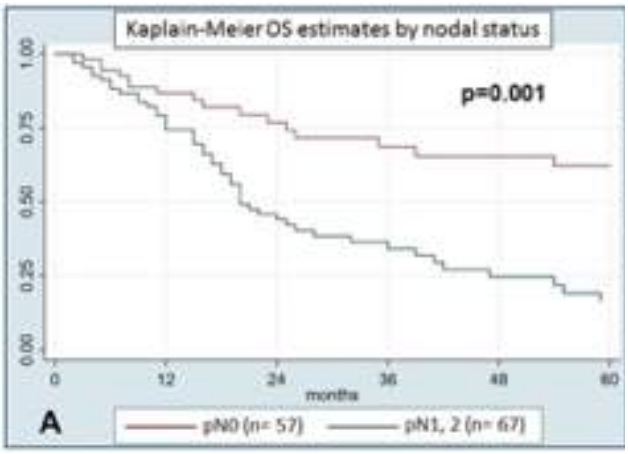
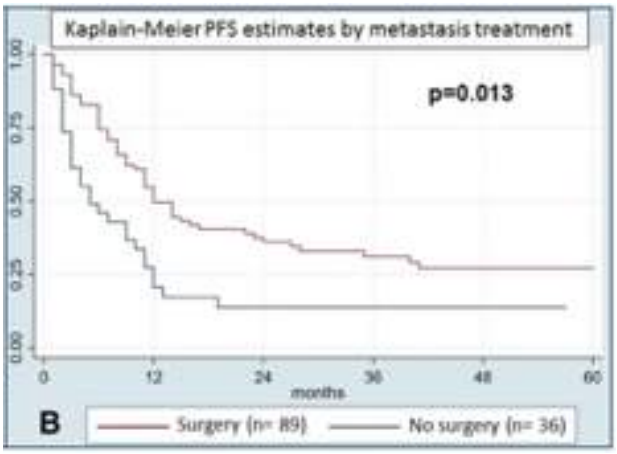
Background: Patients with oligometastatic non-small cell lung cancer (NSCLC) may benefit from radical therapy. We aimed to identify factors related to better prognosis, in a multicenter analysis of patients who underwent surgery of primary tumours, in combination with radical treatment of metastatic sites, and chemo- or chemoradiation. **Method:** We retrospectively reviewed the records of oligometastatic patients who all underwent anatomical resection of primary tumor, treated at 4 centers, (August 2001-November 2018). Oligometastasis was defined as ≤5 synchronous metastases in ≤2 organs. Radical metastatic treatment was surgery (n=48), radiotherapy (n=36) or a combination (n=41). Univariate analysis and multivariate Cox proportional hazards model were used for identification of prognostic factors on overall survival (OS) and progression-free survival (PFS). Survival was estimated by Kaplan-Meier analysis. P-value < 0.05 was considered significant. **Result:** We treated 125 patients; 72 (58%) were male, aged 60±9.8 years, with 88 (70%) adenocarcinoma, and following pathological (pN) stage: pNx: 1 (1%), pN0: 57 (46%), pN1: 23 (18%), pN2: 44 (35%). Brain metastasis was most common (n=76; 61%) followed by adrenal (n=13; 11%) and bone (n=12; 10%). Systemic therapy was administered in 102 (82%). Median follow-up was 60 months (95%, CI: 41-86). One-, 2-, 3-, and 5-years OS was 80%, 58%, 49% and 36% respectively. Several patient-related and treatment-related factors showed a correlation with OS at univariate analysis. Multivariate analysis showed that patients ≤60 years (HR 0.47, 95% CI:0.28-0.78, p=0.004), and/or pN0, compared to pN1,2 (HR 0.38, 95% CI: 0.22-0.66, p=0.001), had a significant survival benefit (Figure 1A). Bone metastasis were associated with worse prognosis (HR 2.122, 95% CI: 1.00-4.48, p=0.05). Twenty-eight patients were ≤60 years with pN0, and had 1- and 5-year survival of 100 and 83%. PFS at 1-, 2-, 3- and 5-years was 41%, 29%, 25% and 23% respectively. In the multivariate analysis, absence of mediastinal lymphnode involvement (HR: 0.483, 95% CI: 0.305-0.764, p=0.002) and surgical treatment of metastasis (HR: 0.553, 95% CI: 0.347-0.880, p=0.013) remained independently associated with better outcome (Figure 1B). The administration of treatments after first progression was strongly associated with better prognosis (HR: 0.252, 95% CI: 0.076-0.834, p=0.013).





Conclusion: Our experience demonstrates, in a multicenter setting, that radical treatment of selected oligometastatic NSCLC results in excellent 5-year survival. Nodal status correlates with both OS and PFS. Surgical metastasectomy appears to improve PFS, but multimodality treatment, especially in case of recurrence, remains mandatory. These data might contribute to develop future combined strategies in the era of immunotherapy.

Keywords: synchronous oligometastasis, surgical therapy, multimodality treatment

MA01.07 PROGNOSTIC FACTORS OF SURGICAL TREATMENT IN NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS IN OLIGOMETASTATIC STAGE-M1B OF DISEASE

D. Dziedzic, G. Wojciech, R. Piotr, R. Langfort, T. Orlowski

National Institute of Chest Diseases, Warsaw, Poland, Warsaw/Poland

Background: Non-small cell lung cancer in stage IV is rarely the subject of surgical treatment. Most cases are considered as inoperable and qualified for palliative treatment. Long-term results in this group of patients are poor despite systemic oncological treatment. A special group of patients are patients with a single metastasis beyond the lung (grade M1b), in which in some cases surgery may significantly improve the prognosis. The aim of the study was to determine the prognostic factors of surgical treatment of non-small cell lung cancer in stage IVA with a single distant metastasis (oligometastatic stage-M1b) **Method:** A retrospective study was based on data from the National Register of Cancer of the Lung conducted by the Polish Group of Lung Cancer. The study included 387 patients (242 men and 145 women) between 41 and 87 years of age (median 60.4 +/- 8.4 years) with established NSCLC and single synchronous metastasis most often to: second lung (55.5%), brain (24.8%) and adrenal glands (14.5%). All patients underwent resection of the pulmonary parenchyma and resection of the metastatic focus. The size of the primary tumor was respectively: 1-2 cm in 16.0%, 2-3 cm in 26.4%, 3-5 cm in 23.5%, 5-7 cm in 12.4% 7-10 cm in 14, 0% and over 10cm in 7.8%. The features of N0, N1, and N2 were diagnosed in 69.8%, 15.5% and 14.7% of patients respectively. Radical oncology R0, R1 and R2 were obtained in 96.1%, 2.1% and 1.8% of cases respectively. Anatomical resection was performed in 70% and minor resection in 30% of patients. Preoperative chemotherapy was used in 7.5% of cases, and postoperative in 21.2% of patients. **Result:** The 5-year survival in the entire M1b group was 27.3%. Multivariate analysis showed that the negative prognostic factors were male gender (HR = 1.56, 95% CI-1.16-2.1, P <0.003), age> 50 (HR = 1.39, 95% CI-0.87-2.22, P <0.002), tumor size (HR = 34.32, 95% CI-2.39-7.82, P <0.001), feature N1 (HR = 1.53, 95% CI-1.02-2.29, P <0.04) and the N2 trait (HR = 2.71; 95% CI -1.8-4.06, P <0.001). Patients undergoing anatomical resection vs lower (HR = 0.5, 95% CI-0.35-0.72, P <0.001) and postoperative preoperative chemotherapy (HR = 0.69, 95% CI-0.48-0.97, P <0.034) have better prognosis. The number of lymph nodes removed during the procedure is also significantly affected - 5-year survival at 1-5 removed nodes was 24.6%, and in the case of 6-10 nodes 32.4%. **Conclusion:** Surgical treatment of NSCLC in the M1b stage in a selected group of patients allows for the improvement of long-term results. Negative prognostic factors are gender, age, tumor size and metastases to lymph nodes. The scope of resection in this group of patients should be the same as in the lower stages with the predominance of anatomical resection and mediastinal lymphadenectomy. Post-operative chemotherapy may have a beneficial effect on long-term results.

Background: NSCLC patients harboring EGFR mutation generally develop resistance to EGFR TKI less than one year. Prior studies indicated that local consolidative therapy is associated with improved outcomes in patient with limited metastatic NSCLC. Radiotherapy is one of the ideal control methods for locally progressed patients, however, the optimal intervention time in order to slow the occurrence of EGFR-TKI resistance for advanced NSCLC patients with EGFR-sensitive mutations is still unclear. Our preliminary clinical and animal studies suggest that early combined radiotherapy prior to EGFR-TKI resistance can significantly improve the prognosis of patients. Our hypothesis is that the optimal intervention time of radiotherapy for EGFR mutation patients is 3 months after the beginning of EGFR-TKI. **Method:** This is a prospective, multicenter, randomized controlled study to evaluate stereotactic body radiation therapy (SBRT) as a potential treatment for limited stage IV NSCLC (primary plus up to 3 metastatic sites) with sensitive EGFR mutation. The patients did achieve partial response or stable disease after three months treatment of the first-generation EGFR-TKI would be randomized to TKI combined SBRT (TS) or TKI alone. The primary endpoint was PFS (the time from the beginning of EGFR-TKI treatment to disease progression or death). The secondary endpoint was overall survival (OS) and safety. TKI wasn't interrupted during the irradiation. **Result:** A total of 61 patients were enrolled from Feb, 2017 to Jan, 2019. Median follow up was 22.3 months. Patients who TS (n: 30) had a significantly longer median PFS compared to those with TKI alone (n: 31) (PFS: 17.4 vs. 8.9 months P =0.042). T790M mutation was observed in 57.9% acquired resistance patients for TS group, and 39.3% for TKI alone group. Median PFS of T790M mutated patients was 17.4 months compared to 10.3 months of TKI alone group (P = 0.007). Multivariable analysis revealed that radiation fields were positively associated with PFS, 21.8 months for just primary tumor; 10.6 months for metastatic lesions and 18.3 months for primary and metastatic lesions (P= 0.006). OS data was not yet mature. None experienced >= grade 3 SBRT related toxicities. **Conclusion:** A trend of improved long term PFS was noted in patients receiving SBRT for primary tumor combined EGFR TKI at the third month after the beginning of TKI. Moreover, this data suggested that benefit from radiation might be associated with delay the occurrence of T790M mutation. Further studies are required to investigate the molecular mechanisms underlying this association. Clinical Trial information: NCT03595644

Background: Whether epidermal growth factor receptor tyrosine-kinase inhibitors (EGFR-TKIs) plus local consolidative therapy (LCT) has better survival benefit than EGFR-TKIs alone remains controversial in lung adenocarcinoma patients with EGFR mutation and bone oligometastases. **Method:** We conducted a retrospective study to assess the effects of LCT on bone oligometastases lung adenocarcinoma patients with EGFR mutation. The primary endpoint was overall survival (OS); The secondary endpoints was progression-free survival (PFS). **Result:** A total of 127 lung adenocarcinoma patients with EGFR mutation and bone oligometastases were identified. There were 65 patients received EGFR-TKIs alone (monotherapy group) and 62 patients received EGFR-TKIs plus local consolidative therapy (LCT) (combination group). Addition of LCT was associated with a significantly longer OS (36.3 *vs.* 21.0 months, P=0.01, hazard ratio [HR]=0.537, 95% confidence interval [CI]:0.360-0.801, p=0.01) and PFS (14.0 *vs.* 8.1 months, P=0.01, HR=0.613, 95%CI: 0.427-0.879, p=0.01) in the whole cohort (Figure 1). All subgroups showed OS benefit in faver of combination therapy except for PS scores greater than or equal to 2 group, and all subgroups analyzed derived PFS benefit in favor of combination therapy (Figure 2). **Conclusion:** In patients with EGFR-mutant lung adenocacinoma and bone oligometastases, LCT plus EGFR-TKIs therapy was associated with significantly longer OS and PFS than EGFR-TKIs therapy alone, indicating that LCT plus EGFR-TKIs therapy might be a better therapeutic option for those patient population.

MA01.11 IMPROVING SURVIVAL IN LUNG CANCER PATIENTS WITH OLIGOMETASTATIC DISEASE PROGRESSION USING STEREOTACTIC BODY RADIATION THERAPY

L. Raez[1], M. Castillo[2], A. Botero[1], A. Falchook[3], I. Castellon[3], B. Hunis[1]

[1]*Memorial Cancer Insitute/Florida International University, Pembroke Pines/United States of America,* [2]*Florida Atlantic University, Pembroke Pines/United States of America,* [3]*Memorial Cancer Institute, Pembroke Pines/United States of America*

Background: In patients (pts) with stage IV non-small cell lung cancer (NSCLC) receiving systemic therapy, stereotactic body radiation therapy (SBRT) can eliminate oligometastatic disease progression (OMP). This allows NSCLC pts to continue the same systemic therapy, and its is especially important when the therapy is well tolerated as is the case for many pts receiving immunotherapy (IMMUNO) and targeted therapy (TARGET). The purpose of this study is to quantify the progression free survival (PFS) and overall survival (OS) of pts receiving systemic therapy who experience OMP that is treated with SBRT, and subsequently continue the same systemic therapy. **Method:** Retrospective review of one hundred pts with metastatic NSCLC undergoing chemotherapy (CHEMO), IMMUNO or TARGET that had OMP defined as less than 4 sites of metastasis and underwent SBRT were evaluated for PFS and OS. PFS1: Time between initiation of systemic therapy and development of OMP. PFS2: Time between OMP treated with SBRT and development of further PD requiring a change in systemic therapy. Pts received IMMUNO for second line and beyond. SBRT doses were determined based on the disease site and dose tolerance of the adjacent organs. SBRT was delivered in 1-5 fractions on consecutive days or every other day. Radiation dose was determined by target volume and adjacent dose-limiting organs. **Result:** OMP presented as brain metastasis (BM) in 45 pts and extracranial metastasis (EM) in 55 pts. 34 pts were receiving CHEMO, 34 TARGET and 32 IMMUNO at the time of OMP. Pts with BM that received SBRT were able to continue the same therapy for a period of 6.5-9 extra months due to the control of BM. Pts with EM that have developed PD were able to continue the same therapy an 17-21 extra months due to the ablation of OMP by SBRT. For the entire cohort PFS was: 16.5m for BM and 34m for EM and the OS were: 31m and 53m respectively.

Location of oligo-metastatic progression (OMP)	Median PFS1	Median PFS2	PFS	Median OS
Extracranial (N=55)	13	21	34	53
chemo	7	17	24	47
Immuno	13.5	20.5	34	49
Target	12	21	33	53
Brain (N=45)	9	7.5	16.5	31
Chemo	5.5	6.5	12	25.5
Immuno	7	8	15	27
Target	11	9	20	47

Conclusion: PFS and OS may be prolonged due to the use of SBRT in pts that develop OMP. This intervention allowed patients to continue with the same systemic treatment. Our CHEMO cohort is composed of long term survivors under therapy and may not represent the average PFS/OS of pts on CHEMO. Prospective trials are needed to verify these results.

Background:•Postop platinum-based CT improves outcomes in completely resected NSCLC with nodal involvement, (St II-IIIA). Customization is feasible in adjuvant setting (tissue availability). Analysis of expressionin genes involved in DNA repair could be use to select CT regiment. •BRCA1 plays an important role in DNA repair pathways and functions as a differential regulator of response to cisplatin and antimicrotubuleagents. SCAT trial results found that for low BRCA1 levels subgroup Cis-Gemcitabine was superior to Cis-Docetaxel and in high BRCA1 levels subgroup Docetaxel single agent without platinum achieved similar survival to Cis-Doc. Analysis of recurrence pattern in different subgroups of the trials has been performed **Method:** From Jun/2007 to May/2013 591 patients were screened and 500 p were included (108 in Control arm treated with Cisplatin-Docetaxel and 392 in Experimental arm treated with Cisplatin-Gemcitabine, Cisplatin-Docetaxel or Docetaxel alone according terciles BRCA1 expression level). With a cut-off September 30th 2018 and a median follow-up of 60 months, recurrence pattern are analysed in each arm and subgroup treatment and comparison are made for incidence of risk of recurrence, single/multiple recurrence, thoracic/extrathoracic and site of metastases (liver, bone, brain) **Result:** Cumulative recurrence 232/456 evaluable patients (p) (50.8%). Recurrence were seen in 182/354 patients treated in experimental arm and in 50/102 p treated in the control arm (RR 1.04; 0.83-1.30) (p=0.672). Majority of recurrences 159/232 (68.5%) were single site recurrence. Intrathoracic recurrences in 121/232 (52%) while extrathoracic metastatic disease 111/232 (47.8%). No significant differences were seen for single/multiple, intra/extrathoracic recurrences between experimental and control arm. More frequent distant metastatic sites were: bone (42 p), brain (38 p) and liver (11 p) In the experimental group between different treatments no significant differences were found for the overall metastatic rate or for the single/multiple, intrathoracic/extrathoracic recurrences. For specific metastatic sites related to experimental treatment a significant reduction of risk of brain metastases were found in the experimental group with high level BRCA1 treated with Docetaxel single agent (p=0.0016) **Conclusion:** For NSCLC resected patients with lymph node involvement (Stages II-IIIA) risk of recurrence remains high with cumulative rate > 50%. There were no differences in the Relative Risk (1.04) of recurrence when control and experimental arm are compared. Majority of recurrences were single site (68.5%) and intrathoracic (52%) but distant metastases developed in 47.8% os p. More frequent metastatic site was bone, followed by brain and liver. Brain metastases risk were significant lower for patients with low BRCA1 expression treated with single agent Docetaxel

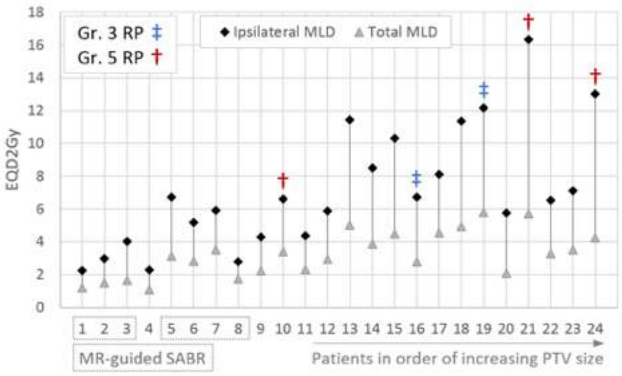
MA02.02 TOXICITY OF LUNG SABR IN PATIENTS WITH COEXISTING INTERSTITIAL LUNG DISEASE

T. Finazzi[1], M. Ronden[2], E. Nossent[2], H. Tekatli[2], I. Bahce[2], B. Slotman[2], F. Spoelstra[1], S. Senan[1]

[1]*Amsterdam University Medical Centers, Location VUmc, Amsterdam/Netherlands,* [2]*Amsterdam University Medical Centers, location VUmc, Amsterdam/Netherlands*

Background: Patients with lung tumors and coexisting interstitial lung disease (ILD) are at increased risk of toxicity following stereotactic ablative radiotherapy (SABR). We report on our institutional experience with SABR in such patients. **Method:** Institutional patients undergoing lung SABR with coexisting ILD were identified. ILD subtypes were determined by a pulmonologist specializing in ILD. From late 2015, patients were routinely counseled about the increased treatment risks. Magnetic resonance (MR-) guided SABR was used to reduce target volumes from 2016. Overall and progression-free survival (OS, PFS) were estimated using the Kaplan-Meier method, and dosimetric predictors of radiation pneumonitis (RP) were analyzed based on total lung minus planning target volumes (PTV). **Result:** Twenty-four SABR patients treated for lung cancer (n=22) or metastasis (n=2) between 2007-2018 were identified. Median patient age was 74 years, and the commonest ILD diagnosis was idiopathic pulmonary fibrosis. The commonest fractionation schemes were 60 Gy in 8 fractions (n=11), or 55 Gy in 5 fractions (n=6), and SABR was delivered on a Linac (n=17) to a motion-encompassing internal target volume, or with MR-guided SABR (n=7). At median follow-up of 36.9 months (95% CI, 15.8 to not reached), median OS and PFS were 16.6 and 13.3 months, respectively, and 12-month local control was 88.9%. Five patients (20.8%) developed grade ≥3 RP, of which 3 (12.5%) were fatal. Patients with grade ≥3 RP had a higher total lung V20Gy, and a higher ipsilateral and total mean lung dose (MLDEQD2; Fig. 1) than those without (p <.05).



Conclusion: Our findings confirm that ILD patients have a poor prognosis and are at high risk for developing severe RP following SABR. Treatment should be preceded by patient counseling by an experienced ILD team. Careful attention must be given to limiting lung doses, and MR-guided SABR is our preferred approach in such patients.

Background: Patients with interstitial lung disease(ILD) have higher incidence of lung cancer. Treatment for this group is challenging, and long term outcome is poor. We investigated the outcome of patients with lung cancer and ILD after surgical resection, along with risk factor of survival and acute exacerbation.Patients with interstitial lung disease(ILD) have higher incidence of lung cancer. Treatment for this group is challenging, and long term outcome is poor. We investigated the outcome of patients with lung cancer and ILD after surgical resection, along with risk factor of survival and acute exacerbation. **Method:** Between Januery 2002 and August 2016, total 3413 patients underwent pulmonary resection for lung cancer, among them 74 patients had combined ILD. The demographics, operative and survival data were reviewed. **Result:** Mean age was 68±7 years-old for 74 ILD patients. 51 (68.9%) patients received video-assisted thoracic surgery (VATS). Lobectomy and sublobar resection were performed to 58 (78.4%) and 15 (20.3%) patients, respectively. 30 (41.5%) patients experienced respiratory complication during early postoperative period. 30-, 90- days mortality and 5-year survival rate were significantly worse than patients without ILD in the same study period (8.1%, 21%, and 21.2% vs. 1.3%, 3.1%, and 73.8%, respectively, p<0.001). Patients with ILD who experienced respiratory complication showed significantly worse 5-year survival than those who has not (18.2% vs. 44.9%, p<0.001). The leading cause of death was cancer related (47.8%), followed by postoperative complications (23.9%). Among 23 patients who received adjuvant therapy, 10 patients died during or shortly after adjuvant therapy. Open thoracotomy (HR 4.02, p=0.017) was risk factor for respiratory complication. Sublobar resection showed similar survival rate in each stage (stage I, p=0.825 and stage II-III, p=0.633) and lower rate of respiratory complication than lobectomy, although statistically not significant (26.7% vs. 43.1%, p=0.246). **Conclusion:** Interstitial lung disease increased the risk of pulmonary resection for lung cancer. Thoracotomy was associated with higher rate of respiratory complication. Sublobar resection showed similar survival with lower respiratory complication rate compared to lobectomy. Adjuvant therapy should be considered after careful weighing of risk and benefit.

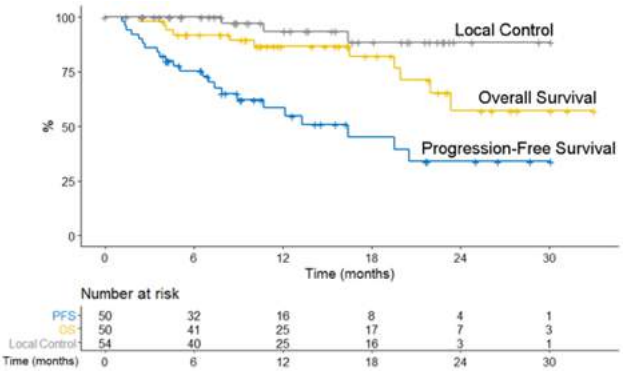
MA02.05 PATIENT SELECTION AND EARLY CLINICAL OUTCOMES OF MR-GUIDED SABR IN 54 LUNG TUMORS

T. Finazzi, C. Haasbeek, F. Spoelstra, M. Palacios, M. Admiraal, A. Bruynzeel, B. Slotman, F. Lagerwaard, S. Senan

Amsterdam University Medical Centers, Location VUmc, Amsterdam/ Netherlands

Background: Magnetic resonance (MR-)guided stereotactic ablative radiotherapy (SABR) with daily replanning was performed for patients in whom treatment delivery was challenging due to tumor location, motion or pulmonary comorbidity. We describe patient characteristics and early clinical outcomes using this novel approach. **Method:** 50 consecutive patients (54 lung tumors) underwent MR-guided SABR at a single center between 2016-2018 for either primary lung cancer (n = 29 tumors) or lung metastases (n = 25). Patients had one or more factors predisposing to toxicity, including a central tumor location (n = 27 patients), previous thoracic radiotherapy (n = 17), and interstitial lung disease (n = 7). A daily 17-second breath-hold MR scan was acquired in treatment position, followed by on-table plan adaptation. Gated delivery was performed using repeated breath-holds under continuous MR-guidance. Local control, overall (OS) and progression-free survival (PFS) were estimated using the Kaplan-Meier method, with PFS defined as time to disease progression or death from any cause. **Result:** Breath-hold SABR delivery was well tolerated, with all but one patient completing the planned schedule. With daily replanning, a biologically equivalent dose (BED10Gy) ≥100Gy to 95% of the planning target volume was delivered in 51 tumors (94%). Median follow-up was 15.8 months (95% CI, [11.4-22.5]). Local control, OS and PFS at 12 months were 93.4%, 86.7% and 58.4%, respectively (Fig. 1). In-field recurrences developed in 2 patients who were re-irradiated for a local recurrence after previous SABR, and one marginal recurrence was observed. Overall rates of any grade ≥2 and ≥3 toxicity were 24% and 4%, respectively. No grade ≥4 toxicity was seen. Commonest toxicities were grade ≥2 radiation pneumonitis (8%) and chest wall pain (8%; including one rib fracture).



Conclusion: Early follow-up of the largest patient cohort to date undergoing thoracic MR-guided SABR indicates low toxicity rates, and promising local tumor control.

MA02.06 DOSE-VOLUME FACTORS PREDICTING AIRWAY STENOSIS AFTER SBRT FOR ULTRA-CENTRAL LUNG TUMORS

A. Jackson, C. Wang, E. Yorke, D. Geldblum, A. Apte, J. Yang, A. Rimner, A. Wu

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: The safety of SBRT is uncertain for ultra-central tumors (near the proximal airways or esophagus). One potential toxic effect of ultra-central SBRT is stenosis of the proximal airways, which can lead to airway obstruction and lung collapse. Predictors of such toxicity in this population are urgently needed. We therefore studied dose-volume correlates of airway stenosis after ultra-central SBRT. **Method:** 88 patients with tumors abutting the proximal bronchial tree (PBT) or PTVs overlapping esophagus (n = 76 and 23; 11 met both criteria) were included. 53 (60%) had primary/ locally recurrent lung cancer, and 35 had lung metastases. All had 5, 8 or 15 fractions of image-guided radiotherapy with BED ≥84Gy (α/β=10). The lobar bronchi (LB) were contoured from the takeoff from the main bronchus to the bifurcation into segmental bronchi. The primary endpoint was grade 2 or higher lobar bronchial stenosis (LBS), defined as radiographic evidence of narrowing or complete obstruction of at least one lobar bronchus (CTCAE v4). Dose-volume histograms (DVHs) using linear-quadratic equivalent doses in 2 Gy fractions were calculated for the LB with α/β = 3 Gy. Mean equivalent doses (MEDs) to the LB were tested for correlation with LBS using a Cox proportional hazards model, and the log rank test with patient data split at the median value of the MEDs to the LB. Statistical significance was defined as p < 0.05. **Result:** Median follow up was 14.3 months. There were 24 cases of LBS (27%). Median time to onset of LBS2+ was 8.6 months after end of treatment (range 2-19 months). LBS was significantly correlated with MED to the LB (p = 0.02). Incidence of LBS was significantly different in patients with MED to the LB < or > the median value of 35.4 Gy (p = 0.004 log-rank test), with actuarial rates of 19% and 55% respectively at 14 months, and 19% and 70% respectively at 24 months; and with raw rates of 15.9% and 38.6% respectively. **Conclusion:** We observed

a high rate of lobar stenosis after ultra-central SBRT. Incidence of lobar stenosis was significantly correlated with dose to the lobar bronchi. In particular, mean equivalent dose to the lobar bronchi was significantly correlated with LBS. Our analysis suggests that limiting the mean equivalent dose to the lobar bronchi to < 35.4 Gy results in a two year actuarial incidence of LBS of <19%, and a raw incidence <16%.

MA02.07 A PHASE I TRIAL OF AN IMMUNE CHECKPOINT INHIBITOR PLUS STEREOTACTIC ABLATIVE RADIOTHERAPY IN PATIENTS WITH EARLY STAGE NON-SMALL CELL LUNG CANCER

M. Daly[1], A. Monjazeb[1], A. Mirhadi[2], D. Eastham[3], F. Lara[1], J. Riess[1], E. Wiegner[4], K. Kelly[1]

[1]*University of California Davis Comprehensive Cancer Center, Sacramento/United States of America,* [2]*Samuel Oschin Comprehensive Cancer Institute, Los Angeles/United States of America,* [3]*Joint Radiation Oncology Center, David Grant USAF Medical Center, Travis AFB/United States of America,* [4]*Mercy Medical Group, Sacramento/United States of America*

Background: Stereotactic ablative radiation therapy (SABR) is the standard-of-care for medically inoperable, early stage non-small cell lung cancer (NSCLC), but regional and distant failures remain problematic. Based on *in vivo* preclinical data showing synergy between radiation and immune checkpoint inhibitors (ICI) and the known efficacy and mild toxicity profile of ICI in Stage III and IV NSCLC, we conducted a phase I study to determine the safety, tolerability and maximum tolerated dose of neoadjuvant, concurrent, and adjuvant atezolizumab with SABR for high risk early stage NSCLC (NCT02599454). **Method:** Eligible patients had histologically confirmed T1-3 NSCLC with one or more features predictive of increased recurrence risk: diameter ≥1 cm, SUV ≥6.2 on FDG PET, or moderately/poorly differentiated histology. Patients were medically inoperable or refused surgery, and had a Zubrod PS ≤2. Patients received 6 cycles of atezolizumab IV in 21 day cycles. A 3+3 dose finding design was employed with three dose levels: 3 mg/kg, 10 mg/kg, and 1200 mg flat dosing. SABR was delivered starting cycle 3 to 50 Gy over 4-5 fractions. Patients were restaged after cycle 2, prior to SABR. Dose limiting toxicity (DLT) was assessed during the first 9 weeks of treatment. **Result:** From April 2016-June 2018, a total of 15 patients enrolled, with 12 evaluable for DLT assessment. Three patients chose to discontinue treatment due to travel issues (1 pt), a COPD exacerbation (1 pt) and grade 2 liver function tests (LFTs) (1 pt). One patient on dose level 2 developed DLT, a grade 3 rash requiring discontinuation of protocol therapy. No other DLTs occurred, resulting in a recommended dose of 1200 mg for future studies. Eleven patients completed protocol treatment. Other grade 3 toxicities include transient lymphopenia in 4 patients. One patient each developed grade 2 pneumonitis, grade 2 hypothyroidism, and grade 2 hyperthryoidism. Three patients had a radiographic partial response and 1 patient had a minor response following 2 cycles. No patient had progressive disease prior to SABR. Results of correlative blood and tissue studies will also be reported. **Conclusion:** Neoadjuvant, concurrent, and adjuvant atezolizumab in combination with SABR for early stage NSCLC is well-tolerated, with radiographic PR prior to SABR in 25% of our cohort. Overall efficacy data is premature. Enrollment to an expansion cohort is ongoing, and this combination will be tested in an upcoming randomized phase III trial SWOG/NRG S1914. This work was supported by the Office of the Assistant Secretary of Defense for Health Affairs through the Lung Cancer Research Program under Award no. W81XWH-15-2-0063.

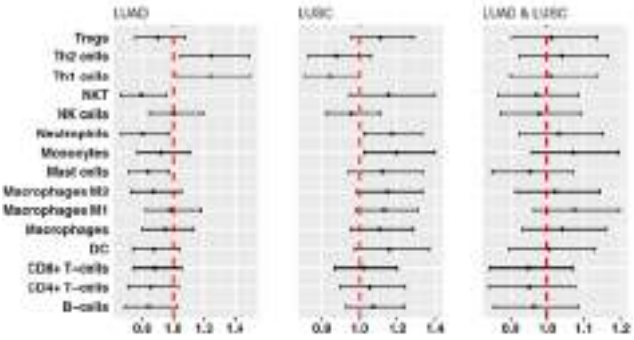
MA02.09 PROGNOSTIC IMPACT OF IMMUNE CELL BIOMARKERS IN SURGICALLY RESECTABLE NON-SMALL CELL LUNG CANCER

S. Tuminello, R. Veluswamy, F. Petralia, P. Wang, R. Flores, M. Van Gerwen

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Immune cells within the tumor microenvironment (TME) play an important role in the development, progression and eventual outcomes of non-small cell lung cancer (NSCLC). The relative balance of immune effector and regulatory cell subpopulations may tilt the TME to be either detrimental or supportive of tumorogenesis and will have a profound impact on the tumor's eventual destiny. In early-stage lung cancer, the role of individual immune cell subtypes in the TME on survival outcomes following surgical resection is unknown. **Method:** This project made use of The Cancer Genome Atlas (TCGA) Program data. We computed sample-specific scores for different immune cells using xCell, a new model for estimating different immune cell types from RNAseq data, for all stage I-IIIA NSCLCs. Then, we assessed the association between each cell type and survival with Cox Regression, while adjusting for important clinical variables (i.e., stage, age, gender, smoking status). We stratified the analysis according to histological subtype. **Result:** There were 910 surgically resected early-stage NSCLC analyzed, of which 438 were adenocarcinomas (LUADs) and 472 were squamous cell (LUSC) samples. Higher levels of natural killer cells, neutrophils, and mast cells within tumors were associated with significantly improved survival in LUAD patients, whereas no immune cell type was associated with survival for LUSC patients or the combined analysis. *Figure 1: Adjusted Survival According to Estimated Immune Cell Infiltration*



Hazard ratios are adjusted for stage, gender, age and smoking status **Conclusion:** Innate and adaptive immune cells within the TME may have prognostic value in early-stage NSCLC patients undergoing surgical resection. However, the role of individual immune cells may vary according to histological subtype. Prospective research should continue to assess the association of the immune cell composition of the TME with clinical outcomes.

Background: Lymphovascular invasion (LVI) has been reported as a risk factor in patients with stage I Non-Small Cell Lung Cancer (NSCLC). Although lobectomy is a standard treatment, sublobar resection may be performed in patients with stage IA NSCLC. This study aimed to evaluate the prognostic effect of LVI in stage IA patients who underwent lobectomy and sublobar resection. **Method:** We retrospectively reviewed data from 2134 patients with stage IA NSCLC from 2007 to 2016. By using the Cox proportional hazard regression model, we calculated the prognostic impact of LVI quantitatively. To reduce the effects of observed confounding between LVI-positive and negative patients, propensity score matching (PSM) was applied in patients with lobectomy and sublobar resection, respectively. **Result:** Among patients with stage IA NSCLC (n=2134), 184 (8.6%) were pathologically diagnosed with LVI, which were 144 (8.9%) in lobectomy group (n=1614) and 40 (7.7%) in sublobar resection group (n=520). In multivariable analysis, LVI was a significant risk factor for both overall survival (OS) and recurrence-free survival (RFS) (OS: hazard ratio [HR], 2.03; 95% confidence interval [CI], 1.39–2.96; p < .001; RFS: HR, 2.31; 95% CI, 1.68–3.17; p < .001). After PSM, the prognostic impact of LVI was shown much greater in patients with sublobar resection (HR = 1.77 and 2.51 for OS and RFS) than those with lobectomy (HR = 4.93 and 4.25 for OS and RFS). **Conclusion:** The presence of LVI significantly affected OS and RFS in stage IA NSCLC patients. Survival outcomes were more affected by the presence of LVI in patients with sublobar resection than those with lobectomy. Subsequent completion lobectomy could be considered in patients diagnosed with LVI after sublobar resection.

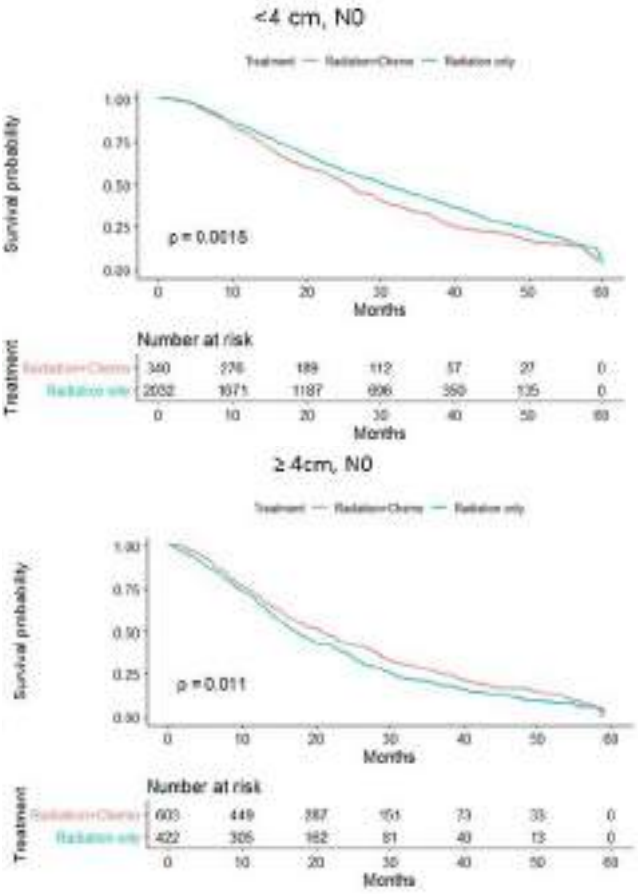
MA02.11 ADJUVANT CHEMOTHERAPY FOLLOWING SBRT FOR EARLY STAGE NON-SMALL CELL LUNG CANCER (NSCLC) IN OLDER PATIENTS

A.K. Ganti, A. Kusi Appiah, V. Ernani, C. Zhang, W. Zhen, A. Marr, L. Smith

University of Nebraska Medical Center, Omaha/United States of America

Background: Adjuvant chemotherapy following surgery has been shown to be beneficial in NSCLC >4 cm in size, regardless of age. We have recently shown that adjuvant chemotherapy improves overall survival following stereotactic body radiotherapy (SBRT) in patients with tumors ≥4 cm in size. We aim to evaluate the role of adjuvant chemotherapy following SBRT in older patients (>70 years) with early stage NSCLC. **Method:** Patients (>70 years) diagnosed with clinical stages I-II NSCLC (AJCC 7th Edition) from 2004 to 2013, who received SBRT, were identified using the National Cancer Database (n=7,934). The Kaplan-Meier method was used to estimate overall survival (OS) distributions and the log-rank test was used to compare distributions by treatment strategy. Clinical stages I and II were subdivided according to the TNM staging and log-rank tests was used to compare survival distributions by treatment strategy within each subgroup. **Result:** There were 3991 male patients (50.3%), and 6219 (78.4%) had stage I disease. Among stage I patients, 670 (10.8%) received adjuvant chemotherapy (defined as chemotherapy within 90 days of completion of SBRT), compared to 742 stage II patients (43.3%) received adjuvant chemotherapy. Median OS was better with SBRT in patients with stage I disease (25.2 vs. 19.9 months; p<0.001); while patients with stage II NSCLC had better OS with SBRT + chemotherapy (19.9 vs. 14.6 months; p<0.001). On multivariate analysis, after adjusting for age, gender and facility type, patients with stage I NSCLC who received SBRT alone had better overall survival [HR for death: 0.79 (95% CI, 0.73, 0.87)]. SBRT alone was associated with an increased risk of death in patients with stage II disease [HR: 1.37 (95% CI, 1.23, 1.53). When patients with N0 disease were evaluated based on tumor size, those with tumors ≥4 cm had better OS with SBRT + chemotherapy (18.5 vs. 15.5 months; p=0.003). In contrast, patients with tumors <4 cm did better with SBRT alone (median OS of 24.1 vs. 20.3 months; p<0.001)

Overall Survival



Conclusion: Adjuvant chemotherapy following SBRT is associated with improved OS in patients >70 years of age and tumors ≥4 cm in size or lymph node involvement.

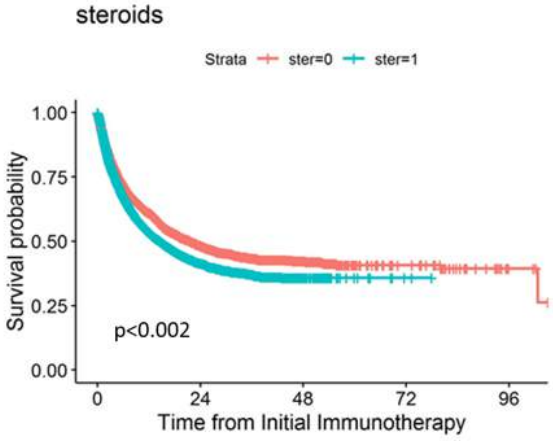
MA03.01 THE IMPACT OF EARLY STEROIDS ON CLINICAL OUTCOMES IN PATIENTS WITH ADVANCED NSCLC TREATED WITH IMMUNE CHECKPOINT INHIBITORS- A CANCERLINQ COHORT

P. Patil, X. Jia, B. Hobbs, N. Pennell

Cleveland Clinic, Cleveland/United States of America

Background: Immune checkpoint inhibitors (ICIs) have changed the treatment paradigm for patients with NSCLC, however only a fraction of patients have objective responses to these agents. Identifying clinical factors that influence efficacy of ICIs is crucial for optimal patient selection for treatment. Since ICIs produce anti-tumor responses by reinvigorating cytotoxic effector T cells, one can surmise that patients who receive steroids within a short interval of initiating ICIs will have less robust anti-tumor responses. Clinical trials usually exclude patients receiving steroids for this reason. In clinical practice, patients with NSCLC often receive corticosteroids for various indications such as brain metastases, appetite stimulation, autoimmune disorders, or COPD. By analyzing data obtained from a large real world cohort of patients with NSCLC, we aim to study the impact of early steroids (within 30 days) on clinical outcomes in patients with advanced NSCLC treated with ICIs. **Method:** Using the Cancerlinq Discovery Database which consists of data aggregated from the electronic medical records of oncology practices, 11,143 patients with advanced NSCLC treated with ICIs were identified. Of these, 1581 patients were prescribed or administered ≥ 10 mg of prednisone or equivalent corticosteroid dose within the first 30 days of initiating ICIs. To account for prognostic heterogeneity within the population, we created matched cohorts of patients that exhibited similar prognostic clinical characteristics such as age (using 65 years as a cutoff) and gender. Association between time on treatment with ICIs and early steroid use was evaluated using the Student's t-test. Overall survival (OS) was estimated using the Kaplan-Meier method and analyzed using the Cox proportional-hazards model. **Result:** The cohort consisted of a predominantly white population (53.4%), with a median age of 76 years and a slight male predominance (54.9%). The median time on ICI treatment was 3.8 months. Patients who received steroids within the first 30 days had a shorter time on treatment- median of 3.36 months vs 3.86 months for those without steroid use (p= 0.023). Early steroid use was also associated with significantly worse overall survival [HR 1.16, 95% CI (1.05, 1.28) p<0.002]. Figure: Kaplan-Meier survival analyses of patients with NSCLC treated with ICIs according to early steroid use



Conclusion: The use of ≥ 10 mg of prednisone equivalent corticosteroid dose within 30 days of initiating ICIs was associated with shorter time on treatment and worse overall survival in this large real world cohort of NSCLC patients. It is prudent that clinicians judiciously prescribe corticosteroids upon initiation of ICIs.

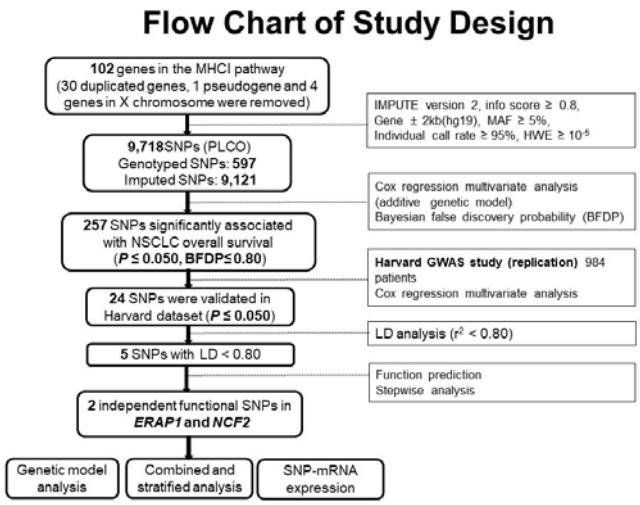
MA03.02 GENETIC VARIANTS IN ERAP1 AND NCF2 IN THE MHC CLASS I RELATED GENES ARE ASSOCIATED WITH NON-SMALL CELL LUNG CANCER SURVIVAL

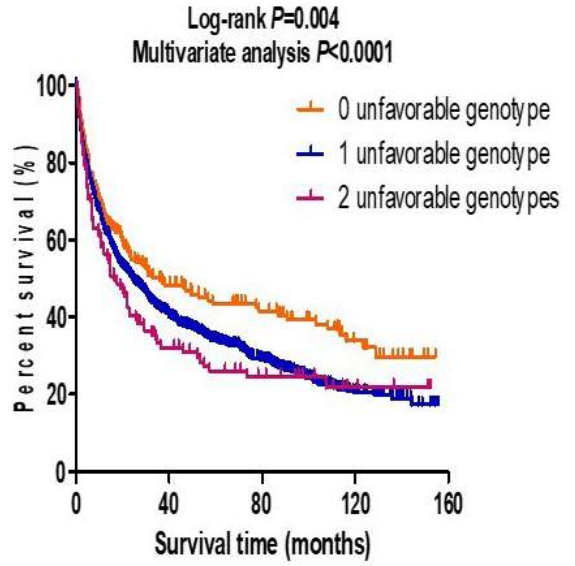
S. Yang[1], Q. Wei[2], D. Christiani[3], Q. Wang[1]

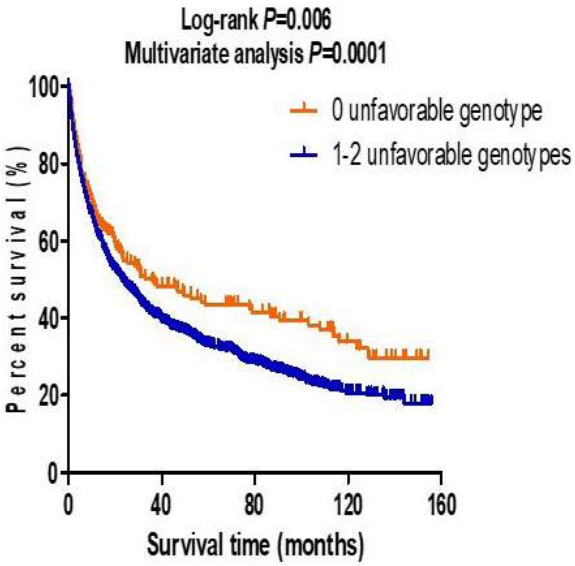
[1]*The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China,* [2]*Duke Cancer Institute, Duke University Medical Center, Durham/United States of America,* [3]*Departments of Environmental Health and Department of Epidemiology, Harvard School of Public Health, Boston/United States of America*

Background: Adaptive immunity, particularly the presence of tumor-infiltrating $CD8^+$ T cells, is crucial in the control of tumor cells and preventing overall cancer progression. However, the process of $CD8^+$ T cells recognizing and killing tumor cells depends on the expression of MHC class I (MHCI) complex presented on tumor cell surface. **Method:** In the present study, we performed a two-phase analysis of two independently published genome-wide association studies (GWASs) to evaluate associations between genetic variants in the MHCI-related gene-set and overall survival (OS) of patients with non-small cell lung cancer (NSCLC). In the discovery GWAS dataset, we performed multivariate Cox proportional hazards regression with Bayesian false-discovery probability for multiple test corrections and evaluated associations between 9,718 single-nucleotide polymorphisms (SNPs) in 102 genes and survival of 1,185 NSCLC patients. After validation in another GWAS dataset, we performed linkage disequilibrium, function prediction and a multivariate stepwise Cox proportional hazards regression analysis. **Result:** We found that two independent, potentially functional SNPs in two genes (*ERAP1* rs469783 T>C and *NCF2* rs10911362 C>T) were significantly associated with NSCLC survival, and their meta-analysis showed an adjusted hazards ratio (HR) of 0.83 [95% confidence interval (CI) =0.77–0.89] and $P_{meta} = 8.2\times10^{-7}$; 1.31 (1.06-1.73) and P_{meta} =0.0009; respectively. A genetic score of unfavorable genotypes of these two SNPs revealed a decreased OS in a dose–response manner (P_{trend} <0.0001). Further expression quantitative trait loci (eQTL)

analysis showed significant associations between the genotypes and mRNA expression levels. Furthermore, the expression levels of these genes in tumor and normal tissues were different and had an effect on patient survival as well.







Conclusion: Taken together, the genetic variant of the *ERAP1* rs469783 and *NCF2* rs10911362 from the MHCI pathway genes may be a promising predictor of survival in NSCLC patients via *ERAP1* and *NCF2* expression alteration.

MA03.03 CEA AND CYFRA 21-1 AS PROGNOSTIC BIOMARKERS OF BENEFIT FROM NIVOLUMAB AND AS A TOOL IN TREATMENT MONITORING IN ADVANCED NSCLC

F.G. Dall'Olio[1], F. Abbati[1], F. Facchinetti[2], F. Gelsomino[1], B. Melotti[1], M. Massucci[1], S. Buti[1], M. Veneziani[3], M. Tiseo[2], A. Ardizzoni[1]

[1]*Policlinico di Sant'Orsola - University of Bologna, Bologna/Italy,* [2]*University of Parma, Parma/Italy,* [3]*Azienda Ospedaliero-Universitaria di Parma, Parma/Italy*

Background: To assess the role of pre-therapy levels of Carcinoembryonic antigen (CEA) and Cytokeratin-19 Fragments (CYFRA 21-1) as prognostic marker in advanced NSCLC patients treated with nivolumab, and their change as an early predictor of treatment outcome. **Method:** This is a retrospective cohort study including all patients with stage IIIB – IV NSCLC who received nivolumab after first-line chemotherapy in 2 Italian institutions. Median Overall Survival (OS), Overall Response Rate (ORR), Disease Control Rate (DCR) and Time to Treatment Failure (TTF) were chosen as endpoints. **Result:** 100 patients were included. Cyfra 21-1 > ULN resulted correlated with OS (FIG.1A) both in univariate (HR 2.77, 95% CI 1.53 – 5.30, p 0.001) and multivariate analysis (HR 2.72, 95% CI 1.44 – 5.16, p 0.002). The only other factor correlated with OS in multivariate was ECOG PS (0-1 vs 2) (HR 5.46, 95% CI 3.07 – 9.91, p< 0.001) (Table 1). ECOG PS (0-1 vs 2) and CYFRA 21-1 (≤ 3.5 vs > 3.5) where combined to create a prognostic score (FIG.1B). Median OS was 23.9 months for patients without risk factors, 6.3 months with one (HR 2.75, 95% CI 1.40 – 5.40 p 0.003) and 1.3 months with 2 risk factors (HR 14.50, 95% CI 6.35 – 33.09, p< 0.001). Early 20% reduction after 3rd cycle was correlated with OS for CEA, HR 0.05 (95% CI 0.01–0.41), p 0,003 and borderline for CYFRA 21-1, HR 0.29 (95% CI 0.09 – 1.01), p 0.052. (FIG.1C-1D).

	Univariate		Multivariate	
Covariate	**HR (95% CI)**	**P value**	**HR (95%CI)**	**P value**
ECOG PS 2 vs 0-1	5.40 (3.21 – 9.09)	< 0.001	5.46 (3.07 – 9.91)	< 0.001
Cyfra > vs ≤ ULN	2.77 (1.53 – 5.03)	0.001	2.72 (1.44 – 5.16)	0.002
Liver metastasis yes vs no	2.19 (1.26 – 3.78)	0.005		0.102
Neutrophil/lymphocyte ratio ≥ 4 vs < 4	1.99 (1.23 – 3.20)	0.005		0.105
KRAS mutated vs wild type*	0.39 (0.21 – 0.74)	0.004		0.262
Bone metastasis yes vs no	1.75 (1.10 – 2.79)	0.018		0.362
Response to previous therapy yes vs no	0.51 (0.29 – 0.91)	0.023		0.376
CEA > vs ≤ ULN	1.41 (0.88 – 2-25)	0.150		0.418
Stage IV vs IIIB	1.63 (0.75 – 3.54)	0.22		0.449
Squamous vs non squamous	0.79 (0.48 – 1.28)	0.334		0.689
Smoker vs never smoker	0.88 (0.65 – 1.18)	0.386		0.694
Second-line vs third or more	0.94 (0.60 – 1.47)	0.77		0.843
Brain metastasis yes vs no	1.16 (0.66 – 2.04)	0.603		0.594

Conclusion: Our data suggests that Cyfra 21-1 pre-therapy assessment, both alone and in combination with other factors in a prognostic/predictive score, may provide clinicians with further information on the prognosis of patients treated with nivolumab. CEA and CYFRA 21-1 repeated measures could be useful as an early surrogate marker of clinical benefit. Further analysis are warranted to confirm these findings.

Background: PD-1/PD-L1 immune checkpoint blockade (ICB) has revolutionized the treatment of non-small cell lung cancer (NSCLC), but only a minority of patients achieve durable clinical benefit. Although classic *EGFR/ALK* alterations are correlated with ICB resistance, it is unknown if patients with other molecular subtypes of NSCLC also derive poorer outcomes from ICB. We investigated if there are oncogene-driven NSCLC associated with higher response rates (RR) and progression-free survival (PFS) to ICB. **Method:** Two independent retrospective cohorts of oncogene-driven NSCLC treated with ICB monotherapy were analyzed for clinical outcome: MD Anderson (MDACC) and Flatiron Health-Foundation Medicine Clinico-Genomic Database (FH-CGDB). PD-L1 expression (Dako 22C3 - FoundationCore) and tumor mutational burden (TMB - FoundationCore; TCGA and MSK-IMPACT – cbioportal.org) were compared across distinct molecular subtypes of NSCLC to determine differences in clinical outcome. **Result:** Among five oncogene defined groups from the MDACC cohort, *BRAF*-mutant NSCLC had the highest response rate (RR) (RECIST 1.1) (P<0.01) and PFS (P<0.01) when treated with ICB (Table). These differences remained significant after adjusting for PD-L1 expression. Classic *EGFR* and *HER-2* mutant NSCLC had the lowest RR and PFS (Table). Similar results were observed in the independent FH-CGDB cohort where *BRAF*-mutant NSCLC had longer real-world (rw) PFS and OS to ICB monotherapy (Table). PD-L1 expression (tumor score ≥1% and ≥50%) and TMB were higher in *BRAF*-mutant NSCLC compared to *EGFR* and *HER-2* (P<0.01). *BRAF* V600E NSCLC had lower TMB compared to non-V600E (5.9 vs 13.7 mut/Mb, P<0.01), but both had high PD-L1 expression (≥1%: 72% vs 61%; ≥50%: 42% vs 32%).

	KRAS	BRAF	Classic EGFR	EGFR exon 20	HER2
MDACC cohort					
Patients – N	87	10 (V600E 3 / non-V600E 7)	28	25	15
RR – %	24.3	62.5	4.5[b]	10[b]	8.3
Median PFS – mo (95% CI)	2.76 (2.23-3.30)	7.37 (not estimable)[a]	1.78 (1.18-2.37)	2.73 (1.71-3.75)	1.88 (1.63-2.12)
FH-CGDB					
Patients – N	503	68 (V600E 32 / non-V600E 36)	52	42	25
Median rwPFS - mo (95% CI)	3.55 (3.15-4.24)	6.0 (2.89-11.6)	2.17[b] (1.77-2.63)	2.66[b] (2.23-5.13)	1.87[b] (1.31-4.34)
Median rwOS – mo (95% CI)	10.28 (8.51-12.02)	16.07 (8.64-NA)	5.29[b] (3.25-17.68)	9.89[b] (3.68-20.86)	10.81 (4.17-NA)
FoundationCore cohort – N	NA	188 (V600E 74 / non-V600E 114)	386	96	57
TMB – mean (mut/Mb)	NA	10.6[a]	3.7	3.8	5.8
PD-L1 TPS ≥ 50% (%)	NA	36[a]	19	23	16

a: *P*<0.01 vs all groups; b: *P*<0.05 for pairwise comparison vs BRAF.

Conclusion: NSCLCs with *BRAF* mutations are associated with increased benefit from ICB when compared to tumors harboring other targetable oncogenic drivers. Oncogene driver mutations are associated with distinct patterns of TMB and PD-L1 expression. These findings highlight the importance of developing mutation-specific clinical trials in NSCLC.

Background: The RTK AXL is implicated in epithelial-to-mesenchymal transition, negative regulation of anti-tumour immunity and resistance to multiple therapies including immune checkpoint inhibitors. Bemcentinib (BGB324) is a first-in-class, oral, highly selective and potent AXL inhibitor which has been demonstrated to enhance anti-PD1 therapy. **Method:** This phase II trial (Cohort A, NCT03184571) enrolled 48 advanced lung adenocarcinoma patients with progression on or after no more than one prior line of platinum-based chemotherapy. Patients with EGFR/ALK mutations were included in this study and must have progressed on or after at least one standard targeted therapy. The primary endpoint was ORR according to RECIST v1.1. Additional endpoints included efficacy according to biomarker expression, DCR, PFS, OS, and safety. Tumour biopsies were analysed for PD-L1 expression (22C3 pharmDx), AXL by IHC, and infiltrating immune cells. **Result:** As of April 2019, the trial was fully recruited: median age 65 (range 39-82) yrs, 61% male, 76% smokers or ex-smokers. At time of writing, a total of 210 treatment cycles had been completed by all patients. 17 patients were ongoing. 17 of 32 biomarker-evaluable patients (53%) were PD-L1 negative, 13 (41%) had TPS 1-49%, and 2 (6%) had TPS ≥50%. Of 28 biomarker-evaluable patients, 14 (50%) expressed AXL on their tumours. Among patients who had at least 1 evaluable on-treatment scan: 5 responses were observed in 13 AXL positive patients (38%), and 7 in 30 patients with TPS 0-49% (23%). There were 10 responses observed among 34 evaluable patients overall (29%). In Stage 1, two of the 4 AXL positive responses are ongoing; mDoR is not mature in the AXL positive patients. mPFS was 5.9 mo in AXL positive patients (n=10, 3.0-NR) and 4.0 mo (95% CI 1.9-NR) overall (n=24). mOS was not mature. The most common TRAEs (occurring in ≥10% of patient in both stages) were transaminase increases (34%), asthenia/fatigue (30%), diarrhoea (26%), nausea (13%), anaemia (11%), decreased appetite (11%), and pruritus (11%). All cases of transaminase increase were reversible and resolved with concomitant administration of systemic corticosteroids and interruption of study treatments. **Conclusion:** Patients had predominantly low or no PD-L1 expression; approximately half were AXL positive. The combination of bemcentinib and pembrolizumab was well tolerated and showed promising efficacy in previously treated IO-naïve NSCLC patients, particularly in those with AXL positive disease, including PD-L1 negative patients. Mature ORR for both stages, as well as 12-month OS for stage 1 will be presented at the meeting.

Keywords: Pembrolizumab, bemcentinib, AXL

Background: Management of advanced non-squamous non-small cell lung cancer (NSCLC) is an area in dire need of therapeutic innovation. In recent years, multiple randomized clinical trials (RCT) have combined atezolizumab, programmed death ligand 1 (PDL-1) antibody, with chemotherapy as first-line treatment of advanced non-squamous NSCLC. In patients with EGFR/ ALK genetic alterations, PDL-1 or programmed death receptor 1 (PD-1) inhibitors monotherapy previously failed to demonstrate survival benefits compared to standard chemotherapy. The purpose of our study is to explore the efficacy of atezolizumab in combination with chemotherapy for first-line treatment of advanced non-squamous NSCLC harboring EGFR or ALK genetic alterations. **Method:** We conducted a comprehensive literature search using PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019. RCTs utilizing first-line atezolizumab combination regimen in patients with advanced non-squamous NSCLC were incorporated in the analysis. A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for progression-free survival (PFS) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q -statistic. Random effects model was applied. **Result:** 3 RCTs (IMpower – 130, 132 and 150) including 2101 patients with advanced non-squamous NSCLC were eligible. The study arm used standard chemotherapy regimens in combination with atezolizumab while control arm used only standard chemotherapy regimens. The randomization ratio was 2:1 in IMpower130 study and 2:1 in other studies. The I^2statistic for heterogeneity was 0, suggesting homogeneity among RCTs. 1949 patients were EGFR/ ALK wild type and 152 patients from Impower 130 and 150 were positive for EGFR/ ALK genetic alterations. The pooled HR for PFS was statistically significant at 0.62 (95% CI: 0.56-0.69; P < 0.0001) in patients with EGFR or ALK genetic alterations, favoring first-line atezolizumab chemoimmunotherapy regimen. In the EGFR/ ALK wild type population, the pooled HR for PFS was 0.63 (95% CI: 0.43 to 0.94; P = 0.02). **Conclusion:** Our meta-analysis demonstrated that atezolizumab in combination with chemotherapy significantly improved progression-free survival compared to standard chemotherapy in patients with advanced non-squamous NSCLC, regardless of the presence or absence of EGFR/ ALK genetic alterations.

MA03.09 DRAMATIC RESPONSES TO IMMUNE CHECKPOINT INHIBITORS IN MET EXON 14 SKIPPING MUTATION (METEX14MUT) NON SMALL CELL LUNG CANCERS

M. Mayenga[1], I. Monnet[2], M.-A. Massiani[3], J.-B. Assié[2], L. Tabeze[1], S. Friard[1], S. Fraboulet[1], A.-C. Metivier[1], C. Chouaid[2], L. Zemoura[4], E. Longchampt[4], S. Melaabi[5], L.-J. Couderc[1], H. Doubre[1]

[1]*Hopital Foch, Suresnes/France,* [2]*CHI Creteil, Creteil/France,* [3]*Hôpital René Huguenin-Institut Curie, Saint Cloud/France,* [4]*Hôpital Foch, Suresnes/France,* [5]*Institut Curie, Saint-Cloud/France*

Background: METex14 mutations occur in 2-3% of Non-Small-Cell Lung Cancers (NSCLC), with a higher prevalence in patients aged over 70-years-old, non-smokers and women. Crizotinib, a MET-inhibitor, allows remarkable, but often short, tumor responses. Immune Checkpoint Inhibitors (ICIs) have become pivotal treatments in NSCLC but seem less efficient in non-smokers and in case of oncogenic addiction. We report durable strong responses in four non-smoker women (A, B, C, D) and two smokers (E, F) treated by ICIs in a second-line setting for NSCLC harboring METex14 mut. **Method:** We studied the clinical and biological characteristics and the tumor response after ICIs for each patient. The complete DNA sequencing of the tumor was available after the beginning of ICIs (explaining why crizotinib was not proposed in second line). PDL1 expression on tumor cells was evaluated by antibody clone E1L3N (Cell signaling Technology). **Result:** Table 1 summarizes patient and tumor characteristics, and the evolution during ICIs:Nivolumab for all patients except E (pembrolizumab). There were neither EGFR, BRAF, KRAS mutations, nor ALK or ROS translocations (except minority KRAS mutation for C). No concurrent MET amplification was found.

	Age at diagnosis (years)	Histological subtype	Metastatic site	First line treatment	MET Mutation	PDL1 expression	Time between diagnosis and ICI	Time under ICI	Tumor response
A	69	Adenocarcinoma	None then adrenal	Cisplatin - Pemetrexed	c.3082+1 G>A	70%	5,5 months 12 months when rechallenging	24 months (ongoing)	Complete
B	71	Adenocarcinoma	Brain Then brain, lung and pleura	Carboplatin -Pemetrexed	c.3082+1 G>C	20%	10,5 months	23 months	Partial
C	71	Sarcomatoid carcinoma	Bone	Carboplatin -Paclitaxel	c.3082G>A KRAS c.34G>A (minority)	40%	4,5 months	24 months	Complete
D	69	Adenocarcinoma	Pleural	Cisplatin -Pemetrexed -Bévacizumab	non available	40%	34 months	40 months (ongoing)	Partial
E	80	Adenocarcinoma	pancreas, brain	Carboplatin -Pemetrexed	c.3082+1 G>C	90%	5 months	16 months (ongoing)	Partial
F	57	Adenocarcinoma	None (locally advanced)	Cisplatin – Pemetrexed+ radiotherapy	non available	non available	24 months	18 months (ongoing)	Partial

Partial or complete response was rapidly (2 months) obtained in five patients, while pseudo-progression was first observed in D. After a grade 3 diarrhea and diabetic ketoacidosis, ICI was stopped in A but the reintroduction one year later did not cause any toxicity. The tolerance was excellent for the 5 other patients. Response was maintained from 16 to 40 months and treatment is ongoing in four patients. C stopped ICI after 26 months (Complete response on PETscan). B had an isolated bone progression after 7 months of ICI which benefited from a local radiotherapy. After almost 2 years of ICI, a multisite progression occurred and crizotinib was proposed. **Conclusion:** ICIs should be discussed in the treatment of METex14 mut NSCLC.

Background: We have already reported three different molecular (MSC: plasma miRNA-*signature* classifier, *Boeri, Clin Cancer Res 2019*) and clinico-biochemical scores (DiMaio: *Di Maio, EJC 2010*; EPSILoN: *Ann.Onco 2018 supp*) able to differently predict prognosis in advanced non-small cell lung cancer (aNSCLC) patients treated with immunotherapy (IO). Exploiting the ability of each test we developed a combined clinico-biological composite score called DEMo (DiMaio EPSILoN MSC). Objective of the study is to prospectively evaluate the prognostic value of DEMo in aNSCLC patients treated with IO. **Method:** We enrolled 127 consecutive aNSCLC patients treated with IO in first (n=37) and further-lines (n=90) at Istituto Nazionale dei Tumori, Milan. All patients had complete clinico-laboratoristic data necessary for both scores: DiMaio (ECOG-PS, sex, histology, stage, uses of platinum-based therapy at first-line and response to first-line) and EPSILoN (ECOG-PS, Smoke, Liver, LDH, NLRatio). MSC was prospectively evaluated in plasma samples collected prior starting IO and the risk level were assessed. Progression-free survival (PFS) and overall survival (OS) in strata of MSC/DiMaio/EPSILoN alone or DEMo and overall response rate (ORR), were considered as endpoints. Kaplan Meier were used to generate survival curves and Cox hazard model were employed to perform multivariate analyses. **Result:** In multivariate analyses, adjusted for age, sex, pack/year and ECOG-PS, patients with high MSC and high DiMaio and EPSILoN scores reported a lower PFS (MSC: HR 1.72 CI95% 1.06 – 2.77, p=0.027; DiMaio: HR 2.63 CI95% 1.40 – 5.00, p=0.002; EPSILoN: HR 2.17 CI95% 1.16 – 4.16, p=0.014) and OS (MSC: HR 2.17 CI95% 1.29 – 3.70, p=0.003; DiMaio: HR 3.57 CI95% 1.66 – 7.69, p=0.001; EPSILoN: HR 2.50 CI95% 1.15 – 5.26, p=0.020). DEMo stratified patients into four risk groups according to the presence of 3–2–1–0 bad markers (High MSC/DiMaio/EPSILoN or none). Groups had 0%–0%–32.2%–53.3% 1-year PFS (p<0.0001) and 4.4%– 19.4% – 66.9% – 75.4% 1-year OS (p<0.0001). We further compared 0/1 to 2/3 combined groups. At the multivariate Cox model group 2/3 had a mPFS 1.9 vs 9.4 mo compared to group 0/1 (HR 3.70 CI95% 2.08 – 6.67, p<0.0001) and mOS 4.1 vs 22.4 mo (HR 4.76 CI95% 2.56 – 9.10, p<0.0001). Regarding ORR, DEMo group 0/1 had a 3.86 (CI95% 1.76-8.47) fold higher probability to respond compare to 2/3 group (p=0.0007). **Conclusion:** DEMo composite biomarker is able to predict better prognosis compared to each single score and can be a useful tool for guiding IO treatment choices. In particular, DEMo allowed a good selection for those patients who are less likely to benefit from IO.

Background: Studies have suggested that chemotherapy after immune checkpoint inhibitors may confer an improved response in patients with non–small cell lung cancer (NSCLC). However, potential selection bias in such studies has not been addressed. We therefore applied propensity score analysis to investigate the efficacy of subsequent chemotherapy after PD-1 inhibitors (CAP) compared with chemotherapy alone. **Method:** We conducted a multicenter retrospective cohort study for patients with advanced or recurrent NSCLC who were treated at 47 institutions across Japan between 1 April 2014 and 31 July 2017 with chemotherapy (docetaxel with or without ramucirumab; S-1; or pemetrexed) either after PD-1 inhibitor therapy (CAP cohort) or alone (control cohort). The primary end point was objective response rate (ORR). Inverse probability weighting (IPW) was applied to adjust for potential confounding factors, including age, sex, smoking status, performance status, histology, EGFR or ALK genetic alterations, brain metastasis, and recurrence after curative radiotherapy. **Result:** A total of 1439 patients (243 and 1196 in the CAP and control cohorts, respectively) was available for unadjusted analysis. Several baseline characteristics—including age, histology, EGFR or ALK alterations, and brain metastasis—differed significantly between the two cohorts. After adjustment for patient characteristics with the IPW method, ORR was 18.9% for the CAP cohort and 10.8% for the control cohort (ORR ratio, 1.75; 95% confidence interval [CI], 1.25–2.45; P = .001). Median PFS was 3.5 and 2.6 months for the CAP and control cohorts, respectively (hazard ratio [HR], 0.862; 95% CI, 0.743–0.998; P = .048). The PFS rate at 3, 6, and 12 months was 53.3%, 28.5%, and 4.6%, respectively, for the CAP cohort, and 44.3%, 19.7%, and 6.1% for the control cohort. Median OS was 9.8 months for the CAP cohort and 10.3 months for the control cohort (HR, 0.979; 95% CI, 0.813–1.179; P = .822). **Conclusion:** After adjustment for selection bias using propensity score–weighted analysis, CAP showed a significantly higher ORR and longer PFS compared with chemotherapy alone, with the primary end point of ORR being achieved. However, these results did not translate into an OS advantage, and no PFS benefit was apparent at 12 months despite the improvement observed at 3 and 6 months. Our findings suggest that prior administration of PD-1 inhibitors may result in a synergistic antitumor effect with subsequent chemotherapy, but that such an effect is transient. CAP therefore does not appear to achieve durable tumor control or confer a lasting survival benefit.

MA04.01 DEVELOPMENT OF AN IN VIVO PLATFORM TO IDENTIFY NOVEL MECHANISMS GOVERNING LUNG CANCER RESPONSE TO IMMUNOTHERAPY

K. Thu, S. Kubli, A. Wakeham, A. Elia, T. Mak

Princess Margaret Cancer Centre, Toronto/Canada

Background: Immune checkpoint inhibitors (ICIs) have emerged as a promising therapy for the treatment of advanced stage lung cancer. While these agents elicit durable responses in some patients, most do not respond. An improved understanding of the mechanisms governing ICI response in a complex *in vivo* setting has potential to reveal novel therapeutic combinations to enhance ICI efficacy and associated biomarkers indicative of response. We have developed a syngeneic lung tumour model for *in vivo* CRISPR/Cas9 screens to deduce novel tumour-intrinsic mediators of response to anti-PD1 therapy. **Method:** To delineate physiologically relevant ICI response mechanisms, an *in vivo*, syngeneic and orthotopic lung tumour model with an intact immune system is required. For this purpose, we have developed the *KRAS*-mutant Lewis Lung Carcinoma (LLC) model. Flow cytometry and immunohistochemistry were used to characterize immune cell composition in resected tumours and *in vivo* experiments were conducted to determine the effects of anti-PD1 treatment on LLC tumour growth. **Result:** Luciferase-tagged LLC cells were implanted into the lungs of syngeneic C57BL/6 mice using orthotopic injection and mice reached humane endpoints 10-14 days post injection. Immunophenotyping of dissociated tumours revealed changes in the proportions of myeloid and lymphocyte populations relative to tumour-naïve lungs. CD8+ T-cells were present and tumour cells expressed PDL1 suggesting LLC has the capacity to respond to ICI. Consistent with these observations, orthotopic LLC growth was delayed in mice treated with anti-PD1 therapeutic antibody compared to anti-IgG2a isotype control, demonstrating that LLC is an appropriate model for identifying mechanisms that confer sensitivity and/or resistance to ICI therapy. Based on these findings, we generated LLC-Luciferase cells stably expressing Cas9. Since genome-wide screens are not feasible with this *in vivo* tumour model, we are synthesizing a custom, focussed guide RNA (gRNA) library. Genomic analyses have identified ~500 candidate immunomodulatory genes expressed in LLC and clinical lung tumours that will be targeted to determine the effects of inactivating these candidates on anti-PD1 response. **Conclusion:** This platform will enable high-throughput genetic screens to elucidate novel tumour-intrinsic determinants of ICI response *in vivo*. Our discoveries will have potential to inform novel biomarkers predictive of response, and putative targets for new combination therapies to enhance the anti-tumour effects of ICIs. Collectively, this work will improve our understanding of the biological mechanisms governing ICI sensitivity, thereby stimulating the development of new strategies to maximize therapeutic benefit from ICIs in lung cancer patients.

SUNDAY, SEPTEMBER 8 13:30–15:00

MA04.02 MOLECULAR PROFILING OF ADENOCARCINOMA AND SQUAMOUS CELL LUNG CANCER AT SINGLE CELL RESOLUTION

F. Wu[1], Y. He[1], Z. Yiqi[2], A. Xiong[1], J. Yu[1], W. Li[1], N. Fang[2], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China,* [2]*Singleron Biotechnologies Ltd, Nanjing/China*

Background: Adenocarcinoma and squamous are two main subgroups of lung cancer: adenocarcinoma (ADC) accounts for 30-50% and squamous cell carcinoma (SCC) accounts for nearly 30% of all cases respectively. ADC and SCC have different pathological phenotypes and respond differently to various therapies, including immunotherapy. However, the underlying molecular mechanism of such differentiated drug responses still needs to be further characterized. **Method:** To achieve high resolution of both tumor cells and their tumor microenvironment (TME), we used single cell RNA sequencing method to characterize ADC and SCC tumors from Stage IV NSCLC patients. Tissue biopsy samples from 21 patients (12 patients with ADC, 9 with SCC) were collected. For each sample, single cell RNA sequencing was performed on an average of 1930 cells. A graph-based clustering approach was used to classify cells into different cell types based on their gene expression patterns. The cellular subtypes of both cancer cells and TME in ADC and SCC samples were analyzed. **Result:** ADC and SCC show distinct patterns at single cell resolution. Cancer cells from all ADC patients form two closely related clusters, while cancer cells from SCC patients show high intra-and inter-patient heterogeneity. Gene Ontology (GO) analysis demonstrated that ADC samples are enriched in genes of neutrophil degranulation and activation, while SCCs are enriched in genes related to epidermal cell differentiation and glutathione metabolic process. Genes related to cancer progression and metastasis, such as LSD1 and FASCIN, are normally expressed at higher level in SCC than in ADC. Furthermore, ADC samples contain higher percentage of a specific myeloid cell population, while SCC has higher percentage of fibroblasts, demonstrating the difference also in TMEs of ACD versus SCC. **Conclusion:** The significantly higher level of heterogeneity for SCC can be a possible reason for poor responses to standard lung cancer therapies, including immunotherapy. Accurate characterization of SCC with single cell resolution could hold the key to more effective therapeutic strategies.

MA04.03 LUNG TUMORSPHERES CHARACTERIZATION REVEALS CANCER STEM-LIKE CELLS POTENTIAL TARGETS AND PROGNOSTIC MARKERS IN NON-SMALL CELL LUNG CANCER

A. Herreros-Pomares[1,2], E. Jantus-Lewintre[1,2,3], S. Calabuig-Fariñas[1,2,4], J.D. De-Maya-Girones[5], R. Lucas[4], A. Blasco[2,6], R. Guijarro[2,6], M. Martorell[2,6], E. Escorihuela[1,2], M.D. Chiara[7], E. Durendez-Saez[1,2], C. Gandia[5], R. Sirera[2,3], R. Farràs[5], C. Camps[1,2,4,6]

[1]*Molecular Oncology Laboratory, General University Hospital Research Foundation, Valencia/Spain,* [2]*CIBERONC, Spain/Spain,* [3]*Univesitat Politècnica de València, Valencia/Spain,* [4]*Universitat de València, Valencia/Spain,* [5]*Centro de Investigación Príncipe Felipe, Valencia/Spain,* [6]*Hospital General Universitario de Valencia, Valencia/Spain,* [7]*Hospital Central de Asturias, Oviedo/Spain*

Background: Non-small cell lung cancer (NSCLC) is the leading cause of death cancer-related worldwide due to late diagnosis and high resistance against treatments. This resistance has been associated to cancer stem-like cells (CSCs), a highly tumorigenic subpopulation for which the identification of targets and biomarkers is still under development. **Method:** Tissue samples from 8 NSCLC patients were successfully established and cultured using a sphere-forming assay for CSCs enrichment. Adherent counterparts were used as differentiated control cells. Proliferation, chemorresistance, invasion and differentiation capacities were tested *in vitro*, whereas tumor initiation capacity was determined *in vivo*. The expression of 44 CSCs-related genes was assessed by qPCR and protein expression of the best contributors to distinguish adherent cells from tumorspheres was determined by immunoblot and immunofluorescence. The prognostic role of these genes was evaluated in a cohort of 661 resected NSCLC patients from TCGA and validated in an independent cohort of 114 resected lung adenocarcinoma patients. **Result:** Patient-derived tumorspheres showed unlimited exponential growth, high resistance against chemotherapy, great invasion and differentiation capacities *in vitro* in addition to a higher tumorigenic potential than adherent cells *in vivo*. The expression of 17 genes was significantly overexpressed in lung tumorspheres, being *NANOG, NOTCH3, CD44, CDKN1A, SNAI1,* and *ITGA6* the best contributors. Proteins encoded by these genes were consistently increased in tumorspheres from adenocarcinoma patients and showed differential localization and expression patterns. The expression of *CDKN1A, SNAI1* and *ITGA6* was associated to prognosis based on Cox regression analysis (Z-score > 1.5), so their absolute regression coefficients from a multivariate model were used to calculate a gene expression score. Kaplan-Meier survival analysis showed that patients with high score have shorter OS in the entire cohort [37.7 vs. 60.4 mo., $p = 0.001$] and the adenocarcinoma subcohort [36.6 vs. 53.5 mo., $p = 0.003$], but not in squamous cell carcinoma one. Multivariate analysis indicated that this gene expression score was an independent biomarker of prognosis for OS in both, the entire cohort [HR: 1.498; 95% CI, 1.167-1.922; $p = 0.001$] and the adenocarcinoma subcohort [HR: 1.869; 95%

CI, 1.275-2.738; p = 0.001]. The prognostic value of this score was confirmed in an independent cohort of 114 lung adenocarcinoma patients (42.90 vs. NR mo, p = 0.020). **Conclusion:** Proteins encoded by *NANOG, NOTCH3, CD44, CDKN1A, SNAI1,* and *ITGA6* are potential targets against lung CSCs. Elevated gene expression levels of *CDKN1A, SNAI1* and *ITGA6* are associated with worse prognosis. Funded by CB16/12/00350 from CIBEROnc, PI12-02838, and PI15-00753 from ISCIII and Fundacion Arnal Planelles.

Background: The mechanisms underlying the progression of bronchial lesions to squamous cell lung cancer remain undefined. Previously, we hypothesized that bronchial lesions presented individually or combined with each other in the bronchi of non-small cell lung cancer (NSCLC) patients mirror the different scenarios of the premalignant process: individual basal cell hyperplasia (iBCH) – the stoppage at hyperplasia, BCH plus squamous metaplasia (SM) – the progression of hyperplasia to metaplasia, and SM plus dysplasia – the progression of metaplasia to dysplasia. In this study, we aimed to assess the molecular profile of BCH, SM, and dysplasia depending on their co-occurrence in the bronchi of NSCLC patients and to identify mechanisms that are involved in the different scenarios of the premalignant process. **Method:** The samples of lung tissue were obtained at a distance of 4-5 cm from the tumor during surgery of 21 NSCLC patients. Normal bronchial epithelium, BCH, and SM, as well as dysplasia, were isolated from tissue sections using laser microdissection PALM (Carl Zeiss). The microdissected samples underwent whole genome (One Step WGA, Bioron) and transcriptome (Ovation PicoSL WTA System V2, Nugen) amplification and sequenced using the SeqCap EZ Human Oncology Panel (Roche) and profiled using SurePrint G3 Human GE v2 8x60K microarrays (Agilent). Additionally, the samples were sequenced using the Pico Methyl-Seq Library Prep Kit (Zymo Research). Changes in gene expression were confirmed using immunohistochemical staining. **Result:** Genetic alterations were observed already at the early stages of the premalignant process in the bronchial epithelium; however, their number varied from sample to sample. For example, one case of BCH showed more than 10 deleterious mutations in the *GRM5*, *MAML2*, *SP1*, *ETV4*, and other genes, whereas other BCHs carried single alterations. No significant differences were found in the mutational landscape between the iBCH and BCH combined with SM. Bisulfite sequencing demonstrated significant changes in the methylation status of the *SAPCD2* and *ST14* genes in BCH. Importantly, these changes differed between various forms of BCH. Sequencing of SM and dysplasia is in progress and results will be presented later. Gene expression profiling showed differences in the activity of immune response genes between the iBCH and BCH combined with SM and the cell cycle and cilium assembly genes between SMs co-presented with BCH and dysplasia. Overall, the transcription profile of SM co-presented with BCH was closer to BCHs, whereas SM co-detected with dysplasia was similar to dysplasia. Several genes were identified to be expressed specifically in different forms of BCH and SM, among which *CCDC114*, *MAP7D2*, and *LIFR* were confirmed by immunohistochemistry. The loss of CCDC114 and MAP7D2 in SM may serve as an indicator of its progression to dysplasia. **Conclusion:** Taken together, this study demonstrates the significant differences between various types of BCH and SM. These differences support the hypothesis that the isolated and combined forms of the bronchial lesions mirror the different scenarios of the premalignant process as well as explore the mechanisms underlying the progression of hyperplasia and metaplasia to dysplasia. The study was supported by RFBR (#17-29-06002) and the Russian President Fellowship (#SP-1549.2018.4).

MA04.06 LUNG EPITHELIUM WHOLE TRANSCRIPTOME SIGNATURES THAT REFLECT INCIDENT LUNG CANCER CASE-CONTROL STATUS

S. Spivack, X. Dong, M.K. Shi, W. Han, S. Keller, A. Maslov, Y. Suh, J. Vijg

Albert Einstein College of Medicine, Bronx/United States of America

Background: Focusing early detection and prevention efforts on those at high risk for lung cancer is central to leveraging such strategies. Notably, that risk persists even after removal of a lung cancer, as reflected in lung recurrences, which are common, and usually occur remote from the surgical removal site. This implies risk for future incident lung cancer is represented in the biology of broad areas of lung epithelium, before, during, and after diagnosis. Given that somatic mutations in the bronchial tree are known to persist for decades, there is a suggestion that smoking transforms the entire epithelium at several somatic and gene regulatory levels. *We hypothesize* that the normal lung epithelium contains expression and epigenetic epithelial signatures that are representative of donor case-control status, that is poised for carcinogenesis. **Method:** Methods:As a first step, in order to identify differentially expressed genes (DEGs) associated with aging, smoking and cancer case-control status, we analyzed RNA-seq transcriptome data of laser capture microdissected (LCM) bronchial and alveolar epithelium separately, in paired tissue sets of 40- and 74 respective individuals, summarized here. Read count was the main normalization variable. We also measured differentially methylated sites (DME) by whole genome bisulfite genome sequencing (WGBSeq), covering >60% of the genome/methylome [as of this deadline, these methylome data are not yet fully analyzed]. Result:Mean subject age for 77 total subjects was 65 (+/-9.9), 19% current-, 76% former, 5% never smokers. For each cell type, we modeled gene expression level as a result of aging, gender, smoking and case-control status. We put all four clinical variables age, gender, smoking status, case-control status) along with cell type (alveolar/bronchial) into the model, to avoid potential confounding effects. We discovered 175 DEGs discriminating case-control status (FDR p<0.05) in alveolar and bronchial cells combined, and 420 case-control DEGs with bronchial cells alone. Bronchial cells displayed 31 DEGs discriminating current versus former smokers (FDR-adjusted P<0.05). Gene ontology (David) clusters for case-control discrimination in these "normal" bronchial epithelia included energetics pathways (GO 0042776/0006754; ATP biosynthesis) as well as transcriptional and translational regulation pathways; KEGG clusters also included oxidative phosphorylation pathways (hsa00190), among others. **Conclusion:** There is a donor case-control discriminant expression signature for human lung bronchial captured cells, emphasizing bioenergetically-deranged metabolic pathways, among others. If confirmed in larger studies that measure deranged metabolites directly, metabolomics biomarkers representing bioenergetics and other pathways may serve to define those individuals whose epithelia is tilted toward carcinogenesis, and therefore are at increased risk for lung cancer.

Keywords: transcriptome, case-control, normal lung epithelium

MA04.07 INHIBITION OF CXCR2+ NEUTROPHIL MIGRATION AS A TARGETED THERAPY IN KRAS-DRIVEN LUNG ADENOCARCINOMA

M. De Meo[1], R. Rayes[1], S. Milette[1], M. Vagai[1], M. Usatii[1], A. Chandrasekaran[2], B. Giannias[1], F. Bourdeau[1], C. Moraes[2], S. Huang[2], D. Quail[2], L. Walsh[2], V. Sangwan[1], N. Bertos[1], S. Camilleri-Broet[1], P. Broet[3], P. Fiset[1], J. Cools-Lartigue[1], L. Ferri[1], J. Spicer[1]

[1]*McGill University Health Center, Montreal/Canada,* [2]*McGill University, Montreal/Canada,* [3]*Montreal University, Montreal/Canada*

Background: Lung adenocarcinoma (LUAD) accounts for 40% of all lung cancer cases. Although driver mutations in the K-RAS oncogene occurs in 25% of all LUAD cases, to date, there are no available targeted therapies. Infiltrating neutrophils in LUAD are indicative of the worst survival outcomes. The C-X-C motif chemokine receptor 2 (CXCR2) mediates their recruitment to the tumour microenvironment where they promote a pro-tumorigenic environment. CXCR2 ligand expression is higher in KRAS-driven LUAD compared to the other most frequently mutated oncogenes. Therefore, we hypothesize that K-RAS-driven LUAD may be the best candidate for a CXCR2 targeted treatment strategy. **Method:** The PREdiction of Clinical Outcomes from Genomic Profiles (PRECOG) is a dataset of gene expression and survival outcome. The dataset includes data from approximately 18 000 human patients with 39 different malignancies. The dataset was used to determine whether high neutrophil infiltration, CXCR2 expression and CXCR2 ligand expression were associated with poor survival outcomes in LUAD. A 100 patient LUAD tissue microarray was built and stained for neutrophil elastase and CXCR2 by immunohistochemistry. Kaplan-Meier curves were used determine the effect of high neutrophil or CXCR2+ cell infiltration in the LUAD tumour microenvironment on survival outcome. The Cancer Cell Line Encyclopedia (CCLE) is an online dataset that provides gene expression and genotype data from 947 human cancer cell lines (36 cancer types). Expression data of all LUAD cell lines (n=70) from CCLE was obtained for all known CXCR2 ligands. The expression of CXCR2 ligands in K-RAS, EGFR, ALK and ROS-1-driven LUAD cell lines was compared. Microfluidics devices were used to compare the neutrophil recruitment to K-RAS, EGFR, ALK and ROS-1-driven LUAD cell lines. The neutrophil recruitment to each of the cell lines was compared in the presence and absence of CXCR2 inhibition. **Result:** Using the PRECOG dataset, we found that CXCR2 expression in neutrophils is at least 18-fold greater than its expression in other immune cell types. Using all the LUAD cell lines (n=70) available on the CCLE, we found that K-RAS-driven LUAD is the highest CXCR2 ligand expresser as compared to EGFR, ALK and ROS1-driven LUAD. Moreover, using PRECOG, we found that poorer survival outcome is associated with high expression of eight out of nine known CXCR2 ligands ($p < 0.05$). In addition, high neutrophil infiltration in LUAD is associated with the worst survival outcome compared to other immune cell infiltrates ($p < 0.001$). In accordance with the PRECOG data, the presence of infiltrating neutrophils in a 100 patient LUAD tissue microarray is associated with poorer survival outcome when compared to patients with no infiltrating neutrophils ($p < 0.05$). Neutrophil migration to K-RAS, EGFR, ALK and ROS1-driven LUAD cell lines was examined in microfluidics devices and found to be highest in K-RAS-driven LUAD. CXCR2 inhibition reduced neutrophil migration only in K-RAS-driven lung adenocarcinoma ($p < 0.05$). **Conclusion:** CXCR2 inhibition could be an exciting potential targeted treatment for patients with K-RAS-driven LUAD. CXCR2 inhibition is in clinical trials for metastatic melanoma, pancreatic, breast and head and neck cancer. Current evidence suggests that CXCR2 inhibition is safe and tolerable.

Background: Exosomes are small membranous vesicles secreted by a most type of cells (especially in tumoral processes), around 40-130 nm of size, that carry relevant information to distant tissues and being able to modulate its physiology. Exosomes have been detected in different clinical samples and may play a key role in NSCLC, participating in several processes such as horizontal transfer of RNA from tumor to microenvironmental cells, angiogenesis, pre-metastatic niche formation, immunosuppression; and could also be key elements in stem cell differentiation (from different origins). The principal objective of this study was to analyze the exosomes cargo from NSCLC cell lines and primary cultures with diverse characteristics under different growth conditions: suspension cultures with cancer stem cells (CSCs) features and monolayer cultures. **Method:** Primary cultures from resected NSCLC patients and NSCLC cell lines were successfully established. Differentiated tumor cells were cultured under adherent conditions (2D) whereas CSCs were established in suspension cultures (3D tumorspheres). Exosomes isolation was performed by ultracentrifugation. Exosomes characterization was carried out through nanovesicles tracking analysis (NTA) and electron microscopy; and the determination of surface markers through immunoblot and flow cytometry. Exosomal DNA was extracted in order to determine the mutational status of the *EGFR* and *RAS* genes by BEAMing Digital PCR (*Sysmex)*. Transcriptomic analysis has been carried out from exosomal RNA through whole genome gene expression microarrays, (*Affymetrix*). The data was normalized by Robust Multi-Array Average (RMA) and analyzed using Transcriptome Analysis Console (TAC), MultiExperiment Viewer (MeV) software and Partek Genomics Suite. Statistical significance was established at ($p \leq 0.01$). **Result:** In reference to the characterization, NTA and electron microscopy showed that exosomes were obtained free of cellular debris and their size ranges from 108-125 nm, according to the size of tumor-derived microvesicles. Exosomal surface markers analyzed by immunoblot and flow cytometry were detected in samples, confirming proper isolation. Mutational analysis of EGFR and RAS genes performed on exosomal DNA shown the same pattern displayed by the origin cells. Transcriptomic analysis of the exosomal content showed that the expression of mRNAs, miRNAs and precursors were significantly different between 3D and 2D-derived exosomes. Finally, a pathway enrichment analysis was carried out to know in which biological processes (cancer-related) are involved. Significant differential expressions were also found between mRNAs, miRNAs and pre-miRs present in exosomes from adenocarcinoma (ADC) vs. squamous cell carcinoma (SCC). Interestingly, 7 miRNAs differentially expressed in exosomes (miR-200c; miR-29a; miR-339; miR-224; miR-31; miR-21; miR-33a) had already been identified as overexpressed in tumor tissue from NSCLC patients by our group. Moreover, miR-339 y miR-21 were related to prognosis ($p < 0.05$) in ADC group. **Conclusion:** Differences in exosomal mRNA, miRNAs and pre-miRs expression have been observed between: i) lung-tumorspheres vs. more differentiated tumor cells and ii) ADC vs. SCC cultures. In addition, the same mutational pattern was detected in exosomes as compared with their parental cultures. Therefore, exosomes can be a useful source for biomarkers analysis in NSCLC. Supported by grant GV/2018/026, PI18/00266, & Asociación Española Contra el Cáncer (AECC Valencia).

MA04.10 DEVELOPMENT AND VALIDATION OF A GENE EXPRESSION-BASED PROGNOSTIC SIGNATURE IN EARLY-STAGE SQUAMOUS CELL CARCINOMA OF THE LUNG

P. Bose[1], A. Boylos[1], L. Petersen[1], O. Kovalchuk[2], I. Kovalchuk[2], M. Dean[1], D. Itani[1], K. Kopciuk[1], D. Bebb[3]

[1]*University of Calgary, Calgary/Canada,* [2]*University of Lethbridge, Lethbridge/Canada,* [3]*Alberta Health Services, Calgary/Canada*

Background: Squamous cell carcinoma of the lung (SqCCL) accounts for about 30% of all lung cancers and is usually associated with smoking. The clinical outcomes of early stage SqCCL are heterogeneous; while 60% of Stage I and II SqCCL patients never present with recurrence after surgery, the remaining will ultimately succumb to the disease. Therefore, a robust prognostication tool is an unmet clinical need. Here, we describe the development and validation of a gene expression-based prognostic signature in Stage I and II SqCCL patients. **Method:** A total of 673 primary tumour samples obtained from surgically resected Stage I and II SqCCL patients were included in this study. The Cancer Genome Atlas (TCGA) cohort contained 365 patients with gene expression data generated using RNA sequencing (RNAseq). Five data sets (GSE30219, GSE37745, GSE50081, GSE4573, GSE14814) containing 308 patients profiled using Affymetrix microarrays were obtained from the Gene Expression Omnibus (GEO) database; batch effect mitigation of gene expression data was performed using ComBat. An additional cohort of consecutive Stage I and Stage II SqCLC patients was assembled at the Tom Baker Cancer Centre (TBCC), University of Calgary and gene expression was profiled using RNAseq. We performed a two-stage development of the gene signature by performing penalized elastic net Cox regression analysis in the TCGA training cohort followed by refinement of the gene list in the compiled GEO database patients. Final validation was performed using the in-house TBCC cohort. Progression-free survival (PFS) and overall survival (OS) were the primary and secondary outcomes of interest, respectively. **Result:** All datasets used in this study were found to consist of patients with comparable clinical characteristics. A gene expression signature associated with PFS was developed in TCGA cohort that significantly stratified patients into high and low risk groups. The signature was refined in the complied GEO database cohort and validated in the U of C cohort. The signature also effectively stratified patients into high and low risk groups based on OS. We are currently performing multivariable analysis of the refined gene signature, adjusting for covariates of known prognostic value. **Conclusion:** Our signature, if prospectively validated, will guide clinical decision making in SqCCL. Effective risk stratification using our signature may identify Stage I patients that will benefit from adjuvant therapy and stage II patients that could be spared adjuvant treatment following surgical resection.

MA04.11 BIOLOGICAL AND PROGNOSTIC IMPLICATIONS OF THE LONG NON-CODING TRANSCRIPTOME IN TUMOUR-INFILTRATING IMMUNE CELLS

K. Ng, A. Sage, E. Marshall, K. Enfield, W. Lam

BC Cancer Research Centre, Vancouver/Canada

Background: The lung tumour microenvironment is defined by complex infiltration patterns of immune cells which can contribute to both tumour progression and rejection. The advent of targeted immunotherapies has transformed cancer therapy, leading to durable regression even in late-stage lung tumours. Single-cell RNA sequencing and deconvolution of bulk tumour samples have provided insight into the transcriptomes of tumour-infiltrating immune populations and the regulatory networks that promote cytotoxicity and exhaustion transcriptional programs. Long non-coding RNAs (lncRNAs) have emerged as master regulators of gene expression in tumour cells, but their role in immune cells remains undercharacterized. We sought to delineate lncRNA expression profiles in healthy and lung tumour-infiltrating immune cells in order to better understand transcriptional reprogramming in tumour-infiltrating immune cells and to explore their potential as biomarkers of patient outcome and response to immunotherapy. **Method:** RNAseq profiles of flow-purified adaptive and innate immune subsets were analysed for lncRNA expression, yielding 4919 expressed lncRNAs. Immune lncRNAs were then mapped to tumour and paired non-malignant lung adenocarcinoma samples (TCGA n=108, BCCA n=72) and associated with infiltrating immune populations by deconvolution and methylation-based purity scores. Associations with tumour immunogenicity were assessed by somatic mutational load and expression of tumour-associated antigens. Immune-specific expression of lncRNAs was confirmed in an external single cell RNAseq dataset of lung adenocarcinomas (n=5). **Result:** We found that lncRNA expression patterns display markedly greater cell-type specificity than protein-coding genes in healthy samples, supporting their role in cell-intrinsic transcriptional regulation. 323 immune lncRNAs were differentially expressed in lung tumours compared to matched non-malignant tissue, with enriched expression of immune lncRNAs in tumours with high antigenic load. Many of these genes were positively correlated with CD45 expression and negatively correlated with tumour purity, suggestive of immune cell-restricted expression patterns. Furthermore, a substantial proportion of these genes showed decreased expression in microdissected tumour samples, suggesting that immune-derived lncRNAs may account for gene expression patterns observed in bulk tumour data. We validated these findings in a scRNAseq dataset and analysed co-expression patterns of immune lncRNAs with immune cell markers in order to identify specific immune cell phenotypes and assess the interaction of immune lncRNAs with cytotoxicity and exhaustion transcriptional networks. We identify immune lncRNAs which may regulate expression of important immune genes related to NK and CD8+ T cell cytotoxicity, as well as immune lncRNAs which predict patient outcome and response. **Conclusion:** We present an atlas of lncRNAs expressed in innate and adaptive immune cells, emphasizing the multifaceted roles of lncRNAs in homeostasis and anti-tumour immunity. We highlight the potential of immune infiltrate to confound differential expression analysis of bulk tumour RNAseq data, with consideration needed for tumour purity and immune infiltration levels. Our data provide a resource that will facilitate further identification of functionally and clinically useful lncRNAs.

Background: Surgical resection plays an important role in the management of selected patients with malignant pleural mesothelioma (MPM). Early experience with anti-PD-1 immunotherapy showed promise in MPM, but it is yet uncertain if it can improve outcomes when tumour relapses following surgical resection, radiotherapy and chemotherapy. We reviewed our experience in patients who received Pembrolizumab or Nivolumab following multimodality therapy. **Method:** Retrospective study including patients with histologically-proven MPM having completed multimodality therapy and received anti-PD-1 immunotherapy as 2nd or 3rd line treatment. Data were retrieved from a prospective mesothelioma database. Histopathology, BAP1, MTAP and PD-L1 (22C3) immunohistochemistry were performed on surgical specimens and reported by a senior pathologist. All patients had chest computed tomography and positron emission tomography (PET-CT) as part of their normal follow-up. Response evaluation was determined using RECIST 1.1 criteria. **Result:** 16 patients received anti-PD-1 immunotherapy between August 2015 and March 2019.

All patients had total pleurectomy/decortication, prophylactic radiotherapy (21Gy/3) and systemic chemotherapy based on pemetrexed and platinum. Median age was 68.5 years, with male predominance (13/16). 56% had epithelioid type, 44% had biphasic type. Median time to starting immunotherapy was 20 months (range 11-42) following surgery. Median ECOG performance status was 0. Twelve patients received Pembrolizumab and 4 received Nivolumab. Median number of cycles of anti-PD-1 therapy received was 5 (range 1-33). Disease control rate at 12 weeks was 56.2% and 7 (43.7%) patients had disease progression. Adverse events were observed in 6 patients (one Grade 3). Eight patients were alive by 1st April 2019. Median OS from starting immunotherapy was 13.5 months. Three patients received treatment for 14 months or more. Five patients started further therapy after discontinuing immunotherapy. **Conclusion:** In our cohort, second or third-line anti-PD-1 immunotherapy showed efficacy with DCR comparable to non-surgical setting. Further studies are warranted to validate our preliminary findings.

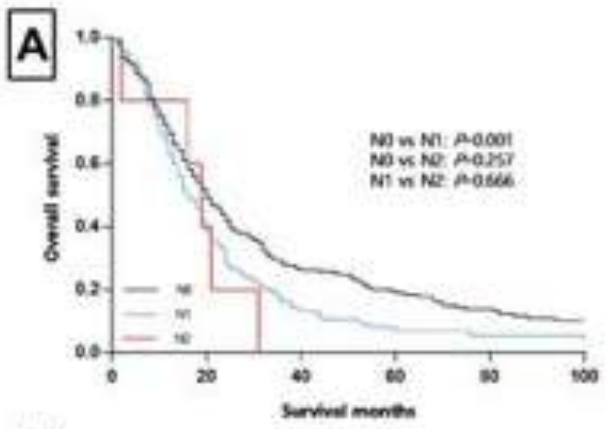
MA05.02 LOG ODDS OF POSITIVE LYMPH NODES PREDICTS OVERALL SURVIVAL AND THE BENEFIT OF POSTOPERATIVE RADIOTHERAPY IN MALIGNANT PLEURAL MESOTHELIOMA

Y. Wo, Y. Wang, T. Lu, W. Jiao

Affiliated Hospital of Qingdao University, Qingdao/China

Background: Nodal categories of malignant pleural mesothelioma (MPM) are mostly adopted from lung cancer staging criteria and the N descriptors in the eighth edition of TNM staging system have not been fully verified. We aimed to evaluate the effectiveness of the current N descriptors and a novel prognosticator—the log odds of positive lymph nodes (LODDS)—in predicting overall survival (OS) and postoperative radiotherapy (PORT) benefit in MPM. **Method:** Patients in the Surveillance, Epidemiology, and End Results (SEER) database with MPM undergoing surgery and lymph nodes examination were extracted and restaged according to the 8th edition TNM staging system. LODDS was calculated as $\log_e$[(positive nodes count+0.5)/(negative nodes count+0.5)]. X-tile software determined the optimal cut-point for LODDS. Log-rank tests along with Cox regression analyses were adopted for survival analyses. Harrell's C-index statistic measured discriminatory ability and prognostic performance. **Result:** A total of 534 patients were enrolled in this study. N descriptors were unevenly distributed. Most cases were staged as N0 (51.9%) and N1 (47.0%), with only 1.1% staged as N2. The eighth edition N descriptors failed to clarify the survival difference between adjacent categories and were incapable of predicting PORT benefit. The cut-points for LODDS were classified as follows: LODDS1 (≤-2.61), LODDS2 (-2.56≤LODDS≤0.62), and LODDS3 (≥0.87). The median survival of LODDS1 was 23.1 months compared with 17.9 months (HR=1.397, *P*=0.005) and 13.0 months (HR=2.317, *P*<0.001) for LODDS2 and LODDS3, respectively. The survival curves stratified by LODDS separated nicely without overlapping and the benefit of PORT was limited to cases with LODDS3 (≥0.87). LODDS also provided better C-index than the conventional N descriptors.



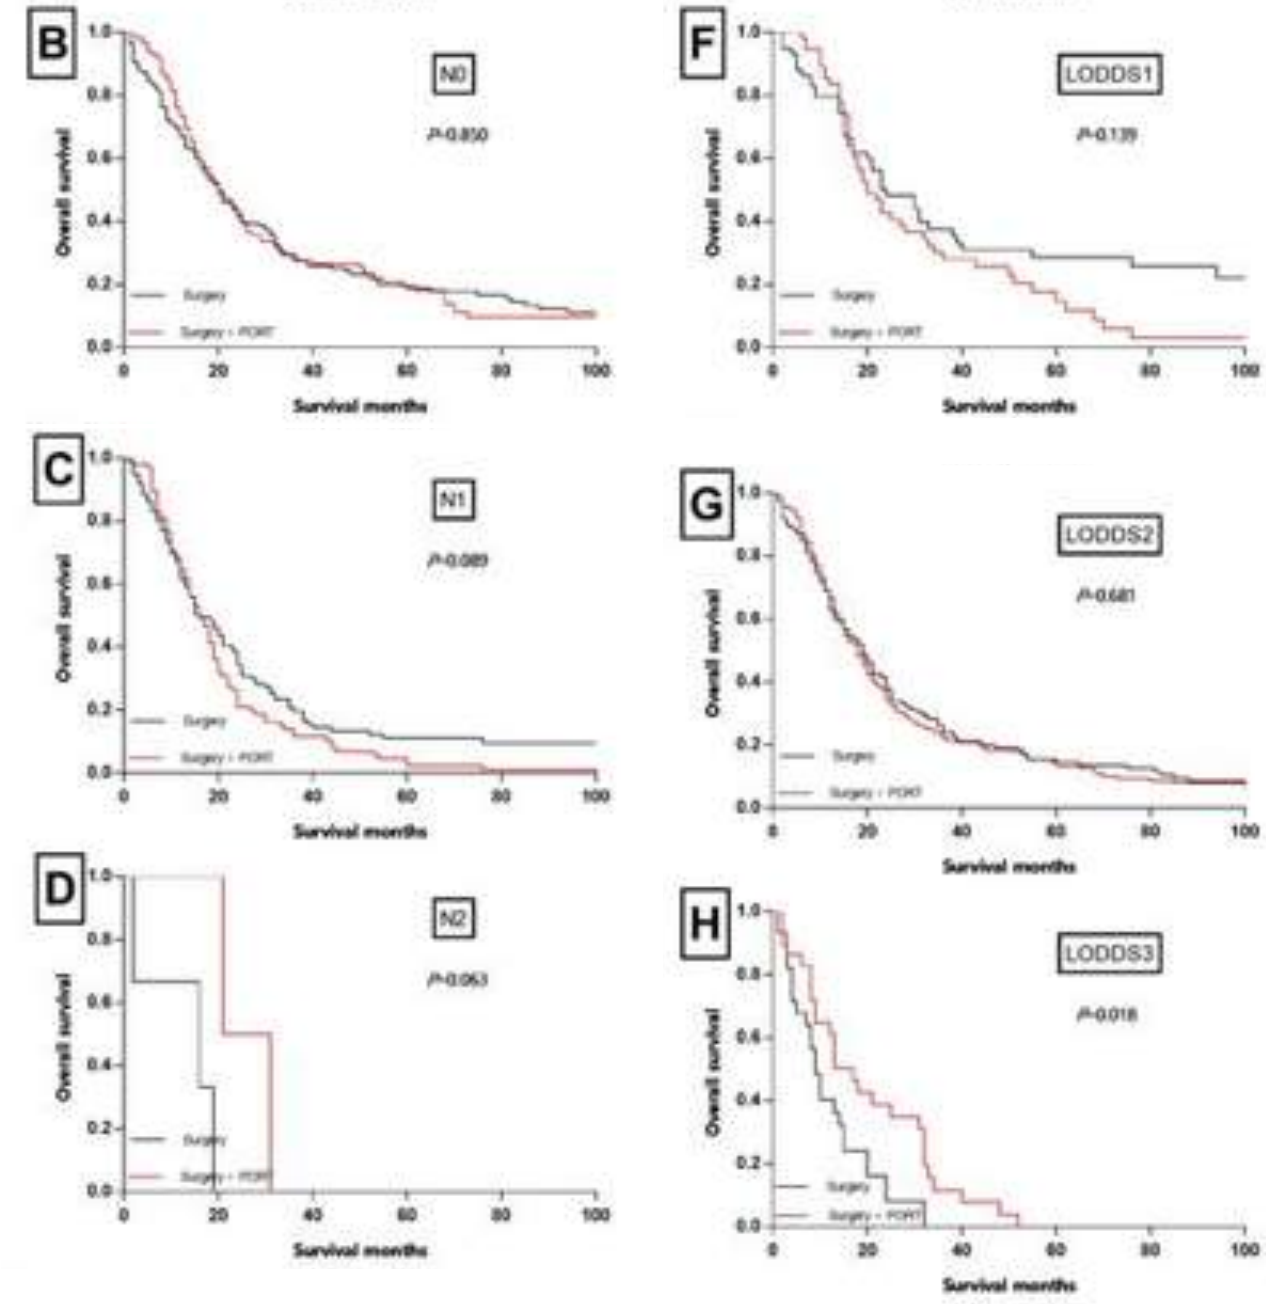


Figure 1 Survival curves stratified by (A) N stages, (B) treatment modality in N0, (C) treatment modality in N1, (D) treatment modality in N2, (E) LODDS, (F) treatment modality in LODDS1, (G) treatment modality in LODDS2, and (H) treatment modality in LODDS3.

Conclusion: LODDS performs better than N descriptors for predicting survival and benefits of PORT in resected MPM, and it could be considered as a potential parameter to compensate for defects in the 8th AJCC TNM staging for MPM.

MA05.03 IMPACT OF TIME TO SURGERY ON OUTCOMES IN PATIENTS UNDERGOING OUTRIGHT RESECTION FOR MALIGNANT PLEURAL MESOTHELIOMA

S. Voigt, V. Raman, O. Jawitz, C.-F.J. Yang, T. D'Amico, D. Harpole

Duke University, Durham/United States of America

Background: We hypothesized that a longer interval to surgery would be associated with worse overall survival for patients with malignant pleural mesothelioma (MPM). **Method:** The National Cancer Database (NCDB) for patients with cT1-3N0-1M0 MPM who underwent surgery without induction therapy. Patients with interval of <1 or >180 days were excluded. Patients were grouped into quartiles based on distribution of time intervals to surgery: Q1 (1-30 days), Q2 (31-50 days), Q3 (51-80 days), and Q4 (>80 days). The primary outcome was overall survival. Secondary outcomes were upstaging to pN2 and margin-positive (>R0) resection rate. Survival was estimated using the Kaplan-Meier and Cox Proportional Hazards methods. Nodal upstaging and >R0 resection rates were modeled with multivariable logistic regression. **Result:** A total of 812 patients met study criteria. The median interval from diagnosis to surgery was 52 days. The unadjusted median survival for Q1, 2, 3, and 4 was 16, 19, 20, and 27 months, respectively (log-rank p=0.004). In multivariable analysis, increased time to surgery was not associated with worse overall survival (Table 1), and Q4 (>80 days) was independently associated with improved survival compared to Q1. When modeled as a continuous variable, an increased time to surgery was associated with a small but clinically insignificant increase in survival (AHR 0.997; 95%CI 0.995-0.999; p=0.005). In a multivariable regression of factors predicting pathologic upstaging to N2, increased time to surgery was significantly associated with upstaging (adjusted odds ratio [AOR] for Q4 compared to Q1: 2.26; 95%CI 1.04-5.28). In a separate regression of >R0 resection, an increased interval to surgery was not associated with margin-positive resection (AOR 0.70; 95%CI 0.41-1.21). **Conclusion:** An increasing interval from diagnosis to definitive surgery for MPM was not associated with worse overall survival or margin-positive resection, but was associated with higher likelihood of pathologic nodal upstaging in this analysis.

Variable	Adjusted HR	95% CI	P value
Interval (ref:Q1) Q2 Q3 Q4	1.07 0.96 0.74	0.84-1.36 0.76-1.22 0.58-0.95	0.61 0.75 0.02

Background: MAPS phase 3 trial assessing the addition of bevacizumab to pemetrexed-cisplatin doublet set a new standard of care in malignant pleural mesothelioma (MPM) patients, showing 18.8 months median overall survival (OS) with triplet combo. While both arms were well balanced in terms of 2L treatments, the size of the OS benefit from second-line treatments remains controversial. **Method:** Long-term survival data were collected in the 342 MAPS patients alive at the end of the first-line (1L) treatments, in both arms. Median OS and 2-year survivals were calculated from the initiation of 2L. Multivariate analysis using Cox model included the stratification variables of the MAPS trial, along with the treatment arm (with or without bevacizumab). **Result:** 342/442(77.4%) patients received 2L treatment for disease progression after MAPS trial, of which 324 received chemotherapy (CT), 18 palliative radiotherapy (RT), while 100/442 (22.6%) remained untreated. 160/342 patients (46.8%) had a platinum-based doublet CT. 163 patients (47.7%) received a single-drug CT. 172/324 (53.1%) received a pemetrexed-containing regimen (alone or with platinum), 84 (25.9%) a gemcitabine-based CT, 16 (4.9%) vinorelbin alone, 48 (14.8%) gemcitabine alone, while in 12 (3.7%) single-agent bevacizumab was resumed. Median age was lower in patients with doublet CT (64.4 years, IQR 60.2-68.9) vs. single-drug CT patients (66.3 years, IQR 61.5-70.3), patients receiving RT (68.5 years, IQR 63.3-70.5) or untreated patients (67.8 years, IQR 63.4-71) (p=0.007). There were more PS=2 patients (10%) in the untreated group, compared with 0.6%, 1.8% and 5.6% in those receiving doublet, monotherapy or radiotherapy, respectively (p<0.001). A lower proportion of patients receiving 2L doublet CT had sarcomatoid/biphasic MPM (11.2%) compared with 21.5%, 38.9% and 25% in those with single-arm agent, RT or untreated, respectively (p=0.002). When compared with those treated with 2L single-agent, patients with 2L doublet had more frequently objective response (11.9 vs. 3.1%, p=0.005) and disease control (60.3 vs. 34.6%, p<0.0001). From the date of 2L therapy initiation, median OS was 3.2 months, 95%CI [1.7-5.0] for RT vs. 7.0 months 95%CI[5.6-7.8] for single-agent CT, or 12.2 months 95%CI [9.5-14.1] for doublet CT. HRs were adjusted for 1L treatment type (bevacizumab-containing or not), PS, smoking, and histology. Adj.HR (single-agent vs. doublet) was 1.21, 95% CI(0.96-1.53), p=0.11. Adj.HR (monotherapy vs. RT) was 0.39, 95%CI[0.24-0.65], p=0.0003. Adj.HR (combination CT vs. RT) was 0.32 95%CI[0.19-0.54], p<0.0001. 1-year OS was 11.8%, 95%CI [0.0-27.1], 48.7%, 95%CI [39.9-57.5], and 32.9%, 95%CI [25.1-40.6], in patients with RT alone, single agent CT or combination CT, while 2-year OS was 0%, 14.2%, and 20.0% respectively. **Conclusion:** Second-line monotherapy only gave a 7-months median OS in MPM patients, comparing unfavorably to 11.9 and 15.9-months median OS with 2nd/3rd-line nivolumab or nivolumab+ipilimumab respectively, in the IFCT-1501 MAPS-2 randomized phase 2 trial. Conversely, 2L platinum-based chemo, in younger fit patients, still gave a 12.2-months median OS, not statistically different from monotherapy in the multivariate analysis, as a consequence of PS influence, although clinically meaningful. Based on these results, immunotherapy might be preferred for 2L/3L MPM patients, while monotherapy CT shows limited survival benefit.

MA05.06 FEASIBILITY AND SAFETY OF TRANSARTERIAL CHEMOPERFUSION FOR ADVANCED PLEURAL MESOTHELIOMA: INTERIM RESULTS OF A PHASE 2 STUDY

B. Creelan, M. Pereira, J. Logeman, B. Morse, D. Jeong, G. El-Haddad, J. Choi, J. Fontaine, T. Tanvetyanon, B. Kis

Moffitt Cancer Center, Tampa/United States of America

Background: Transarterial chemoperfusion (TAC) treatment selectively delivers relatively high concentration of chemotherapy to the targeted tissue's arterial bed maximizing antitumoral effect and minimizing systemic side effects. Advanced malignant pleural mesothelioma (MPM) carries a poor prognosis. The current prospective study investigates the disease control rate, overall survival and adverse events of TAC treatment in patients with recurrent, advanced MPM. This interim analysis reports the feasibility and safety of TAC in advanced MPM. **Method:** Eligibility criteria included progressive disease following at least one line of chemotherapy and with disease site amenable to TAC. The number of prior treatments was 1.95±1.4 (range: 1-6). Patients had TAC treatment in every 4 weeks with cisplatin (35 mg/m^2), methotrexate (100 mg/m^2) and gemcitabine (1000 mg/m^2) via the ipsilateral internal mammary artery and/or descending thoracic aorta. Response rate was evaluated by modified RECIST for mesothelioma. Survival was defined from date of trial enrollment. **Result:** 23 patients, 3 female and 20 males (age 71±6.5 years) were treated between 3/2016-1/2019. Histology was epitheliod 19, sarcomatoid 3, and biphasic 1. At the data cutoff date (January 31, 2019) 15 patients had died and 128 TAC treatments had been performed; 82 via radial artery access

and 42 via femoral artery access. The median number of treatments was 4/patient (range 1-18). There was no treatment related mortality. Major complication rate was 1.6% (1 fever, 1 ischemic stroke, fully recovered). There were 110 events of minor complications; the most common was chest wall pain during TAC into the internal mammary artery (52), followed by nausea (20). The disease control rate was 70% (1 PR, 15 SD, 7 PD). In addition, clinical benefits of localized tumor shrinkage in the chemoperfused area were observed. Median progression free survival was 4.6 months (95% CI 1.1-8). Median OS was 7.9 months (95% CI 3.6-12.3). **Conclusion:** TAC treatment with triplet chemotherapy in every 4 weeks is feasible and safe. The treatment has promising disease control rate in this group of heavily pretreated patients with MPM. ClinicalTrials.gov Identifier: NCT02611037

MA05.07 EFFICACY AND SAFETY OF RE-TREATMENT WITH TREMELIMUMAB AND DURVALUMAB WITHIN THE NIBIT-MESO-1 STUDY

L. Calabro'[1], G. Rossi[1], A. Morra[2], A.M. Di Giacomo[1], G. Amato[1], C. Rosati[1], O. Cutaia[1], M.G. Daffinà[1], D. Giannarelli[3], M. Maio[1]

[1]*Center for Immuno-Oncology, University Hospital of Siena, Siena/Italy,* [2]*Department of Radiology, Euganea Medica Diagnostic Center, Padua/Italy,* [3]*Regina Elena National Cancer Institute, ROME/Italy*

Background: Targeting immune-checkpoint inhibitors (ICI) had proven effective in a variety of tumor types. However, primary and secondary resistance to treatment is emerging as a major limitation of ICI therapy, and scattered information is available on the therapeutic efficacy of re-treatment in ICI-resistant subjects. Here we investigated the efficacy and safety of re-treatment with tremelimumab and durvalumab in malignant mesothelioma (MM) patients who developed resistance to these agents in the phase II NIBIT-MESO-1 study (Calabrò L et al, Lancet Resp Med 2018). **Method:** Patients eligible for re-treatment *per* the NIBIT-MESO-1 protocol were those who completed 4 dosing cycles of tremelimumab combined with durvalumab, and achieved partial response (PR) or stable disease (SD), followed by progressive disease (PD) during the maintenance with durvalumab or the follow-up phase. Subjects who met the re-treatment criteria received tremelimumab (1 mg/Kg, i.v.) and durvalumab (20 mg/Kg, i.v.) every 4 weeks (Q4W) for 4 doses (re-induction phase), followed by durvalumab (20 mg/Kg, i.v.) Q4W for additional 9 doses (maintenance phase). Objective response rate (ORR), disease control rate (DCR), *per* immune-related (ir)-modified RECIST criteria, overall survival (OS), and safety were evaluated. Adverse events (AEs) were recorded according to CTC v4.0. **Result:** Seventeen (42.5%) of the 40 MM patients enrolled in the NIBIT-MESO-1 study met the criteria for re-treatment and received therapy. Among them 8 (47%) completed the re-induction phase, 7 (41.2.%) went on maintenance phase, and 1 (5%) entered the follow-up phase. As of April 1st 2019, 16/17 patients were discontinued during re-treatment because of PD, and 7 received additional lines of therapy. Seven out of the 17 (41.2%) re-treated subjects had an irSD, while no ir-ORR were observed. At a median follow-up of 35.8 months, median OS of re-treated patients was significantly (p=0.005) higher (25.6 months, 95% CI: 6.1-45.1) as compared to the 23 subjects who were not re-treated (9.9 months, 95% CI: 7.7-12.1). Grade 1-2 irAEs occurred in 6/17 (35%) re-treated patients, were most frequently dermatological and reversible *per* protocol guideline; no grade 3-4 irAEs were observed. **Conclusion:** Re-treatment with tremelimumab and durvalumab of MM patients who developed resistance to therapy in the course of the NIBIT-MESO-1 study is clinically effective and safe in a sizeable proportion of re-treated subjects. Clinical trial infomation: NCT02588131

MA05.09 REAL-WORLD DATA OF NIVOLUMAB AND PEMBROLIZUMAB IN CHEMOTHERAPY PRE-TREATED MESOTHELIOMA PATIENTS

D. Dumoulin, L. Cantini, B. Belderbos, D. Mercieca, R. Cornelissen, J. Aerts

Erasmus University Medical Center, Rotterdam/Netherlands

Background: Both nivolumab and pembrolizumab have shown positive results in phase II studies in patients following chemotherapy in mesothelioma patients. However, these studies were done in a limited number of patients with strict inclusion criteria, while reports show a difference between real life and study setting. **Method:** In our mesothelioma center, we treated patients that progressed during or after chemotherapy treatment with nivolumab 3mg/kg once every 2 weeks independent of PD-L1 expression or with pembrolizumab 200mg once every 3 weeks when PD-L1 expression was ³1%, both in Early Patient Access programs. All patients were pre-treated with at least one cycle of platinum/folate treatment. CT scan evaluation was done using modified RECIST every 6 weeks. **Result:** In total, we treated 78 patients with nivolumab and 13 patients with pembrolizumab. Median age of the patients was 71 years (29-85) at start of the checkpoint inhibitor treatment, 80 (88%) were male. Performance status was ECOG 0 in 19 patients, ECOG 1 in 57 patients, ECOG 2 in 9 patients. Data analysis thus far showed 9 partial responses (10%) and 31 patients with stable disease (29%) and therefore a disease control rate of 39% at twelve weeks of treatment. Median progression free survival is 2.4 months and median overall survival 6,3 months. Median duration of response had not been reached yet. These data will be updated for the meeting. Two cases of pseudoprogression were seen on checkpoint inhibition therapy where progression according to modified RECIST was followed by response during continuation of PD-1 therapy. Toxicity was in line with historical data. **Conclusion:** We believe that this large dataset, using real-world data, can truly give an insight in the clinical benefit of these immune checkpoint inhibitors. In comparison with the published phase I and II trials on nivolumab and pembrolizumab, the response rates appear to be lower in a real-life setting. However, clinically meaningful and durable responses are seen in a population that has no other proven therapy options.

Background: Checkpoint inhibitor (CPI) therapies have demonstrated clinical benefit in patients (pts) with malignant pleural mesothelioma (MPM) and are now included in the NCCN guidelines as an acceptable treatment option. Herein, we report our initial experience treating pts with MPM in the palliative second line or greater setting. **Method:** Between January 2016 and November 2018, 74 pts with biopsy proven MPM were treated with pembrolizumab every three weeks until confirmed disease progression or unacceptable toxicity. Progression-free survival (PFS) and OS were defined as the time from first pembrolizumab dose to recurrence and death, respectively, or to last contact. Response rates (RR) were measured by a dedicated thoracic radiologist using modified RECIST 1.1 criteria. Adverse events were routinely recorded/scored at each follow up visit. according to CTCAE 4.0 with level of attribution to pembrolizumab. **Result:** Demographics of the 74 pt cohort are shown in table 1. Twenty-nine (39%) of pts experienceda total of 39

grade 1-2 adverse events, possibly or definitely related to therapy (Table 2). There was one grade 4pneumonitis that resulted in new requirement for oxygen, which resolved with steroids; and one patient experienced leukoencephalopathy that resulted in death. The overall response rate (including only partial responses by modified RECIST 1.1) for the entire cohort was 26%. Median progression free survival and overall survival for the entire cohort were 2.8 months and 7.9 months, respectively.

Table 1: Demographics		
Age in Years	median (range)	
Min	73	(52-92)
Gender	Patients (N=74)	
Female	29	39%

Conclusion: Pembrolizumab in the Tx of MPM was reasonably well tolerated in this large, single institution experience. RR, PFS and OS appear remarkably similar to recent published data from a registry study of off-label use of pembrolizumab in pts with MPM in Switzerland and Australia (include reference). Ongoing studies include analysis of PDL-1 and other potential immunotherapy response biomarkers.

MA05.11 SAFETY AND EFFICACY OF NINTEDANIB IN COMBINATION WITH PEMBROLIZUMAB IN PATIENTS WITH REFRACTORY/RELAPSING MALIGNANT PLEURAL MESOTHELIOMA

A. Varga[1], G. Zalcman[2], C. Gomez-Roca[3], S. Ammari[4], C. Caramella[4], V. Gounant[2], A. Rabeau[3], X. Paoletti[5], C. Baldini[1], P. Martin-Romano[1], S. Champiat[1], P. Vuagnat[1], J. Michot[1], L. Mezquita[6], C. Massard[1], B. Besse[6], J.C. Soria[1], A. Marabelle[1], D. Planchard[7]

[1]*Drug Development Department, Gustave Roussy Cancer Campus, Villejuif/France,* [2]*Ap-Hp Hôpital Bichat, Paris/France,* [3]*Recherche Clinique, Institut Universitaire Du Cancer de Toulouse, Toulouse/France,* [4]*Radiology Department, Gustave Roussy Cancer Campus, Villejuif/France,* [5]*Biostatistics, Gustave Roussy Cancer Campus, Villejuif/France,* [6]*Medical Oncology, Thoracic Group, Gustave Roussy Cancer Campus, Villejuif/France,* [7]*Department of Medical Oncology, Thoracic Group, Gustave Roussy Cancer Campus, Villejuif/France*

Background: Malignant pleural mesothelioma (MPM) is an aggressive disease with no standard of care after progression to first line pemetrexed and platinum-based chemotherapy. Combinations between anti-angiogenic agents and immunotherapy are being developed as angiogenesis and immunosuppression influence each other leading to a more powerful anti-tumor response. Both Nintedanib and Pembrolizumab have been investigated as single agents or in different treatment combinations in MPM patients with interesting activity. **Method:** The PEMBIB trial is a multi-centric open-label non-randomized basket phase 1 trial evaluating the combination of nintedanib with pembrolizumab in multiple tumor types. The safety and activity of the dose escalation part of the study were reported at AACR & ASCO meetings in 2018 with an established DLT defined as grade 3 alanine and/or aspartate aminotransferase elevation (ALT/AST). The recommended phase 2 dose is set at 150

mg BID of nintedanib with 200 mg flat dose of pembrolizumab. We would like to report the safety and activity of one of the expansion cohorts of patients with relapsing/refractory MPM which has now been completed. Eligible MPM patients were 18 years or older with an ECOG performance status of 0 or 1, histologically proven MPM that relapsed after at least one line of pemetrexed and platinum-based combination, specific anti-angiogenic eligibility criteria such as no radiographic evidence of cavitary/necrotic or tumors with local invasion of major blood vessels. Updated results on the safety profile and efficacy of this anti-angiogenic and anti-PD-1 combination therapy including overall response rate as per RECIST, irRC and mRECIST criteria, disease control rate will be presented at the meeting. **Result:** The first patient from the MPM cohort was enrolled in July 2017 and the last one in April 2019. Thirty-one eligible MPM patients have been evaluable at the data cut off onJuly 2019, one of them had been enrolled since the dose-escalation part at dose level of 200mg. The age at inclusion was 68 (ranging from 38 to 85), 68% of the patients having an ECOG of 1 and 58% of the histological type was epithelioid. The most frequent adverse events (grades 1, 2 and 3) related to any of the combination drugs were liver enzymes increase, fatigue, decreased appetite, nausea, diarrhea and hypothyroidism. There were two cases of myocarditis, one of grade 3 (pembrolizumab related) and one of grade 5(pembrolizumab and nintedanib related). At the time of the data analysis the efficacy data shows six partial responses (overall response rate of 21%) and seventeen stable disease (disease control rate at 61%.). **Conclusion:** The combination of Nintedanib with Pembrolizumab shows promising activity in relapsed MPM patients .The toxicity profile appear consistent with previous reports of anti-angiogenic agents and immunotherapy combination.

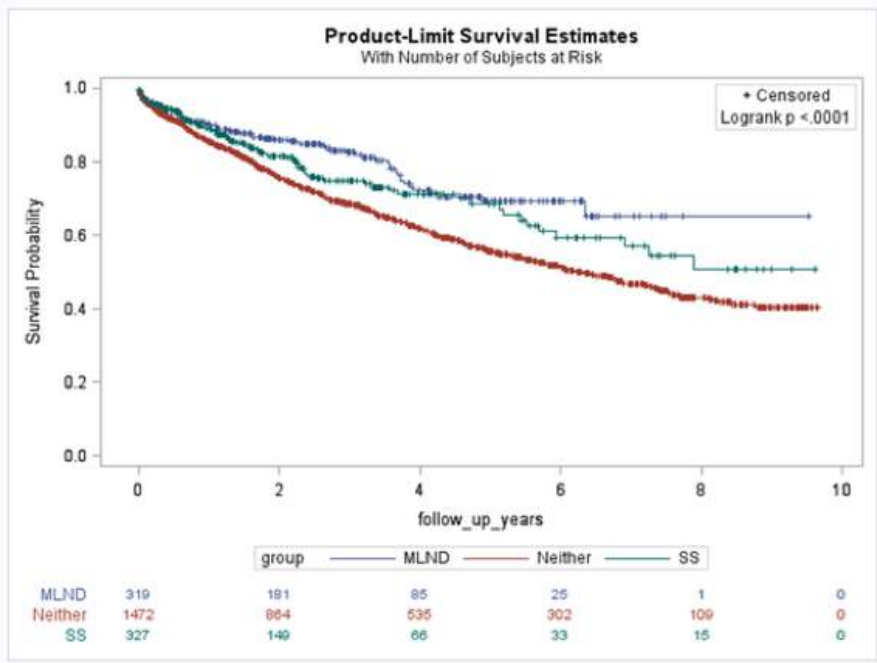
Keywords: mesothelioma, nintedanib, pembrolizumab

MA06.01 MEDIASTINAL LYMPH NODE DISSECTION (MLND) V SYSTEMATIC SAMPLING (SS) V NEITHER (NN) IN POPULATION-BASED COHORT

M. Ray[1], N. Faris[2], C. Fehnel[2], C. Houston-Harris[2], O. Akinbobola[2], P. Ojeabulu[2], M. Smeltzer[1], R. Osarogiagbon[2]

[1]*University of Memphis, Memphis/United States of America,* [2]*Baptist Cancer Center, Memphis/United States of America*

Background: American College of Surgeons' Oncology Group (ACOSOG) Z0030 revealed similar survival after MLND v SS for early-stage non-small cell lung cancer (NSCLC), but a recent meta-analysis of 1,980 patients in 5 randomized controlled trials from 1989-2007 suggested superior survival after MLND, raising doubts about Z0030 findings. We compared survival of patients with MLND v SS v NN in a population-based cohort. **Method:** All resections for NSCLC in all institutions within 4 contiguous United States Hospital Referral Regions from 2009-2018 stratified by ACOSOG Z0030 nodal examination criteria into MLND (stations 2R,4R, 7, 8, 9 and 10R for right-side resections; 4L, 5, 6, 7, 8, 9, and 10L for left-sided), SS (minimum of 4R, 7, and 10R on the right and 5,6,7 and 10L on the left, but MLND definition not met), and NN (neither MLND nor SS). Using appropriate statistical tests, we compared demographic and clinical characteristics, perioperative complication rates and survival, adjusting survival for extent of resection, histology, age, race, sex and insurance. **Result:** 2118 patients met Z0030 eligibility criteria (clinical T1/2,N0/non-hilar N1,M0): 15% had MLND, 15% SS, 69% NN. The distribution of age, race, insurance was similar, but 54% v 51% v 43% of MLND v SS v NN, were female (p=.0002). Use of preoperative PET-CT scans was similar (p=.5797), but invasive staging was used in 21% v 19% v 28% (p<.01), Although the distribution of clinical T,N and aggregate stage was similar (p>.05), 10% of the patients who met neither MLND nor SS criteria had no lymph nodes examined (pathologic NX). The median (interquartile range) number of mediastinal lymph nodes examined was 8(6-12), 5(4-8), 2 (0-5) (p<.001); hilar/intrapulmonary nodes 5(2-9), 6(3-10), 3(1-7) (p<.001). Postoperative complication rates were similar, including rates of cardiac arrhythmia, chylothorax and ICU re-admission. ICU length of stay (LOS) was 1(1-2) days in all groups, hospital LOS was 5(3-7), 5(3-8), 6(4-10) days. The 30-day mortality rate was 4% for all groups. Unadjusted hazard ratio (HR) was 0.80 (0.56-1.10, p=1.664) between MLND and SS; adjusted (a)HR 0.81 (0.58-1.138, p=0.2273). Survival of MLND and SS patients was significantly better than NN (Figure): aHR 0.62(0.48-0.81, p=0.0004) for MLND v NN; aHR 0.76 (0.60-0.98, p=0.0304) for SS v NN.



Conclusion: ACOSOG systematic nodal dissection was achievable and safe in a 'real-world,' population-based cohort. SS was associated with similar survival to MLND in early-stage NSCLC, corroborating Z0030 findings. However, the majority of resections did not attain either criteria, with significantly worse survival.

MA06 CHALLENGES IN THE TREATMENT OF EARLY STAGE NSCLC
SUNDAY, SEPTEMBER 8 13:30–15:00

MA06.02 NSCLC SURGERY OUTCOMES BETWEEN FACILITY TYPES AND ASSOCIATION WITH GUIDELINE DIRECTED SURGICAL QUALITY OF CARE METRICS

M. Von Itzstein[1], R. Lu[1], Y. Xie[1], D. Gerber[2]

[1]UT Southwestern, Dallas/United States of America, [2]UT Southwestern Medical Center, Dallas/United States of America

Background: Non-small cell lung cancer (NSCLC) treatment outcomes differ between facility types. Surgical outcome differences may be related to modifiable factors and likelihood of receiving guideline centered care, which could be improved with new policy initiatives. We therefore analyzed the National Cancer Database (NCDB), to determine the variables related to different outcomes between facility types. **Method:** The NCDB is a cancer registry curated by the Commission on Cancer that captures demographic and clinical data for an estimated 80% of NSCLC patients in the United States. A retrospective analysis of the NCDB was performed from 2004-2013 for Stage 1, 2 and 3a NSCLC patients treated with surgery. We compared overall survival between academic comprehensive cancer programs (ACAD) and community cancer programs (CCP) and four surgical quality metrics; lobectomy or greater vs sublobectomy, positive vs negative margin status, whether regional lymph node (LN) surgery was performed and number of nodes removed (less that 10 or equal to or greater than 10), in addition to 16 other demographic and clinical variables known to affect NSCLC survival. Kaplan-Meier estimates, log-rank test, multivariate Cox proportional hazard models and propensity score matching were used to evaluate survival differences while adjusting the effects of covariates. Quality of matching was checked using Wilcoxon rank sign test, chi-square test, and multivariate logistic regression models. **Result:** The total cohort was 75,976 patients. After propensity matching for clinical and demographic variables, median overall survival (OS) for Stage 1, 2 and 3a was 76, 51 and 36 months for ACAD and 67, 43 and 32 months for CCP respectively ($p<0.002$ for all). Overall, selection of lobectomy or greater was the same between facility types ($p=0.645$), but ACAD were more likely to have negative margins (92.3% vs 89.8%, $p<0.00001$), perform LN dissection (89.5% vs 84.3%%, $p<0.00001$) and remove greater than 10 LN (37.4% vs 23.1%%, $p<0.00001$). After contrast matching for the surgical quality metrics, OS for Stage 1, 2 and 3a was 73, 49 and 34 months for ACAD and 67, 43 and 32 months at CCP respectively, with a non-significant P value for Stage 3a sub-cohort. Analysis revealed that the four key surgical quality measures explained 38% of the OS difference in median survival ($p<0.00001$). **Conclusion:** In this large cohort of Stage 1, 2 and 3a NSCLC patients treated surgically, OS was higher at ACAD compared to CCP, which was in part explained by differences in surgical quality metrics. In the era of discussions of nationalized healthcare, policymakers will need to consider the differential treatment outcomes at different centers and consider consolidating treatment for NSCLC at high performing centers or improving the quality care measures of low performing centers.

SUNDAY, SEPTEMBER 8 13:30–15:00

MA06.03 POOR PULMONARY FUNCTION DOES NOT DEFINE "MEDICAL INOPERABILITY": SHORT AND LONG TERM RESULTS OF A MATCHED LUNG CANCER COHORT

A. Sholi, M. Kamel, A. Nasar, A. Naik, S. Harrison, B. Lee, J. Port, N. Altorki, B. Stiles

New York Presbyterian Hospital-Weill Cornell Medical College, New York/ United States of America

Background: Patients with suboptimal pulmonary function tests (PFTs) are often denied surgery for NSCLC. However, there is no consensus definition of compromised lung function. This study compared morbidity and survival following surgery in patients with preoperative %predicted FEV_1 or DLCO ≤50% (Low-Group) versus those with both values >50%(High-Group). **Method:** A prospectively-maintained database was reviewed for patients undergoing surgery for NSCLC between 1990–2019. Propensity matching (1:2) was performed based on age, gender, histology, pathologic stage, and comorbidity index. Overall survival (OS) was estimated using Kaplan-Meier analysis and multivariable analysis identified predictors of survival. **Result:** Among 2982 patients with PFT data, 372(12.5%) had FEV_1 or DLCO ≤50%. We matched 321 patients with FEV_1 or DLCO ≤50% to 637 patients with both PFTs >50%. No significant differences were observed in perioperative complications(Table) or 30-day mortality between Low and High groups (0.3% vs. 0.6%, $p=0.668$). The Low group more frequently underwent sublobar resection (41% vs. 22%, $p<0.001$). Median follow-up was 41 months, and median, 3-, and 5-year OS for the Low and High groups was 118 vs.148 months, 79% vs. 82%, and 70% vs. 74%, respectively ($p=0.003$). Patients with both FEV_1 and DLCO ≤50% (n=44) had a median survival of 109 months and 3- and 5-year OS of 77% and 71%. Multivariable analysis identified advanced age (HR=1.03, CI 1.01–1.05), higher clinical stage (HR=1.85, CI 1.22–2.82), and earlier year of surgery (HR=1.06, CI 1.01–1.12) as predictors of poor survival, but not FEV_1 or DLCO ≤50% ($p=0.672$). Among the Low group only, advanced age (HR=1.05, CI 1.02–1.07) and sublobar resection (HR=1.60, CI 1.04–2.45) predicted worse OS.

Matched Patients (N= 958)	Low PFT Group (N= 321)	High PFT Group (N= 637)	P value
Median LOS, days (IQR)	5 (4 – 8)	5 (4 – 6)	< 0.001
Any complication	69 (22%)	115 (18%)	0.202
Pulmonary complications	51 (16%)	74 (12%)	0.064
Cardiovascular complications	22 (7%)	40 (6%)	0.733
Thromboembolic complications	3 (1%)	6 (1%)	1
Infectious complications	8 (2%)	14 (2%)	0.774
Mortality (30-day)	1 (0.3%)	4 (0.6%)	0.668
Median survival, months (IQR)	118 (107 – 132)	148 (139 – 152)	0.003
5-year Overall Survival	70%	74%	

Conclusion: Patients with decreased lung function have comparable perioperative outcomes to patients with normal lung function and experience excellent long-term survival. "Medical inoperability" should therefore be determined by surgeons and not by pulmonary function alone.

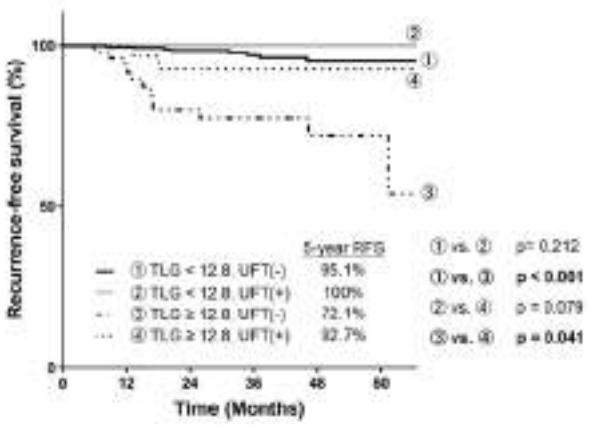
MA06.05 PREDICTIVE PERFORMANCE OF QUANTITATIVE METABOLIC METRICS OF FDG-PET/CT ON SURVIVAL AND THE EFFECT OF ADJUVANT CHEMOTHERAPY IN LUNG CANCER

Y. Makino, Y. Shimada, S. Maehara, H. Masaru, M. Kakihana, N. Kajiwara, T. Ohira, N. Ikeda

Tokyo Medical University, Tokyo/Japan

Background: Growing evidence suggests metabolic metrics of tumors, maximum standardized uptake value (SUVmax), metabolic tumor volume (MTV), and total lesion glycolysis (TLG) on FDG-PET/CT, reflect the malignancy of early-staged lung cancer. We aimed to investigate the role of metabolic metrics in predicting prognosis and response to adjuvant chemotherapy in pathological stage I (the 7th Edition of TNM Staging of Lung Cancer) lung adenocarcinoma (p-I Ad). **Method:** The study included 452 patients with p-I Ad who underwent FDG-PET/CT followed by complete resection between July 2012 and December 2017. In this study, MTV is defined as the total tumor volume with an SUV > 2.5 while TLG is calculated as mean of SUV x MTV. The three metabolic metrics measured by a three-dimensional workstation and clinico-pathological factors were analyzed to identify the factors associated with unfavorable overall survival (OS) and recurrence-free survival (RFS). We assessed whether the metabolic metrics were associated with response to oral adjuvant chemotherapy with uracil-tegafur (AC with UFT) in patients with p-I Ad amenable to the treatment. **Result:** All the three metabolic metrics were significantly correlated with unfavorable OS and RFS on univariate analyses (SUVmax; p=0.047 / p<0.001, MTV2.5; p=0.003 / p<0.001, TLG2.5; p=0.005 / p<0.001). On multivariate analyses, smoking status (p=0.043), the value of serum CEA (p < 0.001), and SUVmax (p=0.001) were independent determinants for poorer RFS while gender (p=0.013) and MTV2.5 (p=0.028) were independent significant factors for unfavorable OS. The receiver operating characteristic areas under the curves for SUVmax, MTV2.5, and TLG2.5 relevant to recurrence were 0.901, 0.849, and 0.872, respectively. Among 239 patients who fitted the criteria of AC with UFT (p-IA > 2cm or p-IB), 80 patients (33.4%) received the treatment (250 mg of tegafur per square meter of body-surface area per day). Although the administration of AC with UFT did not significantly affect RFS and OS (p=0.411 and 0.753), patients with TLG2.5 > 12.8, which value corresponded to the cut-off level, who were not given AC with UFT exhibited worse RFS than those who received the treatment (5-year RFS rate of 72.1% vs. 92.7%; p=0.041).



Conclusion: Metabolic metrics on FDG-PET/CT such as SUVmax, MTV, and TLG enable us to estimate survival outcomes and the effectiveness of AC with UFT in patients with p-I Ad. Patients with metabolically active tumors should be considered high risk, and this information can be useful for the selection of appropriate therapeutic strategy including AC with UFT.

Background: Post-operative UFT (tegafur/uracil) has been shown to prolong survival of Japanese patients with completely resected, p-stage I (T1> 2 cm) non-small cell lung cancer (NSCLC). This trial, the Japan Clinical Oncology Group (JCOG) 0707, aimed at estimating the efficacy of S-1 (tegafur/gimeracil/oteracil) compared to UFT as adjuvant therapy in this population. **Method:** Eligible patients had received complete resection with lymph node dissection for p-stage I (T1-2N0M0, T1> 2 cm, by 5thEdition UICC TNM) NSCLC, within 56 days of enrollment. Patients were randomized to receive: oral UFT 250mg/m^2/day for 2 years (Arm A), or oral S-1 80mg/m^2/day for 2 weeks and 1 week rest, for 1 year (Arm B). The initial primary endpoint was overall survival (OS). Based upon the monitoring in Jun. 2013, which showed the combined OS of the 2 arms better than expected (4-year OS of 91.6% vs. presumed 5-year OS of 70-76.5%), it was judged to be underpowered. The study protocol was amended so that the primary endpoint is relapse-free survival (RFS). With the calculated sample size of 960, this study would detect the superiority of Arm B over Arm A with power 80% and one-sided type I error of 0.05, assuming the 5-year RFS of 75% in Arm A and the hazard ratio of 0.75. **Result:** From Nov. 2008 to Dec. 2013, 963 patients were enrolled (Arm A:482, Arm B:481): median age 66 (range: 33 to 80), male 58%, adenocarcinoma 80%, p-T1/T2 46%/54%. Only 2 received pneumonectomy. ≥Grade 3 toxicities (hematologic/nonhematologic) were observed in 15.9 (1.5/14.7) % in Arm A, and in 14.9 (3.6/12.1) % in Arm B, respectively. 60.0% of the patients in Arm A and 54.7% of them in Arm B completed the protocol treatment (p=0.10). There were 4 cases of deaths during protocol treatment, probably of cardio-vascular origin, with 1 in Arm A and 3 in Arm B. At the data cut-off of Dec. 2018, the hazard ratio (HR, Arm B vs. Arm A) of RFS was 1.06 (95% confidence interval (C.I.): 0.82-1.36), showing no superiority of S-1 over UFT. The HR of OS was 1.10 (95% C.I.: 0.81-1.50). The 5-year RFS/OS rates were 79.4%/88.8% in Arm A and 79.5%/89.7% in Arm B, respectively. Pre-specified subset analyses for gender, age, smoking, stage, tumor side, lymph node dissection area, pleural invasion and histology revealed no remarkable results; S-1 arm was not superior to UFT arm in each analysis. Of the 77 and 85 OS events for Arm A/Arm B, 45 each (58%/53%, respectively) were due to the NSCLC. During the follow-up period, secondary malignancy was observed in 85 (17.8%) and 84 (17.8%) in Arm A and Arm B, respectively. **Conclusion:** Post-operative adjuvant therapy with oral S-1 was not superior to that with UFT in stage I (T>2 cm) NSCLC after complete resection. UFT remains standard in this population. Future investigation should incorporate identification of high-risk population for recurrence, since survival of each arm was so good with substantial number of OS events due to other causes of deaths in this trial.

Background: Adjuvant chemotherapy (chemo) for resected early stage NSCLC provides modest survival benefit with limited comparison data between regimens. From this trial we previously reported that adding bevacizumab (B) to adjuvant chemo failed to improve either disease free survival (DFS) or overall survival (OS). Here we update outcomes by chemotherapy regimen with an additional 30 months of follow-up. **Method:** Enrolled patients with resected early stage NSCLC, stratified by stage, histology, sex, and chemo option, were randomized 1:1 to chemo alone or with B (15 mg/kg every 3 weeks for up to 1 year). Chemo consisted of a planned 4 cycles of every 3 week cisplatin with either vinorelbine (V), docetaxel (D), gemcitabine (G) or pemetrexed (P). **Result:** From July 2007 to September 2013, 1501 patients were enrolled with this distribution of chemo: V 25.0%, D 22.9%, G 18.9% and P 33.2%. P was added in 2009 and restricted to non-squamous (NSq) pts. Chemo regimen was chosen (not randomized). Arms were well balanced for known prognostic factors; 28% had Sq histology. Median f/up per chemo group is: V 83.5 months(m); D 89.9m; G 87.8m; P 71.9m. In pooled analysis DFS differed by histology ranging from 29.9m(G)-43.5m(V) for NSq and 59.4m(V)-77.3m(G) for Sq. OS also differed by histology ranging from 80m(D)-98.8m(P) for NSq and 98m(G)-119m(V) for Sq. A non-significant decline in both DFS and OS was seen when B was added to D or V regimens, regardless of histology. Conversely, the addition of B to P improved both DFS (HR 0.74, p= .00994) and OS (HR 0.65, p= .00368). We thus compared outcomes across non-B regimens and though numerical differences were seen in median DFS and OS, these failed to reach statistical significance. Toxicity details were presented previously. **Conclusion:** B did not improve OS when added to adjuvant chemo for patients with surgically resected early stage NSCLC, though variable DFS and OS outcomes by chemotherapy regimen have emerged with longer-term follow-up. These include a significant positive improvement in DFS and OS with B combined with P and trends of worse outcomes when B was added to other regimens. Ongoing molecular analysis of samples will hopefully elucidate the etiology of these differences.

MA06.09 TIMING OF DRIVER MUTATION DEVELOPMENT AND THE GENETIC EVOLUTION OF SEMI-SOLID LUNG NODULES INTO EARLY NSCLC

G. Woodard, V. Ding, I.-J. Kim, K. Jones, G. Chavez, G. Haro, J. Kratz, M. Mann, J. Rotow, C. Blakely, D. Jablons

University of California San Francisco, San Francisco/United States of America

Background: The genetic changes that drive the appearance of a ground glass opacity and subsequent development of an invasive solid component within a semi-solid lesion (SSL) are not well understood. Biomarkers that predict the transition to invasive cancer are needed to determine when ground glass lesions will evolve into invasive cancer. **Method:** From a prospective database 65 patients with surgically resected SSL between 2011-2018 were identified. Clinical characteristics and disease free survival was compared between SSL and 155 stage I adenocarcinomas resected during the same time period. Paraffin tissue blocks were obtained from 22 of the SSL and areas of normal lung (NL) ground glass (GG) and solid (S) tumor were identified and microdissected separately from within the same lesion. Next generation sequencing (NGS) was performed on DNA extracted from 19 nineteen matched GG and S samples on twenty-five common lung cancer driver mutations. Affymetrix microarray of over 48,000 transcripts was performed on S, GG, and NL samples from eight patients with SSL. **Result:** No patients with a resected SSL has recurred to date with significant differences in 5-year disease free survival verses stage I adenocarcinomas from the same time period (100% vs 80.9%, log-rank p-value 0.007). Driver mutations in the solid component of SSL were EGFR mutation (43%; L858R 26% and exon 19 deletion 11%), KRAS mutation (21%), and no mutation identified (42%). All driver mutations present in S component of SSL were also identified in GG regions of the same lesion with very similar gene expression profiles. Only 32 transcripts were significantly different between GG and S areas of the same tumor. The greatest difference observed between GG and S portions of the same tumor was significantly higher expression of secreted phosphoprotein 1 (SPP1) in the invasive solid portion suggesting that SPP1 may serve as a biomarker of invasive potential. **Conclusion:** This is the first study to examine the systems genetics of mutations and gene expression from the microenvironments of solid and ground glass areas within the same tumor. Mutations are present in the ground glass portion of a semi-solid tumor suggesting early development of driver mutations. Increased expression of SPP1 emerged as the most promising biomarker of invasive potential of a semi-solid lesion. In other studies SPP1 has been shown to correlate with poor prognosis and is a biomarker that warrants further study.

MA06.10 STEREOTACTIC ABLATIVE RADIOTHERAPY IN THE MANAGEMENT OF SYNCHRONOUS EARLY STAGE NON-SMALL CELL LUNG CANCERS

Z. Ayoub, E. Brooks, J. Welsh, A. Chen, S. Gandhi, J. Heymach, A. Vaporciyan, J. Chang

UT MDACC, Houston/United States of America

Background: The aim of the study is to evaluate the efficacy and patterns of failure of early stage synchronous non-small cell lung cancer (NSCLC) treated with stereotactic ablative radiotherapy (SABR). **Method:** Patients with synchronous NSCLC who received SABR (50 grays in 4 fractions or 70 grays in 10 fractions) to at least one lesion were reviewed. Synchronous lesions were defined as multiple ipsilateral or contralateral intrapulmonary lesions diagnosed within 6 months. **Result:** Out of a total of 912 patients treated with SABR for early stage NSCLC between 2005 and 2015, 82 (9%) had synchronous disease. The median age was 70 years and 34 (41.5 %) patients were males. The median diameter was 2.1 cm (Interquartile range (IQR) 1.6-3 cm) for index lesions and 1.5 cm (IQR 1.1-2.2 cm) for second lesions. At a median follow-up time of 58 months, the 1, 3 and 5-year progression-free survival (PFS) rates were 85.4%, 47.3% and 28.5%, respectively; the corresponding overall survival rates were 95.1%, 66.9% and 52.4% and the 1, 3 and

5-year local recurrence (LR)-free survival rates were 97.3%, 79.6% and 70.8%, respectively. Among the 39 (47.6%) patients with disease progression, intralobal LR was the first site of failure in 15 (18.3%) patients, with a total of 19 local recurrences out of 169 (11.2%) thoracic lesions. Isolated regional recurrence occurred in 3 (3.7%) patients, and distant failure in 221 (25.6%) patients. On multivariate analysis, factors associated with improved PFS were an improved ECOG PS score (HR 10.786; 95% CI 2.845-40.902; p-value <0.001), DLCO (HR 0.947; 95% CI 0.903-0.994; p-value 0.026) and an index lesion pathology of adenocarcinoma (HR 0.167; 95% CI 0.033-0.841; p-value 0.030). Only the ECOG PS score maintained significance (HR 6.165; 95% CI 2.081-18.263; p-value 0.001) on multivariate analysis for OS. No association was found between the use of chemotherapy as part of the initial management strategy and survival outcomes. Similarly, no difference in outcomes was observed whether all lesions were treated with SABR compared to SABR and other modalities. **Conclusion:** SABR achieves promising long-term survival and tumor control rates and may be a potential curative treatment for synchronous early stage NSCLC. Our data indicates that patients presenting with synchronous NSCLC lesions can be approached as having two separate primary lung tumors, and be offered definitive local therapy with aims of cure.

SUNDAY, SEPTEMBER 8 13:30–15:00

MA06.11 CT-GUIDED PERCUTANEOUS RADIOTRACER LOCALIZATION AND RESECTION OF INDISTINCT/SMALL PULMONARY LESIONS

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Detection of small pulmonary lesions has increased and often they are difficult to localize and resect. We present our mature experience with preoperative computer-tomography (CT)-guided radiotracer localization followed by resection of these lesions. **Method:** Patients with pulmonary nodule smaller than 1 cm and/or deep below the visceral pleura underwent CT-guided injection of radiotracer technetium macroaggregates (99mTc-MAA) in/close to the lesion. A gamma probe was used to localize the marked area that was resected and in case of primary lung cancer, a lobectomy with nodal dissection was performed. **Result:** Between November 2007 and December 2017, 262 patients (196 men; median age 63 years) underwent preoperative radiotracer injection with a successful marking in all patients. Complications included 35 (13.4%) asymptomatic pneumothoraces, 36 (13.7%) parenchymal hemorrhage suffusions, and 2 (0.7%) mild allergic reaction to contrast medium. In all cases, except for 3, the gamma probe revealed the pulmonary lesion. Mean distance from the pleura was 10 mm (range, 0-40 mm). Pulmonary resection was performed by thoracoscopy in 212 (80.9%) cases, intentional thoracotomy in 42 (16.0%), converted thoracoscopy in 8 (3.1%). Mean pathological nodule size was 9.3 mm (range, 2-25 mm). 166 (63.4%) nodules were nonsolid, 64 (24.4%) were partially solid, and 32 (12.2%) had a solid morphology. Histology showed 16 (6.1%) benign and 246 (93.9%) malignant lesions (218 primary lung cancers). **Conclusion:** Preoperative radiotracer localization of small/indistinct pulmonary lesions is simple and feasible with a high rate of success. It may be an effective and attractive alternative in managing lung lesions.

[1]*Gustave Roussy, France/France,* [2]*Gustave Roussy Cancer Campus, Villejuif/France,* [3]*Hôpital Européen Georges Pompidou, Paris/France,* [4]*Gustave Roussy, Villejuif/France*

Background: Neutrophils are active regulators of the antitumor immune response, with pro- and antitumor- properties, but generally are associated with progression (PD) and poor outcomes. We reported that pretreatment dNLR ((neutrophils/[leucocytes-neutrophils]; high>3) correlated with immune checkpoint inhibitor (ICI) outcomes in advanced (a) NSCLC pts. Although neutrophil population is heterogeneous, the immature neutrophils (i.e. CD15+CD244-CD16^{low}, among others) seem to be a key subpopulation linked to PD. Tumor-associated neutrophils (TAN) can be also modulator on the microenvironment. We aimed to assess the role of pretreatment circulating immature-neutrophils and tissue-TAN, combined with dNLR, on ICI outcomes in aNSCLC pts. **Method:** aNSCLC pts treated with ICI at our institution between 11/2012 and 08/2018 were eligible. Pretreatment immunophenotyping of monocytes, monocytic MDSC (mMDSC) and granulocytes (CD15, CD11b, CD33, CD244, CD16, CD14, CD32, CD64, HLA-DR) was prospectively performed by flow cytometry in fresh whole blood in 58 pts; we defined immature-neutrophils as CD15+CD244-CD16^{low}. TAN in the stroma were assessed using H&E staining from archival specimen, available from 80 pts. dNLR was retrospectively collected; available from 343 pts. Correlation between baseline circulating neutrophils phenotype, TAN and dNLR was evaluated as well as their impact on outcomes: progression-free survival (PFS), overall (OS), including death before 12 weeks (12wk-death) (fast-PD) **Result:** 366 pts included; 320 (90%) smokers, median age 63; 280 (77%) nonsquamous, 117 (64%) ≥1%PDL1 and 183 missing. Median PFS (mPFS) was 1.93 months (m) [95%CI, 1.8-2.3] and mOS 8.8m [6.5-11.6]. Overall, 12wk-death rate was 31% [25.9-35.6]. Pretreatment high-dNLR (143/343; 42%) was correlated with poor PFS (P=0.002), OS P=0.0003) and a 12wk-death rate of 43% [34.5-50.9]. Pretreatment high immature-neutrophils (30/58; 53%), defined by logrank maximization method (>0.22%), were also associated with poor PFS (P=0.04), OS (P=0.0007) and a 12wk-death rate of 48.7% [26.7-64.1]. TAN (9/80; 11%) were not correlated with outcomes. There was not a correlation between immature-neutrophils, tissue-TAN and dNLR. When evaluating pretreatment immature-neutrophils and dNLR together, we identified a fast-PD phenotype (high immature-neutrophils/high-dNLR, 10/58; 17%), with a mOS of 1.3m [0.73- not reached (NR)] and 12wk-death rate of 60% [14.5-81.3] compared to a responder-phenotype (low immature-neutrophils/low-dNLR, 12/58; 21%), associated with good outcomes: mOS NR [18.23-NR] (P=0.002). **Conclusion:** Pretreatment high circulating immature-neutrophils (CD15+CD244-CD16^{low}) correlate with early failure to ICI and fast-PD phenotype. The combination of circulating immature-neutrophils and dNLR could improve the identification of this population. The impact of immature-neutrophils on ICI should be more deeply explored.

Background: The [neutrophils/[leucocytes-neutrophils] ratio (dNLR) correlates with immune checkpoint inhibitors (ICI) outcomes in advanced non-small cell lung cancer (aNSCLC) patients. Significance of early dNLR change after the first course of ICI is unknown. **Method:** Patients with NSCLC treated with ICI (PD(L)1+/- CTLA4) between Nov. 2012 and Jun. 2018 at 16 EU/US centers were included. A control group treated with chemotherapy (CT) only was also evaluated (NCT02105168). dNLR was collected at baseline (B) and at cycle 2 (C2). Patients were categorized as low vs high dNLR at each timepoint (defined as < vs > 3, as previously done), and the change between B and C2 (good = low at both timepoints, poor = high at both timepoints, mixed = different at each timepoint). **Result:** 1485 patients treated with ICI were analyzed. PDL1 was negative in 162 (11%), 1-49% in 178 (12%), ≥50% in 201 (14%), and missing in 944 (64%). dNLR at B and C2 did not associate with PD-L1 status. At baseline, dNLR was high in 509 (34%) patients and associated with worse PFS compared to those patients with low dNLR at baseline (HR 1.56, P<0.0001) and OS (HR 2.02, P<0.0001). At C2, dNLR was high in 484 (34%) and similarly associated with worse outcomes compared to patients with low dNLR at C2 (PFS HR 1.64, P<0.0001; OS HR 2.13, P<0.0001). Between B and C2, dNLR remained low in 804 (56%, « good ») or high in 327 (23%, « poor ») or changed in 310 pts (22%, « intermediate »). Those with a good dNLR demonstrated mPFS 5.3, mOS 18.6 mo), followed by those intermediate with mixed dNLR (mPFS 3, mOS 9.2 mo), and finally poor dNLR (mPFS 2, mOS 5mo). Outcomes were independant of PD-L1 expression (adjusted HR for PFS 1.94 for intermediate and 3.16 for poor groups, compared to good dNLR group, P<.001; adjusted HR for OS was 2.08 for intermediate and 3.67 for poor groups, *P*<0.001).A bootstrap tested the stability of OS/PFS prediction (*P*<0.001). In the chemo-cohort (n=173), high C1-dNLR (n=81, 47%) was not associated with OS (*P*=0.84). **Conclusion:** dNLR at baseline, at cycle 2, and the change between these two timepoints associated with outcomes in patients treated with immunotherapy independent of PD-L1, but not in patients treated with chemotherapy alone. dNLR is specifically prognostic in the context of immunotherapy.

SUNDAY, SEPTEMBER 8 13:30–15:00

MA07.03 A CIRCULATING MICRORNAS-BASED TEST AS BIOMARKER OF PRIMARY AND SECONDARY RESISTANCE IN PD-L1 ≥50% NSCLC TREATED WITH IMMUNOTHERAPY

C. Proto[1], A. Prelaj[1], C. Verri[2], D. Signorelli[1], G. Lo Russo[1], R. Ferrara[1], G. Galli[1], B. Trevisan[1], M. Mensah[1], F. De Braud[2], M. Garassino[1], G. Sozzi[2], M. Boeri[2]

[1]*Fondazione IRCCS Istituto Nazionale Tumori of Milan, MILAN/Italy,* [2]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/Italy*

Background: PD-L1 represents the only clinically approved biomarker to select patients for immunotherapy. However, about 20-25% of PD-L1≥50% NSCLC patients do not benefit of ICIs treatment. We showed that a plasma microRNA signature classifier (MSC), reflecting the switch towards an immunosuppressive profile of immune cells, identifies NSCLC patients with worse prognosis after ICIs, irrespective from PD-L1 expression. Aim of this trial is to prospectively define the MSC role as biomarker of primary or secondary resistance in PD-L1≥50% NSCLC treated with ICIs. **Method:** Fifty consecutive advanced NSCLC patients with PD-L1≥50% treated with ICI as first (n=32) or further line were enrolled. Plasma samples, as well as demographics information, smoking history and ECOG PS were collected before starting ICI treatment. The MSC test identified patients at high (H) risk vs intermediate/ low (I/L) risk levels. According to RECIST 1.1 criteria, patients were classified as responders (R), patients with stable disease (SD), and progressors (P). Objective Response Rate (ORR), Progression Free Survival (PFS) and Overall Survival (OS) in MSC risk level strata at the baseline were considered as endpoints. For 26 R or SD patients with extended follow-up, additive, not mandatory plasma samples were collected and analyzed at the time of revaluations. To determine changes in the risk level during follow-up, we evaluated changes in the probability of having progressive disease after two consecutive MSC tests, considering all possible combinations. **Result:** Overall 17 (34%) R, 17 (34%) patients with SD, 11 (22%) P and 5 (10%) not evaluable patients were identified. Considering the baseline blood samples 11 (22%) NSCLC patients were MSC H. ORR was 0% in MSC H vs 45% for other patients (p=0.0090). Median PFS was 2.3 months for MSC H vs 10.9 months for other patients (HR=0.38; 95%CI=0.17-0.84; p=0.0174). Median OS was 2.9 months for MSC H vs 22.0 months for other patients (HR=0.18; 95%CI=0.07-0.47; p=0.0004). Data remained significant adjusting for age, sex, pack-years and ECOG performance status: PFS HR=0.31 (95%CI=0.13-0.73; p=0.0072) and OS HR=0.13 (95%CI=0.04-0.39; p=0.0003). Among the 26 patients with longitudinal evaluation of MSC risk level, all the 12 patients reaching progression during treatment showed an increase in the risk level (Sign-test p-value=0.0039). Conversely, when considering the 14 NSCLC patients still maintaining SD or responding to ICIs at the time of the analysis, the risk level decreased for 9 (64%) of them (Sign-test p-value=0.1655). **Conclusion:** These preliminary results suggest that MSC risk level at the baseline and during treatment could help to identify primary or secondary resistance in PD-L1≥50% NSCLC patients treated with ICIs. Ongoing clinical trials are validating these results.

Background: ICPis deeply changed the NSCLC therapeutic algorithm in the past few years. Unfortunately, a majority of patients experiences disease progression. ICPi re-challenge could be an attractive option but no data supporting this strategy are available. Here we report outcomes of a large cohort of NSCLC patients treated with ICPi re-challenge. **Method:** We retrospectively collected data about 144 advanced NSCLC patients (diagnosis between 2010 and 2018) from 26 French centers. Patients were re-challenged with ICPi after at least 12 weeks of discontinuation for toxicity, disease progression or clinical decision. Progression Free Survival (PFS) and Overall Survival (OS) were calculated from the start of first or second ICP to disease progression (PFS1;PFS2) and death or last follow-up (OS1;OS2) respectively. **Result:** Median age was 63 year [39 –83], most of patients were male (67%), smokers (87%), adenocarcinomas (62%) and stage IV at diagnosis (66%). Most of patients received the first ICPi round in first or second line (66%) and the second ICPi round in third line or later (79%). In both settings patients received preferentially an anti-PD1 (87%) and no differences were detected regarding brain metastasis or ECOG PS (*P* = 0.7827 and *P* = 0.3164 respectively). The Best Response during the second ICPi was not correlated to that one achieved to the first ICPi (*P* = 0.149). The median PFS1 and PFS2 were 13 months [95% CI 10-16.5] and 4.4 months [95% CI 3-6.5] respectively. PFS2 was longer in patients discontinued because of clinical decision (6.5 months [95% CI 2.5-11.9]) or toxicity (5.8 months [95%CI 3.5-18]) compared to disease progression (2.9 months [95% CI 2.0-4.4]) (*P* = 0.021) and in those receiving a chemotherapy between the two ICPis (5.8 months [95%CI 4.1-10.5]) compared to those who did not (3.0 months [95% CI 2.0-4.4])(*P* = 0.002). Median OS1 was 3.3 years [95% CI 2.9-3.9] without differences according to the discontinuation reason (*P* =0.266). Median OS2 was 1.5 y [95%CI 1.0-2.1] and was longer in patients discontinuing the first ICPi due to toxicity (2.1y [95%CI 1.4-NR]) compared to disease progression (1.0y [95%CI 0.4-1.5]) or clinical decision (1.5y [95%CI 0.4-NR]) (*P* = 0.031). Neither OS1 nor OS2 were affected by treatments received between the two ICPis (*P* = 0.345 and *P* = 0.117 respectively). **Conclusion:** ICPi re-challenge might be a useful option mainly in patients discontinuing the first ICPi because of toxicity or clinical decision. Chemotherapy administration between the two ICPis might improve PFS under the second ICPi.

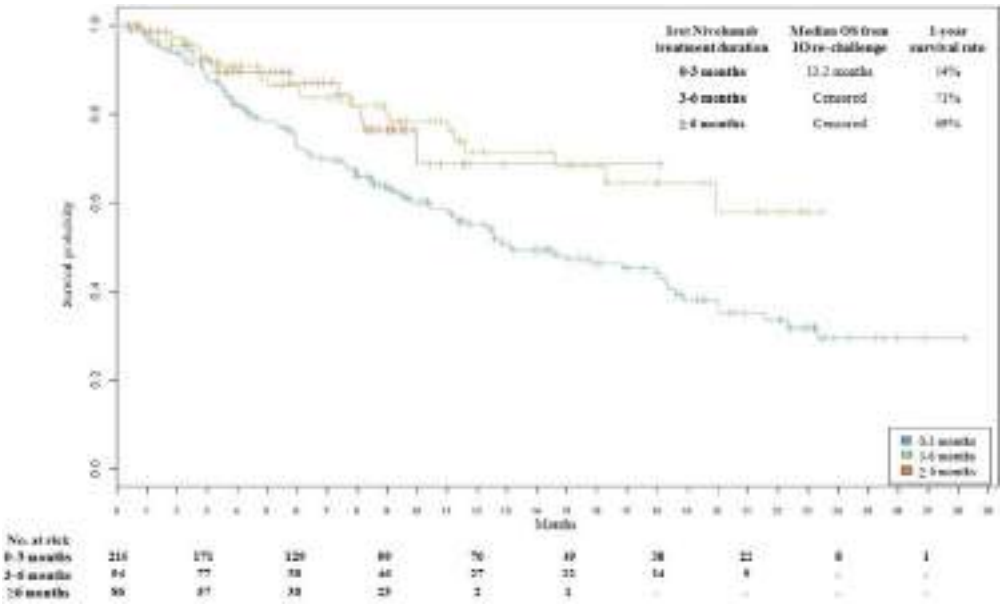
MA07 CLINICAL QUESTIONS AND POTENTIAL BLOOD MARKERS FOR IMMUNOTHERAPY
SUNDAY, SEPTEMBER 8 13:30–15:00

MA07.06 IMMUNOTHERAPY RE-CHALLENGE AFTER NIVOLUMAB TREATMENT IN ADVANCED NON-SMALL CELL LUNG CANCER IN FRENCH REAL-WORLD SETTING

M. Giaj Levra[1], F.-E. Cotté[2], R. Corre[3], C. Calvet[2], B. Jouaneton[4], R. Jolivel[4], A.-F. Gaudin[2], V. Grumberg[5], J.-B. Assié[6], C. Chouaid[6]

[1]*Centre Hospitalier Universitaire Grenoble Alpes (CHUGA), Grenoble/France,* [2]*Bristol-Myers Squibb France, Rueil-Malmaison/France,* [3]*CHU, Hôpital Ponchaillou, Rennes/France,* [4]*HEVA, Lyon/France,* [5]*Grenoble Alpes University, Grenoble/France,* [6]*GRC OncoThoParisEst, CHI Créteil, UPEC, Créteil/France*

Background: Real-world evidence of nivolumab as treatment for advanced non-small cell lung cancer (aNSCLC) can complement evidence from clinical trials to optimize routine usage and personalization of care. Further, little is known about treatment options and outcomes after discontinuation of nivolumab. **Method:** Based on the National hospitals database (PMSI), we built a retrospective cohort of all NSCLC patients (ICD code: C34*) starting nivolumab in 2015-2016 and followed them until Dec 2017. Information on patients' baseline characteristics (demographics, comorbidities, treatment history) was retrieved. Nivolumab treatment was considered discontinued if ≥3 infusions were missed. Time to treatment discontinuation (TTD) and overall survival (OS) were estimated with Kaplan-Meier methodology. Re-challenged patients were analyzed according to their first nivolumab treatment duration i.e. <3; 3-6; ≥6 months. **Result:** We identified 10,452 NSCLC patients initiating nivolumab during the inclusion period (male: 71%; mean age; 63.8±9.6 years; squamous histology: 44%; cerebral metastasis: 17.4%; median aNSCLC history: 12.5 months; previous curative surgery: 15.6%; median time since first chemotherapy: 10.5 months; mean dose of nivolumab: 213±54mg). Median TTD and OS were 2.8 months and 11.6 months. One-year and 2-year OS rates were 48.8% and 27.4%. Overall, 5118 (53.4%) patients received subsequent systemic therapy after nivolumab discontinuation. Among them, 1517 patients (29.6%) were re-treated with anti-PD1 agents (nivolumab: 98.8%) either after a therapeutic break ('immunotherapy resumption group': n=1127; mTTD: 4.1 months; mOS: 14.9 months from second initiation) or after chemotherapy ('immunotherapy re-challenge group': n=390; mTTD: 3.0 months; mOS: 18.2 months from second initiation). The Figure presents OS curves of the 're-challenge group' according to first nivolumab treatment duration.



Conclusion: After nivolumab discontinuation, around 30% of patients received immunotherapy again, either as a resumption or as a re-challenge following non-immunotherapy treatment. The influence of the first nivolumab treatment duration on re-challenged patients' OS should be further investigated.

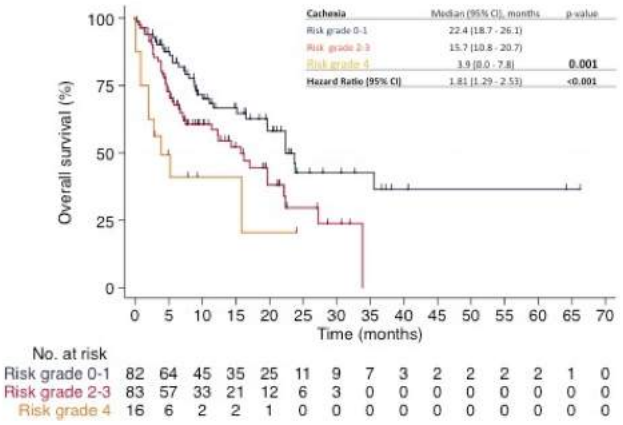
MA07.08 THE ROLE OF A CACHEXIA GRADING SYSTEM IN PATIENTS WITH NSCLC TREATED WITH IMMUNOTHERAPY: IMPLICATIONS FOR RESPONSE AND SURVIVAL

J. Turcott[1], A.F. Cardona[2], L. Ramírez-Tirado[1], Z.L. Zatarain Barrón[1], F. Barrón[1], L. Corrales[3], C. Martin[4], P.A. Barragán Castillo[5], D. Flores-Estrada[1], A. Ruiz-Patiño[6], O.G. Arrieta[1]

[1]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [2]*Clínica del Country, Bogotá/Colombia,* [3]*Hospital San Juan de Dios, San José/Costa Rica,* [4]*Fleming Institute, Buenos Aires/Argentina,* [5]*UPAEP University, Puebla/Mexico,* [6]*Fundación para la Investigación Clínica y Molecular Aplicada del Cáncer-FICMAC, Bogota/Colombia*

Background: The association between cancer-induced weight-loss (CIWL) and poor clinical outcomes is well established. However, many of these studies were performed in the chemotherapy era. Meanwhile, current standard of care for NSCLC patients has shifted towards the more efficacious immunotherapy agents (IO). IO has improved survival outcomes, nonetheless clinicians face the challenge of identifying who will derive substantial clinical benefit from these more costly agents. Response to IO is influenced by several patient-related factors, including microbiome, medications, and nutritional status. **Method:** In this study we sought to evaluate the effect of cachexia in survival of NSCLC patients undergoing treatment with IO. Included patients had advanced NSCLC (IIIB, IV), who received IO agents in any line of therapy, and had a good performance status. All the patients were evaluated by the nutritionist specialist and were graded according to a previously documented cachexia scale which takes into consideration body mass index (BMI) and weight loss in order to stratify patients into 5 risk categories (0 [pre-cachexia] - 4 [refractory cachexia]). Primary endpoint was overall survival (OS), secondary endpoints included objective response rate (ORR) and progression-free survival. **Result:** A total of 181 patients met the inclusion criteria and were included in the analysis. Among these 82 (45%) were classified in the first category (risk grade 0-1 [low risk]), 83 (46%) were classified in the second category (risk grade 2-3[intermediate risk]) and 9% were in the third category (risk grade 4 [high risk]). Patients classified as low-risk had a significantly longer OS compared to those with intermediate or high risk (22.4 months [95%CI: 18.7-26.1] vs. 15.7 [95%CI: 10.8-20.7] vs. 3.9 [0.0-7.8]; p<0.001; Hazard ratio: 1.81 [1.29-2.53]; p<0.001). In the multivariate analysis ORR, hemoglobin and risk category were independent factors associated with OS. Grade of cachexia was also significantly associated with ORR, with low-risk patients having a significantly higher ORR compared to intermediate and high-risk patients (36.6% vs. 17.3% vs. 25%; p=0.021). PFS was also influenced by risk category, with low risk patients having a longer PFS compared with intermediate and high-risk patients.



Conclusion: Cachexia is independently associated with worse OS in NSCLC patients who receive IO, while better nutritional status is related to higher ORR, highlighting a potential role for nutritional assessment in the selection of patients who are candidates for IO. Early assessment of nutritional status in these patients is imperative in order to timely diagnose and treat anorexia-cachexia and improve outcomes.

Keywords: cachexia, Immunotherapy, overall survival

MA07 CLINICAL QUESTIONS AND POTENTIAL BLOOD MARKERS FOR IMMUNOTHERAPY
SUNDAY, SEPTEMBER 8 13:30–15:00

MA07.09 IMPACT OF BODY MASS INDEX ON CLINICAL OUTCOMES OF IMMUNE CHECKPOINT BLOCKERS IN ADVANCED NON-SMALL CELL LUNG CANCER

A. Kulkarni[1], S. Zhang[1], T. De For[2], M. Patel[1]

[1]*University of Minnesota MN 55455, Minneapolis/United States of America,* [2]*University of Minnesota, Minneapolis/United States of America*

Background: Studies have suggested that obesity may have a paradoxical effect on the efficacy of immune check-point blockers (ICB). Higher Body Mass Index (BMI) has been associated with favorable outcomes with ICB. There is limited data on the impact of BMI on ICB efficacy in real-world patients with advanced non-small-cell lung cancer (NSCLC). We evaluated whether BMI is associated with survival outcomes in metastatic NSCLC patients treated with ICB. **Method:** We identified advanced NSCLC patients treated with anti-PD1/PD-L1 at our institution between 5/2015 to 1/2019. Data regarding BMI at the beginning of ICB treatment were collected. Patients with BMI ≥ 25 (overweight and obese) were assigned to high-BMI group and patients with BMI < 25 were assigned to low-BMI group. The primary outcome was overall survival (OS). Secondary outcomes were progression-free survival (PFS) as assessed by Response Evaluation Criteria in Solid Tumors (RECIST version 1.1). Cox proportional hazards model were used for statistical analysis. **Result:** 148 patients with NSCLC were eligible for inclusion. The median follow-up time was 12 months. Median age was 66 years. Majority of patients were female (52.1%), Caucasian (93%), had adenocarcinoma histology (66%), current or previous smokers (88%) and received Nivolumab (88%) in the 2nd or later line setting. The median number of treatment doses were 7. Median BMI of the patient population was 25.4 kg/m^2. 64/148 (43%) of patients were in the low-BMI group (BMI < 25) and 84/148 (57%) patients were included in the high-BMI group (BMI ≥ 25). Patients in high-BMI group had superior OS (HR=0.64, 95% CI 0.45-0.90; p=0.01) that was statistically significant. 1-year OS was 46.4% and 39.0% in the high-BMI and low-BMI group respectively. PFS was also greater in high-BMI group with a trend towards statistical significance (HR=0.73, 95% CI 0.51-1.03; p=0.07). 1-year PFS was 25.0% and 15.6% in the high-BMI and low-BMI group respectively. In multivariate analysis, OS benefit remained statistically significant after adjustment for clinical covariates (age, sex, performance status, number of previous lines of therapy, smoking status and brain metastasis). **Conclusion:** Our study provides independent validation of previously published results demonstrating an association of BMI with survival outcomes in NSCLC patients treated with ICB. The OS benefit in the high-BMI group is independent of classical prognostic factors. While the reasons underlying this relationship remains unknown, prospective studies are needed to confirm this association. Future clinical trials with ICB should consider stratification of patients based on BMI.

SUNDAY, SEPTEMBER 8 13:30–15:00

MA07.10 THE INFLUENCE OF SEX ON IMMUNOTHERAPY EFFICACY IN NON-SMALL CELL LUNG CANCER

S. Tuminello[1], R. Veluswamy[1], N. Alpert[1], J. Lazar[2], R. Flores[1], M. Van Gerwen[1]

[1]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [2]*Georgetown University School of Medicine, Washington, DC/United States of America*

Background: Patient's sex impacts clinical outcomes for multiple cancers, including non-small cell lung cancer (NSCLC). A recent meta-analysis demonstrated sex may also impact response to novel immunotherapeutic agents, where men appear to derive greater benefit than women. However, the role of important clinical confounders of immunotherapy response that differ according to sex was not accounted for. The aim of this project was to investigate the effect of sex on immunotherapy benefit for NSCLC patients using a large, nationally representative database while adjusting for important clinical confounders. **Method:** Advanced metastatic NSCLC patients diagnosed between 2013-2015 were identified in the National Cancer Database (NCDB). A Cox Proportional Hazards model was used to assess the interaction between sex and immunotherapy treatment for overall survival. This model was also adjusted for histology, stage, age, race, tumor size, comorbidities and other treatment (i.e. chemotherapy, radiation). **Result:** Of 103,525 advanced NSCLC patients, 69,120 (67%) had adequate follow-up information for survival analysis. Of these, 37,423 (54.1%) were males and 31,697 (45.9%) females; 4,012 patients received immunotherapy as first-course treatment. In the adjusted model, both males (Hazard Ratio [HR]adj: 0.77, 95% Confidence Interval [CI] 0.73-0.81) and females (HRadj: 0.80, 95% CI 0.76-0.85) receiving immunotherapy had improved survival compared to those not receiving immunotherapy. The interaction between sex and immunotherapy was not significant (p=0.2539) after adjusting for clinical variables. Among the covariates, younger age, adenocarcinoma histology, Black race, smaller tumor size, lower comorbidity score and additional cancer treatment (either chemotherapy or radiation) were independently associated with better survival (p<0.0001 for all comparisons). **Conclusion:** Patient sex does not appear to affect the benefit of immunotherapy in advanced NSCLC patients after adjusting for potential clinical confounders. Other clinical factors may play a role in immunotherapy response and should be explored in future research.

MA07.11 SURVIVAL OUTCOMES BASED ON GENDER OF ADVANCED NONSMALL CELL LUNG CANCER PATIENTS TREATED WITH PEMBROLIZUMAB OR NIVOLUMAB IN EVERYDAY CLINICAL PRACTICE

D. Ksienski[1], E. Wai[1], N. Croteau[2], A. Freeman[1], L. Fiorino[1], A. Chan[3], D. Fenton[1], G. Geller[1], E. Brooks[1], Z. Poonja[1], S. Irons[1], M. Lesperance[2]

[1]*BC Cancer-Victoria, victoria/Canada,* [2]*University of Victoria, Victoria/Canada,* [3]*BC Cancer-Surrey, Surrey/Canada*

Background: Women are underrepresented in clinical trials of PD1 Ab. We investigated the relationship between gender and overall survival (OS) in aNSCLC patients (pts) treated with PD1 Ab in a large Canadian provincial cohort. **Method:** All aNSCLC pts treated with nivolumab (NIV) or pembrolizumab (PEM) between 06/2015 and 11/2018 at BC Cancer were identified. Demographic, tumor, treatment details, and survival status were collected from chart review. Kaplan-Meier (KM) curves of OS from initiation of PD1 Ab were generated and compared by the log-rank test. **Result:** Of 527 pts analyzed (58.9% NIV, 36.1% PEM), 50.5% were female. Women were more likely to have Eastern Cooperative Oncology Group Performance Status (ECOG PS) 0/1 at PD1 Ab initiation (72.9% vs. 64.8%, p=0.05), lower median Charlson Comorbidity Index score (CCI, 2.0 vs. 3.0, p=0.006), and tumors with non-squamous histology (83.5% vs. 69.7%, p<0.001) or Epidermal Growth Factor Receptor (EGFR) mutation (9.8% vs. 3.4%, p=0.006). No significant gender variation in age at diagnosis, smoking status, and programmed death ligand 1 tumor proportion score (PD-L1 TPS) was observed. In addition, there were no differences in type of PD1 Ab, line of treatment, duration of treatment, or treatment discontinuation due to immune related adverse events. With a median follow-up of 16.3 months by reverse KM method, 65% of pts had died. In the entire cohort, women had a longer median OS than men (10.2 vs. 8.1 months, p=0.029). In the subgroup of ECOG PS 2/3 pts, men had worse OS (3.9 vs. 6.5 months, p=0.034). Women ≥60 years of age at initiation of PD1 Ab demonstrated superior median OS to men (12.2 vs. 6.1 months, p=0.006). On multivariable analysis of NIV pts, male gender (HR=1.3, 95% CI 1.0-1.7, p=0.02), baseline ECOG PS 2/3 (HR=2.5, 95% CI=1.9-3.2 p<0.001), CCI score≥3 (HR=1.6, 95% CI=1.3-2.1, p<0.001), and EGFR/ALK aberration (HR=2.3, 95% CI 1.4-3.9, p<0.001) predicted for worse survival; for PEM pts, only ECOG PS 2/3 (HR=2.5, 95% CI 1.6-3.9, p<0.001) was associated with OS. **Conclusion:** In this large series with a significant proportion of women, females treated with PD1 Ab for aNSCLC lived longer than men (especially if ECOG PS 2/3 or age≥ 60 years.) Despite similarities in smoking status and PD-L1 TPS, gender divergence in outcome could be attributed to more favorable histology and baseline ECOG PS in females. Increased enrollment of women in PD1 Ab trials would facilitate evaluation of gender as a predictive variable.

MA08 PAWING THE WAY TO IMPROVE OUTCOMES IN STAGE III NSCLC
SUNDAY, SEPTEMBER 8 15:15–16:45

MA08.01 ANALYSIS OF PD-L1 EXPRESSION ON CIRCULATING STROMAL AND TUMOR CELLS IN LUNG CANCER PATIENTS TREATED WITH CHEMORADIATION THERAPY AND ATEZOLIZUMAB

S. Lin[1], A. Augustyn[1], J. He[1], Y. Qiao[1], Z. Liao[1], A. Raghavakaimal[2], K. Gardner[3], J. Heymach[1], A. Tsao[1], D. Adams[3]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Rutgers University, New Brunswick/United States of America,* [3]*CreatvMicrotech, Inc., Monmouth Junction/United States of America*

Background: We have previously shown dynamic changes to PD-L1 expression during chemoradiotherapy (CRT) could be tracked by evaluating PD-L1 expression on circulating cells. How these changes relate to immunotherapy response is unknown. We prospectively monitored PD-L1 expression in 2 cell types found in circulation (Circulating tumor cells [CTCs] and Cancer Associated Macrophage-like Cells [CAMLs]) in locally advanced non-small cell lung cancer (LA-NSCLC) patients (pts) treated with atezolizumab and CRT. **Method:** Samples were taken from a completed phase II DETERRED trial (NCT02525757) where atezolizumab was added for one year after completing CRT (N=10) or concurrently and after CRT (N=30). Samples from 39 pts from the study were available for analysis. Baseline blood sample (7.5 ml) were drawn prior to start of CRT (T0), and a second sample was drawn ~1 month after completing CRT (T1), and a 3rd sample was drawn ~2 months after completing CRT (T2). Blood was processed by CellSieve™ microfilters; stained for cytokeratin/PDL1/CD45 to identify CTCs and CAMLs. PD-L1 intensity was measured and grouped by 4 scores: 0-negative, 1-low, 2-medium, & 3-high. Tumor IHC for PD-L1 levels from core biopsies was done with Dako 22c3 and was compared to T0 samples. PD-L1 levels from tumor and in circulating cells were used to evaluate PFS and OS. Significance was assessed by log-rank testing. **Result:** PD-L1 IHC was available for 85% of pts, and there was at least one cytokeratin positive cell (CTC or CAML) found in 100% of T0 samples. CTCs were found in 33% of T0, 24% of T1 & 43% T2. CAMLs were found in 92% of T0, 97% of T1, & 97% of T2 samples. No correlation was seen comparing tumor PD-L1 expression percentage and the T0 PD-L1 staining intensity on CTCs/CAMLs. Tumor PD-L1>1% was found in 58% and >50% in 24% of IHC samples, yet there was no correlation between tumor PD-L1 expression and PFS or OS. At T0, PD-L1 expression in CTCs/CAMLs was low (0-1) in 18 pts and high (2-3) in 15, but no relationship to PFS (HR=0.6, 95%CI 0.2-1.7, p=0.48) or OS (HR=1.7, 95%CI 0.5-6.4, p=0.66) was found. However, pts with high PD-L1 at T1 or T2, regardless of levels at T0, had a trend towards improved PFS (HR 2.5, 95%CI 0.7-8.6, p=0.13), and a significantly better OS (HR 14.2, 95%CI 2.4-81.8, p=0.003). Interestingly, of the 15 pts who had low PD-L1 at T0, 7 had induced PD-L1 expression at T1 or T2. All samples with induced PD-L1 expression had better PFS (HR 8.3, 95%CI 1.4-50.2, p=0.02) and OS (HR 8.7, 95%CI 1.2-64.0, p=0.03) compared to those who remained low. **Conclusion:** While baseline tumor or circulating cellular PD-L1 expression was not correlated with clinical outcomes, sequential monitoring of high PD-L1 expression in CTCs/CAMLs after CRT appeared to be associated with better clinical outcomes in pts who received consolidation atezolizumab after CRT, particularly in pts who had induced expression at follow up during the consolidation phase. Dynamic tracking of PD-L1 may serve as a predictive biomarker for immunotherapy effectiveness in LA-NSCLC after CRT.

Background: Stage III NSCLC represents a very heterogeneous population with extremely different treatment modalities including surgery, chemotherapy (CT) and radiotherapy (RT), mostly in combination. The results of the PACIFIC trial have now been reported in full including an overall survival (OS) benefit with durvalumab in addition to concomitant CT-RT. An electronic European survey was circulated to evaluate the impact of durvalumab in the staging and treatment strategy of stage III disease. **Method:** A Young Investigator EORTC Lung Cancer Group survey containing 31 questions, was distributed between 31/01/18 and 31/03/19 to EORTC LCG and several European thoracic oncology societies' members **Result:**

206 responses were analyzed (radiation oncologist: 50% [n=103], pulmonologist: 26.7% [n=55], medical oncologist: 22.3% [n=46]; 81.5% with >5 years experience in treating NSCLC). Italy (27.7%, n=57), Netherlands (22.8%, n=47), France (13.6%, n=28), and Spain (11.6%, n=24) contributed most. 83.5% (n=172) confirmed that they had access to durvalumab at the time of the survey. 97.6% (n=201) report that treatment decision is made by a multidisciplinary board. Regarding staging, 76.7% (n=158) support the need of a mediastinal pathological staging in case of suspect lymph-nodes, with a preference for EBUS/EUS (61.2%, n=126). 81.6% (n=168) treated more than half of patients with a concomitant CT-RT with the 1st cycle of chemotherapy in 39.7% (n=81). 95.1% consider durvalumab as practice changing, especially given the OS results (77.9%, n=152/195). 30% (n=119/395) will give patients concomitant CT-RT if PD-L1 >1%, and in borderline resectable cases 17.7% (n=70/395) will propose concomitant CT-RT instead of surgery. Durvalumab administration will be given regardless of PDL1 status in 13.1% (n=27) and 28.6% (n=59) would consider the possibility of a rebiopsy after CT-RT in case of negative PD-L1. 38.8% (n=80) foresee some problems with PD-L1 testing in this population due to availability of cytologic or small histologic samples. About 53.8% (n=105/195) normally will start durvalumab within 6 weeks after CT-RT and 48.5% (n=100) would also use durvalumab after sequential CT-RT **Conclusion:** Durvalumab results are changing the treatment approach to stage III unresectable (and maybe resectable) NSCLC and planned strict adherence to the patient population as recruited to the PACIFIC study, was not demonstrated. This survey was released after the EMA approval of durvalumab and PD-L1 status seems to play a role in the treatment strategies, but surprisingly almost half of the clinicians will use durvalumab after sequential CT-RT without safety or efficacy data.

Background: The standard treatment option for stage IIIA-N2 subgroup is still under discussion with controversies. We hypothesize that immune checkpoint inhibitor consolidation therapy could have an additional role in prolongation of the disease-free survival (DFS) for stage IIIA-N2 NSCLC treated with tri-modalities therapy. **Method:** This is a phase 2 study evaluating the clinical efficacy of pembrolizumab treatment after CCRT with curative resection in stage IIIA-N2 NSCLC pts (NCT03053856). Pathologically confirmed pts were treated with five cycles of CCRT, weekly paclitaxel (50mg/m^2) and cisplatin (25mg/m^2) combined with radiotherapy (total of 44Gy over 22 fractions) followed by curative resection. Adjuvant Pembrolizumab (200mg fixed dose) is applied every three weeks up to 2 years or until disease recurrence. The primary objective is disease-free survival of more than 20 months. The first patient was recruited in October 2017, and the data for this abstract was locked at 20th of January, 2019. **Result:** Total of 40 pts were screened, and 37 pts received treatment. Median age was 64 years (range 39-74), and twenty-three pts were male (62.2%). As a curative surgery, pts received lobectomy (n=34), bi-lobectomy (n=2), or pneumonectomy (n=1). Adenocarcinoma was predominant (n=27, 73.0%). After the neoadjuvant CCRT, down-staging were observed in nine pts (24.3%). The median follow-up duration was 10.6 months (range 3.1-17.2), and pts received a median of 11 cycles (range 1-22) of adjuvant pembrolizumab. DFS is not reached. Fourteen patients discontinued treatment due to disease progression (n=9), adverse events (n=4) and withdraw consent (n=1). There was a case of grade 4 pneumonitis and a case of grade 3 autoimmune hepatitis which lead to discontinuation of the treatment. Otherwise, grade 1-2 hypothyroidism (n=6), pneumonitis (n=5), skin rash (n=3) were observed. Patients with severe immune-related adverse event showed a significantly high percentage of Ki-67 + cells among CD8 T-cells in peripheral blood. **Conclusion:** This study is the first study to demonstrate the feasibility of adjuvant pembrolizumab monotherapy in stage IIIA-N2 patients. Updated clinical outcome will be presented at the conference.

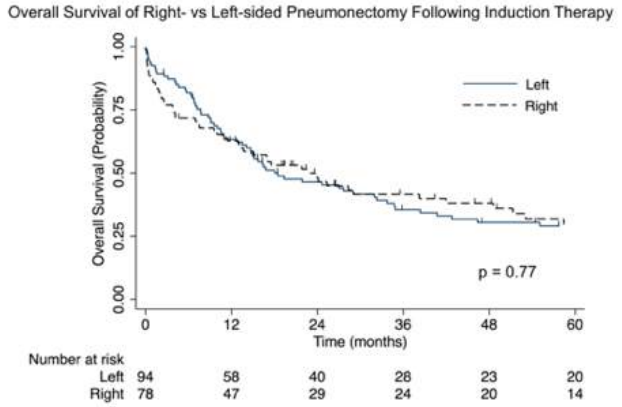
MA08.05 A MULTI-CENTER ANALYSIS OF RIGHT VS LEFT-SIDED PNEUMONECTOMY FOLLOWING INDUCTION THERAPY

C.-F.J. Yang[1], N. Mayne[2], A. Battoo[3], S. Yendamuri[3], T. Demmy[3], R. Mckenna[4], T. D'Amico[2], M. Berry[5]

[1]*Stanford, Mountain View/United States of America,* [2]*Duke University, Durham/United States of America,* [3]*Roswell-Park Cancer Institute, Buffalo/United States of America,* [4]*St. Johns Health Center, Santa Monica/United States of America,* [5]*Stanford University School of Medicine, Stanford/United States of America*

Background: Previous single-center studies of pneumonectomy following induction therapy for non-small-cell lung cancer (NSCLC) have found a significant perioperative risk associated with right-sided pneumonectomy. We examined the impact of laterality on long-term survival after induction therapy followed by pneumonectomy in a multi-institutional analysis. **Method:** Perioperative and long-term outcomes of patients with NSCLC who underwent pneumonectomy following induction chemotherapy with or without radiation from 2000-2016 across 3 institutions were evaluated using multivariable logistic regression, Cox proportional hazards modeling and propensity score-matched analysis. Patients who underwent a completion pneumonectomy or who had M1 disease were excluded from the analysis. **Result:** During the study period, 172 patients (right n = 78 [45%], left n = 94 [55%]) met inclusion criteria. Right-sided pneumonectomy was associated with a similar perioperative complication rate (38% [30/78] vs 27% [25/94], p=0.10), and 30-day (13% [10/78] vs 9% [8/94], p=0.36) and 90-day mortality (23% [18/78] vs 13% [12/94], p=0.08) when compared to left-sided pneumonectomy. In multivariable analysis, right-sided pneumonectomy was not found to be a predictor of higher perioperative complications (OR 0.85 [95% CI: 0.33-2.14], p=0.73) or 30-day (OR 2.06 [95% CI: 0.44-9.69], p=0.36) and 90-day mortality (OR 2.06 [95% CI: 0.54-7.88], p=0.29). Overall survival between right and left pneumonectomy was not significantly different in unadjusted (5-year survival 30% [95% CI: 19%-41%] vs 29% [95% CI: 20%-39%], log-rank p=0.77 [Figure]) or multivariable analysis (adjusted hazard ratio, 1.05 [95% CI: 0.63-1.76], p = 0.84). A propensity score-matched analysis of 108 patients balancing baseline characteristics—including pulmonary function, tumor size and stage—was also performed, and found no significant differences in perioperative complication rates (46% [25/54] vs 48% [26/54], p=0.85), 30-day (17% [9/54] vs 7% [4/54], p=0.14) and 90-day mortality (26% [14/54] vs 13% [7/54], p=0.09) between right versus left pneumonectomy, respectively. Overall survival was not significantly different between right- and left-sided pneumonectomy (5-year survival 33% [95% CI: 20%-47%] vs 28% [95% CI: 16%-41%], log-rank p=0.98).



Conclusion: In this multi-center analysis, right-sided pneumonectomy after induction therapy was not associated with significantly higher perioperative mortality rates or worse long-term survival when compared to a left-sided pneumonectomy.

SUNDAY, SEPTEMBER 8 15:15–16:45

MA08.06 PERIOPERATIVE OUTCOMES OF LUNG CANCER PATIENTS WITH INTERSTITIAL PNEUMONIA

A. Kobayashi, Y. Okubo, M. Yotsukura, Y. Yoshida, K. Nakagawa, N. Motoi, S. Watanabe

National Cancer Center Hospital, Tokyo/Japan

Background: Interstitial lung disease is mostly found in elderly male smokers who also have relatively high risks of developing lung cancer. For these patients, modality to treat malignancy is limited to prevent acute exacerbation of interstitial pneumonia. We analyzed the perioperative outcomes of this group of patients with both interstitial pneumonitis and resectable lung cancer with curative intent. **Method:** We retrieved the characteristics and medical courses of consecutive patients who had undergone pulmonary resections from medical records. In this analysis, usual interstitial pneumonia (UIP) was characterized by the presence of basal predominant, subpleural reticular abnormalities with traction bronchiectasis and honeycomb cysts detected in bilateral lung field on chest computed tomography preoperatively. Pathological findings on surgical specimen were used confirmation of diagnosis. The incidence and outcomes of acute exacerbation within 30 days from operation were analysed. **Result:** From 2015 to 2017, there were 1,477 patients who underwent pulmonary resection for primary lung cancer at our institute. Among them there were 81 (5.5%) patients diagnosed as UIP by specific findings on chest computed tomography. Of 81 patients evaluated, 68 (84.0 %) were men, the median age was 73 years (range, 55-88). For Eastern Cooperative Oncology Group (ECOG) performance status, all 81 patients were categorized in status 0. Seventy-four patients (91.4%) underwent lobectomy, 1 (1.2%) bi-lobectomy, 2 (2.5%) segmentectomy and 4 (4.9%) wide wedge resections for primary lung cancer. The mean duration of surgery was 129 mins (range, 54-316), and mean value for blood loss was 36.5 ml (range, 0-396). A complete resection (R0) was achieved in 79 cases (97.5%). Postoperative complications were observed in 19 patients (23.5%) including prolonged air leakage (n=4, 4.9%), late onset of air leakage (n=3, 3.7%), surgical site infection, chylothorax and cerebral infarction. Nine patients (11.1%) manifested acute exacerbation of interstitial pneumonia within 30 days after surgery. There were 3 post-operative deaths (3.7%) within 30 days after surgery. Two deaths (2.5%) were due to acute exacerbation of interstitial pneumonia and 1 (1.2%) case of SAH on 1POD. **Conclusion:** Pulmonary resection for patients with interstitial lung disease led to 9 (11.1%) cases of acute exacerbation within 30 days from surgery. Mortality related to acute exacerbation was found only 2 cases (2.5%) at our hospital, which was tolerable postoperative outcome for pulmonary resection for lung cancer with curative intent.

Keywords: interstitial pneumonia, acute exacerbation, pulmonary resection

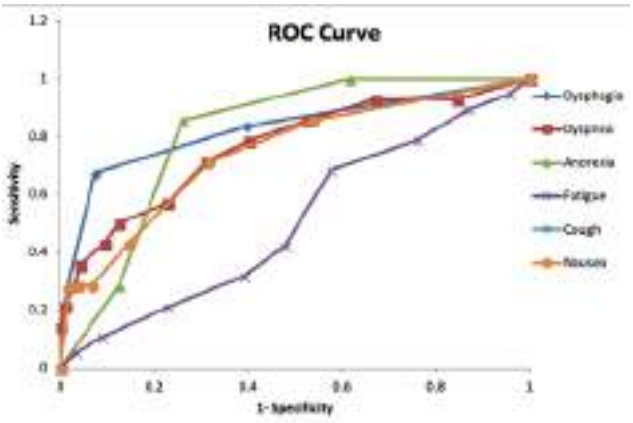
MA08 PAWING THE WAY TO IMPROVE OUTCOMES IN STAGE III NSCLC
SUNDAY, SEPTEMBER 8 15:15–16:45

MA08.07 THE CONCORDANCE BETWEEN PATIENT REPORTED OUTCOMES AND CLINICIAN REPORTED OUTCOMES DURING RADIOTHERAPY IN LUNG CANCER PATIENTS

E. Veldhuijzen, I. Walraven, M. Kwint, L. Roose, J. Belderbos, T. Janssen

The Netherlands Cancer Institute, Amsterdam/Netherlands

Background: Capturing information on toxicity in (non-)small cell lung cancer patients receiving radiotherapy or chemoradiotherapy, is crucial for optimal symptom management. Patient Reported Outcomes (PROs) have the potential to improve toxicity detection by adding direct information from the patient perspective. The aim of this study is therefore to determine the predictive and additional value of PROs on prospectively scored clinician reported toxicity. **Method:** An observational study was performed in lung cancer patients (n=111) treated with (chemo)radiation with curative intent. The EORTC QLQ-C30 and the EORTC LC-13 questionnaires were used to score PROs on a scale of 0-100 for a selection of commonly occurring toxicities (i.e. dysphagia, dyspnea, anorexia, fatigue, cough and nausea). Clinicians prospectively scored the maximum toxicity during, and at the end of treatment using the Common Toxicity Criteria for Adverse Events (CTCAE) version 4.0. Receiver operating characteristic (ROC) curves were constructed to evaluate the performance (i.e. discrimination) of PROs on predicting clinician scored CTCAE toxicity (grade ≥2). Furthermore, cut-off points were determined from the ROC-curve on the basis of the best trade-off values between sensitivity and specificity (0,5). Validity of the model was assessed with the ability to predict the number of grade ≥2 toxicities (calibration). **Result:**



Assessment of predictive performance in our cohort demonstrated a good fit for anorexia (AUC: 0,810 95% CI 0,699 to 0,921) and dysphagia (AUC: 0,828 95% CI 0,743 to 0,914) with sensitivity scores of 85,7%, 67,4% and specificity scores of 74,0% and 92,6% respectively. Both dyspnoea (AUC: 0,765 95% CI 0,60 to 0,910) and nausea (AUC: 0,745, 95% CI 0,548 to 0,942) showed a fair fit with sensitivity score of 74,1% for both toxicities and specificity of 69,1% and 68,3% respectively. A poor fit was found for cough (AUC: 0,667 95% CI 0,495-0,839) with a sensitivity of 55,6% and specificity of 30,4%. The model failed to discriminate for fatigue (AUC: 0,507 95% CI 0,368-0,645). Calibration showed that clinician based CTCAE toxicities substantially underestimated all PRO-based toxicities. **Conclusion:** This study has identified that patient reported toxicities and clinician reported toxicities do not always concord. Only anorexia and dysphagia showed good agreement, while for the other toxicities, the agreement was only fair to poor. Furthermore, we showed that clinicians substancially underreport the existence of toxicities. This study adds to the growing body of evidence indicating the potential beneficial role of using PRO-based toxicity reporting in clinical cancer care for lung cancer.

Keywords: Patient Reported Outcomes, toxicity, Clinician report

MA08.09 RESULTS OF TRIMODALITY THERAPY FOR PATIENTS WITH CN2 LUNG CANCER DIAGNOSED BY VIDEO-ASSISTED MEDIASTINOSCOPIC LYMPHADENECTOMY (VAMLA)

S. Call[1], C. Obiols[1], R. Rami-Porta[1], S. Catot[2], M. Nuñez[3], M. Campayo[1], J.F. Perez-Ochoa[1], M. Serra-Mitjans[1], J. Belda-Sanchis[1]

[1]*Hospital Universitari MútuaTerrassa, Terrassa/Spain,* [2]*Althaia, Xarxa Assistencial Universitaria de Manresa, Manresa/Spain,* [3]*Consorci Sanitari de Terrassa, Terrassa/Spain*

Background: After a properly performed transcervical lymphadenectomy, invasive restaging of the mediastinum is unnecessary because there is no material left for a new biopsy. Therefore, when video-assisted mediastinoscopic lymphadenectomy (VAMLA) is used at primary staging, the only parameters to select patients for lung resection after induction therapy are: the stability of the primary tumor and the absence of extrathoracic disease assessed by PET-CT. The aim of this study is to analyze the results of those patients with cN2 NSCLC diagnosed by VAMLA who underwent trimodality treatment in terms of feasibility and survival. **Method:** Prospective observational single-center study of 250 patients (206 men; median age, 65.7; range, 42-86) with NSCLC cN0-1 (by PET-CT) who underwent VAMLA from 01-2010 to 12-2017. Patients with cN2 diagnosed by VAMLA who underwent trimodality treatment (cisplatin-based chemotherapy concomitant with radical radiotherapy [mean 54Gy, range 40-70Gy] plus lung resection) were analyzed. Follow-up was completed in March 2019. Median follow-up for surviving patients was 39.5 months (range, 8-108). Survival analysis was performed by the Kaplan-Meier method; the log-rank test was used for comparisons. Patients who died within 90 days after resection were excluded from survival analyses. A p-value of less than 0.05 was considered significant. The IBM SPSS Statistics for Mac, version 20.0 was used. **Result:** The rate of unsuspected N2-3 disease in the whole series was 14.5% (35 patients). 28 patients out of 35 were considered for trimodality treatment. The results of restaging based on the PET-CT were: disease progression in 8 (28.5%) (mostly distant metastases), and stability of the primary tumor or partial response in 20 patients (71.5%). Of 20 patients without progression, 13 (46.5%) underwent lung resection; the remaining 7 were considered unfit for surgery. Three- and 5-year survival rates for those candidates for chemoradiotherapy (n=28) were: 91.7% and 80.2%, respectively, for patients in whom complete lung resection was achieved; 34.3% and 0%, respectively, for those considered unfit for surgery; and 19% and 0%, respectively, for those with progression after chemoradiotherapy ($p < 0.0001$)(Figure 1).

Conclusion: The use of VAMLA to select patients for trimodality treatment is feasible. Based on the results obtained (high rate of unsuspected cN2 diagnosed by VAMLA and prolonged survival of those patients in whom the trimodality treatment was accomplished), VAMLA should be included in the current staging algorithms, especially for those tumors with intermediate risk of N2 and normal mediastinum by PET-CT.

MA08.10 EARLY AND LATE OUTCOMES AFTER SURGERY FOR PT4 NSCLC RECLASSIFIED BY AJCC 8TH EDITION CRITERIA

J. Mouhanna[1], A. Katz[2], P. Fiset[2], R. Rayes[2], A. Siblini[2], E. Lee[2], A. Seely[1], C. Sirois[2], D. Mulder[2], J. Cools-Lartigue[2], L. Ferri[2], J. Spicer[2]

[1]*University of Ottawa, Ottawa/Canada,* [2]*McGill University Health Center, Montreal/Canada*

Background: Classically, T4 non-small cell lung cancers (NSCLC) are tumors of any size that have features of local extension often precluding surgical resection or necessitating complex extended pulmonary surgery. However, the new AJCC 8thedition includes tumors greater than 7cm regardless of adjacent organ extension. The early perioperative outcomes from T4 resections must be contextualized to the increasingly heterogeneous classification offered by the new staging system. Our goal was to examine perioperative and long-term outcomes from pT4 resections based on the AJCC 7thedition versus those of the expanded criteria of the 8thedition. **Method:** This is a retrospective study of pT4 surgical resections at the Montreal General Hospital from 2011-2018. Data was analyzed using GraphPad Prism and SPSS. **Result:** We identified 158 patients with pT4 tumors based on AJCC-8: 40 by AJCC-7 criteria (Group1) and 118 with tumors >7cm considered pT4 in AJCC-8 (Group2). Demographics and clinical characteristics are detailed in Table 1. The incidence of major complications (grade 3 or 4) was similar in both cohorts (17.5% in Group1 and 13.6% in Group2; p=0.37), with 3.8% in-hospital mortality (7.5% in Group1 and 2.5% in Group2; p=0.16). Overall survival was 76% at 1 year, 44% at 3 years and 34% at 5 years. Median overall survival was 27 months and was similar between Group1 and Group2 (25.8 and 27.4 months, respectively p=0.7). Nevertheless, Group2 had better peri-operative survival than Group1: 99% vs 92% 90-day mortality (p=0.02) and 95% vs 83% 6-month mortality (p<0.01). Finally, Kaplan-Meier curves adjusted for predictors of survival with Cox regression analysis show early mortality in Group 1 with equalization of the curves at 1 year (Figure 1).

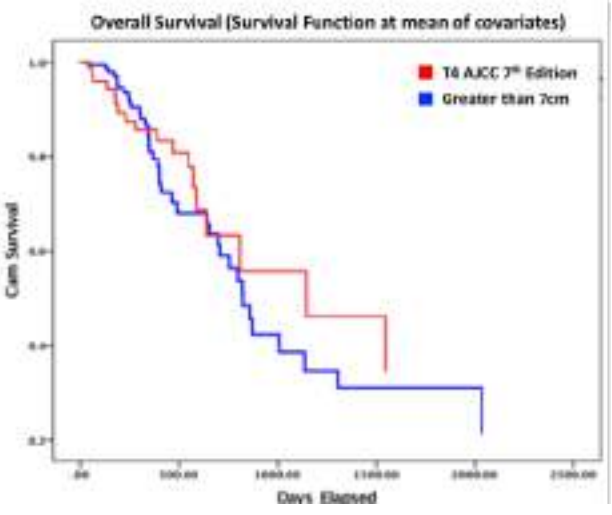

Figure 1. Overall survival of Group1 and Group2. Adjusted survival curves for Group1 (T4 AJCC 7th Edition; red curve) and Group 2 (Greater than 7cm; blue curve) generated using SPSS. Covariates in the Cox regression model included age, sex, laterality, histology, lymph node status, synchronous metastasis status, resection margins, tumor size, lymphovascular and visceral pleural invasion, surgical approach and treatment.

Conclusion: While long-term oncological outcomes are similar for pT4 >7cm to those of AJCC-7 pT4 patients, differences in perioperative outcomes point to the heterogeneity of the new AJCC-8 classification with regards to surgical management.

Background: The Spanish Lung Cancer Group (SLCG) developed a multicenter trial in which completely resected pathological N positive NSCLC patients received different schemes of adjuvance based on level of tumoral BRCA expression (SCAT trial). We assess here surgical topics, with an in-depth analysis of quality of lymphadenectomy based on IASLC recommendations, evaluating their effect on survival. **Method:** Phase-III SLCG-SCAT trial included patients with completely resected (R0) NSCLC with pathological hilar and/or ipsilateral mediastinal lymph node (LN) involvement. Patients from SLCG-SCAT trial in which complete pathologic report with information about mediastinal lymph node dissection was available (including number of lymph nodes assessed and involved by tumor in each hilar and mediastinal region), were included for our study. We also analyzed data about estimated overall survival (OS) and disease-free survival (DFS). All patients underwent surgical resection in high-volume departments of thoracic surgery. **Result:** Lymph node assessment From the whole series (451 patients), in 33.7%, 17.7% and 49.9% of cases, regions 7, 10 and 11 respectively were not assessed. No lymph nodes were biopsied from region 8, 9 and 12 in 80%, 61.9% and 91.1% of cases, respectively. Region 10 was that with the higher number of lymph nodes resected (medium 4.64). From them, 27.9% were involved by tumor. Median assessed mediastinal regions was 4. In 21.1% of patients, lymph nodes from only one or two regions were obtained. In most of the patients (91.8%), one or two N1 regions were assessed. From 272 patients with N1 (no N2) involvement, 15.4% had no N2 regions biopsied, 20.2% had one N2 region evaluated and only 39.7% had three or more N2 regions assessed. On the other hand, from 179 patients with positive N2, 8.9% had no N1 regions biopsied and 54.7% had one. From 409 patients with at least one N2 lymph node resected, 120 (29.3%) shown the highest region involved. Number of mediastinal regions assessed and affected, and number of lymph nodes resected and affected were significantly higher in patients with N1 plus N2 disease than those with isolated N1 or N2 involvement. Survival Median follow-up was 52.3 months. Five-year OS was 55.7% (CI95% 50.8%-60.3%). Differences were found on OS regarding type of lymph node involvement (N1, N2 or both) (p=0.002). Five-year OS was 61.7% (CI95%:55.4%-67.4%), 51.5% (CI95%:39.2%-62.4%) and 42.3% (CI95%:32.1-52.2%) for patients with N1, N2 and N1+N2 disease, respectively. No differences were found in survival regarding total number of N1 or N2 regions evaluated. Both number of regions involved and number of lymph nodes with tumor were significantly related to worse prognosis. **Conclusion:** International recommendations for surgical lymph node assessment in NSCLC were not deemed for the design of the trial and were not followed in a high proportion of cases. Patterns of N1 and N2 involvement shown to impact prognosis. The design of trials assessing surgical series of patients undergoing complete resection requires the control of surgical procedures in order to avoid recruitment biases.

MA09.01 A PHASE I/II TRIAL OF DASATINIB AND OSIMERTINIB IN TKI NAÏVE PATIENTS WITH ADVANCED EGFR-MUTANT NON-SMALL CELL LUNG CANCER (NSCLC)

C. Kim, S. Liu, J. Crawford, D. Subramaniam, G. Giaccone

Georgetown University, Washington, DC/United States of America

Background: EGFR tyrosine kinase inhibitor (EGFR-TKI) therapy is the standard of care in patients with EGFR-mutant NSCLC. However, a fraction of patients do not respond to EGFR-TKI therapy or have short duration of response. In addition, virtually all patients develop resistance. In a preclinical study, we have shown that overexpression of Cripto-1, a member of the EGF–CFC family, contributes to the development of resistance to EGFR-TKI therapy through the Src pathway and that the combination of EGFR-TKI therapy and Src inhibition works synergistically. **Method:** This is an open-label, single-arm phase I/II trial of osimertinib and dasatinib, a Src inhibitor, in treatment-naïve patients with advanced EGFR-mutant NSCLC (NCT02954523). Patients with pleural or pericardial effusions were excluded. The primary endpoint of the phase I portion was to establish a safe and tolerable phase II dose of osimertinib and dasatinib. Dose escalation includes 2 dose levels (DLs) (DL1: osimertinib 80 mg QD, dasatinib 50 mg BID, DL2: osimertinib 80 mg QD, dasatinib 70 mg BID). 2 DLs below the starting dose level (DL-1: osimertinib 80 mg QD, dasatinib 70 mg QD; DL-2: osimertinib 80 mg QD, dasatinib 50 mg QD) could be explored if necessary. Adverse events (AEs) were assessed per CTCAE 4.03. **Result:** 10 patients (DL2: 3, DL1: 6, DL -1: 1) were enrolled. None of the patients enrolled at DL2 had dose limiting toxicities (DLTs) but given the frequent dose reductions required and toxicities beyond the DLT period, DL1 was further assessed. 3 (50%) of 6 patients at DL1 experienced a DLT (grade 3 headaches and body pain, grade 3 neutropenia, grade 3 rash, one each). One patient was enrolled at DL -1 and did not have a DLT. The most common treatment-related adverse events (TRAEs) included pleural effusion (n=9), diarrhea (n=8), rash (n=7), AST elevation (n=6), ALT elevation (n=6), most of which were grade 1 or 2. 4/4/1 patients had grade 1/2/3 pleural effusion, respectively. 7 (70%) patients had grade 3 TRAEs. No grade 4 or 5 toxicities were observed. Eight (80%) patients had a partial response (including 1 unconfirmed partial response) and 2 had stable disease. Median PFS was 27.2 months; median OS was not reached. The recommended phase II dose was determined as osimertinib 80 mg QD and dasatinib 70 mg QD. Pharmacokinetics (PK) analysis is being performed and will be presented. Due to slow accrual after approval of osimertinib in first-line, the trial was closed to enrollment. **Conclusion:** The combination of dasatinib and osimertinib demonstrated encouraging anticancer activity. Median PFS is longer than what is historically reported with osimertinib alone in first-line setting, although definitive conclusions cannot be drawn given the small sample size. The tolerability of the combination was limited by TRAEs, but they were generally manageable with dasatinib dose reductions and supportive measures.

Background: *EGFR* Exon 20 insertions (Ex20Ins) are the 3rd most common class of *EGFR* activating mutation, but patients with NSCLC harboring EGFR Ex20Ins lack effective approved EGFR-TKIs. Newer-

generation TKIs and combination strategies with EGFR-monoclonal antibodies (moAbs) may enhance activity against EGFR Ex20Ins. **Method:** Xenografts derived from CRISPR-modified H2073 cells with Ex20Ins (A763_Y764InsFQEA, D770_N771InsSVD or V769_D770InsASV) and Ex20Ins patient-derived xenografts (PDXs) (D770_N771InsSVD, A797_V769dupASV, D770_N771_InsG, H773_V774_InsNPH) were treated with vehicle, osimertinib, cetuximab, and osimertinib+cetuximab. Ex20Ins spheroid models (D770_N771InsSVD and M766_A767InsASV) were treated with cetuximab at fixed dose and increasing concentrations of osimertinib. Ex20Ins PDX (A763_Y764InsFQEA) was also treated with afatinib and erlotinib; Ex20Ins PDX (D770_N771InsSVD) was treated with these combinations plus afatinib+cetuximab. Immunoblotting for pharmacodynamic studies of on-target and downstream proteins, phospho-proteins and apoptosis markers were performed at relevant timepoints for D770_N771InsSVD PDX and CRISPR model. A phase 1 clinical trial with a dose expansion cohort in Stage IV EGFR Ex20Ins NSCLC is currently open to accrual at osimertinib 80 mg qd and the EGFR-moAb necitumumab 800 mg IV D1 and D8 of 21D cycle with response assessment by RECIST 1.1 (NCT02496663). **Result:** The combination of osimertinib and cetuximab achieved significant tumor growth inhibition compared to osimertinib alone across PDX and CRISPR cell line xenograft models (p=0.05), except for the A763_Y764InsFQEA PDX model where osimertinib alone and osimertinib+cetuximab were equivalently effective (both p<0.001 compared to control). Spheroid models for D770_N771InsSVD and M766_A767InsASV showed significantly increased cytotoxicity from the addition of cetuximab across multiple doses of osimertinib. Osimertinib+cetuximab was superior to erlotinib, cetuximab, afatinib and afatinib+cetuximab in a D770_N771InsSVD PDX model (p<0.001). In this model, inhibition of p-EGFR, p-ERK, p-HER2 and increased caspase 3 cleavage were noted, consistent with significant tumor growth inhibition. In the phase 1 EGFR Ex20Ins expansion cohort of necitumumab in combination with osimertinib, 6/18 patients enrolled with 4 patients evaluable for response; 2 patients achieved a partial response and median PFS was 5.3 months. **Conclusion:** *In vivo* and *ex vivo* modeling in CRISPR cell line xenografts, PDXs and organoids demonstrated preclinical activity of dual EGFR blockade with osimertinib and EGFR monoclonal antibody in the 5 most common EGFR Ex20Ins representing a frequency of ~60% of detectable EGFR Ex20Ins in clinical practice. Osimertinib alone was as active as osimertinib plus cetuximab in A763_Y764InsFQEA, consistent with known sensitivity of this proximal insertion to single-agent EGFR-TKI. In a phase 1 study, osimertinib and the EGFR moAb necitumumab demonstrates preliminary clinically activity in EGFR Ex20Ins NSCLC.

Background: Insertions/mutations in exon 20 of EGFR occur in ~2% Insertions/mutations in exon 20 of EGFR occur in ~2% of all lung adenocarcinomas. These alterations are characterized by primary resistance to approved tyrosine kinase inhibitors (TKIs) with response rates of <12%. We have shown that exon 20 insertions restrict the size of the drug-binding pocket, limiting binding of large inhibitors. However, poziotinib can circumvent these steric changes and is a potent inhibitor of EGFR exon 20 mutants. In our investigator-initiated phase 2 trial of EGFR exon 20 mutant NSCLC, poziotinib was associated with a best objective response rate of 55% (Heymach et al, 19th WCLC). Herein, we use preclinical models and clinical samples from our phase 2 study to identify mechanisms of acquired poziotinib resistance (NCT03066206). **Method:** EGFR exon 20 insertion (D770insNPG) genetically engineered mice (GEM) were treated with poziotinib until progression. Upon progression, tumor DNA and protein were analyzed using whole exome sequencing (WES) and reverse phase protein assay (RPPA). Mandatory and optional biopsies were obtained at baseline and progression, respectively, from patients treated in our phase 2 trial of poziotinib in EGFR exon 20 mutant NSCLC. Serial cfDNA was collected at baseline, 8 weeks of therapy, and on progression. Patient samples were analyzed using targeted next generation sequencing or WES. **Result:** Poziotinib acquired-resistance GEM tumors acquired mutations in ErbB4, KRAS, and other genes which represent potential targetable bypass pathways. Resistant GEM tumors displayed increased activation of MAPK, AKT, ERK and MEK compared to sensitive tumors, suggesting that poziotinib acquired resistance is associated with reactivation of the MAPK/PI3K pathways. We enrolled 50 EGFR exon 20 mutant patients in our phase 2 trial. Analysis of matched pre-poziotinib and on-progression samples from 20 responding patients revealed acquired EGFR tyrosine kinase domain point mutations in 4 patients (T790M (2), V774A (1), D770A, (1)). Ba/F3 cells co-expressing EGFR exon 20 insertion (S768supSVD) and T790M were resistant to poziotinib, suggesting that T790M is a poziotinib resistance driver. Potential acquired EGFR-independent resistance mechanisms identified in patients to date include PIK3CA E545K (1), MAP2K2 S94L (1), MET amplification (1), EGFR amplification (2), and CDK6 amplification (2). **Conclusion:** Parallel to acquired resistance mechanisms seen in classical EGFR mutation, acquired resistance to poziotinib can be mediated through EGFR-dependent mechanisms, notably T790M and other EGFR tyrosine kinase domain point mutations. EGFR-independent resistance mechanisms include activation of bypass pathways. Preclinical validation of resistance mechanisms and additional analysis of patient samples will be presented at the meeting.

MA09.05 GENOMIC CORRELATES OF DIFFERENTIAL RESPONSE TO EGFR-DIRECTED TYROSINE KINASE INHIBITORS

N. Vokes[1,2], T. Nguyen[3], C. Lydon[2], E. Chambers[1], L. Sholl[4], M. Nishino[3], E. Van Allen[3,5], P. Jänne[6,7]

[1]*Broad Institute, Cambridge/United States of America,* [2]*Dana Farber Cancer Institute, Cambridge/United States of America,* [3]*Dana Farber Cancer Institute, Boston/United States of America,* [4]*Brigham and Women's Hospital, Boston/United States of America,* [5]*Broad Institute, Boston/United States of America,* [6]*Belfer Center for Applied Cancer Science, Dana-Farber Cancer Institute, Boston/United States of America,* [7]*Dana Farber Cancer Institute, USA/United States of America*

Background: Oncogenic mutations in *EGFR* are powerful biomarkers of response to EGFR tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer (NSCLC). However, there remains significant heterogeneity in duration of response to therapy and overall survival, and the molecular determinants of this differential response have been incompletely characterized. **Method:** We identified NSCLC patients at our institution with sensitizing oncogenic *EGFR* mutations who had been treated with EGFR TKI(s) and who had at least one tumor specimen profiled via targeted next generation sequencing (OncoPanel). Duration of therapy (DOT) on first-line EGFR TKI and overall survival (OS) were assessed. Mutations associated with differential benefit to therapy were identified by comparing mutation rates in outliers with DOT or OS ≥75th percentile vs ≤25th percentile. Fisher's exact test was used to calculate statistical significance, and the Benjamini-Hochberg method was used to correct for false discovery rate (FDR). Time to event outcomes were assessed with the Kaplan-Meier method. **Result:** We identified 270 patients for inclusion in our cohort. 70% were female (190/270), 60% were never smokers (163/270), and median age was 62 (range 29-93). Sensitizing EGFR mutations were predominantly exon 19 deletion (51%, 138/270) or L858R (38%, 103/270). 94% of patients were treated with first-line erlotinib (253/270), and 30% received second-line osimertinib (82/270). The median DOT on first-line TKI was 12 months (range 0-72 months) and median OS was 28 months (range 1-133 months). Pre-treatment sequencing was available for 188 patients, 65 of whom also had documented assessment of resistance mechanism (T790M 78%, other 22%). Pre-existing concurrent *TP53* mutations were associated with shorter DOT (median 10 vs 16 mo, p=0.0017), but there was no significant difference in OS (median 25 vs 36 mo, p=0.2) and no association with resistance mechanism (p=0.674). In

addition to *TP53*, *BCOR* and *SMARCA4* mutations were enriched in patients with shorter DOT, whereas *MTOR* mutations were enriched in patients with DOT in the top quartile, though these analyses did not pass FDR correction. Pre-treatment *SMARCA4* mutations were more frequent in patients with survival in the bottom quartile (Fisher's p=0.01), and were associated with decreased OS (median 32 vs 12 mo, log-rank p<0.0001). **Conclusion:** Genomic features may contribute to differential outcomes in patients with EGFR-mutated NSCLC. In addition to *TP53* mutations, pre-treatment *SMARCA4* mutations may associate with worse outcomes in these patients.

MA09.06 ADAPTIVE MECHANISMS OF RESISTANCE TO TARGETED THERAPY IN EGFR MUTANT BRAIN METASTASIS

S. Adua[1], M. Zhao[1], D. Cross[2], P. Smith[2], D. Nguyen[1]

[1]*Yale University School of Medicine, New Haven/United States of America,* [2]*AstraZeneca, Cambridge/United Kingdom*

Background: A subset of non-small cell lung cancers (NSCLCs) can be effectively treated with EGFR tyrosine kinase inhibitors (TKIs). However, a significant proportion of patients with brain metastasis progress after front-line treatment, underscoring the central nervous system (CNS) as a unique sanctuary site for persistent disease. Herein, we performed an integrated examination of the cellular, pharmacological, and molecular causes of resistance to targeted therapies in brain metastases. **Method:** The efficacy of osimertinib, a brain penetrant third generation TKI, was studied in mice using EGFR mutant NSCLC models derived from cell lines or patient biopsies. Animals with multi-organ metastases were treated continuously until disease progression was detected in the brain parenchyma. We also developed an *in situ* transcriptomic approach, referred to as Brain Metastasis Xenograft-RNA Sequencing (BMX-seq), to distinguish the transcriptome of tumor versus stroma *in vivo*. Molecular and biological responses were integrated with pharmacological analysis of loco-regional distribution of osimertinib in and around brain lesions. **Result:** In EGFR mutant models with multi-organ metastases, extra-cranial tumors could be effectively controlled, while brain metastases eventually progress despite strong osimertinib penetrance into the normal and tumor bearing CNS. Importantly, tumor cells isolated from progressing brain metastases did not exhibit resistance *in vitro*. However, these cells exhibited an enhanced resistant capacity when transplanted into the brain, demonstrating that this resistant phenotype is selected for and that exposure to the brain is a requirement for drug resistance *in vivo*. BMX-seq reveals that the stroma of drug resistant brain metastasis is characterized by activation of innate pro-inflammatory pathways. Reciprocally, we identified stromal induced activation of cytoskeletal and interferon response genes in drug resistant tumor cells. Interestingly, several of these genes are induced *in situ* independently of drug treatment, suggesting that the brain metastatic niche can precondition tumor cells for ensuing drug resistance. Finally, we demonstrate that inhibiting mediators of interferon and cystoskeletal signaling increases the sensitivity of brain metastasis to osimertinib *in vivo*. **Conclusion:** Although advances have been made in the brain penetrating abilities of targeted therapies, acquired resistance in this unique TME still develops. Our results suggest that adaptive molecular interactions within the brain TME preconditions metastatic cells for TKI resistance and that targeting such pathways in combination with osimertinib should be explored to treat NSCLC patients suffering from or at risk for brain relapse.

MA09.07 ACTIVITY OF LAROTRECTINIB IN TRK FUSION LUNG CANCER

A. Farago[1], S. Kummar[2], V. Moreno[3], J. Patel[4], U. Lassen[5], L. Rosen[6], N. Ku[7], M. Cox[7], S. Nanda[8], B. Childs[8], D. Hyman[9], A. Drilon[9]

[1]*Massachusetts General Hospital Cancer Center, Boston/United States of America,* [2]*Stanford Cancer Institute, Stanford/United States of America,* [3]*START MADRID-FJD, Hospital Fundación Jiménez Díaz, Madrid/Spain,* [4]*University of Chicago, Chicago/United States of America,* [5]*Department of Oncology, Rigshospitalet, Copenhagen/Denmark,* [6]*UCLA, Los Angeles/United States of America,* [7]*Loxo Oncology, South San Francisco/United States of America,* [8]*Bayer HealthCare Pharmaceuticals, Whippany/United States of America,* [9]*Memorial Sloan Kettering Cancer Center, New York/United States of America*

Background: Tropomyosin receptor kinase (TRK) fusions involving *NTRK1*, *NTRK2*, and *NTRK3* occur in a range of tumor types. Larotrectinib, the first FDA-approved highly selective TRK inhibitor, has demonstrated an overall response rate (ORR) of 75% by independent central review across a broad spectrum of tumors that harbor *NTRK* gene fusions (Drilon et al., *NEJM* 2018;378:731–9). Here, we report updated data on the patients with lung cancer who have been treated with larotrectinib. **Method:** Patients with non-small cell lung cancer (NSCLC) in two clinical trials (NCT02122913 and NCT02576431) with TRK fusion cancer were included in this analysis. Larotrectinib (100 mg BID) was administered on a continuous 28-day schedule until withdrawal, unacceptable toxicity, or disease progression. Response was assessed by investigator (INV) and independent review committee (IRC) per RECIST v1.1. **Result:** As of July 30, 2018, 11 patients with metastatic lung adenocarcinoma were enrolled. Median age was 52 years (range 25–76 years). Eight patients had fusions involving *NTRK1* and diverse fusion partners: *EPS15* (n=2), *TPM3* (n=2), *IRF2BP2* (n=2), *TPR* (n=1), and *SQSTM1* (n=1). Three patients had fusions involving *NTRK3* (fusion partner: *SQSTM1* [n=2] and *ETV6* [n=1]). Ten patients had prior systemic therapy (five patients had three or more prior therapies) with best responses on last prior therapy being one partial response, four with stable disease, three progressive disease, and three unknown or unevaluable. Seven patients were evaluable for response to larotrectinib. INV and IRC assessment were in agreement, with one complete response, four partial responses (including one patient with central nervous system [CNS] metastases), and two with stable disease (ORR 71%). Results from four patients not evaluable at the July 30, 2018 data cut-off due to insufficient follow-up are expected in April 2019 and will be presented at the meeting. The median time to response was 1.8 months. One patient with brain metastases had an intracranial near complete response (–95% reduction) to larotrectinib, as well as an extracranial response. The duration of response by IRC ranged from 7.4^{+} months to 25.8^{+} months; the median duration of response was not reached. One patient continued receiving treatment post-progression. Two patients discontinued treatment due to disease progression and one withdrew without cause. Larotrectinib was well tolerated, with treatment-related adverse events being predominantly grade 1–2. **Conclusion:** Larotrectinib is highly active in advanced lung cancer patients harboring *NTRK* gene fusions, including those with CNS metastases, with a favorable safety profile. These results support the use of larotrectinib in *NTRK* fusion NSCLC.

Background: In *EGFR*-mutant NSCLC, *MET* amplification may cause resistance to EGFR tyrosine kinase inhibitors (TKIs). In a Phase Ib/II study in EGFR TKI-resistant patients with *EGFR*-mutant MET+ NSCLC, progression-free survival (PFS) and objective response rate (ORR) after ≥6 months of follow-up were improved with tepotinib (a highly selective MET TKI) plus gefitinib, compared with chemotherapy, particularly in patients with *MET* amplification. Here we present data at ≥18 months of follow-up. **Method:** Asian patients with advanced, EGFR+, T790M-, MET+ NSCLC with resistance to prior EGFR TKIs were randomized to receive oral tepotinib 500 mg/day+gefitinib 250 mg/day or ≤6 cycles of cisplatin/carboplatin+pemetrexed chemotherapy±pemetrexed maintenance until confirmed progression, unacceptable toxicity, or withdrawal. Primary endpoint was investigator-assessed PFS. Secondary endpoints included ORR, overall survival (OS) and safety. Subgroup analyses were preplanned in MET IHC3+ and *MET* amplification populations (NCT01982955). **Result:** Low recruitment halted full enrolment with 55 of 156 planned patients enrolled. As of 12-Dec-2018, median (range) duration of treatment with tepotinib+gefitinib was 21.4 (4.6, 110.9) weeks, with 3 patients still receiving treatment; and with pemetrexed was 18.0 (3.0, 60.4) weeks. 15 patients (62.5%) received ≥4 cisplatin/carboplatin cycles. Better outcomes were reported with tepotinib+gefitinib vs chemotherapy (Table), particularly in patients with MET IHC3+ (PFS: HR 0.35 [90% CI 0.17–0.74], OS: 0.32 [0.14–0.75]) or *MET* amplification (PFS: HR 0.13 [90% CI 0.04–0.43], OS: 0.08 [0.01–0.51]). Drug-related grade ≥3 adverse events (AEs) occurred in 17 (54.8%) patients receiving tepotinib+gefitinib and 12 (52.2%) patients receiving chemotherapy. Any-cause AEs leading to discontinuation occurred in 3 (9.7%) patients receiving tepotinib+gefitinib and 1 (4.3%) receiving chemotherapy. Dose reductions due to AEs were reported in 5 (16.1%) vs 4 (17.4%) patients. **Conclusion:** Tepotinib+gefitinib has durable antitumor activity in patients with *EGFR*-mutant NSCLC with MET IHC3+ or *MET* amplification, and was generally well tolerated. *MET* amplification will be further explored as a biomarker for tepotinib.

Table: Summary of efficacy data

Population		Tepotinib + gefitinib	Chemotherapy	HR/OR (90% CI)
Overall MET+*	Patients, n	31	24	
	mPFS, months (90% CI)	4.9 (3.9, 6.9)	4.4 (4.2, 6.8)	0.67 (0.35, 1.28)
	mOS, months (90% CI)	17.3 (12.1, 37.3)	18.7 (15.9, 20.7)	0.67 (0.33, 1.37)

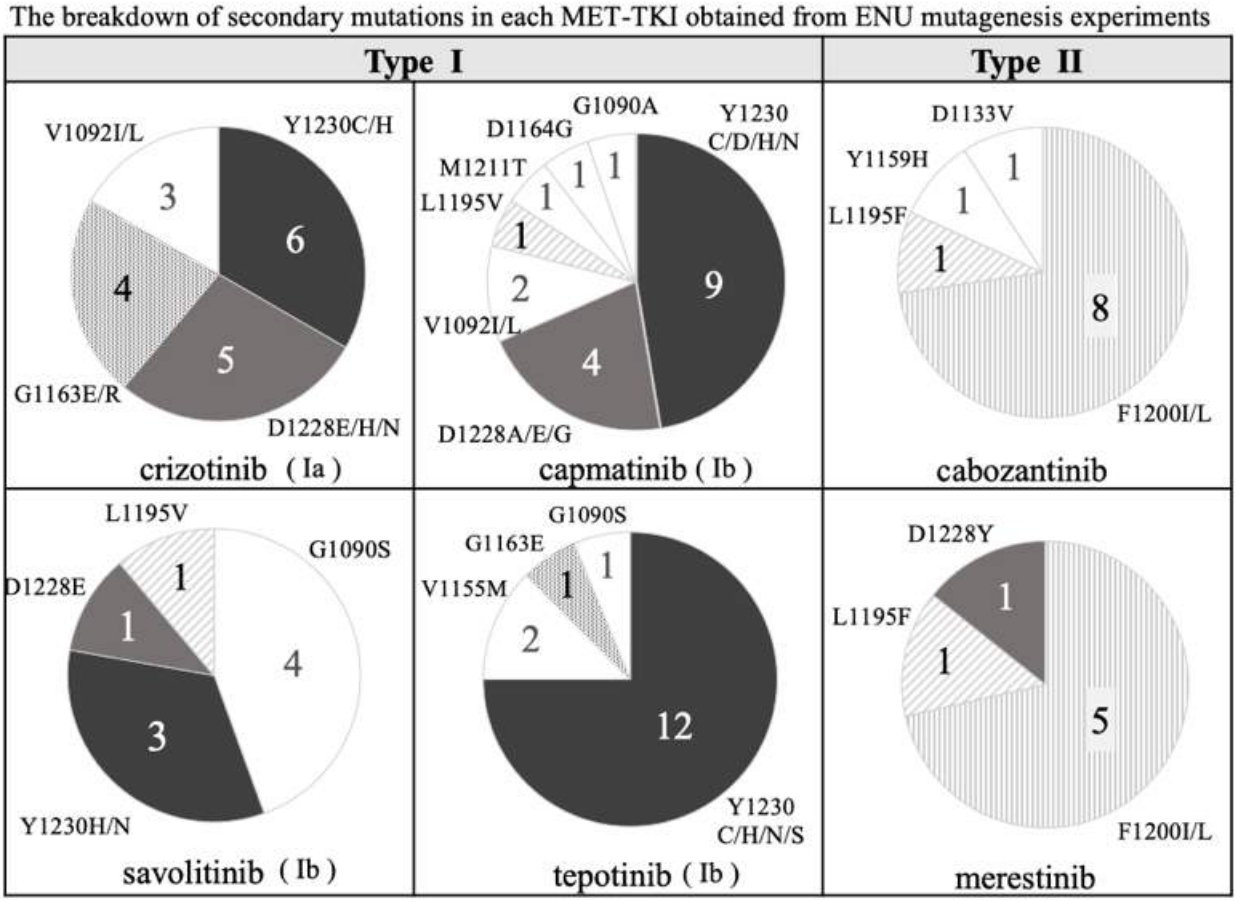
MA09.10 COMPREHENSIVE ANALYSIS OF SECONDARY MUTATION AS RESISTANCE MECHANISM TO SEVEN MET-TKIS FOR MET EXON 14 SKIPPING IN VITRO

T. Fujino, Y. Kobayashi, K. Suda, T. Koga, M. Nishino, S. Ohara, M. Chiba, A. Hamada, T. Takemoto, J. Soh, T. Misudomi

Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Background: MET exon 14 skipping mutation have been attracting attentions of thoracic oncologists as a new target of therapy for lung cancer. The efficacy of MET-TKI has been reported, while these tumors, almost always acquire resistance, as in the case of other oncogene-addicted lung cancers. However, its resistance mechanisms are not fully understood. **Method:** MET exon14 skipping mutation was introduced to Ba/F3 cell retrovirally. Using N-ethyl-N-nitrosourea mutagenesis, we derived resistant clones to seven MET-TKIs and searched for secondary MET mutations. We evaluated their sensitivities to following different TKIs. Type Ia, crizotinib; Type Ib, capmatinib, tepotinib and savolitinib; Type II, cabozantinib, merestinib and glesatinib. **Result:** We sequenced 201 resistant clones and could obtain 80 clones which had secondary mutations in the MET tyrosine kinase domain. A total of 26 different missense mutations occurring at 12 codons were identified. Of them, D1228 and Y1230 in the activation loop were common sites for type I TKIs that bind to active kinase form (DFG-in), while L1195 and F1200 were those for type II TKIs that bind to inactive form (DFG-out). In general, resistant mutations against type I were sensitive to type II, and vice versa.



Conclusion: We identified mutation sites specific for TKI types as resistance mechanisms and complementary activities between type I and type II inhibitors against those mutations. These finding should provide relevant clinical implication for treating patients with lung cancer harboring MET exon 14 skipping.

MA09.11 MECHANISMS OF RESISTANCE TO MET TYROSINE KINASE INHIBITORS IN PATIENTS WITH MET EXON 14 MUTANT NON-SMALL CELL LUNG CANCER

G. Recondo[1], M. Bahcall[2], L. Sholl[3], G. Leonardi[1], B. Ricciuti[1], T. Nguyen[1], D. Venkatraman[1], G. Lamberti[1], R. Umeton[4], P. Jänne[1], M. Awad[1]

Background: Type I and II MET tyrosine kinase inhibitors (TKIs) are under development for patients with *MET* exon 14 mutant non-small cell lung cancer (NSCLC). Understanding the mechanisms driving resistance to MET TKIs is critical to design novel treatment strategies for this molecular subtype of NSCLC. **Method:** Among patients with MET exon 14 mutant NSCLC treated with MET TKIs, pre- and post-TKI tumor tissue specimens and plasma samples were analyzed using next-generation sequencing (NGS) to explore genomic mechanisms of resistance upon disease progression. **Result:** Between April 2014 to March 2019, 38 patients were treated with MET TKIs. Among these, paired samples from 15 individuals were evaluable for this study. Patients were treated with MET TKIs in the first-line (N=7; 46.7%), second-line (N=5; 33.3%), third-line (N=1; 6.7%) and fourth-line (N=2: 13.3%) setting. Eight patients were treated with one type I MET TKI and 7 patients received ≥2 MET TKIs. On target mechanisms of resistance were identified in 5 patients (33.3%), through secondary mutations in the *MET* tyrosine kinase domain (N=4) and *MET* amplification (N=1). Single MET kinase domain mutations D1228H/N were detected in 2 patients progressing on treatment with a type I MET TKI. In two cases, tumor tissue revealed only one resistance mutation (case #1 with Y1230H; case #2 with H1094Y), whereas paired plasma analysis demonstrated ≥3 resistance mutations in ctDNA (case #1 with G1163R, D1228N, Y1230H/S; case #2 with H1094Y, L1195F/V), reflecting the emergence of polyclonal on-target resistance. Off-target mechanisms of acquired resistance were identified in 7 patients treated with Type I MET TKI (46.7%) and involved amplification of *EGFR* (N=2), *EGFR/HER2* (N=1), *EGFR/HER3* (N=1), *KRAS* (N=1), *EGFR/KRAS/BRAF* (N=1), *CCND1* (N=1). In 2 cases with bypass activation, sequential treatment with type II MET TKIs did not confer benefit. A concurrent *NF1* mutation was present at baseline in a patient with primary resistance to MET TKI (6.7%). In 2 patients (13.3%), no genomic mechanisms of resistance were identified. **Conclusion:** The landscape of resistance mechanisms to MET TKIs in NSCLC includes single and polyclonal secondary kinase domain mutations and bypass track activation by amplification of key oncogenes involving the ErbB/HER family of tyrosine kinase receptors and the MAPK signaling pathway. Given the complexity of resistance, therapeutic efforts to prevent acquired resistance in MET exon 14 mutant NSCLC should be developed.

MA10.01 INVASIVE ADENOCARCINOMA IN SCREEN DETECTED PURE GROUND-GLASS NODULES (GGN)

R. Myers[1], J. English[2], S. Atkar-Khattra[1], J. Mayo[3], J. Yee[3], A. Mcwilliams[4], M. Tsao[5], S. Lam[1]

[1]*British Columbia Cancer Research Center, VANCOUVER/Canada,* [2]*Vancouver Coastal, Vancouver/Canada,* [3]*Vancouver General Hospital, vancouver/Canada,* [4]*Fiona Stanley, Perth/Australia,* [5]*University Health Network, Toronto/Canada*

Background: A major criticism of lung cancer screening initiatives is their propensity to instigate enhanced surveillance and over-treatment of otherwise indolent disease, including adenocarcinoma-in-situ (AIS). These nodules present radiographically as GGN. There are wide variations in the recommendations for surveillance (repeat imaging), diagnosis (biopsy) and therapeutic intervention (resection) for these lesions. To further our understanding of the optimal management of screen detected GGN, we used data from two screening studies in Canada with up to 17 years of follow-up to determine the proportion of persistent GGN that are invasive adenocarcinomas. **Method:** Two lung cancer screening studies data sets were reviewed: the BC Lung Health Study (BCLHS) with 1365 participants and the Pan-Canadian Early Detection of Lung Cancer Study (PanCan) with 2537 participants. BCLHS enrolled ever smokers 45-74 years of age with >30-year smoking history. The median follow-up in this cohort was 12 years (0.1-17.6) The PanCan study screened participants age 50-75 years with a PLCOm2008 6-year lung cancer risk > 2%. The median follow-up was 5.5 years (3.2-6.1). The nodules were followed until they resolved, demonstrated stability for >2 yrs or were surgically resected. All pure GGO resected were re-reviewed and classified by two pulmonary pathologists according to the revised 2015 World Health Organization classification of lung tumours. Cancers were staged using the 8th edition of the AJCC/UICC cancer staging manual. **Result:** A total of 18,589 nodules in 3902 participants were reviewed. 2392 (13% of all nodules) were classified as pure GGN. 1073 of the 2392 were > 5mm at the baseline scan. Of these 1073 GGN, 156 (15%) resolved, 879 (82%) remained pure GGN, 38 (3.5%) became part-solid or solid. 32(3%) of the GGN from 29 patients that demonstrated growth were resected. The median size prior to resection was 16 mm (range 7 to 33 mm). The histopathology distribution included: 19 invasive adenocarcinomas, 7 minimally invasive adenocarcinomas, 6 adenocarcinoma-in-situ. The TNM stage distribution and average size of the GGN on the CT prior to resection are listed in Table 1. Sixty-one percent of the invasive cancers (Stage IA1 to IIIA) were less than 20 mm. Eleven percent of the invasive adenocarcinomas had lymph node metastasis.

Stage	N=	Mean (mm)	Range (mm)
0	6	12	10-13
1A1mi	7	14	9-25
IA1	3	9	7-10
IA2	9	16	11-20
IA3	4	25	21-26
IB	1	33	33
IIB	1	23	23
IIIA	1	18	18

Conclusion: A high proportion of pure GGN that demonstrate growth are invasive cancers. The majority were < 20mm in size when they were resected. This has significant implication in the development of recommendations to manage screen detected GGN.

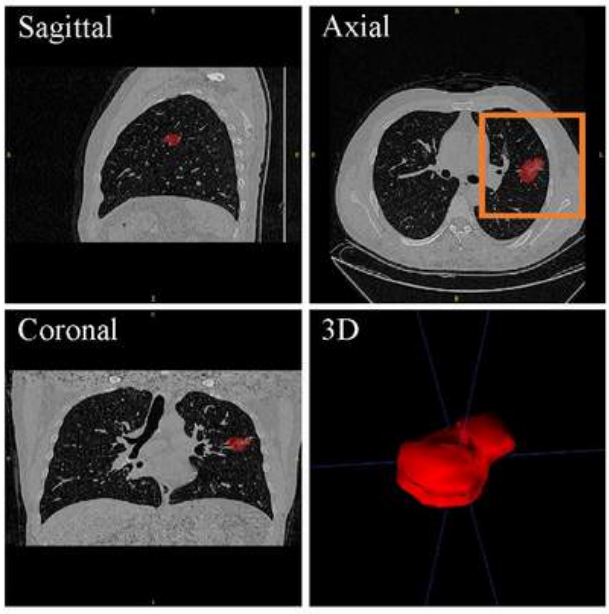
Keywords: Screening, GGN, nodule management

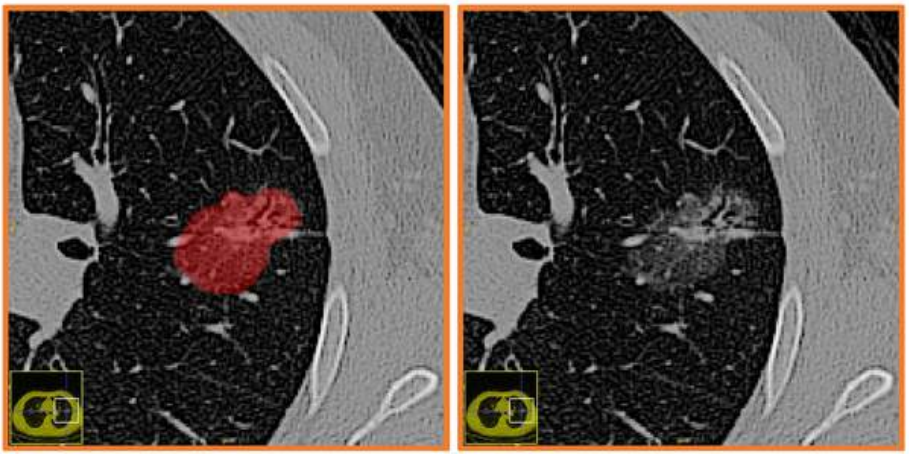
MA10.02 DEEP LEARNING WITH RADIOMICS MAY PREDICT HIGH-GRADE LUNG ADENOCARCINOMA BASED ON HISTOLOGICAL PATTERNS IN GROUND GLASS OPACITY LESIONS

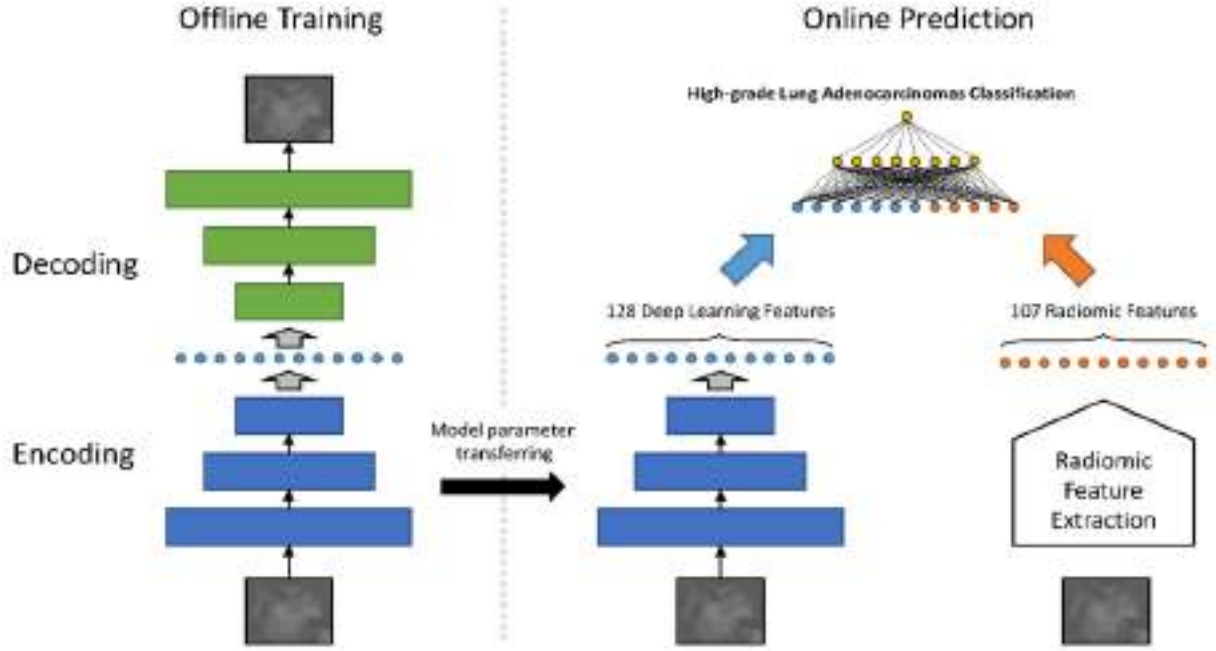
X. Wang[1], L. Zhang[2], L. Tang[3], X. Yang[4], Q. Li[5], N. Wu[1]

[1]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/China,* [2]*Center for Data Science, Peking University, Beijing, China, Beijing/China,* [3]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Radiology, Beijing/China,* [4]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Department of Pathology, Beijing/China,* [5]*MGH/BWH Center for Clinical Data Science, Boston, Beijing/China*

Background: Adenocarcinoma (ADC) is the most common histological subtype of lung cancers in non small cell lung cancer (NSCLC) in which ground glass opacifications (GGOs) found on computed tomography (CT) scans are the most common lesions. These lesions are usually treated with limited lung resection. However, the presence of a micropapillary or solid component is identified as an independent predictor of prognosis, indicating a more extensive resection. The accurate classification of subtypes still remains difficult in radiology or in frozen pathological analysis, even with the help of classical radiomics. The purpose of our study is to explore imaging phenotyping using a novel method combining radiomics with deep learning (RDL) to predict high-grade patterns within lung ADC. **Method:** Included in this study were 111 patients differentiated as having GGOs and pathologically confirmed ADC. Four different methods were compared to classify the GGOs for the prediction of the pathological subtypes of high-grade lung ADCs, including classic machine learning, radiomics, deep learning method, and a proposed novel method referred as RDL. A four-fold cross-validation approach was used to evaluate the performance of such methods. **Result:** We analyzed 32 patients with high-grade patterns and 79 without such patterns. The proposed RDL has achieved an overall accuracy of 0.888, which significantly outperforms classic machine learning, radiomics, and deep learning alone (p< 0.001, paired t-test).







Conclusion: High-grade lung ADC based on histologic pattern spectrum in GGO lesions might be predicted by a novel framework combining radiomics with deep learning, which reveals a significant advantage over traditional methods.

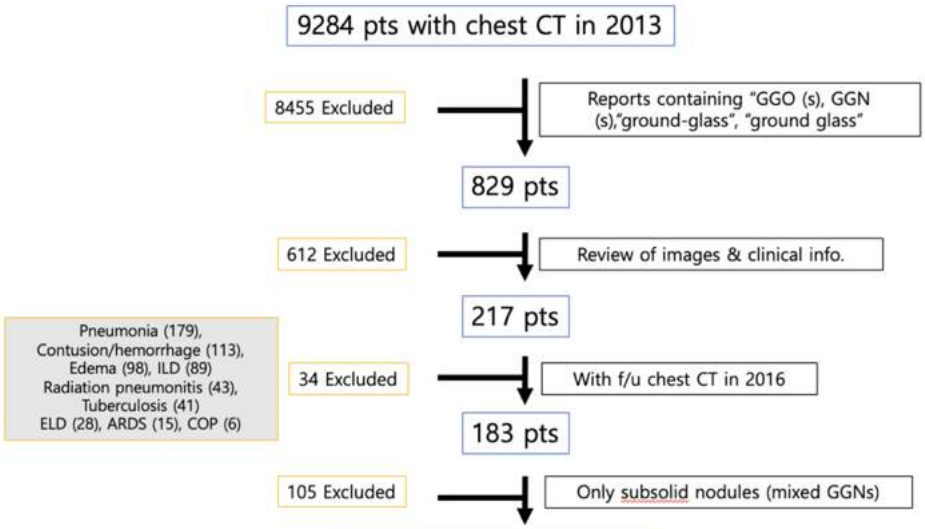
Keywords: ground glass opacifications, deep learning, NSCLC

MA10.03 QUANTITATIVE COMPUTED TOMOGRAPHY (CT) BASED TEXTURE ANALYSIS; COULD WE PREDICT THE FUTURE GROWTH OF THE PURE GROUND GLASS NODULES?

J. Sun[1], H.L. Kim[1], S. You[1], Y. Choi[2], Y.G. Min[1], K.J. Park[1]

[1]*Ajou University School of Medicine, Suwon/Korea, Republic of,* [2]*St. Carollo Hospital, Sooncheon/Korea, Republic of*

Background: To evaluate whether the quantitative computed tomography based texture analysis (QTA) could predict the future growth of the pure ground glass opacity nodule (GGN) or not. **Method:** We retrieved CT images of 9284 patients who underwent chest CT in 2013 from the picture archiving and communication system (PACS). We queried the database of PACS to filter reports of chest CT containing one of these key words, as follows; "ground-glass", ground glass", or "GGO(s)". 78 patients were finally included [5 patients (5GGNs) who underwent operation due to growth of GGN during follow-up and 73 patients who had 3-year-follow-up CT]. Total 90 GGNs from 78 patients were analyzed by QTA. The parameters of QTA were mean HU value, standard deviation (SD), entropy, mean positive pixels (MPP), skewness, and kurtosis. QTA was performed with image filtration step to remove photon noise, filtration technique enhanced features of different sizes based on the spatial scale filter (SSF) value varying from fine-texture (SSF2), medium-texture (SSF3), and coarse-texture (SSF4). We focused on the change of volume% of GGNs [(follow-up volume of GGN/ initial volume of GGN)*100%], and assessed the differences of QTA parameters' value according to the change of volume % for three cut-off levels (150%, 170%, and 200%); group 1a (≤130%), group 1b (>130%);group 2a (≤150%), group 2b (>150%);group 3a (≤170%), group 3b (>170%). **Result:**



P value / CO	Entropy			
	SSF0	SSF2	SSF3	SSF4
130	0.1701	0.2121	0.2015	0.2142
150	0.0770	0.0495	0.0487	0.0535
170	0.0271	0.0167	0.0144	0.0187

P value / CO	Mean HU value				Standard deviation			
	SSF0	SSF2	SSF3	SSF4	SSF0	SSF2	SSF3	SSF4
130	0.9649	0.8639	0.6628	0.5404	0.8950	0.8977	0.6378	0.6439
150	0.4558	0.8229	0.9549	0.8994	0.6326	0.5914	0.8327	0.5529
170	0.3932	0.3624	0.6673	0.9153	0.3274	0.7941	0.4279	0.1864

P value / CO	Mean positive pixels				Skewness				Kurtosis			
	SSF0	SSF2	SSF3	SSF4	SSF0	SSF2	SSF3	SSF4	SSF0	SSF2	SSF3	SSF4
130	0.4754	0.8942	0.7990	0.5707	0.3924	0.7389	0.6689	0.2597	0.7771	0.2902	0.6219	0.9580
150	0.8215	0.6456	0.9662	0.9378	0.4807	0.9386	0.9018	0.4717	0.2994	0.2386	0.2234	0.3589
170	0.4884	0.5170	0.7161	0.9782	0.3798	0.6618	0.9429	0.9122	0.2891	0.4968	0.4802	0.1366

Only entropy was a variable that showed statistically significant difference between group 3a and 3b with all the filtrations (SSF2, 3, 4) applied or without filtration (SSF0). The mean, SD, MPP, kurtosis and skewness, showed no significant difference according to the cut-off value of volume % change (130%, 150%). There was no significant difference in QTA parameters in group2a vs 2b, group3a vs 3b. **Conclusion:** The initial entropy parameter of texture analysis for GGNs may have the potential to predict the GGNs growth.

MA10.05 BREATH ANALYSIS: NEW KEY-CHALLENGES FOR EARLY DETECTION OF LUNG AND PLEURAL NEOPLASMS

A. Catino[1], G. De Gennaro[2], A. Di Gilio[2], L. Facchini[2], D. Galetta[1], T. Mongelli[2], J. Palmisani[2], F. Porcelli[2], N. Varesano[1], P. Pizzutilo[1], M. Montrone[1], V. Longo[1], G. Del Bene[1], A. Mastrandrea[1], F. Pesola[1], D. Ricci[1], P. Petrillo[1], A. Zacheo[1]

[1]*Clinical Cancer Centre "Giovanni Paolo II", BARI/Italy,* [2]*University of Bari, BARI/Italy*

Background: The growing interest about breath analysis relies on the need of tools to get an early diagnosis of respiratory pathologies with high mortality rate such as lung cancer (LC) and malignant pleural mesothelioma (MPM). Nowadays the key-challenge of the scientific community is the search for non-invasive diagnostic biomarkers able to identify patients at risk of developing cancer or with early stage cancer. A diagnostic progress would be crucial to improve the survival outcome of these neoplasms, generally detected at an advanced stage. The analysis of Volatile Organic Compounds (VOCs) pattern in human breath for early detection and follow-up of diseases such as cancer is low-cost, non-invasive and promising alternative to traditional exams (i.e., colonoscopy, biopsy). **Method:** This study is based on the development and validation of a methodological approach aimed to the identification of VOCs breath pattern to discriminate between patients affected by both LC and MPM, and healthy controls (CTRL). A total of 80 breath samples from 36 patients with LC, 14 patients with MPM and 30 CTRL have been collected into inert Tedlar bags, transferred to sorbent tubes (biomonitoring, Markes) and analysed by TD-GC/MS (TD Markes Unity 2 - GC Agilent 7890/MS Agilent 5975). **Result:** Non parametric test as Wilcoxon/Kruskal Wallis tests (R version 3.5.1) allowed to identify the most weighting variables in discrimination between LC, MPM and HC breath samples. On the basis of p-values lower than 0.05 (selection between CTRL and LC, and between CTRL and MPM) and current knowledge on metabolic processes, a multivariate statistics (Principal Components Analyses (PCA) -PAST 3.20) has been applied on breath samples, considering only selected variables. The preliminary statistical elaboration by PCA of data collected from the analysis of LC and CTRL samples have shown two principal components: PC1 characterized by higher loadings of benzoic acid, methylcyclohexane and hexanal, and PC2 characterized by high loadings for dimethyldecane, pentane and pentanal. Similar results were obtained by PCA applied to MPM and CTRL breath samples considering 2-methylpentane, cyclopentane, hexane and 2-butanone as discriminant variables. **Conclusion:** PCA was able to discriminate between LC and CTRL and between MPM and CTRL breath samples. Leave-one-out cross-validation method was applied to calculate the prediction accuracy obtaining good sensitivity (88%), accuracy (86%) and specificity (92%). Further investigation about breath analysis is strongly warranted, due to the need of biomarkers potentially useful both for the screening of high-risk subjects and for the early diagnosis of lung and pleural neoplasms.

MA10.07 INTEGRATIVE ANALYSIS OF EPISTASIS INVOLVING ONCOGENESIS-RELATED GENES IN LUNG CANCER RISK DEVELOPMENT

Y. Li[1], X. Xiao[1], Y. Bossé[2], Y. Han[1], C. Amos[1]

[1]*Baylor College of Medicine, Houston/United States of America,* [2]*Laval University, Quebec City/Canada*

Background: Our previous study identified significant genetic interactions within oncogenesis-related genes in lung cancer risk development. More genetic interactions may exist between oncogenesis-related genes and outside regions in the genome. A functional annotation and pathway analysis of the identified epistasis-related genes will advance our understanding about the complicated biological mechanisms underlying lung tumorigenesis. **Method:** The genotypes from two independent lung cancer GWAS studies including a total of 23,351 lung cancer patients and 19,657 health controls with European ancestry were collected for the analysis. Pairwise epistasis was conducted between 27,722 SNPs, from 2,027 oncogenesis-related genes, and 317,624 SNPs from the rest of the genome. A two-stage study design including discovery and replication studies, and stringent Bonferroni correction for multiple statistical analysis were applied in the analysis, Additional genotyping and gene expression data from 409 independent individuals with Caucasian ancestry were used to evaluate the effect of identified epistasis on gene expression levels. The epistasis-involved genes, were submitted to DAVID, Reactome, and GeneMANIA for gene functional annotation and pathway analysis. **Result:** Significant genetic interactions were identified between SNPs in gene pairs ATR-GALNT18 (Interaction OR=0.76, p value=7.98x10-13) and MET-DPF3 (Interaction OR=0.76, p value=1.62x10-12) in lung adenocarcinoma; and PICALM-PDZRN4 (Interaction OR=1.47, p value=1.67x10-12) in lung squamous carcinoma. None of these genes have been identified from previous main effect association studies in lung cancer. Further eQTL gene expression analysis revealed the significant association in expression levels between joint genotypes at rs637304:rs285581 and the PICALM gene expression (p=0.009). A total of 12 unique genes, from six significant interactions, including those from within oncogenesis-related genes and between oncogenesis-related genes and outside variants, were submitted to functional annotation and pathway analysis. Three of them (ATR, MET and FHIT) are shown to be related with lung cancer, and six of them (RAD51B, FHIT, CALNT18, RGL1, SYNE1 and TSPAN8) are involved in tobacco-use disorders. The top 10 pathways include TP53 regulates transcription of DNA repair genes (FDR=1.67x10-2), homologous DNA pairing and strand exchange (FDR=2.57x10-2), and Meiotic synapsis (3.08x10-2), etc. GeneMANIA predicted one gene network harboring all the 12 candidate genes, supporting the epistasis at 3 genes pairs and indirect interactions at 3 gene pairs. **Conclusion:** We identified novel genes involved in lung cancer risk development by interacting with other genetic variants. The study provides evidence that epistasis explains part of the missing heritability in lung cancer; and complex gene network and pathways contribute to lung carcinogenesis.

MA10.10 UPTAKE IN LUNG CANCER SCREENING – DOES CT LOCATION MATTER? A PILOT STUDY COMPARISON OF A MOBILE AND HOSPITAL BASED CT SCANNER

E. Bartlett[1], S. Kemp[1], S. Desai[1], S. Mirsadraee[1], C. Ridge[1], J. Morjaria[1], P. Shah[1], K. Morris[2], J. Derbyshire[2], M. Chen[2], C. Peacock[1], N. Ivashniova[1], M. Martins[1], J. Addis[1], S. Padley[1], A. Devaraj[1]

[1]*Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom,* [2]*Royal Marsden Partners West London Cancer Alliance, Royal Marsden NHS Foundation Trust, London/United Kingdom*

Background: Community based lung cancer screening has been proposed as a method of increasing uptake for lung cancer screening by reducing barriers to participation. We report baseline statistics for a lung cancer screening pilot study in which patients were scanned on either a community based mobile CT unit or on a University Hospital based fixed-site CT scanner. **Method:** Ever smokers aged 60-75 registered at 17 participating general practitioner practices (GP) in West London were invited for a lung health check at either a mobile unit situated in a supermarket car park or in a hospital site. The location offered was based upon proximity to the participant's home address. On attendance a lung health check, assessing lung cancer risk, was undertaken. Participants with a LLP_{v2} score of ≥2.0% and/or $PLCO_{M2012}$ score of ≥1.51% were offered a same day low dose CT (LDCT) scan. Uptake, attendance and non-attendance (DNA) rates were compared using Chi-squared (χ^2) test. **Result:** 8366 potentially eligible participants were invited for a lung health check appointment; 5135 (61.4%) to the hospital site, and 3231 (38.6%) to the mobile site. 1749/8366 (20.9%) participants responded (males n=954/1749 (54.5%)). 1047/5135 (20.4%) were booked an appointment at the hospital site and 702/3231 (21.7%) at the mobile site (p=0.14). No difference was observed in lung cancer risk between participants at the two sites. Patients at the mobile site were more likely to be ex-smokers (p=0.048). The DNA rate at the hospital site was 96/1047 (9.2%) and at the mobile site was 48/702 (6.8%) (p=0.08). On attendance, 63 patients were ineligible for screening; 52/1749 (3.0%) did not meet the entry criteria and 11/1749 (0.6%) were acutely unwell. Therefore 1542 patients attended and had a risk score calculated and of these 1145/1542 (74.3%) underwent CT. Median [range] risk scores for scanned patients were 1.97 [0-25.34] for $PLCO_{M2012}$ and 4.71 [0.94-35.92] for LLP_{v2}. Lung cancer was confirmed in 17/1145 (1.5%) participants at baseline. A further 151/1145 (13.2%) participants will undergo interval CT for indeterminate nodules. **Conclusion:** There was a small but non-significant increase in participant response rates for the community based mobile site compared to the hospital site CT scanner, but no difference in DNA rates. While community based mobile scanners may provide valuable additional capacity to lung screening programmes, the magnitude of any benefit to participant uptake needs to be balanced against the additional complexity of setting up these stand-alone facilities. Further work is ongoing to understand the interaction between CT location and other factors that influence recruitment, with a view to using effective methods to increase uptake at all sites for future screening invitations.

SUNDAY, SEPTEMBER 8 15:15–16:45

MA10.11 SENSITIVITY AND OPTIMAL CLINICOPATHOLOGICAL FEATURES OF GENETIC TARGETED LIQUID BIOPSY IN PN0M0 LUNG ADENOCARCINOMA

M. Ito[1], Y. Miyata[1], S. Hirano[1], F. Irisuna[1], N. Kishi[1], Y. Tsutani[1], R. Rosell[2], M. Okada[1]

[1]*Hiroshima University, Hiroshima/Japan,* [2]*Germans Trias i Pujol Science Inst., Catalan Institute of Oncology (ICO Badalona), Barcelona/Spain*

Background: Liquid biopsy for diagnosis of early-stage lung cancer is still challenging. The optimal marker and methodology has not been established. In Asia, almost 40-50% of lung adenocarcinomas harbor the *EGFR* mutation and L858R is a representative of a somatic *EGFR* mutation. We evaluated the usefulness of the *EGFR* somatic mutation in liquid biopsy using droplet digital PCR (ddPCR), which is a sensitivity device to detect several types of genetic mutations. **Method:** We examined weather L858R could be detected from preoperative ctDNA by ddPCR. Cases without *EGFR* mutation (wild type) were utilized as negative control. All involved cases underwent surgical resection after preoperative HRCT and PET-CT. Serum for ctDNA extraction was collected before the operation. L858R in the primary site was confirmed by resected surgical specimen. Clinicopathological features (e.g.: whole and invasive tumor size on HRCT, SUV max on PET-CT, histological subtype) were also explored for an optimal liquid biopsy candidate. **Result:** Forty-five pN0M0 lung adenocarcinoma patients harboring L858R were enrolled. Twenty-one and 24 cases showed part-solid and pure solid appearance on HRCT, respectively. Median whole and invasive tumor size on HRCT was 21 and 19 mm, respectively. 91.1% (41/45) cases were clinical stage IA1-IB and 97.8% (44/45) cases were pathological stage IA1-IB. In wild type cases, positive droplet for L858R was almost completely undetectable. Whereas, L858R was significantly detected in 7 *EGFR* mutant cases (sensitivity is 15.56%, 7/45). Among 7 positive cases, 6 cases showed pure solid appearance in preoperative HRCT. Except for pure solid appearance, there was no significant features related to the positive result. If cases are limited to pure solid appearance, 25.0% (6/24) of cases could be diagnosed by liquid biopsy. Even small-sized tumors (1.1 cm in diameter) or tumors with slight accumulation on PET-CT (SUV max 0.5) could be detected if it showed pure solid appearance on HRCT. **Conclusion:** L858R can be a definitive marker for liquid biopsy using ddPCR in pN0M0 lung adenocarcinoma. 15.56% (7/45) of cases were diagnosed in pN0M0 cases. Limited to pure solid tumor, 25.0% (6/24) could be detected. Liquid biopsy can be a useful diagnostic option, especially for tumors with pure solid appearance.

MA11.01 MULTIFACTORIAL MODEL TO PREDICT RESPONSE TO PD-(L)1 BLOCKADE IN PATIENTS WITH HIGH PD-L1 METASTATIC NON-SMALL CELL LUNG CANCER

K. Arbour[1], M. Oprescu[2], J. Hakim[2], H. Rizvi[1], M. Leiserson[3], M. Ginsburg[1], A. Plodkowski[1], J. Sauter[1], I. Preeshagul[1], S. Gillett[2], P. Rosenfield[2], L. Mackey[2], M. Dudik[4], M. Hellmann[1]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Microsoft Research New England, Cambridge/United States of America,* [3]*University of Maryland, College Park/United States of America,* [4]*Microsoft Research New York, New York/United States of America*

Background: High PD-L1 expression (≥50%) is a routine biomarker but is incompletely predictive, with response rates to PD-1 monotherapy only 35-45% in patients with lung cancer. Beyond PD-L1, additional individual pre-treatment variables, including clinical (smoking history, BMI), genomic (TMB, STK11, EGFR), and laboratory features (baseline dNLR), individually associate with response but have not been comprehensively examined in combination. We hypothesized that a multifactorial model incorporating routinely available clinical, pathologic, and genomic variables could improve prediction of response in high PD-L1 patients receiving first line anti-PD-(L)1 monotherapy. **Method:** 190 patients from MSKCC with advanced, PD-L1 high NSCLC (PD-L1 ≥50%) treated with PD-1 or PD-L1 inhibitor were identified and separated into training (n=134, 70%) and validation cohorts (n=56, 30%). In addition to PD-L1 expression, 39 variables were collected, including histology, clinical (age, gender, performance status, smoking, clinical trial vs standard of care treatment), molecular (TMB, EGFR, KRAS, STK11, KEAP1, TP53, ALK, ROS1, BRAF), and baseline CBC (including dNLR). Radiologic response assessments were performed according to RECIST 1.1. To distinguish responders vs. non-responders, a logistic regression classifier with an elastic net penalty was used to restrict the number of variables considered and to optimize generalizability to independent cohorts. The parameters of the model were optimized using only the training cohort and its performance was measured on the validation cohort. **Result:** In PD-L1 high NSCLC patients treated with PD-(L)1 blockade, the ORR was 43%. In the training cohort, 5 features (PD-L1 expression, current smoking status, lymphocyte count, platelets, total WBC) associated with response. Three features (EGFR mutation, STK11 mutation, standard of care treatment) associated with lack of response. TMB was not predictive within this selected PD-L1 high cohort. In the training cohort, the eight identified features

were used to develop a multifactorial model which improved BOR prediction (AUC 0.83) compared to PD-L1 alone (AUC 0.65), p=0.02. Improved performance of the model was confirmed in the validation cohort (AUC 0.66 for multifactorial model vs. AUC 0.52 for PD-L1 alone). **Conclusion:** Among patients with high PD-L1 expression, multiple clinical, molecular, and baseline laboratory features impact response to PD-(L)1 monotherapy. The addition of these routinely available variables to PD-L1 in a multifactorial model improves prediction of response to PD-(L)1 blockade in patients with high PD-L1. This approach may help further stratify patients within the PD-L1 high population and identify which patients are likely to benefit from PD-(L)1 monotherapy vs those who should consider chemotherapy + immunotherapy.

Background: In the global, open-label KEYNOTE-042 study (NCT02220894), pembrolizumab significantly improved OS vs chemotherapy in PD-L1–positive locally advanced/metastatic NSCLC without targetable *EGFR/ALK* aberrations (HRs: TPS ≥50%, 0.69; ≥20%, 0.77; and ≥1%, 0.81). We present the very first results for Chinese patients enrolled in the KEYNOTE-042 global and China extension (NCT03850444) studies. **Method:** The global and extension studies were designed identically. Patients were randomized 1:1 (stratified by ECOG PS 0/1, squamous/nonsquamous histology, and TPS ≥50%/1-49%) to up to 35 cycles of pembrolizumab 200 mg Q3W or up to 6 cycles of paclitaxel/pemetrexed + carboplatin with optional pemetrexed maintenance (nonsquamous only). Primary endpoints were OS in patients with PD-L1 TPS ≥50%, ≥20%, and ≥1%. No alpha was allocated to the China extension analysis. Overall, ~350 patients from China will be enrolled including 140 patients with TPS ≥50%, to determine the OS effect of pembrolizumab and consistency across outcomes in Chinese patients. **Result:** As of September 4, 2018, 262 Chinese patients with PD-L1–positive (TPS ≥1%) NSCLC were enrolled (global, n=92; China extension, n=170) and randomized to pembrolizumab (n=128) or chemotherapy (n=134). 146 patients (55.7%) had PD-L1 TPS ≥50%; 204 (77.9%) had PD-L1 TPS ≥20%. After median (range) follow-up of 11.3 (0.1-23.2) months, 32 patients (25.0%) were still receiving pembrolizumab and 6 (4.8%) were receiving pemetrexed maintenance. Pembrolizumab improved OS vs chemotherapy in patients with PD-L1 TPS ≥50%, ≥20%, and ≥1% (Table). Among patients who received ≥1 dose of pembrolizumab (n=128) or chemotherapy (n=125), grade 3–5 drug-related AEs occurred in 17% vs 68%, respectively.

Overall Survival				
		n	Median (95% CI), mo	HR (95% CI)
PD-L1 TPS ≥50%	Pembrolizumab	72	20.0 (15.5–NR)	0.62 (0.38–1.00)
	Chemotherapy	74	14.0 (10.0–17.9)	
PD-L1 TPS ≥20%	Pembrolizumab	101	20.0 (17.4–NR)	0.62 (0.41–0.95)
	Chemotherapy	103	13.7 (10.1–17.9)	
PD-L1 TPS ≥1%	Pembrolizumab	128	20.0 (17.4–NR)	0.65 (0.45–0.94)
	Chemotherapy	134	13.7 (10.1–17.9)	
PD-L1 TPS 1–49%[a]	Pembrolizumab	56	19.9 (11.9–NR)	0.69 (0.40–1.20)
	Chemotherapy	60	10.7 (8.3–20.9)	

NR, not reached. [a]Exploratory analysis.

Conclusion: Pembrolizumab monotherapy improved OS with a favorable safety profile vs platinum-based chemotherapy as first-line therapy in Chinese patients with locally advanced/metastatic NSCLC without sensitizing *EGFR/ALK* aberrations and a PD-L1 TPS ≥1%. Findings are consistent with the global study primary endpoints, supporting first-line use of pembrolizumab for PD-L1–expressing advanced/metastatic NSCLC in China.

Background: Immunotherapy is now the standard of care for non-small cell lung cancer patients without actionable mutations, due to a clear survival benefit in large phase III trials, further this benefit can be translated into the first-line setting, alone or in combination with chemotherapy. Nonetheless, due to several circumstances many patients do not receive immunotherapy as first-line. The effect of the combination therapy with pembrolizumab plus docetaxel in previously-treated NSCLC patients has not been prospectively assessed. **Method:** In this phase II clinical trial, we evaluated the effect of a combination therapy with pembrolizumab plus Docetaxel (PD) compared with Docetaxel (D) for the treatment of advanced NSCLC patients who had progressed to previous lines of therapy. Primary endpoint was overall response rate (ORR); secondary endpoints included progression-free survival (PFS), overall survival (OS), and safety profile. **Result:** Eighty patients met the inclusion criteria and were enrolled in the study, among which 78 were randomized 1:1. Forty patients were allocated to receive PD, while thirty-eight were allocated to receive D. Baseline characteristics, including sex, age, tobacco index, performance status and EGFR mutation were well-balanced between both arms of the trial. We found a statistically significant difference in terms of ORR (42.5% vs. 15.8%; OR: 3.9 [95%CI: 1.34-11.5]; p=0.01), in patients receiving PD compared with D alone. Further, patients receiving PD had a significantly longer PFS compared with those receiving D monotherapy (9.5 months [95%CI: 4.2-NR] vs. 3.9 [95%CI: 3.2-5.7]; HR: 0.24 [95%CI:

0.13-0.46]; p<0.001). In the multivariate analysis the therapeutic intervention was an independently associated factor with better PFS (Figure). In terms of safety, a total of 22.5% vs. 5.3% of patients experienced any-grade pneumonitis in the PD and D arm of the trial respectively (p=0.048), while 27.5% vs. 16% experienced any-grade hypothyroidism (p=0.20). No new safety signals were identified. **Conclusion:** Patients who receive the combination therapy have a significantly increased ORR and PFS, with a significant decrease in the hazard of progressing. This work was performed through a grant from MSD (Investigator Initiated Study). The sponsor did not have any role in the acquisition or interpretation of the data.

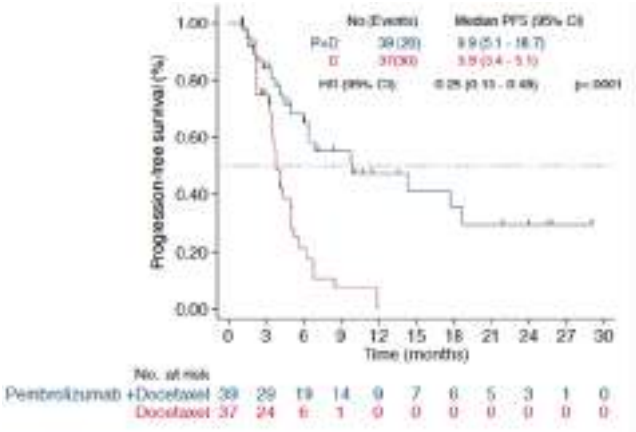

Figure. Kaplan-Meier curve for the progression-free survival of patients in the experimental (P+D) vs. the control (D) arm of the trial.

Background: Studies of single agent immune checkpoint inhibitors with platinum-based chemotherapy in non-small cell lung cancer (NSCLC) have demonstrated survival benefit over chemotherapy alone. The primary objective of this multi-centre study was to evaluate the safety and tolerability of durvalumab (Du), a PD-L1 inhibitor, +/- tremelimumab (Tr), a CTLA-4 inhibitor, with one of four standard platinum-doublet regimens (pemetrexed (pem), gemcitabine, etoposide (each with cisplatin or carboplatin) or nab-paclitaxel (with carboplatin)), in order to establish a recommended phase II dose (R2PD) for each combination. This abstract updates the results in the NSCLC cohort in this study. **Method:** Patients (pts), regardless of tumour PD-L1 status, were enrolled into one of six dose levels (Table 1). Dose escalation was according to a Rolling Six type design. Concurrent enrollment of cohorts was allowed.

Table 1

Dose level	DURVALUMAB Dose concurrent with chemotherapy*	TREMELIMUMAB Dose concurrent with platinum chemotherapy	DURVALUMAB Dose after chemotherapy completion	TREMELIMUMAB Dose after platinum chemotherapy completion
4	1500 mg q3 weeks	75 mg q3 weeks up to 4 doses	1500 mg q4 weeks	75 mg to complete up to a maximum TOTAL of 5 doses
3	1125 mg q3 weeks	56 mg q3 weeks up to 4 doses	1125 mg q3 weeks**	56 mg to complete up to a maximum TOTAL of 6 doses
2b	15 mg/kg q3 weeks	3 mg/kg single concurrent dose	20 mg/kg q4 weeks	3 mg/kg q8 weeks up to 2 doses
2a	15 mg/kg q3 weeks	1 mg/kg q6 weeks up to 3 doses	20 mg/kg q4 weeks	1 mg/kg q8 weeks up to 2 doses
1	15 mg/kg q3 weeks	1 mg/kg single concurrent dose	20 mg/kg q4 weeks	1 mg/kg q8 weeks up to 2 doses
0	15 mg/kg q3 weeks	None	20 mg/kg q4 weeks	None

*Chemotherapy regimens included (all 21 day cycles):
pemetrexed (500mg/m2) day 1 + cisplatin (75 mg/m2) or carboplatin (AUC = 6) day 1 +/- pemetrexed maintenance
gemcitabine (1250mg/m2) days 1 and 8 + cisplatin (75 mg/m2) or carboplatin (AUC = 5) day 1
nab-paclitaxel (100 mg/m2) days 1, 8 & 15 + carboplatin (AUC = 6) day 1
** q4 week schedule was allowed after discussion with CCTG after completion of the tremelimumab doses

Result: Seventy-three pts (median age=63 (range 34-80); 52% female; 77% non-squamous) were enrolled. The majority of drug-related adverse events (AEs) were grade 1 or 2. Most AEs were related to chemotherapy; other AEs were chemotherapy or immune-related (renal, hepatic, skin and pulmonary toxicity). AEs that were considered related to Du or Tr (immune related AEs (irAEs)) were mainly grade 1 or 2. The most common irAEs were fatigue (64%), rash/itch (42%), diarrhea/colitis (34%), anorexia (22%), thyroid dysfunction (19%), and nausea/vomiting (21/12%). The most common grade 3 or 4 irAEs were diarrhea/colitis (11%), fatigue (10%), and rash (5%). No treatment related grade 5 toxicities were reported. Twenty pts (27%) discontinued treatment due to an AE. Twelve pts (16%) discontinued treatment for toxicity related to D+/-T. Objective response rate (ORR) was 50.7% (95% CI = 38.7-62.6%). Median progression free survival (mPFS) was 6.5 months (95% CI = 5.5-9.4). Median overall survival (mOS) was 19.8 months (95% CI = 14.8-not yet reached). ORR was similar for all levels of PD-L1 staining including PD-L1 negative patients. ORR for pts with EGFR mutations (N=5) was similar to the ORR of wild type pts. Exploratory analyses suggest mPFS and mOS were longer in patients who experienced irAEs. **Conclusion:** In this PD-L1 unselected patient population, Du and Tr can be safely combined with full doses of platinum-doublet chemotherapy. The ORR, mPFS and mOS are similar to results reported from other immunotherapy + chemotherapy combination trials. A randomized trial, CCTG BR.34, is evaluating the incremental benefit of adding platinum doublet to Du+Tr.

Co, Shanghai/China*

Background: EGFR TKI is the standard 1st line therapy for the patients with advanced NSCLC harboring EGFR mutations. While PD-1 checkpoint blockade has become an integral component of disease management for EGFR wild type NSCLC patients at various settings, platinum-based chemotherapy is still the standard of care for EGFR mutated NSCLC pts who progressed after EGFR targeting therapy. Early attempts to combine EGFR TKI with checkpoint blockade had resulted in exacerbated immune related toxicity in the lung. Here we aimed to prospectively evaluate toripalimab, a humanized PD-1 mAb approved for 2nd line treatment of melanoma, in combination with chemotherapy to treat EGFR mutated NSCLC patients failed to EGFR TKI therapies. **Method:** This is a phase II, multicenter, open-label, single-arm study for pts with *EGFR* activating mutations who have failed prior EGFR-TKI therapies without *T790M* mutation or failed osimertinib treatment. Pts were treated with 240mg or 360mg fixed dose toripalimab once every 3 weeks in combination with carboplatin and pemetrexed for up to 6 cycles, followed by toripalimab plus pemetrexed maintenance therapy until disease progression or intolerable toxicity. Primary endpoint was objective response rate as assessed by investigator per RECIST v1.1 once every 6 weeks. **Result:**

Forty pts were enrolled from Apr 25, 2018 to March 22, 2019 with 52.5% female patients and a median age of 57. 57.5% pts harbored *EGFR* exon19 deletion while 42.5% pts had exon21 L858R mutation. Only 1 pt had T790M mutation who progressed after osimertinib treatment. As of Apr 3 2019, among 31 evaluable pts, 17 partial response and 12 stable disease were observed for a 54.8% ORR (95% CI, 36.0% to 72.7%) and a 93.5% DCR (95% CI, 78.6% to 99.2%). Median PFS was 7.6 months, while median DOR was not reached. Treatment emergent adverse events (TEAE) occurred in 86.5% of the pts, grade 3 or higher events occured in 51.4% of patients including one death. Most common AE included leukopenia, neutropenia, thrombocytopenia, anemia, nausea, and loss of appetite. Treatment discontinuation due to AE occurred in 10.8% of the pts. **Conclusion:** Anti-PD-1 mAb, toripalimab in combination with carboplatin and pemetrexed has shown a promising anti-tumor efficacy with a tolerable safety profile for advanced NSCLC patients with *EGFR* mutated who progressed after EGFR TKI therapies. Pts will be continuously monitored for safety and efficacy readouts (DOR, PFS and OS). A phase III registration study will be initiated in May 2019. (Clinical trial information: NCT03513666)

MA11.07 EFFICACY OF IMMUNE-CHECKPOINT INHIBITORS AND EGFR-TKIS IN NSCLC PATIENTS WITH HIGH PD-L1 EXPRESSION

K. Masuda, H. Horinouchi, M. Tanaka, R. Higashiyama, Y. Shinno, J. Sato, T. Yoshida, Y. Matsumoto, Y. Goto, S. Kanda, N. Yamamoto, Y. Ohe

National Cancer Center Hospital, Tokyo/Japan

Background: Recently, several studies have demonstrated that patients with non-small cell lung carcinoma (NSCLC) harboring epidermal growth factor receptor (EGFR) mutations show poor clinical outcomes in response to treatment with anti-programmed cell death-1 (PD-1) inhibitors. Conversely, EGFR tyrosine kinase inhibitors (EGFR-TKIs) are not effective in NSCLC showing high programmed death ligand 1 (PD-L1) expression levels. In this study, we retrospectively investigated the relationship between high PD-L1 expression and the efficacy of PD-1 inhibitors and EGFR-TKIs in patients with NSCLC. **Method:** The subjects of this study were patients with NSCLC who had received treatment with PD-1 inhibitors at the National Cancer Center Hospital between March 2017 and December 2018. The PD-L1 expression in the tumor cells was divided into two groups based on the tumor proportion score (TPS): <50% (low) and ≥50% (high). **Result:** Of the 414 patients treated with PD-1 inhibitors, the 263 patients in whom the PD-L1 expression levels could be evaluated were considered as being eligible for inclusion in this study. Among the 153 patients with high PD-L1 expression, we assessed the efficacy of PD-1 inhibitors according to the EGFR mutation status. The objective response rate (ORR) was 29.4% (95% confidence interval [CI], 1.3 to 53.1) in the EGFR-mutated patients and 43.4% (95% CI, 35.4 to 51.8) in the EGFR wild-type patients. The median progression-free survival (PFS) was 5.3 months (95% CI, 1.3 to 12.4) in the EGFR-mutated patients and 8.3 months (95% CI, 6.0 to 11.7) in the EGFR wild-type patients (hazard Ratio [HR] = 0.62; 95% CI, 0.62 to 1.14). A total of 33 patients received EGFR-TKI therapy. We assessed the efficacy of EGFR-TKIs according to the PD-L1 expression level. The ORR was 50.0% (95% CI, 28.0 to 72.0) in the high PD-L1 expression group and 52.9% (95% CI, 31.0 to 73.8) in the low PD-L1 expression group. The median PFS was 18.8 months (95% CI, 2.8 to 35.7) in the high PD-L1 expression group and 12.7 months (95% CI, 7.2 to 20.9) in the low PD-L1 expression group (HR = 0.83; 95% CI, 0.38 to 1.81).

	PD-L1 High EGFR+	PD-L1 High EGFR−	PD-L1 Low EGFR+	PD-L1 Low EGFR−
Total N	17	136	18	92
Median age, years (range)	62 (47–85)	62 (33–87)	64.5 (37–83)	62 (33–83)
Sex (n) Female Male	7 10	36 100	15 3	25 67
ECOG PS (n) 0, 1 2	14 3	125 11	16 2	81 11
Smoking history (n) Nev-er-smoker Smoker	7 10	21 115	12 6	13 79
EGFR mutation status (n) Ex 19 del L858R Others	7 6 4		13 2 3	
ICI agent used (n) Pembrolizumab Nivolumab	11 6	105 31	4 14	21 71
Line of ICI therapy (n) First-line Second-line Third-line or more	2 3 12	85 42 9	5 64 23	0 2 16
Efficasy ORR (%) PD-1 inhibitors EGFR-TKIs PFS (months) PD-1 inhibitors EGFR-TKIs	29.4 50.0 5.3 18.8	43.4 8.3	0 52.9 1.6 12.7	16.3 3.8

Conclusion: Even in a population of NSCLC patients showing high PD-L1 expression, the efficacy of PD-1 inhibitors tended to be lower in the EGFR-mutated patients as compared to the EGFR wild-type patients. In regard to EGFR-mutated patients with a PD-L1 TPS of ≥50%, our findings suggested that high PD-L1 expression might not predict a poor efficacy of EGFR-TKIs.

Background: Non-small cell lung cancer (NSCLC) exhibits a high mutational burden. As a result, patients afflicted by this tumor type experience greater responses to immune checkpoint blockade. This is largely due to the ability of T cells to destroy tumor cells on the basis of antigens recognized by their T cell receptor (TCR). However, the lungs are exposed to carcinogens and pathogens which can also trigger a T cell response distinct from cancer. Therefore, a better understanding of the T cell repertoire in the lungs is needed to improve upon the success of current immunotherapies in NSCLC. **Method:** We obtained peripheral blood, tumors, and adjacent uninvolved lungs from a cohort of 236 early stage NSCLC patients. Whole exome sequencing, RNA microarray, immunohistochemistry (CD3, CD4, CD8, CD57, CD68, FoxP3, CD45RO, GzmB, PD-1, and PD-L1) and T cell repertoire sequencing were performed in NSCLC patients and lungs from organ donors and COPD patients. Antigen specificity was predicted using the Grouping of Lymphocyte Interactions by Paratope Hotspot (GLIPH) algorithm. Single cell TCR and RNA sequencing as well as sequencing of the virome are underway. **Result:** Clonality was associated with CD8 T cells (r=0.31; p=0.0003), GzmB (r=0.29; p=0.001) and IFN-γ (r=0.52; p<0.0001) production as well as with tumor mutational burden (r=0.19; p=0.015), HLA-B (r=0.29; p=0.0005) and β2-m expression (r=0.20; p=0.018). Patients with classical EGFR mutations exhibited lower T cell clonality (p=0.003) even after adjustment for TMB, highlighting the impact of this driver mutation on the T cell response. Surprisingly, clonality was higher in the adjacent uninvolved lung than tumor (p<0.0001), suggesting an active antigenic response outside the tumor. Comparison of the composition of the T cell repertoire between the uninvolved lung and tumor revealed 57% of the top 100 T cells in the tumor were also found in the adjacent normal lung, highlighting certain parallels in the ongoing antigenic responses. Deeper analysis suggested that shared T cells may have been reactive against mutations shared between the normal lung and tumor (r=0.23, p=0.028) or viruses (p<0.0001). Accordingly, patients with a more reactive T cell repertoire outside the tumor (i.e. bystanders) exhibited shorter disease-free survival (p=0.036) suggesting these responses against shared mutations and/or viruses may detract from the anti-tumor T cell response. **Conclusion:** Our findings highlight the importance of understanding the specificity of the T cell repertoire in the lungs in patients with NSCLC treated with immunotherapy. As a high proportion of bystander T cells appear to reside in the lungs, their reactivation could contribute to the impaired responses and/or increased toxicity observed in certain patients with NSCLC treated with immunotherapy.

Background: Neoadjuvant PD-1 blockade has emerged as a promising treatment for resectable NSCLC. The neoadjuvant setting provides a unique opportunity to examine temporal-spatial dynamics of the T cell repertoire in the peripheral and tumoral compartments in response to PD-1 blockade. **Method:** T-cell receptor (TCR) repertoire dynamics and composition were assessed in matched tumor, normal lung, and longitudinal peripheral blood from 20 NSCLC patients treated with neoadjuvant nivolumab (NCT02259621) and were correlated with major pathologic response (MPR, ≤10% viable tumor in resected specimen) at the time of resection. Treatment-induced dynamics of activated T cell clonotypes were additionally evaluated using TCR sequencing (TCRseq) of flow-sorted PD-1+ T cell populations. To focus on the phenotype of on-treatment intratumoral T cell clones that were recruited from the periphery, combined single-cell RNAseq/TCRseq was performed on post-treatment tumors of 6 patients (3 MPR and 3 non-MPR). **Result:** MPR was associated with a more clonal intratumoral TCR repertoire and greater clonotypic sharing between pre-treatment blood and post-treatment tumor bed relative to non-MPR. Peripheral repertoire remodeling in response to anti-PD-1 treatment correlated with increased tumor infiltration. Specifically, in patients with MPR, the post-treatment tumor bed was enriched with T cell clones that were peripherally expanded between 2-4 weeks after PD-1 blockade. Clonotypic tracking of the peripherally expanded clones revealed persistence of those clones in the periphery 1+ years following surgical resection and cessation of PD-1 blockade. Single-cell RNAseq/TCRseq analyses revealed distinct phenotypes of peripherally expanded TIL for patients with MPR, with upregulated gene programs associated with cytotoxicity and cytoprotective effects against oxidative stress. Long-term peripherally-persistent TILs had significant upregulation of genes including GZMK, DUSP2, NKG7, 4-1BB and down-regulation of CTLA-4, CXCL13 and PDCD1 as compared to short-lived clones. **Conclusion:** Our findings support the notion that neoadjuvant checkpoint blockade expands anti-tumor T cell clones in the periphery that can accumulate in tumor bed, facilitate tumor regression, and promote clonotypic persistence in the periphery. Importantly, our data demonstrate the systemic effect of neoadjuvant PD-1 blockade and indicate that the periphery may be an underappreciated originating compartment of effective anti-tumor immunity.

Background: Addition of pembrolizumab (P) to platinum-doublet chemotherapy [carboplatin (or cisplatin) and pemetrexed (CP)] prolongs overall survival and is a standard of care (SOC) for the 1st line treatment of metastatic *EGFR/ALK* wild-type (wt) non-squamous non-small cell lung cancer (mnsNSCLC). Despite widespread use of the CPP regimen, molecular determinants of clinical benefit from the addition of P to CP remain poorly defined. We previously identified genomic alterations in *STK11/LKB1* as a major driver of primary resistance to PD-1/PD-L1 blockade in mnsNSCLC. Here, we present updated data on the impact of *STK11/LKB1* alterations on clinical outcomes with CPP chemo-immunotherapy from a large retrospective multi-institution international study. **Method:** 620 pts with mnsNSCLC and tumor genomic profiling encompassing *STK11/LKB1* from 21 academic institutions in the US and Europe were included in this study. Clinical outcomes were collected for two distinct patient cohorts: a) 468 pts treated with first-line CPP (or >1st line following FDA-approved TKIs) that were alive for 14 days thereafter and b) 152 *STK11/LKB1*-mt pts that received CP prior to regulatory approval of CPP. **Result:** Among 468 CPP-treated pts, *STK11/LKB1* genomic alterations (N=118) were associated with significantly shorter PFS (mPFS 5.0m vs 6.8m, HR 1.45, 95% CI 1.11 to 1.91; P=0.007) and shorter OS (mOS 10.6m vs 16.7m, HR 1.46, 95% CI 1.04 to 2.07; P=0.031) compared with *STK11/LKB1*-wt tumors (N=350). The likelihood of disease progression as BOR to CPP differed significantly between the two groups (29.5% vs 17%, P= 0.006). Similar results were obtained when limiting the analysis to *EGFR* and *ALK*-wt tumors (N=435) (mPFS 5.0m vs 6.9m, HR 1.48, 95% CI 1.12-1.95, P=0.006 and mOS 10.6m vs 16.7m, HR 1.45, 95% CI 1.02-2.05, P=0.036). Importantly, in pts with *STK11/LKB1*-mt mnsNSCLC, addition of pembrolizumab to CP did not result in significant improvement of PFS (mPFS 5.0m vs 3.9m, HR 0.82, 95% CI 0.63 to 1.07, P=0.14) or OS (mOS 10.6m vs 9.1m, HR 0.93, 95% CI 0.67 to 1.30, P=0.69) compared to CP alone. **Conclusion:** In mnsNSCLC, *STK11/LKB1* alterations define a subgroup of pts with inferior clinical outcomes with CPP and lack of benefit from the addition of pembrolizumab to CP chemotherapy. Novel therapeutic strategies are required to establish effective antitumor immunity in *STK11/LKB1*-mutant NSCLC.

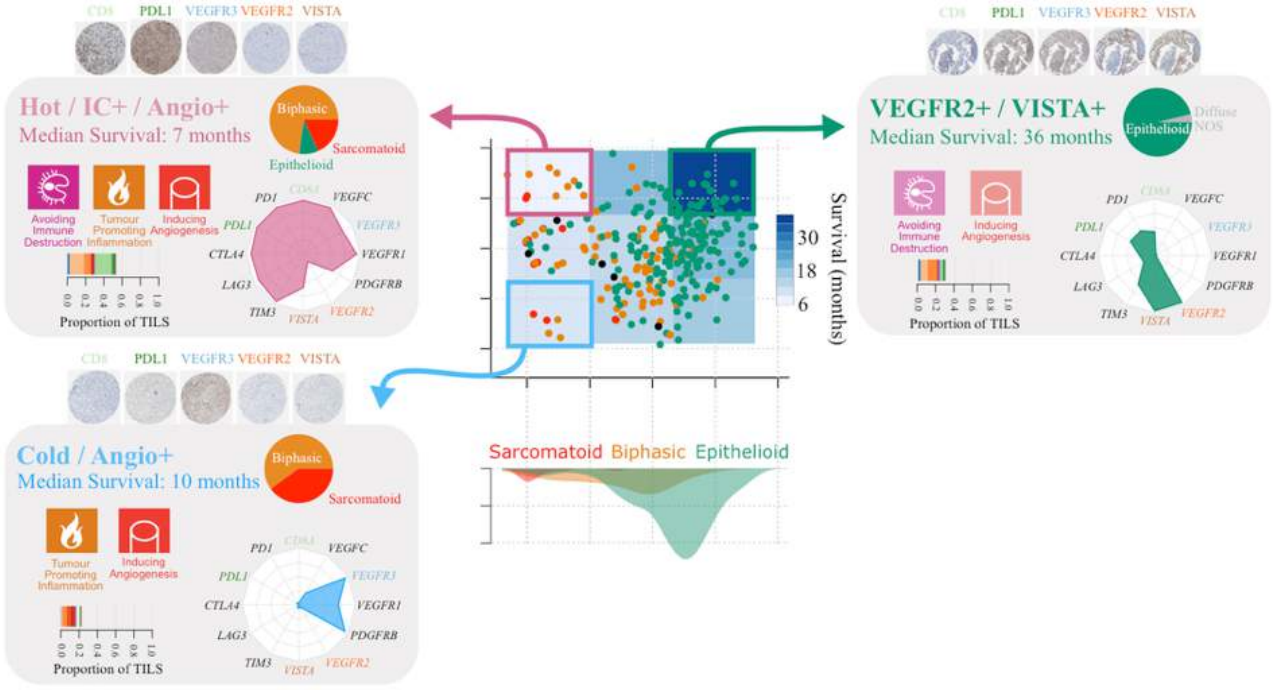
Background: Malignant Pleural Mesothelioma (MPM) is a deadly disease. The current histopathologycal classification recognises three major types (epithelioid, biphasic, and sarcomatoid) with different prognosis, but showes high interobserver variability. This classification also has a role in the clinical decision-making although, ultimately, MPM becomes refractory to all conventional treatment modalities, and alternative therapeutic options have been evaluated with limited success. **Method:** We have performed unsupervised analyses of publicly available RNA-seq data of 284 MPM tumours[1,2] with no assumption of discreteness. We have performed an orthogonal validation in a subset of 187 samples, and we have replicated the findings in an independent series of 77 MPM from the French MESOBANK. **Result:** A continuum of molecular profiles appeared to explain the prognosis of this disease better than discrete models based on the histopathological classification or on expression data. We identified the immune and vascular pathways as major sources of molecular variation, with strong differences in the expression of immune checkpoints and pro-angiogenic genes across samples; the extrema of this continuum had very specific molecular profiles: a "hot" bad-prognosis profile (median survival of 7 months), with high lymphocyte infiltration, and high expression of immune checkpoints and pro-angiogenic genes; a "cold" bad-prognosis profile (median survival of 10 months), with low lymphocyte infiltration and high expression of pro-angiogenic genes; and a better-prognosis profile (VEGFR2+/VISTA+, median survival of 36 months), with high expression of the immune checkpoint *VISTA* and the pro-angiogenic *VEGFR2* gene. We selected five genes belonging to the immune and vascular pathways (*CD8A, PDL1, VEGFR3, VEGFR2*, and *VISTA*), which expression was enough to capture the three molecular profiles, to validate the expression of these genes at the protein level by immunohistochemistry on a subset of 187 samples from the discovery cohort, and to replicate the molecular profiles as well as their prognostic value in an independent series of 77 MPMs.



Conclusion: In this study we found that the prognosis of MPM is best explained by a continuous model, which extremes show characteristic molecular profiles with specific expression patterns of genes involved in the angiogenesis and immune response[3]. These data may inform future classifications of MPM and provides insights that may assist the clinical management of this disease. Background: Nuclear grading system has been validated as a powerful prognostic tool for epithelioid malignant pleural mesothelioma (MPM) whilst growth patterns had demonstrated prognostic value in earlier studies. We aim to externally validate the previous findings and evaluate the utility of a composite architecture-nuclear grade scoring system. **Method:** We retrospectively reviewed 614 consecutive cases of epithelioid MPM diagnosed at our institution over a 15-year period. Clinicopathological information including predominant growth pattern (Solid, Tubulo-papillary, Trabecular, Micropapillary, Microcystic, Discohesive, Pleomorphic) and 2-tier nuclear grade were retrieved from an institutional mesothelioma database. The tumours were categorised into High Grade (Solid, Micropapillary, Score=1) and Low Grade (All others, Score=0). A composite score (0-2) was generated based on growth pattern and 2-tier nuclear grade (0-1). Survival analysis was performed using Kaplan-Meier method. **Result:** Pleomorphic epithelioid MPM was associated with the worst median overall survival (5.4 months), followed by micropapillary- (6.2 months), solid- (10.5 months), microcystic- (15.3 months), discohesive- (16.1 months), trabecular- (17.6 months) and tubulo-papillary- (18.6 months) patterns. The composite scoring system further improved stratification of overall survival based on 2-tier nuclear grade (19.8 vs. 13.4 vs. 8.1 months, p<0.001).

Conclusion: Epithelioid MPM growth patterns predicted survival in our cohort. Composite architecture-nuclear grade scoring system further improved prognostic stratification.

Background: BRCA1 associated protein 1 (*BAP1*), a nuclear deubiquitinase involved in DNA double-strand (DSB) break repair by homologous recombination (HR), is frequently mutated in mesotheliomas. Because poly (ADP-ribose) polymerase inhibitors (PARPIs) target PARP1 and PARP2 and induce synthetic lethality in *BRCA1/2* mutant cancers deficient in HR, we evaluated whether *BAP1* inactivating mutations confer sensitivity to PARPIs in mesotheliomas. **Method:** Ten patient-derived mesothelioma cell lines were generated and characterized for *BAP1* mutation status, protein expression and function. Cellular sensitivity to two clinical PARPIs, olaparib and talazoparib were tested as single agents, and in combination with temozolomide. *BAP1*-deleted mesothelioma cellular models were generated by CRISPR/Cas9 and assessed for sensitivity to PARPIs. Because Schlafen 11 (SLFN11) and O^6-methylguanine methyltransferase (MGMT) also drive response to temozolomide and PARPIs, we tested their expression and relationship with drug response. **Result:** *BAP1* inactivating mutations were present in eight of ten cell lines, with two harboring homozygous deletion. Cell lines exhibiting BAP1 expression also showed deubiquitinase activity (DUB). IC_{50} of olaparib and talazoparib plot classified them into sensitive or resistant population irrespective of BAP1 status (Figure 1). Although *BAP1* knockout led to the loss of DUB activity, it did not increase the sensitivity of the cell ines to PARPI. Interestingly, cellular sensitivity to PARPI was increased by temozolomide in MGMT-negative and SLFN11-positive cell lines (Table 1).

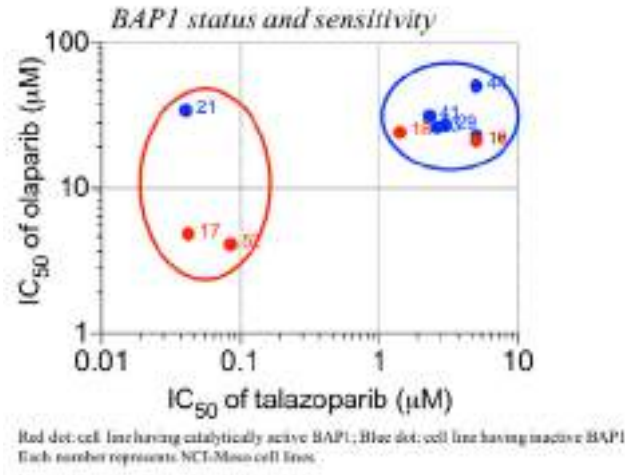

Figure 1. IC_{50} of olaparib vs talazoparib – based plot shows a separation of sensitive (red oval) and resistant (blue oval) cell line clusters independent of BAP1 activity.

NCI-Meso63	+	+	2.6	>250	-*

*Chou-Talay analysis has shown a strong synergistic effect. However the fraction affected is less than 0.5 indicating that the drugs do not make a meaningful combination, we therefore consider it as a negative synergism in our study.
* Synergism observed only in higher concentration ratio compared to sensitive cell lines

Table 1. Summary reflecting combination study between talazoparib and temozolomide in different cell lines having varying MGMT and SLFN11 expression status.

Conclusion: BAP1 status does not determine cellular sensitivity to PARPIs in patient-derived mesothelioma cell lines. In MGMT-deficient and SLFN11-positive cells, combination of PARPI and temozolomide is synergistic.

Keywords: BAP1, MGMT, PARP Inhibitor

MA12.05 GENOMIC ANALYSIS OF LONG TERM MALIGNANT PLEURA MESOTHELIOMA PATIENTS TREATED WITH PALLIATIVE CHEMOTHERAPY

F. Torricelli[1], A. Saxena[2], R. Nuamah[2], M. Neat[3], L. Harling[4], W. Ng[3], J. Spicer[5], A. Ciarrocchi[1], A. Bille[6]

[1]*AUSL-IRCCS Reggio Emilia, Reggio Emilia/Italy,* [2]*Guy's Hospital, London/United Kingdom,* [3]*Guys Hospital, London/United Kingdom,* [4]*Guy's & St.Thomas NHS Trust, London/United Kingdom,* [5]*King's College London, Guy's Hospital, London/United Kingdom,* [6]*Guy's Hospital NHS Foundation Trust, London/United Kingdom*

Background: Malignant Pleural Mesothelioma (MPM) is an aggressive tumor related to asbestos exposure with a median survival of 9 months from diagnosis. The aim of this study was to evaluate correlation between genetic mutations and survival in patients who received only palliative chemotherapy. **Method:** From 2005 to 2015, 720 patients underwent a surgical pleural biopsy and were diagnosed with malignant pleural mesothelioma. Among these, 27 patients survived longer than 30 months (long survival) from diagnosis and 113 survived less than 30 months. The pleural biopsy of the long term survival patients were reviewed and 12 FFPE samples were considered suitable and matched with 12 FFPE biopsy samples from patients who survived less than 12 months. **Result:** The DNA of 24 patients was sequenced. One sample did not reach quality to be further considered and was excluded. The mean age of total population was 71.6±8.8 and 15 patients were males (table 1). Eleven patients had a mean overall survival of 5.5 months while 12 patients lived more than 30 months. The mutational analysis identified a total of 428 alterations of which 148, classified as somatic and functional, were further considered. Among these, 85% were missense variants, 8% were variants causing a stop gain, 6% were splice variants. UQCRC1 was significantly associated with a reduced survival of MPM patients (p=0.027); figure 1. Positive trend of correlation was observed between mutations in ACTR1 and CUL1 and short MPM survival. By contrast, no significant correlation was observed between gene mutations and long survival. Figure 1.

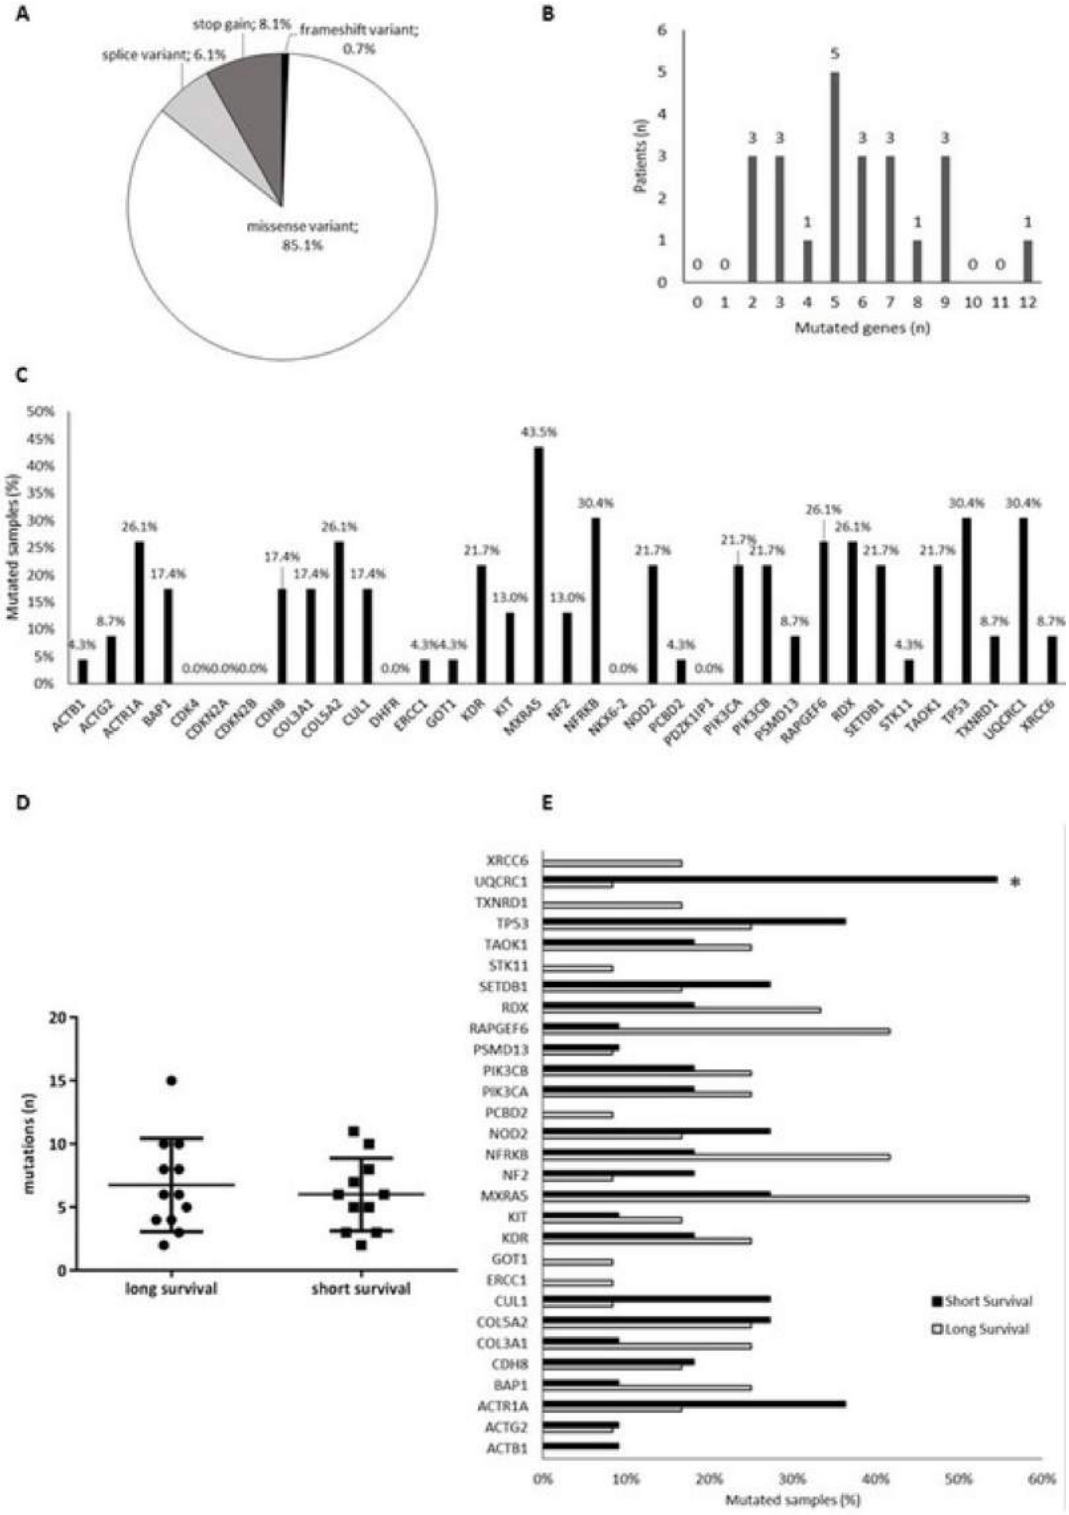

Table 1. patient characteristics.

Variable	Long survival n=12 (%)	Short Survival n=11 (%)	P value
Age (median)	67	72	0.216
Sex			0.193
Female	6 (50)	2 (18.2)	
Male	6 (50)	9 (81.8)	
Side			0.684
Right	7 (58.3)	5 (45.5)	
Left	5 (41.7)	6 (54.5)	

Conclusion: This is the first study that focusing on MPM patients not suitable for multimodality treatment investigated differences in mutational profile between short and long survivors. Our results suggest a possible role of mitochondria metabolism in mesothelioma aggressiveness.

Keywords: malignant pleural mesothelioma, genetic mutations, palliative chemotherapy

MA12.06 PATIENT-DERIVED ORGANOTYPIC TUMOR SPHEROIDS (PDOTS) FACILITATE THERAPEUTIC SCREENING FOR MALIGNANT PLEURAL MESOTHELIOMA

D. Larios[1], E. Ivanova[2,3], A. Aref[2,3], A. Portell[2,3], A. De Rienzo[4], D. Barbie[3], C. Paweletz[2,3], R. Bueno[4]

[1]*Harvard Medical School, Boston/United States of America,* [2]*Belfer Center for Applied Cancer Science, Boston/United States of America,* [3]*Dana-Farber Cancer Institute, Boston/United States of America,* [4]*Brigham and Women's Hospital, Boston/United States of America*

Background: While genotype directed therapies are an essential aspect of personalized medicine in non-small cell lung cancer (NSCLC), this modality is not currently an option in mesothelioma. Instead there is a need for improved functional testing via predictive platforms that can help identify the susceptibility of patient tumors to drug therapies. Here, we demonstrate the use of a novel *ex vivo* functional system utilizing 3D microfluidic culture and patient-derived organotypic tumor spheroids (PDOTS) as a platform to study the tumor microenvironment and predict tumor responses to treatment in mesothelioma. **Method:** We evaluated 31 mesothelioma patient specimens under an IRB approved protocol. PDOTS of mesothelioma were generated as previously described (Larios et al. AACR. 2017; Jenkins et al. Cancer Discovery. 2017). Samples were treated with standard chemotherapy (pemetrexed and cisplatin combined) as well as immunotherapy (ipilimumab and pembrolizumab combined) and live/dead quantification was conducted using dual labeling de-convolution fluorescence microscopy. Positive responses *ex vivo* included samples with significant cell death to control while positive *in vivo* responses were based on radiologic lack of tumor recurrence using the response evaluation criteria in solid tumors (RECIST, version 1.1) to assess for disease progression. **Result:** We found that in treatment naïve specimens prolonged ischemic times were associated with decreased tissue viability (ischemia >25 minutes resulted in decrease of live cells from an average of 81% to 56%), lower tumor yield (< 50% tumor content), and decreased generation of spheroids (< 20 spheroids/well). Specimens with prior treatment were consistently associated with low tissue viability irrespective of ischemic times. Of the 31 specimens studied, 10 samples met viability and tumor content standards to undergo further treatment with standard chemotherapy and immunotherapy, and 5 of those samples were tracked to available patient-treatment response data. Ultimately, comparison of *ex vivo* and *in vivo* treatment responses demonstrated that 4 of 5 samples treated with standard chemotherapy had concordant responses to those of patients who received the same or similar post-operative therapy. Notably, our discordant sample exhibited large variation in standard deviations due to technical variability. **Conclusion:** Here we demonstrate that analysis of *ex vivo* mesothelioma tissue correlates to *in vivo* responses. These results suggest that PDOTS can serve as a predictive platform for therapies. Further work streamlining human tissue collection and optimizing factors that affect formation of PDOTS prior to *ex vivo* treatment analysis should be further investigated.

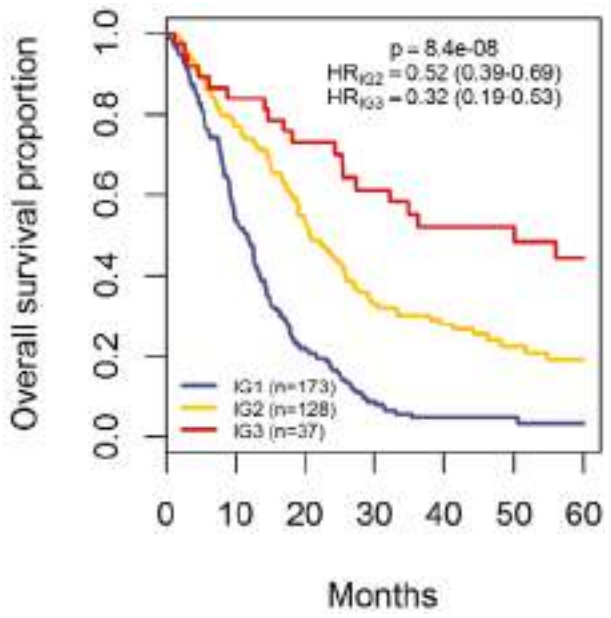
MA12.07 INTEGRATIVE TRANSCRIPTOME ANALYSIS OF MALIGNANT PLEURAL MESOTHELIOMA REVEALS A CLINICALLY-RELEVANT IMMUNE-BASED CLASSIFICATION

A. Alay[1,2], D. Cordero[1,2,3], E. Aliagas[1,2], S. Hijazo-Pechero[1,2], V. Moreno[1,2,3,4], R. Palmero Sánchez[1,2], J.C. Ruffinelli[1,2], R. Ramos[5], I. Macia[5], X. Solé[1,2,3], E. Nadal[4,6,7]

[1]*Catalan Institute of Oncology, L'Hospitalet de Llobregat/Spain,* [2]*Bellvitge Biomedical Research Institute (IDIBELL), L'Hospitalet de Llobregat/Spain,* [3]*Consortium for Biomedical Research in Epidemiology and Public Health (CIBERESP), Madrid/Spain,* [4]*University of Barcelona, Barcelona/Spain,* [5]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona/Spain,* [6]*Catalan Institute of Oncology, Barcelona/Spain,* [7]*Bellvitge Biomedical Research Institute (IDIBELL), Barcelona/Spain*

Background: Malignant pleural mesothelioma (MPM) is a rare and aggressive neoplasia affecting the lining of the lungs. Immune checkpoint inhibitors in MPM have not been extremely successful, likely due to a poor identification of suitable candidate patients for the therapy. The aims of this study were: to identify immune fractions associated with clinical outcome and classify MPM samples based on their immune contexture; to characterize the immune-based groups at the genomic and transcriptomic levels; and to identify potential therapeutic strategies for each group. **Method:** Seven gene-expression datasets of MPM were used to assess the immune microenvironment of 516 samples. The abundance of 20 immune fractions in each sample was inferred using Gene Set Variation Analysis. Identification of clinically-relevant fractions was performed with Cox Proportional-Hazards Models adjusted for age, stage, sex, and tumor histology. **Result:** T-Helper 2 (TH2, HR=2.14, $p=1.5x10^{-4}$) and cytotoxic T cells (CTC; HR=0.57, $p=9.1x10^{-3}$) were found to be consistently associated with overall survival in multiple datasets. Three immune clusters (IG) were subsequently defined based on TH2 and CTC immune infiltration levels: IG1 (54.5% of samples) was characterized by high TH2 and low CTC levels, IG2 (37%) had either low or high levels of both fractions, and IG3 (8.5%) was defined by low TH2 and high CTC levels. This classification was associated with overall survival independently of tumor histology, with an improving survival from IG1 to IG3 (HR_{IG2}=0.52 (0.39–0.69); HR_{IG3}=0.32 (0.19–0.53); $p=8.4x10^{-8}$).



IG3 was significantly enriched in epithelioid tumors (90% IG3 vs. 62% IG1, p=0.001) and patients were younger compared to the other groups (60 years IG3 vs. 66 years IG1, p=0.021). These groups showed differential molecular profiles, with IG1 enriched for CDKN2A

and IFN-related genes deletions. At the transcriptional level, IG1 samples showed upregulation of proliferation and DNA repair-related gene-sets, while IG3 samples presented upregulation of immune and inflammation-related pathways. Finally, integration of gene expression with functional signatures of *in vitro* drug response showed that IG3 patients are more likely to respond to immune checkpoint inhibitors, while IG1 patients could be more sensitive to PARP inhibitors. **Conclusion:** Analysis of publicly available MPM transcriptome data reveals three major immune-based groups, based on TH2 and CTC composition. These clusters are associated with distinct genomic profiles and clinical outcome. Further validation of this classification is warranted in an independent cohort of MPM.

MA12.09 CHECKPOINT INHIBITORS SYNERGIZE WITH DENDRITIC CELL-THERAPY IN PRE-CLINICAL MODELS AND MESOTHELIOMA PATIENTS

R. Belderbos, F. Dammeijer, M. Gulijk, M. Lukkes, D. Dumoulin, R. Cornelissen, J. Aerts

Erasmus University Medical Center, Rotterdam/Netherlands

Background: Malignant Pleural Mesothelioma (MPM) is a lethal, treatment resistant neoplasm. Checkpoint inhibitors (CI) have shown promising clinical effects in a minority of patients. It is hypothesized that low response rates to CI are correlated to low numbers of tumor-infiltrating T-cells in MPM patients. Dendritic cell (DC) therapy instigates an immune response and activates tumor-specific T-cells. DC therapy has proven to be effective in pre-clinical models and in a subset of MPM patients. Upregulation of PD-L1 and PD-1 co-inhibitory checkpoints may suppress DC-therapy induced anti-tumor immune response and limit clinical efficacy. To investigate this, we conducted a preclinical and clinical study to evaluate the clinical and immunological effects of DC therapy combined with CI. **Method:** Immune competent CBA/J mice were orthotopically injected with a syngeneic mesothelioma cell line. Mice were treated with DC-therapy alone or in combination anti-PD-L1 antibodies at high tumor load when DC-monotherapy was found to be ineffective. Peripheral blood and tumors were obtained for flow cytometric analysis and survival was monitored.

In a clinical setting, nine patients that received DC therapy were sequentially treated with CI. Progression free survival (PFS) was determined from start of CI, using the modified RECIST criteria. **Result:** Tumors of mice treated with DC-therapy exhibited a three-fold increase in CD8+ T-cell infiltration which was paralleled by heightened expression of PD-L1 on tumor cells (r^2=0.69, *p=0.0015*). Whereas both anti-PD-L1 and DC-monotherapies were ineffective in prolonging survival in our model, combination immunotherapy did (median OS: 24 vs 35 days, *p=0.0063)*. Immune monitoring analyses demonstrated a synergistic increase in proliferation and activation of circulating T-cell following combination therapy. In the clinical trial 3 patients had partial response, 5 patients had stable disease and 1 patient had progressive disease. Median PFS was 5,2 months and median OS was 17,5 months. Currently 3 patients are still alive and two patients are still progression free. There were no grade 3/4 adverse events. PD-L1 expression in tumor biopsies was increased after DC therapy in two of the three responders to CI. **Conclusion:** In a murine model the synergy between DC therapy and CI was proven and efficacy was driven by activation of CD4+ and CD8+ positive cells. In humans, CI after DC therapy is safe and feasible. Disease control was seen in 8 out of 9 patients treated with CI after DC therapy. DC therapy induces tumor-specific CD8+ T-cell proliferation which is correlated to PD-L1 expression on tumor cells and possibly synergizes with CI treatment.

MA12.10 NOVEL GERMLINE MUTATIONS IN DNA-DAMAGE REPAIR AND DNA REPLICATION IDENTIFIED IN PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA (MPM)

R. Guo, M. Duboff, M. Kris, M. Ladanyi, D. Mandelker, M. Zauderer

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Recent efforts to characterize the germline genetic landscape of MPM have uncovered a surprising prevalence of pathogenic variants in DNA-damage sensing and repair genes. Increasingly, next-generation sequencing has helped bring new insight into critical mutations or pathways involved in the development of MPM. Additionally, observations from these studies could direct new screening, prevention, and therapeutic approaches for patients and families. **Method:** With IRB approval, we performed deidentified analysis on 87 additional cancer-predisposing genes on our NGS platform among patients with MPM previously consented to a BAP1 germline testing protocol. Additionally, germline variants in an additional 380 genes associated with somatic alterations in cancer, but not associated with hereditary cancer predisposition, were screened for loss of function variant or pathogenic entries in ClinVar. All variants were reviewed according to the American College of Medical Genetics and Genomics and Association for Molecular Pathology consensus guidelines. Founder mutations were excluded. Clinicopathologic information was also collected. Comparisons were done using Fisher's exact test. P values <0.05 were considered significant. **Result:** Of 88 patients with MPM analyzed, 11% (10/88) had pathogenic variants. Clinical characteristics such as age, sex, histology, and self-reported asbestos exposure, were similar between patients with and without pathogenic variants (Table 1). Pathogenic variants previously unreported in mesothelioma were identified: MSH3 1/88 (1%; 95% CI: 0-7%), BARD1 1/88 (1%; 95% CI: 0-7%), and RECQL4 2/88 (2%; 95% CI: 0-8%). We also identified pathogenic variants previously associated with mesothelioma: BAP1 in 3/88 (3%; 95% CI: 1-10%), BRCA2 1/88 (1%; 95% CI: 0-7%), and MRE11A 1/88 (1%; 95% CI: 0-7%). One patient had a potentially pathogenic alteration in SHQ1, which has not been associated with a heightened susceptibility to cancer. Patients with germline pathogenic variants were more likely to have more than 2 first-degree family members with cancer compared to those without germline mutations (40% vs 13%; p = 0.049). **Conclusion:** While the overall incidence of germline mutations identified is similar to prior reports, we identified germline pathogenic alterations in three DNA damage repair and replication genes not previously reported in mesothelioma. Furthermore, we describe a novel germline alteration in SHQ1, which has not been reported with hereditary cancer predisposition. Whether these variants increase the risk of mesothelioma is still under investigation, but given the high rate of germline pathogenic variant in individuals with pleural mesothelioma, germline testing for hereditary cancer susceptibility should be considered in all patients with MPM.

MA12.11 ANTI-TUMOR EFFICACY OF MESOTHELIN TARGETED IMMUNOTOXIN LMB-100 PLUS PEMBROLIZUMAB IN MESOTHELIOMA PATIENTS AND MOUSE MODELS

Q. Jiang, A. Ghafoor, D. Rathkey, I. Mian, J. Zhang, B. Morrow, I. Pastan, R. Hassan

National Institutes of Health, Bethesda/United States of America

Background: LMB-100 is an immunotoxin targeting mesothelin (MSLN) that is highly expressed in malignant mesothelioma and lung adenocarcinoma. Given the clinical efficacy of immune checkpoint inhibitors in these cancers, we aimed to evaluate if LMB-100 in combination with αPD-1 antibody will result in greater anti-tumor efficacy. **Method:** Patients who were treated on a phase I clinical trial of LMB-100 and then received pembrolizumab were evaluated for anti-tumor response and overall survival. We also evaluated LMB-100/αPD-1 combination efficacy in humanized mouse model transplanted with the tumor cells derived from the mesothelioma patient who achieved complete response and healthy donor's PBMCs. Immune gene expression in pre- and post- LMB-100-treated mesothelioma patient tumor biopsies was detected with NanoString. To further understand the mechanisms of anti-tumor efficacy of LMB-100 plus αPD-1 therapy,we established a human MSLN expressing lung adenocarcinoma syngeneic mouse model with mouse lung adenocarcinoma cell line 531LN2 stably transfected with a vector encoding hMSLN. Using NanoString gene expression assay and flow cytometry, we analyzed drug induced cancer immune responses in 531LN2-hMSLN tumors. Finally, to understand the role of $CD8^+$ T cells in the anti-tumor effects, we depleted $CD8^+$ T cells in LMB-100 plus anti-PD-1 treated 531LN2-hMSLN bearing mice. **Result:** Nine mesothelioma patients received pembrolizumab, off-protocol, within 3-4 weeks post LMB-100 treatment. Two patients had disease progression before they could be evaluated for tumor response. Out of the 7 patients who were evaluable for response, 4 had durable objective tumor response including 1 complete and 3 partial responses with progression free survival of 104.3+, 49.6, 49.2 and 37.7 weeks. The overall survival of patients with response was 30.2+, 27.7, 23.8+, and 13.8 months from the start of LMB-100 treatments. The immune cell type signature scores including $CD45^+$, $CD8^+$ T cells, exhausted $CD8^+$ T cells, dendritic cells and macrophages were increased in 4 of 6 patients post LMB-100 treatments. The enhanced anti-tumor effects with LMB-100/αPD1 combination were also observed in the PBMC humanized mouse model transplanted with the tumor cells derived the patient with complete response. In the 531LN2-hMSLN mouse syngeneic model, tumor growth was significantly inhibited by LMB-100/αPD-1 treatments than either monotherapy and overall survival was improved in the combination treated mice. The median tumor volume was 865mm^3, 420mm^3, 277mm^3, and 65mm^3 in untreated, LMB-100-treated, αPD-1-treated, and combination treated groups respectively on day 34 post tumor inoculation ($p<0.001$). We observed increased expression of genes related to $CD8^+$T cells and antigen presentation in tumors treated with LMB-100/αPD-1 compared to either agent alone. Flow cytometry confirmed the $CD8^+$T cells increase in LMB-100 /αPD-1 treated 531LN2-hMSLN tumor. Depletion of $CD8^+$T cells significantly negated the anti-tumor benefits in LMB-100/αPD-1-treated mice. **Conclusion:** Pembrolizumab following LMB-100 is associated with durable tumor response in mesothelioma patients as well as pre-clinical models of mesothelioma and lung cancer. This combination is currently being evaluated in a prospective clinical trial in patients with mesothelioma (clinicaltrials.gov # NCT03644550).

MONDAY, SEPTEMBER 9 14:00–15:30

MA13.01 ASSOCIATIONS BETWEEN BASELINE SERUM BIOMARKER LEVELS AND CACHEXIA/PRE-CACHEXIA IN PRETREATED NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS

G. Lobato[1], M.J. Fidler[2], J. Fialkoff[1], M. Multani[1], C. Wakefield[1], S. Basu[2], M. Batus[2], P. Bonomi[2], J. Borgia[1]

[1]*Rush University Medical Center, Chicago/United States of America,* [2]*Rush University Medical Center, chicago/United States of America*

Background: We previously reported associations of pretreatment serum biomarkers with clinical outcomes in a cohort of advanced NSCLC patients that progressed on front-line therapy. This study aims to elucidate mechanisms underlying cancer cachexia/ pre-cachexia by evaluating relationships between baseline serum biomarker values and sequential changes in body weight, body mass index (BMI), and neutrophil/lymphocyte ratio (NLR) in NSCLC patients. **Method:** We used Luminex immunobead assays to survey 101 protein biomarkers in sera from advanced NSCLC (n=138) collected prior to their salvage regimen. Serial parameters associated with cancer cachexia included body weight, BMI, and NLR. Outcome variables (progression-free survival (PFS) and overall survival (OS)) were extracted with full IRB-approval. Biomarkers were evaluated as continuous variables with the cachexia surrogates using Pearson correlations, whereas associations of PFS and OS were accomplished with the Cox PH test. **Result:** High baseline values of BMI and low baseline NLR were associated with both OS and PFS (each p<0.05), though weight failed to reach significance. PFS and OS were similarly associated with percent changes (relative to baseline) in weight (p<0.01), BMI (p<0.01), and NLR (p<0.001). Thirteen biomarkers were found to be associated (p<0.05) with baseline BMI values, including positive correlations with leptin, sol. VEGFR2, and c-peptide and inverse correlations with adiponectin, ferritin, ghrelin, IGFBP-1 and IL-8; fifteen biomarkers were associated with baseline NLR (all p<0.05), including positive correlations with visfatin, insulin, and serum amyloid A and inverse correlations with IGF-II. Fifteen biomarkers were found to be associated (p<0.05) in common with percent weight and BMI changes, including positive correlations with IGFBP-3 and inverse correlations with insulin, FGF-2, TNF-alpha, and resistin. Only prolactin and placental growth factor were found to be associated (p<0.05) with percent change in NLR. **Conclusion:** A series of circulating protein biomarkers primarily connected with metabolic regulation and systemic inflammation/ acute phase response were found to be associated with cachexia/ pre-cachexia in NSCLC patients. Additional cohorts are currently being tested to verify these findings.

[1]*Shimane University Faculty of Medicine, Shimane/Japan,* [2]*Hiroshima Prefectural Hospital, Hiroshima/Japan,* [3]*St. Marianna University School of Medicine, Kanagawa/Japan,* [4]*Kurashiki Central Hospital, Kurashiki/Japan,* [5]*Tohoku University Hospital, Sendai/Japan,* [6]*Hiroshima University Hospital, Hiroshima/Japan,* [7]*National Hospital Organization Iwakuni Clinical Center, Iwakuni/Japan,* [8]*Asahi Chuo Hospital, Asahi/Japan,* [9]*National Hospital Organization Iwakuni Clinical Center, Kure/Japan,* [10]*Yamaguchi-Ube Medical Center, Ube/Japan,* [11]*Hiroshima Red Cross Hospital & Atomic-bomb Survivors Hospital, Hiroshima/Japan,* [12]*Kochi Medical School, Kochi University, Kochi/ Japan,* [13]*Saitama Medical University, Saitama/Japan*

Background: Venous thromboembolism (VTE) is a most well-known kind of cancer associated thrombosis, and a common complication of malignancy. However, little is known about the incidence of VTE at the time of lung cancer diagnosis. This information is important for clinicians and patients to inform their decision-making about cancer treatment. **Method:** The Rising-VTE/NEJ037 study was a multicenter, prospective, observational study with 40 participating Japanese institutions. It included 1,021 patients diagnosed with lung cancer unsuitable for radical resection or radiation between June 2016 and August 2018. The incidence of VTE and characteristics of patients diagnosed with VTE based on contrast-enhanced computed tomography or ultrasonography of the leg are described. Diagnosis of VTE was confirmed via central review by two radiologists. **Result:** Baseline data was available for 1,013 patients. The median age was 71 years (range 30-94). Eighty-six percent of patients had non-small cell lung cancer and 13.5% had small cell lung cancer. Histological types included adenocarcinoma (N=645, 63.7%), squamous cell carcinoma (N=180, 17.8%), small-cell lung cancer (N=137, 13.5%) and others (N=42, 4.1%). There were 59 patients (5.8%) diagnosed with VTE, of whom 53.9% had deep vein thrombosis (DVT), 28.7% had pulmonary embolism (PE) and 24.6% had both DVT and PE. Most patients with VTE had adenocarcinomas (89.1%). **Conclusion:** The incidence of VTE in this study seems to be higher than in the clinical setting, suggesting that screening may be desirable. Adenocarcinoma of the lung seems to be a risk factor for VTE that we should consider more carefully. The primary endpoint of this trial is the rate of symptomatic or asymptomatic recurrence or newly diagnosed VTE during 2 years after registration. Follow-up is ongoing, with a report of final findings planned for 2021. Clinical trial information: UMIN000020194. Funding: Daiichi Sankyo Company.

MONDAY, SEPTEMBER 9 14:00–15:30

MA13.03 RETROSPECTIVE STUDY OF INTRATHECAL THERAPY FOR NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS WITH LEPTOMENINGEAL CARCINOMATOSIS

N. Vilariño[1], J.A. Marín[1], M. Simó[2], R. Velasco[2], M. Alemany[2], M. Jove[1], J.C. Ruffinelli[1], I. Brao[1], M. Arellano[1], R. Palmero Sánchez[1], J. Bruna[2], E. Nadal[3]

[1]*Institut Català d'Oncologia, L'Hospitalet de Llobregat, L'Hospitalet de Llobregat/ Barcelona/Spain,* [2]*Bellvitge Hospital, Barcelona/Spain,* [3]*Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona/Spain*

Background: Leptomeningeal carcinomatosis (LMC) is a devastating cancer-related neurological complication with poor prognosis. In *EGFR*-mutant (mut) NSCLC patients (pts), osimertinib achieves high penetration into cerebral-spinal fluid (CSF) and promising efficacy. However, for *EGFR*-mut *T790M*-negative pts treated with prior 1st- and 2nd-generation tyrosine kinase inhibitors (TKI) and for driver negative NSCLC pts, a combination of intrathecal therapy (IT) and systemic therapy (ST) seems to be an appropriate approach. Our purpose is to explore the clinical outcome of IT combined with ST among NSCLC with LMC depending on *EGFR* status. **Method:** NSCLC pts with LMC treated with IT in our institution between 2010 and 2018 were retrospectively studied. After LMC diagnosis, intrathecal methotrexate (scheduled: 12mg twice weekly for 4 weeks, then 12mg weekly for 4 weeks) was given in combination with ST. A Kaplan-Meier survival analysis was performed for overall survival (OS) and progression free survival (PFS). **Result:** A total of 39 pts were included. Patient's clinical characteristics are summarized in table 1. *EGFR* status was 17 mut (del19: 11pts); 11 wild-type (wt) and 11 unknown (unk). LMC and NSCLC diagnosis were more likely to be synchronous in *EGFR* wt compared with *EGFR* mut. The median follow-up from LCM diagnosis was 10.2 months. At the time of this analysis, only 6 pts were alive. Thirty-two pts received ST in combination with IT, 18 (46%) pts chemotherapy (6wt/ 3mut/ 9unk), while 14 (36%) pts an *EGFR* TKI (1wt/ 13mut). Clinical response (improvement of neurological symptoms and/or KPS) was seen in 11 (65%) *EGFR* mut pts vs 2 (18%) wt pts (p=0.033). Median OS and PFS for the whole cohort were 23 weeks (95%CI, 8.1 to 37.9) and 10 weeks (95%CI, 7.1 to 12.8) respectively. Median OS was higher for *EGFR* mut pts compared to wt pts, 38 weeks (95%IC 13.6-62.4) and 19 weeks (95%IC, 4.06-33.9) respectively, however this difference was not statistically significant (p=0.36) probably due to lack of statistical power.

Background: *nab*-Paclitaxel maintenance therapy after *nab*-paclitaxel/carboplatin induction in patients with advanced squamous NSCLC was evaluated in the phase III, randomized, controlled, open-label, multicenter ABOUND.sqm trial. At the 12-month follow-up, there was no statistically significant difference in progression-free survival (PFS) between patients randomized to maintenance *nab*-paclitaxel + best supportive care (BSC) vs BSC alone. However, a trend of an overall survival (OS) advantage was observed with *nab*-paclitaxel + BSC vs BSC alone. Here we report the 18-month follow-up of OS. **Method:** Patients (aged ≥ 18 years) with histologically or cytologically confirmed stage IIIB/IV squamous NSCLC and no prior chemotherapy were eligible. Patients received four 21-day cycles of *nab*-paclitaxel 100 mg/m^2 (days 1, 8, and 15) plus carboplatin AUC 6 (day 1) as induction. Patients with radiologically assessed complete or partial response or stable disease without clinical progression after 4 cycles were randomized 2:1 to maintenance *nab*-paclitaxel 100 mg/m^2 (days 1 and 8 of each 21-day cycle) plus BSC or BSC alone until disease progression. The primary efficacy analysis was performed on the ITT population. PFS from randomization into the maintenance part of the study was the primary endpoint. Secondary endpoints included safety, OS (from randomization), and response. **Result:** 420 patients received induction therapy; 202 were randomized to maintenance *nab*-paclitaxel + BSC (n = 136) or BSC alone (n = 66). The median PFS in patients in the *nab*-paclitaxel + BSC arm vs those in the BSC-alone arm was 3.1 vs 2.6 months (HR, 0.85; *P* = 0.349), respectively; the median OS was 17.8 vs 12.2 months (HR, 0.71; *P* = 0.058), respectively. The overall response rate was 69.1% vs 57.6% (RRR, 1.20; *P* = 0.087). Following the maintenance part, 73.5% (*nab*-paclitaxel + BSC) and 68.2% (BSC alone) of patients received subsequent anti-cancer treatment. Over the entire study, the most frequent grade 3/4 TEAEs were neutropenia (53.1% vs 50.0%) and

anemia (33.1% vs 32.3%); only peripheral neuropathy occurred in ≥ 5% of patients during maintenance (13.1% in the *nab*-paclitaxel + BSC arm). **Conclusion:** Although PFS and OS differences were not statistically significant in the ITT population, the 18-month follow-up of OS demonstrated the feasibility of *nab*-paclitaxel maintenance therapy for patients with anced squamous NSCLC. ClinicalTrials.gov identifier: NCT02027428

Background: Our previous phase 3 study established carboplatin plus the oral fluorinated pyrimidine formulation S-1 as a standard option for first-line treatment of advanced non–small cell lung cancer (NSCLC) (J Clin Oncol 2010; 28:5240). The importance of maintenance therapy for patients with advanced squamous NSCLC has been unknown, however. **Method:** WJOG7512L was designed as a randomized phase 3 study to evaluate whether maintenance therapy with S-1 improves clinical outcome after induction therapy with carboplatin plus S-1 in such patients. Before randomization, patients received carboplatin (AUC of 5 on day 1 every 3 weeks) plus S-1 (40 mg/m^2 twice per day on days 1 to 14 every 3 weeks) as induction therapy. Those who did not progress after four cycles of induction therapy were randomized to receive either S-1 plus best supportive care (BSC) or BSC alone. The primary objective was to confirm the superiority of S-1 plus BSC with regard to progression-free survival. **Result:** Of the 365 patients enrolled, 347 participated in the induction phase and 131 of these individuals were randomized to receive S-1 plus BSC (*n* = 67) or BSC alone (*n* = 64). Baseline demographics and clinical characteristics of the subjects, including the response to induction therapy, were well balanced. Patients receiving S-1 plus BSC showed a significantly reduced risk of disease progression compared with those receiving BSC alone (hazard ratio [HR], 0.548; 95% confidence interval [CI], 0.374–0.802; *P* = 0.0019). Median overall survival from randomization did not differ significantly between the two arms: 17.8 months for BSC alone and 16.7 months for S-1 plus BSC (HR, 0.890; 95% CI, 0.583–1.357). Time to deterioration in quality of life also showed no significant difference (*P* = 0.8754 for FACT-TOI, *P* = 0.9016 for FACT-LCS). The incidence of adverse events during maintenance therapy was low, with neutropenia, anemia, and thrombocytopenia of grade 3 or 4 each occurring in ~1% to 4% of patients. **Conclusion:** Maintenance with S-1 plus BSC is an effective and well-tolerated treatment option for patients with advanced squamous NSCLC.

Background: Combination chemotherapy of carboplatin (CBDCA) plus weekly nab-paclitaxel (nab-PTX) showed a favorable efficacy for elderly (70 year or older) patients with squamous non-small cell lung cancer (Sq-NSCLC) in a subgroup analysis of the CA031 study. We conducted a phase I/II study of CBDCA plus nab-PTX in chemo-naïve elderly patients with advanced Sq-NSCLC. **Method:** Patients aged ≥75 years with untreated, measurable lesion, advanced Sq-NSCLC, performance status (PS) 0-1, and adequate organ function were eligible. In a phase I study, doses of carboplatin at an area under the curve (AUC) of 5 or 6 mg/mL min on day 1 (levels 1 and 2, respectively) were administered along with weekly nab-PTX (100 mg/m^2) on days 1, 8, and 15 every 4 weeks up to 6 cycles using a modified 3 + 3 design. The primary endpoint for the phase II study was the 6-month progression-free survival (6m PFS) rate and hypothesis required 36 patients to be enrolled with expecting and threshold values for the primary endpoints of 40% and 25% (one-sided alpha = 0.05; beta = 0.2). **Result:** A total of 46 patients were enrolled in this study. The median age was 78 (range 75-85 years); male (n = 41); PS 0/1, (n = 15/31). Ten patients were enrolled in the phase I part. At dose level 1, 2/7 patients showed dose-limiting toxicities (DLTs) of grade 3 diarrhea and febrile neutropenia, and at dose level 2, 1/3 patient showed DLT of grade 3 anorexia. The recommended dose was determined to be level 2. Additional 36 patients were enrolled, and a total of 39 patients were evaluated in the phase II study. The median number of cycles was 4 (range 1-6), and the median follow-up time was 17.5 months (range 5.6-28.9). The 6m PFS rate was 59% (90% CI, 44.8-71.4), and the primary endpoint was met. The median overall survival time was 23.5 months (95% CI, 11.6-35.4), and the median PFS was 6.8 months (95% CI, 5.4-9.1). The response rate was 54% and disease control rate was 92%. Nineteen patients (49%) received post-study treatment and 14 out of 19 patients (74%) received immunotherapy. Common toxicities of grade 3 or 4 were neutropenia (61.5%), anemia (46.2%), thrombocytopenia (17.9%), and febrile neutropenia (15.4%). There was no treatment-related death. **Conclusion:** Combination chemotherapy of CBDCA plus weekly nab-PTX had a promising efficacy and acceptable toxicities in elderly (aged ≥75) patients with advanced Sq-NSCLC. Clinical trial information: UMIN000011216.

MA13.09 CISPLATIN SUSTAINS LUNG CANCER METASTASIS THROUGH THE SYSTEMIC ACTIVATION OF SDF-1/CXCR4 AXIS

G. Bertolini[1], V. Cancila[2], C. Tripodo[2], G. Sozzi[1], G. Lo Russo[1], O. Fortunato[1], M. Milione[1], G. Centonze[1], M. Tortoreto[1], S. Scala[3], L. Roz[1]

Background: Standard chemotherapy regimens have limited long-term efficacy in lung cancer patients due to chemoresistance and inefficacy in controlling metastatic disease. In pre-clinical models we have shown that cisplatin treatment enriches for the chemoresistant fraction of CD133+CXCR4+ lung cancer metastasis initiating cells (MICs), increasing distant metastasis development that can be prevented by CXCR4 blockade. Therefore, we hypothesize that the SDF-1/CXCR4 axis, implied in MICs maintenance/migration and in immune and stromal cells trafficking, could play a critical role in cisplatin-induced pro-metastatic effects. **Method:** To study the effects of cisplatin in promoting a pre-metastatic niche, naïve SCID mice were treated with cisplatin plus/minus peptide R (5mg/kg), a novel inhibitor of CXCR4 and after 72h injected intravenously with metastatic H460 cell line. To assess the effect of the combination treatment in pre-clinical model, H460 subcutaneous xenografts were treated with cisplatin alone or with peptide R for three weeks. Content of MICs in xenografts, number and phenotype of lung metastasis and immune cells modulationt were evaluated by FACS and IHC **Result:** We showed that cisplatin treatment of naïf SCID mice resulted in a rapid BM expansion of the subset of CCR2+CXCR4+Ly6C^{high} inflammatory monocytes (IM), concomitantly with their recruitment to murine lungs guided by increased level of SFD-1 released by PDGFRβ+ stromal cells in response to cisplatin. Peptide R partially prevented these effects. Tail-vein injection of H460 human lung cancer cells 72h after cisplatin administration resulted in augmented number of lung metastases (p=0.003), that showed a 3.5-fold enrichment in CD133+CXCR4+ MICs (p=0.005) and increase of IM and derived macrophages. Pre-treatment with peptide R abolished these effects. We verified that the abundance of CXCR4+CCR2+IM together with increased endothelial permeability caused by cisplatin may favor tumor cells extravasations and expansion of MICs through SDF-1/CXCR4 axis activation which determined metastasis overgrowth. SDF-1 was also increased in cisplatin-treated subcutaneous H460 xenografts that expanded the subset of chemoresistant CD133+CXCR4+ MICs and recruited CXCR4+tumor associated macrophages which may allow MICs to escape primary tumor. At the metastatic site cisplatin treatment of H460 xenografts caused an increase in stromal SDF-1 and recruitment of both CXCR4+ inflammatory monocytes/macrophages (1.6-fold change p=0.01) and MICs subset (1.8-fold change p=0,04), overall resulting in a boost in micrometastases. CXCR4 inhibition prevented the co-recruitment and cross-talk of MICs and IM at distant site, counteracting the pro-metastatic effects of cisplatin. Matched case series of stage III chemo-naive NSCLC patients and cisplatin-based neo-adjuvant treated patients demonstrated a significant increased in SDF-1 after chemotherapy (p=0,0001). An high expression of tumoral SDF-1 (Score: staining intensity x % positive tumor cells >6) induced by cisplatin neo-adjuvant treatment was associated with a shorter DFS (p=0,0056) and poor OS (p=0,029). **Conclusion:** Our data reveal a paradoxical pro-metastatic effect of cisplatin that fosters MIC-IM recruitment and cross-talk via SDF-1/CXCR4 axis activation. A new combination strategy based on CXCR4 inhibition may disrupt these interactions, providing more effective and long-lasting results for lung cancer treatment

Background: Because of the high risk of exacerbation of pre-existing interstitial lung disease (ILD), patients with concomitant advanced non-small cell lung cancer (NSCLC) and ILD have been excluded from most clinical trials of chemotherapy, despite the high prevalence (around 10%) of all NSCLC cases. This study prospectively evaluated the efficacy and safety of albumin-bound paclitaxel (*nab*-paclitaxel) in combination with carboplatin in advanced NSCLC patients with pre-existing ILD. **Method:** Enrolled patients had treatment-naïve, advanced NSCLC with pre-existing ILD. Patients received 100 mg/m^2*nab*-paclitaxel weekly and carboplatin at area under the concentration-time curve (AUC) 6 once every 3 weeks for 4-6 cycles. The primary endpoint was overall response rate (ORR); secondary endpoints included toxicity, progression-free survival (PFS) and overall survival (OS). The interactions between histology [Squamous (Sq) vs. Non-Squamous (Non-Sq)] and treatment outcomes were also investegated. **Result:** Thirty-six patients were enrolled between April 2014 and September 2017. Sixteen patients (44.4%) had an adenocarcinoma, followed by 15 (41.7%) squamous cell carcinoma, and 5 (13.9%) non-small cell carcinoma. The median number of cycles administered were 4 (range: 1-6). The ORR, the primary endpoint, was 55.6% (95% confidence interval [CI]: 39.6-70.5%). The median PFS and OS were 5.3 months (95% CI: 3.9-8.2 months) and 15.4 months (95% CI: 9.4-18.7 months), respectively. There was no significant difference between two groups, however, numerically better treatment outcomes were observed in the Sq group: the ORR was 66.7% (95% CI: 41.7–84.8%) in the Sq group compared with 47.6 % (95% CI: 28.3–67.6%) in the Non-Sq group (P =0.254); median PFS was 8.2 months (95% CI: 4.0–10.2 months) in the Sq group vs. 4.1 months (95% CI: 3.3-5.4 months) in the Non-Sq group (HR, 0.60 [95% CI, 0.30–1.20]; p=0.15); median OS was 16.8 months (95% CI: 9.8 months–not reached) in the Sq group vs. 11.9 months (95% CI: 7.3-17.4 months) in the Non-Sq group (HR, 0.56 [95% CI, 0.24–1.28]; p=0.17). Two patients (5.6%) experienced grade ≥2 pneumonitis and one patient (2.8%) died. **Conclusion:** This is the first prospective phase 2 study of weekly nab-paclitaxel in combination with carboplatin in advanced NSCLC patients with pre-existing ILD. This treatment showed favorable efficacy and was well tolerated.

Background: Cisplatin-sb-Pac is the one of current standard of chemotherapy in aNSCLC, It produced 15% to 32% objective response rate (ORR) and 7.9 to 10.6 months of median overall survival (OS). Alternative nab-paclitaxel to sb-Pac only increased ORR but not improved progression-free survival (PFS) and OS. Thus the unmet medical need for new chemo regimen remains. **Method:** From May 2015 to Jan 2018 448 untreated patients (pts) with stage IIIB to IV NSCLC from 24 sites were randomly assigned 2:1 to receive 230 mg/m^2 pm-Pac and cisplatin 70 mg/m^2 on day 1 of a 3-week cycle, and then dose escalation of pm-Pac to 300 mg/m^2 from the second cycle if no prespecified toxic effects observed or 175 mg/m^2 sb-Pac plus cisplatin 70 mg/m^2 once every 3 weeks. Pts were stratified by stage and histology. The primary end point was ORR by Independent review committee (IRC) and Investigator (INV) in the intent-to-treat population. The second endpoints included PFS, OS and safety. Data cutoff was Jan 26, 2019. **Result:** 300 pts were assigned to pm-Pac and 148 to sb-Pac. Baseline characteristic were balance in both arms. Nonsquamous carcinoma (non-squ) and stage IV were 57.3% and 81.0% in pm-Pac and 58.1% and 81.8% in sb-Pac respectively. 73.2% pts in pm-Pac arm escalated their dose to 300mg/m^2, 0.7% down to 184mg/m^2. ORR and PFS in pm-Pac were significant better than that in sb-Pac (table 1). OS was immature. For histology subgroup the ORR was 58.6% v 37.1% (P=0.0054) in squamous carcinoma (Squ) and 44.2% v 18.6% (P<0.0001) in non-squ. Grade ≥3 AEs was 80.0% for pm-Pac and 79.7% for sb-Pac. No new safety issues were identified. **Conclusion:** The phase 3 trial met its primary endpoint. pm-Pac significantly improved ORR and PFS than sb-Pac, and pm-Pac regimen should be a new standard chemo for aNSCLC. (NCT 02667743).

Background: Recent studies on next generation sequencing (NGS) data from cancer patients have demonstrated that germline mutations in genetic predisposition genes were more common than previous known in many cancer types including lung cancer. However, most previous studies have focused on western patient population and the germline mutation landscape in Asian lung cancer patients and the clinical and genomic features in these patients are largely unknown. **Method:** NGS data from a targeted panel of 1,021 known cancer genes from paired cancer and germline DNA of 1,797 Chinese lung cancer patients was analyzed to identify pathogenic or likely pathogenic (P/LP) germline variants in predisposition genes based on American College of Medical Genetics and Genomics (ACMG) 2015 guideline. **Result:** Totally, 5.95% of lung patients were found to harbor germline variants in 35 cancer predisposition genes. The prevalence of germline mutations was higher in patients under 40 compared to older counterparts (10.1% vs 5.74%, p=0.103, Chi-Square test) although it did not reach statistical significance. However, germline *BRCA1/2* mutations were associated with earlier age of onset (median 52.5 vs 60 years-old, *p*=0.0080 by Mann-Whitney test). Furthermore, patients with P/LP germline mutations had significantly more somatic mutations in *KRAS* (*p*=0.012, fisher's exact test) and *c-MET* (*p*=0.018, fisher's exact test) oncogenes, but less in tumor suppressor gene *TP53* (*p*=0.019, fisher's exact test). Compared to western lung cancer patients enrolled in TCGA, P/LP germline mutations in *BRCA2, FANCA, ATM, MUTYH, BLM, TP53, BRCA1, CHEK2, PMS2, NBN* and *FANCC* were identified in both current Chinese cohort and TCGA cohort with *BRCA2* germline mutations significantly more common in Chinese cohort than TCGA cohort (p=0.015, Fisher's exact test). In addition, *RAD51D*, *FANCD2*, *BRIP1*, *MSH6*, *PMS1*, *PALB2*, *RAD51C*, *SDHA*, *TSC2*, *BAP1*, *CDH1*, *FLCN*, *NF1* and *RUNX1*) were exclusively identified in Chinese patients, while *RET, ERCC3*, *FANCG* and *VHL* were only detected in TCGA cohort. **Conclusion:** These results implied that there might be both common and unique cancer predisposition germline mutations for lung cancer between Asian and Western patient populations.

Background: Entrectinib potently inhibits kinases encoded by NTRK and ROS1 genes. It achieves therapeutic levels in the CNS with antitumor activity in intracranial tumor models. We report integrated analysis data (31 May 2018 data cut-off) from three Phase 1/2 entrectinib trials (ALKA-372-001 [EudraCT 2012-000148-88]; STARTRK-1 [NCT02097810]; STARTRK-2 [NCT02568267]) for a large cohort of adult patients with NTRK fusion-positive solid tumors (NTRK+) or ROS1 fusion-positive NSCLC (ROS1+), with baseline CNS metastases. **Method:** Patients had locally advanced/metastatic NTRK+ solid tumors or ROS1+ NSCLC by nucleic acid-based assays confirmation. Baseline CNS metastases were identified by CT/MRI. Tumor assessments were performed at baseline, week 4, and then every 8 weeks by blinded independent central review (RECIST v1.1). Primary endpoints were overall response rate (ORR), duration of response (DOR). Secondary endpoints included progression-free survival (PFS), overall survival (OS), intracranial efficacy in patients with CNS metastases, safety. **Result:** Most patients were treated first-line or after one line of prior therapy; baseline characteristics relating to measurable CNS metastases for patients with NTRK+ solid tumors and ROS1+ NSCLC are presented (Table). Intracranial outcomes for the NTRK+ solid tumors (n=54; 18% NSCLC) and ROS1+ NSCLC (n=53) efficacy evaluable populations are reported (Table). Durability of treatment effect and potential delayed progression in the CNS was observed; time to CNS progression was 17.0 months (95% CI: 14.3–NE) for NTRK+ solid tumor patients and NE (95% CI: 15.1–NE) for ROS1+ NSCLC. In the subset of patients with NTRK+ NSCLC (n=10), 6 patients had CNS metastases at baseline (by BICR); IC-ORR was 66.7% (4/6), 2 CR; IC-DOR was NE. In both the NTRK+ and ROS1+ populations, entrectinib was tolerable with a manageable safety profile; most treatment-related AEs were grade 1–2. **Conclusion:** Entrectinib induced clinically meaningful durable responses in patients with *NTRK*+ solid tumors or *ROS1*+ NSCLC with CNS disease at baseline. Funding: This study was funded by F. Hoffmann-La Roche

Background: Telisotuzumab vedotin (ABBV-399; teliso-v) is an anti-c-Met antibody conjugated with monomethyl auristatin E, a tubulin polymerization inhibitor. Preliminary activity was reported for the teliso-v + erlotinib combination in c-Met overexpressing (c-MET+) non-small cell lung cancer (NSCLC) patients, with an activating *EGFR* mutation and for whom prior EGFR TKI failed. We present mature data from the *EGFR* M+ subgroup of the teliso-v + erlotinib cohort of a phase 1b study (NCT02099058). **Method:** Teliso-v was administered at 2.4 mg/kg (dose-escalation phase) or 2.7 mg/kg intravenously once every 3 weeks, and erlotinib at 150 mg orally once a day/prior tolerated dose in adult patients with advanced NSCLC. For efficacy analysis, c-Met+ was defined as central lab IHC H-score ≥150 or local lab MET amplification (MET/CEN7 ≥2); *EGFR* M+ was defined as del19 or L858R by local lab. Pharmacokinetics were assessed. All patients who received teliso-v + erlotinib were evaluated for safety. **Result:** As of Dec 2018, 42 NSCLC patients received teliso-v + erlotinib; 37 were c-MET+ (36 evaluable: 35 H-score≥150, 1 MET amplified). Median age was 65 years, 25 patients (69%) had ECOG PS 1, 29 (81%) were *EGFR* M+ (of these: 48% had T790M, 10% had MET amplification, 3% had polysomy, 97% had prior EGFR TKI, 55% 3rd-generation TKI, 69% TKI as last prior therapy, and 62% platinum doublet). All-grade (≥20%) adverse events (AEs) were dermatitis acneiform (38%), diarrhea (36%), peripheral motor/sensory neuropathy (52%; 7% Grade 3), dyspnea, fatigue, hypoalbuminemia (31% each), decreased appetite, nausea (24% each), asthenia, vomiting (21% each). Grade ≥3 (≥10%) AE: pulmonary embolism (14%). Pharmacokinetics of teliso-v for the combination were similar to single-agent teliso-v. The table presents efficacy data.

	Patients with EGFR mutation (n=29)
Objective response rate*, % (95% CI) Complete response, n	34.5 (17.9, 54.3) 1
Median duration of response, months (95% CI)	NR (2.8, NE)
Median PFS, months (95% CI)	NR (2.8, NE)
Median follow-up, months	4
6-month PFS rate, % (95% CI)	51 (30, 69)
Median treatment duration, month (range) Teliso-v Erlotinib	3.5 (0.71–10.4) 5.3 (0.71–25.4)
Objective response rate by subgroup of interest, n (%) Received prior 3rd generation EGFR TKI C-met amplified, copy number gain, or polysomy EGFR TKI-containing regimen as last-line therapies	 6/16 (37.5) 5/7 (71.4) 8/20 (40.0)

*RECIST version 1.1. EGFR, epidermal growth factor receptor; NE, not estimable; NR, not reached; PFS, progression-free survival; RECIST, Response Evaluation Criteria in Solid Tumors; TKI, tyrosine kinase inhibitor;

Conclusion: These data suggest acceptable safety and promising activity of teliso-v + erlotinib in patients with c-Met+ NSCLC with an activating *EGFR* mutation and for whom EGFR TKI has failed.

Keywords: teliso-v, NSCLC, Phase 1b

Background: Fruquintinib, an orally active kinase inhibitor that selectively targets vascular endothelial growth factor (VEGF) receptor, demonstrated significant benefit in progression-free survival and disease control in a randomized Phase II study in patients with non-small-cell lung cancer (NSCLC) who had failed two lines of chemotherapy. This Phase III FALUCA trial is a randomized, double-blind, placebo-controlled, multicenter trial designed to confirm the efficacy in the same patient population (NCT02691299). **Method:** From December 2015 to February 2018, 45 clinical centers across China participated in the trial. A total of 730 patients aged 18-75 with advanced NSCLC who had failed two lines of chemotherapy were screened and 527 who met the eligibility criteria were enrolled into the study. Patients were stratified based on epidermal growth factor receptor mutation status and prior use of VEGF inhibitor therapy, and were randomized in a 2:1 ratio to receive fruquintinib (n=354) or placebo (n=173) once daily in a 3 weeks on/1 week off 4-week cycle. The primary end point was overall survival (OS). Secondary end points included progression-free survival (PFS), objective response rate (ORR), disease control rate (DCR), duration of response. The final data cutoff was on September 21, 2018. **Result:** Median OS was 8.94 months for fruquintinib and 10.38 months for placebo (hazard ratio, 1.02; 95% CI, 0.816 to 1.283; p=0.841). Median PFS was 3.68 months for fruquintinib comparing to 0.99 months for placebo, respectively (hazard ratio, 0.34; 95%CI, 0.279 to 0.425; p<0.001). The ORR and DCR were 13.8% and 66.7% for fruquintinib, compared

with 0.6% and 24.9% for placebo (both p<0.001), respectively. The most frequent treatment-emergent adverse events with fruquintinib (≥grade 3) were hypertension (20.7%), hand-foot syndrome (11.0%), and proteinuria (1.4%). A sensitivity analysis revealed that median OS was significantly prolonged with fruquintinib compared with placebo in patients who received no subsequent systemic anti-tumor therapies (7.00 months versus 5.09 months; hazard ratio, 0.65; 95%CI, 0.462 to 0.913; p=0.012). **Conclusion:** The FALUCA trial failed to meet the primary end point of OS while confirming significant benefit in secondary end points including PFS, ORR and DCR. The safety profile of fruquintinib in this patient population was acceptable and consistent with that identified in the Phase II study. A post-hoc sensitivity analysis revealed that the anti-tumor therapies that patients received post disease progression probably contributed to the failure of this study on the primary end point.

Background: Second line chemotherapy used in advanced Non Small Cell Lung Cancer (NSCLC) have demonstrated a slight survival benefit in patient refractory to a first line platinum based doublet chemotherapy. In exploratory analysis, Nintedanib in combination with docetaxel have shown interesting result in second line setting for refractory NSCLC patients. Objective: To assess the efficacy in terms of progression-free survival (PFS) of the nintedanib - docetaxel combination in second-line treatment in refractory no squamous NSCLC (NsqNSCL) patients **Method:** This prospective, multicentric open-label phase II trial, included patients with advanced Nsq NSCLC (EGFR, ALK wild-type), PS 0-1, progressing during the first four cycles of cisplatin-based induction chemotherapy. Patients received Nintedanib (200 mg X2 /d d2-d20)- Docetaxel (75 mg/m^2 d1-d21) combination until progressive disease or unacceptable toxicity. The primary endpoint was the PFS rate at 12 weeks. Secondary endpoints included median PFS, median overall survival (OS), overall response rate (ORR) and tolerability. Based on a A'Hern's single-stage phase II design trial (sample size determination is based on exact binomial distribution), the Nintedanib-Docetaxel strategy will be rejected if the primary endpoint was below 22/53 patients at the end of study. **Result:** The analysis included 53 evaluable patients managed in 21 centers; last patient included at the end of January 2019. Mean age 58.4 years, male 73 %, adenocarcinoma 97.5%, current/former smokers: 42/50 %, PS 0/1: 25%/75%; weight loss >5%:19%, stage IV: 100% (38% with brain metastasis, median metastasis 2). All patients received for induction chemotherapy, a platin doublet (22% with bevacizumab), number of cycle 1-2/ 3-4: 57%/ 43%. Interim analysis reviewed by the independent committee conducted as planned, after the 27 first inclusions concluded that there was no sign of unexpected toxicity (adverse events grade 3-4 :22%, grade 5 :0%) or futility (9 patients meet primary end point on 25 evaluable). The results of the final analysis on the whole population (PFS at 12 weeks (primary end point), median PFS, median OS and toxicity) will be presented at the meeting Academic grant from Boehringer Ingelheim **Conclusion:** Section not applicable

MA14.07 PHASE I EXPANSION COHORT OF RAMUCIRUMAB PLUS PEMBROLIZUMAB IN ADVANCED TREATMENT-NAÏVE NON-SMALL CELL LUNG CANCER (JVDF)

R. Herbst[1], H. Arkenau[2], J. Bendell[3], E. Arrowsmith[4], M. Wermke[5], A. Soriano[6], N. Penel[7], R. Santana-Davila[8], H. Bischoff[9], I. Chau[10], B. Chao[11], D. Ferry[11], G. Mi[12], L. Paz-Ares[13]

[1]*Yale University School of Medicine, New Haven/United States of America,* [2]*University College London, London/United Kingdom,* [3]*Sarah Cannon Research Institute/Tennessee Oncology, Nashville/United States of America,* [4]*Tennessee Oncology, Tennessee/United States of America,* [5]*University Hospital Carl Gustav Carus, Dresden/Germany,* [6]*Florida Cancer Specialists, Englewood/United States of America,* [7]*Centre Oscar Lambret, Lille/France,* [8]*University of Washington, Seattle/United States of America,* [9]*Thoraxklinik-Heidelberg Ggmbh, Heidelberg/Germany,* [10]*Royal Marsden Hospital, Sutton/United Kingdom,* [11]*Eli Lilly and Company, New York/United States of America,* [12]*Eli Lilly and Company, Indianapolis/United States of America,* [13]*12 de Octubre University Hospital, Seville/Spain*

Background: Emerging data suggest blockade of vascular endothelial growth factor receptor 2 (VEGFR-2) with ramucirumab (R) and programmed cell death 1 protein (PD-1) with pembrolizumab (P) has anti-tumor activity. The JVDF study (NCT02443324) evaluated the safety and efficacy of R+P in locally advanced and unresectable or metastatic gastric/gastroesophageal junction adenocarcinoma, non-small cell lung cancer (NSCLC), urothelial carcinoma, and biliary tract cancer. Data from NSCLC patients receiving R+P as first-line therapy are reported. **Method:** Eligible patients had treatment-naïve, PD-L1 positive, histopathologically confirmed nonsquamous or squamous NSCLC and received R 10 mg/kg and P 200 mg on Day 1 every 21 days for up to 35 cycles until confirmed disease progression or discontinuation for other reasons. Response and progression were assessed using RECIST 1.1 with confirmatory scans. PD-L1 was assessed using the PD-L1 IHC 22C3 pharmDx assay; PD-L1 positivity was defined as a tumor proportion score (TPS) ≥1%. **Result:** As of August 31, 2018, 26 patients were treated. Baseline characteristics were as expected for an advanced, treatment-naïve population. Median follow-up was 17.4 (13.4, 20.1) months. Adverse events were consistent with R+P, with no additive toxicities. Eleven (42.3%) patients experienced Grade ≥3 treatment-related adverse events (TRAEs), most commonly hypertension (15.4%) and myocardial infarction (7.7%). No patients discontinued because of TRAEs; the two on-study deaths were due to disease progression. Efficacy results are shown in the table.

Summary of efficacy endpoints with R+P in treatment-naïve NSCLC.

	All Patients (N=26)[a]	PD-L1 weakly positive (n=9)[b]	PD-L1 strongly positive (n=16)[c]

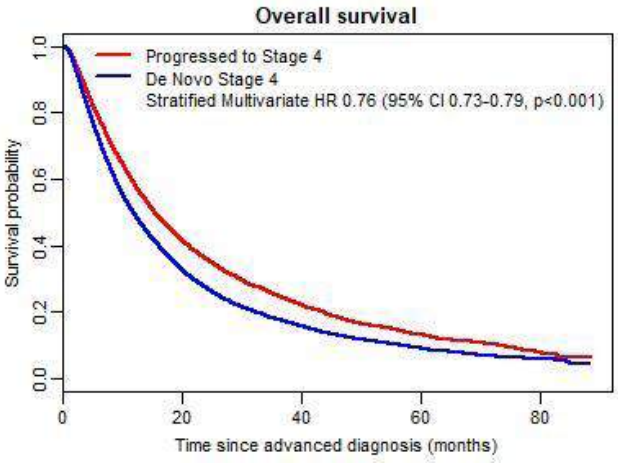
MA14.09 REAL-WORLD SURVIVAL OF RELAPSED COMPARED TO DE-NOVO STAGE IV DIAGNOSIS OF ADVANCED NON-SMALL CELL LUNG CANCER

K. Kerrigan[1], B. Haaland[1], B. Adamson[2], S. Patel[1], W. Akerley[1]

[1]*Huntsman Cancer Institute, Salt Lake City/United States of America,* [2]*Flatiron Health, New York City/United States of America*

Background: Differences in tumor biology and cancer therapy in early stage lung cancer may affect overall survival (OS) of patients with relapsed stage IV disease compared to others with de-novo stage IV disease. This study aimed to compare real-world survival of these patients. **Method:** We selected patients with advanced NSCLC diagnosed between 2011 and 2017, who received at least one line of therapy, from the US Flatiron Health electronic health record-derived database. Patient data was collected through June 2018, providing at least 6 months of follow-up. OS was defined as time from advanced or metastatic diagnosis to the event of death, censored at last clinic visit or end of oral therapy. The unadjusted OS of patients was estimated using the Kaplan-Meier method. We fit multivariable Cox proportional hazards models to compare the hazard of death between groups. **Result:**



The study included 30,310 patients with median age of 68.8 years, 46.7% female, and 76.8% non-Hispanic white. We observed 22.8% had relapsed and 77.2% were de-novo stage IV. Relapsed patients had median OS of 15.5 months (95% CI: 14.9-16.2). Patients with de-novo stage IV had median overall survival of 12.0 months (95% CI: 11.7-12.2). The force of mortality among relapsed stage IV patients was 24% lower than the rate of death among de-novo stage IV patients (Hazard Ratio [HR]: 0.76; 95% CI 0.73-0.79; p <0.001), adjusting for age, gender, state, histology, smoking, race/ethnicity, and stratifying by year of diagnosis. Sensitivity analyses of an unadjusted model (HR 0.79, p <0.001) and a sub-group analysis of patients with advanced diagnoses in 2016-2017 (HR 0.74, p <0.001) suggested the results were robust. **Conclusion:** Among patients with stage IV NSCLC that received at least one treatment, those who relapsed had better OS than those who presented with de-novo stage IV disease. These findings have implications for future clinical trial design.

MA14.10 CLINICAL OUTCOMES IN METASTATIC SQUAMOUS LUNG CANCER WITH TARGETABLE DRIVER ALTERATIONS

W. Lewis[1], G. Simon[1], F. Mott[1], V. Papadimitrakopoulou[1], W. Rinsurongkawong[2], J. Lewis[2], J. Lee[2], J. Roth[2], S. Swisher[2], J. Heymach[1], J. Zhang[1], V. Lam[1]

[1]*MD Anderson Cancer Center, Houston/United States of America,* [2]*The University of Texas MD Anderson Cancer Center, Houston/United States of America*

Background: Genomic profiling is not routinely performed for metastatic squamous (SCC) and adenosquamous (ASC) NSCLC. However molecular profiling may be ordered if demographic features suggest a higher likelihood of a targetable driver alteration (e.g. never or remote smoking history). Response and survival data are scant in pts with actionable alterations treated with targeted therapy. **Method:** We reviewed the clinical data and molecular profiling (FISH, PCR, tissue NGS, ctDNA) of metastatic SCC and ASC pts treated at our institution from Feb 2010-Dec 2018. Pts with typical sensitizing mutations in *EGFR* or *BRAF* V600E or fusions in *ALK* or *ROS1* treated with matched targeted therapy for ≥ 2 months were included in this analysis. Response assessment was based on RECIST v1.1. **Result:** Among 261 metastatic SCC or ASC pts with available molecular profiling, 16 total pts (6%) were found to have actionable targets, consisting of 13 SCC and 2 ASC (median age 53, 81% female, 88% never-smoker). The distribution of driver alterations in this cohort was 56% (9/16) *EGFR* ex19del/L858R/G719A, 38% (6/16) *ALK* fusion, and 6% (1/16) *BRAF*. The overall objective response rate (ORR) and median progression free survival (PFS) to targeted therapy was 69% and 5.2 months respectively. By mutational subgroup, ORR was 67% (6/9) for *EGFR*, 67% (4/6) for *ALK*, and 100% (1/1) for *BRAF*. Median PFS was only 4.5 months (95% CI 3.0 – 6.0) for *EGFR* pts and 2.8 months (95% CI 0 – 6.4) for *ALK* pts, and the lone *BRAF* pt had a PFS of 8.5 months. In *EGFR* pts with available NGS, co-mutations in *TP53* (75% [6/8]) and *PIK3CA* (38% [3/8]) were seen at rates higher than previously reported in *EGFR*+ ADC (*TP53* 55%, *PIK3CA* 12%; Blakely et al, Nat Gen 2017). In *ALK* pts with available NGS, co-mutations in *TP53* (80% [4/5]) were also higher than recently reported in *ALK*+ ADC (24%; Kron et al, Ann Oncol 2018). **Conclusion:** Despite initial responses comparable to those previously reported in ADC, matched targeted therapy in pts with SCC and ASC histology is associated with shorter PFS. A higher prevalence of adverse co-mutations such as *TP53* and *PIK3CA* may contribute to early targeted therapy resistance in these histologies. These findings may have implications for the use of targeted therapy in squamous lung cancer.

MA14.11 CARETRACK: AN APPLICATION-BASED METHOD OF DOCUMENTATION FOR IMPROVING PATIENT COMMUNICATION IN CANCER CARE

J. Younus, J. Raphael, P. Blanchette, F. Khan, V. Sharma, M. Black, M. Vincent, S. Kuruvilla, M. Sanatani

London Regional Cancer Program, London/Canada

Background: Patients being able to accurately understand and recall medical information correctly has been shown to improve outcomes, however, most studies suggest that patient information understanding in oncology tends to be poor with as much as 40-80% of information being relayed by healthcare professionals being forgotten (Kessels, 2003). **Method:** Our study aimed to implement the use of 'CareTrack', an easy-to-use iPad application, as a simple yet complete app-based information package that provides an appointment summary sheet with no identifying information for patients to take home. An iPad pre-loaded with the CareTrack application was provided to oncologists and they filled in the form for their patients at the end of the initial consultation for lung cancer. A hard printout copy was provided to the patient to take home and the option of an email copy was sent as well. Approximately one-week later a patient satisfaction questionnaire was administered over the phone to patients who participated in the study. **Result:** Six oncologists were recruited to the study with 35 patients consented to the study and 25 of these patients completing the follow-up surveys. Our primary objective was to assess feasibility of the CareTrack application. The average physician time to complete the CareTrack form for each patient was 1 minute and 29 seconds thus demonstrating that this is a quick and easy tool for physician use. Our secondary objective was to assess patient satisfaction with a brief survey. Ninety-six percent (24/25) of patients found the CareTrack information provided useful and 100% (25/25) of patients found the information easy to understand. Most patients did not require frequent review of the CareTrack form (28%, 7/25) nor needed the form to remember the information (56%, 14/25) or when discussing diagnosis/stage/treatment at home (44%, 11/25). Importantly, 96% (24/25) of patients were comfortable seeing their cancer information and treatment plan displayed on the CareTrack tool and 84% (21/25) of patients would like to receive additional CareTrack information in the future if their staging and/or treatment planned is changed/updated. **Conclusion:** To conclude, the CareTrack application was found to be easy to use and was able to effectively provide new lung cancer patients with a comprehensive yet easy-to-understand summary of their initial consult. In the future, we envision this project expanding province- and nation-wide as well as expanding to other disease sites (e.g. breast, colorectal etc.).

Background: Tumor invasion and metastasis are the major causes of treatment failure and mortality in lung cancer patients. However, the precise molecular targets responsible for tumor invasion remain unclear. **Method:** In this study, we identified a group of genes with differential expression in in situ and invasive lung adenocarcinoma tissues by cDNA microarray analysis; among these genes we further characterized the association of the upregulation of PRNP, the gene encoding cellular Prion protein (PrPc), with lung adenocarcinoma invasiveness through immunohistochemistry and in situ hybridization analysis on clinical tissues. The roles of PrPc in lung cancer cell lines were also verified by using immunofluorescence staining, *in vitro* transwell assay and in vivo metastasis mouse model. In addition, the impact of PrPc on the activation of the JNK signaling pathway was investigated by Western blot analysis. Finally, luciferase reporter assay and chromatin immunoprecipitation assay were used to identify the transcriptional activators of PRNP. **Result:** Immunohistochemistry on clinical specimens showed association of PrPc expression with invasive but not in situ lung adenocarcinoma. Consistently, the expression of PrPc was higher in the highly invasive than in the lowly invasive lung adenocarcinoma cell lines. Knockdown of PrPc expression in cultured lung adenocarcinoma cells decreased their lamellipodium formation, *in vitro* migration and invasion, and in vivo experimental lung metastasis. Phosphorylation of JNKs was found to correlate with PrPc expression and the inhibition of JNKs suppressed the PrPc-induced up-regulation of lamellipodium formation, cell migration, and invasion. Moreover, we identified the nuclear factor, interleukin 3 regulated (NFIL3) protein as a transcriptional activator of the PRNP promoter. Accordingly, NFIL3 promoted lung cancer cell migration and invasion in a PrPc-dependent manner. High NFIL3 expression in clinical specimens of lung adenocarcinoma was also associated with tumor invasiveness and poor survival of patients. **Conclusion:** Our observations suggest that PRNP expression is associated with the invasiveness of lung adenocarcinoma, and cell line model demonstrated that PrPc serves as a critical factor for lung cancer cell lamellipodia formation, migration and invasion via JNK signaling. A novel transcription factor, NFIL3, was identified to upregulate PRNP

expression in lung cancer cells; further characterizations showed that NFIL3 promotes lung cancer cell migration through PrPc-dependent manner. Moreover, high NFIL3 expression was found to be associated with lung cancer invasiveness in clinical tissues. Overall, NFIL3/PrPc axis plays a critical role in lung cancer invasiveness and metastasis, and may be the potential therapeutic targets in the future.

MA15.02 DEEP LEARNING APPROACH FOR AUTOMATED TUMOR CELLS DETECTION AND ESTIMATION OF PD-L1 22C3 ASSAY EXPRESSION IN LUNG ADENOCARCINOMA

D. Lin[1], J. Wu[1], W. Sun[1], C. Liu[2], X. Liu[2], Y. Zhang[2], J. Zhang[2], H. Wang[1], X. Liu[1], X. Yang[1], S. Ling[2]

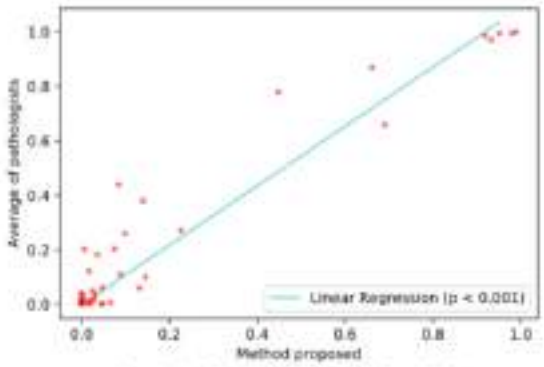
[1]*Peking University Cancer Hospital & Institute, Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/China,* [2]*Genome Wisdom Inc., Beijing/China*

Background: It is vital and challenging to assess an accurate PD-L1 expression status on tumor cells for immunotherapy in lung cancer. The purpose of this study was to set up an automated system to detect the tumor cells and estimate the tumor proportion score (TPS) of PD-L1 immunohistochemistry (IHC) expression for lung adenocarcinoma based on deep learning, and provide a potential Artificial Intelligences (AI) assistive diagnostic tool in the quantification of PD-L1 interpretation. **Method:** Fifty PD-L1 22C3 IHC slides of lung adenocarcinoma samples on digitized whole-slide images (WSI) database was employed. We first designed a model with a fully convolutional neural network (FCNN) based on U-ResNet architecture to obtain the cancer segmentation. Representative regions were selected from each slide, and 100 regions were collected for manual annotations as a training set for cancer detection. Another 50 regions were used to validate the performance of automated cancer detection and TPS estimation as a test set. After the quality control, a whole model of automated cancer cell segmentation and membrane positive estimation was set up on standard PD-L1 22C3 IHC staining. TPS could be automatically predicted by AI tool and then compared with the interpretations of pathologists. **Result:** The results of automated lung adenocarcinoma cells segmentation on the test set of 22C3 IHC staining showed a moderate sensitivity (71.46%) with a high specificity (95.94%) which was much more crucial for TPS counting. In rest 43 out of 50 regions after a quality control, TPS estimated by the automated PD-L1 analysis based on cancer segmentation showed a significant correlation with the average scores (r=0.9609, p<0.001) and the median scores (r=0.9523, p<0.001) of pathologists' interpretations.

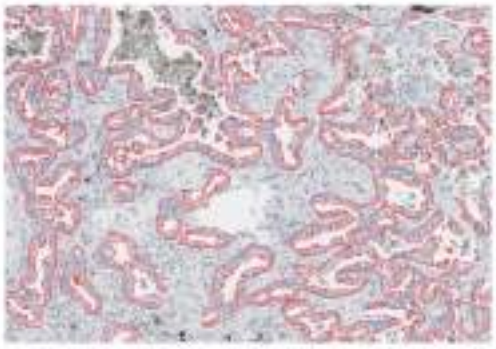
Table	Sensitivity	Specificity	Precision	Accuracy	F1-score
22c3 IHC cancer segmentation	71.46%	95.94%	92.08%	91.24%	79.68%

Performance of cancer detection model

TPS by pathologists and method proposed



Correlation between the average of pathologists and method proposed



Cancer segmentation result

Conclusion: We provide an automated tumor cells detection and TPS estimation model for lung adenocarcinoma and demonstrate the potential of using machine learning methods to access PD-L1 IHC status conveniently. A further validation of AI tool for automated scoring PD-L1 in diagnostic routine is highly recommended in the future.

Keywords: PD-L1, Tumor proportion score, Artificial Intelligence

MA15.03 EXPLORING DIGITAL PATHOLOGY-BASED MORPHOLOGICAL BIOMARKERS FOR A BETTER PATIENTS' SELECTION TO THE IMMUNE CHECKPOINT INHIBITOR OF LUNG CANCER

N. Motoi[1], H. Yoshida[1], T. Kiyuna[2], H. Horinouchi[1], T. Kohno[3], S. Watanabe[1], Y. Ohe[1], A. Ochiai[4]

[1]*National Cancer Center Hospital, Tokyo/Japan,* [2]*NEC Corporation, Tokyo/Japan,* [3]*National Cancer Center Research Institute, Tokyo/Japan,* [4]*Exploratory Oncology Research and Clinical Trial Center, National Cancer Center, Chiba/Japan*

Background: For eligible patients' selection for immune checkpoint inhibitor therapy (ICI), it is important to establish more accurate predicting biomarkers, in addition to PD-L1 IHC and MSI-high. We hypothesized that morphological characteristics should reflect genetic alteration, thus could predict ICI responsiveness. In this study, we examined the predictive potential of morphological characteristics using digital whole-slide images as a new biomarker for ICI-treatment on non-small cell lung cancer (NSCLC) and their relationship to PD-L1 IHC and genetic alterations. **Method:** 71 NSCLC who received ICI therapy were recruited. Digital images of H&E and PD-L1 (22C3) IHC stained slides of pre-treatment biopsied or resected materials were examined by previously reported image analysis techniques using e-Pathologist ® (NEC, Japan). Morphological characteristics of cancer cells (three and six parameters of nuclear shape and chromatin texture) were extracted as MC-scores. Of 11 cases (pilot cohort), PD-L1 IHC (22C3) and tumor mutation burden (TMB) by the NGS-based target sequence (NCC oncopanel ®) were examined. Correlation between MC-score, PD-L1 IHC, TMB status, and clinical outcome was calculated. A p-value of less than 0.05 was defined as statistically significant. Decision tree analysis for evaluating predicting ICI-responsiveness was built using statistically significant MC-scores. We also tested the predictive value of a deep learning analysis (AI model) with 5-fold cross-validation. AUC (area under the curve) of ROC analysis was calculated. **Result:** Of the responders, the MC-score of cancer cell were statistically different from those of the non-responders; nuclear texture contour complexity (11.8 vs. 8.25, median value of responder vs. non-responders; p<0.01), homogeneity (0.396 vs. 0.421; p<0.01), angular second moment (ASM) (0.0203 vs. 0.0214; p=0.049) and nuclear circularity (0.878 vs. 0.885, p=0.026). Circularity (p=0.011) and texture homogeneity (p=0.048) correlated with TMB. ASM texture correlated with PD-L1 expression (p=0.018). The decision tree model for predictive and screening purposes resulted in 0.83 and 0.62 accuracies, respectively. AUC of AI-model for ICI responsiveness resulted in fair (0.74 on average, range 0.55-0.81). **Conclusion:** Our results indicate the substantial value of the morphological feature as a biomarker for ICI therapy. Morphological characteristics are eligible from archived FFPE samples, showed good correlation to the underlying genetic alteration. Digital pathology can serve useful predictive morphological biomarkers for precision medicine of lung cancer patients, and promising the power of AI-assisted pathology.

MA15.05 COMPUTERIZED MEASUREMENTS OF CELLULAR DIVERSITY ON H&E TISSUE ARE PROGNOSTIC OF OS AND ASSOCIATED WITH MUTATIONAL STATUS IN NSCLC

V. Velcheti[1], C. Lu[2], K. Bera[2], X. Wang[2], P. Fu[2], M. Yang[3], D. Rimm[4], K. Schalper[4], A. Madabhushi[2]

[1]*NYU Langone Cancer Center, New York/United States of America,* [2]*Case Western Reserve University, Cleveland/United States of America,* [3]*University Hospitals Cleveland Medical Center, Cleveland/United States of America,* [4]*Yale University School of Medicine, New Haven/United States of America*

Background: Tumor heterogeneity is known to be implicated in chemotherapeutic resistance and poor prognosis for non-small cell lung cancer (NSCLC). In this study we sought to evaluate the role of computer extracted features reflecting the intrinsic cellular morphological diversity (ICMD) of tumors from digitized H&E stained images of early-stage NSCLC patients. Additionally, we sought to evaluate the association of these ICMD features in adenocarcinomas with the ALK and EGFR mutational status. **Method:** Two cohorts, D_1 and D_2, of digitized H&E stained tissue microarray images (TMA) of NSCLC, n=395 and n=91, respectively, were used for modeling the ICMD predictor. A pretrained deep learning model was used for segmentation of nuclei, and clusters of proximally located nuclei were identified. The ICMD features were then extracted as the variations in shape, size, and texture measurements of nuclei within the clusters. A Cox proportional hazard model using the ICMD features was then trained for lung adenocarcinomas (LUAD, n=270), and squamous cell carcinomas (LUSC, n=216), separately, and was validated on independent cohort from (D_3) The Cancer Genome Atlas (TCGA) (n=473) to predict Overall Survival (OS). Univariate and multivariate analyses were performed on (D_3). **Result:** In (D_3), high risk patients predicted by the ICMD features had significantly poorer survival (HR (95% CI) = 1.48 (1.06-2.06), p=0.021 for LUSC, HR (95% CI) = 1.59 (1.11-2.29), p=0.006 for LUAD) in univariate analysis. In multivariate analysis, controlling for major clinical variables, ICMD was independently associated with 5-year OS (p<0.016). (See Table 1) We also found that ICMD features were associated with driver mutations ALK (p=0.0204) and EGFR (p=0.0017) in LUAD. Table 1| Multivariate analysis for overall survival on the validation set D_3.

Multivariate Cox Proportional Hazard Model Analysis Controlling for Other Variables				
	TCGA-LUSC		**TCGA-LUAD**	
Variable	HR (95% CI)	*p* value	HR (95% CI)	*p* value
Age (>65 vs <=65)	1.14(0.81-1.61)	0.451	0.89(0.63-1.28)	0.540
Smoking status	1.36(0.83-2.23)	0.221	1.14(0.64-2.01)	0.661
Overall Stage (Stage II vs I)	1.13(0.66-1.94)	0.651	1.86(1.04-3.32)	0.037
T-Stage (T2,3 vs T1)	1.26(0.85-1.87)	0.244	1.25(0.85-1.85)	0.263
N-Stage (N1 vs N0)	1.36(0.77-2.41)	0.292	3.11(1.55-6.23)	0.001
Developed Model High risk vs. Low risk 1.52(1.08-2.13)		0.016	1.55(1.09-2.22)	0.015
CI = 95% confidence interval; HR = Mantel-Haenszel Hazard ratio. Values in bold are statistically significant, p<=0.05.				

Conclusion: Computer extracted image features of cellular diversity were able to predict OS in NSCLC and were also associated with the ALK and EGFR mutational status. Future work will entail evaluating ICMD features in predicting added benefit of adjuvant therapy in early stage NSCLCs as well as correlating with gene expression data.

[1]*Boston University School of Medicine, Boston/United States of America,* [2]*Lahey Hospital & Medical Center, Burlington/United States of America,* [3]*David Geffen School of Medicine at UCLA, Los Angelos/United States of America,* [4]*Johnson and Johnson Innovation, Cambridge/United States of America*

Background: Stage I lung adenocarcinomas (LUADs) show heterogeneity in histologic patterns which correlate with malignant behavior. Solid, micropapillary and cribriform patterns are associated with worse survival whereas lepidic (in situ) predominance has the best prognosis. In this study, we sought to characterize histologic pattern specific gene expression in resected clinical stage I LUADs. We also aimed to train and validate a genomic biomarker predictive of histologic aggressive patterns with the ultimate goal of being able to impact surgical and therapeutic decision making for post-biopsy management. **Method:** A training cohort of 56 tumors from patients meeting NCCN high-risk screening criteria with stage I LUAD was included for pathologic annotation and whole exome RNA sequencing. Histologic pattern subtyping in 5% increments including all diagnostic slides was performed. A single representative FFPE block was chosen for RNA library-prep with Illumina TruSeq Access Kit and sequencing. Negative binomial models were used to identify gene expression differences associated with percent solid, cribriform, or micropapillary histology, and EnrichR was used for gene pathway enrichment analysis. Ss-GSEA was used to predict tumor infiltration of 20 immune cell types. A random-forest classifier for predicting aggressive histologic patterns was trained using 5-fold cross validation. A set of tumors from 16 independent patients with ≤2.0 cm clinical stage I LUAD was macro-dissected into 32 paired components (lepidic + non-lepidic regions) and subjected to RNAseq. Six tumors were defined as non-aggressive (lepidic + acinar/papillary) and ten tumors were defined as aggressive (lepidic + solid/micropapillary/cribriform). Four aggressive tumors were upstaged after surgical resection. **Result:** In the training cohort, we identified 1322 genes associated with tumor histologic composition(FDR q <0.05 and fold-change > 2). Genes whose expression differs with solid histology% are enriched for involvement in DNA replication, cell cycle regulation and inflammation (FDR q<0.001). Genes whose expression is associated with micropapillary% are enriched for involvement in tRNA-aminoacylation and decrease of T-cell activity (FDR q<0.001). The functional enrichment of genes whose expression is associated with cribiform% was less informative. LUADs with micropapillary patterns exhibited gene expression consistent with decreased antigen presentation and low T-cell infiltration, and solid patterns exhibited gene expression consistent with increased infiltration of T-regulatory and Th2 cells (FDR q<0.05). A gene expression classifier was trained to predict the presence of aggressive histologic patterns. We validated this classifier on a set of 16 tumor specimens from which we macro-dissected and analyzed tissue from the most aggressive histologic pattern (AUC = 1.00). We also found that this classifier could differentiate lepidic regions isolated from aggressive tumors from lepidic regions isolated from non-aggressive tumors (AUC = 0.74). **Conclusion:** We identified solid-, micropapillary- and cribriform-specific gene expression and associated immune response among clinical stage I LUADs, and developed a classifier predictive of aggressive histologic features using either lepidic (in situ) or non-lepidic components. As such, this biomarker has the potential to predict histologic aggressiveness even from pre-surgical tumor biopsies where all histologic patterns may not be represented. Such a biomarker may be useful in guiding clinical decision making including extent of surgical resection.

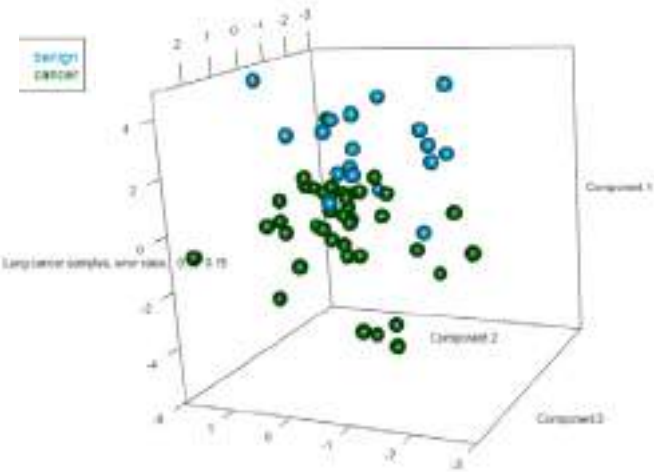
MA15.07 CIRCULATING MIRNA: A BIOMARKER FOR CLASSIFICATION OF LUNG CANCER AND BENIGN LUNG DISEASE

A. Qvick[1,2], A. Wirén[2], M. Rönnqvist[3], G. Helenius[1,2]

[1]*Region Örebro län, Örebro/Sweden,* [2]*School of Medical Sciences, Örebro University, Örebro/Sweden,* [3]*Södersjukhuset, Stockholm/Sweden*

Background: Circulating biomarkers for cancer have great potential for diagnosis as well as follow up of treatment. MicroRNAs (miRNA) are involved in the expression of a majority of proteins with different cell types having different miRNA expression. The aim of this study was to create a circulating miRNA-based model to discriminate patients with lung cancer from patients with benign lung disease. **Method:** Samples were collected from patients under investigation for lung cancer at Örebro University hospital. Patients were then divided into groups based on diagnosis, which resulted in NSCLC adenocarcinoma (n=24), NSCLC squamous cell carcinoma (n=13), SCLC (n=4) and a heterogeneous group consisting of different benign lung diseases (n=19). Healthy controls were collected separately (n=17). Circulating miRNA was processed using the extraction-free library preparation miRNA Whole Transcriptome Assay with probes for 2083 human mature miRNAs and analyzed with massive parallel sequencing. Differential expression between groups was estimated using edgeR. MiRNAs that had the highest impact on patient grouping were used in a sPLS discriminant analysis. The resulting classification model was validated using the leave-one-out method. **Result:** The final model for comparison between patients with benign lung disease and patients with lung cancer contained 19 miRNAs. The model had an error rate of 15 % with errors distributed evenly between groups. A sub-analysis of patients with mutations in EGFR (n=5) and KRAS (n=6) was performed showing two distinct patterns in miRNA expression.



Conclusion: MiRNA shows promise as a circulating biomarker for lung cancer but may not be sufficient as an independent classifier. The predictive power may be improved by using several biomarkers in combination. The difference in expression between tumors with different mutations may be derived from alternate driving processes in these tumors.

Keywords: microRNA, Circulating biomarkers

MA15.09 PD-L1 STATUS IN RELATION WITH NON-SMALL CELL LUNG CANCER MAJOR SUBTYPES, DIFFERENTIATION, MOLECULAR PROFILING AND SMOKING HISTORY

A. Surette, M. Castonguay, D. Bethune, A. Drucker, D. French, H. Henteleff, M. Macneil, W. Morzycki, M. Plourde, S. Snow, Z. Xu

Dalhousie University/QEII HSC, Halifax/Canada

Background: Continued advances in lung cancer precision medicine have allowed targeted therapies based on an individual tumor's genetic makeup. Recent advances in immune therapy based on immune checkpoint inhibitors have provided additional promising results. Currently, the majority of lung cancer mutational data available in the literature are from advanced stage non-small cell lung cancer. Mutational data from early stage lung cancer patients is limited. There is also limited data on PD-L1 tumor status is relation to mutational status along with other pathological and clinical characteristics. In this study, we evaluated these issues in 871 cases of surgically resected lung cancer. **Method:** Multiplexed molecular profiling in 871 surgically resected lung cancer specimens was performed. A panel of genes including EGFR, KRAS, BRAF, PIK3CA, HER2 and ALK was tested. Tumor PD-L1 status was also evaluated by immunohistochemistry using pharmDx22C3. PD-L1 status was measured by tumor proportional score (TPS): <1%, 1-49% and ≥50% tumor cell positivity. Correlations between PD-L1 and gene mutation status, smoking history, histological grade, gender and age of paraffin embedded blocks were analyzed. **Result:** This cohort includes adenocarcinoma (68%), squamous cell carcinoma (SCC) (22%) and other subtypes (10%). The average age is 67. Females account for 52%. A positive smoking history was present in 93%. Well differentiated tumors (G1) account for 11%, moderately differentiated (G2) 37% and poorly and undifferentiated (G3) 52%. EGFR mutations were identified in 7.4% and KRAS mutations in 31.7%. TPS <1% accounted for 48.8%, 1-49% for 34.6% and ≥50% for 16.5%. There was no statistically significant difference in PD-L1 TPS between histological subtypes or gender. Significantly more G1 tumors had a TPS <1% (76.7%) compared to G2 (57.4%, p=0.0013) and G3 tumors (41.8%, p<0.0001). Fewer G1 tumors had a TPS 1-49% (20.9%) than G2 (34.1%, p=0.015) and G3 (35.2%, p=0.01) tumors. G3 tumors were more likely to have a TPS ≥50% (24.6%) than G1 (2.3%, p<0.0001) and G2 (7.63%, p<0.0001) tumors. Never smokers were more likely to have a TPS <1% (71.1% vs 50.6%, p=0.04) and less likely to have a TPS ≥50% (5.8% vs 16.5%, p=0.04). Tumors with EGFR mutation were more likely to have a TPS <1% than those without EGFR mutation (70.7% vs 47.3%, p=0.0003) and less likely to have a TPS 1-49% (20.0 vs 35.5%, p=0.011). Tumors with KRAS mutations were less likely to have a TPS <1% (36.6% vs 54.9%, p<0.0001) and more likely to have a TPS 1-49% (40.6% vs 31.5%, p=0.0086) and ≥50% (22.8% vs 13.6%, p=0.0007). PD-L1 IHC performed on blocks stored for 2 years or longer had a statistically significant higher rate of TPS <1% compared to blocks stored for less than 2 years. **Conclusion:** This study provides information relating to the relationship between PD-L1 levels and tumor molecular profile, histological grade and patient demographics. Additionally, we raise the possibility of false negatives on IHC performed for PD-L1 on paraffin embedded blocks stored for 2 years or more.

MA15.10 STROMAL MARKERS OF ACTIVATED TUMOR ASSOCIATED FIBROBLASTS PREDICT POOR SURVIVAL AND ARE ASSOCIATED WITH NECROSIS IN NON-SMALL CELL LUNG CANCER

J. Alcaraz[1], J.L. Carrasco[1], M. Laura[2], A. Martínez-Romero[3], J. Sánchez De Cos[4], R. Rami-Porta[5], L.M. Seijo[6], J. Ramirez[7], N. Reguart[7], E. Barreiro[3], E. Monsó[8]

[1]*University of Barcelona, Barcelona/Spain,* [2]*Hospital Universitari Parc Taulí, Sabadell/Spain,* [3]*Hospital del Mar, Barcelona/Spain,* [4]*Hospital San Pedro de Alcántara, Cáceres/Spain,* [5]*University Hospital Mutua de Terrassa, Barcelona/Spain,* [6]*Fundación Jímenez Díaz, Madrid/Spain,* [7]*Hospital Clinic Barcelona, Barcelona/Spain,* [8]*Hospital Parc Taulí de Sabadell, Sabadell/Spain*

Background: Tumor associated fibroblasts (TAFs) are essential contributors of the progression of non-small cell lung cancer (NSCLC). Most lung TAFs exhibit an activated phenotype characterized by the expression of α-SMA and fibrillar collagens. However, the prognostic value of these activation markers in NSCLC remains unclear. **Method:** We conducted a retrospective multicentric study of the prognostic value of the standard markers of activated fibroblasts. For this purpose, we conducted a quantitative image analysis of α-SMA immunostaining and picrosirius red staining of fibrillar collagens imaged by bright-field and polarized microscopy, respectively, using tissue microarrays with samples from 220 surgical patients, which elicited a percentage of positive staining area for each marker and patient. **Result:** Kaplan-Meier curves showed that all TAF activation markers were significantly associated with poor survival, and their prognostic value was independent of TNM staging as revealed by multivariate analysis, which elicited an adjusted increased risk of death after 3 years of 129% and 94% for fibrillar collagens imaged with bright-field (p = 0.004) and polarized light (p = 0.003), respectively, and of 89% for α-SMA (p = 0.009). We also found a significant association between all TAF activation markers and tumor necrosis, which is often indicative of hypoxia, supporting a pathologic link between tumor desmoplasia and necrosis/hypoxia. **Conclusion:** Our findings identify patients with large histologic coverage of fibrillar collagens and α-SMA+ TAFs to be at higher risk of recurrence and death, supporting that they could be considered for adjuvant therapy. Moreover it supports that antifibrotic drugs aiming to target tumor fibrosis may be an effective therapeutic approach to improve survival in NSCLC.

Keywords: fibrosis, staging, prognosis

MA15.11 ESTABLISHING A CELL SOCIOLOGY PLATFORM FOR THE ASSESSMENT OF TARGETABLE INTERACTIONS TO PREDICT LUNG CANCER OUTCOME

E. Marshall, K. Enfield, P. Gallagher, M. Guillaud, C. Macaulay, W. Lam

BC Cancer Research Centre, Vancouver/Canada

Background: The tumor microenvironment (TME) is a complex mixture of tumor epithelium, stroma and immune cells. The immune component of the TME is highly prognostic for tumor progression and patient outcome. Immune functionality, however, is often dictated by direct cell-to-cell contacts and cannot be resolved by simple metrics of cell density (for example, number of cells per mm2 or flow cytometry). For example, direct contact between CD8+ T cells and target cells is necessary for CD8+ T cell activity, and direct contact between PD1+ and PD-L1+ cells is necessary for the efficacy of immune checkpoint inhibitors. Current immunohistochemistry (IHC) techniques identify immune cell numbers and densities, but lack assessment of spatial relationships (or "cell sociology"). Here, we develop a platform to examine these direct interactions within the TME, and assess their relationship with patient outcome in two independent non-small cell lung cancer (NSCLC) cohorts. **Method:** Tissue sections of primary tumors from lung adenocarcinoma (LUAD) patients with known clinical outcome were stained using 2 multiplex IHC panels: CD3/CD8/CD79a (Panel 1) and PD1/PDL1/CD8 (Panel 2).

Hyperspectral image analysis determined the phenotype of all cells. Using the same IHC panels, these observations were assessed in a secondary NSCLC dataset (n=674). Deconvolution of these images was used to identify cell types, and cellular 'neighborhoods' were assessed using a Voronoi approach. This cohort was also profiled by for gene expression to validate immune subset fractions. We further identified other tumor features, including the presence of tertiary lymphoid organs (TLOs; transient immune structures necessary for antibody production from B cells). **Result:** High density of intra-tumoral CD8+ T cells was associated with non-recurrence of tumors. However, we find that a non-random cell sociology pattern of CD8+ T cells directly surrounded by tumor cells was more significantly associated with non-recurrence compared to density alone. Monte Carlo re-sampling analysis determined that these cell sociology patterns were non-random. **Conclusion:** Hyperspectral cell sociology expands our understanding of the complex interplay between tumor cells and immune infiltrate. This technology improves our understanding of the tumour microenvironment and allows us to directly quantify interactions that dictate immune responses to cancers. Consequently, the implementation of this platform could improve predictions of responses to immunotherapy and lead to a deeper understanding of anti-tumor immunity.

MA16 PRIORITIZING USE OF TECHNOLOGY TO IMPROVE SURVIVAL OF LUNG CANCER SUBGROUPS AND OUTCOMES WITH CHEMOTHERAPY AND SURGERY
MONDAY, SEPTEMBER 9 15:45–17:15

MA16.01 PROJECT PRIORITY: A PATIENT-FOUNDED AND PATIENT-DRIVEN RESEARCH PARTNERSHIP ON REAL-WORLD DATA ON EGFR-POSITIVE LUNG CANCER

U. Basu Roy[1], I. Elkins[2], A. Figueras[3], T. Kennedy[2]

[1]*Lungevity Foundation, Bethesda/United States of America,* [2]*Egfr Registers, Deerfield/United States of America,* [3]*Egfr Resisters, Deerfield/United States of America*

Background: Despite increases in PFS in EGFR-positive lung cancer patients due to EGFR TKIs, patients eventually develop resistance to these drugs. Project PRIORITY (**P**atient **R**eported **I**nitiative **O**n **R**esistance, **I**ncidence, **T**reatment stud**Y**) is a patient-founded and patient-driven longitudinal study aimed at understanding unmet needs of the global EGFR-positive lung cancer community. **Method:** A comprehensive 103-question, IRB-approved patient-facing survey about the diagnostic and treatment journey of patients (including risk factor exposure, treatments, symptom and side-effect management, access to biomarker testing and clinical trials) was developed with input from US FDA statisticians and expert clinicians, and then pilot-tested among English-speaking patients both locally and internationally. Differences between US and international participants were analyzed by Chi-square (for categorical variables) and ANOVA. **Result:** Of the 253 respondents, 27.7% were international participants. In line with previous studies with EGFR patients, participants reported low rates of active tobacco exposure (16.4%) and high rates of second-hand tobacco exposure (34.7%). Also, first-line use of afatinib (OR = 2.5, p <0.05) and erlotinib (OR = 3.3, p< 0.05) were associated with the development of a T790M mutation reflecting similarity in clinical characteristics. US participants were more likely to report childhood exposure to secondhand smoke, family history of cancer (other than lung cancer), use of more than one line of therapy, and combination first-line therapy (P<0.05 for all variables). International participants were more likely to report first-line treatment with 1st/2nd generation TKI, less use of tissue and plasma NGS, lower clinical trial participation, and more use of whole-brain radiation for brain metastasis (P<0.05 for all variables). **Conclusion:** This first-of-its-kind international study provides a comprehensive picture of the treatment of EGFR-positive lung cancer patients in the real-world setting and highlights the existence of diagnostic (low NGS rates) and treatment gaps (low clinical trial participation and different treatment sequencing) both within the US and internationally.

MA16.02 T790M ALLELIC FRACTION LEVEL DID NOT CORRELATE SURVIVAL IN T790M POSITIVE NSCLC – OBSERVATIONS FROM AN EARLY ACCESS PROGRAM

O.S.H. Chan[1], K.C. Lam[2], V. Lee[3], S.F. Nyaw[4], M.W.R. Yeung[5]

[1]*Hong Kong Integrated Oncology Centre, Hong Kong/Hong Kong PRC,* [2]*Prince of Wales Hospital, Shatin, New Territories/Hong Kong PRC,* [3]*The University of Hong Kong, Queen Mary Hospital, Hong Kong/Hong Kong PRC,* [4]*Tuen Mun Hospital, Tuen Mun/Hong Kong PRC,* [5]*Pamela Youde Nethersole Eastern Hospital, Chai Wan/Hong Kong PRC*

Background: Osimertinib is an irreversible third-generation EGFR-TKI indicated for patients with metastatic EGFR T790M mutation positive NSCLC after progression of initial TKI therapy. An early access program (EAP) was started in 2015 providing ethical access of Osimertinib to patients with metastatic NSCLC running out of treatment options in Hong Kong. As some prior data suggested that T790M allele fraction (AF) correlated survival outcomes in patients receiving Osimertinib, we try to validate it with data from this EAP. Survival outcomes and safety data of Osimertinib in the real world practice under this EAP were also analysed. (NCT03219970) **Method:** This retrospective analysis included EAP patients who had advanced or metastatic NSCLC harbouring EGFR T790M mutation that progressed on prior TKI ± chemotherapy. EAP subjects received Osimertinib at 80mg daily until disease progression, intolerable toxicities or death. The T790M mutation can be assessed by any approved molecular tests in any specimen types. The AF levels in patients with T790M mutation confirmed by quantitative plasma genotyping (QPG) using ddPCR technique of the same vendor were retrieved. The primary objective was to assess the relationship of post-Osimertinib overall survival (OS) and T790M AF level. Secondary objectives included investigator-assessed response, time to discontinuation (TTD) of Osimertinib, safety (Osimertinib-related adverse events of special interest, AESIs) and OS of all EAP participants. **Result:** From Sep 2015 to Feb 2017, 156 patients enrolled in the EAP and received treatment. At time of data cut-off (11 Oct 2018), 74 (47%) were alive. Median follow-up was 23.4 (range: 1–30) months, median age 62 years, 62% female, 26% ECOG PS ≥2, 96.8% with metastatic disease. Besides T790M, 56% of patients had exon 19 deletions and 41% had exon 21 L858R mutations. Ninety-one patients had QPG using ddPCR method with AF data. OS, best response rate and TTD were not significantly related to T790M AF level as a continuous variable (p=0.20; hazard ratio 1.022, 95% CI 0.989 to 1.057), confirmed through sensitivity analysis with different AF threshold values. The investigator assessed best response rate was 41.7% (65/156) and disease control rate was 62.2% (97/156). Median TTD was 15.77 (12.43, 18.98) months. Median OS was 21.88 (95% CI 19.14–26.21) months. AESIs were reported in 7.7% of patients overall: 5.8% QTc prolongation and 1.9% pneumonitis. **Conclusion:** T790M AF level did not correlate with TTD and OS in this EAP cohort but the limitations should not be overlooked. The survival outcomes concurs other reported series.

MA16 PRIORITIZING USE OF TECHNOLOGY TO IMPROVE SURVIVAL OF LUNG CANCER SUBGROUPS AND OUTCOMES WITH CHEMOTHERAPY AND SURGERY
MONDAY, SEPTEMBER 9 15:45–17:15

MA16.03 BIG DATA ANALYSIS FOR PERSONALIZED MEDICINE IN LUNG CANCER PATIENTS

M. Torrente[1], B. Núñez-García[1], F. Franco[1], V. Calvo De Juan[1], E. Menasalvas[2], A. Rodríguez-González[2], C. Parejo[1], M. Provencio[1]

[1]*Hospital Puerta de Hierro, Majadahonda/Spain,* [2]*Universidad Politécnica de Madrid, Pozuelo de Alarcón/Spain*

Background: The use of Big Data in healthcare is in its early days, and most of the potential for value creation remains unclaimed. Electronic Health Records (EHR) contain a large amount of information about the patient's condition, which can potentially revolutionize the clinical practice, such information is seldom considered due to the complexity of its extraction and analysis. We report on a first integration of an NLP framework for the analysis of clinical records of lung cancer in Puerta de Hierro University Hospital (HUPHM). **Method:** A cohort of 1000 patients diagnosed of non-small cell lung cancer (NSCLC) from 2009 to 2018 at HUPHM were included in this observational study. Unstructured clinical data were obtained from the EHR. The semantic indexing and the information analysis was performed by the Politecnica University of Madrid, using Big Data and machine learning techniques. Clinical notes were converted into usable data, and combined with genomic data, images and bibliography, such as PubMed or Drugbank. **Result:** A total of 251.730 documents were analyzed (240.851 notes and 10.879 reports). These heterogeneous sources of information were analyzed and integrated in an interactive user interface (Figure 1). As a result, all this large amounts of data turns into actionable and exploitable information for clinicians and authorities for planning public health policies and also create new clinical trials. The interactive platform will allow the clinician obtain immediate and personalized information of each patient and will elaborate predictive models for long survivors, identify risk patients, reduce overtreatments, etc. **Conclusion:** By using Big Data we will be able to exploit large amounts of clinical information and combine them with multiple databases developing interactive user interface, increasing lung cancer knowledge and directing medicine towards a more personalized one. This work was supported by the EU H2020 programme, under grant agreement Nº 727658 (Project iASiS).

MA16.05 WEARABLE TECHNOLOGY FOR PRECONDITIONING BEFORE THORACIC SURGERY: A FEASIBILITY STUDY

Y. Patel[1], D. Hylton[1], M. Rok[1], M. Beauchamp[1], J. Wald[2], L. Mbuagbaw[2], C. Finley[1], J. Agzarian[1], Y. Shargall[1], C. Fahim[1], W. Hanna[1]

[1]*McMaster University, Hamilton/Canada,* [2]*McMaster University / St. Joseph's Healthcare Hamilton, Hamilton/Canada*

Background: Preconditioning before surgery can lower complication rates, but there are significant barriers to its adoption in the lung cancer population, which is characteristically older, suffers multiple comorbidities, and is averse to exercise. In an effort to overcome these barriers, we designed Move For Surgery (MFS), a home-based, preoperative preconditioning program which involves aerobic exercise using wearable technology and deep breathing exercises. We aimed to test the feasibility of MFS in preparation for a randomized controlled clinical trial. **Method:** In this prospective feasibility study, patients undergoing resection for NSCLC were preoperatively enrolled and provided with a wearable activity tracker (Fitbit) and a booklet describing various aerobic exercises, deep breathing exercises, and nutritional and smoking cessation tips. The daily step count, sleep cycle, and calories burned were synced and tracked remotely. Daily step goals were set by increasing the participants' baseline step count by 600 steps each week until the day of surgery. Participants were encouraged and motivated to reach their daily step goal by daily automatic reminders through the Fitbit. Participants completed the EQ-5D-5L health-related quality of life instrument at baseline and on the day of surgery. Data is presented as mean +/- SD and median (range). Continuous variables were compared using Student's t-test, and categorical variables were compared using Chi-square or Fischer's exact test, with a level of significance p<0.05. **Result:** Of the 40 patients screened, 62.5% (25/40) were eligible and enrolled. Of the 15 not eligible, 80% (12/15) did not have a smartphone. Participants (n=25) were enrolled from 11/2017 to 07/2018. Median age was 62 (33-82) and 72% (18/25) were women. The mean predicted FEV1 and DLCO were 88.9% +/- 23.4% and 74.9% +/- 19.8% respectively. Participants spent a median of 25 days (8-55) on trial, and wore their Fitbits 90.0% +/- 25.2% of the time. The mean baseline daily step count for this cohort was 7,586 +/- 4,082, and the participants were able to achieve the daily step goal in 40.8% +/- 30.0% of the time. Participants with higher baseline step counts (≥6,000/day) were more likely to achieve the daily step goals (52.2% vs 20.5%; p=0.0083). Significant improvement was seen in the overall health component of the EQ-5D-5L from before the intervention (76.4 +/- 15.45) to after the intervention (80.4 +/- 14.57; p=0.03). Overall, 96.0% (24/25) of the participants completed the recommended deep breathing exercises,

100% (25/25) recommended MFS for future patients, and 96.0% (24/25) stated they will buy their own Fitbits and continue this lifestyle post-surgery. **Conclusion:** A preoperative preconditioning trial with wearable technology prior to lung cancer resection is feasible based on encouraging enrollment rates, use of the device, and goal achievement, but it is only applicable to participants with smart devices. MFS motivates patients to undergo preconditioning before lung cancer resection and to continue with a healthy lifestyle after surgery. A revision of the daily step goal is required to improve compliance. A randomized trial is in progress to determine the impact of MFS on postoperative outcomes in the thoracic surgery population.

MA16.06 DETERIORATION IN HEALTH-RELATED QUALITY OF LIFE DIMINISHES BENEFIT OF LUNG CANCER RESECTION IN OLDER ADULTS

A. Blakely, H. Hu, L. Wong, D. Raz, L. Erhunmwunsee, V. Sun, J. Kim

City of Hope National Medical Center, Duarte/United States of America

Background: Outcomes of oncologic resection are related to tumor biology as well as patient-reported health factors. However, data regarding changes in functional status and health-related quality of life (HRQOL) before and after lung surgery are currently lacking. **Method:** We identified lung cancer patients from the SEER-Medicare Health Outcomes Survey (MHOS) linked database. HRQOL survey data captured physical/mental health, activities of daily living (ADLs), and medical comorbidities. Patients who underwent surgery with 1) baseline HRQOL survey prior to cancer diagnosis and 2) follow-up survey at least one year after diagnosis were selected. Patient, disease, and HRQOL measures were analyzed using Cox proportional hazards regression in regard to overall survival (OS) and disease-specific survival (DSS). **Result:** Overall, 138 patients were evaluated, of whom 67 (49%) were male. Mean age at diagnosis was 74 years. The majority of patients were Caucasian (n=112, 81%). Disease extent was localized for 75 (54%), regional for 58 (42%), and distant for 5 (4%). In general, the cohort experienced a decline in physical HRQOL, mental HRQOL, and ADLs; and an increase in the number of major comorbidities (see Table). Median OS was 74 months. Decreased OS was independently associated with male sex (HR 1.7, p=0.03), more advanced disease (regional vs. localized: HR 1.8; distant vs. localized: HR 2.1; p=0.04), and decline in ADLs (HR 1.8, p=0.02). Decreased DSS was independently associated with male sex (HR 2.2, p=0.03), more advanced disease (regional vs. localized: HR 2.9; distant vs. localized: HR 3.1; p=0.01), and decline in mental HRQOL (OR 2.1, p=0.02).

Variable		Baseline	Follow-Up
Physical HRQOL	At or above population mean (score 50+)	37 (27%)	8 (6%)
	Below population mean (score <50)	101 (73%)	130 (94%)
Mental HRQOL	At or above population mean (score 50+)	94 (69%)	83 (60%)
	Below population mean (score <50)	43 (31%)	55 (40%)
Katz ADL scores	Independence with each ADL = 1 point	5.4 (±1.1)	4.6 (±1.8)
Bathing	No difficulty	126 (91%)	102 (74%)
	Have difficulty or unable to do	10 (7%)	36 (26%)
Dressing	No difficulty	133 (96%)	110 (80%)
	Have difficulty or unable to do	5 (4%)	28 (20%)
Eating	No difficulty	135 (98%)	123 (89%)
	Have difficulty or unable to do	3 (2%)	15 (11%)
Getting in and out of chairs	No difficulty	119 (86%)	100 (72%)
	Have difficulty or unable to do	18 (13%)	38 (27%)
Walking	No difficulty	102 (74%)	77 (56%)
	Have difficulty or unable to do	36 (26%)	58 (42%)
Using the toilet	No difficulty	133 (96%)	124 (90%)
	Have difficulty or unable to do	5 (4%)	14 (10%)
Total number of self-reported comorbidities	0	72 (53%)	57 (42%)
	1	48 (35%)	56 (42%)
	≥2	17 (12%)	22 (16%)

HRQOL = health-related quality of life; ADL = activity of daily living

Conclusion: The potential survival benefit of lung resection for malignancy is diminished by declines in physical and mental health. Among older surgical patients at risk for functional and HRQOL deterioration, identification and mitigation of such deterioration may in turn optimize oncologic outcomes.

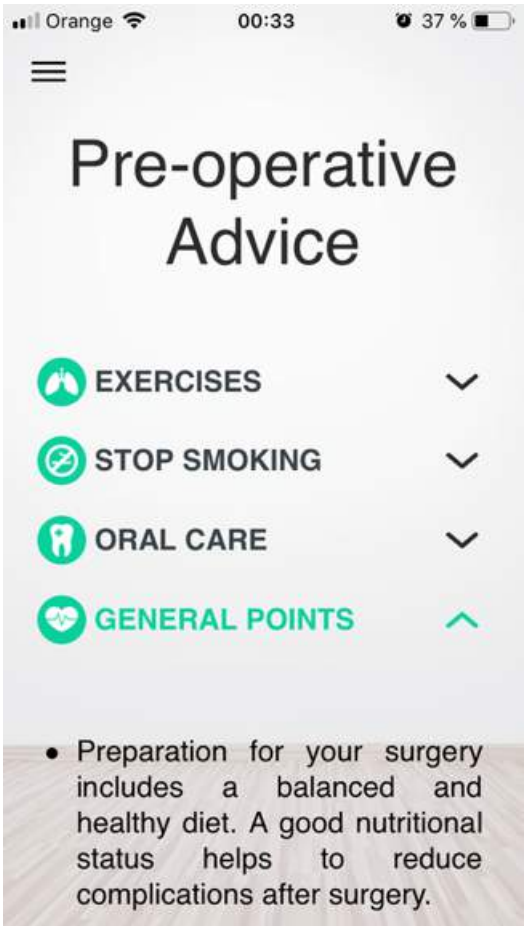
MA16 PRIORITIZING USE OF TECHNOLOGY TO IMPROVE SURVIVAL OF LUNG CANCER SUBGROUPS AND OUTCOMES WITH CHEMOTHERAPY AND SURGERY
MONDAY, SEPTEMBER 9 15:45–17:15

MA16.07 IMPLEMENTATION OF A SMARTPHONE APP TO FACE POSTOPERATIVE PERIOD IN PATIENTS WITH NSCLC UNDERGOING LUNG RESECTION SURGERY

C. Fraile Olivero[1], L. Milla Collado[1], J. Jarabo Sarceda[2], E. Fernández Martín[2], C. Cerdan Santacruz[3], J. Gastardi[2], A. Gómez Martínez[2], P. Arribas Manzanal[4], P. Santos Capa[4], M. Martínez Tardido[4], V. Alen[2], F. Hernando-Trancho[2]

[1]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [2]*Hospital Clínico San Carlos, Madrid/Spain,* [3]*Hospital Arnau Vilanova, Lleida/Spain,* [4]*Hospital Clínico San Carlos, MAdrid/Spain*

Background: Preoperative patient education and counseling helps to set expectations about surgical procedure and to prepare for it. Thoracic surgery procedures are related to postoperative complications and strategies to reduce them begin prior to surgery. Lung expansion maneuvers, the importance of early ambulation and pain control are best taught before the procedure. The aim of this prospective study was to implement the use of a smartphone application in a cohort of patients undergoing lung resection surgery and describe their feedback results. **Method:** We created a Smartphone application as a multidisciplinary tool including: peri-operative medical advice (stop smoking, mouth health, early mobilization and pain control) (Fig1), ten chest physical exercises (with animated images) and programmable Smartphone daily notifications. Complete information to download, set up and interaction with the software was given to patients. A Multiple-Choice-Question survey was applied to patients at the moment of hospital discharge in order to evaluate their experience. This prospective and observational study included clinical data and results of surveys applied.



Result: A total of 68 patients interacted with the application before surgery and answered the survey after the procedure. Median age was 66.5 years and 67.6% were males. Of them, 51 patients (75%) considered the content "very compressible". 54 patients (79.4%) considered "positive" the contribution of the application to face the postoperative period. Additionally, 31 patients (45.6%) deemed "appropriate" the quantity of time and physical effort needed to complete the interaction with the tool and reach the goals. **Conclusion:** This is the first smartphone application created by thoracic surgeons to improve patient´s education and helps them to prepare for surgery. This new technological tool was successfully implemented in our thoracic surgery department. For patients, it is easy to download, setup and contents comprehensible information that contributes to face positively the postoperative period with an adequate physical effort and quantity of time.

MA16.09 CLINICAL PRACTICE AND OUTCOMES IN PATIENTS WITH STAGE III UNRESECTABLE NON-SMALL-CELL LUNG CANCERAN ACADEMIC CENTRE, CANADA

G. Kasymjanova[1], D. Small[1], C. Pepe[1], L. Sakr[1], V. Cohen[1], M. Lecavalier[1], H. Wang[1], A. Spatz[1], M. Hurry[2], R. Walton[2], J. Agulnik[1]

[1]*Jewish General Hospital, Lady Davis Institute, McGill University, Montreal/ Canada,* [2]*AstraZeneca, Toronto/Canada*

Background: The prognosis of patients with stage III unresectable non-small cell lung (NSCLC) cancer is poor: five-year OS is only 19-24% for stage IIIA and 7- 9% for stage IIIB. In light of the approval of immunotherapy maintenance treatment, after completion of CRT, we undertook a retrospective study to characterize management and report outcomes of patients with stage III, unresectable NSCLC treated with chemoradiation (CRT) at the Jewish General Hospital, Montreal. **Method:** Patients diagnosed with stage III unresectable NSCLC,and treated with combined CRT, either concurrent (cCRT) or sequential (sCRT) treatment,between January 2007 to December 2018 were included in the study. Overall survival was calculated using the Kaplan-Meier approach and calculated from the start of radiotherapy. Physician defined progression-free survival was calculated from the start of radiotherapy until documented progression based on radiologic assessment. A multivariate analysis using Cox regression was carried out to assess clinical factors impacting survival. **Result:** 134/263 patients were deemed unresectable and received combined CRT. 124/134 (92.5%) received CRT as initial treatment and 10(7.5%) received CRT after progression to stage 3 post surgery for an earlier stage NSCLC.114/134 received cCRT and 20/134 received sCRT. Patients on cCRT were significantly younger with a slight prevalence of non-squamous histology and had N1 or single station N2 disease.Median OS (mOS) was 18.7 months (95%CI, 12.4-24.8) for the overall cohort; mOS in cCRT of 23.3 months (95%CI,14.3-32.2) was significantly better compared to 11.33 months with sCRT (95% CI, 10.2-24.8 p=0.01). PFS was slightly better in patients with cCRT (7.97mo, 95%CI 1.75-11.18) compared to sCRT (5.26mo, 95% CI 4.06-6.48 p=0.08).86/134 (64%) progressed and received subsequent therapy: 49 (57%)-chemotherapy alone, 15 (17.4%)–radiation alone, 13 (15.1%)-immunotherapy and 9 (10.5%)-targeted therapy.In multivariate analysis, the tumor size (HR 1.5, 95%CI 1.08-1.97) and nodal status (HR 2.5, 95%CI 3.34-4.74) were the only prognostic factors for OS. Gender, age, ECOG, smoking status, histology, chemotherapy protocol, subsequent therapy, mutation status and cCRT were not statistically significantin multivariate analysis. cCRT was not significant, likely due to patient selection. **Conclusion:** Unresectable stage III NSCLC is a heterogenous group that is challenging to manage. Combined CRT has beenthe standard of care for this group of pts. In our patient cohort, a trend of improved survival was seen in the cCRT group. Tumor size and nodal status were prognostic factors for OS. Future studies evaluating survival with newer IO therapies is of interest.

MA16.10 ANTIOXIDATIVE EFFECT OF ERDOSTEINE ON PLATINUM-BASED DOUBLET CHEMOTHERAPY INDUCED NEPHROTOXICITY

C.Y. Lee[1], S.H. Jang[2], M.-G. Lee[1]

[1]*Hallym University Medical Center, Chuncheon/Korea, Republic of,* [2]*Department of Pulmonary, Allergy and Critical Care Medicine, Hallym University Sacred Heart Hospital, Anyang/Korea, Republic of*

Background: Many classes of antineoplastic agents including the platinum coordination complexes are also known to generate free radicals which have a role in the side effects of chemotherapy. Despite the introduction of new treatments including target and immunotherapy, platinum-based doublet chemotherapy is one of the most widely used and most potent chemotherapy drugs to treat lung cancer patients especially with small cell lung cancer. However, side effects in normal tissues and organs, notably nephrotoxicity in the kidneys, limit the use of platinum-based doublet chemotherapy. There are several experimental evidences which support the protective effect of erdosteine in acute injury induced by a variety of pharmacological or noxious agents, mediated by products of oxidative stress. Erdosteine is a multifactorial drug currently used in lung disease. In the last decade, data from several studies to the possible antitussive and anti-inflammatory properties of erdosteine and an indirect anti-inflammatory mechanism of action related to the ROS scavenging activity was suggested. The purpose of this study is to investigate whether erdostein can reduce the renal toxicity of lung cancer with platinum-based doublet chemotherapy by antioxidant role. **Method:** This study was a prospective, randomized, double-blind clinical trial on 153 patients with lung cancer(small cell lung cancer and non-small cell lung cancer). Patients who was treated with platinum-based doublet chemotherapy were randomly assigned into 2 groups of intervention(erdostein) group and control(non-erdostein) subjects regardless of the type of lung cancer. Intervention group took erdosteine 600 mg orally twice a day. We measured CCr, serum/urine NGAL, serum/urine Cystatin C, urine KIM-1 of the lung cancer patients who underwent platinum-based doublet chemotherapy to assess renal injury. And also we measured the activity of specific antioxidant enzymes, such as catalase and superoxide dismutase to evaluate oxidative stress. Serum and urine samples were collected from the patient before and after chemotherapy. **Result:** There was no significant difference of renal status between intervention and control groups at baseline. However, Statistically there was a significant decline in CCr among control group regardless of the type of lung cancer and the resimen of chemotherapy. NGAL expression of blood and urine was decreased in intervention group (especially patient treated with cisplatin and small cell lung carcer patients) but Cystatin C levels showed no difference between two groups. The decrease in urinary KIM-1 after cisplatin-based doublet chemotherapy in intervention group were observed compared to control group. Superoxide dismutase levels of serum were approximately increased to twice the initial level to the level measured after chemotherapy in the treatment group while the level of catalase did not change significantly in both the groups. **Conclusion:** These results show that erdosteine may be a promising drug for protection against platinum-based doublet chemotherapy-induced nephrotoxicity, especially for patients with cisplatin-based doublet chemotherapy and small cell lung cancer. However, further studies with different dose of erdosteine are warranted for clarifying the issue.

MA16.11 EARLY AND LATE SURVIVAL COMPARISON BETWEEN ONCOLOGICAL VERSUS NON-ONCOLOGICAL PATIENTS ADMITTED TO A GENERAL INTENSIVE CARE UNIT IN CHILE

S. Samtani, R. Lopez, J. Graf, J.M. Montes, R. Perez

Clinica Alemana, Santiago/Chile

Background: Cancer patients are a heterogeneous population and usually admission to ICU units was discouraged due to negative outcomes. In the past years, literature supports the admission at ICU for oncological patients that need invasive mechanical ventilation (IMV) with new admission policy known as the ICU-trial, with aim to recognize a group of patients that may benefit of limited time of intensive support and treatment. The purpose of this trial is to describe the characteristics and overall survival of a prospective cohort of invasive mechanical ventilation (IMV) patients admitted to an ICU of Clinica Alemana. **Method:** This is an observational, prospective and analytical cohort study conducted in Clínica Alemana de Santiago. We included patients with cancer > 18 years old, with baseline Eastern Cooperative Oncology Group (ECOG) performance status classification from 0 to 3, who were admitted to ICU and needed IMV between October 2017 and February 2019. Demographic, physiologic, laboratory, clinical and treatment data were extracted prospectively in a database-updated daily. Survival data was obtained from national death registry database. **Result:** A total of 1,490 patients were admitted between October 2017 and February 2019. A total of 358 patients (24%) had oncological diagnosis and 100 patients were supported with IMV. According to ICU plan, 76 patients were treated as full code and 24 patients as ICU-trial. Among all IMV patients ICU mean of length of stay (LOS) was of 7 days. At the comparison between oncological vs non-oncological patients, APACHE II score and the first-day SOFA score were not statistically different between both groups. Among oncological patients, 73,3% of patients were ECOG 1 and solids tumors were more common than hematological malignancies (90% vs 10%). Lung and digestive cancer were the most frequent malignancies. Full code management was the most frequent strategy at ICU admission in comparison to ICU-trial (76% vs 24%). Survival at day 28 between oncological and non-oncological patients was 76.3% vs 79.3% respectively (p=0.588). However, survival was significantly different at day 90 (64.3% vs 78.8% respectively, p=0.015) and at end of following period (52% vs 76.2% respectively, p<0.001). Remarkably, survival adjusted by cox regression showed a significant lower survival in oncological patients with ECOG 2 and ECOG 3 while the patients with ECOG 0 and 1 had a similar survival to non-oncological patients. According to ICU plan management statistically significant difference was observed in the group of oncological patients with higher survival in full code vs ICU-trial (59.5% vs 29.2% respectively, p=0.015) with a hazard ratio 0.52 [0.28-0.94]. **Conclusion:** Our data suggest that in oncological patients the short-term survival is determined for severity of the critical illness and the late survival is lower respect to non-oncological patients if poor performance status is documented. In patients with cancer admitted under ICU-trial criteria and supported with invasive mechanical ventilation a late survival close to 30% was observed. Similar to previous studies, our study emphasizes that ICU admission should not be limited only on the basis of a patient having a neoplastic disease and different variables should be considered from patient to patient.

MA17.01 CELL LINEAGE AND CHROMATIN LANDSCAPE OF LUNG CANCER ARE CONTROLLED BY GATA6

A. Arnal Estapé[1,2], W. Cai[1], A. Albert[1], F. López-Giráldez[1], M. Zhao[1], L. Stevens[1,3], K. Patel[1], D. Nguyen[1,2]

[1]*Yale University School of Medicine, New Haven/United States of America,* [2]*Yale School of Medicine, new haven/United States of America,* [3]*Dana-Farber Cancer Institute, Boston/United States of America*

Background: Thoracic malignancies are histologically and biologically heterogeneous. The underlying causes of this heterogeneity are believed to be linked to the complex cellular ontogenies of lung cancers and their relationship to pulmonary development. Lineage selective transcription factors (TFs) are critical determinants of airway cell differentiation and homeostasis, but their biological requirements are often conditional. Analogously, several developmental TFs can paradoxically enhance or inhibit lung cancer progression, depending on cellular and epigenetic contexts which remain largely undefined. In this study, we report a novel function for the endodermal and pulmonary specifying TF GATA6 in lung cancer. **Method:** To understand the role of GATA6 in lung tumorigenesis we used a genetically engineer mouse model (GEMMs) harboring Kras p53 mutations using progenitor cell specific gene targeting. We combined GEMMs biology with integrated analysis of the transcriptome and the chromatin landscape of lung cells derived from GATA6 deficient tumors. **Result:** In this study, we uncover a conditional role for the endodermal and pulmonary specifying TF GATA6 during the initiation and progression of Kras mutant lung adenocarcinoma (LUAD). Inhibition of Gata6 in genetically engineered mouse models dampens the proliferation and increases the differentiation of LUAD tumors. These effects are influenced by the epithelial cell type that is targeted for transformation, demonstrating that GATA6 expression is an important molecular determinant of the cell of origin in Kras mutant lung cancer. In LUAD cells derived from surfactant protein C expressing progenitors, we identify multiple genomic loci that are bound by GATA6. Moreover, suppression of Gata6 in these cells significantly alters chromatin accessibility, particularly at distal enhancer elements. Analogous to its paradoxical activity in the developing lungs, GATA6 expression fluctuates during different stages of LUAD progression and can epigenetically control diverse lineage programs associated with cell proliferation, alveolar specification, BMP signaling, and epithelial plasticity. In summary: 1) GATA6 expression varies during different stages of disease progression in the lung adenocarcinoma (LUAD) subtype 2) Suppression of Gata6 can diminish the proliferation and progression of LUAD in a manner that is influenced by the transforming progenitor of origin 3) GATA6 differentially modulates chromatin accessibility across the genome of LUAD cells 4) This epigenomic mechanism results in the activation of different lineage specific programs, including the BMP signaling pathway. **Conclusion:** These findings reveal how GATA6 can modulate the chromatin landscape of lung cancer cells to control their divergent lineage dependencies during tumor progression. MA17.02 IDENTIFY VULNERABLE PATHWAYS AND IMPROVE TREATMENT OUTCOMES IN LKB1-DEFICIENT LUNG TUMORS

M. Welliver, F. Jin, J. Amann, M. Koenig, X. Mo, D. Carbone

The Ohio State University, Columbus/United States of America

Background: The LKB1 tumor suppressor is inactivated in about 20% of non-small cell lung cancers (NSCLC) by mutations. Cancer cells with LKB1 deficiency exert complex effects on signal transduction and transcriptional regulation, which may cause these cells more susceptible to certain therapies comparing to cells with intact LKB1 function. Phenformin, an antidiabetic medicine from the biguanides class, has shown activities against NSCLC. Phenformin as a single agent has been shown to reduce tumor burden and prolonged survival in Kras;Lkb1 compound mutant mice but not Kras;p53 mice, suggesting specific activities in tumor with LKB1 deficiency. Currently patients with unresectable locally advanced NSCLC are treated standardly with concurrent chemoradiotherapy followed by checkpoint inhibitor, durvalumab. In this project, we test treatment sensitivity to radiotherapy and/or phenformin in lung cancer cells with intact or deficient LKB1. **Method:** Human lung cancer cell lines described below were used in (1) clonogenic survival assays as well as (2) generating tumor xenograft on nude mice for tumor growth delay experiments. A549, HCC15 and Calu-1 cell lines obtained from ATCC were cultured in RPMI1640 containing 5% FBS, without antibiotics. A549 cells (LKB1 deficient, TP53 WT and KRAS mutated) or HCC15 (LKB1 deficient, TP53 mutated and KRAS WT) were transfected with empty vector or WT LKB1 or LKB1-K78I plasmids; Calu-1 (LKB1 WT, KRAS mutated and p53 deleted) transfected with empty vector or LKB1 CRIPR KO were generated as described previously. **Result:** A549 cells with transfected WT-LKB1 were significantly more resistant to ionizing radiation (IR) induced cell kill (8.7% survival at 8 Gy) comparing to cells transfected with empty vector (3.7%) or kinase-dead LKB1 genes (4.2%). Similarly, HCC15 cells with transfected WT-LKB1 are significantly more resistant to IR induced cell kill (7.5%) comparing to cells transfected with empty vector (4.1%) or kinase-dead LKB1 genes (3.4%). Calu-1 cells harbor WT LKB1, and it is significantly more resistant to IR induced cell kill (8.3%) comparing to their counterpart with LKB1 KO (Calu-1 transfected with LKB1 CRIPR KO) (4.1%). When A549 cells were pretreated with 30 μM phenformin prior to, during and after IR, there was no change in survival in cells transfected with WT LKB1; however there was significant further reduction in survival in cells transfected with empty vector (LKB1 deficient). Xenograft tumors were generated in nude mice with A549 cells with the above genetic alterations. There was significant further tumor growth delay in those with A549 with deficient LKB1 comparing to those with A549 with WT LKB1 gene add-back. This tumor growth delay was further enhanced when these mice were treated with oral phenformin prior to, during and after IR treatment, confirming the *in vitro* experimental results. **Conclusion:** Human lung cancer with deficient LKB1 are more sensitive to ionizing radiation *in vitro and in vivo*. This was regardless of the TP53 or KRAS mutation status. A549 cells with deficient LKB1 were also more sensitive to phenformin treatment. Phenformin treatment further sensitized LKB1 deficient lung cancer cells to IR. This suggested that LKB1 can serve as a predictive biomarker to triage patient treatments.

MA17.03 IMPORTANCE OF CULLIN4 UBIQUITIN LIGASE IN MALIGNANT PLEURAL MESOTHELIOMA

M. Meerang, J. Kreienbühl, V. Orlowski, M. Kirschner, W. Weder, I. Schmitt-Opitz

University Hospital Zurich, Zurich/Switzerland

Background: Loss of the tumor suppressor NF2 is frequent in malignant pleural mesothelioma (MPM). NF2 suppresses tumorigenesis in part by inhibiting Cullin4 ubiquitin ligase (CUL4) complex. Here we aimed to evaluate an importance of CUL4 in MPM. **Method:** We evaluated the expression of CUL4A and CUL4B in tissue microarrays using immunohistochemistry. We tested the efficacy of cullin inhibition by pevonedistat, a small molecule inhibiting cullin neddylation, in 13 cell lines and 3 primary cells in 2D and 3D culture. Four groups of SCID mice haboring intraperitoneal (ip.) pevonedistat sensitive (MSTO211H) or resistant (ACC-Meso1) cell lines were treated with pevonedistat (50 mg/kg; ip.) on a 5day on/5day off schedule for 3 cycles. Treatment efficacy was assessed by means of overall survival. **Result:** CUL4B expression was associated with clinical outcomes (figure 1). Five MPM cell lines (38%) were highly sensitive to pevonedistat (IC50<500 nM). This remained true in 3D spheroid culture. The treatment induced S/G2 cell cycle arrest and accumulation of cells undergoing DNA re-replication (containing >4N DNA content) known to be mediated by p21 and CDT1 accumulation. Indeed the accumulation of p21 and CDT1 was more pronounced in pevonedistat sensitive cell lines after the treatment. Two of primary cells (67%) were sensitive to pevonedistat and also showed higher CDT1 accumulation following the treatment compared to the resistant cells. *In vivo,* pevonedistat treatment significantly prolonged survival of mice bearing both sensitive and resistant MPM tumors. Pevonedistat treatment reduced growth (phosphorylated histoneH3 positive) in pevonedistat sensitive tumor but increased apoptosis (cleaved–caspase3 positive) in pevonedistat resistant tumor.

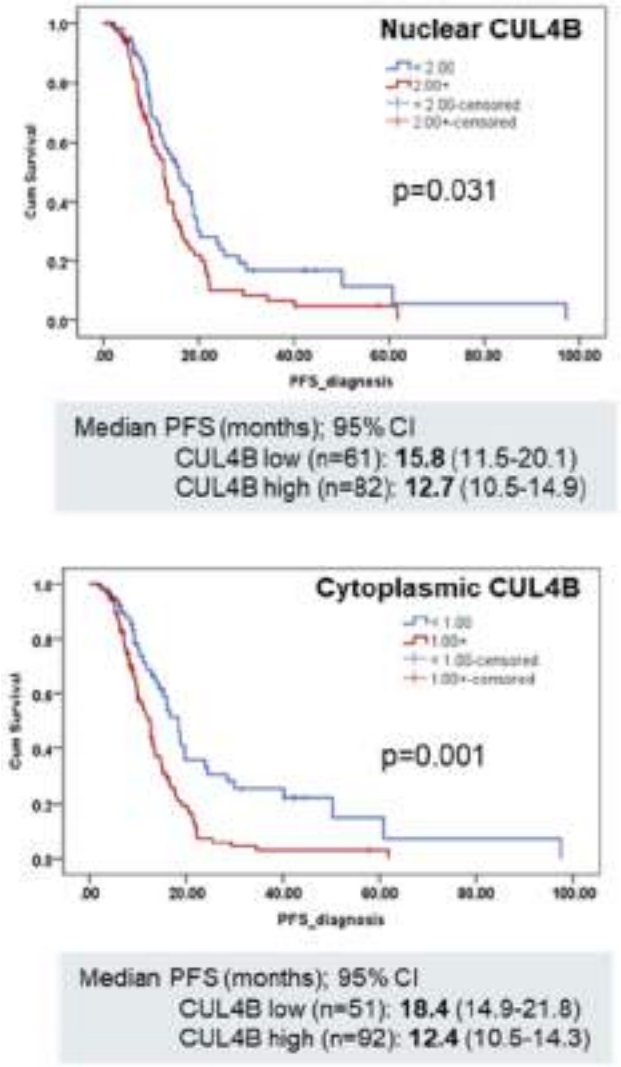

Figure 1. High expression of CUL4B was significantly associated shorter progression free survival (PFS).

Conclusion: High CUL4B expression may play a role in MPM progression. Inhibition of cullins by pevonedistat induced growth arrest and DNA re-replication strongly in a subset of MPM. The major mechanism seems to be mediated by p21 and CDT1 accumulation *in vitro*. Investigation of mechanisms *in vivo* is ongoing.

MA17.05 DNA-BINDING AND GENE EXPRESSION PROFILES IN MAX DEFICIENT SMALL CELL LUNG CANCER

P. Llabata, M. Torres-Diz, A. Gomez, M. Sanchez-Cespedes

Cancer Epigenetics and Biology Program-PEBC (IDIBELL), L'Hospitalet de Llobregat/Spain

Background: The MYC pathway is frequently altered in cancer, mostly by gene activation of the MYC-family of oncogenes (fMYC) but also by genetic inactivation of MAX, the obligate partner of MYC. While the oncogenic properties of fMYC have been extensively studied, the tumour suppressor role of MAX and the function of fMYC in MAX-mutant cells remain unclear. Further, inactivating mutations in MGA, a gene that codes for another MAX-binding partner, have been found in lung cancer. MGA is a component of the non-canonical polycomb repressive complex 1 (ncPRC1) but its precise role in lung cancer development is unknown. **Method:** RNA-sequencing, chromatin immunoprecipitation and proteomic analysis were performed to identify and compare the DNA binding and gene expression profiles of MYC, MGA and MAX in MAX-restituted human small cell lung cancer (SCLC)-derived cell lines. **Result:** SCLC is a high-grade neuroendocrine type of lung cancer with recurrent inactivating mutations in MAX. Recent findings have described two major SCLC subtypes based on the high expression of either *ASCL1* or *NEUROD1* transcription factors. According to this, *ASCL1* and *NEUROD1* control the expression of different set of genes which defines the two subgroups of SCLC. Here, we found that MAX-mutant SCLC cells belong to the *ASCL1*-transcription factor dependent group of SCLCs. In the absence of MAX, even after ectopic overexpression of MYC, there was no recruitment of MYC to the DNA. The DNA binding profile of MAX in MAX-restituted cells remained unaltered after co-overexpression of MYC, despite opposed effects in gene expression. Moreover, restitution of MAX significantly shifted the DNA occupancy of MGA, from E2F6 consensus binding sites to MYC-consensus binding sites (E-boxes). Our observations also demonstrated that ncPRC1 complex is formed regardless of the presence or absence of MAX. **Conclusion:** Our data supports that MYC lacks transactivation capabilities in the absence of MAX and that the tumour suppressor role of MAX relies on its capability to counteract the gene expression triggered by its partnering with fMYC. Further, we conclude that the tumor suppressor role of MGA may be related, in part, to the regulation of E2F6 promoters.

MA17.06 PLAKOPHILIN 1 ENHANCES MYC EXPRESSION, PROMOTING SQUAMOUS CELL LUNG CANCER

J. Martin-Padron[1,2,3], L. Boyero[1,2], M. Rodríguez[1,4], A. Andrades[1,4], I. Díaz-Cano[1,2,3], P. Peinado[1,4], C. Baliñas[1,4], J.C. Álvarez Pérez[1,4], I. Coira[1,4], M.E. Fárez-Vidal[2,3], P. Medina[1,4]

[1]*GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Regional Government, Granada/Spain,* [2]*Department of Biochemistry and Molecular Biology III and Immunology, University of Granada, Granada/Spain,* [3]*Institute for Biomedical Research (IBS) of Granada. University Hospital Complex of Granada, Granada/Spain,* [4]*Department of Biochemistry and Molecular Biology I, University of Granada, Granada/Spain*

Background: Plakophilin 1 (PKP1) is a member of the arm-repeat (armadillo) and plakophilin gene families, being an important component of the desmosome. Although desmosomes loss-of-function has been associated with increased cell migration and pro-oncogenic activity, we have observed consistent PKP1 overexpression in patient samples of squamous cell lung cancer (SqCLC) in comparison with lung adenocarcinoma (LUAD) and non-tumoral controls from two datasets achieved by our group, and also from three additional independent datasets. **Method:** In order to explore this paradox, we developed *in vitro* and *in vivo* PKP1 gain/loss functional models in SqCLC cell lines and also we challenged our hypothesis in some LUAD cell lines. **Result:** Greater cell dissemination but reduced cell proliferation was observed in CRISPR-Cas9 induced, PKP1-knockout clones. Furthermore, PKP1 expression promoted cell proliferation, cell survival, and *in vivo* xenograft engraftment. Interestingly, we demonstrated through several functional experiments (chromatin immunoprecipitation, RNA immunoprecipitation, direct mutagenesis combined with luciferase assays, Western blot, qPCR.. among others), and in 7 cell lines from different lung cancer subtypes (5 SqCLC and 2 LUAD cell lines), and different contexts (with and without PKP1 basal expression in order to set up gain and loss expression assays), that these pro-oncogenic activities were mediated by the functional direct relationship between PKP1 and the oncogene MYC. Specifically, PKP1 enhances MYC translation, and MYC increases PKP1 transcription, linking both proteins in a positive feedforward loop. **Conclusion:** These observations provide a new molecular mechanism of cancer development, revealing PKP1 as a novel oncogene in SqCLC, and as an effective post-transcriptional regulator of MYC, which has been described as overexpressed in around 70% of NSCLC tumors. Moreover, PKP1 unveiled as a valuable diagnostic biomarker and a potential therapeutic target for SqCLC. Importantly, PKP1 inhibition may open up the possibility of indirectly targeting MYC, not only in NSCLC (where, as mentioned before, is frequently overexpressed), but also in other tumors. This is of particular interest, because MYC is an oncogene that is dysregulated in most human cancers and is acknowledged as a "most wanted" target for cancer therapy.

Keywords: Squamous Cell Lung Cancer, PKP1, MYC

MA17.07 IDENTIFICATION OF AHR AS A NOVEL REGULATOR OF LUNG CANCER METASTASIS

S. Nothdurft[1], F. Breitenbuecher[1], R. Okimoto[2,3], T. Bivona[2,3], B. Gruener[4], M. Hoelzel[5], J. Forster[6], S. Kalmbach[1], A. Schramm[1], M. Schuler[1,6]

Background: Curative treatment of early stage and locally advanced non-small cell lung cancer (NSCLC) relies on surgery and radiotherapy. Adjuvant or simultaneous platin-based chemotherapy is used for risk reduction in patients with large tumors and/or lymph node metastases. Still a large fraction of curatively treated patients dies from metastatic relapse. A better mechanistic understanding of lung cancer metastasis is expected to guide the development of novel rational interventions from prevention, early detection and treatment. **Method:** Using a barcoded shRNA library we performed a functional *in vivo* screen in an orthotopic NSCLC mouse model to find target genes involved in metastatic processes. Barcoded shRNAs with significantly different representation between primary tumors and metastases were identified by next generation sequencing. Prioritized hits were functionally validated by targeted suppression in NCI-H1975 cells. Mechanistic studies were conducted in several NSCLC models *in vivo* and *in vitro*. **Result:** We identified AHR, a ligand-activated transcription factor involved in regulation of biological responses to planar aromatic hydrocarbons, as potential modulator of lung cancer metastasis. Suppression of endogenous AHR by shRNA enhanced the migratory and invasive capacity of NSCLC cells *in vitro*. Importantly, NCI-H1975 with targeted suppression of AHR showed increased metastasis formation in an orthotopic model *in vivo*. High RNA expression of AHR correlates with lower likelihood of progression and superior overall survival in patients with stage I NSCLC. Mechanistically, AHR impacts matrix remodeling genes (*MMP19*, *MMP24*) as well as asparagine synthetase (*ASNS*), all of which have been implied in metastatic progression. **Conclusion:** *AHR* is a novel metastasis-modulating factor in NSCLC. Its mechanism of action provides rational targets for diagnostic and therapeutic interventions.

Keywords: NSCLC, metastasis, AHR

MA17.09 5-AZACYTIDINE INHALED DRY POWDER FORMULATION PROFOUNDLY IMPROVES PHARMACOKINETICS AND EFFICACY FOR LUNG CANCER THERAPY

P. Kuehl[1], C. Tellez[1], M. Grimes[1], M. Burke[2], A. Badenoch[2], D. Dubose[2], S. Belinsky[1]

Background: Epigenetic therapy through its ability to activate hundreds of genes silenced by promoter hypermethylation in lung cancer could produce durable and sustained tumor regression. The demethylating agent 5-azacytidine (5AZA) is unstable in aqueous solution and subject to hydrolysis and catabolism by cytidine deaminase (CDA) in liver, thereby reducing drug concentration after systemic administration prior to reaching the lung. Delivering 5AZA by inhalation could mitigate these barriers. **Method:** A stable, respirable (3.5 μM) dry powder formulation of 5AZA was generated. Pharmacokinetic (PK) studies in rats compared systemic dosing to inhaled delivery of a dry powder or aqueous formulation of 5AZA in the presence and absence of the CDA inhibitor tetrahyroduridine (THU). An orthotopic nude rat lung cancer model compared efficacy of inhaled dry powder versus aqueous 5AZA for treatment of engrafted human adenocarcinoma (Calu6, Calu3), adenocarcinoma in situ (H358), and squamous cell (RH2) tumor lines. Three weeks following engraftment (lungs contain multiple tumors), rats were treated 4 times weekly for 4 weeks, then sacrificed to assess tumor burden and genome-wide effects on the methylome in vehicle and treated tumors using the Illumina EPIC array. **Result:** Plasma PK showed a ~10-fold increase in area under the curve (AUC) and a 1.5 and 5-fold increase in maximum concentration (Cmax) comparing inhaled dry powder (0.6 mg/kg) to systemic (2 mg/kg, equivalent to the human injectable dose of 75 mg/m2) and inhaled aqueous (0.6 mg/kg) 5AZA that was augmented by THU. Inhaled dry powder and aqueous 5AZA PK in lung were similar and greatly exceeded systemic (30-fold Cmax; 47-fold AUC). PK in liver and brain were superior for dry powder with 7- and 26-fold increase in AUC and 7- and 3.3-fold increase in Cmax compared to systemic or aqueous dosing. The efficacy study comparing inhaled delivery of equivalent doses (0.6 mg/kg lung dose) showed dry powder was significantly better than aqueous with a 70–80% compared to 33–50% reduction in tumor burden for Calu6, Calu3, and RH2 and equally effective in largely curing H358 tumors. A significantly increased median number of genes (175–320 versus 25–270) exhibiting ≥30% demethylation of CpGs across their promoter region was seen for Calu6, Calu3, and H358 tumors exposed to dry powder versus aqueous 5AZA, with equivalent numbers of genes demethylated for RH2. **Conclusion:** Delivery of a dry powder formulation of 5AZA via an inhaler could be used to treat local and metastatic lung cancer (Support–CA196590).

MA17.10 LACTATE TRANSPORTER BLOCKADE AS A STRATEGY TO OVERCOME VEGF INHIBITOR-RESISTANCE IN LKB1-DEFICIENT NSCLC

I. Guijarro[1], A. Poteete[1], S. Cho[1], T. Zhou[1], Y.-H. Fan[1], E. Roarty[1], M. Nilsson[2], E. Parra[3], B. Mino[1], I. Wistuba[1], J. Wang[2], F. Skoulidis[4], J. Heymach[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*MD Anderson Cancer Center, Houston/United States of America,* [3]*University of Texas, Houston/Texas/United States of America,* [4]*UT MD Anderson Cancer Center, Houston/United States of America*

Background: *STK11/LKB1* alterations are found in 20-30% of NSCLC and used to co-occur with *KRAS* mutations. Because LKB1 activates AMPK, many of the best known functions of LKB1 are attributed to its ability to control metabolic alterations in cells. Our laboratory have previously reported that loss of LKB1 promotes enhanced glycolysis and elevated lactate production and more recently we demonstrated that *STK11/LKB1* mutations are the strongest predictors of *de novo* resistance to immunotherapy in NSCLC. Prior studies have revealed an association between alterations in the LKB1/AMPK pathway and worse clinical outcomes in NSCLC and in patients treated with chemotherapy and bevacizumab. Given the roles of LKB1 in the regulation of cell metabolism and resistance to immunotherapy, it is feasible that LKB1 also impacts on the response to anti-angiogenic therapies. **Method:** Xenograft mouse models were established by subcutaneous injection of H460 cells (LKB1-deficient) and H460 LKB1-expressing in nude mice and LKR10 (*KRAS*^{G12D}) *LKB1* wild-type (K) or *LKB1*- knockout (KL) into 129Svmice. Mice were randomized to vehicle or B20-4.1.1 anti-VEGF antibody. Glycolytic activity of LKB1-intact and -deficient NSCLC cells was measured by Seahorse assay. We analyzed gene expression of SLC16A3 (MCT4) by qPCR and Western blot. Genetic disruption of MCT4 in the K and KL cell lines was done using CRISPR-Cas9 and mouse models were established by subcutaneous injection into mice. **Result:** Mice bearing LKB1-expressing H460 xenografts treated with anti-VEGF antibody showed a significant decrease in tumor volume ($p<0.05$) compared with their vehicle-treated counterparts. However, mice bearing LKB1-deficient H460 xenografts showed markedly reduced efficacy of anti-VEGF therapy compared with that in LKB1-expressing xenografts. Anti-VEGF therapy significantly reduced growth of LKR10 K tumors ($p<0.001$) but not in LKR10 KL tumors. Microvascular density was not increased in KL tumors following anti-VEGF treatment compared to K. Human isogenic LKB1-deficient cells showed a significantly increased rate of glycolysis and lactate secretion compared with cells expressing LKB1. Human and murine LKB1-deficient cells also had increased MCT4 expression compared

to K cells. Immunofluorescence and RPPA analysis of tumor samples from the K and KL mouse models showed that KL tumors upregulated MCT4 protein expression compared with K tumors (p<0.0001). The genetic disruption of MCT4 KL tumors significantly improved tumor volume reduction to anti-VEGF therapies *in vivo* (p<0.001). **Conclusion:** LKB1 loss is associated with increased lactate secretion and resistance to VEGF inhibition in NSCLC. The targeting of the lactate transporter MCT4 enhance the sensitivity of LKB1-deficient NSCLC to anti-VEGF therapy.

MA17.11 HIGH SENSITIVITY TO PD-1 BLOCKADE THERAPY AFTER LD1 DEPLETION IN KRAS-DRIVEN LUNG CANCER THROUGH CD8+/CD3+ TUMOR INFILTRATION AND PD-L1 INDUCTION

I. Baraibar[1], M. Román[2], I. López-Erdozain[2], A. Oliver[2], A. Vilalta[1], D. Ajona[2], S. Vicent[2], C. De Andrea[1], R. Pio[2], J.J. Lasarte[3], A. Calvo[2], I. Gil-Bazo[1]

[1]*Clínica Universidad de Navarra, Pamplona/Spain,* [2]*Program in Solid Tumors, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona/Spain,* [3]*Program of Immunology and Immunotherapy, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona/Spain*

Background: PD-1/PDL-1 inhibitors are approved for non-small cell lung cancer (NSCLC). However, many patients do not benefit and therapeutic combinations are under investigation. We have previously described Id1, involved in proliferation, angiogenesis and immunosuppression, as a prognostic factor in lung adenocarcinoma (LUAD) (Ponz-Sarvise, Clin Cancer Res 2011), Id1's role in lung cancer metastasis (Castanon, Cancer Letters 2017) and more recently shown that Id1 sustains mutant *KRAS*-driven progression and metastasis in NSCLC (Roman, Cancer Res 2019). In a previous syngeneic murine lung cancer model with depleted levels of Id1 using Id1-/- and Id1 wildtype C57BL/6 mice inoculated with Lewis Lung Carcinoma (LLC), we tested a combined therapeutic strategy targeting PD-1 and Id1, showing impaired tumor growth and increased survival (Gil-Bazo, presented at WCLC 2018). Here we study a combined strategy targeting PD-1 and Id1 in a *KRAS*-mutant murine LUAD model and the immune-related mechanisms involved. **Method:** First, a correlation between Id1 and PD-L1 mRNA expression was studied in mutant and wild-type *KRAS* LUAD cohorts from The Cancer Genome Atlas data set (TCGA). Secondly, a syngeneic tumor model using Balb/c mice through subcutaneous injection of *KRAS*-mutant LUAD (Lacun3) cells and *Id1*-silenced Lacun3 (Id1sh) cells. *In vitro,* proliferation was measured in both cell lines through MTS assays. IFNg-induced PD-L1 expression in both cell lines and flow cytometry was used to evaluate its mechanistic effects on the immune response. After tumor cells injection, mice were treated with an anti-PD-1 (RMP-1-14) monoclonal antibody or PBS, i.p. Tumor volumes according to Id1 status in tumor cells and the treatment administered were quantified. Vectra 3.0™ multispectral microscopy was used to characterize the tumor associated immune cells in paraffin-embedded tissues from our previous syngeneic murine lung cancer model using Id1-/- and Id1 wildtype C57BL/6 mice inoculated with LLC in which the combined blockade had been reported as effective. Immune marker antibodies were used to study expression of CD3, CD4 and CD8. **Result:** An inverse, moderate and statistically significant correlation between Id1 and PD-L1 expression in mutant and wild-type *KRAS* LUAD cohorts from TCGA was found in both cohorts (-0.367 and -0.351, respectively, p<0.001), indicating that Id1 depletion may lead to PD-L1 expression induction. *In vitro* assays showed that Id1 silencing reduced Lacun3 cells proliferation (p<0.001). Up-regulation of surface PD-L1 expression occurred in Id1sh cells, but not in Lacun3 cells, after receiving IFNg (p=0.0022). Mechanistically, in the syngeneic murine model, *Id1* inhibition in the injected cells, combined with anti-PD-1 treatment, significantly induced a tumor growth impairment (p<0.001). An intense CD8+ and CD3+ immune cell infiltration was observed in LLC Id1-/- C57BL/6 mice treated with anti-PD1 (p<0.05 for CD3+ TILS), compared the control groups, possibly explaining the dramatic tumor growth impairment previously shown on the treated animals. **Conclusion:** Id1 silencing may induce PD-L1 overexpression according to *in silico* and *in vitro* results. Id1 and PD-1 combined blockade in our *KRAS*-mutant syngeneic murine LUAD model significantly impaired tumor growth, compared to each strategy alone. A significantly increased CD3+ and CD8+ tumor infiltration and IFNg-induced PD-L1 tumor expression after the combined blockade may explain these findings.

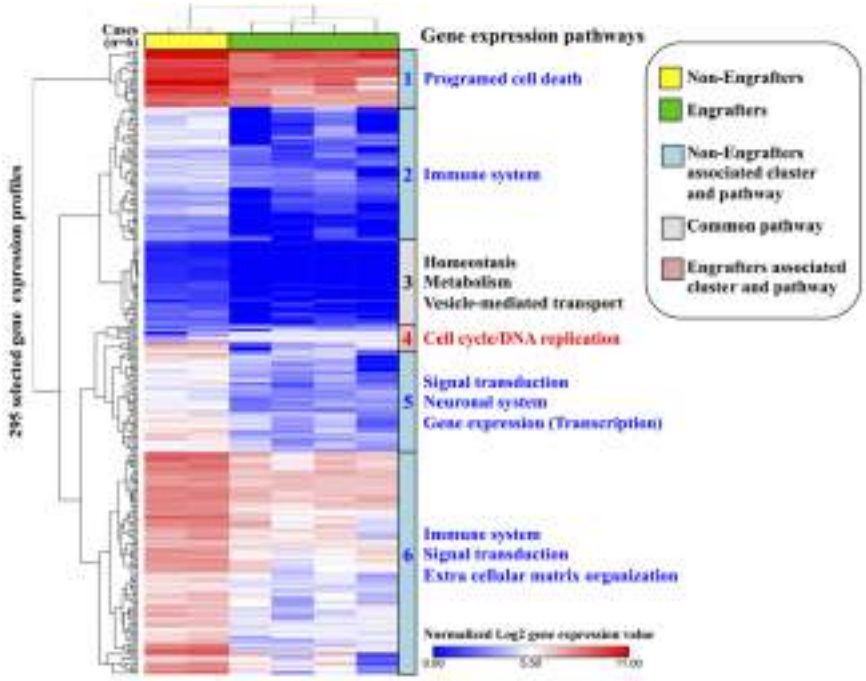
MA18 ADVANCES IN DIAGNOSIS OF COMMON TYPES OF NSCLC
TUESDAY, SEPTEMBER 10 11:30–13:00

MA18.01 PATIENT-DERIVED XENOGRAFTS OF LUNG SQUAMOUS CELL CARCINOMA SHOW A CHARACTERISTIC GENETIC PROFILE INDICATING A SPECIFIC BIOLOGICAL SUBTYPE

Y. Kim, A. Shiba-Ishii, M. Noguchi

University of Tsukuba, Tsukuba shi/Japan

Background: Patient-derived xenograft (PDX) models are considered preferable to preclinical models for research on cancers including non-small cell lung cancers (NSCLCs). PDXs basically retain the histological features, heterogeneity, and genomic profiling of the original tumors, even after a series of passages. Among NSCLCs, a high rate of engraftment of lung squamous cell carcinoma (LUSC) into immunodeficient mice has been steadily reported. However, no previous study has examined the specific or characteristic expression profiles of LUSC, which is easy to establish in PDX. In this study, we compared the genetic profiles of resected LUSCs that had been successfully engrafted and with those that had not. **Method:** Fifty-one surgically resected NSCLCs, including 10 LUSCs, were inoculated into immunodeficient mice and xenografts were established. The resected tumors and established xenografts were examined histologically and their gene expression profiles were determined by RNA sequencing. The distinct genetic features of tumors from which PDX was successful (engrafters) and those from which PDX was unsuccessful (non-engrafters) were compared using bioinformatics methods, and their subtypes were evaluated. To validate the genetic profiling associated with engraftment and the subtype, we analyzed gene expressions, mutations, and patient outcomes obtained from The Cancer Genome Atlas (TCGA) database. **Result:** Among the 51 lung carcinomas, 38 were adenocarcinomas, 10 were LUSC, and 3 were other histological subtypes. Among the 10 LUSCs, 2 were non-engrafters and 4 were engrafters that were stably transplantable beyond passage three. RNA sequencing analysis revealed that non-engrafters had higher expression of genes related to programmed cell death, immune system, and signal transduction than engrafters, whereas engrafters showed higher expression of genes related to the cell cycle and DNA replication. Patients with non-engrafter-associated genetic profiles showed a poorer outcome than those with engrafter-associated genetic profiles. Recently, Wilkerson *et al.* classified LUSC into four subtypes – basal, classical, secretory and primitive – on the basis of biological and genetic differences. Interestingly, we found that non-engrafters had a genetic profile similar to the secretory subtype in the mid-late stage, whereas engrafters had the classical subtype of the early-mid stage of differentiation.



Conclusion: LUSC from which PDX is successful has a characteristic expression profile and shows a favorable prognosis, with a marked tendency for squamous epithelial differentiation.

MA18 ADVANCES IN DIAGNOSIS OF COMMON TYPES OF NSCLC
TUESDAY, SEPTEMBER 10 11:30–13:00

MA18.02 S100A10 UPREGULATION ASSOCIATES WITH POOR PROGNOSIS IN LUNG SQUAMOUS CELL CARCINOMA

K. Sato[1], Y. Saiki[1], K. Arai[2], K. Ishizawa[1], S. Fukushige[1], A. Sakurada[3], Y. Okada[3], A. Horii[1]

[1]*Tohoku University School of Medicine, Sendai/Japan,* [2]*Shizuoka General Hospital, Shizuoka/Japan,* [3]*Institution of Development, Aging and Cancer, Tohoku University, Sendai/Japan*

Background: S100A10 is one of the members of S100 protein family. This molecule predominantly functions in a complex with annexin A2, and stimulates plasminogen activator (tPA)-dependent plasmin formation. Plasmin cleaves and activates metalloproteases (MMPs). Several studies have established that plasmin is an important protease involved in cancer cell migration and invasion. Expression of the S100 protein family is detected in many human cancers and has been related to a poorer prognosis, but relationship between S100A10 expression and progression of human lung cancer has not been clarified. In this study, we focused on S100A10 and aimed to clarify its effect to progression in lung adenocarcinomas and lung squamous cell carcinomas (SCCs). **Method:** We investigated expressions of S100A10 and MMPs by immunohistochemistry in resected 98 primary lung adenocarcinomas and 120 primary lung SCCs, and its associations with clinicopathological parameters were evaluated. S100A10-positivity was defined when more than 10% tumor cells showed positive staining. In lung SCC cases, we particularly evaluated cancer cell surface at the invasive front. Kaplan-Meier analysis and Cox proportional hazard models were used to estimate the effect on survival. Next we observed the expression of S100A10 in 6 lung adenocarcinoma and 6 lung SCC cell lines, and performed siRNA-mediated knockdown against *S100A10* in highly-expressing cell lines. **Result:** Seventy-four (78.6%) of 98 adenocarcinomas were S100A10-positive cases, and correlations with poorer prognosis (p=0.0413), lymphatic invasion (p=0.0335), and expression of MMP2 (0.0081), were observed, although S100A10 expression was not an independent predictor of a poorer survival in the multivariable analysis (HR 1.7334, 95%CI 0.4340-11.523, p=0.4647). In the same way, 33 (27.5%) of 120 SCCs showed S100A10-positive staining and correlation with poorer prognosis (p=0.0094), p-TNM stage (p=0.0119), nodal involvement (p=0.0006), lymphatic invasion (p=0.0005), and tumor size (p=0.0003) were observed. As for lung SCCs, S100A10 expression was an independent predictor of a poorer survival in the multivariable analysis (HR 9.5916, 95%CI 1.0702-128.208, p=0.0434). Then we performed knockdown of *S100A10* in lung cancer cell lines and found that knockdown of *S100A10* suppressed cell proliferation in adenocarcinomas and SCCs, and invasion in adenocarcinomas.

	sample	5year survival rate
S100A10 −	57	87.19%
S100A10 +	10	55.56%
total	67	82.29%

Conclusion: In this study, we found that S100A10 expression associates with poorer survival in lung SCCs, but not in lung adenocarcinoma. Our present results suggest that S100A10 protein plays an important role in proliferation of lung cancer, possibly in association with invasion by MMPs. Future studies are necessary to further understanding of importance of S100A10 in progression of human lung cancer, including some differences between histological subtypes.

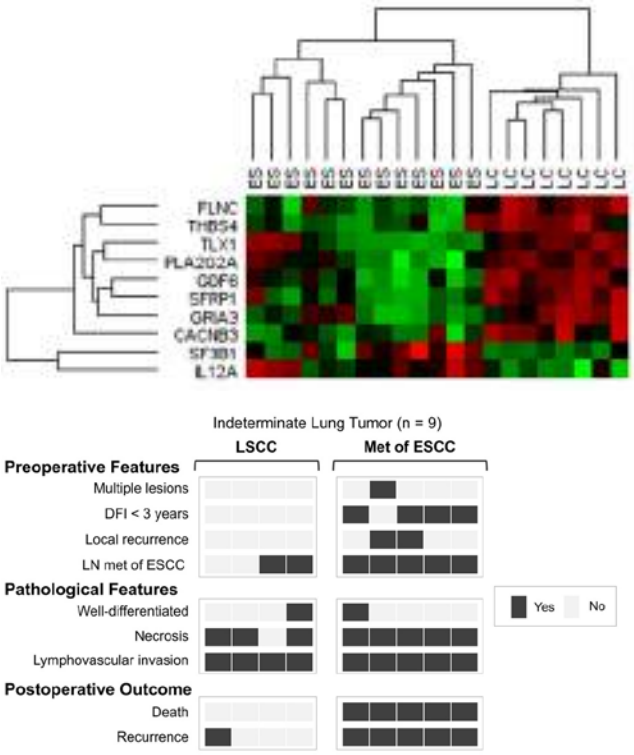
Keywords: lung squamous cell carcinoma, S100A10, MMP

MA18.03 DISTINCTION BETWEEN PRIMARY LUNG CANCER AND PULMONARY METASTASIS OF ESOPHAGEAL CANCER USING THE NANOSTRING NCOUNTER SYSTEM

J. Ichinose[1], H. Ninomiya[2], H. Nagano[2], Y. Matsuura[1], M. Nakao[1], S. Okumura[1], M. Mun[1]

[1]*Cancer Institute Hospital, JFCR, Tokyo/Japan,* [2]*The Cancer Institute, JFCR, Tokyo/Japan*

Background: It is very difficult to distinguish between primary lung squamous cell carcinoma (LSCC) and pulmonary metastasis of esophageal squamous cell carcinoma (ESCC) in patients with past history of ESCC, even by histological examination of the resected specimen. This study aimed to distinguish between LSCC and metastasis of ESCC by multiplex gene expression analysis using the Nanostring nCounter analysis system. **Method:** RNA was extracted from the FFPE samples of eight LSCCs, thirteen ESCCs, and nine indeterminate SCCs in the lung of patients with history of ESCC. We selected ten genes which were differently expressed markedly between LSCC and ESCC using the nCounter PanCancer Pathways Panel (XT-CSO-PATH1-12). We performed linear discriminant analysis between the two groups. The derived discriminant function was applied to the nine indeterminate SCCs. The nCounter diagnosis was compared to the preoperative features, pathological findings and postoperative prognosis. **Result:** Four of nine pulmonary tumors were diagnosed as LSCC and five were diagnosed as metastasis of ESCC. None of four patients with LSCC died and one developed recurrence, while all of five patients with metastasis of ESCC died and all developed recurrence. The prognosis of the latter was significantly poorer than the former (logrank test, p = 0.02). The preoperative features which indicate metastasis of ESCC (multiple lesions, short disease-free interval and presence of local recurrence) were found only in the metastasis group.



Conclusion: Multiplex gene expression analysis using the nCounter was useful for discrimination between LSCC and pulmonary metastasis of ESCC.

Keywords: Lung cancer, nCounter, esophageal cancer

MA18.05 DIAGNOSTIC DIFFERENCE BETWEEN NEUROENDOCRINE MARKERS IN PULMONARY CANCERS: A COMPREHENSIVE STUDY AND REVIEW OF THE LITERATURE

H. Brunnström[1,2], J. Staaf[2], L. Tran[1], L. Söderlund[1], B. Nodin[2], K. Jirström[1,2], H. Vidarsdottir[3], M. Planck[2,4], J. Mattsson[5], J. Botling[5], P. Micke[5]

[1]*Laboratory Medicine Region Skåne, Lund/Sweden,* [2]*Division of Oncology and Pathology, Lund/Sweden,* [3]*Helsingborg Hospital, Helsingborg/Sweden,* [4]*Skåne University Hospital, Lund/Sweden,* [5]*Uppsala University, Uppsala/Sweden*

Background: The diagnostic distinction of pulmonary neuroendocrine (NE) tumors from non-small cell carcinomas (NSCC) is of high clinical relevance for prognosis and treatment. Diagnosis is based on morphology and immunohistochemical staining. The current WHO classification of lung tumors emphasizes synaptophysin and chromogranin A but also recommends CD56 as NE markers. The aim of the present study was to determine the diagnostic value of the insulinoma-associated protein 1 (INSM1) gene, in comparison with the established neuroendocrine markers, in pulmonary tumors. **Method:** Tissue microarrays with tumor tissue from 54 resected pulmonary NE tumors and 632 NSCC were stained for INSM1, CD56, chromogranin A and synaptophysin. In a subset, gene expression data was available for analysis. Also, 419 metastases to the lungs were stained for INSM1. A literature search identified 37 additional studies with data on NE markers in lung cancers from the last 15 years, whereof six with data on INSM1. **Result:** Depending on cut-off level (1%+ or 10%+ positive tumor cells), the sensitivity and specificity for INSM1 to separate NE tumors from NSCC were 72-91% and 98-99%, respectively. In comparison, the sensitivity and specificity for CD56 were 85-89% and 96-98%, for chromogranin A 56-67% and 98-99%, and for synaptophysin 85-93% and 86-92%, respectively. Analysis of literature data revealed that CD56 and INSM1 were the best markers for identification of high-grade NE pulmonary tumors when considering both sensitivity and specificity (see table). *INSM1* gene expression was clearly associated with NE histology.

NE marker / Type of lung cancer	CD56	Chromogranin A	INSM1	Synaptophysin
Carcinoid tumor	365/403=**91%** (83%-100%)	396/407=**97%** (93%-100%)	204/205=**99%** (98%-100%)	366/375=**98%** (94%-100%)
Large cell neuroendocrine ca.	311/362=**86%** (61%-94%)	211/363=**58%** (46%-85%)	53/70=**76%** (61%-91%)	254/363=**70%** (55%-88%)
Small cell carcinoma	511/568=**90%** (63%-100%)	243/489=**50%** (4%-83%)	295/327=**90%** (75%-100%)	375/488=**77%** (52%-100%)
NSCC (any type)	283/3664=**8%** (0%-28%)	324/4040=**8%** (0%-66%)	16/1030=**2%** (0%-4%)	497/4219=**12%** (0%-69%)
Adenocarcinoma	86/1657=**5%** (0%-22%)	41/1637=**3%** (0%-41%)	11/665=**2%** (0%-3%)	227/1698=**13%** (0%-72%)
Squamous cell carcinoma	133/1450=**9%** (0%-18%)	59/1529=**4%** (0%-26%)	5/365=**1%** (0%-4%)	86/1647=**5%** (0%-43%)

Number of evaluated and frequency of positive cases and frequency in different studies (x%-y%)

Conclusion: The solid data of our investigation and previous studies confirm the diagnostic value of INSM1 as a NE marker in pulmonary pathology. The combination of CD56 with INSM1 or synaptophysin should be the first-hand choice to confirm high-grade NE pulmonary tumors.

Keywords: Neuroendocrine markers, INSM1, Pathological diagnostics

MA18.06 GENE EXPRESSION AND CLUSTERING OF PULMONARY NEUROENDOCRINE TUMORS AT THE BORDER OF LOW/INTERMEDIATE AND HIGH GRADE MORPHOLOGY

O. Sazonova[1], V. Manem[2], M. Orain[2], P. Joubert[2]

[1]*University Laval, Quebec/Canada,* [2]*Quebec Heart and Lung Institute Research Center, Quebec/Canada*

Background: The WHO classification of lung tumors is based on several features such as cell morphology, cell size, growth patterns, mitotic rate and presence of necrosis. Pulmonary neuroendocrine tumors are stratified into two categories, namely, low/intermediate grade (pulmonary carcinoid tumors) and high grade (pulmonary neuroendocrine carcinomas). Mitotic rate assessment on H&E stained slides play a crucial role in morphological classification of pulmonary carcinoids and high grade neuroendocrine carcinomas. Neuroendocrine tumors with 0-10 mitoses/ 2 mm^2 are classified as carcinoids and those with mitotic rate higher than 10 mitoses/ 2 mm^2 as neuroendocrine carcinomas. However, rare tumors which lie on the border of the spectrum with mitotic rates exceeding 10 mitoses/ 2 mm^2 but falling far below the average mitotic rates of high grade neuroendocrine carcinomas may actually share more molecular characteristics with carcinoids than high grade neuroendocrine carcinomas. The objective of the project was to explore gene expression of those tumors and a potential utility of molecular features in their classification. The study was based on the next generation RNA-sequencing. **Method:** Five borderline tumors that exceeded the threshold of 10 mitoses/ 2 mm^2 in 3 hot-spot areas but remained on the lowest end of the spectrum of malignity for large cell neuroendocrine carcinomas (LCNECs) were selected from institutional archives. These tumors were defined by mitotic counts of 11 to 30 mitoses/ 2 mm^2. Besides, one case with higher mitotic rate in hot-spot zone (42 mitoses/ 2 mm^2) but lower than 30 mitoses/ 2 mm^2 in the other areas was included in a group of borderline tumors. Seven pulmonary carcinoids and 6 LCNECs were selected for control groups. Ki-67 proliferation index and expression of p53 and pRB proteins were assessed by immunohistochemistry. Next generation RNA-sequencing was performed on fresh frozen tissues from all 18 samples on Illumina platform. Then, unsupervised hierarchical clustering was used to stratify the cases. **Result:** Pulmonary carcinoids and LCNECs clustered into 2 different groups with no overlap. Borderline tumors presented as a heterogenous group where 3 tumors clustered with carcinoids and the other two with LCNECs. Tumors that clustered with LCNECs expressed higher mitotic rate and presented more prominent necrosis. One of 2 cases that clustered with LCNECs had abnormal p53 expression. There were no cases with pRB loss among borderline tumors. For comparison, p53 and pRB expression was preserved in all carcinoid tumors. A subset of tumors in LCNEC group had abnormal p53 expression (strong diffuse expression or complete loss) and pRB loss. **Conclusion:** Next generation RNA-sequencing coupled with hierarchical clustering analysis allowed to demonstrate that a subset of borderline tumors classified as LCNEC by the current morphology-based WHO classification shows gene expression that is more compatible with pulmonary carcinoids. The data add to the evidence that molecular classification would prove to be a useful tool in stratification of low/intermediate and high grade pulmonary neuroendocrine tumors. However, immunohistochemistry for p53 and pRB is not sufficient for differentiation between pulmonary carcinoid and LCNEC.

Keywords: neuroendocrine tumors, pulmonary carcinoid, next generation RNA-sequencing

MA18.07 IDENTIFICATION OF NEUROENDOCRINE TRANSFORMATION IN ANAPLASTIC LYMPHOMA KINASE REARRANGED (ALK+) TUMORS AFTER TYROSINE KINASE INHIBITORS

P. Pal, A. Fares, D. Patel, E. Stewart, N. Perera-Low, A. Grindley, F. Allison, N.-A. Pham, R. Shi, N. Leighl, F. Shepherd, P. Bradbury, A. Sacher, P. Rogalla, K. Yasufuku, M. Cabanero, M. Tsao, G. Liu, S. Martins-Filho, L. Nguyen

University Health Network, Toronto/Canada

Background: Acquired resistance after ALK tyrosine kinase inhibitors treatment has multiple known mechanisms: new mutations or gene amplifications, bypass signaling and rarely neuroendocrine histological transformation. Here we describe results of a program utilizing routine biopsy post-progression in ALK+ patients for clinical and research purposes. **Method:** Since 2014, ALK+ lung cancer patients treated at the Princess Margaret Cancer Centre have undergone routine biopsies at disease progression time points upon failure of an ALK-tyrosine kinase inhibitor (TKI) for both clinical purposes and research purposes, in particular to obtain tissue for primary derived xenograft (PDX) engraftment. **Result:** All 9/9 patients consented for research sampling during clinical biopsy procedures (median 2 extra cores/passes); 2 patients were biopsied more than once; 3 PDX models from 2 patients have engrafted; 3 additional models are too early to assess engraftment. Engraftment occurred in patients with clinically aggressive tumors and poor survival outcomes. In this process, we identified 2 patients with neuroendocrine transformation post-second generation ALK TKI: (a) a 59 yo Asian female, never smoker, diagnosed six years prior with metastatic disease, heavily pretreated with crizotinib (12 months), pemetrexed (16 months), ceritinib (25 months), alectinib (6 months) and brigatinib (3 months); post-alectinib biopsy showed no transformation, while post-brigatinib liver biopsy demonstrated transformation to large cell neuroendocrine carcinoma; (b) a 75 yo Caucasian female, never smoker, diagnosed eight months prior and started on alectinib with a partial response, progressed in a single site; endobronchial biopsy demonstrated high grade neuroendocrine transformation. Both biopsies were positive for neuroendocrine markers (chromogranin and synaptophysin), TTF-1 and diffusely co-expressed ALK on immunohistochemistry. Assessment of PDX engraftment of these models is ongoing. **Conclusion:** Routine combined clinical and research biopsy of ALK+ patients at time of TKI failure helped to identify these recent cases of neuroendocrine transformation as a possible mode of resistance and provide tissue for model development. This is the first time that ALK+ transformation to large cell neuroendocrine carcinoma is reported in the literature. (PP, AFF, SNMF, LN contributed equally).

MA18.09 PROTEIN PROFILING OF SMALL LUNG ADENOCARCINOMAS: AN IN-DEPTH ANALYSIS

T. Dai[1], J. Adachi[2], Y. Minami[3], T. Tomonaga[2], M. Noguchi[4]

[1]*Tsukuba Human Tissue Biobank Center, University of Tsukuba Hospital, Tsukuba/Japan,* [2]*Laboratory of Proteome Research, Laboratory of Proteomics for Drug Discovery, Center for Drug Design Research, National Institutes of Biomedical Innovation, Health and Nutrition, Osaka/Japan,* [3]*Pathology, National Hospital Organization Ibarakihigashi National Hospital, Tokaimura/Japan,* [4]*Department of Pathology, Faculty of Medicine, University of Tsukuba, Tsukuba/Japan*

Background: Among various cancers, lung cancer has one of the poorest prognoses, and adenocarcinoma is the most common histological subtype. Lung adenocarcinoma shows multistep progression from adenocarcinoma in situ (AIS) to invasive adenocarcinoma through minimally invasive adenocarcinoma (MIA). Recently, LC-MS/MS with multiple peptide labeling and a new fractionation method has made quantitative proteomic analysis feasible using small amounts of protein obtained by laser-microdissection. In this study, we performed quantitative protein profiling of AIS, MIA and early invasive lung adenocarcinoma and

selected proteins that showed statistically significant differences in expression among them. **Method:** Fresh tumor samples from five cases each of AIS, MIA and early invasive lung adenocarcinoma were collected by laser-microdissection, and proteins were extracted by the Phase Transfer Surfactant method. The samples were trypsinized, labeled with a TMT labeling kit, and fractioned with C18-SCX Stage Tip. Quantitative proteomic analysis was performed by LC-MS/MS (Q-Exactive plus) and analyzed with Proteome Discoverer software. **Result:** A total of 4278 proteins were identified. Among them, the expression of 12 proteins – EEF1A2, CRABP2, NDRG1, NOL3, SCIN, DHCR24, CEACAM5, HIBADH, AK4, PIP4K2C, ASRGL1 and IFITM3 – was two-fold or higher in invasive adenocarcinoma than in AIS, and the expression increased gradually from AIS to invasive adenocarcinoma through MIA. Among these proteins, NDRG1 and AK4 are known to be related to hypoxia, whereas NOL3 and DHCR24 reportedly have an anti-apoptosis function. **Conclusion:** Quantitative proteomic analysis of AIS, MIA and early invasive lung adenocarcinoma identified a total of 4278 proteins, 12 of which are thought to be associated with lung adenocarcinoma progression. These proteins may determine the grade of malignancy and could be potential targets for molecular therapy.

Keywords: lung adenocarcinoma, stepwise progression, proteomics

MA18.10 MULTICENTER STUDY OF INTRAOPERATIVE RAPID IHC FOR UNDIAGNOSED PULMONARY TUMOR USING NON-CONTACT ALTERNATING-CURRENT ELECTRIC-FIELD MIXING

K. Imai[1], S. Takashima[1], N. Kurihara[1], M. Atari[1], T. Matsuo[1], S. Watanabe[1], H. Iwai[1], H. Suzuki[1], Y. Minamiya[1], Y. Tanaka[2], Y. Maniwa[2]

[1]*Akita University Graduate School of Medicine, Akita/Japan,* [2]*Kobe University Graduate School of Medicine, Kobe/Japan*

Background: It is widely recognized that pathology is the most important factor for staging and selecting effective chemotherapy for patients with cancer. Immunohistochemistry (IHC) is a reliable screening method, but intra-operative diagnosis by frozen section with IHC is not possible because IHC takes approximately 6 hours. Our aim was to evaluate the clinical utility reliability and sensitivity of a novel intraoperative rapid-IHC by taking advantage of the non-contact mixing effect in microdroplets subjected to an alternating current (AC) electric field. **Method:** With the new device we have developed, we apply a high-voltage, low-frequency AC electric field to the sections. The antibody is mixed within the microdroplet as the voltage is switched on and off at specific intervals (Figure 1). The resultant coulomb force stirs the diluted solution on the sections, which increases the opportunity for contact. This rapid-IHC enables rapid detection of target cells in frozen sections and can provide a surgeon with an intraoperative diagnosis within 20 min. We will recruit total 150 patients with undiagnosed pulmonary tumor until December 2022.

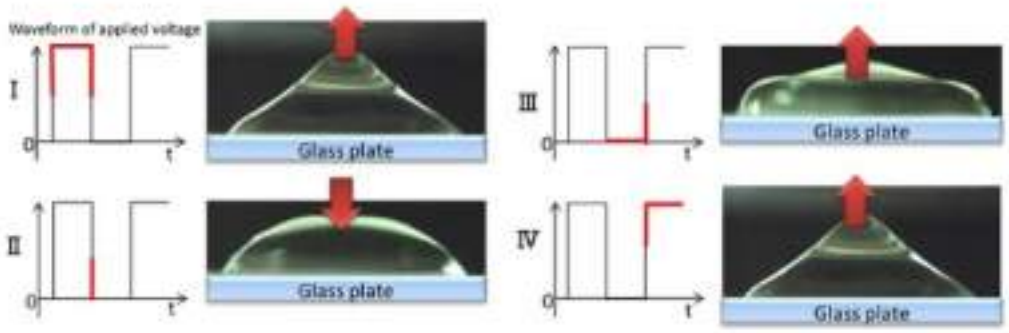

Figure 1.
Schema of the changes in the microdroplet as the voltage is switched on and off.
The antibodies are mixed within the microdroplet as the voltage is switched on and off in a time series (I→II→III→IV). The resultant coulomb force stirs the probe solution on the sections, and the opportunity for contact between the antibody and antigen is increased because as the voltage is turned on and off at regular intervals, the microdroplet's shape is transformed.

Result: We enrolled 60 patients for now (the achievement rate is 40.0%). The rate of agreement between rapid-IHC and final pathological diagnosis was 95%. In contrast, the rate of agreement between conventional H&E stain and final pathological diagnosis was 83.3%. When diagnosing pulmonary tumor intraoperatively based on rapid-IHC, we achieved a higher performance level than was achieved using H&E stain alone. **Conclusion:** We have shown that the rapid-IHC can be used as a clinical tool for prompt diagnosis in pulmonary tumor samples. Our method will help pathologists and surgeons when diagnosing intraoperatively.

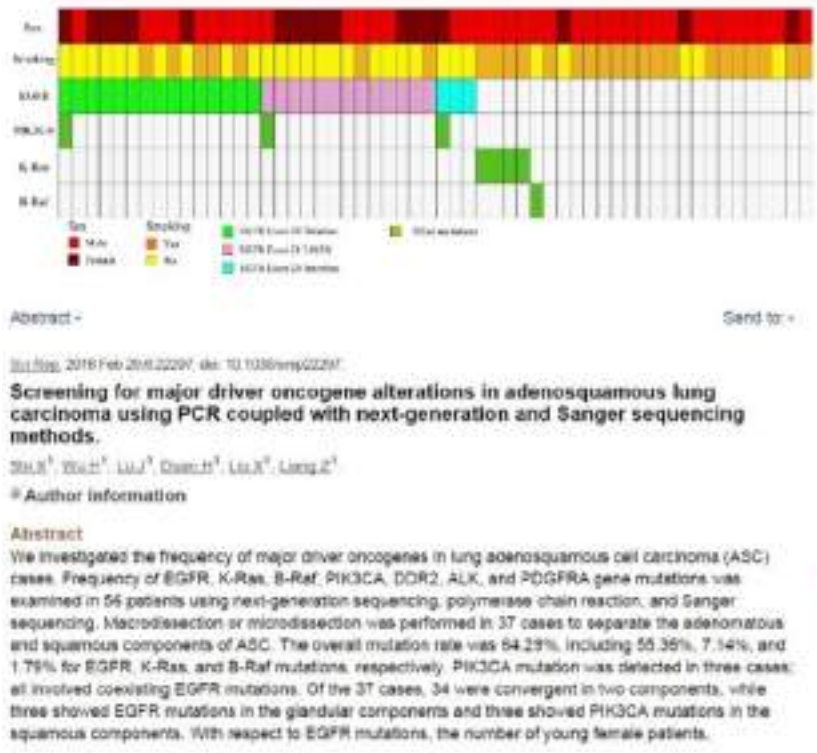
MA18.11 SNAI2 IS THE MOST HIGHLY DIFFERENTIAL EXPRESSED GENES BETWEEN THE ADENOMATOUS AND SQUAMOUS COMPONENTS OF LUNG ADENOSQUAMOUS CELL CARCINOMA

X. Shi, T. Feng, S. Wu, Y. Liu, X. Zeng, Z. Liang

Peking Union Medical College Hospital, Beijing/China

Background: Lung adenosquamous cell carcinoma is a hybrid tumor with adenomatous and squamous components in one tumor, it has the worst prognosis among the non small cell lung cancer. Our previous work has prooved that lung adenosquamous cell carcinoma has a similar EGFR mutation rate as lung adenocarcinoma which is 51.79% in 56 patients. Further squencing results showed that the majority of adnematous and squamous components had identical mutation type (34/37). EGFR mutated adenosquamous cell carcinoma patients are prone to be young, female and non-smokers, which are similar with the clinical charateristics of lung adenocarcinoma. Besides the corcodant mutation profile between the two different components of lung adenosquamous cell carcinoma, if there are any differentail expressed genes remained mysterious. our study will addressed this question.



Abstract ▾ Send to ▾

Screening for major driver oncogene alterations in adenosquamous lung carcinoma using PCR coupled with next-generation and Sanger sequencing methods.

Author information

Abstract

We investigated the frequency of major driver oncogenes in lung adenosquamous cell carcinoma (ASC) cases. Frequency of EGFR, K-Ras, B-Raf, PIK3CA, DDR2, ALK, and PDGFRA gene mutations was examined in 56 patients using next-generation sequencing, polymerase chain reaction, and Sanger sequencing. Macrodissection or microdissection was performed in 37 cases to separate the adenomatous and squamous components of ASC. The overall mutation rate was 64.29%, including 55.36%, 7.14%, and 1.79% for EGFR, K-Ras, and B-Raf mutations, respectively. PIK3CA mutation was detected in three cases; all involved coexisting EGFR mutations. Of the 37 cases, 34 were convergent in two components, while three showed EGFR mutations in the glandular components and three showed PIK3CA mutations in the squamous components. With respect to EGFR mutations, the number of young female patients.

Method: NanoString nCounter technology was employed in our study. it has been increasingly used for mRNA or miRNA differential expression studies because of its advantages of feasibility in formalin fixed paraffin embedded samples. We compared the differential expressed gene profiles between the paired matched adenomatous and squamous components in 24 adenosquamous cancer tissues. **Result:** SNAI2 is found to be the most differential expressed genes between the two components in lung adenosquamous cell carcinoma. It is higher expressed in squamous component compared with the adenomatous component. SNAI2 is a member of epithelial to mesenchymal transition signalling pathway. Other research results showed that SNAI2 played a pivotal role in controlling the epithelial and mesenchymal transdifferentiation, stem cell property of cancer cell, and the metastasis ability. **Conclusion:** Our preliminary results showed that SNAI2 which is a member of EMT signalling pathway is highly expressed in the squamous component compared with the adenomatous component of lung ASC. It may contribute to the phenotype transdifferentiated and invasion of lung ASC

MA19.01 EMPIRICAL IDENTIFICATION OF DISTRESS CLUSTERS IN LUNG CANCER PATIENTS

T. Lillis[1], M.E. Hand[1], M. Pasquinelli[2], Z. Deliu[2], C. Weldon[3], J. Trosman[3], L. Feldman[2], M. Huber[2]

[1]*Rush University Cancer Center, Chicago/United States of America,* [2]*University of Illinois Hospital & Health Sciences System, Chicago/United States of America,* [3]*Northwestern University, Chicago/United States of America*

Background: Screening for distress from the time of diagnosis is emerging as standard cancer care. Although there is heterogeneity in patients' experience of distress, identification of subgroups of patients with unique distress profiles may inform interventions for distressed patients. Accordingly, we aimed to identify unique subgroups of patients based on their distress screening responses from a large sample of newly diagnosed lung cancer patients across two urban academic medical centers in Chicago, IL. **Method:** Lung cancer patients (N=596) were screened for distress at their diagnostic visit between (2/22/16 – 8/14/18) with the Coleman Foundation "Patient Screening Questions for Supportive Care" tool; a 34-item screener that identifies patient needs across psychological, physical, family/caregiver, and treatment and care concerns. A Two-Step cluster analysis was conducted to identify natural clusters of patients based on similar responses to distress screening items. **Result:** Cluster analysis results revealed a two-cluster outcome: "High Distress" (N=332) and "Low Distress" (N=264). The items that best distinguished High Distress patients from Low Distress patients were concerns about cancer stage/diagnosis, concerns about prognosis/long-term outcome, concerns about treatment options, and having higher average number of total concerns. Cancer stage at screening was not predictive of cluster membership. Demographic characteristics, descriptive statistics, and group difference tests for survey items by cluster and for the total sample are presented in Table 1. **Conclusion:** More than half of lung cancer patients were grouped as experiencing high distress on screening. While cancer stage was not predictive of high distress grouping, concerns about stage, treatment, and prognosis were most predictive of high distress cluster membership. An intervention to improve communication between providers and patients about these concerns may reduce distress. Table 1

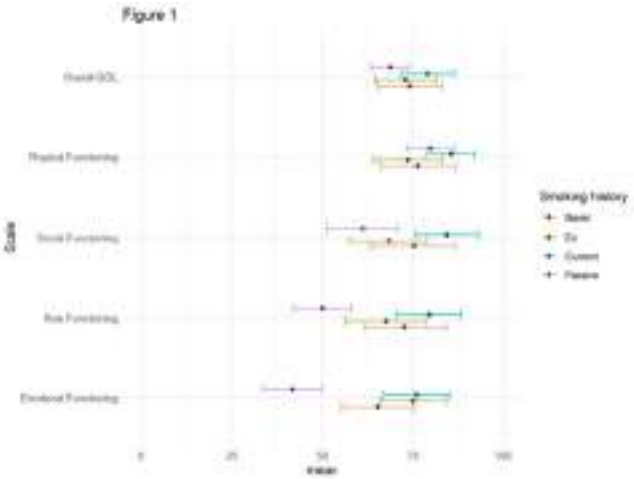
MA19.02 PSYCHOLOGICAL DISTRESS IN NEVER, EX, CURRENT, AND PASSIVE SMOKERS DIAGNOSED WITH LUNG CANCER - ANALYSES FROM THE ENRICH PROGRAM

B. Brown[1], J. Simes[1], M. Boyer[2], P. Hogg[1], A. Joshua[3], J. Young[1], C. Brown[1]

[1]*University of Sydney, Camperdown/Australia,* [2]*Chris O'Brien Lifehouse, Camperdown/Australia,* [3]*The Kinghorn Cancer Centre, Darlinghurst/Australia*

Background: Lung cancer is associated with greater psychological distress than any other cancer. In Australia, the prevalence of anxiety and depression in those with lung cancer is nearly 30% higher than the average of other major cancers. More than 50% of patients experience distress, anxiety and/or depression, resulting in diminished quality of life (QoL), and a fourfold increase in likelihood of suicide than the general population. Lung cancer stigma, arising from presumption about tobacco exposure and associated smoking stigma, contributes to high levels of distress. A national survey found that more than a third (35%) of Australians believe those living with lung cancer "have only themselves to blame" and almost 40% indicated, before expressing concern, the first question they would ask someone diagnosed with lung cancer is whether they smoked. This stigma makes lung cancer patients reluctant to seek psychosocial support and reduces their sense of entitlement to care and empathy. However, approximately one fifth (21%) are life-long never-smokers. This study aimed to describe differences in levels of psychological distress in never-and ever-smokers enrolled in the Sydney Catalyst EnRICH Program, a prospective clinical cohort of patients with lung cancer in New South Wales, Australia. **Method:** Measures: EnRICH incorporates patient-reported outcome measures (PROMs) that assess dimensions of anxiety, depression, emotional function, and psychological distress, namely, the: (i) EORTC QLQ-C30; and (ii) NCCN Distress Thermometer. Sample: All patients with newly diagnosed lung cancer presenting to study hospitals are eligible for the EnRICH cohort. Consenting patients who completed PROMs comprise the sample for the current analyses. Statistical Methods: Subscales of the QLQ-C30 reflecting overall QoL and emotional function, and scores on the NCCN Distress Thermometer, were compared between patient groups by smoking status. Groups were combined into never-smokers (never, passive) and ever-smokers (ex, current) for analyses. Mean differences and 95% confidence intervals were computed. **Result:** Among 205 patients who completed PROMs (69% of consenting patients), there were 52 never-smokers, 5 passive-smokers, 161 ex-smokers and 52 current-smokers at the time of diagnosis. Emotional function was worse in never-smokers (ever=75.3, never=63.2, difference=12.1 points 95%CI 2.4-21.7). There were no differences in other subscales. Although numbers are small, passive-smokers had the lowest mean scores for emotional-, role-, and social-functioning (Figure 1). Distress thermometer scores were 1.2 points worse in never-smokers [95%CI (0.56-1.8)].



Conclusion: Never-smokers had worse emotional function and higher distress than other lung cancer patients. If confirmed in larger studies, additional supportive care services may improve outcomes for these patients.

MA19.03 DIFFERENCES IN SYMPTOM BURDEN BETWEEN RESPONSIVE AND PROGRESSIVE DISEASE IN ADVANCED NON-SMALL CELL LUNG CANCER (ANSCLC)

L. Williams[1], Q. Shi[1], B. El Ferjani[1], M. Hirschmann[1], D. Ponce[1], S. Dibaj[1], S. Chandwani[2], E. Roarty[1], W. Rinsurongkawong[1], J. Lewis[1], T. Burke[2], C. Cleeland[1], J. Lee[1], J. Roth[1], S. Swisher[1], J. Heymach[1], J. Zhang[1], G. Simon[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Merck & Co., Kenilworth, NJ/United States of America*

Background: We have established a real-world Advanced Non-Small Cell Lung Holistic Registry (ANCHoR) to assess how immunotherapy impacts treatment choice, clinical outcomes, and patient-reported outcomes (PROs) of aNSCLC. Our aim in this analysis was to assess the ability of the MDASI-LC to differentiate between patients who are responding or who are progressing during treatment. **Method:** Between May 2017 and December 2018, patients with aNSCLC at a single institution were enrolled in ANCHoR and completed the MDASI-LC prior to therapy (PTT) and at routine clinic visits. The MDASI-LC consists of 16 symptom severity and 6 interference items rated on 0-10 scales (0 = no symptom or interference, 10 = worst imaginable symptom or complete interference). MDASI-LC scores from PTT to first recorded response determination (FRD) were compared by response group using linear mixed modeling (LMM). **Result:** One hundred one patients completed the MDASI-LC PTT and at FRD. Mean patient age was 63.8 years (standard deviation = 10.29) and 55% were males. Fifty percent of patients received chemotherapy (CTX), 22% immunotherapy (IM), 19% CTX+IM or angiogenesis inhibitor, and 9% targeted therapy. Median time from PTT to FRD was 105 days (lower quartile = 63, upper quartile = 224). Forty-six percent of patients had a complete or partial response (RECIST criteria CR, PR), 14% had stable disease (RECIST SD), and 41% progressed (RECIST PD). LMM showed progressing patients had significantly more fatigue (estimated effect [est] =1.39; p = 0.031), sleep disturbance (est=1.37; p = 0.046), and drowsiness (est=1.33; p = 0.037) and reported significantly more interference with work (est=1.67; p = 0.016) over time than responding patients. **Conclusion:** The MDASI-LC differentiated the symptom burden of patients with responding disease from that of patients with progressive disease. Patients with progressive disease had more fatigue, disturbed sleep, drowsiness, and greater interference with work than those with responsive disease. Further research is needed to determine if the MDASI-LC can predict response to therapy in patients and may be useful in delineating treatment benefit.

MA19.05 IMPROVING LUNG CANCER OUTCOMES AND QUALITY IN THE US COMMUNITY SETTING WITH THE CREATION OF LUNG CANCER CENTERS OF EXCELLENCE PROGRAM

L. Raez[1], R. Osarogiagbon[2], L. Fine[3]

[1]*Memorial Cancer Insitute/Florida International University, Pembroke Pines/United States of America,* [2]*Baptist Cancer Center, Memphis/United States of America,* [3]*GO2 Foundation, San Carlos/United States of America*

Background: The Addario Lung Cancer Foundation community hospital Centers of Excellence (COE) Program encourages community cancer centers in the US to implement 'best practices' across the lung cancer care continuum, including provision of coordinated, multidisciplinary care. By comparing performance metrics within and outside the network of COEs, the program seeks to ensure that lung cancer patients (pts) receive the highest quality of care in their local area whilst also enabling COE hospitals to gain insights that facilitate the rapid implementation of quality improvement cycles. **Method:** The Impact Study was launched to conduct a comprehensive comparative analysis of COE member and non-member institutions across numerous quantitative and qualitative metrics from within the lung cancer care continuum. The 2018 analysis included 17 COE sites and 19 non-COE community hospitals representing approximately 5,000 pts in each cohort. The COE Impact study captured pts' demographic and clinical information as well as performance metrics from early stage screening through late stage diagnosis and all aspects of pts' care. Result:

Variable	COE	Non-COE	P value
# Cancer centers/hospitals	17	19	
Answers collected by nurse navigator	41%	100%	<0.001
Average # of hospital beds	565	342	0.104
Average # of lung cancer pts/institution	497	470	0.968
Lung cancer screening program	94%	42%	0.001
Endoscopic Bronchoscopy Ultrasound (EBUS)	23%	16%	0.323
Screening of pts for clinical trials	81%	35%	<0.001
Race: Caucasians	81%	37%	<0.001
Pathologist in tumor boards	100%	67%	0.012
ER visits the first 4 months of therapy	14%	32%	0.022
Molecular testing of pts with metastatic disease	81%	48%	0.001
Next generation sequencing	58%	22%	0.009

Conclusion: Improved structure and processes of care delivery at COE hospitals may translate into improved quality of care, outcomes, and patient experiences. The Lung Cancer COE program, now including 38 community cancer centers encompassing 12,000 lung cancer patients, plans to conduct this study annually with prospective, longitudinal data collection for future trend analyses as a means of facilitating continuous quality improvement in community-level lung cancer care.

MA19.06 SUCCESSFUL DEVELOPMENT OF REALTIME AUTOMATICALLY UPDATED DATA WAREHOUSE IN HEALTH CARE (ROOT-S)

H.A. Jung, S. Hong, J. Park, M.R. Park, J.-M. Sun, S.-H. Lee, J.S. Ahn, M.-J. Ahn, K. Park

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: Clinical information is often not recorded in an organized way, and converting it to a structured format can be a time-consuming task that may not successfully capture all facets of the information. Clinical Data Warehouse is a real time database that consolidates data from a variety of clinical sources to present a unified view. However, the clinical data extracted from the CDW have not only structured data (SD) but also natural language (NP) generated during clinical practice, and there is a limitation that it is difficult to apply to clinical trials because it is not structured and formatted to find key-point contents. This study aims at developing a systematic and comprehensive cohort through an automatic real-time update system called CDW. **Method:** The aim of this study was to evaluate clinical data of non-small cell lung cancer, small cell lung cancer, head and neck cancer, thymic cancer, and mesothelioma. In this study, we developed a unique algorithm that is optimized for each disease category using comprehensive natural language processing (NLP) systems and structured information from unstructured free text and structured data capture (SDC). We developed an algorithm using clinical information of patients diagnosed and treated during the past 10 years and designated validation sets of patients diagnosed and treated in 2018 for validation that these algorithms work automatically. **Result:** We collected clinical data of 23,735 NSCLC patients, 2,077 SCLC patients, 5,032 head and neck cancer patients, 3,948 esophageal cancer patients, 747 thymic cancer patients and 138 mesothelioma patients diagnosed at Samsung Medical Center. We could demonstrate using the validation set that the program accurately extracts the data needed for the cohort of each cancer.

The program is updated automatically every 24 hours, the source of each data is indicated separately, and the data that need to be integrated is transformed and systematically organized. The biggest advantage is that the scattered information is systematically integrated and automatically buildup to match the patient's cohort, so you can capture most updated survival or test results or treatment outcomes almost in real time. Data on the development of this program will be presented. **Conclusion:** This study is the first study that successfully developed and validated real-time updated cohort using CDW. This study suggests a blueprint for constructing a big data -based cohort for clinical research and is expected to be a landmark trial. The detailed analysis of each cancer through the development of the program will be presented.

MA19.07 TESTING AN OPTIMAL CARE COORDINATION MODEL (OCCM) FOR LUNG CANCER IN A MULTI-SITE STUDY

M. Smeltzer[1], T. Asfeldt[2], N. Faris[3], A. Kramar[4], C. Amorosi[5], V. Nolan[1], M. Ray[1], M. Dawkins[4], M.C. Nalan[1], W. Stevens[3], L. Lucas[4], R. Oyer[6], C. Lathan[7], R. Osarogiagbon[3]

[1]*University of Memphis, Memphis/United States of America,* [2]*Sanford USD Medical Center, Sioux Falls/United States of America,* [3]*Baptist Cancer Center, Memphis/United States of America,* [4]*Association of Community Cancer Centers, Rockville/United States of America,* [5]*Health Quality Solutions, Washington/United States of America,* [6]*Lancaster General Hospital, Lancaster/United States of America,* [7]*Harvard Medical School, Boston/United States of America*

Background: Medicaid-insured lung cancer patients have worse outcomes than others. To address barriers to optimal care in the US Medicaid population, the Association of Community Cancer Centers (ACCC) created and tested the OCCM. **Method:** The OCCM included 13 assessment areas: Patient Access to Care, Prospective Multidisciplinary Case Planning, Financial/Transportation/Housing, Care Coordination, Electronic Health Records, Survivorship Care, Supportive Care, Tobacco Cessation, and Clinical Trials. Each area had 5 defined levels of quality care delivery. With support from the Bristol-Myers Squibb Foundation, we pilot tested the model in 7 US cancer centers. Sites selected 1-2 assessment areas to evaluate using OCCM, developing relevant data benchmarks. Sites enrolled patients on Medicaid and Non-Medicaid controls. The ACCC team worked with each site to develop quality improvement projects with bi-weekly conference calls and 2 on-site visits. Data were collected and analyzed at a centralized data coordinating center. Statistical analyses were performed with Kruskal Wallis and chi-squared tests. **Result:** Seven sites spanning 3,081 miles evaluated 10 of the 13 OCCM areas. Total enrollment was 927 patients (257 Medicaid/ 670 Non-Medicaid). The Medicaid population had an average age of 62 years, ranging from 58-68 across sites. The clinical stage distribution was 40% stage I/II and 60% stage III/IV. Medicaid patients were 47% adenocarcinoma histology, 29% squamous cell, 14% small cell, and 10% other. Sites differed by patient age (p=0.0041), race (p<0.0001), and smoking status (p=0.028). Three sites evaluated models for prospective multidisciplinary case planning for Medicaid patients including: bi-weekly tumor board (BTB), virtual tumor board (VTB), and multidisciplinary team huddle (MTH). VTB and MTH allowed for presentation of higher percentages of eligible patients (BTB: 23%, VTB: 100%, MTH: 100%, p<0.0001). BTB and MTH discussed all cases prospectively, while VTB achieved 80%. Median days from diagnosis to presentation were 18 (BTB), 14 (VTB), and 9 (MTH,

p=0.14). Two sites evaluated smoking cessation programs. One, using trained cessation counselors, had 62% (18/29) active smokers, of whom 56% (10/18) expressed readiness to quit. Another site, using the freedom from smoking initiative, had 50% (11/22) active smokers and 55% (6/11) readiness to quit. 83% of those who started the cessation program quit smoking. Patient access to care was evaluated with timeliness of care metrics at two sites: one found 13 days (median) from lesion discovery to diagnosis and 21 days from diagnosis to treatment in Medicaid patients, which did not differ from Non-Medicaid controls (p=0.96 and 0.38). 94% met the site goal of treatment initiation within 45 days. Another site found 16 days (median) from discovery to diagnosis and 27 days from diagnosis to treatment (did not differ from Non-Medicaid controls, p=0.68 and 0.83). **Conclusion:** Sites successfully used the OCCM to identify areas to improve and developed meaningful data benchmarks. The OCCM is a valuable tool for cancer centers to identify specific areas to target to improve lung cancer care delivery.

MA19.09 ASSESSING CLINICAL FRAILTY IN ADVANCED LUNG CANCER PATIENTS - AN OPPORTUNITY TO IMPROVE PATIENT OUTCOMES?

F. Gomes, K. Baker, J. Woods, J. Bruce, M. Eaton, P. Higham, L. Cove-Smith, A. Garbett, A. Cree, C. Ng, F. Blackhall, N. Bayman

The Christie NHS FT, Manchester/United Kingdom

Background: The median age of non-small cell lung cancer (NSCLC) diagnosis in England is 73 years. At that age, 40% of the general population has some degree of clinical frailty which may impact survival, quality of life, anti-cancer treatment tolerability and access to clinical trials. However, clinical frailty is often not addressed or managed at the time of anti-cancer treatments. This project was designed to integrate frailty assessments and build frailty pathways within an advanced cancer care setting in order to better support patients and improve outcomes. **Method:** This quality improvement project that used Plan-Do-Study-Act (PDSA) methodology. Phase one of the project focused on establishing a multidisciplinary team to integrate a frailty screening tool, the Rockwood Clinical Frailty Scale (CFS), into standard clinical practice. The primary aim was to implement and screen ≥80% of all new lung cancer patients at a high-volume tertiary cancer centre. The secondary aim was to explore the correlation of CFS with age, performance status (PS), treatment selection and systemic anti-cancer treatment (SACT) tolerability. Specialised training was provided to the clinical team and the CFS was integrated from 26/11/2018 on an electronic form routinely completed by clinicians. A digital dashboard was set-up to monitor real-time data and the frail group was defined as CFS score >3. Data cut-off for this analysis was 29-03-2019. **Result:** 335 lung cancer patients were screened using CSF by a team of 20 clinicians with a compliance rate of 89%. There was a strong correlation between PS and CFS (r= 0.77, p<0.01). The distribution of both CFS and PS correlated with ageing (r= 0.2 and r= 0.17, respectively; p<0.01). Patients ≥70 years were more likely to be frail (56% vs 40%; OR 1.4, 95%CI 1.2-1.7; p<0.01). Frailty reduced the likelihood of receiving any anti-cancer treatment by 20%. Amongst those who started SACT, patients classed as frail were less likely to go beyond the first cycle of treatment (64% vs 91%; OR 0.7, 95%CI 0.5-0.9; p<0.01). **Conclusion:** CFS screening is feasible within a busy clinical practice when incorporated as a digital tool. CFS helps to identify patients who may potentially benefit from specialised frailty assessment and management. This could ultimately be used to better inform on treatment selection, and support requirements during treatment, to improve outcomes for patients in the future.

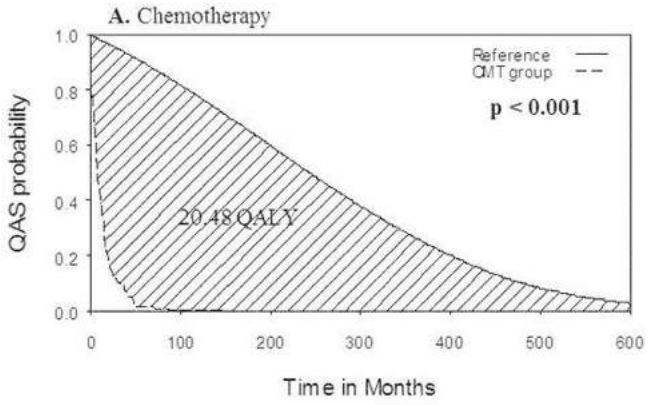
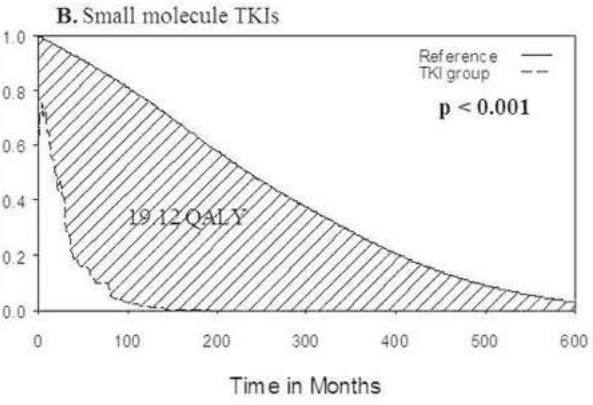
MA19.10 ESTIMATION OF QUALITY-ADJUSTED LIFE EXPECTANCY FOR STAGE AND SYSTEMIC TREATMENT IN NON-SMALL CELL LUNG CANCER IN RAJAVITHI HOSPITAL, THAILAND

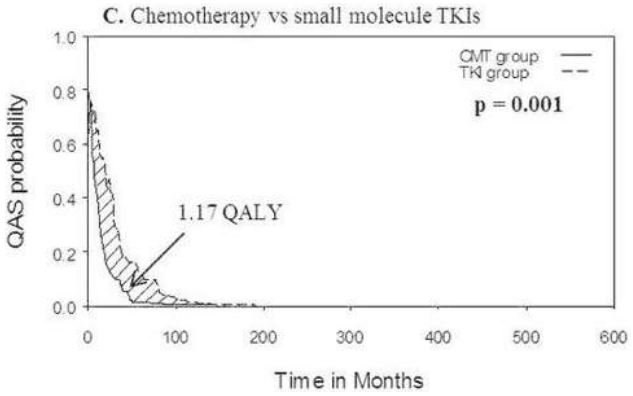
S. Sa-Nguansai[1,2], O. Kamnerdtong[2], K. Maneenil[1,2]

[1]*College of Medicine, Rangsit University, Bangkok/Thailand,* [2]*Rajavithi Hospital, Bangkok/Thailand*

Background: Owing to the high mortality and rapidly growing costs related to lung cancer, it is worth examining the health benefits of treatment in this cancer. This study attempts to quantify the real-life practice quality-adjusted life expectancy (QALE) of non-small cell lung cancer (NSCLC) patients with different stages and systemic treatments. **Method:** This cross-sectional study was conducted by reviewing and collected quality of life (QoL) data from 256 eligible all stages NSCLC patients treated at Rajavithi hospital from May 1st to October 31st, 2018. The iSQoL statistical package was used to evaluate QALE compared with the reference Thai population in different stage of disease. For advanced stage, QALE was compared among treatment groups (chemotherapy and Epidermal growth factor receptor tyrosine kinase inhibitors; EGFR TKIs) **Result:** The QALE for patients with early and advanced stage NSCLC were 4.49 ± 0.43 and 1.03 ± 0.08 QALY, with the corresponding loss-of-QALE were 14.02 ± 0.44 and 20.13 ± 0.09 QALY, respectively. The difference of QALE between early and advanced stage was 3.46 QALY (p<0.001). Based on systemic treatment in advanced stage, The QALE for patients who received chemotherapy and TKIs were 1.05 ± 0.08 and 2.19 ±0.28 QALY, with the corresponding loss-of-QALE were 20.48 ± 0.09 and 19.12 ± 0.29 QALY, respectively. The difference of QALE between treatment with chemotherapy and TKIs was 1.17 QALY (Figure, p=0.001).







Conclusion: The utility gained from treatment with TKIs in advanced NSCLC is substantial. Early stage had better QALE than advanced stage NSCLC patients.Future study will assess the cost-effectiveness of targeted therapy in Thailand.

MA19.11 POPULATION BASED ANALYSIS OF END OF LIFE TREATMENT PATTERNS IN THORACIC MALIGNANCIES

G. Pitson[1], L. Matheson[2], P. Eastman[1], M. Rogers[2]

[1]*Barwon Health, Geelong/Australia,* [2]*Barwon South West Integrated Cancer Service, Geelong/Australia*

Background: Active cancer treatment within the last month of life is unlikely to meaningfully benefit patients and ASCO guidelines recommend chemotherapy treatment rates be kept as low as possible. Patients with thoracic malignancies often have rapidly progressive disease and significant symptom burden and there is little population based data on patterns of care near end of life. **Method:** The Evaluation of Cancer Outcomes Registry records clinical information on all newly diagnosed cancer patients within a region of Victoria, Australia. Core diagnostic, demographic, treatment and outcome details were extracted for all patients diagnosed from 2009-2015 with death data through to end of 2016. Patients with thoracic malignancies were further analysed for treatment patterns at end of life. Details of palliative radiotherapy (pRT) and active systemic treatment (AST – intravenous chemotherapy, targeted therapy and/or immunotherapy) were recorded for all patients. Details on oral chemotherapy and stereotactic radiotherapy were not recorded. **Result:** The total cohort during the study period comprised 12760 patients. Of these, 1328 patients were recorded with a thoracic malignancy (TM) (non small cell lung cancer 82%, small cell lung cancer 10%, mesothelioma 7%) and 1118 of these died. At total of 39% (518) and 41% (538) of the 1328 TM patients received AST and pRT respectively at some point. Of these patients 15% (77/518) received AST and 23% (121/538) pRT within 30 days of death, compared with 7.0% (242/3436) (p<0.01) and 19% (178/965) (p=0.06) respectively for the total cohort excluding TM patients. Patients receiving AST within 30 days of death had a similar median age (66.7 vs. 67.8 years, p=NS) but shorter median survival from diagnosis (146 v. 281 days, p<0.01) than patients receiving final AST within 1-6 months. The frequency of some change in AST agents within the prior month was highest in the last month of life. The most common AST agents used in the final month of life were pemetrexed, etoposide and gemcitabine and most patients were treated with single agents. More pRT treatments were started in the last 30 days of life than in any other month near end of life. Patients receiving pRT in the last month of life also had a shorter median survival from diagnosis (113 v. 215 days, p<0.01) and the sites most commonly treated with pRT in the last month of life were chest/lung, spine and whole brain. **Conclusion:** Patients with thoracic malignancies have higher rates of AST treatment within the last 30 days of life than other patients with cancer in the same geographic region. Those treated within 30 days of death also have shorter median overall survival and higher frequencies of changing AST agents or starting pRT, possibly suggesting aggressive, symptomatic and poorly responding disease.

MA20.02 GAD1 EXPRESSION AND ITS METHYLATION BECOME INDICATORS OF MALIGNANT BEHAVIOR IN THYMIC EPITHELIAL TUMOR

S. Soejima, K. Kondo, M. Tsuboi, R. Kishibuchi, K. Muguruma, B. Tegshee, K. Kajiura, Y. Kawakami, N. Kawakita, M. Yoshida, H. Takizawa, A. Tangoku, N. Wusiman

Graduate School of Biomedical Sciences, Tokushima University, Tokushima/Japan

Background: Genome-wide screening for aberrantly methylated CpG islands was performed in 7 thymic carcinoma (TC) samples and 8 type-B3 thymoma samples using HumanMethylation450 K BeadChip (Illumina, Santa Clara, CA, USA) analysis. We identified 93 genes as commonly hypermethylated in TC comparing to type-B3 thymoma. *GAD1* (glutamic acid decarboxylase 1) was one of the most significant hypermethylated genes in TC. GAD1 catalyzes the production ofγ-aminobutyric acid (GABA). Some recent reports showed that GAD1 expression is significantly increased in neoplastic tissues. However, the underlying mechanism of elevated GAD1 remains elusive. In this study, we examine mRNA and protein expressions and DNA methylation of *GAD1* in thymic epithelial tumors (TETs). **Method:** In total, 95 thymic tumor samples (A; 9, AB; 11, B1; 19, B2; 21, B3; 14, carcinoma; 21) and 22 paired normal tissues were obtained from patients with histologically proven TET, who underwent surgery at the Tokushima University Hospital (Tokushima, Japan) between 1990 and 2016. The methylation status of thymic epithelial tumor samples was validated by pyrosequencing. The expression status was analyzed by quantitative polymerase chain reaction (qPCR) and immunohistochemistry (IHC). **Result:** The previous study (Oncogene 2015, 1–14) showed that the key locus responsible for GAD1 reactivation was mapped to DNA methylation-sensitive CTCF-binding site (CTCF-BS3) within the third intron of *GAD1*. We targeted this region for pyrosequencing, which confirmed that DNA methylation of *GAD1* in TC was significantly higher than in thymoma (32.8% versus 4.0%, P<0.001). It revealed a high degree of both sensitivity and specificity for discriminating TCs and thymomas (AUC=0.936). There was no significant difference in the methylation rate between thymoma and normal thymus (P = 0.917); however, the DNA methylation rate in TC was higher than in normal thymus (P=0.015). qPCR revealed that GAD1 mRNA expression levels in TC were higher than in thymoma (qPCR; 2.03 vs 0.38, P < 0.001). IHC showed statically different GAD1 expression between TC and thymoma (93.75% vs 28.98%, P < 0.001). There was a slight positive correlation between the mRNA expression levels and methylation levels (Spearman's rank correlation coefficient, ρ = 0.427); however, no differences of DNA methylation and expression of GAD1 was observed among subtype of thymoma according to WHO histologic classification. **Conclusion:** TC had frequent DNA methylation of CTCF-binding site 3 in *GAD1*, and high levels of mRNA and protein of GAD1. *GAD1* may resent an epigenetic therapeutic target in TC.

Keywords: Thymic carcinoma, GAD1, DNA methylation

MA20.03 DNA METHYLATION OF MT1A AND NPTX2 GENES PREDICT MALIGNANT BEHAVIOR OF THYMIC EPITHELIAL TUMORS

K. Muguruma[1], K. Kondo[1], R. Kishibuchi[1], M. Tsuboi[2], S. Soejima[1], B. Tegshee[1], K. Kajiura[1], Y. Kawakami[1], N. Kawakita[2], M. Yoshida[1], H. Takizawa[1], A. Tangoku[1]

[1]*Graduate School of Biomedical Sciences, Tokushima University, Tokushima/Japan,* [2]*Department of Thoracic, Endocrine Surgery and Oncology, Tokushima/Japan*

Background: Our previous studies showed that DNA methylation of cancer-related genes, such as *DAP-K*, *p-16*, *MGMT*, *HPP1* was higher in thymic carcinoma (TC) than in thymoma (Lung Cancer 64:155-, 2009, 83:279-,2013). Genome-wide screening for aberrantly methylated CpG islands was performed in 7 TC samples and 8 type-B3 thymoma samples using HumanMethylation 450 K BeadChip (Illumina, Santa Clara, CA, USA) analysis. We identified 93 genes as commonly hypermethylated in TC comparing to B3 thymoma.We chose 2 candidate cancer-related genes; *MT1A* and *NPTX2*. *MT1A* which is an isozyme of metallothioneins is related to metabolism of trace elements, such as zinc, copper. DNA methylation of *MT1A* was higher in malignant melanoma than in normal melanocytes. *NPTX2* has studied as synapse-related proteins. DNA methylation of *NPTX2* was higher in some cancers than in normal tissues. **Method:** In total, 48 thymic tumor samples (thymoma;31, carcinoma; 17) and 22 paired normal tissues were obtained from patients with histologically proven thymic epithelial tumor (TET), who underwent surgery at Tokushima University Hospital (Tokushima, Japan) between 1990 and 2016. The methylation status of TET samples was validated by pyrosequencing. The expression of mRNA in *MT1A* and *NPTX2* genes was validated by RT-PCR (SYBR® Green method). **Result:** DNA methylation of *MT1A* gene was significantly higher in TC compared to thymoma (26.4% versus 9.5%, *P*<0.01). It revealed high degrees of sensitivity and specificity for discriminating TCs and thymomas (AUC=0.903). Although DNA methylation was significantly higher in TC than in normal thymus, there was no significant difference between DNA methylation of thymoma and normal thymus. No differences of *MT1A* DNA methylation was observed among subtype of thymoma according to WHO histologic classification. In *MT1A* gene, there was no correlation has observed between DNA methylation and mRNA expression. On the other hand, *NPTX2* gene was also significantly higher in TC compared to thymoma (38.0% vs 17.5%, *P*<0.01). It revealed high degrees of sensitivity and specificity for discriminating TCs and thymomas (AUC=0.765). Although DNA methylation was significantly higher in TC than in normal thymus, there was no significant difference between DNA methylation of thymoma and normal thymus. No differences of *NPTX2* DNA methylation was observed among subtype of thymoma according to WHO histologic classification. There was no correlation has observed between DNA methylation and mRNA expression in all TETs, there was a reverse correlation in thymic carcinomas. The mean value of the frequency of the DNA methylation of was *MT1A* and *NPTX2* divided into higher and lower level groups. A significant difference was observed in the relapse-free survival between the higher and lower level groups (p=0.015, p=0.042). **Conclusion:** DNA methylation of *MT1A* and *NPTX2* was significantly higher in TC compared to thymoma and normal thymus. Epigenetic alteration may be related to progression and malignancy in TET. In *NPTX2* gene, there was a reverse correlation between DNA methylation and mRNA expression in thymic carcinomas. It may act as tumor suppressor gene.

MA20.05 FOLLOW-UP UPDATE OF 2 PHASE II STUDIES OF PEMBROLIZUMAB IN THYMIC CARCINOMA

G. Giaccone[1], J. Cho[2], C. Kim[1], M.-J. Ahn[2]

[1]*Georgetown University, Washington DC/United States of America,* [2]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of*

Background: Two phase II studies of pembrolizumab 200 mg every 3 weeks in advanced thymic carcinoma have recently been published (Giaccone et al. Lancet Oncol. 2018, study #1; Cho et al. JCO 2018, study #2). Both studies reported a response rate in about 20% of patients and a rate of autoimmune disorders that is higher than in other tumor types. **Method:** This report provides a follow-up update of these 2 studies, with particular emphasis on duration of response, and occurrence of autoimmune disorders. Both studies included patients with thymic carcinoma who had progressed after at least one line of chemotherapy. **Result:** In study #1 a total of 40 patients with advanced thymic carcinoma were treated, with a median follow up of 40.6 months. The response rate did not change (22.5%) compared to the original publication, however one patient who had developed myositis, myocarditis and myasthenia gravis (MG), continues to be in nearly complete response after only two cycles of pembrolizumab, 36 months from initiation of treatment. One patient who had developed myositis and hepatitis with unclear signs of MG developed overt MG symptoms several months after the interruption of therapy. No other new autoimmune disorders were observed (6/40 = 15%). Five patients completed 2 years of treatment according to protocol and 4 of them elected to continue treatment. Three patients who had been off therapy were rechallenged with pembrolizumab upon progression (one responded). Median duration of response was 38 months (from 22.4 in initial report), median PFS was 4.2 months (identical) and median survival was 25.8 months (24.9 in the initial report). At completion of this study, an amendment was introduced to add epacadostat 10 mg BID to pembrolizumab in the same patient population. Four patients were treated before the study was closed after the results of a randomized trial of the combination in melanoma failed to meet its primary endpoint. No patient responded (2 stable and 2 progressions). One patient developed grade 2 myocarditis. In study #2 a total of 26 patients with advanced thymic carcinoma were included, with a median follow up of 33.4 months. The response rate (19.2%) did not change, and no other autoimmune disorder appeared since the initial publication (5/26 = 19%). Median duration of response (9.7 months), median PFS (6.1 months) and median survival (14.5 months) did not change compared to the initial publication. No additional autoimmune disorders were documented compared to the original publication. A total of 5 patients received 2 years of pembrolizumab according to protocol; no patient continued beyond 2 years or was retreated upon progression with pembrolizumab. **Conclusion:** These two studies confirm definite activity of pembrolizumab in advanced thymic carcinoma. Recently pembrolizumab was included in the NCCN guidelines for thymic carcinoma. No additional autoimmune disorders were noted after discontinuation of pembrolizumab. There are significant differences in duration of response and overall survival in the 2 studies and potential factors are being investigated. In study #1 pembrolizumab was continued beyond 2 years in several patients and rechallenge was an available option.

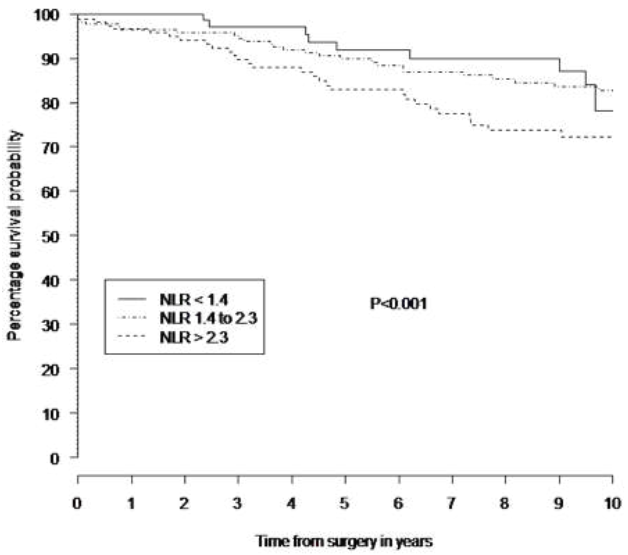
MA20.06 NEUTROPHIL TO LYMPHOCYTE RATIO IS AN INDEPENDENT PROGNOSTIC PREDICTOR IN THYMOMA

P. De Sousa[1], F. Gallina[2], A. Tamburrini[3], M. Nizami[1], C. Igwe[1], K. Amer[3], E. Lim[1], V. Ambrogi[2]

[1]*Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom,* [2]*Tor Vergata University Policlinic, Rome/Italy,* [3]*University Hospital Southampton NHS Foundation Trust, Southampton/United Kingdom*

Background: Thymoma is the most common primary neoplasm of the anterior mediastinum in adults and conventional prognostic factors include Masaoka Stage, WHO histology and completeness of resection. Little is known of preoperative peripheral neutrophil-to-lymphocyte ratio (NLR) as an independent additional discriminator of prognosis. **Method:** We performed an international multicentre retrospective cohort study (UK Health Research Reference 19/HRA/0440 and EU internal approval reference xxxxxx). We included patients who underwent complete resection for thymoma and data was acquired through patient medical records with follow up data obtained through national database and hospital records. NLR calculated on pre-operation bloods results. **Result:** From July 1987 to December 2017, 433 patients underwent surgery for thymoma. The majority were male 228(53%) with a mean age (SD) of 55(15) years. The surgical approach was sternotomy in 335 patients (77%), thoracotomy in 23(5%) and VATS in 75(17%). The WHO classification was type A 63(15%), AB 126(29%), B1 98(23%), B2 55(13%) and B3 86(20%) patients. The Masaoka-Koga stage was I in 135(33%) II in 194(47%), III in 54 (13%) and IV in 31(7%) patients. Median (IQR) follow-up time was 86 (30 to 152) months with a 5 and 10-year survival of 88% and 79% respectively. The median NLR was 2.1 (1.5 to 3.1), when split into three groups (NLR < 1.4, NLR between 1.4 and 2.3 and NLR > 2.3), higher NLR was associated with poorer survival (log rank P<0.001) that persisted on Cox regression after adjustment for WHO grade and Masaoka stage with a HR of 1.69 (95% CI 1.20 to 2.39; P=0.002).



Conclusion: Pre-operative NLR is a simple, low cost biomarker that can stratify risk of death independent to WHO grade and Masaoka stage in patients undergoing surgery for thymoma.

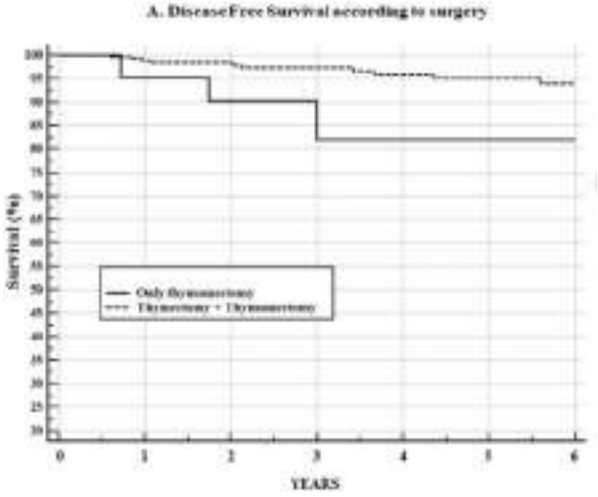
Background: Resection of thymic tumors has traditionally included removal of the tumor and the thymus gland (thymothymomectomy). Nevertheless, in recent years, some authors questioned the need to remove the thymus gland in non-MG thymomas, suggesting that resection of the tumor (simple-thymomectomy) is enough from an oncological point of view in Stage I (TNM stage classification) thymoma patients. The aim of our study was to compare short- and long-term outcome of thymothymomectomy vs. simple-thymomectomy using European Society of Thoracic Surgeons (ESTS) Thymic Database. **Method:** We investigated 1131 patients with thymic epithelial tumors included in the ESTS-Thymic Database. Three-hundred twenty-four clinical stage I (cT1N0M0, according to the 8th edition of the UICC/AJCC TNM stage classification) without Myasthenia Gravis (non-MG) thymoma cases were evaluated from 23 contributing centers (2000-2017), of which 300 (93%) thymothymomectomy and 24 (7%) simple-thymomectomy. Surgical upstaging was evaluated. In pathological stage I, we compared the completeness of resection, the rate of complications, the 30-day mortality, the overall survival and the disease-free survival (DFS).



Result: Overall, we observed an upstaging to stage III in 10 (3%) patients. We did not observe any significant difference between the two techniques in terms of the completeness of resection, the rate of complications and the 30-day mortality. The 5-year overall survival rate was 94% in the thymothymomectomy group and 56% in the simple-thymomectomy group (Figure 1 - P= 0.0004). The 5-year DFS was 95% in the thymothymomectomy group and 82% in the simple-thymomectomy group (Figure 1 -P= 0.013). **Conclusion:** Patients affected by stage I TNM non-MG thymoma submitted to thymothymomectomy presented a significantly better DFS and overall survival than those submitted to simple-thymomectomy. Thymothymomectomy should be considered the procedure of choice in Stage I TNM non-MG thymomas, also considering the not negligible rate of pathological upstaging.

MA20.09 BREAST IMPLANT ASSOCIATED ANAPLASTIC LARGE CELL LYMPHOMA: OUTCOMES OF A NEWLY-RECOGNIZED MALIGNANCY OF THE THORACIC WALL

M. Clemens, R. Miranda

MD Anderson Cancer Center, University of Texas, Houston/United States of America

Background: In 2016, the World Health Organization provisionally classified breast implant-associated anaplastic large cell lymphoma (BIA-ALCL) as a novel lymphoma and the National Comprehensive Cancer Network (NCCN) established evidence-based consensus guidelines for the diagnosis and surgical management of the disease. BIA-ALCL progresses locally as a solid tumor, invading the chest wall and mediastinum and leading to respiratory compromise in advanced cases. Local disease is treated surgically while aggressive disease involving regional lymph nodes and metastasis are currently managed with systemic chemotherapy, most commonly CHOP regimens (cyclophosphamide, vincristine, doxorubicin and prednisone). The goal of this study is to evaluate the efficacy of different therapies in the treatment of BIA-ALCL with chest wall invasion. **Method:** A prospective study of all institutional cases from 2013 to 2018 was performed for patients with advanced disease (Stage IIA-III) locally invasive into the chest wall. Pathologic findings, treatments, and outcomes were reviewed. **Result:** Eighteen consecutive patients were identified with BIA-ALCL Stage IIA-III. The median and mean follow-up times were 42 and 27 months, respectively (range, 6 to 226 months). Patients who underwent a complete en bloc resection had better OS (P = .022) and EFS (P = .014) than did patients who received partial resection, systemic chemotherapy, or radiation therapy. Perioperative complications included one pneumothorax. Two disease recurrences (7.8%) were noted at an average of 5 months from surgery. All patients eventually achieved complete remission (100%). The median overall survival (OS) time after diagnosis was 13 years, and the OS rate was 94% and 90% at 3 and 5 years, respectively. Patients presenting with chest wall invasion demonstrated significantly longer time from diagnosis to definitive surgery (21 versus 8 months, P = 0.039). Partial tumor resection resulted in disease hyperprogression in two cases. **Conclusion:** BIA-ALCL with chest wall invasion may be a consequence of a delay in diagnosis or treatment. Complete en bloc surgical excision is essential for curative treatment of BIA-ALCL. Patients who receive textured surface breast implants need to be advised of the risk of developing BIA-ALCL, as well as the common presenting symptoms, such as a mass or delayed onset (>1 year) of effusion. When treated appropriately and in a timely fashion, BIA-ALCL has an excellent prognosis. Future research is warranted to determine modifiable risk factors and stratification of at-risk populations.

MA20.10 LONG-TERM PROGNOSTIC FACTORS AFTER MINIMALLY INVASIVE ESOPHAGECTOMY (MIE) FOR ESOPHAGEAL CANCER

Y.-H. Huang, P.-W. Yang, K.-C. Chen, P.-M. Huang, J.-M. Lee

National Taiwan University Hospital, Taipei City/Taiwan

Background: MIE has been demonstrated to associate a better peri-operative outcome to treat esophageal cancer as compared to that done by open surgery. However, the long-term clinical impact of MIE and its prognostic factors still requires further clarification. **Method:** In current study, we evaluated the survival results and the factors influencing the prognosis of patients with esophageal cancer who received total minimally invasive esophagectomy using thoracoscopic and laparoscopic esophagectomy and esophageal reconstruction. **Result:** A total of 483 patients were included in the study with 179 and 304 receiving Ivor Lewis and McKeown MIE respectively. Neoadjuvant chemoradiation was administered to 379 (78 %) of the patients. The overall and disease progression-free survival curves of all the patients were constructed with five-year survival rates of 48.3% and 40.3% respectively. Multivariate analysis revealed that pathological tumor stage was a significant factor for prognosis after surgery both in the patients treated with and without neoadjuvant CCRT (P< 0.05). Of the patients with patholoigical stage I or ypStage I esopahgeal cancer after CCRT, overall survival was significantly improved with the increased number of dissected lymph nodes (P=0.022). **Conclusion:** The survival of patients with esophageal cancer undergoing MIE was influenced by their tumor staging, irrespective the use of neoadjuvant CCRT. Of these patients with stage I and ypStage I disease, improved survival can be facilitated with increased number of dissected lymph nodes during MIE.

MA20.11 SURGICAL TREATMENT FOR METASTATIC LUNG TUMORS FROM SARCOMAS OF SOFT TISSUE AND BONE

H. Yamamoto[1], K. Namba[1], H. Yamamoto[1], T. Toji[1], J. Soh[1], K. Shien[1], K. Suzawa[1], T. Kurosaki[1], S. Ohtani[1], M. Okazaki[1], S. Sugimoto[1], M. Yamane[1], K. Takahashi[2], T. Kunisada[1], T. Oto[1], S. Toyooka[1]

[1]*Okayama University Hospital, Okayama/Japan,* [2]*Center for Sarcoma, International University of Health and Welfare, Mita Hospital, Tokyo/Japan*

Background: Sarcoma is one of the refractory malignant tumors and often develops pulmonary metastasis. The purpose of this study was to evaluate the impact of surgical resection for metastatic lung tumors from sarcomas of soft tissue and bone retrospectively. **Method:** Between 2006 and 2015, we had a total of 158 patients with metastatic lung tumors from soft-tissue and bone sarcomas who underwent pulmonary metastasectomy for the first time. In total, 265 surgical procedures were performed in Okayama University Hospital in this period. We analyzed the age, sex, site of primary lesion, histology, extent of primary tumors at the initial diagnosis, extent of pulmonary metastases at the first pulmonary metastasectomy, presence or absence of local recurrence and/or extrapulmonary metastases with or before pulmonary metastases, operative procedures, size of the largest lesions resected, maximum number of the resected tumors, postoperative complications, and the prognosis at the end of 2018. **Result:** Average number of resected tumors per intervention was 4.0 (range 1-19). These sarcoma patients consisted of 36 males and 122 females, and their average age was 53.7 years (range 14-88 years). Leiomyosarcoma was the most common histological subtype (n = 92, 58.2%) and uterus was the most common location of the primary disease (n = 71, 44.9%). Operative procedures were composed of 202 partial resections, 35 segmentectomies with or without partial resections, 26 lobectomies with or without partial resections, 1 pneumonectomy, and 1 basal segmental auto-transplantation after pneumonectomy. The postoperative complications were limited, showing that pulmonary metastasectomies for sarcomas are acceptable. Overall 3-year survival after the first pulmonary metastasectomy was 50.6%. In univariate analysis, the survival was significantly better for the group with disease-free interval of more than 2 years from the date of the initial treatment for primary disease until the date of diagnosis for the first pulmonary metastasis, the one who underwent pulmonary resections three times or more, and the one in which size of the largest resected lesion was 20 mm or less. Those factors significant in univariate analysis were all significant in multivariate analysis. **Conclusion:** Surgical resections for metastatic lung tumors from sarcomas of soft tissue and bone were performed without major complications, indicating the acceptable feasibility. If disease-free interval is more than 2 years and the size of the largest resected lesion is less than 20 mm, patients may maximally benefit from pulmonary resection. In order to increase the opportunities of pulmonary resections, we should preserve the lung parenchyma as much as possible when performing pulmonary metatstasectomy, resulting in the better survival.

MA21.01 GENERATION AND CHARACTERIZATION OF NOVEL PRECLINICAL DISEASE MODELS OF NSCLC WITH NRG1 REARRANGEMENTS TO IMPROVE THERAPY

E. Gladstone, M. Vojnic, M. Offin, L. Delasos, A. Lui, E. Siau, H. Sato, R. Benayed, R. Kurth, M. Mattar, I. Khodos, E. De Stanchina, R. Daly, A. Schram, A. Drilon, M. Ladanyi, R. Somwar

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Chimeric proteins encoded by NRG1 rearrangements retain the EGF-like domain of NRG1, a HER3 ligand that triggers HER3-HER2 heterodimerization and drives tumor growth. Activating NRG1 fusions have been identified in a variety of cancers including lung, pancreatic, breast, head and neck, etc, and previous work by our group has shown that anti-HER3 antibody (GSK2849330) therapy was effective at inducing a durable response in a NSCLC patient with a CD74/NRG1-fusion. It is possible that targeting both HER2 and HER3 would be more effective than targeting HER3 alone given that HER3-HER2 dimerization is necessary for tumorigenesis induced by NRG1 rearrangements. However, this has not been explored extensively due to a paucity of well-characterized preclinical models of NRG1-driven NSCLC. We aimed to establish patient-derived xenograft (PDX) and cell line models with NRG1-rearrangements to evaluate signaling networks and the role of novel therapies for this recently identified oncogene. **Method:** Approximately 30,000 tumor samples were evaluated for the presence of NRG1-fusions by targeted DNA and RNA sequencing (using the MSK-IMPACT and MSK-Fusion panels, respectively). Fresh tumor samples were collected and implanted into immune-compromised mice to generate PDX models and/or used to generate cell lines. Separately, NRG1-fusions were genomically engineered using CRISPR-Cas9 systems or by lentiviral transduction of cDNAs into immortalized human bronchiolar epithelial (HBEC) cells. RT-PCR and Sanger sequencing were used to verify NRG1-fusion mRNA expression, whereas western blot analysis examined fusion protein expression and phosphorylation. Subsequently, cell viability following inhibition of HER2, HER3 and downstream signaling pathways was assessed. **Result:** NRG1 fusions were identified in 24 patients (9 NSCLC); and we successfully generated two PDX models with corresponding cell lines from two NSCLC surgical specimens (2/2). One model harbors a CD74/NRG1 fusion whereas the second harbors a SLC3A2/NRG1-fusion. Using CRISPR-Cas9 mediated gene editing, we are introducing NRG1 fusions that were identified in NCSLC (CD74/NRG1, SLC3A2/NRG1, VAMP2/NRG1) into HBEC cells, and have generated a stable cell line with VAMP2/NRG1 fusion to date. In addition, we established a CD74/NRG1-positive model in HBEC cells using lentiviral transduction. Treatment of NRG1-fusion positive cells with small molecule inhibitors of HER2 (afatinib, neratinib, sapitinib) or trastuzumab inhibited growth, induced caspase 3/7 activity and blocked activation of PI3K and ERK signaling. Neratinib was more potent than other small anti-HER2 molecules. The PI3K inhibitor pictilisib inhibited growth of NRG1 fusion-positive cells as a single agent with little effect on non-tumor control cells. **Conclusion:** We generated novel NSCLC PDX and cell line models with verified NRG1 chromosomal rearrangements. *In vitro* studies show that targeting HER2 and PI3K effectively inhibits growth and induces apoptosis. Studies exploring the efficacy of additional agents targeting HER2, HER3 and PI3K alone or in combination using in vivo models are ongoing and results will be presented.

Keywords: NRG1, NSCLC

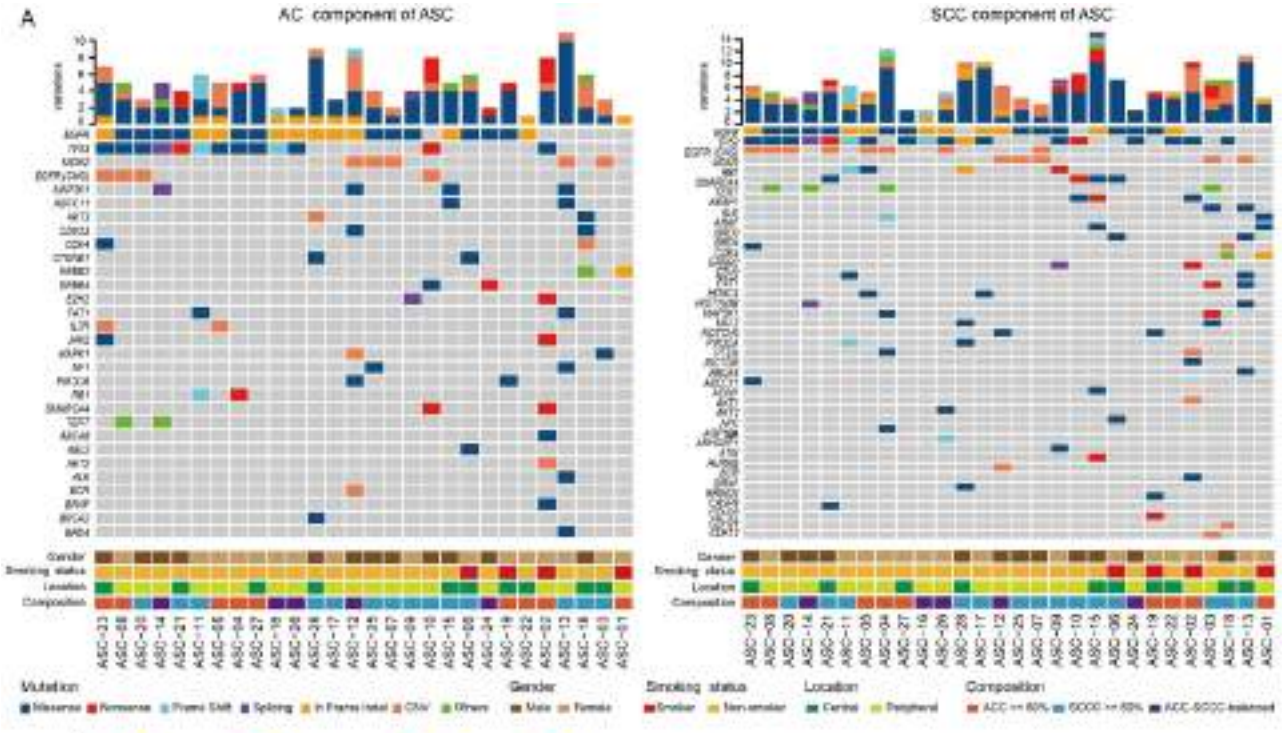
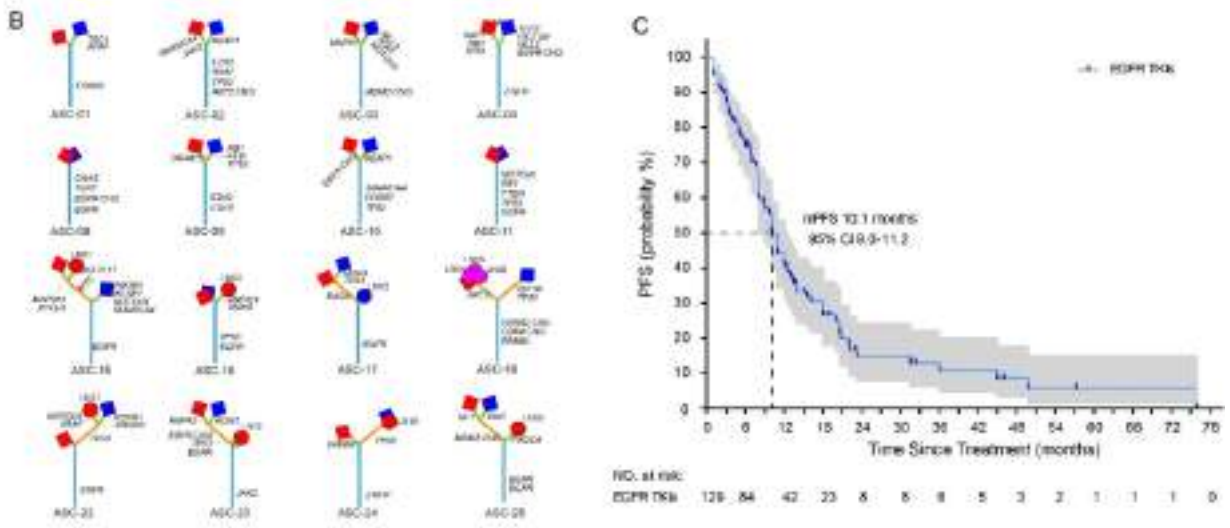
Background: Lung adenosquamous carcinoma (ASC) is a heterogeneous disease that comprises of both adenocarcinoma (AC) and squamous cell carcinoma (SCC) components. Their genomic profile, evolutionary origin, and clinical management remain controversial. Objective of this study is to define the genomic origin of this heterogeneous tumor by independent genomic analyses of the AC and SCC components. **Method:** Surgical ASCs were collected. AC component and SCC component were obtained separately by microdissection, and Lymph node (LN) metastases were gathered. Targeted sequence was performed for the two components using a 1021-gene panel, independently. Evolutionary relationship of the two components was analyzed. The independent cohorts of adenocarcinoma (n=170) and squamous cell carcinomas (n=62) were used for comparison. *EGFR* and concomitant mutations with response to EGFR-TKI were analyzed. Retrospective 517 ASCs underwent *EGFR* detections were collected from 11 centers. Objective response rate (ORR), disease control rate (DCR) and progression free survival (PFS) were analyzed in *EGFR*-positive patients received EGFR-TKIs. **Result:** 28 ASCs were collected. NGS was performed on AC component and SCC component samples, respectively. The most frequent alterations in 28 ASCs were *EGFR* mutation (79%), *TP53* mutation (68%), *MAP3K1* mutation (14%), *EGFR* amplification (32%), and *MDM2* amplification (18%). 27 patients had trunk variations in the both components suggesting the monoclonal origin of ASCs. The prevalence of trunk mutations was correlated to those of AC, indicating that ASC might originate from AC. Only one patient did not carry any trunk variations between AC and SCC components, which were clearly and geographically distinguishable under the microscope. 22 had AC component or/and SCC component specific variations suggesting the common event of branch evolution. The 23 LNs of 13 patients mainly contained AC and ASC components (AC, SCC, and ASC: 11, 1, and 11, respectively), and each of the LNs carried the trunk mutations of the primary ASC. Like pure AC, the alterations of L858R and Exon 19 Dels of *EGFR* were common in the 28 ASCs. Unfortunately, these patients have not been treated with TKIs. Further, of 517 retrospective ASCs from 11 centers, 51.8% were *EGFR*-positive. For the 129 *EGFR*-positive ASCs who had received TKIs, the ORR and DCR were 56.6% and 89.1%, respectively. The median PFS was 10.1 months (95% CI: 9.0-11.2).





Conclusion: The AC and SCC components share a monoclonal origin, and a majority have branching evolution. ASC may represent a subtype of adenocarcinoma with *EGFR* mutation being the most common genomic anomaly and sharing similar efficacy to EGFR-TKIs.

Background: Evidence-based standards for molecular testing of lung cancer have been established, but the global frequency and practice of testing are not well understood. The IASLC conducted an international survey to evaluate current practice and barriers to molecular testing. **Method:** Distributed to IASLC members and other healthcare professionals, content included: 7-question introduction, 32 questions for those requesting tests/treating patients, 45 questions on performing/interpreting assays, and 24 questions on tissue acquisition. All respondents were asked to provide 3-5 barriers to implementing/offering molecular testing. Respondents' countries were grouped by geography or developing/developed using IASLC and World Bank criteria. Surveys were available in 7 languages. Regional comparisons used the Chi-squared test or ANOVA; free-text was analyzed with Nvivo. **Result:** We obtained 2,537 responses from 102 countries. Respondents were 45% Medical Oncologists, 12% Pulmonologists, 12% Thoracic Surgeons, 9% Pathologists, and 22% scientists or other. 56% of responses were from developing countries, 44% developed. Regions included: 52% Asia, 19% Europe, 11% Latin America, 11% US/Canada, 7% Other. 1683 (66%) chose the requesting/treating track (50% government, 42% academic, 8% other). 61% reported most patients in their country do not receive molecular testing, with the lowest rates in Latin America/Other (p<0.0001). 39% were not satisfied with the conditions of molecular testing in their country. Indications for requesting testing included: adenocarcinoma (89%), never-smoker (61%), female (57%), and young (54%) (variable by region, p<0.0001). 99% ordered EGFR, 95% ALK, 84% PDL1, 79% ROS1, all other tests <50%. 56% typically received results within 10 days. Only 67% were aware of CAP/IASLC/ AMP guidelines, least frequently in Asia/Other (p=0.041). 37% have trouble understanding molecular testing result reports, most of whom cited a need for more technical and scientific knowledge. 75% had multidisciplinary tumor boards, but 23% met <1/month. The 316 (12%) testing track respondents were from laboratories that were 49% academic, 35% government, and 16% private/other. 94% of laboratories offered EGFR, 83% ALK, 69% KRAS, 68% BRAF, 64% ROS1, 56% HER2, and others <50%; 68% tested for PDL1. 57% offered Multiplex assays, less frequently in Latin America/Asia (p=0.0294). 69% tested blood-derived DNA, less frequently in US/Canada/ Other (0.0013). 23% of respondents reported >10% of cases are rejected due to inadequate samples; however, 47% stated there is no policy or strategy to improve the quality of the tissue samples in their country. 52% reported patients/physicians are not satisfied with the state of molecular testing in their country. Respondents performing/interpreting assays (334, 14%) were typically informed of biopsy results (91%), and notified when the sample was inadequate (84%). The most frequent barrier to molecular testing in every region was cost, followed by quality/standards, turnaround-time, access, and awareness. After cost, time was the most common barrier in developed countries, while it was quality in developing countries. The second largest barrier was quality in Asia, access in Europe/Latin America/Other, and turn-around time in US/Canada. **Conclusion:** These preliminary analyses show molecular testing usage varies across the globe. Barriers vary by region, and one-third of respondents were unaware of evidence-based guidelines. Global and regional strategies should be developed to address barriers.

[1]*Niigata University Graduate School of Medical and Dental Sciences, Niigata/Japan,* [2]*Nishi-Niigata Chuo National Hospital, Niigata/Japan,* [3]*Nagaoka Red Cross Hospital, Nagaoka/Japan,* [4]*National Cancer Center Hospital, Tokyo/Japan,* [5]*Shinrakuen Hospital, Niigata/Japan,* [6]*Niigata Prefectural Central Hospital, Joetsu-City/Japan,* [7]*Chiba University, Chiba/Japan,* [8]*Niigata Cancer Center Hospital, Niigata/Japan,* [9]*Niigata Medical Center Hospital, Niigata-city/Japan*

Background: Alectinib is a 2nd generation highly selective anaplastic lymphoma kinase (ALK) inhibitor. Although alectinib has improved progression-free survival (PFS) in patients with *ALK*-positive Non-Small Cell Lung Cancer (NSCLC), there are limited treatment options after progression of alectinib. Recent evidences have described promising results of the combination of bevacizumab with EGFR-TKIs, cytotoxic chemotherapies and immune-checkpoint inhibitors. We report the results from a phase II study of the combination of alectinib with bevacizumab in *ALK*-positive Nonsquamous NSCLC patients who were treated with alectinib and showed disease progression (UMIN 000017828). **Method:** Patients with *ALK*+ Nonsquamous NSCLC who had progressed after alectinib treatment were enrolled. Primary objective of this study was PFS and safety. Secondary endpoints included overall survival, objective response rate and disease control rate. **Result:** Twelve patients received alectinib (600 mg/day) with bevacizumab (15 mg/kg, Q3W). Nine patients were treated with crizotinib and alectinib, and 2 patients were treated with crizotinib, alectinib and ceritinib before enrollment to this study. The median PFS was 3.1 months (95% CI 1.2-16.1) and the median survival time was 32 months (95% CI 8.3-NE). The median treatment cycle was 5 (range, 1-37) and 3 patients received alectinib with bevacizumab more than 20 cycles. The objective response rate and disease control rate were 8% and 67%, respectively. The most common treatment related adverse events were decreased appetite (42%), proteinuria (42%), hypertension (33%), anemia (33%) and fatigue (33%). Treatment related adverse events of grade ≥ 3 were anemia (8%), proteinuria (8%), diarrhea (8%) and hypokalemia (8%). No severe adverse events were observed. **Conclusion:** This is the first study to investigate the combination of alectinib and bevacizumab. This combination had clinical efficacy and was well tolerated.

Background: Treatment options are limited for epidermal growth factor receptor (EGFR)-mutant non-small cell lung cancer (NSCLC) resistant to EGFR tyrosine kinase inhibitors (TKIs), in particular osimertinib. Overall, 57%–83% of NSCLC tumors express human epidermal growth factor receptor 3 (HER3). Because signaling through HER3 is not an established mechanism of resistance to EGFR TKIs, treatment with an anti-HER3 antibody–drug conjugate (ADC) presents an approach to targeting diverse resistance mechanisms in EGFR-mutant NSCLC. U3-1402 is a HER3-targeted ADC with a fully humanized antibody, novel cleavable peptide-based linker, and topoisomerase I inhibitor payload. Here, we present the safety/tolerability and antitumor activity data from the dose-escalation phase of an ongoing, multicenter, phase 1 study (NCT03260491). **Method:** Patients had locally advanced or metastatic EGFR TKI-resistant, EGFR-mutant NSCLC. Patients with stable brain metastases were eligible. Dose escalation was based on dose-limiting toxicities (DLTs) guided by a Bayesian logistic regression model. U3-1402 was administered every 3 weeks via intravenous infusion. Pretreatment tumor tissue was required for retrospective HER3 immunohistochemistry analysis. Next-generation sequencing analysis was performed on available tumor tissue. Primary objectives included safety, tolerability, and identification of the recommended dose for expansion (RDE). **Result:** As of May 2019, 30 patients were enrolled across 4 doses (3.2 [n=4], 4.8 [n=9], 5.6 [n=12], and 6.4 [n=5] mg/kg). Thirteen patients (43%) have discontinued (progressive disease [n=9], clinical progression [n=1], consent withdrawal [n=2], adverse event [AE; n=1]). All 30 patients received prior *EGFR* TKIs, of which 28 (93%) received prior osimertinib, and 15 (50%) prior chemotherapy. Activating EGFR mutations were reported in all patients (Ex19del: 57%; L858R: 40%; L861Q: 3%). All 25 evaluable tumors demonstrated HER3 expression (median HER3 membrane H-score, 183 [range, 56–290]). History of central nervous system (CNS) metastases was reported in 15 patients (50%). Treatment-emergent AEs were reported in 29 patients (97%; 13 patients [43%] reported grade 3/4). Two DLTs (grade 3 febrile neutropenia and grade 4 platelet count decrease) were reported in 1 patient (5.6 mg/kg) and 3 DLTs (all grade 4 platelet count decrease) in 3 patients (6.4 mg/kg). Of patients with a history of CNS metastases, 9 have progressed (2 with CNS progression; 3 with both CNS and non-CNS progression). One patient without a history of CNS metastasis progressed with new CNS disease. Of 26 efficacy-evaluable patients, 6 had confirmed partial responses (2 each at 4.8, 5.6, and 6.4 mg/kg), including 2 patients with an EGFR C797S mutation. Median best percentage change in sum of diameters (SoD) was −25.7% (range, −82.6% to 13.3%), including decreases in SoD in patients with *CDK4* amplification (–25.7% and –17.8%), *HER2* amplification (–28.6%), and both *CCNE1* amplification and *PIK3CA* mutation (–28.8%). **Conclusion:** U3-1402 demonstrated tolerable safety and antitumor activity in this ongoing study. Antitumor activity of U3-1402 was seen in cancers with EGFR-mediated and other resistance mechanisms. These findings support the hypothesis that targeting HER3 with U3-1402 may provide clinical benefit to patients with *EGFR*-mutant NSCLC with diverse mechanisms of resistance. RDE evaluation is ongoing.

Background: Oncogenic BRAF-V600 mutations are observed in 1-2% of non-small cell lung cancer (NSCLC). Targeted therapies including vemurafenib (V), dabrafenib (D) or combination of

dabrafenib plus trametinib (D+T) are associated with favorable outcomes in these patients (pts). The mechanisms of resistance to BRAF-targeted therapies (BRAF-TT) in NSCLC are largely unknown. **Method:** We performed genomic profiling of serial circulating-tumor DNA (ctDNA) in a cohort of 79 metastatic BRAF-mutant NSCLC pts (96% V600E, 4% non-V600). BRAFmutational status was ascertained based on local testing. Plasma samples were collected, from 2014-2018 in 27 Hospitals, from pts treated with V (n=34), D (n=2) or D+T (n=23). We collected 41 plasma samples at baseline to BRAF-TT, 40 at progressive disease (PD) and ~200 samples during treatment follow-up, concomitant to routine radiological evaluation. Inivata InVisionSeq™ assay was used to detect the presence of SNVs, indels and CNAs in 36-cancer related genes. **Result:** At baseline, 72,5% of BRAF mutations (V600E and non-V600E) were detected in plasma. BRAF-V600E detection in plasma was associated with the presence of liver metastasis, versus BRAF-V600E-negative cases (22% vs. 7%, respectively). Co-occurring molecular alterations at baseline, besides BRAF-V600E, were observed in 18/26 (70%) cases: FGFR2 (1pt), PIK3CA (2pts), ERBB2 (1pt), CTNNB1 (2pts) and IDH1 (2pts). FGFR2, PIK3CA or CTNNB1 alterations were associated with PD as the best response to the subsequent BRAF-TT. TP53 and STK11 mutations were observed in 54% (14/26) and 8% (2/26) of pts, respectively. Complete clearance of BRAF-V600E in plasma at baseline was observed at the first CT-scan evaluation in 42% (3/7) and 82% (9/11) pts treated with V or D+T, respectively. These pts were in complete or partial response, suggesting that monitoring BRAF-V600E levels in plasma on treatment may be a clinically useful marker of tumor response. At PD, a consistent rebound in BRAF-V600E plasma levels was observed in 60% (24/40) pts. Resistance to V was associated with alterations in the MAPK pathway: 1pt (KRAS), 1pt (GNA11), 1pt (NRAS and GNAS) and 1pt (MAP2K1 and NFE2L2). Activating PI3KCA mutations were observed in 4 pts who progressed in <6 months on V treatment. ctDNA analyses at PD under D+T revealed that, similar to what we observed in patients who progressed on V, alterations in KRAS, NRAS, PIK3CA and CTNNB1 are associated with D+T resistance. Prediction of the impact of these alterations, at the protein level, was assessed using in silico structure modeling and will be presented. **Conclusion:** ctDNA monitoring might be an informative tool for assessing disease response and resistance in NSCLC pts treated with BRAF-TT. MAPK reactivation remains an important resistance mechanism to BRAFi-monotherapy or to BRAFi and MEKi combination therapy.

MA21 NON EGFR/MET TARGETED THERAPIES
TUESDAY, SEPTEMBER 10 14:30–16:00

MA21.09 TYROSINE KINASE INHIBITORS' PLASMA CONCENTRATION AND ONCOGENE-ADDICTED ADVANCED NON-SMALL LUNG CANCER (ANSCLC) RESISTANCE

A. Geraud, L. Mezquita, E. Auclin, D. Combarel, J. Delahousse, C. Naltet, C. Jovelet, P. Lavaud, A. Gazzah, L. Lacroix, J. Remon, C. Caramella, D. Planchard, O. Mir, A. Paci, B. Besse

Institut Gustave Roussy, Villejuif/France

Background: The development of TKIs against driver molecular alteration has changed treatment paradigm in aNSCLC patients (pts). All tumors eventually progress and a resistance mechanism is identified in only a fraction of pts. Plasma concentration of TKI can decrease after chronic exposition but limited data are available. Our hypothesis is that an insufficient plasma exposure could contribute to tumor progression (PD). **Method:** We assessed the plasma concentration of TKI in pts with aNSCLC harboring *ALK* rearrangement, *EGFR* or *BRAF V600E* mutation. We defined chronic exposure as a treatment administered > 3 months. Patients' characteristics and co-medications were collected. Residual plasma concentrations were measured using Ultra Performance Liquid Chromatography coupled with tandem mass spectrometry validated methods. We compared results to currently recommended therapeutic targets and correlated exposure levels to treatment benefit. **Result:** Between Apr. 2014 and Feb. 2019, 51 samples were prospectively collected (gefitinib n=11, osimertinib n=10, erlotinib n=13, crizotinib n=7, dabrafenib + trametinib n=5) in 41 pts. Median time of exposure was 20.3 months (range 2.18 - 67.813). Low plasma concentration was observed in 31 (61%) samples. Out of 14 samples collected in pts with ongoing benefit, 10 (71%) had low plasma exposure. Smoking status was associated with low plasma TKI concentration (P=0.01) whatever the TKI used. A total of 37 samples were collected at PD, 21 (57%) had low plasma exposure. The median time to treatment failure (TTF) in the 'low exposure group' (n=31) was 14.9 months (95% CI 12.48 – 33.2) vs. 24.6 months (95% CI 8.65 -not reached (NR) in the 'normal exposure group' (P=0.55). No significant impact of protons pump inhibitors on TTF was found (p=0.12), including with gefitinib and erlotinib (p=0.76; n=24). In case of isolated brain PD (n=4), 3 pts (75%) had low plasma exposure. TKI dose was reduced in 14 pts because of toxicity, median TTF was 17.0 months (95% CI 10.4-NR) vs. 20.1 months (95% CI 10.4-59.8, P=0.45 in pts treated with standard dose. In the *EGFR* mutated aNSCLC population at PD (n=19), T790M resistance mutation was more frequent in the 'normal exposure group' (37.5%, n= 3/8,) than in the 'low exposure group' (9.1%, n=1/11), OR=0.13 95%CI (0.01-1.29), p=0.08. **Conclusion:** TKI is underdose in the majority of aNSCLC patients at PD. Low TKI concentration were more frequent in pts without tumor resitance mechanism. Altogether, it suggests that low TKI exposure might contribute to PD.

MA21 NON EGFR/MET TARGETED THERAPIES
TUESDAY, SEPTEMBER 10 14:30–16:00

MA21.10 PHASE II STUDY OF 160MG OF OSIMERTINIB IN EGFR T790M POSITIVE NSCLC WITH BRAIN OR LEPTOMENINGEAL METASTASES WHO PROGRESSED ON PRIOR EGFR TKI

M.-J. Ahn, S. Park, S. Hong, J. Park, M.R. Park, H.A. Jung, J.-M. Sun, S.-H. Lee, J.S. Ahn, K. Park

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: EGFR tyrosine kinase inhibitor (TKI) has successfully improved clinical outcome in non-small cell lung cancer (NSCLC) with activating EGFR mutation. However, up to 40% of TKI treated patients present with disease progression in the central nerve system (CNS) either as brain metastases (BM) or leptomeningeal metastases (LM). Osimertinib is a 3rd generation EGFR TKI effective in T790M mutant NSCLC and characterized by high blood-brain barrier penetration. In this phase II, multicenter prospective single-arm two cohort study, the clinical efficacy of 160mg of osimertinib in T790M mutant BM or LM patients progressed on prior EGFR TKI was evaluated. (NCT0325712) **Method:** BM only patients were included in the BM cohort (n=40). Patients with cerebrospinal cytology confirmed LM with or without BM were included in the LM cohort (n=40). 3rd generation TKI, including 80mg of osimertinib, was exposed to 18 patients in BM and 16 patients in LM cohort. T790M need to be identified from either tissue, plasma or cerebrospinal fluid. The primary endpoint was overall response rate (ORR) (H_1=30%) for BM cohort and overall survival (OS) (H_1=5months) for LM cohort, respectively. **Result:** Median follow-up duration was 7.9 months for BM and 8.3 months for LM cohort. In BM cohort, median progression-free survival (PFS) was 7.3 months (95% confidential interval [CI] 3.6-13.7), and median OS was not reached (NR). Intracranial ORR and disease control rate (DCR) was 40.0% and 77.5%. Extracranial ORR and DCR was 30.0% and 67.5%. In LM cohort, median PFS was 8.9 months (95%CI 5.6-NR) and median OS was 13.2 months (95%CI 8.0-NR). When response of leptomeningeal lesion is separately evaluated, CR rate was 25.0% (n=10) and non-CR/non-PR rate was 65.0% (n=26). Extracranial ORR and DCR was 22.5% and 85.0%. Intracranial median PFS was not reached in both BM and LM cohort. Grade 3 adverse event (AE) was observed in 7 BM and 11 LM patients. Four patients required dose reduction due to AE. Among the patients who previously received 3rd generation TKI, 33.3% (6 out of 18) in BM cohort and 81.2% (13 out of 16) in LM cohort showed an intracranial DCR to 160mg of osimertinib. Extended survival analyses and exploratory outcomes will be presented at the conference. **Conclusion:** In this study, 160mg of osimertinib demonstrated promising ORR and survival benefit with tolerable safety profile in EGFR T790M positive NSCLC patients with CNS metastasis who progressed on prior EGFR TKI.

MA21.11 A MULTICENTER PHASE II STUDY OF LOW-DOSE ERLOTINIB IN FRAIL PATIENTS WITH EGFR MUTATION-POSITIVE, NON-SMALL CELL LUNG CANCER: TORG1425

S. Otani[1], K. Yamada[2], S. Miyamoto[2], K. Azuma[2], H. Ishii[2], A. Bessho[2], S. Hosokawa[2], H. Kunitoh[2], K. Miyazaki[2], H. Tanaka[2], S. Miura[2], H. Aono[2], Y. Nakahara[2], K. Kusaka[2], Y. Hosomi[2], A. Hamada[2], H. Okamoto[2]

[1]*Kitasato University School of Medicine, Sagamihara/Japan,* [2]*Thoracic Oncology Research Group, Yokohama/Japan*

Background: We conducted a multicenter phase II trial evaluating the efficacy of low-dose erlotinib (ERL) in frail patients with EGFR-mt non-small cell lung cancer (NSCLC). The primary endpoint was met, with the objective response rate (ORR) of 60%. Here we present the final overall survival (OS) results. Furthermore, we investigated the effect of ABCB1 genetic polymorphisms on the ERL plasma concentration pharmacokinetics (PK) and pharmacodynamics (PD). **Method:** Chemotherapy-naïve NSCLC patients with *EGFR* mt who had frailty were enrolled and received ERL 50 mg/d. Patient's frailty was defined as follows: (Group 1) 20 to 74 years of age with Eastern Cooperative Oncology Group performance status (PS) ≥2 or Charlson Comorbidity Index (CCI) ≥6 points; (Group 2) 75 to 80 years of age with PS ≥1 or CCI ≥6 points; (Group 3) ≥81 years of age with any PS and CCI. ABCB1 gene polymorphism analysis were using the i-densy™ genetic testing platform, and blood samples for the ABCB1 genetic testing were collected prior to treatment. Steady-state trough plasma ERL concentration was measured with a high-performance liquid chromatograph-tandem mass spectrometry at 15 days (±7 days) after initiating ERL administration. **Result:** From December 2014 and April 2017, 80 patients were enrolled: males/females 26/54; median age 80 (range 49-90); Group 1/2/3 15/28/37; Ad/Sq/Others 76/1/3. *EGFR* mt types were: exon 19/21 42/38. All 80 patients were included in efficacy and safety analysis. Median progression-free survival and OS were 9.3 (95%CI: 7.2-11.4), 26.1 (95%CI: 21.9-30.4) months respectively. The trough of ERL could be measured in 48 patients, and 45 of these patients were analyzed for ABCB1 genetic polymorphism. The ORR for the 48 patients was 62.5%, and their median trough of ERL was 685ng/ml (range 153-1950), which surpassed the reported "effective" level (500ng/ml). Nine (60%) of 15 the patients who failed to achieve the level responded. Genetic polymorphisms were not correlated with ERL PK, nor were they associated with efficacy and adverse events. **Conclusion:** This is the first prospective study evaluating low-dose ERL for frail patients with *EGFR* mt NSCLC. This treatment was safe and effective, and the ABCB1 genetic polymorphisms did not affect ERL PK/PD. Clinical trial information: UMIN 000015949.

Keywords: erlotinib, frail, NSCLC

MA22 PARTNERING WITH PATIENTS TO UNDERSTAND STIGMA, DISPARITIES AND VALUES LEADING TO IMPROVED LUNG CANCER CARE
TUESDAY, SEPTEMBER 10 14:30–16:00

MA22.01 LUNG CANCER PATIENTS' UNIQUE VALUES AND PREFERENCES LEAD TO CLINICAL TRIAL PREFERENCES

A. Ciupek[1], C. Kraft[2], J. King[1]

[1]*GO2 Foundation for Lung Cancer, Washington/United States of America,* [2]*Allergy & Asthma Network, Vienna/United States of America*

Background: Only about 5% of cancer patients participate in clinical trials. We previously conducted a survey of U.S. lung cancer patients and found that only 22% reported discussing clinical trials with their oncologist at the time of making treatment decisions. We hypothesize these low rates of trial discussion and participation may be due in part to current clinical trial designs not reflecting unique values and preferences of lung cancer patients that differ from other non-cancer conditions. **Method:** Utilizing an online survey inquiring about clinical trial attitudes of patients with several different clinical diagnoses in the United States, we chose to compare a group of lung cancer patients (LC group) to patients diagnosed with a non-cancerous condition (chronic allergies or asthma) (AA group). 229 participants in the LC group and 367 in the AA group were asked to indicate the personal impact of several information sources for finding out about clinical trials and several potential motivators for clinical trial participation. **Result:** The LC group reported the doctor's office as their main information source for clinical trials, while the AA group indicated advertisements as their primary source for finding out about trials. In terms of motivation to join trials, 60% of the LC group said having their doctor's support for joining a given trial was very important to them (only 33% of the AA group said so). Being paid for participation was reported as being motivating by 69% of the AA group versus only 23% of the LC group. When asked about what they valued when looking for a clinical trial, the LC group said extending quality and length of life and receiving access to otherwise unavailable therapy options were very important. The AA group placed much less importance on these same values. **Conclusion:** We should consider the unique ways lung cancer patients seek information and what they value when designing a strategy to recruit to or educate about a clinical trial. Effective, tailored strategies may include increasing the use of providers as primary trial educators and focusing outreach surrounding trials on lung cancer patient motivators that differ from those with other diagnoses.

MA22.02 THE IMPACT OF PATIENT ENGAGEMENT ON STUDY DESIGN AND PATIENT RECRUITMENT IN A PRAGMATIC TRIAL TO IMPROVE CANCER CARE DELIVERY

A. Bell-Brown[1], S. Sullivan[2], G. Lyman[1], D. Hershman[3], K. Watabayashi[1], K. Kreizenbeck[1], S. Shirley[1], A. Ciccarella[4], G. Walia[5], J. Johnson[4], C. Seigel[4], G. Mason[6], F. Kurttila[4], B. Segarra-Vazquez[7], S. Ramsey[1], B. Haddock Lobo Goulart[1]

[1]*Fred Hutchinson Cancer Research Center, Seattle/United States of America,* [2]*University of Washington, Seattle/United States of America,* [3]*Columbia University, New York/United States of America,* [4]*SWOG, Portland/United States of America,* [5]*Genentech, South San Francisco/United States of America,* [6]*Inflammatory Breast Cancer Research Foundation, West Lafayette/United States of America,* [7]*University of Puerto Rico, San Juan/Puerto Rico*

Background: SWOG trial S1415CD is a pragmatic study comparing outcomes of Colony Stimulating Factor (CSF) use in usual care with care that uses guideline-informed standing CSF orders. A 21-person External Stakeholder Advisory Group (ESAG), including 10 patient partners, has informed the design, implementation, recruitment and dissemination planning for the study. Recruitment has been a challenge for study sites, specifically around approaching and consenting patients in the window between diagnosis and first cycle of chemotherapy. This abstract explores the impact of the ESAG patient partners on the patient recruitment process for S1415CD. **Method:** Patient partners are convened each year over monthly teleconferences, one in-person meeting and targeted email communication. Patient partner input from 2014-present has been tracked and reviewed for impact on the patient recruitment process. After the start of accrual in October 2016, a teleconference was held in spring 2017 focused on barriers to patient accrual, specifically patient approach. Study sites submit monthly screening logs detailing reasons for patient ineligibility. **Result:** Prior to the start of accrual, patient partners collaborated with the research team to create 2 resources to assist clinic staff with presenting the trial in lay terms: a patient brochure and a summary handout for clinical research associates (CRAs). CRAs reported high use of the brochure as a valuable, simple tool for explaining the trial to eligible patients. Patient partners were also engaged in developing consent forms for trial participants. In addition, patient partners developed strategies for approaching patients in the timeframe between diagnosis and first cycle of chemotherapy which were compiled into a document for study sites and incorporated into the trial's frequently asked questions. Between October 2016-June 2017, the approach and consent process (i.e. the inability to consent patients in the narrow timeframe) accounted for 22% of all reported ineligible patients, however after the implementation of patient-formulated strategies, during June 2017-December 2018, the approach and consent process has accounted for only 10% of all reported ineligible patients. **Conclusion:** Sustained engagement and active participation of patient partners throughout S1415CD has provided unique experiential knowledge and feedback to improve the patient approach and consent process across study sites, leading

to increased opportunities for patient recruitment. Engaging patient partners early and throughout the study design and conduct phases of the research has been successful in providing patient-centered solutions to recruitment and implementation challenges, including the challenge of timing, to ensure success in reaching the study accrual goals.

MA22.03 THE ROS1DERS: PARTNERING TO DRIVE RESEARCH AND IMPROVE OUTCOMES IN ROS1+ CANCERS

L. Goldman, L. Buonnano, J. Freeman-Daily, T. Tomalia

The ROS1ders, Mountain View/United States of America

Background: ROS1 fusions are found in a dozen types of cancer. However, these fusions are rare, occurring in a small fraction of patients (e.g.,1%-2% of non-small cell lung cancer). The small population hampers gathering sizeable patient cohorts and investment in medical research. The ROS1ders are a group of patients and caregivers dealing with ROS1-positive (ROS1+) cancer who strive to better outcomes for all ROS1+ cancers by supporting patients and caregivers, increasing awareness and education, accelerating research, and improving access to effective diagnosis and treatment. **Method:** We created a private ROS1+ Facebook group for sharing personal information and support among patients and caregivers. We created a public Facebook group for outreach. We launched a website at ROS1cancer.com to share sourced information about ROS1 drugs, clinical trials, expert clinicians, and research developments as well as patient blogs and tips for living with our disease. We attended medical conferences and met with cancer advocacy organizations, clinicians, researchers, and industry; we collectively began working on projects to accelerate research into our disease through the Global ROS1 Initiative. We are active in developing and implementing our projects as well as serving as fundraisers and the ROS1+ public face. **Result:** The ROS1ders is the largest cohort of ROS1+ patients and caregivers ever collected. We add new members weekly, and have grown to include 400+ members from 28 countries. We network with ROS1+ communities who communicate in languages other than English in Europe, China and Japan. Expert ROS1 clinicians collaborate with us to ensure we provide accurate information about our disease in our Facebook groups and our website. ROS1+ patients have donated fresh tissue and pleural fluid specimens to the ROS1 Cancer Model Project to create cell lines and patient-derived xenograft (PDX) mice; the resulting cell lines have been shared with several institutions in academia and industry. We have contributed data to an epidemiological study. We are collaborating to develop a registry-based study of blood clots in ROS1+ and other lung cancer patients. Some ROS1ders are developing new projects in their home countries. **Conclusion:** The ROS1ders are breaking new ground, sharing current information, collecting data and biospecimens from ROS1+ patients, and enabling research and development of treatments for our cancer in ways that were not possible before. The Global ROS1 Initiative is truly a partnership between patients, caregivers, advocacy organizations, clinicians, researchers, and industry.

Background: Incidence of lung cancer in women is rising overtime reporting evident gender-based differences in epidemiology, biology, and treatment outcome. However, little is known about gender-differences regarding psychological, economic and social aspects. The objectives of this prospective study are to evaluate the psychosocial and economic impact of metastatic non-small cell lung cancer (NSCLC), according to gender. Additionally, to assess the emotional burden and the economic impact of the disease on the primary caregiver from a gender perspective **Method:** Multicenter, prospective, observational, study of two cohorts of patients with metastatic NSCLC (male and female) in Oncology departments of 20 Spanish hospitals. The following measurement tools were used: the APGAR questionnaire (family functionality: adaptability, partnership, growth, affection, and resolve), the Relationship impact scale, the DUKE-UNC scale (perceived socio-affective support), the patient and the caregiver economic impact scale and the Zarit scale (caregiver burden). All questionnaires were performed at the first visit, repeated 4 months later and following the first and second disease progression. **Result:** Of the 333 pts included, 104 were females and 229 male, of whom 63% and 97%, respectively, were smokers/ex-smokers (p=0.0001). More women than men (85% vs 70%) had adenocarcinomas. The median overall survival was longer in women but did not reach statistical significance [17.1 vs 11.0 months, HR 0.732 (95% CI 0.534 to 1.005), p=0.0524]. Most families considered themselves functional (high score in APGAR questionnaire) with no changes in their partner relationship and social support was evaluated as optimal for majority of patients. Around a quarter of interviewed patients said their economic situation was a little worse after the lung cancer diagnosis, without remarkable differences by gender. Statistically significant differences were found between both groups regarding the caregiver´s relationship to the patient (more parents were the caregiver in females than in males) (p <0.0001) and the caregiver's employment situation (more employed caregivers in females) (p<0.0001). Most caregivers of both sexes considered that taking care of their relative did not pose a significant burden. No remarkable differences by gender were found between the different variables across the study. **Conclusion:** This study provides a preliminary insight into gender-related characteristics in the management of advanced NSCLC and its impact on the emotional, social and economic burden of patients and their caregivers, and recall the high priority of researching in cancer from a gender perspective

MA22.06 LONGER LUNG CANCER TIME INTERVALS AMONGST CULTURALLY AND LINGUISTICALLY DIVERSE PATIENT THAN ANGLO-AUSTRALIAN PATIENTS

D. Mazza[1], X. Lin[1], J. Emery[2], F. Walter[3], J. Young[4], D. Barnes[5], P. Mitchell[6], B. Brijnath[7], A. Martin[4], K. O'Byrne[8]

[1]*Monash University, Notting Hill/Australia,* [2]*University of Melbourne, Parkville/Australia,* [3]*University of Cambridge, Cambridge/United Kingdom,* [4]*University of Sydney, Camperdown/Australia,* [5]*Royal Prince Alfred Hospital, Newtown/Australia,* [6]*Austin Health & University of Melbourne, Heidelberg/Australia,* [7]*National Ageing Research Institute, Parkville/Australia,* [8]*Princess Alexandra Hospital and Queensland University of Technology, Brisbane/Australia*

Background: Lung cancer is the leading cause of cancer mortality worldwide. Culturally and Linguistically Diverse (CALD) patients are especially vulnerable, with poorer outcomes than non-immigrant patients. The LEAD (Lung cancer diagnostic and treatment pathways: A comparison between CALD and Anglo-Australian patients) study aimed to measure and compare the lung cancer diagnostic and treatment pathways between CALD and Anglo-Australian patients. **Method:** LEAD is a mixed-method, observational cohort study. The presentation reports findings from the quantitative arm comprising a patient questionnaire and reviews of patients' hospital and general practice records. A total of 577 (407 Anglo-Australian and 170 CALD) patients were recruited from Melbourne, Sydney and Brisbane, and their hospital records were reviewed. The questionnaire was returned by 189 patients (135 Anglo-Australian and 54 CALD) and a record review was completed by the General Practitioners (GPs) of 99 patients (76 Anglo-Australian and 23 CALD). Survival and Cox regression analyses were conducted to examine differences in time intervals between the two groups. LEAD is funded by Cancer Council Australia with the assistance of Cancer Australia. **Result:** CALD patients reported longer time intervals from referral to diagnosis (Median = 30 days, 95% CI = 26 - 34) than Anglo-Australian patients (Median = 17, 95% CI = 14 - 20), p =. 003, Exp (B) = 1.32. This difference persisted after the impact of relevant factors, such as age and stage of lung cancer, was taken into consideration. CALD patients also reported longer time in five other intervals, including from 1) symptom notification to GP presentation, 2) GP presentation to referral, 3) referral to treatment, 4) symptom notification to treatment, and 5) symptom notification to diagnosis. However, the differences in these five intervals failed to reach significance. **Conclusion:** LEAD is the first Australian study to comprehensively measure and compare the time intervals along the lung cancer pathways amongst CALD and Anglo-Australian patients. It found that CALD patients have longer time intervals from referral to diagnosis than Anglo-Australian patients.

MA22.07 A CULTURALLY SAFE ADVOCACY MODEL OF CARE FOR INUIT CANCER PATIENTS AND THEIR FAMILIES

C. Roberts[1], C. Bornais[1], P. Wheatley-Price[2], T. Asmis[1], G. Nicholas[1], G. Barton[1]

[1]*The Ottawa Hospital, Ottawa/Canada,* [2]*University of Ottawa, Ottawa/Canada*

Background: The Ottawa Hospital is the tertiary care center for Inuit living in the Baffin Island region of Nunavut, in Canada's far North. Inuit – once relatively cancer free – now have among the highest lung cancer rates in the world (Young et al., 2016). Approximately 30% of Inuit diagnosed with cancer between 2000 and 2010 did not access any cancer services (Asmis, 2016), for which they must travel thousands of kilometers where they are displaced from family, community and culture. Colonization has had a detrimental impact on the social determinants of health for Inuit in Nunavut and has created a lack of trust in government institutions. This context creates an advocacy need at the individual and systems level to address access and equity issues, with the goal of advancing positive health outcomes. **Method:** The Champlain Indigenous Cancer Program (CICP) team has developed a patient-centered, culturally appropriate, land-based approach to support Inuit patients using the principles of the "Supportive Care Framework" (Fitch, 1994) as a guiding ideology. Recognizing the social and economic inequities (Inuit Tapiriit Kanatami, 2019), the Nurse Navigator developed an unconventional approach to connect with Inuit patients. She prioritizes developing therapeutic, trusting relationships with patients and families based on the observation that Inuit patients often feel most comfortable outside the confines of a hospital office. Developing these relationships on the land has become a cornerstone of her work. **Result:** The approach that the CICP has implemented has achieved far-reaching success. Between the first six months and latest six months of tracking (through 2017-2018) there has been a 400%+ increase in patient encounters with the Nurse Navigator role. Clinicians report an increased awareness and understanding of the unique context of Inuit patients and families, resulting in increased numbers of referrals to CICP. Within the Inuit community, there is a recognition and appreciation of the Inuit-specific approach, leading to an increase in self-referrals. **Conclusion:** The CICP is continuing to actively pursue tracking and reporting initiatives to demonstrate a shift in access to cancer care and the long-term outcomes for Inuit patients and families. The program is also continuing to increase access to cultural awareness education for staff to combat misunderstandings about Inuit. By sharing experiences and stories garnered through this work, the Nurse Navigator will help attendees to question and redefine the perception of the traditional role of a cancer nurse.

MA22.10 THE ROLE OF STIGMA IN DIFFERENTIAL CARE FOR LUNG CANCER PATIENTS: A DECADE OF PATIENT AND ONCOLOGIST ATTITUDES

J. King[1], E. Rapsomaniki[2], M. Rigney[1]

[1]*GO2 Foundation for Lung Cancer, Washington/United States of America,* [2]*AstraZeneca, Gaithersburg/United States of America*

Background: The presence of lung cancer stigma is well documented (Chapple et al, 2004; Chambers et al, 2012; Marlow et al, 2015) and has been shown to impact the care and treatment of lung cancer survivors (Tod et al. 2008; Carter-Harris et al 2014). In 2008, a large survey of over 200 patients, 200 oncologists, and 1000 members of the general population revealed that most participants felt that lung cancer was principally caused by external factors, that it was preventable, and that lung cancer patients were at least partly to blame for their illness (Weiss et al. 2014; Weiss et al. 2017). The last decade has brought significant changes in the treatment paradigm for lung cancer but it was unknown if the perceptions that affect the care of lung cancer patients have changed. **Method:** 1001 members of the general public, 208 patients with lung cancer, and 205 oncologists who treat lung cancer were surveyed with the identical survey instrument from 2008 survey along with 5-15 additional questions at the end. The survey was carried out by phone and online between June 6 and July 26, 2018. Statistical analysis was performed comparing 2008 and 2018 datasets using paired t-tests if normally distributed or Mann-Whitney U tests for continuous data and Chi-squared or Fisher's exact test for categorical data. **Result:** In 2018, significantly more oncologists feel they have adequate treatment options for metastatic lung cancer

(67% vs 36%, p<.001) and the majority of patients report being satisfied with their medical care (87%) and treatment options (71%). Nevertheless, significantly more patients felt that there was a stigma associated with having lung cancer (70% vs. 54%, p<.0001) and that society treats them differently (63% vs 45%, p<.0001). There was a non-significant increase in oncologists indicating that there is a stigma associated with lung cancer (68% in 2018 vs 60% in 2008) and that patients blame themselves (67% vs 57%). Despite the improvements in lung cancer treatment over the past decade, stigma is still evident in care for those with lung cancer. Similar to 2008, 57% of oncologists indicated that patients with different types of cancer were thought about, approached, or handled differently and lung cancer patients were most frequently cited. In 2018, more patients reported that patients with lung cancer are treated differently by doctors and nurses (40% vs. 26%, p=.01). For both groups, the most common differential treatment referenced was "received less sympathy from medical staff." **Conclusion:** After a decade of research progress in lung cancer, stigma surrounding the disease remains a critical problem even in a healthcare setting. Patients are perceiving stigma at higher levels and oncologists are not reporting any improvement. This work underscores the need to address stigma with proactive multilevel approaches including the need for medical providers to practice empathic communication.

MA22.11 AN EMPATHIC COMMUNICATION SKILLS TRAINING MODULE TO REDUCE LUNG CANCER STIGMA IN PATIENTS WITH LUNG CANCER: PILOT RESULTS

J. Ostroff[1], S. Banerjee[1], N. Haque[1], C. Bylund[2], M. Shen[3], M. Rigney[4], H. Hamann[5], P. Parker[1]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*University of Florida, Gainseville/United States of America,* [3]*Weill Cornell Medicine, New York/United States of America,* [4]*Lung Cancer Alliance, Washington DC/United States of America,* [5]*University of Arizona, Tucson/United States of America*

Background: Most patients diagnosed with lung cancer report experiencing stigma, with 48% reporting stigma attributable to interactions with health care clinicians. Lung cancer stigma may result in multiple negative psychological outcomes such as misreporting and underreporting of symptoms and smoking behaviors and avoidance of help-seeking. One promising intervention strategy for reducing patients' experiences of lung cancer stigma is improving empathic communication in lung cancer patient-clinician interactions. This abstract describes the conceptual model, development, and preliminary evaluation of a clinician-targeted empathic communication skills training to reduce lung patient's experience of stigma. **Method:** The goal of this new training module was to enhance responsiveness to lung cancer patients' expression of stigma and psychological distress focusing on greater use of seven communication strategies: agenda setting, history taking, recognizing or eliciting a patient's empathic opportunity, shared understanding of the patient's emotion/experience, empathic responding, coping and connection to social support, and closing the conversation. Participating cancer care clinicians learned specific communication skills such as providing a rationale for tobacco use discussion, normalizing, acknowledging, preparing patients for recurring smoking questions, and encouraging expression of feelings. The 2-hour training module was delivered to thoracic oncology clinicians (physicians, advanced practice clinicians) (n=28) using a brief didactic presentation (30 min) with exemplary video demonstrations, followed by experiential role play exercises (90 min) with standardized patients. **Result:** We examined preliminary efficacy of the empathic communication module by assessing participant evaluation of the training and their perceived self-efficacy before and after the training. Overall, participating clinicians reported favorable evaluations of the training, with 93% participants agreeing or strongly agreeing to all 12 training module evaluation items. Of note, perceived self-efficacy to communicate empathically with lung cancer patients increased significantly, t(27)=-4.42, p<.001 from pre- (M=3.64,SD=.68) to post-training (M=4.36,SD=.49). **Conclusion:** Overall, results indicate that the new empathic communication skills training module was well received by thoracic oncology care clinicians and demonstrated significant improvements in self-efficacy from pre- to post-training. Examination of patient outcomes is needed.

MA23.01 PHASE II TRIAL OF AN ORAL FGFR INHIBITOR AZD4547 AS SECOND OR THIRD LINE THERAPY IN MALIGNANT PLEURAL MESOTHELIOMA: FINAL RESULTS OF FRAME STUDY

W.-S. Lam[1], A. Nowak[2], F. Chen[3], S. Muruganandan[4], S. Arunachalam[4], M. Chin[4], M. Millward[4], C. Read[4], K. Murray[2], J. Creaney[2], Y.C.G. Lee[4]

[1]*Fiona Stanley Hospital, Perth/Australia,* [2]*University of Western Australia, Perth/Australia,* [3]*Lions Eye Institute, Nedlands/Australia,* [4]*Sir Charles Gairdner Hospital, Nedlands/Australia*

Background: Treatment options are limited after first line platinum-based therapy for malignant pleural mesothelioma (MPM). FGFR-9 is a mitogenic ligand that activates the FGF-receptor (FGFR) family and is overexpressed in pleural fluid and tumour samples from mesothelioma patients. In mesothelioma mouse models, FGF-receptor inhibitors reduce tumour burden. Hence, we examined the efficacy of the FGFR tyrosine kinase inhibitor, AZD4547 as second/third line therapy in MPM. **Method:** From April 2016 to January 2019, we conducted a single-site, single arm, open-label study of AZD4547 in patients with MPM. Eligible patients had histologically or cytologically confirmed mesothelioma, measurable disease and had progressed after first or second line therapy. Patients received oral 80mg twice-daily AZD4547 with protocol dose reductions as required. The primary end point was 6-month progression free survival (PFS6); key secondary endpoints included PFS, response rate, overall survival, and safety and tolerability. Using a Simons' two-stage design, 26 patients would be recruited to the first stage and the study would be declared negative if fewer than 7 (27%) of 26 patients achieved PFS6. **Result:** 24 patients (21 (87%) male), median age 69.5 (range 53-84) were recruited. Histological subtype was epithelioid (83.3%), biphasic (8.3%), sarcomatoid (8.3%). Most patients had one prior regimen (14; 58%). Common toxicities included grade 1 and 2 hyperphosphataemia, nail changes, stomatitis, and ophthalmological changes, consistent with reported toxicities of this drug class. No adverse events required hospitalisation. There were two partial responses (8%); 17 patients (70%) had stable disease (SD) for at least 6 weeks, and 5 patients (21%) had progressive disease as their best response. Three of 24 patients (12%) were progression free at 6 months. Hence, the study fulfilled stopping criteria regardless of further recruitment and was discontinued once the criteria for progressing to stage 2 could not be met. Progression free survival was 3.9 months and overall survival was 9.3 months. One patient remained on study with SD for 16 months, experiencing ongoing grade 2 hyperphosphatemia, alopecia of body and facial hair and grade 2 onycholysis. **Conclusion:** The FGFR inhibitor AZD4547 was ineffective for patients with MPM who had progressed on first or second line therapy. Continuous grade 2 cutaneous and ocular toxicities were observed with prolonged therapy

Background: Novel therapeutic approaches are needed to improve the clinical outcome of patients with malignant pleural mesothelioma (MPM). In the current study, we investigate the antitumor activity of CDK4/6 inhibitors in preclinical models of MPM. **Method:** MPM cell lines (H28, H226, H2052, H2452, MSTO-211H) and primary cultures (ICO_MPM1, ICO_MPM2, ICO_MPM3) were treated with abemaciclib or palbociclib for 24 and 72 hours. Cell viability was evaluated by cell counting and crystal violet assays. Cell death and cell cycle distribution were analyzed by flow cytometry and senescence was quantified by β-galactosidase expression. For transcriptomic studies, mRNA expression was assessed through RNA sequencing analysis. Gene set enrichment analysis (GSEA) was used to identify signaling pathways deregulated in MSTO-211H cells treated with CDK4/6 inhibitors. MSTO-211H cells were implanted subcutaneously in athymic mice that were randomly assigned to the following cohorts (n=7): i) vehicle; ii) cisplatin + pemetrexed; iii) palbociclib alone and iv) palbociclib + gemcitabine. Tumors' size and mice weight was monitored during 4 weeks to evaluate efficacy. **Result:** Treatment with abemaciclib or palbociclib at 100nM induced a significant decrease in cell proliferation (mean 50.9% ± 7.6; mean 47.3% ± 9.9, respectively) in distinct MPM cell models, including cells derived from patients who progressed to prior cisplatin and pemetrexed. Both CDK4/6 inhibitors induced G1-phase cell cycle arrest, while cell death was slightly affected (up to 1-5%). At concentrations ranging from 250 to 500nM, the percentage of senescent cells was increased after abemaciclib (15-26%) and palbociclib (18-25%) treatment in all the analyzed cell models. GSEA revealed that CDK4/6 inhibitors promote interferon signaling pathway and MHC presentation. In the *in vivo* experiment, a significant reduction in tumor growth was observed in response to palbociclib alone or combined with gemcitabine for 4 weeks (vehicle = 1335.8±586.4 mm^3; cisplatin + pemetrexed= 726±573.5 mm^3; palbociclib = 479±235.7 mm^3; palbociclib + gemcitabine = 517±487.4 mm^3; $p< 0.05$). **Conclusion:** CDK4/6 inhibitors reduce cell proliferation in culture models of MPM mainly by blocking cell proliferation at G1 and by inducing senescence. Palbociclib alone or combined with gemcitabine reduces *in vivo* tumor growth of subcutaneously implanted MSTO-211H cells compared to chemotherapy.

MA23.03 BAP1 LOSS INDUCES GENOME INSTABILITY THROUGH BRCA1-DEPENDENT AND INDEPENDENT MECHANISMS IN MESOTHELIOMA

A. Singh
University of Leicester, leicester/United Kingdom

Background: BRCA1 associated protein 1 (BAP1) is a tumor suppressor that is the most frequently mutated in the majority of mesotheliomas. We have previously reported that loss of BRCA1 expression in mesothelioma is a common event, and mediates resistance to spindle checkpoint activator vinorelbine, a drug with relevance to treatment of mesothelioma. However, the loss of BRCA1 is unknown in mesothelioma. The aim of this study is to determine the functional relationship between BAP1 and BRCA1 and examine their role in vinorelbine resistance in mesothelioma cells. **Method:** We conducted functional genetic analysis of BAP1 and BRCA1 in two MPM cell lines, MSTO and H2452, the latter carrying an inactivating A95D mutation in the UCH domain of BAP1. BAP1 knockdown was achieved by siRNA transfection, while BRCA1 knockdown was achieved by doxycycline induction of an integrated shRNA. Patient samples were processed for BAP1 and BRCA1 immunohistochemistry from MEDUSA cohort. **Result:** Loss of BAP1 expression led to reduced expression of BRCA1, whereas knockdown of BRCA1 did not affect BAP1 expression. Treatment with the proteasome inhibitor, MG132, restored BRCA1 expression in the absence of BAP1 indicating that BAP1 contributes to post-translational stabilization of BRCA1 protein and the stabilization of BRCA1 by BAP1 is independent of its de-ubiquitination activity. Knockdown of BAP1 induced SAC deficiency and vinorelbine resistance concurrent with reduced expression of BRCA1 and the SAC component, MAD2L1. We also identified a positive and significant correlation between BAP1 and BRCA1 expressionin patient samples. **Conclusion:** Our data demonstrates that BAP1 regulates BRCA1 expression through regulating its protein stability. Our findings suggest that BAP1 inactivation dysregulates the spindle assembly checkpoint via BRCA1 dependent and independent mechanisms, conferring resistance to vinorelbine. As such BAP1 may have potential as a predictive biomarker for spindle poisons, to underpin chemotherapy stratification. A hypothesis that would be tested in a multicentre randomised phase II VIM trial.

MA23.05 A PHASE II TRIAL OF NINTEDANIB IN RECURRENT MALIGNANT PLEURAL MESOTHELIOMA (MPM)

A. Wozniak[1], B. Schneider[2], G. Kalemkerian[2], R. Daly[3], W. Chen[4], J. Ventimiglia[4], M. Nagasaka[4], M. Zauderer[3]

[1]*UPMC Hillman Cancer Center, Pittsburgh/United States of America,* [2]*University of Michigan, Ann Arbor/United States of America,* [3]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [4]*Karmanos Cancer Institute, Detroit/United States of America*

Background: Malignant pleural mesothelioma (MPM) is a disease that is resistant to chemotherapy and there remains an unmet need for better therapeutic options. Nintedanib (BIBF 1120) is an oral multikinase inhibitor impacting VEGF, FGF, PDGFR, and other kinase activity such as TGFß signaling pathways. VEGF, FGF, and TGFβ are commonly expressed in MPM. We conducted a phase II trial in patients with recurrent MPM after platinum-based chemotherapy. **Method:** Methods: Patients (pts) with MPM previously treated with platinum-based chemotherapy, performance status (PS) 0-1, adequate organ function, and no contraindications to anti-angiogenic therapy were eligible for treatment. Nintedanib 200 mg twice per day was administered until disease progression or unacceptable toxicity. The primary endpoint was the 4-month progression-free survival (PFS). A two-stage design was used and >4 pts had to have a PFS of ≥4 months to proceed to the second stage. **Result:** Twenty pts. were enrolled. The median age was 70 yrs. (32-81), 90% were male, and 80% were PS=1. The histology was 70% epithelioidal, 5% sarcomatoid, 10% biphasic, and 15% unknown. 15% had prior bevacizumab. The median follow-up is 16.4 mo. A median of 2 treatment cycles (range 1-18) were delivered. There were no responses but 40% had stable disease. The median PFS was 1.8 mo. (95% CI: 1.68, 3.55) and the PFS rate at 4 mo. was 13%. The median OS was 4.2 mo. (95% CI: 2.53, 8.74) and the OS rate at 4 mo. was 55%. Toxicities were usually grade 1-2 and included diarrhea, fatigue, edema, transaminase elevation, anorexia, nausea, vomiting and dyspnea. **Conclusion:** Conclusions: The activity of nintedanib in previously treated MPM pts. was modest. The trial did not meet the primary PFS endpoint. However, there was a small subset of pts. that had prolonged stable disease for >4 months thus potentially deriving some clinical benefit from treatment. Supported by Boehringer Ingelheim.

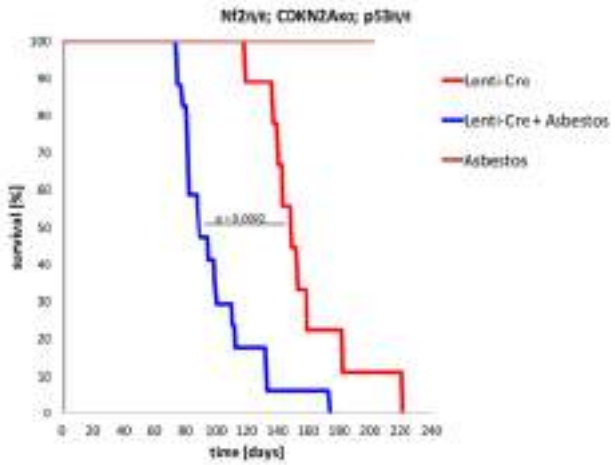
MA23.06 DEVELOPMENT OF A NOVEL GENETICALLY ENGINEERED MOUSE MODEL OF MALIGNANT PLEURAL MESOTHELIOMA

K. Gyuraszova[1], T. Monteverde[2], T. Chernova[3], R. Duffin[4], K. Blyth[1], A. Berns[5], M. Macfarlane[3], D. Murphy[1]

[1]*University of Glasgow, Glasgow/United Kingdom,* [2]*Cancer Research UK Manchester Institute, Manchester/United Kingdom,* [3]*MRC Leicester, Leicester/United Kingdom,* [4]*University of Edinburgh, Edinburgh/United Kingdom,* [5]*Netherlands Cancer Institute, Amsterdam/Netherlands*

Background: Malignant pleural mesothelioma (MPM) is an aggressive neoplasm strongly associated with inhalation of asbestos. MPM is difficult to diagnose and typically occurs after long latency period. Most of the studies are restricted to the end-stage disease and little is known about pre-malignant disease. Efforts to develop targeted therapeutic strategies based on cell culture have largely failed. Our aim was to develop a novel genetically engineered mouse model that combines deletion of the major tumour suppressors lost in human MPM with intra-pleural injection of asbestos. This model will allow us to investigate how mutagenesis combines with fibre-induced inflammation to drive disease evolution. **Method:** We used genetic engineering to develop an accelerated mesothelioma mouse model combining pleural-restricted, CRE-mediated deletion of NF2, Tp53 (Tp53 is lost in c.10% of human MPM) and full-body knock-out of Cdkn2a with intra-pleural injection of asbestos recapitulating the disease-relevant inflammatory microenvironment. We used immunohistochemistry to analyse the tissue and the lesions. **Result:** Intra-pleural injection of asbestos dramatically accelerates mesothelioma development in mice triple deleted for NF2, Cdkn2a and Tp53, with all such mice succumbing to malignant disease within 3-4 months (Figure 1). These mice develop malignant lesions in the mesothelial lining of the thoracic cavity accompanied with pleural effusion showing high similarity with human malignant mesothelioma. IHC analysis shows positive staining for mesothelioma markers, e.g. pancytokeratin, vimentin and WT-1. Positive macrophage staining (F4/80) strongly indicates involvement of inflamatory component.



Conclusion: In our model, we combined conditional mouse genetics with dose-defined exposure to asbestos to mimic development of human MPM. Our system provides unique insights into the critical transition from pre-malignancy to MPM and will allow us to test emerging therapeutic interventions in the most physiologically relevant pre-clinical setting possible.

MA23.07 LOSS OF EXPRESSION OF BAP1 AND/OR MTAP AIDS IN THE DIAGNOSIS OF MALIGNANT MESOTHELIOMA METASTATIC TO LYMPH NODES

A.C. Roden[1], T. Peikert[1], J. Vrana[1], A. Hudson[1], D. Wigle[1], M.C. Aubry[1], A. Mansfield[2]

[1]*Mayo Clinic Rochester, Rochester/United States of America,* [2]*Mayo Clinic, Rochester/United States of America*

Background: Stage and histology are the strongest prognostic parameters in malignant pleural mesothelioma and aid management of patients. However, the distinction between reactive intranodal mesothelial cells and metastatic malignant mesothelioma (MM) can be challenging. Loss of BRCA1 associated protein-1 (BAP1) and/or methylthioadenosine phosphorylase (MTAP) expression has been identified in a subset of MM but not in reactive mesothelial proliferation. We investigated the value of these markers in the distinction between reactive mesothelial cells and metastatic MM in lymph nodes. **Method:** Surgical files of Mayo Clinic Rochester (1996-2018) were searched for metastatic MM in lymph nodes. All cases and if available corresponding primary MM were reviewed by a thoracic pathologist (ACR) to confirm the diagnosis. Primary MM and lymph nodes were stained with BAP1 (clone C-4) and MTAP (2G4). Absence of nuclear staining of BAP1 and absence of nuclear and cytoplasmic staining of MTAP in essentially all tumor cells was considered as loss of expression. **Result:** Forty-four patients (25 males, 56.8%) had a median age of 64 years (range, 24-75) at time of surgery. Tissue was available from nodal metastases in all cases, either paired with the primary MM at time of nodal sampling (N=37) or at a different time (N=4) (time between tissue collections, range, 1day- 4 years, respectively), or without paired primary MM (N=3). Thirty-seven pleural, 6 peritoneal and 1 pericardial MM were of epithelioid (N=39) or biphasic (N=5) subtype. Patients underwent extrapleural pneumonectomy (N=17), pleurectomy (N=7), resection (N=9), debulking (N=2), biopsy (N=8), or autopsy (N=1). In nodal metastases, BAP1 and/or MTAP expression was lost in 29 (of 43, 67.4%) cases; specifically, BAP1 expression was lost in 28 (of 44, 63.6%), MTAP was lost in 14 (of 43, 32.6%), and both were lost in 12 (of 43, 27.9%) cases. Agreement in expression/loss of expression of BAP1 and/or MTAP in primary and metastatic MM occurred in all cases. During a median follow up of patients who underwent extrapleural pneumonectomy or pleurectomy (available in N=23) of 14.8 months (range, 1-119) 17 patients died within a median time of 16 months. **Conclusion:** BAP1 and MTAP immunostains are helpful in the distinction between metastatic MM and reactive mesothelial cells in lymph nodes when one or both markers lost expression in the mesothelial cells. Expression of both markers does not exclude the possibility of metastatic MM.

MA23.09 FUSION GENES IDENTIFIED FROM WHOLE GENOME AND WHOLE TRANSCRIPTOME SEQUENCING OF MALIGNANT PLEURAL MESOTHELIOMA TUMOURS

T.M. Chee[1], H. Oey[2], K. Fong[3], I. Yang[3], L. Krause[2], R. Bowman[3]

[1]*University of Queensland, Chermside/Australia,* [2]*University of Queensland, Brisbane/Australia,* [3]*The Prince Charles Hospital, Chermside/Australia*

Background: Malignant Pleural Mesothelioma (MPM) is an asbestos-related cancer without curative treatment. Fusion genes result from structural chromosomal rearrangements such as translocation, inversion, amplification and deletions, leading to erroneous apposition of components of two or more genes. Consequences include abolition of gene functions that protect against tumourigenesis, or increased activation of genes that promote cell proliferation. To identify fusion genes in MPM genomes, we executed whole genome sequencing (WGS) on eight MPM tumours, and validated the expression of putative fusion genes identified from WGS by whole transcriptome analysis (RNA-Seq). **Method:** Histology of eight MPM tumours was confirmed by two qualified anatomical pathologists,

prior to extraction of genomic DNA and RNA. Whole genome and whole transcriptome sequencing were performed using Illumina HiSeq platforms. Following stringent data processing and filtration, putative fusion variants were called using an in-house bioinformatics pipeline. Fusion events with potential functional consequences were then validated by whole transcriptome analysis, and annotated using TCGA Fusion Gene Data Portal and The Gene Ontology Resource. **Result:** A total of 592 and 321 putative fusion variants were called respectively from WGS data using Delly, and from RNA-Seq using STAR-Fusion computational tools. Expression of WGS putative fusion variants was confirmed in RNA-Seq data, resulting in twelve fusion genes being identified. Among 24 genes involved in fusion events, twenty-two were listed in TCGA Fusion Gene Data Portal with gene partners that were not identified in our cases. Two genes were novel to that database. Multiple functional processes that may lead to tumour development were attributable to these genes including protein polyubiquitination, protein deubiquitination, antioxidant activity, DNA repair, immune response, integrin-mediated signalling pathway, chromatin organization, transcription coactivator activity, angiogenesis, natural killer cell proliferation and DNA-binding transcription factor activity. **Conclusion:** In combination, WGS and RNA-Seq data analysis revealed several fusion genes that warrant further investigation as possible drivers of malignant mesothelioma, and which may serve as diagnostic and therapeutic targets.

MA23.10 LOW NUMBER OF MUTATIONS AND FREQUENT CO-DELETIONS OF CDKN2A AND IFN TYPE I CHARACTERIZE MALIGNANT PLEURAL MESOTHELIOMA

A. Nastase[1], A. Mandal[1], S.K. Lu[1], S. Gennatas[1], H. Anbunathan[1], M. Edwards[1,2], D. Morris-Rosendahl[1,2], A. Newman Taylor[1], R.C. Rintoul[3,4], E. Lim[5], S. Popat[6], A. Nicholson[1,7], M. Lathrop[8], A. Bowcock[1], M. Moffatt[1], W. Cookson[1]

[1]*Imperial College London, London/United Kingdom,* [2]*Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom,* [3]*Papworth Hospital NHS Foundation Trust, Cambridge/United Kingdom,* [4]*University of Cambridge, Cambridge/United Kingdom,* [5]*Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom,* [6]*The Royal Marsden Hospital; and National Heart and Lung Institute, Imperial College London, London/United Kingdom,* [7]*Royal Brompton and Harefield NHS Trust, London/United Kingdom,* [8]*McGill University-Génome Québec Innovation Centre, Quebec/Canada*

Background: Malignant pleural mesothelioma (MPM) is an aggressive tumour with dismal prognosis and overall survival. To expand our understanding of molecular background of MPM and to identify novel targetable aberrations we report an integrated genomic analysis of 121 tumour samples. **Method:** Fresh-frozen tumour samples (obtained from Mesobank UK,the BLF funded Mick Knighton Mesothelioma Tissue Bank, Respiratory BRU Biobank Diagnostic Archive, Royal Brompton Hospital and an Imperial College London prospective study) were analysed by whole exome sequencing (WES, n=50), SNP genotyping (n=118) and targeted capture sequencing (n=119) for 57 genes. Sequencing libraries were prepared using Target Enrichment Systems for the Illumina Multiplexed Sequencing platform. Somatic mutations were called using VarScan after recalibration of alignments by Genome Analysis Toolkit (GATK). SNP genotyping was performed with the Human Infinium Omni-Express-Exome v1.3/1.4 Bead Chips arrays. Segmentation and copy number calling was performed using a combination of Allelic specific copy number analysis of tumour (ASCAT), DNACopy and GISTIC softwares. **Result:** Analysis of WES paired samples revealed a median of 31 non-synonymous somatic mutations per tumour, lower than melanoma (315 somatic mutations) or lung cancer (187.5 for squamous and 158 for adenocarcinoma), two types of tumours linked to known carcinogen exposure. Investigation of copy number showed significant frequent deletion (q-value>0.05) of 9p21 locus where *CDKN2A, MTAP* and *IFN* type I genes are located. Deletion of *CDKN2A* was seen in 71/121 patients with homozygous deletion in 58/71 patients. Homozygous co-deletion of *CDKN2A* and *IFN* type I was seen in 38/58 patients, homozygous codeletion with *MTAP* in 49/58 patients while 37 patients showed all three as homozygous co-deleted. Patients with *CDKN2A* and *IFN* type I deletions had worse overall survival compared with the *CDKN2A* wild type and patients *CDKN2A* only deleted patients (median 8.3 months vs 13.1 months, p-value=0.016). Deletion of 3p21.1 locus and mutations in *BAP1* were detected in 54.5% of the patients, making *BAP1* the second most commonly altered gene. *RB1* (13q14.2) was commonly altered mainly by deletion in 25.6% of the patients. *NF2* and *TP53* were affected by mutations in 19.8% and 7.4% of the patients, repectively. Patients with mutations in *TP53* had worse overall survival compared with *TP53* wild type patients (p-value=0.0005). **Conclusion:** Co-deletion of *CDKN2A*, *MTAP* and *IFN* type I genes could have therapeutic implications for the patients. Deletion of *IFN* type I may have direct implications for patient responses to immunotherapy. In the contex of multiple vulnerabilities, the presence of both *CDKN2A* and *RB1* loss might define an important group of patients susceptible to CDK4/6i targeted therapies.

MA23.11 ANALYSIS OF IMMUNE PHENOTYPE COMPOSITION IN MALIGNANT PLEURAL MESOTHELIOMA (MPM) USING BULK RNA SEQUENCING

A. Mandal[1], A. Nastase[1], S.K. Lu[1], S. Gennatas[1], H. Anbunathan[1], M. Edwards[1,2], D. Morris-Rosendahl[1,2], A. Newman Taylor[1], R.C. Rintoul[3,4], E. Lim[5], S. Popat[6], A. Nicholson[1,7], A. Bowcock[1], M. Lathrop[8], M. Moffatt[1], W. Cookson[1]

[1]*Imperial College London, London/United Kingdom,* [2]*Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom,* [3]*Papworth Hospital NHS Foundation Trust, Cambridge/United Kingdom,* [4]*University of Cambridge, Cambridge/United Kingdom,* [5]*Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom,* [6]*The Royal Marsden Hospital, London/United Kingdom,* [7]*Royal Brompton and Harefield NHS Trust, London/United Kingdom,* [8]*McGill University-Génome Québec Innovation Centre, Quebec/Canada*

Background: Exploiting the immune status of the tumour microenvironment (TME) is increasingly being adopted for many cancer types. Investigation into immune phenotype composition of the TME is at present lacking for malignant pleural mesothelioma (MPM) but critically important in light of the cancer's overall poor prognosis and lack of targeted therapy as clinical standard of care. In this study, CD8+ve tumour infiltrating lymphocyte (TIL) level has been used as a starting point to compare differences in mutational patterns, histology and survival in MPM. **Method:** Bulk RNA sequencing of tumour tissue from 35 MPM patients (in-house cohort) was performed. Sequencing read alignment and gene count estimation were performed using STAR (v.2.5.2b). To increase the sample size, raw data from Bueno *et al.* (n=211 subjects) was accessed and gene count estimations performed. In addition, the TCGA-MESO cohort (n=86 subjects) count data was included from the GDC (Genomic Data Commons) website. All count data were normalized cohort-wise using the 'voom' method implemented in *limma* package. Deconvolution of constituent immune phenotypes in the TME from the bulk RNA-sequencing data was performed by applying CIBERSORT (v.1.04) on normalized count data sets. For assessing the genetic context of observed immune phenotypes, somatic mutations were profiled using targeted sequencing of a custom gene panel for the in-house cohort. For the Bueno *et al.* and the TCGA-MESO cohorts, somatic mutations were either available from an overlap of whole-exome sequencing (WES) and targeted gene panel, or from WES only. **Result:** A total of 27 samples (3 of 35 (8.6%), 21 of 211 (9.9%) and 3 of 86 (3.5%) from the in-house, Bueno *et al.* and TCGA-MESO cohorts respectively) were identified with immune phenotype enriched for CD8+ve TIL. Histological subtype distribution in the CD8+ve enriched samples was seen to be almost equivalently split between Epithelioid and Biphasic subtypes (51.85% and 48.15% respectively). Interestingly, *BAP1* mutation was found to be present in only 7.7% of the samples. Considering in addition the genes *NF2, SETD2, SETD6*, *SETDB1*, *TP53* and *LATS1/2*, mutations were only found to be present in 57.7% of the samples in total. As such >40% of samples with CD8+ve TIL do not have any mutations detected in known hotspot genes for MPM. Histological subtype is not significantly different between these 'wild-type' and hotspot gene(s) mutated samples. Median survival for the groups was found to be 1.85 and 0.73 years respectively. **Conclusion:** In the present study, approximately 3-10% of MPM samples were found to have enrichment for CD8+ve TIL. Nonetheless on closer

examination of the genetic context, mutation patterns emerge that warrant further investigation. For samples that have *TP53* (n=3) mutation or mutations in multiple hotspot genes (*BAP1*, *NF2*, *SETD2*, *LATS2*; n=1), survival understandably is lowest (0.27 years average). This raises a number of further questions including what sustains a tumour despite high CD8+ve TIL population? And more importantly with lack of tumour mutational burden what other TME signals draw effector immune cells? Further investigations, by comparing additional immune markers with copy number changes that might be present in hotspot genes, are therefore required.

MA24.02 DEVELOPING REGIONAL ACTIVITY FOR A NATIONAL CHARITY: THE LUNG CANCER CANADA EXPERIENCE

P. Wheatley-Price[1,2,3], P. Robertson[3], M. Brennan[3], J. Hamer-Wilson[3], A. Redway[3], M. Bouris[3], D. Manii[3], J. Ricard[3], S. Singh[3]

[1]*Ottawa Hospital Research Institute, Ottawa/Canada,* [2]*University of Ottawa, Ottawa/Canada,* [3]*Lung Cancer Canada, Toronto/Canada*

Background: Lung Cancer Canada (LCC) is the only national charity solely committed to the most common cancer in Canada. Its mission is to raise awareness; to advocate; and to provide support and educational resources for lung cancer patients and caregivers. At a strategic planning event the LCC Board held in 2017, the goal of building regional hubs was identified - to deliver the charities mandate within local contexts. **Method:** A group of key stakeholders (patients, caregivers, fundraisers, social workers, nurses and physicians) met to identify local priorities. Specific programs were developed, with other initiatives flowing from that initial effort. Here we describe the group's achievements. **Result:** From the initial stakeholder meeting two prime opportunities were identified. 1. Create a support group for women with lung cancer. 2. Take advantage of being in the national capital to more purposefully engage with Federal politicians. In addition to the stakeholder meeting, subsequent social gatherings of key individuals helped build momentum. Through partnership with a local charity (Ottawa Regional Cancer Foundation), marketing through LCC, recruitment through the cancer centre, and program development from a senior psychosocial oncology social worker, the support group was formed for an initial 12 week period, and has now grown to an established permanent fixture. The benefits have been previously reported, but out of this group further local initiatives have included: regular patient-led lung cancer information sessions in the cancer centre; a regional patient summit for all lung cancer patients to learn latest research, patient testimonies and psychosocial challenges; the funding and initiation of an LCC podcast series. Concurrently more individuals and families have become engaged in fundraising for lung cancer: events including quiz nights, makeovers, golf days, wine raffles and more, which in addition to raising funds also builds awareness and builds the local community. These individuals have partnered with physicians to stimulate the second goal, initiating regular meetings with municipal, provincial, federal and senatorial politicians, in addition to military leadership and indigenous groups. This itself helped the national organization to hone the advocacy message we share (lung cancer awareness, lung cancer screening, access to treatments, and the establishment of a national registry). **Conclusion:** Through identification of local champions who effectively work together, many initiatives have successfully developed. With funding and support from LCC, the charity's mandate is being delivered within the local context. This serves as a model for other centres across Canada to develop local programs.

MA24.03 FACTORS IMPACTING PATIENTS' WORRIES (ACCESSING TREATMENT, TREATMENT TOXICITY, & EMOTIONAL BURDEN) ASSOCIATED WITH LUNG CANCER TREATMENTS

U. Basu Roy[1], S. Janse[2], E. Janssen[3], A. Meara[4], C. Presley[2], P. Kneuertz[2], A. Ferris[1], J. Bridges[2]

[1]*LUNGevity Foundation, Bethesda/United States of America,* [2]*The Ohio State University, Columbus/United States of America,* [3]*Center for Medical Technology Policy, Baltimore/United States of America,* [4]*Ohio State University, Columbus/United States of America*

Background: Understanding patient experiences with lung cancer can guide research, treatment, and policy decisions. Conducted as part of a larger study (Project Transform) that aimed to quantified patient experiences, we sought to study the primary concerns of lung cancer patients and their caregivers and to determine what demographic and clinical factors impact these worries. **Method:** Lung-cancer worries were identified from patient interviews and the literature. A novel an instrument assessing 13 potential worries on a 3-point importance scale was incorporated as part a national survey of lung cancer patients (inclusive of all types/stages of disease) and caregivers recruited through LUNGevity Foundation. Factor analyses was used to identify key constructs among the 13 worries. We then explored variation in the standardized factor scores across demographic and clinical indicators collected in the survey. **Result:** Of the 426 participants in the survey, there were 385 patients and 41 caregivers. The average age of respondents was 58.9 years, 54% earned less than $75,000 per year, and 67.6% had completed college. Three factors were identified associated with worrying: 1) "accessing treatments" (incorporating knowledge, communication, access); 2) "treatment toxicity" (incorporating both side-effects and financial impact); and 3) "emotional burden" (including worries about dying, emotional toll, and being a burden), with Cronbach's alphas of 0.89, 0.73, and 0.74 respectively. Worries about accessing treatment were lower among NSCLC (P=0.006), presence of MET mutations (P = 0.027) and those not currently receiving therapy (P=0.033). Worries about treatment toxicity were higher among non-white (P<0.001), non-retired (P<0.001), those earning less than $75,000 (P<0.001), younger patients (P<0.001), and those with ALK (P=0.026) or HER2 (P=0.041) mutations. Worries about treatment toxicity were lower among patients on Medicare or Medicaid during treatment (P = 0.023) and NSCLC patients (P=0.018). Worries about the emotional burden of treatment were lower among those >=60 years (P=0.002) and those who are retired (P=0.021) and higher among those having surgery (P=0.039). Table 1: Marginal effects of patient factors on standardized worry scores

Factor	Accessing Treatment	Treatment toxicity	Emotional burden

Notes: Standard errors in parentheses, * p<0.05, ** p<0.01, ***p<0.001

Conclusion: Patients worry to differing extents about accessing treatment, treatment toxicity, and the emotional burden of lung cancer, yet caregivers and patients (on the whole) have similar worries. Lung cancer researchers, clinicians, and policymakers should make decisions in ways that address the heterogeneous experience of patients. Patients worries vary across a confluence of demographic, disease, and treatment factors, hence greater attention to the individual needs of the patient is needed.

MA24.05 LUNG CANCER IN EUROPE: STRENGTHENING POLICY RESPONSES ONE COUNTRY AT A TIME

M. Bussell, A. Lovell

The Economist Intelligence Unit, London/United Kingdom

Background: Despite diagnostic and treatment progress in lung cancer, outcomes remain poor and costs remain high. Prevalence and mortality rates in Europe are higher than the global average and five-year survival rates stand at a mere 11.2% for men and 13.9% for women. The Economist Intelligence Unit is conducting research to identify the impact of policy on lung cancer incidence and outcomes, sponsored by MSD. Recommendations stemming from our research will support countries to build improved systemic responses for lung cancer. **Method:** Our research centres on twelve countries: Austria, Belgium, Finland, Germany, Greece, Netherlands, Norway, Poland, Romania, Spain, Sweden, and the UK. Following an initial literature review using evidence from internationally-recognised sources (e.g. Globocan, OECD, and proprietary Economist Intelligence Unit sources), we organised our thinking into five domains. This is operationalised by quantitative and qualitative indicators to provide insight into how each country addresses cancer planning and guideline usage as well as how strategic thinking impacts behaviour and access. At a meeting with leading European experts, we presented our initial findings and validated our framework. The next step was to populate our scorecard to compare policy and practice in each country. Individual country profiles were developed from our findings, examining local barriers to progress in terms of service delivery, systems, access, financing and governance. Workshops were then held in each country. Meeting with a range of leading clinicians, patient organisations, and other key stakeholders ensured a detailed examination of our preliminary findings and, most importantly, enabled us to obtain further information on conditions within each country. This nuanced information provides us with a clearer grasp on approaches to the provision of lung cancer care to a greater degree than we could have obtained from desk research alone. **Result:** Preliminary results indicate patches of good practice, yet no country scores highly across all of our measurements and each country has several opportunities for improvement. For example, all but one country has a national cancer control plan: of eleven plans, nine are over five years old which means that they are not taking account of recent oncological innovations. Often, a country's national lung cancer clinical guidelines lack details regarding fast-tracking suspected patients for diagnosis as well as referral pathways for moving a patient to secondary/tertiary care, supportive/palliative care, shared decision-making, and provision of psychological support in specific time periods. Cancer registries exist in each country, yet clinicians report that clinically-focused cancer registries could provide useful information on patient care. Finally, reimbursement for all four commonly used biomarkers for lung cancer is available in only five countries. **Conclusion:** Significant room for improvement in lung cancer policy exists across all of the countries and domains we have studied. Our country-based workshops have ensured that our research focuses on the most important opportunities for improving the delivery of lung cancer care from the standpoint of each country. We are now entering the policy development phase of our research where our goal is to assist policy-makers to improve care for people living with lung cancer in Europe.

MA24.06 USING GLOBAL DATA AS AN ADVOCACY TOOL – THE GLOBAL LUNG CANCER COALITION'S E-ATLAS OF LUNG CANCER

S. Winstone[1], W. Boerckel[2], M. Rigney[3], J. Fox[4], P. Horton-Fawkes[1]

[1]*Incisive Health Ltd, London/United Kingdom,* [2]*CancerCare, Syosset/United States of America,* [3]*Lung Cancer Alliance, Washington/United States of America,* [4]*Roy Castle Lung Cancer Foundation, Liverpool/United Kingdom*

Background: The Global Lung Cancer Coalition is the international voice of lung cancer patients and is committed to improving disease outcomes for all. The Coalition's work includes activities to support lung cancer advocates in campaigning for actions that will improve research, information, treatment, and care for people living with lung cancer. Significant variations exist both between and within different countries in lung cancer incidence, mortality and survival. Advocates can use evidence of these variations to make the case for legislative, policy or regulatory change. In 2014 the GLCC brought together multiple, comparable, statistical sources about lung cancer's impact and outcomes in different nations in the first Global Lung Cancer E-Atlas. For the first time, national lung cancer data became easily accessible in a single place online. In 2019, a new edition was published incorporating more recent global data, breakdowns by gender and age, and features to make it easier for advocates to use. **Method:** Incidence and mortality data were drawn from GLOBOCAN 2018, which provides estimates, by age and gender, for 185 countries of the world. Survival data were drawn from: CONCORD-2, covering 67 countries; the EUROCARE-5 study, covering 29 European countries; and the International Cancer Benchmarking Partnership (ICBP), comprising Australia, Canada, Denmark, Norway, Sweden and the United Kingdom. The E-Atlas also details whether countries operate a cancer plan, have national cancer registries in place, or have implemented the WHO Framework Convention on Tobacco Control. GLCC members were invited to validate their country's data. Any more recent national data identified was included alongside the data from other sources. **Result:** The Lung Cancer E-Atlas is publicly accessible on the GLCC's website for anyone in the world to use. Data can be compared, turned into graphs and infographics, and shared via social media. It can also be downloaded ready for use in presentations. Clinicians have used the data in presentations to national and regional congresses. Patient advocacy groups are using it to support their engagement with national policymakers and media. **Conclusion:** Feedback from GLCC members confirms that the E-Atlas continues to be an essential resource in their campaigning and advocacy. Policymakers respond positively to being able to see how their country's national data compares to that of other countries. The GLCC is keen to increase the profile of the E-Atlas so that any lung cancer advocate – whether a clinician, patient, carer, researcher, advocacy group or journalist – is aware of it and able to use it. The GLCC is also keen to receive feedback on national data for inclusion or suggestions for further development.

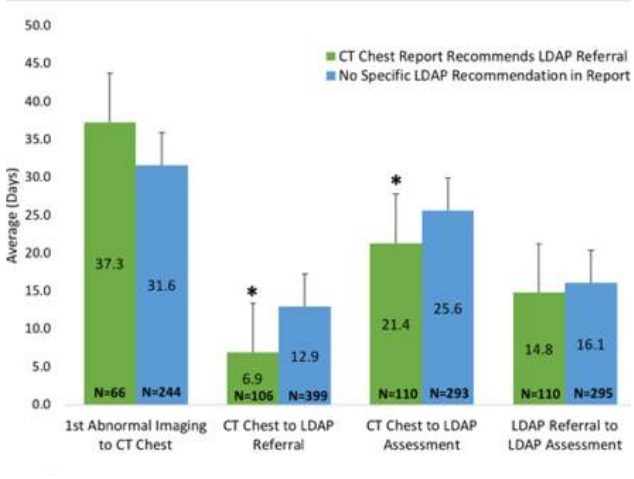
MA24.07 IMPACT OF RADIOLOGIST RECOMMENDATIONS ON TIMELINESS OF LUNG CANCER REFERRAL: BASELINE DATA TO GUIDE A QUALITY IMPROVEMENT INITIATIVE

M. Mullin[1], T. Howard[2], G. Dhillon[2], G. Digby[1,3]

[1]*Internal Medicine, Kingston/Canada,* [2]*Department of Radiology, Kingston/Canada,* [3]*Department of Respirology, Kingston/Canada*

Background: Lung cancer (LC) diagnostic pathways are typically initiated following suspicious radiographic imaging. In southeastern Ontario, Canada, we identified delays from first thoracic imaging suspicious for LC to referral for evaluation at our regional LC rapid assessment clinic, the Lung Diagnostic Assessment Program (LDAP). Given that delays in diagnosis of LC are associated with worse patient outcomes, we sought to characterize local processes to guide Quality Improvement (QI) initiatives. **Method:** We retrospectively reviewed all patients referred to the LDAP between

January and October 2018. Collected data included dates of: first imaging suspicious for LC, first CT chest (if different from first suspicious imaging), LDAP referral, LDAP assessment, and details regarding Radiologist recommendations in the report. Data are reported as mean days (± standard error); unpaired t-tests were used to assess for significance. **Result:** Of 558 patients referred to the LDAP, 509 (91.2%) patients had a CT chest performed prior to LDAP referral. Of these, 110 (21.6%) had a CT chest report issuing a specific Radiologist recommendation for LDAP referral. When such a recommendation was made, time from CT chest to LDAP referral was significantly faster than if no recommendation was made (6.9 versus 12.9 days, p=0.017), as was time from CT Chest to LDAP assessment (21.4 versus 25.6 days, p=0.026). Of all patients with a Radiologist recommended LDAP referral, 38 (34.5%) were not assessed in the LDAP for reasons including: patient followed by the LDAP, a Respirologist, or an Oncologist, inpatient status, or patient refusing assessment. Data are presented in Figure 1.



Conclusion: We identified that a Radiologist recommendation for LDAP referral leads to significantly faster patient referral and assessment for evaluation of suspected LC. A QI initiative is underway, consisting of knowledge sharing and regional standardization of radiologist reporting recommendations for imaging suspicious for LC in order to expedite LDAP referral.

MA24.09 STIGMA IN EARLY STAGE LUNG CANCER

J. Culling, S. Bedard, S. Turner, S. Johnson, J. Pellizzari, E. Bedard

Division of Thoracic Surgery, University of Alberta, Edmonton/Canada

Background: Lung cancer stigma, arising from the causative relationship between smoking and lung cancer, can result in those with a lung cancer diagnosis being seen by themselves and others as responsible for and even deserving of their condition. Lung cancer stigma is linked to adverse outcomes for patients, including decreased quality of life and depression. Most studies have focused on stigma in patients with advanced lung cancer, whose experiences may differ from earlier stage, surgical patients with better prognosis. The objective of this study is to establish a baseline of stigma related experiences for patients presenting with early stage lung cancer. The overarching goal is to assist in determining appropriate interventions to decrease harmful stigma for patients with lung cancer. **Method:** This study is a descriptive cross-sectional design using the 25-item previously validated Lung Cancer Stigma Inventory (LCSI). The LCSI was self-administered by patients with newly diagnosed lung cancer at a tertiary referral thoracic surgical clinic to quantitatively measure their experience of lung cancer stigma. Statistical comparisons were performed with Student's t-test. **Result:** 128 patients were approached to participate and 53 completed the LCSI (response rate= 41.4%), 33 were women. All had resected early stage lung cancer except one patient staged pIIIA (I=41, II=11). 38 patients (71.7%) met the established threshold of a total LCSI score of 37.5, indicating a clinically meaningful level of stigma. Stigma was experienced predominantly on the Internalized Stigma subscale (mean 2.64/5), whereas scores on the Constrained Disclosure and Perceived Stigma subscales were lower (mean 1.84/5, 1.66/5). There was a trend towards higher overall stigma scores in current and former smokers compared to never smokers (mean 53.9 vs 39.8, p=0.12) There was no difference in stigma experience based on gender or stage, surgical approach or use of adjuvant chemotherapy. **Conclusion:** A surgical population of patients with early stage lung cancer experienced lung cancer stigma at a high rate, and at a level similar to previously studied populations with more advanced disease. Respondents experienced more internal stigma than stigma stemming from society or others. Exploratory analysis of this study's results have informed the development of a further study, currently underway, using patient interviews to better understand patients' experiences of lung cancer stigma, which may help to identify potential interventions to decrease lung cancer stigma and its impacts.

MA24.10 ESTIMATION OF DEATHS DUE TO LACK OF ACCESS TO IMMUNOTHERAPY FOR BRAZILIAN PATIENTS DIAGNOSED WITH ADVANCED NSCLC WITHOUT ANY DRIVER MUTATION

V. Goncalves, V. Lorandi, S. Stefani, L. Paludo, R. Piccoli

Hospital Mãe de Deus, Porto Alegre/Brazil

Background: Lung cancer is a major cause of cancer worldwide. Despite efforts to curtail risk factors such as tobacco consumption, it remains both common and lethal. More recently novel targeted therapies and the development of immunotherapy provided a substantial increase in the expected survival of patients diagnosed with advanced lung cancer. Nonetheless, the lack of access to these medications, especially in low and middle-income countries, is a trending concern. Brazil is considered to be a middle-income country and its citizens have access to a universal healthcare system (Sistema Único de Saúde – SUS) – fully funded by the government. Around 75% of the population rely exclusively on this public system when treating their diseases. Many high-cost drugs, such as immunotherapy and TKI's, are not provided due to budget constraints. This study has the goal of estimating the impact in premature lives lost in the Brazilian population due to lack of access to the best currently available therapy for patients with advanced non-small cell lung cancer (NSCLC) without driver mutations. **Method:** Firstly, we searched for data regarding the incidence of lung cancer in the Brazilian population using INCA's (Brazilian National Cancer Institute) database, demographic data from the Brazilian Government and compiled staging and histologic data from different private and public oncologic centers. For analytic reasons, we compared the incidence data with the ones observed in the American Surveillance, Epidemiology, and End Results (SEER). Using survival data from the pivotal phase 3 studies for immunotherapy in NSCLC (PACIFIC, Keynote 189 and 407) we estimated the expected total number of patients alive one year after diagnosed with stage III or IV NSCLC (excluding those with driver mutations) considering they had received the best treatment available according to the NCCN guidelines. This number was compared with the expected survival for patients receiving the standard treatment in the Brazilian SUS (chemoradiation followed by observation for stage III NSCLC and palliative Carboplatin + Paclitaxel for stage IV NSCLC without driver mutations). **Result:** After compiling all data of interest, we estimated that 2.332 premature deaths would occur in Brazilian patients with advanced NSCLC one year after diagnosis, exclusively due to lack of access to immunotherapy. Comparing Brazilian incidence data with the American data from SEER, this number may actually be underestimated and can reach up to 11.193 premature deaths in a single year. **Conclusion:** The lack of access to immunotherapy is a major concern for countries in development and this can lead to an enormous impact on survival of patients with lung cancer. Further studies are needed to best estimate the economic impact and provide data to help decide when to adopt new technologies and drugs to treat these patients. Strategies may rapidly be implemented in order to avoid further unnecessary premature deaths of NSCLC patients.

MA24.11 A PROJECT TO CONTROL PASSIVE SMOKING BY LUNG CANCER PATIENTS "DON'T SMOKE NEAR ME! DON'T BE LIKE ME!"

K. Hasegawa[1], H. Saito[2], F. Miyake[3], C. Nakamura[3], Y. Tanaka[3], T. Ito[3], S. Inaba[3], C. Endo[3], K. Onishi[3], M. Onishi[3], N. Kishimoto[3], Y. Komatsu[3], I. Tanaka[3], M. Tanaka[3], T. Hatsuda[3]

[1]*Japan Lung Cancer Alliance, Japan/Japan,* [2]*Teikyo University Graduate School of Public Health, Tokyo/Japan,* [3]*Japan Lung Cancer Alliance, YOKOHAMA/Japan*

Background: According to a survey of patient group members (n = 215, 2017), 31% of lung cancer patients who continue to work were exposed to passive smoking at workplaces. Once Japanese tobacco industry used to be a national monopoly, so Japan is one of the countries where a ban on indoor smoking has not been realized. Although education on smoke prevention in elementary and junior high schools tells the fact that smoking is one of the risks for lung cancer, it is unknown that lung cancer patients are living frightened of cancer relapse, especially with the fear of being exposed of passive smoking. Lung cancer patients encourage highly dependent smokers who cannot stop smoking despite they have colleagues or families suffering from lung cancer to visit smoking cessation clinics. **Method:** Intervention to close persons is difficult. In order to overcome the difficulties, we select ambassadors from each patient group. Then we provide training on education, action guidelines and tool development, have them participate in tool development, and have them become mentors when scaling up. The state of the activity is published on the Internet, and we spread media interview invitations in parallel. We let families, colleagues, community members, professionals, medical professionals, media and politicians know that lung cancer patients are frightened of passive smoking. The activities already done are as follows. -Granted Global Bridge grant of tobacco control personnel development department in Mayo Clinic, USA • Ambassador briefing session was held twice. (Kobe and Tokyo) • Selected 13 ambassadors from 11 lung cancer patient group and held 5 workshops. • Planned communication strategies • Communication tactics currently developing **Result:** [Activity (project) evaluation] • Won 13 ambassadors from all over Japan • No withdrawal of the ambassador • One of the ambassadors changed job to be in charge of tobacco control in a public administration. • One of the ambassadors was appointed as a member of patient information evaluation committee of National Cancer Center Japan. **Conclusion:** [Future plans] • Completion of Tool • Hold briefing session to member in each patient group • Campaign implementation • Campaign evaluation

Background: Randomized studies have demonstrated that pembrolizumab plus chemotherapy improves OS, PFS, and ORR compared with chemotherapy alone in patients with advanced NSCLC regardless of tumor PD-L1 expression level. We present a post hoc pooled analysis of pembrolizumab plus chemotherapy versus chemotherapy alone in patients with advanced NSCLC and no PD-L1 expression (ie, TPS <1%), representing an area of unmet need. **Method:** Patients enrolled in KEYNOTE-021 cohort G (nonsquamous; NCT02039674), KEYNOTE-189 (nonsquamous; NCT02578680), and KEYNOTE-407 (squamous; NCT02775435) were included. Patients with nonsquamous NSCLC were randomized to pemetrexed-platinum with or without pembrolizumab; those with squamous NSCLC were randomized to carboplatin-paclitaxel/nab-paclitaxel with or without pembrolizumab. OS, PFS, and ORR were evaluated for the pooled intent-to-treat population. Response was assessed per RECIST v1.1 by blinded independent central review. Across studies, PD-L1 expression was assessed centrally using PD-L1 IHC 22C3 pharmDx assay (Agilent Technologies, Carpinteria, CA). Analyses were descriptive. **Result:** Of 1298 patients enrolled across the 3 trials, 428 (33%) had PD-L1 TPS <1% (pembrolizumab plus chemotherapy, n=243; chemotherapy alone, n=185) and were included in this analysis. 52% had nonsquamous histology, 63% had ECOG PS of 1. Median (range) follow-up at data cutoff was 10.2 (0.1-34.9) months. OS, PFS, and ORR were improved with pembrolizumab plus chemotherapy versus chemotherapy alone (Table). Grade ≥3 AEs (all-cause) occurred in 68% of patients receiving pembrolizumab plus chemotherapy versus 72% receiving chemotherapy alone. Immune-mediated AEs and infusion reactions occurred in 26% who received pembrolizumab plus chemotherapy versus 12% who received chemotherapy alone.

	Pembrolizumab + Chemotherapy n=243	Chemotherapy Alone n=185
Median (95% CI) OS, mo	19.0 (15.2–24.0)	11.0 (9.2–13.5)
Hazard ratio (95% CI)	0.56 (0.43–0.73)	
Median (95% CI) PFS, mo	6.5 (6.2–8.5)	5.4 (4.7–6.2)
Hazard ratio (95% CI)	0.67 (0.54–0.84)	
ORR, % (95% CI)	46.9% (40.5%–53.4%)	28.6% (22.3%–35.7%)
Difference (95% CI)	18.3% (9.0%–27.1%)	

Conclusion: Our results highlight the clinically meaningful efficacy benefit and acceptable safety profile of pembrolizumab plus chemotherapy versus chemotherapy alone in patients with advanced NSCLC and no PD-L1 expression. Benefit was consistent with that observed in the overall study populations, suggesting pembrolizumab plus chemotherapy should be considered standard-of-care first-line therapy for all patients with NSCLC, irrespective of PD-L1 expression.

MA25.02 ARRANGEMENT AND ARCHITECTURE OF TUMOR-INFILTRATING LYMPHOCYTE ON H&E SLIDES PREDICT OS IN NIVOLUMAB TREATED NON-SMALL CELL LUNG CANCER

X. Wang[1], C. Barrera[1], K. Bera[1], C. Lu[1], M. Feldman[1], K. Schalper[2], D. Rimm[2], V. Velcheti[3], A. Madabhushi[1]

[1]*Case Western Reserve University, Cleveland/United States of America,* [2]*Yale University School of Medicine, New Haven/United States of America,* [3]*NYU Langone, Perlmutter Cancer Center, New York/United States of America*

Background: Immune checkpoint inhibitors (ICI) are a promising and novel approach to treating chemotherapy refractory advanced NSCLC as well as first-line combination therapy in certain NSCLC. Nivolumab, a PD-L1 inhibitor is a promising ICI showing durable benefit with low toxicity in these patients. While PD-L1 positivity is an established tissue based biomarker for response to Nivolumab, studies have shown response rates ranging from 20-50%. Recent research has shown that TILs have been implicated in cancer aggressiveness as well as immune response. In this work, we go beyond simply counting TILs, and apply novel computer-extracted features characterizing the interaction and spatial co-localization of

TILs and cancer nuclei (SpaTIL) in stratifying patients based on OS following nivolumab therapy. **Method:** H&E tissue slides obtained from pre-treatment biopsies of 96 NSCLC patients treated with nivolumab were digitized and included for this study from 3 different institutions with the tumor region annotated by pathologists. Then 85 SpaTIL features related to TIL density, architecture and co-localization with tumor cells have been extracted to represent each patient. The most discriminative and uncorrelated features were selected by Elastic-Net regularized Cox-regression model to predict OS. The model was trained on D1 (n=25) and independently validated in D2 (n=32) and D3 (n=64). Multivariate analysis with clinico-pathologic factors was also performed. **Result:** The top features consisted of the abundance of TILs around tumor cells and the distribution of the TILs. On the validation set, SpaTIL classifier yielded a HR=3.03 (95%CI=1.1 -8.35; p=0.042) on D2 and HR=4.12 (95%CI=1.87-9.09; p=0.02) on D3 by a log-rank test. On multivariate analysis with stage, smoking, histologic type, total lymphocyte count (See Table 1) SpaTIL was independently prognostic of OS (HR=7.88; 95%CI=1.66 – 37.216; p=0.009).

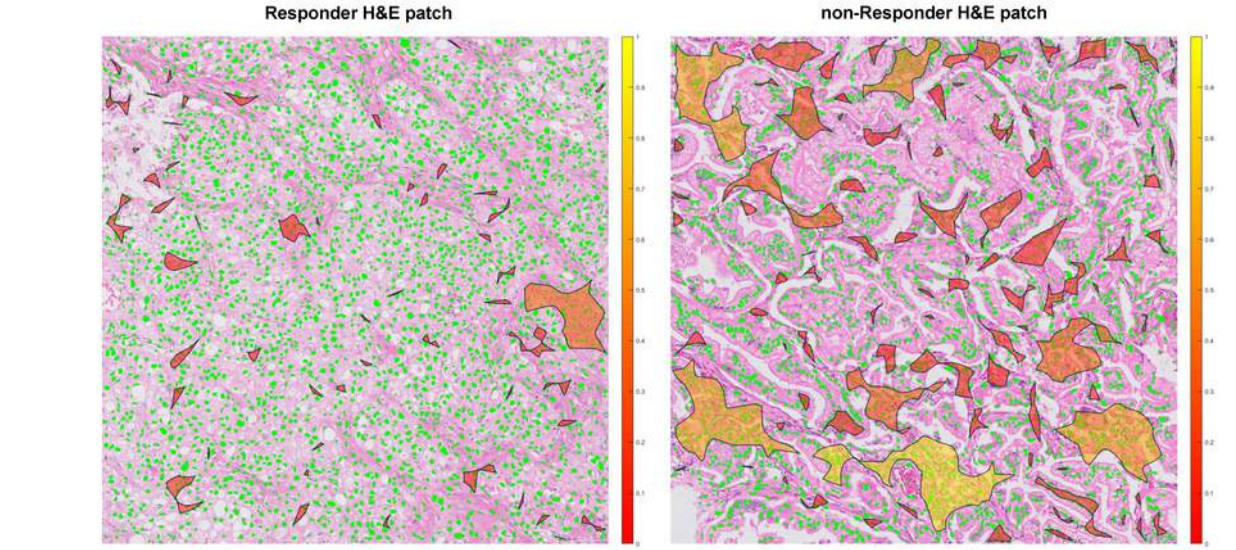

Table 1. Multivariate analysis for overall survival on the validation sets D2 and D3

Variables	HR(95% CI)	*p* value
Age (>65 vs <=65 yrs)	0.99(0.97-1.03)	0.67
Gender (Male vs Female)	1.05(0.75-2.79)	0.88
Smoking Status (Former vs Never smoker)	3.19(0.92-11.061)	0.07
Histological Subtypes (Adeno vs Squamous)1	1.06(0.13-8.54)	0.95
EGFR status	1.32(0.49-3.52)	0.58
ALK status	0.63(0.36-1.10)	0.10
Total lymphocyte count	0.99(0.99-1.00)	0.33
SpaTIL Classifier	7.88(1.66-37.216)	0.009

CI = confidence interval; HR = Mantel-Haenszel Hazard ratio. Values in bold are statistically significant, p<=0.05.

Conclusion: Spatial interaction of TILs and cancer are independently prognostic of OS in nivolumab treated NSCLC. Further validation needs to be done to evaluate its utility.

Keywords: predictive image signatures, TILs, response to immunotherapy

MA25.03 TUMOR-INFILTRATING LYMPHOCYTES (TIL) AND OUTCOMES WITH IMMUNOTHERAPY (ICI) OR CHEMOTHERAPY IN ADVANCED NSCLC (ANSCLC) PATIENTS

L. Mezquita[1], I. Gataa[1], C. Rossoni[1], E. Auclin[1], M. Kossai[1], F. Aboubakar[1], S. Le Moulec[2], J. Massé[2], M. Masson[3], N. Radosevic-Robin[3], M. Rouanne[1], M. Bluthgen[1], C. Caramella[1], L. Hendriks[1], A. Gazzah[1], D. Planchard[1], J.-P. Pignon[1], B. Besse[4], J. Adam[1]

[1]*Gustave Roussy, Villejuif/France,* [2]*Institut Bergonié, Bordeaux/France,* [3]*Centre Jean Perrin, Clermont-Ferrand/France,* [4]*Institut Gustave Roussy, Villejuif/France*

Background: Tumor infiltrating lymphocytes (TIL) morphologically assessed is prognostic in early stages in several tumors. We previously reported the correlation of TIL with immune checkpoint inhibitors (ICI) outcomes in 98 advanced (a) NSCLC patients treated with ICI. We aimed to assess the role of TIL in a larger cohort treated with ICI, and in patients exclusively treated with chemotherapy (CT). **Method:** aNSCLC patients with treated with single-agent ICI, with H&E stained sample available, were included between 11/2012 and 02/2017 in 3 cancer centers (immuno-cohort). Patient's characteristics, biological data were retrospectively collected. The CT-cohort was extracted from the prospective MSN study (NCT02105168), between 06/2009 and 10/2016, enrolling aNSCLC patients treated with platinum-based CT, and tissue available. TIL in the stroma was evaluated in archival samples. High-TIL was defined as ≥10% density. Multivariate Cox model was used to study its prognostic values on overall and progression-free survival (OS, PFS). **Result:** A total of 221 patients were included in the immuno-cohort: 142 (64%) male, with median (m) age of 63, 182 (84%) smokers, 161 (77%) PS≤1, 162 (63%) adenocarcinoma; 125 (57%) received ICI as second-line. High-TIL was observed in 49/221 (28%), non-assessable in 46. High-TIL had independent impact on OS and PFS (HR 0.40; 95% CI 0.25-0.63, *P*<0.0001). The mPFS and OS were 3.1months (mo.) (2.5-4.9) and 11mo. (7.0-13.2) respectively. The high-TIL group had mPFS of 13mo. (5.0-NR) vs. 2.2mo. (1.7-3.0) in low-TIL group (*P*<0.0001). High-TIL group had mOS not reached (NR) (12.2-NR) vs. 8.4 mo. (5.0-11.6) in low-TIL (*P*=0.007). The CT-cohort (N=189) had high-TIL in 103/189 (54%). The mPFS and mOS were 5.7mo. (4.9-6.7) and 11.7mo. (9.3-13.0) respectively, with no association with TIL.

	OS, Immuno-cohort (n=221)		OS, Chemo-cohort (n=188)	
	Hazard ratio (HR) 95% confidence interval (CI)	P-value	HR 95% CI	P-value
TIL ≥10% (high)	0.46 (0.28-0.81)	0.006	1.03 (0.76-1.41)	0.84
Age ≥65 y	0.86 (0.50-1.46)	0.57	0.99 (0.72-1.38)	0.99
Line of treatment* ≥ second line	0.69 (0.44-1.09)	0.11	0.84 (0.60-1.16)	0.29
N# metastatic sites >2	1.40 (0.88-2.20)	0.16	1.50 (1.07-2.12)	0.02
Performance status ≥2	2.75 (1.73-4.37)	<0.0001	1.94 (1.23-3.04)	0.004
Histology Squamous	1.13 (0.70-1.81)	0.62	1.09 (0.65-1.83)	0.75

*Line of treatment: lines of immunotherapy for the Immuno-cohort; lines of chemotherapy for the Chemo-cohort.

Conclusion: High-TIL (≥10%) is a simple and accessible marker associated with better ICI outcomes, but not with CT. This suggests a potential predictive value that must be validated in larger prospectively studies.

MA25.04 BLOOD-BASED TUMOR MUTATION BURDEN AS A PREDICTIVE BIOMARKER FOR OUTCOMES AFTER PEMBROLIZUMAB BASED FIRST LINE THERAPY IN METASTATIC NSCLC

C. Aggarwal[1], J. Thompson[1], A. Chien[1], K. Quinn[2], M. Lefterova[2], R. Nagy[2], S. Yee[1], M. Lariviere[1], C. Ciunci[1], A. Singh[1], J. Bauml[1], R. Cohen[1], C. Langer[1], E. Carpenter[1]

[1]*University of Pennsylvania, Philadelphia/United States of America,* [2]*Guardant Health, Redwood City/United States of America*

Background: PD-1 blockade with pembrolizumab (P) as monotherapy in patients with PD-L1 TPS ≥ 50% or in combination with platinum based chemotherapy (PC) is the current standard front-line therapy for metastatic non-small cell lung cancer (mNSCLC). We explored the correlation of blood (b) based tumor mutational burden (TMB) using circulating tumor DNA (ctDNA) with outcomes after front line P and PC therapy. **Method:** Patients with newly diagnosed metastatic NSCLC starting standard of care front line P-based therapy were enrolled. Plasma was prospectively collected at baseline prior to initiation of P or PC therapy for mNSCLC. A 2.145 megabase (Mb) next-generation sequencing panel was used to assess bTMB. A bTMB cutoff of ≥16 mut/Mb was selected based on previously published data (*Gandara et al, Nature 2018*). Response was assessed using RECIST 1.1. Durable clinical benefit (DCB) was defined as complete response/ partial response/ stable disease that lasted > 6 months. Correlations were made for patient demographics, tumor characteristics, DCB, progression free survival (PFS), and overall survival (OS) using logistic regression and Cox proportional hazards models. Significance was determined at the 0.05 level. **Result:** 66 pts with mNSCLC were enrolled, median age 67 years (range 47-89), current or ex-smokers (n=61, 92%). Thirty-one patients (47%) received P (all PD-L1>50%); 35 received platinum-pemetrexed based PC. At the time of data cut off, median OS for P was 14.8 months, and not reached for PC. bTMB was evaluable for 52 patients (n=26 P, 26 PC), median bTMB was 16.8 mutations per Mb (mut/Mb, range 1.9-52.5). There was no correlation between bTMB and tumor PD-L1 (p=0.28). Median bTMB for patients achieving DCB was higher than for those with no clinical benefit, 21.3 mut/Mb vs. 12.4 mut/Mb, p=0.004. For patients with bTMB ≥ 16 mut/Mb, median PFS was 13.8 vs. 4.7 months for patients with bTMB <16 mut/Mb (HR 0.27 [0.13-0.55]). Median OS was not reached for bTMB ≥ 16 mut/Mb (HR 0.47 [0.20-1.1]). Loss of function mutations in *STK11, KEAP1,* or *PTEN,* or *ERBB2* exon 20 insertion were enriched in patients with no clinical benefit. Combined score using bTMB ≥ 16 mut/Mb and mutations in *STK11, KEAP1,* or *PTEN,* or *ERBB2* exon 20 insertions resulted in improved prediction for DCB; PFS HR of 0.18 [0.08-0.41] and OS HR of 0.27 [0.10-0.73]. **Conclusion:** Our early results suggest that bTMB using plasma ctDNA may predict therapeutic outcomes after first line P-based therapy in mNSCLC. Loss of function mutations in *STK11/KEAP/PTEN* and *ERBB2* exon 20 insertion mutations appear to be negative predictors of benefit. As the sample size is limited and findings are reported on a pooled group of P and PC patients, the role of bTMB and response to P and PC based therapy separately should be validated in a larger prospective study.

Keywords: Blood based TMB, pembrolizumab, chemo-immunotherapy

MA25.07 GENOMIC PROFILING OF LUNG ADENOCARCINOMA BY TARGETED NGS USING EXTRACELLULAR VESICLE-DERIVED DNA IN BRONCHOALVEOLAR LAVAGE FLUID

S. Lee[1], K.Y. Lee[2], J.Y. Hur[3], H. Kim[3], W.S. Kim[3], I.A. Kim[2], H.Y. Park[4]

[1]*Konkuk University Medical Center, Konkuk University School of Medicine, Seoul, seoul/Korea, Republic of,* [2]*Konkuk University Medical Center, Seoul/Korea, Republic of,* [3]*Konkuk University School of Medicine, Seoul/Korea, Republic of,* [4]*Busan Paik Hospital, Inje University College of Medicine, Busan/Korea, Republic of*

Background: Extracellular vesicles (EV) are membrane-bound and nanometer-sized particles shed from most types of cells in our body and found in circulation, containing double-stranded genomic DNA reflecting mutational status of the parental tumor cells. Recently, we demonstrated that EVs successfully isolated from bronchoalveolar lavage fluid (BALF) in non-small cell lung cancer (NSCLC) patients. Several studies also have shown that EV-derived DNA is superior to cfDNA in plasma for detection of mutations in NSCLC and pancreatic cancer. We identified that liquid biopsy for *EGFR* genotyping using EV-derived DNA in BALF showed almost 100% sensitivity with tissue typing in advanced NSCLC patients. Therefore, we hypothesized that targeted next–generation sequencing (NGS) using EV-derived DNA in BALF may correlate with results using tissue in patients with *EGFR*-mutated lung adenocarcinoma. **Method:** To address this hypothesis, we compared with the targeted NGS profile using between BALF EV-derived DNA and tissue DNA in 20 patients with *EGFR*-mutated lung adenocarcinoma. Four types of somatic variants (SNVs, small indels, CNVs and gene fusions) of BALF-EV or FFPE tissue samples were analyzed by CancerSCAN™, a capture-based targeted sequencing platform, which targets 375 genes covering about 2.5-megabase genomic regions including full CDSs of 374 genes, selected intronic regions of 23 genes for fusion detection, and 1kb *TERT* promoter region. **Result:** Targeted sequencing resulted in over 99% of the target regions covered at a mean depth of 190-750× except one sample. DNA yields were higher in tissue DNA than EV-derived DNA (827.02ng vs 89.10ng). Depth of coverage (753x vs 379x) and estimated tumor purity (53% vs 23%) were also higher in tissue DNA than EV-derived DNA. However, estimated library size was not significantly different between tissue DNA and EV-derived DNA (50G vs 47G) and fragment size of DNA were longer in EV-derived DNA than tissue DNA (175.5bp vs 169.5bp). These findings support that EV-derived DNA has sufficient quality and quantity for NGS. By using mutations detected in tissue DNA as a reference, we achieved 83% sensitivity for somatic and clinically significant variants in EV-derived DNA. Clinically significant mutations in *EGFR*, *TP53*, *PTEN*, *APC*, JAK3 and PIK3CA were identified with an overall concordance of 81% in matched tissue DNA and EV-derived DNA. Variants in *EGFR* and *TP53* were most common, with concordance of 80% and 100%, respectively. Variant allele frequencies of *EGFR* and *TP53* were most abundant in range of 10-25% in tissue DNA, while much lower (<5%) in EV-derived DNA. Tumor mutation burdens (TMB) of EV-derived DNA showed correlation with tissue DNA (R^2=0.21). **Conclusion:** To our knowledge, this is the first of study of comprehensive clinical NGS panel using EV-derived DNA of BALF and matched tumor tissue biopsies in patients with lung adenocarcinoma. Although EV-derived DNA demonstrated comparable results to tissue DNA, it is needed much higher sequencing coverage and optimization of NGS-pipeline to detect low-allele frequency variants of EV-derived DNA. This study demonstrates the feasibility and clinical utility of BALF EV-derived DNA for patients with lung adenocarcinoma.

MA25.08 CHARACTERISATION OF TUMOR AETIOLOGY USING MUTATIONAL SIGNATURES FROM THE NON-SMALL CELL LUNG CANCER GENOME

C. Lindsay[1], S. Rafee[1], P. Nicola[1], A. Wallace[2], G. Burghel[2], H. Schlecht[2], K. Baker[1], E. Baker[2], L. Priest[1], J. Rogan[3], S. Moghadam[3], M. Carter[1], W. Newman[2], F. Blackhall[1]

[1]*The Christie NHS Foundation Trust, Manchester/United Kingdom,* [2]*Manchester Centre for Genomic Medicine, Manchester/United Kingdom,* [3]*Manchester Cancer Research Centre Biobank, Manchester/United Kingdom*

Background: Somatic genome and exome analyses in cancer are currently dominated by a search for actionable mutations that inform new treatments for stage IV patients. Tumour mutational signatures, originally described by the Sanger centre, offer the potential to understand cancer cure and prevention strategies by using the genome/exome to define aetiological contributions to cancer from both environmental and endogenous sources. **Method:** 132 NSCLC samples were resected from 131 Greater Manchester patients and submitted to the UK 100,000 Genomes Project (Genomics England). A 5×5×5 mm fresh tumour sample was taken from the surgical specimen and stored at -80°C before undergoing genomic testing. To determine the neoplastic cell count, an additional tumour biopsy was taken for routine histological assessment. Germline DNA for comparable whole genome analysis was extracted from peripheral blood lymphocytes from a paired whole blood sample.Whole genome sequencing (WGS) was performed on tumor specimens and matched blood samples. Through the 100,000 Genomes Project pipeline, coverage was calculated from high-quality, non-overlapping bases present on well-mapped reads, as defined by SAMtools v1.1. Whole genome sequencing analysis was undertaken with the Illumina North Star pipeline v2.6.53.23. Data were then mined for tumour mutational burden (TMB) and mutational signature profiles. Signatures were extracted if they accounted for >5% of the mutations per sample. Clinical characteristics including tumor size, nodal status and stage were documented. Mann-Whitney and Fisher's exact tests were used for statistical comparisons. **Result:** Signature 8 (unknown aetiology) was the most prevalent mutational process overall (122/132 samples, 92.4%), while smoking signature 4 was the main mutational process in 86/131 (65.6%) of NSCLC cases. SIgnature 4 contributed as a principal or secondary mutational process to a total of 105/131 (80.2%) cancers; 104/105 (99%) of these patients were annotated as smokers or ex-smokers. Signature 5 (unknown aetiology) was the second most common driving signature (24/131, 18.3% cancers), contributing to an additional 19 cancers as a secondary mutational process (43/131, 32.8% of cancers overall). Median number of signatures contributing to signature 4 NSCLC was four, whilst non-smoking mediated NSCLC had contributions from a median of 5.5 mutational signatures (range 2-8). A median of four signatures contributed to both adenocarcinomas and squamous cancers, with 61/88 (69.3%) adenocarcinomas and 25/41 (61%) squamous cancers associated with signature 4 as their main mutational process. More results will follow on duration of signature 4 persistence following discontinuation of smoking, as well as prevalence of each signature according to common molecular subtypes of NSCLC. **Conclusion:** Tumor mutational signatures have the potential to inform cancer prevention by offering a new level of genetic detail that reflects environmental and endogenous carcinogenesis. As expected, signature 4 offers the main contribution to NSCLC although a number of other aetiological factors are involved in its carcinogenesis. In particular, signatures 5 and 8, both currently of unknown aetiology, significantly contribute to the NSCLC genome. Along with that reported by the Sanger centre, this work lays the foundations for characterisation and identification of new carcinogens.

Background: Anlotinib is an oral multi-targeted anti-angiogenic drug, and its clinical predictor for non-small cell lung cancer (NSCLC) patients is still elusive. The aim of this study is to screen predictor for anlotinib via non-invasive genetic profiling of plasma cell free DNA and circulating tumor DNA (cfDNA & ctDNA). **Method:** Tumor-specific target capture to profile the circulating DNA of ALTER0303 (Evaluating NSCLC clinical anti-tumor efficacy through anlotinib therapy) study participants. Acquired mutations were screened out via comparing genetic profiling between baseline (BL) and progression disease (PD), and were used for anlotinib stratification. Based on the sequencing data at BL, tumor mutation index (TMI) was established from three independent predictors germline and somatic mutation burden (G+S MB), nonsynonymous and synonymous mutation burden (N+S MB) and unfavorable mutation score (UMS), and was used for predicting anlotinib responders. In addition, TMI combined with *IDH1*^{Exon4} mutation status also be examined for serving as predictor for anlotinib stratification. **Result:** Our data firstly indicated no benefit (NB, PFS $\leq$ 45 days) patients can be mainly excluded via analysis of *ARID1A* and *BRCA2* genetic profiling. Secondly, for the no durable benefit (NDB, 45 days < PFS $\leq$ 130 days) and durable clinical benefit (DCB, PFS > 130 days) patients, harboring lower mutation burden (G+S MB, N+S MB, and UMS) received more benefit from anlotinib therapy. Subsequently, we found the predictor-TMI can predict anlotinib responders upon discovery cohort (Median PFS: 210 days vs 126 days; p = 0.0238; AUC = 0.77), and validation cohort (Median PFS: 210 days vs 127 days; p = 0.0352) and all patients (Median PFS: 210 days vs 127 days; p = 0.0044) more effectively. Furthermore, the *IDH1*^{Exon4} mutation was identified as an unfavorable factor to anlotinib therapy under TMI-based stratification. Lastly, the TMI plus *IDH1*^{Exon4} mutation status predict response to anlotinib significantly (Median PFS: 210 days vs 127 days, p < 0.0001, AUC = 0.90; Median OS: 423 days vs 162 days, p < 0.0001, AUC = 0.80). **Conclusion:** This study provides circulating DNA sequencing-based stratification for underlying anlotinib responders via non-invasive approach, and thus potentially improve clinical outcome for NSCLC patients at 3rd line.

P1.01-01 CLINICAL RELEVANCE OF TARGETING PROTEINS REQUIRED FOR MITOTIC PROGRESSION TO IMPROVE CHEMOTHERAPY RESPONSE IN NON-SMALL CELL LUNG CANCER

M. Adams, J. Burgess, D. Richard, K. O'Byrne

Institute of Health and Biomedical Innovation, Queensland University of Technology Translational Research Institute, Woolloongabba/Australia

Background: Lung cancer is the leading cause of cancer-related mortality worldwide with a ~14% 5-year survival rate. Patients with non-small cell lung cancer (NSCLC), may undergo surgery followed by platinum-based chemotherapy for resectable disease, chemoradiotherapy for locally advanced disease, systemic treatment for advanced disease and palliative care. The primary issue with chemotherapy is that only 20-40% of patients have responsive disease. Although combinations with immunotherapy can enhance drug response in advanced disease, new strategies are needed to (1) identify which patients are most likely to benefit from platinum based therapy and (2) enhance the effectiveness of the current drug strategies. Herein we describe cell division cycle associated protein-3 (CDCA3) and CDCA8 as a novel prognostic factors and therapeutic targets to delay or prevent platinum resistance in NSCLC. Both CDCA3 and CDCA8 are key regulators of the cell cycle mediating mitotic entry and progression. CDCA3 functions to enable cell entry into mitosis through degradation of the mitosis inhibitory factor WEE1. Whereas, CDCA8 promotes mitotic progression functioning in concert with the chromosomal passenger complex to ensure accurate chromosomal segregation. **Method:** Tissue microarray (TMA), immunohistochemistry, Bioinformatics, Western blot, siRNA library, CRISPR-Cas9 knockout, cell viability, mass spectrometry. **Result:** Our preliminary data point to CDCA3 and CDCA8 as novel therapeutic options in NSCLC. CDCA3 and CDCA8 protein are markedly elevated in NSCLC cases with heterogeneous staining associated with Ki67+ cases and strongly prognostic in adenocarcinoma cases. Bioinformatics analysis of clinical trial data (UT Lung SPORE cohort; observation arm vs adjunct chemotherapy arm) indicated that NSCLC patients with elevated CDCA3 and CDCA8 and treated with adjuvant chemotherapy had a poorer outcome than $CDCA3^{low}$/$CDCA8^{low}$ patients. Accordingly, *in vitro* analysis of CDCA3 and CDCA8 expression in NSCLC cell lines identified a strong correlation with cisplatin sensitivity whereby $CDCA3/CDCA8^{high}$ cell lines have greater cisplatin IC50 values. Consistently, silencing of either CDCA3 or CDCA8 significantly enhanced cisplatin sensitivity. As a means to reduce either CDCA3 or CDCA8 levels in tumours, we identified that, for CDCA3 in particular, cisplatin induces phosphorylation of CDCA3 (Ser222) which is dependent upon casein kinase 2 (CK2). Inhibition of CK2 with the small molecule CX-4945 (Senhwa Biosciences) abrogated CDCA3 phosphorylation and consequently suppressed CDCA3 levels. CK2 inhibition also suppressed CDCA8 levels whereby CDCA8 protein stability is dependent upon CDCA3. The sensitivity of cisplatin was enhanced by CX-4945 across a panel of 11 NSCLC cell lines, particularly in $CDCA3/CDCA8^{low}$ cell lines. Cisplatin efficacy was further enhanced in CDCA3 or CDCA8 depleted NSCLC cells. **Conclusion:** Our data highlight CDCA3 and CDCA8 as novel factors mediating NSCLC cell proliferation and sensitivity to cisplatin. Our data also suggest that novel strategies to suppress CDCA3/CDCA8 protein levels, using agents such as CX-4945, might ultimately benefit NSCLC patient outcome by delaying or preventing cisplatin resistance.

P1.01-02 PEMETREXED-CARBOPLATIN VERSUS PACLITAXEL (WEEKLY)-CARBOPLATIN AS FIRST LINE CHEMOTHERAPY IN ADVANCED NON-SQUAMOUS NSCLC

P. Malik, A. Yadav, D. Jain, S. Pathy, A. Mohan, S. Khurana, S. Kumar

All India Institute of Medical Sciences, New Delhi/India

Background: Platinum doublet chemotherapy has been standard of care in treatment naïve advanced non-small cell lung cancer (NSCLC) without targetable driver mutation until recent approvals of first line immune check point inhibitors. Pemetrexed-platinum combination has been preferred over other combinations in non-squamous NSCLC (ns-NSCLC). However there has been no direct comparison to Paclitaxel-carboplatin. **Method:** This open label randomized control trial was designed to compare Pemetrexed-Carboplatin versus Paclitaxel (weekly)-Carboplatin combination in treatment naive advanced/metastatic ns-NSCLC without driver mutations and ECOG PS 0-2. The study was powered to detect superiority of Pemerexed-Carboplatin over Paclitaxel-Carboplatin by 15% in terms of 6 months PFS rates (primary outcome) and total 182 events were required for the same. Patients received either Pemetrexed 500 mg/m2 and Carboplatin AUC 5 every 3 weekly cycle for 4 cycles (with standard vitamin supplementation) or Paclitaxel 80 mg/m2 day 1, day 8 and day 15 with Carboplatin AUC 5 every 4 weekly cycles for 4 cycles. Patients in both arms were allowed to receive Pemetrexed maintenance in absence of progressive disease after 4 cycles. Patients, in whom EGFR mutation or ALK rearrangement were detected after randomization, were allowed to receive appropriate targeted therapy after 4 cycles or earlier as per physician's discretion. The trial was approved by institute ethics committee and registered with CTRI (CTRI/2016/12/007605). **Result:** A total of 180 patients were enrolled between April 2016 and January 2019. The study was terminated early due to slow accrual, however at the time of analysis (31stMarch 2019) total 129 events (70.8% of required) had occurred. Finally, 164 patients were evaluable, 83 in Pemetrexed-Carboplatin arm and 81 in Pacitaxel-Carboplatin arm. After a median follow up time of 15 months, PFS rates at 6 months were not different in two treatment arms (43.3% vs 43.2%; p=0.98). Median PFS were 5.63 months (95%CI 3.73-7.3) in Pemetrexed-Carboplatin arm and 5.03 months (95%CI 2.63-7.43) in Paclitaxel-Carboplatin arm (p=0.61; HR 1.09(95%CI 0.77-1.54). Median overall survival wasn't different, 13.4 months (95%CI 8.6-17.63) and 10.13 (95%CI 7.6-19.7) respectively (p=0.11; HR 1.07(95%CI 0.71-1.61). All grade toxicities were similar except for alopecia and peripheral neuropathy, which were significantly higher in the Paclitaxel arm.

Baseline Characteristics of the patients

Characteristics	Pemetrexed arm N (%)=83	Paclitaxel arm N(%)= 81	p
Median Age	52 years (29-65)	52 years (28-65)	0.6
Gender Males Females	56 (67.47%) 27 (32.5%)	58 (71.6%) 23 (28.4%)	0.61
Smoking Status Non smokers Smokers	45 (54.22%) 38 (45.78%)	39 (48.15%) 42 (51.85%)	0.5
ECOG PS 0 1 2	9 (10.84%) 51 (61.45%) 23 (27.71%)	3 (3.7%) 57 (70.37%) 21 (25.9%)	0.18
Histology Adenocarcinoma NSCLC- NOS	83 (100%) 0	76 (95%) 4 (5%)	0.039
EGFR mutation Positive Negative Not available	20 (24.39%) 47 (57.32%) 16 (19.2%)	18 (22.2%) 48 (59.26%) 15 (18.52%)	0.94
ALK rearrangement Positive Negative Not available	08 (9.76%) 50 (60.98%) 25 (30.12%)	07 (8.64%) 50 (61.73%) 24 (29.61%)	0.66
Stage (AJCC 7th) Stage 3B Stage 4	02 (2.41%) 81 (97.59%)	03 (3.7%) 78 (96.3%)	0.59
Pleural/Pericardial Effusion Present Absent	32 (38.55%) 51 (61.45%)	27 (33.33%) 54 (66.67%)	0.48
Brain metastasis Present Absent/ Not evaluated	16 (19.28%) 67 (80.7%)	16 (19.75%) 65 (80.2%)	0.93

Conclusion: Pemetrexed-Carboplatin is not superior to Paclitaxel (weekly) -Carboplatin as first-line regimen in advanced ns-NSCLC in terms of 6 months PFS rates.

Background: QL1101 is a biosimilar molecule of bevacizumab (BEV, Avastin®), a monoclonal antibody (mAb) that binds and inhibits vascular endothelial growth factor (VEGF).The main purpose of the study is to evaluate whether the effectiveness of QL1101 is bioequivalent to that of Avastin®, and the secondary purpose is to evaluate the bioequivalence on safety and immunogenicity between QL1101 and Avastin®. **Method:** Total 512 patients with locally metastatic or recurrent non-squamous cell non-small cell lung cancer were planned to recruit in the study (NCT03169335). The patients were divided into QL1101 (test group) or Avastin® (control group) at 1:1 ratio in combination respectively with paclitaxel/carboplatin (paclitaxel 175mg/m^2, carboplatin AUC=5). QL1101 or Avastin was given every 3 weeks as one treatment cycle for 6 cycles with the same dose of 15mg/kg per time, then followed by QL1101 single-drug maintenance treatment. The primary endpoint was the best objective response rate (ORR) at week 18 as evaluated by the blind independent imaging review committee, and the secondary endpoints include DOR, PFS and OS. **Result:** A total of 675 subjects were screened and 532 were finally enrolled and treated including 266 in the trial group and 266 in the control group. At week 18, the ORR of the QL1101 group and Avastin group were 52.26% (CR: 0, PR: 139) and 56.02% (1 cases CR, 148 PR), respectively, and risk ratio (RR) value and 90% CI was 0.933 (0.818-1.064), which met the pre-specified equivalence margins (0.75-1.33). The mDOR in QL1101 group and Avastin group was 5.88 and 6.93 month (P=0.5044)respectively, and mPFS were 7.88 and 8.34 months (P=0.2760) accordingly, the 12-month OS in the two groups was 69.18% and 75.10% respectively. The incidence of CTCAE≥ grade 3 adverse events was 31.20 % in QL1101 group and 24.06 % in Avastin group, respectively (P = 0.0808). The immunogenicity (ADA and Nab tested) of the two groups was similar. **Conclusion:** QL1101 and Avastin are equivalent in clinical efficacy, and the safety profile (including immunogenicity) is quite similar in patients with non-squamous cell non-small cell lung cancer. There are no unexpected serious adverse reactions were found during the study.

Background: The optimal treatment in patients with advanced non-small cell lung cancer (NSCLC) after failing second- or third-line chemotherapy, i.e. NSCLC in salvage setting, has yet to be established. A small study reported that solvent-based paclitaxel (sb-P) monotherapy was safe and efficacious and could be a treatment option for NSCLC in salvage setting (Anticancer Res 2005). Nanoparticle albumin-bound paclitaxel (nab-P) showed a higher overall response rate (ORR) and better tolerability than sb-P when combined with carboplatin (CBDCA) as a first-line chemotherapy (J Clin Oncol 2012). These results suggest that nab-P monotherapy could be better therapeutic option than sb-P monotherapy for NSCLC in salvage setting. We therefore planned NICE Salvage study aiming to assess the efficacy and safety of nab-P monotherapy for NSCLC patients in salvage setting. **Method:** NICE Salvage study was a multicenter single arm phase II study. Eligibility criteria included patients aged >= 20 years, with PS 0-2 and adequate organ function, and who have failed two or three prior lines of chemotherapy including at least a platinum-containing regimen for pathologically-proven advanced NSCLC. Patients who had treatment history with sb-P or nab-P, or had tumors harboring *EGFR* mutation or *ALK* fusion gene were excluded. Nab-P was administered at a dose of 80 mg/m^2 on days 1,8 and 15 of a 28-days cycle and repeated until progressive disease, unacceptable toxicity, or patient's refusal. The primary endpoint was progression-free survival (PFS). Secondary endpoints included overall survival (OS), ORR, disease control rate (DCR), efficacy according to prior use of docetaxel, quality of life, and safety. The study is powered to detect a 1.5-month improvement in median PFS in the investigational arm beyond the 2.0-month median PFS estimated from historical data. Assuming a one-sided 0.10 level of Type I error and 80% power, target sample size is calculated at 35. (UMIN000016173). **Result:** Thirty-eight patients were enrolled and a patient was excluded from efficacy and safety analysis. Patient's characteristics (n = 38) were as follows: median age = 68 years, male/female = 31/7, adenocarcinoma/squamous cell carcinoma /others = 20/15/3. Median PFS and OS was 3.5 month (95% confidence interval (CI), 1.7-3.8), and 13.4 month (95%CI, 9.1-25.1), respectively. ORR and DCR were 10.8% (95%CI, 2.9-24.8) and 56.8% (95%CI, 38.3-71.3), respectively. Grade 3 or 4 treatment-related adverse events were neutropenia (10.8%), anemia (2.7%), hepatotoxicity (2.7%) and diarrhea (2.7%). One treatment-related death (pulmonary infection) was observed. **Conclusion:** This study failed to meet predefined primary endpoint. However the results showed that nab-P monotherapy was moderately efficacious and well-tolerated, suggesting the need for further investigation for NSCLC in salvage setting.

P1.01-05 PHASE I STUDY OF INHALED 5-AZACYTIDINE (5-AZA) IN PATIENTS (PTS) WITH ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

H. Cheng[1], N. Fan[1], Y. Zou[1], C. Shah[1], B. Halmos[1], T. Bhagat[1], R. Gucalp[1], B. Piperdi[2], M. Kim[1], A. Verma[1], S. Spivack[1], R. Perez-Soler[1]

[1]*Montefiore Medical Center/Albert Einstein College of Medicine, Bronx/United States of America,* [2]*Merck & Co., Inc., Kenilworth/United States of America*

Background: Our previous study in an endo-bronchial NSCLC murine model suggested that aerosolized 5-Aza could inhibit cancer growth, prolong survival, and induce re-expression of methylated tumor suppressor genes. This is the first in human phase I study of 5-Aza delivered by inhalation in pts with advanced NSCLC. **Method:** Main inclusion criteria: Stage IV or recurrent NSCLC with predominantly lung involvement, ≥1 prior systemic therapy, ECOG PS 0-1, and good pulmonary function. Pts were treated with inhaled 5-Aza daily, D1 to D5 and D15 to D19 of a28-day cycle. Initial dose escalation used an accelerated titration scheme, followed by a 3 + 3 dose escalation and de-escalation design. The starting dose was 15mg/m^2 (derived from preclinical studies that showed it to be a safe and DNA demethylating dose), followed by 30 and 45 mg/m^2. The primary objective was to determine the MTD and toxicity (especially pulmonary toxicity). Secondary objectives included PK, methylation profiles pre and post 5-Aza (bronchoscopy), efficacy (RECIST 1.1), PFS and OS. **Result:** From 3/2015 to 12/2017, 8 pts were treated with 3 escalating doses of inhaled 5-Aza, including 2 at the highest level of 45mg/m^2. Median follow up: 15m. Median age 70, 62.5% female, 62.5% blacks, all PS=1, 87.5% adenocarcinoma with 1 *EGFR* and 2 *KRAS* mutants, 62.5% active/former smoker, mean number of prior therapies: 3 lines. Mean treatment cycles: 3.4 (1-12). No treatment related adverse events were reported. No DLTs were observed. Preliminary PK study indicated no detectable 5-Aza in the blood. No objective response was observed, 37.5% (3/8) had stable disease (SD). Median PFS and OS were 2 m and 12 m respectively. One pt had SD > 17 m and received a total of 2 cycles, whereas another KRAS-

mutant pt had SD >29 m and received a total of 12 cycles. **Conclusion:** Inhaled 5-Aza was well-tolerated with no treatment-related toxicity. The administration of 5-Aza by inhalation was feasible for multiple cycles in pts with advanced NSCLC without any significant pulmonary toxicity. The methylation studies in bronchial epithelium are ongoing and will be presented. Our results suggest that inhaled 5-Aza may represent a novel and safe therapeutic strategy for patients with lung-confined malignant and/or premalignant lesions. Clinical trial information: NCT02009436. Supported by NIH CA154755

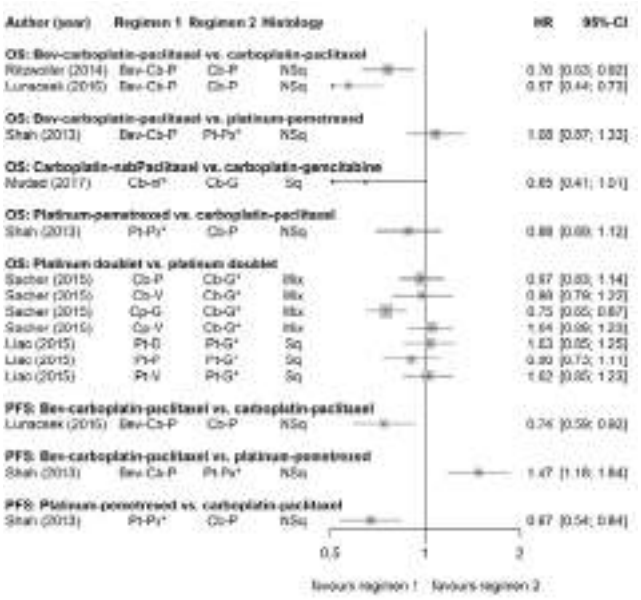
Keywords: 5-Aza, inhaled therapy, NSCLC

P1.01-06 COMPARATIVE EFFECTIVENESS OF FIRST LINE (1L) THERAPIES FOR ADVANCED NON-SMALL CELL LUNG CANCER (ANSCLC): A SYSTEMATIC LITERATURE REVIEW (SLR)

S. Goring[1], T. Li[1], A. Gara[1], N. Varol[2], B. Korytowsky[3], N. Hertel[2], P. Baas[4]

[1]*ICON Plc, Vancouver/Canada,* [2]*Bristol-Myers Squibb, Uxbridge/United Kingdom,* [3]*Bristol-Myers Squibb, Princeton/United States of America,* [4]*Netherlands Cancer Institute, Amsterdam/Netherlands*

Background: The therapeutic landscape for aNSCLC has shifted in recent years. Novel therapies, including immunotherapies, have been tested in clinical trials but less is known about their effectiveness and safety in real-world (RW) settings. Our primary objective was to quantify the relative effectiveness and safety of 1L therapies for aNSCLC in a RW setting. **Method:** An SLR was conducted using EMBASE and MEDLINE (2012-2018), alongside searches of conference proceedings (2015-2018). Two reviewers assessed eligibility and included observational studies involving at least two chemotherapy or immunotherapy-based 1L therapies for aNSCLC. EGFR+, ALK+, and KRAS+ mutation-targeting therapies and sub-populations were excluded. Effectiveness and safety endpoints were extracted; relative effects were presented using forest plots. Pooled estimates were not generated due to study design heterogeneity and limited number of studies per treatment comparison. Risk of bias was assessed using ROBINS-I. **Result:** From 4,307 abstracts, 18 RW chemotherapy-based studies were included; no immunotherapy-based studies were identified. Of the 18 studies, only seven used methods to balance patient characteristics across treatments. Of these seven, relative effect estimates trended toward improved overall survival (OS) and progression-free survival (PFS) associated with chemotherapy doublets involving pemetrexed, nab-paclitaxel, or the addition of bevacizumab, relative to older platinum-based chemotherapy doublets (Figure 1). Significantly higher objective response rates (ORR) were observed for pemetrexed-based doublets relative to paclitaxel- and gemcitabine-based doublets reported in one multi-group study. There were no significant differences in non-hematologic and few significant differences in hematologic adverse event rates.



Conclusion: This SLR provides complementary evidence showing relative effect sizes of 1L chemotherapies in the RW setting, which were broadly consistent with those observed in clinical trials. Comparative RW evidence for immunotherapies in 1L aNSCLC is lacking and is expected to emerge in the future; however, this research provides a benchmark against which new evidence can be compared.

P1.01-07 REAL WORLD DATA OF DOCETAXEL PLUS NINTEDANIB FOR PRETREATED NSCLC PATIENTS: 4 YRS UPDATE COMPASSIONATE USE PROGRAM SINGLE INSTITUTION IN MEXICO

S. Campos-Gomez, K. Campos-Gomez, J.J. Valdéz-Andrade, J. Esquivel Gutierrez

Centro Oncologico Estatal ISSEMyM, Toluca/Mexico

Background: Nintedanib is an oral, potent, tyrosine kinase inhibitor that simultaneously targets vascular endothelial growth factor receptors 1-3, platelet-derived growth factor receptors α and β, and fibroblast growth factor receptors 1-3, as well as FLT3 and Src. Currently, the molecule has proved benefit for second-line in non-small cell lung cancer patients. Previous we report the results of a cohort of NSCLC patients receiving nintedanib within a compassionate-use program (CUP) in México demonstrated significant improvement in progression-free survival. **Method:** Patients with advanced NSCLC progressing after one line of chemotherapy were enrolled. Eligible patients received docetaxel 75 mg/m(2) (day 1) plus nintedanib 200 mg twice daily; days 2-21) in 21-day cycles. Data collection was monitored. Treatment continued until disease progression or unacceptable drug-related AEs. The intention of this CUP was to provide controlled access to nintedanib. Here, we report a 4-year update, representing the longest follow-up of a real world study evaluating nintedanib docetaxel in combination therapy. **Result:** From February 2014 to April 2015, 24 patients (54.2% female 45.8% male; median age: 61 years [range: 29-83 years]) were enrolled. ECOG performance status 0-1 in 100% of patients. Patients received nintedanib 200 mg BID (n=16). Median PFS was 15 months (range, 5-24). OS median, 16 months [95% CI = 9.59–22.4]. Among 24 evaluable patients, 20 (83%) had a partial response and 3 (12.5%) had stable disease by Response Evaluation Criteria In Solid Tumors criteria. The most frequent drug-related adverse events (all grades) were diarrhea (32%), fatigue (58%), nausea (37%), vomiting (8.2%), neutropenia (12.5%), anemia (24.9%) and elevations in alanine aminotransferase (37.5%) and aspartate aminotransferase (31.2%). Dose-limiting toxicities (all grade 3 hepatic enzyme elevations) occurred only in 2/24 patients (8.3%). All hepatic enzyme elevations were reversible and manageable with dose reduction. No new safety signals were observed compared with the 2015 first analysis **Conclusion:** Based on cohort result update, continuous treatment with second-line nintedanib combined with docetaxel was well tolerated and showed efficacy in Mexican patients with advanced non-small-cell lung cancer.

Background: The subset analysis of CA031 trial showed a significant improvement of overall response rate (ORR) for carboplatin (CBDCA) plus weekly nab-PTX versus CBDCA plus PTX in patients (pts) with

POSTERS

squamous cell histology (41% vs 24%). We conducted a phase II study comparing CBDCA plus weekly nab-PTX (CnP) to cisplatin plus gemcitabine (CG), one of the standard regimens in pts with squamous cell lung cancer (SCC). **Method:** Chemo-naïve stage IIIB/IV or postoperative recurrent SCC pts were randomly assigned to receive either cisplatin (80 mg/m^2) on day 1 plus gemcitabine (1000 mg/m^2) on days 1, 8 every 3 weeks or CBDCA (area under the curve [AUC] 6 mg/ml/min) on day 1 plus nab-PTX (75 mg/m^2) on days 1, 8, 15 every 3 weeks. The primary endpoint was ORR. Secondary endpoints were progression-free survival (PFS), overall survival (OS), disease control rate (DCR) and toxicity. Assuming that an ORR of 40% in eligible pts indicates potential usefulness and ORR of 20% is the lower limit of interest, the estimated accrual was 32 pts in each arm. Allowing for dropouts, the accrual goal was determined to be 35 pts in each arm (alpha, 0.05; beta, 0.20).Thisstudy was planned to enroll 70 pts in total. **Result:** Between June 2013 and October 2018, 71 pts were enrolled and assigned to CG arm (n=35) and CnP arm (n=36). The median follow-up time was 10.8months. At data cutoff (March 31, 2019), ORR was 43% (95% confidence interval [CI]: 27.3-58.5) in CG arm and 47% (95%CI: 31.7-62.7) in CnP arm. DCR was 77% in CG arm and 80% in CnP arm. Median PFS was 4.6 months in CG arm and 4.1months in CnP arm. Median OS was 15.2months in CG arm and 10.2months in CnP arm. Of the grade 3 or higher adverse events, anemia was more common in CnP arm (CG, 17% and CnP, 53%). There was one treatment-related death in CG arm and no treatment-related death in CnP arm. **Conclusion:** In this study, CBDCA plus weekly nab-PTX was likely to be equivalent to cisplatin plus gemcitabine despite carboplatin-based regimen. CBDCA plus weekly nab-PTX could be a promising regimen for SCC.

P1.01-09 RANDOMIZED TRIAL COMPARING MAINTENANCE PEMETREXED WITH OBSERVATION FOLLOWED BY PEMETREXED AT PROGRESSION IN ADVANCED NSCLC

K. Stokke[1,2], T.O. Halvorsen[1,3], O. Flotten[4], S. Sorhaug[2,5], T. Madebo[6], S. Raj[1,2], K. Killingberg[1,2], S. Fluge[7], K. Hornslien[8], B.H. Gronberg[1,3]

[1]*NTNU, Norwegain University of Technology and Science, Trondheim/Norway,* [2]*St. Olavs Hospital, Trondheim, Trondheim/Norway,* [3]*St. Olavs Hospital, Trondheim/Norway,* [4]*Haukeland University Hospital, Bergen, Bergen/Norway,* [5]*NTNU, Norwegian University of Science and Technology, Trondheim/Norway,* [6]*Stavanger University Hospital, Stavanger/Norway,* [7]*Haugesund Hospital, Haugesund, Haugesund/Norway,* [8]*Oslo University Hospital, Oslo, Oslo/Norway*

Background: Previous placebo-controlled studies show that maintenance treatment with pemetrexed prolongs progression free survival (PFS) and overall survival (OS) in advanced non-squamous non-small-cell lung cancer (NSCLC) patients who do not progress on induction platinum-doublet chemotherapy. There were, however, a few limitations of these studies: Few on the control arms received pemetrexed at progression, few patients >70 years were enrolled, and patients with performance status 2 (PS2) were ineligible. **Method:** In this open phase III trial, patients with stage IIIB/IV non-squamous NSCLC ineligible for curative treatment who had PS 0-2, and non-progression after four courses of carboplatin (AUC=5) day 1 + vinorelbine (25 mg/m^2 IV day 1 and 25 mg/m^2 IV or 60 mg/m^2 PO day 8) were randomized to receive immediate pemetrexed maintenance therapy or observation followed by pemetrexed at progression. There was no upper age limit. The primary endpoint was OS, secondary endpoints were PFS and toxicity. To demonstrate an improvement in median OS from 6 to 8 months (from the time of randomization) with an α=0.05 and β=0.20, 198 patients were required on each arm. Accounting for a drop-out of maximum 10%, we aimed to randomize 436 patients. **Result:** 105 patients were randomized between May 2014 and September 2017 at 19 hospitals in Norway (maintenance: n= 54, observation: n=51). Inclusion was stopped prematurely due to poor recruitment after immunotherapy became available. Median age was 67 years (range 46-83), 34% were >70 years, 14% had PS 2, 93% stage IV, and 54% were women. 75% of the patients received pemetrexed at progression. The median number of pemetrexed courses were 4 (maintenance: 3, observation: 4; p=0.265). Patients in the maintenance-arm had a significantly longer PFS (median 3.1 vs. 1.9 months; p=0.02), and a 2 months longer median OS (12.0 vs. 10.0 months; p=0.10). In a Cox regression analysis adjusting for baseline patient and disease characteristics (gender, stage of disease, PS), there was a trend towards a statistically significant difference in OS (HR 0.67 95% CI 0.436-1.030; p=0.068). There were no significant differences in toxicity between those who received maintenance therapy and those who received pemetrexed at progression. **Conclusion:** Maintenance pemetrexed therapy prolongs PFS and with a trend towards improved OS in non-squamous NSCLC compared with observation followed by pemetrexed at progression in a cohort including more elderly patients than previous studies of maintenance pemetrexed therapy and when allowing PS2 patients.

P1.01-10 IMPACT OF ANTI-COPD SUPPORT TREATMENT IN ADVANCED NSCLC PATIENTS WITH COPD UNDERGOING CHEMOTHERAPY AS FIRST-LINE TREATMENT

F. Wang[1], X. Xie[1,2], X. Lin[2], Y. Qin[2], Z. Xie[2], J. Zhang[2], M. Ouyang[2], C. Zhou[2]

[1]*The First Affiliated Hospital of Guangzhou Medical University, Guangzhou, Guangzhou/China,* [2]*State Key Laboratory of Respiratory Disease, National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Health, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China*

Background: To investigate the impact of standardized anti-COPD support treatment of advanced NSCLC patients complicate with COPD undergoning chemotherapy as the first-line treatment, which without driver mutations. And putting forword the new concept of "simultaneous treatment of cancer and lung itself". **Method:** The clinical data of advanced NSCLC patients complicated with COPD were analyzed retrospectively. And patients were divided into observation group and control group according to whether the patients received standardized anti-COPD support treatment. Compared the survival statistics of the two groups. **Result:** The study consisted of 76 patients, only 31 patients received standardized anti-COPD support treatment. The courses of first-line chemotherapy in observation group were more than that of control group (4.8vs.3.8, p<0.05), and patients in observation group were more likely to received second-line chemotherapy (95.7%vs.75.0%,p<0.05). Progression-free surival (PFS) and overall survival(OS) of observation group were significantly higher than control group (6.0 months vs.3.5 months,p<0.05;18.0 months vs.15.0 months,p<0.05).

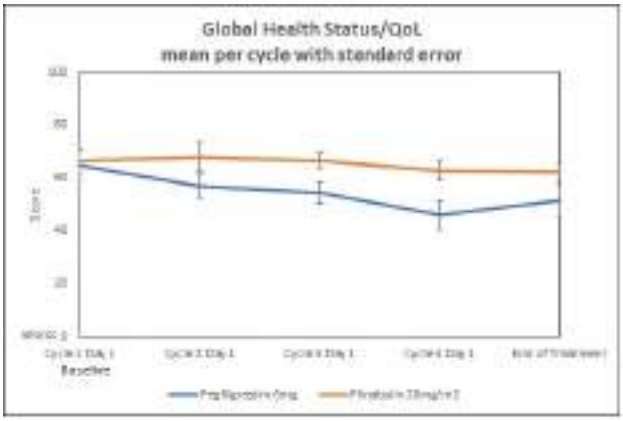
P1.01-11 QUALITY OF LIFE IN NSCLC PATIENTS TREATED WITH DOCETAXEL AND EITHER PLINABULIN OR PEGFILGRASTIM FOR PREVENTION OF NEUTROPENIA

D. Blayney[1], D. Mitchell[2], Y. Lelorier[3], L. Huang[3], R. Mohanlal[4]

[1]*Stanford University, Stanford/United States of America,* [2]*Logimetrix, Montreal/Canada,* [3]*BeyondSpring, New York/United States of America,* [4]*BeyondSpring Pharmaceuticals, New York/United States of America*

Background: Plinabulin is a novel small molecule, in development for the prevention of chemotherapy-induced-neutropenia (CIN). Plinabulin has anticancer activity and is separately developed through a global 3 trial (NCT02504489) for 2nd and 3rd line NSCLC patients. In contrast to pegfilgrastim, plinabulin does not produce bone pain, a chief complaint of patients taking pegfilgrastim. As part of the Phase 2 CIN protocol we measured patient quality of life (QoL) comparing pegfilgrastim and plinabulin. **Method:** In the Phase 2 portion of the Phase 2/3 Study 105 (NCT03102606), patients received docetaxel 75 mg/ m2 on Day 1, and were randomly assigned to either one of three plinabulin doses: 5 mg/m2 (n=14), 10 mg/m2 (n=13), 20 mg/m2 (n=14) mg/m2 on Day 1 (30 minutes after docetaxel infusion) over 4 cycles or no plinabulin and pegfilgrastim on Day 2. QoL was assessed with the validated health related questionnaires EORTC QLQ-C30 on D1 of each of the 4 cycles prior to study drug, and end of treatment. Day 1 Cycle 1 was baseline QoL. The data was analyzed using the standard methodology from the EORTC QLQ-C30 scoring manual which converts the 30 questions into three categories: global health status / QoL, functional scales, and symptom scales. The individual scores as well as the combined quality of life status, functional scales, symptoms scales, and the overall summary EORTC QLQ-C30 scores were analyzed. The difference between the treatment arms was analyzed using a linear mixed model for repeated measures with baseline and treatment arms as covariates. **Result:** Plinabulin 20mg/m^2 (clinically effective dose for CIN) demonstrated a significant improvement in QoL over 4 treatment cycles in three of the four parameters measured: global health status (p-value >0.0001), symptom scales (p-value 0.0093), and summary score (p-value 0.0195). In addition, there were significant improvements in three symptom scales: fatigue (p-value 0.0317), pain (p-value 0.0274), and insomnia (p-value 0.05).



Conclusion: Although these results are preliminary, they are significant and indicate improvements in QoL in patients being treated for advanced NSCLC with docetaxel and the addition of plinabulin for CIN prevention. This trend will be further investigated in ongoing Phase 3 trials for both NSCLC (NCT02504489), and CIN (NCT03102606 and NCT03294577).

Keyword: NSCL Neutropenia QoL

P1.01-12 TRENDS IN THE NATIONAL CANCER INSTITUTE (NCI) SPONSORED LUNG CANCER CLINICAL TRIALS PRE AND POST NCI'S NATIONAL CLINICAL TRIALS NETWORK (NCTN)

S. Malik[1], G. Mishkin[1], A. Denicoff[1], J. Zhao[2], E. Korn[1], M. Mooney[1]

[1]*National Cancer Institute/NIH, Rockville/United States of America,* [2]*The Emmes Company, Rockville/United States of America*

Background: On March 1, 2014, NCI launched the new NCTN, transforming NCI's longstanding Cooperative Group Program. The NCTN coordinates and supports cancer clinical trials at more than 3,000 sites across the United States and Canada providing the infrastructure for NCI-funded trials to improve the lives of people with cancer. **Method:** We reviewed 10 years of lung cancer treatment trials accrual data that included 5 years pre-NCTN trial activations and accruals to these trials between3/1/2009-2/28/2014 and 3/1/2014-2/28/2019 for post-NCTN.More than 3,800 patients were enrolled to lung cancer treatment clinical trials that activated pre-NCTN during the pre-NCTN period, while more than 2,300 were enrolled in the post-NCTN period. Histology identifiers of small cell vs. non-small cell and Phase II vs. Phase II/III or III were sorted. **Result:** Table 1 Histology and Phase

Trial Information		PRE-NCTN	POST-NCTN
Number of trials		**19**	**23**
Lead disease	Non-small cell lung cancer	15	22
	Small cell lung cancer	4	1
Phase	Phase II	13	11
	Phase III (including II/III)	6	12

Table 2 Trial Status

		PRE-NCTN	POST-NCTN
Trial status	**Active**	**1**	**9**
	Closed	18	14
Closed trials	Completed	8	6
	Premature closure	10	8
Among Prematurely Closed Trials			
Reasons for premature closure	Interim monitoring	4*	5
	Drug supply/ external information		1
	Unacceptable toxicity	2	
	Inadequate accrual rate	4	2

While there is a 20% increase in activated trials in post NCTN era, the number of phase III trials has doubled. A decrease in small cell lung cancer clinical trials due to lack of active new drugs is noted. Enrollment of non-whites and females improved in post NCTN era and there was an increase in ethnicity and gender data capture. Additional demographic data will be available to report at the meeting and a discussion of evolving treatment trends. **Conclusion:** In this era of precision medicine trials, the total treatment trial patient numbers have deceased, however; the screening part of the NCI master protocol trials were excluded from this analysis. ALCHEMIST enrolled patients 3264 patients that were screened but not enrolled in the treatment arms of ALCHEMIST. All the patients screened on ALCHEMIST will be followed for a total of 10-years and their tumor will also undergo genomic analysis. Similarly, LungMap screening trial included 1278 patients that did not get assigned to any treatment protocol.

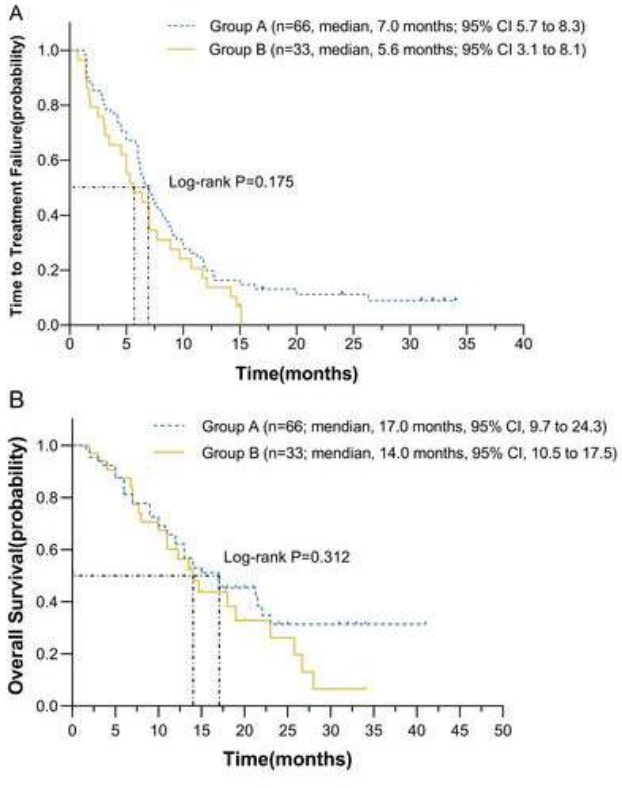
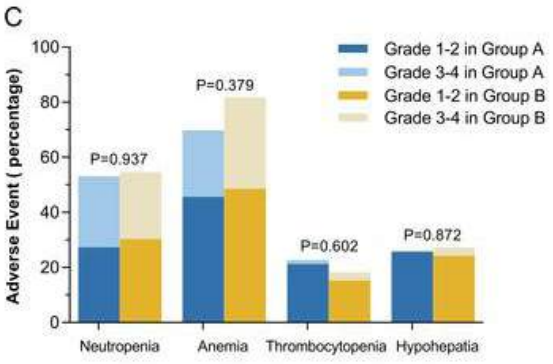
P1.01-13 EFFICACY AND SAFETY OF CONCURRENT ANTI-TUBERCULOSIS TREATMENT AND CHEMOTHERAPY IN LUNG CANCER PATIENTS WITH CO-EXISTENT TUBERCULOSIS

M. Ye, S. Su, W. Cen, X. Zhang, Z. Huang, J. Zou, Y. Zeng, Y. Zhang

Guangzhou Chest Hospital, GUANGZHOU/China

Background: This study evaluated the safety and efficacy of concurrent anti-tuberculosis (TB) and chemotherapy in patients with advanced lung cancer and active tuberculosis in a large sample size. **Method:** We retrospectively analyzed treatment naïve patients with advanced lung cancer diagnosed at Guangzhou Chest Hospital from 2015 to 2017. These patients were categorized into two groups: lung cancer patients without a history of TB treated with first-line standard anti-cancer chemotherapy (group A) and lung cancer patients with active TB treated concurrently with anti-TB and first-line chemotherapy(group B). Patients in group A were matched (2:1) to patients in group B with similar age, stage and tumor histology. Adverse events (AEs) and objective response rate (ORR) were tested using Chi-square test or Fisher's exact tests. Time to treatment failure (TTF) and overall survival (OS) were evaluated with Kaplan-Meier method and compared with the log-rank test. **Result:** A total of 99 patients were eligible (group A, n=66; group B, n=33). Grade≥3 treatment-related AEs (TRAEs), primarily hematologic toxicity, occurred in 41% and 48% of patients, for the A versus B groups, respectively. The hepatic insufficiency in two groups was generally grades 1 or 2, and their incidences were similar (26% and 27%, respectively). After two cycles of chemotherapy, ORR was 42.4% in group A and 33.3% in group B, which did not show any significant difference (P = .383). There were also not statistically significant in TTF (median, 7.0 vs 5.6 months for groups A and B, p= .175) and OS (median, 17.0 vs 14.0 months, p= .312). Among group B patients, rates of sputum negative conversion and lesion absorption were 100% within 3 months, and no recurrence was observed within 1 year.





Conclusion: Compared with chemotherapy alone in lung cancer patients, the combination of anti-TB treatment and chemotherapy did not increase hematological toxicity and hypohepatia of chemotherapy in lung cancer patients with pulmonary TB, which was safety and feasibility.

Keywords: Lung cancer, Pulmonary tuberculosis, Chemotherapy

P1.01-14 THE IMPACT OF SYSTEMIC TREATMENT ON BRAIN METASTASIS IN PATIENTS WITH NON-SMALL-CELL LUNG CANCER: A NATIONWIDE POPULATION-BASED COHORT STUDY

Y.H. Ko[1], J.H. Hong[1], D.S. Sun[1], H.S. Won[1], J.S. Lee[2], H.W. Lee[3]

[1]*College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea, Seoul/Korea, Republic of,* [2]*College of Medicine, The Catholic University of Korea, Uijeongbu, Republic of Korea, SEOUL/Korea, Republic of,* [3]*Ajou University School of Medicine, Suwon, Korea, Republic of (South), Suwon/Korea, Republic of*

Background: We performed a large-scale, retrospective, nationwide, cohort study of the incidence of brain metastasis in patients with advanced non-small-cell lung cancer (NSCLC) according to the systemic treatment administered. **Method:** The data were extracted from the Health Insurance Review and Assessment Service of Korea database from January 1, 2011 to November 30, 2016. Of the 29,224 patients newly diagnosed with stage IIIB or IV NSCLC who received first-line cytotoxic chemotherapy (CC group) or targeted therapy (TT group), 22,508 patients without brain metastasis were analyzed. **Result:** In total, 1,131 (5.0%) patients subsequently developed brain metastasis. The overall cumulative incidence of brain metastasis was significantly higher in the TT group than in the CC group (1-year cumulative incidence: 8.7 ± 0.6% vs. 3.8 ± 0.3%; 3-year: 17.2 ± 0.7% vs. 5.0 ± 0.3%, respectively; P < 0.001), despite the higher rate of brain metastasis in the CC group at < 3 years after diagnosis. Younger age, female sex, living in a rural area, anticoagulant use, and first-line TT (relative risk, 2.17 ± 0.03; 95% confidence interval, 1.92–2.50, P < 0.0001) retained significant associations with subsequent brain metastasis after adjusting for all variables. **Conclusion:** In the Korean population, the overall cumulative incidence of brain metastasis was significantly higher in patients in the TT group than in those in the CC group; the former could be regarded as having mutations in the EGFR or ALK gene.

P1.01-15 MULTICENTER, SINGLE-ARM PHASE II STUDY OF NAB-PACLITAXEL/CARBOPLATIN IN UNTREATED PS2 PATIENTS WITH ADVANCED NSCLC: TORG1426

K. Naoki[1], Y. Ichikawa[2], A. Bessho[3], S. Hosokawa[3], T. Shimokawa[4], M. Yomota[5], Y. Hosomi[6], S. Otani[1], Y. Nakahara[1], S. Iwasawa[7], T. Tokito[8], N. Seki[2], H. Okamoto[9]

[1]*Kitasato University, School of Medicine, Sagamihara (Kanagawa)/Japan,* [2]*Teikyo University School of Medicine, Tokyo/Japan,* [3]*Japanese Red Cross Okayama Hospital, Okayama/Japan,* [4]*Yokohama Municipal Citizen's Hospital, Yokohama/Japan,* [5]*Tokyo Metropolitan Cancer and Infectious diseases Center Komagome Hospital, Tokyo/Japan,* [6]*Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Tokyo/Japan,* [7]*Chiba University, Chiba/Japan,* [8]*Kurume University School of Medicine, Kurume/Japan,* [9]*Thoracic Oncology Research Group, Yokohama/Japan*

Background: Performance Status (PS) has been shown to predict survival in patients with advanced non-small cell lung cancer (NSCLC). To date, PS2 patients have been underrepresented in clinical trials due to concerns about tolerability. Consequently, no standard of care exists for these patients. In CA031 trial, nab-paclitaxel/carboplatin (nab-PTX/CBDCA) demonstrated significantly higher response rate (RR) compared with PTX/CBDCA in PS0-1 patients with advanced NSCLC. Furthermore, in elderly subgroup, nab-PTX/CBDCA tended to show superior progression-free survival (PFS) and overall survival (OS) based on better tolerability compared with PTX/CBDCA. Therefore, this phase II trial was designed to characterize the efficacy, safety, and tolerability of nab-PTX/CBDCA in untreated PS2 patients with advanced NSCLC. **Method:** Chemotherapy-naive PS2 patients with stage IIIB/IV NSCLC were treated with nab-PTX (70 mg/m^2 on day1, 8, and15, q4w) and CBDCA (AUC 5 on day1, q4w) up to 6 cycles if they did not have uncontrolled brain metastasis or pleural effusion. The primary endpoint was PFS rate at 6 months. Its achievement of more than 50% was considered worthy of further development of this regimen, whereas that of less than 30% was considered insufficient for further investigation. The estimated power was 80% with type I error of 0.05, resulting in 35 patients needed. Concurrently, Symptom Score and Charlson Comorbidity Index (CCI) were evaluated. **Result:** This trial was terminated due to slow accrual. Between September 2015 and August 2018, 17 patients (median age, 68 years [range, 50-73]) were enrolled and received a median of 3 cycles. The reasons for PS2 were tumor progression (71%), comorbidities (12%), or both (17%). The PFS rate at 6 months was 20.8% (95% confidence interval, 0%-41.6%). The median PFS, OS, RR, and disease control rate (DCR) were 3.0 months, 9.5 months, 17.4%, and 70.6%, respectively. Grade 3-5 adverse events (AE) included fatigue (24%), lung infection (24%, including 6% of grade 5), neutropenia (18%), and anemia (18%), resulting in trial withdrawal rate of 24%. The median PFSs of 11 patients with and 6 patients without 2nd line chemotherapy were 5 months and 1.7 months, respectively (p = 0.009). Symptom Score was improved by chemotherapy (p = 0.004), whereas comparison between lower and higher CCI values demonstrated no difference regarding chemotherapy cycles administered (p = 0.5) and regarding chemotherapy efficacy (p = 0.268). **Conclusion:** Nab-PTX/CBDCA did not meet its primary endpoint, but could be a feasible treatment option for untreated PS2 patients with advanced NSCLC. Clinical trial information: UMIN000019458

P1.01-16 EVOLUTION OF SYSTEMIC THERAPY UPTAKE IN NSCLC OVER TIME: THE IMPACT OF NEW THERAPIES

P. Wheatley-Price[1,2], K. Laurie[1], M. Mckinnon[1]

[1]*Ottawa Hospital Research Institute, Ottawa/Canada,* [2]*University of Ottawa, Ottawa/Canada*

Background: Non-small cell lung cancer remains the most common cancer worldwide, and the leading cause of cancer deaths, partly because half of all patients are diagnosed at stage IV. Due to comorbidities or poor functional status many never receive systemic therapy. In previous research, we reported only 55% of advanced NSCLC patients received systemic therapy between 2009-2012 following out-patient oncology consultation (Brule et al. Lung Cancer 2016). Since then there has been broader emergence of rapid diagnostic assessment pathways, targeted therapies and immunotherapy, so we explored whether treatment rates have increased. **Method:** With ethics approval, we reviewed all cases of de novo stage IIIB/IV NSCLC seen in out-patient medical oncology consultation between 10/2015 and 09/2017. Patients treated with curative intent were excluded. The primary endpoint was the proportion of patients who received any line of systemic therapy. Further descriptive analysis looked at rates of targeted therapy and immunotherapy uptake. **Result:** In the study period, 461 patients met eligibility for analysis. Of these, 205 (44%) women; 425 (92%) stage IV, 343/82/36 adenocarcinoma/squamous/other. Median age was 69 years. Median time from pathological diagnosis to medical oncology consult was 13 days. Overall, 286 patients (62%) received at least one line of systemic therapy (155 patients received one line only, 90 received two lines, 34 received three lines and four patients received >=four lines). Among the 175 patients who did not receive any systemic therapy, the most common stated reasons were; poor PS (104, 59%), patient choice (48, 27%) or comorbidities (7, 4%). From 379 non-squamous NSCLC patients, 314 (83%) had a documented EGFR test (42/245/27 positive/negative/inconclusive) and 339 (89%) had a documented ALK test (12/311/13 positive/negative/inconclusive). Among the 42 EGFR+ patients, 90% received systemic therapy and among the 12 ALK+ patients, 92% received systemic therapy. For the non-EGFR, non-ALK patients, the proportion who received systemic therapy was 61%. Immunotherapy was prescribed in 87 patients: 3 in first line, 72 in second line and 12 in three+ line. **Conclusion:** In our academic centre between 2009-2012 only 55% of patients seen in out-patient oncology consultation received any line of systemic therapy. With more widespread molecular testing and the emergence of immunotherapy this has climbed to 62%. With an increase in first-line immunotherapy and more widespread molecular profiling, this should continue to improve, giving more patients the option of effective therapy.

P1.01-17 CHANGES IN PULMONARY FUNCTION DURING PLATINUM-DOUBLET CHEMOTHERAPY FOR LUNG CANCER

J. Götschke, C. Von Wachter, L. Sellmer, P. Mertsch, D. Kauffmann-Guerrero, Z. Syunyaeva, A. Tufman

Ludwig-Maximilians-University of Munich, Munich/Germany

Background: Lung cancer treatments, including checkpoint inhibitors, tyrosine kinase inhibitors, chemotherapy and multimodal treatments, may cause pulmonary side effects. Clinical trials document pulmonary toxicity but rarely include mandatory serial pulmonary function testing. As such, little is known about the changes in pulmonary function during systemic treatments, in particular in patients without manifest pulmonary toxicity. We present a longitudinal analysis of platinum-based chemotherapy for lung cancer and examine the effect of different chemotherapies on pulmonary function. **Method:** We retrospectively analyzed lung cancer patients treated with platinum-doublets and correlated lung function (FEV1, vital capacity, total lung capacity and diffusion) changes with the type of chemotherapy received. **Result:** We included 838 patients at the Munich Lung Cancer Centre from January 2013 until April 2019. The average patient age was 66,8 ± 9,79 years. 510 patients were male (60,9%). Histology was as follows: 410 adenocarcinoma, 153 small cell neuroendocrine carcinoma, 147 squamous cell carcinoma and 128 cases with other histologies. Platin was paired with pemetrexed (n=279), vinorelbine (n=205), etoposide (n=190), taxanes (docetaxel, paclitaxel, nab-paclitaxel; n=93) or gemcitabine (n=53). Lung function tests performed before and after chemotherapy were analyzed. During treatment, lung function parameters often improved. Pneumonitis was rare. There were chemotherapy-subgroup differences in lung function during treatment. **Conclusion:** Platinum doublets are associated with clinically relevant changes in lung function. Pneumonitis during chemotherapy is rare, and many patients experience improvements in pulmonary function during chemotherapy. The choice of chemotherapeutic agents may affect pulmonary outcomes. Larger studies of the effect of individual chemotherapeutic agents on pulmonary function in this setting and combined with immunotherapies are warranted.

Keywords: Lung function, Lung cancer, Chemotherapy

P1.01-18 INTEGRATED GENOMIC AND DNA METHYLATION ANALYSES OF NON-SMALL CELL LUNG CANCER PATIENTS WITH BRAIN METASTASES

Y. Fan[1], Y. Xu[1], Z. Huang[1], K. Chen[1], H. Han-Zhang[2], J. Ye[2], H. Lu[1], J. Qin[1], F. Xie[1], N. Han[1], L. Gong[1], X. Xu[1]

[1]*Zhejiang Cancer Hospital, Hangzhou/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: Brain metastases (BM), with a dismal prognosis, are a common and lethal complication of non-small cell lung cancer. Approximately, 10% patients present with BM at their initial diagnosis. Although, surgery and/or radiation therapy remain to be the mainstay treatment, targeted therapies are finding increasing application in treating BM. However, due to the very limited accessibility of brain lesions, its genomic and epigenomic landscape remain elusive. **Method:** Capture-based targeted sequencing for somatic mutation profiling was performed on 27 treatment-naïve advanced NSCLC patients with paired lung primary and BM lesions using a pane consisting of 520 cancer related genes. DNA methylation analyses was performed on same samples using a DNA methylation panel consisting of 100,000 CpG sites. **Result:** Collectively, we identified 370 (291 SNVs+Indels, 78 CNVs and 1 rearrangement) and 574 (245 SNVs+Indels, 327 CNVs and 2 rearrangements) mutations from lung primary lesions and BM, respectively. Among them, 242 mutations were shared; 128 were lung primary-specific and 332 were BM-specific. Among the BM specific mutations, a majority of them (82%, 272/332) were copy number variations (CNVs). Only 16% of CNVs were shared by lung lesions and BM. The concordance for SNVs and indels were much higher-54% between the two sources of tissues. Furthermore, we observed a much higher concordance rate (79%) in *TP53* and classic lung cancer driver genes than other genes (p<0.001), indicating that they might be stem mutations. Next, we performed pathway analysis of genes that were only mutated in BM and revealed an enrichment of genes participating in PI3K-AKT and focal adhesion pathways. We also compared tumor mutation burden (TMB) between them and revealed comparable TMB (p=0.1). Our DNA methylation analysis revealed distinct methylation patterns with 268 blocks that are significantly differentially methylated between primary lung lesions and BM. Among them, 211 blocks were hypermethylated in BM and the remaining 57 blocks were hypermethylated in lung lesions. These blocks were enrichment in genes participating in cell adhesion, Rap1 signaling and calcium signaling pathways. **Conclusion:** We revealed diverse somatic mutation and DNA methylation profiles between lung primary lesions and BM. BM had significantly more unique CNVs. A great concordance was observed for classic lung cancer driver genes and *TP53*. Our study provided a comprehensive view of genomic and DNA methylation profiling for lung primary lesions and BM, paving the avenue for the development of targeted therapies for treating BM.

P1.01-19 PREDICTIVE AND PROGNOSTIC VALUES OF CTDNA CLEARANCE IN OSIMERTINIB TREATED ADVANCED NON-SMALL CELL LUNG CANCER COHORT

Y. Song[1], S. Ma[2], M. Shi[3], X. Xu[4], X. Chen[2], Y. Wang[5], Z. Yang[6], T. Zhang[7], M. Li[7], H. Li[7], L. Zhang[7], X. Mao[7]

[1]*Jinling Hospital Nanjing University School of Medicine, Nanjing/China,* [2]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou/China,* [3]*Affiliated Cancer Hospital of Nanjing Medical University, Jiangsu Cancer Hospital and Jiangsu Institute of Cancer Research, Nanjing/China,* [4]*North Jiangsu General Hospital, Yangzhou/China,* [5]*Anhui Provincial Hospital, Hefei/China,* [6]*Nanjing First Hospital Affiliated to Nanjing Medical University, Nanjing/China,* [7]*Burning Rock Biotech, Guangzhou/China*

Background: Although growth advantage of certain clones would ultimately translate into a clinically visible disease progression, radiological imaging does not reflect clonal evolution at the molecular level. Circulating tumor DNA (ctDNA), validated as a tool for mutation detection in lung cancer, reflects dynamic molecular changes. Here, we evaluated the potential of ctDNA in monitoring molecular changes and predicting clinical outcomes of *EGFR* T790M-positive osimertinib treated NSCLC patients. **Method:** This prospective multicenter study, enrolled 72 T790M positive osimertinib-treated advanced NSCLC patients who progressed on prior EGFR-TKI to evaluate the potential of ctDNA in monitoring, is part of the ongoing ASTRIS study (NCT02474355). Longitudinal plasma samples, collected from 52 patients, were subjected to sequencing using a panel consisting of 168 lung cancer-related genes. **Result:** Genomic profile prior to the initiation of osimertinib revealed that mutations participating in cell cycle (14 patients, p=0.004) and P53 pathways (43 patients, p=0.032) were associated with shorter OS (*p53* was excluded from analysis due to high mutation frequency). Interestingly, patients with undetectable ctDNA at first follow-up (within 50 d, n=41) were correlated with longer PFS (p=0.009) and OS (p=0.022). With a median follow-up of 168 d (ranged from 40 - 550 d), 32 patients experienced radiological disease progression. Among them, 11 (34%) experienced molecular progression reflected by emergency of new mutation or increased allelic frequency of existing mutation prior to radiological progression, with an average leading time of 74 days. Patients with molecular PD prior to radiological PD were more likely to harbor any gene copy number amplification (CNA, p=0.035) and *p53* (p=0.023) mutations at radiological PD. In addition, patients with CNA at radiological PD had shorter PFS (p=0.002) and OS (p=0.052). **Conclusion:** This clinical trial study demonstrates that ctDNA clearance at first follow-up can serve as a predictive and a prognostic marker for patients undergoing osimertinib treatment. Furthermore, it revealed the potential of ctDNA in early detection of disease progression, preceding imaging modalities with an average lead time of 74 days.

Keywords: Osimertinib, Non-Small Cell Lung Cancer, ctDNA clearance

P1.01-20 THE ASSOCIATION BETWEEN BRAF MUTATION CLASS AND CLINICAL FEATURES IN BRAF-MUTANT CHINESE NON-SMALL CELL LUNG CANCER PATIENTS

Q. Lin[1], H. Zhu[2], Y. Li[1], H. Zhang[3], H. Ding[4], J. Qian[5], H. Han-Zhang[6], J. Lin[6], J. Xiang[6]

[1]*The First Affiliated Hospital of Wenzhou Medical University, WENZHOU/China,* [2]*The First Affiliated Hospital of Soochow University, Suzhou/China,* [3]*The First Affiliated Hospital of Bengbu Medical College, Bengbu/China,* [4]*Ningbo Diagnostic Pathology Center, Ningbo/China,* [5]*The Affiliated Suzhou Hospital of Nanjing Medical University, Suzhou/China,* [6]*Burning Rock Biotech, Guangzhou/China*

Background: BRAF mutations, occurring in 2-4% NSCLC patients, can be classified into 3 classes based on signaling mechanism and kinase activity: V600-mutant RAS-independent kinase activating monomers (class I), RAS-independent kinase activating dimers (class II) and RAS-dependent kinase inactivating heterodimers (class III). The association between functional classes and clinical features of Chinese NSCLC patients remain elusive. **Method:** Sequencing data of either plasma or tissue samples obtained from 8,405 Chinese (Stage I-IV NSCLC) patients were retrospectively analyzed to screen for *BRAF* mutations. Of the patients with *BRAF* mutations, 79% (188/238) were diagnosed with adenocarcinoma,7.6% with squamous cell carcinomas (SCC) and the remaining patients were either adenosquamous carcinoma or large cell carcinoma. **Result:** *BRAF* mutations were detected in 238 patients, revealing a prevalence of 2.8%. Among them, 32% (75/238), 21% (51/238) and 13% (31/238) had class I, II and III mutations, respectively. The remaining 35% (81/238) had other *BRAF* mutations. V600 (32%, 75/238) and G469 (13%, 32/238) were the 2 most predominant mutations. *BRAF* mutations, when considered collectively, including non-class I-III mutations, were more likely to occur in males (p<0.01). However, class I mutations have a female predominance (p=0.003); whereas, class II mutations showed a trend of male predominance (p=0.09) and class III had no gender preference (p=0.22). We also revealed no association between histology types and the class of *BRAF* mutations. Next, we investigated co-occurring classic lung cancer driver mutations in this cohort and revealed that patients with class II and III mutations were more likely to have concurrent *KRAS* mutations (p=0.001). We also compared the overall survival (OS) of chemotherapy-treated patients and revealed comparable OS among the 3 groups. **Conclusion:** Our study revealed a 2.8% *BRAF* mutation rate in Chinese NSCLC patients. Our data also showed a male predominance when all *BRAF* mutations were considered collectively, and a female predominance for class I mutations. Furthermore, patients with *BRAF* V600E is less likely to have concurrent *KRAS* mutations.

P1.01-21 SPUTUM CAN SERVE AS AN ALTERNATIVE SOURCE FOR LIQUID BIOPSY IN PATIENTS WITH LUNG CANCER

L. Qin[1], T. Guo[1], H. Yang[2], Q. Gu[1], L. Cao[2], P. Deng[2], B. Li[3], Z. Chen[3], C. Hu[2]

[1]*Xiangya Hospital, Central South University, Changsha/China,* [2]*Department of Respiratory Medicine, Xiangya Hospital, Central South University, Changsha/China,* [3]*Burning Rock Biotech, Shanghai/China*

Background: With the advancements in the development of targeted therapy, the detection of actionable mutations has become routine practice in diagnosing lung cancer, especially in non-small cell lung cancer (NSCLC). Due to its non-invasiveness and great accessibility, plasma-based mutation profiling, with a sensitivity of approximately 70%, is widely used in clinical settings. Profiling using other body fluids have been actively explored. In this study, we investigated the potential of sputum obtained from non-small cell lung cancer (NSCLC) patients for mutation profiling. **Method:** We performed capture-based ultra-deep targeted sequencing on matched Falin-Fixed Paraffin-Embedded (FFPE), plasma and sputum samples of 11 treatment-naïve NSCLC patients using a panel consisting of 168 lung cancer-related genes. Among the 11 patients, with a median age of 57, 8 were diagnosed with adenocarcinoma and 3 with squamous cell carcinoma. In addition, 4 patients were classified with central types and the other 7 were classified with peripheral types. Five of them were non-smokers and the remaining were smokers. Three of them were females and 8 were males. All patients were diagnosed with advanced disease (stage III or IV). **Result:** Collectively, we identified 52, 40 and 33 mutations from FFPE, plasma and sputum samples, respectively. Using FFPE samples as a reference, both plasma and sputum had an overall concordance rate of 61.5%. If only actionable classic driver mutations were considered, the concordance rate increased to 91% for sputum and 82% for plasma. Profiling of sputum revealed 8 patients with classic lung cancer driver genes: 4 patients with *EGFR* mutation, 1 with *ALK* rearrangements, 2 with *KRAS* mutation, and 1 with *ERBB2* mutation. The *ERBB2* mutation revealed by sputum was not detected from the corresponding plasma sample. Furthermore, our study revealed that the allelic fractions (AFs) from sputum were significantly higher than AFs from plasma samples (p=0.039). For smokers, the difference of AFs between sputum and plasma was more significant (p<0.001). Furthermore, among the mutations which were detected from both sputum and plasma, 92% mutations had higher AF in sputum. In contrast, for non-smokers, only 29% of mutations had higher AF in sputum. Our data revealed for non-smokers, two media had comparable AFs (p=0.273). **Conclusion:** Our study demonstrated that sputum from advanced stage NSCLC patients is an alternative media for mutation profiling. Potentially, it may serve as a better source for mutation profiling than plasma in smokers. Larger studies are needed to confirm our findings.

P1.01-22 INVESTIGATION OF ACQUIRED RESISTANCE FOR EGFR-TKI PLUS BEVACIZUMAB AS 1ST LINE TREATMENT IN PATIENTS WITH EGFR SENSITIVE MUTANT NSCLC

Y. Zhang[1], L. Zeng[1], N. Yang[1], T. Jiang[2], C. Zhou[3]

[1]*Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha/China,* [2]*Shanghai Pulmonary Hospital, Shanghai/China,* [3]*Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/China*

Background: The progression-free survival (PFS) advantage of EGFR-TKI plus Bevacizumab (A+T) over standard TKI monotherapy (T) in the 1st line treatment of *EGFR* mutant non-small cell lung cancer (NSCLC) has been confirmed in prospective clinical trials. However, the acquired resistance mechanism which impacts the subsequent management was poorly understood. We did the first analysis to unveil it using next generation sequencing (NGS). **Method:** 256 *EGFR* sensitive mutant (*EGFR* 19del and L858R) NSCLC patients received NGS of 168 genes panel of tumor tissue in baseline from Jan, 2015 to Aug, 2018 was enrolled in this study. 60 patients treated with A+T were recognized as cohort A. Using Propensity Score Matching (Ratio of 1:2), 120 patients treated with single T were chosen as cohort B. Clinical outcomes and resistance mechanism (also by the 168 genes NGS panel) were evaluated. **Result:**

Newly present alterations in cohort A	%	N
EGFR amp	3.2%	1
MET amp	3.2%	1
MET amp+EGFR amp+TP53	3.2%	1
RB1	3.2%	1
RB1+TP53	3.2%	1
RB1+TP53+EGFR amp	3.2%	1
SMAD4	3.2%	1
T790M	22.6%	7
T790M+BRAF V600E	3.2%	1
T790M+EGFR exon 18 p.V834L+TP53	3.2%	1
T790M+TP53	6.5%	2
TP 53	16.1%	5
unknown	25.8%	8
Total	**1**	**31**

Newly present alterations in cohort B	%	N
EGFR amp	6.8%	7
EGFR exon 7 p.T263P	1.0%	1
EGFR exon18 p.G724S	1.0%	1
ERBB2 amp	1.0%	1
KRAS	1.0%	1
MET amp	4.9%	5
MET skipping	1.0%	1
RET+KRAS	1.0%	1
SCLC	2.9%	3
T790M	37.9%	39
T790M+BRAF V600E	1.0%	1
T790M+EGFR amp	8.7%	9
T790M+MET amp	1.9%	2
T790M+TP53	1.9%	2
TP53	4.9%	5
TP53+RB1	1.0%	1
unknown	22.3%	23
Total	**1**	**103**

There was no different for clinical characteristics between Cohort A and B. Comparing with single T, A+T significantly prolonged the medium PFS (16.5m *vs.*12.0m, HR=0.7, p=0.001). A+T significantly increased the overall response rate (95% *vs* 74.2%, *p*<0.05). Until Jan 2019, 31 patients in cohort A, 103 patients in cohort B were evaluated with progressed disease and received tissue re-biopsy for NGS with the same 168 genes panel. In cohort B, T790M was defined as the domain acquired resistance mechanism, contributing to 51.5% (53/103) of progressed patients, followed by *EGFR* amplification 15.5% (16/103), *MET* amplification 6.8% (7/103), *TP53* mutations 6.8% (7/103) and small cell lung cancer transformation 2.9% (3/103). However, in cohort A, although T790M was also defined as the domain acquired resistance mechanism, the mutation ratio was decreased to 35.5% (11/31), followed by *TP53* mutations 29.0% (9/31), *RB1* mutations 9.7% (3/31), *EGFR* amplification 9.7% (3/31), *MET* amplification 6.5% (2/31), and novel *SMAD4* mutations 3.2% (1/31), *EGFR* uncommon mutation (p.V834L) 3.2% (1/31). **Conclusion:** Treatment of 1st line A+T significantly extends the time to progression and increases the response rate with acceptable safety profile. The dominant acquired resistance mechanism retained in T790M but with lower probability. *SMAD4* mutation and *EGFR* p.V834L were considered as novel resistant mechanism to A+T.

P1.01-23 RETROSPECTIVE ANALYSIS OF REAL-WORLD CLINICO-GENOMIC DATA FOR CLINICAL IMPACT OF GENOMIC PROFILING OF CTDNA IN NSCLC

R. Madison[1], A. Schrock[1], J. Gregg[1], K. Carson[2], E. Castellanos[2], G. Singal[1], V. Miller[1], S. Ali[1], B. Alexander[1], J. Chung[1]

[1]*Foundation Medicine, Cambridge/United States of America,* [2]*Flatiron Health, New York/United States of America*

Background: Liquid biopsy (LBx) and comprehensive genomic profiling (CGP) of circulating tumor DNA (ctDNA) is a minimally-invasive approach that is increasingly used for detection of targetable genomic alterations (GA) in patients with NSCLC. To determine the clinical utility of LBx-based CGP in routine clinical practice, we evaluated responses to targeted therapy post-LBx in the real-world setting. **Method:** The Flatiron Health-Foundation Medicine Clinico-Genomic Database included 475 NSCLC patients with LBx CGP results (FoundationACT): clinical characteristics and real-world tumor response (rwTR) were obtained via technology-enabled abstraction of clinician notes and radiology/pathology reports and linked to CGP data. Targetable GAs were defined as genomic alterations with a matched FDA-approved targeted therapy or in NCCN guidelines (Table). Patients with a targetable GA were evaluated for rwTR to matched targeted therapy. Real-world overall response rates (rwORR: fraction of patients with partial or complete response) to matched targeted therapy after LBx versus tissue-based CGP (TBx, [FoundationOne/FoundationOneCDx, N=3,956]) were compared. **Result:** At the time of LBx, 61% of patients had ≥1 line of prior therapy (vs 49% for TBx). Median ctDNA fraction was 1%. There was evidence of ctDNA in 86% (408/475) of LBx cases; among these 24% (96/408) had a targetable GA (vs 21% for TBx). Post-detection of a targetable GA, 35% (34/96) of LBx patients received matched targeted therapy (vs 38% for TBx). 21 patients with targetable GAs were evaluated for LBx-based rwTR to matched targeted therapy (Figure): rwORR was 76.2% (vs 62.8% for TBx; p=0.25), including 76.5% (13/17) for FDA-approved matched targeted therapy and 75.0% (3/4) for NCCN targeted therapies (Table).

Table: rwORR to matched targeted therapy for LBx vs TBx

Targetable GAs	Class of targeted therapy	# evaluated for response (LBx v TBx)	rwORR to matched targeted therapy (%, LBx v TBx)
EGFR exon 19del/L858R	Approved	8 v 115	75% v 69%
EGFR G719X/S768I/L861Q	Approved	0 v 12	NA v 50%
EGFR T790M	Approved	1 v 22	0% v 73%
ALK rearrangement	Approved	8 v 43	88% v 70%
ROS1 rearrangement	Approved	0 v 11	NA v 64%
BRAF V600E	Approved	0 v 9	NA v 44%
MET exon 14 skipping and/or high-level amplification	NCCN	3 v 16	67% v 50%
RET rearrangement	NCCN	0 v 2	NA v 100%
HER2 activating mutation	NCCN	1 v 12	100% v 8%
	rwORR (% LBx v TBx)		
All targetable GAs	76.2% v 62.8%; p = 0.25		
GAs with approved therapies	76.5% v 66.8%; p = 0.59		
GAs in NCCN guidelines	75.0% v 35.5%; p = 0.28		

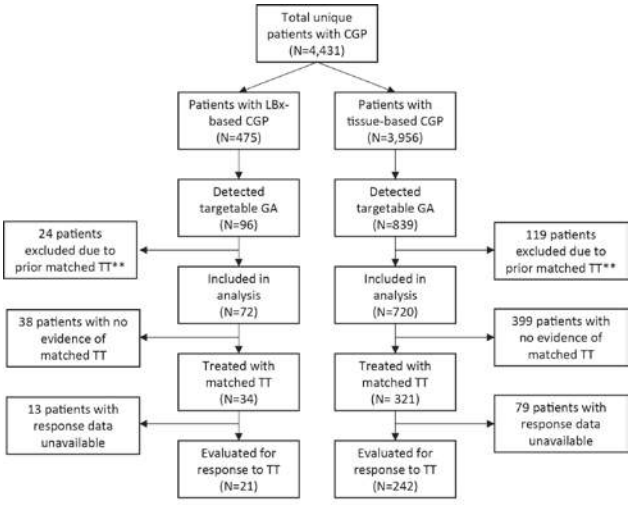

Figure: Diagram showing how patients were selected for analysis of response to matched targeted therapy (TT). **Responses were evaluated for first-line TT. Subsequent line TT was excluded from the analysis, except for approved second-line TT including osimertinib or ALK inhibitors post-crizotinib.

Conclusion: Retrospective analysis of real-world clinico-genomic data from a large series of NSCLC cases demonstrated that the frequency of detected targetable GAs and rwTR to matched targeted therapy was similar for LBx and TBx CGP.

Keywords: Real-world data, ctDNA, liquid biopsy

P1.01-24 PRECLINICAL PROTEOMIC EVALUATION OF ALTERNATING ALK TKI THERAPY VERSUS CONTINUOUS DOSING IN ALK NSCLC TO INFORM THE ALKTERNATE CLINICAL TRIAL

M. Itchins[1,2,3], A. Hudson[1,2], R. Harvie[1,2], T. Zaw[4], M. Mckay[4], S. Clarke[1,2,3], V. Howell[1,2], N. Pavlakis[1,2,3], S. Hayes[1,2]

[1]*University of Sydney, St Leonards/Australia,* [2]*Kolling Institute, St Leonards/Australia,* [3]*Royal North Shore Hospital, St Leonards/Australia,* [4]*Australian Proteome Analysis Facility (APAF), Macquarie University/Australia*

Background: Despite recent advances in the management of advanced *ALK*-rearranged NSCLC, with high objective response rates to ALK TKI therapy and survival gain, resistance to TKIs is inevitable. Mechanisms of *ALK*-dominant and non-dominant resistance are being increasingly recognized, although in many patients the underlying cause of drug resistance is unexplained. ALKternate is a clinical trial recruiting pre-treated patients, testing the hypothesis that with fixed alternating TKI therapy, the emergence of ALK resistant clones can be suppressed through applying variable selection pressure compared to continuous treatment with a TKI. This has been tested pre-clinically with a human cell line to complement the clinical trial in progress, ALKternate (Abstract #2043). Genetic profiling to complement these data are presented in #2074. **Method:** ALK TKI treatment was conducted on resistant *ALK*-rearranged cell lines (methods in Abstract #2074). Protein profiling was performed using the SWATH-MS 2.0 algorithm, conducted on the Sciex 6600 TripleTOF on cell pellets collected prior to treatment and at cycles (C) 5, 11 and 17 of both alternating lorlatinib with crizotinib (ALT) and continual lorlatinib (CONT) treatment arms. **Result:**

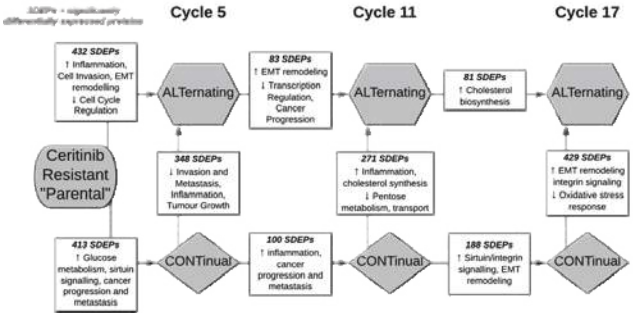

Figure 1: Significantly different proteins and pathways identified by proteomic profiling Overall, LC-MS/MS data was extracted for 3850 proteins. Significantly differentially expressed proteins (SDEPs) identified between CONT/ALT cell lines (FC>1.5, p<0.05) are shown in Figure 1. There was significant enrichment of a number of pathways between the treatment arms. At cycle 5, the EIF pathway, which helps to drive tumour invasion and progression, was the most dysregulated. At C11, elevated activity of cholesterol biosynthesis was observed in the ALT treatment arm. It is notable that hypercholesterolemia is a known side effect of lorlatinib treatment. At the end of C17, the top dysregulated pathways in the CONT line involved sirtuin/integrin signalling, EMT remodelling, while all of the dysregulated pathways for the ALT line were related to cholesterol biosynthesis. **Conclusion:** This study represents the first of proteomics used to identify resistance mechanisms to ALK TKIs. Data from this *in vitro* work will inform the ALKternate clinical trial.

P1.01-25 REAL-WORLD OUTCOMES OF ADVANCED NSCLC PATIENTS WITH COMMON AND UNCOMMON/COMPLEX EGFR MUTATION PROFILES

G. Riely[1], C. Lovly[2], C. Messina[3], S. Bienert[3], K. Alexander[4], W. Pao[3], K. Magee[5], S. Baxi[5], R. Doebele[6]

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Vanderbilt University Medical Center, Nashville/United States of America,* [3]*F. Hoffmann-La Roche AG, Basel/Switzerland,* [4]*F. Hoffmann-La Roche AG, Pleasanton/United States of America,* [5]*Flatiron Health, New York/United States of America,* [6]*University of Colorado Cancer Center, Aurora/United States of America*

Background: In patients with advanced non-small cell lung cancer (aNSCLC) with non-squamous histology, the evaluation of EGFR mutations is standard of care and informs treatment selection. EGFR mutations are well-defined and can be classified into common, uncommon/complex mutation subtypes that are known to have different response rates to approved EGFR tyrosine kinase inhibitors (TKIs). **Method:** We used data from the nationwide Flatiron Health electronic health record-derived database in this study. Our retrospective cohort included patients diagnosed in the US from Jan-2014 to Mar-2018 who had a positive EGFR test at time of first-line (1L) therapy initiation. Patients with baseline EGFR T790M mutations (n=44) or variants of unknown significance were excluded. Demographics, clinical characteristics, 1L treatment duration, and overall survival outcomes were compared between patients with common (Exon 19 E746-A750 del, Exon 19 del other, or Exon 21 L858R) vs. uncommon/complex EGFR mutations (all other EGFR mutations [i.e. Exon 18 G719X, Exon 20 insertions, Exon 21 L861Q], and/or concomitant mutations [KRAS, BRAF]). Minimum follow-up after initiation of 1L therapy was 4 months. **Result:** 23,321 patients had non-squamous or NOS histology. 1,315 patients had EGFR mutations detected prior to or during 1L treatment. Of those, 1,000 (82% common, 18% uncommon/complex mutations) had 1L EGFR TKI therapy initiated (median age 70 years, 70% women, 57% Caucasian, 47% smokers). In this population, 1L median treatment duration was longer for patients with common mutations than for those with uncommon/complex mutation profiles (11 vs 7 months; p<0.0001). Median overall survival was also affected by mutation status (24 vs 15 months; unadjusted HR 1.6; 95% CI 1.3–2.1; p<0.001). Among 315 patients (59% common, 41% uncommon/complex mutations) who initiated 1L treatment with non-EGFR TKI systemic therapies (median age 68 years, 59% women, 57% Caucasian, 53% smokers), median overall survival also improved with common vs uncommon/complex mutations (30 vs 17 months; unadjusted HR 1.7; 95% CI 1.3–2.4; p<0.001). However, there were no significant differences in median 1L (non-EGFR TKI) treatment duration (4 months common vs 6 months uncommon/complex mutations). Notably, 60% of patients with a common mutation treated with other 1L systemic therapies went on to receive a 2L EGFR TKI. **Conclusion:** Uncommon/complex mutations were present in over 20% of aNSCLC patients with any EGFR mutations. Increased overall survival and 1L treatment duration with EGFR TKI therapy were observed in patients with common mutation subtypes vs. uncommon/complex mutation subtypes.

P1.01-26 TP53 MUTATIONS IN EGFR MT+ NSCLC IV: STRONG INDEPENDENT PREDICTIVE FACTOR FOR ORR, PFS AND OS IRRESPECTIVE OF T790M

J. Roeper[1], M. Falk[2], F. Otto-Sobotka[3], F. Griesinger[1]

[1]*Pius Hosptial Oldenburg, Germany, Oldenburg/Germany,* [2]*Hämatopathologie Hamburg, Hamburg/Germany,* [3]*Carl Ossietzky University of Odenburg, Oldenburg/Germany*

Background: The impact of TP53 mutations in EGFR mt+ pts on PFS and OS is controversial, and different classifications of TP53 mt+ with respect to functional and potential predictive impact have been published. Therefore, we retrospectively analyzed the impact of TP53 aberrations on ORR, PFS and OS in a cohort of EGFR mt+ NSCLC IV pts (UICC 7) using different classifications of TP53 mutations. **Method:** 75 EGFR mt+ NSCLC IV pts were analyzed for TP53 co-mutations. TP53 mt+ were classified according to Poeta et al. into (1) disruptive vs. non-disruptive, according to structural prediction and biophysical characteristics into (2) pathogenic vs. non-pathogenic and finally into (3) exon 8 vs. non-exon 8 mutations according to Crino et al. The endpoints ORR according to Recist 1.1, PFS and OS were calculated by Kaplan Meier. **Result:** 69 of the 75 EGFR mt+ pts (92%) had a common mutation in EGFR E19/21. In 59/75 pts (79%) material was sufficient for successful TP53 analysis. TP53 mt+ were found in 29/59 pts (49%), 16/59 (27%) had a TP53 disruptive mt+, 13/59 (22%) a TP53 non-disruptive mt+ and 30/59 a TP53 WT configuration. Using the structural/biophysical classification, 7/59 (12%) had a TP53 non-pathogenic and 22/59 (37%) a TP53 pathogenic mt+. Of the 29 mutated pts, 6 had a TP53 Exon 8 mt+. Median PFS on 1st line TKI was 12 vs. 18 months for non-disruptive/disruptive mt+ vs. WT (p<0.004), 11 vs. 17 months for pathogenic vs. non-pathogenic/WT (p<0.0001), and 7 vs. 12 vs. 18 months for exon 8 vs. non-exon 8 vs. WT (p<0.006). Median OS was 24 vs. 42 months in non-disruptive/disruptive mt+ vs. WT (p<0.0009), 23 vs. 42 months in pathogenic vs. non-pathogenic/WT (p<0.001) and 12 vs. 28 months for TP53 exon 8 vs. non-exon 8 mt+ (p<0.024). Additionally ORR was significantly impacted by TP53 mt+. In rebiopsy samples on acquired resistance, no new TP53 mutations were observed and there were no correlations of TP53 mutations with clinical factors and the EGFR mt+ type including T790M. **Conclusion:** TP53 seems to be a frequent co-mutation in EGFR mt+ NSCLC and has a strong impact on all clinical endpoints on TKI therapy. These data might have an impact on the management and follow up of pts with TP53 mt+. Furthermore, there is an urgent need for further therapeutic approaches in this patient group.

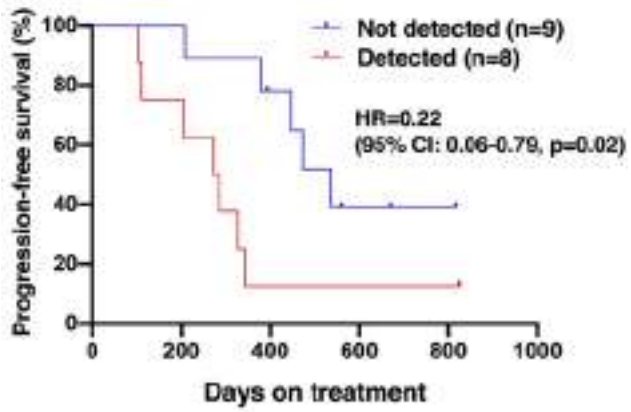
Keywords: advanced NSCLC, EGFR, TP53

P1.01-27 SERIAL CIRCULATING TUMOR DNA (CTDNA) ANALYSIS OF BLOOD AND SALIVA PREDICTS OSIMERTINIB RESPONSE AND RESISTANCE IN EGFR-MUTANT NSCLC

C. Kim[1], L. Xi[2], C. Cultraro[1], F. Wei[3], J. Cheng[3], A. Shafiei[4], T. Pham[2], N. Roper[1], E. Akoth[1], C. Strom[3], M. Tu[5], W. Liao[5], D. Chia[3], C. Morris[6], A. Rajan[1], M. Bagheri[4], G. Jones[6], D. Wong[3], M. Raffeld[2], U. Guha[1]

[1]*Thoracic and GI Malignancies Branch, CCR, NCI, NIH, Bethesda/United States of America,* [2]*Laboratory of Pathology, CCR, NCI, NIH, Bethesda/United States of America,* [3]*University of California Los Angeles, Los Angeles/United States of America,* [4]*Radiology and Imaging Sciences, Clinical Center, NIH, Bethesda/United States of America,* [5]*EZLife Bio Inc., Woodlind Hills/United States of America,* [6]*Inivata, Cambridge/United Kingdom*

Background: ctDNA has emerged as a promising non-invasive tool to detect lung cancer associated genomic alterations. We assessed whether serial ctDNA monitoring of plasma and saliva correlates with tumor burden and predicts response, resistance, and progression free survival to osimertinib, the 3rd generation EGFR TKI during treatment of EGFR mutated NSCLC. **Method:** Plasma and saliva samples were collected at every clinic visit from patients with metastatic EGFR mutant NSCLC enrolled in a clinical trial of local ablative therapy (LAT) upon oligoprogression (5 or less sites of progression) on osimertinib (NCT02759835). Plasma ctDNA was analyzed by droplet-digital PCR (ddPCR) *EGFR* mutation detection and InVisionSeq Tagged-Amplicon next-generation sequencing. Saliva ctDNA was analyzed by Electric Field-Induced Release and Measurement (EFIRM) liquid biopsy (eLB) assay. Tumor burden was assessed by volumetric CT scoring of all target lesions and other soft tissue lesions ≥10 mm. ctDNA-level changes were correlated with clinical response. **Result:** We analyzed 389 plasma samples from 20 patients by ddPCR, 126 plasma samples from 16 patients by NGS and 298 saliva samples from 18 patients by eLB. A high correlation between ddPCR and NGS allele frequencies (AFs) was found (Spearman g=0.96; p<0.001). Plasma ddPCR and NGS also correlated with saliva eLB assay for mutant *EGFR* detection (Spearman g=0.42 and 0.45, respectively; p<0.001 for both). Among 14 patients who progressed, ctDNA progression (AFs increased two consecutive times by ddPCR) predated RECIST progression by a median of 87 days (range: 28-216 days) in 8 patients. Of 6 patients without ctDNA progression, 2 patients had increase in *EGFR* mutation-level by eLB and 1 patient by NGS. ctDNA clearance on day 42 or 56 (2 cycles of osimertinib treatment) predicted PFS (HR=0.22, 95% CI=0.06-0.79, p=0.02; figure 1). Both baseline sensitizing *EGFR* mutation AF and copy number, but not baseline tumor volume, were significantly associated with PFS. Acquisition of *MET, EGFR,* and *ERBB2* amplifications and the *EGFR* C797S mutation were identified as key resistance mechanisms by NGS in this cohort of patients.



Conclusion: Serial assessment of plasma and saliva ctDNA is clinically useful for monitoring the therapeutic response to osimertinib and for early detection of resistance mechanisms for clinical decision making. Three assays used in this study, the ddPCR and NGS for plasma ctDNA detection, and eLB for saliva ctDNA detection are complementary with each having unique advantages.

P1.01-28 MUTATIONAL HETEROGENEITY BETWEEN PRIMARY PULMONARY CANCER LESIONS AND MATCHED BRAIN METASTASES

L. Li[1], Y. Chen[1], H.-X. Tian[1], D.-X. Zhou[2], D. Zhou[2], X.-F. Lin[2], K. Yin[1], H.-B. Feng[1], W.-B. Guo[1], Z. Xie[1], W.-Q. Yan[1], Z.-Y. Lv[1], D.-X. Lu[1], X.-N. Yang[1], Y.-L. Wu[3], X.-C. Zhang[1]

[1]*Guangdong Lung Cancer Institute, Guangzhou/China,* [2]*Department of Neurosurgery, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [3]*Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: Brain metastasis (BM) is a severe and common lethal condition in non-small cell lung cancer patients. A few data have been reported about the molecular landscape of genomic alterations in BM of non-small cell lung cancer (NSCLC). Yet little is known about molecular heterogeneity and evolution process during the cancer metastases from lung to brain. We seek to profile the genomic alterations in paired specimens of primary lung lesions (PL) versus brain metastasis (BM). **Method:** Paired specimens of thirteen patients with BM were collected. MassARRAY LungCarta (26 genes) and Next Generation Sequencing (NGS, 285 genes) assays were performed to generate genomic profiles. **Result:** Thirteen patients were aged mean 58 (range 40-74), 10 adenocarcinoma and 2 squamous carcinoma and 1 small cell lung cancer, 9 males and 4 females, 5 smokers and 8 non-smokers, 7 stage IV, 3 stage III, 2 stage II and 1 stage I. By LungCarta test, we detected 6 *EGFR*m (1 concurrent *STK11*, 1 concurrent *TP53*), 2 *KRAS*m, 1 *STK11*m cases and 4 wild type primary lung cancers. All corresponding BM lesions harbored the same mutations of *EGFR, KRAS*, *TP53* and *STK11,* and additional *EGFR* T790M in 1 *EGFR* mutated case. By NGS test, in 9 patients all above mutations were detected along with additional genomic alterations. There were average mutated 9 genes in primary lung lesions and 13 mutated genes in BM. Common altered genes in PL included *EGFR, KRAS, TP53, STK11, NF2, ARID1B* and *ATM*. Shared mutated genes between PL and BM had *EGFR, KRAS, TP53, KMT2C* and etc. BM specific altered genes included *ARID1A, SMARCA4, ATM, ATR, EPHA5, RB1, KMT2C, LRP1B*, and *SETD2,* etc. Notably, genes involved in the chromatin remodeling or modification and cell cycle pathways were enriched in BM. **Conclusion:** There were heterogeneous molecular alterations between PL and BM of NSCLC. Differential genes involved in the chromatin remodeling and modification and cell cycle checkpoint may be highly related to the process of BM, suggesting future therapeutic development on these potential molecular targets.

P1.01-29 MLPH PROMOTES EPITHELIAL–MESENCHYMAL TRANSITION AND BRAIN METASTASIS VIA CDC42/PAK1 SIGNALING IN NON-SMALL CELL LUNG CANCER

C. Wei, L. Peng, F. Tong, X. Dong

Huazhong University of Science and Technology, Wuhan/China

Background: Brain metastasis (BM) is associated with poor prognosis, recurrence, and death in patients with non-small cell lung cancer (NSCLC). Therefore, a better understanding of molecular mechanisms underlying NSCLC development and progression could provide helpful insights for NSCLC prevention and effective treatment. Melanophilin (MLPH), an actin-based transport binding partner, involves in cancer progression. However, the role of MLPH in NSCLC remains unclear. Here we elucidated the functional significance, molecular mechanisms and clinical impact of MLPH in NSCLC. **Method:** RNA-Sequencing was performed to identify differentially expressed genes in lung tissues of NSCLC patients with (BM+) and without BM (BM-). The expression of MLPH was examined in the serum of BM+ and BM- patients by PCR. Integrative database analysis was used to examine MLPH levels in NSCLC tissues and analyze the relationship between MLPH levels and patient survival. Lentivirus containing small hairpin (sh) RNA targeting MLPH or empty vector was designed to explore its role in NSCLC. The cell counting kit-8 assay, wound healing assay, transwell assay, flow cytometry analysis, Phalloidin staining, xenografted tumor model and brain metastasis model were used to determine the effects of MLPH on the proliferation, migration, invasion, EMT, tumorigenesis and brain metastasis of NSCLC. Western blot analysis was used to explore the underlying mechanism. **Result:** High-throughput sequencing showed that MLPH mRNA was significantly differentially expressed in lung tumors between BM+ and BM- NSCLC patients. MLPH was frequently overexpressed in NSCLC tissues and cells, and high levels of MLPH correlated with poor prognosis of NSCLC patients. Silencing MLPH by shRNA suppressed NSCLC cell proliferation, migration, invasion and TGF-β-induced EMT, and triggered cell cycle arrest and apoptosis. Being in consistent with the *in vitro* findings, the *in vivo* experiment exhibited that knockdown of MLPH inhibited xenograft tumorigenesis and brain metastasis in nude mice. Mechanically, we identified TGF-β as a key downstream effector of MLPH. MLPH silencing attenuated Cdc42/PAK1 signaling activation at least in part through the downregulation of TGF-β. Furthermore, EMT phenotypes changes caused by MLPH knockdown were partially dependent on TGF-β inhibition. **Conclusion:** Our findings uncovered the role of MLPH in NSCLC progression and provided evidence for MLPH positively modulating the Cdc42/PAK1 signaling pathway to promote EMT and metastasis via TGF-β in NSCLC cells. MLPH may have the potential as a therapeutic target against metastatic NSCLC.

P1.01-30 NON-SMALL CELL LUNG CANCER (NSCLC) NEXT GENERATION SEQUENCING (NGS): INTEGRATING GENOMIC SEQUENCING INTO A PUBLICLY FUNDED HEALTH CARE MODEL

K. Perdrizet, T. Stockley, J. Law, M. Shabir, T. Zhang, L. Le, A. Lau, M. Tsao, S. Kamel-Reid, P. Pal, M. Cabanero, J. Schwock, H. Ko, G. Liu, P. Bradbury, A. Sacher, F. Shepherd, N. Leighl

University Health Network, Toronto/Canada

Background: Standard of care (SOC) molecular diagnostics for stage IV NSCLC patients in Ontario, Canada includes publicly reimbursed *EGFR/ALK,* and *BRAF/ ROS-1* testing in selected cases. Other genomic alterations are not tested routinely at all institutions; however, enhanced molecular testing may broaden treatment options for patients by identifying actionable targets. This study evaluated costs, identified actionable targets, and determined clinical trial eligibility as a result of using the Oncomine Comprehensive Assay v3 (OCA v3, ThermoFisher) NGS in stage IV NSCLC patients at a single institution. **Method:** This prospective study of stage IV NSCLC out-patients at Princess Margaret Cancer Centre (Toronto) began in February 2018 and recruitment is ongoing (NCT03558165). NSCLC patients without *EGFR/ALK/KRAS/ BRAF* alteration (unless failure of prior targeted therapy and tissue rebiopsy), had diagnostic samples tested by OCAv3 (ThermoFisher; 161 genes: hotspots, fusions, and copy number variations). Primary endpoints were identification of incremental actionable targets and clinical trial opportunities as a result of broader OCAv3 testing.

Secondary endpoints include feasibility and cost from the Canadian public healthcare perspective. **Result:** From Feb 2018- Jan 2019 65 patients were enrolled [62% (N=40) completed/ 21% (N=14) screen fail/ 17% (N=11) pending], median age of completed cohort was 65, 60% (N=24) female, never/light smokers 68% (N=27), Asian 38% (N=15), previously treated 33% (N=13). Actionable targets beyond SOC were identified in 33% (N=13): *ERBB2* (N=8), *BRAFV600* (N=3), *NRG* fusion (N=1), *MET* exon 14 (N=1). Failure of NGS was secondary to insufficient tissue. 91% (N=10) of screen failures was secondary to tissue exhaustion from prior sequential SOC molecular testing. New clinical trial options were identified in 70% as a result of OCA v3 testing. Incremental costs per case beyond *EGFR/ALK* are estimated at $540 CAD. If *ROS-1* and *BRAF* testing were publicly reimbursed at current rates, the incremental profiling cost with OCAv3 would be $90 CAD per case. **Conclusion:** The OCAv3 consolidates genomic testing, identifies additional actionable targets, and substantially increases clinical trial eligibility for patients at a small incremental cost. Sample failures are reflective of exhausted diagnostic tissue as a result of prior sequential genomic testing. The key barrier to implementation of NGS remains funding in the Canadian health care system.

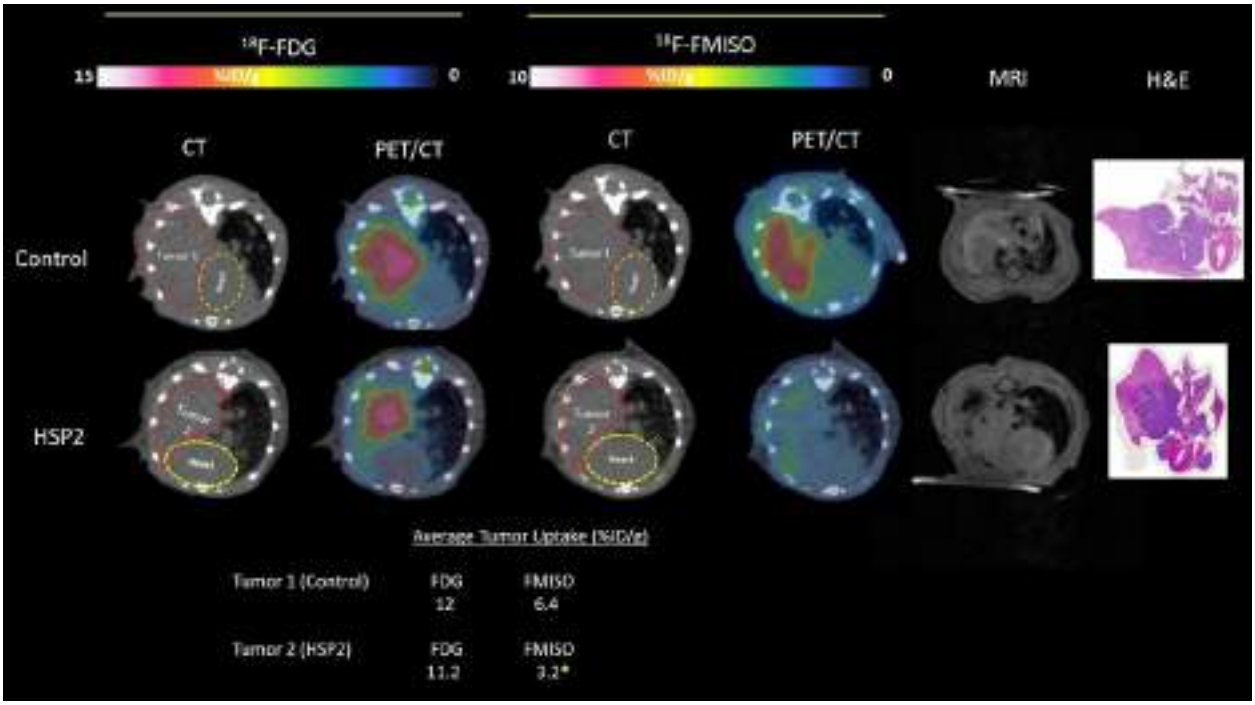
P1.01-31 EVALUATING ENGINEERED HEME-SEQUESTERING PEPTIDES FOR TREATING NON-SMALL CELL LUNG CANCER ORTHOTOPIC TUMOR MODEL USING MULTI-MODALITY IMAGING

S. Zhong[1], J. Chen[1], J. Campbell[1], J. Gerberich[1], G. Hao[1], L. Zhang[2], L. Liu[1]

[1]*The University of Texas Southwestern Medical Center, Dallas/United States of America,* [2]*The University of Texas at Dallas, Richardson/United States of America*

Background: There is still an urgent need to develop novel strategies to treat lung cancer. Lung cancer is the leading cause of cancer-related death in the US. About 85-90% of cases are classified as non-small cell lung cancer (NSCLC). Despite the advent of targeted therapies and immunotherapies, an effective treatment or cure for lung cancer remains an unlikely outcome for most patients. The five-year survival rate remains 10-20%, lower than many other cancers, such as breast (90%) and prostate (99%) cancers. Clearly, novel strategies are still needed for dramatic improvement in the overall survival rate of NSCLC patients. **Method:** NSCLC H1299-Luc cells in serum-free medium containing 50% Matrigel were implanted orthotopically in 8 weeks old NOD/SCID mice (n=6 for each treatment group) by surgery. BLI was carried out to monitor tumor growth and treatment. Treatments with HSP2 started 3-4 weeks after tumor implantation and BLI signal was reached to $1x10^5$. Anatomical T1-weighted MRI was performed with a 9.4T small animal MRI system. Two radiolabeled tracers, ^{18}F-FDG and^{18}F-fluoromisonidazole (^{18}F-FMISO), were selected for PET-CT scanning. FDG and FMISO-PET imaging data were correlated with MRI and histology. About 120μCi of ^{18}F-FMISO or ~100μCi of ^{18}F-FDG was injected via tail vein, 7 minutes list-mode PET at 1 hour post-injection of radio-tracer. CT imaging parameters used 360 projections at 80kV, 500μA and 140ms exposure. The mean radioactivity of ^{18}F-FDG and ^{18}F-FMISO tumor uptake were calculated using a decay correction from the entire ROI, and were compared between mice with or without treatment. After PET/CT imaging, mice were administered intravenously with pimonidazole to evaluate the extent of hypoxia within the tumor by immunohistochemistry (IHC) staining. **Result:** FDG uptake was identical in treated and control tumors. However, tumors treated with HSP2 revealed less hypoxia than control tumors as evidenced by less FMISO uptake within the tumor region. When comparing the ratio of FMISO and FDG uptake in treated versus control tumors, tumors treated with HSP2 had significantly less FMISO/FDG uptake compared to control tumors (p=0.003). **Conclusion:** Together, these results provided a solid foundation for further studies to determine the degree to which HSP2 influences tumor vasculature and oxygenation. Furthermore, we demonstrate the potential of HSP2 to increase treatment efficacy when used in combination with chemotherapy or radiotherapy in lung tumor models.

Keyword: Lung cancer, 18F-FDG, 18F-FMISO PET/CT



P1.01-32 BRONCHOALVEOLAR LAVAGE AS AN ALTERNATIVE TO REBIOPSY FOR DETECTION OF T790M MUTATION IN NSCLC PATIENTS WITH ACQUIRED RESISTANCE TO EGFR-TKIS

H. Kim[1,2], J.Y. Hur[1,2], I.A. Kim[2], S. Lee[1], W.S. Kim[1], K.Y. Lee[1,2]

[1]*Konkuk University School of Medicine, Seoul/Korea, Republic of,* [2]*Konkuk University Medical Center, Seoul/Korea, Republic of*

Background: Rebiopsy is current standard to detect T790M mutation, but has limited value due to inaccessibility in significant number of patients. Plasma liquid biopsy using ctDNA has been adopted, but the sensitivity is not satisfactory. Extracellular vesicles (EVs) have been proven to contain double-stranded genomic DNA reflecting mutational status of the parental tumor cells in non-small cell lung cancer (NSCLC). Accordingly, EVs can be translated into clinically useful liquid biopsy for EGFR genotyping using bronchoalveolar lavage fluid (BALF) obtained from the tumor site. We investigated the role of BALF for detecting T790M mutation in the patients who developed acquired resistance to EGFR-TKI by comparing with standard tissue rebiopsy and liquid biopsy using plasma ctDNA. **Method:** Forthy-eight EGFR mutation-positive NSCLC patients with acquired EGFR-TKI resistance were evaluated respectively. EVs were isolated from BALF by ultracentrifugation and EVs DNA extracted after eliminating free-floating DNA. PNA clamping-assisted fluorescence melting curve analysis (PANAMutyper™) were used to assess the EGFR mutation status in rebiopsy tissue, plasma and BALF. **Result:** Median age of 48 patients was 63.5 years (range, 44-87 years); 26 (52.1%) were women; and 27 (56.3%) were never-smokers. Thirty-three of 48 patients (62.5%) underwent a repeated biopsy with results as follows: there was insufficient tissue in 3 of 33 (9.1%) and T790M mutation in 12 of 30 patients who were pathologically confired as NSCLC (40.0%). Fifteen of 48 patients (31.3%) did not undergo a repeated biopsy at progression for the following reasons: patient with target lesion less than 10 mm in 6 cases; and no lesion amenable to biopsy such as leptomeningeal seeding, distant metastasis to bone or adrenal gland and lung nodules which is difficult to agmqccess in 9 case. The EGFR mutation-positive rate from BALF (37.5%) was higher than that determined from plasma or tissue at 16.7% and 25.0%, respectively. Interestingly, out of the 36 patients who were not able to undergo a repeated biopsy, whose biopsy results were insufficient for diagnosis or who did not have T790M mutation, five (10.4%) and three (6.3%) samples were additionally positive from the BALF and plasma test, respectively. **Conclusion:** Less invasive genotyping by PNA clamping-assisted fluorescence melting curve analysis with EVs DNA extracted from BALF is a promising approach to the detection of T790M mutation during EGFR TKI treatment.

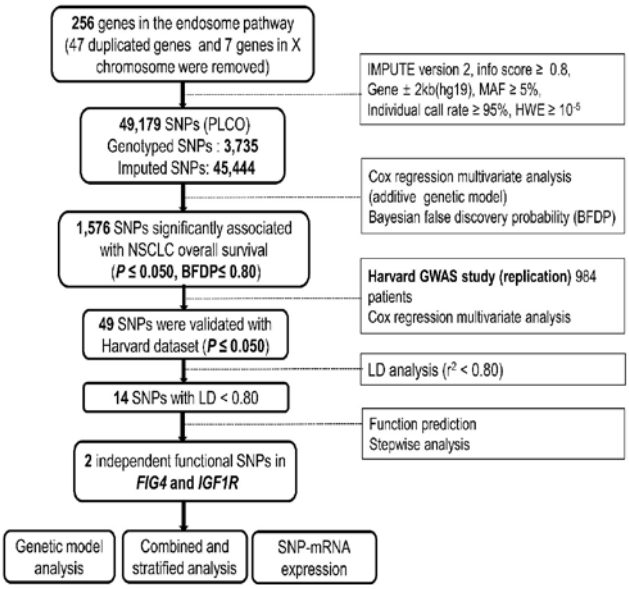
P1.01-33 GENETIC VARIANTS IN FIG4 AND IGF1R IN THE ENDOSOME-RELATED GENES ARE ASSOCIATED WITH NON-SMALL CELL LUNG CANCER SURVIVAL

S. Yang[1], Q. Wei[2], D. Christiani[3], Q. Wang[1]

[1]*The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China,* [2]*Duke Cancer Institute, Duke University Medical Center, Durham/United States of America,* [3]*Departments of Environmental Health and Department of Epidemiology, Harvard School of Public Health, Boston/United States of America*

Background: The endosome is a membrane-bound organ inside most eukaryotic cells and is known to play an important role in the adaptive immunity of mammals. The endocytosed antigens in the antigen presenting cells are delivered to both MHC class I and MHC class II pathways via the endosome. **Method:** In the present study, we performed a two-phase analysis of two independently published genome-wide association studies (GWASs) to evaluate associations between genetic variants in the endosome-related gene-set and overall survival (OS) of patients with non-small cell lung cancer (NSCLC). In the discovery GWAS dataset, we performed multivariate Cox proportional hazards regression with Bayesian false-discovery probability (≤ 0.80) for multiple testing corrections and evaluated associations between 49,179 (3,735 genotyped and 45,444 imputed) single-nucleotide polymorphisms (SNPs) in 256 genes and survival of 1,185 NSCLC patients. After further validation in the Harvard Lung Cancer Susceptibility study, we performed linkage disequilibrium, functional prediction and a multivariate stepwise Cox model. **Result:** We found that two independent, potentially functional SNPs in two genes (*FIG4* rs6899506 C>A and *IGF1R* rs3743254 C>T) were significantly associated with NSCLC survival, and their meta-analysis showed an adjusted hazards ratio (HR) of 1.16 [95% confidence interval (CI) =1.06–1.26, P_m =0.001] and 0.78 (0.67-0.91, P_m =0.002); respectively. A genetic score of unfavorable genotypes of these two SNPs revealed a decreased OS in a dose–response manner (P_{trend} = 0.007). Further expression quantitative trait loci (eQTL) analysis showed significant associations between the genotypes and mRNA expression levels. It was found that the survival-associated *FIG4* rs6899506C allele, but not the *IGF1R* rs3743254T allele, was significantly associated with decreased mRNA expression levels of *FIG4* in 373 lymphoblastoid cell lines.



Conclusion: Taken together, the genetic variant of the *FIG4* rs6899506A allele and *IGF1R* rs3743254T allele from the endosome pathway genes may be a promising predictor of survival in NSCLC patients via *FIG4* and *IGF1R* expression alteration.

P1.01-34 EARLY ASSESSMENT OF THERAPY RESPONSE IN NON-SMALL CELL LUNG CANCER (NSCLC) VIA LONGITUDINAL CTDNA ANALYSIS

S. Yaung[1], X. Ma[1], C. Ju[2], C. Woestmann[3], L. Xi[1], B. Hinzmann[3], M. Thomas[4], C.-P. Heussel[4], F. Lasitschka[5], M. Meister[4], M. Schneider[4], F. Herth[4], T. Muley[4], B. Wehnl[6], J. Palma[1]

[1]*Roche Sequencing Solutions, Inc., Pleasanton/United States of America,* [2]*Roche Molecular Systems, Inc, Pleasanton/United States of America,* [3]*Roche Sequencing Solutions, Inc., Potsdam/Germany,* [4]*Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,* [5]*Heidelberg University Hospital, Heidelberg/Germany,* [6]*Roche Diagnostics GmbH, Penzberg/Germany*

Background: Quantifying circulating tumor DNA (ctDNA) is an emerging method to non-invasively assess treatment effect for solid tumors. Despite disease heterogeneity in NSCLC, we set out to identify a broadly applicable ctDNA-based method for disease monitoring. By employing plasma taken during early treatment cycles, we tested whether early response assessed by ctDNA level could predict treatment effect. **Method:** Using a 197-gene NGS assay, the AVENIO ctDNA Surveillance Kit (For Research Use Only, not for use in diagnostic procedures), we measured ctDNA levels in post-treatment plasma samples based on variants identified at baseline. We used samples from an observational German Lung Cancer Multi-Marker Study. In a cohort of 83 stage IV lung adenocarcinoma treated with first-line chemo or chemoradiation therapies, we evaluated the association between survival and ctDNA levels in the first available post-treatment plasma sample (median number of days after start of treatment = 23). We used a ctDNA-based monitoring algorithm, and applied it to an independent set of 22 late stage lung squamous cell carcinoma that also underwent chemo or chemoradiation therapies

to further evaluate the algorithm in different histology subtypes. **Result:** We divided the 83 adenocarcinoma cohort into training (n=53) and test (n=30) sets. We found that subjects with longer progression free survival (PFS) had mean allele fraction (AF) < 1% in the training set. We applied the classifier to our adenocarcinoma test set and found that subjects with mean AF < 1% had longer PFS (HR 0.35; 95% CI 0.12 - 0.93; log-rank P = 0.028) and overall survival (OS) (HR 0.29; 95% CI 0.09 - 0.89; log-rank P= 0.021). Using cutoffs identified in adenocarcinoma, we applied the same algorithms to the squamous cell carcinoma cohort. Subjects with mean AF < 1% had longer PFS (HR 0.26; 95% CI 0.10 - 0.71; log-rank P = 0.005) and OS (HR 0.12; 95% CI 0.05 - 0.51; log-rank P= 0.001). **Conclusion:** Even in heterogeneous diseases such as NSCLC, changes in ctDNA levels in response to treatment may prove to be a valuable way of identifying subjects who may not benefit, before current standard of care methods like computed tomography (CT) scan. Future prospective studies to confirm these results are warranted.

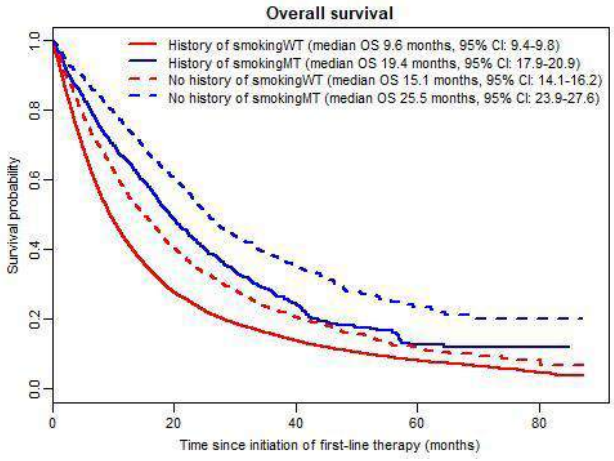
P1.01-35 REAL WORLD CHARACTERIZATION OF ADVANCED NON-SMALL CELL LUNG CANCER IN NEVER SMOKERS

K. Kerrigan[1], B. Haaland[1], B. Adamson[2], S. Patel[1], W. Akerley[1]

[1]*Huntsman Cancer Institute, Salt Lake City/United States of America,* [2]*Flatiron Health, New York City/United States of America*

Background: NSCLC in never smokers is vastly different from those with a history of smoking in terms of etiology, driver-mutations and response to immunotherapy. We have previously demonstrated a hereditary contribution in never smokers which is not identified in smokers[1]. This study compares the real-world survival of NSCLC in never smokers to those with a smoking history by mutation status. **Method:** The study included patients in the Flatiron Health nationwide electronic health record-derived database who were diagnosed with NSCLC, received biomarker testing results (EGFR, BRAF, ALK, and ROS1), and initiated therapy between 2011-2017 with follow-up through June 2018. Overall survival (OS) of patients by smoking and driver mutation groups was summarized via Kaplan-Meier survival estimates, and compared in the context of a multivariate Cox proportional hazard model adjusted by age at stage IV diagnosis, gender, state of residence, histology, smoking status, and race/ethnicity, stratified by categories of advanced diagnosis date within practices. **Result:** The study included 30,310 patients with median age of 68.8 years, 46.7% female, 76.8% non-Hispanic white, and 12.6% never smokers. Actionable mutations were reported in 9.0%, differentially as 34.2% in non-smokers and 5.5% in smokers. OS differed by smoking and driver-mutation categories (adjusted and stratified p<0.001). The median OS for patients with wild-type mutation status and history of smoking was 9.6 months, for mutated smokers was 19.4 months (adjusted and stratified hazard ratio [HR] relative to WT smokers 0.65 (95% CI 0.60-0.71)), for wild-type never-smokers was 15.1 months (0.78 (0.73-0.83) relative to WT smokers), and for mutated never-smokers was 25.5 months (0.52 (0.48-0.58) relative to WT smokers).



Conclusion: Never-smokers with NSCLC survived longer than those with smoking history, in both groups of wild-type and mutation-positive patients. Findings highlight that in patients with NSCLC, a smoking history may have similar effect on hazard of death as actionable mutation status.

Keywords: never smokers, lung cancer, real world data, advanced NSCLC

P1.01-36 CLINICAL POTENTIAL OF TISSUE TUMOR MUTATIONAL BURDEN (TTMB) AND BLOOD TMB (BTMB) AS A BIOMARKER IN NON-SMALL CELL LUNG CANCER

J. Zhou[1], J. Zhou[1], X. Chen[1], Y. Zhu[1], L. Fang[1], Z. Bao[1], R. Liu[1], H. Cao[1], W. Sun[1], T. Zhang[2], J. Lin[2], B. Yu[2]

[1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: Higher tissue TMB (tTMB) or blood TMB (bTMB) levels are associated with better response of immunotherapy in patients with non-small cell lung cancer (NSCLC). The clinical utility of bTMB and tTMB for clinical indications remain to be determined. **Method:** Comprehensive genomic profiling were performed on 28 paired tissue and plasma samples using 520-gene panel, which has been validated to accurately reflect the actual tTMB and bTMB using in-house validation. The max allelic fraction (max.AF) of 5% in tissue and 0.5% in plasma were defined as the detection limit for TMB assessment, and samples with max.AF < 5% (n=1) in tissue and 0.5% in plasma (n=6) were excluded. Union-TMB represents the union of tTMB and bTMB, and union-TMB-class-10 denotes union-TMB of 10 is used as the cutoff for grouping. **Result:** Correlation analysis revealed that bTMB and tTMB diaplayed significant consistency with each other (R^2=0.953). Next, associations of clinical characteristics and TMB status were analyzed. Older patients were significantly associated with higher tTMB (p=0.009) than younger ones, but slightly correlated with TMB-max (p=0.055) and TMB-union (p=0.079). We also found that male patients more commonly had higher tTMB (p=0.001), bTMB (p=0.011), max-TMB (p<0.001), union-TMB (p<0.001) and union-TMB-class-10 (p=0.018) than female ones with statistical significance, while smokers usually had higher tTMB (p=0.003), max-TMB (p=0.011), union-TMB (p=0.004) and union-TMB-class-10 (p=0.044) than non-smokers. Next, the correlation between TMB and clinical response were investigated in 19 patients who received nivolumab treatment. We found patients who had partial response to nivolumab commonly had higher bTMB than those experienced stable disease or progression (p=0.076); patients with bTMB>=10 or bTMB>=16 achieved higher objective response rate (ORR) than that with bTMB<10 (42.9% vs 0.0%) or bTMB<16 (66.7% vs 10.0%); patients with squamous cell carcinoma achieved significantly favorable progression-free survival than those with adenocarcinoma (p=0.019). **Conclusion:** We revealed that tTMB and bTMB were strongly correlated with each other for TMB assessment. Higher tTMB was strongly correlated with smokers and males compared with non-smokers and females. Higher bTMB predicted better response and ORR to nivolumab, indicating that bTMB could function as a biomarker for prognosis prediction. Prospective studies are necessary to investigate the clinical implications of tTMB and bTMB in a larger cohort of patients.

Keywords: bTMB, NSCLC, tTMB

P1.01-37 RADIOTHERAPY CHANGED THE SUBCLONAL COMPOSITION OF BRAIN METASTASIS FROM NON SMALL CELL LUNG CANCER: NGS-BASED ANALYSIS OF CEREBROSPINAL FLUID

X. Zhu[1], L. Wang[2], X. Duan[3]

Background: Radiotherapy(RT) is an effective treatment for brain metastasis (BM) of non-small cell lung cancer (NSCLC). Cerebrospinal fluid (CSF) can be used for dynamic monitoring the oncogenic mutations of BM from NSCLC. **Method:** A total of 22 CSF samples from 8 patients with BM from NSCLC were collected at three time points(before the start, in the middle and at the end of RT)and analyzed using NGS. **Result:** Five patients (D01, D03, D04, D07, D08) exhibited a significantly decreased mutation number after RT, and new mutation was detected in two patients (D03, D07). A large number of new copy number variations (CNVs) were detected after RT in one patient (D06), and the mutation abundance of the primary clone also increased significantly. One patient (D08) showed a slight increase in mutation abundance of the primary clone after RT. Mutation detections at all time points were negative in two patients (D02, D05).

Patients	Gender	Pathology	Baseline mutation status (Sample type)	Radiotherapy regime	concurrent systematic treatment	Brain metastasis	Changes of CSF mutation status			
							Pre-radiation	Post-radiation		
							Common driven mutation	mutation abundance	mutation number	New mutations
D01	Male	Squamous cell carcinoma	Unknown	SIB-IMRT: WBRT 40Gy/20F, GTV 56Gy/20F	No	Newly diagnosed	No	↓	↓	No
D02	Female	Adenocarcinoma	C-MET(+++) (Tissue from BM)	SIB-IMRT: WBRT 40Gy/20F, GTV 56Gy/20F	Pem+Cis	Newly diagnosed	No	—	—	—
D03	Male	Adenocarcinoma	EGFR 19-Del (Tissue from lung lesion)	SIB-IMRT: WBRT 36Gy/20F, GTV 54Gy/20F	Erlotinib	Newly diagnosed after TKI	No	↓	↓	EGFR 19del
D04	Male	Unknown	Unknown	3D-CRT: WBRT 40Gy/20F	No	Newly diagnosed	EGFR 19-Del	↓	↓	No
D05	Female	Adenocarcinoma	EGFR 19-Del (Tissue from lung lesion)	SIB-IMRT: WBRT 36Gy/20F, GTV 56Gy/20F	Erlotinib	Progressed after TKI	No	—	—	—
D06	Male	Adenocarcinoma	EGFR 21 L858R(+) (Tissue from lung lesion)	WBRT 40Gy/20F SRS 16Gy	Erlotinib	Progressed after TKI	EGFR 21 L858R(+)	↓ at first and then ↑	↑	CNVs
D07	Female	Adenocarcinoma	EGFR 21 L858R(+) (Blood plasma)	3D-CRT: WBRT 30Gy/10F	No	Newly diagnosed after TKI	EGFR 21 L859R(+) MET amp	↓	↓	MAP3K13 p.R585Q
D08	Female	Adenocarcinoma	ALK(+) (Tissue from lung lesion)	SIB-IMRT: WBRT 40Gy/20F, GTV 56Gy/20F	Crizotinib	Newly diagnosed after TKI	ALK(+)	slightly ↑	↓	No

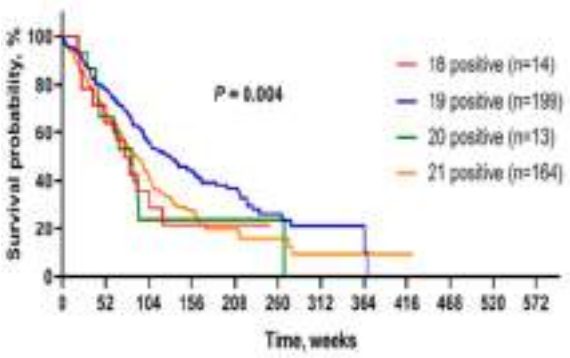
P1.01-38 CLINICAL SIGNIFICANCE ACCORDING TO EGFR MUTATION SUBTYPES IN LUNG ADENOCARCINOMA: KOREAN MULTICENTER EXPERIENCE

J. Chang[1], H.Y. Yoon[1], D. Kim[2], J.-S. Ryu[3], S. Lee[4], Y. Sim[5], J. Choi[4]

[1]*Ewha Womans University, Seoul/Korea, Republic of,* [2]*Soonchunhayng University Bucheon Hospital, Bucheon/Korea, Republic of,* [3]*Inha University College of Medicine, Incheon/Korea, Republic of,* [4]*Korea University Guro Hospital, Seoul/Korea, Republic of,* [5]*Hallym University Kangnam Sacred Heart Hospital, Seoul/Korea, Republic of*

Background: Adenocarcinoma is the most common type of non-small cell lung cancer causing genetic mutations. The most common gene mutations associated with EGFR receptors are deletion at exon 19 and point mutation at exon 21, L858R. However, other uncommon mutations cover 10 to 18% of all EGFR mutations. Mutations in exon 18 and 20 are important in incidence among uncommon mutations. We aimed to analyze the clinical significance according to EGFR mutation subtypes in lung adenocarcinoma. **Method:** Data were collected from 5 university hospitals in Seoul and Gyeonggi province of Korea. During the period from 2010 to 2016, patients of lung adenocarcinoma of stage 3 to 4 who were not treated surgically and examined for EGFR mutation were enrolled. The total subjects were 1021 persons. Patients were retrospectively analyzed for clinical features by subtypes of EGFR mutation. **Result:** EGFR positivity was 38.1%: mutation positive group was significantly lower in males and smokers compared to mutation negative group, while in mutation positive group the proportion of patients receiving traditional chemotherapy or EGFR targeted therapy was significantly higher and also percentage of stage IV were significantly more than that of stage III. Among EGFR positivity, the incidence of mutations in exon 18, 19, 20, and 21 were 3.6%, 51.2%, 3.3%, and 41.9%, respectively. Among the four subtypes, the age was relatively low at exon 19 mutation (p=0.006), while the proportion of smokers was particularly high at exon 20 mutation (p=0.016). EGFR positive group survived significantly longer than the negative group (p<0.001), and there was a significant difference in survival among the four subtypes of EGFR positive group (p=0.004): mutation in exon 19 showed a better survival probability compared to the other subtypes (p<0.001), whereas mutation in exon 21 showed a poorer prognosis (p=0.006). Univariate and multivariate analysis showed that mutation in exon 19 was the only significant factor that lowered the mortality rate (HR:0.415, p=0.001) and mutations in exon 18, 20 and 21 were not significant. In EGFR positivity, TKI non-responder showed significantly higher proportion of exon 21 mutation, compared to TKI-responder (p<0.05).



Survival probability according to EGFR mutation subtype in EGFR positive adenocarcinoma

Conclusion: Presenting mutation of exon 19 in advanced lung adenocarcinoma prospects better survival than other EGFR mutations. Unlike the previous reports, mutation in exon 18 or 20 was not a worse factor than mutation in exon 21.

Keywords: adenocarcinoma, EGFR mutation, Survival

P1.01-39 IS THERE AN ASSOCIATION BETWEEN INTRACRANIAL PROGRESSION AND OVERALL SURVIVAL OR NEUROLOGIC DEATH IN PATIENTS WITH EGFR POSITIVE NSCLC?

M. Doherty[1], M. Ramotar[2], D. Shultz[2]

[1]*Sunnybrook Odette Cancer Centre, Toronto/Canada,* [2]*Princess Margaret Cancer Centre, Toronto/Canada*

Background: Many studies have examined the incidence of Brain Metastases (BrM) in EGFRm+ NSCLC, and their impact on radiographic and survival outcomes. We have examined the incidence of ND and predictive factors in a retrospective cohort. The clinical significance of ICP remains controversial; patients who develop new lesions may be treated with further locoregional treatment such as stereotactic radiosurgery (SRS). This study examines the association between ICP and survival or ND, to help define appropriate endpoints for future trials. **Method:** All patients treated for BrM from EGFRm+ NSCLC between 2004 and 2016 were identified from an institutional registry. Clinical data regarding demographics, progression events, pattern of progression, and treatment were extracted from medical records and verified with imaging reports. A multivariable competing-risks model was constructed to test the association between ICP at 6, 12 and 18 months and the outcome of ND. A separate model tested the association between ICP and OS. **Result:** 198 patients were included in the study. Median age was 61 years, 67% of patients were female, 46% had BrM at NSCLC diagnosis. Median DS-GPA was 2.5. Median OS for the group was 20 months, and the 5-year cumulative incidence of neurologic death was 40%. 111 patients (56%) had ICP and median intracranial PFS was 16 months; 29% had ICP within 6 months and 33% between 6 and 12 months, 18% at 12-18 months and 21% at >18 months. ICP was due to new BrM in 51%, progression of existing BrM in 34% and leptomeningeal carcinomatosis in 15%. Among patients with ICP, earlier progression was associated with ND (HR 2.48, p=0.01, see table). In addition, pattern of ICP was significant; patients with leptomeningeal spread (HR 3.74, p<.001) had higher risk of ND than those with new BrM or progression of existing lesions. In a multivariable model, early ICP, pattern of ICP and more initial BrM were independently associated with higher risk of ND and also shorter OS.

BrM at Diagnosis	0.93 (0.54-1.60)	0.78	1.45 (0.77-2.73)	0.26	0.93 (0.65-1.32)	0.69

Conclusion: Among patients with brain metastases from EGFRm+ NSCLC, shorter time to intracranial progression was associated with higher rates of neurologic death, as was the pattern of progression. This supports the validity of studies using intracranial progression as an endpoint, particularly if pattern of disease is taken into account.

P1.01-40 EGFR CTDNA DETECTION: THE IMPACT OF SITE OF PROGRESSION AND BURDEN OF PROGRESSIVE DISEASE

A. Pender[1], C. Hughesman[2], E. Law[2], A. Kristanti[2], K. Mcneil[2], T. Tucker[2], I. Bosdet[2], S. Young[2], J. Laskin[1,3], A. Karsan[2,3], S. Yip[2,3], C. Ho[1,3]

[1]*BC Cancer, Vancouver/Canada,* [2]*British Columbia Cancer Agency, Vancouver/Canada,* [3]*University of British Columbia, BC Cancer, Vancouver/Canada*

Background: *EGFR T790M* testing is standard of care for activating EGFR mutant (EGFRm) NSCLC progressing on 1st/2nd generation TKIs to select patients for osimertinib. Despite sensitive assays, detection of circulating tumour DNA (ctDNA) is variable and influenced by clinical factors. We reviewed the number and location of sites of progressive disease (SPD) at time of testing to explore the effect on ctDNA detection and T790M positivity. **Method:** Following extraction of cell-free DNA from plasma using the QIAamp Circulating Nucleic Acid Kit, custom ddPCR assays were used to test for *EGFR* ctDNA using the Bio-Rad QX200 system. The ddPCR assays have a limit of detection of <0.1% variant allele fraction. Baseline characteristics and imaging reports at time of blood draw were reviewed retrospectively for all patients undergoing ctDNA testing from February 2018-March 2019. **Result:** 175 patients with EGFRm adenocarcinoma had 211 *EGFR* ctDNA tests performed. At the time of testing: median age 66, 63% female, 61% never smokers, 53% Asian. Initial TKI: 63% gefitinib, 34% afatanib, 2% erlotinib. Tissue genotype: 54% exon 19 deletion, 35% exon 21 mutation, 10% >1/rare mutation, 1% de novo T790M mutation. *EGFR* ctDNA testing results: 57% indeterminant, 29% *EGFR*m + T790M, 12% *EGFR*m alone, 2% T790M alone.

Variable	OR for ctDNA positivity (95% CI)	p value	MVA for ctDNA positivity (95% CI)	p value
Progression (absent vs present)				
Intrathoracic	1.32 (0.69-2.48)	0.40		
Extrathoracic	2.11 (1.19-3.73)	0.01		
Site of progression disease (absent vs present)				
Adrenal	0.89 (0.24-3.26)	0.86		
Bone	2.92 (1.61-5.33)	<0.001	2.78 (1.44-5.38)	0.002
Brain/LM	0.68 (0.32-1.43)	0.31		
Liver	2.9 (1.23-6.85)	0.02	3.12 (1.22-7.18)	0.018
Lung	0.95 (0.53-1.7)	0.87		
Lymph nodes	1.83 (0.95-3.54)	0.07	1.73 (0.84-3.55)	0.14
Number of sites				
0-2 sites	1		1	
3-5 sites	2.71 (1.38-5.32)	0.004	2.03 (0.98-4.19)	0.057
6-10 sites	2.12 (1.01-4.43)	0.047	1.22 (0.53-2.77)	0.64
>10 sites	2.31 (0.78-6.81)	0.13	0.95 (0.28-3.29)	0.94

Of ctDNA positive specimens, T790M positivity was not influenced by location or number of SPD compared to EGFRm. **Conclusion:** EGFR ctDNA was most likely to be detected in patients with progressing liver or bone lesions, independent of the number of SPD. Clinicians may consider these predictive variables in selecting patients for ctDNA re-testing. If ctDNA was detected, T790M positivity was not dependent on location or number of SPD.

P1.01-41 INVOLVEMENT OF THE JNK PATHWAY IN BRUCEINE D-INDUCED APOPTOSIS IN HUMAN NON-SMALL CELL LUNG CANCER CELLS

B. Tan[1], F. Wang[1], Y. Huang[1], L. Lan[2], B. Zhang[1], N. Lin[1]

[1]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou, Zhejiang, China, 310006, zhejiang/China,* [2]*Institute of Agricultural Bio-Environmental Engineering, College of Biosystem Engineering and Food Science, Zhejiang University, Hangzhou, Zhejiang/China*

Background: Non-small cell lung cancer (NSCLC), which accounts for 80% of lung cancer, is the leading cause of cancer mortality. Bruceine D (BD), a quassinoid isolated from *Brucea javanica's* fruit (a traditional Chinese herbal medicine), exhibits anti-cancer activity. This study aimed to investigate the effect of BD for non-small cell lung cancer (NSCLC) cells *in vitro.* **Method:** CCK-8 was used to detect the proliferation inhibitory effects of different concentrations of BD on A549, H460 cells. Cell clone formation was observed by clone formation assay. Annexin V/PI assay was used to detect the apoptosis induced by different concentrations of BD, and Western blot was used to detect the expression of apoptosis-related proteins and p-JNK after BD treatment. **Result:** The proliferation of A549, H460 cells was significantly inhibited by the different concentrations of BD (0.75, 1.5, 3, 6, 12 μmol·L-1) for 48 h in a concentration-dependent manner ($P < 0.05$), with IC50 values of 0.6 and 0.5 μmol/L, respectively. Annexin V/PI assay of apoptosis showed that different concentrations of BD had significant apoptosis-inducing effect on the two NSCLC cells ($P < 0.05$). Western blot results showed that cleaved-caspase-3 and cleaved-PARP were activated 48 h after BD treatment in NSCLC cells. Mechanistically, p-JNK protein expression was significantly increased after BD treatment for 2 h. Furthermore, the anti-cancer effects of BD were alleviated effectively by a specific JNK inhibitor SP600125 in NSCLC cells. **Conclusion:** BD can inhibit the proliferation of NSCLC cells and induce its apoptosis in a concentration-dependent manner. Its mechanism may be through the activation of JNK-caspase-PARP signaling pathway. All results suggest BD exhibits potent usefulness for preventing and treatment of NSCLC.

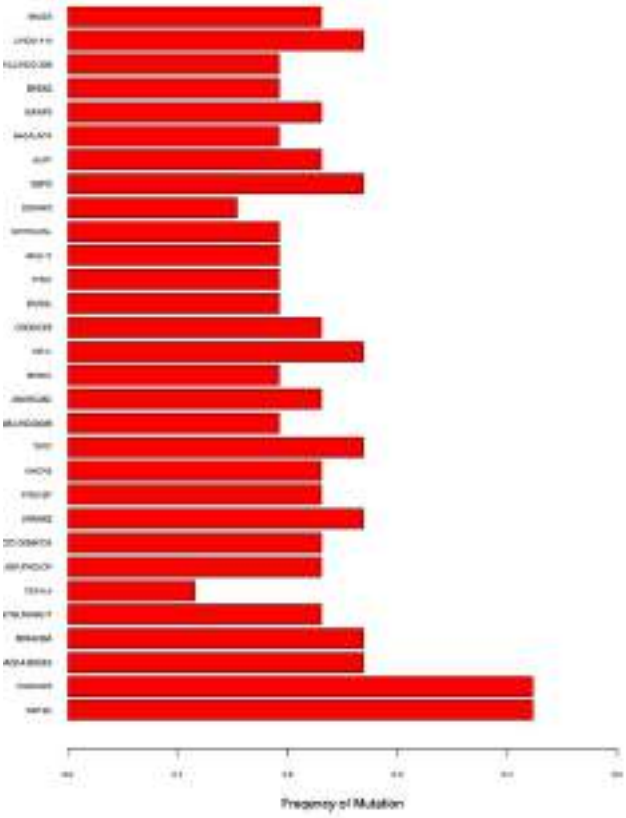
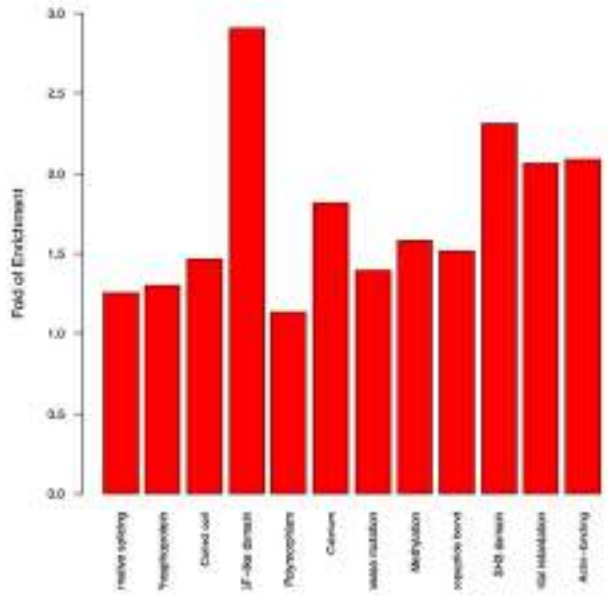
P1.01-42 WHOLE-EXOME SEQUENCING IDENTIFIES NOVEL SOMATIC MUTATIONS ASSOCIATED WITH PROGNOSIS IN LUNG CANCER METASTATIC TO THE BRAIN

C. Su, X. Li, C. Zhao, J. Zhao

Shanghai Pulmonary Hospital, Shanghai/China

Background: Lung cancer is the leading cause of cancer-related mortality in China and worldwide. Patients with lung cancer are the major origin of metastastatic brain tumor. Understanding the difference between primary lung lesion and brain metastases may contribute to the treatment strategy. **Method:** To investigate the difference of somatic mutations in patients with non–small-cell lung cancer (NSCLC) and brain metastases. Whole-exome sequencing method were used in 13 paired lung cancer and brain metastasis samples from our institute. **Result:** 6,318 SNVs and 56,686 mutation events in 3864 genes were observed in 13 paired lung cancer and brain metastasis samples. We identified 46 driven gene mutations which are most frequently related to lung cancer. Several lung cancer metastases associated genes (KMT2C, BAGE2 and FER1L4) and epigenetic factors (CHEK2P2, miR-4436A, miR-6077) were found as well. A mean of 3.1 driver mutation events per tumor with the dN/dS of 2.06 (95%CI: 1.73-2.4) in these samples which indicating a significant enrichment of the cancer driven mutations. Mutation spectrum analysis found that these samples have more similar transition (Ti) and transversion (Tv) profile,in which C->T transitions is more frequently seen in brain metastasis samples, while lung primary tumor have a higher frequency of C->A transversion. Furthermore we found the most important tumor onset and metastasis pathways in these samples, such as focal adhesion,PI3K-Akt signaling pathway and MAPK signaling pathway. What's more, Glioma pathway were also identified which highly indicating the solid finding of the study.





Conclusion: In summary, we conducted an exome-wide sequencing through pairwised lung primary and brain metastasis samples and identified some novel cancer and metastasis related mutation which provided potential biomarkers for prognosis and novel therapeutics.

P1.01-43 PROGRAMMED-DEATH LIGAND 1 SPECTRUM IN A LARGE COHORT OF GENETICALLY CHARACTERIZED NON-SMALL CELL LUNG CANCER PATIENTS

E. Marin, C. Teixido, E. Carmona, A. Arcocha, C. Cabrera, D. Martinez, P. Jares, N. Viñolas, A. Prat, N. Reguart

Hospital Clinic Barcelona, Barcelona/Spain

Background: Programmed-death ligand 1 (PD-L1) expression, assessed by immunohistochemistry (IHC), is used to select patients (pts) for checkpoint inhibitors. However, the pattern of PD-L1 expression across rare oncogenic alterations remains poorly characterized. We aimed to evaluate PD-L1 expression in a large dataset of pts with activating molecular alterations to define the potential responsiveness to immunotherapy. **Method:** From 2016 to 2018, we prospectively characterized advanced NSCLC pts from a single institution. Tumor Proportion Score (TPS) for PD-L1 protein expression was evaluated by IHC (22C3 clone) using formalin-fixed paraffin-embedded tumor samples and scored into <1% (negative), 1-49% (weakly positive) and >=50% (high). DNA and RNA were extracted and analysed by Oncomine Solid Tumour panel (22 genes) and a customized nCounter-based panel (*ALK*, *ROS1*, *RET*, *NTRK1*, *METΔ14*). Associations between PD-L1 expression and the most prevalent driver alterations were assessed. Smoking habit and its possible relationship with PD-L1 expression was also appraised. Statistical analyses were performed using Kruskal-Wallis and Mann-Whitney tests. **Result:** TPS for PD-L1 expression was available for a total of 140 patients (pts) fully genotyped. The cohort included: 36% women; 89% adenocarcinoma; 87% smokers. TPS for PD-L1 expression was negative (<1%), weak (1-49%) and high (>=50%) in 40%, 35% and 25% of pts, respectively. Actionable drivers were found in 84 pts (60%) being *KRAS* (n=43.31%) the most commonly detected, followed by *EGFR* (n=22.16%), *BRAF* (n=7.5%), *METΔ14* (n=8.6%), *ALK* (n=3.2%) and *ERBB2* (n=1, 1%). Thirty (21.4%) [ME1] pts harboured *TP53* co-mutations. By comparing all genotyped cohorts, *METΔ14* alteration was associated with higher PD-L1 expression levels compared with other subgroups (median TPS 58.62 vs 25.26, p=0.017[ME2]). In addition, PD-L1 expression was also higher in pts harbouring any *TP53* co-mutation than those with any alteration but *TP53*-WT (median TPS 41.53 vs 21.45, p=0.035). When *KRAS-mut*, *BRAF-mut* and *EGFR-mut* were evaluated separately, PD-L1 expression was higher in *TP53 mutated* tumors compared to *TP53* WT only in *BRAF-mut* (p=0.028). Finally, no significant differences were found regarding patients' smoking status (p=0.527). **Conclusion:** Our results suggest differential expression of PD-L1 based on the presence of MET alterations and *TP53* mutations and highlight the need of further characterizing PD-L1 expression across oncogenic alterations.

Background: The functional role of microbiota on the development of cancer has attracted an accumulating attention recently. However, the impact of fecal and sputum microbiome in the formation and development of Non-small-cell lung cancer (NSCLC) are mostly unknown. Our study aimed to characterize and compare fecal and sputum microbiome of NSCLC patients with healthy control subjects, and analysis the fecal microbiome of NSCLC patients with or without brain metastasis (BM). **Method:** We collected 102 fecal and 71 sputum samples from Wuhan Union Hospital. The Illumine Miseq sequencing platform was used to analyze 16S rRNA variable regions V3 and V4 in these samples. C57/BJ mice were treated with an antibiotic cocktail to postnatally deplete the microbiota. The effect of antibiotic was subsequently investigated both in xenograft model and brain metastases model. **Result:** Clinical characteristics of the participants including age, gender and body mass index were matched between the compared groups. (1) The sputum microbial diversity of healthy control group (n=18) was higher than NSCLC group (n=53, $P < 0.05$). Genus Actinomyces was significantly more abundant in sputum samples of NSCLC patients than the healthy controls ($P < 0.05$), while Neisseria was more abundant in the controls. The area under the curve of genus Actinomyces used to predict lung cancer was 0.71 (95% CI: 0.69 - 0.91). (2) However, no difference in alpha diversity was showed between the fecal microbial of healthy control group (n=22) and NSCLC group (n=80). Genus Haemophilus was significantly more abundant in fecal sample of NSCLC patients than the healthy controls ($P < 0.05$). The area under the curve of genus Actinomyces used to predict lung cancer was 0.75 (95% CI: 0.65 - 0.84). (3) The alpha diversity of fecal microbial was similar between patients with brain metastasis group (BM+, n=18) and patients without BM group (BM-, n=32). But there were some differences in the microflora structure between the 2 groups. (4) An impaired microbiota of mouse, antibiotic treatment, promoted tumorigenesis in subcutaneous xenograft, but inhibited tumorigenesis in brain metastasis. Impaired microbiota at least partially influenced the progression of Lewis cell line through acute and chronic inflammation of the intestine. **Conclusion:** The genus Actinomyces in sputum samples and Haemophilus in fecal samples were abundant in NCSLC group and exhibited moderate classification potential. The microflora structure of BM(-) and BM(+) group was significantly different. Antibiotic treatment at least partially influenced Lewis progression through acute and chronic inflammation of the intestine.

Keywords: brain metastasis, Microbiota, NSCLC

P1.01-45 A NGS-BASED CTDNA TEST TO MONITOR DISEASE PROGRESSION AND TREATMENT RESPONSE IN ADVANCED STAGE NON-SMALL CELL LUNG CANCER

J. Jen[1], J. Jang[1], J. Zhang[2], A. Tang[1], K. Pierson[1], A. Schrandt,[1], H. Xie[1], P. Yang[1], S. Mandreka[1], A. Mansfield[1]

[1]*Mayo Clinic, Rochester/United States of America,* [2]*Sino-Japan Friendship Hospital, Beijing/China*

Background: The gold standard for clinical monitoring of lung cancer is CT imagining which is subjective and insensitive requiring a minimal of 2-3 months between repeat scans to be meaningful. As such, there is an urgent need to develop tests that can monitor anticancer treatment response and disease progression in real time. In this study, we evaluted the use of Next Generation Sequencing (NGS) for tumor associated genetic changes in circulating tumor DNA (ctDNA) to identify tumor mutations and the frequency of mutations detected in cfDNA to track tumor progression. We compared the results of a plasma based multigene mutation detection assay in advanced stage lung cancer patients to that of the routine CT scan and clinical observations. **Method:** EDTA whole blood were prospecitvely collected within 48 hours of the CT scan and during the course of patients' clinical treatment. Platelet poor plasma were collected within 6 hours of the blood draw and stored at -80°C until use. In total, we accrued 121 plasma samples from 46 consented patients with advanced stage lung cancer and undergoing therapy at Mayo Clinic in Rochester, Minnesota. All data are stored in a RAVE databased and RECIST criteria were reviewed individually by an attending oncologist. NGS analysis were performed using a modified Plasma*Select*-R™ (Personal Genome Diagnostics, Maryland) assay to assess mutation type and fraction of ctDNA in plasma sample from each patient. The results were compared with CT scans at the time of each blood draw for their ability to 1) detect the cancer based on tumor associated mutations and 2) correlate with the clinical status (RECIST) of the disease based on the fraction of ctDNA in plasma. **Result:** Among 121 plasma samples tested from 46 unique patients, 29 patients had three blood draws and 17 had a base line plus a follow up blood draw available for evaluation. More than 20 different tumor related mutations were observed. The number of mutations in each plasma sample ranged from 0 in eight patients to 5 in two individuals with allele frequencies ranging from 0.07% for *TP53* gene mutation to 29% in the *KRAS* gene. Tumor associated mutations were detected in approximately 70% of the plasma samples. In a pilot set of 10 cases with baseline and one follow up blood draw, those with progression of disease (PD, n=4) had tumor associated mutations detected in both baseline and follow up blood draws. In contrast, the remaining six patients with stable disease (SD) or partical response (PR) by RECIST had zero or fewer mutations at follow up. **Conclusion:** Our results suggeststst that a liquid biopsy approach is highly feasible and very promising in clinical settings. For patients whose tumors carry a mutation, the use of liquid biopsy to monitor treatment response and disease progression reduces patients' exposure to unnecessary radiation for surveillance of recurrent disease and enables a more sensitive and real-time monitoring of patients' clinical status to guide

further thearpeutic decisions. Complete mutational analysis with detailed clinical responses of each patients will be reported at the time of conference.

Keywords: liquid biopsy, Next generation sequencing, NSCLC

P1.01-46 RESPONSE ASSESSMENT USING PLASMA CELL-FREE DNA (CFDNA) – WHEN IS THE OPTIMAL TIME TO ASSESS RESPONSE?

M. Cheng[1], C. Lau[1], M. Milan[1], J. Supplee[1], J. Riess[2], P. Bradbury[3,4], C. Paweletz[1], G. Oxnard[1]

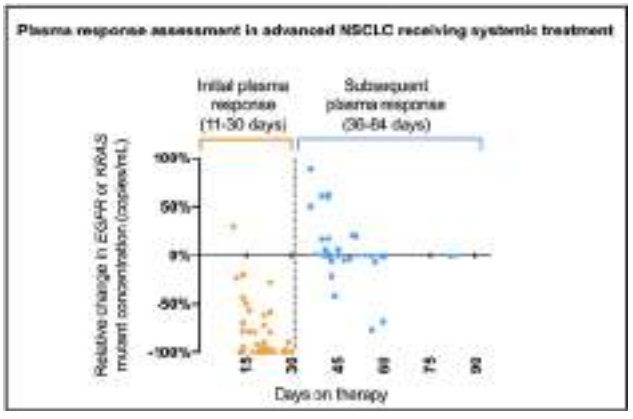
Background: Plasma cfDNA analysis is routine for non-invasive genotyping of advanced NSCLC, however response assessment using plasma cfDNA is not well characterized. We hypothesized that response in cfDNA would be an early process occurring well before routine imaging timepoints. **Method:** We retrospectively analyzed a total of 48 baseline and serial on-treatment plasma samples collected from 16 patients enrolled across three Experimental Therapeutics Clinical Trials Network (ETCTN) phase I trials of osimertinib combinations in advanced *EGFR*-mutant NSCLC. For validation, we also retrospectively analyzed a total of 201 baseline and serial on-treatment samples from an institutional cohort of 67 advanced NSCLC patients receiving systemic treatment. Using droplet digital PCR (ddPCR) of key *EGFR* or *KRAS* driver mutations, plasma response was defined as any decrease in mutation concentration to below baseline levels. We compared the magnitude of initial (baseline to day 11-30) and subsequent (day 11-30 to day 36-84) plasma response. Finally, we prospectively assessed response using serial amplicon-based plasma next-generation sequencing (NGS) in a pilot cohort of 8 NSCLC patients starting systemic therapy. **Result:** Of 15 ETCTN patients with any plasma response, best plasma response was seen at the initial response timepoint in 12 patients (80.0%) and ≥90% of the total plasma response was seen at the initial response timepoint in 14 patients (93.3%). In the validation cohort of 61 patients with any plasma response (Figure), best plasma response was seen at the initial response timepoint in 39 patients (63.9%) and ≥90% of the total plasma response was seen at the initial response timepoint in 52 patients (85.2%). Complete plasma responses (-100%) were seen as early as 11 days after initiating therapy. In the prospective clinical cohort, plasma NGS detected genomic alterations and enabled monitoring of changes in mutant allele fraction in all 8 patients. The median turnaround time of the assay was 8 days.



Conclusion: Plasma response is an early phenomenon, with the vast majority of plasma response seen within 30 days, and as early as 11 days. These findings suggest that early plasma cfDNA analysis may permit response assessment well before standard imaging timepoints, with potential as an early marker of drug effect. Additional investigation to understand the relationship between early plasma response, radiographic response, and durability of treatment effect is still needed.

Background: The AURA and FLAURA studies have shown that EGFR T790M mutation detected in cfDNA is correlated with efficacy of osimertinib as measured via overall response rate (ORR), and progression-free survival (PFS). However, the following clinical-related questions have been raised: Can other different assay systems confirm the results mentioned above? Does T790M level affect osimertinib treatment efficacy? Do mutations at loci other than EGFR influence treatment efficacy? **Method:** This is a prospective observational study, joining 27 Japanese hospitals. Plasma samples from patients with non-small cell lung cancer (NSCLC) who acquired resistance to EGFR-TKI (gefitinib, erlotinib, afatinib) were collected between Feb 2017 and Jan 2019. We tested T790M by MBP-QP method which has been newly developed using cfDNA and investigated the concordance with the result by cobas EGFR mutation Test v.2 (tissue and/or plasma) which is commercially available. We also checked the allele frequency (AF) of T790M in cfDNA by ddPCR and the mutational status of cancer related actionable genes by cfDNA specific NGS (Guardant360). The major objectives were ORR, disease control rate (DCR) to osimertinib and PFS in patients with T790M positive by MBP-QP method. **Result:** Among 145 NSCLC patients who acquired resistance to 1st or 2nd EGFR-TKI, T790M was detected in 57 patients by cobas (tissue and/or plasma), and these patients received osimertinib (80mg daily). T790M was detected by cobas in 16 patients from plasma, 44 patients from tissue, 3 patients from both samples. Among assessable patients, ORR, DCR and PFS in patients with T790M positive by cobas from plasma were 66.7%, 86.7%, 194 days, those of tissue were 53.5%, 97.7%, 186 days, respectively. In these 57 patients, MBP-QP also could detect T790M from 10 patients from plasma, and ORR, DCR and PFS in patients with T790M positive by MBP-QP from plasma were 75.0%, 87.5%, 184 days, respectively. These results suggest that T790M detection from cfDNA not only by cobas but also MBP-QP is correlated with RR of osimertinib. Now, using ddPCR and Guardant360, we have been investigating about the relationship between T790M AF and RR to osimertinib, and the influence of mutations at loci other on efficacy of osimertinib. **Conclusion:** cfDNA analysis can be predictive for osimertinib efficacy, just as re-biopsy. Whether comprehensive approach including AF and coexistence of other actionable genes is more precisely informative for drug efficacy has been continuously analyzed.

P1.01-48 EGFR TESTING IN ENGLAND – REAL WORLD EVIDENCE FROM THE NATIONAL LUNG CANCER AUDIT (NLCA) SPOTLIGHT ON MOLECULAR TESTING

J. Tweedie[1], A. Khakwani[2], R. Hubbard[2], N. Wood[3], S. Harden[4], P. Beckett[5], N. Navani[6]

[1]*University College London, London/United Kingdom,* [2]*University of Nottingham, Nottingham/United Kingdom,* [3]*Public Health England, London/United Kingdom,* [4]*Cambridge University Hospitals, Cambridge/United Kingdom,* [5]*Royal College of Physicians, London/United Kingdom,* [6]*University College London Hospital, London/United Kingdom*

Background: In 2010, the use of tyrosine kinase inhibitors (TKIs) was approved for the first-line treatment of patients with advanced non-small cell lung cancer (NSCLC) harbouring an epidermal growth factor receptor (EGFR) mutation, and EGFR mutation analysis in these patients has become a standard of care. However, limited real world data exist in the UK on EGFR testing, and treatment and outcome. We therefore carried out a nationwide retrospective study to evaluate sample acquisition, testing, turnaround times and therapies related to EGFR testing in routine clinical practice. **Method:** In collaboration with Public Health England, a dedicated portal was designed allowing hospitals in England to log in and provide information on patients identified with stage 3B and 4 PS0-2 NSCLC diagnosed between June and December 2017. The portal for data collection was open for a period of 11 weeks, from 19 October 2018 to 4 January 2019. **Result:** Of the 142 hospitals in England, 60 took part in this spotlight audit of which 19 had on-site EGFR testing: 1,157 individual patient records were uploaded on to the portal; 512 (44%) patients were female, 353 (31%) were under the age of 65 and 758 patients (66%) had adenocarcinoma. Common methods of tissue acquisition were percutaneous lung or lymph node biopsy (31%), endobronchial ultrasound (EBUS) (24%) and from pleural fluid or pleural biopsy (11%). In a multivariate analysis, patients undergoing pleural procedures as an initial investigation were twice as likely to require a second procedure for molecular analysis as patients undergoing EBUS. Of the 758 patients with an adenocarcinoma subtype, 701 (92%) underwent EGFR testing. Testing failed in only 3% of patients and 71 (9.4%) had a sensitising EGFR mutation. The median time from biopsy to EGFR result was 18 days (interquartile range 14–23) with a median of 9 days from arrival in the molecular lab to EGFR result. In patients with a sensitising EGFR mutation, 53 (75%) received a first-line TKI, 3 (4%) received first-line chemotherapy, 1 (1%) patient received immunotherapy and treatment was unknown in 14 (20%). The median survival of patients with an EGFR mutation was 19 months **Conclusion:** In this study, samples acquired by pleural procedures were less suitable for EGFR testing. Comprehensive EGFR testing has been successfully implemented on a national scale using regional centres. Further quality improvement measures are required to reduce time to EGFR result.

Keywords: EGFR, adenocarcinoma, real world

P1.01-49 SERIAL CHANGES IN WHOLE-GENOME CELL-FREE DNA (CFDNA) TO IDENTIFY DISEASE PROGRESSION PRIOR TO IMAGING IN ADVANCED NSCLC

A. Davis[1], W. Iams[2], D. Chan[3], M. Oh[1], R. Lentz[1], N. Peterman[4], A. Robertson[4], A. Shah[4], R. Srivas[4], N. Lambert[4], T. Wilson[4], A. Tezcan[4], J. Spinosa[4], H. Tezcan[4], N. Mohindra[1], V. Villaflor[1], Y.K. Chae[1]

Lurie Comprehensive Cancer Center of Northwestern University, Chicago/United States of America,* [2]*Vanderbilt University Medical Center, Nashville/United States of America,* [3]*Cancer Care Assoc-TMPN, Redondo Beach/United States of America,* [4]*Lexent Bio, Inc., San Francisco/United States of America*

Background: Response to treatment in advanced lung cancer is usually determined by clinical and imaging assessment. We analyzed longitudinal changes in blood whole-genome cfDNA to investigate whether a molecular response assessment could provide potentially actionable information prior to imaging. **Method:** We prospectively enrolled and serially collected blood from 35 patients with advanced non-small cell lung cancer (NSCLC). Baseline blood samples were drawn prior to initiation of a new treatment and at one or two additional time points, after the first cycle (median 21 days) and the second cycle (median 42 days). 4 mL of plasma was separated from peripheral blood collected in Streck tubes. Next, cfDNA was isolated from plasma and used to prepare libraries (15 with bisulfite conversion) for whole-genome sequencing at approximately 20X depth. Based on a patient-specific profile of whole-genome features, changes in the fraction of tumor-derived cfDNA were quantified over the initial course of treatment. Imaging was performed per standard practice with treatment response determined by an independent radiologist according to RECIST guidelines. **Result:** Median age of patients was 72 (range 48-87), and 49% were female. 69% of patients were on their first line of therapy (range 1-5). Patients were treated with an immune checkpoint inhibitor +/- chemotherapy (22), chemotherapy alone (11), or targeted therapy (2). Patients with predicted progression by cfDNA (n=4), indicated by an increase in tumor fraction at either post-treatment blood collection, had worse progression-free survival (PFS) compared to patients who did not show an increase (n=31) (hazard ratio 22.3, [95% CI 3.9-127.8], log-rank p=9 x 10-7). For the patients who were predicted to progress, the cfDNA assay preceded clinical evaluation by a median of 34 days. Median PFS was 56 days for patients with predicted progression versus 370 days for others. All patients with predicted progression were later confirmed to progress at the first follow-up evaluation (4/4, 100% positive predictive value). For the remaining patients, 27 of 31 did not progress (87% negative predictive value). Therefore, sensitivity for the assay was 50% and specificity was 100%. **Conclusion:** Analyzing tumor-derived cfDNA early in the course of a new therapy holds promise to identify patients with early disease progression across multiple types of treatment. This technology may enable early switching to other potentially effective therapies, increasing the value proposition of all delivered treatment.

P1.01-50 IMPACT OF CONCOMITANT HER2 ALTERATIONS IN MEDIATING CLINICAL OUTCOMES OF EGFR-MUTANT PATIENTS TO DIFFERENT GENERATION OF EGFR-TKIS

Y. Cheng[1], Y. Liu[1], L. Ma[1], J. Zhu[1], C. Yang[1], L. Zhang[1], T. Zhang[1], H. Jiang[1], Y. Zhang[1], Y. Wang[1], J. Hao[1], L. Zhang[2], H. Zhang[2], T. Zhang[2], J. Lin[2], L. Shi[2]

[1]*Jilin Cancer Hospital, Changchun/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: The 2nd generation EGFR-TKI are selective and potent irreversible pan-HER inhibitors. Given their effect on HER2 besides EGFR, we investigated the role of *HER2* co-alterations in mediating the clinical outcomes of *EGFR*-mutant non-small cell lung cancers to 2nd generation or other generation EGFR-TKIs. **Method:** Plasma/tissue samples from advanced NSCLC before and after 1L EGFR-TKI treatment were sequenced using 168-/520-cancer-related gene panels, respectively. Clinical records of 94 *EGFR*-mutant pts (92 adenocarcinomas and 2 adenosquamous cell carcinomas) after 1st/3rd (n=73) or 2nd generation (afatinib, n=16; dacomitinib, n=5) EGFR-TKI treatment were collected for clinical outcomes evaluation. Event-time distributions were estimated using Kaplan-Meier and compared with long-rank test. **Result:** Among the 94 pts identified as *EGFR*-positive at baseline, 8 (8.5%) had concurrent *HER2* gain-of-function alterations (amplification or active mutation). Survival analysis showed that for those with concomitant *EGFR* and *HER2* alterations at baseline, pts achieved favorable PFS (23.2 vs 5.6 months, p=0.04) to 2nd generation (n=2) than to 1st/3rd generation EGFR-TKI (n=6) as 1L treatment. And for those receiving 1L 1st/3rd generation EGFR-TKI (n=73), the presence of baseline *HER2* alterations (n=6) was associated with shorter PFS (5.6 vs 9.8 months, p=0.16) and OS (15.7 vs 21.0 months, p=0.06) than absence of *HER2* (n=67), although the difference was not significant due to a small sample size. In addition, we found all the samples (n=21) obtained from pts after 2nd generation EGFR-TKI resistance were *HER2*-negative, but pts progressed on 1st or 3rd generation EGFR-TKI with *HER2* as the only resistance mechanism were observed in our study cohort. **Conclusion:** Our findings suggested that, for *EGFR*-mutant pts combined with *HER2* alterations at baseline or those resistant to 1L treatment of 1st/3rd EGFR-TKI due to *HER2* alterations only,2nd EGFR-TKI might be a better choice.Our findings suggested that, for *EGFR*-mutant pts combined with *HER2* alterations at baseline or those resistant to 1L treatment of 1st/3rd EGFR-TKI due to *HER2* alterations only,2nd EGFR-TKI might be a better choice.

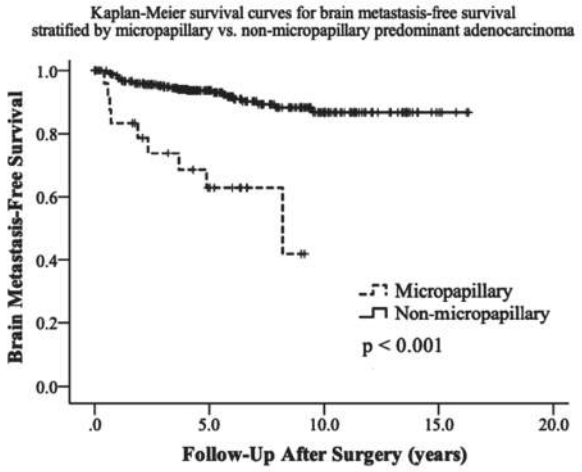
Keyword: HER2 EGFR-TKI afatinib

P1.01-51 MICROPAPILLARY PREDOMINANT AND PATHOLOGIC STAGE WERE RISK FACTORS FOR POSTOPERATIVE BRAIN METASTASIS IN LUNG ADENOCARCINOMA

T. Shigenobu[1], Y. Masugi[2], R. Hanawa[1], A. Tajima[1], Y. Takahashi[3]

[1]*Saiseikai Utsunomiya Hospital, Utsunomiya/Japan,* [2]*Keio University School of Medicine, Shinjuku/Japan,* [3]*Aichi Cancer Center Research Institute, Nagoya/Japan*

Background: Brain metastasis from non-small cell lung cancer following curative resection is a significant issue because it often causes critical symptoms and may require different therapeutic approaches from other recurrence. On this background, we aimed to investigate correlation between clinicopathological variables and brain metastasis in resected lung adenocarcinoma. **Method:** Clinicopathological data of 358 patients who had undergone complete resection for lung adenocarcinoma at Saiseikai Utsunomiya Hospital between 2002 and 2015 were retrospectively reviewed. Brain metastasis-free survival was calculated from the date of surgery to the date when brain metastasis was diagnosed or the date of last follow-up by using Kaplan-Meier method. We analyzed the risk factors of postoperative brain metastasis by log-rank analysis and Cox regression analysis. **Result:** The median follow-up period was 60.4 months (range, 1.0 - 195.6 months). Thirty-six patients developed brain metastasis after complete resection of lung adenocarcinoma during follow-up. Thirty-three patients were diagnosed as brain metastasis by contrast-enhanced brain MRI and the others were diagnosed by contrast-enhanced brain CT. Five-year brain metastasis-free survival rate was 91.4%. Log-rank analysis demonstrated that pathologic stage IB or higher ($p < 0.001$), lymphovascular invasion ($p < 0.001$), presence of spread through alveolar spaces ($p < 0.001$) and micropapillary predominant pattern ($p < 0.001$) were significantly associated with recurrence of brain metastasis. Cox regression analysis demonstrated that pathologic stage IB or higher ($p = 0.004$) and micropapillary predominant pattern ($p = 0.007$) were independent risk factors for brain metastasis.



Conclusion: Our findings suggest that careful follow-up may be required for patients with higher pathologic stage as well as micropapillary predominant lung adenocarcinoma after complete resection. It may also emphasize clinical significance of micropapillary subtype in resected lung adenocarcinoma.

Keywords: brain metastasis, lung adenocarcinoma, Micropapillary predominant

P1.01-52 CELL-FREE TUMOR DNA (CTDNA) UTILITY IN DETECTION OF ORIGINAL SENSITIZING AND RESISTANT EGFR MUTATIONS IN NON-SMALL CELL LUNG CANCER (NSCLC)

J. Agulnik, G. Kasymjanova, D. Small, C. Pepe, L. Sakr, G. Chong, H. Wang, A. Papadakis, A. Spatz, V. Cohen

Jewish General Hospital, Lady Davis Institute, McGill University, Montreal/Canada

Background: With the use of personalized therapy the need for repeat biopsies in lung cancer patients (pts) has increased. For most lung cancer pts, a tissue biopsy can be quite challenging and potentially risky.The aim of this study was to evaluate the utility of ctDNA to detect the EGFR original mutation (OM) and to identify the T790M resistance mutation in advanced NSCLC pts who received EGFR-TKI. **Method:** This is a prospective cohort study utilizing theCobas EGFR ctDNA testing kit V2 in pts with confirmed EGFR-mutant advanced NSCLC by tissue biopsy. The blood was obtained from 66 pts at 4 time points: baseline, time of 1st CT, time of progression, and 1 month after starting new treatment. **Result:** From January 2017 to January 2019, 66 pts were enrolled in the study, of which 41(62%) had an exon 19 deletion and 25(38%) had an exon 21 mutation. 23/66 pts were TKI naive and 43/66 were already on TKI treatment. Adequate ctDNA was found in the plasma of 97% of cases. The OM was identified in 42 % of pts at first blood test with higher detection rates in TKI naïve pts 12/23(52%) compared to 16/43(37%) in TKI group. Best response to first line TKI was evaluated in 64 pts; in 56 (88%) pts, disease was controlled (CR+PR+SD) with TKI, in 8 (12%) pts the treatment had failed and was discontinued. A significant correlation between OM detection and response to first line TKI was found ($p = 0.05$) with higher detection rate in non-responders 6/8(75%) compared to responders 21/56 (38%). In TKI naïve pts OM was detected in 4/5(80%) of non-responders and in TKI group in 2/3 (67%) pts. The resistance mutation (T790M) was detected in 12/66 (18%) pts. All 12 (100%) pts initially responded to TKI and OM was no longer detected. Median duration of TKI until progression was 25.5 (SD 12.7) mo. The OM re-occurred in 11/12 (92%) at the time of progression. **Conclusion:** ctDNA can be noninvasively assessed in the circulation and be used to monitor responses to treatment and detect development of secondary resistance. The re-occurrence of OM on repeat liquid biopsy seems to be a sign of resistance to first line treatment. In the future, instead of extensive imaging and invasive tissue biopsies, ctDNA test by NGS panel could be used to find other mutations and to guide cancer treatment decisions.

Keywords: EGFR, ctDNA, NSCLC

P1.01-53 CLINICAL UTILITY OF TWO DIFFERENT PLASMA-BASED EGFR MUTATION TESTS IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

Y.-G. Lee, K. Lee, S. Lim, M.-J. Kwon, H. Park, H.-Y. Woo

Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: When tumor biopsies from patients (pts) with advanced NSCLC yield infeasible or insufficient for successful molecular subtyping, plasma cfDNA genotyping has been widely adopted due to its convenience and high positive predictive value. However,a different assay sensitivity makes the optimal choice more difficult. In this study, we have analyzed the clinical utility of two different plasma-based EGFR-mutation (mEGFR) tests in pts with advanced NSCLC. **Method:** We prospectively enrolled consecutive pts with advanced NSCLC with adequate tissue before EGFR genotyping in single institution (June 2017-December 2018). EGFR tissue genotyping was performed using peptide nucleic acid (PNA) based PANAMutyper R EGFR assay (PANAGENE, Daejeon, Korea).EGFR plasma genotyping was performed using Cobas EGFR Mutation Test v2(Roche, Mannheim, Germany) and PANAMutyper R EGFR assay. All pts provided informed consent. **Result:** We included 72 patients. 44 (61%) were treatment naïve. Overall sensitivity for mEGFR positive was 52% (23/44) from tissue, but 34% (15/44) from Cobas and 30% (13/44) from PANAMutyper. Among 21 pts with tissue mEGFR-negative, plasma mEGFR test found additional 2 pts with mEGFR positive from Cobas and 1 pts from PANAMutyper. EGFR sensitivity with tissue increased to 57% and 55% when combining with plasma by Cobas and PANAMutyper, respectively. Concordance rate of tissue mEGFR was same as 73% with Cobas and

PANAMutyper (kappa 0.46). Among 28 pretreated mEGFR-positive advanced NSCLC, sensitivity for mEGFR positive was 71% (20/28, include 6 cases of T790M) from tissue re-biopsy, and 68% (19/28, include 8 cases of T790M) from Cobas and 57% (16/28, include 6 cases of T790M) from PANAMutyper. Cobas plasma mEGFR test found additional 2 pts with T790M. T790M sensitivity with tissue (30%) increased to 40% for both tissue and plasma by Cobas. In pretreated setting, concordance rate of tissue mEGFR was 96% with Cobas (kappa 0.92) and 86% with PANAMutyper (kappa 0.70). **Conclusion:** In pts with treatment naïve advanced NSCLC, sensitivity for tissue mEGFR was higher than plasma mEGFR genotyping. Though plasma mEGFR test found additional mEGFR positive patients, overall sensitivity was slightly increased when combining both methods. In pts with pretreated mEGFR-positive, overall sensitivity for tissue mEGFR was similar with Cobas plasma mEGFR genotyping with high concordance rate.

Background: Li-Fraumeni syndrome (LFS) is a rare hereditary condition that consists of *TP53* mutations inherited in autosomal dominant manner that confer high risk of developing cancer, including lung adenocarcinoma (LUAD). *EGFR*-mutated LUAD were reported in the context of LFS but there is no systematic description of somatic mutations and characteristics of lung cancer (LC) patients with LFS. **Method:** We present a retrospective analysis of clinical and molecular characteristics of patients with LFS diagnosed with LC at the Catalan Institute of Oncology from 1999 to 2019. We collected demographical and clinicopathological features, germline and somatic mutational alterations, treatment and progression-free survival (PFS) and overall survival (OS). **Result:** A total of 7 patients with LC and LFS were identified in the Genetic Counseling Unit database. They were carriers of germline mutations in *TP53*. Five of them were classified as pathogenic: c.638G>A; p.(Arg213Gln), c.725G>A; p.(Cys242Tyr), c.742C>T; p.(Arg248Trp), c.844C>T; p.(Arg282Trp) and c.1010G>A; p.(Arg337His) and two of them as likely pathogenic: c.374C>T; p.(Thr125Met) and c.473G>A; p.(Arg158His). Six out of 7 patients were female and 5 out of 7 never smoker. Median age at diagnosis was 38 year-old (range: 29-74). Five patients had stage IV at diagnosis and the most common histologic subtype was LUAD (5). Six patients had first grade family history of cancer with a median of 2 family members (range: 1-4) and 2 patients had prior history of cancer. Tumor somatic profile in LC was obtained in 6 patients, consisting on a *ROS-1* rearrangement in one patient and *EGFR* mutations in 5 patients (exon 19 deletion in 3 patients and missense mutations in 2 patients, p.(Gly719Ala) at exon 18 and p.(Leu858Arg) at exon 21) and in 1 patient was unknown. All patients with mutant EGFR received EGFR tyrosine kinase inhibitors (TKI) with a median PFS of 29 months (95% CI 0-67). Four had partial response and one a complete response to TKI treatment. At disease progression, one patient had small cell transformation and another acquired *EGFR T790M* mutation. Median lines of treatment were 4 (range 1-6). Two patients are alive at data cut off. Median OS is 47 months (95% CI 32-62). **Conclusion:** Patients diagnosed with LC and LFS are enriched with actionable genomic alterations and have an earlier onset of the disease. Clinical outcome of patients with *EGFR* mutations and LFS did not differ from *EGFR* mutated LC patients who do not carry *TP53* germline mutations.

P1.01-55 UPDATED ANALYSIS OF OUTCOMES BY HISTOLOGY VS CYTOLOGY PD-L1 22C3 ANTIBODY TESTING IN ADVANCED NON-SMALL CELL LUNG CANCER

A. Sathiyapalan[1], Y. Wang[1], R. Juergens[1], M. Butcher[1], A. Naqvi[2], J.-C. Cutz[1]

[1]*Juravinski Cancer Center, McMaster University, Hamilton/Canada,* [2]*McMaster University, Hamilton/Canada*

Background: Immune checkpoint inhibitors (CPIs) have changed the treatment algorithm for advanced non-small cell lung cancer (NSCLC). PD-L1 expression using 22C3 immunohistochemistry (IHC) help determine the treatment options in which CPI are used. Previous studies demonstrated that PD-L1 expression is comparable on cytology versus solid biopsy/histology specimens and no difference in survival between the testing methods among PD-L1 high (≥50%) expression patients. We assess the clinical outcomes in an expanded population of patients tested for any PD-L1 status (<1%, 1 – 49%, ≥50%) using cytology versus histology specimens. **Method:** This retrospective cohort study reviewed both histology and cytology specimens processed for PD-L1 status between January 2015 and June 2017. All patients who had PD-L1 testing completed for advanced NSCLC and who had follow-up with a medical oncologist were included in the final analysis, regardless of PD-L1 status. Clinical characteristics were extracted from electronic medical records. Clinical outcomes were compared between cytology and histology specimens following a chart review, including overall survival (OS) (defined as time from diagnosis of advanced NSCLC to death). This was adjusted for age, ECOG, weight loss, Charlson Comorbidity Index, and receipt of palliative intent radiotherapy, targeted therapy, and CPI. **Result:** 512 patients with PD-L1 status testing were assessed. Amongst those, 152 fulfilled eligibility criteria with cytology (n=55) and histology (n=97) samples respectively. Baseline characteristics of the two groups are comparable in age, gender, ECOG, and histological subtype. Comparatively, the cytology group had more patients who were PD-L1 high (≥50%) (60% vs 39%) and had a significantly higher number of patients with baseline pleural effusion (29% vs 12%, p=0.011) and lymph node involvement (55% vs 37%, p=0.037). The histology group received more palliative intent radiation (67% vs 36%, p=0.001) while the cytology group was more likely to receive any systemic therapy (84% vs 64%, p=0.010) and any line of CPI (31% vs 28%, p=0.048). No difference was observed in OS between the cytology and histology groups. Median OS in the cytology group was 11.8 versus 9.8 months in the histology group (HR 0.94 (95% CI 0.676-1.321)). Amongst patients who received systemic therapy, survival was significantly longer if patients were exposed to CPI during their course of treatment regardless of cytology or histology groups. However, this finding is no longer significant among patients who receive second line treatment only (HR 0.92 (95% CI 0.54-1.58, p=0.78). On multivariate analysis, there is a significant improvement in survival with the receipt of any systemic therapy (HR 0.20 (95% CI 0.11-0.38, p=0.000), while a baseline ECOG status of 3 compared to an ECOG status of 0 was associated with worse survival (HR 4.37, (95% CI 1.17-16.27)). **Conclusion:** In advanced NSCLC, specimens analyzed by cytology versus histology were equivalent in survival, suggesting that the approach to biopsy should prioritize non-invasive procedures, patient preference and disease characteristics over the specimen type. Additionally, baseline performance status and receiving treatment are associated with improved outcomes, with a trend towards harm with higher ECOG scores, signifying the importance of careful patient selection in the era of CPI.

Background: Fusion involving anaplastic lymphoma kinase (*ALK*), RET proto-oncogene (*RET*) or v-ros UR2 sarcoma virus oncogene homolog 1 (*ROS1*) occur in non-small cell lung cancers (NSCLC) and are important biomarkers for targeted therapies. However, little is known about the RNA expression levels of these genes regardless of fusions. **Method:** We used a custom nCounter panel (NanoString Technologies) designed to detect several genetic alterations, including fusions and mRNA expression levels of *ALK*, *ROS1* and *RET* in formalin-fixed paraffin embedded (FFPE) samples. RNA was purified from NSCLC tumor samples and analyzed with the custom panel. The counts corresponding to the 3' probes were normalized using the geometrical mean of the housekeeping genes and then added to evaluate total mRNA expression levels. Cut-off values for overexpression were established as the average counts for each gene plus two times the standard deviation. **Result:** A total of 400 stage III-IV NSCLC patients (p) from two different institutions were retrospectively analyzed. Overexpression of ALK was found in 55 p (13.8%). Of them, 48 (87%) were also positive for EML4-ALK fusions. One ALK-translocated patient with low levels of ALK mRNA expression did not respond to therapy. Fifteen p (3.8%) showed ROS1 overexpression. In contrast with ALK, only three of them (15%) had a concomitant ROS1 fusion. Among the remaining 12 patients overexpressing ROS1, four were ALK positive, five harbored mutations in EGFR and three were non-smoker females with no known drivers. Regarding RET, high expression levels were found in 14 p (3.5%) and only one of them showed a RET fusion (7%). Among the remaining 13 p, three presented neuroendocrine features and seven were smoker or ex-smoker without other known drivers. **Conclusion:** Overexpression of ALK mRNA in NSCLC is associated with EML4-ALK translocations. In contrast, a significant number of fusion negative patients show high ROS1 or RET mRNA levels. Further research is warranted to determine the clinical relevance of this finding.

P1.01-57 ASSOCIATION OF INITIAL PD-L1 EXPRESSION WITH T790M-ACQUIRED RESISTANCE IN ADVANCED EGFR-MUTANT LUNG ADENOCARCINOMA PATIENTS

K. Nishino, A. Kubota, K. Kunimasa, M. Kimura, T. Inoue, M. Tamiya, H. Kuhara, T. Kumagai

Osaka International Cancer Institute, Osaka/Japan

Background: The primary objective was to investigate the association between initial programmed cell death-ligand 1 (PD-L1) expression levels and the frequency of T790M-acquired resistance to epidermal growth factor receptor (EGFR)-tyrosine kinase Inhibitor (TKI) in patients with advanced *EGFR*-mutant lung adenocarcinoma. **Method:** We examined patients with advanced *EGFR*-mutant lung adenocarcinoma whose initial PD-L1 expression levels and T790M-acquired mutation status after EGFR-TKI failure (gefitinib, erlotinib or afatinib) could be evaluated. We retrospectively investigated the patients' characteristics and survival, as well as the association between initial PD-L1 expression levels and frequency of T790M-acquired resistance **Result:** Overall, 100 patients were enrolled. Nine (9%) patients had an initial PD-L1 tumor proportion score (TPS) of ≥50%, 19(19%) had PD-L1 TPS of 1%-49%, and 72 (72%) had PD-L1 TPS of <1%. T790M-acquired mutation (T790M+) was identified in 57 (57%) patients. Initial PD-L1 expression levels were not associated with the frequency of T790M-acquired mutations in patients (p=0.822). Positive PD-L1 expression (PD-L1+) was associated with lower OS compared with negative PD-L1 expression (PD-L1-) (median overall survival [OS], 40.3 vs 74.3 months, p=0.0053). Furthermore, T790M+ was associated with longer OS compared with T790M- in total and PD-L1- population (total: median OS, 74.3 vs 41.3 months, p=0.0154, PD-L1-: median OS, 82.0 vs 41.2 months, p=0.00412), but not in PD-L1+ population (median OS, 36.2 vs 46.2 months, p=0.792). Among 57 patients with T790M-aquired mutation, 49 received osimertinib treatment. The estimated median progression-free survival rate of osimertinib was 13.2 months in PD-L1- patients (n=37) and 6.9 months in PD-L1+ patients (n=12) (p=0.224). **Conclusion:** There was no association between initial PD-L1 expression levels and the frequency of T790M-aquired mutations in patients. However, PD-L1+ expression levels in patients with treatment-naïve advanced *EGFR*-mutant lung adenocarcinoma predicted poorer outcomes. Intriguingly, T790M-aquired mutations were related to longer OS in PD-L1- patients, but not in PD-L1+. Thus, for patients with T790M-acquired mutant and initial PD-L1 positive lung adenocarcinoma in whom the use of osimertinib is indicated, other treatment options should be considered without hesitation if the treatment effects are not as expected.

Background: Availability of tumour material at baseline and disease progression is increasingly important for patient management in non-small-cell lung cancer (NSCLC), especially in tyrosine kinase and immune checkpoint inhibitor treatment. Here, we report the experience with prospective biobanking for advanced NSCLC from a pilot project in the academic setting. **Method:** Main objective was the longitudinal collection of snap-frozen in addition to formalin-fixed paraffin-embedded (FFPE) biopsies required for routine diagnostics, along with blood samples and detailed clinical annotation using standardized questionnaires. **Result:** Over five years, 205 patients were enrolled yielding 387 cryoconserved biopsies and 1098 serum, plasma and buffy-coat samples. The feasibility of obtaining cryoconserved in addition to FFPE biopsies was 89 % for newly diagnosed cases, but dropped down to 56 % and 47 % at first and second disease progression, respectively. Main obstacle was increased procedural risk due to patient deterioration, but no complications occurred. Biopsies had a tumour cellularity of 34 % and yielded 13.6 µg DNA and 12 µg RNA in median. **Conclusion:** Despite the poor condition and limited prognosis of most NSCLC patients, systematic, serial biomaterial acquisition including routine collection of cryoconserved biopsies is feasible in order to facilitate individualized management and support research that will advance therapeutic options.

Background: In NSCLC, large-scale mutational analysis facilitates access to targeted treatments but is still not routinely employed due to significant technological barriers. The Alleanza Contro il Cancro (ACC) network of Italian Cancer Centers developed an affordable targeted sequencing panel for the identification of multiple genetic alterations with potential clinical utility, and designed a prospective multicentric trial to recruit 1000 newly diagnosed advanced NSCLC patients, aiming to i) compare panel performance against a set of externally validated biomarkers, including alterations in standard-of-care (EGFR, ROS1 and ALK) and non-standard-of-care (KRAS, BRAF, MET) biomarkers; ii) identify alterations in a large dataset of driver and potentially actionable genes; iii) correlate genotypes to survival outcomes and toxicity; iv) carry out ancillary studies on additional biomarkers and/or on specific patient groups (e.g. mutational burden, cfDNA, extensive characterization of immunotherapy-treated patients); v) build a centralized data repository for mutation interpretation and clinical recommendation. **Method:** Through systematic literature mining and ad-hoc developed bioinformatic pipelines we identified: i) a set of 164 potentially actionable genes in solid tumors; ii) additional 18 genes with predicted driver function in NSCLC; iii) 70 actionable fusion transcripts; iii) 141 SNPs associated with pharmacogenomics markers. We designed a custom enrichment panel (~800 kb target) and compared PCR- and hybridization-based enrichment on semiconductor or by-synthesis sequencing to be subsequently deployed in a large observational trial. Sequencing is decentralized, to allow rapid turnaround time, but raw and processed data are collected in a single informatic infrastructure for centralized quality control and continuous bioinformatic pipeline improvement. **Result:** PCR/semiconductor sequencing was selected for deployment based on cost and feasibility (2-day, highly automated workflow). 182 patients have been enrolled to date (90% stage IV, 10% IIIB). Of 65 patients with treatment information available, 28 (43%) subsequently received immunotherapy and 13 (20%) targeted therapy. For 56 patients with complete sequencing data, EGFR and KRAS status was concordant in 9/10 and 38/41 cases; discordant cases are being validated with orthogonal methods. Clinically significant MET amplifications were called in 2/2 cases. Remaining target regions did not show pathogenic alterations. Multiple alterations in potentially actionable genes were identified. **Conclusion:** Large-scale sequencing is reliable, feasible and sustainable across multiple hospitals and provides clinically relevant results. The increased availability of genomic information may result in enhanced access to tailored therapies. Data and sample integration in centralized, shared repositories will allow multiple ancillary studies.

Background: EGFR tyrosine kinase inhibitors (TKIs) are recommended as first-line systemic therapy for advanced non-small cell lung cancer (NSCLC) with sensitizing EGFR mutations. The programmed death-ligand 1 (PD-L1) expression on tumor cells has emerged as a prognostic marker after surgical resection in various tumors including NSCLC. This study investigated the predictive value of PD-L1 expression on the duration of treatment and the emergence of T790M mutation in patients treated with EGFR-TKIs. **Method:** We retrospectively enrolled 109 patients with advanced NSCLC who had been treated with EGFR-TKIs as first-line systemic treatment at Seoul National University Bundang Hospital and Seoul National University Hospital between December 2012 and October 2018. Patients without sensitizing EGFR gene mutations (exon 19 deletion, exon 21 L858R, and L861Q) were excluded. The PD-L1 expression on tumor cells was scored using two immunohistochemistry assays (22C3 or SP263). The Kaplan-Meier survival estimation and log rank test were used for survival analyses. **Result:** Among the 109 patients (Median age 65; Male:Female = 37:72), 17 (15.6%), 37 (33.9%) and 55 (50.5%) patients had strong (≥50%), weak (1%-49%), and negative (<1%) PD-L1 expression, respectively. In univariate analysis, the median time-to-treatment failure (TTF) of EGFR-TKI treatment was 7.6 months in strong expression, 14.2 months in weak expression, and 13.0 months in negative expression (log-rank; Strong vs. Weak, P=0.008; Strong vs. Negative, P=0.031). There was no statistically significant difference of TTF between the patients with weak expression and negative expression (log-rank, p=0.191). After adjustment of age, sex, and smoking status, strong PD-L1 expression remained as a significant predictor of short TTF (hazard ratio [HR] for strong vs. weak, 2.68; 95% CI, 1.35-5.33; P=0.005). The detection rates of T790M mutation after EGFR-TKI failure were similar in three groups (23.53% in strong, 29.73% in weak, and 32.73% in negative PD-L1 expression; P=0.478). In patients treated with 3rd generation EGFR-TKIs (n=35), there was no statistically significant difference of TTF according to PD-L1 expression (p=0.889). Figure. Kaplan-Meier survival curve for TTF of 1st line EGFR-TKIs according to PD-L1 expression **Conclusion:** Strong PD-L1 expression of tumor might be a surrogate indicator of poor response to EGFR-TKIs in NSCLC patients with sensitizing EGFR mutations.

Ltd, Shanghai/China

Background: The role of PD-L1 expression in 2nd line and beyond non-small cell lung cancer (NSCLC) remains controversial. Camrelizumab (SHR-1210) is a potent anti-PD-1 monoclonal antibody and has shown promising activity in NSCLC in Phase I studies. We report results from the SHR-1210-201 study (NCT03085069), a phase II umbrella study of camrelizumab monotherapy in different PD-L1 expression cohorts in Chinese patients with previously treated advanced or metastatic NSCLC. **Method:** Patients who progressed during or following platinum-based doublet chemotherapy were enrolled and assigned to one of 4 cohorts based on PD-L1 expression. Patients with EGFR or ALK genomic alterations were eligible provided they had disease progression with at least one approved tyrosine kinase inhibitor and with ≥50% PD-L1 expression in tumor. All enrolled patients received camrelizumab at 200 mg IV Q2W until loss of clinical benefit. The primary endpoint was objective response rate (ORR), other endpoints included progression-free survival (PFS) and overall survival (OS). **Result:** As of Aug 1st 2018, of all the 259 patients who underwent screen, 229 cases could be pathologically evaluated. PD-L1 expression were 47.6% (109/229) in PD-L1 < 1%, 27.1% (62/229) in PD-L1 ≥1-<25%, 8.7% (20/229) in ≥25-<50% and 16.6% (38/229) in ≥50%. A total of 63.8% (146/229) patients were enrolled. 89.0% of patients had stage IV NSCLC and 54.8% had non-squamous tumor histology. ORR was 18.5% (95%CI: 12.6%–25.8%) in ITT population. Subgroup analysis showed increased PD-L1 expression was associated with better response rate (Table 1). No response was observed in patients with EGFR mutation. The responders had durable response (median: 15.1 months; 95%CI: 5.5–not reached). Median PFS was 3.2 months (95%CI: 2.0–3.4) and median OS was 19.4 months (95%CI: 11.6–not reached) (Table 1). Treatment-related adverse events (AEs) occurred in 87.7% of patients (all Grade); 20.5% had ≥G3 related AE; and 15.8% had related SAE. 21.2% of AEs led to dose interruption and 7.5% led to treatment discontinuation.

Conclusion: In Chinese patients with previously treated advanced/metastatic NSCLC, camrelizumab demonstrated improved ORR, PFS, and OS compared with historical data of the 2nd line chemotherapy. The efficacy in patients with PD-L1 <1% is similar as the 2nd line mono-chemotherapy, while patients with higher PD-L1 expression derived greater benefit from camrelizumab, the ORR, PFS and OS in patients with PD-L1 ≥25% was comparable to the 1st line doublet chemotherapy in advanced NSCLC. Camrelizumab was well tolerated. This phase 2 data warrant further clinical studies of camrelizumab in NSCLC.

Keywords: camrelizumab, PD-L1 expression, advanced/metastatic non-small cell lung cancer

Table 1 - Efficacy data in subgroups

Population	No of pts	ORR, % (95%CI)	PFS (month), median (95%CI)	1YOS, % (95%CI)	OS (month), median (95%CI)
PD-L1<1%	74	12.2% (5.7%, 21.8%)	2.1 (1.9, 3.2)	47.1% (33.8%, 59.2%)	11.6 (7.8, NR)
PD-L1 ≥1% and < 25%	31	19.4% (7.5%, 37.5%)	3.1 (1.8, 4.9)	76.7% (57.2%, 88.2%)	NR (NR, NR)
PD-L1 ≥25% and < 50%	11	45.5% (16.7%, 76.6%)	6.0 (1.9, NR)	81.8% (44.7%, 95.1%)	NR (2.9, NR)
PD-L1 ≥50% (without EGFR mutation)	25	28.0% (12.1%, 49.4%)	7.6 (3.3, 11.4)	55.2% (32.3%, 73.2%)	NR (8.6, NR)
PD-L1 ≥50% (with EGFR mutation)	5	0	1.7 (1.2, NR)	40.0% (5.2%, 75.3%)	10.3 (1.2, NR)
ITT	146	18.5% (12.6%, 25.8%)	3.2 (2.0, 3.4)	56.6% (47.3%, 64.9%)	19.4 (11.6, NR)

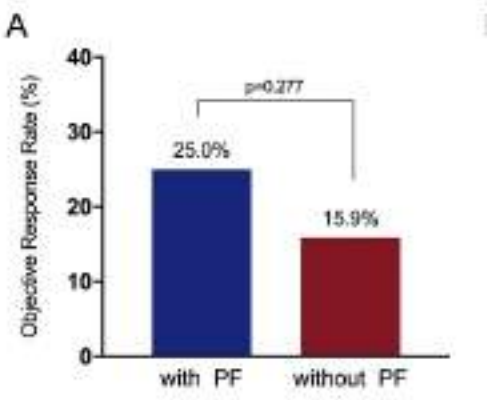
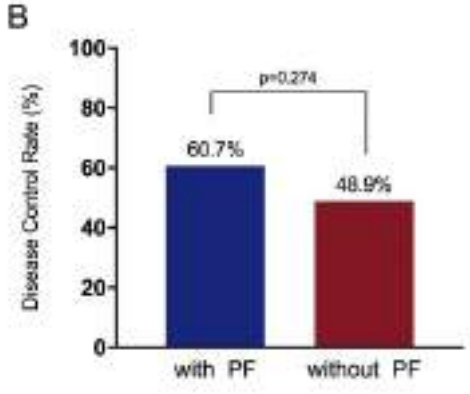
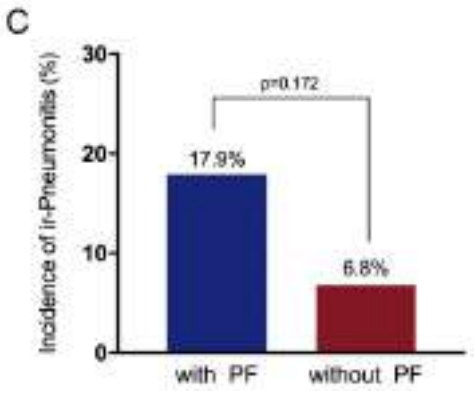
Background: PD-1/PD-L1 inhibitors have become standard care for previously treated advanced non-small cell lung cancer (NSCLC). However, not all patients are suitable for the immunotherapy. This study aimed to investigate the efficacy and safety of PD-1/PD-L1 inhibitors in patients with advanced NSCLC and pre-existing pulmonary fibrosis (PF). **Method:** Patients who had a NSCLC diagnosis, received anti-PD-1/PD-L1 monotherapy and had baseline chest HRCT screen at Shanghai Pulmonary Hospital, Tongji University were retrospectively collected from January 2016 to February 2019. The pre-existence of PF was identified by reviewing baseline chest imaging. Baseline clinicopathologic characteristics, treatment outcomes and immune-related pneumonitis were collected. **Result:** 116 patients were included with 61 age < 65. Among them, 97 (83.6%) were male, 76 (65.5%) were smoker, 51 (44%) were squamous, 61 (52.6%) received anti-PD-1 monotherapy (Pembolizumab n=62, Nivolumab n=28) as 2nd line setting, 28 (24.1%) had PF prior to PD-1 inhibitors. Baseline characteristics such as age, gender, ECOG PS, smoking history, pathology are similar between patients with or without PF. Patients with PF had a comparable response (ORR: 25% vs 15.9%, p=0.277, figure A), disease control (DCR: 60.7% vs 48.9%, p=0.274, figure B) and PFS (median 2.5 vs 2.8 months, p=0.950). The incidence of immune-related pneumonitis in the entire cohort was 9.2%, which was numerally higher in PF group (17.9% vs 6.8%, p=0.172, figure C). No death from immune-related pneumonitis occurred.







Conclusion: NSCLC patients with pre-existing PF showed comparable response to PD-1 inhibitors but a higher incidence to immune-related pneumonitis.

Keywords: NSCLC, pulmonary fibrosis, Immunotherapy

P1.01-63 IMPACT OF PRIOR RADIATION PNEUMONITIS ON INCIDENCE OF IMMUNOTHERAPY RELATED PNEUMONITIS

M. Kier, M. Marmarelis, C. Davis, V. Jain, A. Berman, J. Bauml, A. Singh, C. Ciunci, C. Aggarwal, C. Langer, R. Cohen

University of Pennsylvania, Philadelphia/United States of America

Background: Patients with a history of radiation pneumonitis (RP) requiring steroids have generally been excluded from immuno-oncology (IO) trials of PD-1/PDL-1 monoclonal antibodies for safety concerns. The risk of IO-associated pneumonitis (IOP) in this group of patients (pts) is therefore unknown. We evaluated the frequency of IOP in pts who had prior RP. **Method:** We evaluated all pts with non-small cell lung carcinoma (NSCLC) treated at our institution between 2011 and 2018 who were diagnosed with RP and at a later point received IO. Demographics, tumor characteristics, steroid use and outcomes were extracted from the electronic medical record. Median overall survival (mOS), median progression free survival (mPFS), and median time to treatment failure (mTTF) from the start of IO were estimated from Kaplan-Meier curves. **Result:** We identified 29 pts: median age at diagnosis 63 yrs, 51.7% male, none had received prior targeted therapies. IO treatments were: atezolizumab (2), durvalumab (2), nivolumab (12), and pembrolizumab (13). Median time from RP diagnosis to start of IO was 14.2mo (2.2-75 mo). 23 pts (79%) had experienced prior grade ≥ 2 RP requiring steroids. Only 2 of the 29 pts (6.9%) developed IOP. Both pts had required steroids for prior RP and both received durvalumab; one pt was on prednisone ≥ 10mg at the start of IO. Both required steroid treatment of IOP, are still on IO and have not progressed (censored at 8.3mo and 9.9mo). OS and PFS after IO are similar (Table 1) whether or not pts required treatment for RP or were on prednisone ≥ 10 mg (or steroid equivalent) at the start of IO. Table 1: IO outcomes based on RP history and steroid use at start of IO

	RP Grade ≥ 2 n=23 (95% CI)	RP Grade < 2 n=6 (95% CI)	Prednisone ≥ 10mg n=7 (95% CI)	Prednisone < 10mg n=22 (95% CI)	All patients n = 29 (95% CI)
mPFS (mo)	5.44 (2.1-12.6)	12.95 (0.95-)	6.16 (2-)	5.44 (2.1-)	6.16 (2.4-)
mOS (mo)	6.6 (3.93-13.8)	NR	14.3 (5.3-)	8 (3.4-16.8)	8 (5.3-15)
mTTF[a] (mo)	2.3 (1.9-4.8)	2.3 (1.9-)	4.4 (2-)	2.3 (1.9-10.9)	2.75[a] (2-7)

[a]**n=28: 1 pt lost to follow up after start of IO**

Conclusion: In our cohort, the incidence of IOP after RP is low and similar to the rate of pneumonitis reported with pembrolizumab in pts with prior exposure to thoracic radiation.

P1.01-64 PREDICTIVE VALUE OF K-RAS SUBSET MUTATIONS AND PD-L1 IN PULMONARY SARCOMATOID CARCINOMA (PSC)

I. Eldessouki[1], R. Hassan[1], P. C. Ma[2], N. Abdel Karim[3]

[1]*University of Cincinnati, Cincinnait/United States of America,* [2]*WVU Cancer Institute, West Virginia University, Morgantown/United States of America,* [3]*Medical College of Georgia/ Augusta University, Augusta/United States of America*

Background: Pulmonary sarcomatoid carcinoma (PSC) is a rare malignant neoplasm that accounts for a 0.4% of non-small- cell lung carcinomas (NSCLC). It is associated with poor response to therapy. We studied clinical, genetic and molecular criteria of PSC by analyzing their KRAS, TMB, TP53 and PD-L1 status. **Method:** This is a retrospective study that included 8,469 NSCLC patients with equivalent number of samples collected prospectively. Next generation sequencing (NGS) was performed for molecular and genetic analysis of the samples.Categorical variables were reported as counts and percentages, and we used Fisher's exact test and Chi (X2) test for comparisons as appropriate. **Result:** Among the 8,469 patients there were 53 patients with pulmonary sarcomatoid carcinoma (PSC). PSC was more prevalent in males (64.2%) vs other NSCLC histopathological subtypes (49.8%) (P=0.039). PD-L1 analysis revealed 79.2% positive expression (>1%) in PCS vs 51.0% in other NSCLC histopathological subtypes (P<0.001). KRAS analysis showed that G12V was the most common mutatedKRAS codon in PSC (31.3%). Of the 53 patients with pulmonary sarcomatoid carcinoma, sixteen patients were k-ras mutant (31%). Of the 16 patients with mutant k-ras, fifteen had PD-L1 positive status (Table 1). PDL-1 was positive in 64.3% (n=27) of PSC cases with wild-type KRAS and 35.7% in mutant KRAS, P=0.087. (Table 2). KRAS MAF was higher in PSC (median 51.00 [34.50, 57.25]) vs 29.00 [19.00, 42.00] in other NSCLC histopathological subtypes (P=0.003). Using NGS, TP53 was found to be mutated in 58.8% of all NSCLC cases compared to 27.3% of the mutant k-ras where G12C was the most common subtype (39.1%). Our analysis revealed no difference in TP53 NGS, TP53 exon, TP53 MAF, KRAS NGS, KRAS codons or specimen site (P>0.05). We correlated the clinical and genetic profiles of 53 PSC patients and it was significant in the younger age population (r=-0.29, p=0.037). **Conclusion:** PSC was significant in males, younger age group with more common G12V k-ras sub-type (31.3%) compared to the G12c subtype (25%). PD-L1 expression was significantly higher in PSC (79.2%) compared to other NSCLC subtypes (51%). Table 1:showing the results for mutant KRAS subpopulation in relation to PDL122c3 expression. It also illustrates the percentage expression within each subtype of KRAS pathologic mutation:

KRAS mutation	PDL122c3 expression (n, %)		Total (n, %)
	Negative	Positive	
G12V	0 0.0	5 33.3	5 31.3
G12D	0 0.0	2 13.3	2 12.5
G12A	0 0.0	2 13.3	2 12.5
G12C	1 100.0	3 20.0	4 25.0
G12S	0 0.0	2 13.3	2 12.5
9.0	0 0.0	1 6.7	1 6.3
Total (n, %)	1 100.0	15 100.0	16 100.0

P1.01-65 IMMUNE GENE EXPRESSION, BAYESIAN NETWORK AND GENETIC MUTATION ANALYSIS IN ADVANCED NSCLC PATIENTS TREATED WITH IMMUNOTHERAPY

S. Baglivo[1], F. Bianconi[2], F. Tofanetti[1], B. Ricciuti[3], L. Pistola[1], A. Siggillino[1], M. Reda[1], G. Metro[1], G. Bellezza[4], V. Minotti[1], F. Roila[1], V. Ludovini[1]

[1]*Medical Oncology, S. Maria della Misericordia Hospital, Perugia/Italy,* [2]*Independent Researcher, Perugia/Italy,* [3]*Dana-Farber Cancer Institute, Boston/United States of America,* [4]*Department of Experimental Medicine - Section of Anatomic Pathology and Histology - Medical School - University of Perugia, Perugia/Italy*

Background: Immune checkpoint inhibitors (ICIs) have dramatically revoluzionized the therapeutic paradigm for NSCLC, but only a small subset of patients achieves durable benefit. The only adopted predictive biomarker, PD-L1 IHC testing, suffers from some limitations. A better understanding of biomarkers associated with response to ICIs is needed. Here, we studied immune gene-expression and genetic mutation profiles and association with clinical response to immunotherapy in advanced NSCLC patients treated with ICI. **Method:** A total of 37 Formalin-fixed, paraffin-embedded (FFPE) samples from advanced NSCLCs were analyzed by RNA-Seq using the Oncomine Immuno Response Assay (OIRRA) (ThermoFisher Scientific) on Ion Torrent PGM and Transcriptome Analysis Console (TAC) 4.0 Software. This panel measures the expression level of 395 genes associated with 36 functional groups including checkpoint pathways, lymphocyte regulation and cytokine interactions. Gene network analysis based on Bayesian algorithm was performed by GeneMANIA database querying with the genes selected through mRNA expression analysis. Cancer somatic mutation analysis were performed using Ion NGS Panel on PGM Instrument. **Result:** Among 37 FFPE samples only 18 showed more than 300 OIRRA detectable target genes. In this subgroup, gene expression analysis revealed 7 genes (CCR2, CRTAM, FASLG, SELL, TIGIT, TNFRSF4, and TP63) up-regulated and one gene (CXCL8) down-regulated (p-value < 0.05) in ICI-responders compare to ICI-no responders. Bayesian enrichment computational analysis of eight gene expression signature showed a more complex network which involves other 10 genes (SIRPG, GZMK, XCL2, CD8A, CD2, IFNG, SIT1, TAGAP, PTPRC and GZMH), correlated with different functional groups. Three main immune-pathways were identified (p < 0.01) (T cell activation, leucocyte activation and migration) involving TIGIT, TNFRSF4, CCR2 and CXCL8 genes among the gene expression signature identified. Gene mutational analysis was feasible for 28 samples. *KRAS* mutation was detected in 41% of ICI-responders respect to 12.5% of ICI-no responders. Conversely, no *STK11* mutation was found in ICI-responders, consistent with previous reports. **Conclusion:** Our results revealed an immune response gene expression signature of 8 genes differentially expressed between ICI and ICI-no responders. Cancer systems biology analysis approach strengthen our findings identifying an immune molecular network and confirm the correlation of the gene expression signature with relevant immune regulatory functions. If validated, our results may have an important role for the development of a robust test to select patients properly and predict immune response to enable precision immunotherapy. Furthermore, TMB assessment in such subset of patients is under investigation and more data will be available for the meeting.

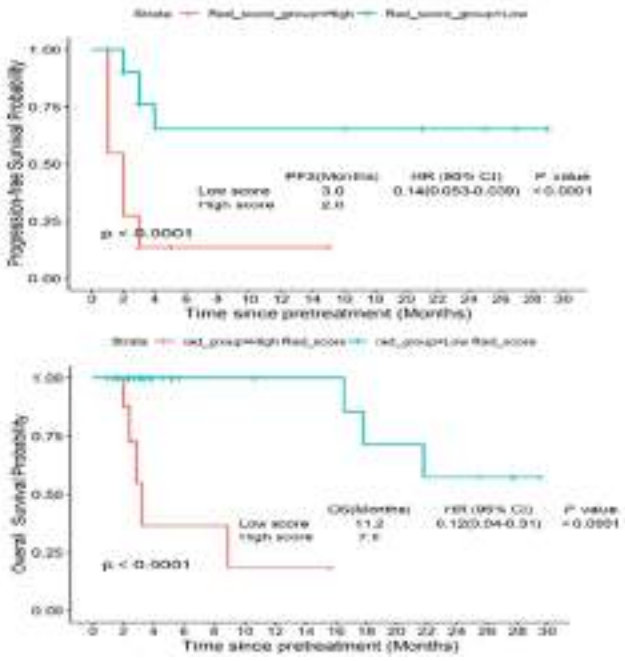
P1.01-66 A CT-BASED RADIOMICS APPROACH TO PREDICT PD1 INHIBITOR RESPONSE IN NON-SMALL-CELL LUNG CANCER

J. Wang, S. Wang, H. Yu, C. Liu, X. Zhao, S. Sun, J. Chang, J. Qiao, X. Wu

Fudan University Shanghai Cancer Center, Shanghai/China

Background: The purpose of this study was to investigate the use of radiomics features as predictive parameters of clinical outcomes of non-small-cell lung cancer (NSCLC) patients treated with PD1 inhibitor. **Method:** Forty-three stage IIIB/IV NSCLC patients without EGFR mutation or ALK rearrangement who received nivolumab were enrolled between Apr 2016 and Jan 2019. High-dimensional quantitative feature analysis via Pyradiomics was applied to extract 852 radiomics features of pre-anti-PD1 treatment CT. A radiomic score model was constructed from these features with the use

of least absolute shrinkage and selection operator (LASSO) Cox regression. The radiomic score for each patient was computed using an equation in which the coefficients were derived from the LASSO Cox model to subgroup patients by progression-free survival (PFS). The median value of radiomic score was used as the cut-off value to cluster patients into high or low score groups. **Result:** We developed a radiomic signature for PFS that included seven variables. The median value of radiomic score was 0.23. The objective response rate (ORR) was 16.3% (7/43), the median PFS was 2 months and median overall survival (OS) was 3.2 months of all 43 patients. A low radiomic score was associated with a higher ORR (33.7% vs 0%, p= 0.0036), improved PFS (median: 3 months vs 2 months; HR 0.14, 95% CI 0.053-0.39, P<0.0001) and longer OS (median: 11.2 months vs 7.0 months; HR 0.12, 95%CI 0.04-0.31, p < 0.0001). Multivariate analysis also showed that a low radiomic score was related to better PFS (HR 0.12, 95% CI 0.041-0.32, P<0.0001) and OS (HR 0.11, 95%CI 0.03-0.28, p < 0.0001).



Conclusion: The radiomic signature as an imaging predictor provided a promising way to predict clinical outcomes for NSCLC patients treated with PD-1 inhibitor.

Lurie Comprehensive Cancer Center of Northwestern University, Chicago/United States of America,* [6]*Northwestern University, Chicago/United States of America,* [7]*University of Chicago, Chicago/United States of America*

Background: Combination chemotherapy and immunotherapy have significantly improved survival for patients with treatment-naïve advanced non-small cell lung cancer (NSCLC). We sought to evaluate the safety and efficacy of adding pembrolizumab to a standard regimen at the time of study development, *nab*-paclitaxel and carboplatin. Safety data from phase I have been reported, and phase II commenced with the same chemotherapy doses and flat dosing of pembrolizumab at 200 mg. **Method:** Patients with treatment-naïve, stage IIIB/IV NSCLC AJCC 7 (all histology), any PDL1, no EGFR or ALK, ECOG 0-1, received carboplatin AUC 6 day 1, *nab*-paclitaxel 100 mg/m2 days 1, 8, 15, and pembrolizumab 200 mg day 1 q21 days for 4 cycles followed by maintenance pembrolizumab q3wks. Co-primary endpoints were progression-free survival (PFS) and response rate (RR). PDL1 was assessed prior to treatment and from biopsies obtained after cycle 4. **Result:** 46 patients enrolled, 14 on phase I and 32 in phase II, from June 2015–July 2018. Accrual stopped after data was presented from similar phase III trials. 43 were evaluable for the primary endpoints. Median age was 65 years, 48% female, 45% adenocarcinoma, 94% current/former smokers, 9% brain metastases. PDL1 expression (TPS) by <1%, 1-49%, and ≥ 50% cutoffs was 44%, 28%, and 28%, respectively. ORR was 28%. Median PFS was 5.6 months (CI, 4.2-10.5 mo). Median OS was 15.7 mo (CI 11.1-22.3 mo). There was no statistical differences in PFS or OS outcomes by PDL1 status. Paired PDL1 results from pre- and post-treatment biopsies were available in 8 patients. PDL1 status changed categories in 4/8 samples (n=3, 0% to positive; n=1, 99% to 0%). The most common grade 3-4 adverse events (AEs) were neutropenia (64%), anemia (31%), thrombocytopenia (24%), leukopenia (16%) and fatigue (11%). Other notable AEs included rash (58%), diarrhea (47%), neuropathy (22%), arthralgia (18%), transaminitis (13%), and myalgia (11%). 18% discontinued treatment due to AEs. In an exploratory analysis, there was no difference in median PFS for those receiving total *nab*-paclitaxel dose of 400–799 mg/m2 compared to ≥800 mg/m2 (6.2 mo vs. 8.2 mo, p=0.62). **Conclusion:** Although the study did not meet its pre-specified endpoints of PFS 9 months and RR of 50%, results were similar to previously reported phase III Keynote 407 (squamous histology). Despite hematologic toxicity, the combination could safely be administered, and outcomes were similar for those receiving moderate doses of *nab*-paclitaxel compared to those with an average of at least 200 mg/m2 per cycle.

P1.01-68 MONITORING CLINICAL RESPONSES MEASURING PD-L1 IN CFRNA IN PLASMA OF NON-SMALL CELL LUNG CANCER PATIENTS UNDERGOING SYSTEMIC THERAPY

L. Raez[1], J. Usher[2], K. Danenberg[2], D. Sumarriva[1], B. Hunis[1], G. Domingo[1], Y. Jaimes[2], P. Danenberg[3], S. Rabizadeh[4]

[1]*Memorial Cancer Institute/Florida International University, Pembroke Pines/United States of America,* [2]*Liquid Genomics, culver city/United States of America,* [3]*University of Southern California, Los Angeles/United States of America,* [4]*Nanthealth, culver city/United States of America*

Background: .Cell-free circulating tumor RNA (cfRNA) extracted from plasma of cancer patients (pts) can measure dynamic changes in gene expression that can help to evaluated disease status and predict outcome to anti-tumoral therapy in solid tumors [T. Ishiba et al. Biochem Biophys Res Commun. 2018 Jun 7; 500 (3):621-625]. We want to show that PD-L1 assessed by RNA RT-PCR is a potential biomarker that can be used to follow Immunotherapy responses in non-small cell lung cancer (NSCLC). **Method:** 54 pts with NSCLC undergoing systemic therapy (STX) were enrolled in a 1-year study. cfRNA was extracted from resulting plasma and generated random-primed cDNA. Total cfRNA was quantitated by qPCR of β-actin, and correlated with pt response (CR/PR/SD/PD) determined by CT scans. All gene expressions were measured relative to β-actin. Changes in PD-L1 expression were used to monitor response to immunotherapy in lung cancer pts. Ten milliliters of blood were collected in each of two tubes containing a proprietary nucleic acid preservation cocktail. Blood was drawn every 6-8 weeks with an average of 5 collections were done per pt. **Result:** Of the 54 enrolled pts, 30 completed 1-3 lines of STX with outcomes. The overall mutation frequency was 33% (10/30), with 27% in KRAS and 6% in EGFR. Increases or emergence of mutant allele fractions were predictive of PD status (later determined by imaging), while decreases or disappearance of mutations were predictive of SD and PR status after treatment. PD-L1 expression was detected in 87% (26/30) of pts in at least one blood draw. Immunotherapy: (Nivolumab, Pembrolizumab, Atezolizumab), 11/30 pts underwent immunotherapy (IO) txt at some point. Changes in PD-L1 during IO were associated with STX outcomes. Increases in PD-L1 were associated with PD, while decreases or no changes in PD-L1 were associated with SD and PR. Of the 23 blood draws from these 11 pts, the overall concordance between changes in PD-L1 and IO outcome was 91% (21/23). Chemotherapy: 19/30 pts were given carbo/pemetrexed at some point during their STX. Increases or decreases in PD-L1 across 28 blood draws during therapy were likewise associated with resistance or sensitivity to STX outcome (increases infer resistance; decreases infer sensitivity) in 24/28 (86%). **Conclusion:** A noteworthy concordance was observed

between clinical responses and changes in plasma PD-L1 done by RT-PCR cfRNA levels in NSCLC pts treated with IO or chemotherapy. Monitoring cfRNA expression levels of PD-L1 is a reliable method for predicting response and resistance to IO as well as chemotherapy irrespective of KRAS and EGFR

Gemelli IRCCS, Roma/Italy*

Background: The selection of patients (pts) deriving clinical benefit from immune checkpoint agents represents the modern challenge for clinicians. Tumor-derived Serum Amyloid A (SAA) inhibits the immune response through the expansion of IL-10-secreting neutrophils in pts with melanoma. We investigated the predictive value of blood SAA monitoring in a cohort of Advanced Non-Small-Cell Lung Cancer (ANSCLC) pts receiving up-front Pembrolizumab (P). **Method:** Pts with ANSCLC (PD-L1≥50%) receiving upfront P, were prospectively evaluated for blood SAA and radiological response at baseline and every 9 weeks during the treatment. The primary endpoint was response rate (RR) according Immune-related Response Evaluation Criteria in Solid Tumors (IrRECIST); the secondary endpoints were progression-free survival (PFS) and overall survival (OS). The most accurate SAA cut-off to predict response was established with a ROC-analysis. **Result:** Forty-two patients were enrolled. Pts characteristics: male/female (71/29%), number of sites 1/2/3/≥ 4 (5/38/40/17%), ECOG PS 0/≥ 1 (38/62%); never or former/current smokers (12/78%); median age 70.5 (range 35-86) years. The overall RR was 38% (95%CI 25-53%). After a median follow-up of 13.5 months (m), baseline SAA ≤ the ROC-derived cut-off (29.9 mg/L, AUC 0.74, 95% CI 0.59-0.87, *p=0.002*; 14 [33%] pts) was significantly associated with a higher RR *(*53.6vs 7.1%, OR 15, 95% CI 1.72-130.7*, p<0.01),* longer PFS (17.4 vs 2.1 m, HR 0.18, 95%CI 0.06-0.51*, p<0.0001)* and OS *(*not reached [NR]vs7.2 m, HR 0.08, 95%CI 0.02-0.39*, p<0.0001)* compared with SAA >29.9 mg/L. Multivariate analysis confirmed pre-treatment low SAA as independent predictor of longer PFS (*p=0.029*) and OS (*p=0.018*). Considering SAA at baseline and the dynamic monitoring (pts=40), the median PFS was 17.4 m (95% CI 10.7-14.7) when SAA remained low (n=14) compared with 2.1 m (95%CI 1.3-5.6) when SAA remained high (n=12) (*p<0.0001).*The SAA monitoring was also significantly associated with OS (*p=0.0002*), with a median OS of 7.2 m (95% CI 5.6-13.4) in pts maintaining high SAA versus NR median at 18-m for pts with SAA remained low or changed. No deaths occurred in the permanently low-SAA group at the current data-lock. **Conclusion:** Baseline low SAA predicts good outcomes of 1stline P and the SAA monitoring throught simple blood test could help to easily identify patients who derived the greatest benefit from immunotherapy. The strong relationship with RR and the known immunosuppressive activity support a potential predictive value of this serum marker. A multi-institutional validation set is currently ongoing to confirm the role of SAA in this setting.

P1.01-70 DOMINANT CIRCULATING MYELOID POPULATIONS ARE ASSOCIATED WITH POOR RESPONSE IN NSCLC TREATED WITH 1ST LINE PD-1 MONOTHERAPY

S. Lau[1], L. Le[1], S.W.S. Chan[1], E. Smith[1], M. Ryan[1], M.C. Brown[1], K. Hueniken[1], L. Eng[1], D. Patel[1], R.Q. Chen[1], M. Sung[1], A. Zer[2], P. Bradbury[1], P. Ohashi[1], F. Shepherd[1], M. Tsao[1], N. Leighl[1], G. Liu[1], A. Sacher[1]

[1]*University Health Network, Toronto/Canada,* [2]*Davidoff Cancer Center Rabin Medical Center, Petah Tikva/Israel*

Background: Immune subpopulations within the tumor microenvironment (TME) play a central role in determining response to checkpoint inhibitors. Myeloid derived suppressor cells (MDSC), a heterogeneous population of immature myeloid cells, have a predominantly immunosuppressive role by stimulating T regulatory cells. We hypothesize that elevated myeloid-to-lymphocyte measures in the peripheral blood predict for greater numbers of myeloid derived suppressor cells in the TME and worse outcomes. **Method:** We identified all advanced NSCLC patients treated with immunotherapy between 2010-2019 at the Princess Margaret Cancer Center. Patients who received first line monotherapy with a PD-1 inhibitor were reviewed for clinical information including age, sex, histology, stage, smoking status, ethnicity, PD-L1 expression and tumor genotype. Myeloid cells lines analyzed included neutrophils, monocytes and platelets, expressed as ratios to peripheral lymphocytes. Multivariate analyses were conducted using the cox and logistic regression models to adjust for confounders. **Result:** We identified 75 patients who were eligible for analysis. Disproportionate increases in the different myeloid cell types were highly correlated with each other (all Pearson's rho>0.8) and the neutrophil to lymphocyte ratio (NLR) was selected as representative. A high NLR (>5) was associated with shorter time-to-treatment-failure (median TTF 9.7 vs 29.4 months) that remained significant after adjusting for confounders including PD-L1 and presence of liver metastases (p=0.004). High NLR was also an independent predictor of poor OS (median 11.3 vs 56.8 months, HR 3.02, p=0.04). Although NLR was not predictive of radiographic response, there was a trend to association with a rapidly progressive phenotype defined by primary progressive disease and a duration of therapy ≤2 months (p=0.06). Other predictive factors included the presence of liver metastases, which was associated with a worse OS (HR3.37 p=0.05) but not TTF (p=0.14). An association was also seen between NLR and liver metastases (mean NLR 6.6 vs 25.2 in the absence and presence of liver metastases respectively, p<0.001). **Conclusion:** A disproportionate increase in peripheral immune myeloid populations may represent a systemic, myeloid-driven, immunosuppressive state that is significantly associated with primary refractory disease, rapid progression, and poor survival. A subset of about 50 patients with biobanked tissue are presently being analyzed using multiplex immunofluorescence to assess for MDSCs in the TME to correlate with peripheral blood findings.

P1.01-71 BONE METASTASES AND SKELETAL-RELATED EVENTS IN PATIENTS WITH METASTATIC NSCLC TREATED WITH ICIS: A MULTI-INSTITUTIONAL STUDY

A. Qin[1], S. Zhao[2], A. Miah[2], L. Wei[2], S. Patel[2], A. Johns[2], M. Grogan[2], E. Bertino[2], K. He[2], S. Olugbile[2], P. Shields[2], G. Kalemkerian[1], S. Gadgeel[1], N. Ramnath[1], B. Schneider[1], K. Hassan[1], D. Carbone[2], C. Presley[2], G. Otterson[2], D. Owen[2]

[1]*University of Michigan, Ann Arbor/United States of America,* [2]*The Ohio State University, Columbus/United States of America*

Background: Skeletal-related events (SRE) occur frequently in patients (pts) with metastatic NSCLC (mNSCLC) and confer a poor prognosis. Data on SRE and the effects of bone modifying agents (BMA) in NSCLC pts treated with immune checkpoint inhibitors (ICI) are limited as is the effect of bone modifying agents (BMA) on development of SRE and overall survival (OS). Here we report the incidence, impact on survival, and risk factors for SRE in pts with mNSCLC treated with ICI in a multi-institutional cohort. **Method:** We conducted a retrospective study of pts with mNSCLC treated with ICI at our institutions from 2014 to 2017. Overall survival (OS) was calculated from the date of ICI initiation to death from any cause or last follow-up. Cox regression model was used to study the

association between OS and baseline bone metastases (BM). The associations between SRE and categorical outcomes were studied using chi-square/Fisher's exact test. The study was approved by each institution's ethics review board. **Result:**

Table 1. Multivariate survival analysis.

Parameter	Level	Hazard Ratio	95% HR Confidence Limits	P-value
BM at baseline	Absent	Ref		<0.0001
	Present	1.847	1.414-2.413	
ECOG	0	Ref		0.0006
	1	1.494	1.017-2.196	
	2	1.506	0.969-2.341	
	3	3.788	1.442-9.949	
Histology	Adenocarci-noma	Ref		0.969
	Squamous	1.057	0.786-1.420	
Lines of Therapy	1	Ref		0.0007
	2	1.580	1.123-2.223	
	>=3	2.064	1.417-3.005	

We identified a cohort of 330 pts: 259 (72%) treated in second line or beyond; 211 (64%) received nivolumab; median age 63.4; median OS 10.4 mo (95% CI: 8.6, 12.5). In our cohort, 124 (38%) pts had BM at time of ICI, and 43 (13%) developed SRE after ICI (median 2.8 months; 19 pathologic fractures, 1 cord compression, 26 palliative radiation, 8 surgery). Patients with BM at ICI had shorter OS after controlling for ECOG, histology, and line of therapy (Table 1; Hazard Ratio 1.847; 95% CI 1.414 - 2.413; p <0.0001) compared to pts without baseline BM. Development of SRE was associated with presence of BM at baseline but not age, histology, or mutation status (EGFR, KRAS, and TP53). The use of BMA was not associated with OS or decreased risk of SRE. The development of new or progression of existing BM (22% of pts) during ICI was associated with a worse prognosis (mOS 7.1 vs 11.6 mo, p=0.017). **Conclusion:** Bone metastases and SRE are a significant cause of morbidity in pts with mNSCLC treated with ICI. The presence of BM at baseline was associated with a worse prognosis after controlling for multiple clinical characteristics. In our cohort, the use of BMA was not associated with decreased risk of developing SRE, osseous progression, or survival.

Background: The RTK AXL is implicated in epithelial-to-mesenchymal transition, negative regulation of anti-tumour immunity and resistance to multiple therapies including immune checkpoint inhibitors. Bemcentinib (BGB324) is a first-in-class, oral, highly selective and potent AXL inhibitor which has been demonstrated to enhance anti-PD1 therapy. The combination of bemcentinib and pembrolizumab was well tolerated and showed promising efficacy in previously treated IO-naïve NSCLC patients (Cohort A, NCT03184571), particularly in those with AXL positive disease, including PD-L1 negative patients. The novel combination is now being assessed in patients refractory to anti-PD-(L)1 therapy, considering the emerging need in this population and AXL's role as a mediator of resistance. **Method:** This is an open-label, single-arm, 2-stage phase II study (Cohort B, NCT03184571) to evaluate the safety and efficacy of bemcentinib (200mg/d) in combination with pembrolizumab (200mg/q3wk) in patients post anti-PD-(L)1 therapy. The primary endpoint is overall response rate (ORR), and additional endpoints include efficacy by biomarker expression, duration of response (DoR), disease control rate (DCR), progression free survival (PFS), overall survival (OS), and safety. Clinical efficacy endpoints are based on tumour imaging evaluable by RECIST v1.1. Eligible patients received a maximum of 2 prior lines of therapy, with the most recent course having included a PD-(L)1 inhibitor. To be eligible, patients must have exhibited disease control (CR/PR/SD) for at least 6 months on prior PD-(L)1 inhibitor therapy with disease progression occurring within 12 weeks since last dose. Bemcentinib will be administered as a loading dose of 400mg on days 1, 2 and 3 followed by a dose of 200mg once daily. A fixed dose of 200 mg pembrolizumab will be given by intravenous infusion over 30 minutes every 3 weeks. Bemcentinib and pembrolizumab will be given until disease progression, unacceptable dose toxicity, or for a maximum of 35 cycles. Tumour specimens will be analysed for PD-L1 expression (22C3 pharmDx), AXL by IHC, and infiltrating immune cells. The pre-specified efficacy threshold for continuation into the second stage is 1 objective response among the first 13 patients, at which point up to a further 16 patients may be evaluated, for a total of 29 patients. **Result:** Section not applicable **Conclusion:** Section not applicable

P1.01-73 AN EXPLORATIVE ANALYSIS OF PEMETREXED +/- PEMBROLIZUMAB MAINTENANCE FROM KEYNOTE-189 VERSUS PARAMOUNT, PRONOUNCE, AND JVBL

E. Garon[1], R. Govindan[2], V. Papadimitrakopoulou[3], C. Wang[4], R. Varea[5], J.S. Kim[4], J. Aerts[6]

[1]*David Geffen School of Medicine at UCLA/Translational Research in Oncology-US Network, Los Angeles/United States of America,* [2]*Section of Medical Oncology, Division of Oncology, Washington University School of Medicine, St. Louis/United States of America,* [3]*Department of Thoracic/HN Medical Oncology, MD Anderson Cancer Centre, Houston/United States of America,* [4]*Eli Lilly and Company, Indianapolis/United States of America,* [5]*Eli Lilly and Company, Madrid/Spain,* [6]*Erasmus Cancer Institute, Erasmus Medical Centre, Rotterdam/Netherlands*

Background: Recently, the phase 3 KEYNOTE-189 study demonstrated improved progression-free survival (PFS) and overall survival (OS) when pemetrexed/platinum doublet was combined with pembrolizumab as first-line treatment in patients with non-squamous NSCLC. The specific benefits of maintaining pemetrexed in combination with pembrolizumab after the triplet with platinum has not been previously assessed. **Method:** Using patient level data, we selected patients who had ≥5 cycles of pemetrexed (including the induction phase with platinum) from 3 randomized non-pembrolizumab clinical trials (PARAMOUNT, PRONOUNCE, and JVBL; N=486). As such, patients in the KEYNOTE-189 trial who had ≥5 cycles of pemetrexed in both arms (placebo arm; N=135, versus pembrolizumab arm; N=310) were analyzed. PFS and OS were evaluated by Kaplan-Meier estimator and Cox proportional hazard model; treatment emergent adverse events (TEAEs) were compared by descriptive statistics. **Result:** Baseline characteristics of the selected population with ≥5 cycles of pemetrexed were comparable between the pooled trials and KEYNOTE-189. Median PFS for patients with ≥5 cycles of pemetrexed was 5.6 months (95% CI: 4.6-5.8) from the pooled non-pembrolizumab trials and 6.6 months (95% CI: 5.4-7.1) in the placebo plus pemetrexed/platinum arm in KEYNOTE-189 (un-stratified HR: 1.29; 95% CI: 1.02-1.62). Median PFS in the selected population with ≥5 cycles of pemetrexed in KEYNOTE-189 was 9.3 months (95% CI: 9.0-11.1) in the pembrolizumab plus pemetrexed/platinum arm, and when compared with the

placebo plus pemetrexed/platinum arm in KEYNOTE-189, resulted in an un-stratified HR of 0.53 (95% CI: 0.42-0.68). Incidence rates of TEAEs were similar in those 3 selected populations (Table 1).

Table 1. PFS and TEAE Grade 3-5 in patients with pemetrexed treatment ≥5 cycles: descriptive comparison between the pooled data (PARAMOUNT, PRONOUNCE, JVBL) and KEYNOTE-189 trial

	Pooled historical data Pemetrexed ≥5 cycles (N = 486)	KEYNOTE-189	
		Placebo Arm Pemetrexed ≥5 cycles (N = 135)	Pembrolizumab Arm Pemetrexed ≥5 cycles (N = 310)
Median PFS, months (95% CI)	5.6 (4.6-5.8)	6.6 (5.4-7.1)	9.3 (9.0-11.1)
TEAE Grade 3-5, n (%)	284 (58.4)	86 (63.7)	200 (64.5)

CI, confidence interval; PFS, progression-free survival; TEAE, treatment emergent adverse event

Conclusion: In a selected population with pemetrexed maintenance in KEYNOTE-189, the placebo arm showed numerically comparable efficacy with historical data on pemetrexed maintenance. Pemetrexed/platinum in combination with pembrolizumab proved consistent clinical benefit in the same population with ≥5 cycles of pemetrexed, compared to the placebo arm in KEYNOTE-189 and historical controls.

P1.01-74 A RETROSPECTIVE STUDY EVALUATING CLINICAL PREDICTORS OF DURATION OF RESPONSE TO IMMUNE CHECKPOINT INHIBITORS IN ADVANCED NSCLC

Y. Ibrahim[1], K. Sankar[2], H. Mouzaihem[2], S. Kim[3], A. Haddad[4], H. Mamdani[3]

[1]*Wayne State University, Detroit/United States of America,* [2]*Wayne State University School of Medicine, Detroit/United States of America,* [3]*Karmanos Cancer Institute, Detroit/United States of America,* [4]*Providence/Providence Park Hospitals, Southfield/United States of America*

Background: Immune Checkpoint Inhibitors (ICI) with/without chemotherapy have become the standard of care for the treatment of advanced/metastatic non-small cell lung cancer (NSCLC). Similar to the response rate, durability of response to ICI is quite variable. While PDL1 expression and Tumor Mutational Burden (TMB) have been described to predict response to ICI, little is known about the clinical predictors of duration of response (DoR). **Method:** A retrospective chart review of patients (pts) with advanced NSCLC treated with ICI based therapy at Karmanos Cancer Institute was conducted. Data were collected on demographics, clinical characteristics, and tumor characteristics. Univariable and multivariable cox regression analyses were performed for six pre-chosen covariates (histology, prior radiation therapy, brain metastasis, occurrence of immune-related adverse events (irAEs), statin use and smoking status) to see the associations with the DoR to ICI. **Result:** One hundred thirty-one pts were included in the analysis (68% adenocarcinoma, 60% received prior radiation, 20% had brain metastasis, 26% developed irAEs, 33% were on a statin, 69% former smokers, 12% current smokers and 19% never smokers). Overall median DoR was 149 days (range, 14-1934). On multivariable analysis, longer DoR to ICI was observed in pts with non-adenocarcinoma histology (HR: 0.65; p = 0.050; CI: 0.42-1.00, median DoR 242.5 days) and current smokers (HR: 0.53; p = 0.031; CI: 0.30-0.95, median DoR 206.5 days). Other variables, including the presence of brain metastasis, prior radiation therapy, occurrence of irAEs and statin use had no significant relationship with the DoR. **Conclusion:** Tumor histology and smoking status were statistically and clinically significant predictors of durability of response to ICI in advanced NSCLC, presumably secondary to higher TMB. Presence of brain metastasis did not adversely impact DoR to ICI.

P1.01-75 PROGNOSTIC IMPACT OF NEUTROPHIL-TO-LYMPHOCYTE RATIO (NLR) FOR ADVANCED NON-SMALL CELL LUNG CANCER

M. Ishihara, R. Ochiai, T. Haruyama, Y. Tagami, T. Sakamoto, S. Tanzawa, T. Honda, S. Ota, Y. Ichikawa, K. Watanabe, N. Seki

Teikyo University, Tokyo/Japan

Background: Recently, the neutrophil-lymphocyte ratio (NLR) has been attracting attention as a prognostic factor for advanced non-small cell lung cancer (NSCLC) patients treated with immune checkpoint inhibitors (ICIs). However, other chemotherapies have not been well reviewed about the usefulness of NLR. Therefore, we retrospectively examined whether NLR at the start of first-line chemotherapy, including cytotoxic anticancer drugs and molecular-targeted drugs, could be a useful biomarker for overall survival (OS). **Method:** We examined advanced NSCLC patients, including recurrent cases after surgery or radiotherapy, who received first-line chemotherapy at our institution between 2008-2018. Patients were divided into two groups according to gene expression (EGFR/ALK mutant type [mt] and wild type [wt]) to differentiate the therapeutic effects of first-line chemotherapies. Furthermore, only patients treated with molecular-targeted drugs as first-line therapy were included in the mt group, whereas only patients treated with cytotoxic anticancer drugs as first-line therapy were included in the wt group. Blood test to measure NLR was performed within 3 days prior to the initiation of first-line chemotherapy. According to the levels of NLR (NLR < 5 or NLR ≥ 5), OS curves between NLR-low and NLR-high subgroups were compared using log-rank test in the mt and wt groups, respectively. To evaluate the prognostic impact of NLR, background factors such as age, sex, performance status, smoking history, clinical stage, and LDH were adjusted using multivariate Cox proportional hazards model analysis. **Result:** 1113 cases were reviewed, 276 cases of which met the eligibility criteria, including 90 cases (32.6%) in the mt group and 186 cases (67.4%) in the wt group. In the mt group, median survival times (MSTs) of NLR-low and NLR-high subgroups were 37.2 months and 18.1 months, respectively (p < 0.001). Similarly, in the wt group, MSTs of NLR-low and NLR-high subgroups were 16.2 months and 6.3 months, respectively (p < 0.001). On the other hand, significantly independent factors for worse OS in the mt group were NLR-high (hazard ratio [HR]; 3.54, 95% confidence interval [CI]; 1.96 to 6.38, p < 0.001), LDH-high (HR; 2.31, 95% CI; 1.30 to 4.11, p = 0.004), and poor performance status (HR; 3.58, 95% CI; 1.98 to 6.48, p < 0.001). Similarly, significantly independent factors for worse OS in the wt group were NLR-high (HR; 2.10, 95% CI; 1.40 to 3.14, p < 0.001), LDH-high (HR; 1.57, 95% CI; 1.11 to 2.22, p = 0.009), and poor performance status (HR; 2.17, 95% CI; 1.48 to 3.20, p < 0.001). **Conclusion:** The low levels of NLR at the start of first-line chemotherapy might be associated with better OS regardless of the types of anticancer drugs.

P1.01-76 RANDOMIZED PHASE II STUDY OF IMMUNOTHERAPY WITH OR WITHOUT LOW DOSE CHEMOTHERAPY FOR PATIENTS WITH PERFORMANCE STATUS OF 2

T. Ahmed, J. Ruiz, T. Lycan, S. Addo, P. Gandhi, J. Miller, B. Levine, P. Triozzi, M. Bonomi, W.J. Petty

Wake Forest School of Medicine, Winston-Salem/United States of America

Background: Combination chemo-immunotherapy has become a standard of care for patients with non-small cell lung cancer (NSCLC) who have performance status (PS) of 0-1. Limited information is available regarding optimal immunotherapy treatment options for patients with PS 2. In the current study, we examined the clinical and immunologic effects of immunotherapy alone or in combination with low dose carboplatin and paclitaxel as a potential treatment option for the PS 2 population. **Method:** This randomized phase II study will enroll 40 patients total with 1:1 randomization to pembrolizumab 200 mg day 1 every 3 weeks or pembrolizumab 200 mg day 1 with carboplatin AUC 1 and paclitaxel 25 mg/m2 days 1, 8, and 15 every 3 weeks. At the time abstract preparation, 36 evaluable patients have been enrolled with 28 patients having completed response evaluation. Blood for circulating immune cell phenotyping, soluble program death ligand 1 (sPDL1), and immune-modulatory miRs was collected prior to treatment and at weeks 4 and 7. Investigator assessed irRECIST responses were examined at week 8 and every 12 weeks thereafter. **Result:** Responses have been observed in 6 out of 16 patients (38%) in the control arm and 7 out of 12 patients (58%) in the experimental arm. Treatment related adverse events have been similar between the two arms with increases in infusion reactions in patients receiving low-dose carboplatin and paclitaxel. Interim biomarker analyses indicate circulating myeloid derived suppressor cells numbers decreased in patients receiving pembrolizumab combined with carboplatin and paclitaxel but not in patients receiving pembrolizumab alone. Accrual is expected to complete soon with updated response rates and progression free survival are anticipated to be mature and will be presented at the time of the

meeting. **Conclusion:** The combination of pembrolizumab with low-dose weekly carboplatin and paclitaxel is well-tolerated and active in the PS 2 population. Comparison of this regimen to pembrolizumab alone will be performed once data have matured.

Background: Nivolumab (Nivo) has shown promising effects in patients with non-small-cell lung cancer (NSCLC) as a second- or later-line treatment. However, some drugs are reported to influence the efficacy of immune checkpoint inhibitors (ICIs). For example, steroids are related with worth prognosis treated with ICIs. On the other hands, opioids have direct and indirect effects on anti-tumor immunity. The aim of this study is to disclose the impact of oral drugs in patients harboring NSCLC treated with Nivo. **Method:** In this study, data for 201 patients treated with Nivo during 17 December 2015 to 31 July 2016 at three respiratory medical centers in Japan were retrospectively reviewed. We collected clinical data including age, sex, smoking history, performance status (PS) score, body mass index (BMI), histological types, tumor proportion score (TPS) of program death-ligand1 (PD-L1), epidermal growth factor receptor (EGFR) mutation status, number of previous treatments, steroid use, opioid use, statin use, biguanide use and fibrates use at the time of Nivo treatment commencement. We investigated relationship between progression free survival (PFS), overall survival (OS) and drug use at the time of Nivo treatment. Patients were followed-up for disease status until October 2017. **Result:** The median age at the time of administration Nivo was 68 years, 135 patients were male, 157 patients had smoking history, 152 patients had a PS score of 0–1, median BMI was 21.4kg/m^2, 42 patients had squamous cell carcinoma, 24 patients had PD-L1 TPS 50 or over, 37 patients had positive EGFR mutation, 78 patients received 3 or more treatments before Nivo treatment, 23 patients received steroids, 33 patients received opioids, 12 patients received statin, 6 patients received biguanide and 2 patients received fibrates. In the multivariate analysis including above factors, steroid use was significantly associated with poor PFS (hazard ratio [HR]: 2.17; 95% confidence interval (CI): 1.31–3.43; p = 0.003) and OS (HR: 2.10; 95% CI: 1.18–3.58; p = 0.014). Moreover, opioid use was significantly associated with poor OS (HR: 1.87; 95% CI: 1.11–3.08; p = 0.020). **Conclusion:** Steroid use at baseline was significantly associated with worse PFS and OS. Furthermore, opioid use at baseline was significantly associated with worse OS.

Background: Non-small cell lung cancer (NSCLC) accounts for majority of lung cancer, the leading cause of cancer-related mortality in both sexes. Atezolizumab, an anti- programmed death ligand 1 (PDL-1) antibody, has shown significant antitumor activity against NSCLC. Atezolizumab in combination with chemotherapy as a first-line treatment of advanced NSCLC have shown to improve survival in recent studies. Yet, there are notable adverse events. We conducted a systematic review and meta-analysis of randomized controlled trials (RCT) to determine the risk of treatment-related adverse events (TRAE) and treatment discontinuation due to TRAE. **Method:** We performed a comprehensive literature search using PUBMED, MEDLINE, EMBASE databases and various meeting abstracts from inception through March 2019. RCTs utilizing first-line atezolizumab combination regimen in patients with advanced NSCLC were incorporated in the analysis. The primary meta- analytic approach was a random effects model using the Mantel-Haenszel (MH) method. It was used to calculate the estimated pooled risk ratio (RR) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q-statistic. **Result:** 4 RCTs (IMpower – 130, 131, 132 and 150) including 2725 patients with advanced NSCLC were included in the meta-analysis. The study arm used standard chemotherapy regimens in combination with atezolizumab while control arm utilized only standard chemotherapy regimens. The randomization ratio was 2:1 in IMpower130 study and 2:1 in other studies. The I^2 statistic for heterogeneity was 0, suggesting homogeneity among RCTs. All-grade TRAE incidence was 94.5% in study group vs 91.8% in control group (RR, 1.03; 95% CI: 0.99 – 1.06, P = 0. 01). High-grade TRAE was 12.94% higher in study arm compared to control arm (RR, 1.22; 95% CI: 1.14 – 1.30, P < 0.0001). Treatment-related deaths were reported in 34 (2.28%) in study arm vs 20 (1.62%) in control arm. The pooled RR was 1.45 (95% CI: 0.82 –2.54, P = 0.20) and RD was 0.01 (95% CI: - 0.00 – 0.02, P = 0.08). Treatment discontinuation due to TRAE was noted in 419 (28.10%) vs 255 (20.66%) in control group with RR of 1.36 (95% CI: 1.19 –1.56, P < 0.0001) and RD of 0.08 (95% CI: - 0.04 – 0.11, P < 0.0001). **Conclusion:** High-grade treatment-related adverse events were increased in front-line atezolizumab chemoimmunotherapy regimen and patients on the study arm experienced significant drop outs due to TRAE, despite showing survival benefits in studies. Good supportive care may enhance patients' quality of life and compliance.

Keyword: atezolizumab meta-analysis immunotherapy

P1.01-79 G8 SCREENING SCORES IN ELDERLY ADVANCED LUNG CANCER PATIENTS: A PROSPECTIVE SINGLE INSTITUTION STUDY

X. Wu[1], U. Janzic[2], C. Milner-Watts[1], D. Walder[1], R. Kumar[1], A. Minchom[1], R. Gunapala[1], J. Bhosle[1], M. O'Brien[1]

[1]*Royal Marsden Hospital, London/United Kingdom,* [2]*University Clinic Golnik, Golnik/Slovenia*

Background: Standard evaluation of elderly patients based on ECOG performance status (PS) may lead to excessive toxicity or undertreatment and loss of efficacy. We used the G8 score classification to assess the correlations between G8 scores, treatment decisions and clinical outcomes. **Method:** Elderly patients (≥ 70 years old) with advanced lung cancer treated at the Royal Marsden hospital between July 2016 and July 2018 were prospectively assessed by standard clinical methods and the G8 questionnaire. The G8 score did not influence the physician decision. Total G8 scores were < 11 low score, 11-14 intermediate group, and > 14 as the high score group. We correlated treatment decisions, relative dose intensity (RDI) of first two cycle, proportion of dose attenuation, ≥G3 toxicity and hospitalisation in each G8 score group. **Result:** Patient characteristics and clinical outcomes in each G8 score group are listed as Table 1. The G8 score correlated inversely with PS. More patients in the low score group (56%) had PS ≥2 compared to other two groups. Physicians tended to offer BSC to low score patients; 49%, 12% and 5% patients in low, intermediate and high score group respectively did not receive any systemic treatment. More patients in high score group (53%) received full dose chemotherapy on first cycle. Patients in high score group also tended to tolerate full dose chemotherapy better with relatively high RDI for the first two cycles (0.9) and less frequent (0%) ≥G3 toxicity. Patients in intermediate score group had similar frequency of ≥G3 toxicity and hospitalisation to patients in low score group, who received chemotherapy.

	G8 < 11 points (high risk)	G8 11 - 14 (intermediate risk)	G8 > 14 (low risk)
No of patients: n (%)	45 (42)	42 (40)	19 (18)

P1.01-80 LUNG CANCER PROGNOSTIC INDEX PERFORMANCE IN US REAL-WORLD ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

R. Shah[1], A. John[1], M. Alexander[2]

[1]*Roche Diagnostics, Pleasanton/United States of America,* [2]*Peter MacCallum Cancer Centre, Melbourne/Australia*

Background: The Lung Cancer Prognostic Index (LCPI) is a previously validated index that uses routinely available risk factors to ascertain overall survival. The purpose of this analysis is to validate the performance of the LCPI in advanced non-small cell lung cancer (aNSCLC) patients using real-world data from the United States. **Method:** Using the US-based Flatiron Health electronic health record-derived database, adult aNSCLC patients diagnosed on or after January 1, 2011 were identified and followed through January 31, 2019. Patient-level LCPI scores were derived using stage, smoking status, age, sex, respiratory comorbidities and actionable mutation status (EGFR, ALK or ROS1 positivity), and 4 groups (1-4) were created; performance status and weight loss at diagnosis were omitted due to low data yield. Overall survival was estimated using the Kaplan-Meier method and Cox proportional hazards models were used to estimate hazard ratios (HR) and 95% confidence intervals (CI) for the association of the LCPI with all-cause mortality. **Result:** Of 48,872 aNSCLC patients with a mean (SD) age of 68 (9.8) years, 53% were male, 88% had a history of smoking, 75% were stage IIIB or IV at diagnosis, 70% had a non-squamous histology and 20% were squamous, 25% had a respiratory comorbid condition and 67% did not have an actionable mutation. Median survival time for LCPI groups 1-4 was 652, 525, 371 and 258 days, respectively. In the adjusted model, compared to LCPI group 1, all-cause mortality (HR [95% CI]) for groups 2, 3 and 4 was 1.20 (1.15, 1.25), 1.55 (1.50, 1.61) and 2.09 (2.02, 2.17), respectively. **Conclusion:** For those in LCPI group 4, the risk for all-cause mortality was doubled and median survival time was less than half of that seen in LCPI group 1. The results from this analysis were consistent with the previously validated LCPI results, thus validating the performance of the LCPI in a large US cohort of aNSCLC patients. The predictive model includes clinical risk factors such as mutation status, and facilitates the use of precision medicine in routine practice to inform treatment decisions, clinical trial eligibility and standardized risk assessment for comparative research.

P1.01-81 A NEW PROGNOSTIC INDEX COMBINES THE METABOLIC RESPONSE AND RECIST 1.1 TO EVALUATE THE THERAPEUTIC RESPONSE IN PATIENTS WITH LUNG CANCER

W. Tang[1], Q. Hou[2], J. Lin[1], Z. Dong[1], Y. Li[1], J. Chen[3], H. Yan[1], S. Wang[2], Y.-L. Wu[1], W.-Z. Zhong[1]

[1]*Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [2]*Weilun PET Center, Nuclear Medicine Department, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China,* [3]*Guangzhou Twelfth People's Hospital, Guangzhou/China*

Background: Response Evaluation Criteria in Solid Tumors (RECIST) is occasionally insufficient for evaluation. We propose a new prognostic index (NPI) that combines the standardized uptake value (SUV), metabolic tumor volume (MTV) and RECIST. **Method:** In total, 163 patients with lung cancer who underwent positron emission tomography-computed tomography prior to and after treatment were included. We formulated the NPI by estimating the hazard ratios of overall survival for ΔMTV, ΔSUV_{max} and ΔD (tumor size based on RECIST). Then the regression coefficients were used, which gave rise to the HRs, as weights to formulate the new prognostic index (NPI). Progression-free survival (PFS) and overall survival (OS) were compared between RECIST and the NPI. **Result:** ROC curve analysis identified two cutoff values based on the NPI (≤-44.0% and >40.4%) to discriminate partial remission (NPR), stable disease (NSD) and progressive disease (NPD). The concordance rate between RECIST and NPI was 74.2% (κ = 0.572, P<0.001). Based on RECIST, survival analysis did not discriminate significantly on either PFS or OS between the PR, SD and PD groups. However, according to the NPI, PFS and OS differed significantly between the NPR, NSD, and NPD groups (training set: PFS, P = 0.007; OS, P = 0.027; validation set: PFS, P = 0.003; OS, P = 0.044). In total, 83 patients with SD were reclassified based on the NPI (20 with NPR, 57 with NSD, 6 with NPD), and the patients reclassified as NPR showed prolonged PFS (P = 0.004) and OS (P = 0.026) compared with those in the NSD+NPD group. **Conclusion:** The NPI shows superiority for evaluation of the therapeutic response and survival for patients with lung cancer, especially in the assessment of SD patients based on RECIST.

P1.01-82 THE DIFFERENT FREQUENCIES AND GENETIC PROFILES OF HISTOLOGIC TRANSFORMATION AFTER DIFFERENT EGFR-TKIS IN EGFR-MUTANT ADENOCARCINOMAS

J. Kang, H.-J. Chen, B.-C. Wang, Z. Wang, X.-C. Zhang, X.-M. Li, Q.-M. Deng, Y.-L. Wu, J.-J. Yang

Guangdong Lung Cancer Institute (GLCI), Guangdong Provincial People's Hospital (GDPH), Guangzhou/China

Background: Histologic transformation is a mechanism of resistance to epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor(TKIs) in *EGFR*-mutant non-small cell lung cancers(NSCLCs). Those adenocarcinomas with histologic transformation usually underwent poor prognosis. However, few studies have focused on the different occurrence rates and genetic profiles between *EGFR*-mutant adenocarcinomas treated with different generations of EGFR-TKIs. **Method:** Pathology was confirmed in 345 *EGFR*-mutant patients at baseline and recurrence. Among these patients,235 patients were treated with gefitinib or erlotinib,54 with afatinib and 56 with osimertinib. But only 11 patients with sufficient tumor specimens could be evaluated for the genetic profiles by next-generation sequencing (NGS). Demographics, disease features, and outcomes of these patients were analyzed. **Result:** The frequency of these *EGFR*-mutant adenocarcinomas with histologic transformation after the treatment of different generation TKIs were quite different. The frequency of gefitinib/erlotinib group was 7.2% (17/235),while the others were 5.6%(3/54, afatinib group)and 17.9%(10/56, osimertinib group). The median progression free survival (PFS)to EGFR-TKIs of those patients were 12.2 months(gefitinib/erlotinib group), 5.3 months (afatinib group)and 7.7 months(osimertinib group) respectively. Four adenocarcinomas treated with gefitinib/erlotinib all harbored *TP53* mutations at baseline. One adenocarcinoma treated with afatinib was founded to have acquired MET amplification and transformed to small-cell lung cancer meanwhile. Moreover, the PFS of one patient to afatinib was just 3 months and her genetic profile at baseline was characterized by *Rb1*, *TP53*, and *PIK3CA* mutations. There were 3 patients treated with osimertinib underwent histologic transformation from adenocarcinomas to squamous carcinoma. One patient after progressive disease of osimertinib did not have enough tissue to detect NGS,and her blood NGS result just showed *EGFR L858R* and *T790M* mutation. The tissue NGS result of the second patient showed *EGFR* p.Glu746-Ala750 deletion, *EGFR T790M* and *C797S* mutations, *CDK4/ CCND1/ EGFR/ KRAS* amplifications. The second patient received the chemotherapy of pemetrexed+ carboplatin + bevacizumab and the best response was partial response. The third patient take palbociclib and osimertinib meanwhile and his symptoms improved with the tissue NGS of EGFR T790M mutation and *CDK4/ MDM2/ EGFR* amplifications. They were characterized by *EGFR* amplification and *CDK4* amplification. The others transform from adenocarcinomas to small cell cancers or neuroendocrine tumors were seem to harbor with TP53, Rb1 and PIK3CA mutations. **Conclusion:** It seems more common in some subtypes that the *EGFR*-mutant adenocarcinomas treated with osimertinib undergo histologic transformation. The genetic profiles vary greatly between transformation to squamous carcinomas and transformation to small-cell cancers/neuroendocrine tumors in EGFR-mutant adenocarcinomas treated with osimertinib. Further verification is needed.

P1.01-83 COMPARATIVE EFFICACY ANALYSIS BETWEEN ENTRECTINIB TRIAL AND CRIZOTINIB REAL-WORLD ROS1 FUSION-POSITIVE (ROS1+) NSCLC PATIENTS

R. Doebele[1], L. Perez[2], H. Trinh[3], M. Martinec[2], R. Martina[4], T. Riehl[3], M. Krebs[5], N. Meropol[6], W. Wong[3], G. Crane[7]

[1]*University of Colorado, Aurora/United States of America,* [2]*F. Hoffmann-La Roche Ltd, Basel/Switzerland,* [3]*Genentech, South San Francisco/United States of America,* [4]*University of Liverpool, Liverpool/United Kingdom,* [5]*Division of Cancer Sciences, The University of Manchester, NIHR Clinical Research Facility, The Christie NHS Foundation Trust, and the NIHR Manchester BRC, Manchester/United Kingdom,* [6]*Flatiron Health, New York/United States of America,* [7]*F. Hoffmann-La Roche Ltd, Welwyn Garden City/United Kingdom*

Background: Entrectinib is an oral tyrosine kinase inhibitor for *ROS1* fusion-positive (*ROS1+*) NSCLC. Three phase 1/2 single-arm studies showed entrectinib efficacy in this population (Doebele WCLC 2018). Due to the rarity of *ROS1+* patients generating direct comparative evidence in prospective randomized trials is difficult. We identified a retrospective real-world cohort of *ROS1+* NSCLC patients from electronic health records (EHR), to compare crizotinib, the current standard of care, to entrectinib as reported in clinical trials **Method:** Crizotinib-treated patients with advanced *ROS1+* NSCLC diagnosed 1 Jan 2011 to 30 Jun 2018, were identified with technology-enabled abstraction in the Flatiron Health EHR-derived database (>2.1 million cancer patients from US oncology practice). Entrectinib trial inclusion/exclusion criteria were applied to match the crizotinib cohort as closely as possible. Primary endpoint: time to treatment discontinuation (TTD), adapted from Gong (ASCO 2018); real-world progression-free survival (rwPFS; physician/scan report) and overall survival (OS) were secondary outcomes. Time-to-event analyses used Kaplan-Meier survival curves and Cox proportional hazard models on propensity score weighted populations; age, gender, race/ethnicity, smoking status, brain metastasis and previous lines of therapy were prognostic factors. **Result:** We analyzed 53 entrectinib and 69 crizotinib *ROS1+* NSCLC patients. Median weighted TTD: entrectinib, 14.6 months (95% CI: 8.3–23.8); crizotinib, 8.8 months (95% CI: 8.2–9.9). When rwPFS from crizotinib was compared to trial PFS, entrectinib had longer PFS vs crizotinib (weighted HR: 0.44; 95% CI: 0.27–0.74). Median OS with entrectinib was not reached (median follow-up: 15.5 months); weighted median OS with crizotinib was 18.5 months (95% CI: 15.1–19.9). Findings were consistent across multiple sensitivity analyses. **Conclusion:** Entrectinib was associated with longer TTD and PFS in *ROS1+* NSCLC patients vs a matched real-world crizotinib population. Control populations derived from real-world cohorts can supplement evidence from clinical trials in settings where new standards of care are needed, but where only limited data are available and randomization is not feasible. Funding: This study was funded by F. Hoffmann-La Roche

P1.01-84 INTERACTION OF LORLATINIB WITH CYP2B6, CYP2C9, UGT, AND P-GP PROBE DRUGS IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

Background: Lorlatinib is a small-molecule anaplastic lymphoma kinase (ALK) inhibitor approved for treatment of patients with *ALK*-positive advanced non-small cell lung cancer (NSCLC). Because lorlatinib is an inducer and inhibitor of various cytochrome P450 (CYP) enzymes and transporters, an evaluation of its effect on these substrates at steady state is warranted. A drug-drug interaction (DDI) sub-study was conducted in patients with advanced NSCLC to evaluate the net effect of these interactions. **Method:** Probe drugs utilized included bupropion for CYP2B6, tolbutamide for CYP2C9, acetaminophen for uridine 5'-diphospho-glucuronosyltransferase (UDP-glucuronosyltransferase, UGT), and fexofenadine for P-glycoprotein-1 (P-gp). Thirty-two patients (to have at least 6 evaluable patients per probe drug) were administered a single dose of a probe drug alone on Day −2 to determine plasma exposure of the probe drug alone. Starting on Cycle 1 Day 1, patients began lorlatinib tablets 100 mg daily. On Cycle 1 Day 15, another single dose of the same probe drug was administered concurrently with lorlatinib. **Result:** Co-administration of lorlatinib 100 mg with bupropion, a sensitive CYP2B6 probe drug, decreased bupropion geometric mean plasma AUC_{inf} and C_{max} by 25% and 27%, respectively. For tolbutamide, a sensitive CYP2C9 probe drug, lorlatinib decreased tolbutamide AUC_{inf} and C_{max} by 43% and 15%, respectively. Likewise, for acetaminophen, a sensitive UGT substrate, lorlatinib decreased acetaminophen AUC_{inf} and C_{max} by 45% and 28%, respectively. Finally, for fexofenadine, a sensitive P-gp substrate, lorlatinib decreased fexofenadine AUC_{inf} and C_{max} by 67% and 63%, respectively.

POSTERS

Conclusion: Critical steady-state–based DDI evaluations can be conducted in patients with cancer in carefully designed studies. Per FDA guidance, strong, moderate, and weak inducers are drugs that decrease the AUC of sensitive index substrates by ≥80%, ≥50% to <80%, and ≥20% to <50%, respectively. Based on these criteria, lorlatinib behaved as a net weak inducer of CYP2B6, CYP2C9, and UGT; and a net moderate inducer of P-gp. The results of this sub-study can help guide recommendations for dose modifications when lorlatinib is given concomitantly with drugs that are metabolized by these enzymes or transporters. Based on the current results, only drugs that are P-gp substrates of narrow therapeutic index may require dose adjustments when used concomitantly with lorlatinib.

Keywords: DDI, lorlatinib, NSCLC

P1.01-85 TREATMENT FOR ADVANCED NSCLC WITH EGFR MUTATIONS AND DE NOVO MET AMPLIFICATION/ OVEREXPRESSION

H.-M. Wang[1,2], W.-F. Li[2], Q.-M. Deng[2], J. Kang[2], H.-J. Chen[2], Z. Wang[2], Q. Zhou[2], C. Xu[2], X.-C. Zhang[2], J. Su[2], H. Yan[2], Y.-L. Wu[2], J.-J. Yang[1,2]

[1]*School of Medicine, South China University of Technology, Guangzhou/ China,* [2]*Guangdong Lung Cancer Institute; Guangdong Provincial People's Hospital(GDPH) & Guangdong Academy of Medical Sciences, Guangzhou/ China*

Background: Combination of epidermal growth factor receptor (EGFR) and mesenchymal-epithelial transition (MET) tyrosine kinase inhibitors (TKIs) are effective in advanced non-small-cell lung cancer (NSCLC) patients harboring *EGFR* mutation and acquired *MET*-amplification. However, there are few reports about treatments of patients with *EGFR* mutation and *de novo MET* amplification/ overexpression. **Method:** We retrospectively screened 88 consecutive advanced NSCLC patients harboring *EGFR* mutation and *de novo MET* amplification/overexpression at Guangdong Provincial People's Hospital of China from January, 2014 to December, 2018. Among them, a total of 41 patients receiving first-line targeted therapy were included and stratified into *EGFR*-driven, *MET*-driven and *EGFR/MET* co-driven groups illustrated respectively in Table 1.

Table 1. Classification of advanced NSCLC with EGFR mutation and MET overexpression/amplification.

Group	*EGFR* mutation	*MET* overexpression/ amplification	Response to first-line TKI
EGFR-driven	Exon 19 deletion or exon 21 L858R mutation (tested by next generation sequencing (NGS) or amplification refractory mutation system (ARMS) or polymerase chain reaction (PCR)).	Overexpression: strong intensity staining was in more than 50% of tumor cells (tested by immunohistochemistry (IHC)). Amplification: CNG≥5, or *MET*/ centromeric portion of chormosome 7 ratio≥2.2, with an additional criterion of focal amplification was in more than 10% of tumor cells (tested by fluorescence in situ hybridization (FISH)).	PFS>3 months, best response is complete response (CR)/partial response (PR)/stable disease (SD); not receiving MET-TKIs in later-line treatment, or had MET-TKIs but PFS≤3 months.
MET-driven			PFS≤3 months, receive MET-TKIs monotherapy or MET-TKIs plus EGFR-TKIs in later-line treatment and PFS>3months, or PFS≤3 months,but with acquired mechanism to *MET*.
EGFR/ MET co-driven			Response to EGFR-TKIs at least one time, receiving EGFR-TKIs plus MET-TKIs in later-line treatment and PFS>3 months, or PFS≤3 months, but with acquired mechanism to *MET*.

Result: Among enrolled patients, 40 of them received first-line first-generation EGFR-TKIs while 1 treated with MET-TKI. Twenty-eight received targeted therapy in the later-line treatments after resistance. Thirty-one (75.6%), 5 (12.2%) and 5 (12.2%) patients were classified into *EGFR*-driven, *MET*-driven and *EGFR/MET* co-driven groups. Median progression-free survival (PFS) was 12.1, 1.0 and 5.3 months respectively in the first-line setting. Objective response rates were 58.1%, 0.0% and 20.0% (P=0.028) respectively. Among 28 patients receiving subsequent targeted therapies, 58.1% (18/31), 100.0% (5/5) and 100.0% (5/5) were *EGFR*-driven, *MET*-driven and *EGFR/MET* co-driven respectively. Median PFS was 7.0, 6.5 and 10.3 months for the *EGFR*-driven group receiving subsequent EGFR-TKIs, the *MET*-driven group receiving MET-TKIs with or without EGFR-TKIs, and the *EGFR/MET* co-driven group treating with EGFR-TKIs plus MET-TKIs respectively (P=0.399). Also, no significant difference was observed in overall survival for these 28 patients (33.8 vs. 11.8 vs. 27.9 months, P=0.098). **Conclusion:** Subsequent individualized targeted therapy or co-targeted therapies might favor clinical outcomes for both *MET*-driven and *EGFR/MET* co-driven patients with advanced NSCLC after resistance to first-line EGFR-TKIs.

P1.01-86 OCCURRENCE OF DE NOVO DUAL HER2/HER3 OR HER2/EGFR TMD MUTATIONS: EXTENDING THE SPECTRUM OF TARGETABLE MONO-HER2 TMD IN NSCLC?

S.-H. Ou[1], A. Schrock[2], E. Bocharov[3], J. Lee[2], R. Madison[2], L. Gay[2], V. Miller[2], B. Alexander[2], H. Husain[4], J. Riess[5], S. Ali[2], V. Velcheti[6]

[1]*Chao Family Comprehensive Cancer Center, University of California Irvine, Irvine/United States of America,* [2]*Foundation Medicine, Inc., Cambridge/ United States of America,* [3]*Shemyakin-Ovchinnikov Institute of Bioorganic Chemistry, Russian Academy of Sciences, Moscow/Russian Federation,* [4]*Moores Cancer Center University of California, San Diego, La Jolla/United States of America,* [5]*UC Davis Comprehensive Cancer Center, Sacramento/ United States of America,* [6]*NYU Langone Cancer Center, New York/United States of America*

Background: HER2 (ERBB2) TMD mutations have recently been described as novel solo actionable drivers in NSCLC responsive to afatinib in small series. However, dual occurrence of de novo EGFR or HER3 (ERBB3) TMD mutations together with HER2 TMD mutations, which may have implications for dimerization patterns and treatment, has not been described. **Method:** Hybrid-capture based comprehensive genomic profiling was performed on blood-based circulating tumor DNA (n=5,200) or FFPE tissue (n= 45,780) samples collected during clinical care from 50,980 unique NSCLC patients. **Result:** HER2 TMD mutations were identified in 0.12% (60/50,980) of cases and included V659E (n=33), V659D (n=8), G660D (n=15), V659E+G660R, V659_I661>VVEGI, G660E>R, and S653C (1 each). Within this subset, the median age of patients was 61 years (range 33-91) and 62% were female. No co-occurring known NSCLC driver alterations were detected, except one case with *EGFR* exon 19 deletion and one case with EGFR L858R and lung co-primary tumors noted. However, co-occurring HER3 (I649R) or EGFR (G652R) TMD mutations were found in 18% (11/60) and 5.0% (3/60) of cases, respectively. Notably, these ERBB3 or EGFR TMD mutations only co-occurred with HER2 TMD V>D (8/9 cases) or G>D (7/15 cases), but not with V>E changes (0/34 cases; p=0.0002). *HER2* amplification co-occurred with V659E in 15% (5/34) of cases, and G660D mutation was seen with the oncogenic extracellular domain S310F mutation in one case. Importantly, neither EGFR G652R nor ERBB3 I649R was found in the absence of a HER2 TMD mutation. Preliminary modelling studies suggest formation of a salt-bridge which would increase propensity for HER2/HER3 and HER2/EGFR heterodimerization favoring receptor activation. Two patients in this series with V659E were previously reported to have responded to afatinib and 1 patient with G660D+I649R did not respond to afatinib. Updated clinical data for these patients and others treated with HER2-tageted therapies will be presented. **Conclusion:** HER2 TMD mutations (V659D/E or G660D/R) are uncommon but targetable driver alterations in NSCLC. In cases with HER2 TMD V>D or G>D, a de novo co-existing EGFR or HER3 TMD mutation was frequently observed (88% and 47%, respectively), which may explain differential dimerization preference and in turn response to ERBB inhibitors. We hypothesize that dual HER2/HER3 or HER2/EGFR TMD mutants may be more aggressive than single HER2 TMD mutants due to the arginine-aspartic acid interaction, and these dual mutants may require combined kinase inhibitor + antibody therapy to block dimerization. Studies utilizing models to further characterization these co-alterations are in progress.

Background: Osimertinib is a 3rd generation TKI approved for stage IV EGFR+ NSCLC in the first line or post-progression with *T790M*. The spectrum of osimertinib resistance mutations and clinical outcomes post-osimertinib progression are not well described. **Method:** Single-center retrospective review of patients with stage IV EGFR+ NSCLC treated with osimertinib was conducted. Resistance mutations were determined via tissue biopsy or circulating tumor DNA (Guardant) prior to and at time of progression on osimertinib. PFS was calculated using Kaplan-Meier method. PFS1 is start of osimertinib to radiographic progression. PFS2 is start of next therapy after osimertinib to next radiographic progression. **Result:** We identified 95 patients with stage IV EGFR+ lung adenocarcinoma treated with osimertinib detected via NGS (56/95), real-time PCR (29/95), Sanger sequencing (8/95), and other techniques (2/95). Most patients were female (63/95) and never smokers (72/95). Osimertinib resistance and post-progression patterns are shown in Table 1. Potentially targetable mutations were found in 55% (26/47) samples and 14% (6/47) samples had oncogenes targetable with available TKIs. *TP53* mutations prior to osimertinib did not significantly influence PFS (36 weeks vs 39 weeks; p = 0.13). *MET* amplification was only seen in the setting of undetectable *T790M* or in patients who received first line osimertinib. Median PFS1 for 1st line EGFR TKI (n=17), 2nd line EGFR TKI (n=41), 3rd or greater line EGFR TKI (n=29) was 36, 45 and 39 weeks respectively (p=0.268) with median follow up of 59, 81, and 64 weeks. 10 patients received locally ablative radiotherapy for oligoprogressive disease (defined as ≤ 3 progressive sites) and continued osimertinib post-progression with median PFS2 of 49 weeks.

	Osimertinib in first line	Osimertinib after prior EGFR inhibitor
EGFR mutations at stage IV disease	**N = 18**	**N = 77**
Exon 19 deletion	12/18 (67%)	42/77 (55%)
L858R	4/18 (22%)	28/77 (36%)
G719X	1/18 (5%)	3/77 (4%)
L861Q	1/18 (5%)	1/77 (1%)
Exon 20 insertion	0/18 (0%)	3/77 (4%)
Systemic therapy prior to osimertinib	**N = 18**	**N = 77**
No chemotherapy or immunotherapy	17/18 (94%)	51/77 (66%)
Chemotherapy	1/18 (6%)	22/77 (28%)
Immunotherapy	0/18 (0%)	2/77 (3%)
Radiographic progression on osimertinib	**N = 17**	**N = 70**
Yes	10/17 (59%)	57/77 (74%)
No	7/17 (41%)	13/77 (26%)
Osimertinib resistance testing available	**N = 7**	**N = 40**
Liquid biopsy	5/7 (72%)	20/40 (50%)
Tissue biopsy	1/7 (14%)	12/40 (30%)
Both	1/7 (14%)	8/40 (20%)
Resistance EGFR alterations	**N = 7**	**N = 40**
T790M not detected	0/7 (0%)	19/40 (48%)
C797S	0/7 (0%)	9/40 (23%)
792 H/V	0/7 (0%)	2/40 (5%)
A289T	0/7 (0%)	2/40 (5%)
L718Q	0/7 (0%)	1/40 (3%)
Targetable oncogenes with approved agents	**N = 7**	**N = 40**
MET amplification (MET/CEP7 ≥ 3)	2/22 (10%; tissue only)	2/22 (10%; tissue only)
EML4-ALK fusion	0/7 (0%)	1/40 (3%)
BRAF V600E	0/7 (0%)	1/40 (3%)
Potentially targetable mutations	**N = 7**	**N = 40**
Non-BRAF V600E	0/7 (0%)	4/40 (10%)
FGFR 1 / 2	0/7 (0%)	4/40 (10%)
PDGFRA	0/7 (0%)	2/40 (5%)
KRAS	0/7 (0%)	2/40 (5%)
GNAS	0/7 (0%)	3/40 (8%)
PIK3CA	0/7 (0%)	2/40 (5%)
BRCA 1 / 2	0/7 (0%)	3/40 (8%)
Post-progression therapies	**N = 10**	**N = 54**
Chemotherapy with osimertinib	2/10 (20%)	9/54 (16%)
Chemotherapy without osimertinib	0/10 (0%)	8/54 (15%)
Immunotherapy alone	0/10 (0%)	2/54 (4%)
Chemoimmunotherapy with osimertinib	2/10 (20%)	1/54 (2%)
Chemoimmunotherapy without osimertinib	0/10 (0%)	6/54 (11%)
Radiotherapy	3/10 (30%)	9/54 (17%)
Addition of new targeted TKI therapy	0/10 (0%)	5/54 (9%)
Clinical Trial	2/10 (20%)	3/54 (5%)
Other / Hospice	1/10 (10%)	9/54 (16%)

Conclusion: There is utility to repeat biopsy after progression on osimertinib as targetable oncogenes can be found. Presence of *TP53* prior to starting osimertinib did not influence PFS1. Continuing osimertinib and adding radiotherapy for oligoprogressive disease does increase post-progression PFS.

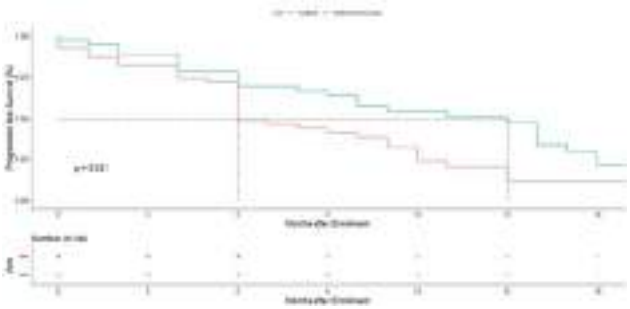
P1.01-88 PS 2 PATIENTS WITH ADVANCED EGFR MUTANT NSCLC: SUBSET ANALYSIS OF A PHASE III RANDOMIZED TRIAL COMPARING GEFITINIB TO GEFITINIB WITH CHEMOTHERAPY

K. Prabhash, V. Noronha, V. Patil, A. Joshi, A. Chougule

Tata Memorial Center, Mumbai/India

Background: Performance status is an important prognostic indicator in lung cancer. Most landmark trials excluded PS 2 patients; however, many patients we see in the clinic are PS 2, hence management of these patients is an extrapolation of the data from trials done in fitter patients. **Method:** We had conducted a Phase III randomized trial in patients with advanced NSCLC harboring *EGFR* sensitizing mutation, ECOG PS 0 to 2 planned for first-line palliative therapy. Performance status was a stratification factor, thus there was an equal proportion of PS 2 patients in the two arms. Randomization was 1:1 to gefitinib 250 mg orally daily (gef) or pemetrexed 500 mg/m^2 and carboplatin AUC 5 IV 3-weekly for 4 cycles, followed by maintenance pemetrexed with gefitinib from day 1 (gef+C). Primary end-point was progression-free survival (PFS); secondary end-points included overall survival (OS), response rate and toxicity. We present the subset analysis of the PS 2 patients in the trial. **Result:** Between 2016 and 2018, 75 PS 2 patients were randomly assigned to gef (n=39) and gef+C (n=36). The median age was 56 years, 63% were females, 23% had brain metastases and 50% had comorbidities. Median follow-up was 20 months (range, 7 to 28). Radiologic response rates were 83% and 67% in gef+C and gef arms respectively, P=0.117. Estimated median PFS was significantly longer with gef+C than gef [15 months, (95% CI, 10.6 to 19.4) versus 6 months (95% CI, 4.3 to 7.7); hazard ratio for disease progression or death, 0.57; 95% CI, 0.33 to 0.98; P=0.031] (Fig 2). Data for OS are immature. Clinically relevant ≥ grade 3 toxicities occurred in 58% and 28% of patients in gef+C and gef arms respectively, P=0.008.



Conclusion: In *EGFR* mutant PS 2 patients, combining pemetrexed and carboplatin chemotherapy with gefitinib led to a significant PFS prolongation, with an increase in clinically relevant severe toxicities. PS 2 patients with driver mutations appear to benefit from treatment intensification.

Background: First and second-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are largely ineffective against EGFR exon 20 insertion mutations (ins20) and, while several novel agents targeting EGFR ins20 are in development (poziotinib, TAK-788), preliminary reports suggest that EGFR-related adverse events are common and may limit long-term efficacy (Heymach, WCLC 2018, Neal WCLC 2018). Targeted therapies which are safe and effective in patients with EGFR ins20 are needed. CLN-081 (also known as TAS-6417) is a novel, orally available EGFR TKI that selectively inhibits ins20 mutant EGFRs (Mol Cancer Ther 2018; 17:1648). In a cell-based assay using genetically engineered cell lines, CLN-081 potently inhibited intracellular phosphorylation of a wide spectrum of ins20 mutant EGFRs. The selectivity for mutant over wild type EGFR (WT/mut ratio) ranged from 4 to 134-fold depending on the specific mutation, representing an unprecedented level of mutant specificity. **Method:** This is an adaptive phase 1/2a trial evaluating CLN-081 as monotherapy in advanced non-small cell lung cancer (NSCLC) harboring EGFR ins20. Dose escalation will proceed initially according to an accelerated titration (AT) design, converting to a rolling six (R6) design based upon pre-specified safety criteria. Cohort expansion in Phase 1 can occur at one or more doses where responses are observed in R6 cohorts. Transition from Phase 1 into Phase 2a is based upon a Simon-Two Stage design. The starting dose will be 60mg. Once daily and twice daily dosing will be explored. Approximately 90 patients will be enrolled. Eligible patients will have advanced, exon 20 insertion mutation positive NSCLC, and at least one prior platinum containing treatment regimen. EGFR ins20 will be identified based on local testing (tissue or plasma). Patients who have discontinued a previous EGFR TKI due to progressive disease will be allowed in AT dose escalation cohorts but will be excluded from R6, and the Phase 1 and 2a expansion cohorts. The primary objectives in Phase 1 are to demonstrate safety and determine the maximum tolerated dose. Secondary Phase 1 objectives include evaluation of PK and preliminary efficacy. The primary objectives in Phase 2a are to define the recommended phase 2 dose and evaluate the overall response rate. The secondary Phase 2a objectives include additional measures of response and confirmation of CLN-081's safety profile. **Result:** Section not applicable **Conclusion:** Section not applicable

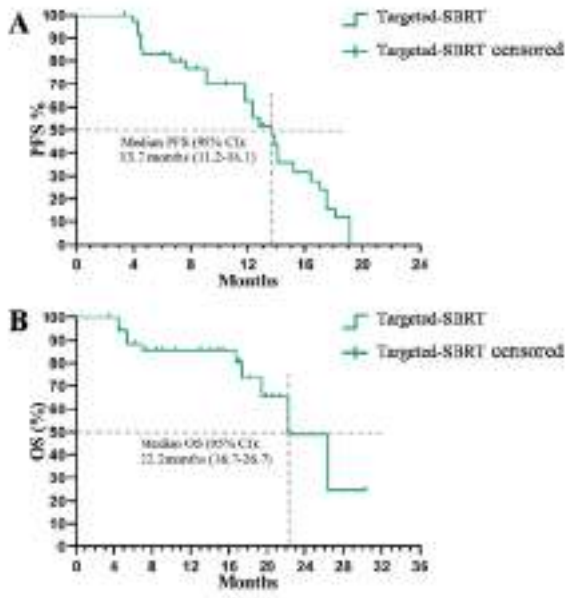
P1.01-90 UPDATE PHASE II RESULTS OF EARLY PRIMARY TUMOR STEREOTACTIC BODY RADIOTHERAPY COMBINED WITH FIRST-LINE EGFR-TKI IN ADVANCED EGFR MUTATED NSCLC

D. Lv[1], H. Xu[1], Y. Meng[2], W. Wang[2], X. Wu[1], F.-M. Kong[2], H. Yang[2]

[1]*Affiliated Taizhou Hospital at Enze of Wenzhou Medical University, Taizhou/China,* [2]*Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China*

Background: Our previous work (ChiCTR-OIN-17013920) has reported the efficacy and safety of early primary tumor stereotactic body radiotherapy (SBRT) combined with Icotinb in advanced EGFR mutated (EGFRm) NSCLC patients (2018 IASLC WCLC Abstract #11985). Hani Ai-halabi et al. reported that about 80% of EGFR TKI drug resistance was at the primary site. Here we report the updated results. **Method:** Patients with pathologically confirmed advanced NSCLC with 19/21 EGFRm were enrolled between September 2016 and March 2019. SBRT was performed during the first month of oral first-line EGFR-TKI (Icotinib 125mg three times daily or Gefitinib 250mg once daily) in patients who were assessed as partial response or stable disease according to RECISE v1.1 assessment. The primary tumor was given SBRT at dose of 50Gy/5F or 60Gy/8F for peripheral and central primary, respectively. The primary endpoints were progression free survival] (PFS) and pattern of failure, while the second endpoints were overall survival time (OS) and adverse events (AEs). **Result:** 36 patients were recruited in this study. The follow-up time was 14.5 months (range 3.4-30.4). Median age was 66 years (range 49-83). There were 20 males and 16 females. Eighteen patients with 19-del mutation and 18 had L858R mutation. Overall, median PFS and median OS was 14.1 months and 26.3 months (Figure 1), respectively. Three patients had progression at the primary site, 5 patients had mixed progression and 19 patients with distant progression only. In subgroup analysis, the median PFS was 14.1 months vs. 12.8 months in 19-del vs. L858R mutation patients. The median OS was 19.4 months in L858R mutation group while that in 19-del mutation was immature. Additionally, there was no ≥grade 3 AEs in patients treated with this regimen.



Conclusion: This study suggested that early primary tumor SBRT may play a role to delay resistance of first-line EGFR-TKI in advanced EGFRm NSCLC patients. Patients with 19-del mutation may gain a better survival time compared with L858R mutation. The promising results are to be validated in a multi-center, comparable randomized phase III clinical trial (Target-SBRT, NCT03727867).

P1.01-91 CLINICAL OUTCOMES OF VARIOUS RESISTANCE MECHANISMS OF OSIMERTINIB IN CHINESE ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

P. Xing[1], Y. Mu[1], S. Wang[1], D. Ma[1], J. Lin[2], H. Liu[2], H. Han-Zhang[2], A. Lizaso[2], J. Xiang[2], X. Mao[2], X. Hao[1], J. Li[1]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: Increasing efforts have been invested in elucidating the resistance mechanisms to osimertinib. Major resistance mechanisms include but not limited to acquired *EGFR* mutations, predominantly C797, mutations in bypass pathways and small cell lung cancer (SCLC) transformation. However, no study has comprehensively investigated clinical outcomes of various mechanisms of resistance. **Method:** 103 T790M positive advanced Chinese non-small cell lung cancer (NSCLC) patients who progressed on 1st generation EGFR-TKI were enrolled. Targeted sequencing, using a panel consisting of 168 lung cancer related genes, was performed on paired plasma samples collected prior to osimertinib and after the development of disease progression (PD) to profile mutation spectrum. 7 patients with no mutation detected at PD were excluded from analyses. **Result:** Major acquired mutations included 25% *EGFR* mutations, predominantly C797 and L792, 16% *MET* amplification, 8% *TP53* mutations, 4% *KRAS* mutations, 4% *RET* fusions, 4% *ERBB2* amplification and 6.25% RB1 mutations. Acquired *RB1* mutation may indicate the possibility of SCLC transformation. Approximately, 30% of patients with no known resistance mechanisms at PD. In this cohort, we had 61 patients with 19 deletion and 35 patients with EGFR L858R prior to the initiation of osimertinib. We revealed patients with 19del acquired more mutations (p=0.014) and were more likely to acquire mutations in MAP/PI3Kpathway (p=0.04) and *TP53* at PD (p=0.021). On the other hand, acquired *ERBB2* amplifications were only detected in L858R-mutant patients (p=0.047). Furthermore, 36 patients preserved T790M and 60 patients lost T790M at PD. Our data revealed patients retaining T790M, often associated with activation of bypass signaling pathways or continued *EGFR* activation through tertiary mutations, had a longer progression-free survival (PFS) (p=0.047) and overall survival (OS) (p=0.04) comparing to patients with T790M loss, often with diverse and *EGFR*-independent mechanisms. We also show that patients with acquired C797S had significantly longer PFS (p=0.031), while patients with acquired *MET* amplifications had significantly shorter PFS (p=0.033). **Conclusion:** Collectively, we revealed differential clinical outcomes associated with various resistance mechanisms, representing an important step in advancing the understanding of resistance mechanisms of osimertinib.

P1.01-92 UNDERLYING MECHANISMS THAT POTENTIALLY AFFECT PROGNOSIS TO EGFR-TKI IN EGFR-POSITIVE PATIENTS WITH NON-SMALL CELL LUNG CANCER

Y. Cheng[1], L. Ma[1], Y. Liu[1], Y. Xin[1], Y. Chen[1], J. Zhu[1], L. Zhang[1], C. Yang[1], C. Wu[1], T. Zhang[1], S. Wang[1], Z. Li[1], L. Bai[1], X. Mao[2], T. Zhang[2], J. Lin[2], L. Shi[2]

[1]*Jilin Cancer Hospital, Changchun/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: Conventional detection methods cannot fully reflect the overall landscape of tumor, which misguide the use of targeted drugs and lead to poor prognosis. Here, based on the results of genomic profiling obtained by NGS, we interrogate the underlying mechanism of differential response to EGFR-TKI in *EGFR*-positive patients with lung cancer. **Method:** 207 patients with advanced non-small cell lung cancer (NSCLC) carrying *EGFR*_L858 or 19del (identified by conventional methods) from 7 clinical trials (such as FLAURA, CTONG1405 and CTONG1509) were enrolled. 457 plasma (n=335) or tissue (n=122) samples from baseline and follow-up points of the cohort were profiled using 168-/520-cancer-related gene panels. Molecular characteristics in patients with rapid progression (PFS<3 months, n=10) and durable response (PFS>24 months, n=6) to EGFR-TKI treatment were analyzed. **Result:** The accuracy of NGS and conventional methods for identifying *EGFR* driver mutations in tissue samples was 97.1%, and that of driver mutation detection in plasma and tissue samples was 81.9%. Using NGS, several alterations at baseline that may potentially affect prognosis were identified, in addition to *EGFR* oncogenic mutations revealed by traditional methods. Ten patients progressed rapidly on EGFR-TKI therapy (no response, n=4; stable disease, SD, n=2; partial response, PR, n=4). Of the 4 patients who did not respond to EGFR-TKI, *ALK* fusion, *NTRK* fusion, *MET* amplification (*METamp*) and *EGFR*_E709A were identified at baseline using NGS. Of the 2 patients received SD, NGS revealed that one case carried mutations in *TP53*, *PMS2*, *PALB2* and *ARID1A*, while another case carried *TP53*_R213* and *ERBB2amp*. As to the 4 patients achieved PR, NGS results showed that one patient carried *TP53*_R342* and *EGFR*_L62R; one patient with *CDK4amp* and *RET* pathogenic mutation; one patient had *TP53*_V216L, *CDK4amp*, *ERBB2amp* and *EGFRamp*; and another patient harbored *CDK4amp*. In contrast, of the 6 patients achieved durable response to EGFR-TKI, NGS revealed that 4 patients did not carry any alteration or well-established factor associated with poor prognosis other than *EGFR* driver mutations. The other 2 patients with *TP53* mutation and *EGFRamp* received combination treatment of EGFR TKI and chemotherapy. **Conclusion:** NGS had good consistency with conventional methods in identifying *EGFR*-driver mutation. Compared with traditional methods, NGS can represent more comprehensive landscape of tumor and provide more reliable guidance for treatment. For patients with *EGFR*-driver mutations along with tumor suppressor or oncogene mutations, combination therapy of TKI and chemotherapy might be a better option than TKI alone. In addition, we revealed that *EGFR*_E709A and *EGFR*_L62R may be potential resistance mechanisms of EGFR TKI.

Background: ALK gene rearrangements are detected in 3-7% of Non-Small-Cell-Lung-Cancer (NSCLC) p. EML4-ALK translocation was first identified as an oncogene in NSCLC p in 2007. To date, published real-world data on the prognostic factors of patients with ALK-positive advanced NSCLC in Spain are limited. We aim to evaluate the effect of number of metastases (M1) organs on overall survival (OS) in a multicenter cohort of Spanish ALK-positive NSCLC p diagnosed between 2008 and 2017. **Method:** We included p with stage IV at diagnosis since 2011 to April 2018. OS (months [m]) was estimated with the Kaplan-Meier method. Survival curves were compared between groups of p using the log-rank test. Hazard risk (HR) to death was estimated with multivariable Cox model, adjusted by site of metastases, gender, age and first line type of treatment. **Result:** Out of the 163 p in the cohort a total of 98 p were included, with a median follow-up of 28.6 m and 45 deaths reported. Characteristics at diagnosis were median age 58 years, female 46.9%, never-smokers 59.2%, 50% with comorbidities, PS by ECOG 0-1 93%, 58.2% lung M1, 45.9% central nervous system M1, 42.9% bone M1, 22.4% liver M1 and 29.6% pleural M1. 54.3% p and 89.4% p were treated with ALK inhibitors as first line and second line respectively. The median OS was 34.4 months, being 46.9 months in p treated with ALK inhibitors and 38.8 months in p treated with chemotherapy as first line (p= 0.9). There were 72 p who presented M1 in more than one organ and 26 p in a single organ. The risk of death increased with greater number of organs involved at diagnosis (HR= 3.0, p=.016), and presenting liver M1 at diagnosis (HR=2.2, p=.046, with OS of 19.1 m), compared to p single site involvement (OS: 45.4 m). **Conclusion:** OS was worse with increased metastatic sites involved at diagnosis in p with ALK positive NSCLC, being liver M1 associated with the highest risk of mortality. Brain metastases at diagnosis were not a prognostic factor for OS in our series.

Background: JNJ-61186372 (JNJ-372), a bispecific antibody that targets the EGFR and cMet receptors, is currently being explored in a first-in-human study in patients with non-small cell lung cancer (NSCLC). Preliminary JNJ-372 clinical data have suggested activity in patients with diverse EGFR mutations, including Exon 20 insertions (Exon20ins), which carry primary resistance to tyrosine kinase inhibitors (TKIs; Cho BC et al. *Ann Oncol* 2018;29(suppl_8):mdy292.118). To better understand the mechanism of JNJ-372 activity in this patient population, we conducted preclinical studies exploring the activity of JNJ-372 in different EGFR Exon20ins models. **Method:** BaF3 cells were transduced with retrovirus expressing various EGFR Exon20ins, as described. Cell titer glo assays were used to measure cell proliferation; western blot analysis was used to study EGFR and cMet signaling cascade events. For mouse tumor models, JNJ-372 was administered i.p. daily at 10mg/kg or 30mg/kg. Referenced patients with Exon20ins disease were administered 1050mg JNJ-372 i.v. weekly for the first 4-week cycle, then biweekly for each subsequent cycle (Park et al. *J Thorac Oncol* 2018;13:S344-5). **Result:** In a dose-dependent manner, JNJ-372 inhibited the growth of BaF3 cells harboring diverse Exon20ins mutations. Mechanistic assays revealed down-modulation of EGFR and cMet receptor levels and decreases in phospho-EGFR and cMet, as well as inhibition of downstream signaling events including p-ERK, p-Akt and p-S6. Cleaved caspase-3 and BIM_{EL} were upregulated at antiproliferative doses, suggesting caspase-mediated cell death as part of the mechanism of action. JNJ-372 demonstrated corresponding antitumor activity in PDC and PDX models harboring different Exon20ins mutations with concomitant inhibition of EGFR signaling and induction of apoptosis. In the ongoing first-in-human trial, two patients with Exon20ins disease (P772_H773insPNP and H773delinsNPY) continue to demonstrate durable clinical benefit (13 and 22 cycles), with maximum tumor reductions of –23% and –63%, respectively, as demonstrated by baseline and postbaseline CT scans. **Conclusion:** In EGFR Exon20ins disease, JNJ-372 demonstrates preclinical antitumor activity and initial clinical responses. Preclinically, JNJ-372 induces antitumor activity in models of EGFR Exon20ins disease by decreasing EGFR and cMet receptor levels, inhibiting downstream signaling cascades, and activating apoptotic signaling. These results provide an understanding of the activity of JNJ-372 being observed in the ongoing clinical study and support the continued examination of JNJ-372 in NSCLC patients with Exon20ins and other EGFR mutations.

Keywords: Exon 20 insertion, EGFR, cMet

P1.01-95 EFFICACY AND SAFETY OF ANLOTINIB IN COMBINATION WITH CHEMOTHERAPY AS FIRST-LINE THERAPY IN ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS

B. Han, T. Chu, X. Zhang, H. Zhong, B. Zhang, H. Wang, A. Gu, W. Zhang, C. Shi, R. Zhong

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Anlotinib (AL3818) is a novel multi-target angioenesis TKI targeting the VEGFR, FGFR, PDGFR and c-Kit. In the ALTER0303 trial, Anlotinib as third-line treatment significantly improved progress-free survival (PFS) and overall survival (OS) in advanced NSCLC patients. This is the first trial evaluating the combination of chemotherapy and anlotinib in treatment-naive advanced NSCLC and is one arm of Phase II anlotinib-based trial (NCT03628521). **Method:** Patients with previously untreated EGFR/ALK/ROS1 negative advanced NSCLC were enrolled. Eligible patients received anlotinib (12 mg QD from day 1 to 14 of a 21-day cycle) combined with carboplatin (AUC 5) and pemetrexed (adenocarcinoma, 500mg/m^2)/gemcitabine (squamous, 1.0g/m^2,day1&8) for four to six cycles (21-day cycle). Maintenance treatment was followed by using pemetrexed and anlotinib (anlotinib alone for squamous) until disease progression or treatment intolerance. The primary outcome was objective response (ORR) and secondary outcomes were PFS, disease control rate (DCR) and OS. **Result:** Until the 21st March 2019, the curative effect was assessed in 30 enrolled patients according to the RECIST 1.1. Among these patients, eighteen of them achieved PR (all confirmed), eleven of them achieved SD and only one patient developed to disease progression. The objective response rate was 60.0 % while the disease control rate was 96.7 %. The most common Grade 3 adverse events were decreased platelet count (20 %), hypertriglyceridemia (10 %) and oral mucositis (6.67 %). 3 patients showed Grade 4 decrease of platelet count (10 %), and both of them belong to the gemcitabine group. **Conclusion:** The combination of anlotinib and chemotherapy showed the potential effect and a manageable safety profile in patients with previously untreated EGFR/ALK/ROS1 negative advanced NSCLC. Table 1: Response rates

Response	Assessed
CR	0
PR	18/30(60.0%)
SD	11/30(36.7%)
PD	1/30 (3.3%)
ORR, n/N(%)	18/30 (60.0%)
DCR, n/N(%)	29/30 (96.7%)

Keywords: combination of chemotherapy and anlotinib, NSCLC, first-line therapy

P1.01-96 US REAL-WORLD MANAGEMENT OF EGFR-MUTATED ADVANCED NSCLC: SURVIVAL AFTER FIRST-LINE EGFR-TYROSINE KINASE INHIBITOR TREATMENT

J. Nieva[1], K. Reckamp[2], A. Taylor[3], B. Thakrar[3], J. Wong[4], D. Potter[3], N. Bakker[3], W. Rubinstein[5], P. Sun[3]

[1]*University of Southern California, Los Angeles/United States of America,* [2]*City of Hope Comprehensive Cancer Center, Duarte/United States of America,* [3]*AstraZeneca, Cambridge/United Kingdom,* [4]*AstraZeneca, Gaithersburg/United States of America,* [5]*CancerLinQ LLC, American Society of Clinical Oncology, Alexandria/United States of America*

Background: Outside of the clinical trial setting there are limited data defining clinical outcomes in patients with EGFR mutation-positive (EGFRm) advanced NSCLC treated with first-line EGFR-tyrosine kinase inhibitors (TKIs). To understand the impact of clinical features on outcomes to first-line EGFR-TKI treatment, we investigated overall survival (OS) across a range of variables obtained from real-world clinical practice in the US using the CancerLinQ database. **Method:** We utilised the American Society of Clinical Oncology CancerLinQ Discovery® database to characterise a cohort of patients with EGFRm advanced NSCLC receiving first-line EGFR-TKIs. CancerLinQ Discovery includes de-identified, demographically, and geographically diverse, longitudinal data. Data were obtained from a network of US cancer centres and community oncology practices participating in CancerLinQ. Patient-level data were derived from electronic health records or underlying data warehouses as structured data, and augmented through technology-assisted human curation of unstructured notes and scanned documents, and include diagnosis, anatomic pathology, imaging, surgery, medications, radiotherapy, molecular pathology, etc. OS was assessed as the duration between the start date of first-line treatment and last follow-up. **Result:** We identified 426 patients with EGFRm advanced NSCLC who had received first-line EGFR-TKI treatment between 2011–2017. Median (interquartile range [IQR]) age at diagnosis was 65.0 years (55.0–75.0); 240 (56%) patients were female; 378 (89%) adenocarcinoma histology; 165 (39%) former/current smoking status. Median (IQR) time between diagnosis of advanced staging and first-line EGFR-TKI treatment was 31.0 days (18.0–57.8). First-line treatments received were erlotinib (n=376, 88%), afatinib (n=48, 11%), and gefitinib (n=2, 0.5%). Median (IQR) duration on first-line treatment was 7.8 months (2.7–14.3). Overall OS was 25 months (95% confidence interval: 21–29). Further OS data are summarised in the table. **Conclusion:** OS for patients with EGFRm advanced NSCLC receiving first-line EGFR-TKIs in US clinical practice is in line with expectations based on clinical trials of first- and second-generation EGFR-TKIs

	n	Events	Median overall survival (95% CI), months
All patients with EGFRm advanced NSCLC	426	228	25 (21, 29)
EGFR mutation type			
Exon 19 deletion/L858R	200	106	28 (25, 33)
Other mutations/mutation not reported	226	122	20 (17, 27)
Brain metastases present before or after first-line treatment	304	137	30 (17, 26)
No brain metastases reported	122	91	30 (16, 41)
ECOG performance status*			
0/1	186	99	24 (20, 30)
≥2	53	25	17 (13, NA/A)
Unknown or missing	187	104	27 (22, 31)
Age group at diagnosis of advanced NSCLC			
18–64 years	211	117	25 (21, 36)
65–74 years	99	48	31 (21, 58)
75+ years	116	63	24 (16, 30)

*ECOG performance measure at initial diagnosis of advanced NSCLC or as the first measurement after diagnosis.
CI, confidence interval; ECOG, Eastern Cooperative Oncology Group; EGFRm, epidermal growth factor receptor mutation-positive; N/A, not applicable.

P1.01-97 MODIFIED RANO-LM CRITERIA TO EVALUATE THE RADIOLOGICAL RESPONSE OF OSIMERTINIB IN EGFR T790M POSITIVE NSCLC WITH LEPTOMENINGEAL METASTASES

M. Seong[1], S. Park[1], H.A. Jung[2], J.-M. Sun[2], S.-H. Lee[2], J.S. Ahn[2], K. Park[2], S.T. Kim[1], M.-J. Ahn[2]

[1]*Department of Radiology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Korea, Seoul/Korea, Republic of,* [2]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of*

Background: There is no standardized method in tracking the clinical response of leptomeningeal (LM) disease. Based on the recently proposed RANO criteria for LM, we made a further modification which could apply to the clinical trials and real clinical setting. In this study, the feasibility of modified RANO-LM criteria is tested in the exploratory dataset from our prospective clinical trials conducted in EGFR T790M positive non-small cell lung cancer patients with LM (NCT0325712). **Method:** Based on the previous RANO-LM criteria, up to five leptomeningeal nodules, leptomeningeal enhancement and cranial nerve (CN) enhancement from the baseline was recorded and then changes were scored between -3 to 3 at each post-baseline time point of brain MRI imaging using modified RANO-LM criteria. According to the pre-defined scoring system (figure), all LM lesions were categorized as complete response (CR), partial response (PR), stable disease (SD), or progressive disease (PD). Presence of hydrocephalus or parenchymal lesion is seperately assessed as non-LM lesion

Modified RANO criteria scoring system

	Baseline	1st MRI		2nd MRI	3rd MRI
Leptomeningeal (LM) lesion	Presence or absent (1 or 0)	Presence or absent (1 or 0)	Changes compared to baseline (-3 to 3)		
Nodules (subarachnoid or ventricular, up to five lesions)					
Leptomeningeal enhancement					
Cranial nerve enhancement					
Sum of score					
LM response* (CR/PR/SD/PD)					
Non-leptomeningeal lesion	Presence or absent (1 or 0)	Presence or absent (1 or 0)	Changes comment		
Hydrocephalus					
Parenchymal (brain metastases)					
Non-LM response¶ (CR/PR/SD/PD)					
Overall response					

*LM response based on sum of score:
if only 1 LM lesion is observed (ex. Cranial nerve enhancement only), +3 (CR), +2 (PR), +1 (SD)
if 2 LM lesions are observed (ex. Leptomeningeal enhancement, cranial nerve enhancement), +6 (CR), +4 to +5 (PR), +1 to +3 (SD)
if 3 LM lesions are observed, +9(CR), +8 to +5 (PR), +4 to -2 (SD)
PD is assessed if -2 or -3 score change is observed in any lesion or sum of score is below -3.

¶ Non-LM response based on the following:

PD if any new lesion (hydrocephalus or parenchymal metastasis) develops. CR if all lesions disappear.
Parenchymal metastasis is assessed as nodule (up to five lesions) – PD: increase by >25% in the summed product of orthogonal diameters.
PR: decreases by >50% in the summed product of orthogonal diameters.
If hydrocephalus persists, SD regardless of the volume.

Result: Response of osimertinib in LM was evaluated in 34 patients. Baseline MRI identified LM enhancement in 67.6% (n=23), CN enhancement in 55.9% (n=19), hydrocephalus in 35.3% (n=12) and parenchymal metastases in 79.4% (n=27) but no nodular lesion (n=0). LM specific overall response rate was 63.9% by showing CR (n=10, 29.4%), PR (n=13, 38.3%), SD (n=8, 23.5%), PD (n=1, 2.9%) in evaluable patients. Eight patients showed treatment resistance by showing disease aggravation in LM lesion (n=2), non-LM lesion (n=5) and both (n=1). **Conclusion:** Modified RANO-LM criteria seems to be effective in evaluating treatment response and disease progression in patients with LM. Despite the complexity of the scoring system, modified RANO-LM criteria is a feasible method to evaluate LM status which could be applicable both to the clinical trials and to daily clinical practice. Further validation in independent patient cohort will be performed.

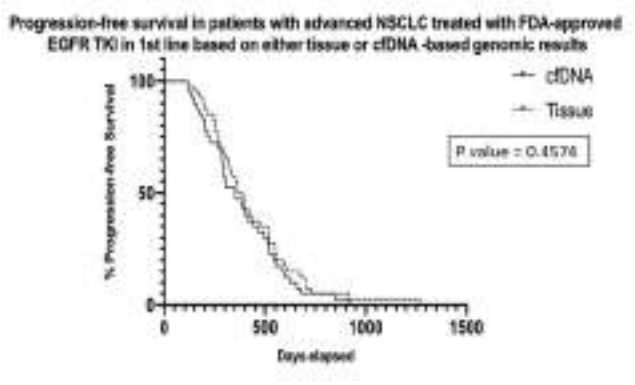
P1.01-98 OUTCOMES IN ADVANCED NSCLC PATIENTS TREATED WITH 1ST LINE EGFR-TKI BASED ON MUTATION DETECTION FROM TISSUE OR CFDNA-BASED GENOMIC SEQUENCING

H. Tran[1], V. Lam[1], M. Vasquez[1], L. Hong[1], R. Colen[1], N. Elshafeey[1], I. Hassan[1], V. Papadimitrakopoulou[1], G. Blumenschein Jr[1], B. Carter[1], G. Simon[1], R. Lanman[2], V. Raymond[2], Y. Elamin[1], M. Altan[1], A. Tsao[1], D. Gibbons[1], J. Zhang[1], J. Heymach[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Guardant Health, Redwood City/United States of America*

Background: Tumor genomic information from tissue has been the standard of practice for identifying actionable molecular alterations. The same genomic profiling is also widely available by a non-invasive blood test (cfDNA). We hypothesized that treatment naïve patients with advanced non-small cell lung cancer (NSCLC) and actionable oncogenic driver mutations identified by tumor and cfDNA would have similar clinical outcomes after treatment with targeted therapies. **Method:** Patients with any EGFR-TKI sensitive mutation and received FDA-approved EGFR-TKI as first line therapy for their advanced NSCLC were included in this retrospective analysis. Consecutive patients were identified from our GEMINI database with therapy initiated that was based solely from either the tissue or cfDNA report were divided into each cohort, respectively. Assessment of PFS was from date of therapy initiation until disease progression. Tissue genomic profiling was performed on our institution's CLIA-certified hotspot NGS assay covering 40-50 genes. For blood based genomic profiling, blood was sent for NGS of cfDNA with a panel of up to 70 cancer-related genes at a CLIA-certified lab (Guardant360, Guardant Health, Redwood City, CA). Kaplan–Meier methodology was used to calculate median PFS with Log-rank (Mantel-Cox) test assessment at significance level 5%. **Result:** Forty patients for each group were identified between 2014-2016. The results as summarized in table and PFS graph below:

	Tissue (n=40)	cfDNA (n=40)
Gender (Female/Male)	22/18	23/17
Age (median, range)	63(42-81)	57(30-83)
EGFR mutations:		
Exon 19 del	21	20
L858R	18	16
others	1(G719A)	4(L718Q, L861Q x 2, S768I)
PFS (median, range)	379 days (118-1266)	352 days (115-919)
Log-rank (Mantel-Cox) test	P value	0.4196



Conclusion: There was no progression-free survival difference in patients treated with FDA-approved front-line EGFR-TKI directed by genomic profiling from tissue vs blood -based testing. These results indicate that similar treatment outcomes with targeted therapy based on tissue or blood-based NGS profiling are both viable options for patient with newly diagnosed, advanced NSCLC.

Keywords: cfDNA, EGFR, advanced NSCLC

P1.01-99 EGFR-WILD TYPE PATIENTS RESPONDING TO TKI: REVISITING PATHOLOGY WITH NEWER TECHNOLOGY

A. Papadakis, G. Kasymjanova, D. Small, C. Pepe, L. Sakr, G. Chong, H. Wang, A. Spatz, J. Agulnik, V. Cohen

Jewish General Hospital, Lady Davis Institute, McGill University, Montreal/ Canada

Background: Molecular testing of lung adenocarcinoma is now considered standard of care and an integral component of the diagnostic algorithm. Technology platforms are rapidly evolving and becoming more sensitive, specific, comprehensively cover clinically relevant actionable mutations and adapted for low input of limiting samples. Targeting EGFR receptors is an important treatment modality in EGFR-mutant patients. However, despite demonstrated benefit in overall survival (OS) and progress free survival (PFS) wild-type patients are deemed to be not suitable for TKIs therapy. Data on long-term responders to TKI among EGFR-wild type patients is limited and requires investigation. Herein, we re-tested samples, which tested negative for EGFR by in-house real-time PCR testing, of patients who responded to TKIs in order to explore the possible indicators of response using FoundationOne NGS assay. **Method:** This is a prospective cohort study of EGFR-wild-type patients by in-house testing (period 2004-2016, real-time PCR) who were light or non-smokers and were treated with TKI (Erlotinib) at the single Academic Centre of the Jewish General Hospital. Erlotinib was given to patients in first- or second-line after failure of systemic chemotherapy. The Formalin Fixed Paraffin Embedded tissue (FFPE) of samples were sent to be analyzed by FoundationOne assay. **Result:** Nineteen samples of patients who were treated with Erlotinib were sent to be tested. 16/19 were treated with TKI for ≥6 mo, 11/16 responded to TKI (defined as staying on treatment over 100 days with median response of over 600 days). Only 2/11 responders received erlotinib in first line, the 9/11 received it after progressing on first-line platinum-based doublets. Sensitizing EGFR mutations were found in 4/11 responders, which can be explained by increased coverage and sensitivity of the NGS platform. Among the remaining 7 patients that were confirmed to be negative by FoundationOne test, one patient had a rearrangement of EGFR (truncation), and two had RBM10 mutations, one an ERBB2 amplification, and 3 had MAP3K1 mutations as well as multiple novel alterations of unknown significance. These alterations may shed light to patient responses and require further exploration. **Conclusion:** The algorithms for molecular testing is based on the specimen pathology and local clinical and laboratory circumstances. There are a multitude of platforms available for somatic mutational and fusion testing and these are rapidly evolving with availability and accessibility of NGS. Comprehensive NGS panels and multidimensional data sets will widen our understanding of genetic dependencies associated with responses and pave the road to new therapeutic avenues.

P1.01-100 EFFECT OF OSIMERTINIB IN NON-SMALL CELL LUNG CANCER PATIENTS WITH BRAIN METASTASES AFTER PROGRESSION FOLLOWING FRONT-LINE EGFR-TKI THERAPY

X. Yu, Y. Fan

Zhejiang Cancer Hospital, Hangzhou/China

Background: Osimertinib has been adopted as the standard of care for T790M-mediated acquired epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) resistance. In this study, we aim to investigate the effect of osimertinib in advanced NSCLC with brain metastases after the failure of first-line therapy. **Method:** We retrospectively studied 43 NSCLC patients with BM received osimertinib after progression following front-line EGFR-TKI therapy from January 2013 to December 2016 at our institution. Overall survival (OS) was measured from the date of brain metastases. **Result:** Among the 43 patients, 25(58.1%) received EGFR-TKIs as first-line therapy, 15(34.9%) were treated with EGFR-TKIs therapy after the progression of chemotherapy, and there're also 3(7.0%) received the combination of EGFR-TKIs and chemotherapy as first-line therapy. 16(37.2%) were EGFR T790M positive, 4(9.3%) were EGFR T790M negative and 23(53.5%) were unknown T790M status. 34(79.1%) patients had received local radiation therapies (RT). The median overall survival (OS), and the median intracranial progression free survival (iPFS) was 32.0 months, 14 months, respectively. Patients with EGFR T790M mutation had the median OS of 24.7 months, these without T790M mutation had the median OS of 17.0 months, and the patients with unknown status of T790M showed the longest OS of 34.4months, although it did not reach statistical significance (*P* =0.727). There was also no difference in iPFS among the T790M-positive group, T790M-negetive group and the unknown status group (5.0 vs. 7.0 vs. 18.0 months, P=0.195). Similar results in OS were found among the first line TKIs group, chemotherapy followed by EGFR-TKI therapy group and the combination of TKIs and chemotherapy group (*P*=0.491). Three patients had leptomeningeal metastasis (LM), showed to have a worse iPFS of 12 months compared to 14 months of these without LM (*P*=0.991). **Conclusion:** Osimertinib had a good efficacy in patients with brain metastasis of advanced non–small-cell lung cancer in whom disease had progressed following front-line EGFR-TKIs.

Keywords: Osimertinib, Brain metastases, epidermal growth factor receptor tyrosine kinase inhibitor

P1.01-101 EFFICACY OF IMMUNE CHECKPOINT INHIBITION IN RET FUSION POSITIVE NON-SMALL CELL LUNG CANCER PATIENTS

A. Sireci[1], D. Morosini[1], S. Rothenberg[2]

[1]*Loxo Oncology, Inc, a wholly owned subsidiary of Eli Lilly, Stamford/United States of America,* [2]*Loxo Oncology, Stamford/United States of America*

Background: Activating RET fusions are oncogenic drivers in 1-2% of non-small cell lung cancer (NSCLC). Ongoing clinical trials indicate that the investigational selective small molecule inhibitor LOXO-292 is efficacious in RET fusion-positive NSCLC patients, with fewer side effects than available anti-RET multikinase inhibitors. While immune checkpoint inhibitors (CPIs) are standard treatment for advanced NSCLC in multiple treatment settings, a growing body of evidence suggests that CPIs are less active in oncogene-driven NSCLC than in driver-negative cancers. We undertook to examine the efficacy of CPIs in a large cohort of RET fusion-positive NSCLC patients **Method:** A retrospective search for NSCLC patients with RET fusions was performed using multiple electronic health record (EHR) databases. Patients with NSCLC harboring a RET fusion

and a history of treatment with a CPI (either as monotherapy or in combination with chemotherapy) were selected. Data extracted from these sources includes: descriptive demographic information such as age and sex, line of therapy in which CPI was administered and time on CPI. **Result:** 106 RET fusions were identified out of over 13,500 total NSCLC patients queried. Of these, over 30 have a history of treatment with a CPI. In this cohort of CPI-treated patients, we will report the time on therapy as the main outcome, which will serve as a surrogate marker for efficacy of CPI in RET fusion NSCLCs. **Conclusion:** While CPIs are generally accepted to be less effective in EGFR-mutant and ALK fusionpositive NSCLC, their efficacy (or lack thereof) is not understood in other oncogenic driver-positive NSCLCs. The aim of this study is to examine the real-world efficacy of CPIs in RET fusion-positive NSCLC patients identified from multiple EHR databases. These results are expected to guide the selection of CPI and TKI therapy for patients with RET fusion-positive NSCLC.

P1.01-102 ACTIONABLE GENE ABERRATION AND THE RESPONSE OF MATCHED THERAPY AMONG PATIENTS WITH NON-SMALL-CELL LUNG CARCINOMA

T. Mizuno[1,2], Y. Fujiwara[1,3], N. Yamamoto[1], K. Sunami[1], T. Kubo[4], T. Ichikawa[4], R. Morita[1], J. Sato[1], Y. Goto[1], H. Horinouchi[1], S. Kanda[1], S. Murakami[1], T. Yoshida[1], Y. Ohe[2], T. Kohno[5]

[1]*National Cancer Center Hospital, Tokyo/Japan,* [2]*The Jikei University Graduate School of Medicine, Tokyo/Japan,* [3]*Mitsui Memorial Hospital, Tokyo/Japan,* [4]*National Cancer Center, Tokyo/Japan,* [5]*National Cancer Center Research Institute, Tokyo/Japan*

Background: Tumor genotyping using multiplex gene panel is now standard for precision medicine in non-small-cell lung carcinoma (NSCLC). We sought to assess the prevalence of actionable genomic alterations among NSCLC patients using our next-generation sequencing panel (NCC Oncopanel) and the response of matched therapy. **Method:** This is a post-hoc analysis of prospective study in which patients with advanced solid cancer were prospectively enrolled to undergo the comprehensive genomic profiling panel (NCC Oncopanel) conducted between July 2013 and March 2018 in National Cancer Center Hospital. The NCC Oncopanel assay, a multiplexed next-generation sequencing (NGS) assay of 114 cancer-associated genes, was performed in a CLIA-compliant laboratory in National Cancer Center. Subjects were primarily patients without any known actionable alteration such as *EGFR* or *ALK*. Patients with NSCLC were extracted into this analysis. Clinical data and treatment outcomes were retrospectively collected. **Result:** In total, 100 patients were extracted. Sufficient tumor tissue for NGS analysis were available in 91 patients; median age was 57 (range 30-77); 74 (81.3%) adenocarcinoma; 44 (48.4%) female; 42 (46.2%) never smoker. According to the OncoKB and CIViC database, and the Clinical Practice Guidelines for NGS in Cancer Diagnosis and Treatment issued by three major Japanese cancer-related societies, 85 patients (93.4%) had at least one potential pathogenic alteration. Actionable gene aberrations were identified in 49 (53.9%). Evidence levels were ranked as follows: 24 (26%) harbored level 1 aberrations (*ALK, EGFR, ROS1, BRAF*); 15 (16%) harbored level 2 (*RET, DDR2, MET, ATM, BRCA2, CDK4, CTNNB1, EZH2, JAK2, NRAS, TSC1*); 10 (11%) harbored level 3A (*CDKN2A, ERBB2, HRAS, PTEN, SMARCA4, STK11*). Matched therapy was administered into 29 (31.9%) leading to the objective response rate of 58.6% and the disease control rate of 79.3% with the median progression-free survival of 10.5 months (95%CI; 5.1-15.8). **Conclusion:** Multiplex gene panel is feasible and useful in screening candidates for matched therapy among NSCLC patients. NSCLC patients without any known actionable mutations should be considered to undergo comprehensive genomic profiling.

P1.01-103 PRELIMINARY RESULTS OF BRIGATINIB IN JAPANESE PATIENTS (PTS) WHO PREVIOUSLY RECEIVED ALECTINIB: BRIGATINIB-2001 STUDY

S. Murakami[1], T. Seto[2], M. Satouchi[3], M. Nishio[4], H. Hayashi[5], Y. Ohe[1], T. Asato[6], P. Zhang[7], K. Nakagawa[5]

[1]*National Cancer Center Hospital, Tokyo/Japan,* [2]*National Hospital Organization Kyushu Cancer Center, Fukuoka/Japan,* [3]*Hyogo Cancer Center, Akashi/Japan,* [4]*The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/Japan,* [5]*Kindai University Faculty of Medicine, Osaka/Japan,* [6]*Takeda Pharmaceutical Company Limited, Osaka/Japan,* [7]*Millennium Pharmaceuticals, Inc., Cambridge, MA, USA, a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge/United States of America*

Background: Brigatinib is a next-generation ALK inhibitor with broad preclinical activity against ALK resistance mutations. To evaluate efficacy and safety of brigatinib in Japanese pts, a single-arm, multicenter, phase 2 study of brigatinib in pts with ALK-positive NSCLC (NCT03410108) in Japan is ongoing, with the primary endpoint of objective response rate (ORR) by independent review. This study has a safety evaluation lead-in phase to confirm the tolerability and pharmacokinetics of brigatinib with a small number of Japanese pts prior to the expansion phase. Here we report the preliminary results from pts in the safety lead-in phase who had been heavily pre-treated with ALK tyrosine kinase inhibitors (TKIs), including alectinib and ceritinib. **Method:** Stage IIIB, IIIC, or IV NSCLC with documented ALK rearrangements were enrolled. Up to 4 ALK TKIs (alectinib, ceritinib, crizotinib and lorlatinib) and 3 lines of prior other systemic anti-cancer treatment were allowed only for the safety evaluation lead-in phase. Brigatinib of 180 mg QD with 90 mg QD lead-in for the first 7 days (90→180mg QD) was administered and efficacy was evaluated every 8 weeks. **Result:** All 9 pts previously received prior alectinib, of whom 6 received 2 or more prior ALK TKIs. The standard dose of 90→180mg QD was well tolerated among Japanese pts. Only 1 dose-limiting toxicity (DLT) was observed: grade 3 lipase increase without clinical evidence of pancreatitis. The most common AEs were increased blood creatine phosphokinase (n=7), increased aspartate aminotransferase (n=6), and hypertension (n=5). By investigator assessment, 5 of 9 pts (56%) had confirmed partial response by the end of cycle 6. Tumor samples from 5 pts were collected prior to the start of brigatinib treatment, and 2 cases had secondary mutation, including one pt with a G1202R mutation who had a confirmed partial response to brigatinib by investigator assessment. Intensive PK sampling data in Japanese pts are comparable with those in non-Japanese pts. **Conclusion:** Standard dose of brigatinib 90→180mg is tolerable in Japanese pts and show promising preliminary anti-tumor activity in the post-alectinib setting.

Keywords: brigatinib, advanced NSCLC, ALK

P1.01-104 SURVIVALS IN ROS1-REARRANGED ADVANCED NON-SMALL-CELL LUNG CANCER TREATED WITH FIRST-LINE CRIZOTINIB

Y.-E. Gao, C. Lu, H.-J. Chen, Z. Wang, B.-C. Wang, X.-C. Zhang, C.-R. Xu, Y.-L. Wu, J.-J. Yang

Guangdong Lung Cancer Institute (GLCI), Guangdong Provincial People's Hospital (GDPH), Guangzhou/China

Background: The c-ros oncogene 1 (*ROS1*)-rearranged non-small-cell lung cancer (NSCLC) can be treated effectively with crizotinib, a tyrosine kinase inhibitor (TKI) of anaplastic lymphoma kinase (ALK), ROS1, and mesenchymal-epithelial transition (MET). However, few studies have investigated on survivals in *ROS1*-rearranged advanced NSCLC patients treated with first-line crizotinib. **Method:** We retrospectively analyzed clinicopathological and survival data of *ROS1*-rearranged patients with advanced NSCLC treated with crizotinib between August 2013 and January 2019 at the Guangdong Provincial People's Hospital. *ROS1* rearrangements were detected by Reverse Transcription-Ploymerase Chain Reaction(RT/PCR),Fluorescence in situhybridization (FISH), or Next-generation Sequencing (NGS) . Overall survival (OS) and progression-free survival (PFS) were compared between first-line crizotinib, chemotherapy followed by crizotinib and first-line chemotherapy without any subsequent targeted therapy. **Result:** Among totally 40 patients with *ROS1*-rearranged advanced NSCLC, 29 were treated with crizotinib (16 with first-line; 13 with second- or further-line), and 11 were not treated with crizotinib at data cutoff (April 4, 2019).

POSTERS

Median OS was significantly prolonged in patients with first-line crizotinib (N=16) than those with first-line chemotherapy followed by subsequent crizotinib (N=9), not reached vs. 27.1 months, *P*=0.042. However, there was no significant difference in median PFS between the two groups, 16.3 vs. 5.7 months, *P*=0.054. Meanwhile, first-line crizotinib (N=16) was significantly superior to first-line chemotherapy without any subsequent targeted therapy (N=8) in both median OS (not reached vs. 9.1 months, *P*=0.024) and PFS (16.3 vs. 4.8 months, *P*=0.017). **Conclusion:** First-line crizotinib prolongs survivals than chemotherapy for patients with *ROS1*-rearranged advanced NSCLC.

P1.01-105 US REAL-WORLD MANAGEMENT OF EGFR-MUTATED ADVANCED NSCLC: PRESCRIBING AND ATTRITION DATA FROM FIRST-TO-SECOND-LINE TREATMENT

K. Reckamp[1], J. Nieva[2], A. Taylor[3], B. Thakrar[3], J. Wong[4], D. Potter[3], N. Bakker[3], W. Rubinstein[5], P. Sun[3]

[1]*City of Hope Comprehensive Cancer Center, Duarte/United States of America,* [2]*University of Southern California, Los Angeles/United States of America,* [3]*AstraZeneca, Cambridge/United Kingdom,* [4]*AstraZeneca, Gaithersburg/United States of America,* [5]*CancerLinQ LLC, American Society of Clinical Oncology, Alexandria/United States of America*

Background: Following first-line epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) therapy for EGFR mutation-positive (EGFRm) advanced NSCLC, not all patients are able to receive second-line treatment. A significant proportion of patients die before second-line treatment, or are only eligible to receive palliative care. To better understand patient attrition, we investigated temporal trends in treatment patterns among first-line EGFR-TKI treated patients in real-world practice in the US. **Method:** We utilised the American Society of Clinical Oncology CancerLinQ Discovery® database to characterise a cohort of patients with EGFRm advanced NSCLC receiving first-line EGFR-TKIs between 2011–2017. CancerLinQ Discovery includes de-identified, demographically, and geographically diverse, longitudinal data. Data were obtained from a network of US cancer centres and community oncology practices participating in CancerLinQ. Patient-level data were derived from electronic health records or underlying data warehouses as structured data, and augmented through technology-assisted human curation of unstructured notes and scanned documents, including diagnosis, anatomic pathology, imaging, surgery, medications, radiotherapy, molecular pathology, etc. Patient data were divided into two cohorts: those who were diagnosed and received first-line treatment pre-2015 versus 2015 onwards. **Result:** We identified 426 patients with advanced EGFRm NSCLC who received first-line EGFR-TKI treatment between 2011–2017. Median (interquartile range [IQR]) age at diagnosis was 65.0 years (55.0–75.0); 240 (56%) patients were female; 378 (89%) adenocarcinoma histology; and 165 (39%) former/current smokers. Median (IQR) time between diagnosis of advanced staging and first-line treatment was 31.0 days (18.0–57.8); median (IQR) first-line treatment duration was 7.8 months (2.7–14.3). The table shows first- and second-line treatments received, and patient attrition data. Osimertinib was the most common second-line treatment in the 2015 onwards cohort. **Conclusion:** These real-world data confirm that approximately 44% of patients with EGFRm advanced NSCLC receive second-line treatment, and nearly one-third of patients die without receiving second-line treatment.

P1.01-106 OSIMERTINIB PLUS PLATINUM/PEMETREXED IN NEWLY-DIAGNOSED ADVANCED EGFRM-POSITIVE NSCLC; THE PHASE 3 FLAURA2 STUDY

P. Jänne[1], D. Planchard[2], P. Howarth[3], A. Todd[3], K. Kobayashi[4]

[1]*Dana-Farber Cancer Institute, Boston/United States of America,* [2]*Institut Gustave Roussy, Villejuif/France,* [3]*AstraZeneca, Cambridge/United Kingdom,* [4]*Saitama Medical University, Hidaka-City/Japan*

Background: Osimertinib is a third-generation, CNS-active EGFR-TKI that potently and selectively inhibits both sensitizing EGFR and T790M mutations. Osimertinib is considered the standard of care for patients with newly-diagnosed advanced/metastatic NSCLC harbouring EGFR-activating mutations, based on results of the phase 3 FLAURA trial, which demonstrated a statistically and clinically significant progression-free survival (PFS) benefit for osimertinib over erlotinib or gefitinib. Evidence indicates that adding chemotherapy to gefitinib improves efficacy outcomes versus EGFR TKI monotherapy in newly-diagnosed patients with EGFRm NSCLC (Nakamura et al JCO 2018;36:9005). Adding platinum/pemetrexed to osimertinib could further improve outcomes for newly-diagnosed patients with EGFRm-positive NSCLC. **Method:** The phase 3, open-label, FLAURA2 study aims to assess the efficacy and safety of osimertinib plus cisplatin/carboplatin plus pemetrexed in adults with locally-advanced/metastatic *EGFR*m-positive (Ex19del and/or L858R) NSCLC who have not received prior therapy for advanced disease. Patients are required to have a WHO performance status (PS) 0-1, life expectancy >12 weeks and not be amenable to curative surgery or radiotherapy. An initial non-randomised run-in phase (n=30) will assess the safety and tolerability of osimertinib 80 mg once daily (QD) with either cisplatin or carboplatin, and pemetrexed, both administered every 3 weeks (Q3W) for 4 cycles, followed by osimertinib 80 mg QD plus pemetrexed maintenance Q3W until progression or discontinuation. Based on evaluation of safety data from the run-in after ≥12 patients from each group have received ≥3 cycles of study treatment or discontinued therapy, the second phase will randomise approximately 556 patients 1:1 to receive osimertinib 80 mg QD with pemetrexed and cisplatin/carboplatin for 4 cycles followed by osimertinib plus pemetrexed maintenance Q3W or osimertinib alone (80 mg QD), to be continued until progression or discontinuation. Randomisation will be stratified by race (Chinese/Asian vs. non-Chinese/Asian vs. non-Asian), WHO PS (0 vs. 1), and tissue EGFR mutation test at enrolment (cobas® EGFR Mutation Test vs local assessment). A futility analysis of the randomized phase is planned for when approximately 83 PFS events have occurred. The primary endpoint is PFS based on investigator assessment of

response using RECIST 1.1 criteria (blinded central assessment is included as a sensitivity analysis). Secondary endpoints include overall survival, objective response rate, duration of response, PFS2, health-related quality of life and safety. Effects on CNS metastases in patients with lesions at baseline will be included as an exploratory endpoint. Enrolment is planned for Q3 2019 for the safety run-in and Q1 2020 for the randomized phase. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: Immune checkpoint–based therapy has revolutionized the care of patients with non–small cell lung cancer (NSCLC). Pembrolizumab-based combination therapy aims to improve clinical outcomes over pembrolizumab monotherapy. Identification of biomarkers associated with improved response to different combination therapies may improve overall outcomes and yield a more precise approach to the use of immunotherapies in NSCLC. To test the clinical usefulness of a biomarker-informed, pembrolizumab-based combination therapy, this phase 2 KEYNOTE-495 trial (NCT03516981) will be carried out in patients with treatment-naive, advanced NSCLC. **Method:** KEYNOTE-495 is a randomized, multicenter, open-label, phase 2 trial. Tumor tissue from patients with treatment-naive, advanced NSCLC will be initially screened for 2 validated, independent, next-generation biomarkers: T cell–inflamed gene expression profile (GEP) and tumor mutational burden (TMB). Based on the results of this biomarker screening, patients will be assigned to 1 of 4 groups: $TMB^{low}GEP^{low}$, $TMB^{high}GEP^{low}$, $TMB^{low}GEP^{high}$, and $TMB^{high}GEP^{high}$. Within each group, patients will be randomly assigned to receive pembrolizumab combined with MK-4280 (anti–LAG-3), lenvatinib, or MK-1308 (anti–CTLA-4). This is a group-sequential, adaptive randomization trial. Patients will be randomly assigned to MK-4280 or lenvatinib first, after which MK-1308 will be introduced; randomization has been modified to accommodate the delayed introduction of MK-1308. Response will be assessed by tumor imaging every 9 weeks for the first year, then every 12 weeks thereafter using RECIST v1.1. Treatment will continue for 35 cycles (~2 years). Patients in the pembrolizumab + lenvatinib arm who complete 35 treatments may continue with lenvatinib monotherapy until disease progression or toxicity. After a patient experiences disease progression or starts new anticancer therapy, the patient will be followed up and contacted every 12 weeks until death, withdrawal of consent, or study end, whichever occurs first. Safety will be monitored throughout the study and for 30 days after treatment or before initiation of a new anticancer treatment, whichever occurs first. Treatment arms may be terminated during the interim analysis because of safety, prespecified futility criteria, or both. The primary end point is investigator-assessed objective response rate (RECIST v1.1). Secondary end points are progression-free survival, overall survival, and safety. Recruitment and screening are ongoing in more than 14 countries and will continue until ~288 patients are randomly assigned across the biomarker-defined groups to determine the optimal treatment for each subgroup. **Result:** Section not applicable **Conclusion:** Section not applicable

P1.01-108 PACIFIC-6: A PHASE II STUDY OF DURVALUMAB FOLLOWING SEQUENTIAL CHEMORADIOTHERAPY IN PATIENTS WITH STAGE III, UNRESECTABLE NSCLC

M. Garassino[1], C. Faivre-Finn[2], J. Mazieres[3], M. Reck[4], U. Emeribe[5], A. Franks[5], N. Trunova[5]

[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/Italy,* [2]*The University of Manchester and The Christie NHS Foundation Trust, Manchester/United Kingdom,* [3]*Institut Universitaire du Cancer de Toulouse, Toulouse/France,* [4]*Lung Clinic Grosshansdorf, Grosshansdorf/Germany,* [5]*AstraZeneca, Gaithersburg/United States of America*

Background: Non-small cell lung cancer (NSCLC) represents 85% of all lung cancers, with ~30% of patients (pts) presenting with Stage III disease. Platinum-based chemoradiotherapy (CRT) has historically been the standard of care (SoC) in this setting, but with poor long-term outcomes. Durvalumab is a selective high-affinity, human IgG1 monoclonal antibody that blocks PD-L1 binding to PD-1 and CD80. The phase III PACIFIC trial assessed durvalumab vs placebo in pts with locally advanced, unresectable, Stage III NSCLC, who did not progress following ≥2 overlapping cycles of platinum-based concurrent CRT (cCRT) (Antonia et al, NEJM 2017; 2018). Significant improvements in progression-free survival (PFS) and overall survival (OS) were observed with durvalumab (HR for PFS, 0.52; 95% CI 0.42–0.65; P<0.001; HR for OS, 0.68; 99.73% CI 0.47–0.997; P=0.0025). This data, along with comparable safety profiles between durvalumab and placebo in PACIFIC, supports the PACIFIC regimen (durvalumab following cCRT) as the new SoC in this setting. However, a proportion of pts are ineligible for cCRT for various reasons, and receive sequential CRT (sCRT) instead. PACIFIC-6 (NCT03693300) will assess the safety, efficacy, and quality of life of durvalumab in NSCLC pts who have not progressed following platinum-based sCRT. **Method:** PACIFIC-6 is a phase II, open-label, multi-centre study to be conducted in 6 countries across Europe and North America. Pts ≥18 years old, with histologically or cytologically documented Stage III, unresectable NSCLC who have not progressed following platinum-based sCRT, and are ECOG PS ≤2 are eligible for inclusion; enrolment is not restricted to a biomarker-defined population. Approximately 150 pts will receive durvalumab (1500 mg intravenously) every 4 weeks for 24 months or until disease progression. Pts will be divided into 2 cohorts according to PS status. Pts will be assessed every 12 weeks, until death, withdrawal of consent, or the end of the study. The primary objective is to assess the safety and tolerability of durvalumab, as defined by grade 3 and 4 treatment-related adverse events (TRAEs) occurring within 6 months from initiation of durvalumab. Secondary objectives include investigator-assessed efficacy measurements such as PFS, overall response rate, duration of response (according to RECIST v1.1), as well as OS, lung-cancer mortality, and further safety assessments of all AEs and serious AEs. Exploratory objectives include assessment of pt-reported symptoms and quality of life, as well as evaluation of the association of tumour-based biomarkers (including PD-L1 expression and tumour mutational burden) with efficacy. Recruitment is ongoing. **Result:** Section not applicable **Conclusion:** Section not applicable

Keywords: durvalumab, NSCLC, sequential chemoradiotherapy

P1.01-109 PHASE II TRIAL OF PEMETREXED/ CARBOPLATIN/BEVACIZUMAB +/- ATEZOLIZUMAB IN NSCLC PATIENTS THAT ARE EGFR MUTATED OR NEVER SMOKED

J.N. Bodor[1], J. Patel[2], E. Ross[1], S. Litwin[1], J. Treat[1]

[1]*Fox Chase Cancer Center, Philadelphia/United States of America,* [2]*University of Chicago, Chicago/United States of America*

Background: Patients with advanced NSCLC who harbor an EGFR mutation or are never smokers do not benefit from single-agent immunotherapy. Retrospective subgroup analyses from recent phase III trials suggest that immunotherapy-chemotherapy +/- VEGF inhibition may overcome the resistance to immunotherapy seen in these patients, though further prospective research is needed and no checkpoint inhibitor to date is approved in the first-line for EGFR patients after TKI failure. This trial will exclusively examine a population of patients with stage IV non-squamous disease who either have an EGFR exon 19 or 21 mutation or are never smoker wild-types to determine whether the PD-L1 inhibitor atezolizumab in combination with pemetrexed/carboplatin and bevacizumab can improve outcomes. **Method:** This is a phase II double-arm, multi-

center, open-label trial to assess pemetrexed/carboplatin and bevacizumab +/- atezolizumab in 117 subjects with stage IV non-squamous NSCLC. Randomization will be 2:1 with twice the number in the + atezolizumab arm, and randomization will be stratified by EGFR mutation status (i.e. EGFR exon 19 or 21 vs. never smoker wild-type) to ensure equal distribution in each arm. Never smoker wild-type is defined as smoking < 100 cigarettes in a lifetime and without any EGFR mutation or ALK or ROS1 rearrangement. Patients with EGFR exon 19 or 21 mutations must have progression or intolerance of treatment with prior TKI therapy. All patients must be chemotherapy, immunotherapy, and VEGF inhibitor therapy naïve. Primary endpoint will be progression-free survival (PFS). Secondary endpoints will include overall survival (OS), overall response rate, duration to response, and time to response. Primary objective is to compare PFS between arms. Secondary objectives include a safety analysis in all treated subjects, and comparisons of PFS and OS between arms for the subset of patients with tumors with EGFR exon 19 or 21 mutations. Correlative studies will include evaluation of biomarkers of the signaling network and tumor microenvironment, and characterizing the potential contribution of estrogen metabolites. Enrollment for this trial will open in August of this year and accrual will continue for 31 months. **Result:** Section not applicable - Trial in progress **Conclusion:** Section not applicable - Trial in progress

Keywords: EGFR mutation, Trial in progress, never smoker

P1.01-110 NOVEL REGIMENS VERSUS STANDARD-OF-CARE IN NSCLC: A PHASE II, RANDOMIZED, OPEN-LABEL, PLATFORM TRIAL USING A MASTER PROTOCOL

D. Spigel[1], M. Garassino[2], B. Besse[3,4], A. Sacher[5], M. Barve[6], S. Cousin[7], M. Schenker[8], D. Rogan[9], S. Yadavilli[10], A. Acusta[10], O. Amit[10], A. Leighton-Swayze[10], M. Ballas[10], A. Hoos[10], M. Reck[11]

[1]*Sarah Cannon Research Institute, Nashville/United States of America,* [2]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milano/Italy,* [3]*Gustave Roussy, Villejuif/France,* [4]*Paris-Sud University, Orsay/France,* [5]*Princess Margaret Cancer Center, Toronto/Canada,* [6]*Texas Oncology-Presbyterian Cancer Center Dallas, Dallas/United States of America,* [7]*Institut Bergonié, Bordeaux/France,* [8]*Centrul de Oncologie "Sf Nectarie", Craiova/Romania,* [9]*GlaxoSmithKline, Research Triangle Park/United States of America,* [10]*GlaxoSmithKline, Collegeville/United States of America,* [11]*Lungen Clinic, Großhansdorf/Germany*

Background: Although non-small cell lung carcinoma (NSCLC) is intrinsically resistant to immunotherapy agents, a subset of tumors are susceptible to T cell-mediated antitumor effects. Treatment regimens combining agents that target different processes within the cancer immunity cycle have the potential to enhance response in relapsed or refractory NSCLC. GSK3359609 is a humanized IgG4 antibody with potent agonist activity against Inducible T cell Costimulator (ICOS) and no or low depleting effect on antibody-dependent cell-mediated cytotoxicity. **Method:** This is a randomized, phase II, open-label, platform trial utilizing a master protocol in patients with advanced NSCLC who have progressed on initial PD1/PDL1-based immunotherapy and platinum-based chemotherapy. The trial will consist of several sub-studies, with each sub-study comparing novel combinations vs. current standard-of-care (SOC). No treatment crossover is allowed. Additional sub-studies may be added over time following protocol amendments. In the first sub-study, patients are centrally randomized by internet to SOC (docetaxel) or novel ICOS drug combination (NIDC) (GSK3359609 + docetaxel) in a 1:2 ratio, stratified by squamous versus non-squamous NSCLC and line of PD1/PDL1; randomization to SOC is minimized thereafter. Primary endpoint is overall survival (OS). Secondary endpoints are survival rate at 12 and 18 months; tumor response according to RECIST 1.1 and iRECIST criteria; pharmacokinetic parameters of the novel immunotherapy; and safety. Exploratory endpoints include tumor and blood-based biomarker evaluations such as tumor mutational burden and gene expression. Interim analysis of OS will be done after approximately 45 deaths in both study groups, with ≥18 deaths in the combination immunotherapy group; final analysis will be done after 85 deaths (35 in combination immunotherapy group). The study will employ a Bayesian decision-making framework based on predictive probability of observing a significant improvement in OS in a future phase III trial. A sample size of ≤70 participants in each combination immunotherapy group and ≥35 participants in the SOC group will provide ≥81% power with a type 1 error of ≤2.3% for each pairwise comparison. Sub-study 1 will compare the efficacy of GSK3359609 plus docetaxel versus docetaxel alone. At least 105 patients are expected to enroll. GSK3359609/docetaxel will be administered for ≤2 years or 35 visits, or until disease progression, death or unacceptable toxicity. Both drugs are given as an IV infusion (docetaxel 75mg/m^2; GSK3359609 80 mg). **Result:** Study enrollment has begun and the primary endpoint results of sub-study 1 are expected mid-2020. **Conclusion:** The study will provide information on the efficacy of novel immunotherapies used in combination. GlaxoSmithKline (NCT03739710).

Background: Brain metastases (BM) are a frequent complication in non-small cell lung cancer (NSCLC), have significant impact on quality of life and are associated with poor prognosis. Systemic therapies might be an alternative approach to whole brain radiotherapy (WBRT) to avoid cognitive-related adverse events. Immune checkpoint inhibitors (ICI) showed intracranial activity in advanced NSCLC patients with BM. However clinical data about efficacy and safety of immune checkpoint inhibitors in combination with chemotherapy in patients with untreated BM are limited and further research in this setting is needed. We hypothesize that addition of ICI to conventional platinum-based chemotherapy may increase intracranial tumor response and provide clinically relevant benefit in terms of PFS, OS and quality of life to the patients with asymptomatic and non-previously treated BM. **Method:** This is an ongoing multicenter, open-label, single-arm phase 2 study (EUDRACT: 2017-005154-11) to evaluate the efficacy and safety of atezolizumab 1200 mg combined with 4-6 cycles of carboplatin AUC 5 and pemetrexed 500mg/m2 every 3 weeks followed by maintenance with atezolizumab 1200 mg plus pemetrexed 500mg/m2 every 3 weeks in stage IV non-squamous NSCLC patients with untreated synchronous BM. Patients should have multiple and measurable BM, adequate performance status and organic function, do not harbor EGFR or ALK genomic alterations, be treatment naïve and do not have any contraindication to receive immunotherapy. Exclusion criteria consist of active neurological symptoms, dexamethasone dose ≥ 4 mg QD, prior treatment with brain radiotherapy, presence of leptomeningeal carcinomatosis, spinal or hemorrhagic metastases in the central nervous system. Primary endpoints are progression-free survival (PFS) at 12 weeks according to RANO-BM and RECIST v1.1 criteria and safety based on CTCAE v4. Both primary endpoints will be assessed in 40 patients in 15 sites using a Bayesian approach. Patients will undergo tumor assessments by body CT scan and brain MRI at baseline every 6 weeks for the first 12 weeks and thereafter tumor assessments will be performed every 9 weeks until disease progression or loss of clinical benefit. Secondary endpoints: intracranial and systemic objective response rate and duration of response. Exploratory endpoints: to assess neurocognitive function and quality of life; to determine time to neurological deterioration and time to need of salvage brain radiotherapy. Enrollment started on August 2018 and currently 12 patients have been included in the study. **Result:** Clinical trial in progress **Conclusion:** Clinical trial in progress

Background: The anti–PD-1 antibody pembrolizumab, as monotherapy or in combination with chemotherapy, is the standard of care for most patients with untreated metastatic non–small-cell lung cancer (NSCLC) with no *EGFR/ALK* aberrations. Lenvatinib is an anti-angiogenic multireceptor tyrosine kinase inhibitor that enhanced the antitumor activity of PD-1 inhibitors *in vitro* and showed clinical activity in combination with pembrolizumab in patients with metastatic NSCLC in a recent open-label, phase 1b/2 study (NCT02501096). LEAP-007 (NCT03829332) further evaluates the safety and efficacy of pembrolizumab plus lenvatinib in patients with metastatic NSCLC. **Method:** This randomized, double-blind, phase 3 trial enrolls previously untreated adult patients with stage IV NSCLC and PD-L1 TPS ≥1% without sensitizing genetic aberrations. Patients are randomized 1:1 to pembrolizumab 200 mg Q3W plus lenvatinib 20 mg daily or pembrolizumab plus matching placebo, stratified by geographic region (East Asia vs other), ECOG PS (0 vs 1), and TPS (1%–49% vs ≥50%). Treatment continues until verified disease progression (PD), unacceptable AE, illness, withdrawal of consent, noncompliance, or administrative reason. Radiographic imaging occurs Q9W from randomization through 54 weeks, then every 12 weeks until confirmed PD or start of a new anticancer regimen, and is assessed by blinded independent central review (BICR) using RECIST v1.1. Primary outcomes are PFS (RECIST v1.1 by BICR) and OS. Secondary outcomes include ORR (RECIST v1.1 by BICR), safety (AEs graded according to NCI CTCAE v4.0), and health-related quality of life. PFS and OS will be analyzed using the Kaplan-Meier method and stratified log-rank test; hazard ratios will be estimated using a stratified Cox regression model. ORR will be analyzed using the stratified Miettinen and Nurminen method, and differences will be estimated using the stratified Miettinen and Nurminen method with strata weighting by sample size. Target enrollment is 620 patients from 165 sites. As of April 5, 2019, 13 patients have been screened. **Result:** Not applicable **Conclusion:** Not applicable

Background: Cabozantinib is an inhibitor of tyrosine kinases involved in tumor growth, angiogenesis, and immune regulation, including MET, VEGFR, RET, ROS1, and TAM family kinases (Tyro3, AXL, MER). Preclinical and clinical studies suggest that cabozantinib promotes an immune-permissive tumor environment, which may enhance response to immune checkpoint inhibitors (ICIs) such as the anti–PD-L1 mAb atezolizumab. Cabozantinib has demonstrated clinical activity in phase 1/2 studies of advanced NSCLC. Atezolizumab is approved for select patients with advanced NSCLC as monotherapy or as part of a combination regimen. Clinical studies in solid tumors, including NSCLC, indicate that the combination of a VEGF-targeting agent with an ICI may reverse ICI resistance.Here we present the study design of an ongoing phase 1b trial of cabozantinib alone or in combination with atezolizumab that includes cohorts with advanced non-squamous (nsq) NSCLC. **Method:** This global, phase 1b, open-label trial (COSMIC-021) is evaluating the safety, tolerability, preliminary efficacy, and pharmacokinetics of cabozantinib alone or in combination with atezolizumab (NCT03170960). The study consists of a dose-escalation stage (completed) and an expansion stage. In the expansion stage, 18 cohorts are being enrolled at the recommended expansion dose of cabozantinib (40 mg po qd) + a standard dose of atezolizumab (1200 mg q3w IV), including 3 advanced NSCLC cohorts: (1) nsqNSCLC with prior ICI therapy, (2) nsqNSCLC without prior systemic anticancer therapy for metastatic disease, and (3) EGFR-mutant nsqNSCLC with prior EGFR-targeting therapy. Thirty patients are being enrolled per cohort, with potential for extended enrollment pending Study Oversight Committee review. Two exploratory single-agent cohorts (N=30) are being enrolled to receive a 60-mg dose of cabozantinib, including a cohort of patients with nsqNSCLC who received prior ICI therapy. Patients will continue treatment as long as they experience clinical benefit per investigator or until unacceptable toxicity. The primary endpoint of the expansion stage is the objective response rate for each cohort. Exploratory objectives include correlation of tumor and plasma biomarkers and immune cell profiles with clinical outcome. **Result:** Section not applicable **Conclusion:** Section not applicable

Keywords: cabozantinib, NSCLC, Atezolizumab

P1.01-114 A PHASE 2 STUDY OF MLN4924 (PEVONEDISTAT) IN COMBINATION WITH CARBOPLATIN AND PACLITAXEL IN ADVANCED NSCLC PREVIOUSLY TREATED WITH IMMUNOTHERAPY

T. Leal[1], J. Lang[1], J. Schehr[1], K. Schneider[1], D. Wheeler[1], J. Malhotra[2], E. Bertino[3], J. Eickhoff[1], A. Traynor[1]

[1]*University of Wisconsin Carbone Cancer Center, Madison/United States of America,* [2]*Rutgers Cancer Institute of New Jersey, New Brunswick/United States of America,* [3]*The Ohio State University, Columbus/United States of America*

Background: Development of combination strategies after development of resistance to front-line immunotherapy is an area of unmet need in advanced NSCLC. One developing novel therapeutic strategy in NSCLC considers the molecular pathway of the ubiquitin (Ub)/proteasome system (UPS) and is a promising therapeutic target being investigated in hematologic and solid malignancies. Up-regulation of the neddylation pathway has been shown in NSCLC. In a study evaluating expression of neural precursor cell expressed, developmentally down-regulated 8 (NEDD8)-activating enzyme (NAE) (E1) and NEDD8-conjugating enzyme (E2) expression and global-protein neddylation, both squamous cell and adenocarcinoma NSCLC tumors consistently demonstrated overactivation of the entire neddylation pathway and higher expression of neddylation pathway was associated with poor overall survival (OS). MLN4924 (pevonedistat) is a first-in-class, small molecule NAE inhibitor. The combination of carboplatin/paclitaxel and MLN4924 (pevonedistat) has been investigated in the phase I setting in multiple solid tumors. Consistent with preclinical studies reporting synergy between MLN4924 (pevonedistat) and platinum-chemotherapy, the objective responses in patients resistant to prior platinum/taxane therapy suggest the potential reversal of resistance by the addition of MLN4924 (pevonedistat). **Method:** This is a phase 2, single arm study of MLN4924 (pevonedistat) 20 mg/m2 (Days 1, 3, 5) + carboplatin AUC 5 (Day 1) and paclitaxel 175 mg/m2 (Day 1) every 21 days for at least 4 cycles in patients with advanced NSCLC. At any time after 4 cycles of the combination, pts may continue with a) carboplatin, paclitaxel, and MLN4924 (pevonedistat), or b) continue carboplatin and MLN4924 (pevonedistat) without paclitaxel, or c) observation. Target accrual: 25 patients. Eligible patients have ECOG PS 0-1, measurable disease per RECIST 1.1, progression on prior checkpoint inhibitor and platinum-doublet chemotherapy, and adequate organ function. The primary endpoint is overall response rate (ORR). Secondary endpoints include progression-free survival, OS and safety. Correlative studies include: to evaluate the NQO1 and SLC7A11 gene expression, changes in the total number of circulating tumor cells (CTCs) and evaluate markers of DNA damage on CTCs, and tumor NAE1 and UBC12 protein expression. **Result:** Clinical Trials in Progress: Section not applicable. **Conclusion:** This study has been approved by the Cancer Therapy Evaluation Program (CTEP)/NCI and will open through the NCI Experimental Therapeutics Clinical Trials Network (ETCTN) in August 2019.

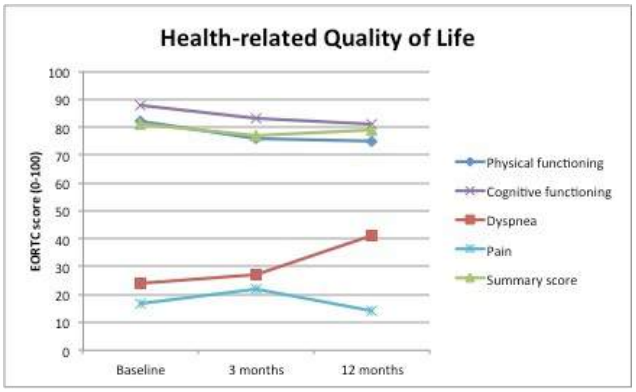
Keyword: NSCLC, MLN4924(Pevonedistat), Carboplatin/paclitaxel

P1.01-115 LONG-TERM EFFECTS OF CONCURRENT CHEMORADIOTHERAPY ON QUALITY OF LIFE IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

I. Walraven[1], E. Veldhuijzen[1], J. Aerts[2], F. Koppe[3], E. Dieleman[4], P. Van De Vaart[5], M. Van Den Heuvel[6], J. Belderbos[1]

[1]*The Netherlands Cancer Institute, Amsterdam/Netherlands,* [2]*Erasmus University Medical Center, Rotterdam/Netherlands,* [3]*Verbeeten Institute, Tilburg/Netherlands,* [4]*Amsterdam UMC, Amsterdam/Netherlands,* [5]*MC Haaglanden, The Hague/Netherlands,* [6]*Radboudumc, Nijmegen/Netherlands*

Background: Concurrent chemoradiotherapy imposes beneficial effects on overall survival (OS) in patients with locally advanced non-small cell lung cancer (NSCLC). Currently, it is unknown what the effects on long-term health-related quality of life (HRQOL) are. Therefore, we investigated long-term HRQOL in locally advanced NSCLC patients treated with concurrent chemoradiotherapy, using an accelerated fractionation scheme of 24 x 2.75 Gy +/- Cetuximab. **Method:** A 2-armed phase II, multi-center study (NTR2230) was performed with the initial aim to assess the effect of additional Cetuximab to concurrent chemoradiotherapy in locally advanced NSCLC patients. Arm A received high dose accelerated radiotherapy (24 x 2.75 Gy) and concurrent daily low-dose cisplatin (6 mg/m^2). Arm B additionally received weekly Cetuximab (400 mg/m^2 one-week pre-treatment followed by weekly 250 mg/m^2). HRQOL was assessed using the EORTC QLQ-C30 at baseline, 3 months post treatment and after 1 year. The primary endpoints included dyspnea, pain, physical functioning, cognitive functioning and the QLQ-C30 summary score. Following the EORTC guidelines, the scores of the endpoints were linearly transformed to 0–100 scales. Higher scores correspond to improved functioning for the functioning scales and for the summary score while for symptom scales (pain and dyspnea), higher scores indicate more symptoms. Linear mixed-modeling was used to assess differences over time. Standardized effect sizes based on the t-test statistic were calculated: (2*t)/(√degrees of freedom). Effect sizes of 0.2 were considered small, 0.5 moderate and clinically relevant, and 0.8 large. **Result:** Between February 2009 and May 2011, 102 patients were randomly allocated in two arms; 51 patients (50%) in arm A and 51 patients (50%) in arm B. Of those, 79 (77%) patients had at least one evaluable questionnaire. Figure 1 shows the development of the HRQOL endpoints over time. Over time, physical functioning (ES 0.48, P-value 0.003), cognitive functioning (ES 0.37, P-value 0.020), dyspnea complaints (ES 0.67, P-value <0.001) and the summary score (ES 0.44, P-value 0.006) significantly worsened. Only pain showed a reversing pattern in which pain was less present at 1 year (ES 0.37, P-value 0.021). No differences between the two arms were found.



Conclusion: In this randomized study of locally advanced NSCLC patients treated with concurrent chemoradiotherapy with or without Cetuximab, a clinically meaningful and long-term decline for all HRQOL endpoints except pain was observed. This analysis suggests that although concurrent chemoradiotherapy improves OS in NSCLC patients, efforts should also be taken to improve long-term HRQOL.

P1.01-116 EARLY IMMUNE-RELATED ADVERSE EVENTS UNDER PD-1/PD-L1 INHIBITORS PREDICT BETTER PROGRESSION-FREE SURVIVAL IN NSCLC

M. Boussageon[1], S. Ortiz-Cuaran[2], S. Chabaud[1], D. Pérol[1], V. Avrillon[1], B. Mastroianni[1], J. Fayette[1], F. Ghiringhelli[3], E.-M. Neidhardt[1], A. Swalduz[1], V. Paulus[1], C. Kaderbhai[3], J.-D. Fumet[3], P. Saintigny[1,2], M. Perol[1]

[1]*Centre Leon Berard, Lyon/France,* [2]*Cancer Research Center of Lyon / Centre Léon Berard, Lyon/France,* [3]*Centre Georges François Leclerc, Dijon/France*

Background: Immune checkpoint blockers (ICB) targeting the PD-1/PD-L1 axis improve survival in patients with advanced non-small-cell lung cancer (NSCLC) without oncogenic addiction; however, they are also responsible for immune-related adverse events (irAE) sometimes leading to treatment discontinuation. Despite a clear association with response to ICB in melanoma, the predictive significance of a better outcome for irAE in NSCLC is unclear. **Method:** We retrospectively collected clinical and basic biological data from 160 stage IV NSCLC patients who received nivolumab, pembrolizumab or atezolizumab as second-line single agent in two cancer centers in France between January 2015 and December 2017. All irAE were collected using the Common Terminology Criteria for Adverse Events v5.0 ; general symptoms (*e.g.* fatigue) and cancer-related symptoms were discarded. We used two different statistical approaches to evaluate whether early irAE (≤ 12 weeks) were correlated to a better progression-free survival: i- a 12-week landmark method, including a multivariate Cox proportional hazards model (with ECOG PS and PD-L1 as covariates), ii- a propensity score matching (PSM) method, using PD-L1 level as the matching variable, followed by a Cox proportional hazards model. Finally, we investigated whether grade and number of early irAE were associated with improved PFS. **Result:** Most patients were male (n=107; 66.3%), smokers (n=146; 91.3%) and ECOG PS 0-1 (n=121; 75.7%) and received ICB as second (n=96; 60%), third line (n=38; 23.8%) or more (n=22; 13.8%). Nivolumab was the most used ICB (n=145; 90.6%). Within the first 12 weeks of treatment, 46 irAE occurred in 30 patients (18.8%), including 3 grade 3 irAE (1 pneumonitis, 1 myocarditis, 1 renal failure). Musculoskeletal (8.8%) and skin toxicity (5%) were the most frequent irAE. Clinical baseline characteristics were comparable between patients displaying early irAE (irAE+) and those who did not (irAE-), except for ECOG status (71.5% of PS 0-1 patients in irAE-group versus 93.3% in irAE+, p = 0.023) and PD-L1 level (PD-L1 ≥ 50% in 13.1% of patients in irAE- group versus 30.0% of patients in the irAE+ group, p = 0.016). The 12-week landmark analysis included 80 patients; 23/80 (28.8%) of them experienced at least 1 early irAE. PFS was improved in the irAE+ group in both univariate (HR = 0.24 [0.11-0.53], p < 0.001), and multivariate Cox models (HR = 0.33 [0.14-0.76] p = 0.009). After matching irAE+ and irAE- patients on PD-L1 level, early irAE were still associated with prolonged PFS (HR = 0.29 [0.15-0.57], p = 0.001). In the 12-week landmark population, grade ≥2 irAE were associated with even longer PFS (HR = 0.43 [0.26-0.71], p = 0.0009), and so were multiple co-occurring early irAE (HR = 0.30 [0.15-0.60], p = 0.0007). **Conclusion:** Early occurrence of irAE before 12 weeks appears to be associated with prolonged response to ICBs, independently of PD-L1 baseline expression in advanced NSCLC.

P1.01-117 PULMONARY FUNCTION MONITORING IN PATIENTS WITH OLIGOMETASTATIC NSCLC WHO RECEIVE STEREOTACTIC BODY RADIATION THERAPY

M. Arroyo-Hernandez[1], M. Blake-Cerda[1,2], L. Gochicoa-Rangel[3], S. Monraz-Pérez[3], M.F. Cuevas Góngora[1], D. Valle Bautista[1], P.A. Barragán Castillo[1], F. Maldonado Magos[2], O. Rodríguez[1], D. Flores[1], O.G. Arrieta[1]

[1]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [2]*Instituto Nacional de Cancerología, CDMX/Mexico,* [3]*Instituto Nacional de Enfermedades Respiratorias, CDMX/Mexico*

Background: Patients with early and oligometastatic stage Non-small cell lung cancer (NSCLC) who are non-surgical candidates benefit from new radiation treatment modalities, such as stereotactic body radiotherapy (SBRT). Previously we reported the correlation of lung function decline and the presence of lung toxicity related to concomitant chemo-radiotherapy. This work aims to evaluate lung function performance after SBRT in patients with oligometastatic

POSTERS

NSCLC. **Method:** A one-year prospective multicentric study was conducted at the Instituto Nacional de Cancerología in Mexico. Twenty-six patients with stage IV NSCLC with a single metastasis considered non-operable were treated with SBRT. Lung function was assessed at the baseline and at one, six, twelve, twenty-four and fifty-two weeks after SBRT, using forced spirometry with a bronchodilator, a carbon monoxide diffusing capacity (DLCO) test and oxygen saturation (SpO_2) measurement. The study was registered in clinicaltrials.gov (NCT01580579). **Result:** Fourteen patients were evaluated with lung function tests, the results were adjusted for the Mexican population. At baseline, the mean for post-bronchodilator (post-BD) FVC (l) was 2.16 (±1.09), for FEV_1 2.25 (±1.06), DLCO (ml/min/mmHg) 20.22 (±8.44) and SpO2 of 94% (±2.81). A reduction of <10% of relative change (max. 294 ml) was observed in lung volume in FEV_1 and FVC (l) post-BD follow-up with non-significant results. A statistically significant reduction in DLCO 18% (*p=0.03*) at week 12 was observed, Fig.1. All patients maintained an oxygen saturation level over 90% during the study. Quality of life reduces significantly at week six after SBRT *(p=0.03),* while respiratory symptoms were non-considerable in the first 12 weeks after receiving SBRT.

Conclusion: Although lung function tests showed a reduction trend, no statistically significant differences were found. The magnitude of lung volume reduction had no significant impact on respiratory symptoms, these findings could suggest that there is less damage in the surrounding tissue after SBRT. This research is an ongoing prospective study of one-year follow-up where several patients continue the be monitored; therefore, we expect to strength our findings by the end of the study.

Background: With three generations of EGFR tyrosine kinase inhibitors (TKIs) now available for the treatment of *EGFR* mutation-positive (*EGFR*m+) NSCLC, it will be important to identify the optimal sequence of EGFR TKIs to maximise survival. The observational GioTag study (NCT03370770) investigated outcomes in patients with *EGFR*m+ NSCLC who were treated with sequential afatinib and osimertinib in a 'real-world' clinical setting, including patients with poor prognosis (ECOG PS ≥2: 15%; stable brain metastases: 10%).[1] Time to treatment failure (TTF) was encouraging (overall: 27.6 months; Del19-positive patients: 30.3 months; Asians: 46.7 months). In this updated analysis, we report OS and updated TTF. **Method:** Data were retrospectively collected between Dec 2017 and June 2018 for 203 pts with *EGFR*m+ (Del19, L858R) NSCLC who had T790M-positive disease after first-line afatinib and subsequently received osimertinib. TTF was the primary outcome; OS analysis was exploratory. Data were collected from electronic health records (EHRs; n=126) or medical charts (n=77). For logistical reasons, this interim analysis includes updated data (as at April 2019) from patients with available EHRs (all from USA; n=94); final analysis incorporating updated data from manual chart reviews is anticipated in early 2020. **Result:** After a median follow-up of 30.3 months, median OS was 41.3 months (90% CI: 36.8–46.3) in the overall dataset (n=203) and 45.7 months (90% CI: 45.3–51.5) in Del19-positive patients (n=149); 80% of patients were alive after 2 years. OS in Asians was immature. Updated median TTF was 28.1 months (90% CI: 26.8–30.3) in the overall dataset, and 30.6 months (90% CI: 27.6–32.0) in Del19-positive patients. Outcomes were not affected by afatinib starting dose. Median TTF with osimertinib was 15.6 months (90% CI: 13.8–17.1) in the overall dataset, and 16.4 months (90% CI: 14.9–17.9) in Del19-positive patients. **Conclusion:** Sequential afatinib and osimertinib is associated with encouraging OS and TTF in pts with *EGFR* T790M-positive NSCLC, especially in Del19-positive patients, indicating that the sequential regimen is a feasible option in this setting. Of note, prior treatment with afatinib did not preclude prolonged TTF with second-line osimertinib (15.6 months overall; 16.4 months in Del19-positive patients). The final analysis will provide further insights into the long-term OS of patients treated with sequential afatinib–osimertinib, including Asians. 1. Hochmair MJ, et al. Future Oncol. 2018;14:2861–74.

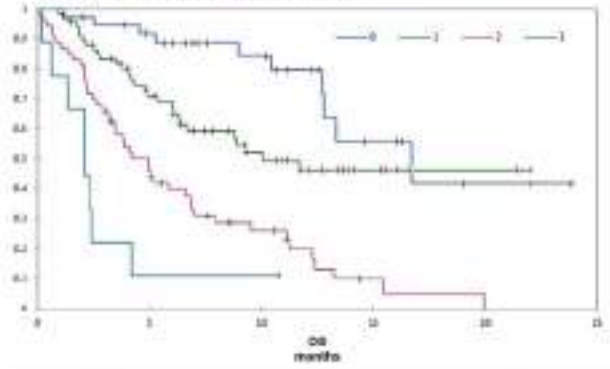
P1.01-119 MODIFIED LUNG IMMUNE PROGNOSTIC INDEX (MLIPI) AS A PREDICTIVE TOOL OF NIVOLUMAB OUTCOMES IN ADVANCED NSCLC PATIENTS

R. Moor[1], K. Roberts[1], R. Mason[2], R. Ladwa[1], Z. Lwin[3], B. Hughes[3], K. O'Byrne[1]

[1]*Princess Alexandra Hospital, Wooloongabba/Australia,* [2]*Gold Coast University Hospital, Southport/Australia,* [3]*Royal Brisbane and Women's Hospital, Brisbane/Australia*

Background: Identification of sub-populations of patients with a greater likelihood of response to anti-programmed death-1 (PD-1) inhibitors in NSCLC continues to be a focus of intense interest. A Lung Immune Prognostic Index (LIPI) has previously been proposed by Mezquita et al. JAMA 2018, based on baseline LDH and dNLR. We have previously presented data on the association between the development of immune mediated Adverse Events (IrAE) with improved outcomes (including median PFS, OS and higher rates of clinical response) and univariate analysis of baseline clinical, biochemical and radiological factors associated with improved outcomes in advanced NSCLC patients treated with Nivolumab across seven oncology institutions in Queensland, Australia. We now propose a modified prognostic index (mLIPI) using baseline performance status (PS), Lactate dehydrogenase (LDH), and Neutrophil to Lymphocyte Ratio (NLR) to better predict patients' likely response to immune checkpoint inhibitors and investigate the relationship between the prognostic index and occurrence of IrAE. In addition, updated survival data for the real world 220 patient cohort, a 12 week landmark toxicity analysis and multivariate analysis will be presented for the first time. **Method:** Multi-institutional retrospective cohort study of 220 patients who received Nivolumab across seven oncology institutions in Queensland, Australia. The mLIPI score was calculated by allocating 1 point for each of the three poor prognostic factors, PS 2-3, NLR >3, and LDH >1.5 x ULN, resulting in 4 groups (good, intermediate, poor and very poor) and was compared against the LIPI score for the same cohort. A multi institutional ethics approval was obtained. **Result:**

Figure 1: Overall Survival by mLIPI Score



Total Points	mLIPI score	mOS	95% CI	HR	Clinical benefit
0	Good	16.73	(12.79 – NR)	49%	81%
1	Intermediate	10.05	(8.38 – NR)	25%	57%
2	Poor	4.93	(3.24 – 6.84)	13%	38%
3	Very Poor	2.08	(1.35 – 2.43)	0%	11%
		p-< 0.001			

The occurrence of IrAE was associated with a lower number of poor prognostic factors at baseline (lower mLIPI score), *P value = 0.013*. **Conclusion:** The mLIPI score correlated with outcomes (median PFS and OS) and was able to better identify those patients likely to obtain benefit from single agent Nivolumab therapy in this cohort when compared against published scores. Patients with a high mLIPI score, indicating a higher number of poor prognostic factors at baseline were less likely to derive a clinical benefit, or develop IrAE.

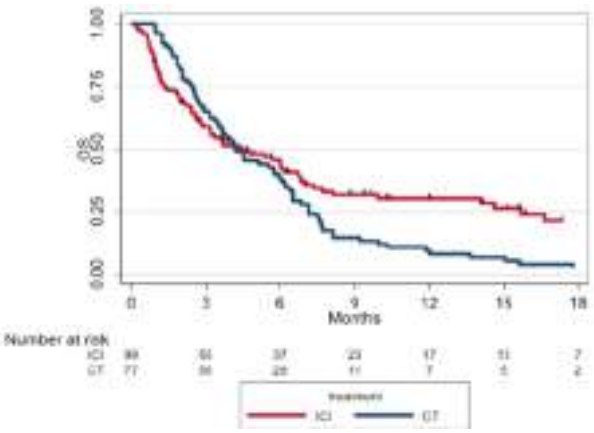
Background: Anti Programmed Death-ligand (PD1/PD-L1) directed immune-checkpoint-inhibitors (ICI) are widely used to treat patients with advanced non-small cell lung cancer (NSCLC) who progress after first line chemotherapy. The best strategy after early progression under first line has not been specifically studied **Method:** We conducted a multicenter, retrospective study including

all consecutive NSCLC patients progressing within the first 3 months following introduction of first-line chemotherapy and being treated with second line ICI monotherapy or chemotherapy between March 2010 and November 2017. We analysed the clinicopathological data and outcome under second line chemotherapy *vs.* second line ICI: progression-free survival (PFS), overall survival (OS), and objective response rate (ORR). **Result:** We identified 176 patients with refractory disease, 99 who received subsequent immunotherapy and 77 undergoing chemotherapy. The 2 populations were comparable regarding the main prognostic criteria, median age was 60, main histology was adenocarcimoma (68,2%). Compared to chemotherapy, ICI treated patients had a superior OS (logrank test, p=0.03) (Median [95% CI] OS 4.6 [2.8-6.7] versus 4.2 months [3.4-5.9] and a non-significant improvement in ORR (17.2% and 7.9%, respectively, p = 0.072). PFS was not significantly different (1.9 [1.8-2.1] versus 1.6 months [1.4- ; 2.0] (p=0.125). Poor performance status (ECOG PS≥2) and a higher number of metastatic sites (≥3) were associated with poorer prognosis. KRAS-mutated patients did not seem to benefit more from ICI than chemotherapy. Table 1 Multivariable analysis of characteristics associated

n= 175	OS		PFS	
Variable	HR [CI 95%]	p value	HR [CI 95%]	p value
Treatment		0.045		0.040
Chemotherapy (ref)	1.00		1.00	
Immunotherapy	0.70 [0.49 ; 0.99]		0.71 [0.51 ; 0.98]	
Number of metastatic location before 2nd line		0.005		0.011
0-1-2 (ref)	1.00		1.00	
3 or +	1.64 [1.16 ; 2.31]		1.52 [1.10 ; 2.10]	
Performance Status		**0.038**		
0 -1	1.00			
2 - 3 - 4	1.46 [1.02 ; 2.09]			

Figure 1: Kaplan Meier curves for Overall Survival for ICI group and CT group



Conclusion: ICI appears to be the preferred second-line treatment for patients who are refractory to first line chemotherapy

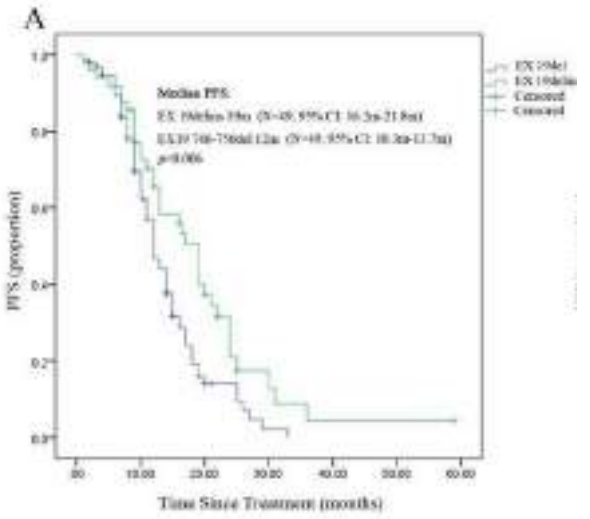
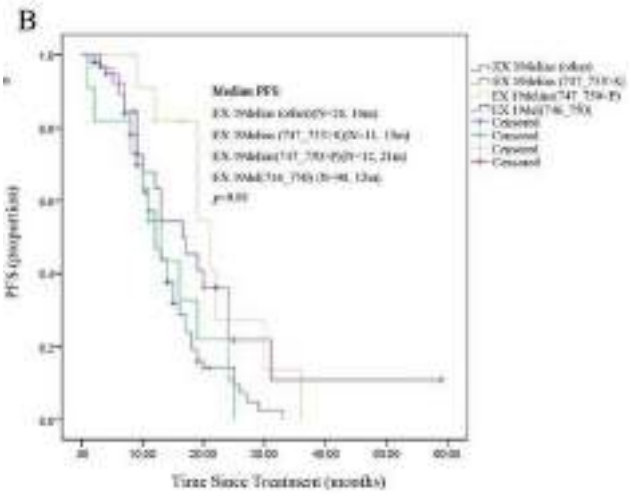
P1.01-121 SUPERIOR OUTCOMES OF 1ST LINE EGFR TKI IN NEXT-GENERATION SEQUENCING IDENTIFIED UNCOMMON EGFR EXON 19DELINS MUTATION NON-SMALL CELL LUNG CANCER

Y. Zhang[1], N. Yang[1], T. Jiang[2], C. Zhou[3]

[1]*Hunan Cancer Hospital/The Affiliated Cancer Hospital of Xiangya School of Medicine, Central South University, Changsha/China,* [2]*Shanghai Pulmonary Hospital, Shanghai/China,* [3]*Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/China*

Background: First line EGFR-TKI showed promising efficacy on *EGFR* mutant advanced non-small cell lung cancers (NSCLC). However, the response duration time differs with different mutation variants. The aim of our study was to evaluate the efficacy and resistance mechanism of first-line EGFR TKI in NSCLC patients with uncommon mutation of *EGFR* 19del mutations. **Method:** Among 1530 lung cancer patients who received detection of next generation sequencing (NGS) from Jan, 2015 to Aug, 2018, 49 gefitinib or erlotinib treated EGFR exon 19delins mutant advanced NSCLC patients received NGS of 168 genes panel using tumor tissue in baseline was enrolled in this study for cohort A. Using Propensity Score Matching (Ratio of 1:2), 98 patients carrying *EGFR* sensitive mutation of EGFR exon19del (745-760del) were set as cohort B. EGFR exon 19delins mutation variants in cohort A, clinical outcomes and resistance mechanism for bc





In cohort A, 19 *EGFR* exon 19delins variants were detected and 10 variants were novel. Among exon 19 delins variants, L747-A750delinsP and L747-A753delinsS were the domain variants, contributing to 24.5% (12/49) and 22.5% (11/49) respectively. In cohort A, 38 patients were evaluated with progress disease and 11 patients were ongoing current treatments. In cohort B, 73 patients were evaluated with progress disease and 36 patients were ongoing current treatments. There was no difference between cohort A and B for base characteristics, treatment drugs and response rate. The

median PFS of cohort A and B was 19.0 months *vs.* 12.0 months (p=0.006). In all the 19del variants, the mPFS of L747-A750delinsP subtype was significantly prolong for 21 months (p=0.03). All the progress disease patients received re-biopsy and NGS detection. T790M was defined as the domain acquired resistance mechanism, contributing to 26.3% in cohort A and 45.2% in cohort B, followed by pathology transformation (5.3% *vs* 4.1%) and *MET* amplification (5.3% *vs* 4.1%). **Conclusion:** Our results indicated that patients with EGFR exon 19delins mutation presented with significantly better outcomes for first line EGFR-TKI. Dominate resistant mechanism were still for EGFR exon 20T790M but significantly be decreased in uncommon EGFR mutations.

[1]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [2]*Northern Cancer Institute, University of Sydney, Sydney/Australia,* [3]*Resolution Bioscience, Kirkland/United States of America*

Background: Although EGFR and ALK testing in non-small-cell lung cancers (NSCLC) is now considered standard practice, next generation sequencing (NGS) for extended molecular testing of uncommon drivers is often difficult to perform in the community due to factors surrounding tissue adequacy, availability and turnaround time. We set out to prospectively determine the clinical utility of plasma ctDNA NGS in detecting uncommon actionable drivers and their plasma guided treatment response. **Method:** Patients with advanced NSCLC who were driver unknown after routine EGFR and ALK testing were eligible. Patients were enrolled prospectively at Memorial Sloan Kettering Cancer Center (NY, USA) and Northern Cancer Institute (Sydney, Australia). Peripheral blood (10-20mL) was collected and sent to Resolution Bioscience (*Kirkland, WA*) for targeted ctDNA NGS using a bias-corrected hybrid-capture 21 gene assay in a CLIA laboratory achieving a mean unique read of at least 3000x and sensitivity above 0.1%. Clinical endpoints included detection of uncommon oncogenic drivers defined as actionable alterations in *ROS1*, *RET*, *BRAF*, *MET*, *HER2*, turnaround time, concordance with tissue NGS when available, and plasma guided treatment outcome. **Result:** 614 patients were prospectively accrued. Plasma NGS detected an uncommon oncogenic driver in 7% (45/614) of patients including *ROS1*, *RET* fusions, *BRAF*, *MET* exon 14 and *HER2* exon 20 mutations, of whom 3% (20/614) were matched to targeted therapy producing 12 partial responses. Mean turnaround time for plasma NGS was significantly shorter than tissue NGS (10 vs 25 days, P <0.0001). 399 patients had concurrent tissue NGS results available for concordance analysis; Overall concordance, defined as the proportion of patients for whom an uncommon driver was uniformly detected or absent in both plasma and tissue NGS, was 94.7% (378/399, 95% confidence interval [CI] 92.1 – 96.7%). Among patients who tested plasma NGS positive for uncommon drivers, 87.5% (28/32, 95% CI 71.0-96.5%) were concordant on tissue NGS, and among patients tested tissue NGS positive for uncommon driver, 62.2% (28/45, 95% CI 46.5-76.2%) were concordant on plasma NGS. **Conclusion:** Plasma NGS uncovered uncommon oncogenic drivers with faster turnaround time than tissue NGS, directly matched patients to targeted therapy and produced clinical responses independent of tissue results. A positive finding of an oncogenic driver in plasma is highly specific and can immediately guide treatment, but a negative finding may still require tissue biopsy. Our findings provide prospective evidence to support a "blood first" approach in molecular diagnostics for the care of patients with NSCLC.

Background: Although definitive treatment with chemoradiotherapy is standard for non-small cell lung cancer (NSCLC) with N2 disease, surgery still has a role in improving the prognosis of patients with resectable tumors. In this study, we evaluated the recent clinical outcomes of upfront surgery followed by adjuvant treatment in pathological N2 (pN2) disease. **Method:** We performed a retrospective analysis of clinical outcomes in patients with pN2 disease who underwent surgery as first-line therapy. Multivariate Cox regression analysis was used to identify the significant factors for overall survival (OS) and recurrence-free survival (RFS). **Result:** From 2004 to 2015, a total of 706 patients who underwent complete anatomical resection were enrolled in this study. With a median follow-up of 40 months, the median OS and RFS times were 52 and 23 months and 5-year OS and RFS were 44.7% and 33.8%. The patients' clinical N stages were: cN0, 308 (43.6%); cN1, 123 (17.4%), and cN2, 275 (39.0%). Adjuvant chemotherapy, radiotherapy, and chemoradiotherapy were administered in 169 (23.9%), 115 (17.4%), and 299 patients (42.4%), respectively. According to subdivided pN2 descriptors, median OS time was 80, 53, and 37 months in patients with pN2a1, pN2a2, and pN2b, respectively. Patients with clinical N0-N1, so-called occult N2 disease, showed better prognosis than those with clinical N2 (P value = 0.018 for OS and 0.022 for RFS). Adjuvant chemotherapy was a significant prognostic factor for both OS and FFR (P value < 0.001 for OS and RFS). **Conclusion:** Recent upfront surgery followed by adjuvant therapy in patients with N2 NSCLC showed favorable outcomes compared to those reported in previous studies. Adjuvant chemotherapy is essential for improving the prognosis in patients undergoing upfront surgery for N2 disease.

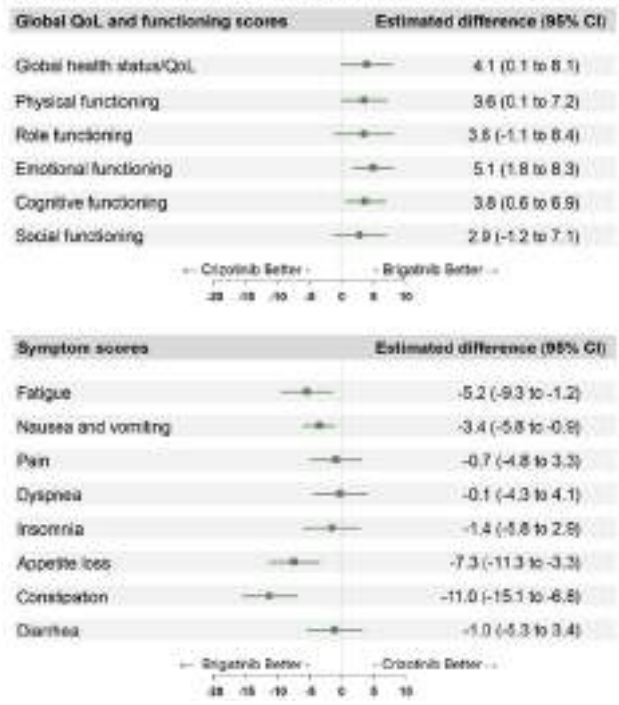
P1.01-124 HEALTH-RELATED QUALITY OF LIFE (HRQOL) DATA IN A PHASE 3 STUDY OF FIRST-LINE BRIGATINIB VS CRIZOTINIB IN NSCLC (ALTA-1L)

R. Garcia Campelo[1], H. Lin[2], M. Perol[3], M. Jahanzeb[4], S. Popat[5], Y. Zhu[2], P. Zhang[2], D.R. Camidge[6]

[1]*University Hospital A Coruña (XXIAC-SERGAS), A Coruna/Spain,* [2]*Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge/United States of America,* [3]*Department of Thoracic Oncology, Centre Léon Bérard, Lyon/France,* [4]*University of Miami Sylvester Comprehensive Cancer Center, Deerfield Beach/United States of America,* [5]*The Royal Marsden Hospital; and National Heart and Lung Institute, Imperial College London, London/United Kingdom,* [6]*University of Colorado Cancer Center, Aurora/United States of America*

Background: Results from ALTA-1L (NCT02737501) showed that brigatinib vs crizotinib as first-line ALK therapy significantly improves progression-free survival (PFS; HR: 0.49, 95% CI, 0.33, 0.74) in advanced ALK+ NSCLC. HRQoL was evaluated as a secondary objective. **Method:** ALK+ NSCLC patients were randomized 1:1 to brigatinib or crizotinib as first-line ALK therapy. HRQoL was assessed with the EORTC QLQ-C30 and LC13. Change from baseline, duration of improvement, and time to worsening were analyzed in the ITT-PRO population (n=131 for both groups). **Result:** HRQoL compliance was >90% for both groups. Brigatinib substantially improved overall HRQoL vs crizotinib, as demonstrated by the estimated mean difference on change from baseline (4.1, *P*<0.05; Figure 1) and duration of improvement for GHS/QoL (HR=0.16, *P*<0.001; Figure 2), which was also supported by improvement in several functional domains and symptoms (Figure 1). No domains significantly favored crizotinib. Similar results were also observed in patients with baseline CNS metastases.

Figure 1. LS Means of Change from Baseline for EORTC QLQ-C30 Scores



Conclusion: Consistent with the prolongation of PFS seen in first-line treatment of advanced ALK+ NSCLC, brigatinib improved HRQoL and prolonged the duration of improvement in GHS/QoL, and the majority of functional and symptom domains vs crizotinib.

P1.01-125 UNIPORTAL VERSUS MULTIPORTAL THORACOSCOPIC LOBECTOMY WITH SYSTEMATIC MEDIASTINAL LYMPHADENECTOMY FOR N2(+) STAGE III NSCLC

Y.-J. Deng[1], J.-Q. Wang[2], Z. Wang[1], Z. Wang[2], J.-W. Mu[1], G.-S. Wang[2]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, shenzhen/China,* [2]*Shenzhen People's Hospital, Second Affiliated Hospital, Medical College of Jinan University, ShenZhen/China*

Background: With its growing popularity and potential better outcomes, uniportal(UP) thoracoscopic surgery has been used in the treatment of non small cell lung cancer(NSCLC). In this study,we aimed to evaluate the perioperative and long-term outcomes of uniportal thoracoscopic lobetectomy with systematic mediastinal lymphadenectomy for NSCLC in comparison to multiportal(MP) surgery in our institute. **Method:** A total of 97 consecutive N2(+) stage III NSCLC patients were chosen to undergo thoracoscopic lobetectomy with systematic mediastinal lymphadenectomy in our institute from March 2013 to March 2018. Data such as clinicopathologic characteristics and perioperative outcomes, disease free survival(DFS) and overall survival(OS) were restrospectively reviewed in this article. **Result:** There were 25 patients in the UP group, and 50 patients in the MP group from March 2013 to March 2018.UP group took less time than the MP group in the total operation duration (184.7 ± 69.5 vs 235.5 ± 79.9, P < 0.01). The conversion rate,the average dissected mediastinal lymph node stations,number of mediastinal lymph nodes dissected,the volume of estimated blood loss,volume of thoracic drainage,thoracic tube drainage time,length of postoperative hospital stay,perioperative complication were similar between the two groups(P >0.05). Postoperatively, UP and MP groups showed similar results in terms of disease free survival(DFS) and overall survival(OS). **Conclusion:** In comparison with multiportal thoracoscopic surgery, UP thoracoscopic lobectomy with systematic mediastinal lymphadenectomy showed higher efficiency,and acquired equivalent perioperative short-term and long-term outcomes in the surgical treatment of N2(+) stage III NSCLCs. Further studies based on a larger population and better methodology are required to determine its further benefits towards patients.

POSTERS

Background: Human epidermal growth factor receptor 2 (ERBB2, HER-2) 20 exon insertion (ERBB2ex20ins) has been identified as an oncogenic driver in lung cancer, for which no valid therapy is currently approved. Concurrent alterations may elucidate its refractory features. Previous studies on Afatinib, a pan-ERBB inhibitor, have revealed an inconsistent clinical activity of it for this group of patients. **Method:** Plasma or tissue samples of 112 patients with ERBB2ex20ins were performed next generation sequencing (NGS) for 59 or 1021 cancer-related genes in a Clinical Laboratory Improvement Amendments-certified Laboratory from July 2016 to December 2018. The sequencing data of MSKCC Cohort was downloaded from the public Cancer Genome Atlas Database. The clinical outcomes of 18 patients receiving Afatinib treatment were collected by each contributing doctor in charge and pooled for analysis. **Result:** Among the 112 patients, most of cases were female (54%, 60/112) and adenocarcinoma (68%, 76/112). Considering the insertions sites, three subtypes were A775ins (71%; 79/112), G776indel (17%; 19/112) and P780ins (12%; 14/112) in the order of frequency. 80.4% (90/112) of patients had at least one additional alteration. The most frequent co-occurring genes were TP53 (66.1%, 74/112), LRP1B (18.2%, 10/55), EPHA5 (9.1%, 5/55), MLL3 (9.1%, 5/55) and RB1 (8.0%; 9/112). Putative other driver aberrations were mutually exclusive from ERBB2ex20ins. Furthermore, cell cycle pathway was the most commonly involved pathway (84.0%; 94/112) of all the concurrent genes. No substantial differences of concurrence in genomic or pathway level were observed among the three ERBB2 insertion subtypes. The co-occurring genomic feature of ERBB2ex20ins in Our Cohort of Chinese people had an overall strong concordance with the MSKCC Cohort from the United States (R^2=0.74, P<0.01). For the prognosis, patients had a worse OS when co-occurring mutation in TP53 [median OS:14.5m (95%CI: 12.7m-16.3m) vs 30.3m (95% CI: not reached)], while the OS was not significantly different among three subtypes. The median duration time for patients with disease control of Afatinib was 4.5 months (95%CI: 3.6m-5.4m; range: 2.5m-13.4m). Of note, ERBB2ex20ins in subclonal status was a significantly independent factor relating to shorter PFS of Afatinib [median PFS: 1.2m (95%CI: 0.8-1.6m) vs 4.3m (95%CI: 3.3m-5.3m), P<0.05]. Dynamic detection in two patients found ERBB2 amplification may be a resistance mechanism for Afatinib. **Conclusion:** Concurrence of genetic alterations in NSCLC patients with ERBB2ex20ins was common. The complex genomic characteristic should be fully considered by stratifying patients according to potentially relevant co-mutations other than ERBB2 insertion sites in the designing regimens for them. In addition, the therapeutic effect of Afatinib on patient with ERBB2ex20ins is limited, the clonal status of ERBB2ex20ins may be an important factor with prognosis value.

Keywords: ERBB2 exon 20 insertion, concurrent mutation, Afatinib

Background: We report results of a phase 1/2 open-label, multicenter study of TAK-788 (NCT02716116), an oral investigational EGFR/HER2 inhibitor. **Method:** Patients with advanced, previously treated NSCLC received daily TAK-788 in dose escalation and expansion cohorts based on tumor genotype. Antitumor activity was determined for patients with EGFR exon 20 insertions who received TAK-788 160 mg QD. Safety is reported for all patients across all doses and at 160 mg. To improve gastrointestinal tolerability, food intake instructions in this ongoing study were amended to allow for administration with or without a low-fat meal based on emerging clinical pharmacokinetic data in a healthy volunteer study (data on file). **Result:** As of 14 Sep 2018, 101 patients (median age, 61 y; female, 70%; ≥2 prior anticancer therapies, 76%; brain metastases, 53%) were treated with TAK-788 at 5–180 mg QD. RP2D was determined to be 160 mg QD. 28 patients with EGFR exon 20 insertions were treated with 160 mg QD during dose escalation or in expansion cohort 1 (3.6 months on treatment; 3.8 treatment cycles [medians]); 24 patients remain on treatment. At data cutoff, best response (RECIST v1.1) among 26 patients with ≥1 disease assessment was PR, n=14; SD, n=9; and PD, n=1 (objective response rate, 54%; 95% CI: 33.4%–73.4%); 2 patients were unevaluable. 7/14 objective responses (all PR) were confirmed (6 awaiting confirmation; 1 unconfirmed PR at 160 mg QD); median time to response in these 14 patients was 56 days. 23/26 patients (89%; 95% CI: 69.9%–97.6%) achieved disease control. 23/24 evaluable patients with EGFR exon 20 insertions treated at 160 mg QD had decreased target lesion measurements (median best percent change, -32.6% [-79.1%–3.8%]). Most common TEAEs (≥20%) in patients treated with 160 mg QD: diarrhea (85%), rash (43%), nausea (41%), vomiting (30%), decreased appetite (28%), stomatitis (22%); grade ≥3 TEAEs (≥5%): diarrhea (26%); hypokalemia, nausea, stomatitis (7% each). Among patients treated with 160 mg QD, median dose intensity was 93%, rate of dose reduction due to AEs was 21.7%, and rate of treatment discontinuation due to AEs was 10.9%. There was no clear trend that response to TAK-788 was enriched in any single EGFR exon 20 insertion variant. **Conclusion:** In NSCLC patients with EGFR exon 20 insertions, TAK-788 demonstrated antitumor activity and a safety profile consistent with other EGFR TKIs.

P1.01-128 CHOICE OF POSTOPERATIVE RADIOTHERAPY FOR RESECTED IIIA-N2 NON-SMALL CELL LUNG CANCER: IMPACT OF LOG ODDS OF POSITIVE LYMPH NODES

Y. Wo[1], H. Yang[2], Y. Wang[1], T. Lu[1], W. Du[1], W. Jiao[1]

[1]*Affiliated Hospital of Qingdao University, Qingdao/China,* [2]*Qingdao Central Hospital, The Second Affiliated Hospital of Qingdao University, Qingdao/China*

Background: Surgical resection alone results in poor survival in patients with stage IIIA-N2 non-small cell lung cancer (NSCLC) owing to high incidence of locoregional recurrence and distant metastasis. One possible way to improve surgical outcome is the administration of postoperative radiotherapy (PORT). However, the benefit and indication of administrating PORT remains controversial for stage IIIA-N2 NSCLC. We aimed to assess log odds of positive lymph nodes (LODDS) as a predictor of the benefit of PORT. **Method:** Patients with resected stage IIIA-N2 NSCLC were extracted from the Surveillance, Epidemiology, and End Results (SEER) database between 2004 and 2015. LODDS was defined as $\log_e$[(metastatic nodes count+0.5)/(negative nodes count+0.5)]. X-tile software determined the optimal cut-points for LODDS based on minimal p value method. Survival analyses were conducted with log-rank tests and Cox proportional hazard models. **Result:** Among patients enrolled in this study (n=4197), 1630 (38.8%) received PORT. LODDS was categorized into four groups: LODDS1 (LODDS≤-1.61), LODDS2 (-1.58≤LODDS≤-0.85), LODDS3 (-0.83≤LODDS≤0.00), and LODDS4 (LODDS≥0.01). The median survival in LODDS group 1, 2 ,3, and 4 was 53, 44, 35, and 25 months, respectively. PORT conferred significant improved survival for stage IIIA-N2 NSCLC. According to multivariate Cox regression analyses, PORT and LODDS were both identified as independent prognostic factors. When analyzed by LODDS group, the benefit of PORT was limited to patients with LODDS4 (LODDS≥0.01), whereas the PORT benefit was not observed in LODDS1-3.

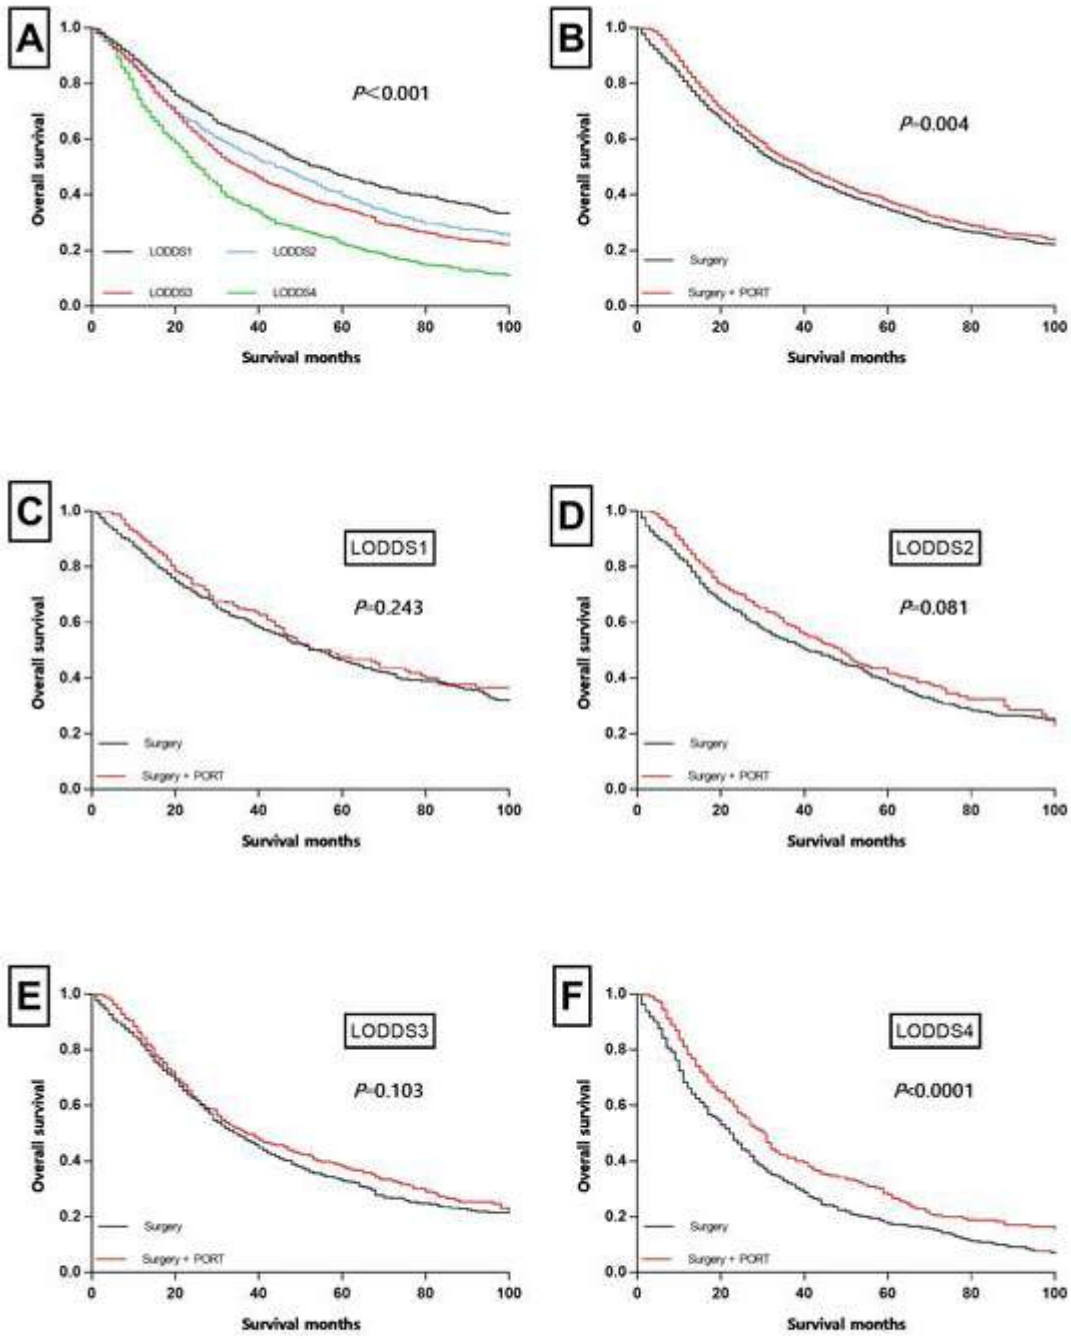

Figure 1 Survival curves stratified by (A) LODDS Categories, (B) treatment modality in whole cohort, (C) treatment modality in LODDS1, (D) treatment modality in LODDS2, (E) treatment modality in LODDS3, and (F) treatment modality in LODDS4.

Conclusion: Our study validates LODDS as a significant prognostic factor in stage IIIA-N2 NSCLC. It is worth noting that LODDS may predict which group of patients could benefit from PORT.

P1.01-129 PRECLINICAL GENETIC EVALUATION OF ALTERNATING ALK TKI THERAPY VERSUS CONTINUOUS DOSING IN ALK NSCLC TO INFORM THE ALKTERNATE CLINICAL TRIAL

M. Itchins[1,2,3], A. Hudson[1,2], S. Hayes[1,2], R. Harvie[1,2], G.H. Wei[4], M. Buckland[4], S. Clarke[1,2,3], V. Howell[1,2], N. Pavlakis[1,2,3]

[1]*University of Sydney, St Leonards/Australia,* [2]*Kolling Institute, St Leonards/Australia,* [3]*Royal North Shore Hospital, St Leonards/Australia,* [4]*The University of Sydney Brain and Mind Center, Camperdown/Australia*

Background: Despite recent advances in the management of advanced *ALK*-rearranged NSCLC, with high objective response rates to ALK TKI therapy and survival gain, resistance to TKIs remains inevitable. Mechanisms of *ALK*-dominant and non-dominant resistance are being increasingly recognized, although in a many patients the underlying cause of drug resistance is unexplained. ALKternate is a clinical trial recruiting pre-treated patients, testing the hypothesis that with fixed alternating TKI therapy, the emergence of ALK resistant clones can be suppressed through applying variable selection pressure compared to continuous treatment with a TKI. This has been tested pre-clinically with a human cell line to complement the clinical trial in progress, ALKternate (Abstract #2043). Proteomic pathway profiling to complement these data are presented in #2072. **Method:** The H3122 human cell line (EML4(13)-ALK(20) variant 1 fusion) was treated with continuous ceritinib to induce resistance as confirmed by triplicate cytotoxicity assays. Once ceritinib resistance had developed, treatment continued with either continuous lorlatinib ('CONT' arm) or alternating continuous lorlatinib intercalated with crizotinib ('ALT' arm) to recapitulate ALKternate. Treatment continued for 17 cycles. Total nucleic acid was extracted from cells after cycles 5,11 and 17 of treatment and targeted next generation sequencing performed using the Oncomine Lung total nucleic acid assay on the Ion S5 system (Thermo-Fisher Scientific). Results were compared between treatment arms and over time. **Result:** The genetic changes are detailed in Figure 1. The number of mutations identified increased with treatment duration.

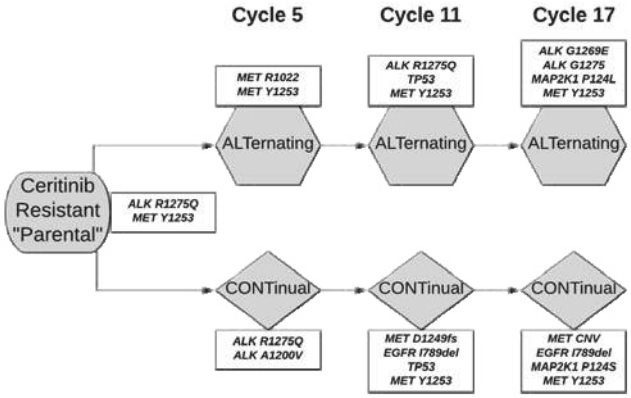

Figure 1: Mutations and copy number gains (CNV) identified. **Conclusion:** In keeping with the hypothesis, the genetic profiles identified demonstrate the emergence of different clones over time and between treatment strategies. This supports further investigation into the novel strategy of alternating therapy as planned in the ALKternate trial.

Hospital Universitario Guadalajara, Guadalajara/Spain,* [6]*Virgen de la Salud Hospital, Toledo/Spain,* [7]*Fundación Jiménez Díaz University Hospital, Madrid/Spain,* [8]*Móstoles University Hospital, Madrid/Spain,* [9]*Fuenlabrada University Hospital, Madrid/Spain,* [10]*Ramón y Cajal University Hospital, Madrid/Spain*

Background: Lung cancer is the leading cause of cancer deaths worldwide. Nintedanib is a triple angiokinase inhibitor approved with docetaxel for non-small cell lung cancer after chemotherapy. The aim of this study is to analyze the efficacy and safety of nintedanib in combination with docetaxel in patients treated in various Spanish centers. **Method:** We conducted a retrospective multicenter study, which included all patients with non-small cell lung cancer who received nintedanib with docetaxel in second o third line of treatment. **Result:** We enrolled 124 patients from ten different Spanish centers. The male –female ratio was 3:2, with an average age of 62 years. 82,7% were smokers, 12,2% never smokers and 5,7% former smoker. The most frequent histology was adenocarcinoma (97,6%) and respect mutational state only 5 patients were EGFR mutate and 1 patient presented ALK translocation. PDL1 status was unknown in 46,3% of cases, negative in 32,5% and positive in 21,1%. The majority of patients were diagnosis in stage IV (74%) and in stage III (13,8%). In the first line, 98,4% had received platinum-based chemotherapy and 40,7 % had received previous bevacizumab therapy with an average of 4,1 cycles. The average of nintedanib cycles was 6 and the median time of treatment was 496 days. 65,9% of patients included had progressed to the first line in less than 9 months. The disease control rate was 61% (25,2% stable disease, 34,1% partial response and 1,6% complete response). Progression free-survival was 4,1 months and the overall survival was 26,9 months. The most common adverse events were: fatigue (82,1%), diarrhea (63,4%), nausea (32,5%), neutropenia (33,3%) and cough (18,2%). Thirty-one patients (25,2%) required dose adjustment (15 patients decrease to 200 mg daily and 18 patients to 300 mg daily). **Conclusion:** The efficacy and safety of nintedanib in our cohort is similar to the previously reported. Nintedanib in combination with docetaxel is an effective treatment option for patients with advanced non-small cell lung cancer.

Keyword: non-small cell lung cancer, nintedanib.

P1.01-131 THE COMPARISON BETWEEN NON-INTUBATED AND INTUBATED ANESTHESIA VIDEO-ASSISTED THORACOSCOPIC SURGERY: A META-ANALYSIS

G. Qiu

The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center for Respiratory Disease, Guangzhou/China

Background: It remains unclear whether the feasibility and safety of non-intubated VATS under LA is comparable or advantageous compared with conventionally intubated VATS under GA in different thoracic diseases. Consequently, a meta-analysis was conducted with the aim of assessing whether non-intubated VATS offered better perioperative outcomes over intubated VATS in terms of diverse thoracic diseases, including pulmonary nodules, spontaneous pneumothorax, and malignant pleural effusion. **Method:** A comprehensive search of online databases was performed. Intraoperative and postoperative variables were compared between the subgroups. The odds ratio (OR) or SMD and its 95% CI was calculated using a random effects model. Heterogeneity across studies was examined by the Cochran Q chi-square test and the I^2 statistic. **Result:** A total of 15 eligible studies including 1964 patients were recruited. Each included study had comparable baseline characteristics and the same surgical procedures except for the regimens of anesthesia and ventilation. Non-intubated anesthesia VATS was performed on 959 patients, whereas the other 1005 patients underwent intubated VATS. In the overall analysis, patients who underwent non-intubated surgery associated with significant shorter postoperative hospital stays (SMD=-0.36, p<0.001), postoperative fasting time (SMD=-2.80, p<0.001) and anesthesia time as well as lower rates of mortality, postoperative overall, respiratory, and cardiovascular complications. Patients underwent non-intubated surgery also manifested a trend toward shorter operative time and less blood loss with no significant significance. **Conclusion:** Non-intubated VATS was confirmed as a safe and feasible alternative to intubated VATS and potentially provided a more rapid postoperative rehabilitation than intubated VATS overall and specifically in the management of pulmonary nodules, spontaneous pneumothorax, and malignant pleural effusion. Future large-scale multicenter studies are supposed to focus on prospective validation of feasibility and safety and immunological changes for non-intubated thoracoscopic approach

Keywords: Thoracoscopic Surgery, non-intubated, video-assisted

P1.01-132 CLINICOPATHOLOGICAL AND GENOMIC COMPARISONS BETWEEN DIFFERENT HISTOLOGIC COMPONENTS IN COMBINED SMALL CELL AND NON-SMALL CELL LUNG CANCER

M.-W. Lin[1], K.-Y. Su[2], M.-S. Hsieh[1], S.-L. Yu[2], J.-S. Chen[1]

[1]*National Taiwan University Hospital, Taipei City/Taiwan,* [2]*National Taiwan University College of Medicine, Taipei/Taiwan*

Background: Histologic transformation from adenocarcinoma to small cell lung cancer (SCLC) is one of the mechanisms of acquired resistance after epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI) treatment. Furthermore, de novo combined SCLC/non-small cell lung cancer (NSCLC) have occasionally been reported; however, their mutational statuses and clinicopathological features have not yet been elucidated. In this study, we aimed to profile the genetic backgrounds of these 2 different histologic components by investigating patients with de novo combined SCLC/NSCLC as well as those with lung adenocarcinoma who experienced SCLC transformation after TKI treatment. **Method:** Four patients with de novo combined SCLC/NSCLC were investigated, as were 4 other patients with lung adenocarcinoma who experienced SCLC transformation after TKI treatment. The different histologic components of the tumors in each patient were tested for thyroid transcription factor-1, p40, synaptophysin, chromogranin A, p53, retinoblastoma protein (Rb), and achaete-scute homolog 1 (ASCL1) via immunohistochemistry, and were macroscopically dissected for mutational analysis using next-generation sequencing with the Oncomine Focus Assay and Comprehensive Assay panel. **Result:** Our study comprised two groups of patients: the first group were patients with de novo combined SCLC/NSCLC and the second group were lung adenocarcinoma with SCLC transformation after TKI treatment. De novo combined SCLC/NSCLC patients have poor prognoses and poor responses to EGFR TKI. In both groups, identical EGFR/TP53/RB1 mutations and p53/Rb expression patterns were observed in both SCLC and NSCLC components. A high frequency of activating mutations involving PI3K/AKT1 signaling pathway was observed in de novo combined SCLC/NSCLC and also in the SCLC component of the second group after TKI treatment. Nuclear ASCL1 expression was present in SCLC but absent or barely present in adenocarcinoma in 7 cases. **Conclusion:** Our data imply that inactivation of TP53/RB1 function is a possible early event in the histogenesis of synchronous and metachronous SCLC/NSCLC. Moreover, the non-adenocarcinoma (SCLC) component might arise from the adenocarcinoma (NSCLC) component through a mechanism that involves the activation of the ASCL1 and PI3K/AKT1 signaling pathways.

Background: Transforming growth factor β (TGF- β) promotes tumor progression via immune- and non–immune-related processes. Bintrafusp alfa* (M7824) is an innovative first-in-class bifunctional fusion protein composed of 2 extracellular domains of TGF-βRII (a TGF-β "trap") fused to a human IgG1 monoclonal antibody against PD-L1. Targeting these independent and complementary pathways may restore and enhance antitumor responses. An expansion cohort of the NCT02517398 study of patients with advanced NSCLC (n=80) treated with bintrafusp alfa in the second-line setting presented at ESMO 2018 showed an objective response rate of 86% in the subgroup with high PD-L1 tumor expression at the recommended phase 2 dose (1200 mg intravenously [IV] every 2 weeks [Q2W]). Observed data support the hypothesis that bintrafusp alfa may be superior to other PD-(L)1 inhibitors, including pembrolizumab, for the treatment of NSCLC. Based on the promising antitumor activity and manageable safety profile, this study will evaluate bintrafusp alfa treatment in patients with advanced NSCLC in the 1L setting. **Method:** Here we present a global, randomized trial comparing bintrafusp alfa vs pembrolizumab in the 1L treatment of patients with metastatic NSCLC with high PD-L1 expression levels. Patients in this study must have a histologically confirmed diagnosis of advanced NSCLC with high PD-L1 expression on tumor cells (defined as either ≥80% by the Dako 73-10 pharmDx kit or ≥50% by the Dako 22C3 pharmDx kit since both assays are expected to select a similar patient population at their respective cut-offs). ECOG performance status must be 0 or 1. Patients must not have received prior systemic treatment for advanced NSCLC. Patients with tumors with actionable mutations (for which targeted therapy is locally approved) are not eligible. Patients will receive 1200 mg Q2W or pembrolizumab 200 mg Q3W as an IV infusion until confirmed disease progression, unacceptable toxicity, or trial withdrawal. Dual primary endpoints are progression-free survival and best overall response; key secondary endpoints include overall survival, duration of response, and safety. Estimated enrollment is 300 patients. Clinical trial information: NCT03631706. *Proposed INN. **Result:** Section not applicable **Conclusion:** Section not applicable

P1.01-134 SAVANNAH: PHASE II TRIAL OF OSIMERTINIB + SAVOLITINIB IN EGFR-MUTANT, MET-DRIVEN ADVANCED NSCLC, FOLLOWING PRIOR OSIMERTINIB

M.-J. Ahn[1], M. Cantarini[2], P. Frewer[2], G. Hawkins[2], J. Peters[2], P. Howarth[2], G. Ahmed[2], T. Sahota[2], R. Hartmaier[3], X. Li-Sucholeiki[3], G. Oxnard[4]

[1]*Samsung Medical Center, Seoul/Korea, Republic of,* [2]*AstraZeneca, Cambridge/United Kingdom,* [3]*AstraZeneca, Waltham/United States of America,* [4]*Dana-Farber Cancer Institute, Boston/United States of America*

Background: The toxicity profile of the third-generation epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) osimertinib makes it an attractive backbone for combination with other targeted agents, possibly overcoming acquired resistance mechanisms. Combination with a MET-inhibitor is an intuitive approach as *MET*-amplification was identified as the most common mechanism of resistance to osimertinib in preliminary ctDNA data from the Phase III FLAURA (15% of patients) and AURA3 (19% of patients) studies. Savolitinib (AZD6094, HMPL-504, volitinib) is an oral, potent and highly selective MET-TKI that had an acceptable safety profile when combined with osimertinib in the Phase Ib TATTON study, providing the basis for this Phase II SAVANNAH study (NCT03778229). Other mechanisms of acquired resistance to osimertinib, including secondary *EGFR* mutations (e.g. C797S), RAS/RAF activation, and oncogenic gene fusions, provide additional opportunities for developing osimertinib-based combinations. **Method:** Eligible patients will have histologically or cytologically confirmed *EGFR*-mutant, locally advanced or metastatic non-small cell lung cancer (NSCLC), and *MET*-driven (MET+) disease by central fluorescence *in situ* hybridization (FISH), central immunohistochemistry (IHC), or local next-generation sequencing (NGS; retrospectively confirmed by central FISH/IHC). Patients must have documented radiological progression following 1–3 lines of prior therapy (must include osimertinib). Patients will receive osimertinib plus savolitinib in 28-day cycles. The primary objective is efficacy (RECIST 1.1) by overall response rate (ORR) in patients who are MET+ by central FISH. Secondary endpoints include: ORR (MET+ by central IHC and all patients); progression-free survival, overall survival, duration of response, percent change in tumor size, HRQoL, and *EGFR* mutation ctDNA clearance (MET+ by central FISH, central IHC, and all patients); safety, and pharmacokinetics (all patients). Based on the TATTON study, we anticipate enrolling ~172 patients with MET+ disease, to include ≥117 patients with MET+ disease by central FISH. Enrolment began in Q1 2019. Ongoing development of complementary trials targeting other osimertinib resistance mechanisms will also be discussed. **Result:** Section not applicable **Conclusion:** Section not applicable

P1.01-135 SALVAGE CHEMOTHERAPY AFTER IMMUNOTHERAPY FAILURE IN NON-SMALL-CELL LUNG CANCER PATIENTS

G. Randon, G. Galli, A. De Toma, F. Pagani, B. Trevisan, D. Signorelli, C. Proto, A. Prelaj, R. Ferrara, M. Ganzinelli, L. Pallavicini, R. Di Mauro, N. Zilembo, F. De Braud, M. Garassino, G. Lo Russo

Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/Italy

Background: Objective response rate (ORR) to salvage chemotherapy (sCT) in non-small-cell lung cancer (NSCLC) patients failing upfront platinum-based doublets is limited (≈5-15%). Recently, unexpected favorable outcomes have been reported for sCT upon progression to immune checkpoint inhibitors (ICIs) as compared to historical data, with ORR observed in up to 53% and 27% in Asian and Caucasian patients respectively. Few data are available regarding prior response to ICIs and sCT performance, especially in Caucasian patients. **Method:** All consecutive patients with advanced NSCLC who started ICIs at our institution from Apr 2013 to Dec 2018 were retrospectively reviewed. Patients who underwent sCT after progression to ICIs and had at least one radiological response assessment were included. ORR was calculated as the percentage of complete or partial responses according to RECIST 1.1 as best response. Survivals were estimated with Kaplan-Meier method. Correlation was assessed using Spearman's test. **Result:** Out of 283 patients included, 43 received sCT after ICIs. Among them, 29 (67%) had adenocarcinoma and 14 (37%) squamous cell carcinoma. 11 (26%) patients received sCT as second line therapy and 32 (74%) as third or more advanced treatment. sCT regimens included platinum based doublets (14; 32.5%), docetaxel or paclitaxel (20; 46.5%), and other monotherapies such as gemcitabine or vinorelbine (9; 21%). ORR to sCT was 30%. Median progression free survival and overall survival were 3.6 and 8.4 months, respectively. All patients receiving taxanes as sCT had already been treated with platinum based therapy and their ORR to sCT was 40%. ORR to upfront chemotherapy was 50%, while ORR to the last chemotherapeutic regimen prior to ICIs was 35%. ORR to sCT in pretreated patients was non-inferior to that observed in chemo-naïve ones (31% and 27%, respectively). High ORR (25%) was observed even in patients receiving sCT beyond third line. Neither response to ICIs (P=0.36) nor to prior chemotherapeutic regimens (P>0.05) were associated to the likelihood of achieving tumor response to sCT. **Conclusion:** We provide further evidence that NSCLC patients progressing to ICIs might still benefit from sCT even if heavily pretreated, regardless of sensitivity to ICIs or previous chemotherapy regimens. Further investigations are needed for uncovering bases of increased sensitivity to genotoxic agents in patients with innate or acquired resistance to ICIs and exploiting optimal treatment sequence.

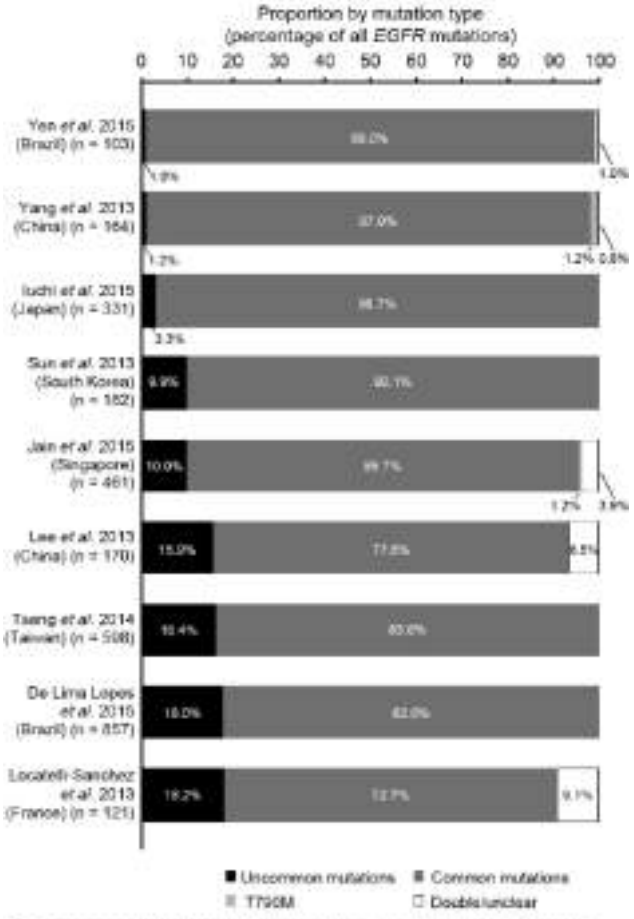
P1.01-136 UNCOMMON EGFR MUTATIONS IN NON-SMALL CELL LUNG CANCER: A SYSTEMATIC LITERATURE REVIEW OF PREVALENCE AND CLINICAL OUTCOMES

T. John[1], A. Taylor[2], H. Wang[3], D. Cripps[2], C. Eichinger[4], C. Freeman[5], M. Ahn[6]

[1]*Olivia Newton-John Cancer Research Institute, Austin Health, Heidelberg/Australia,* [2]*Oncology Business Unit, Astrazeneca Pharmaceuticals, Cambridge/United Kingdom,* [3]*Oncology Business Unit, Astrazeneca Pharmaceuticals, Gaithersburg/United States of America,* [4]*Pharmagenesis London, London/United Kingdom,* [5]*Pharmagenesis Oxford Central, Oxford/United Kingdom,* [6]*Department of Hematology and Oncology, Samsung Medical Center, Seoul/Korea, Republic of*

Background: Mutations in exons 18–21 of the epidermal growth factor receptor gene (*EGFR*) can confer sensitivity to tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer (NSCLC). About 90% of detected mutations are either deletions in exon 19 or the exon 21 L858R substitution. Comparatively few data are available on the prevalence, treatment sensitivity or clinical outcomes associated with the remaining 10%, termed 'uncommon mutations'. To collate available published evidence, we conducted a systematic literature review (SLR) focussing on these uncommon *EGFR* mutations in metastatic and locally advanced NSCLC. **Method:** Embase, MEDLINE and the Cochrane Library were searched using terms for NSCLC and *EGFR*; abstracts from relevant congresses were also reviewed. Screening identified clinical trials and observational studies published 2012–2019 that included patients with uncommon *EGFR* mutations (all mutations except exon 19 deletions, L858R and T790M). For prevalence data, only studies in which exons 18–21 were sequenced in their entirety were considered relevant; studies that used targeted methods to detect *EGFR* mutations were not included. We assessed the overall prevalence of uncommon *EGFR* mutations, and also compared response to treatment and progression-free survival (PFS) in patients with common and uncommon mutations. **Result:** In total, 20 epidemiology and 90 clinical studies met the inclusion criteria, with broad variation in geography and study population. The prevalence of uncommon mutations varied widely across studies, between 1.0% and 18.2% of all *EGFR* mutations (Figure). The most frequently reported uncommon mutations, either singly or occurring in double/triple mutations, were G719X (0.9–4.8% of all EGFR mutations), exon 20 insertions (0.8–4.2%), L861X (0.5–3.5%) and S768I (0.5–2.5%). Patients with common mutations typically experienced better treatment response and longer PFS than patients with uncommon mutations when receiving TKIs. However, there was considerable heterogeneity across studies, which is likely to result partly from variations in TKI-sensitivity between different types of *EGFR* mutations and disparities in the uncommon mutation types represented in each study. In several studies, exon 20 insertions were associated with worse outcomes than other uncommon mutations, particularly mutations in exon 18.

Figure. Uncommon *EGFR* mutation rates in the prevalence studies identified in the systematic review.



Studies reporting data that allowed calculation of the overall prevalence of common and uncommon EGFR mutations are included. The study of Yang *et al.* (2013) did not differentiate between common and uncommon exon 21 mutations, and therefore the proportion of uncommon mutations may be an underestimate.

Conclusion: This comprehensive SLR indicates that uncommon mutations may comprise a clinically significant proportion of the *EGFR* mutations occurring in NSCLC worldwide. As there are apparent disparities in TKI-sensitivity between some of the most frequently reported uncommon mutations, assessment and reporting of outcomes by specific mutation type will prove invaluable in identifying the most appropriate treatment strategy in each case.

P1.03-01 POLYMORPHISMS IN GLYCOLYSIS-RELATED GENES ARE ASSOCIATED WITH CLINICAL OUTCOMES OF PACLITAXEL-CISPLATIN CHEMOTHERAPY IN NSCLC

S.H. Choi, J. Park, S.K. Do, J.E. Choi, J.Y. Jeong, S.S. Yoo, S.Y. Lee, E. Lee, J.Y. Park

Kyungpook National University Medical Center, Buk-gu/Korea, Republic of

Background: The shift from oxidative phosphorylation to glycolysis is a hallmark of cancer cells. Rapidly proliferating cells, such as cancer cells, exhibit increased glucose uptake, enhanced glycolysis, and reduced oxygen consumption even in the presence of a normal oxygen supply, leading to the accumulation of lactate. This phenomenon, commonly referred to as the Warburg effect, is thought to occur because cancer cells must deal with increased needs for both energy and biosynthetic intermediates to support their growth and invasiveness . In this study, we hypothesized that polymorphisms in genes involved in glycolysis affect energy production, macromolecular biosynthesis, and other non-glycolytic functions in cancer cells, thus influencing the clinical outcomes of chemotherapy in patients with NSCLC. To test this hypothesis, we evaluated the association of genetic variants in the glycolytic pathway with the chemotherapy response and survival of patients with NSCLC undergoing first-line paclitaxel-cisplatin chemotherapy. **Method:** A total of 377 patients with NSCLC were enrolled. Fifty-seven single-nucleotide polymorphisms (SNPs) in 25 genes involved in the glycolytic pathway were investigated. The association of the SNPs with the chemotherapy response and overall survival (OS) were analyzed. **Result:** Among the 57 SNPs investigated, PFKL rs2073436C>G and GPI rs7248411C>G were significantly associated with clinical outcomes after chemotherapy in multivariate analyses. PFKL rs2073436C>G was significantly associated with a worse response to chemotherapy (adjusted odds ratio [aOR] = 0.64, 95% CI = 0.45–0.90, P = 0.01) and with worse OS (adjusted hazard ratio [aHR]= 1.35, 95% CI = 1.14–1.61, P = 0.001). GPI rs7248411C>G was significantly associated with both a better chemotherapy response (aOR= 1.58, 95% CI = 1.07–2.23, P = 0.02) and better OS (aHR= 0.80, 95% CI = 0.66–0.98, P = 0.03). When stratified by tumor histology, PFKL rs2073436C>G was significantly associated with OS only in squamous cell carcinoma, whereas GPI rs7248411C>G exhibited a significant association with the chemotherapy response and OS only in adenocarcinoma. **Conclusion:** This result suggests that the PFKL rs2073436C>G and GPI rs7248411C>G polymorphisms are useful for predicting the clinical outcome of first-line paclitaxel-cisplatin chemotherapy in NSCLC.

P1.03-02 NINTEDANIB SELECTIVELY INHIBITS ANGIOGENESIS INDUCED BY THE CONDITIONED MEDIUM OF LUNG ADENOCARCINOMA TAFS IN VITRO

N. Díaz-Valdivia[1], P. Duch[1], R. Ikemori[1], M. Gabasa[1], F. Hilberg[2], N. Reguart[3], J. Alcaraz[4]

[1]*Universidad de Barcelona, Barcelona/Spain,* [2]*Boehringer Ingelheim RCV GmbH Co KG, Vienna/Austria,* [3]*Hospital Clinic Barcelona, Barcelona/Spain,* [4]*University of Barcelona - Faculty of Medicine, Barcelona/Spain*

Background: Nintedanib is an antifibrotic and antiangiogenic drug that was clinically approved to treat EGFR-wild-type lung adenocarcinoma (ADC) patients based on the positive therapeutic results elicited in combination with docetaxel in the LUME-Lung1 clinical trial in ADC but not in squamous cell carcinoma (SCC) patients. However, the mechanisms underlying the selective therapeutic effects of nintedanib in ADC remain poorly understood. Tumor-associated fibroblasts (TAFs) are the most abundant stromal cell type and have been implicated in all steps of tumor progression, including growth, angiogenesis, invasion, metastasis and resistance to therapies. Of note, we recently reported that nintedanib elicits larger antifibrotic effects in ADC-TAFs compared to SCC-TAFs *in vitro*. However, the antiangiogenic effects of nintedanib in TAFs remain unknown. **Method:** ADC-TAFs and SCC-TAFs were activated with TGF-β1 in the presence or absence of nintedanib, and the corresponding conditioned medium was used to stimulate endothelial cells (HUVECs and HMVECs) to either migrate or form vascular networks on Matrigel. **Result:** Our results showed that the conditioned medium from ADC-TAFs and SCC-TAFs induced an increase in human endothelial cell migration. In contrast, the conditioned medium from ADC-TAFs promoted an increase in angiogenesis that was selectively inhibited by nintedanib, whereas such inhibition was not observed in SCC-TAFs. **Conclusion:** Our results reveal that nintedanib inhibits the pro-angiogenic effects elicited by factors secreted by ADC-TAFs but not SCC-TAFs, thereby supporting that angiogenesis may be regulated by TAFs through distinct mechanisms in ADC and SCC.

Keyword: Angiogenesis, TAFs, nintedanib

P1.03-03 INHIBITION OF H1299 LUNG CANCER CELL PROLIFERATION AND SURVIVAL BY ROSEMARY EXTRACT IS ASSOCIATED WITH AMPK ACTIVATION

E. Tsiani

Brock University, St. Catharines/Canada

Background: Non-small cell lung cancer (NSCLC) represents around 80% of all lung cancer cases and is characterized by low survival rates due to chemotherapy and radiation resistance. New treatments to inhibit NSCLC cell proliferation and survival are urgently needed. The energy sensor AMP-activated protein kinase (AMPK) is a serine/threonine kinase that plays a critical role in cancer cell metabolism, proliferation and survival. Activated AMPK leads to downstream inhibition of the mammalian target of rapamycin (mTOR) and p70S6K resulting in inhibition of protein synthesis and proliferation. Compounds of plant origin have attracted scientific attention for use as agents for cancer prevention and treatment. Rosemary extract (RE) has been shown to have anti-cancer effects. The objectives of the present study were to examine the effects of RE on H1299 human NSCLC cell proliferation and survival, and to investigate its effects on AMPK and its downstream signaling pathways which regulate cell growth and survival. **Method:** Cell proliferation was measured using the crystal violet assay, clonogenic assays were performed to examine the effects of RE on cell survival and immunoblotting with specific antibodies was performed to examine signaling events. **Result:** RE dose-dependently inhibited H1299 cell proliferation and survival. Maximum inhibition of H1299 cell proliferation (30.7±3.0% of control, p<0.001) was seen with 25μg/mL of RE. In addition, significant inhibition (42.3±1.9 % of control, p<0.001) of cell survival was seen with 2.5 μg/mL RE while 10 μg/mL RE caused near complete inhibition of survival (0.8±0.6% of control, p<0.001). AMPK phosphorylation levels were significantly increased by RE treatment. **Conclusion:** Our data indicate that treatment with RE significantly inhibits NSCLC cell proliferation and survival. AMPK phosphorylation/activation is significantly increased by RE treatment and the effects on signaling molecules downstream of AMPK are under investigation. Overall, our data suggest that RE may have potent anticancer properties in NSCLC and warrants further investigation.

P1.03-04 USE SUPERNATANT OF MALIGNANT PLEURAL EFFUSION TO IDENTIFY DRIVER MUTANTS AND MONITOR RESPONSE TO TARGETED THERAPY

Y. Wang[1], S. Xiao[2], R. Lin[2], R. Mao[2], T. Wang[2]

[1]*The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou/China,* [2]*Hangzhou Repuegen Technology Co., Ltd., Hangzhou/China*

Background: Malignant pleural effusion (MPE) from patients with non-small cell lung cancer (NSCLC) is useful for genetic testing due to advantages including availability, less-invasiveness, and less-heterogeneity. Generally, cell pellets of MPE are used. This study is to further address whether supernatant of MPE is a suitable source to identify key oncogenic mutants in NSCLC patients and provide evidence for clinical molecular testing. **Method:** MPE samples from 12 NSCLC patients were centrifuged to obtain supernatants and cell pellets, and DNA were extracted. The DNA samples were analyzed by next generation sequencing (NGS) panels using Illumina HiSeq platform. **Result:** First, MPE samples with the corresponding cancer tissues were collected from 3 NSCLC patients and analyzed with a 500-gene comprehensive cancer panel. Nine mutants were identified

in both the paired MPE and cancer tissue samples. We then analyzed nine more NSCLC patient samples using an 18-gene panel to detect key oncogenic mutants; in total, 8 mutants including EGFR L858R, 19DEL, or T790M were identified in the MPE samples. For all of the 17 mutants from the 12 MPE samples, 10 mutants were observed in both the supernatants and pellets of the matched sample sets, of which more pairs (6 out of 10) had supernatants with higher abundance of mutants than the corresponding cell pellets. Importantly, 7 of the 17 mutants were detected only in the supernatants but not the pellets of the paired MPE samples. These results suggest that supernatant of MPE is a better source to detect key oncogenic mutants of NSCLC. Interestingly, 2 patients had both sensitive and resistant mutants to EGFR tyrosine kinase inhibitor (TKI) detected in supernatants of MPE; both patients had treated with EGFR TKI previously, suggesting the development of TKI resistant mutant and supporting the usage of MPE supernatants in monitoring TKI resistance. **Conclusion:** This study demonstrates that supernatant of MPE is a suitable source for identifying key oncogenic driver mutants for NSCLC and can also be used to monitor response to targeted therapy. The study provides evidence of using supernatant of MPE as an alternative for molecular testing and thus direct precise targeted therapy and surveillance of the therapy effect.

Keywords: Pleural effusion, supernatant, mutant

P1.03-05 COMMD4 IN LUNG CANCER: TOWARDS A NEW THERAPEUTIC TARGET AND DIAGNOSTIC BIOMARKER

A. Suraweera, M. Adams, C. Jekimovs, D. Richard, K. O'Byrne

Translational Research Institute, Brisbane/Australia

Background: Lung cancer has the highest incidence and mortality among all cancers. As resistance to the current therapies are inevitable, there is a great need to identify new therapeutic targets. In order to prevent cancer, cells possess a complex network of signalling pathways called the DNA damage response, which is involved in the detection, signalling, and subsequent repair of DNA. Failure of the DNA damage response results in cancer and tumorigenesis. The aims of this study were to investigate the therapeutic potential of COMMD4, a new protein within the DNA damage response, in lung cancer. **Method:** The expression of COMMD4 in squamous and nonsquamous non-small cell lung cancer was investigated using bioinformatics, qPCR, lung cancer TMAs and immunoblotting experiments from immortalised human bronchial epithelial cell (HBEC) and lung cancer cell lines. We investigated the function of COMMD4 using *in vitro* assays in HBEC and lung cancer cells that were depleted of COMMD4 using siRNA. **Result:** The *COMMD4* gene was found to be upregulated in lung cancer cells compared with the non-malignant tissue. High levels of *COMMD4* correlated with poor patient prognosis. Additionally, COMMD4 protein levels were upregulated in some lung cancer cells compared with the control HBEC cell line and COMMD4 protein was increased in NSCLC tissue. The depletion of COMMD4 markedly reduced the proliferation of NSCLC cells and not the control cell line. Furthermore, COMMD4-depleted cells were hypersensitive to DNA damaging chemotherapeutic agents which are currently used in the clinic and these agents lead to the induction of apoptosis and mitotic catastrophe in COMMD4-depleted cells. **Conclusion:** Taken together, our data suggests COMMD4 as a potential therapeutic target and diagnostic biomarker in lung cancer, through the induction of cell death and inhibition of tumour growth.

Keywords: DNA damage response, Lung cancer, COMMD4

P1.03-06 INTEGRATIVE OMICS ANALYSIS REVEALS IMPORTANT ROLES OF ADENOSINE DIPHOSPHATE IN HAEMOSTASIS AND PLATELET ACTIVATION IN NSCLC

L. Hoang[1], C. Domingo-Sabugo[1], E. Starren[1], S. Willis-Owen[1], A. Nicholson[1,2], D. Morris-Rosendahl[1], M. Moffatt[1], W. Cookson[1]

[1]*National Centre for Mesothelioma Research, Imperial College London, London/United Kingdom,* [2]*Royal Brompton and Harefield NHS Trust, London/United Kingdom*

Background: Lung cancer is the leading cause of cancer-related deaths in the world. The most prevalent subtype, accounting for 85% of cases, is non-small cell lung cancer (NSCLC). Lung squamous cell carcinoma (LUSC) and lung adenocarcinoma (LUAD) are the most common subtypes. Despite recent advances in treatment, the low 5-year survival rate of NSCLC patients (approximately 13%) reflects the lack of early diagnostic biomarkers and incomplete understanding of the underlying disease mechanisms. **Method:** We hypothesised that integration of metabolomic, transcriptomic and genetic profiles of tumours and matched normal tissues could help to identify important factors and potential therapeutic targets that contribute to tumorigenesis. We integrated omics profiles in tumours and matched adjacent normal tissues of patients with LUSC (N = 20) and LUAD (N = 17) using multiple system biology approaches. **Result:** We confirmed the presence of previously described metabolic NSCLC pathways, particularly those mediating the Warburg effect. In addition, through our combined omics analyses we found that metabolites and genes that contribute to haemostasis, angiogenesis, platelet activation and cell proliferation were predominant in both subtypes of NSCLC. **Conclusion:** The important roles of adenosine diphosphate (ADP) in promoting cancer metastasis through platelet activation and angiogenesis suggests this metabolite could be a potential therapeutic target.

Keywords: NSCLC, Metabolomic, Transcriptomic

P1.03-07 ADVANTAGES AND SETBACKS OF EGFR MUTATION TESTING FROM LIQUID BIOPSY OF ADVANCED LUNG ADENOCARCINOMA PATIENTS IN SERBIA

J. Spasic, A. Krivokuca, I. Boljevic, M. Pavlovic, J. Rakobradovic, V. Jokic, D. Radosavljevic, E. Malisic, R. Jankovic, M. Cavic

Institute for Oncology and Radiology of Serbia, Belgrade/Serbia

Background: With approximately 8000 newly diagnosed cases in 2018, lung cancer has become the most common malignant disease in Serbia. *EGFR* gene mutation testing as companion diagnostic for treatment with tyrosine kinase inhibitors (TKIs) has been introduced in 2011 in Serbia only for advanced lung adenocarcinoma patients. In 2016. additional *EGFR* mutation testing was employed from liquid biopsy samples of patients who have progressed on TKIs or whose biopsies were unavailable for initial testing. **Method:** *EGFR* mutation testing was performed from FFPE tumor samples or glass slides of advanced lung adenocarcinoma patients (stage IIIB or IV, and ECOG performance status 0, 1 or 2,) using the Cobas® EGFR Mutation Test. Patients with sensitizing *EGFR* mutations were treated with first generation TKIs until progression. Resistance to TKI was tracked from liquid biopsy samples (10 mL of plasma) of patients who progressed in the first three months of first-line TKI treatment. **Result:** In the period between 2011-2018, 4750 *EGFR* mutation analyses were performed, with around 11% of mutated samples detected, which is in good accordance with literature data for the Caucasian population. Although *EGFR* mutation testing has been successfully implemented in routine management of lung cancer patients in Serbia with an average turnaround time of 5 working days, we still had approximately 3% of tumor samples with insufficient material for successful DNA isolation. In such cases, 124 plasma samples were tested, and 9 mutations were detected (7.3 % of total) with a turnaroud time of 2 days, and a 99.2 % testing success rate. Testing liquid biopsy samples of 104 patients who progresses on first-line TKIs showed an accordance rate of 93 % with driver mutations, and 34 patients (33% of total) had the T790M mutation which rendered them eligible for third-generation TKIs in Serbia. Additional 2 patients who tested *EGFR* wt from plasma and were rebiopsied proved to have the T790M mutation as well. **Conclusion:** In developing countries, testing from circulating tumor DNA, as an alternative sample source for patients with scarce biopsy material or without any at all is an acceptable cost/benefit option. However, routine monitoring of molecular disease progression from liquid biopsy before clinical progression occurs has still not been implemented in Serbia for economic reasons.

P1.03-08 RNF43 UBIQUITINATES AND DEGRADES PHOSPHORYLATED E-CADHERIN BY C-SRC TO FACILITATE EPITHELIAL-MESENCHYMAL TRANSITION IN LUNG ADENOCARCINOMA

Y. Zhao

Second Affiliated Hospital of Xi'an Jiaotong University, Xi'an/China

Background: In epithelial cells, tyrosine kinases induce tyrosine phosphorylation and ubiquitination of the E-cadherin complex, which is responsible for the epithelial-mesenchymal transition (EMT). However, the precise mechanisms remain unclear. **Method:** Protein antibody microarray was applied to identify the potential E3 ligase to downregulate E-cadherin. EMT was determined by morphology, epithelial-mesenchymal markers and aggressive behavior *in vivo*with the lung adenocarcinoma cell lines and tissues. The molecular biological methods including western blotting, immunoprecipitation, MALDI-Mass, immunohistochemistry, et al were applied to explore the signaling of RNF43-mediated EMT. **Result:** Protein antibody microarray and E3 ligase profiling revealed that RING finger protein 43 (RNF43) is linked with E-cadherin downregulation within the context of c-Src activation in lung adenocarcinoma tissues. In addition, c-Src-Caspase-8 interaction markedly increased c-Src activity. Activated c-Src phosphorylated E-cadherin at the tyrosine 797 site to initiate RNF43-mediated E-cadherin ubiquitination at lysine 816 and subsequent degradation, thus freeing β-catenin into the nucleus to upregulate Vimentin and RNF43 in lung adenocarcinoma cell. Decreased E-cadherin and increased Vimentin induced EMT phenotype and promoted tumor metastasis. Frizzled 8 (Frz8)-RNF43 induced ubiquitination of phosphorylated E-cadherin was blocked by monoclonal antibody against the cysteine-rich domain (CRD) of Frz8 but not by antibodies against the protease domain (PA) of RNF43. **Conclusion:** Our data suggest that RNF43 participates in the regulation of EMT in the metastasis of lung adenocarcinoma, through ubiquitination and degradation of phosphorylated E-cadherin by activated c-Src.

Keywords: Caspase-8, RNF43, c-Src

P1.03-09 ATYPICAL UBIQUITIN AS A MOLECULAR TARGET IN LUNG CANCER

S. Nakazawa, K. Shimizu, T. Ibe, K. Obayashi, N. Kawatani, T. Yajima, K. Shirabe

Gunma University Hospital, Maebashi/Japan

Background: Atypical ubiquitin is a newly identified type of posttranslational modification. Although the role of most atypical ubiquitins remains unknown, linear ubiquitin (M1Ub) was shown to regulate activation of NFkB signaling. M1Ub is specifically assembled by an enzyme complex known as linear ubiquitin chain assembly complex (LUBAC), composed of the proteins HOIP, HOIL-1L, and Sharpin. Since the role of M1Ub and LUBAC in lung cancer is unclear, our study aimed to identify the potential value of LUBAC as a molecular target in lung cancer. **Method:** We searched for lung cancer cell lines with high LUBAC expression. We inhibited LUBAC activity by siRNA or CRISPR/Cas9 and analyzed effect on tumor proliferation, migration, and tumor formation. We also analyzed prognostic impact of LUBAC expression in lung cancer patients and searched for mutations known to activate LUBAC activity. **Result:** Several adenocarcinoma cell lines showed high LUBAC expression. LUBAC inhibition resulted in lower proliferation, migration, and tumor formation, partly via activation of NFkB and ERK signaling. LUBAC knockdown also showed increased apoptosis via activation of caspases. The expression of LUBAC was a significant prognostic factor in survival of lung adenocarcinoma patients. Few patients were identified with a mutation of HOIP related to LUBAC formation, resulting in high LUBAC expression. **Conclusion:** We identified that LUBAC components regulate proliferation, migration, and apoptosis in certain lung cancer cell lines. LUBAC expression was also associated with prognosis of lung cancer. LUBAC components may become a potential treatment target in lung cancer.

Keywords: Lung cancer, ubiquitin

P1.03-10 HIGH-RISK GROWTH PATTERNS OF LUNG ADENOCARCINOMA SHOW DISTINCT MODES OF METASTASIS AND RECURRENCE

M. Sereno[1,2], C. Smith[1,2], J. Le Quesne[1,2]

[1]*University of Cambridge, Leicester/United Kingdom,* [2]*University of Leicester, Leicester/United Kingdom*

Background: Following curative surgery for non-small cell lung cancer, around half of patients ultimately succumb to recurrent/metastatic disease. This may occur in many ways, such as recurrence at the surgical site, within the pleura, or by metastatic spread via lymphatics or blood vessels. This study aims to identify tumour-intrinsic pathological risk factors which predict particular modes of recurrence of lung adenocarcinoma, to improve our understanding of both the clinical course of disease and the biology underlying tumour recurrence. **Method:** A single-centre cohort of 1025 patients who had surgically resected primary lung adenocarcinoma between the years of 1998 and 2015 was used. Full clinicopathological data were collected from patient records and slide review. All available radiology image data were examined to identify first recurrence site(s) for each case; these were grouped as surgical site, ipsilateral lung, ipsilateral pleura, nodal recurrence and distant recurrence. 824 cases with complete recurrence data were included in the final analysis. Univariate and multivariate Cox models of time to recurrence after surgery for each recurrence site were constructed. Depending on recurrence site, models included growth pattern (predominance or presence), tumour size, nodal involvement, vascular invasion, pleural involvement, surgical procedure and R stage. **Result:** 408 patients (49.5%) had recurrent disease, with 200 (24.2%) patients showing simultaneous recurrence at multiple sites. Of the patients who developed recurrences, 99 (24.3%) recurred at the surgical site. 118 (28.9%) patients recurred within the ipsilateral lung and 75 (18.4%) within the ipsilateral pleura. There were 168 instances of nodal recurrence, most often within N2 lymph nodes (n=95, 56.5%). 316 cases of distant recurrence were reported, with the most common sites being the contralateral lung (n=110, 34.8%), bone (n=71, 22.5%) and brain (n=67, 21.2%). Distant recurrence is associated with significantly shorter post-recurrence survival (PRS) than locoregional recurrence (50% PRS 7.9 vs. 11.1 months, P=0.008). Surgical site recurrence is related to subanatomical wedge resection (HR=4.98, 95% CI: 2.45-10.12, P<0.001), tumour size (HR=1.01, 95% CI: 1.00-1.03, P=0.042) and positive resection margins (HR=4.05, 95% CI: 2.01-8.15, P<0.001). Ipsilateral pleural recurrence is strongly predicted by advancing PL stage (PL2 vs. PL0, HR=2.61, 95% CI: 1.18-5.77, P=0.018; PL3 vs. PL0, HR=3.74, 95% CI: 1.64-8.51, P=0.002). Notably, recurrence in the ipsilateral lung (HR=2.08, 95% CI: 1.29-3.35, P=0.003) and nodal recurrence (HR=2.11, 95% CI: 1.29-3.46, P=0.003) are both independently predicted by the presence of any micropapillary component of tumour growth. In contrast, distant recurrence is related to solid pattern predominance (HR=2.50, 95% CI: 1.43-4.35, P=0.001) univariately, and with near independence in multivariate analysis (HR=1.79, 95% CI: 0.99-3.24, P=0.054). In multivariate models, only solid-predominant tumours are significantly associated with recurrence in the brain (HR=8.52, 95% CI: 1.13-64.01, P=0.037). **Conclusion:** We present evidence that the two high-risk patterns of tumour growth, solid and micropapillary, have predilections for recurrence/metastasis via haematogenous and lymphatic vascular systems respectively. This distinction raises important biological questions about mechanisms of tumour spread, and may help to inform future treatment and prevention strategies.

P1.03-11 MOLECULAR TESTING OF SMALL BRONCHOSCOPY SPECIMENS USING NANOSTRING TECHNOLOGY

B. Parris, I. Yang, R. Bowman, K. Fong

The Prince Charles Hospital, Chermside/Australia

Background: Molecular testing for driver variants in oncogenes is crucial for NSCLC management to predict response to targeted therapy. In the majority of cases, NSCLC is diagnosed by trans-thoracic needle aspiration or more commonly bronchoscopy techniques resulting in small diagnostic tissue biopsies or cytological samples. As such specimens may be inadequate for molecular testing, we tested the accuracy of a novel digital molecular barcoding

assay to detect actionable mutations in a single-centre cohort. **Method:** A consecutive cohort of 46 specimens (19 endobronchial biopsy, EnBx; 18 transbronchial biopsy, TBBx; seven bronchoalveolar lavage, BAL; and two transbronchial needle aspirate, TBNA) were obtained ancillary to primary diagnostic specimens from 36 patients undergoing EBUS-guided bronchoscopy at The Prince Charles Hospital. Specimens containing at least 5ng DNA after standard column-based extraction methods were analysed using the NanoString SNV Solid Tumour Panel for testing of 104 somatic variants across 25 genes of clinical significance. NanoString variants calls were compared with routine clinical testing results from the primary diagnostic sample. Agreement analyses for variants common to both methods revealed the positive, negative and overall percentage agreement (PPA, NPA, OPA). One discordant case was validated using droplet digital PCR. **Result:** Using NanoString, molecular analysis was feasible for 60.1% (28/46) of specimens. At least one variant was identified in 8/28 (28.6%) cases (Table 1). Two (7.1%) cases harboured dual mutations. *KRAS* mutations were detected in six (21.4%) cases, and *EGFR* in two (7.1%). Two patients would be eligible for targeted therapy. Agreement analysis for the two methods revealed PPA, NPA and OPA of 100%, 88.9% and 92.3%. In one discordant case, NanoString identified a *KRAS* G12C mutation and was confirmed by ddPCR with a mutant allele frequency of 5.5%. The mean time for reporting clinical mutation test results was 19.6 days. Of the 18 excluded cases with insufficient DNA, five had routine testing results for comparison however 3/5 cases cited insufficient DNA for reliable *EGFR* testing.

Table 1: Clinical and molecular characteristics of bronchoscopy samples used for molecular testing

Mean			2.58			19.6		

Conclusion: The performance of the NanoString platform for SNV characterisation was highly concordant with alternate clinical testing methods for those with sufficient DNA. Advantages of NanoString include its multiplex capacity, high sensitivity, low nucleic acid input, reduced turn-around time (<24hr) compared to alternate testing methods. The NanoString platform is a robust method for identification of actionable variants in NSCLC where at least 5ng of DNA is available.

P1.03-12 PRECLINICAL VALIDATION OF AN EPIGENETIC PANEL OF SEVEN MIRNAS AT EARLY STAGES NSCLC PATIENTS AND ITS PROGNOSTIC IMPLICATIONS

D. Sanchez Cabrero[1], P. Cruz[2], O. Pernia[2], O. Vera[1], I. Esteban[1], R. Rosas[1], J. Jimenez[1], I. Losantos[1], J. De Castro Carpeno[3], I. Ibañez[1]

[1]*University Hospital La Paz, Madrid/Spain,* [2]*University Hospital La Paz, MADRID/Spain,* [3]*Hospital Universitario La Paz, Madrid/Spain*

Background: Despite radical intent, many patients in early stages of NSCLC will recur. There is a need to find novel biomarkers able to help to identify patients in higher risk. Previous results from our group provide a miRNA signature from "*in vitro*" studies that might be involved in worst prognosis in NSCLC patients (PMID: 29158814). The main objective of this work is to analyse and compare the miRNA seven-panel signature in paired plasma (CIRmiARN) and tumor tissue samples (TmiARN) obtained from early stages NSCLC patients and to study the clinical implications. **Method:** We conducted a descriptive study including 16 paired samples of patients diagnosed with early stage NSCLC. Both RNA from fresh tissue and plasma were extracted and the seven mRNAs levels were measured by qRTPCR(miR-7, -132, -335, -148, -10a, -124 and -9). Association between qualitative variables was analyzed using the chi-square test or Fisher's exact test. Mann-Whitney U test and the t-student test were used for qualitative and quantitative data comparison. A Kaplan Meier survival analysis (log-rank analysis) was carried out to study the overall survival and progression-free survival. Patients were also clustered in terms of tissue and plasma values, and then subgroups analyzed in terms of Survival. Difference between groups was analyzed with Cox Regression. **Result:** There was no association between CIRmiARN and TmiARN expression levels and between clinical parameters. We found significant data associated with three miRNAs. There were significant differences ($p<0.05$) with low TmiR-132 expression level and worse survival and also a clear trend towards the group of patients with high levels of CIRmiR-7 and CIRmiR-124 and worst survival. Interestingly, we found an inverse correlation between CIRmiARN-132 and -124($p<0.05$). Patients clustered regarding TmiR132 and CIRmiR-124 and -7levels, segregate in three clusters statistically significant in terms of survival ($p<0.005$), identifying a group of patients with a reduced risk of 78,6% (Hazard Ratio of 0.214 p<0,005). **Conclusion:** Many patients diagnosed in early stages of NSCLC present a tumor relapse during the first 5 years. Genetic and epigenetic profiles help us to identify tumors with a greater risk of recurrence. In our study, we have identified three potential molecular candidates, both in liquid and tissue biopsies, which could have potential clinical use stratifying patients with higher risk of recurrence. Further studies will be needed to gain insight into the prognostic impact of these biomarkers in early and advanced stages NSCLC patients.

P1.03-13 GENOMIC LANDSCAPE OF BRAZILIAN NON-SMALL CELL LUNG CANCER

L. Leal[1], P. De Marchi[1], L. Sussuchi Da Silva[1], F. Ferreira Da Silva[1], L. Campanha Novaes[1], Y. Camargo Rodrigues[1], W. Dos Santos[1], E. Albino Da Silva[1], A. Evangelista[1], R. Reis[1,2,3]

[1]*Barretos Cancer Hospital, Barretos/Brazil,* [2]*University of Minho, Braga/Portugal,* [3]*ICVS/3B's-PT Government Associate Laboratory, Braga/Guimarães/Portugal*

Background: Non-Small Cell Lung Cancer (NSCLC) is the most common type of lung cancer with low survival rates. Therefore, NSCLC patients may be benefited by tailored treatment based on genomic profiling. However, the genomic landscape of Brazilian NSCLC remains unknown. Thus, our aim was to evaluate the genomic profiling of NSCLC of a Brazilian series. **Method:** We analyzed 96 NSCLC patients from Barretos Cancer Hospital, Brazil. Exome sequencing of paired tumor/blood DNA was performed by Illumina HiSeq2500™ and VarScan was applied for germline alterations exclusion, variant calling, and annotation. Cancer Genome Interpreter was employed for identification of driver genes. Mutational Signatures were performed using Somatic Signature. Copy Number Variations (CNV) were determined using Circular Binary Segmentation. Gene expression analysis was assessed by NanoString and pathway enrichment was performed using KEGG. **Result:** Overall, 61 cases were adenocarcinomas, 34 squamous cell carcinomas and 1 was adenosquamous (I, n=19; II, n=14; III, n=23; IV, n=40). Regarding smoking, 82 patients were current/former smokers and 12 patients were never smokers and most of the cases presented the mutational signature 4. More than 30,000 mutations were identified and 733 were classified as drivers (known: 90; predicted: 643). *TP53* gene was the most recurrently mutated gene (56% of the cases). Besides of *TP53* gene, recurrent mutations were found in *KRAS* (23%), *EGFR* (12.5%), *NFE2L2* (9%), *HERC2* (9%), *STK11, ROS1, PIK3CA and CDKN2A* (8%). *KRAS*, *EGFR, STK11* and *ROS1* mutations were mutually exclusive. CNV gain was observed in 1q21.3, 1q22, 3q26, 31q29, 7q11.21, 7p11.1-q11.1, 8p11.1-q11.1, 19q13. Downregulation of *DKK1, IBSP, LAMC2, NGFR* and *LAMB3* and upregulation of *LAMC3, MAPK8IP1, IL5RA, NR4A1, AXIN2, PLA2G4E, COL6A6, CACNA2D2, LRP2, NR4A3, FOS, BMP5*, and *FGFR2* were observed in disease stages I/II indicating enrichment of PI3K-Akt, MAPK, Ras, Rap1 and Wnt signaling pathways. Downregulation of *MCM2, VEGFA, E2F1, HMGA1, CCNE1, CHEK1, RAD51, FOSL1, CCNB1, GNG4, IL11* and *IL8* and upregulation of *WNT10B, MAPK10, GNG7, WNT4, IL7R, PIK3CG*, and *FGFR2* were observed in never smokers indicating enrichment of Cell cycle, Pathways in cancer and PI3K-Akt signaling. Differential expression of *KRAS*-mutated tumors indicated enrichment of ECM-receptor interaction, Focal adhesion, and PI3K-Akt pathway and *TP53*-mutated tumors indicated enrichment of Cell Cycle. **Conclusion:** The genomic profiling of Brazilian NSCLC indicated remarkable driver mutations and genomic amplifications. Gene expression profiling indicates the enrichment of key pathways enrolled in *TP53*- and *KRAS*-driven tumors. Our results may contribute for improving the knowledge about the molecular pathogenesis of Brazilian NSCLC.

Background: Cisplatin and cetuximab have little effect in head and neck squamous cell carcinoma (HNSCC) and lung squamous cell carcinoma (LSCC). HLA-E expression suppressed the cetuximab effect and HLA-E is overexpressed in both HNSCC and LSCC. In addition, FAT1 inactivating mutations are present in 30% of HNSCCs and 19% of LSCCs. Dihydroartemisinin (DHA) inhibits STAT3 and increases cisplatin effect in HNSCC. Osimertinib and olmutinib increase intracellular accumulation of doxorubicin by blocking the efflux function of ABC transporters. We posit that osimertinib or olmutinib, plus DHA, could have activity in the HNSCC cell lines, FaDu and CAL27, with loss of FAT1 expression. **Method:** Osimertinib and olmutinib plus DHA were tested in the FaDu and CAL27 cell lines. Tumor cell proliferation assays (MTTs) and mouse xenografts were performed, and western blotting analysis was carried out. FaDu CTXR clone #3 (cetuximab-resistant, a gift from Bhola) and SCCNC4

(EGFR exon 20 S768_D770 dup, a gift from Hermsen) were also examined. **Result:** 1. DHA decreased HLA-E protein levels in a dose dependent manner in the FaDu CTXR. 2. DHA was able to induce the expression of FAT1 in FaDu and CAL27 cells. 3. Osimertinib plus DHA had a synergistic effect (<1, Combination index (CI)=0.468 and 0.593 in FaDu and CAL27, respectively). Olmutinib with DHA was also synergistic (CI=0.773 and 0.762 in FaDu and CAL27). 4. Osimertinib plus DHA was validated in vivo in FaDu and CAL27 mice xenografts with significant tumor regression. 5. Osimertinib plus DHA suppress the expression of onco-effectors: STAT3, Src, YAP and AXL. 6. Osimertinib plus DHA was also synergistic in SCCNC4 (CI=0.596). **Conclusion:** The findings indicate that DHA can revert resistance to cetuximab by repressing the expression of HLA-E. The combination of DHA plus osimertinib was active in the parental FaDu, but not in FaDu CTXR. For tumors with lack of FAT1 expression, the use of DHA reactivates FAT1 and YAP1 inhibition was noted. DHA has been tested for the treatment of systemic lupus erythematosus (SLE), orally, daily for 2 years. The results encourage development of clinical trials with DHA to re-sensitize HNSCC and LSCC cells to cetuximab-based therapy.

Background: ALK inhibitors have led to important improvements in ALK-positive non-small cell lung cancer (NSCLC) patient's survival and quality of life. However, despite the good responses, resistance mutations inevitably emerge. Several resistance mutations in ALK domain have been describe. Remarkably different mutations can confer different sensitivities to different ALK inhibitors. However, 2nd and 3rd line treatment is often prescribe empirically without knowing the molecular mechanism underlying treatment failure. **Method:** 21 samples from ALK-positive NSCLC patients were collected at disease progression. Circulating Nucleic Acids were isolated from platelets, exosomes and plasma. Libraries were prepared using 20ng of template and Oncomine™ Pan-Cancer Cell-Free Assay. Samples were sequenced on an Ion GeneStudio S5 Plus System. Sequencing data was first analyzed using Torrent Suite software. Subsequently variant calling, annotation and filtering was performed on the Ion Reporter (v5.10) platform using the Oncomine TagSeq Pan-Cancer Liquid Biopsy w2.1 workflow. **Result:** In 14 (67%) patients a somatic mutation was identified in the plasma sample collected at disease progression. The average number of mutations detected per sample was 2.6. Noteworthy, 14 mutations were found in oncogenes that have been previously associated with ALK inhibitors resistance (5 mutations in ALK locus, 4 mutations in PIK3CA, 1 mutation in EGFR, 1 mutation in KIT, 1 mutation in KRAS, 1 mutation in MTOR and 1 mutation in MYC). The rest of mutations (N=21) were found in TP53 gene. Secondary resistance mutation in ALK locus occurred in 24% of the cases. Specifically, p.G1269A (N=2), p.G1202E (N=1), p.R1275Q (N=1) mutations were found in ALK-positive NSCLC who had progressed on crizotinib and p.G1202R mutation was found in 1 ALK-positive NSCLC who had progressed on ceritinib. **Conclusion:** Secondary ALK-TKI resistance mutations could be detected using liquid biopsies in a high proportion of patients. Non-invasive molecular profiling of samples collected at disease progression is feasible being useful for further treatment selection in ALK-positive NSCLC patients.

P1.03-16 ANTI-TUMOR EFFECT OF PAN-RAF INHIBITOR IN NSCLC CELLS HARBORING BRAF MUTATION

S. Miyauchi, K. Shien, K. Araki, K. Nakata, A. Miura, K. Namba, K. Suzawa, H. Yamamoto, M. Okazaki, S. Tomida, S. Toyooka

Okayama University Hospital, Okayama/Japan

Background: *BRAF* mutation occurs in 0.5-3% of lung adenocarcinoma and acts as an oncogenic driver. Dabrafenib (BRAF inhibitor) combined with trametinib (MEK inhibitor) has shown substantial antitumor effect in patients with non-small-cell lung cancer (NSCLC) harboring *BRAF* V600E mutation. However, in patients with NSCLC harboring *BRAF* non-V600E mutation, there are few reports of effective targeted therapy. LY3009120, a newly discovered pan-RAF inhibitor, showed strong anti-tumor effect in *BRAF*-mutant cancers, such as melanoma, colorectal and pancreatic cancers in preclinical studies. In this study, we evaluated the anti-tumor effect of LY3009120 in *BRAF*-mutant NSCLC cells. **Method:** We examined the sensitivity of LY3009120 against normal bronchial cells BEAS-2B which ectopically overexpressing wild-type or mutant *BRAF*. Human cDNAs encoding full-length *BRAF* (wild-type and its variants V600E and G469V) were inserted into the pIDT-SMART (C-TSC) vector, pCMViRTSC. In addition, we treated four *BRAF*-mutant NSCLC cell lines, one *BRAF*-mutant colorectal cancer cell line, and one *KRAS*-mutant cell line with LY3009120. The type of *BRAF* mutation consisted of V600E, L597V, G469A, and G466V. We determined cell proliferation by MTS assay and calculated the IC50 values. We also performed Western blotting to investigate downstream signaling pathways. **Result:** BEAS-2B cells ectopically overexpressing wild-type BRAF or mutants (V600E and G469V) showed constitutive auto phosphorylation of BRAF and activation of downstream signaling by Western blotting. The IC50 values in *BRAF* mutant cell lines ranged from 9.4nM to 1,193nM, which suggests strong anti-tumor effect of LY3009120. This effect was observed regardless of the type of *BRAF* mutation, including non-V600E mutation. On the other hand, LY3009120 did not show anti-tumor effect in *KRAS*-mutant cell (IC50 value, 6,948nM). LY3009120 suppressed the phosphorylation of downstream MEK and ERK activation in *BRAF*-mutant cell lines by Western blotting. **Conclusion:** LY3009120 showed strong anti-tumor effect in NSCLC cells harboring *BRAF* mutation regardless of the type of mutation, suggesting that LY3009120 can be a promising therapeutic option in the treatment of NSCLC harboring *BRAF* mutation.

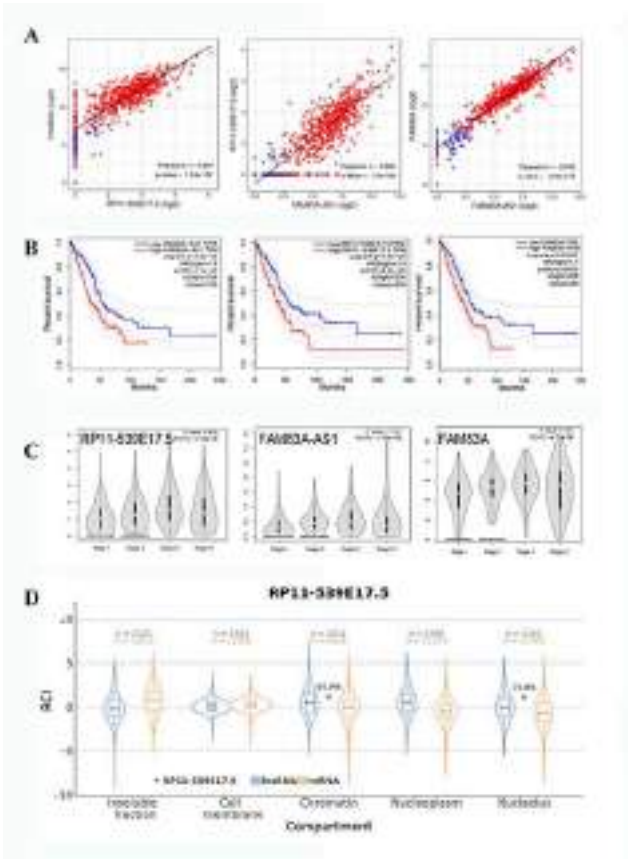
P1.03-17 FUNCTION OF ANTISENSE LNCRNA RP11-539E17.5 AND FAM83A-AS1 UP-REGULATING FAM83A IN LUNG ADENOCARCINOMA TUMORIGENESIS AND DEVELOPMENT

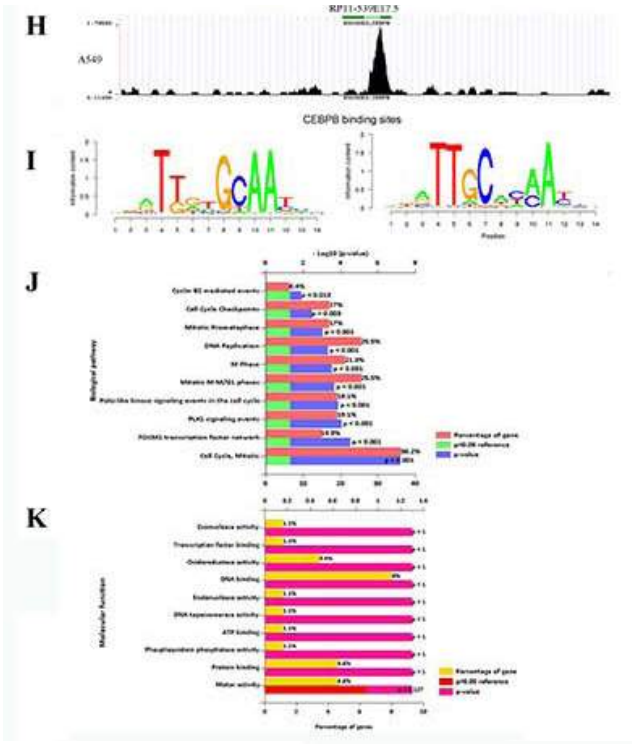
X. Wang, W. Wang, Y. Meng, S. Zhou, F.-M. Kong, H. Yang

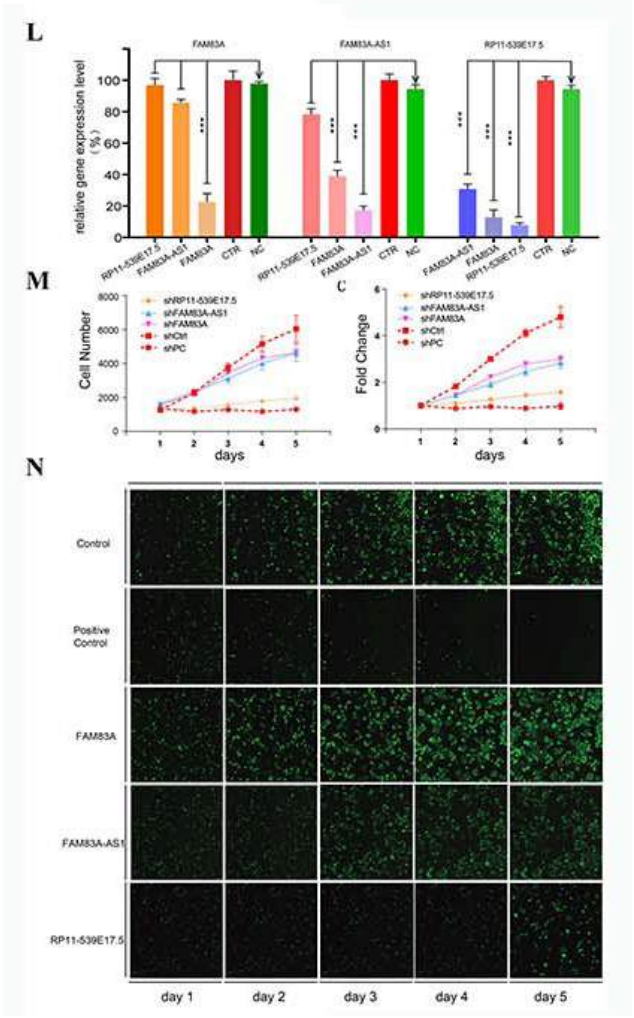
Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China

Background: Chromosome 8q24 lies in a gene desert with only a few predicted coding genes, but its variation is associated with multiple tumors. FAM83A in this region activates both PI3K/AKT/TOR and RAS/MAPK signaling cascades downstream of EGFR. The contribution of long noncoding gene in the antisense chain of FAM83A (RP11-539E17.5 and FAM83A-AS1) to the risk of lung adenocarcinoma (LUAD) need to be studied. **Method:** We use systematic informatics method to identify the differential expression genes of the Cancer Genome Atlas (TCGA) LUAD transcriptome sequencing data. Then use data mining method to analysis the lncATLAS, USCS, Cistrome, and ENCODE database to infer the biological role of these two lncRNAs. Significant analysis of gene ontology (GO) terms enrichment analyzed the co-expression genes of RP11-539E17.5 in the LUAD and adjacent tissues. At last we use cell experiment to verify the lncRNA function. **Result:** FAM83A-AS1 and RP11-539E17.5 located in Chromosome 8q24 were significantly different expressed between cancer and adjacent tissues (log2foldchange>5, p<0.05). The two lncRNA expression levels had notable correlation with FAM83A expression (coR> 0.8, P<0.005) and were significantly associated with patient overall survival and clinical stage (p<0.05). RP11-539E17.5, located in the enhancer element GH08J123181,belong to the enhancer lncRNA group. lncRNA subcellular localization data (lncATLAS) results showed that RP11-

539E17.5 transcripts in K562 cells is mainly distributed in the nucleus, and most around the nucleolus and chromosomes. USCS, Cistrome, and ENCODE data mining identified four transcription factors (FOSL2, CTBP2, CEBPB, and MAFK) have significant correlation with the expression of FAM83A-AS1 and RP11-539E17.5. In K562 cell line with high expression of FAM83A-AS1, RP11-539E17.5 and FAM83A showed that expanded regions of RP11-539E17.5 gene sequence were marked by enhancer-specific modifications (H3K27ac domains and H3K4me3 domains). This region also showed an excellent source of DNase sensitive site, and with several binding sites for CTCF, FOSL2, CTBP2, CEBPB and MAFK. In addition, RP11-539E17.5 gene also with enriched DNA methylation feature. RP11-539E17.5 and FAM83A-AS1 knocked down both inhibited the expression of FAM83A the proliferation of PC9, and RP11-539E17.5 gene owning a more significant effect. GO terms enrichment analysis of the co-expressed genes with RP11-539E17.5 showed that the most significantly activated biological pathways is involved with Cell cycle,and cell mitotic signaling pathway, while the molecular function involved with transcription factor binding, DNA binding, ATP binding, endonuclease activity, DNA topoisomerase activity.







Conclusion: We found a LncRNA RP11-539E17.5 with enhancer character up regulate FAM83A expression in LUAD. These results can lay a theoretical foundation for LUAD corresponding countermeasures.

Keywords: LncRNA RP11-539E17.5 and FAM83A-AS1, FAM83A, lung adenocarcinoma (LUAD)

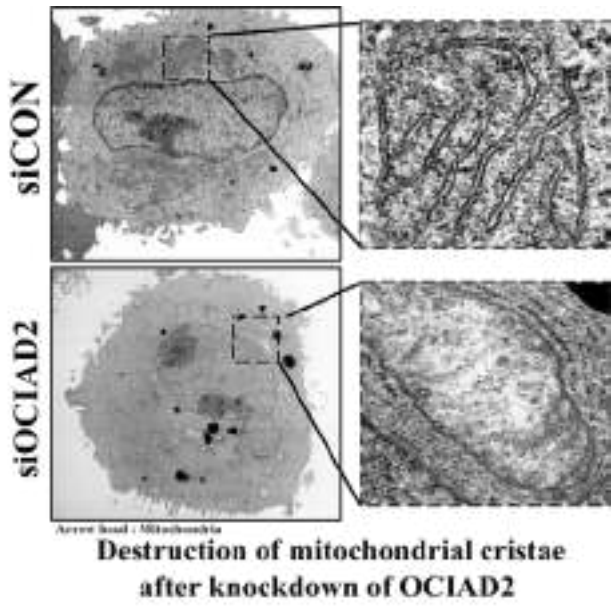
Background: Lung cancer is one of the leading causes of cancer-related death worldwide. However, the mechanisms that trigger the progression of early-stage lung cancer remain unclear. Our group has identified a novel cancer-specific protein localized in mitochondria, ovarian carcinoma immune-reactive antigen domain 2 (OCIAD2), which shows significantly higher expression in invasive adenocarcinoma than in adenocarcinoma *in situ* (Ishiyama T *et al*. 2007). Although several reports have focused on OCIAD2 expression in malignant tumors, the roles of OCIAD2 remain unknown. Here we show that OCIAD2 is associated with mitochondrial morphology, including mitochondrial distribution and crista formation. We have also revealed that OCIAD2 regulates mitochondrial crista formation in lung adenocarcinoma by interacting with optic atrophy 1 (OPA1). **Method:** The effects of siRNA transfection on the expression of OCIAD2 mRNA and protein in a lung adenocarcinoma cell line (A549) were examined by real-time RT-PCR and Western blotting. Cellular proliferation was assessed by the WST-8 assay and apoptosis was examined by Western blotting using apoptosis-related proteins such as cleaved caspase -3, -9, and PARP. Moreover, using transmission electron microscopy (TEM), we investigated alterations of mitochondrial morphology in A549 cells after OCIAD2 knockdown. Endogenous and exogenous binding of OCIAD2 and OPA1 were then confirmed by co-immunoprecipitation and Western blotting. **Result:** We confirmed that OCIAD2 expression was downregulated at both the mRNA and protein levels in A549 cells after siRNA-OCIAD2 transfection. Cellular proliferation was significantly decreased after OCIAD2 knockdown. Moreover, suppression of OCIAD2 induced mitochondria-dependent apoptosis by activating cleavage of caspase -3, -9, and PARP. In addition, suppression of OCIAD2 led to alterations of mitochondrial morphology such as crista destruction. Moreover, we confirmed endogenous and exogenous binding of OCIAD2 and OPA1 in A549 cells

.



Conclusion: OCIAD2 contributes to the imbalance of cellular proliferation and apoptosis in lung adenocarcinoma. Overexpression of OCIAD2 might prevent tumor cell apoptosis through substantial crista formation by interacting with OPA1. Since OCIAD2 is a tumor-associated protein and is not expressed in normal cells, we believe that OCIAD2 could be a promising therapeutic target for lung adenocarcinoma.

P1.03-19 CIRCULATING TUMOUR CELLS IN NON-SMALL CELL LUNG CANCER

K. O'Byrne

Institute of Health and Biomedical Innovation, Queensland University of Technology Translational Research Institute, WOOLLOONGABBA/Australia

Background: Metastasis in cancer patients is reflected by measurable levels of circulating tumour cells (CTCs) in the blood of cancer patients. CTCs represent cancer cells from the primary and metastatic sites, thereby providing a comprehensive representation of the tumour burden of an individual patient. **Method:** Our study was designed to use microfluidic devices for the capture and characterization of CTCs in non-small cell lung cancer (NSCLC) patient samples (n=105). **Result:** We demonstrated a higher CTC capture efficiency using microfluidic CTC enrichment platforms. Using a novel multi-flow microfluidic device, we demonstrated label free CTC capture with high purity (>87%) and high recovery rate (>93%) with clinically relevant CTC concentrations. Molecular alterations present in the primary tissue were confirmed in the CTCs by 3D DNA FISH (ALK-translocations) and Immunohistochemistry (EGFR mutations, PD-L1). The presence of CTC clusters asssociated with poorer patient outcomes. **Conclusion:** Our data suggests that PD-L1 is frequently expressed in NSCLC CTCs and an immunoscore may be able to identify patients likely to benefit from immunotherapy. The isolation and characterisation of CTCs by a simple blood draw provides a non-invasive means by which to sample the tumour dynamics prior to treatment and over the course of therapy.

Background: Lung adenocarcinoma (LUAD) is the most frequent subtype of lung cancer, which is the leading cause of cancer death worldwide. Unraveling the molecular mechanisms of LUAD is crucial for identifying novel biomarkers and molecular targets for the diagnosis, prognosis and treatment of LUAD. One of the main molecular mechanisms responsible for LUAD and other cancers is the accumulation of driver somatic mutations, which undergo positive selection. However, driver mutations only represent a small proportion of the total mutations in a tumor and identifying true drivers can be challenging, especially in non-coding regions. Non-coding RNAs are RNA molecules that do not code for protein. Increasing evidence suggests that many non-coding RNAs, especially microRNAs (miRNAs) and long non-coding RNAs (lncRNAs), play critical roles in most, if not all hallmarks of cancer. However, very little is known about the driver mutations that affect non-coding RNAs in cancer and, in particular, in lung adenocarcinoma (LUAD). **Method:** We performed targeted next-generation sequencing on genomic DNA from 70 LUAD primary tumors, focusing on 1470 miRNAs and 913 lncRNAs. We developed a novel bioinformatics pipeline to identify somatic mutations by combining three state-of-the-art mutation calling tools, and then we prioritized the high-confidence somatic mutations based on various published functional impact metrics specifically designed for miRNAs and for lncRNAs. In addition, we further validated our pipeline and our results using whole-genome sequencing data from 59 LUAD primary tumors from The Cancer Genome Atlas (TCGA). **Result:** We identified 193 miRNA mutations in our cohort of 70 LUAD primary tumors. These included 16 mutations affecting seed regions and 48 mutations affecting mature miRNAs. Using miRNA target prediction tools, we identified one somatic mutation that affected the seed of a well-known miRNA and that significantly altered the predicted targets of the miRNA. In lncRNAs, we found 2004 mutations in out cohort, out of which 565 passed preliminary filters based on the predicted functional impact. Of those mutations, 91 were recurrent in more than one patient, and some affected well-known lncRNAs such as HOTAIR and PVT1. The

results from our internal cohort differed greatly from those obtained from TCGA patients. Future work will focus on refining the mutation prioritization pipeline and experimentally validating the most significant results. **Conclusion:** Our novel pipeline may aid in the identification of novel driver mutations in non-coding RNAs, which may reveal novel biomarkers and molecular targets for the diagnosis, prognosis and treatment of LUAD.

Background: Cancer-associated fibroblasts (CAFs) provide a microenvironment suitable for tumor development. CAFs have been shown to hold the capacity to facilitate carcinogenesis, drug resistance, tumor recurrence and metastasis through the signaling networks. Most studies investigating the impact of CAFs have focused on the cancer cells. The issue that how CAFs could induce carcinogenesis in the adjacent normal tissues, including genetic and epigenetic changes; however, attracts less attention. We aimed to characterize CAF-driven molecular changes in non-tumorous epithelial cells by genome/epigenome-wide study. **Method:** We primary cultured CAFs from NSCLC patients and co-cultured CAFs with normal human epithelial cells (BEAS2B). We performed *in vitro* soft agar assay and processed the established cocultured clones onto the methylome and transcriptome high-throughput platforms. **Result:** We found that the CAF-BEAS2B coculture could form colonieson the soft agar while CAFs or BEAS2B alone could not. Following isolation, the cells of cocultured clones developed more colonies than the parental BEAS2B by colony formation assay. The absence of CAF marker CD90 staining indicated no CAF contamination in the cocultured clones. In addition, DNA methylation profiling integrated with gene expression identified clusters (eg. ROBO1) that could discriminate cocultured clones from parental BEAS2B cells. The results of this study showed that CAFs could induce normal epithelial cells to undergo oncogenic transformation via DNA methylation regulation, suggesting the pro-tumorigenic potency of CAFs. **Conclusion:** Exploring the molecular interaction between CAFs and surrounding normal cells could help clarify the role of CAFs predisposed in the microenvironment in transforming normal cells epigenetically.

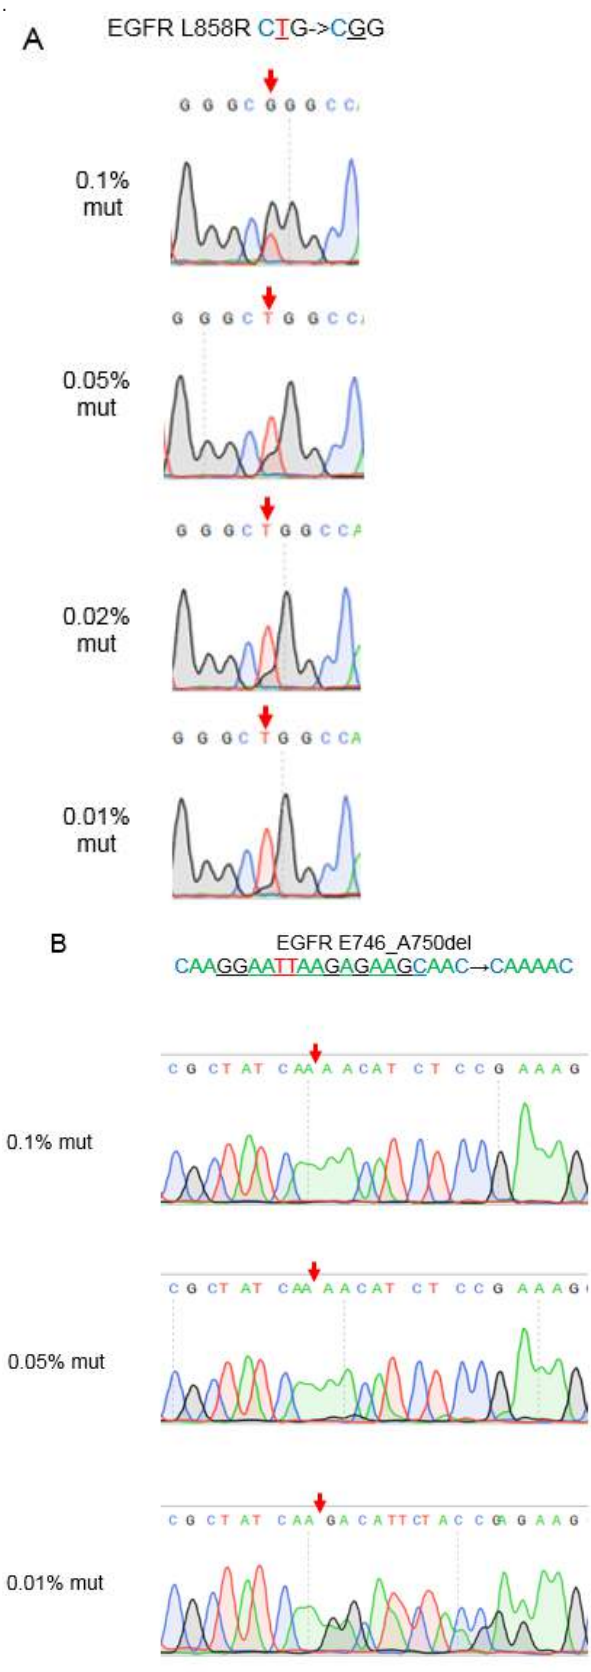
Keywords: oncogenic transformation, Cancer-associated fibroblasts, Epigenome-wide association study

P1.03-22 A NOVEL METHOD FOR DETECTING LOW ABUNDANT MUTANTS IN THREE TYPES OF LIQUID BIOPSIES BY CAPTURING MUTANT-ALLELES

R. Lin, Y. Pu, T. Wang

Hangzhou Repugene Technology Co., Ltd., Hangzhou/China

Background: Liquid biopsy can facilitate early detection of cancers, treatment selection, and disease monitoring. Improved methods to detect low abundant circulating tumor DNA (ctDNA) are needed for clinical samples including plasma, pleural effusion, and cerebrospinal fluid that carry a large amount of wild-type DNA. **Method:** We have developed a novel method, namely PEAC, with an ultra-high sensitivity to detect low abundant mutants from ctDNA through mutant capturing followed by Sanger sequencing or next-generation sequencing (NGS). This novel approach combines the high discrimination power of locked–nucleic acid (LNA) modified nucleotide sequence and short probes as bait to capture mutant fragment under an optimized temperature. Mutant fragments bound by biotin-labelled, LNA-modified probes are enriched by streptavidin beads and amplified by PCR, and then sequenced for detection. **Result:** Using circulating cell-free DNA (cfDNA) reference standards, we demonstrated that PEAC technology can enrich mutants up to 5000-fold (panel B of the figure below) and empower to detect clinically relevant EGFR mutants such as L858R, 19Del, and T790M mutant at the abundance as low as 0.01-0.1% by Sanger sequencing or NGS analysis. The clinical implications of PEAC technology were further validated using ctDNA from liquid biopsy specimens of non-small cell lung cancer (NSCLC) patients. EGFR L858R, 19DEL or T790M mutants were detected at the abundance >50% after PEAC enrichment from plasma samples of NSCLC patients, whereas the corresponding ctDNA samples without PEAC enrichment were undetectable by Sanger sequencing and hardly detected by NGS analysis. One cerebrospinal fluid and two pleural effusion samples had dominated 19DEL, L858R and T790M peaks after PEAC enrichment, respectively, but exhibited almost the background signal levels prior to PEAC



Conclusion: PEAC technology can enrich ctDNA from body fluids of cancer patients to detect ultra-low abundant clinically relevant mutants. Combined with other methods including NGS, the technology may serve as an attractive detection method in clinical practice.

P1.03-23 DELTA-LIKE 1 HOMOLOG (DLK1) EXPRESSION IN NON-SMALL-CELL LUNG CANCER AND THE DEVELOPMENT OF RADIOIMMUNOTHERAPY TARGETING DLK1

H. Takagi[1], S. Zhao[2], S. Muto[1], H. Mine[1], M. Watanabe[1], Y. Ozaki[1], N. Okabe[1], T. Hasegawa[1], Y. Shio[1], M. Aoki[2], C. Tan[2], S. Shimoyama[2], K. Nakamura[3], A. Inano[2], H. Suzuki[1]

[1]*Fukushima Medical University Department of Chest Surgery, Fukushima/Japan,* [2]*Fukushima Medical University Advanced Clinical Research Center, Fukushima/Japan,* [3]*Chiome Bioscience Inc., Kanagawa/Japan*

Background: Currently, treatments for advanced non-small-cell lung cancer (NSCLC) have progressed with the development of molecular targeted drugs and immune checkpoint inhibitors. However, most tumors have become resistant to these treatments. In small cell lung cancer (SCLC), the Notch receptor ligand family, which regulates cell proliferation, is expected to be a therapeutic target. Among this family, Rovalpituzumab is an antibody-drug conjugate directed against Delta-like ligand 3 (DLL3) and showed promising effects in phase 1 trials. However, in NSCLC, clinical impact of this Notch ligand family is still unknown. We therefore focused on Delta-like 1 homolog (DLK1), a noncanonical Notch ligand, which is not also yet fully understood in lung cancer. **Method:** We assessed the correlation between clinical features and DLK1 expression in resected specimens from 101 NSCLC patients who had undergone complete resection in the Fukushima Medical University Hospital between January 2012 and January 2017, and were available for analysis. We assessed DLK1 expression on tumor cells using immunohistochemistry with anti-DLK1 antibody (clone DI-2-20, IgG1). Moreover, cell and animal experiments were performed for the development of radioimmunotherapy using this anti-DLK1 antibody. **Result:** In 101 patients with NSCLC, 17 (16.8%) had DLK1 positive tumors. There was no association between DLK1 expression and pathological staging. DLK1 expression was associated with recurrence-free survival ($p<0.01$) but not overall survival. In addition, iodine-125 labeled anti-DLK1 antibody (HuBA-13D) was specifically incorporated into DLK1 on the tumor cell membrane in cell lines of human SCLC and human neuroblastoma. Furthermore, the complex was specifically incorporated into tumor tissue in a mouse model with human neuroblastoma. **Conclusion:** The results of the present study indicate that DLK1 expression could be a promising prognostic factor for recurrence in patients with resected NSCLC. In addition, DLK1 could be a therapeutic target for radioimmunotherapy for NSCLC by using our DLK-1 antibody.

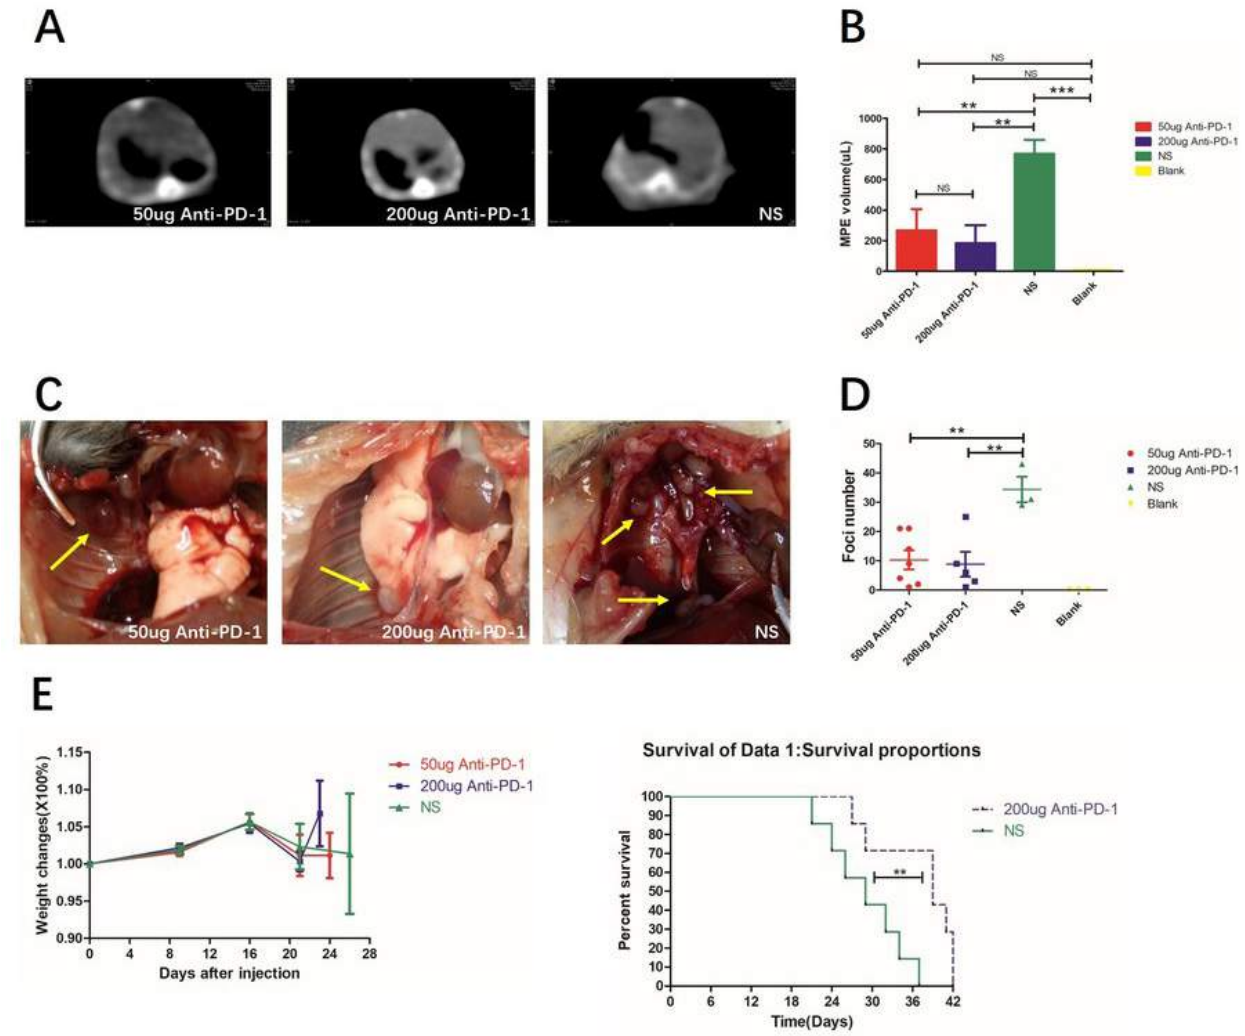
Keywords: Notch ligand, DLK1, Radioimmunotherapy

P1.03-24 THORACIC INJECTION OF PD-1 BLOCKING ANTIBODY IMPROVES THE MURINE MODEL OF MALIGNANT PLEURAL EFFUSION

X.-Y. Li[1], G. Wu[1], C. Chen[2], Y. Zhao[3], J. Yin[1], T. Lv[3], Y. Song[3]

[1]*Jinling Hospital, Nanjing University School of Medicine, Nanjing, China, Nanjing/China,* [2]*Jinling Hospital, Southern Medical University (Guangzhou), Nanjing/China,* [3]*Jinling Hospital, Nanjing/China*

Background: Malignant pleural effusion (MPE) occurs as a common complication of lung cancer with poor prognosis. It should be mainly attributed to pleura metastasis and lymphatic obstruction by cancer cells. Despite that intravenous immune-checkpoint inhibitor (ICIs) shows remarkable therapeutic capacity, the effect of thoracic injection of anti-PD-1 antibodies remains undefined. **Method:** MPE xenografts mice model was established by intralumen injection of Lewis lung carcinoma (LLC) cells and randomly divided into three groups: high dose of anti-PD-1 monoclonal antibody (200ug), low dose of anti-PD-1 monoclonal antibody (50ug) and an equal volume of saline. Drugs were injected into the pleural cavity on Day 7 and Day 14. Computed tomography (CT) was performed 14 days after LLC injection. All mice were sacrificed on day 21 and the volume of pleural effusion, the number of pleural nodules were quantitatively recorded. Expression of PD-1, PD-L1, $CD8^+$ and CD31 in tumor and normal pleural tissues were evaluated by western blot and immunohistochemical staining (IHC). Flow cytometry was performed on mice spleen after grinding. Weight and survival were recorded. **Result:** The volume of pleural effusion, the number of pleural tumor foci and the proportion of $CD8^+$ T cells in the spleen of mice were significantly reduced in both high and low dose of anti-PD-1 antibody treatment groups. Western Blot results showed that the expression of PD-1 in tumor and adjacent pleura was significantly inhibited after anti-PD-1antibody treatment. IHC results showed that $CD8^+$ T cells in tumor area of mice in high dose anti-PD-1 monoclonal antibody group were significantly less than those in low dose group, and the expressions of PD-1 and PD-L1 were significantly increased. Anti-PD-1 monoclonal antibody treatment was associated with much longer survival ($p=0.0098$). Median survival in the anti-PD-1 antibody treated group was 39 days, versus 29 days in the control group.



Conclusion: Intralumen delivery of anti-PD-1 antibody could significantly reduce MPE volume and improve survival by inhibiting the expression of PD-1, reducing the number of $CD8^+$ T cells in the tumor region and spleen, and affecting angiogenesis.

Keywords: Malignant pleural effusion, pd-1, thoracic injection

P1.03-25 SYNERGISTIC LETHALITY OF FERROPTOSIS INDUCER-DISULFIRAM/COPPER COMPLEX AND WEE1 KINASE INHIBITOR FOR RAS/TP53 MUTANT NSCLC

B. Su, D. Liu, W. Xu, G. Lin, M. Zhao, N. Wang

Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China

Background: Co-mutation of RAS and TP53 is prevalent in NSCLC but with no reagents targeting this specific subtype. Drug synergy is a feasible approach in targeting the tumor with the multi-site mutation. In this study, the synergistic lethality of disulfiram/copper complex (DSF-Cu) and WEE1 kinase inhibitor, and its association with RAS/TP53 status were interrogated in NSCLC. **Method:** DSF was approved by the FDA for alcoholism treatment for decades, and its role in cancer therapy arose extensive interest recently with uncertain mechanisms. Three $RAS^{mut}/TP53^{mut}$ NSCLC cell lines [H1299, TP53-knockout A549 (A549-KOTP53), TP53-knockout H460 (H460-KOTP53)], two $RAS^{mut}/TP53^{wt}$ NSCLC cell lines (A549, H460), and one $RAS^{wt}/TP53^{mut}$ cell line (H522) were used to examine the anti-cancer effect of DSF-Cu complex, which was tested with MTT and colony formation assay. The mechanism of DSF-Cu's anti-tumor effect was determined by flow cytometry, western blot and ferroptosis staining. The synergistic lethality effect of DSF-Cu and WEE1 inhibitor was estimated under 2D and 3D cell culture systems. **Result:** The anti-tumor effect of DSF-Cu was more evident in $RAS^{mut}/TP53^{mut}$ NSCLC than in $RAS^{mut}/TP53^{wt}$ or $RAS^{wt}/TP53^{mut}$ NSCLC. We firstly found that the anti-tumor effect of DSF-Cu was associated with ferroptosis accompanied by lipid peroxidation of cell membrane (Figure 1A, 1B). DSF-Cu also inhibited WEE1 sumoylation (Figure 1C) to induce G2/M checkpoint arrest by eliciting oxygen radicals in $RAS^{mut}/TP53^{mut}$ NSCLC cell lines. A WEE1 kinase inhibitor, Adavosertib combined with DSF-Cu showed synergistic lethality in $RAS^{mut}/TP53^{mut}$ NSCLC cell lines compared with other non-co-mutation NSCLC cell lines (Figure 1D, 1E).

POSTERS

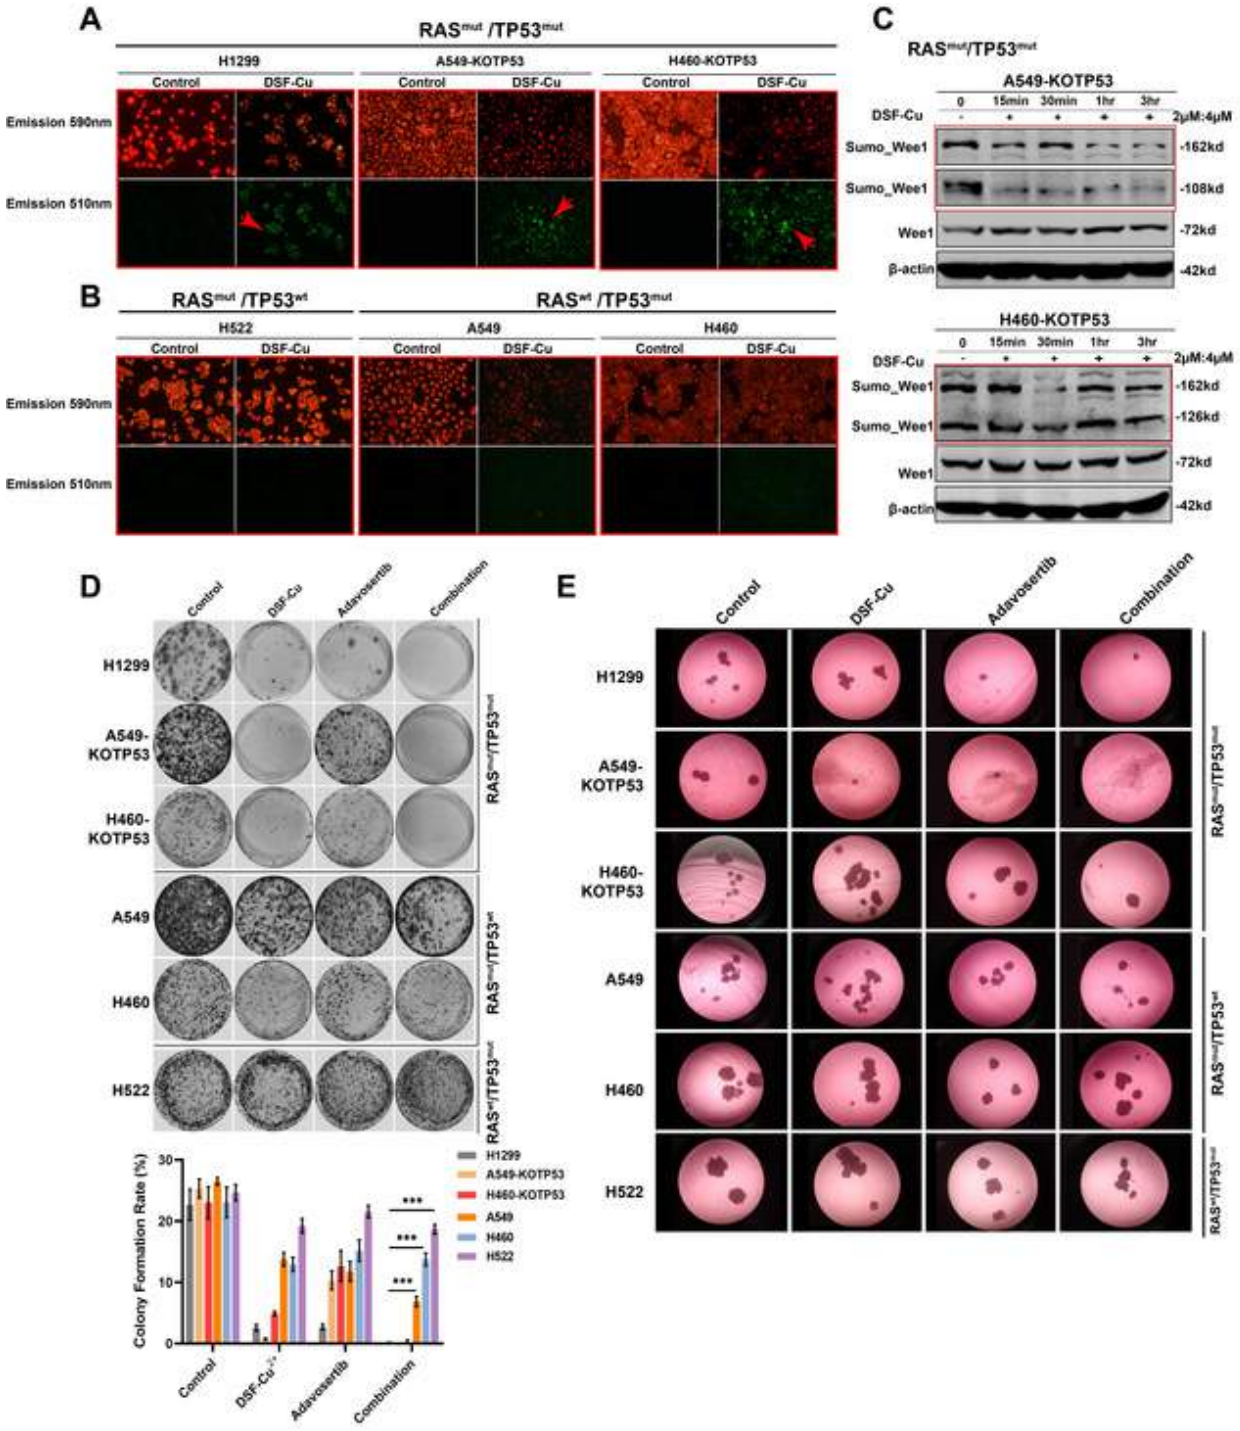


Figure 1

Conclusion: Our study elucidated a novel mechanism of the anti-tumor effect of DSF-Cu, that the subsequent elicitation of oxygen radicals can induce both WEE1 sumoylation inhibition and ferroptosis, especially in the RAS^{mut}/TP53^{mut} NSCLC. The synergistic lethality of DSF-Cu with adavosertib may be a promising treatment strategy for RAS^{mut}/TP53^{mut} NSCLC.

P1.03-26 GENETIC AND MOLECULAR PROFILING OF NON-SMOKING RELATED LUNG ADENOCARCINOMAS

E. Pros[1], M. Saigi[1], J.J. Alburquerque-Béjar[1], M.J. Pajares[2], B. Martínez-Delgado[3], J. Carretero[4], R. Tonda[5], A. Esteve-Codina[5], S. Verdura[1], I. Català[6], N. Reguart[7], O. Juan[8], E. Nadal[9], E. Felip[10], L. Montuenga[2], M. Sanchez-Cespedes[1]

Background: The etiology and many details of the genomic profile and molecular basis of lung adenocarcinomas (LuADs) in nonsmoker patients remain elusive. Further, the scarcity of primary cultures available from non-smoking related lung adenocarcinomas (NSK-LuADs) contributes to hamper our biological understanding of these tumors. **Method:** We established patient-derived cancer cell (PDCs) cultures from NSK-LuADs, and performed whole exome sequencing (WES) and RNA sequencing (RNA-seq) analysis to delineate their genomic architecture. For validations, we analyzed independent cohorts of LuADs. **Result:** The analysis revealed non-smoker related alterations such as those at the growth factor receptors *RET, ALK, EGFR* and *ERBB2.* There were also mutations affecting signal transduction molecules such as *AKT1, BRAF* and *KRAS*, and mutations in tumor suppressor genes, including *TP53, CDKN2A*, *RB1, ARID1A, ATM* and *STK11.* We also identified new fusions and recurrent mutations in some genes, one of them, a possible regulator of gene expression, affecting ten percent of the LuADs, thus constituting a potentially relevant tumor suppressor gene. We also report a predominance of *RB1*-inactivation, mostly complex intragenic rearrangements (homozygous deletions or duplications) in *EGFR*-mutant tumors. Three *EGFR-/RB1*-mutant tumors, treated with EGFR-TKIs, and one *EGFR*-wild type tumor, treated with standard chemotherapy, developed small cell lung cancer and/or squamous cell carcinoma transformation, evident in the re-biopsies and/or PDCs. Finally, we found pathogenic germ-line mutations at genes associated to familiar-cancer syndromes, especially the *TP53*-associated Li Fraumeni syndrome, affecting ten percent of *EGFR*-mutant LuADs patients, underscoring a genetic predisposition origin for a subset of NSK-LuADs. **Conclusion:** The recurrent gene inactivation found in candidate gene in LuADs heralds a tumor suppressor role which deserves further exploration. The pre-existent inactivation of *RB1* predominates in *EGFR*-mutant tumors and may underlie an extremely ductile nature, albeit additional gene alterations are required to overcome sensitivity to the TKIs. Given their potential clinical and therapeutic implications, testing for *RB1*-alterations and for the Li-Fraumeni syndrome in *EGFR*-mutant LuADs patients may need to be incorporated in the clinical settings.

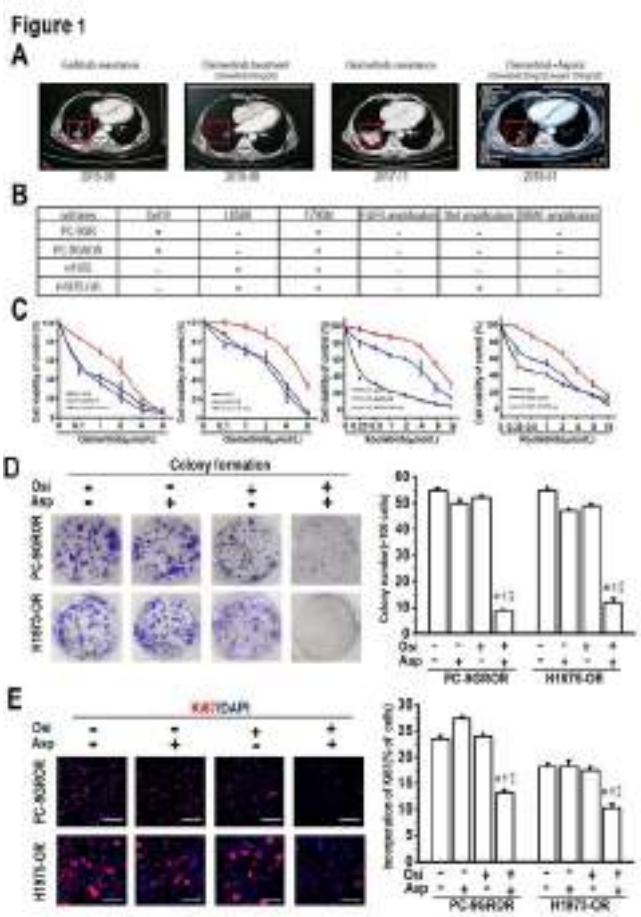
P1.03-27 ASPIRIN OVERCOMES ACQUIRED RESISTANCE TO OSIMERTINIB IN HUMAN LUNG CANCER CELLS VIA BIM-DEPENDENT APOPTOSIS INDUCTION

H. Yong[1], H. Rui[2]

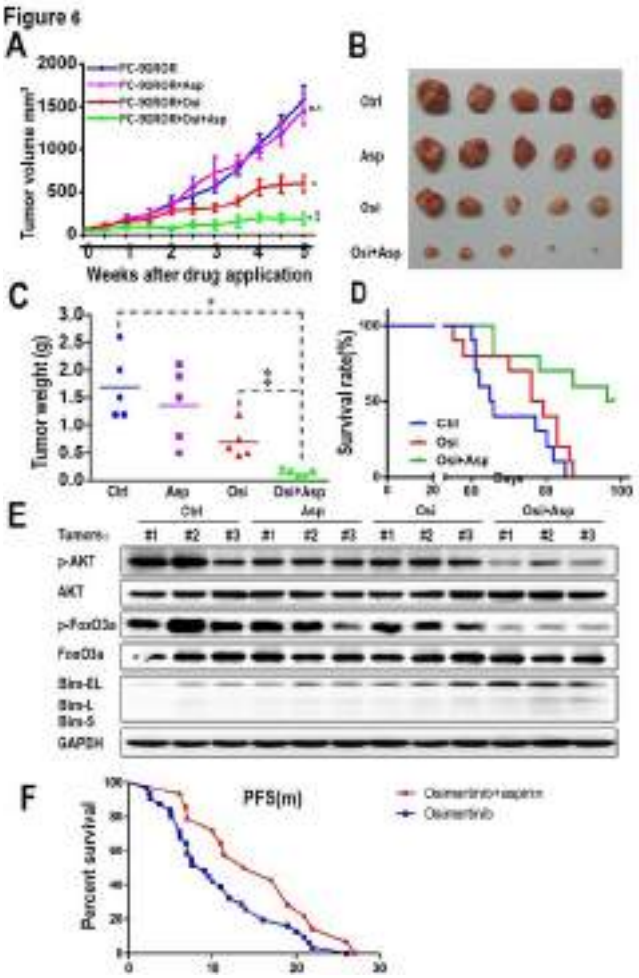
[1]*Daping Hospital, Army Medical University, chongqing/China,* [2]*Department of Respiratory Disease, Daping Hospital, Army Medical University, chongqing/China*

Background: Osimertinib, a third-generation irreversible epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI), provides remarkable clinical benefit for patients with EGFR-TKI sensitizing and/or EGFR T790M resistance mutations. Unfortunately, osimertinib can be changed to acquired resistance eventually occurs, which limits its clinical effects. There is currently no effective method to overcome this acquired resistance. The current study aims to identify a new method to overcome acquired osimertinib resistance. **Method:** The effects of combination treatment with osimertinib and aspirin on osimertinib-resistant non-small cell lung cancer (NSCLC) cell lines (PC-9GROR and H1975-OR) were assayed using MTT and Ki67 incorporation assays, flow cytometry, immunofluorescence staining, Western blotting analysis, and xenograft tumor implantation. Data of NSCLC patients who received osimertinib treatment in Daping hospital between January 2015 and January 2019 were reviewed retrospectively. **Result:** Two patients with NSCLC who were gradually developing resistance to osimertinib began aspirin for thrombosis; a partial anti-tumor response was unexpectedly observed. The combination of osimertinib and aspirin induced strong anti-proliferative and pro-apoptotic effects in osimertinib-resistant NSCLC lines through inhibition of Akt/FoxO3a signaling phosphorylation and increased Bim expression. Furthermore, siRNA knockdown of Bim expression significantly attenuated the ability of aspirin to re-sensitize osimertinib. In vivo, the combination of aspirin and osimertinib significantly decreased tumor growth of xenografts based on the PC-9GROR cell line through inhibition of Akt/FoxO3a signaling phosphorylation and elevation of Bim. The retrospectively analyze clinical data of 45 cases of NSCLC patients showed the median progression-free survival (PFS) in osimertinib plus aspirin group patients were significantly longer than those in osimertinib alone group patients.

Figure 1



POSTERS



Conclusion: Aspirin, a generally safe and inexpensive drug, has synergistic effects with osimertinib via modulation of Bim-dependent apoptosis in osimertinib-resistant NSCLC cell lines and xenografts. It may be an effective strategy for overcoming acquired resistance to osimertinib and prolonging survival in patients with NSCLC.

Keyword: osimertinib, aspirin, resistance

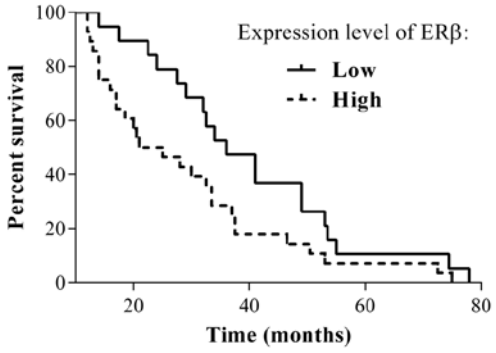
P1.03-28 PROGNOSTIC VALUE OF ESTROGEN RECEPTOR BETA TUMOR EXPRESSION IN NON-SMALL CELL LUNG CANCER PATIENTS AFTER RADICAL SURGERY

A. Basharina[1], T. Bogush[2], E. Bogush[2], A. Grishanina[2], O. Ryabinina[2], N. Vichlzantseva[2], S. Kolomiytsev[2], B. Polotsky[2]

[1]*"N.N. Blokhin National Medical Research Center of Oncology" of the Health Ministry of Russia, Moscow/Russian Federation,* [2]*"N.N. Blokhin National Medical Research Center Of Oncology" of the Health Ministry of Russia, Moscow/Russian Federation*

Background: Estrogens play significant role in development and progression of non-small cell lung cancer (NSCLC), but prognostic value of estrogen receptors (ERα and ERβ) in cancer tissue are controversial. Moreover, there is no accurate information about frequency of ERs expression in tumor cells as the key for antiestrogens which is a promising NSCLC therapy. Therefore, *we aimed to 1) evaluate expression of ERβ in NSCLC cancer tissue and 2) estimate prognostic value of ERβ on survival of patients.* **Method:** Expression of ERβ in 125 surgical NSCLC samples was evaluated quantitatively by immunofluorescent assay and flow cytometry. The primary anti-ERβ (14C8, ab288) and secondary (DyLight650, ab98510) antibodies were used. The level of ERβ expression was calculated as the ratio (%) of specifically fluorescent cells to the control (incubation with the secondary antibody only). The prognostic value of ERβ expression in tumor tissue was studied in 49 patients without neoadjuvant therapy who died in 6.5 years after radical surgery. There was division into two level expression groups: high – ERβ were revealed in ≤40% and low – >40% cells. Statistical analysis was performed by Kaplan-Meier curves analysis (log-rank test) and Cox-regression in software packages: GraphPad Prism 7.0 and SPSS 22.0. **Result:** 1. Expression of ERβ was revealed in all the investigated NSCLC samples. Significant heterogeneity of the marker expression level was shown: the mean and median of the marker index were 42.3%±15.6 and 44.0% respectively. 2. It was shown in comparison of Kaplan-Meier curves in patients with low vs high level of ERβ expression (see Fig.1) that the survival median of the patients who died in 6.5 years after radical surgery was more than 1.5 times greater in the group with the low vs high level of ERβ expression: 36.0 and 22.0 months respectively (p=0.04). The risk of death in follow-up period after radical surgery was 2.0 times greater in the group classified as high level of tumor ERβ expression: hazard ratio has been statistically significant – 1.8 (95% CI: 1.1–6.4, p=0.05).

Fig. 1. Kaplan-Meier survival curves of NSCLC patients with low and high level of ERβ expression



Conclusion: 1. ERβ tumor expression has prognostic value in NSCLC patients, namely, the high level of ERβ (in more than 40% tumor cells) is a negative prognostic marker. 2. The fact of ERβ expression in all the NSCLC specimens investigated has shown that hormonal antiestrogen therapy could be a promising option for all the NSCLC patients.

P1.03-29 CELLULAR BIOLOGY DETERMINES ABILITY OF XIST TO ACT AS A MIRNA SPONGE IN NON-SMALL CELL LUNG CANCER

G. Stewart[1], E. Marshall[1], A. Sage[1], W. Lam[1], C. Brown[2]

[1]*BC Cancer Research Centre, Vancouver/Canada,* [2]*University of British Columbia, Vancouver/Canada*

Background: XIST, the female-specific lncRNA canonically involved in silencing the X chromosome, has been suggested by many studies to function as a miRNA sponge. This sponge mechanism has been suggested to affect many cancer types, including lung adenocarcinoma (LUAD). However, determination of miRNA:lncRNA interaction is largely based on sequence homology, impeding the identification of functional gene pairs. The sex-specificity of XIST provides the opportunity to study the biological relevance of these interactions. Here we take a comprehensive approach by considering factors that affect preferential regulation through XIST-miRNA sponging in LUAD. **Method:** Sequencing data from 568 LUAD and non-malignant samples (304 female and 264 male) were downloaded from CancerBrowser and processed to provide gene expression for mRNAs, miRNAs, and XIST. 3'UTR sequences of all candidate genes were run through the miRanda binding prediction algorithm. Spearman's tests were performed to identify positively correlated candidate sponged genes. **Result:** To identify the best sponge-regulated candidates, we considered genes that (1) were positively correlated with *XIST* expression and (2) are targeted by shared miRNA with XIST, and (3) expressed in lung adenocarcinoma. This revealed a robust set 128 of genes potentially positively regulated by *XIST* through the sequestration of 804 shared miRNAs. As *XIST* is sex-specific, we compared the changes in miRNA-target gene relationships in *XIST*-high and *XIST*-low systems to identify a high-confidence set of 13 miRNA-gene pairs. In order to interact with the exclusively nuclear expressed *XIST,*miRNAs must also be expressed in the nucleus. We validate the

nuclear presence of several of these high confidence miRNAs using RT-qPCR, confirming the co-localization required for *XIST* to interact with these species. **Conclusion:** We use a biology-driven approach to identify genes defended from miRNA-based inhibition by the lncRNA *XIST* in LUAD. Importantly, we identify that the miRNAs that mediate the *XIST*-target gene axis are enriched in the nucleus, co-localizing with XIST in lung cancer cell models. Our results reinforce the necessary consideration of biological features in future studies of lncRNA:miRNA interactions.

P1.03-30 TRANSCRIPTOME SIGNATURES OF TOBACCO CARCINOGENS ON LUNG ADENOCARCINOMA CELL LINES

M. Pepe[1], A.S. Lamort[1], N. Kanellakis[2], F. Pelizza[1], M. Spella[2], G. Stathopoulos[1]

[1]*ILBD/CPC Helmholtz Zentrum Munchen, München/Germany,* [2]*University of Patras, Patras/Greece*

Background: Lung adenocarcinoma (LUAD) sequencing studies and carcinogens induced LUAD in animal models show how different mutational processes leave their specific signatures in the genome. Unluckily those signatures were obtained from heterogeneous tissues containing tumor and stromal cells. Moreover, whole-genome analyses provide a comprehensive collection of genome alterations but tend to lose specificity in the signature that affects the coding region of cancer genomes. AIM: To address the importance of mutational signature in the transcriptome of carcinogens induced LUAD cell lines. **Method:** We investigated the raise of mutations and the changes in the transcriptome profiles of ten different carcinogen-induced LUAD cell lines derived from three different mouse strains and induced with urethane or diethyl-nitrosamine. Data were analyzed for transcripts abundance, sequences alignments, pathways and geneset enrichment, and analyzed the single nucleotide variations (SNV) effect on the three-dimensional structure of proteins and on their functions. **Result:** The LUAD cells gene expression profiles show classical hallmarks of cancer, where proliferation pathways are up-regulated and adhesion control pathways are down-regulated. Among those altered pathways in LUAD cell lines transcriptome profiles, we observed a clear reprogramming of the metabolism through the up-regulation of the nucleotides synthesis and a contemporary down-regulation of the amino acids synthesis as a switch in the metabolic usage of glucose across the glycolytic pathway. We detected in our LUAD cell lines an average of 10000 SNV. When we focused on the flanking bases of those SNV, we noticed a pure tendency in two specific transitions, A>G and T>C, where the dominant 5´ flanking nucleotide is C and the dominant 3´ is G. We investigated the distribution of common SNV across the chromosomes to highlight mutational hotspots. In *Kras*-mutant LUAD cell lines, we observed that both carcinogens tend to leave their specific mutational fingerprints with a major density in the terminal regions of the chromosomes. When we compared the specific genomic position of every induced SNV and correlated it with the different levels of heterogeneity in LUAD cell lines, we observed in all of them 15 common SNV in 11 different genes. Among those genes, we pinned two key genes of the glycolytic pathway: *G6pd2* and *Aldort1*. **Conclusion:** From the tobacco carcinogens transcriptome signatures of LUAD cells, we propose here an uncharted role of two altered forms of *G6pd2* and *Aldort1*. Their corresponding proteins: G6PD2 and ALDOA, are able to drive the glucose usage toward the nucleotide synthesis, resulting in an enhancement of the tumor cells proliferation and in the LUAD pathogenicity. We believe that those two proteins could be more investigated as novel pharmacological targets for human LUAD treatment

P1.03-31 BRAF MUTATIONS: CLASSES I, II AND III IN NSCLC PATIENTS INCLUDED IN THE SLLIP TRIAL, TARGETED TREATMENT ACCORDING TO CLASS

J. Bracht[1], N. Karachaliou[1], T. Bivona[2], M. Fernández-Bruno[3], J. Berenguer[1], M. Gonzalez-Cao[4], R. Lanman[5], I. Faull[6], R. Nagy[5], A. Drozdowskyj[7], A. Aguilar Hernandez[4], J.J. Garcia Mosquera[4], M.A. Molina-Vila[1], R. Rosell[8]

[1]*Pangaea Oncology. Quirón-Dexeus University Institute, Barcelona/Spain,* [2]*University of California, San Francisco, California/United States of America,* [3]*Institute of Oncology Rosell (IOR), University Hospital Sagrat Cor, QuironSalud Group, Barcelona/Spain,* [4]*Institute of Oncology Rosell (IOR), Quirón-Dexeus University Institute, Barcelona/Spain,* [5]*Guardant Health, Redwood City/United States of America,* [6]*Guardant Health, Barcelona/Spain,* [7]*Pivotal, Madrid/Spain,* [8]*Germans Trias i Pujol Science Inst., Catalan Institute of Oncology (ICO Badalona), Barcelona/Spain*

Background: BRAF V600 mutations have been found in 2% of non-small cell lung cancer (NSCLC) patients, with FDA approved treatment of dabrafenib plus trametinib and progression free survival (PFS) of 10.9 months. However, 50-80% of BRAF mutations in lung cancer are non-V600, and can be class 2, with intermediate to high kinase activity and RAS independence, or class 3, with impaired kinase activity, upstream signaling dependence and consequently sensitivity to receptor tyrosine kinase (RTK) inhibitors. Non-V600 tumors require combinatory therapy with RAF/MEK inhibitors and blockers of RTK signaling, like SHP2 (PTPN11) inhibitors. **Method:** Plasma DNA of 185 newly diagnosed advanced lung adenocarcinoma patients was examined for BRAF and other mutations with a clinically validated cell-free DNA (cfDNA) assay (Guardant360, Guardant Health Inc. CA, U.S), and results were correlated with patient outcome. In addition, two NSCLC cell lines and one Triple Negative Breast Cancer (TNBC), H1395 (class 2 BRAF mutation), H1666 (class 3 BRAF mutation) and MDA-MB-231 (class 2 BRAF mutation) were treated with single or combined BRAF, MEK and SHP2 inhibitors and cell viability was assessed. **Result:** BRAF mutations were found in 17/185 (9%) and BRAF amplification in five patients (3%). Three patients had BRAF V600E mutations (2%) and 14 patients non-V600 BRAF mutations (8%), including four class 2 and four class 3 mutations. Patients were treated with chemotherapy and/or immunotherapy, or targeted therapy for other co-alterations. PFS was 1.8, 6.1, 5.0, 5.3 and 5.3 months for Class 1, 2, 3, other BRAF, and BRAF amplification, respectively. These low survival rates indicate that new treatment options are urgently needed. *In vitro* results confirm sensitivity of class 3, and resistance of class 2 BRAF mutations to single SHP2 inhibition with RMC-4550 and SHP099, with similar results in TNBC and lung cancer cells. Combined dabrafenib and trametinib treatment indicated antagonistic effects, especially in the class 3 BRAF mutant cell line. Concomitant MEK and SHP2 inhibition was synergistic in both class 2 and 3 BRAF mutations. **Conclusion:** It is evident that different classes of BRAF mutations require distinct treatments, which could even outweigh tumor type. Therefore, we should examine BRAF class in daily clinical practice. Upfront targeting of the MAPK signaling pathway combined with SHP2 inhibitors reveals synergistic interactions, and additional inquisition may pave the way for new treatment options in the most frequently found mutations in BRAF patients.

P1.03-32 KNOCKDOWN OF CENPF GENE INHIBITS THE PROGRESSION OF LUNG ADENOCARCINOMA MEDIATED BY ERβ2/5 PATHWAY

H. Tang[1,2], Y. Bai[1], L. Xiong[1], J. Zhao[1], M. Lanuti[2]

[1]*Zhongnan Hospital of Wuhan University, Wuhan/China,* [2]*Massachusetts General Hospital, Boston/United States of America*

Background: The signal transduction pathway of estrogen receptors (ER) mainly includes gene and non-gene pathways. Studies have shown the gene pathway of ER is related to expression of nuclear proteins, and our previous research showed that estrogen promotes progression of lung cancer via ERβ. Four GEO datasets (two NSCLC, two lung adenocarcinomas (LUAD)) were analyzed and found elevated expression of the nuclear protein gene, human centromere protein F (CENPF) in LUAD. This study explores the relationship between ERβ and CENPF in lung cancer. **Method:** We verified the above phenomenon by analysis of Oncomine database, specimen transcriptome and protein mass spectrometry in LUAD patients. Co-expression of CENPF and ERβ in the nucleus of LUAD cells were

confirmed by cellular immunofluorescence and tissue microarray analysis. This result was also verified by analysis of GEPIA and TCGA databases. Finally, cell culture and animal models of lung cancer were treated with a CENPF knockdown gene and/or combination with fulvestrant (ERβ inhibitor) and assessed for cell survival and tumor volume. Mechanism was assessed with markers of ER β2/5 or surrogates of other signaling pathways. **Result:** The high expression of CENPF was associated with high TNM stage (*p <0.001, Figure 1A), low overall survival (OS, p =0.01, Figure 1B) and low disease-free survival (PFS, p =0.027) in LUAD. CENPF and ERβ2/5 were highly co-expressed and this co-expression positively related with high TNM stage in LUAD patients (p <0.001). Knockdown of CENPF gene significantly inhibited the biological effects of LUAD cells (p <0.05, Figure 1 C-D), tumor growth in mice (p <0.05, Figure 1 E, F, H), and the expression of ERβ2/5 (p <0.05, Figure 1 G).* **Conclusion:** Both CENPF and ERβ2/5 play important roles in the progression of LUAD, and knockdown of the CENPF gene can inhibit the progression of LUAD by inhibiting the expression of ERβ 2/5.

P1.03-33 ANALYSIS OF LIPID METABOLISM GENES IN ADVANCED SMALL CELL LUNG CANCER

M. Merino[1], L. P. Fernández[2], M. Sereno Moyano[1], A. Ramírez De Molina[2], J. Moreno Rubio[1,2], G. Colmenarejo[3], C. Gómez Raposo[1], M. López Gómez[1], S. Falagán Martínez[1], C. Aguayo Zamora[1], F. Zambrana Tévar[1], A.M. Jiménez Gordo[1], E. Casado Sáez[1]

[1]*Infanta Sofía University Hospital, San Sebastián de los Reyes/Spain,* [2]*IMDEA Food Institute, CEI UAM + CSIC, Madrid/Spain,* [3]*IMDEA-Food Institute, CEI UAM+CSIC, Madrid/Spain*

Background: Lung cancer is the leading cause of cancer death worldwide. Although most of the knowledge about metabolic dysregulation in cancer focuses on carbohydrates, the importance of alterations related to lipid metabolism is starting to be recognized. There is increasing data on lipid metabolism and non-small lung cancer, but much less is known about this in small cell lung cancer (SCLC). In order to improve our knowledge of these alterations we evaluated a genetic profile related to lipid metabolism and studied clinical outcomes **Method:** We performed a retrospective analysis of 22 genes related to lipid metabolism in 37 tumoral tissue samples of SCLC patients and evaluated clinical features and outcomes. Advanced SCLC patients enrolled from November 1, 2008 through December 31, 2015 were included in this analysis. Clinical data were collected from medical records at the time of enrollment. The study was approved by an Ethics Comittee and all patients signed an Informed Consent form. We used formalin-fixed, paraffin- embedded tumor tissue. Samples were deparaffinated and total RNA was extracted. A Taq-Man Low Density Array (Applied Biosystems) was specifically designed and gene-expression assays were performed in a HT-7900 Fast Real time PCR. RT-StatMiner software was used to detect and determine the quality control and differential expression analyses of data. **Result:** We included 37 patients, 73 % males and 27 % women, with a median age of 62. 29 patients (78%) had stage IV tumor and nearly all of them (92%) were treated with platinum- based chemotherapy. 11 % (4/37) received thoracic radiotherapy and 5% (2/37) received whole brain radiotherapy. 6 patients (16%) were on chronic treatment with metformin and 15 (40%) on statins. We performed a multivariable analysis and found that overexpression of two metabolic genes (a mitochondrial enzyme and a lipid metabolism regulator) led to longer overall survival. (HR 0.13 (0.04-0.42), p 0.0019, $p_{adjusted}$ 0.04 and HR 0.11 (0.03-0.35) p 0.0006, $p_{adjusted}$ 0.01, respectively). **Conclusion:** These genes contribute to normal functioning and regulation of lipid metabolism and could be considered as potential prognostic biomarkers. There is no previous evidence of association between levels of expression of these genes and overall survival in SCLC. Validation in a larger series of patients is ongoing.

P1.03-34 THE LNCRNA NEAT1 PROMOTES RADIORESISTANCE VIA THE MIR-491-5P/CAPG AXIS IN NSCLC

S. Zhou, H. Yang

The Affiliated Taizhou Hospital, Wenzhou Medical University, Taizhou/China

Background: Long noncoding RNAs (lncRNAs) have been implicated in various biological processes and pathological conditions in cancer. However, the exact roles of LncRNA NEAT1 and its underlying mechanisms in radioresistance of non-small cell lung cancer (NSCLC) remain largely unclear. **Method:** The expression of LncRNA NEAT1 was measured in NSCLC tissues and cell lines by reverse transcriptionquantitative polymerase chain reaction (RT-qPCR). The radiosensitivity of NSCLC cells including H358, H226, HCC827, H1975, H1395 and H23 were detected by colony formation. Lentivirus-mediated short hairpin RNAs were used to knock down NEAT1 expression in H358 cells. Furthermore, the role of NEAT1 on tumor cell biological behavior and radioresistance were explored through MTT, colony formation, transwell migration, and invasion assays *in vitro*. Luciferase reporter assay was used to verify interaction between miR-491-5p and NEAT1, CAPG. The potential mechanism of LncRNA NEAT1 was identified by Western blot. Additionally, the association between the survival time and miR-491-5p expression in lung adenocarcinoma patients were evaluated based on the TCGA data. **Result:** NEAT1 was highly expressed in NSCLC tissues and cell lines. NEAT1 was up-expressed in radiosensitive NSCLC cells and low-expressed in radioresistant NSCLC cells. Conversely, miR-491-5P was low-expressed in radiosensitive NSCLC cells and up-expressed in radioresistant NSCLC cells. In addition, we revealed a reciprocal repression between NEAT1 and miR-491-5P. CAPG was identified as a down-stream target of miR-491-5P. Further experiments revealed that lncRNA NEAT1 silencing inhibited cell proliferation, invasion and radioresistance *in vitro*. Overexpression of CAPG rescued the effects of NEAT1 downregulation on proliferation, invasion and radioresistance. In addition, mechanistic analysis showed that lncRNA NEAT1 upregulated the miR-491-5p-targeted gene CAPG through acting as a competitive "sponge" of miR-491-5p. By cox regression analysis, a tendency towards a survival benefit in patients with high miR-491 expression was observed in 430 lung adenocarcinoma patients of the TCGA database. **Conclusion:** Our findings suggest that NEAT1 regulated proliferation, invasion and radioresistance by modulating the miR-491-5p/CAPG axis in NSCLC.

Keywords: NSCLC, NEAT1, miR-491

P1.03-35 ANALYSIS OF TET2 GENE ABERRATIONS IN EAST ASIAN NON-SMALL-CELL LUNG CANCER PATIENTS AND EVALUATION OF THEIR PROGNOSIS

Y. Zhang[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

Background: Ten-eleven translocation 2 (*TET2*) enzymes are frequently deregulated in cancer, but the genetic spectrum of *TET2* mutation non-small cell lung cancer patients (NSCLC) patients is unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *TET2* mutations. **Method:** A total of 895 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *TET2* mutations and other genes were detected by next generation sequencing. **Result:** *TET2* gene mutation rate was 1.90% (17/895) in non-small cell lung cancer, including G126W (1 patient), E1477* (1 patient), I1871Nfs*4 (1 patient), T665K (1 patient), Y60F (1 patient), D932H (1 patient), M533I (1 patient), R1262W (1 patient), N71Kfs*5 (1 patient), Q769* (1 patient), W1198C (1 patient), Y1645Ifs*16 (1 patient), Q1532* (1 patient), R369W (1 patient), D648Y (1 patient), G1370V (1 patient) and T344K (1 patient), and median overall survival (OS) for these patients was 19.0 months. Among them, all patients were *TET2* gene with co-occurring mutations. Briefly, patients with (n=15) or without (n=2) co-occurring *TP53* mutations had a median OS of 19.0 months and 4.0 months respectively (P<0.01); patients with (n=3) or without (n=10) co-occurring *CTNNB1* mutations had a median OS of 13.0 months and 19.0 months respectively (P=0.90); patients with (n=3) or without (n=10) co-occurring *NF1* mutations had a median OS of not up to now

POSTERS

months and 13.0 months respectively (P=0.87), patients with (n=3) or without (n=10) co-occurring *KDM5C* mutations had a median OS of not up to now months and 13.0 months respectively (P=0.75). **Conclusion:** *TET2* oncogenic activation through mutation defines a novel and distinct subset of NSCLC. *CTNNB1*, *NF1* and *KDM5C* gene accompanied may have less correlation with *KIT* mutation in NSCLC patients. *TP53* accompanied mutations might play a good prognosis in *TET2* gene mutation non-small cell lung cancer.

Keywords: non-small-cell lung cancer, TET2 mutation, prognosis

P1.03-36 CELL-FREE DNA LEVELS IN LIQUID BIOPSY FROM PATIENTS WITH NON-SMALL CELL LUNG CANCER AND ASSOCIATION WITH CLINICAL PARAMETERS AND DISEASE OUTCOME

N. Zampieri Pontes[1,2], F. Ferreira Da Silva[2], Y. Camargo Rodrigues[2], P. De Marchi[2], A. Lengert[2], R. Reis[2,3,4], L. Leal[2]

[1]*Faculdade de Ciências da Saúde de Barretos Dr. Paulo Prata, Barretos/Brazil,* [2]*Barretos Cancer Hospital, Barretos/Brazil,* [3]*University of Minho, Braga/Portugal,* [4]*ICVS/3B's-PT Government Associate Laboratory, Braga/Guimarães/Portugal*

Background: Patients with non-small cell lung cancer (NSCLC) are constantly submitted to invasive biopsies for clinical management and for guiding tailored treatment based on molecular targets. The liquid biopsy is a minimally invasive collected sample that contains cell-free circulating DNA (cfDNA), which may reflect clinical conditions and outcome based on their levels. Thus, the aim of this study was to assess the cfDNA levels in liquid biopsy samples from NSCLC patients and to correlate with the clinical parameters, overall survival, and disease outcome. **Method:** cfDNA was manually isolated from the liquid biopsies NSCLC patients (n=38) employing MagMax Cell-free cfDNA Isolation Kit. The cfDNA levels were checked by fluorometry and fragments size were evaluated by TapeStation. The cfDNA levels were associated with clinical parameters from NSCLC patients and disease outcome. **Result:** Overall, 18 cases were adenocarcinomas and 20 squamous cell carcinomas. Regarding smoking, 34 patients were current or former smokers and 4 patients were never smokers. cfDNA was successfully isolated from 31 cases, whose presented detectable levels of cfDNA (median: 0.862 ng/μL; range 0.144– 4.36 ng/μL), and 7 cases presented undetectable levels of cfDNA. All cfDNA fragments were successfully confirmed by TapeStation. Of note, patients with detectable levels of cfDNA were diagnosed at stages I (n=2), II (n=4), III (n=10), IV (n=14). However, disease staging at diagnosis was not associated with cfDNA levels (Kruskal-Wallis p=0.54). cfDNA levels were not associated with overall survival (Log-Rank p=0.86). Nonetheless, detectable levels of cfDNA were associated with unfavorable outcome (Qui-Square test p=0.03). **Conclusion:** Our results may reassure the use of liquid biopsy in personalized medicine, although these results should be confirmed in a larger series. Our results show that liquid biopsy is a useful non-invasive tool for prognostication of NSCLC patients.

Keywords: NSCLC, cfDNA, liquid biopsy

P1.03-37 IMPACTS OF DSB REPAIR PROTEIN, NBS1, ON LUNG CANCER

Y.-F. Wei[1], Y.-T. Yeh[2], J.-T. Wu[3], M.S. Huang[3]

[1]*E-DA Hospital/I-Shou University, Kaohsiung City/Taiwan,* [2]*Aging and Disease Prevention Research Center, Fooyin University, Kaohsiung/Taiwan,* [3]*E-DA Hospital, Kaohsiung City/Taiwan*

Background: The maintenance of genomic integrity is essential for cell survival and normal function, while genomic instability has been demonstrated in the development and progression of multistep cancers including lung cancer. Double strand breaks (DSB) repair protein, Nijmegen breakage syndrome 1 (NBS1), play a critical role in sensing DNA lesions, arresting cell cycle and repairing damages via forming a complex with Mre11 and Rad50 protein. Controversially, elevated NBS1 protein levels have frequently associated with the resistance to chemotherapy/radiotherapy in certain cancers. This study aims to investigate if NBS1 aberrations may contribute to NSCLC. **Method:** Immunohistochemistry was used to analyze the distribution patterns of NBS1 protein in lung cancer (n=127) and the results were further statistically correlated with clinicopathological characteristics and survival rate. XTT, invasion assay and immunoblotting were used to explore a part of bioimpacts and underlying mechanisms of the NBS1 and its interplay with nicotine in lung cancer cells. **Result:** The Kaplan–Meier plotter shows that 1926 lung cancer patients, regardless of tissue types, with high NBS1 mRNA levels will have an improved overall survival rate (p=0.004). Further immunohistochemistry showed that Increased nuclear NBS1 frequency was inversely correlated with LN metastasis (p=0.044). The significant survival difference between smoker and non-smoker (p<0.001) was lost when they presented high nuclear NBS1 frequency (p=0.095). In addition, the significant survival difference seen in relapse and relapse-free patients (p<0.001) was lost in adenocarcinoma cases when they presented with high NBS1 expression frequency (p=0.658). Intriguingly, a short term nicotine treatment increased NBS1 expression but did not significantly increase proliferation rate of the parental A549 cells. Nevertheless, the A549N cells that had been treated with nicotine for 6 months not only maintained increased NBS1 expression but also had increased cisplatin-sensitiveness. **Conclusion:** Our results showed that reduced nuclear frequency of NBS1 might be required for cigarette carcinogenic content-mediated advanced development. In addition, NBS1 might play a role in the treatment response of lung adenocarcinoma.

Keyword: Double strand breaks repair protein, Nijmegen breakage syndrome 1, lung adenocarcinoma

P1.03-38 EGFR MUTATION STATUS AS A PROGNOSTIC MARKER IN STAGE 1 LUNG ADENOCARCINOMA AFTER DEFINITIVE SURGICAL RESECTION

C. Galvez[1], S. Jacob[1], J. Zhao[1], K. Tegtmeyer[1], B. Finkelman[1], Y.K. Chae[2], N. Mohindra[2], B. Jovanovic[3], A. Behdad[1], V. Villaflor[2]

[1]*Northwestern University Feinberg School of Medicine, Chicago/United States of America,* [2]*Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago/United States of America,* [3]*Northwestern University, Chicago/United States of America*

Background: With tumor molecular genetics at the forefront of precision medicine, EGFR mutation status has been paramount for predicting response to therapy in advanced and metastatic NSCLC. However, little is known about the implications of EGFR mutation status in stage 1 disease following definitive surgical therapy, particularly in regard to prognosis and disease recurrence. **Method:** We retrospectively studied the clinical outcomes in 101 EGFR-positive patients and 97 age-matched EGFR-negative controls with stage 1 lung adenocarcinoma who underwent definitive surgical resection +/- chemoradiation. EGFR status was determined by pathologic molecular testing performed at time of diagnosis and TNM stage was determined at time of treatment. These cases were then followed for pathologically confirmed cases of recurrence and assessed for stage at recurrence, time elapsed since definitive treatment, and disease-free survival at 1, 2 and 5 years. **Result:** EGFR-positive disease demonstrated higher rates of metastatic recurrence with 15% vs 3% in controls (p=0.007). Median time to progression among those who progressed, defined as time to recurrence or death, was significantly shorter in EGFR-positive cases (82 weeks vs 158 weeks, p=0.048). There was no significant difference in rates of recurrence (p=0.32) between both groups. Disease-free survival in EGFR-positive cases was most notably lower at 2 years, with 0.86 (0.78-0.94) vs 0.94 (0.89-0.99).

	EGFR	Non-EGFR	P-value for comparison
Number in each group	101	97	-
Recurrence rate, N (%)	16 (16%)	10 (10%)	0.32 (chi-square)
Metastatic recurrence rate overall, N (%)	15 (15%)	3 (3%)	0.007 (chi-square)
Time to progression among those who progressed (weeks), Median (IQR)	82 (42, 130)	158 (75, 182)	0.048 (Wilcoxon rank sum test)
Progression free survival rates, based on Kaplan-Meier method (95% CI):			
1 year (52 weeks)	0.92 (0.86, 0.98)	0.98 (0.95, 1.00)	
2 years (104 weeks)	0.86 (0.78, 0.94)	0.94 (0.89, 0.99)	
5 years (260 weeks)	0.70 (0.58, 0.84)	0.69 (0.56, 0.86)	

Conclusion: This study suggests that EGFR-positive disease may be associated with a higher risk of metastatic recurrence and decreased time to progression in individuals who ultimately progress. EGFR molecular testing may be a promising tool for risk stratification and surveillance following definitive management for stage 1 disease. Future prospective modeling may be indicated in this disease.

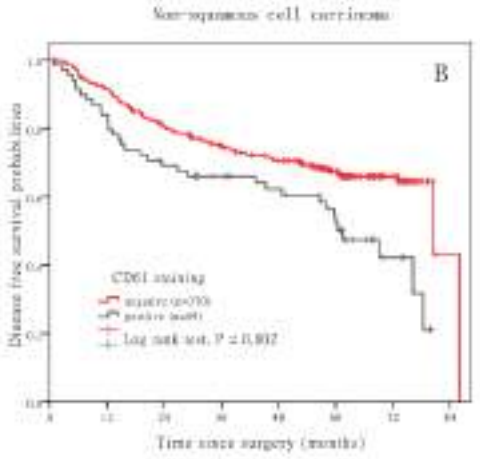
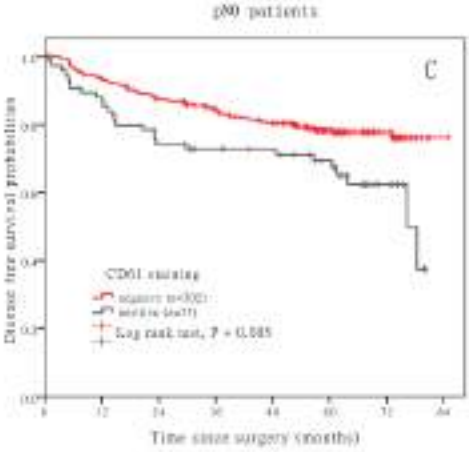
P1.03-39 INTRA-TUMORAL CD61+ MEGAKARYOCYTES PREDICTS POOR PROGNOSIS IN NON-SMALL CELL LUNG CANCER

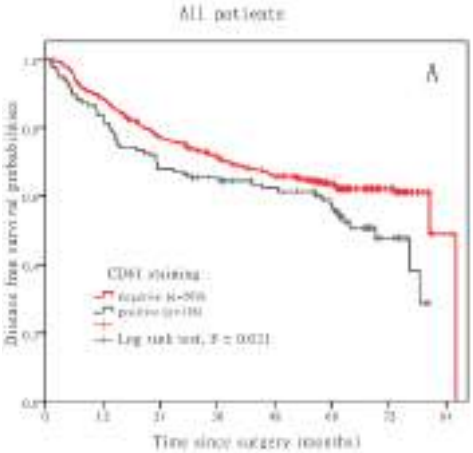
W. Liang[1], W. Huang[2], J. He[1], Q. He[1]

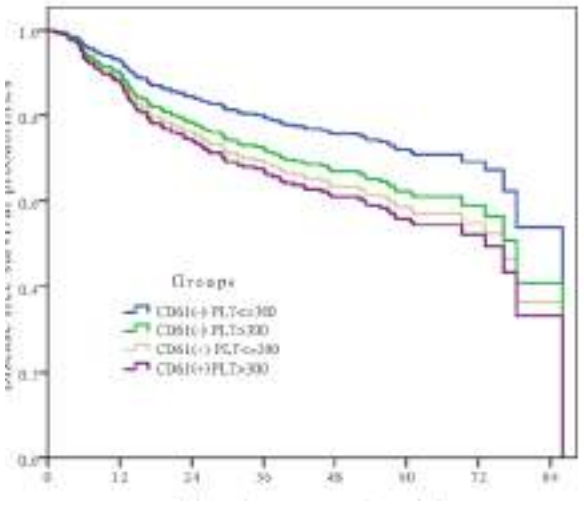
[1]*The 1st Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/China,* [2]*Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China*

Background: Lung is a reservoir for MKs to produce platelets. The aim is to investigate relationship between intra-tumoral MK with the recurrence of NSCLC. **Method:** The tissue sections of 629 patients with resected NSCLC were stained with hematoxylin, anti-CD61, anti-CD34 and stromal cell-derived factor-1 (SDF-1). CD61+ giant cells localized in CD34+ capillaries were identified as MKs. The impact of MKs and DFS was investigated. **Result:** Overall, 18.9% of patients were positive for the presence of MKs. In univariate analysis, the median DFS of the MK+ group was shorter than the median DFS of the MK- group (69.1 vs. 80.5 months; *P*=0.021). Multivariate analysis indicated that MKs in tumor tissue was an unfavorable prognostic factor for DFS (HR 1.351, *P*=0.065), the impact of which was more significant in non-squamous cell carcinoma (NSCC) (HR 1.710, *P*=0.008) and in patients with N0 (HR 1.883, *P*=0.009). Although systemic platelet count of the MK+ group was significantly higher than the MK- group (270.6 vs. 243.6 $\times 10^9$/L, *P*=0.007), the stratified subgroup DFS curves (*P*=0.003) showed that the effect of MKs on prognosis was independent of the blood platelet count. In addition, the positive association of SDF-1, CD61 and microthrombi indicated a potential mechanism by which increased MKs facilitate blood metastasis.









Conclusion: CD61+ MKs in tumor tissue predict unfavorable prognosis in NSCLC. The prognostic impact of MKs in addition to that of systemic platelet count implies that regional MK-producing platelets in tumors might contribute to NSCLC metastasis.

P1.03-40 USING MODEL SYSTEMS TO IMPROVE OUTCOMES FOR EARLY STAGE NSCLC

M. Steliga[1], J. Muesse[1], I. Shin[2], K. Arnaoutakis[2], S. Maraboyina[2], S. Jeffus[2], S. Pina Oviedo[2], E. Peterson[2], D. Johann[2]

[1]*University of Arkansas, Little Rock/United States of America,* [2]*WP Rockefeller Cancer Institute, Little Rock/United States of America*

Background: Improving outcomes for lung cancer patients with early stage disease is an unmet medical need, and model systems offer promise in this area. Model systems provide the ability to test and probe individual tumor samples with a wide array of discrete therapeutic agents, as well as novel combination strategies. Carefully engineered 3D model systems can run biological assays with animal model-like complexities, but with the speed, simplicity and affordability of traditional cell culture. A model validation step further informs assay fidelity and predictability. Upon human tumor recapitulation in a mouse, how do we know if this model is good? To what extent does the mouse-derived tumor reflect the human tumor? A clinical trial is underway at UAMS. Patients with early NSCLC have surgery for curative intent, and model systems are developed for insight towards therapeutic strategies upon recurrence. **Method:** All human tumor samples were obtained with patients' consent and IRB approval. Following surgical resection, human NSCLC tumors were grown in PDX models (JAX NSG). Tumor 3D spheroid cultures are performed on primary tumor material as well as PDX derived tumor material. All tumor material undergoes extensive modalities of NGS (ie, DNA, RNA) following best practices from the Broad Institute, and therapeutic targets are assessed. **Result:** Multiple methods and modalities are used for model system analysis and validation. Standard histopathology and multi-omic techniques are employed to examine and contrast the human tumor along with the associated PDX recapitulation through three or more passages. Specifically, the analyses include: i) copy number variation, ii) disease specific mutations via a high coverage DNA panel, iii) expressed mutations, and iv) gene and isoform expression. This is done for initial model validation and also following experiments employing specific therapeutic agents. Model systems will be compared and contrasted from PDX proper, as well as 3D tumor spheroid assays from the primary tumor and a variety of PDX passages. **Conclusion:** As model systems improve, so will the clinical outcomes for cancer patients. To improve model systems, robust bioinformatics approaches are needed for initial model assessment and validation, as well as to aid in the complex analyses associated with drug-based individualized therapy programs. Improved model systems offer the promise of enhanced scientific insights and clinical advances for cancer patients. Limitations in preclinical models are a major weakness in cancer research and is directly associated with the low success rates for translating discoveries to clinical care.

P1.03-41 CHRONIC NICOTINE EXPOSURE AFFECTS PD-L1 EXPRESSION AND SENSITIVITY TO EGFR-TKI IN LUNG CANCER

C. Yeo, S.H. Lee, I.K. Kim, H.S. Kang

The Catholic University of Korea, Seoul/Korea, Republic of

Background: Smoking histories are independently associated with poor response to epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer (NSCLC) patients with activating EGFR mutations. The aim of the present study was to determine the effect of nicotine exposure on programmed death-ligand 1 (PD-L1) expression in EGFR mutant lung cancer cells. **Method:** Human lung adenocarcinoma PC9 cells were exposed to 1 μM nicotine for 3 months designated as PC9/N, and cells were stimulated with gefitinib (0, 0.1, or 1 μM) for 48 hrs. Cell viability by the MTT assay and morphological changes by immunofluorescence staining were assessed. The protein expression of EGFR, mTOR, AKT, α1-nicotine acetylcholine receptor (nAchR) and PD-L1 were measured by Western blot. Gene expression of α1-nAchR and PD-L1 were examined by RT-PCR. Intratumoral levels of PD-L1 expression were compared according to the burden of smoking dosage in EGFR mutant lung cancer patients. **Result:** Cellular growth was inhibited by treatment with gefitinib, and PC9 cells were significantly more sensitive to gefitinib than PC9/N cells. Pleomorphic appearance with atypical nuclei and to be detached and shrunken with condensed nuclei in PC9 than PC9/N cells. The gene expression level of α1-nAchR and PD-L1 gene were higher in PC9/N cells compared to those in PC9 cells after treatment with gefitinib. Phosphorylation levels of EGFR, mTOR, AKT and PD-L1 level were decreased by gefitinib in PC9/N cells, which was to a lesser extent than that in PC9 cells. In tumors, heavy smokers (≥ 30 PY) showed 28.5% of ≥ 50% PD-L1 tumor proportion score (TPS) while light smoker and never smokers had 12.5% and 9.7% of ≥ 50% PD-L1 TPS, respectively. **Conclusion:** Chronic nicotine exposure could increase PD-L1 expression related to intrinsic resistance to EGFR-TKI in NSCLC patients harboring activating EGFR mutation. Considering the clinical importance of inevitable EGFR resistance, further studies regarding the role of anti-PD-1/PD-L1 treatment are needed, especially in EGFR mutant smokers.

P1.03-42 ANGIOTENSIN SYSTEM INHIBITORS IMPROVE SURVIVAL IN STAGE IIIA NSCLC AND SHOW ANTI-TUMOR EFFECT IN COMBINATION WITH CHEMOTHERAPY IN A MODEL OF NSCLC

H. Tang[1,2], M. Sojoodi[1], S. Li[1], D. Erstad[1], S. Ghoshal[1], G. Arora[1], E. Abston[1], K. Tanabe[1], B. Fuchs[1], M. Lanuti[1]

[1]*Massachusetts General Hospital, Boston/United States of America,* [2]*Zhongnan Hospital of Wuhan University, Wuhan/China*

Background: There is increasing interest in the renin-angiotensin system and its influence on tumor microenvironment. This study investigates the anti-tumor effect of angiotensin system inhibitors (ASI) on the multi-modality treatment of stage IIIA NSCLC and examines a potential mechanism in a murine model of lung cancer. **Method:** We retrospectively reviewed the medical records of 125 patients at a single institution diagnosed with clinical stage IIIA NSCLC who underwent induction chemo-radiotherapy followed by surgery between 2009-2015. Overall survival was compared in patients on or off ASI's. To assess the antitumor efficacy and mechanism of ASI's, cell culture models of lung cancer were treated with losartan or combination losartan+cisplatin and assessed cell survival. Mechanism was investigated with markers of epithelial-mesenchymal transition or surrogates of other signaling pathways (AKT, Stat3, PD-L1). Losartan was then tested in a murine model of lung cancer. **Result:** ASI was associated with improved overall survival on multi-variate analysis of patients treated with multi-modality therapy for stage IIIA NSLC (p =0.047) [Figure 1A]. Losartan(≥0.5μM) significantly *inhibited proliferation and migration of multiple human lung cancer cells, (H441, H358, H1299, SW1573) and a murine lung cancer adenocarcinoma, TC-1. The combination of Losartan and cisplatin significantly improved the cytotoxic effect of cisplatin in lung cancer cells in vitro (*SW1573 p =0.020, TC-1 p =0.012) and reduced the tumor volume of (SW1573$^{\text{-Nude mice}}$, p =0.045 [Figure 1B]; TC-1$^{\text{-C57BL/6 mice}}$, G, p =0.001) in a murine flank tumor model as compared to single drug treatment. Combination

treatment also significantly inhibited epithelial to mesenchymal transition and down-regulated the expression of AKT, Stat3, and PD-L1. **Conclusion:** ASI treatment influences survival in stage IIIA NSCLC. Losartan improves the anti-tumor effect of cytotoxic chemotherapy in lung cancer invitro and significantly reduces tumor burden in a murine lung cancer model. This study suggests a role for ASI therapy in the treatment of lung cancer.

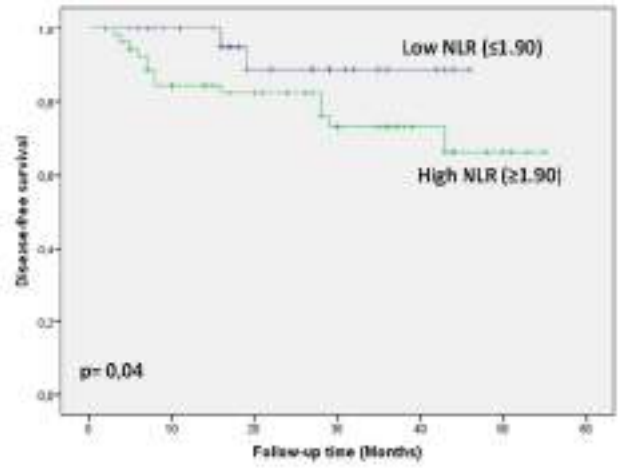
P1.03-43 PREOPERATIVE PROGNOSTIC VALUE OF IMMUNE-INFLAMMATION INDEX IN PATIENTS WITH OPERABLE NON-SMALL CELL LUNG CANCER

C. Fraile Olivero[1], L. Milla Collado[1,2], M. Mecho Carratala[2], A. Ojanguren Arranz[2], J. Trujillano Cabello[2], C. Cerdan Santacruz[2], M. Montesinos[2], C. Rombolá[2]

[1]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [2]*Hospital Arnau Vilanova, Lleida/Spain*

Background: There is increasing evidence that the systemic immune-inflammation response is correlated with clinical outcomes in diverse solid tumors. The aim of the study was to determine preoperative values of neutrophil to lymphocyte ratio (NLR), platelet to lymphocyte ratio (PLR) and lymphocyte to monocyte ratio (LMR), and to analyze their impact on histologic outcomes and prognosis in patients with operable non-small cell lung cancer (NSCLC). **Method:** Retrospective study of patients diagnosed of stage I-IIIA NSCLC (7th edition TNM) between May 2014 and October 2018. Exclusion criteria included neoadyuvant therapy, R1-R2 resection, previous autoimmune or hematological disorders, active pre- or postoperative infection, steroid therapy, perioperative blood transfusion and previous history of malignancy other than NSCLC. The NRL, PLR and LMR were calculated by means of a peripherical blood sample 4 weeks prior to surgery. Receiver operating characteristic (ROC) curve was used to determine the optimal cut-off values for above mentioned ratios. The association between NRL, PLR and LMR, and histological outcomes, recurrence, disease free interval (DFI) and overall survival were analyzed. **Result:** Eighty-six patients who underwent surgery for NSCLC were included in this retrospective analysis (51% males, median age 69,5 years). Mean follow-up was 45,7 months. Median overall survival and DFI were 27 and 24 months respectively. There was no statistically significant association between PLR, MLR, and histological variables, DFI or overall survival. The optimal cut-off value was 1.90 for NLR. In our series, INR values superior to 1.90 showed a significantly higher recurrence rate (23.6% vs. 5.5%, p=0.04) (Fig. 1) and a decreased overall survival (90% vs. 97%, p=0.031).



Conclusion: This study demonstrated that NLR is an independent poor outcome marker for patients with I-IIIA NSCLC who underwent surgery. In our series NLR (cut off value >1.90) could be used preoperatively as a valuable prognostic marker for disease free interval and overall survival.

P1.03-44 ROLE OF SERUM PROCALCITONIN AS DIAGNOSTIC BIOMARKER OF PNEUMONIA IN LUNG CANCER PATIENT

A. Dewi, E. Burhan, A. Putra

Universitas Indonesia, Jakarta/Indonesia

Background: Pneumonia accounts for higher morbidity and mortality than any other infections in lung cancer patients. Procalcitonin (PCT) is a clinical biomarker that widely used to diagnose infection including pneumonia. The cut off level of serum procalcitonin to diagnose pneumonia in lung cancer patient still unclear. The current study aimed to determine the role of PCT in diagnosing pneumonia in lung cancer patients. **Method:** Diagnostic test with cross sectional design was conducted in lung cancer patients with suspected pneumonia admitted to emergency and pulmonary ward of Persahabatan Hospital Jakarta, Indonesia between August – October 2018. Pneumonia was defined as the presence of new or progressive infiltrate or air bronchograms on chest radiograph with minimal 2 acute signs and symptoms of lower respiratory tract infection. Serum PCT level (sPCT), leucocyte count, and absolute neutrophil count between lung cancer patients with and without pneumonia was measured followed by statistical analysis. The optimal sPCT cut off point to diagnose pneumonia in lung cancer was determined using ROC curve. **Result:** A total of 60 subjects enrolled in this study. Lung cancer patients presented with pneumonia was found in 31 patients (51.7%) with mean age 54.68±10.59 yo, which 77.4% were males, 51.6% were adenocarcinomas, 83.9% were stage IV cases, 45.2% were patients with ECOG performance status of 3, 45.2% were underweight and 54.8% were ex-smokers. The sPCT were significantly higher in lung cancer patients with pneumonia compared to those without pneumonia [1.81 (0.08-200) µg/L vversus 0.30 (0.05-3.67) µg/L; p<0.001]. In both group showed an elevation of leucocyte count (17.340 cells/µL versus 13.660 cells/µL) and absolute neutrophil count (14.955 cells/µL versus 11.872 cells/µL) with no significant differences (p=0.297 and p=0.290, respectively). The sPCT showed a good accuracy to diagnose pneumonia in lung cancer with AUC 0.829 (CI 95% 0.722-0.935). The optimal cut off point of sPCT to diagnose pneumonia in lung cancer was 0.65 µg/L with 77.4% sensitivity and 79,3% specificity. **Conclusion:** The sPCT was significantly higher in lung cancer patients with pneumonia than those without pneumonia and showed a better performance in differentiating pneumonia in lung cancer patients compared to leucocyte count and absolute neutrophil count. The optimal cut off level of sPCT to diagnose pneumonia in lung cancer was 0.65 µg/L.

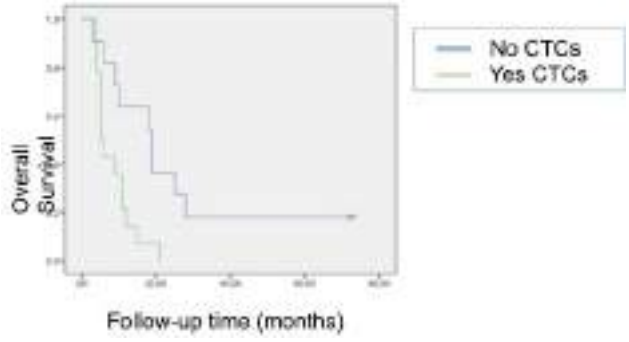
P1.03-45 CIRCULATING TUMOR CELLS' CLEARANCE IN BLOOD SAMPLES AFTER CHEMOTHERAPY: A GOOD PROGNOSTIC FACTOR FOR OS IN ADVANCED NSCLC

L. Milla Collado[1], C. Fraile Olivero[2], C. Cerdan Santacruz[1], T. Valverde Higueras[3], J.L. Gonzalez Larriba[4], I. Cal Vazquez[5], J. Jarabo Sarceda[4], E. Fernández Martín[4], F. Hernando-Trancho[4]

[1]*Hospital Arnau Vilanova, Lleida/Spain,* [2]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [3]*Hospital Clinico San Carlos, Madrid/Spain,* [4]*Hospital Clínico San Carlos, Madrid/Spain,* [5]*Hospital La Princesa, Madrid/Spain*

Background: The poor prognosis of patients diagnosed with non-small cell lung cancer (NSCLC) patients in advanced stages requires a close monitoring of treatment´s response in order to plan early changes when necessary. The presence of circulating tumor cells (CTC) in periferic blood samples has showed worse prognosis in different tumors. The aim of the study is analyzing the relationship between the presence of CTCs in periferic blood samples and overall survival (OS) and progression-free interval (PFS) in advanced stages of NSCLC patients. **Method:** Periferic blood samples were obtained from 25 patients diagnosed with NSCLC in advanced stages from April of 2010 to January of 2013 suitable for chemotherapy treatments. One blood sample was taken before treatment (S1) and the other one, after one cycle of chemotherapy (S2). Blood samples were analyzed by CellSearch method. Probability of survival was calculated following the Kaplan-Meier method; differences in survival were examined by the Long-Rank test. **Result:** Median OS and PFS were 10 months and 6 months respectively. OS was 6 months in patients with isolation of CTC in S1 vs 11 months in those with no isolation of CTC; no statistical differences (p=0.978). OS was longer in those patients in whom there was no isolation of CTC in

S2 compared to those in whom CTC were isolated (19 months vs 5 months; p=0.006). Contrary to this, no difference was observed considering PFS with a median of 6.5 months in patients without CTCs in their S2 and 6 months with CTCs present.



Conclusion: In our study, patients with CTC´s isolation in S2 had a worse prognostic, median of 14 months OS, compared to those in whom there were no CTC isolation.

Keywords: circulating tumour cells, advance stage

P1.03-46 LNCRNA H19 DOWNREGULATION PROMOTED RESISTANCE TO EGFR-TKIS THROUGH REGULATING AKT AND SRC ACTIVATING IN NSCLC CELLS

C. Li, B. Zhang

Tianjin Medical University Cancer Institute and Hospital, Tianjin/China

Background: Most NSCLC patients with EGFR activating mutations initially respond to EGFR-TKI treatment. However, acquired resistance to EGFR-TKIs inevitably occurs after treatment for several months. There are evidences that suggest lncRNAs could play important roles in EGFR-TKI resistance, but limited data is available now. In previous study, we found that LncRNA H19 was downregulated in EGFR-TKI-resistant cells. **Method:** We established two erlotinib-resistant cell lines HCC827-ER and PC9-ER. Real-time quantitative PCR (qPCR) was used to detect H19 levels. We detected gene mutations in the ER cell lines through whole-exome sequencing. We used H19 and H19 shRNA lentiviral expression vector to overexpress or knockdown its expression. MTT cytotoxic and clone formation experiments were performed to assess cell growth inhibition. The apoptosis analysis was evaluated by PARP and caspase-3 degradation. Protein levels in AKT and SRC were examined by western blotting. **Result:** H19 expression was lower in HCC827-ER and PC9-ER cells than in their parental sensitive (PS) cells. We did not detect mutations in EGFR T790M, PI3KCA, or KRAS by whole-exome sequencing of ER cell lines. MTT and clone formation assays showed H19 knockdown caused resistance to erlotinib in PS cells, whereas H19 overexpression not only enhanced erlotinib sensitivity in PS cells but also recapitulated erlotinib sensitivity in HCC827-ER and PC9-ER cells. Treatment with erlotinib increased PARP and caspase-3 cleavage in H19-ovexpressing ER and PS cells. We also found erlotinib treatment decreased levels of phosphorylated AKT and SRC in PS cells, and further lowered their levels in H19-overexpressing PS cells. On the contrast, erlotinib treatment had no effect on levels of phosphorylated AKT and SRC in H19-knockdown PS cells. Finally, we measured the expression of H19 using qPCR in 20 fresh frozen EGFR-mutant NSCLC specimens. Lower expression of H19 was observed in EGFR-TKI-resistant tissue samples. **Conclusion:** H19 was downregulated in erlotinib-resistant NSCLC cells. H19 inhibited AKT and SRC activating to restore sensitivity to erlotinib, which could provide new insight into resistance mechanisms to EGFR-TKIs.

Keywords: LncRNA H19, EGFR-TKIs, NSCLC

P1.03-47 KEAP1 MUTATIONS IN EAST ASIAN PATIENTS WITH NSCLC: AN INVESTIGATION OF PREVALENCE, CLINICOPATHOLOGIC CHARACTERISTICS AND PROGNOSIS

Z. Yu[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Fuzhou General Hospital, Fuzhou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: The KEAP1/NRF2 pathway is a master regulator of the cellular redox state through the induction of several antioxidant defence genes implicated in chemotherapeutic drugs resistance of tumor cells. Because of the rarity of those mutations, associated clinical features and prognostic significance have not been thoroughly described so far. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *KEAP1* mutations. **Method:** A total of 317 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *KEAP1* mutations and other genes were detected by next generation sequencing. **Result:** *KEAP1* gene mutation rate was 10.09% (32/317) in non-small cell lung cancer, including D618Tfs*54 (2 patients), W252L (1 patient), G158C (1 patient), D618Tfs*54 (1 patient), L237Q (1 patient), R415C (1 patient), K97N (1 patient), C368F (1 patient), A95T (1 patient), C273F (1 patient), S243F (1 patient), E149K (1 patient), H96L (1 patient), L70Q (1 patient), G558W (1 patient), E493K (1 patient), A40P (1 patient), E343V (1 patient), E219* (1 patient), G158C (1 patient), D235Tfs*3 (1 patient), I125T (1 patient), R320L (1 patient), R470H (1 patient), E244* (1 patient), G158V (1 patient), C368F (1 patient), I185F (1 patient), N157_M161del (1 patient), R336* (1 patient) and E219Q plus D526N (1 patient), and median overall survival (OS) for these patients was 13.5 months. Among them, all patients were *KEAP1* gene with co-occurring mutations. Briefly, patients with (n=20) or without (n=12) co-occurring *TP53* mutations had a median OS of 14.5 months and 13.5 months respectively (P=0.71); patients with (n=15) or without (n=17) co-occurring *KRAS* mutations had a median OS of 15.0 months and 12.0 months respectively (P=0.79); patients with (n=16) or without (n=16) co-occurring *STK11* mutations had a median OS of 13.5 months and 18.0 months respectively (P=0.60); patients with (n=4) or without (n=28) co-occurring *PIK3CA* mutations had a median OS of not up to now and 12.0 months respectively (P=0.16). **Conclusion:** *KEAP1* gene mutation coexists with other gene mutation in NSCLC. *TP53*, *KRAS*, *STK11* and *PIK3CA* gene accompanied may have less correlation with *KEAP1* mutation in NSCLC patients. Analysis of *KEAP1* mutations shows promise as a way to refine individual patients with NSCLC, and provides more insight into effective treatment strategies for patients with *KEAP1* mutations.

Keywords: prognosis, non-small-cell lung cancer, KEAP1 mutation

P1.03-48 VASOHIBIN 2 PROMOTES ANGIOGENESIS AND LYMPHANGIOGENESIS OF LUNG SQUAMOUS CELL CARCINOMA THROUGH SNAIL-DEPENDENT VEGF-D SIGNALING PATHWAY

P. Liu, L. Han, R. Zhang, W. Zhang, J. Yu

Cancer Molecular Diagnostics Core, Tianjin Medical University Cancer Institute & Hospital, Tianjin/China

Background: Tumor metastasis is a process in which tumor cells spread to the secondary sites via the lymphatic and blood vessels. In lung squamous cell carcinoma (LUSC), the molecular mechanisms involved in lymphangiogenesis and lymphatic metastasis remain unclear. **Method:** We analyzed mRNA expression profiles of 535 primary LUSC samples from TCGA to screen the most differentially expressed genes related to the poor prognosis of LUSC patients and validated in an independent Chinese LUSC cohort. We focused on *Vasohibin 2* (VASH2) and investigated its biological functions in LUSC proliferation, apoptosis, migration, invasion, as well as lymphangiogenesis by forced over-expressing VASH2 in LUSC cell line H520 *in vitro*. We also investigated the anti-tumor efficacy of VASH2 target treatment in LUSC xenograft-bearing mice models. **Result:** We identified 12 genes closely related to poor prognosis of LUSC patients, among which VASH2 was validated in an independent Chinese LUSC cohort and displayed high potential of lymphatic metastasis. Forced over-expression of VASH2 promoted the proliferation and invasion of LUSC cells via up-regulating

specific transfer factor snail. Furthermore, VASH2 facilitated lymphangiogenesis and angiogenesis via up-regulation of snail-dependent vascular endothelial growth factor-D (VEGF-D) in LUSC cells *in vitro and vivo*. Importantly, specific VASH2 blocking antibody dramatically inhibited tumor development and progression in LUSC xenograft-bearing mouse models by interfering tumor proliferation and lymphangiogenesis *in situ*. **Conclusion:** In conclusion, VASH2 might serve as a novel predictive biomarker and a potential therapeutic target for LUSC via inhibiting tumor growth and local lymphangiogenesis.

P1.03-49 SYSTEMATIC DYSREGULATION OF CELL CYCLE BY LNCRNAS IN LUNG ADENOCARCINOMA

X. Shi[1], A. Chen[2], Z. Zheng[2], X. Dong[1], K. Huang[2], X. Liu[1], D. Lu[1], S. Feng[1], K. Cai[1]

[1]*Nanfang Hospital, Guangzhou/China,* [2]*Mendel Genes Inc, Guangzhou/China*

Background: LncRNAs are associated with tumor progression, immune escape, and survival, but how do lncRNAs systematically change the tumor microenvironment and what biological function is dysregulated are less reported. **Method:** In our previous report, lung adenocarcinoma (LUAD) RNA sequencing data were downloaded from The Cancer Genome Atlas (TCGA). Differential analysis and lncRNA- protein-coding-gene co-expression analysis was performed; the signal pathways of expressed genes are clustered and enriched. **Result:** AC109642.1, RP11-582J16.4, RP11-378A13.1, TBX5-AS1, AC090616.2, AC079630.4, SFTA1P, FENDRR, RP11-736K20.4, RP11-389C8.2 and MIR22HG are low expressed in cancer tissue compared to tumor-matched normal tissue, while the EEF1A1P6, MBNL1-AS1, ADAMTS9-AS1, LINC00987, LINC01197, EP300-AS1, PCAT19, OR7E47P, AC093110.3, RP11-366L5.1, LINC00968, CTD-2562J17.6, RP11-203P23.2, AF131215.2, RP11-434D9, LINC00702, RP11-1024P17.1 and MAGI2-AS3 are high expressed. These lncRNAs regulated coding proteins are clustered into seven categories and systematically mediated cell cycle dysfunction in LUAD.

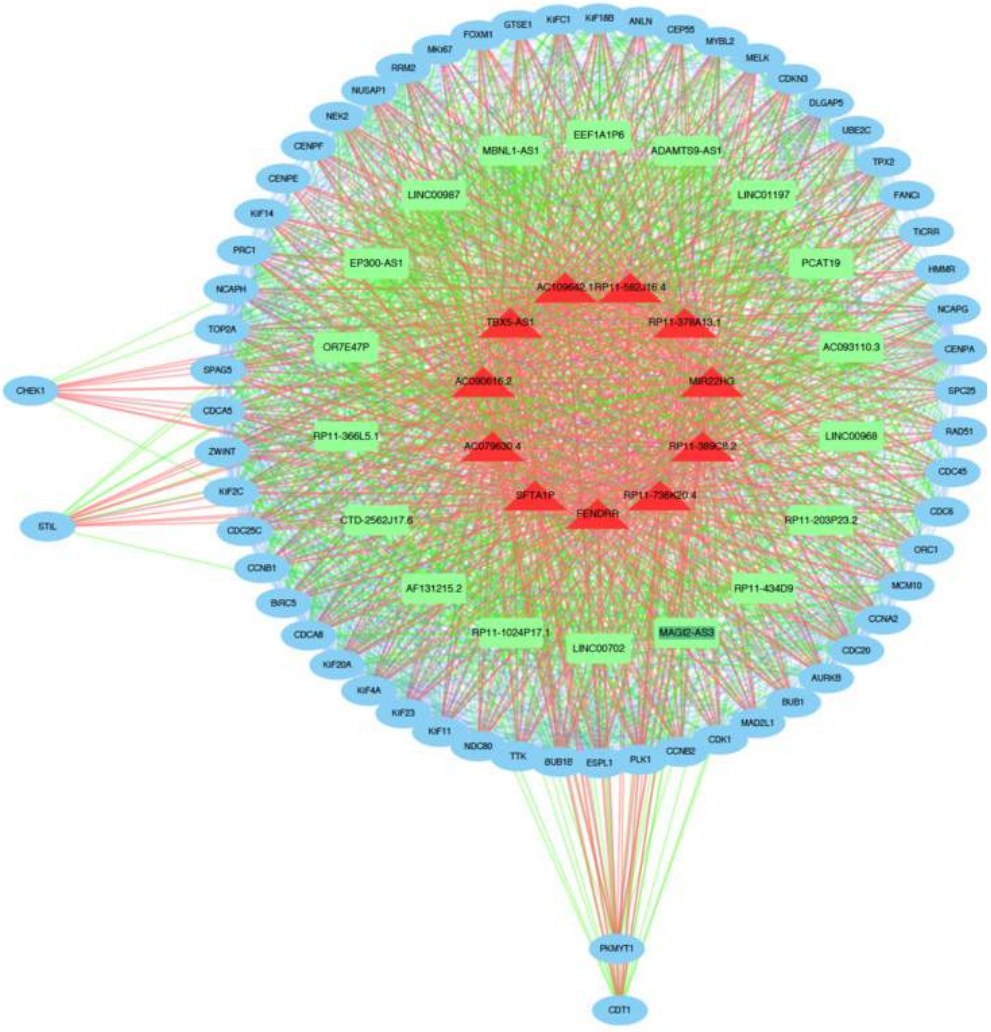

Figure 1 The network of lncRNAs regulated protein-coding genes. The red triangles indicate low expressed lncRNAs in tumor tissue; the green rectangular indicate high expressed lncRNAs in tumor tissue and the blue ovals indicate regulated coding genes. **Conclusion:** This is the first time to reveal that the dysregulated lncRNAs systemically affect the cell cycle in LUAD tissue. The dynamic change of lncRNAs and the associated protein-coding genes network could give us a better epigenetic understanding and future direction of targeting uncontrollable LUAD growth.

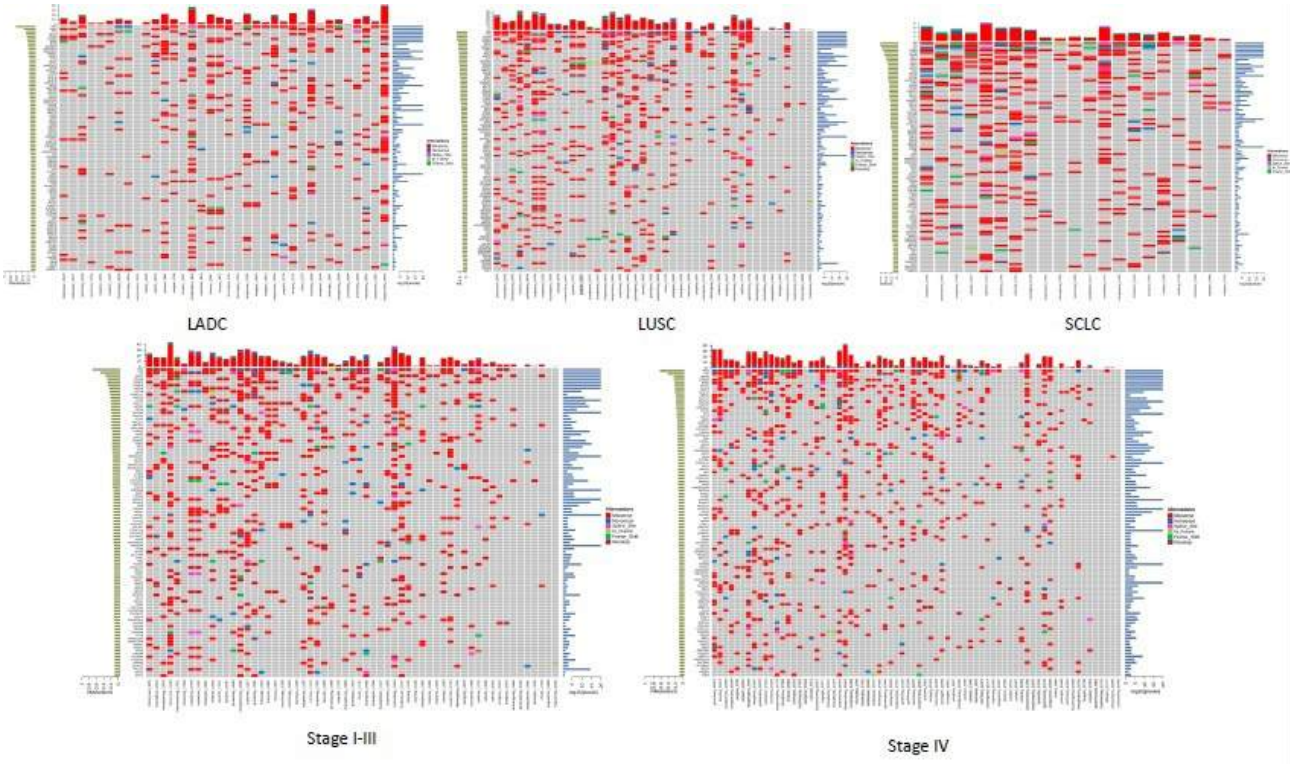
P1.03-50 TYPE- AND STAGE-SPECIFIC GENOMIC PROFILES IN EAST ASIAN LUNG CANCER PATIENTS WITH NO TKI-RELATED DRIVER GENE MUTATIONS

Y. He[1], X. Chen[1], B. Chen[1], L. Song[2], X. Li[2], S. Chen[2], G. Liu[2], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China,* [2]*Haplox, Shenzhen/China*

Background: It is widely accepted that the development of advanced lung cancer or distant metastases rely on driver gene mutations, but the carcinogenesis of lung cancers without key driver gene mutations has not been fully understood. The genomic landscape of lung adenocarcinoma (LADC), lung squamous cell carcinoma (LUSC) and small cell lung cancer (SCLC) without TKI-related driver gene mutations in East Asian has not been well investigated. Systematic study of these subtypes may identify biomarkers to distinguish different types and find novel tractable targets for therapy. We have therefore studied the genomic profiles of these types of lung cancers to identify type-specific and stage-specific gene mutations. **Method:** 32 LADC patients, 43 LUSC patients and 26 SCLC patients with no TKI-related driver gene (EGFR, ALK, ROS1, RET, BRAF, C-MET, HER2) mutations were included in this study. Genomic profiles were determined with lung cancer tissue by whole-exome sequencing (WES). Sequencing data were analyzed with R packages and statistics was performed with SPSS 20. **Result:** In 101 patients enrolled, TP53, TTN, MUC4, ZFHX4 and CSMD3 mutations were commonly detected in all 3 types of lung cancer, and TP53 was the commonest mutated gene. Markedly, KRAS mutations were found only in LADC, and CSMD1 mutations were more frequent in LUSC, whereas RB1 mutations were observed exclusively in SCLC. LRP1B and RYR2 mutations were found more frequently at late stages. Copy number variations (CNV) in TERT, RICTOR and FGFR1 were seen in all 3 subtypes. The PIK3CA copy number gain was commonly seen in LUSC and SCLC other than that in LADC. In contrast, the CDKN2A copy-number loss was found in LADC and LUSC, but not in SCLC. The PTEN copy number loss was only identified in LUSC. No significant differences in TMB were observed among these 3 subtypes of lung cancer. However, statistical significance in TMB was attained between non-small cell lung cancer (NSCLC) and SCLC (P=0.022) in stage IV patients when the cut-off of TMB was set to 4.5 muts/MB.



Conclusion: Results from this genomic study confirmed the mutual and exclusive gene variations (including gene mutations and copy number variations) in 3 subtypes of lung cancer. It showed that gene variations were associated with lung cancer subtypes in patients with no TKI-related driver gene mutations. These findings might detecte subtype-specific biomarkers to assist histological-based diagnosis, and help to identify potential type-specific targets for lung cancer therapy.

P1.04-01 BODY MASS INDEX AND AGE DO NOT INFLUENCE SURVIVAL IN PATIENTS WITH LUNG CANCERS TREATED WITH PD1/PDL1 IMMUNE CHECKPOINT INHIBITORS

C. Richard[1,2], A. Elkrief[3], J. Malo[3], L. Cvetkovic[3], M. Florescu[3], N. Blais[3], M. Tehfe[3], A. Gagné[4], C. Labbe[4], M. Orain[4], P. Joubert[4], F. Ghiringhelli[2], B. Routy[3]

[1]*1 rue Professeur Marion, Dijon/France,* [2]*Centre Georges François Leclerc, Dijon/France,* [3]*Centre Hospitalier de l'Universite de Montreal, Montreal/Canada,* [4]*Quebec Heart and Lung Institute Research Center, Quebec/Canada*

Background: Age and body mass index (BMI) are important factors in patients treated with chemotherapy. However, in the era of immune checkpoint inhibitors (ICI), the importance of these baseline characteristics is unclear. For example, pooled analysis of age did not influence the clinical response to ICI, whereas patients with BMI >35 had better outcomes in melanoma and renal cell carcinoma. More data are needed to clarify the role of these two characteristics in non-small cell lung cancer (NSCLC) patients amenable ICI. **Method:** We conducted a retrospective analysis of patients treated with anti-PD1 ICI for advanced NSCLC at the Dijon Cancer Center (n=177), University of Montreal University Hospital (n=106) and Quebec Heart and Lung Institute (n=98). BMI and age were considered as continuous or categorical variables. Patients' baseline characteristics were compared using the Chi-squared test. Survival curves were estimated by the Kaplan-Meier method and compared with the Log-rank test in a univariate analysis. Multivariate cox regression model was used to determine hazard ratios and 95% confidence intervals for progression-free survival (PFS) and overall survival (OS) between the groups, adjusting for other clinicopathologic features. **Result:** Among 381 patients included, the median BMI was 24.5 (range 16.2-43.4) and 32.7% and 13.6% were classified as overweight or obese respectively. The median age was 66 (range 37-89) and 29% were older than 70 years-of-age. Considering BMI and age as continuous or categorical variables, they were not associated with PFS or OS, with the exception of BMI in the Dijon cohort (continuous: HR=0.95, 95%CI[0.91-0.99]; < 25 vs > 25: HR=0.68, 95%CI[0.47-0.99]). Subgroup analysis and multivariate cox regression did not reveal significant interaction of these two factors with outcomes. There was no difference in toxicity between the groups. ECOG performance status was the only significant factor in the three cohorts. **Conclusion:** Unlike previously described in the era of chemotherapy, obesity and age were not associated with outcomes in NSCLC patients treated with ICI.

P1.04-02 EFFICACY AND SAFETY OF SINTILIMAB WITH ANLOTINIB AS FIRST-LINE THERAPY FOR ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

B. Han[1], T. Chu[1], R. Zhong[1], H. Zhong[1], B. Zhang[2], W. Zhang[1], C. Shi[1], J. Qian[1], Y. Han[1]

[1]*Shanghai Chest Hospital, Shanghai/China,* [2]*Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China*

Background: Given the synergy effect of immunotherapy and anti-angiogenic therapy in advanced NSCLC, FDA approved atezolizumab plus bevacizumab and chemotherapy as first-line treatment. However, chemo-free first-line strategy of PD-1/PD-L1 inhibitor combining angiogenesis modulator remains to be explored. This is the first trial evaluating sintilimab (anti-PD-1) plus anlotinib (multi-target TKI against tumor angiogenesis and proliferation) in treatment-naive advanced NSCLC patients and is also one arm from phase I anlotinib-based trial (NCT03628521). **Method:** Treatment-naive, stage IIIB/IV NSCLC patients aged 18-75 with ECOG PS 0-1 were eligible. Patients with EGFR, ALK or ROS1 mutations were excluded. Participants were given intravenous sintilimab (200mg q3w) and oral anlotinib (12mg/d 2 weeks on/1 week off) until progression or unacceptable toxicity. The primary endpoints were ORR and safety. The secondary endpoints included DCR, PFS and OS. AEs were graded according to CTCAE v4.0. **Result:** From Septembe-2018 to February-2019, 22 patients were enrolled. Most were male (95.5%), former/current smokers (63.6%) and squamous cell histology (54.5%). 4 had baseline brain metastases. All patients have received at least one tumor assessment as of Jul-3th-2019. Among all, 17 achieved confirmed PR, 5 achieved SD, ORR was 77.3% and DCR was 100%. 6m-PFS rate was 93.8% (95%CI: 63.23%, 99.10%). Overall, sintilimab and anlotinib was well tolerated. 7 (31.8%) had grade 3 and above treatment related adverse event (TRAE). The most common TRAE were hematuria, hyperuricemia, hypertension, increased ALT and rash, etc. 21 patients had baseline PD-L1-evaluated and 17 patients got TMB status (details in table). Notably, 2 of 5 SD patients developed cavities inside, suggesting a sign of synergetic anti-tumor effect from combination regimen. **Conclusion:** In this interim analysis, sintilimab plus anlotinib showed high ORR (77.3%) and DCR (100%) with tolerable safety profile, supporting worthy of further development from this convenient chemo-free regimen in first line setting.

Table 1. Response rates

Best Overall Response	Overall (n=22)	PD-L1 + (n=13)	PD-L1 - (n=6)	TMB ≥ 10 (n=6)	TMB <10 (n=11)
CR, n (%)	0	0	0	0	0
PR, n (%)	17 (77.3%)	9 (69.2%)	7 (87.5%)	5 (83.3%)	8 (72.7%)
SD, n (%)	5 (22.7%)	4 (30.8%)	1 (12.5%)	1 (16.7%)	3 (27.3%)
PD, n (%)	0	0	0	0	0
ORR, n (%)	17 (77.3%)	9 (69.2%)	7 (87.5%)	5 (83.3%)	8 (72.7%)
DCR, n (%)	22 (100%)	13 (100%)	6 (100%)	6 (100%)	11 (100%)

P1.04-03 HLA AFFINITY FOR MUTANT EGFR DERIVED PEPTIDES IDENTIFIES A GROUP OF PATIENTS WITH EGFR DRIVEN NSCLC AND FAVORABLE PROGNOSIS

A. Dimou[1], P. Grewe[1], M. Campbell[1], T. Brunetti[1], J. Sidney[2], A. Sette[2], A. Van Bokhoven[1], P. Norman[1], R. Doebele[1]

[1]*University of Colorado Denver, Aurora/United States of America,* [2]*La Jolla Institute for Immunology, La Jolla/United States of America*

Background: Tumor mutations generate neopeptides with the potential to elicit T cell responses. Most commonly, passenger mutations are involved in this process, whereas driver mutations are restricted by the HLA genotype. Here, we hypothesized that peptides derived from mutant EGFR with ability to be presented by the host HLA molecules might elicit T cell responses against EGFR mutation positive tumors. **Method:** We used the NETMHCpan platform to predict HLA A, B and C alleles that bind to peptides derived from EGFR p.L858R and EGFR p.E746_A750del but not to the closest wild type peptides. We termed the identified alleles as "protective alleles" based on their potential to elicit T cell responses against mutant EGFR. Further, we classified patients with EGFR mutation positive lung adenocarcinoma in the TCGA database with known HLA genotype into having at least one protective allele ("protected" group) or having none of these alleles ("non-protected" group). **Result:** We identified HLA alleles A*31:01, A*33:01, A*68:01 and B*08:01 as protective for EGFR p.L858R and alleles A*03:01 and A*11:01 as protective for EGFR p.E746_A750del. These alleles with the exception of A*11:01 are found more common in European compared to Asian populations. In the TCGA population, we identified 20 patients with EGFR p.L858R and 14 patients with EGFR p.E746_A750del positive lung adenocarcinoma and complete follow up and HLA data. Among them, 11 classified in the "protected" and 23 in the "non-protected" group. There were no significant differences in the two groups with respect to gender, age or stage at diagnosis. Patients in the "protected" group had longer overall survival (p value=0.0011) and disease-free survival (p value=0.0047) compared to the "non-protected" group. Presence of the same alleles did not affect prognosis in patients from the TCGA with KRAS mutation positive adenocarcinoma. Difference in overall survival remained significant after controlling for stage, gender and age at diagnosis in a Cox proportional hazards model (risk ratio 0.01, 95% CI 0.001-0.34). **Conclusion:** Here, we present a methodology to identify HLA alleles with the potential to elicit EGFR directed T cell responses against mutant EGFR. Interestingly, the identified alleles are more common in European populations, known to carry less risk for EGFR mutations compared to Asian populations. Presence of such alleles

predicts better prognosis in an early stage EGFR mutation positive lung cancer population, consistent with our hypothesis that they might drive adaptive immunity against mutant EGFR.

Keywords: HLA, EGFR, adaptive immunity

P1.04-04 DNA DAMAGE RESPONSE GENE ALTERATIONS ARE ASSOCIATED WITH HIGH TUMOR MUTATIONAL BURDEN AND CLINICAL BENEFIT FROM PD-1 AXIS INHIBITION IN NSCLC

B. Ricciuti[1], M. Cheng[1], G. Recondo[1], R. Umeton[1,2], M. Nishino[2], L. Sholl[3], M. Awad[1]

[1]*Dana-Farber Cancer Institute, Boston/United States of America,* [2]*Dana Farber Cancer Institute, Boston/United States of America,* [3]*Brigham and Women's Hospital, Boston/United States of America*

Background: DNA damage response (DDR) gene alterations are associated with increased tumor infiltrating lymphocytes, higher genomic instability, and higher tumor mutational burden (TMB) in cancer. Whether DDR alterations are associated with benefit from immune-checkpoint inhibitors (ICIs) in non-small cell lung cancer (NSCLC) is unknown. **Method:** Clinicopathologic and genomic data were collected from patients (pts) with advanced NSCLC at the Dana-Farber Cancer Institute treated with PD-(L)1 inhibitors. Targeted next-generation sequencing (NGS) by OncoPanel was used to determine DDR gene mutation status and TMB. All loss-of-function alterations in DDR genes (including nonsense, frameshift, or splice site) were classified as pathogenic. Missense mutations were manually evaluated and classified as pathogenic if considered to be deleterious in the Catalogue of Somatic Mutations in Cancer (COSMIC) and ClinVar databases, as well as the PolyPhen-2 (Polymorphism Phenotyping v2) functional prediction tool. **Result:** Of 223 pts with successful NGS who received ICIs, 116 (52.0%) were identified as having pathogenic DDR mutations (DDRpos) with alterations in the following genes: FANC genes (20%) ATM (13.9%), POL genes (11%), ERCC genes (8%), BRCA1/2 (8%), MLH1/MSH2/MSH6 (7%), CHEK1/2 (7%), RAD genes (6%), ATR (5%), BRIP1 (3%), XRCC genes (3%), BARD1 (2%), PMS (2%), NEIL (2%), BAP1 (1%), PALB2 (1%). DDRpos and DDR negative (DDRneg) groups were well balanced in terms of age, gender, histology, performance status (PS), smoking status, baseline presence of brain metastasis. The median TMB was significantly higher in the DDRpos group compared to the DDRneg group (12.9 vs 8.3 mutations/megabase [mut/Mb], P < 0.001), including among never smokers (11.0 vs 6.8 mut/Mb, P = 0.02). No difference in median PD-L1 expression was observed between groups (50% vs 50%, P = 0.52). Compared to DDRneg pts (N=107), DDRpos pts had a significantly higher objective response rate (30.4% vs 16.8%, P = 0.001), longer median progression-free survival (4.3 vs 2.3 months, HR: 0.64 [95%CI: 0.48-0.86], P = 0.003) and median overall survival (16.5 vs 11.2 months, HR: 0.62 [95%CI: 0.44-0.88], P = 0.008) with PD-(L)1 therapy. After adjusting for ECOG PS, smoking status, baseline brain metastasis, and line of therapy, DDRpos status was associated with significantly longer PFS (HR: 0.64 [0.48-0.86], P < 0.01) and OS (HR: 0.58 [95%CI: 0.41-0.83], P < 0.01) in multivariate analysis. **Conclusion:** Pathogenic DDR alterations are frequent in NSCLC and are associated with higher TMB and improved clinical outcomes among NSCLC pts treated with PD-1 axis inhibition.

P1.04-05 PD-L1 EXPRESSION (SP263) IN LUNG CANCER AND PAIRED BRAIN METASTASES – A SINGLE CENTER STUDY IN 211 PATIENTS

A. Kündig[1], C. Fung[2], A. Scherz[3], A. Ochsenbein[3], E. Herrmann[4], E. Ermis[4], R. Schmid[5], E. Hewer[1], S. Berezowska[1]

[1]*Institute of Pathology, University of Bern, Bern/Switzerland,* [2]*Department of Neurosurgery, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland,* [3]*Department of Medical Oncology, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland,* [4]*Department of Radiation Oncology, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland,* [5]*Division of General Thoracic Surgery, Inselspital, Bern University Hospital, University of Bern, Bern/Switzerland*

Background: Lung cancer presents with brain metastases (BM) in a significant number of cases and resected BM are often the only tissue available for analysis of predictive biomarkers. Studies have shown some molecular divergence between BM and primary lung tumor, but data on paired samples is rare. Here we analyzed the expression of the predictive biomarker programmed cell death ligand 1 (PD-L1) in BM and paired primary tumors. **Method:** In a single-center retrospective study, we assembled a cohort of consecutive BM resected and diagnosed at our University hospital between 2000 and 2015. We analyzed PD-L1 expression (Ventana SP263 kit) on full slides of lung cancer BM (N=211) and available paired primary tumors (N=87), using the increments <1%, 1-49% and ≥50%. **Result:** Our BM cohort comprised 145 (68.7%) adenocarcinomas, 24 (11.4%) squamous cell carcinomas, 34 (16.1%) small cell carcinomas and large cell neuroendocrine carcinomas and 8 (3.8%) others. PD-L1 staining was evaluable in 193 BM and 87 paired primary tumors. There was no tumoral PD-L1 expression in the high-grade neuroendocrine carcinomas. Among the non-neuroendocrine cancer BM, 86/165 (52.1%) expressed <1% PD-L1, 36/165 (21.8%) 1-49%, and 43/165 (26.1%) ≥50%. PD-L1 scores significantly correlated between BM and primary tumors (p<0.001), with a complete congruence in 62/77 cases (80.5%). Clinically significant discrepancies (cut-off 50%) were present in 9/77 (11.7%) cases: 6 cases were primary tumor-positive/BM-negative, and 3 cases BM-positive/primary tumor-negative. Only 4/9 patients with discrepant PD-L1 scores received chemotherapy in between tissue acquisition of BM and primary tumor, failing to serve as an explanation. Tissue from at least 2 separate brain metastases was available in 12 patients, with discrepant PD-L1 scores regarding the 50% cut-off in only 1 patient (8.3%), and regarding the 1% cut-off in 2 patients (16.7%). There was no association between PD-L1 expression in the BM and overall survival (p=0.95). **Conclusion:** In conclusion, we show that PD-L1 scores are concordant in most of paired BM and primary tumors. The discordant cases could not be explained by longer time lapses or chemotherapy or radiotherapy in between tissue acquisition, nor by scarce tissue availability of the primary tumor, e.g. due to biopsies only, and may be due to tumor heterogeneity.

Keywords: Lung cancer, brain metastasis, PD-L1

P1.04-06 TUMOR MICROENVIRONMENT LANDSCAPE IN LUNG ADENOCARCINOMA BY SINGLE-CELL SEQUENCING

B.M. Ku[1], H.A. Jung[2], J.-M. Sun[2], S.-H. Lee[2], J.S. Ahn[2], K. Park[2], M.-J. Ahn[2]

[1]*Samsung Medical Center, Seoul/Korea, Republic of,* [2]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of*

Background: Lung cancer is the leading cause of cancer cell death in worldwide. Failure of early detection, high recurrence rate and metastasis all contribute to the low survival rate in this detrimental disease. In particular, frequent brain metastasis confers an imperative challenge in the management of lung cancer. Single-cell RNA sequencing provides specific profiling of cell populations at the single-cell level. Interpretation of single-cell transcriptome data for the discovery of therapeutic targets and prognostic biomarkers is an ongoing challenge in precision cancer medicine. Especially, the influence of immune microenvironment in tumor has been accepted as a key factor for determining the therapeutic outcome. Despite the diversity of immune infiltrates in lung adenocarcinoma, single-cell RNA sequencing has not yet been applied for a large-scale tumor and immune profiling. **Method:** Samples were obtained from the primary tumor, lymph node or brain metastases, and pleural fluids of 44 patients with lung adenocarcinoma. Following lung tumor resection, normal lung tissues from a distal region as well as normal lymph nodes were collected for comparison. We dissociated the whole tissues into single cell suspension and then performed scRNA-seq using droplet-based 10x Genomics Chromiunm platform. **Result:** After quality filtering, we cataloged a total of 208,506 cells into 9 distinct cell lineages annotated by expression of known marker genes. We identified epithelial cells including cancer cells, stromal cells (fibroblasts and endothelial cells), immune cells (T, NK, B, myeloid, and MAST cells) as common cell types, and oligodendrocytes uniquely from brain metastases. The most abundant immune cell populations at the lung tumor site were T lymphocytes and myeloid cells. Notably, primary tumor and lymph node metastases showed substantial differences in the immune cell composition. These differences reflected the original tissue microenvironment, grossly altered by tumor progression and invasion. Therefore, our lung adenocarcinoma atlas illustrates the dynamic cellular landscape during cancer progression which may reveal progression associated changes for each cellular component in unprecedented

scale and manner. **Conclusion:** These results provide specific tumor microenvironmental patterns in lung adenocarcinoma. Thus, single cell-level transcriptome profiles provide clues to expand therapeutic windows into the combination therapy with immune and anti-cancer reagents.

P1.04-07 IMMUNE SUPPRESSIVE MICROENVIRONMENT AND HIGHLY CLONAL CONCORDANCE OF TCR REPERTOIRE IN BRAIN METASTASES FROM NON-SMALL CELL LUNG CANCER

Y. Kudo[1,2], C. Haymaker[2], J. Zhang[2], A. Reuben[2], D. Duose[2], J. Fujimoto[2], S. Roy-Chowdhuri[2], L. Solis[2], H. Dejima[2], E. Parra Cuentas[2], B. Mino[2], N. Ikeda[1], R. Luthra[2], D. Gibbons[2], J. Zhang[2], F. Lang[2], J.J. Lee[2], J. Huse[2], H. Kadara[2], I. Wistuba[2]

[1]*Tokyo Medical University, Tokyo/Japan,* [2]*The University of Texas MD Anderson Cancer Center, Houston/United States of America*

Background: The tumor immune microenvironment (TIME) of lung cancer brain metastasis is largely unexplored. We performed immune profiling and sequencing analysis of paired resected primary tumors and brain metastases of non-small cell lung carcinoma (NSCLC). **Method:** TIME profiling of archival formalin-fixed and paraffin embedded specimens of paired primary tumors and brain metastasis from 39 patients with surgically resected NSCLCs was performed using a 770 immune gene expression panel (NanoString Technologies, Seattle, WA) and by T cell receptor beta repertoire (TCRß) sequencing (Adaptive Biotechnologies, Seattle, WA). Immunohistochemistry was performed for validation. Targeted sequencing was performed to catalog hot spot mutations in cancer genes (ThermoFisher Scientific, Waltham, MA). **Result:** Somatic hot spot mutations were mostly shared between both tumor sites (28/39 patients; 71%). We identified 161 differentially expressed genes, indicating inhibition of dendritic cell maturation, Th1, and leukocyte extravasation signaling pathways, in brain metastases compared to primary tumors ($p < 0.01$). The proinflammatory cell adhesion molecule vascular cell adhesion protein 1 was significantly suppressed in brain metastases compared to primary tumors. Brain metastases exhibited lower T cell and elevated macrophage infiltration compared with primary tumors ($p < 0.001$). T cell clones were expanded in 64% of brain metastases compared with their corresponding primary tumors. Further, while TCR repertoires were largely shared between paired brain metastases and primary tumors, T cell densities were sparse in the metastases. **Conclusion:** We present findings that the TIME in brain metastases is immunosuppressed when compared to matched primary tumors in NSCLC patients, and that thus may help guide immunotherapeutic strategies for NSCLC brain metastases.

P1.04-08 RANDOMIZED CONTROLLED PHASE III TRIAL OF ADJUVANT CHEMOIMMUNOTHERAPY TO LUNG CANCER PATIENTS: RESULTS OF MALIGNANT EFFUSIONS

H. Kimura

Chiba Cancer Center, Chiba city/Japan

Background: Elucidation of cancer immunoediting from immune surveillance to immune escape and approval of immune check point inhibitors by FDA prompted immunotherapy became a forth modality next to surgery, chemotherapy and radiotherapy. We have recruited advanced lung cancer patients with poor prognosis who had undergone surgery to improve prognosis by immunotherapy. **Method:** Objective and methods: Post-surgical lung cancer patients were randomly designated to receive either chemoimmunotherapy (4 courses of chemotherapy with 10-14 courses of cellular immunotherapy: group A) or chemotherapy (4 courses of chemotherapy: group B). Immunotherapy comprised adoptive intravenous transfer of autologous activated killer T cells and dendritic cells (AKT-DC) obtained from the regional lymph nodes of lung cancer patients. The study inclusion criteria were: <76 years; PS 0 or 1; non-small cell lung cancer; pathological stage, IB-IV. Patients whose surgery was palliative or in whom macroscopic residual tumors remained after surgery were excluded but those with microscopic residual tumors detected after a cytopathological examination were included in the study. Patients with pleural dissemination were excluded but those with malignant pleural effusion were included and received intra-thoracic chemotherapy with 20mg CDDP 4 times (group B) or chemotherapy with 4 to 8 courses of AKT-DC immunotherapy (group A) through a subcutaneous port with intrathoracic catheter installed in the thoracic cavity after resection of the primary tumors. A patient who had a recurrence of malignant ascites in group A received peritoneal infusion of AKT-DC after cell-free concentrated ascites reinfusion therapy (CART). **Result:** A hundred-and three patients were selected for randomization. The 2-, 5-, and 7-year overall survival rates were 96.0% 69.4%, and 55.1 in group A (n=51) and 64.7%, 45.1%, and 38.1% in group B (n=52), respectively. The Hazard ratio was 0.439 in favor of group A by multivariate analysis. There were 11 group A and 9 group B patients with malignant pleural effusion. One patient in group A and 6 patients in group B had recurrence and 3 died within 2 years in group B. The difference was also significant in favor of group A. A patient with malignant ascites(received 5 times AKT-DC therapy with 7 courses of CART in 2 months. Complete elimination of tumor cells accompanied with ascites eradication resulted in 9 months prolongation of survival after recurrence. **Conclusion:** Patients with lung cancer benefited from adoptive cellular immunotherapy as an adjuvant to surgery. Intrathoracic and peritoneal cellular immunotherapy with AKT-DC are effective to patients with malignant effusions.

P1.04-09 PREDICTIVE CLINICAL AND MOLECULAR FEATURES OF LONG-TERM SURVIVORS RECEIVING IMMUNE CHECKPOINT INHIBITORS FOR STAGE 4 NON-SMALL CELL LUNG CANCER

A. Franke[1], S. Antonia[2], E. Haura[1], A. Chiappori[1], T. Tanvetyanon[1], J.E. Gray[1], B. Creelan[1]

[1]*Moffitt Cancer Center, Tampa/United States of America,* [2]*Lee Moffitt Cancer Center and Research Institute, Tampa/United States of America*

Background: We hypothesized that clinical features could predict for durable response in patients treated immune checkpoint inhibitors (ICI). We performed an exploratory retrospective analysis with the primary endpoint of determining features associated with long-term survival. **Method:** We identified 212 consecutive patients with stage 4 NSCLC who received PD-1-ICI on clinical trials between 2011-2015. Overall survival (OS) was estimated by Kaplan–Meier; multivariate analyses were performed using Cox regression. **Result:** Baseline Characteristics: median age 67, 52% male, 69% non-squamous, median 31 pack-years-smoking, 63% chemotherapy-naïve, 31% *KRAS*-mutant, 11% *PIK3CA*-mutant. At a 57-month minimum follow-up, median OS was 12.2 mo (95%CI 10.2-14.2). Attaining PR/CR was associated with long-term survival (HR 0.21, $p < 0.001$). Long-term (>4-yr) survivors were more likely non-squamous histology, *PIK3CA*-wild-type, and low baseline neutrophil-to-lymphocyte proportion (Figure_1). Patients who received dual PD-1/CTLA-4-ICI (39%) had improvements in ORR (43% vs. 23%), time-to-progression (TTP, $p = 0.001$) and OS (HR 0.63, $p = 0.006$) versus PD-1 alone.

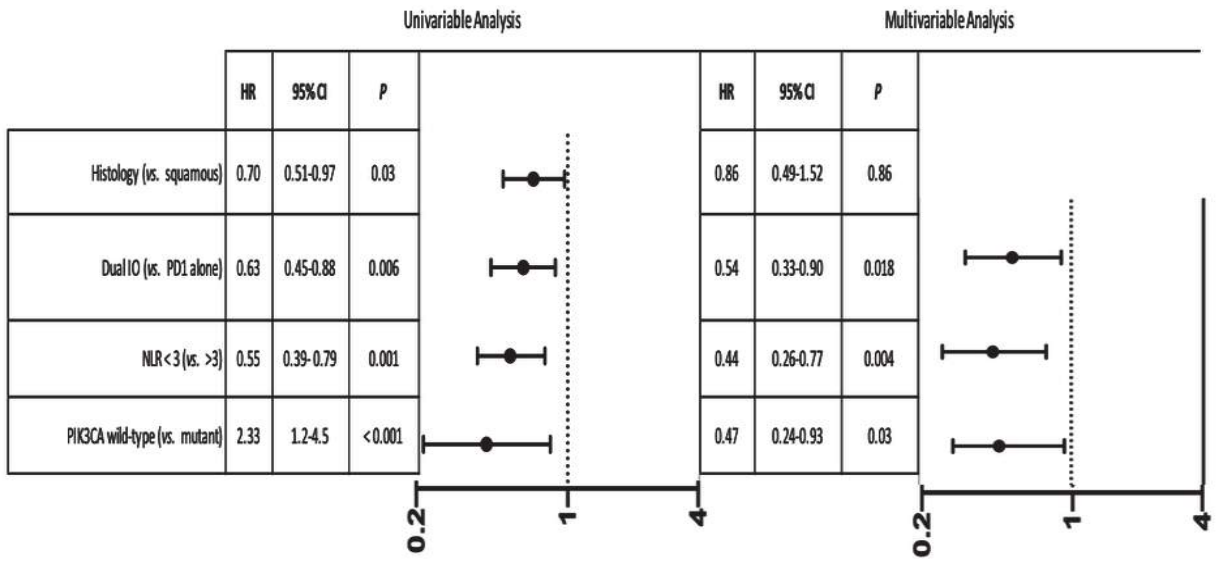

Figure 2. Treatment and outcomes of >4-year survivors (N = 38).

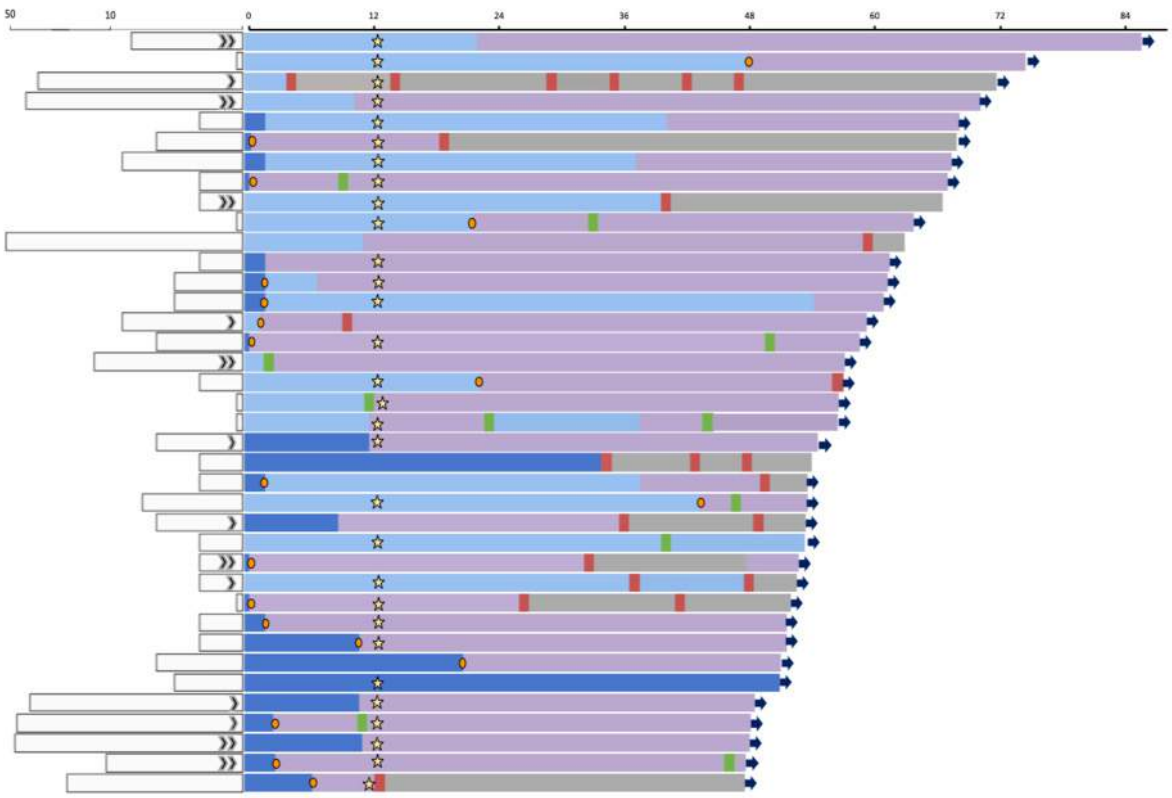

Figure Legend: OS, overall survival; CR, complete response; PR, partial response; NED, no evidence of disease; Dual ICI, anti-PD-1/CTLA-4 agents; TTD, time to treatment discontinuation

Conclusion: Objective responses to ICI with subsequent oligoprogression may be effectively salvaged with local ablative therapy in select cases. Prospective validation of surrogate biomarkers of immune response remain of paramount importance. Furthermore, durable responses exceeding 5 years may be attained despite early cessation of ICI. The role and clinical significance of *PIK3CA* mutations and ICI-resistance requires further investigation.

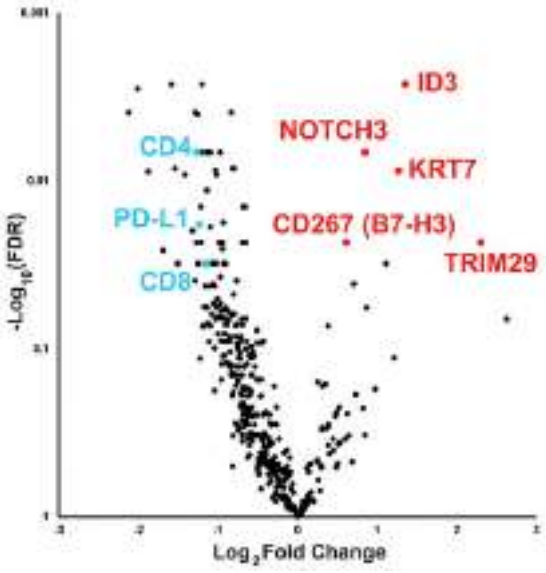
Keywords: Checkpoint inhibitors, Non-Small Cell Lung Cancer, Immunotherapy

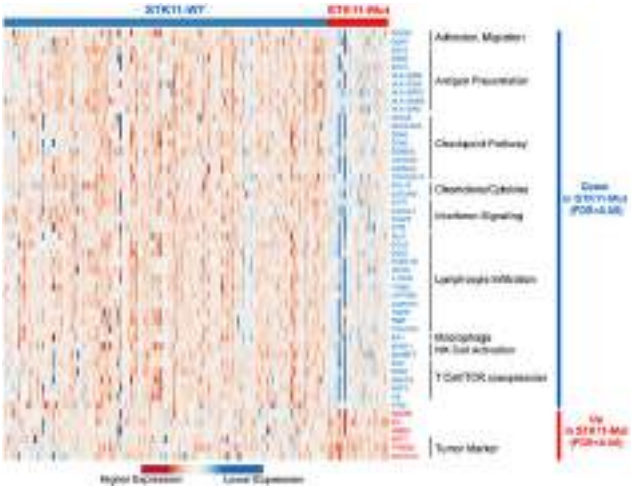
P1.04-10 IDENTIFICATION OF IMMUNOTHERAPY TARGETS IN STK11 MUTANT NON-SQUAMOUS NON-SMALL CELL LUNG CANCER

E. Yau[1], S. Glenn[2], A. Papinicalou-Sengos[2], M. Nesline[2], C. Morrison[2], G. Dy[1]

[1]*Roswell Park Comprehensive Cancer Center, Buffalo/United States of America,* [2]*Omniseq Inc, Buffalo/United States of America*

Background: The use of PD-1/PD-L1 checkpoint inhibitors (CPI) has dramatically altered the treatment of advanced Non-Small Cell Lung Cancer (NSCLC). However, a large proportion of patients with NSCLC do not derive clinical benefit from CPI treatment. Recent studies have identified STK11 mutations leading to loss of LKB1 in non-squamous NSCLC as drivers of primary resistance to CPI treatment. Using a clinical cohort of patients whose tumors underwent comprehensive genomic and immune transcriptomic analysis, we characterized the immune gene expression profile of STK11 mutant non-squamous NSCLC tumors and identified potential novel immunotherapy targets in STK11 mutant non-squamous NSCLC. **Method:** We performed comprehensive analysis of the genomic and immunological landscape of 204 formalin-fixed, paraffin-embedded tumor samples (obtained prior to CPI treatment) from advanced stage non-squamous NSCLC patients treated at Roswell Park Comprehensive Cancer Center using a CLIA-certified laboratory test that included targeted NGS genomic sequencing, gene fusion analysi,s and RNA-seq of 394 immune transcripts. Differential gene expression analysis was performed using R/Bioconductor package limma with Benjamini-Hochberg adjusted p-values reported . This study was approved by Roswell Park internal review board review (protocol BDR 091817) according to institutional policy for nonhuman subjects research. **Result:** Among the cohort of 204 cases, 30 contained truncating STK11 mutations. STK11 mutant cases showed an immunosuppressive environment with decreased PD-L1 mRNA expression (p=0.01) and decreased T-cell inflammation gene expression signature (p=0.0029). Analysis of differentially expressed immune genes signatures showed significant decreases in antigen presentation (p=0.015) and processing (p=0.044), NK cell activation (p=0.039), chemokine and cytokine signaling (p=0.044), immune checkpoint pathways (p=0.015), and Interferon gamma signaling (p=0.039). The top upregulated gene was TRIM29 (p=0.024). Other overexpressed targets included CD276 (p=0.024) also known as B7-H3, ID3 (p=0.002), KRT7 (p=0.008), and NOTCH3 (p=0.006). Interrogation of the TCGA LUAD dataset also demonstrated elevated TRIM29 expression (p=0.006) in KRAS/STK11-mutant (KL) compared to KRAS/STK11-wild-type samples. We also confirmed elevated TRIM29 expression in a panel of KL human cell lines. TRIM29 is an E3 ubiquitin ligase known to play a role in innate immune responses to DNA viral infections through targeting STING for degradation. Given recent studies implicating decreased STING expression in STK11 mutant cell line panels, TRIM29 represents a potential novel therapeutic candidate in this cohort of patients resistant to CPI treatment.





Conclusion: Using a large clinical cohort of non-squamous NSCLC patients we characterized the immunsuppressive environment of STK11 mutant tumors and identified the E3 ubiquitin ligase TRIM29 as a potential therapeutic target.

Background: Studies from our group and others have shown that bacteria and viruses present in the tumor may impact therapeutic responses. In the specific context of non-small cell lung cancer (NSCLC), intra-tumoral viral DNA and bacteria have been reported previously to be linked to therapeutic outcomes. However, the interplay between intra-tumoral microorganisms and the host immune response in NSCLC remains unknown. Moreover, the prognostic and predictive therapeutic value of localized NSCLC-specific microbial composition has yet to be defined. **Method:** RNA-sequencing (RNA-seq) (n=82) and whole exome sequencing

(WES) (n=80) was performed on surgically resected (pTNM I-III) tumors from lung cancer patients enrolled in the ImmunogenomiC prOfiling of NSCLC (ICON) project. Intra-tumoral bacteria, viruses and fungi were queried with MetaPhlAn2, a bioinformatical analysis pipeline which employs unique clade-specific marker genes, using reads from RNA-seq and WES that did not map to the human genome/transcriptome. Generated data were correlated to patients' clinicopathologic parameters as well as immune profiling using previously validated multiplex IHC panels based on Vectra 3.0™ multispectral microscopy IHC panels and image analysis (InForm™ 2.2.1 software). **Result:** Our analyses revealed that 18.29% (n=15/82) of tumors contained bacterial signatures. The most frequent bacterial signature was related to *Escherichia* (n=9/15). Moreover, 6.49% (n= 5/77) of tumors had evidence of human viral signatures, including the Epstein-Barr virus (n=1/5). No tumors contained fungal signatures. Preliminary clinicopathologic analyses suggested that patients whose tumors harbor bacterial signatures had a trend towards decreased overall survival (p=0.12). Tumors from former smokers were also more likely to contain bacterial signatures (p=0.11). Preliminary multiplex immune cell IHC analyses did not highlight statistically significant associations with the presence of intra-tumoral bacteria. **Conclusion:** Our results suggest that a significant proportion of localized NSCLC tumors may harbor components of the human microbiome. Further studies using larger cohorts and dedicated intra-tumoral microbiome and virome methodologies will be needed to better define these findings and to delineate associations with the local immune infiltrate.

P1.04-12 TUMOR UPTAKE AND BIODISTRIBUTION OF 89ZR-LABELED PEMBROLIZUMAB IN PATIENTS WITH METASTATIC NON-SMALL-CELL LUNG CANCER

A.-L. Niemeijer[1], D. Oprea-Lager[1], M. Huisman[1], R. Boellaard[1], O. Hoekstra[1], L. De Wit - Van Der Veen[2], I. Bahce[1], D. Vugts[1], G. Van Dongen[1], E. Thunnissen[1], E. Smit[1,2], J. De Langen[1,2]

[1]*Amsterdam University Medical Center, location VUmc, Amsterdam/Netherlands,* [2]*NKI-AvL, Amsterdam/Netherlands*

Background: Pembrolizumab, a monoclonal antibody targeting PD-1, is approved as monotherapy for the treatment of advanced NSCLC, depending on tumor PD-L1 (T-PD-L1) expression level. However, T-PD-L1 expression correlates moderately with response to pembrolizumab treatment. Therefore, there is need for biomarkers that accurately discriminate between responders and non-responders. Whole body ^{89}Zr-pembrolizumab PET/CT allows to quantify pembrolizumab uptake in tumor lesions and to study pembrolizumab biodistribution in non-malignant tissues. **Method:** Patients with advanced stage NSCLC and eligible for pembrolizumab monotherapy were enrolled. Following tracer injection (standard dose: 2mg ^{89}Zr-pembrolizumab, 37 MBq), the first 3 patients received whole body PET/CT-scans at 1h, 72h, 120h and 168h post-injection. Subsequent 10 patients were scanned at 72h and 144h post-injection. Biodistribution and tumor uptake were assessed visually by an experienced nuclear physician. Quantitative uptake was calculated as SUV_{peak} for delineable lesions and correlated to T-PD-L1/PD-1 IHC and response. A tumor biopsy after the last line of prior treatment was required to assess T-PD-L1/PD-1 IHC status (22C3 assay). Response was defined as partial or complete, after 6 months, according to RECIST criteria. **Result:** Thirteen patients (5 ≥50%, 4 1-49%, 4 negative by PD-L1 IHC) were enrolled (6 first line, 7 second/third line treatment). One patient experienced grade 3 myalgia after tracer injection. ^{89}Zr-pembrolizumab biodistribution was comparable to ^{89}Zr-nivolumab biodistribution with relatively high uptake in the spleen, likely due to binding to PD-1 receptors on lymphocytes/dendritic cells, and in the liver likely due to catabolism of the tracer. Imaging revealed tumor uptake in all patients, but not in all lesions. Visual assessment confirmed 70 lesions (including non-malignant lymph nodes) at 72h post-injection (SUV_{peak} range 1.7-13.0). Not all tumor lesions showed tracer uptake and uptake was heterogeneous within and between patients. In 3 patients response was observed. Pretreatment T-PD-L1≥50% was predictive for response (p=0.023). SUV_{peak} was higher in responding patients than in non-responding patients (median $SUV_{peak\ of\ all\ visible\ lesions}$ 8.0 vs 5.5, p=0.033). In line with these results, responding lesions (n=10) had a higher SUV_{peak} compared to non-responding lesions (n=24, median 8.1 vs 5.5, p=0.025). Tumor tracer uptake did not correlate with PD-1 expression (low PD-1 expression SUV_{peak} 6.0 vs high PD-1 expression SUV_{peak} 7.7, p=0.3). **Conclusion:** ^{89}Zr-pembrolizumab injection was safe with only one grade 3 possibly related adverse event. Tumor ^{89}Zr-pembrolizumab uptake correlated with response to pembrolizumab treatment. Further research is needed to study the value of this biomarker as standalone biomarker or as added information to T-PD-L1 expression by immunohistochemistry.

P1.04-13 DELINEATING SPATIAL HETEROGENEITY OF TUMOR MUTATIONAL BURDEN (TMB) COUNTS IN PULMONARY ADENOCARCINOMA

D. Kazdal[1,2], M. Allgäuer[1], J. Budczies[1], M. Kriegsmann[1], J. Leichsenring[1], A.-L. Volckmar[1], M. Kirchner[1], O. Neumann[1], R. Brandt[1], E. Rempel[1], S. Tala[1], A. Harms[1,2], C. Plögler[1], M. Von Winterfeld[1], R. Penzel[1], P. Schirmacher[1], V. Endris[1], A. Stenzinger[1,2]

[1]*University Hospital Heidelberg, Heidelberg/Germany,* [2]*German Center for Lung Research (DZL), Heidelberg/Germany*

Background: Tumor mutational burden (TMB) is an emerging biomarker to identify patients more likely to benefit from immuno-oncologic therapy. Therefore, academia- and industry-driven endeavors are underway to establish mostly panel-based sequencing solutions. Aside from various unsettled technical aspects, tumor biology itself might play an important role in determining a tumor's TMB. Intratumor heterogeneity (ITH) is frequent in pulmonary adenocarcinoma (ADC) and seems to be a key factor regarding response failure and resistance development during therapy. In addition, ITH might contribute to inconsistent distribution of a biomarker and therefore an assay's readout might depend on the region of tumor which is submitted for testing. Therefore, the assessment of ITH is an essential step in the evaluation of new diagnostic applications. **Method:** All ADC specimens used for this study were obtained from surgical procedures at the Thoraxklinik at Heidelberg University and diagnosed according to the criteria of the 2015 WHO Classification of lung tumors at the Institute of Pathology at Heidelberg University. Formalin-Fixed Paraffin-Embedded tissue sections were supplied by the tissue bank of the National Center for Tumor Diseases. To evaluate the significance of ITH on TMB estimation, 2-4 intratumoral regions (total 69) and up to 2 locoregional lymph node metastases (total 23) derived from 24 patients were analyzed. Following DNA extraction, all samples were sequenced using the 1.7 Mbp sized TruSightTM Oncology 500 panel, on a NextSeq 500 sequencing system (both Illumina Inc., San Diego, CA, USA). Procession of sequencing data and mutation calling was carried out using the TruSightTM Oncology 500 Local App (pipeline version 1.3.0.39). **Result:** TMB counts of the multiregional tumor samples and locoregional lymph node metastases ranged from 0 - 52.55 mut/Mbp and had a median value of 7.04 mut/Mbp. TMB status of tumor segments, lymph node metastasis or a case specific aggregate TMB were determined applying a cut-point of 10 mut/Mbp. 71% of the analyzed tumors had consistent TMB values when considering all associated estimates. Three cases were TMB-high except for at least one lymph node metastasis. Another three cases had inconsistent TMB approximations between different tumor regions. In one case only the aggregate TMB value would justify a TMB-high classification, whereas the individual analysis of each tumor segment resulted a TMB-low status. In a paired analysis of the average TMB values lymph nodes hada significantly (p = 0.016) lower TMB values compared to corresponding tumor segments. **Conclusion:** Our data demonstrate that panel-based TMB estimation applying the TSO500™ panel correlates strongly and significantly with WES-based TMB determination. The multiregional analysis showed that TMB measurement can be subject to intratumor heterogeneity in pulmonary ADC, which can impact clinical decision making and therapy. However, spatial genetic heterogeneity reflecting tumor biology needs to be carefully dissected from technical conditions resulting in pseudo-heterogeneity, especially a valid tumor cell content estimation and the correct identification of polymorphisms / germ line mutation seem to be crucial points in this consideration. Further, lymph node metastases had significantly lower TMB values compared to corresponding tumor tissue, questioning the applicability of these samples for TMB estimation in a clinical setting.

Background: Previously we reported that changes in the plasma levels of CXCL2 and MMP2, measured by a bead-based multiplex assay: Bio-Plex 200 system, were significantly associated with the clinical outcomes of anti-PD-1 therapy (Matsuo, et al. *IJC*. 2018). Here we attempted to validate CXCL2 and MMP2, measured by ELISA, as a marker of the effectiveness of anti-PD-1 therapy in expanded patient cohort. **Method:** Peripheral blood samples were taken from 97 patients with non-small cell lung cancer before nivolumab or pembrolizumab treatment and after 4-10 weeks from the patients who continued these drugs. The levels of CXCL2 and MMP2 were examined before and after anti-PD-1 therapy. We employed Cox regression analysis for CXCL2 and MMP2 as a single explanatory carriable. In comparing the fitness of CXCL2 and MMP2 Cox models, discrimination was assessed by the Harrell's C-statistic for survival data. Bootstrap methods with 10000 resamplings were used to assess the stability of the regression analysis predictors. The optimal cutoff point was determined as the point at which the Youden index was maximized by ROC curve. Survival curves were generated using the Kaplan–Meier method and comparisons made using the log-rank test. **Result:** The changes in the plasma levels of CXCL2 after treatment were significantly correlated with PFS (HR 1.003, 95%CI: 1-1.005, *P*=0.026) and OS (HR 1.004, 95%CI: 1.001-1.007, *P*=0.003). The C-statistic of the CXCL2 model for PFS and OS were 0.652 (95% CI: 0.437-0.727) and 0.626 (95% CI: 0.528-0.722), respectively. The decreasing revels of CXCL2 tended to be related to better DCR (*P*=0.134). The changes in the plasma levels of CXCL2 < 29.1 pg/ml was associated with better PFS (HR 2.872, 95%CI: 1.785-4.618, *P*<0.001) and OS (HR 2.800, 95%CI: 1.633-4.801, *P*<0.001). The changes in the plasma levels of MMP2 after treatment were also significantly correlated with PFS (HR 0.998, 95%CI: 0.996-0.999, *P*=0.003) and OS (HR 0.998, 95%CI: 0.996-0.999, *P*=0.001). The C-statistic of the MMP2 model for PFS and OS were 0.599 (95% CI: 0.515-0.673) and 0.614 (95% CI: 0.523-0.703). The increasing revels of MMP2 was significantly related to better DCR (*P*=0.020). The changes in the plasma levels of MMP2 > 0.847 ng/ml was associated with better PFS (HR 0.614, 95%CI: 0.388-0.971, *P*=0.037) and OS (HR 0.501, 95%CI: 0.295-0.852, *P*=0.011). **Conclusion:** The early change of CXCL2 and MMP2 were significantly associated with the clinical outcomes of anti-PD-1 therapy. Since these factors in plasma can be easily measured by minimally invasive method, they could be clinically applicable as biomarkers for predicting the clinical benefit of anti-PD-1 therapy for NSCLC patients.

Keywords: CXCL2, MMP2, pd-1

P1.04-15 SMOKING STATUS IS NOT A REPLACEMENT BIOMARKER FOR TUMOR MUTATION BURDEN IN NON-SMALL LUNG CANCER

M. Sharpnack[1], J.H. Cho[1], T. Johnson[1], G. Otterson[1], P. Shields[1], K. Huang[2], D. Carbone[1], K. He[1]

[1]*The Ohio State University, Columbus/United States of America,* [2]*Indiana University College of Medicine, Indianapolis/United States of America*

Background: Recent clinical studies suggest tumor mutation burden (TMB) as a promising therapeutic biomarker of anti-tumor immune checkpoint blockade (ICB). Given the causal link between cancer-causing mutations and tobacco smoking, patients with a significant smoking history may respond better to ICB. However, it is not clear if smoking history is an adequate surrogate biomarker for TMB. Here, we sought assess the clinical utility of smoking history in predicting tumor mutation burden. **Method:** Publicly available smoking history and DNA somatic alteration data from NSCLC were downloaded from The Cancer Genome Atlas and a large dataset of lung adenocarcinoma tumors published by Imielinski, et al (*Cell*, 2012) Tumor mutation burden was calculated as the sum of all somatic mutations divided by the exome sequencing coverage. Smoking history was analyzed both as categorical (ever, never, former) and semi-continous variables (pack years). Hypermutancy was defined as greater than or equal to 10 mutations per megabase. **Result:** A total of 395 LUAD and 419 LUSC patients were included in this analysis. Smokers had significantly higher tumor mutation burdens than non-smokers; however, in both LUAD and LUSC, there were smokers with low TMB and non-smokers with high TMB. Smoking pack year history (SPY) was weakly positively correlated (Spearman $\rho = 0.20$, $p = 2.5 \times 10^{-4}$) in LUAD but uncorrelated (Spearman $\rho = -0.026$, $p = 0.61$) in LUSC. Non-smokers and patients without a recorded SPY were excluded from the SPY analysis. We calculated AUCs for predicting hypermutancy in tumors, using variable thresholds of SPY. In LUAD and LUSC, SPY had an AUC of 0.38 and 0.47 in predicting TMB, showing that SPY was not better than random prediction. We also sought to predict TMB from smoking as a binary variable. In LUSC, 8/18 (44%) non-smokers and 253/447 (57%) smokers were hypermutant. In LUAD, 9/61 (15%) non-smokers and 219/391 (56%) smokers were hypermutant. Additionally, we repeated this analysis on matched smoking history and TMB from an independent cohort of 162 LUAD tumors published by Imielinski, et al. Similarly, we found that 1/27 (4%) of nonsmokers and 66/135 (49%) of smokers were hypermutant. In this cohort, the AUC in predicting TMB with SPY was 0·21. **Conclusion:** In this study, we investigated the relationship between tobacco smoking and TMB. While the average lung cancer patient with a history of tobacco smoking has a higher TMB than the average never-smoker, there is not a clear relationship between the extent of exposure in pack years and TMB. In general, smoking is not an informative biomarker for TMB, however, non-smokers who develop LUAD are unlikely to have high TMB. This study highlights the value of next generation sequencing for TMB in predicting therapeutic response to ICB.

Background: Several studies found that cancer patients treated with PD-1 immune checkpoint inhibitors (CKIs) who receive antibiotics (ATX) had worse efficacy outcomes because ATX can dysregulate gut microbiota. There are some data in pretreated non-small-cell lung cancer (NSCLC) and few data about the route of ATX administration, but it`s unkown whether ATX administration can also affect efficacy of CKIs in first line setting in patients treated with pembrolizumab monotherapy. **Method:** This is a multicenter retrospective study. We included consecutive patients with advanced NSCLC with high PD-L1 expression (50%) treated with pembrolizumab monotherapy in first line, between September 2016 and March 2019, from 12 hospitals in Spain. The aim of the study was to evaluate if patients taking ATX 2 months before or within the first month after starting CKIs had worse OS, and if OS was affected by the route of administration and type of prescribed ATX. **Result:** 121 patients were evaluated. Median age was 68 years (38-88). 90 (74,4%) were male and 90 (74,4%) had PS1. Predominant histologies were adenocarcinoma (68,6%) and squamous-cell carcinoma (23,1%). Median number of cycles was 7 (1-33). Median follow-up: 6,5 months. Most were current or former smokers (95,9%). Only 1 patient had driver mutation (ALK rearrangement). 66,9% had 2 or more metastatic locations, 18,2% had central nervous system (CNS) disease, 17,4% liver metastasis, and 41,3% bone metastasis. 45,5% received ATX,

65,5% of them intravenously and 34,5% orally. Most prescribed ABX were quinolones (40,7%) and penicillin or derivatives (35,2%). 21,5% received subsequent chemotherapy. Response rate was 40,4% according to RECISTv1.1 criteria. 11% had hyperprogression and 7,2% pseudoprogression. Estimated 12-month-OS was 62% (95%CI: 49.1%-72.5%) and estimated 12-month-PFS was 44.2% (95%CI: 31.1%-56.5%) Patients who received ABX had more risk of disease progression as best response (52,2% vs 24,5%,RR: 2.1, 95%CI: 1.2-3.7, p=0.007). Patients who received ATX had shorter OS (HR:1.9, 95%CI: 1.1-3.7, p=0.047) and shorter PFS (HR:2.6, 95%CI: 1.4-4.8, p=0.002). Patients who received ATX intravenously had shorter OS than those not treated (HR:2.8, 95%CI: 1.4-5.6) and than those who received ABX orally (HR:3.5, 95%CI: 1.2-10.3, p=.025)). Patients treated with ABX also had shorter PFS than those not treated (HR: 3.5, 95%CI:1.8-6.8, p<0.001) and than those who received ABX orally (HR: 2.2, 95%CI:1-4.8, p=0.05). Similar HR were estimated adjusting by age, gender, stage, and hepatic and bone metastasis presence. There were no OS and PFS differences between patients who received ABX orally and those who did not received them. There were no survival differences according to type of ABX. **Conclusion:** Our results suggest that use of intravenous ABX has a negative impact on disease control rate and survival outcomes (PFS and OS) in patients with naïve advanced NSCLC and high PD-L1 expression treated with pembrolizumab monotherapy in first line setting. Patients who received oral ABX had similar efficacy than those not treated with ABX. To our knowledge, this is the first retrospective study evaluating the impact of ATX on the efficacy of CKIs in first-line treatment setting of NSCLC patients.

Background: Single-agent nivolumab has limited efficacy in thoracic tumors. The antitumor activity of VEGF TKIs is typically attributed to their effect on angiogenesis; however, emerging data suggest these agents can modulate the immune system, especially in the immune suppressive microenvironment. Preliminary results in multiple solid tumors demonstrated clinical benefit when nivolumab was added to anti-angiogenic agents albeit with increased toxicities. Vorolanib was designed to improve the safety profile without compromising efficacy. No dose-limiting toxicities (DLTs) from vorolanib were reported in multiple single-agent phase I trials. **Method:** NCT03583086 is an ongoing multi-institutional, phase I/II study of nivolumab and vorolanib in patients with thoracic tumors who have failed at least one prior line of therapy. A standard 3+3 dose escalation design was planned with three doses of vorolanib (200, 300, and 400 mg once-daily) and 240 mg nivolumab every two weeks to determine the maximum tolerated dose. Phase II will evaluate the response rate in five cohorts: PD-1/PD-L1 naïve non-small cell lung cancer (NSCLC), PD-1/PD-L1 primary refractory (defined as progression on PD-1/PD-L1 therapy within 12 weeks), NSCLC patients with acquired resistance (achieved at least stable disease and then progressed) to PD-1/PD-L1, thymic carcinoma, and small cell lung cancer patients who have progressed on prior platinum-based chemotherapy. Exploratory correlatives will assess changes in the innate and adaptive immune responses after treatment. **Result:** Phase I enrolled 10 patients (eight NSCLC and two thymic cancers); one patient was not evaluable for DLT and replaced. No DLTs were observed in three patients at the first dose level of 200 mg. Vorolanib was escalated to 300 mg, and elevated ALT (Grade 3) occurred in two of six patients just beyond the DLT period but deemed clinically significant; thus, 200 mg vorolanib with 240 mg nivolumab is being evaluated in expansion cohorts. The most common adverse events were elevated ALT, AST, and lipase, diarrhea, and fatigue; most were Grade 1/2. Grade 4 hyperglycemia and elevated lipase and Grade 3 elevated serum amylase occurred in one patient each. In seven efficacy-evaluable patients (2 immunotherapy naïve NSCLC; 3 NSCLC with prior immunotherapy; 2 thymic cancer), two partial responses were observed (1 PD-1/PD-L1 naive NSCLC and 1 thymic cancer patient); the NSCLC patient was also PD-L1 negative. Three NSCLC patients with prior PD-1/PD-L1 inhibitors had tumor regression; two of these had acquired resistance and the other was primary refractory to prior immunotherapy. **Conclusion:** The combination of 200 mg vorolanib and 240 mg nivolumab was generally well tolerated. Clinical activity was observed in both PD-1/PD-L1 naïve patients and those treated with prior immunotherapy. Final phase I results and available phase II data will be presented.

P1.04-18 INTERLEUKIN-5 DRIVES THE EXPANSION OF PULMONARY B-1 B CELLS AND RESTRICTS LUNG TUMOR GROWTH

R. Cederberg[1], A. So[2], E. Franks[1], M. Hughes[2], K. Mcnagny[2], K. Bennewith[1]

[1]*BC Cancer, Vancouver/Canada,* [2]*University of British Columbia, Vancouver/Canada*

Background: Therapies that target immune cells to treat lung cancer are becoming commonplace, highlighting the critical role of the immune system in the lung microenvironment. The lungs are host to a variety of immune populations, including B cells, whose primary function is to secrete antibodies that target foreign pathogens. Despite the presence of B cells in solid tumors and their prevalence in the lung, the role of B cells in lung cancer is largely undefined. We have found that transgenic mice which over-express the protein IL-5 (IL5Tg mice) have both an expansion of lung B cells and a decrease in lung tumor burden. IL-5 has previously been shown to induce the proliferation, recruitment, and antibody production of certain B cell subsets. Therefore, we hypothesize that IL-5-responsive B cells may decrease lung tumor growth. **Method:** We used IL5Tg transgenic mice that over-express IL-5 to study the impact of B cells on tumor growth in the lungs. Lewis lung carcinoma (LLC) cells were injected intravenously (IV) to seed the lungs. Circulating serum antibodies were quantified by ELISA. Flow cytometry was used to quantify immune cell subsets in the lungs, as well as antibody binding to tumor cells and tumor cell cytotoxicity. Histological analysis was used to measure tumor burden. **Result:** We found that the increase in lung B cells in IL5Tg mice was due to an increase in B-1 B cells which co-expressed the antibody class immunoglobulin M (IgM). Importantly, IL5Tg mice had a decrease in lung tumor burden compared to WT mice, as well as an increase in the total number of lung-infiltrating B cells compared to naive mice. Circulating IgM was elevated in IL5Tg mice compared to WT, and we found that these IgM antibodies were able to bind to LLC cells. Binding of IgM antibodies to the surface of target cells has previously been shown to induce cell death via the complement pathway, and preliminary data suggests that serum antibodies from IL5Tg mice can induce tumor cell cytotoxicity. **Conclusion:** We have found that excess IL-5 drives the expansion of lung B-1 B cells and decreases lung tumor burden, suggesting that IL-5 may promote anti-tumorigenic immune cell activities in the lungs. Illuminating the specific role of B cells in lung cancer growth will help deconvolute the complex interplay between host immune cells and malignant cells and could reveal new avenues for immunotherapy development.

P1.04-19 ASSOCIATION BETWEEN EFFICACY AND IRAES IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER RECEIVING IMMUNE-CHECKPOINT INHIBITORS

M. Riudavets[1], J. Mosquera[2], R. Garcia Campelo[2], J. Serra[1], G. Anguera[1], P. Gallardo[1], I.G. Sullivan[1], A. Barba[1], M. Majem[1]

[1]*Hospital de la Santa Creu i Sant Pau, Barcelona/Spain,* [2]*Hospital Universitario A Coruña, A Coruña/Spain*

Background: Immune-checkpoint inhibitors (ICIs) are a standard treatment in advanced non-small cell lung cancer (NSCLC). They can induce immune-related adverse events (irAEs) that may compromise treatment continuation. We report our experience in advanced NSCLC patients receiving ICIs, the incidence of irAEs and its correlation with efficacy. **Method:** 267 patients with advanced

NSCLC receiving ICIs in two Spanish institutions from March 2013 to August 2018 were analyzed. IrAEs were graded following CTCAE v4.0. Kaplan Meier and log-rank tests were used to evaluate progression-free (PFS) and overall survival (OS) using landmark analysis. **Result:** Median age was 66.1 years [26-85], 70% were male. 86 (32%) patients presented squamous and 181 (68%) non-squamous histology. Most frequent ICIs were nivolumab (44%), pembrolizumab (26%) and atezolizumab (17%), used as monotherapy (78%), in combination with chemotherapy (12%) or with anti-CTLA4 (9%). 30% patients were treated with ICIs in first line and 70% in second line or beyond. Median duration of treatment was 2.8 months [0.1-56.4]. 152 patients (57%) experienced a total of 255 irAEs, and the median number of irAEs/patient was 1 [0-5]. Most frequent irAEs was skin toxicity (34%), followed by diarrhea (16%) and hypothyroidism (11%). 36 patients (14%) presented grade 3-4 irAEs and there were 5 treatment-related deaths: 4 pneumonitis and 1 hepatitis. Patients receiving ICIs in second line or beyond experienced significantly less irAEs (49%) than those treated in first line (74%) (p <0.001). With a median follow-up time of 8.5 months [0.3-56.4], the landmark analysis showed that PFS was significantly longer in patients with irAEs: 12.4 months (95%CI, 1.9-22.9) vs 4.1 months (95%CI, 2.6-5.6) (p < 0.001). Similarly, OS among patients with irAEs was significantly higher: 28.2 months (95%CI, not calculated) vs 12.5 months (95%CI, 10.8-14.2) (p < 0.001). Disease control rate was significantly better in patients with irAEs: 77% vs 39%, odds ratio 0.20 (95%CI, 0.11-0.34) (p < 0.001). Besides, duration of response was significantly longer: 6.1 months [0.5-50] vs 2.6 months [0.2-51.9] (p < 0.001). 44 patients (17%) discontinued treatment due to toxicity. Within this group, 66% patients did not progress after immunotherapy, in contrast to 29% in the rest of the population (p < 0.001). Multivariable analysis revealed that cutaneous, endocrinological and reumathological toxicities were significantly associated with increased OS. **Conclusion:** The presence of irAEs in advanced NSCLC patients treated with ICIs was associated with better outcomes. Patients who discontinued ICIs due to toxicity showed a higher disease control rate.

P1.04-20 PD-L1 MRNA DERIVED FROM TUMOR-EDUCATED PLATELETS PREDICTS THE CLINICAL OUTCOME OF IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER

J. Chang, Z. Hu, S. Sun, H. Yu, X. Wu, J. Wang

Fudan University Shanghai Cancer Center, Shanghai/China

Background: Immunotherapy was promising treatment of advanced non-small cell lung cancer (NSCLC), but only a small part of patients could benefit from the immune checkpoint inhibitors (ICIs). Development of novel biomarkers was of great importance to improve the selection of patients and to avoid unnecessary toxicity. **Method:** We collected data from advanced NSCLC patients who received immunotherapy alone or in combination with chemotherapy as first- or second-line treatment at a single institution. All the patients were wild type of EGFR/ALK and enrolled into clinical trials on ICIs, including nivolumab, pembrolizumab, atezolizumab, durvalumab, tremelimumab and camrelizumab. PD-L1 messenger RNA (mRNA) was detected from tumor-educated platelets before ICIs treatment. Meanwhile, tumoral PD-L1 expression was also determined by immunohistochemistry in archived tissue samples to explore its predictive value and association with TEPs- derived PD-L1 mRNA expression. **Result:** Of 76 patients enrolled into this study, 68 patients (89.5%) received only immunotherapy and 23 patients (30.3%) responded to the treatment, and the median PFS was 3.81 months. There was no correlation between tumoral PD-L1 expression and TEPs-derived mRNA of PD-L1 by Pearson Correlation test (P=0.32). Based on the median of PD-L1 mRNA, 19 patients (44.4%) responded to immunotherapy in high PD-L1 group compared to 5 patients (13.9%) in low PD-L1 group (P<0.01). The median PFS were 2.76 months in low PD-L1 group, compared to 8.28 months in high PD-L1 group (P<0.001), respectively. For the 64 patients who received only immunotherapy, the PFS advantage was persistent in high PD-L1 group (2.76 vs 8.02 months, p=0.002). The median OS was not reached in high PD-L1 group, while it was 13.47 months in low PD-L1 group (P<0.01). **Conclusion:** Tumor-educated platelets derived PD-L1 mRNA could be a surrogate biomarker predicting the PFS and OS of immunotherapy in patients with advanced non-small cell lung cancer.

P1.04-21 CELLULAR LANDSCAPE OF NORMAL ADJACENT TO TUMOR MICROENVIRONMENT IN NON-SMALL CELL LUNG CANCER

Y. Li, L. Wu, Y. Cheng, W. Tao

Renmin Hospital of Wuhan University, Wuhan/China

Background: Cellular heterogeneity is the dominant ingredient in tumor microenvironment, which plays essential roles in cancer malignancy. Growing evidence have shed light on the important role of tumor-infiltrating immune and stromal cells in cancer progression. **Method:** Here, we portrayed the cellular landscape of a total of 64 cell types in 313 normal lung tissues, 110 adjacent normal tissues and 992 non-small cell lung cancer (NSCLC) tissues using transcriptomic data by integrated bioinformatics analysis. **Result:** In general, adjacent normal tissues presented an intermediate state between normal and tumor tissues, which was that the fraction of immune cells decreased while fraction of stromal cells increased from normal, adjacent to tumor tissues. Moreover, huge difference of tumor-infiltrating cells were detected between lung adenocarcinoma (LUAD) and lung squamous cell carcinoma (LUSC). Interestingly, in LUAD, rather than in LUSC, subtypes of CD4+ and CD8+ T cells were significant higher in tumor tissues compared with adjacent and normal tissues. Stromal cells, such as fibroblast and endothelial cells, also showed great diversity among the normal, adjacent and tumor tissues. Moreover, immune inhibitory receptors (PD1, CTLA4, LAG3 and TIM3) were more commonly co-expressed on certain subtypes of T cells in both LUAD and LUSC compared with adjacent normal tissues. Besides, significant clinical relevance between tumor-infiltrating cells and tumor stages were more prevalence in LUAD, compared with LUSC. Lastly, there were 45 cell types and 27 cell types were significantly correlated with patients overall survival in LUAD and LUSC, respectively. Surprisingly, certain subtypes of T cells were adverse prognosis factors for NSCLC. Taken together, we built powerful prognosis predictors for LUAD and LUSC patient using tumor-infiltrating cells. **Conclusion:** In summary, our analysis provided extensive details of cellular landscape in normal adjacent to tumor tissues in NSCLC and how they were involved in tumor progression. Better understanding of the complex crosstalk between tumor cells and infiltrating cells might provide novel therapeutic targets and biomarker for NSCLC, especially in the immune therapies.

P1.04-22 POTENTIAL DNA REPAIR BIOMARKER FOR RESPONSE TO IMMUNOTHERAPY OF LUNG CANCER PATIENTS

Z. Livneh[1], T. Paz-Elizur[1], Y. Leitner-Dagan[1], K. Meyer[2], B. Barak Markus[1], F. Giorgi[2], M. O'Reilly[2], H. Kim[2], Y. Evgy[1], R.C. Rintoul[3], B. Ponder[2]

[1]*Weizmann Institute of Science, Rehovot/Israel,* [2]*University of Cambridge, Cambridge/United Kingdom,* [3]*Papworth Hospital NHS Foundation Trust, Cambridge/United Kingdom*

Background: Because only a fraction of cancer patients responds to immunotherapy, there is an urgent need for methods to predict responders, in addition to the current methods of PD-L1 expression, tumor mutation burden, and mismatch repair deficiency (MSI-H biomarker). With the goal of harnessing DNA repair to fight cancer, we have developed personalized DNA repair blood tests that measure enzymatic activity of OGG1 (8-oxoguanine DNA-glycosylase), MPG (methylpurine DNA-glycosylase) and APE1 (apurinic/apyrimidinic endonuclease-1), which repair primarily oxidative and methylation DNA damage. The three are then combined to yield a personalized DNA repair score (*Cancer Prevention Res.* 7, 398-406:2014; *J. Natl. Cancer Inst.* 104, 1765-1769:2012). The question we posed was whether there is any correlation between the DNA repair score and systemic effects on gene expression. **Method:** The study included 121 non-small cell lung cancer cases and 92 controls. The DNA repair score was determined in PBMC, and gene expression was measured using RNAseq in nasal epithelial cells from all subjects. Gene expression was also measured in bronchial cells from 37 patients. Analysis using DESeq2 software was performed separately on the different tissues (nasal/bronchial) and disease state (cases/controls), with experimental batch, age, gender, smoking status (never, former and current smokers) and cancer histology (in cases) as adjusting factors. Gene Set Enrichment Analysis (GSEA) was used in order to identify whether there is an over-representation of genes belonging

to specific pathways annotated by Gene Ontology. **Result:** With a False Discovery Rate threshold of 0.01, we could find very few genes whose expression correlated with the DNA repair score. However, using GSEA we found that the expression of 185 immune system-related pathways exhibited negative correlation with the DNA repair score, each with q-value<0.001. This correlation was observed in lung cancer patients, but not in control subjects. The dramatic enrichment in the immune response pathways was by far the most pronounced effect, and it was robust against sub-sampling, indicating that it is not a sampling bias. **Conclusion:** Low DNA repair score correlates with broad up-regulation of immune-response pathways in lung cancer patients, but not controls. Low DNA repair might cause more mutations, and increases neoantigens, contributing to the activation of the immune system, similar to tumors with a mismatch-repair deficiency. Since only about 1% of lung cancer cases exhibits a mismatch-repair deficiency, we suggest that a low DNA repair score might serve as a biomarker for response to immunotherapy of these patients, pending additional studies.

P1.04-23 CHARACTERIZING THE TUMOR IMMUNE MICROENVIRONMENT OF NON-SMALL CELL LUNG CARCINOMA IN PEOPLE LIVING WITH HIV USING IMAGING MASS CYTOMETRY

R. Yusuf, F. Villarroel-Espindola, K. Schalper, B. Emu

Yale School of Medicine, New Haven/United States of America

Background: Non-AIDS defining cancers (NADCs) have become a leading cause of cancer incidence and mortality in people living with HIV (PLWH). Lung cancer is the most common NADC in this population, with non-small cell lung cancer (NSCLC) as the most common histologic subtype. PLWH develop NSCLC at younger ages, present with later stage of disease, and have worse outcomes. Global immune dysfunction caused by HIV infection, independent of absolute CD4 count, is hypothesized to contribute to this phenomenon. Imaging Mass Cytometry (IMC) provides for multidimensional protein detection using metal-conjugated antibodies and mass spectrometry. Here, we use IMC to investigate the NSCLC tumor microenvironment of HIV+ and HIV- patients, identifying differences in immune function. **Method:** Paraffin-embedded tumor tissue from 18 HIV+ patients and 19 HIV- matched patients were obtained from the Pathology department of Yale-New Haven Hospital. Controls were matched on the basis of age, sex, histology, stage at presentation, and year of cancer diagnosis. An antibody panel consisting of 36 structural, phenotypic, and functional targets was used to characterize these tissues by IMC. Unsupervised clustering with PhenoGraph was used to identify major cell populations. Chi-square test and t-test were used to compare categorical and continuous variables, respectively. **Result:** Between HIV+ and HIV- patients, median age was 53 and 59 years, 61% and 58% presented at stages III/IV, and median overall survival was 8 and 89 months respectively (log rank; $P = 0.006$). Among HIV + patients, 78% were on antiretroviral therapy and 56% had an undetectable viral load at time of cancer diagnosis. No significant difference in overall CD3, CD4, CD8, CD20, or CD68 signal was detected between HIV+ vs HIV- cases. Similarly, no significant difference was seen in expression of inhibitory T-cell receptors (PD1, TIM3, LAG3) on CD4+ or CD8+ cells. CD68 cells from HIV+ cases demonstrated increased PD-L1 expression compared with CD68 cells from HIV- cases (P = 0.006). Three unique subpopulations of epithelial tumor cells were identified by PhenoGraph; these subsets differed in expression of PD-L1, MHC class I and II antigen presentation proteins (HLA-ABC, HLA-DR), and cellular proliferation markers (KI67). Distribution among these three tumor cell subsets varied significantly between HIV+ and HIV- cases (P =0.005). **Conclusion:** In this well-matched cohort of NSCLC, we investigated the tumor microenvironment using highly multiplexed imaging mass cytometry. Despite having similar stages at presentation as HIV- cases, overall survival was markedly decreased among HIV + cases. Though no significant difference in tumor infiltrating immune cells or lymphocyte T cell inhibitory receptor expression was seen, monocytes from HIV+ patients demonstrated increased PD-L1 expression. In addition, distinct subpopulations of tumor cells were identified, with tumors from PLWH having different proportional representation among these subsets. Further genomic and transcriptomic analysis of HIV-associated NSCLC tumors may provide further insight into the effect of HIV infection on tumor phenotype and prognosis.

P1.04-24 CIRCULATING SUPPRESSIVE IMMUNE CELLS PREDICT THE EFFICACY OF ANTI PD-1 IMMUNOTHERAPY IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

J. Koh[1,2], Y. Kim[1,3], K.Y. Lee[1], M.S. Kim[1], B.M. Ku[1], J.-M. Sun[1], S.-H. Lee[1], J.S. Ahn[1], K. Park[1], M.-J. Ahn[1,2]

[1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of,* [2]*Sungkyunkwan University, Seoul/Korea, Republic of,* [3]*Samsung Changwon Hospital, Sungkyunkwan University School of Medicine, Changwon/Korea, Republic of*

Background: The major suppressive immune cells in tumor sites are myeloid derived suppressor cell (MDSC), tumor associated macrophage (TAM), and regulatory T (Treg) cell, and the major roles of these suppressive immune cells include hindering T cell activities and supporting tumor progression and survival. In this study, we analyzed the pattern of various circulating suppressive immune cells in patients with non-small cell lung cancer (NSCLC) to see whether those suppressive immune cells hinder T cell activities leading to poor clinical outcomes. **Method:** Baseline blood samples were collected from stage I to IV NSCLC patients (n=59), and baseline and one week after the therapy paired blood samples from stage IIIB to IV NSCLC patients (n=83) undergoing anti PD-1 immunotherapy either pembrolizumab or nivolumab. The efficacies of peripheral blood suppressive immune cells along with $CD39^+CD8^+$ T cells individually or collectively in anti-PD-1 immunotherapy were evaluated using flow cytometry and T cell suppressive assay. **Result:** G-MDSCs, M-MDSCs, TAMs, Treg cells, and $CD39^+CD8^+$ T cells increased according to NSCLC stage, and MDSCs effectively suppressed T cell activities and induced T cell exhaustion *ex vivo*. Further, the analysis of 83 NSCLC patients treated with anti-PD-1 immunotherapy demonstrated that low G-MDSCs (P_{PFS} = 0.03, Pos = 0.04), M-MDSCs (P_{PFS} = 0.04, Pos = 0.005), TAMs (P_{PFS} = 0.007, Pos = 0.01), and $CD39^+CD8^+$ T cells (P_{PFS} = 0.57, Pos = 0.02) were associated with longer progression-free survival (PFS) and overall survival (OS) compared with high groups. When we performed combined analysis of three suppressive immune cells, G-MDSCs, M-MDSCs, and TAMs collectively, patients who had low frequency of all three suppressive immune cells showed more prominent difference of PFS (6.7 months vs 2 months; P = 0.006), OS (8.5 months vs 4.2 months; P = 0.004), and response rate (94.5% vs 50%) compared to patients with high levels of all three suppressive immune cells. We further sorted patients with all suppressive immune cells plus $CD39^+CD8^+$ T cells low and high. Again, PFS (6.1 months vs 0.8 months; P = 0.006), OS (11 months vs 2.4 months; P = 0.01), and response rate (85.7% vs 16.7%) of all suppressive immune cells low and $CD39^+$ $CD8^+$ T cells low group were significantly increased. **Conclusion:** The analysis of 83 advanced NSCLC patients treated with anti-PD-1 immunotherapy demonstrated that G-MDSC, M-MDSC, TAM and $CD39^+CD8^+$ T cell frequencies in peripheral blood individually and collectively might be useful as potential predictive biomarkers.

P1.04-25 CT BASED VESSEL TORTUOSITY FEATURES ARE PROGNOSTIC OF OVERALL SURVIVAL AND PREDICTIVE OF IMMUNOTHERAPY RESPONSE IN NSCLC PATIENTS

M. Alilou[1], P. Patil[2], P. Fu[1], K. Bera[1], V. Velcheti[3], A. Madabhushi[1], P. Vaidya[1]

[1]*Case Western Reserve University, Cleveland/United States of America,* [2]*Cleveland Clinic, Cleveland/United States of America,* [3]*NYU Langone Cancer Center, New York/United States of America*

Background: Recently majority of patients with advanced non-small cell lung cancer (NSCLC) without targetable mutations are treated with immune checkpoint inhibitors (ICI). Since there are currently no validated biomarkers for predicting benefit of immunotherapy (IO), there is an unmet clinical need for development of such biomarkers. The tumor vasculature is a key component of the tumor micro-environment that can influence its behavior and therapeutic refractoriness. We aimed to evaluate the prognostic and predictive potential of quantitative vessel trotuosity (QVT), in the NSCLC patients treated with ICI drugs. Two hypotheses were established: first, the QVT on pre-treatment CT scans of NSCLC patients are associated with overall survival (OS). Second, the prognostic QVT features can lead to identify the patients who will benefit from IO.

Method: This study include 128 patients with advanced NSCLC. All patients underwent a baseline contrast CT imaging. Patients who did not receive IO drugs after 2 cycles due to a lack of response or progression as per RECIST were classified as non-responders. The dataset was splitted into a discovery (N=64) and validation sets (N=64). A set of 74 QVT features pertaining to tortuosity and curvature of tumor vasculature was extracted in CT scans. The initial set of QVT features were reduced to 8 features using least absolute shrinkage and selection operator (LASSO) in conjunction with OS data of the patients. Then, cox proportional hazard model was used to determine the contribution of each feature for categorizing survival groups. The weighted sum of selected 8 features gave a risk score (QRS) per patient. Patients in validation set were stratified based on QRS using the cutoff and feature weights learned in the discovery set. Prognostic features in conjunction with a linear discriminant machine learning model and OS were used to build a model to predict the response to IO. The prognostic features were also used for unsupervised clustering of the patients. **Result:** The QRS risk score was able to stratify patients into two survival groups in validation set (Fig1. a-b) with p-value=0.022, Hazard ratio (HR)=0.47 and concordance index (CI)=0.61. The response prediction model yielded an AUC of 0.64±0.03 (Fig1.c). The agreement between patients with high OS and positive response to therapy was found to be 0.62 on unsupervised clustering method (Fig1. d).

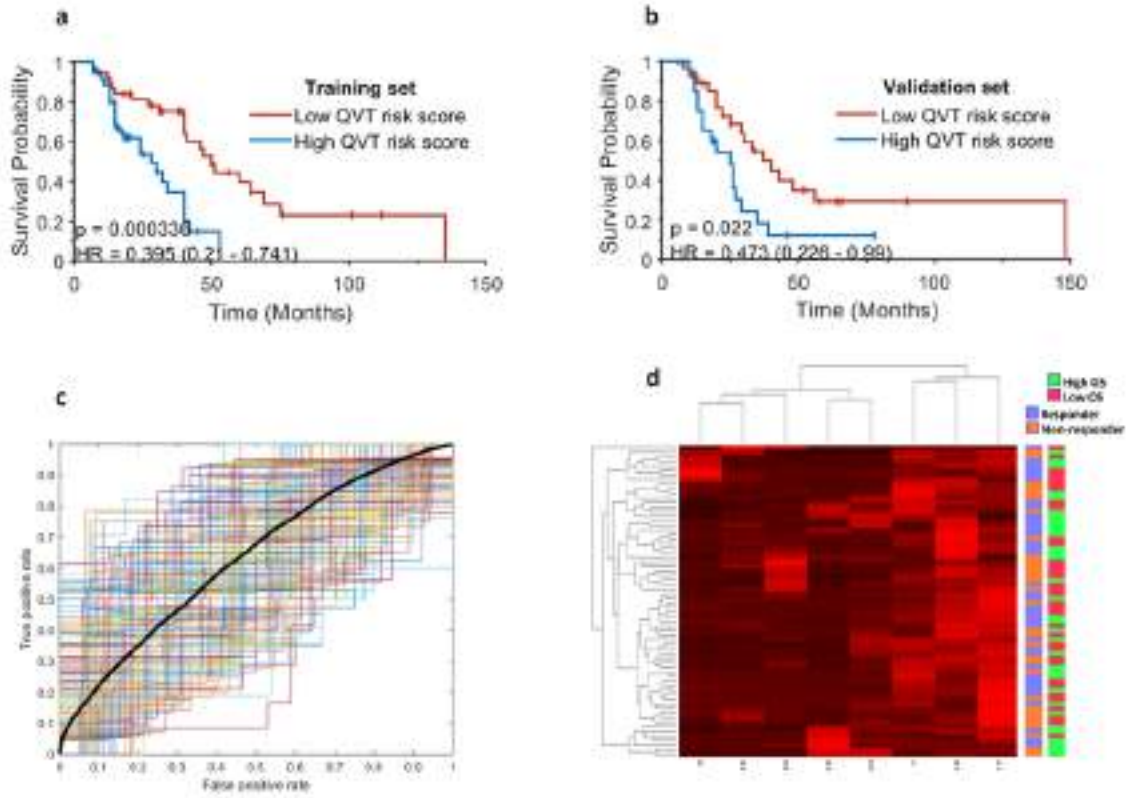

Fig1. a-b) Kaplan-Meier curves of survival estimates for the patient groups with low- and high- QRS scores in training and validation sets. c) The ROC curve of the response prediction model. d) The patients clusters which were created based on prognostic features.

Conclusion: The CT extracted QVT features was found to be prognostic of OS and also showed predictive value that could be used to identify patients who will benefit from IO.

P1.04-26 EMT-ASSOCIATED RESPONSE AND RESISTANCE TO MEK INHIBITOR AND IMMUNE CHECKPOINT BLOCKADE COMBINATIONS IN KRAS-MUTANT NSCLC

P.-O. Gaudreau[1], D. Peng[1], B. Rodriguez[1], J. Fradette[1], L. Gibson[1], C. Della Corte[1], T. Sen[2], S. Kundu[1], L. Chen[1], J. Wargo[1], D. Gibbons[1]

[1]*The University of Texas MD Anderson Cancer Center, Houston/United States of America,* [2]*Memorial Sloan-Kettering Cancer Center, New York/United States of America*

Background: Current work by our group using mutant KRAS and TP53 (KP) mouse models of NSCLC have shown that rationally designed therapies combining PD-L1 immune checkpoint blockade (ICB) with MEK inhibitors (MEKi) significantly decreases tumor growth and metastases compared to either monotherapies in syngeneic KP mice tumors. Despite these encouraging results, therapeutic resistance still occurs. Analyses from these tumors showed an increase in T_{regs} and CTLA-4 immune checkpoint expression. As anti-CTLA-4 ICB is particularly effective in increasing the CD8 / T_{reg} ratio, we hypothesized that the addition of this agent may improve the outcome. **Method:** Using *in vivo* KP syngeneic mouse models, we compared tumor size, tumor weight and lung metastatic nodules between two treatment regimens: the triple combination of selumetinib (MEKi) and anti-PD-L1 with either: 1) anti-CTLA-4 or; 2) IgG2b isotype control. FACS-based immunoprofiling was conducted at the time of response (5 weeks following treatment initiation) and resistance (maximal tumor volume). Whole tumors at the time of response and resistance, as well as *ex vivo* resistant cell lines, were also characterized by qPCR and Western Blotting (WB). Moreover, whole tumors from multiple treatment combinations and KP models were processed for custom codeset *Nanostring* mRNA analyses. **Result:** The addition of anti-CTLA-4 to anti-PD-L1 and MEKi improved survival in the epithelial 393P KP mouse model (HR=3.517; p=0.03). Because FACS immunoprofiling of cytotoxic $CD8^+$ T cells subtypes, NK cells and T_{regs} did not reveal statistically significant changes (p>0.05), we investigated potential tumor-intrinsic mechanisms. All resistant 393P cell lines displayed a mesenchymal morphology. Furthermore, whole tumors from the anti-CTLA-4 group demonstrated significantly less expression of Zeb1 (WB; p=0.05) at the time of response. *Nanostring* analyses comparing anti-PD-1 + anti-CTLA-4 vs anti-PD-L1 monotherapy in 344SQ KP mesenchymal tumors also showed statistically significant downregulation of epithelial-to-mesenchymal (EMT) markers (p=0.001). Finally, *in vivo* experiments using resistant 393P (MEKi + ICB) and mesenchymal 344SQ cells, demonstrated abrogation of the survival benefit initially observed with sensitive epithelial 393P cells upon treatment with combination therapies. **Conclusion:** The combination of a MEKi, anti-PD-L1 and anti-CTLA-4 improves survival in epithelial syngeneic KP pre-clinical models of NSCLC, and this benefit is associated with downregulation of EMT markers. Therefore, further in-depth studies are required to understand the effect of ICB on EMT. In an upcoming single center, Phase I / II clinical trial, two combination schedules of selumetinib, tremelimumab and durvalumab will be compared with historical controls in patients with previously treated, metastatic NSCLC.

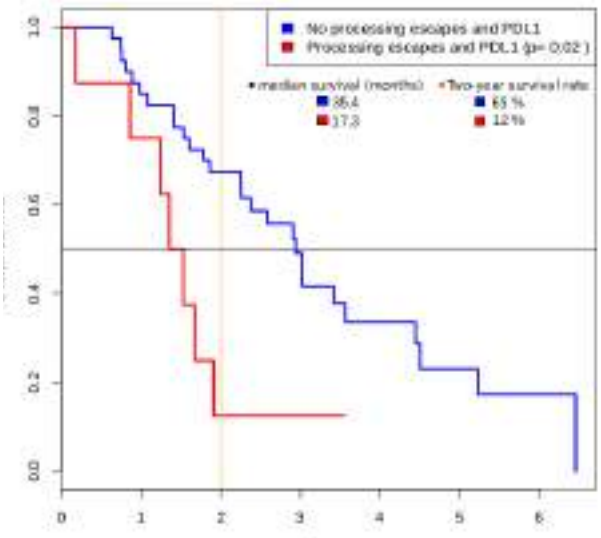
Background: Immune checkpoint inhibition, especially the blocking of PD-1 and PD-L1, has become one of the most thriving therapeutic approaches in modern oncology. Unfortunately, 60-80% of all patients will develop long-term resistances under immunotherapy. We believe immune evasion caused by altered tumour epitope processing may be one possibility to explain therapy resistance. In a previous work, we were able to establish these so-called processing escapes as an intrinsic immune escape mechanism in patients suffering from neuroendocrine lung cancers. In the present study, we aim to demonstrate the effects of processing escapes on immunotherapy outcome in NSCLC-patients. **Method:** Whole exome sequencing data of 400 NSCLC-patients (AdC and SCC) were extracted from the TCGA database serving as a training cohort. The validation cohort was composed of primary tumour probes from 48 NSCLC-patients, who received Nivolumab treatment. Mutational characteristics of these patients were determined by targeted amplicon-based sequencing including hotspots and whole exomes of 22 genes. The effect of mutations on proteasomal processing was evaluated by deep learning methods previously trained on 1260 known MHC-I ligands. Cox-regression modelling was used to determine the influence on overall survival. **Result:** In the training cohort, processing escapes were connected to decreased overall survival (p= 0.025) as well as lowered expression of immune factors including Granzyme K (p= 0.15), CD20 (p=0.05) and CD40L (p= 0.025). In the validation cohort, the group of patients showing high abundances of processing escapes in combination with high levels of PD-L1 (n=9/48) had a significantly decreased overall survival (figure 1). The predictive significance of processing escapes proved to be independent of mutational load or PD-L1 status in multivariate analysis.



Conclusion: Based on our retrospective data, the impact of processing escapes and PD-L1 status as a composite predictive score for checkpoint inhibitor response in NSCLC should be further investigated in prospective studies.

P1.04-28 COAST: DURVALUMAB ALONE OR WITH NOVEL AGENTS FOR LOCALLY ADVANCED, UNRESECTABLE, STAGE III NON-SMALL CELL LUNG CANCER

R. Herbst[1], F. Barlesi[2], L. Paz-Ares[3], D. Raben[4], C. Aggarwal[5], J. Bothos[6], R. Samadani[6], P. He[6], N. Angra[6], P. Martinez[6]

[1]*Yale University School of Medicine, New Haven/United States of America,* [2]*Aix Marseille University and Assistance Publique des Hôpitaux de Marseille, Marseille/France,* [3]*Hospital Universitario 12 de Octubre, Madrid/Spain,* [4]*University of Colorado Denver, Aurora/United States of America,* [5]*Hospital of the University of Pennsylvania, Philadelphia/United States of America,* [6]*AstraZeneca, Gaithersburg/United States of America*

Background: The standard of care for patients with unresectable stage III non-small cell lung cancer (NSCLC) is platinum-based chemotherapy with concurrent radiotherapy, followed by durvalumab consolidation for 12 months. When administered after completion of concurrent chemoradiotherapy (cCRT) in patients with unresectable NSCLC in the PACIFIC study, durvalumab demonstrated superior clinical outcomes vs placebo in terms of progression-free survival (PFS; hazard ratio [HR] 0.51; 95% CI: 0.41, 0.63) and overall survival (OS; HR 0.68; 99.73% CI 0.47, 0.997; p=0.0025).[1] Comparing durvalumab with placebo, the 24month OS rate (95% CI) was 66.3% (61.7, 70.4) vs 55.6% (48.9, 61.8), median PFS was 17.2 months (13.1, 23.9) vs 5.6 months (4.6, 7.7) and objective response rate was

30.0% (25.8, 34.5) vs 17.8% (13.0, 23.6).[1,2] However, despite cCRT followed by durvalumab, most patients with unresectable stage III NSCLC relapse and eventually die from NSCLC. The COAST study (NCT03822351) is a platform trial that aims to identify potential combinations of durvalumab with novel agents to improve response rates over monotherapy. **Method:** This multidrug, randomized, phase 2 trial is evaluating the clinical activity and safety of durvalumab alone or in combination with the novel agents oleclumab (MEDI9447) and monalizumab (IPH2201) in patients with unresectable, stage III NSCLC who have not progressed following definitive cCRT. New treatment arms evaluating other durvalumab combinations may be added based on emerging preclinical and clinical data. The primary endpoint is objective response per RECIST v1.1 with monotherapy and combination therapy. Secondary endpoints include safety, efficacy (duration of response, disease control, PFS, 12-month PFS rate, OS), pharmacokinetics and immunogenicity. The COAST study is open for accrual with an estimated total target enrollment of up to 60 patients per treatment arm. References [1]Antonia SJ, et al. N Engl J Med 2018;379:2342–50. P1.04-29 DYNAMIC CHANGES OF PLASMA PD-L1 MRNA EXPRESSION PREDICT RESPONSE TO ANTI-PD-1/ANTI-PD-L1 TREATMENT IN MALIGNANCIES

J. Sun, Q. Yang, M. Chen, J. Gu, L. Zheng, Y. Yu, F. Li, L. Zhang, K. Niu

Cancer Institute of People's Liberation Army, Chongqing/China

Background: PD-L1 expression in malignant tumor tissues is a rational biomarker to predict the efficacy and prognosis of anti-PD-1/anti-PD-L1 treatment, but few studies focus on the role of blood PD-L1 expression. **Method:** Fifty-one paired tissue samples and blood samples, as well as clinicopathologic features, were collected from patients with diverse malignancies to investigate the correlation among tissue PD-L1 (tPD-L1) expression, plasma PD-L1 mRNA expression, soluble PD-L1 (sPD-L1) expression and clinicopathologic features. Tissue PD-L1 were measured by immunohistochemistry. PD-L1 mRNA and self-designed plasma external reference PLACON were measured by quantitative real-time PCR. Soluble PD-L1 were detected by ELISA kit. Then, dynamic changes of blood PD-L1 expression (at baseline and within 2 months) were measured to evaluate the efficacy of patients with malignancies (n=24) who received anti-PD-1/anti-PD-L1 treatment. **Result:** Moderate correlation between tPD-L1 and PD-L1 mRNA (r=0.62, *P*<0.001), weak correlation between tPD-L1 and sPD-L1 (r=0.37, *P*=0.007) and weak correlation between PD-L1 mRNA and sPD-L1 (r=0.32, *P*=0.02) were found. Most clinicopathologic features had no significant correlation with PD-L1 mRNA and sPD-L1 expression. Interestingly, patients without metastasis had higher PD-L1 mRNA and sPD-L1 expression than counterparts. Further, patients with over 2.03-fold PD-L1 mRNA increase (n=11) during treatment experienced improved progression-free survival (PFS) than those with less than 2.03-fold increase (n=13), these patients also had higher best overall response (bOR) rate (45.45% vs. 7.69%). By comparison, the dynamic changes of sPD-L1 expression had no significant correlation with PFS and bOR.

Conclusion: Our study demonstrates that plasma PD-L1 mRNA expression was significantly correlated with tissue PD-L1 expression, and provides proof for the application of plasma PD-L1 mRNA as a predictor for anti-PD-1/anti-PD-L1 treatment.

Background: In the management of advanced Non-Small Cell Lung Carcinoma (NSCLC), both PD1/L1 immune checkpoint inhibitors (ICIs) have been shown to increase overall survival (OS) over standard second-line chemotherapy. While this long-term increase in OS is driven by about 20% of patients, others display disease progression during the first weeks (w.). PIONeeR aims to understand, through a strategy based on a comprehensive biomarkers assessment, and overcome, through rescue IO strategies, the resistance to ICIs. **Method:** Stage IV or recurrent NSCLC patients (n=450), with an archived pre-ICI tumor block, planned for a standard 2nd or 3rd line ICIs monotherapy, will be screened. If eligible, after signing an informed written consent, they will be blood-sampled, every cycle throughout the 18 w. post C1D1, and systematically be re-biopsied (primitive or metastasis tumor) at 6 w. of treatment. Efficacy of ICIs will be assessed by RECIST, after 6, 12 and 18 w. Feces will be self-collected by patients, before and during ICIs, to analyze impact of gut microbiome in resistance to ICIs. Characterization of the specific immune contexture of each patient to potentially predict the efficacy of ICIs will be based on the investigation of tumors and their microenvironment (Immunoscore® IC & Multiplex ImmunoHistoChemistry, Tumor Mutational Burden –T cell clonality- ctDNA investigation), effector immune cells, cytokines and endothelial activation (ELISA-Flow cytometry). Protocol's legal and ethical authorizations were obtained on February 2018 (NCT03493581), patient inclusions were enhanced on April 2018 with the activation of 3 main centers; 10 satellites centers were opened at Q4 2018, inclusions are expected to be completed at Q4 2020. Patients who will progress between 6 and 18 w. (n=150) will be randomized within a precision immuno-oncology experimental masterprotocol using a Bayesian, adaptive design (4 combinations of PDL1i and NKG2Ai, STAT3i, ATRi or CD73i or a control arm). Legal authorizations were obtained on December 2018 (NCT03833440), the inclusion period is expected to last 24 months, from the beginning of Q2 2019.Descriptive statistics will be used to characterize distributions of marker's expression and to evaluate their predictive value on treatment response and prognostic value on Progression Free Survival., in both protocols. The primary endpoint of the randomized clinical trial is the 12-week Disease Control Rate, assessed in each arm of treatment. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: CD28, CD57 and KLRG1 on circulating T-lymphocytes have been identified as markers of immunosenescence. The characterization of a senescent immune phenotype (SIP) in advanced NSCLC (aNSCLC) and its impact on anti-PD(L)-1 (IO) or platinum-based chemotherapy (PCT) treatments are unknown. **Method:** The percentage of circulating $CD8^+CD28^-CD57^+KLRG1^+$ T-lymphocytes (SIP) was assessed by flow cytometry on fresh blood from aNSCLC patients treated with IO or PCT. A SIP cut-off was identified by log-rank maximation method. Correlations with categorical or continuous variables were performed by logistic regression or t-test. Survival curves were estimated with Kaplan Meier and compared with log-rank. **Result:** In the IO cohort, 43 patients were evaluated for SIP: 32% ≥ 65 years, 92% non-squamous, 51% with tumoral PD-L1 expression ≥1%, 93% chemotherapy pretreated. Disease control rate (DCR), median PFS and OS and FU were 57%, 4.6 (95% CI 0.5; 8.8) months, 13 (95% CI 2.8-23.2) months, and 14 (95% CI 8.8-19.8) months, respectively. SIP median value was 15.4% (min 1.6%, max 57.7%). 32% of patients had >21.72% $CD28^-CD57^+KLRG1^+CD8^+$ lymphocytes (SIP^+). SIP was not significantly associated with clinical characteristics. SIP changed according to IO response by T-sne algorithm (Figure 1A). Compared to SIP^-, SIP^+ patients had significantly lower DCR (81% vs 28%, p=0.002), PFS [7.3 (95% CI 4.1; 10.4) vs 1.7 (95% CI 1.2; 2.3), p=0.02] and OS [NR (95% CI 6.04; NR) vs 2.4 (95% CI 1.7; 3.1), p=0.01]. SIP was significantly associated with specific immune populations [higher peripheral activated ($Ox40^+ICOS^+PD1^+$) T-regulatory ($CD25^{high}CD127^{low}$) cells, TEMRA ($CCR7^-CD45RA^+$) $CD8^+$ and T-helper 1 ($CXCR5^-CXCR3^+CCR4^-CCR6^-CCR10^-$) $CD4^+$] (Figure 1B). The PCT cohort included 61 patients, 43% SIP^+. No significant difference in DCR, PFS or OS were observed according to SIP.

Fig 1A. T-sne algorithm (unsupervised analysis)

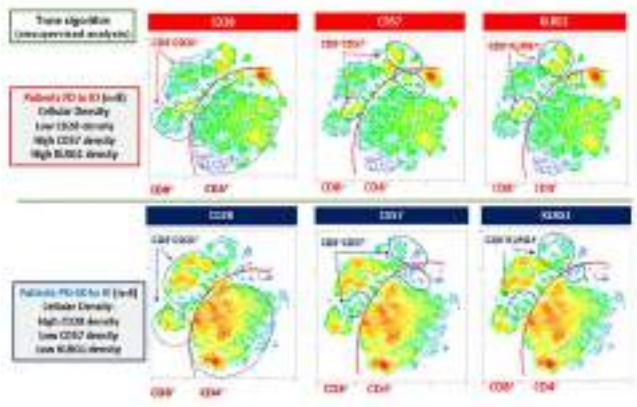

Fig 1B. Heatmap hierarchical clustering

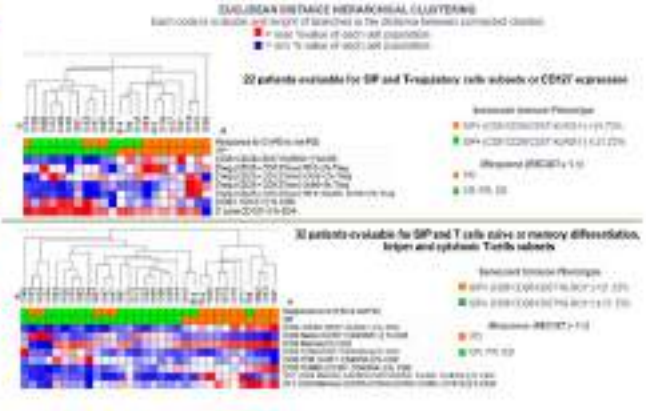

Conclusion: Immunosenescence is observed in 32% of aNSCLC patients before IO and correlates with specific immune phenotypes. Immunosenescence predicts lower DCR, PFS and OS from IO but not from PCT.

P1.04-32 KI67$^+$PD-1$^+$ CENTRAL MEMORY CD8 T-CELL FREQUENCIES PREDICT RESPONSE UPON NIVOLUMAB+IPILIMUMAB IN MALIGNANT PLEURAL MESOTHELIOMA

J. Mankor[1], M. Disselhorst[2], M. Poncin[1], H. Vroman[1], P. Baas[2], J. Aerts[1]

[1]*Erasmus University Medical Center, Rotterdam/Netherlands,* [2]*Netherlands Cancer Institute, Amsterdam/Netherlands*

Background: New treatment options for malignant pleural mesothelioma (MPM) are urgently needed, as the only standard treatment, chemotherapy, has only modest activity in the majority of the patients. Recent clinical trials with checkpoint inhibitors have shown promising results in MPM patients who progressed after first line platinum-based chemotherapy. We reported on 2 phase II clinical trials which assessed nivolumab (aPD-1) monotherapy (NIVOMES) and the combination of nivolumab + ipilimumab (INITIATE). At the 12-week time point, the disease control was 47% for nivolumab and 68% for the combination. Here we report on differences in T cell subsets present in the peripheral blood at baseline and during treatment in both trials. **Method:** Peripheral blood of 31 MPM patients enrolled in NIVOMES and 38 MPM patients enrolled in INITIATE was collected at baseline and 6-weeks after start of treatment. T-cell subsets frequencies and the expression of Ki67 and PD-1 on these subsets were determined by flow cytometry. **Result:** An increased proportion of proliferating Ki67$^+$ T-cells was found after 6-weeks of combination treatment with nivolumab/ipilimumab, which was not observed 6-weeks after treatment with nivolumab monotherapy. Increased proliferation was particularly observed in the effector memory (EM) and central memory (CM) CD4$^+$ T-cells and EM CD8$^+$ T-cells. Additionally, patients with a clinical response on combination therapy had a significantly higher frequency of PD-1$^+$ Ki67$^+$ CM CD8$^+$ T-cells and effector memory re-expressing RA (EMRA) CD8$^+$ T-cells compared to non-responders at baseline. These differences were not seen in patients that responded to nivolumab monotherapy. No alterations in the frequencies of either activated or naïve regulatory T cells (Tregs) were found in both treatment groups comparing baseline to 6 weeks. **Conclusion:** Our results indicate that specifically in patients that respond to combination therapy the frequency of PD-1$^+$Ki67$^+$ CM CD8 T-cells at baseline was significantly increased, whereas combination therapy in both responding and non-responding patients increased proliferation of memory T-cell subsets. This indicates that addition of ipilimumab to nivolumab treatment reinvigorates T-cell responses in general, whereas responding patients present with elevated immune activation already at baseline. In conclusion, we were able to select MPM patients that are most likely to benefit from combination therapy of nivolumab and ipilimumab at baseline.

[1]*Centre de Recherche en Cancerologie, Marseille/France,* [2]*Institut Paoli Calmettes, Marseille/France,* [3]*David Geffen School of Medicine at UCLA/ Translational Research in Oncology-US Network, Los Angeles/United States of America*

Background: Medical treatment of lung cancer has irreversibly changed since the development of immune checkpoint inhibitors like pembrolizumab. However, immune biomarkers of efficacy are still lacking. Preliminary data in melanoma showed that a high baseline blood level of classical monocytes was associated with improved outcome in patients treated with programmed cell death-1 (PD-1) inhibitors. This led us to explore the immune landscape of non-small cell lung cancer (NSCLC) patients treated with pembrolizumab on KEYNOTE-001 using high-dimensional mass cytometry. **Method:** We analyzed 38 advanced NSCLC patients treated with pembrolizumab on KEYNOTE-001 at UCLA. Mass cytometry (CyTOF) was performed on baseline peripheral blood mononuclear cells (PMBC). We used a panel of 31 antibodies defining major immune populations of myeloid cells (plasmacytoid and myeloid dendritic cells, myeloid-derived suppressor cells, classical and CD16$^+$ monocytes), lymphoid cells (B cells, NK cells, T_{Reg}, γδ T-cells, sub-populations of CD4$^+$ and CD8$^+$ T-cells), selected co-stimulatory (CD28, ICOS, 41BB), co-inhibitory molecules (PD-1, PD-L1, TIM3, LAG3, CTLA-4) and cytotoxicity molecules (perforin, granzymeB). Unsupervised clustering combined with predictive regression model (Citrus algorithm, false discovery rate = 1%) was used to detect immune populations differing between patients that experienced an objective response on trial, as assessed by immune-related response criteria (responders) *vs* those that did not (non-responders). Classical manual gating (FlowJo software) was used to confirm the Citrus results. **Result:** Among the 38 patients analyzed via CyTOF, 27 patients had sufficient viable cells for analysis. Citrus algorithm comparing responders (n=7) and non-responders (n=20) revealed significant frequency differences in specific subtypes of three immune populations: monocytes, CD4$^+$ and CD8$^+$ T-cells. Manual gating confirmed that responders (*vs* non-responders) had increased frequency (%CD45$^+$) of classical monocytes perforin$^+$ granzymeB$^+$ (5.54% *vs* 2.55%, p=0.029), central memory CD4$^+$ T-cells ICOS$^+$ CD28$^+$ PD1$^+$ (1.29% *vs* 0.83%, p=0.06) and over-expression of 41BB (mean metal intensity (MMI)=0.15 *vs* MMI=0.09, p=0.006) and perforin (MMI=108.4 *vs* MMI=70.7, p=0.004) in effector memory CD8$^+$ T-cells. **Conclusion:** Mass cytometry in the blood reveals that a high baseline frequency of activated and cytotoxic monocytes, CD4$^+$ and CD8$^+$ T-cells predicted for pembrolizumab efficacy in advanced NSCLC. Preliminary analyses correlating immune cell populations and overall survival are ongoing and suggest a similar increase in the three immune cell populations found to be higher in responders *vs* non-responders.

Background: Pembrolizumab is effective as first-line treatment for advanced non-small cell lung cancer (NSCLC) patients expressing high programmed death-ligand 1 (PD-L1). However, it is unclear whether the efficacy of first-line pembrolizumab treatment in elderly patients (aged ≥75 years) is similar to that in non-elderly patients expressing high PD-L1. Therefore, we aimed to investigate the efficacy and safety of first-line pembrolizumab monotherapy in elderly patients with NSCLC expressing high PD-L1. **Method:** Between February 2017 and February 2018, 128 patients (comprising 47 elderly) with advanced NSCLC expressing high PD-L1 received first-line pembrolizumab monotherapy at 10 Japanese institutions. Baseline characteristics, efficacy of pembrolizumab treatment, and adverse events were recorded. **Result:** Overall, 47 patients (40 men and 7 women) (median age, 79 [range, 75–88] years) were included in our analysis. In these patients who received first-line pembrolizumab monotherapy, the overall response, disease control rates, median progression-free survival (PFS), and overall survival (OS) were 53.1%, 74.4%, 7.0 months, and not reached, respectively. Common adverse events included anorexia, fatigue, skin rash, and hypothyroidism. Two treatment-related deaths due to pneumonitis and infection were noted. First-line pembrolizumab monotherapy with non-progressive disease (PD) was associated with better PFS. Pembrolizumab monotherapy with good performance status and non-PD was also linked to better OS. **Conclusion:** First-line pembrolizumab monotherapy among elderly patients with NSCLC expressing high PD-L1 was effective and safe and showed outcomes equivalent to those in non-elderly patients. First-line pembrolizumab monotherapy without PD, and with good performance status and non-PD, might be associated with better PFS and OS, respectively.

P1.04-35 IDENTIFICATION AND CHARACTERIZATION OF A UNIQUE KLRG1-EXPRESSING SUBSET OF CD4+FOXP3+ TREGS IN NON-SMALL CELL LUNG CANCER

D. Adeegbe, J. Semidey-Hurtado, D. Noyes, A. Schultz

Moffitt Cancer Center, Tampa/United States of America

Background: It is well established that CD4+FOXP3+ T regulatory cells (Tregs) contribute to dampening anti-tumor responses. Despite our improved understanding of their role in cancer, there remains a knowledge gap with respect to the clonal composition and heterogeneity of tumor-infiltrating Tregs in solid cancers. **Method:** We addressed this outstanding issue by conducting comprehensive phenotypic profiling of Tregs present in lung adenocarcinomas of a genetically engineered mouse model of non-small cell lung cancer (NSCLC) as well as those in resected tumors of NSCLC patients. **Result:** Multi-parameter flow cytometric analysis revealed that unlike the peripheral tissues, the tumor harbors a distinct sub-population of Tregs that express the co-inhibitory receptor, KLRG1. Compared to their negative counterparts, the KLRG1+ Treg subset exhibited heightened expression of a number of Treg signature proteins as well as higher levels of activation and memory molecular markers suggesting that they are a highly activated and differentiated Treg pool that is recruited to, or induced in the tumor microenvironment. Consistent with this phenotype, these KLRG1+ Tregs were superior in their capacity to suppress T cell proliferation relative to the KLRG1- cells. **Conclusion:** Collectively, these findings demonstrate that the tumor microenvironment in non-small cell lung cancer harbors a unique Treg sub-population that is characterized by dominant expression of KLRG1, and which represents a clonal pool with the most potent inhibition of T cell responses. These studies highlight the installment of distinct Treg subsets in NSCLC that have implications for regulation of anti-tumor responses.

P1.04-36 AN IN VIVO INFLAMMATORY LOOP POTENTIATES KRAS BLOCKADE

K. Arendt[1], G. Ntaliarda[2], V. Armenis[2], G. Stathopoulos[2]

[1]*Helmholtz Center Munich, munich/Germany,* [2]*Faculty of Medicine, Rio/Greece*

Background: Several reports from different groups suggest that novel KRAS inhibitors are not effective *ex vivo*, but the mechanism(s) responsible for this are unknown. We performed complex experiments that highlight the huge discrepancy between the marked *in vivo* and the minimal *in vitro* effects of KRAS inhibitors. Furthermore, we identified and validated the mechanism of the *in vivo*-restricted actions of KRAS inhibitors in immunocompetent mice, which can be translated to successful new treatments for patients with *KRAS*-mutant cancers. **Method:** We treated tumor cells with defined *KRAS* mutation status with KRAS inhibitors deltarasin, cysmethynil, and AA12 and used different *in vitro* assays as readout. Additionally *KRAS* silencing and overexpression were done using shRNA and $KRAS^{G12C}$ vectors and included in the experimental setup. In parallel C57BL/6 wildtype mice or deficient in interleukin (IL)-1β (*Il1b-/-*) or chemokine receptors (*Ccr2-/-*, *Cxcr1-/-*, *Cxcr2+/-*) received s.c. *KRAS*-mutant or wild-type tumor cells followed by saline or deltarasin treatments. Microarrays were done using a large set of *Kras*-mutant and *Kras*-wildtype cell lines. **Result:** We identified that KRAS inhibitors exerted comparable effects against cancer cells *in vitro* irrespective of *KRAS* status. However, mice only with *KRAS*-mutant tumors responded selectively to deltarasin treatment. Similar *in vivo*-restricted effects were evident after genetic manipulation of KRAS. Microarrays identified a 42-gene signature specific to *Kras*-mutant cancer cells and responsive to *Kras* manipulation, which contained *Kras*, *Ccl2*, *Il1r1*, *Ccl7*, and *Cxcl1*. Deltarasin was effective in halting *KRAS*-mutant flank tumors in *Wt*, *Cxcr1-/-*, and *Cxcr2+/-*, but not in *Ccr2-/-* and *Il1b-/-* mice. qPCR results revealed a strong regulation of *Il1r1/IL1R1* mRNA expression depending of *Kras/KRAS* mutation status and drug treatment. Thereby, KRAS inhibition can be effective *in vivo* via blockade of the positive feedback loop of KRAS-CCL2-IL1ß. **Conclusion:** Inflammatory signaling loops are synthetic lethality targets for *KRAS* mutant tumors and only druggable by KRAS inhibitors *in vivo*. Hence *in vitro* drug screens may be suboptimal settings for anti-KRAS drug discovery.

P1.04-37 DIOSCIN ELICITS ANTI-TUMOR IMMUNITY BY INHIBITING MACROPHAGES M2 POLARIZATION VIA JNK AND STAT3 PATHWAYS IN LUNG CANCER

Y. Yao, L. Cui, J. Ye, J. Zhou

Department of Respiratory Medicine, The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China, Hangzhou/China

Background: Tumor associated macrophage (TAM) is an important component in tumor microenvironment. Generally, TAM exhibits the function of M2-like macrophage, which is closely related to angiogenesis and tumor progression. Dioscin, a natural steroidal saponin, has shown its powerful anti-tumor activity recently. However, the mechanism of dioscin involved in immune-regulation is still obscure. Our study aimed to find the potentional anti-tumor role of dioscin in macrophages polarization regulation in lung cancer. **Method:** Flow cytometry was used to analyze the percentage of M1 macrophages($CD86^+F4/80^+$ or $NOS2^+F4/80^+$) and M2 macrophages($CD209^+F4/80^+$ or $CD206^+F4/80^+$) with dioscin treatment in vivo and *in vitro*. Real-time quantitative PCR was used to detect the expression of Arg-1, CD206 and NOS2, IL-6 mRNA. The level of IL10 and IL-12 secreted by macrophages was also analyzed using flow cytometry. Phagocytosis was determined by the amount of fluorescence-labeled latex beads internalized by BMDMs with microscopy and Flow cytometry. JAK-STAT and MAPK signaling pathways were detected by Western-Blot method. **Result:** We observed dioscin induced macrophages M2-to-M1 phenotype transition *in vitro* and inhibited IL-10 secretion. Meanwhile, the phagocytosis of macrophages was enhanced. In subcutaneous lung tumor models, dioscin inhibited the augmentation of M2 macrophage populations. Furthermore, dioscin down-regulated STAT3 and JNK signaling pathways in macrophages *in vitro*. Additionally, condition mediums from dioscin-pretreated macrophages inhibited the migration of 3LL cells and the tube-formation capacity of HUVEC cells. **Conclusion:** Dioscin may act as a new anti-tumor agent by inhibiting TAMs via JNK and STAT3 pathways in lung cancer.

Keywords: dioscin, macrophages polarization, anti-tumor

P1.04-38 EFFICACY AND SAFETY OF IMMUNOTHERAPY IN ELDERLY PATIENTS WITH NON-SMALL CELL LUNG CANCER

G. Galli[1], A. De Toma[1], F. Pagani[1], G. Randon[1], B. Trevisan[1], A. Prelaj[1], R. Ferrara[1], C. Proto[1], D. Signorelli[1], M. Ganzinelli[1], N. Zilembo[1], F. De Braud[1,2], M. Garassino[1], G. Lo Russo[1]

[1]*Fondazione IRCCS Istituto Nazionale dei Tumori, Milan/Italy,* [2]*Università Degli Studi di Milano, Milan/Italy*

Background: Most trials with Immune Checkpoint Inhibitors (ICIs) for Non-Small Cell Lung Cancer (NSCLC) included only small subgroups of patients (pts) aged ≥65. As NSCLC is often diagnosed in pts aged ≥70, real-world data about efficacy and safety of IO in elderly pts are essential. **Method:** We retrospectively collected data about all pts with advanced NSCLC treated with IO at our Institution between April 2013 and March 2019. All ICIs administered for ≥1 cycle were admitted. Pts were stratified for age as follows: <70 year-old (yo), 70-79 yo, ≥80 yo. Chi-square test was used to compare qualitative variables. Survival was estimated with Kaplan-Meier method. Log-rank test was used to compare curves. Multivariate analyses were performed with Cox model. **Result:** We reviewed 290 cases, with a median age of 67 (range: 29-89). Pts aged<70, 70-79 and ≥80 yo were 180, 94 and 16, respectively. Two hundred five pts received an anti-PD1, 77 an anti-PDL1, 8 an anti-CTLA4 or a combo-IO. Clinical/pathological variables were uniformly distributed across age classes, except for a higher rate of males (p 0.0228) and squamous histology (p 0.0071) in the intermediate class. Response Rate (RR) was similar across age groups (21.5% vs 22.3% vs 18.8% for pts aged<70 vs 70-79 vs ≥80 yo, respectively; p 0.9470). Median PFS did not differ according to age (2.8 vs 3.5 vs 2.6 mos for pts aged<70 vs 70-79 vs ≥80 yo, respectively; p 0.2020). Similarly, median OS was similar across age classes (9.1 vs 11.3 vs 9.6 mos for pts aged<70 vs 70-79 vs ≥80 yo, respectively; p 0.9144). These results did not change after stratification for sex (p 0.516 for PFS, p 0.5154 for OS) and histology (p 0.9057 for PFS, p 0.1002 for OS). The incidence of toxicity was comparable across subgroups (grade ≥2 adverse events in 35.8% vs 32.7% vs 37.5% for pts aged<70 vs 70-79 vs ≥80 yo, p 0.6493). The only variables influencing outcome at both univariate and multivariate analyses were performance status (p<0.0001 for PFS, p 0.0192 for

OS), number of metastatic sites (p 0.0842 for PFS, p 0.0235 for OS) and IO line (p<0.0001 for both PFS and OS), regardless age group. **Conclusion:** Advanced age is apparently not associated to a reduced efficacy of IO in our case series. Furthermore, no toxicity concern emerges even among the eldest pts. Therefore, to our opinion ICIs should be considered irrespective of age, provided an optimal PS at baseline. Of note, IO is often the only therapeutic option applicable to these cases considering the toxicity of chemotherapy.

P1.04-39 MOLECULAR CHARACTERISTICS, IMMUNOPHENOTYPE, AND IMMUNE CHECKPOINT INHIBITOR RESPONSE IN BRAF NON-V600 MUTANT LUNG CANCERS

M. Offin, T. Pak, S. Mondaca, J. Montecalvo, N. Rekhtman, D. Halpenny, S. Wu, M. Kris, P. Paik, G. Riely, C. Rudin, D. Hyman, M. Hellmann, A. Drilon, J. Land, L. Buie, P. Lito, R. Yaeger, D. Liu, B. Li

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Targeted therapy for Class I *BRAF* mutant lung cancers (V600) is well described and there is growing literature on their response to immune checkpoint inhibitors (ICI). In contrast, the molecular characteristics, immunophenotype, and response rates of class II and III *BRAF* mutations are not well defined. **Method:** Patients with *BRAF* Class I, II, III mutant and variants of unknown significance (VUS) lung cancers detected on NGS (MSK-IMPACT) from 1/2014-1/2018 were identified. PD-L1 by immunohistochemistry (E1L3N) was evaluated. Tumor mutation burden (TMB; mut/Mb) was determined by MSK-IMPACT. Best objective response to ICI was assessed by RECIST v1.1. Time to treatment discontinuation (TTD) and overall survival (OS) were assessed. Statistical analysis was performed with Fisher's exact and Kaplan-Meier. *BRAF* V600 lung cancers were used as a comparator and analyzed separately from *BRAF* non-V600. **Result:** 6.0% (177/2962) of lung cancers harbored a *BRAF*-mutation. Median TMB of *BRAF* non-V600 mutant lung cancers was 10.8 mut/Mb (n=136) overall compared to 4.9 mut/Mb in V600 (n=41; p<0.0001) and 5.9 mut/Mb in *BRAF* wild-type patients (n=2785; p<0.0001). 69% (127/177) of *BRAF*-mutant cases were metastatic (29 Class I, 36 Class II, 23 Class III, and 39 VUS). 57% of patients were female, 82% were smokers, and 90% were adenocarcinoma. More smokers were seen in the BRAF V600 group than in the non-V600 group (n = 16 vs 88 respectively, p<0.0001). PD-L1 expression in 49 non-V600 cases with available tissue was 0%, 1-49%, and ≥50% in 59% (n=29), 31% (n=15), and 10% (n=5) respectively. 7 *BRAF* V600 cases with PDL1 testing had expression of 0%, 1-49%, and ≥50% in 2, 3, and 2 cases, respectively. No *BRAF* V600 cases had concurrent *RAS/NF1*-alterations compared to 11 non-V600 (p=0.07). 36 patients with *BRAF* non-V600 mutations received ICI (nivolumab (n=25), pembrolizumab (n=5), atezolizumab (n=2), ipilimumab/nivolumab (n=4); median line of therapy=2) with an ORR of 22% (8/36). 10 *BRAF* V600 mutant lung cancer patients received ICI (nivolumab (n=5), pembrolizumab (n=2), atezolizumab (n=1), ipilimumab/nivolumab (n=2); median line of therapy=2) with an ORR of 10% (1/10). There was no difference in ORR between non-V600 and V600 patients that received ICI (p=0.66). TTD in *BRAF* non-V600 was 3.2 months compared to 1.4 months for *BRAF* V600 mutant lung cancer patients (HR 0.59, p=0.26). Median TMB in patients with *BRAF* non-V600 mutations that responded vs those who did not was 13.2 and 10.8 mut/Mb respectively (p=0.92). One response to ICI was seen in a *BRAF* V600 with TMB of 19.3. OS of *BRAF* non-V600 patients was 1.7 years compared to 2.5 years in V600 (HR 1.25, p=0.38). OS was higher in *BRAF* non-V600 lung cancer patients who received ICI (2.4 years) compared to those that did not (1.2 years; HR 0.60, p=0.04). **Conclusion:** The molecular characteristics and immunophenotype of *BRAF* non-V600 mutant lung cancers is typified by high TMB and low PD-L1 expression, with reasonably higher response rates and improved OS to later line ICI compared to *BRAF* V600. Further studies of immunotherapy in this oncogene subset is warranted.

Background: Blockade of PD-1 pathways by anti-PD-1 antibodies restore the function of exhausted T cells and release perforin and granzyme B which induce cytotoxic activity against tumor cells. We examined serum perforin and granzyme B as biomarkers of response to nivolumab and pembrolizumab in non-small cell lung cancer (NSCLC) patients. **Method:** Advanced NSCLC patients treated with nivolumab or pembrolizumab were studied. Serum were collected on days 1, 2, 8 and 15 for nivolumab and on days 1, 2, 8, 15 and 22 for pembrolizumab. Concentration of perforin and granzyme B was determined by enzyme-linked immunosorbent assay (ELISA). Best objective response was evaluated by Evaluation Criteria in Solid Tumors (RECIST) 1.1. **Result:** Sera from 40 patients with nivolumab and 26 patients with pembrolizumab were analyzed. Optimal cutoff levels for baseline concentration of perforin (day 1) were determined by efficacy. The calculated optimal cutoff levels were 5450.46 pg/ml with nivolumab (area under the receiver-operating-characteristic curve [AUC], 0.703) and 6631.16 pg/ml with pembrolizumab (AUC, 0.806). With nivolumab, median progression-free survival (PFS) was 6.8 months (95% confidence interval [CI], 2.8 to 3.7) in high concentration group (85%) versus 0.7 months (95% CI, 0.13 to not reached) in low concentration group (15%; hazard ratio [HR] for disease progression or death, 0.24; 95% CI, 0.09 to 0.68, p=0.007). Median overall survival (OS) was 14.9 months (95% CI, 10.2 to not reached) in high concentration group versus 1.8 months (95% CI, 0.13 to not reached) in low concentration group (HR for death, 0.19, 95% CI, 0.05 to 0.78, p=0.022). With pembrolizumab, median PFS was 6.7 months (95% CI, 3.5 to not reached) in high concentration group (73%) versus 0.7 months (95% CI, 0.37 to 5.7) in low concentration group (26%; HR for disease progression or death, 0.31; 95% CI, 0.11 to 0.89; p=0.03). Median OS was not reached (95% CI, 7.9 to not reached) in high concentration group versus 2.1 months (95% CI, 0.57 to not reached) in low concentration group (HR for death, 0.2; 95% CI, 0.05 to 0.77; p=0.018). Ratios of sequential perforin levels to baseline levels were analyzed, however, their AUC were not high enough, considered as low predictive power. Serum granzyme B was difficult to measure by ELISA. **Conclusion:** With anti-PD-1 antibody therapies, in patients with advanced NSCLC, higher baseline serum perforin levels before treatment were associated with significantly longer progression-free and overall survival.

Maria", Reggio Emilia/Italy,* [3]*Radiation Oncology Division, Perugia/Italy,* [4]*Radiotherapy Unit, Rome/Italy,* [5]*Radiotherapy Unit, Verona/Italy,* [6]*Radiotherapy Unit, Milano/Italy,* [7]*Radiation Oncology Unit, Florence/Italy,* [8]*Radiation Oncology Unit, Brescia/Italy,* [9]*Radiation Oncology Section, Perugia/Italy,* [10]*Radiotherapy Unit, Chieti/Italy,* [11]*Medical Oncology Unit, Modena/Italy,* [12]*AOU Careggi - Radiation Oncology Unit - Oncology Department, Firenze/Italy*

Background: Immunotherapy (IT) has enhanced the treatment armamentarium for aNSCLC. Radiobiological studies and initial clinical reports suggest a potential synergistic effect of radiotherapy

(RT) and IT. Aim of the study is to investigate the safety of cytoreductive RT (palliative or ablative) delivered in association with Nivolumab (NIVO), Pembrolizumab (PEM) or Atezolizumab (ATE) in aNSCLC setting. **Method:** We analyzed 179 consecutive pts affected by aNSCLC treated with a combination of RT and IT with NIVO/PEM or ATE from January 2015 to February 2019. One hundred eighteen patients were male and 61 female. Mean age was 65 (range 38-81). Adenocarcinoma was diagnosed in 101 of patients, while squamous cell carcinoma constituted 43.6% of our population. Eleven patients received IT as first line therapy, while the other 168 pts received at least a first line of systemic therapy before IT. One hundred thirty patients received NIVO, 42 PEM and 7 ATE. Concerning RT, 109 patients were treated before first cycle of IT (within 40 days), 49 pts during IT and the remaining 21 received RT immediately after the last IT session (within 40 days) due to disease progression (DP). **Result:** After a mean follow up (FUP) of 24.1 months (range 3-142), 63/179 patients were still alive. During FUP 115 patients (62.4%) experienced DP after RT-IT. One and 3-year Overall Survival were 60.3%±3.8%SE and 26,7%±4,5%SE, respectively. RT was delivered in 96 cases to bone metastasis, in 49 to brain mts, in 11 to lung nodules, in 12 to lymph nodes, in 6 to surrenalic gland and in 5 pts to other sites. RT was delivered to 109 patients as a pure palliative treatment (8-36 Gy in 1-12 fractions), to 49 pts using stereotactic ablative doses (18-54 Gy in 1-5 fractions) and to 21 with high dose moderately-hypofractionated schedules(24-51 Gy in 3-17 fractions) . In 107 patients, RT was planned using a 3D conformal approach, while in 72 an inverse planning system was used (IMRT/VMAT/Tomotherapy). Mean number of IT administrations was 11 (2-58). No patient had an interruption of systemic therapies during or after RT. Severe acute toxicities (Grade 3 by 4.0 CTCAE scale) were reported only in three cases because of the RT treatment: 1 case of radiodermitis and two lung toxicities. Known systemic side effects from IT were observed in 44 pts, 12 of whom with ≥G3 : 6 pneumonitis, 3 colitis, 2 thyroid toxicities, 1 oesophageal toxicity, 1 pt asthenia. **Conclusion:** RT and IT with checkpoint inhibitor NIVO/PEM/ATE represent a safe, well tolerated and efficient multimodal treatment in aNSCLC, with the available data suggesting also potential, synergistic effects on local and systemic disease in aNSCLC pts even when non-radical RT doses are prescribed. Ongoing studies set out to understand the optimal timing, RT doses and ideal combination between RT and IT in aNSCLC.

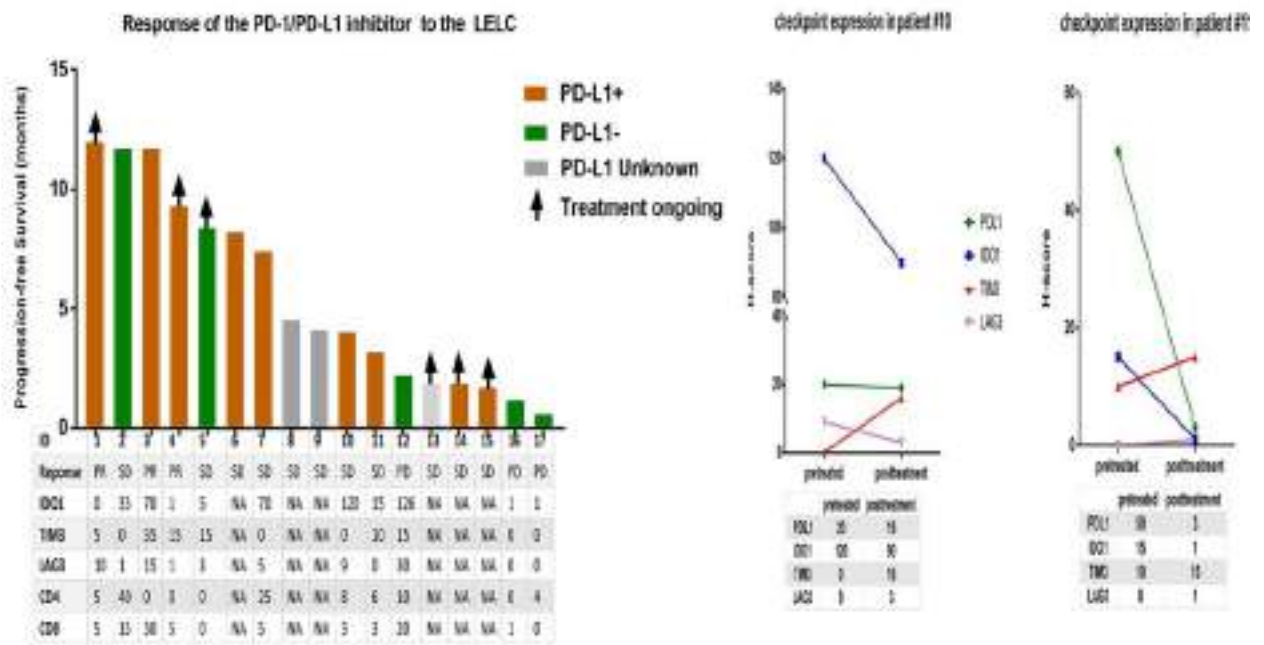
Background: Primary pulmonary lymphoepithelioma-like carcinoma (LELC) is Epstein-Barr (EB) virus related subtype of non-small-cell lung cancer. Evidence of immunotherapy in LELC is scarce. The role of immune markers in tumor microenvironment and their relation with the efficacy of PD-1/PD-L1 inhibitors in LELC remain poorly explored.Primary pulmonary lymphoepithelioma-like carcinoma (LELC) is Epstein-Barr (EB) virus related subtype of non-small-cell lung cancer. Evidence of immunotherapy in LELC is scarce. The role of immune markers in tumor microenvironment and their relation with the efficacy of PD-1/PD-L1 inhibitors in LELC remain poorly explored. **Method:** A total of seventeen patients treated with PD-1/PD-L1 inhibitors in Guangdong Lung Cancer Institute were enrolled. We detected multiple immune markers including PD-L1, IDO1, TIM3, LAG3, CD4 and CD8 by immunohistochemistry in eleven of these patients. Dynamic changes of the checkpoint biomarkers in two patients (#10 and #11) treated with PD-1 inhibitors were analyzed. Tumors with 1% TPS (tumor proportion staining) were defined as PD-L1 positive. H-score of PD-L1, IDO1, TIM3 and LAG3 was calculated by multiplying percentage of positively stained cells and intensity score (0, absent; 1, weak; 2, moderate; 3, strong). For CD4 and CD8, the H-score equals the percentage of staining positive lymphocytes among all nucleated cells. **Result:** In the 17 patients, most of them suffered from lines of chemotherapy (only two patients (2/17, 11.8%) received PD-1/PD-L1 inhibitors as the first line therapy). There are eight males and nine females. The median age was 47 years (range from 13 to 63). All of them were stage IIIB and IV. Thirteen of seventeen patients received single agent PD-1/PD-L1 inhibitor. PD-1/PD-L1 inhibitor showed an 82.4% disease control rate and 17.6% objective response rate. The median progression free survival was 7.4 months. The overall survival was not reached. Biomarkers of IDO1, LAG3, and TIM3 were not mutually exclusive with PD-L1, and could be highly expressed in responder patients to PD1/PD-L1 inhibitors. Notably, TIM3 expression was up-regulated at disease progression in two patients treated with PD-1 inhibitor.



Conclusion: PD-1/PD-L1 inhibitors had preliminary good activity, and TIM3 up-regulation might be a mechanism of resistance to PD-1 inhibitors in advanced pulmonary LELC.

[1]*CRUK Lung Cancer Centre of Excellence, Macclesfield/United Kingdom,* [2]*Christie NHS Foundation Trust, Manchester/United Kingdom,* [3]*University of Manchester, Manchester/United Kingdom,* [4]*The Francis Crick Institute, London/United Kingdom,* [5]*Leeds Cancer Centre, Leeds/United Kingdom,* [6]*University of Leeds, Leeds/United Kingdom,* [7]*Weston Park Hospital, Sheffield/United Kingdom,* [8]*University College Hospital London, London/United Kingdom,* [9]*Cancer Research UK Manchester Institute, Manchester/United Kingdom*

Background: Radiotherapy (RT) is delivered to 30-50% of NSCLC patients. However, over half of patients progress following RT and mechanisms of resistance are poorly understood. RT has immune-modulatory properties such as the ability to upregulate tumour PD-L1 expression and can recalibrate the immune contexture. Blockade of the PD-1/PD-L1 axis has been shown to enhance the efficacy of RT in several pre-clinical models and the recent PACIFIC trial. Exploiting immuno-regulatory effects of RT therefore has the ability to enhance local and distant anti-cancer effects of RT, especially when combining RT with immunotherapies such as anti-PD-1 or costimulatory agonists. **Method:** PDRAD is a prospective UK multi-centre feasibility study of paired pre- and post-treatment biopsies in NSCLC patients receiving palliative or radical RT. The study will recruit up to 30 patients with inoperable disease that is accessible to core biopsy by CT or bronchoscopy within the proposed RT field. Patients with archival baseline histology containing sufficient tumour material are eligible. Consented patients undergo a repeat biopsy in the second week of RT (fig.1). Blood samples will be collected at baseline, repeat biopsy, and following RT to assess immune changes that may correlate with the tumour microenvironment (TME). PDRAD opened to recruitment in November 2018 and will continue recruitment over 16 months. Research aims include investigating: •Feasibility and acceptability of obtaining paired biopsies •Changes in the immune contexture in irradiated tumour and 'out of field' sites •Immune changes in the TME and peripheral blood •Interim feasibility results after recruitment of 15 patients will be presented at World Lung.

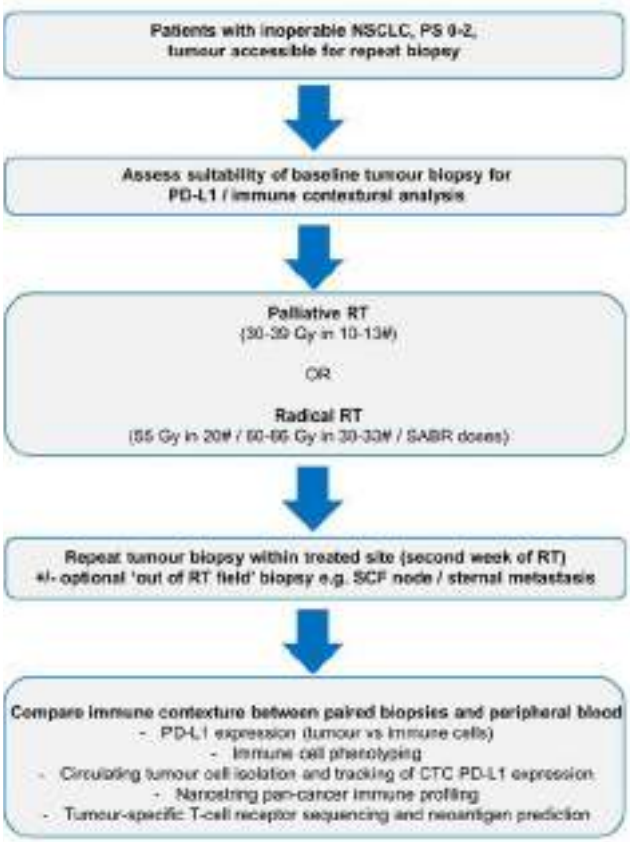

Fig. 1: Trial design

Result: Section not applicable **Conclusion:** We are at a pivotal point in evolving our knowledge of how the TME may influence responses to RT. The PDRAD study will help to influence further clinical trials, including combination studies with immunotherapies and predictive and prognostic biomarker development within the field.

P1.04-44 RADIOMICS FOR PREDICTING RESPONSE TO FIRST-LINE ANTI-PD1 THERAPY IN ADVANCED NSCLC

C. Ackermann, I. Fornacon-Wood, R. Tay, P. Manoharan, G. Price, C. Lindsay, C. Faivre-Finn, F. Blackhall, D. Cobben

The Christie NHS Foundation Trust, Manchester/United Kingdom

Background: Radiomics is the high-throughput extraction of quantitative imaging features from medical images that can reflect underlying tumour pathophysiology. Imaging biomarkers have the potential to improve disease characterisation and predict patient outcomes. In this study, the utility of radiomic features to predict response and survival to first-line immune check-point inhibition with pembrolizumab in advanced non-small cell lung cancer (NSCLC) was explored. **Method:** Patients with Stage IIIB/IV NSCLC treated with first-line pembrolizumab and PD-L1 ≥50% were retrospectively identified and stratified by Best Overall Response (BOR) by RECIST 1.1. Patients with the primary tumour in situ and a contrast-enhanced CT thorax/abdomen (minimum 5mm CT slice thickness) at baseline were included. The single largest thoracic lesion was segmented in the diagnostic image using the Pinnacle radiotherapy treatment planning system. All tumour delineations were supervised by a highly experienced certified senior radiologist. Lesions <1cm, inflammatory and indeterminate lesions were excluded from delineation. A total of 47 radiomic features including shape, first-order and texture features were extracted from the segmented tumour using PyRadiomics. No pre-processing of the images was performed. Highly correlated features (r>0.85) were removed from further analysis. Least Absolute Shrinkage and Selection Operator (LASSO) feature selection was performed to find informative features that could predict either best overall response or overall survival. Univariate logistic regression and cox proportional hazard models were then used for an initial assessment of the potential of these features in predicting response and survival respectively. **Result:** Sixteen patients with evaluable

best overall response (partial response n=9, progressive disease n=7) were selected for the initial discovery-cohort. Mean age was 68 years with 63% adenocarcinoma histology. From the 47 features extracted, 32 were highly correlated to each other and were removed from further analysis. For predicting best overall response, LASSO selected 5 features with univariate logistic regression suggesting that tumour surface area to volume ratio might be informative (p=0.057, AUC of 0.83 (95% CI 0.61-1.0)). With respect to overall survival, LASSO selected 3 features with univariate cox regression suggesting the first-order feature skewness might be predictive (HR = 0.27, 95% CI 0.08-0.88, p=0.03). When split on the median skewness value the Kaplan-Meier plot showed a significant survival difference between high and low risk patients (p=0.007). **Conclusion:** Radiomic features extracted from baseline contrast-enhanced CT scans may have the potential to predict response and survival in patients treated with first-line pembrolizumab in advanced NSCLC. We emphasize the exploratory nature of these results given the very limited number of patients in the study. We are expanding this discovery cohort to further investigate and validate these results. Updated results will be presented at the meeting.

Background: Immune-checkpoint inhibitors (ICI) represent a new standard of care for Non-Small Cell Lung Cancer (NSCLC) patients. Beyond tumor PD-L1 protein expression, other biological parameters are emerging as potential predictive biomarkers. We evaluated high-throughput immune-related Gene Expression Profiles (GEP) in tumor tissue from ICI-treated patients, correlating immune activation data with clinical response to immunotherapy. **Method:** RNA was isolated from tumor tissues of 44 metastatic NSCLC patients treated with Nivolumab (as 2nd or 3rd line therapy) and collected from different Italian centers. The nCounter® PanCancer IO360™ Panel was applied on NanoString platform to analyze 770 genes involved in key immuno-oncology pathways. Clinical-pathological data, as well as best response to ICI treatment, have been collected. **Result:** Patients were dichotomized as responders (7 Partial Response and 19 Stable Disease) and non-responders (18 Progressive Disease). A pre-identified T-cell inflamed signature was evaluated at single gene level and the expression of *CCL5, CD27, CD276, CMKLR1, CXCL9, CXCR6, LAG3, NKG7, PDCD1LG2, PSMB10, TIGIT* was higher in the responder group, although not reaching statistical significance. Moreover, higher *STING, CGAS* and *IRF3* genes expression level appeared to be more commonly associated with non-responder patients. Considering the disease stage at the time of diagnosis, a different gene panel (CCL5, CD27, CD274, CD8A, CXCL9, CXCR6, HLA-DQA1, HLA-DRB1, HLA-E, IDO1, LAG3, NKG7, PSMB10, TIGIT) resulted to be more expressed in early and locally advanced (16 from stage I to IIIA) compared to metastatic (28 stage IV) tissue samples. **Conclusion:** A trend in differential expression patterns was observed between responders and non-responders NSCLC patients treated with Nivolumab and additional analyses on this cohort could reveal specific pathways able to predict unresponsiveness to ICI treatment. Different disease stage seems also to influence immune-related GEPs.

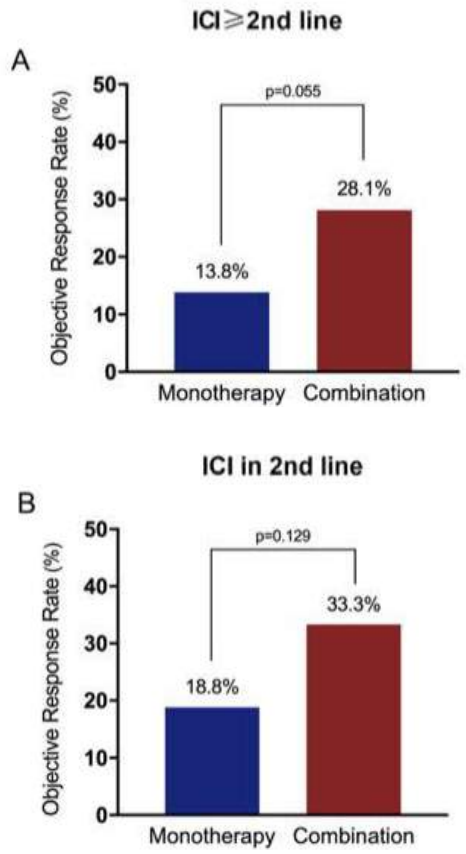
Keywords: gene expression profile, predictive biomarker, Immunotherapy

P1.04-46 PD-1 INHIBITOR PLUS CHEMOTHERAPY AS 2ND/SUBSEQUENT LINE SETTING DEMONSTRATE SUPERIOR EFFICACY OVER PD-1 INHIBITOR ALONE IN PTS OF ADVANCED NSCLC

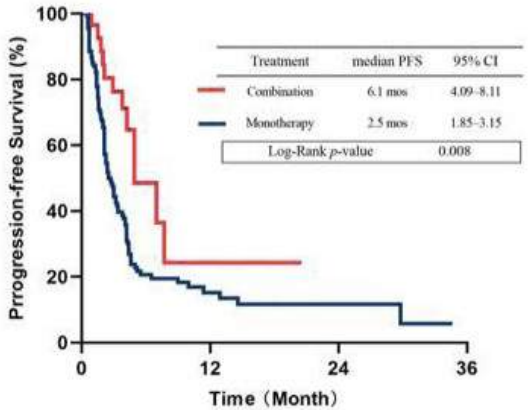
S. Ren[1], Y. Liu[1], F. Zhou[2], T. Jiang[1], C. Su[1], X. Chen[3], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Shanghai/China,* [2]*Shanghai Pulmonary Hospital, Tongji University School of Medicine, SHANGHAI/China,* [3]*Shanghai Pulmonary Hospital, Tongji University, Shanghai/China*

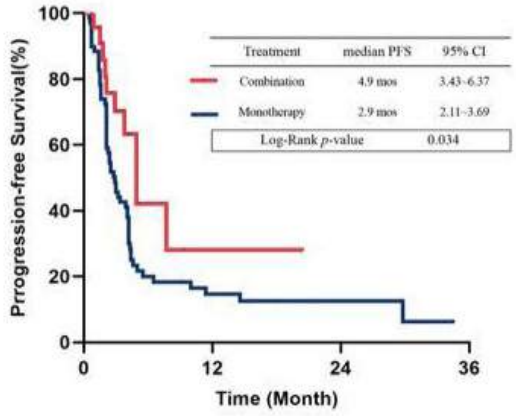
Background: PD-1/PD-L1 inhibitors have become standard of care as the 2nd-line setting and also approved as 1st line setting when combined with doublet chemotherapy in patients with advanced NSCLC. This study aims to compare the efficacy of PD-1 inhibitor plus chemotherapy with PD-1 inhibitor alone as 2nd/subsequent lines setting in patients with advanced NSCLC **Method:** Patients who received PD-1 inhibitor monotherapy or PD-1 inhibitor plus chemotherapy as 2nd/subsequent lines setting in Shanghai Pulmonary Hospital, Tongji University were retrospectively collected. Detailed clinicopathologic characteristics and therapeutic outcomes were analysis. **Result:** From January 2016 to February 2019, 148 patients who meet the criteria were included. Among them, 116 were in PD-1 inhibitor monotherapy group and 32 were in PD-1 inhibitor plus chemotherapy group. Chemotherapy regimens were pemetrexed(n=9), docetaxel(n=2), nab-paclitaxel(n=18) and gemcitabine(n=3). The baseline characteristics such as age, gender, smoking status, histology, PD-1 mono-antibodies, line of therapy were similar in the 2 groups. Combination group showed a favorable ORR (28.1% vs. 13.8%, p=0.055) and a significantly longer PFS(median 4.9 vs 2.5 months, p=0.005) compared with ICI monotherapy. Overall survial (OS) data was immature in the cutoff date of follow up. In the subgroup of 96 patients (monotherapy group n=69/ Combination group n=27) who were included as 2nd line setting, PD-1 inhibitor plus chemotherapy had significantly higher ORR(ORR:33.3% vs 18.8%, p=0.129) and longer PFS(median PFS: 4.9 vs 2.9 months, p=0.041).



C



D



Conclusion: PD-1 inhibitor plus chemotherapy as 2nd/subsequent lines setting demonstrated superior efficacy over PD-1 inhibitor alone in patients with advanced NSCLC.

Keyword: immunotherapy, chemotherapy, NSCLC

P1.04-47 TUMOR MUTATION BURDEN THROUGH HYBRID CAPTURE – CIRCULATING TUMOR DNA MAY PREDICT RESPONSE TO IMMUNOTHERAPY IN NSCLC

R. Grinberg[1], L. Roisman[1], S. Geva[2], M. Lefterova[3], K. Quinn[3], L. Soussan Gutman[4], A. Dvir[4], R. Yair[4], R. Lanman[5], D. Mehta[5], L. Kiedrowski[5], L. Raez[6], N. Peled[1]

Background: Immunotherapy has become the therapy backbone for patients with NSCLC. Currently, prediction to therapy response is based on tissue biopsy biomarkers such as PD-L1 expression, tumor mutation burden (TMB), genomic alterations in *EGFR/ ALK/ROS1* and *KRAS/TP53/STK11* mutations, all competing for limited tissue biopsy samples. Therefore, we investigated whether these biomarkers can be detected from a non-invasive plasma sample. Challenges of assessment of TMB with cell-free DNA next-generation sequencing (NGS) include the limited size of liquid biopsy gene panels and the fact that low shedding of tumor DNA into circulation may fail to detect hypermutated tumors. **Method:** In this retrospective study, data was collected from 100 NSCLC patients treated in medical centers in Israel and USA between 2014 and 2018. NGS on ctDNA was used to evaluate whether mutational burden influence the response to immunotherapy in these patients. Response to immunotherapy was defined by a cutoff of four months of progression free survival (PFS). Liquid biopsy tests were obtained three months or less before immunotherapy treatment start. **Result:** Overall, 100 NSCLC patients underwent NGS on ctDNA. Clinical treatment information and full clinical data was available for 66 patients. 23 patients underwent liquid biopsy tests within a range of 3 months or less before immunotherapy initiation. 9 patients were considered responders and 14 patients progressors by a cutoff of 4 months PFS. Preliminary results showed that in the group of responders, the median TMB was 5 with a standard deviation of 5.49. An average TMB of 2.3 was calculated for the group of progressors with a standard deviation of 1.44. ctDNA signature will be further presented based on a 73-gene ctDNA NGS panel that adjusts for the degree of tumor shedding. **Conclusion:** ctDNA collection was feasible in 66 patients, amongst which 23 underwent liquid biopsy testing 3 months or less before immunotherapy treatment initiation. As the preliminary data is promising on this pilot cohort, we are planning on expending the cohort study and presenting a complex analysis that includes multifactorial mutation load approach that integrates TMB and prediction to immunotherapy response.

P1.04-48 PREDICTION OF TUMOR DOUBLING TIME OF LUNG ADENOCARCINOMA USING RADIOMICS MARGIN CHARACTERISTICS

H.J. Yoon[1], H. Park[2], H.Y. Lee[3], I. Sohn[3], J. Ahn[3], S.-H. Lee[2]

[1]*VHS Medical Center, Seoul/Korea, Republic of,* [2]*Sungkyunkwan University, Suwon/Korea, Republic of,* [3]*Samsung Medical Center, Seoul/Korea, Republic of*

Background: Because shape or irregularity along the tumor perimeter can result from interactions between the tumor and the surrounding parenchyma, there could be a difference in tumor growth rate according to tumor margin or shape. However, no attempt has been made to evaluate the correlation between margin or shape features and tumor growth. Thus, the purpose of our study was to identify the tumor doubling time (DT) of lung adenocarcinomas (ADCs) through margin-related radiomic features. **Method:** We evaluated 52 lung ADC patients who had at least two computed tomographic (CT) examinations before curative resection. Volume-based DTs were calculated based on CT scans, and patients were divided into two groups according to the growth pattern of their ADCs (gradually growing tumors [GP I] vs. growing tumors with a temporary decrease in DT [GP II]). CT radiomic features reflecting margin characteristics were extracted, and radiomic features reflective of tumor DT were selected. **Result:** Among the 52 patients, 41 (78.8%) were assigned to GP I and 11 (21.2%) to GP II. Of the 94 radiomic features extracted, eccentricity, surface-to-volume ratio, LoG uniformity (σ = 3.5), and LoG skewness (σ = 0.5) were ultimately selected for tumor DT prediction. Selected radiomic features in GP I were surface-to-volume ratio, contrast, LoG uniformity (σ = 3.5), and LoG skewness (σ = 0.5), similar to those for total subjects, whereas the radiomic features in GP II were solidity, energy, and busyness. **Conclusion:** This study demonstrated the potential of margin-related radiomic features to predict tumor DT in lung ADCs. The results of this study may help predict tumor aggressiveness and behavior in patients with lung ADC and contribute to the development of treatment strategies

P1.04-49 QUANTITATIVE COMPUTED TOMOGRAPHY (CT) BASED TEXTURE ANALYSIS (QTA) MIGHT IDENTIFY RESPONDERS TO IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER

Z. Megyesfalvi[1,2], C. Kugler[1], A. Fülöp[1], S. Gergely[1], B. Megyesfalvi[1], A. Kerpel-Fronius[2], B. Döme[3], R. Korn[4], G. Weiss[5], Z. Lohinai[1]

[1]*Semmelweis University and National Institute of Oncology, Budapest/ Hungary,* [2]*National Koranyi Institute for Pulmonology, Budapest/Hungary,* [3]*Medical University Vienna, Vienna/Austria,* [4]*Imaging Endpoints, Scottsdale/ United States of America,* [5]*Beth Israel Deaconess Medical Center/Harvard Medical School, Boston/United States of America*

Background: Quantitative computed tomography (CT) based texture analysis (QTA) can characterize tumor heterogeneity, that might be associated with tumor infiltrating immune cells, including T-cells, a hallmark of ongoing immune surveillance with potential therapeutic importance. Therefore, QTA might represent prognostic

and predictive biomarker in terms of immunotherapy administration. In this study, we investigate the potential of tumoral QTA and a novel machine learning approach to differentiate responders from non-responders using baseline pre-treatment CT imaging in advanced-stage NSCLC patients treated with immune checkpoint inhibitors. **Method:** The QTA was applied separately on 50 contrast and 50 non-contrast CT images of histologically confirmed NSCLC patients. All patients included were treated with second-line immunotherapy (nivolumab, pembrolizumab or atezolizumab). Three-dimensional tumor segmentation was performed using the 4.10 version of 3D Slicer, and a total of 104 CT parameters from each CT image was obtained. For data pre-processing and standardization, we used the Sklearn machine learning library in Python programming language, reducing the number of CT parameters by Principal Component Analysis (PCA). The components thus obtained were further analyzed with hierarchical cluster analysis. According to QTA, responders were differentiated from non-responders based on naïve Bayes and k-means clustering. Response was defined as complete response, partial response, or stable disease at the first follow-up CT scan after immunotherapy initiation while non-response was defined as either visible signs of progression at time of or death prior to first follow-up CT scan. To verify the accurateness of the machine learning algorithms, leave-one-out cross-validation was performed. **Result:** Overall, we analyzed the CT scans of 88 advanced-stage NSCLC patients including 40 woman and 48 men. PCA identified eight major principal components which characterize the 104 CT features with an accuracy of 90%, suggesting no loss of essential CT-related information. We further evaluated these eight principal components and hierarchical cluster analysis clearly identified two major subgroups both in the contrast and non-contrast CT image group. According to the QTA, based on naïve Bayes clustering, the machine learning algorithm was able to differentiate responders from non-responders with an accuracy of 66.6% in the contrast CT image group but was not predictive in the non-contrast group. K-means clustering also showed an accuracy of 66.6%, thus confirming the results of the naïve Bayes clustering. **Conclusion:** Advanced-stage NSCLC patients can be classified into two major subgroups according to their CT features principal components with hierarchical cluster analysis using both contrast and non-contrast CT images. The clinical relevance of these principal component related subgroups should be further investigated in future prospective studies. By evaluating the contrast CT images, machine learning algorithms based on naïve Bayes and k-means clustering may predict the response to immunotherapy, however, further studies on "Big Data" are needed to define the exact prognostic value of QTA in NSCLC patients regarding immunotherapy administration. Application of QTA to prognostication for progression-free survival and overall survival is in progress.

Background: Pembrolizumab has demonstrated its usefulness as a primary treatment for metastatic non-small cell lung cancer (NSCLC) in Keynote-024 and Keynote-042. However, there is little information on the usefulness of pembrolizumab in clinical practice. The purpose of this study is to examine whether the efiicacy reported in Keynote-024 and Keynote-042 is reproduced in real world setting. **Method:** This study is retrospective multicenter trial. From Feb, 2017 to Dec, 2018, patients with histologically diagnosed, advanced, metastatic or recurrent NSCLC, TPS score of 50% or greater, and PS 0 or1, received pembrolizumab at 1st line were enrolled in this study. Clinical data were collected from electronic medical records and pharmacy databases. **Result:** Seventy-four consecutive patients received pembrolizumab monotherapy at seven centers between Febrary 2017 and December 2018. The median age was 72 years (range 51-89), 55 males, 59 smokers, 48 had adenocarcinomas. Nine patients had clinical stage III disease, 55 had IV, and 10 postoperative relapses. The antitumor effect was 6 cases for CR, 27 cases for PR, and 20 cases for SD. Overall response rates and disease control rates were 44.6% (95% confidence interval(CI): 33.3-55.9) and 71.6% (95%CI: 61.3-81.9), respectively. Progression-free survival and overall survival were 7.7 months (95%CI: 4.4-11.0) and 18.5 months, respectively. Immune-related adverse events were observed in 33 cases (44.6%). ILD was noted in 13.5% of cases. Two treatment related deaths were observed. **Conclusion:** In conclusion, our initial results in this real world cohort show pembrolizumab as a single agent therapy is a safe, effective treatment. Our results suggest that the results of Keynote-024 and Keynote-042 studies colud be reproduced in clinical practice.

P1.04-51 TREATMENT WITH IMMUNE CHECKPOINT INHIBITORS FOR ADVANCED NSCLC IN ELDERLY AND FRAIL PATIENTS. A REAL-LIFE EXPERIENCE

K. Fuglsang Junker[1], G. Persson[2,3], J. Lykkegaard Andersen[3], J. Sørensen[1,2], S. Langer[1,2], M. Pøhl[1]

[1]*Rigshospitalet, Copenhagen University Hospital, København Ø/Denmark,* [2]*Faculty of Health, University of Copenhagen, Copenhagen/Denmark,* [3]*Herlev Hospital, Copenhagen University Hospital, Herlev/Denmark*

Background: Immune checkpoint inhibitors (ICIs) has changed the standard treatment in advanced stage non-small cell lung cancer (NSCLC). However, patients above 75 years and patients in performance status (PS) 2 are underrepresented in randomized clinical trials. Hence, the efficacy and safety of treatment in these large subgroups of patients remains unclear. We report a real-life study of such patients treated with immunotherapy in a second-line setting. **Method:** Data from consecutive patients with advanced NSCLC who had 2nd line treatment with ICIs at the University Hospitals in Copenhagen during November 2015 to March 2019 were obtained from medical records. Treatment efficacy and safety was evaluated, and treatment related adverse events (AEs) were registered. **Result:** A total of 224 NSCLC patients were treated with either nivolumab or pembrolizumab: The median follow up time of was 12.3 months. The median progression free survival (PFS) was 4.9 months, and median overall survival (OS) was 12.9 months CI [9.7-14.6]. The median age was 67.7 years, while 45 patients (20%) were 75 years or older. There were no significant difference when comparing patients ≥ 75 years *vs.* < 75 years with respect to PFS (5.3 *vs.* 4.9 months, p = 0.81) nor in OS (14.2 *vs.* 12.8 months, p = 0.93). PFS and OS were correlated with PS: The PFS was 7.7, 4.7 and 2.0 months (p = 0.0003) in PS 0, PS 1 and PS 2, respectively. OS was 20.9, 12.0 and 3.0 months (p > 0.0001) in PS0, PS1 and PS 2, respectively. AEs were reported in 183 patients (82%), among whom 44 patients (20%) experienced grade 3-5. There were no difference in AEs in younger patients compared to older ≥ 75 years (p = 0.18). The incidence of grade 3-5 AEs was significantly higher among patients in PS 2 (35%) compared to PS 0-1 (17%), (p < 0.001). **Conclusion:** NSCLC patients ≥ 75 years had efficacy and safety profiles in second-line ICIs comparable to those of younger patients. However, treatment with ICIs in patients with PS 2 was associated with a significant lower PFS and OS. The high risk of seriously AEs in patients with PS 2 is of concern and warrants further investigation.

P1.04-52 THE ROLE OF BLOOD BIOMARKERS IN RADIATION THERAPY FOR THORACIC MALIGNANCIES

E. Gkika[1], S. Adebahr[2], T. Schimek-Jasch[1], G. Niedermann[2], U. Nestle[1,3], A.-L. Grosu[2], D. Duda[4]

[1]*Department of Radiation Oncology, Medical Center, Faculty of Medicine, University of Freiburg, Freiburg/Germany,* [2]*Department of Radiation Oncology, Medical Center, Faculty of Medicine, University of Freiburg; German Cancer Consortium (DKTK) Partner Site Freiburg and German Cancer Research Center (DKFZ) Heidelberg, Freiburg/Germany,* [3]*Kliniken Maria Hilf GmbH Mönchengladbach, Mönchengladbach/Germany,* [4]*5E. L. Steele Laboratories for Tumor Biology, Department of Radiation Oncology, Boston/ United States of America*

Background: Radiation (RT) of malignant tumors has the potential to induce immunomodulatory and vascular effects, which can influence the anti-tumor immunity and normal tissue radiosensitivity. We prospectively evaluated the role of different chemokines and

cytokines in patients treated with radiotherapy for different thoracic malignancies concerning survival (OS) and development of radiation induced lung toxicity (RILT). **Method:** Fifty-six patients with lung cancer (n=41), esophageal cancer (n=14) or thymoma (n=1) treated either with conventionally fractionated (n=43) or hypo-fractionated (n=13) radiotherapy were enrolled prospectively in the study. The serum levels of IL-10, IFN-γ, IL-12p70, IL-13, IL-1β, IL-4, IL-6, IL-8, TNF-α, bFGF, Flt-1, PlGF, VEGF, VEGF-C, VEGF-D were analysed by multiplex array (MesoScale Discovery) and measured in a USA CLIA-certified core at MGH Boston.at predefined time points: before, during and at the end of treatment as well as in the first and second follow-up. Toxicities were scored according to common toxicity criteria for adverse events. **Result:** We observed an upregulation of IL-10, IFN-γ, PlGF, VEGF-D and a downregulation of IL-8, TNF-α, VEGF, VEGF-C during and at the end of radiotherapy. IL-6 was upregulated during radiotherapy and downregulated at the end of treatment and Flt-1 was downregulated during radiotherapy and upregulated at the end of treatment. Furthermore, the baseline concentrations of several chemokines correlated with OS such as IFN-γ, IL-13, IL-6, TNF-α, but couldn't be sustained after Bonferroni correction. On the contrary a higher IL-13 concentration during radiotherapy (p<0.000, HR 19.456, 95% CI 4.254-89.070), IL-6 (p<0.000, HR 1.055, 95% CI 1.024-1.086), IL-1β (p=0.004, HR 11.200, 95% CI 2.160-58.074), IL-8 (p=0.009, HR 1.014, 95% CI 1.003-1.024) and bFGF (p<0.000, HR 1.170, 95% CI 1.075-1.274) and of the IL-6 at the first follow up (p=0.001, HR 1.140, 95% CI 1.057-1.229) correlated with OS. Seventeen patients (30%) developed radiologic signs of RILT Grade≥1 but only two of them (3.6%) developed clinical symptoms (Grade 2). We could not find any association between the different serial blood biomarkers and a higher incidence of RILT. **Conclusion:** In our study early changes in blood biomarkers during radiotherapy could indicate an early immune response and might play a role on the outcome of the threatmentbut they don't seem to play a significant role in the development of early stage (grade 1) RILT.

Keywords: Immuno biomarkers, Thoracic radiation

P1.04-53 A HIGH PD-L1 EXPRESSION IN NON-SMALL CELL LUNG CANCER CORRELATES WITH EXPRESSION OF SPOP AND CD8 TUMOR-INFILTRATING LYMPHOCYTES

M. Inoue, J. Yoshida, S. Oka, Y. Honda, Y. Chikaishi, D. Yasuda

Shimonoseki City Hospital, Shimonoseki/Japan

Background: Immunotherapy that targets PD 1 pathway has emerged as a novel treatment modality for malignant diseases. Clinical trials have reported durable responses and long-term remissions using PD-1/PD-L1. However, despite promising clinical results, checkpoint blockade therapies are only successful in a subset of patients. Thus, it is crucial to more fully understand the mechanisms behind immunotherapies. Recently, it has been reported that PD-L1 expression can be regulated at both transcriptional and post-transcriptional levels, including HIF-1, STAT3, NF-κB, AP-1, cyclin-dependent kinase 4 (CDK4) and speckle-type POZ protein (SPOP). In this study, we focused on the regulation of PD-L1 expressionin lung cancer, and we investigated the association between the expression of PD-L1 and biomarkers in regard to clinical outcomes. **Method:** We investigated CDK4, CDK6 and SPOP expression of lung cancer, and CD4 and CD8 expression of tumor-infiltrating lymphocytes (TILs) by immunohistochemistry of 52 patients with non-small cell lung cancers who had undertaken an operation or chemotherapy from May 2008 to December 2018 and analyzed PD-L1 expression (negative:<1%, low expression:1-49%, high expression:≥50%). The staining intensity of CDK4, CDK6 and SPOP was scored as 0 (negative), 1 (weak), 2 (medium), and 3 (strong). Extent of staining was scored as 0 (0-10%), 1 (11-25%), 2 (26-50%), 3 (51-75%), and 4 (76-100%) according to the percentages of the positive staining areas in relation to the whole cancer area. For CD4+ and CD8+ cells, a numbers of stained cells were counted semi-quantitatively in high-powered fields (400x). A numbers of CD8+ cells in tumor tissue were scored as 0 (0-5 cells/HPF), 1 (6-10 cells/HPF), 2 (11-25 cells/HPF), 3 (26-50 cells/HPF), and 4 (51- cells/HPF). The observed protein expression levels and TILs counts were analyzed for correlation to PD-L1 expression and clinicopathological parameters. **Result:** PD-L1 expression was observed in 33 (64%) patients of lung cancer, being low in 19 (37%) and high in 14 (27%). The positive rate of expression of SPOP was 42% in tumors with negative expression of DP-L1, 53% low expression and 14% high expression. That of CDK4, CDK6 and CD8 in tumor tissue was 79%, 79%, 57% and 53%, 63%, 43%, and 41%, 41%, 92%, respectively. The positive rate of SPOP of CDK4 positive group was significantly higher than that of CDK4 negative group (50% vs 7%, p=0.005). The positive rate of SPOP of high PD-L1 expression group was significantly lower than negative and low expression groups (14% vs 47%, p=0.03). CD8+ cell counts showed positive relation to PD-L1 expression. **Conclusion:** In previous report, CDK4/6 inhibitors treatment decreased SPOP protein abundance and elevated PD-L1 protein. Our data supported those findings that PD-L1 expression is regulated by CDK4 and SPOP. Then combination treatment with CDK4/6 inhibitors and PD-1/PD-L1 immune checkpoint blockade may have potential to enhance therapeutic efficacy for cancers.

Keyword: PD-L1, SPOP, CDK4

P1.04-54 INTER-TUMOR HETEROGENEITY OF PD-L1 EXPRESSIONS IN NON-SMALL CELL LUNG CANCER

Y. Saito, S. Horiuchi, H. Morooka, T. Ibi, N. Takahashi, T. Ikeya, E. Hoshi, Y. Shimizu

Saitama Cardiovascular and Respiratory Center, Kumagaya, Saitama/Japan

Background: Following to approval of Pembrolizumab for patients with advanced NSCLC, PD-L1 IHC 22C3 pharmDx (Dako) was adopted as a companion diagnostic test. While PD-L1 IHC 28-8 pharmDx (Dako) was established as a complementary diagnostic for Nivolumab. Recently many groups demonstrated the intra-tumor heterogeneity of these PD-L1 expressions, but there have been a few reports about the intra-patient or inter-tumor heterogeneity. We aimed to investigate the inter-tumor heterogeneity of PD-L1 IHC 22C3 and 28-8 pharmDx (Dako). **Method:** Between December 1, 2014 and May 7, 2018, total 517 patients with NSCLC underwent surgical resection at our hospital. We excluded all patients with no informed consent, with no lymph node metastasis, with chemotherapy/radiotherapy before surgery and with never enough volume of material for genetic testing. Finally 35 formalin-fixed paraffin-embedded primary tumors with paired metastatic lymph nodes were available in this study. After staining by PD-L1 IHC 22C3 and 28-8 pharmDx (Dako) respectively, we counted tumor cells exhibiting membrane staining and calculated Tumor Proportion Score (TPS). Afterward, all cases were classified into three subgroups as follows; No Expression (TPS: <1%), Low Expression (TPS: 1-49%) and High Expression (TPS: ≥50%). **Result:** Average age of 35 patients was 66.8 years old and there were 10 females (28.6%), 10 never smokers (28.6%), 27 adenocarcinomas (77.1%) and 11 tumors with EGFR mutation. The number of cases in No Expression, Low Expression and High Expression in 22C3 were 7 (20.0%), 22 (62.8%) and 6 (17.1%) in primary tumor, meanwhile 18 (51.4%), 13 (37.1%) and 4 (11.4%) in metastatic lymph node, respectively. The concordant rate was 28.6% between TPS subgroups in primary tumor and that in metastatic lymph node. About 28-8 antibody, No Expression, Low Expression and High Expression were 8 (22.9%), 21 (60.0%) and 6 (17.1%) in primary tumor, meanwhile 18 (51.4%), 11 (31.4%) and 6 (17.1%) in metastatic lymph node, respectively. The concordant rate was 31.4% between TPS subgroups in primary tumor and that in metastatic lymph node. **Conclusion:** Our result demonstrated apparent discrepancy of TPS between primary tumor and metastatic lymph node in both PD-L1 IHC 22C3 and 28-8.

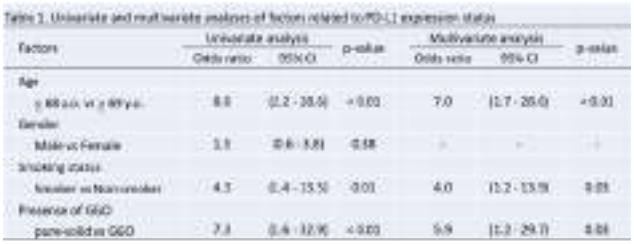
P1.04-55 COMPARISON OF PD-L1 EXPRESSION STATUS BETWEEN PURE-SOLID VERSUS PART-SOLID TUMORS IN LUNG ADENOCARCINOMAS

K. Suda, S. Shimizu, M. Shimoji, K. Sato, S. Ohara, T. Fujino, M. Nishino, T. Koga, A. Hamada, K. Tomizawa, T. Takemoto, J. Soh, T. Mitsudomi

Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Background: Recent studies have reported clinicopathological and prognostic differences between lung adenocarcinomas with ground-glass opacity (GGO) versus those without GGO (pure-solid tumors). However, it is unknow if the expression status of PD-L1 protein differs between these two groups. **Method:** One-hundred twenty-four stage IA – IB lung adenocarcinoma patients who received pulmonary resection between 2007 – 2009 were included in this study. PD-L1 staining was performed in our previous study

using E1L3N antibody. PD-L1 status was classified as positive if 1% or more tumor cells showed membrane staining; and was classified as strong positive if 50% or more tumor cells did so. **Result:** Among 124 lung adenocarcinoma patients, 45 had lung adenocarcinomas with GGO and 79 had pure-solid lung adenocarcinomas. We observed no significant differences between these two groups in terms of clinical factors (gender, age, and smoking status). However, the rates of PD-L1 positive tumors (4% vs 25%, p < 0.01) and PD-L1 strong positive tumors (2% vs 16%, p = 0.02) were significantly lower in lung adenocarcinomas with GGO. In multivariate analyses, these correlations between the presence / absence of GGO and PD-L1 expression status were still evident as shown in Table 1.



Conclusion: Lung adenocarcinomas with GGO were less frequent to express PD-L1 compared to pure-solid lung adenocarcinomas.

Background: Tumor mutational burden (TMB) can be defined as the total number of nonsynonymous mutations present in a tumor. High mutation load correlates with an immunogenic tumor microenvironment with increased expression of tumor specific neo-antigens that can be targeted by activated immune cells. Recent evidences have shown that certain tumor types such as NSCLCand melanoma with high tumor mutation rate respond well to immune check point inhibitors. TMB of a certain tumor type is associated with neoantigen load and outcome on immune check point inhibitors. The study focuses on using TMB as a predictive biomarker for response of Immune check point inhibitors. **Method:** The study population comprised of 53 NSCLC patients who had undergone comprehensive genomic profiling (CGP) using commercially available NGS test (Positive Select). **Result:** TMB calculation is done by measuring the number of somatic mutations occurring in the sequenced genes and extrapolating to the genome as a whole. In the present study, hybrid-capture based targeted next generation sequencing was used to estimate TMB as the total number of synonymous and non-synonymous mutations present at ≥5% allele frequency (after filtering) in the sequenced tumor genome. Results are expressed as mutations/megabase. Targeted sequencing of 350-cancer related genes was carried out on ctDNA/FFPE from the patients using the Illumina Next-seq platform. The target region includes >5000 coding exons of canonical transcript isoforms, >100 exons of noncanonical transcripts, as well as 35 introns of 15 recurrently rearranged genes. The bioinformatics analysis of the raw data was done using our trademark TEST pipeline to call out all four categories of genomic variants; SNVs, Indels, CNVs and Structural variants. The mean age of the patient population is 57 ± 11.25 years. The patient population had 34% females and rest were males. Most of the patients were recorded with metastatic disease. The analysis was performed on circulating tumor DNA sample (92% patients) and FFPE blocks (8% patients). Out of the 53 subjects, 4 (7.54%) patients were found to have TMB >10 mutations/megabase and were categorized as eligible candidates for showing a higher likelihood of benefit from immune check point inhibitors. Among the four samples showing high TMB, only one of the sample showed high microsatellite instability with the TMB being 11.12 mutations/megabase.

Important Actionable genomic alterations detected in NSCLC patients having high TMB

Patient Number	Actionable mutations	TMB (mut/megabase) and MSI status	Therapy recommendations
I	*KDR* [p.Q472H]	TMB=21.68 mut/megbase MSI=low	VEGF Inhibitors and immune check point inhibitors
II	*CDKN2B* [loss]	TMB= 33.4 mut/megbase MSI=low	CDK4/6 inhibitors and immune check point inhibitors
III	*MAP2K1* [p.Q56P-Subclonal]	TMB= 11.12 mut/megbase MSI=high	Immune check point inhibitors
IV	*PTEN* [C211*], *NOTCH4* [amplification]	TMB=20.44 mut/megabase MSI=low	mTOR inhibitors and immune check point inhibitors

Conclusion: The prevalence of high TMB was found in 7.5% Indian NSCLC patients. Testing for TMB and MSI in the above cases provided an option for treating the patients with immune check point inhibitors along with targeted therapy.

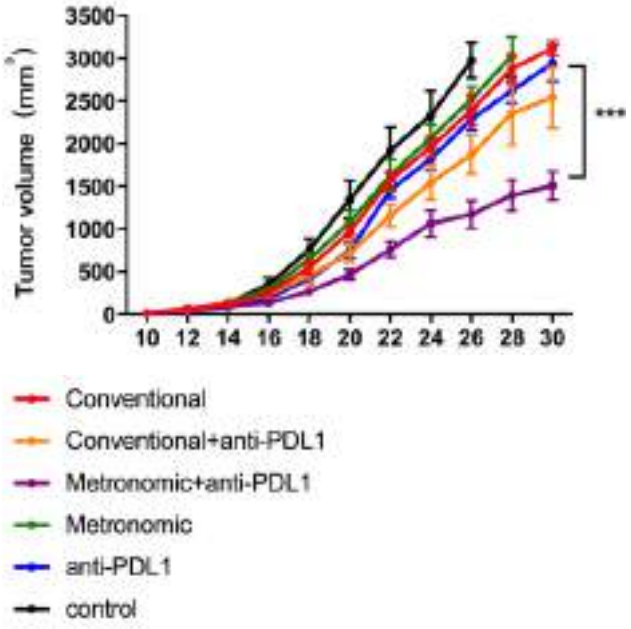
P1.04-57 METRONOMIC DOSING OF CHEMOTHERAPY ALTERS ANTITUMOR IMMUNITY AND SYNERGIZES WITH PD-1/PD-L1 INHIBITION IN NON-SMALL CELL LUNG CANCER

Y. Jia[1], T. Jiang[1], S. Zhao[1], X. Li[2], C. Zhao[1], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, SHANGHAI/China,* [2]*Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/China*

Background: The combination of immune checkpoint blockade with chemotherapy is currently under investigation as a promising strategy for the treatment of non-small cell lung cancer. Although it has been reported that metronomic dosing of cisplatin can be immune stimulating, the impact of its combination with anti-PD-1/PD-L1 immunotherapy for the treatment of lung cancer remains to be evaluated. Therefore, the current study aimed to explore whether combining low-dose continuous chemotherapy and anti-PD-L1 treatment can induce synergistic antitumor effect by enhancing antitumor immune response in murine lung cancer. **Method:** We evaluated the antitumor effects of conventional dose of cisplatin and low-dose metronomic dose of cisplatin as monotherapy or in combination with anti-PD-L1 monoclonal antibody in a murine lung cancer model using Lewis lung cancer cells (LLC). And the changes of immune components in tumor were tested in different treatment groups by flow cytometry and immunohistochemistry. **Result:**



The results showed that low-dose metronomic use of cisplatin could eradicate Foxp3⁺ regulatory T cells (Tregs) and myeloid derived suppressive cells (MDSCs). Furthermore, combining low-dose cisplatin and anti-PD-L1 therapy could not only increase the inflitration of $CD8^+$ T cells ,especially IFN-γ^+CD8^+ T cells, but also significantly reduce the expression of PD-1 and PD-L1. In a syngeneic mouse model of NSCLC, we observed that concurrent use of low-dose cisplatin and anti–PD-L1 delayed tumor growth and enhanced survival. **Conclusion:** Low-dose continuous cisplatin treatment can modify tumor immune microenvironment by eliminating immunosuppressive components like Tregs and MDSCs and enhance antitumor immune response, which can be enhanced by PD-1/PD-L1 blockade and therefore induced a synergistic anti-tumor effect.

P1.04-58 UNCOVERING THE TUMOR MICROENVIRONMENT OF KRAS-DRIVEN LUNG ADENOCARCINOMA: THE LINK BETWEEN TH17 SIGNALING AND B CELL

S. De Summa, D. Petriella, R. Lacalamita, D. Galetta, M. Montrone, A. Catino, P. Pizzutilo, M.A. Botticella, F.A. Zito, M. Zambetti, A. Zonno, R. Pinto, S. Tommasi

IRCCS Istituto Tumori "Giovanni Paolo II", Bari/Italy

Background: Non small cell lung cancer, been histologically classified into adenocarcinoma (AD) and squamous cell carcinoma, is one of the most deadly malignancy worldwide. Lung AD (LUAD) could benefit of a plethora of target therapies and, in the last few years, also of immunotherapies. Here we focused on a cohort of LUAD aiming to gain insights into the immune contexture of such a malignancy. **Method:** 20 patients affected by advanced LUAD, previously analyzed through the CE-IVD Oncomine solid tumor DNA kit, have been included in our cohort. DNA and RNA were isolated from 6 μm thick FFPE sections usingthe QIAamp DNA/RNA FFPE Tissue Kit (Qiagen). Two custom panels were designed using Ion Ampliseq Designer Tool. DNA and RNA libraries were prepared according to manufacturer's instructions. Torrent suite variant caller and Vardict tool were used to call variants, subsequently annotated with Annovar. RNA raw read counts were analyzed by DESeq2 R package. TIMER web-tool was used to deconvolve immune-cytotype composition and LUAD-TCGA dataset has been used to validate our findings. Immune infiltration results were validated with immunohistochemistry in an independent cohort. **Result:** We explored the mutational status of 41 genes and the expression of 94 genes, related to immune-checkpoint, inflammation and stromal microenvironment. Surprisingly, we found that our cohort has a very low mutational burden if we consider our panel as its surrogate. Regarding gene expression data, we identified 31 genes significantly deregulated in tumor tissues compared with a pool of normal pleura samples. Unsupervised hierarchical clustering of the deregulated genes is able to identify two clusters of tumor samples, differently enriched in alterations in actionable. In particular, we identified a cluster enriched in patients carrying KRAS alterations. GO/KEGG enrichment displayed terms related, as expected, to T cell differentiation but more interestingly term linked to Th17 lymphocytes. Thus, we perform in silico deconvolution through TIMER algorithm. Estimation performed on our gene expression matrix showed that, after stratification based both on cluster and KRAS mutational status, B cell infiltration is lower in KRAS-mutated enriched cluster. Notably, also in LUAD-TCGA dataset, B cell infiltration is significantly low in KRAS mutated patients. Such a finding has been validated in situ through immunohistochemistry in an independent cohort. Moreover, cases in LUAD-TCGA with low B cell infiltration have a significantly worse overall survival than those with higher levels. In our cohort we observed that cases belonging to cluster enriched in KRAS-mutated patients have a poor outcome. **Conclusion:** LUAD driven by KRAS mutation represents an unmet clinical need, being refractory to pharmacological inhibition. Our results link KRAS mutations to composition and in particular to B cell infiltration. The role of B cell in tumor microenvironment of lung cancer has been previously explored, demonstrating that low level of infiltration is related to short survival. Interestingly, we found that deregulated genes are enriched in GO/KEGG terms related to Th17, which, through CXCL13 signaling, support B cell recruitment. Thus, the present findings could be helpful in a better definition of immunotherapeutic approaches for KRAS mutated patients.

Keywords: KRAS, LUAD, B-Cell

P1.04-59 MODIFIED GLASGOW PROGNOSTIC SCORE PREDICT SURVIVAL AMONG NON-SMALL CELL LUNG CANCER PATIENTS TREATED WITH IMMUNE CHECKPOINT INHIBITORS

C. Freitas[1], N. Tavares[1], M. Jacob[1], D. Mendonça[2], P. Oliveira[2], D. Araújo[1], H. Novais-Bastos[1], G. Fernandes[1], A. Magalhães[1], H. Queiroga[1], V. Hespanhol[1]

[1]*Centro Hospitalar Universitário de São João, Porto/Portugal,* [2]*Instituto de Ciências Biomédicas Abel Salazar, Porto/Portugal*

Background: Immune checkpoint (ICP) inhibitors improved survival among patients (pts) with metastatic non-small cell lung cancer (mNSCLC). Modified Glasgow Prognostic Score (mGPS) is an inflammation-based score with prognostic value in lung cancer. We investigated predictive value of pre-treatment mGPS among mNSCLC pts treated with ICP inhibitors. **Method:** Data of mNSCLC pts treated with ICP inhibitors at Hospital São João, Porto, Portugal, were retrospectively collected. Pre-treatment mGPS was calculated using pre-treatment albumin and C-reactive protein. Survival was estimated with Kaplan-Meier method and curves were compared by log-rank test. Multivariate analysis was performed using Cox proportional hazard model. **Result:** 77pts were included, 71.4% were male and mean age was 66.2±9.7 years old. Most of pts had previous smoking history (77.9%) and an ECOG 0 or 1 (83.1%). Concerning tumour features, 69.5% were adenocarcinoma and 28.6% squamous cell carcinoma with a mean of PD-L1 expression of 47.6±34.3%. 10.4% had a driver mutation. Nivolumab was used in 71.4% and pembrolizumab in 28.6%. Partial response was achieved in 27.3%, stable disease in 31.2% and 39.0% had disease progression. Overall, progression-free survival (PFS) and overall survival (OS) were 5.0 (95% CI, 2.0-7.9) and 15.0 (95% CI, 8.4-21.6) months (mo), respectively. Adverse effects (AE) occurred in 26.0%. A lower mGPS was associated with superior OS (0: not reached; 1: 7.0 mo; 2: 3.0 mo, p=0.002) and PFS (0: not reached; 1: 4.0 mo; 2: 2.0 mo, p<0.001). In addition, ECOG 0-1was associated with superior OS (16.0 vs 3.0mo, p=0.011) and PFS (6.0 vs 2.0mo, p=0.023), comparing to ECOG 2-3. Better survival was also verified in pts with AE occurrence (OS: p=0.001 and PFS: p<0.001) and in pts with lower number of metastatic sites (OS: p=0.004 and PFS: p<0.001). In a multivariate model, adjusting for ECOG, number of metastatic sites and AE occurrence, lower mGPS was associated to a better survival, regarding OS (p=0.004) and PFS (p=0.002). **Conclusion:** Pre-treatment mGPS influenced OS and PFS and may represent a useful tool to predict survival in pts with mNSCLC treated with ICP inhibitors.

P1.04-60 IMPACT OF METASTATIC LOCATION ON SURVIVAL IN STAGE-IV NON-SMALL CELL LUNG CANCER (NSCLC) TREATED WITH IMMUNOTHERAPY

A.R. Naqash[1], S. Jonnalagadda[1], S. Macherla[1], S. Polsani[1], M. Muzaffar[1], C. Cherry[2], N. Abdel Karim[3], P. Walker[1]

[1]*East Carolina University, greenville/United States of America,* [2]*East Carolina University, Greenville/United States of America,* [3]*Medical College of Georgia/ Augusta University, Augusta/United States of America*

Background: Emerging preclinical data suggests that the heterogeneity in the metastatic site-specific tumor immune microenvironment, as well as organ specific mutational diversity, may impact antitumor response to immune checkpoint inhibition (ICI). However, there is a paucity of clinical data describing the efficacy of ICI across metastatic compartments. Therefore, we sought to elucidate the impact of the metastatic location on survival in ICI treated stage-IV NSCLC. **Method:** We conducted a retrospective review of 140 stage-IV NSCLC patients treated with ICI between 4/2015 to 12/2018 at East Carolina University Cancer Center. Any non-skeletal lesion >0.5 cm on computerized tomography at an extrapulmonary site was considered as metastasis. Bone liesions were identified based on bone scan or positron emission tomography. ICI consisted of nivolumab, pembrolizumab, atezolizumab, Nivolumab+ ipilimumab and concurrent chemo+ ICI. Targeted next-generation sequencing (NGS) using Caris life sciences platform was used to determine tumor molecular profile. PD-L1^{pos} was defined as ≥ 1% staining using 22c3 Dako assay. Tumor mutational burden (TMB) was measured by counting all somatic non-synonymous missense mutations using targeted NGS (592 genes). TMB-high (H) was defined as ≥ 10 mut/Mb. Chi-Square test compared categorical variables. Kaplan Meier method was used for progression-free survival (PFS) and overall survival (OS) analysis. **Result:** Median age at treatment was 64 years. Bone (Bo-44.3%) was the most common metastatic site followed by brain (Br-37.9%) and liver (L-17.1%). Majority of patients had an oligometastatic disease (58.6%) with Br only metastasis present in 30.0% and Bo only metastasis in 26.4%. L only metastasis was rare (4.3%) but more commonly associated with bone involvement (L+Bo) in 17.7%.TMB was assessed in 34.3% and PD-L1 in 46.4%. NGS identified TMB-high to be more prevalent in patients with Br metastasis compared to no-Br disease (84.6 vs 52.1%; p=0.02). Across metastatic sites, Br only metastasis had a greater proportion of TMB-high compared to Bo only (85.0 vs 33.3 %; p=0.01). L+Bo had lower median PFS vs. Br alone (3.2 vs 8.3 months; p<0.01) and a trend towards inferior PFS vs. Bo alone (3.2 vs 4.1 months; p=0.08). L+Bo also had shorter OS compared to Br alone (3.2 vs 10.2, p<0.01) and Bo alone (3.2 vs.8.8; p=0.047). Patients with >1 metastatic site had inferior PFS (9.4 vs 11.8 months ;p=0.04) and inferior OS (3.70 vs 11.0 months; p=0.01). 30.7% of the patients were treated with concurrent chemo+ICI. In the entire cohort, compared to ICI alone, concurrent chemo+ICI had significantly better median PFS (9.2 vs 4.3 months; p<0.01) and OS (Not reached vs 5.2 months; p <0.001). In patients with an oligometastatic disease, chemo+ICI also demonstrated improved OS for both Br only (Not reached vs 6.7 months; p=0.01) and Bo only disease (Not reached vs 4.8 months;p=0.06). **Conclusion:** Our data demonstrate non-uniform responses to ICI based on the site of metastasis and the number of metastatic sites. We observed Br to have a higher proportion of TMB-high with improved survival when treated with concurrent chemo+ICI. Further studies to identify metastatic site-specific biomarkers to optimally guide ICI related treatment decisions are required.

P1.04-61 NEUTROPHIL-LYMPHOCYTE RATIO: A PREDICTIVE BIOMARKER OF IMMUNOTHERAPY IN LUNG CANCER?

M. Mendes, N. China, D. Reis, S. Campainha, M. Dias, A. Barroso

Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia/Portugal

Background: Identifying predictive biomarkers of immunotherapy in advanced non-small cell lung cancer (NSCLC) is essential to select the patients that could benefit more from this revolutionary therapy. Besides PD-L1 expression, neutrophil-lymphocyte ratio (NLR) has been explored as a potential predictor of clinically meaningful outcomes. Aim: Assess if NLR is an independent predictor of response to immunotherapy in advanced NSCLC. **Method:** Retrospective study of patients with locally advanced or metastatic NSCLC treated with immunotherapy in the second or further lines setting in a Multidisciplinary Thoracic Tumor Unit between 2015 and 2018. Pre-treatment NLR was calculated from baseline peripheral blood cell counts. NLR was categorized as a binary variable: "low" (<5) or "high" (≥5). Cox regression models were used for overall survival (OS) and progression-free survival (PFS) analysis. **Result:** From a total of 63 patients, 49 were treated with nivolumab and 14 with pembrolizumab. At the beginning of immunotherapy, baseline patient characteristics were: men: 79.4%; median age (IQR): 62 (56-70) years; ever smokers: 82.5%; ECOG PS 0-1: 82.5%; adenocarcinoma: 63.5%; squamous cell carcinoma: 31.7% and NSCLC-NOS: 4.8%; stage IV: 76.2%; PD-L1 expression <1%: 47.6%. Twenty three patients (36.5%) received immunotherapy in the third or further lines of treatment. Median PFS and OS were 5 months (2-10) and 8 months (4-13), respectively. After adjusting for gender, age, tobacco habits, ECOG PS, histology and PD-L1 expression, "high" NLR was an independent predictive factor of worse PFS (HR 2.22; 95% CI 1.06-4.66; p 0.035) and OS (HR 2.74; 95% CI 1.19-6.30; p 0.017). **Conclusion:** In our cohort, patients with NLR≥5 had a higher risk of disease progression and death compared to those with NLR<5. NLR is an inexpensive and affordable biomarker that could help to predict response to immunotherapy. Further large prospective studies are needed to validate this biomarker and to establish the optimal cut-off level.

Background: Nivolumab (Nivo) has demonstrated with its efficacy against metastatic non-small cell lung cancer (NSCLC). However, it has been also reported that Nivo does not show beneficial effects in approximately 80% of patients. The predictive ability of biomarkers still is yet unclear; thus identifying biomarkers which better predict overall survival (OS) of such patients treated with Nivo is crucial. In this study, we conducted multivariable cox regression analysis including biomarkers and clinical factors measured at the time of initiating treatment with Nivo to assess predictive ability of OS of patients. Results of the multivariable analysis were elucidated with a nomogram which estimates the OS of Nivo in previously treated patients with advanced NSCLC. **Method:** In this study, data for 201 patients treated with nivolumab during 17 December 2015 to 31 July 2016 at three respiratory medical centers in Japan were retrospectively reviewed. We collected clinical data at the time of nivolumab treatment commencement, and we evaluated two programmed cell death ligand 1 (PD-L1) immunohistochemistry (IHC) assay systems (22C3 and 28-8). **Result:** The median age at the time of administration nivolumab was 68 years, 135 patients were male, 157 patients had a smoking history, and 152 patients had a performance status (PS) score of 0–1. 39 patients had EGFR (37) or ALK (2) mutation positive. For 22C3 and 28-8, 36.3% and 36.8% of patients were negative, 17.4% and 14.4% had PD-L1 status of 1-49%, and 11.9% and 14.9% had PD-L1 status of ≥50%, 34.3% and 33.8% had PD-L1 status of missing, respectively. Kendall's rank correlation coefficient between 22C3 and 28-8 was 0.8414. The median OS of all patients was 333 (95% confidence interval (CI): 116-520) days. In the multivariate analysis, PS score ≥2 (hazard ratio (HR): 2.23; 95%CI: 1.36-3.66 p<0.001), high LDH level at baseline (HR: 1.13 95%CI: 1.03-1.24; p=0.008, and progression disease (PD) of pre-treatment response (HR: 3.64 95%CI: 2.29-5.79 p<0.001) were significantly associated with poor OS. There was not significant distance between PD-L1 status and OS of Nivo. Based on these analyses, we created the nomogram to estimate the OS of Nivo in previously treated patients with advanced NSCLC. **Conclusion:** PS score ≥2, high LDH levels at baseline, and PD of pre-treatment response were predictive of poor

OS of Nivo, moreover the nomogram might be useful to estimate the OS of Nivo in previously treated patients with advanced NSCLC. (UMIN-ID: UMIN000025908)

P1.04-63 CORRELATION OF MUTATIONS IN TP53, CDKN2A AND PIK3CA WITH VISTA EXPRESSION IN PLEOMORPHIC LUNG CARCINOMA

A. Januszewski[1,2], Y.Z. Zhang[3,4], C. Brambilla[5], W.-C. Chang[4,6], U. Laggner[5], A. Bowman[4], T. Adefila-Ideozu[5], I. Vivanco[7], W. Cookson[2], M. Moffatt[2], A. Nicholson[2,4], S. Popat[1], A. Bowcock[2,8]

[1]*The Royal Marsden Hospital, London/United Kingdom,* [2]*National Heart and Lung Institute, London/United Kingdom,* [3]*Imperial College London, London/United Kingdom,* [4]*Royal Brompton and Harefield NHS Trust, London/United Kingdom,* [5]*Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom,* [6]*MacKay Memorial Hospital, Taipei/Taiwan,* [7]*Institute of Cancer Research, London/United Kingdom,* [8]*Mount Sinai, New York/United States of America*

Background: Pleomorphic Lung Carcinoma (PC) is a rare subtype of NSCLC poorly responsive to systemic therapy. VISTA is an immune checkpoint that negatively regulates T-cells and offers an alternative therapeutic approach to immune checkpoint manipulation. It has increased expression in the tumour microenvironment. We aimed to identify the genomic associations of PC with VISTA immunohistochemistry (IHC) expression and establish its correlation with PD-L1 IHC expression. **Method:** Histopathological assessment and diagnosis was confirmed for 42 cases of resected PCs from the Royal Brompton Hospital histopathology diagnostic archive. DNA was isolated and a targeted capture panel for next generation sequencing performed. Samples were stained with H&E to confirm diagnosis, VISTA (D1L2G) and PD-L1 (28-8) and scored as the proportion of positively stained cells. Normal lung acted as control. **Result:** VISTA was increased in tumour infiltrating immune cells compared to background lung and tumour (median: 33% (0-85) vs. 0% (0-15); vs. 0% (0-11); P<0.001). VISTA was upregulated on infiltrating immune cells of cases with variants in *TP53* (n=25, median 52.5% vs. 24% P=0.008) and *CDKN2A* (n=4, median 57.5% vs. 30%; P=0.068) but was reduced in cases with *PIK3CA* mutations (n=4; median 7% vs. 35%; P=0.029). There was no association of VISTA with PD-L1 expression (spearman rank: -0.19; P=0.22). Figure 1: Percent of VISTA staining of immune cells according to tumour mutation

		VISTA IHC		
	N =	Median	Range	
TP53 mutant	25	42.5	5 - 85	P = 0.008
TP53 wild-type	17	24	5 - 64	
CDK2NA mutant	4	57.5	37.5 - 69	P = 0.068
CDK2NA wild-type	38	30	5 - 85	
PIK3CA mutant	4	7	5 - 42.5	P = 0.029
PIK3CA wild-type	38	35	6 - 85	

Conclusion: VISTA is raised in infiltrating immune cells of tumours with *TP53* and *CDKN2A* mutations. This may suggest dampening of the immune reaction to tumours defective in cell cycle control. Conversely, tumours with PIK3CA mutations had reduced VISTA expression by infiltrating immune cells. VISTA and PD-L1 exhibited no association in their levels of expression and therefore offers a therapeutic opportunity.

Keywords: VISTA, PD-L1, Pleomorphic lung carcinoma

P1.04-64 THE OPPOSITE ROLE OF PD-L1 EXPRESSION IN EGFR MUTANT LUNG CANCER TREATED WITH PD-1 INHIBITOR BEFORE AND AFTER EGFR TKI: PILOT STUDY

H.S. Park, S.S. Cho, H.J. An, J. Yoo, B.Y. Shim, S.K. Kim, D.G. Cho, S.W. Kim, J.M. Ko, Y.H. Park, C.H. Kim

St. Vincent Hospital, Suwon/Korea, Republic of

Background: Standard treatment of EGFR mutant lung cancer is EGFR tyrosine kinase inhibitor (TKI). But PD-1 inhibitor in EGFR mutant lung cancer is also effective treatment option. PD-L1 expression is suggested as predictive biomarker for drug efficacy, but in EGFR mutant lung cancer, PD-L1 expression change after TKI have not been established and their role in PD-1 inhibitor treatment was not studied well. **Method:** This study evaluated 18 EGFR mutant lung cancer patients treated with PD-1 inhibitor at St. Vincent hospital from April 2016 to January 2019. Following baseline data were recorded at the time of PD-1 inhibitor treatment: Age, Sex, ECOG performance status, PD-1 inhibitor type, line of treatment, lymphopenia, NLR (neutrophil-lymphocyte ratio), hyponatremia, presence of brain, liver and bone metastasis, EGFR status, PD-L1 expression. Progression free survival (PFS) and overall survival (OS) was evaluated and Cox survival analysis was used for these analyses. **Result:** Median age was 61 years old and female was predominant (66.7%). Nivolumab and pembrolizumab was treated in 11 (61.1%) and 7 (38.9%) patients, respectively. Lymphopenia (<1,000/microleter) was 8 (44.4%) and high NLR (≥ 3) was 9 (50.0%). Hyponatremia (135 mEq/L) was noted in 5 (27.8%) and metastasis of brain, liver and bone were 9 (50%), 5 (27.8%) and 8 (44.4%). Median PFS and OS were 42 days and 102 days, respectively. Although high PD-L1 expression (SP263 ≥10%) before EGFR TKI is not significant predictive factor (Hazard ratio (HR): 0.47, 95% confidence interval (CI): 0.09-2.45, P-value: 0.368) for PFS, high expression of PD-L1 before EGFR TKI tend to have favorable outcome. But, high PD-L1 expression (SP263 ≥10%) after EGFR TKI is associated with poor PFS outcome (HR: 2.20, 95% CI: 0.42-11.53). Regarding OS, high PD-L1 expression (SP263 ≥10%) before EGFR TKI is associated with prolonged survival (HR: 0.47, 95% CI, 0.09-2.41, P-value: 0.362), although it is not statistically significant. But, high PD-L1 expression after EGFR TKI tend to have shorter survival (HR: 3.34, 95% CI: 0.64-17.51, P-value: 0.154). **Conclusion:** The role of PD-L1 expression between before EGFR TKI and after EGFR TKI is opposite. This study is small study as a pilot setting and further studies are needed to evaluate these findings.

P1.04-65 MICROENVIRONMENT-DERIVED ADAM28 IMPACTS THE ONSET OF LUNG CANCER

C. Hubeau[1], C. Gerard[1], O. Carnet[1], M. Moser[2], R. Fässler[2], A. Noël[1], N. Rocks[1], D. Cataldo[1]

[1]*University of Liège (Uliege), Liège/Belgium,* [2]*Max-Planck-Institute of Biochemistry, Martinsried/Germany*

Background: ADAM28 expression is upregulated in non-small cell lung carcinoma and correlated with cell proliferation and metastatic dissemination. Moreover, *in vivo* studies have shown that knockdown of ADAM28 in tumor cells decreased the primary tumor growth and formation of lung metastasis. Besides, ADAM28 is thought to be an important regulator of inflammatory signaling pathways as it sheds the pro-inflammatory cytokine, *pro-TNF-alpha*. ADAM28 protease also interacts with integrins and the P-selectin glycoprotein ligand-1 leading to inflammatory cell migration. Altogether, these findings suggest that ADAM28 contributes to cellular mechanisms leading to cancer development and progression. **Method:** This study aims to characterize the effects of microenvironment-derived ADAM28 on lung metastasis formation. To achieve this purpose, we generated *ADAM28*$^{-/-}$ mice into two different mouse strains (C57BL/6 and BALB/c). Lung metastatic dissemination was assessed in both *ADAM28*$^{-/-}$ and wild-type (WT) mice after intravenous injection of Lewis Lung Carcinoma cells, B16K1 melanoma cells or 4T1 breast carcinoma cells. As ADAM28 promotes leukocyte transendothelial migration, lymphocyte subtypes implicated in tumor cytotoxicity or in regulation of immune response were studied by flow cytometry. **Result:** An unexpected increased tumor burden was found in lungs of *ADAM28*$^{-/-}$ mice as compared to WT mice. Flow cytometry analysis revealed that less CD8$^+$ T were infiltrated within lungs of *ADAM28*$^{-/-}$ tumor-bearing mice. Moreover, a reduced CD8$^+$ T cell population was observed in the spleen of naïve *ADAM28*$^{-/-}$ mice that is not caused by an impaired T cell maturation in the thymus. *Ex vivo* assays demonstrated that intrinsic properties of CD8$^+$ T cells from *ADAM28*$^{-/-}$ mice were not affected by ADAM28 deficiency as their proliferation, migration and activation was similar. Besides, we found no expression of ADAM28 in isolated CD8$^+$ T cells from the spleen of *ADAM28*$^{-/-}$ and WT mice. Therefore, we hypothesized that ADAM28 indirectly modulates the anti-tumor cytotoxic immune response. We also found that ADAM28 depletion is associated with a reduced infiltration of NK cell within lungs of *ADAM28*$^{-/-}$ tumor-bearing mice. **Conclusion:** Our results demonstrate a protective effect of microenvironment-derived ADAM28 by regulating the tumor-associated immune response.

P1.04-66 THE PERCENTAGE OF PD-L1 BESIDES 50% POSITIVITY PREDICTS OBJECTIVE RESPONSE TO PEMBROLIZUMAB IN NON-SMALL CELL LUNG CANCER

A. Poma[1], G. Pasquini[2], R. Bruno[3], G. Alì[3], A. Proietti[3], I. Pecora[2], L. Petrini[2], E. Vasile[2], A. Chella[2], G. Fontanini[1]

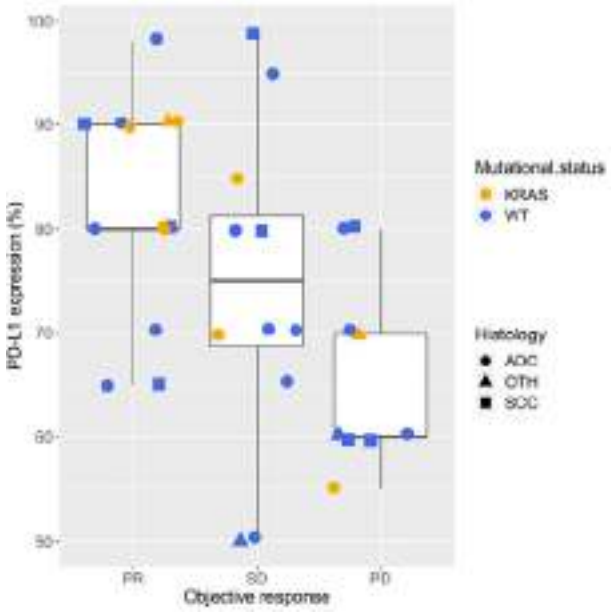
Background: Pembrolizumab is the first-line standard of care for advanced Non-Small Cell Lung Cancer (NSCLC) that have a PD-L1 expression level greater than 50%. In this prospective monocentric study, we evaluated how the expression levels of PD-L1 above 50% impact on the objective response rate. **Method:** Thirty-four advanced NSCLC patients with a PD-L1 expression level greater than 50% treated with Pembrolizumab in first-line setting between 2017 and 2019 were enrolled in this study. Patient and tumor characteristics were correlated with treatment outcomes. Patients clinical evaluation has been performed every 3 months from the beginning of treatment. Responses were defined according to the Response Evaluation Criteria in the Solid Tumors guidelines, version 1.1. Tumor assessments were performed locally. The mutational status of *KRAS, BRAF, NRAS, PIK3CA, ALK, ERBB2, DDR2, MAP2K1, EGFR* and *RET* was determined using a Mass Spectrometry assay. PD-L1 expression levels among the objective response groups were compared by Kruskal-Wallis test. A logistic regression model was used to evaluate the impact of PD-L1 expression levels above 50% on the objective response using mutational status, age, smoking habits, presence of toxicities, performance score and histology as confounders. **Result:** Thirteen patients had partial response (PR), 12 stable disease (SD) and nine progression disease (PD). Nine out of 34 tumours harboured *KRAS* mutations; no alterations were found in the other tested genes. PD-L1 expression levels were different among the objective response groups (P=0.01) with the PR and PD groups having the highest (median 80%, IQ range 80-90%) and the lowest (median 60%, IQ range 60-70%) expression respectively (Figure 1). In the multivariate analysis, PD-L1 level was the only significant predictor of objective response (P=0.03) with an odds ratio of 0.91 (95%CI 0.81-0.98).



Conclusion: In our series, PD-L1 expression above 50% confirmed to be an imperfect biomarker; however, the higher is the expression level the better is the objective response. For this reason, it could be relevant to provide clinicians with the exact PD-L1 percentage. Further investigations are warranted to define the best cut-off to select patients for monotherapy or combination with chemotherapy.

P1.04-67 FIRST-LINE IMMUNE CHECKPOINT INHIBITORS IN ADVANCED NON-SMALL-CELL LUNG CANCER (NSCLC) – A NETWORK META-ANALYSIS BY PD-L1

P. San Tan[1], P. Nazareth Aguiar Junior[2,3], M. Husnain[4], B. Haaland[5], G. Lopes[4]

[1]*Karolinska Institutet, Stockholm/Sweden,* [2]*Faculdade de Medicina do ABC, Santo André/Brazil,* [3]*Américas Centro de Oncologia Integrado, São Paulo/Brazil,* [4]*University of Miami, Miami/United States of America,* [5]*University of Utah, Salt Lake City/United States of America*

Background: Emerging trials suggested survival benefits of first-line immune checkpoint inhibitors (ICIs) alone or in combination with chemotherapy in advanced NSCLC. However, little is known about the head-to-head comparisons of different ICIs and their relative effects at different PD-L1 expression levels. Here, we compared overall survival (OS) with ICIs head-to-head in a network meta-analysis and computed rankings of ICIs by PD-L1 expression levels. **Method:** PubMed and conference abstracts were searched for randomized clinical trials evaluating first-line ICI alone or in combination with chemotherapy in advanced NSCLC. We excluded studies assessing other trigger biomarkers (e.g. TMB). Bayesian network meta-estimates were computed by pooling reported OS hazard ratios (HRs) on the logarithmic scale and incorporation of both within and between studies heterogeneity. Treatment rankings by PD-L1 expression levels were compared in terms of surface under the cumulative ranking curve (SUCRA), probability best, probability better than chemotherapy, and posterior HR with corresponding 95% credible interval (CrI). **Result:** Seven trials were included in network meta-analysis. Pembrolizumab+chemotherapy was ranked to have the best OS benefit with HR ≤0.60 and >99% probability to outperform standard chemotherapy across all PD-L1 expression categories. Atezolizumab+chemotherapy and pembrolizumab monotherapy showed >95% probability to outperform standard chemotherapy in PD-L1≥50%. Nivolumab monotherapy showed little to no benefit across PD-L1 categories. Head-to-head comparisons of pembrolizumab+chemotherapy versus pembrolizumab monotherapy were HR 0.76 (0.48-1.19) for PD-L1≥50%. Detailed meta-estimates by PD-L1 expression for ICI alone or in combination with chemotherapy versus standard chemotherapy are provided in table below.

Treatment	PD-L1 expression	OS HR (95% CrI)	Probability better than standard chemotherapy
Pembrolizumab+chemotherapy	≥50%	0.51 (0.34-0.75)	> 99%
	1-49%	0.56 (0.39-0.81)	> 99%
	≥1%	0.55 (0.41-0.73)	> 99%
	<1%	0.60 (0.42-0.85)	> 99%
Atezolizumab+chemotherapy (include immune-cell cut-offs)	≥50%	0.70 (0.47-1.05)	96%
	1-49%	1.03 (0.74-1.42)	43%
	<1%	0.83 (0.66-1.06)	93%
Pembrolizumab	≥50%	0.67 (0.53-0.83)	> 99%
	1-49%	0.92 (0.69-1.23)	73%
	≥1%	0.81 (0.63-1.04)	95%
Nivolumab	≥50%	0.90 (0.60-1.36)	70%
	≥1%	1.08 (0.80-1.46)	30%

Conclusion: Pembrolizumab+chemotherapy demonstrated best survival benefit compared to other ICIs across all PD-L1 expression levels in the first-line treatment of advanced NSCLC.

Keywords: Pembrolizumab, Atezolizumab, cost-effectiveness

P1.04-68 LIVER METASTASES PREDICTS POORER PROGNOSIS IN ADVANCED NSCLC PATIENTS WHO RECEIVING NIVOLUMAB MONOTHERAPY

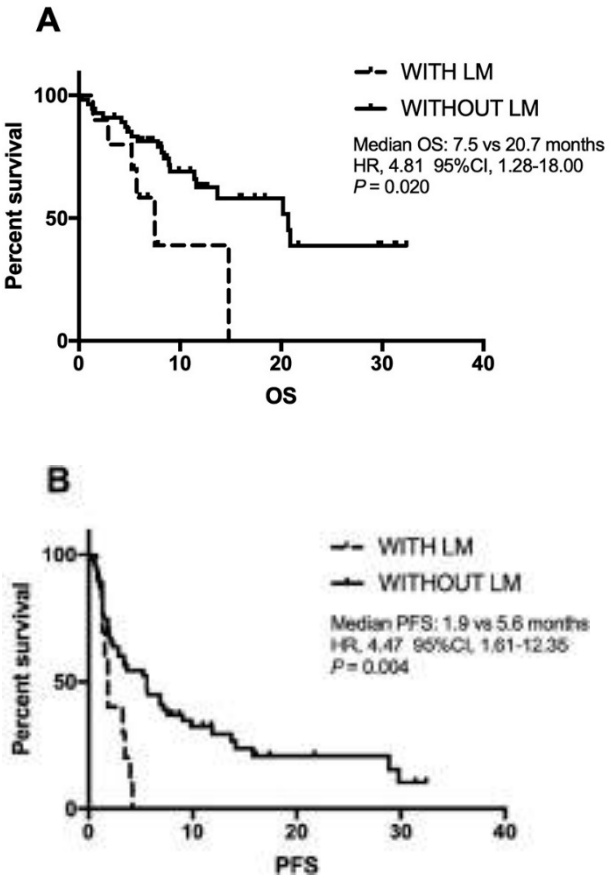
G. Zhang[1], R. Cheng[2], H. Wang[1], Z. Ma[1]

[1]*The Affiliated Cancer Hospital of Zhengzhou University, Zhengzhou/China,*
[2]*The First Affiliated Hospital of Zhengzhou University, Zhengzhou/China*

Background: Nivolumab is a fully human IgG4 monoclonal antibody targeting the programmed death-1 (PD-1). It's a standard second-line treatment for advanced NSCLC. Liver metastases(LM) is one of the worst prognostic NSCLC metastatic sites, but the attention to LM is far lower than brain metastases and bone metastases. **Method:** Patients with stage IIIB-IV NSCLC treated with second-line or later nivolumab monotherapy were retrospectively collected from January 2016 to July 2018. The patients were divided into two cohorts based on the presence or absence of LM at the time of first dose. Study endpoints included OS and PFS. **Result:** 65 patients were included, including 10 patients with and 55 patients without LM. Baseline characteristics of the two cohorts were comparable, as shown in the below table.

Characteristic	*All*	*LM (n=10)*	*Without LM (n=55)*	*P-Value*
Sex(Female/Male)	16/49	2/8	14/41	0.999
Mean age (years)	59.0±10.2	60.1±8.0	58.8±10.5	0.713
ECOG PS				0.999
0-1	59	9	50	
⩾2	6	1	5	
Histologic subtype				0.203
Squamous carcinoma	26	2	24	
Adenocarcinoma	36	7	29	
Others	3	1	2	
Stage				0.999
IV	62	10	52	
IIIB/IIIC	3	0	3	
Lines of therapy				0.673
2nd Line	53	9	44	
⩾3rd Line	12	1	11	
Driver gene status				0.580
EGFR mutations	4	0	4	
KRAS mutations	4	1	3	
Other mutations	5	0	5	
Driver gene negative	27	6	21	
Unknown	25	3	22	
Other metastatic sites				0.958
Central nervous system	24	4	20	
Bone	20	2	18	
Adrenal gland	6	0	6	
Intrathoracic	47	6	41	
Other/unspecified	9	1	8	

The median OS of the patients with and without LM was 7.5 and 20.7 months, respectively(HR =4.81:95%CI, 1.28-18.00:p=0.020). Their median PFS was 1.9 and 5.6 months, respectively(HR =4.47:95%CI, 1.61-12.35:p=0.004). COX multivariate regression analysis suggested LM was an independent prognostic factor. Kaplan-Meier curves of OS and PFS were shown in the below figure.



Conclusion: The outcome of advanced NSCLC patients with LM treated with Nivolumab monotherapy is relatively poor compared with those without LM.

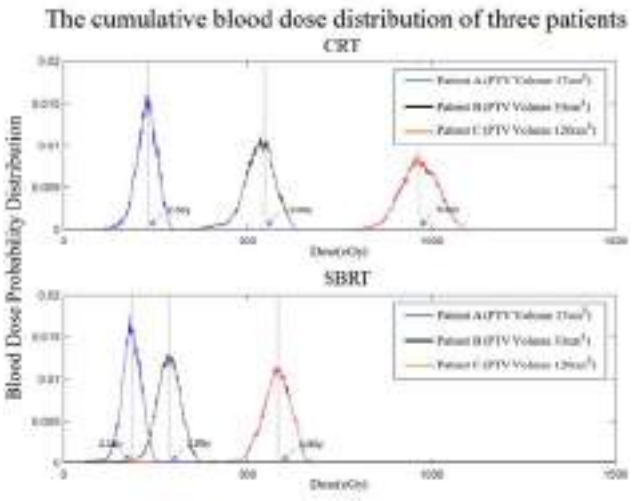
P1.04-69 MODELLING THE IMMUNOSUPPRESSIVE DIFFERENCE OF SBRT AND CRT BY SIMULATING THE DOSE TO CIRCULATING LYMPHOCYTES IN NON-SMALL CELL LUNG CANCER

Y. Shen, Y. Meng, X. Tang, P. Gu, C. Yu, W. Wang, F.-M. Kong, H. Yang

Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China

Background: Radiation-dose delivered to circulating lymphocyte (CL) has detrimental effect on immune system for cancer patients. Our study established a model to compare the cumulative dose on CL of patients with conventional fractionation radiotherapy (CRT) and stereotactic body radiation therapy (SBRT) in lung cancer with different target volume. **Method:** The improved model is based on convolution algorithm suggested by Yovino(Cancer Investigation, 2013). The current blood DVHs of each organ were multiplied with treatment field DVH to generate original DVHs. During one second, 0.6% of whole-body blood circulates through each organ and rest body according to blood circulating pattern and then new DVHs of organ were generated. The new DVHs would be used for next second's calculation with treatment field DVH. Conventional fractionated non-small cell lung cancer plan 60Gy (30 fractions*2.0Gy) and SBRT plan 50Gy (5fractions*10Gy) are constructed for three patients with different target volumes. The primary endpoint is peak cumulative blood dose (PCBC). **Result:** PCBC of three patients with CRT and SBRT were calculated as Figure 1. PCBC with CRT to circulating lymphocyte (CL) were 2.5Gy, 5.6Gy, 9.5Gy in PTV-volume 17cm^3, 33cm^3, 120cm^3, respectively. And PCBC with SBRT to circulating lymphocyte (CL) were 2.1Gy, 2.9Gy, 6.0Gy in PTV-volume 17cm^3, 33cm^3, 120cm^3, respectively. PCBC gap of SBRT to circulating lymphocyte (CL) was decreased 0.4Gy, 2.7Gy, 3.5Gy in PTV-volume 17cm^3, 33cm^3, 120cm^3, respectively.



Conclusion: An improved simulation-model was established, SBRT, compared to CRT, will lead to decreased cumulative dose on CL, which may cause less impact on immune system with the enlargement of PTV-volume.

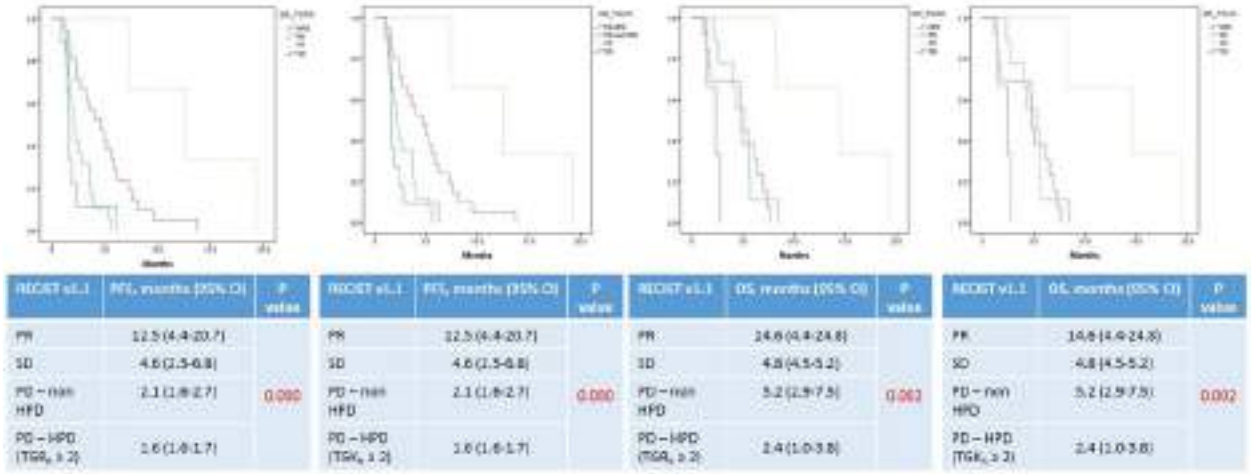
[2]*Chonnam National Univeristy Hwasun Hospital, Jeonnam/Korea, Republic of*

Background: Immune checkpoint inhibitors (ICIs) have suggested substantial options for treatment in advanced non-small cell lung cancer (NSCLC) without driver oncogenes. However, existing criteria for response assessment have limitations in differentiating categories of disease progression upon ICI treatment: primary resistance, pseudoprogression or hyperprogression (HPD). This study was aimed to investigate a real-world feasibility of pre- and on-treatment tumor kinetics for ICIs-specific response assessment in NSCLC. **Method:** We retrospectively recruited stage III/IV NSCLC patients treated with anti-PD-1/PD-L1 monotherapy after failure of first-line platinum-doublet chemotherapy (n=91) between June 2016 and October 2018. Based on medical records from response-evaluable patients, we analyzed tumor kinetics prior and upon ICI treatment using ratio of tumor growth rate (TGR ratio, TGR_R), tumor growth kinetics (TGK ratio, TGK_R) and difference in TGR (delta TGR, ΔTGR), respectively. HPD was defined as $TGR_R \geq 2$, $TGK_R \geq 2$ and ΔTGR >50%. **Result:** After excluding 18 patients without CT scan after start of ICIs, 73 patients were enrolled. Of response-evaluable patients, 47 patients (64%) stopped ICI treatment due to disease progression or death. Overall response rate by RECIST v1.1 was 16.4% (12/73) and disease control rate was 62% (45/73). HPD patients was 12% (9/73) and 15% (11/73) when defined by TGR_R and TGK_R, respectively. There was no HPD patients defined by ΔTGR. HPD patients classified by each criterion were associated with shorter median progression-free survival (PFS) according to iRECIST ($TGR_R \geq 2$, 1.6 vs 2.1 months, p<0.001; $TGK_R \geq 2$, 1.6 vs 2.1 months, p<0.001) and median overall survival (OS) than non-HPD-PD patients ($TGR_R \geq 2$, 2.4 vs 5.2 months, p=0.002; $TGK_R \geq 2$, 2.4 vs 5.2 months, p=0.002). HPD was not associated with age, sex, histology, stage, brain metastasis, nor PD-L1 expression at baseline. There was no pseudoprogression in patients classified as HPD.



RECIST v1.1	PFS, months (95% CI)	P value
PR	12.5 (4.4-20.7)	
SD	4.6 (2.5-6.8)	
PD – non HPD	2.1 (1.8-2.7)	0.000
PD – HPD ($TGR_R \geq 2$)	1.6 (1.0-1.7)	

RECIST v1.1	PFS, months (95% CI)	P value
PR	12.5 (4.4-20.7)	
SD	4.6 (2.5-6.8)	
PD – non HPD	2.1 (1.8-2.7)	0.000
PD – HPD ($TGK_R \geq 2$)	1.6 (1.0-1.7)	

RECIST v1.1	OS, months (95% CI)	P value
PR	24.6 (4.4-24.8)	
SD	4.8 (4.5-5.2)	
PD – non HPD	5.2 (2.9-7.5)	0.002
PD – HPD ($TGR_R \geq 2$)	2.4 (1.0-3.8)	

RECIST v1.1	OS, months (95% CI)	P value
PR	24.6 (4.4-24.8)	
SD	4.8 (4.5-5.2)	
PD – non HPD	5.2 (2.9-7.5)	0.002
PD – HPD ($TGK_R \geq 2$)	2.4 (1.0-3.8)	

Conclusion: HPD defined by pre- and on-treatment tumor kinetics was observed in 12-15% of patients with advanced NSCLC treated with second-line ICI monotherapy, and correlated with shorter PFS and OS. TGR and TGK could classify HPD patients from non-HPD PD with similar discriminability. Further studies are needed to investigate clinical and molecular determinants that distinguish HPD from non-HPD PD and pseuoprogression.

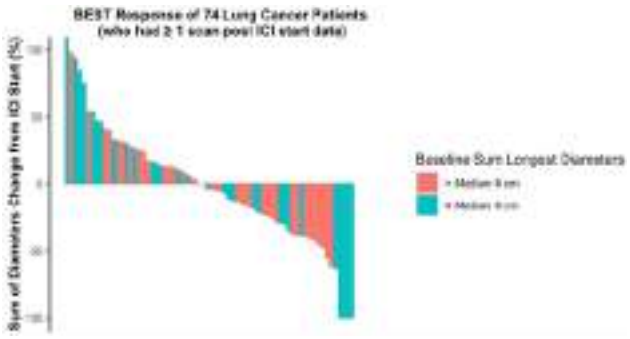
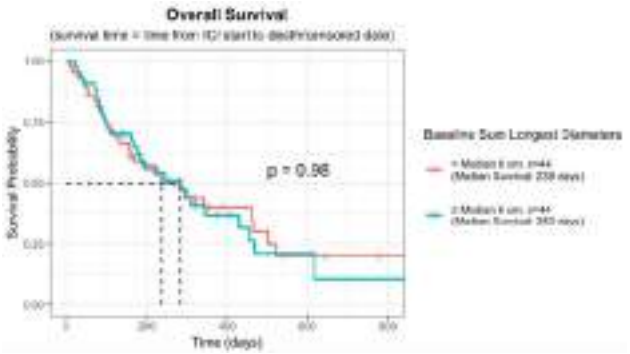
P1.04-71 TUMOR BURDEN IS NOT ASSOCIATED WITH EFFICACY OF IMMUNE CHECKPOINT INHIBITORS IN ADVANCED LUNG CANCER

D. Gerber, V. Popat, R. Lu, J. Saltarski, Y. Gloria-Mccutchen, F. Fattah, J. Park, Y. Xie

UT Southwestern Medical Center, Dallas/United States of America

Background: Tumor bulk has long been cited as an impediment to efficacy of certain immunotherapeutic agents, such as vaccines. However, the association between tumor burden and efficacy of immune checkpoint inhibitors (ICI) is unknown. **Method:** We prospectively enrolled patients with diverse cancer types treated with immune checkpoint inhibitors on a registry trial. Demographic, disease, and treatment data were collected on patients with advanced non-small lung cancer (NSCLC). Imaging studies (predominantly computed tomography) were reviewed, and tumor dimensions were recorded according to Response Evaluation Criteria in Solid Tumors (RECIST) 1.1. Associations between tumor number and dimensions, and radiographic response, progression-free survival (PFS), and overall survival (OS) were determined using log-rank tests, cox proportional-hazard regression, and logistic regression. **Result:** Eighty-nine patients treated with ICI (without concurrent or sequential chemotherapy or radiation therapy) were included in the analysis. Median baseline sum of largest diameters (BSLD) was 6 cm; median baseline largest single diameter was 3 cm; median number for both target and non-target lesions was 2. There was no significant difference between cases with BSLD ≤6 cm and >6 cm for response rate (OR=1.06; *P*=0.94) (Figure 1), PFS (HR 0.99; 95% CI, 0.60-1.64; *P*=0.97), or OS (HR 0.99; 95% CI, 0.59-1.68; *P*=0.98) (Figure 2). No significant differences were observed for these endpoints when cases were considered according to largest single diameter, number of target lesions, or number of non-target lesions.





Conclusion: Although tumor burden was considered a potential mediator of efficacy of vaccines and other early immunotherapies, it does not appear to impact outcomes from ICI.

Background: There is an unmet need for biomarkers that will identify patients more likely to respond to immune checkpoint inhibitors (ICIs) in non-small cell lung cancer (NSCLC). We aimed 1) to investigate the impact of tumor mutational burden (TMB) on outcomes of NSCLC patients treated with ICIs, 2) to determine the relationship between TMB, PD-L1 expression, and tumor-infiltrating lymphocytes (TILs), and 3) to present an algorithm that can best predict ICI therapy response through a combination of biomarkers. **Method:** We performed targeted deep sequencing on 22 primary and 8 paired metastatic NSCLC from 15 patients treated with ICIs (two primary samples from 7 patients). **Result:** The median TMB across all samples was 9.46 mutations/Mb (IQR 1.762–22.03). Applying the cutoff of TMB to 8 mutations/Mb, which best predicts ICI response using receiver operating characteristic curves, 46.7% and 53.3% were high and low TMB group, respectively. There was no correlation between TMB, PD-L1 expression, and TILs. The response rate (RR) to ICIs for patients with high versus low TMB was 3/7 (42.8%) versus 1/8 (12.5%; p>0.05) (Figure 1). The median TMB for responders (n=4) versus nonresponders (n=11) treated with ICIs was 11.2 versus 8.8 mutations/mb. When patients were classified into four groups according to TMB (Figure 2), PD-L1 positivity, and TIL, 50% (2/4) of the patients with $TMB^{hi}PD\text{-}L1^{pos}TIL^{hi}$ showed clinical benefit to ICI. One of the two patients who did not respond to ICI despite $TMB^{hi}PD\text{-}L1^{pos}TIL^{hi}$ group was sarcomatoid carcinoma and one was KRAS-mutant adenocarcinoma. In patients with $TMB^{hi}PD\text{-}L1^{neg}TIL^{low}$ and $TMB^{low}PD\text{-}L1^{pos}TIL^{hi}$, the RR was 40% (2/5). All of $TMB^{low}PD\text{-}L1^{neg}TIL^{low}$ group were non-responder (0/6)

Conclusion: TMB can be a potential predictive biomarker of response to ICI treatment in NSCLC patients. An algorithmic approach, which takes into account the integration of TMB, PD-L1 expression, and TIL, may be more effective in screening ICI response groups.

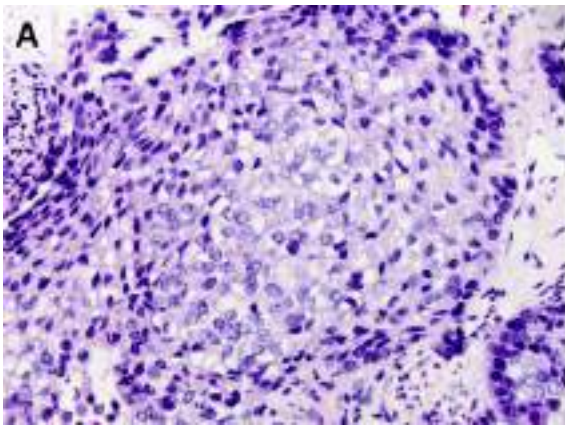
P1.04-73 SMALL CELL TRANSFORMATION OF NON-SMALL CELL LUNG CANCER (NSCLC) ON IMMUNE CHECKPOINT INHIBITORS: CASE REPORT AND LITERATURE REVIEW

K. Sehgal, A. Varkaris, P. Vanderlaan, D. Rangachari, D. Costa

Beth Israel Deaconess Medical Center, Boston/United States of America

Background: Histological transformation of oncogene-driven lung adenocarcinoma to small cell lung cancer (SCLC) following treatment with tyrosine kinase inhibitors (TKI) is a well-described phenomenon. However, it is unknown whether a similar transformation may drive acquired resistance to immune checkpoint inhibitors (ICPi) in NSCLC by altering tumor-related immune evasion. **Method:** We present a case of a patient with NSCLC treated at our institution with transformation to SCLC during second line therapy with nivolumab. We conducted a review of the literature to identify similar cases and patient outcomes. **Result:** This is a case of a 69 year-old woman with a 35 pack-year tobacco history presenting with stage IV squamous cell lung cancer (figure 1A). Her disease progressed within 4 weeks of first line carboplatin/gemcitabine and she was transitioned to next line nivolumab with sustained partial response lasting 18 months. She then developed rapid, bulky progression of mediastinal disease. Biopsy showed transformation to SCLC (figure 1B). Comparison of genomic profiling results from the initial NSCLC diagnosis and SCLC transformation revealed similar tumor profiles (*TP53 R283fs*62*). Absence of *RB1* loss and initial protracted response to nivolumab suggested that transformation likely occurred as a result of treatment-induced selection pressure. The patient had a near complete response following 4 cycles of carboplatin/etoposide and remained alive 7 months post-transformation. Review of the literature revealed 7 reported cases where SCLC transformation was thought to result from acquired resistance to ICPi (Table 1). **Conclusion:** We add to the emerging evidence of transformed SCLC as an acquired resistance mechanism following ICPi treatment in advanced NSCLC. Although only a few reports are available at this time, the real-world frequency may well be under-estimated due to relative infrequency of post-progression biopsies in NSCLC patients not being treated with TKIs. The underlying genomic/epigenetic mechanisms that may explain acquired resistance with neuro-endocrine transformation remain to be elucidated.



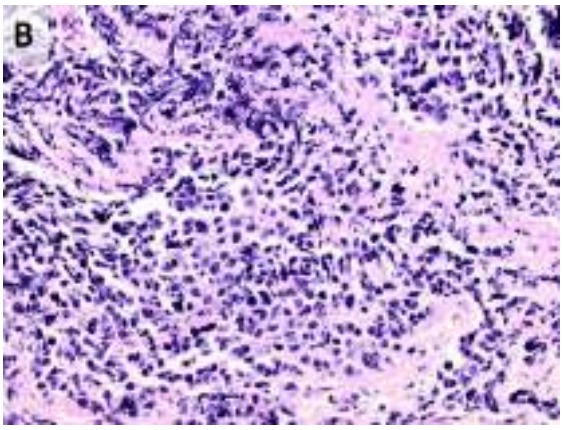


Table 1. Summary of literature on NSCLC cases transformed to SCLC on ICPi

Serial No. (Reference)	Original histology	Original genomic profile	ICPi details	Genomic profile of transformed SCLC	Outcome post SCLC transformation
1 (Index case)	Squamous cell carcinoma	*TP53* mutation	Nivolumab (2nd line, 47 cycles)	*TP53* R283fs*62 mutation	Alive 7 months post SCLC
2 (Iams *et al,* JTO 2018)	Adeno-carcinoma	*KRAS* G12C mutation	Nivolumab (2nd line, 33 cycles)	*KRAS* G12C mutation, *TP53* R273C mutation	Died 16 months post SCLC
3 (Iams *et al*, JTO 2018)	Adeno-carcinoma	*KRAS* G12C mutation	Nivolumab (2nd line, 36 cycles)	*TP53* S315S mutation, *RB1* splice site mutation	Died 11 months post SCLC
4 (Imakita *et al*, Respir Med Case Rep. 2017)	Poorly differentiated carcinoma	Neg for *EGFR / Alk*	Nivolumab (2nd line, 3 cycles)	Not described	Died 2 months post SCLC
5 (Abdallah *et al*, Lung Cancer [Auckl]. 2018)	Adeno-carcinoma	Neg for *EGFR / Alk*	Nivolumab (2nd line, 5 cycles)	Not described	Response after 2 chemotherapy cycles

P1.04-74 CHARACTERISTICS OF T CELL RECEPTOR REPERTOIRE OF LUNG CANCER PATIENTS

N. Liang[1], D. Gu[2], R. Chen[2], X. Xia[2]

[1]*Peking Union Medical College, Beijing/China,* [2]*Geneplus-Beijing Institute, Beijing/China*

Background: As the importance of T cell receptor (TCR) repertoire gains appreciation, particularly given their potential utility for cancer immunotherapeutic prognostication, the characteristics of TCR repertoire are needed. We detected the complementarity determining region 3 (CDR3) by TCR sequence to describe diversity and changes in human's immune system with age and difference clinical stage . **Method:** The TCRβ repertoire of 19 stage IV lung cancer patients and 77 stage I/II/III lung cancers patients was analyzed. Genomic DNA was extracted from peripheral blood and used to amplified and sequenced the CDR3 region of rearranged TCRβ genes. Finally, we got the relative frequencies of patients T cell clones. Shannon index was calculated on the clonal abundance of all productive TCR sequences. The normalized Shannon index was determined by dividing Shannon index by the natural logarithm of the number of unique productive TCR sequences. **Result:** Diversity of the TCR repertoire can be measured using the Shannon index. Analysis had been made to test the diversity relationship among a cluster of clinical features, such as stages, age and gender. Diversity were significantli decreasing with clinical stages(p=0.0482). Comparison of the diversity between stage IV and stage I/II/III patients, we found stage IV lung cancer has more lower diversity(p=0.0048). In these patients, diversity had showed a significantli correlation with age(r=-0.3036, p=0.0026). Diversity was significantly lower in patients 55 years of age or older compared to younger patients (p=0.0083). **Conclusion:** These results suggest that patients with advanced cancer exhibit limited TCR repertoire diversity and that this diversity is further limited in patients with advanced clinical stage and older age. Interestingly, these factors are often associated with a poor immune status.

P1.04-75 IMMUNE-RELATED ADVERSE EVENTS AND THE NEUTROPHIL TO LYMPHOCYTE RATIO AS PREDICTORS OF CLINICAL RESPONSE TO IMMUNOTHERAPY

H. Powery[1], L. Raez[2], D. Johnson[3], I. Pelt[3], K. Dumais[1], G. Domingo[4], B. Hunis[2], P. Izquierdo[2], C. Smith[1]

[1]*Memorial Cancer Institute, Pembroke Pines/United States of America,* [2]*Memorial Cancer Insitute/Florida International University, Pembroke Pines/United States of America,* [3]*Memorial Cancer Institute/Florida A&M University, Pembroke Pines/United States of America,* [4]*Memorial Cancer Institute, Pembroke Pines/United States of America*

Background: Several immune checkpoint inhibitors (ICPis) have been approved for the treatment of non-small cell lung cancer (NSCLC). PD-L1 expression seems to correlate with activity of ICPis; however, it is not a completely accurate biomarker. Therefore, other clinical or molecular predictors of response are needed. **Method:** The purpose of this study was to assess the value of immune-related adverse events (irAEs) and the neutrophil to lymphocyte ratio (NLR) in predicting response to ICPis. Furthermore, since Hispanics (H) are often not stratified in clinical trials, we sought to evaluate if incidence of irAEs and the baseline NLR were similar between H and non-Hispanic (NH) patients (pts). This was a retrospective review of 70 pts diagnosed with NSCLC and treated with ICPis at our institution between July 2014 and 2017. The electronic medical record was utilized to collect pt demographics, occurrence of irAEs, baseline NLR (categorized as < 5 or ≥ 5), progression free survival (PFS) and overall survival (OS). The data cutoff date was March 31, 2019. **Result:** The median age of the pts was 65.5 years (range 51 to 89 years). The male to female ratio was 1.2. There were 19 H and 51 NH pts. Most of the pts were treated with single agent ICPis. The irAEs positive group had increased median PFS (7.5 vs 2.1 months; p-value 0.001) and OS (14.7 vs 4.7 months; p-value 0.001) compared to the irAEs negative group. OS at 12 months was 58.1% in the irAEs positive group compared to 20.5% in the irAEs negative group (p-value 0.001). There was a non-statistically significant trend towards improved outcomes in pts with baseline NLR < 5 vs ≥ 5. The overall incidence of irAEs was similar between H and NH pts; however, hypothyroidism was observed more frequently in H than NH pts (45% vs 20%; p-value 0.020). Baseline NLR < 5 vs ≥ 5 was similar between H and NH pts. **Conclusion:** Occurrence of irAEs might be useful in identifying potential responders to ICPis. H pts on ICPis might be at a higher risk for developing hypothyroidism. Since our total number of pts is small, these findings should be further evaluated in prospective studies.

P1.04-76 PREDICTIVE FACTORS OF EARLY THERAPEUTIC FAILURE TO IMMUNOTHERAPY IN PATIENTS WITH METASTATIC NSCLC

V.A. Ramos Sousa, V. Fonseca De Jesus, T. Pimentel Muniz, M. Da Rosa Barbosa, H. Freitas, V. De Lima

AC Camargo Cancer Center, Sao Paulo/Brazil

Background: Immunotherapy helped to improve the outcomes of patients diagnosed with metastatic NSCLC. Nevertheless, survival curves show that some patients do not benefit from treatment and progress rapidly. Identifying factors capable of predicting early failure to immunotherapy is clinically useful. We determined factors associated with disease progression before nine weeks of treatment with anti-PD1. **Method:** We retrospectively reviewed the medical records of patients with metastatic NSCLC treated in second or more line with anti-PD1 at AC Camargo Cancer Center-Brazil, from January 2006 until April 2018. Altogether, 87 patients were identified and had pre-treatment (data collected within 30 days of immunotherapy initiation) characteristics collected. Univariate analysis was performed using binomial logistic regression (disease progression occurring till 9 weeks versus after); variables with p value < 0.20 were selected for multivariate analysis. A multivariate model to predict disease progression (DP) until 9 weeks was developed using the likelihood ratio test and Akaike Information Criteria (AIC). Median follow-up was estimated using reverse Kaplan-Meier method. Median progression-free (mPFS) and overall survival (mOS) were obtained from Kaplan-Meier curves. **Result:** Median follow-up was 18 months (95% CI 14.0-20.3), mPFS was 3.3 months (95%CI 2.1-3.7) and mOS was 15.8 months (95%CI 7.5-25.5). Univariate analysis demonstrated that the number of metastatic sites (OR=1.79; 95%CI 1.25-2.68; p=0.002), hemoglobin level (OR=0.791; 95%CI 0.55-0.88; p=0.003), monocyte count (OR=1.24; 95%CI 1.08-1.47; p=0.004), platelet count (OR=1.44; 95%CI 1.01-2.14; p=0.051), dNLR (derived neutrophil to lymphocyte ratio) (OR=1.19; 95%CI 0.95-1.54; p=0.14), ECOG (OR=2.43; 95%CI 1.00-6.048; p=0.051), T stage (OR=2.15; 95%CI 0.78-6.14; p=0.14), N stage (OR=4.26; 95%CI 1.51-14.13; p=0.010) and treatment line (OR=0.53; 95%CI 0.22-1.25; p=0.15) were significantly associated with early treatment failure. The final multivariate model demonstrated that N stage (OR=8.14; 95%CI 1.50-44.11; p=0.015), the number of metastatic sites (OR=2.10; 95%CI 1.24-3.55; p=0.005), hemoglobin level (OR=0.62; 95%CI 0.44-0.89; p=0.010), monocyte count (OR=1.44; 95%CI 1.12-1.84; p=0.004) and dNLR (OR=1.40; 95%CI 1.03-1.91; p=0.029) are independent factors associated with DP until 9 weeks of treatment. **Conclusion:** N stage, the number of metastatic sites, hemoglobin level (g/dL), the monocyte count and the dNLR are factors independently associated with early disease progression (until 9 weeks from immunotherapy initiation). This can help to better select metastatic NSCLC patients for anti-PD1 therapy in second line.

P1.04-77 EFFICACY OF ANTI-PD-1/L1 THERAPY FOR ADVANCED NON-SMALL CELL LUNG CANCER WITH PREEXISTING AUTOIMMUNE MARKERS

T. Inoue, M. Kimura, K. Kunimasa, M. Tamiya, H. Kuhara, K. Nishino, T. Hino, T. Kumagai

Osaka International Cancer Institute, Osaka/Japan

Background: Targeting therapies against the programmed cell death protein-1/ligand 1 (PD-1/L1) pathway has become a standard for patients with advanced non-small cell lung cancer (NSCLC). However, most clinical trials have not evaluated its safety and efficacy in patients with autoimmune diseases or with preexisting autoantibodies. Antinuclear antibodies (ANAs) are a spectrum of autoantibodies that target various nuclear and cytoplasmic components of the cells. Rheumatoid factors (RFs) are antibodies (immunoglobulin M) that react with immunoglobulin G. They are usually used as serological markers for autoimmune diseases. Recently, the relationship between these antibodies and some types of cancers has been identified, suggesting that autoantibodies might be associated with carcinogenesis and represent a state of pre-autoimmunity. Preexisting autoantibodies have been reported to be a surrogate marker of the efficacy of immunotherapy, but the trend is different by reporting. **Method:** To examine the effects of preexisting autoantibodies in anti-PD-1/L1 therapy, clinical data including ANAs and RF were reviewed retrospectively in patients with advanced NSCLC who received monotherapy with a PD-1/L1 inhibitor. Survival outcome was estimated with the Kaplan-Meier method and was compared between patient groups with the log-rank test. **Result:** In this retrospective analysis, we evaluated 275 patients with advanced NSCLC who received nivolumab, pembrolizumab or atezolizumab monotherapy, at Osaka International Cancer Institute in Japan between December 2015 and December 2017. The median age was 68 (range 27 to 80 years). 199 were men. ANAs were analyzed in 176 of 275 (64%) patients, and RF were analyzed in 161(56%). 68 of 176 (38.6%) were positive for ANAs (more than 1:40 serum dilution) and 21 of 161(13%) were positive for RF (more than 15IU/ml). None of the patients had active symptoms of an autoimmune disease. The median Time to Treatment Failure (TTF) was significantly shorter in patients positive for RF, 1.9 (95%CI, 0.5-2.9) months, than in those without RF, 3.5 (95%CI, 2.0-4.3) months. No significant differences in Overall Survival (OS) (12.5 versus 19.8 months) were observed between patients with or without RF, but OS in patients positive for RF tended to be shorter. Although no significant differences in OS (21.1 versus 19.4 months) and TTF (3.6 versus 2.8 months) were observed between patients with or without preexisting ANAs, OS in patients strongly positive (more than 1:160 serum dilution) for ANAs tended to be shorter compared to mildly positive patients (1:40, 1:80 serum dilution) (22.2 versus 12.7 months). **Conclusion:** The presence of preexisting RFs may be a factor for poor prognosis in NSCLC patients undergoing anti PD-1/L1 therapy. There was no significant difference between patients with and without ANAs, but high titer of ANAs may be a factor in poor OS.

Background: Checkpoint inhibitors (ipilimumab, nivolumab, pembrolizumab, or atezolizumab) have created a fundamental paradigm shift in the management of non-small cell lung cancer (NSCLC). In recent years, many randomized clinical trials (RCT) have combined different checkpoint inhibitors with various standard chemotherapy regimens as first-line treatment of advanced non-squamous NSCLC. In general, these trials have included patients across different levels of PD-L-1 expression. The purpose of our study is to consolidate the efficacy of checkpoint inhibitors in combination with chemotherapy for first-line treatment of advanced non- squamous NSCLC. **Method:** We systematically conducted a comprehensive literature search using PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019. RCTs of first-line chemotherapy +/- immunotherapy in patients with advanced non-squamous NSCLC were incorporated in the analysis. A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for overall survival (OS) and progression-free survival (PFS) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q -statistic. Random effects model was applied. **Result:** A total of 3228 patients with advanced non-squamous NSCLC from 6 RCTs (Keynote – 021,189, IMpower – 130, 132, 150, and Lynch et al.) and a subgroup of another RCT (Checkmate-227) were included. The study arm used standard chemotherapy regimens in combination with ipilimumab, pembrolizumab, atezolizumab, or nivolumab while control arm used only standard chemotherapy regimens. The randomization ratio was 2:1 in IMpower-130 and Keynote-189 studies and 1:1 in other studies. The I^2statistic for heterogeneity was 15, suggesting some heterogeneity among RCTs. The pooled HR for PFS was statistically significant at 0.61 (95% CI: 0.55-0.67; P < 0.00001), and the pooled HR for OS was noted at 0.78 (95% CI: 0.65- 0.94; P = 0.01).The PFS benefit was observed in all PD-L1 categories, including PD-L1 negative/ tumor proportion score (TPS) of less than 1% cohort (HR, 0.67; 95% CI: 0.53- 0.84; P = 0.0005), PD-L1 low/ TPS ≥1-49% cohort (HR, 0.62; 95% CI: 0.52- 0.74; P < 0.00001) and PD-L1 high/ TPS ≥ 50% cohort (HR, 0.42; 95% CI: 0.33- 0.52; P < 0.00001). **Conclusion:** Our study showed that first-line checkpoint inhibitors in combination with chemotherapy significantly improved PFS and OS compared to standard chemotherapy in patients with advanced non-squamous NSCLC and the PFS benefit was consistent regardless of PD-L1 expression.

Background: Immune checkpoints inhibitors (ICI), in monotherapy or combination with chemotherapy, are the standard of care for lung adenocarcinoma (ADC) patients. Unfortunately, only a restricted number of patients will respond to ICI. Combination therapies such as CD73 inhibitors, are being studied with the goal to achieve synergic effects. CD73 is a membrane-bound protein with immunosuppressive functions. We previously reported that higher immune cell infiltration was associated mainly to CD73 basolateral (BL) expression, in this abstract, we show the correlation of CD73 expression at luminal (L) and BL membrane of ADC malignant cells (MCs), with annotated clinicopathological characteristics, immune and molecular biomarkers. **Method:** CD73 IHC expression (clone D7F9A) was evaluated in 106 archived ADCs from patients that underwent surgical treatment without neoadjuvant therapy between February 1999 and February 2012 at MD Anderson Cancer Center (Houston, Texas, USA). We scored % and H-score of CD73 expression at the luminal (L) and basolateral (BL) membrane, we calculated the Total (T) CD73 as the average of L and BL, and classified ADCs in three groups: 'T High' (TH) (upper quartile for all tumors); 'T Low' (TL); 'T Neg' (TN) (<1%). We correlated T, L and BL expression and the three groups with clinicopathological characteristics, mutational status of KRAS and EGFR, TP53, STK11 and Tumor mutation burden (TMB), and cell densities of CD3, CD8, CD68, CD45RO, FOXP3, and Granzyme B, and PD-L1 expression (clone E1L3N) in MCs. **Result:** T CD73 expression was found in 76%; BL in 60% and L in 57%; among ADCs with luminal membrane present (n=72), L CD73 was present in 83%. T+ and L+ expression was more frequent in never smokers (p=0.02 and p=0.003). Also higher frequency of L+ was found in older patients (>65) (p=0.01), tumors with non-solid histology patterns (p<0.001), EGFR mutation (p=0.048), non-mutated p53 (p=0.002), negative PD-L1 (p=0.03), and low TMB (<10 mut/MB) (p=0.001). Higher levels of L expression were found in KRAS mutated tumors (p=0.049). Higher BL expression positively correlated with p53 mutated tumors (p=0.038), PD-L1+ in MCs (p=<0.0001), and higher TMB (p=0.040). Our group analyses revealed that TH and TN were associated with ADCs from patients with >30 pack-year of smoking history (p=0.04), presence of any-solid histology pattern (p=0.03), p53 mutation (p= 0.005) and higher TMB (p=0.003) compared with TL. TH also had higher frequency of PD-L1+ tumors, and a higher cell density of CD3 (p=0.0001), CD8 (p=0.001), CD68 (p=0.048), CD45RO (p=0.036), FOXP3 (p=0.053), and Granzyme B (p=0.024) compared to TL and TN. TN showed higher frequency of STK11 mutation (p=0.034). **Conclusion:** Based on the CD73 expression we defined subsets of lung adenocarcinomas that have distinct histological, molecular and immunological characteristics that may play a role in the response to ICI. Our characterization could help us to understand patient's response to ICI, and identify patients that could potentially benefit from combination therapies.

Background: Widespread use of immune checkpoint inhibitors (ICIs) for the treatment of lung cancer has exposed a large number of patients to these medications, increasing the incidence of rare adverse reactions such as thromboses. The present study elaborates on factors related to the occurrence of these events. **Method:** In a retrospective cohort study, a total of 48 patients, 24 who experienced thrombosis and 24 matched controls who underwent evaluation after initiation of ICIs therapy for advanced/metastatic NSCLC, were included. Clinical and pathological as well as serum inflammatory and coagulation markers were evaluated. **Result:** Among the 48 patients, 46% (n=26) were female, median age was 62 years old and all patients had an ECOG performance score of < 2. The

median overall survival reached by the cohort was 22.47 months. Among patients who developed thrombosis there were 8 cases of deep venous thrombosis (DVT) (33%), 13 pulmonary embolisms in addition to DVT (62.5%) and 1 case of brain venous sinus thrombosis (4.2%). Apart from expected thrombosis markers such as D dimer, differences in inflammatory and immune related markers between patients who experienced thrombosis and those who did not, were observed. Abnormal values were found in the thrombosis group for B2glycoprotein 1 (33% vs 0%, OR= 4.08, [95%CI 1.65 - 12.1], p= 0.005), B2glycoprotein 1 IgG (29.2% vs 0%, OR= 4.64, [95%CI 1.73 – 16.9], p= 0.007), C Reactive protein (83.3% vs 12.5%, OR= 35, [95%CI 7.9 - 213], p< 0.001), B2microglobulin (62.5% vs 8.3%, OR= 14, [95%CI 3.11-103.7], p = 0.002), Prothrombin time (41.7% vs 4.2%, OR= 2.4, [95%CI 1.64 -3.69], p =0.01) and C Coagulation protein (50% vs 16.6%, OR =1.79, [95%CI 1.53 – 2.91], p <0.001). **Conclusion:** Abnormalities in antiphospholipid antibodies, C reactive protein, B2microglobulin and coagulation in patients who suffered thrombosis during ICI treatment suggest that this phenomenon could be the result of immune and auto-inflammatory induced intravascular dysfunction.

Background: Immunotherapy related hyperprogression is poorly characterized in Latin American patients. In this study we sought to characterize and identify factors associated with the presentation of hyperporgression after initiation of immunotherapy in patients with advanced non-small cell lung cancer (NSCLC). **Method:** A multicenter international retrospective study on 110 patients was conducted. Clinical variables as well as routine blood studies were recorded before initiation of treatment. Regression analysis was used to find associations. A random forest tree analysis (RFTA) based on continuous and discrete variables was used to subcategorize patients based on occurrence of hyperprogression. **Result:** Median age was 64 years (Range 34-90) and 59.8 % were male patients. ECOG performance status was >1 on 8.8% of patients. Median overall survival was 12.7 months (95% CI 9.67-14 months) and progression-free survival of 4.27 months (95% CI 3.97-5.0). 44 hyperprogressors were documented (19.8%, [95%CI 14.5-25.1%]). Median time to progression was approximately 5 weeks after initiation of treatment. Factors associated included albumin and hemoglobin levels (p = 0.046 and 0.037 respectively), presence of CNS (p= 0.0009) and bone metastasis (p = 0.004) and weight loss (p= 0.004). RFTA revealed that a leucocyte count over 5.300 cells/dl was present in all hyperprogressors. **Conclusion:** Hyperprogression is a phenomenon after initiation of immunotherapy which is associated with clinical and paraclinical variables. These associations could be used to withhold certain agents and prevent its occurrence in NSCLC treatment.

Background: Immunotherapy (IO) has become standard of care in NSCLC. Immune-related adverse events (irAEs) have shown to be associated with survival benefit in several tumor types in small reports. However, its predictive role as a clinical marker for efficacy to PD-1 inhibition in NSCLC remains uncertain. **Method:** We conducted a retrospective analysis of patients (pts) with NSCLC treated with IO at six centers between Nov 2013 and Feb 2019. We categorized patients in two groups (irAEs and no-irAEs group) and evaluated overall response rate (ORR), disease control rate (DCR), progression-free survival (PFS) and overall survival (OS). A 6-week cutoff was established to evaluate the impact of early vs. late onset of irAEs. Correlations were assessed using Fisher's exact tests. Kaplan-Meier was used to estimate survival rates and compared using log-rank. **Result:** A total of 269 NSCLC pts treated with ICIs were included, 48 pts (17.8%) developed Grade 3-4 irAEs. Among them, median age 66 years [range 47 - 86], 31 (65%) were male, 42 (87.5%) current or former smoker and 42 (87.5%) had PS 0-1, PDL-1 tumor proportion score (TPS) was ≥ 50% in 17/26 pts (65.4%), 5 pts (11%) received baseline corticoids; 15 pts (31%) were treated in first-line. No statistical significant differences in baseline characteristics were observed. Median follow-up from IO was 15.8 months [95%CI 12.1 – 19.7]. Median number of cycles to toxicity was 5 [range 1 – 60]. Most common grade 3-4 events were pneumonitis (n=12), adrenal insufficiency (n=7), thyroiditis (n=7), rash (n=6) and nephritis (n=6). There were 5 (10%) treatment-related deaths. Patients with irAEs had significantly higher ORR and DCR vs. no-irAEs: 48% (23/48) vs. 26.7% (59/221) p=0.005 and 83% (40/48) vs. 58% (128/221) p<0.001, respectively. Similarly, median PFS and OS were significantly prolonged in pts with irAEs vs. no-irAEs: 17.1 months [95%CI 8.1 – 25.9] vs. 6.6 months [95%CI 4.9 – 8.3] p=0.02 and 29.4 months [95%CI NR] vs. 12.9 months [95%CI 10.0 – 15.9] p=0.01, respectively. Early onset of irAEs (≤6 weeks) had significantly shorter PFS and OS vs. late onset (>6 weeks): 2.43 months [95%CI 0 - 9.02] vs 21.0 months [95%CI 14.57 - 27.44] p=0.006 and 3.94 months [95%CI NR] vs NR p=0.010, respectively. **Conclusion:** In our cohort, we observed a correlation between irAEs and efficacy in NSCLC patients treated with IO. This potential predictive value needs to be validated in larger prospective cohorts to drive definitive conclusions.

P1.04-83 COMBINING IMMUNE GENE POLYMORPHISM AND IMMUNE PROFILE PREDICTS BRAIN METASTASES AND DEATH IN A BRAZILIAN COHORT OF NON-SMALL CELL LUNG CARCINOMA

J. Machado-Rugolo[1], A. Fabro[2], C. Rainho[3], C. Farhat[4], V. De Sá[5], A.C. Herbst[6], V. De Lima[5], E. Parra[7], V. Capelozzi[4]

[1]*University Hospital, Botucatu Medical School, São Paulo State University, Botucatu/Brazil,* [2]*Ribeirão Preto Medical School, University of São Paulo, Ribeirão Preto/Brazil,* [3]*Institute of Biosciences, São Paulo State University, Botucatu/Brazil,* [4]*University of São Paulo Medical School, São Paulo/Brazil,* [5]*AC Camargo Cancer Center, Sao Paulo/Brazil,* [6]*AC Camargo Cancer Center, São Paulo/Brazil,* [7]*University of Texas, Houston/United States of America*

Background: Combining immunotherapies such as anti–PD-1 and anti–CTLA-4 agents, which target complementary pathways in the cancer-immunity cycle, might result in additive or synergistic antitumor activity, and has been suggested to improve survival of patients with advanced non-small cell lung carcinomas (NSCLC). This study was conducted to investigate whether polymorphisms of immune checkpoints genes is associated with the tumor immune cell profile and with the risk of brain metastases and death of patients with advanced stage NSCLC. **Method:** A total of 75 NSCLC patients were enrolled. The specimens included 37 (50%) adenocarcinomas (ADC), 25 (33%) squamous cell carcinomas (SqCC), and 13 (17%) large cell carcinomas (LCC). Using multiplex immunofluorescence

(mIF) and image analysis, we evaluated programmed death ligand 1 (PD-L1) expression in malignant cells (MCs), CD68+ macrophages, and cells expressing the immune markers CD3, CD8, CD57, CD45RO, FOXP3, PD-1, and CD20. We used high-throughput next-generation sequencing (NGS) to evaluate single nucleotide variants (SNVs) in immune checkpoints genes CD274 (PD-L1), CTLA-4, PDCDL1LG2 (PD-L2), LAG3 and B7H4 (VTCN1) in NSCLC by TruSeq Custom Amplicon Panel (Illumina, Inc., San Diego, CA). A total of five single nucleotide polymorphisms (SNPs) were selected: rs2297136G/A (PD-L1), rs231775A/G (CTLA-4), rs7854303C/T (PD-L2), rs870849T/C (LAG3) and rs10754339G/A (B7H4). Cell phenotype data were then integrated with clinicopathologic characteristic and next-generation sequencing gene profiles. **Result:** The patients were 47 men (median age, 78yr) and 22 women (median age, 75yr). Tobacco history was present in 22 (30%) patients. Lymph node and brain metastases were observed respectively in 28 (37%) and 8 (10%) patients, and all the patients with brain metastases also presented lymph node metastases. Twenty-three (31%) of patients received adjuvant therapy. The percentage of MCs-PD-L1+ was < 1% (40%), 1-10% (40%) and > 10% (20%). The density of immune cells/mm2 was CD3+ (330), CD3CD8+ (110), CD3-PD1+ (85), CD68+ (58), CD68-PD-L1+ (2.5), CD3CD45RO+ (260), CD3CD45FOXP3+ (260) and CD20+ (46). The frequency of genotypes was: CTLA-4 (AA=40%; AG=25%; GG=10%), CD274 (AA=32%, GA=26%, GG=17%), PDCDL1LG2 (CC=100%), LAG3 (TC=32%, CC=31%, TT=12%) and VTCN1 (AA=57%, GA=13%, GG=5%). A significant association was found between CTLA-4 and CD20+ lymphocytes (R=-0.32; p=0.02), PD-L1and VTCN1 (R=0.26; p=0.02) and PD-L1 polymorphism and MCs-PD-L1 (R=0.26; p=0.04). Different models to predict risk of death were constructed by Cox Regression analysis. Initially, the model was constructed with patient age, histologic type, N stage, brain metastases and adjuvant treatment (p<0.05). Thus CTLA-4, CD274, PDCDL1LG2, LAG3 and VTCN1 genes were included in the model (p<0.05). The second model excluded PDCDL1LG2, VTCN1 genes and introduced MCs-PD-L1 and CD3CD8+, (p<0.05). The final model, controlled for age, histologic types and adjuvant treatment, reliably predicted low risk of brain metastases and death for patients in N1 stage (β coefficient=3.24; p=0.01), CTLA-4 rs231775 AG genotype (β coefficient=-3.71; p=0.04); CD274 rs2297136 GA genotype (β coefficient= -8.55; p=0.03), LAG3 rs870849 TC genotype (β coefficient=2.16; p=0.04), low density of MCs-PD-L1 (β coefficient=6.43, p=0.04) and high density of CD3+CD8+ lymphocytes (B coefficient=-3.06; p=0.04). **Conclusion:** Incorporating immune checkpoints genes polymorphisms into immunoprofiling score improves prediction of brain metastases and death in Brazilian NSCLC and may be promise as combining target therapy.

P1.06 MESOTHELIOMA
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.06-01 COMBINING IMMUNOPROFILE, IMMUNOGENIC COLLAGEN AND MISMATCH REPAIR PROTEINS PREDICTS RISK OF DEATH AND TARGET THERAPY IN MALIGNANT MESOTHELIOMA

J. Machado-Rugolo[1], M. Balancin[2], V. Martins[2], J. Miranda[3], A. Assato[2], N. Souza[3], A.P. Velosa[3], R. Falzoni[3], A. Ab´saber[3], W. Teodoro[3], V. Capelozzi[2]

[1]*University Hospital, Botucatu Medical School, Botucatu/Brazil,* [2]*University of São Paulo Medical School, São Paulo/Brazil,* [3]*University of Sao Paulo, Sao Paulo/Brazil*

Background: Malignant mesothelioma (MM) is a devastating disease characterized by aggressive growth and local invasion, poor outcome and limited therapeutic options. The immunogenic Type V collagen (Col V) has been identified as a significant risk factor for invasion in lung cancer, but the role of this collagen in MM is unknown. Although mismatch repair (MMR) proteins in malignancies function as genomic gatekeeper is not attained, these proteins may indirectly reinforce a high tumor mutation burden. We hypothesized that the cross-talk between Col V, MRR proteins and immune environment may elicit a paradoxal immunogenic response, promoting "cold-hot" switching while acting as a barrier, isolating and protecting neoplastic cells against cytotoxicity, chemotherapy and checkpoint inhibitors. **Method:** Ninety MM patients were enrolled, located in pleural and peritoneal serosae. We quantified through image analysis and employed immunofluorescence to evaluated Col V and immunohistochemistry to detect programmed death ligand 1 (PD-L1) expression in malignant cells (MCs), cells expressing the immune markers CD4, CD8 and CD20, BAP1, and MMR proteins (MLH1, PMS2, MSH2, MSH6). **Result:** 52 patients were men (median age, 61) and 25 women (median age, 60). Malignant mesothelioma involved the pleura (N=57), peritoneum (N=17) and testis (N=4). Histologic types included epithelioid (N=85) and non-epithelioid (N=7) and subtypes were solid (N=58), (N=13), papillary (N=11), micropapillary (N=4) and sarcomatoid (N=1). MCs-PD-L1 expression was 7/mm2, inflammatory cells expressing PD-L1 2.94/mm2, immune markers CD4+ 60/mm2, CD8+ 301/mm2 and CD20+ 186/mm2. Loss of BAP1 occurred in 61 (59%) cases. Col V fibers mean density were 2.67/mm3. The mean MMR protein expression in tumor cells was MLH1 (713/mm2), PMS2 (957/mm2), MSH2 (1306/ mm2) and MSH6 (855/mm2). We found significant association between expression of MLH1 with necrosis (R=-0.23;p=0.02), CD4+ (R=-0.32, p=0.002) and Col V (R=0.40, p=0.0001); PMS2 with necrosis (R=-0.30, p=0.02), BAP1 (R=0.22, p=0.03), MCs-PD-L1+ (R-0.27, p=0.009), inflammatory cells expressing PD-L1 (R=0.30, p=0.008) and Col V (R=0.54, p=0.0001); MSH2 with necrosis (R=-0.23, p=0.02) and CD4+ (R=-0.26, p=0.01), and MSH6 with MCs-PD-L1 (R=0.23, p=0.03), CD20+ (R=-0.24, p=0.01) and Col V (R=0.44, p=0.0001). Compared to non-epithelioid MPM, epithelioid MPM presented a significant association with MCs-PD-L1 (p=0.04), inflammatory cells expressing PD-L1 (p=0.002) CD8+ (p=0.005), MLH1 (p=0.001), PMS2 (p=0.01), MSH2 (p=0.04), MSH6 (p=0.02) and Col V (p=0.04). Different models to predict risk of death were constructed by Cox Regression analysis. The final model reliably predicted high risk of death for MM with necrosis (ß coefficient = -9.92, p=0.01), high nuclear grade (ß coefficient = 7.34, p=0.003), low MCs-PD-L1 (ß coefficient = -0.20, p=0.002), and inflammatory cells expressing PD-L1 (ß coefficient = -0.32, p=0.006), loss of BAP1 expression ((ß coefficient = 8.25, p=0.005), low CD4+ (ß coefficient = -1.70, p=0.008), increased expression of MLH1 (ß coefficient = 0.003, p=0.002), and MSH2 (ß coefficient = -0.04, p=0.01), and high Col V fibers (ß coefficient = 1.07, p=0.004). There was no significant difference between pleural and non-pleural disease. **Conclusion:** PD-L1 depends on the cross-talk between Col V and tumor mutation burden to promote cold-hot immunogenic switching and to predict death and target therapy in MM in pleural and non-pleural MM.

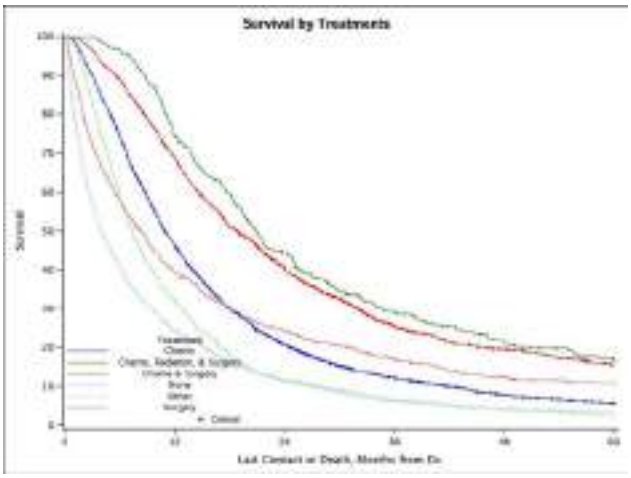
P1.06-02 NATIONAL TRENDS IN OUTCOMES IN PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA

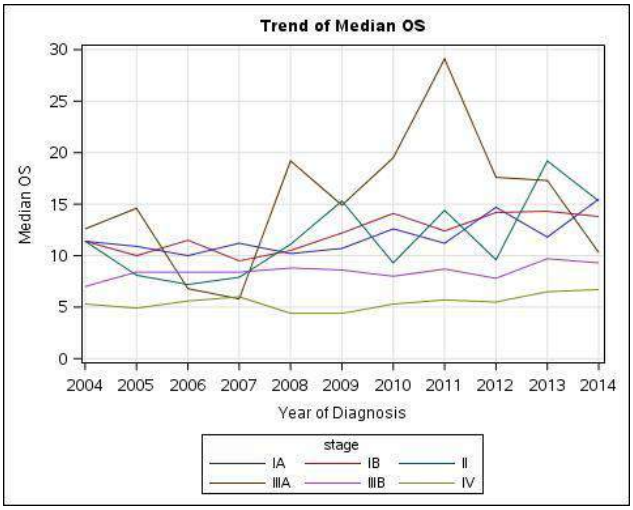
K. Parikh, U. Durani, S. Funni, J. Inselman, K. Leventakos, A. Mansfield

Mayo Clinic, Rochester/United States of America

Background: Malignant pleural mesothelioma is an aggressive tumor and is often incurable. We aim to identify national practice patterns and trends in survival in patients with mesothelioma. **Method:** We queried National Cancer Database from years 2004-2014 to identify adult mesothelioma cases. We collected baseline characteristics were collected and analyzed treatment patterns and survival trends. Multivariable Cox regression models were applied to identify factors associated with survival. **Result:** Of 11,372 patients 4354 (38%) had epithelioid histology, 1431 (12%) sarcomatoid, 880 (0.7%) biphasic, and 4707 (41%) unspecified. 20% were stage IA, 22% stage IB, 2% stage II, 1% stage IIIA, 31% stage IIIV, and 23% were stage IV. Sarcomatoid histology was associated with worst overall survival (HR 2.2) while epithelioid histology had best survival (referent). Chemotherapy alone was the most common treatment modality (36%). Combined treatment with surgery, radiation, and chemotherapy was associated with best overall survival (HR 0.45) followed by chemotherapy combined with surgery. However, 1 year and 5-year OS remain low at 41.2% and 6.5% respectively. There has been no clinically significant improvement in overall survival from 2004 to 2014.

Multivariate Cox Regression		
Variable	**Level**	**HR (95% CI)**
Age	Unit=1	1.018 (1.015-1.020)
Academic	No vs Yes	1.171 (1.124-1.221)
Charlson Score	1 vs 0	1.104 (1.053-1.158)
	2 vs 0	1.201 (1.109-1.300)
	>=3 vs 0	1.460 (1.279-1.666)
Histology	Biphasic vs Sarcomatoid	0.737 (0.675-0.805)
	Epithelioid vs Sarcomatoid	0.460 (0.432-0.491)
	NOS vs Sarcomatoid	0.552 (0.518-0.587)
Sex	Female vs Male	0.817 (0.779-0.857)
Year	Unit=1	0.984 (0.977-0.990)
Insurance	Medicaid vs Private	1.193 (1.043-1.364)
	Medicare vs Private	0.993 (0.940-1.048)
	Other/None/Unknown vs Private	1.038 (0.938-1.148)
Stage	IB vs IA	1.156 (1.088-1.228)
	II vs IA	1.229 (1.056-1.431)
	IIIA vs IA	1.442 (1.164-1.788)
	IIIB vs IA	1.459 (1.379-1.544)
	IV vs IA	1.801 (1.695-1.913)
Treatment	Chemo vs None	0.613 (0.584-0.643)
	Chemo, Radiation, & Surgery vs None	0.450 (0.396-0.512)
	Chome & Surgery vs None	0.468 (0.436-0.504)
	Other vs None	0.737 (0.682-0.796)
	Surgery vs None	0.694 (0.638-0.756)





Conclusion: Survival outcomes in mesothelioma remain poor. There is a need for more clinical trials using combinatorial approaches to improve outcomes in mesothelioma.

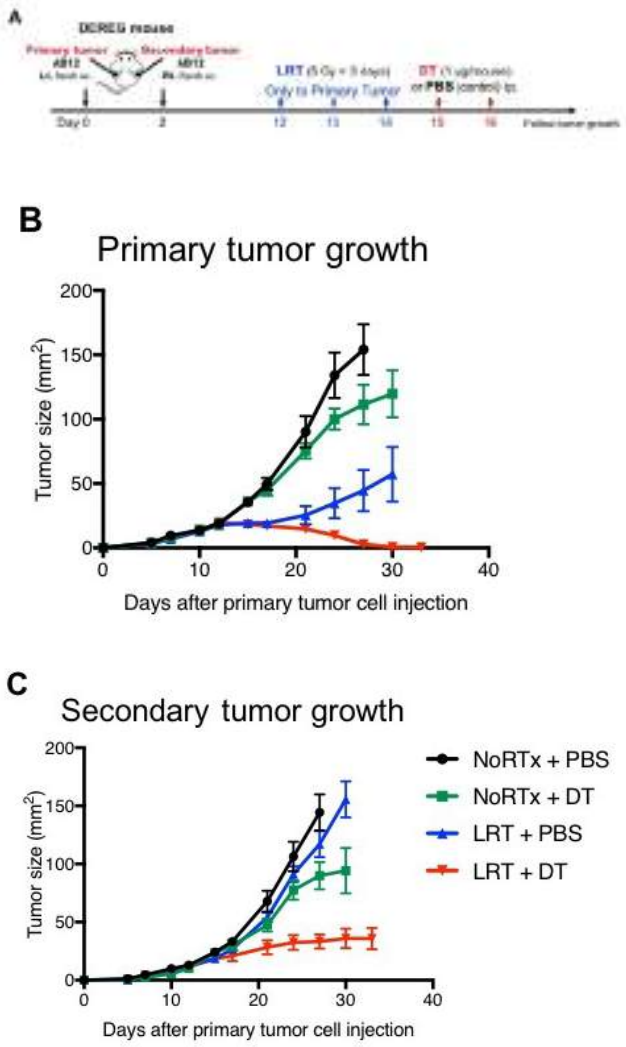
P1.06-03 SELECTIVE DEPLETION OF FOXP3⁺ REGULATORY T CELLS AFTER LOCAL RADIOTHERAPY INDUCES ABSCOPAL EFFECTS IN MURINE MALIGNANT MESOTHELIOMA

M. Kohno[1], J. Murakami[2], L. Wu[2], M.-L. Chan[2], Z. Yun[2], M. De Perrot[1]

[1]*Toronto General Hospital, University Health Network, Toronto/Canada,*
[2]*Toronto General Research Institute, University of Toronto, Toronto/Canada*

Background: Increasing evidence indicates that local radiotherapy (LRT) can invoke both local and systemic immune responses. Combining blockade of radiation-induced immunosuppressive responses with LRT may augment antitumor effects. Mice expressing a diphtheria toxin (DT) receptor under control of the *Foxp3* locus (DEREG mice) allow conditional and efficient depletion of Foxp3⁺ regulatory T cell (Treg) by DT injection. This study aimed to elucidate the antitumor effect of selective depletion of Tregs combined with LRT in a murine malignant mesothelioma model. **Method:** The infiltration of CD8⁺ T cells and Tregs was examined by flow cytometry at different time points after nonablative hypofractionated radiation (5 Gy x 3 days) in a murine mesothelioma model. AB12 murine mesothelioma cells were injected s.c. into syngeneic DEREG mice at two separate sites, defined as a "primary" site that was irradiated and a "secondary" site outside the radiation field. These mice were treated with LRT alone, DT injection alone, or a combination of LRT and DT injection. **Result:**

POSTERS



The proportion of CD8⁺ T cells and Tregs of total CD45⁺ cells in tumors were not different between radiated and untreated mice on day 2 and 5 after LRT. However, on day 7 and 12, both CD8⁺ T cells and Tregs in tumors significantly increased in mice treated with LRT compared with those without LRT. Selective Treg depletion by DT injection after LRT showed the best tumor growth delay in both primary and secondary tumor sites compared with LRT alone and DT injection alone. CD8⁺ T cells in spleen showed increased intracellular IFN-γ and Granzyme B production in mice treated with a combination of LRT and DT injection. **Conclusion:** Selective Treg depletion after LRT has the potential to evoke efficient local and systemic antitumor responses in murine mesothelioma. Our findings might have implications for future therapeutic strategies in mesothelioma patients.

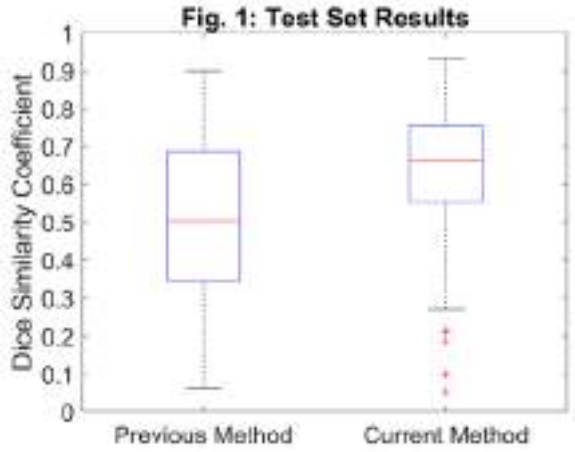
P1.06-04 DEEP LEARNING-BASED SEGMENTATION OF MESOTHELIOMA ON CT SCANS: APPLICATION TO PATIENT SCANS EXHIBITING PLEURAL EFFUSION

E. Gudmundsson, C. Straus, F. Li, H. Kindler, S. Armato

University of Chicago, Chicago/United States of America

Background: Tumor volume has been a topic of interest in the evaluation of treatment response, staging and prognosis of malignant pleural mesothelioma patients. Many mesothelioma patients present with or develop pleural fluid, the presence of which may complicate tumor segmentation on CT scans. We implemented a method for the automated segmentation of mesothelioma tumor on CT that explicitly excludes pleural effusion, which, if included in the segmentation of tumor, could confound the assessment of tumor volume. **Method:** Deep convolutional neural networks (CNNs) were trained for the segmentation of mesothelioma tumor in each hemithorax. A database was collected of 180 CT scans of 160 mesothelioma patients who exhibited tumor and pleural effusion. 6026 axial sections containing segmented tumor (1243 sections exhibiting pleural effusion) from 134 chest CT scans were used to train deep CNNs for segmentation of mesothelioma tumor. A radiologist contoured tumor on a test set of 94 axial sections that exhibited both tumor and pleural effusion; these sections were randomly selected from 46 CT scans of 34 patients not included in the training set. Performance was evaluated on the test set by calculating the Dice Similarity Coefficient (DSC) between computer-generated and reference segmentations; DSC is a measure of overlap between a pair of segmentations (a value of 0 indicating no overlap, 1 indicating complete overlap). We compared the performance of the present method to a previously published deep learning-based method for the automated segmentation of mesothelioma tumor on CT scans; differences in DSC values achieved on the test set by the two methods were assessed through a two-tailed paired Wilcoxon signed-rank test. **Result:** A boxplot of DSC values achieved on the test set by the current method and the previously published method is shown in Fig. 1. The median DSC on the test set achieved by the current method was 0.66 (inter-quartile range 0.20); the median DSC on the test set achieved by the previously published method was 0.51 (inter-quartile range 0.34). The difference in DSC between the two methods was statistically significant ($p < 0.0001$).



Conclusion: A deep CNN was implemented for the task of automated segmentation of mesothelioma tumor on CT scans of patients who also exhibit pleural effusion. The present method achieved a statistically higher overlap ($p < 0.0001$) with radiologist-provided reference contours than a previously published method on a test set of 94 axial CT sections of mesothelioma patients exhibiting both tumor and pleural effusion.

P1.06-05 CLINICAL FEATURES AND OUTCOMES OF RECURRENCE AFTER PLEURECTOMY/DECORTICATION FOR MALIGNANT PLEURAL MESOTHELIOMA

A. Nakamura[1], M. Hashimoto[1], A. Kuroda[1], T. Nakamichi[1], S. Matsumoto[1], N. Kondo[1], T. Kijima[2], S. Hasegawa[1]

[1]*Hyogo College of Medicine, Nishinomiya/Japan,* [2]*Hyogo College of Medicine, Hyogo/Japan*

Background: Malignant pleural mesothelioma (MPM) is an aggressive tumor while most patients experience recurrence after multimodality treatment. However, few clinical studies have been conducted to evaluate the recurrence pattern and survival after Pleurectomy/decortication (P/D) for MPM. **Method:** We reviewed the patients who registered in the prospective MPM database of our hospital surgery program between September 2012 and December 2017. Eligibility criteria were age ≤80 years, histological subtype on pleural biopsy was epithelioid, clinical stage T1-3N0-1M0 (8th edition), an Eastern Cooperative Oncology Group performance status of 0-1, no major comorbidity. Neoadjuvant chemotherapy (NAC) consisted of pemetrexed followed by cisplatin was performed in all patients who met previously mentioned inclusion criteria. After NAC for three cycles, curative-intent surgery was planned in patients who showed no apparent tumor progression. In our hospital, P/D

was introduced in September 2012, and since then P/D was main operative method for MPM. After P/D, If the patients keep good general condition, the patients underwent adjuvant chemotherapy consisted of pemetreced follow by cisplatin. The subjects were 90 patients who underwent NAC followed by P/D from September 2012 to December 2017. Survival and recurrence were calculated by the Kaplan-Meier method using the log rank test. Clinical factors related to survival after recurrence was assed by a multivariable analysis using Cox proportional hazards model. **Result:** Between September 2012 and December 2017, 140 consecutive patients were eligible for multimodality treatment. All patients completed neoadjuvant chemotherapy. Of these, 112 patients proceeded to surgery, and the remaining 28 patients didn't because of progressive disease (N= 20) or because they refused to provide consent (N= 8). Of 112 patients who proceeded to surgery, 12 patients underwent Extrapleural pneumonectomy, 10 patients underwent exploratory thoracotomy. Finally, 90 patients underwent P/D. Of 90 patients, 65 patients (72.2%) completed multimodality treatment. The 1-year and 3-year overall survival rates after diagnosis were 93.3% and 65.3%, respectively. A recurrence developed in 57 (63.3%). The median time to recurrence was 19.0 months. 1-year and 3-year recurrence free survival were 69.7% and 34.0%, respectively. In the initial recurrence, local recurrence only was developed in 39 patients (68.4%), distant recurrence only in 6 patients (10.5%), and both local and distant recurrence in 12 patients (21.1%). 1-year survival rates after recurrence was 59.5%. 43 patients (75.4%) received a treatment for recurrence. On multivariable analysis, treatment for recurrence (hazard ratio, 0.16; 95% confidence interval, 0.06–0.41: P < 0.0001) and disease-free interval greater than 12 months (hazard ratio, 0.34; 95% confidence interval, 0.14 –0.79; P = 0.01) were identified as independently significant prognostic factors of survival after recurrence. **Conclusion:** The local recurrence remain the most frequent pattern of recurrence after P/D. Most of patients who had recurrence after P/D enabled treatment for recurrence. Treatment for recurrence and disease-free interval greater than 12 months are important prognostic factors of survival after recurrence.

Background: P/D is considered a valid surgical approach in selected pts with resectable MPM with less morbidity than extrapleural pneumonectomy. The procedure is however, poorly standardized and never radical, and is hence preferably preceded or followed by systemic chemotherapy. EORTC 1205 aims at comparing the optimal sequencing of chemotherapy with P/D with regard to overall treatment time and feasibility. **Method:** Functionally operable treatment-naïve pts with T1-3 N0-2 epithelial or biphasic mesothelioma and PS 0-1 are randomized between adjuvant (arm A) and neo-adjuvant chemotherapy (arm B). Chemotherapy in both arms consists of 3 cycles of cisplatin and pemetrexed at standard dosage and with premedication. P/D is performed by experienced thoracic surgeons in credentialed centers. Strict timelines between both procedures apply and surgical quality is audited with intra-operative mapping and imaging and comprehensive registration of complications. Primary endpoint in the intention-to-treat population is successful completion of the multimodality treatment within 20 weeks of randomisation and being alive with no signs of PD and/or persistent grade III-IV toxicity. **Result:** As of April 10, 2019, 30 pts of the required sample size of 64 have been randomized and 17 operated. Baseline patient and tumor characteristics appear well balanced sofar (table).

Characteristics and treatment results as per 1/04/2019

Table	Arm A	Arm B	All
N	16	14	30
Male gender (%)	56	71	63
Median age (y)	62	66	64
WHO PS 0/1	10/6	7/7	17/13
TNM Stage 1/2/3 at presentation	6/6/4	9/2/3	15/8/7
% administered 3 cycles of chemotherapy	88	100	94
N operated	9	8	17
Median time between randomization and 1st treatment modality (weeks)	2.9	1.6	2.0
Median time between 1st and 2nd treatment modality	5.7	11.0	10.1
N completed treatment	9	8	17
Median overall treatment time in those completing treatment	23.7	18.7	21.3

Conclusion: Trial accrual proceeds on schedule and last patient will be included in 2020. A protocol amendment will allow carboplatin/pemetrexed as induction regimen. An updated analysis on all included patients as per 1/08/2019 will be presented at the meeting.

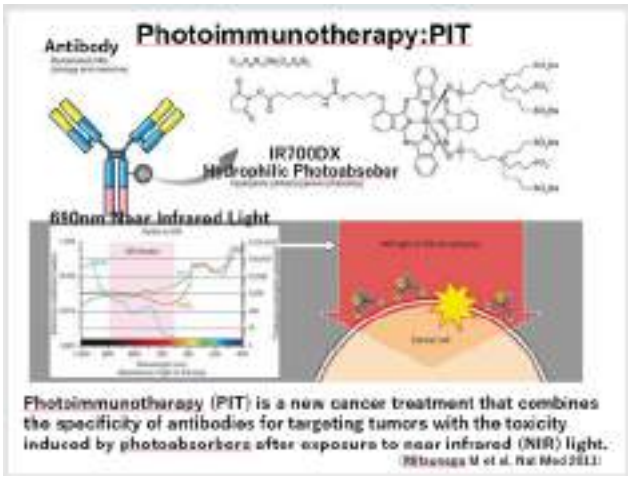
Keyword: mesothelioma pleurectomy/decortication chemotherapy

P1.06-07 TARGETING PHOTO-THERAPY FOR MALIGNANT PLEURAL MESOTHELIOMA; NEAR INFRARED PHOTOIMMUNOTHERAPY TARGETING PODOPLANIN

Y. Nishinaga[1], Y. Isobe[1], H. Yasui[1], K. Takahashi[1], S. Taki[1], T. Matsui[2], K. Sato[1,3], Y. Hasegawa[1,2], Y. Kato[4]

[1]*Nagoya University Graduate School of Medicine, Nagoya/Japan,* [2]*Nagoya University Hospital, Nagoya/Japan,* [3]*Nagoya University, Nagoya/Japan,* [4]*Tohoku University Graduate School of Medicine, Sendai/Japan*

Background:



Malignant pleural mesothelioma (MPM) has a poor prognosis, and the number of patients is thought to increase in the future over the world. However, the therapy for MPM is very limited with few regimens. Thus, development of new therapies for unresectable MPM is highly desirable. Podoplanin is a transmembrane glycoprotein that has been reported to be specifically up-regulated in MPM, and the antibody(D2-40) has been used as a marker to decide MPM in pathological diagnosis. This time, we successfully established a new anti-podoplanin antibody, NZ-1. Near infrared photoimmunotherapy (NIR-PIT) is a recent-developed cancer therapy that combines the specificity of intravenously injected antibodies for targeting tumors with the toxicity induced by photosensitizers after exposure to near infrared (NIR) light. It is now in international Phase III clinical trial against locoregional, recurrent head and neck squamous cell cancer

(LUZERA-301), and expected to be clinically licensed in near future. In this preclinical study, we develop new photo-targeting therapy against MPM, with the combination of NIR-PIT and NZ-1. **Method:** An antibody-photosensitizer conjugate consisting of NZ-1 and a phthalocyanine dye, IRDye-700DX, was synthesized and evaluated its specificity. *In vitro* and *in vivo* experiments were conducted with a podoplanin, luciferase expressing mesothelioma cell line(MSTO-211H/PDPN-luc-GFP). *In vitro* NIR-PIT cytotoxicity was assessed with dead staining and luciferase activity. In vivo NIR-PIT was examined in mice with tumors implanted in the flank or in the thoracic cavity, by in vivo real-time imaging with luciferase activities. **Result:** *In vitro* NIR-PIT-induced cytotoxicity was in a light dose dependent. *In vivo* NIR-PIT led significant reductions in both tumor volume ($p<0.05$ vs. APC) and luciferase activity ($p<0.05$ vs. APC) in a flank model. Bioluminescence indicated that NIR-PIT lead to reduction in pleural dissemination mice model. **Conclusion:** This study suggested that podoplanin-targeting-NIR-PIT with NZ-1 could be a new promising treatment for MPM.

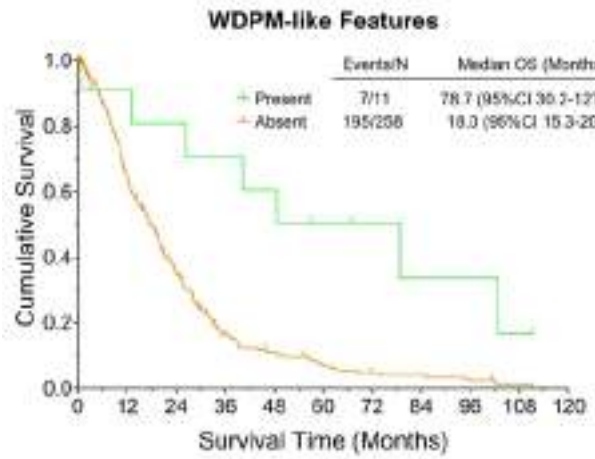
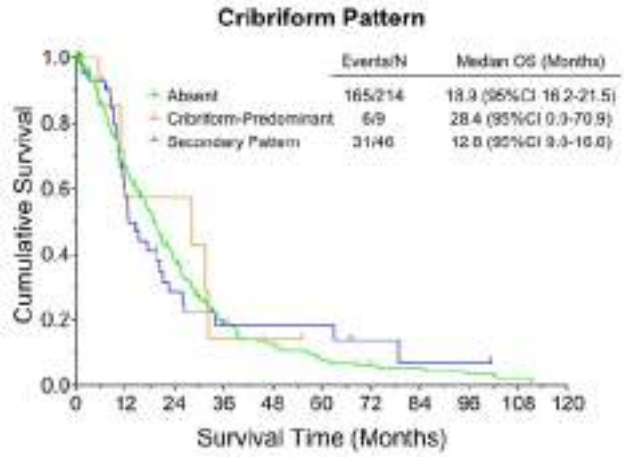
P1.06-08 WDPM-LIKE BUT NOT CRIBRIFORM AS SECONDARY GROWTH PATTERNS MODIFY SURVIVAL IN EPITHELIOID MALIGNANT PLEURAL MESOTHELIOMA

Y.Z. Zhang[1], C. Brambilla[2], A. Rice[2], J. Robertus[2], S. Jordan[2], E. Lim[2], L. Lang-Lazdunski[3], S. Popat[4], A. Husain[5], M. Moffatt[1], W. Cookson[1], A. Nicholson[6]

[1]*Imperial College London, London/United Kingdom,* [2]*Royal Brompton & Harefield NHS Foundation Trust, London/United Kingdom,* [3]*Bupa Cromwell Hospital, London/United Kingdom,* [4]*The Royal Marsden Hospital; and National Heart and Lung Institute, Imperial College London, London/United Kingdom,* [5]*University of Chicago Medical Centre, Chicago/United States of America,* [6]*Royal Brompton and Harefield NHS Trust, London/United Kingdom*

Background: The presence of well differentiated papillary mesothelioma (WDPM)- like and cribriform growth patterns in otherwise unequivocally invasive, tubulo-papillary-predominant epithelioid malignant pleural mesothelioma (MPM) is recognised in clinical practice, but their prognostic impact is largely uncertain. We hypothesise they modify prognosis as secondary patterns. **Method:** We retrospectively reviewed the tubulo-papillary-predominant, invasive epithelioid MPM (n=269) as a subset of 614 consecutive epithelioid MPM diagnosed at our institution over a 15-year period. The diagnostic criteria for WDPM-like and cribriform patterns were inferred from those of canonical WDPM and lung adenocarcinoma. Survival analysis was performed using Kaplan-Meier method. **Result:** We identified 10 cases of tubulo-papillary-predominant epithelioid exhibiting WDPM-like pattern, and one case being predominantly WDPM-like (Estimated incidence 4.1%). They are associated with significantly prolonged median overall survival (78.7 months vs. 18.0 months, p=0.001). On the other hand cribriform neither as predominant (n=9, 3.3%, p=0.672) or secondary growth patterns (n=46, 17.1%, p=0.952) achieved statistical significance in univariate setting compared with tubulo-papillary epithelioid MPM without such pattern.





Conclusion: We propose tubulo-papillary-predominant epithelioid MPM with WDPM-like features as a rare and favourable prognostic group. Further molecular analysis is planned. Cribriform pattern does not appear to be prognostically relevant. We recommend external validation of our findings for both growth patterns.

P1.06-09 PROPHYLACTIC IRRADIATION OF TRACTS IN PATIENTS WITH MALIGNANT PLEURAL MESOTHELIOMA: A SYSTEMATIC REVIEW AND META-ANALYSIS

Y.Y. Soon, B. Vellayappan, C.N. Leong, W.Y. Koh, J. Tey, I.W.K. Tham

National University Cancer Institute, Singapore/Singapore

Background: The role of prophylactic irradiation of tracts (PIT) to prevent tumour seeding at the site of a diagnostic or therapeutic intervention in patients with malignant pleural mesothelioma (MPM) is controversial. This study aimed to determine the efficacy of PITs in preventing procedure tract metastases (PTM) after a procedure in MPM. **Method:** We searched biomedical literature databases and conference proceedings for randomized trials (RCTs) comparing PIT with no PIT in patients who had a chest wall procedure for MPM. We assessed the methodologic quality of individual RCT using the Cochrane Risk of Bias Tool. Meta-analysis was performed using a random effects model. Heterogeneity was assessed using the I^2 values. We used the GRADE approach to assess the quality of the overall evidence. The outcomes of interest were incidence of PTM and time to PTM. **Result:** We found five RCTs including 737 patients. All RCTs have low to unclear risk of bias in their methodologic quality. PIT was associated with a statistically non-significant reduction in the risk of PTM development (risk ratio (RR) 0.67, 95% confidence interval (CI) 0.35 to 1.28, P value (P) = 0.23, I^2 = 43%, GRADE: Moderate quality) and delay in the time to PTM development (hazard ratio (HR) 0.67, 95% CI 0.42 to 1.03, P = 0.07, I^2 = 0%, GRADE: Moderate quality). Limiting the meta-analysis to the two largest contemporary trials demonstrated that PIT significantly reduced the risk of PTM development (RR 0.58, 95% CI 0.37 to 0.92, I^2 = 0%, GRADE: High quality) and delay the time of PTM development (HR 0.60, 95%CI 0.37 to 0.99, I^2 = 0%, GRADE: High quality). **Conclusion:** Summation of contemporary evidence suggests that prophylactic irradiation of tracts can prevent or delay procedure tract metastases, and should be considered in patients with malignant pleural mesothelioma.

P1.06-10 18F-FDG PET/CT IN MALIGNANT PLEURAL MESOTHELIOMA: DIAGNOSTIC/PROGNOSTIC PERFORMANCE AND CORRELATION WITH PATHOLOGICAL RESULTS

F. Lococo[1], O. Rena[2], F. Torricelli[1], A. Filice[1], T. Di Stefano[1], C. Rapicetta[1], C. Coruzzi[1], R. Boldorini[2], A. Ciarrocchi[1], A. Versari[1], M. Paci[1]

[1]*IRCCS-Arcispedale Santa Maria Nuova, Reggio Emilia/Italy,* [2]*University of Eastern Piedmont Novara, Italy, Novara/Italy*

Background: While the role of [18]F-FDG-PET/CT-scan in the staging of malignant pleural mesothelioma (MPM) is almost validated, the diagnostic and prognostic performance of this tool is not clearly established. The aims of this study were: 1) to evaluate the detection rate of [18]F-FDG PET/CT-scan and identify possible factors causing false-negative (FN) results 2) to explore the relationship between radiometabolic findings, pathological features and survival results. **Method:** From 01/09 to 07/18, among all 210 MPM-patients observed and treated in 2 high-volume Institutions, we retrieved the clinical, radiometabolic and pathological aspects of 141 cases who underwent [18]F-FDG PET/CT-scan during the diagnostic work-up examination. The Fisher-test was used to test dissimilarities in the prevalence of categorical variables and Cox-model to evaluate overall survivals differences. **Result:** Mean age and male/female ratio were 70.5±7.8 and 3:1, respectively. The mean FDG-SUVmax was 8.1 (SD±5.1); the overall detection rate was 88.3% with 16 patients (11.6%) presented with SUVmax<2.5 ("PET-negative"). The distribution of clinic-pathological variables according to PET-status was reported in Figure 1. PET-negative cases are more frequently observed in older patients (p=0.027) and early stage tumors (FN at 33.3% in Stage I and FN at 40.0% in T1-tumors, both p=0.014). SUVmax values were higher in sarcomatoid (11.8±4.6) and biphasic (mean 9.3±7.0) than in epitheliod (6.9±3.8) tumors (p<0.001). Concerning long-term survivals, we found that among with Stage (p=0.032) and histology (p=0.014), the FDG metabolic uptake (SUVmax values both as continuos and cathegorical variable) was a prognostic factor as confirmed at multivariable analysis (H.R.:2.65,C.I.:1.23-5.70,p<0.001; see Figure 2).

Conclusion: Despite MPMs have an aggressive biological behavior, a low metabolic uptake at ^{18}F-FDG PET/CT-scan may be observed in part of them (about 12% in our cohort), especially in early-stage tumors occurring in elderly patients. High SUVmax value correlates with locally-advanced stage and non-epitheliod MPMs and is associated with a worse prognosis.

P1.06-11 OVERLAPPING IMMUNOPHENOTYPES BETWEEN MESOTHELIOMA AND ANGIOSARCOMA: USEFULNESS OF CLAUDIN-5 IN THE DIFFERENTIAL DIAGNOSIS

Y. Nakashima[1,2], K. Inamura[1], H. Ninomiya[1], S. Kirimura[2], M. Kobayashi[2], K. Okubo[2], Y. Ishikawa[1]

[1]*The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo/Japan,* [2]*Tokyo Medical and Dental University, Tokyo/Japan*

Background: Differential diagnosis between mesothelioma and angiosarcoma remains challenging because of their overlapping morphological and immunohistochemical phenotypes. Angiosarcoma may show both epithelioid and sarcomatoid morphology and is occasionally a cytokeratin-expressing tumor as with mesothelioma. Generally, endothelial markers are always expressed by angiosarcoma but not by mesothelioma; however, a subset of mesothelioma expresses endothelial markers, making the usefulness of these markers limited. Currently, little information is available about the immunoreactivity of mesothelioma to endothelial markers. Therefore, we investigated immunoreactivities of mesothelioma and angiosarcoma to endothelial markers and sought to identify a useful marker in their differential diagnosis. **Method:** We enrolled 147 cases of pleural mesothelioma, comprising 93 epithelioid, 25 biphasic, and 29 sarcomatoid subtypes. For comparison, we used 41 cases of angiosarcoma occurring in various organs. Using a tissue block showing the representative morphology, the expressions of endothelial (CD31, CD34, factor-VIII, ERG, and claudin-5) and of mesothelial markers (calretinin, WT-1, CK5/6, and EMA) were evaluated by immunohistochemistry. **Result:** Calretinin and WT1 were expressed in 82.2% (120/146) and 82.9% (116/140) cases of mesothelioma, respectively. Among the three subtypes of mesothelioma, the immunoreactivity of sarcomatoid mesothelioma to calretinin was relatively low with the positivity of 48.3% (14/29). Calretinin was expressed in none of the angiosarcoma cases (0/41), whereas WT-1 was expressed in 4.9% (2/41) cases of angiosarcoma. Conventional endothelial marker (CD31, CD34, factor VIII, and ERG) were expressed in 10.3% (15/146), 3.5% (5/142), 3.4% (5/146), and 29.1% (39/134) cases of mesothelioma, respectively. The immunoreactivities of sarcomatoid mesothelioma to conventional endothelial markers were relatively high with the positivity of 31.0% (9/29) for CD31, 7.1% (2/28) for CD34, 10.7% (3/28) for factor VIII, and 56.0% (14/25) for ERG. Claudin-5 expression was observed in all the angiosarcoma cases (36/36), but in none of the mesothelioma cases (0/138). **Conclusion:** We showed overlapping immunophenotypes between mesothelioma and angiosarcoma. Endothelial markers, except for claudin-5, were more frequently expressed than expected by mesothelioma, especially by sarcomatoid mesothelioma. High sensitivity and specificity of claudin-5 in the distinguishment of angiosarcoma from mesothelioma suggest the usefulness of this marker, indicating that claudin-5 should be included in a panel of immunohistochemical markers in the differential diagnosis between mesothelioma and angiosarcoma.

Background: Malignant pleural mesothelioma (MPM) is a tumour with dismal prognosis. Chemotherapeutic treatment with pemetrexed combined with cisplatin shows unsatisfying response-rates of 40%. The reasons for the rather poor efficacy remain largely unknown. However, it is conceivable that DNA repair mechanisms lead to an impaired therapy response. We hypothesize a major role of homologous recombination (HR) for genome stability and survival of this tumour. Therefore, we analysed expression levels of genes compiled under the term "BRCAness". An inhibition of this pathway with olaparib might abrogate this effect and induce apoptosis. **Method:** We evaluated the response of three MPM cell lines and lung fibroblasts, serving as a control to treatment, with pemetrexed, cisplatin and olaparib. Furthermore, we aimed to find correlations between response and gene expression patterns associated with BRCAness phenotype. Therefore, 91 clinical MPM samples were digitally screened for gene expression patterns of HR members. **Result:** We observed a BRCAness-dependent increase of apoptosis and senescence during olaparib-based treatment of BRCA-associated-protein 1 (*BAP1*)-mutated cell lines. The gene expression pattern identified could be found in approx. 10% of patient samples. Against this background, patients could be grouped according to their defects in the HR system. Gene expression levels of Aurora Kinase A (*AURKA*), *RAD50* as well as DNA damage-binding protein 2 (*DDB2*) could be identified as prognostic markers in MPM. **Conclusion:** Defects in HR compiled under the term BRCAness are a common event in MPM. The present data may improve the understanding of underlaying cellular mechanisms and open new possibilities for modern therapeutic approaches for this severe disease. Response to *Poly (ADP-ribose)-Polymerase* (*PARP*)-Inhibition could be demonstrated in the *BAP1*-mutated NCI-H2452 cells, especially when combined with cisplatin. This combination therapy might be effective for up to 2/3 of patients, promising to enhance patients' clinical management and outcome.

P1.06-13 TREATMENT PATTERNS AND OUTCOMES IN ADVANCED MALIGNANT PLEURAL MESOTHELIOMA: SURVEILLANCE, EPIDEMIOLOGY, AND END RESULTS DATA

M. Daumont[1], E. Nwokeji[2], D. Lubeck[3], M. Gleeson[3], J. Penrod[1], M. Danese[3]

[1]*Bristol-Myers Squibb, Princeton/United States of America,* [2]*McKesson Life Sciences, The Woodlands/United States of America,* [3]*Outcomes Insights, Westlake Village/United States of America*

Background: Malignant pleural mesothelioma (MPM) is a rare neoplasm with poor prognosis. With only one approved systemic treatment (Tx) for advanced disease in first-line (1L), pemetrexed with a platinum agent, the objective of this study is to understand patterns of care and overall survival (OS). **Method:** This retrospective cohort study using Surveillance, Epidemiology, and End Results (SEER) data linked with Medicare claims included patients aged ≥ 66 years with a primary diagnosis (Dx) of MPM between 2007–2013 (followed through 2014). Treated patients who received chemotherapy as 1L within 90 days of Dx, second-line (2L), or third-line (3L) therapy were identified. We used Kaplan-Meier product limit estimator for OS. **Result:** Of 1556 patients with MPM, 666 had advanced MPM. Of patients with advanced MPM, 82% were male, 87% white, 78% had AJCC Stage IV, and 70% had no mobility limitation indicators (eg oxygen tank use) at Dx. Chemotherapy for advanced MPM was received by 262 (39%) patients in 1L, 106 (16%) in 2L, and 29 (4%) in 3L. Of 1L patients, 209 (80%) received standard of care (SOC) pemetrexed with platinum (other 1L regimens included pemetrexed monotherapy; gemcitabine and vinorelbine). Of the 209 patients, 41% (n = 86) initiated 2L therapy, of whom 26% (n = 22) initiated 3L. Within 90 days of Dx, 52% of patients visited an emergency department, 78% were hospitalized, and 21% had hospice care. Common 2L therapies were gemcitabine and pemetrexed (alone or in combination); 3L regimens included vinorelbine and gemcitabine. Median OS for all patients was 7.2 months and 10.7 months for 1L (table). Unadjusted OS and Tx Duration

Cohort*	N	Median OS (months; 95% CI)	1-Year Survival (95% CI)	2-Year Survival (95% CI)	Median Tx Duration (days; IQR)
Dx	666	7.2 (6.6–8.2)	0.34 (0.30–0.38)	0.14 (0.11–0.17)	NR
1L	209	10.7 (9.6–12.0)	0.43 (0.36–0.50)	0.15 (0.11–0.22)	84 (42–136)
2L	86	5.3 (4.0–7.0)	0.22 (0.14–0.33)	0.04 (0.01–0.13)	55 (33–102)
3L	22	4.9 (3.8–7.3)	NR	NR	52 (24–77)

*1L, 2L, 3L include only 1L pemetrexed + platinum

Conclusion: This study highlights the significant unmet need in advanced MPM. Low Tx rates and poor overall survival were observed for all patient groups, suggesting patients may benefit from additional tx options.

P1.06-14 POSTERIOR INTERCOSTAL LYMPH NODE POSITIVITY AS A PROGNOSTIC INDICATOR OF OVERALL SURVIVAL IN RESECTABLE MALIGNANT PLEURAL MESOTHELIOMA

A. Hossain[1], J. Chen[2], A. Iddings[1], S. Bathini[1], T. Khashab[3], M. Culligan[3], P. Mohindra[2], K. Scilla[1], C. Rolfo[1], J. Friedberg[3]

[1]*University of Maryland Medical Center, Baltimore/United States of America,* [2]*University of Maryland School of Medicine, Baltimore/United States of America,* [3]*University of Maryland Medical Center, baltimore/United States of America*

Background: Posterior intercostal lymph nodes (PICLN), located between posterior ribs and near the spine, are characterized as N1 disease and not typically sampled in resectable malignant pleural mesothelioma (MPM). It has been noted that positive PICLN were associated with decreased overall survival (OS), suggesting their proposed characterization as N2 disease. We seek to validate their significance in an independent patient cohort. **Method:** This single institution retrospective study included 43 MPM patients who underwent surgery, largely extended pleurectomy/decortication, from March 2015 to February 2019. During surgery, accessible PICLN were sampled for pathologic testing. Patients' demographic information, clinical history, and surgical pathology were collected via review of medical records after IRB approval. To examine associations between OS and number of PICLN, Pearson correlation coefficients were performed. Survival analysis was performed using log-rank test and Cox regression model. **Result:** Patient demographics and clinical characteristics are described in Table 1. Pathologic positivity of PICLN was significantly associated with stage (Fisher exact P=0.006). 11.6% of patients demonstrated disease in all sampled PICLN (all positive PICLN) and 4.6% of patients presented with solely PICLN involvement. Compared to patients with no nodal involvement, patients with all positive PICLN were associated with a shorter overall survival (p=0.08). In a Cox regression model that adjusted for stage, all positive PICLN were associated with an increased risk of death (HR=3.13, P=.048), while the presence of any positive PICLN was not significant (HR=2.03, p=0.23).

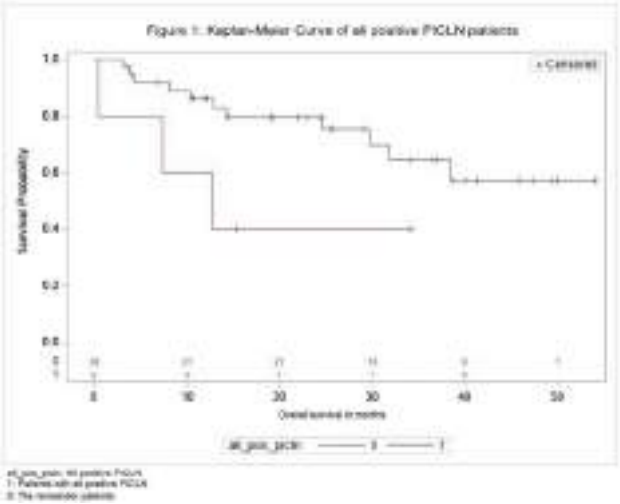
1. Chemotherapy: patient had any pre-surgery, post-surgery, or additional therap
2. Additional chemotherapy: After the post-surgery chemotherapy, some patients chemotherapy. Generally, it is a 2nd or 3rd line therapy, immunotherapy, or targ
3. Radiation therapy: Patient had either X-ray radiation therapy, proton therapy,

* Clinical staging is based on International Association for the Study of Lung Cancer the TNM classification for malignant pleural mesothelioma



Conclusion: In addition to validating the negative prognostic impact of PICN, our analysis suggests that survival may be more so dependent on the degree of PICLN involvement than positivity itself. However, given the limited number of patients with solely PICLN positive lymph nodes, the role of PICLN as an independent prognosticator cannot be confidently determined and larger studies are needed.

P1.06-15 SAFETY OF IRRADIATION COMBINED WITH INTRACAVITARY CISPLATIN-FIBRIN AFTER LUNG-SPARING SURGERY IN A RAT MODEL OF MESOTHELIOMA

O. Lauk, M. Kirschner, M. Meerang, K. Furrer, I. Grgic, V. Orlowski, F. Tschanz, M. Pruschy, I. Schmitt-Opitz

University Hospital Zurich, Zurich/Switzerland

Background: To investigate feasibility and toxicity of new localized therapeutic treatment combinations for malignant pleural mesothelioma (MPM), we performed lung-sparing surgery followed by cisplatin-fibrin application and hemithoracic irradiation in an orthotopic immunocompetent rat model of MPM. **Method:** Male F344 rats (n=9) were implanted sub-pleurally (parietal pleura) with 1 million rat mesothelioma cells (IL45-luciferase). Formed tumor nodules confirmed by IVIS bioluminescence imaging (BLI) were resected on day 9 after implantation. Following resection, animals were treated with local-intracavitary cisplatin-fibrin or placebo (NaCl-fibrin). Three days later, CT guided local irradiation of the former tumor region, resembling IMRT in human patients, was performed. Irradiation was given in a single high dose application using the image-guided stereotactic small animal irradiation X-RAD SmART (small animal radiotherapy) and image guided biological irradiator PXi (precision X-Ray) with precise localization. Treatment schemes after tumor resection were as followed: i) Intracavitary cisplatin-fibrin application (n=2) ii) Irradiation with 10 Gy (n=2) iii) Irradiation with 20 Gy (n=1) iv) Intracavitary cisplatin-fibrin plus 10 Gy radiotherapy (n=2) v) Intracavitary cisplatin-fibrin plus 20 Gy radiotherapy (n=2) Wellbeing of the animals was monitored daily until the predefined termination criteria were reached. Particular attention was given to possible irradiation toxicity related pulmonary side effects and weight loss. **Result:** We successfully treated 1-2 animals per group according to the methods above. The irradiation was performed after visualization of the tumor with BLI- and CT-imaging to ensure an individual treatment plan. None of the animals, whether with radiotherapy alone or in combination with cisplatin-fibrin application, showed any signs of pulmonary side effects. In addition, none had reduced pulmonary functions, measured by increased breathing or the appearance of blue or white colored ear/extremities/eyes assuming desaturation. Furthermore, neither significant body weight loss of ≥ 15%, deterioration of body conditioning score nor of the activity score were observed in the immediate post-interventional phase. In all animals, termination endpoint was reached because of tumor relapse. **Conclusion:** In this pilot study, we have shown that irradiation alone and in combination with local intracavitary cisplatin-fibrin application in rats is safe and feasible up to a dosage of 20 Gy. The efficacy of the various treatment schemes and a possible radio-sensitizing effect by intracavitary cisplatin is currently being evaluated in the same animal model.

Keywords: malignant pleural mesothelioma, intracavitary therapy, irradiation

P1.06-16 MOLECULAR SIGNATURE IN MALIGNANT PLEURAL MESOTHELIOMA (MPM). PRELIMINARY DATA OF RAMES STUDY

M. Pagano[1], F. Zanelli[1], R. Gnoni[1], C. Bonelli[1], M. Tiseo[2], G. Pasello[3], F. Grosso[4], M. Garassino[5], H. Soto Parra[6], P. Zucali[7], C. Giovanni Luca[8], F. Torricelli[1], A. Ciarrocchi[1], M. Larocca[1], M. D'Arcangelo[9], C. Pinto[1]

[1]*AUSL-IRCCS Reggio Emilia, Reggio Emilia/Italy,* [2]*Azienda Ospedaliero-Universitaria di Parma, Parma/Italy,* [3]*IRCCS, Padova/Italy,* [4]*Mesothelioma Unit, SS Antonio e Biagio General Hospital, Alessandria/Italy,* [5]*INT, Milano/Italy,* [6]*UOC, Catania/Italy,* [7]*UO Humanitas Cancer Center-IRCCS, Rozzano/Italy,* [8]*Humanitas Gavazzeni, Bergamo/Italy,* [9]*Department AUSL Romagna-Ravenna, Ravenna/Italy*

Background: MPM is an uncommon cancer with limited therapeutic options and poor clinical outcomes. The relative rarity of these tumor has limited the identification of MPM-driver molecular as well as the development of specific drugs **Method:** RAMES study evaluated the second-line efficacy of gemcitabine/ramucirumab treatment vs. gemcitabine/placebo. From December 2016 to July 2018 (end of enrolment), 164 patients (pts) were admitted to this study. We evaluated by NGS the mutational profile of a panel of 34 genes (ACTB, ACTG1, ACTG2, ACTR1A, BAP1,CDH8, CDK4, CDKN2A, CDKN2B, COL3A1, COL5A2, CUL1, DHFR, GOT1, KDR, KIT, MXRA5, NF2, NFRKB, NKX6,-2, NOD2, PCBD2, PDZK1IP1, PIK3CA, PIK3CB, PSMD13, RAPGEF6, RDX, SETDB1, TAOK1, TP53,TXNRD1, UQCRC1, XRCC6). We reported the results of the first 87 pts (54%): hystotype was epithelioid in 70 pts (80%), biphasic in 14 pts (16%) and sarcomatoid in 3 pts (4%). Median age was 63 years (range 45-81). 70 pts were male (80%) and 17 pts were female (20%). In the present analysis, we included 55 pts in stage III (63%), 26 pts in stage IV (30%) and 6 pts whose stage was unknown. Median first-line PFS platinum/pemetrexed therapy was for 5.75 months (I.C. 95% 4.75-6.76). PFS was ≤6 months for 40 pts (49%), and 6 months for 41 pts (51%). **Result:** 187 functional somatic mutations were identified. Genomic alterations/patient were 1 gene in 29 pts (33%), 3 genes in 18 pts (21%) and ≥5 genes in 2 pts (2%). The most frequent somatic mutations were *RDX in 35 pts (40%), MXRA5 in 20 pts (23%), BAP1 in 13 pts (15%) and ACTG 1 in 9 pts (11%). When patients were collated by stage, the most frequent mutations were*: MXRA5 in 16 pts in stage III (29%), BAP1 in 5 pts in stage IV (19%) and RDX in 16 pts in stage IV (62%). The percentage of somatic mutations in patients with PFS as first-line chemotherapy for ≤6 and >6 months was 2.2 and 1.6 (p=0.032), respectively. The most frequent mutations/patient for ≤6 and >6 months PFS were: RDX in 14 pts (35%) with PFS ≤ 6, RDX in 19 pts (46%) with PFS >6 and MXRA5 in 11 pts (27%) with PFS >6. **Conclusion:** This preliminary data suggests a possible role that a genetic signature may play in distinguishing MPM with different clinical-pathological features. *The results are expected to be clarified further in the second step of the study, which is ongoing.*

P1.06-17 TUMOR TREATING FIELDS (150 KHZ) COMBINED WITH CISPLATIN OR PEMETREXED INHIBITS MESOTHELIOMA CELLS IN VITRO AND IN VIVO

M. Munster[1], K. Gotlib[1], R. Schneiderman[1], Y. Porat[1], T. Voloshin[1], S. Davidi[1], A. Shteingauz[1], N. Kaynan[1], E. Zeevi[1], M. Giladi[1], E. Kirson[1], U. Weinberg[1], A. Kinzel[2], Y. Palti[1]

[1]*Novocure Ltd, Haifa/Israel,* [2]*Novocure GmbH, Munich/Germany*

Background: Malignant pleural mesothelioma (MPM) is an aggressive thoracic cancer mostly linked to asbestos exposure. The standard of care (SOC) therapy for unresectable MPM is cisplatin plus pemetrexed. Tumor Treating Fields (TTFields) therapy is an effective anti-neoplastic treatment modality delivered via noninvasive application of low intensity, intermediate frequency, alternating electric fields. We explored the potential use of TTFields alone and in combination with SOC as a treatment for MPM. **Method:** NCI-H2052 and MSTO-211H cells were treated at various TTFields frequencies for 72 hours using the inovitro system. The combined treatment of TTFields and cisplatin or pemetrexed was tested by applying TTFields at the optimal frequency together with various drug concentrations. Cell counts, clonogenic potential and induction of apoptosis were determined. TTFields (1.2 V/cm, 150 kHz) were applied for 8 days to rats injected to the intrapleural cavity with IL-45 cells, and overall survival was tested. TTFields (2-3 V/cm) were applied to the torsos of Sprague-Dawley rats at 150 kHz for 2 weeks and all major internal organs were histologically compared. **Result:** TTFields optimal frequency was 150 kHz for both human cell lines. TTFields application (1.1 V/cm, 72 hours) at 150 kHz led to 45%-51% reduction in cell counts and 46%-64% additional reduction in clonogenic potential. The combined treatment of TTFields and cisplatin or pemetrexed led to a significant reduction in cell count, induction of apoptosis, and reduced clonogenic potential as compared to each modality alone (p<0.0001(. TTFields significantly prolonged the survival of rats compared to control group. Histological analysis did not reveal any increase in pathological findings with 150 kHz TTFields applied to the rat torso. **Conclusion:** These results demonstrate that TTFields are a potentially effective and safe treatment for mesothelioma. The combination of TTFields with cisplatin or pemetrexed further enhances treatment efficacy. These preclinical data are consistent with those reported in a recent MPM phase 2 study (STELLAR; EF-23 trial, NCT02397928), which showed improved overall survival for combined treatment with TTFields plus pemetrexed and a platinum agent compared with historical control data, with no increase in systemic toxicity. The combination of TTFields with pemetrexed or cisplatin may further enhance treatment efficacy in mesothelioma.

P1.06-18 MICRORNA EXPRESSION IS LINKED TO RESPONSE OF MALIGNANT PLEURAL MESOTHELIOMA TO CISPLATIN-PEMETREXED CHEMOTHERAPY

Y. Zhang[1], V. Orlowski[2], B. Vrugt[2], M. Friess[2], W. Weder[2], I. Schmitt-Opitz[2], M. Kirschner[2]

[1]*The 2nd Hospital of Jilin University, Jilin/China,* [2]*University Hospital Zurich, Zurich/Switzerland*

Background: Treatment of malignant pleural mesothelioma is difficult due to a high intrinsic drug resistance of these tumors. Currently, platinum-based chemotherapy represents the backbone of MPM treatment. However, only approximately 40% of patients respond to this therapy, and true predictors for response have yet to be identified. Towards this end, we here investigate the expression of microRNAs in responders and non-responders to chemotherapy. **Method:** FFPE tumour samples were available from 32 MPM patients, who showed either partial response (PR, N=21) or progressive disease (PD, N=11) following 3-4 cycles of cisplatin-pemetrexed chemotherapy. RT-qPCR based microRNA profiling was performed on chemo-naïve tissue of 5 PD and 5 PR patients using TaqMan Low Density Arrays (TLDAs, Thermo Fisher), which cover the expression of 754 microRNAs. Candidate microRNAs with differential expression ($P \leq 0.05$ Mann-Whitney Test) were then measured in the remaining samples using microRNA-specific RT-qPCR. Expression of these microRNAs was also assessed in post-chemotherapy specimens (obtained during extrapleural pneumonectomy) and compared to that in chemo-naïve samples. In addition, for two candidates, preliminary *in vitro* experiments investigating the effect of microRNA overexpression (transfection with microRNA mimics) on cell growth were performed. **Result:** TLDA-based profiling identified 35 microRNA with differential expression between patients with PD and PR following cisplatin-pemetrexed chemotherapy. The majority of these microRNAs showed higher expression in patients who showed no reponse to therapy. In an initial step, 8 candidates identified from the profiling (miR-145, miR-193a-3p, miR-30a-3p, miR-24, miR-380-5p, miR-494, miR-625-3p, miR-221-3p) were further evaluated in additional 16 PR and 6 PD samples. This confirmed a trend towards differential expression for miR-145 (p=0.08). Interestingly, when comparing expression pre- and post-chemotherapy, levels of miR-145 significantly decreased in patients with PD, while they remained stable in PR. Lack of validation of other microRNAs could be the result of the low number of cases with PD in this preliminary validation set, and additional samples will included. For miR-221-3p and miR-380-5p, preliminary analysis *in vitro* showed that overexpression in established MPM cell lines results in an increased sensitivity towards cisplatin. **Conclusion:** Taken together, our data show that several microRNAs show trends towards differential expression between responders and non-responders to chemotherapy. Overall, higher expression appears to be linked to PD under cisplatin-pemetrexed, however further in-depth investigations are required. Furthermore, preliminary *in vitro* data suggest that altering expression of specific microRNAs has the potential to increase sensitivity of MPM to chemotherapy.

P1.06-19 REGIONAL MESOTHELIOMA MULTIDISCIPLINARY TEAM MEETINGS: PERSPECTIVES FROM A UK CARDIOTHORACIC TERTIARY CENTRE

K. Slaven

Royal Papworth Hospital, Cambridge/United Kingdom

Background: The 2018 British Thoracic Society Guideline for the Management of Pleural Mesothelioma recommend that discussion at Specialist Mesothelioma Multidisciplinary Team (MDT) Meeting 'may improve diagnostic accuracy and recruitment to clinical trials', and that all cases of mesothelioma should be 'referred to a regional mesothelioma MDT'. Royal Papworth Hospital is a tertiary centre situated in Cambridgeshire and is home of the Mesothelioma Centre for the East of England. February 2018 saw the emergence of the weekly Regional Mesothelioma MDT. **Method:** Data from MDT minutes, recorded on an electronic database, from the first year (01.02.2018-31.01.2019) was compared with the targets set by the 2018 National Mesothelioma Audit. Information collected included clinical trials consideration, TNM stage, ECOG performance status, referring hospital, age, histological subtype, asbestos exposure and gender. **Result:** 160 discussions took place concerning 93 patients. Median age 71yrs (range 45-92). 84(90%) had documented occupational asbestos exposure. 9(10%) female. Referrals from distant district general hospitals were more evident. Histological subtype was recorded for all patients who had a biopsy. Second opinion histology was reviewed; no diagnosis overturned. 9(10%) patients had a clinical radiological diagnosis of mesothelioma confirmed. Patients were referred for discussion for various reasons including confirmation of diagnosis, suggested disease management, consideration of trials, and for second/'specialist' opinion.

	National Mesothelioma Audit Standard %	Royal Papworth Regional Mesothelioma MDT %
Performance status	90	92
Staging score (TNM for pleural mesothelioma)	90	100
Discussion at MDT	95	100
Confirmed pathology	95	100
PS 0/1 patients considered for clinical trials		100

Conclusion: Prior to the Regional Mesothelioma MDT, patients were discussed within the lung cancer MDT. The Regional Mesothelioma MDT provides opportunity for discussion among experts who see more than 30 mesothelioma patients each year. More patients are being referred from the local and distant district general hospitals. The hope is that this offers equitable care, treatment and access to clinical trials for all patients with mesothelioma. Future work will look at short and long term outcomes for these patients. *Thank you to the Royal Papworth Hospital Mesothelioma MDT for their support with this abstract.*

Keywords: Mesothelioma, MDT, Audit

P1.06-20 MALIGNANT PLEURAL MESOTHELIOMA: SURVIVAL META-ANALYSIS FROM 15 YEARS OF A STANDARD SYSTEMIC THERAPY

J. Friedberg, M. Culligan

University of Maryland Medical Center, baltimore/United States of America

Background: Malignant pleural mesothelioma is a rare malignancy with an annual incidence of 3,000 cases in the US and is still considered incurable. The standard of care for this cancer, a combination of pemetrexed and a platinum drug, was established in 2003 as the result of a landmark study that reported a median overall survival of 12.1 months for this combination in patients not eligible for surgery. The aim of the current analysis was to determine if there has been a change in the outcome for this population in the past 15 years. **Method:** A PubMed search was performed and 9 prospective, randomized or single arm (minimum n=50), trials were selected. All studies included patients treated using pemetrexed in combination with platimun as front line therapy in unresectable mesothelioma patients. Average and weighted average OS were calculated and also corrected per the reported odds ratio for survival between the epithelioid and non-epithelioid histologies. **Result:** The average OS was 12.9 months and the weighted average OS was 13.3 months (range: 8.5 – 16.1 months). The two studies showing the highest median OS (MAPS and LUME-meso) had a higher percentage of tumors with epithelioid histology, which could explain their favorable outcome. Adjusting the average OS using the reported odds ratios for survival between epithelioid and non-epithelioid histologies eliminated the superior outcome in these studies. Furthermore, correcting average survival per the original ratio between tumor histologies for all studies included in the meta-analysis showed an average and weighted average OS lower than 13 months. **Conclusion:** This analysis strongly supports the contention that survival results for nonoperative patients with mesothelioma should be stratified by histology, epithelioid versus nonepithelioid, similar to the trend in the surgical mesothelioma literature. When factoring in histology, it appears that overall advances in patient care and additional treatments have not significantly changed the overall survival for nonoperative mesothelioma patients in the last 15 years. This meta-analysis underscores the desperate need for new and innovative treatments for this cancer.

Keywords: Survival Meta-analysis in Malignant Pleural Mesothelioma, Survival of Standard Systemic Therapy in Mesothelioma

P1.06-21 SAFETY META-ANALYSIS OF CLINICAL TRIALS DELIVERING TUMOR TREATING FIELDS TO THE UPPER TORSO

G.L. Ceresoli[1], M. Pless[2], U. Weinberg[3]

[1]*Cliniche Humanitas Gavazzeni, Bergamo/Italy,* [2]*Chefarzt Medizinische Onkologie, Winterthur/Switzerland,* [3]*Novocure, Haifa/Israel*

Background: Tumor Treating Fields (TTFields), a non-invasive, loco-regional, antimitotic treatment approved for glioblastoma (GBM), are delivered via transducer arrays to tumor region. Localized dermatitis underneath the arrays were main adverse events (AEs) reported in phase 3 GBM trials. The safety of TTFields was analyzed in phase I and II studies in non-small-cell lung cancer (NSCLC) [EF-15, NCT00749346] and malignant pleural mesothelioma (MPM) [STELLAR, NCT02397928]. **Method:** TTFields studies in this pooled analysis were EF-15 (n=41, advanced NSCLC; plus pemetrexed) and STELLAR (n=80, MPM; plus platinum and pemetrexed). TTFields were applied 12 - 18 hours/day at a frequency of 150 kHz. All patients received standard of care systemic chemotherapy for their disease in addition to TTFields. Severity and frequency of AEs, and association with TTFields treatment were evaluated (CTCAE criteria version 4.0). **Result:** Patients were aged 27-78 years: STELLAR: 67 (27-78) and EF-15: 63 (44-78), ECOG 0-1; 7 patients in EF-15 had ECOG 2. The incidence of grade 1-2 gastrointestinal (GI) toxicities was 35%. The most common low grade GI toxicities were: nausea (17%), vomiting (6%), constipation (10%) and diarrhea (6%). Grade 1-2 general disorders (16% fatigue and 11% asthenia) were common. Dyspnea Grade 1-2 (12%) and Grade 3-4 (5%) were considered related to standard chemotherapy or underlying disease. Grade 1-2 cardiovascular AEs were 7%; one case of severe arrhythmia (atrial flutter) was unrelated to TTFields. The only common TTFields-related adverse event was dermatitis below the transducer arrays. 59% patients had dermatological AEs: 53% Grade 1-2 dermatitis, 4% grade 3 dermatitis and 11% Grade 1-2 pruritus. **Conclusion:** Treatment of solid tumors with TTFields 150 kHz to the thorax did not result in serious AEs or treatment-related pulmonary, cardiac, hematological or gastrointestinal toxicities. Expected dermatological toxicity beneath the device transducer arrays was seen in 59% patients, and resolved after a short treatment break or termination of treatment. These safety results and encouraging survival outcomes support the potential use of TTFields therapy in NSCLC and mesothelioma.

Keywords: Safety meta-analysis of Tumor Treating Fields, Safety Tumor Treating Fields in NSCLC and Mesothelioma, TTFields in lung cancer

P1.06-22 PATHOLOGIC AND IMAGING RESPONSE CORRELATIONS IN PATIENTS TREATED WITH NEOADJUVANT CHEMOTHERAPY FOR MESOTHELIOMA

M. Rehman, A.C. Roden, A. Mansfield

Mayo Clinic, Rochester/United States of America

Background: In light of the emergence of neoadjuvant immunotherapy for the treatment of non-small cell lung cancer, there has been interest in developing neoadjuvant therapies with immune-checkpoint inhibitors for mesothelioma. Neoadjuvant trials allow the incorporation of pathologic responses as endpoints which have not been validated for mesothelioma. We sought to assess the correlation between pathologic and imaging responses in the neoadjuvant setting in patients with mesothelioma. **Method:** We identified patients with mesothelioma who were treated with neoadjuvant chemotherapy and underwent subsequent resection at Mayo Clinic Rochester, MN from 2000-2017. We used modified Response Evaluation Criteria in Solid Tumors (RECIST) to determine radiographic responses. Imaging response was defined utilizing modified-RECIST criteria, with response defined as either complete (disappearance of all pleural and non-pleural disease) or partial (>30% decrease) response and imaging non-response was defined as either progressive (increase in size by 20% and 5 mm from nadir) or stable (meeting criteria for neither) disease. All cases were reviewed by a thoracic pathologist (ACR) to confirm the diagnosis and to define the pathologic response, which was performed blinded to the imaging response. For the purpose of this exploratory study we defined pathologic response as percent viable tumor 50% or less and non-response as >50%. **Result:** We identified 22 patients with sufficient data and tissue available for inclusion in our study. The median age was 65 (range 48-74). There were 20 patients with epithelioid, 2 with biphasic and 0 with sarcomatoid subtypes of mesothelioma. There were 12 (55%) patients with radiographic responses and 9 (41%) with pathologic responses. Five patients had both a pathologic and imaging responses, 7 patients did not have a pathologic response but had an imaging response, 4 patients had a pathologic response without an imaging response, and 6 patients had neither a pathologic nor imaging response (χ^2= 0.0063, p=0.937). **Conclusion:** Since neoadjuvant trials have the potential to improve survival, and may be used to assess drug efficacy and accelerate drug approvals, it is important to have a unified and effective strategy to determine responsiveness of drug therapy. In our single institution, retrospective series we did not identify a significant correlation between imaging and pathologic responses which might be, at least in part, to the fact that mesotheliomas often have large areas of necrosis even without neoadjuvant therapy. Larger studies will be needed to define appropriate pathologic response endpoints in neoadjuvant trials for mesothelioma.

P1.07 NURSING AND ALLIED PROFESSIONALS
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.07-01 LUNG CANCER SUPPORT GROUPS: STILL RELEVANT IN A DIGITAL WORLD?

M. Rigney[1], K. Stein[2]

[1]*Go2 Foundation for Lung Cancer, Washington/United States of America,* [2]*Cancer Support Community, Philadelphia/United States of America*

Background: People diagnosed with lung cancer experience high levels of distress and have greater unmet emotional needs than those with other types of cancer. Historically, an important way to meet unmet social support needs has been through in-person groups, the benefits of which extend beyond psychosocial support and may include increased feelings of control and confidence and decreased depression and distress. Thirty years after the value of in-person support groups was first study documented, in a world where we can instantaneously connect with others from all over the world through a tap or swipe, are support groups still relevant? This study sought to examine overall satisfaction with and impact of in-person lung cancer support group participation on distress, loneliness, self-efficacy and overall quality of life. **Method:** Lung cancer patients, survivors and loved ones enrolled in seven in-person lung cancer-specific support groups and completed baseline questionnaires at their first group with follow-up surveys administered after six months. Validated measures assessed cancer-related distress (15-item CSS, CancerSupportSource®); loneliness (UCLA Three-Item Loneliness Scale); and group satisfaction (Helpful Group Experiences Questionnaire). Three self-efficacy questions were also included and developed specifically for this study. Qualitative data was gathered through focus groups. Statistical comparisons of baseline vs. six-month levels of cancer-related distress, loneliness and positive affect were conducted using paired-samples t-tests. **Result:** Eighty-six participants completed baseline questionnaires with 29 completing/partially completing follow-up surveys. Univariate Analyses demonstrated statistically significant decreases in total cancer-related distress but not loneliness or positive affect. Responses to self-efficacy questions showed high confidence in making treatment decisions (86%). Confidence was also high in communicating with healthcare teams and the ability to access information and resources (both 90%). Group satisfaction was high with 100% (n=27) indicating they would recommend their group to others. The highest rated group experiences included sense of belonging and receiving support and encouragement. The lowest rated experiences included feeling they had helped others and having talked about recurrence fears. **Conclusion:** These results indicate in-person support groups serve an important role in relieving distress and providing connection for people with lung cancer and their loved ones. Convenient digital support platforms like online communities and apps may help to meet the emotional needs of people some people with lung cancer and their loved ones but perhaps are not a replacement for the in-person experience of community.

P1.07-02 IMPLEMENTATION OF A HEALTH AND WELLBEING PROGRAMME IN CONJUNCTION WITH PULMONARY REHABILIATATION

J. Roberts, K. Kontou, S. Davies, T. Gray

The Rotherham NHS Foundation Trust, S Yorkshire/United Kingdom

Background: Pulmonary rehabilitation is currently provided for people who have had surgery, radical radiotherapy, SABR and/or chemotherapy in a dedicated unit called BreathingSpace. A programme has been developed to encompass all aspects of health and well being, including physical, psychological and social support to patients and carers to enhance their recovery,to improve quality of life and offer ongoing support to patients and carers living with and beyond lung cancer. A variety of social events including a choir, yoga, Tai Chi and craft courses have been developed as well as education and infomative sessions on diet, relaxation and benefits advice. Continuous smoking cessation support and advice is also available. **Method:** Patients and carers are invited to participate in the social activities provided in a stimulating environment following completion of the rehabilitation programme. Health and well being initiatives are also offered to all people following a diagnosis of lung cancer or mesothelioma if they require more support with improving breathlessness and excercise. In adddition to this, an analysis of all the local support groups and networks were identified to encourage further support and social integration for people which were not just focused on cancer. A wealth of support mechanisms were identified including Rotherham Get Active, Rotherham Carers Forum, the local football club association and numerous other social groups. **Result:** The implementation of the health and wellbeing programme is ongoing and the trial is still in progress. **Conclusion:** Following completion of the programme, participants will be offered the opportunity to become involved in other social activities dependant on their ability and performance status. Qualitative feedback and evaluations from patients and carers will be utiliised to develop the programme further.

P1.07-03 IMPROVING NON-ONCOLOGY PROVIDER KNOWLEDGE OF UNIQUE IMMUNOTHERAPY ADVERSE EVENTS

E. Esposito Nguyen

St Joseph Hospital, Orange/United States of America

Background: Immunotherapy use is increasing in frequency among oncology patients as a single treatment or in combination with other modalities. Immunotherapy related adverse events (IrAE) have unique presentations that are often overlooked or misdiagnosed outside of oncology. This IRB approved study sought to evaluate the effectiveness of microteaching on non-oncology providers' identification of IrAEs and timely initiation of definitive therapy. A second aim was to review result on patient outcomes through review of EHR. **Method:** Microteaching sessions of 10 minutes in length were scheduled. Sessions occurred before or after staff meetings, at change of shift huddles, and at the monthly ER physician meeting. The six item test pretest/posttest evaluated familiarity with immunotherapy, and identification of and appropriateness of treatment for patients with IrAEs. A paper version of the pretest was given prior to the education which was delivered to nursing in small groups consisting of 2 to10 participants. All physician participants received education at the same time. Immediately following the teaching participants completed the posttest. A retrospective review of electronic health records was conducted to determine timeliness of identification of IrAEs and appropriateness of treatment. **Result:**

All Nurses

	Pre N=129		Post N=125		
	Yes	No	Yes	No	P
Are you familiar with immunotherapy as a treatment for cancer?	53.9% (67)	46.1% (62)	96.8% (121)	3.2% (4)	<.0001
Are you familiar with national guidelines for the management of immunotherapy adverse events?	8.5% (11)	91.5% (118)	90.4% (113)	8% (10)	<.0001
Are you familiar with the intervention(s) needed to start reversing most immunotherapy adverse events?	14% (18)	86% (111)	96% (120)	3.2% (4)	<.0001

	Pre N=129		Post N=167		
	True	False	True	False	P
Immunotherapy and chemotherapy may be administered simultaneously.	52.7% (68)	45% (58)	89.6 % (112)	9.6% (12)	<.0001
Neutropenic patients who are receiving chemotherapy can be treated with steroids.	49.6 % (64)	48.1% (62)	95.2% (119)	4.% (5)	<.0001

A Phi coefficient was calculated to measure the association between pretest and posttest scores on five questions. For all RNs, all items demonstrated an increase in knowledge (p <.0001). Similarly, ER nurses demonstrated an increase in knowledge in all items (p < .0001). Conversely, oncology nurses had better baseline knowledge compared to "all" nurses. This supports the premise that within the oncology specialty, information about irAEs is better known and understood. Although oncology nurses are more prepared to identify and manage these issues, these nurses are not involved in patient care during an ER visit or admission to an ICU. Physicians also had higher baseline scores compared to all nurses, however, to the question 'are you familiar with the intervention (s) needed to start reversing most immunotherapy adverse events?' had a significant increase in knowledge following the micro-teaching in-service (p < .0001). **Conclusion:** Immunotherapy is increasing in use in oncology, as a result, non-oncology providers will progressively encounter patients receiving these agents in non-oncology settings throughout the hospital such as emergency department or ICU. Brief educational sessions were found effective in increasing non-oncology providers knowledge of these immunotherapy agents and their AEs management .

P1.07-04 EARLY LUNG CANCER TEAM INTERVENTION IN EMERGENCY ADMISSIONS

M. Ledson[1], J. Dunbar[2], A. Mciver[2], N. Maddock[2], S. Sanders[2], C. Smyth[2], M. Walshaw[2]

[1]*Liverpool Heart and Chest Hospital, Liverpool/United Kingdom,* [2]*Liverpool Heart & Chest Hospital & Royal Liverpool Broadgreen University Hospital NHS Trusts., Liverpool/United Kingdom*

Background: The Liverpool Lung Cancer Unit is a unique diagnostic service diagnosing approximately 430 patients per year. Although the majority of cases of suspected lung cancer can be managed as outpatients where the diagnostic pathway is well developed, a proportion still present unwell via the emergency department where their subsequent journey is less certain. Along with same-day reporting for emergency scans, we have developed a rapid review service for such individuals and were interested in assessing its performance. **Method:** We looked at all patients with suspected lung cancer who presented through our emergency department at The Royal Liverpool University Hospital in 2018, focussing on outcome, time to be seen following admission, and the histological diagnosis rate. **Result:** Of the 561 referrals to our lung cancer unit, 196 (35%) presented through the emergency department: 73 (37%) were discharged to outpatient cancer investigation. The remaining 123 (63%) were admitted to 26 different locations (8 medical specialities, surgical, vascular and orthopaedic wards). Of these, 72% were seen by the lung CNS within one working day and appropriate management initiated. This was aided by our live CT scan database,

where 69/79 (87%) were coded on the same day. Daily CNS checks of the database ensure early inpatient identification and review by the lung clinician and CNS, often before formal referral from the responsible clinical team is made. Overall 103 patients (84%) who presented as emergencies subsequently were diagnosed with a malignancy. 96 were diagnosed with a primary lung cancer of which 56 (58%) had histological confirmation. **Conclusion:** Our results show that, by coordinating care between the emergency and radiology departments and the lung cancer team, patients presenting unwell can be managed rapidly even if they remain in hospital. In addition, by actively seeking them out we can not only provide them with timely and appropriate investigations but also early CNS intervention, facilitating symptom management, the opportunity to maximise their performance status and offer psychological support to not only the patient but to their families as well. This approach also ensures that the managing medical teams are given the right information from a specialist team. The Lung Cancer Team resource is therefore focussed on looking after lung cancer patients and those patients that do not have cancer but are referred to the team are informed at the earliest opportunity and treatment decisions made accordingly by the team responsible for their care.

Keywords: emergency presentation, Lung cancer nurse

P1.07-05 DEVELOPING A NURSING TRIAGE TOOL TO ASSESS PATIENT SUPPORT NEEDS THROUGH TREATMENT FOR LUNG CANCER

H. Neal, M. Eaton, D. Mcentee, E. Halkyard, J. Fenemore, L. Bostock

The Christie Hospital Foundation Trust, BX/United Kingdom

Background: Improvements in treatments and outcomes within lung cancer has resulted in an increasing number of patients requiring access to appropriate support. Within a tertiary specialised centre for the treatment of lung cancer, stratification of support is required in order to target the patients with the greatest needs and identify services to sign post them to. The Lung cancer Clinical Nurse Specialists (LCNS) are developing a triage tool which uses a red, amber, green approach to stratifying need. It assesses 10 areas of patient vulnerability. On completion of the assessment, those with particular needs will be triggered by an amber or red flag. The tool will proactively identify patient need, whilst helping the LCNSs to work towards a manageble caseload. **Method:** The LCNS team had been assessing patient need through intuition, using their own criteria. The aim of the tool was to create a consistent approach to this assessment and led to the identification of key areas of patient vulnerability. Already validated tools for these key areas were incorporated into the design. A scoring system was developed against each key area and the tool was piloted on a number of patients in order to identify the boundaries of stratification. However, due to the variability in scores and inconsistent outcomes, scores were replaced with red, amber or green for each category. Any category resulting in an amber or red outcome, led to a more complex intervention. All Green Outcomes: Information pack, LCNS contact details, referral back to local CNS Any Amber Outcomes: *In addition to the 'Green' interventions*, a day 8 (of treatment) telephone consultation in nurse led clinic, Community referrals Any Red Outcomes: *In addition to the 'Green and Amber' interventions*, follow up call post initial consultation, specialist service referrals **Result:** The tool will be further piloted by the LCNSs and interventions implemented in line with the outcomes. The aim is to roll the tool out across the Greater Manchester area so that it can be used by CNSs in the District General Hospitals and will be continually used throughout the patient pathway as their needs change. The resulting assessment will be recorded on the electronic patient record and therefore will be auditable across the patient population to ensure that LCNS patient interventions are at the appropriate level to the support need. Outcome measures: - Reduced hospital admissions - Improved outcomes for patients - Patient Satisfaction through service user feedback **Conclusion:** Identifying patient need through their cancer pathway has until now been a process of intuition and individual preference by each LCNS. This triage tool, whilst not replacing clnical judgement, is designed to remove the inconsistency of assessment and create a stratified approach to patient need. This will enable appropriate allocation of resources and provide auditable data to allow service improvement and ultimately enhance the patient experience.

Keywords: Assessment Tool, Lung cancer, Clinical Nurse Specialist

P1.07-06 USE OF THE NUTRITIONAL RISK INDEX AS SCREENING FOR MALNUTRITION IN PATIENTS WITH LUNG CANCER

A. Ferreira[1], I. Gonçalves[2], G. Moreira[2], J. Vasconcellos[2], T. Montella[2], W. Peres[1], C.G. Ferreira[3]

[1]*UFRJ, Rio de Janeiro/Brazil,* [2]*Grupo Oncoclinicas, Rio de Janeiro/Brazil,* [3]*Oncoclinicas Institute, Rio de Janeiro/Brazil*

Background: Introduction: Malnutrition is a critical condition for patients with lung cancer (LC). High turnover clinics require an easy, fast and good sensitivity screening instrument. Objective: To compare Buzby's Nutritional Risk Index (NRI) tool and to correlate it with nutritional status assessment from anthropometric parameters. **Method:** ology: This is a cross-sectional study, with patients with clinical stage IV lung adenocarcinoma, followed at a reference oncology clinic in Rio de Janeiro. During the first visit, data on age, sex, current weight, usual weight, height, arm circumference (AC), triceps skinfold thickness (TST) and serum albumin were collected. To assess the nutritional status, calculations of NRI (Busby et al., 1998), body mass index (BMI), AC adequacy and arm muscle circumference (AMC) adequacy were used. Patients were classified as undernourished or undernourished. The data were analyzed through the SPSS program, version 13.0. **Result:** 23 patients participated in the study, with a mean age of 66.4 ± 11.3 years, of which 52.2% were female. The percentage of patients considered malnourished by IRN was 52.2% for IRN, 21.7% for BMI, 39.1% for CB adequacy and 26.1% for WBC adequacy. The BMI was the index that most classified individuals as without malnutrition (78.3%). When the INR was crossed with the other evaluation methods used, it was found that there was a very low degree of agreement regarding BMI (Kappa = 0,1), p <0.06. **Conclusion:** in this study IRN was more sensitive to identify inadequacy in nutritional status when compared to BMI, CB and CMB. The use of IRN in patients with lung cancer helps to identify the nutritional diagnosis early, favoring nutritional intervention and consequently the quality of life of the patient.

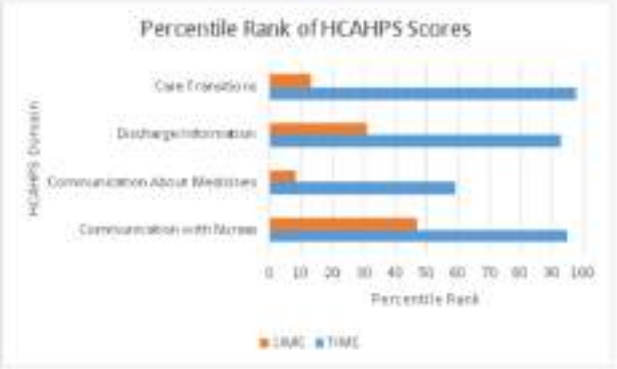
Keywords: Lung cancer, nutritional status, nutritional risk index

P1.07-07 AN INTERDISCIPLINARY COLLABORATIVE APPROACH TO DISCHARGE READINESS ON A THORACIC SURGERY SPECIALTY UNIT

S. Levy, C. Hahner, F. Carhart

Thoracic Intermediate Care Unit, University of Maryland Medical Center, Baltimore/United States of America

Background: This six month process improvement pilot aims to address the U.S. Centers for Medicare & Medicaid Services' mandate that hospitals improve quality of care through improving outcomes such as length of stay (LOS), 30 day readmission, and patient satisfaction. **Method:** A collective of Thoracic Surgery staff established a multidisciplinary process that included daily interdisciplinary rounds to discuss patients' progress and discharge readiness. An interactive discharge readiness tool that looks like a board game, based on an evidence-based concept that is effective in the pediatric patient population, was created to engage the patient and family in discharge readiness. A patient education guide and documenting mechanism were built into the electronic medical record to aid and que staff in educating the patient and allow the multidisciplinary team to view the patients' progress. **Result:** Patient satisfaction scores, measured using the Hospital Consumer Assessment of Healthcare Providers and Systems (HCAHPS), in the domains of Communication with Nurses, Communication About Medicines, Discharge Readiness, and Care Transitions each improved. The Thoracic Intermediate Care Unit (TIMC) ranked above the 90th percentile in three of the four measured domains and significantly outperformed its sister unit, the Surgical Intermediate Care Unit (TIMC), in all categories. Surprisingly, LOS and 30 day readmission increased during the first quarter of the six month pilot.



Conclusion: The improvement in patient satisfaction in all measured domains highlights the positive impact of this initiative. The increase in HCAHPS scores after implementing the Journey Board imparts the benefit of using an interdisciplinary tool to engage the patient and family in discharge readiness. The Care Transitions domain, which examines the patient's perception of their ability to manage their health and understanding of their medication, connects directly to the purpose of the Journey Board. Prior to this pilot the TIMC was underperforming in the Care Transitions domain at 54.6%. During the first quarter of the pilot the HCAHPS score jumped to 80.3% and although it dipped to 72.2% in the second quarter if the pilot this is still a meaningful increase from the pre-pilot period. The improvements in HCAHPS scores are especially notable when comparing the percentile ranks of the TIMC and SIMC, sister units with the same nursing staff. It appears that the having a formal process in place provides the interdisciplinary team with a structure to engage the patients and families in preparation for going home. Although unimproved, the inability to decrease LOS and 30 day readmission can be explained by the concurrent increase in case mix index, a measurement of acuity, of the patients on the TIMC.

Keywords: Interdisciplinary, Discharge Readiness, Patient Education

P1.07-08 SCREENING FOR FEAR OF CANCER RECURRENCE IN OPERABLE LUNG CANCER PATIENTS-SCALE VALIDATION AND CURRENT STATUS

Y.-H. Lai[1], J.-S. Chen[2], Y.-H. Lee[1], I.-C. Huang[3]

[1]*National Taiwan University, Taipei/Taiwan,* [2]*National Taiwan University Hospital, Taipei City/Taiwan,* [3]*Kaohsiung Medical University, Kaohsiung/Taiwan*

Background: Fear of cancer recurrence (FCR) is one of the most distressing concerns for cancer patients. A brief scale to screen FCR is important for use in busy clinical oncology settings. The purposes of the study are to (1) translate the 7-item fear of cancer recurrence scale (FCR7) into Chinese and validate the psychometrics of the 7-item Chinese version (FCR7-C), and (2) explore the level of FCR in a cohort of early-stage lung cancer patients after tumor resection surgery in Taiwan. **Method:** Eligible subjects were recruited from chest surgery outpatient department in a medical center in Taiwan. The FCR7 was first translated and back translated between English and Chinese. The translated FCR7-C was evaluated for content validity and internal consistency reliability (Cronbach's alpha). Construct validity was determined by evaluating correlations between FCR7-C theoretical assumptions and confirmatory factor analysis (CFA). **Result:** In our cohort of 160 patients, the FCR7-C was shown to have satisfactory content validity and internal consistency reliability (Cronbach's α = 0.9). The uni-dimensional structure was confirmed by CFA that showed a good fit for the model. The FCR7-C score correlates positively with the degree of physical symptoms, anxiety, and depression, but correlates negatively with patient age, performance status, and quality of life. We found that 81.9% of patients reported at least some FCR, with a mean FCR severity of 15.2 (SD= 7.8). **Conclusion:** FCR7-C is a brief assessment with good psychometrics. For operable lung cancer patients, FCR is still a concern for most of the early stage lung cancer patients though it is not very severe. We strongly suggest its use for screening cancer patients for FCR to allow for appropriate interventions in lung cancer patients.

Keywords: fear of cancer recurrence, Early Stage Lung Cancer, psychometrics

P1.07-09 IMPLEMENTATION OF A NURSING PROGRAM FOR CANCER PATIENTS TREATED WITH IMMUNOTHERAPY BY AN IMMUNOTHERAPY NURSE SPECIALIST

J. Serra, M. Majem, I.G. Sullivan, M. Riudavets, G. Anguera, A. Barba, I. González, N. Guàrdia

Hospital de la Santa Creu i Sant Pau, Barcelona/Spain

Background: Immunotherapy is one of the fastest-evolving areas of oncology to date including non-small cell lung cancer. Due to their mechanism of action they can produce immune related adverse effects (irAES), in which a coordinated multidisciplinary approach is essential for their management, and immunotherapy nurse practice is rapidly changing achieving an important role as a case manager. To describe the implementation of a nursing program for cancer patients treated with immunotherapy by an immunotherapy nurse specialist. We present preliminary data that will be updated for the presentation. **Method:** Before starting immunotherapy, patients receive health education that includes an explanation of the mechanism of action, prohibited medications, possible side effects and the emergency workup that must be followed in case of occurrence. Additionally, all baseline necessary procedures are revised and concomitant medication is registered. An educational booklet specifically made by the nurse is also given, which also includes the contact information of the nursing consult. In the follow-up visits, toxicities are identified and graded according to CTCAE v4.0 and the patient's health changes are also summarized. In case of toxicity, the nurse starts the process of referral to the specialist and a close follow-up is carried out. Additionally, virtual follow-up visits and doubts and questions about immunotherapy are also answered. **Result:** From August 2018 to April 2019 a total of 703 visits and 270 virtual visits have been done by the immunotherapy nurse specialist. 176 cancer patients have been visited and 100 of them had lung cancer. During this period, it has been necessary to refer patients to the specialist on 71 occasions, mostly to endocrinology, rheumatology, dermatology and pulmonology department. **Conclusion:** The implementation of the immunotherapy nursing program has contributed to an improvement of early detection and management of irAEs in cancer patients receiving immunotherapy as well as a greater patient satisfaction along with a reduction of waiting time for the visit with the specialist.

Keywords: Multidisciplinary, immunotherapy nurse specialist, nursing program

P1.07-10 INVESTIGATION ON NUTRITIONAL STATUS AND QUALITY OF LIFE OF PATIENTS WITH LUNG CANCER TREATED BY RADIOTHERAPY IN DIFFERENT SEXES

S.-P. Xie, Q.-Y. Jiang, S.-Y. Yang, X. Yang, Y.-Y. Gu, J.-Q. Shen

Zhejiang Cancer Hospital, hangzhou zhejiang/China

Background: Malnutrition is the most common complication of lung cancer patients. The purpose of this study was to investigate the nutritional indicators and quality of life of patients with locally advanced non-small cell lung cancer (NSCLC) who received definitive radiotherapy, to compare the nutritional status and quality of life of male and female patients, and to explore the relationship between them. **Method:** Patients with locally advanced NSCLC who received definitive radiotherapy in our hospital were enrolled. The quality of

life of patients was assessed by the Cancer Therapeutic Function Scale. Height, weight and body composition were collected by Inbody 230. Nutritional indicators such as albumin and hemoglobin were recorded within a week. **Result:** Between January 2018 and March 2018, ninety-six male patients and 32 female patients were enrolled. The BMI of 7.3% of male patients was lower than 18.5 kg/m^2, and that of all female patients was more than 18.5 kg/m^2. The proportion of male patients with hypoalbuminemia was equal to that of female patients, accounting for 65.6% of the total number. 6.3% of male patients with hypoalbuminemia and BMI were lower than 18.5 kg/m^2 at the same time. The proportion of male patients with anemia was higher than that of female patients (χ^2 = 7.626, P = 0.006), and the skeletal muscle and water content were higher than those of female patients (T = 5.653, P = 0.000; T = 8.184, P = 0.000). Body mass index, fat content, skeletal muscle content and water content in male patients were positively correlated with quality of life (β = 0.225, P = 0.046; β= 0.232, P = 0.042; β = 0.291, P = 0.009; β= 0.328, P = 0.004), while there was no significant correlation between nutritional indicators and quality of life score in female patients. **Conclusion:** Protein malnutrition is the main type of malnutrition in lung cancer patients,the manifestation is that body weight is maintained in normal range or even overweight, but serum albumin, lymphocyte count and other indicators are abnormal. However, some male patients are suffer from mixed malnutrition, the consumption of weight and decrease of serum nutritional indicators both occurre, which is a serious life-threatening malnutrition. So, male patients with lung cancer are more likely to suffer from serious malnutrition than female patients, and malnutrition has a greater impact on the quality of life of male patients.

Background: The NLCFN workshop group were keen to explore the impact on patient experience of the National Optimal Lung Cancer Pathway (NOLCP). Evaluation of patient experience to collect data on their corresponding pathways. Hospital based lung cancer diagnostic services across the UK at 18 Trusts. **Method:** Newly diagnosed lung cancer patients referred on the 62 day pathway during October 2017 to July 2018 were eligible. 135 patient pathway and questionnaire data were analysed from 15 Trusts. Data Collection Data collection was in two parts: A patient survey and a data collection tool to reflect key points along the patient pathway. All data was anonymised. Data Analysis Data was submitted by 15 Trusts and analysed by the workshop participants **Result:** Overall, patients were satisfied with their experience of the pathway. Data collection demonstrated significant variation across pathways. Service evaluation and development is a key part of the LCNS role, however there were variations in Trust governance processes which caused delays and non submissions. **Conclusion:** Overall, patients were satisfied with their experience of the pathway. Data collection demonstrated significant variation across pathways. Service evaluation and development is a key part of the LCNS role, however there were variations in Trust governance processes which caused delays and non submissions.

P1.07-12 ESSENTIAL PSYCHOSOCIAL REQUIREMENTS FOR QUALITY LUNG CANCER CARE

C. Degi

Babes - Bolyai University and APSCO, Cluj - Napoca/Romania

Background: In 2016 ECCO's board - European CanCer Organization - approved a project on essential requirements for quality cancer care (ERQCC). Available clinical guidelines on cancer care define the medical content of optimal treatment of a given type of cancer but do not give indications on how to organize this treatment and how to measure its outcome. Thus, there is a need for defining organizational criteria on how to deliver this essential care to each patient and subsequently a quality measurement system. **Method:** The ERQCC project aims at: a). improving outcomes for cancer patients in Europe through the adoption and the implementation in Europe of essential requirements for quality cancer care; b). complementing existing clinical guidelines and improving their efficacy; c). shaping the policy environment at European and national levels to improve the quality of cancer care across Europe and decrease inequalities in outcomes; and d). positioning ECCO as the multidisciplinary cancer organization able to reach a consensus on essential requirements for quality cancer care. **Result:** ECCO Essential Requirements for Quality Cancer Care (ERQCC) are checklists and explanations of organization and actions that are necessary to give high-quality care to cancer patients. They are written by European experts representing all disciplines involved in cancer care. Due to its multidisciplinary nature, in this presentation, the essential psychosocial requirements for quality lung cancer care will be presented in two parts. In the first part, the psychosocial challenges in lung cancer are listed in details then in the second part, we expand on the role of psycho-oncology in lung cancer care. Results disseminated at the Congress are part of the ERQCC Lung Cancer Working Group Meetings from Brussels in 2018. **Conclusion:** The information presented here is a description of the requirements to consider essential psychosocial requirements for quality lung cancer care, especially in the European region. More information here: https://www.ecco-org.eu/ERQCC.

Keywords: essential requirements, psychosocial care, Lung cancer

P1.07-13 THE APPLICATION OF INTRACAVITARY ELECTROCARDIOGRAM IN THE FEMORAL VEIN CATHETER TIP LOCATION IN CHEMOTHERAPY PATIENTS WITH LUNG CANCER

J. Zhang

Central South University, Changsha/China

Background: For lung cancer patients with superior vena cava obstruction (SVCO), femoral vein PICC catheter at mid-thigh can be used to achieve chemotherapy. The X-ray, as the gold standard for catheter location, has some limitations such as long time-consuming and delayed in judgment. The intracavitary ECG location has been applied to the superior vena cava(SVC) catheter, which can make up for the shortcomings of X-ray. However, it is not clear whether it is suitable for inferior vena cava(IVC) catheter. Our research aim is to explore the clinical application value of intracavitary ECG location on femoral vein PICC at the mid-thigh . **Method:** From January 2017 to December 2018, a total of 91 patients with SVCO, who were placed femoral vein PICC at the mid-thigh, were in enrolled. In the self-controlled study, catheter tip at the eighth to tenth thoracic vertebrae by X-ray location as the gold standard positive, and catheter tip at the position where the intracavity ECG occurred the first biphasic P wave and then receding 2 cm as the positive for the screening test. The study calculated the authenticity, reliability and practicality indicators of intracavitary ECG location. **Result:** This study found the relationship between the position of the catheter tip and the P wave. When the tip of the catheter was in the IVC, most patients has negative P wave, and some patients has a low flat positive P wave. When the tip of the catheter entered the right atrium(RA), patients has biphasic P wave, and when the tip of the catheter entered the top of the RA, patients has huge biphasic P wave. In the study, the screening test was used to evaluate the accuracy and clinical application potential of intracavitary ECG in femoral vein PICC catheter tip location. In the authenticity index, the sensitivity was 98.73%, and the specificity was 91.67%. Yoden index was 0.90, the accuracy was 97.80%, the false positive rate was 8.33%, the false negative rate was 1.27%, the positive likelihood ratio was 11.85, and the negative likelihood ratio was 0.01. In the

reliability index, the Kappa index value was 0.90. In the practical index, the positive predictive value was 98.73%, and the negative predictive value was 91.67%. **Conclusion:** Intracavitary ECG location can accurately locate the tip of the femoral vein PICC catheter at the mid-thigh. It has higher reliability and practicability, and has more great clinical application potential. It is worthy to clinical application.

Keywords: Femoral vein catheter, Catheter tip location, Intracavitary electrocardiogram

P1.07-14 FRAILTY AND TREATMENT DECISION MAKING IN OLDER PEOPLE WITH LUNG CANCER

A. Tod[1], J. Skilbeck[2], C. Warnock[3], N. Ali[2], J. Ulman[2]

[1]*University of Sheffield, Sheffield/United Kingdom,* [2]*Sheffield Hallam University, Sheffield/United Kingdom,* [3]*Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield/United Kingdom*

Background: Currently there is little research exploring patient or clinician treatment decisions among older lung cancer patients. Existing research has confirmed that variation in treatment preferences exist between patients, and between patients and clinicians, that could be influenced by perceptions of age and frailty. Clinician's concerns about providing certain treatments to patients deemed to be frail may influence an older person's decisions regarding treatment. This was reported in a recent systematic review [1] identifying the most common factor influencing older adult's decision to accept or decline cancer treatment was physician recommendation. **Method:** A prospective qualitative exploratory study was undertaken. Semi-structured interviews conducted with older patients with lung cancer (n=12); and a range of health care professionals (n=12), including respiratory physicians, clinical nurse specialists, oncologists. Data were audio-recorded, transcribed verbatim and analysed using Framework Analysis. **Result:** Three themes illuminated factors influencing treatment decision making in older people with lung cancer. *Perceptions of frailty* illustrates how older people were able to recognise dimensions of frailty but did not consider themselves to be frail. For the healthcare professionals, frailty was not universally considered in treatment decision-making. *Decision making conversations* details the multiple factors that facilitate or hinder the process. *Aspects of service delivery* consider the wider context in which treatment decisions are made. **Conclusion:** There is merit on drawing on the concept of frailty to inform treatment decision making. In the current climate where the use of standardised tools to assess frailty is being promoted [2,3], we propose incorporating a series of trigger questions to be used alongside existing assessment tools. In so doing there is potential to capture a clearer impression of an older person's fitness for treatment.

Keyword: lung cancer, frailty, treatment decisions

P1.07-15 SCREENING FOR LONG TERM OTOTOXICITY IN LUNG AND UPPER AERODIGESTIVE CANCER SURVIVORS TREATED WITH PLATINUM CHEMOTHERAPY

S. Kooner[1], G. Liu[2], K. Hueniken[1], S. Lee[2], J. Harris[2], C. De Guia[2], E. Anokye-Yeboah[2], P. Chow[2], P. Bapat[2], W. Xu[2], D. Howell[2], I. Tymoshyk[2], A. Embleton[2]

[1]*Princess Margaret Cancer Centre, Toronto/Canada,* [2]*University Health Network, Toronto/Canada*

Background: Platinum-induced ototoxicity (PIO) is the hearing disorder that results from the temporary or permanent inner ear dysfunction after treatment with platinum based chemotherapy. Debilitating symptoms can include hearing loss, tinnitus and ear pain, affecting 40-80% of adults treated with platinum chemotherapies (up to 50% of lung cancer patients). There is no cure for PIO and the focus should be on early detection and lifestyle management. Ototoxicity negatively impacts quality of life in survivorship impacted by difficulty in speech recognition, safety concerns, social isolation and depression. At most cancer centres, hearing tests are not routinely performed in adults receiving cisplatin. This study aims to implement screening audiometry initially through formal audiometry testing, and later through a mobile electronic tablet-based platform. Our study goals are: i) to confirm the high prevalence of ototoxicity; and ii) the feasibility of implementing an in-clinic tablet based hearing test as part of routine care for lung cancer patients. **Method:** Using the CIHR Knowledge-to-Action framework, we formally assessed the clinic readiness, barriers to implementation, identification of facilitators, and initiated a pilot outpatient clinic-based study in our lung and head and neck cancer patients to determine viability and sustainability within the clinic. **Result:** Prevalence of hearing loss ranged between 22-58% of cisplatin-treated patients. Barriers to implementation included: (i) difficulty contacting some survivors; (ii) coordinating testing across broad geographic areas; (iii) missing test results; (iv) allocation of physician versus nursing responsibilities in a multidisciplinary setting; (v) health care provider education; and (vii) long-term transition plan to primary care follow-up. Nursing/clinic champions improved uptake substantially. New procedures were necessary to ensure that tests are performed, results checked, and patients were triaged accordingly. **Conclusion:** Substantial barriers were identified for clinical implementation of the routine post-platinum audiometry screening for ototoxicity in lung cancer survivors, but a list of potential solutions has led to good uptake of this process in the clinic. In a future follow-up pilot, we will test the potential benefits (time- and labour-savings; more efficient use of resources) of an in-clinic, portable, brief, tablet-based hearing test screening program, in place of formal audiometry testing.

Keywords: Audiometry, Ototoxicity, Chemotherapy

P1.07-16 TRAINING PROGRAM FOR UNIVERSITY NURSING STUDENTS TO REDUCE LUNG CANCER PATIENT EMOTIONAL DISTRESS

S. Abouabdou

Faculty of Nursing Suez Canal University, Ismailia/Egypt

Background: Communication skills are the cornerstone of the patient provider relationship in cancer care. Lack of these skills can diminish disclosure, increase patient anxiety. Nurses play an important role in providing emotional care and support to lung cancer patients and their families. Unfortunately, few nurses receive sufficient training to ensure they are proficient in key communication tasks. This study was carried out to determine the impact of communication skills training program on reduce lung cancer patient emotional distress. **Method:** A quasi experimental design with pre-post assessment was utilized in this study with sample size of 86 participants from internship year nursing students. The study was conducted in Training Unite and Oncology Units at Suez Canal University Hospitals. Internship year nursing students went through the problem-based learning process and role-playing exercises with regular feedback on basic communication skills, breaking bad news, effectively providing information and how to deal with patient's emotions during the training program. In the training program of the Internship year nursing students,the content was presented utilizing various techniques and approaches including: went through the problem-based learning process and role-playing exercises, group discussion, phrase filling, using media and videos, all of this with regular feedback on basic communication skills. Finally after one week of completing the program, the Communication Skills Observation Form was completed at the lung cancer patients ward of oncology units at Suez Canal University Hospitals **Result:** The training improved internship year nursing students' empathic tendency, empathic and communication skills. "Respect to patients, giving constructive feedback, using effective body language, using continuing and leading reactions" showed gradual improvement during observations while self-disclosure and "ineffective communication techniques" were lower Table 1. Pre- and post-Tests of Empathic Tendencies Scale & Communication Skills Evaluation Scale. (n=36)

POSTERS

Conclusion: Communication skills training programs have effectively improved the empathic tendencies and communication skills of internship year nursing students,. Therefore, although empathy is an innate quality it can be developed through training. It is vital to give importance to give importance to communication in the professions worked with human beings and to develop/proceed empathy which is among the key elements of communication. It can be advised to give a place to the subject in theories and practices before graduation, support with continuous and adequate in-service trainings in professional life, to give priority to the ones working in hospitals with lung cancer patients with special needs such as cancer patients in order to develop empathetic skill of the nurses.

P1.07-17 TRANSFER OF CARE: EFFECTIVE COMMUNICATION TO PROMOTE IMPROVED PATIENT EXPERIENCE

N. Nouriany, T. Cline, J. Cullis

University Health Network - Princess Margaret Cancer Centre, Toronto/ Canada

Background: As the world of cancer research continues to evolve, clinical trials remain a vital component to discover new treatment modalities in the fight against cancer. Across Canada, this percentage is closer to 5%. As cancer treatment evolves, it is imperative that our nursing care and culture does as well in order to support our patients appropriately. There remains a dichotomy of care between patients participating in a clinical trials and patients who are on standard therapies. Nursing practice and processes can be different for each and ultimately the patient is affected by this. Reflecting on our practice, there has not been a formal way of transitioning patients between different types of treatment and care. **Method:** As clinical trial nurses, we have designed a standardized worksheet for nurses to effectively provide more effective transition of care. Over a 6 week period from March 19th to April 30th, 2018, 13 ambulatory and trial nurses completed the worksheet for 29 patients in two GYNE and Thoracic clinics at Princess Margaret Cancer Centre. The worksheet is straight forward, quick and easy to complete. **Result:** Feedback from nurses was evaluated through a multiple choice questionnaire (Likert scales). Clinical trial and Ambulatory Nurses strongly agreed that the worksheet was helpful in streamlining important aspects of care for our patients, improvement in the flow of busy clinics, alerting nurses to important tests, procedures, treatments and toxicities . With the increased awareness of nurses in both trial and ambulatory setting and improved communication amongst the interprofessional team, the team was more efficient and proactive. **Conclusion:** The form facilitates effective communication and collaboration between clinical trial nurses and ambulatory nurses in clinic. Our initiative is grounded in improving continuity of care for the patients and they transition between the two modalities. We will discuss the worksheet component, feasibility amongst disease sites, feedback received and other positive implications of the hand over standardization process.

Keywords: Effective communication, patient experience, Transfer of care

P1.07-18 THE EFFECT OF LUNG CANCER ON PATIENT SEXUAL FUNCTIONING: NURSING VIEW

S. Abouabdou

Faculty of Nursing Suez Canal University, Ismailia/Egypt

Background: Lung Cancer (LC) is a major cause of chronic morbidity and mortality; it is currently the fourth highest cause of death in the world, and is predicted to be the third leading cause of mortality worldwide by the year 2020. Therefor this study aims to assess the effect of Lung Cancer (LC) on sexual functioning of the affected patients compared with healthy group. **Method:** This is a correlational exploratory study design to examine the relationship between LC and patients' sexual functioning. Data were collected from December 2016 to the end of May 2017, at Suez Canal University Hospital, Ismailia, Egypt. The study was approved by the institutional ethics committees and an oral approval from participants was obtained. An accidental convenient sample of one hundred patients were recruited according to the inclusion criteria. **Result:** Table 1. Frequency and percentage distribution of subjects' in relation to socio-demographic characteristics.

P1.07-19 PALLIATIVE CARE SOCIAL WORKERS MULTI-DIMENSIONAL ROLES: A NAMIBIAN PERSPECTIVE

R.J. Freeman

University of Namibia, Windhoek/Namibia

Background: Background and Context This article provides insight on multi-dimensional roles of twenty social workers providing palliative to patients with life-limiting illnesses (e.g. cancer, cardiovascular diseases, diabetes, etc.) in six hospitals in primary care in Namibia. **Method:** Constructive grounded theory as a qualitative research approach was utilized and an ethnographic study was carried out through in-depth interviews with twenty practicing social workers at six public hospitals in Namibia using an audio-tape recorder to explore how social workers perceive their role in providing palliative care to patients with life-limiting illnesses.Purposive, non-probability sampling through qualitative in-depth face-to-face and open-ended interviews. Data were gathered using a narrative approach. Memoranda through field notes, memos assisted in data analysis, applying traditional grounded theory coding techniques applied. Data collection and analysis were conducted interchangeably. **Result:** Social workers perform multi-dimensional roles in the provision of palliative care such as advocate, assessor, broker, counsellor, educator, facilitator, patient liaison, mediator, discharge planner and manager of in-country referrals. Understanding the importance of the multi-dimensional roles of social workers in the provision of palliative care to patients with life-limiting illnesses is critical. **Conclusion:** National palliative care policy guidelines and further research are needed in strengthening social workers' role in the provision of the field of palliative care. This can be achieved through effective training and capacity building of social workers through continuous education in palliative care.

Keywords: Life-limiting illnesses, Namibia, Role of Social workers

P1.07-20 EVALUATION OF THE EFFICACY OF CONTINUING NURSING EDUCATION SESSIONS FOR ONCOLOGY NURSES AT PRINCESS MARGARET CANCER CENTRE

N. Nouriany, N. Perera-Low, P. Merante

University Health Network - Princess Margaret Cancer Centre, Toronto/Canada

Background: The evolving health care systems and ongoing advances in cancer treatments require continual education. Continuing Education (CE) is one of the most common methods that healthcare professions use to keep their members aware of new information issues, and trends in healthcare. Advocates for continuing education state that CE serves to sustain the effectiveness of healthcare professionals by ensuring Clinical competence, thereby enhancing the quality of healthcare[1,2] and reducing malpractice issues[3]. To advance the quality of healthcare, it is expected that participants of CE programs acquire and retain information so that it may be transferred into professional practice[4]. Adult learning theory [5,6,7] and research suggest that effective CE programs should progress from the traditional lecture-based approach and seek new avenues of effective presentation for the adult learner. Nursing education has been said to be effective when it leads to improvement in practice and patient care. The current landscape in oncology nursing is ever evolving which leads nurses to adapt rapidly to the changing practices and therapies to update and improve their knowledge and skills. In February 2018 the Nursing Unit Council at Princess Margaret Cancer Centre recognized a need and developed a plan to implement education sessions for clinical trial, ambulatory, chemo-daycare and student nurses. **Method:** 10 educational sessions lasting 1 hour on various oncologic topics presented by staff oncologists (radiation, medical & pathologists) were held from March 9th 2018 to Mar 29, 2019 for nurses. A questionnaire, which contained 11 sections was created specifically for this project to assess the effectiveness of these sessions. These were completed anonymously by 41 participants (19 trial nurses, 8 ambulatory nurses, 4 student nurses & 10 staff nurses). **Result:** Feedback from nurses was evaluated through a multiple choice survey questionnaire (Likert scales). The information provided contributed to the understanding of the effectiveness of continuing education. The 1 hour format was feasible and liked among the nurses as it generally occurred during the lunch hour. The RN respondents reported collecting 10 hours total continuing education hours, with 84% related to current work. 65% of respondents indicated they learned new skills/information that they will apply to nursing practice. 30 % indicated the CE sessions validated their current practice and 100% of respondents indicated the content of each session fit with their experience level. **Conclusion:** Nurses perceived that learning new skills and information was a strong contributor to their professional development. Furthermore, participating in these sessions enhanced their learning needs. Collecting CE hours and session content were other contributing factors that impacted their decision to attend these sessions. Nursing Educational sessions were deemed valuable and well received by nurses in the various departments at Princess Margaret to improving clinical practice and guiding the future of oncology nursing. P1.09 PATHOLOGY
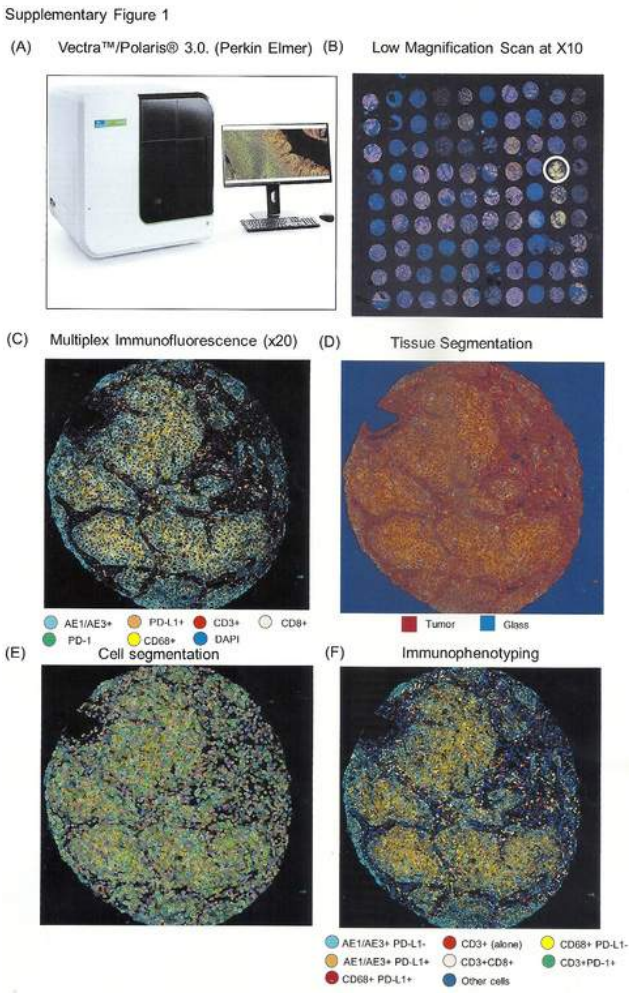
SUNDAY, SEPTEMBER 8 09:45 – 18:00

P1.09-01 IMMUNOPROFILING DEPENDS ON MOLECULAR DETERMINANTS TO PREDICT METASTASES AND TARGET THERAPY IN NON-SMALL CELL LUNG CARCINOMAS

J. Rugolo-Machado[1], A. Fabro[2], C. Farhat[3], E. Parra[4], V. Capelozzi[3]

[1]*State University of Sao Paulo, Botucatu/SP/Brazil,* [2]*University of Sao Paulo Ribeirao Preto Medical School, Ribeirao Preto/SP/Brazil,* [3]*University of Sao Paulo Faculty of Medicine, Sao Paulo/Brazil,* [4]*University of Texas, Houston/Texas/United States of America*

Background: To gain insight into the pathogenesis and progression of non-small cell lung carcinomas (NSCLCs) by 1) characterizing the tumor microenvironment using multiplex immunofluorescence (mIF), image analysis, and genetic mutation analysis and 2) correlating findings with clinicopathologic characteristics and data on tumor progression and prognosis. **Method:** Tissue microarrays from 164 primary tumors from patients with stage I–III NSCLC were examined. The specimens included 94 adenocarcinomas, 51 squamous cell carcinomas, and 19 large cell carcinomas. Using mIF and image analysis, we evaluated programmed death ligand 1 (PD-L1) expression in malignant cells (MCs), CD68+ macrophages, and cells expressing the immune markers CD3, CD8, CD57, CD45RO, FOXP3, PD-1, and CD20 (Figure 1). Cell phenotype data were then integrated with clinicopathologic characteristic and next-generation sequencing gene profiles.



Result: PD-L1 expression by MCs and other cells was associated with specific clinicopathologic characteristics and next-generation sequencing profiles (Figure 2). In addition, higher densities of antigen-experienced T-cells were associated with brain metastases. The most frequent microenvironments in the NSCLC tissues were type II (immunologic ignorance) and type IV (tolerance). Multivariate analysis showed that tumors with 1) brain metastasis, 2) lower densities of T-cells, memory T-cells, and natural killer T-cells, and 3) CD276, CTLA4, MMP-2, and TP53 mutations had worse overall survival compared with tumors without 1) brain metastasis, 2) higher densities of T-cells, memory T-cells, and natural killer T-cells, and 3) tumors without CD276, CTLA4, MMP-2, and TP53 mutations.

Conclusion: We detected cell phenotypes and gene mutations associated with tumor metastases in NSCLC.

Background: Lung cancer is the leading cause of cancer-related morbidity and mortality worldwide. Cancer driver mutations have been examined extensively and are the basis for modern precision therapy. The access of genomic tests in Brazil and, therefore, the prevalence of driver mutations of NSCLC in the country is not well described. The objective of this study is to carry out an epidemiological analysis of the somatic genetic profile of Brazilian NSCLC samples tested with FoundationOne®. **Method:** GBOT 0118/ LACOG 0418 is a retrospective cross-sectional study with patients diagnosed with NSCLC in Brazil and who performed comprehensive genomic profiling (CGP) using FoundationOne® or FoundationACT®. Raw data containing anonymous clinical-pathological characteristics and the results of CGP was analyzed. We described the molecular profile of patients using descriptive statistics. Categorical variables are presented as frequency and compared using the Chi-square test. **Result:** We obtained a total of 513 CGP results, 457 (89.0%) from Foundation One® and 56 (10.9%) from FoundationACT®. Adenocarcinoma was the most common histological subtype (83.8%) followed by NSCLC NOS (16.1%). Median age at testing date was 64 years, and 51.27% were male. *EGFR* activating mutations were detected in 23.39% patients, *ALK* rearrangements in 5.65%, *ROS1* rearrangements in 2.34%, *RET* alterations in 2.53%, *BRAF* mutations in 5.46%, *KRAS* mutations in 25,15% and NTRK fusions in 0,58% . Tumor mutational burden (TMB) analysis was available for 80.51% of samples tested and was measured in mutation per megabase. TMB were divided into three groups based on the Foundation Medicine reports: low (1-5 mutations/mb), intermediate (6-19 mutations/mb) and high (≥ 20 mutations/mb). The of tumors had low (42.69%) or intermediate (32.36%) TMB, and only 5.46% had high TMB. Table 1. Frequency of somatic genetic alterations in tumors tested with FoundationOne® and availability of targeted therapies in Brazil.

GENE	Frequency in NSCLC (%)	Availability in Brazil
EGFR	23.39	Approved
ALK	5.65	Approved
ROS1	2.43	Approved
BRAF	5.46	Approved
KRAS	25.15	No drugs available
RET	2,53	Drugs available but not approved
NTRK	0,58	Drugs available but not approved

Conclusion: This is the most comprehensive study describing CGP of NSCLC in Brazil using FoundationOne® or ACT. Our study shows rates of *EGFR* mutations and *ALK* rearrangements similar to those previously described. The knowledge of the molecular patterns of NSCLC in Brazil may help to improve health policies and access to targeted agents in the country.

P1.09-03 CLINICOPATHOLOGICAL CHARACTERISTICS FOR NSCLC HARBORING EGFR EXON 20 INSERTION

K. Morikawa, K. Kakinuma, T. Inoue, M. Mineshita

St. Marianna University School of Medicine, Kawasaki/Japan

Background: For the majority of EGFR-mutant NSCLC patients harboring exon 19 deletion or exon 21 L858R, EGFR-TKIs are key therapies for outstanding anti-tumor effects. However, for the population harboring minor mutations, clinical benefit of EGFR-TKIs are controversial. Specifically, exon 20 insertion is acknowledged as a poor prognostic mutation type compared to other minor mutations. There are few reports describing clinicopathological characteristics harboring exon 20 insertion NCSLC. **Method:** We retrospectively analyzed patients harboring EGFR exon 20 insertion at our institution over 3 years. Clinical testing for the detection of EGFR mutations was cobas® EGFR Mutation Test v2. We evaluated pathological features for diagnostic specimens or re-biopsy samples, CT or PET images for the detection of primary lesions or metastatic locations. **Result:** A total of 213 EGFR-mutant adenocarcinomas were reviewed for the study and screened. Of these, 19 were positive for exon 20 insertion (8.9%). Of 19 cases, 13 displayed advanced stage while 6 cases were classified as early stage. Compound major mutation was detected in 26.3% (3 cases were exon 19 deletion; 2 cases were exon 21 L858R). In advanced cases, the location of primary lesions was found mainly in the subpleural domain (84.6%), and pleural dissemination was confirmed in 77%. The majority of cases included pleural effusion. Furthermore, 70% contained mucinous type pathologically in advanced cases. In total, more than half of the cases showed well-differentiated subtypes pathologically, which was contrary to a past report[1]). **Conclusion:** Contrary to a past report, EGFR exon 20 insertion in adenocarcinoma often showed pathologically mucinous and well-differentiated subtypes. For clinical characteristics, especially in advanced stage, pleural dissemination and effusion were observed with high frequency, which might be due to the primary lesion often located in the subpleural domain. 1) Mol Cancer Ther; 2012(2); 220–9

Keywords: EGFR-mutant NSCLC, Exon 20 insertion

P1.09-04 COMPREHENSIVE GENOMIC PROFILING IN A BRAZILIAN COHORT OF LUNG CANCER PATIENTS: REAL-WORLD IMPACT

T. Padua[1], M. Monteiro[1], M. Silvino[1], L. Carvalho[1], T. Sousa[1], C. Bognar[1], E. Brabo[2], M. Campelo[2], D. Limeira[2], A.B. Abrahao[1], M. Zukin[2], R. Moreira[1], L.H. Araújo[2]

[1]*Americas Oncologia, Sao Paulo/Brazil,* [2]*Americas Centro de Oncologia Integrado, Rio de Janeiro/Brazil*

Background: The implementation of comprehensive genomic profiling (CGP) for every patient would ideally inform on all types of alterations, both frequent and rare events that might be useful for treatment. However, less than 50% of Brazilian lung cancer patients have access to any molecular testing. Giving the lack of literature data regarding CGP and clinical practice change, we aimed to evaluate how CGP changed patient treatment in a fully-annotated cohort of lung cancer in Brazil. **Method:** A retrospective study was conducted to review lung cancer patients for whom CGP was performed from October 2017 to February 2019 in a national, private oncology institution. Patients with all histological subtypes tested with Foundation One (F1) were included. Data regarding microsatellite instability (MSI), tumor mutational burden (TMB) and genomic findings were collected, as well as therapies/ clinical trials with possible clinical benefit. Demographic data were collected from chart review. **Result:** From 25 patients included in this cohort, 56% were male with a median age of 64-year-old. Tissue and blood sample were analyzed in 80% and 20%, respectively. The most common histological subtype was adenocarcinoma (68%) followed by squamous cell carcinoma (12%). CGP was ordered in 16% of treatment-naive patients; 52% in the first-line treatment and 8% and 12% after second and third line, respectively. None of them had MSI and 12% had high TMB. The most frequent genomic alterations were TP53 (64%); KRAS (32%); STK11 and ARID1A (16%); PIK3, CDKN2AB, and RB1 (12%); ATM, CTNNB1, ERBB2, MLL2, MSH2, PTPN11 and BRCA (8%). One patient was negative for EGFR mutation, tested by COBAS, but was found to have EGFR mutation by CGP. Although CGP showed up to 15 therapies and 37 clinical trials available for this cohort, none of the physicians have changed treatment after testing results due to limited access to clinical trials or one death before the beginning of anti-EGFR therapy. **Conclusion:** In our cohort, 25 patients with lung cancer had CGP tested during 16 months of follow-up, highlighting the limited access to the test. For most cases, CGP was ordered later during the treatment which could negatively impact on patient outcome. Furthermore, due to a paucity of available clinical trials and lack of access to new drugs in the country, the use of CGP had a limited impact in clinical decision making.

Background: ALK-tyrosine kinase inhibitors increase ORR and PFS times in ALK-fusion positive NSCLC patients. It is therefore crucial to assess the efficacy of different methods for detecting ALK rearrangement. At present, there are most testing methods approved by cFDA to detect ALK rearrangement in China. However, many issues regarding to the procedure and quality control (QC) data of ALK testing in the routine clinical practice is still to be studied. This study is to evaluate the ALK testing platforms, testing procedures, result interpretation quality control and clinicopathological characteristics of ALK positive patients in the real world for Chinese lung cancer patients, and achieve expert consensus on the clinical practice of ALK testing. **Method:** Top 31 hospitals with lung cancer patients in China will participate in the study. All advanced NSCLC subjects who received ALK gene test and all ALK positive NSCLC patients who received surgical treatment from Oct. 2018 to Dec. 2019 will be enrolled. The testing platforms include IHC-Ventana,FISH,RT-PCR and NGS. It is expected to enroll a total of 30,000 cases, and the clinicopathological information of the patients will be collected. Ring study and interpretation training will be conducted before the study initiated. When 2,000 and 10,000 cases are enrolled, the interim summary and quality control will be conducted respectively. The results were the interim summary and quality control results of 2,000 cases. **Result:** The 2263 enrollees (mean age, 63 years) included 1365 males (60.32%) and 907 females (39.68%). 205 (of 2263, 9.06%) cases were ALK positive. The ALK positive rate of females (11.10%) was significantly higher than that of males (7.74%). The ALK positive rate of non-smoking patients (11.54%) was significantly higher than that of smoking patients (5.70%). In addition to ALK, the positive rate of EGFR, KRAS, ROS1, HER2, MET, RET and BRAF gene alterations was 46.05%, 9.52%, 3.13%, 3.09%, 2.98%, 2.12% and 0.94%, respectively. Total rate of all driver gene mutation was 60.37% in males, while it was 91.71% in female. Total rate of all driver gene mutation was 59.77% in smoking patients and 90.44% in non-smoking patients. Concurrent mutation of ALK with EGFR, KRAS or ROS1 was 0.33%, 0.45% and 0.22%, respectively. The fusion of EML4-ALK accounted for 75%. The inconsistency rate of IHC-Ventana with FISH, RT-PCR, NGS was 95.07%, 91.30% and 95.45%, respectively. For ALK IHC quality control, 109 slides were used for ring study, and 31 pathologists participated in the interpretion. Among 60 negative cases, 25 cases (41.7%) were diagnosed as positive (false positive) by at least one pathologist. Among 49 positive cases, 12 cases (24.5%) were diagnosed as negative (false negative) by at least one pathologist; 34 cases (31.2%) were diagnosed as inconclusive by at least one pathologist. There were 3.5% and 1.1% of cases found to be misinterpreted during the internal QC and regional QC, respectively. **Conclusion:** NSCLC patients harboring ALK gene translocation have unique clinicopathological characteristics. Some problems will still be encountered in the real world clinical practice of ALK testing, which need to be guided by establishment of expert consensus.

P1.09-06 EVALUATION OF MOLECULAR TESTING IN A DUTCH COHORT OF METASTATIC NON-SMALL CELL LUNG CANCER PATIENTS FROM 2017

C. Kuijpers[1,2], M. Van Den Heuvel[3], A. Van Lindert[2], R. Damhuis[4], S. Willems[1,2]

[1]*Foundation PALGA, Houten/Netherlands,* [2]*University Medical Centre Utrecht, Utrecht/Netherlands,* [3]*Radboudumc, Nijmegen/Netherlands,* [4]*Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht/Netherlands*

Background: Adequate and timely testing for genetic alterations in non-small cell lung cancer (NSCLC) is necessary to consider targeted therapy when a certain genetic alteration is present. Previously, we demonstrated that in the Netherlands molecular testing was suboptimal in 2015, as 25% (EGFR/KRAS and ALK) to 50% (ROS1) of patients were not tested according to the guidelines, and notable variation between laboratories was present. Currently, by analyzing a cohort of metastatic NSCLC from 2017 we aim to assess whether the performance of molecular testing improved. **Method:** All fully registered stage IV non-squamous NSCLC with incidence year 2017 from the Netherlands Cancer Registry were matched to the Dutch pathology registry (PALGA). Using information extracted from pathology excerpts, proportions of tumors tested for EGFR and/or KRAS, BRAF, and HER2 mutation, and ALK, ROS1, and RET rearrangement within 3 months after diagnosis were determined, and reason for not testing were assessed. **Result:** Of 2596 identified patients, we have currently analyzed 511 (20%). Twenty-three patients were non-eligible after matching, leaving 488 patients. Of these patients, 262 (54%) were male and 413 (88%) had an adenocarcinoma. EGFR and/or KRAS testing was performed within 3 months after diagnosis in 412 patients (84.4%). Of the EGFR/KRAS wildtype tumors (n=184), 167 (90.8%) were tested for BRAF, 158 (85.9%) for HER2, 157 (85.3%) for ALK, 110 (59.8%) for ROS1, and 73 (39.7%) for RET. Insufficient tumor tissue and inappropriate specimen were the most stated reasons for not testing. **Conclusion:** These preliminary data show significantly higher testing proportions for EGFR and/or KRAS and ALK as compared to 2015. Further improvement remains possible to identify candidates for targeted therapy. At the WCLC meeting, we expect to present the variation between laboratories for the entire cohort.

Keywords: molecular pathology, variation in care, metastatic NSCLC

P1.09-07 THE CLINICAL UTILITY AND PERFORMANCE OF WHOLE-EXOME SEQUENCING FOR NSCLC PATIENT CARE: A COMPARISON TO STANDARD-OF-CARE

K. O'Byrne[1,2], P. Leo[1,2], J. Ellis[1,2], M. Clout[1,2], D. Pennisi[1,2], L. Anderson[1,2], L. Wheeler[1,2], M. Brown[2]

[1]*Queensland University of Technology, Brisbane/Australia,* [2]*Translational Reseach Institute, Brisbane/Australia*

Background: Next-generation sequencing (NGS) has provided the technology to rapidly profile individual tumours and measure the increasing number of biomarkers particularly relevant to the treatment of NSCLC. The Australian Translational Genomics Centre (ATGC) was established as collaboration between the healthcare sector (Metro South Hospital and Health Service), higher education sector (Queensland University of Technology) and a government-run pathology service (Pathology Queensland) to provide genomic profiling of NSCLC patients at the princess Alexandria Hospital. The program was developed to integrate the ordering, processing and interpretation of large scale NGS sequencing into clinical practice. **Method:** NSCLC samples derived from endobronchial ultrasound (EBUS) or from formalin-fixed, paraffin-embedded (FFPE) histological sections were used for molecular profiling with NGS technologies by the ATGC, providing the first NATA-accredited ISO15189 program for lung cancer in Australian public hospital. The genomic test utilized whole-exome sequencing (WES) in combination with a high-coverage spike-in panel of known cancer genes. The clinical reports included the calculation of tumour purity, tumour mutational burden, the assessment of copy number events and somatic mutations down to 3% allele frequency. In addition, the performance of the genomic profiling was compared to the current standard practice performed by Pathology Queensland, based on a gene panel (and back-up IHC for *EGFR* and *BRAF*) with reporting on Tier 1-2 variants in selcted exons of *EGFR*, *BRAF*, *KRAS* and *NRAS*, and immunohistochemistry on EGFR and ALK. For this purpose, patient biopsies were processed in parallel by ATGC and Pathology

Queensland. **Result:** We demonstrated that samples derived from EBUS and FFPE sections routinely provides high quality diagnostic material of sufficient quality and tumour purity suitable for molecular profiling with NGS technologies. Thirty-six lung cancer samples were tested by WES/panel, and an average of 1.5 clinically significant Tier 1- 2 mutations were detected in NSCLC samples by WES/panel testing, and that 11 out of 36 cases had a high tumour mutational burden (>10 mutations/megabase). Of the 36 cases, 17 were also tested by Pathology Queensland. In 7 of those 17 cases, WES/panel detected variants in genes other than *EGFR, KRAS, NRAS,* and *BRAF* not detected or reported by standard methods; and, based on the additional variants reported by WES/panel, an additional 7 of the 17 patients would be eligible for enrolment in a clinical trial in Australia (source: Molecular Match; www.molecularmatch.com).This did not include trials or medications based on the tumour mutational burden. **Conclusion:** We demonstrate that integration of WES/panel testing into clinical practice is practical and provides significant advantages over standard testing by providing multiplexed testing of current and emerging biomarkers. Furthermore, adoption of WES/panel testing for the care of NSCLC patients is superior to standard-of-care in the stratification of lung cancer patients into appropriate Australian clinical trials.

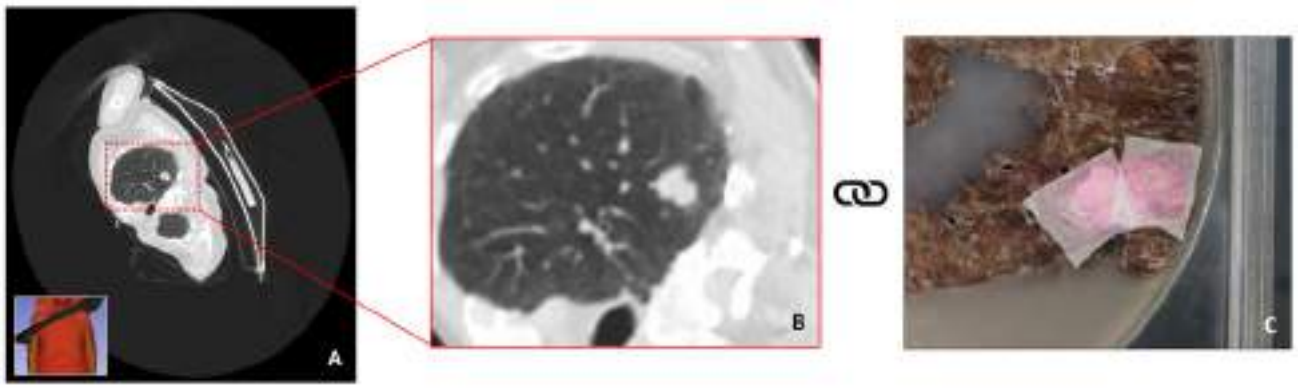
P1.09-08 REGISTRATION OF PRE-OPERATIVE LUNG CANCER PET/CT SCANS WITH POST-OPERATIVE HISTOPATHOLOGY MAPS

G. Reines March[1], X. Ju[1], S. Marshall[2], C. Dick[1], S. Harrow[3]

[1]*NHS Greater Glasgow and Clyde, Glasgow/United Kingdom,* [2]*University of Strathclyde, Glasgow/United Kingdom,* [3]*Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom*

Background: Currently there is insufficient data describing the cellular make-up of a tumour in relation to its functional imaging. This research project focuses on registering pre-operative PET/CT scans from lung cancer patients to their post-operative histology slides, enabling clinicians to draw spatial correlations between the tumour's metabolic fingerprint and its actual histopathology map. **Method:** Between January and June 2018 the research team identified and recruited 9 patients diagnosed with primary NSCLC and referred for radical lobectomy, across NHS Greater Glasgow and Clyde sites. Each participant was scanned in a combined PET/CT scanner prior to surgery, as per standard of care. The resected lobe was fixed in formalin for a minimum of 48 hours and injected with a 4% agar solution through the airways to stiffen the tissue and facilitate slicing. Once solid, the whole lobe was placed in a purpose-built slicing rig and dissected at regular 5-millimetre intervals. Each slice was photographed using a digital camera, then processed using a microtome and stained using immunohistochemistry (IHC) methods. Virtual 3D tumour models were reconstructed from the CT and gross pathology images and registered using a linear affine transformation algorithm in Matlab 2017b (The MathWorks Inc, US). Real CT data was subsequently deformed using the same transformation matrix to match the gross pathology cutting planes. Histology slides were also aligned to the block-face photographs by applying a non-linear registration algorithm, constrained by one-to-one correspondences between common landmarks (i.e. edges, vessels, airways) identified on both image datasets. **Result:** An average Dice similarity coefficient of 83% was obtained for the CT-to-pathology tumour model registration. Due to the quasi-spherical shape of most tumours, the orientation was found to be wrong in 3 cases, despite high overlapping scores. Therefore, we introduced a weighted registration algorithm that considers fiducial markers located in and around the tumour (e.g. airways or vessels) to ensure correct orientation. The figure below shows a sample slice of a transformed CT volume (A,B) which is matched to its corresponding gross pathology photograph (C), with overlapped histopathology data.



Conclusion: Building on the preliminary results presented last year in IASLC WCLC 2018, this proof-of-concept study has managed to spatially match pre-operative CT tumour data with its actual histopathology map, and we are in the process of extrapolating these results to 4D FDG PET data. This acquired knowledge shall provide an informed targeted approach for future radiotherapy studies.

P1.09-09 MODEL TO PREDICT SMALL LYMPH NODES METASTASIS IN NON-SMALL CELL LUNG CANCER

J. Li, F. Su

Fujian Medical University Cancer Hospital, Fujian Cancer Hospital, Fuzhou/China

Background: Accuracy target volume delineation is a fundamental problem in radiotherapy in patients with non-small cell lung cancer(NSCLC). There is a lake of "golden standard" in gross tumor volume(GTV) delineation can be defined so far. Especially in the delineation for lymph node target volume (GTVn).The standard most widely used in NSCLC radiotherapy planning was lymph nodes have a short-axis diameter greater than or equal to 1.0cm was regarded as malignant.However,it is clearly that lymph node size isn't a reliable parameter for the evaluation of metastasis.The aim of this paper is to develop a nomogram model to predict small lymph nodes metastasis in patients with NSCLC,expecting provide guidance for lymph node target volume delineation. **Method:** We retrospectively evaluated patients with NSCLC who had underwent Multi-slice Spiral Computed Tomography (MSCT) before radical surgery between October 2015 and December 2016. The least absolute shrinkage and selection operator regression model (LASSO) was used to selecting features for predicting small lymph node metastasis.Binary logistic regression analysis was applied to build a predicting model based on LASSO regression.The nomogram model were assessed using the C-index, calibration plot, and decision curve analysis(DCA). Internal validation was tested using the bootstrapping validation. **Result:** 279 lymph node stations among 82 patients met with inclusion criteria were observed, 44(15.7%) of them were pathologically confirmed metastasis. Twelve features were reduced to seven potential predictors in the LASSO regression model, including primary tumor location(left lobe and right lob), pathological type (quamous carcinoma,adenocarcinoma and other types),T stage,vascular invasion ALK mutation, lymph nodes clustered and short-axis of the maximum lymph node. The model displayed good discrimination with a C-index of 0.895 and good calibration. High C-index value of 0.856 could still be reached in the internal validation. Decision curve analysis showed that the nomogram model was clinically useful. **Conclusion:** The nomogram model incorporating clinical,radiological and pathological features could be conveniently used to predict the risk of metastasis in small lymph nodes in patients with NSCLC,and contributed to the delineation of tumor target volume.

P1.09-10 MOLECULAR IMMUNOCYTOCHEMISTRY IN VARIOUS NSCLC SAMPLES PREPARED AS NON-CELL BLOCK CYTOLOGY

S. Smojver-Ježek[1], B. Vrabec Branica[2], V. Šimić[2], S. Harabajsa[2], A. Marušić[2], S. Badovinac[2], S. Pleština[2], S. Kukulj[1], M. Jakopovic[1]

[1]*University Hospital Centre Zagreb, School of Medicine, University of Zagreb, Zagreb/Croatia,* [2]*University Hospital Centre Zagreb, Zagreb/Croatia*

Background: Molecular prognostic-predictive immunocytochemistry is obligatory for therapy decision in NSCLC patients. Immunocytochemistry on cell blocks FFPE cytology is preferred because of some validation advantages, but is not always sufficient in terms of samples acquisition and cell number adequacy. Aim of the study is to compare molecular immunocytochemistry expression between cytology samples obtained with bronchoscopy (bronchial washing/brushings and transbronchial fine needle aspirations) and other cytology samples such as pleural effusion, FNA of peripheral lymph nodes and skin nodules and transthoracic FNA/biopsy; all prepared as non-cell block cytology. **Method:** We compared archive records of the 1109 immunocytochemistry (ICC) results of ALK, ROS1 and PD-L1 expression in carcinoma cells in relation to specimen type (bronchoscopic and non-bronchoscopic samples) prepared as smears and cytospins at our institution over a one-year period.

Air dried cytology smears and cytospins of NSCLC samples were stained with Anti-ALK Clone D5F3, Cell Signaling, appendix positive control; Anti-ROS1 Clone D4D6 Cell Signaling, HCC-78 cell line positive control and Anti-PD-L1, Clone 22C3, Dako, placenta imprint positive control; EnVision detection system on Immunocytochemistry Autostainer. PD-L1 protein expression was scored using Tumor Proportion Score (TPS) with positive cut-off of ≥1%, membrane staining. The slides were routinely examined and scored by two cytologists. Internal and external quality control were performed on FFPE cell blocks and histology slides with corresponding Ventana antibodies and staining systems. **Result:** Out of 1109 results, 440 were ALK ICC results, 111 ROS1 and 558 were PD-L1 ICC staining results. Among them 314/440 (71, 36%) ALK, 75/111 (67,57%) ROS1 and 392/558 PD-L1 ICC (70,25%) were in bronchoscopic samples and 126/440 (28,64%) ALK, 36/111 (32,43%) ROS1 and 166/558 (29,75%) PD-L1 ICC were in various non-bronchoscopic samples. Comparison in ALK, ROS1 and PD-L1 ICC distribution between two groups of samples showed no statistical significant difference among groups (X^2 test, df 2, p=0,730). Positive ALK and ROS1 numbers were in observed range, but insufficient for statistical analysis. PD-L1 ICC scored results were in total of 392 samples collected during bronchoscopy and 166 of various other non-bronchoscopic samples: 88 were obtained by FNA of peripheral lymph nodes and skin nodules, 38 by transthoracic FNA/biopsy and 40 pleural effusions. PD-L1 ICC scored negative in total of 281/558 (50,36%) samples, 191 bronchoscopic and 90 non-bronchoscopic. PD-L1 ICC scored positive in total of 277/558 (47,11%) samples of which 201 were obtained with bronchoscopy and 76 of samples collected with other methods. Among of total PD-L1 positive smears, 128 were PD-L1 positive ≥ 50%; 90/128 (70,31%) were bronchoscopical samples and 38/128 (29,7%) other samples. Comparison in PD-L1 expression between two groups of samples showed no statistical significant difference among groups (X^2 test, df 1, p=0,236). Comparison between two groups of PD-L1 positive ≥ 50% showed no statistical significant difference among sample groups (X^2 test, df 1, p=0,436). **Conclusion:** There were no statistical significant differences in molecular ALK, ROS1 and PD-L1 immunocytochemistry results between samples collected during bronchoscopy and non-bronchoscopic samples prepared as non-cell block cytology. PD-L1 scoring results were also independent of cytology sample type in our study.

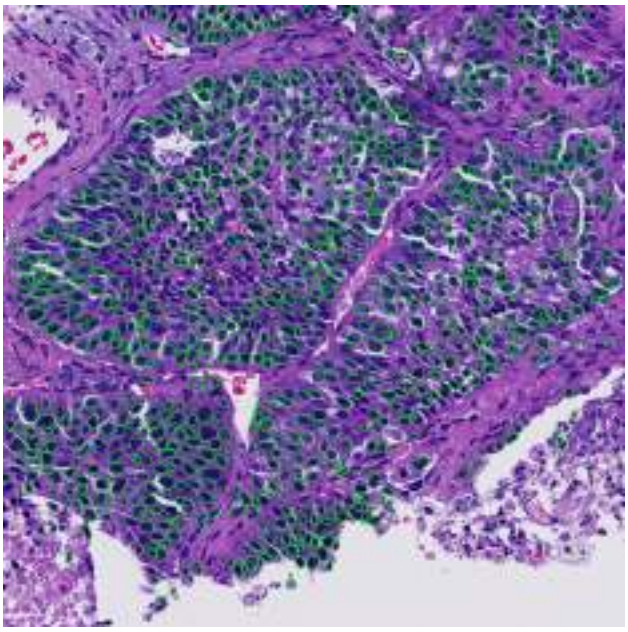
P1.09-11 INFLUENCES OF SAMPLING METHOD TO MORPHOLOGICAL FEATURE MEASUREMENT OF LUNG CANCER CELL

T. Kiyuna[1], N. Motoi[2], H. Yoshida[2], S. Watanabe[2], Y. Ohe[2], A. Ochiai[3]

[1]*NEC Corporation, Tokyo/Japan,* [2]*National Cancer Center Hospital, Tokyo/Japan,* [3]*National Cancer Center, Chiba/Japan*

Background: Progress of imaging technologies in the field of histopathology enables us to exploit artificial intelligence (AI) techniques to detect cancer based on digital images for screening or quality assurance of diagnosis process. Nowadays, reports on the application of AI to cancer detection which claim 99-percent detection accuracy are found in every proceedings or journal of digital pathology. However, little attention has been paid to the influences of sampling method to AI-based histological diagnosis. **Method:** Whole slide images of hematoxylin and eosin (H&E) stained slides collected from 94 non-small cell lung cancer (NSCLC) cases were captured by a virtual slide scanner (NanoZoomer, Hamamatsu Photonics, Japan). Sampling methods were needle biopsy (59 cases), operation (12 cases) and endobronchial ultrasound-guided transbronchial needle aspiration (EBUS-TBNA) (29 cases). Regions of interest (ROI) were selected by an experienced pathologist. After selecting tumor cells only by AI-based tumor cell detecter (Figure.1), following morphological features were calculated: nuclear area, perimeter (Peri), circularity (Circ) and five texture features, i.e., angular secondary moment (ASM), contrast(Cont), homogeneity (Hom) and entropy (Ent) of gray level co-occurrence matrix (GLCM), and contour complexity (CC).



Result: We found significant differences (p<0.05) in most of feature values except nuclear area and perimeter. **Conclusion:** Our results suggest that methods of sampling significantly affect morphological feature values of nucleus and this fact must be taken into consideration when applying AI-based techniques to tissue image classification.

P1.09-12 IN-SITU HYBRIDIZATION VISUAL SCORING OF EPIGENETIC IMPRINTING GENES IMPROVES EARLY DIAGNOSIS AND GRADING OF LUNG CANCERS

R. Yung[1], T. Cheng[2], X. Li[3], X. Wang[3], H. Si[3], P. Zhao[3], R. Shen[4], J. Zhou[5], H. Yu[6], M. Ding[7], S. Lu[8], N. Zhou[2], C. Bai[5]

[1]*Johns Hopkins University School of Medicine, Baltimore/United States of America,* [2]*LiSen Imprinting Diagnostics, Inc., Salt Lake City/United States of America,* [3]*LiSen Imprinting Diagnostics (Wuxi), Inc., Wuxi/China,* [4]*Ohio State University Wexner Medical Center, Columbus/United States of America,* [5]*Zhongshan Hospital/Fudan University, Shanghai/China,* [6]*Shanghai Changzheng Hospital, Shanghai/China,* [7]*The Affiliated Zhongda Hospital of Southeast University, Nanjing/China,* [8]*Zhongshan Hospital, Shanghai/China*

Background: Pathologists rely on cellular morphology to determine cancer diagnosis. However earlier grades (dysplasia) and stages (Carcinoma-in-situ) of cancers which are most treatable have less obvious changes. Epigenetic changes occur at most stages of carcinogenesis, but the application of epigenetic testing in cancer diagnosis is limited. Imprinted genes are normally silenced in one of two parental alleles, but is reportedly reversed in carcinogenesis, with expression of biallelic (Loss of Imprinting-LOI) or multiallelic (Copy Number Variations-CNV) expression (Figure 1A). We present here a novel visual and quantitative approach targeting imprinted genes involved in lung cancer development and progression. **Method:** The Lisen in-situ hybridization(ISH) targets non-coding introns of imprinted genes to provide a visual and quantitative analysis of malignancy associated changes, unlike bisulfite reduction techniques. Formalin fixed lung cancer and benign lung samples are tested with an epigenetic panel (imprinted genes GNAS, GRB10 and SNRPN) stains. Diagnostic algorithm for a grading model based on LOI, CNV and summed "Total Expression (TE)" counts is developed comparing cancer samples in different stages and benign samples (Figure 1A).

Figure 1A

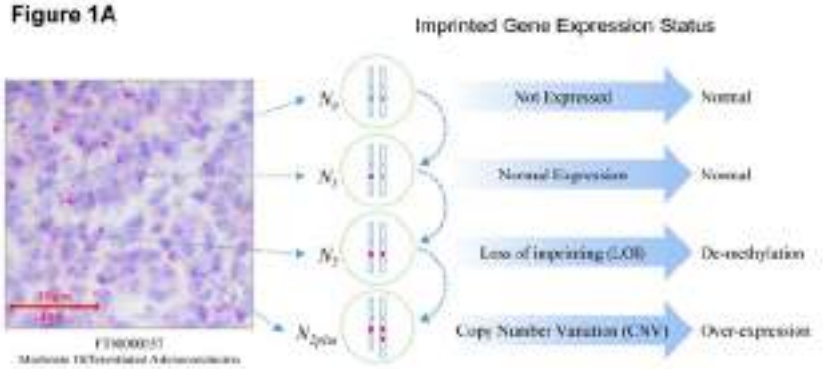


Figure 1B

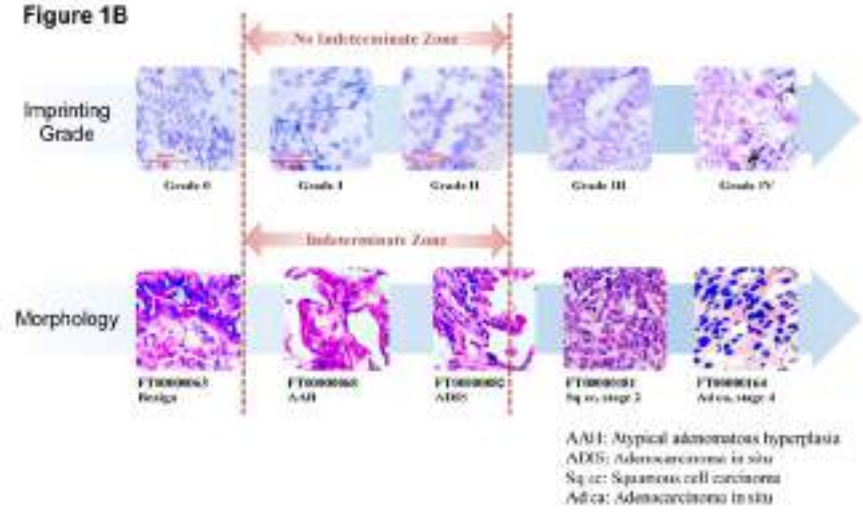

Result: Technicians trained in counting LOI and CNV studied 198 cases of lung samples in a blinded fashion to score LOI, CNV and TE (Figure 1A). These included 29 benign, 20 with Atypical Adenomatous Hyperplasia (peripheral), 11 Adenocarcinoma-in-situ (ADIS), 138 invasive squamous and adenocarcinomas (64 stage 1, 20 stage 2, 54 stages 3&4). A grading model from Grade 0 (benign) to Grade IV (highly malignant) is developed based on the expression pattern of the three genes epigenetic panel to correlate with pathological staging. Grade 0 (benign) corresponds with benign normal, Grade I (malignant potential) corresponds with precancerous AAH, Grade II (limited disease) corresponds to ADIS, Grade III (more invasive) corresponds to stage 1 and 2, and Grade IV (highly invasive) corresponds to stages 3 and 4. (Figure 1B) **Conclusion:** Imprinted gene detection by ISH staining provides a novel way to visualize and quantify epigenetic changes occurring in earlier stages of lung cancer development. The quantitative grading model can reduce the subjective variation in diagnosis and provide a more precise tool to assist the pathologist. Inclusion of an expanded panel of imprinted genes, studying larger specimen sets and adaptation by automated image analysis hold promise of advancing standardization of early lung cancer diagnosis.

P1.09-13 PROGNOSTIC VALUE OF TMPRSS4 EXPRESSION AND ITS ROLE AS DIAGNOSTIC BIOMARKER BY LIQUID BIOPSY IN EARLY STAGE NSCLC

F. Exposito[1,2,3], M. Villalba[1,2,3], M.J. Pajares[1,2,3], C. Sainz[3], A. Remirez[3], E. Jantus[1,4,5], C. Camps[1,4,5], L. Montuenga[1,2,3], R. Pio[1,3], C. De Andrea[2], A. Calvo[1,2,3]

[1]*CIBERONC, ISC-III, Spain/Spain,* [2]*Department of Pathology, Anatomy and Physiology, University of Navarra, Pamplona/Spain,* [3]*IDISNA and Program in Solid Tumors, Center for Applied Medical Research (CIMA), University of Navarra, Pamplona/Spain,* [4]*Molecular Oncology Laboratory, Fundacion para la Investigación del Hospital General Universitario de Valencia, Valencia/Spain,* [5]*Universitat Politecnica de Valencia, Valencia/Spain*

Background: Relapse rates in surgically-resected non-small cell lung cancer (NSCLC) patients are between 30-45% within 5 years of diagnosis, which reflects the clinical need to identify those patients at high risk of recurrence and death. TMPRSS4 is a serine protease that plays a role in lung cancer growth, development of metastasis and resistance to chemotherapy in NSCLC models. TMPRSS4 is overexpressed through promoter hypomethylation in NSCLC tumors. **Method:** Two cohorts of NSCLC patients (MD Anderson (MDA), n=489; and Clinica Universidad de Navarra (CUN), n=95) were used to investigate the prognostic value of TMPRSS4. The WHO 2004 classification and 8th TNM edition was used for tumor stratification. We have also developed a method to quantify he degree of TMPRSS4 and SHOX2 methylation status in liquid biopsy (plasma and bronchoalveolar lavages (BALS)) by digital droplet PCR (ddPCR), in tumor-free individuals and patients with NSCLC. **Result:** High levels of TMPRSS4 were significantly associated with reduced relapse-free survival (RFS, p<0.001) and overall survival (OS, p<0.001) in the MDA cohort, and with OS in the CUN cohort (p<0.049). In univariate Cox regression analysis using the MDA cohort, high TMPRSS4 levels were RFS (HR=2.09; 95% IC [1.53-2.87], p<0.001) and OS (HR=1.82; 95% IC [1.38-2.41], p<0.001). In multivariate analyses, TMPRSS4 was found as an independent prognostic factor for both RFS (HR=1.82, IC [1.28-2.60], p<0.001) and OS (HR=1.44, IC [1.07-1.94], p<0.014).

In our MDA cohort, stage IA and stage IB showed no statistical differences for RFS (p=0.27) or OS (p<0.001). However, when considering the protein expression of TMPRSS4 we were able to substratify stage IA patients in low and high risk patients, since those with high TMPRSS4 levels showed a significantly reduced RFS (p=0.002) and OS (p<0.001). Similar tendency was observed for stage IB, although statistical differences were not found.

After successful establishment of the ddPCR conditions for TMPRSS4 and SHOX2 methylation status, we analyzed plasmas and BALS in case-control studies. In BALS (79 NSCLC patients and 26 controls), significant hypomethylation (p<0.01) was found for TMPRSS4 in the case of patients with early stage NSCLC in comparison with controls, with an AUROC of 0.72 (95% IC, 0.57-0.87) (p=0.008). SHOX2 was significantly hypermethylated in BALS from early stage NSCLC compared to controls (p<0.01), with an AUROC of 0.71 (95% IC, 0.56-0.86) (p=0.01). In the case of plasmas (89 NSCLC patients and 25 controls): in early stages, a significant hypomethylation was found for TMPRSS4 (p<0.05), with an AUROC of 0.73 (95% IC, 0.54-0.90) (p=0.015). For SHOX2, only late stages NSCLC showed significant hypermethylation with respect to controls (p<0.05), with an AUROC of 0.68 (95% IC, 0.54-0.80) (p=0.025). **Conclusion:** High TMPRSS4 levels are associated with worse prognosis in NSCLC patients. TMPRSS4 expression significantly discriminates patients with higher risk of disease progression and poor survival outcome in early stage NSCLC. Methylation status of TMPRSS4 can be used in both plasma and BALS to identify patients with NSCLC.

Keywords: TMPRSS4, liquid biopsy, methylation

P1.09-14 COMPARISON BETWEEN LIQUID BIOPSY AND CONVENTIONAL TISSUE BIOPSY IN EGFR GENOTYPING OF NON-SMALL CELL LUNG CANCER

S.H. Lee, E.Y. Kim, A. Kim, T. Kim, Y.S. Chang

Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of

Background: In lung cancer, tissue biopsy is usually invasive and could provoke a severe procedural complication depending on the location and size, while liquid biopsy is non-invasive, and novel emerging method in lung cancer. In this study, we investigated the sensitivity, specificity, and concordance rate of liquid biopsy (blood and bronchoalveolar lavage fluid (BALF)) comparing with tissue biopsy. **Method:** A total of 31 patients' tissue, blood, and BALF were available. The EGFR mutation status in blood, and BALF were investigated by ultrasensitive droplet-digital polymerase chain reaction (ddPCR) method. We applied two QC criteria for the results of ddPCR were used as previous study showed: 1) the droplet number must be greater than 9000; 2) the wild type levels to be greater than 100 copies/mL. **Result:** Female was 15 (48.4%) and mean age was 66.4 ± 9.6. Clinical sensitivity was 20.0% [2/10] for E19del and 36.4% [4/11] for L858R in plasma, while in BALF, those was 70.0% and 81.8%, respectively. The concordance rates of plasma with tissue-based results of EGFR mutations were 71.0% for E19del and 77.4% for L858R. In BALF, those were 83.9% for E19del, and 90.3% for L858R. The area under the curve (AUC) for E19del was 0.576 in blood and 0.802 in BALF. The AUC for L858R was 0.682 in blood and 0.884 in BALF. The values of AUC between blood and BAL did not show significant difference. **Conclusion:** BALF could be a substitute for biopsy in EGFR genotyping and BALF might be helpful in diagnosis of lung cancer in situations where it is difficult to perform biopsy or rebiopsy is needed. Further prospective large scaled studies are needed to investigate the utility of BAL in lung cancer.

P1.09-15 HYBRID ORGANOID REVEALS THAT PODOPLANIN-POSITIVE CANCER-ASSOCIATED FIBROBLASTS ENHANCE PROLIFERATION OF LUNG CANCER CELL

H. Nakamura[1,2], M. Sugano[2], T. Miyashita[2], H. Hashimoto[2], A. Ochiai[3], K. Suzuki[4], M. Tsuboi[5], G. Ishii[2]

[1]*Juntendo University, Tokyo/Japan,* [2]*Division of Pathology Exploratory Oncology Research & Clinical Trial Center (EPOC), Kashiwa/Japan,* [3]*National Cancer Center, Chiba/Japan,* [4]*JUntendo University, Tokyo/Japan,* [5]*National Cancer Center Hospital East, Kashiwa/Japan*

Background: Podoplanin-positive cancer-associated fibroblasts (CAFs) play an important role in tumor progression. The aim of this study was to evaluate the effect of podoplanin (+) CAFs on the proliferation of cancer cells using a three-dimensional (3D) organoid model. **Method:** We examined the success rate of organoid culture containing PC-9 cancer cells and CAFs. Thereafter, we compared the proliferating index (MIB-1 index) of PC-9 cells co-cultured with podoplanin-overexpressing CAFs and control CAFs using organoid specimens. Furthermore, we compared the MIB-1 labeling index of cancer cells in podoplanin (+) CAFs cases (n = 13) and podoplanin (-) CAFs cases (n = 14) using surgically resected adenocarcinoma specimens. **Result:** Without CAFs, PC-9 cells did not form any organoid (success rate: 0%). When PC-9 cells were mixed with CAFs (1:10), the mixed cells generated round and steric aggregates (hybrid cancer organoids, success rate: 100%). In three independent experiments, the MIB-1 index of PC-9 cells in hybrid cancer organoids containing podoplanin-overexpressing CAFs was significantly higher than that of PC-9 cells in organoids containing control CAFs (Exp. 1: 40.4% vs. 24.4%; Exp. 2: 40.0% vs. 24.5%; Exp. 3: 40.3% vs. 25.2%; p < 0.001). Surgically resected human tumors revealed that the MIB-1 index of adenocarcinoma cells was significantly higher in the case of podoplanin (+) CAFs than in the case of podoplanin (-) CAFs (34.8% vs. 16.2%; p < 0.01). **Conclusion:** Our data suggested that the hybrid cancer organoid model might reflect the growth-promoting effect of podoplanin (+) CAFs in cancer cells, and this new system can be a useful tool for evaluating the tumor microenvironment.

Keywords: podoplanin, cancer associated fibroblast, hybrid cancer organoid

P1.09-16 TUMOR PROLIFERATION IS ASSOCIATED WITH THE TUMOR IMMUNOLOGICAL STATUS: A STUDY ON NSCLC USING MULTIPLEX IMMUNOFLUORESCENCE

A. Spitzmüller[1], T.H. Tan[1], M. Surace[2], L. Rognoni[1], D. Chain[2], V. Pawar[1], J. Rodriguez Canales[2]

[1]*Definiens AG, Munich/Germany,* [2]*AstraZeneca, Gaithersburg/United States of America*

Background: Several studies have been focused on the immunoprofiling of non-small cell lung carcinomas (NSCLC) trying to characterize its immunological microenvironment and its association with therapy, clinical outcome and mutational status, including tumor mutation burden (TMB), with special emphasis on the identification of potential predictive biomarkers. Tumor proliferation index (TPI) evaluated by the expression of Ki67 in the tumor cells had shown clinical relevance as a general prognostic and predictive marker in several tumor types such as breast cancer, although its clinical relevance in NSCLC is not fully clear. Therefore, our goal was to analyze the TPI in NSCLC and to correlate it with the tumor immune profile, including PD-L1 and tumor-associated lymphocytes. **Method:** Formalin fixed, paraffin embedded tissue sections from 48 NSCLC specimens (25 adenocarcinomas, 22 squamous cell carcinomas, 1 NSCLC NOS) were immunostained with a multiplex immunofluorescence (mIF) panel including keratins (AE1/AE3), PD-L1, PD1, CD8, CD68 and Ki67. All samples were obtained according the Declaration of Helsinki. The mIF slides were imaged in a multispectral scanner (Polaris, Akoya Biosciences) and analyzed by using Definiens Insights platform with custom algorithms at Definiens AG (Munich, Germany). The data was then analyzed by various parameters to generate Spearman's correlation coefficients. **Result:** Our preliminary analysis showed that TPI correlated with the percentage of malignant cells expressing PD-L1 (r = 0.63). TPI also correlated with the infiltration by proliferating cytotoxic T-cells (CD8+ Ki67+, r = 0.67). Cell density of proliferating cytotoxic T-cells also correlated with the percentage of PD-L1 expression by malignant cells (r = 0.75), percentage of PD-L1 positive macrophages (r = 0.79), and with the expression of PD-1 by cytotoxic T cells (r = 0.79). Interestingly, we noticed that higher histological tumor grades (but not TNM stage status) presented a trend to show higher readouts including TPI, percentage of PDL1 expression in tumor cells and macrophages, and CD8 cell densities. **Conclusion:** Our multiplex IF analysis on NSCLC including tumor proliferation index shows evidence suggesting a correlation between the tumor proliferative activity and the immune microenvironment, including PD-L1 expression in both, tumor cells and macrophages, as well as higher proliferative cytotoxic T-cells. We hypothesize that the tumor proliferative activity has a mechanistic association with the tumor immunological status; therefore, TPI evaluated by Ki67 expression in tumor cells could be a candidate as a potential biomarker in association with the immunoprofiling data.

P1.09-17 IN THE MINIMALLY INVASIVE ERA, WHAT IS THE ROLE OF INTRA-OPERATIVE FROZEN SECTION PRIOR TO LOBECTOMY: A SINGLE INSTITUTION PERSPECTIVE

A. Kar, A. Patel, B. Tinwell, I. Hunt

St George's Hospital, London/United Kingdom

Background: Current guidelines recommend tissue diagnosis prior to radical surgical resection (lobectomy), especially as there are cases when the final histology may be benign. Regardless of anatomical, technical or patient specific factors, the availability of pre-operative CT guided biopsy and intra-operative frozen section (IOFS) is an important consideration, which likely contributes to variability between surgeons, hospitals, tumour boards and regional/national practice. With the widespread uptake of Robotic and Video-Assisted Thoracoscopic Surgery (RATS/VATS), there has become more of a trend towards 'exploration' with planned 'wedge biopsy', IOFS and then proceeding to anatomical resection if positive for malignancy. This has the potential to minimise delays in the patient cancer pathway. In the era of minimally invasive thoracic surgery, we sought to establish the role of IOFS in our institution. **Method:** A retrospective analysis was performed for 309 consecutive lobectomy pathology specimens from a single institution (six surgeons) between Jan 2016-Jun 2017. 78/309 cases identified without pre-operative tissue analysis (25%) and further interrogated. **Result:** Figure 1 shows management pathway followed for the patients who underwent lobectomy without pre-operative tissue diagnosis. 49% had positive IOFS and proceeded to lobectomy (final histology: all malignancy). There were 8 negative IOFS (10%), which proceeded; half were malignant on final histology (5.1%). 32/78 patients (41%) proceeded directly to lobectomy without diagnosis; 22% had CT-Biopsy attempted while 16% were not amenable. 53% (n=17) had IOFS attempted but not possible. In this cohort 5 cases were benign on final histology.

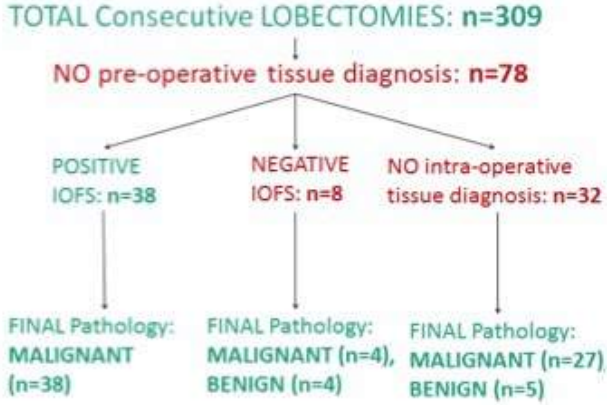

Figure 1: Flow Chart summarising key study findings

Conclusion: Efforts to obtain tissue diagnosis prior to surgical resection should be made, as up to 3% could be for benign pathology. In our tertiary thoracic centre, there was observed variability in CT-guided biopsy protocols between regional tumour boards, along with surgeon specific practice. Nevertheless more than half of patients without a pre-operative tissue diagnosis required IOFS, which was 100% accurate in confirming patients with lung cancer on final histology. Although direct resection is arguably merited based on history, imaging and current stratification (Brock/Herder) models, unnecessary procedures can cause patient morbidity and mortality. Therefore, IOFS still has a key role in thoracic surgical practice and close collaboration between surgeons and pathologists should be fostered in the future. Finally with the introduction of screening for patients deemed high risk for lung cancer likely to increase the case-load for tumour boards, we argue that availability of IOFS in institutions will continue to be necessary to help with optimising the patient cancer pathway.

P1.09-18 SMALL-SIZED SPREAD THROUGH AIR SPACES (STAS) IN RESECTED PULMONARY ADENOCARCINOMA: IS IT NECESSARY TO RECORD IT AS A PROGNOSTIC FACTOR?

A. Yoshizawa, K. Kondo, N. Nakajima

Kyoto University Hospital, Kyoto/Japan

Background: Spread through air spaces (STAS) is a recently recognized invasive pattern of lung cancer that is a prognostic factor in patients who have undergone resection. It is histologically defined as "micropapillary clusters, solid nests, or single cells extending beyond the edge of the tumor into air spaces" in the 2015 World Health Organization classification of lung tumor fascicles; however, the prognostic significance of each pattern has not been studied well. This study evaluated their prognostic significance through a histological review of 1043 resected pulmonary adenocarcinoma (P-ADC) specimens. **Method:** STAS was classified as follows: STAS 1, tumors with mainly small-sized clusters (1–3 tumor cells); STAS 2, tumors with mainly medium-sized clusters (4–20 typical micropapillary-pattern tumor cells); and STAS 3, tumors with large-sized clusters (>20 tumor cells). We recorded the STAS type of each specimen, analyzed its association with clinicopathological parameters, and assessed the prognostic significance of STAS in resected P-ADC specimens. **Result:** Overall, 366 tumors (35.6%) were STAS positive, which was associated with male gender (P = 0.005), larger tumor size (P < 0.001), node metastasis (P < 0.001), lymphovascular and pleural invasion (all, P < 0.001), and higher

stage (P < 0.001). The commonest type of STAS was STAS 2 (n = 262, 24.9% of all tumors), followed by STAS 3 (n = 69, 6.4% of all tumors) and STAS 1 (n = 28, 2.6% of all tumors). Patients with STAS-positive tumors had worse overall survival (OS) and disease-free survival (DFS) than patients with STAS-negative tumors (both P < 0.001). Patients with STAS 3 and STAS 2 tumors had worse prognosis than patients with STAS-negative tumors. However, there were prognostic differences between patients with STAS-negative tumors and those with STAS 1 tumors (log rank test, P = 0.764 for OS; P = 0.958 for DFS). **Conclusion:** STAS is a strong prognostic factor; however, tumors with small-sized STAS (STAS 1) do not differ from tumors without STAS with respect to recurrence and mortality in patients with P-ADCs. This result may indicate that it is not necessary to record or recognize small-sized STAS as STAS.

P1.09-19 HIGH-THROUGHPUT NEXT GENERATION SEQUENCING OF TREATMENT-NAÏVE NON-SQUAMOUS NSCLC: THE SINGAPORE NATIONAL LUNG PROFILING STUDY

A. Tan[1], G. Lai[1], G.S. Tan[2], S.Y. Poon[2], B. Doble[3], T.H. Lim[2], Z.W. Aung[1], A. Takano[2], W.L. Tan[1], M.K. Ang[1], B.S. Tan[2], A. Devanand[2], C.W. Too[2], A. Gogna[2], B.H. Ong[2], T. Koh[2], R. Kanesvaran[1], Q.S. Ng[1], A. Jain[1], T. Rajasekaran[1], A. Lim[2], W.T. Lim[1], C.K. Toh[1], E.H. Tan[1], K.H. Lim[2], D. Tan[1]

[1]*National Cancer Centre Singapore, Singapore/Singapore,* [2]*Singapore General Hospital, Singapore/Singapore,* [3]*National University of Singapore, Singapore/Singapore*

Background: Scaling traditional single biomarker assays are hampered by the need to evaluate an expanding list of therapeutically relevant biomarkers in small biopsies. We sought to compare the performance of targeted NGS panels with traditional assays, and correlate the mutational landscape with PD-L1 status in Singaporean lung cancer patients (pts). **Method:** We identified consecutive pts diagnosed between Jan 2016 to Sep 2017 with residual tissue after standard molecular testing (for EGFR, ALK, ROS1, MET, RET alterations). Tissue samples were tested using a targeted NGS panel (29 selected genes including BRAF, ERBB2, KRAS/NRAS, TP53) and an RNA fusion panel (ALK, ROS1, RET). PD-L1 immunohistochemistry (E1L3) was also performed (TPS: <1%, 1-49%, ≥50%). **Result:** A total of 174 samples were evaluated: PD-L1 (n=170), NGS DNA panel (n=161) and RNA fusion panel (n=118). Median age was 68 years, 53% were male, 58% were non-smokers, 85% were Chinese, 66% had metastatic disease and 95% had adenocarcinoma histology. In NGS DNA profiled pts, EGFR (55%), KRAS (16%), ERBB2 (4%) and BRAF (2%) alterations were found. RNA fusion testing revealed ALK (6%), RET (3%) and ROS1 (1%) fusions. The sensitivity and specificity for NGS versus standard molecular testing was >90% for all subtypes of EGFR mutation. Only 11% of the cohort had both no detectable actionable alteration on NGS (with targeted agents that are approved or in ongoing clinical trials) and PD-L1 <1%. Median turnaround time for NGS was 10 days (range 6-30). Cost-effectiveness analysis demonstrated that current standard testing was less effective and more costly than the other three testing strategies. Compared to sequential testing of NGS in EGFR negative pts only, upfront NGS testing resulted in an additional 1% of pts receiving targeted therapy for an additional SGD$110 and compared to upfront NGS testing, hotspot testing (NGS in EGFR, ALK/RET/ROS1 FISH negative pts only) resulted in an additional 4% of pts receiving targeted therapy for an additional SGD$1044. In the subset of pts with metastatic EGFR mutant NSCLC after first-line therapy with EGFR TKI (n=64), PFS was worse in patients with EGFR and TP53 co-mutation (n=32) compared to EGFR mutation alone (n=32; HR 0.54, 95%CI 0.30-0.98, p=0.042). **Conclusion:** We demonstrated that even in an EGFR mutant predominant population, upfront NGS and PD-L1 testing represents a feasible, cost-effective method of diagnostic molecular profiling. The additional information from NGS in characterizing the wider genomic profile may also have prognostic significance in EGFR mutant pts. More broadly, our results support the implementation of NGS in non-squamous NSCLC to allow pts access to the most appropriate personalized therapy.

P1.09-20 SIGNIFICANCE OF MAXIMAL DIAMETER MEASUREMENT IN SMALL-SIZED ADENOCARCINOMAS

H. Ninomiya[1], J. Ichinose[2], Y. Matsuura[2], M. Nakao[2], M. Mun[2], M. Nishio[3], S. Okumura[2], Y. Ishikawa[4]

[1]*The Cancer Institute, Japanese Foundation for Cancer Research, Tokyo/Japan,* [2]*Cancer Institute Hospital, JFCR, Tokyo/Japan,* [3]*The Cancer Institute Hospital of Japanese Foundation for Cancer Research, Tokyo/Japan,* [4]*International University of Health and Welfare Mita Hospital, Tokyo/Japan*

Background: 8th edition of the TNM classification for lung cancer has been available since Jan. 2017. The changes are based on a new database of about 90000 evaluable patients with lung cancer. The proposed changes primarily reflect stratification of patients with lung cancer into prognostically more-precise categories. The revision includes new tumor-size criteria and better-defined classification of additional tumor nodules, subclassifications of lymph node, and systemic metastases. However, invasive size measurement is difficult in some cases, so interobserver variability is inevitable. A maximal size measurement can reduce the interobserver variability to assess the small tumors. To clarify the significance of the maximal diameter measurement, small-sized tumors (10mm or less in maximal diameter) was also subclassified and prognosis after surgery was compared with conventional classification. In addition, we identified the characteristics of small-sized tumor with a worse prognosis. **Method:** Pulmonary adenocarcinoma treated surgically at our hospital between Jan. 2006 and Dec. 2011 were recruited. All the cases were evaluated according to the 8th TNM classification. Subsequently, the group with maximal diameter 10mm or less were subcategorized. The Kaplan-Meier method was used to calculate survival. Moreover, clinicopathological characteristics of recurrent cases were also reviewed. **Result:** Tumors with 10mm or less maximal diameter comprised 33.6% (94/288) of pTis, pT1mi and pT1a tumors. Average maximal diameter did not differ statistically between pT1mi and pT1a groups (*P*=0.38). Prolapse-free and disease-specific survivals of the cases with maximal diameter 10mm or less tumors without nodal metastasis were 98.8% and 100%, respectively. Only two cases with maximal diameter 10mm or less tumors recurred (2%, 2/94), both being solid type on CT image and one of the two cases exceptionally showed vascular and pleural invasion as well as nodal metastasis. The maximal diameter of recurrent cases clustered around the value of 10mm. **Conclusion:** Only a small fraction of tumors with maximal diameter 10mm or less recurred in our series. Since the recurrent cases clearly showed particular findings including vascular and pleural invasion and a solid image on CT, they can be differentiated from other tumors pathologically or by CT. The maximal diameter measurement is useful in tumors with 10mm diameter or less to estimate the tumor prognosis.

P1.09-21 TUMOR RESPONSES BASED ON TUMOR GROWTH RATE DURING PD-1 INHIBITOR THERAPY IN ADVANCED NON-SMALL-CELL LUNG CANCER PATIENTS

D. Ten Berge[1], D. Hurkmans[2], I. Den Besten[2], J. Kloover[1], R. Mathijssen[2], R. Debets[2], E. Smit[3], J. Aerts[2]

Background: Immune checkpoint inhibitors have emerged as a standard of care treatment for non-small cell lung cancer (NSCLC). However, there remains debate about the tumor growth kinetics during treatment, for instance the incidence of rapid disease progression, described as hyperprogressive disease (HPD). To get insight into variations in tumor growth kinetics and their potential predictive values for outcome we evaluated tumor growth rate (TGR) in patients receiving PD-1 checkpoint inhibitors. **Method:** An analysis and radiological review of all Nivolumab treated NSCLC patients (n=196) between 06-2015 and 09-2017 in an early access program and as standard of care was performed. Differences in TGR before and after the start of treatment were calculated by entering the sum of the longest diameters from CT-scans before and after the initiation of therapy into a formula that assumes a volumetric exponential tumor growth. TGR variations, possible predictors for TGR changes and its relationship to overall survival (OS) were studied. For comparison tumor response was assessed using Response Evaluation Criteria in Solid Tumors version 1.1 (RECIST1.1).

Result: Among the 58 evaluable patients, 37 patients (64%) showed deceleration of TGR and 16 patients (27%) showed acceleration of TGR after initiation of therapy, with a significant difference in median OS of 18.0 versus 6.0 months (HR=0.35; 95%CI:0.18-0.71) between these groups. Four patients (7%) were defined as having HPD. In 5 patients (9%), the tumor growth remained stable. These TGR categories were not significantly different according to age, gender, histology, smoking or previous radiotherapy. Of the patients defined as having progressive disease by RECIST1.1 at first follow up 40% showed response to CPI by a decrease in tumor growth rate. (Figure 1) **Conclusion:** Tumor growth kinetics can be used as a clinically relevant predictor for OS in anti-PD1 treated NSCLC patients, and may provide additional information to RECIST measurements.

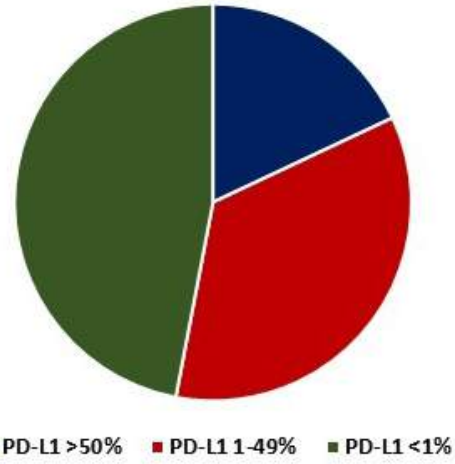
P1.09-22 PROGRAMMED DEATH LIGAND-1 EXPRESSION IN NON-SMALL CELL LUNG CANCER IN MEXICAN POPULATION AND CORRELATION WITH CLINICOPATHOLOGIC FEATURES

L. Bornstein[1], O. Macedo-Perez[2], I. Lyra Gonzalez[3], C. Bautista-Wong[1], J. Cienfuegos-Meza[1], K. Campos-Peralta[2], E. Jimenez-Fuentes[2]

[1]*Inmuno Q S.C., Ciudad de Mexico/Mexico,* [2]*Instituto Nacional de Cancerologia, Ciudad de Mexico/Mexico,* [3]*Princess Margaret Cancer Centre, Toronto/Canada*

Background: Immune checkpoint inhibition is an important therapeutic option in patients with non-small cell lung cancer. Programmed cell death ligand-1 (PD-L1) expression may serve as a predictive and prognostic factor for anti-PD-1/PD-L1 therapies. We conducted a national, retrospective, observational study to determine PDL1 prevalence and correlation with clinicopathologic features. **Method:** Patients with histologic confirmed stage III/IV NSCLC and available tissue block were included. PDL1 tumor expression was performed with PDL1 IHC (SP263) assay on a Ventana Benchmark XT platform. Tumor cell PD-L1 expression was scored as Tumor Proportion Score (TPS) and classified as negative (<1%), 1-49% and ≥ 50% for correlation with clinicopathologic features. **Result:** Of a total of 948 patients included in the study, 170 (18%) were TPS >50%, 333 (35%) and 445 (47%) were TPS 1-49% and negative (<1%) respectively. The TPS was higher in squamous cell carcinomas (p=0.001) due to increased proportion of strong expression (>50%). Among the 778 non-squamous carcinomas, 187 (24%) had EGFR mutations and 31 (4%) showed ALK translocations. A TPS >50% was seen in 25% (47/187) and 21% (6/31) EGFR mutant and ALK translocated tumors, respectively.

Figure 1. Frequency PD-L1 Expression in Mexican population



Conclusion: The overall prevalence of TPS ≥ 50% is slightly lower than previously reported. TPS was significantly higher in squamous cell carcinomas and there was no correlation between PD-L1 expression and molecular abnormalities, or age, gender and smoking status.

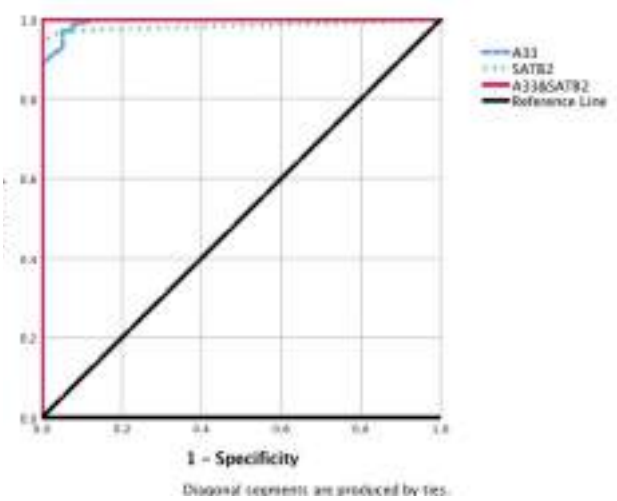
P1.09-23 A33 AND SATB2 IMMUNOHISTOCHEMISTRY FOR DIFFERENTIATING METASTATIC COLORECTAL CARCINOMA FROM PULMONARY ENTERIC ADENOCARCINOMA

L. Hou, C. Wu, W. Zhang, J. Guo

Shanghai Pulmonary Hospital, Shanghai/China

Background: Primary pulmonary enteric adenocarcinoma (PEAD) resemble morphology and immunohistochemistry with metastatic colorectal carcinoma(mCRC). it is sometimes difficult to differentiate PEAD from mCRC. Here, we evaluated the diagnostic value of A33 and SATB2 in discriminating between PEAD and mCRC. **Method:** Resected 39 PEAD and 69 mCRC cases were retrospectively recruited. PEAD patients were performed colonoscopy postoperatively and were followed more than 1 year to exclude mCRC. Patients with mCRC were diagnosed by colorectal carcinoma history before or after thoracic surgery. A panel of immuohistochemistry markers were analyzed including A33, SATB2, CK7, CK20, TTF-1, Napisn A, CDX2 and villin. Tumor staining was scored for positive percentage and intensity, with a maximum possible score of 300. **Result:** A33, SATB2 and CK20 showed specificity for PEAD: 94.9%, 92.3% and 88.9%, respectively; sensitivity for mCRC: 97.1%, 97.1% and 91.3%, respectively. CK7 expression was 91.4% sensitive and 90.9% specific for PEAD. A33 and SATB2 were slightly higher than CK20 for specificity in PEAD. The AUC for tumor staining of A33, SATB2 was 0.994 and 0.984, individually; In combination of them, the AUC was 1.000. The staining of TTF-1 was focal and weak in one mCRC case. No Napsin A expression was found in mCRC. The positive rate of TTF-1 and Naspin A expression in PEAD was 46.2% (18/39) and 25.6% (10/39). There was similar for CDX2 and villin expression between PEAD and mCRC.



Conclusion: Our results showed that a panel of A33 and SATB2 was potentially optimal markers for differentiating PEAD from metastatic colorectal carcinoma.

P1.09-24 TUMOR NECROSIS CORRELATES WITH PD-L1 AND PD-1 EXPRESSION IN LUNG ADENOCARCINOMA

J. Moldvay[1], V. Téglási[2], O. Pipek[3], L. Rojkó[1], T. Glasz[2], A. Vágvölgyi[1], I. Kovalszky[2], M. Gyulai[4], Z. Lohinai[1], E. Rásó[2], J. Tímár[2], B. Döme[1], Z. Szállási[2], L. Reiniger[2]

[1]*National Koranyi Institute of Pulmonology, Budapest/Hungary,* [2]*Semmelweis University, Budapest/Hungary,* [3]*ELTE, Budapest/Hungary,* [4]*County Hospital of Pulmonology, Torokbalint/Hungary*

Background: Predictive biomarkers for immunotherapy in lung cancer are intensively investigated, however, correlations between PD-L1/PD-1 expressions and clinical features or histopathological tumor characteristics determined on hematoxylin and eosin stained sections have not extensively been studied. **Method:** We determined PD-L1 expression of tumor cells (TC) and immune cells (IC), and PD-1 expression of IC by immunohistochemistry in 268 lung adenocarcinoma (LADC) patients, and correlated the data with smoking, COPD, tumor grade, necrosis, lepidic growth pattern, vascular invasion, density of stromal IC, and *EGFR/KRAS* status of the tumors. **Result:** There was a positive correlation between PD-L1 expression of TC and IC, as well as PD-L1 and PD-1 expression of IC. Tumor necrosis was associated with higher PD-L1 expression of TC and PD-1 expression of IC. A negative correlation was observed between lepidic growth pattern and PD-L1 expression of TC and PD-L1/PD-1 expression of IC. *EGFR* mutation seemed to negatively correlate with PD-1 expression of IC, but this tendency could not be verified when applying corrections for multiple comparisons. No significant effect of the *KRAS* mutation on any of the studied variables could be established. **Conclusion:** Here we first demonstrate that the presence of necrosis correlates with higher PD-L1 expression of TC and PD-1 expression of IC in LADC. Further studies are required to determine the predictive value of this observation in LADC patients receiving immunotherapy.

Keywords: PD-L1, lepidic growth pattern, tumor necrosis

P1.09-25 THE USE OF IN-SITU RNA ANALYSIS IN THE DETECTION OF METASTATIC HPV MEDIATED SQUAMOUS CELL CARCINOMA TO THE LUNG WITH P16 CORRELATION

R. Katerji, D. Mulford, M. Velez

University of Rochester Medical Center, Rochester/United States of America

Background: The distinction between metastatic squamous cell carcinoma and a pulmonary primary is often necessary to determine treatment recommendations and communicate prognosis to patients and their families. Human papillomavirus (HPV) is oncogenic mediator of oropharyngeal squamous cell carcinoma (SCC), cervical SCC, including SCC of cutaneous, and other genital sites. The incidence of distant metastases from HPV-mediated oropharyngeal carcinoma can be as high as 12% (Huang, et al Oral oncology 2013) and the lung is the most common site of metastasis. The significance of p16 immunohistochemistry (IHC) expression in primary lung SCC is unknown however; in the oropharynx and cervix, p16 IHC positivity has been established as a surrogate marker for high risk HPV infection. Our study will aim to examine the detection of HPV E6/E7 mRNA transcripts in infected tumor cells using RNAScope® in situ hybridization (ISH) on formalin fixed paraffin embedded tissue and its utility to help differentiate metastatic disease from a lung primary. **Method:** A retrospective review of institutional archives in pathology and laboratory medicine between September 2006 and September 2018 was conducted. Nineteen cases of lung SCC in patients with a history of head and neck, cervical, perianal and perineum squamous cell carcinoma were identified. Materials from the primary sites were allocated. As a control group, nineteen additional cases of pulmonary SCC without a prior history of malignancy were identified and included in the study. Immunohistochemistry for p16 (clone E6H4), HPV RNA ISH for high-risk and low-risk HPV subtypes were performed and evaluated. **Result:** Three of nineteen cases were excluded due to a lack of sufficient material. Ten of Sixteen presumed HPV mediated primaries were positive for p16. The remaining six were negative for p16 and negative for HPV RNA ISH. Seven of Sixteen (44%) cases with a presumed HPV mediated primary were from oropharyngeal sites and were positive for both p16 and high risk HPV RNA ISH while negative for low risk HPV RNA ISH. The remaining ten of sixteen cases (62.5%) were negative for p16, high-risk and low-risk HPV RNA ISH. Two primary cervical squamous cell carcinomas were positive for p16 however, one of two subsequent lung biopsies showed p16 positivity and both were negative for HPV RNA-ISH. In the control group, two of nineteen cases (10.5%) were reactive for p16, however all cases were negative for high and low-risk HPV RNA ISH. **Conclusion:** HPV RNA ISH is a rapid confirmatory assay allowing for detection and confirmation of metastatic disease in patients with HPV mediated malignancy, particularly from oropharyngeal origin. Immunohistochemistry for p16 alone is not specific in distinguishing between a lung primary and metastatic SCC and is not recommended as a surrogate marker for confirming metastatic disease. Detection of viral transcrips allows for successful treatment and prognostic stratification. These preliminary findings may be useful to assess on a larger scale.

Keyword: metastatic, oropharyngeal, HPV

P1.09-26 PREVALENCE OF PD-L1 EXPRESSION RATES IN DIFFERENT NSCLC SPECIMENS

M. Holmes[1], A. Mahar[1], T. Lum[1], M. Boyer[2], S. Kao[2], W. Cooper[1]

[1]*Royal Prince Alfred Hospital, Camperdown/Australia,* [2]*Chris O'Brien Lifehouse, Camperdown/Australia*

Background: Programmed death-ligand 1 (PD-L1) expression on tumor cells by immunohistochemistry (IHC) is a predictor of response to immune checkpoint inhibitors used to treat advanced non-small cell lung cancer (NSCLC). High PD-L1 expression (≥50% of tumor cells) is required for patients to receive first line pembrolizumab monotherapy. Assessing expected PD-L1 expression rates in real-world specimens is an important factor in ensuring patients are accessing the most effective treatments available. The aim of this retrospective assessment was to review the local prevalence of PD-L1 expression in NSCLC and compare different specimen types. **Method:** We retrospectively reviewed cases of NSCLC stained with PD-L1 IHC Ventana SP263 assay between January 2017 and March 2019. PD-L1 expression was assessed as a tumor proportion score (TPS) of 0-<1%, 1-49% or ≥50% positive membrane staining within tumor cells. Results were compared with specimen type and mutation status. **Result:** PD-L1 expression was assessed in 264 cases of NSCLC during the 51 month period. The median patient age was 70 years, 64.4% were >65 years old and 60.9% were male. Histologically, 79.9% were adenocarcinoma, 10.6% squamous cell carcinoma and 9.5% NSCLC-NOS. Overall 29.5% of NSCLC showed high PD-L1 expression (≥50%), 43.9% low (1-49%), and 26.5% no expression (<1%). In known *EGFR/ALK* negative cases (n=176), high, low and negative PD-L1 was seen in 34.7%, 43.2% and 22.1% respectively. Histology samples accounted for 80.7% of cases and 19.3% were cytology. Lung resections accounted for 27.7% with other specimen types (small biopsies, cytology and metastatic resections) accounting for 72.3%. 61.0% were primary tumors and 39.0% were from metastases. A PD-L1 TPS of ≥50% was seen in 29.1% of

histology and 31.4% of cytology specimens, with no statistically significant difference (p=0.55). Amongst lung resections, high PD-L1 expression was observed in 19.2% of cases compared to 33.5% in other specimen types (p<0.01). In primary tumors, high PD-L1 expression was seen in 27.3% compared to 33.0% in metastases (p=0.51) Of the cases that had mutation results available, only 8.8% of NSCLC haboring *EGFR* mutations expressed high PD-L1 expression (≥50%) compared to 44.1% of tumors with *KRAS* mutations (p<0.01). **Conclusion:** Our overall prevalence of PD-L1 expression in cases of NSCLC is in keeping with rates demonstrated in a large clinical trial investigating the efficacy of pembrolizumab as first line treatment in NSCLC. The same rates of high PD-L1 in cytology and histology specimens suggest cytological specimens are valid for assessment.

P1.09-27 INTEROBSERVER VARIATION IN THE CYTOLOGICAL DIAGNOSIS OF PULMONARY ADENOCARCINOMA PRESENTING WITH GROUND-GLASS OPACITY NODULES

H.S. Park[1], J.Y. Pyo[2], S.W. Hong[3], M.-S. Cho[1], Y. Cha[3]

[1]*Ewha Womans University Seoul Hospital, Seoul/Korea, Republic of,* [2]*International St. Mary's Hospital, Incheon/Korea, Republic of,* [3]*Gangnam Severance Hospital, Seoul/Korea, Republic of*

Background: Wide use of chest CT for cancer surveillance and health check-up has led to increase the number of CT-detected small lung nodules with ground-glass opacity (GGO) in South Korea. For persistent GGO lesions larger than 1cm, American College of Chest Physicians recommends a further evaluation such as transthoracic needle aspiration biopsy. Despite these guidelines, cytologic evaluation of GGO nodules is often not used due to the limited access to interventional thoracic radiology and difficulties in the cytologic distinction between benign and well differentiated adenocarcinoma. Herein, we evaluate the cytologic features of small lung adenocarcinoma presenting with GGO nodules and interobserver variation in the cytological diagnosis. **Method:** Sixteen patients with GGO nodules who underwent surgical resection were enrolled in this study. The lesions were identified in fresh state on gross examination. Scrapings were collected by using a glass slide to scrape the cut surface of the nodule. Scraped material was then transferred to another glass slide and smeared using a pull/slide-over-slide technique. All slides were stained with Papanicolaou staining. Three pathologist reviewed the slides and cytological diagnosis was categorized as negative/benign, atypical, suspicious for malignancy, and positive for malignancy. **Result:** The study population consisted of 4 male and 11 female patients. There were 8 invasive adenocarcinoma, 4 adenocarcinoma in situ, and 4 minimally invasive adenocarcinomas. The mean tumor size was 1.27cm, ranging 0.6cm to 3.3cm. The overall concordance rate for cytological diagnosis was 62.5% (mean kappa, 0.51). Totally concordant and cytologically negative cases were 31.2% (5 out of 16) and significantly smaller than 1cm (p=0.037). Discordant cases tends to be either adenocarcinoma in situ or minimally invasive adenocarcinoma, but statistically in significant. **Conclusion:** Cytological diagnosis of pulmonary adenocarcinoma presenting with GGO nodules showed interobserver variation. False negative result could be considered especially in cases with tumor size less than 1cm.

Keywords: cytological diagnosis, lung adenocarcinoma, ground-glass opacity nodule

P1.09-28 A SIGNIFICANT DISCORDANCE BETWEEN PANAMUTYPER™ AND TARGETED DEEP SEQUENCING FOR DETECTING EGFR MUTATION IN NSCLC

J. Lee, S.K. Lee, Y.B. Han, H.J. Kwon, H. Kim, J.-H. Chung

Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Background: Activating mutations in the tyrosine kinase domain of *EGFR* are predictive biomarkers for response to *EGFR*-tyrosine kinase inhibitor (TKI) therapy in non-small cell lung cancer (NSCLC). This study aimed to screen *EGFR* mutations by PNA clamping-assisted fluorescence melting curve analysis (PANAMutyper™) and targeted deep sequencing, and to evaluate the feasibility of targeted deep sequencing for detection of the mutations. **Method:** We examined EGFR mutations in exons 18, 19, 20, and 21 using PANAmutyper™ for consecutive 2170 NSCLC tissues from November 2016 to March 2019. Of these, targeted deep sequencing was performed in 74 patients. **Result:** *EGFR* mutations were identified in 46.4% (1007/2170); 479 (47.6%) had mutations at exon 19, 442(43.9%) at exon 21, 156(15.5%) at exon 20 (including 97 cases with T790M), and 46(4.6%) at exon 18. *EGFR* mutations were significantly more common in women (63.9%) than men (31.4%) (p <0.001), in adenocarcinoma (54.7%) compared to non-adenocarcinoma (15.3%) (p <0.001). 11.3% (11/97) of T790M mutations was identified in TKI-naïve patients. Interestingly, 27.3% (3/11) of the primary T790M existed alone without L858R or exon 19 deletions. We observed a significant discordance (24.3%: 18/74) of the *EGFR* mutation between PANAMutyper™ and targeted deep sequencing. Moreover, targeted deep sequencing revealed eight nonsynonymous single-nucleotide variations, ten insertion-deletion variations and one amplification in EGFR, which were not detectable by the PANAMutyper™. In 2 out of 18 discordant cases, *EGFR* mutations were detected only in PANAMutyper™. **Conclusion:** *EGFR* mutations were found frequently in non-adenocarcinomatous NSCLCs, emphasizing that testing for *EGFR* mutations is essential for all NSCLC patients. As T790M was found in TKI-naive patients, we cannot exclude the possibility of this mutation being a rare mutation existing from the beginning. Taken together, our study demonstrates that primary T790M alone exists and there is a significant discordance between PANAMutyper™ and targeted deep sequencing. The significance of these discrepancies should be carefully interpreted for the patient's treatment and clinical outcome.

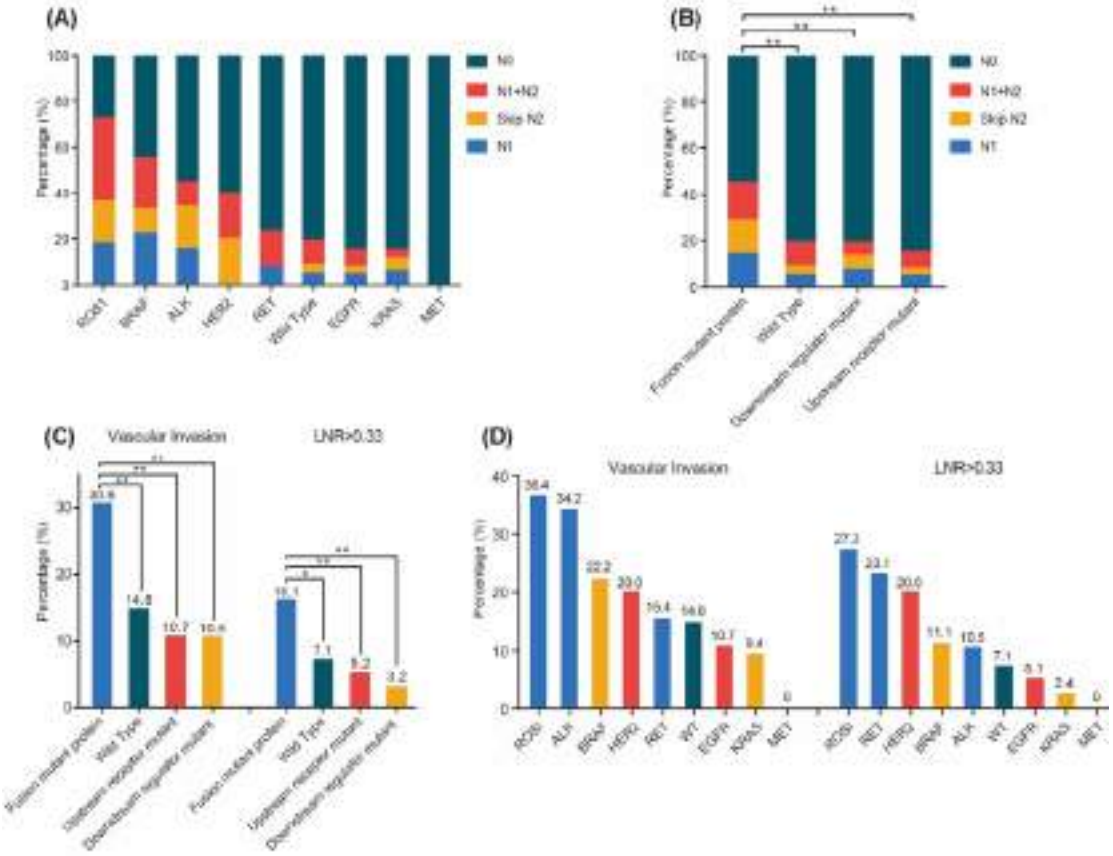
P1.09-29 THE CHARACTERISTICS OF LYMPH NODE METASTASIS IN PATIENTS WITH DIFFERENT ONCOGENIC DRIVER MUTATIONS AMONG T1 NON-SMALL-CELL LUNG CANCER

Z. Liu, H. Liang, J. He, W. Liang

Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University; State Key Laboratory of Respiratory Disease; National Clinical Research Center for Respiratory Disease, Guangzhou/China

Background: Whether mutation is associated with lymph node metastases remains unknown. We aim to investigate the incidence and distribution of lymph node metastasis in patients with different gene mutations among pathological T1 non-small-cell lung cancers (NSCLC). **Method:** NSCLC cases resected in our institution between 2016 and 2018 were included. Driver mutation testing was performed in all resected tumor tissues. These patients were grouped by the type of gene mutations. On the basis of protein that mutant-genes encoded involved in the molecular pathway, the genotypes were further classified into four distinct groups: upstream receptor mutant protein (EGFR, HER2 and MET); downstream regulator mutant protein (KRAS and BRAF); fusion mutant protein (ROS1, ALK and RET) and the wild type group. The incidence of lymph node metastasis was compared among different groups. **Result:** Of the 1,052 patients enrolled, the frequency of positive mutations was 68.0%. The incidence of lymph node metastasis were as follows (Figure 1): wild type (19.3%), ROS1 (72.8%), BRAF (55.5%), ALK (44.7%), HER2 (40%), RET rearrangement (23.1%), KRAS mutation (15.3%), EGFR (15.3%) and MET mutation (0%) (Chi^2=43.45, P<0.001). The incidence of lymph node metastasis was significantly higher in fusion mutant protein group (45.1%) compared with others (wild type 19.3%, downstream signaling regulator protein 19.1%, upstream signaling receptor protein 15.3%, all P<0.001). Patients with fusion genes showed higher proportion of vascular invasion and positive lymph node ratio of greater than 0.33 compared to other (all P<0.005). In subgroup based on gender, age and smoking history, fusion mutant group was still observed with the highest proportion of node metastasis



Conclusion: Different genotypes of NSCLC have different propensity to develop lymph node metastasis. Cases of fusion gene mutations had a higher risk and burden of lymph node metastasis than other genotypes, which may indicate that more intensive treatment or surveillance strategies should be applied for these patients.

P1.09-30 MOLECULAR CHARACTERIZATION OF PREINVASIVE AND INVASIVE LESIONS IN MULTIFOCAL PULMONARY ADENOCARCINOMAS

H.-L. Ho, Y.-C. Yeh, T.-Y. Chou

Taipei Veterans General Hospital, Taipei City/Taiwan

Background: Multifocal pulmonary adenocarcinomas typically present as multiple ground-glass opacities (GGOs) on computed tomography (CT) scan. Pathologically, GGOs in majority represent preinvasive lesions including atypical adenomatous hyperplasia (AAH) and adenocarcinoma in situ (AIS) and rarely, invasive lesions such as minimally invasive adenocarcinoma (MIA). Given that a stepwise progression sequence from AAH to invasive adenocarcinoma (AIV) has been proposed in lung carcinogenesis, we would like to investigate the molecular features between preinvasive and invasive lesions in patients with multifocal pulmonary adenocarcinomas. **Method:** From 2011 to 2015, thirty-three patients with surgically resected preinvasive lesions of lung adenocarcinoma diagnosed in their tumor(s) were included. There were 25 female and 8 male, with a total of 87.9% being never smokers. Twenty-nine patients (87.9%) had at least one preinvasive and one invasive lesions. One hundred and nine tumor lesions composed of 18 AAH, 73 AIS and 18 AIV were analyzed for *EGFR*, *KRAS* and *TP53* mutations. **Result:** Among them, 4 (12%) patients were found to harbor one lesion, 14 (42%) two lesions, 6 (18%) three lesions, and 9 more than four lesions. In patients with more than 3 tumor lesions, these lesions were more likely to localize in the right lateral lung compared to those with lesions less than 2 ($p=0.02$). Of 109 tumor lesions analyzed, *EGFR*, *KRAS* and *TP53* mutations were 22.2%, 0% and 22.2% in AAH, 24.7%, 6.8% and 15.1% in AIS, while 66.7%, 11.1% and 16.7% in AIV. *EGFR* mutation rate of AIV, especially L8585R mutation, was higher than that of AAH and AIS ($p=0.004$). On the contrary, mutations on *KRAS* and *TP53* were randomly distributed between preinvasive and invasive lesions ($p > 0.05$). The discordant pattern of *EGFR*, *KRAS* and *TP53* mutations between AAH, AIS and AIV lesions within the same patients was also observed. Figure 1. The prevalence of *EGFR*, *KRAS* and *TP53* mutations in preinvasive and invasive tumor lesions. *EGFR* mutations are more associated with invasive components. **Conclusion:** Our results showed that *EGFR*, *KRAS* and *TP53* mutations occur early in preinvasive lesions, and only *EGFR* mutation is significantly associated with invasive components. These findings suggested that *EGFR* mutation may contribute to the invasiveness and progression of lung adenocarcinoma. Additionally, presence of distinct mutation profiles in separate preinvasive and invasive lesions from the same patient demonstrated that the emergence of these lesions may come from independent events, implying that genetic heterogeneity does occur in patients with multifocal pulmonary adenocarcinomas.

P1.09-31 CLINICOPATHOLOGICAL FEATURES AND GENOMIC PROFILING OF PULMONARY BLASTOMA WITH HIGH-GRADE FETAL ADENOCARCINOMA COMPONENT

J. Zhao[1], C. Xiang[1], P. Wang[1], P. Guo[2], J. Zheng[2], H. Han-Zhang[2], K. Yu[3], R. Zhao[1], J. Zhang[1], Y. Han[1]

[1]*Shanghai Chest Hospital, Shanghai/China,* [2]*Burning Rock Biotech, Shanghai/China,* [3]*Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China*

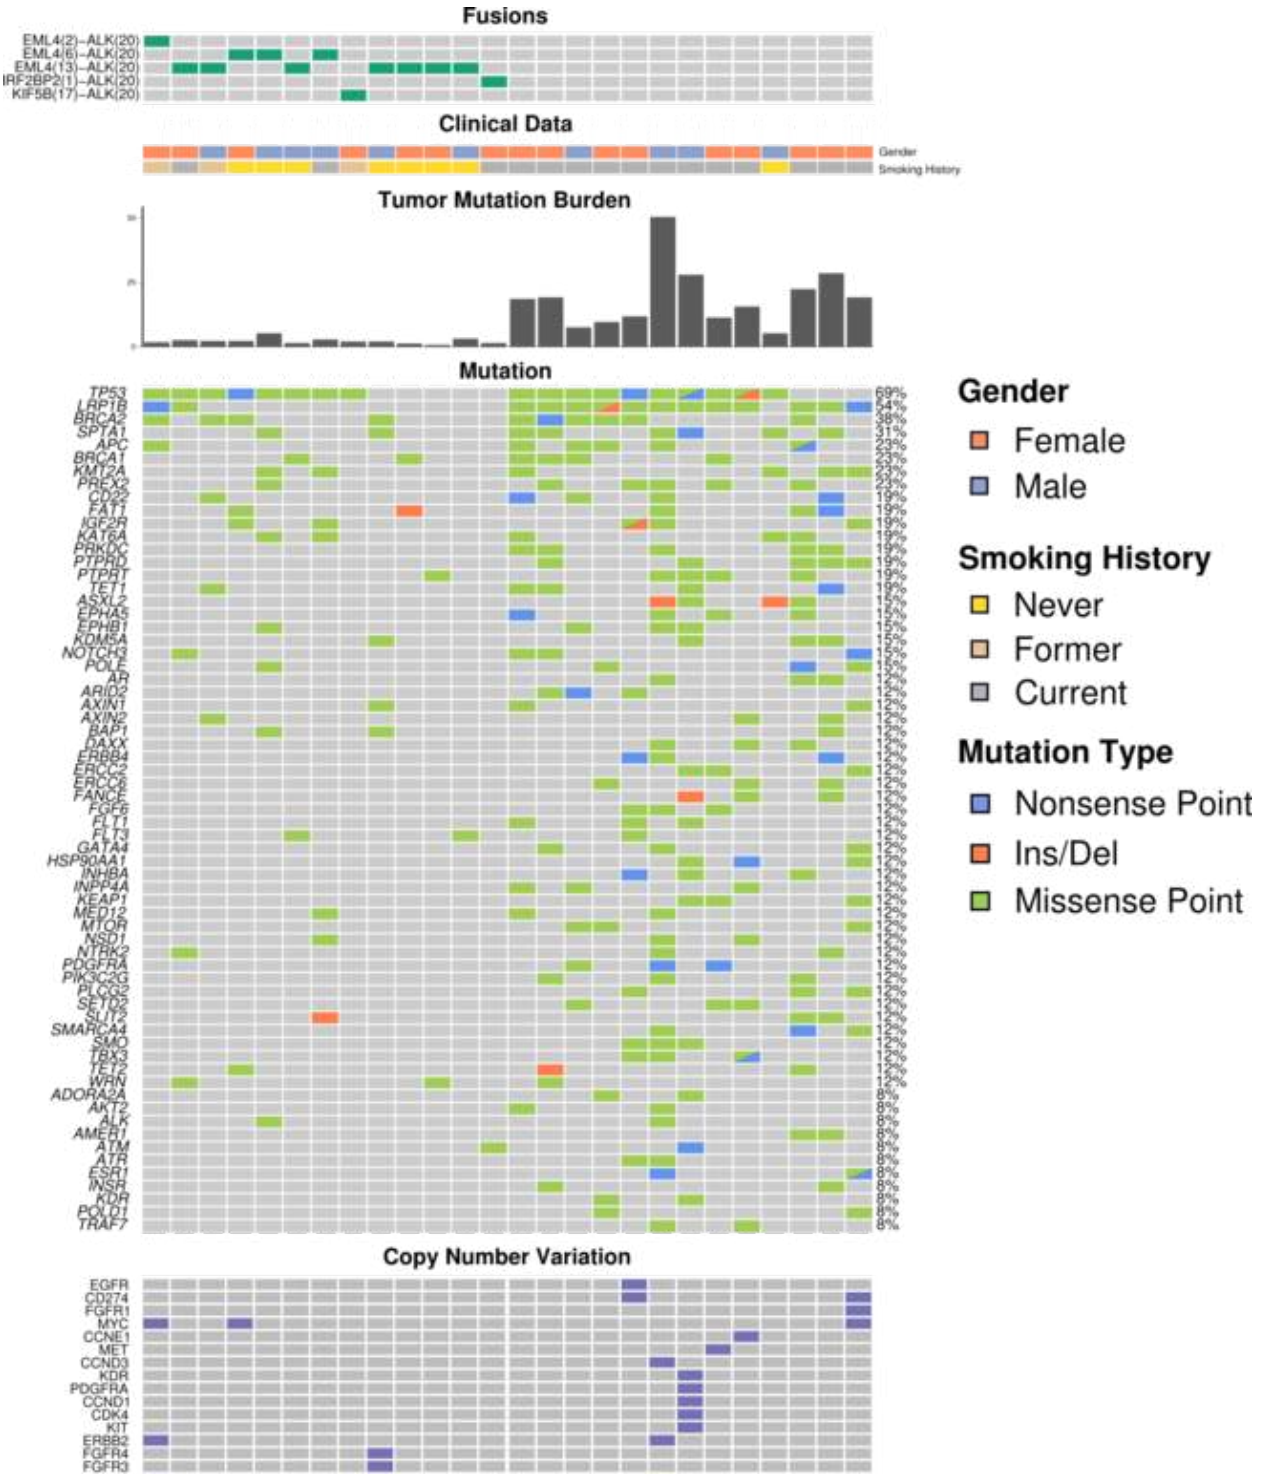
Background: Pulmonary blastoma (PB) is a very rare subtype of sarcomatoid carcinoma with typically low-grade fetal lung adenocarcinoma (L-FLAC) and primitive mesenchymal components. Very few cases of PB contain the high-grade fetal lung adenocarcinoma (H-FLAC) component. The present study was designed to investigate the clinicopathological characteristics and the genomic heterogeneity of epithelial and mesenchymal in PB with H-FLAC. **Method:** Three surgically resected PB cases with H-FLAC component were enrolled in the study. The epithelial of the first case consisted of mostly H-FLAC mixed with limited amount of L-FLAC. The other two PB tumors contained pure H-FLAC and mesenchymal components. Clinic-pathologic information and prognostic data were retrospectively reviewed. Diagnostic immunohistochemistry was performed. The epithelial and mesenchymal components were macroscopically dissected to profile the genetic alterations separately using capture-based targted sequencing. A commercialized panel, consisting of 520 cancer-related genes, was used. **Result:** The cells of H-FLAC components in PB showed obvious atypia with more necrosis and enteric adenocarcinoma-like morphology. The squamoid morules were absent in H-FLAC. Proliferation index of the H-FLAC components (30%-80%) was higher than that of the mesenchymal (15%-20%). No aberrant nuclear expression of β-catenin protein and missense mutation in exon 3 of CTNNB1 gene were observed in H-FLAC and all mesenchymal cells. Within a tumor, epithelial and mesenchymal components exhibited relatively comparable molecular profile. In patient 1, 4 mutations: PB1, FAT3, PTCH1 and LRP1B were shared by both epithelial and mesenchymal components. Epithelial component had additional mutations in BCOR, CTNNB1, CTCF, FAT1 and DICER1. In patient 2, 12 mutations were shared. The epithelial component had BRCA2 mutations and the mesenchymal component had mutations in CREBBP, ALK, DNMT3A, ASXL2, MYCN and RICTOR. Patient 3 had 6 shared mutations. The epithelial component had an additional mutation in KAT6A and the mesenchymal had an additional mutation in APC. Furthermore, both epithelial and mesenchymal components showed significant interpersonal heterogeneity. In other words, the mutation spectrum of the same component (epithelial or mesenchymal)varies significantly among patients. Surprisingly, not a single common mutation was found in the same component among the 3 patients. **Conclusion:** Collectively, we observed heterogeneity between epithelial and mesenchymal components of the same tumor. In addition, we also observed significant inter-personal heterogeneity of the same component among different patients. Parallel detection of genetic abnormalities in epithelial and mesenchymal could provide further evidence to clarify the histopathological difference and molecular heterogeneity in pulmonary blastoma.

P1.09-32 CONCURRENT GENOMIC ALTERATIONS IN ALK-REARRANGED NON-SMALL CELL LUNG CANCER PATIENTS

S. Clavé[1], M. Salido[1], J. Gibert[2], M. Hardy-Werbin[1], E. Weingartner[3], J. Hernandez[3], D. Nichol[3], P. Rocha[1], X. Riera[1], R. Blanco[4], J. Bosch-Barrera[5], Á. Taus[1], L. Pijuan[1], B. Bellosillo[1], E. Arriola[1]

[1]*Hospital del Mar, Barcelona/Spain,* [2]*Hospital del Mar Medical Research Institute, Barcelona/Spain,* [3]*Personal Genome Diagnostics, Baltimore/United States of America,* [4]*Consorci Hospitalari de Terrassa, Terrassa/Spain,* [5]*Catalan Institute of Oncology, Hospital Universitari de Girona Doctor Josep Trueta, Girona/Spain*

Background: Recent progress in genomic analysis using next-generation sequencing (NGS) has enabled the comprehensive detection of targetable alterations in non-small cell lung cancer (NSCLC) patients. As the detection of *ALK* gene fusions is being established by NGS, identification of concurrent alterations will lead to better characterization of the molecular landscape of *ALK*-rearranged patients. **Method:** Thirty-one NSCLC samples with known *ALK* status (18 positive and 13 negative) tested in our Institution using FISH, IHC, and NGS (Oncomine Focus Assay, ThermoFisher Scientific) were further evaluated by an expanded NGS gene panel (PGDx elio™ tissue complete assay (under developement), Personal Genome Diagnostics). This NGS panel comprises 500+ genes and screens for clinically relevant genomic alterations (single base substitutions/insertion and deletions, fusion genes and copy number variations), and provides TMB scores (expressed as mutations per megabase, exome equivalent). Statistical associations were assessed using Pearson's $\chi 2$ and Mann-Whitney U test. **Result:** *ALK* positive patients were 50% female with a median age of 59 years old and 54% of them never smokers. For the *ALK* negative cohort, young patients without any known driver alterations were selected: 69% male with a median age of 54 years old and 92% of them current smokers. Of the 18 *ALK*-positive cases identified, five were considered non-evaluable for expanded genomic analysis due to insufficient sequencing coverage (yield below minimum suggested DNA input). *ALK* fusions were detected by all techniques in the 13 *ALK*-positive cases available for analysis. *EML4*(13)-*ALK*(20) was the most prevalent gene fusion detected in seven out of 13 cases (54%). Remarkably, we detected a rare *ALK* gene fusion that has not been yet described: *IRF2BP2*(1)-*ALK*(20). The concurrent alterations identified by expanded genomic analysis are shown in an OncoPrint figure comparing both groups. The most frequent concomitant alteration was *TP53* mutation: 62% in *ALK*-positive and 69% *ALK*-negative (p> 0.05). Regarding gene amplifications, we identified three *ALK*-positive cases with copy number alterations of which we highlight *MYC* in two of these cases. Interestingly, a high TMB was significantly associated with *ALK*-negative cases with a median of 19.9 mut/Mb compared to 7.0 mut/Mb in *ALK*-positive (p= 0.001).



Conclusion: We have studied the presence of *ALK* fusion genes with a novel NGS panel that showed excellent correlation with standard techniques. *ALK* fusions can be interpreted as early strong drivers to carcinogenesis due to the low frequency of concurrent alterations. It remains to determine the clinical impact of these alterations in larger series.

Background: Very recently, it was suggested that pembrolizumab monotherapy can be extended as first-line therapy to patients (pts) with locally advanced or metastatic non-small-cell lung cancer (NSCLC) without sensitizing *EGFR* or *ALK* alterations and with low PD-L1 Tumor Proportion Score (TPS). Then screening the subset of pts with PD-L1 TPS >= 1% from all the *EGFR*-, *ALK*- locally advanced or metastatic NSCLC pts became important. However, less was known about the percentage of this subset in China. We investigated this percentage taking advantage of the retrospective NSCLC cohort collected by Origimed. **Method:** The Origimed-based NSCLC cohort was a retrospective cohort consisted of more than one thousand Chinese NSCLC pts who underwent both NGS panel sequencing and PD-L1 immunohistochemistry (IHC) in a College of American Pathologists (CAP) certified and Clinical Laboratory Improvement Amendments (CLIA) certified laboratory during the year 2017 and 2018. Antibodies used in the PD-L1 IHC assay included 22C3 and 28-8. TPS was applied. All the slides were reviewed by the same senior pathologist. All the *EGFR* and *ALK* alterations were manually reviewed in Integrated Genomics Viewer for confirmation. Stage III or IV at diagnosis was used as an approximation to the criteria "locally advanced or metastatic". **Result:** Excluding sensitizing *EGFR/ALK* alteration carriers, there were totally 27 locally advanced or metastatic NSCLC pts whose 22C3 PD-L1 TPS were available and 202 locally advanced or metastatic NSCLC pts whose 28-8 PD-L1 TPS were available in the cohort. Among them, 55.6% (15/27) 22C3 stained samples had TPS >= 1%, and 40.6% (82/202) 28-8 stained samples had TPS >= 1%. **Conclusion:** More than 40% of locally advanced or metastatic NSCLC pts without *EGFR/ALK* alterations have PD-L1 TPS >= 1% in China. These pts may benefit from first-line pembrolizumab monotherapy.

P1.10-01 PATTERNS OF BIRTH COHORT-SPECIFIC SMOKING HISTORIES BY RACE AND ETHNICITY IN THE US, 1965-2017

R. Meza[1], P. Cao[1], J. Jeon[1], T. Holford[2]

[1]*University of Michigan, Ann Arbor/United States of America,* [2]*Yale University, New Haven/United States of America*

Background: Smoking prevalence varies greatly by race and ethnicity in the US. However, little is known about how smoking prevalence or the rates of initiation and cessation vary by birth cohort among different sociodemographic groups. **Method:** Data from the National Health Interview Survey 1965-2017 were utilized to obtain smoking-related information for U.S. adults. We developed age-period-cohort models with constrained natural splines to estimate smoking prevalence among different racial/ethnic groups; non-Hispanic Whites (NHW), non-Hispanic Blacks (NHB), Hispanics, American Indians and Alaskan Natives (AIAN), and Asians and Pacific Islanders (API). Annual probabilities of smoking initiation, cessation and intensity by age, birth cohort (1890-1990), sex, and race/ethnicity were also estimated. **Result:** Age-specific probabilities of smoking initiation were highest among AIAN, second highest among NHW and lowest among API and Hispanics (Fig1). Initiation probabilities among NHB were comparable in the past to NHW's, but have decreased relatively more rapidly in recent birth cohorts. In general, cessation probabilities were lowest among AIAN and NHB, and highest among NHW and API across birth cohorts and ages. Taken together the initiation and cessation probabilities result in the observed race/ethnicity patterns of smoking prevalence by race/ethnicity, birth-cohort and age (Fig2), where for instance prevalence among AIAN is generally highest across all ages and birth cohorts. Or where prevalence among NHB, particularly men, is lower than that in NHW for young ages but higher for older ages.

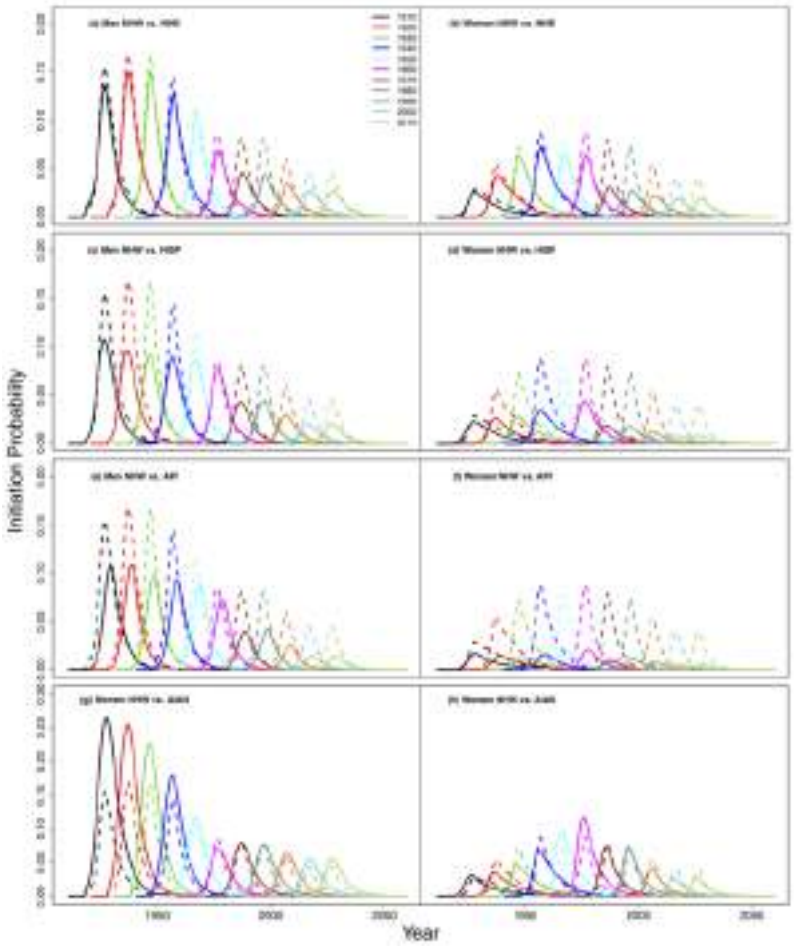
P1.10-02 ROLE MODELS AND LUNG CANCER AWARENESS: DOES IT CHANGE THE MIND-SET AND PERCEPTION OF GENERAL POPULATION?

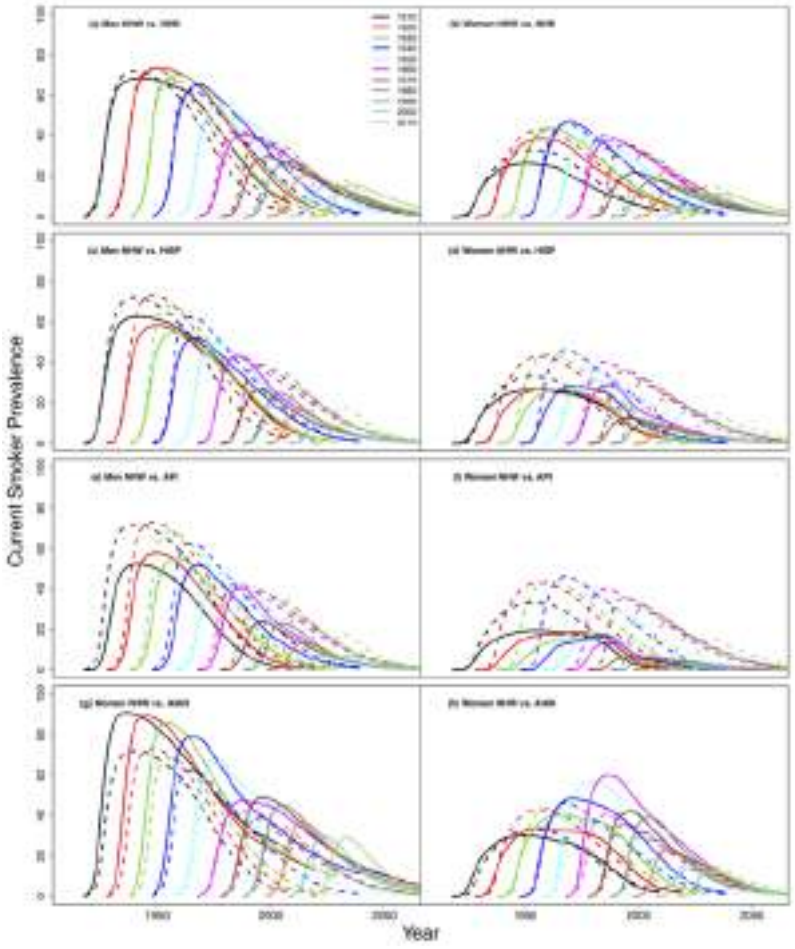
D. Saini[1], M. Khanna[1], A. Dubey[1], S. Roy[1], A. Shankar[2]

[1]*Division of Cancer Prevention, Indian Society of Clinical Oncology, Delhi/India,* [2]*Preventive Oncology, All India Institute of Medical Sciences, New Delhi/India*

Background: Lung cancer has become a major health concern, though easily preventable, with smoking and air pollution being major risk factors. Intentional or unintentional advertisement or use of tobacco product by society role models may affect their attitude towards the smoking and related lung cancer. This study analysed the people mindset and perception for their role models in tobacco advertisement and lung cancer awareness. **Method:** The survey was conducted at various market and public places in Delhi, India. People were interviewed about what is their perception about their role model advertising or using tobacco products. **Result:** Among total participants of 2571, 42.6% people strongly agreed that actors/actresses should not smoke in film or in TV serials. In one subset of people, 50 years and above strongly agreed about film stars should not use cigarettes in movies or serials (p= 0.01). People strongly agreed about banning billboard advertisement of tobacco products near tobacco shops (p= 0.02). Approximately half of the people strongly agreed that TV channels should not display the advertisement of tobacco-related products along with the roadside display. In this study, 57.6% of people felt dissociated from their role models if they see them endorsing or promoting tobacco products. All of the participants strongly agreed about using role models to promote lung cancer awareness in India. People who were less educated were significantly influenced by role models in adopting smoking habits. (p= 0.005). Person with family history of cancer was not affected by his/ her role models (p= .04). **Conclusion:** Role models have an important role to influence people to adopt smoking habits. Role models can be used as an important tool in promoting lung cancer awareness in India. There is an urgent need to ban promotion and advertisement of tobacco products by role models in Television, Internet and display boards. There is also a need to start population-based intervention aiming for behavioural modification and role models can play a vital role to make these campaigns successful.

Keywords: Lung cancer, Role model, Cancer awareness





Conclusion: This study explored in depth historical smoking patterns by race/ethnicity in the US, identifying important differences not only in prevalence, but also on cohort- and age-specific initiation and cessation rates. These differences need be taken into account when planning tobacco control interventions. Among the demographic groups analyzed, AIANs remain as the group with the highest smoking prevalence and initiation and the lowest cessation rates, and thus deserve specific interventions.

Keyword: smoking disparities, smoking initiation and cessation, patterns by birth-cohort

P1.10-02 IMPLEMENTING AN OPT-OUT APPROACH TO SMOKING CESSATION REFERRALS FOR CANCER PATIENTS IN ONTARIO, CANADA

E. Cameron[1], M. Haque[1], N. Schwartz[1], S. Khan[1], S. Rana[1], R. Truscott[1], W. Evans[1,2]

[1]*Cancer Care Ontario, Toronto/Canada,* [2]*McMaster University, Hamilton/Canada*

Background: Smoking is responsible for approximately 30% of all cancer deaths in Canada and more than 85% of lung cancer cases. Continued smoking results in decreased cancer treatment efficacy and safety, increased toxicities, greater risk of cancer recurrence and second primaries, poorer quality of life and decreased survival. Quitting smoking can reduce these adverse effects. In 2013, Cancer Care Ontario (CCO) implemented a smoking cessation program across 14 Regional Cancer Centres (RCCs) in the province of Ontario, Canada, employing a 3As (Ask, Advise, Act) brief intervention model. **Method:** In the first few years of the program, smokers could "opt-in" to smoking cessation services by stating a readiness to quit. However, the provincial rate of smokers accepting support was low. In 2018, CCO adopted an "opt-out" approach, based on emerging evidence and feedback from an expert Advisory Committee. With this approach, healthcare providers (HCPs) automatically refer all smokers to a cessation service, without assessing the patient's readiness to quit. Patients can refuse the referral if they choose. This program change was communicated to the RCCs through a revised program framework, site-specific action plans, and discussion during monthly knowledge exchange meetings with Regional Champions. Communications resources (posters and pocket cards) were created to support HCPs, with suggested scripts. **Result:** The Accepted a Referral (proportion of smokers accepting referral to cessation services) performance metric was used to monitor program implementation. With an opt-in approach, the annual provincial rate of Accepted a Referral improved only slightly over three years (18.1% in 2015/16 to 22.5% in 2017/18). Just prior to launching the opt-out approach in Q3 of 2017/18, the provincial rate of Accepted a Referral was 23.3% (range 9.2% to 37.9% amongst 14 RCCs). One year later, the provincial rate had increased substantially to 31.9% (range 12.9% to 88.7%). Several RCCs showed dramatic increases, while others demonstrated little or no improvement. **Conclusion:** In an effort to help more patients quit smoking and to achieve the best treatment outcomes possible, CCO adopted an opt-out approach to cessation referrals. Overall, there has been a substantial increase in the provincial rate of smokers accepting support, but implementation has varied amongst RCCs. Feedback indicates that while some HCPs found the approach relatively easy to implement, others have been resistant to change, expressing concern about the ethics of referring patients without assessing willingness to quit. Further research into the reasons behind the variable uptake of the opt-out approach will inform future implementation efforts.

P1.10-03 GUT MICROBIOTA AND LUNG CANCER: A MENDELIAN RANDOMISATION STUDY

H. Zhou[1], J. Liu[2], Y. Zhang[1], W. Fang[1], Y. Yang[1], S. Hong[1], Y. Huang[1], L. Zhang[1]

[1]*Sun Yat-Sen University Cancer Center, Guangzhou/China,* [2]*Sun Yat-Sen University, Guangzhou/China*

Background: Several studies have highlighted the association between the gut microbiota and lung cancer. However, robust epidemiological evidence able to discern this causal relationship does not exist. We aimed to investigate whether gut microbiota is causally associated with lung cancer through a two-sample Mendelian randomisation (MR) approach. **Method:** Genetic instrumental variables of 23 genera at genome-wide significance ($P < 5\times10\text{-}8$) were obtained from five available genome-wide association study (GWAS) of the gut microbiota. We conducted a two-sample MR analysis to access the causality between 23 genera of gut microbiota and lung cancer, based on the publicly available GWAS summary data from the International Lung Cancer Consortium (ILCCO, 11 348 lung cancer cases and 15 861 controls) and other consortiums. We applied several different MR methods for deriving causal estimates: Wald ratio, inverse-variance weighted, weighted median, and MR-Egger. Additional sensitivity analyses were utilized to detect potential pleiotropy bias. **Result:** Among 23 genera, a 1 allele increase in single nucleotide polymorphisms related to higher *Oscillospira* was associated with a 26.1% lower risk of lung cancer (odds ratio (OR) 0.739, 95% confidence interval (CI) 0.570 to 0.959, P = 0.023). We also identified genetic predisposition towards higher *Weissella*, based on 1 SNP, was associated with lower risk of lung cancer (OR 0.804, 95% CI 0.693 to 0.933, P = 0.004). No associations were found for the other 21 genera, namely *Acidaminococcus*, *Acinetobacter*, *Aggregatibacter*, *Anaerostipes*, *Atopobium*, *Bacteroides*, *Bifidobacterium*, *Coprococcus*, *Desulfovibrio*, *Dorea*, *Eggerthella*, *Eubacterium*, *Faecalibacterium*, *Lachnospira*, *Lactobacillus*, *Leuconostoc*, *Megamonas*, *Mogibacterium*, *Pseudobutyrivibrio*, *Roseburia*, and *Slackia*. Table 1. Mendelian randomisation estimates of the associations between 23 gut microbiota and risk of lung cancer.

Microbiota	SNP	IVW / (Wald ratio, SNP<3)		Weighted median		MR-Egger	
		OR (95% CI)	P value	OR (95% CI)	P value	OR (95% CI)	P value
Acidaminococcus	5	1.001 (0.999, 1.004)	0.355	1.001 (0.998, 1.004)	0.424	1.000 (0.996, 1.005)	0.894
Acinetobacter	1	1.193 (0.984, 1.447)	0.073				
Aggregatibacter	1	0.960 (0.884, 1.043)	0.335				
Anaerostipes	2	0.989 (0.933, 1.048)	0.701				
Atopobium	1	0.940 (0.876, 1.008)	0.083				
Bacteroides	5	0.999 (0.997, 1.000)	0.134	0.999 (0.997, 1.000)	0.152	0.999 (0.997, 1.000)	0.213
Bifidobacterium	2	1.008 (0.934, 1.087)	0.844				
Coprococcus	1	1.138 (0.732, 1.769)	0.567				
Desulfovibrio	2	0.992 (0.958, 1.028)	0.658				
Dorea	1	1.058 (0.984, 1.137)	0.128				
Eggerthella	1	1.001 (0.998, 1.005)	0.442				
Eubacterium	1	0.999 (0.922, 1.083)	0.987				
Faecalibacterium	3	1.004 (0.952, 1.058)	0.889	1.002 (0.947, 1.060)	0.949	0.990 (0.907, 1.080)	0.852
Lachnospira	1	1.028 (0.925, 1.141)	0.609				
Lactobacillus	2	0.972 (0.897, 1.054)	0.497				
Leuconostoc	1	0.964 (0.860, 1.081)	0.533				
Megamonas	3	1.016 (0.990, 1.043)	0.231	1.016 (0.985, 1.048)	0.307	0.908 (0.725, 1.137)	0.556
Mogibacterium		0.998 (0.897, 1.110)	0.973				
Oscillospira	1	0.739, (0.570, 0.959)	0.023*				
Pseudobutyrivibrio	1	0.961 (0.877, 1.053)	0.397				
Roseburia	1	0.980 (0.843, 1.140)	0.796				
Slackia	1	0.980 (0.935, 1.027)	0.401				
Weissella	1	0.804 (0.693, 0.933)	0.004*				

*: P value < 0.05; IVW: inverse-variance weighted; OR: odds ratio; CI: confidence interval. **Conclusion:** Our present mendelian randomisation study provided evidence of a causal effect of the gut microbiota on lung cancer, suggesting *Oscillospira* and *Weissella* might be the focus of future research. Further studies are needed to confirm these causality and elucidate the potential mechanisms.

Keywords: Gut microbiota, Lung cancer, Mendelian randomisation

P1.10-04 LUNG CANCER IN PATIENTS WITH HIV DISEASE - UNIQUE CLINICAL AND BIOMARKER FEATURES IMPACTING LUNG CANCER SCREENING AND MANAGEMENT

S. Attarian[1], X. Guo[2], B. Ko[3], A. Singh[4], E. Castellucci[3], R. Gucalp[3], M. Haigentz[5], H. Cheng[3], B. Halmos[3]

[1]*Department of Oncology, Northwell Cancer Center, New York/United States of America,* [2]*Department of Pathology, Montefiore Medical Center, Bronx/United States of America,* [3]*Department of Oncology, Montefiore/ Albert Einstein Cancer Center, Bronx/United States of America,* [4]*University of Pennsylvania, Philadelphia/United States of America,* [5]*Atlantic Health Systems, Morristown/United States of America*

Background: Patients with HIV (PWH) are diagnosed with lung cancer at a higher frequency than the general population and lung cancer is emerging as the most common malignancy afflicting PWH. We aimed to study the epidemiological and clinico-pathological characteristics of lung cancer in PWH at an NCI-designated Cancer Center in a service area with a high prevalence of HIV. **Method:** We reviewed charts of 178 PWH who were diagnosed with lung cancer between 2000 and 2018. 126 patients with available pathology specimens were included in this study. Demographics, clinico-pathological characteristics and treatment data were collected. Age and disease stage of this patient group was compared to the overall group of patients with lung cancer at our institution. In 28 patients where sufficient tissue was available, biomarker studies including PD-L1 TPS score assessments were performed (22C3 antibody). **Result:** PWH diagnosed with lung cancer had a mean age at diagnosis of 56.8 years (range 25-71), 67% were men, 45% black, and 25% Hispanic. 98% of patients reported a history of smoking where information was available. At the time of lung cancer diagnosis, 68% had stage IV disease, average CD4 count was 370/mcL and 33% had a CD4 count of less than 200/mcL. Adenocarcinoma was the most common histological type (51%). Patients who were not on ART were younger than those who were on ART (p = 0.010). In comparison with the overall group of patients with lung cancer, PWH were younger (mean age 68.0 vs 56.8, p = 0.014) and had a higher percentage of advanced disease at diagnosis (49% vs 68%, p < 0.001). PD-L1 testing showed a remarkably low rate of PD-L1 positivity (TPS score <1%- 78%, 1-50%- 14% and >50%- 8%). 11 patients received immunotherapy (8 single-agent immunotherapy), 2 subjects had a partial response and 3 patients had stable disease as best response. No patients had any grade ¾ immune adverse events (1 episode of grade 2 colitis and one episode of grade 2 dermatitis – both of unclear association with therapy and no episodes of thyroiditis) and in general checkpoint inhibitor therapy appeared very well tolerated. **Conclusion:** Conclusions: Our cohort study describing one of the largest experiences amongst PWH and lung cancer demonstrates multiple unique features such as significantly younger age and very frequent advanced stage at presentation as compared to the overall patient population with lung cancer calling for dedicated screening measures to reduce lung cancer-related mortality. In addition, a strikingly low frequency of PD-L1 expression was noted in available tumor specimens which might be related to baseline immune suppression and T cell anergy, however at least some patients could benefit from checkpoint inhibitor therapy which was very well tolerated –suggestive of unique immune biology and treatment considerations in this at-risk patient population.

P1.10-05 TOBACCO RETAIL AVAILABILITY AND TOBACCO CESSATION AMONG LUNG CANCER SURVIVORS

L. Eng[1], J. Su[1], K. Hueniken[1], M.C. Brown[1], A. Hope[1], A. Bezjak[1], A. Sacher[1], P. Bradbury[1], F. Shepherd[1], N. Leighl[1], A. Pierre[1], P. Selby[2], D. Goldstein[1], W. Xu[1], M. Giuliani[1], W. Evans[3], G. Liu[1], M. Chaiton[2]

[1]*Princess Margaret Cancer Centre, Toronto/Canada,* [2]*Centre for Addiction and Mental Health, Toronto/Canada,* [3]*Cancer Care Ontario, Toronto/Canada*

Background: Continued smoking after a lung cancer diagnosis is associated with poorer outcomes. Tobacco retail availability is negatively associated with cessation in non-cancer patients but this has not been explored in cancer survivors. We evaluated the impact of tobacco retail availability on tobacco cessation in lung cancer survivors. **Method:** Lung cancer survivors from Princess Margaret Cancer Centre (Toronto, Canada) completed questionnaires at diagnosis and follow-up evaluating changes in tobacco use with a median of 26 months apart. Validated tobacco retail location data were obtained from Ministry of Health and patient home addresses were geocoded using ArcGIS 10.6.1, which calculated walking time/distance to nearest vendor, and vendor density within 250 meters (m) and 500m from patient residences. Multivariable logistic regression and Cox proportional hazard models evaluated the impact of vendor availability on cessation and time to quitting after diagnosis respectively, adjusting for significant clinico-demographic and tobacco covariates. **Result:** 242/721 lung cancer survivors smoked at diagnosis; subsequent overall quit rate after diagnosis was 66%. Mean distance and walking time to a vendor was 0.8 km (range 0-13) and 10 min (range 0-157). On average, there was one vendor (range 0-19) within 250m and five vendors (range 0-36) within 500m from pts; 40% and 64% of pts lived within 250m and 500m from at least one vendor respectively. Greater distance (aOR 1.28 per 1000m [95% CI 0.97-1.70] p = 0.08) and increased walking time (aOR 1.02 per minute [1.00-1.05] p = 0.08) to a tobacco vendor had a non-significant trend towards increased chances of quitting at one year. Living within 250m (aOR 0.43 [0.25-0.74] p = 0.003) or 500m (aOR 0.50 [0.28-0.88] p = 0.02) to at least one vendor reduced quitting at one year. Living near more vendors within 500m had a non-significant trend towards having an increasing dose effect on reducing cessation rates at one year (aOR 0.97 per vendor [0.94-1.00] p = 0.08). Living within 500m to a vendor reduced chance of quitting at any time (aHR 0.70 [0.50-1.00] p = 0.05). **Conclusion:** Close proximity to tobacco retail outlets is associated with reduced cessation rates for lung cancer survivors. Reducing density of tobacco vendors is a cessation strategy that could positively impact lung cancer patient outcomes.

P1.10-06 PATHOLOGICAL CHARACTERIZATION OF RADON-INDUCED LUNG CANCER IN RATS

L. Mezquita[1], J. Adam[2], D. Planchard[2], C. Jovelet[2], E. Rouleau[2], E. Auclin[3], C. Naltet[1], P. Lavaud[4], L. Lacroix[2], S. Chevillard[5], B. Besse[4]

[1]*Gustave Roussy, France/France,* [2]*Gustave Roussy, Villejuif/France,* [3]*Hôpital Européen Georges Pompidou, Paris/France,* [4]*Institut Gustave Roussy, Villejuif/France,* [5]*French Alternative Energy and Atomic Energy Commission, Fontenay-aux-Roses, France, Fontenay-aux-Roses/France*

Background: Radon is a radioactive gas, considered the leading cause of lung cancer in non-smokers. Although the risk of lung cancer is linear, there is no safe level and even low dose can be associated with risk. In humans, no specific pathological subtypes of lung cancer have been clearly associated with radon. In animals, the French Atomic Energy Commission (CEA) exposed to low dose of radon (25 working level month, WLM) a large cohort of rats in a radon-exposure chamber, showing lung cancer induced by low exposure (Chameaud J, Radiation Prot Dosimetry 1984). We aimed to describe pathological features of radon-induced tumors in rats from the CEA's cohort. **Method:** Retrospective assessment of archival samples available of the rats exposed to low-dose radon in the Laboratoire de Pathologie Pulmonaire Experimentale, COGEMA (France), between 1989 and 1992. Autopsy reports were also reviewed. The pathological assessment was performed for a thoracic oncology pathologist (JA) in H&E staining slides according to the current WHO histological classification. **Result:** Samples from 117 rats were collected. Among 104 tumors, to date the analysis has been performed in 94. Forty tumors (43%) were classified as malignant, 28 (30%) as uncertain malignant potential (UMP) and 26 (28%) benign. In 2 rats (2%) synchronous malignant and non-malignant tumors were observed. Among the malignant tumors, 23 (58%) were epithelial and 17 (42%) non-epithelial. Lung carcinoma was the most common primary epithelial tumor (n=10, 43%), followed by abdominal area tumors (n=5, 22%), and thyroid (n=3, 13%). In the UMP group, 7 (25%) were epithelial and 21 (75%) non-epithelial, with no lung tumors observed. In the benign group, most of them (n=24, 92%) were epithelial, with 4 cases with lung atypical adenomatous hyperplasia-like lesions; 2 synchronous with other malignant tumors (n=1 lymphoma, n=1 cutaneous squamous cell carcinoma). A total of 26 tumors (27%) had thoracic involvement: 4 (15%) primary lung non-malignant lesions, 11 primary lung malignancies (42%) and 11 with metastases from other tumors (42%). As primary malignant lung tumors, we observed: 7 (64%) adenocarcinoma in situ, one papillary adenocarcinoma, one undifferentiated large cell carcinoma with bilateral metastases, one metastatic squamous carcinoma and one metastatic undifferentiated tumor, compatible with sarcoma **Conclusion:** In this cohort of radon-induced tumors in rats, we observed different tumor types, from non-malignant lesions to aggressive malignancies, with predominance of epithelial tumors. Lung carcinoma was the most common primary tumor and adenocarcinoma the histological subtype more observed, with histological similarities with humans.

Keywords: Lung cancer, rats, Radon

P1.10-07 CHARACTERISTICS OF CURRENT AND FORMER SMOKERS WHO ACKNOWLEDGE THEIR RISK OF LUNG CANCER: RESULTS FROM THE EDIFICE6 SURVEY

S. Couraud[1], L. Greillier[2], T. De La Motte Rouge[3], C. Touboul[4], C. Lhomel[5], J. Viguier[6], F. Eisinger[7], M. Roupret[8], J.-F. Morère[9]

[1]*Hospices Civils de Lyon, Pierre Bénite/France,* [2]*AP Marseille, marseille/France,* [3]*Centre Eugène-Marquis, Rennes/France,* [4]*Kantar Health, Paris/France,* [5]*Roche, Boulogne-Billancourt/France,* [6]*Hopital Bretonneau, Tours/France,* [7]*Institut Paoli-Calmettes, Marseille/France,* [8]*Hôpital Pitié-Salpêtrière, Paris/France,* [9]*Hôpital Paul Brousse, Villejuif/France*

Background: Self-assessment of personal cancer risk may be a determining factor for lifestyle changes, risk factor control, or adherence to screening. We studied the characteristics of individuals who assessed their own risk of lung cancer (LC) as higher than that of the average population, and the impact of current smoking status in former and current smokers. **Method:** The French nationwide observational survey, EDIFICE 6, was conducted online (June 26-July 28, 2017) on a core sample of 12 046 individuals (18-69y). Representativeness was ensured by quota sampling on age, sex, profession, and stratification by geographical area/type of urban district. **Result:** In the whole population (N = 11 307), current smoking had the strongest correlation (OR = 7.89). Former smoking (quitting age ≥45y) and use of e-cigarettes were also strongly correlated. Current and former smokers represented 54% and 19%, respectively, of those who assessed their own risk of LC as higher than average (N = 3 544). In multivariate analysis, features associated with this perception were (1) among former smokers: ceased tobacco use ≥45y (OR = 2.56 [2.02-3.25]), male (OR = 1.60, [1.31-1.94]), manual work (OR = 1.42, [1.01-1.99]), and social vulnerability (OR = 1.37, [1.14-1.65]); (2) among current smokers: self-employed (OR = 1.82, [1.18-2.89]), and rating cancer prevention programs as ineffective (OR = 1.39, [1.19-1.63]). Current e-cigarette use and being close to someone with cancer or accompanying someone during cancer treatment were common features to former (OR = 1.98, [1.45-2.70], OR = 1.38, [1.15-1.65]) and current smokers (OR = 1.29, [1.05-1.59], OR = 1.20, [1.02-1.41]). **Conclusion:** Our results show that among individuals who assess their own risk of LC as higher than the average of the general population, current smokers belonged to the wealthiest socioprofessional categories and gave little importance to cancer prevention. Former smokers were more likely to be men, who ceased tobacco use ≥45y, and come from a modest social background. Additionally, both groups were more likely to have experienced cancer in someone close, and to be e-cigarette users.

P1.10-08 THE USEFULNESS OF INPATIENT SMOKING CESSATION PROGRAM AT SINGLE CANCER CENTER

I.-J. Oh[1,2], H.-Y. Park[1,2], C.-K. Park[1,2], H.-J. Shin[1], Y.-I. Kim[1,2], Y.-C. Kim[1,2], Y.R. Choe[2], S.-S. Kweon[2]

[1]*Chonnam National University Medical School, Gwangju/Korea, Republic of,* [2]*Chonnam National University Hwasun Hospital, Jeonnam/Korea, Republic of*

Background: Smoking is a well-known risk factor for the development of several diseases including cancer, but smoking cessation is a difficult problem even in patients who need hospitalization. The purpose of the study was to investigate the usefulness of inpatient smoking cessation consultation program. **Method:** This study included patients who admitted to Chonnam National University Hwasun Hospital and were requested for Inpatient smoking cessation program by doctors or nurses from January to December 2018. We assessed the cessation rate at 4 weeks and 6 months, and evaluated clinical characteristics associated with success by electronic medical record system. Enrolled patients got counseling regularly for 6 months, and the success rate was confirmed by urine cotinine and exhaled carbon monoxide level. And we analyzed the differences of clinical characteristic and survival according to the registration status in lung cancer patients. **Result:** A total of 571 patients were requested and 170 (29.8%) were enrolled to this program. One hundred thirty-eight (81.2%) patients had cancer and the majority was lung cancer (42.9%) followed by gastric cancer (11.2%). One hundred eleven (65.3%) patients were enrolled during their first admission. Only 6 (3.5%) patients took smoking cessation drugs in addition to counseling. The smoking cessation rate was 78.5% at 4 weeks and 39.2% at 6 months. The 4 week-cessation rate of cancer patients was higher than non-cancer (63.8% vs. 21.9%, p=0.000) and the rate of first admission group was higher than that of re-admission group, but it was not statically significant (67.0% vs. 47.8%, p=0.098). Also, the 6 month-cessation rate of cancer group was higher than non-cancer (45.7% vs. 3.8%, p=0.000) and the rate of first admission group was higher than that of re-admission, but not statically significant (49.3% vs. 29.4%, p=0.180). And 4 week-successful cessation group showed lower nicotine dependency than failed group (66.2% vs. 33.8%, p=0.046). In 155 of lung cancer patients, 73 (47.1%) were registered and 82 (52.9%) were refused. The registration rate of early stage group was higher than advanced stage group (83.3% vs. 34.4%, p=0.011). And the registration rate of operation group was higher than non-operation (64.5% vs. 42.7%, p=0.043) but the rate of chemotherapy group was lower than non-chemotherapy (41.2% vs. 58.5%, p=0.044). And the Progression free survival and Overall survival of registration group was better than refusal group, but not statically significant (p=0.199, p=0.215). **Conclusion:** Inpatient smoking cessation program was useful with high abstinence rate. Most patients could keep cessation without medication, so the diagnosis of cancer itself might be enough motivation. And smoking cessation after cancer diagnosis could improve survival rate in lung cancer.

P1.10-09 CESSATION RATES OF AN EXPANDED PHARMACY-DRIVEN SMOKING CESSATION PROGRAM

Z. Acosta, B. Ewachiw, J. Feliciano, S. Dalpoas, S. Myers, C. Burdalski

Johns Hopkins Bayview Medical Center, Baltimore/United States of America

Background: In the United States, smoking accounts for approximately one-third of all cancer related deaths. While national oncology organizations advocate smoking cessation integrated into cancer management, only 30-40% of oncologists provide assistance with quitting. Barriers to providing this service are well documented. Pharmacy learners are positioned to provide this intervention with the incorporation of smoking cessation therapies in accredited PharmD curricula. Previous pharmacist-driven programs reported 30-day quit rates of 23%. The purpose of this study is to characterize the smoking cessation rates of a pharmacy-driven smoking cessation program for upper-aerodigestive cancer patients or patients with a pulmonary precancerous diagnosis. **Method:** Patients seen in a multidisciplinary upper aerodigestive clinic between April 2017 and July 2018 were screened. All active smokers and former smokers, who quit in the last 90 days, were eligible and offered enrollment in the program. The primary endpoint is to describe participant's quit-rates at 30, 90, and 180-days and number of patients who abstained from smoking from 30 to 90 days and 30 to 180 days. Tobacco use assessments and smoking cessation counseling were performed and documented by a pharmacy learner (pharmacy resident or student). A licensed pharmacist oversaw learner activity and documentation. Nicotine replacement therapy was provided immediately to eligible participants in a dose based on tobacco use. Participants received follow up via phone or in clinic every two weeks for the first three months, at six, nine, and twelve months of program enrollment. Two follow up phone call attempts were made at each time point to determine if not successfully reached. **Result:** Seventy-seven patients were enrolled in the pharmacy-driven smoking cessation program. The majority of patients were male, 52% (40), and younger than 65 years old, 56% (43). Patient-reported smoking cessation rates at 30-days, 90-days, and 180-days post enrollment were 38% (29), 38% (29), and 30% (23), respectively. Sustained quit-rate from 30-90 days was 29% (22). Sustained quit-rate from 30-180 days was 20% (15). At one, three, and six months, 4%, 9%, and 26% of patients, respectively, were unavailable by phone. **Conclusion:** Thirty percent of participants were successful in smoking cessation at 180 days from program enrollment, which compares favorably to previous pharmacist interventions. Telephone follow up continues to be challenging, especially later in the program. Future efforts will compare pharmacy-driven smoking cessation program to standard of care smoking cessation efforts and explore impacts of smoking cessation on clinical outcomes in patients who are receiving cancer care.

Keywords: smoking cessation, pharmacy, nicotine dependence

P1.10-10 SOCIAL VULNERABILITY AND SURVIVAL IN LUNG CANCER IN EMERGING COUNTRY

P. Costa[1], T. Silva[2], K. Braga Ribeiro[3], P. Pêgo Fernandes[4], R. Terra[5]

[1]*Faculdade de Medicina, Universidade de Sao Paulo, São Paulo/Brazil,* [2]*Escola de Enfermagem, Universidade de Sao Paulo, Sao Paulo/Brazil,* [3]*Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Sao Paulo/Brazil,* [4]*Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo/Brazil,* [5]*Instituto do Câncer do Estado de São Paulo, São Paulo/Brazil*

Background: The association between lung cancer and socioeconomic conditions has been reported more frequently in the last years. Demographical and epidemiological characteristics have changed over time, and these changes are observed mainly in big metropolitan areas of emerging countries with high inequalities scores. Our objective was to analyze the impact of social vulnerability in lung cancer survival in a big urban area of an emerging country. **Method:** We retrieved data from a local cancer database (RHC) including sociodemographic (Paulista Index of social vulnerability-IPVS and educational level), clinical (tumor characteristics, treatment) and survival data. We used median and interquartile range to show the descriptive results, frequencies and proportions to categorical variables. The survival curve was calculated by Kaplan-Meier and Log-rank. **Result:** 8631 patients were diagnosed with lung cancer between 2000 to 2013 and registered in the RHC database. In our population we found a predominance of men (61%), mean age 63 years (SD±11.4), and 52.5% of them were living in areas with low social vulnerability (Index 2). The most frequent histological type was adenocarcinoma (39%), and most patients were at clinical stage IV at diagnosis (56%); 31.4% received chemotherapy and 24.5%, chemotherapy+radiotherapy as a definitive treatment. The mean time from diagnosis to definitive treatment was 44 days (SD±93). The overall survival was 10 months (4-23). When adjusted for clinical stage, the probability of survival was better for patients living in areas of low social vulnerability (p<0.000) and for those who had completed >12 years of schooling (p<0.000).

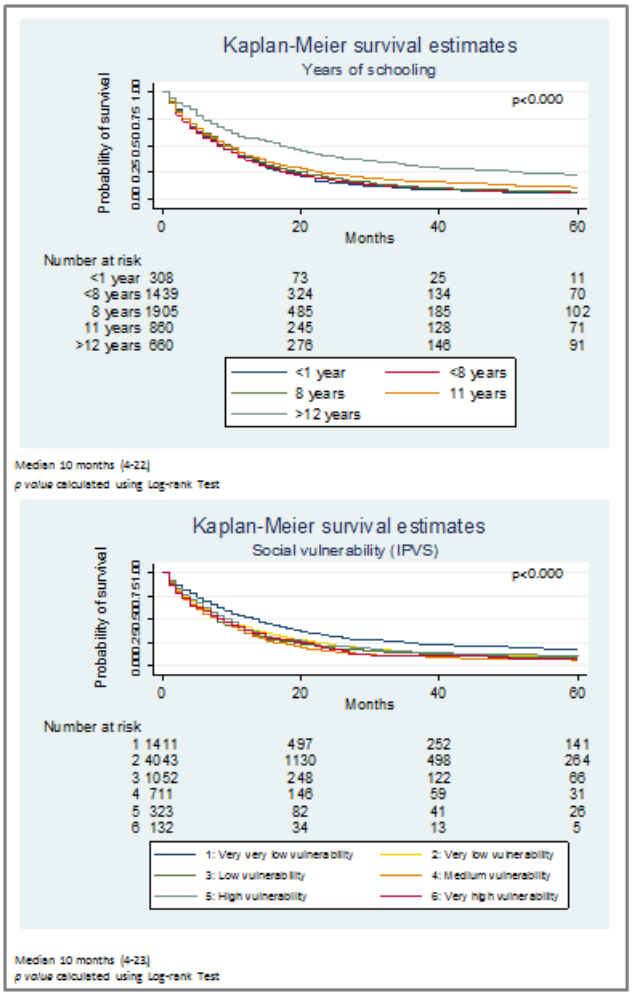

Figure 1. Kaplan-Meier survival curves

Conclusion: Social vulnerability and years of schooling are directly related with survival in lung cancer, even when adjusted for clinical stage. Our results highlight the impact of inequality in health outcomes.

Keywords: Lung cancer, Survival, socioeconomic

P1.10-11 EXAMINATION OF LIFESTYLE FACTORS AND ASSOCIATIONS WITH GENETIC MUTATIONS IN LUNG CANCER CASES

M. Bittoni, R. Harris, R. Arasada, D. Carbone

The Ohio State University, Columbus/United States of America

Background: With the advent of targeted therapy it is extremely useful to know what factors may be associated with specific mutations in order to better target treatment therapies. Few reports have assessed factors related to targeted therapies for lung cancer, especially in the United States. Common driver mutations relevant to lung cancer include EGFR, ROS1, ALK, KRAS and RET. In this report, we examined demographic, clinical and selected lifestyle factors, including age, sex, smoking, body mass index (BMI) and NSAID use and their association with lung cancer specific mutations. **Method:** Electronic medical records were reviewed for lung cancer cases (ICD-9: 162.2-9; ICD-10: C34.X) from the Ohio State University James Cancer Hospital from 2013-2018; demographic, clinical and lifestyle data were extracted, including age, sex, smoking, body mass index (BMI), NSAID use, as well as any driver mutations (EGFR, ROS1, ALK, KRAS and RET). Due to the small sample sizes for some of the mutations, they were combined into one overall mutation variable. Logistic regression analysis was performed to assess whether any associations exists between the risk factors and the presence of a mutation. Odds Ratios (ORs) were used to estimate the associations with alpha=0.05. **Result:** We identified 892 lung cancer cases in which tumor specimens were examined for mutations. Four types of mutations were identified: EGFR (n=89), ALK (n=19), ROS1 (n=8) and RET (n=12), for a total of 127 cases with mutations compared to 765 without mutations. The mean age for both groups was 65 years, with over 61% of the mutation group being female versus 54% of the non-mutation group). Overall, 84% of cases were white race, with slightly more non-whites in the mutation group (86% versus 83%). Logistic regression analyses revealed that age <50 years (OR=1.9; 95%CI=1.1, 3.6), female gender (OR=2.1, 95%CI=1.4, 3.1), and never smoking (OR=7.5, 95%CI=4.08, 3.5) were significantly associated with increased odds of having a mutation after controlling for other factors. Having a BMI>30 approached significance (OR=1.01, 95%CI=0.99,1.02) but NSAID use (aspirin, ibuprofen and/or acetaminophen) did not show significant associations with the presence of lung cancer mutations in this analysis. **Conclusion:** This study revealed significant associations between younger age (<50 years), female gender and never smoking with the presence of driver mutations in lung cancer cases. Previous reports have not assessed the relationship between BMI, NSAID use and lung cancer driver mutations to our knowledge. We also understand the significant limitations in obtaining quality data on NSAID use from the medical charts, and a more in-depth review is being planned. Nevertheless, this report confirms several known predictive factors related to driver mutations, and for the first time shows a lack of correlation with NSAIDs and potentially BMI. Future reports should also aim to assess more diverse populations.

Keyword: NSAIDS, driver mutations, lung cancer

P1.10-12 ROLE MODELS AND LUNG CANCER AWARENESS: DOES IT CHANGE THE MIND-SET AND PERCEPTION OF GENERAL POPULATION?

D. Saini[1], M. Khanna[1], A. Dubey[1], S. Roy[1], A. Shankar[2]

[1]*Indian Society of Clinical Oncology, Delhi/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Lung cancer has become a major health concern, though easily preventable, with smoking and air pollution being major risk factors. Intentional or unintentional advertisement or use of tobacco product by society role models may affect their attitude towards the smoking and related lung cancer. This study analysed the people mindset and perception for their role models in tobacco advertisement and lung cancer awareness. **Method:** The survey was conducted at various market and public places in Delhi, India. People were interviewed about what is their perception about their role model advertising or using tobacco products. **Result:** Among total participants of 2571, 42.6% people strongly agreed that actors/ actresses should not smoke in film or in TV serials. In one subset of people, 50 years and above strongly agreed about film stars should not use cigarettes in movies or serials (p= 0.01). People strongly agreed about banning billboard advertisement of tobacco products near tobacco shops (p= 0.02). Approximately half of the people strongly agreed that TV channels should not display the advertisement of tobacco-related products along with the roadside display. In this study, 57.6% of people felt dissociated from their role models if they see them endorsing or promoting tobacco products. All of the participants strongly agreed about using role models to promote lung cancer awareness in India. People who were less educated were significantly influenced by role models in adopting smoking habits. (p= 0.005). Person with family history of cancer was not affected by his/ her role models (p= .04). **Conclusion:** Role models have an important role to influence people to adopt smoking habits. Role models can be used as an important tool in promoting lung cancer awareness in India. There is an urgent need to ban promotion and advertisement of tobacco products by role models in Television, Internet and display boards. There is also a need to start population-based intervention aiming for behavioural modification and role models can play a vital role to make these campaigns successful.

Keywords: Lung cancer, Role model, Cancer awareness

P1.11-01 THE IMPLEMENTATION OF THE LUNG-RADS™ IN PILOT SILESIAN STUDY WITH LDCT - AN OPPORTUNITY FOR BETTER CONTROL OF OVERDIAGNOSIS

E. Wachula[1], S. Szablowska-Siwik[1], D. Czyzewski[2], M. Adamek[1]

[1]*School of Medicine with the Division of Dentistry in Zabrze , Medical University of Silesia, Katowice/Poland,* [2]*School of Medicine with the Division of Dentistry in Zabrze , Medical University of Silesia, Zabrze/Poland*

Background: A high percentage of false positive results observed in lung cancer screening (LCS) studies with LDCT was the reason for the modification of radiological assesement methods. Originally, all non-calcified nodules with a dimension ≥ 4 mm were considered as positive, whereas the implementation of the Lung-RADS™ recommends additional testing only for nodules ≥ 6 mm in categories 3 and 4. This allowed for the reduction of false positive results and avoiding the effect of "overdiagnosis" (unnecessary interventions). **Method:** We retrospectively analyzed 601 of first round LDCT scans, performed in 2010-2012 in asymptomatic volunteers of Pilot Silesian Study of Early Lung Cancer Detection with Low-Dose CT, with a smoking history of at least 20 pack-years, who actively smoked tobacco or quit smoking in the last 15 years. The analysis of non-invasive (additional examinations with contrast CT) and invasive interventions (bronchoscopy, EBUS, biopsies, surgery) done in screening participants was performed, followed by assessment of nodules according to the Lung-RADS ™ system, grouping them to 2, 3, 4A and 4B categories. Then the percentage of interventions that could be avoided using the ACR LungRADS™ criteria was estimated. **Result:** In total, 1016 nodules of solid, partial-solid and non-solid morphology were identified in 265 participants. In the entire screening cohort 87 interventions were performed, including 58 (66.6%) non-invasive and 29 (33.3%) invasive. Among nodules belonging to category 4A and B, 8 invasive lung cancers were identified, 1lung cancer was overlooked (false negative) and in 1 case metastases from colorectal cancer were diagnosed. With the using of LungRADS™ criteria, 34.4% of non-invasive and 8% of invasive interventions in categories 2 and 3 could be avoided. **Conclusion:** The LungRADS ACR classification system proved to be a practical tool for assessing lung nodules, which allowed to significantly reduce the effect of "overdiagnosis" especially in category 2 where the probability of lung cancer is low (<1%).

Keywords: lung cancer screening, Lung-RADS, LDCT (low dose computed tomography)

P1.11-02 ACCELERATION OF LUNG CANCER DIAGNOSIS: UTILITY STUDY FOR AI-BASED STRATIFICATION OF PULMONARY NODULES

L. Pickup[1], C. Arteta[1], J. Declerck[1], P. Novotny[1], S. Antic[2], A. Balar[2], P. Massion[2,3], T. Kadir[1]

[1]*Optellum Ltd, Oxford/United Kingdom,* [2]*Vanderbilt University Medical Center, Nashville/United States of America,* [3]*Vanderbilt University School of Medicine, Nashville/United States of America*

Background: Lung cancer diagnostic pathway guidelines promote the use of risk stratification models. Artificial Intelligence (AI)-based risk models have been shown to achieve better diagnostic accuracy than clinical models like Mayo Clinic (Mayo) for particular clinical populations. The aim of this study is to examine whether this could translate into faster diagnosis for high-risk cancer patients. **Method:** 116 patients (116 nodules) have been collected from a retrospective consecutive cohort acquired at Vanderbilt University Hospital. Time to diagnosis (TTD) was defined as the number of days between the CT scan and diagnosis date. Mean TTD was calculated on the cohort on which TTD could be defined, and on a reduced group comprising of TTD >31 days only. Risk scores for each nodule were found using the Mayo model and an AI-based Lung Cancer Prediction model (LCP) based on CT images alone. A 65% risk of cancer was taken to be the threshold at which surgical intervention is indicated (according to ACCP guidelines). **Result:** Seven patients were dropped due to negative TTD, and six for having no definitive diagnosis date. The eventual cohort contained 61 cancer patients and 42 controls. Mean TTD is 140 days (Interquartile Range – IQR 1-77 days). 25 patients have TTD=0, 60 are within 31 days (28 cancers, 32 controls) and 43 (33 cancers, 10 controls) are above 32 days. On the full cohort: Mayo risk score is >=65% for 15 cancers and 4 controls (sensitivity, 24.6%, specificity 90.5%), with a mean cancer TTD of 75 days. The LCP scores >=65% in 43 cancers and 10 controls (sensitivity, 70.5%, specificity 76.2%), mean cancer TTD 81 days. On the reduced group: Mayo >=65% for 7 cancers and 2 controls (sensitivity, 21.2%, specificity 80.0%) with mean cancer TTD 150 days. The LCP scores >=65% in 21 cancers and 4 controls (sensitivity, 63.6%, specificity 60.0%), with mean cancer TTD 156 days. **Conclusion:** The LCP risk model could potentially accelerate the diagnosis in 40% more cancer patients who were not worked up fully in the month following a scan (the jump in sensitivity going from Mayo to LCP risk >=65% is 42.4%). For these patients, time to a cancer diagnosis and treatment could be shortened by up to 156 days compared to recommendations if applying the Mayo risk model.

Keywords: Risk model, Diagnosis management, Lung cancer stratification

P1.11-03 DISPARITIES AND NATIONAL LUNG CANCER SCREENING GUIDELINES IN THE U.S. POPULATION

S. Han[1], E. Chow[1], K. Ten Haaf[2], I. Toumazis[1], M. Bastani[1], M. Tammemägi[3], J. Jeon[4], E. Feuer[5], R. Meza[4], S. Plevritis[1]

[1]*Stanford University, Stanford/United States of America,* [2]*Erasmus Medical Center, Rotterdam/Netherlands,* [3]*Brock University, Ontario/Canada,* [4]*University of Michigan, Ann Arbor/United States of America,* [5]*National Cancer Institute, Rockville/United States of America*

Background: Current U.S. Preventive Services Task Force (USPSTF) lung cancer (LC) screening guidelines are based on smoking history and age (55-80). These guidelines may miss those at higher risk, even at younger ages, due to other risk factors such as race or family history. In this study, we characterize the demographic/clinical profiles of those who are selected by risk-based screening criteria, but missed by USPSTF in younger (45-54) or older ages (71-80). **Method:** We used data from the National Health Interview Survey, the CISNET Smoking History Generator, and logistic prediction models for non-smoking risk factors to simulate life-time LC risk-factor data for 100,000 men and women in the U.S. 1950-1960 birth cohorts. We calculated age-specific 6-year LC risk (*r*) for each individual from ages 45-90 using the PLCOm2012 model. We evaluated age-specific screening-eligibility by USPSTF guidelines and by risk-based criteria (varying thresholds between 1.3%-2.5%). **Result:** In the 1950 cohort, 6.73% would be missed for screening in their younger ages by the USPSTF-criteria, but would have been screened by the risk-based criteria. Similarly, 13.97% of the cohort would be ineligible for screening by USPSTF in older ages. Notably, a higher proportion of African Americans will be ineligible for screening by USPSTF at younger (25.6%) or older (19.7%) ages, which is significantly higher than for Whites (7.7% and 15.75% respectively). Similar results were observed for other risk thresholds and for the 1960 cohort.

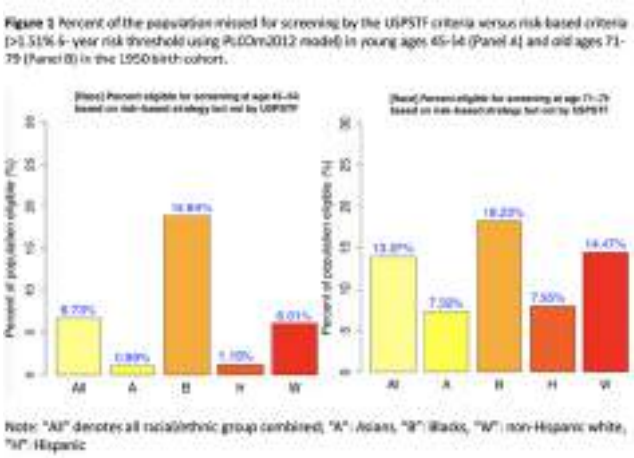

Figure 1 Percent of the population missed for screening by the USPSTF criteria versus risk-based criteria (>1.51% 6-year risk threshold using PLCOm2012 model) in young ages 45-54 (Panel A) and old ages 71-79 (Panel B) in the 1950 birth cohort.

Note: "All" denotes all racial/ethnic group combined; "A": Asians, "B": Blacks, "W": non-Hispanic white, "H": Hispanic

Conclusion: Further consideration is needed to incorporate comprehensive risk factors, including race/ethnicity, into lung screening criteria to reduce potential racial disparities.

P1.11-04 UTILIZING DNA REPAIR ACTIVITY BIOMARKERS FOR LUNG CANCER RISK ASSESSMENT AND EARLY DETECTION

T. Paz-Elizur[1], Y. Leitner-Dagan[1], K. Meyer[2], B. Markus[1], F. Giorgi[2], M. O'Reilly[2], H. Kim[2], Y. Evgy[1], R. Fluss[3], L. Freedman[3], R.C. Rintoul[4], B. Ponder[2], Z. Livneh[1]

[1]*Weizmann Institute of Science, Rehovot/Israel,* [2]*University of Cambridge, Cambridge/United Kingdom,* [3]*Gertner Institute for Epidemiology and Public Health Policy Research, Tel Hashomer/Israel,* [4]*Papworth Hospital NHS Foundation Trust, Cambridge/United Kingdom*

Background: Early detection dramatically increases the 5-year survival rates of lung cancer patients. Yet, current early detection screening criteria miss most cases, highlighting the need to improve risk assessment markers. Because of the crucial role of DNA repair in eliminating DNA damage and mutations, and preventing cancer, we examined the usefulness of a panel of DNA repair blood tests for lung cancer risk assessment. The panel consisted of the DNA repair enzyme activities of OGG1 (8-oxoguanine DNA glycosylase), MPG (methylpurine DNA glycosylase) and APE1 (apurinic/apyrimidinic endonuclease 1), which act primarily on oxidative and methylation DNA damage. **Method:** A case-control study with 150 non-small cell lung cancer cases and 143 controls, blinded to the experimentalists, was conducted in the UK population, with tests and analyses performed in Israel. For each study participant, DNA repair enzymes activities were measured in protein extracts prepared from peripheral blood mononuclear cells, and used to calculate an integrated personalized DNA repair score. Personal characteristic of cases and controls were compared using unpaired t-tests for continuous variables and chi-squared tests for categorical variables. Associations were calculated using logistic regression. **Result:** The mean DNA repair score was lower in lung cancer cases than in control subjects, regardless of the disease stage. Individuals at the lowest tertile of DNA repair score had increased risk of lung cancer compared to individuals at the highest tertile, with OR=7.2, 95%CI 3.0-17.5; P<0.001, which was smoking-independent. ROC analysis yielded an AUC of 0.89. Integrating the DNA repair score into a commonly used risk model based on age and smoking status, led to 4-5-fold increase or decrease in the estimated 5-year risk to develop lung cancer, for low or high DNA repair score, respectively, compared to the risk model without the DNA repair score. **Conclusion:** The results of this study performed in the UK population confirm and extend a similar independent study performed in the Israeli population (Sevilya *et al* 2014 *Cancer Prevention Res*. 7, 398-406; Leitner-Dagan *et al* 2012 *J. Natl. Cancer Inst.* 104, 1765-1769). It validates low DNA repair score as a mechanism-based lung cancer risk biomarker, and can significantly improve current risk models. The DNA repair score can assist in identifying high-risk individuals for early detection by CT scanning, and can perhaps aid in predicting potential malignancy of indeterminate pulmonary nodules.

P1.11-05 GENETIC ARCHITECTURE OF LUNG CANCER USING MACHINE-LEARNING APPROACHES IN GENOME-WIDE ASSOCIATION STUDIES

J. Byun, Y. Han, J. Edelson, Q. Ostrom, C. Amos

Baylor College of Medicine, Houston/United States of America

Background: Genome-wide association studies (GWAS) consisting of up to millions of single nucleotide polymorphisms (SNPs) have studied genetic influences to complex diseases and have identified thousands of associations. Few GWAS have explored interactions among SNPs that influence disease risks. **Method:** Machine learning applications can define how SNPs jointly influence disease risks through interactions. Tree-based machine-learning applications; classification and regression trees (CART) and random forest (RF) methods are popular and convenient tools for understanding interactions influencing disease development. Here we apply these methods to elucidate the higher-order interactions that influence lung cancer risk. We applied tree-based approaches using 18,444 cases and 14,027 controls from lung cancer OncoArray GWAS data. We first selected the SNPs very significantly associated (p<0.00001) with lung cancer risk. RF, which consists of systematically fitting classification trees, was run 1,000 times to identify the most influential SNPs. Subsequently we applied CART to summarize and visualize interactions that predict risk. **Result:** The final parsimonious tree included effects from genetic variants in CHRNA5, CLPTM1L, ZNRD1ASP, HCG9, TERT, CHRNB4, and DNAJC5 for overall lung. The final tree for adenocarcinoma lung showed the combination of genetic effects in or near ATM, CLPTLM1L, TERT, FSTL5, and DCTN4. The final tree for squamous cell carcinoma included CHRNA5, MRPL21, HLA, CASP8, and TAP2. **Conclusion:** Our results confirmed associations with CHRAN5, TERT, and HLA observed in previous study (McKay et al., 2017). Machine learning methods in genomics provide some benefits over logistic regression model with respect to identifying subgroups at higher risk of lung cancer development on the basis of genetic characteristics.

P1.11-06 EXPANDING CRITERIA FOR LUNG CANCER SCREENING REDUCES GENDER DISPARITY

M. Pasquinelli[1], K. Kovitz[1], M. Durham[2], J. Zacny[1], Z. Deliu[1], K. Rygalski[2], L. Liu[2], M. Koshy[3], R. Winn[2], L. Feldman[4]

Background: Women smokers may be more susceptible to lung cancer with less cigarette exposure than men. The NLST found borderline greater mortality benefit to high-risk women screened for lung cancer than men. The NELSON trial found significantly greater mortality benefit for women than men (39-61% for women vs 26% in men at 10 years). Since the NELSON trial included individuals ≥50 years old and ≤20 pack-years smoking history (similar to the NCCN moderate risk group) the aim of this study was to evaluate a cohort of lung cancer patients to determine differences in meeting the USPSTF criteria versus the NCCN moderate risk criteria on the basis of gender. **Method:** Gender, demographics, and smoking history were collected in a retrospective analysis of 703 smokers (current and former) diagnosed with lung cancer between 2010 – 2017 at an urban Chicago academic medical center. Cases were assessed for whether they would have met USPSTF (includes age 55-80, current smoker or former smokers quit time ≤15 years, ≥30 pack-years) and the NCCN moderate risk (includes age ≥50, current or former smokers, ≥20 pack-years) screening eligibility criteria. **Result:** Women smoked less overall, were less likely to smoke ≥30 pack-years (p=0.0002) and less likely to meet USPSTF screening guidelines (46.7% women vs 61.0% of men, p=0.0007) than men (Table 1). This gender disparity in meeting eligibility criteria was reduced by >40% (from 14.4% to 8.0%) when expanding from USPSTF (61.0% men vs 46.7% woman) to the NCCN moderate risk criteria (80.7% men vs. 72.7% women). Women were diagnosed at an earlier stage than men (p=0.02). **Conclusion:** Women diagnosed with lung cancer had a lighter smoking history and were less likely to meet the USPSTF screening criteria than men. Expanding USPSTF criteria to include individuals age ≥50 and ≥20 pack-year smoking history decreased the gender disparity in meeting lung cancer screening guidelines. Table 1: Gender Variation in Lung Cancer Current and Former Smokers

P1.11-07 CFDNA FROM BRONCHOALVEOLAR LAVAGE FLUID FOR THE IDENTIFICATION OF SOLID PULMONARY NODULES: A NEW MEDIUM OF LIQUID BIOPSY

J. Jiang[1], C. Mu[1], J. Zhao[1], D. Zeng[1], C. Wang[1], H. Li[2], J. Ye[2], T. Zhang[2]

[1]*The First Affiliated Hospital of Soochow University, suzhou/China,* [2]*Burning Rock Biotech, Guangzhou/China*

Background: The pulmonary nodule especially small solid nodule (<2cm) represents a common diagnostic challenge for clinicians, which are sometimes very difficult to diagnose by radiographic techniques. In addition, complications of invasive diagnostic procedures of lung cancer are common in clinical practice. Bronchoalveolar lavage fluid (BALF), flushed into a small part of the lung and then recollected for examination, is routinely performed for the diagnosis of lung infections, interstitial lung diseases and sarcoidosis. However, limited evidences support the use of BALF for lung cancer diagnosis. The aim of this study is to investigate the potential value of BALF as liquid biopsy for differential diagnosis of pulmonary nodule characteristics. **Method:** A total of 36 patients with solid pulmonary nodule (<2 cm) at department of respiratory medicine of the first affiliated hospital of soochow university were enrolled. BALF supernatant cfDNA and matched tissue samples were profiled using 168-cancer-related gene panel, with median sequencing depths of 45259× and 2007×, respectively. Patients were eventually diagnosed by surgery, tracheoscopy, transthoracic needle aspiration or follow-up. The consistency of diagnoses based on genomic profiling of BALF and pathological examination were evaluated. **Result:** Of the 36 patients with solid pulmonary nodule (<2 cm), 15 cases were finally diagnosed as malignant nodules (11 by surgery, 4 by tracheoscopy), 16 with benign nodules (5 by surgery, 10 by tracheoscopy and fellow-up ,1 by TTNA), and 5 with uncertain nodules for the present. Using BALF mutation spectrum for diagnosis of pulmonary nodule characteristics, the sensitivities of 168 genes and 10 key genes (*EGFR*, *ERBB2*, *ROS1*, *BRAF*, *RET*, *ALK*, *KRAS*, *MET*, *TP53* and *RB1*) from NGS panel were 80% and 73%, the specificities were as high as 75% and 100%, positive predictive values were 75% and 100%, and negative predictive values were 80% and 80%, respectively. NGS detection consistency between BALFs and tissues was analyzed in paired BALF and tissue samples from 14 malignant patients. Alterations were detected in 11 (78.6%, 11/14) BALF supernatant samples and all the 14 (100%, 14/14) tissues. In total, 45 mutations were detected in paired BALF and tissue samples, of which 27 were detected in BALF samples and 40 in tissue samples,the consistency between tissue and BALF supernatant was 48.9%. **Conclusion:** BALF supernatant cfDNA could reveal the genetic profiles of patients with lung cancer and distinguish benign or malignant solitary pulmonary nodule (<2cm) with high specificity. It should be considered as liquid biopsy medium for identification the solitary pulmonary nodule in clinical practice.

P1.11-08 ARE RISK PREDICTION MODELS SUPERIOR OVER STANDARD CRITERIA FOR LUNG CANCER SCREENING IN EUROPE? MACROSCALE SIMULATION ON LARGE POLISH COHORT

M. Ostrowski[1], T. Marjanski[1], R. Dziedzic[1], S. Kocot[2], W. Rzyman[1]

[1]*Medical University of Gdansk, Gdańsk/Poland,* [2]*Silesian University of Technology, Gliwice/Poland*

Background: Inauguration of the national lung cancer screening programme in Poland is to take place in 2019. Yet, issues such as optimal selection criteria remain unresolved. A computational macroscale simulation of lung cancer risk prediction models' implementation and comparison in a large lung cancer screening cohort of 5,534 individuals from a single, experienced European center was performed. **Method:** A total of 5,534 healthy volunteers (aged 50-79, smoking history ≥30 pack-years) were enrolled in the Moltest Bis Programme (Moltest) between 2016 and 2017. Inclusion criteria were based on the Lung Cancer Screening National Comprehensive Cancer Network Clinical Practice Guidelines. Each participant underwent a low-dose computed chest tomography scan and selected participants underwent a further, diagnostic work-up. A computational macroscale simulation of Tammemagi $PLCO_{m2012}$, Liverpool Lung Project (LLP) and Bach risk models' implementation was applied. Jupyter notebook v.1.0 scientific environment was used to calculate lung cancer probability of all Moltest participants.

Patients i) with 6-year lung cancer probability ≥1.3% were considered as high risk in $PLCO_{m2012}$ model, ii) in LLP model with 5-year lung cancer probability ≥5.0%, and iii) in Bach model with 1-year lung cancer probability ≥2.0%. Such selected patients were eligible for the inclusion to the simulated lung cancer screening programme. Boolean functions were created and data frames containing patients' epidemiological characteristics were joined using Pandas Python Library v.0.23 for Python v.3.7. **Result:** In a computational macroscale simulation 3,897 (70.4%), 3,118 (56.3%) and 925 (16.7%) out of 5,534 Moltest participants met the threshold criteria of lung cancer probability in $PLCO_{m2012}$, LLP and Bach models, respectively. With 199 (3.6%) Moltest individuals initially referred for diagnostic work-up in the programme, lung cancer was confirmed in 105 (1.9%) cases. Contrarily, among high-risk individuals selected based on $PLCO_{m2012}$, LLP and Bach models, respectively, 103 (2.6%), 56 (1.8%) and 24 (2.6%) constituted the lung cancer cases primarily detected in the Moltest programme. Thus, in $PLCO_{m2012}$, LLP and Bach models the proportions of screen-detected lung cancer cases were 98.1%, 53.3% and 22.9%, respectively. **Conclusion:** Risk prediction models provide a vast disparity in selecting lung cancer high-risk individuals. Lung cancer screening enrollment based on Tammemagi's $PLCO_{m2012}$ risk prediction model is superior over LLP, Bach models and standard selection criteria based on age and pack-years.

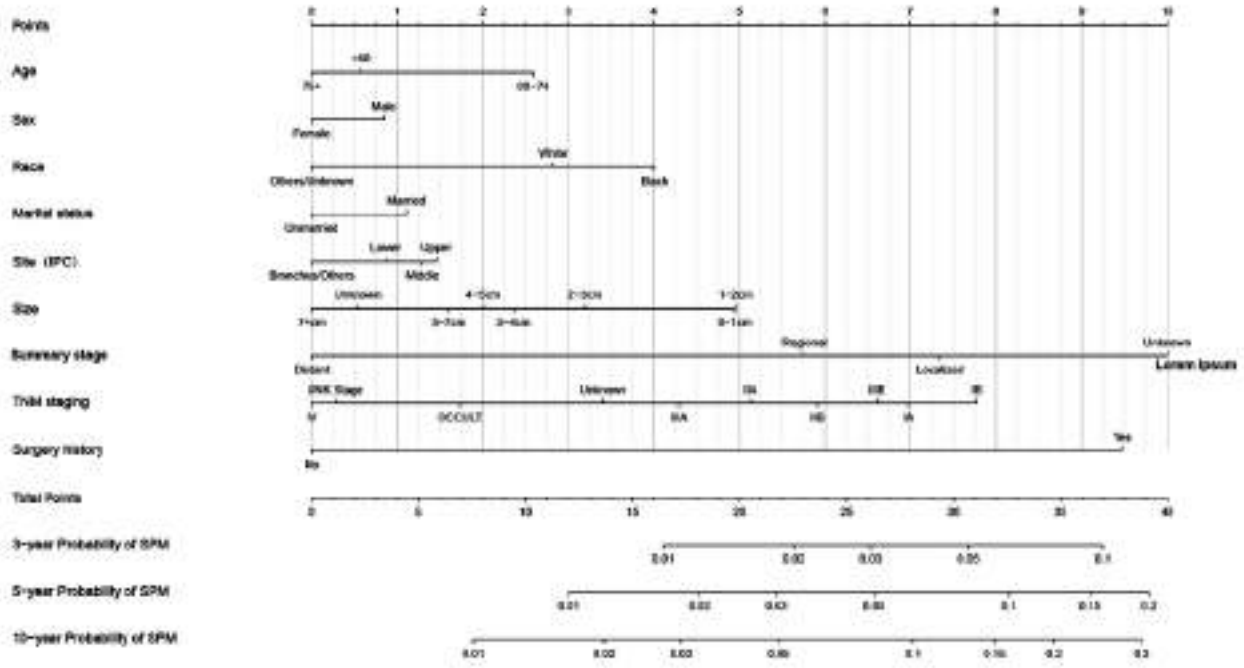
Keywords: lung cancer screening, risk prediction model, low-dose computed tomography

P1.11-09 RISK OF SECOND PRIMARY MALIGNANCY AFTER NON-SMALL-CELL LUNG CANCER: A COMPETING RISK NOMOGRAM BASED ON THE SEER DATABASE

H. Zhou[1], J. Shen[2], Y. Zhang[1], Y. Huang[1], W. Fang[1], Y. Yang[1], S. Hong[1], G. Chen[1], S. Zhao[1], X. Chen[1], Z. Zhang[1], J. Liu[3], W. Xian[3], Y. Zhao[1], X. Hou[1], Y. Ma[1], T. Zhou[1], H. Zhao[1], L. Zhang[1]

[1]*Sun Yat-Sen University Cancer Center, Guangzhou/China,* [2]*Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou/China,* [3]*Sun Yat-Sen University, Guangzhou/China*

Background: With the improvement of survival for non-small-cell lung cancer (NSCLC), research focused on second primary malignancy (SPM) in NSCLC survivors is becoming urgent. This study aimed to estimate the incidence and risk of SPM in NSCLC patients. **Method:** We retrospectively analysed 78,175 NSCLC patients diagnosed between 2004 and 2010 in SEER database, with 3,161 (4.04%) SPM cases observed. We firstly evaluated the crude and cumulative incidence of SPM. SPM incidence in NSCLC survivors compared to that in the age-specific reference population was calculated as standardized incidence ratio (SIR). A competing risk nomogram was also built, to predict the risk of SPM. **Result:** The crude and 10-year cumulative incidences of SPM were 4.04% and 5.05% (95% CI 4.87%-5.25%), respectively, while the SIR was 1.62 (95% CI 1.56-1.68). Initial primary cancer (IPC) diagnosed when aged 60-74 years old, male, black people, being married, IPC in the upper lobe and indicators of better prognosis of IPC were risk factors of SPM after the initial primary NSCLC. A competing risk nomogram was built for the prediction of SPM after the initial primary NSCLC. (Fig. 1) The nomogram was well calibrated and had good discriminative ability, with c-index of 0.80. It showed a significantly wide interval of SPM cumulative incidence between the first and tenth-decile according to the risk model (1.04% vs. 16.70%, p<0.05). The decision curve analysis indicated that the clinical net benefit of the risk model was larger than that in other scenarios (all-screening or no-screening) in a range of threshold probabilities (1% to 20%).



Conclusion: Our study firstly performed a systematic estimation of the incidence of SPM in NSCLC, which implied the necessity of a risk predicting model. We developed the first competing risk nomogram to predict the risk of SPM, which performed well in the evaluation and might be helpful for individualized SPM screening.

P1.11-10 SERUM MICRORNA BIOMARKERS FOR SCREENING OF RESECTABLE LUNG CANCER

K. Asakura[1,2], T. Kadota[3,4], J. Matsuzaki[3], Y. Yoshida[1], K. Nakagawa[1], H. Asamura[2], S. Watanabe[1], T. Ochiya[3]

[1]*Department of Thoracic Surgery, National Cancer Center Hospital, Tokyo/Japan,* [2]*Division of Thoracic Surgery, Department of Surgery, Keio University School of Medicine, Tokyo/Japan,* [3]*Division of Molecular and Cellular Medicine, National Cancer Center Research Institute, Tokyo/Japan,* [4]*Division of Respiratory Diseases, Department of Internal Medicine, The Jikei University School of Medicine, Tokyo/Japan*

Background: An accurate early screening method for lung cancer would be a powerful tool for decreasing lung cancer–related mortality. Computed tomography (CT) scanning is an effective method for lung cancer screening in high-risk populations. However, screening by CT scan has a limitation of low specificity (61%) for detection of lung cancer, resulting in unnecessary follow-up CT scans or invasive lung biopsies. In this study, we investigated the diagnostic potential of serum microRNAs (miRNAs) for detection of resectable lung cancer. **Method:** Using the 3D-Gene® miRNA Labeling kit and the 3D-Gene® Human miRNA Oligo Chip (Toray Industries), we generated comprehensive miRNA profiles (expression levels of 2588 miRNAs) from 3744 serum samples obtained from 1566 patients with resectable lung cancer and 2178 participants with no cancer. We created a reliable diagnostic model for resectable lung cancer based on the combined expression levels of two miRNAs in the discovery set (208 lung cancer patients, 208 non-cancer participants). We then confirmed the diagnostic performance of the model in the validation set (1358 lung cancer patients, 1970 non-cancer participants). **Result:** The combination of miR-A and miR-B yielded the best discrimination in the discovery set (AUC, 99.3; sensitivity, 99.0%; specificity, 99.0%). We then confirmed the diagnostic performance of the model in the validation set, and showed that the model was accurate (AUC, 0.973; sensitivity, 95.0%; specificity, 99.0%). According to univariable logistic regression analysis, the odds ratio of the diagnostic model for the presence of lung cancer was 21.76 (95% confidence interval [CI], 15.98–29.63). The diagnostic index exhibited high performance for all pathological stages (IA, 96.1%; IB, 93.7%; IIA, 97.3%; IIB, 96.7%; IIIA, 90.2%; IIIB, 83.3%; IV, 100%), and histological types (adenocarcinoma, 95.1%; squamous cell carcinoma, 94.2%; small-cell lung cancer, 90.9%). **Conclusion:** A comprehensive analysis of serum levels of 2588 miRNAs in 1566 patients with lung cancer and 2178 non-cancer participants identified a combination of two miRNAs that could reliably detect resectable lung cancer. This study was the largest of its kind performed to date, and the results confirm that evaluation of serum miRNAs is an effective method for detection of resectable lung cancer. The high sensitivity and specificity of this screening model could help to decrease lung cancer–related mortality, as well as the number of unnecessary follow-up CT scans and invasive lung biopsies.

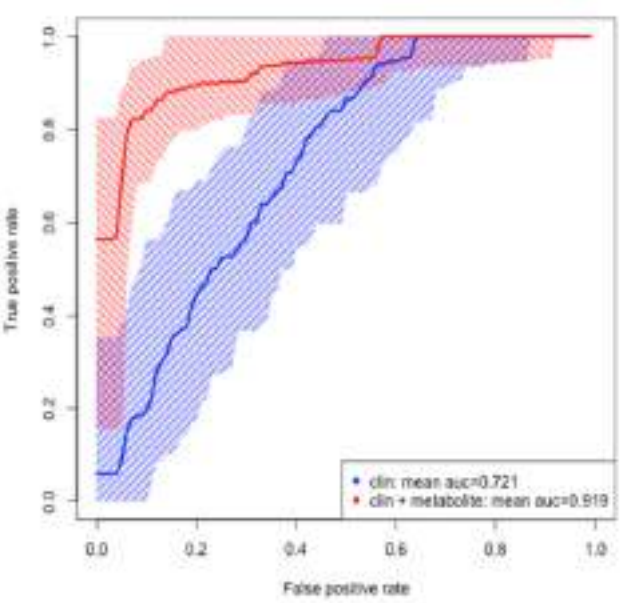
P1.11-11 INITIAL DISCOVERY OF EXHALED SMALL POLAR ENERGETICS-RELATED METABOLITES BY GC-MS FOR LUNG CANCER RISK ASSESSMENT

S. Spivack, M.K. Shi, D. Patel, A. Desai, J. Dobkin, C. Shah, D. Hosgood, K. Ye, Y. Qiu, I. Kurland

Albert Einstein College of Medicine, Bronx/United States of America

Background: There is a need for non-invasive airway-based biomarkers in lung carcinogenesis for both risk assessment, and earlier diagnosis. Exhaled breath condensate (EBC) contains airway lining fluid molecules, including small molecules of polar and non-polar lipid origin, presumably in part from epithelial cellular origins. Here we pilot a GC-MS strategy for measurement of small, polar molecules in exhaled breath condensate in EBC from lung cancer patients and controls. **Method:** Exhaled breath condensate (EBC) was collected non-invasively, using a handheld device (RTube) in ambulatory subjects engaged/recruited/consented through our pulmonary and thoracic surgery practices, under IRB protocol. A volume of 50 ul of EBC samples were combined with 200uL of methanol, containing 2 internal standards, 1nmol U13_succinate, 5nmol U13_citrate. Then, the samples were vortexed and 240 µl of supernatant was transferred to a sampling vial. The samples were dried under gentle nitrogen flow and derivatized with a two-step derivatization procedure, including a methoxyamine step for 90 minutes, and a silylation step for 60 minutes. QC sample was run multiple times during the analysis. The samples were analyzed by gas chromatography time-of-flight mass spectrometry (GC-TOFMS premier, Waters, USA). **Result:** A number of 282 variables were detected after alignment and excluding any known artificial peaks, 49 of them were annotated. The data was normalized to the intensity of the sum of all the metabolites. The data set was then imported into SIMCA-p software (Umeå, Sweden) for multivariate analysis. A multivariate case-control ROC discriminant analysis compared the clinical model (AUC 0.72) to clinical plus exhaled small polar discriminant metabolites combined (AUC 0.92), showed incremental discrimination attributable to these metabolites (p=2.22e-62).



ROC comparing clinical model (AUC 0.72) to clinical model plus metabolites (AUC 0.92); the difference attributable to metabolites was significant (p=2.22e-62). **Conclusion:** This exhaled biomarker platform can yield case-control discriminant small polar molecule sets related to known metabolic pathways, some of which are known to be deranged in cancers. Once further distilled and validated, our goal is to apply this non-invasive biomarker approach to prospective cohorts for non-invasive lung cancer risk assessment of the at-risk epithelium, in order to better select higher risk individuals to undergo effective CT screening. Supported by NIH-R21 CA192168-01; DoD-CDMRP- LC150738, NIH-NCI P60DK020541.

P1.11-12 GENETIC LANDSCAPE AND IMMUNE MICROENVIRONMENT FEATURES IN RECURRENCE IN STAGE IA OF LUNG ADENOCARCINOMA

L. Yang[1], J. Zhang[2], H. Xu[2], G. Yang[1], F. Xu[1], Y. Song[3], X. Shi[3], L. Wu[3], H. Zhang[3], J. Ying[2], Y. Wang[1]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, beijing/China,* [2]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [3]*Genecast Precision Medicine Technology Institute, Beijing/China*

Background: Lung adenocarcinoma (LUAD) leads to majority of lung cancer deaths. Various somatic mutations and copy number variations have been reported in LUAD, but their relevance to clinical prognosis of early stage LUAD is poorly understood. Besides, nearly 30% of patients with stage IA NSCLC eventually die of recurrence or metastasis in spite of the use of standard staging procedures. This study was designed to explore the genomic landscape in stage IA LUAD patients and find immune microenvironment features in recurrences. **Method:** 43 eligible stage IA LUAD patients with radical surgery and without adjuvant therapy from Cancer Hospital, Chinese Academy of Medical Science and Peking Union Medical College were included in this study. Up to last follow-up in April 9th, 2018, 22 patients were relapsed and 21 were not recurrent. Clinical data were collected in the baseline data analysis. Whole-exome sequencing

and RNA IO panel sequencing were performed in tumor and normal lung tissues. **Result:** There were no significant differences in terms of clinical and pathological features comparing recurrences to non-recurrences. The most common mutated genes were TP53(48%), EGFR (18%) and KRAS (9%). Tumor mutation burden (TMB) values ranged from 0.2 to 16.4 Mutations/Mb, with a median of 2.5Mutations/Mb. Twenty-two differential genes were screened out and classified to five signatures in terms of its function. These five signatures including tumor cell proliferation, tumor antigen, cytotoxic T cells activity, T lymphocyte chemotactic factor, and natural killer cell activation were dramatically high expressed in non-recurrences ($p<0.05$). Besides, cytolytic activity was significantly higher in non-recurrences ($p<0.05$), which were represented as the log-average expression of GZMA and PRF1. Furthermore, six genes out of twenty-two genes were found to be significantly important in terms of disease-free survival (DFS) in stage IA LUAD with radical resection according to Kaplan-Meier analysis. However, there was no relation between TMB and DFS ($p=0.501$). **Conclusion:** This is the first study reporting the relation of gene landscape and immune microenvironment features with prognosis in stage IA LUAD after curative resection. Host immunity is significantly related with the recurrence, whereas tumor mutation and TMB were not. Six genes related with host immunity have been found and promised to be novel prognostic factors in prognosis of stage IA LUAD.

P1.11-13 MASS SPECTROMETRY PROTEOMICS ANALYSIS DISCOVERS BIOMARKERS IN SERUM MONTHS TO YEARS BEFORE NON-SMALL CELL LUNG CANCER: THE HUNT STUDY

O.T. Nguyen[1], M. Markaki[2], A. Sharma[1], C. Chatzipantsiou[2], V. Lagani[3], I. Tsamardinos[4], O. Røe[1]

[1]*Norwegian University of Science and Technology, Trondheim/Norway,* [2]*University of Crete, Heraklion/Greece,* [3]*Ilia State University, Tblisi/Georgia,* [4]*Gnosis Data Analysis PC, Heraklion/Greece*

Background: The high incidence and high mortality rate of non-small cell lung cancer (NSCLC) calls for identification of methods for early diagnosis. Early diagnosis is key for effective treatment and thereby increasing survival. Searching of cancer-related proteins and proteins signature in biofluids is an emerging approach in early diagnostic of malignancies. In the present study we have used proteomics-based profiling of serum collected 2 months to 5 years before NSCLC diagnosis to search for early diagnostic biomarkers. **Method:** All serum samples in this study were obtained from the Nord-Trøndelag Health Study (HUNT) Research Centre's Biobank. *Discovery sample set (Cohort I):* Serum samples from 24 individuals that subsequently developed NSCLC (adenocarcinoma n=12, squamous cell carcinoma n=12) and 24 matched controls were obtained. *Validation sample set (Cohort II):* Serum samples from 10 future NSCLC patients (adenocarcinoma n=5, squamous cell carcinoma n=5) and 10 matched controls were obtained. The serum samples in both cohorts were collected in a time frame of 2 months to 5 years before diagnosis. All controls included were matched to the cases for smoking status (pack years and quit time), gender and age, and were cancer-free at least 5 years before blood sampling. All subjects were smokers or ex-smokers. Twenty (20) µl of serum was depleted of its high-abundant proteins and the cleaned-up peptides were analysed by LC- MS with an Orbitrap Elite mass spectrometer. Data were processed/analysed using MaxQuant software. Using Cohort I as training set, proteins most related to diagnosis were identified at first with limma univariate analysis. Reference and equivalent signatures were identified using JADbio with SES as feature selection algorithm. The JADbio matched pipeline with 50 repetitions for performance assessment (AUC with 95% CI) was used. On the basis of the top differentially expressed proteins by limma, pathway analysis was performed on Ingenuity Pathway Analysis (IPA) software using p-value threshold of 0.05 and abs log2 fold change 0.5. **Result:** In the serum samples of Cohort I, a three-protein signature (AUC=0.692 [CI 0.515-0.748]) was detected where one protein was validated in Cohort II. The pathway analysis identified the pathways catecholamine biosynthesis ($p=0.00278$), phenylethylamine degradation I ($p=0.00278$) and LXR/RXR Activation ($p=0.00312$) as the top three most enriched pathways. **Conclusion:** Proteomic analysis indicated that differential levels of a few proteins in serum may help detecting NSCLC 2 months to 5 years prior to clinical diagnosis. On the basis of the top differentially expressed proteins according to limma, IPA detected biologically relevant pathways. This is one of the first large-scale proteomics screening studies of pre-diagnostic serum of future NSCLC patients. Further validation studies are in progress.

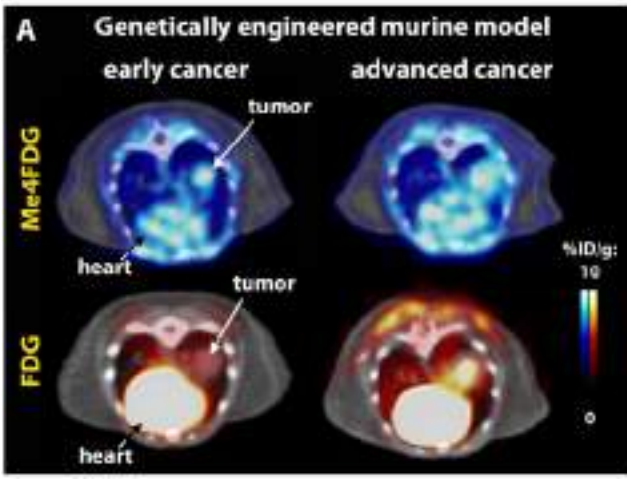
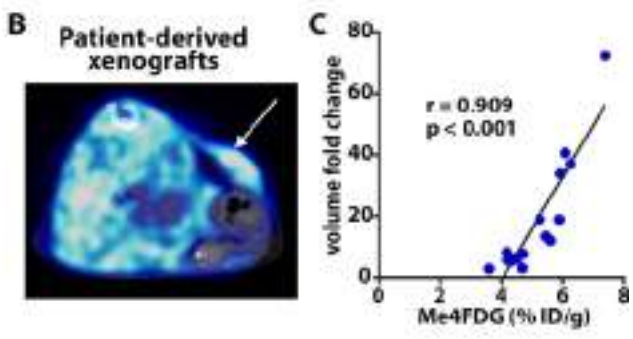
P1.11-14 SGLT2 IS A DIAGNOSTIC AND THERAPEUTIC TARGET FOR EARLY-STAGE LUNG ADENOCARCINOMA

B. Villegas, E. Koziolek, J. Liu, J. Barrio, W.D. Wallace, D. Elashoff, D. Aberle, J. Yanagawa, D. Shackelford, S. Dubinett, C. Scafoglio

David Geffen School of Medicine, University of California Los Angeles, Los Angeles/United States of America

Background: Early diagnosis of lung adenocarcinoma (LUAD) is crucial. The National Lung Screening Trial showed a 20% reduction in lung cancer mortality in high risk individuals using low-dose helical computed tomography (CT). CT is highly sensitive for detecting lung nodules, but is limited by low specificity, especially for LUAD. On CT, LUAD may appear as solid or subsolid nodules. Most subsolid nodules are not cancer, and many will remain stable or resolve; however, subsolid lesions can represent premalignancy or adenocarcinoma in situ. These lesions in the early spectrum of LUAD may persist for months to years before transforming into invasive disease. As a result, current standard of care is to follow these patients with CT imaging to monitor these indeterminate lesions for radiologic signs of malignant progression. The identification of novel biomarkers to predict the malignant potential of these nodules at their initial identification is of paramount importance. **Method:** We have recently discovered that premalignant ad early invasive lesions of the LUAD spectrum rely on sodium-glucose transporter 2 (SGLT2) for glucose uptake, whereas advanced carcinomas up-regulate transporters of the GLUT family. This is consistent with the observation that positron emission tomography (PET) with 2-[^{18}F] fluorodeoxyglucose (FDG), which detects GLUT but not SGLT activity, is a standard tool for staging advanced disease, but has low sensitivity for early-stage LUAD. We measured SGLT2 activity in vivo with the PET tracer methyl-4-[^{18}F] fluorodeoxyglucose (Me4FDG). **Result:** Me4FDG detects early-stage, FDG-negative LUAD in mouse models and in patients. Importantly, Me4FDG uptake correlates with tumor growth rate in patient-derived LUAD xenografts (fig. 1). Targeting SGLT2 with FDA-approved inhibitors significantly reduces tumor growth and prolongs survival in genetic and patient-derived murine models, confirming an important role of SGLT2 in early-stage LUAD. Fig. 1. Me4FDG PET detects early lung adenocarcinoma and predicts growth rate. A) Time course of Me4FDG and FDG imaging in genetically engineered mice with LUAD. The early time point was taken when tumor nodules reached an average diameter of 7 mm (left panels), and the advanced time point was performed on the same mice 1 month later (right panels). B) Representative image of Me4FDG PET/CT imaging in mice carrying patient-derived LUAD xenografts. C) Correlation between Me4FDG uptake in the patient-derived xenografts and the fold increase in volume in a 1-month period following the PET/CT scan.





Conclusion: SGLT2 is a promising biomarker not only to diagnose early-stage tumors by PET imaging, but also to predict response to SGLT2 inhibitors.

Keywords: lung adenocarcinoma, glucose transporter, PET imaging

P1.11-15 FEASIBILITY OF A LUNG HEALTH CLINIC FOR EARLY LUNG CANCER IDENTIFICATION IN HIGH-RISK INDIVIDUALS IN SOUTH-EAST LONDON

A. Nair[1], A. Saleem[2], G. Selman[3], H. Kerslake[3], R. Breen[3], S. Ho[4], S.M. Mak[1], Y. Akande[5], J. Turville[5], T. Rua[4], J. Peacock[5], G. Santis[3], R. Razavi[4]

[1]*Guy's & St Thomas NHS Foundation Trust, London/United Kingdom,* [2]*Lambeth CCG, London/United Kingdom,* [3]*Guy's & St Thomas NHS Trust, London/United Kingdom,* [4]*King's College London, London/United Kingdom,* [5]*King's College London, LONDON/United Kingdom*

Background: Lung cancer screening (LCS) using low-dose CT (LDCT) reduces mortality amongst high-risk individuals in clinical trial settings. However LCS uptake remains low, especially amongst currently smoking and socioeconomically deprived individuals. It is suggested that an invitation to a lung health clinic (LHC) to holistically approach lung health in a positive manner, in addition to LCS, could increase uptake. In Southeast London, where no LCS programme exists, the feasibility of this approach is unknown, and requires quantification to inform strategic decisions on early lung cancer detection. We aimed to evaluate the uptake of LDCT when offered as part of an LHC, in patients aged 55-80 who are current or former smokers (quit within the last 15 years) in our socioeconomically deprived region in London. **Method:** A prospective cohort feasibility study used a targeted approach for scaled recruitment, identifying participants broadly meeting the criteria for age and smoking status through primary care case-finding in two deprived boroughs in South-east London (Lambeth and Soutwark). Opportunistic referrals from pharmacies, respiratory clinic, and smoking cessation clinics were also accepted. Potentially eligible high-risk (Liverpool Lung Prediction v2 lung cancer risk estimate of ≥5% over 5 years) participants were invited to an LHC assessment and offered spirometric assessment, smoking cessation referral, and same-day chest x-ray (CXR) and LDCT. Participants who declined the invitation were asked to indicate this negative engagement. LDCT interpretation by two thoracic radiologists using volumetric assessment and computer-aided detection (CAD) where possible were performed. Nodules were managed according to a protocol based on British Thoracic Society recommendations. Additional findings potentially impacting cardiothoracic health (e.g. coronary calcification) along with specific recommendations for action were communicated to the participant and their primary care physician. All participants are being followed up for a period of 12 months. We assessed the proportion of the target population eligible and recruited to the lung health clinic, the proportion accepting smoking cessation, and the number of lung cancers detected thus far. **Result:** 15,227 individuals aged 55-80 years were approached using GP case-finding. 2,949 (19.4%) engaged with the study, 2,352 responded positively (79.8% of all responders, 15.4% of total invited) and 597 negatively (20.2% of responders). No referrals from pharmacy, respiratory clinic or smoking cessation clinics were received. Following eligibility assessment, 373 participants were recruited (15.9% of positive responders, 2.4% of total invited). 10 participants had confirmed lung cancer (2.8% of total recruited), 4 at baseline and 6 at follow-up thus far. 30 (8.0%) participants accepted a smoking cessation referral, with 20 (5.4%) actually accessing the service. **Conclusion:** GP case-finding recruitment to a lung health clinic can feasibly engage high risk participants to potentially identify early lung cancer in deprived areas of South East London. However, more work is required to increase positive engagement and smoking cessation uptake which are vital to the long-term success of such efforts. The non-utilisation of alternative opportunistic referral routes suggests there may be barriers to using such routes, or that these routes require active pursuit, rather than just awareness, to drive engagement from them.

P1.11-16 SQUAMOUS CELL LUNG CANCER RISK IS ASSOCIATED WITH RARE, PATHOGENIC GERMLINE VARIANTS IN BRCA2 AND FANCONI ANEMIA GENES

M. Esai Selvan, R. Klein, Z. Gumus

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Lung cancer is the leading cause of cancer deaths worldwide. Patients have substantial better prognosis in early stage as opposed to late state disease. Identifying genetic factors for lung squamous carcinoma (SqCC) risk will enable their use in risk stratification, and personalized intensive surveillance, early detection, and prevention strategies for high-risk individuals. **Method:** In this study, we analyzed whole-exome sequencing datasets of 318 cases and 814 controls (discovery cohort) and then validated our findings in an independent cohort of 444 patients and 3,479 controls (validation cohort), all of European descent, totaling a combined cohort of 765 cases and 4,344 controls. We focused on rare pathogenic variants found in the ClinVar database and used penalized logistic regression to identify genes in which such variants are enriched in cases as compared to the controls. We performed these analyses both at gene and biologically linked gene set levels. All statistical tests were two-sided. **Result:** At gene level, consistent with previous studies, we observed an overall enrichement of rare, deleterious germline variants in *BRCA2* (joint OR=3.2, *p*=8.7e-08, 95% CI=2.1–4.7). Notably, at gene-set level, we observed an overall enrichment of rare, deleterious germline variants in *Fanconi Anemia* genes in cases with SqCC (joint analysis OR=3.08, *p*=1.4e-09, 95% confidence interval [CI]=2.2-4.3). More importantly, rare deleterious germline variants were enriched in *Fanconi Anemia* genes even without the *BRCA2* rs11571833 variant that is strongly enriched in lung SqCC cases (joint OR=2.76, *p*=7.0e-04, 95% CI=1.6-4.7). **Conclusion:** Overall, the findings in this study increase our understanding of SqCC predisposition, and warrant the inclusion of all *FA* genes in current *targeted* gene sequencing studies offered in the clinic that gather data on many patients (e.g. MSK-IMPACT panel). Targeted sequencing can be performed in much larger patient cohorts due to their relatively lower price when compared to exome sequencing. Such studies will support the development of a multi-gene genetic diagnostic test that identifies high-risk individuals. Studies in other cancers have shown that high-risk individuals can benefit from personalized precision medicine based surveillance programs (frequent screening for *BRCA* risk mutation carriers in breast and ovarian cancers), as well as chemoprevention options (daily dose of aspirin for colorectal cancer) in both the affected individuals and their families. While current surveillance options for SqCC with low-dose CT scanning may be risky for individuals with *FA* variants, high-risk individuals will then greatly benefit from the development of intensive surveillance and early detection approaches.

Keywords: germline risk, Genomics, squamous lung cancer

P1.11-17 OSTEOPOROSIS, CORONARY ARTERY CALCIFICATION, AND COPD IN A LUNG CANCER SCREENING COHORT

J. Finigan, K. Lowe, C. Thiele, C. Wilson, S. Humphries, D. Lynch, E. Regan

National Jewish Health, Denver/United States of America

Background: The US Preventative Services Task Force recommends annual lung cancer screening with low-dose CT scans in adults aged 55-80 who are current smokers (or have quit within the past 15 years) with a >30 pack-years history. The advent of lung cancer screening programs provides an opportunity to assess the resultant CT scans for signs of smoking-related diseases other than lung-cancer. We aimed assess the prevalence of Chronic Obstructive Pulmonary Disease

(COPD), coronary artery calcification, and osteoporosis within a lung cancer screening cohort. **Method:** We recruited subjects from the National Jewish Health Lung Cancer Screening (LCS) Program. In addition to the LCS CT-scan, participants completed a DXA scan, spirometry, a sit-to-stand test, and reported their medical history. Participants were classified by GOLD (Global Initiative for Chronic Obstructive Lung Disease) spirometry grade to correlate lung function, and co-morbid disease. **Result:** One hundred and thirty-five subjects participated in the study (68 males, 67 females). Mean age was 64.0 (5.8) years, and 32.6% were current smokers. 51% of the cohort had moderate to severe COPD (GOLD 2 or greater). While those who were GOLD 3 or 4 had all been previously diagnosed with COPD, 34% of those classified as GOLD 2 and 85% of GOLD 1 participants had not been previously diagnosed. Undiagnosed coronary artery disease (CAD) was common in the population. Eighty-three percent of those with CAC scores over 1000 did not report a prior diagnosis of CAD. Osteoporosis, or its precursor osteopenia, is present in a large proportion of the LCS cohort. The prevalence of osteoporotic disease increases with increasing COPD severity. Thirty-seven percent of GOLD 3 participants, and 44% of GOLD 4 participants have a Z-score of less than -2.5 (osteoporosis). Osteopenia (Z-score<-1.0) is more common, seen in 100% of GOLD 4 participants, 68% of GOLD 3 participants, 56% of GOLD 2 participants, 27% of GOLD 1, 65% of normal spirometry (GOLD 0), and 32% of PRISm participants. Increasing spirometric disease was associated with reduced physical function as measured by the sit-to-stand test and the SF-36 physical score. **Conclusion:** Patients enrolled in LCS programs often have disease other than lung cancer that may be detected using a low-dose chest CT scan. Clinicians should consider using these CT scans to screen for osteoporosis and coronary artery disease. Given the prevalence of undiagnosed COPD in LCS patients, further research should investigate a potential benefit of screening these patients for COPD using spirometry.

Background: A large strand of research supports the idea of implementing a population-based lung cancer screening program using low-dose computer tomography to reduce lung cancer mortality. It has been recognized that one of the key factors contributing a successful lung screening program is its combination with smoking cessation intervention. This study provides results of smoking cessation intervention in a population-based lung cancer screening trial. **Method:** Korean Lung Cancer Screening Project (K-LUCAS) is a single arm prospective nationwide lung cancer screening trial. In K-LUCAS, all currently smoking participants were provided with mandatory smoking cessation counselling. Smoking status of 5,144 currently smoking participants in K-LUCAS were surveyed by telephone 6 months after participation. There were some variations in the intervention; the department of which counselling is provided within; publically or privately operated smoking clinics; and whether or not counselling is provided simultaneously with screening results. The impact of such variations on smoking cessation is also reported. **Result:** Participant's motivation to quit smoking increased by 9.4% on average after participating in lung cancer screening. The smoking cessation rate was 24.7% and over 80% of quitters said that participation in lung cancer screening motivated them to quit smoking. The smoking cessation counselling was more effective when the smoking clinics are operated by national health insurance services than when operated privately by hospital and when counselling was provided simultaneously with screening results than when provided separately with screening results. The screening results itself also affected smoking cessation. The probability of quitting smoking for participants with positive screening results were significantly higher than participants with negative results. **Conclusion:** Smoking cessation intervention combined with lung cancer screening program encourages smoking cessation for screening participants. Our results the highlights the importance of incorporating smoking cessation intervention in lung cancer screening program which would further enhance the effectiveness of lung cancer screening program.

P1.11-19 TRIAL IN PROGRESS: CANCER SCREENING STUDY WITH OR WITHOUT LOW DOSE LUNG CT TO VALIDATE A MULTI-CANCER EARLY DETECTION BLOOD TEST

S. Janes[1], J. Dickson[1], A. Devaraj[2], C. Horst[1], S. Quaife[1], C. Levermore[3], K. Gyertson[3], A.-M. Mullin[1], L. Farrelly[1], B. Allen[4], N. Zhang[4], C. Clarke[4], S. Hamilton[4], A.-R. Hartman[4], A. Hackshaw[1]

[1]*University College London, London/United Kingdom,* [2]*Imperial College London and Royal Brompton Hospital London, London/United Kingdom,* [3]*University College London Hospitals NHS Foundation Trust, London/United Kingdom,* [4]*GRAIL, Inc., Menlo Park/United States of America*

Background: Few effective screening tests exist for cancer, and each is specific to a single cancer type. A single blood test that directly measures tumor cell-free DNA and can detect several cancer types, including lung, pancreatic, colon, and head & neck cancers, with high specificity may reduce cancer burden. The SUMMIT Study is designed to validate the ability of an investigational blood test to detect multiple cancer types among a high-risk population undergoing LDCT for lung cancer screening, as well as in a lower risk population. **Method:** SUMMIT is designed to enroll 50,000 participants aged 50-77, and will follow participants for up to 10 years via medical records and the national cancer registry. There will be two groups: Group A (n=25,000), individuals at high-risk for lung and other cancers due to substantial smoking history (per United States Preventive Services Task Force LDCT screening criteria, or PLCOm2012 six-year risk estimate of ≥1.3%); and Group B (n=25,000), individuals not meeting Group A criteria. Exclusion criteria include active cancer treatments. Potential participants are identified from the records of 540 general practices across North Central and East London, and are invited by letter to attend a dedicated LDCT scanning unit (Group A) or clinical unit (Group B), where eligibility is confirmed and consent obtained. Group A participants will provide a blood sample, complete a questionnaire, and receive a baseline LDCT, and then provide a blood sample and complete a questionnaire at 12 and 24 months post-baseline. Those with a negative baseline LDCT (without lung nodules) will be randomised to either have a LDCT at 12 and 24 months or no further scans. Participants with lung nodules at baseline could have more frequent scans. Group B participants complete a questionnaire and provide a blood sample at three study appointments (baseline, 12 months, 24 months). The primary endpoint is cancer incidence and stage. Blood test performance will be determined by sensitivity and false-positive rates (specificity). Blood test results will not be returned to physicians or participants. Group A enrollment began in April 2019, and Group B enrollment is targeted to start later in 2019. The study is designed to determine the performance and cost-effectiveness of this investigational multi-cancer blood test compared to or combined with LDCT for identifying lung cancer, and in detecting cancers for which there are no effective screening tests. The SUMMIT Study may therefore inform new approaches to finding cancer early. **Result:** Section not applicable **Conclusion:** Section not applicable

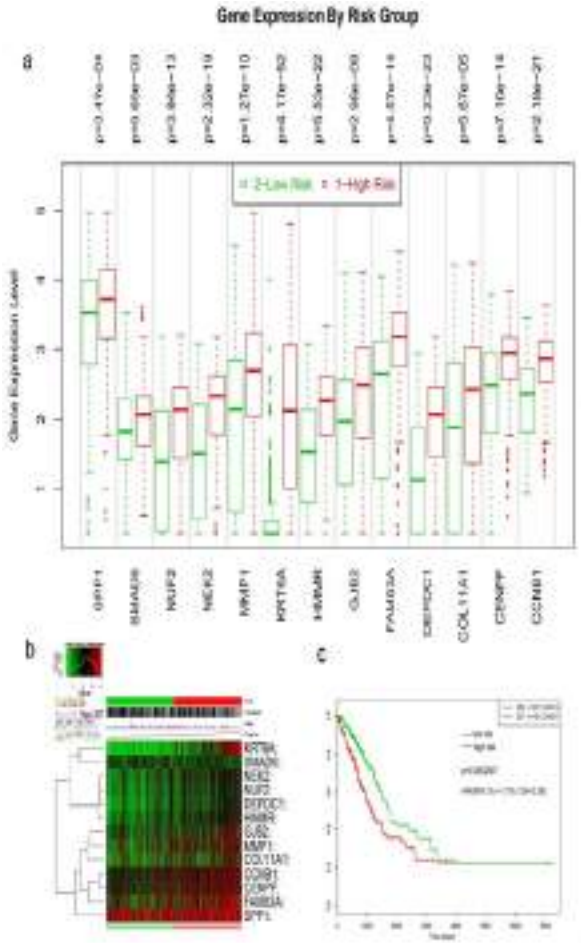
P1.11-20 IDENTIFICATION OF A THIRTEEN-GENE PROGNOSTIC SIGNATURE FOR LUNG ADENOCARCINOMA

Y. Wang, Y. Wo, T. Lu, W. Jiao

Affiliated Hospital of Qingdao University, Qingdao/China

Background: The incidence of lung adenocarcinoma has gradually surpassed that of lung squamous cell carcinoma. It is especially important for the diagnosis and treatment of lung adenocarcinoma. Therefore, we used the GEO and TCGA databases to assess the integration of several gene signatures and clinical stages associated with survival. **Method:** RNA sequencing was performed on LUAD-affected tissues and paired with non-cancerous tissue samples, and the intersection of differentially expressed genes was obtained using the Gene Expression Omnibus datasets GSE117370 and GSE19188, and a protein-protein interaction network was constructed to obtain the hub genes. Then corresponding overall survival information of LUAD patients from The Cancer Genome Atlas project-LUAD were included in the present study. An analysis of the Kyoto Encyclopedia of Genes and Genomes database and Gene Ontology were carried out to study the signature mechanism. **Result:** In this study, we identified thirteen candidate genes (SPP1, SMAD6, NUF2, NEK2, MMP1, KRT6A, HMMR, GJB2, FAM83A, DEPDC1, COL11A1, CENPF, CCNB1) closely related to survival in LUAD. A linear prognostic model of the eight genes was constructed and weighted by the regression coefficient (β) from the multivariate Cox regression analysis of The Cancer Genome Atlas-LUAD cohort to divide patients into low- and high-risk groups. The prognostic ability of the signature was validated in LUAD patients at our hospital. Patients assigned to the high-risk group exhibited poor overall survival compared to patients in the low-risk group. Finally, functional enrichment analysis showed that cell division played a vital role in the development of LUAD.



Notes: *a. Box plots of expression differences of the eight-gene signature in low (green) and high (red) risk groups of TCGA-LUAD patients. X-axis, gene expression value of each gene; above the box plot, P-values of the expression difference between risk groups. b. Heatmap shows that the gene expression of the 13 genes associated with survival at risk score, with red representing high expression and green representing low expression. c. Kaplan-Meier survival plots showing that high expression of the eight-gene signatures is associated with poor survival in TCGA-LUAD patients. Abbreviations: TCGA, The Cancer Genome Atlas; LUAD, lung adenocarcinoma; HR, hazard ratio; CI, concordance index.*

Conclusion: Our results highlighted a mRNA signature including thirteen genes, which may serve as a potential prognostic marker of LUAD.

Keywords: prognosis, lung adenocarcinoma, signature

P1.11-21 LIVERPOOL HEALTH LUNG PROJECT: SIGNIFICANT INCIDENTAL FINDINGS IN A SMOKER-PREDOMINANT COHORT

M. Ledson[1], Y. Cheng[2], E. Gaynor[3], J. Field[2]

[1]Liverpool Heart and Chest Hospital, Liverpool/United Kingdom, [2]University of Liverpool, Liverpool/United Kingdom, [3]Liverpool CCG, Liverpool/United Kingdom

Background: The Liverpool Healthy Lung Project (LHLP) is a prospective screening cohort which recruits ever-smokers or subjects with COPD aged 58-75 with a lung cancer risk of ≥5% in 5 years by the LLP_{v2} model. It aims to identify lung cancers at a treatable stage. On chest computed tomography scans, it is common to detect incidental findings with the frequency ranging 36% - 55%, but most of them are minor findings requiring no further management. Thus, it is presumed to be cost-effective if the most significant incidental findings are managed as appropriate in lung cancer screening programmes. **Method:** In the LHLP, radiologists alert a significant incidental finding (SIF, not relevant to suspicious lung cancer or indeterminate lung nodule) in the radiological reports if the Radiologist considers an urgent intervention is required; it's referred to a specialist or general practitioner outside the project. This paper reviewed the alerted reports with SIFs and followed up their final diagnosis and corresponding interventions in three hospital clinical databases. **Result:** Among a total of 3336 eligible participants who have completed the baseline scans during Apr 2016 - Feb 2019, 124 SIFs have been identified in 122 individuals (3.7%). The most frequently reported SIFs at baseline are possible extra-pulmonary cancers (45 of 124, 36.3%), followed by lung infections (39 of 124, 31.5%) which often need (post-antibiotic) follow-up to confirm resolution. Nine extra-pulmonary malignancies (7.4% in SIFs, 0.3% in the LHLP) have been pathologically or radiologically confirmed, including 5 lymphomas/leukaemias (4.1%), 2 renal cancers (1.6%), 1 breast cancers (0.8%) and 1 liver metastasis with unknown origin (0.8%). Two lymphoma/leukaemia patients have been treated with chemotherapy and/or radiotherapy, and the other three are currently under active monitoring. Both of the two renal cancer patients have undergone laterally radical nephrectomy, without recurrence in 6 and 20 months after surgery, respectively. The remaining two established cancer patients are still under further investigation. Other common SIFs included 14 interstitial lung diseases (11.3%), three of which have progressed during a post-baseline follow-up time of 6 months - 2 years, and 10 aneurysms/dilated aortas (8.0%), of which two patients have undergone surgical repair and another one has commenced a preventive therapy of statin and anti-plate agent. **Conclusion:** Identification by radiology of these SIFs in 3.7% of our screened population facilitates urgent clinical review, and appropriate management of these important, but unexpected findings.

Keywords: lung cancer screening, significant incidental findings

P1.11-22 LUNG CANCER GROWTH: IMPACT OF DIFFERENT ASSUMPTIONS

M. Siddique, R. Yip, C. Henschke, D. Yankelevitz

Icahn School of Medicine at Mt. Sinai, New York/United States of America

Background: The purpose of this study is to determine which of two models, exponential or linear best approximates growth of lung cancer so as to predict when follow up CT exams should be obtained when a nodule is found. **Method:** We reviewed our database of documented lung biopsies and identified those cases where the diagnosis of lung cancer in a solid nodule was confirmed and there were a total of three scans. Volume doubling times (VDTs) were calculated based on the first two scans using either the exponential method or the radial method and the third time point was used to determine which model best fit the actual result. We also allowed for measurement error to be considered based on the QIBA small nodule profile. **Result:** We identified 100 cases that met the inclusion

criteria. All were adenocarcinomas. On the first scan, the median nodule size was 8.2mm [Interquartile range(IQR):6.0-11.8)]. The median time between scans was 133.5 days (IQR:77.5-202 days) for the first and second scans, 75 days (IQR: 31.5-186.0 days) between second and third scans and 242.0 days (IQR: 131.5-424.0 days) between first and third scans. Median VDT from the first two scans was 139.0 days (IQR: 73.8-365.1 days). Using the calculated VDT from the first two scans, we found that 94 of the 100 cases had the third scan within 3 VDTs as estimated from the two scans. For these 94 cases, when accounting for the QIBA error measurements, both the linear or exponential models are plausible. For the 6 cases where the time interval between the second and third scan was longer, the exponential model provided a better fit for two, the linear model was better for two, and for the remaining two cases, it was not clear which model provided the better fit. **Conclusion:** When considering the short time intervals typically used in obtaining follow-up CT scans for small pulmonary nodules, we found that it had minimal impact in predicting the ultimate size of the nodule as measurement error could account for results using either method. It was only after at least 3 doubling times that the potential impact of choice of method becomes apparent as with the exponential method the doubling time remains constant while with the radial method the doubling time increases with increasing size and therefore overall growth substantially decreases with longer time interval.There remains uncertainty in terms of how nodules grow, whether it is only along the advancing edge or by all cells doubling. This has little impact clinically in terms of short term follow up. However, when considering situations where there may be long delays between CT scans such as moving the interval for screening from 1 year to 2 years, it has a very large impact.

Keywords: tumor growth models, exponential growth, linear radial growth

P1.11-23 THE IMPACT OF THE FAMILY HISTORY OF DIFFERENT CANCERS ON LUNG CANCER

J. Li[1], C. Li[1], B. Cheng[1], J. He[2], W. Liang[1]

[1]*The 1st Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/China,* [2]*Department of Thoracic Surgery and Oncology, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China*

Background: The definition of the high-risk population of lung cancer screening remains controversial. People with a family history of lung cancer will have a distinctly increase risk of lung cancer, but the influence of family history of other cancers it is still unclear. **Method:** We performed a case-control study to compare the exposure of different cancer family history between lung cancer and other cancers. All cancer patients who were hospitalized in our center between 2007 and 2018 were included and records of each patient's family history were retrieved. Logistic regression analysis was conducted after excluding the patients with a family history of non-lung cancer who had diagnosed the corresponding system cancer. **Result:** This study enrolled 23,977 cancer patients including 15,120 lung cancer and 8,857 non-lung cancer. Lung cancer patients had a higher exposure to a family history of lung cancer compared with non-lung cancer patients(OR=2.418, P< 0.001), and had a potential higher exposure to the patients with the family history of pancreatic cancer(OR=1.769,P=0.597)and kidney cancer(OR=1.326,P=0.596) without statistical difference. Sex had no significantly impact on the association between cancer family history and lung cancer risk (interaction P >0.05).

Table1

Family history of cancer	OR	95%CI for Exp (B)	p-value
lung cancer	**2.418**	1.789-3.269	**0.000**
esophagus cancer	0.479	0.198-1.156	0.101
ovarian cancer	0.245	0.045-1.336	0.104
stomach cancer	0.562	0.271-1.167	0.122
breast cancer	0.693	0.331-1.452	0.331
Nasopharynx cancer	0.740	0.379-1.446	0.378
cervical cancer	0.489	0.069-3.474	0.475
prostatic cancer	0.552	0.078-3.921	0.553
liver cancer	0.835	0.432-1.614	0.592
kidney cancer	**1.326**	0.467-3.765	**0.596**
pancreatic cancer	**1.769**	0.213-14.700	**0.597**
colorectal cancer	0.938	0.476-1.848	0.853
bladder cancer	0.967	0.283-3.303	0.957

Conclusion: Patients with a family history of lung cancer should be considered a high-risk population for lung cancer screening, whereas there is no strong evidence to support that family history of other cancer will influence the risk of lung cancer. More researches are required to determine the relationship between lung cancer risk and family history of pancreatic and kidney cancers.

Keywords: family history of cancer, Lung cancer, risk

P1.11-24 IMPLEMENTATION OF AN ORGANIZED LUNG CANCER SCREENING PROGRAM IN KOREA

Y. Kim[1,2]

[1]*National Cancer Control Institute, National Cancer Center, Goyang/Korea, Republic of,* [2]*National Cancer Center, Goyang-si, Gyeonggi-do/Korea, Republic of*

Background: Lung cancer is the leading cause of cancer mortality worldwide and has a low survival rate due to difficulties concerning early detection. The Korean Lung Cancer Screening demonstration project (K-LUCAS) was started in February 2017. K-LUCAS will assess the effectiveness, harm, and feasibility of lung cancer screening in order to implement a population-based screening program. K-LUCAS will evaluate the validation of the new standard of reporting form of low-dose computed tomography (LDCT) and the quality of lung cancer screening by a web-based network system using computer-aided nodule detection program (CAD). **Method:** K-LUCAS is a population-based single arm trial conducted in 14 cancer hospitals that targets a high-risk population aged 55-74 years with at least 30 pack-year smoking history within the last 15 years from Feb. 2017 to Dec. 2018. Participants were recruited when visiting the national cancer screening centers or smoking cessation clinics based on a lung cancer risk evaluation questionnaire. Lung cancer screening was provided by LDCT with at least a 16-row multidetector CT scanner and screening results were reported by Lung Imaging Reporting and Data System (Lung-RADS). All participants should have their results explained to them by a physician and current smokers should receive smoking cessation counselling. **Result:** Total 13,692 participants had joined K-LUCAS. The positive screening rate (categories 3 and 4 in Lung-RADS) was 15.3%. Among them, 78 lung cancers were detected. Stage I and II lung cancers among confirmed lung cancer cases were 52.8% and 15.3%, respectively. CAD detects more positive findings but decreases the variation of positive rate among screening units. About 75% of abnormal findings, including emphysema, coronary artery calcification etc. besides lung nodules, were detected in K-LUCAS. Psychological anxiety level for lung cancer was decreased after screening than before. Over 70% of currently smoking participant's motivation to quit smoking was increased after counselling about lung cancer screening results. **Conclusion:** K-LUCAS shows promising results in effective detection of early stage lung cancer and controlling diagnosis quality by a web-based network system. Based on the observations from K-LUCAS, a decision will be made as to whether lung cancer screening will be included in national cancer screening program.

Keywords: Korea, Lung cancer, Screening

P1.11-25 ADJUSTMENT FOR LEAD-TIME BIAS AND OVER-DIAGNOSIS IN LUNG CANCER SCREENING

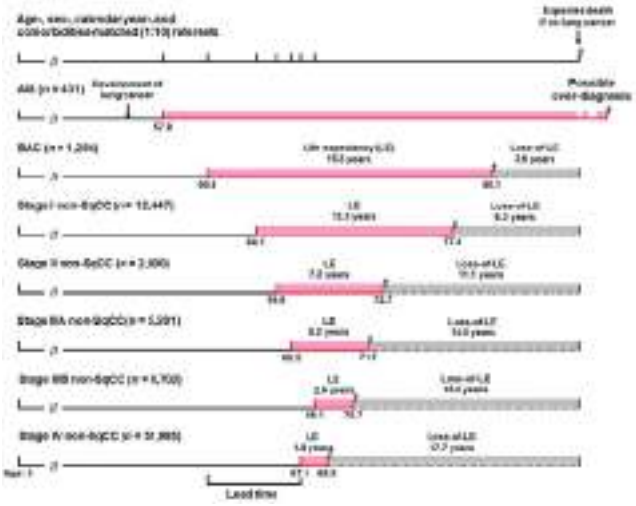
S.-C. Yang[1,2], J.-D. Wang[1,2]

[1]*Department of Public Health, College of Medicine, National Cheng Kung University, Tainan/Taiwan,* [2]*Department of Internal Medicine, National Cheng Kung University Hospital, Tainan/Taiwan*

Background: To develop an empirical method for adjustment of lead-time bias and over-diagnosis in lung cancer screening. **Method:** From 2002-2017, 113,151 nationwide lung cancer patients stratified by pathology and stage were matched by age, sex, calendar year, and comorbidities with 1,131,170 referents selected from general population. Loss-of-life expectancy (LE) was calculated as the difference between the life expectancy of patients and that of matched referents, which could be multiplied by the pathology- and stage-shifting in screening to adjust for lead-time bias. Cases without loss-of-life expectancy would be considered as over-diagnosis. **Result:** The life expectancies of bronchioloalveolar carcinoma (BAC) and stage IV non-squamous-cell lung cancer (non-SqCC) were 19.3 and 1.8 years, respectively, with a difference of 17.5 years (=19.3-1.8, as shown on the Figure). However, if we took different age, sex, and year of diagnosis into consideration

POSTERS

and compared the loss-of-life expectancies, the difference would be lowered down to 14.1 (=17.7-3.6) years, which implies a correction of lead time. Patients with adenocarcinoma in situ (AIS), BAC, and stage IA non-SqCC, had 18%, 9%, and 4% probabilities without loss-of-life expectancy, or, over-diagnosis.



Conclusion: Counting difference in loss-of-life expectancies could adjust for lead-time bias. The likelihoods of over-diagnosis appear modest and could possibly occur in cases with AIS, BAC, and stage IA non-SqCC.

Keywords: lead-time bias, over-diagnosis, lung cancer screening

P1.11-26 THE EPIDEMIOLOGY OF GROUND GLASS OPACITY (GGO) LUNG ADENOCARCINOMA: A NETWORK BASED CUMULATIVE META-ANALYSIS

X. Li, Y. Wang, S. Zhao, J. Chen, S. Xu

Tianjin Medical University General Hospital, Tianjin/China

Background: An increasing number of early-stage NSCLC with ground glass opacity (GGO) have been detected with lung cancer screening. GGO lung cancer is considered as a low-grade adenocarcinoma with noninvasive or minimally invasive growth patterns. The long term survival for GGO lung cancer is very much better compared to the solid counterparts. In this study, we investigate the epidemiological data of GGO lung cancer and outline the variation tendency through cumulative meta-analysis. **Method:** Two individual researchers conducted the platform searches on the PubMed, Cochrane Library and Embase from the inception dates to Dec. 1st, 2018. For counting data, such as number of female and non-smoking patients, the single rate is determined along with the corresponding 95% confidence interval (CI). For measurement data, such as average diagnosis age of patients, the single mean value is determined along with the corresponding 95% confidence interval (CI). We performed cumulative meta-analysis and metatrend analysis for the epidemiology data. Data analyses was performed using the Stata version 13.0 (Stata Corp LLC, College Station, Texas, USA). **Result:** A meta-analysis from a total of 50 articles with 8565 GGO patients between 1977 and 2018 showed that the rate of female GGO lung cancer was 0.62. The average age of all GGO lung cancer patients was 62.10 and the cumulative meta-analysis showed the average age has been decreasing from 66.40 to 59.06 which variation tendency was statistically significant (p<0.05). From 21 articles included smoking status of 4262 GGO lung cancers, it showed that the total rate for non-smoking patients was 0.72 and there was a significant increasing tendency (0.65 to 0.79, p<0.05). **Conclusion:** Our analysis indicates that there are much more GGO lung cancers in females compared to males. In recent years, it showed the average age of GGO lung cancer patients has been declined prominently while the non-smoking rate significantly increased. This investigation has challenged the current criteria of lung cancer screening which excludes a huge population of younger and non- or light-smoking patients who may have GGO lung cancers. Further study has to set up a more refined model which contributes to detect early stage NSCLC with GGO manifestation, which would significantly decrease the mortality of lung cancer.

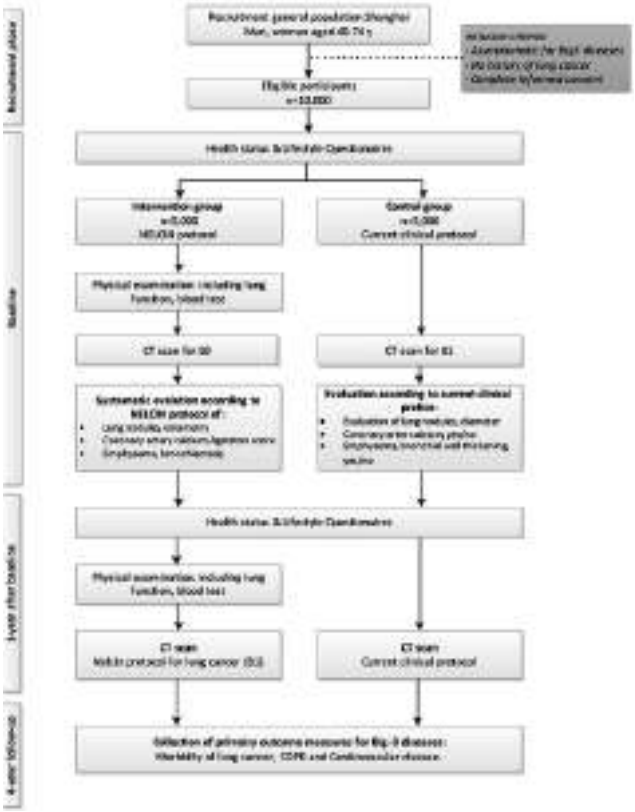
Keyword: ground glass opacity (GGO), lung adenocarcinoma, cumulative meta-analysis

P1.11-27 COMPUTED TOMOGRAPHY SCREENING FOR EARLY LUNG CANCER, COPD AND CARDIOVASCULAR DISEASE IN SHANGHAI: RATIONALE AND DESIGN OF A POPULATION-BASED COMPARATIVE STUDY

Y. Du[1], Q. Li[2], G. Sidorenkov[1], M. Vonder[1], J. Cai[2], G. De Bock[1], M. Rook[1], R. Vliegenthart[1], M. Heuvelmans[1], M. Dorrius[1], H. Groen[1], P. Der Harst[1], Z. Ye[3], X. Xie[4], W. Wang[5], M. Oudkerk[6], S. Liu[2]

[1]*University Medical Center Groningen, Groningen/Netherlands,* [2]*Shanghai Changzheng Hospital, Shanghai/China,* [3]*Tianjin Medical University Cancer Institute and Hospital, Tianjin/China,* [4]*Shanghai General Hospital, Shanghai/China,* [5]*Shanghai Center for Disease Control and Prevention, Shanghai/China,* [6]*University of Groningen, Groningen/Netherlands*

Background: Volume-based management for lung nodules is associated with a lower rate of unnecessary referral for further work up as compared to diameter-based management in European population. Screening for chronic obstructive pulmonary disease (COPD) and cardiovascular disease (CVD), in addition to lung cancer, may significantly increase the benefits of lung cancer low-dose computed tomography (CT) screening. While this is unclear in Chinese population. The aim of this study is to assess the diagnostic performance of volume-based lung nodule management for lung cancer CT screening as compared to diameter-based management, and to improve the effectiveness of CT screening for COPD and CVD based on quantitative measurement of CT imaging biomarkers in a Chinese screening setting. **Method:** A comparative population-based study is ongoing, that will include 10,000 asymptomatic participants between 40 and 74 years old from Shanghai urban population in China. Participants will be randomized into the intervention and control groups and will undergo a low-dose chest CT scan at baseline and one year after baseline. NELCIN-B3 protocol will be applied in the intervention group. It recommends management of detected solid and part-solid lung nodules based on the volume and volume doubling time (VDT) of a lung nodule. The imaging biomarkers for COPD and CVD, such as emphysema score, bronchial wall thickness from inspiratory and expiratory chest CT scan, and coronary calcium score from ECG-triggered cardiac CT scan will be evaluated. In addition data on laboratory parameters and lung function test will be collected. The participants in the control group will be managed according to the standard hospital protocol based on visual assessment of the CT images. It recommends management of detected lung nodules based on the diameter according to the NCCN Clinical Practice Guideline in Oncology for Lung Cancer Screening. Epidemiological data (eg., risk factors) will be collected through questionnaires for all participants. Four years after the initial assessment the incidence of the three diseases will be evaluated. The design is shown in Figure 1.



Result: The unnecessary referral rate will be compared between the NELCIN-B3 and standard protocol for early detected lung nodules management. The effectiveness of quantitative measurement of CT imaging biomarkers for early detection of lung cancer, COPD and CVD will be evaluated. **Conclusion:** We expect that the quantitative assessment of the CT imaging biomarkers will reduce the number of unnecessary referrals for early detected lung nodules and improve the early detection of COPD and CVD in Chinese urban populations.

Keywords: chronic obstructive pulmonary disease, computed tomography screening, Lung cancer

P1.11-28 LUNG CANCER: SUSCEPTIBILITY AND SURVIVAL DIFFERENCES FOR WOMEN AND MEN

R. Yip, E. Fevrier, A. Wolf, N. Triphuridet, C. Henschke

Icahn School of Medicine at Mt. Sinai, New York/United States of America

Background: To determine the lung cancer susceptibility to tobacco carcinogens and survival after diagnosis of lung cancer for women and men in the International Early Lung Cancer Program (I-ELCAP). **Method:** We used the prospective I-ELCAP cohort of asymptomatic men and women to identify all who were 40 years and older, had smoked at least 5 pack-years, and had low-dose CT screening in I-ELCAP between 1992 and 2018 at participating institutions in two continents, North America or Europe. Logistic regression models were used to calculate the odds ratio (OR) for lung cancer in women compared to men, adjusting for age, smoking history, and location. To account for time from baseline to lung cancer diagnosis, hazard ratio (HR) using Cox proportional hazards models were calculated for lung-cancer-specific mortality in women and men, conditioned on age, smoking history, disease stage, histology, whether resection was performed, and continent (NA or Europe). Interaction between sex and location was also evaluated. **Result:** Of the 23,438 women, 18,451 were in North America, 4987 in Europe. Of the 31,365 men, 18,451 in North America, 22,812 in Europe. Lung cancer was diagnosed in 475 women and 509 men; in NA, frequency was significantly higher in women (2.2% vs. 1.5%, p<0.0001) while in Europe, it was significantly lower (1.4% vs. 2.0%, p =0.007). As the interaction between sex and continent was significant (p<0.0001), separate multiple logistic regression analyses were performed which showed sex to be a significant independent predictor of lung cancer in North America (OR_{women}=1.7, 95% CI:1.4-2.0), but not in Europe (OR_{women}=0.8, 95% CI: 0.6-1.1). Median follow-up time of the 742 and 242 lung cancer patients in North America and Europe was 89.8 months and 67.0 months, respectively. Lung cancer deaths occurred less frequently in women than in men in North America [NA: 47/406 (11.6%) vs. 59/336 (17.6%)] and in Europe [3/69 (4.4%) vs. 17/173 (9.8%)]. In North America, the risk of death was significantly lower for women (unadjusted HR_{women} = 0.6, 95% CI: 0.4-0.9), but no longer significant when adjusted for other covariates. In Europe, unadjusted HR_{women} = 0.44 (95% CI: 0.13-1.50) was not significant. **Conclusion:** Women appear to have an increased susceptibility to tobacco carcinogens in NA but not in Europe. In both continents, however, rates of fatal outcome from lung cancer were slightly, but not significantly lower for women.

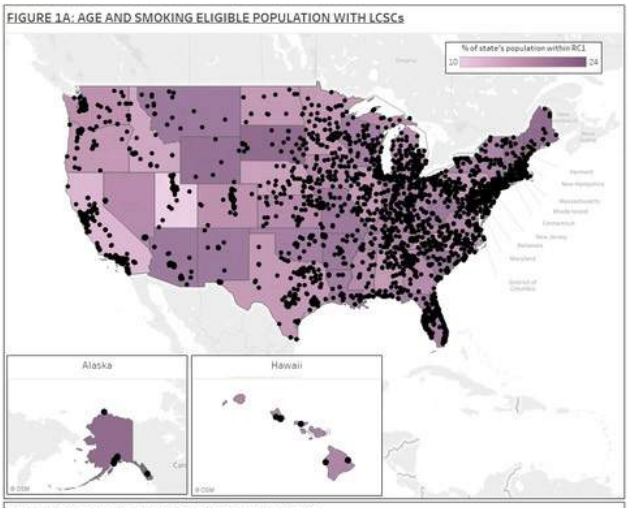
Keywords: Screening, lung cancer risk, gender differences

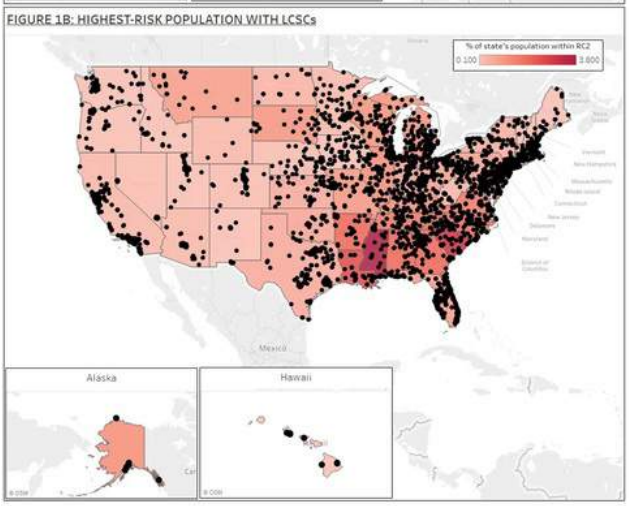
P1.11-29 RELATIONSHIP BETWEEN LUNG CANCER SCREENING CENTERS IN THE UNITED STATES AND HIGH-RISK INDIVIDUALS

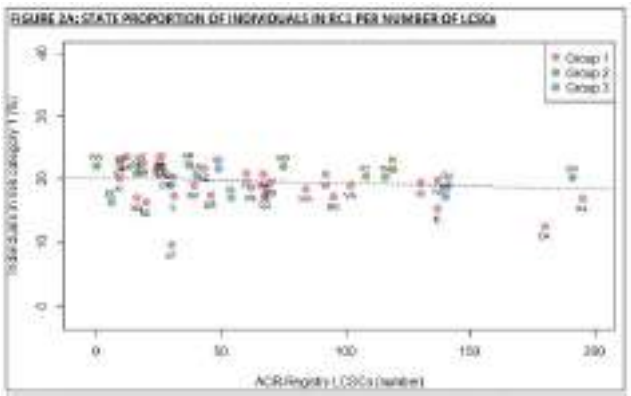
C. Wilshire[1], C. Henson[1], S. Chiu[2], C. Gilbert[1], E. Vallieres[1], J. Gorden[1]

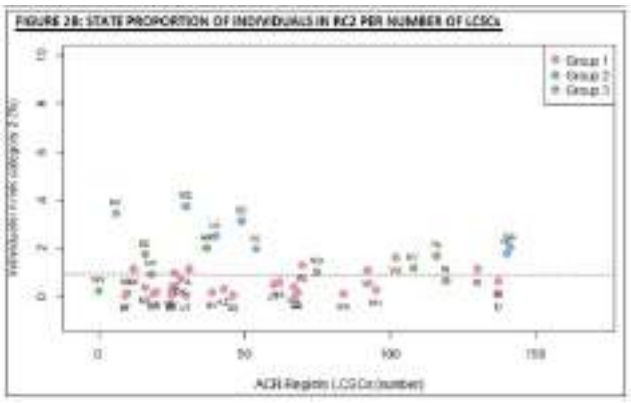
[1]*Swedish Cancer Institute, Seattle/United States of America,* [2]*Providence St. Vincent Medical Center, Portland/United States of America*

Background: Lung cancer screening center (LCSC) numbers are increasing. The location of LCSCs relative to the geographic distribution of the highest-risk lung cancer populations has not been determined. We aimed to determine the distribution of at-risk populations, and their geographic relationship to LCSCs registered with the American College of Radiology (ACR). **Method:** Population statistics datasets were obtained from the 2016 American Community Survey and Behavior Risk Factor Surveillance System. Due to differences between the two datasets, weighting and propensity matching was performed to obtain a weighted population of 477,665 individuals matched by age/race/education/income with merged smoking data. The proportion of the state population at-risk for lung cancer was calculated by two Risk Categories - RC1: 55-77 years/current-former smoker; and RC2: 55-77 years/current-former smoker/<=high school/income<$35,000/African American-American Indian. These were mapped and the 3,910 ACR-registry LCSCs superimposed. Pearson Correlation Coefficient (PCC) between at-risk populations and number of LCSCs per state was calculated. A cluster analysis based on risk characteristics categorized states into three risk groups: G1–baseline, G2 - >RC1 individuals, G3 - >RC2 individuals. Rural-Urban Continuum Codes determined metropolitan/non-metropolitan/rural status. **Result:** The national distribution of RC1 and RC2 individuals in relation to LCSCs shown in figure 1. There was no correlation between the proportion of at-risk populations and number of LCSCs [PCC for RC1=-0.23; PCC for RC2=-0.03]. Although clustering identified states with significantly different risk groups, there was no difference in the number LCSCs between the groups [median(IQR) G1=60(70), G2=75(103), G3=49(110); p=0.684] (figure 2). Of the LCSCs, 83% (3,245) were in metropolitan counties, 12% (469) in non-metropolitan and 5% (196) in rural.









Conclusion: LCSCs are not evenly distributed at the national/state/county level. There is also no significant correlation between the proportion of at-risk populations and LCSCs, even though some states have higher proportions of at-risk populations. The distribution of LCSCs may be important to LCS access.

P1.11-30 VERY RAPID GROWTH OF SMALL PULMONARY NODULES PREDICTS BENIGNITY

J. Barnett[1], I. Pulzato[1], T. Burn[1], S. Zafar[1], J. Hine[1], E. Bartlett[1], P. Shah[1], A. Nicholson[2], C. Ridge[1], S. Padley[1], P. Molyneaux[3], S. Kemp[1], A. Devaraj[1]

[1]*Royal Brompton Hospital, London/United Kingdom,* [2]*Royal Brompton and Harefield NHS Trust, London/United Kingdom,* [3]*Imperial College London, London/United Kingdom*

Background: Growth of pulmonary nodules on repeat CT is used to identify malignant lesions, although very rapid growth is thought to imply an inflammatory process. Few data exist examining the optimum threshold at which rate of growth predicts a benign aetiology. **Method:** Using an institutional CT database of small (<15mm) solid pulmonary nodules (n=784), we identified patients with antecedent (≥30 days prior) thin section (≤2mm) CT imaging and a final diagnosis of primary lung malignancy or a definite benign diagnosis based on pathology or longitudinal CT follow up data (n=137). Enlarging nodules (volume growth >25%) were identified (n=63) using semi-automated volumetry, and the volume doubling time (VDT) calculated. In cases where no nodule existed on the antecedent CT, a volume of 5mm^3 was assigned, permitting the calculation of a 'virtual' VDT. Comparison of volume doubling time between benign and malignant nodules was made using Wilcoxon signed rank test. A receiver operator curve was constructed, and the optimum threshold of nodule growth rate predictive of benignity was calculated using the methods of Miller. **Result:** The final study population consisted of 63 nodules in 57 patients [32/62 (50.8%) malignant, median age 67 years (range 34–85 years), male = 30/57 (52.6%)]. There was no difference in patient age nor in smoking status between groups, although patients with malignant diagnoses significantly more likely to be female (p < 0.001). The median time between baseline (T1) and antecedent (T0) scans was 260 days (interquartile range 343 days). At baseline (T1), benign lesions (median diameter 10mm, median volume 380 mm^3, range 10-4300mm^3) were significantly smaller than malignant nodules (median diameter 13mm, median volume 890mm^3, range 60-4250 mm^3); p = 0.001. 24/31 benign lesions and 3/32 malignant lesions were not visible on the T0 scan, and were assigned a volume of 5mm^3. The median benign lesion VDT was 70 days (interquartile range 270 days), malignant median VDT was 188 days (interquartile range 170 days); p = 0.2. The majority of lesions with very rapid growth (VDT < 90 days) were benign diagnoses (n= 17/24 [70.8%]). When examining these rapidly growing nodules, the optimal cut-point of the receiver-operator was a VDT of 50 days, AUC = 0.735. This provided 100% specificity for benign disease. **Conclusion:** Our results confirm that very rapid nodule growth predicts benignity; a VDT of <50 days was 100% specific for benignity. Further work is required to validate these findings in other cohorts.

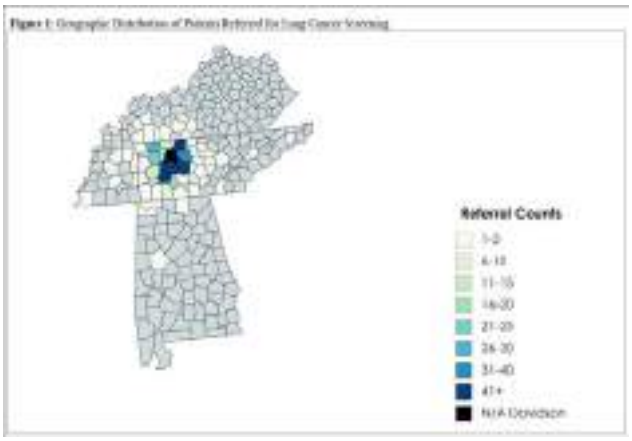
Keywords: Volume Doubling Time, Small pulmonary nodules, Rapid growth

P1.11-31 UNDERSTANDING REFERRAL PATTERNS IN A LUNG CANCER SCREENING PROGRAM

D. Haddad[1], A. Paulson[1], S. Kapoor[2], D. Conway[1], P. Massion[1], K. Sandler[1], S. Deppen[1]

[1]*Vanderbilt University Medical Center, Nashville/United States of America,* [2]*Vanderbilt University, Nashville/United States of America*

Background: Lung cancer screening (LCS) provides an important way to reduce the morbidity and mortality of lung cancer, however, the uptake of LCS has remained strikingly low, which has been attributed to both patient and provider level factors. We examined referring clinician and patient characteristics to direct interventions to promote LCS. **Method:** We examined the sociodemographic and geophysical characteristics of patients and their initial referring providers at a single institution LCS program from 1/1/2015-7/15/2018. Using data from the clinical record, we geocoded patients, generated maps, and estimated area deprivation indices, a proportional estimate of community socioeconomic status incorporating education, employment and poverty, at the census track level. We performed descriptive analysis of patient level factors such as race, insurance status, and their distribution across referring providers. **Result:** 1085 unique individuals—909 (84.0%) whites, 143 (13.2%) blacks, and 30 others (3.7%) were referred for LCS by 268 unique providers with 36 cancers detected. Approximately half (137) of providers referred one only individual and 27(10.1%) referred 52% of the patients screened. Primary care providers consisted of 76.4% of referrers, followed by pulmonologists (7.6%) and oncologists (5.3%). 211 referrers (78.7%) were affiliated with our institution. Referral of non-white patients was uniformly distributed among 170 referring providers. Referrals were geographically clustered in counties neighboring the hospital (Figure 1). Average area deprivation was 0.347 with a broad range (0.0770-0.838), with no difference between whites and blacks (0.345 vs 0.354, p=0.482), despite higher PLCO model estimated risk in blacks(7.1 vs 4.9, p<0.001).



Conclusion: A small number of physicians referred the majority of patients for LCS, however the distribution of minorities was nearly uniform across referrers. We demonstrate broad knowledge of LCS by the large number of referrers, in spite of low referral volume by most providers. These results are guiding ongoing initiatives to improve the overall uptake of LCS by targeted provider communication and community education strategies.

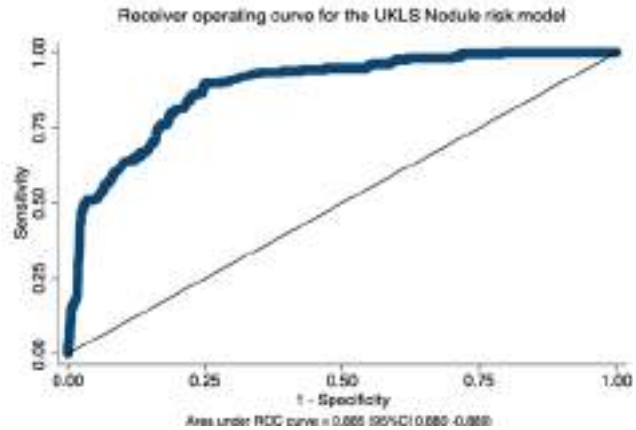
P1.11-32 THE UKLS NODULE RISK MODEL (UKLS-NRM): UTILISING NODULE VOLUMETRY

M. Marcus[1], S. Duffy[2], A. Devaraj[3], M. Oudkerk[4], D. Baldwin[5], J. Field[1]

[1]*The University of Liverpool, Liverpool/United Kingdom,* [2]*Queen Mary University of London, London/United Kingdom,* [3]*Royal Brompton and Harefield NHS Foundation Trust, London/United Kingdom,* [4]*University of Groningen, Groningen/Netherlands,* [5]*Nottingham University Hospitals, Nottingham/United Kingdom*

Background: Estimating the clinical probability of malignancy in patients with pulmonary nodules will facilitate early diagnosis, determine optimum patient management strategies and reduce overall costs. Currently there are two risk prediction models, which are recommended by BTS; the Brock University model, for nodules ≥300mm^3 or ≥8mm diameter, and where the risk is estimated at >10%, the Herder model after PET-CT. However, none of these models employ volumetry and all were developed for use at baseline **Method:** The UK Lung Cancer Screening (UKLS) trial data were analysed, utilising multivariable logistic regression models to identify independent predictors and develop a parsimonious model to estimate the probability of lung cancer in lung nodules detected at baseline, three month and twelve months repeat screening. **Result:**



1994 UKLS participants had a CT scan; 1013 had a total of 5063 lung nodules and 52 (2.6%) developed lung cancer during a 4 year median follow-up. Covariates that predict lung cancer included: female gender, asthma, bronchitis, asbestos exposure, history of previous cancer, early and late onset of family history of lung cancer, smoking duration, forced vital capacity, nodule type and volume. The final model had excellent discrimination; area under the receiver-operating characteristic curve (AUC [95% CI] = 0.885 [0.880 to 0.889]). Internal validation indicated that the model will discriminate well when applied to new data (optimism-corrected AUC = 0.882 [0.848-.907]). The risk model had a good calibration (goodness-of-fit χ 8.13, P = 0.42). **Conclusion:** The UKLS Nodule Risk Model (UKLS-NRM) estimates the probability of lung cancer in nodules detected at baseline, three months and twelve months from baseline. The model is based on readily available, strong, and plausible covariates that have been implicated in the aetiology of lung cancer. The application of UKLS-NRM has the potential to be used in both the research and clinical setting.

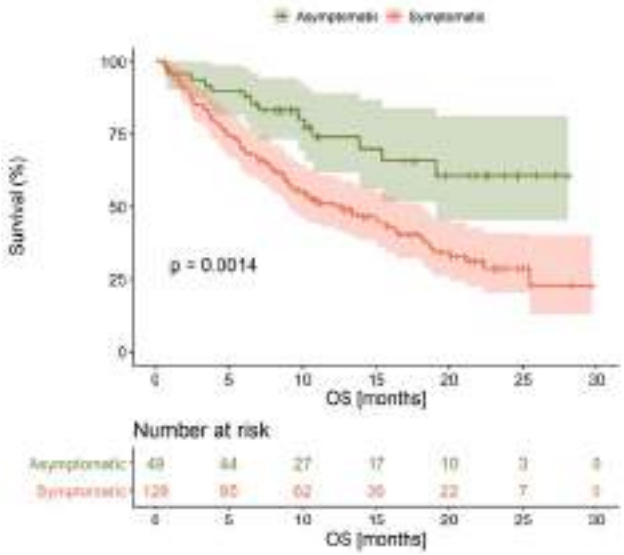
P1.11-33 PROGNOSTIC VALUE OF SYMPTOMS AT LUNG CANCER DIAGNOSIS: A TWO-YEAR OBSERVATIONAL STUDY

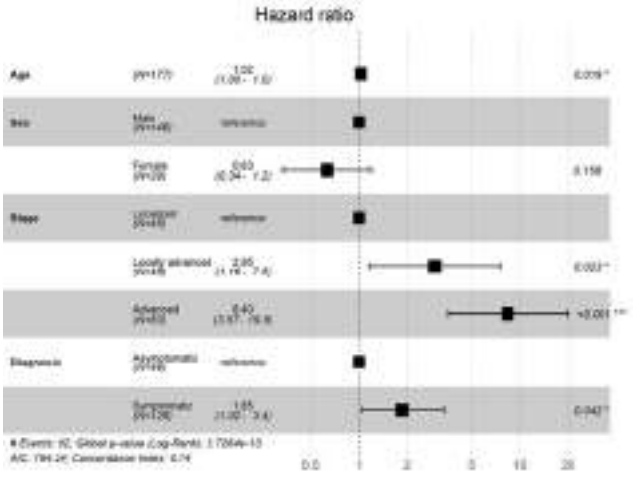
D. Polanco[1], A. Mas[1], S. Bertran[2], G. Fierro[3], A. Seminario[4], S. Gomez[1], F. Barbé[5]

[1]*Hospital Universitari Arnau de Vilanova; Biomedical Research Institute of Lleida (IRB Lleida), Lleida/Spain,* [2]*Biomedical Research Institute of Lleida (IRB Lleida); Respiratory Disease Biomedical Investigation Center (CIBERES), Lleida/Spain,* [3]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [4]*Hospital Joan XXIII, Tarragona/Spain,* [5]*Hospital Universitari Arnau de Vilanova; Biomedical Research Institute of Lleida (IRB Lleida); Respiratory Disease Biomedical Investigation Center (CIBERES), Lleida/Spain*

Background: Lung cancer is mainly diagnosed at advanced or locally advanced stages, usually when symptoms become evident. However, sometimes lung cancer may be diagnosed incidentally on chest imaging performed during routine care. Differences in prognosis based on symptomatic state at the time of diagnosis have been partially explored. Our aim was to analyze the prognostic value of the initial symptomatic state in a general lung cancer cohort. **Method:** Longitudinal prospective study including all patients consecutively diagnosed with primary lung cancer between January 2016 and December 2017. Patients were followed up until death or until the end of the study in July 2018. Collected data included clinical, functional, radiological and histological variables. Lung cancer symptom that led to initiation of the diagnostic process was defined as the symptom of presentation. When there were no symptoms at the identification of the lung cancer lesion it was considered an incidental diagnosis. **Result:** 177 patients were analyzed, 83.6% men, with a mean (SD) age at diagnosis of 67.9 (10.8) years. Incidental diagnosis was ascertained in 27.7% of cases. Asymptomatic patients were significantly older, diagnosed with localized stage disease and more frequently underwent surgical treatment. At the end of follow-up period survival was significantly superior in the asymptomatic group, with a 2-year OS of 60.8% versus 28.59% (p<0.001). The median OS of asymptomatic patients was not achieved during the first 24 months of follow-up, while in the symptomatic group, the median OS was 12.2 months (p = 0.0014) (Figure 1)



After performing an adjusted Cox proportional hazard model we obtained a HR (95% CI) of 1.85 (1.02 - 3.4) associated with symptomatic presentation, independent of stage at diagnosis (Figure 2).



Conclusion: Lung cancer patients who are asymptomatic at diagnosis exhibit a significantly better prognosis regardless of the stage of the disease. These findings encourage us to continue further investigations regarding early detection of and screening for lung cancer.

Keyword: Lung cancer; Prognosis; Incidental diagnosis

P1.11-34 THE LIVERPOOL HEALTHY LUNG PROJECT – CHAMPIONING THE IMPORTANCE OF LUNG HEALTH

M. Ledson[1], M. Ahmed[2], R. Arvanitis[3], M. Timoney[3], E. Gaynor[3], J. Field[4]

[1]*Liverpool Heart and Chest Hospital, Liverpool/United Kingdom,* [2]*Aintree University Hospital, Liverpool/United Kingdom,* [3]*Liverpool CCG, Liverpool/United Kingdom,* [4]*The University of Liverpool, Liverpool/United Kingdom*

Background: Liverpool has high levels of deprivation and one of the highest rates of respiratory morbidity in England with double the incidence of lung cancer, most prevalent in the lower socioeconomic groups. To tackle this health inequality, in February 2016 in partnership with Liverpool CCG, Liverpool University, and primary care, we embarked on the 4-year Liverpool Healthy Lung Project. **Method:** Based on primary care records, individuals aged 58-75 with COPD, a history of smoking or asbestos exposure were invited to a face-to-face lung health check conducted by an experienced respiratory nurse. At this interview positive lifestyle messages were promoted and their 5-year personal lung cancer risk calculated (www.MyLungRisk.org) using the LLPv2 risk model. Those without a diagnosis of COPD underwent spirometry, and those who triggered the 5% threshold lung cancer risk threshold were offered a low dose thoracic CT scan. We now report our results to January 2019. **Result:** 8350 of 21409 (40%) patients invited to the lung health check had attended. Of these, 5501 (59%) underwent spirometry and 10% were diagnosed with COPD. A further 2947 (35%) underwent the CT scan and of these 98 (3.3%) were suspicious of malignancy. Lung cancer was ultimately diagnosed in 55 (1.9%) and 45 of these (81%) were offered radical treatment. Of the remaining 43 patients, 10 underwent an invasive test and there was 1 benign resection. 265 patients (9%) needed repeat scans for lung nodules. **Conclusion:** These early results show that this innovative project is already improving access to respiratory healthcare in a deprived area of Liverpool, has identified new COPD patients, and over time should improve outcomes for lung cancer in this disadvantaged population.

P1.11-35 COMPARISON OF LUNG CANCER SCREENING TRIALS FROM EAST ASIA; SOUTH KOREA, JAPAN, AND TAIWAN

S.W. Shin

School of Medicine, Korea University, Seoul/Korea, Republic of

Background: Lung cancer remains the leading cause of cancer mortality in East Asian countries. Recently, the development of the National Lung Cancer Screening Program with Low Dose Computational Tomography (LDCT) initiated by the Korean Government. To understand the possible barrier and difficulties before implementing the LDCT Lung Cancer Screening for high-risk individuals in Korea, we compared the results of recently conducted Lung Cancer Screening Trial from South Korea, Japan, Taiwan, and the NLST trial in the U.S. **Method:** We analyzed the recently reported data of LDCT based Lung Cancer Screening Trials from Korea (Pilot National Lung Cancer Screening Program in Korea conducted in 2017-2018, reported in 2019), Japan (A population-based cohort study in Hitachi city, Japan, results published in 2018), Taiwan (National Lung Screening Program in Taiwan, reported in 2018). We compared the results with the NLST trial in the U.S. **Result:**

Table 1. Comparison of Lung Cancer Screening trials from three countries from East Asia, South Korea, Japan and Taiwan.

	South Korea	Japan	Taiwan	U.S. (NLST Trial)
Design of Trial	Pilot Single Arm Trial	A population-based cohort study	Prospective single arm	Randomized Clinical Trial
Sample Size	13691	18935	10397	53454
Age (male %)	63 (77)	56 (55)	61 (26.9)	61 (59)
Smoking History	>30 pack -years	Never smoker included (24% Male, 90% in Female)	Never Smoker with one of risk factors (family history, pulmonary tuberculosis or COPD)	>30 pack -years
Screening Interval/Duration	Single Screening	LDCT screening at least once between 1998 and 2006	3 annual screening	3 annual screening
Definition of Positive Results.	>4 mm	Non calcified SPN >5-7 mm	> 6 mm or > 5mm Ground Glass Nodule	>4 mm
Screening Positive Rate (%)	15.3	26.3	Not Available	27.3 (T0)
False Positive rate (%)	14.8	Not Available	Not Avaiable	26.6
Lung cancer Detection Rate (%)	0.56	1.5	2.34	1.03
Early Stage Detection Rate (%)	68.1	Not Available	96.7	67.5
Lung Cancer Mortality RR(95% CI)	Not Available	Not Available	Not Available	0.85 (0.5-0.95)

East Asian Lung Cancer Screening Trials frequently included low-risk smokers or never smokers, along with high-risk smokers. Consequently, the results were very different compared to the NLST trial, in terms of cancer detection rate and positivity rate. Specifically, the cancer detection rate of Korean Trial was low with 0.56%, similar to that of Chest X-ray group in the NLST trial. **Conclusion:** Recently, the Korean government plans to initiate National LDCT Lung Screening. However, to date, no country has established a nationwide organized LDCT lung cancer screening program. Although evidence suggests that LDCT screening trial for lung cancer North American and European results in a favorable, however, the balance of benefit and harms was tenuous. Hasted implementation of the Western trial to Korean could have many difficulties due to low cancer detection rate. The selection of screen-eligible patients, the quality of imaging and image interpretation, the management of screen-detected findings, and the effectiveness of smoking cessation interventions need to be carefully contemplated before implementation of DLDCT screening. Additional research is needed to optimize the approach to low-dose CT screening in Korea.
