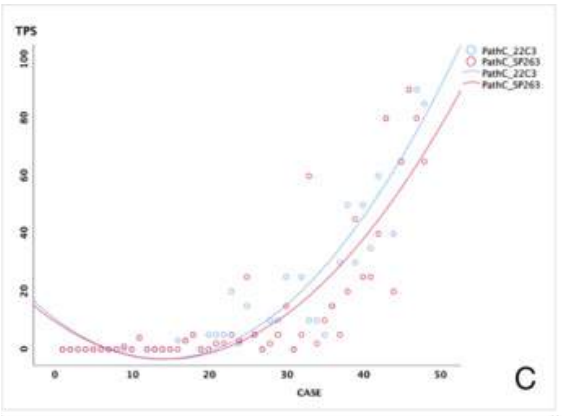
D. Lin, X. Yang

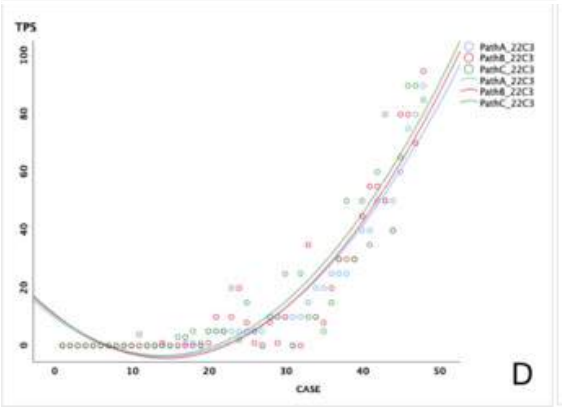
Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/China

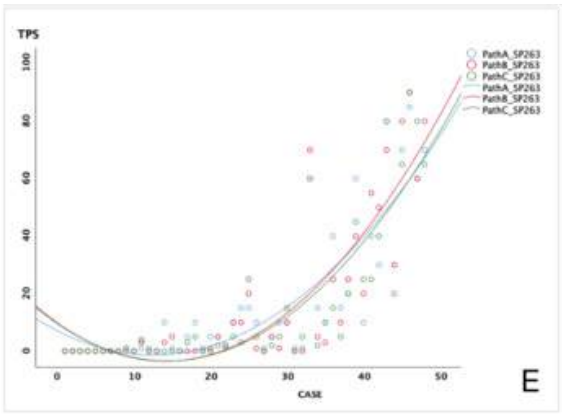
Background: FDA has approved several anti-PD1/PD-L1 checkpoint inhibitors for the treatment of a variety of cancers. It has been shown the expression level of PD-L1 in NSCLC tumor cells is associated with the response to anti-PD-1/PD-L1 treatment. Currently, five anti-PD1/PD-L1 inhibitors have been approved for either as a companion diagnostic (e.g., pembrolizumab) or as complementary diagnostic (e.g., nivolumab, atezolizumab and durvalumab). The blueprint studies and several others have reported the concordance on different PD-L1 IHC assays, however, few Chinese samples were included for assay consistence study; in addition, it remains unclear how these two assays perform in inter-reader variability of pathologists in China. **Method:** Surgical specimens from 48 NSCLC patients were selected for PD-L1 IHC by Ventana SP263 and Dako 22C3. Tumor proportion scores (TPS) were interpreted by three pathologists from three centers. Inter-assay consistency were evaluated by Kappa test at different cut-off value (1%, 25%, and 50%) for each pathologist; and inter-reader precision were performed by Kendall's W test for Ventana SP263 and Dako 22C3, respectively. **Result:** 1) Inter-assay consistency: When TPS were categorized as <1%, 1% to 24%, ≥25%, the overall agreement percentage (OPA) between two IHC assays was 81.25% observed by Pathologist A(κ=0.710), 89.6% observed by Pathologist B (κ=0.84) and 79.2% observed by Pathologist C (κ=0.684); If the TPS were categorized as <1%, 1% to 50%, ≥50%, the OPA were 81.25%, 93.75% and 85.4% (κ= 0.675, 0.899 and 0.760), respectively. 2) Inter-reader precision: The interpretation results on Ventana SP263 by three pathologists were consistent, when TPS was categorized as <1%, 1% to 49%, ≥50% (p=0.017) or <1%, 1% to 24%, ≥25% (p=0.047) respectively; the consistency was not optimal, when TPS was further categorized with narrower groups as <1%, 1% to 24%, 25% to 49%, ≥50% (p=0.065). The interpretation results of Dako 22C3 were inconsistent among three observers in all categories above, with all p values greater than 0.05.











Conclusion: 1) The inter-assay consistency of PD-L1 assays is high between Ventana SP263 and Dako 22C3; 2) The interpretation results of Ventana SP263 is more consistent among different observers.

Keywords: PD-L1 Assays, TPS, Non-Small Cell Lung Cancer

P2.09-15 PD-L1 EXPRESSION AND LYMPHOCYTE INFILTRATION IN RESECTED STAGE IIIAN2 NSCLC: PRELIMINARY DATA FROM A LUNG ART ANCILLARY STUDY

J. Adam[1], A. Bardet[1], V. Thomas De Montpreville[2], F. Barlesi[3], N. Pourel[4], G. Noël[5], U. Nestle[6], O. Mercier[2], J. Edwards[7], P.A. Thomas[8], C. Le Pechoux[1]

[1]*Gustave Roussy, Villejuif/France,* [2]*Hopital Marie Lannelongue, Le Plessis Robinson/France,* [3]*Aix Marseille University and Assistance Publique des Hôpitaux de Marseille, Marseille/France,* [4]*Institut Sainte Catherine, Avignon/France,* [5]*Centre Paul Strauss, Strasbourg/France,* [6]*University Medical Center, Freiburg/Germany,* [7]*Northern General Hospital, Sheffield/United Kingdom,* [8]*Hôpital Nord, Assistance Publique-Hôpitaux de Marseille, Aix-Marseille University, Marseille/France*

Background: Patients with resectable stage IIIA N2 NSCLC, are at high risk of both systemic and loco-regional relapse following surgical resection, necessitating neo-adjuvant or adjuvant treatments. Prognostic biological markers are needed. Parameters from the immune microenvironment, including PD-L1 expression and lymphocytic infiltration, have been poorly described in this group of patients. Thus we assessed simultaneously PD-L1 expression and TIL density in a cohort of stage IIIA N2 Lung ART patients, and correlated the results with clinical and pathological features before adjuvant treatment. **Method:** Formalin fixed paraffin-embedded tumor surgical specimens from 247 patients included in the Lung Adjuvant Radiotherapy Trial (NCT00410683) were studied. PD-L1 immunohistochemistry was performed centrally on whole slides using a validated clinical PD-L1 assay. Expression of PD-L1 in tumor cells (TC) and immune cell (IC) was scored by a trained pathologist. Morphological assessment of TIL density (percentage of tumor area) was performed on whole hematoxylin-eosin stained slides. Surgical and pathology reports were reviewed by an independent expert committee for tumor staging. Association between immune parameters and baseline clinical characteristics were assessed in exploratory analyses in order to provide insights on immune activity in resected NSCLC patients. **Result:** PD-L1 expression in ≥1% TC, ≥50% TC, ≥1% IC, ≥10% IC was observed in 47.8%, 21.9%, 61.5%, 7.3% of patients, respectively. In univariate analysis, high PD-L1 expression in both tumor cells and immune cells for all cut points correlated strongly with a higher TIL density (p-values ≤0.001). In 41 (16.6%) patients with preoperative chemotherapy (CT), a higher TIL density was observed (mean 28.1 vs. 17.5%, p=0.0018) as compared to patients without preoperative CT, but no difference was noted for PD-L1 expression in both TC and IC,. Skip N2 metastases were associated with a higher TIL infiltration (mean 22.9% vs. 17.4% p=0.014). We found no significant correlation between PD-L1 or TIL infiltration with the number of mediastinal lymph nodes stations involved on pathological examination and with histological tumor subtypes (squamous cell carcinoma vs. adenocarcinoma). **Conclusion:** PD-L1 expression levels in TC and IC appeared similar in stage IIIA N2 NSCLC as compared to other stages. Expression in both TC and IC strongly correlated with TIL infiltration, suggesting a prominently immune-induced expression mechanism. Preoperative chemotherapy was associated with a higher TIL infiltration but not higher PD-L1 expression. Patients with skip N2 metastases harbored a higher level of TIL density, a finding consistent with a more active immune microenvironment in this group of patients with better prognosis. These data will be subsequently updated on a larger number of patient and correlated to clinical follow-up.

P2.09-16 ASSESSMENT OF PD-L1 AND CD8 EXPRESSION IN LUNG CANCER USING RNA IN SITU HYBRIDISATION

A.-M. Baird[1], M. Wright[2], L. Mccarra[2], H. Thirstrup[3], A. Schønau[3], S. Cuffe[4], S. Finn[2], S. Gray[1]

[1]*Trinity College Dublin, Dublin/Ireland,* [2]*St. James's Hospital, Dublin/Ireland,* [3]*Visiopharm, Hoersholm/Denmark,* [4]*St. James's Hospital/Trinity College Dublin, Dublin/Ireland*

Background: PD-L1 is routinely assessed using immunohistochemistry (IHC) as a companion-diagnostic test. However, patients may be missing out on therapy as issues exist in determining PD-L1 positivity. This is partly due to the use of different antibodies, staining platforms and positivity cut-offs. The use of RNA *in-situ* hybridisation (RISH) for the detection of *PD-L1* levels may be a way to address this; particularly as *PD-L1* mRNA expression levels are

associated with better overall survival in NSCLC. It is well established that PD-L1 expression is associated with increased numbers of Tumour Infiltrating Lymphocytes (TILs) including those which are CD8+. Therefore, it may also be worthwhile to combine PD-L1 testing with additional marker testing such as CD8. The aim of this study is to investigate the expression of PD-L1 and CD8 by RISH in a cohort of NSCLC samples and correlate with clinical outcome. **Method:** RISH protocols (RNAScope® 2.5 HD assay, Advanced Cell Diagnostics, Inc.) were initially optimised on a well annotated cell line TMA (low, moderate and high expression) and compared with standard IHC (DAKO - clone 22C3). Following successful optimisation of the technique, a test cohort of 35 full-face FFPE NSCLC samples were examined for PD-L1 expression by both RISH and IHC. All slides were scored independently by a pathologist. RISH slides were scored as per ACD guidelines (0-4; based on number of positive dots per cell and number of dot clusters). IHC was scored using the standard tumour proportion score system. Image analysis (IA) was subsequently performed by Visiopharm®. Currently, a further cohort of 200 FFPE samples is being assessed, in addition to 50 FFPE samples from patients who received an anti-PD-1 therapy. Optimisation is on-going for dual CD8/PD-L1 RISH staining. **Result:** In the initial 35 samples, PD-L1 was detected in 20% of cases by IHC (≥50% positivity) with mRNA expression identified in 14% of cases by RISH (≥2). In contrast with other recently published studies, issues were identified between IHC and RISH. There were 3 cases which scored positive by IHC, which were negative by RISH. Additionally, 1 case was positive by RISH but negative by IHC. The comparison between both assays produced a 'moderate agreement' as assessed using Cohen's kappa coefficient (κ=0.528, p=0.002). IA undertaken on both assays could not be statistically compared using Cohen's kappa coefficient due to the use of a composite scoring matrix to quantify RISH mRNA signals. However, IHC stained sections scored by IA showed similarity to IHC scored by a pathologist. Further optimisation is required on the RISH IA scoring algorithm. A comparison of PD-L1 IHC with RISH, combined with dual CD8/PD-L1 staining in a larger cohort of clinical samples is on-going, which will further determine the clinical utility of this technique. **Conclusion:** Data from our test cohort of samples have shown that PD-L1 detection by RISH is feasible and compares well to IHC. Preliminary data would also suggest that IA may be better than a pathologist alone, particularly in borderline cases. RISH may be a suitable method for improved detection of *PD-L1* in NSCLC.

Keywords: PD-L1, RISH, CD8

P2.09-17 REAL-WORLD CONCORDANCE ACROSS PATHOLOGISTS FOR PD-L1 SCORING IN NON-SMALL CELL LUNG CANCER: RESULTS FROM A LARGE NATIONWIDE INITIATIVE

J. Adam[1], V. Hofman[2], A. Mansuet-Lupo[3], I. Rouquette[4], J.-M. Vignaud[5], C. Badoual[6], H. Bégueret[7], M.-C. Copin[8], D. Damotte[3], C. Danel[9], F. Forest[10], S. Garcia[11], L. Gibault[6], F. Penault-Llorca[12], S. Lantuejoul[13], A. Cazes[9], N. Le Stang[13]

Background: PD-L1 immunohistochemistry (IHC) is an important routine biomarker in patients with metastatic and locally advanced non resectable non-small cell lung cancer (NSCLC). Currently, the thresholds of ≥1% and ≥50% of tumor cells stained are clinically relevant. Scoring concordance across pathologists was reported only in small groups of pathologists or across thoracic pathology experts. Here, we provide real-world concordance data in a large group of pathologists (n=161) with various experience of PD-L1 testing and practice in thoracic pathology. **Method:** Twenty-nine NSCLC samples, mostly biopsies, stained in routine clinical pathology practice with PD-L1 IHC standardized assays (22C3, 28-8 and SP263), were selected to represent various PD-L1 expression levels. Slides were digitalized and scored for the percentage of tumor cells with membranous staining by 161 pathologists using an online digital platform. A consensus score was defined for each case by a group 15 expert pathologists. Data regarding experience, training and practice of PD-L1 testing were also collected for each pathologist. **Result:** Consensus score determined by the expert group highly correlated with the median of scores for each case (correlation coefficient=0.992). Overall concordance across pathologists was moderate, higher for the ≥50% cutoff (K=0.64) than the ≥1% cutoff (K=0.58). A higher concordance was achieved in the expert group (15 pathologists) as compared to the other pathologists (146 pathologists), in particular for the ≥1% cutoff. Concordance across pathologists correlated with training to PD-L1 scoring as well as the number of PD-L1 tests evaluated weekly. No correlation was found with the number of years of thoracic pathology practice or the type of pathology practice (private laboratory, community hospital, university hospital). The issues observed in the most discrepant cases were evaluated and described. **Conclusion:** Concordance across pathologists for PD-L1 scoring in NSCLC was higher in the expert group of pathologists as compared to other pathologists, in particular for the ≥1% cutoff. Training to PD-L1 scoring and experience in routine pathology practice correlated with higher concordance. These data emphasize the importance of training to achieve a high concordance across pathologists in the real-world setting.

P2.09-18 LYMPHOCYTE INFILTRATION PATTERN AND STING EXPRESSION IDENTIFY DIFFERENT PROGNOSTIC GROUPS IN EARLY STAGE NSCLC

F. Tabbò[1], F. Guerrera[2], P. Bironzo[1], M. Gagliasso[1], C. Cartia[1], A. Rigutto[1], S. Izzo[1], F. Veneziano[2], F. Arizio[1], F. Ardissone[1], M.G. Papotti[2], M. Volante[1], S. Novello[1], L. Righi[1]

[1]*University of Torino, Orbassano/Italy,* [2]*University of Torino, Torino/Italy*

Background: Lymphocyte infiltration has been described has a potential biomarker of lung cancer patients' survival. Different studies de-convoluted immune cell compartment (i.e. stromal CD8 density) trying to identify clinically relevant immune patterns. **Method:** A series of 178 early-stage (IB-IIIA) NSCLC has been retrospectively collected at Department of Oncology, San Luigi Hospital (Orbassano, Italy). From Formalin-Fixed and Paraffine-Embedeed (FFPE) tumor blocks, Tissue Microarrays (TMA) were constructed (4 cores were selected for each case). Lymphocyte infiltration pattern was determined by light-microscopy on Hemathoxylin-Eosin (HE) whole slides. Immunohistochemistry was performed as follow: CD8 (SP57) and STING (D2P2F) antibodies were tested with Ventana Benchmark and PD-L1 (22C3) with Dako Autostainer. Infiltration pattern has been clustered in 4 different categories: brisk-diffuse, non-brisk multifocal, non-brisk focal and none. CD8 was quantified as positivity percentage, PD-L1 through TPS (<1%, 1-49% and ≥50%) and STING taking advantage of H-score. Overall survival (OS) and Progression Free Survival (PFS) were estimated using the Kaplan-Meier method and compared using log-rank test. **Result:** Most represented patients had following features: male (119-71%), current or previous smokers (145-82%), stage II (94-53%) and adenocarcinoma histology (119-67%). Distribution of lymphocyte infiltration pattern was: 110 cases with brisk-diffuse (62%), 56 with non-brisk (multi-focal and focal) (31%) and 12 with none pattern (7%). CD8 positivity was distributed in 3 categories: high (66 - 37%), intermediate (75 - 42%) and low (37 -21%) density. For PD-L1 TPS analyses 111 cases (62%) had <1%, 39 cases (22%) 1-49% and 28 cases (16%) >50%. STING high-expressors were 88 (49%) and low-expressors 90 cases (51%). Lastly, were identified 81 samples (45%) with STING positivity at high-density on immune cells (IC) and 97 samples (55%) with low-density. As expected, Brisk-infiltrated samples presented an higher CD8 density (p=0.015). At PFS analyses, STING IC resulted associated (p=0.05) with a worse PFS for high-density patients. At OS analyses, brisk lymphocyte infiltration pattern appeared to have a negative impact (p=0.05) and STING higher-expressors on tumor cells had a worse prognosis (p=0.04). **Conclusion:** NSCLC with wider lymphocyte infiltration and expression of immune activation markers (as STING) appeared to be associated with a worse prognosis (PFS and OS). These date need further validation at multivariate analyses.

Keywords: immunoscore, CD8 density, STING

P2.09-19 EFFECT OF NEOADJUVANT (RADIO) CHEMOTHERAPY ON PD-L1 EXPRESSION IN RESECTED NON-SMALL CELL LUNG CANCERS

P. Zens[1], C. Bello[1], A. Scherz[2], A. Ochsenbein[2], M. Von Gunten[3], R. Schmid[4], C. Neppl[1], S. Berezowska[1]

[1]*Institute of Pathology, University of Bern, Bern/Switzerland,* [2]*Department of Medical Oncology, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland,* [3]*Pathologie Länggasse, Ittigen/Switzerland,* [4]*Division of General Thoracic Surgery, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland*

Background: Programmed cell death ligand 1 (PD-L1) expression has been established as a predictive biomarker for checkpoint-inhibitor treatment in advanced non-small-cell lung carcinomas (NSCLC). Inclusion of PD1/PD-L1 inhibitors into existing neoadjuvant regimens is currently evaluated in clinical trials. However, data on the impact of neoadjuvant regimens on tumoral PD-L1 expression is rare. We aimed to assess the PD-L1 expression in NSCLC before/after neoadjuvant treatment, including its prognostic relevance. **Method:** Our single-center, retrospective study cohort comprised 131 consecutive patients with NSCLC resected after neoadjuvant therapy, diagnosed 2000-2016, including 63 available pretreatment biopsies. Tumor types comprised 59 squamous cell carcinomas (SQCC), 66 adenocarcinomas (ADC) and 7 others. The pathological slides and clinical records were reevaluated assessing tumor-size according to current IASLC-recommendations by multiplying the vital tumor percentage with the macroscopic tumor bed. Biologically matched cohorts of 60 locally advanced (pN2) primary resected ADC and 54 SQCC served as controls. PD-L1 was immunohistochemically stained using the Ventana SP263 KIT and tumoral expression was assessed on whole slides by two investigators using the increments: <1%, 1-<25%, 25-<50%, ≥50%. The results were correlated with clinico-pathological parameters. **Result:** PD-L1 could be evaluated in 112 specimens after neoadjuvant chemotherapy, including 24 following neoadjuvant radiochemotherapy: 53 cases scored <1%, 31 1-<25%, 4 25-<50% and 24 ≥50%. In pre-treatment biopsies, 50/63 (79.4%) cases scored <50%, 13/63 (20.6%) ≥50%. Eight/63 (12.7%) cases were discordant regarding the clinically relevant cut-off 50%, 4 cases (2 ADC, 2 SQCC) having a higher expression and 4 cases (2 ADC, 2 SQCC) with lower expression after neoadjuvant radiochemotherapy. PD-L1 expression was significantly higher in primary resected SQCC (n=53) compared to neoadjuvantly treated SQCC (n=52, p=0.014; n=41 neoadjuvant chemotherapy only, p=0.033), with 14 cases scoring <1%, 21 1-<25%, 4 25-49% and 14≥50%. There was no significant difference regarding PD-L1 expression for the paired ADC-groups. In neoadjuvantly treated NSCLC, there was no correlation between PD-L1 expression (increments or 50% cut-off) and ypT, ypN, UICC/AJCC-stage, histological tumor regression, tumor size or the size of the tumor bed. PD-L1 expression was not associated with overall survival nor progression free survival in any cohort. **Conclusion:** We document a discordance of 12.7% regarding the cut-off 50% between pre-treatment biopsies and resections after neoadjuvant therapy, which may be due to tumor-heterogeneity. The higher PD-L1 expression in primary resected SQCC compared to SQCC resected after treatment provides evidence that the influence of neoadjuvant therapy on PD-L1 expression might depend on the histological tumor type.

Keywords: PD-L1 expression, Neoadjuvant therapy

P2.09-20 THE POSSIBLE CLINICAL SIGNIFICANCES OF INFILTRATION OF CD8+ LYMPHOCYTES IN NON-SMALL CELL LUNG CANCERS

K. Shiomi, M. Ichinoe, S.-X. Jiang, M. Naito, M. Mikubo, Y. Matsui, S. Tamagawa, A. Mitsui, S. Hayashi, Y. Satoh, Y. Matsuo

Kitasato University School of Medicine, Sagamihara/Japan

Background: Understanding of the immune contexture of tumor microenvironments might provide knowledge predicting the effect of immunotherapies and prognosis. The amount of CD8+tumor-infiltrating lymphocytes (TILs) seems to be a promising candidate as positive prognostic factor in non-small cell lung cancer (NSCLC). However, few details are understood. Hence, we investigated the prognostic significance of CD8+TILs in NSCLC. **Method:** Of the NSCLCs surgically resected in our institution between 2011 and 2013, those with more than 10% of their tumor cells growing in a solid pattern were immunohistochemically studied to evaluate the CD8+TILs in both tumor parenchyma and stroma. The number of CD8+TILs in tumor parenchymal elements and the percentages of stromal CD8+TILs compared with the total amount of nucleated cells in stromal elements which means "density" were assessed by a digital pathology scoring software. Data were analyzed with Kaplan-Meier survival analysis and Cox proportional hazards models. The primary endpoint of this study was relapse-free survival (RFS). **Result:** Eighty-four patients were included in this study. The median age was 69 (range 31-81) years and the majority of patients were men (85%). Histologically, 52 cases were squamous cell carcinomas, 19 adenocarcinomas, 9 pleomorphic carcinoma and 4 other types. In univariate analysis, the density of stromal CD8+TILs was a significant poor prognostic factor (P=0.0053), while the number of intraparenchymal CD8+TILs showed no prognostic significance. In addition, the multivariate analysis also indicated that the density of stromal CD8+TILs was a significant poor prognostic factor (HR, 3.62; 95% CI, 1.37-9.55; P=0.0094). **Conclusion:** Our data showed that a high density of stromal CD8+TILs might be associated with patient's shorter RFS. Further studies are needed to verify the presenting findings.

P2.09-21 A PROSPECTIVE STUDY OF THE CONCORDANCE FOR PD-L1 STATUS IN CORE NEEDLE BIOPSY AND CORRESPONDING RESECTION SPECIMEN IN NSCLC

D. Lin, W. Sun, X. Yang

Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education/Beijing), Peking University Cancer Hospital and Institute, Beijing/China

Background: Some studies have demonstrated a relatively poor concordance of PD-L1 IHC expression between biopsies and corresponding resection specimens. To address this central and relevant issue having a significant impact on treatment stratification for patients with NSCLC, we evaluated a novel method to compare and evaluate PD-L1 status in biopsies and resection samples. **Method:** Randomly core needle aspiration biopsy was performed in 170 resected NSCLC samples with 1 to 2 biopsies per centimeter in *longest* diameter of tumor. Among these 170 cases, a total of 52 cases were selected for the study. 41 cases were characterized as PD-L1 positive as a PD-L1 TPS≥ 1%), 1 case which the TPS<1% resected specimen with obvious stained tumor area and randomly 10 specimens being PD-L1 negative. In total 221 biopsies were available for the 52 resection cases. The PD-L1 expression in resected specimens and corresponding biopsies were evaluated by the PD-L1 IHC 22C3 pharmDx assay (Agilent) on the Dako Autostainer. **Result:** In our investigation, the concordance of PD-L1 status in biopsy and resection was not influenced by number of tumor cells at 1% and 50% cut-off's. The length of biopsy improves concordance of PD-L1 status but is not statistically significant (table 1). In figure 1. under 1% cut-off, the PD-L1 status in biopsy and resection is concordant irrespective of biopsies density, whereas the density of biopsies improves the concordance for 50% cut-off. The threshold was 1 per centimeter in longest diameter of tumor.

Table 1. Relevance trend between different length of biopsy and consistency ration in 1% and 50% cutoffs.

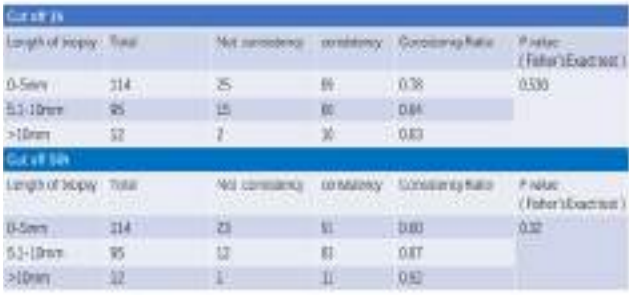

Figure 1. Correlation between PD-L1 accuracy and biopsy density through logistic regression at a cutoff of 1% and 50%.

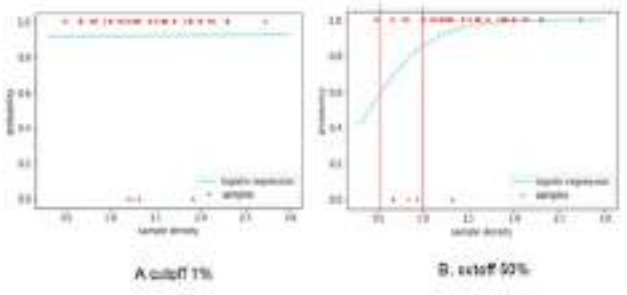

Conclusion: The concordance between biopsy and resected specimen is related to the length, density of biopsy and the clinical cutoff. Increasing the biopsy density will improve accuracy of PD-L1 detection.

P2.09-22 MOLECULAR AND IMMUNOLOGICAL PROFILES OF LUNG CARCINOMA: ARE THEY ASSOCIATED?

A. Cruz, I. Guerreiro, M.J. Silva, M.J. Leitão, A. Rodrigues, I. Azevedo, I. Pousa, J. Oliveira, C. Oliveira, A. Rosinha, M. Cassiano, A.L. Cunha, M. Soares

Portuguese Institute of Oncology - Porto, Porto/Portugal

Background: Lung cancer, usually related to tobacco and other exposures, has also risk factors that suggest a genetic susceptibility. Thus, there has been increasing interest in the definition of oncogenic changes that allow targeted therapy. On the other hand, immunological checkpoint inhibitors have been shown to be increasingly effective, regardless tumor histology or expression of PD-L1. We aimed to characterize the presence of predictive response mutations to target therapies and the immunological profile of non-small cell lung cancer (NSCLC), and to study possible associations between them. **Method:** Retrospective study of NSCLC cases submitted to the determination of PD-L1 by the Pathology Service since January 2017 until March 2019 and, in those patients, description of the predictive response mutations in the EGFR, ALK and ROS1 genes. Data were analyzed using simple descriptive statistics methods. To test hypotheses, we used the chi-square test, and the predictive factor search was performed through logistic regression. **Result:** A total of 794 patients were identified, 73.8% male (n=586), with a median age of 67 years (IQR, 13). The histological type was classified as adenocarcinoma in 69.3% of cases (n=550) and squamous cell carcinoma in 22.8% (n=181). Among the adenocarcinomas, we found predictive mutations in the EGFR gene in 17.6% of the patients (n=97), translocation in the ALK gene in 4.9% (n=27), and rearrangement in the ROS1 gene in 0.9% (n=5). PD-L1 expression was positive in 54.2% of the cases (n=430), and superior to 50% in 22.9% (n=182). Overall, the association between PD-L1 expression and EGFR status was not statistically significant. However, there was an association between PD-L1 expression and EGFR mutation in females (p=0.013). There was also an overall association between PD-L1 expression and ALK translocation (p<0.001), and this association was maintained in the gender analysis for the male patient group (p=0.003). In the multivariate analysis, the ALK translocation was a predictor of PD-L1 expression. **Conclusion:** The molecular profile of lung carcinoma was similiar to what is described in the literature. In our study, there was a statistically significant association between ALK translocation and PD-L1 expression in the global population. It would be interesting to understand the biological behavior of this group of tumors and, in the future, to study the role of eventual therapeutic associations.

P2.09-23 PD-L1 EXPRESSION OF PAIRED PRIMARY RESECTED NON SMALL CELL CARCINOMA AND METASTATIC LYMPH NODE FINE NEEDLE ASPIRATES

A.M. Quinn[1], R. Bowden[2], A. Moss[3], R. Bloor[4], C. Harreld[5], C. Mcnulty[5], A. Montero[5], P. Crosbie[6], F. Blackhall[3], Y. Summers[3]

[1]*University College Hospital Galway, Galway/Ireland,* [2]*Salford Royal NHS Foundation Trust, Manchester/United Kingdom,* [3]*The Christie NHS Foundation Trust, Manchester/United Kingdom,* [4]*Wythenshawe Hospital, Manchester University NHS Foundation Trust, LT/United Kingdom,* [5]*Wythenshawe Hospital, Manchester University NHS Foundation Trust, Manchester/United Kingdom,* [6]*University of Manchester, Manchester/United Kingdom*

Background: Small biopsy or cytology samples may present with a different level of PD-L1 expression compared to resected samples (which usually entail scoring of a much greater number of cells) resulting in relatively increased or reduced tumour proportion scores (TPSs). Many PD-L1 results are based on cytology fine needle lymph node aspirates (FNLNAs), encompassing analysis of metastatic disease and the substitution of cytology for histology samples. We compared the PD-L1 TPS of metastatic FNLNAs with that of resected non small cell carcinoma. **Method:** The pathology archive at Wythenshawe Hospital was searched for cases with adequate material over a period spanning 2010-2016. The Ventana SP263 PD-L1 clone was used to stain blocks select from 50 resected NSCCs and matched FNLNA cell blocks from each individual, along with a fresh H&E and negative PD-L1 control section. **Result:** Four of the cell block sections were inadequate for TPS assessment. The remaining 46 cases comprised 21 adenocarcinomas, 3 large cell carcinomas, 1 large cell neuroendocrine carcinoma, 1 atypical carcinoid tumour, and 20 squamous carcinomas. 34 cell block PD-L1 TPSs (68%) were in broad agreement with the corresponding resection block TPS, based on cut-off levels of 1% and 50%. Of the 12 (32%) cases in which differences occurred, 6 (50%) reflected an increase in TPS from resection to FNA, while 6 reflected a decrease causing a change in therapeutic cut-off. Nine of the FNLNAs were sampled after the resection, favouring the presence of recurrent disease.

TABLE 1. PD-L1 expression of resections versus FNLNAs across TPS categories								
	Resection Tumour Proportion Scores n, (%)				FNLNA Tumour Proportion Scores n, (%)			
		0 / <1%	1 - 49%	≥ 50%	*p*	0 / <1%	1 - 49%	≥ 50%
Total n = 46	12 (26)	15 (33)	19 (41)		16 (35)	7 (15)	23 (50)	0.14
Median age at diagnosis (yrs)	63	64	64		62	69	64	
Adenocarcinoma Squamous ca. Other[a]	2 (4) 7 (15) 3 (7)	8 (20) 6 (11) 1 (2)	10 (22) 8 (17) 1 (2)	0.132	2 (4) 10 (22) 4 (9)	5 (11) 2 (4) 0 (0)	13 (28) 9 (20) 1 (2)	0.035
Discrepant cases n = 12	1 (8)	9 (75)	2 (17)		4 (33)	2 (17)	6 (50)	

[a] Includes large cell carcinoma, large cell neuroendocrine carcinoma, atypical carcinoid

Conclusion: The majority of metastatic TPS FNLNAs are in broad agreement with a primary resected carcinoma TPS. FNLNAs tended to score less in the 1-49% category, possibly due to limits of cellularity. In addition to heterogeneity of expression, sampling of recurrent rather than residual disease may contribute to discrepancies.

Keywords: resection, PD-L1, metastatic

Background: PD-L1 immunohistochemistry (IHC) is now performed for advanced non-small cell lung cancer (NSCLC) patients to examine their eligibility for pembrolizumab treatment, as well as in Europe for durvalumab therapy after chemoradiation for stage III NSCLC patients. Four PD-L1 clinical trial validated assays (commercial assays) have been FDA/EMA approved or are *in vitro* diagnostic tests in multiple countries, but high running costs have limited their use; thus, many laboratories utilize laboratory-developed tests (LDTs). Overall, the PD-L1 testing seems to be diversely implemented across different countries as well as across different laboratories. **Method:** The Immune biomarker working group of the IASLC international pathology panel conducted an international online survey for pathologists on PD-L1 IHC testing for NSCLC patients from 2/1/2019 to 5/31/2019. The goal of the survey was to assess the current prevalence and practice of the PD-L1 testing and to identify issues to improve the practice globally. The survey included more than 20 questions on pre-analytical, analytical and post-analytical aspects of the PDL1 IHC testing, including the availability/type of PD-L1 IHC assay(s) as well as the attendance at a training course(s) and participation in a quality assurance program(s). **Result:** 344 pathologists from 310 institutions in 64 countries participated in the survey. Of those, 38% were from Europe (France 13%), 23% from North America (US 17%) and 17% from Asia. 53% practice thoracic pathology and 36%, cytopathology. 11 pathologists from 10 countries do not perform PD-L1 IHC and 7.6% send out to outside facility. Cell blocks are used by 75% of the participants and cytology smear by 9.9% along with biopsies and surgical specimens. Pre-analytical conditions are not recorded in 45% of the institutions. Clone 22C3 is the most frequently used (61.5%) (59% with the commercial assay; 41% with LDT) followed by clone SP263 (45%) (71% with the commercial assay; 29% with LDT). Overall, one or several LDTs are used by 57% of the participants. A half of the participants reported turnaround time as 2 days or less, while 13% reported it as 5 days or more. Importantly, 20% of the participants reported no quality assessment, 15%, no formal training session for PD-L1interpretation and 14%, no standardized reporting system. **Conclusion:** There is marked heterogeneity in PD-L1 testing practice across individual laboratories. In addition, the significant minority reported a lack of quality assurance, formal training and/or standardized reporting system that need to be established to improve the PD-L1 testing practice globally.

P2.09-25 TUMOR SPREAD THROUGH AIR SPACES (STAS) WAS CORRELATED WITH MULTIPLE ADVANCED CLINICOPATHOLOGICAL FACTORS

T. Okazaki, M. Kusano, K. Shimada

Osaki Citizen Hospital, Osaki/Japan

Background: Tumor spread through air spaces (STAS) has been reported as a form of tumor invasion having a poor prognosis mainly in lung adenocarcinoma. However, STAS appears not only in adenocarcinoma but in squamous cell carcinoma and neuroendocrine carcinoma. The aim of this study was to analysis STAS in recent resected lung cancers. **Method:** This study included 103 patients with assessment of STAS of 163 NSCLC who underwent complete surgical resection at Osaki Citizen Hospital between April 2017 and March 2019. STAS were assessed tumor edges to find floating tumor cells or clusters. A statistical analysis was performed to determine the impact of clinicopathologic parameters on STAS and to clarify the relationship between STAS and recurrence. **Result:** STAS was present in 34 of 103 cases (33.0%). Cases with STAS contained 28 of adenocarcinoma, 4 of squamous cell carcinoma and 2 of small cell carcinoma. STAS was correlated with the value of carcinoembryonic antigen (CEA), tumor size, invasion size, pathological T factor (pT), pathological N factor (pN), pleural invasion (pl), intrapulmonary metastasis (pm), lymphatic invasion (ly) and blood-vessel invasion (v). Although this study has short-term follow up periods, there was a significant association between presence of STAS. In a multivariate Cox proportional hazards model, no significant predictor of RFS was defined. **Conclusion:** We found STAS in 33% of resected lung cancers. Presence of STAS was correlated with multiple advanced clinicopathological factors and recurrence, but not significant in multivariate analysis.

Keywords: Lung cancer, STAS

P2.09-26 INADEQUATE SURGICAL MARGINS AT VIDEO-ASSISTED THORACOSCOPIC WEDGE RESECTION OF GROUND-GLASS OPACITY LUNG ADENOCARCINOMA

M. Naruke

AOI Hospital, Kanagawa/Japan

Background: Limited resection is now indicated for more patients with ground-glass opacity (GGO) lung cancer, supported by advances in histological analysis and prognostic assessment of this disease. This study involved pathological examination of the possibility of inadequate surgical margins at video-assisted thoracoscopic (VATS) wedge resection of GGO lung cancer. **Method:** Among 12 patients with GGO lung cancer who underwent VATS wedge resection in a 4-year period (April 2012-March 2016), 4 (12%) had local recurrence detected by follow-up computed tomography (CT). Surgical margins determined intraoperatively in these 4 patients were reexamined pathologically. The median proportion of GGO component determined by preoperative CT was 78.75%. In principle, percutaneous CT-guided lung needle marking of the center of a lesion was performed immediately before surgery, and the lesion was excised with 1-cm margins from the collapsed lung under one-lung ventilation. VATS wedge resection was selected based on the patient's decision and was performed with the intention of complete removal of the lesion with adequate margins in each case. **Result:** Mean follow-up duration was 55 months in the 12 patients, and median time to local recurrence was 27 (range, 15-60) months after surgery in the 4 patients. Pathological re-examination in the 4 patients revealed a diagnosis of adenocarcinoma with a mean invasion zone size of 0.68 (range, 0.18-1.4) cm. The distances of margins determined pathologically were shorter than those intended perioperatively; margins were positive in 3 of the 4 specimens. Although the edges of the 0.6-cm margins around the primary lesion were negative, numerous tumor cells were observed in the remaining 1 specimen. **Conclusion:** In wedge resection, it is difficult to identify accurate surgical margins of the GGO lesion and to detect multiple lesions near the surgical margin without palpation. Thus, surgical margins at VATS wedge resection determined solely by visual inspection can be inadequate and may result in incomplete removal of the lesion.

P2.09-27 CORRELATION BETWEEN DIFFERENT ROS1 CLONES (SP384 & D4D6) AND CONSISTENCY WITH ROS1 FLUORESCENCE IN SITU HYBRIDIZATION (FISH) RESULTS

B. Öz, O. Dulger, Ş. Batur

Istanbul Universitesi Cerrahpasa Tip Fakültesi, Istanbul/Turkey

Background: Since treatment options for ROS1 translocated Non-Small Cell Cancer cases has been revealed, ROS1 testing was included in NSCLC guidelines. FISH method is essential for the detection of these cases. Immunohistochemically ROS1 testing in the guidelines is recommended as an aid to the FISH method. The most commonly used commercial ROS1 clone is D4D6. Recently a new immunohistochemical (IHC) clone which has higher sensitivity and specificity (SP384) is available. The aim of this study is to compare these ROS1 antibodies and to interpret with FISH results. **Method:** Twenty-three patients (fourteen ROS1 FISH-positive, nine ROS1 FISH-negative) were included for this study. The material available for all tumors had been formalin-fixed and paraffin-embedded (FFPE). D4D6 clone from Cell Signaling Technology and SP384 clone were provided by Ventana Medical Systems, which were used for ROS1 expression. The staining study was performed according to previously published methodology. ROS1 expression was evaluated by intensity scoring. IHC staining patterns of tumor cells was also interpreted as cytoplasmic or membranous and/or both pattern predominantly. All samples of FISH testing has been performed with LSI ROS1 Break Apart Probe; Abbott Molecular probe. Incompatible cases according to FISH and IHC results AmoyDx gene fusions detection kit testing has been used as confirmatory RT-PCR method. **Result:** Table 1. The immunhistochemical and FISH results of the cases

*Break apart, **İsolated 3', *** Negative -The immunhistochemical and FISH results of the cases are presented on Table1. -The study included 14 FISH positive, 6 FISH negative and 3 incompatible cases by FISH and IHC results -All ROS1 FISH rearrenged cases were also positive for both D4D6 and SP384 clones but the intensity was mostly higher; SP384 showed almost always higher intensity except in two cases (case22 and 23). -Incompatible 3 cases (Case 20, 21 and 23) FISH results were confirmed by RT-PCR but IHC results were variable. -Break apart pattern FISH positive cases did not showed membranous staining in both immunhistochemstry clones

Conclusion: -ROS1 SP384 is more feasible then D4D6 for ROS1 protein evaluation. However, both clones may rarely be incompatible with FISH results. -We recommend that the IHC and FISH study should be done together. -In incompatible cases, the RT-PCR study will be determinant with the FISH study.

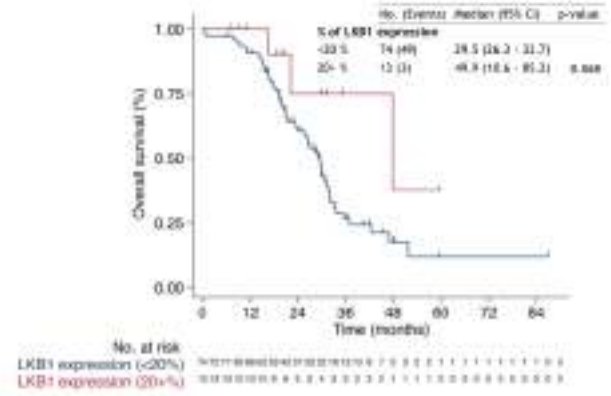
P2.09-28 PROGNOSTIC IMPACT OF LKB1 EXPRESSION IN ADVANCED NON-SMALL-CELL LUNG CANCER

D.A. Diaz-Garcia[1], L.A. Ramírez Tirado[2], A. Aviles-Salas[2], A.F. Cardona[3], A. Rodriguez-Rios[2], F. Barrón[1], O.G. Arrieta[1]

[1]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [2]*Instituto Nacional de Cancerología (INCan), Mexico/Mexico,* [3]*FICMAC- Fundación para la Investigación Clínica y Molecular Aplicada al Cáncer, Bogotá/Colombia*

Background: LKB1 is a tumor suppressor gene that regulates cell energy homeostasis, cell polarization, and apoptosis. Within lung cancer, LKB1 ranks as the third most common mutation found in lung adenocarcinoma, both alleles are somatically inactivated in 30%. LKB1 mutations are linked to smoking history, moreover, it have been associated with more aggressive clinical phenotype in KRAS-mutant NSCLC patients, according to preclinical models. Additionally, LKB1 has been associated with primary resistance to PD-1 axis inhibitors in lung adenocarcinoma. However, its expression and clinical implication has not been extensively studied. The aim of the study was to evaluate LKB1 expression in patients with advanced NSCLC. **Method:** In retrospective way patients with advanced NSCLC with and without *EGFR* mutations from México and Colombia were analyzed. Patients received therapy according *EGFR* status (TKI anti-EGFR or chemotherapy). Inclusion criteria were a histopathological confirmed diagnosis, adequate tissue to determine the expression of LKB1 by immunohistochemistry through the clone HPA017254 (Sigma®). The primary outcome was overall survival (OS). **Result:** A total of 87 patients were included in the analysis, 25.3% of them had *LKB1* positive expression. Median score intensity was 20%. There was a significant association of *LKB1* positive expression with wood-smoke exposure (76.9 vs 23.1%, p=<0.001), *EGFR* mutation (54.5 vs 45.5%, p=<0.001) compared to *LKB1* negative. Global Median OS was 29.7 months. Median OS for *LKB1* positive was 33.3 months (CI 95%, 8.9 - 57.6) and 29.5 months (CI 95%, 26.1 - 32-8) for LKB1 negative (p=0.42). After stratifying patients by percentage of LKB1 expression, cut-off of 20% showed a tendency to increase OS in patients with ≥20% expression (figure 1); 49.9 months (IC 95%, 10.6 - 85.2 months) vs 29.5 months (IC 95%, 26.3 - 32.7 months), (p=0.068). Furthermore, a similar trend in OS was observed in patients with ≥50% expression, median OS was not reached compared with 29.5 months (IC 95%, 26.2 - 32.7 months) in patients with <50% expression (p=0.091).



Conclusion: We found a trend to higher OS in patients with *LKB1* expression >20%. This data should be confirmed in prospective study in order to determine the role of *LKB1* as biomarker in NSCLC patients.

P2.09-29 CORRELATION OF TUMOR SPREAD THROUGH AIR SPACES AND CLINICOPATHOLOGICAL CHARACTERISTICS IN SURGICALLY RESECTED LUNG ADENOCARCINOMAS

M.-W. Lin[1], S.-Y. Hu[2], M.-S. Hsieh[1], J.-S. Chen[1]

[1]*National Taiwan University Hospital, Taipei City/Taiwan,* [2]*National Taiwan University Hospital, Taiwan, Taipei City/Taiwan*

Background: Tumor spread through air spaces (STAS) has recently been reported as a novel invasive pattern in lung adenocarcinoma, but the correlation between other clinicopathological and genetic profiles has not been well studied. The aim of this study was to investigate these correlations in patients with surgically resected lung adenocarcinoma. **Method:** Five hundred consecutive patients with lung adenocarcinoma who underwent curative lung tumor resection and with available STAS profile were reviewed retrospectively from January to December 2016. The correlations of STAS presence and clinicopathological and genetic characteristics were analyzed. **Result:** One hundred thirty-four patients (26.8%) had positive STAS. The pathological stage of these patients was adenocarcinoma in situ, IA, IB, II, and III in 25 (5%), 343 (68.6%), 63 (12.6%), 29 (5.8%), and 40 (8%), respectively. Multivariate analysis showed that the presence of STAS was significantly correlated to higher T (p=0.001) and N (p=0.032) stages, moderate/poor differentiation (p=0.001), and the presence of lymphovascular invasion (p=0.001). Although positive epidermal growth factor receptor mutation and non-lepidic histologic subtypes were correlated with the presence of STAS in the univariate analysis, they were not significantly correlated with the presence of STAS in the multivariate analysis (p=0.676 and 0.286, respectively).

Multivariate analysis of the correlation among clinicopathological characteristics, genetic mutation, and presence of STAS.

Positive	269	86 (32.0)			
Negative	187	44 (23.5)	0.891	0.519–1.529	0.676

Values are presented as n (%), OR, or 95% CI.
Abbreviations: *CEA*, carcinoembryonic antigen; *CI*, confidence interval; *EGFR*, epidermal growth factor receptor; *OR*, odds ratio; *SD*, standard deviation; *STAS*, spread through air spaces.

Conclusion: STAS was significantly correlated with several invasive clinicopathological characteristics, including higher T and N stages, moderate/poor differentiation, and the presence of lymphovascular invasion in surgically resected lung adenocarcinoma. The correlation may lead to poor clinical outcomes in patients with positive STAS. Based on our results and current evidence, the presence of STAS may be considered as a staging profile in future staging system.

P2.09-30 PD-L1 TESTING AND CLINICAL BENEFIT IN PATIENTS TREATED WITH CPI

M. Kovacevic, M. Ivanovic, I. Kern, T. Cufer

University Clinic Golnik, Golnik/Slovenia

Background: PD-L1 expression in tumor cells should predict better response rate in lung carcinoma patients treated with immune checkpoint inhibitors. **Method:** Retrospective analysis of 46 NSCLC lung cancer patients with cytology/pathology samples from primary tumor/metastasis tested for PD-L1 expression and comparing the PD-L1 testing results with clinical benefit. Follow-up period was 6 to 24 months. Samples were stained with PD-L1 mouse monoclonal antibody (clone 22C3, DAKO, Denmark) or with rabbit monoclonal antibody (clone SP263, Ventana/Roche, USA) on an automated staining platform (Benchmark ultra, Ventana/Roche, USA). Samples were divided into four categories: Cytology, histology, primary tumor and metastasis. Number of positive tumor cells was assessed semiquantitatively and divided into three categories: 0%, 1 to 49% and 50 to 100%. We compared PD-L1 expression with clinical course of patients treated with immune checkpoint inhibitors (nivolumab, pembrolizumab and atezolizumab), considering complete response, partial response and stable disease (RECIST criteria) as clinical benefit. Progress of the disease was considered as no clinical benefit. **Result:** We had 37% cytological and 63% histological samples. Overall PD-L1 expression was present in 76% of all samples (1 to 49% and 50 to 100% categories, 13% and 63%, respectfully). We observed clinical benefit in 33 patients (5, 5 and 23 with 0%, 1 to 49% and 50 to 100%, respectively). Progress of the disease was observed in 13 patients (6, 1 and 6 with 0%, 1 to 49% and 50 to 100%, respectively). Out of 29 patients with histological samples, 22 had clinical benefit (2, 5 and 15 with 0%, 1 to 49% and 50 to 100%, respectively). Progress of the disease was observed in 7 patients (5, 0 and 2 with 0%, 1 to 49% and 50 to 100%, respectively). Out of 17 patients with cytological samples 11 had clinical benefit (3, 0 and 8 with 0%, 1 to 49% and 50 to 100%, respectively). Progress of the disease was observed in 6 patients (1, 1 and 4 with 0%, 1 to 49% and 50 to 100%, respectively). We had 29 samples from primary tumor and 17 samples from metastasis. 23 patients with primary tumor sample (2, 4 and 16 with 0%, 1 to 49% and 50 to 100%, respectively) and 10 with metastasis sample (3, 0 and 7 with 0%, 1 to 49% and 50 to 100%, respectively) had clinical benefit. Progress of the disease was observed in 6 patients with primary tumor sample (4, 0 and 2 with 0%, 1 to 49% and 50 to 100%, respectively) and in 7 patients with metastasis sample (2, 1 and 4 with 0%, 1 to 49% and 50 to 100%, respectively) . **Conclusion:** Histological samples from primary tumors seem to have the best, while cytological samples from metastases the poorest predictive value for assessment of clinical benefit for NSCLC patients treated with immunotherapy.

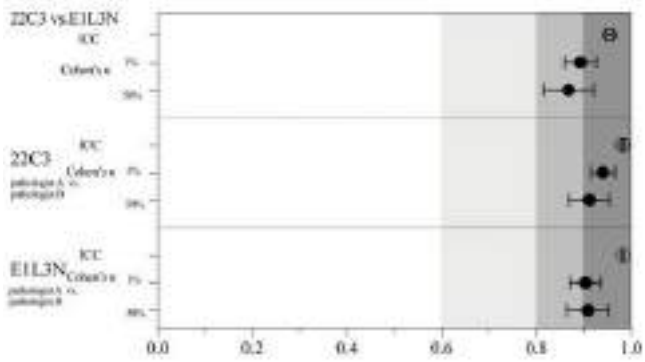
P2.09-31 HIGH CONCORDANCE OF PD-L1 ANTIBODY BETWEEN CLONE 22C3 AND CLONE E1L3N IN NON-SMALL CELL LUNG CANCER BIOPSY SAMPLES

W. Zhang, C. Wu

Shanghai Pulmonary Hospital, Shanghai/China

Background: PD-L1 22C3 pharmDx was approved as a companion diagnostics for predicting response to pembrolizumab of advanced non-small cell lung cancer (NSCLC) patients. However, the laboratory developed tests (LDTs) for PD-L1 immunohistochemistry were widely available and urgently be standardized in clinical routine practice. We compared the concordance between PD-L1 antibody clone E1L3N and clone 22C3 expression on the DaKo AutostainerLink48 platform in NSCLC biopsy samples. **Method:** 171 non-small cell lung cancer (NSCLC) biopsy samples were recruited in this study, Serial sections of FFPE blocks were used for IHC staining. The staining protocol was performed according to the standard of PD-L1 IHC 22C3 pharmDx package. **Result:** PD-L1 clone E1L3N and 22C3 distributed a similar pattern in NSCLC biopsy samples. The two assays scoring of E1L3N and 22C3 were highly concordant (lower Kappa value was 0.868 for two cutoff). There was very strong reliability among two pathologists in evaluating PD-L1 scoring with two assays (the lowest PPA was 88.9% for two cutoff). The PPA range was 85.7%-96.3% for all samples. In the Bland-Altman analysis, the mean difference in percentage of tumor cells positively stained for PD-L1 between the paired assay findings was 1.36% for all samples, and 0.57%, -0.66% between the two pathologists for 22C3 and E1L3N assay, respectively.



Conclusion: The results indicated that clone E1L3N assay has a high concordance with 22C3. PD-L1 clone E1L3N assay is reliable and cost-effective, which could be used as a primary screening agent for PD-L1 IHC staining in the pathological laboratory.

Keywords: Non-Small Cell Lung Cancer, PD-L1, immunohistochemistry

P2.09-32 HIGHER PREVALENCE OF EGFR MUTATIONS SIGNIFICANTLY CORRELATES WITH LOWER PD-L1 EXPRESSION IN CHINESE LUNG ADENOCARCINOMA

S. Wen[1], Y. Jiang[2], J. Guo[3], X. Fan[4], X. Pan[5], Y. Dai[5], D. Chen[5], K. Wang[5], X. Dong[5], S. Zhang[6]

[1]*Fourth Hospital of Hebei Medical University, Shijiazhuang/China,* [2]*Shandong Provincial Hospital Affiliated to Shandong University, Jinan/China,* [3]*Xingtai People's Hospital, Xingtai/China,* [4]*Qilu Hospital Qingdao Branch, Qingdao/China,* [5]*Origimed, Shanghai/China,* [6]*OrigiMed, Shanghai/China*

Background: *EGFR* mutations are more prevalent in lung adenocarcinoma compared with other non-small cell lung cancer and are more prevalent in East Asians compared with the other populations. At the same time, we observed lower PD-L1 Tumor Proportion Score (TPS) in Chinese lung adenocarcinoma patients (pts) compared with that in Chinese lung squamous cell carcinoma pts and we also observed the proportion of PD-L1 positive (TPS >= 1%) in Chinese lung adenocarcinoma pts was lower than that in other multicenter cohorts. Then we hypothesize that the higher prevalence of *EGFR* mutations in Chinese lung adenocarcinoma pts correlates with lower PD-L1 expression. **Method:** The Origimed-based lung adenocarcinoma cohort was a retrospective cohort consisted of more than one thousand Chinese lung adenocarcinoma pts who underwent both NGS panel sequencing and PD-L1 immunohistochemistry (IHC) in a College of American Pathologists (CAP) certified and Clinical Laboratory Improvement Amendments (CLIA) certified laboratory during the year 2017 and 2018. Antibodies used in the PD-L1 IHC assay included 28-8 (sample size = 883) and 22C3 (sample size = 158). Tumor Proportion Score (TPS) was applied. All the slides were reviewed by the same senior pathologist. All the *EGFR* mutations were manually reviewed in Integrated Genomics Viewer for confirmation. After confirmation, each pts was assigned to *EGFR* positive group or *EGFR* negative group. Fisher' s exact test and Student' s t-test were applied. **Result:** For antibody 28-8, PD-L1 IHC was positive (TPS >= 1%) in 18% (66/370) *EGFR* positive pts and was positive in 35% (180/513) *EGFR* negative pts (fisher exact test p value = 1.6e-5). For antibody 22C3, PD-L1 IHC was positive (TPS >= 1%) in 14% (9/64) *EGFR* positive pts and was positive in 45% (42/94) *EGFR* negative pts (fisher exact test p value = 3.8e-3). And we observed a significantly lower PD-L1 TPS in *EGFR* positive pts for both antibodies (t-test p value = 3.5e-11 for PD-L1 antibody 28-8; t-test p value = 6.0e-5 for PD-L1 antibody 22C3). **Conclusion:** The observation demonstrated that lower PD-L1 TPS in Chinese Lung Adenocarcinoma pts was significantly correlated with East-Asian-specific high prevalence of *EGFR* mutations. The observation reassured that *EGFR* mutation status should be examined simultaneously with PD-L1 IHC in lung adenocarcinoma pts because it was a confounding factor for predicting immunotherapy outcome using PD-L1 TPS. The observation partly explained the generally higher PD-L1 TPS in Chinese lung squamous carcinoma pts compared with that in Chinese lung adenocarcinoma pts.

Keywords: EGFR, IHC, PD-L1

P2.09-33 PREVALENCE OF ROS1 (SP384)-REACTIVE TYPE II PNEUMOCYTE STAINING IN LUNG TISSUE

C. Le, R. Huang, T. Foutch, C. Patel, A. Newell, G. Pate, I. Menzl

Roche Tissue Diagnostics, Tucson/United States of America

Background: Availability of a positive control sample is important to ascertain that specimen preparation and immunohistochemistry (IHC) processes are performed correctly. Lack of proper control tissue may result in an invalid IHC interpretation. Given the low prevalence (1-2%) of *ROS1* gene fusions (which leads to overexpression of ROS1) in non-small cell lung cancer (NSCLC), the feasibility of using *ROS1*-fusion positive NSCLC tissue as a control sample is challenging. ROS1 wild-type (WT) protein expression has been shown to be absent in normal lung tissue; however, ROS1 reactivity has been observed in reactive type II pneumocytes in non-neoplastic lung tissue. Hence, we sought to characterize the prevalence of VENTANA ROS1 (SP384) Rabbit Monoclonal Primary Antibody (ROS1 (SP384)) reactive type II pneumocytes in normal or benign lung tissue in order to assess the feasibility of using type II pneumoctyes as a control tissue for ROS1 (SP384). **Method:** One hundred seventy-seven (177) formalin-fixed, paraffin-embedded (FFPE) normal or benign lung tissue samples were randomly procured. Tissues sectioned at 4 µm were stained with hematoxylin and eosin (H&E), Rabbit Monoclonal Negative Control Ig, and ROS1 (SP384) IHC. ROS1 (SP384)-stained specimens were evaluated for presence of type II pneumocytes. If present, type II pneumocytes were evaluated for reactivity based on a 0 to 3-point stain intensity scale. Reactivity was defined as any staining greater than 0. Data was analyzed for percent distribution for a range of stain intensities. **Result:** Out of the 177 specimens evaluated, 165 ROS1 (SP384)-stained slides were evaluable (12 cases were unacceptable due to tissue loss or were identified as neoplastic lung tissue). Type II pneumocytes were present in all 165 evaluable samples. Forty-seven type II pneumocyte samples (28.5%, 47/165) demonstrated no staining with ROS1 (SP384) while 71.5% of the type II pneumocyte samples (118/165) demonstrated reactivity with ROS1 (SP384). In addition, 23.0% (38/165) of the type II pneumocyte samples demonstrated a stain intensity of at least 2. **Conclusion:** Herein, this cohort demonstrates a high prevalence of ROS1 reactivity in type II pneumocytes, with a range of stain intensities, in normal or benign lung tissue with VENTANA ROS1 (SP384) Rabbit Monoclonal Primary Antibody. This finding suggests that use of reactive type II pneumocytes in normal or benign lung tissue as a control tissue for ROS1 (SP384) is feasible.

P2.09-34 NEXT-GENERATION SEQUENCING IMPLEMENTATION IN NON-SMALL CELL LUNG CANCER MOLECULAR DIAGNOSIS

S. Clavé, B. Bellosillo, M. Salido, G. Tagmouti, Á. Taus, P. Rocha, M. Hardy-Werbin, L. Moliner, X. Riera, C. Fernández-Rodríguez, E. Arriola, L. Pijuan

Hospital del Mar, Barcelona/Spain

Background: Currently, all patients with advanced non-small cell lung cancer (NSCLC) require *EGFR, ALK, ROS1* and *BRAF* molecular characterization. Next-generation sequencing (NGS) allows the simultaneous analysis of these biomarkers optimizing both the sample and the economic cost. The purpose of this study was to compare NGS results with those obtained using single gene analysis in a prospective clinical setting. **Method:** During 12 months, 50 paraffin-embedded samples from patients with advanced NSCLC (46 adenocarcinomas and four NSCLC-NOS) were prospectively analyzed in our institution. Molecular characterization was carried out using the NGS Oncomine Solid Tumor DNA and Fusion Transcript Kits for hotspot mutations and gene fusions (Thermo Fisher) and results were compared with Therascreen *EGFR* RGQ PCR Kit (Qiagen), and Vysis *ALK* and *ROS1* Break Apart FISH Probe Kits (Abbott Molecular, ZytoVision). **Result:** All samples studied by NGS for hotspot mutations were assessable and we detected pathogenic alterations in 90% (n= 45). Regarding targetable alterations, we identified nine patients harboring *EGFR* mutations (18%), in agreement with real-time PCR (except for one case which had an exon 20 insertion not interrogated by Therascreen), and one patient with a *BRAF* mutation (2%). We highlight the presence of *TP53* mutations in 27 cases (54%), *KRAS* in 16 cases (32%) and *STK11* in three cases (6%). *TP53* mutations were concomitant with other alterations in 70% of the cases (n= 19), without being significantly associated with any of them. Gene fusion analysis by NGS was assessable in 80% of the samples (n= 40): six samples had insufficient RNA quality and four had not enough material. We detected only one case with an *ALK* rearrangement (2%), confirmed by FISH. **Conclusion:** NGS technology for NSCLC molecular diagnosis could be considered as the initial screening test although the success rate in gene fusion assessment is closely related to RNA paraffin-embedded evaluation. NGS also detected other genomic alterations that allowed referral of patients to clinical trials.

P2.09-35 PROPOSAL TO REVISE VENTANA ALK SCORING INTERPRETATION GUIDE FOR NON-SMALL CELL LUNG CARCINOMA: INTERPRETATION OF ALK HETEROGENEITY

L.-X. Yan[1], Q. Cui[2], D.-L. Luo[2], Y. Ge[2], J. Chen[2], Z. Li[2], Y.-L. Wu[3], Y.-H. Liu[1]

[1]*Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [2]*Guangdong Provincial People`s Hospital, Guangdong Academy of Medical Sciences, Guangzhou/China,* [3]*Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: A small number of non-small cell lung cancer (NSCLC) cases showed heterogeneity of anaplastic lymphoma kinase (ALK) by VENTANA immunohistochemistry (IHC) in clinical practice. According to the ALK Scoring Interpretation Guide for VENTANA anti-ALK (D5F3), the presence of strong granular cytoplasmic staining in tumor cells (any percentage of positive tumor cells) is called positive for ALK. However, we know little about ALK heterogeneous cases. Multiple detection platforms are used to analyze molecular variability and pathological features in anticipation of clinical treatment decisions for such cases. **Method:** A total of 2228 NSCLC cases with successful ALK IHC (VENTANA, D5F3, Roche) detection in Guangdong Provincial People`s Hospital were recruited between January 2012 and April 2018. Positive and negative system control and a negative agent control were established for each case. ALK IHC positivity was defined as the presence of strong granular cytoplasmic staining in 100% tumor cells; ALK IHC heterogeneity as the presence of strong granular cytoplasmic staining in 1-99% tumor cells; ALK IHC negativity as no tumor cells show strong granular cytoplasmic staining. Fluorescence *in-situ* hybridization (FISH) (Vysis ALK Break Apart FISH Probe Kit, Abbott) and next-generation sequencing (NGS) (OseqTMLung Cancer Gene Detection, BGI, China) was performed for cases showed ALK (D5F3) IHC heterogeneity. **Result:** ALK (D5F3) double-blind review analysis showed 201 (9.0%) ALK-positive cases, 10 (0.4%) ALK-heterogeneous cases, and 2017 (90.5%) ALK-negative cases. The heterogeneity cases included 2 large cell neuroendocrine carcinomas, 1 lymphoid epithelioid carcinoma, and 7 squamous cell carcinomas. The percentages of tumor cells with strong granular cytoplasmic staining were 1% to 30%. The *ALK* FISH break apart signal of these ten cases were 0% to 12%, indicating *ALK* FISH negativity. Nine ALK-heterogeneous cases were successfully detected by NGS, and no *ALK*gene variations (including gene fusion, copy number variation, insertion/deletion or single nucleotide variation) were found. Immunohistochemical staining showed that some ALK-heterogeneous cases showed neuroendocrine differentiation.

POSTERS

Table. Comparison of IHC, FISH and NGS results of the ALK-heterogeneous cases.

						ALK IHC	ALK FISH	ALK FISH	ALK NGS	ALK NGS	
Case No.	**Gender**	**Age**	**Biopsy/ surgery**	**Diagnosis**	**Tumor cell content**	**Strong positive staining tumor cells**	**Break apart signal**	**Interpretation result**	*ALK* **fusion**	*ALK* **INDEL/ SNV/CNV**	**8th TNM**
1	M	69	Wedge resection	Large cell neuroendocrine carcinoma	70%	2%	0%	Negative	Negative	Negative	pT1bN0M0
2	M	55	Lobectomy	Large cell neuroendocrine carcinoma	85%	20%	4%	Negative	Negative	Negative	pT2bN0M0
3	F	33	Lobectomy	Lymphoid epithelioid carcinoma	60%	5%	0%	Negative	Negative	Negative	pT3N0M0
4	M	68	Lobectomy	Squamous cell carcinoma	70%	5%	6%	Negative	Negative	Negative	pT3N0M0
5	M	69	Lobectomy	Squamous cell carcinoma	70%	5%	12%	Negative	Negative	Negative	pT2aN0M0
6	M	52	Lobectomy	Squamous cell carcinoma	80%	1%	0%	Negative	Negative	Negative	pT2aN1M0
7	M	73	Lobectomy	Squamous cell carcinoma	90%	5%	2%	Negative	Negative	Negative	pT3N0M0
8	M	70	Lobectomy	Squamous cell carcinoma	80%	5%	4%	Negative	Negative	Negative	pT2bN1M0
9	M	69	Biopsy	Squamous cell carcinoma	85%	15%	0%	Negative	Negative	Negative	sT3N1M0
10	M	60	Biopsy	Squamous cell carcinoma	85%	30%	0%	Negative	NA	NA	cT2bN3M0

Abbreviations: INDEL, insertion and deletion; SNV, single nucleotide variation; CNV, copy number variation; NA, NGS was not performed due to insufficient tumor tissues.

Conclusion: Multi-platform detection of ALK-heterogeneous cases did not show evidence of *ALK*gene variation, and the effect of ALK-TKI treatment was unknown. therefore, the VENTANA ALK scoring interpretation guide for non-small cell lung carcinoma should be revised. It is recommended that ALK-heterogeneous cases be defined as ALK (D5F3) uncertain equivocal cases. The molecular pathology report should clearly state that the clinical significance is unclear, and it is recommended to conduct further testing by FISH or NGS.

Keywords: Non-Small Cell Lung Cancer, VENTANA ALK, Heterogeneity

P2.10-01 ANALYSIS OF HUMAN PAPILLOMA VIRUSES (HPV) AND HUMAN POLYOMA VIRUSES (HPYV) IN LUNG CANCER FROM SWEDISH NEVER-SMOKERS

T. Ramqvist[1], C. Ortiz-Villalón[1], E. Brandén[2], H. Koyi[2], L. De Petris[1], G. Wagenius[3], O. Brodin[1], C. Reuterswärd[4], T. Dalianis[1], M. Jönsson[4], J. Staaf[4], R. Lewensohn[1], M. Planck[4]

[1]*Karolinska Institutet, Stockholm/Sweden,* [2]*Gävle Hospital, Gävle/Sweden,* [3]*Karolinska University Hospital, Stockholm/Sweden,* [4]*Division of Oncology and Pathology, Lund/Sweden*

Background: A possible role for oncogenic infections in the etiology of lung cancer has been investigated in a large number of studies, with contradictory results. High-risk mucosal human papillomaviruses (HPV), recognized as being associated with cervical cancer and oropharyngeal cancer, has been suggested as a causative factor also in lung cancer [1,2], whereas other studies found no, or at most very limited, involvement of HPV in lung cancer [3,4]. To investigate human papillomaviruses (HPV) and human polyomaviruses (HPyV) as possible causative factors behind lung cancer in never-smokers, we analyzed the presence of these viruses in a subset of tumors within a larger Swedish cohort of never-smoking lung cancer patients [Swedish Molecular Initiative against Lung cancer, SMIL; Salomonsson et al. Abstract WCLC 2019]. **Method:** Eighty-seven surgically resected lung cancer samples from never-smokers, diagnosed 2005-2014 in Stockholm, Sweden, were analyzed by Luminex assays for the presence of 27 HPV types (including all HPV types currently regarded as high-risk types) and for 10 HPyV species (BKPyV, JCPyV, KIPyV, WUPyV, TSPyV, MWPyV, HPyV6, 7, 9, and 10). **Result:** All samples were positive for the β-globin gene, confirming the presence, amplification and detection of cellular DNA. All samples were negative for the HPV types included in the assay. The only viral DNA detected in the tumors were low amounts of Merkel cell polyomavirus (MCPyV) DNA, of unknown significance, in 15 samples. **Conclusion:** Our study shows no evidence for neither HPV nor HPyV in the etiology of lung cancer in Swedish never-smokers. Background: Tobacco is the leading cause of lung cancer. The fight against the smoking habit is essential and should be continuous, to detect the national situation that makes it possible to design health care policies against this consumption. To do so, the *Grupo Español de Cáncer de Pulmón* (Spanish Lung Cancer Group) made this analysis within the context of the Thoracic Tumor Registry (TTR). **Method:** The TTR is an observational cohort multicenter study in Spain. The study is conducted according to the Declaration of Helsinki and approved by the institutional review board of each participating site. The registry was approved by the Spanish Drug Agency, as a non-post-authorization, non-interventional study. **Result:** We collected data from 6,600 patients diagnosed of lung cancer from 58 different Spanish hospital sites. A total of 3,039 patients were former smokers (46%), 2,611 were active smokers (39%) and only 866 (12%) patients stated to be non-smokers; the status in 2% is unknown. If we make a comparison by gender regarding the presence of this habit, large differences (p-valor < 0.001) are observed, with a greater number of non-smokers in women (37 % vs. 4.5% in males), while the percentage of former smokers is much higher in the males (53.4% vs. 27.9% in women) and a minor difference in active smokers (42.1% vs. 34.4% in women). Significant differences were observed in the study on the distribution of the smoking habit by gender and year of diagnosis. An increase is also observed in the last two years regarding the percentage of patients who were active smoked, both for the total population as well as for each one of the two genders separately. The increase is greater among the women and, also, the number of women who are active smokers is greater in recent years. Mean age of onset of the smoking habit is 18.2 years. Significant differences are observed between both genders (p-valor < 0.001), with a mean age of initiation of 17.9 years in the men (95%CI 17.6-18.2 years) and 19.2 years in the women (95%CI 18.5-19.8 years). Significant differences between Regional Communities were also found in the mean age at onset of the habit, with much lower levels in the Valencian Community (16.6 years) or Navarra (16.9 years) regarding other communities, such as the Region of Murcia (22.9 years) or the Balearic Islands (21.6 years) **Conclusion:** Lung cancer in Spain is associated to tobacco consumption in 85% of the cases diagnosed. Consumption has shown an increase in both genders in recent years and is especially rapid and worrisome in women. Anti-smoking campaigns should be reactivated and the causes of the regional differences analyzed in depth

Keywords: smoking habit, tobacco consumption

P2.10-03 PREVALENCE OF TOBACCO USE DISORDER IN PATIENTS DIAGNOSED WITH LUNG CANCER AND THEIR TOBACCO USE CHARACTERISTICS

C.K. Park[1], C.D. Yeo[1], J.S. Kim[1], S.H. Lee[1], Y.K. Kim[1], S.H. Paik[2], J.E. Jeong[3], D.J. Kim[3], S.J. Kim[1]

[1]*The Cancer Research Institute, College of Medicine, The Catholic University of Korea, Seoul/Korea, Republic of,* [2]*Addiction Center, Keyo Hospital, Seoul/ Korea, Republic of,* [3]*Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/Korea, Republic of*

Background: Tobacco use disorder (TUD), previously termed as nicotine dependence, was associated with increased risk of lung cancer. However, little is known about the prevalence of TUD and symptom manifestation in smokers with lung cancer. The aim of the present study was to investigate the prevalence of TUD using DSM-5 diagnostic criteria in patients diagnosed with lung cancer and determine their tobacco use characteristics. **Method:** A total of 200 histologically confirmed lung cancer patients who used tobacco within prior 12-month period at the time of diagnosis were recruited for this study. Participants were assessed with interviewer-administered questionnaires on symptoms of TUD and smoking-related behaviors and self-administered Fagerstrom Test for Nicotine Dependence (FTND). **Result:** The prevalence of DSM-5 TUD was 92.0% (n = 184). Of a total of 200 subjects, 23 (11.5%), 35 (17.5%), and 126 (63.0%) were classified as mild, moderate, and severe TUD, respectively. A total of 19 (81.3%) moderate TUD and 98 (77.8%) severe TUD patients had attempted smoking cessation.

Of these subjects, 21 (21.4%) severe TUD patients and 12 (63.2%) moderate TUD patients had tried more than three times. The number of satisfied criteria of DSM-5 TUD was positively correlated with FTND score, cumulative lifetime smoking amount, and daily smoking amount. **Conclusion:** Smokers diagnosed with lung cancer had high prevalence of DSM-5 TUD. Their heavy and consistent tobacco use characteristics might be less motivated to maintain abstinence and make them to be less stick to quit.

Keywords: Tobacco, Lung cancer, Tobacco use disorder

P2.10-04 PREDICTING NON-COMPLIANCE IN ROUTINE LUNG CANCER SCREENING FOR HIGH-RISK ADULTS

M. Tammemagi[1], K. Nguyen[1], C. Mcgarry[1], H. Schmidt[2], Y. Leung[1], G. Darling[1]

[1]*Cancer Care Ontario, Toronto/Canada,* [2]*University Health Network, Toronto/Canada*

Background: Lung cancer is the most common cause of cancer-related deaths, which can be effectively reduced by routine screening. To detect lung cancer early, annual screening in high-risk adults aged 55-74 years using low-dose computed tomography (LDCT) is recommended by the Canadian Medical Association guidelines. High-risk adults are recommended an annual screen within 11-15 months of their baseline scan. However, screening compliance is a challenging area influenced by a series of complex biopsychosocial, behavioral and cognitive processes. This study aims to describe the participants and identify predictors of noncompliance in the Lung Cancer Screening Pilot for People at High Risk Program (HR LCSP) conducted in Ontario, Canada. **Method:** During 2017-18, HR LCSP has recruited over 5,999 high-risk adults from 3 sites in Ontario, with 5,502 adults undergone risk assessment for screening eligibility, and 2,997 baseline scans conducted. Baseline and follow-up participant experience surveys assess satisfaction especially around test result communication. During risk assessment, all individuals who identify as current smokers are referred to smoking cessation services irrespective of their eligibility. The clinical data are collected using an internationally accepted standard, the Resident Assessment Instrument Minimum Data Set at each site. We hypothesize that participant compliance is predicted by the satisfaction of their first screening experience in additional to socio-demographic and clinical factors. A multivariable logistic regression model will be conducted to predict non-compliance, which is defined by a return interval >15 months or missing. The model will contain individual level factors including age, sex, aboriginal status, education, income estimates, geographic distance; system level factor includes physician-referral/self-referral status; clinical factors include the risk prediction by PLCOm2012, which assesses smoking status including intensity and duration; other clinical factors include personal and family history of cancer, history of lung disease, body mass index; psychosocial/behavioral factors include smoking cessation program participation, baseline screening results including the presence of actionable incidental findings and appropriate follow-up of the abnormal results. Data linkage is under way and results will be presented at the conference. **Result:** This study will provide a granular view on the predictors of routine screening compliance among high-risk adults, which will be used to improve the program recruitment and retention especially when designing targeted messages. Findings will have implications for health care professionals when communicating with high-risk individuals about routine screening for lung cancer. **Conclusion:** Section not applicable.

Keywords: non-compliance, organized screening program, predictors

P2.10-05 INDOOR RADON AND LUNG CANCER RISK. A POOLING STUDY ON THE SECOND RISK FACTOR FOR LUNG CANCER

A. Ruano-Ravina[1], M. Lorenzo-González[1], M. Provencio[2], M. Torres-Durán[3], I. Parente-Lamelas[4], I. Vidal-García[5], J. Barros-Dios[1]

[1]*University of Santiago de Compostela, Santiago de Compostela/Spain,* [2]*Hospital Puerta De Hierro Majadahonda, Madrid/Spain,* [3]*Hospital Álvaro Cunqueiro, Vigo/Spain,* [4]*Ourense Hospital Complex, Ourense/Spain,* [5]*Complejo Hospitalario Universitario de A Coruña, A Coruña/Spain*

Background: Residential radon is the second risk factor of lung cancer following tobacco consumption, according to WHO (World Health Organization) and United States EPA statements. It is recognized as the first cause of lung cancer in never-smokers by both organizations. Nevertheless, case-control studies performed in radon prone areas are still scarce and with limited sample sizes. We aim to know the relationship between residential radon and lung cancer risk in a study performed in a radon-prone area, and where inhabitants live for a long time in the same dwelling. **Method:** We have pooled results from 5 different case-control studies performed in the same geographical area to assess the relationship between indoor radon and lung cancer. One of these studies was focused specifically in never smokers and other in Small Cell Lung Cancer. All cases and controls were older than 30 and cases had a confirmed diagnosis of lung cancer. Controls were selected for attending hospital for trivial surgery. Controls were selected through a frequency-based sampling based on age and gender distribution of cases. The information and questionnaires collected was the same in all studies, with special focus on tobacco consumption. Radon devices of an alpha track type were placed at the participants' homes for at least three months. Odds Ratios of lung cancer due to radon exposure have been calculated adjusted by age, gender, and tobacco consumption. **Result:** We included 1691 cases and 1698 controls. Median age was 63 and 67, respectively, and females comprised 33% of both cases and controls. Adenocarcinoma was the most frequent histology (43%) and participants lived a median of 30 years in the same dwelling. The table show the risk of lung cancer due to radon exposure.

Table. Residential radon and lung cancer.

Variable	Cases n (%)	Controls n (%)	OR[a] (95% CI)	OR[b] (95% CI)
Residential radon exposure, Bq/m³				
≤50	219 (14.9)	346 (24.1)	1 (---)	1 (---)
51-100	352 (24.0)	350 (24.4)	1.61 (1.28-2.02)	1.66 (1.28-2.15)
101-148	265 (18.1)	235 (16.4)	1.75 (1.37-2.25)	1.89 (1.43-2.50)
149-200	194 (13.2)	162 (11.3)	1.86 (1.41-2.45)	2.00 (1.48-2.72)
>200	435 (29.7)	343 (23.9)	2.00 (1.60-2.52)	2.32 (1.80-3.00)
Tobacco consumption				
Never-smokers	523 (33.4)	900 (54.5)		1 (---)
1-33	205 (13.1)	423 (25.6		1.51 (1.17-1.94)
34-66	425 (27.2)	223 (13.5)		6.19 (4.78-8.02)
>66	412 (24.4)	104 (6.3)		12.1 (8.96-16.4)

[a]Adjusted by age and sex [b]Adjusted by age, sex and tobacco consumption.

Conclusion: Residential radon is a relevant risk factor for lung cancer, even below concentrations established as safe by USEPA and WHO.

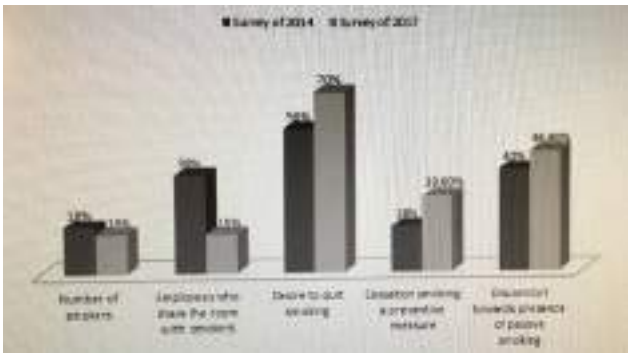
Keywords: Indoor radon, case-control study, ionizing radiation

P2.10-06 SMOKING PREVALENCE AND PERCEPTIONS AMONG HEALTHCARE PROFESSIONALS: A SURVEY IN AN ITALIAN CLINICAL CANCER CENTRE

D. Bafunno, A. Catino, V. Lamorgese, D. Galetta, V. Longo, A. Mastrandrea, M. Montrone, F. Pesola, P. Petrillo, P. Pizzutilo, D. Ricci, N. Varesano, A. Zacheo

Clinical Cancer Centre "Giovanni Paolo II", BARI/Italy

Background: A survey has been conducted on employees of our Clinical Cancer Centre about the smoking prevalence and knowledge of the smoking-related harms. The results have been compared to those emerged from a previous survey when the current smoke-free-hospital policies (national and internal) were not yet active. **Method:** In June 2017, during two weeks, 400 subjects received an anonymous questionnaire (36items) investigating demographics, smoking-habits, secondhand-smoke exposure, knowledge of Italian smoke-free legislation. **Result:**



104 subjects (26%) returned the self-completed form (M=45.34years, SD=10.5; 67.3%women). 17,8%of responders were smokers, 26,2%former smokers, 56% no smokers, while in 23,8% the data were missing. Among the former smokers, the mean age of smoking cessation was 33,3 years (sd=10,2), without drugs in 77,3% of cases, for the following reasons: preventive health purposes (29,6%),a child birth (26%),suggestions from family members (3,%); no one stopped on medical advice. The ex-or never smokers share the working room with one (23,2%) or more (8,5%) smokers, pointing out the smoke exposure in hospital (30%), and feeling intense uneasiness (46,8%). The smoke-free-hospitals policy is not fully accepted, indeed only 40% declared that the smoking ban is observed and 63,2% said to smoke during the working-time. Regarding the policies that prohibit smoking inside and outside the hospital, the responders perceived it as a good way to protect the health (65,4%), to reduce the prevalence of smokers in hospital (20%), to protect non-smokers (46,1%) and to decrease tobacco-related disorders (37,5%) (p<0,001). The implementation of Italian smoke-free policies has favoured the reduction of the number of smoked cigarettes (55%), but did not increase the desire of a complete cessation (63%). A comparison of the surveys conducted in 2014 and 2017 is showed in Figure. **Conclusion:** The adopted strategies are partially efficient; among personnel there is a large prevalence of smokers and interventions aimed at the development of a culture of health promotion are needed.

Keywords: Survey, Smoking prevalence, Antismoking in-hospital policy

P2.10-07 DOES SHORT-TERM CESSATION OF SMOKING BEFORE LUNG RESECTIONS REDUCE THE COMPLICATION RISK?

T. Takenaka[1], M. Edagawa[1], K. Yamazaki[2], F. Shoji[2], M. Takenoyama[3], S. Takeo[2]

[1]*Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hirosima city/Japan,* [2]*NHO Kyushu Medical Center, Fukuoka/Japan,* [3]*National Kyushu Cancer Center, Fukuoka/Japan*

Background: Smoking cessation is one of the most important preoperative preparatory acts before thoracic surgery; however, the optimal timing for preoperative smoking cessation has not been clarified. In this study, we examined the effect of short-term smoking cessation before pulmonary resection for preventing postoperative pulmonary complications (PPCs). **Method:** We enrolled 753patients who underwent curative surgical resection for thoracic malignancies from 3institutions. We instructed patients with a smoking history to quit smoking by at least four weeks prior to surgery in order to reduce the incidence of pulmonary events. We collected information on the preoperative smoking status, duration of smoking cessation before surgery, and occurrence of postoperative pulmonary complications. Study subjects were classified into three groups based on their smoking status. Recent smokers were defined as any who had smoked within two months before surgery, and former smokers were defined as those who had abstained from smoking for more than two months prior to the operation. Never-smokers were defined as those who had never smoked. We examined the relationship between the duration of the preoperative smoke-free period and the development of PPCs. **Result:** The mean age of the patients was 68 years old, including 426 males and 327 females. Former smoker accounted for 48% (n =361) of the cases, followed by never smokers (n=287, 38%) and recent smokers (n=105, 14%). Surgery was performed for 660 primary lung cancer and 93 metastatic lung tumor. The types of procedures performed included lobectomy (n=542), pneumonectomy (n=11), wedge resection (n=167) and segmentectomy (n=33). PPCS were observed 62 cases (8%) among all patients. The incidence of PPCS among recent, former and never-smokers was 15%, 8% and 6%, respectively (p=0.01). The mean duration of post-operative chest tube drainage among recent, former and never-smokers 3.2, 2.2 and 2.2 days, respectively (p=0.04). The mean post-operative hospital stay among recent, former and never-smokers was 12.1, 10.6 and 10.2 days, respectively (p=0.07). There were no cases of 30-day mortality.

Table Relationship between characteristics of the patients, outcome and smoking status

Factor	Never smokers (n=287)	Former smokers (n=361)	Recent smokers (n=105)	p-value
Mean age	68.4 (38-90)	67.6 (21-92)	65.6 (28-86)	0.15
Gender				
male	67 (23%)	280 (78%)	79 (75%)	<0.01
female	220 (77%)	81 (22%)	26 (24%)	
%VC	106.2%	103.1%	102.3%	0.02
FEV1.0%	76.7%	72.8%	71.5%	<0.01
Surgical procedure				
partial resection	57 (20%)	93 (26%)	17 (16%)	0.08
segmentectomy	15 (5%)	15 (4%)	3 (3%)	
lobectomy	214 (75%)	245 (68%)	83 (79%)	
pneumonectomy	1 (1%)	8 (2%)	2 (2%)	
PPCs				
No	270 (94%)	332 (92%)	89 (85%)	0.01
Yes	17 (6%)	29 (8%)	16 (15%)	
Mean hospital stay	10.2 (1-23)	10.6 (2-73)	12.1 (1-73)	0.07
Mortality	0 (0%)	0 (0%)	0 (0%)	1.00

Conclusion: Cigarette smoking was associated with PPCS such as respiratory failure, pneumonia, empyema, atelectasis and prolonged air leakage. In addition, cigarette smoking generated a harmful effect for post-operative short-term outcome. Smoking abstinence for at least 2 months prior to surgery was not shown to reduce the incidence of PPCs.

Keywords: smoking cessation, surgical resection, post-operative pulmonary complication

P2.10-08 ASSOCIATION BETWEEN SMOKING AND ANXIETY/DEPRESSION IN RESPIRATORY TRACT CANCERS

Z. Deliu[1], J. Zhang[1], M. Pasquinelli[1], H. Wang[1], C. Weldon[2], L. Liu[3], L. Feldman[1], M. Huber[1]

[1]*University of Illinois Hospital & Health Sciences System, CHICAGO/United States of America,* [2]*Northwestern University, Chicago/United States of America,* [3]*University of Illinois at Chicago, Chicago/United States of America*

Background: Several studies have shown that depression can reduce patients' immune and endocrine functions. The prevalence of depression and anxiety is the highest among respiratory tract cancers, which in turn has a negative impact on treatment outcomes. Interestingly, patients with lung cancer have the highest rates of depression when compared to those with other types of cancers. We believe one possible reason for this is that they may suffer from the stigma that lung cancer is self-induced by smoking. Society has shifted perspectives greatly on how smoking is viewed. From widely disseminated anti-smoking ads to increased political campaigns and regulations to ban smoking in public spaces, lung cancer has now become almost synonymous with a disease of smoking. In this study, we analyzed the association between PHQ-4 scores and smoking status in lung and head and neck cancer patients. **Method:** Medical records for 395 lung and head and neck cancer patients (never smokers=83, former smokers=142, and current smokers=170) at University of Illinois Hospital were assessed using the validated Patient Health Questionnaire (PHQ-4) scale, a four-item health questionnaire that measures anxiety and depression. Patient data from the two-year time May 2016 to Aug 2018 was matched for important demographics like age, race, sex, and cancer diagnosis. Multivariate analyses examined correlations between PHQ-4 score, smoking status (based on CDC definitions), and other characteristics including: insurance, pain level, fatigue level, level of physical concern, level of physical activity, **Result:** Being a current smoker demonstrated a very strong correlation with elevated anxiety and

depression levels (p = 0.0003), while being a former smoker did not have the same effect. Insurance also had a significant positive correlation, with Medicaid patients having the highest average PHQ-4 score (p = 0.02). As expected, pain, fatigue, physical concerns, and physical activity scores were also highly correlated with depression and anxiety with p < 0.0001 for all of these measures. A multivariate model adjusting for the most salient patient parameters affecting PHQ-4 distress scores was generated and found that being a smoker had a significant increase on PHQ-4 score of on average 0.84 points over non-smokers (p = 0.03). In this model, pain, fatigue, and physical concerns also had increases of 0.14, 0.22, and 0.25 respectively in PHQ-4 scores (p = 0.0046, p < 0.0001, and p < 0.0001). **Conclusion:** Our findings show that there is a correlation between smoking status, and PHQ-4 scores in lung and head and neck cancer patients. Distress and anxiety can interfere with a patient's ability to effectively cope with cancer, its physical symptoms, and its treatment. Thus, screening for anxiety and depression, identifying it, and referring patients to smoking cessation clinics and other supportive services is an integral part of cancer treatment. Since lung and head and neck cancers are associated with smoking, patients feel that their smoking is the culprit of the disease, and this in turn can lead to self-inflicted stigma. We are currently investigating whether higher PHQ-4 scores in lung and head and neck cancer patients are correlated with higher levels of perceived cancer-related stigma.

Keywords: Distress Screening, Treatment care concerns, Psychosocial aspects of lung cancer

P2.10-09 ENVIRONMENTAL POLLUTION IN THE CITY OF MEXICO AS A RISK FACTOR FOR LUNG CANCER AND ITS PROGNOSTIC IMPACT

O. Macedo-Perez[1], I. Lyra Gonzalez[2], L. Bornstein[3], J. Castellanos[4], K. Campos-Peralta[1], E. Jimenez-Fuentes[1]

[1]*Instituto Nacional de Cancerologia, Ciudad de Mexico/Mexico,* [2]*Princess Margaret Cancer Centre, Toronto/Canada,* [3]*Inmuno Q S.C., Ciudad de Mexico/Mexico,* [4]*Universidad Nacional Autonoma de Mexico, Ciudad de Mexico/Mexico*

Background: Lung cancer is the leading cancer in incidence and mortality worldwide. Smoking is the main risk factor, however, in Mexico up to 40% of the population has no history of smoking and its development has been associated with other risk factors such as chronic exposure to wood smoke and environmental pollution. Mexico City and the Metropolitan Area of the State of Mexico have high levels of environmental pollution. In this work, we analyze the prognostic impact of environmental pollution in lung cancer among patients diagnosed with lung cancer who live in those highly polluted areas. **Method:** We retrospectively analyzed patients diagnosed with non-small cell lung cancer (NSCLC) treated at the National Institute of Cancer, who lived in Mexico City or in the State of Mexico within 10 years before diagnosis of NSCLC. We correlated pollution indexes according with the Atmospheric Monitoring System of the Goverment of Mexico City (http://www.aire.cdmx.gob.mx/default.php?opc=%27YqBhnmU=%27), with the coordinates of their home (Google Maps / Earth R Studio program) to analyze the intensity of contamination with survival. In addition, we correlated the contamination indexes with the degree of differentiation, molecular profile, gender and with the stage at the time of diagnosis. **Result:** We analyzed the information of 422 patients diagnosed with NSCLC treated in the period between 2011 and 2018. The median age was 62.4 years (SD ± 12.5), 56.6% were women, 41.5% were non-smokers. At the time of diagnosis, 80% were stage IV and 15% stage III. The histology was adenocarcinoma (83%), squamous (10.4%) and small cells (4%). EGFR mutation was detected in 26.5% of the patients and PD-L1 was positive in 2.6% (analyzed 128/422, clone SP263). At the time of this analysis, 43% of the patients had died. The risk of death was higher among patients with the combination of smoking and living in highly polluted areas (RR 9.3), followed those living in highly polluted rates (RR 6.1). Patients living in highly polluted areas showed an increased incidence of poorly differentiated tumors than those who lived in different areas (72% vs 23%); also, a lower incidence of EGFR mutations was detected. **Conclusion:** High pollution rates are associated with more aggressive tumors and poor prognosis. According with our results, combination of high levels of environmental pollution and smoking had a significant impact in decreased survival. More studies are required to confirm the association between pollution and survival outcomes, also, this study established a baseline to new analysis like massive sequencing of genes to identify associations between NSCLC diagnosis and smoking versus NSCLC and environmental pollution, which could have prognostic and therapeutic implications (eg, response to immunotherapy).

Keywords: contamination, NSCLC, environmental pollution

P2.10-10 IMPACT OF SCHOOL BASED ANTI-TOBACCO EDUCATION FOR KNOWLEDGE ENHANCEMENT AMONG HIGH SCHOOL CHILDREN OF ERNAKULAM CITY, INDIA

E. Aluckal

Mar Baselios Dental College, Kothamangalam, Ernakulam/India

Background: Tobacco is considered to be the single largest cause of premature death, which kills more than 6 million people globally every year. The mortality due to tobacco is more than that associated with tuberculosis, HIV/AIDS, and malaria combined. The state of Kerala, located in the south west corner of India, also suffers from the tobacco menace in spite of its high literacy and better health care systems. The Global Adult Tobacco Survey reports that the prevalence of any form of tobacco use in Kerala among the adult male population is 35.5%. GYTS also pointed out that second hand smoke exposure was found among one in five students at homes, where others smoked. This study was conducted to understand the extent of knowledge pertaining to tobacco before and after conducting awareness programs in schools of Ernakulam city of central Kerala, India. **Method:** The study was conducted in the Ernakulam city of Ernakulam District located in the central part of Kerala, India. A multistage cluster sampling design was adopted for selecting the study units. In Ernakulam Educational District, there are 27 Government, 57 Private aided and 14 private unaided schools. In the initial phase, giving an adequate representation, from these 18 schools was selected randomly (5 Government, 10 private aided and 3 private unaided schools). From each school, 2 divisions were randomly selected in the next stage. A cross-sectional study was conducted in these 18 schools (36 divisions with a sample population of more than 1000 high school children) using a pretested semi structured questionnaire where in, students tobacco use, knowledge on tobacco hazards before and after delivering anti-tobacco messages, were collected. The data obtained was subjected to statistical analysis using SPSS software version 16. **Result:** The overall prevalence of students who reported users of tobacco in the current academic year was 7.2% (95% CI 5.74–8.72). Knowledge assessment scores revealed a statistically significant increase in the mean knowledge scores after post training evaluation (mean score = 9.84) when compared to pre training evaluation (mean score = 7.85). The age-wise comparison of knowledge scores during both pre and post evaluations showed significant difference between the age groups (p>0.05). **Conclusion:** Adolescent health education, targeting tobacco in particular, should be implemented in schools and has to be continued systematically. Apart from anti-tobacco awareness programs, strict monitoring of tobacco products trade near educational institutions has to be conducted consistently to curb this tobacco menace.

Keywords: anti-tobacco education, high school children, knowledge assessment

P2.10-11 THE RELATIONSHIP AND SIGNIFICANCE OF ASBESTOS BODIES AND FIBERS IN THE LUNG FOR THE COMPENSATION OF ASBESTOS-RELATED LUNG CANCER IN JAPAN

T. Kishimoto

1-10-25 Chikkomidorimachi, Okayama City/Japan

Background: From the Helsinki criteria 1997, for the criteria of asbestos in the lung tissues for asbestos-related lung cancer patients is more than 5,000-15,000 asbestos bodies or more than 5 million asbestos fibers(more than 1 micrometer) per 1gram of dry lung tissues. Therefore, we examined the relation between numbers of asbestos bodies and fibers in the same patients was studied and also checked the kind of asbestos fibers and verified the validity. **Method:** Total 201 lung tissues from lung cancer patients obtained by surgery or autopsy were examined by the method of Kohyama using sodium hypochlorite. The number of asbestos bodies were counted by phase-contrast microscopy and numbers and kinds of asbestos fibers were counted by transmission electron microscopy

using metal analyzer. The number of asbestos bodies was classified into 4 divisons for asbestos –related lung cancer whose asbetos bodies are more or less than 5,000 asbestos bodies and more than 1 micrometer asbestos fibers are more or less than 5 million per 1 gram of dry lung tisses. **Result:** The number of asbestos bodies and fibers are positive co-relation with a correlation coefficient of 0.703. There are 21 cases whose more than 1 micrometer asbestos fibers are more than 5 million in spite of lower than 5,000 asbestos bodies per 1 gram. As the main component of asbestos fibers, 10 cases are crocidolite, 6 chrysotile, 4 tremolite/actinolite and one amosite. For the occupational histories, 6 cases are construction workers 4 cases are asbestos material producer and each 2 cases are shipbuilder and steel maker. **Conclusion:** The number of asbestos bodies and fibers in the lung are positive co-relation. There are 21 cases whose asbestos bodies in the lung are less than 5,000, but more than 1 micrometer asbestos fibers are more than 5 million. who should be compensated as asbestos-related lung cancer in Japan. Occupational histories are important for these cases approval of compensation of asbestos-related lung cancer and the count of asbestos fibers in the lung is important in spite of the lack of the count of asbestos bodies approved compensation criteria.

P2.10-12 CLINICOPATHOLOGICAL ANALYSIS OF THE LUNG CANCER PATIENTS WHO HAVE HISTORY OF ASBESTOS EXPOSURE

H. Koga[1,2], T. Morohoshi[1], K. Ando[1], Y. Kameda[3], M. Masuda[2]

[1]*Yokosuka Kyosai Hospital, Yokosuka/Japan,* [2]*Yokohama City University Graduate School of Medicine, Yokohama/Japan,* [3]*Yokohama Rosai Hospital, Yokohama/Japan*

Background: Because of the delayed cessation of the asbestos use in industry, the malignant pleural mesothelioma patients are increasing in Japan. Simultaneously, lung cancer patients, who have history of asbestos exposure, is increasing in our hospital. **Method:** We analyzed the characteristics of the lung cancer with the history of asbestos exposure. This study enrolled 1216 patients operated on in our department with a diagnosis of lung cancer since January 2003 to March 2018. Among them, 153 patients (12.6%) had the history of asbestos exposure. **Result:** The patients were 145 men and 8 women, the age were 47 to 83 (mean 70) years old, shipyard workers were 22 men. 64 patients pointed out by the regular medical checkup, 61 were in the middle of detailed examination for other disease, 10 had hemoptysis, and 9 patients were suffering from cough. The affected sites were right 92, left 61. The operative procedures were pneumonectomy 2, lobectomy 116, segmentectomy 8 and wedge resection 21. Postoperative complications were 49 episodes in total, such as bronchopleural fistula, pneumonia, ALI. 30 days mortality was 3cases (0.02%). The histology were adenocarcinoma 87, Squamous cell carcinoma 49, adenosquamous cell carcinoma 5, small cell carcinoma 4, Large cell carcinoma 2, and LCNEC 4. The postsurgical stage (UICC ver,6, UICCver.7) were StageIA(33%,33%),IB(29%,33%),IIA (7.8%,5.8%), IIB(9.8%,8.1%),IIIA(3.9%,17.4%),IIIB(5.9%,0%),IV(2.0%,1.2%), respectively. Over all 5 years survival rate was 62.1%. Asbestos bodies count (by Smith method) were analyzed for 51 cases. The numbers were 3 to 718041 AB/g dry lung. **Conclusion:** The characteristics of the lung cancer patients who have history of asbestos exposure were not unique, and no very special issues, in the aspects of symptom, histology and prognosis.

Keywords: Lung cancer, asbestos

P2.10-13 EFFECTS OF THE ADVANCED TOBACCO CONTROL TRAINING (ATCT) ON HEALTHCARE PROFESSIONALS' SMOKING CESSATION KNOWLEDGE AND COUNSELING

Y.-H. Lai[1,2], H.-W. Tsai[1,3]

[1]*Taiwan Association of Tobacco Control & Smoking Cessation Education, Taipei/Taiwan,* [2]*National Taiwan University, Taipei/Taiwan,* [3]*Hsin Sheng Junior College of Medical Care and Management, Taoyuan/Taiwan*

Background: Smoking is the major threat to health and it may cause cancer and many chronic illnesses. Due to nature of nicotine dependence, it is not easy to quit smoking. Trained health care personnel play important roles in helping people in smoking cessation (SC). This study is part of a national project. The purpose of the study is to (1) explore the influencing factors related to providing SC counseling interventions among healthcare professionals; and (2) examine the effects of an "advanced tobacco control (ATC) in healthcare professionals of its effects on their SC knowledge, attitudes and providing SC counseling. **Method:** It is a health outcome research with pretest-post-test design. Eligible subjects were health care professionals with basic knowledge of tobacco control. In Taiwan, a national advanced tobacco control training (ATCT) was applied for them and examine of its further effects. A total of 383 subjects participated the study (combining from four groups of trainings). The self-report questionnaire was used before the ATCT as baseline data (T0). The 3 and 6 months post-training examination were again delivered (T1 & T2). A generalized estimating equation (GEE) was used for data analyses. **Result:** Several important findings were found. (1) Subjects with more knowledge, more positive attitude, less barriers, and higher self-efficacy reported to provide more smoking cessation counseling to smokers. (2) Subjects had significantly higher scores in knowledge, more positive attitudes and increasing providing smoking cessation counseling in 3 and 6 month post-training compared to before training the basic point. **Conclusion:** The advanced tobacco control training (ATCT) has short-term (3 month) and lasting effects (6 months) on providing smoking cessation counseling to smokers. It suggests that the ATCT is effective and worthwhile to implement nationally and internationally to enhance the effect the tobacco control.

P2.10-14 PREVALENCE, PATTERN, AND INTENTION TO QUIT USE OF SMOKED TOBACCO IN A RURAL COMMUNITY IN SOUTH EASTERN NIGERIA

U. Ofonakara[1], O. Ekesi[2], T. Kotey[3]

[1]*National Primary Health Care Development Agency, Abuja/Nigeria,* [2]*Madona University, Okija/Nigeria,* [3]*Lagos University Teaching Hospital, Lagos/Nigeria*

Background: Introduction Prevalence studies have consistently reported higher rates of tobacco use in the South-Eastern parts of Nigeria but little is known about the pattern and intention to quit use of smoked tobacco in these parts of the country. The aim of this study was to determine the prevalence, pattern, and intention to quit use of smoked tobacco, among residents of Ukpo community of southeastern Nigeria. **Method:** A cross-sectional descriptive study was carried out among 490 residents of Ukpo community selected using a two-stage sampling method. Data was collected using anonymous pre-tested interviewer-administered questionnaires adapted from the Global Adult Tobacco Survey. Odd ratios and 95% confidence intervals were computed and P values of < 0.05 were considered statistically significant. **Result:** The results showed that there were male respondents 300(61.2%) than females 190(38.8%). The age range was 20-70 years with a mean of 42.18 ± 15.412 years. About one quarter, 116 (23.7%) were ever-users of smoked tobacco with 69 (14.8%) remaining as current users. Cigarette 93 (80.2%) was the most common form used. Majority 41(59%) use within 5 minutes after waking up, 11 (15%) within 6-10 minutes, 3 (4%) within 31-60 minutes. The highest prevalence was among the age group 81-100 with 4 people (66.7%) followed by age group 71-80 with 4 people (36.4%). More males 105(35.0%) than females 11(5.8%) were ever users. For marital status, the highest prevalence was among widowed with 36 people (83.7%). Of 116 smokers who visited the hospital, only 36(16.7%) were asked if they use smoked tobacco and 29 (25%) were advised to stop and 68 (58.6%) were willing to quit. Majority of people tried to quit through counseling at a cessation clinic 22 (10.2%), followed by nicotine replacement therapy 15 (6.9%). Age (p<0.055) male gender (p<0.0001), tribe (p<0.003), and low educational attainment (p<0.003) were significantly associated with smoking. **Conclusion:** Efforts targeted at raising community awareness of the health effects of smoked tobacco use are needed in rural communities where tobacco use is disproportionately high. Programs should be directed at older males with lower levels of education.

Keywords: Prevalence, Pattern, Intention to quit use of smoked tobacco

POSTERS

P2.10-15 LUNG CANCER AND SMOKING RELATED MYTHS AMONG GENERAL POPULATION: DO WE NEED TO MAKE PEOPLE MORE AWARE?

S. Roy[1], A. Shankar[2], M. Khanna[1], A. Dubey[1], D. Saini[1]

[1]*Indian Society of Clinical Oncology, Delhi/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: With increasing incidence of lung cancer, there are various myths regarding lung cancer and smoking related facts among general population. Myths in present digital era spread like wildfire and can be harmful to people. This study was conducted to know general population perception about myths and facts related to smoking and associated lung cancer. **Method:** This survey was conducted at various places in Delhi-NCR about the various facts and myths about smoking and associated lung cancer among general public. People were asked to complete the survey with response from strongly agree to strongly disagree. There were 18 questions on general myths regarding smoking and lung cancer in the questionnaire. **Result:** Among 2571 participants, 67.9% and 57.6% people accepted that radiation from mobile tower and tea in plastic cups can cause lung cancer respectively. Smoking cannot cause lung cancer if diet rich in anti-oxidants is consumed was strongly agreed by 62.8% people because it prevent lung cancer. Almost 25% people strongly agreed that Hukka & E-Cigarettes are less harmful than normal cigarettes. Participants aged 50 year and above strongly agreed that cancer treatment has more side effects then benefits (0.016), Food cooked in microwave oven can cause cancer (p= 0.001), Smoking once and twice in a month don't cause Cancer (p= 0.029). Less educated people strongly agreed with most of the myths such as smoking once and twice in a month don't cause Cancer (0.02), Sugar makes cancer worse (0.008), E-Cigarettes are less harmful then cigarettes (0.002), Hukka is safe as smoke get filtered by water (0.001). However, participants with family history of cancer knows about these myths and they don't believe that E-Cigarettes are less harmful then cigarettes (p= .006), Sugar makes cancer worse (0.001), only smokers get lung cancer (0.038), no family history of cancer makes you safe from cancer (p= 0.002). **Conclusion:** There is an urgent need to make people aware regarding smoking related facts and myths along with lung cancer risk factors, symptomatology, screening, diagnosis and treatment. There is a need of more frequent population based lung cancer awareness program to make general population more informed about the lung cancer.

P2.10-16 LUNG CANCER OCCURRENCE ATTRIBUTABLE TO PASSIVE SMOKING AMONG NEVER SMOKERS IN CHINA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y. Du[1], X. Cui[1], G. Sidorenkov[1], H. Groen[1], R. Vliegenthart[1], M. Heuvelmans[1], S. Liu[2], M. Oudkerk[3], G. De Bock[1]

[1]*University Medical Center Groningen, Groningen/Netherlands,* [2]*Shanghai Changzheng Hospital, Shanghai/China,* [3]*University of Groningen, Groningen/Netherlands*

Background: Quantifying lung cancer occurrence due to passive smoking is a necessary step for policy makers. The aim of this study is to estimate the proportion of lung cancer cases attributable to passive smoking among never smokers in China. **Method:** A systematic review and meta-analysis was conducted in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-Analysis (PRISMA) statement. We comprehensively searched six databases up to July 2019 for original observational studies in both English and Chinese languages. Studies that reported relative risks (*RR*) or odds ratios (*OR*) for lung cancer occurrence associated with passive smoking in Chinese never smokers were included. For each selected publication, two reviewers assessed publications in English and Chinese independently and assessed the quality of included studies using the Newcastle-Ottawa Scale (NOS). Any disagreements encountered were settled through a consensus. The population attributable fraction (PAF) was calculated using the combined proportion of lung cancer cases exposed to passive smoking and the pooled *OR* yielded from meta-analysis under the assumption of homogeneity. **Result:** Thirty-one studies (all designed as case-control) were identified, comprising 9,614 cases and 13,093 controls. The overall proportion of lung cancer cases among never smokers attributable to passive smoking was estimated at 20.5% (95% CI: 16.0% - 24.7%), based on the proportion of lung cancer cases exposed to passive smoking (61.6%) and the pooled *OR* for passive smoking and lung cancer risk of 1.50 (95% CI: 1.35-1.76).). The PAF was 15.5% (95%CI: 9.3%-21.0%) based on population-based studies and was 22.7% (95%CI: 16.6%-28.0%) based on hospital-based studies. The subgroup analysis (Table 1) showed that the PAF was similar in non-smoking men (20.9%) and women (21.3%). The proportion of lung cancer cases attributable to household passive smoking was much higher than workplace passive smoking (19.2% vs 10.5%).

Table 1 Population attributable fraction (PAF) of lung cancer caused by passive smoking among never smokers in subgroups

Study setting											
hospital-based	24	5.60	7428	4767	64.18%	1.67	1.47-1.9	68.50%	<0.001	25.75%	20.52% - 30.40%
population-based	9	6.44	2172	1220	56.17%	1.31	1.14-1.51	0.00%	0.464	13.29%	6.90% - 18.97%

Conclusion: Around 20% of lung cancer cases in never smokers, both men and women, are potentially attributable to passive smoking in China. These lung cancer cases in never smokers might be potentially prevented by eliminating exposure to passive smoking, in particular with regards to household passive smoking.

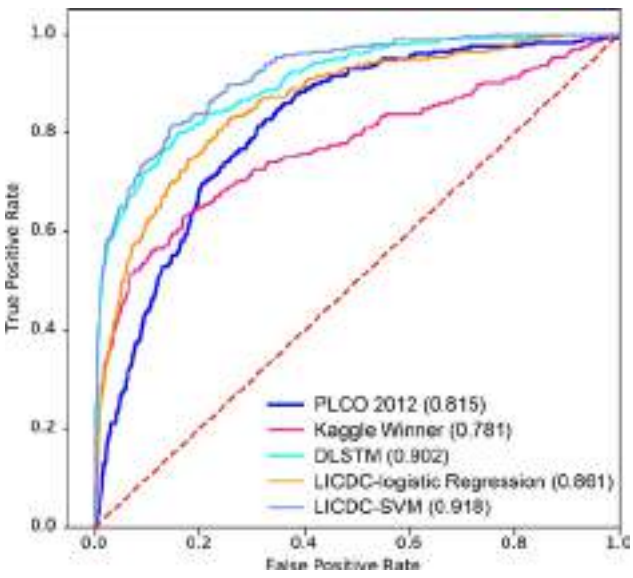
Keywords: Environmental Tobacco Smoke, Lung cancer, Population attributable fraction

P2.11-01 NOVEL FLEXIBLE LONGITUDINAL MACHINE LEARNING COUPLED WITH PATIENT DEMOGRAPHICS IMPROVES LUNG CANCER RISK PREDICTION USING WHOLE SCREENING CTS

K. Sandler[1], R. Gao[2], Y. Huo[2], A. Paulson[1], J. Williams[1], P. Massion[3], S. Deppen[1], B. Landman[2]

[1]*Vanderbilt University Medical Center, Nashville/United States of America,* [2]*Vanderbilt University, Nashville/United States of America,* [3]*Vanderbilt University School of Medicine, Nashville/United States of America*

Background: The inherent variability of screening scans in clinical practice limits existing machine and deep learning techniques, who have difficulty accessing all available information. As a result, cohorts are less generalizable or require integrating human intervention to initiate data definition. We created a deep learning prediction model for lung cancer screening that could define temporally static and time varying imaging features and combine them with common epidemiological factors collected at the time of shared decision making. We propose a new longitudinal lung cancer detection method, called longitudinal imaging and clinical data co-learning (LICDC), which integrates the temporally flexible deep imaging features and clinical features from the PLCO model. **Method:** 722 individuals with cancer and 1072 random participants without cancer with more than one scan were selected from the NLST. We initiated the deep learning model using Kaggle contest algorithm discovered features for cancer using each CT scan (n=4781) in its entirety as an independent observation (temporally varying features are not created). We then applied our flexible long and short-term temporal memory methodology to extract additional longitudinal features and generate a neural network model. This training for the LICDC model used NLST participants (n=829) and scans (n=3588) and 826 participants (367 had multiple scans) with 1193 scans from our local screening program. Ten-fold cross-validation was performed on a participant basis. Cancer risk probabilities from imaging-only deep learning model (DLSTM) were combined with PLCO model predictions and regressed together (LICDC-Logistic Regression). Additionally, individual variables from the PLCO model and the cancer probability from DLSTM were fitted with support vector machine (SVM) method using linear kernels (LICDC-SVM) and their area under the receiver operating curve was estimated (AUC). All AUC curves were calculated from the same 1655 patients (829 from NLST and 826 from our local screening program). **Result:** PLCO's predicted risk and basic imaging features (Kaggle winner) had similar accuracy with AUC of 0.815 and 0.781, respectively. Combining risk estimates from the full longitudinal deep learning and PLCO model in a simple logistic regression increased AUC to 0.861. Re-estimation of PLCO and imaging features LICDC-SVM further increased AUC to 0.918. **Conclusion:**



Risk prediction for lung cancer in patients who are eligible for screening is improved by combining longitudinal machine learning CT imaging data with demographic information. These methods allow for risk prediction based on a complete CT imaging data set with varying time between scans and across participants without relying on a segmented nodule.

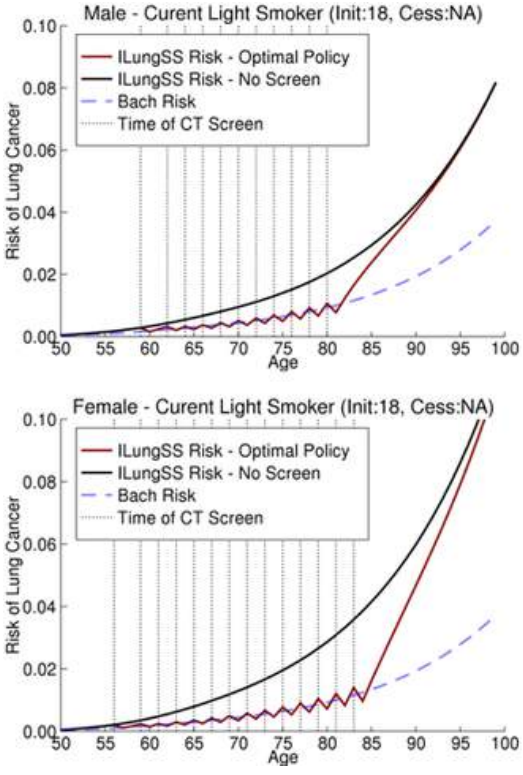
Keywords: machine learning, Lung Screening, Risk prediction

P2.11-02 INDIVIDUALIZED RISK-BASED LUNG CANCER SCREENING INCORPORATING PAST SCREENING FINDINGS AND CHANGES IN SMOKING BEHAVIORS

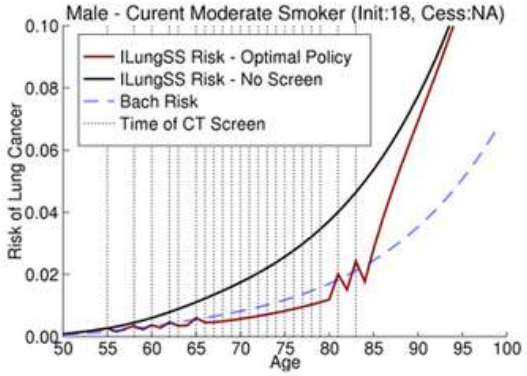
I. Toumazis[1], O. Alagoz[2], A. Leung[1], S. Plevritis[1]

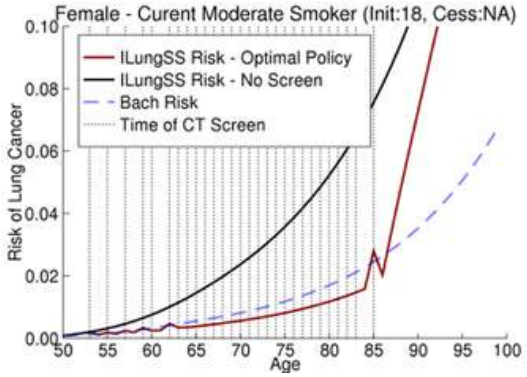
[1]*Stanford University, Stanford/United States of America,* [2]*University of Wisconsin-Madison, Madison/United States of America*

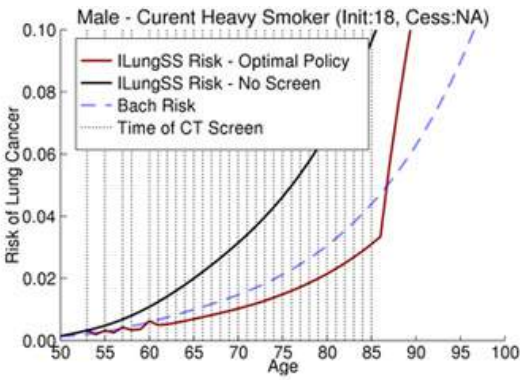
Background: Risk-based lung cancer screening guidelines are actively being pursued as an alternative to existing guidelines. However, current risk-based approaches do not capture the dynamic nature of the risk and ignore information collected from past screening findings. **Method:** We develop and apply a novel decision tool, the Individualized Lung Screening Scheduler (ILungSS), to optimize lung cancer screening for asymptomatic ever-smoked individuals by maximizing the expected quality-adjusted life years (QALYs) gained from screening. The ILungSS models health progression and smoking behavior of US ever-smokers as a dynamic and stochastic process using a partially observable Markov decision process (POMDP). A POMDP is typically used to model sequential decision making under uncertainty and provides a well-suited framework to optimize screening decisions. Screening decisions are based on the personal lung cancer risk of individuals, which is updated leveraging on information obtained from past screening exams and changes in smoking behaviors. **Result:** The ILungSS offers personalized optimal screening policies for ever smoked individuals that include the optimal screening starting and stopping ages, and screening frequency. The ILungSS offers fully dynamic screening policies and age-specific risk thresholds that define screening eligibility. The ILungSS yields higher QALYs and lung cancer-specific mortality reduction, recommends extending screening coverage to current light smokers but increases the number of screening exams as compared to the US Preventive Services Task Force (USPSTF) strategy. Upon smoking cessation, the ILungSS adjusts future screening decisions recommending less screens as compared to the USPSTF guidelines. The clear presentation of the health benefits associated with smoking cessation, in terms of personal lung cancer risk and number of recommended future screening exams, could support a smoking cessation program supplementing screening.

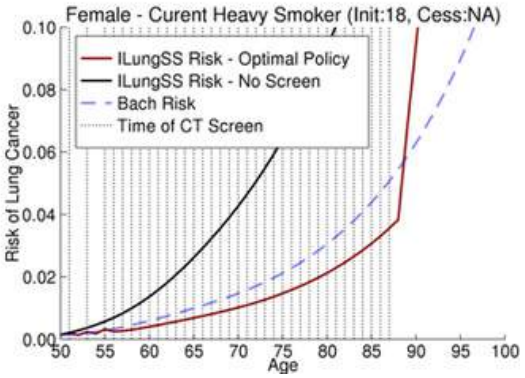


POSTERS









Conclusion: Personalized, dynamic risk-based lung cancer screening could improve the effectiveness of lung cancer screening. The ILungSS integrates screening with a smoking cessation program that could further improve the effectiveness of screening.

P2.11-03 IMPLEMENTING PHYSICIAN EDUCATION TO INCREASE LUNG CANCER SCREENING COMPLIANCE

C. Olazagasti[1], A. Rothman[2], D. Sampat[3], D. Chow[2], N. Seetharamu[1], D. Steiger[2]

[1]*Northwell Health, New Hyde Park/United States of America,* [2]*Mount Sinai Beth Israel, New York City/United States of America,* [3]*University of Alabama, Birmingham/United States of America*

Background: Lung cancer is the leading cause of cancer-related deaths worldwide. The USPSTF recommends annual low-dose CT chest (LDCT) for lung cancer screening in adults who meet the appropriate criteria: age 55-80, current smokers or former smokers who quit within 15years, with a 30 pack-year smoking history. Even with these recommendations, screening rates in these patients remain low. We created a study to assess compliance in an outpatient Internal Medicine clinic to assess the barriers for obtaining LDCT. We hypothesized that by providing an educational program, overall compliance would increase. **Method:** The study was divided in two arms: a pre-intervention arm and a post-intervention assessment. Initially, 35 physicians completed a questionnaire on their attitudes to LDCT screening and their reasons for not screening high risk patients. We created a lung cancer screening education program, which consisted of lectures provided to physicians. Following the lectures, consecutive patient visits were reviewed to assess compliance with screening. **Result:** In the first arm, 678 visits were reviewed. 115 patients met USPSTF criteria of whom 26% underwent screening. 29/546 (5%) underwent LDCT without meeting criteria. The most common reasons for not ordering LDCT scans in patients meeting criteria included: poor knowledge of criteria (22%), failure to determine if patients qualified (13%), and patient refusal (8%). Following the education, 208/955 patients reviewed met USPSTF criteria, of which 78% underwent LDCT and 27/738 (3.6%) who did not meet criteria were screened for lung cancer. Our study showed that after education, physicians were ten times more likely to screen patients for lung cancer (Odds ratio 9.98, 95% CI 5.87-16.94, p<0.0001). **Conclusion:** We confirmed there was a suboptimal adherence to established LDCT lung cancer screening guidelines, mainly due to unfamiliarity with the screening criteria. By providing educational lectures, compliance improved significantly. We concluded that educating physicians about lung cancer screening guidelines can effectively increase LDCT screening tenfold, and therefore benefit patients at high risk for developing lung cancer.

Keywords: Quality Improvement, lung cancer screening

P2.11-04 LONGITUDINAL SURVEILLANCE OF CIRCULATING TUMOR CELL IN PATIENTS WHO PRESENTED WITH RESECTABLE PULMONARY LESION SUSPICIOUS MALIGNANCY

C.Y. Wu[1], C.-L. Lee[2], C.F. Wu[1], J.Y. Fu[3], C.T. Wen[1], Y.H. Liu[1], H.-P. Liu[1], C.H. Hsieh[3]

[1]*Chang Gung Memorial Hospital, Linkou, Taoyuan/Taiwan,* [2]*Taichung Veterans General Hospital, Taichung/Taiwan,* [3]*Chang Gung Memorial Hospital, Taoyuan/Taiwan*

Background: Lung cancer is a leading cause of cancer-related death. The major factor that affect patients' survival was recurrence and could only detect by image tools. The most crucial disadvantage of image modalities was only detected the space occupying lesions instead of minimal residual disease. ((More and more undetermined lung lesions were identified by lung cancer screening and majority were early stage non small cell lung cancer. We need a less invasive tool to help us detecting minimal residual disease in order to improve patients' survival. The aim of this study was tried to clarify the clinical significance of CTCs for patients with resectable lesion suspect malignancy **Method:** From January 2017 to December 2018, 51 consecutive patients were enrolled into this study. One patient who could not tolerable tumor resection due to unstable intraoperation saturation was excluded. All patients received tumor resections. CTCs and image survey were check at scheduled time table. Data from medical record were collected and analyzed with CTCs in order to analyze the its clinical significance **Result:** Median follow-up time of 12.1 (1.5 – 23.6) months, a total of 386 CTC tests were performed in this cohort when the cutoff data was in December 2019. The mean and median number of CTC testing of the whole cohort were both 7.0 cells/mL (range, 4.0-12.0; SD, 2.4). CTC counts declined with statistical significance in all patients. CTC count declined in first 3

days was 2.2637 (cells/ ml/ day) which was statistically significant in cancer group. (P = 0.0009) The daily decline of CTC counts in lung cancer without recurrence (n=30) was 2.5359 (cells/mL/day) within the first 3 days of surgery and 1.4 (cells/mL/day) in lung cancer with recurrence (n=11). For lung cancer without relapse, the daily decline of CTC counts is statistically significant after adjust. (P=0.0068). The CTC decline in stage I and Tis group (n=26) was 2.8526 cell/ ml/ day and remained statistically significant after adjust. (P = 0.0079) **Conclusion:** CTCs had high detection rate in all clinical scenarios that could be identified in resectable undetermined lung lesions. CTC counts drop the lowest point in post-operation day 1 in all scenarios and rebound in post-operation day 3 for those patients were confirmed with relapse. Greater CTC count declined in first 3 days were identified in patients who presented with benign lesion and non small lung cancer without relapse.

Keywords: circulating tumor cell, Non small cell lung cancer, relapse predition

P2.11-05 PERIPHERAL BLOOD-BASED T CELL RECEPTOR SIGNATURES AS POTENTIAL BIOMARKERS FOR EARLY DIAGNOSIS OF LUNG CANCER

M. Li[1], S. Deng[1], C. Zhang[2], Y. Wang[2], J. Li[2], C. Hu[1]

[1]*Xiangya Hospital, Changsha/China,* [2]*Geneplus-Beijing Institute, Beijing/China*

Background: As more and more solitary pulmonary nodules (SPNs) are detected by low dose CT (LDCT) screening following with high false positive rate, early diagnosis of lung cancer is challenging. Immuno-sequencing provides a feasible strategy for investigate the immune microenvironment of SPNs. However, whether T cell receptor signatures are potential peripheral biomarkers for early diagnosis of lung cancer is unclear. **Method:** Resected SPNs, which were detected by LDCT screening, and paired peripheral blood from 92 patients were collected, including 27 benign SPNs and 65 lung cancers consisting of 15 LUSC and 50 LUAD. T cell repertoire of tissue and PBMC was evaluated by T cell receptor β genes (TCRβ) sequencing. The GLIPH-based algorithm was referenced to clustered TCR clones according to the motif, and SPN status was predicted by using the clone data from peripheral blood. **Result:** The Shannon index, indicated diversity in PBMC in malignant patients is lower than that in health cohort (p=8.2e-05). Comparing LUSC and LUAD with Benign patients, lower Shannon index was detected in LUSC patients(p=0.036). With the increase of stage, the Shannon index was gradually decreased(p=0.042). By analysis of the TCR clone similarity of tissues, more similar was found in malignant patients than benign ones (p=2.5e-11), indicating that there are some clones enriched in tumor contributing to the similarity in malignant patients. And then, to get the enriched clones, we built an algorithm which is fishing the clones by enriched motif firstly and by clone incidence secondly. Finally, we got seven enriched clones for number-limited malignant tumors. Seven enriched clones were detected in 34 malignant tissues and 4 benign tissues. Meanwhile, enriched clones also found in PBMC of 25 patients, containing 20 malignant bloods and 5 benign ones, indicating that clones relating to tumor could be a biomarker for peripheral diagnosis for lung cancer. And then we did the validations by independent sets, the sensitivity was 11.9% in 84 lung cancer patients. What's more, the specificity was 95.8% in 260 healthy cohorts, and 100% in 16 benign nodules. **Conclusion:** Our preliminary data demonstrate that the distinct immune microenvironment in different SPNs may be associated with particular pathological features. Meanwhile, our approach implied that blood TCR sequencing can provide a high specificity diagnosis of SPNs, accordingly avoiding false positive test and treatment. As the number of patients increases, a more extensive enriched-clone system that covers more population by using our strategy will be constructed.

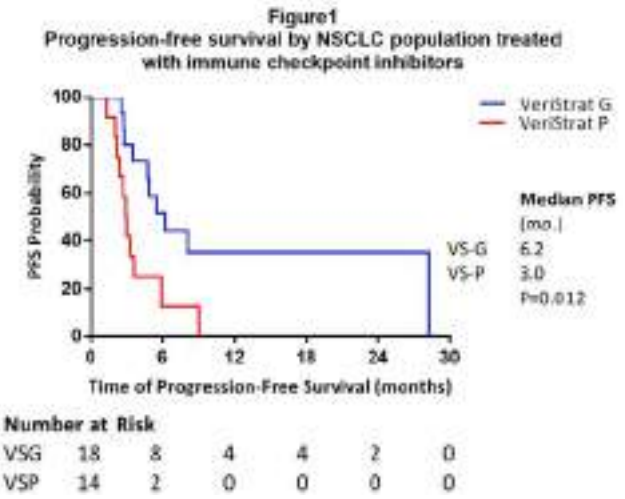
Keywords: T cell receptor signature, liquid biopsy, early detection of lung cancer

P2.11-06 SERUM PROTEOMIC SIGNATURE AS A POTENTIAL BIOMARKER FOR SURVIVAL IN PATIENTS WITH NSCLC RECEIVING IMMUNOTHERAPY

W.B. Kim[1], P. Viveiros[1], J. Anker[1], N. Simon[1], K. Rhee[1], J. Song[1], A. Cho[1], S. Chang[1], T. Ko[1], M. Oh[1], A. Davis[1], L.C. Park[2], Y.K. Chae[3]

[1]*Northwestern University Feinberg School of Medicine, Chicago/United States of America,* [2]*Kosin University, Seoul/Korea, Republic of,* [3]*Northwestern Medicine Developmental Therapeutics Institute, Chicago/United States of America*

Background: The VeriStrat Test is a serum assay which uses a mass spectrometry (MS)-based proteomic signature derived from machine learning. It is currently used as a prognostic marker for patients with NSCLC receiving chemotherapy. However, little is known about its role for NSCLC patients receiving immune checkpoint inhibitors (ICIs). **Method:** This is a retrospective study that includes 47 patients with advanced stage NSCLC without an activating *EGFR* mutation, who underwent the VeriStrat Test from 2016 to 2018. Spectra from blood samples were evaluated to assign patients into the VeriStrat 'Good' (VS-G) or VeriStrat 'Poor' (VS-P) risk group. The clinical outcomes of 32 patients who received programmed cell death 1(PD-1) inhibitors nivolumab or pembrolizumab were analyzed by the VeriStrat status. **Result:** The VS-G group demonstrated significantly higher progression-free survival (PFS) and overall survival (OS) compared to the VS-P group among overall NSCLC patients regardless of treatment (median PFS of 7.1 vs. 4.2 months, p=0.013, and median OS, not reached vs. 17.2 months, p=0.012). Among NSCLC patients treated with ICIs, VS-G classification was associated with significantly increased PFS in comparison to VS-P classification (median PFS of 6.2 vs. 3.0 months, p=0.012), while the differences in OS trended towards significance (median OS, not reached vs. 16.5 months, p=0.076). Multivariate analyses showed that the VeriStrat status had a borderline significance (p=0.051) in predicting PFS in NSCLC patients treated with ICIs.



Conclusion: MS-based serum proteomic signature has a potential as a biomarker for survival outcome in NSCLC patients receiving immunotherapy.

Keywords: Serum proteomic test, Non-small cell lung cancer (NSCLC), immune checkpoint inhibitor

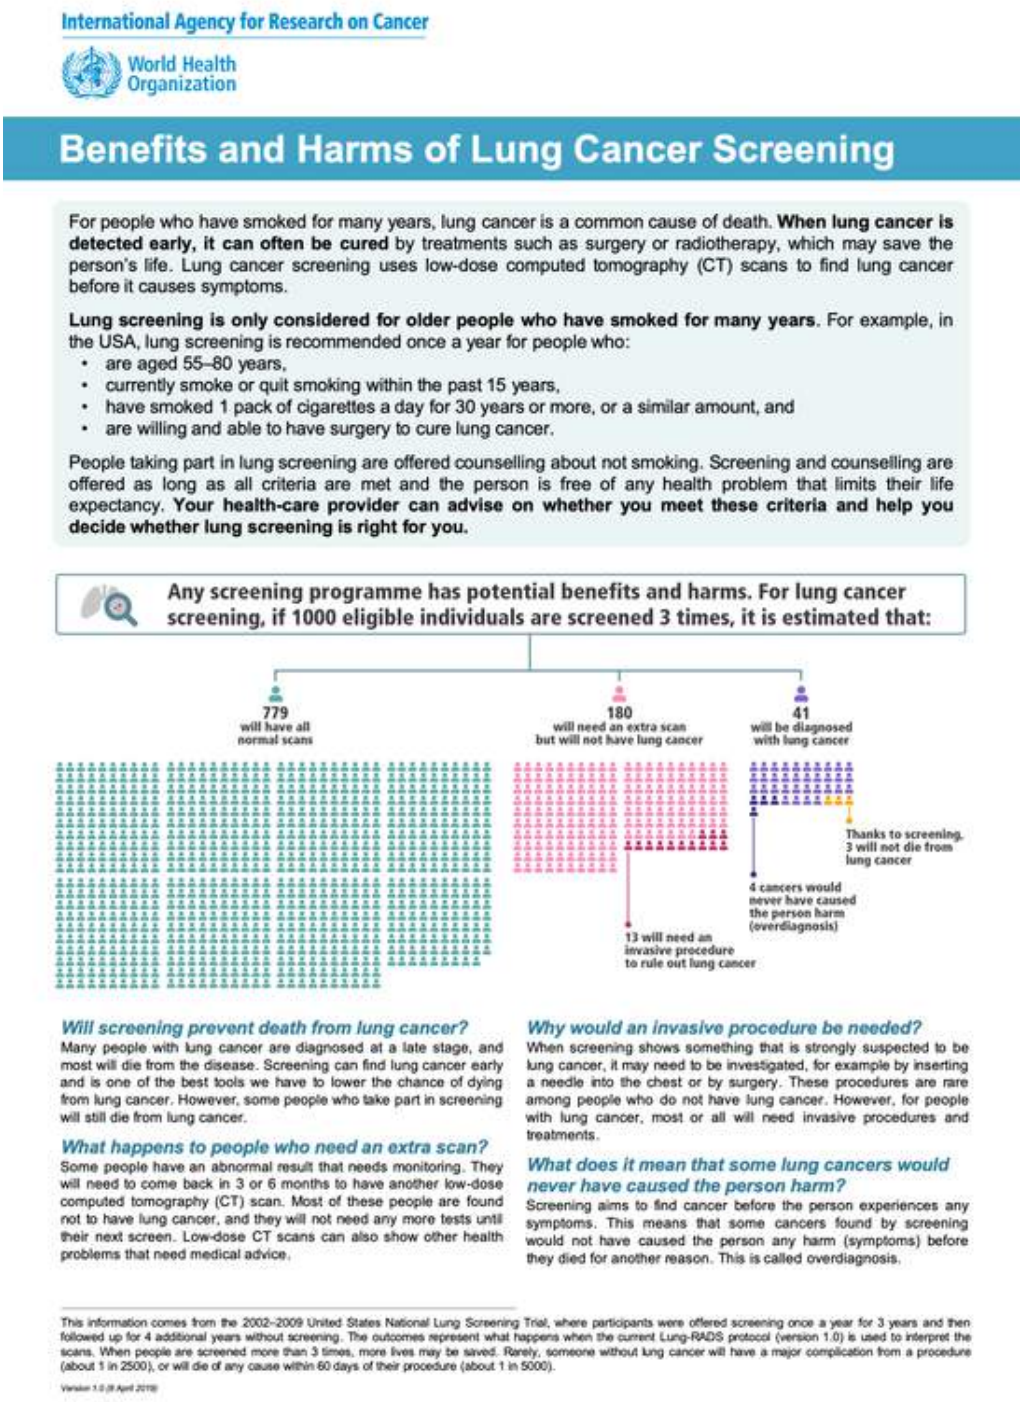
P2.11-07 BENEFITS AND HARMS OF CONTEMPORARY LUNG CANCER SCREENING: AN INFOGRAPHIC TO SUPPORT PUBLIC AND PATIENT EDUCATION

H. Robbins[1], M. Callister[2], P. Sasieni[3], S. Quaife[4], L. Cheung[5], P. Brennan[1], H. Katki[5], C. Berg[5], D. Baldwin[6], M. Johansson[1]

[1]*International Agency for Research on Cancer, Lyon/France,* [2]*Leeds Teaching Hospitals, Leeds/United Kingdom,* [3]*Kings College London, London/United Kingdom,* [4]*University College London, London/United Kingdom,* [5]*National Cancer Institute, Rockville/United States of America,* [6]*Nottingham University Hospitals, Nottingham/United Kingdom*

Background: Quantifying and communicating the benefits and harms of low-dose CT (LDCT) lung cancer screening is a complex challenge. Multiple tools have been developed based on the US National Lung Screening Trial (NLST). However, some of these have

produced debate and confusion in the public-facing media due to the outdatedness of the NLST protocol and the complexity of the information presented. **Method:** We developed a new infographic to represent the benefits and harms of contemporary lung screening. We applied the current US nodule management protocol (Lung-RADS v1.0) to the NLST retrospectively. Across the 3 NLST screens and 4 years of follow-up, we used individual-level data to quantify the number of people per 1000 who would have had (a) all normal results (Lung-RADS categories 1 and 2) without lung cancer; (b) any abnormal results (Lung-RADS 3 and 4A/B/X) without lung cancer; (c) invasive diagnostic procedures without lung cancer; and (d) lung cancer diagnosed. We estimated overdiagnosis using the published NLST estimate (18.5%) and reduced the mortality benefit from screening using the reduction in sensitivity from Lung-RADS (13.3%). **Result:** Applying Lung-RADS to NLST, we found that 779 per 1000 people would have had all normal results, 180 any abnormal results without lung cancer, and 41 lung cancer. Among the 180, 13 would have had an invasive procedure, 0.4 (1 in 2500) a major complication, and 0.2 (1 in 5000) death from any cause within 60 days of the procedure. Finally, among 41 lung cancers, 4 represent overdiagnosis and 3 prevented lung cancer deaths. We compiled these results into an infographic (Figure).



Conclusion: Compared with the NLST protocol, modern nodule management reduces harms from screening. Our infographic tool may facilitate communication about lung screening to providers, patients, and the public. It should be updated as additional trial data become available.

P2.11-08 CT SCREENING OF NEVER SMOKERS

C. Henschke, R. Yip, D. Yankelevitz

Icahn School of Medicine at Mt. Sinai, New York/United States of America

Background: We wanted to update our previous reports of the impact of SHTS on lung cancer and cardiovascular disease in never smokers and the usefulness of low-dose CT (LDCT) screening using the I-ELCAP protocol. **Method:** Never smokers, defined as having smoked less than 100 cigarettes in their lifetime, were enrolled in our LDCT screening program. All signed IRB-HIPAA compliant consents. Patient demographics, medical history, and validated SHTS-exposure questionnaire were obtained at baseline. The SHTS-exposure score was computed for all participants together with LDCT Ordinal score for coronary artery calcifications (CAC), emphysema, lung cancer diagnosis and treatment were documented. At two of the institutions, we also performed pulmonary function tests, and measured the main pulmonary artery(MPA) and ascending aorta(AA) measurements, determined the automated aortic calcium score and extent of atherosclerotic plaque present in the coronary arteries using CT angiograms. Frequency of abnormal pulmonary function (FEV1/FVC ratio<0.7) and MPA/AA ratio≥1.0 were evaluated. We examined the relationship between SHTS exposure and these disease conditions. **Result:** Among 14,018 never smokers, 6733 (48.1%) were women, 7276 (51.9%) men. Among them, 5236 (37.4%) had at least one noncalcified nodules (NCNs). Of the 14,018, 855 (6.1%) had at least one NCN 6.0 mm but less than 15.0 mm for which follow-up LDCT is recommended and 113 (0.8%) had NCN 15.0 mm or larger (Table 1). Lung cancer was diagnosed in 55 (0.4%); 53(96.4%) resulting from findings on baseline LDCT and 2(3.6%) from the subsequent annual repeat LDCTs. Of the 55, 47 (85.5%) were clinical stage I; 49 had surgical resection, 4 treated with radiation therapy, and 2 with chemotherapy. Diagnosis was adenocarcinoma in 44, squamous-cell in 7, small-cell in 1 and other in 3. Post-surgically, 45 (81.8%) of the 47 were pathologic Stage IA (T1a-1cN0M0). Of the 14,018 never smokers, the CAC score was 0 for 10,956 (78.2%), 1-3 for 1941 (13.9%), and 4-12 for 1211(8.0%). Emphysema was present in 310 (2.2%) participants. The prevalence of lung cancer (p=0.04) was significantly associated with SHTS exposure, as was CAC (p<0.0001) and emphysema (p=0.03). In the subset of participants where additional measurements are available, abnormal pulmonary function tests (p=0.04), automated aortic calcium score (p=0.009), MPA/AA ratio≥1.0 (p=0.009) and presence and extent of coronary artery plaque (p<0.0001). **Conclusion:** These results suggest that LDCT screening is of benefit for never smokers exposed to SHTS for identification of early lung cancer, cardiovascular disease and emphysema.

P2.11-09 AUSTRALIA-WIDE CROSS-SECTIONAL SURVEY OF GENERAL PRACTITIONERS' KNOWLEDGE AND PRACTICE OF LUNG CANCER SCREENING

P. Abeyweera[1], F. Brims[2], F. Piccolo[3], C. Lei[4], D. Manners[3]

[1]*Sir Charles Gairdner Hospital, Nedlands/Australia,* [2]*Curtin University, Bentley/Australia,* [3]*St John of God Public and Private Hospital, Midland/Australia,* [4]*Currambine Family Practice, Currambine/Australia*

Background: High quality randomised controlled trials have demonstrated that low dose computed tomography (LDCT) screening reduce lung cancer deaths in high risk individuals yet current Australian guidelines do not recommend nor fund screening. 1-3 Little is known about current screening practices in Australia. **Method:** A survey was distributed to a nationally representative sample of 4 000 Australian general practitioners (GPs) registered with the commercial database of the Australasian Medical Publishing Company. The questionnaire included, respondent demographics, self-reported screening practices, knowledge of screening recommendations, recent screening education and potential factors influencing GPs' screening practice. Two logistic regression models identified factors associated with self-reported chest X-ray (CXR) or LDCT screening within the last 12 months. **Result:** A total of 323 General Practitioners attempted the survey (participation rate 8.1%); 21 were excluded as they did not report recent screening practice. Participants were mostly females (153/302, 50.6%), from collective/group practices (239/302, 79.1%) and metropolitan-based practices (222/302, 73.5%). Despite the majority of responders understanding that screening is not recommended by Australian professional societies (215/302, 71.2%) a substantial proportion of participants requested a CXR or LDCT screening (140/302, 46.4% and 63/302, 20.8% respectively). A variety of shared factors (GP reassurance, perceived cost-effectiveness of screening, believing screening is funded) and unique practice, educational and cognitive factors were associated with self-reported LDCT and CXR screening, with the strongest association being recent education about screening from radiology practices (aOR for LDCT screening 10.443, p<0.001, Table 1).

Table 1: Multivariate logistic model for factors associated with LDCT screening

Variable	Adj Odds Ratio	95% CI	P value
LDCT SCREENING			
Practice location			0.01
- Metropolitan	Reference		
- Rural or remote	2.517	1.012-6.186	
Screening funded by MBS/Medicare			0.008
- No	Reference		
- Yes	2.502	1.012-6.186	
- Don't know	0.576	0.260-1.276	
Screening education from radiology providers	10.443	4.258-25.612	<0.001
Agreeing with the following statements (Per point on a 5-point disagree-to-agree Likert scale)			
"Screening can provide me with reassurance my patient does not have lung cancer"	1.548	1.002-2.392	0.04
"Screening can lower the chance that my patient will die from lung cancer"	1.818	1.083-3.048	0.02
"Lung cancer screening would cost our society too much money"	0.622	0.423-0.915	0.02
CHEST X-RAY SCREENING			
Practice type			0.009
- Collective/Group practice	Reference		
- Solo practice	2.47	1.005-6.09	
- -Corporate practice	4.764	1.229-18.46	
Screening funded by MBS/Medicare			0.02
- No	Reference		
- Yes	2.839	1.315-6.128	
- Don't know	1.056	0.612-1.823	
Agreeing with the following statements (Per point on a 5-point disagree-to-agree Likert scale)			
"Screening can provide me with reassurance my patient does not have lung cancer"	1.357	1.016-1.811	0.04
"It is too hard for my patients to access a radiology practice with CT scans"	1.534	1.016-2.165	0.01
"I am more likely to recommend screening if my patient has respiratory symptoms like a cough or breathlessness"	1.451	1.085-1.946	0.01
"Lung cancer screening would cost our society too much money"	0.724	0.546-0.960	0.02
MBS: Medical Benefits Scheme. Alpha intercept estimates: LDCT model 0.3895 CXR model 1.8726			

Conclusion: In Australia, lung cancer screening is occurring outside a coordinated programme and there is discordance between reported screening practice and national recommendations due to a variety of factors. This highlights an urgent need for clearer guidance and direction from national and professional bodies.

P2.11-10 DISCOVERY OF POTENTIAL BIOMARKERS THAT DISCRIMINATE EARLY STAGE NSCLC FROM CONTROLS BY NON-TARGETED METABOLOMICS PROFILING

J. Kim[1], R. Balshaw[2], C. Trevena[2], S. Banerji[1], L. Murphy[2], D. Dawe[1], L. Tan[2], S. Srinathan[2], G. Buduhan[2], B. Kidane[2], G. Qing[2], M. Domaratzki[2], M. Aliani[2]

[1]*CancerCare Manitoba, Winnipeg/Canada,* [2]*University of Manitoba, Winnipeg/Canada*

Background: Detection of NSCLC at the early stage is a potential means to reduce mortality and morbidity of lung cancer. Development of an accurate, non-invasive, economical, and safe test to detect early stage NSCLC remains a challenge. We explored metabolomics profiling of plasma to discriminate early stage NSCLC cases from Cancer-Free Controls (CFC). **Method:** Frozen plasma samples collected from 2004 to 2014 from 250 patients with clinical early stage NSCLC (drawn prior to surgical resection) and 250 CFCs were obtained from a provincial biorepository. Samples were thawed, extracted, and analyzed in duplicate by blinded laboratory

personnel using non-targeted Ultra High Performance Liquid Chromatography/Quadrupole Time-Of-Flight Mass Spectrometry (UHPLC-QTOF-MS). Individual metabolic entities were identified and quantified using Mass Profiler Professional Software (Agilent Technologies, CA, USA). Analysis was restricted to known human metabolites identified by the Metlin and Human Metabolome databases. Candidate metabolites quantified in less than 20% of samples were dropped; missing values were replaced with one-half of the smallest measurement for each metabolite. Final candidate metabolites were screened for differential abundance (DA) between NSCLC cases and CFCs using: (1) False discovery rate (FDR)-adjusted p-values less than 1% after controlling for age, sex and smoking status in linear regression; (2) <1% change in DA due to covariates; (3) up-regulation in NSCLC. **Result:** Of the 250 NSCLC Cases, 185 (74%) had adenocarcinoma, 65 (26%) had Squamous Cell Carcinoma; 204 (81.6%) had pathological Stage I/II disease (AJCC 7th ed) and 46 (18.4%) had stage III/IV disease. Median age was 70 (range 46-88) in NSCLC cases and 56 (20-89) in CFCs (p<0.001), and NSCLC cases had more males compared to CFCs (46.4% vs 31.2%, p <0.001). NSCLC patients had a higher proportion of current (27.2% vs 6%) or ex-smokers (64.8% vs 20.8%) compared to CFCs (p<0.001). A total of 1,209 known human metabolites were detected using UHPLC-QTOF-MS technique, of which 676 were present in a minimum of 80% of all samples and were used for modeling. Table 1 lists candidate metabolomics biomarkers strongly upregulated in NSCLC cases versus CFCs which were unaffected by covariates of age, sex, and smoking. A multiple logistic regression model using the top 3 metabolites correctly classified NSCLC case from CFC with an overall accuracy of 93.6% and an area under the curve of 0.975.

Table 1: Rank List of Top Potential Endogenous Metabolomics Biomarkers Which Distinguished NSCLC Cases from Controls.

Rank	Metabolite	Classification	ESI mode	Log_2 Fold Change	FDR-adjusted P-Value
1	N-Acetylornithine	Amino Acid Derivative	+	8.9273	<0.00001
2	13S-hydroxyoctadecadienoic acid	Fatty Acyl	+	8.9191	<0.00001
3	9,10-Epoxyoctadecenoic acid	Fatty Acyl	+	8.9191	<0.00001
4	Alpha-dimorphecolic acid	Fatty Acyl	+	8.9191	<0.00001
5	12,13-EpOME	Fatty Acyl	+	8.8911	<0.00001
6	Dodecanedioylcarnitine	Hydroxy Acid	+	10.0674	<0.00001
7	PI(16:0/18:1(11Z))	Glycerophospholipid	+	7.3867	<0.00001
8	PI(16:0/18:1(9Z))	Glycerophospholipid	+	7.3867	<0.00001
9	PI(16:1(9Z)/18:0)	Glycerophospholipid	+	7.3867	<0.00001
10	PI(18:0/16:1(9Z))	Glycerophospholipid	+	7.3867	<0.00001
11	PI(18:1(11Z)/16:0)	Glycerophospholipid	+	7.3867	<0.00001
12	PI(18:1(9Z)/16:0)	Glycerophospholipid	+	7.3867	<0.00001
13	PI(16:0/18:0)	Glycerophospholipid	+	6.8392	<0.00001
14	PI(18:0/16:0)	Glycerophospholipid	+	6.8392	<0.00001
15	17-Hydroxyprogesterone	Steroid	+	5.4172	<0.00001
16	Deoxycorticosterone	Steroid	+	5.2858	<0.00001
17	Nonanoylcarnitine	Hydroxy Acid	+	4.2974	<0.00001
18	1b,3a,12a-Trihydroxy-5b-cholanoic acid	Steroid	-	5.5153	<0.00001
19	Cholic acid	Steroid	-	5.5153	<0.00001
20	Ursocholic acid	Steroid	-	5.5153	<0.00001
21	Arachidonic acid	Fatty Acyl	-	4.7791	<0.00001
22	8,11,14,17-Eicosatetraenoic acid	Fatty Acyl	-	4.7791	<0.00001
23	Farnesol	Prenol Lipids	-	4.8348	<0.00001
24	Cinnamic acid	Cinnamic Acids	+	1.9656	0.0188

Legend: ESI = Electrospray Ionization Detection Mode; FDR = False Discovery Rate

Conclusion: Metabolomics profiling of plasma represents a potential means to distinguish NSCLC cases from CFCs. Further targeted metabolomics analyses of specific classes of metabolites in larger cohorts are warranted.

Keywords: early detection, metabolomics, Biomarker

P2.11-11 EXOSOMAL MIRNAS AS DIAGNOSIS BIOMARKERS FOR DISTINGUISHING BENIGN AND MALIGNANT NODULES IN NON-SMALL CELL LUNG CANCER

D. Zheng[1], Y. Yang[1], C. Wu[1], H. Wang[2], S. Liu[2], X. Xu[2], D. Zhang[2], F. Li[2], J. Ni[1], J. Xu[1], G. Jiang[1]

[1]*Shanghai Pulmonary Hospital, Shanghai/China,* [2]*Research and Development Institute of Precision Medicine,* [3]*D Medicines Inc., Shanghai/China*

Background: Lung cancer is the most common malignancy worldwide with the highest morbidity and mortality. The milestone National Lung Screening Trial (NLST) demonstrated a 20% reduction in lung cancer-specific mortality in high-risk individuals with screening low-dose computed tomography (LDCT). However, the high false positive rate of LDCT demands more accurate diagnostic technique. Liquid biopsy represent a valuable non-invasive approach when tumors are not suitable for biopsy or resection. Till now, it is rare to see the studies on plasma exosome-derived miRNAs as early diagnosis biomarkers to distinguish benign and malignant nodules based on miRNA sequencing. **Method:** Forty-eight patients including twenty-eight lung adenocarcinoma and twenty benign nodules with various pathological characteristics (granuloma, atypical neoplasia, fibrosis, tuberculosis, and other benign types) were enrolled as a training cohort. A testing cohort consisted of 46 patients with benign and malignant nodules. Exosomes were precipitated from the plasma of patients, and RNA sequencing were performed to identify the differential expressed miRNAs. The statistical model was trained and tested to discriminate benign nodules from malignant ones. **Result:** The typical exosome markers CD9 and CD63 were successfully confirmed by western blotting of extracted exosomes. Seven differential expressed miRNAs (let-7b-3p, let-7d-3p, miR-150-5p, miR-30e-5p, miR-125b-5p, miR-361-5p, and miR-378c) with median expression > 50 were selected by LASSO-penalized regression to classify the samples into correct groups. LOO-CV (leave one out cross validation) was used to stabilize the model parameter with minimal error rate (16.7%). ROC curves with area under curve (AUC) of the model are achieved to 0.952, while sensitivity and specificity of distinguishing between benign and malignant nodules were 93% and 85%, respectively. In addition, the AUC in a part of testing cohort (1 benign and 11 tumor) was up to 1.000. The rest samples of testing cohort were being detected using RNA sequencing. **Conclusion:** This study using plasma exosome-derived miRNA sequencing identified seven miRNAs to train and test a model to distinguish benign and malignant nodules, which provides insights into the feasibility of exosomal miRNA as a novel early diagnosis approach for lung cancer.

P2.11-12 SPUTUM LIQUID BIOPSY PROVIDES A NON-INVASIVE MODALITY TO ASSESS DRIVER MUTATIONS AND TUMOR HETEROGENEITY IN NSCLC

V. De Sa[1], H. Freitas[2], C. De Paula[1], V. Lima[2], D. Carraro[1], V. De Sá[2]

[1]*AC Camargo Cancer Center, SAO PAULO/Brazil,* [2]*AC Camargo Cancer Center, Sao Paulo/Brazil*

Background: The incidence of lung cancer has significantly increased over the last century and remains the most common cause of cancer death worldwide. Our better understanding of the tumor microenvironment and of how tumors interacts with the host systemically, combined with the recent advent of the liquid biopsy, may allow non-invasive, assessment of tumor heterogeneity and evolution. Sputum has been used for the investigation of biomarkers in lung cancer since it carries airway epithelial cells, and molecular alterations identified in sputum are most likely to reflect tumor-associated changes. Our aim is to evaluate whether the molecular alterations identified in the sputum is representative of the mutations found in the tumor. **Method:** Sputum samples were prospectively collected from 30 patients with lung adenocarcinoma at AC Camargo Cancer Center, from January 2017 till November 2018. Samples were collected at the time of diagnosis for further evaluation of actionable mutations in 14 genes, including *EGFR, KRAS, BRAF* and *NRAS*. Driver mutations were detected in 16 (53%) patients in tissue biopsy (six in *KRAS* and 10 in *EGFR*), and 2 cases also had *EGFR* T790M detected in circulating tumor DNA (ctDNA) isolated from plasma after disease progression post EGFR-TKI. **Result:** Mutations were detected in 9 out of 16 sputum samples with previously known driver mutations: 3/7 with *KRAS* mutation (codon 12 and 61) and 6/9 with *EGFR* with (four exon 19 deletions, five L858R point mutations and one exon 18 G719A). Two patients with mutant *KRAS* detected in their sputum, did not exhibit *KRAS* mutations in tissue biopsy of primary tumor. One of them had a *KRAS* mutation detected only in a metachronous brain metastasis. *EGFR* T790M mutation was detected in sputum in 1 out of two samples previously positive for T790M in plasma ctDNA. All seven sputum samples negative for mutations were derived from peripheral lesions or cases with low tumor burden. **Conclusion:** As a preliminary result, analysis of driver mutations in sputum had a good correlation with tissue biopsy (60%), especially in patients with centrally located tumors and high tumor burden, and seems to reflect tumor heterogeneity.

Keyword: liquid biopsy, sputum, non-invasive approach, driver mutation, lung adenocarcinoma

P2.11-13 WHAT IS THE IMPACT OF LOCALISED DATA WHEN TRAINING DEEP NEURAL NETWORKS FOR LUNG CANCER PREDICTION?

A. Devaraj[1,2], I. Pulzato[1,2], S. Kemp[2], C. Ridge[2], S. Padley[2], A. Nicholson[1,2], C. Arteta[3], P. Novotny[3], L. Pickup[3], J. Declerck[3], T. Kadir[3]

[1]*Imperial College, London/United Kingdom,* [2]*Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom,* [3]*Optellum Ltd, Oxford/United Kingdom*

Background: Deep neural networks (DNN) have been shown to offer a viable alternative for risk cancer prediction of indeterminate pulmonary nodules (IPNs). While the type of data used for training is known to impact performance, this issue has not been extensively studied. We present, for the first time, a study of the effect of including training data that matches the clinical pathway of the independent validation dataset, a nodule clinic of incidental findings. **Method:** Two identical DNNs were trained on the task of diagnosis prediction of pulmonary nodules from CT images. The first one (*DNNnlst*) used purely screening data from the US National Lung Screening Trial (922 cancer and 14733 benign nodules), while the second one (*DNNnlst+incidental*) included data of incidentally detected nodules from European hospitals (1064 cancer and 7207 benign nodules). Both models were evaluated in an independent validation set of nodules coming from a referral center in the UK (Royal Brompton and Harefield Hospital, London) consisting of baseline scans of 406 cancer and 325 benign nodules. The models were compared in terms of AUC, as well as their ability to reclassify cancer patients with intermediate risk nodules. The Intermediate risk sub-population was defined by selecting patients with nodules in the size range of 8 to 15mm, and who were followed-up within a year with CT, referred to PET-CT, or referred to biopsy. Within this sub-population, a cancer prevalence of 30% was assumed. The operating points of the cancer prediction models were chosen by setting a cancer risk of 70%, corresponding to high-risk nodules in the guidelines of the British Thoracic Society. **Result:** The *DNNnlst* and *DNNnlst+incidental* models achieved an AUC of 84.33 (95%CI: 81.49, 87.15) and 87.43 (95%CI: 84.79, 89.82) respectively on the entire validation set, showing an improvement in the discrimination capabilities ($p < 0.01$). For reference, using the nodule's maximum axial diameter as a predictor led to an AUC of 79.07 (95%CI: 75.73, 82.73). Additionally, considering only the intermediate risk population of the data, all of which would require workup according to guidelines, the *DNNnlst+incidental* model correctly classified as high risk 34.34% more cases than the *DNNnlst model (sensitivity* 59.39% (95%CI: 47.68, 75.17) vs. 44.21% (95%CI: 20.98, 64.42)), an improvement significant at $p < 0.05$. **Conclusion:** Although a DNN trained only on the US lung cancer screening data could have clinical utility in an incidental setting, exposing it to further incidental data can not only increase its discriminability, as expected, but also make it a potentially more effective tool for speeding up the diagnosis of cancer patients with intermediate risk nodules and reducing unnecessary workups.

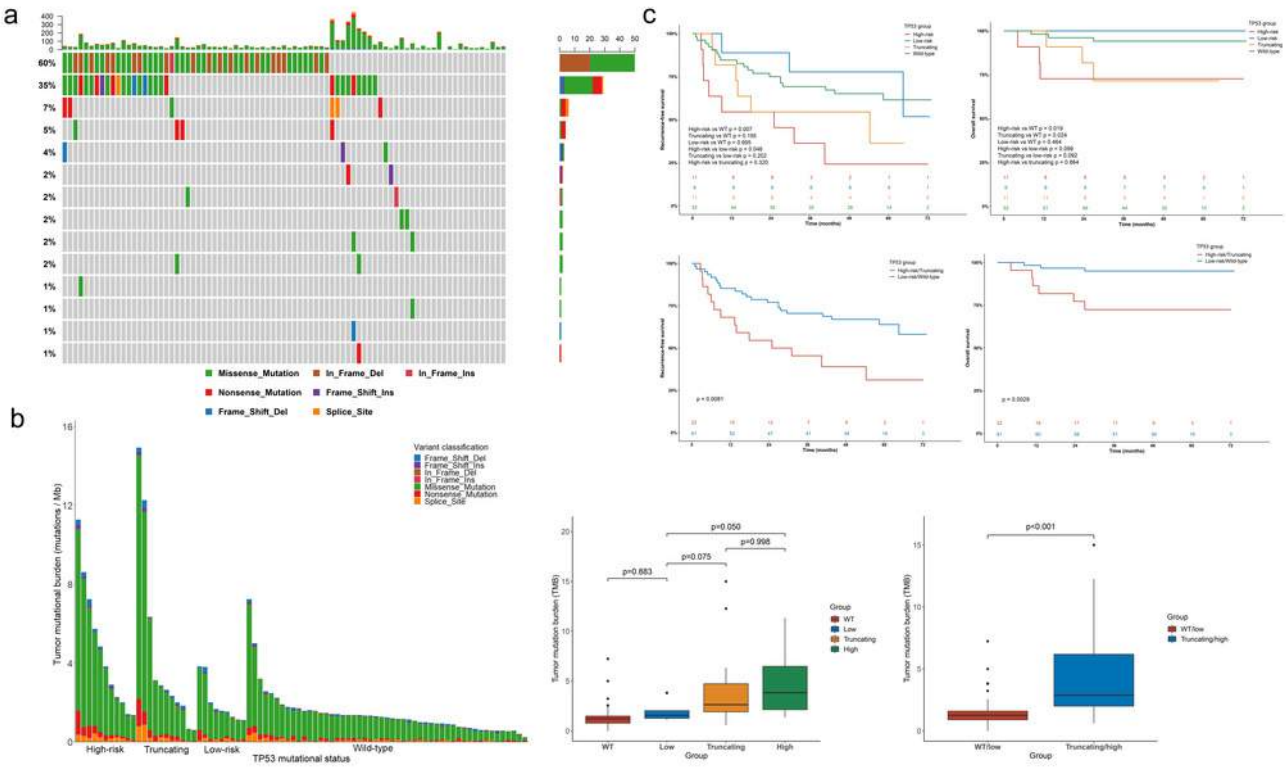
P2.11-14 EVOLUTIONARY ACTION SCORE OF TP53 PREDICTS THE PROGNOSIS OF PATIENTS WITH STAGE I LUNG ADENOCARCINOMA

Y. Zhao, H. Han, Y. Li, Z. Gao, H. Chen

Fudan University Shanghai Cancer Center, Shanghai/China

Background: Several studies have reported that *TP53* mutations were associated with poor prognoses for patients with non-small-cell lung cancer. *TP53* was reported to have a mutation rate of 46% in lung adenocarcinoma patients. Whether these mutations are of the same prognostic value is questionable. Here we use an algorithm named Evolutionary Action of *TP53* (EAp53) which stratifies *TP53* missense mutations into high-risk and low-risk groups based on the scores calculated to see whether different types of *TP53* mutations are of prognostic value for patients with stage I lung adenocarcinoma. **Method:** Whole-exome sequencing was performed on 83 patients who underwent surgery and with a pathologically confirmed adenocarcinoma between January 2011 and August 2013 at Fudan University Shanghai Cancer Center. No patient underwent neoadjuvant therapy. Missense *TP53* mutations were classified to low-risk and high-risk groups according to their EAp53 score, which assesses the genotype-phenotype perturbation of point mutations. Patients were divided into 4 groups based on *TP53* mutational status: wild-type *TP53*, truncating mutations, including frame-shift mutations, nonsense mutations, small indels, and splice-site mutations; high-risk missense mutations, defined as missense mutations with an EAp53 score >75.00; low-risk missense mutations, defined as missense mutations with an EAp53 score ≤75.00. **Result:** Mutations of major driver genes, tumor suppressor genes and genes of interest for lung adenocarcinoma, including *EGFR* (60%), *TP53* (35%), *RB1* (7%), *RBM10* (5%), *NF1* (4%), *CDKN2A* (2%), *ERBB2* (2%), *KRAS* (2%), *PIK3CA* (2%), *SMARCA4* (2%), *APC* (1%), *BRAF* (1%), *KEAP1* (1%) and *STK11* (1%) were identified in our cohort of 83 stage I lung adenocarcinoma patients (fig 1a). *TP53* mutations were identified in 29 patients (35%), with 11 high-risk, 9 low-risk, and 11 truncating mutations. Compared with patients with wild-type *TP53*, patients with *TP53* mutations had a significantly lower tumor mutational burden ($p < 0.001$, fig 1b). Furthermore, there was a significant difference between the wild-type/low-risk group and the truncating/high-risk group ($p < 0.001$, fig 1b). Compared with the low-risk group, the high-risk group had significantly worse recurrence-free survival ($p = 0.046$), while there was no significant difference between the low-risk group and the wild-type group ($p = 0.695$, figure 1c). Moreover, when we combined the groups into a high-risk/truncating group and a low-risk/wild-type group, the high-risk/truncating group had a significantly worse recurrence-free survival ($p = 0.0081$, figure 3c) and overall survival ($p = 0.0029$, figure 1c).



Conclusion: *TP53* mutational type is of prognostic value for patients with stage I lung adenocarcinoma.

P2.11-15 DETECTION OF CIRCULATING GENETICALLY ABNORMAL CELLS IMPROVES THE DIAGNOSTIC ACCURACY IN LUNG CANCER PRESENTING WITH GGNS

B. Zhang[1], S. He[2,3], C. Chen[1], Y. Chen[2,3], Y. Li[1], M. Huang[2,3], D. Yue[1], C. Huang[2,3], C. Li[1], Y. Xin[2,3], J. Zhang[2,3], C. Wang[1]

[1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin/China,* [2]*Joint Research Center of Liquid Biopsy in Guangdong, Hong Kong and Macao, Zhuhai/China,* [3]*Zhuhai Sanmed Biotech, Zhuhai/China*

Background: Popularization of low-dose computed tomography (LDCT) screening enables more finding of pulmonary ground glass nodules (GGNs). It remains a challenge for distinguishing between malignant and benign nodules in patients with size ≤30mm GGNs depending on CT. Moreover, serum tumor markers showed poor prediction value. There is an urgent need to develop a noninvasive and highly accurate biomarker for detection. Recent studies have suggested that circulating genetically abnormal cells (CACs) can be identified by fluorescence in situ hybridization (FISH) from peripheral blood of early-stage lung cancer in Caucasian. This study aimed to use CACs to improve the diagnostic accuracy of early-stage lung cancer with GGNs in Chinese population. **Method:** Peripheral blood was collected from 107 patients with GGNs and 55 healthy donors. All GGNs identified by CT were between 5-30mm in diameter and confirmed with histopathological diagnosis after surgical resection. The level of serum-based biomarkers (CEA, NSE, TPSA, SCC, PROGRP, CA19-9 and CYFRA21-1) were measured. CACs were enriched by density gradient separation, and visualized by 3p22.1, 3q29, 10q22.3, CEP10 FISH. CACs were identified by finding gains in two or more probes. **Result:** Of these 107 GGNs, 96 were malignant (45 pure GGNs and 51 mixed GGNs) and 11 were Benign. All malignant GGNs were stage I lung adenocarcinomas. CACs were detected in 68 of 96 lung cancers, while serum-based biomarkers were just positive in 39 of those. The sensitivity, specificity of CACs test were 70.8%, 77.3% respectively for this cohort (96 malignant GGNs, 11 benign GGNs and 55 healthy donors). The area under the receiver operating characteristic (ROC) curve was 0.760 from this data set. There was no significant difference in CACs test sensitivity between GGNs size of <20mm and ≥20mm (71.3% vs 68.8%, p=0.84). Comparing to serum-based biomarkers, the sensitivity of CACs test was significantly improved. Combining the CACs test results with serum-based biomarkers, the overall sensitivity increased to 77.1% without lowering specificity.

	Sensitivity on malignant GGNs (N=96)	Sensitivity on malignant pure GGNs (N=45)	Sensitivity on malignant mixed GGNs (N=51)
CACs	70.8%	68.9%	72.5%
serum-based biomarkers	40.6%	40.0%	41.2%
Sig.	P<0.05	P<0.05	P<0.05

Conclusion: Our study showed that using CACs as a noninvasive malignant biomarker could improve the diagnostic accuracy in early-stage lung cancer presenting with GGNs.

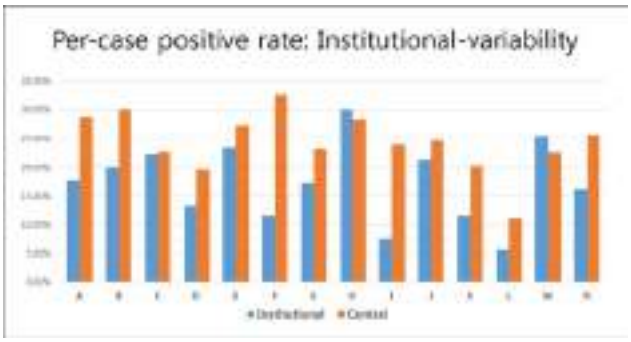
P2.11-16 VARIABILITY IN READING LOW-DOSE CHEST CT: INDIVIDUAL READERS VS. CENTRAL REVIEW IN A NATIONWIDE LUNG CANCER SCREENING PROJECT

E.J. Hwang[1], J.M. Goo[2], S.H. Yoon[1], H.Y. Kim[3], Y. Kim[3], J. Yi[4]

[1]*Seoul National University Hospital, Seoul/Korea, Republic of,* [2]*Departments of Radiology, Seoul National University College of Medicine, Seoul/Korea, Republic of,* [3]*National Cancer Center, Goyang-si, Gyeonggi-do/Korea, Republic of,* [4]*Coreline Soft Co., Seoul/Korea, Republic of*

Background: Variability in interpretation among readers or institutions is an important issue in the nationwide lung cancer screening. The potential of computer-aided detection and volumetry

in reducing interobserver variability has rarely been investigated in the actual screening situation. This study aimed to evaluate the variability among experts in a nationwide lung cancer screening project. **Method:** We evaluated 1647 consecutive baseline screening CT scans obtained during one month period of December 2017 from a nationwide lung cancer screening project in Korea (K-LUCAS) in which 14 institutions participated. One of 20 chest radiologists in each institution assessed CT scans using a thin-client system equipped with semi-automated nodule segmentation and computer-aided detection software based on Lung-RADS (institutional reading). One chest radiologist retrospectively reviewed all these CT scans while minimizing modification of segmentation results and rejection of tiny nodules (central review). Reading results between institutional reading and central review were compared. Per-case and per-nodule positive rates of central review using Lung-RADS and NELSON criteria were also compared. **Result:** Per-case positive rate was significantly higher in central review (24.9% [410/1647; 11.1-32.7% across institutions] vs. 19.3% [319/1647; 5.6-30.0% across institutions]; *P*<.001), while per-nodule positive rate was significantly higher in institutional reading (10.2% [511/4497; 5.2-21.9%] vs. 19.9% [382/1920; 9.5-60.6%]; *P*<.001). The number of detected nodules was significantly larger in central review (3.04 vs. 1.17 nodule/case; *P*<.001), while the size of detected nodules was significantly smaller in central review (4.0 vs. 5.1 mm; *P*<.001). Variability in positive rates among institutions was significantly lower in central review (coefficient of variability, 21.9% vs. 40.2%; *P*=.044). Manual measurements after rejecting result of semi-automated segmentation occurred in 1.6% (80/5008) of nodules at central review and in 17.8% (342/1920) nodules at institutional reading. Positive rate with Lung-RADS was significantly higher compared with that of NELSON criteria (24.9% vs. 3.9%; *P*<.001), however, including indeterminate scan by NELSON criteria which requires additional scanning, positive rate was higher in NELSON criteria (24.9% vs. 33.4%; *P*<.001).



Conclusion: Even in a situation where computerized tools are adopted, considerable variability was observed in interpretation of lung cancer screening CT even among expert chest radiologists. The variability was mainly caused by discarding tiny nodules and modifying or rejecting segmentations results, and reduced by central review. The NELSON criteria did not reduce the number of additional scanning in nodule management compared with Lung-RADS. The value of reducing variability by applying stricter rules should be further investigated.

P2.11-17 ANALYSIS OF LUNG ADENOCARCINOMA EGFR MUTATION BY LAMP METHOD COMPARISON WITH PCR METHOD AND IDENTIFICATION OF A NOVEL EXON19 DELETION MUTATION

S. Horiuchi, Y. Saito, H. Morooka, T. Ibi, N. Takahashi, T. Ikeya, E. Hoshi, Y. Shimizu

Saitama Cardiovascular and Respiratory Center, Kumagaya, Saitama/Japan

Background: Detection of EGFR mutation has been widely used for the lung cancer treatment. The accuracy of detecting EGFR mutations is, therefore, very important. We here adopted a method of Loop-mediated isothermal amplification (LAMP) used for the detection of bacteria, which amplifies DNA with high specificity and efficiency under isothermal conditions. So that we evaluated the usefulness of LAMP for detecting various EGFR mutations using cancer tissues in comparison to conventional PCR technique. **Method:** We enrolled 59 surgically resected lung adenocarcinoma patients. We used Therascreen EGFR PCR Kit as a conventional PCR. Then, we tried to detect EGFR mutations for those specimens using LAMP method, and compared the result of LAMP to that of Therascreen. **Result:** 26 cases had no mutation in the analysis using Therascreen and LAMP method. In 32 cases which showed positive mutations according to Therascreen, and LAMP method, however, we found a single case showing no mutations by LAMP method, and exon 19 deletion by Threascreen. The direct sequence analysis revealed no mutations in the case as shown with LAMP method. Here, we repeated several experiments using LAMP method for the purpose of comfirmation of EGFR status of the case. These additional tests revealed Exon 19 deletion using the LAMP method, moreover, another direct sequencing discovered a novel EGFR mutation. Sensitivity for LAMP method was calculated as 97.0%, specificity as 100%, positive predictive value (PPV) was 100%, negative predictive value (NPV) was 96.3 % and accuracy was 98.3%. **Conclusion:** The accuracy of detecting EGFR mutation in LAMP method was nealy equivalent to that in Therascreen. Moreover, we detected a novel EGFR exon 19 deletion mutation with the direct sequence.

P2.11-18 CIRCULATING SERUM KLK5 AND L1CAM LEVELS POTENTIALLY PREDICT CLINICAL OUTCOME TO ANLOTINIB THERAPY IN NSCLC PATIENTS

J. Lu[1], Q. Shi[2], L. Zhang[1], J. Wu[3], B. Zhang[1], S. Wang[1], X. Zhao[4], B. Han[1]

[1]*Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China,* [2]*Baoshan Branch of Shuguang Hospital, Shanghai/China,* [3]*East China Normal University, Shanghai/China,* [4]*Shanghai Jiao Tong University, Shanghai/China*

Background: Anlotinib is an oral multi-targeted tyrosine kinase inhibitor (TKI), which has been demonstrated to be effective upon non-small cell lung cancer (NSCLC) in clinical trials at 3rd line. However, the underlying anlotinib-responsive patients remain elusive. In the present study, we aimed to screen out the potential biomarkers for anlotinib-responsive stratification via transcriptome analysis. **Method:** Anlotinib-resistant NCI-H1975 cells were established *in vitro*. Toxicologic effects undergoing anlotinib stress were observed upon NCI-H1975 cells and anlotinib-resistant NCI-H1975 cells, respectively. Transcriptome profiling was performed to screen anlotinib resistance-associated genes between NCI-H1975 cells and anlotinib-resistant NCI-H1975 cells. The correlations between mRNA levels of the anlotinib resistance-associated genes and clinical outcomes of NSCLC patients were analyzed via Kaplan-Meier survival analysis in TCGA cohort. Potential biomarkers for anlotinib-responsive stratification were examined in a 28 patients' cohort of anlotinib clinical trial (NCT02388919). **Result:** Anlotinib-induced cytotoxic effects nearly disappeared in anlotinib-resistant NCI-H1975 cells, which are majority attributed to the modulated gene expression of multiple biological processes. Among these biological processes, angiogenesis plays an important role in anlotinib resistance. Up-regulation of angiogenesis-related *KLK5* and *L1CAM* are mostly associated with poor clinical outcome in NSCLC patients. Knockdown of *KLK5* and *L1CAM* contribute to increase anlotinib-induced cytotoxicity upon NCI-H1975 cells and anlotinib-resistant NCI-H1975 cells. High serum levels of KLK5 and L1CAM are also associated with poor anlotinib response in NSCLC patients at 3rd line. **Conclusion:** This study suggested that serum levels of KLK5 and L1CAM potentially serve as biomarkers for anlotinib-responsive stratification in NSCLC patients at 3rd line.

P2.11-19 EFFECTS OF INCORPORATING A LUNG CANCER SCREENING EDUCATIONAL INTERVENTION INTO TOBACCO CESSATION COUNSELING

D. Raz[1], A. Alem[2], S. Park[2], R. Nelson[1], V. Sun[1], E. Haupt[2], M. Ismail[2], M. Gould[2]

[1]*City of Hope, Duarte/United States of America,* [2]*Kaiser Permanente, Pasadena/United States of America*

Background: Lung cancer screening (LCS) with low-dose computed tomography (LDCT) reduces lung cancer mortality in high-risk patients, but most of those eligible are not referred for screening, and most eligible smokers are not aware about LCS. Tobacco cessation counseling may be an opportune time to educate smokers about LCS, but it is unclear whether providing such information is effective in improving LCS utilization and what effects it may have on success of

tobacco cessation. **Method:** We randomized 1281 smokers age 55-80 who underwent tobacco cessation services between January 2016 and February 2018 in a large integrated health care system to view a web-based educational video about LCS (n=1026) or to receive usual care (n=255). We analyzed results according to both intention-to-treat as well as a pre-planned subset analysis of participants who completed the video. A survey on perceptions of LCS was included at the completion of the video and this was analyzed as well. We then compared the utilization of chest CT scan (any chest CT or specifically LDCT for LCS) in both groups of participants during a specified 90 day follow-up period and modeled the incidence rate ratios (IRR) for participants who completed the video and all invited to view the video compared with controls. **Result:** In the intervention arm, 191 (14.9%) patients watched part of the video, and 136 (10.6%) of participants completed watching the video. The video was well received by those completing it. Overall, 47(4.6%) of participants in the intervention group underwent chest CT and 31 (3.0%) underwent LDCT compared with 12 (4.7%, p=0.082) and 7 (2.8%, p=0.30) in the control group during a 90 day follow-up. Among participants who completed watching the video, 18 (13.2%, p=0.033 compared with control) underwent chest CT and 10 (7.4%) underwent LDCT during follow-up (p= 0.003 compared with control). IRR for participants completing the video was 2.01 (95% CI 1.06-3.82, p=0.03) for LDCT compared with control, and 2.15 (95% CI 1.30-3.55, p=0.003) for chest CT compared with control. **Conclusion:** These data suggest that a lung cancer screening educational intervention may be effective in improving utilization of LDCT in eligible smokers at the time of tobacco cessation counseling. Our study was limited by relatively low response rate to viewing the educational video. We plan to study the optimal way to deliver LCS education in the setting of tobacco cessation. Further research on the effect of lung cancer screening education on the effectiveness of tobacco cessation interventions is also needed.

Keyword: Lung cancer screening, Low-dose computed tomography, tobacco cessation

P2.11-20 RISK FACTORS OF LUNG CANCER DEVELOPMENT IN IPF PATIENTS

H.S. Kang[1], I.K. Kim[1], C. Yeo[2]

[1]*The Catholic University of Korea, Seoul/Korea, Republic of,* [2]*Eunpyeong St. Mary's Hospital, Seoul/Korea, Republic of*

Background: Idiopathic pulmonary fibrosis (IPF) is known as a risk factor for lung cancer (LC) by several previous studies, and that the presence of LC shortens survival in patients with IPF. However, the risk factors for the development of LC after the diagnosis of IPF have not been fully evaluated. We investigated the predictive factors for LC by longitudinal cohort analysis. **Method:** This was a retrospective study of a single center interstitial lung disease cohort. Study patients were consecutively enrolled to the cohort between March 2006 and December 2018 at Bucheon St. Mary's Hospital, The Catholic University of Korea. This cohort study consists of 102 patients with IPF, and the incidence of LC and the outcomes were investigated. **Result:** During the mean follow-up periods of 62.7 months, 27 patients (26%) developed LC. The most frequent cell type was Squamous cell carcinoma, and the proportion of male was higher in IPF-LC group (92.6% vs 70.7%, p=0.021). In univariate cox regression analysis, low forced vital capacity (FVC) <75% (p<0.001), and low diffusion capacity of the lungs for carbon monoxide (DLco) <55% (p<0.001) was associated with LC development. In Cox proportional hazards model, low FVC (hazard ratio [HR]: 5.65; 95% confidence interval [CI]: 1.78-17.84, p=0.003) and low DLco (HR: 27.5; 95% CI: 1.97-386.6, p=0.014) were independent predictive factors for LC in stepwise multivariate analysis. **Conclusion:** Low FVC and Low DLco, which are pulmonary function parameters reflecting their severity of IPF, are suggested as independent risk factors for LC development in IPF patients.

Keywords: Lung cancer, idiopathic pulmonary fibrosis, pulmonary function

P2.11-21 USEFULNESS OF DIFFUSION-WEIGHTED WHOLE-BODY IMAGING WITH BACKGROUND SUPPRESSION IN THE POSTOPERATIVE FOLLOW-UP PERIOD

K. Suemori, M. Kataoka, D. Okutani, T. Fujita, I. Togami, M. Saeki

Okayama Saiseikai General Hospital, Okayama/Japan

Background: Diffusion-weighted whole-body imaging with background suppression (DWIBS), a magnetic resonance diffusion-weighted imaging method of the whole body, has recently been adopted as a method for detecting malignant lesions, but there have been few reports discussing the usefulness of this technique with respect to the detection of recurrent postoperative lesions. Herein, we describe the usefulness of DWIBS for identifying recurrence, following surgery for primary lung cancer. **Method:** We performed a retrospective investigation of the accuracy of detection of recurrent lesions using DWIBS in 76 patients (46 men, 30 women) between November 2016 and October 2018, who were being followed up after primary lung cancer surgery. Diagnosis of recurrence was made after comprehensive imaging findings, clinical findings, and histopathological findings. While performing DWIBS, photographs were taken using a SIEMENS MAGNETOM Skyra 3.0T device and no contrast agent was used. The b factors were set to 0 and 1000, and high signal and low apparent diffusion coefficient (ADC) values in the diffusion weighted image (b = 1000) were evaluated visually. **Result:** The mean period from surgery to DWIBS was 1243 days (range: 116-3557 days) and the median period was 999 days. Of the 76 cases considered, recurrence was observed in 32 cases, of which DWIBS detected the lesion in 24 cases (75%). Of the 44 non-recurrent cases, 18 exhibited a strong signal in DWIBS. Of these 18 cases, 12 were false positives and 6 were primary lesions. Accuracy was 73.6%, sensitivity was 78.9%, and specificity was 68.4%, respectively. The breakdown of the location of lesions identified through DWIBS that were indicative of recurrence was as follows: Lymph nodes: 15 and bones: 8; with others located in the lungs, liver, and pancreas. In addition, the breakdown of the location of lesions identified in the chest through DWIBS that were not indicative of recurrence was as follows: Pulmonary recurrence: 6, hilar lymph node recurrence: 1, and mediastinal lymph node recurrence: 1. The reasons for performing DWIBS were elevated tumor marker values in 33 cases and whole-body testing for recurrence via computed tomography (CT) in 24 cases. **Conclusion:** We believe that DWIBS is a useful technique when performing whole-body malignancy screenings after surgery for primary lung cancer. As this technique is less sensitive in identifying small recurrent lesions in the chest, it may be necessary to make a comprehensive diagnosis based on other findings as well, such as contrast-enhanced CT and PET results.

Background: Objective: To compare the sensitivity to detect lung cancer of two lung cancer screening selection criteria, the USPSTF (≥30 pack-years smoked, quit-time ≤15 years, age 55-80) and the PLCOm2012 model 6-year risk ≥1.5%, in a racially diverse population including a high proportion of Blacks. **Method:** Lung cancer cases diagnosed at a Chicago academic hospital in 2010–2017 were retrospectively analyzed for whether they met lung cancer screening eligibility using the USPSTF and PLCOm2012 criteria. Contingency table analysis with McNemar's odds ratios, confidence intervals and p-values evaluated comparisons. **Result:** The race/ethnic distribution of the 823 lung cancer cases was 245 (29.8%) Whites, 435 (52.9%) Blacks, 75 (9.1%) Hispanics, 39 (4.7%) Asians, and 29 (3.5%) others. Overall, data on criteria risk factors were available for 770 (93.6%) individuals: 68.3% were positive by PLCOm2012 criteria and 49.9% were positive by the USPSTF (Table 1, McNemar's odds ratio (ORM)=11.9, 95%CI 6.8-22.9, p<0.0001). Limited to Blacks, the

USPSTF criteria identified 50.8% and the PLCOm2012 identified 74.9%. Only 3 individuals were USPSTF+ve/PLCOm2012-ve and 104 individuals were PLCOm2012+ve/USPSTF-ve (Table 2, ORM=34.7, 95%CI 11.5-170.8, p<0.0001). **Conclusion:** Overall and especially in Blacks, compared to the USPSTF criteria, the PLCOm2012 criteria was significantly more sensitive at identifying lung cancer patients.

Table 1. Lung cancer cases (N=770) stratified by USPSTF and PLCOm2012 selection criteria status, all races/ethnicities. Cells contain number, (row percent), [column percent].

	PLCOm2012 risk < 1.5%	PLCOm2012 risk ≥1.5%	Total
USPSTF criteria -ve	231 (59.8%) [94.7%]	155 (40.2%) [29.5%]	386 (100.0%) [50.1%]
USPSTF criteria +ve	13 (3.4%) [5.3%]	371 (96.6%) [70.5%]	384 (100.0%) [49.9%]
Total	244 (31.7%) [100.0%]	526 (68.3%) [100.0%]	770 (100.0%) [100.0%]

Table 2. Lung cancer cases (N=419) stratified by USPSTF and PLCOm2012 selection criteria status, Black race only. Cells contain number, (row percent), [column percent].

	PLCOm2012 risk < 1.5%	PLCOm2012 risk ≥1.5%	Total
USPSTF criteria -ve	102 (49.5%) [97.1%]	104 (50.5%) [33.1%]	206 (100.0%) [49.2%]
USPSTF criteria +ve	3 (1.4%) [2.9%]	210 (98.6%) [66.9%]	213 (100.0%) [50.8%]
Total	105 (25.1%) [100.0%]	314 (74.9%) [100.0%]	419 (100.0%) [100.0%]

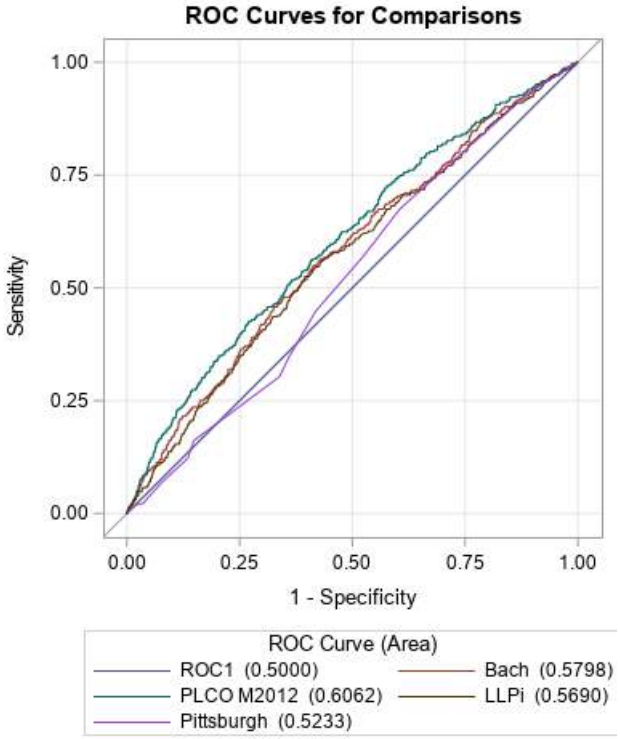
P2.11-23 PERFORMANCE OF LUNG CANCER RISK PREDICTION MODELS IN I-ELCAP SMOKERS

R. Yip, C. Henschke, D. Yankelevitz

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: To determine the performance of lung cancer risk prediction models in predicting lung cancer in smokers enrolled in the International Early Lung Cancer Program (I-ELCAP). **Method:** 62,071 asymptomatic ever-smokers enrolled into the international multi-institutions I-ELCAP for low-dose CT screening between 1993-2018. Demographics, smoking history, comorbidities, exposures and family history of lung cancer were collected at time of baseline CT scan. All participants received a baseline screening scan and subsequently annual repeat CT scans, and they were prospectively followed for the diagnosis of lung cancer. Diagnosis and treatment of lung cancer were verified and documented in the ELCAP Management System. To compare the predicted risk of lung cancer, we applied four lung cancer risk models: the Bach Model, the Liverpool Lung Project Incidence (LLPi) Risk model, the Prostate, Lung, Colorectal, and Ovarian Cancer Screening Trial Model 2012 (PLCOM2012), and the Pittsburgh Predictor Model to the I-ELCAP cohort. Model calibration and discrimination were assessed using expected-to-observed (E/O) ratio and the area under the curve (AUC) statistics. E/O ratio >1 indicates that the model predicts more lung cancer cases than observed. **Result:** PLCOM2012 model was the most predictive of lung cancer for ever-smokers in I-ELCAP with the AUC 0.61 being the highest, followed by Bach model (AUC 0.58), LLPi model (AUC 0.57) and Pittsburgh Predictor (AUC 0.52). E/O ratios suggested that the PLCOM2012 model, Bach model, LLPi model and Pittsburgh Predictor model tends to overestimate the number of lung cancers. The LLPi model overestimated as many as 4 times more lung cancer cases.



Conclusion: Using data from I-ELCAP, the four existing lung cancer risk prediction models have AUCs ranged between 0.52-0.61, PLCOM2012 model was the top performer out of the four models.

P2.11-24 THE FIRST COMPREHENSIVE PRIMARY CARE PROVIDER TRAINING FOR LUNG CANCER CARE IN THE U.S. - AN INNOVATIVE ONLINE COURSE

C. Worth, M. Jones, R. Mattingly, S. Sthapit-Gaines, C. Sorrell

University of Louisville, Louisville/United States of America

Background: Lung cancer (LC) is the leading cause of cancer death in the U.S., and primary care provider (PCP) education is essential for reducing the country's overall LC burden. Despite recent LC treatment advances, several studies show that LC patients receive treatments at lower rates than other cancer patients, regardless of stage of diagnosis. Despite decades of research into tobacco use treatment, many PCPs still lack the expertise to assist patients in their quit attempts. PCP understanding and adoption of the U.S. Preventive Services Task Force (USPSTF) recommendation for LC screening with low-dose CT (LDCT) remain low, making PCP education crucial for impacting the leading cause of cancer death. **Method:** The LuCa National Training Network provides training, materials, and technical assistance for professionals who educate PCPs and other health care professionals on LC. In developing an online training course on lung cancer care for PCPs, LuCa moved beyond the traditional, using innovative technology to engage PCPs and influence practice behaviors. The free course, *Lung Cancer and the Primary Care Provider,* delivers comprehensive, interactive education on best practices related to lung cancer prevention, early detection, treatment, and survivorship. The course includes a library of practice tools available for download. This presentation will provide an overview of the online course, lesson content, features, interactivity, and results to date. **Result:** *Lung Cancer and the Primary Care Provider* launched in April 2019 and is the only comprehensive online course on LC care for PCPs in the U.S. Learners complete pre- and post-tests and evaluations immediately following the course and three months later regarding practice changes. Up-to-date participation and evaluation trends, demographic comparisons, knowledge changes, lessons learned, and participant feedback will be shared. This presentation will review the practice areas on which the course had the strongest influence, based on PCP self-reported data.

Conclusion: PCPs play a pivotal role in determining the care pathways for their patients who are at risk for, or diagnosed with, lung cancer. They are an ideal audience for pertinent lung cancer-focused educational interventions. Creative online learning has tremendous potential to improve patient care and achieve broad reach to this critical provider audience. Adoption of new screening and prevention modalities takes time, but high quality training with simple downloadable practice tools can accelerate adoption of these best practices. Provider education must be engaging, evidence-based, on-demand, and cutting-edge in order to capture focus with competing demands, and affect knowledge and confidence on complex lung cancer topics.

P2.11-25 PRE- AND POST-SURGERY METABOLOMIC PROFILES IN EARLY-STAGE NSCLC PATIENTS

W. Laosuangkoon[1],[2], S. Oranratnachai[2], N. Paiyabhroma[1], L. Chailurkit[1], D. Munthum[1], N. Trachu[1], P. Sanvarinda[1], B. Ongphiphadhanakul[1], T. Reungwetwattana[1]

[1]*Mahidol University, Bangkok/Thailand,* [2]*Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/Thailand*

Background: Finding biomarkers to detect cancer at its early stage is of importance. Since metabolic reprogramming is a hallmark of cancer, oncometabolite is thus a promising target.Progress in cancer metabolomics opens the door for large scale screening of cancer-specific metabolites that could be future applied for subclinical stage detection and novel therapeutic targets. **Method:** Seventy paired pre- and postoperative plasma samples of early-stage NSCLC patients who had completed curative surgery during 2015-2018 with ≥ 3 months disease free were retrieved. Demographic and Clinical data were collected. All samples were subjected to targeted metabolomics analysis using AbsoluteIDQ® p180 Kit on ESI 5500 LC-MS/MS System equipped with 1260 Series HPLC, according to the manufacturer's instruction.Multivariate analysis including PCA and OPLS-DA were used to identify the difference between pre- vs post-operative sample set. T-test was used to confirmed if the metabolites significantly different among groups at the univariate level ($p < 0.05$). **Result:** Of the 70 patients, 31 (44.3%) were male and 39 (55.7%) were female. Median age was 63 years old (23 - 85). Majority of them were never-smokers (64.3%). Adenocarcinoma was the most common histology (91.4%). EGFR mutation was tested in 34 (48.6%) patients, of which, 22(64.7%) of them were positive. Metabolomic analysis revealed tryptophan as the most statistically significant change, together with other amino acids, carnitines, biogenic amines, and lipids (Table1). Besides glutamate, all metabolites increased postoperatively. Metabolites with VIP scores (Variable Importance in Projection) ≥ 1.5, including tryptophan, lysophosphatidylcholine-acyl C16:0, lysophosphatidylcholine-acyl C18:0, and carnitine, were assembled together for a predictive model which will be presented at the congress. Table 1: Metabolites with significant difference between pre- and post-surgery in early-stage NSCLC patients

Metabolite (ng/ml)	Pre operation (N=70)		Post operative (N=70)		Fold change	p-value	VIP score
	Mean	SD	Mean	SD			
Amino acid							
Glutamate	17,449.31	7,808.80	10,192.53	5,294.28	-0.374	<0.001	1.21

lysoPC a C16:1	740.24	287.44	1,256.99	588.67	0.842	<0.001	1.33
lysoPC a C17:0	303.24	90.78	521.36	200.39	0.853	<0.001	1.45
lysoPC a C18:0	8,449.64	2,593.82	14,854.50	5,047.03	0.885	<0.001	1.60
lysoPC a C18:2	6,818.04	2,466.61	11,990.73	4,760.87	0.965	<0.001	1.37

Conclusion: We identified a distinct cluster of significant metabolic biomarkers associated with early-stage NSCLC. Tryptophan is the most significant one that associated with cancer metabolome. These would be potential biomarker profile for early-stage NSCLC detection.Larger cohort is needed to be validated.

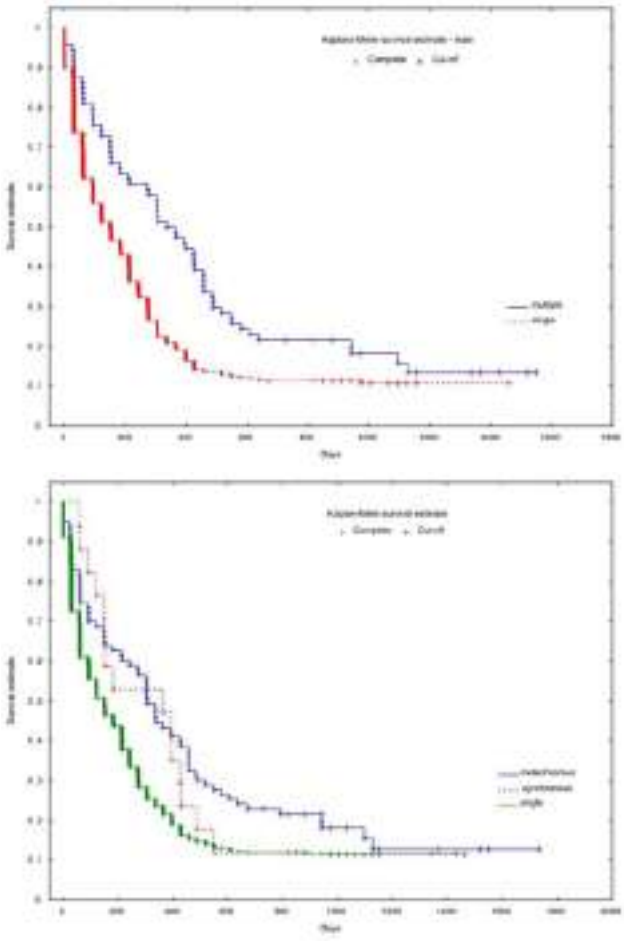
P2.11-26 SURVIVAL OF PATIENTS WITH MULTIPLE PRIMARIES AND SINGLE LUNG CANCER - A COMPARATIVE ANALYSIS

A. Romaszko-Wojtowicz[1], A. Buciński[2], J. Romaszko[3], A. Doboszyńska[3]

[1]*University of Warmia and Mazury, Olsztyn/Poland,* [2]*Nicolaus Copernicus University, Collegium Medicum, Bydgoszcz/Poland,* [3]*University of Warmia and Mazury, Collegium Medicum, Olsztyn/Poland*

Background: From the mid-1980s, lung cancer is the most commonly diagnosed malignant tumor. Longer survival is associated with an increased likelihood of new, subsequent neoplasms. The incidence of multiple primary neoplasms in the oncology population ranges from 0.73 to 11.7%. The aim of the study was to assess the survival of patients with single lung cancer in relation to patients with multiple primary neoplasms. **Method:** The study was conducted based on the retrospective analysis of data collected from patients hospitalized at the Center for Pulmonary Diseases in Olsztyn (Poland). Data on multiple malignancies (140 patients) were collected from January 2013 to December 2017. Data on single primaries (601 patients) were collected from January 2016 to December 2017. Total survival was calculated beginning from the date of the first cancer diagnosis to the day of death or last observation. The statistical analysis was conducted using Statistica version 12. **Result:** Based on the collected data, it was revealed that the survival of patients with a single lung cancer (0.17 years; SD 0.81) is significantly shorter than those who had multiple primaries (7.15 years; SD 7.42) (p <0.05). The average survival time of cancer patients with metachronous tumors (8,29 years; SD: 7.58) is significantly longer than patients with synchronous tumors (1.30 years; SD: 1.17) (p <0.05) and single ones (0.71 SD: 0.82) (p<0.05). It was also revealed that patients who smoked in a group of single cancer lived shorter than those with multiple malignancies (p<0.05). The average number of packyears for patients with multiple tumors was 33.95 (SD: 24.95), and with single primaries 39.90 (SD: 21.26).



Conclusion: Survival time for patients with single lung cancer is worse than for patients with multiple tumors, both in relation to the first and subsequent tumors. Smoking reduces survival time of patients with both multiple and single primaries.

Keywords: multiple primary malignanices, Lung cancer, Survival

P2.11-27 EARLY DETECTION OF LUNG CANCER: OPTIMAL STRATEGIES

O. Kshivets

Roshal City Hospital, Roshal/Russian Federation

Background: Significance of blood cell subpopulations in terms of early detection of lung cancer (LC) was investigated. **Method:** In trial (1987-2019) consecutive cases after surgery, monitored 115 LC patients (LCP) (m=100, f=15; lobectomies=115) with pathologic stage IA (tumor size=1.86±0.30 cm; squamous=51, adenocarcinoma=59, large cell=5; T1N0M0=115; G1=39, G2=42, G3=34, 5-year survival=100%) and control group (CG) (n=402): 120 healthy donors (HD) (m=69, f=51) and 282 patients with lung non-malignant pathology (NMP) (m=188, f=94; pneumonectomies=5, lobectomies=179, segmentectomies=98; non-malignant tumors=100; abscess=112; tuberculoma=70) were reviewed. Variables selected for study were input levels of blood cell circuit, sex, age, TNMG. Differences between groups were evaluated using discriminant analysis, clustering, nonlinear estimation, structural equation modeling, Monte Carlo, bootstrap simulation and neural networks computing. **Result:** It was revealed that early detection of LC from CG (n=517) significantly depended on: leucocytes (abs, total), segmented neutrophils (%, abs, total), lymphocytes (%), monocytes (%, abs, total) (P=0.048-0.000). Neural networks computing, genetic algorithm selection and bootstrap simulation revealed relationships of early detection of LC and lymphocytes (rank=1), segmented neutrophils (rank=2), monocytes (3), eosinophils (4), leucocytes (5), stick neutrophils (6). Correct recognition of early LCP from CG was 100% by neural networks computing (error=0.000; area under ROC curve=1.0). **Conclusion:** Early detection of LC from HD and NMP significantly depended on blood cell subpopulations.

P2.11-28 LATE-BREAKING ABSTRACT - CLINICAL POTENTIAL OF SPUTUM HYALURONAN MEASUREMENT IN THE DIAGNOSIS AND PROGNOSIS OF PATIENTS WITH NSCLC

J. Chinoca[1], H. Freitas[2], V. De Lima[3], M. Tariki[1], P. De Marchi[4], D. Carraro[1], J.R. Martins[5], V. De Sá[6]

[1]*Ac Camargo Cancer Center, Sao Paulo/Brazil,* [2]*Clinical Research Unit, Ac Camargo Cancer Center, Sao Paulo/Brazil,* [3]*Medical Oncology Department and Translational Immune-Oncology Group, Ac Camargo Cancer Center, Sao Paulo/Brazil,* [4]*Hospital de Câncer de Barretos, São Paulo/Brazil,* [5]*Biochemistry and Molecular Biology, Universidade Federal de São Paulo, São Paulo/Brazil,* [6]*Genomic and Molecular Biology, Ac Camargo Cancer Center, Sao Paulo/Brazil*

Background: Lung cancer is the most frequently diagnosed and also the most lethal due to late diagnosis. Many efforts are being made to mitigate this problem. In this scenario, sputum is a potentially attractive source of biomarkers present in the extracellular matrix such as hyaluronan (HA). The aim of this study is to validate HA levels in sputum's patients with non-small cell lung cancer (NSCLC) at the time of diagnosis and after first-line treatment evaluation response and correlate the values response rate in patients submitted to definitive treatment with chemotherapy and/or radiotherapy, progression and recurrence. We also evaluated the HA concentrations in chronic obstructive pulmonary Disease (COPD) and healthy volunteers and its impact on the screening and diagnosis of lung cancer patients. **Method:** HA was examined in sputum samples of 64 NSCLC, 14 COPD patients and 15 healthy controls. All the patients and healthy controls selected underwent a sputum induction.The levels of HA were measured in ng/ug of protein by a noncompetitive ELISA-like fluorometric assay. **Result:** A significant different concentration pattern of HA in the sputum was found among NSCLC (median: 33.25 ng/mg), COPD (median:16.6ng/ug) and healthy individuals (median: 12.2 ng/ug), (p<0.001, Fig. 1A), as well as NSCLC before first-line treatment (median:33.25ng/mg) and after 6 months treatment regimens with good response (median:6.2ng/ug), (p<0.001, Fig 2). **Conclusion:** Based on the results obtained so far, we rely on the clinical potential of sputum as a screening tool in the early detection of lung cancer.

P2.11-29 DIAGNOSIS AND SURVEILLANCE OF SOLITARY PULMONARY NODULES WITH CTDNA METHYLATION SEQUENCING: PROTOCOL FOR A PROSPECTIVE MULTICENTER STUDY

W. Liang[1], J. He[1], J. Fan[2], N. Zhong[1], C. On Behalf Of The Bell Study Investigators[1]

[1]*The 1st Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/China,* [2]*AnchorDx Medical Co., Ltd., Guangzhou/China*

Background: LDCT screening can identify early-stage lung cancers yet introduces excessive false positives, which calls for better non-invasive diagnostic tools. We previously established a diagnostic model of early stage lung cancer based on high-throughput DNA methylation sequencing of ctDNA (Theranostics 2019; 9(7)). The aim of the present study is to assess the role of ctDNA methylation markers in differential diagnosis and surveillance of pulmonary nodules. **Method:** A prospective cohort of 10,560 patients from 20 centers in China with non-calcified nodules range from 0.5 to 3 cm in diameter indicated by LDCT or CT will be included and followed up for 2 to 3 years. Each patient will undergo LDCT/CT follow-up and their information as well as blood sample will be collected at baseline, 3, 6, 12, 24 and 36 months. Blood samples will be subjected to ctDNA methylation test. Sensitivity, specificity, positive predictive value and negative predictive value are used to measure the diagnostic value of ctDNA methylation test in differentiating benign and malignant pulmonary nodules. **Result:** This study is registered in clinicaltrials.gov (NCT03651986, BELL study) and has launched since Oct 2018. Upon submission, 975 cases had been enrolled from 13 centers who had begun recruiment. Completion of data collection is anticipated by March 2023. **Conclusion:** To the best of our knowledge, this is the first and largest study worldwide to test the efficacy of ctDNA methylation markers in differential diagnosis and surveillance of pulmonary nodules.

Keywords: solitary pulmonary nodules, ctDNA, methylation

P2.11-30 EFFECTS OF THE SIZE OF NODULES, RECONSTRUCTION SLICE THICKNESS AND CONVOLUTION KERNEL ON RADIOMICS MODEL IN CLASSIFYING PULMONARY NODULES

Y. Xu[1], L. Lu[2], W. Lian[3], L. Schwartz[2], Z. Yang[1], B. Zhao[2]

[1]*Beijing Friendship Hospital, Capital Medical University, Beijing/China,* [2]*New York Presbyterian Hospital, Columbia University Medical Center, New York/United States of America,* [3]*Yancheng Third People's Hospital, Yancheng/China*

Background: In recent years, the number of chest CT and LDCT scans for annual lung cancer screening has been increasing, the detection rate of the intermediate pulmonary nodules (IPNs) has increased, especially small pulmonary nodules (PNs). A non-invasive method be needed to early diagnosis the benign and malignant of IPNs, then it would be possible to reduce the false positives, missed diagnosis rate, and avoid overdiagnosis and over-treatment. The ability of radiomics to classify PNs by radiologists has been widely described, however, the detection performance of each radiomics varies greatly and the reproducibility was poor that are identified from these studies. Variability of acquisition parameters like contrast enhancement, slice thicknesses can affect the diagnostic performance of radiomic biomarkers. But there are few reports on the effect of PN size, reconstruction slice thickness and convolution kernels on the performance of radiomics in classifing PNs. **Method:** We retrospectively collected 696 patients with 316 benign and 380 malignant PNs who underwent preoperative chest CT in the institution from March 1, 2015 to March 31, 2018. First, we analyzed the CT image of all the patients, and then we divided these images according to the nodule size and reconstruction kernel to test the diagnostic performance of the radiomic. 696 PNs were classified into three groups by nodule diameter: T1a (diameter $\leq$ 1.0 cm), T1b (1.0 cm < diameter $\leq$ 2.0 cm) and T1c (2.0 cm < diameter $\leq$ 3.0 cm). All CT images divided three groups according convolution kernels: Setting 1 (1mm/1.25 mm sharp), Setting2 (5 mm sharp), Setting 3 (5 mm smooth). Totally 1160 radiomic features were extracted from PNs segmentation on CT image delineated by an experienced radiologist. Sixteen radiomic models for predicting the malignancy of PNs in different size, reconstruction slice thickness and convolution kernels were built, respectively, based on the extracted radiomic features. Random selection of cases (70% Training and 30% testing) was employed to estimate the area under the receiver operating characteristic curve, accuracy, sensitivity and specificity to indicate the performance of the prediction models. **Result:** The performance (AUC, accuracy, sensitivity and specificity) on prediction PN malignancy in different size PN with all convolution kernels were 0.817, 0.766, 0.807, 0.717 of all size-modal; 0.679, 0.756, 0.629, 0.796 of T1a-model; 0.700,0.690,0.757,0.594 of T1b-model and 0.703, 0.684, 0.673, 0.731 of T1c-model, respectively. AUC of all size PN with setting 1,2,3 group were 0.793, 0.800, 0.793, respectively. AUC was the highest in T1a with setting 2 model which equal 0.841, and the lowest in T1c with setting 4 which equal 0.625. **Conclusion:** Reconstruction slice thickness and convolution kernel have significant influence on the diagnosis performance of radiomics in classifying of less than 1cm PNs in CT images, and using 1 mm shin sharp reconstruction algorithm can obtain the best diagnosis performance in less than 1cm PNs. Big samples of PNs could alleviate the effect of reconstruction slice thickness and convolution kernel on radiomics in classifying of less than 3cm PNs in CT images and improve the diagnostic performance of radiomics of larger than 1cm PNs

Keywords: pulmonary nodule, kernel, Radiomics

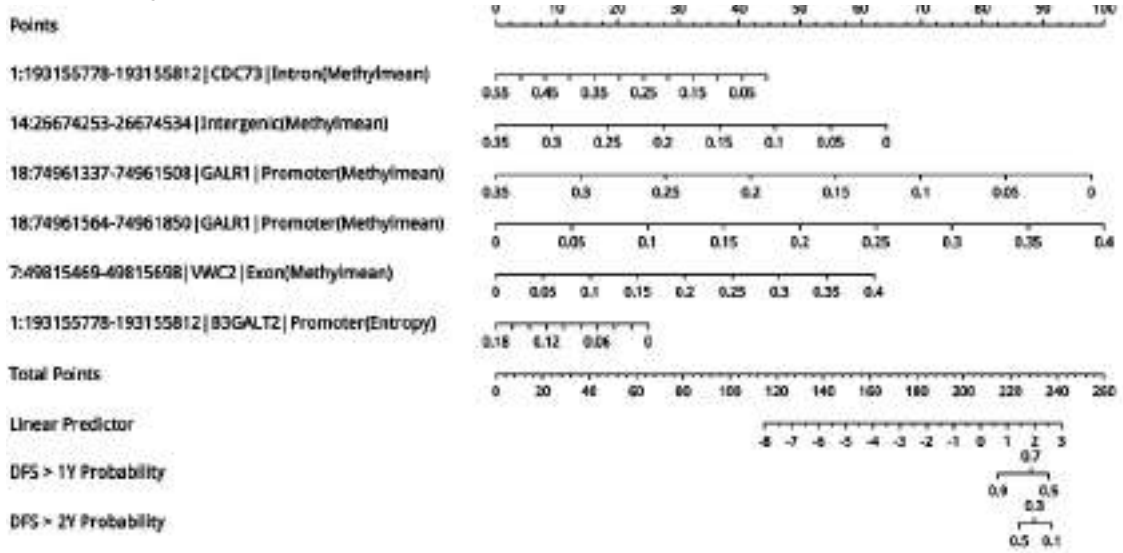
P2.11-31 DNA METHYLATION MARKERS FOR PREDICTION OF RECURRENCE IN STAGE I NON-SMALL CELL LUNG CANCERS

Y. Wang[1], J. Ying[1], L. Yang[1], J. Zhang[1], T. Zhang[2], J. Lin[2]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [2]*Burning Rock Biotech, Guangzhou, People's Republic of China, Guangzhou/China*

Background: Surgery with curative intent is the standard of care for patients with stage I non-small cell lung cancer (NSCLC). However, many patients die of recurrent disease despite of lesion resection. The value of DNA methylation for predicting the recurrence of early-stage, resected NSCLC remains to be determined. The aim of this

study was to find DNA methylation markers for recurrence prediction. **Method:** 39 paired tumor tissues and adjacent normal tissues from stage Ia NSCLCs were sequenced using bisulfite sequencing panel which covers 80,672 CpG sites and spans 1.05 mega base of human genome. The average sequencing depth was 1000X. Methylation blocks (MBs) were defined as the genomic region between the neighboring CpG sites and 8312 MBs were generated using the linkage disequilibrium and statistical modeling. Methylmean indicates the mean methylation value of MB, and methyentropy denotes the randomness of DNA methylation pattern of MB. **Result:** A total of 726 tumor-specific MBs shared by 1098 Methylentropy and 1316 Methylmean variates were obtained from matched tumor tissues and adjacent normal tissues using t-test (P<0.05). Then the multivariable analysis, conducted via the Cox regression model, generated 15 significant disease-free survival (DFS)-related MBs which shared by 56 methylentropy and 46 methylmean variates. A final model was selected using a backward step-down process and 6 significant DFS-related MBs were selected (1 methylentropy and 5 methylmean variates). A nomogram model that incorporated the 6 MBs was established to predict the DFS, and it performed well (C index=0.729, Figure 1).



Conclusion: We established an effective nomogram that may well distinguish the potential subgroup of patients with different DFS based on DNA methylation. Further perspective study should be conducted to validate this nomogram model in larger cohorts.

Keywords: DFS, NSCLC, DNA methylation

P2.11-32 PROJECT ACTS (ADHERENCE TO CT SCREENING): DEVELOPING PATIENT ENGAGEMENT TOOLS TO SUPPORT LUNG CANCER SCREENING ADHERENCE

U. Basu Roy[1], M. Byrne[2], J. Mccoy[2], C. Blair[3], J. Studts[3]

[1]*LUNGevity Foundation, Bethesda/United States of America,* [2]*Moffitt Cancer Center, Tampa/United States of America,* [3]*Markey Cancer Center, Lexington/United States of America*

Background: The National Lung Screening Trial and the NELSON trial have established that low-dose computed tomography (LDCT) is beneficial for early detection of lung cancer among high-risk individuals. In 2014 the USPSTF began recommending LDCT scans for people at high risk for developing lung cancer. Part of the recommendation includes annual screening as well as follow-up for abnormal scans per Lung-RADS recommendations. However, rates of adherence to annual screening have been less than desirable with some screening programs anecdotally reporting rates as low as 20% and 50%. Concerns have also been raised regarding adherence to recommended interval scans following suspicious LDCT results. To address this need, Project ACTS aims to create a toolkit to facilitate lung cancer screening (LCS) adherence rates by addressing barriers and enhancing facilitators to participating in lung cancer **Method:** To explore barriers and facilitators of screening program adherence, this study employed a sequential qualitative and quantitative assessment to identify components of a successful screening adherence paradigm. Semi-structured interviews and surveys were conducted with 15 Lung Cancer Screening (LCS) Program Directors and staff and 8 LCS Program Participants. Interviews were transcribed and analyzed using direct content analysis. **Result:** Using the socio-ecological model of health promotion as a conceptual framework for analysis, the team mapped interview and survey findings to identify facilitators and barriers to adherence. Significant findings included: (1) the importance of personalized delivery of scanning results, embedding the opportunity to ask questions; (2) positive interactions with the CT techs; (3) the importance of a consistent program contact for engagement and continuity of care; (4) preference for increased screening accessibility with more locations and the option of weekend or later hours; and (5) the benefits of an active reminder system that utilizes multiple communication approaches. In addition, LCS program staff indicated interest in receiving training in shared decision-making and patient engagement strategies. **Conclusion:** Our formative research highlights the complex and multi-factorial nature of screening adherence and identifies facilitators and barriers that may impact optimal adherence. The next step in this research will involve development, usability testing, and pilot studies of the proposed patient engagement toolkit.

Keywords: lung cancer screening, early detection, screening adherence

P2.11-33 ORGANIZATIONAL READINESS FOR IMPLEMENTATION OF LUNG CANCER SCREENING IN A VETERANS AFFAIRS HEALTHCARE SYSTEM

L. Spalluto[1,2], J. Lewis[1,2], C. Callaway-Lane[1], D. Stolldorf[2], B. Prusaczyk[2], H. Limper[2], C. Audet[2], T. Vogus[3], R. Wiener[4,5], C. Slatore[6,7], D. Yankelevitz[8], C. Henschke[9], R. Dittus[1,2], P. Massion[1,2], C. Lindsell[2], S. Kripalani[2], D. Moghanaki[10], C. Roumie[1,2]

Sinai, New York/United States of America,* [9]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [10]*Atlanta VA Medical Center, Atlanta/United States of America*

Background: Implementation of high quality lung cancer screening is complex and requires close coordination between radiology and primary care teams. Organizational readiness for change (ORC) is an important factor in successful implementation of complex healthcare programs such as lung cancer screening. Using the Consolidated Framework for Implementation Research (CFIR), we tested the hypothesis that ORC would differ between radiology and primary care prior to deployment of a centralized lung cancer screening program. **Method:** We conducted a cross-sectional observational study. We invited all radiology and primary care providers (hospital and community-based) and affiliated staff at a single large VA Healthcare System in the US by email to participate in a web-based survey. We measured demographic information and adapted 9 validated items on ORC (domains of change commitment and change efficacy) and 10 items on change valence (value of a planned organizational change) using a 7-point Likert-type scale. Respondents' ORC and change valence scores were calculated by averaging individual item responses for each scale. The primary outcome, ORC, was evaluated as a continuous variable with higher scores representing more readiness. We compared mean ORC scores between radiology and primary care using independent 2-sample t-tests. **Result:** The overall response rate was 54% (76/128 [59.4%] radiology, 206/398 [51.8%] primary care). After 12 respondents were excluded for incomplete data (5 from radiology and 7 from primary care), the analytical sample was 270 respondents. Respondents were on average 47 years old [SD 11.24], 72% female, and 17% self-identified as having a leadership role. Individuals affiliated with radiology reported higher ORC than those affiliated with primary care (5.50 [SD 1.42] versus 5.07 [SD 1.22], p=0.03). Individuals self-identifying as having leadership roles in implementation of lung cancer screening reported higher ORC than those without leadership roles (5.56 [SD 1.38] vs 5.11 [SD 1.28], p=0.05). Those with leadership roles reported higher change valence than those without (5.91 [SD 1.20] vs. 5.36 [SD 1.88], p=0.006). We found no difference in reported change valence between radiology and primary care. **Conclusion:** Radiology providers and staff have higher perceived ORC to implement a centralized lung cancer screening program compared to primary care. Providers and staff with implementation leadership roles reported higher ORC than those without leadership roles. Understanding these differences in readiness will inform future work as we focus on strategies to engage primary care providers and staff during implementation of lung cancer screening. We will deploy these strategies at Veterans Health Administration facilities across the US with the support of the VA-Partnership to increase Access to Lung cancer Screening (VA-PALS) and the VA Office of Rural Health.

Background: Since the efficiency of CT mass-screening was reported in NEJM in 2013, many countries have been actively adopting CT screening for detection of lung cancers, especially peripheral-type lung adenocarcinoma. On the other hand, another mass-screening method, "sputum cytology", has a very low cancer detection rate and its use has been decreasing worldwide. Nevertheless, sputum is one of the easiest types of sample to collect from patients, and sputum samples are thought to contain not only cancer cells, but also cancer cell-free DNA.The present study examined genomic abnormalities in DNA contained in sputum, and investigated the efficiency of next-generation sequencing (NGS) for detection of lung cancer or identifying patients at high risk. **Method:** Using the Saccomanno method, we collected sputum samples from 15 patients (5 with squamous cell carcinoma, 5 with adenocarcinoma, and 5 with non-neoplastic conditions). A 1500 µl volume of each sample was centrifuged, and the sediment was resuspended in 180 µl of supernatant. After incubation with protease K at 56ºC for 90 min, DNA was extracted using MagLead 6GC (Precision System Science Co., Ltd., Japan). All DNA samples were subjected to NGS using Ion AmpliSeq Cancer Hotspot Panel v2 (Thermo Fisher Scientific, USA). **Result:** The median age of the patients overall was 71 years (range, 56–94 years), and that of patients with squamous cell carcinomas, adenocarcinomas and non-neoplastic conditions was 66 years (64-78), 71 years (67-73) and 86 years (56-94), respectively. HRAS and p53 mutations were found only in cancer patients (HRAS 2/10, p53 4/10). There were no significant differences in mutation pattern between squamous cell carcinoma and adenocarcinoma patients. Although mutations of ALK, PIK3CA, PTEN, KRAS, FLT3, and RB1 were frequently found in samples from cancer patients (ALK 5/10, PIK3CA 5/10, PTEN 7/10, KRAS 7/10, FLT3 4/10, and RB1 8/10), such mutations were also present in non-neoplastic conditions. Mutations at the same locus in ALK, PIK3CA, PTEN and RB1 were also found in non-neoplastic conditions (ALK 1/5, PIK3CA 1/5, PTEN 2/5, and RB1 1/5). Seventeen out of 48 gene mutations were found only in non-neoplastic conditions. **Conclusion:** Detectable mutation patterns differed between cancer and non-neoplastic conditions, but were similar between squamous cell carcinoma and adenocarcinoma. Validation tests will be performed on DNA extracted from more than 400 sputum samples.

Keywords: mass-screening method, sputum cytology, Next-generation sequencing

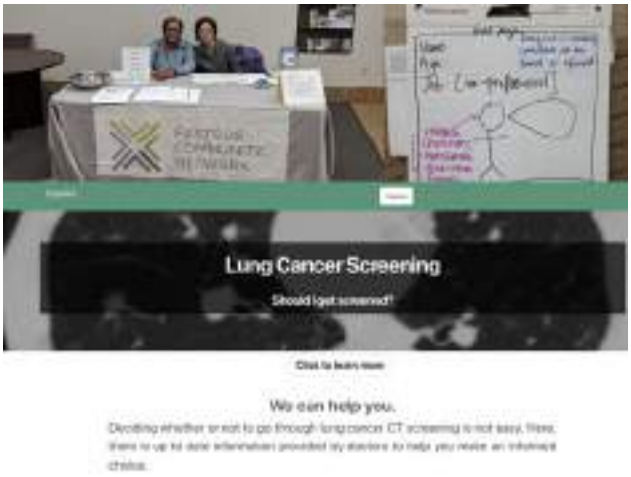
P2.11-35 LUNG CANCER SCREENING KNOWLEDGE, PERCEPTIONS AND DECISION-MAKING AMONG AFRICAN AMERICANS

Y.K. Lau[1], H. Bhattarai[1], P.-Y. Hung[1], E. Jimenez-Mendoza[1], T. Caverly[2], M. Cote[3], D. Arenberg[2], R. Meza[1]

[1]*University of Michigan, Ann Arbor/United States of America,* [2]*University of Michigan Medical School, Ann Arbor/United States of America,* [3]*Wayne State University, Karmanos Cancer Institute, Detroit/United States of America*

Background: Significant lung cancer disparities exist in the USA, where African American men have the highest incidence rate. However, most available web-based lung cancer screening decision aids have been designed without substantive feedback from African Americans, and few have been validated in this population. Therefore, we sought to evaluate and redesign an existing decision aid with input from African Americans in Detroit. **Method:** Using insights obtained from participatory design workshops in this population, we implemented content changes to shouldiscreen.

com and evaluated this modified version with a before-after study. Surveys took place between April and July 2018. Data were collected from 78 participants who were current/former smokers, had no history of lung cancer, and aged between 45 and 77. Participants were contacted six months after to assess if they took steps to receive lung cancer screening.



Result: Knowledge about risk factors and screening between before and after viewing the decision aid was 6.4 and 8 out of 15 points, respectively (25% increase). Notably, half of the participants felt uncomfortable answering surveys electronically and requested paper versions. There was a 31% improvement in knowledge score among those who took the electronic survey (6.7 to 8.8), and 18% for paper (6.1 to 7.2). Acceptability was high: 93% of all participants said the tool helped them consider screening. Concordance between individual preference and eligibility for screening increased from 22% to 34% (n = 74). The primary source of discordance was from those who should not be screened but prefer to be screened, although the largest improvement came from those who were unsure. There was significant loss to follow-up at six months: only 14 out of 78 participants were successfully contacted. Of these, three were eligible for screening according to USPSTF criteria. Five followed up with their physicians, and the three who were eligible were strongly encouraged to be screened. Two went through with lung cancer screening and one had quit smoking. **Conclusion:** Use of the tool led to improvements in lung cancer screening knowledge and concordance with current recommendations. Additional design modifications and modes of information delivery of current decision aids should be considered to increase their efficacy in helping populations with lower educational attainment and computer literacy. Partnering with community organizations and community leaders to demonstrate the use of the tool and explain the benefits of screening is paramount to help encourage those who might benefit most from it.

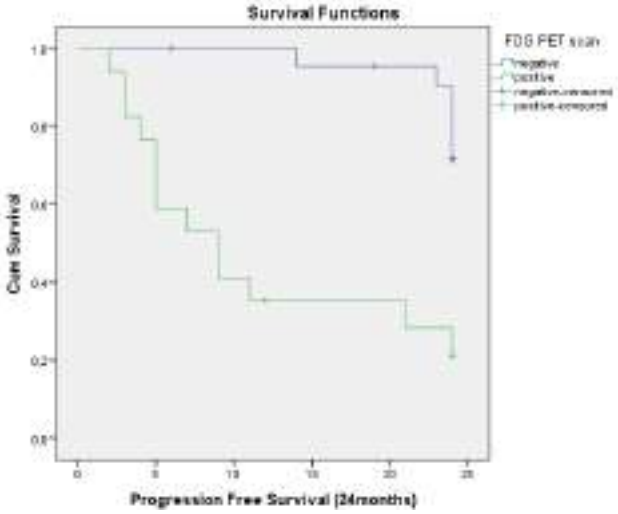
P2.11-36 THE ROLE OF FDG-PET SCANS IN PRE-INVASIVE ENDOBRONCHIAL LESIONS

I. Smesseim[1], E. Comans[2], J. Daniels[1]

[1]*Department of Pulmonary Diseases, Amsterdam University Medical Center, Amsterdam/Netherlands,* [2]*Department of Radiology and Nuclear Medicine, Amsterdam University Medical Center, Amsterdam/Netherlands*

Background: Pre-invasive endobronchial squamous lesions, especially high-grade lesions, may serve as risk markers for developing lung cancer. However, it remains difficult to determine whether individual lesions will progress to lung cancer. 18 fluorodeoxyglucose (18F-FDG)-positron emission tomography (PET) is currently used as a golden standard for staging patients with lung cancer and to monitor treatment response. The role of FDG-PET-scans in patients with pre-invasive lesions has not yet been established. In our study we report the outcome of surveillance of 40 subjects with pre-invasive endobronchial lesions and investigate the use of 18F-FDG-PET-scans as part of a surveillance program. **Method:** We retrospectively selected patients with pre-invasive endobronchial lesions who underwent pre-treatment FDG-PET scans at the VU Medical Center Amsterdam between 1995 and 2016. Patients with signs of invasive carcinoma at baseline, as confirmed by histology, were excluded. Autofluorescence bronchoscopy (AFB) was used for tissue sampling. The minimum follow up period was three months and the group underwent close surveillance with repeated AFB. Outcomes included progression-free survival (PFS) and overall survival (OS). **Result:** Among 40 included patients, 17 patients had a positive FDG-PET-scan at baseline of which 13 (76,5%) patients developed lung cancer during follow up. Twenty-three patients had a negative FDG-PET of which 6 (26,1%) developed lung cancer during follow-up. The FDG-PET-positive group had a median progression free survival of 5,0 months and the FDG-PET-negative group 33,0 months (p<0,0001, Figure 2). There was no significant difference in overall survival between both groups.



Conclusion: Our present work demonstrates that subjects with pre-invasive endobronchial lesions and a positive FDG-PET scan are at high risk to develop lung cancer. We reported a significantly longer progression free survival in patients with pre-invasive lesions with a negative FDG-PET scan. This suggests that FDG-PET scan can be used to select patients that require more radical cancer treatment.

P2.11-37 LOW-DOSE CT LUNG SCREENING: ANALYSIS OF RISK FACTORS RELATED TO LUNG CANCER

Y. Jin, N. Wu

Peking Union Medical College/Chinese Academy of Medical Sciences, Cancer Hospital, Beijing/China

Background: LDCT has been increasingly accepted as an efficient screening method for lung cancer detection and mortality reduction in high-risk populations. Screening data based lung cacer risk factors analysis is supposed to benefit identifying high-risk population of lung cancer.The aims of this study are to provide data support for identifying high-risk groups of lung cancer and to improve the effectiveness of LDCT lung cancer screening. **Method:** Subjects consisted of 5366 asymptomatic and voluntary participants (includes 2762 males and 2604 females) aged 40-87 years old, who received LDCT in Cancer Hospital, Chinese Academy of Medical Sciences between Jan 1st, 2014 and Dec 31st, 2017. Participants finished questionnaires relevant to risk factors and were provided Low-dose CT scans. The LDCT Radiological results were interpreted according to the I-ELCAP lung Screening Protocol. Multivariate logistic regression examined associations of risk factors within Age, Sex, Smoking status, Second-hand smoking status, COPD, Asthma, Family history of lung cancer, History of tuberculosis, Occupational exposure and Diabetes. **Result:** 389 of the 5366 participants had a positive(including lung cancer) screen with LDCT, 26 participants were pathologically confirmed lung cancer. Multivariate logistic regression showed that age and smoking (previous smoking and current smoking) were risk factors related to lung cancer and positive nodules. There was no risk factor in distinguishing between lung cancer and positive nodules(excluded lung cancer). Stratified by age, Multivariate logistic regression did not identify any risk factor related to lung cancer and positive nodules in 40-49 years old group, while 3 risk factors were identified in ≥50 years old group (age, smoking, and history of tuberculosis).

Conclusion: • Age, smoking are risk factors related to lung cancer and positive nodules. • ≥50 years old with a history of smoking or tuberculosis may be a high risk group for lung cancer in China.

Keywords: Lung cancer, Risk Factors, LDCT screening

POSTERS

P2.11-38 CREATING A SUCCESSFUL MULTIDISCIPLINARY CONFERENCE FOR REVIEW OF SUSPICIOUS LUNG NODULES

D. Dyer, P. Zelarney, J. Finigan, L. Carr, E. Kern

National Jewish Health, Denver/United States of America

Background: National Jewish Health established a weekly Multidisciplinary Conference for review of suspicious lung nodules in December 2016. The conference provides a forum to guide prompt work-up and provide management recommendations to providers. Experience with the conference and lessons learned are described. **Method:** A Lung Nodule Registry with a tracking system for the management of incidental lung nodules was implemented in 2011. Nodule follow-up recommendations are based on Fleischner Society guidelines, with an additional category, Track Dx, created within the tracking system for radiologists to flag reports with highly suspicious lung nodules. A local Lung Cancer Screening Registry was created in 2015 based on LungRADS. Radiologists provide a Tracker phrase or a LungRADS classification at the bottom of their reports. The Lung Nodule Registry and the Lung Cancer Screening Registry are data-mined weekly to create a report of patients who have received a Screen 4A, 4B, 4X or Track Dx recommendation in their imaging reports. These entries populate a list of cases for the upcoming Nodule Conference and ordering providers for the patients are invited to attend. Ideally the ordering provider attends the conference to review the patient history and engage in the discussion of recommended next steps. The radiologist prepares cases for review. The conference occurs immediately following Thoracic Tumor Board and is attended by thoracic radiology, pulmonology, thoracic surgery, oncology and interventional pulmonary. After the conference the lung nodule navigator and radiologist send an email summarizing the recommendations to the ordering provider. Cases are entered into a REDCap database for long term follow-up to ascertain outcomes. **Result:** From December 2016 – March 2019, 681 suspicious nodule cases were identified and reviewed at Nodule Conference. Of these, 155 were screening CTs classified as 4A, 4B or 4X. 371 were Track Dx cases. 133 additional cases were reviewed at the request of the ordering providers. Successful components and lessons learned from the conference are: Timely review of cases on a weekly basis is important to promote prompt work-up and evaluation. It is beneficial to schedule the Nodule Conference immediately after the regular Thoracic Tumor Board since the key people are already gathered. While LungRADS 3 cases are considered "positive," there is usually little debate about the recommendation for a 6 month follow-up CT. We initially included the LungRADS 3 cases in our Nodule Conference but soon discovered this was unnecessary and subsequently included only the LungRADS 4 cases. The radiologist covering the conference adds an addendum to the original radiology report outlining the recommendations from Nodule Conference so this is documented in the EHR. The radiologists add the LungRADS 4 and Track Dx notations to the radiology reports for PET-CT and outside exam interpretations so these can be data-mined and tracked. **Conclusion:** The conference has been well received by the ordering providers. The conference has resulted in a cultural change in our clinical staff with increased provider awareness of the need for timely nodule management and multiple requests for assistance with nodule cases.

Keyword: nodule management, suspicious nodules, multidisciplinary committee review

P2.11-39 MULTIMODAL MONITORING OF PATIENT-DERIVED EARLY-STAGE LUNG ADENOCARCINOMA WITH THE CHICKEN CHORIOALLANTOIC MEMBRANE SYSTEM

E. Koziolek[1], B. Villegas[2], G. Abdelhady[3], J. Liu[2], J. Barrio[2], W. Wallace[4], J. Yanagawa[2], D. Shackelford[2], S. Dubinett[2], C. Scafoglio[2]

[1]*University of California Los Angeles, Santa Monica/United States of America,* [2]*University of California Los Angeles, Los Angeles/United States of America,* [3]*University of California Los Angeles, Los Angeles/United States Minor Outlying Islands,* [4]*UCLA - David Geffen School of Medicine, Los Angeles/United States of America*

Background: Positron-emission-tomography (PET), imaging uptake of [18F] fluorodeoxyglucose (FDG), is a powerful tool for lung cancer staging, but lacks sensitivity in early lesions. We have recently discovered that early-stage lung adenocarcinoma (LUAD) depends on another system for glucose uptake, the sodium- glucose transporter 2 (SGLT2), not detected by FDG PET. The tracer methyl 4-[18F] fluorodeoxyglucose (Me4FDG) is specific for SGLTs. Because the establishment of patient-derived xenografts (PDXs) from early-stageLUAD is characterized by low efficiency and long experimental times, we have developed an alternative model to study tumor metabolism in LUAD, based on the implantation of tumor tissue on the chorioallantoic membrane (CAM) of chicken eggs (in ovo system). **Method:** PDXs of LUAD were established in ovo by implanting tumor fragments or dissociated cells in matrigel onto the CAM of fertilized chicken eggs. Xenografts were grown for up to 10 days. After day 7, the eggs were imaged with FDG and Me4FDG PET to characterize glucose uptake, then rescanned with both tracers after treatment with SGLT2 inhibitor dapagliflozin to prove SGLT2 specificity of Met4FDG. Multiparametric magnetic resonance imaging (MRI) was performed to assess tumor growth, morphology (T1w, T2w, diffusion-weighted imaging) and vasculature (angiography; GadospinP). At day 10, the xenografts were harvested for histology and immunohistochemistry or reimplanted onto a new CAM for continuous passaging. **Result:** FDG- and Me4FDG-PET adenocarcinomas confirmed the presence of both glucose transporters, GLUT1 and SGLT2. MRI angiography revealed that both tumor plaques and tumor fragments were connected to the embryonic vasculature. Following dapagliflozin treatment, Met4FDG uptake was successfully blocked in the PD tumor fragments. **Conclusion:** The CAM xenograft model is useful for studying the heterogeneity of glucose uptake in ovo by imaging the activity of different transporters with FDG and Me4FDG. The novel PET tracer Met4FDG allows to validate SGLT2 expression as well as its blockage by SGLT2 inhibitors gliflozins.

P2.11-40 INTEGRATION OF INDIVIDUALIZED TOBACCO CESSATION COUNSELING IN A LUNG CANCER SCREENING PROGRAM

P. Franklin[1], C. Barone[1], J. Muesse[2], N. Tingquist[2], M. Steliga[2]

[1]*WP Rockefeller Cancer Institute, Little Rock/United States of America,* [2]*University of Arkansas, Little Rock/United States of America*

Background: Many patients in a lung screening program are unable to quit despite the knowledge that smoking is harmful. Continued smoking leads to increased risk of poorer outcomes in all patients. Our lung cancer screening program has a high rate of patients smoking at the time of the Low Dose Computed Tomography (LDCT) (70.2% smoking; 309/440). Screening with LDCT has been considered a teachable moment and a possible time for intervention with smoking cessation resources. Providing counseling at the point of service may be a convenient and effective method to deliver smoking cessation resources to a population in need. **Method:** Individualized counseling was provided for all patients in our lung cancer screening program as a standard part of their care using an opt-out framework. All patients were surveyed for use, and cessation support consisted of individual counseling by a nurse practitioner and tailored to the patient. The counselor met the patient at the time of the LDCT in the radiology department for a structured tobacco cessation intervention which typically lasted 10-15 minutes. Data regarding use was entered in the electronic medical record and an IRB approved database. Exhaled breath carbon monoxide testing was used in some cases to validate cessation or reduction. The intervention consisted of counseling and referral to a quitline, a group counseling session, and/or recommendations for over-the-counter pharmacotherapy. **Result:** A total of 263 patients had undergone LDCT, had been smoking at the time of the LDCT, and have follow up data available. A combination of retrospective chart review, scripted telephone survey, and/or in-person follow up was used to collect data regarding tobacco use. Of those who were smoking and received a LDCT, 12.9% (34/263) of patients had quit smoking while after receiving personalized counseling. Of the 229 patients still smoking, the quantity that they were smoking was available for 156 of these patients. Of those with data available, 50.0% (78/156) who were still smoking had decreased the amount that they were using. **Conclusion:** Patients who undergo screening with LDCT are receptive to individualized in person counseling when provided at the point of service. This model of opt-out cessation counseling was well received and yielded a 12.9% cessation rate, with one session of counseling and referral to an outside resource. Due to the logistics of the intervention in the radiology department, the counselors did not directly provide pharmacotherapy to the patients in this intervention, but made recommendations. Cessation rates

would likely increase when pharmacotherapy and further counseling is used. Even in those who do not quit, half of patients decrease the amount used on a daily basis.

Keywords: smoking cessation, Screening, Tobacco

P2.11-41 IMPROVING ANNUAL ADHERENCE IN A COMMUNITY BASED LUNG CANCER SCREENING PROGRAM

K.A. Braithwaite, J. Schneider

NYU Winthrop Hospital, Mineola/United States of America

Background: Lung cancer is the third most common type of cancer diagnosed in the United States, but it is the leading cause of cancer deaths (U.S. Cancer Statistics Working Group, 2018). Lung cancer is most often diagnosed at late stages which have low survival rates. The National Lung Screening Trial (NLST) was an NCI funded trial which determined that screening with annual low dose CT as compared to chest radiograph would reduce mortality by 20% in high risk populations (Team, 2011). Since the implementation of our screening program in 2012 we witnessed a steady increase in our initial screening LDCT scans. However the rate of overall adherence was surprising low at 40.1% despite programmatic efforts to contact patients for annual LDCT scans. The NLST included an impressive level of adherence of 95% in the LDCT group and 93% in the radiography group (Cattaneo II, Meisenberg, Geronimo, Bhandari, Maxted, & Brady-Copertino, 2018). We designed a quality improvement project seeking to increase our annual adherence rate. **Method:** At the start of 2018 we created a reminder letter directed towards the patients' referring providers. Using the existing tracking system which was put into place to ensure the necessity of follow up scans are communicated to the patients and completed, we generated reminder letters to the referring providers as well as the patients for anyone that had a scan in 2017. **Result:** Based on our added communications with the referring community providers, we increased our overall adherence rate to 58.2%. Looking at smoking status, current smokers increased their adherence by 15.3%, former smokers increased by 16.1%, recent smokers increased by 23.1%. Looking at patients that indicated they had prior lung disease, we increased their adherence by 15.5%. Those who indicated no prior lung disease, we increased their adherence by 17.8%. Patients who identified a family history of lung cancer we increased their adherence by 18.1%. Those who indicated no family history of lung cancer, we increased their adherence by 17.1%. Patients in their 50s, we increased their adherence by 23.3%. Patients in their 60s, we increased their adherence by 17.5% Patients in their 70s we increased their adherence by 7.8%. Males increased their adherence by 20.1% and females by 14.7%. From 2012-2017, we diagnosed 5 lung cancer and 7 non lung cancers. In 2018 we diagnosed 7 lung cancers and 1 non lung cancer. **Conclusion:** We have found communicating with referring community providers as well as patients increase adherence in a community based lung cancer screening program. This led to increased diagnosing of early stage lung cancers in high risk populations.

Background: Lung cancer (LC) is one of the most prevalent and fatal cancer worldwide. The prognosis of LC is closely related to the stage. Low-dose computed tomography (LDCT) is recommended for LC screening in high risk population. More and more lung nodules were detected, but only less than 4% patients were LC. Also, the access to LDCT scan for the high risk population was very low. We conducted a prospective, multicenter study to assess the diagnostic accuracy of combined 6 tumor markers (TMs, CEA, CYFRA21-1, CA15-3, SCC, NSE and ProGRP) for aid in diagnosis in lung nodule patients. **Method:** Patients, ≥18years old, who were newly diagnosed with lung nodules, 830 mm, by CT scan were prospectively recruited. Blood samples were obtained by peripheral venipuncture in all patients before the final diagnosis had been established. The patients were divided into two groups according to the pathology result or clinical diagnosis: LC group and benign lung nodule group. The 6 serum TMs were tested for all patients. When these six TMs were assessed in combination, the presence of ≥1 abnormal TM values were considered as abnormal. Sensitivity (SN), specificity (SP), positive predictive value (PPV) and negative predictive value (NPV) were calculated and the area under the receiver operating characteristic curve (AUC) was analyzed. **Result:** A total 492 predominant lung nodules patients were included in the study analysis, with median age of 59 (IQR: 53-66) years old. 59.6% of the patients were female and 67.5% were non-smokers. Median lung nodule size was 15.75 mm (IQR: 11.75-21.00). 374 (76.02%) patients were diagnosed with LC, of which 94% patients were at I-II stage. SN, SP, PPV, and NPV of the combined 6 markers for LC diagnosis were 39.57% (95%CI, 34.62%, 44.53%), 75.42% (95%CI, 67.66%, 83.19%), 83.62% (95%CI: 78.16%, 89.07%) and 28.25% (95%CI, 23.28%, 33.23%), respectively. AUC showed the combined 6 markers had better diagnostic performance than each individual marker. **Conclusion:** Combined 6 TMs increased the diagnostic performance for LC, comparing to the use of individual marker. Given its higher specificity, the presence of ≥1 abnormal TM values could support LC diagnosis in patients with predominant lung nodule detected by CT scan.
