Background: Pulmonary nodules are frequently detected on low-dose CT screening of the chest. Most of them are benign and lung cancer is only a part, so handling of pulmonary nodules is a major issue. Although the guidelines of the Japanese Society of CT Screening have been published, the examination of their usefulness is not sufficient. Therefore, the pulmonary nodules detected on CT were handled according to the guideline (version 2), and the clinical significance and the usefulness of the guideline were examined. **Method:** Pulmonary nodules with 5mm or larger in size on initial chest CT were followed up prospectively at five facilities in Nagasaki Prefecture. CT Images and clinical data were collected in one center, and analysis was performed on the same workstation (Aquarius Net Station ver. 1.5). In the central review, measurement at the workstation and evaluation of visual characteristics of the nodules were performed by two or more experienced radiologists, and the results were returned to the participating facilities to be reflected in the handling and follow-up of the nodules. **Result:** 131 cases were registered in total, 39 cases were excluded and the remaining 92 cases were analyzed (57 women, 35 men, average age 65.6 (39-87) years old). 39 cases were solid nodule, 17 cases were part solid ground-glass nodule (GGN) and 36 cases were pure GGN. 20 cases were surgically resected, and histological findings were obtained for 17 nodules: 14 adenocarciomas (two solid nodules, 7 part solid GGNs and 5 pure GGNs), two squamous cell carcinomas (two solid nodules), one lung metastasis (solid nodule). Fifteen cases shrank or disappeared overtime (7 solid nodules, 4 part solid GGNs and 4 pure GGNs). Twenty-four month follow-up was completed in 57 cases (27 solid nodules, 3 part solid GGNs and 27 pure GGNs). **Conclusion:** Although handling of pulmonary nodules detected on chest CT was conventionally left to the discretion of the institution /in-charge doctor, using this guideline made the policy of clearer and became possible to evaluate the natural history of pulmonary nodules correctly. There were no cases that became inoperable due to the appearance of distant metastasis during follow-up, and this guideline was considered appropriate.

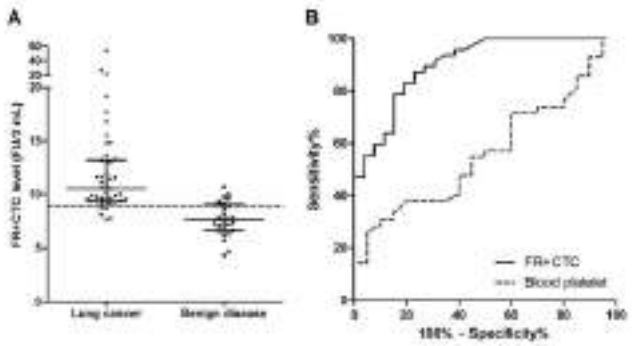
Keywords: pulmonary nodule, CT screening

P2.11-44 A PRELIMINARY STUDY INVESTIGATING THE IMPACT OF PLATELET ON CIRCULATING TUMOR CELL ENUMERATION

Y. Chen, P. Peng, Y. Chen, S. Xia

Department of Oncology, Tongji Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China

Background: Circulating tumor cell (CTC) is generally considered as the source of cancer metastasis. Blood platelet has been reported to interact with CTCs and enhance its survival. However, the "masking effect" of blood platelet may lead to the false-negative results in CTC test. In this preliminary study, we aimed to investigate the impact of platelet on CTC enumeration. **Method:** A total of 73 treatment-naïve participants with indeterminate pulmonary nodules according to computed tomography scan were recruited. Three milliliters of baseline peripheral blood samples were collected from each participant for CTC enumeration. Negative enrichment and ligand-targeted polymerase chain reaction methods were used to examine the expression level of folate receptor-positive CTC (FR+CTC). All participants subsequently undergo surgery or biopsy to obtain tumor specimens for pathological assessment. ROC analysis was used to determine the diagnostic performance of FR+CTC. For the recruited lung cancer patients, the association between FR+CTC levels and platelet count was also analyzed.



Result: 47 patients with pathologically confirmed lung cancer and 26 patients with benign lung diseases (considered as the control group) were included in this analysis. In agreement with previous studies, lung cancer patients showed a significantly higher FR+CTC level compared to the control group (10.6 versus 7.7 FU/3 mL, P<0.0001). With 9.1 FU/3 mL as the cut-off threshold, the sensitivity and specificity of FR+CTC were 87.23% and 76.92%, respectively (Area under curve=0.9006, 95% confidence interval: 0.8291-0.9720). Among the 42 patients with platelet count in the lung cancer group, 36 (85.7%) were positive for CTC and 6 (14.3%) were negative for CTC. The levels of platelet count in CTC-positive group were lower than those in CTC-negative group, but the difference was not statistically significant (217.8±73.6 versus 253.5±41.4 ×109 /L, P=0.1833). Correlation was also not statistically significant between the FR+CTC level and platelet count (Spearman R=-0.2113, P=0.0993). **Conclusion:** CTC enumeration in this study was not affected by the surface epitope masking effect of blood platelet, suggesting that FR+CTC detection has better applicability than the positive enrichment and immunocytochemical method. Further systematic study is required to validate the hypothesis.

Keywords: circulating tumor cell, Enumeration, Platelet

P2.11-45 ECONOMICAL SCREENING FOR LUNG CANCER IN A DEVELOPING COUNTRY - 5 YEARS EXPERIENCE

S. Sankarkumaru

Geeyes Diabetes and Hypertension Research Centre, Tirunelveli/India

Background: In India where the tobacco use in the form of smoking like cigarettes,Beedi and cigars is highly prevalent and to screen for lung cancer earlier is essential and should be economical considering the less healthcare funds.Hence this study. **Method:** Patients attending the General Medicine department for the past five years from 2014 to 2018 with the history of smoking of any type,of duration of more than ten years and cough for more than ten days duration were enlisted for this screening for lung cancer. Passive smokers like wives of the husbands who smoke were also considered for screening.The duration of smoking ranges from 12 years to 25 years and the mean duration was 18 years. The duration of cough ranges from 11 days to 20 days and the mean duration was 15 days.The tests are easily available and affordable.Totally 100 patients were screened.Ninety males and ten females were included in the study. The age ranges from 35 years to 60 years and the mean age was 52 years.The investigations conducted were X- ray chest PA view as a first line of screening. If shadows were found suspicious of possible malignancy in the imaging,the blood investigations ESR,Hb and LDH total were estimated for every patient listed for study. The increase in ESR more than 50 mm per hour,Hb ,less than 10 Gms and the total LDH more than 500 units per litre (normal being upto 350 units per litre) were the screening criteria.When all the three criteria of blood fulfilled or two,then CT Scan chest was ordered.Out of 100 patients screened,24 males and 2 females underwent CT Scan.CT Scan showing possible malignant lesions were subjected to CT guided biopsy of the lesion and reported about the malignancy and types. **Result:** Out of 100 patients,24 males and 2 females undergone CT Scan Chest. Biopsy has been taken in all the above patients by CT guidance.15 males and 1 female were reported as malignancy. The statistical significance cannot be applied because of the non availability of control patients.The details of the types and grading will be presented.All were referred for further management to Oncology centres. **Conclusion:** When suspecting lung cancer in a smoker or passive smoker,following the already described investigations which are economical before going for CT Scan and guided biopsy,will be economical for developing countries like India because of the less availability of funds.This study highlights the economical method of screening for Lung Cancer especially in developing countries.

Keywords: economical screening of lung cancer, x-ray chest, CT-guided biopsy

P2.12 SMALL CELL LUNG CANCER/NET
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.12-01 SMALL CELL LUNG CANCER (SCLC) TREATMENT AND SURVIVAL IN THE UK: A REAL-ONCOLOGY ANALYSIS FROM THE I-O OPTIMISE INITIATIVE

M. Snee[1], S. Cheeseman[1], M. Thompson[1,2], R. Bowman[1,2], L. Lacoin[3], W. Sopwith[1,2], C. Chaib[4], A. Juarez-Garcia[5], M. Daumont[6], J. Penrod[7], J. O'Donnell[7], G. Hall[1,8]

[1]*The Leeds Teaching Hospitals NHS Trust, Leeds/United Kingdom,* [2]*IQVIA, London/United Kingdom,* [3]*Epi-Fit, Bordeaux/France,* [4]*Bristol-Myers Squibb, Madrid/Spain,* [5]*Bristol-Myers-Squibb, Uxbridge/United Kingdom,* [6]*Bristol-Myers Squibb, Braine-l'Alleud/Belgium,* [7]*Bristol-Myers-Squibb, Princeton/United States of America,* [8]*University of Leeds, Leeds/United Kingdom*

Background: Outcomes for patients with extensive disease (ED) SCLC are poor. Treatment options have remained mostly unchanged for several decades. As part of I-O Optimise, a multinational research platform providing insights into the real-world management of lung cancers, clinical characteristics and outcomes of patients with ED-SCLC at Leeds Cancer Centre, UK, are presented. **Method:** This retrospective cohort study used longitudinal data collected from electronic medical records of adult patients diagnosed with ED-SCLC between January 2007 and August 2017 (follow-up to December 2018). ED was defined as stage IV disease at diagnosis or, where staging was missing, by clinical review using the Veterans Administration Lung Cancer Study Group (VALSG) system. Patients with a concomitant malignant primary tumour or missing data for age or sex were excluded. Distinct lines of therapy (LoTs) were identified using a clinically verified algorithm based on name and date of systemic anti-cancer therapy (SACT) prescribed. Overall survival (OS) was determined using Kaplan–Meier methods. **Result:** Of 5834 patients diagnosed with lung cancer during the study period, 695 (11.9%) had SCLC. Of 655 patients remaining after study exclusions, 425 (64.9%) had ED-SCLC. Where complete years of data were available (2007–2016), there was a decrease in the proportion of ED-SCLC diagnoses (from 76.3% to 60.0%). Among patients with ED-SCLC, median age was 69 years (range: 62–75) and 50.4% were male; 31.3% had a World Health Organization performance score (PS) of 0–1, 23.8% had PS2, 21.9% had PS3, and 7.3% had PS4. In total, 272 patients (64.0%) received SACT. Annual rates of treatment were similar between 2007 and 2016. Proportions treated were highest in patients with PS0–1 (87.2%) and lowest in those with PS4 (9.7%).

Almost all treated patients (96.7%, n=263) received platinum-based SACT as first LoT; 47 patients (17.3% of treated patients) received a second LoT. Median OS (Q1–Q3) for patients with ED-SCLC receiving SACT was 7.2 months (4.3–10.5) versus 0.7 months (0.3–1.6) for those not receiving SACT. Median OS was similar for treated patients with PS0–1 and PS2 (7.4 and 7.2 months, respectively). **Conclusion:** In line with other real-world studies, outcomes for patients presenting with ED-SCLC are poor, especially if untreated. Levels of treatment have not improved over the past decade. Availability of new immune checkpoint inhibitors may provide improved survival for some patients, but additional approaches are urgently needed.

P2.12-02 INTERTUMORAL HETEROGENEITY IN SMALL CELL LUNG CARCINOMA ACCORDING TO THE PRIMARY TUMOR VERSUS LYMPH NODE METASTASES DELINEATED BY RNA SEQUENCING

Z. Megyesfalvi[1,2], Z. Lohinai[1], B. Döme[3,4]

[1]*Semmelweis University and National Institute of Oncology, Budapest/Hungary,* [2]*National Koranyi Institute for Pulmonology, Budapest/Hungary,* [3]*National Koranyi Institute of Pulmonology, Budapest/Hungary,* [4]*Medical University Vienna, Vienna/Austria*

Background: The pathological diagnosis of small cell lung cancer (SCLC) was determined mainly based on the simple morphological pattern for decades with no significant therapeutic advancements. Exploring the gene expression profile of matched primary and lymph node (LN) metastatic SCLC tumors might provide unique insights into new potential therapeutic approaches. **Method:** A total of 32 histologically confirmed SCLC patients underwent surgical resection with available tumor tissue specimen were included in our study. We performed targeted RNA sequencing, to analyze tumor heterogeneity in terms of differences in gene expression and relevant pathways according to primary tumor and LN metastases. **Result:** We found 6% (n=154) RNA genes with significant differences and only 13.1% (n=336) of all genes in the entire panel had a strong correlation between the primary tumor and LN metastases. Transcription factors had higher percentage of correlation compared to genes in importance in extracellular and cell adhesion receptors and signaling. According to the top 25 RNA genes in our gene panel with significant difference in RNA gene expression the majority of these RNA genes were downregulated (n=20) in LN metastases, having a wide range of functions including proliferation, growth and survival. In contrast, the upregulated top RNA genes (n=5) have a major role in cell adhesion, lymphoid tissue development and inflammatory response. **Conclusion:** Our findings highlight the RNA gene discordance between primary tumors and corresponding LN metastases indicating a non-homogeneous nature of the tumor mass at different anatomical locations with potential therapeutic applications.

Keyword: small cell lung cancer, lymph node metastasis, tumor heterogeneity

P2.12-03 BUILDING AND VALIDATING A LYMPHOCYTE NADIR BASED MODEL TO PREDICT SURVIVAL IN PATIENTS WITH LIMITED STAGE-SMALL CELL LUNG CANCER

Y. Yu[1,2], L. Wang[1], P. Fu[1], S. Cao[1], W. Wang[1], M. Machtay[3], J. Yu[2], F.-M. Kong[1]

[1]*Case Western Reserve University, Cleveland/United States of America,* [2]*Shandong University Affiliated Shandong Cancer Hospital, Jinan/China,* [3]*University Hospitals Cleveland Medical Center, Cleveland/United States of America*

Background: Increasing evidence indicates host immunity participate in cancer progression and metastases. It has been reported that the lymphocyte nadir is an independent prognostic marker for survival in various cancers. We have previously reported a survival significance of baseline lymphocyte in limited stage small cell lung cancer (LS-SCLC). Here we hypothesize that treatment induced lymphopenia, like the lymphocyte nadir during the course of treatment, in combination of clinical factors can predict survival better than conventional models in patients with LS-SCLC. **Method:** This is a retrospective study of 616 patients from a single Institution. Consecutive patients with LS- SCLC treated with thoracic radiation (with or without concurrent chemotherapy) from 2013 to 2017 were included. Additional eligibility included availability of complete-blood-count data from baseline and at least two time points during the course of radiotherapy. These 616 patients were randomly divided into a training dataset (n=308) and a validation dataset (n=308). The primary endpoint was overall OS. Univariate proportional hazard (PH) cox model was used to assess potential clinicopathological predictors on OS. The multivariable Cox PH model was constructed by the forward selection. According to the final Cox model built using significant variables from training dataset, we calculated the risk score for every patient and validate the predictive valuable of the risk score on OS in the validation set. **Result:** Under univariate analysis, younger age (HR 1.02 per 1 yr, 95%CI 1.006-1.043, p=0.008), female gender (HR 1.40, 95%CI 0.95-2.07, p=0.09), earlier stage (stage I-II vs stage III, HR 2.2, 95%CI 1.11-4.33, p=0.02), concurrent chemotherapy (concurrent vs. not, HR 0.61, 95%CI 0.42-0.88, p=0.01) and a higher lymphocyte nadir (HR 0.48, 95% CI 0.20-1.14, per 103 lymphocytes/ μL, p=0.097) was significantly associated with increased OS in the training dataset. Using lymphocyte nadir in combination of significant clinical factors from univariate analysis, we developed a multivariable Cox PH model (lymphocyte nadir: HR 0.39, 95% CI 0.16-0.99, per 103 lymphocytes/ μL, p=0.048) with concordance (C)-index of 0.63. In the validation dataset, the multivariable model revealed that lymphocyte nadir had a borderline significance on OS (HR 0.45, 95% CI 0.19-1.06, per 103 lymphocytes/ μL, p=0.067) with a comparable c-index of 0.60. Moreover, the risk score calculated using the coefficients from the final Cox model built using the training dataset remained to be a significant predictor for OS (HR 2.04, 95% CI 1.36-3.07, per 1 risk score increase, p<0.0001) in validation dataset. **Conclusion:** This may be the first study validated a survival predictive model based on lymphocyte nadir in a large sample of patients with LS-SCLC. Should it should be validated in an external dataset, this model might provide some prediction for each patient and provide an opportunity to individualize treatment based on the individual's survival probability.

Keywords: LS-SCLC, lymphocyte nadir, overall survival

P2.12-04 CLEPSIDRA: A PHASE II TRIAL COMBINING IADADEMSTAT WITH PLATINUM-ETOPOSIDE IN PLATINUM-SENSITIVE RELAPSED SCLC PATIENTS

M. Ropacki[1], A. Navarro[2], T. Maes[1], S. Gutierrez[1], R. Bullock[1], C. Buesa[1]

[1]*Oryzon Genomics SA, Cornella de Llobregat/Spain,* [2]*Vall d´Hebron University Hospital and Institute of Oncology (VHIO), Barcelona/Spain*

Background: Small cell lung cancer (SCLC), an aggressive neuroendocrine malignancy, shows a dismal prognosis with the current pharmacopeia. Notch is a tumor suppressor repressed in SCLC. Iadademstat is the leading selective LSD1 inhibitor and has been shown to re-activate the NOTCH pathway in SCLC, resulting in the repression of ASCL1, a well-known non-druggable SCLC tumor driver, and to produce robust, and in some cases complete and durable, tumor regression in some chemoresistant PDX models. In a previous Phase I study in acute leukemia, iadademstat was safe and well tolerated, supporting it is a meaningful candidate for combination therapy with other agents. This is the first combo trial in SCLC with a LSD1 inhibitor and the current SoC. **Method:** CLEPSIDRA (EudraCT nº 2018-000469-35) is a Phase II study of iadademstat as a second line treatment in combination with platinum plus etoposide re-challenge chemotherapy in patients with relapsed extensive stage SCLC, that includes biopsy biomarkers expression as inclusion criteria to increase likeliness of response to iadademstat treatment. CLEPSIDRA is an open label single-arm multicenter study to assess for the first time the safety, tolerability, dose finding and efficacy of iadademstat in combination with chemotherapy in SCLC patients. It is planned to enroll up to 36 patients. The study is composed of a dose/regime finding part aimed to establish the recommended dose and regime of the combination, and a second part to assess clinical activity by RECIST criteria. **Result:** The design of the trial and the preliminary results in safety, tolerability and clinical activity as per August 2019 cut-off will be presented and discussed. Preliminary results of the first three subjects with RECIST data available as per April showed a 72% RECIST reduction (from 80 at screening to 43 on cycle 2 and 23 after 4 cycles of treatment) in one subject and stable disease at cycle 2 in the other two subjects. **Conclusion:** Combination of multiple oncological drugs requires careful selection of doses and regimes as their toxicity is often accentuated by the addition of a

new component. Neutropenia induced by the etoposide-platinum has to be managed when dosing iadademstat. Current data suggest that these toxicities may be managed in an acceptable manner. The initial clinical responses observed also suggest that the combination of iadademstat with SoC may be clinically effective in second line relapsed SCLC patients.

Keywords: SCLC, LSD1 inhibitor, epigenetic

P2.12-05 A PHASE II TRIAL OF PEMBROLIZUMAB WITH CHEMOTHERAPY IN METASTATIC OR UNRESECTABLE HIGH GRADE NEUROENDOCRINE CARCINOMA

R. Ramirez[1], M. Matrana[1], S. Satti[1], B. Voros[2]

[1]*Ochsner Clinic Foundation, New Orleans/United States of America,* [2]*Louisiana State University Health Sciences Center, New Orleans/United States of America*

Background: Combination chemotherapy is the mainstay of treatment for patients with high-grade gastroenteropancreatic neuroendocrine carcinoma (GEPNECs) and neuroendocrine carcinomas (NECs) of the lung. Pembrolizumab, a potent humanized immunoglobulin G4 (IgG4) monoclonal antibody (mAb), has high specificity for binding to the programmed cell death 1 (PD-1) receptor thus inhibiting its interaction with programmed cell death ligand 1 (PD-L1) and programmed cell death ligand 2 (PD-L2). In combination with chemotherapy, pembrolizumab blocks the protective mechanism of cancer cells and allows the immune system to destroy them. Combination chemotherapy and pembrolizumab was recently FDA approved and ongoing trials are utilizing this or similar combinations with data demonstrating a promising safety profile. The purpose of this study is to test the efficacy, safety, and tolerability of combination chemotherapy with pembrolizumab in patients with high-grade neuroendocrine carcinomas of the gastroenteropancreatic system or lung who are chemotherapy naïve. **Method:** This is an open label, phase II, single institution, multi-site trial using pembrolizumab in combination with either cisplatin or carboplatin and etoposide in patients with high grade neuroendocrine carcinomas of the gastroenteropancreatic system or lung who are chemotherapy naïve. Patients with a histologic diagnosis of a GEPNECs with a Ki-67 of 55% or higher or a large cell NEC of the lung will be eligible for inclusion in this study. Subjects must be deemed unresectable and have not undergone prior chemotherapy for metastatic disease. Patients must also have at least one measurable lesion per Response Evaluation Criteria in Solid Tumors (RECIST) 1.1, an Eastern Cooperative Oncology Group (ECOG) performance score of 0-1, and a predicted life expectancy > 3 months. Approximately 36 GEPNEC patients will be enrolled with an exploratory LCNEC of the lung cohort of approximately 6 patients. Patients will receive pembrolizumab 200mg IV in combination with cisplatin 80 mg/m2 or carboplatin AUC 6 on day 1 and etoposide 100mg/m2 on days 1-3 of a 21-day cycle. Tumor response will be assessed by computerized tomography scan every 6 weeks calculated with the first CT within 7 days of initiation of treatment. RECIST 1.1 will be used for treatment decisions until there is evidence of progressive disease (PD). Those patients who have responsive or stable disease after 4-6 cycles of platinum-based chemotherapy will move to maintenance pembrolizumab every 3 weeks. The primary endpoint will be progression free survival (PFS) per RECIST 1.1. ClinicalTrials.gov Identifier: NCT03901378 **Result:** Section not applicable **Conclusion:** Section not applicable

Keywords: Pembrolizumab, Anti–PD-1 Immunotherapy, High Grade Neuroendocrine Carcinoma

P2.12-06 FACTORS OF IMPORTANCE FOR SURVIVAL AFTER PLATINUM RE-CHALLENGE IN PLATINUM-SENSITIVE SMALL-CELL LUNG CANCER PATIENTS

S. Tendler, Y. Zhan, A. Pettersson, R. Lewensohn, K. Viktorsson, F. Fang, L. De Petris

Karolinska Institutet, Stockholm/Sweden

Background: Small-cell lung cancer (SCLC) patients showing sensitivity to platinum-based chemotherapy (PDCT) are usually offered the same combination at the time of tumor progression, if this occurs >3 months after the completion of the first-line treatment. However, no decision tools are available to predict what patients might benefit most from this approach. The aim of the present study was to investigate if certain clinical factors could be of prognostic relevance for re-challenge of PDCT in previously platinum-sensitive patients **Method:** This retrospective study was based on patients diagnosed with SCLC in Sweden between January 2008 and February 2016. The study included patients who had received ≥ 1 cycle of PDCT in the 1st and 2nd line setting, respectively, and had "sensitive relapse", which was defined as PFS ≥180 days after the start of first-line PDCT. The following baseline characteristics were collected; Age, Gender, Stage of the disease, presence of Brain metastasis, treatment with Consolidating thoracic radiotherapy or Prophylactic brain irradiation (PCI) after completion of 1st line PDCT and "Sensitivity days", which was defined as the interval between the initiation of 1st and 2nd line PDCT, respectively. In addition, Performance status (PS) and Laboratory values (Hb, Na, C-reactive protein, Albumin, LDH) before starting 2nd line PDCT were compiled. The uni- and multi-variate analyses were performed using the cox proportional hazards regression model to assess the relationship between clinical characteristics and prognosis. Overall survival was defined as the interval between the initiation of 2nd line until death due to any cause. **Result:** The patient cohort consisted of 101 subjects. The distribution of baseline characteristics was as follows: male/female 46/55, median age (IQR) 68y (61-72), Stage II/III/IV 3/41/57, Brain metastases present/absent 39/62, Thoracic radiotherapy Y/N 30/71, PCI Y/N 52/49, median Sensitivity days (IQR) 399 days (307-511), PS 0/1/2/3 23/38/36/4. The statistically significant independent prognostic factors for overall survival on the multivariate model were PS, LDH values (HR, 95% CI for unit increase 2.10, 1.13-3.91), PCI (HR, 95% CI for presence vs absence 0.27, 0.13-0.56) and "Sensitivity days" (HR, 95% CI for unit increase 0.15, 0.07-0.32). **Conclusion:** The results of this retrospective data analysis suggest that besides PS, other clinical factors that showed robust prognostic relevance for re-challenge with PDCT in platinum-sensitive SCLC are baseline LDH values, the time elapsed between the start of 1st-line PDCT until the start of 2nd-line PDCT, which we have defined as "Sensitivity days", and the administration of PCI after completion of 1st-line chemotherapy. These elements might potentially be taken into consideration for patient selection in this setting.

Keywords: clinical prognostic factors, platinum-sensitive, platinum re-challenge

P2.12-07 PHASE I STUDY OF AMRUBICIN AND CISPLATIN WITH CONCURRENT THORACIC RADIOTHERAPY (TRT) IN LIMITED-DISEASE SMALL CELL LUNG CANCER (LD-SCLC)

M. Fukuda[1], M. Shimada[1], H. Yamaguchi[1], T. Kitazaki[2], D. Ogawara[3], K. Nakatomi[4], Y. Nakamura[5], T. Yamazaki[1], N. Hayashi[2], H. Mukae[1]

[1]*Nagasaki University Hospital, Nagasaki/Japan,* [2]*Japanese Red Cross Nagasaki Genbaku Hospital, Nagasaki/Japan,* [3]*Sasebo City General Hospital, Sasebo/Japan,* [4]*Ureshino Medical Center, Ureshino/Japan,* [5]*Tochigi Cancer Center, Utsunomiya/Japan*

Background: Amrubicin and cisplatin is one of active regimens for patients with extensive-disease small cell lung cancer (ED-SCLC). Combined modality of combination chemotherapy and concurrent thoracic radiotherapy has been recognized as standard treatment for LD-SCLC. This study aimed to determine the maximum tolerated dose (MTD), and dose limiting toxicity (DLT) of amrubicin and cisplatin with concurrent TRT in LD-SCLC. **Method:** Patients fulfilling the following eligibility criteria were enrolled: chemotherapy-naïve, PS0-1, age =<75, LD-SCLC, and adequate organ function. Patients received escalating doses of amrubicin on days 1, 2, and 3, under a fixed 60 mg/m2 of cisplatin on day 1. Four cycles of chemotherapy were repeated every 4 weeks. TRT of once-daily 2Gy/day commenced on day 2 of the first cycle of chemotherapy. The initial doses of amrubicin was 20 mg/m2 (level 1), and the dose was escalated to 25 (level 2) and 30 (level 3) mg/m2. **Result:** Eight patients were enrolled at three dose levels. male/female=3/5; PS 0/1=4/4; median age (range) =68.5 (60-73). Two of two in level 3 experienced DLTs. The presentation of DLTs was grade4 neutropenia and leukopenia lasting more than four days. The MTD determined level 3, and level 2 was recommended for this combined modality. Evaluation of responses were 7 partial response and 1 progressive disease (response rate 87.5%) and the median overall survival time was 24.7 months, and suggested the regimen seemed to be modest activity. **Conclusion:** In combined modality of this chemotherapy with TRT for LD-SCLC, MTD was amrubicin 30 mg/m2 and cisplatin 60 mg/m2, and DLTs were neutropenia and leukemia.

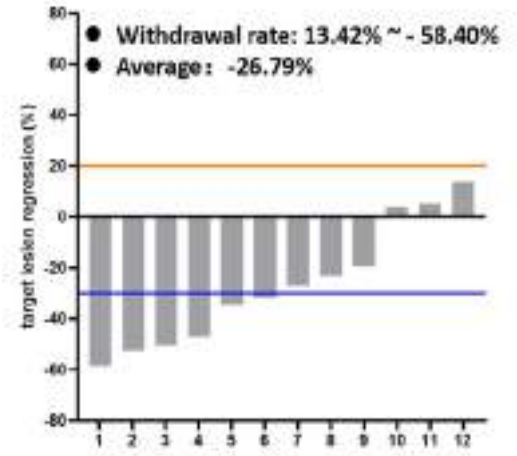
Keywords: amrubicin, cisplatin, radiotherapy

P2.12-08 SURPRISINGLY PROMISING TUMOR CONTROL RATE OF S1 COMBINATION WITH ANLOTINIB WITH REFRACTORY RELAPSED SCLC WHO FAILED ≥ 2 LINES CHEMOTHERAPY

H. Yang[1], W. Wang[1], D. Lv[2], Y. Meng[1], S. Zhou[1], X. Wu[2], F.-M. Kong[1]

[1]*Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China,* [2]*Affiliated Taizhou Hospital at Enze of Wenzhou Medical University, Taizhou/China*

Background: Patients with refractory relapsed small cell lung cancer (SCLC) who failed more than 2 lines chemotherapy have limited options. Objective Response Rate (ORR) of Immunotherapy (CheckMate-032 and Keynote-158) was only 20%. Anlotinib is a novel TKI on multi-kinase (VEGFR, c-Kit, PDGFR, FGFR) angionesis inhibitor, had ORR of only 4.9% in ALTER1202 for the third-line and further-line treatment of SCLC. S-1, a combination of three pharmacological compounds, namely tegafur (prodrug of 5-fluorouracil), gimeracil, and oteracil potassium, is a new oral fluoropyrimidine derivative designed to enhance anticancer activity and reduce gastrointestinal toxicity, has been used for treatment of SCLC with ORR of 4% (MOLECULAR AND CLINICAL ONCOLOGY 1: 263-266, 2013). In patients without any option of systemic therapy, our clinic started combined use of these drugs. This study aimed to report the preliminary results of combined S1 and anlotinib therapy in these refractory released SCLC. **Method:** This study retrospectively analyzed refractory relapsed in SCLC who failed to more than 2 lines' chemotherapy. Eligible patient must have received Anlotinib (12 mg PO QD from day 1 to 14, every 3 weeks) and S1(60mg PO Bid from day 1 to 14, every 3 weeks) combined therapy. The primary endpoints were ORR and disease control rate (DCR). The secondary endpoints were PFS, OS, and safety and tolerability. **Result:** A total of 12 patients were recruited from Nov 2018 in this study. There were 2 females and 10 males. The median age was 64 years (37-75 years). 6 patients had failed 2 lines of refractory diseases and 6 cases failed 3 lines's chemotherapy. Until 31 March 31, 2019, 2, 3, 3, 2, and 2 cases had accomplished 6, 5, 4, 3, and 2 cycles, respectively. The ORR and DCR were 50% and 100%, respectively (Figure 1). The median PFS and OS were not reached at the time of data analysis. The most common Treatment-related adverse events (TRAEs) were hypertension, anorexia, fatigue, blurred vision, and hand-foot syndrome. Grade ≥3 TRAEs occurred in 5 (41.7%) of patients. Anlotinib was reduced to 8mg in 2 patients and 10mg in 3 patients due to grade 3 TRAEs.



Conclusion: The study demonstrates that S1 combination with anlotinib seemed to be an effective treatment option for patients with surprisingly promising response rate in refractory relapsed SCLC. Prospective clinical trial (SALTER Trial, ClinicalTrials.gov ID: NCT03823118) is ongoing to confirm the promising results.

Keywords: S1, Anlotinib, Objective Response Rate (ORR)

P2.12-09 PHASE 2 STUDY OF TALAZOPARIB PLUS LOW-DOSE TEMOZOLOMIDE IN PATIENTS WITH RELAPSED/ REFRACTORY EXTENSIVE-STAGE SMALL CELL LUNG CANCER

A. Cummings[1], J. Goldman[1], M. Mendenhall[1], D. Kanamori[2], A. Nguyen[3], D. Kim[1], Z. Wainberg[1]

[1]*David Geffen School of Medicine, University of California, Los Angeles, Los Angeles/United States of America,* [2]*Comprehensive Blood & Cancer Center, Bakersfield/United States of America,* [3]*Comprehensive Cancer Centers of Nevada, Las Vegas/United States of America*

Background: Talazoparib exhibits cytotoxic effects by inhibiting poly (ADP-ribose) polymerase (PARP) proteins 1 and 2 in addition to "trapping" PARP on DNA. Temozolomide (TMZ) has been shown to increase antitumor response when combined with a PARP inhibitor in small cell lung cancer (SCLC) models (Wainberg AACR 2016). Combining PARP inhibition with TMZ as second-line therapy for ES-SCLC may improve disease-related outcomes. **Method:** This is a phase 2, open-label, single-arm study of the safety and efficacy of talazoparib plus TMZ in patients with extensive-stage SCLC. The primary endpoint is objective response rate (ORR) based on RECIST 1.1 criteria. Secondary endpoints include progression-free survival, overall survival, duration of response, and time to response. Exploratory endpoints include biomarker studies such as DNA damage response gene analysis and patient reported outcomes (PRO). Participants are required to have relapsed (progressed within 6 months) or refractory (progressed during or within 4 weeks of completing 1stline platinum-based regimen) ES-SCLC. Those with a best response of progressive disease to first-line therapy per RECIST 1.1 or more than one line of cytotoxic therapy are excluded. Prior immunotherapy is allowed. Participants receive talazoparib 0.75 mg po daily on 28-day cycles with TMZ 37.5 mg/m2 po on days 1-5. 15 participants will be enrolled in the first part of a Simon two-stage design; if 3 or more responses are seen, an additional 13 participants will be enrolled. The null hypothesis will be rejected if 8 or more objective responses are observed compared to a historical control of 15% ORR in second-line topotecan (Horita Sci Rep 2015). **Result:** As of 8 March 2019, 3 participants were evaluable for treatment response. Median age was 51 (range 46-80). One participant had a confirmed partial response (PR) with 50% reduction in target lesions, one had stable disease with 16% reduction in target lesions, and one had progressive disease (PD). Biomarker and PRO analysis correlated with the radiographic response. In the participant with PR, Guardant circulating tumor DNA testing showed PIK3CA amplification and TP53 mutations at baseline that were not detectable at week 5 of treatment, whereas the other subjects has persistent ctDNA. Patient-reported outcomes similarly noted improvement in the participant with PR within 2 weeks while the one with PD showed no improvement throughout treatment course. Adverse events were hematologic, including one grade 4 thrombocytopenia that resolved within 2 weeks. **Conclusion:** Combination talazoparib and TMZ used as second-line therapy in ES-SCLC is tolerable and has shown promising preliminary results. The trial will continue to enroll. Updated response and biomarker data will be presented.

P2.12-10 THE CIRCULAR RNA CESRP1 SENSITIZES SMALL CELL LUNG CANCER TO CHEMOTHERAPY

L. Guo, W. Huang

Zhujiang Hospital, Southern Medical University, guangzhou/China

Background: Circular RNAs (circRNAs), a novel class of non-coding RNAs, have been drawn lots of attention in the pathogenesis of human cancers. However, the biological roles and clinical significance of Circular RNA (circRNAs) in chemosensitivity are not fully understood. In this study, we aim to investigate the biological function, mechanism and clinical significance of hsa-circ-0084927, which we termed ESRP1 gene derived circRNA (cESRP1), in small cell lung cancer (SCLC). **Method:** Differentially expressed circRNAs between chemoresistant cell line and chemosensitive cell line were identified by circRNA microarray and confirmed by qRT-PCR. The functional roles of cESRP1 were demonstrated by a series of in-vitro and in-vivo experiments. The miRNA RNA pull-down, RNA immunoprecipitation, serial deletion analysis and luciferase analyses were used to investigate the potential mechanisms of cESRP1.

Result: The results showed that cESRP1 expression was significantly downregulated in chemoresistant cell lines in comparison with parental chemosensitive cell lines. cESRP1 controlled multiple drugs sensitivity through miR-93-5p in SCLC. In exploring the underlying interaction between cESRP1 and miR-93-5p, we identified that cytoplasmic cESRP1 directly binds to miR-93-5p and inhibits the transcriptional repression of miR-93-5p, thereby up-regulating miR-93-5p downstream target-Smad7/p21 expression and forming a negative feedback loop to regulates TGF-β signaling pathway-induced epithelial-mesenchymal transition. Furthermore, interfering cESRP1 expression or inhibiting TGF-β signaling pathway by inhibitors altered tumor chemotherapy response in mice xenografts including PDX model. In addition, we found cESRP1 was low expressed in SCLC tissues and associated with the patient's survival prognosis. **Conclusion:** Together, our findings reveal the indispensable role of cESRP1 in negative regulation of Smad7/P21-dependent TGF signaling pathway involvement in EMT-induced chemotherapy resistance, providing insights toward a better understanding of the mechanism of resistance to chemotherapy drugs and peripheral recurrence of SCLC.

Background: Anlotinib significantly improved progress-free survival of advanced small cell lung cancer (SCLC) patients in ALTER1202 trial. In this post-hoc analysis, we assessed the effect of anlotinib on health-related quality of life in ALTER1202 trial. **Method:** In the randomised, phase 2, multicentre ALTER1202 trial, patients with advanced SCLC that received at least two previous lines of chemotherapy were enrolled from 11 centers in China. Eligible patients were randomly assign (2:1) to receive anlotinib or placebo. Health-related quality of life was assessed by EQ-5D scores. Patients filled out questionnaires at screening period and the end of each treatment cycle. **Result:** Between March 30, 2017 and June 8, 2018, a total of 120 patients were enrolled. There were 119 patients with completed questionnaires at screening period, and 106 patients completed questionnaires at the end of the first treatment cycle (76 in anlotinib group, 30 in placebo group). EQ-5D scores had no significant difference between baseline and the end of the first treatment cycle in patients with anlotinib (0.85 versus 0.85, P=0.706). The median EQ-5D VASscores were 80.0 versus 85.0 in anlotinib and placebo group respectively (P=0.323) at screening period, and 90.0 versus 82.5 at the end of the first treatment cycle (P=0.273). The change of EQ-5D VAS scores from baseline to the end of the first treatment cycle was statistically significant (P=0.001) in patients with anlotinib compared to patients with placebo. **Conclusion:** This post-hoc analysis showed that anlotinib maintained health-related quality of life in advanced SCLC patients.

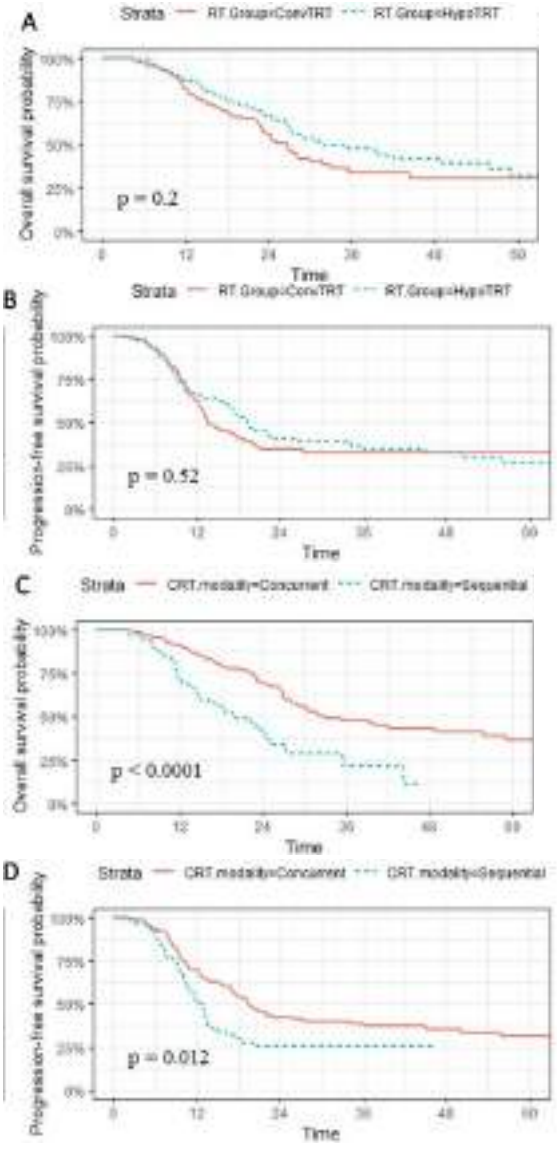
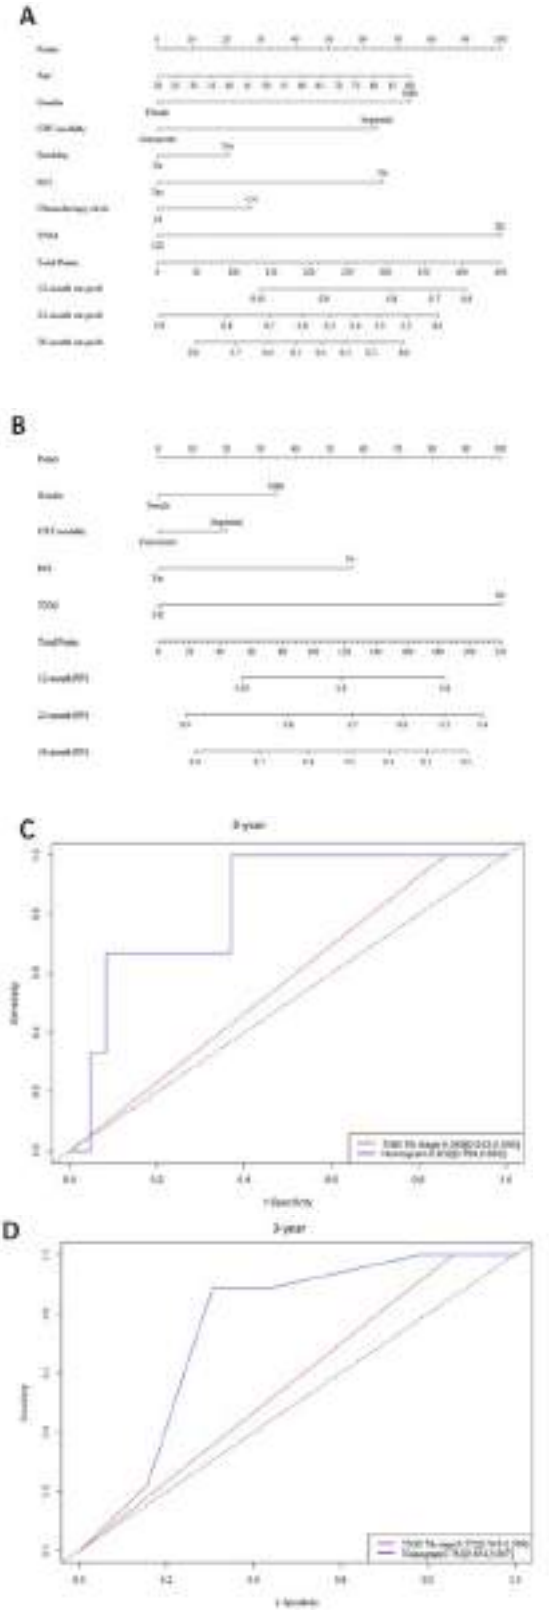
P2.12-12 NOMOGRAMS TO PREDICT SURVIVAL IN PATIENTS WITH LIMITED STAGE SMALL CELL LUNG CANCER TREATED WITH DEFINITIVE CHEMORADIOTHERAPY

J. Wen[1], J. Zhang[2], J. Chen[1], D. Liu[1], X. Xu[1], M. Fan[1]

[1]*Fudan University Shanghai Cancer Center, Shanghai/China,* [2]*Fudan University Shanghai Cancer Center Minhang Branch Hospital, Shanghai/China*

Background: To build nomograms to predict progression-free survival (PFS) as well as overall survival (OS) in patients with limited stage small cell lung cancer (LS-SCLC) treated with definitive chemoradiation. **Method:** A total of 170 patients treated with chemotherapy and hypo- (HypoTRT) (n = 69) or conventionally (ConvTRT) (n = 101) fractionated radiotherapy between 2010 and 2013 were included. Primary endpoints were progression-free survival (PFS) and overall survival (OS). The prognostic effects of variables were analyzed using Kaplan–Meier method and Cox regression model. Nomograms were established for estimating 1-, 2- and 3-year OS and PFS based on Cox regression model. The utility of the proposed model was evaluated using the time-dependent ROC and area under ROC (AUC). **Result:** The survival analysis showed no difference between HypoTRT and ConvTRT combined with chemotherapy. However, regard with the chemoradiotherapy (CRT) modality, the median PFS and OS were 19.4 and 33.0 months in the concurrent group, which was significantly better than those in the sequential group (PFS 12.2 months, p=0.012, OS 20.1 months, p<0.001). According to the multivariate analysis, the final nomograms for OS and PFS were developed. Two nomograms shared common variables including gender, CRT modality, prophylactic cranial irradiation (PCI) and TNM stage, while age at diagnosis, smoking status and chemotherapy circle were only incorporated in the OS nomogram. Nomograms showed better performance than TNM algorithm (3-year AUC for OS: TNM, 0.569; nomogram, 0.832; 3-year AUC for PFS: TNM, 0.572; nomogram, 0.761).





Nomograms for OS (A) and PFS (B) in LS-SCLC patients. ROC curve of the in prediction of prognosis at 3 year point for OS (C) and PFS (D).

Conclusion: Our nomograms are reliable and powerful tools for distinguishing and predicting the survival of LS-SCLC treated with definitive chemoradiation, thus helping to better select medical examinations and optimize treatment options in collaboration with medical oncologists.

Background: L is a new agent that exerts antitumor activity through inhibition of trans-activated transcription and modulation of tumor microenvironment. Preclinical evidence of synergism was observed for L in combination with P and I. **Method:** Activity of combinations with LP and LI in small cell lung cancer (SCLC) was reviewed in two phase Ib trials. Patients were enrolled following a 3+3 dose escalation design. SCLC patients with ECOG performance status (PS) 0-1 and pretreated with at least one platinum-based chemotherapy are presented. Extensive pharmacokinetic (PK) sampling for L and P or I was performed. **Result:** 19 pts were treated: 7 with LP and 12 with LI. Baseline characteristics (LP/LI) were: males, 57%/45%; median age, 55/57 years; ECOG PS score 1, 57%/92%; chemotherapy-free interval (CTFI) >90 days, 43%/67%; median (range) prior lines, 1 (1-3)/2 (1-3); liver metastases, 29%/33%.

	Lurbinectedin-Paclitaxel (L: 2.2 mg/m^2 – 5 mg FD + P: 60-80 mg/m^2) * (n=7)	**Lurbinectedin-Irinotecan (L: 1-2.4 mg/m^2 + I: 75 mg/m^2) ** (n=12)**
ORR (CR+PR) CR PR	71% (n=5) 14% (n=1) 57% (n=4)	25% (n=3) 0% 25% (n=3)
ORR in CTFI >90d	67%	38%
CB (CR+PR+SD≥4m)	71%	67%
Median DOR	2.3 m 95% CI (2.0-NR)	4.6 m 95% CI (3.0-6.8)
Median PFS	4.8 m 95% CI (1.8-12.5)	5.6 m 95% CI (1.4-8.3)

* Combination with P given for up to 6 cycles, followed by single-agent L 2.2 mg/m^2. ** One patient received L 3 mg/m^2 + I 15 mg/m^2. CB, clinical benefit; CR, complete response; CTFI, chemotherapy-free interval; d, days; DOR, duration of response; FD, flat dose; I, irinotecan; L, lurbinectedin; m, months; NR, not reached; ORR, overall response rate; P, paclitaxel; PFS, progression-free survival; PR, partial response; SD, stable disease.

Adverse events (AEs): grade (G) 4 neutropenia LP/LI 43%/27% of patients; no episodes of febrile neutropenia in LI, one (G3) in LP; no G4 anemia or G4 thrombocytopenia in either study. Non-hematological toxicity was mild and mainly consisted of G3 fatigue (18%) and G3 nausea (7%) in LI; no G3/4 toxicities were found in LP. No toxic deaths and no discontinuations were due to AEs. PK: mean clearance of L (12 L/h in combo with P, and 9.5 L/h in combo with I), of P (31.5 L/h) and of I (32.2 L/h) are comparable with reported data (11.2 L/h, 31.4/h and 25 L/h, respectively). **Conclusion:** LP and LI combinations showed promising activity after first-line therapy in SCLC. This activity seems consistent with that observed in other trials with L given alone or in combination. Both combinations showed acceptable safety profile. So far, no evidence of major PK drug-drug interactions has been observed. Further development of these combinations is warranted.

P2.12-14 A PILOT STUDY OF SERIAL PLASMA METABOLOMICS IN SMALL CELL LUNG CANCER PATIENTS

S.-H. Lee[1], K. Pathak[2], M. Mcgilvrey[2], K. Mansfield[2], D. Cridebring[3], D. Roe[4], T. Whitsett[5], P. Pirrotte[2], J.-M. Sun[1], J.S. Ahn[1], M.-J. Ahn[1], K. Park[1]

[1]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of,* [2]*Collaborative Center for Translational Mass Spectrometry, The Translational Genomics Research Institute, Phoenix, AZ/United States of America,* [3]*Molecular Medicine Division, The Translational Genomics Research Institute, Phoenix/United States of America,* [4]*Mel and Enid Zuckerman College of Public Health, The University of Arizona Cancer Center, University of Arizona, Tucson, AZ/United States of America,* [5]*The Translational Genomics Research Institute, Phoenix, AZ, Phoenix/United States of America*

Background: Small cell lung cancer (SCLC) is among the deadliest cancers. SCLC is characterized by high proliferation and high turnover metabolism. There are few results of metabolomics analysis correlated with outcomes of SCLC patients. **Method:** This study included 27 patients after excluding eight who were treated with immunotherapy or placebo. Median age of the patients was 65 years (range, 43 to 82), and 23 male patients were included. Three (11%) never-smoker patients were included. Twelve patients were limited disease (LD) and 15 were extensive disease (ED) including three patients with brain metastases. All patients were treated with etoposide and platinum (EP, 20 cisplatin and 7 carboplatin), and nine among 12 patients with LD were treated concurrently with radiotherapy since 3rd cycle of EP chemotherapy. We planned to collect blood samples at diagnosis (T1), after two cycles of chemotherapy (T2) and at the first progression (T3). We analyzed 27 T1 samples, 14 T2 samples, and 18 T3 samples. Metabolomics analysis included 183 metabolites (21 amino acids, 19 biogenic amines, 40 acylcarnitines, 14 lysoglycerophosphocholines, 74 glycerophospholipids, and 14 sphingolipids, 1 hexose) using Absolute*IDQ*® p180 kit (Biocrates Life Sciences AG, Innsbruck, Austria). **Result:** Baseline levels of five acylcarnitines and one glycerophospholipid were associated with progression free survival whereas, the amino acid proline and acylcarnitine (C10:1) were associated to overall survival. In comparison to LD, amino acid, asparagine was elevated while two acylcarnitines (C10:2 and C12:1) were lower in patients with ED. After two cycles of chemotherapy without progression, plasma concentration of 37 lipids (5 LysoPC, 24 glycerophospholipids, 3 sphingolipids and 5 acylcarnitines) were increased. Five mono and poly unsaturated glycerophosphospholipids (PC aa and PC ae) with C42 and C44 fatty acid chains were significantly (adj $p < 0.05$) lower. Of these, chemotherapy and induction of remission induced change in glycerophospholipid PC ae C42:5 was related to overall survival ($p < 0.05$). The 7 glycerophospholipids with C42 and C44 fatty acids were elevated when patients relapsed post chemotherapy. Five glycerophospholipid metabolites were significantly lower in response to chemotherapeutic exposure. The metabolites tended to increase towards baseline levels upon relapse. **Conclusion:** With this preliminary exploratory study, we identified association of metabolites and initial status and outcomes of SCLC. We observed significant modulation in glycerophospholipids upon chemotherapy and relapse which may serve as indicators of therapeutic response and resistance. Further exploration and validation is being underway in larger SCLC population.

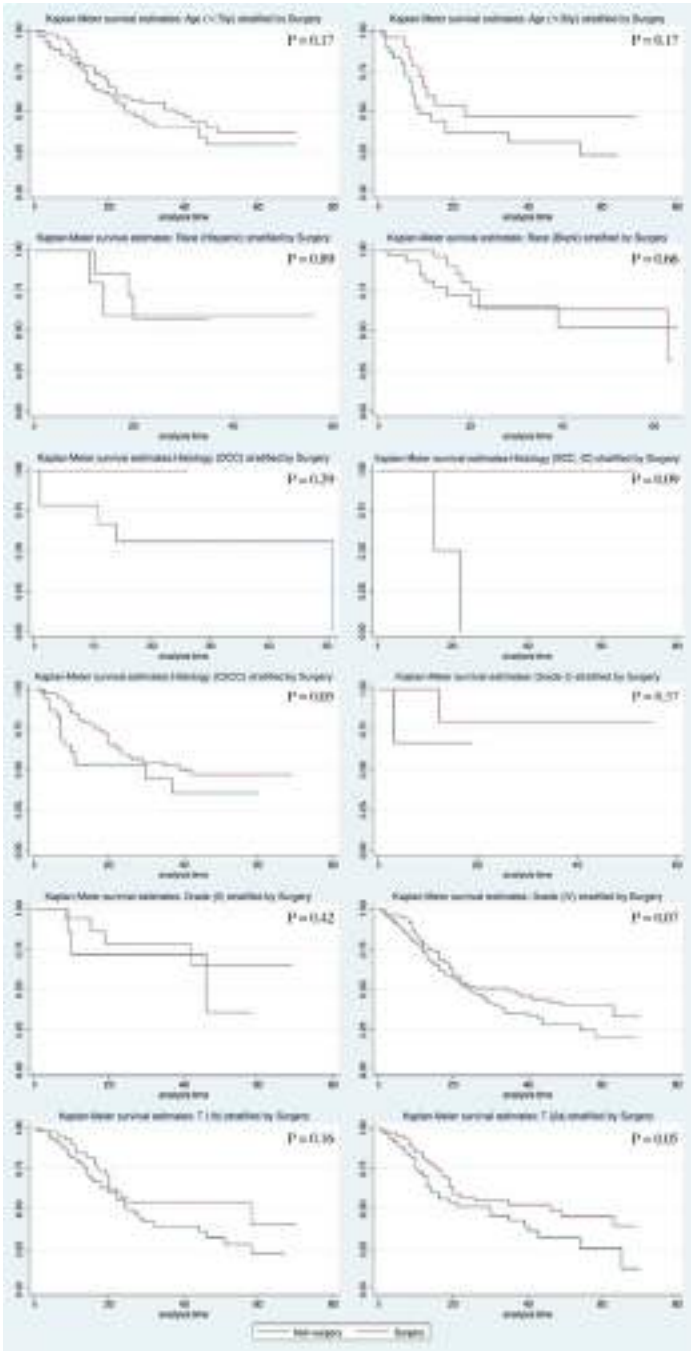
Keywords: small cell lung cancer, glycerophospholipids

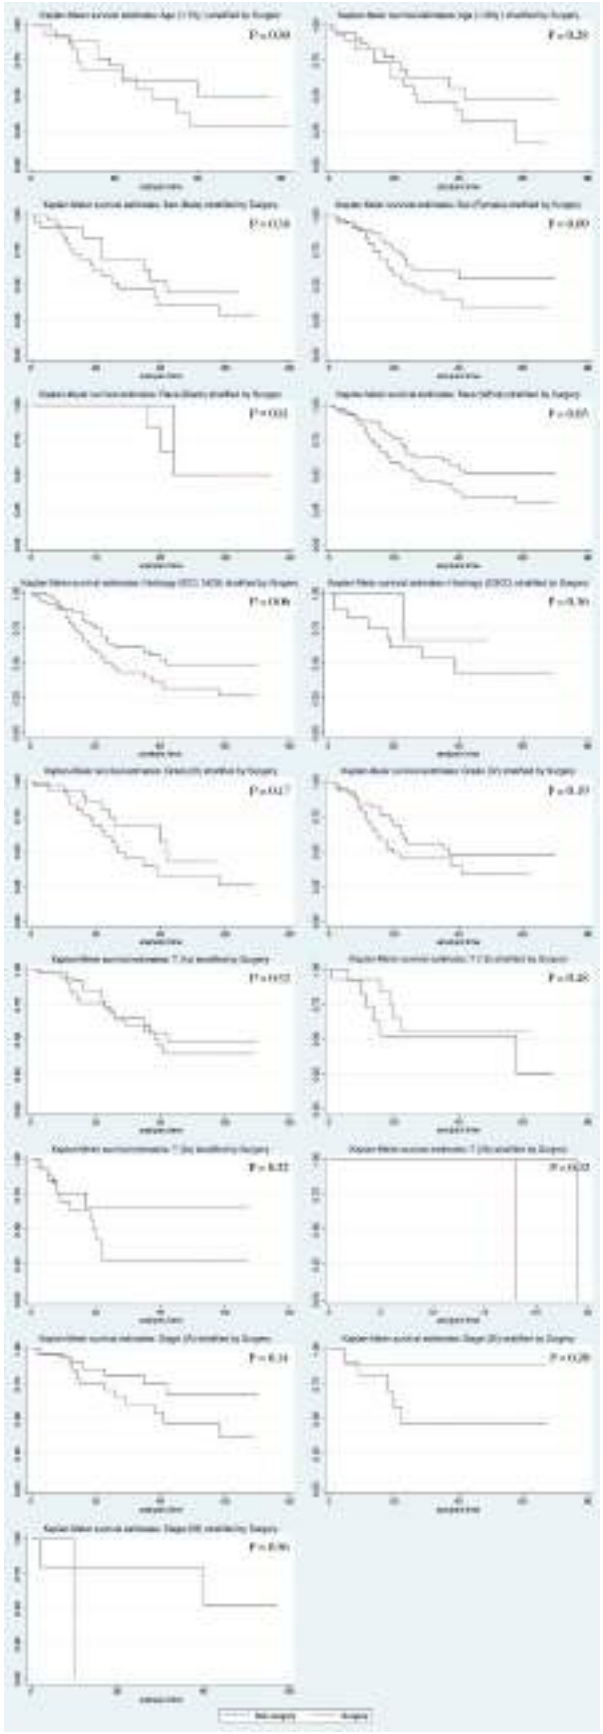
P2.12-15 THE ROLE OF SURGERY IN PATIENTS WITH SMALL CELL LUNG CANCER: A PERIOD PROPENSITY SCORE MATCHING ANALYSIS OF THE SEER DATABASE, 2010-2015

X. Du[1], D. Tian[2], L. Liu[1], J. Xiao[1], H. Zhou[2], W. Liu[1], S. Yuan[3], J. Zhang[1]

[1]*The Affiliated Hospital of Guizhou Medical University, Guiyang/China,* [2]*Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangzhou/China,* [3]*Guiyang Public Health Clinical Center, Guiyang/China*

Background: Surgery for non-small cell lung cancer has been widely accepted for years. However, the role of surgery for small cell lung cancer (SCLC) remains controversial. We therefore performed this period propensity score matching analysis using the SEER database the Surveillance, Epidemiology, and End Results (SEER) Registry database to explore the role of surgery on survival in patients with SCLC. **Method:** Patients with SCLC from 2010 to 2015 were identified from the SEER. Individual data for each case were retrieved regarding general clinical characteristics, surgery of primary site, cause-specific death classification and survival time. Differences of cause-specific survival (CSS) between subgroups were estimated by log-rank test. Cox regression analysis was used to evaluate the effects of multiple variables on CSS. Difference of cause-specific death incidence was examined using chi-square (Chi2) test. **Result:** 1707 records met the criteria and were retrieved for analysis. There were significant differences of CSS in Clinical pathological features of N (P=0.01), Stage (P=0.00), and Surgery (P=0.00) when compared non-surgery with surgery, and in N (P=0.000), Stage (P=0.006), Surgery (P=0.049) compared sublobectomy with lobectomy or bilobectomy (bi-/lobectomy). More patients who did not receive surgery (P=0.00) or received sublobectomy (P=0.03) were at risk of death compared with receiving surgery and bi-/lobectomy respectively (Fig 1 and 2).





Conclusion: To conclude, surgery should be taken into account when initial treatment strategy is made in SCLC patients with clinical stage I-IIA (T1-2,N0,M0) even age older than 50 years, in spite of sex, histology and grad. It seems that some SCLC patients with stage IIB (N1) can also benefit from bi-/lobectomy, although further investigation is needed. Simultaneously, bi-/lobectomy is preferred than sublobectomy when a surgery is performed. However, the role of pneumonectomy for SCLC is unclear in this study.

Keywords: small cell lung cancer, surgery, Survival

P2.12-16 CHANGES OF PERIPHERAL BLOOD SPD-L1 IN PATIENTS WITH SMALL CELL LUNG CANCER DURING CHEMOTHERAPY AND ITS CLINICAL SIGNIFICANCE

H. Tian[1], X. Kang[2], L. Yang[1], H. Zhu[2], W. Guo[2], X. Song[2]

[1]*Shanxi Medical University, Taiyuan, Shanxi/China,* [2]*Shanxi Tumor Hospital, Taiyuan, Shanxi/China*

Background: As a new immunotherapeutic target, the inhibitors of programmed death 1 (PD-1) and programmed death ligand-1 (PD-L1) pathway have been used to treat a variety of tumors including small cell lung cancer (SCLC). However, the biomarkers now used to predict the efficacy of SCLC immunological checkpoint inhibitors are still in the exploratory phase. The aim of this prospective study was to investigate the prevalence and prognostic roles of soluble PD-L1(sPD-L1) protein in the blood of patients with lung cancer. **Method:** A total of 94 patients with SCLC who were diagnosed by histopathology or cytopathology between March 2018 to November 2018 were enrolled. Blood samples plasma were collected at the time of diagnosis. 17 samples of healthy subjects matching in sex and age from the Health care Center of the hospital were also studied as control. The level of sPD-L1 protein in the blood was measured using an enzyme-linked immunosorbent assay (ELISA). And the correlation of sPD-L1 expression with tumor stage, distant metastasis, and pro gastrin releasing peptide (ProGRP) was analyzed. **Result:** Expression of sPD-L1 in SCLC patients was significantly higher than healthy people(P<0.05).A cut-off value of 1.362ng/ml was distinguished in patients according to Receiver operating characteristic curve (ROC). Dynamic changes of sPD-L1 are associated with progressive disease(PD)a, partial response(PR)a and stable disease(SD)b in SCLC patients(a P<0.01,b P>0.05).The expression of sPD-L1 in serum was positively correlated with ProGRP.

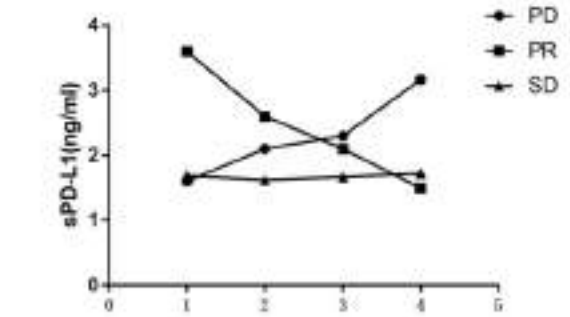


Figure 1 Trend of sPD-L1 in patients with small cell lung cancer during treatment

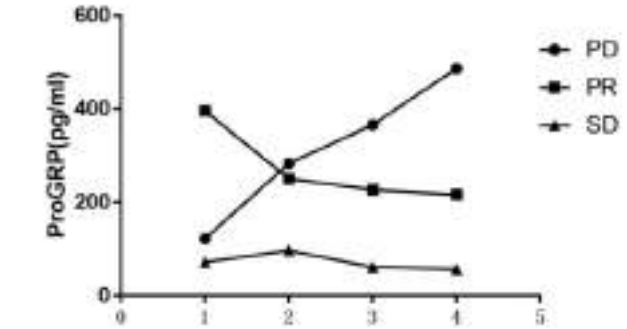

Figure 2 Trend of ProGRP in patients with small cell lung cancer during treatment

Conclusion: Our results indicated that changes of plasma SPD-L1 levels in SCLC patients are associated with prognosis. Plasma sPD-L1 protein is a great biomarker in SCLC and may play an important role in sifting the beneficiaries of immunotherapy.

P2.12-17 TREATMENT PATTERNS IN SMALL CELL LUNG CANCER (SCLC): AN OBSERVATIONAL STUDY OF 2016–2018 EHR DATA

K. Öhrling[1], M. Cai[2], D. Felici[3], J. Gold[3], N. Tran[2], M.-A. Smit[2], L. Raskin[2]

[1]*Amgen (Europe) GmbH, Rotkreuz/Switzerland,* [2]*Amgen Inc., Thousand Oaks/United States of America,* [3]*SimulStat Inc., Solana Beach/United States of America*

Background: SCLC is an aggressive neuroendocrine malignancy with a poor prognosis. Treatment for SCLC has remained largely unchanged for more than two decades, and treatment options for patients remain limited. Recently, immune checkpoint inhibitors have shown efficacy either in combination with chemotherapy in first line or as monotherapy in second or later lines. To better characterize the SCLC treatment landscape, we investigated treatment patterns in a large electronic health record (EHR) dataset. **Method:** Patients ≥18 years of age diagnosed with SCLC from 2016 through 2018 at a US Oncology Network or Onmark community oncology practice were included. Patients enrolled in clinical trials were excluded. Baseline characteristics were compared between treated and untreated patients, and treatment regimens were described by year and by line of therapy. **Result:** A total of 4,589 patients were diagnosed with SCLC during the study period, of whom 85% were treated. Demographics and disease characteristics were similar between treated and untreated groups. Patients were predominately female, former smokers, and residents of the southern United States. Approximately 33% of the treated patients had at least 2 lines of therapy, and 9% had at least 3 lines. The most commonly used treatment regimen in first line across years was platinum + etoposide ± other; in second line, topotecan and nivolumab were most common; in third or later lines, paclitaxel, topotecan, and nivolumab were most common. See Table for details.

POSTERS

SCLC Treatment Regimens by Year and Line of Therapy						
	2016		2017		2018	
Line	Regimen	n (%)	Regimen	n (%)	Regimen	n (%)
1		N = 1,096		N = 1,427		N = 1,347
	Plat +Eto ± Other	1,042 (95.1)	Plat + Eto ± Other	1,320 (92.5)	Plat + Eto ± Other	1,186 (88.1)
	Plat + Irinotecan	14 (1.3)	Topotecan	23 (1.6)	Plat + Irinotecan	37 (2.8)
	Topotecan	11 (1.0)	Nivolumab	18 (1.3)	Nivolumab	27 (2.0)
2		N = 142		N = 495		N = 651
	Topotecan	66 (46.5)	Topotecan	160 (32.3)	Nivolumab	187 (28.7)
	Plat +Eto ± Other	19 (13.4)	Nivolumab	106 (21.4)	Topotecan	127 (19.5)
	Nivolumab	14 (9.9)	Plat +Eto ± Other	67 (13.5)	Plat + Eto ± Other	114 (17.5)
3		N = 8		N = 181		N = 195
	Paclitaxel	2 (25.0)	Topotecan	28 (23.7)	Nivolumab	78 (40.0)
	Topotecan	2 (25.0)	Nivolumab	25 (21.1)	Topotecan	26 (13.3)
	Irinotecan	2 (25.0)	Paclitaxel	20 (16.7)	Ipilimumab + Nivolumab	18 (9.2)
Plat = platinum-based chemotherapies; Eto = etoposide. Note: Overall number of treated patients is provided for each year and line of therapy. Percentages are calculated by year and line.						

Conclusion: In this database of community oncology practices covering 2016-2018, platinum-based chemotherapy regimens were the most commonly used treatments for patients with SCLC across lines of therapy and years. Other commonly used chemotherapy agents included topotecan, paclitaxel, and irinotecan. Immune checkpoint inhibitors were used predominantly in second and third lines, and utilization increased from 2016 to 2018.

P2.12-18 PREVALENCE OF DLL3 EXPRESSION AND ITS PROGNOSTIC ROLE IN EXTENSIVE STAGE SMALL CELL LUNG CANCER

S. Lim, M. Hong, S.P. Kim, S.H. Chung

Wonju Severance Christianity Hospital, Wonju/Korea, Republic of

Background: Extensive stage small cell lung cancer (ES-SCLC) is a highly aggressive disease with a very poor prognosis, and there is a highly unmet need to develop new treatment strategy for them. Rovalpituzumab tesirine (Rova-T), an antibody drug conjugate directed against Delta-like protein 3 (DLL-3) has shown good efficacy in phase I and II clinical trials for the patients with ES-SCLC. We herein examined the prevalence of DLL3 protein expression and its prognostic role in ES-SCLC patients. **Method:** Tumor samples of ES-SCLS were subjected to immune-histochemical staining for DLL3 (AbbVie Stemcentrx). Expression in at least 50% of cancer cells were defined as DLL3-high. The association of patients' characteristics including gender, metastatic sites, and smoking history with DLL3 expression was analyzed by medical chart review. The correlation of DLL3 protein expression status with chemotherapy effect (PFS, OS and response rate) was analyzed. All the statistical analyses were performed by SPSS ver. 18.0 program. **Result:** A total of 56 patients' sample were included in our analysis. The median age was 54 with a range of 44 to 86, and the majority of patients (N=49, 89.1%) are male. Above 90 percent of patients (N=50, 90.9%) received etoposide and cisplatin as chemotherapeutic regimen, and among the 47 patients evaluable for the response, the objective response rate (ORR) was 61.7% (1 complete response and 28 partial response). The median progression free survival (PFS) and overall survival (OS) was 175 days (95% confidence interval (CI), 130.4-220.0) and 250 days (95% CI, 184.0-316.0), respectively. DLL-3 high expression was observed in 91% of patients (N=50). It is not correlated with any of the patients' characteristics and response to chemotherapy. In addition, there was no difference in PFS (242.0 vs. 165.0 days, p=0.900) or OS (160.0 vs. 250.0 days, p=0.975) according to DLL-3 expression. **Conclusion:** Our study showed that DLL3 high expression was found in almost all tumor samples in ES-SCLC. Also, its expression was not correlated with the patients' characteristics and prognosis of them. Further studies are warranted.

Keywords: small cell lung cancer, DLL3, Prognostic factor

P2.12-19 SMALL CELL LUNG CANCER (SCLC) TREATMENT AND SURVIVAL IN PORTUGAL: AN IPO-PORTO ANALYSIS FROM THE I-O OPTIMISE INITIATIVE

M. Soares[1], L. Antunes[1], P. Redondo[1], M. Borges[1], R. Hermans[2], D. Patel[2], C. Chaib[3], L. Lacoin[4], A. Juarez-Garcia[5], M. Daumont[6], J. Penrod[7], J. O'Donnell[7], M. Bento[1], F. Rocha-Goncalves[1]

[1]*Portuguese Oncology Institute of Porto (IPO-Porto), Porto/Portugal,* [2]*IQVIA, London/United Kingdom,* [3]*Bristol-Myers Squibb, Madrid/Spain,* [4]*Epi-Fit, Bordeaux/France,* [5]*Bristol-Myers-Squibb, Uxbridge/United Kingdom,* [6]*Bristol-Myers Squibb, Braine-l'Alleud/Belgium,* [7]*Bristol-Myers-Squibb, Princeton/United States of America*

Background: Approximately 15% of lung cancers are SCLC, which is an aggressive disease associated with poor patient outcomes and limited treatment options. As part of I-O Optimise, a multinational research platform providing insights into the real-world management of thoracic malignancies, the IPO-PORTO study aimed to characterise treatment options and their impact on overall survival (OS) in patients diagnosed with SCLC in Portugal's largest oncology hospital. **Method:** IPO-PORTO collects data on patients with various cancers and is linked to the North Region Cancer Registry (RORENO), covering Northern Portugal. This analysis included all adult patients diagnosed with non-resected limited disease (LD)- or incident extensive disease (ED)-SCLC at IPO-PORTO between January 2012 and June 2017, with follow-up to December 2017. ED was defined as metastatic because Veterans Administration Lung Study Group staging was not available. Systemic anti-cancer therapy (SACT) information was available from 2015 onwards. Bespoke and clinically validated rule-based algorithms were applied to describe treatment patterns. The Kaplan–Meier method was used to estimate OS. **Result:** Of 227 patients diagnosed with incident SCLC, 61 (26.9%) had non-resected LD and 166 (73.1%) had ED. Median age was 65 years (range: 59–72) and most patients (83.7%) were male. Most patients with LD-SCLC had stage IIIA/IIIB disease (78.7%). Sites of metastasis in ED-SCLC were bone (47.6%), liver (45.2%), lymph nodes (17.5%), or brain/CNS (13.3%). In patients diagnosed with LD-SCLC from 2015 onwards, 16 of 25 (64.0%) received SACT; among these, 11 received SACT associated with radiotherapy (68.8%). In patients diagnosed with ED-SCLC from 2015 onwards, 53 of 83 (63.9%) were treated with SACT. Among the 69 patients treated with SACT after diagnosis, only 9 received 2nd-line treatment (13.0%). Almost all patients received a platinum-based regimen including cisplatin or carboplatin and etoposide as 1st-line treatment. In patients diagnosed from 2012 onwards, the 1-year OS rate was 54% (95% CI, 43–69) for patients with LD-SCLC and 17% (95% CI, 12–24) for ED-SCLC. Among treated

patients with ED-SCLC who were diagnosed from 2015 onwards, the 1-year OS rate was 18% (95% CI, 9–35). **Conclusion:** Patients with SCLC had a high disease burden; most patients were diagnosed with ED and nearly three-quarters died within a year of diagnosis. The study confirmed that the majority of ED-SCLC patients diagnosed at IPO-PORTO after 2015 were treated with SACT; despite this, 1-year OS rates remained low (<20%).

P2.12-20 NRG ONCOLOGY/ALLIANCE LU005: A PHASE II/III RANDOMIZED STUDY OF CHEMORADIATION VERSUS CHEMORADIATION PLUS ATEZOLIZUMAB IN LS-SCLC

K. Higgins[1], C. Hu[2], H. Ross[3], S. Jabbour[4], D. Kozono[5], T. Owonikoko[1], B. Movsas[6], C. Xiao[7], T. Solberg[8], T. Williams[9], J. Simko[8], X. Wang[10], T. Stinchcombe[11], J. Bradley[12]

[1]*Winship Cancer Institute, Emory University, Atlanta/United States of America,* [2]*The Johns Hopkins University School of Medicine, Baltimore/United States of America,* [3]*Mayo Clinic Arizona, Phoenix/United States of America,* [4]*Rutgers Cancer Institute of New Jersey, New Brunswick/United States of America,* [5]*Dana-Farber Cancer Institute, Boston/United States of America,* [6]*Henry Ford Health System, Detroit/United States of America,* [7]*Yale University, Orange/United States of America,* [8]*University of California, San Francisco, San Francisco/United States of America,* [9]*The Ohio State University, Columbus/United States of America,* [10]*Duke Biostatistics and Bioinformatics, Durham/United States of America,* [11]*Duke University, Durham/United States of America,* [12]*Washington University in St Louis, St Louis/United States of America*

Background: Clinical outcomes for limited stage small cell lung cancer (LS-SCLC) remain suboptimal. Standard of care chemoradiation with platinum/etoposide and thoracic radiation to 45 Gy delivered twice daily followed by prophylactic cranial irradiation yields a median overall survival of 30 months. LU005 is a randomized phase II/III trial designed to test the addition of atezolizumab to concurrent chemoradiation (ClinicalTrials.gov Identifier: NCT03811002). **Method:** Patients with LS-SCLC (Tx-T4, N0-N3, M0) are randomly assigned in a 1:1 ratio to either standard chemoradiation, consisting of thoracic radiation (45 Gy twice daily or 66 Gy daily) with concurrent platinum/etoposide chemotherapy, or the experimental arm, consisting of the same chemoradiation regimen plus the addition of atezolizumab beginning concurrently with thoracic radiation, and continued every 3 weeks for 12 months duration. Thoracic radiation begins with the second cycle of chemotherapy in both treatment arms. Stratification variables include radiation schedule (once daily vs. twice daily), chemotherapy (cisplatin vs. carboplatin), sex, and performance status (PS 0/1 vs. 2). Prophylactic cranial radiation is recommended for patients who have a response to treatment. The phase II primary endpoint is progression free survival (PFS) and the phase III primary endpoint is overall survival (OS). It is hypothesized that the addition of atezolizumab will yield a hazard ratio of 0.62 for PFS, for a sample size of 280 patients in the phase II portion of this study. The overall sample size for phase II/III will be 506, with the OS analysis designed to provide at least 85% power to detect a hazard ratio of 0.71 at a 1-sided significance level of 0.025. Secondary endpoints include objective response rates, local control, distant metastases free, and quality of life. This study includes a robust translational science component including blood and tissue based assays to further understand which patients may benefit most from immunotherapy. **Result:** This study activated in May 2019 and is currently enrolling patients. **Conclusion:** NRG Oncology/Alliance LU005 is a randomized II/III trial testing the addition of atezolizumab to standard chemoradiation for LS-SCLC. The estimated date of study completion is May 2024. *Authors Higgins and Ross are co-first authors and contributed equally to this work.

P2.12-21 OUTCOMES WITH IMMUNE CHECKPOINT INHIBITORS (ICI) FOR RELAPSED SMALL CELL LUNG CANCER (SCLC) IN A SWISS COHORT

L. Mauti[1], S. Schmid[1], I. Demmer[1], A. Friedlaender[2], V. Blum[3], S. Rothschild[4], H. Bouchaab[5], P. Froesch[6], C. Britschgi[7], D. Koenig[8], L. Wannesson[9], W.-D. Janthur[10], S. Schaer[11], A. Addeo[2], W. Jochum[1], M. Früh[1]

[1]*Kantonsspital St. Gallen, St. Gallen/Switzerland,* [2]*Hôpitaux Universitaires de Genève, Genève/Switzerland,* [3]*Luzerner Kantonsspital, Luzern/Switzerland,* [4]*Universitätsspital Basel, Basel/Switzerland,* [5]*Centre Hospitalier Universitaire Vaudois, Lausanne/Switzerland,* [6]*Ospedale Regionale di Bellinzona e Valli, Bellinzona/Switzerland,* [7]*Universitätsspital Zürich, Zürich/Switzerland,* [8]*Kantonsspital Winterthur, Winterthur/Switzerland,* [9]*Istituto Oncologico della Svizzera Italiana, Bellinzona/Switzerland,* [10]*Kantonsspital Aarau, Aarau/Switzerland,* [11]*SAKK Koordinationszentrum, Bern/Switzerland*

Background: Chemotherapy for relapsed small-cell lung cancer (SCLC) has limited activity. Results from early clinical trials showed promising outcomes in a subset of patients with relapsed SCLC receiving ICI. Therefore, nivolumab +/- ipilimumab, pembrolizumab or atezolizumab have been used off-label in Switzerland. **Method:** 9 cancer centers in Switzerland contributed data to this retrospective cohort of patients who received off-label ICI for relapsed SCLC. Patient characteristics including age, smoking status, stage at diagnosis and previous treatments were collected. Outcomes of ICI were assessed by the local investigators using standard RECIST v1.1 criteria. Tumor tissues were assessed centrally for PD-L1 expression, tumor mutational burden and immune-related gene expression signatures. **Result:** 45 patients were included between November 2016 and January 2019. Median age was 63 years. 73% were males, 4% never smokers and 18% had a performance status (PS) ≥2. ICIs were given as second line treatment in 24 patients (53%). 24 patients (53%) received combination immunotherapy with ipiliumumab and nivolumab. 28 patients (62%) had undergone tumor irradiation (RT) prior to or during ICI. In the entire population, the overall response rate was 31%, while 49% had progressive disease as best response. Median progression-free survival was 2.5 months and median overall survival 6.5 months. There was no significant association between type of ICI (mono vs. combo) or prior RT vs. no RT with survival outcomes in a multivariate analysis. There were no new safety signals. One patient died of immune-related pneumonitis. **Conclusion:** This is the first report of "real-world" data on ICI in relapsed SCLC also including patients with poor PS. We confirm the efficacy and safety of ICI in relapsed SCLC as previously shown in clinical trials. No clinical prognostic marker could be identified. Results on the prognostic value of tissue-based biomarkers will be presented at the meeting.

P2.12-22 RISK FACTORS FOR BM INCIDENCE IN SCLC: A PREDICTIVE MODEL FOR SCLC PATIENTS ON BRAIN METASTASIS

J. Zhang[1], H. Li[2], Q. Chen[2], C. Wu[2], H. Pan[2], Y. Pan[2], J. Zheng[2], J. Wen[2], L. Ouyang[2], C. Zhou[3]

[1]*State Key Laboratory of Respiratory Disease, National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Health, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China,* [2]*Guangzhou Medical University, Guangzhou/China,* [3]*The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China*

Background: As one of the serious complications in patients with lung cancer, brain metastasis (BM) have been demonstrated more common when patients were diagnosing with small-cell-lung cancer (SCLC). After developing a BM, patients' median overall survival will be obviously shorten. Prophylactic Cranial Irradiation (PCI) used to be an optimal therapy to prevent the occurrence of BM in SCLC patients, while recently its status was shaken. This retrospective study aimed to find out the potential risk factor relative to the incidence of BM and construct a predictive mode for SCLC, also to see the efficiency of PCI on SCLC patients' ICPFS. **Method:** Patients pathologically diagnosed with SCLC were consecutively enrolled from May 1st 2006 to February 15th 2019 and reviewed. The intracranial progression-free survival (ICPFS) were calculated by a Kaplan-Meier approach. And the candidate prognosticators of the ICPFS were checked by COX regression analysis. Using these risk factor and its coefficient obtained in the multivariate analysis, a model were constructed to anticipate the incidence of BM. And the

receiver-operating characteristic (ROC) curve was constructed to access the prediction ability. **Result:** Totally 261 SCLC patients were eligible for analysis, including 78 cases had developed a BM (29.9%) after the first diagnosis. We used Cox proportional hazards to analyze and adjust the confounding factor to the incidence of BM, and got the result, that there were five factors showed the significance both in Uni-(P<0.15) and multivariate(P<0.05) analysis, including smoking index <400(P=0.017); vascular invasion (P=0.012); number of primary lesion (P=0.042); staging (P=0.018); and hyponatremia (P=0.05). And a predicative model was constructed by using these factors (except the hyponatremia), with an AUC value of 0.743. And we used this model to distinguish low and high risk group. Two groups' ICPFS showed a remarkable significance (P<0.001). We also simplified it to make it more convenient in clinical work, which also showed an outstanding significance (P<0.001). However, the PCI in our study was not reach the significance, even though it prolonged the ICPFS (P=0.211). **Conclusion:** Factors included smoking index >=400, vascular invasion, number of primary lesion, staging, and hyponatremia, increasing the risk of BM occurrence. In the era of individualized treatment, a predictive model based on smoking status and image science can give some suggestions for clinical work by anticipating the highly risky incidence of brain metastasis on SCLC patients.

P2.12-23 RADIOLOGICAL FEATURES OF SCLC-LIKE AND NSCLC-LIKE LARGE CELL NEUROENDOCRINE CARCINOMA (LCNEC)

B. Hermans[1], J. Derks[1], H. Gietema[1], E. Van Den Broek[2], E.-J. Speel[1], A.M. Dingemans[1]

[1]*Maastricht University, Maastricht/Netherlands,* [2]*PALGA Foundation, Utrecht/Netherlands*

Background: Large cell neuroendocrine carcinoma (LCNEC) can be divided in two pathological subtypes: the SCLC-like LCNEC with *RB1* mutations/loss of RB1 staining and the NSCLC-like LCNEC with preserved RB1 staining. The radiological presentations of NSCLC and SCLC are different, with SCLC mainly presenting with bulky disease and a central tumor. Here, we investigated if a distinction between SCLC-like and NSCLC-like LCNEC can be made based on radiological features. **Method:** A survey was developed with chest CT-scans and X-rays of patients with pathological confirmed stage-IV LCNEC (N=52). For reference, images of 10 SCLC and 10 NSCLC patients were randomly included. The survey was distributed among oncology pulmonologists in the Netherlands. Responders could score images as 'SCLC-like', 'NSCLC-like' or 'not possible to determine (nptd)'. Cases were considered as SCLC-like if no more than 1 responder scored NSCLC-like and no more than 67% scored 'nptd'. A similar approach was used to classify NSCLC-like cases. Images not fulfilling both approaches were regarded not applicable (NA). **Result:** The survey was completed by 23 pulmonologists with >5 years of experience, of which 12 had >15 years of experience. 90% NSCLC reference CT-scans were correctly classified, in contrast to only 30% correctly classified SCLC CT-scans (Table). For 36/52 LCNEC RB1 immunohistochemical status was known; 9/36 were RB1 positive and 27/36 RB1 negative. In RB1 positive LCNEC 6/9 scans were allocated to the NSCLC-like group. In RB1 negative LCNEC 2/27 scans were allocated to the SCLC-like group and 17/27 to the NSCLC-like group. If the scan was assessed as SCLC-like, RB1 was negative in 100% of cases. However, in cases assessed as NSCLC-like, only 26% was RB1 positive. No distinction between SCLC-like and NSCLC-like LCNEC could be made based on X-rays (Table).

Results of survey radiological features of LCNEC				
	Pathological diagnosis			
	Controls		LCNEC	
	SCLC	NSCLC	RB1 Pos-neg	RB1 Pos-pos
X-thorax	N=7	N=9	N=21	N=8
Survey SCLC-like	2 (500%)	0 (0%)	0 (0%)	1 (100%)
Survey NSCLC-like	2 (100%)	5 (6.0%)	9 (75%)	3 (25%)
Survey NA	2 (500%)	0 (0%)	12 (75%)	4 (25%)
CT-thorax	N=10	N=10	N=27	N=9
Survey SCLC-like	3 (500%)	0 (0%)	2 (100%)	0 (0%)
Survey NSCLC-like	2 (18%)	9 (82%)	17 (78%)	6 (26%)
Survey NA	5 (83%)	1 (17%)	8 (73%)	3 (27%)

Conclusion: In LCNEC, a CT-scan assessed as SCLC-like is highly predictive for RB1 negative status, whereas a NSCLC-like CT-scan can be both of the RB1 negative and positive subtype. During WCLC results including RB1 status of all 52 LCNEC will be presented.

P2.12-24 UNDERUTILIZATION OF SURGERY FOR LOCALIZED SMALL CELL LUNG CANCER: A NATIONWIDE ANALYSIS

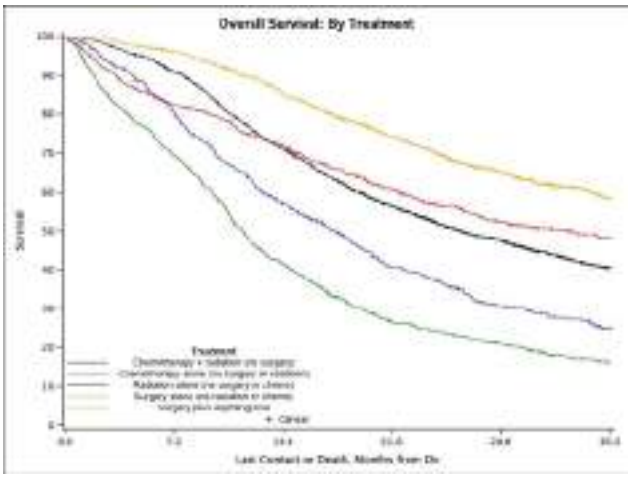
K. Parikh, U. Durani, J. Inselman, S. Funni, K. Leventakos, G. Goyal, R. Go, A. Mansfield

Mayo Clinic, Rochester/United States of America

Background: Although surgery has been recommended in node-negative localized small-cell lung cancer (SCLC), utilization has been low (<10%) in the past. Here, we evaluate treatment patterns and outcomes of surgery in localized SCLC over the last decade to determine if routine practice follows the growing literature in support of surgery in localized SCLC. **Method:** We queried years 2006-2014 of the National Cancer Database, a hospital dataset capturing 70% of incident cancers in the United States, to identify adults with Stage IA to IIA (T1-T2N0M0) SCLC who underwent treatment. Temporal practice patterns and multivariable survival outcomes were assessed. **Result:** In the cohort of 5877 patients, 2892 (49%) received chemoradiation, 1300 (22%) received surgery with radiation or chemotherapy, 639 (11%) received chemotherapy alone, 628 (11%) received surgery alone, and 418 (7%) received radiation alone. Amongst patients receiving surgery, 1277 (66%) received a lobectomy or pneumonectomy. Likelihood of receiving surgery in combination with radiation or chemotherapy was higher in later years of diagnosis (15% in 2006 vs 25% in 2014, p<0.001). Stage IA was more prevalent in the group that received surgery alone (77%) or surgery with chemotherapy or radiation (75%) compared to chemoradiation (45%), chemotherapy (49%), and radiation (63%). Median overall survival was most favorable for surgery with chemotherapy or radiation (51.8 months) followed by surgery alone (33.2 months) compared to chemotherapy + radiation (26.2 months), radiation alone (17.8 months), and chemotherapy alone (11.8 months)(p<0.001). In a multivariable Cox model (Table), surgery with chemotherapy and/or radiation was associated with decreased mortality versus chemoradiation (hazard ratio=0.6, P<0.001).

	Hazard ratio	95% CI
Treatment Chemoradiation Chemotherapy alone Radiation alone Surgery alone Surgery + chemotherapy or radiation	Ref 2.1 1.4 0.9 0.6	1.9-2.3 1.2-1.6 0.7-0.9 0.6-0.7
Female sex	0.8	0.8-0.9
Stage IA IB IIA	Ref 1.1 1.2	1-1.2 1.1-1.3

*Model also included age, insurance, median income quartile, Charlson comorbidity score, region, and race (not shown)



POSTERS

Conclusion: Utilization of surgery in localized SCLC remains low, despite its association with improved survival. Future clinical trials may be needed to establish the best therapeutic strategy for these patients.

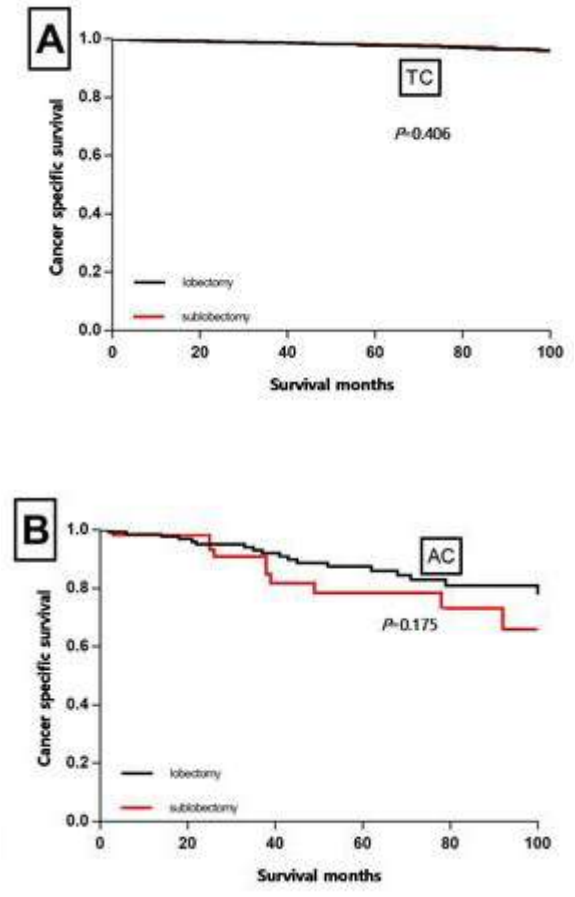
Keywords: SCLC surgery, early stage small cell lung cancer, ES-SCLC

P2.12-25 SURGICAL MANAGEMENT OF PULMONARY CARCINOID ≤3CM: EXTENT OF RESECTION AND LYMPH NODES EXAMINATION

Y. Wo, T. Lu, Y. Wang, W. Jiao

Affiliated Hospital of Qingdao University, Qingdao/China

Background: Early stage lung cancer is being detected at a higher frequency with the development of advanced screening programs. We aimed to investigate the optimal surgical approach in pulmonary carcinoid ≤3cm. **Method:** Patients with microscopically confirmed pulmonary carcinoid tumors ≤3cm were retrieved from the Surveillance, Epidemiology, and End Results (SEER) database between 2000 and 2015. Cancer specific survival (CSS), defined as the survival time from cancer diagnosis to death specific to cancer-related death, was the primary outcome variable. Survival curves were plotted with Kaplan-Meier analysis and the difference in survival was estimated by log-rank tests. Multivariate Cox regression methods determined the independent prognostic factors after adjusting for other confounding factors. **Result:** A total of 2986 patients were included in this study, which comprised 2785 typical carcinoids (TC) and 201 atypical carcinoids (AC). AC histology was associated with larger tumor size and increased risk of nodal metastasis. Lobectomy was performed for bigger carcinoid and correlated with more resected lymph nodes. Sublobectomy was noninferior to lobectomy with regards to CSS. Although lymph nodes involvement conferred significantly decreased survival, lymph nodes resection did not improve survival in either typical or atypical carcinoids.



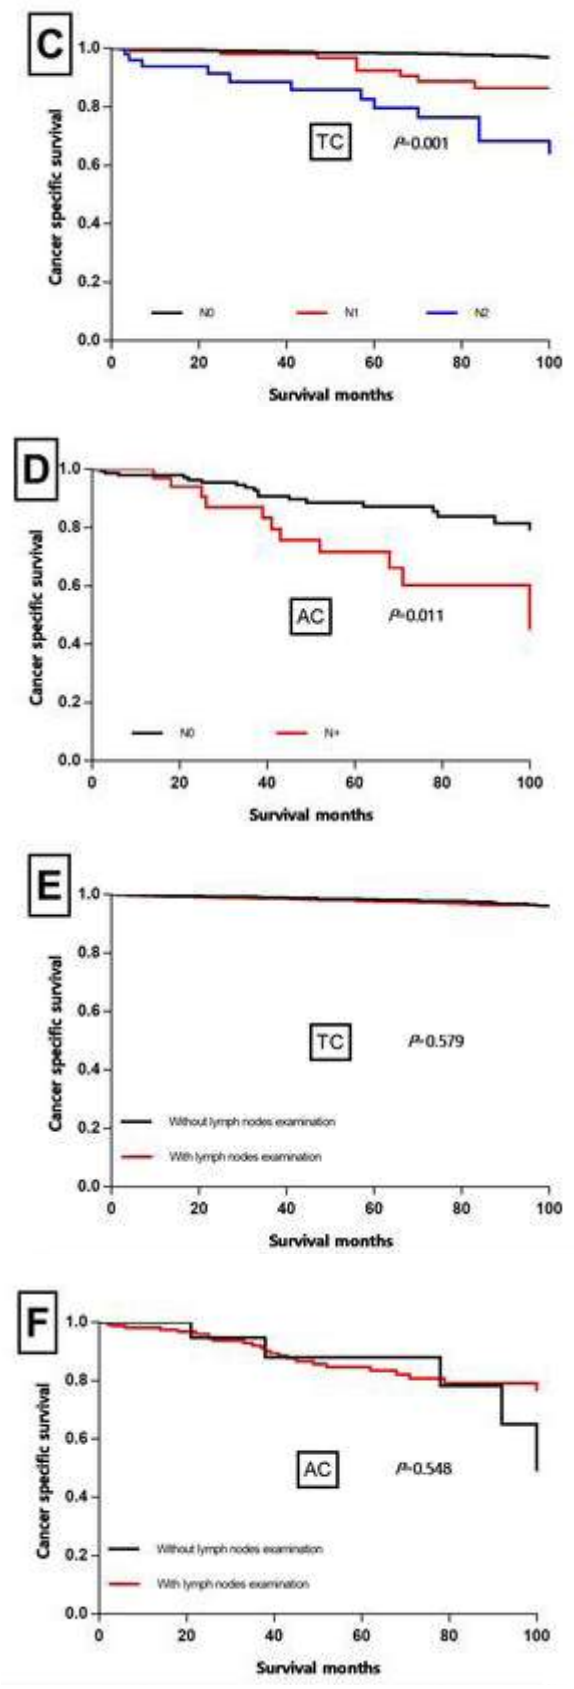


Figure 1 Survival curves stratified by (A) Extent of resection in TC, (B) Extent of resection in AC, (C) Lymph nodes status in TC, (D) Lymph nodes status in AC, (E) Lymph nodes examination in TC, and (F) Lymph nodes examination in AC.

Conclusion: For patients with T1-sized pulmonary carcinoids, sublobar resection results in similar survival rate compared with lobectomy. Lymph nodes examination did not independently predict survival.

Keywords: pulmonary carcinoid tumor, lymph node

Background: ALTER1202 trial (NCT03059797), a multicentre, randomized, double-blind phase II study has demonstrated that anlotinib significantly prolonged progress-free survival (PFS) in relapsed SCLC patients as 3rdor further line treatment. Here, we performed a comparative analysis for patients with brain metastases in the placebo and anlotinib arms. **Method:** Eligible either limited- or extensive-stage SCLC pts who failed ≥2 lines of chemotherapy (n=120) were randomized 2:1 to receive anlotinib or placebo (12 mg QD from day 1 to 14 of a 21-day cycle) till progression or intolerable toxicity. The primary endpoint was PFS. This subgroup analysis was based on patients with brain metastases at baseline. **Result:** There are 30 pts with brain metastases in anlotinib and placebo groups (n=21 vs 9). Anlotinib significantly improved PFS (3.84 vs 0.76 months; HR = 0.15; 95% CI, 0.04–0.51; P = 0.0005) and OS (6.08 vs 2.56 months; HR = 0.26; 95% CI, 0.09–0.73; P = 0.0061) comparing to placebo in patients with brain metastases at baseline. In anlotinib group, loss of appetite (47.62%), loss of weight (42.86 %), leukopenia (38.10%) and hypertriglyceridemia (38.10%) were the most common adverse events (AEs); then, in placebo group were emesis (44.44%) and loss of appetite (33.33 %). **Conclusion:** For patients with brain metastases in ALTER1202 trial, significant improvement in OS and PFS were found in anlotinib treated group with a manageable safety profile.

P2.13 STAGING
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.13-01 PET-CT UNDERESTIMATES UNEXPECTED PN2 IN LUNG ADENOCARCINOMA

S. Garcia-Reina[1], E. Fernandez-Araujo[1], M. Lacambra[2], C. Martinez-Barenys[1], C. Centeno[1], P. Lopez De Castro[1]

[1]*Hospital Universitari Germans Trias i Pujol, Badalona/Spain,* [2]*Hospital Mutua de Terrassa, Terrassa/Spain*

Background: Accuracy in lung staging is essential for the management of lung cancer. Positron emission tomography (PET-CT) allows us to identify occult disease and avoid unnecessary surgeries in patients with extended disease. In recent years, the histological distribution has varied in non-small cell lung carcinomas. Historically, squamous carcinoma had been more frequent, but in recent years adenocarcinoma has been progressively increasing its incidence. **Method:** We have retrospectively reviewed all patients that underwent surgery after cN0-N1 staging. Staging studying consisted in chest computed tomography, PET-CT and fiberbronchoscopy. In case of increased mediastinal PET-CT uptake, hiliar lesion, N1 involvement or tumour greater than 3 cm an endobronchial ultrasound (EBUS) and / or mediastinoscopy was performed. Our aim was to study if this histological change has increased our occult pN2 in cN0-N1 patients **Result:** Between January 2010 and March 2016, 484 patients were consecutively operated. 112 patients (92 men and 20 women) had hilar or mediastinal homolateral involvement. The average age was 63.62 years +/- 8.99. The initial nodal involvement was cN0 73.2% (82 patients), cN1 21.4% (24p) and ycN0 after neoadjuvant therapy 5.4% (6p). The following data were analysed: age of the patient, sex, histology of the lesion, staging, location, type of resection performed, laterality and nodal involvement. Subsequently, the statistical analysis was performed with SPSS 25. The most frequent histology was adenocarcinoma in 256 patients (52.89%), squamous carcinoma in 198 (40.9%), other 30 (6.1%). 25.78% adenocarcinoma (66p) and 23.23% squamous carcinoma (46p) presented nodal involvement. By zones, N1 and N2 involvement was 11.71% (30p) and 14.06% (36p) in adenocarcinoma group. 16.16% (32p) and 7.07% (14p) in squamous group (p <0.05). The odds ratio for occult pN2 was 1,988 in adenocarcinoma (p<0.05). **Conclusion:** PET-CT underestimates the presence of unexpected pN2 in adenocarcinoma lung cancer. Further mediastinal investigations may be necessary in these patients prior to surgical resection

Keywords: Lung cancer, PET-CT, staging

P2.13-02 PERSISTENT OCCULT MICROMETASTASES IN MEDIASTINAL LYMPH NODES ARE ASSOCIATED WITH REDUCED SURVIVAL AFTER NEOADJUVANT THERAPY

P. Gwóźdź, M. Pasieka-Lis, K. Kołodziej, K. Solarczyk-Bombik, J. Pankowski, M. Zielinski

Pulmonary Hospital, Zakopane/Poland

Background: This study was undertaken to evaluate the utility of the detection of occult micrometastases (OM) by immunohistochemical (IHC) staining of mediastinal lymph nodes (LN) obtained during surgical restaging after neoadjuvant treatment of NSCLC patients with mediastinal LN metastases. **Method:** In years 2007-2018, 55 patients with pathologically confirmed mediastinal LN metastases were restaged with TEMLA (transcervical extended mediastinal lymphadenectomy) after neoadjuvant chemotherapy or chemoradiotherapy. Routine haematoxylin&eosin staining of harvested mediastinal LN showed no metastases and all patients subsequently underwent curative pulmonary resection. To detect OM, we retrospectively performed IHC staining with anticytokeratin antibodies on all (1613) mediastinal LN obtained during TEMLA. **Result:** Persistent OM were found in mediastinal LN of 7 patients (12,7%). In all cases, only single LN was affected. After a median observation period of 24 months (range 4 to 60) after curative surgery, OM+ patients showed significantly reduced overall survival in comparison to OM- patients (log-rank, p=0.035). In Cox multivariable analysis, OM persistence was independent negative factor for overall survival. **Conclusion:** IHC staining of mediastinal LN obtained during TEMLA allows for more accurate restaging. Persistent mediastinal OM after neoadjuvant treatment are associated with reduced survival after pulmonary resection.

Keywords: restaging, Mediastinal Lymph nodes, neoadjuvant

P2.13-03 IS IT TIME TO REPLACE CERVICAL MEDIASTINOSCOPY WITH EBUS-FNAC IN INVASIVE MEDIASTINAL STAGING FOR NSCLC?

V.K. Tiwari, C.S. Pramesh, S. Jiwnani, G. Karimundackal

Tata Memorial Centre, Parel, Mumbai/India

Background: Cervical mediastinoscopy is considered the gold standard for mediastinal staging in NSCLC. However, the morbidity of this procedure is not inconsiderable and EBUS+/-EUS with guided FNAC is rapidly evolving as a replacement for mediastinoscopy. **Method:** Aim: To evaluate EBUS-FNAC, in invasive mediastinal staging and assess the incremental value of mediastinoscopy. Methods: Retrospective analysis of a prospectively maintained database of patients who underwent EBUS followed by mediastinoscopy and/or surgery within a month for potentially resectable NSCLC from February 2017 to March 2019. Lymph nodes in stations 2 and 4 bilaterally and 7 were sampled, if size 5mm or more/met radiological criteria on ultrasound. Patients with negative EBUS underwent mediastinoscopy and surgery depending on the results. Data regarding PET CECT features, sampling, cytology and final histopathology was analysed. **Result:** During the study period, 126 patients underwent EBUS for staging. Thirty-eight patients had positive mediastinal nodes, 34 with N2 and 4 with N3 disease. Eighty-eight patients were staged as N0 on EBUS, of which 15 received definitive chemoradiotherapy and 8 patients had progression of disease or were lost to follow up before definitive treatment. Sixtyfive EBUS negative patients underwent either mediastinoscopy followed by lung resection(56) or upfront lung resection with systematic mediastinal lymph node dissection(9). Nine of these patients (65) had N2 disease, 5 detected on mediastinoscopy and 4 detected on surgery (three positive in stations not accessible

by mediastinoscopy or EBUS and one in a patient who could not undergo mediastinoscopy). The 5 additional N2 cases detected by mediastinoscopy had sub centimetre lymph nodes with SUV < 3, but had undergone adequate sampling(median-3 passes) on EBUS. **Conclusion:** Presence of metastatic disease in sub centimetre mediastinal lymph nodes with low SUV cannot be excluded by imaging and this may be critical in this era of multimodality management. The sensitivity of EBUS although excellent is further augmented by mediastinoscopy and it remains an integral part of mediastinal staging.

Keyword: EBUS, NSCLC Staging, mediastinoscopy

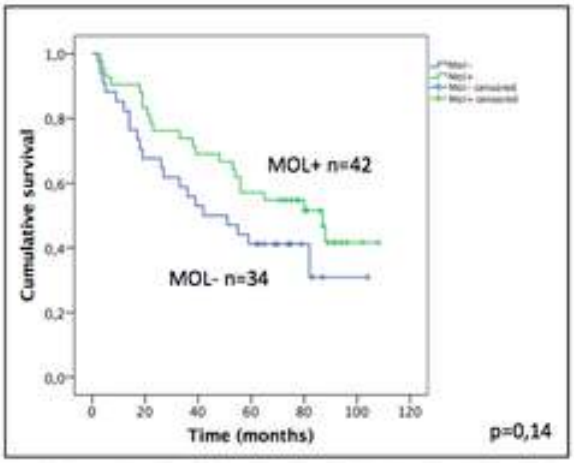
P2.13-04 MOLECULAR NODAL RESTAGING BASED ON EMBRYONIC MARKERS EXPRESSION ADDS NO RELEVANT CLINICAL INFORMATION IN RESECTED LUNG CANCER

I. Macia[1], G. Aiza[2], R. Ramos[1], F. Rivas[1], A. Ureña[1], S. Aso[1], G. Rosado[3], P. Rodriguez-Taboada[3], C. Deniz[1], E. Nadal[4], I. Escobar[1], G. Capella[5]

[1]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona/Spain,* [2]*Institut Català d'Oncologia, L'Hospitalet de Llobregat, Barcelona/Spain,* [3]*Hospital Joan XXIII de Tarragona, Tarragona/Spain,* [4]*Institut Català d'Oncologia, Barcelona/Spain,* [5]*Institut d'Investigació Biomèdica de Bellvitge, L'Hospitalet de Llobregat, Barcelona/Spain*

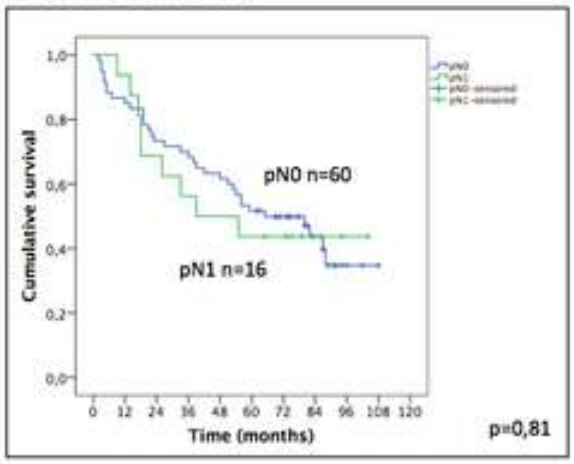
Background: The relapse rate in non-small cell lung cancer (NSCLC) is high, even in localised disease, suggesting that the current approach to pathological staging is insufficiently sensitive to detect occult micrometastases present in resected lymph nodes. Therefore, we aimed to determine the prognostic value of the expression of embryonic molecular markers in histologically-negative lymph nodes of completely-resected NSCLC. **Method:** 76 NSCLC patients undergoing radical resection were included. Primary tumours and 347 lymph nodes were studied. The molecular markers finally were selected based on testing of 27 normal lung and 129 lung tumour samples as well as 25 lymph nodes obtained from non-neoplastic diseases. CEACAM5, FGFR2b, and PTPN11 expression levels were evaluated through mRNA analysis using real-time RT-qPCR assay. Statistical analyses included the Kruskal-Wallis test, Kaplan Meier curves, and log-rank tests. **Result:** CEACAM5 expression levels were scored as high in 90 lymph nodes (26%). The molecular-positive lymph nodes lead to the restaging of 37 (62%) pN0 patients as molecular N1 or N2 and 5 (31%) pN1 cases were reclassified as molecular-positive N2. Surprisingly, molecular-positive patients (42, 55%) associated with a better OS (overall survival, p=0,04) than molecular-negative patients (34, 45%). FGFR2b overexpression was observed in 41 (12%) lymph nodes leading to the restaging of 17 patients (22%). Again a trend was observed towards a better DFS (disease-free survival) in the restaged patients (p=0,09). PTPN11 expression levels were high in 109 (31%) lymph nodes and led to the restaging of 41 (54%) patients who did not correlate with clinical outcome (p=0,61). The combination of CEACAM5-FGFR2b restaged the same number of patients than CEACAM5 only. Accordingly, high expression levels of CEACAM5 or FGFR2b in the primary tumour were related to better DFS (p<0,06; p<0,02, respectively); PTPN11 did not correlate with prognosis (p=0,37).

Disease-free survival



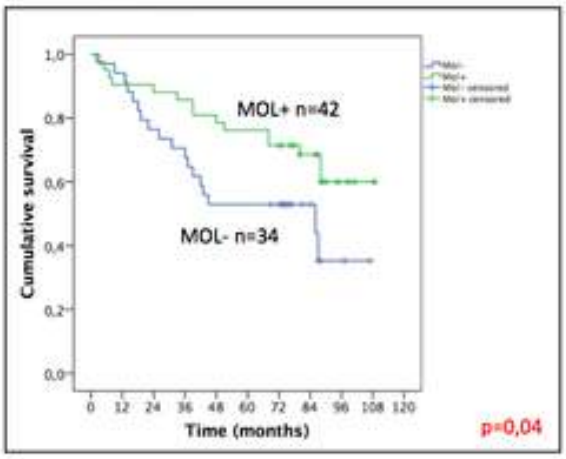
N at risk	0-m	12-m	24-m	36-m	48-m	60-m	72-m	84-m	96-m	108-m	120-m
Mol+	42	38	32	31	28	24	22	13	2	0	0
Mol-	34	28	23	19	17	14	8	2	1	0	0

Disease-free survival



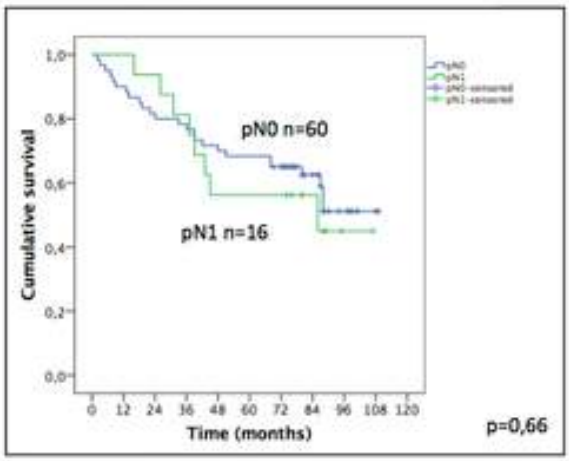
N at risk	0-m	12-m	24-m	36-m	48-m	60-m	72-m	84-m	96-m	108-m	120-m
pN0	60	51	44	41	37	31	24	12	2	0	0
pN1	16	15	11	9	8	7	6	3	2	0	0

Overall survival



N at risk	0-m	12-m	24-m	36-m	48-m	60-m	72-m	84-m	96-m	108-m	120-m
Mol+	42	38	37	36	33	32	29	20	6	1	0
Mol-	34	32	26	23	18	18	16	6	2	0	0

Overall survival



N at risk	0-m	12-m	24-m	36-m	48-m	60-m	72-m	84-m	96-m	108-m	120-m
pN0	60	54	48	46	42	41	36	21	7	1	0
pN1	16	16	15	13	8	7	6	5	1	0	0

Conclusion: Molecular nodal restaging based on expression levels of CEACAM5 and/or FGFR2b, does not add relevant clinical information to pathological staging of NSCLC likely related to the better prognosis of their overexpression in primary tumors.

Background: The adequate mediastinal restaging following neo-adjuvant therapy (NAT) in operable patients with non-small cell lung cancer (NSCLC) and N2 spread is crucial. Mediastinoscopy is the gold standard for mediastinal restanging, but endosonographic procedures are less invasive and can be an alternative. AIM: Evaluate the role of endobronchial ultrasound-guided transbronchial needle aspirate EBUS-TBNA in mediastinal the restaging of NSCLC. **Method:** Prospective study with 32 patients with CPNCP N2 spread confirmed by TNBA-EBUS, collected from June 2010 to October 2018. These patients were subjected to neoadjuvant treatment (chemotherapy or radio-chemotherapy), subsequently were performed mediastinum restage with TNBA-EBUS. The negative cases were subjected to mediastinoscopy or thoracotomy. **Result:** Of the 32 cases, the basal characteristics are detailed in table 1. Were analysed 229 lymph nodes, 42 of these were malignant (18%). TNBA-EBUS after neoadjuvant treatment showed persistence of N2 spread in 19 cases (52%). In negative cases (n=13; 41%) were performed mediastinoscopy (n=11) or surgery (n=1). After these procedures were confirmed mediastinal disease in 3 cases, 9 lymph nodes of 43 removed. The sensitivity, specificity, positive predictive value, negative predictive value and diagnostic accuracy were 86.4%, 100%, 100%, 72.7% and 90% respectively. There was recurrence of the disease in 15 cases (47%). We found a significant difference between recurrence and the type of neoadjuvant treatment (chemotherapy vs. radio-chemotherapy), p=0.047. Table 1.

Basal Characteristics	N (32)
Age	62.1 +/- 9.4
Sex	
Male	23 (72%)
Tumour localization	
Right upper lobe	15 (47%)
Right lower lobe	8 (25%)
Left upper lobe	8 (25%)
Left lower lobe	1 (3%)
Histology	
Adenocarcinoma	15 (47%)
Squamous carcinoma	12 (37%)
NSCLC not typified	5 (16%)
Neoadjuvant treatment	
Chemoradiotherapy	26 (81%)
Only chemotherapy	6 (19%)

Conclusion: TBNA-EBUS is an appropriate semi-invasive tool in mediastinal restage after neoadjuvant treatment, with high diagnostic accuracy. Nevertheless, in negative cases is still necessary support with invasive procedures.

P2.13-06 FINDING A PLACE FOR PATHOLOGICAL NEAR COMPLETE RESPONSE PATIENTS FOLLOWING NEOADJUVANT/INDUCTION THERAPY IN THE TNM STAGING

H. Melek, G. Çetinkaya, T. Sevinç, A. Deligönül, E. Özer, E. Çubukçu, A. Bayram, T. Evrensel, C. Gebitekin

Uludag University, Bursa/Turkey

Background: It has been shown that 10% or less in the number of live tumor cells in patients who underwent surgery after neoadjuvant/induction (N/I) treatment for locally advanced non-small cell lung cancer (NSCLC) is a more important prognostic factor than the tumor diameter. Therefore, to improve the accuracy of TNM staging, the IASLC recommends calculating the new pathological ypT stage by multiplying the percentage of viable tumor cells with the total tumor size (Picture 1). The aim of this study was to determine the effect of this recommendation on long-term survival rates. **Method:** Data of 1190 patients who underwent segmentectomy or larger lung resections for NSCLC in our academic center between 1996 and 2017 were prospectively recorded and evaluated retrospectively. Four hundred and sixty-nine (39.4%) patients who underwent surgery after N/I treatment for locally advanced NSCLC were included in the study. The patients were divided into 3 groups; Pathological complete response (CR, Group 1) as defined as no viable tumor cells regardless of tumor size, group 2 was accepted as near complete response (nCR), where the tumor contained ≤%10 live tumor cells, tumor size > 5 cm without lymph node metastasis, group 3 consisted of ypStage1 patients. The long term survival and its impacting factors were analyzed. **Result:** In histopathological examination, 16.6% (78/469) patients had CR, 4% (19/469) had nCR, 17.7% (83/469) had ypStage 1a and 7.7% (36/469) had ypStage 1b. Five-year survival; 72.5% in Group 1, 30% in Group 2 and 63.4% in Group 3. **Conclusion:** The best survival was observed in patients with pathological CR. Although, IASLC suggests that the nCR should be considered as Stage 1, because of the significantly low survival figures, T3-4 seems to be the more appropriate classification than the IASLC proposal.

Picture 1. A 48y male patient with 12-cm mass adjacent to the trachea (1a). Diagnosis of NSCLC was confirmed. Major response was observed after chemoradiotherapy (1b). After negative mediastinoscopy, right upper lobectomy and lower lobe superior segmentectomy was performed with a bronchoplasty. Histopathological examination revealed a tumor size of 7.5x6 cm

POSTERS

with live tumor cells ≤5% without lymph node metastasis. The IASLC recommends (T stage = Tumor Size x Number of Live Tumor Cells (5%)) patient's stage as ypStage 1.

P2.13-07 CT STAGING FOR SUSPECTED LUNG CANCER; SHOULD WE ROUTINELY IMAGE THE PELVIS?

E. Barclay, A. Sharman, R. Booton, R. Duerden, M. Evison

Manchester University NHS Foundation Trust, Manchester/United Kingdom

Background: Hospital trust imaging protocols for CT staging of suspected lung cancer vary with regard to inclusion of the pelvis. Imaging the pelvis allows for potential detection of pelvic metastases and appropriate subsequent management, but exposes the patient to a higher radiation dose. This study was designed to determine whether current practice could be improved and standardised. **Method:** Retrospective study across 11 hospital trusts in the United Kingdom. All patients who had a PET-CT scan in 2014 for a new diagnosis of lung cancer were identified from hospital databases. PET-CT reports were reviewed and categorised by the lung cancer stage given in the report. Stage IV disease was further subcategorised into stage IV with pelvic metastases or stage IV without pelvic metastases.The initial staging CT was reviewed in all stage IV patients with pelvic metastases on PET-CT. The CT protocol was documented in addition to whether or not the pelvic metastases were identified. **Result:** Pelvic bony metastases were identified in 4% of PET scans (66 patients). 11 of these 66 patients initially had a contrast-enhanced CT chest, abdomen and pelvis staging scan; 3/11 scans reported pelvic metastases. The remaining 55 patients did not have pelvic imaging prior to PET. Overall radiation exposure and costs were calculated; routine imaging of the pelvis during staging CT could result in an 18% increase in radiation exposure to the population and a 2% reduction in overall cost if subsequent PET imaging decreased by 4%. **Conclusion:** Trust imaging protocols for CT staging of suspected lung cancer vary with regard to inclusion of the pelvis. Pelvic metastases from primary lung cancer are an uncommon finding on PET-CT scans (4%). CT chest and abdomen scans are sufficient for staging lung cancer given the low incidence of pelvic metastases and significant radiation exposure associated with pelvic imaging.

P2.13-08 WHICH IS THE RELIABLE PROGNOSTICATOR FOR EARLY METASTASIS AND RECURRENCE OF NON-SMALL CELL LUNG CANCER, RELATED WITH STAS?

S.-Y. Ham[1], D.Y. Kang[2], B. Ko[3], Y. Lee[1]

[1]*Kangbuk Samsung Hopsital, Seouyl/Korea, Republic of,* [2]*Kangbuk Samsung Hopsital, Seoul/Korea, Republic of,* [3]*Ulsan University Hospital, Ulsan/Korea, Republic of*

Background: In recent years, many studies had investigated the correlation between STAS and the clinical parameters and prognosis of lung cancer. The majority of these studies focused on AdC, and a number of tumor-related factors were considered to be influenced by STAS. The incidence of STAS in AdC ranged from 14.8% to 56.4%, and STAS was demonstrated to have an association with AdC histologic type. For proper magement of lung cancer, correct perioperative evlauation and assessment is crucial, Recently the concept and signoficance of STAS has great interest. . **Method:** Materials and methods We retrospectively reviewed 171 non-small cell lung cancers, analyzed 45 cases, underwent lobectomy or pneumonectomy with pathology report and medical record. Tumor STAS was defined as detached tumor cells within the air spaces in the lung parenchyma beyond the edge of the main tumor clinicopathological factors, including clinical outcome. Comparison was done with visceral pleural invasion and lymphovascular invasion. **Result:** STAS was identified in 12 of 45 patients (26.6%). The patients with STAS had a significantly worse 5-year recurrence-free survival (RFS) in stage I, but not in stage II and III. A multivariate analysis showed that the presence of STAS was an independent predictive factor of and an independent prognostic factor (hazard ratio = 3.01; 95% confidence interval, 1.54-5.89; p = 0.0013) in stage I. Positive for STAS, and lymphovascular invasion was 10/45 and positive for STAS, and viscera pleural invasion was 6/45 and all positive lung cancers were 3/45 **Conclusion:** We found that STAS was detected in 26.6% of surgical resected non-small cell caricnomas, and it was associated with recurrence and worse prognosis in early stage lung cancers. Therefore, we suggest that STAS is a reliable prognosticator and play promising roles for the lung cancer managements.

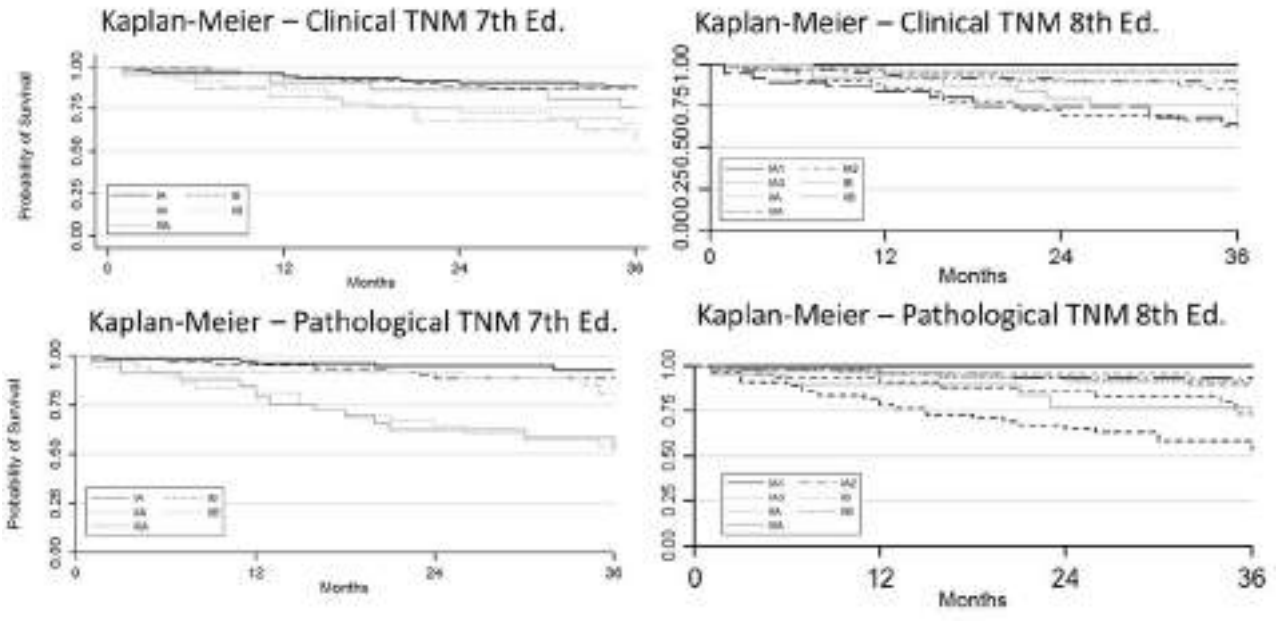
P2.13-09 THE IMPACT OF THE 8TH EDITION OF IASLC STAGING IN PATIENTS WHO UNDERWENT SURGICAL TREATMENT OF LUNG CANCER

P.H. Leite[1], M. Soares[1], P. Costa[1], P. Pêgo Fernandes[2], R. Terra[1]

[1]*Instituto do Câncer do Estado de São Paulo, São Paulo/Brazil,* [2]*Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo/Brazil*

Background: TNM cancer staging main function is to unify the language of patient´s evaluation. It is supposed to be a global initiative, however participation of latin american patients in the IASLC database is limited and the performance of staging in such a population is unknown.Our study aims to describe the performance of TNM 7th and 8th editions in predicting survival of patients with lung cancer who underwent surgical treatment in a latin american country. **Method:** This is a retrospective study conducted in a Oncologic hospital of São Paulo, Brazil. We selected the patients who underwent surgical treatment of lung cancer between January 2011 and December 2015. Clinical data was obtained from the institutional database including exactly the same variables as the IASLC database. Patients were classified according to the TNM clinical and pathological staging system, both in 7th and 8th editions. Then we performed a survival analysis in 36 months according to each classification using the Kaplan–Meier method. A Cox regression was made with the clinical and pathological staging as variables, in order to determine which classification was more precise in risk prediction. **Result:** The mean age was 63,9 (±11.6), female predominance (53%), and strong association with current or former smoking (74%). The most common histological type was invasive adenocarcinoma (54%) followed by squamous cell carcinoma (22%). Both TNM classifications stratified risk adequately as demonstrated in Image 1.

Image 1



According to the Cox regression, TNM 8th edition had a better performance in survival prediction. Clinical 7th ed (LL=-329.14095; LR=6.29) versus Clinical 8th ed (LL=-25.91923; LR=12.73). Pathological 7th ed (LL=-318.82608; LR=26.92) versus Pathological 8th ed (LL=-315.19067; LR=34.19). **Conclusion:** TNM 7th and 8th editions predicted adequately survival in patients of a Latin American country, suggesting that these classifications are generalizable for such a population. 8th edition had a better performance when compared to 7th edition.

P2.13-10 LYMPH NODE UPSTAGING EVALUATION AFTER ROBOTIC RESECTION FOR NSCLC IN BRAZIL

R. Terra[1], A. Dela Vega[2], R. Haddad[3], J.R. De Campos[2], C.E. Lima[4], F. Braga[5], P. Pêgo Fernandes[1]

[1]*Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, São Paulo/Brazil,* [2]*Hospital das Clinicas HCFMUSP, Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo, SP, BR., São Paulo/Brazil,* [3]*Pontifícia Universidade Católica do Rio de Janeiro - PUC-Rio, Rio de Janeiro/Brazil,* [4]*Universidade Estadual do Rio de Janeiro, Rio de Janeiro/Brazil,* [5]*Cirurgiões Torácicos Associados do RJ., Rio de Janeiro/Brazil*

Background: An adequate lymph node staging plays a key role in the management of Non-Small Cell Lung Cancer (NSCLC) having great value in determining the necessity for adjuvant therapy. Inasmuch as the development of surgical robotic devices and robotic lobectomy is prominent, it is important to study if the robotic approach is capable of yielding the same or better lymph node staging as open or video assisted technique(VATS).The prevalence of nodal upstaging has been used as an adequate evaluation of the completeness of lymphadenectomy. The aim of this study was to determine the prevalence of lymph node upstaging in patients treated for NSCLC using robotic approach during the initial adoption of this method in Brazil. **Method:** It was a descriptive analysis with retrospective collection of data from patients submitted to treatment for NSCLC with curative intention using robotic technique in different centers in Brazil. All data regarding demographics in addition to clinical and pathological details about nodal staging were collected. Patients with incomplete records about staging were excluded. **Result:** We included 172 patients operated on from January 2015 to March 2019 . The average age was 65.7 years, 87 were female and 85 male. The most frequent histologic types were adenocarcinoma with 131(75.7%) cases, carcinoid tumors with 22(12.7%) cases followed by 17(9.8%) squamous carcinomas, 2 (1.1%) large cell carcinomas and 1 (0.5%) adenosquamous carcinoma. One of the patients had 2 tumors with different histotypes (large cell carcinoma and adenocarcinoma). The most frequent stage was IA both in clinical (118,68.6%) and pathological (114, 66.2%) and the average tumor size was 20mm. There was upstaging in 34 (19.7%) cases and down staging in 30(17.4 %) cases. Lobectomy was the most frequent type of resection with 140 cases. On average 11.9 lymph nodes were resected and 5.8 node categories were addressed. Nodal upstaging occurred in 17 cases (9.8%) of which 8(4.6%) were N1-2 upstaging 6(3.4%) N0-1 upstaging and 3(1.7%) N1-2 upstaging. The incidence of nodal upstaging found was comparable with others studies. **Conclusion:** In our experience, the treatment for NSCLC using the robotic approach was able to perform an adequate lymphadenectomy with prevalence rate comparable to previous data in literature.

P2.13-11 PREDICTING MICROMETASTASIS IN MEDIASTINAL LYMPH NODES IN PATIENTS WITH NON-SMALL CELL LUNG CANCER

S. Erus[1], H. Süer[2], M. Kapdağlı[3], S. Tanju[1], Ş. Dilege[1]

[1]*Koç University School of Medicine, Istanbul/Turkey,* [2]*Koç University, Istanbul/Turkey,* [3]*VKF American Hospital, Istanbul/Turkey*

Background: Non-small-cell lung cancer staging is the most important factor affecting both the potential treatment and the prognosis. The evaluation of non-small cell lung carcinoma staging uses the TNM classification (tumor, node, metastasis). The N factor plays a more critical role in staging than T and M factors, because of its unpredictability. We know that undiagnosed micrometastatic nodal disease has a poor prognosis. Detecting micrometastasis is expensive and time consuming, so that's why we aimed to investigate the factors predicting micrometastatic mediastinal disease. **Method:** We collected all the lymph nodes from the patients that we operated between July 2012 and July 2013. We excluded all the patients who had an induction treatment and preoperatively diagnosed with mediastinal metastasis. We studied the expressions of three biomarkers; EpCAM, CEACAM5 and KRT19 using quantitative reverse transcriptase polymerase chain reaction (qRT-PCR) in lymph nodes and compared the expressions with healthy controls. If all three of them are positive, we have accepted it as micrometastasis. We compared the presence of micrometastasis with the pathological data to identify possible predictive factors. **Result:** We analyzed 86 lymph nodes from 32 patients. Twenty seven out of 86 lymph nodes (%31.4) were positive for micrometastasis. Eighteen out of 32 patients (%56.3) became micrometastatic and 16 out of 32 patients are upstaged. Four of them are upstaged from N1 to N2 and 12 of them are upstaged from N0 to N2. Micrometastatic patients tend to have poorer survival compared to non-micrometastatic patients but without an statistical significance. However micrometastasis was found significantly higher in tumors with less than 2 cm (p: 0.03) and lower in tumors without lymphovasculary invasion (p: 0.03). **Conclusion:** In our study tumors with smaller than 2cm in diameter and without lymphovascular invasion have significantly higher micrometastatic potential. In order to validate these parameters as predictive markers this experiment should be performed in a larger cohort with increased control population.

P2.13-12 ENDOBRONCHIAL ULTRASOUND FOR DIAGNOSIS AND STAGING OF LUNG CANCER: OUR EXPERIENCE

A. De Palma[1], G. Garofalo[1], E. Maiolino[1], T. Panza[1], F. Signore[1], A. Fiorella[1], O. Pizzuto[1], X. Trabucco[2], G. Marulli[1]

[1]*Section of Thoracic Surgery, University of Bari, Bari/Italy,* [2]*Division of Pathology, University of Bari, Bari/Italy*

Background: Surgical treatment of non-small cell lung cancer (NSCLC) can only be achieved in 20-25% of affected patients. Staging, deriving from the TNM classification, is the most relevant element for the selection of patients and N parameter is an essential prognostic factor. In recent years, in order to assess the N parameter with an endoscopic approach, ultrasound probes of small size have been assembled at the tip of the videobronchoscope (EBUS: Endobronchial Ultrasonography), allowing to perform real-time, ultrasound guided, transbronchial needle aspiration (TBNA) and/or transbronchial needle biopsies (TBNB) of hilar and mediastinal lymph nodes. This invasive examination of the tracheo-bronchial tree is nowadays of primary importance for the diagnosis and staging of lung cancer. We report our experience with this innovative endoscopic technique. **Method:** We retrospectively analyzed data of patients submitted to EBUS-TBNA/TBNB at our Section of Thoracic Surgery, from September 2008 to December 2018, considering the following factors: gender, EBUS-TBNA/TBNB positivity/negativity, duration of the procedure, number of samples taken from each lymph node station, complications related to the procedure. **Result:** EBUS was performed in 131 patients (95 men, 36 women) and repeated twice in 5/131 patients, for a total number of 136 EBUS procedures. Ultrasound evidence of lymph nodes was positive in 120/136 cases, in which TBNA/TBNB was performed, with the following cyto/histopathological results: positivity in 61 cases (51%), negativity in 23 cases (19%), inadequate material for diagnosis in 28 cases (23%), suspect/doubt in 6 cases (5%), no results in 2 cases (2%). Mean duration of the procedure was 30 minutes (range 15-60 minutes) and mean number of samples for each lymph node station was 3. No intra- or postprocedure complications were observed. Only 19 on 36 cases without diagnosis could undergo diagnostic surgery with the following results: 9 sarcoidosis, 6 lung cancer, 1 lymphoma, 1 epitelioid hemangioendotelioma, 1 paraganglioma, 1 antracosis. **Conclusion:** In our experience, EBUS-TBNA/TBNB resulted a safe and free from major complications procedure, easily repeatable, in a standardized way, after an adequate "learning curve" and it can avoid more invasive diagnostic technique such as mediastinoscopy. In fact, according to the current guidelines of the ESTS (European Society of Thoracic Surgeons) EBUS-TBNA should be used as the first diagnostic test in patients with hilar-mediastinal lymphadenopathy with or without the presence of a suspect lung mass, in order to obtain both staging and diagnosis.

P2.13-13 SHOULD VISCERAL PLEURAL INVASION BE PROGNOSTIC FACTOR IN PATIENT WITH SMALLER SIZED ADENOCARCINOMA?

K. Park

DCMC, Daegu/Korea, Republic of

Background: Visceral pleural invasion(VPI) is an adverse prognostic indicator as T2 irrespective of size in case of 3cm and less in 8th AJCC staging system. We analysed the effect of VPI status on recurrence in 3cm or less sized resected adenocarcinoma with another clinicopathological parameters. **Method:** We retrospectively reviewed a total of 97 patients with 3cm smaller sized stage I adenocarcinoma that underwent curative resection and MLND. The risk factors were statistically analyzed using Cox proportional hazard model and the Kaplan meier method. **Result:** The median follow-up period was 43.4months (range 7.0-188.7). In univariate analysis, the significant variables for recurrence were ever smoker at the time of surgery, sex, pathologic tumor size, SUVmax in PET-CT, solid predominant histologic subtype. In multivariate analysis, pathologic tumor size(p=0.049, HR=3.52, CI 1.01-12.31) was the independent risk factor for higher probability of recurrence. The 5-year overall survival rate was 77.0%. **Conclusion:** VPI was not a prognostic factor in 3cm sized pathologic stage I adenocarcinoma. 3cm size tumor or less with VPI may be designated as T1 not T2. But further study should be needed to validate.

Keywords: adenocarcinoma, visceral pleural invasion, staging

P2.13-14 THE UTILITY OF THREE-DIMENSIONAL CT FOR PREDICTION OF TUMOR INVASIVENESS IN CLINICAL IA LUNG ACENOCARCINOMA

Y. Kawaguchi, M. Nakao, J. Ichinose, Y. Matsuura, S. Okumura, M. Mun

Cancer Institute Hospital of JFCR, Tokyo/Japan

Background: In the evaluation of clinical T factor, there are some cases that the measurement of the solid component diameter of the tumor is difficult in conventional two-dimensional computed tomography (CT) because of heterogeneity and indistinctness of tumor density. So there is a problem in the preoperative estimation of the tumor invasiveness in these cases. Three-dimensional image analysis software, Synapse Vincent can quantify the volume of solid component of the lung nodule based on the CT value semi-automatically.The purpose of this study was to investigate the relationship between the histological grade of adenocarcinoma and the solid component volume by three-dimensional CT. **Method:** We enrolled 195 cases of cIA adenocarcinoma resected at our hospital in 2017. Two observers measured the solid component diameter of the tumors after consultation. The relationship of solid component diameter (2D), solid component volume (3D) and pathological subtypes (AIS, MIA or invasive cancer) were analyzed. We additionally performed the same analysis with a focus on 57 cases (29.2%) in which we judged that 2D measurement of the tumor was difficult. The cut-off value of each item was determined using the ROC curve. **Result:** The number of AIS / MIA were 86 and of invasive cancer were 109 cases respectively. The median value of 3D was 442.2 mm3 (0-7044 mm3). About the prediction of invasive cancer by 2D, the sensitivity was 95.4% and the specificity was 64.0%. In the analysis of 3D, the sensitivity was 93.6% and the specificity was 69.6% assuming that the 3D cutoff value was 225 mm3. They were not statistically higher than that of 2D. In subgroup analysis for 57 cases with difficulty in 2D measurement, when the cutoff value of 3D is 225mm3, the sensitivity is relatively good at 92.9% and the specificity 65.5%, and the accuracy is almost the same as the usual tumors with measurable solid components for invasive cancer prediction. In the analysis of 2D, the sensitivity was good at 92.9%, but the degree of specificity clearly decreased at 44.8%, and the diameter of the solid component tended to be overestimated. **Conclusion:** Measurement of the solid component diameter by two-dimensional CT tends to over-estimate shadows that are difficult to measure. Three-dimensional CT, semi-automatic measurement of solid component volume, can be performed easily, and the usefulness of it was suggested, especially in cases with the tumors which are difficult to measure the solid component diameter by two-dimensional CT.

Keywords: three-dimensional CT, pathological subtypes, adenocarcinoma

P2.14 TARGETED THERAPY
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.14-01 REAL WORLD TREATMENT OUTCOMES IN CHINESE PATIENTS WITH RET-REARRANGED LUNG CANCER

L. Yang[1], Z. Liu[2], W. Qiu[3], G. Yang[1], H. Xu[4], Y. Wang[5]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, beijing/China,* [2]*Chinese People's Liberation Army General Hospital, Beijing/China,* [3]*Haalthy Inc, Beijing/China,* [4]*National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing/China,* [5]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China*

Background: One global, multicenter study has identified available multi-targeted kinase inhibitors has limited activity in patients with RET-rearranged non-small-cell lung cancer (NSCLC). However, there is limited molecular and clinical data with RET-rearranged NSCLC in China. **Method:** Retrospective real-world analysis of clinical, molecular, and treatment outcome of a web-based patient registry and hospital chart review in China. **Result:** By 28/03/2019, 73 patients with RET-rearranged lung cancers from multiple hospitals in China were registered. The majority of patients were female (56.5%), never smokers (62.9%) with NSCLCs (98.4%). 15 different molecular subtypes of infusion partners were identified in which twelve subtypes were not reported before. KIF5B-RET was the most common (51.6%) followed by CCDC8-RET (25.8%). Two patients coexist with ALK fusion, one patient with EGFR mutation, and one patient with C-MET amplification. Median OS was 20.8m (95%CI 14.9-96.4) for 46 stage IV NSCLCs. Median PFS was 7.0m (95%CI 2.7-11.7) in patients who received 1st-line treatment including chemotherapy and multi-targeted kinase inhibitors. Patients with CNS (N=14, 30.4%) had significantly shorter PFS with those without CNS (N=32, 69.6%) (4.4m vs 9.1m; p=0.04, HR 2.343[1.040-5.279]). There was no statistically significant difference in PFS in terms of upstream fusion partners (KIF5B v other partner) (p=0.059). Besides, sixteen patients received one or more lines multi-targeted kinase inhibitors: cabozantinib (fourteen patients), vandetanib (two patients) and anlotinib (three patients). The median line of systemic therapy of the first RET TKI administered was as second line (range, first to third line). The median PFS of multi-targeted kinase inhibitor therapy in patients with CNS was 9.0m (95%CI 2.5-15.5m). **Conclusion:** This is the first real-world study reporting clinical outcomes of Chinese RET-rearranged advanced NSCLC patients by now, which included the most samples, either. Most patients received chemotherapy with unfavorable survival, although several patients may benefit more from available multi-targeted kinase inhibitors. CNS is an important risk factor whereas upstream fusion partners are not. More and novel targeted therapies for RET-rearranged patients are urgently needed in China.

Keywords: real-world study, non-small-cell lung cancer, RET-rearranged

P2.14-02 INTERIM SURVIVAL ANALYSIS OF GEFITINIB PLUS VINORELBINE IN ADVANCED EGFR-MUTANT NON-SMALL CELL LUNG CANCER (GENOA TRIAL)

C. Genova[1], G. Rossi[1], A. Pezzuto[2], G. Valmadre[3], E. Rijavec[4], F. Biello[5], G. Barletta[1], M. Tagliamento[1], M.G. Dal Bello[1], S. Boccardo[1], S. Coco[1], A. Alama[1], C. Sini[6], G. Burrafato[5], C. Maggioni[1], E. Bennicelli[1], L. Cerbone[1], L. Zullo[1], A. Ricci[2], F. Grossi[4]

Morelli, Sondalo/Italy,* [4]*Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico, Milan/Italy,* [5]*AOU Maggiore della Carità, Novara/Italy,* [6]*ASSL Olbia, Olbia/Italy*

Background: Patients affected by advanced non-small cell lung cancer (NSCLC) harboring mutations of the epidermal growth factor receptor (*EGFR*) are eventually destined to experience disease progression in spite of initial benefit from EGFR Tyrosine kinase inhibitors (TKIs). Preclinical studies have suggested that combining cytotoxic agents with EGFR TKIs to treat *EGFR*-mutant tumors may increase their inhibitory effect; in a preclinical study conducted within our Institution, the administration of vinorelbine

followed by gefitinib resulted in increased activity due to synergistic effect of the combined drugs. Here we present the interim analysis of GEfitinib plus viNorelbine in Advanced EGFR mutated NSCLC (GENOA TRIAL), which was designed to investigate the role of oral vinorelbine followed by gefitinib for the management of treatment-naïve patients affected by *EGFR*-mutant NSCLC (Clinicaltrials.gov: NCT02319577). **Method:** This was a multi-centric, open-label, randomized phase II trial designed to explore activity and tolerability of vinorelbine followed by gefitinib compared to gefitinib alone in patients affected by *EGFR*-mutant NSCLC. The estimated enrolment was equal to 80 patients; enrolled patients were randomized (1:1) to receive oral vinorelbine (60 mg/m2) on days 1,8 followed by gefitinib (250 mg) on days 9-21 (Arm A) or gefitinib alone (250 mg) on days 1-21 (Arm B) in three-weekly cycles. The primary end-point of the study was to determine the increase in terms of 6-month progression free survival (PFS) rate with Arm A compared to Arm B, while median PFS and median overall survival (OS) were secondary end-points; PFS data were defined according to response evaluation criteria in solid tumors (RECIST) v.1.1. Safety was assessed according to common terminology criteria for adverse events (CTCAE) v. 4.0. **Result:** Data from 44 patients (Arm A= 23; Arm B= 21) are available for this interim analysis, with a median follow up of 19.1 months. All the patients had advanced lung adenocarcinoma with *EGFR* mutation (exon 18=2; exon 19= 16; exon 21= 21; multiple exons= 5). The 6-month PFS rate was 48% for Arm A compared to 66% for Arm B (Fisher p= 0.24). Median PFS was 6.2 months for Arm A vs. 9.5 months for Arm B (Log Rank p= 0.17), while median overall survival (OS) was 18.2 months for Arm A and not reached for Arm B (Log Rank p= 0.12). Response rate was 47% for Arm A vs. 55% for Arm B (Fisher p= 0.76). Severe adverse events (AEs) were similarly uncommon in both arms; more specifically, two patients in Arm A experienced grade 3 white blood cells reductions, and two patients in Arm B experienced grade 3 increase of liver alanine aminotransferase. No treatment-related deaths were reported. **Conclusion:** At the interim analysis of GENOA Trial, the combination of oral vinorelbine plus gefitinib was not associated with increased 6-month PFS rate over gefitinib alone; similarly, no advantages in terms of response, PFS or OS were observed in the experimental arm. With regards to safety, no significant difference in terms of AEs was reported, nor unexpected toxicity was observed. The study was interrupted on the basis of this interim analysis.

Keywords: gefitinib, vinorelbine, EGFR

P2.14-03 PREDICTIVE FACTORS OF OSIMERTINIB AS SALVAGE TREATMENT FOR METASTATIC EGFR T790M POSITIVE LUNG ADENOCARCINOMA

S.H. Jang[1], J.Y. Park[1], Y.I. Hwang[1], H.Y. Kim[2], J.W. Seo[3]

[1]*Department of Pulmonary, Allergy and Critical Care Medicine, Hallym University Sacred Heart Hospital, Anyang/Korea, Republic of,* [2]*Department of Hematology-Oncology, Hallym University Sacred Heart Hospital, Anyang/Korea, Republic of,* [3]*Department of Pathology, Hallym University Sacred Heart Hospital, Anyang/Korea, Republic of*

Background: EGFR T790M mutation is a robust biomarker for the efficacy of osimertinib. But its clinical efficacy is very limited in a part of patients with non-small cell lung cancer harboring EGFR T790M mutation, suggesting primary resistance. The purpose of this study was to discover clinical predictive factors for the efficacy of osimertinib **Method:** This retrospective study analyzed patients with stage IV, EGFR T790M positive lung adenocarcinoma given osimertinib as salvage treatment. Various baseline clinical factors were investigated according to favorable or unfavorable osimertinib efficacy group. Unfavorable efficacy (primary resistant) group was defined as progression-free survival (PFS) < 6 months with osimertinib. **Result:** Thirty patients were eligible for this analysis (19 of favorable and 11 of unfavorable efficacy group). PFS of favorable and unfavorable efficacy group with osimertinib were 9.9 months (95% CI 9.5-10.3) and 3.3 months (95% CI 2.4-4.2), respectively (p<0.001). Response rate of osimertinib was 89.5% vs. 18.2% (p<0.001). The cases with age at the time of lung cancer diagnosis ≥ 60 years, baseline (before starting osimertinib) Neutrophil to Lymphocyte Ratio (NLR) ≤ 3.5, pre-osimertinib treatment with first generation EGFR-TKI (gefintinib or erlotinib) rather than second generation EGFR-TKI (afatinib) were more frequent in the favorable efficacy group (p=0.058, 0.058, and 0.088, respectively, chi-square test). Age at the time of lung cancer diagnosis, ECOG performance, baseline NLR, pre-osimertinib EGFR-TKI generation, and PFS with previous EGFR-TKI were revealed as potential predictive factors through Kaplan-Meier PFS estimation. Finally, Cox proportional hazard regression analysis confirmed age at the time of lung cancer diagnosis ≥ 60 years (HR 0.292, 95% CI 0.104-0.819, p=0.019) and baseline NLR ≤ 3.5 (HR 0.238, 95% CI 0.083-0.677, p=0.007) were good predictive factors for the efficacy of osimertinib **Conclusion:** Relatively old age and low neutrophilic inflammation were associated with favorable efficacy of osimertinib.

Keywords: Osimertinib, resistance, predictive factor

P2.14-04 CLINICAL VALIDATION OF LARGE NGS GENE PANEL USING RESIDUAL SPECIMEN

T. Sakamoto, K. Arai, K. Yamane, Y. Hirayama, Y. Teruya, M. Yanai, N. Kinoshita, K. Yamaguchi, H. Makino, M. Kodani, T. Igishi, A. Yamasaki

Tottori University Hospital, Yonago/Japan

Background: Precision medicine based on driver oncogenes is now developed for non-small cell lung cancer (NSCLC). A large number of next-generation sequencing (NGS) gene panels with various characteristics have been developed, and it is important to use properly according to the purpose. TruSight™ Oncology (TSO) 500 is an NGS tumor profiling assay that targets over 500 genes to analyze cancer-related biomarkers including SNVs, indels, fusions, splice variants, tumor mutation burden (TMB) and microsatellite instability (MSI). **Method:** Of the cases diagnosed with advanced NSCLC at Tottori University Hospital, 30 cases with consent to this observational study were enrolled. TSO500 was performed at the CLIA-certified laboratory (RIKEN GENESIS CO., LTD.) using DNA and RNA extracted from archived formalin-fixed paraffin-embedded (FFPE) lung cancer specimens. These were compared with gene alterations measured in the clinical practice. **Result:** Specimens were collected by bronchoscopy in 21 cases (70%), percutaneous biopsy in 3 cases (10%), surgery in 3 cases (10%), cell block of pleural effusion in 2 cases (7%) and thoracoscopy in 1 case (3%). The success rates of DNA analyses, including TMB and MSI analysis, and RNA analyses were 83% (25/30 cases) and 97% (29/30 cases), respectively. In the 30 cases analyzed, a total of 25 actionable gene alterations (13 EGFR mut, 4 ALK fus, 2 KRAS mut, 2 BRAF mut, 2 MET ex14 skipping, 1 RET fus, 1 PIK3CA mut) were detected in 24 cases (80%). Of the 21 cases that actionable gene alterations were identified in the clinical practice, TSO500 detected similar gene alterations in 20 cases (95%) except for one case that RNA analysis was failed. In addition, TSO500 detected BRAF V600E mutation in one case that had not been tested for BRAF mutation. TMB analysis succeeded in 26/30 cases (87%) and 9/26 cases (35%) were TMB-high when 10 mutations per mega base was set as the threshold. **Conclusion:** Despite analyzing small biopsy specimens with a large NSG panel, TSO500 could detect not only gene alterations for clinical use but also exploratory gene alterations.

P2.14-05 EGFR MUTATION STATUS AND PROGNOSTIC IMPACT IN PATIENTS WITH SURGICALLY RESECTED LUNG ADENOCARCINOMA

Y. Tokunaga, Y. Kita, T. Okamoto

Kochi Health Sciences Center, Kochi/Japan

Background: Epidermal growth factor (EGFR) gene mutation status in lung adenocarcinoma has been demonstrated to reflect the therapeutic efficacy of tyrosine kinase inhibitors (TKIs). In this study, we investigated the association of EGFR mutation status with prognostic impact. **Method:** From January 2010 to December 2018, we retrospectively reviewed 450 patients with resected lung adenocarcinomas who underwent EGFR mutation status analysis. Clinicopathological factors analyzed included age, sexgender, smoking history, serum carcinoembryonic antigen (CEA) levels, lymphatic invasion (Ly), vascular invasion (V), histological grade, malignant component, pathological stage, and EGFR mutation. Univariate and multivariate analyses of overall survival (OS) and recurrence-free survival (RFS) were conducted. **Result:** The study group comprised 450 patients (260 men, 190 women; age range: 32–88 years; mean age: 67.6±9.9 years). The median follow-up period was 35.4 months. A total of 282 patients were smokers

and 168 were nonsmokers. EGFR mutation analysis identified 186 patients with EGFR mutation and 264 patients with wild-type EGFR. Preoperative CEA was elevated in 117 patients. Ly, V, high grade, high malignant component and advanced stage were observed in 72, 73, 209, 120 and 102 patients, respectively. The 5-year OS in patients with EGFR mutation was 80.6% compared with 75.6% for those with wild-type EGFR (p=0.011). The 5-year RFS in patients with EGFR mutation status was 77.1% compared with 66.8% for patients with wild-type EGFR (p=0.036). There were no significant differences in OS and RFS between patients with exon 21 L858R, exon 19 deletion and other mutation subtypes. In addition, there was no survival difference in patients with EGFR mutation who received TKI or not after lung cancer recurrence. In multivariate analysis for OS, EGFR mutation status was an independent significant prognostic factor, as well as age, Ly, and pathological stage. **Conclusion:** EGFR mutation status is an independent good prognostic factor in patients with resected lung adenocarcinoma regardless of TKI use. EGFR mutation subtypes did not show significant differences in prognosis.

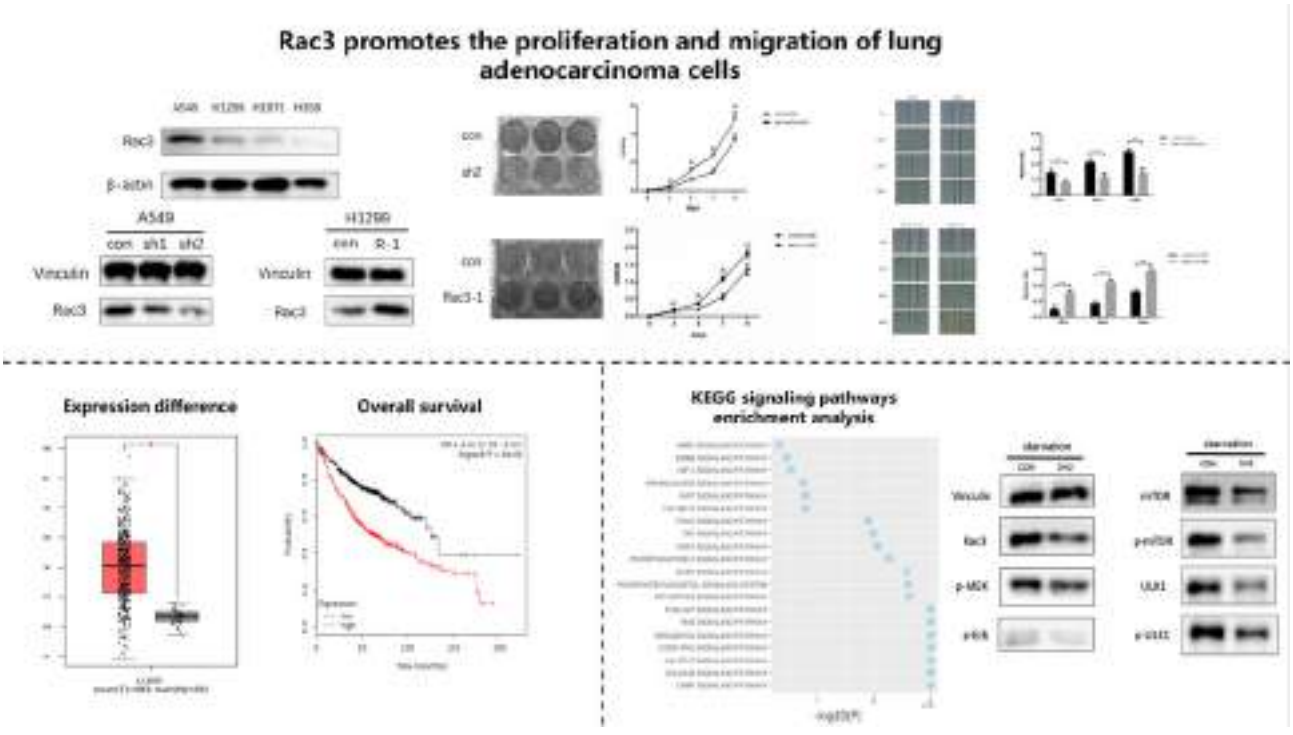
Keywords: lung adenocarcinoma, EGFR mutation, risk factor

P2.14-06 THE STUDY OF RAC3 MOLECULAR MECHANISM THROUGH ERK SIGNALING PATHWAY IN LUNG ADENOCARCINOMA

J. Li, H. Sun, G. Wang, C. Zhang, Y. Zhang, G. Wang, P. Zu, H. Liu

Liaoning Cancer Hospital & Institute, Shenyang/China

Background: To find out the relationship between Rac3 gene and prognosis of lung adenocarcinoma, the role of Rac3 in the proliferation and migration of lung adenocarcinoma cells, and the mechanism of Rac3 promoting the proliferation and migration of lung adenocarcinoma cells. **Method:** 542 patients with lung adenocarcinoma in the TCGA database were selected for analysis, the expression of Rac3 in cancer tissues and normal lung tissues were compared. Kaplan-Meier Plotter database was selected to analyze the relationship between Rac3 expression and 5-year overall survival rate of patients by Kaplan-Meier method. Human lung adenocarcinoma cell lines A549 and H1299 were used to build Rac3 knockdown and high-expression cell lines. The role of Rac3 in the proliferation and migration of lung adenocarcinoma cells was detected by cell proliferation and healing-wound test. The Rac3 knockdown cell lines were used to detect the changes of intracellular signaling pathways by serum starvation test and Western Blot experiment, screening out the signaling pathways with significant differences and study the biological function of them. **Result:** The results of TCGA database analysis showed that Rac3 expression in 542 patients with lung adenocarcinoma was significantly higher than that in normal lung tissues, and the result is statistically significant (P<0.01). Kaplan-Meier survival analysis showed that patients with high Rac3 expression had a significantly shorter 5-year overall survival than those with low Rac3 expression (P<0.0001). In A549 and H1299 cell lines, Rac3 shRNA is used to build Rac3 knockdown and high expression cell lines by lentivirus infection. The proliferation and migration of lung adenocarcinoma cells were detected by cell proliferation test and healing-wound test. Compared with the control group, the proliferation and migration ability of Rac3-shRNA group was significantly decreased, while that of Rac3 high expression group was significantly increased (P < 0.01). Serum starvation test and Western Blot results showed that in A549 cell lines, the phosphorylation of ERK pathway was significantly reduced after Rac3 expression was knocked down by shRNA compared with the control group.



Conclusion: Rac3 is highly expressed in lung adenocarcinoma. The overall survival (OS) of patients with high Rac3 expression was significantly shorter than those with low Rac3 expression. Rac3 promotes the proliferation of lung adenocarcinoma cells. Rac3 promotes the migration of lung adenocarcinoma cells. Rac3 probably regulates the ERK signaling pathway to promote the proliferation in lung adenocarcinoma cells.

Keywords: Rac3, lung adenocarcinoma, ERK signaling pathway

P2.14-07 EFFICACY OF SINGLE BEVACIZUMAB INTRAPLEURAL OR INTRAPERICARDIAL INJECTION IN THE TREATMENT OF LUNG CANCER-MEDIATED MALIGNANT EFFUSION

D. He, H. Yang, Q. Deng, F. Wang

The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China

Background: Malignant pleural or pericardial effusion is common in lung cancer, and drug intrapleural and intrapericardial injection plays an important role in the treatment. Local injection drugs include chemotherapy drugs and sclerosing agents. Patients with chemotherapy are vulnerable to bone marrow suppression and gastrointestinal side effects, and sclerosing agents would cause severe local side effects and be forbidden in the intrapericardial injection. The level of vascular endothelial growth factor (VEGF) in the malignant effusion increases significantly, therefore injecting bevacizumab locally may achieve a good response. So we investigated the efficacy and safety of single bevacizumab intrapleural or intrapericardial injection in the treatment of non-small cell lung cancer (NSCLC)-mediated malignant effusion. **Method:** This prospective, open-labeled, single arm, phase II clinical trial was undertaken at the First Affiliated Hospital of Guangzhou Medical University, China. Eligible patients had histologically or cytologically confirmed NSCLC with malignant pleural or pericardial effusion. Patients unsuitable for or rejecting the systemic therapy were included in. Patients could receive TKI continous treatment after TKI-resistance while only emerging malignant effusion. And lung cancer related symptoms were caused mainly by malignant effusions. Patients were administrated by single bevacizumab 100mg intrapleural or intrapericardial injection after the drainage of effusions. Lung cancer symptom scale (LCSS), efficacy and safety were evaluated before and after the treatment. **Result:** Twenty patients with lung adenocarcinoma and two patients with lung squamous cell carcinoma were included in the study from January 2014 through March 2019. LCSS after the treatment (score 494±78, mean±SD) were significantly improved compared with that before the treatment (score 377±77, mean±SD) (paired differences: score 117±64, mean±SD, 95% CI: score 89-145, P<0.001). Malignant effusions decreased obviously three weeks after the treatment compared with those before the treatment (P<0.001). The median duration of response was 91 days (127±40 days, mean±SD) in the 14 patients receiving intrapleural injection, and 111 days (91±11days, mean±SD) in the 8 patients with intrapericardial injection. There was no significant difference in the remission time of local injection between malignant pleural and pericardial effusions (P=0.987). Moreover, no severe side effects emerged, only one patient had mildly dizziness. **Conclusion:** Single bevacizumab intrapleural or intrapericardial injection is effective and safe in the treatment of lung cancer-mediated malignant effusion, while rapidly improving the malignant effusion-related symptoms in NSCLC patients. Certainly further more clinical trials were needed to confirm the results.

Keywords: malignant effusion, local injection, Bevacizumab

P2.14-08 BANF1 PREDICTS LUNG CANCER SURVIVAL AND SENSITIVITY TO PLATINUM-BASED CHEMOTHERAPY

J. Plowman, E. Bolderson, J. Burgess, D. Richard, K. O'Byrne

Institute of Health and Biomedical Innovation, Queensland University of Technology Translational Research Institute, WOOLLOONGABBA/Australia

Background: Barrier to autointegration factor 1 (BAF/Banf1) is a small, 10 kDa protein that functions as a non-specific DNA-binding homodimer and localises to the nuclear envelope during mitosis where it tethers DNA loops to the nuclear envelope. Mutations in Banf1 are associated with the severe premature ageing syndrome, Néstor–Guillermo Progeria Syndrome. Previously, key proteins associated with other progeria syndromes have been shown to play a role in both tumourigenesis and ageing, and now more recently, Banf1 expression has been associated with poor gastric cancer survival. With lung cancers being the leading cause of cancer-related deaths worldwide, identifying markers of improved prognosis, particularly in association with specific chemotherapy treatments, is essential to maximising drug effectiveness and promoting patient survival. **Method:** A variety of cell and tissue biology techniques including cellular Banf1 protein depletion and overexpression in a panel of lung cancer cell lines, drug treatments, immunofluorescence, immunoblotting and tissue microarray analysis, have been utilised in this study. **Result:** Kaplan-Meier analysis of mRNA datasets from 1926 patients diagnosed with lung cancer show a statistically significant association (p=7.8e-12) between "low" Banf1 mRNA and increased median overall survival of patients at 88.7 months, compared with the 52-month median survival of the "high" Banf1 mRNA cohort. Depletion of Banf1 in a panel of Non-Small Cell Lung Cancer (NSCLC) lines followed by cisplatin drug treatment demonstrated a heterogeneity of response, with a subset of cell lines experiencing improved survival while others displayed increased sensitivity to the drug compared with control cells. **Conclusion:** Banf1 is a candidate marker of lung cancer patient prognosis with Banf1 depleted cells having altered sensitivity to cisplatin treatment. Understanding the mechanism by which Banf1 affects lung cancer cell sensitivity to this drug is an ongoing research process that may have major implications for lung cancer treatment. Identification of patient Banf1 expression levels may contribute to improved therapeutic tailoring while modulation of Banf1 expression may ultimately lead to significantly increased survival of diagnosed patients.

P2.14-09 CONCURRENT TP53 MUTATION ADVERSELY IMPACT THE EFFICACY OF CRIZOTINIB IN ROS1-REARRANGED LUNG CANCER PATIENTS

G. Lin[1], H. Xu[2], J. Zhao[3], J. Kong[4], X. Ai[5], F. Yu[6], K. Du[7], L. Zhu[8], L. Li[9], H. Ma[10], Q. Wang[2], H. Xiong[2], R. Chen[2], X. Xia[2]

[1]*Fujian Cancer Hospital, Fujian Medical University Cancer Hospital, Fuzhou/China,* [2]*Geneplus-Beijing Institute, Beijing/China,* [3]*Beijing Cancer Hospital, Beijing/China,* [4]*The First Affiliated Hospital of Guangxi Medical University, Nanning/China,* [5]*Shanghai Chest Hospital, Shanghai/China,* [6]*The Second Xiangya Hospital of Central South University, Changsha/China,* [7]*Zhejiang Rongjun Hospital, Jiaxing/China,* [8]*Jiangsu Province Hospital, Nanjing/China,* [9]*Beijing Hospital, Beijing/China,* [10]*The Affiliated Traditional Medical Hospital of Xinjiang Medical University, Urumqi/China*

Background: ROS1 tyrosine kinase inhibitors (TKIs) are now standard of care for patients with advanced *ROS1*-rearranged NSCLC. But factors that may affect the efficacy of ROS1 TKIs remain to be explored. **Method:** We conducted a retrospective multicenter study of lung cancer patients with *ROS1* rearrangements. Treatment and survival follow-up was done and clinical records were reviewed. PFS distribution was analyzed by Kaplan-Meier method with log-rank test. **Result:** In total, we included 94 lung cancer patients with *ROS1* fusion genes profiled by next-generation sequencing from May 2016 to September 2018. Fifty of them were female. The median diagnosis age was 54 (25-83). The most common histologic type was adenocarcinoma, which was confirmed in 75 of 78 patients with available pathological results. The most common fusion partners were CD74, EZR, SDC4 and SLC34A2 identified in 42, 19, 12 and 8 patients respectively. Concurrent actionable mutations were uncommon for *ROS1* fusion-positive patients. The most frequent concomitant mutated gene was *TP53*, which was detected in 33% of all the patients. After excluding 29 patients who were lost to follow-up at the very start, the median follow-up time was 8.5 (0-28) months from the moment when mutation profiling was performed. Thirty-nine patients received treatment with crizotinib, among whom 27 were treatment-naïve patients. The median PFS of the 39 patients with crizotinib was not reached yet. Patients with baseline CNS metastasis tend to have shorter PFS compared to patients without (median, 12 *vs* NR, p = 0.0073). Besides, concurrent *TP53* mutations were correlated with worse PFS (median, both NR, p = 0.0417). Mutation profiles of 10 patients were derived from ctDNA testing. No difference was found in PFS between these 10 patients with others whose genomic profiles were based on fresh tissue or FFPE specimens, suggesting that plasma ctDNA serves as good specimen source for mutation profiling to monitor clinical treatment. **Conclusion:** Concurrent *TP53* mutation and presence of CNS metastasis are associated with decreased PFS of *ROS1*-positive patients treated with crizotinib.

Keywords: ROS1, TP53, crizotinib

P2.14-10 IDENTIFICATION OF FREQUENT, ACTIVATING HER2 MUTATIONS AND HER2 INHIBITOR RESPONSE AND RESISTANCE IN CANINE LUNG CANCER

G. Lorch[1], V. Zismann[2], N. Perdigones[2], T. Contente-Cuomo[2], A. Nazareno[2], S. Facista[2], S. Wong[2], W. Liang[2], J. Amann[1], S. Sinicropi-Yao[1], M. Koenig[1], K. La Perle[1], A. Lalani[3], I. Diala[3], L. Eli[3], T. Whitsett[2], J. Trent[2], M. Murtaza[2], D. Carbone[1], W. Hendricks[2]

[1]*The Ohio State University, Columbus/United States of America,* [2]*TGen, Phoenix/United States of America,* [3]*Puma Biotechnology, Inc., LA/United States of America*

Background: Naturally occurring primary canine lung cancers share clinical and pathologic features with human never-smoker lung cancer, but their genetic and biologic underpinnings have been unknown. We mapped the genomic landscape of canine lung cancer, discovering somatic HER2 (*ERBB2*) mutations in ~38% of canine pulmonary adenocarcinomas (cPACs). We describe our genomic findings, effects of HER2 mutations on cell signaling and HER2 inhibitor response/resistance, and results of pharmacokinetic (PK) studies of the HER2 inhibitor neratinib in healthy dogs. **Method:** We performed multi-platform genomic analysis of 92 primary canine lung tumors or cell lines. We evaluated HER2 signaling by Western blot. Neratinib and lapatinib responses were assessed in HER2-mutant and wild-type cPAC cell lines *in vitro*. HER2-mutant cell lines were continuously treated with IC50 neratinib doses to select for drug resistance, then evaluated for resistance mutations. Neratinib tolerability and PK were evaluated in healthy, mixed-breed, middle-aged dogs given a single 6 mg/kg oral neratinib dose with or without maropitant citrate or loperamide. Plasma samples for PK were collected pre-dose and timepoints from 0.5-24h after dosing. **Result:** Canine lung cancers exhibited low tumor mutation burden. HER2 was the most commonly mutated gene in cPACs, occurring in ~38%, but was absent from canine adenosquamous or squamous cell carcinomas. HER2 hotspot V659E transmembrane domain (TMD) mutations were most common and comparable to activating TMD mutations in human cancer. HER2 V659E correlated with constitutive phosphorylation of Akt in cPAC cell lines. HER2 V659E lines displayed hypersensitivity to neratinib and lapatinib relative to wild-type lines. Continuous treatment of HER2-mutant cell lines led to rapid development of resistance. Characterization of resistance-driving alterations is ongoing, as are efficacy studies in mouse xenografts. A dose of 6 mg/kg neratinib in healthy dogs showed that neratinib was tolerable and achieved therapeutic levels from IC50 studies. Evaluation of neratinib tolerability and efficacy in dogs bearing HER2-mutant lung cancer is ongoing. **Conclusion:** HER2 TMD mutations are common in otherwise low-mutation-burden primary canine lung cancers. They confer constitutive HER2 signaling and HER2 inhibitor response in cell lines. Dosing and tolerability studies in healthy dogs have shown that therapeutically relevant doses are achievable. Study of HER2 inhibitor response/resistance in cell lines and mouse xenografts is ongoing as is clinical evaluation of neratinib activity in dogs with spontaneous lung cancer. These data offer immediate diagnostic and therapeutic opportunities for pet dogs and bear implications for comparative understanding of human never-smoker lung cancers and other HER2-mutant cancers.

Background: Epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitor (TKI) is remarkably effective against non-small cell lung cancer (NSCLC) harboring *EGFR* activating mutation. However, tumors almost inevitably develop resistance approximately after one year of EGFR-TKI treatment. In addition, some patients can not tolerate an EGFR-TKI treatment because of adverse events and result in discontinuation of the treatment. In such cases, the same or other EGFR-TKI may be re-administered. However, its efficacy is not fully evaluated. **Method:** We retrospectively investigated patients who received EGFR-TKI between January 2008 and August 2017. Among these patients, the response rate and time to treatment failure (TTF) for each re-administered TKI were assessed. We assessed each TTF for patients who discontinued the prior EGFR-TKI because of progressive disease (PD group) and patients who discontinued TKI because of adverse events (AE group). We also evaluated the overall survival (OS) for the patients who received the retreatment with EGFR-TKI and who did not. **Result:** A total of 1400 patients from 11 institutions were enrolled in this study. Among them, 570 patients received retreatment with EGFR-TKI, and 541 were eligible. Among the 395 patients who discontinued prior EGFR-TKI because of disease progression, the response rate and the median TTF of subsequent Gefitinib/Erlotinib/Afatinib were 8%/8%/18%, and 4.9/3.2/4.3 months, respectively. The median TTF for the AE group was significantly longer than that for the PD group (10.8 months vs 3.8 months, p<0.0001). In the AE group, The OS for patients receiving retreatment with EGFR-TKI was significantly better than the OS for patients without retreatment (Hazard Ratio = 0.256, p < 0.0001). Similarly, in the PD group, the OS for patients receiving retreatment with EGFR-TKI was significantly better than the OS for patients without retreatment (Hazard Ratio = 0.456, p < 0.0001). **Conclusion:** Retreatment with EGFR-TKI was shown to be effective for both patients who discontinued prior EGFR-TKI because of disease progression as well as adverse events.

Background: Acquired resistance to osimertinib in epidermal growth factor receptor (*EGFR*)-mutated non-small cell lung cancer (NSCLC) is a poorly understood phenomenon and presents an ongoing challenge. Previously described mechanisms include emergence of mutations at *EGFR* C797S, *MET* amplification, transformation to small cell lung cancer, and *BRAF* mutation. Next-generation sequencing (NGS) of tumors at progression through osimertinib may help to illuminate novel mechanisms of resistance to osimertinib. **Method:** We surveyed University of Chicago Medicine case records for osimertinib-treated NSCLC patients treated who progressed through therapy. Panels utilized for NGS included, among others, the University of Chicago's validated panel (the UCM-OncoPlus, surveying greater than 1,100 genes) and Guardant (Guardant Health; Redwood City, CA). Patients were stratified according to presence of *EGFR* T790M mutation at the initiation of osimertinib therapy. **Result:** 28 patients were identified to have progressed through osimertinib. 23 patients (82.1%) had next-generation performed at the time of progression. Among osimertinib-resistant patients who had NGS, 17 (73.9%) demonstrated at least one resistance mechanism, of which 8 (34.8% of tested patients) were subsequently treated with tyrosine kinase inhibitor-containing regimens or clinical trial of targeted therapy. Mutational profile at progression through osimertinib included: 2 patients (11.8%) with *EGFR* C797 mutation, 2 patients (11.8%) with *MET* amplification, 2 patients (11.8%) with *RET* fusion protein, 2 patients (11.8%) with *MET* point mutation, 1 patient (5.9%) with *EGFR* amplification, and 1 patient (5.9%) with small cell transformation. Newly identified resistance mechanisms (n = 1 for each) included mutation to *EGFR* G724 and L718 residues, *ROS1* fusion protein, and in the same patient *CBLB* Q371* and *SMAD4* loss. Of the 23 patients undergoing NGS at progression, 11 (47.8%) harbored *EGFR* T790M mutations prior to treatment, 3 (27.3%) of whom demonstrated resistance mutations susceptible to additional tyrosine kinase inhibitor therapy. **Conclusion:** On the basis of these data, we confirm many previously described mechanisms of osimertinib resistance, including *EGFR* amplification, *MET* amplification, fusions involving *RET*, and transformation to small cell lung cancer, as well as novel resistance mechanisms including

ROS1 fusion protein. We demonstrate the utility of NGS at the time of progression through osimertinib in our practice, regardless of the patient's *EGFR* T790M status. We conclude that re-biopsy and utilization of NGS identifies a significant subset of osimertinib-resistant patients in whom well-tolerated tyrosine kinase inhibitor therapies remain an option and, in the interests of both patient well-being and clinical trial enrollment, should be considered standard practice at progression.

Background: The treatment with EGFR tyrosine kinase inhibitors (EGFR-TKIs), such as erlotinib, in patients with *EGFR*-mutant lung adenocarcinoma causes tumor regression and improved prognosis. However, drug resistance and tumor relapse eventually occur, and the molecular mechanisms remain to be fully revealed. In this study, we elucidated the novel mechanism of EGFR-TKI resistance and clarified the clinical significance using erlotinib-resistant lung adenocarcinoma cell lines and patient specimens. **Method:** The erlotinib-resistant cell line, PC9/ER was obtained from PC9 cell line by exposing to increasing concentrations of erlotinib for 6 months. The sensitivity of erlotinib was evaluated by the MTT assay. In order to identify erlotinib-resistance related factors, we performed a proteomics analysis, followed by western blotting. To evaluate the roles of the candidate factor, we performed gene knockdown analysis using siRNAs. The autophagy activity was assessed by the amount of LC3B-II protein or visualization of autophagosomes using LC3B-RFP expression vector. Immunohistochemical staining was performed on tumor biopsies obtained from lung adenocarcinoma patients with activating mutation in *EGFR*, and we examined the correlation between the staining intensity and clinical EGFR-TKI resistance. **Result:** Initially, we performed the sequencing analysis of *EGFR* exons 18 to 21, which cover the tyrosine kinase domain, and found that there was no difference between PC9 and PC9/ER cells. The proteomics analysis revealed ribosomal and translation-related proteins were abundantly identified in PC9/ER cells, compared with PC9 cells. Among them, we found that eukaryotic translation initiation factor 3 subunit C (eIF3c) was overexpressed in PC9/ER cells. The knockdown of eIF3c expression with siRNA improved the sensitivity of EGFR-TKI in PC9/ER cells. Additionally, we observed that LC3B-II increased in PC9/ER cells, but decreased by the knockdown of eIF3c. Consistently, the overexpression of eIF3c upregulated the number of autophagosomes. Moreover, the inhibition of autophagy with chloroquine attenuated erlotinib-resistance in PC9/ER cells. Finally, the frequency of eIF3c-positive samples was higher in biopsy specimens from the patients' refractory to EGFR-TKI therapy than in those from the patients prior to the treatment with EGFR-TKI. Furthermore, patients with eIF3c-positive tumors had shorter progression-free survival in EGFR-TKI treatment than eIF3c-negative patients. **Conclusion:** The increased eIF3c expression conferred the resistance to EGFR-TKI in lung adenocarcinoma cells via enhancement of autophagy. Moreover, the patients with increased eIF3c expression in biopsy samples showed poor prognosis. The inhibition of eIF3c could be a new therapeutic strategy for overcoming EGFR-TKI resistance in lung adenocarcinoma patients.

Background: The NRG1 (Neureguline-1) fusion gene has been recently described as a new molecular feature of non small cell lung cancer (NSCLC), strictly related to invasive mucinous adenocarcinoma (IMA) subtype. Despite of *NRG1* fusion partners, all Nrg1 chimeric ligands were predicted to retain the EGF-like domain of the wild-type NRG1 III-β3 isoform that produces oncogenic signals through ErbB2-ErbB3 heterodimers and leads to phosphorylation of ErbB3. To date, the *NRG1* fusions were quite exclusively identified by RNA sequencing and only in few cases confirmed by fluorescent in situ hybridization (FISH) analysis, mainly due to the cellular features of IMA subtypes that produce interference in fluorescent signals detection. An accurate detection of *NRG1* rearrangement/fusions in clinical tumor samples is actually demanded. In this study we compared the performance of two molecular testing approaches to detect *NRG1* breaks in paraffin embedded formalin fixed (FFPE) IMA lung tissues. **Method:** A total of 19 lung FFPE IMAs were screened by immunohistochemistry (IHC) to evaluate the expression of phosphorylated-ErbB3 (pErbB3) receptor. Samples positive for pErbB3 staining were tested by using by break-apart FISH to detect putative *NRG1* rearrangements and RNA-targeted next generation sequencing (NGS) to identify fusion variants. **Result:** Eleven cases showed an increased expression of pErbB3 in cancer cells compared to the adjacent non-involving bronchial epithelium which demonstrated a basal level staining of the protein. pErbB3 positive cases were investigated by FISH and showed <15% of rearranged nuclei (range 17-47%, mean 29%). In addition to the canonical signal split pattern, the FISH *NRG1* assay reveals that cells also showed rearrangement patterns in form of isolated 3' signals, thus indicating a strength analogy with *ALK* and *ROS1* fusions, where a 5' gene deletion was frequently observed. *CD74-NRG1* fusion variant was identified by NGS analysis in four cases, whereas in three cases a 3'/5' *NRG1* imbalance was detected. For both approaches, we identified assay characteristics that likely contributed to false-negative results. **Conclusion:** Our investigations confirm the usefulness of IHC/FISH combined approach for *NRG1* broken tumors identification, but also highlight the crucial role of NGS to identify NRG1 functional chimeric transcripts. Such combined molecular testing should enhance the selection of *NRG1*-positive patients to include in clinical trials with specific compounds designed to inhibit the RTK downstream signal.

P2.14-15 IMPACT OF COEXISTING GENE MUTATIONS IN EGFR-MUTATED NON–SMALL CELL LUNG CANCER BEFORE TREATMENT ON EGFR T790M MUTATION STATUS AFTER EGFR-TKIS

M. Takeda, K. Sakai, H. Hayashi, K. Tanaka, K. Haratani, T. Takahama, R. Kato, K. Yonesaka, K. Nishio, K. Nakagawa

Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Background: The T790M secondary mutation of epidermal growth factor receptor gene (*EGFR*) is the most common mechanism of acquired resistance to first- or second-generation EGFR tyrosine kinase inhibitors (TKIs). We investigated the association between gene mutation profile in *EGFR* mutation–positive non–small cell lung cancer (NSCLC) before EGFR-TKI treatment and T790M status after treatment. **Method:** A total of 57 *EGFR* mutation–positive NSCLC patients who had undergone a repeat biopsy (tissue or liquid) after failure of treatment with a first- or second-generation EGFR-TKI and who had sufficient tumor tissue available from before treatment for genetic analysis was enrolled. The gene mutation profile of tumor tissue obtained before EGFR-TKI treatment was evaluated by next-generation sequencing with a comprehensive cancer gene panel (409 genes). The number of potentially damaging

nonsynonymous mutations was predicted with PolyPhen-2 software. **Result:** Progression-free survival during EGFR-TKI treatment did not differ significantly between patients who developed T790M-mediated resistance and those who developed T790M-independent resistance. The predicted number of damaging nonsynonymous mutations in pretreatment tumor tissue was significantly lower in patients who developed T790M-mediated resistance than in those with T790M-independent resistance (P = 0.024). **Conclusion:** Coexisting mutations in tumor tissue before EGFR-TKI treatment may contribute to the emergence of cell clones responsible for development of T790M-dependent or T790M-independent TKI resistance in patients with *EGFR*-mutated NSCLC. Multiplex genomic testing of pretreatment tumor tissue may thus provide a means of identifying patients likely to develop T790M-mediated TKI resistance and therefore inform treatment selection.

P2.14-16 T790M OR C797S CONFERS ACQUIRED RESISTANCE TO TARLOXOTINIB AND POZIOTINIB IN EGFR EXON 20 INSERTION-DRIVEN LUNG CANCER MODELS IN VITRO

K. Suda[1], M. Nishino[1], T. Koga[1], T. Fujino[1], S. Ohara[1], J. Soh[1], A. Vellanki[2], V. Tirunagaru[2], T. Misudomi[1]

[1]*Kindai University Faculty of Medicine, Osaka-Sayama/Japan,* [2]*Rain Therapeutics, Newark/United States of America*

Background: Lung cancers with EGFR exon 20 insertion mutations are refractory to current available tyrosine kinase inhibitors. Recent evidence suggests the therapeutic potential of the novel hypoxia-activated prodrug, tarloxotinib, a potent pan-HER inhibitor, or the repurposed 3rd generation inhibitor, poziotinib in these tumors. However, it is assumed that acquired resistance to these agents will be inevitable. In this study, we explored secondary mutations that may confer resistance to these agents using Ba/F3 models. **Method:** Ba/F3 cells with various EGFR exon 20 mutations (A763insFQEA, V769insASV, D770insSVD, and H773insNPH) were generated by retroviral transfection. TKI resistant clones were established by exposure of parental cells to either tarloxotinib-E (active form of tarloxotinib) or poziotinib after treatment with N-ethyl-N-nitrosourea (ENU) mutagenesis agent. *EGFR* secondary mutations were detected by direct sequencing. **Result:** ENU mutagenesis resulted in 62 tarloxotinib-E-resistant clones and 56 poziotinib-resistant clones using 200 nM of either drug. Ba/F3 cells with A763insFQEA were highly sensitive to these agents and only 1 tarloxotinib-resistant clone (C797S) was obtained. In Ba/F3 cells with V769insASV, all 14 tarloxotinib-resistant clones and 15 poziotinib-resistant clones developed T790M mutation. In Ba/F3 cells with D770insSVD cells, all 24 tarloxotinib-resistant clones and 20 poziotinib-resistant clones developed C797S mutation. In Ba/F3 cells with H773insNPH cells, 22 of 23 tarloxotinib-resistant clones and 21 of 22 poziotinib-resistant clones developed T790M mutation, while the rest of the clones harbored C797S mutation. **Conclusion:** These results suggested that either T790M or C797S could cause acquired resistance to tarloxotinib and poziotinib in lung cancer models with EGFR exon 20 insertion mutations. Interestingly, the type of resistance mutation is likely to be dependent on the context of the original EGFR exon 20 insertion mutation.

Keywords: EGFR-TKI, secondary mutations, prodrug

P2.14-17 CORRELATION BETWEEN CLINIC-PATHOLOGICAL DATA AND T790M DETECTION IN EGFR MUTATED NSCLC PATIENTS PROGRESSING ON 1ST/2ND GENERATION TKIS

D. Pignataro, M. Tagliamento, M.L. Reale, F. Tabbò, M. Bungaro, C. Paratore, V. Cetoretta, M. De Filippis, V. Bertaglia, F. Passiglia, L. Righi, P. Bironzo, S. Novello

University of Turin; San Luigi Gonzaga Hospital, Orbassano/Italy

Background: Despite osimertinib is moving to the first-line for advanced NSCLC harboring EGFR activating mutations, some patients still receive a frontline first- or second-generation EGFR-TKI. In this setting, factors predicting the emergence of T790M resistance mutation at progression (PD) are lacking. The aim of this retrospective study was to investigate the correlations between clinic-pathological features and T790M positivity (T790M+) in a single-center cohort of EGFR mutated stage IV or recurrent NSCLC patients, who underwent liquid (LB) or tissue biopsy (TB) at PD when treated with first- or second-generation EGFR-TKIs. **Method:** Data from 122 patients (80 female, 42 male) treated between 2012 and 2019 were considered for the analysis. EGFR mutations were detected with real time-polymerase chain reaction (RT-PCR) on LB and pyrosequencing or next generation sequencing on TB. PD was determined by RECIST 1.1 criteria. Univariate analysis by Fisher exact test was performed to assess any association. **Result:** At diagnosis, 117 patients carried common EGFR mutations (84 exon 19 deletions; 33 exon 21 mutations), 5 had rare mutations (3 exon 18 mutations; 2 exon 20 mutations other than T790M) . At PD, 29 patients (24%) underwent only LB, 29 only TB (24%), 64 both (52%). The overall T790M+ rate was 67% (82/122). T790M+ was significantly higher among patients with exon 19 deletion than in those with exon 21 mutation (77% vs 51%, p=0.008). T790M+ was significantly more frequent in patients with exclusively intrathoracic PD as compared to extrathoracic PD (81% vs 56%, p=0.007). Patients with pleural involvement (PI), considered as pleural effusion or/and pleural disease, as site of PD (n=45) had a significantly higher frequency of T790M+ than those with stable or absent PI (n=77) (82% vs 58%, p=0.009), irrespectively of the pattern of PD. No correlation with other sites of PD was found. **Conclusion:** Exon 19 deletion, intrathoracic PD and PI as site of PD are significantly associated with higher frequency of T790M+ in patients progressing to first-or second-generationEGFR-TKIs. These results, if confirmed by an independent validation cohort, may allow the development of a T790M+ predictive score accounting for type of mutation and sites of progression.

Keywords: NSCLC EGFR mutated, T790M detection, clinic-pathological data and T790M correlation

P2.14-18 UPREGULATION OF AURKA LEADS TO ACQUIRED RESISTANCE IN EML4-ALK NSCLC CELL LINE

G. Umapathy, R. Palmer, B. Hallberg

Institute of Biomedicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg/Sweden

Background: Molecular targeted therapies in NSCLC often results in profound initial patient responses, these responses are short-term due to the development of acquired resistance. In an EML4-ALK NSCLC background, acquired resistance can be developed in two ways ALK dependent (ALK secondary mutations) and ALK independent (alternative oncogenic pathways). In our study, we have shown that increased expression of Aurora kinase A (AURKA) leads to acquired resistance upon treatment with ALK TKI crizotinib. **Method:** In order to determine the mechanism for acquired resistance, we treated the EML4-ALK NSCLC cell line H2228 with increasing dose of crizotinib until cells develop resistance. RNA sequencing was performed in both parental and resistant cell lines to identify differentially expressed genes. Resazurin assay was performed to evaluate cell viability. Protein levels were determined using western blotting. **Result:** In this study, we describe the upregulation of AURKA gene expression leads to acquired resistance in EML4-ALK cell line H2228. The R2: genomics analysis and visualization platform (http://r2.amc.nl) revealed that high *AURKA* expression is associated with poor prognosis in lung adenocarcinoma patients. Based on RNA seq data, we identify upregulation of AURKA in crizotinib resistance cell line when compared to the parental cell line. The resistant cell lines were sensitive to treatment with AURKA inhibitor MLN8237 and underwent apoptosis. **Conclusion:** Our results indicate a new mechanism to acquire resistance upon treatment with ALK TKI crizotinib. Inhibition of both ALK and AURKA activity might be beneficial for ALK TKI resistant tumors with increased AURKA gene expression/activity.

Keyword: EML4-ALK, AURKA, Resistance

P2.14-19 NOTCH3 AND β-CATENIN ARE FREQUENTLY CO-EXPRESSED IN EGFR MUTANT NSCLC

R.R. Arasada, S. Suman, W. Wang, D. Carbone

The Ohio State University, Columbus/United States of America

Background: In the USA approximately 15% of the patients with lung adenocarcinoma have tumors associated with “driver” mutations in the EGFR gene that demonstrate major clinical responses to EGFR

Tyrosine Kinase Inhibitors (EGFR TKIs). However, despite the fact that these mutations are always "truncal" (present in every tumor cell), and dramatic tumor shrinkage is seen initially in almost all patients, EGFR TKIs are never curative and tumors always recur. Some tumors that develop resistance appear to have pre-existing resistant sub clones, but the majority appear to acquire resistance by mutational target reactivation or bypass mechanisms. In order to develop acquired resistance, a subset of cells must survive at initial stage of therapy ("drug persister cells", or DPCs) which are known to serve as a reservoir for accumulation mutation rendering drug resistance. We have demonstrated that Notch3 mediated β-catenin activation enables drug persistence, an essential step for the development of drug resistance. **Method:** We have conducted tumor protein expression analysis on a tissue micro array (TMA) containing 86 NSCLC tumors obtained before therapy. These TMAs were subjected to IHC analysis to detect the expression of Notch3 and β-catenin signaling which is known to regulate drug persistence. We have also performed cell viability and biochemical assays under various perturbations to study drug persistence mechanisms in EGFR mutant NSCLC cells. **Result:** Previously, we have demonstrated that EGFR TKI treatment leads to drug persistence through Notch3 mediated β-catenin activation. Using pre-treatment NSCLC patient tissue micro array (TMA) we identified that there is frequent co-expression of Notch3 and β-catenin (total) proteins in 90% of EGFR mutant NSCLC. We also observed that there are a relatively low proportion (10%) of patients with active β-catenin in these pretreatment samples. This suggests that the EGFR mutant tumors upregulate Notch3 protein expression, but that β-catenin is predominantly transcriptionally inactive before EGFR TKI treatment. We have also identified that Notch3 is a novel transcriptional target of β-catenin which in turn promotes both β-catenin and EGFR stability. These findings suggest that the Notch3 and inactive β-catenin co-expression is characteristic of EGFR mutant tumors, and β-catenin activation at baseline is infrequent. EGFR TKI therapy activates β-catenin signaling in a Notch3 dependent manner, and here we show that both proteins are frequently highly expressed in these tumors. **Conclusion:** The concept of DPCs serving as a reservoir for accumulation of mutations that could cause drug resistance is novel. However, signaling pathways that are associated with the activation of drug persistence are not well characterized. For the first-time, our studies demonstrate that Notch3, β-catenin andEGFR regulate each other and EGFR TKI therapy mediated Notch3 activation leads to β-catenin activation which is essential for the maintenance of drug persister cells in a positive feedback loop. By understanding and targeting the Notch3 - β-catenin axis that control DPCs, these studies can develop therapeutics to prevent resistance to EGFR TKI therapy.

Background: Dacomitinib is a second generation EGFR tyrosine kinase inhibitor (TKI) with irreversible pan-HER inhibitory activity. In the phase III ARCHER 1050 trial, median PFS was improved from 9.2 months to 14.7 months in the gefitinib and dacomitinib groups respectively. Significantly, median overall survival (OS) was also improved from 26.8 months to 34.1 months. However, dacomitinib commenced at 45 mg orally daily was associated with increased toxicity, higher rates of dose reductions and treatment discontinuation. Despite this, post-hoc analysis revealed the efficacy of dacomitinib (PFS and OS) was similar in dose-reduced patients and the overall study population. This investigator-initiated trial aims to evaluate an alternative dose titration strategy to improve the safety and tolerability of dacomitinib while maintaining treatment efficacy. The trial is being conducted by the Asian Thoracic Oncology Research Group (ATORG) – a co-operative lung cancer trials group in Asia. **Method:** ATORG-003 is a multi-national, multi-centre, single-arm, open-label, phase 2 clinical trial of dacomitinib in newly diagnosed stage IIIB/IV or recurrent EGFR mutant (exon 19 deletion or L858R mutation) NSCLC patients. Importantly, subjects with asymptomatic central nervous system (CNS) metastases will be eligible. Patients will be administered dacomitinib 30 mg orally daily for one cycle (4 weeks), after which subjects with ≤G1 toxicity attributable to dacomitinib may escalate to 45 mg with shared investigator and patient decision. Dose reductions to 30 or 15 mg daily will be permitted. The primary objective is to evaluate PFS rate at 12 months. Key secondary objectives include OS, objective response rate (ORR), time to treatment failure (TTF) and intracranial objective response rate (iORR). Exploratory objectives include evaluation of dacomitinib resistance mechanism(s) using next-generation sequencing (NGS) on tissue and plasma circulating tumour DNA (ctDNA). Across 15 sites in six Asian countries (Hong Kong, Korea, Malaysia, Singapore, Taiwan, Thailand), a planned 118 subjects will be enrolled. Primary analysis will be conducted on subjects without CNS metastases only, with 94 subjects required to achieve a one-sided significance level of 5% and 90% power to detect a 15% improvement in 12 month PFS rate for dacomitinib versus historical control for gefitinib (i.e. 55% versus 40%) using the intent-to-treat (ITT) analysis population. Enrollment is due to begin in July 2019. **Result:** Section not applicable. **Conclusion:** Section not applicable.

P2.14-21 LIQUID BIOPSY IN LUNG CANCER: COMPARISON BETWEEN REAL-TIME PCR AND MALDI-TOF FOR CTDNA MOLECULAR PROFILING

P.-J. Lamy[1], N. Lozano[1], L. Gambier[1], C. Ilardo[1], C. Alix-Panabières[2]

[1]*Institut d'Analyse Genomique, Montpellier/France,* [2]*University Medical Centre of Montpellier, EA2415, Montpellier/France*

Background: Circulating cell free DNA (cfDNA) could now be used for lung cancer molecular testing when tissue is limited and/or insufficient. Tests' sensitivity and mutation coverage could have a great implication for the patient care. In this study we analyzed and compared results of cfDNA from lung carcinoma patients tested with different technologies. **Method:** 100 cfDNA samples were extracted from blood plasma (Qiagen), DNA quality and quantity were assessed using the LabChip GX Touch 24 (PerkinElmer). We used PCR based Cobas® EGFR Mutation Test v2 (Roche) that identifies 42 mutations in the EGFR gene and UltraSEEK™ Lung Panel on MALDI-TOF based MassARRAY® (Agena Bioscience): 67 mutations in 5 oncogenes: EGFR (43), BRAF (4), ERBB2 (2), KRAS (14) and PIK3CA (4) with a sensitivity down to 0.1%. For UltraSEEK we used 11-40 µl cfDNA (avg. 8.87 ng). For Cobas we initially used 70 µl (avg. 24.39 ng) and re-tested a subset (63 samples) with lower input volumes as were used for UltraSEEK. **Result:** All samples showed the expected fragment-size distribution and no significant abundance of genomic DNA on the LabChip. With high cfDNA input on Cobas we detected EGFR activating mutations in 60 patients with Cobas and in 57 with UltraSEEK and 16 and 18 EGFR T790M with Cobas and UltraSEEK, respectively. In addition, with the UltraSEEK Lung Panel 9*KRAS and 2*BRAF V600E were identified and one more double mutations (G719A/L861QR). For the subset of 63 samples with the same cfDNA input between technologies 4 (6%) were invalid for analysis on Cobas. None were invalid with USK. 85% of patients (50/59) had concordant results for overlapping markers in EGFR. The EGFR T790M mutation was detected in 7 and 10 samples with Cobas and UltraSEEK, respectively (70% concordance). In total, with UltraSEEK 10 additional EGFR mutations (4*Exon 19 deletion, 3*T790M, 1*Exon 20 insertion, 1*L861Q/R, 1*G917A) were detected in 8 of 59 patients (14%). Conversely, 1 EGFR Exon 19 deletion (2%) was detected by Cobas (wild-type in initial analysis by Cobas). The UltraSEEK Lung Panel identified 7 non-EGFR mutations (6*KRAS, BRAF) in 6 patients (10%). **Conclusion:** This study showed that the MassARRAY UltraSEEK Lung Panel improved sensitivity for ctDNA analysis especially for samples with low input in comparison to Cobas EGFR Mutation Test v2, a method widely used in clinical routine. The UltraSEEK Lung Panel could detect more EGFR primary or secondary resistance mutations. Additional mutations to EGFR (KRAS, BRAF) could also be detected in ctDNA and used as guidance for therapy.

P2.14-22 LOSS OF ECT2 EXPRESSION IMPAIRS CELL-MATRIX ADHESION AND FAK/SRC SIGNALING IN LUNG ADENOCARCINOMA CELLS

Z. Kosibaty[1], Y. Murata[1], Y. Minami[2], M. Noguchi[1]

[1]*Department of Pathology, Faculty of Medicine, University of Tsukuba, Ibaraki/Japan,* [2]*Department of Pathology, National Hospital Organization, Ibaraki Higashi National Hospital, Ibaraki/Japan*

Background: Cell adhesion is a crucial step in cancer development and progression. We have previously demonstrated that epithelial cell transforming sequence 2 (Ect2), a guanine nucleotide exchange factor for the Rho family small GTPases Rac1, RhoA, and Cdc42, is overexpressed in early invasive adenocarcinoma. We subsequently showed that suppression of Ect2 significantly reduces cell growth, migration, and invasion of lung adenocarcinoma cells. In the present study, we investigated the potential role of Ect2 on cell-matrix adhesion and adhesion signaling complex in lung adenocarcinoma. **Method:** Cell attachment assay was used to assess the viability of attached Calu-3 and PC-9 cells after suppression of Ect2 using small interfering RNA (siRNA). Adhesion of cells to extracellular matrix (ECM) was examined by adhesion assay, and changes in cell morphology were observed by immunofluorescence. RT-PCR and Western blotting analysis were conducted to examine the effects of Ect2 suppression on molecules involved in the adhesion cascade in Calu-3 and NCI-H2342 cells. To evaluate the effect of Ect2 on adhesion complex formation, immunoprecipitation was performed after treatment with siRNA-Ect2 in Calu-3 cells. **Result:** We found that suppression of Ect2 significantly reduced the viability of attached cells. Furthermore, PC-9 and Calu-3 cells transfected with siRNA-Ect2 showed markedly decreased adhesion to collagen I and fibronectin. In terms of morphological changes, Calu-3 and PC-9 cells showed non-cohesive growth and a clear rounded shape after siRNA-Ect2 treatment. To investigate the underlying molecular mechanism, we examined the levels of expression of several proteins that are directly associated with cancer cell adhesion. We found that focal adhesion kinase (FAK), a key regulator of cell adhesion, was markedly down-regulated at both the mRNA and protein levels after treatment of the lung adenocarcinoma cells with siRNA-Ect2. Consistently, the levels of expression of molecules involved in the adhesion cascade, including integrin β1, paxillin, p-Src (Tyr416), p130Cas, and Crk, were further decreased in siRNA-Ect2. Since FAK/Src signaling can be activated through interaction the adhesion molecules on the cell surface, we speculate that these interactions might be affected by Ect2. Our data showed that Ect2 suppression impairs FAK interaction with Src, integrin β1, and paxillin in lung adenocarcinoma cells. **Conclusion:** We have obtained novel data suggesting that Ect2 suppression leads to attenuation of cell adhesion to ECM, with a consequent impact on adhesion complex formation. These findings further demonstrate that Ect2 plays an essential role in the pathological steps of lung adenocarcinoma progression, and could be a potential molecular target for therapy.

P2.14-23 INITIAL ANALYSIS IN NSCLC PART OF RANDOMIZED TRIAL EVALUATING TOPICAL CORTICOSTEROID FOR THE FACIAL ACNEIFORM RASH BY EGFR INHIBITORS

Y. Fujiwara[1], K. Nishino[2], M. Tamiya[2], K. Kikuchi[3], R. Saito[3], T. Kobayashi[4], T. Hamaguchi[5], K. Nozawa[1], H. Fukuda[1], Y. Kiyohara[6], N. Yamazaki[1]

Background: Epidermal growth factor receptor (EGFR) inhibitors commonly induce skin toxicities including facial acneiform rash. The incidence of facial acneiform rash with any grade estimetes 60-90% in previous clinical trials. This FAEISS study, NCCH1512, is designed to evaluate the effects of reactive topical corticosteroid therapies with serially ranking down from very strong levels compared with that with serially ranking up from weak levels for facial acneiform rash induced by EGFR inhibitors. **Method:** Patients with EGFR-mutated non-small cell lung cancer (NSCLC) and RAS wild-type colorectal cancer who started treatment with EGFR inhibitors were enrolled first in this study (first-phase). All patients received pre-emptive therapy of oral minocycline 100 mg/day and heparinoid moisturizer from the initiation of EGFR inhibitors. Enrolled patients who developed facial acneiform rash within two weeks were randomised either to group A (ranking-up) and group B (ranking-down) (second-phase) by minimization method for balancing institution, type of EGFR inhibitors, and sex. Primary endpoint in this study was incidence of grade 2 (moderate) or higher facial acneiform rash during the 10-week skin treatment period. Here, we present the initial analysis in NSCLC patients who received EGFR tyrosine kinase inhibitors of afatinib and erlotinib. This study was registered with UMIN-CTR as UMIN000024113 (www.umin.ac.jp/ctr/). **Result:** From November 2016 to August 2018, 51 NSCLC patients treated with afatinib (n=30) and erlotinib (n=21) were enrolled in first-phase. Thirty four patients were female and 17 were male, with a median age of 66 years (range 39-79). Thirty five patients (68.6%) didn't develop facial acneiform rash within two weeks. While facial acneiform rash occurred in 16 patients (grade 1 [n=14, 27.4%] and grade 2 [n=2, 3.9%]). No patients developed severe facial acneiform rash (grade 3 or higher). Nine (30.0%) patients who received afatinib and seven (33.3%) who received erlotinib developed facial acneiform rash within two weeks. One patient treated with erlotinib was excluded due to hepatotoxicity by minocycline and 15 (29.4%) were assigned to second-phase (9 in group A and 6 in group B). Skin adverse events in second-phase (n=15) were non-facial acneiform rash (n=14), pruritus (n=8), paronychia (n=5), and dry skin (n=3). Major non-skin adverse events related to EGFR inhibitors were diarrhea (grade 3 [n=2]), ALT increased (grade 2 [n=2]), stomatitis (grade 3 [n=1]), and pneumonitis (grade 1 [n=1]). **Conclusion:** In NSCLC patients who received EGFR tyrosine kinase inhibitors, pre-emptive therapy of oral minocycline and heparinoid moisturizer could be effective for prevention of facial acneiform rash.

Lee Moffitt Cancer Center, Tampa/United States of America,* [11]*Indiana University, Indianapolis/United States of America*

Background: Osimertinib, a third-generation EGFR inhibitor, has become the first-line therapy for patients with metastatic EGFR-mutant NSCLCs since 2018. Osimertinib is well-tolerated, therefore, it opens opportunities to be combined with other therapeutic agents to enhance the treatment outcome. In preclinical models, it has been shown that upregulated VEGF signaling mediates acquired resistance to EGFR therapies. In xenograft models, combination of anti-VEGF medications with EGFR inhibitors were significantly more effective than erlotinib or gefitinib alone. Ramucirumab, a monoclonal antibody targeting VEGF receptor 2, is approved with docetaxel in as second line treatment for NSCLCs. In clinical trial evaluations, the phase 3 RELAY trial (NCT02411448) studying ramucirumab plus erlotinib in patients with metastatic untreated EGFR-mutant NSCLC patients showed a statistically significant improvement in progression-free survival in the combination group compared to erlotinib alone. A phase I study of osimertinib with ramucirumab (NCT02789345) demonstrated safety and feasibility of this combination. With strong preclinical and clinical evidence showing dual inhibition of VEGF/EGFR signaling prolongs progression-free survival for EGFR-mutant lung cancers, and demonstrated safety, we are conducting a phase 2 trial to evaluate the osimertinib ramucirumab combination's efficacy in treatment-naïve EGFR-mutant NSCLC. **Method:** The OSI+RAM trial is a randomized phase 2 study with the primary endpoint being progression-free survival in osi+ram group as compared to osimertinib monotherapy group. The major inclusion criteria include patients with metastatic NSCLC harboring EGFR mutations (L858R/Exon 19 del). The major exclusion criteria include prior anti-EGFR or anti-

VEGF treatments. Patients with stable CNS metastasis are allowed. Based on the results from erlotinib bevacizumab (NEJ026) study, we expect an improvement of PFS from 18.9 months to 29.7 months, corresponding to a hazard ratio of 0.65. The trial plans to enroll total of 150 patients, with 100 allocating to osi+ram arm and 50 to osimertinib monotherapy. Total of 9 study sites in the USA are planned. Hoosier Cancer Research Network will facilitate the execution of the trial. The trial protocol has received IND exemption from US FDA and has been approved by IRB at MD Anderson Cancer Center. The first subject is expected to be enrolled in May 2019. A planned interim analysis will be performed after the first 75 subjects are enrolled. NCT03909334. **Result:** Section not applicable **Conclusion:** Section not applicable

P2.14-25 LORLATINIB INDUCED PROTECTIVE AUTOPHAGY VIA THE AKT–MTOR PATHWAY IN ALK-REARRANGEMENT LUNG CANCER CELLS

C. Lu, L. Li, H. Rui, C. Lin, S. Hao, C. Hu, Y. Wang, H. Chen, H. Yong

Daping Hospital of Army Medical University, PLA, Chongqing/China

Background: Lorlatinib, also known as PF-6463922, is a third-generation anaplastic lymphoma kinase (ALK) tyrosine kinase inhibitor that had been approved clinic treatment with patients who failed previous ALK inhibitors. However, the growth inhibitory effects of Lorlatinib on NSCLC and the underlying mechanism. **Method:** The growth inhibitory effects of Lorlatinib were investigated in H3122 and H2228 cell lines. Cell death and proliferation were assessed with MTT and Colony formation assay. Flow cytometry assays was performed to study the cell apoptosis. Cyto-ID® immunofluorescence staining was performed to study the cell autophagy. Signaling transduction was demonstrated with western blot. **Result:** We observed that Lorlatinib induces cytotoxicity in H3122 and H2228 cells. trigger autophagy in both H3122 and H2228 cells by increasing the expression of phosphatidylethanolamine-modified microtubule-associated protein light-chain 3 (LC3) and decreasing the expression of p62, still can trigger apoptosis by increasing the expression of B cell lymphoma 2 interacting mediator of cell death (Bim). In the presence of the autophagy blocker (chloroquine) and autophagy enhancer (rapamycin), enhanced the cytotoxicity of Lorlatinib and the Lorlatinib -induced increase in Bim was further augmented. The levels of total and phosphorylated ALK can decrease by Lorlatinib. Lorlatinib inhibited the phosphorylation of AKT and the main autophagy repressor mammalian target of rapamycin (mTOR), pharmacological inhibition of AKT by MK-2206 enhanced Lorlatinib-induced cell death, and it increased LC3 and Bim level. **Conclusion:** We demonstrated that the growth inhibitory effects of Lorlatinib on NSCLC via induced autophagy and apoptosis through AKT/ mTOR signaling pathway, and Pharmacological Intervention of Lorlatinib -induced Autophagy Enhances the Cytotoxicity of Lorlatinib. Our findings provided preliminary data for therapeutic strategies to enhance Lorlatinib efficacy in NSCLC patients.

P2.14-26 OUTCOMES IN PATIENTS WITH COMPOUND EPIDERMAL GROWTH FACTOR RECEPTOR (EGFR) MUTATIONS AFTER TREATMENT WITH TYROSINE KINASE INHIBITORS (TKIS)

S. Breslin, J. Thompson, J. Morrissette, C. Ciunci, A. Singh, C. Aggarwal, R. Cohen, C. Langer, J. Bauml, M. Marmarelis

University of Pennsylvania, Philadelphia/United States of America

Background: TKIs targeting EGFR have changed the therapeutic paradigm for patients (pts) with non-small cell lung cancer (NSCLC) harboring classic sensitizing mutations in *EGFR (L858R and Exon 19del).* Less is known about the efficacy of TKIs when a sensitizing mutation is co-existent with another, not resistance-associated EGFR mutation (compound *EGFR* mutations). We report the outcomes of pts with *de novo* compound *EGFR* mutations treated with TKIs. **Method:** We identified pts with compound *EGFR* mutated NSCLC (plasma or tissue detection) treated at a single center. All disease-associated EGFR mutations were included with the exception of T790M and C797S. Time to treatment failure (TTF) was calculated from the start of TKI therapy until treatment discontinuation for any reason (i.e. disease progression, toxicity, pt choice or death). Overall survival (OS) was calculated from the start of TKI until death. Median OS (mOS) and TTF (mTTF) were estimated from Kaplan-Meier curves. **Result:** 24 pts with compound *EGFR* mutations were identified (median age 60, 67% female, 29% never smokers) between 2011 and 2018 (Table 1). Of the 16 (67%) who received a TKI, the most common mutation was G719X (n=9). Exon 19 deletions (del) were present in 2 patients (1 with G719X). L858R was found in 5 patients. Of the 8 pts who did not receive a TKI, 4 had early stage NSCLC that never progressed, 2 had local recurrence treated with surgery/radiation and 2 had metastatic recurrence. Among those treated with a TKI, the mTTF was 13.6 months (mo) and mOS was 32.7 mo. There was no difference in mTTF between erlotinib (n=10) and afatinib (n=6) (13.6 vs. 8.8 mo, log rank p=0.67). Median follow up was 33 mo. In 7 pts who had both baseline tissue and plasma testing, plasma detected all non-classic mutations. **Conclusion:** The mOS and mTTF in this cohort of pts with compound EGFR mutations compare favorably to the historical progression free survival and mOS for pts with classic sensitizing mutations in *EGFR* treated with erlotinib or afatinib. Table 1: Compound EGFR mutations (n=24)

P2.14-27 EFFICACY AND PROGNOSTIC FACTOR OF APATINIB PLUS EGFR-TKI IN TREATING ADVANCED NON-SMALL-CELL LUNG CANCER WITH EGFR-TKI RESISTANCE

G. Dong

Tangshan People's Hospital, Tangshan/China

Background: Treatment failure frequently occurs in patients with epidermal growth factor receptor (EGFR)-mutant non-small cell lung cancer (NSCLC) who respond to EGFR-TKIs initially. Apatinib is an oral TKI against VEGFR-2 and is effective as third- or later-line treatment in advanced NSCLC. EGFR and VEGF/VEGFR pathways are interrelated. We conducted this study to investigate the efficacy and safety of apatinib plus EGFR-TKI as second-line treatment in patients with advanced NSCLC. **Method:** From August 2017 to December 2018, 23 patients of advanced NSCLC acquired resistance for EGFR-TKI (gefitinib 250mg qd:erlotinib 150mg qd:icotinib 125 mg, bid) treated with original targeted drugs plus Apatinib (250 mg, qd, orally). Treatment was continued until disease progression or unacceptable toxic effects. **Result:** In 23 patients, there were 17 patients available for efficacy and safety evaluation. the objective response rate (ORR) was 17.6 % and the disease control rate (DCR) was 82.4 %. The median progression-free survival (PFS) was 8.0 months, patients with and without hypertension was 6.8 months and 4.1 months, respectively. The median overall survival had not reached. The most frequent treatment-related adverse events were hypertension (64.7 %, 11/17), hand-foot syndromes (29.4 %, 5/17) and fatigue (11.8 %, 2/17). **Conclusion:** Apatinib plus EGFR-TKI is efficacious in treating patients with advanced NSCLC after EGFR-TKI treatment failure, with acceptable toxic effects. Hypertension could be an effective prognostic factor for in apatinib-treated NSCLC patients.

P2.14-28 REAL-WORLD MANAGEMENT AND OUTCOMES OF UNCOMMON EGFR MUTATION-POSITIVE NSCLC PATIENTS AT TWO TERTIARY CANADIAN CANCER CENTRES

R. Tudor, A. Gibson, F. Hao, M. Dean, K. Kopciuk, D. Bebb

University of Calgary, Calgary/Canada

Background: The evolution of targeted therapies has transformed the management of *EGFR*–mutation positive NSCLC patients, especially for those with exon 19 deletion and exon 21 (L858R). However, uncommon *EGFR*-mutation carriers represent a unique group with differential sensitivities and dynamic responses to treatment. We aimed to analyze the demographic profile, management patterns and outcome of these patients. **Method:** Data were extracted from the institutional Glans-Look Lung Cancer database. Adult patients diagnosed with uncommon *EGFR* mutation(s) and treated in the palliative setting during 2010-2017 were included. Demographics and clinical characteristics were reviewed retrospectively (Table 1). **Result:**

Table 1. Demographic and clinical profile (n=38)

Variable	No	(%)
Age, years		
Median	72.7	
Range	50.2 - 88.3	
Sex		
Female	24	(63.2%)

Uncommon *EGFR* mutations were observed in 38 patients, comprising approximately 10% of all *EGFR*mut+ NSCLC patients (348) diagnosed and treated in Alberta, Canada (2010-2017). Of the total 38 patients, 63% were female, 60% had a smoking history, and 75% were Canada-born. Dual/-triple mutation positivity was found in 40% of patients. 4/38 patients expired prior to receiving any form of palliative treatment. Upon classifying patients as per TKI treatment, it was found that most received gefitinib (67%) as first line systemic palliative treatment (Table 2). Median OS of the entire cohort was 15.1 months; meanwhile those with complex double/-triple mutations experienced longer mOS of 24.9months vs 11.8months for single uncommon carriers. **Conclusion:** This Canadian study supports that uncommon *EGFR* mutation carriers are infrequent in clinical lung cancer practice. Of note, they represent a unique sub-population amongst *EGFR*mut+ NSCLC patients, and experience differential sensitivity and varied responses to treatment. We observed favorable responses to *EGFR*-TKIs in patients with double/-triple uncommon mutations, supporting that these patients may benefit from *EGFR*-TKIs.

Keywords: uncommon EGFR mutation, Target therapy, EGFR TKI

P2.14-29 CLINICAL IMPACT OF NEXT-GENERATION SEQUENCING (NGS) IN BLOOD LIQUID BIOPSIES FOR TREATMENT DECISIONS IN ADVANCED NSCLC

M. Garcia Pardo[1], I. Martinez Delfrade[1], I. Aparicio Salcedo[1], M. Arregui Valles[1], M. Alva Bianchi[1], V. Tirado Anula[1], R. Alvarez[2], A. Calles Blanco[3]

[1]*Hospital General Universitario Gregorio Marañon, Madrid/Spain,* [2]*Hospital Universitario Gregorio Marañon, Madrid/Spain,* [3]*Hospital General Universitario Gregorio Marañon, Madrid/Spain*

Background: Blood-based NGS is emerging as either complementary or alternative to standard tissue genotyping in metastatic non-small-cell lung cancer (NSCLC). In cases where tissue is not enough to complete standard EGFR, ALK, and ROS1 testing, or when patients are tested as triple-negative for these genetic alterations, additional tumor genotyping can lead to the detection of further actionable mutations. Moreover, NGS provides valuable genomic information that could be used to select for immunotherapy in metastatic NSCLC. We aimed to describe the molecular findings obtained by liquid biopsy of a cohort of advanced NSCLC patients with unknown/negative EGFR, ALK and ROS1 and how the results modified treatment decisions. **Method:** We performed a retrospective study of advanced NSCLC patients that were analyzed with NGS as part of a molecular pre-screening for clinicals trials in our institution in Madrid (Spain) between October 2016 and March 2019. Patients >18 years-old, PS ECOG 0-2, stage IIIC-IV NSCLC were routinely tested for EGFR, ALK, and ROS1, in addition to PD-L1 (22C3). Those wild-type for EGFR, ALK, or ROS1, or without enough tissue to perform the triple testing were considered for blood-based NGS. The different diagnostic assays for ctDNA NGS used depended on clinical trial molecular pre-screening protocol: Foundation One® Liquid or Guardant360®. We analyzed the frequency of oncogenic drivers, the proportion of patients treated with genotype-directed therapy, and survival. **Result:** We analyzed 95 NSCLC pts with valid NGS results from ctDNA (blood sample). We detected 14 oncogenic driver mutations (15%): 5 EGFR (5.2%), 1 ALK fusion (1%), 1 BRAF V600E (1%), 2 METex14 (2.1%), 2 RET fusion (2.1%) and 3 HER2 mutations (3.2%). We also found 16 KRAS mutations (16.8%), and genetic alterations in tumor suppressor genes: 39 TP53 (41%), and 6 NF1 mutations (6.3%). So far 8/14 patients were treated with genotype-directed therapy (8.4%), 2 of them under clinical trial: 5 pts were treated with an anti-EGFR treatment, 2 pts received alectinib (1 pt for ALK rearrangement, 1 pt for RET rearrangement) and 1 pt with tepotinib (MET splice mutation) Of the 6 patients with NF1 mutations, 4 pts were women (66%), 5 pts were current smokers (83%), median age at diagnosis was 69 years (66-80), and 5 pts had non-squamous histology (83%). PDL1 tumor expression was determined in 4 patients: 2 pts >50%, 1 pt 10%, and 1 pt 0%. NF1 was co-mutated in 4 pts with RAS (66%), 1 with both RAS and TP53, and 1 HER2 A775:G776insYVMA. 3/6 NF1 mutant patients were treated with single agent ICI: 2 pts with first-line pembrolizumab, and 1 pt second-line pembrolizumab. In addition, one patient with germline NF1 mutation was treated with 2nd line atezolizumab. All 3 pts obtained responded to ICI (1 pt with atypical response). We will present updated data on PFS and OS. **Conclusion:** Blood-based NGS can guide treatment decisions in metastatic NSCLC, with special interest in those patients without enough tumor tissue, or wild-type

POSTERS

to standard-tissue diagnostic tests. NF1 mutations in NSCLC could predict responses to immune-checkpoint inhibitors, and warrants further evaluation.

P2.14-30 PREDICTIVE VALUE OF CTDNA IN PATIENTS WITH EGFR POSITIVE NSCLC RECEIVING 3RD GENERATION TKI

F. Moiseenko, M. Stepanova, A. Zhabina, A. Myslik, V. Klimenko, D. Krylova, N. Rysev, N. Volkov, V. Moiseenko

St. Petersburg Clinical Research Center of Specialized Types of Care (Oncology), St. Petersburg/Russian Federation

Background: The third generation TKI (osimertinib) according to AURA III trial results achieved longer PFS compared to standard platinum based chemotherapy in patient's resistant to 1-2 generation TKIs due to T790M mutation (8.5 vs 4.2 months). The evolution of resistance profile during thins therapy can be analyzed based on ctDNA. **Method:** In this study patients with metastatic EGFR mutated NSCLC, with a confirmed disease progression during treatment with 1/2 generation TKIs, T790M positive which included patients received osimertinib 80 mg daily. Before the treatment and then every 2 months, whole blood was taken, for qualitative assessment of ctDNA dynamics by RT-PCR. The aim of the study was to assess the relationship between the disappearance of T790M + ctDNA and the time to progression on osimertinib. **Result:** From August 2016 to December 2018 22 patients with T790M positive progression were identified. 18/22 (81.9%) were women, 4/22 (18.1%) - men. The mean age was 61.2 years (50-75). Only 1/22 had a smoking history > 30 pack/years. Primary activating mutations in EGFR gene were ex19del, L858R and G719S + S768I in 16, 5 and 1 patients respectively. Median PFS on the first line TKI was 21.7 months (CI 95%, 10.8 – 53.3). In 59.1% (13/22) progressive disease was characterized by the appearance of new metastases and in 40.9% (9/22) by the growth of previously identified metastases. 22 patients were evaluable for response. PR and SD were achieved in 11/20 (50%) and 10/20 (45/5%) respectively. Median PFS was in a whole group 16.7 months (CI 95%, 11.4 - 22.0). T790M in ctDNA was negative after 2 months of osimertinib treatment in 12/22 patients. Median PFS was 18.9 months (CI 95%, 14.8–19.7) in patients with undetectable T790M in ctDNA after 2 month of therapy compared to 8.0 months (CI 95%, 4.2 – 11.8) in patients remaining ctDNA T790M positive. No clinical factors were associated with the disappearance of ctDNA by statistical analysis. **Conclusion:** The disappearance of T790M + ctDNA after 2 months osimertinib therapy is predictive of greater PFS in patients with EGFR mutation positive NSCLC, receving of 2nd line.

Keywords: Osimertinib, ctDNA, resistance

P2.14-31 MELATONIN INHIBITS PROLIFERATION AND INVASION THROUGH DOWNREGULATING CIRCRNA NID1 IN NON-SMALL CELL LUNG CANCER CELLS

Y. Wang, Y. Wo, T. Lu, W. Jiao

Affiliated Hospital of Qingdao University, Qingdao/China

Background: Melatonin could product anti-cancer effects via several mechanisms, including by induction of apoptosis. In this way, it has been shown to be of use, in combination with chemoradiotherapy, for cancer treatment. More and more circular RNAs (circRNAs) revealed to play a critical role in the initiation and progression of cancer, however, the effects of circRNAs on non-small cell lung cancer (NSCLC) remain largely undetermined. The study described here has evaluated effects of melatonin on dysregulated circRNAs and how to affect cell viability, proliferation and apoptosis in human lung adenocarcinoma cell lines (A549, H1299, and H460), which previously had only limited data. **Method:** The dysregulated circular RNA after melatonin treatment was examined. Cells were treated with melatonin alone at 1 nM, 1 μM and 100 μM concentration for 0, 12, 24, 48 and 72 h in culture. Cytotoxicity was measured by CCK-8 assay. Apoptosis induction was detected by annexin V/PI staining using flow cytometric analysis and DAPI nuclear staining. Transwell assay was used to detect the invasion of lung adenocarcinoma cell lines after treating. Western blot for detection of protein levels regulated by circular RNA. **Result:** In the present study, we screened the dysregulated circRNAs in human lung adenocarcinoma cell lines after treating and identified circRNA NID1 was to be significantly up-regulated in NSCLC and demonstrated it promotes NSCLC progression *in vitro* and in vivo. Then, we revealed the expression of miR-16-5p, a downstream factor of circRNA, was significantly down-regulated in NSCLC and acted as a tumor inhibitor, Yes-associated protein 1 was examined up-regulated in cancer and associated with proliferation. **Conclusion:** Our results highlighted circRNA NID1 promoted NSCLC cell proliferation, invasion, and migration by increasing Yap1 expressions through direct inhibition of miR-16-5p, which may serve as a potential prognostic marker of LUAD.

Keywords: lung adenocarcinoma, melatonin, circRNA

P2.14-32 EPIGENETIC SILENCING OF SPARC IN NSCLCS

F. Fabrizio[1], A. Sparaneo[1], A. Rossi[2], A. Pantalone[3], A. Fontana[4], F. Centra[1], F. Fiordelisi[5], N. Orlando[5], P. Graziano[5], D. Trombetta[1], V. Fazio[1,3], L. Muscarella[1]

Background: The silencing of *SPARC* gene through methylation of its promoter region has been commonly observed in many solid tumors and is frequently associated with tumor progression and an aggressive clinical outcome. At present, the data concerning the mechanisms of *SPARC* deregulation in lung cancer are almost incomplete and correlation analysis with disease clinical course and specific therapeutic strategies is ongoing. Here we present the epigenetic profile of SPARC gene promoter in a collection of NSCLC cell lines and tissue samples and assess its prognostic value in surgical NSCLC resected patients. **Method:** Four cell lines (3 adenocarcinoma, ADC and 1 large cell carcinoma, LCC) and 66 primary NSCLC tissues from surgically resected patients (30 squamous cell carcinoma, SqCC and 36 ADC) and 11 lung non-neoplastic tissues were epigenetically scanned. Promoter methylation analysis was performed using a quantitative methylation specific PCR assay in real-time (QMSP). The downstream effect of epigenetic silencing was also investigated in A549 and H1573 NSCLC cell lines by 5-Aza-2'-deoxycytidine treatment to demonstrate if the demethylating agent was able to restore SPARC mRNA expression levels. *SPARC* methylation levels were correlated with clinicopathological features. **Result:** A tumor-specific DNA methylation of the *SPARC* gene promoter region was found as a specific feature of NSCLC (p=00643 Mann-Whitney test) and was also observed in all cell lines analyzed. In particular, it was detected in 56% of SqCCs (20/36) and 64% of ADCs (19/30), with SqCC showing the highest levels of methylation. Overall, we found promoter hypermethylation in 59% of NSCLCs. Moreover, a direct correlation with mRNA levels was confirmed by *in vitro* 5-azacytidine treatment. In SqCCs, *SPARC* methylation levels correlated with a negative prognosis (p<0,012 Supremum Test for Functional Form, HR=1,93; 95%CI). **Conclusion:** Our results further suggest that epigenetic deregulation of the SPARC gene could be involved in the cancerogenesis of NSCLC. Additional studies on a larger cohort of NSCLCs and correlation with clinic-pathological features may contribute to disease progression prediction and new molecular basis to codify the response to therapy in lung cancer patients.

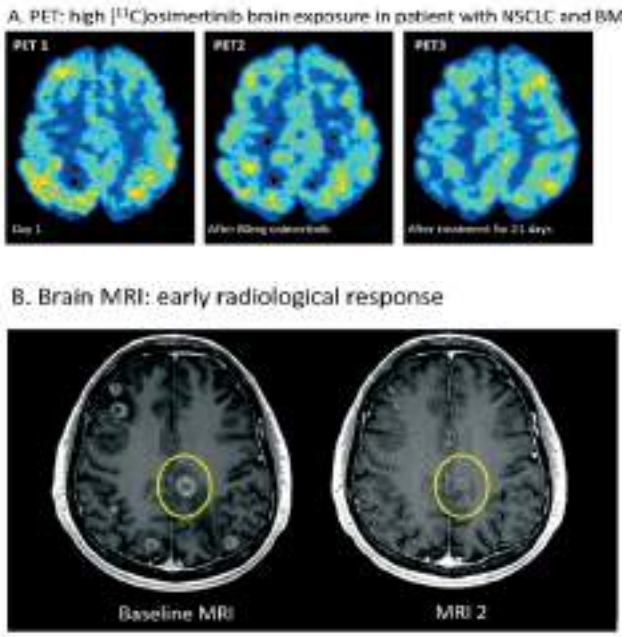
Background: CNS metastases are associated with poor prognosis in patients with advanced NSCLC. Osimertinib is a third-generation, irreversible, oral EGFR-TKI that potently and selectively inhibits both EGFR-TKI sensitising (EGFRm) and EGFR T790M mutations, and has demonstrated efficacy in NSCLC CNS metastases. Osimertinib has also shown superior brain exposure (preclinical/clinical), compared to other EGFR-TKIs. We report preliminary data on brain distribution of 11C-labelled osimertinib ([11C]osimertinib) in patients with NSCLC with brain metastases (BM) using positron emission tomography (PET). Early effects on BM measured by magnetic resonance imaging (MRI) is also presented. **Method:** This open-label, single-centre Phase I study (NCT03463525) enrolled adult patients with EGFR-mutated advanced NSCLC and BM, as confirmed by MRI. Patients could be EGFR-TKI-naïve or have progressed on a prior EGFR-TKI with confirmed EGFR T790M. Intravenous microdoses of [11C]osimertinib and PET examinations were performed pre-dose on Day1, ~6hrs post-dose on Day2, and following ≥21 days of once-daily dosing with osimertinib 80mg. Following the 3rd PET scan, patients completed another MRI scan to investigate early effects on tumour size according to RECIST 1.1 criteria. The primary objective was determination of brain exposure of [11C]osimertinib at baseline and following treatment, in the whole brain. During PET examinations, arterial blood samples were collected to measure radioactivity/radiometabolites of [11C]osimertinib. **Result:** Currently, six patients have been screened. Three enrolled, of whom two completed all imaging visits. PET examinations demonstrated rapid uptake of [11C]osimertinib into the brain and distribution into metastases; MRI scans showed significant decrease in size of brain lesions after 21 treatment days, consistent with partial response according to RECIST 1.1 criteria (Figure).



Conclusion: These early outcomes support the CNS efficacy reported in previous osimertinib studies: high brain-uptake and efficacy after a short dosing period. Further data on distribution, efficacy and PET/MRI imaging will be presented.

Background: From October 2013 there is a possibility to treat patients with NSCLC and with activated epidermal growth factor receptor (EGFR) mutations with three TKI in the Czech Republic. We have tried to find differences among patient groups treated with single TKI in 1st line of treatment. **Method:** The TULUNG registry was used as a data source for this analysis. This clinical registry is focused on the collection of epidemiological and clinical data of patients with NSCLC treated with target therapy in the Czech Republic. A total of 959 patients treated with TKI inhibitors was enrolled in registry until December 31, 2018. Only patients with EGFR mutation and in which 1st line treatment started in October 2013 and later were included in analysis. With respect to defined inclusion criteria we analysed 470 patients. With gefitinib were treated 234, with afatinib 180 and with erlotinib 56 patients. Descriptive statistics and frequency tables were used to characterize the sample data set. Statistical significance of differences among three TKI inhibitors subgroups was assessed using the Fisher's exact test or Kruskal-Wallis test for continuous variables. OS and PFS were estimated using Kaplan-Meier method and all point estimates include 95% confidence intervals (95% CI). Statistical significance of differences in survival between subgroups was assessed using the log-rank test. All statistical tests were performed at a significance level of α=0.05. **Result:** There was statistically significant difference according to age (< 0.001) and PS (< 0.001), patients treated with gefitinib were statistically significant older and had significantly significant higher PS than patients treated with afatinib and erlotinib There was statistically significant difference in the occurrence of adverse events (p<0.001). Patients treated with gefitinib had a significantly lower incidence of adverse events than patients treated with afatinib and erlotinib. Between these three groups of patients there was no statistically significant difference in sex (p=0.863), in smoking habits (p=0.463, in type of EGFR mutation (p=0.103), in adenocarcinoma proportion (p=0.183). There was no statistically significant difference according to disease control (p=0.183), in response to treatment (p = 0.804), in OS and (p=0.053, in PFS (p=0.06). **Conclusion:** Between these three groups of patients we found a statistically significant difference in age, PS segmentation and in occurrence of adverse events. We have not found any important statistically difference in sex, smoking, in histology type of EGFR mutation, difference in response to treatment, in disease control and OS.

Background: ALK-positive NSCLC cells (ALK+ NSCLC) present high glycolysis. Targeting cancer cell metabolism with the glycolysis inhibitor, 2-deoxyglucose (2DG), is a viable strategy that sensitizes the fist-line ALK-TKI crizotinib; but the effects of combination of 2DG and Crizotinib on ALK+ NSCLC cells and the mechanism of action are unknown. **Method:** ALK+ NSCLC cells H2228 and H3122 were incubated with crizotinib with or without 2DG, and subjected to the MTT. H2228 cells was treated with crizotinib or/and 2DG to explore the impact of cell growth and potential mechanism of action by clones formation, Ki67 incorporation assay, small interfering RNA technology, Western blot analysis. **Result:** A clear synergistic anti-proliferative interaction between 2DG and crioztinib was observed with a combination index value<1 (CI<1).The combination of crizotinib and 2DG effectively inhibited the clones formation and invasion ability of H2228 cells. The glucose consumption and Lactate production of H2228 cell treated with increasing concentration of 2DG was reduced to accompany a markedly decrease of HK2 expression. ALK-positive NSCLC cells showed a higher level expression of HK2 than ALK-negative NSCLC, down-regulation of HK2 by siRNA, obviously enhanced the ability of crizotinib to suppress proliferation activity. The westblot results displayed a significantly inhibition of AKT/mTOR signaling pathway in H2228 cells treatment with combination of 2DG and crizotinib. **Conclusion:** This study demonstrated that 2DG would be a promising drugs to sensitize crizotinib via suppressing HK2 expression to inhibit the activity of AKT/mTOR signaling pathway induced by ALK phosphorylation.

Background: Patient-derived tumor organoids (PDOs) have recently emerged as robust preclinical models. However, few studies were published on lung cancer organoid. This study aims to describe the genomic characteristics of PDOs as a disease model of NSCLC. **Method:** Samples from resected tumors were collected for organoid culture. DNA was extracted from tumor, organoids and matched PBLs samples and sequenced with whole-exome sequencing. **Result:** Seven pts were enrolled, including six LUAD (86 %) and one LUSC (14 %). A total of 1625 somatic mutations were detected in tumors. TP53 (71%), EGFR (43%), and KRAS (29%) mutated most frequently in this cohort, and occurred with frequencies of (57%), (43%) and (29%) in matched PDOs. Based on gene catalog related to lung cancer, the median consistency between tumor and organoid was 87 % (0% ~ 100%). Sample purity was significantly positively related to the variant allele frequency (r=0.82, P=0.0005), and may result in the inconsistence between paired samples. Besides, number of driver gene showed no difference between first- and second-generation organoids.

Table1. Characteristics of the Patients at baseline

Characteristic	Patients (n=7)
Age	
Mean ±SD	63.9±5.5
Median (Range, years)	66(56-69)
Sex-no. (%)	
Female	1(14)
Male	6(86)
Histologic diagnosis-no. (%)	
Adenocarcinoma	6(86)
Squamous-cell carcinoma	1(14)
Clinical disease stage	
I	3(43)
II	3(43)
III	1(14)
Smoking status-no. (%)	
Never	2(29)
Former or current	5(71)

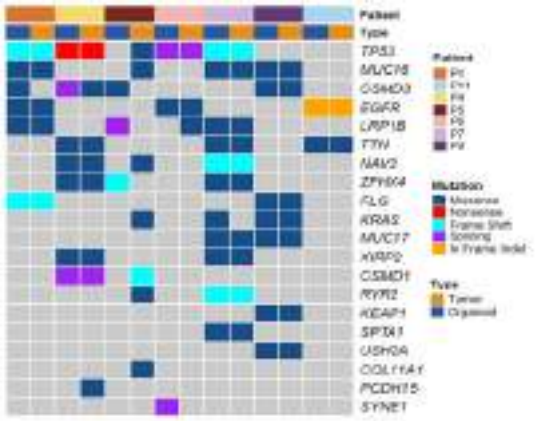

Figure 1. Mutation detected in paired tissues (tumor and organoid) based on gene catalog related to lung cancer (Top20 genes were shown)

Conclusion: This study firstly revealed genomic landscape of NSCLC organoid. In spite of heterogeneity, driver mutations presented high consistency between PDOs and paired tumor. Further study is continuing to evaluate outcomes from patients enrolled.

Background: To investigate the clinical and radiologic characteristics and risk factors of anaplastic lymphoma kinase (ALK) inhibitor induced pneumonitis (ALK-IIP) in patients with non-small cell lung cancer (NSCLC). **Method:** A total of 250 NSCLC patients who had been treated with ALK inhibitors from January 2015 to January 2018 were retrospectively enrolled. Clinical characteristics and clinical course were reviewed from the medical records. Chest CT of ALK-IIP was analyzed and classified into four CT patterns, i.e. organizing pneumonia (OP), hypersensitivity pneumonitis (HP), diffuse alveolar damage (DAD), and nonspecific interstitial pneumonia (NSIP), using the American Thoracic Society/European Respiratory Society

classification of interstitial pneumonia. Clinical characteristics including toxicity grading according to the National Cancer Institute Common Terminology Criteria for Adverse Events and treatment course was analyzed in regarding to the classified CT patterns. Clinical characteristics were compared between patients with ALK-IIP and without ALK-IIP. **Result:**

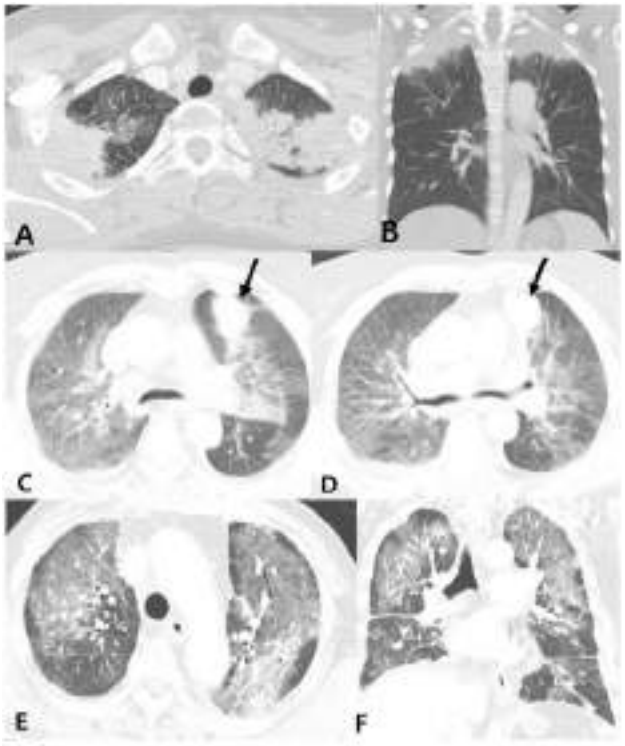

Figure. Spectrum of the CT patterns of ALK-IIP. (A and B), ALK-IIP with an OP pattern in a 56-year-old male patient. Chest CT demonstrated the development of multifocal mass-like consolidations with ill-defined GGO and mild interstitial thickening involving the subpleural areas of both upper lobes and both lower lobes representing the OP pattern. (C and D), ALK-IIP with a HP pattern in a 79-year-old female patient. Chest CT demonstrated diffuse GGO with focal areas of air trapping in both lungs and thus indicative of HP pattern. Lung cancer was noted in the left upper lobe (arrows). (E and F), ALK-IIP with DAD pattern in a 74-year-old male patient. Chest CT axial and coronal images demonstrated diffuse and bilateral gound glass opacity and consolidation with mild thickening of the interlobular septa in both lungs.

ALK-IIP was identified in 11 patients (4.4%). The most common CT pattern was the OP pattern (n = 7, 63.6%) and followed by the HP pattern (n = 2, 18.2%) and the DAD pattern (n = 2, 18.2%). ALK-IIP showed pneumonitis toxicity grade ranged from 1 to 3, and DAD pattern had the highest toxicity grade, followed by HP and OP patterns (median grade: 3.5, 2.5, 1). All of the patients with the OP pattern were successfully treated, while half of patients with the DAD pattern died during treatment. The smoking history and extrathoracic metastasis were more frequent in patients with ALK-IIP ($P < 0.005$). The smoking history was associated with a higher incidence of ALK-IIP [odds ratio: 3.586, 95% confidence interval: 1.058-13.432, $P = 0.049$]. **Conclusion:** ALK-IIP showed a spectrum of chest CT patterns and various toxicity grades, and CT patterns reflected the toxicity grades of ALK-IIP. The OP pattern was the most common CT pattern of ALK-IIP, and patients with ALK-IIP of the OP pattern were successfully treated. ALK inhibitors should be used with caution in NSCLC patients with smoking history.

P2.14-38 ATAD2B-ALK, A NOVEL FUSION IN LUNG ADENOCARCINOMA IDENTIFIED USING NEXT-GENERATION SEQUENCING (NGS)

H. Bai[1], W. Jia[2], X. Jin[3], H. Mao[1], D. Wu[1], R. Chen[2], X. Xia[4], H. Wu[1]

[1]*Department of Thoracic Surgery, Peking University Shenzhen Hospital, Shenzhen/China,* [2]*Geneplus-Beijing Institute, Beijing/China,* [3]*Department of Pathology, Peking University Shenzhen Hospital, Shenzhen/China,* [4]*GeneplusBeijing Institute, Beijing/China*

Background: Anaplastic lymphoma kinase (ALK) rearrangements is an important molecular subtype of non-small cell lung cancer (NSCLC), and patients with this variant are sensitive to ALK inhibitors. Since the discovery of the *EML4-ALK* fusion ten years ago, several fusion partners of *ALK* in NSCLC have been reported, including *KIF5B*, *KLC1*, *HIP1*, *TPR* and so on. According to previous reports, different fusion partner lead to various function and activity of the fusion product. Here, we identified a novel fusion partner for *ALK* in a lung adenocarcinoma patient. **Method:** A 46-year-old smoking Chinese male was diagnosed with lung adenocarcinoma of left lower lobe. In Oct 2017, the patient accepted lobectomy and lymph node dissection, then received 4 cycles of adjuvant chemotherapy. Lymph node metastasis occurred one and a half years after his surgery. The lymph node biopsy sent for genomic testing with a NGS-based pan-cancer 1021-gene panel. Immunohistochemistry (IHC) of ALK was performed to confirm the ALK fusion. **Result:** A novel ATPase family AAA domain containing 2B(ATAD2B)-ALK fusion was identified in the lymph node biopsy tissue. The fusion occurred in intron 1 of ATAD2B gene and intron 19 of ALK gene located on short arm of chromosome 2 (ATAD2B(PMT.IVS1)_ALK(IVS19.END)). ATAD2B is a phylogenetically conserved nuclear protein expressed during neuronal differentiation and it was also reported to play a role in tumorigenesis. As IHC confirmed the expression of ALK, we proposed the fused promoter of *ATAD2B* had driven the expression of ALK kinase domain. The patient is currently treated with crizotinib. **Conclusion:** The novel ALK fusion gene probably served as oncogenic driver of the patient's tumor. This case is the first report of ATAD2B-ALK fusion in clinical tumor samples and could provide a new diagnostic and therapeutic candidate target for patients with lung cancer.

Keyword: ALK, ATAD2B, ALK rearrangement, NGS, lung adenocarcinoma

P2.14-39 EFFECTS OF RENAL FUNCTION ON LORLATINIB SAFETY AND PHARMACOKINETICS

S. Lin[1], J. Gong[2], Y. Pithavala[1]

[1]*Pfizer, San Diego/United States of America,* [2]*Pfizer, New York/United States of America*

Background: Lorlatinib (Lorbrena®) is a small-molecule inhibitor of the anaplastic lymphoma kinase (ALK) and c-ROS oncogene 1 kinase recently approved at the recommended starting dose of 100 mg once daily in the United States, Japan, and Canada for the treatment of patients with *ALK*-positive metastatic non-small cell lung cancer (NSCLC). In humans, unchanged lorlatinib accounted for less than 1% of dose in urine, indicating minimal urinary excretion of parent drug. Therefore, renal impairment would not be expected to have a major effect on lorlatinib pharmacokinetics (PK) or safety. However, results from a population PK analysis demonstrated that baseline creatinine clearance was a statistically significant predictor of variability in lorlatinib plasma clearance; the median estimated single-dose lorlatinib clearance was 18% and 26% lower in NSCLC patients with mild and moderate renal impairment, respectively. Therefore, it is important to evaluate the potential impact of varying degrees of renal impairment on the safety and PK of lorlatinib via a prospective study. Preliminary results from the ongoing study, B7461010 (NCT03542305), of single-dose lorlatinib in subjects with mild, moderate and severe renal impairment are reported here. **Method:** B7461010 is an ongoing multi-center, open-label, single-dose study comparing the safety and PK of lorlatinib in otherwise healthy subjects with varying degrees of renal impairment. This study was planned to enroll 28–32 subjects (8 each in normal, mild and moderate impairment groups and 4–8 in severe impairment group) who complete PK assessments. Group assignment was based on estimated glomerular filtration rate calculated using the Modification of Diet in Renal Disease equation and as defined in the Kidney Disease Outcomes Quality Initiative guidelines. Subjects with increasing

severity of renal impairment have been enrolled sequentially to allow for safety evaluations. Subjects with normal renal function will be enrolled and matched based on age, sex and weight following completion of dosing of the renal impairment groups. **Result:** As of March 14, 2019, 8 subjects with mild renal impairment, 7 with moderate renal impairment and 3 with severe renal impairment not requiring dialysis have been enrolled. All 18 subjects to date received the clinical dose of lorlatinib 100 mg and completed the study. Among them, 6 subjects experienced adverse events (AEs), which were all transient and of mild or moderate intensity. Only 3 AEs (elevation of blood pressure, myalgia and diarrhea) were deemed related to study treatment. Preliminary analysis of plasma PK in 8 mild renal impairment subjects demonstrated similar exposures (geometric mean [%CV] Cmax of 549.7 [51.7%] and AUCinf of 8609.2 [29.2%]) compared to previous data from patients with normal renal function. **Conclusion:** Data showed that a single dose of lorlatinib 100 mg administered in subjects with mild, moderate or severe renal impairment was well tolerated. No dose adjustment was indicated for mild renal impairment. Updated results will be reported.

Keyword: lorlatinib, NSCLC, renal

P2.14-40 TUMOR-STROMAL MICROENVIRONMENT INTERACTIONS IN A PDX MODEL OF EGFR TKI DRUG TOLERANCE

E. Stewart, R. Navab, S. Martins-Filho, N.-A. Pham, G. Liu, M. Tsao

University Health Network, Toronto/Canada

Background: Sixty to eighty percent of advanced stage lung adenocarcinoma patients with sensitizing epidermal growth factor receptor (*EGFR*) mutated tumors respond to EGFR tyrosine kinase inhibitors (TKIs). However, the vast majority of patients eventually progress due to acquired resistance. *In vitro* evidence suggests that minor populations of drug tolerant cells (DTCs) may be important for tumors surviving TKI. These studies cannot investigate changes in non-cancerous cell populations found within tumors. Yet, stromal cells have been implicated in protecting cancer cells from treatment-induced death and early stage lung adenocarcinomas responding to neoadjuvant EGFR TKI exhibited DTCs within large areas of fibrosis (NCT00188617). We hypothesize that molecularly characterizing DTCs *in vivo* in comparison to an untreated tumor in a patient-derived xenograft (PDX) model may delineate stromal changes that sustain DTCs, and potentially mimic clinical events. **Method:** DTCs were harvested after one month of chronic erlotinib exposure in a lung adenocarcinoma PDX model harboring an exon 19 deletion; an untreated baseline (BL) tumor was also harvested. Histological characterization and single-cell RNA-sequencing (scRNA-seq) of DTCs and BL tumors were compared. ScRNAseq cell-types were assigned using reference component analysis. RNA expression levels of receptor/ligands were explored in cell populations. **Result:** Post-erlotinib treatment, cell-type proportions within the tumor shifted dramatically, with substantially fewer cancer cells and more fibroblasts, mesenchymal stem cells (MSCs), and natural killer cells (NKCs). Two antigen presenting cell transcriptomic states (APC1 and APC2) were identified in both DTC and BL tumors: APC1s exhibited translation-related gene expression profiles while APC2s exhibited immune-response profiles. BL tumors contained mostly APC1s, whereas DTC tumors exhibited more equal proportions of both APC types. Expression profiles for some cell-types also shifted after treatment. Fibroblasts and NKCs exhibited shifts toward more inflammatory and immune-responsive expression profiles post-treatment. Fibroblasts and endothelial cells demonstrated gene expression shifts towards decreased angiogenesis and vasculature development. Paired ligand-receptor interactions between cancer-stromal cells were increased or decreased congruently post-treatment. Specifically, fibroblasts exhibited a shift from alpha-SMA+ myofibroblastic to more IL6+ inflammatory phenotypes, by mRNA and equivalent immunohistochemistry, post-treatment. Cancer cells exhibited a reciprocal increase in IL6R receptor expression post-treatment. **Conclusion:** Using an *EGFR* mutant PDX model sensitive to EGFR TKIs, we see substantial post-treatment changes after chronic TKI exposure in non-cancerous (stromal) cell population composition involving their proportions, expression profiles, and their inferred communication with cancer cells. Understanding these potentially protective shifts in non-cancerous cell populations post-TKI-treatment may help identify clinically-relevant mechanisms of drug tolerance.

Keywords: drug tolerance, persisters, tumor microenvironment

P2.14-41 RISK FACTORS FOR BRAIN METASTASIS IN PATIENTS WITH EGFR MUTANT NON-SMALL CELL LUNG CANCER

T. Tozuka[1], M. Seike[1], Y. Murata[2], T. Sugano[1], S. Nakamichi[1], Y. Minegishi[1], R. Noro[1], T. Hirose[2], K. Kubota[1], A. Gemma[1]

[1]*Nippon Medical School, Tokyo/Japan,* [2]*Nippon Medical School Tamanagayama Hospital, Tokyo/Japan*

Background: Brain metastasis is associated with a poor prognosis in patients with EGFR mutant non-small cell lung cancer (NSCLC). EGFR tyrosine kinase inhibitors (TKIs) may be an effective treatment, but their influence on brain metastasis development is unclear. We aimed to identify risk factors for brain metastasis in patients with EGFR-mutant NSCLC. **Method:** This retrospective study included 166 consecutive advanced NSCLC patients with EGFR major mutations (Ex 21 L858R or Ex 19 del) who received EGFR–TKI monotherapy at the Nippon Medical School Hospital and Nippon Medical School Tamanagayama Hospital from November 2010 to June 2018. Patients who had brain metastases before EGFR–TKI monotherapy were excluded. We evaluated the cumulative actuarial incidence of brain metastases by Gray's test, univariate and multivariate analyses. **Result:** The median age was 72 years (range, 26-95 years), the majority of patients were female (n=103), and most patients had adenocarcinoma (n=153). Patients carried either an EGFR L858R (n=88) or 19del (n=78) mutation, and had been treated with gefitinib (n=97), erlotinib (n=22) or afatinib (n=47). The time to brain metastasis did not significantly differ between the three EGFR-TKI groups. The time to brain metastasis was significantly shorter in patients <75 years than >75 years (29.0 months versus not reached; HR 4.70; 95% CI 1.72-12.87). Univariate and multivariate analyses showed that age <75 years and non-adenocarcinoma histology were significant predictors of brain metastasis. In patients <75 years, the time to brain metastasis in patients who underwent EGFR-TKI dose reduction or intermittent treatment was significantly shorter than patients with constant EGFR-TKI treatment (24.9 versus 39.9 months; HR 2.40; 95% CI 1.10-5.22). **Conclusion:** Age <75 years is a risk factor for brain metastasis in patients with EGFR mutant NSCLC. We do not recommend EGFR–TKI dose reduction or intermittent administration in these patients.

P2.14-42 EMERGENCE OF CCDC6-RET FUSION WITH MAINTAINED EGFR T790M MUTATION AFTER RESISTANCE TO OSIMERTINIB IN NSCLC: A CASE REPORT

Y. Guo[1], R. Guo[2], H. Cheng[2], H. Wang[2], F. Lou[2], S. Cao[2], W. Guo[1], X. Song[1]

[1]*Shanxi Cancer Hospital, Taiyuan/China,* [2]*AcornMed Biotechnology Co., Ltd., Beijing/China*

Background: First- and second-generation EGFR-TKIs have been widely used for advanced patients with *EGFR* mutation-positive non-small cell lung cancer (NSCLC); however, acquired resistance to these inhibitors, such as *EGFR T790M* mutation, could be present in resistant cases. Several third-generation EGFR-TKIs including osimertinib, have been explored and approved for conquering this resistance, whereas acquired resistance to osimertinib is evident and resistance mechanisms remain complex and incompletely elucidated. **Method:** A 56-year-old never-smoking Asian woman presenting with back and groin pain for 2 years, and was diagnosed with stage IV lung adenocarcinoma with multiple lung, liver, brain and bone metastases in February 2015. The patient carried *EGFR* exon 19 deletion and clinically responded to initial erlotinib treatment, who progressed on erlotinib after 20 months, and a *T790M* mutation was detected by next-generation sequencing (NGS). Osimertinib treatment was administrated for 13 months during which time the patient remained stable according to the Response Evaluation Criteria in Solid Tumors. The patient progressed with bone metastases in January 2018 and no other mutations were detected by NGS, who then started the treatment with osimertinib, bevacizumab, and complementary radiation therapy. However, the patient discontinued the treatment due to the progress with bilateral lung nodules. In order to probe into the subsequent therapy, circulating tumor DNA (ctDNA) was analyzed using NGS with Acornmed Panel in August 2018. **Result:** The genomic profile of the tumor disclosed actionable mutations including *EGFR* exon 19 deletion, *EGFR T790M* mutation, and *CCDC6-RET* fusion. Osimertinib and bevacizumab discontinued because of

the rapid progress, serious adverse effects of gradeIIsuppression of bone marrow, and shortness of breath. Based on the molecular test results, the patient received treatment with cabozantinib and osimertinib in October 2018, which also failed to slow down the progress of the disease. Further ctDNA test in November 2018 showed *EGFR* exon 19 deletion, *EGFR T790M* mutation, and *CCDC6-RET* fusion were identified again; however, no novel mutations were detected. Unfortunately, the symptoms worsened quickly and the patient died of respiratory failure in December 2018. **Conclusion:** The specifc mechanisms of acquiring drug resistance for EGFR-TKIs have not been fully elucidated. Based on ctDNA-based NGS, we reported a case maintained *EGFR T790M* mutation and acquired *CCDC6-RET* fusion after resistance to osimertinib, which was rare since acquired *RET* fusion was only found in *EGFR T790M* lost patients. More studies about the mechanism should be explored to lead to effective treatment strategies in this population.

Keywords: Acquired Resistance to Osimertinib, CCDC6-RET fusion, maintained EGFR T790M mutation

P2.14-43 COST-EFFECTIVENESS OF 1ST-LINE TREATMENT EGFR-TKIS FOR ADVANCED NSCLC PATIENTS HARBORING EGFR MUTATION IN MEXICO

L.A. Ramírez Tirado[1], S. Guzmán[2], C. Goycochea-Robles[2], F. Barrón[1], L. Cabrera-Miranda[3], D. Flores-Estrada[1], O.G. Arrieta[4]

[1]*Instituto Nacional de Cancerología (INCan), Mexico/Mexico,* [2]*HS Estudios Farmacoeconómicos, Mexico/Mexico,* [3]*Instituto Nacional de Cancerología, Mexico City/Mexico,* [4]*Instituto Nacional De Cancerología, Mexico City/Mexico*

Background: As cancer care costs are rising at an unprecedented rate, it is crucial to provide evidence-based justification for promising but expensive therapeutic approaches such as Epidermal growth factor receptor-tyrosine kinase inhibitors (EGFR-TKIs). EGFR-TKIs such as gefitinib, erlotinib and afatinib had become the standard first-line treatment for EGFR gene mutation-positive non-small cell lung cancer (NSCLC) improving progression-free survival (PFS) and overall survival (OS) of these patients. However, the economic impact of them remain unclear. Hence, we aimed to assess healthcare costs during and after progression to treatment and to compare the cost-effectivess and safety of the 1st-line treatment with EGFR-TKIs in patients with advanced non-small cell lung cancer (NSCLC) in Mexico. **Method:** The health and economic outcomes of three first-line strategies (gefitinib, erlotinib, and afatinib) among NSCLC patients harboring EGFRmutations were estimated and assessed. Costs in the Mexican setting were obtained from local hospital data and public national purchasing sources. The structure used in this analysis was a Markov model with three possible health states: free of progression, progression and death considering a time horizon of 3 and 5 years. The probabilities of transition and the use of resources used to feed the model were retrospectively collected by reviewing medical records of patients who were treated at the Instituto Nacional de Cancerologia (INCan) of Mexico between April 2013 and June 2017. Probabilistic sensitivity analysis (PSA) was conducted with a Monte Carlo simulation. **Result:** Similar hazards of progression and death were obtained when constrasting afatinib vs. erlotinib, [HR:0.91 (95% CI: 0.59 -2.07) and 0.82 (95% CI: 0.56-2.65), respectively] as well as when contrasting the hazards of progression and death of afatinib vs. gefininib [HR:0.87 (95% CI: 0.87-1.53) and 0.94 (95% CI: 0.74-1.55), respectively]. However, statistically significant differences were identified between the costs of the treatment both the total cost (p<.001) and the daily cost (p <0.001) of treatment. The most expensive treatment was with afatinib, followed by erlotinib and gefitinib. In addition, treatment with afatinib showed the highest cost associated with adverse events. PSA with Monte Carlo simulations showed robustness of estimations.

Cost-effectiveness analysis

Treatment	Overall Mean cost	Incremental cost	Efectiveness	Incremental effectiveness	ICER
Progression-free survival					
Gefitinib	$161,800		8.18		
Erlotinib	$215,700	$53,900	6.7	-1.48	
Afatinib	$348,200	$186,400	9.46	1.28	$145,625.00
Overall survival					
Gefitinib	$161,800		27.1		
Erlotinib	$215,700	$53,900	21.7	-5.4	
Afatinib	$348,200	$186,400	37.1	10	$18,640.00

Conclusion: Although equivalent effectiveness and safety of the three arms of the study was found, substantial differences in treatment costs were observed. Nonetheless, we should highlight that patient selection is absolutely critical for cost-efectiveness analyses; as well as longer follow-up of existing data could substantially alter the conclusions of this analysis.

Keywords: EGFR-TKIs, NSCLC, cost-effectiveness

P2.14-44 TUMOR MUTATION BURDEN AND EFFICACY OF MOLECULAR TARGETED THERAPY IN LUNG CANCER

K. Arai, T. Sakamoto, K. Yamane, Y. Hirayama, Y. Teruya, M. Yanai, N. Kinoshita, K. Yamaguchi, H. Makino, M. Kodani, T. Igishi, A. Yamasaki

Tottori University Hospital, Yonago/Japan

Background: Precision medicine based on driver oncogenes is now developed for non-small cell lung cancer (NSCLC). Recently, next-generation sequencing (NGS) has made it possible to analyze Tumor mutation burden (TMB), and it was revealed that TMB is an effective biomarker of immune checkpoint inhibitors. However, the impact of TMB on the effects of targeted therapy for driver alterations is still unclear. **Method:** Of the cases diagnosed with advanced NSCLC at Tottori University Hospital, 30 cases with consent to this observational study were enrolled. TruSight™ Oncology (TSO) 500 was performed at the CLIA-certified laboratory (RIKEN GENESIS CO., LTD.) using DNA and RNA extracted from archived formalin-fixed paraffin-embedded (FFPE) lung cancer specimens. **Result:** Specimens were collected by bronchoscopy in 21 cases (70%), percutaneous biopsy in 3 cases (10%), surgery in 3 cases (10%), cell block of pleural effusion in 2 cases (7%) and thoracoscopy in 1 case (3%). The success rate of TMB analysis was 83% (25/30 cases). In the 25 cases, a total of 23 actionable gene alterations (11 EGFR mut, 4 ALK fus, 2 KRAS mut, 2 BRAF mut, 2 MET ex14 skipping, 1 RET fus, 1 PIK3CA mut) were detected in 22 cases (88%). The median TMB was 7.84 (1.56-21.11) mutations/Mb. 7 of 25 (28%) patients showed high TMB, and the others showed low TMB when 10 mutations per mega base was set as the threshold. 5 of 7 (71%) patients with high TMB had one of the common driver mutations (2 EGFR mut, 2 BRAF mut and 1 PIC3CA mut) and 17 of 18 (94%) patients with low TMB had one of the driver mutations (9 EGFR mut, 4 ALK fus, 2 KRAS, 2 MET ex14 skipping and 1 RET fus). Additionally, no ALK fusion was identified in patients with high TMB. 12 of 15 patients (80%) received targeted therapy with low TMB achieved clinical response, while no patient (0/2 pts, 0%) received targeted therapy with high TMB achieved clinical response. **Conclusion:** TMB might have the impact for the presence of driver alterations and the effects of targeted therapies.

P2.14-45 EML4-ALK FUSION SUBTYPE IS ASSOCIATED WITH THERAPEUTIC EFFICACY IN ADVANCED NON-SMALL CELL LUNG CANCER

H. Wang, H. Li, J. Ma, X. Yan, P. Li, M. Zhang, X. Zhang, G. Zhang, Z. Ma

The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou/China

Background: The aim of this study was to investigate the molecular characteristics of each subtype of the EML4-ALK fusion gene and to evaluate the efficacy of first-line crizotinib or pemetrexed in combination with platinum in the treatment of patients with advanced NSL4-ALK fusion subtypes of advanced NSCLC. **Method:** From August 2015 to September 2018, the clinicopathological data of patients who received driver genes detection for lung cancer in the Affiliated Cancer Hospital of Zhengzhou University were collected,NGS was used for gene detection.The EML4-ALK fusion gene was divided into E13: A20 subtype (variant 1, V1), E20: A20 subtype (variant 2, V2), E6: A20 subtype (variant 3, V3) and Other subtypes (V4) 4 groups. The primary study endpoint was progression-free survival. **Result:** A total of 122 patients with ALK fusion gene-positive NSCLC were screened. Of the 122 patients, 41 (33.6%) had V1 variants, 14 (11.5%) had V2 variants, 35 (28.7%) had V3 variants, and 32 (26.2%) had other variants. There was no correlation between EML4-ALK gene mutation subtypes and distant metastasis (x2=0.570, P=0.903), brain metastasis (x2=4.447, P=0.217) and bone metastasis (x2=1.547, P=0.672). The median was 13.3 months (95% CI: 9.45-17.10) and 6.83 months (95% CI:

POSTERS

5.30-8.36),respectively, in patients receiving first line Crizotinib and chemotherapy, with statistically significant differences (P =0.001). In the first-line application of crizotinib, the ORR of V1, V2, V3 and V4 variants were 55.56% (10/18), 62.50% (5/8), 44.44% (4/9) and 43.75%, respectively. (7/16), median PFS were 11.96 months, 15.08 months, 12.88 months, and 7.62 months, respectively. There was no significant difference. The ORR of V1, V2, V3 and V4 variants in first-line patients treated with pemetrexe-platinum regimen was 41.18%(7/17), 37.50% (3/8), 36.36%(4/11)and 41.18% (7/17), respectively. The median PFS were 9.13 months, 3.22 months, 7.52 months, and 7.85 months, respectively. There was no statistically significant difference in PFS between V1: V3, V2: V3, and V1: V4. However, the PFS differences in the V1:V2 group (V1:V2=9.13 months: 3.22 months, P=0.007) and the V2:V4 group (V2:V4=3.22 months: 7.85 months, P=0.015) . **Conclusion:** Among all ALK fusion subtypes, E13:A20 subtype (V1 variants) is the most common. Smoking history was a factor affecting crizotinib PFS.Compared with chemotherapy, patients with E20:A20 subtype (V2 variant) showed significant benefit with crizotinib.The median PFS of the pemetrexed combined with platinum regimen was lower than that of the E13:A20 subtype.

[1]*Department of Respiratory and Critical Care Medicine, and Ludwig Boltzmann Institute of COPD and Respiratory Epidemiology, Otto Wagner Hospital, Vienna/Austria,* [2]*Institute of Pathology and Clinical Microbiology, Wilhelminenspital, Vienna/Austria,* [3]*Department of Thoracic Surgery, Otto Wagner Hospital, Vienna/Austria,* [4]*Division of Clinical Oncology, Department of Medicine, Medical University of Graz, Graz/Austria,* [5]*Department of Internal Medicine, District Hospital Schwaz, Schwaz/Austria,* [6]*Department of Internal Medicine II, Hospital Brothers of Saint John of God, Eisenstadt/Austria,* [7]*Department of Respiratory Medicine, Klinikum Klagenfurt, Klagenfurt/Austria*

Background: Patients with non-small cell lung cancer (NSCLC), showing anaplastic lymphoma kinase (ALK)-or proto-oncogene 1 (ROS1)-rearrangement are routinely treated with tyrosine kinase inhibitors (TKIs). Although treatment is usually very effective resistance invariably develops over time. Lorlatinib a third generation TKI was recently approved by the FDA for patients who progressed on crizotinib and at least one other tyrosine kinase inhibitor. Here we report our experience with this novel brain-penetrant TKI. **Method:** 32 NSCLC patients, heavily pretreated with various chemotherapies and TKIs, have been treated with lorlatinib (100mg daily p.o.) as part of a pre-approval access program (PAA) between June 2016 and April 2019 at the Otto-Wagner-Hospital. We collected patient characteristics including sex, age, race and smoking history. Clinical response rates and progression free survival was assessed in all. **Result:** 21 patients were women and 11 men. The overall mean age was 57.3 years (59.2 female/53.2 male). 20 patients were never smokers (62.5%), 7 were former smokers (21.9 %), 2 were active smokers (6.3%). Smoking history was unknown in 3 patients (9.4%). Of the 32 patients 23 were ALK+ and 9 ROS1+. Lorlatinib was given in various lines of treatment from 2nd up to 6th line while one patient even received it in 11th line. All treated patients were Caucasian. Three patients showed a complete response (9.4%), 8 a partial response (25%), 5 are still showing stable disease (15.6%). Disease progression was noted in 16 patients (50%). The mean PFS (progression free survival) was 8.5 months, whilst treatment of 15 patients is still ongoing. ALK+ patients (n=23) showed a mean PFS of 7.9 months and ROS1+ patients (n=9) a mean PFS 9.8 months. Patients receiving brigatinib before switching to lorlatinib reached a mean PFS of 9.4 months (n=13; 12 ALK+/1 ROS1+) while patients who received lorlatinib after alectinib experienced a mean PFS of 4.93 months (n=8 ALK+). After crizotinib we found a mean PFS of 9 months (n=5; 5 ROS1+) and after ceritinib a mean of 10 months (n=6; 3 ALK+/3 ROS1+). The treatment was generally well tolerated. **Conclusion:** Lorlatinib was overall well tolerated and it was highly effective in these pretreated ALK and ROS1 rearranged NSCLC patients.

[1]*Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia,* [2]*Department of Medicine, Faculty of Medicine and Health Science, University Malaysia Sarawak, Kota Samarahan/Malaysia,* [3]*Department of Clinical Oncology, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia,* [4]*Beacon International Specialist Centre, Kuala Lumpur/Malaysia,* [5]*Subang Jaya Medical Centre, Subang Jaya/Malaysia,* [6]*Hospital Tengku Ampuan Afzan, Kuantan/Malaysia,* [7]*Gleneagles Hospital, Penang/Malaysia,* [8]*Pantai Medical Centre, Kuala Lumpur/Malaysia*

Background: Afatinib is an irreversible, second-generation epidermal growth factor receptor *(EGFR)*-tyrosine kinase inhibitor (TKI) that has been shown to be more potent than platinum doublet chemotherapy as well as the first-generation *EGFR*-TKI. This study aimed to look into the efficacy, side-effects and resistance mechanisms of first-line afatinib in the real-world setting. **Method:** This is a multicenter observational study of Malaysian patients with*EGFR*-mutant advanced non-small cell lung cancer (NSCLC) started on first-line afatinib from 1st October 2014 to 30th April 2018. **Result:** Of 85 patients analyzed, *EGFR* mutations harbored by the tumors included *exon 19* deletion in 80.0%, *exon 21 L858R* point mutation in 12.9%, and rare or complex *EGFR* mutations in 7.1%. Among the 85 patients, 18.8% had an ECOG performance status of 2-4, 29.4% had symptomatic brain metastases and 17.6% had abnormal organ function. Afatinib 40 mg or 30 mg once daily was the most common starting and maintenance doses. Only one-tenth of patients experienced severe side-effects and none had grade 4 toxicities.The objective response rate was 76.5% while the disease control rate was 95.3%. At the time of analysis, 56 (65.9%) patients had experienced disease progression (PD) with a median progression-free survival (mPFS) of 12.2 months (95% CI, 8.9-15.5 months). Only 12.5% of the PD patients developed new symptomatic brain metastases. Multivariate analysis demonstrated only patients with *exon 19* deletion had significantly longer mPFS than those with rare or complex *EGFR* mutations (13.5 versus 9.0 months, HR, 0.31; 95% CI, 0.11-0.84; p = 0.021).The overall survival data was not mature. Of the patients who experienced PD while on afatinib, 55.3% were investigated for acquired resistance mechanisms. *Exon 20 T790M* mutation was detected in 42.0% of these patients. **Conclusion:** Afatinib is an effective first-line treatment for patients with *EGFR*-mutant advanced NSCLC with good response and disease control rates as well as long PFS even in patients with unfavorable clinical characteristics. The side-effects of afatinib were manageable and acquired *T790M* mutation was a common mechanism causing treatment failure.

P2.14-48 CLINICAL SEQUENCING USING A NGS-BASED MULTIPLE GENE ASSAY IN PATIENTS WITH NON-SMALL CELL LUNG CANCER

Y. Gao[1], Z. Dong[1], X. Li[2], H. Ge[1], X. Yang[1], P. Guzenda[1], W. Shi[1], L. Ruan[1], G. Zhu[1]

[1]*Amoy Diagnostics Co., Ltd., Xiamen/China,* [2]*Tangdu Hospital, Fourth Military Medical University, Xi'an/China*

Background: Patients with non-small cell lung cancer (NSCLC) often harbor driver mutations in multiple oncogenes, including *EGFR, ALK*, *ROS1*, *BRAF*, *HER2*, *MET*, *RET*, etc. The presence of gene alterations can impact the selection of and the response to targeted therapies. Testing of lung cancer for multi-gene alterations is important for identification of potentially efficacious targeted therapies. Therefore, identifying mutations in oncogenes and tailoring therapy become a standard in clinical cancer management. A genetic testing assay based on next-generation sequencing (NGS), named AmoyDx Essential NGS Panel, has been developed for multiplexed and targeted deep sequencing of variants in 10 driver genes. Clinical validation using FFPE tissue was conducted in the present study. **Method:** A total of 294 formalin-fixed and paraffin-embedded (FFPE) tissue samples collected from NSCLC patients were tested by AmoyDx Essential NGS Panel, which enables the simultaneous detection of single-nucleotide variants (SNVs), insertions/deletions and fusions in 10 driver genes (*EGFR*, *KRAS*, *NRAS*, *BRAF*, *PIK3CA*,

ALK, *ROS1*, *HER2*, *RET*, and *MET*) in DNA samples. DNA sequencing was performed on the Illumina sequencer. Golden standard Sanger sequencing was used as a reference method to test the same cohort. The concordance of alterations determined with the AmoyDx Essential NGS Panel was assessed compared to the reference method. **Result:** In total of 294 samples, 98.30% (289/294) of patients were successfully detected by both AmoyDx Essential NGS Panel and Sanger sequencing. 68.86% (199/289) were identified with positive mutation/fusion by NGS assay (Table 1). The overall concordance rate of alterations determined with AmoyDx Essential NGS Panel compared with reference was 90.66%.

Table 1 Alterations detected by NGS

Variant type	Number of patients	Positive rate
EGFR mutation	126	43.60%
KRAS mutation	40	13.84%
NRAS mutation	1	0.35%
BRAF mutation	1	0.35%
PIK3CA mutation	3	1.04%
ALK fusion	22	7.61%
ROS1 fusion	2	0.69%
HER2 mutation	6	2.08%
RET fusion	1	0.35%
MET mutation	0	0.00%
Total	199	68.86%

Conclusion: The NGS analysis with AmoyDx Essential NGS Panel represents an accurate and efficient approach to detect genetic alterations in 10 driver genes with high concordance rate of 90.66% compared with Sanger sequencing.

P2.14-49 MOLECULAR CHARACTERISTICS OF HER2 MUTATIONS IN NON-SMALL CELL LUNG CANCER

X. Wei[1,2], X. Gao[2], X. Zhang[2], Z. Chen[2], Y.-L. Wu[2], Q. Zhou[1,2]

[1]*School of Medicine, South China University of Technology, Guangzhou/China,* [2]*Guangdong Lung Cancer Institute, Guangdong Provincial Key Laboratory of Translational Medicine in Lung Cancer, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: Earlier clinical trials targeting on HER2 exon 20 mutations show promising results. However, target therapy also had shown a favorable effect on non-tyrosine kinase domain (non-TKD) mutations in preliminary studies and case report, while no systemic study was reported about non-TKD mutations in HER2. Hence, The study aims to comprehensively outline the mutation landscape of HER2 in NSCLC. **Method:** HER2 profile data (patients, N=5,222) from thirteen NSCLC studies in the cBioPortal for Cancer Genomics was screened. Finally, after excluding duplicated data (n=2,725) and no HER2 profile data (n=563), 1,934 individuals were enrolled in the analysis. The mutation subtype, mutation type, mutation region, biological effect of mutations referred to OncoKB, and HER2 copy number variation were described. **Result:** 4.3% (84/1934) of NSCLC patients were detected with HER2 mutation, and three patients carried double HER2 mutations, totally eighty-seven HER2 mutations were identified in the study. Fifty-three HER2 mutation subtypes were identified, and the most common mutation subtypes were Y772_A775dup (24%, 21/87), S310F (6%, 5/87), G776delinsVC (5%, 4/87) and G778_P780dup (5%, 4/87) respectively. HER2 fusion was identified in 8% (7/87) of mutations with a tendency to concurrent with HER2 copy number increased (5 amplification, 2 copy number gain). As for mutation region, 43% (37/87) of mutations occurred in TKD, while biological effect was not validated in 16% (6/37) of TKD mutations. Notably, biological effect of 56% mutations was inclusive or unknown. In gain of function subset, 82% (31/38) of mutations located at TKD, 13% (5/38) and 5% (2/38) were located at furin-like cysteine rich region and transmembrane domain.

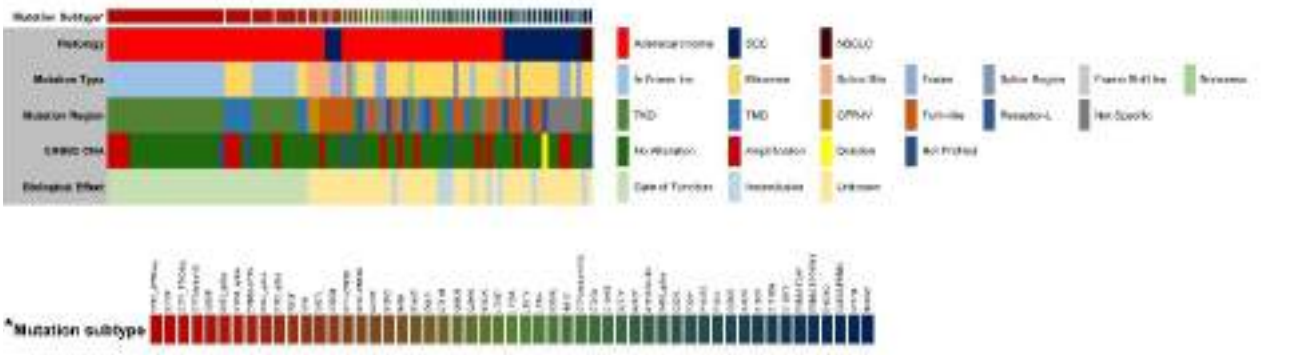

Figure 1. Molecular characteristics of HER2 mutations in NSCLC (n=87).
SCC, squamous cell carcinoma; NSCLC, non-small cell lung cancer; TKD, tyrosine kinase domain; TMD, transmembrane domain; GFR-IV, growth factor receptor domain IV; Furin-like, furin-like cysteine rich region; Receptor-L, receptor-L domain; CNA, copy number alteration.

Conclusion: Mutation subtypes were diverse in HER2. Though accounting for more than half of HER2 mutations, the effect of non-TKD mutations was fewly understood rather than TKD mutations. Biological effect and clinical implication of non-TKD mutations need to be further investigated in the near future.

P2.14-50 LOW TEMPERATURE PLASMA NEEDLE INDUCES CELL CYCLE ARREST OF EPITHELIAL LUNG CANCER CELLS IN VITRO VIA A P21-DEPENDENT PATHWAY

M. Cavic[1], N. Selakovic[2], N. Gligorijevic[1], N. Puac[2], G. Malovic[2], S. Radulovic[1], Z. Petrovic[2,3]

[1]*Institute for Oncology and Radiology of Serbia, Belgrade/Serbia,* [2]*Institute for Physics, University of Belgrade, Belgrade/Serbia,* [3]*Serbian Academy of Sciences, Belgrade/Serbia*

Background: Low temperature plasma sources which operate at atmospheric pressure produce reactive oxygen species (ROS) and reactive nitrogen species which can cause cancer cell death. In this study we investigated the effect of our low temperature plasma needle system on a non-small cell lung cancer cell line A549 and studied its mechanism of action. **Method:** The housing of the pen lookalike atmospheric plasma source (plasma needle) was made of Teflon. A Pyrex glass tube (o.d. 6 mm and i.d. 4 mm) through which 1 slm of helium was released as the feeding gas was positioned within the housing. The central electrode, a tungsten wire, was powered with a 13.56 MHz sine wave and placed within a ceramic tube inside the glass tube. The central electrode was sticking 1 mm outside of the ceramic and glass tubes, so the discharge occurred on its tip as a weak glow. The cytotoxic activity was determined using MTT assay. The potential of inducing cell cycle perturbations and apoptosis, and changes in the level of ROS was investigated by flow cytometry. The influence of plasma treatment on growth inhibition of multicellular tumor spheroids (MCTS) was also investigated. Evaluation of gene expression was performed by qPCR. All experiments were performed in triplicate, with statistical significance set at p<0.05. **Result:** Our plasma needle exerted a cytotoxic effect with lower sensitivity towards BEAS-2B normal cells than towards A549 cells. A decrease in the number of cells in the G1 phase (up to 45%), increase in the G2 phase (up to 27%), and an increase in the sub-G1 phase (up to 12%) with fragmented DNA was detected upon treatment. The plasma treatment exerted a mild apoptotic effect (around 15% of apoptotic cells), and an increase in the level of ROS in a power dependent manner. There was no significant reduction in growth of MCTS after plasma treatment under investigated experimental conditions. A statistically non-significant proapoptotic effect (increase in Bax, decrease in Bcl2 and decrease in SKP2) was observed at the genetic level. A significant overexpression of the cyclin-dependent kinase inhibitor 1 (p21) was also observed at the genetic level in a power dependent manner. **Conclusion:** Our low temperature plasma needle induced cell cycle arrest of epithelial lung cancer cells through overexpression of p21. The effect of combined plasma treatment with existing treatment modalities (cisplatin, PARP inhibitors) is currently under *in vitro* investigation.

Background: First line crizotinib response duration time differs with different fusion patterns in *ALK*-rearranged advanced non-small cell lung cancer (NSCLC) patients. Some former researches have elucidate the impact of *EML4-ALK* variants on crizotinib efficacy, however, there was little data about the efficacy of crizotinib considering different fusion partners including one patient with two or more fusion partners or non-*EML4* partners. **Method:** 150 patients with NGS-identified *ALK*-rearranged NSCLC from March 2014 to July 2018 in Hunan Cancer Hospital were enrolled in this study. Among them, 112 patients received crizotinib as first-line treatment. Efficacy of crizotinib was evaluated and categorized according to different fusion partners. **Result:** Among 150 advanced NSCLC patients with NGS-identified *ALK*-rearranged, 181 fusion partners were detected including 43 novel fusion partners. 122 patients (81.3%) were identified with single *ALK* fusion partners, 28 patients (18.7%) were identified with dual or triple *ALK* fusion partner patients. Among 112 patients received first line crizotinib treatment, 89 patients were identified with single fusion partner (79 for *EML4*, 10 for non-*EML4*). 23 patients were identified with dual fusion partner (20 patients with dual fusion partners, 3 patients with triple fusion partners). The overall response rate (ORR) was 85.2% and the median progression-free survival time (mPFS) was 11.7 months. The frequency of brain metastasis was high in dual fusion partner patients. Patients with dual *ALK* fusion partners have a significantly shorter mPFS compared with patients carrying single *ALK* fusion partner (6.1m *vs.* 12.0m, *p*=0.001). Patients with *EML4* partners have a significantly longer mPFS compared with patients carrying non-EML4 fusion partners (12.6m *vs.* 6.1m, *p*=0.004).

Conclusion: Efficacy of first-line crizotinib in *ALK*-rearranged NSCLC patients differs based on different *ALK* fusion partners. Dual *ALK* fusion partners were poor prognostic factors in first-line crizotinib treatment NSCLC. It also correlated with more brain metastasis compared with single fusion partners.

Background: EGFR mutation analysis of plasma circulating tumor DNA (ctDNA) has been reported to be useful to detect resistant mutations and to predict the efficacy of treatment. In NEJ026 study, we demonstrated the PFS of erlotinib plus bevacizumab (BE) treatment was significantly superior to the erlotinib alone (E) in NSCLC patients harboring EGFR mutation. Evaluation of plasma EGFR mutations included in NEJ026 study as preplanned analysis. **Method:** At the time points of pretreated (P0), 6 weeks after study treatment started (P1), and confirmed progressive disease (P2), the plasma samples were collected from the patients enrolled to NEJ026 study. The number of enrolled patients were 112 in BE and 114 in E. Plasma ctDNA analysis for detection of the activating EGFR mutation and T790M mutation were performed by modified PNA-LNA PCR clamp method. **Result:** The total numbers of collected plasma samples in BE and E were 108 (96.4%) and 107 (95.5%) at P0, 95 (84.8%) and 97 (86.6%) at P1, and 42 (37.5%) and 53 (47.3%) at P2, respectively. In eligible patients having EGFR activating mutation detected by cytohistological specimens, detection rate of plasma EGFR mutation at P0 was 68% (147/215). The detection ratio of T790M mutation at P2 were similar in both arms: 8 (19.0%) in BE and 11 (20.8%) in E. By detection pattern of activating EGFR mutation, PFS was evaluated among three groups: type A (P0 (-),P1 (-)), type B (P0 (+), P1(-)), and type C (P0 (+), P1(+)). Type A achieved the best response to both TKI [Type A BE: 18.1 M (n = 32, 95% CI, 11.5 to upper limit not reached(NR)), E: 16.7 M (n = 26, 95% CI, 11.2 to NR)]. Type B also had better PFS to TKI and BE is more favorable effect than E compared to other types [type B BE: 15.5 M (n = 48, 95% CI, 12.4 to 23.3), E: 11.1 M (n = 57, 95% CI, 8.5 to 13.7)]. Type C showed worse response to both treatment [type C BE: 6.0M. (n = 12, 95% CI 2.6 to NR), E: 4.3 M (n = 10, 95% CI, 2.8 to 20.2)]. BE had better PFS in all types. **Conclusion:** Frequency of T790M in P2 was similar among BE and E. When patients still had detectable activating EGFR mutation in plasma ctDNA after treatment for 6 weeks, you should consider that they might have poor response to both BE and E.

Background: *MET* exon 14 splice site (*MET*ex14) mutations were recently described in Non Small Cell Lung Cancer (NSCLC) and reported to correlate with efficacy of MET tyrosine kinase inhibitors. High diversity of these alterations make them hard to detect by DNA sequencing in clinical practice. Because *MET*ex14 mutations induce increased stabilization of the MET receptor, it is anticipated that these mutations are associated with MET overexpression. We aim to determine whether NSCLC with high MET overexpression could define a subset of patients with a high rate of *MET*ex14 mutations. **Method:** From the IFCT Predict.amm cohort of 843 consecutive patients with a treatment-naïve advanced NSCLC who were eligible for a first-line therapy, 108 NSCLC samples with high MET overexpression defined by an immunochemistry (IHC) score 3+ were tested for *MET*ex14 mutations using fragment length analysis combined with optimized targeted next generation sequencing (NGS). *MET* copy number analysis was also derived from the sequencing data. **Result:** *MET*ex14 mutations were detected in two patients (2.2%) who also displayed a TP53 mutation and a PIK3CA mutation, respectively. A *MET* gene copy number increase was observed in 7 additional patients (7.7%). NGS analysis revealed inactivating mutations in *TP53* (52.7%) and *PTEN* (1.1%) and oncogenic mutations in *KRAS* (28.6%), *EGFR* (7.7%), *PIK3CA* (4.4%), *BRAF* (4.4%), *NRAS* (2.2%), *GNAS* (1.1%) and *IDH1* (1.1%). **Conclusion:** The rate of *MET*ex14 mutations in NSCLC with high MET overexpression was similar to that found in unselected NSCLC. Moreover, we observed a high frequency of driver alterations in other oncogenes. Consequently these findings do not support the use of MET IHC as a surrogate marker for *MET*ex14 mutations.

Background: Chromosomal rearrangements involving *RET*, with incidence of 1-2% in non-small-cell lung cancer, define a distinctive molecular subset. Here, we aim to determine the clinicopathological characteristics of patients with advanced NSCLC harboring the *RET* fusion gene. **Method:** We identified 59 consecutive cases with *RET* rearrangements by using break-apart fluorescence in situ hybridization (n=14), next-generation sequencing (n=37), or both (n=8). Clinical data, including baseline characteristics, initial presentation, responses to chemotherapy and/or immunotherapy were retrospectively analyzed. **Result:** The median age was 56 years, and 53% of patients were male. Approximately half of the patients (51%) were never-smokers. Adenocarcinoma was the predominant histologic subtype (90%), followed by pleomorphic (3%), neuroendocrine (3%), squamous cell (2%), and small cell carcinoma (2%). For the 19 patients with small primary lesions (<3cm), 32% (6/19) had N2 and 37% (7/19) had N3 disease. 17 patients (29%) had an intracranial lesion at the initial presentation or at the time of recurrence, and additional 11 patients (19%) developed brain metastasis during follow-up. Cerebrospinal fluid cytology exam confirmed leptomeningeal seeding in four patients (7%) with concomitant parenchymal metastasis. The median time to development of brain metastases was 19.0 months (range 3.8-51.8). Of 30 patients whose fusion partners were identified, kinesin family member 5B (*KIF5B)* was the most common, followed by coiled-coil domain containing 6 gene (*CCDC6*), nuclear receptor coactivator 4 (*NCOA4*), and myosin 5C (*MYO5C*) and lisH domain and HEAT repeat-containing protein KIAA1468 homolog (*KIAA1468*). Additionally, a novel fusion partner, phytanoyl-CoA 2-hydroxylase interacting protein like (*PHYHIPL)*, was reported in one patient. Only two patients harbored concomitant *EGFR* mutation, and no *ALK* alterations were reported. The median overall survival was 35.3 months (95% confidence interval [CI]: 21.7-48.9). In 46 patients who were treated with pemetrexed-based chemotherapy, the overall response rate (ORR) and progression-free survival (PFS) time were 53.0% and 8.5 months (95% CI: 6.3-10.7), respectively. In 13 patients who were treated with immunotherapy, the ORR and PFS were 7.7% and 1.5 months (95% CI: 1.3-1.7), respectively, with no significant difference according to the level of PD-L1 expression. **Conclusion:** Our study revealed the unique clinical characteristics and outcomes of advanced NSCLC patients harboring *RET* fusion gene. Considering the high incidence of CNS metastases, relatively poor response to immunotherapy, and a recent development of *RET* kinase inhibitors (such as cabozantinib and vandetanib), more efforts are warranted for identification of patients with *RET* fusion as a candidate for targeted therapies.

Keywords: NSCLC, RET fusion, CNS metastases

P2.14-55 REAL-WORLD SAFETY AND EFFICACY DATA OF OSIMERTINIB IN PATIENTS FROM JAPAN WITH EGFR T790M-POSITIVE NSCLC

Y. Ohe[1], T. Kato[2], W. Shimizu[3], K. Sakamoto[4], M. Sugeno[4], R. Tamura[4], T. Tokimoto[4], A. Gemma[3]

Background: Osimertinib, a third-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor (TKI), was approved in Japan on 28 March 2016 as second- or later-line treatment for patients with EGFR T790M mutation-positive non-small cell lung cancer (NSCLC) who have progressed on EGFR-TKIs. Post-marketing activities included the Japan-local All-patient Clinical Experience Investigation, reporting Japanese real-world safety and efficacy of osimertinib in the approved indication. **Method:** Overall, 3629 patients investigated at 718 hospitals between 28 March 2016 and 31 August 2018 were included. Adverse events were assessed by attending physicians to determine whether they were possibly causally-related to osimertinib. Osimertinib antitumour activity was evaluated by attending physicians using RECIST version 1.1. Progression-free survival (PFS) and overall survival (OS) were also analysed. The planned observation period was 12 months. **Result:** The median observation period for patients in the safety analysis set (n=3578) was 343 days (range: 1–764). Adverse drug reactions occurred in 58.1% (2079/3578) of patients. Adverse drug reactions (as per Japanese Prescribing Information) of interstitial lung disease, prolonged QT interval, liver disorder, and haematotoxicity were reported in 6.8% (245/3578) (Gr≥3, 2.9% [104/3578]), 1.3% (45/3578) (Gr≥3, 0.1% [5/3578]), 5.9% (212/3578) (Gr≥3, 1.0% [35/3578]), and 11.4% (409/3578) (Gr≥3, 2.9% [104/3578]) of patients, respectively. The objective response rate and disease control rates for patients in the efficacy analysis set (n=3563) were 69.9% (2492/3563; 95% confidence interval [CI] 68.4, 71.4) and 86.7% (3090/3563; 95% CI 85.6, 87.8). PFS rates at 6 months and 12 months were 77.4% (95% CI 75.9, 78.9) and 53.2% (95% CI 51.3, 55.1). OS rates at 6 months and 12 months were 88.3% (95% CI 87.2, 89.4) and 75.4% (95% CI 73.8, 77.0). Selected subgroup analyses of efficacy are presented in Table 1.

Table 1. Selected subgroup analysis of real-world osimertinib efficacy in patients from Japan					
Subgroup	Category	N	ORR % (95% CI)	PFS rate at 6 months % (95% CI)	PFS rate at 12 months % (95% CI)
Age	<75	2458	69.4 (67.6, 71.3)	76.1 (74.2, 77.8)	50.4 (48.1, 52.7)

	Yes	939	62.3 (59.1, 65.4)	74.8 (71.6, 77.7)	50.3 (46.4, 54.0)
CI, confidence interval; EGFRm, epidermal growth factor receptor mutation; ORR, objective response rate; PFS, progression-free survival; PS, performance status					

Conclusion: These data support the currently established benefit–risk assessment of osimertinib in patients with EGFR T790M positive NSCLC.

Keywords: T790M, Japanese, Osimertinib

P2.14-56 OSIMERTINIB OVERCOMES ALECTINIB RESISTANCE CAUSED BY AMPHIREGULIN IN A LEPTOMENINGEAL CARCINOMATOSIS MODEL OF EML4-ALK LUNG CANCER

S. Arai[1], S. Takeuchi[1], K. Fukuda[1], A. Nishiyama[1], A. Tanimoto[1], H. Taniguchi[1], M. Satouchi[2], S. Nanjo[1], R. Katayama[3], M. Nishio[4], M. Zheng[5], Y.-L. Wu[6], S. Yano[1]

[1]*Cancer Research Institute Kanazawa University, Kanazawa, Ishikawa/Japan,* [2]*Hyogo Cancer Center, Akashi/Japan,* [3]*Cancer Chemotherapy Center, Japanese Foundation for Cancer Research, Tokyo/Japan,* [4]*The Cancer Institute Hospital, Japanese Foundation for Cancer Research, Tokyo/Japan,* [5]*Guangdong Lung Cancer Institute, Guangzhou/China,* [6]*Guangdong Lung Cancer Institute, Guangdong Provincial People's Hospital & Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: Central nervous system (CNS) metastasis, such as brain metastasis and leptomeningeal carcinomatosis (LMC), occurs in 20–40% of all patients with cancer. Anaplastic lymphoma kinase (ALK) is a clinically validated drug target and *ALK* rearrangements are found in approximately 3-5% of non-small cell lung cancer (NSCLC). ALK tyrosine kinase inhibitor (TKI) shows dramatic clinical efficacy in *ALK*-rearranged NSCLC patients, and the second-generation ALK-TKI alectinib is effective against CNS metastasis of *ALK*-rearranged NSCLC. However, the patients with *ALK*-rearrangement acquire resistance to alectinib over time and develop recurrent LMC metastasis. This study aimed to clarify the mechanism of resistance to alectinib in LMC and seek a novel therapeutic strategy. **Method:** Alectinib-resistant cell line (A925L/AR) was established by continuous treatment with alectinib in the LMC mouse model inoculated with the alectinib-sensitive human lung cancer cell line, A925LPE3, which harbors the *EML4-ALK* gene fusion. The tumor level was measured by in vivo imaging system. To clarify the mechanism of alectinib resistance, tumor cell culture supernatants, patient cerebrospinal fluid (CSF), and patient serum were measured using ELISA kits for EGFR ligands. **Result:** A925L/AR cells were moderately resistant to various ALK-TKIs, such as alectinib, crizotinib, ceritinib, and lorlatinib, compared with parental cells *in vitro*. A925L/AR cells acquired resistance through epidermal growth factor receptor (EGFR) activation due to overexpression of its ligand, amphiregulin. EGFR-TKIs and anti-EGFR antibodies re-sensitized A925L/AR cells to alectinib *in vitro*. In the LMC model with A925L/AR cells, combined treatment with alectinib and an EGFR-TKI, such as erlotinib and osimertinib, successfully controlled LMC progression. Imaging mass spectrometry showed accumulation of EGFR-TKIs in the tumor lesions. Moreover, notably high amphiregulin levels were detected in the cerebrospinal fluid from *ALK*-rearranged NSCLC patients with alectinib-resistant LMC compared with those in *EGFR*-mutated NSCLC patients with EGFR-TKI-resistant LMC or patients without LMC. **Conclusion:** We demonstrated that *EML4-ALK* lung cancer cells acquired moderate resistance to alectinib in the leptomeningeal space due to amphiregulin-triggered EGFR activation. Moreover, combined use of alectinib and EGFR-TKIs, including the third-generation inhibitor osimertinib, could overcome resistance in the LMC model. Our findings may provide rationale for clinical trials to investigate the effects of novel therapies dual-targeting ALK and EGFR in *ALK*-rearranged NSCLC with alectinib-resistant LMC.

P2.14-57 EFFICACY OF 3RD GENERATION EGFR-TKIS AFTER FAILING FIRST OR SECOND GENERATION EGFR-TKIS IN EGFR MUTATION-POSITIVE NSCLC (ROOT-EGFR)

H.A. Jung, S. Hong, J. Park, M.R. Park, J.-M. Sun, S.-H. Lee, J.S. Ahn, M.-J. Ahn, K. Park

Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of

Background: Over the past decade, treatment of EGFR mutation –positive NSCLC has been revolutionized with the development of next generation EGFR TKIs. Four epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs), erlotinib, gefitinib, afatinib and osimertinib, are currently available in Korea. Recent trials have compared the available and emerging EGFR TKIs head to head. The highly anticipated findings of the phase III FLAURA trial showed a nearly doubling of PFS with frontline osimertinib, a third-generation TKI, versus erlotinib or gefitinib.The optimal sequence of EGFR TKIs is still controversial. And many countries 3rd generation EGFR TKI is not readily available. The purpose of this study is to analyze the efficacy in patients who received first-line gefitinib, erlotinib, or afatinib and followed by 3rd generation EGFR-TKIs. **Method:** This non-interventional observational study through big data analysis will retrospectively collect de-identified patient data from clinical data warehouse (CDW) using a unique algorithm with Standard Query Language (SQL) called ROOT project. **Result:** Over 10 years, 2,358 patients were diagnosed recurrent or metastatic non-small cell lung cancer and received 1st or 2nd generation EGFR TKIs at Samsung Medical Center. 72.9% (1720/2358) of EGFR mutation-positive NSCLC patients received 1st or 2nd generation EGFR-TKIs as first

line palliative chemotherapy. In total population, 30.8% (727/2358) patients received 3rd generation EGFR TKIs. Among them, patients who received 3rd generation EGFR TKI after 1st or 2nd generation EGF TKIs showed better overall survival (45.0 months (95% CI, 41.8-48.2). Among 1720 patients who received 1st or 2nd generation EGFR-TKIs as first line palliative chemotherapy, 313 patients received 3rd generation EGFR-TKIs as 2nd line chemotherapy and 200 patients received as more than 3rd line chemotherapy. However, there was no difference of overall survival between them (44.0 months vs 47.0months, p-value=0.104). **Conclusion:** This study was meaningful as a study of what can be the best sequence in EGFR-TKI treatment. Updated and detail clinical and exploratory biomarker outcome will be presented at the meeting.

Keywords: NSCLC, EGFR TKI, 3rd generation

P2.14-58 A PHASE IIIB, OPEN-LABEL STUDY OF AFATINIB IN CAUCASIAN EGFR TKI-NAÏVE PATIENTS WITH EGFRM+ NSCLC: AN INTERIM ANALYSIS

KG, Vienna/Austria,* [19]*Oncology Centre and Institute, Warsaw/Poland*

Background: First-line afatinib demonstrated significantly improved median PFS in patients with *EGFR* mutation-positive (*EGFR*m+) NSCLC versus chemotherapy in LUX-Lung 3/6 (HR [95% CI]: 0.58 [0.43–0.78]/0.28 [0.20–0.39]), and versus gefitinib in LUX-Lung 7 (0.73 [0.57–0.95]). Since these trials had strict inclusion criteria, it is important to support these findings with real-world studies of broader patient populations. We report interim results of a Phase IIIb study of afatinib treatment for *EGFR*m+ NSCLC in a patient population similar to real-world practice. **Method:** EGFR TKI-naïve patients with locally advanced/metastatic *EGFR*m+ NSCLC, and ECOG PS 0–2, received afatinib 40 mg/day. Dose reduction was permitted (minimum 20 mg/day). Primary endpoint: adverse events (AEs; descriptive fashion). Efficacy was also assessed. **Result:** At data cut-off (30-April-2018), 479 patients were enrolled and treated (Caucasian/Asian/other: 97%/2%/<1%; ECOG PS 0–1/2: 92%/8%; 1st/2nd/≥3rd-line therapy: 78%/17%/5%; common/uncommon mutations: 87%/13%; brain metastases: 17%). Median time on afatinib: 359 days. Objective response and disease control rates were 46% and 86%, respectively. Other efficacy outcomes are in the Table. The most common grade ≥3 afatinib-related AEs were diarrhoea (16%) and rash (11%). 258 (54%) patients had AEs leading to dose reduction (most frequently diarrhoea [25%]/rash [11%]), and 37 (8%) had TRAEs leading to discontinuation (most frequently diarrhoea [3%]; all others [<1%]). Serious afatinib-related AEs occurred in 39 (8%) patients.

*Missing (n=1); †Del 19 and/or L858R with or without uncommon mutation; ‡Includes, n (%, of those with uncommon mutations): ex 20 ins: 37 (60), T790M: 12 (19), G719S/A/C: 12 (19), L861Q: 10 (16), S768I: 9 (15). TTSP, time to symptomatic progression; PFS, progression-free survival

Conclusion: This interim analysis indicated predictable and manageable safety, and encouraging efficacy, with afatinib in a broad patient population. The high proportion of patients with tumours harbouring exon 20 insertions may account for the differences in TTSP/PFS by common/uncommon mutation subgroup. Independent of treatment line, median TTSP/PFS in patients with ECOG PS 0–1 (LUX-Lung trials' inclusion criteria) was 15.8/13.8 months, and, notably, was 18.9/14.1 months in those also aged ≥65 years. These findings by ECOG PS/age are consistent with those of the LUX-Lung trials.

P2.14-59 OSIMERTINIB IN EGFR T790M ADVANCED NSCLC: ANALYSIS OF UNCOMMON/COMPLEX EGFR MUTATIONS IN A REAL-WORLD STUDY (ASTRIS)

Background: The challenges of treating uncommon/complex EGFR mutations impact treatment decisions in clinical practice. Osimertinib is a third-generation, irreversible, oral EGFR-TKI that potently and selectively inhibits both EGFR-TKI sensitising (EGFRm) and EGFR T790M mutations and has demonstrated efficacy in NSCLC CNS metastases. ASTRIS is an ongoing, international, real-world study of osimertinib in EGFR T790M positive advanced NSCLC (NCT02474355). We report a subset-analysis of patients with

uncommon/complex mutations. **Method:** Patients with stage IIIB/IV T790M positive NSCLC previously treated with an EGFR-TKI were enrolled and received osimertinib 80 mg once-daily. Progression-free survival (PFS), clinical response and time to treatment discontinuation (TTD) were analysed in both full analysis set (FAS) and patients with uncommon/complex EGFR mutations. Uncommon mutation combinations included: T790M+G719X, T790M+S768I, T790M+ex20ins; complex mutations included T790M+two or more mutation(s). **Result:** From 18 September 2015 to 15 October 2018 data cut-off, 3015 patients across 16 countries had received ≥1 dose of osimertinib (FAS), 53(2%) of these patients had uncommon/complex EGFR mutations. Baseline demographics between this patient subset and the FAS were similar (Asian: 55%/69%; female: 57%/64%; median age: 59 [30–80] years/62 [range, 27–92]; WHO performance status 2: 9%/11%, respectively). Baseline EGFR mutation status at enrolment of the FAS is shown in Table 1. Clinical outcomes appeared to be lower in the uncommon/complex mutation subset than in the FAS: response rate (measured in a FAS subset with ≥1 documented response assessment) was 50% [95% CI, 35.2, 64.8] in the uncommon/complex mutation group, and 57% [55.2, 58.9] in the FAS; median PFS was 8.1 [5.4, 10.1] and 11.1 [11.0, 12.0] months; median TTD was 9.0 [6.7, 11.5] and 13.5 [12.6, 13.9] months, respectively. Overall survival data are immature.

Table 1. Baseline EGFR mutation status (full analysis set)

EGFR mutation, n (%)**	Osimertinib (N=3015)
Uncommon/complex EGFR mutations	53 (2)

*T790M + 4 other mutations (complex mutations)***	*2 (<1)*
+ Ex19del + L858R + G719X + S768I	*2 (100)*

*Patients can have more than one mutation and specimens are not necessarily tested for all mutations
#Uncommon/complex EGFR mutations are italicised
§Percentages quoted are as proportion of those with T790M+1 mutation (n=2611)
¶Percentages quoted are as proportion of those with T790M+2 mutations (n=30)
**Percentages quoted are as proportion of those with T790M+4 mutations (n=2)
Ex19del, exon 19 deletion; Ex20ins, exon 20 insertion.

Conclusion: Whilst clinical outcomes appeared to be lower in the uncommon/complex mutation subset than the FAS, they were favourable and support use of osimertinib 80mg in this heterogeneous population.

Keywords: Osimertinib, NSCLC, EGFR

P2.14-60 AFATINIB IN EGFR MUTATION-POSITIVE NSCLC: ACTIVITY IN PATIENTS WITH BRAIN METASTASES, AND IMPACT ON CNS PROGRESSION/SPREAD

K. O'Byrne[1], J. Yang[2], Y.-L. Wu[3], V. Hirsh[4], N. Yamamoto[5], S. Popat[6], A. Tamiya[7], A. Märten[8], M. Schuler[9]

[1]*Princess Alexandra Hospital and Queensland University of Technology, New South Wales/Australia,* [2]*National Taiwan University Hospital and National Taiwan University Cancer Center, Taipei/Taiwan,* [3]*Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/China,* [4]*McGill University, Montreal/Canada,* [5]*Wakayama Medical University, Wakayama/Japan,* [6]*The Royal Marsden Hospital, London/United Kingdom,* [7]*Kinki-Chuo Chest Medical Center, Osaka/Japan,* [8]*Boehringer Ingelheim International GmbH, Ingelheim am Rhein/Germany,* [9]*West German Cancer Center, University Hospital Essen, University Duisburg-Essen, Essen/Germany*

Background: In the LUX-Lung 3 and 6 trials, first-line afatinib significantly improved progression-free survival (PFS) versus chemotherapy in patients with *EGFR* mutation-positive (*EGFR*m+) NSCLC and baseline brain metastases (hazard ratio [HR], 0.50; P=0.0297).1 In LUX-Lung 7, similar PFS improvement with afatinib versus gefitinib was observed in patients with, and without, brain metastases (HR, 0.76 and 0.74; Pint=0.93).2 The aims of this study were to assess: i) the impact of afatinib on central nervous system (CNS) progression or metastatic spread in LUX-Lung 3, 6, and 7; ii) efficacy of afatinib in patients with brain metastases in a similar setting to 'real-world' practice. **Method:** Competing risk analysis of CNS/non-CNS progression or death was performed in patients who received afatinib in LUX-Lung 3, 6, and 7, based on the cumulative frequency of the event of interest versus the competing risk event. Separate analysis was performed of an Asian phase IIIb study, which assessed afatinib in a broad population of EGFR TKI-naïve patients with *EGFR*m+ NSCLC (NCT01953913).3 PFS and time-to-symptomatic progression (TTSP) in patients with baseline brain metastases were calculated by Kaplan–Meier methodology. **Result:** In patients with baseline brain metastases receiving afatinib in LUX-Lung 3 and 6 (n=48; median follow-up: 10.3 months), the risk of CNS progression was 40% lower than the risk of extracranial progression; 31.3%/52.1% of patients had CNS/non-CNS progression, respectively. In patients without baseline brain metastases receiving afatinib in LUX-Lung 3, 6, and 7 (n=485; median follow-up: 13.0 months), the risk of *de novo* CNS/non-CNS progression was 6.4%/78.4%. Cumulative risk of CNS/non-CNS progression was 1.3%/17.2% at 6 months and 2.6%/41.2% at 12 months. In the Asian phase IIIb study, there was no difference in PFS (median 10.9 vs 12.4 months; P=0.18) or TTSP (median 14.8 vs 15.4 months; P=1.0) between patients with (n=92) or without (n=387) brain metastases. **Conclusion:** Competing risk analyses of LUX-Lung 3, 6, and 7 suggest that afatinib delays the onset/progression of brain metastases. Real-world data are consistent with LUX-Lung 3, 6, and 7, and support the use of afatinib in patients with EGFRm+ NSCLC and baseline brain metastases. 1. Schuler, M. et al. P2.14-61 ACQUIRED RESISTANCE TO ENTRECTINIB ASSOCIATED WITH ACTIVATION OF RAS SIGNALING PATHWAY IN ROS1-REARRANGED NON-SMALL CELL LUNG CANCER

B.M. Ku[1], H.A. Jung[2], J.-M. Sun[2], S.-H. Lee[2], J.S. Ahn[2], K. Park[2], M.-J. Ahn[2]

[1]*Samsung Medical Center, Seoul/Korea, Republic of,* [2]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul/Korea, Republic of*

Background: ROS1 is a receptor tyrosine kinase (RTK) that is not usually expressed at high levels in normal lung tissue. The wild-type function of ROS1 is unknown, and a natural ligand has not been identified. *ROS1* gene rearrangements occur in ~1-2% of patients with NSCLC, and have also been identified in colorectal, gastric and ovarian cancers, glioblastoma and cholangiocarcinoma. *ROS1* rearrangements with oncogenic potential have been found to constitutively activate ROS1 signaling, and although it remains unclear exactly how the ROS1 fusion proteins are activated, the PI3K/AKT, MAPK/ERK and JAK/STAT3 pathways are known to be involved. Thus, *ROS1*-rearranged NSCLCs are 'addicted' to ROS1 for cell growth and survival. Knocking down or pharmacologically inhibiting ROS1 has been reported to inhibit growth or induce

apoptosis in *ROS1*-rearranged cell lines. Entrectinib is a pan-tyrosine-kinase inhibitor that targets oncogenic rearrangements in *NTRK*, *ROS1* and *ALK*. The combined results of two clinical trials demonstrated the efficacy of entrectinib in *ROS1*-rearranged NSCLC. Because the development of drug resistance is inevitable, it would be helpful to determine the mechanisms of entrectinib resistance in a *ROS1*-rearranged tumor model so that future therapeutic strategies can be developed. **Method:** To investigate the effects of entrectinib on *ROS1*-rearranged NSCLC, we used HCC78 cells harboring an *SLC34A2-ROS1* fusion. Entrectinib-resistant HCC78 (HCC78ER) cells were newly established in our laboratory through the exposure of HCC78 cells to gradually increasing concentrations of entrectinib (starting at 100 nM and ending with 5 μM) over 6 months. **Result:** Here, we characterized the molecular basis of resistance in entrectinib-resistant *ROS1*-rearranged HCC78 cells (HCC78ER cells). These cells were analyzed by next-generation sequencing and genetic profiling, which revealed the acquisition of *KRAS* G12C and the amplification of *KRAS* and *FGF3*. However, there were no secondary mutations in the ROS1 kinase domain. We also found that sustained ERK activation was involved in entrectinib resistance, and that combined treatment with selumetinib resensitized HCC78ER cells to entrectinib in cell viability and colony formation assays. **Conclusion:** Our data suggest that activation of the RAS signaling pathway can cause entrectinib resistance in *ROS1*-rearranged NSCLC, and is unlikely to be overcome by sequential single agent ROS1-targeting strategies against such tumors. Instead, co-targeting ROS1 and MEK may be an effective strategy for overcoming entrectinib resistance in *ROS1*-rearranged NSCLC.

P2.14-62 EARLY, SUBCLINICAL SCLC TRANSFORMATION IN PATIENTS WITH EGFR MUTANT LUNG CANCER RECEIVING OSIMERTINIB, DETECTED THROUGH CELL-FREE DNA

E. Stewart[1], S. Martins-Filho[1], M. Cabanero[1], A. Wang[2], J. Huang[2], H. Bao[2], X. Wu[2], D. Patel[1], Z. Chen[1], J. Law[1], P. Bradbury[1], F. Shepherd[1], N. Leighl[1], M. Tsao[1], T. Pugh[1], S. Bratman[1], G. Liu[1], A. Sacher[1]

[1]*University Health Network, Toronto/Canada,* [2]*GeneSeeq, Toronto/Canada*

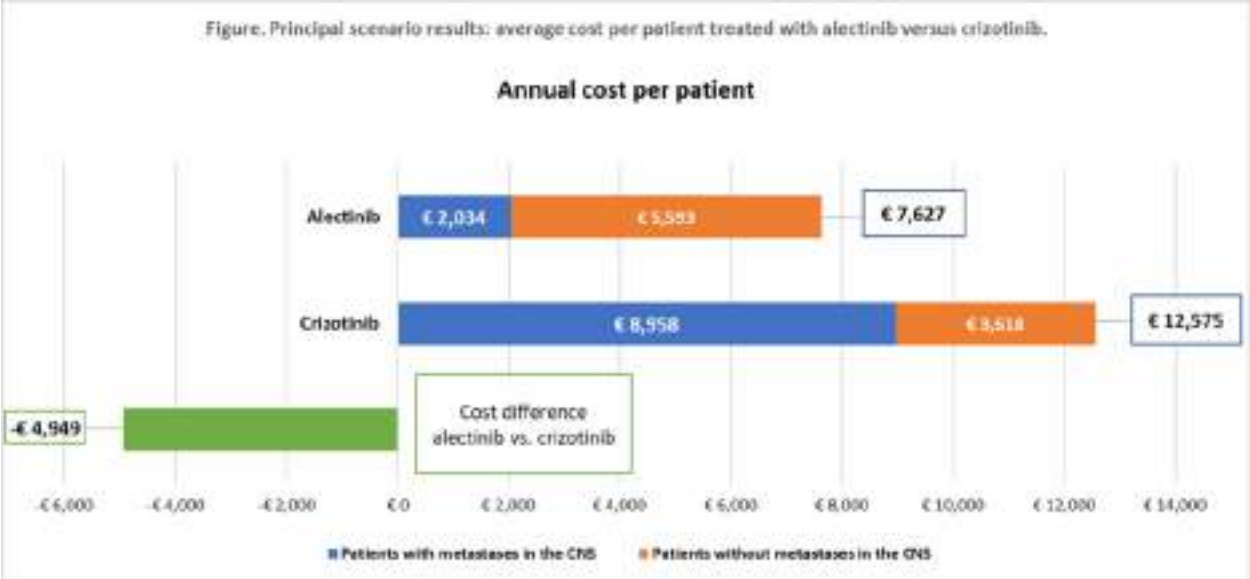
Background: Liquid biopsies provide a convenient approachfor serial sampling and real-time disease monitoring, leading to the early detection of treatment response, disease progression and drug-resistance. Here,we present genomic profiling of serial liquid biopsies from seven lung cancer patients with activating*EGFR*mutations receiving osimertinib in clinical practice. **Method:** At Princess Margaret Cancer Centre, in the Lung Cancer Outpatient Clinics, plasma samples were obtained from each patient at defined clinical visits (between ~1–5 months in-between visits). Cell-free DNA (cfDNA; with a median of 57 ng; range: 3.5 to 3806 ng) was extracted from plasma samples and profiled using targeted capture next-generation sequencing with the Geneseeq Prime 425-gene panel, at a mean coverage depth of 4892X (with a deduplicated mean coverage depth of 2108X). **Result:** Systemic tumour burden correlated with the detection of genomic alterations in cfDNA: Four of four of the patients with low tumour burden, despite minor disease progression, exhibited minimal EGFR and co-mutation allele frequencies (AFs). Conversely, significant increases in systemic (but not central nervous system) tumour burden led to increases in driver and co-mutation AFs (two our of three patients). EGFR C797S mutation and inactivating mutations in RB1 and TP53 were detected in the cfDNA of one patient nearly four months prior to the development of small cell lung cancer (SCLC) transformation confirmed on tissue biopsy with distinct transformed and untransformed areas. Both of the specific RB1 and TP53 mutations found in cfDNA have been previously associated with SCLC. Subsequent combination cisplatin-etoposide chemoradiation resulted in temporary complete remission of the transformed SCLC, corresponding to loss of RB1 mutation detection by cfDNA testing. **Conclusion:** Profiling of plasma cfDNA using hybrid capture deep sequencing of a large gene panel can detect early subclinical transformation of *EGFR*-mutated lung cancer into small cell lung cancer (i.e., neuroendocrine transformation), leading to earlier diagnosis and management of the transformed disease. Serial liquid biopsy profiling can also be used to monitor disease progression. However, detection sensitivity of tumour cfDNA largely depends on systemic tumour burden.

P2.14-63 COST ANALYSIS OF THE MANAGEMENT OF CNS METASTASES IN PATIENTS WITH ADVANCED ALK+ NSCLC: ALECTINIB VS CRIZOTINIB

B. Massuti[1], M. Lazaro[2], D. Isla[3], R. Gordo[4], L. Ruiz De Alda[4], N. Ortega[5], I. Oyagüez[5]

[1]*Hospital General de Alicante, Alicante/Spain,* [2]*Complexo Hospitalario Universitario de Vigo, VIGO/Spain,* [3]*Hospital Clinico Universitario Lozano Blesa, Zaragoza/Spain,* [4]*Roche Farma S.A, Madrid/Spain,* [5]*Pharmacoeconomics & Outcomes Research Iberia, Madrid/Spain*

Background: The high prevalence of CNS metastases in ALK+ NSCLC leads to a significant clinical and economic burden. Alectinib demonstrated superior CNS activity and significantly delayed CNS progression versus crizotinib in untreated patients. Therefore, alectinib could reduce the brain metastasis-related healthcare resource utilization and costs. The objective is to estimate the cost associated with the management of patients with advanced ALK+ NSCLC with and without CNS metastases, and to perform an analysis of the annual cost comparing patients treated with alectinib or crizotinib. **Method:** Using the disaggregated consumption of resources provided by a panel of expert oncologists, the cost/year of the management of patients with ALK+ NSCLC with/without development of CNS metastases was estimated. The cost of management (€,2018) included the quantification of medical visits, hospitalisations, diagnostic and laboratory tests, imaging techniques and radiotherapy procedures. The unit costs of the resources were obtained from eSalud (Spanish database). Using the 12-month cumulative incidence rate of CNS metastases in the ALEX trial for alectinib (9.4%) and crizotinib (41.4%), the annual cost of management with each therapy was estimated and compared. An alternative analysis was performed considering the management of adverse events (AE) observed in the ALEX trial, with costs obtained from the literature. **Result:** The cost/year of managing NSCLC was €6,173.42/patient without CNS metastases and €21,637.50/patient with CNS metastases. In patients treated with alectinib, the average cost per patient was lower than in patients with crizotinib (-€4,948.51 patient/year) in the Spanish healthcare setting. Considering the cost of AE, the average cost/year difference would be -€5,044.26/patient treated with alectinib vs crizotinib.



Conclusion: The delay in the appearance of CNS metastases associated with the treatment of alectinib vs crizotinib may result in a reduction in cost per year in the management of ALK+ NSCLC. Comprehensive approach of cost analysis should be adjusted to each disease characteristics.

P2.14-64 IS ALK INHIBITOR A CONTRAINDICATION FOR SUBSEQUENT IVF PREGNANCY?

R. Gillis[1,2], M. Ben David Hadani[3], A. Hourvitz[4], N. Peled[1,2]

[1]*Ben Gurion University of the Negev, Beer Sheva/Israel,* [2]*Soroka Medical Center, Beer Sheva/Israel,* [3]*Ruppin Academic Center, Emek Chefer/Israel,* [4]*Sheba Medical Center, Ramat-Gan/Israel*

Background: Anaplastic lymphoma kinase (ALK) inhibitors drugs, such as crizotininb, are currently at the focus of treatment for ALK positive metastatic non-small cell lung cancer. Although the FDA statement that crizotinib may be detrimental to fetus development, there is no direct prohibition against the use of crizotinib during pregnancy, neither comment regarding its consumption under assisted reproductive pregnancy. Here we report, for the first time, a normal development of twins that their oocytes were aspirated while undergoing Crizotinib therapy. Furthermore, we discuss some ethical issues raises from this report. Our report along with the rapidly improvement of the ALK inhibitors therapies, raises ethical issues such as, the debate around the right for parenthood while having a progressive uncurable disease and the right for proceeding an assistant reproductive therapy while treated with biological therapies.

Background: Dabrafenib plus trametinib (D-T) combination is approved in Europe Union for *BRAF*V600E–mutant metastatic non-small cell lung cancer(NSCLC) but there is few published data's on this efficacy and tolerance outside clinical trail results. Objective: to assess efficacy and tolerance of D-T in real world setting. **Method:** Retrospective, multicentric study including *BRAF* V600E-positive advanced NSCLC receiving D-T outside a clinical trial. Overall survival (OS) and progression free survival (PFS) were analyzed in all population and according lines of D-T treatment (first line treatment or subsequent line treatments). **Result:** the analysis included 40 BRAF V600E advanced NSCLC patients managed in 14 centers; at diagnosis: mean age 71 ±9.6 years, female 55 %, adenocarcinoma 95 %, currents/formers smokers 17.5%/50 %, At D-T initiation: PS 0-1/2 or+: 86.8%/13.2%, loss weight> 5%: 24%, symptomatic disease: 92%, stage IV: 95%, mean metastatic site: 2.3 (main metastatic sites: pleura: 46%, bone: 33%, respectively).Mean line of treatment before D-T: 1.5. D-T was a first line treatment in 22.5 %, second line or more 77.5% (25% received one BRAF TKI before). Median time between diagnosis and D-T treatment was 0.7 [95%CI: 0.2-1.3] months in first line setting and 17.3 [95%CI: 10.8-27.2] months. At the time of analysis 67.5% patients were in treatment with D-T and median follow up since beginning of D-T treatment was 8.7[95%CI: 5-12] months in whole population [7,5, 95%CI: 1-12.3]months for patients treated in first line). D-T dose was modified for 32.5.0% of the patients and definitively discontinued for 12,5 % because of severe adverse events. Median PFS and OS were not reach and follow up is continued. The mature results of PFS and OS (whole population and subgroups) will be showed to the WLCC meeting. **Conclusion:** Section not applicable

Keywords: braf, Dabrafenib, trametinib

P2.14-66 COMBINATION ALK AND MEK INHIBITION IN ALK-POSITIVE LUNG CANCER

J. Ashton, N. Shrestha, A. Bland

University of Otago, Dunedin/New Zealand

Background: ALK positive lung cancer can be treated with ALK inhibitors, but resistance typically develops within 1 or 2 years. One strategy to overcome drug resistance is combination therapy. In particular, MEK has been suggested as a target for combination therapy with ALK inhibitors. We investigated this hypothesis with *in vitro* and in vivo experiments. **Method:** Human lung adenocarcinoma cells harbouring the ELM4-ALK rearrangement (H3122) we exposed to varying concentrations of the ALK inhibitor crizotinib, and the MEK inhibitor selumetinib, and cytotoxicity assayed using the SRB assay. Cell cycle, apoptosis, and Western blot assays were used to further investigate mechanisms of co-action. Balb/c mice were then dosed with crizotinib (5 or 25mg/kg, po) and/or selumetib (25 mg/kg, po) for 14 days and toxicity assessed. Nude mice were then injected with H3122 cells to produce a flank tumour, and the effects of treatment with crizotinib (25 mg/kg, po) and/or selumetinib (25 mg/kg, po) ascertained. **Result:** Combination crizotinib and selumetinib killed both crizotinib naieve and crizotininb resistant H3122 cells in a synergistic manner. The combination treatment caused a small increase in apoptosis, and a large decrease in cells in S phase. Western blot showed strong combination effects on suppression of phoshpo-ERK, and cyclin DI, and upregulation of BIM. No toxicity for liver or kidney function was detected with 25 mg/kg crizotinib and selumetinib. In xenograft experiments, the combination suppressed tumour growth to a greater extent than either drug alone. **Conclusion:** This work has successfully replicated recent findings for combination ALK and MEK inhibition in ALK lung cancer experiments, but using different specific drugs than previously. The drugs were were well tolerated in combination. Cell based experiments shed further light on mechanisms of action for this drug combination, and revealed two further druggable targets: BIM and CDK1.

Keyword: ALK, MEK, crizotinib, selumetinib

P2.14-67 METASTATIC RET-REARRANGED LUNG ADENOCARCINOMAS TREATED WITH ALECTINIB: RETROSPECTIVE ANALYSIS OF A SINGLE INSTITUTION

M. Ribeiro, A. Gongora, L. Oliveira, J.V. Alessi, K. Saccardo, B. Zucchetti, F. Barbosa, D. Muniz, A. Shimada, C. De Souza, O. Feher, A. Katz

Hospital Sírio-Libanês, Sao Paulo/Brazil

Background: RET-rearrangements are well-described drivers in lung adenocarcinomas (LADC), identified in nearly 1-2% of the tumors, for which there are no current specific targeted therapies approved. Although several tyrosine-kinase inhibitors (TKI) (e.g vandetanib, cabozantinib, lenvatinib, etc) demonstrate anti-RET activity, poor tolerability and overall response rates less than 50% has been limiting its widespread adoption. The structural homology between the kinase domains of ALK and RET, as well as the documented *in vitro*activity, and well-known toxicity profile makes alectinib an attractive drug for evaluation in clinical trials and, possibly, for off-label use in the setting of progression upon pemetrexed-based chemotherapy. **Method:** Retrospective assessment of the clinical and molecular characteristics, drug efficacy and tolerability of RET-rearranged LADC patients treated with alectinib in a single institution. **Result:** Among the four patients identified, 100% were white, female and non-smokers, between 59-66 years old; 2/4 presented with high carcinoembryonic antigen levels and 1/4 with poorly differentiated LADC. All patients were TKI naïve and underwent evaluation with FoundationOne® next-generation sequencing platform, which showed *KIF5B-RET*fusion in 3/4 (75%) and *CCDC6-RET*in 1/4 (25%) of the cases. Among other alterations shared, 3/4 (75%) presented with *CDKN2A/B*loss; in all cases, the tumors were microssatelite stable (MSS) and had low tumor mutational burden (1-9 muts/Mb). All patients were treated with 600 mg bid of alectinib. Among the four patients assessed, one was not available for radiological response evaluation and the drug was withheld within two months of treatment due to clinical deterioration. The best ORR was partial response in 2/4 (50%), with PFS ranging from 4-5 months. In one patient, after 5 months of therapy, an asymptomatic oligoprogression in soft-tissue was observed; the patient was treated with local radiation therapy and remains on alectinib for 12 months. No grade 3/4 adverse events, dose reductions or discontinuation due to toxicity were observed. **Conclusion:** Although this is a small single center evaluation, alectinib demonstrated clinical activity in RET-rearranged LADC, apart from being a well-tolerated treatment. Nevertheless, the concurrent molecular alterations, its prognostic significance, the ideal dosing regimen and the precise magnitude of benefit are all questions to be addressed in clinical trials, in order to consider alectinib a treatment option for this small subset of patients.

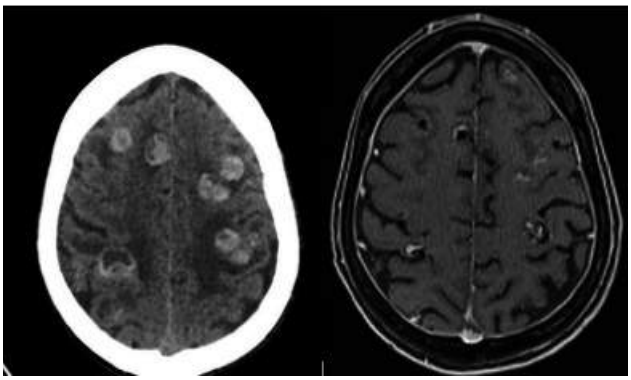
Keywords: alectinib, RET-rearranged

P2.14-68 DRAMATICAL INTRACRANIAL RESPONSE TO OSIMERTINIB IN PATIENT HARBOURING THE UNCOMMUM EGFR G719S/L861Q MUTATION

J.V. Alessi, M. Ribeiro, A. Katz

Hospital Sírio-Libanês, Sao Paulo/Brazil

Background: Almost 10% of EGFR mutations are represented by uncommom mutations, which represents a heterogenous group of rare molecular alterations, where the presence of co-mutations are even more rarely seen. Third generation shows efficacy and safety in these patients (Pt). **Method:** We hereby report a case of dramatic intracranial response to osimertinib in a poor performance status Pt with lung cancer harbouring the uncommom epidermal growth factor receptor (EGFR) co-mutations encoded in exon 18 (G719S) and exon 21 (L861Q). The Pt was a 76-year-old male, smoker (60 packs-year), who visited our hospital with a prior history of 2-weeks mental confusion and seizures. Computed tomography detected several brain lesions with moderate edema, as well as lung, cervical and mediastinal lymphadenopathy, liver, adrenal and bone lesions. A biopsy specimen obtained from his cervical adenopaHty suggested primary stage IVB lung cancer with sarcomatoid differentiation (T2a N2 M1c) and PDL-1 expression of 10%. A MRI-brain was not performed due to the Pt altered mental status and also because his condition prevent the use of sedation. Due to the dramatic nature of the case and a very poor clinical condition, systemic treatment with carboplatin, paclitaxel and pembrolizumab was started while we waited for the results of NGS. There was no clinical evidence of response to this treatment. Just prior to the schedule day of the second cycle of chemotherapy we had access to the NGS result, which disclosed the presence of EGFR G719S (allele frequency of 49.7%) and L861Q (allele frequency of 50.8%). **Result:** Based on recent reported data we started osimertinib 80mg/day. He had unequivocal clinical improvement over the following weeks with relieve of neurologic symptoms. After 42 days of treatment restaging PET-CT demonstrated complete response and brain MRI with remarkable response. Osimertinib has been well-tolerated for the Pt. Before and after 6w of osimertinib



Conclusion: This case report corroborates the promising activity of osimertinib in uncommom EGFR mutation. We have described the first case showing dramatic cranial response in these rare EGFR co-mutations.

Keywords: Osimertinib, EGFR G719S/L861Q

P2.14-69 LORLATINIB RESCUE THERAPY FOR LIFE THREATENING CNS DISEASE IN CRIZOTINIB-RESISTANT ROS1-POSITIVE NON–SMALL CELL LUNG CANCER (NSCLC)

A. Franke, V. Nair, M. Shafique, S. Mokhtari

Moffitt Cancer Center, Tampa/United States of America

Background: C-ros proto-oncogene-1 (*ROS1)* chromosomal translocations result in constitutively activated receptor tyrosine kinase in 1-2% of NSCLC. Although crizotinib, a first-generation Tyrosine Kinase Inhibitor (TKI) of Anaplastic Lymphoma Kinase (ALK) and *ROS1* translocations, has demonstrated efficacy in treatment of *ROS1* NSCLC, patients invariably acquire resistance mutations, with a high incidence of brain metastasis at relapse owing to poor CNS drug penetration. Lorlatinib is a novel, third-generation TKI with improved CNS penetration and preclinical activity against crizotinib-resistance mutations, which recently demonstrated efficacy in a phase I/II trial. We report a patient who developed secondary crizotinib-resistance and was successfully treated with lorlatinib. **Method:** A 73-year-old, female, never-smoker with recently diagnosed stage-IV *ROS1*-rearranged NSCLC presented with refractory seizures and coma. The patient was on first-line treatment with crizotinib for 6-months, with an excellent systemic response at 2 months. Brain MRI after presentation demonstrated multiple intracranial metastasis with vasogenic edema (Fig.1A). Neurologic status was unchanged despite mannitol, steroids and anti-epileptics. **Result:** As salvage therapy, the patient received bevacizumab for vasogenic edema and lorlatinib (100mg/daily). After 48-hours, substantial clinical improvement in neurologic function and mental status was observed. A repeat MRI (D+4) demonstrated a slight interval decrease in the largest metastasis and associated edema. At 1-month follow-up, the patient continued to improve clinically with no evidence of lorlatinib toxicity. Brain MRI showed a decrease in the sizes and/or resolution of all previously noted lesions and no new metastases or significant peritumoral edema (Fig.1B).

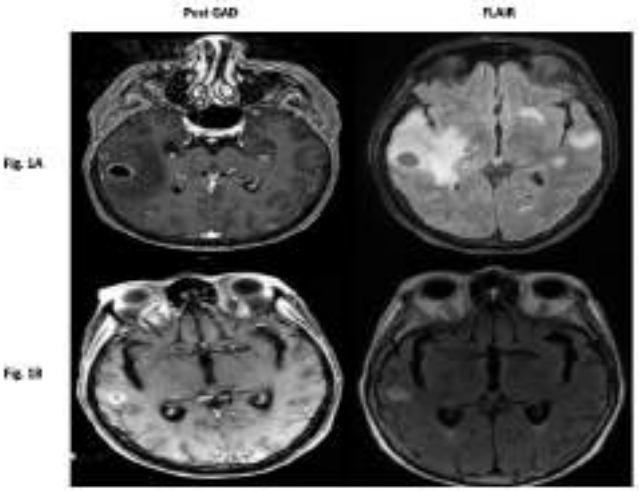


Figure 1. Brain magnetic resonance imaging, pre-treatment baseline post GAD an FLAIR sequences are shown **(Fig.1A)**, followed by near complete resolution of two posterior fossa lesions and associated edema, and significant reduction in tumor volume of a right lateral temporal lobe lesion after 1 month of loralatinib therapy **(Fig.1B)**

Conclusion: Since clinical trials typically exclude patients with symptomatic, untreated CNS disease, efficacy of newer, targeted agents in mutated-NSCLC is unclear. Here we report on a patient with life threatening, acute neurologic deterioration who derived a meaningful clinical reduction in CNS lesions at 1 month, with favorable CNS response at 2 months. In addition, we observed early evidence of tumor regression on MRI after 4 days of lorlatinib therapy. Of note, her rapid clinical response may have in part been attributable to the addition of bevacizumab. Another important consideration for our patient is that she avoided whole-brain radiation in the acute setting, and its potential adverse sequalae. We note a limitation was the absence of available testing for secondary resistance mutations that developed in this patient, which was highly susceptible to lorlatinib. However, current clinical guidelines (NCCN) do not specifically recommend resistance mutation testing upon progression, and outside of a clinical trial, the current algorithm supports lorlatinib as the agent of choice post-crizotinib failure.

P2.15 THYMOMA/OTHER THORACIC MALIGNANCIES MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.15-01 SURGICAL RESECTION OF 61 CASES OF INFLAMMATORY MYOFIBROBLASTIC TUMOR OF THE LUNG

J. Zhang[1], N. Chen[2], J. Qi[1], Q. Liu[1], B. Zhou[1], X. Qiu[1]

[1]*China Medical University Lung Cancer Center, The First Hospital of China Medical University, SHENYANG/China,* [2]*Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, SHENYANG/China*

Background: Inflammatory myofibroblastic tumor (IMT) of the lung is rare soft tissue tumor, with low malignant potential. Here we report 61 cases of surgically resected IMT of the lung. **Method:** Surgically resected IMT of the lung, during the period of September 2004 to July 2010 were retrospectively studied. Of the 61 patients, 40 were male (65.6%), 21 female (34.4%); aged 34 to 77 years old (middle age 55). The symptoms included cough in 32 cases (52.5%), bloody sputum 19 (31.1%), sputum 14 (23.0%), fever 13 (21.3%), chest pain 10 (16.4%), hemoptysis 8 (13.1%), shortness of breath 6 (9.8%), shoulder pain 2 (3.2%), sore throat 1 (1.6%), and asymptomatic 9 (14.8%). Chest CT showed 50 cases (81.2%) were round-ball-like pulmonary nodules, most with smooth and clear borders, while speculated 18 (29.5%), lobulated 13 (21.3%), cavity or vacuole sign 12 (19.7%), calcification 7 (11.5%), pleural indentation 6 (9.8%), and vessel convergence 1 (1.6%). Fibrobronchonscopy was performed in 13 cases but no malignant evidence obtained. CT guided fine-needle biopsy was refused by the patients, and surgical resection was requested. **Result:** Wedge resection was performed in 29 cases (47.5%), and lobectomy in 27 cases (44.3%) (lymph node dissection was performed in 6 suspected cases), segmentomy 5 cases (8.2%). Frozen pathological diagnosis were performed in 59 cases (96.7%), IMT was diagnosed in 38 cases (64.4%) (with alveolar epithelial dysplasia in 14 cases), inflammation or benign disease in 18 cases (30.5%), granulomatous inflammation in 2 cases (3.4%), and malignant in 1 case (1.7%). All patients recovered smoothly except one case received second thoracotomy on the day of surgery due to postoperative hemothorax; no other serious complications happened; all cases were discharged on about the 10th day postoperatively as usual. IMT was confirmed in all these 61 surgical resected cases by the postoperative pathological diagnosis. Follow-up showed all patients recovered well, and no recurrence and metastasis found. **Conclusion:** IMT of the lung has no specific symptoms, lacks specific CT imaging characteristic to distinguish from lung cancer. Surgical resection is of first choice for treatment of IMT of the lung, with no recurrence and metastasis found; wedge resection is recommended; lobectomy and lymph node dissection may be reasonable and necessary for certain suspected cases. Surgical resected IMT of the lung has a good prognosis according to our limited cases and short-time observations. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05, 17-230-9-71)

P2.15-02 PRIMARY SALIVARY GLAND-TYPE LUNG TUMOURS, SURGICALLY TREATABLE RARE ENTITY LUNG CANCER: A SIXTEEN-YEAR EXPERIENCE OF A SINGLE CENTRE

S. Ricciardi[1], G. Alì[2], D. Bacchin[1], M. Ambrogi[1], G. Fontanini[1], F. Melfi[1], M. Lucchi[1]

[1]*University of Pisa, Pisa/Italy,* [2]*Azienda Ospedaliero-Universitaria Pisana, Pisa/Italy*

Background: Primary salivary gland-type lung tumours (PSGT) are uncommon entity, representing 0.09% of overall lung cancer. Due to their rarity, this category of malignancies remain incompletely understood and the role of surgery is poorly known. The primary endpoint of this study was to analyse the impact of surgical treatment on outcome for PSGT lung cancer **Method:** A retrospectively analysis of patients who underwent a surgical treatment for PSGT tumours between January 2001 and January 2017 in a single centre was conducted. Overall survival (OS), disease free survival (DFS) and medical records (for age, sex, clinical conditions, location, surgical treatment, histopathology and tumour grade) were analysed **Result:** Out of a total of 30 PSGT lung tumours, 26 patients (15 female, 11 male) with an average age of 58.1±12.7 years underwent surgical resection with curative intent. Four patients were excluded from this study because of metastatic disease (2) or unresectable masses that underwent only palliative endoscopic treatment (2). Adenoid cystic carcinoma was diagnosed in 14 patients, mucoepidermoid carcinoma in 10 patients, and epithelial-myoepithelial carcinoma in 2 patients. Fourteen patients (54%) were current/former smoker. Twelve tumours originated from main bronchus/trachea, 14 from lobar/sublobar bronchus. The surgical procedure included lobectomy (n = 9, 34.6 %), sub-lobar resection (n=5, 19.2%), tracheal resection (n = 4, 15.4%), pneumonectomy (n = 3, 11.5%), sleeve lobectomy (n = 4, 15.4%), and carinal resection (n = 1, 3.8%). No operative mortality or major complications were reported; minor complications (e.g. air leaking, arrhythmias) occurred in five patients (19.2%). Mean dimension of tumours was 3.67±3.24 cm. Three patients underwent adjuvant therapies (2 radiotherapy, 1 chemotherapy). Cancer recurred in 11 patients (42.3%): 3 were surgically treated, 3 underwent chemotherapy, 1 radiotherapy and 4 combined radio-chemotherapy. With a median follow-up of 70 months, the overall survival was 68.8 months and the disease free survival was 56.8 months. The 5-year OS and DFS were 92% and 68% respectively. Adenoid cystic carcinoma was the most favourable subtype with a median OS of 90 months. Only three cancer-related dead occurred **Conclusion:** Surgical resection of primary salivary gland-type lung cancer is an effective treatment even in case of large tumours that required extended resections. The long-term survival and the DFS after surgical resection are encouraging and redo surgical procedure with a curative intent can be performed in case of local recurrences

P2.15-03 TROPOMYOSIN-RELATED KINASE B CAN BE A BIOMARKER OF PROGNOSIS AND THERAPEUTIC TARGET FOR MALIGNANT THYMIC EPITHELIAL TUMORS

K. Ozono

Miyazaki Prefectural Miyazaki Hospital, Miyazaki/Japan

Background: Thymic epithelial tumors (TETs), mainly thymoma and thymic cancer are most common tumors arise in mediastinum. Histologically, thymoma is divided into Type A, AB, B1, B2 and B3. Clinically, TETs are divided into two groups, benign TETs (bTETs) as Type A, AB, B1 thymoma and malignant TETs (mTETs) as Type B2, B3 thymoma and thymic cancer. Complete surgical resection is vital for the management of TETs, and adjuvant therapy play important roles in the management of recurrent or metastasized cases. But there remains a lack of standard treatment after failure of adjuvant therapy. Development of molecular target therapies for advanced mTETs is a present issue. Tropomyosin receptor kinase (Trk) family is one of tyrosine kinase receptors consists of TrkA, TrkB and TrkC. Among them,TrkB have oncogenic factors in various cancers. **Method:** Patients and case selection We analyzed 48 TETs (43 thymomas and 5 thymic cancers) patients who received curative surgical resection. We divided into two groups due to Masaoka-Koga stage (StageI and II as early stage and StageIII and IV as advanced). Immunohistochemistry Immunohistochemical staining was performed using tissue sections and primary antibodies, TrkA, TrkB and TrkC. We evaluated the immunoreactive cells by Allred score. Anchorage-dependent cell proliferation assay Proliferation assay was performed by using Trk inhibitor K252a, recombinant human BDNF (ligand of TrkB) and siRNA (Control-siRNA, TrkB-siRNA, and BDNF-siRNA). **Result:** Trk expression in TETs. Early stage were 37 cases (77%) and advanced stage were 11 cases (22%). Benign TETs (bTETs) were 29 cases (60%) and malignant TETs (mTETs) were 19 cases (39%). The high expression of TrkA was observed in 5 cases (10%) and TrkB was 7 cases (14%). TrkC expression was not observed in 48 cases (0%). Among the TrkB-high, all the 5 thymic cancer cases indicated TrkB-high expression and remaining two cases were type B2 and type B3 thymoma. The TrkB-high type B2 thymoma was recurrent case. TrkB-high cases showed poor prognosis. Advanced showed significantly higher expression of TrkB than those with early cases (P<0.0001). TrkA and TrkC expression was no correlation with stage (TrkA: P=0.5163, TrkC:-). Cases with TrkB-high expression were significantly more in mTETs than in bTETs (P=0.0004). TrkA-high expression were no correlation with malignancy (P=0.9839). TrkB-high expression cases were significantly shorter overall survival periods (P=0.0482), compared to TrkB-low expression cases. There was no significant correlation between TrkA expression and survival periods (P=0.1484) The BDNF/TrkB signaling involve in proliferation ability of thymic cancer cell Tymic cancer cell, transfected with BDNF-siRNA or TrkB-siRNA showed significantly lower level of proliferation than with Control-siRNA, while administrating rhBDNF to the cell transfected with TrkB-siRNA showed no rising level of proliferation. These indicated knocking down of BDNF or TrkB suppressed proliferation. Cell incubated with rhBDNF showed significantly higher levels of proliferation than without rhBDNF. Administration of K252a and rhBDNF resulted in lower level of proliferation than without administration of K252a. These indicated proliferation was enhanced by rhBDNF and it was abrogated by Trk inhibitor K252a. **Conclusion:** TrkB expression is a biomarker of prognosis and BDNF/TrkB signaling pathway can be a therapeutic target for mslignsnt thymic epithelial tumors.

P2.15-04 IMPACT OF PROGNOSTIC NUTRITIONAL INDEX ON LONG-TERM OUTCOMES AFTER SURGERY FOR PULMONARY METASTASIS FROM COLORECTAL CANCER

M. Yanagiya[1], T. Yoshioka[1], K. Kitano[1], K. Nagayama[1], M. Sato[2], J. Nakajima[2]

[1]*The University of Tokyo Graduate School of Medicine, TOKYO/Japan,* [2]*The University of Tokyo Graduate School of Medicine, Tokyo/Japan*

Background: A prognostic nutritional index (PNI), calculated using serum albumin levels and peripheral lymphocyte counts, has been reported as a predictor of prognosis of various cancers. The aim of this study was to investigate the impact of a PNI on postoperative prognosis of lung resection for pulmonary metastasis from colorectal cancer. **Method:** Retrospective review of patients who underwent curative surgical resection for pulmonary metastasis from colorectal cancer (01/2008-12/2015). Exclusion criteria: missing data. Preoperative serum albumin (Alb) and peripheral lymphocyte counts were measured within 1 month just before the initial lung surgery. We calculated PNI as follows: PNI = serum albumin levels (g/dl) × 10 + total lymphocyte count (per mm3) × 0.005. We used the median value as the optimal cut-off value for PNI (47.5) and divided patients into two groups. We evaluated overall survival using propensity score matching. **Result:** A total of 158 patients underwent 187 lung resections for pulmonary metastasis in this study. One hundred eighteen patients were eligible. Low PNI was significantly associated with older age (P<0.001), wedge resection (P=0.041), open approach (P=0.045) and colon origin (P=0.041). In the non-matched analysis, overall survival was significantly better in high PNI group that low PNI group (77.5% vs 54.0% at 5 years; HR 2.21; 95% CI 1.11-4.39; P=0.024). After propensity score matching accounting for sex, age, surgical procedure, surgical approach and site of origin, there were no significant differences in background between both groups. In the matched analysis, overall survival was significantly better in high PNI group than low PNI group (78.2% vs 43.2% at 5 years; HR 3.46; 95% CI 1.33-8.96; P=0.010).

P2.15-05 INVESTIGATION OF THE TRANS-SUBXIPHOID ROBOTIC THYMECTOMY

H. Numanami, C. Furuta, R. Taguchi, M. Yamaji, T. Akiyama, M. Yano, M. Haniuda

Aichi Medical University, Nagakute/Japan

Background: We have performed a thoracoscopic thymectomy with a trans-subxiphoid approach and have reported its usefulness. This time, we performed enlarged thymectomy by the trans-subxiphoid approach with the robotic surgery support system (da Vinci surgical system TM; da Vinci TM) and report its improved surgical technique. **Method:** The patient was placed in the supine position with 10-15 degree head-up. A 3.5 cm transverse skin incision was typically made 1-2 cm below the lower edge of the xiphoid. Through this incision, the space among the posterior surface of the sternum and bilateral mediastinal pleura was enlarged blindly with a finger. Additional two 8-mm robotic trocars were inserted to the bilateral 6th intercostal space under the guidance of a finger. Carbon dioxide (CO2) was insufflated at a pressure of 8 mmHg to get a working space to resect thymus. The whole thymus was excised for patients with thymic tumor, and simultaneous resection of surrounding adipose tissues was performed for patients with myasthenia gravis. Clinical characteristics and early surgical outcomes of the patients were collected and analyzed retrospectively. **Result:** From April 2017 until March 2019, Fifteen trans-subxiphoid robotic thymectomy were performed. The average age was 58 years, the average operation time was 238.4 minutes (176 - 452 minutes), the console time was 175.3 minutes (97 -390 minutes), the bleeding volume 13.9 g (2- 75 g), the number of surgical ports were all 3 and the resected specimen weight was 41 g (25 - 58 g). The average drainage period was 1.5 days (1 - 2 days), the postoperative hospital stay was 3.2 days (2 - 5 days), no complications were observed. The final pathologic diagnosis was 10 thymoma, 1 thymic cancer, 2 thymic cyst and 2 thymic hyperplasia. **Conclusion:** Compared with thoracoscopic thymectomy by the trans-subxiphoid approach, surgery using da Vinci TM has longer operation time and more surgical ports. However, even in the narrow space from the neck to the upper mediastinum, da Vinci TM can stably perform accurate operation. Therefore, with good manipulation, using da Vinci TM surgical system for the trans-subxiphoid thymectomy was suggested that safer thymectomy could be performed without surgeon's stress.

P2.15-06 PRETREATMENT NEUTROPHIL TO LYMPHOCYTE RATIO PREDICTS SURVIVAL IN THYMIC CARCINOMA PATIENTS

Y. Zhao, Z. Gu, T. Mao, W. Fang

Shanghai Chest Hospital, Shanghai/China

Background: The host inflammatory response plays an important role in carcinogenesis and disease progression. It has been demonstrated that the neutrophil to lymphocyte ratio (NLR), as a marker of the systemic inflammatory response, was associated clinically meaningful outcomes in patients with a variety of cancers. The objective of this study was to evaluate its prognostic value in thymic carcinoma patients. **Method:** From February 2003 to January 2018, 516 consecutive patients with pathologically confirmed thymic carcinomas were treated at the Shanghai Chest Hospital. Clinico-pathological data were retrospectively reviewed. Survival analysis, stratified by NLR quartiles, was used to evaluate the predictive value of NLR. **Result:** The NLR level cutoff of four quartiles was 1.9, 2.6 and 3.9 in our patients. After adjusting for the factors affecting the survival (sex, age, tumor size, Masaoka-Koga stage, completeness of resection, chemotherapy and radiotherapy), NLR level less than 1.9 (NLR<25th percentile, n = 108) remained an independent significant predictor of overall survival (hazard ratio = 1.824, 95% confidence interval = 1.088-3.058, p = 0.023, Table 1). Patients with NLR level <1.9 has an advantage on 5-year overall survival (p = 0.001, Figure 1) than their counterpart.

Table 1. Multivariate Analysis for Overall and Disease-Free Survival in Patients with Thymic Carcinoma

Variable	HR (95%)	p Value[a]
Overall survival		
Sex	1.164(0.804-1.686)	0.421
Age	1.015(1.000-1.030)	0.055
Tumor size	1.115(1.050-1.184)	<0.001[b]
Masaoka-Koga stage	1.392(0.989-1.959)	0.058

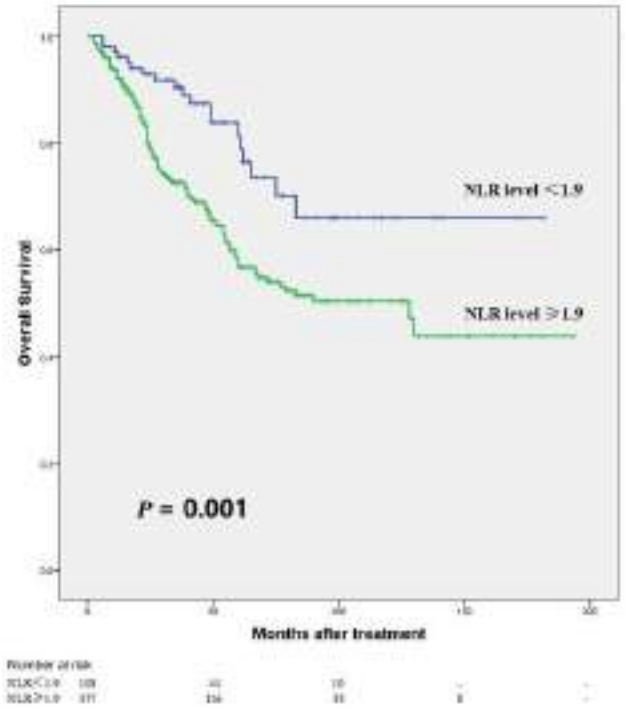
[a] Cox proportional hazards regression analysis. [b] Statistically significant.
CI = confidence interval; HR = hazard ratio; NLR = the neutrophil to lymphocyte ratio.

POSTERS



Conclusion: NLR level less than 1.9 measured before treatment is an independent marker of prognosis in thymic carcinoma patients. The NLR does have the advantage of being a routine procedure in clinical practice, feasibility and inexpensive.

Keywords: The neutrophil to lymphocyte ratio, Survival, Thymic cardinoma

P2.15-07 BIMANUAL EXAMINATION IS INDISPENSABLE IN THE SURGERY OF LUNG METASTATIC TUMORS!

Y. Kahya, A. Yücemen, F. Ibrahimov, B. Kazak, B. Yenigün, M. Özkan, C. Yüksel, S. Enön, A. Kayi Cangir

Ankara University School of Medicine Ibni Sina Hospital Department of Thoracic Surgery, Ankara/Turkey

Background: Thoracic computed tomography (Th CT) is used to evaluate the surgical outcome of lung metastatic tumors. However, Th CT is often inadequate on the detection of millimetric lesions and it alone is a problematic for guiding complete resection. It is recommended for complete resection that the intraoperative bimanual palpation of the lung to be used with care and meticulously. In addition, there are studies for minimally invasive surgical methods may be an alternative to thoracotomy where bimanual evaluation is not possible. In this study, we aimed to evaluate the number of radiological and pathological metastases in patients who underwent metastasectomy with muscle conservative thoracotomy (MCT). **Method:** Between 2008 and 2018, 204 patients with metastatic lung tumors who underwent metastasectomy were included in the Department of Thoracic Surgery, Ankara University Faculty of Medicine. Preoperative Th CT imaging of all patients was evaluated in a multidisciplinary council. The relationship between the numbers of metastases detected by pathological examination of patients and the number of pulmonary nodules reported as 'metastasis' in preoperative Th CT was retrospectively analyzed. **Result:** 55% (n: 111) of the patients were F, 45% (n: 93) were M, mean age was 46.4 (13-77). %25 (n:52) of two hundred and four patients had bilateral, 3% (n: 8) of the patients had 3 and 1% (n: 4) of the patients had 4 metastasectomy with MCT due to contralateral lung metastasis or re-metastasectomy. The number of pulmonary nodules detected in Th CT was 740 (mean: 2,6), although the number of pulmonary nodules resected was 1503 (mean: 5,29). In histopathological evaluation of these nodules, 1120 (mean: 3,94) were reported as metastases. 2,03 fold of the nodules detected in Th CT were detected by bimanual intraoperative examination and 1.5 fold of nodules detected in Th CT were pathologically assessed as metastasis. Primary tumor numbers and histologies of 1120 metastatic nodules respectively; 42% (n: 475) were epithelial tumors and 58% (n: 645) were mesenchymal tumors. **Conclusion:** In this study, 740 pulmonary nodules were reported in Th CT of 204 patients. However, 763 additional pulmonary nodules were detected by bimanual palpation. 49.8% (380/763) of 763 additional pulmonary nodules were metastatic. Although minimally invasive surgery is a successful method for the surgery of many thoracic malignancies, bimanuel palpation of the lung with open surgery is still an effective method for the complete resection of pulmonary metastases. Bimanual examination is indispensable especially in the pulmonary metastasectomy of sarcomas.

Keywords: lung metastasectomy, minimally invasive surgery, lung metastasis count

P2.15-08 MULTICENTER EXPERIENCE WITH COMPLETE SURGICAL RESECTION OF PRIMARY PULMONARY ARTERY SARCOMA

E. Chan[1], S. Ibarra[1], R. Reul[1], V. Ravi[2], O. Shapira[3], M. Kim[1], M. Reardon[1]

[1]*Houston Methodist, Houston/United States of America,* [2]*MD Anderson Cancer Center, Houston/United States of America,* [3]*Hadassah Medical Center, Jerusalem/Israel*

Background: Pulmonary artery sarcoma is a rare and aggressive malignancy and survival is extremely limited without surgical resection. Treatment options for surgical resection are not standardized. We sought to examine our series of complete resections and clinical outcomes over an 18 year experience. **Method:** From 1999 to 2017, we evaluated 17 patients (mean age 56 +/- 12. 9 years) with pulmonary artery sarcoma across three institutions. Fourteen (82.7%) underwent complete surgical resection. **Result:** All 14 patients underwent complete resection of the pulmonary artery sarcoma. Six patients (42.9%) had previously undergone surgical resection and were referred for recurrent disease. Seven patients (50%) underwent neoadjuvant chemotherapy or radiation. Reconstruction of the pulmonary artery trunk was performed with a pulmonary artery allograft, and reconstruction of the right or left main pulmonary artery was performed with a Dacron interposition graft. Additional endarterectomy was performed in two patients with disease extending into the PA branches. Lung resection was performed in five patients (35.8%). Total length of stay was 9.7 +/- 4.6 days including 5.3 +/- 4.2 days in the ICU. Mean survival was 2 +/- 2.8 years. Tumor histology is summarized in table 1.

Pulmonary artery sarcomas	N=17
Male gender	14 (82.65%)
Age at operation (mean ± SD)	56 ± 12.9
Operative	14/17 (82.4%)
Pre-op chemo only	4/14 (23.5%)
Pre-op XRT only	1/14 (5.9%)
Chemo & XRT	2/14 (11.8%)
Recurrent Disease	6/14 (42.9%)
Lung Resection/Pneumonectomy	5/12
ICU Length of stay (mean ± SD)	5.3 ± 4.2
Total length of stay (mean ± SD)	9.7 ± 4.6
Years alive from surgery (mean ± SD)	2 ± 2.8
Histology/Pathology	**Cases (n)**
High Grade Sarcoma	n= 5
High Grade Angiosarcoma	n= 2
Leiomyosarcoma	n= 2
High Grade Intimal Sarcoma	n= 2
High Grade Spindle Cell Sarcoma	n= 1
Pleomorphic Sarcoma	n= 1
Undifferentiated Sarcoma	n= 1

Conclusion: Surgical resection of pulmonary artery sarcomas offers improved long-term outcomes compared to non-surgical management. Complete resection and reconstruction is preferred compared to endarterectomy. Prompt and accurate diagnosis is important for optimal management.

Keywords: Cardiothoracic surgery, Cardiac tumor, Pulmonary artery sarcoma

P2.15-09 CLINICAL FEATURES AND PROGNOSIS OF PRIMARY TRACHEAL CANCER AT OUR INSTITUTION'S EXPERIENCE

Y. Mishina[1,2], H. Arai[1], S. Nakamura[1], H. Masuda[1], K. Shiino[1], K. Okudela[1], T. Iwasawa[1], M. Tajiri[1], M. Masuda[3]

[1]*Kanagawa Cardiovascular and Respiratory Center, Yokohama/Japan,* [2]*Ashigarakami Hospital, Ashigara/Japan,* [3]*Yokohama City University Graduate School of Medicine, Yokohama/Japan*

Background: Primary tracheal cancer (PTC) is rare. Although histological components of the trachea are similar to that of the lung, the reason for its low incidence is still unknown. Because of its rarity, there are no standard treatment strategies. **Method:** PTC is not clearly defined. We defined it as a primary malignant neoplasm arising from the sub vocal cord region to the bilateral main bronchi via the bifurcation. The clinical features and prognosis of patients with PTC from 1999 to 2018 at the Kanagawa Cardiovascular and Respiratory Center were analyzed. **Result:** A total of nine cases, 4 males and 5 females with the median age of 62 years (range:29-81), were included in this study. The clinical symptoms were 3 patients with a cough, 2 with expiratory noise, 2 with hemoptysis, 1 with wheezing, and 1 PTC was detected on screening computed tomography. The tumors were located at upper trachea region in 4 cases, at the lower in 4 cases, and at main right bronchus in 1 case (upper tracheal region is defined as the sub vocal cord area to the lower end of the thyroid and lower tracheal region is defined as the lower end of thyroid to the bifurcation). The histopathological types were 5 (55.6%) adenoid cystic carcinomas (ACC), 2 (22.2%) mucoepidermoid carcinomas, and 2 (22.2%) squamous cell carcinomas. Five patients (55.6%) received radical surgeries and 2 patients (22.2%) who had distant metastasis received palliative surgeries. The remaining 2 (22.2%) patients received tracheal stenting. The postoperative adjuvant therapies included 2 cases with irradiation, and 1 case with chemotherapy. The 2 tracheal stenting cases received full dose irradiation therapy (including case with concurrent chemotherapy) and the 2 cases with palliative surgery also received adjuvant irradiation and chemotherapy, respectively. The overall survival rate was 55.6% at 5 years in all cases. The ACC group tended to have a better prognosis compared to that of the non-ACC group, having the 5-year survival rate was 80.0% vs 25.0%, respectively. In the ACC group, only 1 case (20.0%) died from ACC. The overall survival rate of the radical surgery group and the non-radical group was 60.0% vs 50.0% at 5 years, respectively. **Conclusion:** We found that PTC generally had a poor prognosis. Among the different types of PTC, ACC had a better prognosis than the other histopathological types. Complete resection achieved a better prognosis, especially in ACC.

Keywords: primary tracheal cancer, PTC, adenoid cystic carcinomas

P2.15-10 CLINICAL SIGNIFICANCE OF AGE AT DIAGNOSIS AMONG PATIENTS WITH THYMIC EPITHELIAL TUMOR

M. Liu, L. Gao, C. Wang

Department of Radiation Oncology, Shanghai/China

Background: Thymic epithelial tumors (TET) originate in the thymus and include thymomas and thymic carcinomas. These tumors typically occur in adults with a median age of 50, and rare in children or adolescents. Few studies focusing on the effect of age on TET have been reported to date. Whether different age groups have homogeneous clinical features and survival outcomes remains unexplored. This study aimed to compare clinicopathologic characteristics and survival outcomes in different age groups using the Surveillance, Epidemiology, and End Results (SEER) database. **Method:** Information of 4431 TET patients was retrieved from the Surveilance, Epidemiology, and End Results (SEER) database. Demographic features, clinicopathologic characteristics and survival outcomes were compared between patients diagnosed at different age groups (0-18, 19-30, 31-40, 41-50, 51-60, 61-70, 71-80, 80+). **Result:** A total of 4431 patients were analyzed. Median age was 60-year-old. Twenty-eight (0.6%) patients were aged 1-18, 178 (4.0%) were aged 19-30, 381 (8.6%) were aged 31-40, 742 (16.7%) were aged 41-50, 971 (22.0%) were aged 51-60, 1108 (25.0%) were aged 61-70, 736 (16.6%) were aged 71-80 and 287 (6.5%) were aged 81-90. Gender, race, tumor histology and treatments were similar between different age groups. The 0-18 group was associated with a higher risk of distant metastasis. Compared to patients aged above 80, the hazard ratios of cancer specific survival (CSS) for patients aged 0-18, 19-30, 31-40, 41-50, 51-60, 61-70, 71-80 were 1.079, 0.739, 0.614, 0.621, 0.633, 0.673, and 0.861, respectively. Patients in the 31-40, the 41-50, the 51-60 and the 61-70 age groups had significantly better CSS compared with the 0-18 age group or the 71-80 group or the 81-90 group. From the subgroup analysis, we found that the 19-70 group had significant better CSS and overall survival (OS) than the above 70 group (CSS: p=0.000; OS: p=0.000). Multivariate survival analysis adjusted for gender, race, stage and histology showed that age was an independent prognostic factor for CSS. **Conclusion:** Age is a strong independent prognostic factor for survival in TET. Pediatric TET has a higher risk of distant metastasis and an inferior CSS. For the adults, patients older than 70-year-old were associated with a shorter CSS.

P2.15-11 FAVORABLE LONG TERM SURVIVAL AFTER INITIALLY PALLIATIVE RESECTION FOR A GIANT PRIMARY RIB OSTEOSARCOMA WITH SEVERE MEDIASTINAL SHIFTING

K. Sinn, E. Gschwandtner, R. Hritcu, J.M. Matilla, K. Hötzenecker, G. Lang, S. Taghavi, W. Klepetko, M.A. Hoda, T. Klikovits

Medical University of Vienna, Vienna/Austria

Background: Osteosarcoma is the most common malignancy of the bone with high morbidity and mortality. Treatment of choice is chemotherapy (CHT) followed by surgery and adjuvant CHT. Primary rib osteosarcoma is a rare disease. We present a case of a young patient with a giant primary rib osteosarcoma undergoing palliative resection. **Method:** A 29-year-old woman presented with dyspnea and pain in the left chest wall in August 2012. Computed tomography (CT) showed a large lesion destructing the 3rdleft rib with extension to the left upper lobe. Biopsy revealed an osteoplastic osteosarcoma and staging examinations showed no distant metastases (DM). **Result:** CHT by the EURAMOS-1-protocol was started but was discontinued by the patient after 1 cycle due to side effects. 1.5 years later without any treatment or follow up, the patient was re-admitted with massive thoracic pain, severity of dyspnea and in a very limited general condition. CT showed a major tumor progression with severe mediastinal shift and total atelectasis of the left lung. Due to extreme large tumor size and lack of treatment alternatives, surgery in palliative intent was performed: clamshell incision, complete resection of the tumor including chest wall reconstruction. The postoperative course was challenging but she recovered well and was discharged after several months with no evidence of disease in combined positron-emission-tomography/CT. Thereafter, the patient again refused any further treatment and checkups. 4.5 years later she presented again with local recurrence in the left chest wall and in excellent overall condition without evidence for DM. Accordingly, a re-thoracotomy, partial resection of ribs 6-9, left diaphragm and pericardium and reconstruction was performed. The postoperative course was without complications and the surgery was well-tolerated. **Conclusion:** This case report shows an unexpected favorable outcome after resection in palliative intent for a giant primary rib osteosarcoma with severe mediastinal shifting. Currently, 7 years after diagnosis, the patient is free from disease.

Keywords: osteosarcoma, chest wall

P2.15-12 EPIDEMIOLOGY OF THYMIC EPITHELIAL TUMORS: 22-YEAR EXPERIENCE FROM A SINGLE-INSTITUTION

P. Rioja, S. Lozano, R. Ruiz, M. Galvez Nino, N. Valdivieso, M. Olivera, O. Cabero, M. Guillen, A. De La Guerra, E. Amorin, C. Barrionuevo, L. Mas

Instituto Nacional de Enfermedades Neoplasicas, Lima/Peru

Background: Thymic epithelial tumors (TETs) represents a heterogeneous group of rare neoplasms that represent, however, the most common entity of the anterior mediastinum. Epidemiological data and treatment options for these neoplasms are very limited. **Method:** Retrospective study of TET diagnosed at Instituto Nacional de Enfermedades Neoplasicas (INEN) in Lima, Peru, from 1996 to 2018. Clinicopathological data was retrieved from clinical files. All cases were reviewed by a pathologist and reclassified according to the 2004 WHO classification system. Staging was performed with the Masaoka-Koga Staging System. Treatment and follow-up data were also collected. Survival curves were constructed with the Kaplan-Meier method. **Result:** 84 patients were included. Median age at diagnosis was 55 years old (range 19 to 84) and 51.8% were female. Most patients (95.2%) were in good status performance (Zubrod 0-2) and 36.5% were smokers. The histological type corresponded to thymoma (T) in 63.9% of cases (n=53) and to thymic carcinoma (TC) in 36.1% of cases. T were of type A, AB, B1, B2 and B3 in 15.8%, 19.7%, 3.2%, 3.9% and 7.9% of cases, respectively. The proportion of advanced disease (Masaoka stage III-IV) was higher in TC (89.6%) than in T (51.1%). The most common treatment modality was systemic chemotherapy for advanced disease in 37.3%. With a median follow-up of 88.4 months, median overall survival (OS) was 81.6 months for T and 12.3 months for TC (p=0.01). Survival according to different histological types is shown in table 1.

Histological type	Median OS (months)
Thymoma A, AB, B1	102
Thymoma B2 – B3	16.7
Thymic carcinoma	12.3

Conclusion: The result of this study indicates a clear association between the WHO histological classification and Masaoka-Koga staging system with survival. We found a higher than expected proportion of T with advanced disease at diagnosis. The reasons behind this finding require further research. Being this a rare disease, collaboration is very important to foster knowledge and to promote prospective and randomized clinical trials focused on classification and treatment.

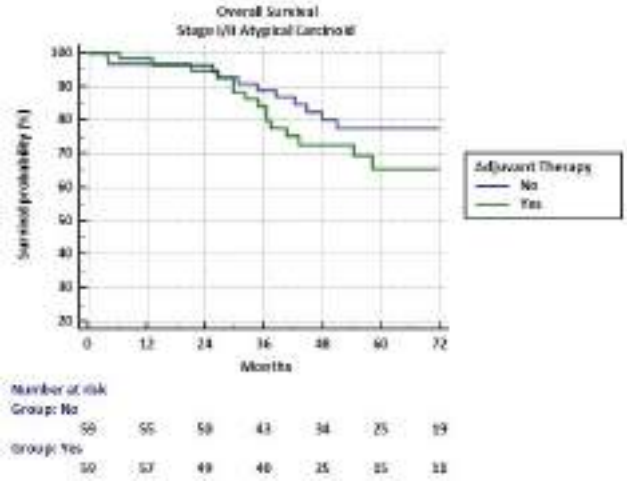
Keywords: WHO classification, Masaoka stage, thymic epithelial tumors

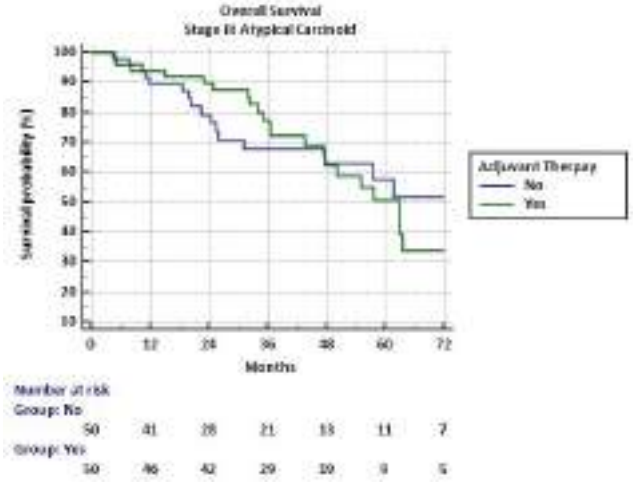
P2.15-13 THE ROLE OF ADJUVANT THERAPY FOR ATYPICAL BRONCHOPULMONARY CARCINOIDS: A POPULATION-BASED ANALYSIS

R. Wegner, S. Abel, S. Hasan, Z. Horne, A. Colonias, B. Weksler, V. Verma

Allegheny Health Network, Pittsburgh/United States of America

Background: Atypical bronchopulmonary carcinoid tumors are rare but carry high recurrence rates following resection. The role of adjuvant therapy remains unclear owing to a lack of high-volume data. To address this knowledge gap, we examined predictors of adjuvant therapy and effects on outcome. **Method:** We queried the National Cancer Database for patients with resected stage I-III atypical carcinoid. Adjuvant therapy was defined as chest radiation, chemotherapy, or a combination thereof. Multivariable logistic regression identified predictors of adjuvant therapy. Multivariable Cox regression evaluated predictors of survival. Propensity matching accounted for indication biases. **Result:** Overall, 533 stage I/II and 129 stage III patients were identified. Predictors for adjuvant therapy in stage I/II disease were stage II, positive margins, lymph node ratio (LNR) of 1-25%, and more remote year of treatment. Predictors for adjuvant therapy in stage III were female gender and LNR of 26-50%. Median overall survival in stage I/II and III was 116 months and 61 months, respectively. Predictors for survival in stage I/II were age, margins, comorbidity score, and LNR; factors for stage III disease were LNR and more remote year of treatment. Delivery of adjuvant therapy was not independently associated with survival in either stage I/II or III patients. Furthermore, propensity matched analysis did not reveal a benefit to adjuvant therapy.





Conclusion: This study shows no clear survival benefit with adjuvant radiotherapy and/or chemotherapy, even in stage III disease. Although this implies that adjuvant therapy should not be routinely delivered, individualized judgment is still recommended.

Keyword: atypical carcinoid, adjuvant treatment

P2.16 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.16-01 RISK FACTORS FOR SHORT-TERM POST-OPERATIVE EVENTS FOLLOWING LUNG CANCER RESECTION

W. Lieberman-Cribbin, A. Wolf, A. Kaufman, D.-S. Lee, D. Nicastri, R. Flores, M. Van Gerwen

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Lung cancer represents 13% of all newly diagnosed US cancers and is the leading cause of all cancer deaths (25%). Reducing postoperative complications and improving quality of life following surgery remains central when providing treatment. We examined risk factors for short-term post-opeartive complications following lung cancer resection in patients treated at Mount Sinai, New York City. **Method:** Data was selected from the General Thoracic Surgery Database (2012-2018). Patients with a primary diagnosis of lung cancer who underwent a Lobectomy (n = 603) or a Wedge resection (n = 659) were included. Preoperative assessments of health, including the Zubrod Performance Score, % predicted FEV1, heart (congestive heart failure, coronary artery disease, peripheral vascular disease) lung (pulmonary hypertension, chronic obstructive pulmonary disease, and interstitial fibrosis) comorbidities, diabetes, and smoking status were measured for each patient. The primary outcome was the occurence of at least one post-operative event (pulmonary/cardiovascular/gastrointestinal/neurological complications, infections, and unexpected readmissions to the operating room or intensive care unit) during their hospital stay or within 30 days of their surgery; SAS v9.4 was used for statistical analyses. **Result:** There were 1262 patients (age 18-95 years); 60% were female, 64% were White, and 55% were Stage 1a / 1b. More patients underwent surgery with a Video-Assisted Thoracoscopic Surgery (VATS) approach (58%) rather than an Open approach (42%). The majority of patients was classified as past smokers (58%), while the remainder were never (27%) and current (15%) smokers. 17% of patients presented with at least one heart comorbidity, while 21% with at least one lung comorbidity. At multivariable analysis, female gender (ORadj 0.64, 95% CI: 0.49-0.96), Wedge resection (ORadj 0.64, 95% CI: 0.44-0.92 compared to Lobectomy), VATS (ORadj 0.54, 95% CI: 0.38-0.77 compared to an OPEN approach), and an increasing % predicted FEV1 were inversely associated with the occurence of a post-operative event. Increasing age (ORadj 1.03, 95% CI: 1.01-1.04), Zubrod performance score (ORadj 1.53, 95% CI: 1.21-1.93), duration of surgery in hours (ORadj 1.10, 95% CI: 1.01-1.21), and currently smoking (ORadj 1.97, 95% CI: 1.14-3.40) were associated with increased odds of a post-operative event. **Conclusion:** Significant risk factors exist for the occurence of a short-term post-operative event following lung cancer resection, which should be recognized to improve post-surgery quality of life. A VATS wedge resection should be utilized whenever appropriate to reduce the likelihood of post-operative complications.

Keywords: surgical approach, post-operative complications, Risk Factors

P2.16-02 RANDOMISING PATIENTS INTO TRIALS OF THORACIC CANCER SURGERY: AN ANALYSIS OF PATIENT AND CANCER TEAM BEHAVIOUR IN PRACTICE

T. Treasure[1], F. Macbeth[2], M. Baum[1], M. Shackcloth[3], J. Edwards[4], T. Batchelor[5]

[1]*University College London, LONDON/United Kingdom,* [2]*Cardiff University, Cardiff/United Kingdom,* [3]*Liverpool Heart and Chest Hospital, Liverpool/United Kingdom,* [4]*Northern General Hospital, Sheffield/United Kingdom,* [5]*Bristol Hospitals NHS Trusts, Bristol/United Kingdom*

Background: Pulmonary Metastasectomy in Colorectal Cancer (PulMiCC) is a multicentre trial funded by Cancer Research UK. In Stage 1 participants were invited to consent for further evaluation within the PulMiCC protocol and if eligible were offered randomisation (Stage 2) to lung metastasectomy or continued active monitoring. Noting a decreasing rate of randomisation during 2016, the Data Monitoring Committee recommended that the reasons should be investigated. **Method:** The three most actively recruiting centres were approached and asked to provide reasons for patients in Stage 1 not being randomised and to provide data according to the fields in the first column of the table. We sought to discover who made the decision to not randomise and to establish what clinical management was then followed. If participants were deemed ineligible we asked for the reason. **Result:** Of 155 patient participants consented into Stage 1 of the trial, and after full information and counselling during the period of assessment, 41 elected to make their own decision. The split to have or not have metastasectomy was 22:19. When the clinicians made the decision 77/78 (99%) patients had metastasectomy. Full data are given in the table. Ten patients had other pathology, nine lung cancer and one carcinoid. The protocol placed no constraint on the number of metastases but one unit set its own limits at 2-4 deeming patients outside as not eligible for randomisation but as suitable for metastasectomy.

Reasons for not randomising a sample of 155 registered patients		
Patients elected to make their own decision	41	
Chose metastasectomy		22 (54%)
Chose to not have metasasectomy		19 (46%)
Clinical team overrode the trial protocol	78	
Metastasectomy		77(99%)
Non-operative management		1 (1%)
Primary lung neoplasia	10	
Deemed ineligible	18	
Local interpretation of the trial protocol		9
Undecided at time of data collection	8	
Total sample	155	

Conclusion: At trial closure, of 512 patients in Stage 1, 82% were not randomised resulting in an inconclusive result despite the efforts of many doctors and scientists and the participation of a large number of patients. In the sample of 155 drawn from the three most active centres, 78 patients deemed eligible had the decision made for them by the clinical team and of the 18 deemed ineligible, half of the reasons were not aligned with the written protocol. That means at least 56% of the patients were lost to randomisation by clinicians' decisions.The 41 patients who elected to make their own decision, to have or not have metastasectomy, did so in numbers which better reflected equipoise. The difficulty faced by clinicians in declaring uncertainty is well recognised. In PulMiCC this resulted in exclusion of many patients who had given their informed consent. Learning from this and similar experiences, later UK trials of thoracic oncology (MARS-2, VIOLETS) have recruited well after specific training in the QuinteT method for randomisation into surgical trials.

P2.16-03 IELCART QUALITY OF LIFE IN THE FIRST YEAR AFTER SURGERY FOR STAGE IA LUNG CANCER PATIENTS: PRELIMINARY RESULTS

E. Fevrier[1], R. Yip[1], E. Taioli[1], B. Becker[2], C. Henschke[1], R. Schwartz[1,3]

[1]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [2]*Florida State University, Tallahassee/United States of America,* [3]*Northwell Health, New York/United States of America*

Background: To compare quality of life (QoL) after lobectomy (L) and sublobar resection (SLR) within the first postoperative year among patients undergoing video-assisted thoracoscopic surgery. **Method:** We used a prospective cohort of Stage I lung cancer patients from the Initiative for Early Lung Cancer Research on Treatment (IELCART). QoL used three validated instruments: SF-12 physical (PCS) and mental health (MCS), FACT-L lung cancer symptoms, and PHQ-4 for anxiety and depression. The QoL scores were measured before surgery, and within 4, 6, and 12 months after surgery. For each QoL measure, a piece-wise linear mixed effects model was used to estimate changes in average scores and test for differences between L and SLR patients within 2 months post-surgery and from 2 to 12 months. Social support was also assessed at baseline using the MOS survey. **Result:** Of the 160 patients, 58 (36.3%) had L and 102 (63.7%) SLR. After adjustment for demographics, BMI, pack-years of smoking, and comorbidities, mean QoL and social support scores at baseline did not differ between L and SLR patients. The post-operative rates of change are given in Table 1. L showed significant decreases in PCS (p = .01) and anxiety scores (p = .0001) within 2 months post-surgery and significant improvement from 2 to 12 months in PCS (p = .005) and FACT-L QoL scores (p = .01). SLR anxiety scores decreased (p = .004) within the first two months post-surgery; PCS did not change significantly within the first two months but improved significantly (p = .02) from 2 to 12 months. Other measures were stable across the year after surgery. No significant differences between L and SLR were detected in the post-operative rates of change.

Table 1: Adjusted trends in QoL measures

	Baseline difference			Rate (within 2 months)			Rate (2 - 12 months)		
PCS (SF-12)	**Estimate**	**SE**	**p value**	**Estimate**	**SE**	**p value**	**Estimate**	**SE**	**p value**
Lobectomy	45.08	1.55		-2.00	0.81	0.01	0.67	0.23	<0.01

Conclusion: Mental health, anxiety, and depression scores either improved or remained stable. Decreases in physical health persisted 2 months postoperatively, but thereafter improved significantly. Implications for intervention include provision of preoperative counseling about anticipated changes in physical function after surgery, and post-op interventions aimed at improving physical function.

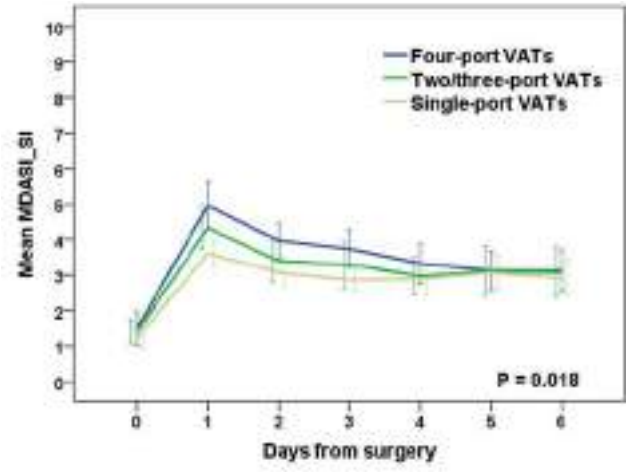
P2.16-04 SINGLE-PORT VIDEO-ASSISTED THORACOSCOPIC SURGERY REDUCES PATIENT-REPORTED SYMPTOM BURDEN IN PATIENTS UNDERGOING LUNG RESECTION

W. Dai[1], S. Xie[1], X. Wei[1], Y. Zhang[2], W. Feng[3], Y. Mu[4], R. Zhang[5], X. Liao[6], C. Wu[1], H. Zhou[1], X. Yang[1], Q. Shi[7], Q. Li[1]

[1]*Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu/China,* [2]*Zigong First People's Hospital, Zigong/China,* [3]*Jiangyou People's Hospital, Jiangyou/China,* [4]*The Third People's Hospital of Chengdu, Chengdu/China,* [5]*The Seventh People's Hospital of Chengdu, Chengdu/China,* [6]*Dazhu County People's Hospital, Dazhu County/China,* [7]*The University of Texas MD Anderson Cancer Center, Houston/United States of America*

Background: Symptom relief has been considered one of the most important targets in recovery from a surgery. This study aimed to evaluate the advantages of single-port video-assisted thoracoscopic surgery (VATS) in reducing postoperative symptom burden, by comparison with multi-port VATS in patients undergoing lung resection. **Method:** Data were collected from an ongoing, real-world, multicenter, prospective, observational study initiated in November 2017 (NCT03341377). The MD Anderson Symptom Inventory for lung cancer (MDASI-LC) was administered to assess the severity of postoperative symptoms and their interference with daily functioning preoperatively and daily postoperatively until discharge. A symptom burden index (MDASI-SI) was generated by averaging the top 5 severe symptoms. MDASI-SI was compared between groups using the Wilcoxon rank sum test. The changes of symptoms over hospitalization were compared using mixed modeling. **Result:** Among 175 patients who underwent lung resection, 89 underwent single-port VATS, 30 two-port VATS, 13 three-port VATS, and 43 four-port VATS. We combined two- and three-port VATS patients due to the small sample size. The top 5 severe symptoms were pain, fatigue, coughing, disturbed sleep, and shortness of breath for all the patients. There were no significant differences between single-, two/three-, and four-port VATS in preoperative MDASI-SI. The median postoperative hospital stay was 6 days for each group. The MDASI-SI scores of single-port VATS (median=3.6; inter quartile range (IQR)=2.4) were significantly lower than those of two/three-port (median=4.6; IQR=2.8; P=0.043) and four-port VATS (median=5.1; IQR=3.3; P=0.0005) on postoperative day (POD) 1.

Compared to four-port VATS, patients who underwent single-port VATS experienced significantly lower symptom burden from POD 1 to POD 6 (estimate=-0.77; SE=0.28; *P*=0.005).



Conclusion: This study provided real-world evidence that the single-port VATS has a significant benefit of reducing symptom burden in patients undergoing lung resection during the early postoperative period. The long-term benefit and its impact on patient's quality of life, adjuvant therapy, and survival need to be investigated in further studies.

P2.16-05 POPULATION-BASED ROS1 TESTING IN LUNG CANCER: CREATING OPPORTUNITY IN A PUBLICLY FUNDED SYSTEM

M. Makarem[1], D. Ezeife[2], A. Smith[3], J. Law[3], M. Tsao[3], N. Leighl[3]

[1]*University of Toronto, Toronto/Canada,* [2]*Tom Baker Cancer Centre, Alberta/Canada,* [3]*Princess Margaret Cancer Centre, Toronto/Canada*

Background: *ROS1* gene rearrangement is found in 1-2% of all non-small cell lung cancer (NSCLC) and is recommended as standard molecular diagnostic testing. This study models the most efficient *ROS1* testing strategy to maximize detection of true positive cases (TP) while minimizing costs and turnaround time (TAT). **Method:** A population-based *ROS1* testing model was developed from a Canadian (Ontario) public healthcare system perspective examining the use of immunohistochemistry (IHC) and next generation sequencing (NGS) versus fluorescence in situ hybridization (FISH, gold standard), reflex versus molecular or clinical selection (never smokers), and blood- versus tissue-based testing. Model inputs were derived from existing literature and expert opinion. Direct testing costs and TAT were obtained from the Ontario public perspective (University Health Network, Cancer Care Ontario). **Result:** The most cost-effective strategy for the outcomes of TAT and TP was reflex testing with IHC and subsequent FISH confirmation; this identified a high proportion of TP within a relatively short TAT. The most costly reflex strategy was NGS, with a greater proportion of missed TP (Table), and long TAT. Clinician selection of never smokers yielded the lowest proportion of TP. Population-based plasma ctDNA testing using commercial assays was the most costly strategy. One-way sensitivity analysis demonstrated that the TP outcome was most sensitive to the population prevalence of *ROS1*, while cost was most sensitive to the specificity of ROS1 IHC. **Conclusion:** Pathologist-initiated reflex testing using IHC with FISH confirmation provides the most cost-effective population-based testing strategy. Clinician-initiated testing significantly lengthens TAT. Selecting only never smokers for testing misses a larger proportion of TP patients who would benefit from targeted therapy despite potential cost savings.

	Strategy	Cost for 4000 cases (CAD)*	Longest TAT**	Proportion of TP
All comers - Reflex	FISH	1590×10^3	6.83	0.915
	IHC - FISH	662×10^3	10.23	0.878
	NGS	3790×10^3	19.64	0.769
Molecular	EGFR, ALK negative	1810×10^3	16.59	0.874
	EGFR, ALK, KRAS negative	3530×10^3	35.63	0.858
Clinician	EGFR, ALK negative	1810×10^3	30.59	0.874
	EGFR, ALK negative, never smokers	1480×10^3	28.71	0.705
	ctDNA	12200×10^3	19.91	0.815

*Excludes administrative costs and professional fees, and was determined based on the number of advanced NSCLC cases in Ontario in 2017

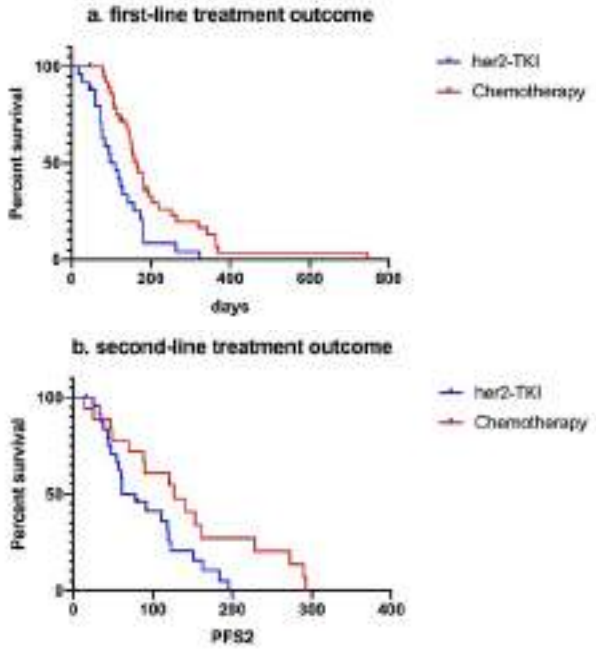
P2.16-06 MOLECULAR FEATURES AND TREATMENT OUTCOME OF HER2 MUTATED ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS IN CHINA

Y. Wang[1], F. Xu[2], G. Yang[2], H. Xu[3], L. Yang[1], Y. Yang[2], W. Qiu[4]

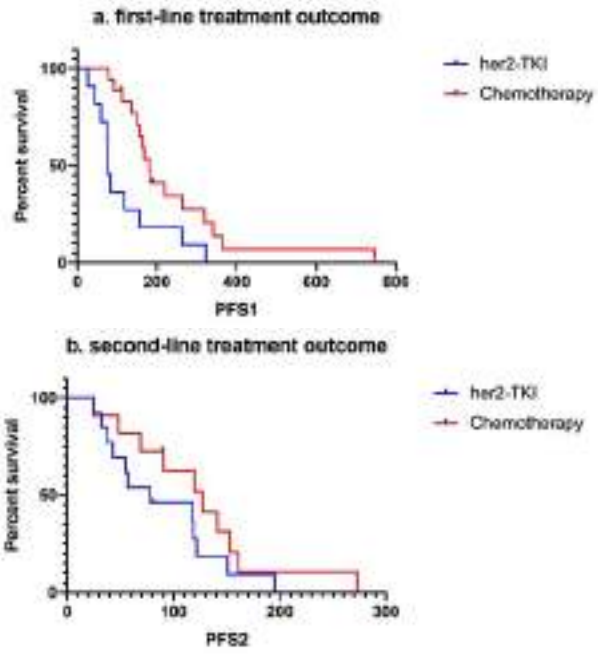
[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [2]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [3]*National Cancer Center, National Clinical Research Center for Cancer, Cancer Hospital, Chinese Academy of Medical Science and Peking Union Medical College, Beijing/China,* [4]*Haalthy, Beijing/China*

Background: HER2 mutations are found in 1-2% of lung adenocarcinoma patients. Chemotherapy remains the standard of care for patients harboring HER2 driver mutations, while many HER2 targeted tyrosine kinase inhibitors (TKIs) have been applied to them in practice in recent years. Studies comparing chemotherapy to HER2-TKIs was limited. This study was aimed to investigate molecular and clinical patterns of HER2 mutations in advanced non-small cell lung cancer (NSCLC), and compare the different outcomes between chemotherapy and HER2-TKIs. **Method:** Advanced or recurrent NSCLC patients with de novo HER2 mutations (N=75) were included in this study. Molecular information, clinical features, and treatment outcomes were retrospectively collected from a web-based patient registry and hospital chart review. **Result:** Between October 2012 and December 2018, 65 patients with in-frame insertion mutations, 8 with point mutations and 2 with gene amplification were found. The most common subtypes of insertion mutations were A775_G776insYVMA, G776delinsVC, and V777_G778insGSP. HER2 mutated patients were mostly young-aged, females, never or light smokers, and adenocarcinoma. For HER2 mutated advanced NSCLC, chemotherapy achieved better outcomes than HER2-TKIs (median PFS: 5.5 vs 3.7 months in first line setting and 4.2 vs 2.0 months in second line setting, *P*=0.001 and 0.031, respectively). Especially for the most common subtype, YVMA insertions, PFS was significantly longer in chemotherapy than HER2-TKIs both in first line (6.0 vs 2.6 months, *P*=0.008) and in second line (4.2 vs 2.6 months *P*<0.001).

Treatment response in HER2 mutated lung cancer patients as a whole



Treatment response in A775_G776insYVMA subtype



Conclusion: Compared to existed HER2-TKIs, chemotherapy might bring more benefit to HER2 mutated advanced lung cancer patients, especially the most common type of HER2 exon 20 insertions, A775_G776insYVMA subtype.

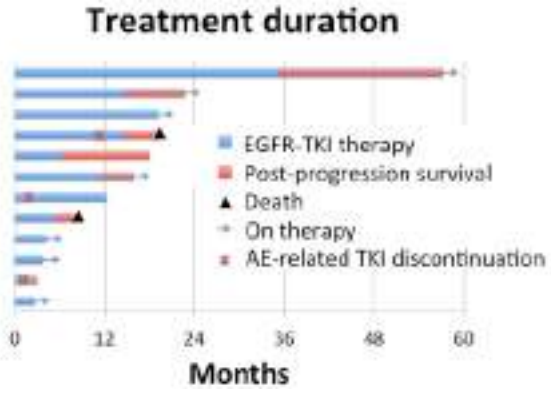
Keywords: HER2, molecular features, treatment outcome

P2.16-07 HOW TO MANAGE TOXICITIES OF EGFR-TKI FOR EXTREME ELDERLY LUNG CANCER PATIENTS: SUPPORTIVE CARE FOR PATIENTS AGED 85 AND OLDER

Y. Seki[1], T. Kazuyori[1], A. Sato[1], S. Fujimoto[1], M. Yamada[1], Y. Yamanaka[1], I. Fujisaki[1], K. Odashima[1], A. Seki[1], T. Ishikawa[1], K. Kuwano[2]

[1]*The Jikei Daisan Hospital, Tokyo, Japan, Komae, Tokyo/Japan,* [2]*The Jikei University Hospital, Tokyo/Japan*

Background: In Japan, the population of extreme elderly individuals (85 years and older) was 5.75 million in 2018, and the number of elderly lung cancer patients is increasing. Recently, several elderly-specific trials showed that epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) is effective and feasible for elderly patients with *EGFR* mutation-positive advanced non-small cell lung cancer (NSCLC). Nevertheless, there have been few reports on the efficacy and safety of EGFR-TKI therapy in patients aged 85 years and older with *EGFR* mutation-positive advanced NSCLC. **Method:** We analyzed the efficacy and safety of EGFR-TKI therapy in patients with *EGFR* mutated NSCLC who were 85 years and older treated at our hospital, between 2014 and 2019. We assessed complications, prognosis, and supportive care needs. **Result:** The median age was 87 years (range, 85-93 years) at last checkup, and only one patient was male. The study population included 12 patients with ECOG performance status 0-1 and all patients had adenocarcinoma. Four patients (33%) were diagnosed with cognitive impairment. Nine patients received gefitinib therapy. Treatment-related deaths were not observed in our analysis. Median progression free survival, overall survival from recent TKI therapy was 11.3 months, and 16.0 months. The response rate and disease control rate were 17%, and 100%. The common adverse events were diarrhea (25%), skin toxicities (25%), and liver dysfunction (25%). One patient (8%) experienced grade 2 EGFR-TKI-related interstitial lung disease. The dose of EGFR-TKI was reduced in 5 patients (42%) and EGFR-TKI therapy was discontinued in 3 patients (25%) due to toxicities, digestive disorders and interstitial lung disease.



Conclusion: EGFR-TKI therapy is tolerable for extreme elderly patients with *EGFR* mutation-positive advanced NSCLC. Approximately half of the patients required a dose reduction or focused supportive care, but well tolerated and had similar efficacy compared to those of the younger. It is important for elderly patients to be treated with a personalized management plan and integrated supportive care.

Keywords: Extreme elderly patients, EGFR-TKI, Toxicity management

P2.16-08 CLINICAL CHARACTERISTICS AND OUTCOMES OF PATIENTS WITH BRAF MUTATED NON-SMALL CELL LUNG CANCER

Y. Mu, P. Xing, Y. Li, X. Hao, J. Ying, J. Li

National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China

Background: BRAF mutation is a driver oncogene identified in 0.5-2% of non-small cell lung cancer (NSCLC) patients in China, and clinical data are relatively inadequate. This study assessed the clinical characteristics, course of disease and treatment outcomes in patients with BRAF mutated NSCLC in a real-world setting. **Method:** Between Apr 1, 2017 and Feb 1, 2019, medical data of patients with NSCLC harboring BRAF mutation in our cancer center was retrospective collected. Patient characteristics and treatment outcomes were reviewed. Data cutoff was Apr 1, 2019. **Result:** A total of 36 patients were identified. BRAF V600E was the most common (31/36, 86.1%), other BRAF molecular subsets were observed in 5 (13.9%) cases including K601E, G469V, G596R and D594N. The majority of patients with BRAF mutation were female (20/36, 55.6%) and non-smokers (20/36, 55.6%), all of them were adenocarcinoma, and median age at diagnosis was 56 (range, 33-79). Twenty-seven patients were recurrent or metastatic NSCLC at data cutoff, most of whom received chemotherapy (16/27, 59.3%) as first-line therapy with median progression-free survival (PFS) of 9.8 months (95%CI 0.0, 21.5) and disease control rate (DCR) of 68.8% (11/16). Eight patients received anti-BRAF targeted therapy (including dabrafenib, trametinib and vemurafenib) in the first-line and showed superior efficacy than those received chemotherapy (median PFS, 15.9 months [95%CI, 4.5, 27.3] vs. 9.8 months [95%CI, 0.0, 21.5], P = 0.183; DCR, 100% vs. 68.8%, P = 0.130). As for distinct molecular subsets, most patients with V600E mutation were female (19/31, 61.3%) and non-smokers (19/31, 61.3%), while four of five (80.0%) patients with non-V600E mutation were male and smokers. All of the 3 patients in non-V600E mutations subgroup with recurrent or metastatic disease received chemotherapy in the first-line, and achieved 2 of SD, 1 of PD.

Table 1. Efficacy of first-line treatment strategies in patients with BRAF mutation.

Treatment strategies in first-line	Overall		V600E	
	DCR	PFS (95%CI)	DCR	PFS (95%CI)
Pemetrexed-contained chemotherapy	11/14, 78.6%	9.9 (0.0, 20.0)	8/11, 72.7%	12.5 (2.5, 22.5)
Paclitaxel-contained chemotherapy	1/3, 33.3%	1.5 (0.7, 2.3)	1/3, 33.3%	1.5 (0.7, 2.3)
Vemurafenib	6/6, 100%	15.4 (0.0, 36.2)	6/6, 100%	15.4 (0.0, 36.2)
Dabrafenib + Trametinib	2/2, 100%	NR	2/2, 100%	NR

DCR, disease control rate; PFS, progression-free survival; NR, not reached.

Conclusion: NSCLC with BRAF mutation was associated with specific characteristics, which were variable between molecular subsets. BRAF inhibitors should be considered firstly in treating patients with BRAF-mutated lung cancers. The prognosis value of non-V600E mutations and treatment selection needs more research.

Keywords: Non-Small Cell Lung Cancer, BRAF mutation

P2.16-09 REAL-WORLD BRIGATINIB USE IN NON-SMALL CELL LUNG CANCER PATIENTS WITH PRIOR USE OF CRIZOTINIB/OTHER ALK THERAPIES IN THE US

H. Lin[1], L. Pan[1], M. Gorritz[2], C. Mcguiness[2], W.-T. Huang[2], C.-C. Chen[2]

[1]*Takeda, cambridge/United States of America,* [2]*IQVIA, Inc., Plymouth Meeting/United States of America*

Background: Anaplastic lymphoma kinase (ALK) gene rearrangements occur in 3 to 8% of non-small cell lung cancer (NSCLC) cases. Targeted therapy options for ALK+ NSCLC patients have increased recently and are associated with improved survival. This study aimed to describe the real-world use of brigatinib, particularly after crizotinib and other ALK-tyrosine kinase inhibitors (TKI), where most brigatinib patients were found in this study. **Method:** Adult (≥18 years) patients with ≥ 1 claim for brigatinib (index claim) after crizotinib were identified between 01-Jan-2011 and 30-Jun-2018 from IQVIA's US-based Longitudinal Patient-Centric Pharmacy Claims Database. Patients had ≥ 6 months of observation before crizotinib and were continuously followed post-index for use of brigatinib and until discontinuation (≥ 90-day gap in brigatinib therapy, switch to another ALK-TKI therapy, or the end of follow-up of brigatinib). Brigatinib on-treatment rates at 6- and 12-months post-index were estimated using Kaplan-Meier analysis in subgroups with > 50 patients. **Result:** The final sample consisted of 92 post-crizotinib brigatinib patients, most of whom were treated with crizotinib and ≥ 1 second generation (2G) ALK-TKI inhibitor (n=72); twenty patients received crizotinib only prior to brigatinib. Among the 72 patients treated with crizotinib and ≥ 1 2G ALK-TKI median (range) age at brigatinib initiation was 58.1 (30-85) years; 68.1% of the sample was female and most had third party insurance (51.4%). Mean (SD) post-index follow-up time was 6.7 (4.2) months. Sixty patients (56.9%) received crizotinib and alectinib (± ceritinib), while twelve (16.7%) received only crizotinib and ceritinib prior to brigatinib. Median brigatinib treatment duration was 8.3 months in patients with prior crizotinib and ≥ 1 2G ALK-TKI (n=72) ; 64.8% and 49.3% of these patients were still on brigatinib 6- and 12- months after initiation. In the subgroup of patients with crizotinib and alectinib ± (ceritinib) prior to brigatinib (n=60), median duration of brigatinib treatment was also 8.3 months; 66.6% and 48.1% were still on brigatinib 6- and 12-months after initiation. **Conclusion:** This US-based real-world study provides early insight into the use of recently approved brigatinib in NCSLC in the post crizotinib setting. These results indicate that use of brigatinib may be associated with potential clinical benefit with patients staying on therapy for a significant duration of time post a 2G ALK-TKI inhibitor. The duration of brigatinib in earlier lines remains to be investigated in future studies when larger sample sizes are available.

Keywords: Non-Small Cell Lung Cancer, ALK-TKI, brigatinib

P2.16-10 ADVANCES IN DIAGNOSIS AND TREATMENT OF NON-SMALL CELL LUNG CANCER ARE TRANSLATING INTO REAL-WORLD SURVIVAL GAINS IN THE UNITED STATES

O. Akinboro[1], S. Nwabudike[1], M. Charlot[2], J. Acevedo[1]

[1]*Boston University Medical Center, Boston/United States of America,* [2]*University of North Carolina School of Medicine, Chapel Hill/United States of America*

Background: The last two decades have been notable for advances in the histologic and molecular classification of non-small cell lung cancer (NSCLC) as well as the introduction of new cytotoxic agents, targeted therapies and immunotherapy into the routine care of metastatic NSCLC based on clinical trial results. We sought to evaluate temporal trends in overall survival (OS) among unselected patients with metastatic NSCLC in the United States (US). **Method:** We utilized the Surveillance, Epidemiology, and End Results (SEER) 9 registries in identifying patients with new diagnoses of stage IV NSCLC. Staging was based on the American Joint Committee on Cancer (AJCC) 3rd and 6th edition staging guidelines for the periods 1986-2003 and 2004-2015, respectively. We calculated median OS over successive 5 year intervals (1986-1990; 1991-1995; 1996-2000; 2001-2005; 2006-2010; 2011-2015) according to the year of initial diagnosis for the entire cohort as well as by subgroups defined by age (20-44 years[y]; 45-64y; 65-74y; 75-84y; ≥85y); gender (male; female); race/ethnicity (Whites; Blacks; Hispanics; Others); region (northeast; south; midwest; west); and histology (adenocarcinoma[AC]; squamous cell carcinoma[SCC]; others). Univariate analysis was performed with Kaplan-Meier analysis and log-rank tests. Independent associations between OS and time periods were examined with a multivariate Cox proportional hazard model that adjusted for the effects of age, gender, race, region, histology, as well as the interaction of time with these covariates. **Result:** There were 113,518 cases of newly diagnosed stage IV NSCLC. Median OS increased from 4 months (m) in 1986-1995 to 7m in 2011-2015. Median OS improved for all age-groups and by subcategories of gender, race/ethnicity, region, and histology. Multivariate analysis demonstrated a progressive decrease in mortality since the 2000s, relative to those diagnosed in 1986-1990 with the following adjusted hazard ratios (aHR) and respective confidence intervals (CI): 1991-1995: 1.09 (95%CI: 0.93, 1.29; p=0.129); 1996-2000: 0.95 (95%CI: 0.81, 1.12; p=0.561); 2000-2005: 0.83 (95%CI: 0.71, 0.97; p=0.017); 2006-2010: 0.79 (95%CI: 0.67, 0.93; p=0.005); 2011-2015: 0.57 (95%CI: 0.48, 0.68; p<0.001). Although all subcategories of patients had improved OS over time, females had a relative improvement in OS over males in 2011-2015 compared to 1986-1990 (aHR: 0.90; 95%CI: 0.85, 0.95; p<0.001). Those aged ≥85y had OS that was comparatively worse than those aged 20-44y in 2011-2015 relative to 1986-1990 (aHR: 1.31; 95%CI: 1.04, 1.65; p=0.023). Additionally, those with SCC had worse OS than those with AC in 2011-2015 relative to 1986-1990 (aHR: 1.13; 95%CI: 1.06, 1.21; p<0.001). There were no relative differences in OS over time by race/ethnicity or region. **Conclusion:** There has been a near doubling in median OS for patients diagnosed with stage IV NSCLC in the US over the 30-year period spanning 1986-2015. These findings suggest that advances in the diagnostic classification and treatment of NSCLC resulting from clinical trial participation are translating into real-world survival gains particularly for those with AC. However, patients with SCC and the most elderly patients have benefited less proportionately underscoring the need for further characterization of SCC with the development of targeted therapies and inclusion of the most elderly in cancer clinical trials.

P2.16-11 ADVANCE-1: DEVELOPMENT AND FEASIBILITY TESTING OF A BENCHMARKING APPROACH FOR QUALITY IMPROVEMENT IN LUNG CANCER CARE

B. Mccann[1], R. Muhr[2], N. O'Rourke[1], T. Blum[2], R. Milroy[3], D. Morrison[4], J. Kollmeier[2], D. Misch[2], J. Van Der Horst[3], B. Sens[5], O. Massalski[6], T. Bauer[2]

[1]*Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom,* [2]*Helios Klinikum Emil von Behring, Berlin/Germany,* [3]*Glasgow Royal Infirmary, Glasgow/United Kingdom,* [4]*University of Glasgow, Glasgow/United Kingdom,* [5]*German Society for Quality Management in Health Care, Cologne/Germany,* [6]*German Benchmarking Centre, Berlin/Germany*

Background: Benchmarking is successfully utilized in industry to improve working process and productivity. In its original sense benchmarking is a systematic process for comparing performances, functions or processes of organisations against the best in the world. However, the majority of research within lung cancer is focused on prevention, diagnosis and treatment rather than examining infrastructure or processes of managing lung cancer patients. ADVANCE-1 is a European Respiratory Society (ERS) funded pilot study with the aim of creating a benchmarking tool that can easily document and reflect the structure and process within a lung cancer centre and its associated registry and how these processes impact on the pathway of a patient through the individual centres. **Method:** The ADVANCE-1 study group was constituted by the two ERS fellowship-holders and senior lung cancer specialists from the two participating lung cancer services in the Beatson West of Scotland Cancer Centre, Glasgow, Scotland, and the Lungenklinik Heckeshorn in the Helios Klinikum Emil von Behring, Berlin, Germany. We created the study design with direct cooperation of the German Benchmarking Centre as well as the University of Glasgow. Final results were externally reviewed by the German Society for Quality Management in Health Care. **Result:** Two benchmarking tools were created; the first for documentation of the service provided at each centre, the underlying cancer registry and a test of the robustness and comprehensiveness of information and data collecting resources available at each centre. Secondly; a patient pathway tool to reflect the journey of a patient through each of the relevant centres. Patient satisfaction surveys and staff satisfaction surveys were also created. Prospective testing of these benchmarking tools in Glasgow and Berlin will allow a comparison between the two centres in order to

ascertain best practice and learning from each centre in a so called 'collaborative' benchmarking approach. **Conclusion:** This unique study has created a benchmarking tool that can easily document the service of a lung cancer centre and the pathway of a patient through that service. With comparison and learning from each other using this tool we aim to improve the patient care and journey through a lung cancer service.

P2.16-12 TREATMENT UPTAKE AND OUTCOMES OF ELDERLY STAGE III NSCLC PATIENTS: A 15-YEAR RETROSPECTIVE REAL-WORLD STUDY

A. Gibson, A. D'Silva, M. Dean, R. Tudor, A. Elegbede, S. Otsuka, D. Bebb

University of Calgary, Calgary/Canada

Background: Incidence of non-small cell lung cancer (NSCLC) is highly correlated with age; the age-specific incidence rate of NSCLC in individuals ≥ 75 is nearly double that of patients < 70. Further, nearly one-third of patients diagnosed with NSCLC present with locally advanced (Stage III) disease. This represents an anatomically heterogeneous, frequently non-resectable tumour for which contemporary practice guidelines, based on two decades of clinical trials, recommend concurrent chemoradiotherapy (cCRT) to maximize both local tumor control and survival. Underrepresentation of elderly patients in clinical trials requires the use of real-world populations to assess whether current recommendations and trial-derived survival outcomes are also applicable to this significant and growing age group. **Method:** A 15-year population-based retrospective analysis of patients with *de novo* Stage III (AJCC 7th edition) NSCLC diagnosed between 1999-2014 was conducted. Demographic, clinical characteristics, treatment and outcome data were extracted from the institutional Glans-Look Lung Cancer Database. We defined elderly patients as those ≥ 75 years at diagnosis, and investigated the treatment intent, type, uptake and outcomes among elderly and non-elderly patients. **Result:** We identified 1040 patients with a Stage III diagnosis. 333 (32%) were elderly. Treatment patterns differed significantly between elderly patients and non-elderly patients: elderly patients were less significantly likely to receive any form of active treatment (82% vs. 58%), particularly curative-intent treatment (41% vs. 14%), and no elderly patients underwent surgical resection. Median overall survival (mOS) favoured non-elderly patients (13.2 vs. 9.7 months, log-rank p <0.001.) Among elderly patients, receipt of curative-intent treatment was associated with significant improvement in mOS (17.4 months vs. 9.3 months for no active treatment/observation, vs. 8.5 months for palliative-intent treatment, p < 0.001). When receiving curative-intent treatment, specifically cCRT, survival outcomes of elderly patients were not significantly different from those of younger patients (24.5 vs. 21.3 months, p=0.81), and had comparable 5-year survival rates (15.9% and 12.2% respectively). **Conclusion:** This real-world population reveals that elderly patients are less likely to receive any, and particularly, curative-intent treatment for their NSCLC diagnosis when compared with a younger cohort. When deemed suitable for a curative-intent regiment of cCRT, elderly patients show comparable outcomes to younger cohorts. This finding reinforces the current guideline recommendations that cCRT is associated with best outcome for non-resectable, locally-advanced NSCLC, even among elderly patients. Further, it supports the critical need for more tolerable and effective treatments for this presentation of disease to improve feasibility of curative-intent treatment for all, but in particular, elderly patients.

P2.16-13 RISK FACTORS OF RADIATION PNEUMONITIS IN LUNG CANCER PATIENTS WITH SUBCLINICAL INTERSTITIAL LUNG DISEASE AFTER THORACIC RADIOTHERAPY

F. Li[1], S. Liang[2], H. Wu[1], Y. Xu[1], M. Chen[3]

[1]*Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China,* [2]*Cancer Hospital Affiliated to Guangxi Medical University, Nanning/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China*

Background: Previous studies reported that patients with subclinical interstitial lung disease were more susceptible to developing radiation pneumonitis after thoracic stereotactic body radiotherapy or thoracic radiation therapy. The present study aimed to evaluate the incidence and risk factors of radiation pneumonitis after thoracic radiation therapy in lung cancer patients with subclinical interstitial lung disease. **Method:** Patients with subclinical interstitial lung disease between January 2016 and December 2017, who were treated with thoracic intensity-modulated radiation therapy in our institutions, were prospectively analyzed. The diagnosis of subclinical interstitial lung disease was based on the pretreatment high-resolution computed tomography imaging, such as honeycombing, subpleural reticular opacities, ground-glass opacity, and traction bronchiectasis. Statistical analysis was performed using SPSS software 22.0 for Mac. Univariate and multivariate analyses were used to assess the correlation of clinical factors, dose-volume histogram-based dosimetric parameters,and imaging characteristics of preexisting subclinical interstitial lung disease with radiation pneumonitis. A P value < 0.05 was considered statistically significant. **Result:** A total of 87 consecutive patients with subclinical interstitial lung disease were prospectively analyzed. The median follow-up time was 14.1 months. RP was observed in 19 (21.8%), 27 (31.0%), 10 (11.5%), 3 (3.4%), and 5 (5.7%) patients with grades 1, 2, 3, 4 and 5 RP, respectively. The location of tumors and mean lung dose were significantly associated with ≥grade 2 RP in univariate analysis (*P*=0.043, *P*=0.024, respectively). Patients who received gemcitabine in the past and the involvement of subclinical interstitial lung disease ≥ 25% of the lung volume were significantly associated with ≥grade 3 radiation pneumonitis in univariate analysis (*P*=0.031, *P*=0.037, respectively). Patients who received gemcitabine in the past and the involvement of subclinical interstitial lung disease ≥ 25% of the lung volume were significantly associated with ≥grade 3 RP in multivariate analysis (*P*=0.046,*P*=0.017, respectively). **Conclusion:** Subclinical interstitial lung disease is associated with an increased risk of radiation pneumonitis. Patients who received gemcitabine in the past and the involvement of subclinical interstitial lung disease ≥ 25% of the lung volume are associated with an increased risk of ≥grade 3 radiation pneumonitis.

Keywords: interstitial lung disease, Lung cancer, Radiation pneumonitis

P2.16-14 SURVIVAL RATES IN NON-SMALL CELL LUNG CANCER PATIENTS IN THE BRAZILIAN PRIVATE HEALTH SYSTEM: A COHORT STUDY

E. Cerqueira[1], C.G. Ferreira[2], R. Buzzatti Peixoto[1], P. Mendoça Batista[1], M. Datz Abadi[1], L. Okumura[3]

[1]*MSD Brazil, São Paulo-SP/Brazil,* [2]*Oncoclinicas Institute, Rio de Janeiro/Brazil,* [3]*Techtrials, São Paulo/Brazil*

Background: Lung cancer is the leading cause of cancer-related mortality in Brazil. Non-small cell lung cancer (NSCLC) is the most prevalent subtype and is associated with high rates of mortality. Despite being diagnosed in late phases, few studies have addressed the survival rates of such disease in the Brazilian private health system. **Method:** An exploratory cohort study based on administrative database claims that included patients with advanced NSCLC diagnosed between 2011 to 2016. The inclusion criteria were defined as having lung cancer diagnosis (ICD-10 code 34 with stage III and IV) and compatible histologic subtype for NSCLC, such as adenocarcinoma, squamous cell, non-squamous cell and others. Non-parametric statistics (Kaplan Meier method, product limit estimator) was used to perform survival analyses, considering diagnosis as index date. **Result:** A total of 5,016 patients were included in this study. At time of diagnosis, most patients had stage IV disease (67%) and were 60 to 69 years old (33.7%). Patients took 31 days on average to receive diagnosis after being attended by a health service. The clinical oncologist was the first professional to

attend the patient in 44% of cases. The average time to start the treatment was 35 days and where patients received chemotherapy (32%) or chemotherapy plus radiotherapy (21%). The median survival rate for stage III NSCLC was 7 months; while for stage IV, 50% of the population was alive in 8 months. **Conclusion:** This study suggests a high percentage of patients diagnosed with stage IV disease. The survival rates were very low, comparable to the public healthcare system where the patient doesn't have access to all medications approved by ANVISA, Brazilian Regulatory Agency, (median overall survival of 8 to 12 months). The results show an opportunity to improve care in private healthcare system.

Keywords: Brazil, private healthcare system, Non small cell lung cancer

P2.16-15 SURVIVAL AND CLINICAL IMMUNOTHERAPY OUTCOMES IN HISPANIC PATIENTS VS NON-HISPANIC WHITE PATIENTS WITH NON-SMALL CELL LUNG CANCER

L. Raez[1], D. Saravia[2], D. Sumarriva[2], R. Ruiz[3], P. Izquierdo[1], D. Cress[4], B. Hunis[1], L. Mas[3], G. Lopes[2], D. Kaen[5]

[1]*Memorial Cancer Insitute/Florida International University, Pembroke Pines/United States of America,* [2]*Sylvester Cancer Center, Miami/United States of America,* [3]*National Cancer Institute Peru, Lima/Peru,* [4]*H Lee Moffit Cancer Center, tampa/United States of America,* [5]*Hospital Escuela y de Clínicas "Virgen María de Fátima", La Rioja/Argentina*

Background: The number of Hispanic (HISP) patients (pts) enrolled in immunotherapy (IMMUNO) trials is minimal or non-existent in non-small cell lung cancer (NSCLC). It's well known that HISP pts with NSCLC have not only a different genomic profile than Non-Hispanic Whites (NHW)- like higher expression of EGFR mutations- but also better outcomes than NHW ("Hispanic Paradox"); thus the need to validate outcomes in HISP pts treated with IMMUNO. **Method:** We present data in 436 NSCLC pts treated with IMMUNO at 5 large institutions (3 in the US, 2 in Latin America). The agents evaluated include: nivolumab, pembrolizumab and atezolizumab. 256 pts were HISP and 180 pts were NHW. Most of the pts were treated with single agent therapy as second line or beyond while a small group of pts were treated as first line. The primary endpoints of the study were: response rate (ORR), progression free survival (PFS) and overall survival (OS). Secondary endpoints were disease control rate (DCR), PD-L1 expression and others. **Result:** The results are consolidated in the table below.

	Hispanics (n=256)	NHW (n=180)	p value
Sex (males)	52%	45%	0.2059
ORR			
First Line	35%	30%	0.6590
Second Line	18%	19%	0.3236
Adeno	22%	24%	0.6714
SQCC	24%	23%	1.0000
PDL1 (+)	29%	32%	0.4839
PDL1 (-)	5%	17%	0.3040
Disease Control Rate: ORR+SD (DCR)			
Adeno	68%	67%	0.8989
SQCC	67%	46%	0.0777
Median PFS	4m	4m	0.7509
Median OS	22m	22m	0.2004

There were no statistical significant differences among HISP and NHW pts regarding ORR, DCR, PFS, OS, and responses according to PD-L1 status. **Conclusion:** No significant differences were found in the clinical outcomes between these 2 ethnic groups despite the "Hispanic Paradox" and expected genomic differences; however pts with actionable mutations were excluded as they usually do not get IMMUNO as first or second line; an approach that might change after IMPOWER 150. This is the largest comparison of NSCLC immunotherapy outcomes in HISP vs NHW pts. These results are comparable to the ones seen in Checkmate and Keynote studies. As expected, higher response rates were seen in first line therapy and pts with PD-L1 (+) status. Further comparisons will be better addressed by a larger prospective study.

P2.16-16 CALF CIRCUMFERENCE IS ASSOCIATED WITH POSTOPERATIVE OUTCOMES IN LUNG CANCER PATIENTS WHO UNDERWENT SURGERY

A. Nagoya, R. Kanzaki, E. Fukui, T. Kanou, N. Ose, S. Funaki, M. Minami, Y. Shintani

Osaka Univiersity Graduate School of Medicine, Suita-City, Osaka/Japan

Background: Sarcopenia has gained considerable attention as a poor prognostic factor in lung cancer after surgical resection. Calf circumference (CC) is an easy-to-measure, non-invasive clinical indicator that reflects body muscle mass as well as subcutaneous fat. For this property, many studies have reported that CC is capable of screening sarcopenia, aside from the assessment of nutritional status. In this study, we investigated the association between CC and postoperative outcomes in lung cancer patients. **Method:** Between 2007 and 2016, 873 lung cancer patients underwent surgery in our institution. Patients who received induction therapy (n=33), with a prior history of the disease that could affect the diameter of lower limb (n=5), and with missing data (n=17) were excluded in advance, leaving 818 patients for this retrospective analysis. CC was measured prior to surgery in the occasion of hospital admission. We chose 34 cm for men and 33 cm for women as the CC cutoff value for predicting low muscle mass, following the previous report in Japan (Kawakami R et al. Geriatr Gerontol Int.). The patient characteristics, operative factors, and surgical outcomes were examined to compare the groups. The Kaplan-Meier method was used to estimate long-term survival. **Result:** The mean age of all patients was 67.9 years. There were 473 men and 345 women, and each of their average CC was 34.4 cm and 32.0 cm. In the smaller CC (s-CC) group (n=427), the average age and the female proportion were significantly higher, whereas BMI, %VC, %FEV1 and %DLco, in addition to the proportion of the other cancer history were significantly lower (P<0.01 each) compared with the other group (n=391). As for operative factors, there were no significant differences in surgical approach, type of resection, operation time and intraoperative bleeding, except that the ratio of systematic hilar and mediastinal lymph node dissection was lower (P<0.01) in the s-CC group. Though overall postoperative complications were equivalent (27.2% vs. 23.0%), complications grade 3 or higher were more frequent in the s-CC group (10.5% vs. 5.9%, P=0.02). The 5-year DFS (65.1% vs. 77.9%, P=0.01) and OS (77.9% vs. 81.7%, P=0.03) were significantly poorer in the s-CC group. **Conclusion:** The smaller CC was associated with severe postoperative complications and poor DFS and OS in patients with resected lung cancer. CC was useful for assessing sarcopenia and therefore predicting postoperative outcomes.

P2.16-17 REAL-WORLD TRENDS IN SYSTEMIC THERAPY FOR NONSQUAMOUS EGFR/ALK-NEGATIVE ADVANCED NSCLC (ANSCLC) IN THE US, 2011–2018

V. Velcheti[1], S. Chandwani[2], X. Chen[2], B. Piperdi[2], T. Burke[2]

[1]*NYU Langone, Perlmutter Cancer Center, New York/United States of America,* [2]*Merck & Co., Inc., Kenilworth/United States of America*

Background: Systemic anticancer therapy (SACT) options for aNSCLC continue to increase each year with approvals of more effective therapies that improve long-term outcomes, as seen with immunotherapies (IO). We aimed to examine real-world trends in SACT distribution and sequence from first- to second-line (1L-2L) for EGFR/ALK-negative nonsquamous aNSCLC from 2011-2018 at US community oncology practices. **Method:** This study used the nationwide Flatiron Health de-identified, EHR-derived database (cutoff: 31Jan2019). Eligible patients were adults with aNSCLC, nonsquamous histology with known EGFR/ALK-negative status, who initiated 1L SACT from Jan2011-Jun2018. SACT regimens were assigned to mutually exclusive classes in hierarchical order, from highest to lowest: (1) PD1/PD-L1 inhibitor (anti-PD1/L1)-based, (2) EGFR/ALK TKI-based, (3) platinum-based chemotherapy (PBC) combination with vascular endothelial growth factor inhibitor (PBC+VEGF), (4) PBC only, (5) single agent chemotherapy, (6) others. 2L regimens were examined for patients initiating 1L SACT only through 2017 to enable sufficient follow-up. Results were stratified by year and by pre-IO/post-IO years of 1L initiation, defined as 2011-2014/2015-2018, respectively, based on earliest IO approval for 2L therapy in Mar2015. **Result:** For 1L, in the pre-IO period, most patients were prescribed PBC (53%) or PBC+VEGF (30%), and post-

IO, most were prescribed PBC (43%), anti-PD1/L1 (25%), or PBC+VEGF (23%). Among patients prescribed 1L therapy, the percentages who received 2L therapy were 50%-62% post-1L PBC; 56%-62% post-1L PBC+VEGF; and 28%-38% post-1L anti-PD1/L1 (table). A substantial percentage (25%) of those initiating 1L anti-PD1/L1 in 2017 were still on therapy at cutoff.

SACT prescribing for EGFR/ALK-negative nonsquamous aNSCLC by 1L initiation year and including three most common 2L regimens overall

1L Regimen	2011 (n=566)	2012 (n=1205)	2013 (n=1621)	2014 (n=2081)	2015 (n=2542)	2016 (n=2712)	2017 (n=2806)	2018(½) (n=1267)

Other, n(%)	33(6)	49(4)	58(4)	58(3)	84(3)	77(3)	45(2)	39(3)

[a]Patients still on 1L or prescribed 2L represent percentages of patients initially prescribed 1L.
[b]Percentages for 2L SACT regimens represent percentages of patients prescribed 2L.
[c]Anti-PD1/L1 regimens included anti-PD1/L1 monotherapy and combination therapy with PBC.

Conclusion: Changing trends in real-world prescribing of 1L-2L SACT for EGFR/ALK-negative nonsquamous aNSCLC from Jan2011-Jun2018 include decreasing use of PBC in 1L and 2L, decreasing use of PBC+VEGF in 1L, and, increasing use of PD1/PD-L1 inhibitors in 1L and 2L. Slightly more than one-half of patients with nonsquamous aNSCLC prescribed 1L PBC are subsequently treated with 2L therapy.

Keywords: nonsquamous NSCLC, real-world therapy trends, Immunotherapy

P2.16-18 OPIOID-INDUCED CONSTIPATION IN PATIENTS WITH CANCER PAIN IN JAPAN (OIC-J STUDY): A POST-HOC ANALYSIS OF LUNG CANCER PATIENTS

H. Imai[1], T. Harada[2], S. Fumita[3], T. Noriyuki[4], M. Gamoh[5], Y. Akashi[3], M. Okamoto[6], Y. Kizawa[7], A. Tokoro[8]

[1]*Gunma Prefectural Cancer Center, Ota/Japan,* [2]*JCHO Hokkaido Hospital, Sapporo/Japan,* [3]*Kindai University Nara Hospital, Ikoma/Japan,* [4]*Onomichi General Hospital, Onomichi/Japan,* [5]*Osaki Citizen Hospital, Osaki/Japan,* [6]*Shionogi & Co., Ltd, Osaka/Japan,* [7]*Kobe University Graduate School of Medicine, Kobe/Japan,* [8]*National Hospital Organization Kinki-Chuo Chest Medical Center, Sakai/Japan*

Background: Opioid-Induced Constipation (OIC) is a common side effect of opioid analgesic therapy. OIC-J study was a multicenter, prospective, observational study of cancer patients who started opioid therapy in Japan (UMIN000025864). The aim of this post-hoc analysis was to clarify the OIC burden focusing on lung cancer patients. **Method:** This post-hoc analysis was conducted by using a lung cancer patient's data from OIC-J study. The incidence of OIC was determined by ROME IV diagnostic criteria based on the record of patient diary for 2 weeks, physician's assessment, spontaneous bowel movement (SBM; <3 SBM/week), Bowel Function Index (BFI; score >28.8) and Patient's assessment. The change in the Patient Assessment of Constipation-Symptoms (PAC-SYM) score and the Patient Assessment of Constipation Quality of Life Questionnaire (PAC-QOL) score in 2 weeks after starting opioids were compared between OIC patients and non-OIC patients determined by ROME IV diagnostic criteria. **Result:** 67 lung cancer patients from 212 in total cancer patients who were registered in OIC-J study were included in this analysis. The incidence of OIC was 48.0% (ROME IV diagnostic criteria), 59.1 % (physician's assessment), 39.1% (SBM) and 53.0% (BFI), respectively. The incidence of OIC by patient's assessment was 43.5% in 2 weeks after starting opioids (40.3% at a week after staring opioids). The change in PAC-SYM and PAC QOL score in OIC-patients compared to non-OIC patients were 0.399 vs -0.122 (p=0.0031) and 0.214 vs -0.016 (p=0.0540), respectively. **Conclusion:** The OIC can occur quickly after the initiation of opioid therapy in lung cancer patients and can have an impact on patient's QOL. These results suggest that an OIC management focusing on a quality and patient's feeling of bowel movement in early stage in opioid analgesic therapy is important for lung cancer patients.

P2.16-19 REAL WORLD DATA IN NON-SMALL CELL LUNG CANCER WITH ACTIVATING EGFR MUTATION - A MULTICENTER OBSERVATIONAL STUDY

M. Kimura[1], K. Nishino[1], Y. Yano[2], M. Mori[2], H. Suzuki[3], T. Hirashima[4], S. Minami[5], K. Komuta[5], T. Shiroyama[6], I. Nagatomo[6], F. Imamura[1]

[1]*Osaka International Cancer Institute, Osaka/Japan,* [2]*National Hospital Organization Osaka Toneyama Medical Center, Toyonaka/Japan,* [3]*Osaka Habikino Medical Center, Osaka/Japan,* [4]*Osaka Habikino Medical Center, Habikino-city/Japan,* [5]*Osaka Police Hospital, Osaka/Japan,* [6]*Osaka University Graduate School of Medicine, Suita city, Osaka/Japan*

Background: Osimertinib demonstrated durable responses in patients with advanced non-small cell lung cancer (NSCLC) harboring major epidermal growth factor receptor (EGFR) mutations (EGFRm+) and T790M resistance mutation (T790M+) in global trials, and approved in March 2016 in Japan. The best treatment strategy of EGFR tyrosine kinase inhibitors (TKIs), especially osimertinib, cytotoxic drugs, and immune checkpoint inhibitors (ICIs) is unknown. **Method:** To evaluate treatment selection with special attention to osimertinib, medical records of the patients with advanced EGFRm+ NSCLC who were under treatments at May 2016 or started a new treatment after May 2016 were collected. **Result:** A total of 543 patients were collected. Median age 69 years (range: 35 to 90); female 67%; never smokers 60%; adenocarcinoma 99%; major EGFR mutations 94%; interstitial lung diseases (ILD) 5%. The first line regimen was started between September 2002 and August 2018. The median total number of regimens was 2 (range: 1 to 13). EGFR-TKIs were administered to all patients, and were rechallenged in 56%; 42% received platinum combination regimens. The median overall survival and the median duration of EGFR-TKI treatments were 85 and 40 months, respectively. Re-biopsy was performed 1 to 6 times for 296 patients, T790M was detected in 47% of them. Osimertinib were used in 167 patients including 7 patients in whom an 1st EGFR-TKI was switched to osimertinib without PD. The median treatment line of osimertinib was 3 (range: 1 to 10), the response rate and the disease control rate of osimetinib was 44% and 71%, respectively, and the median time to treatment failure (TTF) was 13 months while 52% were censored. Osimertinib-induced ILD developed in 4 patients, and one patient died. Sixty-two patients received once or twice ICI treatments: nivolumab, pembrolizumab, and atezolizumab were administered to 38, 19 and 7 patients, respectively. The ICIs-induced ILD developed in 1 patient with nivolumab. The median TTF of ICIs was 2.3 months (range: 0 to 29), the response rate and the disease control rate were 14% and 53%, respectively, and 9% could continue ICI for one year or more. **Conclusion:** Re-biopsy was performed in 55%, and T790M was detected in 47%. In T790M+ including de novo T790M+ patients, osimertinib was used in 94%. Although this analysis has some limitations especially in patient selection, long-term survivors received platinum combination regimens, other cytotoxic drugs, and ICIs in addition to EGFR-TKIs.

P2.16-20 BIG DATA AND SURVIVAL PREDICTORS IN LUNG CANCER PATIENTS

B. Núñez-García[1], M. Torrente[1], E. Menasalvas[2], J.M. Tuñas[2], A. Rodríguez-González[2], F. Franco[1], V. Calvo De Juan[1], M. Provencio[1]

[1]*Hospital Puerta de Hierro, Majadahonda/Spain,* [2]*Universidad Politécnica Madrid (UPM), Madrid/Spain*

Background: Lung cancer is the most common and fatal one (18% of all cancer deaths). Parameters which imply better survival are still unknown. The objective of this project is to turn the large amount of data from each patient into exploitable information. **Method:** Between 2008-2019, 935 non-small cell lung cancer patients from our hospital were enrolled in an observational study. Unstructured data was obtained from the patient Electronic Health Records. Politecnica University from Madrid made the information analysis using Big Data and machine learning techniques. **Result:** A total of 251.730 documents have been analyzed from 935 patients, 54% in stage IV. EGFR/ALK mutation was found in 9%, showing better OS than non-mutated (23.5 months vs 12 months, log-rank p=0.016). Survival curves are shown in figure 1. In a multivariate analysis (table 1), independent predictors of mortality were male sex, squamous histology and PS status. Additionally, independent predictors of survival were receiving immunotherapy, surgery treatment or developing endocrine toxicities. **Conclusion:** Big data is a very useful tool to exploit a large amount of lung cancer data, increasing knowledge about these disease and allowing the development of survival predictive models.

This work was supported by the EU H2020 programme, under grant agreement Nº 727658 (Project iASiS).

POSTERS

P2.16-21 EFFECTS OF MOLECULAR MARKERS ON RESPONSES, RELAPSES, AND SURVIVAL IN LUNG CANCER PATIENTS WITH HIV

N. Reddy[1], V. Villaflor[2], C. Achenbach[1]

[1]*Northwestern University Feinberg School of Medicine, Chicago/United States of America,* [2]*Robert H. Lurie Comprehensive Cancer Center of Northwestern University, Chicago/United States of America*

Background: Patients with HIV are aging due to potent combination antiretroviral therapy (ART) and the incidence of lung cancer has increased. Limited research has been performed on the relationship between HIV and lung cancer prognosis and recurrence. Based on previous data and our clinical experience, patients with HIV and lung cancer have worse prognosis1 potentially due to social and behavioral risk factors, unfavorable molecular markers and differences in treatment patterns. **Method:** We identified patients with HIV and lung cancer between January 1, 2001 and December 31, 2015 using Northwestern Medicine (NM) Electronic Data Warehouse (EDW). Lung cancer cases were verified and treatment/outcome information was extracted by chart review. We then compared the effects of molecular markers on treatment responses, relapses, and survival in lung cancer patients with HIV infection. Incidence and prognosis were compared to historical, non-HIV lung cancer controls. **Result:** We included 36 individuals with HIV and lung cancer in this analysis. The median age at diagnosis was 55 years, 75.0% (27/36) were male, 94.0% (34/36) smokers. Histology: Small Cell – 1 (2.8%), Squamous cell – 10 (27.8%), Adenocarcinoma – 21 (58.3%), Other NSCLC – 2 (5.6%) Unreported – 2 (5.6%). Molecular: EGFR – 2 (5.6%), ROS1 – 0 (0%), ALK – 3 (8.3%), KRAS – 1 (2.8%), PDL1 – 2 (5.6%), Not Reported – 6 (16.7%). Stage at Diagnosis: Stage I – 3 (8.3%), Stage II – 6 (16.7%), Stage III – 2 (5.6%), Stage IV – 21 (58.3%), unreported – 4 (11.1%) Median survival – 2 years for all patients. EGFR – 1 year, ALK – 5.5 years, KRAS – 1 year, PDL1 – 1 year **Conclusion:** In prior research, patients with HIV and lung cancer appear to have decreased survival with reported overall survival of 7 months compared to 25 months for historical controls irrespective of stage and stage appropriate treatment for lung cancer2. In our study cohort, patients appeared to be treated similar to non-HIV controls, and the overall survival is fairly consistent with historic non-HIV controls, but smoking incidence (34/36; 94%) was higher than in non-HIV patients with lung cancer (85%). The prevalence of ALK translocation (3/36; 8%) was higher than typically observed among those without HIV (3-5%) and occurred exclusively in smokers. Typically, ALK translocation occurs in non-smokers. HIV patients treated with ALK inhibitors appeared to respond to similarly to non-HIV patients with NSCLC based on historic clinical data. Increased mortality in HIV, lung cancer patients is likely multifactorial, including concerns for lack of aggressive anti-cancer therapy delivered in this population. Our findings suggest that identifying driver mutations and molecular marker mutations may improve clinical practice for treatment of HIV-associated lung cancer. More prospective study is needed in this population.

Keywords: HIV, molecular markers, median survival

P2.16-22 PREDICTIVE ANALYTIC OF SURVIVAL USING A NEURAL NETWORK IN A REAL WORLD COHORT OF ADVANCED NON SMALL CELL LUNG CANCER PATIENTS

L. Pino[1,2], A. Ospina[2], I. Triana[2], J. Pino[3], C. Camelo[4], J. Mejía[4], D. Peña[4]

[1]*Fundacion Santafé de Bogotá, Bogota/Colombia,* [2]*Fundacion Santafe, Bogota/Colombia,* [3]*Gimnasio Los Cerros, Bogota/Colombia,* [4]*Procalidad S.A., Bogota/Colombia*

Background: When talking about a probabilistic neural network a new concept on survival is introduced. Using advanced statistics, different characteristics amongst patients such as oncogenic driver mutation, smoking status or age can be correlated to calculate the probability of survival in each individual and even for each attending institution. **Method:** We built a neural network model that allowed us to estimate the probability of mortality according to the variables: Oncogenic addiction (EGFR mutation and ALK rearrangements), expression of PDL-1, age, gender and exposure to cigarette. These variables were obtained from a cohort of patients with advanced non-small cell lung carcinoma who received treatment in our institution during the last 3 years. **Result:** Thirty-one patients were included in the model. The accuracy of the neural network was 78.57% for the patients that died and 82.35% for the patients still alive. It was possible to calculate the probability of overall survival and the probability of dying in relation to age, exposure to cigarette, gender, oncogenic addiction and PDL-1 expression for each person and for the whole cohort. Individual results and global results (Kaplan Meier) are shown in table and graphic.

Gender	Age (years)	Exposure to cigarette	Mutation/PDL-1	Probability of overall survival	Probability of dying
M	21	No	PDL1: 1% AL 49%	1.2%	98.8%
F	28	No	EGFR mut	19.1%	80.9%

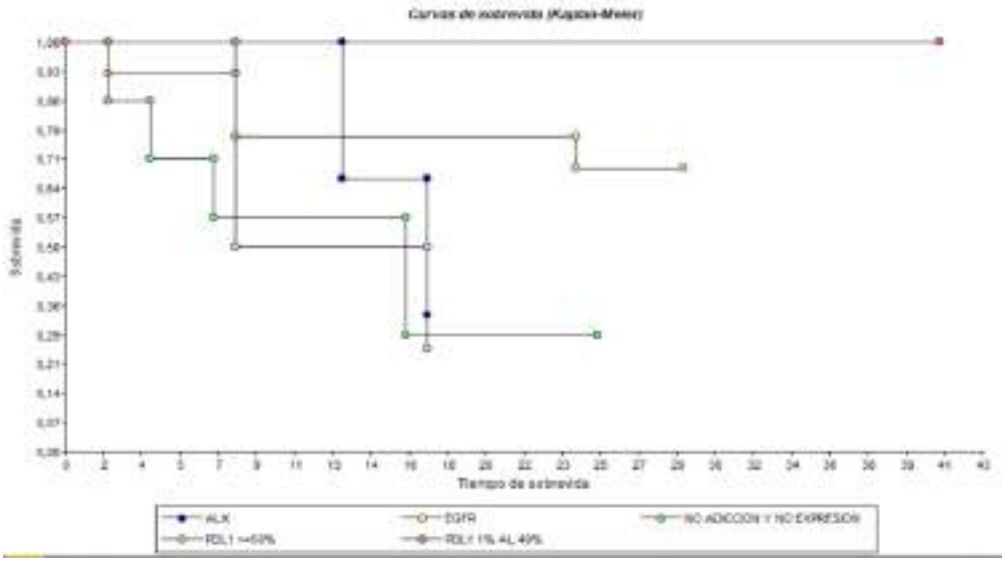
M	85	Si	NO ONCOGENIC ADDICTION – NO PDL1 EXPRESSION	6.2%	93.8%
F	75	No	EGFR mut	1.3%	98.7%
F	62	Si	EGFR mut	17.7%	82.3%
M	53	No	NO ONCOGENIC ADDICTION – NO PDL1 EXPRESSION	5.3%	94.7%
M	56	Si	NO ONCOGENIC ADDICTION – NO PDL1 EXPRESSION	7.8%	92.2%



Conclusion: The minimum data sample required to produce the model was used (n=31), thus it would not be correct to talk about global conclusions. However, this is a representative model of a proof of concept related to predictive analytics related to probability of survival in a real world setting using a neural network that worked on an individual basis according to clinical and biological characteristics. Results for the entire cohort are also available. Using a greater amount of data will increase the accuracy of the neural network to predict survival and other outcomes in an individual and even institutional basis that will improve data analytics in real oncologic settings.

P2.16-23 RATES OF SUPPORT AND CARE OFFERINGS AMONG PATIENTS IN AN ADVOCACY ORGANIZATION SPONSORED LUNG CANCER PATIENT REGISTRY

A. Ciupek[1], R. Acharya[1], A. Moore[2], S. Shaw[2], D. Hicks[2], D. Leduc[2], J. King[1]

[1]*GO2 Foundation for Lung Cancer, Washington/United States of America,* [2]*GO2 Foundation for Lung Cancer, San Carlos/United States of America*

Background: We conducted a survey of lung cancer patients and caregivers in the United States in 2015 and 2016 that identified gaps in access to supportive care and patient education. An additional survey of patients and caregivers in 2016 revealed low rates of molecular testing among lung cancer patients despite being recommended by clinical guidelines. In order to gauge how much progress has been made in addressing these gaps, we looked at self-reported rates among participants in a lung cancer patient registry founded by a patient advocacy organization, the GO2 Foundation for Lung Cancer. **Method:** The Lung Cancer Registry, supported by the GO2 Foundation for Lung Cancer, and partners The American Lung Association and The International Association for Lung Cancer, collects self-reported data from lung cancer patients and caregivers through an online interface on a variety of topics related to patients' lung cancer diagnoses and care experiences. For this study, we analyzed data collected from 939 registry participants between November 2016 to December 2018 on supportive care, assistance, and molecular testing offerings to patients. **Result:** The majority of registry participants reported that their doctors had discussed future treatment options beyond their current line of therapy with them (72%) and that care navigation help had been offered to them by a nurse navigator or care coordinator (60%). Additionally, most participants (88%) reported their clinic had provided educational materials related to their diagnosis or treatment. High rates of molecular testing were also reported among registry participants (76%). Testing most commonly occurred at initial diagnosis. **Conclusion:** Registry participants were offered navigation and patient education resources at high rates. Additionally, molecular testing was offered at high rates occurring early in care. This suggests that significant progress has been made by the lung cancer community in the United States to address previously identified gaps in certain aspects of support and care. However, registry participants represent a highly educated, technology-enabled population, indicating that gaps may still exist and should be looked at further in other demographics such as in rural and lower socio-economic areas where lung cancer is common.

Keywords: Molecular Testing, Lung cancer, patient navigation

P2.16-24 PROGNOSTIC VALUE OF RDW, NLR AND CYFRA 21-1 IN OVERALL SURVIVAL OF PATIENTS WITH METASTATIC NSCLC

C.J. Flores, A. Aguilar, L. Mas, D. Enriquez, J.M. Gutierrez, L. Schwarz, C. Vallejos

Oncosalud - AUNA, Lima/Peru

Background: Lung cancer remains as the main cause of death in many regions around the world. Unfortunately, most cases are diagnosed as advanced disease that determinates dismal outcomes. There is a lack of biomarkers in clinical practice and also high mortality rates not related to cancer. CYFRA 21-1 is an important biomarker related to burden of disease; neutrophils-to-lymphocyte ratio (NLR) and red blood call distribution width (RDW) represent systemic inflammatory biomarkers indirectly related to immune response, and nutritional components, which are critical factors that can increase the risk of death not related to cancer. Our aim was to evaluate the prognosis value of CYFRA 21-1, NLR, RDW and components of nutritional status (albumin, creatinine, and hemoglobin) in overall survival (OS) of metastatic NSCLC patients treated at a private institution (Oncosalud - AUNA). **Method:** We analyzed data of 87 patients with metastatic NSCLC treated at Oncosalud-AUNA 2011 - 2014 (Lima - Peru). The clinical-pathological data were collected from digital medical records. The laboratory data (hemoglobin, albumin, RDW-CV, creatinine, neutrophil, lymphocyte, and monocyte) and CYFRA 21.1 were collected from blood routine tests. Optimal cutoff value of NLR (<3.6 and >3.6), LMR (<4.7 and >4.7), RDW-CV (<15% and >15%) and CYFRA 21.2 (<3.3 and >3.3) were determinate using the maximally selected rank statistics. OS was determinate using Kaplan-Meier method and survival curves comparison were performed using log-rank or Breslow test. Cox model was used to estimate the effect of nutritional components and tumoral biomarkers on overall survival. **Result:** The median age was 68 years (range: 40-84) and 50.6% of cases were women. The 26.4% presented with 2-4 ECOG scale, the most frequent site of metastasis were bone (36%) and brain (22%), and the most common histology was adenocarcinoma (84%). Hemoglobin was low in 16% and 28.7% had abnormal albumin, 44.8% elevated RDW-CV, 24.1% abnormal creatinine, 47.1% elevated NLR, and 72.4% high CYFRA 21-1 value. The 88.5% of patients received chemotherapy and 11.5% had TKI as first-line treatment. The median follow-up was 60 months (95%CI: 44.4-74.6), median survival was 13.2 months (95%CI: 9.8 - 16.7), two and 5-years survival rate were 30.8% and 17.1%, respectively. In univariate analysis, only ³2 ECOG scale (p = 0.062), RDW-CV >15 (p = 0.011), NLR >3.6 (p = 0.019) and CYFRA 21.1 >3.3 ng/mL (p = 0.003) were associated with poor survival. We did not found significant differences with age, sex, Hb, albumin, and LMR. In the Cox model, low values of Hb (HR: 2.1, 95%CI: 1.01-4.5), high values of RDW-CV (HR: 2.6, 95% CI: 1.3 - 5.2), NLR (HR: 1.8, 95% CI: 1.1 – 3.2) and CYFRA21.2 (HR: 2.3, 95% CI: 1.1 - 4.6) were associated with poor OS. **Conclusion:** Overall survival for our patients was similar to reports from other series. Patients with elevated RDW, NLR and CYFRA 21.2 have poor prognostic in our cohort.

Keyword: Metastatic NSCLC, RDW, NLR, CYFRA 21.1, Overall Survival

P2.16-25 EPIDEMIOLOGY OF ADVANCED LUNG CANCER IN PERU

R. Ruiz[1], M. Galvez Nino[1], K. Roque Perez[1], J. Moreno[1], N. Valdivieso[1], M. Olivera[1], J. Rivera[1], E. Amorin[1], L. Raez[2], L. Mas[1]

[1]*Instituto Nacional de Enfermedades Neoplasicas, Lima/Peru,* [2]*Memorial Cancer Institute/Florida International University, Pembroke Pines/United States of America*

Background: Epidemiology and survival data of lung cancer is scarce in Latin America. This information is essential to understand the regional burden that cancer represents and to design and implement targeted interventions for cancer control. Similarly to what happens in the rest of the world, most of our lung cancer patients present with advanced disease. **Method:** Retrospective analysis of metastatic lung cancer cases diagnosed at Instituto Nacional de Enfermedades Neoplasicas (INEN) Lima-Peru between 2010 to 2014 were reviewed. Data was manually curated from clinical files. **Result:** 993 patients were included, corresponding to 85% of total lung cancer cases diagnosed within the same time period. Median age at diagnosis was 63 years old (range 20-91y) and 55% were females. 25% of patients had history of exposure to biomass fumes from cooking inside the house and 20% of patients were smokers. The histologic type was adenocarcinoma, squamous cell carcinoma, adenosquamous carcinoma and large cell carcinoma in 89.2%, 9.8%, 0.8% and 0.2% of the cases, respectively. The adenocarcinoma/squamous cell carcinoma ratio was 9/1. With a median follow-up of 78 months, median overall survival (OS) was 7 months. Median OS for adenocarcinoma, squamous cell carcinoma and adenosquamous carcinoma was 7, 6, and 5 months, respectively. **Conclusion:** The epidemiological profile of lung cancer in Peruvian patients is unique as it is characterized by a younger age at presentation, a preponderance of females over males and a strikingly high frequency of adenocarcinomas. This may be in concordance with the low prevalence of tobacco smoking and the high prevalence of EGFR mutations previously reported for our population as well as with special exogenous exposures. The low survival could be partially attributed to the lack of access to targeted therapy during those years. The molecular characterization of this cohort of patients is ongoing.

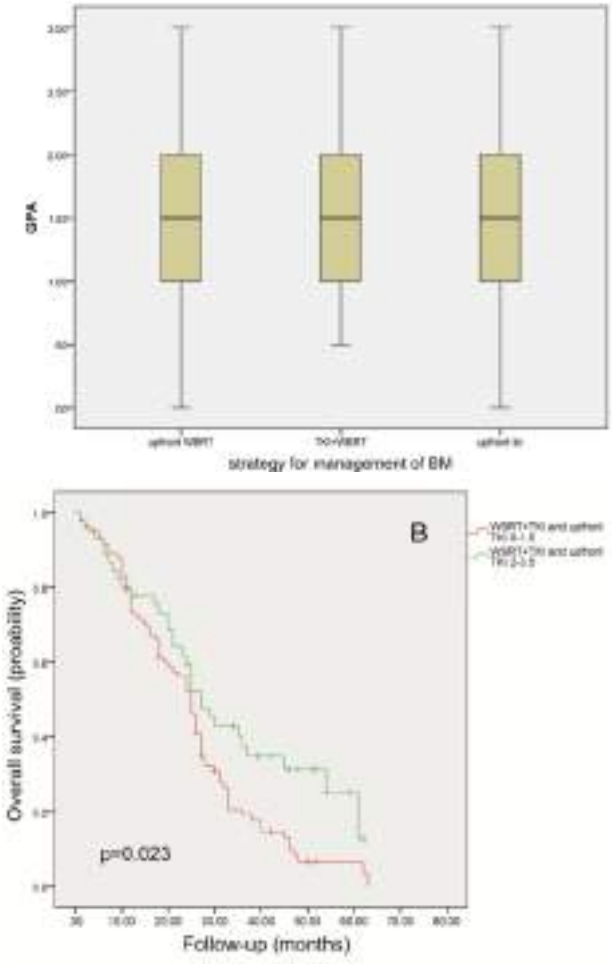
Keywords: Advanced lung cancer, NSCLC, epidemiology

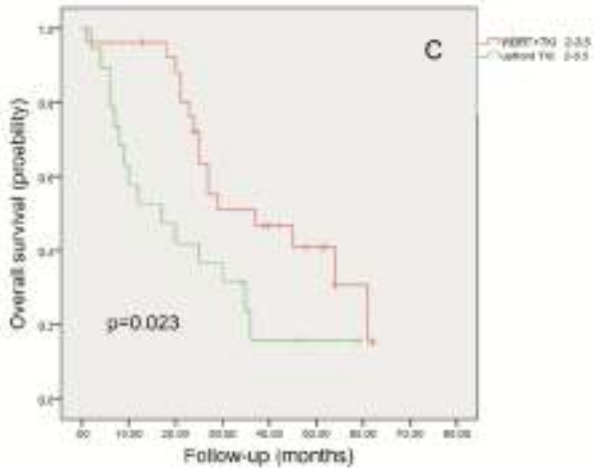
P2.16-26 OPPORTUNITY OF WBRT IN EGFR-MUTATED LUNG ADENOCARCINOMA PATIENTS WITH MULTIPLE BRAIN METASTASES: A RETROSPECTIVE STUDY BASED ON DS-GPA

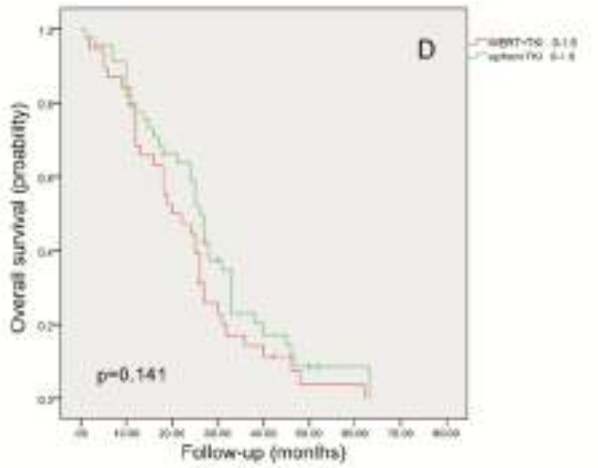
J. Guo, C. Li, X. Zhang

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Whole-brain radiotherapy (WBRT) and epidermal growth factor receptor (EGFR)-tyrosine kinase inhibitors (TKIs) are effective treatment options for multiple brain metastases (BM) in patients with EGFR-mutant adenocarcinoma. This study evaluated the optimal treatment sequence between EGFR-TKI and WBRT in patients with EGFR mutation adenocarcinoma and multiple BM **Method:** A total of 195 patients with EGFR-mutant adenocarcinoma with multiple BM were enrolled in the study. Patients were treated with EGFR-TKI for over 4 weeks after WBRT,received EGFR-TKI concurrently in phase with WBRT or within 4 weeks after WBRTor treated with WBRT during intracranial progression after EGFR-TKI initiation. Overall survival (OS) and disease-specific Graded Prognostic Assessment (DS-GPA) was measured. **Result:** For the entire cohort, the median OS was 27 months (95% CI, 24.6 to 29.4). GPA-based subdivided patients upfront WBRT of GPA, 0 to 1.5 (median: 30 months; n=36; 18%); upfront WBRT of GPA, 2.0 to 3.5 (median:48 months; n=31; 16%); EGFR-TKI concurrently with WBRT of GPA, 0 to 1.5 (median:20 months; n=38; 19%); EGFR-TKI concurrently with WBRT of GPA 2.0 to 3.5 (median:37 months; n=26; 13%); upfront EGFR-TKI of GPA 0 to 1.5 (median:26 months; n=45; 23%); and upfront EGFR-TKI of GPA, 2.0 to 3.5 (median:17 months; n=19; 10%).The prognosis of patients in different GPA groups differed significantly (p<0.0001). The data by these parameters and the results showed no imbalance with respect to the number of patients on GPA scores (T=1.786,p=0.076).In groups at EGFR-TKI concurrently with WBRT and upfront EGFR-TKI, patients with GPA score 2-3.5 demonstrated a significantly longer OS than those at score 0-1.5 (P=0.023), patients with EGFR-TKI concurrently with WBRT is longer than those with upfront EGFR-TKI in subgroup at GPA score 2-3.5(P=0.023).There was no difference in the OS at 0-1.5 score level between the EGFR-TKI concurrently with WBRT group and the upfront EGFR-TKI group (P=0.141).







Conclusion: For EGFR-mutated lung adenocarcinoma patients with multiple BM,the use of upfront WBRT achieved a significantly longer OS in high DS-GPA scores groups.

Keywords: whole brain radiation therapy (WBRT), brain metastases (BM), disease-specific Graded Prognostic Assessment (DS-GPA)

P2.16-27 LONGITUDINAL SKELETAL MUSCLE CHANGES IN PATIENTS WITH ADVANCED SQUAMOUS CELL LUNG CANCER

Y.S. Kim, E.Y. Kim, H.K. Ahn, S.M. Kang, K.W. Kim

Gachon University Gil Medical Center, Incheon/Korea, Republic of

Background: Cancer cachexia is a multifactorial syndrome characterized by an ongoing loss of skeletal muscle mass. Skeletal muscle depletion is prevalent in lung cancer patients and is associated with poor prognosis. This study analyzed the changes in skeletal muscle mass until the end of life in patients with advanced squamous cell lung cancer (SQCLC). **Method:** This retrospective study consisted of 70 consecutive patients who underwent palliative chemotherapy for SQCLC and died between September 2010 and March 2015. A cross-sectional area of muscle at the level of the first lumbar vertebra (L1) was measured using computed tomography scans. An artificial intelligence algorithm was developed and used for serial assessment of muscle area. Sarcopenia was defined as a L1 skeletal muscle index of ≤ 46 cm2/m2 for men and ≤ 29 cm2/m2 for women. Median interval between last scans and deaths was 1.3 months (95% CI, 0.9 to 1.7). **Result:** The median age was 69 years and 82% of patients were male. Sarcopenia was present in 58 patients (76%) at baseline. Median overall survival was 8.7 months (95% CI, 5.9 to 11.5). All patients experienced net muscle loss over the disease trajectory. Mean percentage loss of skeletal muscle between the first and last scans were 16.5±11.0%; mean decrease of muscle area was 17.28±13.00 cm2 (p < 0.001) at a rate of 2.64±2.36 cm2/month. Skeletal muscle loss was accelerated over time. Patients lost an average of 1.64±1.02 cm2, 2.00±1.52 cm2, 2.91±2.69 cm2, and 4.82±4.59 cm2 skeletal muscle per month during the last 12, 9, 6, and 3 months, respectively (p < 0.001). Patients losing skeletal muscle at ≥ 3.24 cm2/month (upper tertile) had shorter overall survival

compared with patients who lost muscle at slower rate (median, 5.7 vs. 12.0 months; p < 0.001). **Conclusion:** Patients with advanced SQCLC lose significant amount of skeletal muscle until death. The rate of muscle mass reduction is faster at the end of life. Patients who lose muscle at the higher rate have shorter survival time.

Keywords: cancer cachexia, muscle, Lung cancer

P2.16-28 RETROSPECTIVE ANALYSIS OF PATIENTS WITH PREVIOUS EXTRATHORACIC MALIGNANCIES AFTER RESECTION OF NON-SMALL CELL LUNG CANCER

A. Wada, K. Nakao, Y. Furuhata

Japanese Red Cross Medical Center, Tokyo/Japan

Background: The number of patients with previous malignancies has increased because survival time is prolonged in various malignancies. Therefore, opportunities to consider surgical indications for non-small cell lung cancer (NSCLC) patients with previous malignancies are increasing. The aim of the study is to compare the backgrounds and prognosis of NSCLC patients who had the history of previous extrathoracic malignancies with no other cancer history. **Method:** Our institutional database of patients after curative resection of NSCLC from 2006 to 2013 was reviewed. Patients with synchronous or metachronous multiple lung cancer were excluded. Clinicopathological features of these patients and information about survival and recurrence were collected from the electronic medical record. Overall survival (OS) and recurrence-free probability (RFP) were estimated using the Kaplan-Meier method. **Result:** In a total of 249 patients, 49 (19.7%) had previous extrathoracic malignancies. The number of previous extrathoracic malignancies was 1 in 44 patients, 2 in 3 patients and 3 in 1 patient. Sixteen patients had colorectal cancers among previous extrathoracic malignancies, 10 patients had gastric cancers and 5 had hematopoietic neoplasms. If patients with previous extrathoracic malignancies were compared to those without, the median age was 69.5 vs. 65.5 (p=0.015), male sex was 71.4% vs. 66.5% (p=0.506), average of Brinkman index was 914.2 vs. 709.7 (p=0.127) and average of serum level of carcinoembryonic antigen was 5.4 ng/mL vs. 7.5 ng/mL (p=0.506). Pathologically, stage 0 and I NSCLC account for 73.5% of patients with previous extrathoracic malignancies and 66.0% of those without it (p=0.311). The 5-year OS was 70.3% vs. 79.1% (p=0.422) and the 5-year RFP was 58.9% vs. 67.7% (p=0.223). **Conclusion:** Patients with previous extrathoracic malignancies are significantly older than those without previous extrathoracic malignancies. Patients with previous extrathoracic malignancies had relatively earlier stage NSCLC. The OS and RFP also tended to be worse in patients with previous extrathoracic malignancies. Further study is needed to consider surgical indication for NSCLC with previous extrathoracic malignancies.

Keywords: Non small cell lung cancer, prognosis, extrathoracic malignancies

P2.16-29 LUNG CANCER IN LLEIDA: AN EPIDEMIOLOGIC STUDY

J. Veas[1], C. Adaniel[2], S. Morales[1], A. Rodriguez[1], A. Gasol[1], A. Salud[1], J.F. Cordoba Ortega[1]

[1]*Hospital Universitario Arnau De Vilanova, Lleida/Spain,* [2]*Clinica Alemana, santiago de chile/Chile*

Background: According to GLOBOCAN, in 2018 lung cancer was associated with the greatest incidence and mortality attributable to cancer worldwide: 27.9 cases/100,000 habitants and 23.5 cases/100,000 habitants, respectively. In Spain, lung cancer is the fourth most frequent cancer but the first cause of cancer mortality in the country. We have undertaken this study to compare the epidemiologic data for lung cancer in our Spanish provincial population with those worldwide and nationwide **Method:** This was an observational, retrospective study. It included all patients with lung cancer in the Lleida province of Catalonia, Spain in a period of 6 years, from January 2011 to December 2016. Data taken from electronic medical records included variables such as sex, age of diagnosis, smoking history, histology, stage, and oncologic treatments, among others. Incidence, prevalence, survival and mortality rates were determined, as well as the main clinical characteristics of the cohort **Result:** Seven hundred eighty-two patients with a diagnosis of lung cancer between January 2011 and December 2016 were included. Median follow-up was 11.7 months. Men comprised 78.6% of the cohort. The median age at diagnosis was 66.6 years. More than half of the patients (53.2%) smoked at the time of diagnosis. The majority were adenocarcinomas (44.1%), with 33.2% squamous cell carcinomas, and 12.1% small cell carcinomas. EGFR testing was performed in 300 patients. 18.7% were positive for a mutation, of which 69.7% were exon 19 insertions. At diagnosis, 52.3% of cases were stage IV, 25.3% stage III, 7.3% stage II, and 14.5% stage I. The average annual incidence rate was 37 cases/100,000 habitants. The median overall survival (OS) was 12.3 months (95% CI: 10.7-13.8). The OS at 1 year was 50.8% (95% CI: 47.3-54.3) and at 5 years was 13.7% (95% CI: 10.2-17.2). The estimated mortality rates were 49.2% in the first year and 86.3% at 5 years **Conclusion:** In the Lleida province of Spain, the incidence and mortality associated with lung cancer are greater than global rates but lower than those of Spain as a whole. Lung cancer survival at 5 years is greater than countrywide statistics. The heathier lifestyle and rural geography may favor the lower incidence of lung cancer in Lleida compared with the rest of Spain

Keywords: Lung cancer, epidemiology, spain

P2.16-30 REAL WORLD DATA OF TARGETED THERAPY VERSUS CHEMOTHERAPY MAINTENANCE AMONG PATIENTS WITH III-IV CLINICAL STAGE LUNG CANCER AT ONCOSALUD – AUNA

A. Aguilar, C.J. Flores, D. Enriquez, L. Mas, C. Vallejos

Oncosalud - AUNA, Lima/Peru

Background: Lung cancer is still a prevalent and fatal neoplasm in developing countries where newer therapies usually had issues about economic toxicity and real clinical benefit in terms of overall survival. In the last decades, chemotherapy maintenance has occupy an important role in the treatment, as well as targeted therapies (tirosin kinase inhibitors and bevacizumab) in the frontline treatment. Our aim was to evaluate the survival impact of targeted therapy in advanced lung cancer at a private Peruvian institution (Oncosalud – AUNA). **Method:** We analyzed retrospectively data of two cohort of patients with advanced NSCLC (III-IV clinical stage) treated at Oncosalud-AUNA during the period 2008 - 2013 (Lima, Peru). The clinical-pathological data were collected from digital medical records. After a clinical response obtained with a standard regimen based on chemotherapy (≥ stable disease), all patients were distributed in two groups. Group 1 received only maintenance chemotherapy and group 2 had maintenance with targeted therapy, either erlotinib or bevacizumab. OS was determinate using Kaplan-Meier method and survival curves comparison were performed using log-rank or Breslow test. Cox model was used for multivariate analysis. **Result:** During the study period 58 cases were included, 30 and 28 cases were distributed in group 1 and 2, respectively. The median age was 65 years (range: 44-85) and male:female ratio was 1:1, less than 16% had ≥2 ECOG scale, and about two thirds were diagnosed as CS IV. No statistically difference was found between both two groups. More than 60% of patients received at least six cycles platins based chemotherapy, only five cases reached complete response (8%), partial response was 47% and stable disease 45%. In the group 2, 46% received combined treatment based on bevacizumab and 54% erlotinib as maintenance therapy. Progression rates were 87 and 86% in groups 1 and 2, respectively. The median follow-up was 3 years, median PFS were 10 months for group 1 and 17 months for group 2, and 2-years PFS rates were 17 versus 30%, respectively (p=0.008). Median OS were longer in the group with targeted therapy (3.7 versus 1.4 years, p=0.014). In multivariate analysis the use of targeted therapy (PFS: HR:0.47, 95% CI[0.26,0.85], p=0.013 and OS: HR:0.36, 95% CI[0.18, 0.74], p=0.005) and age <60 years (PFS: HR:0.41, 95% CI[0.19,0.9], p=0.027 and OS: HR:0.30, 95% CI[0.12, 0.73], p=0.008) were associated to better outcomes. **Conclusion:** An important clinical benefit in terms of survival was obtained with the addition of targeted therapy to the standard of care in the treatment of lung cancer in our cohort.

Keyword: Advanced lung cancer, targeted therapy, Overall Survival

P2.16-31 IMMUNOTHERAPY IN THE REGIONAL SETTING: REAL WORLD EXPERIENCE OF OUTCOME AND TOXICITY

M. Nguyen[1], A. Kuddithamby[2], A. Sahu[2]

[1]*Austin Health, Heidelberg/Australia,* [2]*Goulburn Valley Health, Shepparton/Australia*

Background: Immune checkpoint inhibitors (ICI) have revolutionised the management of lung cancer. These agents have an established role in metastatic non small cell lung cancer (NSCLC) and inoperable NSCLC. Recent studies demonstrate benefit of ICI in first line treatment of metastatic NSCLC. Ongoing studies are exploring the role of ICI in early stage lung cancer and small cell lung cancer. ICI possess a distinct adverse effect profile which differs from cytotoxic chemotherapy. We explore the implications of ICI for patients with NSCLC in a regional setting. **Method:** The medical records of all patients with NSCLC who were treated with an immune checkpoint inhibitor at our cancer centre were examined. Information regarding patient demographics, tumour histology, PDL1 staining, performance status, smoking status and sites of metastasis were obtained. We calculated rates of clinical outcomes including progression free survival and objective response rates. We also examined rates of adverse effects and need for emergency department presentation, hospitalisation and treatment with steroids. **Result:** Forty-five patients with lung cancer who were treated with ICI between 2016 and 2018 were identified. 70% were male. The average age was 70 years. 30 (67%) received nivolumab, 8 (18%) received atezolizumab, 4 (9%) received durvalumab and 3 (6%) received pembrolizumab. 31 (69%) had adenocarcinoma histology. Only 4 patients (9%) had PDL1 stain testing performed; 3 were PDL1 high (greater than 50%) and 1 was PDL1 negative. 13% of patients had brain metastases and 16% had liver metastases. Of the 41 patients with metastatic disease, 10 patients obtained a partial response. The objective response rate was 22%. Median progression free survival was 5.8 months. Median overall survival was 11.6 months. 37 patients (82%) had an adverse effect of any grade and 7 (16%) had a grade 3 or greater adverse effect. The most common adverse effect was fatigue (62% any grade, 6% grade 3 or greater). 36% of patients required steroid treatment. 12 patients (27%) died within 30 days of receiving ICI. **Conclusion:** Treatment of cancer patients in regional settings carry unique challenges which need to be overcome in order to ensure equitable health outcomes. We report the experience of an individual regional cancer centre. Results are comparable to other published reports and demonstrate safe treatment of lung cancer patients in a regional setting.

P2.16-32 BEST SUPPORTIVE CARE FOR EXTREME ELDERLY LUNG CANCER PATIENTS

T. Kazuyori[1], Y. Seki[1], A. Sato[1], S. Fujimoto[1], M. Yamada[1], Y. Yamanaka[1], I. Fujisaki[1], K. Odashima[1], A. Seki[1], T. Ishikawa[1], K. Kuwano[2]

[1]*The Jikei Daisan Hospital, Tokyo, Japan, Komae, Tokyo/Japan,* [2]*The Jikei University Hospital, Tokyo/Japan*

Background: In Japan, the population of extreme elderly individuals (85 years and older) was about 5.8 million in 2018, and the number of extreme elderly lung cancer patients is increasing. Because of their environmental conditions, they often received the best supportive care (BSC) without chemotherapy or definitive therapy. **Method:** We conducted an IRB-approved retrospective analysis of 34 lung cancer patients aged 85 years and older, who were treated at our institute from 2014 to 2017, and assessed their backgrounds and prognosis. **Result:**

Table: Cox proportional hazard analysis of overall survival.

Variable	Hazard.ratio (95% C.I)	p.value
PS = 0-2	0.11 (0.04-0.34)	<0.01
Without cognitive-function disorder	0.35 (0.14-0.89)	0.027
Without metastasis	0.22 (0.07-0.68)	<0.01
Good nutrition (serum albumin ≧ 3.5 g/dL)	0.09 (0.02-0.41)	<0.01
Low plasma CRP(CRP ≦ 10mg/L)	0.27 (0.08-0.92)	0.036

The median age was 89 years (range, 85-96 years), and 22 patients were male. Among the patients considered, 11 had adenocarcinoma (3 harboring EGFR mutation), 8 had squamous cell carcinoma, 5 had NSCLC-NOS, 3 had SCLC, and 7 had an unknown cancer type. Fifteen patients were assigned an ECOG good PS of 0-2, and 19 patients a poor PS of 3-4. The main reasons for receiving BSC alone were poor PS (44%), own will (38%) and cognitive-function disorder (18%). In 10 patients, cancer did not metastasize and 15 patients were transferred to the nursing facility. The median overall survival was 5.6 months. According to univariate analysis (Cox proportional analysis), absence of metastatic disease [hazard ratio: 0.22, 95% confidence interval [C.I.]: 0.07-0.68], PS 0-2 [hazard ratio: 0.11, 95% C.I.: 0.04-0.34], good cognitive function [hazard ratio: 0.35, 95% C.I.: 0.14-0.89], good nutrition (serum albumin ≥ 3.5 g/dL) [hazard ratio: 0.09, 95% C.I.: 0.02-0.41] and plasma C reactive protein(CRP) ≤ 10 mg/L [hazard ratio: 0.27, 95% C.I.: 0.08-0.92] were associated with significantly longer overall survival. Median overall survival of patients with and without metastasis were 1.8 months and 19.7 months, respectively. Patients without metastasis tended to have good PS and had lesser hypoalbuminemia. Most of the patients without metastasis received BSC alone, of their own will. **Conclusion:** In extreme elderly lung cancer patients, BSC alone had often been selected for reasons other than the disease condition. It is important to construct a palliative treatment strategy based on medical and social characteristics of extreme elderly individuals.

P2.16-33 WHAT INFLUENCES PATIENT DECISION-MAKING ABOUT LUNG-CANCER TREATMENT? A DISCRETE CHOICE EXPERIMENT

F. Hegi-Johnson[1], M. Haas[2], D. Ball[1], G. Wright[1], R. De Abreu Lourenco[2]

[1]*Peter MacCallum Cancer Centre, Melbourne/Australia,* [2]*CHERE, UTS, Haymarket/Australia*

Background: Despite major advances in radiotherapy, surgery remains the treatment of choice for patients with stage I non-small cell lung cancer. We sought to investigate what influenced preferences for surgery or SABR among cancer patients. **Method:** Using a discrete choice experiment (DCE) survey, we asked cancer patients to choose between lung cancer treatment options described by: type of treatment, chance of being cancer free for 12 months, chance of experiencing life threatening complications, chance of ongoing complications, impact on usual activities, who recommended treatment, whether treatment is usual care and out-of-pocket (OOP) costs. Each respondent completed nine choice questions. Choices were analysed using latent class analysis. **Result:** A total of 204 responses were received (57% female). Of these, 20 reported a diagnosis of lung cancer; the rest had been diagnosed with other cancers, including 53 with melanoma. Overall, the chance of being without cancer was considered the most important attribute and costs the least. The latent class analysis identified three groups: Group 1 (21%) was focussed on costs and the doctor's recommendation; Group 2 (60%) focused on the intervention (with a preference for surgery over radiotherapy), efficacy, side effects, functioning, doctor's recommendation and the highest level of OOP costs; Group 3 members (19%) were focused on the doctor's recommendation only. Women are more likely to be in Group 1 relative to 3, and those with higher educational attainment are more likely to be in Group 2 than 3. A more substantive analysis showed further differences between groups in terms of their tumour status, gender, educational attainment and health-care card status. **Conclusion:** The results of this study show that a doctor's recommendation is a vital factor in patients' decision-making. The importance of this finding is emphasised by the fact that Group 2, representing 60% of respondents, preferred surgery over radiotherapy. Advocates of radiotherapy as a curative intervention for lung cancer need to educate doctors as well as patients about its potential side-effects, benefits and costs.

P2.16-34 IS PROPHYLACTIC CRANIAL IRRADIATION USEFUL IN REAL WORLD?

R. Gómez Bravo[1], B. Núñez-García[2], J. Sánchez González[2], C. Alfaro Autor[1], B. De La Puente Orteu[1], A. Royuela[1], M. Méndez García[1], B. Cantos Sánchez De Ibarguen[1], V. Calvo De Juan[1], M. Provencio[1]

[1]*Puerta de Hierro, Majadahonda, Majadahonda/Spain,* [2]*Puerta de Hierro, Majadahonda/Spain*

Background: Small cell lung cancer (SCLC) is the most aggressive lung cancer subtype. Just one third of patients are diagnosed as limited stage (LS), in which the goal is to perform a radical treatment. However, the majority will develop metastasis, being in central nervous system (CNS) one of the most frequent. In patients with LS, after systemic treatment, prophylactic cranial irradiation (PCI) should be considered. Nevertheless, the effectiveness of PCI has been a controversial issue in terms of overall survival (OS). **Method:** A cohort of 81 patients diagnosed of localized SCLC were retrospectively analyzed in our center over a 10-year period (January 2008-December 2017). Brain imagen was done before chemo-radiotherapy (CRT) and repeated before PCI. Baseline demographics characteristics and brain metastases rate incidence were described. **Result:** From 81 patients, 48 received PCI and 33 did not. Complete baseline characteristics from both groups are shown in *table 1.* No differences were found in performance status at diagnosis between groups . From those who did not receive PCI, 8 (26%) had developed brain metastases after CRT and before PCI. Brain metastases incidence rate in PCI subgroup was 9/100 people per year vs 35/100 people per year in those who did not receive PCI, in whom 54.5% had brain or systemic progression before PCI planning. Progression free survival in both subgroups was 13.5 months and OS was 21.2 months.

	PCI realized	No PCI realized
NUMBER OF PATIENTS	48	33
SEX	29 male; 19 female	22 male; 11 female
AGE AT DIAGNOSED	62 year (IQR 58-68)	67 (IQR 57-77)
STAGE TNM 8TH	≤ IIIA: 25 IIB ó IIC: 23	≤ IIA: 17 IIB ó IIC: 16
CNS METASTASES DEVELOPMENT YES/NO	14 vs 34	15 vs 18
PERCENTAGE OF CNS PROGRESSION	29% (14/48) p 0,13	45% (15/33) p 0,13
CNS METASTASES BEFORE PCI	0	8
METASTASES DEVELOPMENT INCIDENCE RATE	9/100 people-year	35/100 people-year

Conclusion: In our series, PCI had a significant effect in decreasing brain metastases. This study also confirms the requirement of brain imaging to confirm lack of brain metastases after initial CRT and before PCI.

Keywords: PCI, SCLC, Brain metastases

P2.16-35 FACTORS ASSOCIATED WITH PROLONGED POSTOPERATIVE HOSPITAL STAY IN PATIENTS UNDERGOING LUNG CANCER SURGERY

W. Dai[1], X. Wei[1], S. Xie[1], J. He[1], Q. Shi[2], Q. Li[1]

[1]*Sichuan Cancer Hospital & Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu/China,* [2]*The University of Texas MD Anderson Cancer Center, Houston/United States of America*

Background: It is important to focus on the risk factors associated with prolonged postoperative hospital stay (PHS) as they can significantly increase medical costs. The study aimed to identify independent risk factors of prolonged PHS in patients who underwent lung cancer surgery. **Method:** Data were collected from an ongoing, real-world, multicenter, prospective, observational study (NCT03341377). Inclusion criteria were age 18 years and older, no cognitive impairment and ability to understand the study requirements, pathological primary lung cancer diagnosis, and scheduled surgical procedure. Prolonged PHS was defined as hospitalization for more than 7 days after a lung cancer surgery. Logistic regression was used to identify risk factors of prolonged PHS. **Result:** A total of 192 patients (117 males and 75 females) who underwent lung cancer surgery were included. The median PHS was 7 days (range, 2–46 days). Among 192 patients, 64 (33.3%) had prolonged PHS. Among those with PHS, 73.4% were males and patients with a smoking history accounted for 60.9%, Charlson Comorbidity Index scores of >1 for 57.8%, tumor located in the upper lobe for 64.1%, open surgery for 57.8%, lobectomy for 64.1%, systematic lymphadenectomy for 57.8%, and tumor stage ≥II accounted for 59.4%. The overall in-hospital complication rate was 25%. The most common complication was prolonged air leak. The multivariate analysis revealed that the surgical approach (open vs. video-assisted thoracoscopic surgery) (OR 2.65, 95% CI 1.05-6.67; P=0.039) and in-hospital complications (no vs. yes) (OR 0.15, 95% CI 0.06-0.35; P<0.001) were independent risk factors of prolonged PHS.

Table 1 Correlation between patient characteristics and prolonged PHS

Variables	Total (n = 192)	Prolonged PHS (n = 64)	Normal PHS (n = 128)	P value
Gender				0.012[a]

[a], by $\chi 2$ test; ASA, American Society of Anesthesiologists; BMI, body mass index; CCI, Charlson Comorbidity Index; PHS, postoperative hospital stay; TNM, tumor node metastasis; VATS, video-assisted thoracoscopic surgery.

Conclusion: Prolonged PHS is still very common in the real world. Open surgery and in-hospital complications were the two main reasons of prolonged PHS in patients who underwent lung cancer surgery. Further studies with a larger sample size are warranted to confirm our results.

Keywords: Risk Factors, lung cancer surgery, Postoperative hospital stay

P2.16-36 PATTERNS OF CARE IN A PROSPECTIVE CLINICAL COHORT OF PATIENTS WITH LUNG CANCER - PRELIMINARY ANALYSES FROM THE ENRICH PROGRAM

B. Brown[1], J. Simes[2], M. Boyer[3], A. Joshua[4], P. Hogg[1], J. Young[5]

[1]*Sydney Catalyst Translational Cancer Research Centre, University of Sydney, Camperdown/Australia,* [2]*Nhmrc Clinical Trials Centre, University of Sydney, Camperdown/Australia,* [3]*Chris O'Brien Lifehouse, Camperdown/Australia,* [4]*The Kinghorn Cancer Centre, Darlinghurst/Australia,* [5]*University of Sydney, Camperdown/Australia*

Background: Lung cancer accounts for 9% of all cancer diagnoses, is the most common cause of cancer related death, and is the leading cause of morbidity and burden of disease in NSW and across Australia. The outlook for patients with lung cancer remains poor with only a 15% overall five year survival rate. For patients diagnosed with advanced stage disease, five year survival is less than 5%. There is an urgent need to identify and reduce unwarranted clinical variation that may contribute to morbidity and burden of disease, and to improve quality of care, and thereby ensure best possible outcomes, for the lung cancer population. Sydney Catalyst is addressing this need through the Embedding Research (and Evidence) in Cancer Healthcare 'EnRICH' program, a program of translational research in lung cancer which aims to: describe the natural history of and patterns of care for lung cancer; identify current gaps in evidence and practice for clinical quality improvement; and create a platform for researchers across the T1-T3 translational research spectrum to develop and initiate clinical research and intervention studies to address gaps. The EnRICH dataset currently includes comprehensive patient, diagnostic, treatment and outcome data (including patient reported outcomes) for more than 600 consecutive patients with lung cancer (non-small cell and small cell, any histological type, any clinical/pathological stage) treated in metropolitan and regional hospitals across three Local Health Districts in NSW, Australia. By mid-2020, the EnRICH dataset will include data for more than 1000 patients. **Method:** This preliminary analysis will provide descriptive data on the first 500 consecutive patients in the EnRICH cohort and, specifically, will describe patterns of care stratified by patient and disease characteristics. Patterns of care will be mapped to evidence-based quality indicators to identify clinical variation. **Result:** Data collection is complete for 420 patients. Remaining data collection and analyses will be complete for 500 consecutive patients by 19 July 2019. Data presented will include: Descriptive data Patient characteristics: age; sex; CALD status; comorbidities, symptoms, performance status Risk factors: smoking history; family history of lung cancer; occupational exposure; clinical history of lung disease; previous malignancy Disease characteristics: histological type and sub-stype; pathological stage; clinical stage; genetic mutations Quality indicators Diagnosis - proportion with: clinical stage; pathological stage; appropriate analysis of predictive markers; time from diagnosis to treatment Treatment - proportion: with performance status assessment; reviewed by MDT; undergoing resection, chemotherapy, targeted-therapy, immunotherapy, radiotherapy; receiving no active anti-cancer treatment Referral - proportion: of current smokers with documented smoking cessation counselling; of stage IV patients referred to palliative care; referred to supportive care services; referred to/enrolled in clinical trials OutcomesClinical outcomes: major complications (Clavien-Dindo/CTCAE grade ≥3); hospitalisations; survival Patient reported outcomes: Global health status/QoL; social functioning; physical functioning; role functioning; emotional functioning; cognitive functioning; social functioning; symptoms; distress **Conclusion:** Data from EnRICH for the first 500 consecutive patients treated for lung cancer across a wide geographical area in NSW, Australia will map routine patterns of care, and identify unwarranted clinical variation to be addressed by quality improvement interventions to achieve best possible patient outcomes.

Keywords: Quality Improvement, Patterns of care, Clinical variation

P2.16-37 IMPACT OF BRAIN METASTASES ON HEALTHCARE UTILISATION AND COSTS IN PATIENTS WITH NSCLC TREATED WITH EGFR-TKIS

D. Subramaniam[1], M. Pavilack[2], H. Huo[2], R. Shenolikar[2], A. Kong[3], M. Moynihan[3], E. Marchlewicz[3], C. Larson[3]

[1]*Georgetown University, Washington, D.C./United States of America,* [2]*AstraZeneca, Gaithersburg/United States of America,* [3]*IBM Watson, Ann Arbor/United States of America*

Background: NSCLC with brain metastases is difficult to treat and associated with poor survival. The impact of brain metastases compared with other metastases on healthcare utilisation and costs among patients treated with EGFR-TKIs is not well known. **Method:** Newly-diagnosed adult patients with metastatic NSCLC initiating approved first-/second-generation EGFR-TKI treatment (within 90 days of diagnosis) were identified retrospectively from IBM Watson Health MarketScan® healthcare claims databases from 2013–2017. Patients were divided into mutually-exclusive cohorts based on evidence of brain or non-brain metastasis (BM or NBM). Demographics, clinical characteristics and healthcare expenses were captured at baseline. Healthcare utilisation and cost were analysed during the variable-length follow-up period. Costs were standardised to 2017 US$ and reported as per-patient-per-month (PPPM). Generalised linear models were used to assess the impact of brain metastases, adjusting for baseline demographics, comorbidities, healthcare expenses and length of follow-up. **Result:** Overall, 222 BM and 280 NBM patients were included. BM patients were, on average, younger than NBM patients (59.9 vs 65.7; p<0.05); both cohorts included mostly female patients and had an average of 14 months follow-up. Among all patients, first EGFR-TKI treatment was 82.3% erlotinib, 16.3% afatinib and 1.4% gefitinib; 10 patients treated with osimertinib were excluded. Seizures (9.0% vs 1.1%), headaches (17.6% vs 10.0%) and altered mental status (11.3% vs 5.7%) were more common in the BM vs NBM cohort (p<0.05). NSCLC-related healthcare utilisation was >2-fold higher in BM patients receiving radiation treatment in the inpatient (15.3% vs 6.8%; p<0.05) and outpatient (87.8% vs 37.5%; p<0.05) settings. PPPM radiation costs were also higher among BM patients in the inpatient ($796 vs $464, p=0.172) and outpatient ($2477 vs $762, p<0.05) settings. All-cause inpatient admissions were more common among the BM vs NBM cohort (67.1% vs 57.1%; p<0.05). While all patients had evidence of outpatient services, the PPPM number of outpatient visits was greater among the BM vs NBM cohort (p<0.05) for both NSCLC-related (5.1 vs 4.2) and all-cause (6.4 vs 5.7) healthcare utilisation. Adjusted NSCLC-related and all-cause PPPM costs were 1.2 times higher among BM patients (+$5674 and +$6393, respectively; p<0.05); age was also a significant predictor in both models (p<0.05). **Conclusion:** Healthcare utilisation, hospital admission rates and costs, especially those attributable to radiation treatment, were higher among patients with BM compared with NBM. Future research should assess if central nervous system (CNS)-active EGFR-TKIs have the potential to reduce healthcare utilisation and costs associated with brain metastases.

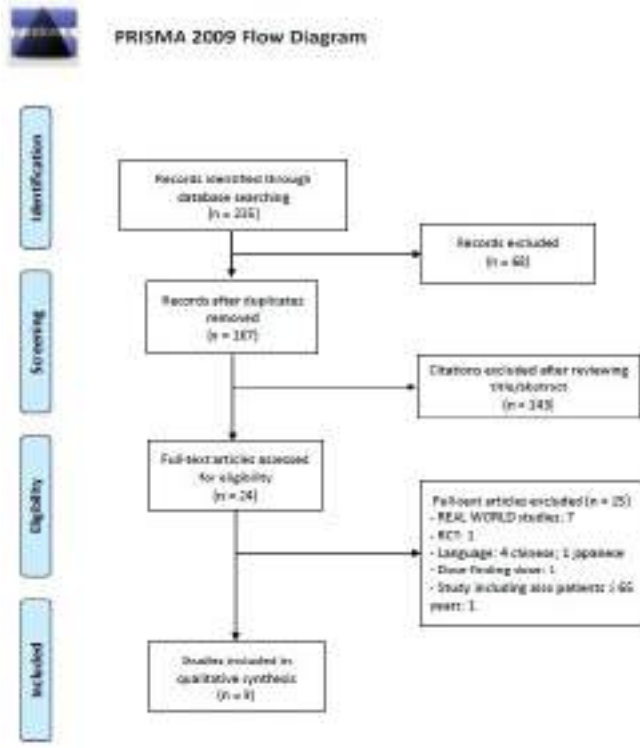
P2.16-38 EFFICACY AND SAFETY OF TARGET THERAPY AND IMMUNOTHERAPY IN ADVANCED NSCLC IN ELDERLY: A SYSTEMATIC REVIEW OF REAL WORLD STUDIES

T. Franchina[1], A. Russo[2], G. Ricciardi[2], V. Franchina[3], V. Adamo[2]

[1]*Department of Human Pathology, University of Messina, Messina/Italy,* [2]*Medical Oncology Unit AO Papardo & Department of Human Pathology, University of Messina, Messina/Italy,* [3]*Medical Oncology Unit AO Papardo, Messina/Italy*

Background: Despite notable advances, treatment of advanced non small cell lung cancer (NSCLC) in the elderly remains a challenge.Target therapy and immunotherapy outcomes have been demonstrated in several randomized controlled trials (RCT), however real world setting may closely mirrors everyday clinical practice in elderly population, characterized by poor performance status, significant comorbidities, concomitant treatments, limited adherence and compliance. Systematic review was conducted to examine the published real-world studies evaluating efficacy and safety of target therapy and immunotherapy in elderly patients with advanced NSCLC. These real-world data were compared to those obtained in

the phase II and III randomized controlled trials. **Method:** Following PRISMA guidelines, in February 2019 we searched the MEDLINE, Web of Science, and Scopus databases in English language.Titles and abstracts were reviewed by 2 independent reviewers (FT; FV); disagreements were resolved by a third. All identified full papers were assessed independently by three researchers (FT, FV, and AV). Included studies were required to be RWS, and evaluate target therapy or immunotherapy in advanced NSCLC elderly patients. The Newcastle Ottawa Scale (NOS) was used for quality assessment of studies included in the systematic review. **Result:** We found 235 studies through the database, 167 remained after duplicate removal and 24 full-text articles were assessed for eligibility (Figure 1). The systematic search of the literature identified 9 studies meeting the selection criteria to analyse in qualitative synthesis.These studies included a total of 1882 elderly patients mainly treated with first-generation EGFR tyrosine-kinase inhibitors (5 studies), osimertinib only in one study. Bevacizumab in association with chemotherapy was evaluated in two studied. Immunotherapy data was available only in one study. Clinical characteristics of each study population are analyzed. The first relevant aspect is the lack of data on Multidimensional Geriatric Assessment and Charlson Comorbidity Index, that should represent main instruments in clinical practice to personalize therapeutic approach. Heterogeneity of first-generation EGFR TKI efficacy among the studies could be influenced by genetic differences among ethnic groups. In general, the results showed that PFS of patients with advanced NSCLC treated with first-generation EGFR TKI in the real world setting were consistent with those observed in clinical trials, while an inferior survival was recorded. Collected toxicity data were limited.



Conclusion: RWS represent a broad picture of the activity and tolerability of new drugs and can provide interesting observations and research ideas in several settings, particularly in elderly patients, integrating and defining data of the RCTs.

Keyword: elderly patients, real-world studies, non small cell lung cancer

P2.16-39 THE ASSOCIATION BETWEEN DIETARY PROTEIN INTAKE AND THE RISK OF LUNG CANCER: A META-ANALYSIS

X. Li[1], L. Wu[1], H. Chen[1], Y. Zhu[1], K. Du[1], W. Wang[2], C. Xu[3]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China*

Background: Dietary protein intake had been explored whether had some effective on lung cancer risk, however, the results were not consistent. This meta-analysis aimed to find exact relationship between them. **Method:** Databases of PubMed, Embase, and Web of Science were retrieved up to January 1, 2019. Summarized odds ratio (OR) with corresponding 95% confidence intervals (CI) were calculated. Publication bias and sensitivity analysis were assessed. **Result:** Seven articles with 8 independently studies (4 population-based case-control studies (PBCC) and 4 hospital-based case-control studies (HBCC)) involving 2990 cases and 7142 participants were used in this paper. The overall analysis suggested that dietary protein intake had no significant association on lung cancer risk (Summarized OR= 0.951, 95%CI= 0.798-1.134, *I2*= 53.0%, *P* for heterogeneity= 0.037). However, when we explored the association between lung cancer risk and geographic location, we found an inverse association among Asian populations (Summarized OR= 0.880, 95%CI= 0.840-0.922), instead of North American populations or European populations. **Conclusion:** Findings from this meta-analysis indicated that higher intake of protein may be associated with decreased of lung cancer risk among Asian populations, instead of other populations. As some limitations listed in our study, more studies are warranted to further confirm the association between them.

Keywords: Protein intake, Lung cancer, Meta-analysis

P2.16-40 ACKNOWLEDGING SOCIAL AND ECONOMIC INEQUITIES EXPERIENCED BY CANADA'S INUIT: IMPLICATIONS FOR DIAGNOSIS AND TREATMENT OF LUNG CANCER

C. Bornais[1], C. Roberts[1], P. Wheatley-Price[2], T. Asmis[1], G. Barton[1], G. Nicholas[1], E. Alie[1], T. Greene[1]

[1]*The Ottawa Hospital, Ottawa/Canada,* [2]*University of Ottawa, Ottawa/Canada*

Background: The Inuit living in Canada's north have the highest rates of lung cancer in the world. Barriers to care are numerous and exist at all phases of the lung cancer journey. Beginning with difficulty in accessing the diagnostic phase of care through to treatment at a tertiary cancer centre located over 2000 km away and little to no palliative care available locally, this population experiences obstacles at each step of their lung cancer journey. The Inuit in Canada's arctic experience dramatically higher rates of social and economic inequity than the rest of Canada with only one hospital serving a land mass similar to the size of Mexico, access to or from many communities is by air only. This means that diagnosis and treatment for lung cancer is provided thousands of kilometres away from family, community and culture, often for months at a time. Along with geographic barriers to care, Inuit peoples also have a historical mistrust of government and mainstream health care services owing to past encounters with colonization and marginalization. A lack of awareness of Inuit specific culture from health care providers (i.e. discrimination) further compounds this lack of trust. These end result of these traumas contribute to the significant health disparities experienced by the Inuit as compared to other Canadians and may in part explain why approximately 30% of Inuit diagnosed with lung cancer between 2000-2010 did not access cancer care. To better meet the needs of this population, TOHCC hired an Indigenous Nurse Navigator in 2016 with a goal to provide culturally safe care for Inuit patients and their families. Collaborative relationships have been built with key stakeholders in Inuit communities through consistent efforts which in turn have garnered awareness of Inuit specific issues within TOHCC and the surrounding city. **Method:** In depth semi-structured interviews with Inuit patients, caregivers and community leaders. The Indigenous nurse navigator will interview participants either in person or by video during April and May 2019. **Result:** The results of these interviews will be presented at the 2019 World Lung Cancer Conference in Barcelona. **Conclusion:** There is still much work to do in breaking down barriers to accessing care at all phases of the lung cancer journey for the Inuit of Canada's North. This presentation offers the opportunity to hear directly from a marginalized community who potentially have the greatest lung cancer needs of any population in the world.

Keywords: Indigenous, Inequity

P2.16-41 PEMBROLIZUMAB FOR PREVIOUSLY TREATED, PD-L1–EXPRESSING ADVANCED NSCLC: REAL-WORLD TIME ON TREATMENT AND OVERALL SURVIVAL

V. Velcheti[1], S. Chandwani[2], X. Chen[2], B. Piperdi[2], T. Burke[2]

[1]*NYU Langone, Perlmutter Cancer Center, New York/United States of America,* [2]*Merck & Co., Inc., Kenilworth/United States of America*

Background: Information from real-world clinical settings remains limited regarding outcomes of pembrolizumab therapy for advanced NSCLC. Our aim was to examine real-world time on treatment (rwToT) and overall survival (OS) for patients prescribed pembrolizumab monotherapy for previously treated, PD-L1–expressing advanced NSCLC, thus clinically similar to patients in the KEYNOTE-10 (KN010) trial. **Method:** This retrospective study used Flatiron Health's nationally representative EHR-derived database to identify adult patients with histologically confirmed advanced NSCLC and PD-L1 tumor proportion score (TPS) ≥1% previously treated with platinum-containing chemotherapy (and appropriate TKI if nonsquamous NSCLC with EGFR/ALK aberration). Eligible patients initiated pembrolizumab monotherapy from January 1, 2016, to May 31, 2018; those with <6 months of follow-up were excluded. Kaplan-Meier (KM) rwToT and OS were calculated. **Result:** Median follow-up was 15.6 months (range 6.0–32.8 months). Of 281 eligible patients (56% male), median age was 68 years; 36% had squamous NSCLC; 10% brain metastases; and 57%, 18%, and 25% ECOG performance status 0–1, ≥2, and unknown, respectively. Baseline characteristics were similar across PD-L1 TPS distributions. The table summarizes rwTOT and OS by PD-L1 TPS categories.

rwToT and OS in months (mo)

Data cutoff Nov 30, 2018	TPS ≥1% n=281	TPS ≥50% n=182	TPS 1–49% n=82
Discontinued, n (%)	189 (67)	120 (66)	56 (68)
KM rwToT, median (95% CI)	5.0 (3.9–6.2)	5.8 (4.4–7.2)	3.9 (2.1–6.2)
12-mo restricted mean (rMean) rwToT (95% CI)	6.1 (5.6–6.7)	6.5 (5.8–7.2)	5.4 (4.4–6.5)
24-mo extrapolated rMean rwToT (95% CI)	9.2 (6.4–12.1) [Gompertz]	9.9 (6.5–13.4) [Gompertz]	8.0 (7.2–9.4) [LogLogist]
12-mo on-treatment rate, % (95% CI)	31.0 (25.3–36.9)	33.9 (26.7–41.3)	26.6 (16.5–37.8)
18-mo on-treatment rate, % (95% CI)	25.9 (19.9–32.3)	27.3 (20.0–35.1)	26.6 (16.5–37.8)
OS events, n (%)	140 (50)	86 (47)	43 (52)
OS, median (95% CI)	13.5 (10.3–16.2)	15.6 (13.0–23.6)	9.7 (7.0–14.9)
12-mo survival, % (95% CI)	53.6 (47.2–59.6)	58.0 (50.0–65.1)	46.2 (33.8–57.7)

Conclusion: Real-world patients treated with pembrolizumab monotherapy after platinum-containing chemotherapy for PD-L1–expressing advanced NSCLC experienced rwToT and OS benefits similar to findings in a clinical trial setting, validating KN010 findings and approved indication in second line.

P2.16-42 THE USE OF A SMARTPHONE APPLICATION IMPROVES POSTOPERATIVE OUTCOMES IN PATIENTS UNDERGOING LUNG CANCER RESECTION

C. Fraile Olivero[1], L. Milla Collado[2], J. Jarabo Sarceda[3], E. Fernández Martín[3], C. Cerdan Santacruz[2], J. Gastardi[3], A. Gómez Martínez[3], P. Arribas Manzanal[3], P. Santos Capa[3], M. Martínez Tardido[3], V. Alen[3], F. Hernando-Trancho[3]

[1]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [2]*Hospital Arnau Vilanova, Lleida/Spain,* [3]*Hospital Clínico San Carlos, Madrid/Spain*

Background: For early stages of lung cancer, complete surgical resection with curative intent for patients who are surgical candidates remains the most effective treatment. However, thoracic surgery procedures are related to postoperative pulmonary complications which increase the morbidity and mortality. Preoperative pulmonary rehabilitation programs improve postoperative outcomes. This study aims to evaluate the role of a smartphone application to improve pulmonary rehabilitation in a group patients scheduled for lung cancer resection. **Method:** A Smartphone application containing peri-operative medical advice (stop smoking, mouth health, early mobilization and pain control) and ten chest physical exercises (aerobic exercise, inspiratory muscle strength and secretion mobilization technique) was created. This prospective and no randomized study was developed between January 2017 and December 2018. All patients scheduled for surgery were asked to participate. A group of 68 patients used and interacted with the software before and after the surgery. The control group (114 patients) received classical information and education by the Department of Physical Medicine and Rehabilitation. Clinical-pathological variables, incidence of postoperative pulmonary complications, duration of chest drainage, length of hospital stay and 30 days mortality rate were recorded and analyzed. **Result:** Postoperative pulmonary complications were developed 17.6% in the intervention group and 33.3% in the control group (P=0.02). The length of hospital stay was shorter in the intervention group (median 3±4.09d vs. 5±6.87d P=0.001). No differences were found in duration of chest drainage or 30 day mortality compared with control group. **Conclusion:** This new technological resource created by thoracic surgeons demonstrates that preoperative rehabilitation program and patient education improve postoperative outcomes in patients undergoing lung cancer resection, decreasing the incidence of postoperative pulmonary complications and length of hospital stay.

P2.16-43 IMMUNOTHERAPY IN ELDERLIES. REAL WORLD DATA

L.F. Sánchez-Cousido, M. Rojas Piedra, M. López Flores, I. Delgado Sillero, A. López González, C. Castañón, B. Nieto Mangudo, M. Pedraza, L. De Sande, S. Medina, Á. Rodriguez, A. García-Palomo, P. Diz Tain

Complejo Asistencial Universitario de León, León/Spain

Background: Because of its tolerability immunotherapy is suitable for unfit patients. Elderly patients are under-represented in clinical trials due to the association between aging and a significant prevalence of comorbid diseases. We analyzed our elderly patients treated with immunotherapy and tried to find any impact on overall survival (OS) from other non-comorbidity factors. **Method:** 24 NSCLC patients older than 70 years received immunotherapy after previous treatment at our hospital from September 2015 and July 2018 according to pharmacy records. Data was collected from medical records. Retrospective observational study whose primary end point was to analyze safety and efficacy in elderly patients was made. Secondary endpoint was to find if toxicity had any impact in OS. **Result:** 23 were men. 17 were former smokers, 6 still smoking. 10 were adenocarcinoma, 12 squamous cell carcinoma, 2 NOS. 7 were stage III, 17 stage IV. 14 had at least one metastatic organ. 2 had liver while 2 had brain metastases. Median number of previous lines was 1 (range=1-4). Best response to any previous treatment

was stable disease (SD) 37.5% (n=9); partial response (PR) 37.5% (n=9). All received Nivolumab. Best response to immunotherapy was PR 8.3% (n=2) with SD 37.5% (n=9); unfortunately, 9 were not valuable. Median number of cycles was 9 (range=1-55). 20 (83.3%) were PS<=1 before immunotherapy while 11 (45.8%) still PS<=1 after. Median overall survival (OS) was 10 months (95%CI 1.33-18.66). Median progression free survival (PFS) was 4 months (95%CI 0.65-7.39). Compared with under 70 years old patients -at our center- OS was not statistically longer in older patients (median OS: 22 vs 10months). OS was higher in those with any grade of toxicity (mean OS: 23 months vs 8 p<0.05); in those with less previous lines (median OS: 17 months in <=1 vs 3 months in more p<0.05); in PS<=1 before immunotherapy (median OS: 17 months vs 2 p<0.05) and in PS<=1 after immunotherapy (mean OS: 22 months vs 7 p<0.05). 37.5% (n=9) had any grade of immune-related toxicity (77.8% <=grade 2). Hypothyroidism was the most common toxicity. 41.7% (n=10) needed corticosteroids to control toxicity. Immunotherapy stopping reasons were progression 16 (66.7%) and related G3-4 toxicity in three out of four cases while the other one was due to persistent grade 2 toxicity. There were no deaths due to immune related toxicities. 29.2% (n=7) received treatment after progressionbeing all of them PS1 after immunotherapy. Best response to treatment after immunotherapy was SD 60% (n=3), PR 40% (n= 2) -in those that could be analysed- with 100% disease control rate. 13 (54.2%) patients died at cut-off. **Conclusion:** Although it is a small number of patients, as in other published studies, it suggests that elderly patients behave to immunotherapy as younger counterparts do.In the analysis made in our center in population under 70 years old, immunotherapy median number of cycles, toxicity frequency, and cause of treatment stop were similar in both populations and there were no statistically differences in OS.Any grade of toxicity was related with higher OS.Elderly people must be considered for immunotherapy treatment just like young patients.

P2.16-44 REAL-WORLD TREATMENT PATTERNS AND OUTCOMES IN ALK+ NSCLC PATIENTS RECEIVING IMMUNO-ONCOLOGY THERAPY IN THE UNITED STATES

X. Pan[1], H. Lin[1], Y. Yin[1], M.-R. Cheng[1], P. Baumann[1], M. Jahanzeb[2]

[1]*Millennium Pharmaceuticals, Inc., a wholly owned subsidiary of Takeda Pharmaceutical Company Limited, Cambridge/United States of America,* [2]*University of Miami Sylvester Comprehensive Cancer Center, Deerfield Beach/United States of America*

Background: Cancer immunotherapies are new treatment options in advanced non-small cell lung cancer (NSCLC). Evidence of immuno-oncology (IO) therapy efficacy in tumors with activating mutations, such as anaplastic lymphoma kinase (*ALK*) rearrangements, is lacking. This retrospective study describes the characteristics of ALK+ NSCLC patients treated with IO therapy and assesses treatment outcomes in these patients (time to treatment discontinuation, real-world progression-free survival [rwPFS]). **Method:** The Flatiron Health Electronic Health Record (EHR)–derived database (Jan 2011–Jun 2018) was used to identify patients with advanced ALK+ NSCLC who had received IO therapies (nivolumab, pembrolizumab, atezolizumab, durvalumab). Discontinuation of IO therapy was defined as switch to an ALK TKI or chemotherapy or addition of chemotherapy (for IO monotherapy), death, gap between IO administrations >120 days, or gap between last IO therapy administration and last follow-up date of >120 days. rwPFS was estimated as the time from treatment initiation to progression (abstracted from clinician notes and radiology reports) or death. Time to discontinuation and rwPFS were analyzed using Kaplan-Meier methods. **Result:** Of 593 ALK+ NSCLC patients with follow-up between 2015–2018, 83 (14%) patients were treated with IO therapy. Mean age was 60.3 years, with 65.1% of patients diagnosed at stage IV, and 61.4% patients receiving nivolumab. Of the 83 IO-treated patients, 50.6% received IO therapy before first ALK TKI, and 38.6% were treated with IO therapy after ≥2 ALK TKIs. Median (95% CI) time to discontinuation of IO therapy was 2.17 mo (1.41–3.32) and rwPFS was 2.34 mo (1.55–3.09). **Conclusion:** We identified ALK+ NSCLC patients who received IO therapy, half of whom were treated post-ALK TKI. Time to discontinuation of IO therapy was short, and real-world effectiveness (rwPFS) was limited. These results point to IO therapy's relative futility in ALK+ NSCLC patients. Compared to IO therapy, several approved ALK inhibitors have shown better effectiveness in both first and later lines of therapy. However, the optimal sequencing of ALK inhibitors with other therapies, including chemotherapy and IO therapy, remains unclear.

P2.17 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.17-01 ANALYSIS OF CLINICAL FEATURES AND PROGNOSIS OF NON-SMALL CELL LUNG CANCER EXCEEDING 30 MM DEPENDING ON THE GROUND GLASS OPACITY (GGO) RATIO

A. Kagimoto[1], Y. Tsutani[1], Y. Izaki[2], Y. Handa[1], T. Mimae[1], Y. Miyata[1], M. Okada[1]

[1]*Hiroshima University Hospital, Hiroshima City Minamiku/Japan,* [2]*Hiroshima University Hospital, Hiroshima city Minamiku/Japan*

Background: The ground glass opacity (GGO) ratio is associated with the prognosis of small (<30 mm) non-small cell lung cancer (NSCLC). However, the clinical features, especially the GGO ratio, and prognosis of NSCLC exceeding 30 mm are not well known. Therefore, this study aimed to determine the characteristics of patients with NSCLC exceeding 30 mm and analyze the clinical significance of the GGO ratio on prognosis. **Method:** Totally, 271 patients with NSCLC tumors exceeding 30 mm on preoperative computed tomography scans and who underwent complete resection at our institution between January 2007 and December 2017 were included. The patients were divided into three groups based on the GGO ratio: pure solid tumors, GGO ratio 0–40%, and GGO ratio ≥40%. The cut-off value of 40% was determined based on the recurrence rate for each GGO ratio group. Clinical feature and prognosis of each group were analyzed. **Result:** Of the included patients, 147 (54%) had pure solid nodule, 67 (25%) had nodules with a GGO ratio 0–40%, and 57 (21%) had nodules with a GGO ratio ≥40%. Among the patients with a GGO ratio ≥40%, 10 underwent limited resection (segmentectomy in 9 patients and wedge resection in 1); no patients experienced recurrence. Among the 147 patients with pure solid nodules, 47 (32%) experienced recurrence. Among the 67 and 57 patients with GGO ratio 0–40% and GGO ratio ≥40%, 16 (24%) and 2 (4%), respectively, experienced recurrence. The 3-year recurrence-free survival (RFS) rate was significantly shorter in patients with pure solid nodules (60.5%) than in patients with GGO ratio 0–40% (74.0%; p=0.010) and GGO ratio ≥40% (93.6%; p<0.001). Moreover, RFS was significantly shorter in patients with GGO ratio 0–40% than in patients with GGO ratio ≥40% (p=0.009). Similar results were observed for overall survival (OS). The 3-year OS rate was significantly shorter in patients with pure solid nodules (79.1%) than in patients with GGO ratio 0–40% (88.2%; p=0.046) and GGO ratio ≥40% (95.6%; p<0.001). Moreover, OS was shorter in patients with GGO ratio 0–40% than in patients with GGO ratio ≥40% with marginal significance (p=0.052). **Conclusion:** A pure solid nodule was a major component among NSCLC tumors exceeding 30 mm. Among such patients, as the GGO ratio decreased, the recurrence rate increased. A GGO ratio of 40% is the appropriate cut-off value, and patients with GGO ratio ≥40% have better prognosis compared to patients with GGO ratio <40% or pure solid nodules. The prognosis of patients with GGO ratio ≥40% who undergo limited resection may be similar to that of patients undergoing lobectomy, the standard operation procedure.

Keywords: GGO ratio, NSCLC exceeding 30mm

P2.17-02 SURVIVAL IN PERFORMANCE STATUS 3 NON-SMALL CELL LUNG CANCER PATIENTS RECEIVING RADICAL RADIOTHERAPY

R. Behrouzi[1,2], N. Bayman[2], M. Harris[2], A. Salem[2], A. Hudson[3], C. Chan[2], C. Faivre-Finn[2], D. Cobben[2], H. Sheikh[2], J. Coote[2], L. Pemberton[2], D. Woolf[2]

[1]*Manchester University NHS Foundation Trust, Manchester/United Kingdom,* [2]*Christie NHS Foundation Trust, Manchester/United Kingdom,* [3]*Manchester Cancer Research Centre, Manchester/United Kingdom*

Background: International guidelines currently recommend radical radiotherapy for non-small cell lung cancer (NSCLC) patients with ECOG performance status (PS)0-2. Despite a paucity of evidence for treating poorer PS patients, modern advances have allowed patients with PS3 to be offered radical radiotherapy. **Method:** PS0-3 NSCLC patients receiving radical radiotherapy at The Christie Hospital, UK between August 2016-October 2017 were retrospectively identified from hospital electronic patient records. Survival was calculated from date of first oncology review to November 2018. Baseline and treatment characteristics for PS3 patients were recorded including adult comorbidity evaluation (ACE)-27 score, pulmonary function, radiation dose volume parameters and radiotherapy regimen (i.e stereotactic ablative radiotherapy (SABR) vs standard radiotherapy (50-55Gy/20 fractions)). **Result:** 504 patients were identified: 440(87%) PS0-2 and 64(13%) PS3. Six PS3 patients withdrew themselves; four before treatment and two after one fraction. Of 58/64(91%) PS3 patients completing radiotherapy, 43(74%), 4(7%), 10(17%) and 1(2%) were Stage I, II, III and IV at diagnosis, respectively. ACE-27 score was 0, 1, 2 and 3 in 3(5%), 8(14%), 16(28%) and 31(53%) patients, respectively. 31(53%) received SABR and 27(47%) standard radiotherapy. On intention-to-treat analysis, there was no significant difference in survival over 18 months in PS3 patients compared to PS0-2; p=0.858 (Fig.1). There was no significant difference in survival among PS3 patients completing radiotherapy when stratifying by stage(I vs II vs III) (p=0.343), ACE-27 score(1 vs 2 vs 3)(p=0.266), or radiotherapy regimen(p=0.655). Lung function tests(FEV1, FVC) and radiotherapy dose volume parameters(PTV, V5, V10,V20) failed to predict survival of PS3 patients at 6, 12 and 18 months.

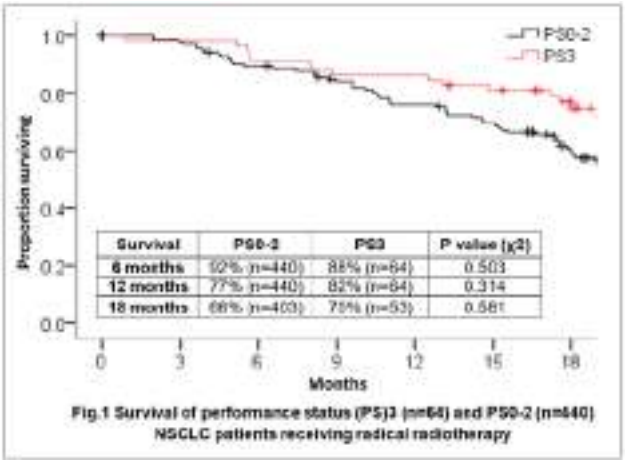

Fig.1 Survival of performance status (PS)3 (n=64) and PS0-2 (n=440) NSCLC patients receiving radical radiotherapy

Conclusion: This study demonstrates that PS3 patients receiving radical radiotherapy had a similar 18-month survival compared to PS0-2 patients and baseline and treatment characteristics did not predict overall survival in PS3 patients. This suggests more PS3 patients could be considered for radical radiotherapy and further studies with larger cohorts are recommended.

Keywords: Non-Small Cell Lung Cancer, radical radiotherapy, performance status

P2.17-03 SURGICAL OUTCOMES OF REPEATED ANATOMICAL PULMONARY RESECTION FOR THE IPSILATERAL SECOND LUNG CANCERS

A. Hattori, K. Takamochi, S. Oh, K. Suzuki

Juntendo University, Tokyo/Japan

Background: The opportunity of pulmonary resection for metachronous second lung cancers is increasing as an effective surgical strategy for properly selected patients in the course of postoperative follow-up after thoracic surgery for the first lung cancer. However, the surgical indication is controversial regarding the repeated pulmonary resection for the ipsilateral second lung cancer. **Method:** Among surgically resected 3316 non-small cell lung cancer (NSCLC) from 2008 to 2018, ipsilaterally detected 104 metachronous second lung cancers (3.6%) was retrospectively reviewed with regard to the surgical outcomes and clinicopathological characteristics. In this study, re-anatomical resection was defined as a repeated anatomical surgery for ipsilateral secondary NSCLC after major lung resection for primary NSCLC. Overall survival (OS) was estimated using the Kaplan-Meier method. Survival outcomes were evaluated using Cox proportional hazard model. A difference was considered statistically significant when the p-value was less than 0.20 in the univariable, and 0.05 in the multivariable models. **Result:** Of all, 61 (67%) were male with an average age of 67y at the second surgery. Pathological-stage I disease was found in 65 (63%). Histologically, adenocarcinoma was frequent in 80 (77%) cases. Seventy-seven (74%) was diagnosed as second primary. The 3y-OS after the second lung resection was 80.1%. Multivariate analysis revealed that radiological pure-solid tumor, pack-year smoking were the independent prognosticators of the OS (p=0.045, 0.001). Operative procedures were not associated with the survival outcomes (re-anatomical: 81.8%, others: 78.2%, p=0.816), however, re-anatomical resection was an independently significant predictor of the postoperative morbidity after the second surgery (p=0.035). Therefore, we focused on the 58 cases that underwent re-anatomical resection. Among them, postoperative morbidity (G3 or more in the CTCAE 4.0) was found in 20 (35%). A multivariable analysis revealed tumor size and postoperative morbidity were the independently significant prognosticators (p=0.003, 0.026). The 3y-OS of tumor less than 20mm was excellent (91.9% vs. 66.6%, p=0.008). Furthermore, we classified them into 2 groups based on the operative modes, i.e., completion pneumonectomy (CP; n=26) and the other re-anatomical resections to avoid CP (non-CP; n=32). The details of non-CP were ipsilateral secondary lobectomy/segmentectomy after the primary lobectomy/segmentectomy in 28 and completion lobectomy after the primary segmentectomy in 4, respectively. Among them, right side operation was more frequent in the non-CP (54% vs. 84%, p=0.011), while intra-pericardial procedure was employed more in the CP (85% vs. 47%, p=0.005). In contrast, the oncological outcomes (3y-OS; 75.8% vs. 87.1%, p=0.881), technical aspects including operative time (242min vs. 234min, p=0.802), bleeding amount (334ml vs. 242ml, p=0.521), blood transfusion (15% vs. 19%, p=0.736), arterial reconstruction (19% vs. 28%, p=0.431), or postoperative morbidity (27% vs. 41%, p=0.275) was similar between CP and non-CP. **Conclusion:** Re-anatomical pulmonary resections for the ipsilateral second lung cancers are oncologically feasible but predictive for the postoperative morbidity. In particular, non-CP could be effective strategy to avoid CP for lung preservation, however, this procedure is technically challenging as well as CP, and strict caution would be warranted for the perioperative management. While oncological outcome of small-sized lung cancer is fully favorable even in case that repeated anatomical resection would be needed.

Keywords: second lung cancer, repeated anatomical pulmonary resection, surgical outcome

P2.17-04 ROLE OF LYMPHADENECTOMY IN THORACOSCOPIC LOBECTOMY FOR NON-SMALL CELL LUNG CANCER

S. Park, C.H. Kang, S. Bae, J. Song, K.J. Na, I.K. Park, Y.T. Kim

Seoul National University Hospital, SEOUL/Korea, Republic of

Background: The adequacy of lymphadenctomy in video-assisted thoracoscopic surgery (VATS) for the patients with non-small cell lung cancer (NSCLC) has been questioned. This study aims to identify the role of lymphadenectomy during VATS lobectomy for NSCLC. **Method:** To include different level of lymphadenectomy proficiency and heterogeneous lymphadenectomy policy, we included all consecutive surgical cases from April 2005 to June 2013, irrespective of surgeon's experience, lymph node sampling or dissection, and solid or subsolid nodule. Patients who underwent VATS lobectomy and who were followed up for more than 5 years were included in this study. The relationship between long-term survival and the number of removed lymph nodes was analyzed. **Result:** During the study period, a total of 2,502 patients underwent curative surgical resection of NSCLC and VATS lobectomy was performed in 1,055 patients (42.2%). The median length of postoperative hospital stay was 5 days and 30-day and 90-day all-cause mortality rates were

POSTERS

0.3% and 0.9%, respectively. Pathological stage I, II, III and IV were 79.0%, 10.6%, 8.7%, and 1.7% and the median number of removed lymph nodes was 24. The 5-year overall and recurrence-free survival rates were 83.9% and 78.5 %, respectively. Recurrences were developed in 233 patients (22.1%) and the most common pattern was distant metastasis (n=153, 14.5%). The number of removed lymph nodes, year of operation, age, tumor size, pathologic stage, histology, and radiologic features were the significant prognostic factor for recurrence-free survival in multivariate analysis. More than 10 lymph node removal was associated with improved recurrence-free survival and the effect lasted until 40. However, the number of removed lymph nodes were not a significant risk factor for overall survival (table). **Conclusion:** The number of removed lymph nodes was closely related with recurrence-free survival after VATS lobectomy. Proper lymphadenectomy should be performed in VATS lobectomy like as open lobectomy.

Keywords: Non-Small Cell Lung Cancer, VATS, lymphadenctomy

P2.17-05 FEASIBILITY STUDY OF ADJUVANT CHEMOTHERAPY WITH CARBOPLATIN AND NAB-PACLITAXEL FOR COMPLETELY RESECTED NSCLC

N. Katsurada, M. Tachihara, Y. Hatakeyama, K. Koyama, M. Yumura, T. Kiriu, R. Dokuni, D. Hazama, S. Tokunaga, D. Tamura, K. Nakata, M. Yamamoto, H. Kamiryo, K. Kobayashi, Y. Tanaka, Y. Maniwa, Y. Nishimura

Kobe University Graduate School of Medicine, Kobe/Japan

Background: Cisplatin-based regimen is the standard adjuvant chemotherapy for patients with completely resected stage II or III non-small cell lung cancer (NSCLC). However, the patients unfit for cisplatin-based chemotherapy due to old age or renal impairment recently increased. This phase II study was conducted to evaluate the tolerability and efficacy of carboplatin and nab-paclitaxel as adjuvant chemotherapy. **Method:** Patients with completely resected stage II to IIIA NSCLC enrolled. Eligible patients received postoperative adjuvant chemotherapy with 4 cycles carboplatin (area under the curve=5, on day1) and nab-paclitaxel (100 mg/m2, on days 1, 8 and 15) administered every 4 weeks. The primary endpoint was to evaluate the completion rate of 4 cycles of chemotherapy. We assumed completion rate of 50% would be the lower limit. **Result:** From Jan 1, 2014 to Jan 31, 2019, 21 patients were enrolled, but two patients were excluded. Two patients of them are on protocol chemotherapy at data cutoff point. Median age of the 17 patients was 73 years (ranging from 53 to 80 years). Four of 17 patients (23.5%) were at stage IIA, 3 (17.6%) were at stage IIB, and 10 (58.8%) were at stage IIIA. Eleven (64.7%) had adenocarcinoma and 6 (35.3%) had squamous cell carcinoma. The most reasons of unfit for cisplatin regimen were old age (≥70 years old, n=14) and renal impairment (n=7). Ten of 17 patients (58.8 (32.9-81.6) %) completed four cycles of regimen. The reasons for discontinuation of the chemotherapy were febrile neutropenia (n=2), neutropenia (n=1), empyema (n=1), drug-induced pneumonitis (n=1), renal failure (n=1), and patient refusal due to fatigue (n=1). Three of 10 patients who completed four cycles needed dose reduction due to grade 4 neutropenia. Nab-paclitaxel on day 15 was omitted in 39 of 49 cycles (79.6%) because of grade 3 or 4 neutropenia. The most common grade 3 or 4 adverse event was neutropenia (n=14, 82.4%), followed by anemia (n=3, 17.6%). Febrile neutropenia, grade 3 pneumonitis, grade 1 peripheral sensory neuropathy were observed in 11.8%, 5.9%, 35.3% of the 17 patients respectively. The median time to disease recurrence was 24.4 (10.8-37.5) months. **Conclusion:** Carboplatin and nab-paclitaxel as adjuvant chemotherapy for NSCLC unfit for cisplatin was not tolerable. Dose reduction should be considered in further study of adjuvant chemotherapy.

Keywords: adjuvant chemotherapy, carboplatin, feasibility study

P2.17-06 ANALYSIS OF LEFT ATRIAL BLOOD FLOW USING 4D FLOW MRI IN THE PATIENT WHO SUFFERED FROM CEREBRAL INFARCTION AFTER LEFT UPPER LOBECTOMY

M. Matsumoto, J. Usuda

Nippon Medical School Hospital, Sendagi, Bunkyo-ku, Tokyo/Japan

Background: Cerebral infarction is one of the complication after left upper lobectomy, and it may be caused by thrombus in left atrial. However, the mechanism of incidence of cerebral infarction has not been elucidated. In order to elucidate it, we performed the blood flow analysis of left atrium including the stump of the left upper pulmonary vein, by 4D flow MRI, which is recently very useful for blood flow analysis. **Method:** We examine blood flow by 4D flow MRI in 3 patients with cerebral infarction after left upper lobectomy. **Result:** Case1: A 76-year-old woman underwent left upper lobectomy for lung adenocarcinoma (cT1aN0M0 stageIA1). She had atrial fibrillation and took edoxaban, oral anticoagulant medicine. Three days after the surgery, she made cerebral infarction in MRI. By chest CT a thrombus was found near the left upper pulmonary vein stump. Case 2: A 42-year-old woman underwent left upper lobectomy due to lung cancer (cT1aN0M0 stageIA1). She had Cushing syndrome. One month after the surgery, she was diagnosed as cerebral infarction in MRI. There was no evidence of incidence of thrombus by chest CT. Case 3: A 77-year-old woman underwent left upper lobectomy for lung adenocarcinoma (cT3N0M0 stageIIB). Five months after the surgery, she was diagnosed as cerebral infarction in MRI. CT showed thrombus in the left atrial appendage. We performed blood flow analysis in left atrium for the three patients by 4D flow MRI. It showed a decrease in blood flow near the left superior pulmonary vein stump and left atrium around the stump in all patients. **Conclusion:** We performed blood flow analysis of left atrium by 4D flow MRI, and it was able to visualize the blood flow after left upper lobectomy. The analysis showed the reduction of blood flow not only in the left superior pulmonary vein stump but also in the left atrium. These results suggest that blood flow stagnation may induce the thrombus formation in left atrium, and cause cerebral infarctions. In future, we will compare the blood flow before and after surgery and simulate the blood flow in left atrium. We hope to select patients at high risk for stroke before left upper lobectomy using flow analysis.

Keywords: left upper lobectomy, thrombus, 4D flow MRI

P2.17-07 ROLE OF ADJUVANT CHEMOTHERAPY AFTER SUBLOBAR RESECTION IN STAGE I NSCLC

R. Pathak[1], S. Goldberg[2], J. Hoag[1], A. Monsalve[2], B. Resio[2], M. Papageorge[1], D. Boffa[2]

[1]Yale School of Medicine | Yale Cancer Center, New Haven/United States of America, [2]Yale School of Medicine, New Haven/United States of America

Background: Adjuvant chemotherapy (AC) has been associated with improved survival for several subsets of surgically managed NSCLC (e.g. nodal metastases, tumors >4cm). The surgical practice of removing less than the entire lobe ("sublobar resection") has been associated with increased risk of NSCLC recurrence, yet the impact of AC in this subset is unknown. Stage I NSCLC patients managed by sublobar resection (SR) in the National Cancer Data Base (NCDB) were studied to evaluate SR as a potential indication for AC. **Method:** The NCDB was queried for completely resected (R0) stage I NSCLC patients who underwent multi-agent AC after SR (wedge resection or segmentectomy) between 2004 & 2014. Survival was calculated from 30 days after surgery to minimize immortal time bias. Multivariable Cox proportional hazards models adjusting for patient, tumor (including visceral pleura invasion (VPI) and lympho-vascular invasion (LVI)) and treatment characteristics were created and stratified by size (0-1 cm, 1.1-2 cm, 2.1-3 cm and 3.1-4 cm). **Result:** Of the 12,063 patients identified, 584 (4.84%) received multi-agent AC. AC patients tended to be younger (median age 66 vs 71 years, p<0.001), privately insured (35.13% vs 23.05%, p<0.001), and with high risk pathological features (VPI: 6.47% vs 4.55%, p<0.001, LVI: 10.32% vs 5.70%, p<0.001, high grade: 47.15% vs 34.50%, p<0.001). In patients with tumors measuring ≤3 cm, AC was not significantly associated with a mortality reduction (Table 1). In patients with tumors measuring 3.1-4 cm (N=1,172), AC (N=145, 12.37%) was associated with a lower mortality (HR 0.65, 95% CI 0.48 to 0.87, p=0.003) (Figure 1).

Tumor size	Total N	AC N (%)	Mortality hazard AC vs no AC		
			HR	95% CI	*P*
0-1 cm	1629	52 (3.19)	1.43	0.93 to 2.21	0.11
1.1-2 cm	6113	214 (3.50)	1.10	0.87 to 1.36	0.45
2.1-3 cm	3149	173 (5.49)	1.12	0.89 to 1.42	0.35
3.1-4 cm	1172	145 (12.37)	0.65	0.48 to 0.87	0.003

Table 1. Impact of AC in patients with stage I NSCLC undergoing SR

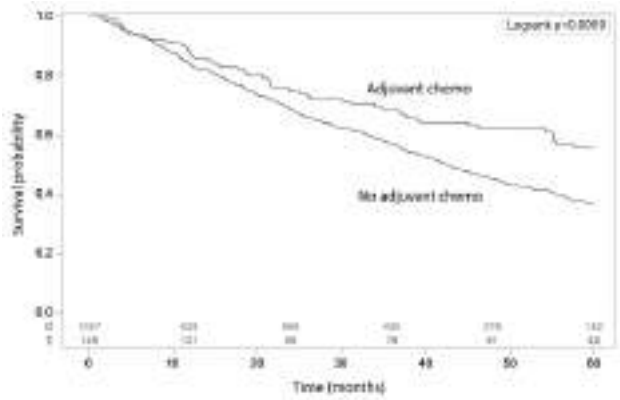

Figure 1. Kaplan-Meier survival curves for patients with 3.1-4 cm stage I NSCLC undergoing SR

Conclusion: The administration of AC was associated with superior survival in stage I NSCLC patients who underwent SR, but only those with tumors 3.1-4 cm. Additional study to validate SR as an indication for AC in stage I NSCLC patients is indicated.

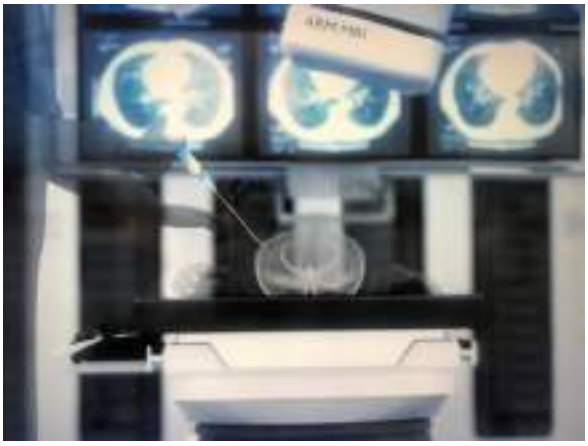
P2.17-08 ETHANOL RELEASE HEAT-GENERATING POLYMER FOR FOCAL THERAPY OF SMALL LUNG CANCERS UNDER OPEN MRI

J. Shimada[1], K. Mori[2], K. Masamune[3]

[1]*Kyoto Prefectural University of Medicine, Kyoto/Japan,* [2]*Nagoya University, Nagoya/Japan,* [3]*Tokyo Woman Medical University, Tokyo/Japan*

Background: Recently, the lung cancer lesions of small GGO lesions are increasingly found. Such an elderly person who found a small cancer lesion reveals low durability for surgery and sometimes has many medical complications around chronic diseases. **Method:** therapy of micro lung cancers under open MRI and developed medical devices. We have synthesized low viscosity silicon material which absorb a trace amount of water, generates heats and indurate in a few minutes. We have adjusted the concentration of titanium catalyzer, and a fine image can be visualized under CT imaging equipment and 0.3T open MRI. In animal experiments, rat lungs are divided in 10-micron unit CT imaging, the indurated conditions of thermosetting resin in the lungs was analyzed as 3D DICOM image data and 0.3T MRI DICOM images of Hitachi Corporation. We have developed non-artifact metallic needle as a biopsy needle under open MRI circumstance.



Result: It was confirmed that the indurated resin was hardened three-dimensionally without cracks, the surrounding cells were damaged, the resin can be detected with CT. The micro resin can be detected with 0.3T Open MRI. **Conclusion:** We have succeeded in synthesizing "Ethanol Release Heat-Generating Polymer" for focal therapy of micro lung cancers and archiving non-artifact medical devises under MRI. The idea of this research is Japanese patent JP6447858. This work was PCT patent pending JP2017/025044 in US and China and supported by JSPS KAKENHI Grant Number JP15K15517 and 18H05377.

Keywords: focal therapy, MRI visible, Polymer

P2.17-09 PREOPERATIVE RISK FACTORS OF POTENTIAL FAILURE FOR LOBE-SPECIFIC NODAL DISSECTION IN CLINICAL EARLY STAGE (I-IIA) NON-SMALL CELL LUNG CANCER

Y. Chong, J.K. Yun, Y.H. Jeong, G.D. Lee, S. Choi, H.R. Kim, Y.-H. Kim, S.-I. Park, D.K. Kim

Department of Thoracic and Cardiovascular Surgery, Asan Medical Center, Seoul/Korea, Republic of

Background: Clinical early stage (I-IIA) non-small cell lung cancer (NSCLC) is treated with pulmonary resection and systematic nodal dissection (SND) or lobe-specific nodal dissection. The aim of this study was to identify the preoperative risk factors for potential failure of lobe-specific nodal dissection in clinical early stage NSCLC. **Method:** A retrospective review was carried out on patients who underwent pulmonary lobectomy and SND for clinical early stage (I-IIA) NSCLC. Patients with computed tomography and positron emission tomography were included, whereas patients with invasive mediastinal staging and right middle lobe tumor were excluded. Lobe-specific nodal dissection failure was defined as unexpected metastasis at inferior mediastinal nodes (stations 7, 8, and 9) for both upper lobe tumors and at superior mediastinal nodes (stations 2R and 4R for right upper lobe tumors and stations 4L, 5 and 6 for left upper lobe tumors) for both lower lobe tumors. The incidence of pN2 disease following the tumor location and the factors for the failure of lobe-specific nodal dissection were analyzed. **Result:** From July 2005 to May 2017, 2130 patients were included in this study. Overall, 12.5% (266/2130) of the patients had pN2 disease. Among them, 33.2% (78/266) of pN2 patients showed potential failure of lobe-specific nodal dissection. Lobe-specific nodal dissection failure was shown in 49 of 764 (6.4%), 21 of 468 (4.5%), 2 of 534 (0.4%), and 6 of 364 (1.6%) cases in right upper lobe, right lower lobe, left upper lobe and left lower lobe, respectively. At multivariable analysis, female (OR: 1.86; 95% CI 1.14-3.03; p = 0.012), right upper lobe tumor (OR: 20.98; 95% CI 5.05-87.08; p < 0.001), right lower lobe tumor (OR:14.81; CI 3.43-63.97; p < 0.001), higher SUVmax (≥ 4.75) (OR: 5.51; 95% CI 3.18-9.55; p < 0.001), and adenocarcinoma histology (OR: 8.89; 95% CI 2.11-37.42; p = 0.003) were significant risk factors for the failure of lobe-specific nodal dissection **Conclusion:** Lobe specific nodal dissection revealed a considerable failure rate in clinical early stage NSCLC. Lobe-specific SND should be performed cautiously in clinical early stage NSCLC, especially in patients with female sex, right sided tumor, higher SUVmax (≥ 4.75) and adenocarcinoma histology.

P2.17-10 EFFECTS OF THE OMEGA-6/OMEGA-3 RATIO ON POSTOPERATIVE COMPLICATIONS AFTER LUNG RESECTION: PRELIMINARY RESULTS

C. Deniz[1], R. Ramos[1], I. Macía[1], F. Rivas[2], A. Ureña[2], G. Rosado[3], P. Rodriguez-Taboada[3], S. Aso-González[4], S. Padrones-Sánchez[4], I. Escobar[2]

[1]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat, Barcelona/Spain,* [2]*Hospital Universitari de Bellvitge, L'Hospitalet de Llobregat/Spain,* [3]*Hospital Joan XXIII de Tarragona, Tarragona/Spain,* [4]*Department of Pulmonology, Bellvitge Hospital, Barcelona University, Barcelona/Spain*

Background: In the last 3 decades, the intake of omega-6 (*n*-6) fatty acids has increased while the intake of omega-3 (*n*-3) has decreased, leading to an increase in the *n*-6/*n*-3 ratio, which is now 20:1. This ratio has been postulated as an inflammatory marker of carcinogenesis, implicated in the development of multiple chronic diseases, and associated with postoperative complications due to the proinflammatory effects of omega 6. Consequently, the preoperative

assessment of nutritional markers, together with immunonutrition, represent a promising target to improve outcomes in patients with lung cancer who are candidates for surgical resection. The aim of this study was to assess the effect of the *n*-6/*n*-3 ratio on postoperative complications in patients undergoing radical-intent surgery for lung cancer. **Method:** Prospective cohort study of 38 patients diagnosed with lung cancer treated with radical surgery between October 2017 and May 2018. The *n*-6/*n*-3 ratio was determined immediately prior to surgery with the patient under anesthesia. **Result:** Of the 38 surgically-treated patients, 29 were men (76%) and 9 women (24%). Mean patient age was 62 ±10 years. Twelve (32%) patients were active smokers at the time of surgery. The most common histological subtype was adenocarcinoma (60%) and most patients underwent lobectomy (68%). The mean body mass index (BMI) was 27 ±5 and the mean preoperative prognostic nutritional index (PNI) score was 48±7. The mean *n*-6/*n*-3 ratio was 20 ±6. The most common complications were prolonged air leak (> 5 days) in 11 patients (29%) and respiratory failure in 6 patients (16%). Patients with prolonged air leak had a significantly higher *n*-6/*n*-3 ratio than patients without prolonged air leak (25 ±3 vs. 18 ±6, respectively; p=0.02). Patients with an *n*-6/*n*-3 ratio > 20 were significantly more likely (p=0.002) to present prolonged air leak. Neither BMI nor PNI were significant predictors of air leak duration. **Conclusion:** These preliminary findings indicate that patients with a higher *n*-6/*n*-3 ratio—that is, those with a greater proinflammatory status—were more likely to present prolonged air leak than those with a lower inflammatory status. Based on these encouraging results, we propose to continue with this line of research to better understand the effects and prognostic value of immunonutritional status on the clinical course of patients after lung cancer surgery.

P2.17-11 EVALUATING PD-L1 AS A PROGNOSTIC BIOMARKER IN SURGICALLY RESECTABLE NON-SMALL CELL LUNG CANCER

S. Tuminello, R. Veluswamy, C. Gamarra, R. Flores, M. Van Gerwen

Icahn School of Medicine at Mount Sinai, New York/United States of America

Background: Identifying biomarkers that can predict which early stage non-small cell lung cancers (NSCLCs) are likely to recur following surgical resection is critical to improving survival outcomes. Programmed Cell Death Ligand-1 (PD-L1) is an immune regulatory protein expressed on tumor cells that inhibits T effector response against tumors. Therefore, high PDL-1 expression on tumor cells may enable evasion of the anti-tumor response and be associated with worst outcomes. We conducted a meta-analysis to determine if PDL-1 expression is associated with survival in surgically resected early stage NSCLCs. **Method:** PubMed was searched to identify eligible studies comparing survival of surgically resected stage I-III NSCLC patients according to PD-L1 tumor expression. Included studies were grouped according to measurement criteria of PDL-1 expression: 1%, 5%, 50% cutoffs or as a continuous variable expressed as H-score. The latter is calculated from the percentage of cells expressing PDL1 multiplied by the intensity of staining. Meta-analysis was performed using a linear mixed-effects model to determine overall survival (OS). I2 was used as a measure of heterogeneity across studies. **Result:** Of the 519 articles queried, 31 articles met eligibility criteria, accounting for 6,713 patients. Nine studies (n=2,407) used H score, where higher PD-L1 expression was associated with worse OS (hazard ratio [HR]meta: 1.68, 95% confidence interval [CI]: 1.17-2.41, I2= 15.45%). Five studies used a 1% cutoff (n=1,073), 14 studies reported using a 5% value (n=2,310) and 6 studies (n=1,572) used a 50% cutoff for evaluating high vs. low PD-L1 expression. PD-L1 expression was not statistically significantly associated with survival according to these cutoffs and there was high inter-study heterogeneity (HRmeta: 1.47, 95% CI 0.89-2.41; I2= 17.57%; HRmeta: 1.09, 95% CI 0.79-1.52; I2= 35.49%; HRmeta: 1.21, 95% CI 0.61-2.40; I2= 58.26% for 1%, 5%, 50%, respectively). **Conclusion:** Higher PD-L1 expression in early stage NSCLCs as measured by H scores was associated with worse post-surgical survival. The measurement of PD-L1 expression as a continuous variable (i.e. H score) may provide more accuracy for predicting survival outcomes over percentage cutoffs. Future research is needed to validate PD-L1 expression as a predictive biomarker of survival for early-stage NSCLCs undergoing surgical resection.

P2.17-12 ROBOTIC ASSISTED SEGMENTECTOMY - INTRAVENOUS VS INTRABRONCHIAL FLUORESCENCE THORACOSCOPY TO IDENTIFY THE INTERSEGMENTAL PLANE

S.M. Kolokotroni, A.-R. Dhanji, H. Wilson, S. Stamenkovic, D. Waller

St Bartholomew's Hospital, Barts Health NHS Trust, London/United Kingdom

Background: Increasingly earlier detection of small lung cancers may permit the possibility of anatomical sublobar resection. Robotic assisted thoracic surgery (RATS) facilitates complex segmentectomy but identification of the intersegmental boundary remains a drawback to minimally invasive techniques. We have employed two contrasting methods using either intravenous (IV) or intrabronchial (IB) indocyanine green (ICG) and compared the efficacy. **Method:** The location of the lesion was identified on CT reconstruction. Patients were allocated to either method by surgeon preference. IV ICG was injected during RATS after division of the target segmental artery. A novel aerosolized IB technique (by fibreoptic bronchoscopy) was used to inject the target segmental bronchus before RATS. All operations were performed using the Da Vinci Xi robot (*Intuitive Surgical, Sunnyvale, CA, USA*) and near infrared thoracoscopy (Firefly®). IV ICG was administered in 18 patients and IB ICG was given in 13 patients. The intersegmental plane was identified by the fluorescence demarcation line, which was then divided using the robotic stapler. **Result:** On univariate analysis, there were no intergroup differences between IV and IB in the patient demographics (median age 70.5 years vs 71 years), number of staple firings (8 vs 10, p>0.05), success in identifying the intersegmental plane (94 vs 100% respectively, p>0.05), postoperative air leak duration (2 vs 3 days, p >0.05), or TNM staging of tumours (T1 64% vs 86% respectively, p>0.05). The total anaesthetic time (230 vs 290 mins, p<0.05) and the operative duration (171.5 vs 193.5 mins, p<0.05) were significantly less in the IV ICG group. In IB ICG, more than half of the segmentectomies involved the apical segment of either lower lobe (5 R S6, 1 L S6; 3 L S1-3, 2L S4-5), whereas in IV ICG more complex segmentectomies were performed (2 R S1-2, 2 R S6, 2 R S7-10; 2 L S1-2, 5 L S1-3, 2 L S4-5, 1 L S7-10, 1 L S7-8). There was no mortality nor major complications in either group. One case was converted to thoracotomy due to extensive adhesions in the IV ICG group. In the same group, there was one R1 resection due to parietal pleura involvement.

Comparison between IV and IB ICG in RATS segmentectomies

Total number of patients	IV ICG (n=18)	IB IVG (n=13)
Excluded patients	1 case converted to thoracotomy	1 wedge resection (frozen section negative) 1 lobectomy (abnormal anatomy)
Patient age (median,range)	70.5 (35-84)	71 (50-89)
Sex (M/F)	11/7	7/6
Target segments (R/L)	R S1-2 2 R S6 2 R S7-10 2 L S1-2 2 L S1-3 5 L S4-5 2 L S7-10 1 L S7-8 1	R S6 5 L S1-3 3 L S4-5 2 L S6 1
Operative duration (median, range)	171.5 mins (111-228)	193.5 mins (178-275)
No of staple firings (median, range)	8 (2-14)	10 (7-15)
Success in identifying the intersegmental plane (%)	16/17 (94%)	11/11 (100%)
Major complications	0	0
Conversion to VATS or open	1(adhesions)	0
Tumour clearance (%)	R0 16/17 (94%)	R0 11/11 (100%)
NSCLC (%) T-status in NSCLC (%)	NSCLC 14/17 (82%) T1 9/14 (64%)	NSCLC 7/11 (63%) T1 6/7 (86%)

Conclusion: In RATS segmentectomy, identification of the intersegmental plane is facilitated by the intraoperative use of ICG. Both IV and IB routes are feasible with comparable results. As the IV route appears to reduce the use of theatre time, a future randomized comparison is suggested.

P2.17-13 THORACOSCORE FAILS TO PREDICT IN-HOSPITAL MORTALITY FOLLOWING ELECTIVE SURGERY IN A BRAZILIAN LUNG CANCER COHORT

E. Ricardo[1], F. Abrao[2,3], F. Moreira[1], I. Abreu[3], R. Younes[3], O. Da Rocha Neto[4], V.J. Agostinho[4]

[1]*Hospital Alemão Oswaldo Cruz, São Paulo/Brazil,* [2]*Hospital Santa Marcelina - Brazil, São Paulo /Brazil,* [3]*Hospital Alemão Oswaldo Cruz, São Paulo/Brazil,* [4]*Hospital Santa Marcelina, São Paulo/Brazil*

Background: According to SEER database only 40% of patients with lung cancer present localized or regional disease at diagnosis. The cornerstone of treatment of potentially resectable lung cancer is surgical removal of the tumor and it is important to estimate the loss of lung function after resection. The risk of in-hospital death can be estimated by some a scores system such as Thoracoscore. The aim of this study is to evaluate the applicability of this risk assessment model for in-hospital mortality in a Brazilian cohort of patients submitted to surgical resection. **Method:** This is a prospective analysis of patients who underwent lung resection for lung cancer in two thoracic surgery centers in Brazil between January 2015 to December 2018. Patients were included if they were 18yo or older, had a histologically proven diagnosis of lung cancer. Tumor staging was done according the seventh edition of the AJCC classification. Data on prognostic factors such as histology, gender, performance status, comorbidities and type of treatment were collected. Thoracoscore was calculated based on the following variables: age, sex, American Society of Anaesthesiologists' class (ASA), performance status classification, dyspnea score, priority of surgery, procedure class, diagnosis group and comorbidities score. A receiver operating characteristic analysis determined the ability of the thoracoscore to predict in-hospital mortality and it would be considered acceptable if AUC > 0.7; significance test for AUC was performed using Chi-square test. Proportion of events was compared between groups according to the Cochran-Armitage linear trend test to evaluate the calibration of Thoracoscore. All P-values were 2-sided. Results were considered significant if $p < 0.05$. Statistical analyses were performed using SAS version 9.4. **Result:** 166 patients were included in the study. Median age was 62 years, 48,8% were male, 57.8% had adenocarcinoma, 71.7% had one or two comorbidities, 40.3%, 36.1%, 19.2% and 3.6% were respectively clinical stage I, II, III and IV, 71% and 13.3% underwent respectively lobectomy/bilobectomy and pneumectomy, 79.5% were ASA ≤2, 100% had ECOG ≤2, elective surgery and dyspnea score ≤2. The observed in-hospital mortality was 13 patients (7.8%). We attributed our mortality to high rate of stage III lung cancer patients and we also included stage IV patients who underwent to palliative surgery. Mean thoracoscore was 3.92 (SD ± 1.41) and the mean predicted in-hospital mortality using thoracoscore was 1.81%. The AUC for thoracoscore was 0.579. When this area was compared with the area of 0.50 (absent discrimination), no significant difference was observed ($p = 0.3642$). Thoracoscore was divided into three risk groups: low (0–3), moderate (3.1–5) and high (≥5.1). The score was not able to differentiate the mortality among the groups ($p = 0.30$). **Conclusion:** Our results corroborate the non-validation of Thoracoescore in a Brazilian population of patients with lung cancer. Additional studies are needed for the development of more accurate mortality risk scores in this population.

Keywords: Lung cancer, mortality risk, surgery

P2.17-14 IMPAIRED IMMUNE DEFENSE IN TUMOR MICRO-ENVIRONMENT IS ASSOCIATED WITH RISK OF RECURRENCE IN EARLY STAGE LUNG ADENOCARCINOMA

Y. Lou, A. Khoor, M. Thomas, J. Kachergus, Y. Ma, Y. Zhang, R. Chen, K. Knutson, A. Thompson

Mayo Clinic, Jacksonville/United States of America

Background: Despite curative surgery with or without chemotherapy, 27-76% of surgically resected early stage lung cancer will unfortunately develop recurrence which is often fatal. Platinum-based adjuvant chemotherapy in NSCLC improves cure rates in only 5% of patients at the cost of significant toxicities. Developing biomarkers to select high risk patients and strategies to reduce recurrence in early stage lung cancer are critical. **Method:** Thirty surgically resected primary lung adenocarcinomas from 16 patients with lung cancer recurrence and 14 patients without recurrence in 4 years were included in this study. Among these 30 patients, 27 have either stage I or II. RNA sequencing (694 genes and 14 key immuno-oncology (IO) pathways) was determined using nanoString technology and RNA from primary tumors from recurrent versus non-recurrent patients. **Result:** Chemokines including CCL18, CCL23, CXCL1, CXCL2, CCL26 and chemokine receptors CXCR2, CX3CR1 and TNFRSF10C were significantly decreased in tumors from patients who had recurrence versus those from patients without recurrence. By contrast, genes related to cancer associated fibroblasts in the stromal microenvironment such as LRRC15 and genes involved in release of cancer cell antigens were significantly increased in adenocarcinomas from recurrent patients.

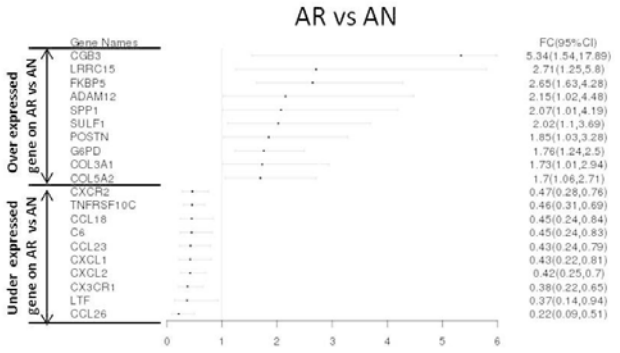

Figure 1. Top 10 gene over-expressed and under-expressed in surgically resected early stage adenocarcinomas from patients with recurrence (AR) versus patients without recurrence (AN)

Conclusion: Our results suggest that recurrence in early stage lung adenocarcinoma might be related to impaired immune defense such as decreased immune cell trafficking and antigen release in tumor micro-environment. Further study with larger sample size is warranted.

P2.17-15 CLINICAL FEATURES AND PROGNOSIS OF LUNG CANCER WITH CAVITY LESION

H. Okuma, S. Tane, Y. Nishioka, H. Ogawa, Y. Kitamura, W. Nishio, M. Yoshimura

Hyogo Cancer Center, Akashi City, Hyogo Prefecture/Japan

Background: There have been conflicting results about the clinical features and prognosis of primary lung cancer with cavity lesion (LC-CL). We, therefore, revisited the clinicopathological features of primary LC-CL and reassessed whether they exhibited poor prognosis in non-small-cell lung cancer. **Method:** Between 2006 and 2014, 377 patients underwent complete resection for clinical T1aN0 non-small-cell lung cancer. Clinical stage was adapted to the seventh edition of the lung cancer stage classification system. Among these cases, 23 (6.1%) were diagnosed as LC-CL. We compared the characteristics and prognosis between LC-CL and the others. **Result:** LC-CL showed higher CEA (≧5 ng/mL) (p<0.01), higher SUV max (≧2.5) (p=0.02), the status of smoking history (p<0.01), larger actual pathologic tumor size (≧3cm) (p<0.01), lymphatic invasion (p=0.03), as compared with the others. The overall and recurrence-free survival of the patients with LC-CL were shorter than those of the others (p=0.01 and 0.03, respectively). Univariate analysis revealed that sex (p=0.01), age (≧70) (p<0.01), CEA (p<0.01), SUV max (p<0.01), smoking history (p<0.01), pathologic tumor stage (≧II) (p=0.01), vascular invasion (p<0.01), lymphatic invasion (p=0.04), pleural invasion (p<0.01) and cavity lesion (p=0.01) showed significant poor prognostic factors. Multivariate analysis revealed that age (p=0.02) and SUV max (p<0.01) remained significant prognostic factors, but cavity lesion was not significant (p=0.17). **Conclusion:** Although the value of its prognostic factor was not significant, primary LC-CL should be considered to have aggressive malignant behavior in non-small-cell lung cancer.

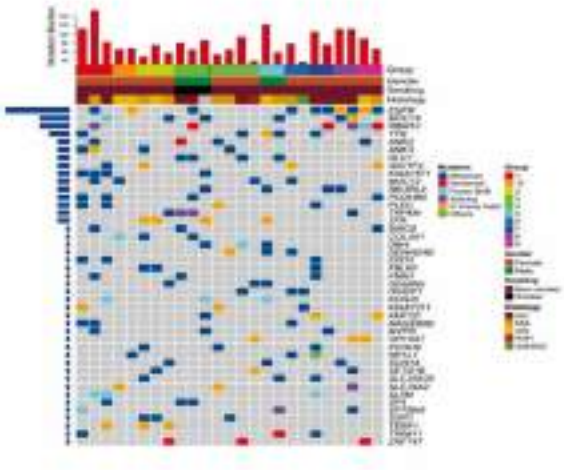
Keywords: Lung cancer, cavity lesion

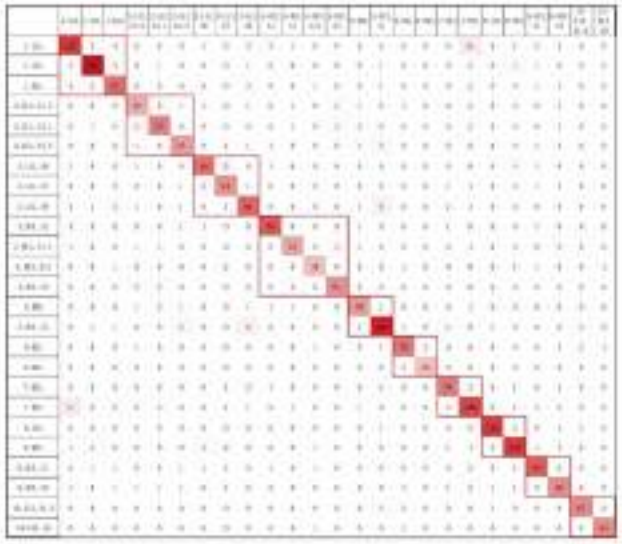
P2.17-16 GENOMIC HETEROGENEITY AND EVOLUTIONARY TRAJECTORY IN MULTIFOCAL SYNCHRONOUS LUNG CANCER

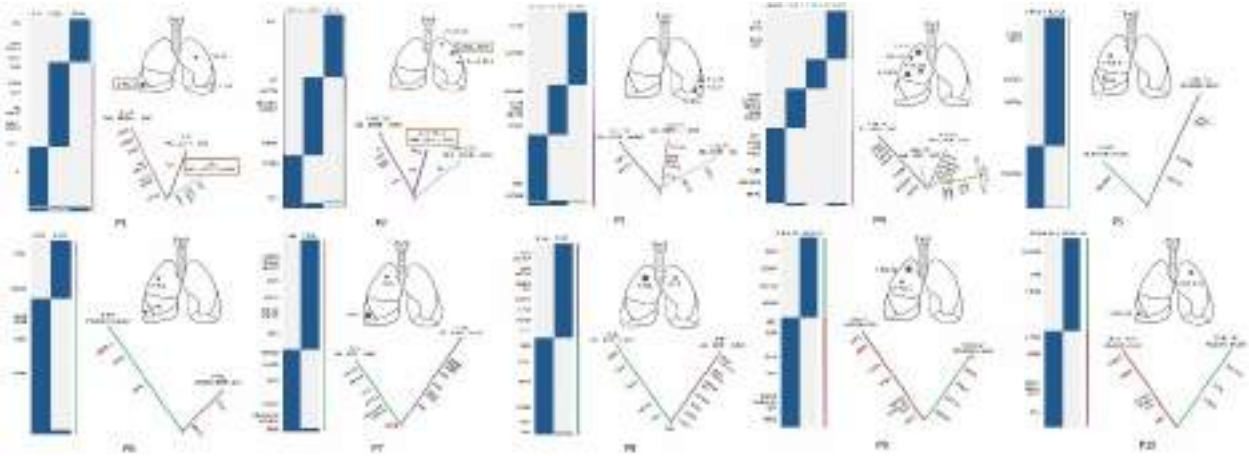
S.-Y. Liu[1], C. Zhang[1], J. Su[1], X. Gao[1], L.-P. Chang[2], H.-H. Yan[1], Y.-F. Guan[2], H. Tu[1], J.-J. Yang[1], X.-C. Zhang[1], X.-N. Yang[1], Y.-L. Wu[1], W.-Z. Zhong[1]

[1]*Guangdong Provincial People's Hospital, Guangzhou/China,* [2]*Geneplus-Beijing Institute, Beijing/China*

Background: Multifocal synchronous lung cancer (MSLC) presented as coexistence of multiple tumor lesions that share an identical germline genetic background and environmental exposure in individual patients. Along with the improved resolution of cross-sectional imaging, multiple types of ground glass opacities (GGOs) have been detected in increasing frequency as well as solid nodules even in an unique patient. However the molecular origins and relationships among the synchronous lesions remain unclear. **Method:** 10 treatment-naive MSLC patients were retrospectively collected while 25 tissue samples were performed whole exosome sequencing. In addition, we constructed phylogenetic trees to estimate the ancestral relationships of individual foci. **Result:** 79 somatic mutations in average were identified in MSLC tissues. The most significant mutated gene *EGFR* has been detected in 10 samples from 7 patients in our cohort. Tumor mutation burden as was significantly higher in IAC lesions than AIS/MIA ones. The mutation spectra of single-nucleotide variations (SNVs) were fairly consistent across the same histologic type even from different patients. Compared to AIS/MIA, IAC samples displayed a preponderance of A>T/T>A transition (Ti) while less frequency of A>C/T>G transversion (Tv). However few share mutations were located by pair of lesions in individual patients. Distinct genomic profiles suggested all were primary tumours. WNT pathway was enriched in AIS/MIA lesions exclusively while IAC appeared TGFβ/TP53 pathway mutation associated with cell proliferation and apoptosis.







Conclusion: Even in the same individual patient different lung cancer lesions may be driven by distinct genomic profiles so that each presented its own evolutionary trajectory. A deeper understanding of tumorigenesis is still in need to improve the diagnosis and treatment of MSLC.

Background: The efficacy of adjuvant chemotherapy in stage IB NSCLC with high-risk factors remains unclear. We analyze the clinical effect of adjuvant chemotherapy in patients with high-risk factors such as visceral pleural involvement, and micro-papillary type, etc. **Method:** This study is a multicenter retrospective study. We retrospectively analyzed 269 stage IB NSCLC with high-risk factors receiving lung resection operation from four academic hospitals. We defined the high-risk factors as visceral pleural invasion, vascular invasion, peri-neural invasion, lymphatic invasion, neuroendocrine tumors, and micro-papillary pattern. We used a Kaplan-Meier survival curve to analyze recurrence-free survival and overall survival. **Result:** There were 139 (51.7%) males and 130 (48.3%) females and the mean patient age was 65.6 ± 9.7 years. There were 142 patients without adjuvant chemotherapy and 127 patients with adjuvant chemotherapy. The median follow-up duration was 31.7 months (range, 2.7 to 60.0 months). And the recurrence-free survival was 48.8 ± 1.8 months in the no adjuvant group, and 54.0 ± 1.5 months in the adjuvant group (*P=0.028*). And the overall survival was 57.9 ± 0.9 months in the no adjuvant group, and 59.3 ± 0.7 months in the adjuvant group (*P=0.124*). In the sub-group analysis (visceral pleural involvement group), the recurrence-free survival was 48.2 ± 2.1 months in the no adjuvant group, and 55.3 ± 1.6 months in the adjuvant group (*P=0.011*) **Conclusion:** Adjuvant chemotherapy may be useful for patients with Stage IB NSCLC with high-risk factors. And, adjuvant chemotherapy should be considered especially when there is visceral pleural involvement

P2.17-18 ACUTE RESPIRATORY DISTRESS SYNDROME AFTER CURATIVE SURGICAL RESECTION FOR LUNG CANCER

S. Choi, D. Cho, H.S. Park, G. Heo, Y. Chang

St. Vincent Hospital, Suwon/Korea, Republic of

Background: Bilateral lung infiltration is the most dreadful sign after lung cancer surgery. Either it is post -operative pneumonia or exacerbation of underlying lung disease (Interstitial lung disease), the lungs gradually shut down and finally develop ARDS (Acute Respiratory Distress Syndrome). Here, we report our experience and treatment outcome of post-operative ARDS after curative surgical resection for lung cancer. **Method:** From October 2008 to April 2017, the patients who underwent curative surgical resection for primary lung cancer were analyzed. We retrospectively reviewed medical records in two hospitals. **Result:** A total of 2140 patients were enrolled. Among them, 1246 were male (58.2%) and 894 were female (41.8%). The mean age was 64.5±10.0. In surgical procedures, 1496 (70%) cases of lobectomy, 117 (5.5%) cases of segmentectomy, 201 (9.4%) cases of wedge resection, 71 (3.3%) cases of bilobectomy, and 31 (1.4%) cases of pneumonectomy were performed. Combined procedures (lobectomy with wedge resection) were 222 (10.4%) cases. With Berlin definition of ARDS, a total of 29 (1.4%) patients were diagnosed. In table 1, we compared two groups and analyzed risk factors using univariable analysis. In multivariable analysis (table 2), advanced age, %VC(vital capacity), and underlying lung disease were associated with ARDS. Of 29 ARDS patients, 19 (65.5%) patients died in spite of maximum treatment. Broad antibiotics (96.6%), and steroid therapy (86.2%) were most applied treatments. We compared the patient's characteristics and the timing of treatment between two groups (survivor / non-survivor). But, there was no clinical significance.

CPFE	20.49	<0.01	4.06	103.51

Table 2. Multivariable risk factor analysis for ARDS

Conclusion: In conclusion, ARDS after lung cancer surgery is rare but fatal. Advanced age, low vital capacity, and patient's underlying lung diseases are possible risk factors for ARDS after surgery. In practice, various treatments including broad antibiotics and steroid therapy are applied to treat or control this disaster. But still, mortality is extremely high and their role is uncertain.

Background: Preserving health related quality of life (HRQOL) plays an important role in considering stereotactic body fractionated radiotherapy (SBRT). The prospective monocenter phase II STRIPE trial investigated long-term HRQOL after SBRT, efficacy and toxicity. **Method:** Patients with ≤ 2 pulmonary lesions ≤ 5cm were treated with 4DPET/CT-based SBRT (3X12.5Gy or risk-adapted 5X7Gy, to the 60% isodose). Follow up (FU) was performed 2 and 7 weeks after SBRT, then 3monthly for 2 years with assessment of response (primary endpoint: 2-year cumulative incidence of local progression (LP); secondary endpoints: local progression free (LPFS), overall survival (OS) and toxicity (CTCAE)). Impact of predefined patient and treatment related factors on HRQOL (EORTC QLQ-C30 and EORTC QLQ-LC13) was evaluated. **Result:** Between 02/2011 and11/2014, 100 patients were given SBRT for 56 NSCLC and 44 pulmonary metastases. Long-term FU overall revealed stable Quality of Life (QoL)/Global health status (GHS), functions-scores and symptoms. For QoL/GHS, patients with low initial QoL/GHS-Score below the median of 50, revealed significantly stronger improvement than those with good QoL/GHS-scores ($p < 0.001$). Probability for LP, LPFS and OS 2 years after SBRT was 8.1%, 53.3% and 62.2%. Lower risk for LP was revealed for 3X12.5Gy ($p=0.043$) and for Dmin (Biological Effective Dose10) in the Planning Target Volume>100Gy ($p=0.023$). ≥G3-Toxicity was < 4%, except dyspnea: ≥G3 dyspnea was 6% at baseline and 14.5% 2 years after SBRT. **Conclusion:** These prospective data on a representative cohort of pulmonary SBRT patients confirm a stable preservation of HRQOL after SBRT and furthermore demonstrate a QoL/GHS-benefit for patients with low initial QoL/GHS-scores, the regimen of 3x12.5 Gy SBRT being efficient and well tolerated. This result may inform shared decision making when discussing SBRT for frail patients

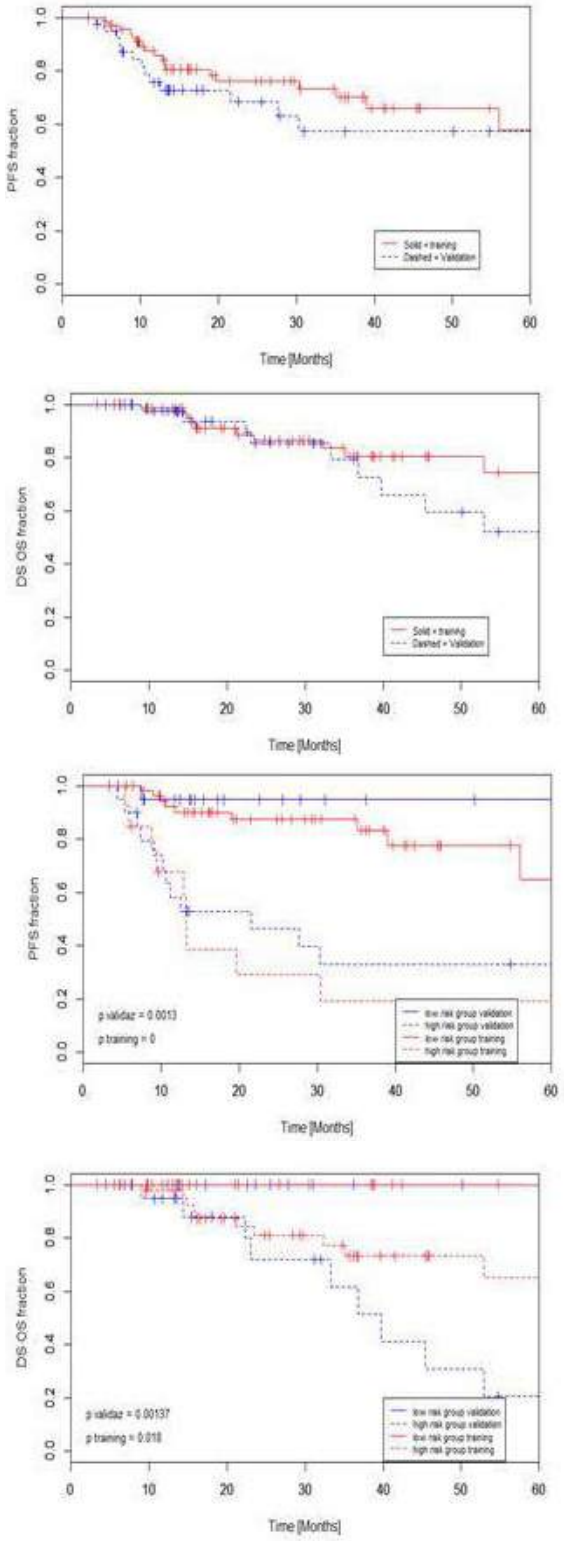
P2.17-20 A RADIOMIC APPROACH TO PREDICT NODAL AND DISTANT RELAPSE IN PATIENTS TREATED WITH STEREOTACTIC BODY RADIATION THERAPY FOR EARLY STAGE NSCLC

D. Franceschini, L. Cozzi, D. Pezzulla, F. De Rose, C. Franzese, S. Tomatis, M. Scorsetti

Humanitas Clinical and Research Centre, Rozzano (Milan)/Italy

Background: Regional and distant relapse remain a significant issue in the treatment of early stage non small cell lung cancer with Stereotactic Body Radiation Therapy (SBRT). There is a need for predictive biomarkers able to identify patients that are at higher risk of relapse. In this work we present a radiomic approach using features extracted by routine planning CT, to predict the risk of nodal and distant recurrence. **Method:** A cohort of 102 patients was retrospectively investigated. All patients were affected by early stage (T1-T2) lung cancer and received the same radiation treatment with 48Gy delivered in 4 fractions. For all patients, a set of 45 radiomics textural features was computed for the tumor volumes segmented on the treatment planning CT images. Patients were split into two independent cohorts used for training (70% of cases) and validation (30% of cases). A stepwise backward linear discriminant analysis (LDA) was applied as a classifier to identify patients at risk of lymph-nodal progression. The performance of the model was assessed by means of standard metrics derived from the confusion matrix. Furthermore, all textural features were correlated to survival data to build predictive models: the features/predictors found significant at univariate analysis and to elastic net regularization, were included in a multivariate model to predict disease specific progression free survival (PFS) and disease specific survival (DS OS). Low and high risk groups were identified by maximizing the separation by means of the Youden method. **Result:** In the total cohort (77 (75.5%) males and 25 (24.5%) females, median age 76.6 years), 15 patients presented nodal progression at the time of analysis (11 in the training and 4 in the validation sets); 19 patients (18.6%) died because of disease specific causes, 25 (24.5%) died for other reasons, 28 (27.5%) were alive without disease and 30 (29.4%) with either local or distant progression. The mean tumor volume was 5.6±6.4cm3. Figure 1 illustrates the actuarial curves for PFS and DS OS over the entire training and test cohorts (in both cases the difference was not significant) and the same data stratified in low and high risk groups identified. In all case highly significant differences were identified.



Conclusion: Radiomics features extracted from treatment planning CT images can distinguish patients with low and high risk of tumor progression and disease specific death in early stage lung cancer treated with SBRT.

P2.17-21 A POST-HOC ANALYSIS OF TROG 09.02 (CHISEL) PHASE III TRIAL INVESTIGATING PULMONARY FUNCTION CHANGES AFTER SABR AND CONFORMAL RADIATION THERAPY

N. Bucknell[1], T. Kron[2], A. Herschtal[2], L. Irving[2], S. Siva[1], D. Ball[1]

[1]*Melbourne University, Melbourne/Australia,* [2]*Peter MacCallum Cancer Centre, Melbourne/Australia*

Background: The TROG 09.02 (CHISEL) trial compared conventional radiotherapy (CRT) administered over a period of four to six weeks with stereotactic ablative body radiotherapy (SABR).(1) Patients randomised to the SABR arm had superior freedom from local failure and longer overall survival.(1) The aim of this analysis was to assess differences in lung function and spirometry tests between SABR and CRT and describe longitudinal changes in respiratory function. **Method:** We conducted a post-hoc analysis of all patients recruited to the CHISEL trial. During this trial patients underwent serial Respiratory Function Tests (RFT) including Forced Expiratory Volume in one second (FEV1), Diffusing capacity of the lungs for carbon monoxide (DLCO), Distance Walked in 6 minutes (SMWT) and Forced Vital Capacity (FVC). These were performed at baseline then 3-6 monthly post-treatment. Patients were assessed per treatment received. Linear regression models were used to compare FEV1, FVC and DLCO between SABR and CRT. Separate models at 3 and 12 months post-treatment were created to assess the two different processes impacting lung function post radiation therapy (acute pneumonitis and chronic fibrosis). Linear regression models were used to assess the association of baseline PFT Measures with decline in respiratory function at 3 and 12 months. **Result:** Between December 2009 and June 2015, 101 patients were treated in 11 centres in Australia and New Zealand. 34 patients were treated with CRT and 63 with SABR. On regression analysis at 3 months there was no evidence of a difference between arms in the change from baseline in absolute values of FEV1 (beta 0.037, 95% CI [-0.063, 0.14], p=0.47), DLCO (beta -0.5, 95% CI [-1.4, 0.37], p=0.26) nor forced VC (beta 0.024, 95% CI [-0.17, 0.22], p=0.81). At 12 months there were no differences observed in change from baseline of FEV1 (beta0.031, 95% CI [-0.12, 0.18], p=0.69), DLCO (beta -0.43, 95% CI [-1.7, 0.84], p=0.51) nor forced VC (beta 0.047, 95% CI [-0.28, 0.18], p=0.69) between arms.There was no evidence of a difference in the change from baseline in SMWT (m) between two arms at 3 months (beta 35.9, 95% CI [-10, 82.3], p=0.13).Patients in both arms demonstrated similar deterioration in all RFT parameters with time. **Conclusion:** Despite the considerably higher biologically effective doses delivered to the tumour in SABR there was no difference in decline in respiratory function observed between the two groups. This is likely due to the higher integral dose, steep dose gradients and reduced margins possible with SABR relative to CRT.

Background: We have recently demonstrated that the presence of the Spread Through Air Spaces (STAS) increased the risk of recurrence after resection for small lung adenocarcinoma (ADC). Currently, the TNM classification of lung cancer was revised and T-factor was changed to be basically determined by its invasive size. The purpose of this study is to examine the impact of presence of STAS in stage IA ADC according to the 8th TNM classification. **Method:** Patients with pleural invasion, lymph node metastasis, distant metastasis, and neoadjuvant therapy were excluded. All available tumor slides from patients with surgically resected solitary lung ADC (2000-2015) were reviewed. Patients with stage IA ADC according to the 8th TNM classification were collected. Overall survival (OS) and recurrence-free probability (RFP) were estimated using the Kaplan-Meier method. Propensity score was generated from age, operation year, gender, lymphatic invasion, vascular invasion, the presence of solid component ≥5%, the presence of micropapillary component ≥5%, limited resection, and invasive size. One-by-one nearest neighbor matching by the presence of STAS was adapted to reduce the bias. **Result:** In all, 295 patients met study criteria with median age of 68. Male gender comprised 48.8% (n=144), lymphatic invasion positive 4.7% (n=14), and vascular invasion positive 14.9% (n=44). By T-factor (7th edition), 216 (73.2%) were T1a, 53 (18.0%) T1b, 23 (7.8%) T2a, 2 (0.7%) T2b, and 1 (0.3%) T3. By T-factor (8th edition), 100 (33.9%) were T1mi, 111 (37.6%) T1a, 70 (23.7%) T1b, and 14 (4.7%) T1c. By operation method, 241 (81.7%) underwent lobectomy, 15 (5.1%) segmentectomy, and 39 (13.2%) partial resection. Adjuvant chemotherapy was given in 2.7% (n=8) of patients. STAS was seen in 22.7% (n=67) of patients. Five-year OS was 95.3% for STAS-negative and 91.1% for STAS-positive (p=0.0262), and the 5-year RFS was 96.8% and 83.9%, respectively (p=0.0003). In matched cohorts, each cohort included 48 patients and the 5-year OS was 95.0% for STAS-negative and 90.6% for STAS-positive (p=0.3201). The 5-year RFS was 93.3% and 91.3%, respectively (p=0.9363). **Conclusion:** Patients with pathologic stage IA ADC with STAS, according to the 8th TNM classification, had a worse prognosis in unmatched cohorts even though adenocarcinoma in situ was excluded. Because of various confounding factors, the propensity score matching revealed the presence of STAS as a non-significant prognostic factor in our matched cohorts. This study was a retrospective analysis, and a prospective study is needed regarding the indication of limited resection.

Background: Adjuvant chemotherapy is accepted as a standard treatment for suitable patients who have undergone surgery for T2N0 non-small cell lung cancer with tumors larger than 4 cm. Despite similar relapse rates, the benefit of adjuvant chemotherapy for smaller tumors with high risk features is not clear. In this retrospective analysis our aim was to evaluate the prognostic impact of adjuvant platin-based chemotherapy in high-risk stage 1 NSCLC patients. **Method:** This cooperative group study included 250 NSCLC patients who underwent curative surgery for stage 1 NSCLC with tumor size 2-4 cm and adverse prognostic factors consisting of visceral pleural invasion(VPI), lympho-vascular invasion(LVI), high grade, presence of solid-micropapillary(SMP) components or STAS. Records of patients were analyzed to investigate the prognostic impact of adjuvant chemotherapy in this cohort. DFS was defined as the time from surgery to the last follow-up, until relapse or death, CSS;time from surgery to death related to cancer or last known contact, OS;time from diagnosis to death or last known contact. Statistical analysis was performed using SPSS 20.0 software(SPSSInc,Chicago,USA). **Result:** Median age at presentation was 63 years (range 18-90). The mean tumor size was 29.4 ± 7.4 mm. The frequency of patients with specified risk factors were: VPI: n: 92 (36.8%); LVI: n: 91 (36.4%); Grade 3:n: 49 (19,6%); SMP:n: 76 (30.4%); STAS:n: 15 (6%). A total of 51 patients had received adjuvant platin-based chemotherapy. There were significantly more patients who received chemotherapy

in the younger age group (<65 ears old, ≥65 years old) and those with larger tumors (2 – 3 cm, 3 – 4 cm). During a median follow-up period of 91.8 months; 79 patients(31.6%) experienced recurrence, 62 patients(24.8%) have died, 144 patients(57.6%) were alive without disease and 24 patients (9.6%) were alive with disease. 5-year and 10-year OS rates were 72.7%(± 3,5) and 46.8%(± 8), respectively. There was a significant improvement in DFS with adjuvant chemotherapy, especially in groups with VPI (93.3% vs 53.6%, p:0.016) and SMP (92.3% vs 57.3%, p:0.03). There was also a non-significant trend for improved CSS and OS among patients who received CT.

Table 1. Effects of chemothrapy on survival.

	Chemotherapy Group Events/N Median 5-years DFS	Non - treatment Group Events/N Median 5-years DFS	P Value
DFS	12/51 NE % 74.9 ± 6.3	81/190 71.1 months % 54 ± 4.2	0,032*
CSS	4/49 NE % 89 ± 5	41/179 91.8 months % 76.9 ± 3.8	0,078
OS	10/49 NE %77.4 ± 6.4	51/179 88.9 months % 72.1 ± 4	0,541

*All values are stratified, respecting to significant confounding factors such as age, gender and tumor size. **Conclusion:** Adjuvant platin-based chemotherapy should be considered for this subset of patients having high grade tumors, or those with VPI, LVI or solid-micropapillary components. Prospective, randomized trials incorporating clinical and molecular risk factors are required to clarify the role of adjuvant chemotherapy for stage 1 NSCLC patients.

P2.17-24 MINIMALLY INVASIVE SURGERY FOR LUNG CANCER IMPROVES SHORT TERM OUTCOMES IN PATIENTS WITH HISTORY OF HEAD AND NECK CARCINOMA

D. Boulate[1], T. Kassegne[1], J. Chenesseau[1], M. Ammi[1], S. Mussot[1], D. Fabre[1], D. Mitilian[1], A. Crutu[1], S. Temam[2], O. Mercier[1], E. Fadel[3]

[1]*Hopital Marie Lannelongue, Le Plessis-Robinson/France,* [2]*Gustave Roussy, Villejuif/France,* [3]*Hopital Marie Lannelongue, Le Plessis Robinson/France*

Background: Lung cancer resections are at high risk for major complications in patients with history of head and neck carcinoma (HNC). We initiated a minimally invasive video assisted thoracic surgery (VATS) program since 2014. Our objective was to determine whether VATS lobectomy had better short term outcome than open lobectomy in this subset of patients. **Method:** We performed a retrospective monocentric analysis of consecutive standard lobectomies performed for lung cancer in patients with history of HNC at our institution between January 2010 and December 2017. Patients with more complex procedures were excluded. Patients' characteristics and short term outcome were compared between VATS and open lobectomy (OL) groups. Quantitative data were compared using parametric test when normally distributed and using non-parametric test when not normally distributed. Qualitative data were compared using Chi2 or exact Fischer's test when appropriate. P<0.05 was considered significant. **Result:** Among 85 patients, 52 underwent an OL and 33 VATS lobectomy. There was no significant difference between the two groups regarding age, sex ratio, HNC location, history of HNC treatment, pathology and stage of lung cancer, history of coronary artery disease, respiratory function or neutrophil to lymphocyte ratio. Postoperative death occurred in 2 patients only in the OL group. In the VATS group, there was a significant decrease in proportion of postoperative life-threatening complications requiring hospitalization in intensive care unit (12/52 vs. 1/33, P=0.01). The main results are reported in the Table.

Table: Patients characteristics and short term outcomes after video-assisted (VATS) or open lobectomy among patients with history of head and neck carcinoma (HNC). IQR: interquartile range; BMI: body mass index; preop: preoperative; N/L ratio: neutrophil to lymphocyte ratio; SCC: squamous cell carcinoma; ICU: intensive care unit. P<0.05 was considered significant.

Conclusion: We found that minimally invasive thoracic surgery was associated with better short term outcomes compared to open surgery for lung cancer resection in patients with history of HNC. Therefore, we suggest that standard lobectomy in patients with history of HNC should be performed by VATS procedure. Further studies are required to confirm our finding.

P2.17-25 GENOMIC INSIGHT INTO STAGE I PULMONARY ADENOCARCINOMA FOR RECURRENCE BY TARGETED NEXT-GENERATION SEQUENCING ANALYSIS

I.A. Kim[1], H. Kim[1], J.Y. Hur[1,2], W.S. Kim[2], J.J. Hwang[1], S.A. Lee[1], K.Y. Lee[1,2]

[1]*Konkuk University Medical Center, Seoul/Korea, Republic of,* [2]*Konkuk University School of Medicine, Seoul/Korea, Republic of*

Background: Despite surgical resection, stage I pulmonary adenocarcinoma has a recurrence rate of 18.4%–25%. Prognostic markers of localized lung adenocarcinoma remain undefined. Targeted next-generation sequencing (NGS) is supposed to be useful to identify recurrence-related genes. We aimed to identify genes and co-occurring mutations that might predict recurrence after surgical resection of stage I pulmonary adenocarcinoma through targeted NGS. **Method:** Tissues from 202 patients who had complete resection of stage I pulmonary adenocarcinoma at Konkuk University Medical Center, from 2005 to 2017 (median follow-up: 48 months), were analyzed by targeted NGS using a panel of the 170 cancer-related genes (KF1 panel by Macrogen Inc. Korea,). We compared RFS (relapse-free survival) according to frequent genetic alterations using the Kaplan-Meier method and compared their combinations to identify recurrence-related genes by multivariate analysis. **Result:** The most frequent genetic alterations were EGFR (56.9%), TP53 (37.7%), KRAS (13.4%), and PIK3CA (10.4%) in surgically resected stage I pulmonary adenocarcinoma. In the tumors with single gene mutation, EGFR mutation was a good prognostic factor and TP53 mutation was a poor prognostic factor for recurrence. (EGFR mutation, HR 0.26, 95% CI 0.07-0.95, p=0.024 vs TP53 mutation, HR 3.39, 95% CI 1.17-9.8, p=0.02). In the tumors with two gene mutations, similar tendency has been observed but there was no statistical significance. Mutation of CTNNB1 was significantly related to recurrence in multivariate analysis (HR3.76, P=0.003) and this finding suggests the CTNNB1 as a molecular biomarker for recurrence by NGS method. TP53 and KRAS combination mutations tended to be associated with shorter RFS (HR=1.89, p=0.08). Recurrence was not associated with the number of the co-occurring mutations but with their specific combinations such as the combination of CTNNB1 and EGFR. **Conclusion:** The CTNNB1 mutation is associated with shorter RFS as compared with wild-type CTNNB1 in resected stage I adenocarcinoma. Larger datasets are required to validate whether the CTNNB1 gene is an independent predictive factor of early stage adenocarcinoma recurrence. NGS can be useful tool to predict the risk of recurrence and select the patient to need the adjuvant chemotherapy in stage I adenocarcinoma.

P2.17-26 INDOCYANINE GREEN VIRTUAL ASSISTED LUNG MAPPING (ICG-VAL-MAP): ANYONE CAN PERFORM A SUCCESSFUL PREOPERATIVE MARKING FOR A SMALL LUNG NODULE

T. Chen-Yoshikawa, S. Tanaka, Y. Yamada, Y. Yuataka, D. Nakajima, A. Ohsumi, M. Hamaji, T. Menju, H. Date

Kyoto University Hospital, Kyoto/Japan

Background: As a preoperative marking of small pulmonary nodules, we developed Virtual Assisted Lung Mapping (VAL-MAP), which is consisted of preoperative simulation using three-dimensional CT images and transbronchial dye marking using indigocarmine (IC). Between 2012 and 2016, we performed VAL-MAP in more than 200 cases in a single institution; however, we sometimes came across a situation, in which an identification of marked IC was difficult at post-marking CT and/or during surgery. Herein, we have developed a new VAL-MAP (ICG-VAL-MAP) using indocyanine green (ICG) and contrast agent. The purpose of this study was to prospectively evaluate the visibility of newly-developed ICG-VAL-MAP in an identification of ICG at post-marking CT as well as during surgery. **Method:** Between January in 2017 and February in 2019, we performed ICG-VAL-MAP, using ICG and contrast agent in addition to IC as a marker for preoperative nodule identification, in 88 patients at our institution. Preoperative marking was performed on the same day as surgery or 1 day before surgery. During surgery, fluorescence endoscope system was used for identification of marked ICG. **Result:** Targeted lesions were 105 nodules with the diameter ranging from 2 to 38 mm (median 8 mm). The depth of the lesion from the pleural surface ranged from 0 to 49 mm (median 8 mm). Total marking numbers were 208 (IC: 99, ICG: 109). At post-marking CT, IC was easily identified in 78 markings (78%), difficult to be identified in 10 markings (10%), and unable to be identified in 11 markings (11%). On the other hand, ICG was easily identified in all markings at post-marking CT. During surgery, IC was easily identified in 74 markings (74%), slightly identified in 4 markings (4%), and unable to be identified in 21 markings (21%). On the other hand, ICG was easily identified in 108 markings (99%) during surgery. Only in 1 case, ICG marking was accidentally placed far from a pleural surface, but ICG was slightly identified in a collapsed lung during surgery. In summary, ICG was significantly easily identified than IC during surgery (P<0.0001) as well as at post-marking CT (P=0.0002). There were no significant perioperative complications related to ICG-VAL-MAP. All nodules were identified intraoperatively and an appropriate surgical resection was conducted in each patient. In details, 53 wedge resections, 48 segmentectomies and 2 lobectomies were performed. Furthermore, all nodules were diagnosed pathologically (74 primary lung cancer, 24 metastatic lung cancer, and 7 benign nodule). **Conclusion:** We confirmed that ICG-VAL-MAP was a novel and promising technique with better visibility than conventional VAL-MAP for the complete resection of small pulmonary nodules.

P2.17-27 EVALUATION OF MEDIASTINAL LYMPHADENECTOMY QUALITY IN PATIENTS OPERATED FOR NSCLC FROM THE PAULISTA LUNG CANCER REGISTRY(PLCR)

L. Lauricella[1,2], R. Terra[1,2], F. Minamoto[2], J. Gross[3], F. Haddad[3], H. Nietmann[4], P. Da Costa[2], P. Pego-Fernandes[5]

[1]*Instituto do Cancer do Estado de Sao Paulo, Sao Paulo/Brazil,* [2]*Faculdade de Medicina, Universidade de Sao Paulo, Sao Paulo/Brazil,* [3]*ACCamargo Cancer Center, Sao Paulo/Brazil,* [4]*Hospital de Base de São José do Rio Preto, Sao Paulo/Brazil,* [5]*Instituto do Coração, Sao Paulo/Brazil*

Background: To describe the quality of mediastinal lymphadenectomy in patients operated on for NSCLC considering the resectability criteria proposed by IASLC in 2005 and to evaluate the impact of the definition of complete, uncertain and incomplete resection in overall survival and disease free survival in 5 years. **Method:** Retrospective data from patients operated on for NSCLC between Jan/ 2002 and Dec/2018 in 4 institutions in the state of São Paulo were extracted from a prospective database, the Paulista Lung Cancer Registry (PLCR). Complete resection was defined by the absence of gross and microscopic residual disease, systematic lymph node dissection, and negativity of the highest mediastinal lymph node removed. Uncertain resection was defined by free resection margins, but with less rigorous lymph node evaluation than systematic dissection and/or positivity of the highest mediastinal lymph node removed. Incomplete resection was defined by the presence of gorss or microscopic residual disease. Patient follow-up was updated until Jan/2019. Overall survival was analyzed by the Kaplan-Meier method, Log rank test and Cox proportional regression. **Result:** A total of 663 patients were identified. Mean age was 65.64 years, 338 men(50.9%). The predominant histological type was adenocarcinoma(n = 466, 70.2%), followed by squamous cell carcinoma(n = 162, 24.4%). Lobectomy was the most commonly performed procedure(n = 576, 86.8%), followed by segmentectomy and pneumonectomy(n = 40, 6.0% and n = 34, 5.1%, respectively). There was 388 patientes(59.81%) classified as stage I, 146(23.1%) stage II, 97(15.3%) stage III and 11(1.74%) stage IV. Resection was complete in 374 cases (56.4%), uncertain in 252 cases(38.0%) and incomplete in 37 cases(5.5%). Mediastinal lymphadenectomy was adequate in 421 cases (63.4%) and inadequate in 242 (36.5%). Reasons for inadequate lymphadenectomy were: no nodal station sampling (n = 30, 4.5%), no station 7 sampling (n = 103, 15.5%) and sampling of less than 3 mediastinal stations (n = 109, 16.4%). The highest mediastinal lymph node removed was positive in 45 cases (6.7%). Surgical margins were positive in 37 cases (5.5%). The median follow-up was 19.5 months (IQR 7.4 - 42.5), and 5 years follow-up was completed in in 15.5%. During follow-up, 133 (20.4%) patients had recurrence of the disease. Median disease-free survival was 64 months in the general group and 84.0, 58.6 and 31.5 months in the complete, uncertain and incomplete resection groups, respectively (log rank p = 0.15). Median overall survival in the complete resection group was 98.3 months, in the uncertain resection group it was 64 months. The incomplete resection group did not reach the median. There was no statistical difference in survival between groups (log

rank p = 0.22). **Conclusion:** The analysis showed a high prevalence of uncertain resection, but comparable to other studies already published. This demonstrates that lymphadenectomy is not being performed according to IASLC recommendations. However, in this study, there was no impact on overall survival and disease-free survival at 5 years, which may be due to the small sample size and the short follow-up time of the vast majority of patients included in the PLCR.

P2.17-28 EXAMINATION OF THE INDICATION AND VALIDITY OF SEGMENTAL RESECTION AS INTENTIONAL AND PALLIATIVE LIMITED RESECTION FOR LUNG CANCER

K. Kojima[1], Y. Morifuji[1], H. Inoue[1], H. Umeguchi[1], M. Kato[2], C. Takasaki[3], M. Yano[3], K. Okubo[4]

[1]*Karatsu Red-Cross Hospital, Karatsu-shi, Saga/Japan,* [2]*Hiramatsu Hospital, Ogi City/Japan,* [3]*Musashino Red-Cross Hospital, Musashino-shi, Tokyo/Japan,* [4]*Tokyo Medical and Dental University, Tokyo/Japan*

Background: Segmental resection with lymph node dissection as intentional limited resection is now regarded as the effective surgical procedure for early lung cancer from the view point of curability and preservation of respiratory function. But the curability of this procedure for more advanced cancer is not well known. We may show it by investigating the detailed results of all segmental resection cases as intentional and palliative limited resection. **Method:** We targeted 167 cases who passed more than five years after operation among 240 lung cancer cases on whom we have performed segmental resection with lymph node dissection between January in 2003 and March in 2019. It was decided that the indication of segmental resection as intentional limited resection was cStage 0, IA1 and IA2 (UICC 8th) with meeting the SUVmax value of FDG-PET was 1.5 or less (=group A). Segmental resection as palliative limited resection was performed on cStage IB or less patients who had difficulty in lobectomy because of poor respiratory function, multiple lung cancer or presence of serious other disease, etc, (=group B). We investigated prognosis and pathological recurrent factors in both groups, and we considered each indication of segmental resection as intentional or palliative limited resection again. **Result:** Group A contains 102 cases and 5-year survival rate was 97% (All death cases died of other disease). In group A, local recurrence occurred in 1 case (pStage IA1, surgical margin insufficient) but distant metastasis did not occur. Group B contains 65 cases and 5-year survival rate was 71% (The original death from lung cancer was 5 cases among 17 death cases). In group B, local recurrence occurred in 4 cases (pStage IA2: 1(surgical margin insufficient), pStage IB: 2, pStage IIIA: 1), distant metastasis occurred in 6 cases (pStage IA3: 1, pStage IB: 1, pStage IIIA: 3, pStage IIIB: 1) and 3 cases on which postoperative adjuvant chemotherapy had been performed had no recurrence (pStage IB: 1, pStage IIB: 2). Recurrence of pStage IA3 was only 1 case (10% in all pStage IA3 cases, Sm, distant metastasis). The multivariable analysis of pathological recurrent factors (pStage, p, v, ly) in group B (except for 3cases on which postoperative adjuvant chemotherapy was performed) showed that lymphatic involvement had a significant influence on recurrence (p-value / Hazard ratio: lymphatic involvement: 0.03 / 6.49, more than pStage II: 0.37 / 2.50). **Conclusion:** We are convinced that the current indication of our intentional limited resection to be almost proper but we have thought that we should include a part of Stage IA3 depending on a condition. In palliative limited resection cases, postoperative adjuvant chemotherapy should be considered if possible when pathological result show lymphatic involvement or more than pStage II.

Background: The ATS/ERS/IASLC adenocarcinoma classification allowed not only a better anatomical-pathological definition, but it showed a significant influence on long-term outcomes. It has been proposed that adenocarcinoma patterns could be divided in three groups according to their clinical and pathological behaviors: low (lepidic), moderate (papillary or acinar) and high grade (micropapillary and solid). Moreover, different patterns might mingle influencing biological features and prognosis. We focused on resected adenocarcinomas analyzing the impact of second predominant pattern on recurrence rate and Disease-Free Survival (DFS). **Method:** We retrospectively collected all stage I and II lung adenocarcinoma operated on between January 2014 and December 2017 in seven European thoracic surgery departments. We selected all patients who underwent an anatomical resection with lymphadenectomy; patients with incomplete follow up, pure adenocarcinoma or those composed by more than two subtypes (if third pattern accounted for more than 10%) were excluded. Mucinous adenocarcinoma were considered separately from other patterns. DFS, incidence and localization of recurrence were calculated according to the second predominant pattern. **Result:** Among 500 patients, 331 were selected. There were 186 male, mean age was 68.1 years (±SD 8.2) and 105 (31.7%) patients were active smokers at the moment of diagnosis. The majority of patients (271, 81.9%) underwent a lobectomy. Low, medium and high-grade first predominant pattern were 45 (13.6%), 208 (62.9%), 57 (17,2%) respectively and 21 cases were mucinous. Second predominant pattern was present as follow: acinar 96 (29%), lepidic 86 (26%), papillary 74 (22.4%), solid 29 (8.8%), micropapillary 26 (7.9%), 20 mucinous (6%). DFS analysis showed a significant impact of grade of the second predominant pattern (p=0.046), while first predominant pattern's grade did not significantly impact on DFS (p=0.322). According to the subtypes of second predominant pattern, lepidic pattern showed a better mean DFS (56.1 versus 49.6 months, p=0.014) and a lower recurrence rate (p=0.018, and, in particular, a lower distant recurrence rate, p=0.016), while micropapillary had a worse DFS (42.3 versus 52.1 months, p=0014), higher recurrence rate (p=0.017, and in particular, a higher regional recurrence, p=0.038); moreover, also pleural invasion influenced DFS significantly (p=0.001). At multivariate analysis, lepidic second pattern and pleural invasion confirmed their influence on DFS (p=0.044, IC 0.28-0.98 and p=0.001, IC 1.36-3.4). When we analyzed the subgroup with only moderate grade (acinar and papillary) first predominant pattern (208 patients), lepidic and micropapillary second predominant patterns and pleural invasion confirmed their significant impact on DFS (p=0.015; p=0.021; 0.015 respectively). **Conclusion:** Our multicentric study confirms the impact of adenocarcinoma patterns on recurrence rate and DFS. The second predominant pattern in early stage resected adenocarcinoma seems to play an important role in influencing the outcomes. Micropapillary and lepidic second pattern demonstrated to be significantly related to recurrence development and their presence should require different and dedicated postoperative management.

P2.17-30 SUPERIOR VENA CAVA RESECTION AND PROSTHETIC REPLACEMENT FOR NSCLC: IS IT WORTHWHILE?

J. Chenesseau[1], D. Mitilian[1], S. Mussot[1], O. Mercier[1], D. Fabre[1], E. Fadel[2]

[1]*Hopital Marie Lannelongue, le plessis robinson/France,* [2]*Hopital Marie Lannelongue, Le Plessis Robinson/France*

Background: Direct involvement of superior vena cava (SVC) by NSCLC requires en-bloc tumor resection with complete vascular clamping and prosthetic replacement. We present our experience with this highly demanding procedure in order to determine whether this complex surgery is warranted **Method:** Since 1980, complete en-bloc resection of NSCLC invading the SVC followed by prosthetic replacement was performed in 48 patients (30 squamous, 18 non-squamous) in our Department. Patients with partial resection of the SVC with or without patch reconstruction, less complex procedure, were excluded. There were 38 male and 10 female with a mean age of 57 years (range, 38-82 years). N2, N3 disease and distant metastasis diagnosed on preoperative workup were considered as a surgical contraindication. Neoadjuvant therapy was given to 17 patients including chemotherapy (n=11), radiotherapy (n=1) or both (n=5). Surgical approach was a right thoracotomy (n=40), median sternotomy (n=5) or an anterior cervico-thoracotomy (n=3). Although vascular shunt was never used, in one patient a VA-ECMO was necessary for ventilation difficulties. Lung resection was carinal pneumonectomy (n=15), pneumonectomy (n=14), upper bilobectomy (n=1), lobectomy (n=16) or a sublobar resection (n=2). Mean SVC clamping time was 31.6 minutes (range, 10 to 120 minutes). On definitive histology, an R0 resection was achieved in 41 (85%) patients, and lymph node involvement was pN0 in 8, pN1 in 23, pN2 in 14 and pN3 in 3 patients. Tumor size ranged from 1.9 cm to 17 cm with a medium size of 5.2 cm. 31 patients received adjuvant therapy including chemotherapy (n=5), radiotherapy (n=1) or both (n=25). **Result:** Postoperative death occurred in 5 patients (10%), all of them underwent a right pneumonectomy (p=0.02). 13 other patients experienced postoperative complications. No neurologic events related to SVC clamping occurred. Graft thrombosis occurred in 2 patients who died postoperatively from bronchopleural fistula. With a median survival of 24 months, 3, 5 and 10 years survival rates were 45%, 40% and 35%, respectively. During follow-up, recurrence occurred in 31 patients and was mostly systemic (n=26). Disease free survival at 3, 5 and 10 years were 37%, 37% and 30%, respectively. By univariate analysis, only incomplete resection was found to be associated with poorer survival (p=0.04). **Conclusion:** In highly selected patients with NSCLC involving SVC, complete en-bloc resection and prosthetic replacement is feasible in expert center with acceptable mortality mainly due to right pneumonectomy. Good long-term survival is obtained provided a complete R0 resection is achieved.

P2.17-31 CENTRAL LUNG TUMORS TREATED WITH STEREOTACTIC RADIOTHERAPY. TOXICITY AND EARLY RESULTS IN A SINGLE INSTITUTION

M. Nuñez[1], A. Folgar[2], L. Diez[1], R. Gomez[1], E. Mur[1], J.M. Sole[1]

[1]*Consorci Sanitari de Terrassa, Terrassa/Spain,* [2]*Hospital Universitario Lucus Augusti, Lugo/Spain*

Background: Stereotactic ablative radiotherapy (SABR) for stage I-II inoperable non-small-cell lung cancer (NSCLC) peripherally located has become a standard treatment. However the role in central located lung cancer remains controversial because potential severe toxic effects. When adaptive dose regimens to location and appropriated dose-volume constraints for normal tissues are used, the expected toxicity are mild and the local control are comparable to those for peripheral lesions. We report our experience with central SABR. **Method:** Retrospective analysis of patients diagnosed with inoperable centrally located early lung cancer, defined as a tumor within 2 cm in all directions of any mediastinal critical structure, who were treated in a single institution between May 2017 and January 2019 with VMAT-SABR. All patients underwent 4DCT simulation. Cone beam CT (CBCT) and fluoroscopy prior and CBCT after to each treatment fraction was performed. Dose to the PTV was prescribed to the 95% isodose line. Acute toxicity was assessed by the CTCAE v.4.03 scale and local control was reported using RECIST criteria. **Result:** 40 patients were treated with stereotactic ablative radiotherapy for early inoperable NSCLC and 15 male patients had centrally located lesions. The mean age of included patients were 75 years (65-81) with a median follow-up of 6.6 months (2,2-19,8). The main cause of inoperability was pulmonary functionalism and cardiac comorbidities. 2 (13%) were treated previously with lobectomy for another primary lung cancer. 8 (53%) were adenocarcinoma, 2 (13%) were squamous carcinoma and 5 (33%) with no biopsy-proven malignancy. The most frequent location were inferior lobes (53%). 10 (66%) were stage cT1b-cN0M0, 4 (27%) cT2a-bN0M0 and 1 (7%) were cT3N0M0 (<5cm) as defined by the 8th edition of TNM. In the majority of patients (53%) the mediastinal staging was performed with PET-CT, however 7 patients underwent pathological mediastinal lymph node evaluation (endobronchial ultrasonography in 4 and mediastinoscopy in 3). The prescribed dose ranged from 48 Gy to 70 Gy in 4 to 10 fractions. Most patients were treated using 50 Gy in 5 fractions, BED 100 Gy10 (47%), followed by 48 Gy in 4 fractions, BED 105.6 Gy10 (20%) and 60 Gy in 8 fractions, BED 105 Gy10 (20%). There were no G3-5 toxicity. Acute G1 toxicities were fatigue (40%), pneumonitis (27%), dermatitis (13%) and cough (7%). 1 patient presented acute toxicity consistent with cough G2. At last follow-up, in terms of disease control, 87% the lesions had partial response or stable disease. 1 patient had local progression. 13 patients (87%) were alive and 2 (13%) died. **Conclusion:** In our serie, VMAT-SABR for centrally located lung tumors is safe and effective and should be considered for its acceptable acute toxicity profile and good early results.

P2.17-32 USING NEXT-GENERATION SEQUENCING TO IDENTIFY GENETIC PREDICTORS OF LOCAL FAILURE AFTER LUNG STEREOTACTIC BODY RADIATION THERAPY

V. Ng, A. Rimner, B. Sidiqi, A. Wu

Memorial Sloan Kettering Cancer Center, New York/United States of America

Background: Lung stereotactic body radiation therapy (SBRT) is a well-established therapy for primary lung tumors or metastatic lung lesions from other primary sites. However, local failure after SBRT still occurs. We hypothesized that next-generation tumor sequencing may identify genetic characteristics that predict local failure. **Method:** We conducted a retrospective analysis of all patients at our institution who received SBRT to the lung for either primary or metastatic tumors, and who underwent next-generation tumor sequencing utilizing an FDA-approved targeted panel of at least 341 genes. Patient and tumor characteristics, local failure, radiation dose, and all genetic alterations identified by the panel were collected. Univariate Cox proportional hazards analysis was performed. Because of the large number of genes in the panel, we limited analysis to genes with at least a 5% incidence of alteration in this cohort. To correct for multiple testing, we used a p-value of $\leq$ 0.001 as the significance threshold for genetic alterations. **Result:** Between 2013 and 2018, 140 patients with 160 lung lesions (76 primary lung, 84 non-lung primary) were treated with SBRT to a median radiation biologically effective dose of 100 Gy (range 48-151 Gy). Median follow-up for local failure was 13.8 months. There were 39 local failures (24.4%) during the study period. On univariate analysis, colorectal histology (HR 2.2, p=0.037), BED<100 Gy (HR 2.1, p=0.019), and larger lesion size (HR 1.2, p=0.023) were associated with higher risk of local failure. 45 mutations occurred with greater than 5% frequency (≥8 times) in our cohort. Univariate analysis identified three genes for which alterations were significantly associated with local failure: APC (mutated 17 times, HR 3.5, p<0.001), ARID2 (n=8, HR 5.5, p<0.0005), and MGA (n=8, HR 5.2, p<0.001) **Conclusion:** Next-generation tumor sequencing was able to identify genetic alterations associated with higher risk of local failure after lung SBRT. This hypothesis-generating study yielded three candidate genes significantly correlated with local failure. Further study is needed to validate the predictive value of these gene mutations, and their potential for selecting patients at higher risk for treatment failure after lung SBRT.

P2.17-33 DETERIORATION IN HEALTH-RELATED QUALITY OF LIFE IS ASSOCIATED WITH LOWER LUNG RESECTION RATES IN OLDER ADULTS

A. Blakely, H. Hu, L. Wong, D. Raz, L. Erhunmwunsee, V. Sun, J. Kim

City of Hope National Medical Center, Duarte/United States of America

Background: Decision making for surgical resection of lung cancer is based on disease characteristics as well as patient-reported health factors. However, data regarding influence of functional status and health-related quality of life (HRQOL) on consideration for lung surgery are currently lacking. **Method:** We identified lung cancer patients with localized disease from the SEER-Medicare Health Outcomes Survey (MHOS) linked database. HRQOL survey data captured physical/mental health, activities of daily living (ADLs), and medical comorbidities. Patients who had 1) baseline HRQOL survey prior to cancer diagnosis and 2) follow-up survey at least one year after diagnosis were selected. Generalized estimating equation (GEE) model was used to compare patients who underwent surgery versus those who did not in regard to demographics and HRQOL measures. **Result:** Overall, 108 patients were evaluated, of whom 75 (69%) underwent surgery. Surgical patients were younger (mean 73 versus 80 years, p<0.0001); otherwise, patient groups were demographically similar. Surgery was not performed based on surgeon recommendation (n=21, 64%), contraindication(s) (n=9, 27%), or patients' decision (n=3, 9%). Surgery and non-surgery groups experienced similar declines in physical HRQOL, mental HRQOL, and Katz aggregate ADL scores; and an increase in the number of major comorbidities (see Table). However, non-surgical patients had significant declines in specific individual ADLs, namely mobility and personal care activities, compared to surgical counterparts. On GEE, adjusting for age, non-surgical patients were significantly more likely to have decreased physical HRQOL (OR 5.7, p=0.008), mental HRQOL (OR 2.1, p=0.049), or ADL scores (OR 2.7, p=0.02); and multiple comorbidities (OR 2.3, p=0.046) compared to surgical patients.

Variable		Surgery Group N = 75 N (%)	Non-Surgery Group N = 33 N (%)	p Value
Physical HRQOL Scores	Decreased	45 (60)	19 (58)	0.81
	Stable or improved	30 (40)	14 (42)	
Mental HRQOL Scores	Decreased	29 (39)	18 (55)	0.13
	Stable or improved	46 (61)	15 (45)	
Major Comorbidities	Increased	16 (23)	10 (37)	0.18
	Stable	52 (77)	17 (63)	
Katz Aggregate ADL Scores	Decreased	16 (21)	9 (27)	0.50
	Stable or improved	59 (79)	24 (72)	
Individual ADLs				
Eating	Decreased	6 (8)	5 (15)	0.26
	Stable or improved	69 (92)	28 (85)	
Bathing	Decreased	18 (24)	14 (42)	0.053
	Stable or improved	57 (76)	19 (58)	
Using the toilet	Decreased	7 (9)	8 (24)	**0.04**
	Stable or improved	68 (91)	25 (76)	
Dressing	Decreased	12 (16)	11 (33)	**0.04**
	Stable or improved	63 (84)	22 (67)	
Getting in and out of chairs	Decreased	16 (22)	16 (48)	**0.005**
	Stable or improved	58 (78)	17 (52)	
Walking	Decreased	27 (37)	24 (73)	**0.0006**
	Stable or improved	46 (63)	9 (27)	

HRQOL = health-related quality of life; ADL = activity of daily living

Conclusion: Patient-reported outcomes reflect patients' perception of their own health, potentially providing information critical to surgical decision making that is not similarly reflected in other assessment tools. Identification and mitigation of such factors may increase surgeons' recommendation for lung resection for patients with localized malignancy.

P2.17-34 INTEGRATED CLINICO-RADIOMIC NOMOGRAM FOR PREDICTING DISEASE-FREE SURVIVAL (DFS) IN STAGE I AND II NON-SMALL CELL LUNG CANCER

K. Bera[1], P. Vaidya[1], P. Velu[2], H. Choi[3], P. Fu[1], A. Gupta[4], V. Velcheti[5], A. Madabhushi[1]

[1]*Case Western Reserve University, Cleveland/United States of America,* [2]*Penn Meddicine, Philadelphia/United States of America,* [3]*Cleveland Clinic, Cleveland/United States of America,* [4]*University Hospitals Cleveland Medical Center, Cleveland/United States of America,* [5]*NYU Langone Cancer Center, New York/United States of America*

Background: Early stage non-small cell lung cancer (ES-NSCLC) comprises about 45% of all NSCLC patients, with 5-year survival ranging between 30-49%. Surgical resection is the standard of care curative modality in these patients but about 30-55% of patients often recur following surgery within the first 3 years. There is currently no validated method to stratify patients based on their risk of recurrence following surgery in these patients. In this project, we develop and validate a nomogram using a combination of CT-derived radiomic textural features and clinco-pathologic factors, in order to predict DFS in ES-NSCLC. **Method:** This study comprised 350 ES-NSCLC patients from two different institutions who underwent surgery (75 patients relapsed). Radiomic textural features were extracted from tumor region (Intratumoral - IT) as well as from the annular ring shaped peritumoral region (PT) with 3mm as a ring thickness and extending 9 mm outside the nodule. A total of 124 features from Gabor, Laws, Laplace, Haralick and Collage feature families were extracted from IT and each PT ring for all patients. The most stable, significant and uncorrelated features were selected from D1 (N=221) and used to build a Lasso-regularized multivariate Cox-regression model to generate a Radiomic Risk Score (RRS) derived from weighted Lasso coefficients. Further, RRS was integrated with clinic-pathologic variables (Lympho-vascular invasion LVI and AJCC stage) which were independently predictive on DFS in multivariate analysis to build a clinical-radiomics score (CRS). A nomogram was constructed to visually assess the CRS and RRS on DFS. Performances were evaluated using hazard ratios (HR), concordance index (C-Index) along with decision and calibration curves to show the differences between the individual and integrated risk scores. **Result:** Top 14 radiomic features included 6 from IT and 8 from 0-9 mm PT distance. The constructed RRS could predict DFS (n=221, C-index=0.69, HR = 3.8; 95% CI- 2.7-5.6, p<0.05) on training (D1) and (n=129, C-index=0.69, HR – 2.5; 95% CI – 1.8-4.7; p<0.05) on a blinded validation cohort (D2), Addition of LVI and pN to build the CRS, increased C-index to 0.74, (p<0.05). Decision and calibration curve analysis shows improved performance of CRS over RRS or clinco-pathologic factors alone.

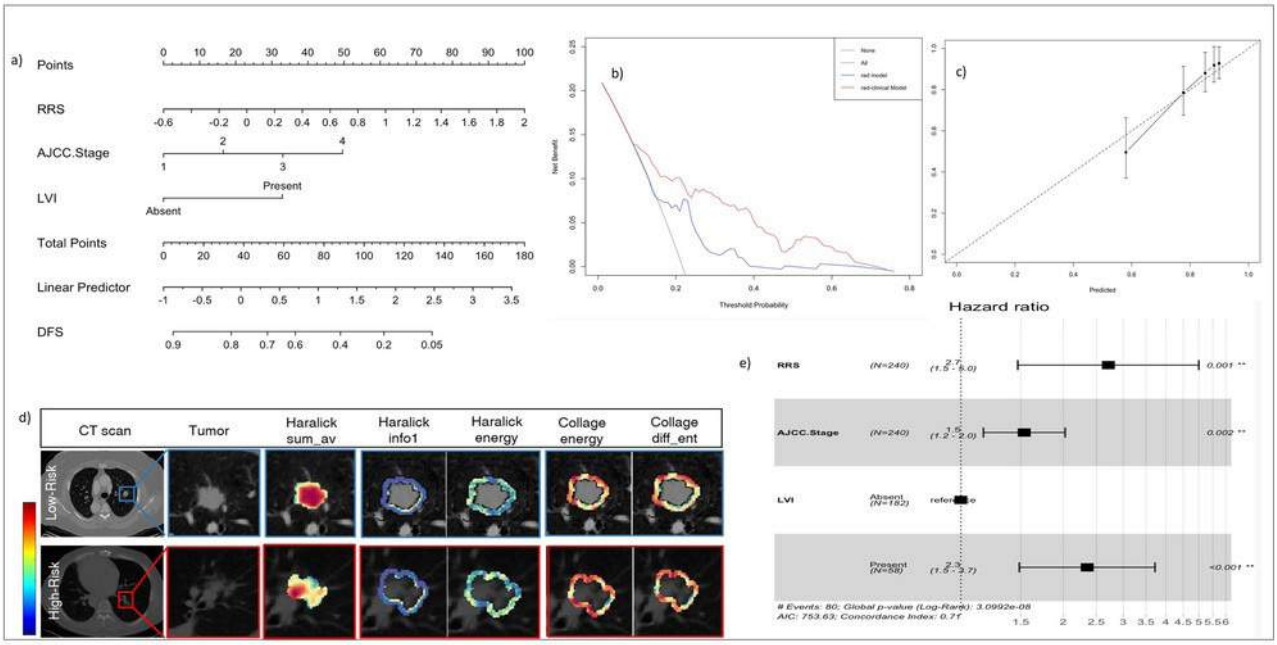

Figure 1: *a) Nomogram with radiomics risk score (RRS) and clinico-pathologic factors (LVI, pN stage) to build a Clinical-Radiomics score to predict DFS following surgery for ES-NSCLC b) Decision curve analysis c) Calibration curve analysis d) Radiomic feature maps from the intra- and peri-tumoral region for high and low- risk patients e) d) Forest plot showing the Hazard Ratios for RRS and clinico-pathologic factors (LVI, Overall AJCC pathological stage)*

Conclusion: Addition of prognostic clinical factors (LVI, AJCC stage) improved the performance of the Radiomic Risk Score model in order to accurately predict DFS in ES-NSCLC patients undergoing surgery.

P2.17-35 INTEGRATING CT RADIOMIC & QUANTITATIVE HISTOMORPHOMETRIC WHOLE SLIDE IMAGE FEATURES PREDICTS DISEASE FREE SURVIVAL IN ES-NSCLC

P. Vaidya[1], K. Bera[1], X. Wang[1], P. Patil[2], V. Velcheti[3], A. Madabhushi[1]

[1]*Case Western Reserve University, Cleveland/United States of America,* [2]*Cleveland Clinic, Cleveland/United States of America,* [3]*NYU Langone Cancer Center, New York/United States of America*

Background: Early-Stage non-small cell lung cancer (ES-NSCLC) accounts for approximately 40% of NSCLC cases, with 5-year survival rates varying between 31-49%. Radiomic textural features from pre-treatment CT scans and QH features from H&E stained WSIs have been shown to be independently prognostic of outcome. With diagnostic CT scans and surgical resection, the standard of care in ES-NSCLC, in this work we seek to take a multimodality approach using routine imaging to improve the predictive performance in determining DFS following resection. **Method:** A retrospective chart review of Stage I and II (ES-NSCLC) pts undergoing surgical resection between 2005-14 with available CT and resected tissue yielded 70 pts. A total of 248 radiomic CT textural features from inside the tumor (Intratumoral –IT) and outside the tumor (Peritumoral – PT) and 242 QH features related to the nuclear shape, texture and spatial orientation and architecture from H&E WSI were extracted. We developed two risk models, Radiomic and QH using the most stable, discriminative and uncorrelated features from CT and WSI respectively determined by Lasso-regularized Cox regression to predict Disease free survival (DFS). Model performances were analyzed using Hazard Ratios (HR), Concordance Index (C-index) and Decision curve analysis. We built a nomogram to calculate the DFS based around the individual models as well as an integration of the QH and Radiomic models. **Result:** Top 6 Radiomic features included 2 IT and 4 PT features from the Haralick and Collage families. The QH model comprised 6 nuclear shape and graph features. In predicting DFS, While the Radiomic model had a HR of 2.4 (p <0.01) with C-index – 0.67, the QH model had HR – 3.1 (p <0.01) with C-index – 0.74. Integration of the Radiomic and QH model yielded a C-index of 0.78 (p< 0.01). After addition of prognostic clinical factors (LVI, AJCC stage) to the model, the C-index was 0.80, almost doubling either modalities alone. The constructed nomogram visualized the apparent benefits of the three models while a decision curve clearly demonstrated the increased benefit of combined integrated model. **Conclusion:** Integration of CT-derived radiomic and tissue-derived QH features was found to show improved performance in predicting RFS when compared to either radiomics or QH alone.

	C-Index	P Value
LVI	0.54	0.05
T Stage	0.66	5e-02
Rad Signature	0.65	0.002
Path Signature	0.72	5e-02
Rad + Path	***0.79***	***2e-03***
Rad + Path + Clinical	***0.82***	***3e-05***

Figure: a) Nomogram representing integrated Rad-Path risk score for predicting DFS; b) Decision curve analysis showing net benefit for the integrated model. The combined Rad-Path-clinical model had the highest net benefit; c) QH nuclear shape feature and radiomic peritumoral Haralick feature heatmeps showing difference between high-risk and low-risk groups; d) Table for individual prognostic clinical factors, and integrated (Rad-Path and Rad-Path-Clinical) models.

P2.17-36 MOLECULAR MARKERS, THERAPEUTIC AND PROGNOSTIC ANALYSIS OF LUNG SARCOMATOID CARCINOMAS

W. Liang[1], Z. Wang[2], J. He[1]

[1]*The [1]st Affiliated Hospital of Guangzhou Medical University, China State Key Laboratory of Respiratory Disease & National Clinical Research Center for Respiratory Disease, Guangzhou/China, [2]Linkdoc Technology Co, Ltd, Beijing/China*

Background: Several molecular markers have been established for therapeutic intervention and prognostic prediction of lung cancer. Less is known about their therapeutic potential and prognostic significance in less common lung cancer subtypes. The present study was therefore designed to assess a set of well-defined molecular markers in patients with lung sarcomatoid carcinomas and their therapeutic and prognostic significance. **Method:** This is a single-center retrospective study of lung cancer patients with histologic types of the sarcomatoid carcinomas who underwent surgical resection at our center during August 2008 to August 2018. The molecular markers analyzed were driver mutations in EGFR, ERBB2, PIK3CA, C-MET, RAS, BRAF, EML4-ALK, RET and ROS1 by ARMS-PCR or NGS, protein expressions of PD-L1 (clone SP-142) in tumors and/or associated lymphocytes by immunohistochemistry. Log-rank test was used to compare the overall survival of patients. **Result:** A total of 74 (1.18%) patients with sarcomatoid carcinomas were identified from 6,285 patients underwent surgical resection. Of the 35 patients underwent mutation testing (including 14 test EGFR and RAS by ARMS), 17 (48.57%) harbored driver mutations (12 RAS, 4 EGFR L859R and 4 EGFR 19del). Proteins expressions of PD-L1 were found in 67.86% of patients. No prognostic significance (DFS and OS) was noted regarding to any driver mutations and PD-L1 expression. Half of the patients (37/74, 50.00%) received adjuvant therapy, 27 of whom used platinum-based chemotherapy (72.97%). Platinum-based adjuvant chemotherapy showed improved DFS (P=0.011) but similar OS (P=0.079). **Conclusion:** A part of lung sarcomatoid carcinomas harbor driver mutation or PD-L1 expression, although they are not prognostic. Platinum-based chemotherapy was preferable in these patients. The role of targeted or immune agents as adjuvant therapy needs further study.

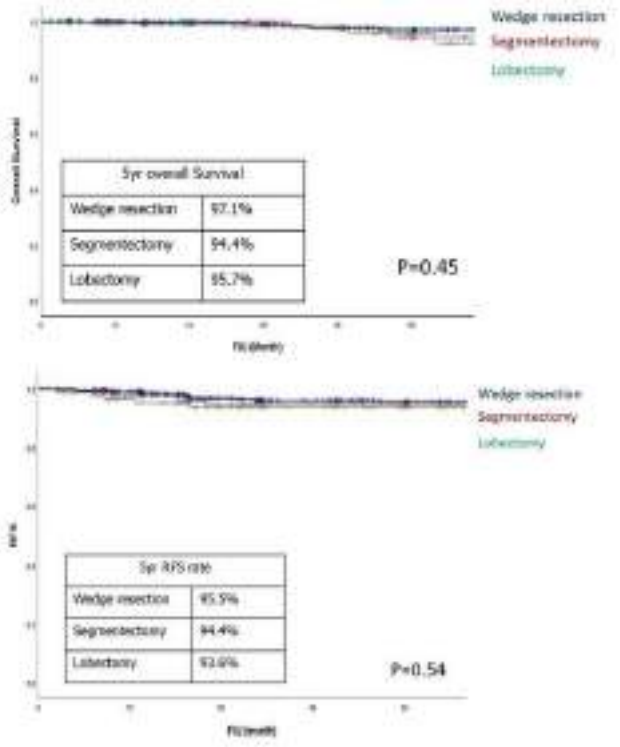
P2.17-37 PROGNOSTIC IMPLICATION OF SURGICAL TREATMENT FOR THE DOMINANT LUNG ADENOCARCINOMA ASSOCIATED WITH PART-SOLID NODULES

Y. Hwang, J.H. Jeon, S. Cho, K. Kim, S. Jheon

Seoul National Bundang Hospital, Seongnam-si/Korea, Republic of

Background: The aim was to analyze the prognostic implication of surgical resection for lung adenocarcinoma appearing as part-solid nodules (PSNs) on computed tomography scans . **Method:** From 2004 to 2017, the cases of a total of 651 patients (male:female = 259:392, median age, 65years) with surgically resected lung adenocarcinomas manifesting as PSNs were retrospectively reviewed. We compared patient characteristics with t tests for continuous variables and $\chi 2$ tests for categorical variables. The prognostic implication of the multiplicity of the surgical extent and other clinical variables in relation to overall-survival (OS) and disease-free survival (DFS) was analyzed by using Cox regression. **Result:** Median maximum diameter and solid component diameter of PSNs were 2.0cm and 1.1cm.(range 0.8-7, 0.5-3.4) PSNs were resected by wedge resection, segmentectomy, or lobectomy in 94 (14.4%), 92 (14.2%), and 465 (71.4%) cases, respectively. Pathologic diagnosis was adenocarcinoma in situ, minimally invasive adenocarcinoma (MIA), or invasive adenocarcinoma (IA) in 4 (0.6%), 70 (10.8%), and 577 (88.6%) cases, respectively. The median follow-up duration was 35.4 months. There was no significant difference of OS and DFS among the surgical extent and type of lymph node dissection (Figure 1). Multivariate Cox regression analysis demonstrated that multiple pulmonary nodules [hazard ratio (HR) = 8.3; 95% confidence interval (CI): 3.5-19.8 1.173; p <0.001] and wedge resection (HR = 3.8; 95% CI: 1.19-11.9; p = 0.02) were independent risk factors for the tumor recurrence.



Conclusion: Among the resected lung adenocarcinoma associated with PSNs, multiple PSN and wedge resection is a significant prognostic factor in the lung cancer recurrence.

P2.17-38 PREDICTIVE FACTORS FOR LYMPH NODE METASTASIS IN PATIENTS WITH CLINICAL STAGE I PART-SOLID LUNG ADENOCARCINOMA

J.H. Jeon, S.Y. Lee, Y. Hwang, S. Cho, K. Kim, S. Jheon

Seoul National University Bundang Hospital, Seongnam-si, Gyeonggi-do/Korea, Republic of

Background: Accurate clinical staging of small part-solid nodule is essential for developing a treatment plan and evaluating suitability for minimally invasive surgery. The aim of this study was to evaluate predictive factors for metastasis of N1 and N2 lymph nodes in clinical stage I part-solid lung adenocarcinoma. **Method:** Medical records of patients with clinical stage I part-solid adenocarcinoma who had undergone anatomic pulmonary resection with systematic node dissection or node sampling between January 2009 and June 2018 were retrospectively reviewed. To identify predictive factors for lymph node metastasis, univariate and multivariate logistic regression analyses were performed. **Result:** Among the 602 patients in this study, the overall prevalence of lymph node metastasis was 3.7% (n = 22), which included 3.0% of N1 lymph nodes (n = 18) and 1.5% of N2 lymph nodes (n = 9). Combined N1 and N2 nodal involvement was found in 5 patients. Nodal metastasis was not observed in tumors with a solid part ≤1.0 cm (cT1mi and cT1a). The nodal metastasis rate in cT1b, cT1c, and cT2a tumors was 4.7% (10/215), 4.8% (3/63), and 12.9% (9/70), respectively. Predictive factors for N1 node metastasis included size of solid part (p = 0.001), and for N2 node metastasis included visceral pleural invasion (p < 0.001) by multivariate analysis. The ratio of ground glass opacity was not associated with lymph node metastasis.

Prognostic factors for N1 lymph node metastasis

Variables	Univariate	Multivariable	
	p value	HR (95% CI)	p value
Age (y)	0.312		
Sex (male)	0.776		
Never smoker	0.073		
Tumor centrality	0.893		
mSUV of mass	0.935		
Size of solid part (mm)	<0.001	1.090 (1.036-1.147)	0.001
Ground glass opacity proportion (%)	0.131		
Visceral pleural invasion (yes)	0.006		
CEA (ng/mL)	0.009		
CYFRA (ng/mL)	0.107		

Prognostic factors for N2 lymph node metastasis

Variables	Univariate	Multivariable	
	p value	HR (95% CI)	p value
Age (y)	0.745		
Sex (male)	0.118		
Never smoker	0.107		
Tumor centrality	0.009		
mSUV of mass	0.116		
Size of solid part (mm)	0.004		
Ground glass opacity proportion (%)	0.943		
Visceral pleural invasion (yes)	<0.001	12.121 (3.143-46.838)	<0.001
CEA (ng/mL)	0.418		
CYFRA (ng/mL)	0.643		

Conclusion: Among the patients with clinical stage I part-solid adenocarcinoma, 3.7% of the patients showed unexpected lymph node metastasis, and large size of solid part and visceral pleural invasion of the tumor were predictive factors of lymph node metastasis in clinical stage I part-solid adenocarcinoma. Sytemic lymph node dissection and anatomic pulmonary resection should be performed, especially in those who have the larger size of solid part and suspicion of visceral pleural invasion.

P2.17-39 RELATIONSHIP BETWEEN EGFR MUTATION AND PATHOLOGICAL DIFFERENTIATION IN PATIENTS WITH CLINICAL STAGE IA LUNG ADENOCARCINOMA

J. Osawa, Y. Shimada, S. Maehara, H. Masaru, M. Kakihana, N. Kajiwara, T. Ohira, N. Ikeda

Tokyo Medical University, Tokyo/Japan

Background: Pathological differentiation is an established prognostic factor for patients with lung adenocarcinoma. There are some correlations between epidermal growth factor receptor (EGFR) mutations and pathological differentiation. EGFR mutation-positive adenocarcinoma is considered to be highly differentiated types that show development of alveolar epithelial substitution. However, the distribution of pathological differentiation and the prognostic impact of the presence or absence of EGFR mutations in early adenocarcinoma are not clear. **Method:** We collected the records of 569 patients who underwent surgical resection for clinical stage IA lung adenocarcinoma between 2008 and 2015, and were also examined their EGFR mutation status. Based on the presence or absence of EGFR mutations and pathological differentiation (well;G1/moderately;G2/poorly;G3), patients were categorized into 6 groups: EGFR mutation positive (E+) with G1, E+ with G2, E+ with G3, EGFR mutation negative (E-) with G1, E- with G2, E- with G3. We examined the distribution of each group,(clinicopathological features and prognosis. **Result:** 303 lung adenocarcinoma had EGFR mutations. The distribution was E+/G1:85,E+/G2:209,E+/G3:9,E-/G1:50,E-/G2:178,E-/G3:38. E+/G3 group was significantly fewer (P<0.001). The 5-year recurrence-free survival (RFS) rates were 95% in E+/G1 group, 78% in E+/G2 group, 33% in E+/G3 group, 100% in E-/G1 group, 75% in E-/G2 group, 61% in E-/G3 group. The 5-year overall survival (OS) rates were 98% in E+/G1 group, 91% in E+/G2 group, 44% in E+/G3 group, 100% in E-/G1 group, 87% in E-/G2 group, 79% in E-/G3 group. The prognosis was significantly worse in the E+/G3 group. There were more women (77%) and non-smokers (89%) in the E+/G3 group. Six patients (66%) had recurrence, and in all cases EGFR-TKI was administered and the response rate was 100%. **Conclusion:** Most of the c-IA EGFR positive adenocarcinomas were highly differentiated, and significantly fewer poorly differentiated cases. Among the poorly differentiated group, EGFR gene mutation positive is particularly poor prognosis. However, The therapeutic effect of EGFR-TKI was not different from other EGFR positive patients.

Keywords: Lung cancer, EGFR, pathological differentiation

P2.17-40 ANALYSIS OF 7 YEARS EXPERIENCES OF UNIPORTAL VIDEO-ASSISTED THORACIC SURGERY FOR STAGE I AND II LUNG CANCER

D.K. Kang, M.K. Kang, Y.-H. Hwang

Haeundae Paik Hospital, College of Medicine, Inje University, Busan/Korea, Republic of

Background: Recently, video-assisted thoracic surgery (VATS) has been accepted as a feasible, safe and effective approach for the treatment of early lung cancer. With the evolution of the VATS technique, uniportal VATS for early lung cancer has been performed and its advantages has been reported including less postoperative pain, less paresthesia and favorable cosmetic results because only one intercostal space is involved. We analyzed our experiences to evaluate results of uniportal VATS in patients with early lung cancer **Method:** We analyzed retrospectively medical records of patients who underwent surgical treatments for stage I and II lung cancer at our institute between March 2011 and December 2018. There were 126 patients in multiportal group (MG) and 102 patients in uniportal group (UG). All patients underwent the lobectomy and mediastinal lymph nodes dissection. Multiport VATS was performed through 3 small incisions (2cm, 2cm and 4-5cm). Uniportal VATS was performed through only one 4-5cm sized incision (Figure 1).

Result: There was no difference between both groups in gender, age, underlying diseases, location of tumor, TNM stage, cell type and the number of dissected lymph nodes. The mean tumor size of UG was slightly smller than that of MG (2.5 vs 3.0 cm, p=0.02). The mean operation time of UG was shorter than that of MG (189 vs 214 minutes, p=0.01). The mean duration of tube drainage and hospital stay of UG was shorter than those of MG (tube drainage:

5.3 vs 6.7 days, p=0.01, hospital saty: 8.1 vs 11.1 days, p<0.01). There were 7 hospital mortalities in MG and 1 hospital mortality in UG (p=0.06). The cause of hospital mortality was ARDS in all patients. There were 4 complications (empyema, pneumothorax, chylothorax and persistent air leak) in MG and 4 complications (chylothorax, pneumothorax in 2 and pleural effusion) in UG. The 5-year disease free survival rate was 77% in MG and 90 % in UG (p=0.59). The 5-year survival rate was 81% in MG and 99% in UG. However, there was no statistically significant difference. **Conclusion:** In our study, uniportal VATS showed similar results with a smaller incision when compared to multiport VATS in the surgical treatment for stage I and II lung cancer. Uniportal VATS might be one of options in the surgery for stage I and II lung cancer.

Keywords: Lung cancer, Video-Assisted Thoracic Surgery, Uniportal VATS

P2.17-41 TREATMENT OUTCOMES OF PULMONARY RESECTION IN NSCLC PATIENTS WITH AUTOIMMUNE DISEASES

S. Fukuda, K. Suda, S. Ohara, M. Nishino, M. Chiba, T. Takemoto, J. Soh, T. Mitsudomi

Kindai University Faculty of Medicine, Osaka-Sayama/Japan

Background: Surgical resection for early stage non-small cell lung cancer (NSCLC) patient with autoimmune disease(s) is a relatively rare occasion. Most of such patients have received steroid therapy with/without immunosuppressant agent for a long period before the surgery. However, short-term or long-term treatment outcomes of NSCLC patients with autoimmune disease are unclear. **Method:** Between January 2007 to December 2018, thirty-nine NSCLC patients with autoimmune disease(s) received pulmonary resection with curative intent in our department. Patients with interstitial lung disease were excluded from this study. Patient clinical and pathological characteristics and treatment outcomes were evaluated. **Result:** There were 17 males and 22 females in out cohort. The median age was 68 years old (39 – 84), and thirty patients were smokers. Twenty-three patients had rheumatoid arthritis, and among them, three patients had additional autoimmune disease (autoimmune hepatitis, Sjogren syndrome, or polyneuropathy). Other autoimmune diseases included Hashimoto disease (n = 4), systemic lupus erythematosus (n = 3), Behcet's disease (n = 2), primary biliary cirrhosis (n = 2), and others. Only three patients received limited resections (2 partial resections and one segmentectomy), and 36 patients received lobectomy or bi-lobectomy. At the post-operative pathological diagnosis, there were 13 patients with squamous cell carcinomas, 21 patients with adenocarcinomas, four patients with pleomorphic carcinomas, and one patient with adenosquamous cell carcinoma. Post-surgical complications included pneumonia (n = 1, 3%), prolonged air leakage (n = 1, 3%), and no patient experienced bronchopleural fistula or empyema. The median post-surgical hospital stay was eight days (4 – 28 days). **Conclusion:** Pulmonary resection for NSCLC patients with autoimmune disease(s) were safely performed. We will also report the long-term outcome for this cohort at the conference.

Keywords: NSCLC, rheumatoid arthritis, surgery

P2.17-42 SURGICAL CHOICE FOR CLINICAL STAGE IA NON-SMALL CELL LUNG CANCER: NOVEL RATIONALE FROM INTRAPULMONARY LYMPH NODE METASTASIS PATTERN

H.-Y. Deng[1], Q. Zhou[2]

[1]*West China Hospitial, Sichuan University, Chengdu/China,* [2]*West China Hospital, Sichuan University, Chengdu/China*

Background: Current available surgical resection methods for early-stage NSCLC mainly consisted of lobectomy and sublobar resection (including segmentectomy and wedge resection) with lobectomy being the preferred option, which was established by the only completed RCT study finding that sublobar resection yielded a significantly higher recurrence rate and a trend toward worse survival than lobectomy. However, there are growing interest in observational studies and systematic reviews exploring the efficacy of sublobar resection in treating early-stage NSCLC, aiming to justify for applying sublobar resection as an alternative to lobectomy for treating these patients but with conflicting conclusions.We aimed to investigate the pattern of intrapulmonary lymph node (LN) metastasis of clinical T1N0M0 peripheral non-small cell lung cancer (NSCLC) to provide novel rationale for surgical choice (lobectomy, segmentectomy, or wedge resection) for these patients. **Method:** We retrospectively collected clinical data of patients undergoing lobectomy with systematic mediastinal LN dissection or sampling for early-stage NSCLC from January 2015 to December 2018. The intrapulmonary LN metastasis pattern was analyzed by tumor size. **Result:** We included a total of 354 patients for final analysis. The rate of intrapulmonary LN metastasis was 13.6% (Table 1). When stratified by tumor size, NSCLC ≤1cm had no hilar/intrapulmonary LN metastasis while NSCLC >2 but ≤3cm had significantly high rates of hilar/intrapulmonary LN metastasis (18.4%) and the rates of hilar, interlobar and peripheral LN metastasis were relatively high (5.4%, 5.4% and 12.2%, respectively). NSCLC >1.5cm but ≤2cm also had a relatively high rate of hilar (6.5%) and peripheral (18.3%) LN metastasis while NSCLC >1cm but ≤1.5cm had a significantly low rate of hillar/intrapulmonary (2.5%) and peripheral (2.5%) LN metastasis. Table 1. Intrapulmonary lymph node metastasis pattern among clinical stage IA (cT1N0M0) peripheral non-small cell lung cancers with different tumor size.

Characteristics	Total (N=354)	Tumor size group			P value
		≤1cm (N=35)	>1cm but ≤2cm (N=172)	>2cm but ≤3cm (N=147)	
Total dissected N1 LN number (Mean±SD)	5.6±3.0	3.6±1.9	5.4±2.7	6.3±3.3	<0.001
Total dissected N2 LN number (Mean±SD)	8.1±4.0	7.0±3.4	7.6±3.6	8.8±4.4	0.008
Lymph node metastasis rate	16.9% (60/354)	0 (0/35)	14.5% (25/172)	23.8% (35/147)	0.002
N1 LN metastasis rate (10-14#)	13.6%(48/354)	0(0/35)	12.2%(21/172)	18.4%(27/147)	0.013
Hilar LN metastasis rate (10#)	4.2%(15/354)	0(0/35)	4.1%(7/172)	5.4%(8/147)	0.348
Interlobar LN metastasis rate (11#)	3.4%(12/354)	0(0/35)	2.3%(4/172)	5.4%(8/147)	0.263*
Peripheral LN metastasis rate (12-14#)	10.5%(37/354)	0(0/35)	11.0%(19/172)	12.2%(18/147)	0.092
N2 LN metastasis rate (1-9#)	8.8%(31/354)	0(0/35)	8.1%(14/172)	11.6%(17/147)	0.088

Note: LN=lymph node; SD=standard deviation. *Fisher's exact test

Conclusion: Based on the pattern of intrapulmonary LN metastasis, our study provided novel perspectives on surgical choice of lobectomy, segmentectomy, or wedge resection for clinical stage IA peripheral NSCLC: for NSCLC ≤1cm both segmentecotmy and wedge resection could be utilized, and for NSCLC >1cm but ≤1.5cm segmentecotmy could be utilized provided that sufficient resection margin could be achieved; while for NSCLC >1.5cm lobectomy should be the preferred surgical option.

Keywords: Non-Small Cell Lung Cancer, surgical option, early-stage

P2.17-43 COMPLETE UNIPORTAL THORACOSCOPIC ANATOMIC LUNG RESECTION WITH SYSTEMATIC MEDIASTINAL LYMPHADENECTOMY FOR NSCLC

Y.-J. Deng[1], G.-S. Wang[2], Z. Wang[1], J.-W. Mu[1], Z. Wang[2]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital & Shenzhen Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Shenzhen/China,* [2]*Shenzhen People's Hospital, Second Affiliated Hospital, Medical College of Jinan University, Shenzhen/China*

Background: With its growing popularity and potential outcome, complete uniportal thoracoscopic surgery has been used in the treatment of thoracic diseases. This study aimed to summarize a personal experience of complete uniportal thoracoscopic anatomic lung resection with systematic mediastinal lymphadenectomy (CUT–ALR–SML) for non-small cell lung cancer (NSCLC) and to evaluate the feasibility and safety of CUT–ALR–SML in our institute. **Method:** A total of 326 patients with NSCLC were chosen to undergo CUT–ALR–SML in our institute from August 2013 to July 2018. Data such as clinicopathologic characteristics and perioperative outcomes were restrospectively reviewed in this article. **Result:** For the 326 cases of anatomic lung resection, the specific procedures and corresponding number of cases were as follows: segmentectomy, 90; lobectomy, 218; sleeve lobectomy, 9; ipsilateral lobe combined with segment resected synchronously (i-L+S), 6; and pneumonectomy, 3. A total of 31 cases required conversion to open surgery, and 4 cases were converted to multiportal thoracoscopic surgery. All patients underwent systematic mediastinal lymphadenectomy. The average mediastinal lymph node stations and mediastinal lymph nodes dissected under CUT–ALR–SML was 3.3±1.4 and 9.6±8.4,respectively. Approximately 99.7% of the patients acquired free resection margins. A total of 42 (12.9%) patients suffered from postoperative complications, and 1 patient died of pneumonia during the perioperative period. **Conclusion:** Complete uniportal anatomic lung resection, particularly for segmentectomy and lobectomy is safe and feasible with low complication rates, and excellent free resection margin rates. Systematic mediastinal lymphadenectomy during complete uniportal thoracoscopic surgery adequately assesses the N2 lymph node. However, further studies need to be conducted to evaluate the role of CUT–ALR–SML in the treatment of NSCLC.

Keywords: systematic mediastinal lymphadenectomy (SML), Non-small cell lung cancer (NSCLC), uniportal thoracoscopic anatomic lung resection

P2.18 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC
MONDAY, SEPTEMBER 9 10:15 – 18:15

P2.18-01 A MULTICENTER, DOUBLE-BLIND, RANDOMIZED, CONTROLLED STUDY OF BINTRAFUSP ALFA (M7824) IN UNRESECTABLE STAGE III NSCLC

E. Vokes[1], A. Adjei[2], M.-J. Ahn[3], F. Barlesi[4], E. Felip[5], E. Garon[6], I. Grenga[7], A. Koenig[8], C. Martin[9], T. Mok[10], F. Mornex[11], N. Munshi[7], D. Raben[12], C. Robinson[13], L. Paz-Ares[14]

Background: The TGF-β pathway promotes tumor immunosuppression, and its inhibition may enhance the antitumor activity of PD-(L)1 monoclonal antibodies and reduce radiation-induced lung fibrosis. Bintrafusp alfa is an innovative first-in-class bifunctional fusion protein composed of the extracellular domain of TGF-βRII (a TGF-β "trap") fused to a human IgG1 mAb blocking PD-L1. In a phase 1 study, second-line bintrafusp alfa therapy demonstrated promising antitumor activity in advanced non-small cell lung cancer (NSCLC) (NCT02517398). In preclinical studies, bintrafusp alfa plus radiotherapy showed enhanced antitumor activity compared with radiotherapy alone in mouse models. This study is evaluating the efficacy and safety of bintrafusp alfa with concurrent chemoradiation (cCRT) followed by bintrafusp alfa vs cCRT plus placebo followed by durvalumab in patients with unresectable stage III NSCLC. **Method:** This global, multicenter, double-blind, randomized, controlled study of bintrafusp alfa (NCT03840902) includes adults with histologically documented stage III locally advanced, unresectable NSCLC, ECOG performance status ≤1, adequate pulmonary function, and life expectancy ≥12 weeks. Patients with tumors with actionable mutations (EGFR, ALK translocation, ROS-1 rearrangement) are also eligible. Mixed small cell lung cancer and NSCLC histology; pleural effusions greater than minimal, exudative, or cytologically positive; significant acute or chronic infections; prior chemotherapy or immune checkpoint inhibitor therapy for NSCLC; and current use of immunosuppressive medication are exclusion criteria. Patients are randomized to receive either bintrafusp alfa 1200 mg IV every 2 weeks (Q2W) with cCRT for 6 weeks followed by bintrafusp alfa 1200 mg IV Q2W (arm A) or placebo with cCRT for 6 weeks followed by durvalumab 10 mg/kg IV Q2W (arm B) until confirmed disease progression, unacceptable toxicity, or treatment ≤1 year. The primary endpoint is progression-free survival; secondary endpoints include overall survival, safety, lung function assessment, objective response, duration of response, pharmacokinetics, and immunogenicity. This phase 2 trial was activated on April 2, 2019 and first patient in is anticipated for May 22, 2019. Target enrollment: 350 patients. **Result:** Section not applicable **Conclusion:** Section not applicable

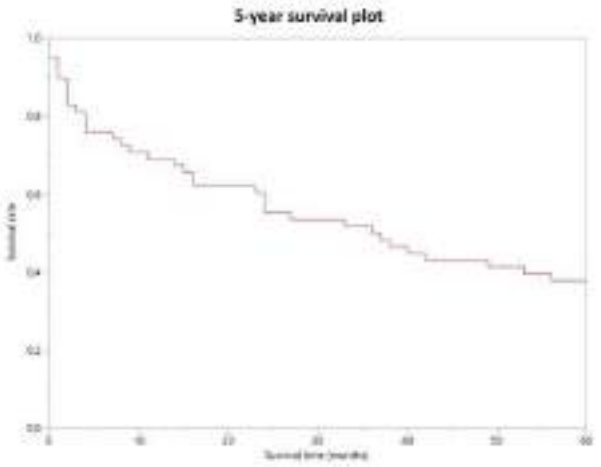
P2.18-02 PNEUMONECTOMY AND LUNG CANCER: A TREACHEROUS COMBINATION

L. Berzenji, J. Hendriks, P. Lauwers, S. Yogeswaran, P. Van Schil

Antwerp University Hospital, Edegem/Belgium

Background: In spite of the progress made in recent years regarding minimally invasive and parenchymal-sparing surgery, pneumonectomy is still necessary in cases where lesser resections are not possible. However, pneumonectomy remains a high-risk surgical procedure associated with significant postoperative morbidity and mortality. We investigated early and long-term results in a recent series of patients undergoing pneumonectomy for lung cancer. **Method:** Clinical and pathological characteristics of non-small cell lung cancer (NSCLC) patients treated by pneumonectomy between January 2008 and December 2013 were retrospectively reviewed. Overall 30- and 90-day mortality and 1-, 2-, and 5-year survival rates were calculated. Postoperative complications and disease progression or recurrence were analysed by descriptive statistics. Univariate and multivariate analyses of factors related to long-term survival were also performed. **Result:** A total of 61 patients, 48 men and 13 women with an overall mean age of 64±8.9 years, underwent pneumonectomy. The 30- and 90-day mortality rates were 6.6% and 16.4%, respectively. Ninety-day mortality was significantly correlated to tumour pathology (p=0.0410) and occurrence of postoperative complications (p=0.0078). Overall 1-, 2-, and 5-year survival rates were 70.5%, 57.4%, and 37.7%, respectively. Progressive or recurrent disease occurred in 45.7% of all patients. Most frequent early complications were atrial fibrillation (41.0%), pneumonia (23.0%), and acute respiratory failure (18.3%).



POSTERS

Conclusion: Despite careful patient selection, pneumonectomy yields high mortality and morbidity rates. Therefore, it should only be performed when no other therapeutic options are available. Furthermore, rigorous preoperative work-up and risk stratification models are necessary to determine whether pneumonectomy is the most suitable treatment option and to obtain acceptable long-term results.

Keywords: NSCLC, pneumonectomy

P2.18-03 SALVAGE SURGERY AFTER CURATIVE-INTENT CHEMO AND/OR RADIATION FOR LOCALLY ADVANCED LUNG CANCER

M. Yamashita, Y. Maki, T. Ueno, H. Suehisa, D. Harada, T. Kozuki, N. Nogami, M. Kataoka

National Hospital Organization Shikoku Cancer Center, Matsuyama/Japan

Background: A chemo and/or radiotherapy (CRT) was thought to be the curative treatment for locally advanced lung cancer (LALC) before 2017. However, after the CRT the cancer sometimes remained at the treatment field. The radical pulmonary resection after CRT (Salvage surgery) is the option for the curative treatment. The safety and perioperative complications of salvage surgery after CRT for locally advanced lung cancer have been problematic. Thisa study aimed to identify the long-term survival and the operative results of this kind salvage surgery. **Method:** The Salvage surgery is defined as resection after platinum based 2-drugs CRT or curative dose radiation therapy for LALC. We retrospectively reviewed our medical records in our institute from January 2008 to March 2019 and collected 33 patients who received salvage surgery. This study was approved by our institutinal review board. **Result:** The mean age at the surgery was 63 years (range 39-86), with 5 women and 28 men. The initial curative-intent therapy were; concurrent CRT in 26, sequential CRT in 2, and stereotactic body radiotherapy in 5. The mean interval from CRT to the surgery was 31 months (range 3-128). All patients except 2 cases underwent complete surgical resection with mediastinal nodal dissection including lobectomy in 20 cases, lobectomy with bronchoplasty in 2 cases, broncho/ pulmonary angioplasty in 7 cases, pneumonectomy in 2 cases. The bronchial stump was covered with pericardial fat tissue or intercostal muscle. Histological type were adenocarcinoma in 19 cases, squamous carcinoma in 10 cases, large-cell-carcinoma in 2 cases, 1 combined cell small-cell carcinoma, and 1 adenosquamous cell carcinoma. The mean operation time was 302 minutes and mean blood loss was 687g. There was no operative mortality nor in-hospital death. Post-operative complication was seen in 12 cases (36%), however there was no broncho-pleural fistula or bronchial dehiscence. The 3-years and 5-years overall survival after the surgery were 70% and 52.3 % with 53 months median follow-up period. Six years after the salvage surgery, there was no recurrence of lung cancer. **Conclusion:** The salvage surgery after curative-intent chemotherapy and/or radiotherapy for LALC is feasible with cautious patient selection, careful operative procedure, and meticulous perioperative care. Six years after salvage surgery the survivors may be expected to be free from lung cancer recurrence.

P2.18-04 IMPROVED OUTCOME IN FEMALE STAGE III NSCLC DIAGNOSES IS DRIVEN BY NON-CURATIVE INTENT TREATMENT, AND ADENOCARCINOMA HISTOLOGY

N. Alsaadoun[1], A. Gibson[1], F. Hao[1], M. Dean[1], A. Elegbede[1], S. Otsuka[1], R. Tudor[1], D. Bebb[2]

[1]*University of Calgary, Calgary/Canada,* [2]*Alberta Health Services, Calgary/ Canada*

Background: Biological sex disparities in incidence, molecular alterations and outcome in NSCLC have been well documented in the literature; however, there are no sex-based approaches to diagnosis and treatment in lung cancer. Recognising differences in therapeutic outcome and survival between the biological sexes could help inform clinical research and further personalized interventions in an effort to improve survival for NSCLC patients. **Method:** Using the Glans-Look Lung Research (GLR) database, a retrospective analysis was undertaken for Stage III (AJCC 7th edition) NSCLC patients diagnosed between 1999 and 2014. Demographic, clinical, treatment and outcome data were extracted to assess sex-based differences in histology, treatment uptake and survival. Univariate methods, including Kaplan-Meier survival analysis were performed to compare outcomes by sex, histology and treatment-intent. **Result:** 1040 Stage III NSCLC were identified, median age 69.6 years (IQR 61.3-76.8), 57.9% female, 89.1% 'ever' smokers, 34% adenocarcinoma (ADC), 36% squamous cell carcinoma (SCC), 20% 'other', 10% unknown. Among female patients ADC is more prevalent (42% vs. 28%, p<0.001), while in SCC patients are more likely to be males (44% vs. 26%, p < 0.001). Males were more likely to receive palliative-intent treatment (44% vs. 37%), while females more likely to receive best supportive care (BSC) (31% vs. 22%), p=0.006. Median overall survival (mOS) for the entire stage III cohort favoured females (14.1 vs. 10.7 months, p=0.001). This trend was also observed across different treatment categories, where female survival significantly exceeded that of males: curative-intent (25.5 vs. 18 months, p=0.035), palliative-intent (9.5 vs. 8.0 months, p = 0.025) and BSC (11.2 vs. 7.2 months, p=0.014). Although no differences in treatment patterns were seen between males and females within ADC or SCC, sex-based disparities in survival were also present within the ADC histology: female ADC mOS exceeded that of males, in overall comparisons (17.6 vs. 12.2 months, p=0.047), within palliative-intent treatment (15.1 vs. 8.0, p=0.008) and BSE (13.2 vs. 3.4, p=0.005), but not in curative-intent combined modality chemo-radiation (26.8 vs. 21.7 months, p =0.972). No differences in mOS, either overall or by treatment category were observed in SCC. **Conclusion:** Higher mOS among females in stage III NSCLC appears to be driven by both the ADC histology and non-curative-intent treatments. Sex-based differences in outcomes should be assessed more deeply as prognostic variable in patients with NSCLC.

P2.18-05 PATIENTS WITH YPN2 NSCLC AFTER NEOADJUVANT CHEMOTHERAPY FOLLOWED BY SURGERY CAN BENEFIT FROM PORT – A RETROSPECTIVE STUDY OF SEER DATABASE

Y. Bao[1], J. Kang[1], Y. Men[1,2], X. Sun[1], M. Yuan[1], M. Zhao[1], X. Yang[1], Z. Hui[1,2]

[1]*National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China,* [2]*National Cancer Center/National Clinical Research Center for Cancer/ Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China*

Background: Neoadjuvant chemotherapy followed by surgery (NCS) is a common therapy pattern of resectable non-small cell lung cancer (NSCLC). However, for patients with ypN2 disease after aforementioned treatment, there is no evidence that postoperative radiotherapy (PORT) should be adopted or not. Our study is to evaluate the effect of PORT on survival of patients with ypN2 NSCLC after NCS from Surveillance, Epidemiology, and End Results (SEER) database. **Method:** We filtrated data from SEER database by the inclusion criteria of patients with NSCLC diagnosed at 2004-2015, treated with NCS, and with ypN2 disease (2004-2009 AJCC 6th, 2010-2015 AJCC 7th). We excluded patients with unclear basic information (such as sex, histology or cause of death), multiple primary malignant tumor and M1 disease. All data were analyzed using the SPSS Statistics (version 25) and propensity-score matched analysis was used to match the base-line characteristics between

PORT group and non-PORT group. Kaplan-Meier method was used to estimate overall survival (OS) and cancer specific survival (CSS). Univariable and multivariable Cox proportional hazards models were adopted to estimate hazard ratios (HR) of predictors of survival. **Result:** From 331 patients receiving NCS, 215 meeting the criteria were included in the final analysis. There were 112 patients (52.1%) with PORT. The baseline characteristics of majority were as follows: age≤65 (55.3%), white (82.3%), female (54.4%), grade 3-4 (63.3%), adenocarcinoma (60.0%), tumor size of 3-5 cm (38.6%), lobectomy (80.0%) and positive lymph nodes≥4 (51.2%). There were 200 patients remained after the prosperity score matching between the PORT group and the non-PORT group, with 100 cases in each. The median OS of the two groups were 36 months vs 26 months and 5-year OS rates were 36.2% vs 20.3%, respectively (P=0.011). The median CSS were 36 months versus 27 months and 5-year CSS were 38.5% vs 21.1%, respectively (P=0.010). Univariable analysis showed that only PORT significantly improved OS (HR=0.648, P=0.013) and CSS (HR=0.639, P=0.012). Multivariable analysis confirmed that PORT was the only significant predictor of OS (HR=0.615, P=0.011) and CSS (HR=0.614, P=0.013). **Conclusion:** For patients with ypN2 NSCLC after NCS, PORT can significantly improve the OS and CSS . However, the result needs to be clarified by prospective randomized clinical trials.

Keywords: PORT, N2, Neoadjuvant chemotherapy

P2.18-06 TRENDS AND OUTCOMES OF MINIMALLY INVASIVE APPROACHES FOR LUNG CANCER RESECTION AFTER INDUCTION THERAPY IN THE UNITED STATES

M. Kamel, A. Sholi, S. Harrison, B. Lee, J. Port, N. Altorki, B. Stiles

New York Presbyterian Hospital-Weill Cornell Medical College, New York/ United States of America

Background: Lung resection following induction-therapy (IT) is technically challenging. To date, a paucity of national data exists on the feasibility of minimally invasive surgical (MIS) approaches in this setting. We assessed national trends and outcomes associated with MIS following IT, compared to open approach. **Method:** The National Cancer Database was queried for NSCLC patients undergoing resection following IT (2010-2016). Trends in MIS utilization were assessed using Mantel-Haenszel test. Propensity-matching (MIS vs. open) was performed (1:1-Caliper 0.2), controlling for age, gender, comorbidity, clinical stage, and histology. Perioperative outcomes and survival were compared between the matched groups. **Result:** Lung resection following IT was performed in 11287 patients. The utilization of MIS approaches increased from 19% in 2010 to 41% in 2016 (Mantel-Haenszel, P<0.001). The number of hospitals performing at least one MIS increased from 166 in 2010 to 305 in 2016. Compared to the traditional open approach, MIS approaches were used more frequently in patients with higher annual-income (>$63000, 37%vs.33%,P<0.001), and in patients treated in academic hospitals (54%vs.47%,P<0.001). The open approach was used more in males (54%vs.49%, P<0001), and in patients with larger tumor size (4.4cm vs. 3.8cm, P<0.001)(Table). In propensity-matched groups, there were no differences in 30-day readmission (3% vs. 4%,P=0.513), or 30-/90-day mortality between the two approaches (3%vs.4%,P=0.145; 6%vs.7%,P=0.685). However, MIS was associated with a shorter median length of stay (5vs.6 days,P<0.001). 5-year overall survival (OS) was slightly better in the open group (45% vs.39%,P=0.002). However, on multivariable analysis, surgical approach was not associated with OS (open approach: HR:0.99, 95%CI:0.91-1.09).

Lung resection following induction therapy 2010-2016 (propensity matched groups)

Patient characteristics and outcomes	MIS (n=3284)	Open (n=3284)	P value
Age, years (median, IQR)*	64 (56-70)	64 (57-60)	0.692
Gender (Male)*	1680 (51%)	1667 (51%)	0.748
Charlson Comorbidity Index (CCI>1)*	370 (11%)	351 (11%)	0.453
Histology (Adenocarcinoma)*	1701 (52%)	1708 (52%)	0.985
Clinical stage (III-IV)*	2345 (71%)	2297 (70%)	0.193
Surgical Procedure (Lobectomy) (n=6137)	2440 (83%)	2556 (80%)	<0.001
Pathological stage (III-IV) (n=5106)	1030 (41%)	1049 (40%)	0.345
Number of lymph nodes resected (median, IQR)	10 (4-16)	10 (5-16)	0.006
Number of positive nodes (median, IQR)	0 (0-2)	0 (0-2)	0.905
Positive resection margin (n=6199)	285 (9.5%)	256 (8%)	0.048
Length of stay, days (median, IQR)	5 (3-7)	6 (4-8)	<0.001
Unplanned 30-day readmission (n=6522)	188 (6%)	201 (6%)	0.513
30-d mortality (n=5351)	72 (3%)	103 (4%)	0.145
90-d mortality (n=5301)	155 (6%)	185 (6.5%)	0.685

* Variables controlled for in the Propensity Score analysis

Conclusion: National use of minimally-invasive surgery following induction therapy increased significantly over the study period. The current study shows that using MIS after induction therapy is feasible and safe, and is associated with a shorter hospital stay compared to open approach, yet without compromising perioperative outcomes or survival.

Keywords: VATS, minimally invasive surgery, induction therapy

P2.18-07 PROGNOSTIC FACTORS AFFECTING BRAIN METASTASIS-FREE SURVIVAL IN NON-SMALL CELL LUNG CANCER PATIENTS

F. Sert, D. Yalman, G. Cosgun, S. Ozkok

Ege University Medical School & Hospital, Izmir/Turkey

Background: Brain metastasis is a poor prognostic factor for survival in all cancer types.Prophylactic cranial irradiation(PCI)has been considered standard of care for patients with small-cell lung cancer because of its favorable effects on survival, however there is no identifiable effect of PCI on survival in non-small cell lung cancer(NSCLC).The aim of this study is to define the factors which may be related to brain metastasis in patients with NSCLC who developed brain metastases after their definitive treatment. **Method:** Two-hundred-eight patients with NSCLC,without brain metastases who received definitive radiotherapy or radiochemotherapy between January 2005 and January 2016 were evaluated retrospectively. Hematological parameters [platelet, neutrophil, lymphocyte counts, LDH, CRP, hemoglobin(Hb)levels,neutrophil-lymphocyte ratio(NLR)and platelet-lymphocyte ratio(PLR)],andFDG-PET/CT parameters(SUVmax values for the primary tumor and mediastinal lymph nodes),and patient characteristics were evaluated for brain-metastasis-free survival(BMFS).Cut-off values were determined byROC analysis. **Result:** Patient and treatment characteristics were indicated in Figure 1. Median follow-up duration was 25 months.Cut-off values for platelet, NLR, PLR, LDH, CRP, and Hb were 290x103/µL, 2.6, 198, 468 IU/L, 2.5 mg/dL, and 11.5 g/dl. We defined each parameter as low or high according to the cut-off values. Fifty six patients(26.9%) developed brain metastases during follow-up.Median BMFS for the whole group was 21 months. In univariate analysis high NLR(71 vs 80months;p=0.001), PLR(71 vs 74months;p=0.037), LDH (65 vs 85months;p=0.028), CRP(47 vs 95months;p=0.002) values, SUVmax value ≥7.5 for lymph nodes(47 vs 79months;p=0.005) were poor prognostic factors for BMFS. In multivariate analysis high NLR(p=0.022), PLR(p=0.017), CRP(p=0.006), stage ≥IIIA disease(p<0.001), multi-stational N2 disease(p=0.036), adenocarcinoma histology(p<0.001) and SUVmax value ≥7.5(p=0.035) were poor prognostic factors for BMFS. Median survival duration after brain metastases was 6.5 months.

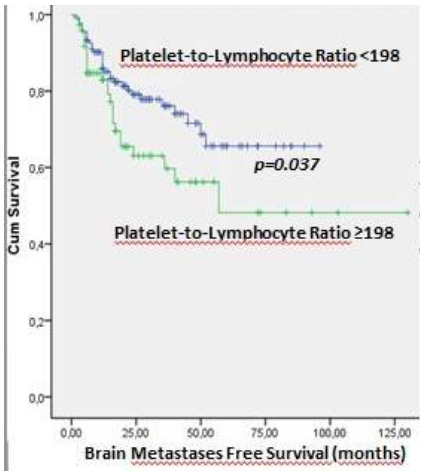
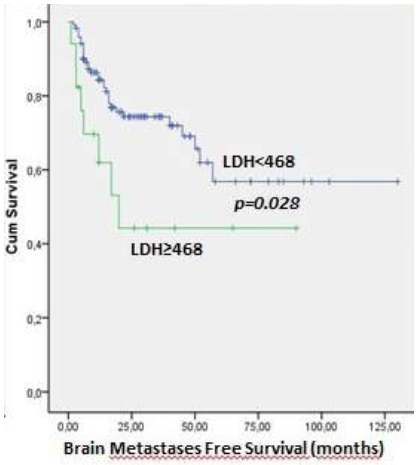
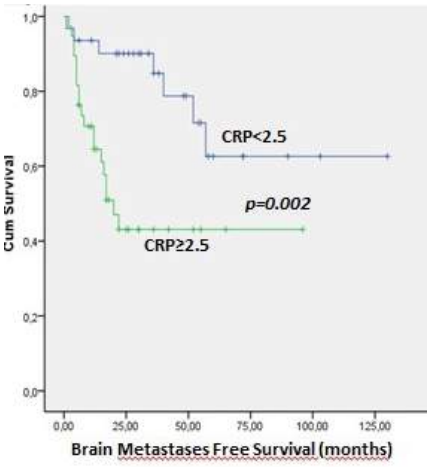
POSTERS







Conclusion: Development of brain metastases after definitive treatment of NSCLC is a serious problem affecting survival unfavorably. High NLR, PLR, LDH, CRP values and high SUVmax values for lymph nodes were additional prognostic factors besides stage, histology, and lymph node status.

Keywords: Non small cell lung cancer, brain metastasis, prognostic factors

P2.18-08 THE NECESSITY AND TECHNIQUE OF THE UPPER ZONE LYMPH NODE DISSECTION FOR NON-SMALL-CELL CARCINOMA OF THE LEFT UPPER LOBE

T. Yokota, S. Ikeda

Mitsui Memorial Hospital, Tokyo/Japan

Background: The removal of the whole regional lymphatic system together with primary tumor is one of the important rules in oncological surgery.(According to the study of regional lymphatic drainage, we considered reasonable lymphadenectomy contributes the post-operative survival of the Left lung cancer patients with mediastinal lymph node metastasis. Due to anatomical limitations imposed by arch of aorta, it is difficult to perform complete dissection of upper zone mediastinal lymph nodes through the left thoracotomy in the left lung cancer. We had devised Systematic extended bilateral mediastinal dissection through a median sternotomy (ND3 operation) for patient with NSCLC of the left lung. This report aimed to introduce procedure of our operation and investigate the prognostic impact of Upper zone lymph node dissection for left upper lobe NSCLC. **Method:** The our operative procedure is as follows. In the supine position, made a median sternotomy. We dissect the meidastinal nodes before pulmonary resection. The dissection is started on the highest area. Tape the right and left recurrent laryngeal nerve and dissect the highest paratracheal lymph nodes in the thoracic inlet. After making the pericardiotomy, the ascending aorta is retracted to the left. Remove the whole upper zone tissue lying in front of the trachea. And dissect the pre and paratracheal nodes, together with bilateral highest nodes. Then, dissect the subcarinal nodes. Tie off the blood vessels (arteries and veins) and airways leading to the affected lobe, and then remove the lobe. We retrospectively studied 213 patients [157 male and 61 female, mean ages 60.4 years (range, 29-75)], underwent ND3 operation due to NSCLC of the left upper lobe, from January 1990 till December 2017. The patients with NSCLC who are estimated to be able to conventional radical operation and aged 75 year-old or less becomes the adaptation of our operation. **Result:** Overall 5-year survival rate in the 218 patients of left upper lung primary was 65.1%. Operative mortality in 218 patients was 2.8%. Lymph node metastasis to the mediastinum was confirmed in 70 (32.1%) patients (pN2 was 43 ,pN3α was 18 ,pN3γ was 9). According to pathological stages, five-year survival rate was 92.7% in stage IA ,80.1% in stage IB, 53.8% in stage IIA, 66.7% in stageIIB, 51.7% in stageIIIA, 38.4% in stageIIIB. And it was 52.1% in pN2 cases, and 55.0% in pN3α cases. Five-year disease free survival rate was was 85.6% in p-stage IA ,74.0% in p-stage IB,49.7% in p-stage IIA, 49.4% in p-stageIIB, 33.3% in p-stageIIIA, 19.4% in p-stageIIIB, 32.6% in pN2 cases, and 27.8% in pN3α cases. **Conclusion:** In this nonrandomized comrarision, the post-operative survival of patients with pN2 and pN3α NSCLC of the left upper lung primary would be remarkably improved by our Systematic Bilateral Mediastinal Dissection. And better local tumor control by our operation does not increase mortality. When faced with a patient with resectable mediastinal lymph node metastasis, we should consider Extended bilateral mediastinal lymph node dissection through a median sternotomy. To improve survival rate, it is important to perform curative operation with upper zone mediastinal dissection.

Keywords: Upper Zone lymph node dissection, Non-small-cell carcinoma of the left upper lung.

P2.18-09 AGE DOES NOT AFFECT THE BENEFIT OF MODERN CHEMORADIATION FOR LA-NSCLC PATIENTS

S. Ramella[1], C. Greco[2], M. Fiore[2], A. Iurato[2], E. Molfese[2], M. Miele[1,2], R. D'Angelillo[1,2]

[1]*Campus Bio-Medico University, Via Alvaro del Portillo (RM)/Italy,* [2]*Radiotherapy Unit, Rome/Italy*

Background: The standard of care for inoperable stage III non-small-cell lung carcinoma (NSCLC) is concurrent chemoradiation which achieves the better results but is affected by higher toxicities. Even if literature data document a significant advantage also for elderly population, these selected group of patients is usually underrepresented in randomized trials. This study analyzed treatment and outcomes at our institution according to elderly (>70 years old) or younger (≤ 70 years) age. **Method:** A secondary analysis on patients with stage III NSCLC treated between January 1992 and September 2014 with concurrent chemoradiation with radical intent enrolled in previous published trials in our institution were analyzed.

Factors analyzed included Eastern Cooperative Oncology Group Performance Status (ECOG PS), sex, stage, histology, treatment period and esophageal and lung toxicities. **Result:** A secondary analysis on 347 patients (≤70years: 188; >70years: 159) with stage III NSCLC treated with concurrent chemoradiation enrolled in previous published trials in our institution were analyzed (age range, 39-92 years). Elderly patients were more frequently male (85% and 72%; p=0.003) and stage IIIB (49% and 34%, p=0.008). ECOG was 0-1 in all cases (elderly: 36% and 29%, p=0.451). No differences were reported according to tumor histology. Median survival was similar between the younger and elderly patients (20,8 and 19,2 months respectively; p=0.503). A significant difference in overall survival was appreciated according to treatment period also for elderly population. Overall survival of all patients treated between 1992-2005 and 2006-1014 was 17.8 and 25,9 months, respectively (p<0.001). According to the same periods, elderly group survival was 16,5 and 24,9 months (p=0.002). No significant differences were reported in esophageal and lung toxicities between elderly and younger patients (Esophageal G2: 18.6% and 21%; Esophageal G3: 1,7% and 2,6%; Lung G2: 6,4% and 6,3%; Lung ≥G3: 5,7% and 3,1%, respectively). **Conclusion:** In this series elderly patients in clinical good condition with locally advanced NSCLC treated with concurrent chemoradiotherapy reached interesting results in terms of overall survival without increased toxicity. The improved outcome obtained in younger patients in the modern era is achievable also for this selected elderly population.

P2.18-10 IMPORTANCE OF THE MULTIDISCIPLINARY TUMOR BOARD IN THE TREATMENT STRATEGY OF STAGE III NON-SMALL CELL LUNG CANCER (NSCLC)

J. Benet[1], A.C. Toffart[1], G. Frey[1], T. Chollier[1], S. Ruckly[2], J. Villa[1], C. Emprou[1], J. Pinsolle[1], I. Dumas[1], P. Guillem[1], G. Ferretti[1], D. Moro-Sibilot[1], M. Giaj Levra[1]

[1]*CHU Grenoble, La Tronche/France,* [2]*ICUREsearch, Parsi/France*

Background: Stage III Non-Small Cell Lung Cancer (NSCLC) represents a heterogeneous population with different treatment strategies, often in combination. The PACIFIC trial is changing practices. It is therefore necessary to evaluate our current practices in order to identify the patients that should most likely receive this treatment after chemoradiotherapy **Method:** A database constructed from our weekly multidisciplinary thoracic oncology meetings was retrospectively screened from 01/2010 to 01/2017. Consecutive patients with stages III NSCLC were included. We aimed to describe proposed treatment strategies and those really performed **Result:** Of the 411 patients studied, 249 had a stage IIIA NSCLC and 162 a stage IIIB NSCLC. Median age was 65 years [IQR 25%-75%, 58-72], 309 (75%) patients were male. The majority of the patients (n=270, 69%, 20 missing data) had an ECOG-Performance status of 0 or 1. Regarding histology, 199 (48%) patients had an adenocarcinoma and 199 (48%) a squamous cell carcinoma. Treatment strategies are described in Table 1. Sixty-nine (17%) patients received exclusive chemoradiotherapy, and 60 (15%) were planned for neoadjuvant chemotherapy for subsequent surgery. Among these 60 patients, after the first cycles of the initial chemotherapy, only 37 (62%) received surgery in accordance with the multidisciplinary meeting decision; 6 (10%) received concurrent chemoradiotherapy and 6 (10%) sequential chemoradiotherapy.

	Received treatment, n=411 N (%)
Surgery upfront	141 (34)
Chemoradiotherapy upfront	73 (17)
- concurrent	26 (36)
- sequential	43 (59)
- followed by surgery	4 (5)
Planned for chemotherapy neoadjuvant followed by surgery	60 (15)
- chemotherapy neoadjuvant followed by surgery	37 (62)
- chemoradiotherapy (concurrent / sequential)	12 (20) (6/6)
- exclusive chemotherapy	10 (17)
- exclusive radiotherapy	1 (2)
Exclusive radiotherapy	24 (6)
Exclusive systemic treatment (chemotherapy or targeted therapy)	68 (17)
Exclusive palliative care	45 (11)

Conclusion: In our cohort, 8% (32/411) of the stage III patients benefited from a chemoradiotherapy upfront. According to the PACIFIC study, these patients could receive adjuvant immunotherapy. We could ask if the patients planned for surgery after neoadjuvant chemotherapy should not be initially proposed for a concurrent chemoradiotherapy to give them the opportunity to receive adjuvant immunotherapy. Survival analyses according to treatment strategy are ongoing

Keywords: locally advanced NSCLC, concomitant treatments, multidisciplinary team

P2.18-11 REAL-WORLD EXPERIENCE OF CONSOLIDATION DURVALUMAB FOR LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER (NSCLC)

A. Barbaro[1], F. Mienko[2], L. Deng[2], N. Ohri[2], B. Halmos[3], R. Perez-Soler[4], R. Gucalp[3], W. Bodner[2], H. Cheng[5]

[1]*Department of Medical Oncology / Montefiore Medical Center, Bronx/United States of America,* [2]*Montefiore Medical Center, Bronx/United States of America,* [3]*Department of Oncology, Montefiore/Albert Einstein Cancer Center, Bronx/United States of America,* [4]*Albert Einstein College of Medicine/Montefiore Medical Center, Bronx/United States of America,* [5]*Montefiore Medical Center/Albert Einstein College of Medicine, Bronx/United States of America*

Background: Durvalumab was recently approved as consolidation treatment following concurrent chemoradiation (CRT) in stage III NSCLC based on the positive PACIFIC trial demonstrating improved progression free survival (PFS) and overall survival (OS). Here, we examined the integration of durvalumab therapy after CRT in an urban comprehensive cancer care center serving a high proportion of Black and Hispanic patients. We aimed to examine treatment barriers in this diverse patient population and gain insights into real-world experience. **Method:** Our study included patients treated with CRT for NSCLC (stage II-III) at Montefiore Medical Center (MMC) from 2007-2018. Retrospective analysis was conducted to evaluate patient characteristics, therapies and outcomes. Patients were grouped based on the PACIFIC trial eligibility criteria for durvalumab. PFS and OS were estimated using the Kaplan-Meier method, and comparisons between subgroups were made using log-rank testing, adjusted by Cox proportional hazards regression. **Result:** 146 patients completed CRT for locally advanced NSCLC from 2007 to 2018. 27% (n=40) would be considered ineligible for durvalumab based on the PACIFIC criteria (Table 1: reasons). Patient demographics were similar in ineligible vs. eligible groups: mean age 67.7 vs 67.9 years, male 57.6% vs 43.5%, Black 36.7% vs 43.5%, Hispanic 22.6% vs 30.1%. In the era of durvalumab therapy (since 9/2017), 68% (n=17) received durvalumab, including 4 patients that did not meet PACIFIC criteria due to co-morbidities and/or additional malignancy. The use of durvalumab therapy has increased with time in eligible patients from 33% in 9/2017-12/2017 to 100% in 10/2018-12/2018. The median time to initiate durvalumab following CRT has decreased from 56 days before 7/2018 to 30 days afterwards (p=0.02). Several eligible patients did not receive durvalumab due to questionable benefit in EGFR–mutant NSCLC (n=2), refusal of treatment (n=1), and unkown (n=1). Compared to patients who received durvalumab, patients who did not receive it were found to be of a lower socioeconomic status (p=0.086). Moreover, there was a trend toward improved 15-month OS rates in durvalumab-treated patients compared with patients who did not receive it (100% vs 87.5%, p=0.131).

Table 1: Reasons for ineligibility based on PACIFIC criteria for durvalumab consolidation treatment	
Reasons for ineligibility	**N (%)**
Severe concurrent illness	13 (32%)
Additional malignancy other than NSCLC	6 (15%)
Not stage III	5 (12%)
Progression after chemoRT	3 (7%)
Persisting Grade 3 toxicity related to chemo-RT	3 (7%)
Incomplete chemoRT	2 (5%)
Autoimmune disease	2 (5%)
Recieved alternate study	2 (5%)
Lost to follow up	2 (5%)
Mixed small cell histology	1 (2%)
Unknown	1 (2%)

Conclusion: Our results reveal more frequent use and improved time to initiate durvalumab following CRT, as well as promising initial survival data in a real world setting. A substantial proportion of patients would be ineligible as per PACIFIC criteria, yet several received durvalumab and remain disease controlled, suggesting that further investigation of durvalumab in this population is warranted.

Keywords: durvalumab, consolidation, NSCLC

P2.18-12 PROGNOSTIC NUTRITION INDEX AFFECTS PROGNOSIS OF TRIMODALITY THERAPY FOR LOCALLY ADVANCED LUNG CANCER WITH HIGH T FACTOR

J. Soh[1,2], K. Suzawa[3], K. Shien[3], S. Otani[3], H. Yamamoto[3], M. Okazaki[3], S. Sugimoto[3], M. Yamane[3], T. Oto[3], K. Kiura[3], S. Toyooka[3]

[1]*Kindai University Faculty of Medicine, Osaka-Sayama/Japan,* [2]*Okayama University, Okayama/Japan,* [3]*Okayama University Hospital, Okayama/Japan*

Background: Pretreatment nutritional status critically affects the clinical outcomes. Induction chemoradiotherapy (iCRT) followed by surgery (trimodality therapy) is a high-invasive treatment option for patients with locally advanced non-small cell lung cancer (LA-NSCLC). LA-NSCLC is a heterogeneous disease. Direct invasion into the surrounding structures easily promotes the invasion-related symptoms which inpair quality of life, but lymph node metastasis rarely causes its related symptoms until the bulky metastatic lymph nodes invade the surrounding structures. These differences of disease extent are expected to affect not only clinical outcome of treatment but also nutritional condition before initiation of treatment. While the prognostic nutritional index (PNI) is known to be correlated with the clinical outcomes after surgery in patients with early NSCLC, the significance of the PNI in LA-NSCLC patients undergoing trimodality therapy has not yet been well examined. In this study, we investigated the clinical impact of PNI in the LA-NSCLC patients who underwent iCRT followed by surgery considering the heterogeneity of disease extent. **Method:** We enrolled 127 patients who received trimodality therapy at our institution between 1999 and 2016. The PNI was examined at all three time-points in the patients: before iCRT, before surgery, and after surgery. **Result:** Fifty-five and 72 patients were diagnosed as clinical T1/2 (cT1/2) and cT3/4 diseases, respectively, and, 42 and 85 patients were cN0/1 and cN2/3, respectively. The PNI significantly decreased as the treatment progressed among all 127 patients. Patients with cT3/4 disease showed significantly lower PNI values before and after surgery than those with cT1/2 disease. By contrast, the PNIs were equivalent at all time-points between patients with cN2/3 and cN0/1 disease. We performed receiver-operating characteristic curve analysis to determine the cutoff the pre-iCRT PNI for overall survival (OS) in all (n = 127), cT3/4 (n = 72) and cN2/3 patients. The ROC curve analyses indicated that a significant cutoff was identified only in cT3/4 patients. Univariate and multivariate analyses revealed that high pre-iCRT PNI values were significantly correlated with better survival in cT3/4 patients. By contrast, the prognostic impact of pre-iCRT PNI values could not be observed in cN2/3 patients **Conclusion:** The nutritional status deteriorates as the treatment progresses during trimodality therapy. Intensive perioperative nutritional intervention is required especially for cT3/4 LA-NSCLC patients receiving trimodality therapy.

Keywords: induction chemoradiotherapy, prognostic nutrition index, locally advanced non-small cell lung cancer

P2.18-13 ENDOBRONCHIAL BRACHYTHERAPY: A SINGLE INSTITUTIONAL EXPERIENCE

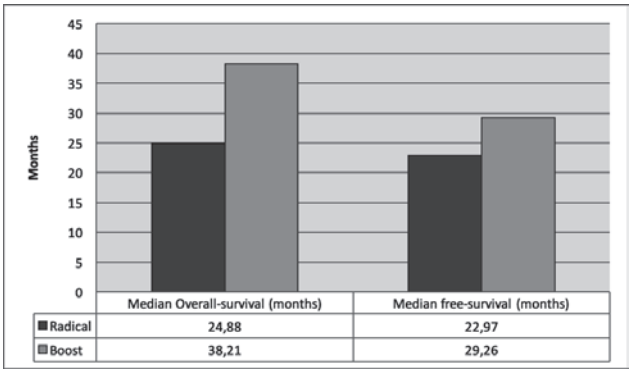
P. Trias Sabrià[1], J. Mases Rosinés[2], M.R. López-Lisbona[1], N. Cubero De Frutos[1], M. Díez-Ferrer[1], S. Padrones Sanchez[1], S. Aso-González[1], D. Najjari Jamal[2], I. Visus Fernández De Manzano[2], A. Slocker Escarpa[2], J. Dorca Sargatal[1], C. Gutierrez Miguelez[2]

[1]*Department of Pulmonology - Hospital Universitari de Bellvitge, University of Barcelona, IDIBELL, CIBERES, Barcelona/Spain,* [2]*Radiation Oncology - Institut Català d'Oncologia, L'Hospitalet de Llobregat/Spain*

Background: High Dose Rate Endobronchial Brachytherapy (HDR-EB) allows treatment of endobronchial lung cancer with minimal radiation of surrounding tissues. It can be both applied as radical intent in local disease or as palliation in metastatic or non-curative setting. The aim of this study is to describe clinical characteristics, complications and survival of a cohort patients treated with HDR-EB as radical intent. **Method:** Retrospective analysis of consecutive patients undergoing radical HDR-EB in our centre since 2010. Clinical, functional and survival variables were recorded, as well as those related to radiation. HDR-EB was performed after placement of the afterloading catheter in the target bronchus with a flexible bronchoscope. All treatment was delivered weekly. Simulation CT and dosimetry was performed before each fraction. Dose was 5Gy/fr, prescribed at 100% of the implant. **Result:** 16 patients were analysed, 15 (94%) males, age 69 (+/-8) years-old, 3 (19%) were active and 13 (81%) former smokers. Lung function was FEV1 62.3% (+/- 21%), DLCO 60.5% (+/- 13%). Pathological diagnose included in-situ carcinoma (n=1, 6%) and invasive squamous cell carcinoma (n=15, 94%). T staging was T1 in 10 (62.5%) patients, T2 in 3 (18.8%) patients and T4 in 1 (6.3%) patient. All patients had N0 staging. 2 patients had exclusive endobronchial disease. 6 patients received 3 (n=3, 18.6%) and 4 (n=3, 18.6%) fractions after external beam radiotherapy as a boost. 10 patients received 5 (n=2, 12.5%) or 6 (n=8, 50%) fractions as exclusive radical HDR-EB.

2 complications were reported: obstructive pneumonitis (n=1) and bronchial stenosis (n=1). Neither deaths nor haemoptysis occurred in relation with the technique. Mean follow-up was 29 (+/- 21) months. Mean overall survival was 29.0 (+/- 22) months. Mean disease free-survival was 24.9 (+/- 21) months. 4 (25%) progressions were observed, of which 3 (19%) were local progression.

Patients who received boost strategy HDR-EB showed an increased overall survival compared to radical intent (38.2 vs 24.8, p>0.05) and a increased median free-survival; which showed no statistical significance.



Conclusion: HDR-EB is a safe technique applicable in radical intention. Longer survival has been described in patients who received boost strategy. Prospective studies are needed to determine long-term benefits.

Keywords: Brachytherapy, Bronchoscopy, radiotherapy

P2.18-14 THE ROLE OF SURGERY IN HIGH GRADE NEUROENDOCRINE TUMORS OF THE LUNG

M. Bedirhan, N. Urer, Y. Seyrek, N. Arda, N. Fener, L. Cansever, M. Kıyık, S. Altun

Yedikule Chest Disease and Thoracic Surgery Hospital, İstanbul/Turkey

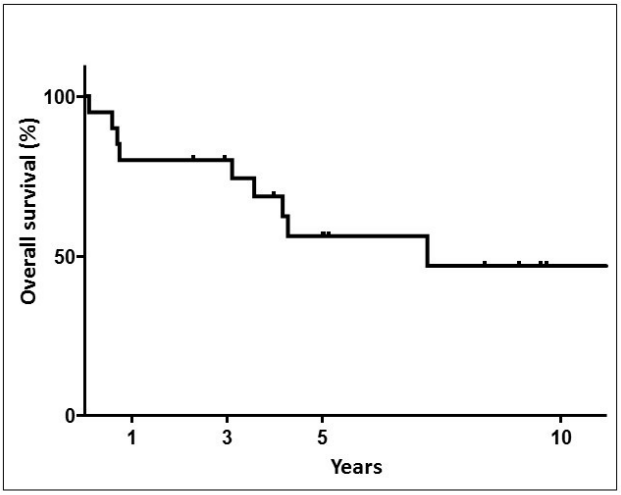
Background: Despite early stage operated lung cancer's better prognosis, high grade neuroendocrine carcinoma (HGNC), including small cell carcinomas and large cell neuroendocrine carcinomas, are rapidly progressive and most cases are inoperable when they are diagnosed (1). The aim of this study is to evaluate the surgical results of HGNCs and try to define what factors influence the prognosis. **Method:** Data was collected retrospecively between the years of january 2009 through December 2017 at Yedikule Hospital for Chest Disease Hospital. Clinical survey has ended in january 2019 . During this period 3946 elective lung cancer operations were performed. Patients with exploratory thoracotomy, neoadjuvan treatment and who lost follow-up were excluded from the study. Seventy-one patients operated for HGNC durig this period were enrolled the study. Sixty-five of them had anatomical resection. The ratio of anatomically resected HGNC to over all anatomic cancer resections was 65 over 3946 (1.64%). Twenty-four of 71 cases were HGN small cell (%33.8) and thirty-five of 71 (%49.3) of the cases were HGN large cell carcinomas. The remaining 12 cases (%16.9) were combined carcinomas.Thirty-one of 71 tumours were T1 (43.6%). Pre-oprerative diagnosis rate in patients with T1 tumors, is 29%. **Result:** Thirty-one of the patients were in stage I (43.6%), twenty-three of the patients were in stage II (32.3%) and seventeen of the cases were in stage III (24.1%). Subgroups of the stages are shown at table I.Overall survival was 60.75 ± 6.93 months when all operated patents were concidered. Five-year -survival was 44.3% .When overall survival were compared by stage there was statistically significant difference. Overall survivals were as follows; in stage I- 67.03±10.86 months, stage II 61.43±10.83 months, stage III- 33.23±8.6 months (p=0.02) (Figure I). Five-year survival were 46% in stage I, 45% in stage II, 32% in stage III for HGNC. When overall survival were compared by histopathologic type, combined neuroendocrine carcinomas reflect the least overall survival value but the difference is not statistically significant. Overall survivals were as follows; in large cell neuroendocrine carcinoma- 59.4±9.23, small cell neuroendocrine carcinoma carcinoma 68.6±12.2 combined type neuroendocrine carcinoma- 40.9±10.1 months (p=0.462) (Figure 2). There is no statistically significant difference betwen small cell and large cell neuroendocrine tumours' overall survival values (p=0.34).When overall survival were compared by N status, overall survival were as follows. Patients with N0 disease 65.9± 8.3, N1 disease 53.6±10.6, N2 disease 37.1±15.3 months. There was no statistically significant difference (p=0.103) (Figure 3). When N0 and N2 patients' survivals are compared p value is 0.094. **Conclusion:** Although high grade nuroendocrine tumors (NET) of the lung have poor prognosis compared with other NSCLCs (11,12,13), satisfactory survival results are asessed in our study. As a result, good overall survival rates can be achieved in surgically operated patients with HGNEC tumors who had post- operative adjuvant chemotherapy, mediastinal radiation therapy when necessary and protective cranial radiotherapy. Nevertheless, thoracic surgeon should be very selective in patients with stage IIIa HGNEC tumors.

P2.18-15 SURGICAL OUTCOMES OF PNEUMONECTOMY AFTER INDUCTION THERAPY FOR NON-SMALL-CELL LUNG CANCER

N. Okumura[1], Y. Otsuki[1], H. Kayawake[2], A. Takahashi[1], T. Nakashima[1], T. Matsuoka[1], T. Yokoyama[1], S. Itasaka[1], Y. Yamamoto[1]

[1]*Kurashiki Central Hospital, Kurashiki/Japan,* [2]*Kyoto University, Kyoto/Japan*

Background: The mortality of pneumonectomy after induction therapy (IT) for locally advanced non-small-cell lung cancer (NSCLC) is reported to be as high as 26%. However, pneumonectomy after IT has also been reported of having an acceptable safety and favorable outcomes. We retrospectively reviewed the postoperative outcomes of this procedure. **Method:** Between April 2004 and September 2016, of 179 patients who underwent neoadjuvant therapy, 20 consecutive patients (11.2%) underwent pneumonectomies for locally advanced NSCLC after IT in our institution. Perioperative management, mortality, postoperative complications and survival were retrospectively analyzed. **Result:** Eighteen patients were men, and the median age was 64 years (range, 38 to 79). Clinical stages (7th edition of TNM classification) were as follows: Stage IIA(n=2), Stage IIB(n=1), StageIIIA(n=15), and StageIIIB(n=2). There were 7 right and 13 left resections. Three patients underwent pneumonectomy after induction chemotherapy and 17 underwent after induction chemoradiation. A pathological complete response(Ef.3)due to IT was obtained in 8 patients (40%). In all cases the bronchial stumps were covered with autologous tissue including pedunculated intercostal muscle or mediastinal fat pad. There were no deaths within 30 days. However, one patient died within 90 days after transferring to a rehabilitation hospital. Postoperative complications of all grades were seen in 15 patients (75%), with major complications (Clavien-Dindo classification ≥IIIa) in 5 patients (25%). Major complications were all late-phase empyema, one with BPF and 4 without BPFs, which were all cured with surgical interventions. 5-year overal and recucurence free suvavals were 56.1 % and 47.4%, respectively. The average observation period of alive patients was 2500 days (range, 836 to 5144 days).



Overall 3-year survival: 80.0%
Overall 5-year survival: 56.1%

Conclusion: Our results suggest that pneumonectomy after IT for locally advanced NSCLC is a feasible and valuable treatment option. However, due to a high complication rate, surgery by experienced surgeons and careful postoperative management are essential for successful outcomes.

Keywords: locally advanced NSCLC, induction therapy, pneumonectomy

P2.18-16 VATS LOBECTOMY AND CHEST WALL RESECTION FOR NSCLC

H. Melek[1], B. Özkan[2], H. Kara[2], E. Kaba[3], A. Bayram[1], M. Ülker[2], E. Erşen[2], A. Turna[2], A. Toker[3], C. Gebitekin[1]

[1]*Uludag University, Bursa/Turkey,* [2]*İstanbul University, İstanbul/Turkey,* [3]*Istanbul Florence Nightingale Hospital, İstanbul/Turkey*

Background: The classic surgical approach in patients with NSCLC invading the chest wall is lobectomy and chest wall resection by thoracotomy in the majority of patients. However, this approach can be performed by video-assisted thoracoscopic surgery (VATS) or robotic surgery (RATS) as a result of increased experience and technological developments. The aim of this study was to evaluate the feasibility of the technique and its results in patients undergoing lung and chest wall resection by means of minimally invasive surgery. **Method:** The data of patients who underwent anatomical lung resection using VATS or RATS for NSCLC in three academic hospitals between 2013-2018 were prospectively recorded and reviewed retrospectively. Fourteen patients, all but three males with a median age of 62 ± 6.0 years, undergoing lung and chest wall resection were included in the study. Surgical results were evaluated. **Result:** Neoadjuvant/induction treatment was chemo-radiotherapy in three and chemotherapy in two patients. The preferred surgical technique was RATS in two patients, and multiportal VATS in 10 and uniportal VATS approach in two patients. Upper lobectomy was performed in 11 patients, lower in two patients and upper lobe posterior segmentectomy in one patient. Standard small incision for chest wall resection was performed in four, Hybrid approach in 10 patients. Five

patients had one, 6 patients had two, two patients had three and one patient had four ribs resections. Chest wall reconstruction was not necessary in any of the patients. The mean operation time was 96.4 ± 21.8 minutes. Complications were observed in 5 (35.7%) of the patients without mortality. The most common complication was prolonged, >5 days, air leak in four patients (28.6%). Ten patients (71.4%) were classified as T3N0, one patient (7.1%) as T4N0, one patient (7.1%) as T4N1, and two patients (14.1%) as T3N0M1. Surgical margins were reported as tumor-free (R0) in all patients. Adjuvant chemotherapy was given in eight patients (57.1%). The two-year survival rate was 66.8%. **Conclusion:** Lobectomy and chest wall resection with minimally invasive surgery is a safe and feasible method in patients with NSCLC with chest wall invasion. Compared with thoracotomy, it provides equivalent oncologic outcomes as well as less postoperative pain, smaller incision, and faster recovery.

Keyword: Minimally Invasive Surgery, VATS, RATS, Robotic Surgery, Chest Wall Resection

P2.18-17 OUTCOME OF SURGICAL TREATMENT FOR CLINICAL N1 NON-SMALL CELL LUNG CANCER

D. Nemoto[1], H. Ito[1], T. Tsuboi[1], D. Eriguchi[1], J. Samejima[1], T. Nagashima[1], H. Nakayama[1], M. Masuda[2]

[1]*Kanagawa Cancer Center, Yokohama/Japan,* [2]*Yokohama City University Graduate School of Medicine, Yokohama/Japan*

Background: Main stem treatment for clinical N1 NSCLC is surgery, but it is sometimes difficult to perform because tumor or metastatic lymph-node invade hilar structures. Nowadays, treatment outcome has been improved. This study aims to reconsider the surgical outcome of N1 NSCLC. **Method:** The data of 337 cases who underwent at least lobectomy and lymph node dissection for NSCLC from 2000 to 2014 was retrospectively reviewed. The factors which may have impact for survival and treatment related death (TRD) were examined. **Result:** Median follow up period was 51.7 months. 337 cases were 15.3% of all lobectomy and pneumonectomy performed in this period. 248 males and 89 females, average age was 67.1. Lobectomy was 309 including 15 bronchoplasty and pneumonectomy was 28. Mean operative time was 212 minutes, blood loss was 110g. TRD was noted in 6 (1.8%); 3 interstitial pneumonia, 2 myocardial infarction and a stroke, 4 cases (1.2%) died within 30 day after surgery.During this time, TRD of clinical N0 was 8 case (0.46%) and N2 was a case (0.82%). TRD of N1 was significantly frequent (p=0.026). Pathologically, N0 was 152 cases (45.1%), N1 was 116 (34.4%) and N2 (20.5%); pathological accuracy of N1 was only one third. 5 year survival rate of clinical N1 was 59.3%, 83.6% in N0 and 54.1% of N2. In histology, adenocarcinoma was 184, 113 squamous, 8 large, 7 adenosquamous and 25 other. Induction therapy, blood loss and pathological N status had negative impact for survival. On the other hand, operative time and right side had negative impact for TRD. **Conclusion:** The outcome of clinical N1 has been improved compared with historical report, but the accuracy of clinical N1 is not satisfied one. TRD rate in N1 was relatively high, surgery for N1 NSCLC should be performed by certified thoracic surgeons.

Keywords: Lymph node metastasis, prognosis, Lung cancer

P2.18-18 IMPACT OF COMBINED EVALUATION USING TUMOR VOLUME AND METASTATIC NODAL EXTENT IN STAGE III NSCLC TREATED WITH CRT

Y. Tamiya, M. Morise, R. Matsuzawa, I. Tanaka, T. Okada, S. Iwano, T. Hase, N. Hashimoto, M. Sato, Y. Itoh, Y. Hasegawa

Nagoya University Hospital, Nagoya/Japan

Background: Chemoradiotherapy (CRT) is the standard treatment for patients with unresectable stage III non-small cell lung cancer (NSCLC). In those, gross tumor volume (GTV) and number of metastatic nodal stations were proposed as possible prognostic factors, while TNM stage classification (stage IIIA vs. stage IIIB/IIIC) did not show significant prognostic impact. However, these evidences remain controversial. The aim of this study was to investigate the prognostic impact of GTV and metastatic nodal extent. **Method:** We retrospectively reviewed stage III NSCLC patients treated with CRT at our institution between October 2005 and December 2018. Simplified GTV (sGTV) was calculated by oval volume formula. We confirmed statistically significant association between sGTV and standard GTV as previous preparation. Metastatic nodal extent was divided into limited nodal extent (≤ND2a) (defined as "LN") or extensive nodal extent (>ND2a)(defined as "EN"). Prognostic impact of sGTV and metastatic nodal extent was evaluated by univariate and multivariate analysis. **Result:** 58 patients were enrolled in this study. Median progression-free survival (PFS) of all patients were 9.0 months. In univariate analysis, patients with sGTV>90cm3 had shorter PFS compared to those with sGTV≤90cm3 (median PFS: 6.7 vs. 11.7, p=0.03). Further, patients with sGTV>90cm3 and EN showed poorer PFS (HR 3.3; 95% CI,1.40-7.87; p<0.01) and OS (HR 3.3, 95% CI: 1.18-9.32, p<0.01) in univariate analysis. Multivariate analysis also showed an independent poor prognosis in patients with sGTV>90cm3 and EN (adjusted HR of PFS: 3.6, 95% CI: 1.49-8.71, p<0.01, adjusted HR of OS 4.1, 95% CI: 1.37-12.6, p=0.01). **Conclusion:** Combined evaluation using sGTV and metastatic nodal extent can be a useful stratified factor for clinical trial in patients with stage III NSCLC.

Background: Neoadjuvant treatment (NT) prior to surgical resection is the standard treatment for operable stage III-pN2 NSCLC. Our objective is to compare the response, radiological and pathological, after induction with radio-chemotherapy (RT-Ch) versus chemotherapy alone (Ch). **Method:** We develop a retrospective study that included 53 patients from four different centres diagnosed of stage III NSCLC (TNM 8th edition). 34 patients received RT-Ch and 19 received Ch between 2012 and 2018, with a median follow-up of 25 months. The radiological response (RR) was assessed by CT at 3-4 weeks after NT using RECIST criteria. The pathologic response (PR) was evaluated in operated patients (44) through the viable residual cells in the tumor and lymph nodes. pN was taken into account to determine the rate of downstaging. The PR, as well as the surgery, were performed in the same center for all 44 patients **Result:** The majority were stage IIIA (33), followed by IIIB (19) and only one was IV (single brain metastasis treated previously with radiosurgery). Comparing the RR in RT-Ch and Ch, we found stable disease and partial response more frequently with a 35.6% vs 52.6% and 61.8% vs 36.9% respectively. A 17.3% and 5.3% of the complete PR was achieved in RT-Ch and Ch respectively. Downstating was feasible in 82.8% of RT-Ch and 40% in Ch. Clinical features and treatment evaluation in Table 1.

Table 1. Clinical, pathological and treatment features (n=53).

	RT-Ch (n=34)	Ch alone (n=19)

Stabilization	0 (0%) - 0 (0%)	6 (40%) - 1 (6.7%)
Partial response	8 (27.6%) - 2 (6.9%)	2 (13.3%) - 2 (13.3%)
Maximum response	20 (69%) - 26 (89.7%)	1 (6.7%) - 6 (40%)
Downstaging		
Yes	24 (82.8%)	6 (40%)
No	5 (17.2%)	9 (60%)

Quantitative variables expressed in median, 25th percentile and 75th percentile. Qualitative variables expressed in absolute count and percentages. RT-Ch= Radio-chemotherapy, Ch= Chemotherapy. *Histological study not conclusive. CDDP= Cisplatin, VP-16= Etoposide, VN= Vinorelbine CBDCA= Carboplatin. [&]According to histological cancer cells viability described as maximum response ≤ 15%, partial response= 20-50%, stabilization= 60-70% and no response ≥ 80%.

Conclusion: In our review we observed that a 45% of the patients treated with Ch had a response of 20% or less in the pN or a local progression after the treatment, in comparison with only a 3.4% in the group of RT-Ch. However, the evaluation of the differences in the PR should be associated with a greater follow-up to assess the impact on overall survival.

EP1.01 ADVANCED NSCLC

EP1.01-01 ATRIAL RESECTION WITHOUT CARDIOPULMONARY BYPASS FOR LUNG CANCER

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Results of resection of lung cancer invading left atrium (T4atrium) without cardiopulmonary bypass (CPB) remain controversial. We reviewed our experience analyzing surgical results and postoperative outcomes. **Method:** Patients who underwent extended lung resection for T4atrium without CPB between 1998 and 2018 were retrospectively reviewed using a prospective database. **Result:** Forty-four patients were collected (34 men, median age, 63 years). Twenty-five patients underwent preoperative mediastinal staging and 27 received induction treatment (IT). Lung resection included 40 (90.9%) pneumonectomies, 3 (6.8%) lobectomies and one bilobectomy (2.3%). Pathological nodal status was N0 in 10 patients (22.7%), N1 in 18 (40.9%), and N2 in 16 (36.4%). Four patients receiving IT had complete pathological response (9.1%). Eight patients (18.2%) had microscopic tumor evidence on atrial resected margins. Mortality was nil. Major complication rate was 11.4%: one BPF, one cardiac herniation, and three hemothorax all requiring re-intervention. Minor complication rate was 25.5%. After a median survival of 37 months (range, 1-144 months), 20 patients (45.4%) were alive. Five-year survival and disease-free interval were 39% and 45.8%, respectively. Patients with N0 and R0 disease had a best prognosis (log-rank test: p=.03, and p=.01, respectively). IT neither influenced survival nor postoperative complications. At multivariate analysis, pN0 [p=.04 (95% CI: 0,65-9,66)] and negative atrial margins [p=.02 (95% CI: 0,96-8,35) were positive independent prognostic factors. **Conclusion:** Resection of T4atrium is technically feasible without mortality and acceptable morbidity. Patients with N2 cancers should not be operated on. Lung cancer invading left atrium should not be systematically considered as a definitive contraindication to surgery.

EP1.01-02 NOVEL PARTIAL TUMOR IRRADIATION IMPROVES TREATMENT OUTCOMES FOR INOPERABLE BULKY LUNG CANCER COMPARED WITH STANDARD OF CARE

S. Tubin[1], H. Popper[2], L. Brcic[2]

[1]*Radiation Oncology, Kabeg Klinikum Klagenfurt, Klagenfurt/AT,* [2]*Pathologie, Meduni, Graz/AT*

Background: Purpose: to report on the improved outcomes by newly developed SBRT exploiting the bystander (BE) and abscopal effects (AE) for the treatment of either inoperable, or bulky lung cancer unsuitable for radical radiotherapy compared with standard of care. In a pre-clinical phase of this translational research it was proven that the hypoxic tumor cells show higher potential for tumoricidal BE and AE compared with normoxic tumor cells. In order to improve the radiotherapy outcome by generating BE and AE, these findings were translated to the clinic and new SBRT-based PArtial Tumor irradiation targeting the HYpoxic segment (SBRT-PATHY), but sparing the tumor immune microenvironment, was developed. The hypothesis is that SBRT-PATHY will improve local and distant tumor control, inducing major regression of the partially irradiated bulky tumor due to BE, but also of unirradiated metastases due to AE. The primary endpoint was bulky response rate. The secondary endpoints included: distant tumor control, survival, safety, symptom control. **Method:** 60 patients with stage IIIB/IV bulky lung cancer considered inoperable or unsuitable for radical radiotherapy were treated (Aug. 2013 - Aug. 2018) with: 1.) Conventional radiotherapy only: 3Gy x 10 to the bulky tumor (20 patients), 2.) Standard chemotherapy only (20 patients), 3.) SBRT-PATHY only: 10 or 12Gy x 1-3 to 70% (based on bulky site and volume) to a so-called Bystander (hypoxic) Tumor Volume (BTV) defined using PET-CT as a hypovascularized-hypometabolic (SUVmax<3) junctional zone between the central necrotic and peripheral hypervascularized-hypermetabolic bulky segment, avoiding the tumor microenvironment (20 patients). Immunohistochemistry was performed on the available tissue samples to explore for modifications within the tumor microenvironment. **Result:** 3 treatment groups were comparable in terms of performance status, histology and disease stage. Table 1 summarizes the results.

Treatment Group	Bulky Response Rate (Cr Or Pr)	Distant Tumor Control	Overall Survival	Cancer Spec. survival	Progression Free Survival	Toxicity (G1-4)	Symptom Control
1.	20%	0% (abscopal effect)	5%	10%	0%	15%	25%
2.	20%	55% (chemo effect)	60%	60%	15%	65%	15%
3.	95%	46% (abscopal effect)	55%	80%	55%	5%	80%

Median follow up was 13 months (range: 4-27), mean bulky diameter: 8.1 cm (range: 6-13.5). Histology: 39% squamous, 51% adenocarcinoma, 10% other. On average the BTV volume corresponded to 32% of the bulky. AE was observed in 46% of patients treated with SBRT-PATHY. Immunohistochemistry showed that the apoptosis-inducing factor was massively upregulated in the partially irradiated bulky and also at the unirradiated, abscopal tumor sites, whereas a dense immune reaction was observed only at the border of the partially irradiated bulky but not at the abscopal site. **Conclusion:** Exploitation of the tumoricidal radiation-hypoxia-induced BE and AE by SBRT-PATHY may potentially enhance the radiotherapy therapeutic ratio.

EP1.01-03 REAL WORLD OUTCOME OF CRIZOTINIB FOR ANAPLASTIC LYMPHOMA KINASE-POSITIVE NON-SMALL CELL LUNG CANCER PATIENTS

C.-M. Choi, Y.J. Kim, J.C. Lee, S.-W. Kim, D.H. Lee, S. Yoon

Asan Medical Center, Seoul/Korea, Republic of

Background: Crizotinib has shown its superiority in clinical trials compared to conventional chemotherapy in patients with anaplastic lymphoma kinase (ALK) positive non-small cell lung cancer (NSCLC) patient, but its use and outcomes in real-world settings are yet to be investigated. This study aimed to assess treatment patterns and outcomes of crizotinib therapy in ALK-positive NSCLC patients, as well as to seek factors associated with progression-free survival and overall survival of ALK-positive NSCLC patients. **Method:** A retrospective medical record review of 176 patients who are diagnosed as metastatic or recurred NSCLC from January 1st, 2006 to June 30th, 2018 and treated with crizotinib was performed. Descriptive analyses were conducted to assess treatment patterns and objective response rate (ORR). Survival analysis to estimate progression-free survival (PFS) and overall survival (OS) was performed. Comparison of the treatment outcomes by the setting of crizotinib initiation was done. Cox regression analysis was used to find predictive factors associated with PFS and OS from initiation of crizotinib. **Result:** Median age was 55.7 (ranged 20 to 84) years and 85 patients (48.3%) were male. Seventy-two (40.9%) patients died at the time of analysis. Seventy-eight patients initiated crizotinib as first-line therapy. Overall response rate was 54.5% (50.0% for first-line recipients, 58.2% for second-/later-line). Median (95% CI) PFS from crizotinib initiation and OS from first dose of chemotherapeutic agent were 14.3 (11.6-17.0) and 41.7 (25.4-58.1) months, respectively. No significant difference of ORR, OS, and PFS, according to the setting of crizotinib initiation was observed. Multivariate Cox analysis showed poor performance status (HR 3.472, p-value < 0.001) and number of metastatic organs (≥3, HR 1.648, p-value 0.017) were independently associated to shorter PFS and OS, while history of getting pemetrexed before use of crizotinib (HR 0.638, p-value 0.039) was independently related to longer OS.

	All patients	Setting of Crizotinib Initiation		
	(n = 176)	First-Line (n = 78)	Second- or Later-Line (n = 98)	P value
Progression-free survival				0.699
Mean (SE)	25.0 (3.1)	28.0 (6.4)	16.6 (1.5)	
Median (95% CI)	14.3 (11.6-17.0)	15.8 (10.0-21.6)	13.1 (9.1-17.0)	
Q1, Q3	5, 27	5, 22	5, 27	
Overall survival				0.137
Mean (SE)	54.1 (4.2)	40.6 (6.1)	57.8 (4.9)	
Median (95% CI)	41.7 (25.4-58.1)	26.3 (14.7-37.9)	43.9 (25.7-62.1)	
Q1, Q3	18, 109	17, 77	19, 109	
1- and 2-year survival rates				
Percent still alive at 1 year after diagnosis (95% CI)	87.1 (86.7-87.5)	85.4 (84.3-86.5)	88.5 (87.8-89.2)	0.483
Percent still alive at 2 years after diagnosis (95% CI)	65.7 (65.0-66.4)	55.4 (51.9-58.9)	69.0 (68.0-70.0)	0.213

Conclusion: Outcomes for crizotinib recipients were in line with previous trials, with PFS and OS appearing more favorable. Poor performance status and number of metastatic organs correlated to worse PFS and OS, while history of previous use of pemetrexed before crizotinib correlated to better OS.

Background: Nanoparticle albumin-bound paclitaxel (nab-PTX) is a cremophor-free formulation of paclitaxel that can be administered safely as a short infusion without dexamethasone or antihistamine premedication. NJLCG1402 consists of multiple, open-label, single arm, phase I/II trials designed to assess the benefit of biweekly nab-PTX treatment in patients (pts) with previously treated advanced NSCLC (UMIN 000014893). **Method:** Eligible patients were aged ≥20 years; had histologically or cytologically confirmed, advanced-stage, previously treated NSCLC. Nab-PTX was administered biweekly at dose of 100 to 150 mg/m^2 in a 28-day cycle. In the phase I part, we aim to determine the recommended phase II dose of nab-PTX. In the phase II part, pts were assessed for efficacy and tolerability. The primary endpoint for the phase II part is the objective response rate. Secondary endpoints were progression free survival, overall survival, disease control rate, and safety. Assuming an expected the objective response rate of 15% and threshold of 5%, a total of 18 pts were required to have 70% power at a two-tailed alpha of 0.2 at the phase II part. **Result:** A total of 27 pts (median age 68 years, male 78%) were enrolled. The dose escalation cohort included 15 pts administered biweekly with 100 to 150 mg/m^2 across 3 dose levels, and 12 patients in the phase II part were administered with 150mg. No dose-limiting toxicities were observed in the phase I part and 150mg was determined as recommend dose. Of the evaluable pts (n=18) at dose of 150mg/m^2, the objective response rate was 22%(4 of 18 pts; 95% CI, 9.5 to 43.5), median progression free survival was 3.6 months (95% CI 1.4 to 5.9), and median overall survival was 7.2 months (95% CI, 0 to 15.0 months). Adverse events (AEs) of grade 3 or higher were observed in 39% of patients. The most common AEs were leukopenia (22%), anemia (22%), and rash (6%). **Conclusion:** Biweekly nab-PTX monotherapy was well tolerated and exhibits promising systemic antitumor activity in previously treated NSCLC pts.

Background: Erlotinib (E) is a first-generation epidermal growth factor receptor (EGFR) tyrosine kinase inhibitor labelled in France and effective as a first-line treatment in advanced non-small-cell lung cancer (NSCLC). E has demonstrated a better efficacy than chemotherapy in EGFR mutant NSCLC in phase III trials. **Method:** We undertook a multicentric study in 42 French Nonacademic Hospital Centres. Patients aged 18 years and older with histologically confirmed stage IIIB or IV NSCLC and harboring a confirmed activating mutation of EGFR received oral E (150 mg/day). We report here patient characteristics, progression-free survival (PFS), overall survival (OS), and safety data. Statistical analyses by R software were based on a Cox model and Kaplan-Meier method. **Result:** Between April 1st, 2014 and March 31st, 2016, 184 patients were recruited: mean age = 72 years old, 125 (69.5%) female, 158 (90.8%) Caucasians, 112 (63.6%) non-smokers, 167 (94.9%) adenocarcinoma (21 stage IIIB and 156 stage IV), 127 (65.6%) ECOG 0-1, 40 (26%) brain

metastasis at inclusion and 75 (42.4%) were treated by E in second- or latter line. 179 patients were included in the PFS and OS analysis. Median follow-up was 23.8 months, median PFS was 11.7 months and median OS was 25.8 months. Median survival rates at one year were 48.6% for PFS and 75% for OS. Risk of death was not correlated with brain metastasis (HR=1.15, IC95:0.67-1.97, p=0.296) but with ECOG = 2 (HR=4.55, IC95:2.05-10.10, p<0,001). E had a manageable safety profile (7.7% grade 3-4 adverse events at 6 months) and no new safety signals were identified.

	N	%
Patients	184	
Mean age (years)	72	
Sex		
Males Females	59 125	30.5 69.5
Race		
Caucasians	158	90.8
Smoking status		
Non-smokers	112	63.6
Histological type		
Adenocarcinoma	167	94.9
Staging		
Stade IIIB Stade IV	21 156	
ECOG		
0 or 1	127	65.7
Brain metastases at inclusion	40	26
Second-lind therapeutic strategy and more		
Erlotinib	75	42.4
Progression-free survival and overall survival	179	
Median Progression-free survival (Months) Median Overall Survival (Months)	11.7 25.8	

Conclusion: Data from EGFR-2013-CPHG real-world study are consistent with the efficacy and safety of E in EGFR mutant NSCLC patients seen in phase III clinical trials.

EP1.01-06 LOSS OF HETEROZYGOSITY OF ONCOGENE ERBB2 WITH AN ACTIVATING MUTATION WAS IDENTIFIED AS DRIVER EVENTIN LEPTOMENINGEAL METASTASIS OF NSCLC

P. Wang[1], Z. Sun[1], W. Guo[2], M. Shi[2]

[1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin/China,* [2]*Genetron Health (Beijing) Co. Ltd, beijing/China*

Background: Due to limited access to leptomeningeal lesions, cerebrospinal fluid (CSF) may be the most representative liquid biopsy to get genomic information from leptomeningeal metastases (LM) in non-small-cell lung cancer (NSCLC). Loss of heterozygosity (LOH) is a common genetic event during cancer tumorigenesis. LOH of tumor suppressor gene in which loss-of-function occurs on alternative allele serves as "second hit" and leads to loss of the remaining functional allele. LOH of tumor suppressor gene, such as *TP53*,in CSF had been reported for its associated with EGFR-TKI resistance in LM. Here, through CSF derived liquid biopsy, we report a LOH of oncogene ERBB2 in LM of NSCLC patient. To the best of our knowledge, this is the first report of LOH of oncogene, no matter in a primary or metastatic tumor. **Method:** Three CSF biopsies and matched peripheral blood were collected within 6 months from one NSCLC patient with LM. Cell-free DNA (cfDNA) was extracted, and somatic mutations were examined using a designed lung cancer panel of 180 genes. SCNAs were further identified through 2x whole genome sequencing (WGS). Genomic alternations identified in all three matched biopsies were included in the subsequent analysis. **Result:** A rare oncogene *ERBB2* activating mutation (V659E) was identified in CSF but not in plasma. V659E lies within the transmembrane domain and results in constitutive activation of Src and Akt signaling. Extreme high variants allele fraction (96.8%) of *ERBB2* V659E in CSF implied the LOH of *ERBB2* in LM. SNPs heterozygosity analysis and low pass WGS were further carried out and confirmed the LOH of entire chromosome 17, but not limited to *ERBB2* region. Furthermore, A consecutive an amplification was observed on the remaining copy of chromosome 17q, on which the activated oncogene *ERBB2* located. The amplification, following *ERBB2* LOH with a concomitant activating mutation, may enhance constitutively active ERBB2 expression and drive the evolution of LM. Besides, there were two more unique mutations in CSF, *TP53* T256fs (45.31%) and *JAK3* R582Q (32.85%). Relatively Low variants allele fraction indicated that they were subclonal mutation occurring after *ERBB2* activating mutation and LOH of chromosome 17. **Conclusion:** We first reported an oncogene *ERBB2* LOH in CSF from one NSCLC patient with LM. Based on phylogeny inference, the *ERBB2* activating mutation and LOH of chromosome 17 were likely to be the earliest driver event.

Background: Long survivors (LS) in non-small-cell lung cancer (NSCLC), defined as an overall survival (OS) greater than 2 years, are less than 10% in most series. Classical prognosis factors include stage, weight loss and ECOG, but more information is missing in the literature. Recently, EGFR, ALK and ROS 1 population (less than 20%) reach OS longer than 2 years. Immunotherapy has demonstrated very promising results with more LS compared to chemotherapy in first and second line setting. In this study, we focused in the analysis of LS patients with advanced NSCLC EGFR wt (wild type) and ALK nt (non-translocated), defined as those with OS greater than 36 months, in 7 hospitals in Madrid. **Method:** In this serie, first of all, we will try to make a clinical, histopathological characterization collecting data from clinical reports according to a previously defined information. In a second step, we will carry out a genetic analysis of these patient samples comparing to an opposite extreme short survivors (SS) samples (OS less than 9 months). Initially, we used a NGS method of RNA-seq technology to identify differentiating profiles of gene expression between the two opposite populations. And finally, we confirmed this preliminary profile by RT-PCR in the rest of samples. **Result:** Ninety-six patients were initially included. The majority were men, smokers or former with adenocarcinoma and ECOG 0- 1. We have obtained a differential transcriptome expression between samples from 6 LS and 6 SS, resulting 13 over-expressed and 42 down-expressed genes in LS comparing to SS transcriptome expression. Some of the genes involved in this initial profile belong to different cellular pathways: Secretin Receptor, Surfactant Protein, Trefoil Factor 1, Serpin Family, Ca-bindings Protein channel and Toll like Receptor family. Finally, we carried on by RT-PCR in 40 samples of SS and LS survivors and only four genes were significantly down-regulated in SS compared to LS in the multivariate analysis. These 4 genes were related to Surfactant Proteins: SFTPA1 (p = 0.023), SFTPA2 (p = 0.027), SFTPB (p = 0.02) and SFTPC (p = 0.047) **Conclusion:** We present a sequential genetic analysis of a LS population with NSCLC EGFR wt (wild type) and ALK nt (non-translocated), obtaining a differential RNA seq- and RT-PCR gene profile based on different surfactant proteins expression. A further confirmation in a larger sample is ongoing.

EP1.01-08 EFFICACY OF OSIMERTINIB IN PATIENTS OF ADVANCED NON-SMALL CELL LUNG CANCER WITH BRAIN METASTASIS: A RETROSPECTIVE ANALYSIS

J. Zhang[1], L. Chen[2], M. Ye[3], H. Li[4], C. Zhou[2], H. Pan[2]

[1]*State Key Laboratory of Respiratory Disease, National Clinical Research Center for Respiratory Disease, Guangzhou Institute of Respiratory Health, The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China,* [2]*The First Affiliated Hospital of Guangzhou Medical University, Guangzhou/China,* [3]*The Guangzhou Chest Hospital, Guangzhou/China,* [4]*Guangzhou Medical University, Guangzhou/China*

Background: Osimertinib (AZD9291) is an oral, irreversible, third-generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) that selectively inhibits both EGFR-TKI-sensitizing and EGFR T790M resistance mutations.The aim of this retrospective study was to evaluate the efficacy of AZD9291 for advanced non-small cell lung cancer(NSCLC) patients with brain metastasis. **Method:** We followed up patients diagnosed with advanced non-small cell lung cancer who were detected with EGFR gene mutation and who received EGFR-TKI from 1st October 2006 to 1st June 2018.Patients finally collected were divided into two groups:One group comprised of 45 patients received first-generation or second-generation EGFR-TKI alone,while other group included 45 patients were given AZD9291. And the 95% confidence interval (CI)and the median progression-free survival (mPFS)were calculated by the Kaplan-Meier method. **Result:** The median progression-free survival(mPFS) was longer with osimertinib than with standard EGFR-TKIs (14.0 months vs. 11.0 months; 95%CI: 10.160-13.840, P=0.017). The mPFS of patients with brain metastasis was significantly longer with osimertinib than with standard EGFR-TKIs(13.0 months vs. 7.0 months; 95%CI: 6.087-11.913, P=0.020). The mPFS of patients with osimertinib was longer with combined radiotherapy than with not receive radiotherapy(18.0 months vs. 13.0 months; 95%CI:7.066-18.934, P=0.915). **Conclusion:** In patients with non-small cell lung cancer with brain metastases, the median progression-free time of patients with osimertinib was longer than that of patients with first- or second-generation EGFR-TKIs alone, but osimertinib combined with radiotherapy showed no statistical significance compared with no radiotherapy.

EP1.01-09 CLINICAL EFFICACY OF CIRCULATING TUMOR DNA TEST IN ADVANCED NON-SMALL-CELL LUNG CANCER PATIENTS WHO MIGHT HAVE T790M MUTATION

N. Kim

Severance Hospital, Seoul/Korea, Republic of

Background: Using EGFR-tyrosine kinase inhibitors (TKIs) in patients with advanced lung cancer led to a significant improvement in survival. However, patients with these TKIs are ultimately resistant to disease, and about 50-60% patients showed EGFR T790M mutation. The purpose of this study was to evaluate the efficacy of tissue biopsy and liquid biopsy in patients undergoing re-biopsy after TKI use. **Method:** We reviewed medical records of 85 NSCLC patients who had done both tissue rebiopsy and liquid sampling from december 2017 to december 2018, at Severance University Hospital, Seoul, Korea. In this patients, the degree of coincidence and an expression level of T790M were examined with rebiopsy tissue for EGFR and circulating tumor DNA (ct DNA). CtDNA in plasma requires 100 copies of EGFRT790M per milliliter of plasma, so allele-specific PCR and digital PCR method were used to increase sensitivity for detection. **Result:** The mean age of the 85 patients was 62.9 ± 11.1 years, and 50 (58.8%) were female. The expression of T790M on rebiopsy was 17.6% (15/85) in ct DNA, and 23.5% (20/85) in tissue. The percentage of T790M from either liquid biopsy or tissue biopsy was 31.4% (27/85). The concordance between liquid biopsy and tissue biopsy was 72.9%. The sensitivity of liquid biopsy was 27%, specificity 72%, positive predictive value 22% and negative predictive value 77%. **Conclusion:** Testing Circulating tumor DNA in patients with NSCLC after TKI use can help to find T790M mutation in addition to rebiopsy of tissue. Combination of liquid biopsy and tissue biopsy is complementary to find the subject of the third-generation TKI, osimertinib. Also, liquid biopsy is less invasive and repeatable than tissue biopsy, it is useful for group of negative finding at tissue biopsy initial

Background: Pembrolizumab, a monoclonal antibody directed against programmed death-1 (PD-1), has been established as preferred treatment as a monotherapy for advanced non-small cell lung cancer (NSCLC) with programmed death ligand 1 (PD-L1) expression of ≥ 50%. Combining immunotherapy with chemotherapy have shown synergistic anticancer activities and pembrolizumab has been studied in combination with various traditional chemotherapy regimens as first-line treatment for advanced NSCLC. Hence, we performed a systematic review and meta-analysis of currently available randomized controlled trials (RCTs) to evaluate the efficacy pembrolizumab in combination with chemotherapy as first-line treatment of advanced NSCLC. **Method:** We conducted a comprehensive literature search using PUBMED, MEDLINE, EMBASE databases and meeting abstracts from inception through March 2019. RCTs utilizing first-line pembrolizumab chemoimmunotherapy in patients with advanced NSCLC were incorporated in the analysis. A generic inverse variance method was used to calculate the estimated pooled hazard ratio (HR) for overall survival (OS) and progression-free survival (PFS) with 95% confidence interval (CI). Heterogeneity was assessed with Cochran's Q-test. Random effects model was applied. **Result:** 3 RCTs (Keynote-021,189 and 407) including 1298 patients with advanced NSCLC were included in the analysis. The study arm used standard chemotherapy regimens in combination with pembrolizumab while control arm used only standard chemotherapy regimens. The randomization ratio was 2:1 in Keynote-189 study and 1:1 in other studies. The I2 statistic for heterogeneity was 0, suggesting homogeneity among RCTs. The pooled HR for PFS was statistically significant at 0.54 (95% CI: 0.47-0.62; P < 0.00001), including in PD-L1 tumor proportion score (TPS) of less than 1% cohort (HR: 0.72; 95% CI: 0.56-0.92; P = 0.010) and PD-L1 TPS ≥ 1% cohort (HR: 0.46; 95% CI: 0.39-0.56; P < 0.00001). The pooled HR for OS was 0.59 (95% CI: 0.45-0.76; P < 0.0001). Improvement in OS was also seen across all PD-L1 categories: in PD-L1 <1% group HR was 0.60 (95% CI: 0.43-0.83; P = 0.002) and in PD-L1 ≥ 1% group HR was 0.55 (95% CI: 0.40-0.75; P = 0.0002). **Conclusion:** Our meta-analysis demonstrated that first-line chemoimmunotherapy with pembrolizumab significantly improved PFS and OS compared to standard chemotherapy in patients with advanced NSCLC. The improvement of PFS and OS were consistent across all PD-L1 expression categories.

EP1.01-11 PROGNOSIS OF LUNG CANCER IN PATIENTS WITH INTERSTITIAL LUNG DISEASE; COMPARISON WITH NSIP AND IPF

S. Kwak[1], M.J. Song[2], S.H. Lee[1], Y.S. Chang[3], H.Y. Kim[4]

[1]*Severance Hospital, Seoul/Korea, Republic of,* [2]*Severance Hospital, Seoul/Korea, Republic of,* [3]*Severance Hospital, Yonsei University College of Medicine, Seoul/Korea, Republic of,* [4]*Korea University Guro Hospital, Korea University College of Medicine, Seoul, Korea, Seoul/Korea, Republic of*

Background: Lung cancer is the leading cause of death in worldwide. Some reports revealed that lung cancer with interstitial lung disease (ILD) is associated with poor prognosis. However, the prognosis of lung cancer according to the subtype of ILD is unclear. We analyzed the outcome of lung cancer according to CT findings of ILD. **Method:** Among the non-small cell lung cancer (NSCLC) patients who visited Severance Hospital, Seoul, Korea from July 2005 to October 2018, patients with idiopathic pulmonary fibrosis (IPF) or non-specific interstitial pneumonia (NSIP) in chest CT image were enrolled in this study. Patients were divided into three groups according to

CT findings; (1) definite + possible IPF, (2) intermediate, and (3) definite NISP + possible NSIP. All patients were diagnosed lung cancer NSCLC on biopsy. The characteristics of study population and prognosis of each group were examined **Result:** A total of 151 patients were investigated in this study. Female was 4.6% and mean age was 70.2 years. 84 patients were definite + possible IPF group, 42 patients were intermediate, and 25 patients were definite NISP + possible NSIP group. The proportion of smokers who smoked once was significantly higher in definite + possible IPF group (p=0.006). Age, FVC, FEV_1 and lung cancer stage were not different between the three groups. Median overall survival were 27.0 months in NSIP group, 15.3 months in intermediate group, and 9.5 months in IPF group (p=0.04). Additionally, 25% of patients in definite + possible IPF group experienced acute exacerbation. **Conclusion:** CT findings of ILD in lung cancer patients could be helpful in predicting prognosis. Furthermore, acute exacerbation is more common in IPF patients. Therefore, careful attention should be paid to the treatment of lung cancer in patients with IPF pattern.

EP1.01-12 SNPS OF ORGANIC CATION TRANSPORTER 6 ASSOCIATE WITH THE EFFICACY OF PLATINUM COMBINATION CHEMOTHERAPY

A. Takeuchi[1], T. Oguri[1], S. Fukuda[1], Y. Kagawa[1], K. Sone[1], O. Takakuwa[1], T. Uemura[2], K. Maeno[1], K. Fukumitsu[1], Y. Kanemitsu[1], H. Ohkubo[1], M. Takemura[1], Y. Ito[1], A. Niimi[1]

[1]*Nagoya City University Graduate School of Medical Sciences, Nagoya/Japan,* [2]*Aichi Cancer Center Hospital, Nagoya/Japan*

Background: Platinum derivatives (cisplatin or carboplatin) are key antitumor drugs to non-small cell lung cancer in combination therapy with not only other cytotoxic agents or vascular endothelial growth factor but also kinase inhibitors or immune checkpoint inhibitors. However, the predictive biomarker of effectiveness about platinum-based chemotherapy is still unclear. Organic cation transporter 6 (OCT6) is one of the solute carrier transporters (coded by *SLC22A16*) which transport substrates by facilitated diffusion or secondary active transport. We previously reported that OCT6 was involved in platinum drug resistance by mediating platinum drug influx in cancer cell. Single nucleotide polymorphisms (SNPs) in genome sequences bring about changes in the amino acid sequence, alter the protein structure, and result in individual differences. The aim of this study is to solve the association between the efficacy of cytotoxic chemotherapy including platinum derivatives and SNPs. **Method:** We retrospectively screened 78 advanced non-squamous non-small cell lung cancer patients who received platinum derivatives (cisplatin or carboplatin) and pemetrexed combination therapy for the first line chemotherapy between October/2010 and May/2018. We investigated the association between SNPs (*rs714368*, *rs723685*, and *rs12210538*) of *SLC22A16* or patients' characteristics and clinical outcomes. **Result:** The median age of patients was 67 years old. Sixty patients were male and 61 patients were current or former smokers. The historical features of Sixty-eight patients were adenocarcinoma, and 18 patients had positivity of EGFR mutation or ALK fusion. We excluded *rs12210538* from covariable of this study as all patients had major homo allele about *rs12210538*. The clinical outcomes of this study were similar to those of previous clinical studies. We found the patients with phenotype "A" of *rs714368* had higher disease control rate (DCR) and longer duration of progression free survival (PFS) compared to phenotype "G" [response rate (RR), 31.4 % vs 25%, p >0.99; DCR, 85.7% vs 37.5%, p<0.01; median PFS, 154 days vs 26,5 days, p<0.01; median overall survival (OS), 666 days vs 471 days, p=0.69, respectively]. On the other hand, genotype of *rs723685* had no association with treatment outcomes [genotype "TT" vs "TC", RR, 32.8% vs 18.2%, p=0.49; DCR, 83.6% vs 63.6%, p=0.21; PFS, 132 days vs 111 days, p=0.37; OS, 558 days vs 1014 days, p=0.46]. Phenotype A of *rs714368* and earlier stage were good predictive factor about PFS in Cox proportional hazard model. **Conclusion:** Gene polymorphisms of *rs714368* may change the function of OCT6 and influence the efficacy of platinum combination chemotherapy.

Background: Leptomeningeal carcinomatosis (LMC) occurs in 10 % of EGFR-mutant lung adenocarcinoma (LA). Retrospective studies have sugeted a clinical benefit of osimertinib in treating LMC in patients with EGFR-mutant LA. We conducted a phase 2 prospective trial to demonstrate the clinical efficacy, activity, and LMC-specific mechanisms of resitance to osimertinib in EGFR-mutant LA patients. **Method:** We performed gadalidium-enhanced brain MRIs at the time of enrollment, followed by scheduled brain imaging once every six weeks. Clinical neurological exams were performed every four weeks. Adverse Events (AEs) were assessed by NCI-CTCAE Ver. 4. Cerebral spinal fluid (CSF) and plasma was obtained on day 1 and 21 for all patients. The CSF osimertinib penetration rate was measured by liquid-chromatography mass spectrometry (LC-MSMS) and compared to plasma osimertinib levels. Targeted droplet digital PCR (ddPCR) was used to detect copy number changes of Met and the EGFR C797S mutation in patients CSF-DNA and plasma cell free (cf) DNA. **Result:** We enrolled six pre EGFR-TKI treated EGFR mutant LA with LMC. We observed a LMC-specific progression free survival of 3.7 months and overall survival of 6.2 months or longer with osimertinib. Four and three of six patients showed neurological and radiological responses, respectively. No patients had any AEs greater than grade 3 and all patients continued osimertinib beyond PD. The osimertinib CSF penetration rate was 1.2±0.5%. Met copy number was normal in plasma, but increased in the CSF of 2/6 patients prior to progression. Met copy number was confirmed in 1/6 patients at the time of progression. An aquired EGFR C797S mutation was observed in 1/6 patients prior to progression.

Patient characteristics	
Male / Female	3/3
Median age	61.5 (50-82)
Performance status (0/1/2)	0/3/3
Median previous EGFR-TKIs	3 (1-4)
Previous RT to Brain metastasis +/-	3/3
L858R / Del19	6/0
T790M in CSF +/-	0/6
T790M outside CSF +/-	6/0

Case	Neurological best response	Radiographical best response	PFS (days)	OS (days)	Acquired resistance
1	Stable	Stable	28	30	Met copy number gain
2	Improve	Improve	57	169	Met copy number gain
3	Improve	Progress	91	469+	Not detected
4	Improve	Stable	182	240+	Not detected
5	Improve	Improve	203+	203+	Not detected
6	Stable	Improve	123	139+	EGFR C797S

Conclusion: Osimertinib 80 mg is efficacious in the treatment of LMC in EGFR mutated LA. CSF-specific MET copy number gain and EGFR C797S mutations arise prior to progression in EGFR-mutant LA patients treated with osimeritinib.

Keywords: Osimertinib, leptomeningeal carcinomatosis, Acquired resistance

Background: Although nivolumab showed the significantly longer overall survival (OS) compared with docetaxel for non-small cell lung cancer (NSCLC) based on two phase III randomized controlled trials, programed death ligand 1 (PD-L1) expression alone is not yet an adequate biomarker in treating nivolumab for NSCLC patients. Furthermore, some prior analyses indicated the liver metastasis, performance status (PS) and pretreatment neutrophil-to-lymphocyte ratio (NLR) is one of the candidates of effect predictors. This retrospective study aimed to analyze the score combining pretreatment patients' status as a predictive marker in NSCLC patients treated with nivolumab. **Method:** ne hundred and twenty-eight patients treated with Nivolumab who could examine the PD-L1 status from December 2015 to July 2016 were retrospectively reviewed. This study was multicenter study conducted by the three respiratory medical centers in Japan. We collected clinical data including age, sex, smoking history, histological types, PS, NLR, existence of Liver metastasis and PD-L1 status. We made the predictive score (PS2-4: 3 points, >NLR 4: 1 point, Liver metastasis +: 1 point, PD-L1 0%: 1 point and over 50%: -1 point) from pretreatment patients' characteristics and evaluate the score (over 4 points is high risk group, 2-3 points is mediate risk group, and under 1 point is low risk group) as a marker of outcomes. The data cut off was on 31th October 2017. **Result:** Median age was 67 years old, 86 patients were male, 101 patients had smoking history, 99 patients were PS 0-1 and 29 patients were PS 2-4, 26 patients were squamous carcinoma, >NLR 4 were 48 patients, and 16 patients had liver metastasis, respectively. Furthermore, PD-L1 expression 0% were 62 patients, 1-49% were 42 patients, and over 50% were 24 patients. Progression disease rate, median progression free survival (PFS) and median OS was 61.1%, 1.1 months, 2.4 months in high risk group; 60.6%, 1.4 months, 10.9 months in mediate risk group; and 36.4%, 4.6 months, 16.3 months in low risk group, respectively. **Conclusion:** We could classify the three group which could predict an patients' outcome according to the patients' characteristics.

EP1.01-15 SYSTEMIC HYPERINFLAMMATION IS A STRONG INDEPENDENT PREDICTOR OF EARLY MORTALITY IN ADVANCED NSCLC

J. Isaksson[1], L. Willén[1], E. Brandén[1], H. Koyi[1], S. Gagatek[2], A. Berglund[3], P. Micke[4], J. Botling[4]

[1]*Gävle Hospital, Gävle/Sweden,* [2]*Uppsala Academic Hospital, Uppsala/Sweden,* [3]*Epistat, Uppsala/Sweden,* [4]*Uppsala University, Uppsala/Sweden*

Background: Prognostic tools in NSCLC are important for treatment decisions and evaluation of new treatment options. Ample evidence support inflammation as a marker of outcome in NSCLC. Our study explores outcome for a population-based real-life cohort of patients in the highest stratum of inflammatory activity. **Method:** The source cohort comprised all patients diagnosed with NSCLC between January 2016 – May 2017 at Gävle County Hospital, Sweden (n=155, inclusion rate 95%). Following exclusion of patients with active infection, the subgroup (n=77) in stage IIIB-IV with complete available laboratory parameters were studied further. Blood parameters were examined individually, and cut-offs (ESR>60 mm, CRP>20 mg/L, WBC>10 x10e9/L, PLT>400 x10e9/L) for high inflammation were set with an aim to pin-point the top echelon of hyperinflamed patients. A prognostic score was developed by assigning one point for each parameter above cut-off (0-4 points). **Result:** One year survival of patients with an inflammation score of ≥2 (n=23) was 0% compared to 50% and 33% among patients with a score of 0 (n=36) and 1 (n=18), respectively (figure 1). The effect of a high inflammation score on overall survival remained significant in multi-variate analysis adjusted for confounding factors (stage, gender, age, smoking status, ECOG PS). The hazard ratio of an inflammation score ≥2 in multi-variate analysis (HR 3.45, CI 1.62-7.34) was on par with a change of ECOG PS from 0 to 2 (HR 3.67, CI 1.44-9.4). **Conclusion:** Inflammation is a well established marker for treatment outcome in solid tumours. Our results show that high level inflammation is a strong independent marker for poor survival in patients with advanced stage NSCLC. This observation may indicate a need to stratify and subgroup patients in clinical studies with regard to systemic hyperinflammation and warrants further research on underlying mechanisms linked to tumour progression.

EP1.01-16 CHARACTERISTICS OF STAGE III LUNG CANCER PATIENTS IN THE PERIOD 2014-2016 IN VIETNAM

K.D. Nguyen[1], T.O. Bui[1], P.T. Tran[1], V.T. Dao[1], V. Dang[2]

[1]*Cancer Research and Clinical Trial Center, National Institute for Cancer Control, National Cancer Hospital, Hanoi/Viet Nam,* [2]*Vietnam National Cancer Hospital, Hanoi/Viet Nam*

Background: Despite lung cancer is the leading cause of cancer-related mortality around the world, data and impact on health systems related to characteristics of the diseases is not fully understood in developing countries. The study aims to describe and evaluate the characteristics stage III lung cancer patients in Vietnam. **Method:** Medical records of patient with diagnosis of stage III lung cancer hospitalized in the period 2012-2015 in the National Cancer Hospital (Vietnam) were retrospectively analyzed. Patients were followed up about the survival information in April 2019 to identify overall survival (OS) rates. We compared the efficacy of treatments between 2 patient groups: surgery and/or radio-chemotherapy (group 1) and radiotherapy only or chemotherapy only or supportive care only (group 2). **Result:** From a total of 5220 lung cancer patient hospitalized in the National Cancer Hospital over 3-year period, we reviewed 600 original medical records, of which 70 stage III lung cancer patients having valid survival information were identified (11.7%). We found 60 patients with death outcome (85.7%) and median OS and its 95% confidence interval were 9.80 [5.39, 19.70]. Patients were mainly men (54, 77.1%) with mean age (SD) was 65.96 (8.62). We found 14 patients with surgery and/or radio-chemotherapy in group 1 (4 surgery and 10 radio-chemotherapy). In group 2, 34 patients were treated with chemotherapy or radiotherapy alone, and 22 patients were provided supportive care only. The estimated 1-year, 3-year and 5-year survival probabilities were 40.7 (30.6 - 54.1) %, 15.5 (08.8 - 27.1)% and 10.3 (04.64 - 22.9)% correspondingly. We estimated 3-year survival probability of patients in group 1 was 34.3 (16.24 - 72.4 %) was higher than group 2 which was 10.6 (4.89 - 23.2)% (p=0.055). **Conclusion:** Our results showed a benefit of surgery and/or radio-chemotherapy treatment on stage III lung cancer patients in Vietnam. Further research is required

EP1.01-17 PREDICTORS OF SURVIVAL OUTCOMES WITH CHEMOTHERAPY IN ADVANCED NSCLC PATIENTS WITH PERFORMANCE STATUS 2 AND ABOVE AND WITHOUT DRIVER MUTATION

H. Kancharla, P. Malik, S. Khurana, D. Jain, S. Kumar, S. Pathy

All India Institute of Medical Sciences, New Delhi/India

Background: Platinum-based combination chemotherapy is recommended as the standard treatment for patients with advanced non-small-cell lung cancer (NSCLC), but its benefit is limited to patientswith performance status (PS) of 0 or 1. However, it is not clear whether these benefits apply to patients with poor performance status (PS 2 and above) and there are no predictors of outcome to suggest whom to treat .This population accounts for a significant portion (up to 30%) of patients of our practice and some of them have been treated with systemic chemotherapy based on clinician's discretion.We have analyzed the outcome of these patientswho have been treated with chemotherapy despite poor performance status. **Method:** We performed a retrospective analysis of patients of advanced NSCLC with poor PS (ECOG PS 2 or more) registered at our lung cancer clinic between January 2016 and December 2017 and treated with systemic chemotherapy. Patients with driver mutations who were treated with first line TKIs were excluded. Hospital case records were reviewed for baseline characteristics, treatment details and outcome data. Patients who haven't come to the hospital in last 3 months were contacted on phone. **Result:** A total of 95 patients were found to be eligible for this analysis. Median age was 62 years (30-84 years, including 23(24%) patients 70 years or above. At presentation out of these 95 patients, 63(66%) were smokers, 31(32%) had cytological proven pleural/pericardial effusion, 10(10.5%) patients had brain metastasis and 34(35.5%) had extra thoracic metastasis (≥2 sites).Majority(64%) patients had ECOGPS 2 but 36 % had PS 3 or 4 also and 44(46%) had one or more associated comorbidities. The most common chemotherapy regimen used was weekly paclitaxel and carboplatin(57.8%) followed by pemetrexed and carboplatin (16.8%).Majority (64%) patients could complete 4or more cycles of chemotherapy however 15 patients (15.7%) could receive only one cycle and 20(21%) patients even received maintenance chemotherapy. Chemotherapy was interrupted due to poor tolerance in 20(21%) patients and grade ¾ toxicity seen in 22(23%) % patients. At least one point improvement in ECOG PS from baseline was observed in 43 patients (45%) after 4 cycles of chemotherapy. Objective response and disease control rates were 20 % and 48.42% % respectively.Aftera median follows up of 8.6 months, median progression free survival was 6.2 months (95%CI 5-10.33).On univariate analysis ,neutrophil –lymphocytic ratio (<5 vs >5)and induction regimen (weekly Taxol+Platinum vs rest) were significantly associated(p=0.02 and p= 0.04 respectively) with better median PFS **Conclusion:** Systemic chemotherapy in modified doses and schedules in advanced NSCLC patients with PS 2 and above is feasible and may be associated with better symptom palliation with clinical benefit and improvement in survival.neutrophil –lymphocytic ratio (<5 vs >5)and induction regimen (weekly Taxol+Platinum vs rest) are predictors of better median PFS. Further studies addressing this neglected subgroup are indicated.

EP1.01-18 CLINICAL FEATURES OF LOCALLY ADVANCED LUNG CANCER PATIENTS WITH RADIATION PNEUMONITIS AFTER INDUCTION CHEMORADIOTHERAPY

K. Araki, K. Suzawa, S. Miyauchi, A. Miura, K. Namba, S. Otani, H. Yamamoto, M. Okazaki, S. Sugimoto, M. Yamane, S. Toyooka

Okayama University Hospital, Okayama/Japan

Background: The therapeutic management of locally advanced non-small cell lung cancer (NSCLC), such as those in the N2-3, bulky N1, or T3-4 stage, remains controversial. Induction chemoradiotherapy (CRT) followed by surgery is one of the potential therapeutic options for locally advanced NSCLC, however, sometimes develops radiation pneumonitis (RP). Severe RP induce remarkable respiratory

disfunction, resulting in a delay of next treatment. The purpose of this study is to reveal the clinical features of NSCLC patients with RP after induction CRT. **Method:** The clinical data of NSCLC patients who underwent surgical resection of lung cancer after induction CRT between 1999 to 2017 at our institution were analyzed. We compared NSCLC patients who had RP with those who didn't, regarding patient's and therapeutic factors, and their prognosis. RP of our cases was defined as RP which occurred between the administration of induction CRT and 30 days after surgery. **Result:** A total of 172 data of NSCLC patients who underwent surgical resection of NSCLC of stage IIB–IIIC after induction CRT was collected. Among them, 34 NSCLC patients had RP, and 15 NSCLC patients received steroid therapy in 30 NSCLC patients, able to be assessed retrospectively. Non-smoking status was significantly associated with RP in univariate analysis (p = 0.006) and in multivariate analysis (odds ratio: 3.70, 95% confidence interval: 1.05-13.10, p = 0.042). Duration between completion of RT and surgery was longer in NSCLC patients with RP than those without RP (range [median]: 14-141 [45.5] vs 23-91 [40.0], p = 0.029). Adjuvant therapy was more frequently given to the patients without RP (p = 0.019). No significant difference in overall survival (OS) was observed between the 2 groups. **Conclusion:** Non-smoking status was the risk factor of RP of NSCLC patients who received induction CRT followed by surgery. The frequency of adjuvant therapy was more in NSCLC patients without RP than those with RP while OS was not different in the 2 groups.

Keywords: Radiation pneumonitis, induction CRT, NSCLC

EP1.01-19 UPDATED STATISTICS OF NEVER-SMOKER FEMALE LUNG CANCER IN KOREA

S.J. Kim, C.K. Park, Y.K. Kim

The Cancer Research Institute, College of Medicine, The Catholic University of Korea, Seoul/Korea, Republic of

Background: The clinical characteristics and prognostic factors of patients with lung cancer are expected to differ with respect to geographical differences from the past to the future. According to epidemiological, clinical and biological characteristics, lung cancer in never-smokers is a different disease from lung cancer in smokers. **Method:** To investigate the updated statistics of never-smoker female lung cancer in Korea, we analyzed data from the Korean Statistical Information Service and the Korea Central Cancer Registry in 2014. **Result:** According to the Korean Statistical Information Service, lung cancer deaths in the Korean population have been increasing in both men and women since the early 1980s. Among the total of 17,980 deaths due to lung cancer in 2017, men accounted for 13,272 and women accounted for 4,708. Of a total of 25,780 incidences of lung cancer in 2016, men accounted for 17,790 and women accounted for 7,990. Considering that the lung cancer incidence in Korean women was 3,592 in 2000, it increased by more than 2-fold in 16 years. However, after age-standardized adjustment, the lung cancer incidence has recently been stable in women. The smoking rate in Korean women was 6.0% in 2017, which has remained stable since 1998. The passive smoking rate in non-smoking women was 6.3% in 2017, which has been decreasing since 2005. Among the total of 6,460 Korean female patients with lung cancer in 2014, 745 patients were investigated from the Korea Central Cancer Registry. Most Korean women who developed lung cancer were never-smokers (87.5%). According to smoking status, female lung cancer characteristics such as symptoms, stage, histopathology, EGFR mutation positivity, and initial treatment modality were significantly different. Never-smoker female patients with lung cancer showed an increase in asymptomatic disease, stage I lung cancer, histology of adenocarcinoma, EGFR mutation positivity, and curative resection compared to ever-smoker female patients. **Conclusion:** The trends in epidemiology and clinical characteristics of lung cancer in Korea have changed over time. The never-smoker lung cancer incidence was estimated to increase in Korea. The reason for the stable incidence after the age adjustment could be growth in the Korean elderly population. Further research is needed to guide patient management, as well as future therapeutic strategies for lung cancer.

Keywords: never-smoker lung cancer, Korea, Updated Statistics

EP1.01-20 A SINGLE-ARM PHASE II TRIAL OF WEEKLY NANOPARTICLE ALBUMIN-BOUND PACLITAXEL MONOTHERAPY AFTER STANDARD THERAPY FOR ADVANCED NSCLC

Y. Kato, Y. Okuma, Y. Hosomi

Tokyo Metropolitan Cancer and Infectious Diseases Centre, Tokyo/Japan

Background: Few studies have investigated the clinical efficacy of later-line treatments after standard therapy for advanced non-small cell lung cancer (NSCLC). Nanoparticle albumin-bound paclitaxel was one of the useful option for treatment of NSCLC. We conducted PII trial for evaluating the efficacy and safety of nanoparticle albumin-bound paclitaxel (nab-paclitaxel) following standard therapy for advanced NSCLC. **Method:** The eligible patients having adequate organ functions with performance status 0–2 were enrolled after completing standard therapy. Standarad therapy defined as chemotherapy including docetaxel and pemetrexed in patients with non-squamous cell lung cancer or docetaxel in patients with squamous cell lung cancer. After the ICI nivolumab was approved by the Ministry of Health, Labor and Welfare of Japan in December 2015, standard therapy was defined as including ICIs treatment. They received weekly nab-paclitaxel 100 mg/m^2 intravenously on days 1, 8, and 15 every 3 weeks. The primary end point was objective response rate (ORR). Median progression-free survival (PFS), overall survival (OS), and adverse events (AEs) were evaluated as secondary end points. **Result:** This trial was discontinued because of late accrual. Twenty-two patients were enrolled from April 2013 and February 2019. All patients recieved chemotherapy including docetaxel and Six patients recieved ICIs tretment. Median follow-up interval was 6.7 months. The total ORR was 22.7% [95% CI: 7.8–45.4] and disease control rate (DCR) was 81.8% [95% CI: 59.7–94.8]. Median PFS was 3.4 months [95% CI: 2.3–4.1] and median OS was 7.4 months [95% CI: 4.2–10.7]. Hematological AEs of Grade 3/4 included anemia (18%), leukopenia (18%), and neutropenia (32%), and the most frequent nonhematological AEs were fatigue (50%) and peripheral neuropathy (36.4%). Severe AEs related to treatment were observed in only one patient. **Conclusion:** Although all patients recieved chemotherapy including docetaxel before protocol tretment, our tral suggested nab-paclitaxel may be a safe and effective later-line chemotherapeutic option for previously treated advanced NSCLC after standard of chemotherapies based on other trials.

EP1.01-21 TIME ON TREATMENT OF FIRST-LINE PD-1 INHIBITOR MONOTHERAPY FOR METASTATIC NON-SMALL CELL LUNG CANCER PATIENTS: REAL-WORLD EXPERIENCE DATA

L. Apter[1], S. Sharman Moser[2], S. Chandwani[3], X. Chen[3], V. Shalev[2], G. Chodick[2], N. Siegelmann-Danieli[1]

[1]*Maccabi Healthcare Services, Tel Aviv/Israel,* [2]*Maccabi Institute For Research & Innovation, Tel Aviv/Israel,* [3]*Merck & Co., Kenilworth/United States of America*

Background: Clinical trials have established the role of immune checkpoint inhibitors for metastatic NSCLC treatment, but real-world data are limited. We describe the first report of a prospective study on real-world time on treatment (rwTOT) for first-line (1L) anti-PD-1 monotherapy in metastatic NSCLC in a 2.3 million member public health provider in Israel. **Method:** Newly diagnosed stage IV NSCLC patients who initiated 1L anti-PD-1 therapy in 2017 were identified from the national cancer registry. rwTOT was defined as the length of time between first and last administration date of anti-PD-1 therapy. Patients were considered discontinued if they had a record of next line of therapy, or death, or whose last activity date was ≥120 days from the last administration date; others were censored. The Kaplan-Meier (KM) median and restricted mean (rMean) rwToT were estimated. Jun 2018 data cutoff was utilized to allow minimum 6 months follow-up. **Result:** A total of 63 patients initiated 1L anti-PD-1 monotherapy; of these, 59 were PD-L1 TPS≥50%, one was TPS<50% and 3 unknown. This cohort comprised of 97% pembrolizumab monotherapy, 65% males, median age=59 yrs, 76% ever smokers, 71% adenocarcinomas, 11% brain metastases, and 62%/14%/24% with 0-1/2-4/unknown ECOG status. The median rwToT was 4.6 (95% CI 2.8-12.8) mo and estimated rMean at 24 months using parametric

extrapolation was 10.9 mo (4.3-16.8). Patients with ECOG 0-1, n=39, had a median rwTOT of 10.6 mo (1.9-19.2). Time on treatment for anti-PD-1 monotherapy

	1L anti-PD-1 Monotherapy N=63	1L Pembroli-zumab Monotherapy N=61
N discontinued (%)	38 (60.3)	36 (59.0)
KM Median rwToT (95% CI)	4.6 (2.8-12.8)	5.0 (3.5-NE)
rMean rwToT @ 12 months (95% CI)	6.5 (5.3-7.7)	6.7 (5.4-7.9)
Parametric (extrapolat-ed) rMean rwToT @ 24 months (95% CI)	10.9 (4.3-16.8) [Gompertz]	11.2 (4.4-17.1) [Gompertz]
6 months on treatment rate, % (95% CI)	44.1 (31.6-55.9)	45.5 (32.7-57.5)
12 months on treatment rate, % (95% CI)	39.7 (27.3-51.9)	41.0 (28.3-53.4)

Conclusion: The results of this unselected real-world cohort of metastatic NSCLC patients treated with 1L anti PD-1 monotherapy show that rwTOT rates compare favorably with published data from clinical trials and other real-world studies.

EP1.01-22 LIQUID BIOPSY IN THE DETECTION OF EGFR ACTIVATING AND RESISTANCE MUTATIONS IN ADVANCED PULMONARY ADENOCARCINOMA

V. Singh[1], P. Malik[2], P. Tanwar[2], A. Mohan[2], D. Jain[1]

[1]*All India Institute of Medical Sciences, new delhi/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Approximately 30% of the advanced pulmonary adenocarcinoma (PADC) patients are found to be mutated with epidermal growth factor receptor (*EGFR*). Nearly 60% of *EGFR* mutated patients develop T790M resistance mutation against which third generation TKIs are available. Detection of T790M mutation is a challenge due to non availability of enough tumour tissues in patients receiving first-generation *EGFR*-TKI treatment. Liquid biopsies (cell- free DNA) are promising for detection of *EGFR* activating and resistance mutations. The current study focuses on detection of *EGFR* mutations in cell-free DNA from patients with histologically confirmed *EGFR* mutation status. **Method:** 50 PADC patients (22 males; 28 females with mean age 63 years) were studied for *EGFR* mutations. Out of them 40 were TKI naïve and 10 patients were treated with *EGFR*-TKIs. Follow up biopsy from TKI treated patients was not available for resistant mutation studies. Real-time PCR and Digital droplet PCR techniques were adopted for studying *EGFR* exon 19 (deletions), 20 (T790M) and 21 (L858R) mutations in tissue and plasma samples respectively. **Result:** Clinically all patients were in stage III-IV and 52% were never smokers. Out of 40 TKI naive cases, 20 cases were positive for *EGFR* activating mutations in tissue and 17 in plasma. Twenty cases were negative for *EGFR* mutations in both tissue and plasma. In 10 *EGFR*-TKI treated patients, founder activating mutation was still present in plasma of 7 cases and 3 of them also showed T790M resistance mutation. Two patients carrying this resistant mutation died subsequently. Remaining three TKI treated patients did not harbour even founder activating mutation in the plasma. **Conclusion:** We observed a concordance of 88% (44/50) between liquid biopsy and tumour tissue. Our study highlights role of liquid biopsy as an alternative for detecting *EGFR* activating and resistance mutations in advanced PADC. *EGFR* mutation analysis in liquid biopsy can be helpful in those patients where the tissue biopsy is not possible.

EP1.01-23 SRC INHIBITION WITH BOSUTINIB AS A POTENTIAL APPROACH FOR RESTORING PEMETREXED RESPONSIVENESS

O. Gaber[1], I. Eldessouki[1], J. C. Morris[1], N. Abdel Karim[2]

[1]*University of Cincinnati, Cincinnait/United States of America,* [2]*Augusta University-Georgia Cancer Center, Augusta/United States of America*

Background: One of the principle approaches in malignant mesothelioma andnon-squamousnon-smallcelllung cancer management is cellular folate-dependentpathways inhibition with pemetrexed(PEM) combined with platinum-basedchemotherapy. Despite the promising activity of PEM, drug resistance demands new approaches allowing for abolishing resistance and better outcomes. In lung cancer, there is an association between*in vitro*PEMresistance, SRC over-expression, and thymidylatesynthase(TS) overexpression. **Method:** We treated lung cancer cell line (A549) and mesothelioma cell line (MSTO) with PEM and bosutinib (a small molecule tyrosine kinase inhibitor (TKI)) which is also an SCR inhibitor. Increasing dose regimen was adopted with these drugs. Then we conducted cellviability assays (MTT tetrazolium), detection of SRC andTS expression by western blot and apoptotic assays (AnnexinV) for drug effect evaluation. **Result:** Data showed that sequential treatment with bosutinib then PEM lowered the IC_{50} of PEM of both cell lines as indicated by cellviability and apoptosis assays. There was a 9% increase in apoptosis with combination regimen compared to PEM only regimen. Nevertheless, a decrease in TS expression was found, with correlation to the decrease in SRC expression. **Conclusion:** Combining bosutinib's SCR inhibition to PEM activity may improve the latter's therapeutic response due to synergism. Further in vivo evaluation for these results are needed to better understand these effects on tumor response

EP1.01-24 LUNG ADENOCARCINOMA: MUTATIONAL PROFILE IN EVER SMOKERS AND NON-SMOKERS PATIENTS

D. Reis[1], C. Marques[1], D. Coutinho[1], E. Silva[1], M. Dias[1], T. Costa[1], S. Campainha[1], S. Conde[1], L. Cirnes[2], A. Barroso[1]

[1]*Vila Nova de Gaia-Espinho Hospital Center, Vila Nova de Gaia/Portugal,* [2]*Institute of Molecular Pathology and Immunology of the University of Porto (IPATIMUP, Porto/Portugal*

Background: Lung cancer occurring in never-smokers had become a distinct entity. This study aims to evaluate the mutational profile in ever smokers and non-smokers patients with pulmonary adenocarcinoma. **Method:** Retrospective analysis (Oct-2016 to Aug-2017) of patients diagnosed with pulmonary adenocarcinoma in our pulmonology department. Next generation sequencing (NGS) was used to identify different mutations and translocations. Pathological variants of genes and variants of uncertain clinical significance were included. **Result:** 60 patients were enrolled in this study: 18 (30%) non-smokers and 42 (70%) ever smokers. In 72.2% of non-smokers and 57.1% of ever smokers were identified at least one mutation. Despite this, ever smokers had an overall higher frequency of mutations (72.6% vs 27.4%) because many patients had concomitant mutations. Although not statistically significant, ever smokers had more mutations that are variants of uncertain clinical significance (40% vs 23.5%; p=0,227) Table 1. Frequency of mutations

	Non-smoker		Ever smokers	
Mutated gene	Patho-logical variants (n)	Variants of uncertain clinical signifi-cance (n)	Patho-logical variants (n)	Variants of uncertain clinical signifi-cance (n)
KRAS	3	0	18	0
EGFR	5	0	4	5
ERBB4	0	0	0	1
MET	0	1	0	3
PTEN	0	0	1	1
HER2	1	2	0	7
PI3KCA	0	1	1	1
BRAF	0	0	1	0
ROS	1	0	1	0
ALK	3	0	1	0
Total	13	4	27	18

Conclusion: Although not statistically significant, smokers and non-smokers appear to have a different mutational profile. Smokers have a higher rate of concomitant mutations, although some of them are variants of uncertain clinical significance. NGS will help to increase knowledge about the mutational profile in these patients.

Keywords: Lung cancer, NGS

EP1.01-25 AN INTERACTIVE INTERFACE FOR PREDICTION OF ANTI-PD-1 EFFICACY IN LUNG CANCER PATIENTS

C. Richard[1], J.-D. Fumet[1], S. Chevrier[2], V. Derangere[2], R. Boidot[3], C. Truntzer[2], F. Ghiringhelli[1]

[1]*Centre Georges François Leclerc, Dijon/France,* [2]*Georges-François Leclerc Anticancer Center, Dijon Cedex/France,* [3]*Georges-François Leclerc Anticancer Center, Dijon Cedex/France*

Background: The past decade has seen a new field of promising treatments for non-small cell lung cancer patients (NSCLC) with immune checkpoint inhibitors (ICI). Medicine community embarks on a biomarker race to identify the one-quarter of responders and potential hyper-progressors. The assessment of PD-L1 tumor expression by IHC is used to select responder patients and is considered as the gold standard biomarker in many studies but it does not predict the absence of anti-PD-1 efficacy. Recent review from Keenan TE *et al.* summaries all potential studied markers in literature as intratumoral T cell infiltration, tumor neoantigens or else mismatch repair deficiency. Despite this abundance of potential markers, recommendations only rely on high PD-L1 expression and more recently on high tumor mutational burden (TMB). In this study, we propose estimations of response probability based on the different data that may be available for clinicians according their molecular biology and material means. **Method:** Based on a cohort of 100 patients with advanced NSCLC treated with nivolumab in second line of treatment, we developed an algorithm enabling the calculation of the probability of survival without progression at 6 or 12 months when treated with ICI. Using Cox proportional hazards multiple regression, we adjusted these three stages of information to estimate the probability of response of a patient based on the type of available data: only clinical data and/or exome analysis and/or RNA sequencing. Stability and predictive ability of these models where evaluated internally and externally through bootstrap procedure. **Result:** Among the 100 patients, 90 had both somatic and constitutional exome sequencings available and 50 had an RNA sequencing. We built a main model based on clinical and pathological data easily available for clinicians. As mandatory criteria, the age, sex, performance status, tumor histology, routine mutational status and PD-L1 immunohistochimical expression were first included in the predictive model. In addition, RECIST response to previous chemotherapy line and antibiotics usage were added into the initial model as they were described significantly associated with respectively good and poor survival to ICI in previous publications. Additional criterion were obtained thanks to extensive DNA tumor analysis such as TMB, mutations in DNA repair pathways, the number of large deletions and intratumoral TCR clones. A third stage of data was added with CD8A and CD274 RNA expressions obtained by RNA sequencing. Thus, several models are available for clinicians to estimate the probability of survival without progression at 6 or 12 months for their patients according to the type of available data. An interactive on-line interface based on R Shiny enables the questioning of all these models for further predictions. **Conclusion:** Altogether, these data provide validated and more complex biomarkers according to the type of available data to predict probability of survival without progression to anti-PD-1 in patients with advanced NLCSC. Further predictions can be obtained thanks to a shiny R free and interactive interface available on-line.

EP1.01-26 NON-SMALL CELLULAR PULMON CANCER ALK POSITIVE IN PEDIATRICS

L. Ramirez[1,2], A. Guerrero Villota[1], J. Herrera Parga[1,2], M. Velasco[2], J. Lòpez[2]

[1]*Centro Medico Imbanaco, Cali/Colombia,* [2]*Universidad Libre, Cali/Colombia*

Background: For 2018 the American Cáncer Society reports 234.030 new cases of lung cáncer, 154.050 people will die from this cause, the average age of diagnosis is approximately 70 years old. Lung cáncer in children and adolescents is extremely rare, in Colombia the incidence in children under 18 is less than 1%. The 85% of lung cancers are classified as non-small cell lung cáncer, there are recent advances in treatment with Anaplastic lymphoma kinase (ALK) inhibitors Crizotinib, Alectinib, Brigatinib for non-small cell lung cáncer ALK positive. This case report is from a 14-year-old adolescent patient treated in our institution with an ALK inhibitor. ALK disease is 3% to 5% of all non-cell lung cancers small adenocarcinoma type, more frequent in young people, women, nonsmokers, and with advanced disease. **Method:** Case report and literature review. **Result:** Male patient 14 years with respiratory symptoms productive cough. Tomography computed tomography: injury to the middle lobe and right lower lobe, biopsy: Adenocarcinoma poorly differentiated, immunohistochemistry: positive for cytokeratin 7, napsin-a, MUC-1, CK1E1 / AE3 positive and transcription factor -1 (TTF-1) and cytokeratin 20 negative, EGFR-KRAS wild type, ALK (EML-4 with clone D5F3) positive. Treatment was started with Crizotinib 250mg every 12 hours, obtaining partial response and with PFS of 36 months, gastrointestinal toxicity, hematological I grade. **Conclusion:** We report the experience of a case with excellent tolerability to an inhibitor of ALK, and its clinical benefit, (partial response and stable disease). Patients under 18 years, are excluded in most clinical trials and can benefit from treatment, increase in progression-free survival, overall survival, avoiding the toxicity of chemotherapy.

EP1.01-27 PRELIMINARY STUDY ON IMMUNE CHECKPOINT AND EMT FEATURE OF CTCS IN ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

L. Zhang, J. Tan, M. Jiang, X. Zhao, Y. Teng, W. Li, T. Zhang

Beijing Chest Hospital, Capital Medical University, Beijing/China

Background: Non-small cell lung cancer (NSCLC) is the most common malignant tumor with high morbidity and mortality. Platinum-containing chemotherapy is the standard first-line chemotherapy regimen for patients with advanced NSCLC. However, 65-75% patients would progress after a few weeks of chemotherapy treatment. The programmed cell death 1 (PD-1)/PD-1 ligand 1(PD-L1) has become the rising star of cancer research only because their development of PD-1/PD-L1 inhibitors has bring cancer patient new hope and changed the landscape of NSCLC therapy. Nevertheless, the high degree of non-responders demonstrates that we are still far from completely understanding the events underlying tumor immune resistance. Circulating tumor cells (CTCs), as an accessible source of tumor for biologic characterization that can be serially obtained with minimally invasive procedure. Studies have shown that presence of PD-L1 on CTC might predict resistance to anti-PD-1 therapy, and PD-L1 positive CTCs usually present an elongated morphology, which was associated with epithelia-mesenchymal transition (EMT). Those research provided evidence that CTC might be a promising object to predict whether the patient could be benefit from the second-line checkpoint inhibitor treatment. In this prospective cohort study, we aimed to describe the molecular background of CTCs from patients with disease progress after first-line chemotherapy. **Method:** We consecutive enroll patients who have been treated with platinum-containing chemotherapy in our hospital from May 2018 to the present, and have been assessed for disease progression (PD) by RECIST version 1.1. 6.5ml of peripheral blood was collected before further treatment. Then we enriched the CTCs and performed in situ co-detection of PD-L1 and EMT marker (Vimentin) using SE-iFISH technology. **Result:** To date we have recruited 13 eligible patients. Detectable CTCs counts range from 1 to 22 in 6.5ml blood. Among them, 4 samples presented PD-L1 positive, 4 samples presented Vimentin positive. Only 1 sample has co-expression of PD-L1 and Vimentin. **Conclusion:** Above results proved that SE-iFISH method could be used for CTC enrichment and detection. Next step, we will wait for those patients' checkpoint inhibitor treatment outcome, analysis the correlation between PD-L1 and Vimentin co-expression and patient response. At the same time, we will continue to include cases, collect CTC samples and evaluate the expression of PD-L1 and Vimentin on CTCs.

Background: Epidermal growth factor receptor (EGFR) tyrosine kynase inhibitors (TKIs) remain the standard of care as first-line therapy for patients with non-small cell lung cancer (NSCLC) harboring an EGFR mutation. These drugs have been associated with improvements in both clinical outcomes and tolerability, compared with platinum-based chemotherapy. Three generations of TKIs are currently approved in the first-line setting, though only first (erlotinib and gefitinib) and second generation blockers (mainly afatinib, but also dacomitinib) have been extensively used in clinical practice nowadays. **Method:** We reviewed 105 patients with NSCLC with advanced or recurrent stages that harbour EGFR mutations, treated with afatinib as first´line therapy among the academic hospitals adhered to the FAETT network. The information of clinical, pathological and treatment characteristics of the patients was collected retrospectively and the statistical analysis was performed with the software SPSS software version 21.0, considering the statistical significance if p-value <0.05. **Result:** The characteristics of the patients are reflected in Table 1. The mean age at the beginning of treatment with afatinib was 61 (37-81) years. 48.6% of the patients were older than 65 years. 27.6% were older than 70 years. With a median follow-up of 15 months (0-82), the median progression-free survival was 14 months (10.74-17.26) Fig 1, and the median overall survival was 31 months (24.00) -37.99). The median PFS and OS among patients older than 65 years, and even those older than 70 years, is not statistically significant (14 vs 13 and 30 vs 31 months, repectively. P-value:0,83 and 0,78 On the other hand, the toxicities between both groups remain similar, with diarrhea and skin rash standing out as the most frequent, as reflected in the data published to date. Table 2

Table1. Baseline characteristics

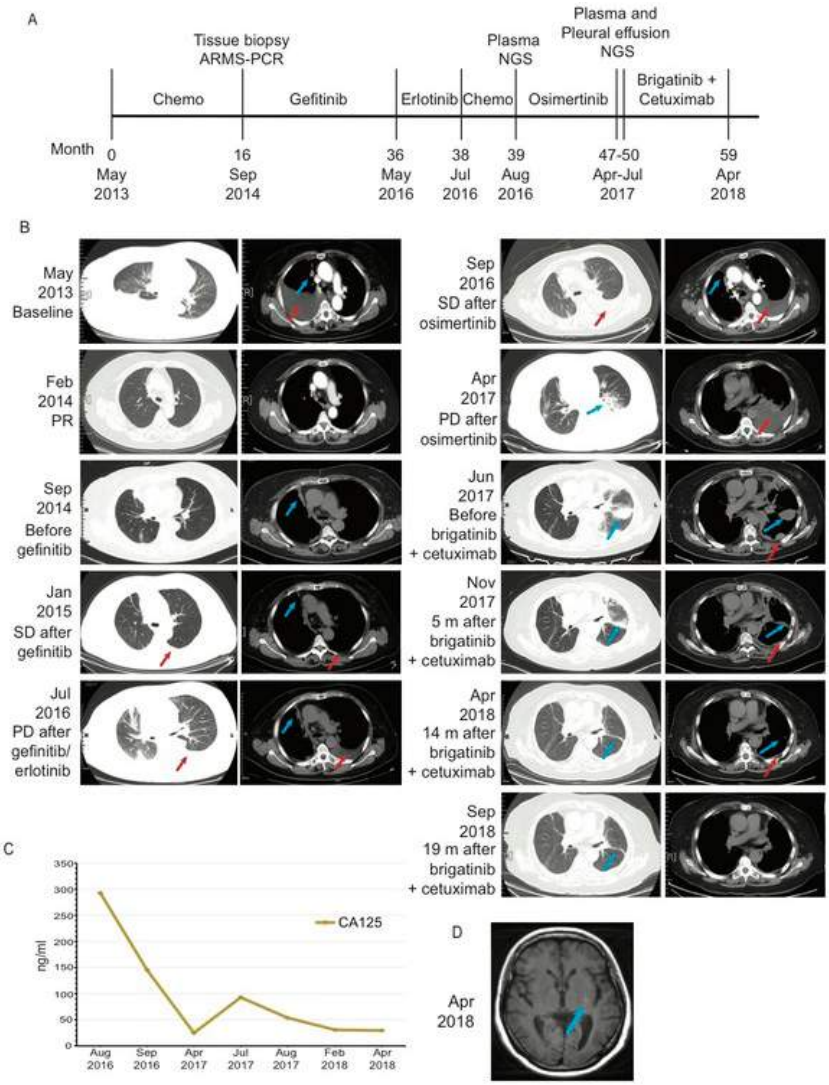
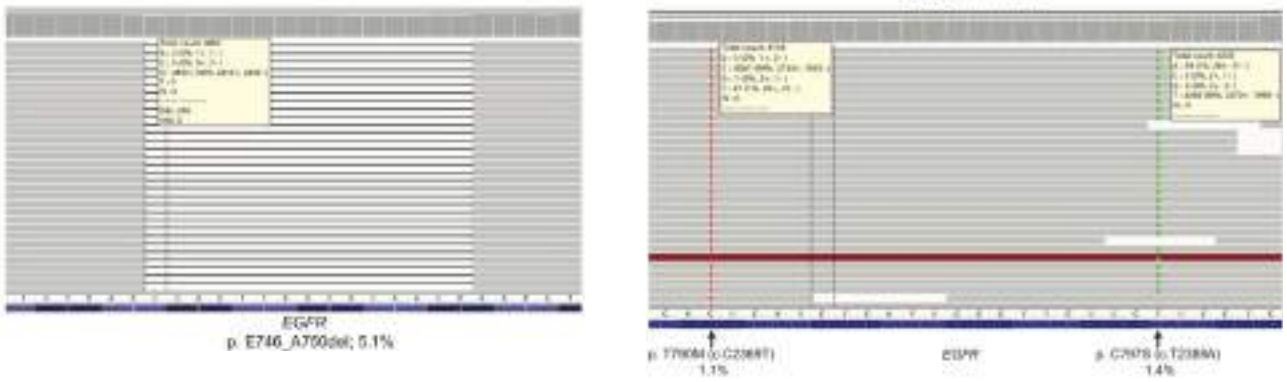
EP1.01-29 LUNG ADENOCARCINOMA HARBORING EGFR-19DEL/C797S/T790M TRIPLE MUTATIONS RESPONDS TO BRIGATINIB AND ANTI-EGFR ANTIBODY COMBINATION THERAPY

X. Wang, B. Gao

Shanghai Ruijin Hospital, Shanghai/China

Background: Treatment of non-small-cell lung cancers (NSCLCs) harboring primary EGFR oncogenic mutations such as L858R and exon 19 deletion delE746_A750 (Del-19) using gefitinib/erlotinib ultimately fails due to the emergence of T790M mutation. Though Osimertinib is effective in overcoming EGFR T790M by targeting Cys797 via covalent bonding, their efficacy is again limited due to the emergence of C797S mutation. **Method:** The study showed one patient with advanced NSCLC treated with targeted therapy, who developed acquired drug resistance to 1st to 3rd generation of EGFR-TKIs. The medical records and imaging studies of the patient were retrospectively reviewed under the approval of the institutional review board and the waiver the informed consent. The study was conducted with agreement of the patient herself. **Result:** This is one of the earliest report which describe cis mutations of T790 and C797s as the resistance mechanism observed in circulating tumor DNA (ctDNA) from a patient with initial response followed by progression on osimertinib and sucesesfuly treated with Brigatinib + Erbitux.





Conclusion: This case report,as to our knoweledge, is the first clinical evidence of efficacy using a combination of brigatinib and cetuximab to target concomitant *EGFR*-T790M and C797S *in cis*.

Keywords: EGFR, T790M, C797S

EP1.01-30 CLINICO-PATHOLOGICAL PROFILE OF ADENOCARCINOMA OF THE LUNG – A PROSPECTIVE STUDY IN A NEPALESE POPULATION

S. Dulal[1], B. Paudel[1], A. Shah[1], P. Neupane[2], B. Acharya[3], S. Chapagain[3], A. Rayamajhi[3], R. Thapa[4], O.T. Brustugun[5], N. Leighl[6]

[1]*National Academy of Medical Sciences, Bir Hospital, Kathmandu/Nepal,* [2]*University of Kansas Medical Center, Kansas/United States of America,* [3]*NAMS, Bir Hospital, Kathmandu/Nepal,* [4]*Damak Hospital, Damak/Nepal,* [5]*Drammen Hospital - Vestre Viken Hospital Trust, Drammen/Norway,* [6]*Princess Margaret Cancer Centre, Toronto/Canada*

Background: Lung cancer represents the most common cause of cancer related mortality in developing countries including Nepal where patients (pts) often present in advanced stage. The purpose of this study was to determine the incidence and clinico-pathological profile of pts with adenocarcinoma of the lung (ACL) presented to a tertiary care center of Nepal. **Method:** An IRB approved prospective study was conducted in pts with ACL over a period of 15 months from April 2017 to July 2018 at a tertiary care center, Bir Hospital, Kathmandu. Demographic data, history of smoking, histological type, presence and type of epidermal growth factor receptor (EGFR) mutations were studied. EGFR-analysis was performed using TheraScreen EGFR mutation kit. **Result:** A total of 253 pts were diagnosed with lung cancer in the period. Of the 83 (33%) diagnosed with ACL, 45 (54%) were males and 38 (46%) females. The mean age at diagnosis was 59.4 years, and 74 (89%) were in stage III/IV. Forty eight (58%) pts were smoker of whom 30 (63%) pts had less than 10 pack years. Sixty one percent (61%) were illiterate. Eighteen (22%) pts had wrongly received anti-tuberculosis treatment before the diagnosis of ACL was made. All ACL pts were tested for EGFR-mutations which were found in 24 (29%) pts, the most common mutation being exon 21 (L858R) (42%) followed by exon 19 deletion (38%). Exon 18 and exon 20 (T790M) mutation were found in 2 pts (8%) each. One pt had dual mutation in exon 20 (T790M) and exon 21 (L858R). **Conclusion:** The frequency of EGFR-mutations in ACL in this Nepalese cohort was lower than in Eastern Asian studies, but higher than in western population. EGFR mutation testing of ACL has to be encouraged in developing countries like Nepal as presence of these mutations predict durable response to oral tyrosine kinase inhibitors. Interestingly, lung cancer is often mistreated as tuberculosis leading to delay in diagnosis and treatment.

EP1.01-31 PET CT RADIOGENOMIC DEPICTION IN PDL1 EXPRESSION IN LUNG CANCER IN INDIAN POPULATION

R. Tripathi[1], A. Jajodia[2], A. Chaturvedi[2], V. Koyyala[2], A. Chaturvedi[2], S. Pasricha[2], S. Goyal[2], U. Batra[2], A. Mehta[2], H. Prosch[3]

[1]*Rajiv Gandhi Cancer Institute and Research Centre, DELHI/India,* [2]*Rajiv Gandhi Cancer Institute and Research Centre, Delhi/India,* [3]*Medical University of Vienna, Vienna/Austria*

Background: Non small cell lung cancer (NSCLC) represents an area of paramount importance wherein patients undergo testing for targetable genetic alterations. Association between the imaging and molecular phenotypes needs to be explored highlighting the growing importance of classifications based on radio genomic characterization. This study was conducted to evaluate the correlations between the radiologic and molecular phenotypes in patients with NSCLC. **Method:** 211 patients with lung cancers during the study period of one year from October 2017 till November 2018 in our institution and undergoing both radiologic (PET-CT) and molecular investigations [Programmed death ligand 1 (PDL1)] were included in the study. Both quantitative and qualitative CT findings were evaluated and correlated with the molecular findings. Quantitative data included SUV max obtained from PET component of CT and maximum diameter of lesion according to the RECIST criteria. Qualitative data recorded included location, pleural tail, pleural effusion, pericardial effusion, opacity, margins, calcifications, obstructive changes, pleural nodules, lung nodules, invasion, air bronchogram, emphysema, pulmonary fibrosis, mediastinal lymph nodes and distant metastasis. Statistical analysis was performed to evaluate the association of the qualitative features with the molecular expression. Receiver operating characteristic curves (ROC) were drawn and the corresponding area under curve (AUC) was calculated. *P*-values <0.05 were considered significant. **Result:** PDL1 expression was observed in 69 patients and 13/14 females and 29/34 non-smokers showed the expression (p-value <0.0001). A total of 1, 19, 22 and 27 patients had <1%, 1-10%, 10-50% and >50% PDL1 expression. SUV max was 11.7±3.7 in the group with PDL1 expression. Correlations were observed between PDL1 expression and location (p-value <0.0001), pleural tail (p-value <0.0001), pleural effusion (p-value <0.0001), obstructive changes (p-value 0.001), pleural nodule (p-value 0.001), lung nodules (p-value <0.0001), air bronchogram (p-value <0.0001), emphysema (p-value <0.0001), mediastinal nodes (p-value <0.0001) and distant metastasis (p-value <0.0001). PDL1 expression correlated with pulmonary fibrosis (p-value 0.001). In ROC curves, in case of PDL1 expression, the AUC was 0.728 on the basis of length. **Conclusion:** The correlation between CT findings and molecular findings highlights the importance of newer radio genomic based characterization for patients with NSCLC for better diagnostic and prognostic approaches.

EP1.01-32 IMPROVING THE PROGNOSIS OF NON-SMALL CELL LUNG CANCER AFTER THE APPROVAL OF IMMUNE CHECKPOINT INHIBITORS: A RETROSPECTIVE ANALYSIS

T. Yamaguchi, Y. Oya, H. Furuta, N. Watanabe, T. Uemura, J. Shimizu, Y. Horio, T. Hida

Aichi Cancer Center Hospital, Nagoya/Japan

Background: Anti-programmed death-1/programmed death-ligand-1 (PD-1/PD-L1) blockade represents a revolutionary breakthrough in the treatment of advanced non-small-cell lung cancer (NSCLC). However, it remains unclear whether the immunotherapy for PD-1 axis are associated with overall survival (OS) in real world patients. **Method:** We retrospectively analyzed consecutive 246 patients with stage IIIB or IV NSCLC who underwent at least 1 regimen of chemotherapy. Patients who have EGFR mutations, ALK/ROS1 rearrangements, or received curative thoracic radiotherapy were excluded. Besides, patients administered any immune checkpoint inhibitors in clinical trials were also excluded. Treatment outcomes were compared between patients who started chemotherapy from January 2012 to December 2014 (cohort A; n=135) and those who started it from January 2016 to December 2017 (cohort B; n=111). Baseline characteristics were balanced using propensity score matching, including variables such as age, sex, performance status (PS), histology, clinical stage, bone metastases, central nervous system (CNS) metastases, liver metastases, pulmonary metastases, and pleural dissemination. **Result:** Median OS was 11.4months in cohort A and 16.6mo in cohort B (HR 0.68, 95%CI 0.50-0.93, P=0.016). In 111 propensity-score matching pairs, median OS was 11.2months in cohort A and 16.6months in cohort B (HR 0.68, 95%CI 0.49-0.94, P=0.021), and the 12-month OS rate was 48.7% in cohort A versus 59.9% in cohort B, respectively. PD-1 axis inhibitors were received 13.5% in cohort A and 64.9% in cohort B. Forest plot for the propensity-matched patient analysis demonstrated a significantly better outcome in cohort B, for patients with PS 0 to 1, smokers, number of metastases ≤1, no bone metastases, no CNS metastases, no liver metastases, no pulmonary metastases, pleural metastases, and squamous histology. **Conclusion:** This result indicates the appearance of immunity checkpoint inhibitors improved the prognosis of driver-mutation negative NSCLC in real world.

EP1.01-33 EXTRACELLULAR MEDIUM OF SENESCENT LUNG CANCER CELLS PROMOTED TUMOR PROGRESSION THROUGH ACTIVATION OF YAP AND PD-L1

L. Zhu, J. Liu, D. Pu, L. Yin, Y. Liu, Q. Zhou

West China Hospital, Sichuan University, Chengdu/China

Background: Cellular senescence has been perceived as a barrier against carcinogenesis. However, the senescence-associated secretory phenotype (SASP) of senescent cells can promote tumorigenesis. Our previous researches revealed that the secretary cytokines from senescent cancer cells induced by bleomycin promoted migration and invasion of associated non-senescent cells, while the impact of hydrogen peroxide (H_2O_2)-induced senescent epithelial originated tumor cells on associated non-senescent tumor cells was rarely reported and the underlying mechanisms has not been discerned. **Method:** Senescence was induced in

human lung adenocarcinoma cancer cells (A549 and NCI-H1299) by Oxidative DNA damage chemical, hydrogen peroxide (H_2O_2), and verified by senescence-associated β-galactosidase (SA-β gal) staining and flow cytometry. A549 and NCI-H1299 cells were treated with condition medium of senescent/non-senescent A549 and NCI-H1299 (senescent vs. non-senescent group), and their protumorigenic roles were tested by cell viability assay, colony formation assay and cell invasion and migration assay. Label-free quantitative proteomics was performed to detect the expression of cytokines in culture medium of senescent/non-senescent A549 and NCI-H1299. To determine whether the YAP and programmed cell death ligand 1 (PD-L1) were involved in the tumorigenic roles, the protein and mRNA expression levels of PD-L1, YAP, CYR61, c-Myc and CTGF in A549 and NCI-H1299 were assessed by Western blot (WB) and quantitative reverse transcriptase PCR (qRT-PCR). To characterize senescent cells in lung cancer patients, we performed SA-β-Gal staining using fresh-frozen tissue sections from 20 normal lung samples and 40 lung adenocarcinoma cancer samples. To elucidate the relationship between YAP and PD-L1 in the same tumor tissue, immunohistochemistry detected the expression of both YAP and PD-L1. **Result:** A549 and NCI-H1299 could be steadily induced senescence with an induced rate of more than 90% at a dose of 200uM and 100uM of H_2O_2, respectively. The proliferation and migration ability of cells was significantly higher in senescent than in non-senescent group. Senescent condition medium significantly promoted cell proliferation and migration in both PD-L1 high-expressing NCI-H1299 and PD-L1 low-expressing A549. However, the presence of senescent condition medium increased the proliferation and invasion of co-cultured cells was significantly less in PD-L1 low-expression A549 than that seen in PD-L1 high-expressing NCI-1299. The secrete proteins identified following H_2O_2 treatment included extracellular matrix protein, inflammatory cytokines, growth factors, chemokines etc. Further mechanistic investigations revealed that mRNA level of target genes of YAP (CYR61, c-Myc, CTGF) and PD-L1 were increased after H_2O_2 treatment and their expression were positively correlated. Besides, in senescent lung adenocarcinoma cancer tissue, PD-L1 positive lung adenocarcinoma cancer samples showed significantly higher nuclear YAP positive ratios compared to PD-L1 negative samples. **Conclusion:** H_2O_2 successfully induced senescence on epithelial tumor cells A549 and NCI-H1299, whose secretary phenotype significantly promoted the proliferation and invasion of associated PD-L1 high-expressing non-senescent lung adenocarcinoma cancer cells compared with PD-L1 low-expressing NSCLC cells *in vitro*. PD-L1 and nuclear YAP are co-expressed in senescent lung adenocarcinoma cancer tissues, enlightening a therapeutic target of the combination of Hippo/YAP signaling pathway with immune checkpoint PD-L1/PD-1 inhibitors.

EP1.01-34 A RETROSPECTIVE STUDY OF THE PATTERN OF LYMPH NODE METASTASIS IN SUPERIOR SULCUS NON-SMALL-CELL LUNG CANCERS

H. Li, J. Liu, X. Fu

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: By comparing the probability of lymph node metastasis between superior sulcus non–small-cell lung cancers (SS NSCLC) and non-SS NSCLC located in the pulmonary apex, we hope to find out whether there is a unique pattern of lymph node metastasis in SS NSCLC. **Method:** During 2008-2014, a retrospective study was performed on NSCLC patients with lesions located in the pulmonary apex. Patients with lesions invading the peripheral tissue structure were enrolled in the SS NSCLC group, while those without lesions invading the peripheral structure were enrolled in the non-SS NSCLC group. A total of 65 patients in the SS NSCLC group received surgery, and all patients in the non-SS NSCLC group received surgery. According to postoperative pathology and enhanced CT before treatment, the location and number of lymph node metastasis were determined. The chi-square test was used to statistically analyze the difference in the probability of N1, N2 and distant metastasis (DM) between the two groups. **Result:** Compared with the non-SS NSCLC group, the T staging of SS NSCLC group was advanced, but the rate of N1 lymph node metastasis was similar. However, the N2 lymph node metastasis rate of the SS NSCLC was significantly lower than that of the non-SS NSCLC, which was 25.3% and 39.8% respectively (P=0.048). Distant metastasis rates were similar at lower levels in both groups,which was 9.3% and 6.4% respectively (P=0.471).

Table Basic information and results

		SS NSCLC	NOn-SS NSCLC	P value	Chi-square
Gender	male	67	65		
	female	8	28		
Median age		61(37-87)	62(42-82)		
	ad	27	67		
Pathology	squ	32	16		
	others	16	10		
T stage	T3+T4	75(100%)	3(3.2%)	0.000*	156.328
N1		25(33.3%)	33(35.8%)	0.771	0.085
N2		19(25.3%)	37(39.8%)	0.048*	3.902
DM		7(9.3%)	6(6.4%)	0.471	0.519

Ad:adenocarcinoma squ: squamous carcinoma DM:distant metastasis * P<0.05. There were significant differences between the two groups.

Conclusion: Although T staging was very late in SS NSCLC, the N2 lymph node metastasis rate and distant metastasis rate did not increase correspondingly. Therefore, enhanced local treatment, such as neoadjuvant concurrent chemoradiotherapy combined with surgery, may lead to better survival benefits.

EP1.01-35 CONCURRENT USE OF LOW DOSE ASPIRIN AND VITAMIN D IN ALK, ROS AND EGFR MUTANT NSCLC: A SINGLE INSTITUTION RETROSPECTIVE ANALYSIS

C. Bernabe[1], S. Sharma[1], J. Sanchez[2], K. Sullivan[1], N. Seetharamu[1]

[1]*Northwell Health Cancer Institute, Zucker School of Medicine at Hofstra/Northwell, Lake Success/United States of America,* [2]*Northwell Health Institute, Zucker School of Medicine at Hofstra/Northwell, New York/United States of America*

Background: Tyrosine kinase inhibitors (TKI) are the backbone therapy for EGFR, ALK and ROS positive (pos) non-small cell lung cancer (NSCLC). Pre-clinical data suggest that low vitamin D level facilitates the growth of mutant EGFR NSCLC through Vitamin D receptor (VDR). VDR is highly expressed in EGFR lung cancer cells, and its interaction with activated 1,25 vitamin D3 (1,25D3) promotes epithelial differentiation and apoptosis while inhibiting cellular proliferation and angiogenesis. Thus vitamin D3 supplementation may potentially add anti-cancer activity to conventional therapy in this population. On the other hand, murine models have shown that prolonged use of aspirin reduces the incidence of distant metastases. It is postulated that biosynthesis of prostaglandins generate a permissive intravascular metastatic niche, through platelet aggregation and endothelial activation. Recent meta-analysis published by Feng et al. analyzed seventeen studies and reported statistically significant reduction in risk of lung cancer by 8% when circulating 25-VD is at 10 nmol/L, this benefit was seen in both Caucasian and Asian population. To our knowledge, there have been no studies looking at influence of concurrent vitamin D or aspirin intake on outcomes in ALK, ROS and EGFR pos NSCLC treated with tyrosine kinase inhibitors. We performed a retrospective single institution analysis to study this association. **Method:** Patients (pts) with ALK, ROS EGFR pos NSCLC treated with first line TKI from January 2014 to June 2017 were included. Information on concurrent use and doses of aspirin and vitamin D supplements were studied. Patients were dichotomized based on use of these individual supportive medications. Two sample t-test was used to compare mean PFS and chi-square test to compare proportions of disease control rate (DCR) at 3 months between groups. **Result:** 74 patients were included. PFS in Vitamin D supplementation (n=41, 55%) group was 11 months compared to 10.2 m in those not on Vitamin D (p = 0.21, CI 1.9). For those on aspirin (n=23, 35%), mean PFS was 16m vs 12.5 m (p = 0.7213; 95% CI -5.5812 to 3.8812). DCR for aspirin use was 50% vs 65% (p = 0.1796) and for vitamin D 48.6% vs 43.7% (p= 0.6989). **Conclusion:** Our study did not show any differences in PFS or DCR in EGFR, ROS and ALK positive NSCLC patients who were concurrently taking vitamin D or aspirin compared with those who

were not. Our study was small and was not powered to pick up any significant differences. Given the strong pre-clinical background, further prospective studies would be interesting to evaluate the synergistic benefit of vitamin D and aspirin with concurrent TKI use.

Keywords: vitamin D, Epidermal Growth Factor Receptor (EGFR), Non Small Cell Lung Cancer (NSCLC)

EP1.01-36 QUALITY OF LIFE IN ADVANCED LUNG CANCER PATIENTS IN A DUTCH POPULATION

R. Sluga

St Antonius Hospital, Nieuwegein/Netherlands

Background: In advanced lung cancer chemotherapy is associated with a statistically significant improvement in overall survival (OS) compared to best-supportive care (BSC) alone, by improving survival with 9% at 12 months and median survival by 1.5 months. However, discussion remains whether adverse events of chemotherapy outweigh the relatively modest increase in survival. We aimed to investigate the quality of life (QoL) of patients with uncurable lung cancer treated with systemic therapy or best-supportive care (BSC) alone. **Method:** The European Organisation for Research and Treatment of Cancer (EORTC) QOL questionnaire (QLQ-C30) and the EORTC QLQ-LC13 were used to assess patients reported outcome measures (PROMs) at baseline, 3, 6 and 12 months in 235 patients with stage IIIb and IV NSCLC or SCLC diagnosed and treated between 2013 and 2017 in 4 large teaching hospitals in the Netherlands. Comparison between systemic therapy and BSC alone were assessed by using change in SS14 score from inclusion to 12 months. The analysis method used for this correlated longitudinal data was linear mixed modelling. **Result:** Out of 58 of 235 patients who received no systemic therapy, the vast majority did not receive any treatment because of patients refusal of treatment (58.6%), followed by poor performance status (20.7%), comorbidities (5.2%) and rapid deterioration (15.5%). Systemically treated patients had a significantly prolonged OS compared to BSC (median OS of 691 vs 219 days ($p<0.0001$)) and a higher number of patients in the best supportive care arm died during the observation period (62.1% vs 44.6%, $p=0.02$). Over time there was no significant time-treatment interaction in global health, functional or symptom scores between systemic therapy and BSC ($p> 0.05$). **Conclusion:** Although, systemic therapy in advanced lung cancer patients led to significantly longer OS compared to best supportive care, the quality of life decreased in both groups non-differently over time.

Keywords: Best supportive care, systemic therapy, Quality of life

EP1.01-37 PLATINUM-BASED CHEMOTHERAPY (CT) RECHALLENGE IN ADVANCED NON SMALL CELL LUNG CANCER (NSCLC) PATIENTS (P): A SINGLE INSTITUTION EXPERIENCE

E. Carcereny[1], A.M. Esteve[1], A. Estival[1], M. Domenech[1], L. Angelats[1], C. Erasun[1], A. Gonzalez[2], A. Plaja[1], N. Garcia[1], S. España[1], M. Cucurull[1], A. Ferrando[1], A. Pous[1], L. Notario[1], S. Sanchez Martin[1], C. Villacorta Garcia[1], T. Moran[1]

[1]*Catalan Institute of Oncology-Badalona; Hospital Universitari Germans Trías I Pujol; B-ARGO; IGTP, Badalona/Spain,* [2]*Facultat d'Economia i Empresa, Universitat de Barcelona, barcelona/Spain*

Background: No phase III trials have been carried out to prove the value of a platinum-doublet rechallenge in p with NSCLC. Currently, the availability of different effective drugs makes the platinum-based salvage therapy unusual. Moreover, the potential cumulative toxicity related to cisplatin or carboplatin can be an issue. However, retreatment with platinum-based CT could be hypothetically proposed for p with a long time to progression (TTP) from the last platinum treatment, in p with a good performance status, who may be symptomatic and with no formal contraindication to receive such treatment We have retrospectively reviewed experience at our institution of platinum-based chemotherapy rechallenge in stage III and IV NSCLC p **Method:** A cohort of 376 p with stage III and IV NSCLC treated with first-line platinum doublets from January 2012 to December 2017 were included. We extracted information on clinical and molecular characteristics, as well as treatment details. Time to progression was evaluated by Kaplan-Meier curves and groups were compared using Log-rank test. **Result:** Overall, 57 p were rechallenged with platinum-based CT (group A). Median age was 57 years (51.5-65) for rechallenged p versus (vs) 62 (56.2-68.8) for the entire cohort (group B)[p=0.001]. Group A include more p with stage III p(54.4% vs. 30.7%; p=0.001), as well as more p with better ECOG Performance Status (PS) (PS 0 70.2% vs. 44.5%; p=0.001). No differences in gender, smoking status, histology and comorbidities were observed between both groups (20.7% and 29.8% were women and 38.6% and 53.9% were smokers in groups A and B, respectively). No differences in molecular profile (EGFR, ALK, ROS1, KRAS, BRAF) were observed. The most common platinum doublet administered in first line setting was cisplatin plus pemetrexed. Group A received more frequently carboplatin plus gemcitabine or vinorelbine. Disease Control Rate (DCR) was 57.9% in p included in group A. No differences in DCR were observed in first line between both groups. Time to progression or death was 9.6 m for gropuo B(5-18.1) vs 20.5 m (14.6-37.3) p <0,001 for p in group A. **Conclusion:** Rechallenge with platinum-based CT doublets could represent an option for NSCLC p with good PS and no contraindications for such therapy.

EP1.01-38 REAL WORLD EXPERIENCE OF 1ST LINE PEMBROLIZUMAB IN PATIENTS WITH METASTATIC NON-SMALL CELL LUNG CANCER (NSCLC)

S. Ansel, P. Mcloone, N. Steele

Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom

Background: In July 2017, Pembrolizumab, a Programmed Cell Death protein-1 (PD-1) inhibitor was approved in Scotland for first-line treatment of metastatic NSCLC in patients with tumours expressing PD-L1 with tumour proportion score (TPS) of ≥50% and no targetable genetic alterations. Approval was based on findings of the KEYNOTE-024 study. We investigated the survival and toxicities experienced by patients receiving Pembrolizumab in the West of Scotland. **Method:** We identified patients with tumours expressing PD-L1 at TPS ≥ 50% from pathology records from August 2017 to August 2018 and subsequently identified 83 patients receiving first-line Pembrolizumab. We collected baseline and treatment characteristics using electronic patient records. Survival was estimated using the Kaplan Meier method. **Result:** Baseline and treatment characteristics are shown in table 1. Thirty patients had pre-treatment CT head and 8 of them had untreated brain metastases, this would have prohibited KEYNOTE-024 trial entry. Furthermore, there were 10 patients (12%) with active autoimmune co-morbidities which would have been excluded from the trial. After 9.4 months median follow-up, 32 (38.6%) patients had died. Survival at 6 months was 69.6% (95% CI: 58.3 to 78.3%) and 57.1% (95% CI: 42.1 to 69.6%) at 12 months. 39 patients (47%) experienced treatment toxicities, 15 (18.1%) experienced ≥ 2 toxicities. Diarrhoea was commonest (14 patients; 16.9%) followed by hypothyroidism (8 patients; 9.6%), pneumonitis (6 patients; 7.2%) and rash (5 patients; 6%).

Table 1: baseline and treatment characteristics

Median number of cycles = 6 (range: 1-24); 31 patients (37.3%) still continuing treatment**		
Reason for discontinuing treatment (n=52; 62.7%)	Poor PS Disease progression Treatment toxicity: - Colitis - Pneumonitis Death: - NSCLC - Unknown cause Patient choice	19 (22.9%) 14 (16.9%) 10 (12%) - 7 (8.4%) - 3 (3.6%) 7 (8.4%) - 5 (6%) - 2 (2.4%) 2 (2.4%)
*These patients would have been ineligible for KEYNOTE-024 trial ** At time of data analysis - 21 February 2019		

Conclusion: Survival at 6 months for our cohort was less than in the KEYNOTE-024 study (69.6% vs 80.2%) however fewer patients were PS 0 (14.5% vs 35.1%) and several had co-morbidities which would have precluded trial entry. The median number of treatment cycles in our cohort was 6 (range: 1-24) vs 10.5 (range: 1 to 26) trial. Toxicity was more common in this real life cohort with 12% discontinuing treatment due to toxicity vs 7.1% in the pivotal trial.

EP1.01-39 A RANDOMISED PHASE II TRIAL OF VITAMIN C SYNERGY WITH HYPERTHERMIA IN PATIENTS WITH ADVANCED NON-SMALL-CELL LUNG CANCER

J. Ou, X. Zhu, P. Chen, Y. Du, Y. Lu, X. Peng, S. Bao, J. Wang, X. Zhang, T. Zhang, C.L.K. Pang

Clifford Hospital, Guangzhou/China

Background: Intravenous vitamin C (IVC) and modulated electrohyperthermia (mEHT) are widely used by integrative cancer practitioners for many years. However, there are no sufficient data in quality of life (QoL) ,clinical response and survival time of the above treatments in patients with stage III-IV Non-Small Cell Lung Cancer (NSCLC). Our phase I clinical trial proved that IVC simultaneously with mEHT were safe for NSCLC patients. **Method:** A randomised phase II controlled trial was performed to compare supportive care with and without IVC + mEHT concomitant treatment (In the active arm: patients were allocated into 1 g/kg d, 1.2 g/kg d, 1.5 g/kg d dosage groups simultaneously with mEHT, three times a week for 25 treatments in total)on tumour size, progression-free survival (PFS) and overall survival (OS) in advanced Chinese NSCLC patients.Subsequently, 97 patients were analysed at the data cut-off (17th July, 2018). Enhanced chest and abdomen CT scans, brain MRI and bone scans were carried out at baseline, and every 4 weeks for the first 12 weeks from the start of the study. Response measurements were carried out according to RECIST 1.1. 3 month disease control rate(DCR) was measured 3 months after the therapy and defined as the percentage of subjects with complete response (CR), partial response (PR) or stable disease (SD) at 3 months relative to all randomly assigned patients. **Result:** After a median follow up of 10 months, both the PFS and OS were significantly improved by IVC + mEHT compared to control (PFS: 3 month vs. 1.85 months, *P*<0.05; OS: 12 months vs. 7.5 months, *P*<0.05). The average scores for the functioning scales increased continuously, so that the QoL improved in the active arm despite the advanced stage of the disease(P<0.05). 3-month DCR after treatment was 42.9% in the active arm and 16.7% in the control arm (*P*<0.05). Both interleukin-6 and c-reactive protein were significantly decrease after treatments in active arm in comparison with control arm (*P*<0.05). However,there were no significant differences in 3 month DCR, PFS and OS between the three groups with different applied dosages of vitamin C. No significant differences were observed between parameters of adenocarcinoma and squamous cell carcinoma and between EGFR(+) and EGFR(–). **Conclusion:** IVC + mEHT treatment significantly improves QoL, prolongs PFS and OS, and moderates cancer-related inflammation, and so is a feasible treatment for patients with advanced NSCLC. This trial is registered in ClinicalTrials.gov (ID: NCT02655913).

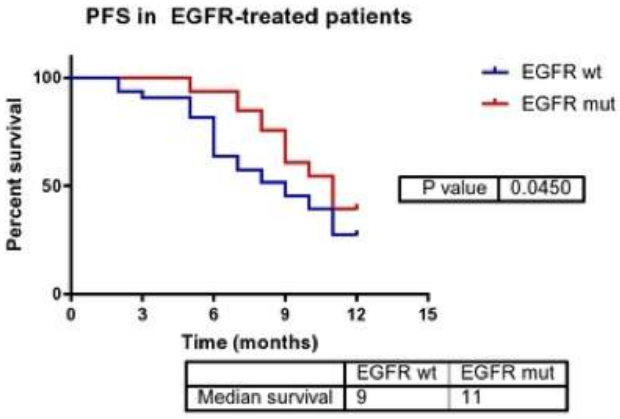
Background: Lung cancer represents major health challenges worldwide including Nepal where patients (pts) often present in advanced stage. The purpose of this study was to compare the objective response rates (ORR), progression free survival (PFS), and quality of life (QoL) of EGFR-mutated (EGFR-mut) and non-mutated (EGFR-wt) pts with adenocarcinoma of the lung (ACL) receiving standard therapy. **Method:** An IRB approved comparative analytical study was performed in pts with ACL. Newly diagnosed stage IV ACL pts were enrolled and ORR, PFS and QoL was compared between EGFR-mut and EGFR-wt (33 pts in each arm) pts. EGFR-mut pts were given gefitinib and EGFR-wt pts were given systemic chemotherapy (pemetrexed/cisplatin or cisplatin/etoposide). Response evaluation was done using RECIST criteria in both arms. PFS was calculated from the date of starting treatment to the date of progression and QoL was evaluated using EORTC QLQ-C30 (version 3) questionnaire and compared between two arms. Adverse effects were assessed using CTCAE criteria. Pts were followed for 1 year. **Result:** Complete response (CR) was achieved in 9.1% vs 3.0 % (p=0.46), and ORR was 27.3% vs 15.2% (p=0.23) in EGFR-mut vs EGFR-wt. The median PFS was 11 and 9 months for EGFR-mut and EGFR-wt respectively (p = 0.045). The mean score of global health status from EORTC QLQ-C30 was 68.1 vs 61.6 in EGFR-mut pts vs EGFR-wt pts (p = 0.036). Skin toxicities were more common in pts receiving gefitinib. One pt had grade 3 skin toxicity. Febrile neutropenia and peripheral neuropathy (either grade 1 or grade 2) were the most common toxicities in pts receiving standard chemotherapy.



Conclusion: EGFR-mut pts treated with EGFR-TKI had improved ORR, PFS and QoL in comparison with EGFR-wt pts treated with chemotherapy. EGFR-mutational analysis and EGFR-directed therapy is feasible and provides survival benefit, also in developing countries as Nepal.

EP1.01-41 FEASIBILITY OF EBUS-TBNA CYTOLOGIES FOR AN EXTENSIVE ASSESSMENT OF PREDICTIVE BIOMARKERS IN LUNG CANCER

R. Martin-Deleon, C. Teixido, R. Reyes, C. Cabrera, R.M. Marrades, N. Viñolas, D. Martinez, J. Ramirez, I. Vollmer, P. Jares, C.M. Lucena, N. Reguart, C. Agusti

Hospital Clinic Barcelona, Barcelona/Spain

Background: Clinical guidelines support the determination of several driver genes as well as PD-L1 to drive treatment decisions in non-small cell lung cancer (NSCLC). Endobronchial-ultrasound transbronchial needle aspiration (EBUS-TBNA) cytology specimens are useful for the initial diagnosis of NSCLC, although its capacity to provide enough material for a complete genotyping remains controversial. The aim of this study is to determine the yield of EBUS for a comprehensive multiplex genotyping in patients (pts) with suspected NSCLC. **Method:** In this single-center, ongoing, prospective study, samples from mediastinal lymph nodes were obtained from pts undergoing EBUS-TBNA for lung cancer diagnosis/staging. Following malignant confirmation and appropriate cell content by rapid on-site evaluation, the study sample was obtained and formalin-fixed paraffin-embedded (FFPE). Three analytes were evaluated (DNA/RNA/protein). DNA and RNA were extracted and analyzed by Oncomine Solid Tumour panel (22 genes) and a customized nCounter panel (*ALK, ROS; RET, NTRK, METDe14*). Tumor Proportion Score (TPS) for PD-L1 protein expression was evaluated by an expert pathologist and scored into <1% (negative), 1-49% (weakly positive) and 50% (high). **Result:** Twenty-five pts with NSCLC have been included and cytology samples of 20 of them molecularly characterized (5 still in progress). Overall, cytological analysis of EBUS-TBNA yield a complete characterization for the three analytes (DNA/RNA/protein) in 15 pts (75%). EBUS-TBNA sampling was sufficient for both, Nanostring and Oncomine evaluation, in a total of 18 pts (90%): 15 patients (83%) had any alteration detected by oncomine (*TP53* 61% [11/18],*KRAS* 44% [8/18], *EGFRe 19*5.5% [1/18], *BRAF V600E* 5,5% [1/18], *DDR2* 5.5% [1/18], *STK11* 11% [2/18]) and 1 pt (5.5 %) by nanostring (*METDex14*). A total of 19 samples were sufficient for PD-L1 expression scoring (95%). TPS for PD-L1 expression was negative in 8 pts (42%), week in 4 (21%) and high in 7 pts (37%). Overall, half of the pts evaluated (10/20) would be potential candidates for an upfront personalized treatment strategy using targeted agents or immunotherapy. **Conclusion:** EBUS-TBNA is a promising alternative source of material for NSCLC genotyping and allows the identification of pts candidates for personalized therapies.

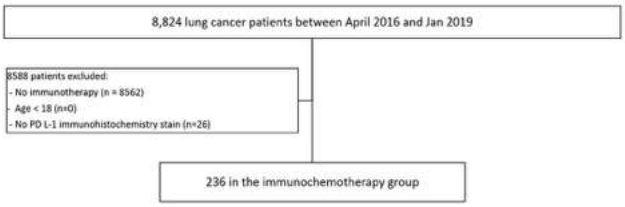
EP1.01-42 IS SERUM LYMPHOCYTE COUNT PREDICTIVE BIOMARKER TO IDENTIFY LUNG CANCER PATIENTS WHO MAY BENEFIT FROM AN IMMUNOTHERAPY?

Y.J. Lee[1], S.Y. Yun[2], T.Y. Park[2], D.K. Kim[2], H.S. Chung[2], J.K. Lee[2], E.Y. Heo[2]

[1]*Seoul National University Hosptial, Seoul/Korea, Republic of,* [2]*Seoul Metropolitan Government Seoul National University Boramae Medical Center, Seoul/Korea, Republic of*

Background: Programmed death ligand 1 (PD-L1) expression is not truly reflected response of immunotherapy. Thus, tumor mutational burden is new biomarker for predict response of immunotherapy. However, sufficient quantity or quality tumor samples must be obtained, so this is limitation. Therefore, we investigated whether high serum lymphocyte is predictive biomarker for immunotherapy response regardless of PD-L1 immunohistochemistry stain among lung cancer patients. **Method:** We retrospectively analyzed the medical charts of lung cancer patients who treated with immunotherapy (pembrolizumab, nivoluamb, ipilimumab, atezolizumab) at Seoul National University Hospital between April 2016 and March 2019. We evaluated correlation the serum lymphocyte count (SLC) with the progression free survival (PFS) using multivariable linear regression. SLC was evaluated when patients **Result:** Total 236 patients treated with immunotherapy for lung cancer. SLC at baseline was not significantly associated with progression free survival (Coeff = -0.00, p = 0.478) after adjustment age, sex, ECOG status, histology and PD L-1 expression status. The 1-year progression free survival rate was 14.8% and patients who survived over 1 year were not revealed difference of SLC compared with those who didn't survive over 1 year. When we divided two group according lymphocyte count as 5000/uL, among patients who were over 5000/uL of lymphocyte related with increased progression probability (hazard ratio for disease progression, 1.68; 95 % CI, 1.03 to 2.77; P=0.04).

Fig1. Flow chart of the study



Conclusion: In this study, we revealed that increased serum lymphocyte count over 5000/uL at baseline when immunotherapy start is associated with decreased progression free survival among lung cancer patients who treated with immunotherapy.

EP1.01-43 IMMUNOTHERAPY AND RADIOTHERAPY - A USEFUL COMBINATION?

S. Eisenmann[1], F. Oezkan[2], I. Vogt[1], N. Lambrecht[1]

[1]*Universitätsklinikum Halle-Wittenberg, Halle/Germany,* [2]*The Ohio State University, James Thoracic Cancer Center, Columbus/United States of America*

Background: Immunotherapy has emerged as a major and effective therapeutic modality in non-small cell lung cancer (NSCLC). With expanding indications for immunotherapy, therapeutic modalities in progressive disease under immunotherapy are needed. **Method:** In a retrospective single center analysis patients treated with immunotherapy and radiation for progressive lesions were identified. Both patients with acquired and primary resistance to immunotherapy were included in the analysis. **Result:** In eight patients (2 adenocarcinoma, 6 SCC) immunotherapy was continued (5 Nivolumab, 1 Pembrolizumab, 2 Atezolizumab) despite disease progression due to good tolerance and missing therapeutic alternatives because of multiple pretreatment regimens and their toxicities. We observed that all 8 patients had a clinical benefit without developing a disseminating disease, we only observed a growth in the previously existing lesions. In 5/8 patients the disease could be stabilized. An abscopal effect could be excluded. In five patients local metastatic growth was treated with radiation to manage pain and local complications. Three additional patients with asymptomatic, progressive lesions were treated with radiotherapy to prevent organ complications. **Conclusion:** Immunotherapy has revolutionized NSCLC treatment. However there are therapeutic modalities questioned in progressive disease under immunotherapy. By maintaining immunotherapy during and after radiotherapy localized progression might be effectively treated. Therefore we summarize that in a number of patients further metastatic evolution might be preventable. Whether peritumoral or systemic prognostic determinants can be identified should be a matter of further research. Either benefits of local ablative techniques or perpetuation of immunotherapy despite of disease progression were recently reported (Gandara et al. 2018, Gettinger et al. 2018). This also suggests a differentiative perspective of local ablative therapy in metastatic NSCLC.

Keywords: Immunotherapy, radiotherapy

EP1.01-44 EARLY AND LONG-TERM RESULTS OF TRACHEAL SLEEVE PNEUMONECTOMY FOR LUNG CANCER AFTER INDUCTION THERAPY

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: The role of induction therapy (IT) and its effects on morbidity and mortality of patients receiving tracheal sleeve pneumonectomy (TSP) are unclear. We evaluated early and long-term outcomes of patients who underwent TSP after IT. **Method:** From 1998 to 2018, 32 patients (26 men; median age, 63 years) underwent TSP. Twenty-two patients (69%) received IT (cisplatin-based chemotherapy). The TSPs were all right sided and included three completion pneumonectomies. Superior vena cava resection was combined with TSP in 15 cases. Diaphragmatic and vertebral resection was also associated in 1 case each. **Result:** Operative mortality was nil. Thirty-day mortality was 9% (n = 3). Major complications occurred in 7 patients (21.8%): bronchopleural fistulas in 3; acute respiratory distress syndrome in 2; cardiac hernia in 1; and empyema in 1. The IT had no significant effects on morbidity and mortality. Resection was complete in 31 patients (97%). Pathologic N status was N0 in 2 cases, N1 in 17, and N2 in 13. Nodal downstaging was diagnosed in 13 of 22 patients (59.1%) who received IT (11 passed from N2 to N1, and 2 to N0). Mean survival was 36 months (range, 1 to 181). Overall 5-year survival and disease-free survival were 30.3% and 27.7%, respectively. Patients receiving IT had a poor survival (p = 0.03). At multivariate analysis, nodal downstaging and adjuvant treatment significantly affected survival (p = 0.035 and p = 0.007, respectively). **Conclusion:** Tracheal sleeve pneumonectomy is a feasible but technically challenging surgical procedure and provides acceptable results in terms of early and long-term outcomes. Induction therapy did not significantly affect morbidity and mortality.

Background: One of the standard treatments in chemo-naïve patients with advanced non-small cell lung cancer (NSCLC) is platinum-containing doublet chemotherapy. Moreover non-squamous NSCLC, patients benefit from pemetrexed maintenance therapy following induction therapy with cisplatin (CDDP) plus pemetrexed. However, no large-scale trial showing the efficacy of maintenance therapy has been reported in squamous cell lung cancer. We evaluated the efficacy and the safety of continuation maintenance therapy with gemcitabine (GEM) after induction chemotherapy with CDDP plus GEM in advanced squamous cell lung cancer. **Method:** This study was a single-arm, multicenter and phase II trial. Main eligibility criteria included Eastern Cooperative Oncology Group (ECOG) performance status (PS) of 0-1, and the aged of 20 to 74 years old. Patients received an induction phase which consisted of 4 cycles of CDDP (80mg/m2, day 1, q3w) plus GEM (1000mg/m2, day 1, 8, q3w). Patients who did not progress after completion of 4 cycles of induction received continuation maintenance therapy with GEM (1000mg/m2, day 1, 8, q3w) until disease progression. The primary endpoint was progression-free survival (PFS) in the intention-to-treat population. **Result:** Between June 2013 and October 2018, 26 patients were enrolled in this study. Although the scheduled numbers were 60, this study was ended early for poor accrual. The mean age was 65.7 years (range, 47 – 74 years). 18 patients (69.2%) completed 4 cycles of CDDP plus GEM, and 16 patients (61.5%) received continuation maintenance therapy with GEM. At the cutoff date of December 31, 2018, overall response rate was 46.2%, median PFS from induction therapy was 5.3 months (95% confidence interval [CI]: 2.9-7.3), and median PFS from continuation maintenance therapy was 3.8 months (95% CI: 2.3-5.2). Median overall survival from induction therapy was 11.9 months (95% CI: 7.5-26.5). The most common grade 4 adverse events were neutropenia (16%) and thrombocytopenia (12%). Pneumonitis ware seen in 3 cases (grade 1: 1, grade 2: 1, grade 3: 1 case). Adverse events except for hematotoxicity were generally well tolerated. There were no treatment-related deaths. **Conclusion:** This study terminated early because of poor accrual and did not meet its primary endpoint. However, this study indicated continuation maintenance therapy with GEM can be well-tolerated treatment option for patients with advanced squamous NSCLC.

EP1.01-46 ACUTE ESOPHAGEAL DAMAGE IN PATIENTS WITH INOPERABLE NON-SMALL CELL LUNG CANCER TREATED WITH CONCURRENT AND SEQUENTIAL CHEMORADIOTHERAPY

S. Crvenkova

University Clinic of Radiotherapy and Oncology, Skopje/North Macedonia

Background: Acute esophageal damage may be dose-limitation factor for application of the full planning radiotherapy dose in patients with inoperable Non Small Lung Cancer-NSCLC. Combination of chemotherapy and radiotherapy may increase esophageal toxicity, however three-dimensional conformal radiotherapy offers better spearing. **Method:** To evaluate the treatment results, study of 75 patients was randomly assigned to one of the two treatment arms. In the sequential arm, 26 (34.7%) patients had previously received sequential chemotherapy with 4 cycles of carboplatin and etoposide followed by conformal radiotherapy (RT). In the second concurrent arm, 49 (65.3%) patients received concurrent chemotherapy of cisplatine and etoposide and conformal RT. We described all phases of the conformal RT. Treatment-related toxicities were assessed according RTOG/EORTC criteria. **Result:** From 2010 to 2013, 73 patients were enrolled in this study. From all included patients, 43 (57.3%) did not present any grade of esophagitis during the treatment. In sequential group 73.1% presented no esophagitis and in concurrent group 49%, respectively. Although there were differences between the two groups, none was statistically significant. The median survival was 13 months for the patients in the sequential arm and 17 months for those in the concurrent treatment arm. The differences were statistically significant (log-rank test p=0.0039). Table 1 and 2 present grade of ezophagitis and the needs of analgesia in the patients of sequential and concurrent treatment arm. The risk of esophagitis was 22%, in patients whose esophageal volume (V50) recieved less than 30% of prescribed dose in comparation, the risk of esophagitis was 71%, in patients whose V50 recieved dose higher than 30% (p=0.0009).

Table 1: Grade of esophagitis according radiotherapy dose

	Sequential arm				Concurrent arm			
	0	1	2	3	0	1	2	3
40 Gy	22 (84.6%)	1 (3.8%)	3 (11.5%)	0	30 (61.2%)	8 (16.3%)	9 (18.4%)	2 (4.1%)
60 Gy	20 (76.9%)	0	6 (23.1%)	0	25 (51.0%)	6 (12.2%)	15 (30.6%)	3 (6.1%)
End of radiotherapy	19 (73.1%)	1 (3.8%)	6 (23.1%)	0	28 (84.6%)	4 (8.2%)	14 (28.6%)	3 (6.1%)

0,1,2,3= grade of esophagitis according RTOG/EORTG

Table 2: Irradiation doses and analgesia

	Sequential arm				Concurrent arm			
	0	1	2	3	0	1	2	3
40 Gy	22 (84.6%)	1 (3.8%)	0	3 (11.5%)	30 (61.2%)	11 (22.4%)	4 (8.2%)	4 (8.2%)
60 Gy	21 (80.8%)	1 (3.8%)	1 (3.8%)	3 (11.5%)	25 (51.0%)	12 (24.4%)	4 (8.2%)	8 (16.3%)
End of radiotherapy	20 (76.9%)	1 (3.8%)	2 (7.7%)	3 (11.5%)	31 (63.3%)	7 (14.3%)	2 (4.1%)	9 (18.4%)

0=no analgesia; 1=anti-inflammatory drugs; 2=opoids; 3=combination of anti-inflammatory and opoids

Conclusion: The reason for good tolerability of the combination of chemotherapy and radiotherapy for patients in this study is using three-dimensional conformal radiotherapy. Further improvements may be obtained with more sophisticated radiotherapy techniques or by using radio protective drags.

Keywords: acute esophageal damage, sequential and concurrent chemo radiotherapy, conformal radiotherapy

EP1.01-47 THYROID RELATED ADVERSE EVENTS PREDICT SURVIVAL IN NSCLC PATIENTS RECEIVING ANTI-PD-1/ PD-L1 THERAPY

Y. Ahmed[1], J. Lee[2], P. Calvert[3]

[1]*University Hospital Waterford, Waterford, X ERE/Ireland,* [2]*Sligo University Hospital, Sligo/Ireland,* [3]*University Hospital Waterford, Waterford, X Ere/ Ireland*

Background: Immune checkpoint inhibitors (ICI) have altered the therapeutic paradigm of advanced non-small cell lung cancer (NSCLC) and produce antitumor effects by activating host immunity, which also causes immune-related adverse events (irAEs). Thyroid irAE is the second most common irAEs after dermatological irAEs following ICI and present in 2%-21% of patients s depending upon the immune checkpoint inhibitors used. It has been reported that irAEs induced by ICI may be associated with possible improvement in survival and better therapeutic outcomes. The aim of this study is to analyze the relationship between PD-1 inhibitors -induced Thyroid irAE and clinical efficacy in advanced NSCLC patients treated at three regional cancer centres. **Method:** Retrospective study was conducted using the Hospitals' Inpatient Enquiry (HIPE) to identify patients with NSCLC stage IV or inoperable stage IIIB who received at least one dose of PD-1 inhibitors (Nivolumab or pembrolizumab) between Januarys 2017 and December 2018. Patients who had no baseline Thyroid function tests (TFTs), abnormal baseline TFT or had a history of thyroid disorder were excluded. Thyroid irAE were identified and classified according to TSH and free T4 (fT4) Efficacy was evaluated with progression free survival (PFS) and median overall survival (OS) according to the development Thyroid IrAEs **Result:** One hundred and eighty-five patients were included, 120 male [64.9%] ,65 female [35.1%] and the median age was median age 66(38-88) years. A total of 38 (20.5 %) patients on PD-1 inhibitors (nivolumab or pembrolizumab) had new-onset Thyroid IrAEs. 76.3% (29/38) of those patients manifested initially with thyrotoxicosis. The remaining 22.6% (9/38) of patients presented with hypothyroidism as the initial presentation. The median times to new-onset Thyroid IrAEs was 46 days. Kaplan Meier survival analysis showed that patients with Thyroid IrAEs had a statistically significant longer median PFS of 9.0 months (95% CI, 9.3–17.1) compared to patients with without Thyroid IrAEs who had a median PFS of 2.0 months (95% CI, 2.0–13.5), hazard ratio = 0.38, (95% CI, 0.20–0.71; P = 0.002). For entire cohort, Thyroid IrAEs was associated with superior survival (median OS 16.0 months for those who developed Thyroid IrAEs compared to 2.9 months of those without Thyroid irAEs ($p < 0.0001$) **Conclusion:** The result of this study emphasizes the association between irAEs and better survival outcomes from anti-PD1 therapy. Development of grade 2 Thyroid IrAEs was a useful predictor of survival outcomes in NSCLC patients treated with ICI. These results support previously published retrospective data. Further prospective studies are required to thoroughly underline the association between ICI induced irAEs, tumor response and long term survival.

Keywords: PD-1 inhibitor, NSCLC, Thyroid

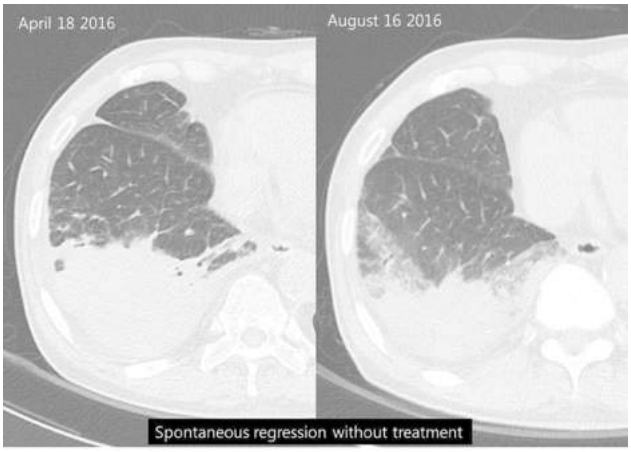
EPOSTERS

EP1.01-48 INVASIVE MUCINOUS ADENOCARCINOMA OF THE LUNG: SERIAL CT FINDINGS, CLINICAL FEATURES, AND TREATMENT OUTCOMES

K. Beck, K.Y. Lee, D.H. Han

Seoul St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Seoul/Korea, Republic of

Background: Invasive mucinous adenocarcinoma of the lung is a rare and distinct subtype of adenocarcinoma, previously described as bronchoalveolar carcinoma (BAC). In our daily practice, we have sometimes encountered spontaneous regression without treatment in patients with invasive mucinous adenocarcinomas, but serial CT findings of this cancer have not been described in the literature. We performed an analysis to describe the serial chest CT findings, clinical features, and treatment outcomes of patients with invasive mucinous adenocarcinoma of the lung.



Method: From January 2013 to June 2018, 49 cases of pathology-confirmed invasive mucinous adenocarcinoma of the lung were identified. Initial chest CT and follow-up CTs were available for 48 patients (23 men and 25 women; median age, 69.5 years; range, 26-82 years). Median follow-up period was 19.0 months (range, 0-110 months). Serial CT scans were reviewed, with emphasis on changes over time and in relation to medical or surgical treatment. Patients were classified as either nodule/mass type or consolidation type according to the initial CT. Clinical, radiological, and treatment outcomes were compared between nodule/mass and consolidation types by adopting the χ^2 test, Mann-Whitney U test, and Kaplan-Meier analysis with log-rank tests. **Result:** There were 33 nodule/mass type and 15 consolidation type at initial CT scan. Of 15 consolidation type, 9 patients showed combined GGO. Consolidation type presented with significantly larger lesion size (p<0.001), higher stage (p<0.001), and multifocality (p=0.001) on initial CT and showed spontaneous regression without treatment during follow-up (p<0.001) compared to the nodule/mass type. Six patients died during follow-up, and they were all from the consolidation group (p<0.001). 33 patients underwent surgery and 11 patients received chemotherapy. Patients with the consolidation type showed reduced progression-free survival (PFS) (mean 9.5 months) compared with those with the nodule/mass type (mean 63.9 months) (p<0.001). **Conclusion:** Invasive mucinous adenocarcinomas of the lung appearing as consolidation on initial CT are larger and multifocal, have higher stage, higher mortality, and reduced PFS, and can show spontaneous regression.

Keywords: CT, invasive mucinous adenocarcinoma, NSCLC

EP1.01-49 HISTOLOGY-DEPENDED PATTERN OF PATHO-HISTOLOGICAL RESPONSE AFTER INDUCTION THERAPY IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER

W. Schreiner, W. Dudek, R. Rieker, R. Fietkau, H. Sirbu

University Hospital, Friedrich-Alexander-University, Erlangen/Germany

Background: Pathological response after induction therapy (IT) is expected to be associated with favorable outcome in locally advanced non-small cell lung cancer (NSCLC). The pathologic response pattern remains unpredictable. Aim of this retrospective study was to analyze the patho-histologic response according to tumor histology, in order to identify the potential correlation and prognostic impact. **Method:** In 57 patients with locally advanced NSCLC the patho-histologic response to IT were assessed and compared for adenocarcinoma vs. squamous cell lung cancer after curative lung resection. The prognostic differences were estimated by Kaplan-Meier method and compared using log-rank test. **Result:** The IT included chemo-radiation with 50.4Gy (range 45-56.4 Gy) combined with platin-based chemotherapy in 54 patients (94.7%) or only platin-based chemotherapy in 3 patients (4.3%). Perioperative morbidity and 30-days-mortality was 36% and 3.5%, respectively. Complete resection was achieved in 93% patients. Significantly improved long-term survival and recurrence-free survival were associated with <15% viable squamous cells and with <60% viable adenocarcinoma cells (long rank 0.013 and 0.012, 0.04 and 0.05, respectively). The median long-term survival for <15% viable squamous cells was 35.2 months, recurrence-free survival was not achieved; for <60% viable adenocarcinoma cells the median long-term and recurrence-free survival were 87.9 and 35.9 months, respectively. **Conclusion:** The patho-histologic response pattern to IT is correlated to tumor histology and has potential implication on pathologic assessment. Distinct prognostic impact can be further reflected in the clinical practice and multimodal treatment strategies.

EP1.01-50 QUANTITATIVE ASSESSMENT OF SUBSEGMENTAL BRONCHI ON THIN-SECTION CT FOR PULMONARY LYMPHANGITIS CARCINOMATOSA

D. Takenaka[1], Y. Ohno[2], C. Tanaka[1], E. Matsushiro[1], A. Higashida[1], T. Hashimoto[1], H. Maeda[1], S. Sakamoto[1], M. Satouchi[1]

[1]*Hyogo Cancer Center, Akashi/Japan,* [2]*Fujita Health University School of Medicine, Toyoake/Japan*

Background: CT is the main modality to measure the of the tumor and/or metastasis of solid malignancies to evaluate the change over time due to conservative therapy, especially in chemotherapy. However, the change of lymphangitis carcinomatosa which appears at advanced stage could be evaluated quantitatively, only. The purpose of this study was to evaluate the availability of CT to quantify the lymphangitis carcinomatosa of lung cancer. **Method:** Fifteen consecutive patients (12 males, three females; 51-76 y.o.) with pulmonary lung cancer who were diagnosed as lung cancer with lymphangitis carcinomatosa by CT were enrolled retrospectively. Each patient's lung cancer was diagnosed by using bronchoscope or CT guided biopsy. All patients underwent CT examination before and after the chemotherapy. All CT studies were performed by using MDCT machine (Aquilion Prime or Aquilion Precision; Canon Medical Systems, Otawara, Japan). All CT examinations were performed with 80 or 160-detector row CT scanner with contrast media. CT images were reconstructed with 1mm slice, 1mm interval, 512 x 512 matrix. The long axis diameters of primary tumors were measured on CT before and after the therapy. The wall area of the sub-segmental bronchus affected by lymphangitis carcinomatosa was defined by Synapse Vincent (Fujifilm Medical; Tokyo, Japan) before and after the therapy. The correlation coefficient of tumor reduction rates between the primary tumor diameter and wall area of the affected sub-segmental bronchus was statistically assessed. P value less than 0.05 was considered as significant in statistical analyses. **Result:** The correlation coefficient of tumor reduction rates between the primary tumor diameter and wall area of the affected sub-segmental bronchus was 0.533 (p = 0.041). **Conclusion:** The positive correlation of tumor reduction rates was significant between the primary tumor diameter and wall area of the affected sub-segmental bronchus. The measurement of wall area of affected sub-segmental bronchus on thin-slice CT has the availability to evaluate the quantitative change of lymphangitis carcinomatosa of lung cancer patients.

Keywords: lymphangitis carcinomatosa, CT, bronchus

EP1.01-51 EFFICACY IMPACT OF SERUM VEGF FOR ELDERLY OR POOR PS PATIENTS RECEIVING ANTI-PD-1 ANTIBODY WITH ADVANCED NON-SMALL CELL LUNG CANCER

R. Shibaki[1], S. Murakami[2], Y. Shinno[2], Y. Matsumoto[2], T. Yoshida[1], Y. Goto[1], S. Kanda[2], H. Horinouchi[2], N. Yamamoto[2], Y. Ohe[2]

[1]*National Cancer Center Hospital, Tokyo/Japan,* [2]*Thoracic Oncology, National Cancer Center Hospital, Tokyo/Japan*

Background: Anti-programmed cell death (PD)-1 antibody therapies have shown durable clinical efficacy and manageable toxicity profiles, and have become a standard therapy in advanced non-small cell lung cancer (NSCLC). Because of manageable toxicity profiles, extensive interest in the potential benefits of anti-PD-1 antibody has expanded to high-risk patients such as the elderly or poor performance status (PS) patients. Here, we aimed to investigate predictive markers for the efficacy of anti-PD-1 antibody in elderly patients and poor PS patients. **Method:** The medical records of 75≥ years old or PS2 NSCLC patients treated with anti-PD-1 antibody (e.g., nivolumab and pembrolizumab) at the National Cancer Center Japan between December 1, 2015, and May 31, 2018, were reviewed retrospectively. We evaluated the association between efficacy for anti-PD-1 antibody and gender, smoking status, histology, PD-ligand 1(PD-L1) expression on tumor cells, white blood cell counts, lymphocyte counts, albumin, lactate dehydrogenase, c-reactive protein, and serum vascular endothelial growth factor (VEGF). We divided patients into two groups with the median values. **Result:** A total of 235 patients with advanced NSCLC treated with anti-PD-1 antibody were reviewed. Of these patients, 31 patients were ≥ 75 years old, and 22 patients were PS2. The median PFS was 6.9 months in patients aged ≥ 75 years and 2.1 months in PS2 patients. Cox proportional hazard regression analysis showed that only the low-VEGF was significantly associated with longer PFS in patients aged ≥ 75 years (HR, 0.35; 95% CI, 0.13-0.88; *P* = 0.025) and in PS2 patients (HR, 0.31; 95% CI, 0.10-0.85; *P* = 0.023). The overall response rate of patients with low-VEGF was tend to be higher than that with high-VEGF among patients aged ≥ 75 years (43% *vs*. 20%; *P* = 0.18) and PS2 patients (20% *vs*. 0%; *P* = 0.084). **Conclusion:** Low-VEGF in patients aged ≥ 75 years and PS2 patients was associated with longer PFS. Serum VEGF may thus be a biomarker for the efficacy of anti-PD-1 antibody therapy.

EP1.01-52 PREFERABLE INTRACRANIAL CHEMOTHERAPY FOR LUNG CANCER PATIENTS WITH MENINGEAL METASTASIS HARBORING CIN IN CSF

P. Wang[1], H. Zhang[2], H. Sun[2], J. Li[2], L. Zhang[2], P. Chen[2]

[1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin/China,* [2]*Beijing Genecast Biotechnology Co., Beijing, P.R. China, Tianjin/China*

Background: Brain metastases occur in about half of the NSCLC patients throughout the course of disease, including brain parenchymal metastasis and meningeal metastasis. It has been reported that compared with plasma detection, next-generation sequencing (NGS) of circulating tumor DNA (ctDNA) from cerebrospinal fluid (CSF) is capable of more comprehensively characterizing the genomic alterations of brain tumor, so as to identify actionable variants. **Method:** We conducted a small sample study consisting of 7 patients with brain metastasis, including 3 lung cancer patients with meningeal metastasis (P314, P316, P318), a lung cancer patient with brain parenchymal metastasis (P323), 2 breast cancer patients with meningeal metastasis (P324 and P328) as well as a gastric cancer patient with meningeal metastasis (P326). Profiling of the specimens from CSF, brain parenchyma and plasma of these 7 patients was performed using NGS along with bioinformatics analysis. **Result:** Among the three patients P314, P316 and P318, high-frequency driver mutations including *ERBB2* p.V659E, *EGFR* p.L858R & *MET* amplification, *EGFR* 19del were detected in the CSF respectively, but all of these variants were not observed in the plasma. Notably, these three patients' brain lesions continued to progress after receiving corresponding targeted agents, while their conditions remained stable in the presence of switching to intracranial chemotherapy. Following bioinformatic analysis revealed the occurrence of chromosome instability (CIN). We wonder if it is a special case or a common phenomenon. To further explore whether there is similar phenomenon in brain parenchymal metastasis, we examined the patient P323. The detection results of his brain parenchyma, CSF and plasma showed that there was no variation of CIN in brain parenchyma and CSF. In view of this, we hypothesized that CIN variants might exist only in lung cancer patients with meningeal metastasis. In addition, our results displayed that no chromosome instability was identified in the CSF of patients P324, P328 and P326. **Conclusion:** In summary, CIN is likely an important genomic feature of lung cancer with meningeal metastasis and is apt to be detected in the CSF. According to our observation, NGS of CSF specimen rather than plasma sample may be more favorable to the selection of appropriate treatment options for lung cancer patients with meningeal metastasis. For such patients with CIN variation, intracranial chemotherapy possibly offers more significant clinical benefit than other treatments such as targeted therapy. It still requires more investigations to verify above hypothesis.

Keywords: lung cancer/meningeal metastasis /chromosome instability (CIN)/intracranial chemotherapy

EP1.01-53 UPDATE OF MUTATION STATUS IN LUNG CANCER. A MULTICENTER LOCAL STUDY

N. Pilnik[1], V. Bengio[2], M. Canigiani[3]

[1]*Cordoba University, Córdoba/Argentina,* [2]*Cordoba Hospital, Córdoba/Argentina,* [3]*Transito Hospital, Córdoba/Argentina*

Background: Advances have been made in the understanding of the biology of NSCLC in relation to the characterization of molecular features such as activations of oncogenes by mutations, translocations and amplifications, which are being used as a targets and predictive biomarkers. Molecular analysis of NSCLC, adenocarcinoma (AC) is now the standard of care for therapy selection. **Method:** We determined the molecular alterations in EGFR, and gene fusion ALK in our Caucasian and Hispanic populations 169 small samples and resection specimens of patients with NSCLC in different institutions of Cordoba were studied during a period (2014 - 2019). In addition to Histopathology Type, we analyzed immunohistochemistry (IHC) characteristics, molecular profiles, and several clinical variables were studied. Different tests were used to detect alterations of EGFR and fusion gene EML4-ALK expression, with the aim to identify our own profile. EGFR mutation was studied by therascreen kit, PCR, in order to detect genetic alterations in exons 18, 19, 20 and 21. ALK translocations were analyzed by FISH (Vysis- Break Apart, Abbott) and IHC (clon D5F3, ventana, Roche). We correlated the molecular profile with different clinical variables (age, gender, and tobacco habits). The statistical method used was the multiple regression logistic model. **Result:** 169 samples were tested for EGFR expression and alk alterations 64% of subjects were men and 89% were smokers. Smoking habit was associated with sex (33% and 67% of smokers were women and men respectively, p=0.009). Smokers were older than non-smokers (p=0.011); to 64.4 (0.98) and 57.5 (2.35) years old for smokers and non-smokers. EGFR alterations were associated with sex (p=0.002, Fig 1). Women had more chance of having positive alterations of the gene (OR 3.57, 95CI:2.04-7.55). Age and smoking habit of patients did not show significant effects (p=0.44, Fig.2, and p=0.09, respectively). Only 1.7% of subjects reported ALK alterations, and were not related to sex (p=0.42), age (p=0.965) and smoking habit (p=0.281). **Conclusion:** Our results showed a comparable frequency in EGFR mutations and gene fusion ALK in relation to the data published in western population. These results allowed a proper diagnosis to provide the most adequate therapy.

EP1.01-54 IMPLEMENTATION OF FINE NEEDLE ASPIRATION OF SUPRACLAVICULAR LYMPH NODE AS A NOVEL MEDIUM FOR GENOMIC PROFILING IN NSCLC

Y. Cheng[1], X. Zhang[1], J. Ni[1], B. Li[2], H. Liu[2], Z. Zhu[1]

[1]*Fudan University Shanghai Cancer Center, Shanghai/China,* [2]*Burning Rock Dx, Guangzhou/China*

Background: Supraclavicular lymph node (SLN) metastasis is not rare in non-small cell lung cancer (NSCLC). Palpation or B-ultrasound guided fine needle aspiration (FNA) of SLN is a very simple, rapid, and minimally invasive tool for diagnosis of these patients. With the development next generation sequencing (NGS) which has been

widely used to catalogue genetic mutations in cancer, uncertainty remains if FNA of lymph node could be combined with NGS and applied in clinical practice. The aim of this study was to evaluate the clinical utility of FNA of SLN in patients with NSCLC **Method:** FNA of SLN samples (stored in 10% neutral buffered formalin) and matched plasma samples from 30 patients with NSCLC were collected. Twenty-three patients (both FNA and plasma samples) were sequenced using a panel covering whole exons and critical introns of 520 cancer-related genes and seven patients (both FNA and plasma samples) were profiled using a panel of 168 lung cancer-related genes. **Result:** During the procedure of next-generation sequencing library construction, the amount of extracted DNA and qualification percentage of FNA samples (n=30) from lymph nodes were similar to those of punctured lung biopsy samples (n=100, randomly selected from burning Rock database). Comparative analysis of mutation spectrums revealed that mutations were positively identified in 93.3% (28/30) FNA samples and 90.0% (27/30) plasma samples, while mutations of eight well-established lung cancer-related genes (EGFR, ERBB2, MET, BRAF, KRAS, ROS1, ALK and RET) were detected in 83.3% (25/30) FNA samples, which was higher than that in plasma samples (63.3%, 19/30). Moreover, FNA was significantly superior to plasma in detecting copy number variation (CNV) (detection frequencies, 88.9% vs 0.9%, $p<0.001$), both for CNVs of all genes in NGS panel (99.5% vs 10.0%) and eight well-established genes (96.0% vs 20.0%). **Conclusion:** Samples from FNA of SLNs were found to be equivalent to plasma during NGS library construction. Moreover, FNA of SLNs was superior to plasma in detecting mutations of eight lung cancer-related genes, as well as CNVs in both all genes of NGS panel and the 8 key genes. This study provides knowledge for the potential use of FNA of lymph nodes in sequencing genomic profiles of patients with lung cancer, and further support its utility in clinical practice.

Keywords: fine needle aspiration, supraclavicular lymph node, Next generation sequencing

EP1.01-55 NEOANTIGEN DELETION LEADS TO HYPERPROGRESSIVE DISEASE (HPD) IN NON-SMALL CELL LUNG CANCER (NSCLC) TREATED WITH PD-1/PD-L1 INHIBITORS

D. Wu[1], X. Hong[1], Y. Liu[2], K. Zhang[1], Y. Hu[1], F. Gu[1], Y. Liu[1], Z. Zhao[2], J. Liu[1], L. Liu[1]

[1]*Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China,* [2]*YuceBio, Shenzhen/China*

Background: Hyperprogressive disease (HPD) is a distinct pattern of progression described in patients with cancer treated with PD-1/PD-L1 inhibitors. The incidence of HPD is reported to be 13.8% in advanced NSCLC. Recently multiple characteristics have been recognized to predict the risk of HPD, however the mechanism underlying have not been systemically studied. **Method:** We report a Chinese patient who developed hyperprogressive disease after 4 cycles of PD-1 blockade treatment. Clinical and demographic data was collected from electronic records. Whole exome sequencing (WES) of the primary tumor was performed to identify tumor mutation burden (TMB) and tumor neoantigen burden (TNB) following the restricted pipeline. Liquid biopsy targeting ctDNA and T cell receptor (TCR) was constructed to monitor the efficacy of immunotherapy. **Result:** A 70-year-old male with smoking history underwent chest CT scan in February 2018 and was found to have a right upper lobe mass with intrapulmonary metastasis in different lobes and multiple lymph nodes. Resection of right lower lung by video-assisted thoracic surgery (VATS) revealed poorly differentiated, squamous cell carcinoma. In July 2018, he progressed after two cycle of chemotherapy and radiation therapy targeting newly bone metastasis of lumbar spine, then he was screened to start Nivolumab at dose of 240mg daily/2 weeks. After four cycle of Nivolumab, he obtained PD and was assigned to palliative thoracic radiation therapy. The PD-L1 expression level of our patient was $1\% \leq TC < 5\%$, next generation sequencing (NGS) didn't show alteration in genes related to HPD, such as MDM2/MDM4 or EGFR. Blood sample retrieved before and after immunotherapy revealed the increase in bTMB (from 7.70 Muts/Mb to 18.00 Muts/Mb), however TNB truly expressed as neoantigens were rather lower compared to TMB, indicating the low immunogenicity of tumor. We also found a sharp fluctuate in the detection of driver genes mutations in ctDNA (TP53,CDKN2A,ERBB3,FBXW7), and the majority of high-frequency TCR dropped significantly during immunotharapy. **Conclusion:** It is reported that NSCLC with a high tumor mutation burden (TMB) may benefit from PD-1/PD-L1 inhibitors treatment, and TMB is considered as the surrogate of tumor neoantigen burden (TNB). However the deletion of neoantigen may occur at different level, including copy number variation at the DNA level, down-regulation of transcription level and inherited variation at the epigenetic level, resulting in the low immunogenicity of primary tumor. Deletion of neoantigen may provide a mechanism of immune evasion which leads to the resistance to PD-1/PD-L1 inhibitors. In this case, treatment of checkpoint inhibitors may activate certain signaling pathway of driver genes to support the hyperprogression disease (HPD). This case report focusing on neoantigen provides a new approach to predict the presence of hyperprogressive disease (HPD) before immunotherapy, and explains the potential mechanism of HPD.

Keywords: hyperprogressive disease, neoantigen, NSCLC

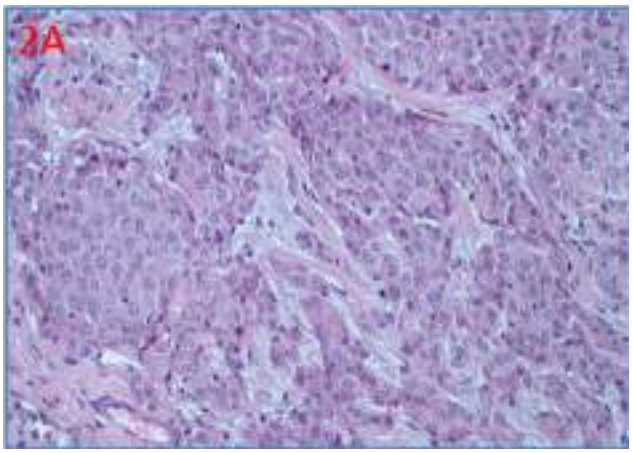
EP1.01-56 CO-PRESENTATION OF ADENOCARCINOMA AND SQUAMOUS CELL LUNG CARCINOMA HARBOURING ALK REARRANGEMENT IN DIFFERENT SITES

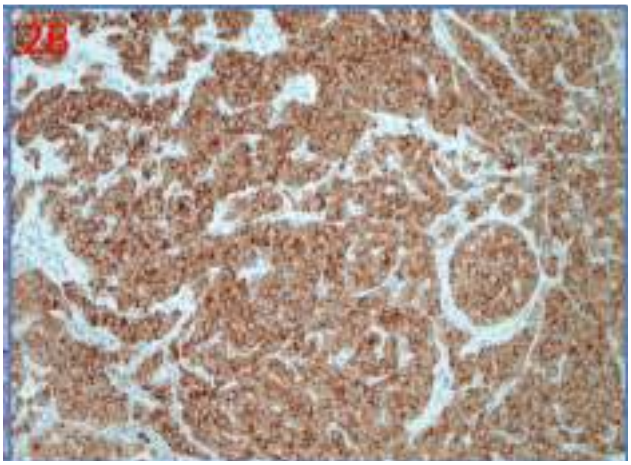
V. Longo[1], A. Catino[2], D. Galetta[2], G. Del Bene[1], R. Lacalamita[3], M. Montrone[2], F. Pesola[1], D. Petriella[3], P. Pizzutilo[2], S. Tommasi[3]

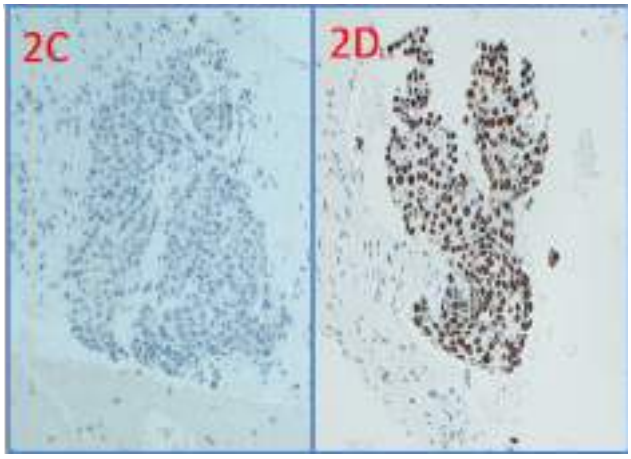
[1]*Thoracic Oncology ,Clinical Cancer Centre "Giovanni Paolo II", BARI/Italy,* [2]*Thoracic Oncology, Clinical Cancer Centre "Giovanni Paolo II", BARI/Italy,* [3]*Pharmacogenetic and Molecular Diagnostic Unit, Clinical Cancer Centre "Giovanni Paolo II", Bari/Italy*

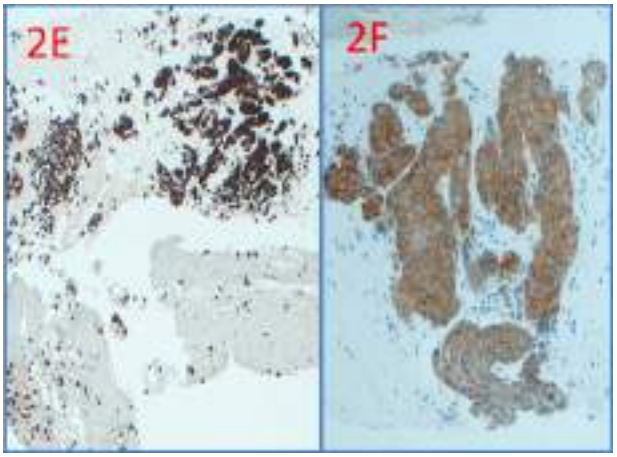
Background: Approximately 4% to 9% of Non Small Cell Lung Carcinoma (NSCLC) contain mixed adenomatous on squamous pathologies (adenosquamous cell carcinoma). The lung ADC to SCC transdifferentiation as a drug-resistance mechanism has been recently described. While the histological transformation mainly described in ALK-positive patients is from NSCLC entity to SCLC, only one case of histologic transformation of ALK rearranged ADC to SCC after treatment with an ALK inhibitor has been reported. Importantly, transformed samples retain the initial genomic alteration, supporting the lineage transition as a novel resistance mechanism.We describe an unique case of co-presentation of ADC and SCC in two different disease sites, both harbouring ALK rearrangement. **Method:** A 57-year-old male never smoker presented with a left adrenal mass. CT Scan showed a right superior lobe mass, bilateral pulmonary nodules (Fig. 1 A), and bone metastases. The lung biopsy documented ADC with moderate differentiation and ALK rearrangement by fluorescence in situ hybridization (FISH) and immunohistochemistry (IHC).

EPOSTERS









Result: The patient was treated with Crizotinib but, after 4 months, the CT showed a near complete response of the pulmonary disease (Fig. 1 B), while a progression of the left adrenal metastasis was observed. (Fig. 2 A, Fig. 2B). A left adrenal biopsy showed a SCC histology, with ALK rearrangement confirmed both by IHC and FISH. The treatment was switched to alectinib without respoinse so the patient received chemotherapy. **Conclusion:** The absence of an initial biopsy of the adrenal mass doesn't allow to distinguish between a lung ADC to SCC transdifferentiation with a consequence of the treatment-induced selection pressure, so a preexisting SCC at the time of diagnosis would exhibit tumor dominance after elimination of the ADC. However, the presence of the ALK rearrangement in the adrenal biopsy suggest a possible ADC to SCC transdifferentiation in the early phase of metastases development as a new potential mechanism of drug resistance

Keywords: Adenosquamous NSCLC, ALK translocation

EP1.01-57 CLINICAL PROFILE AND TREATMENT OUTCOMES OF NSCLC IN ELDERLY SUBJECTS WITH POOR PERFORMANCE STATUS FROM INDIA

D. Behera, V. Muthu, N. Singh, K. Prasad

Postgraduate Institute of Medical Education and Research, Chandigarh/India

Background: Elderly population and subjects with poor performance status (PS) are generally excluded from Lung cancer (LC) trials evaluating various treatment modalities, and their outcome is unclear. Herein, we report the clinical profile, treatment and overall survival (OS) of elderly non-small cell LC (NSCLC) subjects with poor PS. **Method: Method:** We retrospectively reviewed our database (from Jan 2016-Dec 2017) to identify NSCLC subjects aged ≥65 years and having an Eastern cooperative oncology group PS (ECOG-PS) ≥2 at presentation. Demographic profile, treatment details, PS after treatment and OS (as on 15th November 2018) were retrieved. We also report the incidence of grade 3 or 4 adverse events (AE) following chemotherapy. **Result:** 122 patients with a median (interquartile range [IQR]) age of 72.5 (65-88) years were included. Majority were men (86.1%) and smokers (79.5%). ECOG-PS was 2, 3 and 4 in 64.8%, 27.9% and 7.4% patients. Squamous cell carcinoma (53, 43.4%) and adenocarcinoma (51, 41.8%) were the most common histologic subtypes. 69% had TNM (8th edition) stage IV (A in 41%, B in 28%) and 26% had stage III (IIIA 8%, IIIB 10% and IIIC in 8%). Chemotherapy with or without radiotherapy (86%), tyrosine kinase inhibitors (6%) and immunotherapy (1%) were the common treatment modalities, while 10 patients did not receive any treatment. In whom response could be assessed (n=61), the best response achieved was partial response in 38%, stable disease in 49%, complete response in 5% and progressive disease in 8%. Of the subjects undergoing chemotherapy (n=102), 33 experienced grade 3 or 4 AE and 14 subjects had to discontinue chemotherapy before 4 cycles. ECOG PS improved to 0/1 in 22 (19.6%) subjects who underwent any form of treatment. The median survival of the study cohort was 250 days. On a multivariate analysis, the presence of brain metastases was associated with poor OS (HR [95% CI] 7.6 [1.4-41.6]) **Conclusion:** Conclusions: Most of the Elderly patients with NSCLC and poor PS had an advanced stage at presentation. Majority tolerate chemotherapy well and some have an improvement in their PS. The presence of brain metastases is associated with a poor survival.

Keywords: NSCLC, Elderly, Chemotherapy

EP1.01-58 IMPACT OF TUMOUR SIZE ON THE MANAGEMENT AND OUTCOME OF STAGE III NON-SMALL CELL LUNG CANCER (NSCLC)

K. Herbegue, N. Mejri, H. El Benna, H. Rachdi, N. Daoud, S. Labidi, H. Boussen

Abderrahmen Mami Hospital, Ariana/Tunisia

Background: We aimed to evaluate the difference in clinical/radiological presentation and patient management according to tumour size in stage III NSCLC. We also reported its impact on patient's outcome. **Method:** We retrospectively studied 88 patients with stage III NSCLC treated between 2010 and mid-2017 in our oncology department. Various cut-off values for tumour diameter were evaluated. We selected a cut-off value of 4 cm, and considered two groups: tumour size≤4 cm and >4 cm. Epidemiological, anatomo-clinical parameters were collected and compared. Kaplan-Meier method was used to evaluate survival. **Result:** Differences in characteristics of the two groups were described in table 1. Initial

therapeutic strategy was significantly correlated with tumour size; in tumour≤4 cm therapy was concurrent chemoradiation in 0%, neoadjuvant chemotherapy in 53%, upfront surgery 47% vs 25%, 61%, and 14% respectively for tumour size>4 cm group (p=0.003). Among patients receiving neoadjuvant chemotherapy, response was not correlated to tumour size; in≤4 cm group we observed (Partial response (PR) 89%, stable disease (SD)11%, Progressive disease(PD) 0%), in >4cm group response was (PR 39%, SD 36%, PD 25%)(p=0.6). Surgery (upfront or after neoadjuvant chemotherapy) was significantly higher in tumour ≤4cm (65% vs 20%) (p=0.0001). Definitive chemoradiation was more indicated in larger tumours, without statistical significance (75% vs 46%)(p=0.4). Therapeutic discordance between the planned and the administered treatment was significantly higher in larger tumours (68% vs 18%) (p=0.0001). Progression free survival was longer in smaller tumours (18±9.3 vs 11±12.1 months) without being statistically significant. However, median overall survival was significantly correlated with tumour size (41.7± 5.1 in ≤4 cm, 32.8±4.6 months in > 4 cm) (p=0.04). The pattern of recurrence was not correlated to tumour size; it was locoregional in 30%, distant in 20% and both locoregional/distant in 50% in≤4 cm group vs 42%, 24%, and 34% respectively in tumour size> 4 cm (p=0.6). Table 1: Characteristics of patients in the two preselected groups.

Patient characteristics	Tumour size ≤4 cm (n=17)	Tumour size> 4 cm (n=71)	P
Age at diagnosis Median ± SD (years) Elderly (≥70 years),% Young (<70 years),%	. 59±9.1 6% 94%	. 62.27±10.8 28% 72%	0.25 0.05
Gender, % Male Female	. 59% 41%	. 87% 13%	0.006
Performance Status, % 0 1 2	. 6% 94% 0%	. 1% 83% 16%	0.02
Weight loss, %	18%	42%	0.06
Histological type, % Adenocarcinoma Squamous cell carcinoma large cell carcinoma	. 88% 12% 0%	. 47% 52% 1%	0.008
Histological grade, % Well differentiated Moderately differentiated Poorly differentiated	. 18% 76% 6%	. 24% 48% 28%	0.075
T Status, % T1 T2 T3 T4	. 24% 29% 29% 18%	. 0% 7% 18% 75%	0.0001
N Status,% N0 N1 N2 N3	. 6% 6% 71% 17%	. 10% 15% 58% 17%	0.67
Stage,% IIIA IIIB	. 77% 23%	. 44% 56%	0.015

Conclusion: When taking 4 cm as a cut-off value, tumour size influenced clinical presentation and management modalities. It may be considered as a prognostic factor in stage III NSCLC.

Keywords: Tumour size, prognosis, locally advanced NSCLC

EP1.01-59 THE EFFECTIVENESS OF OSIMERTINIB IN A NSCLC PATIENT WITH COMPLEX UNCOMMON EGFR MUTATIONS OF G719X AND S768I: A CASE REPORT

K. Ma, X. Wang, Y. Cai, Y. Xu, Y. Guo, C. Sun

The First Hospital of Jilin University, Chang Chun/China

Background: With the deeper and wider application of gene detection technology in lung cancer, an increasing number of genetic alterations have been identified, especially in the epidermal growth factor receptor (EGFR) gene, including uncommon and complex types of EGFR gene mutations; however, the efficacy of the targeted therapy in these gene mutation types is not clear. **Method:** We report the genetic test results from the analysis of postoperative specimens from a lung adenocarcinoma patient that suggest complex EGFR mutations of G719X and S768I. **Result:** After tumor recurrence, the patient was treated with osimertinib and achieved an excellent and long-lasting clinical response. The patient has taken osimertinib for 18.2 months with an efficacy evaluation partial response (PR), and her follow-up is still ongoing.

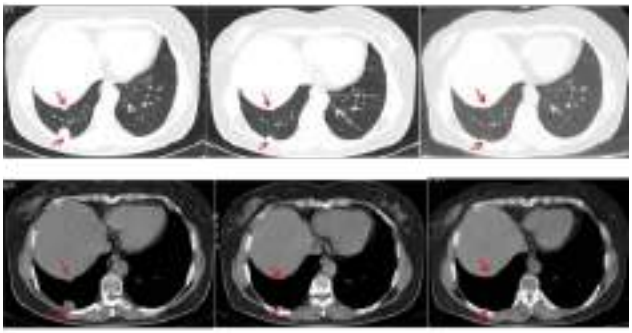


Figure 1. Patient's relevant imaging pictures during treating with osimertinib

Conclusion: Complex uncommon EGFR mutations of G719X and S768I have a good response to osimertinib.

Keywords: uncommon EGFR mutation, Non-Small Cell Lung Cancer, Osimertinib

EP1.01-60 LENT PROGNOSTIC SCORE FOR LUNG CANCER IN THE PRESENCE OF MALIGNANT PLEURAL EFFUSION

G. Cincileviciute[1], R. Zablockis[1,2], E. Danila[1,2]

[1]*Center of Pulmonology and Allergology of Vilnius University Hospital Santaros Klinikos, Vilnius/Lithuania,* [2]*Clinic of Infectious and Chest Diseases, Dermatovenereology and Allergology of Vilnius University, Vilnius/Lithuania*

Background: LENT scoring system is the first validated prognostic score in non-selected malignant pleural effusion (MPE), although its significance in MPE secondary to lung cancer remains unclear. **Method:** 85 consecutive patients (59% male, mean age 67±12yrs) with MPE secondary to lung cancer were enrolled. First episode of MPE presented a new cancer diagnosis in 71% of cases, 29% of MPE were diagnosed on disease progression. Histology types were: adenocarcinoma – 71 (83.5%), small cell carcinoma – 10 (11.8%), NOS – 4 (4.7%). LENT score was calculated on the day of MPE diagnosis confirmed. **Result:** 53 (62%) patients presented moderate risk category by LENT score, and 32 (38%) – high risk category. Mean LENT score was 4 (2–6), median (IQR) survival – 70 (32–281) days. The patients with a moderate risk LENT score had a median (IQR) survival of 147 (70–423) days, those with high risk LENT score – 34 (31–41) days. The ROC analysis showed no significant difference between LENT score and ECOG PS at 1, 3 and 6 months at predicting survival time (p>0.05). MPE group that presented primary cancer diagnosis had a median (IQR) survival of 75 (31-318) days and MPE group that presented disease progression had a median (IQR) survival of 63 (37–185) days, there were no significant difference between these groups. **Conclusion:** Our study meets literature data for LENT score predicting survival prognosis in malignant pleural effusion. However, our study showed no superiority of LENT score over ECOG PS.

EP1.01-61 ISEND MODEL AS A PREDICTOR OF EFFICACY IN IMMUNE CHECKPOINT INHIBITORS FOR NON-SMALL CELL LUNG CANCER: FUKUSHIMA COHORT

N. Okabe[1], H. Mine[1], H. Takagi[1], M. Watanabe[1], S. Muto[1], T. Hasegawa[1], Y. Shio[1], W. Park[2], G. Lopes[2], H. Suzuki[1]

[1]*Fukushima Medical University, fukusima/Japan,* [2]*University of Miami, Miami/ United States of America*

Background: The expression of PD-L1 in tumor tissue and the number of gene mutations (TMB) in tumor tissue have been investigated as predictors of the efficacy of PD-1/PD-L1 inhibitors in non-small cell lung cancer. However. In actual clinical practice, it is difficult to perform these tests in all cases. Therefore, we are searching for an effect prediction marker that can be done easily and inexpensively. Wungki Park et al. constructed the iSEND model as a therapeutic effect predictor and showed its usefulness. We examined the usefulness of iSEND model for non-small cell lung cancer patients who received PD-1 / PD-L1 inhibitor at our institution. **Method:** We retrospectively examined the usefulness of the iSEND model in 56 patients with non-small cell lung cancer who were treated with PD-1/PD-L1 inhibitor in our department after the second treatment. The iSEND model uses patient background and blood tests. Calculated and scored using gender, ECOG performance status, NLR before treatment and after treatment (Neutrophi-to-Lymphocyte Ratios), and divided into three group. For each group, we statistically compared the clinical course such as overall survival and recurrence-free survival. **Result:** In the analysis by Wungki Park et al., The iSEND Poor group has a median overall survival of 4.0 months and 15.9 months, respectively, compared with the iSEND Good group (p = 0.0002), and the median recurrence free period is 1.6 months and 2.6 months, respectively. Months (p = 0.0045), and each showed a significant difference. In our study, no statistically significant difference was found, but a trend similar to the analysis of Wungki Park et al. **Conclusion:** In this study, it is suggested that the iSEND model may be useful as a predictor of the effect of PD-1/ PD-L1 inhibitor.

EP1.01-62 THE SAFETY PROFILE AND PRELIMINARY EFFICACY OF CERITINIB 450MG WITH FOOD IN CHINESE ALK/ROS-1 POSITIVE NSCLC PATIENTS

Y. Tian[1], P. Yu[1], X. Yin[1], K. Wang[2], M. Huang[2], Y. Wang[2], Y. Gong[2], J. Li[1]

[1]*Sichuan Cancer Hospital and Institute, Sichuan Cancer Center, School of Medicine, University of Electronic Science and Technology of China, Chengdu/ China,* [2]*West China Hospital, Sichuan University, Chengdu/China*

Background: Ceritinib have shown potent efficacy in both ALK and ROS-1 rearranged NSCLC. However, high rate of treatment interruption was suffered due to gastrointestinal or liver toxicity using Ceritinib 750mg fasting in previous study. Recently, ASCEND-8 study reported an improved tolerance and a trend to better efficacy with 450mg with food, but little data is available in Chinese patients. This first-time real-world study aims to assess the safety profile and preliminary efficacy of Ceritinib 450mg with food in Chinese patients. **Method:** From Oct 2018 to March 2019, 51 ALK or ROS1 positive NSCLC patients received ceritinib were enrolled from 8 centers in Sichuan province. Safety profile and preliminary efficacy were retrospectively analyzed. The follow-up was to 31st March 2019. **Result:** The baseline characteristics of enrolled patients are listed in Table 1. The median time from diagnosis to Ceritinib treatment is 15.93 months(Range:1.37- 89.97), the median treatment duration is 2.63 months (Range:0.2-5.73)by the time of data cut off. 50 out of 51 patients were assessable for toxicity. The adverse event (AE) rate is 76%, majority of which are grade 1/2. Only 2 patients reduced to 300mg due to AE and no patient dead or terminated treatment due to Ceritinib related AEs. Details are in the Table 2. By the data cut-off, 15 patients have stopped treatment due to disease progression(33.3%),death (53.3%) or other reasons(13.3%. Among the 39 patients underwent radiological assessment,the ORR was 41.0% and DCR was 87.2%.

EP1.01-63 THE USEFULNESS OF "SERUM" SAMPLES TO DETECT EGFR T790M MUTATION IN EGFR-TKI-RESISTANT NON-SMALL CELL LUNG CANCER

K. Kobayashi[1], K. Naoki[2], S. Ikemura[1], H. Yasuda[1], I. Kawada[1], K. Soejima[1]

[1]*Keio University School of Medicine, Tokyo/Japan,* [2]*Kitasato University, School of Medicine, Sagamihara (Kanagawa)/Japan*

Background: Osimertinib, a third-generation epidermal growth factor receptor-tyrosine kinase inhibitor, exerts remarkable effects against *EGFR* T790M resistance mutation-positive NSCLC. Identifying T790M mutation by re-biopsy is essential before prescribing osimertinib. Tissue biopsy is the golden standard for this purpose, but several factors limit its success rate. The liquid biopsy with blood, using circulating tumor DNA, has been an alternative method. However, the true biological meaning and equivalence of liquid biopsy and tumor biopsy are still under investigation. Especially, the usefulness of serum samples to detect T790M mutation is not yet been known. **Method:** We prospectively evaluated the sensitivity, specificity, and parallelism of the detection of *EGFR* mutations in tissue re-biopsy and liquid biopsy (plasma and serum), simultaneously, from June 2016 to May 2017. *EGFR*-mutations in tumor re-biopsy were evaluated by COBAS ver2 and peptide nucleic acid/locked nucleic acid PCR clamp method, and those in liquid biopsy were evaluated with COBAS ver2. **Result:** Fifteen patients were enrolled. In ten patients whose *EGFR* mutation was detected in liquid biopsy, the original *EGFR* mutation (exon 19 del or L858R) was detected in all patients. The detection rate of T790M was lower than that of the original *EGFR* mutation in liquid biopsy compared to that in tissue re-biopsy. The detection of T790M in serum exhibited a higher specificity (67%) and positive predictive value (50%) than that in plasma (50% and 40%, respectively). The detection sensitivity was similar in plasma and serum. Nine patients were treated with osimertinib. The RR was 77.8% and DCR was 100%. One patient who presented a response was positive for T790M in liquid biopsy (both plasma and serum) and negative in tissue re-biopsy. **Conclusion:** We suggest serum samples to be more useful than plasma samples for determining the effectiveness of osimertinib against relapse tumor sites because they were more reliable in the detection of T790M mutation at the relapse tumor tissue sites. Repeated tests with different samples and different methods may improve accuracy of T790M detection and will lead to the maximum benefit for the patient.

Keywords: T790M mutation, liquid biopsy, Osimertinib

EP1.01-64 EFFECT OF AMRUBICIN IN PATIENTS WITH PREVIOUSLY TREATED NON-SMALL-CELL LUNG CANCER

S. Takayama[1], T. Tamura[2], T. Kawajiri[2], T. Nishi[2], K. Kudo[2], S. Kuyama[2], K. Kawakado[2]

[1]*National Hospital Organization Iwakuni Clinical Center, Iwakuni/Japan,* [2]*National Hospital Organization Iwakuni Clinical Center, Iwakuni/Japan*

Background: Although the prognosis of non-small cell lung cancer (NSCLC) has been rapidly improved due to the appearance of various tyrosine kinase inhibitors and immune checkpoint inhibitors, cytotoxic chemotherapy are still important treatment for patients who can't receive these drugs or are ineffective for these drugs. Amrubicin (AMR) couldn't significantly improve the progression free survival compared with docetaxel in a randomized phase III trial of Japanese previously treated NSCLC patients, but median progression free survival (PFS) and overall survival (OS)were comparable in the amrubicin and docetaxel groups. The purpose of this study is to clarify the use of amrubicin in clinical practice. **Method:** From January 2014 to March 2019, 479 progressive or recurrent NSCLC patients received chemotherapy or radiotherapy. Only 27 patients received AMR. We retrospectively evaluated these 27 patients. **Result:** None of the NSCLC patients who received AMR had epidermal growth factor recepter gene mutations nor anaplastic lymphoma kinase gene translocations. Median number of prior chemotherapy regimens was four, and median PFS was 62 days and OS was 229 days. Overall response rate was 7.4% and disease control rate was 37.0%. **Conclusion:** AMR was often used for patients considered to have a poor prognosis, and its effect was limited.

Keywords: Amurubicin, NSCLC, cytotoxic chemotherapy

EP1.01-65 THE RELATIONSHIP BETWEEN PRELIMINARY EFFICACY AND PROGNOSIS AFTER FIRST-LINE EGFR-TKI TREATMENT OF ADVANCED NSCLC

D. Chen, T. Chu, Q. Chang, Y. Zhang, L. Xiong, R. Qiao, J. Teng, B. Han, R. Zhong

Shanghai Chest Hospital, Shanghai/China

Background: Nowadays, patients with *EGFR*-TKI-sensitive advanced non-small cell lung cancer (NSCLC) receive *EGFR* tyrosine kinase inhibitors (*EGFR*-TKIs) as first-line treatment. We aimed to analyze the relationship between preliminary efficacy (tumor shrinkage within 1 month) and progression-free survival (PFS) after first-line *EGFR*-TKI treatment. **Method:** A total of 82 patients with *EGFR*-TKI-sensitive advanced NSCLC confirmed by histopathology from January 2013 to January 2017 were retrospectively analyzed. All patients received first-line *EGFR*-TKI treatment and follow-up at Shanghai Chest Hospital. **Result:** Of 82 patients, 42 (51.2%) patients achieved partial response (PR) within 1 month, and 40 (48.8%) patients achieved stable disease (SD: -30%~0) within 1 month. The median PFS among all patients was 10 months. The median PFS in patients achieving PR within 1 month was 10 months. The median PFS in patients achieving SD (-30%~0) within 1 month was 9.3 months. There was no statistically significant difference between PR within 1 month and SD (-30%~0) within 1 month (P=0.620). In the *EGFR*-sensitive mutation subgroup, there was also no statistically significant difference between PR within 1 month and SD (-30%~0) within 1 month. Univariate and multivariate analysis of first-line *EGFR*-TKI treatment showed that age, *EGFR* mutation type, and T staging had effects on PFS. Patients who were more than 65 years old, had *EGFR* 19del mutation, along with a T staging less than 4, had a longer PFS; these differences were statistically significant. Liver metastasis, bone metastasis, and brain metastasis were not shown to be related to PFS. **Conclusion:** For patients with *EGFR*-TKI-sensitive advanced NSCLC, there is no correlation between preliminary efficacy (tumor shrinkage within 1 month) and PFS after first-line *EGFR*-TKI treatment.

EP1.01-66 DETECTION OF GENOMIC MUTATIONS IN BLOOD AND URINE CTDNA IN LUNG ADENOCARCINOMA WITH EGFR MUTATION ON TISSUE – AN INTERIM PROGRESS REPORT

H. Brooks[1], A. Addeo[1], C. Comins[1], M. Stevens[2], L. Li[2], L. Wade[1], S. Oltean[2]

[1]*Bristol Cancer Institute, Bristol/United Kingdom,* [2]*University of Exeter, Exeter/United Kingdom*

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are effective therapy for stage IIIB/IV EGFR-mutation positive (EGFRm+) NSCLC. Despite initial response, clinical progression occurs, often with development of a second TK mutation. Mutation analysis is performed at time of diagnosis usually on single tissue biopsy. Samples can be difficult to obtain and may not represent neoplastic tissue at other sites due to heterogeneity. On progression, patients rarely undergo repeat tissue biopsy. Therapy is no longer truly personalised. CtDNA may be an alternative to tissue biopsy for mutation analysis. It may be more representative, and provide real time assessment of disease status, maintaining individualised therapy. Published retrospective data are available on detection of EGFR mutations in plasma ctDNA, and evidence that urine can be used is emerging. Clinical use has been limited by lack of evidence for detection methods and concordance with tissue. Retrospective data suggest that on response to TKI, TK mutation load reduces, and on progression, mutation load increases and/or a new mutation emerges. This has not been validated prospectively. **Method:** A prospective pilot study: 20 patients, 2 UK sites; with

stage IIIB/IV EGFRm+ NSCLC on tissue sample, TKI-treatment naïve. Plasma and urine collected prior to TKI treatment and monthly on treatment. CtDNA is extracted from plasma and urine using Quigen kit, and analysed using digital droplet PCR for the 3 most common EGFR mutations – del19, L858R and T790M. Objective: To investigate if urine/plasma ctDNA may be used to prospectively detect and monitor EGFR mutational status at baseline and during TKI therapy Primary Endpoint: To assess if ctDNA from urine/plasma could be a reliable source of EGFR testing Secondary Endpoint: To assess if changes in levels of baseline mutation or development of new mutations in ctDNA correlates with disease response/progression during TKI therapy Outcome: To inform development of a larger study to further investigate and validate the role of liquid biopsy in treatment of EGFRm+ NSCLC **Result:** CtDNA analysis performed on samples from 14patients to date. On baseline tissue, 8 (57%) had del19 mutation, 5 (36%) had L858R mutation, and 1 (7%) had L861Q mutation. Representative of population distribution of EGFR mutations. In those with tissue del19 mutation, del19 mutation was identified on baseline ctDNA in 8/8 (100%) plasma samples and 6/7 (86%) urine samples (one patient did not provide baseline urine sample). None had L858R mutation in plasma/urine. In one plasma ctDNA sample, very low levels of T790M mutation were identified, but no T790M mutations were found in urine ctDNA. In those with tissue L858R mutation, L858R mutation was identified on baseline ctDNA in 3/5 (60%) plasma samples and 4/5 (80%) urine samples. All were found to have del19 mutation on baseline plasma ctDNA, 3/5 had del19 mutation in urine ctDNA. None had T790M mutations in plasma/urine ctDNA. **Conclusion:** Sensitivity is high for identifying baseline EGFR mutations in plasma/urine ctDNA. Very hard to comment on specificity. It's known that del19 and L858R mutations can co-exist. It's possible that mutation analysis performed on DNA extracted away from primary tumour site may carry additional mutations due to heterogeneity.

EP1.01-67 MOLECULAR PROFILING OF K-RAS AND ITS SUBTYPES IN NSCLC PATIENTS WITH LIVER METASTASIS

D. Chandra[1], I. Eldessouki[2], H. Mamdani[3], M. Nagasaka[3], N. Abdel Karim[1]

[1]*Medical College of Georgia/Augusta University, Augusta/United States of America,* [2]*University of Cincinnati, Cincinnait/United States of America,* [3]*Karmanos Cancer Institute, Detroit/United States of America*

Background: Non-small cell lung cancer (NSCLC) tend to have a poor prognosis in the presence of liver metastasis. Molecular profiling of NSCLC has played a major role in identifying a number of oncogenic targets that have led to novel targeted therapies. KRAS is a frequently mutated gene in NSCLC, occurring in approximately 30% of lung adenocarcinomas and most commonly manifesting as the transversion mutations G12C, G12V, G12A. there are presently no targeted therapies approved for *KRAS*-mutant NSCLC. Immunotherapy has emerged as a standard of care for first-line treatment of advanced NSCLC, specifically through targeting the programmed cell death protein-1 (PD-1/PD-L1). Given the aggressive nature of *KRAS*-mutant NSCLC with liver metastases and the lack of approved therapies targeting the KRAS pathway, checkpoint blockade immunotherapy may represent an impactful primary therapeutic option for these patients. **Method:** The CARIS database from 2016 - 2018 was queried and patients with NSCLC were identified. PD-L1 antibody 22c3 ≥1% was considered positive. PD-L1 expression as well as k-ras and TP53 mutation status were analyzed and correlation between different variables were identified using ANOVA **Result:** We identified 361 patients with NSCLC having Liver metastasis. Median age was 67. Gender distribution was equal (51.4% males, 49.7% females). Of the 361 patients, we identified 74 patients with mutated K-ras. Thirty nine out of the 74 patients had PD-L1 expression (52.7%). Twenty one patients had the G12C subtype (28%) with 14 patients (66%) having positive PD-L1 expression. Of the 287 patients with wild type K-ras, 115 patients had PD-L1 positive expression (40%) with no statistical significance (P=0.134) in comparison to the k-ras mutant population.We also studied 2237 K-ras mutant patients without liver metastases where 882 patients had the G12C subtype (39.4%). On the other hand, only 21 patients were positive for G12C k-ras subtype out of the 74 k-ras mutant patients with liver metastases.Among patients with liver metastases, adenocarcinoma was the most common histological subtype (223 patients), Carcinoma NOS was the second common histological subtype (61 patients).Patients with no liver metastasis had median age of 68. Gender distribution was equivocal. **Conclusion:** Patients with k-ras mutant G12C subtype were associated with more frequent PD-L1 expression and less occurrence of liver metastases.

EP1.01-68 IMPACT OF EGFR GENOTYPE ON THE EFFICACY OF OSIMERTINIB IN PATIENTS WITH NON-SMALL CELL LUNG CANCER: A PROSPECTIVE OBSERVATIONAL STUDY

S. Igawa[1], T. Ono[1], T. Ozawa[1], H. Sone[1], S. Kusuhara[1], S. Harada[1], M. Ishihara[1], M. Kasajima[1], Y. Hiyoshi[1], T. Fukui[1], M. Kubota[1], J. Sasaki[2], H. Mitsufuji[3], K. Naoki[1]

[1]*Kitasato University, School of Medicine, Sagamihara (Kanagawa)/Japan,* [2]*Kitasato University School of Medicine, Sagamihara/Japan,* [3]*Kitasato University School of Nursing, Sagamihara/Japan*

Background: A T790M of the epidermal growth factor receptor (EGFR) is the most frequently encountered mutation occurring acquired resistance to EGFR tyrosine kinase inhibitors (TKIs) in non-small cell lung cancer (NSCLC). The aim of this study was to assess the differential clinical outcomes of osimertinib therapy in NSCLC patients with T790M according to the type of active *EGFR* mutation, i.e. exon 19 deletion or L858R point mutation. **Method:** We conducted a prospective observational cohort study to evaluate the efficacy and safety of osimertinib in patients with major EGFR mutation and T790M-positive advanced NSCLC who had disease progression after first-line EGFR-TKI therapy. The efficacy of osimertinib was evaluated according to the type of *EGFR* mutation. **Result:** A total of 51 patients were included in this study. The exon 19 deletion was found in 33 (65%) patients, and the L858R point mutation in 18 patients (35%). An objective response was obtained in 29 patients, indicating an objective response rate of 58.8%. The response rate was 69.7% in patients with exon 19 deletion and 38.9% in patients with L858R point mutation, indicating a statistically significant difference (*P* =0.033). The median progression-free survival (PFS) and overall survival (OS) of the entire patient population were 7.8 and 15.5 months, respectively. Median PFS in the exon 19 deletion and L858R point mutation groups was 8.0 months and 5.2 months, respectively, indicating a statistically significant difference (*P* =0.045). Median OS in the exon 19 deletion and L858R point mutation groups was 19.8 months and 12.9 months, respectively, indicating a statistically significant difference (*P* =0.0015). Multivariate analysis identified exon 19 deletion as a favorable independent predictor of PFS and OS. **Conclusion:** Investigators should consider the proportions of sensitive *EGFR* mutation types as a stratification factor in designing or reviewing clinical studies involving osimertinib.

EP1.01-69 SAFETY AND EFFICACY OF PERCUTANEOUS COMPUTED TOMOGRAPHY-GUIDED THERMAL ABLATION OF NON-SMALL CELL LUNG CANCER METASTASES

K. Tavernaraki[1], I. Gkiozos[2], D. Grapsa[1], A. Charpidou[2], P. Nikolopoulos[3], E. Kokkotou[2], I. Kotteas[1], L. Thanos[3], K. Syrigos[1]

[1]*National and Kapodistrian University of Athens, Athens/Greece,* [2]*Oncology Center of Biomedical Research and Education, Athens/Greece,* [3]*Sotiria Athens General Hospital, Athens/Greece*

Background: Percutaneous computed tomography-guided (CT-guided) thermal ablation is a minimally invasive method for the treatment of adrenal metastases, painful bone metastases and liver metastases originating from non-small cell lung cancer (NSCLC). We aimed to further evaluate the safety and efficacy of CT-guided radiofrequency ablation (RFA) and microwave ablation (MWA) in the management of metastases in a real-life cohort of NSCLC patients. **Method:** The medical records of 142 patients with metastatic NSCLC (71, 32 and 40 patients with adrenal metastases, painful bone metastases and liver metastases, respectively) treated with CT-guided RFA or MWA were retrospectively studied. The efficacy of thermal ablation was evaluated by post-ablation imaging. For painful bone metastases, palliation was assessed by the Brief Pain Inventory (BPI) score. **Result:** Technical success of CT-guided thermal ablation was 100%. No major complications occurred. Among patients with adrenal metastases treated with RFA or MWA, local recurrence was observed in 17.1% and 19.4% of cases at 1-year follow up, respectively. In patients with painful bone metastases, significant pain relief was noted after thermal ablation (p<0,001). Local recurrence was

observed in 3.3% of cases with liver metastases at 1-year follow-up. **Conclusion:** CT-guided RF and MW ablation is a safe and effective local treatment for the management of adrenal, bone and liver metastases from NSCLC. For painful bone metastases RF ablation provides significant pain relief.

EP1.01-70 REIRRADIATION FOR LOCOREGIONALLY RECURRENT LUNG CANCER: OUTCOMES IN NON-SMALL CELL LUNG CARCINOMA

N. Thakur, R. Yadav, P. Roy

GCRI, Ahmedabad/India

Background: Locoregional failure in non-small cell lung cancer (NSCLC) remains high often leading to symptoms like hemoptysis and chest pain and the management for recurrent disease in the setting of prior radiotherapy is difficult. We retrospectively analyzed the outcomes for re-irradiation (reRT) for locoregionally recurrent lung cancer when used with intention of symptomatic relief in NSCLC. **Method:** This is a retrospective analysis of treatment of thirty-four patients of NSCLC who received re-irradiation to the thorax. All received re-irradiation by intensity-modulated radiotherapy. Palliative responses, survival outcomes, and prognostic factors were analyzed. **Result:** Median age of the group was 63 years, all but seven patients were males. All patients received a dose of 30.6 Gy in 17 fractions. Median survival of the group was 4.7 months, median KPS was 70. Relief of haemoptysis could be obtained in 31/34 assessable cases (91%), treatment was less effective for coughing 19/34 (56%) and dyspnoea 11/34 (32%). However, acute toxicities and new disease symptoms limited the duration of palliative benefit in the symptomatic NSCLC patients to a median of 2.3 months. No fatal complications were noted. Grade 2 or greater esophagitis was seen in 3/34(8%) cases. **Conclusion:** Reirradiation to the thorax for locoregionally recurrent NSCLC can provide palliative benefit. Select patients may experience meaningful survival prolongation after reirradiation. Careful selection of patients is necessary to avoid acute toxicity in already symptomatic patients. This experience demonstrates that repeated courses of radiotherapy can be given successfully and safely despite previous radical dosage.

Keywords: Re-irradiation, Non-Small Cell Lung Cancer, Palliative RT

EP1.01-71 THYMIDYLATE SYNTHASE AND FOLATE RECEPTOR ALPHA EXPRESSION AS POTENTIAL BIOMARKERS FOR EFFICACY OF PEMETREXED IN NSCLC

S. Verma[1], P. Malik[1], A. Yadav[1], D. Jain[2], S. Khurana[1], S. Kumar[1]

[1]*Dr. BRA Institute Rotary Cancer Hospital, All India Institute of Medical Sciences, New Delhi/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Predictive biomarkers for chemotherapy in advanced non-squamous NSCLC are lacking. Thymidylate synthase (TS) and folate receptor alpha (FRA) are target enzymes for pemetrexed. Here we investigated TS and FRA expression and their role as a prognostic and predictive biomarker for efficacy of pemetrexed-based chemotherapy. **Method:** We performed immunohistochemistry on pre-treatment tumour specimens for TS and FRA expression and correlated it with patient's demographic and clinical characteristics, treatment responses and survivals in a retrospective training cohort of patients with advanced non-squamous NSCLC treated with pemetrexed-based chemotherapy. Similar analysis for validation was performed in a prospective cohort of patients participating in a randomized control trial "to compare efficacy and safety of pemetrexed-carboplatin versus paclitaxel-carboplatin as induction regimen in advanced non-squamous NSCLC". Chi-square test was used to co-relate TS and FRA expression with clinico-pathological characteristics. Kaplan-Meier methods, Log-rank test and Cox proportional-hazards model were used for survival analysis. **Result:** In the retrospective training cohort median age was 57 (26-70) years with male predominance (ratio=2:1). TS and FRA expression were evaluable in 55 and 47 patients respectively. In this cohort TS and FRA expression didn't co-relate with best overall response rates (ORR), however, low TS expression and positive FRA expression were associated with improved progression free survival (PFS), albeit non-significant. In the prospective validation cohort median age was 52 (28-65) years with 70% males. In this cohort TS and FRA expression were analysed in 113 and 97 patients respectively. High TS expression was significantly associated with better ORR in patients treated with paclitaxel-carboplatin (p=0.04) but there was no co-relation of TS expression with response rates in pemetrexed-carboplatin group. Younger patients (age<40 years) had more TS 'low or negative' status (p=0.04). High TS expression was associated with ALK positivity (p=0.02), bone metastases (p=0.01) and brain metastases (p=0.002). Positive FRA expression was associated with EGFR positivity (p=0.004) and liver metastases (p=0.020). Positive FRA expression was associated with improved PFS in patients treated with pemetrexed-carboplatin (median: 9.23 versus 4.27 months, p=0.01), paclitaxel-carboplatin (median: 10.87 versus 6.47 months, p=0.08) as well as improved OS (median: OS not reached versus 10.13 months, p=0.01), especially in patients treated with pemetrexed-carboplatin (median: 18.73 versus 10.46 months, p=0.08). **Conclusion:** In conclusion, the results from this study suggest that TS or FRA expression doesn't predict efficacy of Pemetrexed, however, high TS expression may predict better ORR in patients receiving paclitaxel-carboplatin. FRA expression may serve as a prognostic factor in patients receiving chemotherapy irrespective of the regimen.

EP1.01-72 TREATMENT OUTCOME OF 2ND GENERATION EGFR-TKI FOR NON-SMALL CELL LUNG CANCER

T. Kondo, Y. Nakahara, R. Usui, S. Murakami, T. Kato, H. Saito, K. Yamada

Kanagawa Cancer Center, Yokohama/Japan

Background: Efficacy of EGFR-TKI has been demonstrated in 1st line treatment for EGFR mutation positive NSCLC. Afatinib, 2nd generation EGFR-TKI inhibits HER2 (ErbB2) or ErbB4 in addition to the EGFR (ErbB1), is expected more effective compared to the 1st generation EGFR-TKI. In this study, we investigated retrospectively on the treatment outcome of the cases that received 2nd generation EGFR-TKI treatment at our institution. **Method:** The subjects were 70 patients treated with a 2nd generation EGFR-TKI afatinib for the period from May 2014 to April 2018. Age, gender, smoking history, performance status (ECOG), EGFR mutation type, starting dose, dose reduction during treatment period, objective response, presence of brain metastasis, EGFR-TKI treatment line and T790M mutation result were retrospectively analyzed the association with the time to treatment failure and survival. **Result:** Among the 70 patients, male 28 cases and female 42 cases, and 42 never smoker included. Median age was 65 years old (43-88 years old). EGFR mutation type included exon 19 deletion 42 cases, exon 21 L858R 13 cases, uncommon mutation 13 cases and compound mutation 2 cases. 18 cases were administered with 40mg initial dose, 28 cases were 30mg and 24 cases were 20mg. 68 cases were good performance status (0 or 1), and 33 (47%) cases had brain metastasis. Dose reduction were performed in 43 (61%) cases, and partial response were observed in 34 (49%) cases. 36 (51%) cases were no pretreatment with EGFR-TKI (afatinib as first EGFR-TKI). Of the 70 cases, 33 (47%) cases were performed re-biopsy, and 15 cases of those were proved T790M acquired resistant mutation. **Conclusion:** Good performance status, dose reduction, good objective response, no brain metastasis, early EGFR-TKI treatment line and T790M mutation positivity were significantly associated with prolongation of the time to treatment failure, but no significant characteristics were associated with prolongation of the survival.

EP1.01-73 TROUSSEAU'S SYNDROME ASSOCIATED WITH PULMONARY PLEOMORPHIC CARCINOMA SHOWING AGGRESSIVE FEATURES: A CASE REPORT

S. Okada, A. Miyagawa-Hayashino, J. Fujinami, K. Kameyama, S. Kitaoka, N. Ishikawa, T. Furuya, S. Ikebe, S. Ishihara, H. Tsunezuka, M. Shimomura, J. Shimada, M. Inoue

Kyoto Prefectural University of Medicine, Kyoto/Japan

Background: Trousseau's syndrome is characterized as an unexpected cancer-related thrombotic event, such as a cerebral infarction or a deep vein thrombosis/pulmonary embolism. The histology of most reported cases of lung cancer with Trousseau's syndrome involves adenocarcinoma. We describe the first reported case of Trousseau's syndrome with pulmonary pleomorphic carcinoma and aggressive features. **Method:** A 74-year-old man, a current heavy smoker (38 pack-years), presented with a well-circumscribed peripheral mass (diameter: 38 mm) in the lower lobe of the left lung. A fluorine-18-fluorodeoxyglucose (FDG) positron-emission tomography scan showed a strong accumulation of FDG in the mass. Serum carcinoembryonic antigen (CEA) and D-dimer levels were 16.0 ng/mL and 0.6 μg/mL, respectively. A left lower lobectomy with systemic mediastinal lymph node dissection revealed the tumor was pleomorphic carcinoma with extensive lymph node involvement and was graded as pT3N2M0, pStage IIIB (pm1, pl1, ly1, v1, br+). The tumor mainly comprised giant cells with high-grade pleomorphism, admixed with a solid adenocarcinoma component and papillary growth pattern. The adenocarcinoma component was positive for periodic acid-Schiff (PAS) stain and resistant to diastase, suggesting mucin production. Moreover, most of the tumor cells were strongly positive for tissue factor (clone TF (H-9)). **Result:** Three months postoperatively, diffuse infiltration rapidly appeared in plain chest radiographs of the left lung, which was identified as lymphangitic carcinomatosis via bronchoscopy. Prior to treatment for cancer recurrence, the patient suddenly presented with dysarthria and left hemiplegia. Magnetic resonance imaging revealed acute ischemic stroke in the right hemisphere accompanied with subacute small infarcts in the left hemisphere and bilateral cerebellum. Magnetic resonance angiography revealed a right middle cerebral artery M2 segment occlusion. An echography and a chest CT showed no evidence of atherosclerotic thrombus or cardiac thrombus in the left atrium or in the stump of the resected pulmonary vein. Plasma D-dimer level was elevated at 17.6 μg/mL, as were the CEA and carbohydrate antigen 125 (CA125) levels (73.4 ng/mL and 331 U/mL), respectively. He underwent mechanical thrombectomy with a stent retriever, and partial recanalization was achieved. The pathology of the retrieved thrombus showed that almost all parts consisted of fibrin without red blood cells. These findings and pathological findings of the primary lung cancer suggested Trousseau's syndrome as the etiology of the cerebral infarction. **Conclusion:** A hypercoagulable state, due to aggressive recurrence of pulmonary pleomorphic carcinoma accompanying with cancer cell production of mucin and tissue factor, may be a potential mechanism for cancer-related thrombosis.

Keywords: Trousseau's syndrome, cerebral infarction, pulmonary pleomorphic carcinoma

EP1.01-74 IMPLANTATION OF PERMANENT PLEURAL CATHETER (PPC) FOR MALIGNANT PLEURAL EFFUSION (PE) IN ADVANCED NON SMALL CELL LUNG CANCER (NSCLC)

M. Martinez-Kareaga[1], I. Intxaurbe-Etxebarria[1], B. Mareque[1], N. Torrego[1], L. Tomás-López[1], C. Sánchez-Vieco[1], A. Narro[1], L. Puntí[1], G. García-Gómez[1], N. Urbieta[2]

[1]*Txagorritxu Hospital, Vitoria-Gasteiz/Spain,* [2]*Biodonostia, Donostia/Spain*

Background: Pleural effusion (PE) is a frequent complication in patients (p) with advanced NSCLC that causes refractory symptoms such as pain and dyspnea. These patients frequently need repeated thoracocentesis to relieve symptoms. Implantation of PPC can avoid repeated thoracocentesis. **Method:** Thirty consecutive patients of our hospital with advanced NSCLC who overwent to PPC implantation from May 2008 to September 2018 were retrospectively evaluated. Baseline characteristics, acute and late complications and outcome were retrospectively collected. Overall survival (OS) was calculated from the date of the PPC implantation to the date of death. **Result:** Thirty patients were evaluated, 20 were male and 10 female. All the patients were death at the cut-off date, the 1st October 2018. Median age at PPC implantation was 66y (range: 47-91) and 80% presented ECOG PS 2. Adenocarcinoma was the most frequent histology (22p). Mean hospital stay was 7 days (range 1-28). Average catheter duration was 60 days (range 3-181). Four patients (13%) suffered an acute complication: 1 pleuro-cutaneus fistula, 1 empyema, 1 hematoma and 1 needed surgical intervention because the catheter guided was at pleural cavity. After hospital discharge, one patient presented a complication, with pleural liquid exit from pericatheter. Twenty-five patients (83%) presented clinical relief and 11p (37%) received chemotherapy after PPC implantation. Citology of pleural liquid was performed in 23p (77%) and resulted positive for malignancy in 14p. Median OS was calculated from PPC implantation to death and resulted of 14.3 weeks (IC 95%, range 1.3-59.1). **Conclusion:** PPC implantation is a safe technique that can cause symptomatic relief in selected patients with malignant pleural effusion. However, average catheter duration and median survival after PPC implantation are low. Therefore a better selection of patients is mandatory in our centre.

Keywords: Lung cancer, Pleural effusion, Pleural Catheter

EP1.01-75 PALLIATIVE THORACIC RADIOTHERAPY FOR LUNG CANCER: WHAT IS THE MOST APPROPRIATE FRACTIONATION?

N. Thakur, R. Yadav

GCRI, Ahmedabad/India

Background: Radiotherapy is the one of the most effective modalities to palliate the symptoms (hemoptysis, pain, breathlessness) of poor-prognosis patients with advanced non-small-cell lung cancer. Most appropriate dose schedule however remains debatable. We conducted a retrospective analysis that compared the efficacy of radiotherapy schedules consisting of 5 fractions of 4 Gy (5 x 4 Gy) versus 10 fractions of 3Gy (10 x 3 Gy) in advanced Non Small Cell Lung Cancer (NSCLC). The end point evaluated was symptomatic relief. **Method:** Between July 2016 and September 2017, 60 patients with advanced NSCLC were randomised to either 5 fractions of 4 Gy (5 x 4 Gy):Arm A or 10 fractions of 3Gy (10 x 3 Gy):Arm B. The eligibility criteria was histologically or cytologically confirmed NSCLC, age $\geq$ 30, stage III or IV disease, Karnofsky performance status (PS) $\geq$ 40, expected survival $\geq$ 3 months. The quality-of-life was assessed using the patient records :European Organization for Research and Treatment of Cancer (EORTC) Quality of Life Questionnaire (QLQ)-C30 and the lung cancer–specific module QLQ-LC13. The primary study end points was control of symptoms viz cough, hemoptysis, pain and dyspnea, and the secondary end point was to evaluate Overall Survival (OS). **Result:** 52 out of 60 patients were males, 18/60 had lost to follow up. Majority of patients presented in 5th and 6th decade of their lives, mean age of presentation was 58.87 (Range31-80). Majority (69%) of patients had presented with poor KPS 70 or less. Most common presenting symptom was cough with expectoration (74.66%) followed by hemoptysis (47.33%). Post treatment 36% reported reduced cough, 44% reported reduced dyspnea, 57% reported reduced pain and 90% reported reduced hemoptysis within 20 weeks from start of treatment, with no statistical difference among the groups. Except for improved hemoptysis at week 5 in Arm A (P =0.03), there was no difference among the groups. Furthermore, the palliative effect of symptoms seemed to last throughout the planned follow-up period. Overall survival for all patients (n=42) revealed no significant survival difference among the treatment groups (P = 0.2). The median survival was 6.2 and 6.7 months in arm A and B, respectively. **Conclusion:** Hypofractionated regimen of 20Gy/5 fractions is atleast as effective at providing symptomatic relief and yields equivalent survival as 30Gy/10 fractions in patients with advanced non-small cell lung cancer and thoracic symptoms besides having the advantage of fewer visits to hospital as well.

EP1.01-76 ONCOMINE TUMOR MUTATION LOAD ASSAY IN NSCLC PATIENTS FROM ARGENTINA: STUDY DESIGN AND FEASIBILITY

V. Denninghoff[1], V. Romano[1], R. Cabrerizo[1], A. Kuzminin[1,2], V. Wainsztein[2,3], G. Recondo[2]

[1]*CEMIC, CABA/Argentina,* [2]*Centro de Educacion Medica e Investigacion Clinica (CEMIC), Buenos Aires/Argentina,* [3]*Centro de Educación Médica e Investigaciones Clínicas (CEMIC), Buenos Aires/Argentina*

Background: High throughput next generation sequencing has improved the understanding of the genomic landscape of cancer. Somatic mutations throughout the exome derive in novel peptide sequences that can be recognized by the host immune system and drive immune responses in patients. The tumor mutational load (TML) is the number of somatic mutations per megabase of DNA and is an emerging biomarker to predict response to immune checkpoint inhibitors. **Method:** The objective of this study was to evaluate the feasibility of assessing TML in tumors from patients with advanced NSCLC, treated with Nivolumab in second with Ion Torrent™ Oncomine™ TML Assay and compare it with TML from WES. The Oncomine TML is a targeted NGS assay that provides quantification of somatic mutations, from limited formalin-fixed, paraffin-embedded (FFPE) samples. **Result:** DNA was purified with QIAamp DNA FFPE Tissue Kit (QIAGEN). We used a new Ion AmpliSeq targeted panel, derived from the Comprehensive Cancer Panel which covers approximately 1.7 Mb of genomic DNA and 409 genes, OTML in S5, Ion Proton (Life Technologies); and WES were performed in NovaSeq 6000 Sequencing System (Illumina). We included 40 patients with advanced NSCLC. 27 (68%) of patients had both, tumor and normal tissue to perform WES. FFPE samples were obtained from lungs (N=21), lymph nodes (N=11), pleura (N= 3), brain (N=1), skin (N= 1), bone marrow (N = 1), soft tissue (N=1). We used 20 ng of DNA to develop the manual library and templating. We covered a large genomic footprint to accurately measure somatic mutations, replacing the need for whole-exome sequencing (WES). Pipeline for analysis of the NGS output will be presented. **Conclusion:** TML estimation with low DNA input requirements from FFPE samples is feasible. Up to 8 samples can be sequenced in a Ion 540™ Chip. Mutation load assessment can be done within 2–3 days. This assay was highly reproducible in FFPE samples. A detailed report provides normalized mutation count per MB as well as mutation signatures.

EP1.01-77 LOCALLY ADVANCED NON SMALL CELL LUNG CANCER - TREATMENT OUTCOME IN REAL WORLD SETTING

S. Pathy, A. Thimmarayappa, P. Malik

All India Institute of Medical Sciences, New Delhi/India

Background: Lung cancer is one of the leading cancers in India. About two-thirds present in advanced /metastatic stage. The mainstay therapy for advanced non small cell lung cancer (NSCLC) is concurrent chemoradiation. Locoregional failure constitutes the predominant failure pattern. A larger proportion of the patients are treated with palliative intent. The current study evaluates the demographic profile, treatment pattern, and outcome and radiation practice for palliative treatment at a tertiary care academic medical institution. **Method:** Medical records of patients treated between June 2016- June 2018 were evaluated Clinical presentation, treatment details and outcome was recorded. Case records with incomplete workup or treatment was excluded. **Result:** A total of 181 patients of NSCLC were registered of which 108 were metastatic at presentation 96 patients received palliative radiotherapy and are analysed. 11 patients has pulmonary metastasis and 85 had extrapulmonary metastasis of which 21 patients had multiple extrapulmonary disease. Ninety-six patients received palliative radiotherapy. 84 patients had ≤ 1comorbidity. Most of the patients were aged ≤65years (80%) with a female preponderance. Cough, chest pain and dyspnea each were present in one-third of patients. Twenty-six patients had bony pain, 18 had symptoms of raised intracranial pressure and 7 patients had SVCO. Adenocarcinoma was the commonest histology observed in 86.4% patients. Bone was the most common site of metastasis, seen in 65(65.7%) patients; followed by brain in 23(24%). Palliative radiotherapy was given to primary in 13(13.5%), brain in 27(28%), bone in 56(58%). Palliative radiotherapy to weight bearing sites was treated with 8Gy in single fraction. Whole brain radiotherapy was treated with 20Gy in 5 fractions. 65% of patients received palliative chemotherapy. Platinum- taxane and platinum-pemetrexed regimens were the most common regimen practiced for among squamous and adenocarcinoma histology respectively. Median follow up was 6.6 months (2 to 37 months). Median time for oncological intervention was 1.2 months (0.1 to 5.4months). Median PFS was 6months (IQR 3- 11.2months) **Conclusion:** The study concludes that a large proportion of patients present in advanced/metastatic disease. In the metastatic setting bone metastasis was the most common site followed by brain. The outcome is dismal and newer treatment techniques /modalities may result in improved outcome in this group of patients.

EP1.01-78 T4 LUNG CANCER INVADING THE DESCENDING THORACIC AORTA: A CASE SUCCESSFULLY TREATED WITH SURGERY BY A MULTIDISCIPLINARY TEAM

A. De Palma[1], G. Nex[1], G. De Iaco[1], D. Brascia[1], M. Schiavone[1], R. Quercia[1], R. Pulli[2], D. Angiletta[2], G. Marulli[1]

[1]*Section of Thoracic Surgery, University of Bari, Bari/Italy,* [2]*Section of Vascular Surgery, University of Bari, Bari/Italy*

Background: T4 lung cancer invading the great vessels was usually considered a relative contraindication for radical surgery, because of technical difficulties and intra/postoperative bleeding complications. Recent studies have proved radical pneumonectomy or lobectomy together with aorta endograft positioning to have low mortality and morbidity rate and fairly good overall survival; however, only few cases have been reported in the literature. We report a case of T4 lung cancer invading the descending thoracic aorta (DTA) successfully treated with surgery by a multidisciplinary thoracic and vascular team. **Method:** A 60-year old male patient was admitted to our Department with a left upper lobe pulmonary tumor of 9 cm invading the DTA, as shown by preoperative computed tomography (CT) scan and magnetic resonance imaging (MRI). 18F-fluorodeoxyglucose positron emission tomography (FDG-PET)/CT total body scan revealed an uptake only at tumor site (SUV max 26.28) with no lymph nodes positivity. Preoperative spirometry values were FEV1 79%, FVC 82% and DLCO 72.5%. Pulmonary perfusion scintigraphy showed 65% for the right lung and 35% for the left one. We performed left pneumonectomy and hilar-mediastinal lymphadenectomy by posterolateral thoracothomy approach, observing about 5 cm long abventitial infiltration of DTA, 3 cm after left subclavian artery origin. An aortic endograft (GORE TAG Comformable Thoracic Stent Graft with ACTIVE CONTROL System) via left femoral artery was disposed 2 cm distal to the subclavian artery origin, then the infiltrated abventitial aortic wall (40% of the aortic circumference) was removed, leaving only the macroscopic healthy endothelium and protecting it with a Goretex mesh (BARD COMPOSIX E/X MESH). **Result:** The patient spent one night in intensive care unit (ICU), transfusing blood once. The only postoperative complication was a transitory atrial fibrillation pharmacologically treated. He was discharged 9 days after surgery. Pathologic analysis showed a non-mucinous lung adenocarcinoma invading the visceral pleura with a metastatic bronchial lymph node (pT4N1M0), with margins free of tumor. Chemotherapy and radiotherapy were administered and the patient is alive and in good condition 6 months after surgery, free of relapse. **Conclusion:** In selected cases, in young patients with good performance status, surgery for T4 lung cancer invading the DTA can successfully be accomplished, without complications, by an experienced multidisciplinary thoracic and vascular surgeons team, in high volume centers.

EP1.01-79 CHEMORADIOTHERAPY IN ADVANCED NON SMALL CELL LUNG CANCER

M. Ait Erraisse, F.Z. Abboud, K. Hassouni

University Hospital Hassan II, Fez/Morocco

Background: Advanced NSCLC is a frequent cancer among our patients. Delay in diagnosis and treatment leads to advanced stages that require complex treatment modalities and poor prognosis. We report our experience in term of epidemiological, diagnostic, therapeutic and prognostic aspects of this disease in our department. **Method:** This is a retrospective study of 38 cases of advanced NSCLC treated with concurrent chemoradiotherapy,

collected in the radiotherapy department in the University Hospital Hassan II in Fez, between January 2012 and January 2017. All cancers were prooved histologically by biopsy. The standard treatment was concurrent chemoradiotherapy alone or after induction chemotherapy mostly due to a large tumor volume where radiotherapy is not feasible upfront. Chemotherapy drugs were mainly cisplatin-based with vinorelbine or paclitaxel and in some cases carboplatin if renal function is not correct. Radiotherapy was delivered through 3D conformal technique after CT-simulation and image fusion with CT or in rare cases PET-CT. After completion of treatment, no patient received adjuvant chemotherapy. Immune therapy was not affordable due to the high price. Follow-up was done clinically and with control CTscan. Tobacco control counseling was recommended to all our patients. **Result:** The average age was 59 years (38 to 81 years). The patients were all males and chronic smokers. Significant clinical symptoms were mainly chest pain, dyspnea and hemoptysis. There were 21 cases of adenocarcinoma, 17 cases of squamous cell carcinoma. 18 cases were classified as stage IIIA, 20 cases as stage IIIB. Neoadjuvant chemotherapy was received in 23 cases from 2 to 4 cycles. All patients received radiotherapy with doses to PTV between 60-70Gy with concomitant chemotherapy including cisplatin or carboplatin. After an average follow-up of 12 months, the evolution was marked by the occurrence of 2 deaths, distant metastasis in 14 patients (6 cases of cerebral metastasis and 8 cases of bone metastasis), 2 cases of progressive disease, 14 patients in complete clinical remission and are always followed, and 6 patients were lost to follow-up, **Conclusion:** It is now proven that the survival of patients with locally advanced lung cancer is better if chemotherapy is combined with radiotherapy. The survival gain obtained is essentially related to better control of micro-metastases even though the local control remains very poor. Some irradiation techniques seem to be able to improve this local control: conformal radiotherapy with intensity modulation, hypofractionation. Immue therapy concomitant to radiation might be the future but still needs randomized clinical trials to approve it.

EP1.01-80 PROGRESSIVE DISEASE WITH T790M MUTATION VS NON-T790M MUTATION IN EGFR POSITIVE PATIENTS TREATED WITH TYROSINE KINASE INHIBITORS

D. Reis[1], N. China[1], M. Dias[1], D. Coutinho[1], E. Silva[1], S. Campainha[1], T. Costa[1], S. Conde[1], L. Cirnes[2], A. Barroso[1]

[1]*Vila Nova de Gaia-Espinho Hospital Center, Vila Nova de Gaia/Portugal,* [2]*Institute of Molecular Pathology and Immunology of the University of Porto (IPATIMUP, Porto/Portugal*

Background: Patients with metastatic non-small cell lung cancer (NSCLC) with a sensitizing EGFR mutation are candidates for treatment with a tyrosine kinase inhibitor (TKI), but acquired resistance is inevitable. The most frequent mechanism of acquired resistance to TKI is the T790M mutation. **Method:** Retrospective analysis of patients with EGFR mutation treated with TKI who progressed from November 2016 to July 2018, for whom the T790M mutation testing was done through liquid or tissue biopsy. **Result:** Progression disease was observed in 18 patients. The mean age was 67.1 ± 14.4 years. Twelve patients (66.7%) were female. Ten patients (55.5%) presented the T790M mutation as a resistance mechanism to TKI.

	T790M positive	T790M negative	p value
Non-smokers Ever smokers	9 (90%) 1 (10%)	2 (25 %) 6 (75 %)	0.005
EGFR mutation Exon 18 Exon 19 Exon 21	0 (0%) 8 (80%) 2 (20%)	1(12.5%) 5(62.5%) 2 (25%)	0.604
Initial TKI Gefitinib Afatinib Erlotinib	2 (20%) 0 (0%) 8 (80%)	2 (25%) 3(37.5%) 3(37.5%)	0.146
Response evaluation Stable disease Partial response	3 (30%) 7 (70%)	6 (75%) 2 (25%)	0.119
PFS with initial TKI - months (mean ± SD)	11 ± 5.3	10 ± 6.9	0.586
Months treated with initial TKI after disease progression due to clinical benefit (median - IQR)	2 - 5	4 - 3	0.409
Progressive disease Increase of primary lesion size Increase of metastasis size New intrathoracic lesions New extrathoracic ± intrathoracic lesions	3 (30%) 3 (30%) 2 (20%) 2 (20%)	3(37.5%) 2 (25%) 0 (0%) 3(37.5%)	0.465

Conclusion: The T790M mutation was the most frequent mechanism of TKI resistance. Non-smokers developed the mutation more often than ex-smokers, although this result was not statistically significant. In the other analyzed variables there were no statistically significant differences.

Keywords: Lung cancer, T790M, TKI

EP1.01-81 RESECTION OF TUMORS WITH CARINAL INVOLVEMENT AFTER INDUCTION THERAPY

D. Galetta, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Tumors involving the carina may be treated with resection of trachea-bronchial bifurcation with or without lung resection. The role of induction therapy (IT) and its effects on morbidity/mortality are unclear. We evaluated surgical and long-term outcomes of patients who underwent carinal resection after IT. **Method:** From 1998 to 2018, 45 patients (35 men; median age, 62 years) underwent carinal resection. Twenty-nine patients (64.4%) received IT (24 chemotherapy and 5 chemo-radiation). Histology included 41 non-small cell lung cancers, 3 adenoid cystic carcinomas, 1 carcinoid. Carinal pneumonectomy was performed in 32 cases (all right sided), carinal resection plus right upper lobectomy in 9, carinal resection plus upper bilobectomy in 1, and carinal resection without pulmonary resection in 3. Superior vena cava resection was associated in 22 cases. **Result:** Operative mortality was nil. Thirty-day mortality was 8.8% (n=4). Major complications occurred in 9 patients (20%): 5 bronchopleural fistulas, 2 ARDS, 2 cardiac hernias. IT did not influence morbidity rate (p=.7371). Pathological N status included 6 N0, 22 N1, and 17 N2. Follow-up was completed for all patients. Median survival was 16 months (range, 1 to 181 months). Overall 5-year survival rates was 35.8%. Overall, 5-year freedom from recurrence was 49.8%. Patients receiving IT had a poor survival (22.6% versus 60%) but it was not statistically significant (p=.0596). Histology, extended resection, and N status, did not influence survival. **Conclusion:** Carinal resection is a feasible but challenging procedure providing acceptable mortality and long-term outcomes. IT did not influence morbidity, mortality, and overall survival.

Keywords: carina, induction therapy, Advanced lung cancer

EP1.01-82 10 YEARS SINGLE CENTER EXPERIENCE WITH RESECTION OF THE SUPERIOR VENA CAVA IN LOCALLY ADVANCED NON-SMALL CELL LUNG CANCER

M.A. Hoda, T. Klikovits, E. Gschwandtner, K. Sinn, R. Hritcu, W. Klepetko

Medical University of Vienna, Vienna/Austria

Background: In patients with locally advanced T4 non-small cell lung cancer (NSCLC) invading the superior vena cava (SVC), combined multimodality treatment including surgery is indicated. However, this treatment approach warrants careful patient selection and adequate postoperative management. We aim to review our institutional experience with SVC resection in advanced NSCLC. **Method:** Between 2006 and 2017, surgery for NSCLC including SVC resection has been performed in 21 patients at our department. We defined "SVC resection" as resection of the SVC and replacement with ring-enforced tube grafts and "SVC reconstruction" as partial resection with direct closure or reconstruction with a bovine pericardial patch. Clinical parameters and long-term outcome were analyzed. **Result:** Overall, 15 male and 6 female patients have been included. Induction treatment was performed in 16 patients, 8 patients received chemoradiation therapy and the other 8 patients had chemotherapy alone. Pulmonary resection included 8 sleeve pneumonectomies, 4 pneumonectomies, 3 lobectomies and 4 sleeve-lobectomies of the right upper lobe, 1 extraanatomical resection of the right upper lobe and one mediastinal tumor debulking. Two patients required cardiopulmonary bypass during surgery. An additional extended resection including chest wall (n=1), phrenic nerve (n=3), pericardium or right atrium (n=4) was performed in 8 patients. Overall 5 patients underwent SVC reconstruction whereas 16 patients had complete SVC resection and replacement. The 90-day-mortality rate was 4.8% (n=1). Major complications occurred in 8 patients (38%) with no difference between patients undergoing SVC resection or reconstruction. Oncological long-term outcome will be presented at the conference. **Conclusion:** Our results suggest that an extended resection including SVC replacement or reconstruction is a feasible and safe procedure for carefully selected patients with NSCLC and SVC involvement with acceptable postoperative morbidity and mortality rates.

EP1.01-83 EFFICACY AND SAFETY OF EGFR-TKI RECHALLENGE TREATMENT IN ELDERLY PATIENTS WITH ADVANCED NSCLC HARBORING SENSITIVE EGFR MUTATIONS

Y. Yamada[1], H. Imai[2], H. Minemura[3], T. Sugiyama[4], K. Kaira[5], K. Kanazawa[3], T. Kasai[4], K. Minato[2], T. Kaburagi[1]

[1]*Ibaraki Prefectural Central Hospital & Cancer Center, Kasama/Japan,* [2]*Gunma Prefectural Cancer Center, Ota/Japan,* [3]*Fukushima Medical University, Fukushima/Japan,* [4]*Tochigi Cancer Center, Utsunomiya/Japan,* [5]*Saitama Medical University International Medical Center, Hidaka/Japan*

Background: Epidermal growth factor receptor–tyrosine kinase inhibitor (EGFR–TKI) is effective as first-line chemotherapy for patients with advanced non-small-cell lung cancer (NSCLC) harboring sensitive EGFR mutations. However, whether the efficacy of second-line EGFR–TKI treatment after first-line EGFR–TKI treatment was poorly studied in elderly patients aged ≥ 75 years harboring sensitive EGFR mutations. Therefore, we aimed to investigate the efficacy and safety of EGFR-TKI re-administration after first-line EGFR–TKI treatment in elderly patients with NSCLC harboring sensitive EGFR mutations. **Method:** Between October 2002 and December 2015, 22 elderly patients with advanced NSCLC harboring sensitive EGFR mutations who were initiated on EGFR–TKI Rechallenge at four Japanese institutions were included in this study. The eligibility criteria were histologically or cytologically confirmed NSCLC, unresectable stage III/IV disease, and a drug-sensitive EGFR mutation (exon 19 deletion or exon 21 L858R). All patients were initially treated with gefitinib (250 mg/day) or erlotinib (150 mg/day) and after recurrence, re-administration of EGFR-TKIs (gefitinib, erlotinib, afatinib) was performed as a secondary chemotherapy **Result:** Ultimately, 22 cases of this study were studied. The median age was 77.5 years (range 75-87 years). Although it was a retrospective analysis, even with re-administration of EGFR-TKI rechallenge, the response rate was 23%, PFS 5.26 months, OS (after EGFR-TKI rechallenge) 14.4 months (the administration lines were 2, 3 and 4 lines). **Conclusion:** Until now it was said that EGFR-TKI rechallenge does not contribute to OS in LUX-LUNG 1 and so on. On the other hand, there are also reports on the usefulness of EGFR-TKI rechallenge. From the results of this study it can be said that it can be one of the options among the limited treatment options for elderly EGFR positive lung cancer.

Evangelismos General Hospital, Athens/Greece

Background: The treatment landscape of non small cell lung cancer (NSCLC) has changed dramatically during the last years involving targeted therapy, chemotherapy ± immunotherapy or/ and antiangiogenic agents, based mainly on patients' molecular characteristics. Not all patients respond well to immunotherapy, so there is an essential need for other effective treatments. **Method:** The aim of this prospective study is to estimate and record, the efficacy of the combination of Docetaxel with Nintedanib as a second line therapy in metastatic NSCLC. There were 20 patients, 16(80%) men, 4(20%) women, median age 62(52-73) years and median ECOG 1(0-3), without driver mutations, consecutively admitted in Evangelismos Oncology Department in Athens, Greece from 27/11/2017-23/02/2019. **Result:** All patients had received Cisplatin/Pemetrexed/ Bevacizumab as first line treatment for their disease, with a median duration of 104(45-255) days. Progressive disease sites were found in lung, liver, and bones in :18/20(90%), 8/20(40%) and 4/20(20%) patients respectively. All received as second line treatment Docetaxel 75mg/m^2 q3weeks plus Nintedanib 400mg p.o., d 2-20 in 21 days cycles. CEA, CA125, NSE, CA19.9, CA72-4 and Cyfra 21.1 tumor markers were monitored according to our clinical protocol. Increased values of these markers were documented at initiation of therapy in 18, 14, 10, 14 ,0, 2 patients respectively. After 3 cycles of treatment all patients were reevaluated and in 2 of them partial response (P.R.) was documented, with 40-50% reduction of CEA, CA125, CA19.9 και Cyfra 21.1, while 12 patients had stable disease (S.D.) with no more than 20% change in the aforementioned tumor markers. Six patients with progressive disease (P.D.) showed significant increase of CEA, CA 125, NSE, CA 19.9 and CA 72-4. The responders (P.R.+ S.D.) continued therapy for a median of 5(3-8) cycles. Among 96 cycles of chemotherapy, any toxicity grade ≥ II occurred in 14 (7%) of them. Anaemia in 7(50%), stomatitis in 4(28.5%), diarrhea in 5(36%) and AST/ALT elevation of >2.5 fold in 3(21%) cycles respectively. All patients were treated symptomatically, without dose reduction in any patients **Conclusion:** The combination of Docetaxel/Nintedanib in metastatic NSCLC adenocarcinoma, following progressive disease post Cisplatin/ Pemetrexed/ Bevacizumab treatment, showed 70% response rate. Although the number of the patients included in the study is small, we concluded that the tumor markers examined, had a clear correlation with the disease outcome. No major toxicity issues were documented. Larger studies are needed in order to make more solid conclusions.

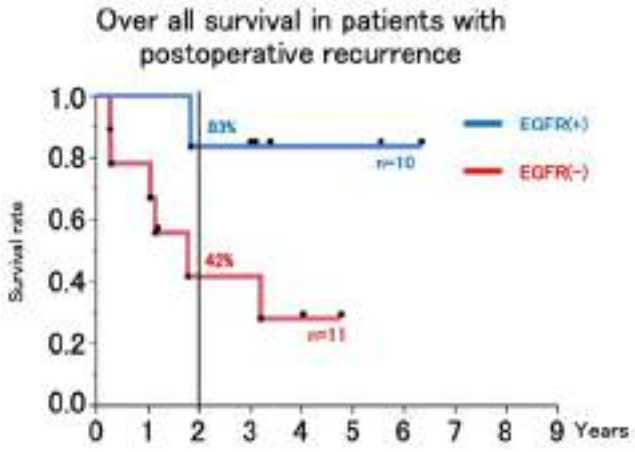
EP1.01-85 PROGNOSIS OF PATIENTS WITH RECURRENT OR ADVANCED LUNG CANCER ACCORDING TO THE STATUS OF EPIDERMAL GROWTH FACTOR RECEPTOR

K. Ito

Kyoto Yamashiro Medical Center, Kizugawa/Japan

Background: We report the 9-year experience of the therapy and prognosis of the patients with postoperative recurrence or advanced lung cancer according to the status of epidermal growth factor receptor (EGFR) status in a single institution. **Method:** We retrospectively evaluated the prognosis of the patients who received the therapy in a single institution from April 2009 to March 2018. Patients who relapsed after surgery and patients with inoperable advanced lung cancer (c-stage IIIB, stage IV) were enrolled. The EGFR gene mutation was examined using surgical specimens in relapsed patients and biopsy specimens at diagnosis in patients with advanced lung cancer. At first treatment, we administered EGFR-tyrosine kinase inhibitors (TKIs) to EGFR gene-positive patients and platinum doublet agents to EGFR gene-negative patients. At the time of progression or the intolerable adverse effects, we went on to the secondary treatment. **Result:** In patients with postoperative recurrence, the 2-year survival rate in EGFF gene-positive patients (83%, n=10) was significantly higher than that in EGFR gene-negative patients (42%, n=11). The locations of recurrence were 14 in the lung, 7 in lymph nodes, 2 in bones, 1 in the brain, adrenal glands, and kidney. In patients with advanced lung cancer, the 2-year survival rate in EGFR (42%, n=9) did not differ from that in EGFR (31%, n=26). The locations of metastasis in patients with advanced cancer were 3 in mediastinal lymph nodes, 12 in the ipsilateral lung, 11 in malignant pleural effusion, 8 in the brain, 4 in the bones, 3 in the adrenal glands, and two in the liver.



Conclusion: We treated EGFR-TKI as the first therapeutic agent for the recurrent and advanced lung cancer patients with EGFR gene mutation positive and obtained relatively good results.

EP1.01-86 COMPREHENSIVE NEXT-GENERATION SEQUENCING-GUIDED TARGETED THERAPY CORRELATES WITH SURVIVAL IN NON-SMALL-CELL LUNG CANCER

Z. Wang, B. Lu, G. Liu, T. Xu, L. Jiang, Z. Chen

The Second Affiliated Hospital of Nanjing Medical University, Nanjing/China

Background: Although increasingly common in clinical practice, whether genetic testing confers a survival benefit remains to be firmly established. **Method:** We performed retrospective analysis of 82 lung adenocarcinoma patients who were diagnosed at the Second Affiliated Hospital of Nanjing Medical University from 2013 to 2018. We evaluated progression-free survival (PFS) with respect to genetic testing status. **Result:** 63 (77%) patients received targeted next-generation sequencing. Of these, 43 (69%) patients received tailored targeted TKI therapies. No significant difference in mPFS was observed between patients with and without genetic testing (Fig.1). However, an increase in PFS started to manifest at later times in patients who received genetic testing. In patients treated with osimertinib, PFS was longer in those who received genetic testing and had EGFR T790M mutation status confirmed (Fig.2 and Table 1). A cis-C797S mutation was identified in a patient who progressed on osimertinib treatment. Patient 6 with EGFR L858R responded poorly to osimertinib. We found that genetic testing was conducted using a 139-gene panel, and more comprehensive testing may be necessary to uncover potential resistance mechanism(s) to osimertinib in this patient.

Figure 1.

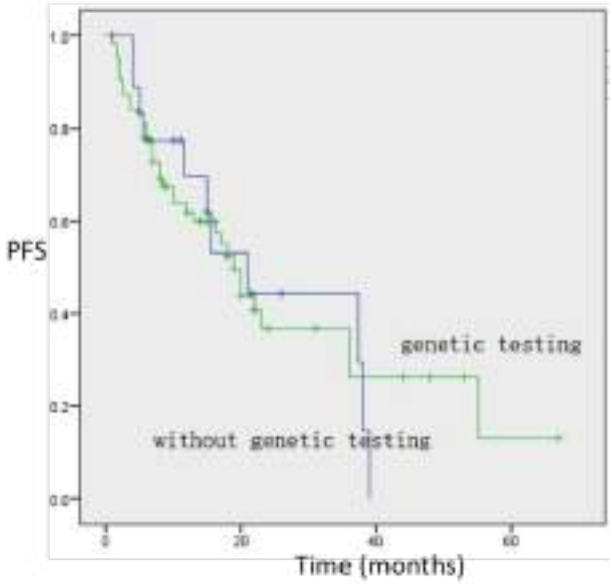

Figure 2.

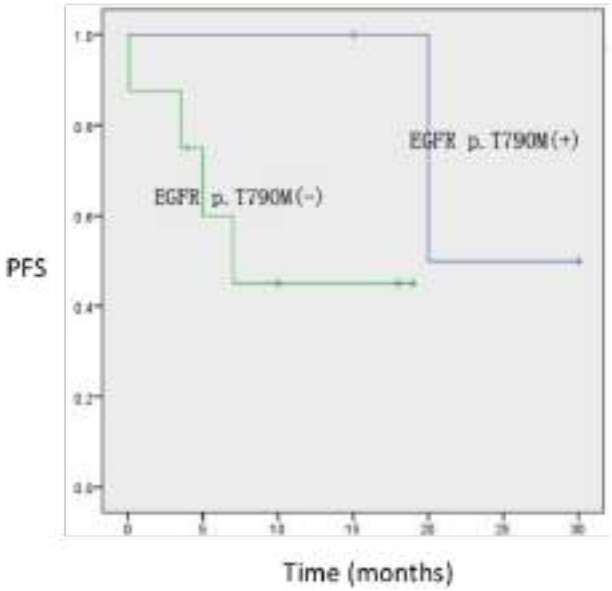

EPOSTERS

Table 1. NSCLC patients treated with osimertinib

Patient ID	Age/ Gender	Sample Type	Previous Targeted Therapy	Mutations	PFS (months after osimertinib
1	65 / F	Blood	Gefitinib	EGFR p.745_750del EGFR p.T790M	20
2	59 / F	Blood/ Tissue	Gefitinib	EGFR p.746_751del EGFR p.T790M	30
3	54 / M	Blood	Erlotinib	EGFR p.L747_ T752del MAP2K1 p. C121S NF1 p.L732X	0.3
4	48 / M	Blood	Osim-ertinib	EGFR p.L858R EGFR p.T790M EGFR p.C797S	4
5	87 / M	Tissue	Osim-ertinib	EGFR p.745_750del	10
6	48 / M	Blood	Osim-ertinib	EGFR p.L858R	4
7	77 / M	Blood/ Tissue	No	EGFR p.L861Q	18
8	60 / F	Blood	Gefitinib	EGFR p.L858R EGFR p.T790M	15
9	77 / M	Tissue	Gefitinib	KRAS	7
10	50 / M	Blood/ Tissue	Osim-ertinib	No	18
11	79 / M	Blood/ Tissue	Osim-ertinib	EGFR p.L858R	5

Conclusion: Routine genetic tests should implemented in treating patients with advanced NSCLC, particularly in those who developed resistance to first-generation TKIs.

Keywords: targeted therapies, Next-generation sequencing, NSCLC

EP1.01-87 CUTANEOUS METASTASIS IN LUNG CANCER – A RETROSPECTIVE STUDY IN A LOCAL HEALTH UNIT IN GUARDA, PORTUGAL

R. Natal, J. Costa, M. Oliveira, A. Amaral, F. Cabral, R. Gomes, L. Ferreira

Local Health Unit of Guarda, Guarda/Portugal

Background: Cutaneous metastasis from lung cancer is rare, occurring in 0.22-12% of cases. Their presence has generally been considered a sign of an already disseminated, poor-prognosis and non-surgical disease. Current data suggest lung cancer is the second most frequent cause of cutaneous metastasis in men, behind malignant melanoma. **Method:** We conducted a retrospective analysis of patients diagnosed with lung cancer and cutaneous metastasis, submitted to skin biopsy to confirmation, from November 2010 to March 2019, in our local health unit. Data regarding demographic characteristics, smoking history; location and histology and of the primary tumor; staging; number, location and type of skin lesion; overall survival and survival after detection of cutaneous metastasis were collected from clinical records. **Result:** Five patients were included, 4 were of male gender (80.0%), with median age of 79 years (range, 56-88). Three patients (60.0%) were former smokers, 1 current smoker and 1 non-smoker. The location of the primary tumor was right upper lobe (3 cases, 60.0%) and left lower lobe (2 cases, 40.0%); histology of adenocarcinoma in 3 patients (60.0%), 1 patient with squamous cell carcinoma and another with neuroendocrine carcinoma. All cases of lung cancer were diagnosed with an initial stage IV disease. Most of them had a unique skin lesion, mainly a nodule, located either in the upper abdominal wall or dorsal region. From the 5 cases, 4 had died, with a median overall survival 0.5 months (range, 0-1) and survival after cutaneous metastasis 15.5 days (range, 12-82). **Conclusion:** According to data, also in our study men had more cutaneous metastasis from lung cancer than women. Previous or active smoking history was present in almost all patients, the main histology type was adenocarcinoma and primary lung cancer was frequently located in right upper lobe, consistent with reported data. In all cases, lung cancer was diagnosed in an advanced stage and survival after diagnosis of cutaneous metastasis was extremely low.

Keywords: cutaneous metastasis, Advanced lung cancer

EP1.01-88 NEXT-GENERATION SEQUENCING IN HISPANIC PATIENTS WITH ADVANCED LUNG CANCER AND CORRELATION WITH RESPONSE TO IMMUNOTHERAPY

D. Saravia[1], L. Raez[2], D. Sumarriva[2], J. Cotta[1], D. Fanfan[1], G. Lopes[1]

[1]*Sylvester Cancer Center, Miami/United States of America,* [2]*Memorial Cancer Institute/Florida International University, Pembroke Pines/United States of America*

Background: Cancer is a leading cause of death among Hispanics (HISP); the largest ethnic minority in the United States (17% of the total population). With the approvals of checkpoint immunotherapy in advanced lung cancer, many patients (pts) are starting to see long-lasting remissions and longer survival rates. However, response to a given treatment often depends on the tumor's genomic profile. Our aim was to analyze NGS results for HISP pts living in the US in an effort to better understand this population's genomic profile and prognosis. **Method:** Retrospective analysis on pts with biopsy proven advanced NSCLC who received checkpoint immunotherapy at two large institutions in the US. Patient charts were reviewed to obtain data on demographic characteristics including race, gender, age, and smoking history. Next generation sequencing (NGS) results were obtained from Guardant Health and Foundation One testing in blood and in tissue, respectively. We assessed progression-free survival (PFS) and overall survival (OS) associated with outcome. **Result:** Seventy HISP pts receiving immunotherapy underwent NGS testing from 10/2013 to 4/2018. 46% were male, 76% were smokers, 89% had adenocarcinoma, and 39% were PD-L1 positive (with 67% of those having TPS ≥ 50%). Thirty pts (43%) had one genetic aberration (GA), and 15 pts (22%) had >5 GA. The most frequent actionable GA was EGFR mutation (26%) and nonactionable mutation was KRAS (40%). Other less common GA were BRAF (10%), MET (10%), and STK11 (9%).

Survival	1 Genetic Aberration	>5 Genetic Aberrations	P value
Median PFS	**3.57m**	**3m**	**0.2767**
Median OS	**14.96m**	**3.8m**	**0.0117**

Conclusion: The presence of >5 GA (actionable and nonactionable) on NGS testing was associated with worse OS when compared to pts with one GA. There was no difference in PFS. In addition, PD-L1 incidence in HISP pts is high with a larger proportion of pts expressing ≥ 50% TPS compared to what is reported for NHW. Given the numerous nonactionable GA encountered, it is clear that continued development of targeted therapies would keep benefitting pts. Increased NGS profiling in HISP pts could potentially broaden treatment and clinical trial options to serve this purpose.

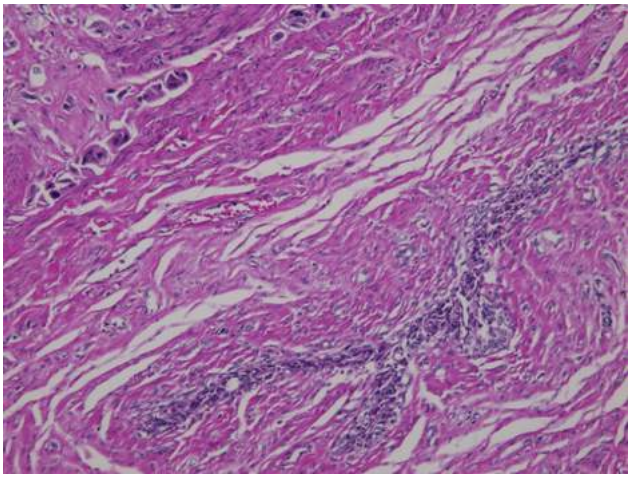
EP1.01-89 RETROPERITONEAL METASTASIS WITH MARKED FIBROSIS FROM LUNG ADENOCARCINOMA: AN AUTOPSY CASE REPORT

H. Ota[1], E. Narisawa[1], H. Chiba[1], H. Nakayama[1], Y. Tsukumo[1], A. Sakamoto[1], N. Honma[2], T. Ota[1]

[1]*Omori Red Cross Hospital, Tokyo/Japan,* [2]*Toho University School of Medicine, Tokyo/Japan*

Background: Retroperitoneal metastasis of lung cancer is rare. Here we report a unique case of retroperitoneal metastasis with fibrosis from lung adenocarcinoma. Case: A 73-year-old woman was admitted to the hospital in June 2018 because of nausea and vomiting of a few days' duration. In February 2018 she had received a diagnosis of lung adenocarcinoma (clinical T3N3M1a stage IVA, epidermal growth factor receptor [EGFR] mutation positive, exon 19 deletion) in the right lower lung and was taking afatinib 20 mg once daily. On admission, chest radiography and computed tomography (CT) showed that the primary tumor was smaller than at the time of diagnosis; however, abdominal CT showed a new retroperitoneal lesion and right hydronephrosis. Contrast-enhanced CT and MRI scan revealed poorly marginated soft tissue around the duodenum and inferior vena cava. She underwent gastrojejunostomy and biopsy of the peritoneum after duodenal obstruction was revealed by examination of the upper gastrointestinal tract (Figure 1). Analysis of the biopsy specimen revealed EGFR mutation–positive adenocarcinoma with exon 19 deletion, which was consistent with retroperitoneal metastasis of the lung adenocarcinoma. She was treated with CBDCA/PEM and CBDCA/PEM/BV each one cool [DK1] but developed cerebral infarction and died 104 days after admission.

Method: Section not applicable **Result:** Autopsy showed that right ureteral obstruction and hydronephrosis were caused by markedly sclerotic retroperitoneum. Histopathologic examination revealed marked fibrosis with scattered adenocarcinoma (Figure 2).



Conclusion: Although rare, metastasis of non–small lung cancer should be considered in patients with doudenal obstruction or hydronephrosis.

Keywords: Retroperitoneal metastasis, fibrosis, lung adenocarcinoma

EP1.01-90 THE PROGNOSTIC ROLE OF MEAN PLATELET VOLUME IN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

K. Cholidou[1], N. Anagnostopoulos[1], D. Grapsa[1], E. Kokkotou[2], R. Trigidou[3], A. Vassias[2], S. Tsagouli[1], P. Bakakos[1], I. Kotteas[1], I. Gkiozos[2]

[1]*National and Kapodistrian University of Athens, Athens/Greece,* [2]*Oncology Center of Biomedical Research and Education, Athens/Greece,* [3]*Sotiria Athens General Hospital, Athens/Greece*

Background: Previous studies suggest the potential correlation between increased mean platelet volume (MPV) and survival in non-small cell lung cancer (NSCLC), but results are often contradictory. We herein aimed to further evaluate the prognostic value of MPV in patients with advanced-stage NSCLC in the real-world setting of a tertiary referral oncology center. **Method:** Demographic, clinicopathological and laboratory data (including complete blood count parameters) of 30 patients with stage IIIB or IV NSCLC were retrieved from the Lung Cancer registry of the Oncology Clinic of Sotiria Athens General Hospital and analyzed. All the above variables (including MPV) were correlated to each other, as well as with overall survival (OS) and progression-free survival (PFS). **Result:** Mean patients' age was 68,5 (SD=7,5) years. The majority of patients were male (76.7%), had positive smoking history (90%), squamous cell carcinoma (53.3%), and stage IV disease (76.7%). No statistically significant correlations between survival and sex, age, smoking history or tumor histology (squamous cell carcinoma versus adenocarcinoma), or between MPV and histology were noted. Worse performance status (p=0.004) and higher white blood cell count (p=0.01) were correlated with reduced OS, while increased MPV was strongly correlated both with OS and PFS (p<0.0001 in both cases). **Conclusion:** Increased MPV may correlate with improved survival of patients with NSCLC, thus potentially representing a marker of favorable prognosis. Our study findings warrant confirmation in larger prospective series

Keywords: Non-Small Cell Lung Cancer, mean platelet volume, prognostic

EP1.01-91 OUTCOMES WITH SYSTEMIC CHEMOTHERAPY WITH WEEKLY REGIMEN IN ADVANCED NSCLC PATIENTS WITH PS 2 AND ABOVE AND WITHOUT DRIVER MUTATION

H. Kancharla, P. Malik, S. Khurana, D. Jain, S. Kumar, S. Pathy

All India Institute of Medical Sciences, New Delhi/India

Background: Platinum-based combination chemotherapy is recommended as the standard treatment for patients with advanced NSCLC, but its benefit is limited to patientswith performance status (PS) of 0 or 1. However, it is not clear whether these benefits apply to patients with poor PS(2 and above)). These patients have inferior outcomes and have been excluded from clinical trials. We have analyzed the outcome of these patients who have been treated with weekly chemotherapy despite poor performance status. **Method:** We performed a retrospective analysis of patients of advanced NSCLC with poor PS (ECOG PS 2 or more) registered at our lung cancer clinic between January 2016 and December 2017 and treated with weekly chemotherapy. Patients with driver mutations who were treated with first line TKIs were excluded. Hospital case records were reviewed for baseline characteristics, treatment details and outcome data. **Result:** A total of 68 patients were found to be eligible for this analysis. Median age was 63.5 years (30-77 years, including 17(25%) patients 70 years or above. At presentation out of these 68 patients, 50(73.5%) were smokers, 22(32%) had cytological proven pleural/pericardial effusion, 7(10.2%) patients had brain metastasis and 35(51.5%) had extra thoracic metastasis (≥2 sites). Majority(61%) patients had ECOGPS 2 but 39 % had PS 3 or 4 also and 29(42%) had one or more associated comorbidities. The most common chemotherapy regimen used was weekly paclitaxel and carboplatin(82.8%) followed by single agent paclitaxel(17.8%).Majority (63%) patients could complete 4 or more

cycles of chemotherapy however 9 patients (13.2%) could receive only one cycle and 16(23%) patients even received maintenance chemotherapy. Chemotherapy was interrupted due to poor tolerance in 10(14.7%) patients and grade ¾ toxicity seen in 16(23%) % patients. At least one point improvement in ECOG PS from baseline was observed in 33 patients (48.5%) after 4 cycles of chemotherapy and objective response and disease control rates were 23.5 % and 50% % respectively. After a median follows up of 13 months, median progression free survival was 7.3 months. **Conclusion:** Systemic chemotherapy in modified doses and schedules in advanced NSCLC patients with PS 2 and above is feasible and may be associated with better symptom palliation with clinical benefit and improvement in survival. Further studies addressing this neglected subgroup are indicated.

Keywords: Weekly chemotherapy, advanced NSCLC, Poor performance status

EP1.01-92 EFFECTIVENESS OF SECOND-LINE TREATMENT WITH NINTEDANIB + DOCETAXEL (ND) IN PATIENTS WITH METASTATIC LUNG ADENOCARCINOMA

J.F. Cordoba Ortega[1], C. Adaniel[2], S. Morales[1], A. Gasol[1], J. Veas[1], A. Rodriguez[1], A. Calles Blanco[3], A. Salud[1]

[1]*Hospital Universitario Arnau De Vilanova, Lleida/Spain,* [2]*Clinica Alemana, santiago de chile/Chile,* [3]*Hospital General Universitario Gregorio Marañon, Madrid/Spain*

Background: Nintedanib is an oral angiokinase inhibitor directed against VEGFR 3, FGFR 1-3, and PDGFR alpha and beta. It is approved by the European Medicines Agency in combination with docetaxel for the treatment of metastatic lung adenocarcinoma previously treated with platinum-doublet chemotherapy. Given the efficacy of checkpoint inhibitors in the second-line treatment of advanced lung cancer, we evaluated the outcomes of ND in this setting **Method:** Patients diagnosed with advanced lung cancer between July 2015 to October 2017 at the University Hospital Arnau de Vilanova (Lleida, Spain) and treated with ND were included. The clinical history, tumor pathology, tumor biologic characteristics, treatments prior and posterior to ND were reviewed. Statistical analysis was realized using IBM SPSS Statistics 23.0 software. Overall survival (OS) was calculated by Kaplan-Meier curve, determining a median OS with 95% confidence interval and estimated mortality rates during each year of follow-up **Result:** Thirteen of 357 patients with advanced lung cancer during the time period specified were treated with ND and included in the analysis. Median follow-up was 14.4 months (range: 7.3 – 41.2 months). Median age at diagnosis was 62.1 years (range: 46-73 years). Never-smokers comprised 15.4% of the patients, ex-smokers 46.2% and active smokers 38.5%. Bone metastases were present in 23.1% of patients, while 15.4% and 15.3% had central nervous system and hepatic metastases, respectively. The majority, 69.2%, received a platinum-doublet first-line and 46.2% received pemetrexed maintenance. The median number of ND cycles was four. Responses to ND were 53.8% partial response (PR), 23.2% stable disease (SD), and 23% progressive disease, with a disease control rate (DCR) of 77%. 53.8% of patients continued with nintedanib maintenance with the following responses: 43% PR, 14.3% SD, and 42.7% progressive disease (DCR 57.3%). There were no grade 2 or greater toxicities in the nintedanib maintenance group. Fifty-four percent of ND patients received third-line therapy: 50% atezolizumab, 16.7% carboplatin + vinorelbine, 16.7% nivolumab, and 16.7% oral vinorelbine. Eleven percent of patients received fourth-line therapy. Median OS was 14.4 months (CI 95%: 11.7 – 17.1 months). OS rates at 2 and 3 years were 69.2% (CI 95%: 44,1% - 94,3%) and 23.1% (CI 95%: 0,2 - 46%), respectively **Conclusion:** ND is an effective second-line treatment for patients with advanced lung adenocarcinoma. In this descriptive analysis, the median OS associated with ND was superior to the results of Lume-Lung 1 and Checkmate 057, although the study is limited by sample size

Keywords: adenocarcinoma, Nintedanib, NSCLC

EP1.01-93 RARE IMMUNE RELATED ADVERSE EVENTS BY IMMUNE CHECKPOINT INHIBITORS IN CLINICAL PRACTICE

T. Saijo[1], A. Tanaka[1], N. Ikeda[2]

[1]*Department of Internal Medicine, Toda Central General Hospital, Saitama/ Japan,* [2]*Department of Surgery, Tokyo Medical University, Tokyo/Japan*

Background: Immune checkpoint inhibitors (ICIs) such as anti-PD-1 and PD-L1 antibodies including nivolumab/pembrolizumab and atezolizumab are available practically in Japan. While ICIs produce excellent antitumor activity and long-term survival, unexpected immune related adverse events (irAEs), which are different from those for cytotoxic drugs, have been reported. We experienced varieties of irAEs which have successfully been treated. **Method:** We retrospectively analyzed irAEs in 50 NSCLC patients treated with ICIs as clinical practice from January 2016 to November 2018 in TODA Central General hospital. **Result:** Nivolumab, pembrolizumab and atezolizumab was given in 27, 11 and 12 patients, respectively. The median age was 69 (43-84). Male/female: 40/10 patients, adenocarcinoma/squamous cell carcinoma/unclassified non-small cell carcinoma: 30/15/5 patients. Tissue proportional score for PD-L1 antibody was strongly positive/weakly positive/negative/unknown in 12/4/12/22 patients, respectively. The treatment response was CR/PR/SD/PD/NE in 3/14/2/22/9 patients, respectively. Various types of irAEs have been observed, exacerbation of rheumatoid arthritis: 1, hypothyroidism: 3, secondary adrenocortical insufficiency with ACTH isolated deficiency: 1, pneumonitis: 6, liver dysfunction: 1, neutropenia: 1, diarrhea: 1, rash: 3, infusion reaction: 1. Each irAEs had been basically managed according to algorism, such as treatment discontinuation, irritative treatment, steroid therapy, hormone replacement therapy etc. One patient, who developed multiple irAEs, diarrhea, liver dysfunction and neutropenia at same time, recovered from irAEs quickly by supportive care including steroid pulse therapy. **Conclusion:** A variety of unexpected irAEs have been experienced in NSCLC patients treated with ICIs, however, excellent tumor response was observed in 10 of 13 patients who developed irAEs. In patient who showed multiple irAEs, tumor size was decreased significantly by nivolumab therapy and tumor progression was not observed 33 months after the final nivolumab administration. IrAEs associated with ICIs are diverse and difficult to predict, so safety management and early detection are important.

EP1.01-94 THE ROLE OF NEOADJUVANT CHEMO-IMMUNOTHERAPY IN UNRESECTABLE NON-SMALL CELL LUNG CANCER

M. Oh[1], A. Davis[1], R. Lentz[1], N. Peterman[2], A. Robertson[2], R. Srivas[2], N. Lambert[2], T. Wilson[2], H. Tezcan[2], A. Bharat[1], Y.K. Chae[1]

[1]*Northwestern University Feinberg School of Medicine, Chicago/United States of America,* [2]*Lexent Bio, San Francisco/United States of America*

Background: Current practices and guidelines invoke a limited role for neoadjuvant therapies in NSCLC. These strategies are not considered for use in advanced, unresectable disease. However, the development of immune checkpoint inhibitors has drastically improved the efficacy of systemic treatments for NSCLC. **Method:** We describe the case of a patient who was diagnosed with squamous cell carcinoma of the lung. **Result:** Imaging demonstrated a 7.9-cm right lower lobe lesion, a 1.8-cm satellite right middle lobe nodule, and ipsilateral mediastinal lymphadenopathy, consistent with stage IIIB disease. The tumor biopsy exhibited 5% PD-L1 positivity in tumor cells. Tissue next generation sequencing (NGS) revealed loss-of-function mutations in *RB1*, *TP53*, and *EP300*, copy number gain in *PIK3CA*, and tumor mutational burden of 4.3/Mb. Analysis of circulating tumor DNA (ctDNA) demonstrated a highest allele fraction of 4.1% (*TP53* mutant clone). As the tumor was deemed unresectable, the patient was started on carboplatin, nab-paclitaxel, and pembrolizumab. Follow-up imaging at 12 weeks after 4 cycles showed partial response, with significant reduction in tumor size and improvement in lymphadenopathy. After tumor board discussion, the decision was made to proceed with surgical resection. A right thoracotomy with bilobectomy was successfully performed. Resected tumor demonstrated major pathologic response with less than 5% viable cancer cells. Whole-genome sequencing of plasma was also carried out on blood collected over the course of treatment.

The observable cancer signal shrank to less than 5% of the baseline as early as 25 days after treatment start. Finally, repeat ctDNA analysis 6 weeks after the surgery showed no detectable somatic variants. **Conclusion:** Conversion of unresectable tumors in NSCLC may be more feasible with modern treatment regimens. The potential efficacy of neoadjuvant strategies using chemoimmunotherapy warrants further clinical investigation.

EP1.01-95 UP-REGULATION OF C-MET BY COX-2 PROMOTES RESISTANCE OF GEFITINIB IN NSCLC PATIENTS

F. Wang

Huazhong University of Science and Technology, Wuhan/China

Background:c-Met amplification is one of the reasons for Gefitinib resistance in NSCLC patients. **Method:** 1.Explore the mechanism of the up-regulation of c-Met by Cox-2; 2.Combination of Cox-2 inhibitor and Gefitinib can overcome Gefitinib resistance in cells or animal study; 3.Test the expression pattern or activity of Cox-2 in NSCLC patients, and evaluate the possibility of Cox-2 serving as biomarker for Gefitinib resistance and prognosis for NSCLC patients. **Result:** 1.Both c-met and Cox-2 are highly expressed in Gefitinib resistant lung cancer cell lines; 2.Cox-2 is highly expressed in malignant lung adenocarcinoma than in matched normal tissues; 3.Inhibition of Cox-2 can decrease c-Met expression, and promote apoptosis induced by Gefitinib in Gefitinib resistant cells. **Conclusion:** Up-regulation of c-Met by Cox-2 promotes resistance of Gefitinib in NSCLC patients

Keywords: NSCLC; Cox-2; c-Met

EP1.01-96 METASTATIC LYMPHOEPITHELIAL LUNG CANCER

A. Nourallah, S. Qureshi

Al Mana Group of Hospitals, Al Khobar/Saudi Arabia

Background: NSCLC remains the leading cause of cancer deaths globally. Lymphoepithelial-like carcinoma (LELC) of the lung, (EBV)-driven tumor; mostly found in East Asian population; is not only one of the rarest subtypes of non-small cell lung cancer (NSCLC) but is also quaint to have a good prognosis. Advanced or metastatic Lymphoepithelial lung cancer is even rarer. LELC of the lung is traditionally considered be chemo-sensitive; although recurrences common lending to chemo-related toxicity and increased morbidity. High predilection of LELC for Programmed Death Ligand-1 (PDL-I) positivity and its long established association with EBV, led to the exploration of the role of PD- 1/PDL- 1 inhibitors in its management. **Method:** poster / case report **Result:** There have been only 4 cases reported in literature highlighting the use of PDL/PDL-1 inhibitors in LELC of lung and that too in recurrent/relapsed setting; out of which three had a favorable outcome and only one patient was treated with Pembrolizumab. We report the first case of a young Pilipino female who presented with metastatic LELC of the lung with vertebral metastases causing severe lower backache; initially treated with chemotherapy, followed by Pembrolizumab alone due to high PDL-I expression in her tumor, resulting in complete remission of symptoms and radiological evidence of complete metabolic resolution of multiple metastatic bony lesions. This case not only necessitates the need for larger prospective trials to assess the role or PD- 1/PDL-1 inhibitors in this rare kind or lung cancer but also reiterates the long-brewing dilemma regarding the duration of treatment with these agents after achievement of complete remission. **Conclusion:** Pembrolizumab used alone in high PDL-I expression, results in complete remission of symptoms and radiological evidence of complete metabolic resolution of multiple metastatic bony lesions in patients with NCSLC Lymphoepithelial-like carcinoma (LELC)

Keywords: High PDL-I expression, Pembrolizumab, Lymphoepithelial-like carcinoma (LELC)

EP1.01-97 IS SURGICAL TREATMENT SUITABLE FOR STAGE III OR IV PRIMARY LUNG CANCER?

Y. Sano, H. Shigematsu, R. Sugimoto, N. Sakao, T. Hayashi, T. Sakaue

Ehime University Hospital, Toon City/Japan

Background: It is generally known that advanced lung cancer is not an indication for surgical treatment, whereas it is an indication for chemotherapy and/or immunotherapy. We examined cases in which surgery was performed for clinical stage III or IV lung cancer and investigated whether this treatment was effective or not. **Method:** We retrospectively reviewed 34 patients who underwent radical resection for stage III or IV primary lung cancer at Ehime University Medical Hospital from October 2010 to February 2019. **Result:** In this series, 23, 5, and 6 patients had stage IIIA, stage IIIB, and stage IV disease, respectively. Following were the histological types: adenocarcinoma, 14; squamous cell carcinoma, 9; large-cell carcinoma, 5 (large-cell neuroendocrine carcinoma [LCNEC], 1); adenosquamous carcinoma, 1; pleomorphic carcinoma, 1; LCNEC + adenocarcinoma, 1; LCNEC + squamous cell carcinoma, 1; and LCNEC + small-cell carcinoma, 1. As preoperative treatment, 8 and 7 patients received full-dose chemoradiotherapy (salvage surgery) and induction chemoradiotherapy, respectively. We also included 2 cases involving salvage surgery after only chemotherapy and 1 case involving salvage surgery after chemotherapy and brain metastasis resection. The remaining 16 patients underwent surgery without any pre-surgical treatment. In addition, adjuvant chemotherapy was administered in 17 cases. In a mean observation period of approximately 4 years, the overall 3-year and 5-year survival rates were 57.2% and 30.6%, respectively. In patients with clinical stage IIIA disease, the 3-year and 5-year survival rates were 55.9% and 21.7%, respectively. In patients with clinical stage IIIB disease, the 3-year and 5-year survival rates were 75% and 50%, respectively. In patients with stage IV disease, the 3-year and 5-year survival rates were 50% and 33.3%, respectively. In patients without any multimodal treatments (n = 16), the 3-year and 5-year survival rates were 55.0% and 23.6%, respectively. In patients who underwent surgery after induction chemoradiotherapy (n = 7), the 3-year and 5-year survival rates were 85.8% and 42.9%, respectively. In patients who underwent salvage surgery (n = 11), the 3-year and 5-year survival rates were 41.7% and 41.7%, respectively. **Conclusion:** Long-term survival can be achieved even in stage III or IV lung cancer patients by combining multimodal treatment with surgery in appropriate cases.

Keywords: Advanced lung cancer, salvage surgery, induction chemoradiotherapy

EP1.01-98 OUTCOMES OF NON-SMALL CELL LUNG CANCER PATIENTS WITH BRAIN METASTASIS TREATED BY WHOLE BRAIN RADIOTHERAPY, A SINGLE INSTITUTION EXPERIENCE

S. Giridharan, A. Jegannathen, S. Vengalil, S. Gilani, H. Weli

University Hospitals of North Staffordshire, stoke on trent/United Kingdom

Background: Whole brain radiotherapy (WBRT) is predominantly used in the treatment of brain metastasis but recent data suggests that it does not significantly contribute to improved overall survival in patients. This study was carried out to review our practice by assessing the survival outcome for NSCLC patients with brain metastasis treated with WBRT in relation to the QUARTZ trial data (Mulvena et al, 2016). **Method:** A retrospective study of such patients over a period of 12 months was carried by obtaining data from electronic record systems and radiotherapy records. Data demographics and analysis of overall survival were calculated and comparison was made with literature findings. **Result:** Over 12 months 39 patients with brain metastasis had received WBRT (30G in 10# or 20G in 5#). 68% (n=29) were of NSCLC origin with a gender ratio of 1:1. The average age at diagnosis of NSCLC was 67.8 and 70 years for males and females respectively. Majority of NSCLCC patients treated with WBRT had a WHO performance status (PS) of 1(41.3%, n=12) or 0 (27.5%, n=8). Mean survival following treatment with WBRT was 16.7 weeks. The median survival was 10 weeks and average ages of death in the female and male patients were 67.8 and 70 years respectively. An incidental finding of longer survival (31.8 weeks) was noted in patients treated with 30Gray and 10 fractions compared with those treated with 20Gray and 5# (9.5 weeks). 43.8% of those receiving 30Gray and 10 fractions were of PS 0 in contrast with 14.2% of those receiving 20G in 5#. **Conclusion:** The

median survival in our patients treated with WBRT was comparable to that obtained in the QUARTZ study (9.2 weeks in those who received WBRT and optimal supportive care). Although a retrospective study, it is suggestive of an above average survival outcome in our practice when compared to the multinational QUARTZ study. The incidental observation of higher survival in the group who received higher RT dose and fraction may be explained by clinical decision influencing RT categorisation due to the fact that patients with better performance status are more likely to tolerate higher doses of RT and be given same.

Keywords: WBRT, Lung cancer, brain metastasis

EP1.01-99 EFFECT OF IMMUNE CHECKPOINT INHIBITORS RE-ADMINISTRATION IN NON-SMALL-CELL LUNG CANCER PATIENTS

T. Kawajiri, T. Tamura, T. Nishi, K. Kudo, S. Kuyama

National Hospital Organization Iwakuni Clinical Center, Iwakuni/Japan

Background: Immune checkpoint inhibitors, drugs targeting the programmed cell death 1 (PD-1) and programmed cell death ligand 1 (PD-L1) pathways, are approved for the treatment of patients with non-small-cell lung cancer (NSCLC) with impressive clinical activity and durable responses in some patients. But the re-administration of immune checkpoint inhibitors have not be clarified. **Method:** From December 2015 to December 2018, 93 NSCLC patients received immune checkpoint inhibitor monotherapy. We retrospectively evaluated these 93 patients. **Result:** 6 patients received re-administration of immune checkpoint inhibitors. Median progression free survival of immune checkpoint inhibitors initial treatment and re-administration were 98 and 55 (p = 0.139). Overall response rate was 24.7% and 0% (p = 0.331) and disease control rate was 53.7% and 16.7% (p = 0.105). There was no significant difference between initial treatment and re-administration. The effect of re-administration of immune checkpoint inhibitor is not so high, but one patient received more than 6months. **Conclusion:** The effect of re-administration of immune checkpoint inhibitors are not high, but few patients can receive long term of therapy.

Keywords: non-small-cell lung cancer, Immune Checkpoint Inhibitors, Re-administration

EP1.01-100 EVALUATION OF THE CLINICOPATHOLOGICAL FEATURES OF PATIENTS IN WHOM RESIDUAL CARCINOMA IN BRONCHIAL STUMP AFTER SURGERY FOR LUNG CANCER

Y. Kameda[1,2], T. Morohoshi[2], H. Koga[3], K. Ando[2], Y. Tsuura[2], M. Masuda[4]

[1]*Yokohama Rosai Hospital, Yokohama/Japan,* [2]*Yokosuka Kyosai Hospital, Yokosuka/Japan,* [3]*Yokosuka Kyosai Hospital., Yokosuka/Japan,* [4]*Yokohama City University Graduate School of Medicine, Yokohama/Japan*

Background: Operation for lung cancer should be carried out with no residual carcinoma at bronchial stump. Rarely, we encounter unexpected microscopic residual carcinoma at surgical bronchial stump after surgery. Additional therapy for these patients is still controversial. **Method:** From January, 2008 to December, 2018, 812 consecutive patients with non-small lung cancer underwent surgery (99 of segmentectomy, 694 of lobectomy, and 19 of pneumonectomy) in our institution. Among them, there were 7 cases (0.9%) which had bronchial stump with residual cancer cells. We investigated the clinicopathological characteristics and outcomes of these patients retrospectively. **Result:** The procedures for the 7 cases consist of 5 lobectomy, 1 segmentectomy, and 1 pneumonectomy. In 3 cases, frozen diagnosis were done and in 2 of 3 cases additional resection were done. Histologically, there were 4 case of adenocarcinomas and 2 of squamous cell carcinomas, and 1 of adenosquamous cell carcinoma. 3 cases were stage IIIB(pT4N2M0, pT3N2M0), and 3 cases were IIIA (pT2bN2M0, pT4N1M0), 1 case was stage II*B (pT1bN1M0) respectively. All cases had lymphatic invasion microscopically.* 6 cases developed recurrence or distant metastasis. 2 had local recurrence at bronchial stump and 4 had distant metastasis (1 was in brain, 1 was at lymph nodes, 1 was at vertebrae, 1 was at bilateral lungs). 5 cases were received postoperative additional therapies. 4 cases were received cytotoxic chemotherapy only, and another case was recieved cytotoxic chemotherapy and TKI. None of them were received radiotherapy for bronchial stump. 5 cases passed away because of cancer progression and 1 case was because chronic heart failier. Another case is alive with lung metastases taking TKI therapy. In all cases, preoperative CT scan didn't show bronchial wall thickning, and preoperative bronchoscopic findings showed normal bronchial mucosa. **Conclusion:** In surgical cases of non-small cell lung cancer, 1.2% had microscopic residual cancer at surgical bronchial stump. Our study revealed that such cases tended to have a relapse as distant metastasis rather than local recurrence. Preoperative evaluation whether bronchial invasion exists or not is difficult and post-operative additional treatment strategy is still uncertain. In postoperative follow-up, systemic survey for not only local region but distant organs is necessary.

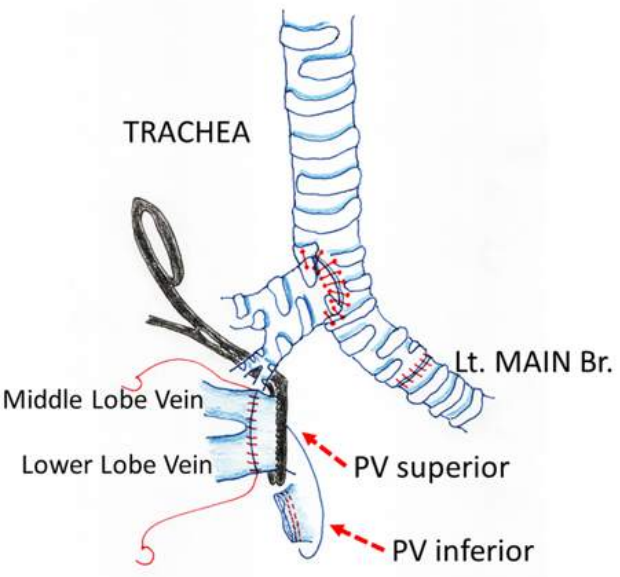
Keywords: Lung cancer, Residual carcinoma, Bronchial stump

EP1.01-101 TRANSPOSITION OF THE PULMONARY VEINS FOR MOBILIZATION OF RT-MIDDLE AND LOWER LOBES FOR SAFE RECONSTRUCTION AFTER CARINAL RT-UPPER LOBECTOMY

T. Shiraishi, T. Sato, S.-I. Yamashita, A. Iwasaki

Fukuoka University, Fukuoka/Japan

Background: A variety of techniques for reconstruction of the carina after carnal or carinal right upper lobe resection have been proposed. The most important point to accomplish this complex surgery is to achieve safe tension free airway anastomosis. Here we report a case of carinal right upper lobectomy, in whom transposition of the middle and lower pulmonary veins to the opening of the *right superior pulmonary vein* was performed to achieve safe tension free anastomosis between the trachea and right intermediate bronchus (RIB). **Method:** A 70-year-old female was admitted with severe cough. Bronchoscopy and CT scan revealed an intraluminal tumor obstructing the right main bronchus. A biopsy returned a diagnosis of adenoid cystic carcinoma. After tumor debulking by rigid-bronchoscope, extension of the tumor to the RIB and left main bronchus (LMB) was clarified and it was judged that complete resection of the lesion is possible by carinal right upper lobectomy. **Result:** A standard posterolateral thoracotomy was performed. Firstly, the trachea and LMB were transected at 2 cartilage rings above and below the carina respectively, and end-to-end anastomosis was safely performed. Then the RIB was transected immediately after the tumor invasion and the carinal right upper lobectomy was completed. Because the patient's LMB was narrow, side-to-end anastomosis of the RIB to the lateral wall of LMB was considered to be at high-risk for anastomotic stenosis. Thus the most desirable reconstruction procedure of the RIB was thought to be the side-to-end anastomosis to the lateral wall of the trachea. However, the opening of the RIB was far apart from the desirable anastomosis point of the trachea despite mobilization procedures such as right hilar release. The right middle and lower pulmonary veins were thus resected and transferred to the opening of the *superior pulmonary vein* and anastomosed by the double-barrel fashion. The opening of the RIB was then elevated and implanted to the lateral wall of the trachea.



EPOSTERS

Conclusion: The technique of pulmonary venous transposition can be an excellent airway release maneuvers to achieve safe tension free anastomosis between trachea and RIB in case of carinal right upper lobectomy.

EP1.01-102 EFFICACY AND TOXICITY OF ERLOTINIB AND GEFITINIB IN MOROCCAN PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER WITH EGFR MUTATION

N. Benchakroun[1], N. Minoungou[2], Z. Bouchbika[1], H. Jouhadi[1], N. Tawfik[1], S. Sahraoui[1], A. Benider[1], A. Acharki[2], M. Lemzah[2]

[1]*CHU Ibn Rochd, casablanca/Morocco,* [2]*CHU Ibn Rochd de Casablanca, casablanca/Morocco*

Background: BACKGROUND Lung cancer, the second most common cancer in Morocco, is a public health problem. It is also the leading cause of cancer death in the world because its prognosis is poor and the diagnosis is often made at a metastatic stage. The advent of tyrosine kinase inhibitors has improved survival in patients with epidermal growth factor receptor mutation (EGFR) There are few studies in Morocco, the aim of this study was to evaluate the efficacy and safety of anti-EGFR in patients with non-small cell lung cancer with EGFR mutated in Morocco. **Method:** METHODS We had collected twenty-three patients followed for metastatic non-small cell lung cancer with EGFR mutation and management in the onco-radiotherapy department of the IBN ROCHD University Hospital of Casablanca (MOROCCO) **Result:** RESULTS Of the twenty-three patients collected, the sex ratio was 7 men to 16 women, the average age was 59 years, only one case had a history of smoking, all cases had adenocarcinoma, the mutation on exon 19 was found in 87%. The median progression-free survival was 4 months and the median overall survival was 12 months, For tolerance; diarrhea and folliculitis were found in all patients with 50% grade II. **Conclusion:** CONCLUSIONS The EGFR mutation appears to be more frequent in women and non-smokers, and anti-EGFR treatment improves survival with a particular tolerance profile that should be known.

Keywords: metastatic lung cancer, EGFR mutation, advanced NSCLC

EP1.01-103 LONG-TERM RESPONSE TO SECOND-LINE AFATINIB FOR THE TREATMENT OF ADVANCED LUNG SQUAMOUS CELL CARCINOMA

K. Ma, Y. Guo, X. Wang, M. Sun, Y. Xu, C. Sun, S. Qiu

First Hospital of Jilin University, Changchun/China

Background: Lung squamous cell carcinoma (SqCC) with large heterogeneity and complex genetic map accounts for 25–30% of non-small-cell lung cancer (NSCLC) cases. SqCC is lack of defined molecular targets and often diagnosed at a advanced stage, which contribute to poor prognosis. Afatinib is an irreversible ErbB family inhibitor that is approved for the second-line treatment of patients with advanced SqCC who progressed after platinum-based chemotherapy based on the significant clinical benefits in Lux-Lung8. **Method:** We presented a case of a 56-year-old male with a 30-year history of smoking was diagnosed as SqCC of the left lung (cT2N3M0, IIIB). After neoadjuvant chemotherapy +sugery + adjuvant chemotherapy, CT scans showed disease progressed with disease-free survival (DFS) of 12 months. Thus, continuous chemoradiotherapy was administered. Seven months later, chest CT suggested that the disease progresssed again. Subsequently, the patient was enrolled into LUX-Lung 8 study and began the second-line therapy of afatinib (40 mg/day). **Result:** The patient remaining in stable disease (SD) after 8 weeks and achieving complete response(CR) after 12 weeks treatment.The patient is still alive and the disease has not progressed more than 5 years since initiation of treatment. There's no obvious side effects during the treatment. **Conclusion:** We found that the patient had a favorable progosis with the overall survial of more than five years treated with afatinib. Long-term response to afatinib in this case provides an important reference for the treatment of patients with advanced SqCC.

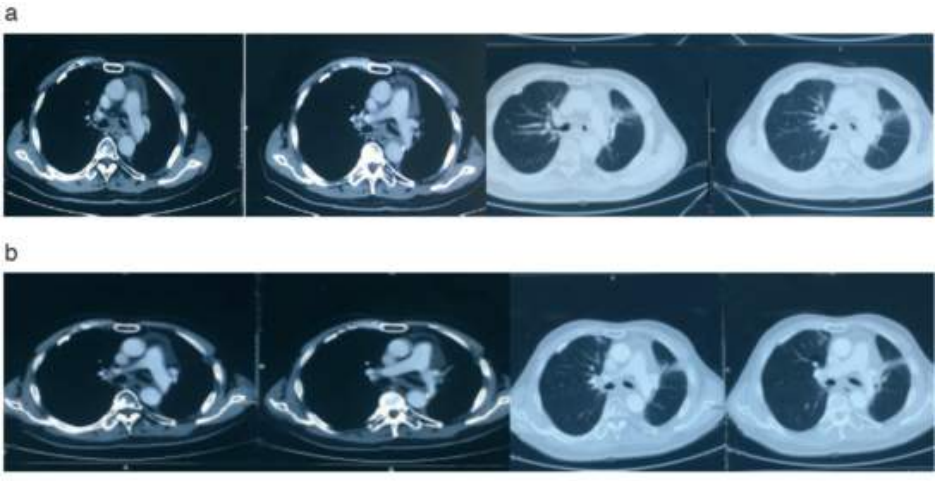

Fig. 1 (a) CT scan showing PD before enrolled into Lux-Lung8.

(b) showing CR after 12 weeks treatment of second-line afatinib.

EPOSTERS

EP1.01-104 DENOSUMAB EXPERIENCE IN LUNG CANCER PATIENTS WITH BONE METASTASES

D. Erdem

Bahcesehir University Medical Faculty, Samsun/Turkey

Background: Denosumab, is a monoclonal antibody against receptor activator nuclear factor kappa B ligand (RANKL). It inhibits the bone resorbtion and therefore decreases skeletal related events (SRE). It is practically used instead of zoledronic acid in the tumors with bone metastasis. This study aims to reveal general characteristics and adverse event profile of lung cancer patients with bone metastasis. **Method:** This study includes 17 patients referred to outpatient clinic who have lung cancer with bone metastasis between July 2014 and July 2018. We retrospectively analyzed the data. The patients who were on denosumab treatment at least 2 months were included. **Result:** All of the patients were men (n=17). The median age was 66,8 years old (range 34-84 years). All of the patients had non small cell lung cancer histology. Six patients (35,2 %) had squamous cell carcinoma and eleven patients were with adenocarcinoma histology. Except for two patients, all had metastatic disease. 3 had bone metastasis after the cancer diagnosis while others had bone metastasis initially. Seven patients had another metastatic sites besides bone metastasis and the most common metastatic site was lung (57,1 %). Among eleven adenocarcinoma patients, 4 had EGFR mutation (36 %): 2 with exon 19 deletion and 2 with exon 21 mutation. These 4 patients had anti-EGFR treatment. The patients had denosumab in the range of 2-33 months, with the median 6,5 months. 10 patients had radiation therapy besides denosumab treatment. Six patients (35,2 %) were switched from zoledronic acid therapy to denosumab because of renal failure. There was no hypocalcemic status because all the patients had laboratory checks for calcium, vitamin D and albümin and treated according to the deficiency before denosumab therapy. Also during denosumab treatment we did not see any osteonecrosis because all had undergone dentist examination before the initiation of the drug. 29,4 % (five patients) died during the therapy. All of the patients passed on because of the disease progression. **Conclusion:** Bone is the most common metastatic site of lung cancer. Bone metastasis cause morbidities like pain, fracture, hypercalcemia and spinal cord compression. In our study, unlike the literatüre, there were no hypocalcemia or osteonecrosis. This outcome may be connected not only the shortness of the follow-up but also the initial replacement of calcium and vitamin D. Because of being effective and with less toxicity, denosumab may be a positive option in lung cancer patients with bone metastasis.

Keywords: lung, cancer, denosumab

EP1.01-105 EXPERIENCE IN TREATING RECURRENT NON-SMALL LUNG CANCER PATIENTS AFTER SURGERY WITH IMMUNE-CHECKPOINT INHIBITOR

M. Yamaguchi, T. Matsubara, S. Takamori, N. Haratake, R. Toyozawa, N. Miura, T. Seto, M. Takenoyama

National Hospital Organization Kyushu Cancer Center, Fukuoka/Japan

Background: Recent rapid advancements in the development of chemotherapy, including immune checkpoint inhibitors (ICIs), such as program death-1 (PD-1) inhibitor or program death-ligand 1 (PD-L1) inhibitors, in the field of non-small cell lung cancer (NSCLC) have remarkably prolonged patients' survival. Several clinical trials currently underway are assessing the efficacy of ICIs in adjuvant chemotherapy (AC) following complete resection of Stage I-IIIA NSCLC. One of the issues with AC for completely resected NSCLC is the limited proportion of patients who benefit from such treatment, as some patients will experience recurrence despite AC while others will not experience recurrence even without AC. Given the emergence of adverse events (AEs), including immune-related AEs at a constant rate, the appropriate timing of treatment with ICI remains unclear whether AC or at the time of recurrence. **Method:** In this single-institutional retrospective study, to clarify the treatment effect of ICIs in terms of the survival or response, we reviewed 21 patients treated with ICIs for recurrent NSCLC who had undergone complete surgical resection between March 2016 and October 2018. **Result:** The median age was 61 years old (range: 47-75 years old). There were 16 men and 5 women. Thirteen patients had adenocarcinoma, 5 had squamous cell carcinoma, and 3 had others. The PD-L1 expression by 22C3 antibody was <1% in 7 patients, 1%-50% in 3 patients, >50% in 5 patients and not done in 6 patients, and the treatment lines of ICIs was first- to second-line in 8 patients and third-line or later in 13 patients. The response was partial response (PR) in 3 patients, stable disease (SD)in 10 patients, progressive disease (PD) in 6 patients and not evaluable in 2 patients. The median overall survival time from the initial administration of ICIs was 22.8 (2.0-80.1) months, while that from surgical resection was 63.7 (9.5-109.7) months. **Conclusion:** The efficacy of administering ICIs after recurrence should be compared with that of AC with ICIs.

Keywords: non-small cel lung cancer, immune-checkpoint inhibitor, recurrence after surgery

EP1.01-106 A SPECIAL CASE OF SYNCHRONOUS MULTIPLE PRIMARY LUNG CANCER WITH MEDIASTINAL LYMPH NODE METASTASES OF UNKNOWN PRIMARY ORIGIN

K. Ma, M. Sun, Y. Xu, X. Wang, C. Sun, Y. Guo, S. Qiu

First Hospital of Jilin University, Changchun/China

Background: Coexisting lung cancers that are independent of each other and have either different or the same histology type are designated synchronous multiple primary lung cancer (sMPLC). The incidence of sMPLC is 0.2%-8% and has been increasing due to the recent development of early detection technology. Cancer of unknown primary site (CUP) accounts for 3%-5% of cancers, it rarely occurs in mediastinal lymph nodes and accounts for only 1.0–1.5% of all CUP cases. **Method:** We presented a 61-year-old man with a history of smoking and old tuberculosis. The image data showed a large mass (2.4 cm*2.3 cm*2.0 cm) in the left lower lobe, and the 5th group of mediastinum lymph nodes was enlarged, suggesting peripheral lung cancer with lymph node metastasis. Multiple GGNs had been found in both lungs and the tuberculosis in the upper lobes of both lungs was identified. No other distant metastases were detected from other image data. Left lower lobe resection and lymph node dissection were performed on the patient. **Result:** Intraoperative pathology revealed squamous cell carcinoma with no driver mutations in the left lower lobe. Adenocarcinoma harbouring the EGFR gene exon 18 mutation (G719A/G719C) was diagnosed in the mediastinum lymph node dissection. Multiple gene sequencing showed that there's no relationship was between two primary sites. The hypothesis of the primary origin of the metastatic mediastinal lymph nodes is scar cancer from tuberculosis or multiple GGNs. Chemotherapy consisting of four cycles of gemcitabine plus cisplatin were prescribed for this patient after the operation. The current status of the patient was evaluated as stable disease (SD) with a PFS of more than 12 months. https://cpaper.ctimeetingtech.com/wclc2019/submission/mediafiles/view?id=1019&type=mediafile **Conclusion:** We found a sMPLC patient with different pathological types between the lung and lymph node lesions. Lung scar cancer or GGNs is highly suspected to be the origin of the metastatic mediastinal lymph node.

Keywords: synchronous muitiple primary lung cancer, cancer of unknown primary site, Lymph node metastasis

EP1.02 ADVOCACY

EP1.02-01 PROSPECTS OF CANCER PATIENTS AND PATIENT ASSOCIATION FROM THE VIEWPOINT OF LIVE SURVEY AT PARTICIPATORY SYMPOSIUM

T. Sawa[1], K. Hamanaka[2], Y. Yamada[2], Y. Yamamoto[2], C. Sakashita[3]

[1]*Gifu Municipal Hospital, Gifu/Japan,* [2]*Cancer Patients Support Organization, Tokyo/Japan,* [3]*Japan Cancer Society, Tokyo/Japan*

Background: At the Japan Cancer Patient Meeting, which is held once a year in November 2018, a live Internet survey was conducted for the symposium "Let's talk together, patient strength". Based on the results, we discussed the status of support for cancer patients and the problems that cancer patients have. And as a patient groups, we put together requests to the government and the medical association. **Method:** We conducted an online questionnaire using the survey-monkey system immediately before the symposium, targeting participants in the cancer patient association (including online viewers). While presenting the results of the questionnaire at the symposium, we exchanged opinions with the panelists and the

participants, and summarized the contents of the request. **Result:** The total number of responses was 257 people in total, including net and documents, including 85% of cancer patients and families. At the time of cancer diagnosis, 59.5% had someone to consult, and 16.6% of those who consulted cancer survivors showed the spread of peer support activities. On the other hand, 12.6% were not available for consultation. The information that helped to get over the cancer was in order of website, patient's association, and medical staff. 95.1% of the participants felt that they could receive support and livelihood from the words of the cancer experienced person. Conversely, 90% wanted to make use of their own cancer experiences. The requests for medical institutions were in the order of palliative care, collaboration with the patient association, and home care. **Conclusion:** While the patient association activities play a role in making the most of "patient strength" through questionnaires and discussions, the place of activity, funding, and aging of the patient association officers were regarded as important issues in the future.

EP1.02-02 THE PATH OF A SURVIVOR

D. Colton

Ms., Calgary/Canada

Background: Being diagnosed with lung cancer was both the worst and best day in my life. Dying was not on my agenda but then again I lived my life the way so many do. Without thought going through the motions of living. I truly started to live after my diagnosis. Funny when you think you have a finite amount of time you live differently. From deep down; at least in some of us comes a strength and determination be change and enact change in the world around us. I found that strength and the deep feeling that I could be the pebble to start the avalanche of change and acknowledgement that seems to be so lacking for lung cancer and those affected by it. Another patient who has a bigger battle then I would ever have put it aptly. We are the invisible cancer, masked behind stigma that is difficult to shake off, myths, misinformation; finally the lack of knowledge people have relating to lung cancer. This means most patients have two fronts to fight; the disease and the stigma. One saps the life out of a person, the other takes their self-respect leaving them having to defend themselves on being diagnosed with lung cancer. I on the other hand had a rather short fight with lung cancer which leaves me the ability and the wherewithal to speak up and bring the world of lung cancer out from behind the mask into the open through dialogue, events, sharing and hopefully supporting others who hqve to endure a much harder, longer battle. Each one of us personally and with organizations need to keep our eye on the end of the road. We are all working for the same outcomes. Each has their own way of doing, presenting the knowledge, sharing. What we should have is the support of each other. A united front; each working in their own manner to achieve results. Creating a safer environment for those diagnosed to speak and be seen without the censor of stigma. Those diagnosed with lung cancer and their caregiver families belong in the world, embraced and supported throughout their ordeal. Not feeling like they need to be hidden away. Every person deserves to be the best and live the best **Method:** As an advocate and patient I continue to speak whenever opportunities present themselves. I have spearheaded and will continue to expand events bringing lung cancer to the forefront. The more it is in the public realm the easier it will be over time. **Result:** Bringing lung cancer into the light; even if one person has a better understanding then we are achieving something. **Conclusion:** not applicable

EP1.03 BIOLOGY

EP1.03-01 MOLECULAR SPECTRUM OF PATIENTS WITH JAK1 MUTATIONS IN EAST ASIAN NON-SMALL CELL LUNG CANCER

X. Yu[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Y. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Affiliated Hospital of Xiamen University, Xiamen/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: JAK1 is a critical effector of pro-inflammatory cytokine signaling and plays important roles in immune function, while abnormal JAK1 activity has been linked to immunological and neoplastic diseases. The aim of this study is to investigate mutations and prognosis of non-small cell lung cancer (NSCLC) harboring *JAK1* mutations. **Method:** A total of 933 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *JAK1* mutations and other genes were detected by next generation sequencing. **Result:** *JAK1* gene mutation rate was 1.50% (14/933) in non-small cell lung cancer, including D660G (2 patients), Q499E (1 patient), L954P (1 patient), C16* (1 patient), R239W (1 patient), S295* (1 patient), I359T (1 patient), E791K (1 patient), Q207L (1 patient), R69H (1 patient), H434Y (1 patient), K218N (1 patient) and E662Q (1 patient), and median overall survival (OS) for these patients was 13.0 months. Among them, all patients were *JAK1* gene with co-occurring mutations. Briefly, patients with (n=3) or without (n=10) co-occurring *EGFR* mutations had a median OS of 14.5 months and 13.0 months respectively (P=0.70); patients with (n=13) or without (n=1) co-occurring *TP53* mutations had a median OS of 15.0 months and 13.0 months respectively (P=0.64); patients with (n=5) or without (n=8) co-occurring *KRAS* mutations had a median OS of 11.0 months and 15.0 months respectively (P=0.79); patients with (n=3) or without (n=11) co-occurring *NF1* mutations had a median OS of 11.0 months and 20.0 months respectively (P=0.11). **Conclusion:** Althoght *EGFR*, *TP53*, *KRAS*, *NF1* gene accompanied may have less correlation with *JAK1* mutation in NSCLC patients, predict which patients may harbor *JAK1* mutations, could have implications in triaging toward *JAK1* variant identification for potential future targeted therapy. These data have implications for the identification of therapeutic target candidates.

Keywords: non-small-cell lung cancer, JAK1 mutation, prognosis

EP1.03-02 FREQUENCY OF MICROSATELLITE INSTABILITY IN PATIENTS WITH PRIMARY NON SMALL LUNG CANCER IN A SINGLE INSTITUTION FROM COLOMBIA

L. Pino[1], M. Mendoza[2], G. Saavedra[2], J. Lozano[2], C. Echevarria[2], J. Pino[3], F. Canro[2], M. Botero[2]

[1]*Fundacion Santafé de Bogotá, Bogota/Colombia,* [2]*Hospital Militar Central, Bogota/Colombia,* [3]*Gimnasio Los Cerros, Bogota/Colombia*

Background: Lung carcinogenesis is a focus of research for prognosis and development of possible therapeutic objectives. The microsatellite instability (MSI) has been described as a potential mechanism of cancer development mainly in colorectal cancer as a marker of prognosis and treatment response. In lung cancer is not known the precise frequency of MSI and its possible implications for precision therapeutics. Past trials reported a low incidence of this biological signature, but this finding could improve some immune characterization of lung cancer focused in immunotherapeutics. Is very important to know the incidence of MSI in lung cancer in a sample of latin patients to know its indicence y relation with some clinical features. **Method:** The present study is a case series were we describe microsatellite instability (MSI) in patients with primary non small cell lung cancer. First, the patients with non-small cell lung carcinomas of the Hospital Militar Central diagnosed between january 2010 and january 2016 were included, then the clinical charts of each patient were reviewed to identify clinical and socio-demographic variables. The immunohistochemical staining were realized in the paraffin blocks using the Ventana Benchmark Ultra and GX equipment allowing the identification of the mismatch repair proteins (MMRP) MLH1, PMS2, MSH2 y MSH6; defining microsatellite instability with the negativity for any of these markers. We reviewed other molecular biology signatures:EGFR mutation and KRAS in some cases were this finding could be avaliable. In Colombia there´s no health system coverage for this mutations. **Result:** 33 patients with non-small cell lung carcinoma

were included in the study. Of this patients we can identify 69.7% with lung adenocarcinoma and 30.3% with squamous cell lung carcinoma. 54.5% of the total of patients were diagnosed in stage IV (TNM 7th edition). We identified a history of tobacco exposition in 45.5% of this patients. In the immunohistochemical staining, we identify that 9.1% of all the patients had microsatellite instability (MSI high); with negativity for the expression for MHL1 gene in 2 patients and for MSH6 gene in 3 patients, all of this patients were diagnosed with lung adenocarcinoma and all of this patients were EGFR wild type, in 1 of this patients we found a registry of KRAS mutated tumor. For the MHL1-negative patients, one of them had tobacco exposition history (heavy smoker) and for the MSH6-negative patients 2 of 3 had a tobacco exposition history. Unfortunately we didn´t found any of this patients treated with immunooncology agents. **Conclusion:** In a small latin population at a single institution the present study found a frequency of 9.1% in 33 patients with non-small cell lung cancer with microsatellite instability (MSI-High). All of this patients were adenocarcinoma subtype, non related with EGFR mutations and with a correlation with tobacco exposure. Unfortunately this is a small case series and we could not establish a response to immunooncology agents because in Colombia we have this medications available since 2018. The frequency of this finding is higher than previous reports and must be confirmed in a multiinstitutional registry from latin population in development.

EP1.03-03 ASSOCIATION BETWEEN MOLECULAR SPECTRUM OF EZH2 VARIANTS AND PROGNOSIS IN PATIENTS WITH NON-SMALL-CELL LUNG CANCER IN CHINESE PATIENTS

H. Wang[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Affiliated Hospital of Academy of Military Medical Sciences, Beijing/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: Enhancer of zeste homolog 2 (*EZH2*) shows upregulated expression in tumors and is an important driver of tumor development and progression. However, the mechanism underlying the mediation of tumor aggressiveness in non-small-cell lung cancer (NSCLC) by *EZH2* remains unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *EZH2* mutations. **Method:** A total of 1122 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *EZH2* mutations and other genes were detected by next generation sequencing. **Result:** *EZH2* gene mutation rate was 0.62% (7/1122) in non-small cell lung cancer, including K515R (1 patient), I55M (1 patient), D142H (1 patient), K222N (1 patient), Q66R (1 patient), P486S (1 patient), and S652C (1 patient), and median overall survival (OS) for these patients was 20.0 months. Among them, all patients were *EZH2* gene with co-occurring mutations. Briefly, patients with (n=2) or without (n=5) co-occurring *EGFR* mutations had a median OS of 16.0 months and 20.0 months respectively (P=0.88); patients with (n=6) or without (n=1) co-occurring *TP53* mutations had a median OS of not up to now and 20.0 months respectively (P=0.79); patients with (n=2) or without (n=5) co-occurring *BRAF* mutations had a median OS of 14.0 months and 20.0 months respectively (P=0.45); patients with (n=2) or without (n=5) co-occurring *SMARCA4* mutations had a median OS of 20.0 months and not up to now respectively (P=0.88). **Conclusion:** *EZH2* mutation may predict a worse prognosis of NSCLC. Methyltransferase inhibitor may be beneficial for NSCLC patients with specific *EZH2* mutations. *EGFR*, *TP53*, *BRAF*, *SMARCA4* gene accompanied may have less correlation with *EZH2* mutation in NSCLC patients. The findings of this study could facilitate both clinical trial design and therapeutic strategies.

Keywords: non-small-cell lung cancer, EZH2 mutation, prognosis

EP1.03-04 ANALYSIS OF POST-SURGICAL SYSTEMIC INFLAMMATORY INDEXES AFTER NON-SMALL CELL LUNG CANCER SURGICAL INTERVENTION

L. Milla Collado[1,2], C. Fraile Olivero[1], M. Mecho Carratala[2], C. Cerdan Santacruz[2], J. Trujillano Cabello[2], A. Ojanguren Arranz[2], M. Montesinos[2], C. Rombolá[2]

[1]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [2]*Hospital Arnau Vilanova, Lleida/Spain*

Background: High NSCLC´s mortality rates pushes the research of new prognostic indexes further tan TNM staging and could help in better treatment´s selection. Neutrophil-Lymphocyte Ratio (NLR) preoperatively determined has demonstrated its relation with the immunologic status of the patient prior to the intervention and its capacity of "beating" tumor growing and its prognostic influence. OBJECTIVE: Evaluate the prognosis influence of NLR, Lymphocyte-Monocyte Ratio (LMR) and Platelet-Lymphocyte Ratio (PLR) in patients who underwent surgery for NSCLC with R0 resection and abscence of neoadjuvant treatment in peripheric blood determinations after surgery. **Method:** A retrospective review of all consecutive patients operated on stage I to IIIA NSCLC from may 2014 – october 2018, completely resected and with no neoadjuvant treatment. Patients with previous oncologic history, haematologic neoplasms, perioperatory blood transfussion, perioperative infections or corticosteroids treatment were excluded. Peripheral blood determinations were taken during the first 6-months follow-up period. NLR, LMR and PLR were calculated. A descriptive analysis of demographic, tumor and surgical details is done. Overall survival (OS) was calculated since the date of surgery to date of death or last follow-up date. Disease-free survival (DFS) was calculated since the date of surgery to the date of recurrence. The discrimination capacity of the ratios was assessed with the calculation of the area under the ROC curve [AUC (CI 95%)]. The relationship among relevant clinico-pathological variables, DFS and OS was calculated. Analysis of recurrence risk factors with univariate and multivariate binary logistic regression (LR) OR(95%CI) was performed. **Result:** 86 patients were included in the analysis. Median follow-up time was 45.7 months. Median OS and DFS were 27 and 24 months respectively. The AUC values of NLR [0.59(0,44-0,74)] and PLR [0,61(0,45-0,76] were not statistically significant, but value of LMR was significant with [0,70(0,57-0,83)]. The LR model found as factors associated with a higher probability of recurrence adjusted by sex and age: the value of LMR with OR=0,38 (0,20-0,73) and a higher stage than the OR=11,3 (1,89-67.5). **Conclusion:** Conversely to other publications, in our study the results showed the only relationship between LMR, tumor stage and risk of recurrence.

EP1.03-05 A META-ANALYSIS OF ASSOCIATION BETWEEN SERUM IRON LEVELS AND LUNG CANCER RISK

H. Chen[1], L. Wu[1], X. Li[1], Y. Zhu[1], K. Du[1], W. Wang[2], C. Xu[3]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China*

Background: Many studies conducted on the relationship between serum iron levels and lung cancer risk had produced inconsistent results. We therefore conducted a meta-analysis to determine whether serum iron levels were lower in lung cancer patients compared to those in controls. **Method:** A literature survey was conducted by searching the PubMed, WanFang, CNKI, and SinoMed databases for articles published as of Mar 1, 2018. Standard mean differences (SMD) with the corresponding 95% confidence intervals (CI) were executed by Stata 12.0 software. **Result:** A total of 13 publications involving 1118 lung cancer patients and 832 controls were included in our study. The combined results showed that serum iron levels in lung cancer cases had no significantly lower when compared to those in controls [summary SMD = -0.125, 95%CI= -0.439, 0.189, Z = 0.78, p for Z test= 0.435], with high heterogeneity (I2= 89.9%, P< 0.001) found. In the stratified analysis by geographic locations, consistent results were found for serum iron levels between lung cancer patients and controls both in Asian populations [summary SMD = -0.113, 95%CI= -0.471, 0.245] and European populations [summary SMD = -0.215, 95%CI= -0.835, 0.404]. **Conclusion:** Publication bias was not found when evaluated by Begg's funnel plot and Egger's regression asymmetry test.In summary, the current study showed that serum iron levels had no significant association on lung cancer risk.

Keywords: Iron levels, Lung cancer, Serum

EP1.03-06 POLD1 MUTATIONS DEFINE A UNIQUE MOLECULAR CLASS OF NON-SMALL CELL LUNG CANCER IN CHINESE PATIENTS

W. Wang[1], C. Xu[2], Q. Zhang[2], W. Zhuang[2], Y. Zhu[3], Y. Huang[2], G. Chen[2], M. Fang[1], T. Lv[4], Y. Song[4]

[1]*Zhejiang Cancer Hospital, Hangzhou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Rongjun Hospital, Jiaxing/China,* [4]*Jinling Hospital, Nanjing/China*

Background: Somatic *POLE* mutations have been found in a subset of non-small cell lung cancer (NSCLC) while *POLD1* mutations are reportedly rare in NSCLC. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *POLD1* mutations. **Method:** A total of 833 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *POLD1* mutations and other genes were detected by next generation sequencing. **Result:** *POLD1* gene mutation rate was 1.20% (10/833) in non-small cell lung cancer, including L357Rfs*36 (1 patient), R225H (1 patient), D76H (1 patient), I659M (1 patient), T582R (1 patient), A930T (1 patient), A749S (1 patient), G178V (1 patient), V455L (1 patient) and D102N (1 patient), and median overall survival (OS) for these patients was 13.0 months. Among them, all patients were *POLD1* gene with co-occurring mutations. Briefly, patients with (n=4) or without (n=6) co-occurring *EGFR* mutations had a median OS of not up to now and 11.0 months respectively (P=0.11); patients with (n=8) or without (n=2) co-occurring *TP53* mutations had a median OS of 13.0 months and 12.6 months respectively (P=0.80); patients with (n=2) or without (n=8) co-occurring *NRAS* mutations had a median OS of 15.0 months and 13.0 months respectively (P=0.61); patients with (n=3) or without (n=7) co-occurring *PTPRD* mutations had a median OS of not up to now and 13.0 months respectively (P=0.79). **Conclusion:** *POLD1* mutations represents an uncommon phenotype in NSCLC and may thus reprensent a candidate biomarker for response to immunotherapy in patients with NSCLC.

Keywords: prognosis, non-small-cell lung cancer, POLD1 mutation

EP1.03-07 PREVALENCE AND CLINICOPATHOLOGICAL CHARACTERISTICS OF EIF1AX MUTATIONS IN CHINESE PATIENTS WITH NON-SMALL CELL LUNG CANCER

W. Wang[1], C. Xu[2], Q. Zhang[2], W. Zhuang[2], Y. Zhu[3], Y. Huang[2], G. Chen[2], M. Fang[1], T. Lv[4], Y. Song[4]

[1]*Zhejiang Cancer Hospital, Hangzhou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Rongjun Hospital, Jiaxing/China,* [4]*Jinling Hospital, Nanjing/China*

Background: The *EIF1AX* gene was recently described as a new thyroid cancer-related gene. Its mutations were mainly reported in poorly differentiated (PDTC) and anaplastic thyroid cancers (ATC), but also in well-differentiated thyroid cancer (WDTC) and in benign thyroid lesions, although less frequently. The prevalence of these mutations in non-small-cell lung cancer (NSCLC) is unknown. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *EIF1AX* mutations. **Method:** A total of 923 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *EIF1AX* mutations and other genes were detected by next generation sequencing. **Result:** *EIF1AX* gene mutation rate was 1.30% (12/923) in non-small cell lung cancer, including D125N (1 patient), G6D (1 patient), R14G (1 patient), G15D (1 patient), W70C (1 patient), K3N (1 patient), G9D (1 patient), R13P (1 patient), R14S (1 patient), R57G (1 patient), G135E (1 patient), and P2L (1 patient), and median overall survival (OS) for these patients was 20.0 months. Among them, all patients were *EIF1AX* gene with co-occurring mutations. Among them, 11 patients with co-occurring mutations had a median OS of 20.0 months, and OS of one patient without complex mutations was 19.8 months. No statistically significant difference was found between the two groups (P=0.84). Briefly, patients with (n=2) or without (n=10) co-occurring *TP53* mutations had a median OS of 14.0 months and 20.0 months respectively (P=0.87); patients with (n=2) or without (n=10) co-occurring *STK11* mutations had a median OS of 4.0 months and 20.0 months respectively (P=0.02); patients with (n=3) or without (n=9) co-occurring *NRAS* mutations had a median OS of 4.0 months and 20.0 months respectively (P=0.17); patients with (n=3) or without (n=9) co-occurring *KRAS* mutations had a median OS of not up to now and 20.0 months respectively (P=0.88). **Conclusion:** There is no significant difference of molecular features in *EIF1AX* gene mutations in NSCLC. Patients with complex mutations benefited more from therapy than those with single mutations. Next generation sequencing provides a simplified strategy and reasonably high detection rate for *EIF1AX* mutation, which suggested application of the strategies into clinical molecular diagnostics.

Keywords: non-small-cell lung cancer, EIF1AX mutation, prognosis

EP1.03-08 MIR-744 FACILITATES NON-SMALL CELL LUNG CANCER PROGRESSION BY TRANSCRIPTIONAL REGULATION OF C-FOS

X. Zhu, S. Li, X. Duan

The Radiation Oncology Department, Nanfang Hospital, Southern Medical University, Guangzhou/China

Background: Metastasis is the leading cause of lung cancer associated death. Here, we focused on the function and downstream molecular mechanism of miR-744 and its potential clinical application in non-small cell lung cancer (NSCLC) progression. **Method:** The clinical cohort and data from TCGA were analyzed for the correlation of miR-744 and clinical outcomes. Multiple NSCLC cell lines and a NSCLC xenograft model were applied for the functional studies *in vitro* and in vivo respectively. Reporter assays were used for transcriptional regulatory mechanism study. **Result:** It was confirmed that the overexpression of miR-744 was significantly correlated with lymph node metastasis and poor prognosis in NSCLC. It was an independent prognostic molecular marker for NSCLC. Both *in vitro* and in vivo studies revealed that miR-744 overexpression aggravated the invasion and metastasis of NSCLC cells. MiR-744 positively regulated c-FOS by directly binding to the promoter of c-FOS. We also identified -358 to -332 bp and -221 to -192 bp upstream of c-FOS gene as the direct and efficient miR-744 binding site in c-FOS promoter region. MicroRNA-744 could regulate MAPK signaling and enhanced the resistance of lung cancer cells to radiotherapy and paclitaxel. **Conclusion:** Our findings uncover the function of miR-744 in NSCLC and reveal a novel mechanism of miR-744 in mediating growth and metastasis of NSCLC cells. Our data suggests that miR-744 may serve as a possible therapeutic target for NSCLC. Support: 81572279, 2016J004, LC2016PY016, 2018CR033.

Keywords: miR-744, transcriptional regulation, c-FOS

EP1.03-09 EPIDEMIOLOGICAL STUDY OF TSC1 MUTATIONS AMONG NON-SMALL CELL LUNG CANCER PATIENTS IN CHINA

Y. Fang[1], C. Xu[2], W. Wang[3], H. Pan[1], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Sir Run Run Shaw Hospital, Hangzhou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: The tuberous sclerosis complex 1 (TSC1) is an endogenous regulator of the mechanistic target of rapamycin (mTOR). While mTOR has been shown to play an important role in neoplasm. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *TSC1* mutations. **Method:** A total of 1106 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *TSC1* mutations and other genes were detected by next generation sequencing. **Result:** *TSC1* gene mutation rate was 1.90% (21/1106) in non-small cell lung cancer, including Q654E (2 patients), R429K (2 patients), A1072D (1 patient), R850S (1 patient), E625K (1 patient), R715Q (1 patient), A84T (1 patient), S1038G (1 patient), M1090I (1 patient), D903H (1 patient), I143N (1 patient), Q3H (1 patient), L134F (1 patient), T1065M (1 patient), V407M (1 patient), S673F (1 patient), D675Y (1 patient), Q149H (1 patient) and T1144P plus L916M (1 patient), and median overall survival (OS) for these patients was 14.0 months. Among them, all patients were *TSC1* gene with co-occurring mutations. Briefly, patients with (n=12) or without (n=9) co-occurring *TP53* mutations had a median OS of 14.0 months and 15.0 months respectively (P=0.58); patients with (n=9) or without (n=12) co-occurring *KRAS* mutations had a median OS of not up to now and 14.0 months respectively (P=0.56); patients with (n=2) or without (n=19) co-occurring *BRAF* mutations had a median OS of 18.5 months and 12.0 months respectively (P=0.71); patients with (n=4) or without (n=17) co-occurring *CDKN2A* mutations had a median OS of 8.0 months and 18.0 months respectively (P=0.47). **Conclusion:** Accompanied gene has not well been connected with *TSC1* gene mutations. Our finding expands the mutant spectrum of *TSC1* gene and adds new understanding of the phenotype.

Keywords: non-small-cell lung cancer, TSC1 mutation, prognosis

EP1.03-10 EXPRESSION OF ANTI-AGING GENE, KLOTHO IS A SURROGATE MARKER OF PEMETREXED FOR LUNG CANCER TREATMENT

K. Takegahara, J. Usuda

Nippon Medical School Hospital, Tokyo/Japan

Background: Adjuvant chemotherapy using cisplatin is recommended for patients with lung cancer p-stage IB-IIIA, who were received surgical resection completely. In order to improve the prognosis of the patients with lung cancers, we need to find a new predictive factor for anti-cancer agents and establish a new regimen for the adjuvant chemotherapy. We have previously reported that anti-aging gene Klotho expression was a prognostic factor for small cell lung cancer and LCNEC so far. Therefore, in this study, we investigate the association between the expression of Klotho and the sensitivity against anti-cancer agents, and we examined the anti-tumor tumor effect of Klotho expression. **Method:** We established a cell line, A549/Klotho, which stably overexpress Klotho, and then examined the association between the expression of Klotho and Epithelial-Mesenchymal Transition related proteins such as N-cadherin, E-cadherin, Snail, Vimentin, etc. Next, we performed the sensitivity test for various anticancer agents including pemetrexed, CDDP, paclitaxel, gefitinib, etc, using A549 cells and A549/Klotho cells. Moreover, we evaluated the role of Klotho expression against anti-tumor effect. **Result:** By western blot analysis, the expression of N-cadherin was completely inhibited in A549/Klotho cells, but in A549 cells. This result suggested that Klotho expression may regulate the expression of N-cadherin and Klotho can play an important role in cancer metastasis/invasion by regulating EMT. Moreover, we clarified that miR145 was related to the inhibition of N-cadherin in analysis of A549/Klotho cells but not miR218, miR67. A549/Klotho cells were more sensitive seven times against pemetrexed compared to A549 cells (IC50; 0.1 micro M) by MTT assay. There is no difference of sensitivity between A549/Klotho cells and A549 cells against molecular target drugs such as gefitinib, other kinds of TKI. **Conclusion:** From these results, we conclude that overexpression of Klotho may regulate the sensitivity against pemetrexed through the inhibition of expression of mir145 and N-cadherin. In the future, we may establish a new strategy of chemotherapy for patients with advanced lung cancer based on the expression of anti-aging gene Klotho.

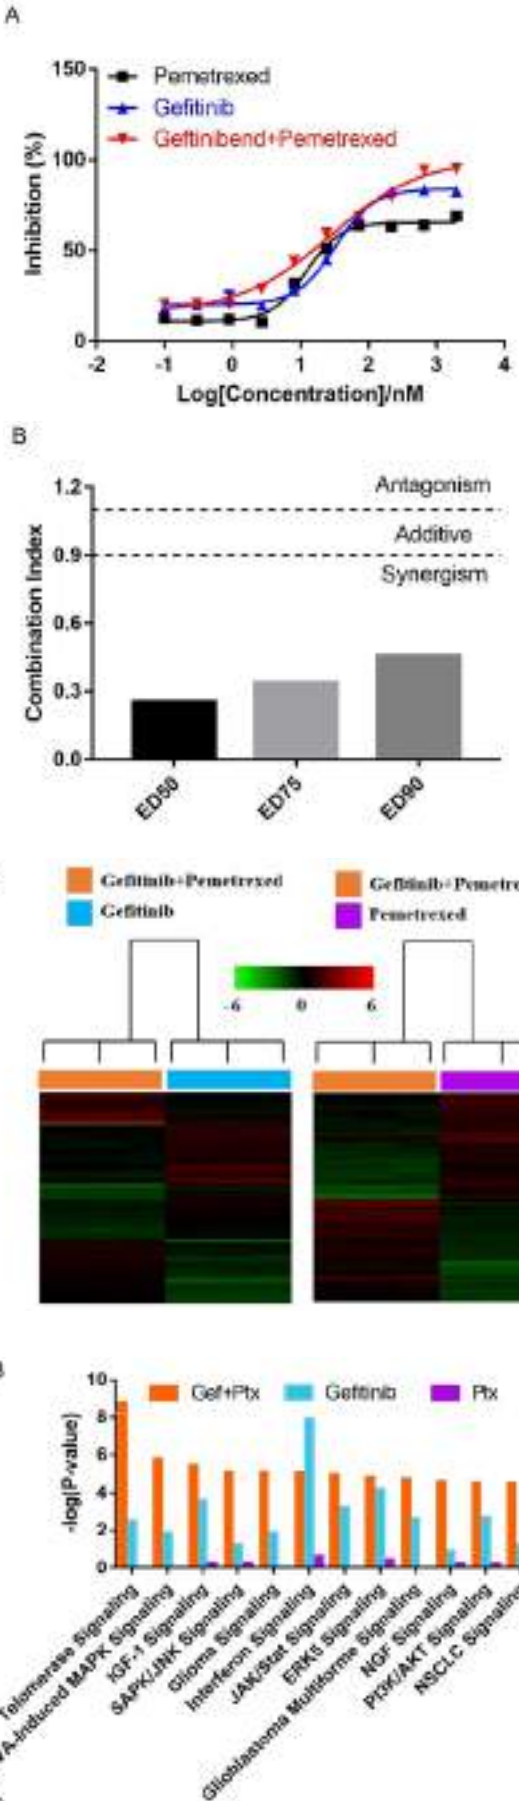
Keywords: Klotho, anti-aging gene, pemetrexed

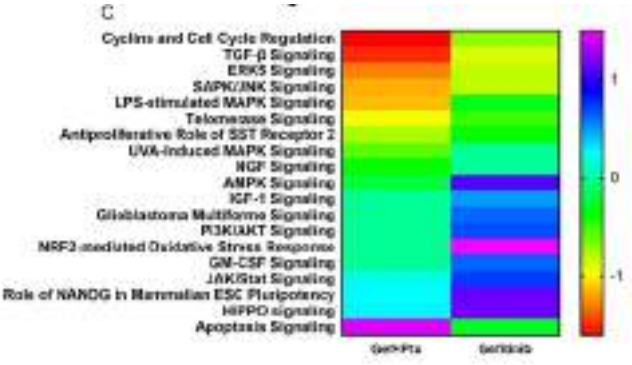
EP1.03-11 MECHANISMS OF GEFITINIB PLUS PEMETREXED ON HUMAN NON-SMALL CELL LUNG CANCER

Y. Lou, J. Xu, Y. Zhang, J. Lu, X. Zhang, H. Wang, W. Zhang, B. Han

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Resistance to EGFR tyrosine kinase inhibitors (EGFR-TKI) is often acquired in non-small cell lung cancer (NSCLC) patients during treatment. We previously demonstrated that combined treatment with EGFR-TKI gefitinib plus chemotherapy improved progression-free survival (PFS) in NSCLC patients carrying sensitive EGFR mutations. **Method:** Pharmacological interaction between gefitinib and pemetrexed was evaluated in NSCLC cell line PC-9 using MTT assay. The influence of combined treatment with gefitinib plus pemetrexed on gene expression profiles and signaling pathways has been investigated using microarray and Ingenuity Pathway Analysis (IPA). **Result:** Synergistic inhibitory effect between gefitinib and pemetrexed was observed in NSCLC cell line PC-9. Figure 1A suggested representative proliferation inhibitory effects of gefitinib, pemetrexed and combined treatment for 48 hours. Figure 1B showed CI values of concurrent gefitinib-pemetrexed treatment in PC-9 NSCLC cell line. CI values at ED50, ED75 and ED90 were shown. Furthermore, widespread gene expression changes and critical signaling pathways were induced significantly by combined treatment in PC-9 cells. Figure 2A was heatmap of gene expression prolifes in human NSCLC PC-9 cell line treated with gefitinib (blue), pemetrexed (purple) or gefitinib-pemetrexed combination (orange) with the criteria P<0.05 and |fold change |>1.5. Genes and samples were listed in rows and columns, respectively. A colour standard for data normalization was shown at the bottom with green representing downregulated genes while red representing upregulated genes. In Figure 2B, pathway enrichment of differential expressed genes was analysed using Ingenuity Pathway Analysis (IPA). Signaling pathways shown here were based on a *P<0.0001*. Figure 2C showed heatmap of critical pathways affected by combined treatment as compared to gefitinib single treatment. Heatmap colour represented the Z-score of signalling pathways. Z-score>0 meant the signalling pathway was stimulated by related treatment while Z-score<0 meant the signalling pathway was inhibited by related treatment.





Conclusion: Gene expression profiles revealed potential signaling pathways contributing to the synergism.

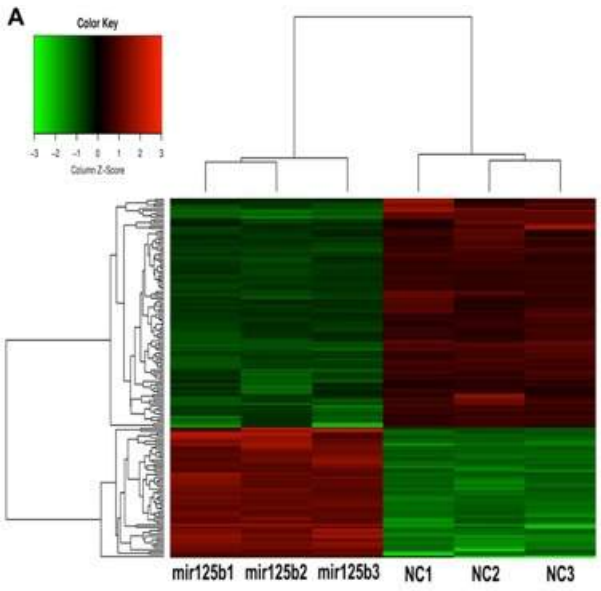
Keywords: synergism, gene expression profile, Non-Small Cell Lung Cancer

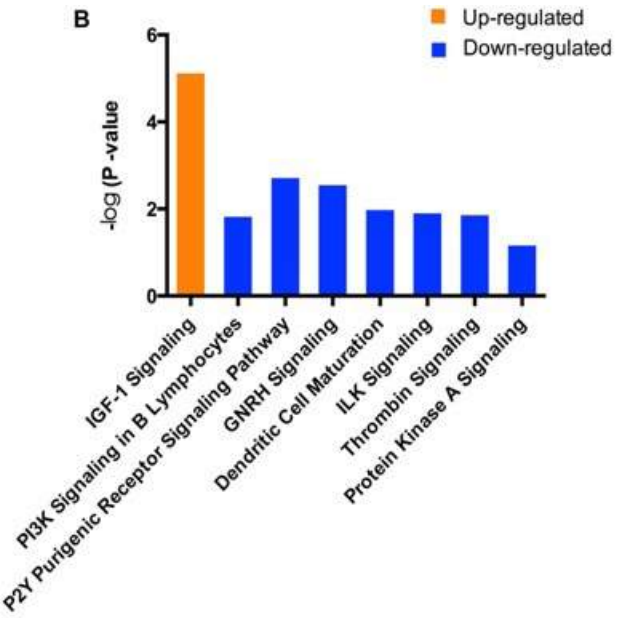
EP1.03-12 IL-10 PROMOTES TUMOR AGGRESSIVENESS IN NON-SMALL CELL LUNG CANCER VIA DOWN-REGULATED THE EXPRESSION LEVEL OF MIR-125B

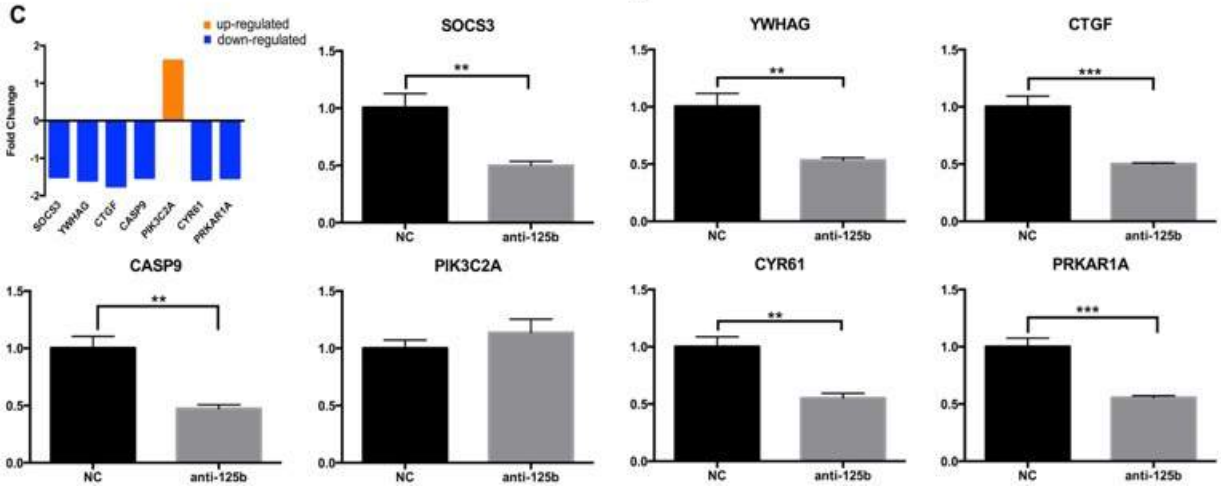
Y. Zhang, B. Han

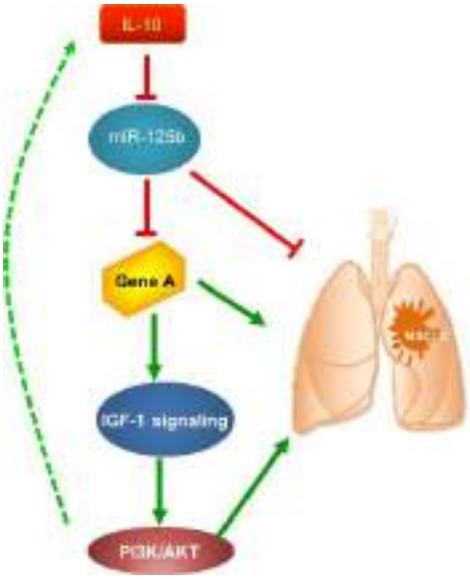
Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: IL-10 is an anti-inflammatory factor with bi-directional regulation of tumor immunity. While, the role and mechanism of IL-10 in lung cancer is not clear. The aim of the present study was to identify the potential mechanisms of IL-10 in lung carcinogenesis. **Method:** RT-PCR was used to detect the expression of miRNAs and mRNAs. CKK8 and flow cytometry assays was performed for the function experiments. Microarray analysis and IPA analysis were used to predict the potential signal pathway. **Result:** IL-10 was found significantly associated with the risk of non-small cell lung cancer (NSCLC). Meanwhile, the expression level of miR-125b in NSCLC cell line was dramatically decreased when stimulated by IL-10. The results of cell function experiments showed that miR-125b inhibited the tumor promoting effects of IL-10 in NSCLC. Then, microarray and IPA analysis found that IGF-1 signaling pathway was significantly activated after down-regulated the expression of miR-125b









Conclusion: IL-10 promotes tumor aggressiveness via down-regulated the expression level of miR-125b in lung cancer.

Keywords: miR-125b, Lung cancer, IL-10

EP1.03-13 MOLECULAR CHARACTERISTICS OF EAST ASIAN PATIENTS WITH VHL-MUTATED NON-SMALL-CELL LUNG CANCER: A RETROSPECTIVE STUDY

J. Li[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Xiamen Cancer Hospital, Xiamen/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: The von Hippel-Lindau (*VHL*) gene is inactivated frequently in sporadic clear-cell renal cell carcinomas (ccRCCs) by genetic alteration. However, the pathological or prognostic significance of *VHL* gene alteration has not been well defined in the other cancers, especially non-small cell lung cancer (NSCLC). The aim of this study is to investigate mutations and prognosis of NSCLC harboring *VHL* mutations. **Method:** A total of 972 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *VHL* mutations and other genes were detected by next generation sequencing. **Result:** *VHL* gene mutation rate was 0.72% (7/972) in non-small cell lung cancer, including W117fs*15 (1 patient), G44A (1 patient), G44V (1 patient), P81S (1 patient), R120T (1 patient), E51K (1 patient) and T100A (1 patient), and median overall survival (OS) for these patients was 22.0 months. Among them, all patients were *VHL* gene with co-occurring mutations. Briefly, patients with (n=2) or without (n=5) co-occurring *EGFR* mutations had a median OS of 22.0months and 12.0 months respectively (P=0.16); patients with (n=3) or without (n=4) co-occurring *TP53* mutations had a median OS of not up to now and 12.0 months respectively (P=0.23); patients with (n=3) or without (n=4) co-occurring *KRAS* mutations had a median OS of 3.0 months and 22.0 months respectively (P=0.07); patients with (n=2) or without (n=5) co-occurring *SETD2* mutations had a median OS of 3.0 months and 22.0 months respectively (P=0.01). **Conclusion:** The present study expanded the database on *VHL* gene mutations in NSCLC and enriched the spectrum of known somatic mutations of the *VHL* gene. Chemotherapy may be considered as a possible treatment for carriers of the mutation. *SETD2* mutated accompanied mutations might play a poor prognosis in *VHL* gene mutation NSCLC.

Keywords: non-small-cell lung cancer, VHL mutation, prognosis

EP1.03-14 CLINICOPATHOLOGIC CHARACTERISTICS AND OUTCOMES OF CHINESE PATIENTS WITH NON-SMALL-CELL LUNG CANCER AND INPP4B MUTATIONS

D. Yang[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Second Affiliated Hospital of Fujian Medical University, Quanzhou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: Inositol polyphosphate 4-phosphatase B (*INPP4B*) has been identified as a tumour suppressor in different human cancers. However, the role of *INPP4B* in the angiogenesis of human non-small cell lung cancer (NSCLC) remains unclear. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *INPP4B* mutations. **Method:** A total of 750 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *INPP4B* mutations and other genes were detected by next generation sequencing. **Result:** *INPP4B* gene mutation rate was 2.80% (21/750) in non-small cell lung cancer, including p.R623K (2 patients), p.N378S (1 patient), p.G187W (1 patient), p.V117I (1 patient), c.1721-1G>T (1 patient), p.R818* (1 patient), p.T829R (1 patient), p.Q753H (1 patient), p.L542M (1 patient), p.I68M (1 patient), p.Q814E (1 patient), p.K448N (1 patient), p.C617F (1 patient), p.Q600H (1 patient), p.G479* (1 patient), p.L155Q (1 patient), p.P572A (1 patient), p.L16V (1 patient), p.F652Y (1 patient), and p.T671S plus p.N228K (1 patient), and median overall survival (OS) for these patients was 15.0 months. Among them, all patients were *INPP4B* gene with co-occurring mutations. Briefly, patients with (n=2) or without (n=19) co-occurring *EGFR* mutations had a median OS of 20.0 months and 5.5 months respectively (P=0.01); patients with (n=17) or without (n=4) co-occurring *TP53* mutations had a median OS of 15.0 months and 14.4 months respectively (P=0.68); patients with (n=7) or without (n=14) co-occurring *PTPRD* mutations had a median OS of not up to now and 15.0 months respectively (P=0.48); patients with (n=8) or without (n=13) co-occurring *KRAS* mutations had a median OS of 17.0 months and 15.0 months respectively (P=0.68). **Conclusion:** *INPP4B* mutations were observed in 2.80 % of cases of NSCLC. *INPP4B*-mutated NSCLC can exhibit other driver gene alterations. No clinical characteristics were significantly associated with *INPP4B* mutation.

Keywords: non-small-cell lung cancer, INPP4B mutation, prognosis

EP1.03-15 COMPARISON OF PLASMA EXPRESSION OF DROSHA AND DICER MRNAS IN EARLY AND ADVANCED STAGES OF NSCLC PATIENTS

A. Grenda[1], M. Szczyrek[1], B. Kuźnar-Kamińska[2], P. Krawczyk[1], G. Balicka[1], M. Jakimiec[1], H. Batura-Gabryel[2], M. Sawicki[1], J. Milanowski[1]

[1]*Medical University of Lublin, Lublin/Poland,* [2]*University of Medical Sciences in Poznan, Poznań/Poland*

Background: Drosha and Dicer are the enzymes necessary during the miRNA biogenesis. They have the same effect on all microRNAs. Many studies have focused on profiling the expression of selected miRNAs or whole miRNom's analysis in serum or plasma, as potential tool for early detection of diseases. We would like to check, whether the expression of *Drosha* and *Dicer* mRNA is detectable in plasma of NSCLC patients, and whether it can differentiate early and advanced stages of this disease. **Method:** We enrolled 59 (43.1%) NSCLC patients in early (I-IIIA) stages and 78 (56.9%) in locally advanced or advanced (IIIB-IV) stages. We isolated total mRNA and reverse transcription PCR (RT-PCR) was performed. RT-PCR was made using High-Capacity cDNA Reverse Transcription Kit (Applied Biosystems). Real-time PCR (qPCR) was performed for assessment of *Drosha* and *Dicer* mRNA expression on Eco Illumina Real-Time PCR system device (Illumina Inc.). We used TaqMan probe Hs00203008_m1 (Applied Biosystems) for *Drosha* and Hs00229023_ m1 (Applied Biosystems) for *Dicer* mRNA expression measurement. *GAPDH* was used a housekeeping gene. Statistical analysis were performed with use of Statistica 13.1 software (Tibco). **Result:** *Drosha* mRNA expression was detectable in plasma of 57 (41.6%) patients. 17 (28.8%) patients with *Drosha* mRNA expression were in early stages and 40 (51.3%) patients were in stages IIIB or IV (χ^2=6.98, p=0.008). Expression of *Dicer* mRNA was detectable in plasma of 71 (57.8%) patients. 15 (25.4%) of patients from this group were in early stages and 56 (71.8%) – in IIIB or IV stages (χ^2=28.93, p<0.0001). Significant higher expression of *Drosha* mRNA was observed in group of patients with lymph node involvement

compared with group of patients without lymph node metastases (p=0.001). Moreover, significantly higher expression of *Dicer* mRNA was observed in group of patients with distant metastases compared with group without metastases (p=0.0002). Furthermore, we found statistically nonsignificant (p=0.07) lower expression of *Drosha* mRNA in stages IIIB-IV compared with early stages. We did not find any differences between *Drosha* or *Dicer* mRNAs expression in patients stratified by age, tumor size or histopathological diagnosis (p<0.1). **Conclusion:** Plasma expression of *Drosha* and *Dicer* mRNAs is detected more often in advanced stages of NSCLC. Probably, different mRNAs from more damaged tumor cells in more advanced disease stages are present in higher expression in blood stream. However, this proves that free mRNAs of *Drosha* and *Dicer* are mainly produced by cancer cells in NSCLC patients. indirectly, it can be concluded that cancer cells have disturbed production of microRNAs. There are necessity to use more sensitive tools (i.e. Next Generation Sequencing method) to asses expression of *Dicer* and *Drosha* mRNAs in early stages of NSCLC.

Keywords: NSCLC patients, Drosha, Dicer

EP1.03-16 LYSIMACHIA CAPILLIPES CAPILLIPOSIDE C RESTORES RADIATION SENSITIVITY IN RADIATION RESISTANT LUNG CANCER CELLS BY ENHANCING ERRFI1 EXPRESSION

K. Wu[1], B. Wang[1], Y. Xu[2], J. Feng[3], L. Zhu[1], X. Chen[4], B. Xia[1], S. Zhang[2], X. Chen[5], S. Ma[4]

[1]*Hangzhou Cancer Hospital, Hangzhou/China,* [2]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, hangzhou/China,* [5]*University of California at Los Angeles, Los Angeles/United States of America*

Background: Radiation therapy is used as the primary treatment for lung cancer. Unfortunately, radiation resistance and local failure remain to be the major clinic problems for lung cancer patients. It is therefore crucial to find new therapeutic targets and/or drugs to enhance the effects of radiation without increasing the adverse effects. Lysimachia capillipes capilliposide C (LC-C) extracts from LC Hemsl. show anti-cancer effects both *in vitro* and in vivo. The purpose of this study is to investigate a potential therapeutic impact of LC-C as a radiation sensitizer in lung cancer cells. **Method:** Non small cell lung cancer (NSCLC) cell line A549 was initially irradiated with a total dose of 60 Gy (3 Gy/Fx, 20 Fx, 2-3 Fx/week) to generate radiation-resistant cancer cell line A549-IR. RNA-seq analysis was used to examine the whole-transcriptome alteration in A549-IR cells treated with or without LC-C, and the differentially expressed genes with most significance were verified by RT-qPCR. Colony formation assays were performed to determine the effect of the target gene ErbB receptor feedback inhibitor 1 (ERRFI1) on radiosensitivity of A549-IR cells. In addition, effects of ERRFI1 on cell cycle distribution, DNA damage repair activity were assessed by flow cytometry and γ-H2AX immunofluorescence staining respectively. Western blot was performed to identify the activation of related signaling pathways. Tumor xenograft experiments were conducted to observe the effect of LC-C and ERRFI1 on radiosensitivity of A549-IR cells in vivo. **Result:** ERRFI1 was significantly up-regulated in A549-IR cells when cells were treated with LC-C (IC20=3.5 μM). With irradiation treatment, clonogenic formation decreased in the ERRFI1 overexpressed cells when comparing to the parental cells, with reduced survival fraction-2 value from 0.54±0.07 to 0.24±0.06 (p<0.01). The sensitizing enhancement ratio for LC-C was 1.667. Furthermore, ERRFI1 overexpression may enhance radiosensitivity of A549-IR cells *in vitro* by inducing G2/M phase arrest and inhibiting DNA damage repair. Overexpression of the ERRF11 decreased the activation of EGFR and STAT3 signaling pathways in A549-IR cells. Knocking down ERRFI1 expression in A549-IR cells attenuated the radiosensitization effect of LC-C. Moreover, in a A549-IR cells-derived xenograft model, combination treatment with LC-C (25 $mg \cdot kg^{-1} \cdot d^{-1}$, qod, ig) and irradiation (6Gy) dramatically enhanced tumor growth suppression comparing with LC-C or radiation alone. **Conclusion:** LC-C can restore the cells' sensitivity to irradiation through regulation of ERRFI1 expression in lung cancer cells. Combination treatment of LC-C and irradiation may serve as a promising therapeutic strategy to overcome the radiation resistance and ERRFI1 may be a poteintal therapeutic target to improve radiosensitivity in NSCLCs.

EP1.03-17 OUTCOMES OF MOLECULAR CHARACTERISTICS IN CHINESE BAP1-MUTANT NON-SMALL CELL LUNG CANCER PATIENTS

H. Ke[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Y. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Affiliated Hospital of Nantong University, Nantong/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: BRCA1-Associated-Protein 1 (*BAP1*) is a dynamic tumor suppressor which, when mutated, has been associated with an increased risk of uveal melanoma, cutaneous melanoma, mesothelioma, and several other cancers. There is some clinical evidence for the use of *BAP1* mutations as prognostic and predictive biomarker. The aim of this study is to investigate mutations and prognosis of non-small-cell lung cancer (NSCLC) harboring *BAP1* mutations. **Method:** A total of 851 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *BAP1* mutations and other genes were detected by next generation sequencing. **Result:** *BAP1* gene mutation rate was 1.88% (16/851) in non-small cell lung cancer, including H94Y (1 patient), T177P (1 patient), E198Gfs*45 (1 patient), R238K (1 patient), D34Y (1 patient), Y173C (1 patient), E450K (1 patient), G41C (1 patient), S325F (1 patient), P293L (1 patient), Q28* (1 patient), E498K (1 patient), E631Q (1 patient), H144D (1 patient), Q280* (1 patient), (1 patient) and R518L (1 patient), and median overall survival (OS) for these patients was 24.0 months. Among them, all patients were *BAP1* gene with co-occurring mutations. Briefly, patients with (n=4) or without (n=12) co-occurring *EGFR* mutations had a median OS of 14.5 months and not up to now respectively (P=0.35); patients with (n=9) or without (n=7) co-occurring *TP53* mutations had a median OS of not up to now and 24.0 months respectively (P=0.79); patients with (n=3) or without (n=13) co-occurring *CDKN2A* mutations had a median OS of 24.0 months and not up to now respectively (P=0.57); patients with (n=4) or without (n=12) co-occurring *KEAP1* mutations had a median OS of 5.0 months and 24.0 months respectively (P=0.07). **Conclusion:** *BAP1* genetic alter occurs in a subset of NSCLC, and improved understanding of the implications of *BAP1* aberrations is critical for the identification of therapeutic target candidates.

EP1.03-18 ANALYSIS OF IDH1 MUTATION SPECTRUM FROM NON-SMALL-CELL LUNG CANCER IN EAST ASIAN PATIENTS

L. Wang[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*Baotou Cancer Hospital, Baotou/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: Isocitrate dehydrogenase 1 (IDH1) is a metabolic enzyme that converts isocitrate to alpha-ketoglutarate. *IDH1* mutations are associated with the accumulation of the oncometabolite D-2-hydroxyglutarate, which acts as an epigenetic modifier, and the development of multiple malignancies. Previous studies uncovered mutations in IDH1 in several malignancies, with the most frequent mutation being IDH1 R132H. It has been demonstrated that IDH1 expression is induced in non-small-cell lung cancer (NSCLC). The aim of this study is to investigate mutations and prognosis of NSCLC harboring *IDH1* mutations. **Method:** A total of 893 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *IDH1* mutations and other genes were detected by next generation sequencing. **Result:** *IDH1* gene mutation rate was 1.23% (11/893) in non-small cell lung cancer, including Q138S (1 patient), D79V (1 patient), T373N (1 patient), C114* (1 patient), W336L (1 patient), I99M (1 patient), G104R (1 patient), R132C (1 patient), A193S (1 patient), Y34C (1 patient) and H67R (1 patient), and median overall survival (OS) for these patients was 11.0 months. Among them, all patients were *IDH1* gene with co-occurring mutations. Briefly, patients with (n=9) or without (n=2) co-occurring *TP53* mutations had a median OS of not up to now months and 8.5 months respectively (P=0.32); patients with (n=2) or without (n=9) co-occurring *KMT2D* mutations had a median OS of 11.5 months and 11.0 months respectively (P=0.80); patients with (n=5) or without (n=6) co-occurring *KRAS* mutations had a median OS of not up to now months and 8.0 months respectively (P=0.22); patients with (n=2) or without (n=9) co-occurring *CREBBP* mutations

had a median OS of 15.5 months and 8.0 months respectively (P=0.67). **Conclusion:** Our results demonstrated that decreased *IDH1* gene mutation correlated with poor overall survival in NSCLC patients. *IDH1* gene mutation may define a subset of patients with lung cancer appropriate for investigational therapeutic strategies.

EP1.03-19 THE FREQUENCY AND PROGNOSIS OF MDM2 MUTATIONS IN EAST ASIAN NON-SMALL-CELL LUNG CANCER PATIENTS

B. Wan[1], C. Xu[2], W. Wang[3], X. Zhang[1], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Z. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*The Affiliated Jiangning Hospital of Nanjing Medical University, Nanjing/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: In neoplasm, the mouse double minute 2 (*MDM2*) is an oncoprotein that contributes to the promotion of cell growth, survival, invasion, and therapeutic resistance. The aim of this study is to investigate mutations and prognosis of non-small cell lung cancer (NSCLC) harboring *MDM2* mutations. **Method:** A total of 1152 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *MDM2* mutations and other genes were detected by next generation sequencing. **Result:** *MDM2* gene mutation rate was 0.52% (6/1152) in non-small cell lung cancer, including D179N (1 patient), S84L (1 patient), T195M (1 patient), V234L (1 patient), A471S (1 patient) and E184Q (1 patient), and median overall survival (OS) for these patients was 24.0 months. Among them, all patients were *MDM2* gene with co-occurring mutations. Briefly, patients with (n=2) or without (n=4) co-occurring *EGFR* mutations had a median OS of 18.5 months and 24.0 months respectively (P=0.89); patients with (n=4) or without (n=2) co-occurring *TP53* mutations had a median OS of 24.0 months and 7.0 months respectively (P=0.05); patients with (n=2) or without (n=4) co-occurring *BRCA1* mutations had a median OS of 24.0 months and 13.0 months respectively (P=0.20); patients with (n=2) or without (n=4) co-occurring *KEAP1* mutations had a median OS of 15.5 months and 24.0 months respectively (P=0.59). **Conclusion:** *MDM2* mutations represent a distinct subset of NSCLC. Next generation sequencing showed that *MDM2* mutations commonly co-existed with other driver genes. Our results show that *MDM2* mutations delineate an aggressive subtype of lung cancer for which a targeted treatment through *MDM2* inhibition might offer new opportunities.

Keywords: non-small-cell lung cancer, MDM2 mutation, prognosis

EP1.03-20 DIAGNOSTIC AND PROGNOSTIC UTILITY OF DIFFERENTIALLY EXPRESSED CIRCULATING MICRORNAS IN INDIAN NSCLC PATIENTS

S. Kumar, S. Sharawat, A. Ali, P. Malik, A. Mohan, R. Guleria

All India Institute of Medical Sciences, New Delhi/India

Background: The presence of circulating tumour DNA, mRNA and non-coding RNAs, such as microRNA (miRNA), in the serum and plasma of cancer patients has sparked great interest because conventional diagnostic tests tend to be imperfect and more invasive, posing logistic difficulties for serial tumour sampling. Hence, identification of differentially expressed circulating miRNAs in the serum of non-small cell lung cancer (NSCLC) patients may have potential as cancer biomarkers for diagnosis, prognosis and predicting therapeutic response. **Method:** For the identification of differentially expressed miRNAs in the serum of NSCLC patients, we performed small RNA sequencing with illumina HiSeq 2000 platform (n=10; 4 NSCLC patients and 6 controls). The expression profile of miRNAs in each subject was analyzed using miRNAkey software and fold change was performed to identify differentially expressed miRNAs in NSCLC as compared to controls. We validated the expression of few differentially expressed miRNAs in the serum of 75 NSCLC patients and 40 controls using miScript qRT-PCR assay. The expression of miRNAs was correlated with overall survival (OS), progression-free survival (PFS), response to therapy and various clinico-pathological parameters. **Result:** The mean age of NSCLC patients and controls was 56.2 years and 55.3 years, respectively (p = 0.3242). Majority of the NSCLC patient and controls were male. 67% of NSCLC patients and 53% of controls were smokers (p = 0.099). Global miRNA profiling revealed 16 differentially expressed miRNAs (cut-off: fold change > 2.0, or p < 0.05, or both) in the serum of NSCLC patients as compared to controls. Our qRT-PCR data revealed significant down-regulation of miR-15a-5p, miR-320a, miR-25-3p, miR-192-5p, let-7d-5p, let-7e-5p, miR-148a-3p and miR-92a-3p in the serum of NSCLC patients as compared to controls. None of the miRNAs were correlated with survival outcome and therapeutic response. The expression of miR-320a, miR-25-3p and miR-148a-3p significantly correlated with stage, while miR-375 expression significantly correlated with lymph node involvement and pleural effusion. **Conclusion:** The expression of majority of miRNAs was down-regulated in the serum of NSCLC patients as compared to controls. Some of the miRNAs, such as miR-375 and miR-320a, are less studied for their involvement in the pathogenesis of NSCLC. Hence, future mechanistic studies are warranted to elucidate their role in disease biology and as candidate biomarkers for diagnosis and prognosis of NSCLC.

EP1.03-21 CIRCULATING TUMOR CELLS ISOLATION IS NOT A USEFUL PROGNOSTIC TOOL FOR NON-SMALL CELL LUNG CANCER PATIENTS CANDIDATES TO SURGICAL TREATMENT

L. Milla Collado[1], C. Fraile Olivero[2], C. Cerdan Santacruz[1], T. Valverde Higueras[3], I. Cal Vazquez[4], J. Jarabo Sarceda[5], E. Fernández Martín[5], J.L. Gonzalez Larriba[5], F. Hernando-Trancho[5]

[1]*Hospital Arnau Vilanova, Lleida/Spain,* [2]*Hospital Universitari Arnau de Vilanova, Lleida/Spain,* [3]*Hospital Clinico San Carlos, Madrid/Spain,* [4]*Hospital La Princesa, Madrid/Spain,* [5]*Hospital Clínico San Carlos, Madrid/Spain*

Background: It is well known that prognostic stratification according to TNM classification of non-small cell lung cancer (NSCLC) patients is somehow imprecise as there exist notable differences among patients endorsed in the same staging. Because of this it is mandatory to find complementary tools to reach a more accurate classification in order to the best selection of treatments for every patient. The presence of circulating tumor cells (CTC) in periferic blood samples has showed worse prognosis in other primary tumors. The aim of this study is analyzing the impact of CTC on disease free survival (DFS) and overall survival (OS). **Method:** Periferic blood samples from 28 patients diagnosed with NSCLC in early stages candidates for surgical treatment were obtained. Study period was from June 2011 to October 2013. Blood samples were obtained at least at three different moments: before surgery (S1), one year after the operation (S2) and the last one 2 years after the operation (S3). Blood samples were analyzed by CellSearch method. Probability of survival was calculated following the Kaplan-Meier method; differences in survival were examined by the Long-Rank test. **Result:** Median OS was 34 months and DFS was 11 months. There was no statistically significant differences among patients with or without CTC in S1, S2 and/or S3. When CTC were present, no relationship was observed between the variations in the number of CTCs among the different blood samples and the OS and DFS. **Conclusion:** In our study, the presence of CTCs in any of the blood samples obtained during the follow-up showed no relationship with OS and DFS. The same results were observed in relation to variations of CTCs' count.

EP1.03-22 PROGNOSTIC VALUE OF SERUM INFLAMMATION BIOMARKERS IN EARLY STAGE LUNG ADENOCARCINOMA

Y. Zhang, M. Hu, B. Han

Shanghai Chest Hospital, Shanghai Jiao Tong University, Shanghai/China

Background: Non-small cell lung cancer is the main cause of cancer-related death worldwide, with a low 5-year survival rate even in early-stage. And adenocarcinoma accounts for the majority of all Non-small cell lung cancer cases. Biomarkers to identify prognosis of early stage lung cancer are needed. Increasing evidences indicate a relationship between inflammation and lung carcinogenesis. One of our previous studies found inflammation biomarkers, BLC and MDC, are significantly related with the risk of early stage lung cancer. The present study was performed to evaluated the value of inflammation biomarker in predicting the prognosis of early stage lung adenocarcinoma. **Method:** Ten inflammation biomarkers were tested by Luminex bead-based

assay in 157 patients with resected early-stage lung adenocarcinoma (IA-IIB) from whom serum samples were collected pre-surgery. **Result:** A total of 152 early stage lung adenocarcinoma patients were analyzed in this study. The mean age (SD) of was 59.9 (9.4) years. 58.6% of them were females, and never smokers accounted for 84.0%. By TNM stage, 109 (71.7%) patients were at stage I and 43 (28.3%) at stage II. The median follow-up time was 60.6 months. Patients with higher MIG levels were at a 70% reduced risk of recurrence compared with patients with lower MIG levels (HR=0.3, 95% CI: 0.1–0.7, *p*=0.0035). As for BLC, patients with higher levels had the risk of recurrence decreased by 50% (HR=0.5, 95% CI: 0.3–0.9, p=0.031) compared with patients with lower levels. After the Bonferroni correction, only MIG was significantly associated with the recurrence risk of early stage lung adenocarcinoma. For overall survival (OS), patients with higher MIG levels were still have a reduced dead risk compared with the lower group (p=0.0065). **Conclusion:** Our results demonstrate for the first time that pretreatment MIG level was identified as a protective factor for the prognosis of early stage lung adenocarcinoma.

EP1.03-23 UPDATE OF THE ANALYSIS OF THE STATUS OF LYMPHOCYTE INFILTRATION IN PATIENTS WITH NSCLC

E. Richardet[1], P. Hernandez[2], M. Paradelo[2], L. Acosta[2], M. Molina[2], A. Riso[2], G. Ferreira[2], M. Richardet[2]

[1]*Instituto Oncologico de Corodba, Cordoba/Argentina,* [2]*IONC, Cordoba/Argentina*

Background: Current evidence highlights the potential role of tumor-infiltrating lymphocytes (TILS) as a prognostic factor in many types of tumors; in non-small cell lung cancer (NSCLC), this relationship is not well determined. TILs are being studied with different methods such as immunohistochemistry and optical microscopy. The primary endpoint is to identify TILS in patients with NSCLC, classified as present or absent, and its relation to progression free survival (PFS). **Method:** Retrospective and analytical case study of Instituto Oncológico de Córdoba. 187 patients with stage IIIB and IV NSCLC were analyzed. TILS are descriptively classified as present or absent. Survival curves were calculated using the Kaplan-Meier method. **Result:** 63% of patients had adenocarcinoma and 37% squamous cell carcinoma. 72% were men. 82% were smokers. 65% of patients with squamous histology and % 58 with adenocarcinoma, showed TILS. Patients with adenocarcinoma with TILS present had higher PFS 13.3 months, compared to patients with absent, 8.8 months. These differences were statistically significant (PFS: p=0.004). The patients with squamous cell carcinoma with TILS had 10.8 months PFS. Those who had infiltrated absent had a PFS of 5.6 months. These differences were also statistically significant (PFS: 0.001). **Conclusion:** Our study shows that patients whose pathological samples presented inflammatory infiltrate had higher PFS. The presence of TILS could be used as an important prognostic factor in this patient population.

EP1.03-24 CLINICOPATHOLOGIC CHARACTERISTICS AND SURVIVAL OUTCOME IN CHINESE PATIENTS WITH NON-SMALL CELL LUNG CANCER AND HGF MUTATIONS

C. Xu[1], W. Wang[2], Q. Zhang[1], W. Zhuang[1], Y. Zhu[3], Y. Huang[1], G. Chen[1], M. Fang[2], T. Lv[4], Y. Song[4]

[1]*Fujian Cancer Hospital, Fuzhou/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Zhejiang Rongjun Hospital, Jiaxing/China,* [4]*Jinling Hospital, Nanjing/China*

Background: Hepatocyte growth factor (*HGF*) is the ligand for the tyrosine kinase receptor *MET* (Mesenchymal Epithelial Transition Factor also known as Hepatocyte Growth Factor Receptor, *HGF*R). HGF and its receptor, MET, play critical roles in cell proliferation, angiogenesis and invasion in a wide variety of cancers, especially non-small cell lung caner (NSCLC). The aim of this study is to investigate mutations and prognosis of NSCLC harboring *HGF* mutations. **Method:** A total of 526 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *HGF* mutations and other genes were detected by next generation sequencing. **Result:** *HGF* gene mutation rate was 4.56% (24/526) in non-small cell lung cancer, including E437K (1 patient), L677I (1 patient), S386L (1 patient), R242Q (1 patient), H717N (1 patient), G520R (1 patient), R234H (1 patient), A713G (1 patient), P703S (1 patient), D264N (1 patient), N127K (1 patient), G506E (1 patient), C84* (1 patient), R647Q (1 patient), G133V (1 patient), D257N (1 patient), S386L (1 patient), S166R (1 patient), P27H (1 patient), C612* (1 patient), W528L (1 patient), G133V (1 patient), G694Wfs*31 (1 patient), and T143S plus G146A (1 patient), and median overall survival (OS) for these patients was 20.0 months. Among them, all patients were *HGF* gene with co-occurring mutations. Briefly, patients with (n=4) or without (n=20) co-occurring *EGFR* mutations had a median OS of not up to now and 20.0 months respectively (P=0.18); patients with (n=19) or without (n=5) co-occurring *TP53* mutations had a median OS of 20.0 months and 21.0 months respectively (P=0.96); patients with (n=4) or without (n=21) co-occurring *BRAF* mutations had a median OS of not up to now and 20.0 months respectively (P=0.46); patients with (n=5) or without (n=19) co-occurring *ERBB4* mutations had a median OS of 20.0 months and 19.6 months respectively (P=0.83). **Conclusion:** *EGFR*, *TP53, BRAF* and *ERBB4* gene accompanied may have less correlation with *HGF* mutation in NSCLC patients. Results of ongoing studies will provide a platform for further research to offer individualized therapy with the purpose of improving outcomes.

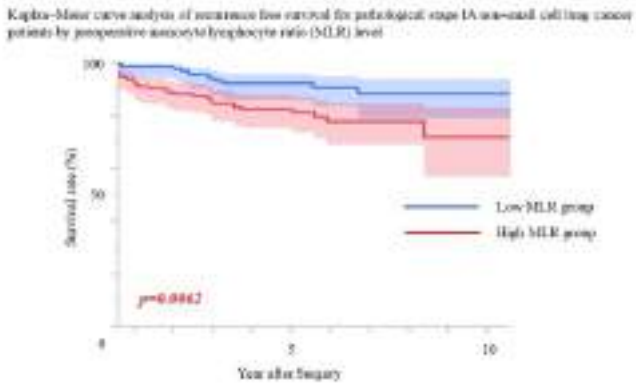
EP1.03-25 IMPACT OF PREOPERATIVE COMPLETE BLOOD CELL COUNT-DERIVED INFLAMMATION BIOMARKERS IN EARLY-STAGED NON-SMALL CELL LUNG CANCER PATIENTS

F. Shoji, Y. Kozuma, G. Toyokawa, K. Yamazaki, S. Takeo

National Hospital Organization Kyushu Medical Center, Fukuoka/Japan

Background: Although stage IA non–small-cell lung cancer (NSCLC) has an optimistic survival rate, up to 10% of these patients relapse after surgery and die. Inflammation plays a critical role in the development and progression of various cancers by promoting cancer cell proliferation and survival, angiogenesis and tumor metastases. Inflammatory cells in the tumor microenvironment significantly affect tumor development, and markers of systemic inflammation may indicate tumor status. In recent years, complete blood cell count (CBC)-derived inflammation biomarkers such as systemic immune-inflammation index (SII), neutrophils lymphocyte ratio (NLR), platelet lymphocyte ratio (PLR) and monocyte lymphocyte ratio (MLR), are used as prognostic factors in various malignancies. These markers are based on two or three parameters selected among neutrophils, lymphocytes, platelets and monocytes. SII has been investigated as a prognostic factor in several malignancies. NLR, PLR and MLR have been used as markers as systemic inflammation and are associated with poor outcomes in sloid tumors. Concerning non-small cell lung cancer, these parameters have been also reported as poor indicators, but few have specifically studied stage IA disease. We retrospectively analyzed clinicopathological features of patients with stage IA NSCLC to identify recurrence predictors and to investigate effects of preoperative CBC-derived inflammation biomarkers. **Method:** We selected 311 consecutive patients with stage IA NSCLC treated from April 2006 to December 2012 for this study, and tested their preoperative SII, NLR, PLR and MLR in uni- and multivariate Cox proportional analyses of recurrence free survival (RFS). **Result:** Preoperative high MLR level was significantly associated with sex, smoking status, postoperative recurrence (P<0.0001, =0.0307 and =0.0146) and preoperative high SII level was only correlated with postoperative recurrence (*P*= 0.0458), although both NLR and PLR were not found any related factors. Intratumoral vascular invasion (*P*= 0.0412), intratumoral lymphatic invasion (*P*= 0.0097) and preoperative MLR level (*P*= 0.0269) were identified as independent predictors of shorter RFS. Relative risk for preoperative high MLR level patients was 2.259 compared with patients with low MLR level (95% CI: 1.094–5.000). 5-year RFS rate in preoperative high MLR group was significantly lower than that in low MLR group (82.21% vs. 92.05%, p=0.0062).



Conclusion: Preoperative MLR level is a simple and novel predictor of recurrence in patients with stage IA NSCLC.

EP1.03-26 ANALYSIS OF GENE EXPRESSION PROFILING OF LUNG ADENOCARCINOMA BRAIN METASTASIS

E.S. Park[1], N. Yoon[1], T. Kim[1], S.-Y. Jun[1], J.E. Kwon[2]

[1]*Incheon St. Mary's Hospital, College of Medicine, The Catholic University of Korea, Incheon/Korea, Republic of,* [2]*Dankook University Hospital, Cheonan/Korea, Republic of*

Background: The molecular biology of lung adenocarcinoma (ADC) brain metastasis is poorly understood. We aimed to explore genes that are implicated in the process of brain metastasis of primary lung adenocarcinoma. **Method:** Twelve primary lung ADC with brain metastasis (ADCBM), six non-metastatic lung ADC (NMADC) and six lung ADC with metastasis except in the brain (ADCEB) were selected. Samples from all primary lung ADC were obtained after surgical resections performed at Incheon St. Mary's hospital. All tumors were analyzed with the NanoString nCounter system for gene expression using the nCounter PanCancer Progression panel composed of 740 genes. Expression data were analyzed using the NanoString nSolver software ver 4.0 and nCouter Advanced Analysis ver 2.0.115. **Result:** Eleven out of the 740 genes were differentially expressed between the ADCBM and ADC without brain metastasis including NMADC and ADCEB. The genes that were downregulated in the ADCBM included RGCC, ACHE, TPSB2, and FHL1. Expression levels of EPHB3, AGRN, ISLR, TNFRSF12A, TPM2, PTRF and BGN were upregulated in the ADCBM compared to ADC without brain metastasis including NMADC and ADCEB. The ADCBM was compared with NMADC and ADCEB, respectively. Four genes were differentially expressed between the ADCBM and NMADC. 23 genes were differentially expressed between the ADCBM and ADCEB. The differentially expressed genes (DEGs) in NMADC vs. ADCEB were not identified the same DEGs in ADCBM vs. NMADC and ADCEB. As a result, the EPHB3, AGRN and TNFRSF12A that were upregulated and the RGCC that was downregulated in ADCBM was common identified. **Conclusion:** Although our findings are not conclusive, we have identified differentially expressed genes that might mediate the brain metastasis process. A prospective validation is needed to confirm candidate genes associated with ADCBM.

Keywords: adenocarcinoma, brain metastasis, gene expression

EP1.03-27 THE ANTI-MIGRATION AND ANTI-INVATION MECHANISMS OF CAPILLIPOSIDE C FROM LYSIMACHIA CAPILLIPES ON LUNG CANCER

Y. Xu[1], S. Zhang[1], S. Ma[2]

[1]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou/China,* [2]*Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, hangzhou/China*

Background: Approximately 50% of lung cancer patients had distant metastases when initial diagnosed. Lysimachia capillipes is one of traditional medicine in China. It is proved to be safety in clinical use. Several studies have showed the antitumor effects of Capilliposide from Lysimachia capillipes (LC) *in vitro*. Our preliminary data showed LC could inhibit the migration and invasion of lung cancer. This study aims to explore the detailed mechanisms of LC as well as its extracts on lung cancer. **Method:** Four non-small cell lines were selected. The invasive response of lung cancer cells was determined by Wound Healing assay. Proteins and the phosphorylation of proteins were evaluated by iTRAQ-based proteomics. The phosphorylation chip was used to evaluate the phosphorylation effect. PC-9 xenografts were used to evaluate the antitumor of LC-C in vivo. Immunohistochemistry (IHC) was used to evaluate the antitumor mechanisms in vivo. **Result:** The migration capa city of lung cancer cells was significantly reduced after treatment of LC-C. Proteomics showed there were 364 differentially expressed proteins and 456 differentially expressed phosphorylated proteins in both LC-C treated PC-9 and H1975 cells. Differentially expressed proteins were enriched in EGF receptor signaling pathway, Wnt signaling pathway, Cadherin signaling pathway, Notch signaling pathway, TGF-beta signaling pathway, and p38 MAPK pathway by bioinformatic analysis. Phosphorylation chip showed LC reduced the phosphorylation of AKT, WNK1 and PRAS40, but not EGFR. Western blot showed the phosphorylation of mTOR, AKT and PRAS40 were significantly inhibited after LC-C treatment; besides, the inhibitory effects of AKT and mTOR were dose-dependent. While the total proteins of AKT and mTOR were not changed. Western blot showed the phosphorylation of Smad2 and Smad3 were significantly inhibited after LC-C treatment. Western blot showed E-Cadherin was up-regulated and N-Cadherin was down-regulated after LC-C treatment; while other EMT related proteins including ZO-1, Snail and Vimentin were not changed. Nor did cell adhesion related protein Claudin-1. PC-9 xenograft model showed the tumor growth inhibitory rates were 114.4% in 7 days after LC-C administration. IHC showed the phosphorylation of AKT was down-regulation after LC-C administration, Ki-67 was also down-regulation, while cleaved caspase-3 was not changed. **Conclusion:** The study showed LC-C inhibit the growth and the capacity of invasion and migration of lung cancer cells. The detailed mechanisms might crosstalk with several critical pathway such as AKT pathway, TGF-β pathway and EMT.

Keywords: Capilliposide C from Lysimachia capillipes, migration, invastion

EP1.03-28 FREQUENCY AND MOLECULAR CHARACTERISTICS OF BRCA1 MUTATIONS IN NON-SMALL CELL LUNG CANCER FROM EAST ASIAN PATIENTS

Y. Huang[1], C. Xu[1], W. Wang[2], Q. Zhang[1], W. Zhuang[1], Y. Zhu[3], Y. Huang[1], G. Chen[1], M. Fang[2], T. Lv[4], Y. Song[4]

[1]*Fujian Cancer Hospital, Fuzhou/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Zhejiang Rongjun Hospital, Jiaxing/China,* [4]*Jinling Hospital, Nanjing/China*

Background: Previously identified as a breast and ovarian cancer susceptibility gene, *BRCA1* has gained major scientific interest as a potential prognostic and/or predictive marker for various tumors, including non-small-cell lung cancer (NSCLC), the leading cause of cancer related mortality worldwide. The aim of this study is to investigate mutations and prognosis of NSCLC harboring *BRCA1* mutations. **Method:** A total of 730 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *BRCA1* mutations and other genes were detected by next generation sequencing. **Result:** *BRCA1* gene mutation rate was 2.60% (19/730) in non-small cell lung cancer, including Y856H (3 patients), M1689T (2 patients), N909I (2 patients), G275D (2 patients), N473S (2 patients), S1217C (1 patient), M1628T (1 patient), E649* (1 patient), R1443* (1 patient), V191I (1 patient), I783V (1 patient), M669T (1 patient), and R71K (1 patient), and median overall survival (OS) for these patients was 14.0 months. Among them, all patients were *BRCA1* gene with co-occurring mutations. Briefly, patients with (n=3) or without (n=16) co-occurring *EGFR* mutations had a median OS of 20.0 months and 13.0 months respectively (P=0.56); patients with (n=4) or without (n=15) co-occurring *TP53* mutations had a median OS of 20.0 months and 19.5 months respectively (P=0.82); patients with (n=4) or without (n=15) co-occurring *PIK3CA* mutations had a median OS of not up to now and 13.5 months respectively (P=0.36); patients with (n=5) or without (n=14) co-occurring *CDKN2A* mutations had a median OS of not up to now months and 13.5 months respectively (P=0.28). **Conclusion:** Our data reveal *BRCA1* mutations represent a distinct subset of NSCLC. NGS might be useful for evaluation of *BRCA1* unclassified variants. Our results show that *BRCA1* mutations delineate an aggressive subtype of lung cancer for which a targeted treatment through PARP inhibition might offer new opportunities.

Keywords: non-small-cell lung cancer, BRCA1 mutation, prognosis

EP1.03-29 THE EVALUATION OF NON-CANONICAL WNT/β-CATENIN LIGANDS EXPRESSION STATUS IN NON-SMALL CELL LUNG CANCER

P. Golec, J. Pancewicz, R. Charkiewicz, A. Sulewska, M. Kozłowski

Medical University of Bialystok, Bialystok/Poland

Background: The family of secreted glycoproteins forming the WNT/β-catenin signaling pathway is shown to play a significant role in many types of carcinomas including NSCLC. Therefore, the aim of the study was to evaluate the WNT pathway status in NSCLC. **Method:** The study was performed on 80 pairs of cancerous and non-cancerous tissue samples and 5 NSCLC cell lines (A549, H1299, H1395, Calu-3, H520 and non-cancerous control line HBEpC). Selected WNT genes expression analysis was assessed with qPCR with TaqMan Gene Expression Assays. The relative expression of chosen genes was estimated with ΔΔCt method. Statistical analyses were performed with the use of: Shapiro-Wilk test, T-test Wilcoxon matched pairs singed-rank test and Mann-Whitney U test. **Result:** In the cell lines deregulation of most selected genes was detected. Fold-change analysis of obtained results has shown a down-regulation of WNT4, -5A, -7A and -11 expression in comparison to control. However, in H520 and A549 cell lines up-regulation of WNT-5A and WNT -11 was found. Analysis of patient's tissue shows statistically significant ($p < 0.05$) inhibition of non-canonical WNT pathway ligands WNT-4, WNT-5A, WNT-7A and WNT-11 in cancerous tissue in comparison to non-cancerous tissue. In adenocarcinoma statistically significant dysregulation of WNT5A ($p = 0.0094$), -7A ($p < 0.0001$), and -11 ($p < 0.0001$) was identify. In squamous cell carcinoma statistically significant dysregulation of WNT4 (p, 0.0001), -7A ($p < 0.0001$) and -11 ($p < 0.0001$) was found. Moreover, in large cell carcinoma statistically significant dysregulation of WNT-4 ($p = 0.0068$), -5A ($p = 0.0210$), -7A ($p = 0.0156$) and -11 ($p = 0.0117$) was discovered. Furthermore, a statistically significant difference of WNT-7A expression between stage IA and IIA tumors ($p = 0.0203$) has been found. **Conclusion:** Dysregulation of non-canonical WNT/β-catenin signaling pathway ligands expression profile in NSCLC tissue samples suggests that it play an important role in NSCLC. Further studies, are necessary to proof the mechanisms of WNT/β-catenin pathway in NSCLC.

Keywords: Non-Small Cell Lung Cancer, WNT signalling pathway

EP1.03-30 FAM83A AND FAM83B AS PROGNOSTIC BIOMARKERS AND POTENTIAL NEW THERAPEUTIC TARGETS IN NSCLC

S. Richtmann[1,2], D. Wilkens[3], A. Warth[4], F. Lasitschka[4], H. Winter[1,2], P. Christopoulos[1,2], F. Herth[2,5], T. Muley[1,2], M. Meister[1,2], M. Schneider[1,2]

[1]*Thoraxklinik at Heidelberg University Hospital, Heidelberg/Germany,* [2]*Member of the German Center for Lung Research (DZL), Heidelberg/Germany,* [3]*Technische Universität Darmstadt, Darmstadt/Germany,* [4]*Heidelberg University Hospital, Heidelberg/Germany,* [5]*Thoraxklinik at University Hospital Heidelberg, Heidelberg/Germany*

Background: Although targeted therapy improved survival rates in the last decade, non-small cell lung cancer (NSCLC) is still the most common cause of cancer related death. As most precision medicines lead to resistance, the challenge of identifying new targets for further effective therapies still remains. The FAMily with sequence similarity 83 (FAM83) members have recently been described as novel oncogenes in numerous human cancer specimens and shown to be involved in EGFR signaling. However, their function in cancer cells is largely unknown and especially their role in lung cancer remains unclear. **Method:** Here, we investigated the expression and function of FAM83A and B in NSCLC. First, gene expression of the two FAM83 members was analyzed in a set of 362 NSCLC patients using qPCR. We further investigated relations in expression and their prognostic value using correlation and multivariate COX regression analyses. Functional assays in NSCLC cell lines were performed to analyze their involvement in proliferation, anchorage-independent growth, migration and the epidermal growth factor receptor (EGFR) pathway. **Result:** We observed a highly increased gene expression level of *FAM83A* (ø = 68-fold) and *FAM83B* (ø = 20-fold) which resulted in poor survival prognosis ($p < 0.0001$ and $p = 0.002$). Correlation analysis showed poor relation between *FAM83A* and *B* in the two sub-histologies adenocarcinoma (ADC) and squamous cell carcinoma (SQCC) but confirmed correlation between *FAM83A* and *B* and *EGFR* expression levels in patients and cell lines. Their expression was further influenced by EGFR pathway signaling and mutation status. Both genes affected cell proliferation and *FAM83A* depletion resulted in reduced migration and AIG. **Conclusion:** The results support the hypothesis that *FAM83A* and *B* have different specific functions in the histological subtypes of NSCLC and might be new therapeutic targets.

Keywords: EGFR-TKI, NSCLC, FAM83

EP1.03-31 CELL MIGRATION AND EPITHELIAL MESENCHYMAL TRANSITION IN LUNG CANCER - DIFFERENT ROADS AND COMMON THEMES

K. Schelch, L. Wimmer, J. Brankovic, M. Grusch

Medical University of Vienna, Vienna/Austria

Background: Cell migration is an indispensable function for many cells in multicellular organisms. When deregulated, however, especially in conjunction with the ability to degrade extracellular matrix and invade surrounding tissues, it is a hallmark of malignancy and forms the basis for cancer metastasis. This is often linked to epithelial mesenchymal transition (EMT) which is widely recognized in cancer cell biology to be intricately connected to metastasis, drug resistance and stemness. Multiple extracellular stimuli that induce EMT and cell migration in diverse cellular contexts have been described, nevertheless, a lot still needs to be learned about pathway-specific mechanisms. We have chosen the Ras-mutated A549 lung adenocarcinoma cell line for investigating how the two growth factors EGF and TGFb, which each play fundamental roles in tumor development but activate clearly distinct signaling cascades both stimulate EMT and migration individually and when acting in cooperation. **Method:** A549 cells were treated with EGF, TGFb or a combination of both in serum-free conditions. Also, inhibitors of downstream pathways were used at sub-lethal concentrations. Changes in cell morphology were determined using ImageJ from microscopy images. Cell migration was assessed by live cell videomicroscopy followed by singe cell tracking. The invasive capacity was determined by a 3D sprouting assay. Expression changes were identified by qPCR and immunoblots. **Result:** Treatment with TGFb and EGF resulted in cell scattering and distinct changes in cell morphology, which were different for each growth factor. While cells treated with TGFb showed classic EMT-like, elongated morphology, cells exposed to EGF rounded up. Combining both factors resulted in a mixed population. EGF-induced changes could be prevented by Akt but not MAPK inhibitors. Importantly, each growth factor induced a significant increase in cell migration compared to untreated cells and the combination of both factors stimulated migration even further. Interestingly, the increase in migration occurred earlier with EGF than with TGFb, and this was in concordance with increased pERK levels. However, only TGFb was able to induce significantly increased sprouting. **Conclusion:** Our data describes two independent signaling pathways which both are able to induce cell scattering and cell migration, albeit along different roads. Especially in cancer cells, a better understanding of signaling pathway-dependency of EMT and migration and potential cross talks could lead to more effective antimetastatic therapies.

EP1.03-32 PREVALENCE OF EGFR AND ALK MUTATIONS IN NON SMALL CELL LUNG CANCER IN VIET NAM NATIONAL CANCER HOSPITAL

V. Dang

Vietnam National Cancer Hospital, Hanoi/Viet Nam

Background: A significant percentage of non small cell lung cancer (NSCLC) have driver mutations. Epidermal growth factor receptor (EGFR) mutations and anaplastic large-cell lymphoma kinase (ALK) rearrangements are now routine biomarkers that have been incorporated into the practice of managing NSCLC. To date, there has been no assessment of the prevalence of these mutations in NSCLC in Viet Nam National Cancer Hospital. The prospective study of formalin fixed paraffin embedded (FFPE) tissues from patients diagnosed with NSCLC was performed to assess the prevalence of EGFR and ALK mutations in NSCLC in Viet Nam National Cancer Hospital. **Method:** Patients with NSCLC in Viet Nam National Cancer Hospital were prospectively enrolled. FFPE tissue samples were tested for EGFR mutation by PCR and for EML4-ALK translocation

by fluorescence in situ hybridization (FISH) **Result:** A total of 103 patients were enrolled, 78 (76.7%) males and 25 females (23.3%), with a mean age of 57.7 years. Adenocarcinoma and Squamous cell carcinoma rate were 89.3% and 10.7%, respectively. EGFR testing of 103 patients (100%) demonstrated the wild type in 76 (73.8%) and mutated forms in 27 (26.2%). Some 74.0% of EGFR positive patients were non-smokers and 44.4% were females. Regarding the EML4-ALK translocation, testing in 103 cases (100%) gave positive results in only 11 (10.7%). Among 11 patients with EML4-ALK translocation, 6 patients (54.5 %) were females and 6 patients (54.5 %) were smokers. Moreover, only two squamous cell carcinoma patients had positive EGFR mutation and only one patient had concurrent EGFR mutation and ALK rearrangement **Conclusion:** In this sudy investigating the prevalence of EGFR and ALK mutations in non small cell lung cancer in Vietnam National Cancer Hospital, 26.2% had EGFR mutation and 10.7% had ALK translocation mutations, as compared to 35% and 6.1%, respectively, in Asian

EP1.03-33 CD26/DPP4 AS A NOVEL PROGNOSTIC MARKER FOR LUNG ADENOCARCINOMA

J.-H. Jang[1], M. Haberecker[1], A. Curioni[1], F. Janker[1], A. Soltermann[1], I. Gil-Bazo[2], I. Hwang[3], K. Kwon[3], W. Weder[1], W. Jungraithmayr[1]

[1]*University Hospital Zürich, Zürich/Switzerland,* [2]*Clinica Universidad de Navarra, Navarra/Spain,* [3]*Keimyung University Dongsan Medical Center, Daegu/Korea, Republic of*

Background: CD26/dipeptidyl peptidase 4 (DPP4) is a transmembrane exopeptidase expressed on various malignancies in conjunction with activity of epithelial-mesenchymal transition (EMT). We found previously that the activity of CD26/DPP4 in human lung adenocarcinoma is four times higher than in normal lung tissue and the inhibition of CD26/DPP4 decreased the growth of lung tumors in experimental models. These data prompted us to analyze the expression of CD26/DPP4 and EMT markers in samples from non-small cell lung cancer patients to unravel a function of CD26/DPP4 as a prognostic marker and potential therapeutic target for lung cancer. **Method:** We employed multi-organ tissue micro array (TMA) of non-small cell lung cancer patient samples from two institutions, University Hospital Zurich and Dongsan Medical Center. To identify CD26/DPP4 and EMT markers (Ecadherin, Vimentin, beta-Catenin, Elastin, Periostin, and Versican), immunohistochemistry (IHC) on TMA was performed. Three pathologists scored the intensity IHC from zero to six in a blinded manner. The cohort consisted of 1126 patients (adenocarcinoma: 593; squamous carcinoma: 443; others (large cell carcinoma, adeno-squamous carcinoma): 90). The overall survival rate of patients was considered as a measure of prognosis. To identify a correlation between CD26/DPP4 and EMT related protein expression in lung cancer the Pearson correlation coefficient test was applied. **Result:** CD26/DPP4 IHC scores revealed that adenocarcinoma expresses significantly higher amount of the protein compared to normal lung or squamous carcinoma or others ($p=0.035$, $p<0.0001$, $p<0.0001$ respectively). In adenocarcinoma, patients with high CD26/DPP4 score (4-6) showed the worst overall survival compared to patients scoring low (1-3) or zero. The correlation analysis of CD26/DPP4 with EMT markers in adenocarcinoma showed that the epithelial marker Ecadherin was negatively correlated ($p=0.001$), while mesenchymal proteins Vimentin, beta-Catenin, Elastin were positively correlated with CD26/DPP4 ($p=0.03$, 0.01, and 0.001 respectively). Periostin and Versican showed no correlation with CD26/DPP4 expression. **Conclusion:** The expression of CD26/DPP4 was significantly higher in adenocarcinoma among non-small cell lung cancers and associated with worse survival of patients. Furthermore, the expression of CD26/DPP4 was significantly correlated with the EMT status. We therefore deem CD26/DPP4 to be a novel prognostic marker for lung adenocarcinoma. In consideration with CD26/DPP4 expression of these cancer samples, inhibition of CD26/DPP4 can potentially improve lung cancer patients' survival.

Keywords: lung adenocarcinoma, CD26/DPP4, Epithelial-mesenchymal transition

EP1.03-34 SINGLE CENTER EPIDEMIOLOGICAL PREVALENCE STUDY OF MOLECULAR MUTATION IN BANGLADESHI PATIENTS WITH ADVANCED STAGE NON-SMALL CELL LUNG CANCER

Q. Chowdhury[1], F. Begum[1], M. Rahman[1], F. Chowdhury[2], S.M.R. Kabir[2], Z. Husain[3]

[1]*Bangladesh Specialized Hospital Limited, Dhaka/Bangladesh,* [2]*North South University, Dhaka/Bangladesh,* [3]*Praava Health, Dhaka/Bangladesh*

Background: In a private tertiary hospital of Bangladesh about 2953 patients have been diagnosed as primary cancer patient of which 17% (510) patients were primary lung cancer patients, 77% of which were in advanced (stage III and IV). The study was performed to investigate the molecular mutations and prevalence of EGRF, T-790M, ROS-1, and ALK mutations in Bangladeshi patients with advanced stage non-small cell lung cancer (NSCLC), as per available local molecular lab facilities. **Method:** This study was retrospective and single center, conducted in 35 patients representing the 77% advanced stage lung cancer patients aged 20 years or above with NSCLC in the outpatient department The Bangladesh Specialized Hospital Ltd. (BSHL) within the timeframe of March 2016 – March 2019 recommended for molecular mutation study. Data were collected from the electronic prescription from hospital imformation system. EGFR, T-790M, ROS-1, and ALK frequency were calculated. The tests were done by tissue sample or Liquid biopsy when tissue sample was unavailable. The tests were carried out by Real Time PCR. The frequency of molecular mutation diagnosis was compared between the number of patients advised for molecular mutation study and number of patients who performed the investigation. **Result:** Of 35 patients 63% (22) were male and 37% (13) were female, median age 61 (range 45-86) and 65% (23) test carried out with Liquid Biopsy. 25.7% (9) patients were found to be EGFR positive, and 74.3% (26) were EGFR negative; also, out of 16 patients recommended for T790M study only 6.3% (1) was positive. ROS positive was found in 40% (14), and 48.6% (17) were negative. ALK screening showed to be positive in 37.1% (13) and negative in 45.7% (16). Among the 392 patients, only 9% performed the study, due to low availability of moleculer diagnosis which was started in Bangladesh since the early July 2017. **Conclusion:** The frequency of molecular testing may not reflect the international studies due to methods applied for the testing and also with the gender frequency as high predominance of male patients. With this limited data we have seen that the prevalence of ROS-1 (40%) mutation was higher than ALK (37.1%) and EGFR (25.7 %). Due to financial constrain and limited access to tests only 9% patients performed the study, though, molecular tests are recommended most oftenly. Due to time being a limiting factor for the sample size further studies can be performed on a larger scale.

EP1.03-35 PREVALENCE, CLINICOPATHOLOGIC CHARACTERISTICS, AND MOLECULAR ASSOCIATIONS OF IGF1R MUTATIONS IN EAST ASIAN PATIENTS WITH NSCLC

X. Zhao[1], C. Xu[2], W. Wang[3], Q. Zhang[2], W. Zhuang[2], Y. Zhu[4], Y. Huang[2], G. Chen[2], M. Fang[3], T. Lv[5], Y. Song[5]

[1]*The Second Hospital of Anhui Medical University, Hefei/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Zhejiang Rongjun Hospital, Jiaxing/China,* [5]*Jinling Hospital, Nanjing/China*

Background: IGF1R is a ubiquitous receptor tyrosine kinase that plays critical roles in cell proliferation, growth and survival. Clinical studies have demonstrated upregulation of IGF1R mediated signaling in a number of malignancies including colon, breast, and lung cancers. The aim of this study is to investigate mutations and prognosis of non-small cell lung cancer (NSCLC) harboring *IGF1R* mutations. **Method:** A total of 812 patients with non-small-cell lung cancer were recruited between July 2012 and December 2016. The status of *IGF1R* mutations and other genes were detected by next generation sequencing. **Result:** *IGF1R* gene mutation rate was 1.60% (13/812) in non-small cell lung cancer, including N977I (2 patients), S751T (1 patient), E1043D (1 patient), G171W (1 patient), E563K (1 patient), R275C (1 patient), F921[2>1] (1 patient), E712K (1 patient), R222W (1 patient), D1024A (1 patient), A760T (1 patient), and K533N (1 patient), and median overall survival (OS) for these patients was 9.0 months. Among them, all patients were *IGF1R* gene with co-occurring mutations. Briefly, patients with (n=3) or without (n=10)

co-occurring *EGFR* mutations had a median OS of 6.0 months and 11.0 months respectively (P=0.10); patients with (n=12) or without (n=1) co-occurring *TP53* mutations had a median OS of 18.0 months and 8.0 months respectively (P=0.68); patients with (n=4) or without (n=9) co-occurring *KRAS* mutations had a median OS of 14.5 months and 7.0 months respectively (P=0.76); patients with (n=5) or without (n=8) co-occurring *NF1* mutations had a median OS of not up to now and 6.5 months respectively (P=0.24). **Conclusion:** *EGFR*, *TP53*, *KRAS*, *NF1* gene accompanied may have less correlation with *IGF1R* mutation in NSCLC patients. We report different mutations than those previously reported, which emphasizes the importance of personalized medicine that could be empowered by the use of bioinformatics tools in the diagnostic process and therapeutic approaches.

EP1.04 IMMUNO-ONCOLOGY

EP1.04-01 ASSOCIATION OF PD-L1 EXPRESSION WITH LUNG ADENOCARCINOMA CONTAINING SOLID OR MICROPAPILLARY COMPONENTS

Y. Kidokoro, A. Nakanishi, S. Matsui, Y. Kubouchi, Y. Takagi, T. Haruki, Y. Taniguchi, Y. Umekita, H. Nakamura

Tottori University, Tottori/Japan

Background: The assessment of programmed cell death ligand 1 (PD-L1) expression by immunohistochemistry (IHC) is important to treat patients in lung adenocarcinoma (LUAD). However, little is known about the relationship between PD-L1 expression and high-grade components, such as solid components (SCs) and/or micropapillary components (MPCs), which show worse prognosis. Here, the aim of this study is to evaluate the association of the PD-L1 expression with LUAD containing high-grade components. **Method:** The expression of PD-L1 protein in 39 surgically resected LUAD was evaluated by IHC analysis using the clone 22C3. PD-L1 tumor proportion score (TPS) were divided to three groups: TPS at least ≥50% was high expression, ≥1% was intermediate expression, and <1% was negative expression. We compared retrospectively the three groups and the percentage of high-grade components. **Result:** PD-L1 high expression was seen in eight patients (20.5%), intermediate expression in 22 patients (56.4%), and negative expression in 9 patients (23.1%). Thirty five cases with at least ≥1% SCs and/or MPCs were identified. The mean of the percentage of high-grade components was 60% in high expression group, 22% in intermediate expression group, and 10% in negative expression group. The statistical significance was shown comparing the PD-L1 high expression with the intermediate expression group (p<0.013), and comparing the high expression and the negative expression group (p<0.002). **Conclusion:** LUAD with many high-grade components showed the PD-L1 high expression. Therefore, PD-L1 IHC should be performed on sections including a high percentage of SCs and/or MPCs in evaluating its expression in surgical resected specimen.

Keywords: PD-L1, solid, micropapillary

EP1.04-02 PREDICTORS OF LUNG TOXICITY IN FIRST LINE PEMBROLIZUMB FOR ADVANCED NSCLC: AN INTERIM ANALYSIS OF PRELUTOX STUDY

Background: Pembrolizumab, an anti-PD–1 antibody, is an immune-checkpoint inhibitor (ICI) approved for advanced disease in frontline setting if PDL1 is ≥ 50%, in second line if PDL1 is >1%. ICIs are associated with immune-related adverse events (irAE), including pneumonitis or interstitial lung disease (ICI–ILD): the mechanisms that lead to irAE are not entirely known. Clinical trials found an incidence of ICI–ILD of 3 to 5% but in recent studies it is greater, with fatal cases described. Reports about real incidence, risk factors, features of pneumonitis are still few. We designed a prospective observational study in this setting of patients in order to predict pulmonary toxicity by clinical -radiological and respiratory functional variables. **Method:** PRELUTOX is a prospective observational study. Our purpose is to enroll at least 50 patients in 2 years. Inclusion criteria: locally advanced or metastatic NSCLC whit PD-L1 expression ≥ 50%, with no EGFR or ALK-ROS1 mutations. Exclusion criteria: previous chemotherapy or thoracic radiotherapy; active infections or systemic autoimmune disease; interstitial lung diseases; prior pneumonitis requiring systemic steroids; immunosuppressive or corticosteroid treatment; renal or hepatic failure. Aims of our study: incidence of ICI – ILD; features of all patients including pulmonary function and comorbidities, especially the respiratory ones; features of patients who develop pneumonitis with greater attention to the HRCT pattern. Patients perform therapy and radiological exams according to routine clinical practice; pulmonary function tests (PFTs) at the beginning of Pembrolizumab and every three months **Result:** This is an interim analysis. 33 patients have been recruited from May 2018 to March 2019. Patients characteristics are summarized in table 1.

Patients' characteristics (n=33)	
Gender	
male	19 (57.6%)
female	14 (42.4%)
Age (median, range)	68.2 (38.7-82.3)
Smoking	
current	6 (18.2%)
former	24 (72.7%)
never	3 (9.1%)
Histological type	
adenocarcinoma	27 (81.8%)
squamous	3 (9.1%)
other	3 (9.1%)
PD-L1 positivity	
≥70%	25 (75.7%)
<70%	8 (24.3%)
ECOG performance status	
0	8 (24.3%)
1	24 (72.7%)
2	1 (3.0%)
Tumour stage	
IIIb	2 (6.1%)
IV	31 (93.9%)

ILD occurred in one patient with thoracic massive involvement (incidence 3%) with an HRCT pattern of organizing pneumonia. He presented progressive worsening of the obstructive ventilatory defect and drastic reduction of diffusing capacity, associated with severe hypoxemia **Conclusion:** In literature incidence of ICI-ILD seems to be higher for NSCLC compared with other cancers: this may be related to the underlying lung status (exposure to tobacco, COPD and the thoracic tumor burden). PFTs have been described in several studies for their capacity to predict lung toxicity. In our preliminary data, during Pembrolizumab therapy, if toxicity does not occur, airways obstruction parameters and lung volumes seem to remain constant and related to the respiratory comorbidity (COPD). The same appears for diffusing capacity. Finally we suppose that the thoracic tumor burden could be related to the risk of lung toxicity but the study is still ongoing.

Keywords: Predictors, Lung-toxicity, Pembrolizumb

EP1.04-03 IMMUNE CELL FILTRATION AS A BIOMARKER FOR THE DIAGNOSIS AND PROGNOSIS OF LUNG ADENOCARCINOMA

T. Lu, Y. Wang, Y. Wo, W. Jiao

Affiliated Hospital of Qingdao University, Qingdao/China

Background: Since tumor-infiltrating immune cells provides meaningfully information of prognosis in lung adenocarcinoma, we aimed to construct a novel prognostic immune model on the basis of a systematic assessment of the immune landscape calculated from cancer transcriptomes of lung adenocarcinoma patients. **Method:** We used an advanced algorithm, which named "Cell type Identification By Estimating Relative Subsets Of RNA Transcripts (CIBERSORT)", to estimate the 22 immune cell types from public datasets. The selection operator model and least absolute shrinkage and random forest method were then applied to develop immune scores for tumor diagnosis and prognosis. **Result:** 355 lung adenocarcinoma patients and 204 normal controls were obtained to develop a diagnostic model and the diagnostic immune risk score (dIRS) suggested high sensitivity and specificity in both the training sets (AUC= 0.93, P<0.01) and validation sets (AUC=0.89). A prognostic immune score (pIRS) was also established and served as an independent prognostic factor for overall-free survival, which showed better prognostic value than TNM stage. Additionally, by integrating the pIRS with clinical information in a complete nomogram, the result suggested higher accuracy of recurrence risk prediction with well-calibrated curves. **Conclusion:** In summary, we studied the potential application of immune cells in cancer diagnosis, prognosis and treatment. The proposed diagnostic and prognostic model (dIRS and pIRS) might provide integrative and meaningful signatures for precision medicine and personal management of lung adenocarcinoma patients.

Keywords: Immune risk score, lung adenocarcinoma, CIBERSORT

EP1.04-04 PEMBROLIZUMAB-INDUCED FATAL ENCEPHALOPATHY

C. Freitas, G. Fernandes

Centro Hospitalar Universitário de São João, Porto/Portugal

Background: Pembrolizumab is a monoclonal antibody against programmed cell death 1 (PD-1) receptor approved for PD-L1 positive metastatic non-small cell lung cancer (NSCLC). Neurologic adverse events associated with anti-PD-1 antibodies are rare but might be fatal. **Method:** We report a case of fatal encephalopathy in a patient with metastatic NSCLC treated with pembrolizumab. **Result:** A 65-year-old former smoker woman with advanced lung adenocarcinoma with a *KRAS*mutation and an intermediate expression of PD-L1 (20-30%) previously treated with combination of carboplatin and pemetrexed started pembrolizumab (200 mg, every three weeks) after disease progression. After the second infusion of pembrolizumab, she presented with seizures and decreased level of consciousness. Concerning neurological examination, the patient was vigil, carried out only simple commands with absence of speech. Additionally, her muscular tonus was increased. Blood tests were unremarkable. Electroencephalogram was consistent with diffuse encephalopathy and also showed frequent epileptiform activity. Cerebral computed tomography and magnetic resonance revealed central nervous system (CNS) multifocal demyelination. Cerebrospinal fluid was acellular with glucose and protein within normal range. Also, microbiologic examination and polymerase chain reaction (PCR) assay for cytomegalovirus, herpes simplex 1 and 2 and John Cunningham (JC) virus were negative. Anti-onconeural antibodies were absent. Systemic corticosteroid therapy (dexamethasone 4 mg, every six hours) was initiated, with no improvement. Best supportive care was decided by a multidisciplinary team and patient died one month after admission. **Conclusion:** After excluding other causes for encephalopathy as paraneoplastic syndrome, CNS infection and metastasis, temporal association with pembrolizumab administration made us suspect of an adverse event of this drug. A case of pembrolizumab-induced encephalopathy was reported in advanced NSCLC, after two doses administration and the patient recovered after high dose corticosteroids. However, another case of nivolumab-induced encephalopathy in advanced renal cell carcinoma was fatal, even with drug discontinuation and high dose corticosteroid therapy. Although anti-PD-1 rarely cause encephalopathy, our case highlights not only its occurrence but also shows that it may be rapidly progressive and irreversible. As this entity probably represents an autoimmune process due to PD-1 block, its course is impossible to predict.

EP1.04-05 OUTCOMES OF IMMUNOTHERAPY IN ELDERLY PATIENTS. RETROSPECTIVE STUDY OF CLINICAL CHARACTERISTICS IN A SINGLE-CENTER AND A 4-YEAR EXPERIENCE

A.L. Ortega Granados, D. Fernández Garay, N. Cárdenas Quesada, J.F. Marín Pozo, L. Díaz Beltrán, C. De La Torre Cabrera, M. Ruiz Sanjuan, M. Fernández Navarro, M.Á. Moreno Jiménez, P. Sánchez Rovira

Complejo Hospitalario de Jaén, Jaén/Spain

Background: Median age of patients with lung cancer is 71 years old. We have study outcomes of NSCLC patients with more than 75 years that have receive immunotherapy since 2014 **Method:** We have performed a retrospective observational study, reviewing all patients with lung cancer treated in Medical Oncology in our institution (tertiary center in Spain) in a 4-year period (2015 to 2019), and followed until April 2019. The inclusion criteria are: 1) Age of 75 years or older at the time of diagnosis of the lung cancer, and 2) Receiving any anti PD-1 or anti PD-L1 therapy in advance disease. We included 16 patients. **Result:** Most patients were male, 79.2%, and average age is 77 years (75-84). They represent a 14.7% of all patients with advanced NSCLC that received any anti PD-1 or anti PD-L1 therapy in our institution (19 patients from a total of 128 patients, in a 4-year period). Squamous cell carcinomas represent a 57% of total, and adenocarcinoma a 39%. None of this patient harbour an oncogenic driver mutation. 51% of patients were diagnosed in stages II-III, and 49% in stage IV; but only 15% patients had a curative-intent therapy at the diagnosis. We study also the pattern of treatment in patients under active cancer therapy. Median survival time is 11.6 months (p-value: 0.001). Longer survival was seen in ECOG 0-1 patients (15.8 months) than in ECOG 2 patients (7 months) Most patients received immunotherapy in second line (16 patients, 2 in first line and 1 in third line). The drugs used were nivolumab (9 patients, 56.2%), followed by atezolizumab (7 patients, 37.5%) and pembrolizumab (3 patients, 6.2%). Median number of cycles received was 4 cycles (1-21). In terms of PD-1 status in biopsy, 5 patients were unknown, 8 patients were PD-1 negative and 6 patients were PD-1 positive (2 of them more than 50%). Most common adverse events related to immunotherapy were hypothyroidism (4 cases, 1 grade 1 and 3 grade 2), pneumonitis (3 cases, 2 grade 1 and 1 grade 2) and diarrhea (2 cases, grade 1). There were also dermatitis, adrenal insufficiency and xerostomia (1 case each). **Conclusion:** Although our cohort is small, we can suggest that immunotherapy is slightly underused in this cohort of patients, because patients of 75 years and older are a 21% of all our patients, and only a 14% of patients received an anti PD-1/PD-L1 drug. Survival rates seems very similar that communicated in younger patients, and they are clearly lower in ECOG 2 patients.

EP1.04-06 ANALYSIS OF THE RELATIONSHIP BETWEEN RATIO N / L AND SURVIVAL IN PATIENTS TREATED WITH IMMUNOTHERAPY IN LUNG CANCER

N. De Dios Alvarez[1], S. Agraso Busto[1], D. Pereiro[1], A. Alonso Herrero[1], M. Lazaro[2], G. Huidobro[3], J. Casal[3]

[1]*Hospital Universitario de Vigo, Pontevedra/Spain,* [2]*Complexo Hospitalario Universitario de Vigo, VIGO/Spain,* [3]*Hospital Universitario de Vigo, Vigo/Spain*

Background: The neutrophil-lymphocyte (N / L) ratio is a marker of general immune response in different stress situations, having shown a relationship between the quotient and the evolution of patients treated with immunotherapy (IT), emphasizing the importance of inflammation in these patients. **Method:** In order to evaluate this relationship in a context of usual clinical practice, a retrospective review of patients with pulmonary neoplasia who received IT treatment in the first line or successive, between November 2015 and December 2018, excluding those who received treatment within of ±±clinical trial. Data were collected from the clinical history of each patient, with special attention to baseline neutrophil and lymphocyte numbers, objective response to therapy by criteria iRECIST 1.1 after 3 months of treatment and overall survival (OS) defined from the beginning of treatment until death

by progression of the disease. **Result:** 92 patients (29 women and 63 men) were analyzed with a mean age of 64 ±8 years. 15 (16,3%) patients received immunotherapy as first line treatment, 65.2% (60 patients) received it as 2nd line and 18,4% (17 patients) as 3rd or succesive lines. The average number of cycles received was 14 (1-52). Two stretches of baseline N / L ratios ≤5 (low) and > 5 (high) were defined. Low ratio N / L (≤5) was identified in 62p (67.4%) of the patients treated with IT and high ratio N/L (> 5) in 30p (32,6%). Of the 62 patients with a low ratio: 41 patients (66.1%) had some type of response or stabilization of their disease, 13 patients (21%) had progression and 8 patients (12.8%) received less than three months of treatment, 6 patients for PS deterioration and the other 2 patients continue with the treatment and are pending reevaluation. Among the 30 patients patients with high N / L quotient: 7 patients (23.3%) presented response or stabilization of the disease, 23 patients (76,7%) presented progression or treatment was interrupted due to deterioration of the ECOG. The average survival in the group with a low N / L ratio (≤5) was 213 weeks compared to the group with a high N / L ratio (> 5) 144 weeks (p <0.05). **Conclusion:** The N / L ratio has been identified in some studies as an adverse prognostic factor in patients treated with IT. Our data from the usual clinical practice support this theory. If these findings are confirmed in future studies, it could be used as a response biomarker for better patient selection.

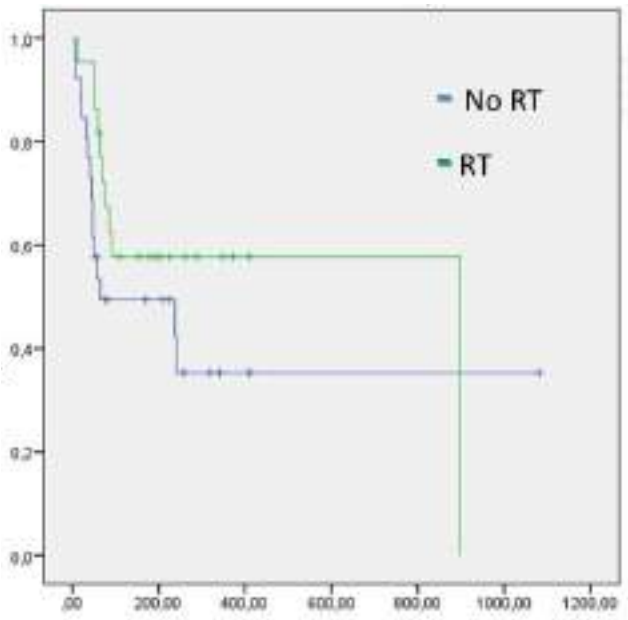
Keywords: RNL

EP1.04-07 INFLUENCE OF RADIOTHERAPY IN SECOND-LINE TREATMENT WITH IMMUNOTHERAPY IN PATIENTS WITH NON-SMALL CELL LUNG CANCER

E. Azkona, S. Carrera, I. Rubio, J.M. Mañe, I. Lacambra, A. Sancho, E. Novo, G. López-Vivanco

Hospital Universitario Cruces, Barakaldo/Spain

Background: The aim of the present study is to analyze the influence of previous radiotherapy (RT) in the efficacy and toxicity in patients (pts) with non small cell lung cáncer (NSCLC) treated with inmunotherapy in second line. **Method: Method:** This is a retrospective study conduted between January 2017 and December 2018 at Hospital Universitario Cruces (Bizkaia) on pts treated with inmunotherapy (nivolumab or pembrolizumab) in second line. The primary end point was to analyze if the RT influence in the progression free survival (PFS) of inmunotherapy or in the toxicity. Secondary end points were overall survival (OS) and if any variable influences the difference between both cohorts in the PFS. **Result:** Forty eight pts were evaluated, and 22 (45.83%) had received RT previously. The baseline characteristics were as follows: median age 62 years (range 40-82); 62.5% males; 91.66% had an ECOG performance status (PS) 0-1; 37.5% had stage IV at diagnosis; only 3 of the 22 pts had received less tan 60 grays (Gys). There were no differences in the PFS, 14.49 months (m) in the cohort without RT and 18.19 m in those who have received it (p = 0.196) (image). The incidence of any grade of toxicity was similar, 26.92% and 22.72% in pts without and with RT respectively (p =0.112). 3 pts in the first group stopped inmonotherapy because of toxicity versus 2 pts in the cohort of RT. The OS was significantly longer in the cohort of RT, 36.49 vs. 20.54m, p = 0.034. It was calculated whether the time interval from the end of RT and the initiation of immunotherapy influences on the PFS; neither the cutoff point of 6 months (p = 0.788) nor the cutoff of 4 (p = 0.454) influenced the PFS. As in the second group more patients were diagnosed in EIII, the possible influence of the stage on the PFS was valued, and no significant differences were seen. Neither the previous QT scheme, sex, state of PD-L1 nor the baseline respiratory pathology influenced the PFS or the incidence of toxicity.



Conclusion: Conclusions: Our study suggests that having received prior RT does not influence the efficacy or toxicity of immunotherapy in the second line of treatment in NSCLC. A larger cohort and more follow-up time is needed to be able to draw conclusions.

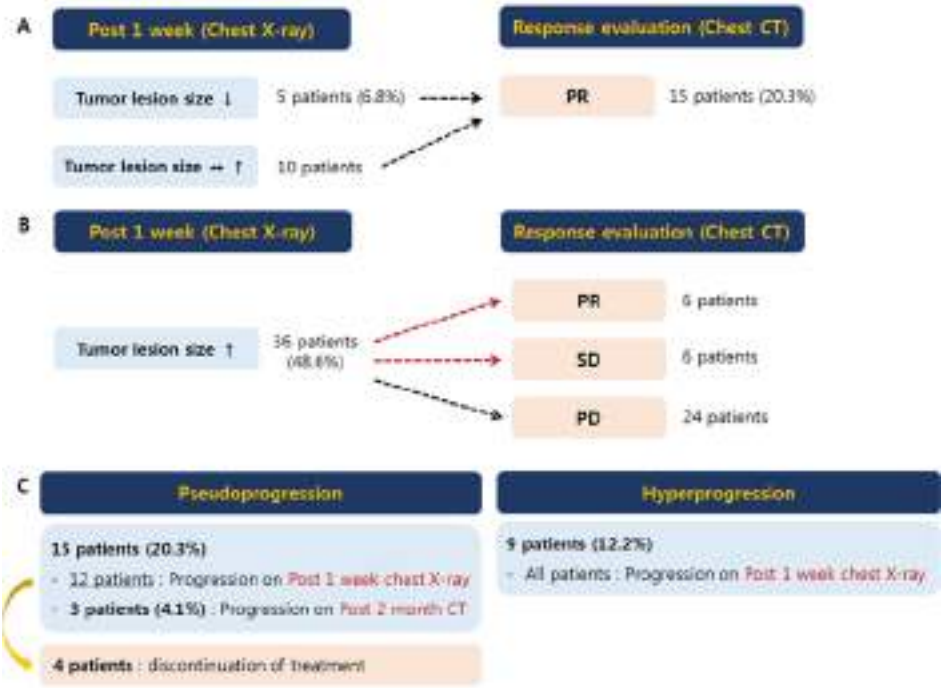
Keywords: Inmunotherapy, radiotherapy, NSCLC

EP1.04-08 IS PSEUDOPROGRESSION REALLY UNCOMMON AFTER IMMUNOTHERAPY IN LUNG CANCER?

D.H. Kang, C. Chung, J.E. Lee

Chungnam National University, Daejeon/Korea, Republic of

Background: Immune checkpoint inhibitors (ICIs) are more effective and less toxic than cytotoxic chemotherapy, which has led to change in the paradigm of lung cancer treatment. However, unlike classical chemotherapy, pseudoprogression has been reported in which the size of a lesion is temporarily increased or a new lesion occurs due to the effect of treatment, not the actual progress of disease. Pseudoprogression was histologically confirmed by necrosis or inflammatory cell infiltration, which is thought to be due to immune-related responses. To date, the incidence of pseudoprogression has been reported to be 4-6% in lung cancer patients. The aim of this study was to evaluate the incidence and prognosis of pseudoprogression in lung cancer patients treated with ICIs. **Method:** We retrospectively analyzed 74 patients who received ICIs at Chungnam National University Hospital from January 2017 to October 2018. Chest x-ray was examined 1 week after the first treatment to identify changes in initial lesions after immunotherapy. The response was evaluated in accordance with RECIST 1.1 and evaluated in chest x-ray as well as computed tomography (CT). Pseudoprogression was defined as the case in which the response was confirmed after continued treatment when the disease progression was showed on chest x-ray or CT. **Result:** Five patients (6.8%) had partial response (PR) on the chest x-ray at 1 week after treatment, and PR of the first response evaluation CT was observed in 15 patients (20.3%). All 5 patients who had PR in the first week x-ray showed response in CT. On the other hand, 36 patients (48.6%) had increased tumor lesions at the first week after treatment. Of these, 24 patients were progression disease (PD), 6 patients were PR, and 6 patients were stable disease (SD) on CT at 2 months after treatment. Pseudoprogression was observed in 15 of 74 patients, with a frequency of 20.3%, which was higher than previously reported. Twelve patients (80%) had progression of lesion on chest x-ray at 1 week after treatment, and showed decreased lesion size on response evaluation CT. Of the 12 patients with early pseudoprogression, 4 patients were unable to proceed with further treatment due to progression-related symptoms and systemic deterioration.



Conclusion: Unlike previous studies, pseudoprogression after immunotherapy is more frequent in lung cancer patients, especially during the early stage of treatment. Pseudoprogression at the beginning of treatment is relatively common to cause symptoms, so it is important to monitor early in the treatment.

Keywords: Chest x-ray, Immunotherapy, Pseudoprogression

EP1.04-09 A CROSS-SECTIONAL STUDY OF CLINICAL TRIALS ON RADIOTHERAPY COMBINED WITH IMMUNOTHERAPY FOR LUNG CANCER

M. Yuan, Z. Hui, Y. Men, J. Kang, X. Sun, M. Zhao, Y. Bao

National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China

Background: For patients with lung cancer, remarkable advances have been made in Immune-Oncology (IO) therapy, especially immune checkpoint inhibitors (ICI). However, multi-modality treatment is needed to improve the efficacy or enlarge the beneficial populations of IO treatment. This study is to comprehensively summarize and analyze the clinical trials focusing on radiotherapy (RT) combined with IO therapy, explore the trend of research, as well as provide a view of the latest landscape of combination strategies. **Method:** Trials registered on the electronic database(https://clinicaltrials.gov)between Jan.2009 and Jan.2019 were searched using "Radiotherapy AND Immunotherapy | Recruiting, Not yet recruiting, Active, not recruiting, Completed, Enrolling by invitation Studies | Interventional Studies | Lung Cancer". SPSS 20.0 was used to analyze the data. **Result:** Totally 69 clinical trials of RT and IO combination therapy for lung cancer were recorded, including 54 active and 15 completed. Geographically, most of the trials were carried out in the USA (n=47, 68.1%), followed by the European countries (n=18, 26.1%). From timeline, the past 2 years has seen a soaring number of 40 clinical trials accounting for 58.0% of the total. The combination therapy trials were more often in non-small cell lung cancer (NSCLC) (n=52, 75.4%) than small cell lung cancer (SCLC) (n=10, 14.5%), with the remaining 7 trials unspecified. As for combination strategies, trials of tumor vaccine combined with RT were the most frequent before 2016. But at present, ICI has exceeded tumor vaccine in the combination with RT and makes up the absolute most (n=62, 89.9%). On the whole, most of the combination therapy trials are in phase I/II (n=64, 92.8%). Although most trials are set for advanced or metastatic cancers (n=43, 62.3%), there are a few exploring the safety and effectiveness of combination therapy for early stage cancers or as adjuvant therapy (n=9, 13.0%). One trial was set as neo-adjuvant therapy. As for RT details, 22 trials were SBRT combined with IO therapy. Two trials were exploring the optimal sequence of RT and IO therapy. And one trial is to compare high versus low dose RT in the combination with ICI in NSCLC. **Conclusion:** From the trials of RT and IO combination therapy for lung cancer, those of ICI combined with RT are increasing rapidly, although most are in phase I/II. Further studies are needed to explore the more detailed rational combination strategies, such as the sequencing, fractionation and dose of RT, and the optimal IO agent.

Keywords: Lung cancer, radiotherapy, Immunotherapy

EP1.04-10 NIVOLUMAB IN NON-SMALL CELL LUNG CANCER (NSCLC): A REAL-LIFE STUDY

D. Reis, A. Mendes, N. China, M. Dias, D. Coutinho, E. Silva, S. Campainha, T. Costa, S. Conde, A. Barroso

Vila Nova de Gaia-Espinho Hospital Center, Vila Nova de Gaia/Portugal

Background: Immunotherapy is an option in locally advanced or metastatic lung cancer (LC), depending on the PD-L1 value. Nivolumab, an anti-PD1 immunological checkpoint inhibitor, can be used in LC in subsequent lines, regardless of the PD-L1 value. The aim of this study was to analyze patients with LC treated with nivolumab in the Multidisciplinary Thoracic Tumor Unit (MTTU) of our hospital. **Method:** Retrospective analysis of patients treated in the MTTU of our hospital who with nivolumab in subsequent lines between Dec-2015 and Dec-2018. **Result:** 49 patients were enrolled in this study with a mean age at the start of immunotherapy of 62.1 ± 9.1 years. 38 patients (77.6%) were male. Regarding the histological type, 30 (61.2%) were adenocarcinomas, 16 (32.7%) squamous cell carcinomas and 3 (6.1%) corresponded to other histological types. Regarding the expression of PD-L1, 30 patients (61.2%) had no expression, 13 (26.5%) had PD-L1 ≥1%, and in 6 patients (12.2%) this parameter was unknown. 27 patients (55.1%) were treated with 1 prior therapeutic line, 12 patients (24.5%) with 2 and 10 patients (20.3%) with > 2 previous therapeutic lines. With immunotherapy, 7 (14.3%) had partial response, 22 (44.9%) stable disease and 12 (24.5%) progressive disease. 28 patients (57.1%) have died so far. The median PFS was 5 months (95% CI 1.4-8.6) and the median overall survival (OS) was 10 months (95% CI 7.6-12.4). There were no significant differences between patients with or without PD-L1 expression. **Conclusion:** The OS of our patients

treated with nivolumab was slightly lower than some literature which perhaps is related to the fact that this is a real-life study, patients had a high number of previous therapeutic lines and there were different histologic types of LC.

Keywords: nivolumab, Lung cancer

EP1.04-11 FREQUENCY OF MICROSATELLITE INSTABILITY (MSI) IN BRAZILIAN TKI NON-TREATABLE NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS

P. De Marchi, G. Noriz Berardinelli, R. Cavagna, F. De Paula, E. Albino Da Silva, J. Miziara, L. Leal, R. Reis

Barretos Cancer Hospital, Barretos/Brazil

Background: Lung cancer is the most common cause of cancer deaths worldwide. Personalized medicine based on driver mutations has improved tailored treatment for patients with non-small cell lung cancer (NSCLC). However, only a subset of patients is benefited with tyrosine kinase inhibitors. Non-treatable advanced NSCLC patients may be eligible for treatment with immunotherapies. Recently, microsatellite instability (MSI) phenotype was reported as a predictive biomarker of response to immunotherapy, making it a crucial biomarker for clinical management for NSCLC patients. This study aimed to determine MSI frequencies in Brazilian NSCLC patients who are not eligible for TKi therapy. **Method:** 522 patients diagnosed with NSCLC patients at Barretos Cancer Hospital (Brazil) were evaluated. All samples were molecularly analyzed for *EGFR* (exons 18, 19, 20 and 21), *KRAS* (codons 12/13) and *BRAF* (exon 11 and 15) mutations by PCR followed by Sanger direct sequencing. The molecular MSI evaluation was performed using a hexa-plex marker panel by PCR followed by fragment analysis. **Result:** The mean age of the patients was 61y (22-87) and 54% were male. *EGFR*, KRAS, and BRAF wild-type status were identified in 62.6% (327/522) of cases. In 297 *EGFR/KRAS/BRAF* wild-type cases, MSI analysis was performed and we observed the presence of MSI-H in only three (1%) cases. Overall, two out of these three patients were female and one was male, the age at the diagnosis ranged from 55 to 76 years old, they were current or former smokers and all three cases were diagnosed at stage IV. Of note, one of the patients with MSI-high status received treatment with immune checkpoint inhibitor, and he is the only one out of the three patients that remains alive with 51-months survival. **Conclusion:** The frequency of MSI-high status is low in Brazilian NSCLC patients, in accordance with other population literature. Nevertheless, these MSI-positive patients are eligible for immunotherapy approaches.

Keywords: NSCLC, MSI, Immunotherapy

EP1.04-12 RESPONSE TO COMBINATION OF METFORMIN AND NIVOLUMAB IN A NSCLC PATIENT WHOSE DISEASE PREVIOUSLY PROGRESSED ON NIVOLUMAB

P. Viveiros, M. Burns, A. Davis, M. Oh, K. Park, S. Jain, Y.K. Chae

Northwestern University Feinberg School of Medicine, Chicago/United States of America

Background: Beyond metformin's success as a widely used anti-diabetic, there is mounting evidence for its anti-cancer properties. Metformin disrupts many molecular pathways, in particular causing mTOR inhibition. Additionally, it causes metabolic alterations that might impact cancer cell survival. Recent experiments have also suggested that metformin has immune modulatory properties. Metformin impairs immunologic exhaustion of CD8+ lymphocytes, potentiating immune response to tumors. Thus, when curbing acquired resistance to immune checkpoint inhibition, adding metformin could prove to be a valid strategy. Here, we present a case of a NSCLC patient for whom the addition of metformin coincided with reversal of disease progression on a single-agent nivolumab. **Method:** This is a case report obtained by medical records revision. **Result:** Case report: A 75-year-old male, ex-smoker, initially presented with symptomatic left pleural effusion and multiple lung nodules 7 years ago. Pathology confirmed poorly differentiated adenocarcinoma, wild-type for molecular targets. Disease was Stage IV based on the presence of a malignant pleural infusion. The patient underwent VATS and left pleurodesis and was started on systemic therapy. After four cycles of pemetrexed-platinum doublet, he was put on maintenance chemotherapy with clinical response but, eventually, maintenance treatment was discontinued due to worsening fatigue. The patient developed significant disease progression resulting in a left peripheral mass adjacent to the cardiac silhouette. He then underwent localized SBRT followed by disease stability for approximately 6 months. 48 months ago, the patient developed progressive disease and was briefly put on vinorelbine. Due to toxicity and worsening kidney function, the treatment was stopped after one cycle. One month later, the patient started the immune checkpoint inhibitor, nivolumab. In the first imaging assessment there was evidence of response to immunotherapy and that was followed by disease control for 10 months. After that, asymptomatic lung and pleural progression ensued. Initial decision was made to continue nivolumab. Repeat scans revealed continued interval increases in the lung nodules. Metformin XR 2000mg PO daily was added to the treatment regimen. Since then, the patient has been tolerating the combination treatment well and new response was observed in the following scans with interval diminishing of the lung nodules followed by on-going stability for 17 months. **Conclusion:** There has been some evidence that metformin can enhance anti-PD-1/PD-L1 activity. We here presented a case of metastatic lung adenocarcinoma with long-term disease stability coinciding with the addition of metformin to nivolumab regimen. A new phase-2 clinical trial (NU16L04) open in our institution has been accruing NSCLC patients, including those previously refractory to anti-PD-1/PD-L1 to receive nivolumab and metformin combination.

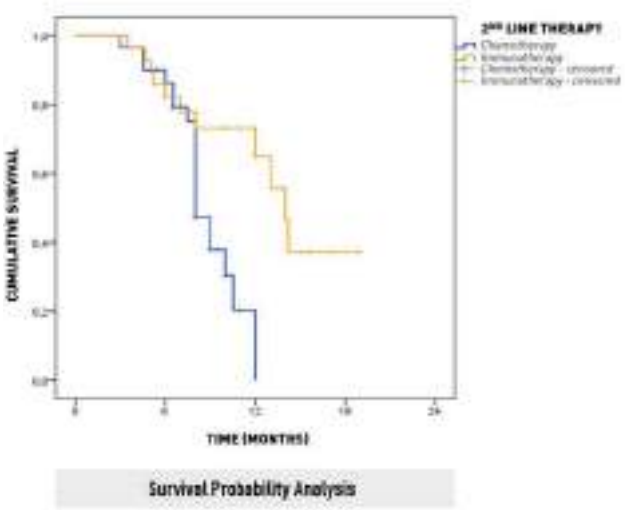
Keywords: Immunotherapy, nivolumab, metformin

EP1.04-13 IMMUNOTHERAPY VERSUS CHEMOTHERAPY FOR PREVIOUSLY TREATED METASTATIC NSCLC. RESULTS FROM DAILY CLINICAL PRACTICE

M. Pavlakis, T. Tegos, N. Alevizopoulos, K. Gioti, M. Vaslamatzis

Evangelismos General Hospital, Athens/Greece

Background: Immunotherapy has shown promising results in the treatment of mNSCLC.The aim of this retrospective analysis was to compare the efficacy and toxicity of chemotherapy and immunotherapy in the 2nd line treatment of mNSCLC. **Method:** Fifty-nine patients with advanced NSCLC consecutively admitted in our Medical Oncology Department were enrolled in the study. A total of 83% were men, and 17% women. Patients had median ECOG 1 (0-3), median age 68 (47-86) years, squamous(32%) and non-squamous histology(68%). All of them were previously treated with 1st line chemotherapy regimens. Following disease progression, they received either chemotherapy or immunotherapy as 2nd line therapy .We compared both the efficacy and toxicity of the two therapeutic options. In the immunotherapy arm, patients received either Nivolumab, or Pembrolizumab. **Result:** The number of patients whose disease progressed after receiving chemotherapy in the 2nd line, was similar to those who received immunotherapy. However, time to progression, was significantly shorter in the chemotherapy arm (p=0,015). There was significant difference in disease progression probability between the two arms in both 3 and 6 months (p<0,05). Patients with at least one adverse event had 2,27 times higher probability of disease progression. Median overall survival was 8 months for the chemotherapy arm in second line, compared to 14 months in the immunotherapy arm.



Survival Probability Analysis

EPOSTERS

There was no difference in survival between the two arms in the 6 month evaluation (p>0,05). However, in the 12 and 18 month evaluation, survival rates were significantly higher for patients in the immunotherapy arm (p=0,006 και p=0,001 respectively). **Conclusion:** Patients who received immunotherapy in 2nd line, had siginificantly higher overall survival rates, compared to those that received chemotherapy (p=0,006). There was no correlation between PD-L1 expression levels and clinical benefit. Immunotherapy had a better safety profile compared to chemotherapy. Data from our daily clinical practice are in line with current literature.

Keywords: Immunotherapy, NSCLC, 2nd Line

EP1.04-14 EFFECTS OF FOXP3-POSITIVE REGULATORY T CELL ON LYMPHOID FOLLICLE FORMATION OF PATIENT WITH LUNG SQUAMOUS CELL CARCINOMA

M. Nishihira, O. Araki, Y. Karube, S. Maeda, M. Chida

Dokkyo Medical University, Mibu/Japan

Background: We have reported that lymphoid follicle formation by tumor infiltrating lymphocytes (TILs) is a negative predictor of patients with lung squamous cell carcinoma (SCC) following surgery. However, the role of FoxP3-positive regulatory T cells on lymphoid follicle formation and survival is still unclear **Method:** Specimens obtained from patients during resection of lung SCC were examined for lymphoid follicle formation and immunohistochemistry of TILs. **Result:** Appearance of CD3/25/FoxP3-triple positive regulatory T cell was correlated with lymphoid follicle formation (p=0.001). Univariate analysis showed that pathological stage (p=0.037), lymphoid follicle formation (p=0.007), pleural invasion (p=0.025), vascular invasion (p=0.013), and appearance of CD3/25/FoxP3-triple positive regulatory T cell (p=0.097) were correlated with overall survival. Multivariate analysis revealed that lymphoid follicle formation (p=0.042) and pleural invasion (p=0.040) were independent prognostic factors related to overall survival, whereas CD3/25/FoxP3-triple positive regulatory T cells were not. **Conclusion:** Appearance of CD3/25/FoxP3-triple positive regulatory T cell was correlated with lymphoid follicle formation. Lymphoid follicle formation, rather than appearance of CD3/25/FoxP3-triple positive regulatory T cell, is a predictor of patient survival following surgery for lung SCC.

Keywords: tumor infiltrating lymphocyte, lung squamous cell carcinoma, lymphoid follicle formation

EP1.04-15 NSCLC RESPONSE DETERMINANTS TO CHEMOIMMUNOTHERAPY: DEEP PROFILING OF TUMORS FOLLOWING NEOADJUVANT CEMIPLIMAB AND CHEMOTHERAPY

T. Marron[1], A. Wolf[1], R. Flores[1], R. Veluswamy[1], J. Gomez[1], M.B. Beasley[1], D. Yankelevitz[1], A. Leader[1], I. Lowy[2], E. Miller[2], G. Thurston[2], V. Jankovic[2], R. Deering[2], B. Brown[1], A. Rahman[1], S. Gnjatic[1], F.R. Hirsch[1], N. Bhardwaj[1], M. Merad[1]

[1]*Icahn School of Medicine at Mount Sinai, New York/United States of America,* [2]*Regeneron, New York/United States of America*

Background: Clinical trials have demonstrated synergistic effects of combination chemoimmunotherapy in patients with locally advanced and metastatic non-small cell lung cancer (NSCLC), however, our understanding is limited as to why and for whom PD-1 blockade with or without chemotherapy is effective, as is our understanding of the mechanism of synergy between these therapies. While most patients with resectable NSCLC receive neoadjuvant or adjuvant chemotherapy, this intervention only changes the natural course of disease for ~5% of patients. Early studies have demonstrated major pathologic responses to neoadjuvant immunotherapy ± chemotherapy. **Method:** To investigate the immunodynamic effect of PD-1 blockade and chemotherapy, and identify potentially more effective immune modifying targets or combinations, we will use novel immunophenotyping platforms to characterize the effect of this combination on the tumor. This trial will enroll 52 patients with Stage Ib-IIIa NSCLC into three cohorts receiving 2 cycles of 1) platinum-doublet chemotherapy, 2) the PD-1 antibody cemiplimab, or 3) combination chemoimmunotherapy. Following surgery, patients will receive additional adjuvant chemoimmunotherapy; in total all patients will receive 4 cycles of standard platinum-doublet chemotherapy and 8 cycles of cemiplimab. All patients will undergo pre-treatment biopsies of their tumor, and blood will be collected at 6 time-points before and after surgery. The primary endpoint for this clinical trial is major pathologic response, defined as ≤10% viable tumor within resection. Secondary endpoints include: delay of surgery, disease-free survival, overall response rate, overall survival, measurement of adverse events, and change in CD8 T-cell infiltration. Exploratory endpoints include in-depth analysis of the pre-treatment tumor biopsies and post-treatment surgical specimens, and paired blood. We will characterize proteomic and transcriptomic changes in the stromal and immune compartment of tumors at the histologic level using a multiplexed ion-beam imaging (MIBI)—a novel multiplex immunohistochemistry platform capable of analyzing >50 markers on a single section of tissue—and at the single-cell level using Cellular Indexing of Transcriptomes and Epitopes by Sequencing (CITEseq), a novel platform combining the proteomic data-potential of mass cytometry (CyTOF) and the transcriptomic data-potential of single cell RNA sequencing including TCR sequencing. Feasibility of this multi-pronged approach has been demonstrated on untreated NSCLC (unpublished data, submitted as abstract to WCLC by our group). To probe for biomarkers correlating with response or resistance to therapy, we will perform unbiased analysis of peripheral blood lymphoid and myeloid populations by CyTOF, and measure nearly 100 soluble factors in serum using Olink. **Result:** This trial opened to accrual April 2019. **Conclusion:** Section not applicable.

Keywords: neoadjuvant, chemoimmunotherapy, immunophenotype

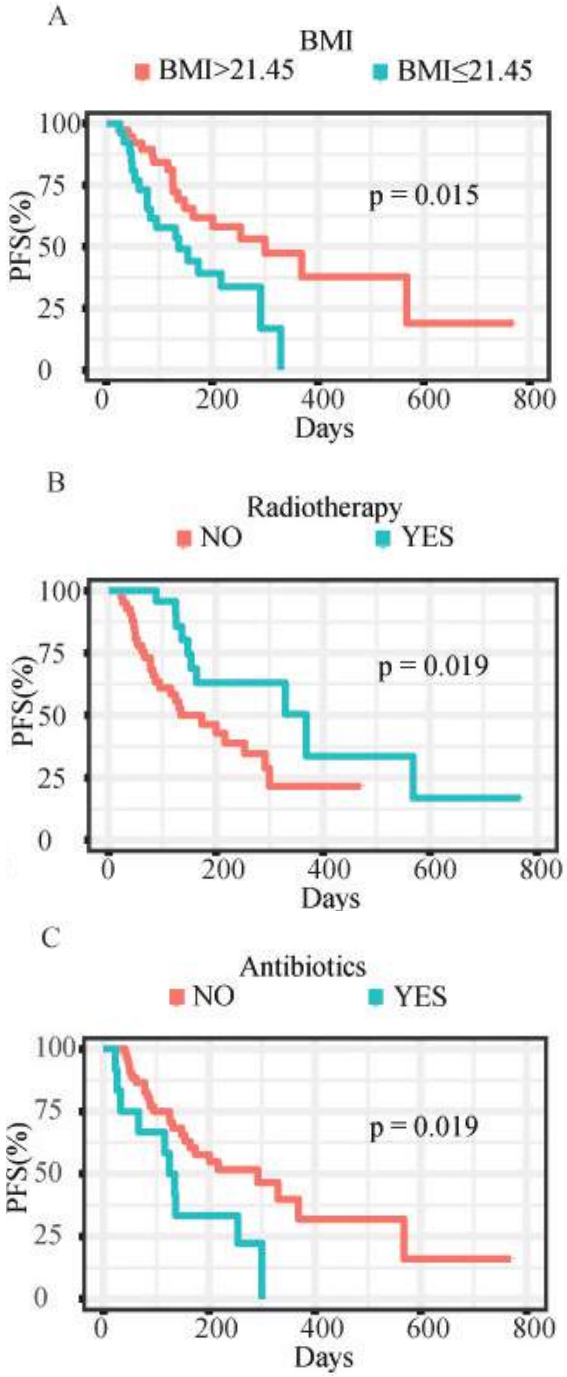
EP1.04-16 PREDICTIVE MARKERS FOR EFFICACY IN MALIGNANCIES TREATED WITH IMMUNE CHECKPOINT INHIBITORS

J. Sun, M. Chen, Q. Yang, P. Zhou, L. Chen, Q. Jia, B. Zhu

Cancer Institute of People's Liberation Army, Chongqing/China

Background: Predictive markers for tumor response and efficacy of immune checkpoint inhibitors (ICIs) are still controversial. Measurements of the widespread biomarkers, such as PD-L1 expression or tumor mutational burden, are invasive and costly. Therefore, we investigated several accessible factors to predict prognosis. **Method:** Clinicopathologic features and previous treatment records were collected from 64 patients with diverse malignancies between 2016 and 2018 in oncology department of Xinqiao hospital. Endpoints were progression free survival (PFS) and best overall response (bOR). The best cut-off points of continuous variables were determined by R. Kaplan-Meier was applied to analyze survival. The correlations between bOR and biomarkers were analyzed by Chi-square test. **Result:** After a median follow-up of 5.5 months, a significant improvement in PFS was observed in 38 patients with higher body mass index (BMI, cut-off=21.45kg/m^2) compared to the other 26 patients (10.0 months vs 4.6 months, p=0.015), also the former experienced a tendency of higher bOR rate (28.9% vs 11.5%, p=0.178). Moreover, patients who had radiotherapy records experienced better PFS (12.3 months vs 4.5 months, p=0.019) and higher bOR rate (26.1% vs 19.5%, p=0.542) than the others. Further, receiving antibiotics during immunotherapy was a negative factor in the prognosis of ICIs, which led to worse PFS (4.2 months vs 9.7 months, p=0.019) and lower bOR rate (8.3% vs 25.0%, p=0.383) than its counterparts.

Progression-free survival analysis



Conclusion: Higher BMI and radiotherapy records are associated with better clinical outcomes of immunotherapy, while receiving antibiotics is negatively correlated with efficacy of ICIs.

Keywords: Biomarker, ICIs, Efficacy

EP1.04-17 THE ASSOCIATION OF CLINICOPATHOLOGIC FEATURES AND PERIPHERAL BLOOD PARAMETERS WITH HIGH PD-L1 EXPRESSION IN NON-SMALL CELL LUNG CANCER

B. Bilgin[1], M. Hizal[2], S. Yucel[1], M.A. Sendur[2], N. Akyürek[3], M.B. Akinci[2], U. Yilmaz[4], B. Yalcin[2]

[1]*Ankara Chest Disease and Chest Surgery Hospital, Ankara/Turkey,* [2]*Ankara Yildirim Beyazit University, Ankara/Turkey,* [3]*Gazi University, Ankara/Turkey,* [4]*Ataturk Chest Disease and Chest Surgery Hospital, Ankara/Turkey*

Background: Programmed death ligand 1 (PD-L1) is a marker that widely used for prediction of response to immune check-point inhibitors (ICIs). Especially, PD-L1 tumor proportion score (TPS) of 50% or greater strongly predict the response of ICI in non-small cell lung cancer (NSCLC). However, dynamic alteration of PD-L1 expression are the major problems for reflection of the actual status of the PD-L1 expression level. Because of that, we aimed to investigate the factors that may be associated with PD-L1 TPS expression level for reflection of the actual status of PD-L1 TPS expression. **Method:** The patients who diagnosed with NSCLC and known PD-L1 expression level at the diagnosis were enrolled to study. The data was collected as retrospectively. PD-L1 expression was assessed by using PD-L1 IHC 22C3 pharmDx assay. The patients were stratified according to PD-L1TPS expression level as ≥ 50% and < 50%. For detection of PD-L1 related factors, clinicopathologic features and peripheral blood parameters which were obtained at the diagnosis and before the initiation of any treatment was used. Neutrophil-lymphocyte ratio (NLR) and the platelet-lymphocyte ratio (PLR) were calculated and also systemic immune-inflammation index was calculated by using formula as follow: (Neutrophil x Platelets)/ Lymphocyte. **Result:** Totally, 152 patients were enrolled to study. A hundred four of 152 patients (68.4%) were PD-L1 TPS expression level < 50% and 48 of 152 patients (31.6%) were also PD-L1 TPS expression level ≥ 50%.The clinicopathologic features were similar between TPS ≥ 50% and < 50% groups, except the amount of cigarette consumption. In univariate analyses; NLR, PLR, and SII were found significantly lower in patients with TPS ≥ 50% (p: 0.003 for NLR, p: 0.019 for PLR, p: 0.008 for SII).In correlation analyses NLR and PLR were found negatively correlated with PD-L1 TPS expression (r: -0.170, p:0.037 for NLR; r: -0.184, p: 0.024 for PLR).

The association of PD-L1 TPS expression and peripheral blood parameters

Parameter	PD-L1 TPS < 50% (Median)	PD-L1 TPS ≥ 50% (Median)	p
Hemoglobin (g/dl)	12.95	12.90	0.54
RDW	14.7	14.8	0.37
LDH (mg/dl)	220	218	0.66
CRP (mg/dl)	7.8	8.28	0.88
Albumin (mg/dl)	3.9	3.92	0.62
NLR	3.96	3.19	0.003
PLR	177.8	145.7	0.019
SII	1253.1	999.6	0.008

Conclusion: According to the results of our study, NLR, PLR, and SII can be used to the prediction of the high PD-L1 expression level. In addition, NLR and PLR, easily accessible - assessable and also cheap markers, can be used for reflection of current PD-L1 expression status in the during the treatment with ICIs that targeted to PD-1/PD-L1.

Keywords: PD-L1, NLR, PLR, SII, immune check-point inhibitors

EP1.04-18 REAL-WORLD TREATMENT WITH CHECKPOINT INHIBITORS: THE SWEDISH EXPERIENCE

S. Gagatek[1], M. Backman[2], J. Mattsson[2], K. Lamberg[1], E. Broström[1], J. Botling[2], P. Micke[2], J. Isaksson[2,3]

[1]*Uppsala University Hospital, Uppsala/Sweden,* [2]*Uppsala University, Uppsala/Sweden,* [3]*Gävle Hospital, Gävle/Sweden*

Background: The introduction of checkpoint inhibitors has fundamentally changed the treatment of advanced NSCLC patients. **Method:** In order to evaluate if the encouraging results from clinical trials translates into the clinical routine and to confirm the value of biomarker testing we evaluated NSCLC patients that were treated with a checkpoint inhibitor in the Uppsala-Gävle health care region between Januari 2016 and October 2018. Latest patient follow up was done in March 2019. Patient information, including therapy, response rates and survival were obtained from patient records **Result:** In total, 86 patients, were identified (44 female, median age 71 years; performance status 0=18, 1=45; 2-3=23). 28 patients were treated in the first line setting and 58 patients after previous chemotherapy. Checkpoint inhibitors that were given included pembrolizumab (31), nivolumab (36), atezolizumab (7). Two patients received a combination (durvalumab och tremelimumab). 67 of 86 patients were evaluable for response and of these 23 patients showed progressive disease, 17 stable disease, 22 partial response and 5 complete response. However, most patients that were not

evaluable for response either had only 1-2 cycles because of severe side effects or died early independent from treatment. Thus, for all patient treated with at least one course of checkpoint inhibitors response rate were lower (SD:20%; PR:26% and CR:6%). PD-L1 analysis was done for 69/86 patients (80%). The response (PR or CR) was numerically higher in the group with PD-L1 positivity ≥1% or ≥50% than with negative PD-L1 expression (54% vs 47% vs 13%), although not statistically significant (p=0.11). Median overall survival for patients with PD-L1 <1% was 2.3 years, for patients PD-L1 ≥1% 2.7 years and PD-L1≥50% 3.9 years (log rank-test, p=0.95). **Conclusion:** In conclusion, the response rates to checkpoint inhibitors in the first and second line were comparable to those observed in clinical trials. We confirmed that patients with low PD-L1 expression are unlikely to respond to checkpoint inhibition.

Keywords: NSCLC, checkpoint inhibitors, PD-L1 expression

EP1.04-19 FIRST EXPERIENCE WITH ATEZOLIZUMAB IN SLOVAKIA

P. Kasan[1], P. Berzinec[2], M. Cerna[3], I. Andrasina[4], A. Cipkova[5], G. Chowaniecova[2], L. Denkova[1], R. Godal[6], H. Kuzmova[2], Z. Svihelova - Liskova[1], M. Martak[1], J. Mazal[7], J. Obertova[6], Z. Pribulova[5], M. Urda[7], M. Vesela[1]

[1]*Comenius University Hospital, Bratislava, Bratislava/Slovak Republic,* [2]*Specialised Hospital of St Zoerardus Zobor, Nitra/Slovak Republic,* [3]*Slovak Medical University, Bratislava/Slovak Republic,* [4]*P.J. Safarik University, Kosice/Slovak Republic,* [5]*East Slovakian Cancer Institute, Kosice/Slovak Republic,* [6]*National Cancer Institute, Bratislava/Slovak Republic,* [7]*Faculty Hospital, Banska Bystrica/Slovak Republic*

Background: New immunotherapeutics, PD-1 and PD-L1 checkpoint signalling inhibitors, have improved the prospects of patients with advanced non-small cell lung cancer (NSCLC). The purpose of this study was to assess the first results achieved with the PD-L1 inhibitor atezolizumab in the treatment of advanced NSCLC in Slovakia. **Method:** The data of patients who entered the pre-approval access programme with atezolizumab between June 2017 and September 2017 were reviewed in the retrospective multicentre study. Data regarding patients were obtained from the databases of participating institutions and patient files. Statistical analyses were performed using MedCalc® software. PFS and OS were estimated using the Kaplan–Meier method, based on the data available by the end of March 2019. **Result:** Altogether 22 patients were included. Characteristics of patients: median age, years (range): 63 (41 - 85), female/male: 3/19, ECOG PS: 0, 1, 2, 3 in 6, 11, 3, 2 patients, respectively. Histology: 8 squamous, 14 non-squamous. Patients with locally advanced disease: 1, with metastatic disease: 21. Treatment lines before atezolizumab: median: 2 (range: 1 - 3). Median PFS: 5 months (95%CI: 4 - 10). Median OS: 11 months (95%CI: 8 – 20). Complete/partial response: 1/4 patients. Median PFS in patients with complete or partial response was not achieved but will be over 19 months (range: 13 – 21+). Two patients only had to discontinue atezolizumab due to toxicities (pneumonitis and hepatitis). **Conclusion:** Results from our retrospective study are similar to those seen in the phase III trial OAK, excepting PFS. However, the different CT scanning schedules for the response evaluations and follow up in the different participating institutions could influence numerically better PFS seen in our patients.

EP1.04-20 PHASE I TRIAL OF IN SITU VACCINATION WITH AUTOLOGOUS CCL21-MODIFIED DENDRITIC CELLS (CCL21-DC) COMBINED WITH PEMBROLIZUMAB FOR ADVANCED NSCLC

A. Lisberg, B. Liu, R. Salehi-Rad, J.M. Lee, L. Tran, K. Krysan, R. Li, Y. Lin, A. Tseng, F. Abtin, R. Suh, S. Oh, D. Aberle, L. Winter, W.D. Wallace, D. Elashoff, E. Garon, S. Sharma, S. Dubinett

University of California, Los Angeles, Los Angeles/United States of America

Background: Effective immunotherapy options are lacking for patients with advanced non-small cell lung cancer (NSCLC) who progress on a programmed cell death-(ligand)1 [PD-(L)1] inhibitor and for those that are epidermal growth factor receptor (EGFR) mutation or anaplastic lymphoma kinase (ALK) rearrangement positive after progression on tyrosine kinase inhibitor (TKI) therapy. One potential approach to improve immune checkpoint efficacy in these patient populations is to promote cytolytic T cell infiltration into tumors. This can be accomplished via *in situ* vaccination with functional antigen presenting cells (APCs) which can take advantage of the full repertoire of tumor antigens and convert the tumor into a lymph node-like environment promoting both local and systemic T cell activation. The chemokine CCL21 promotes co-localization of naive T cells and dendritic cells (DCs) to facilitate T cell activation. Our preclinical studies and phase I trial of intratumoral (IT) administration of DC genetically modified to overexpress CCL21 (CCL21-DC) revealed augmentation of tumor antigen presentation *in situ*, resulting in effective T cell responses and systemic antitumor immunity. However, increased PD-L1 expression was observed in some patient tumors, suggesting that tumor-mediated impairment of T cell function may be forestalling a more robust antitumor response. Similarly, improved PD-(L)1 inhibitor efficacy may be possible with enhanced T cell infiltration and augmented APC function following IT CCL21-DC. Therefore, we are conducting a phase I trial, combining IT CCL21-DC with pembrolizumab in patients with advanced NSCLC that are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. **Method:** This is a phase I, single institution, non-randomized, dose-escalating, multi-cohort trial followed by dose expansion. A maximum of 24 patients (9-12 escalation + 12 expansion) with stage IV NSCLC will be evaluated who have tumors accessible for IT injection and are either (1) EGFR/ALK wild-type after progression on a PD-(L)1 inhibitor or (2) EGFR/ALK mutant after progression on TKI therapy. Three IT injections of autologous CCL21-DC (days 0, 21, 42) will be concurrently administered with pembrolizumab, followed by q3wk pembrolizumab up to 1 year. Primary objective of dose escalation is safety and determination of maximum tolerated dose (MTD) of IT CCL21-DC ($5x10^6$, $1x10^7$, $3x10^7$) when combined with pembrolizumab. Primary objective of dose expansion is objective response rate (ORR) of CCL21-DC at MTD combined with pembrolizumab. Secondary objectives include adverse event profiling and determination of drug target activity by immune monitoring studies. This trial, NCT03546361, is currently open for enrollment. **Result:** Section not applicable **Conclusion:** Section not applicable

Background: To investigate potential associations between clinical and standard peripheral blood biomarkers and clinical outcome in patients with non-small cell lung cancer (NSCLC) treated with nivolumab. **Method:** A total of 120 patients with advanced NSCLC treated at seven comprehensive cancer care centers were analyzed in this national retrospective study. Survival statistics were evaluated using Kaplan–Meier method and Cox analysis. **Result:** Among clinical parameters, histology was significantly associated with progression-free survival. Univariate Cox-proportional hazards model indicated prognostic and predictive role of a panel of laboratory parameters reflecting chronic inflammatory pattern (elevated neutrophil count, neutrophil-to-lymphocyte ratio, platelet-to-lymphocyte ratio, C-reactive protein and decrease in hemoglobin and albumin). Higher serum calcium concentration was also associated with nivolumab treatment effect. **Conclusion:** Tumor histology was the only clinical parameter predicting the outcome of nivolumab treatment. Among the laboratory parameters, our analysis identified a laboratory panel reflecting chronic inflammation as potential predictive marker of nivolumab treatment.

Keywords: NSCLC, nivolumab, predictive factor

EP1.04-22 EFFICACY AND SAFETY OF IMMUNE CHECKPOINT INHIBITORS IN A DANISH REAL LIFE NON-SMALL CELL LUNG CANCER POPULATION

B. Bjørnhart[1,2,3], K. Hansen[2,3], T. Jørgensen[2,4], J. Herrstedt[4,5], T. Schytte[1,2]

[1]*University of Southern Denmark, Odense/Denmark,* [2]*Odense University Hospital, Odense C/Denmark,* [3]*OPEN, Odense Patient Data Explorative Network, Odense C/Denmark,* [4]*Academy of Geriatric Cancer Research (AgeCAre)., Odense/Denmark,* [5]*Zealand University Hospital, Roskilde/ Denmark*

Background: To investigate effect and toxicity of immune checkpoint inhibition (ICI) in a Danish unselected real life non-small cell lung cancer (NSCLC) population. By including patients underrepresented in clinical trials, such as those with brain metastasis (BM), higher age, more comorbidity, autoimmunity and poorer performance status (ECOG), comparison to pivotal data on clinical trial populations is possible. **Method:** Retrospective real life data were gathered from 118 consecutive NSCLC patients with incurable/recurrent disease stage IIIA-C and metastatic stage IV (revised according to the IASLC 8th Edition Lung Cancer TNM Staging) treated with ICI at the Department of Oncology at the University Hospital of Odense, Denmark from September 2015-April 2018. Immune related Adverse Events (irAE) grade 3-5 were registered prospectively during the same period. Patient, tumor and treatment characteristics were obtained from electronic patient records including charlsons comorbidity index score (CCIS). Overall survival (OS), progression free survival (PFS) and best response were assessed using Kaplan Meier estimates and the log-rank test. Cox regression was used for univariate analysis of factors affecting survival. Reasons for termination of ICI including level of irAEs grade 3-5 toxicity leading to termination of ICI was reported as well. **Result:** Median age for patients was 66 [IQR 59-71] and 62 [range: 55-64] for those with BM. Females 63%; adenocarcinoma/squamous/others 69%/23%/8%; ECOG ≥ 2 10%; bone/brain/liver metastases 36%/18%/15%; PD-L1 (TPS) <1%/ ≥1%≤ 49%/≥50%/NR: 3%/14%/68%/15%; baseline autoimmunity 10%, Charlsons Comorbidity Index Score (CCIS) ≥ 2 39%, treatment line: 1st/2nd/ ≥3rd 39%/30%/31%. Median OS of all patients and patients with BM comprised 16.1 months [95% CI 10.7-21.5] and 8.2 months [95% CI 1.0-15.5], respectively. Twenty-four percent of patients terminated ICI due to irAE grade 3-5 alone (grade 5, n=1). There was no association of age or BM with irAE grade 3-5. **Conclusion:** OS and PFS were comparable to clinical trial reports. Long-lasting remission is possible in patients with BM. Real life populations have higher rates of irAE grade 3-4 than reported in clinical trials, but it does not seem to impact median OS.

Keywords: Non small cell lung cancer, real-life patients, Checkpoint inhibitors

EP1.04-23 ONGOING PHASE II TRIAL OF ANTI-PD1 THERAPY IN COMBINATION WITH CIMAVAX-EGF IN PATIENTS WITH ADVANCED NSCLC OR SQUAMOUS CELL HEAD AND NECK CANCER

G. Dy[1], T. Crombet[2], K. Leon[2], Z. Mazzora[2], D. Hernandez[2], A. Lage[2], A. Dozier[1], H. Chen[1], A. Hutson[1], D. Plessinger[3], C. Johnson[1]

[1]*Roswell Park Comprehensive Cancer Center, Buffalo/United States of America,* [2]*Center for Molecular Immunology, Havana/Cuba,* [3]*Innovative Immunotherapy Alliance, Havana/Cuba*

Background: CIMAvax-EGF (CE) is a novel EGF-depleting immunotherapy consisting of human recombinant EGF conjugated to recombinant P64k derived from *Neisseria meningitidis*, that elicits an anti-EGF antibody response, resulting in reduction of circulating EGF levels. A randomized phase III study of CIMAvax-EGF administered after first-line platinum-based chemotherapy as switch maintenance therapy, in patients with advanced NSCLC, demonstrated improved overall survival versus best supportive care alone, particularly in patients with high baseline serum EGF levels. A recently completed phase I trial combining CE with nivolumab (N), an anti-PD1 immune checkpoint inhibitor, as second-line therapy for advanced NSCLC, demonstrated the combination is safe and induces a higher frequency of good anti-EGF antibody responses compared to the historical experience with CE alone (Figure 1). In addition, promising efficacy was observed in patients with PD-L1 low (< 1%) tumors. These results led to the initiation of this multi-arm phase II trial.

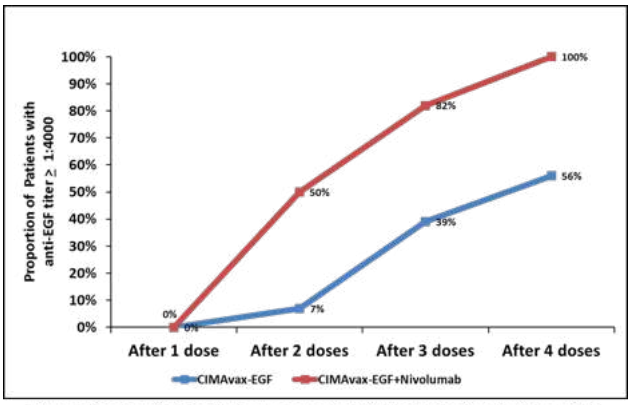

Figure 1. Good anti-EGF antibody response (>1:4000) elicited at earlier time points during induction for patients receiving CIMAvax-EGF in combination with Nivolumab compared to CIMAvax-EGF monotherapy experience in a phase 3 NSCLC study.

Method: CIMAvax-EGF (2.4 mg IM every 2 weeks x 4 doses, then every 4 weeks thereafter) in combination with Nivolumab (240mg IV every 2 weeks) is being evaluated in this multi-arm phase II study (NCT02955290) as second-line therapy in patients with advanced NSCLC (cohort A), advanced/recurrent head and neck squamous cell cancer (cohort B) and is also being tested as first-line therapy in combination with pembrolizumab (200 mg IV every 4 weeks) in patients with advanced NSCLC with PD-L1 ≥ 50% (cohort C). The primary and secondary endpoints are to evaluate 12-month OS and PFS in cohorts A and B, and to evaluate objective response rate, PFS and 12-month OS in cohort C. Exploratory objectives include characterizing tissue-based immune and EGFR signaling as well as serum EGF levels, anti-EGF antibody levels and other blood-based biomarkers in relation to clinical outcomes. **Result:** A total of 10 patients have been enrolled to this ongoing study with a planned enrollment of up to 127 patients. An update on accrual along with interim safety, efficacy and correlative data will be presented. **Conclusion:** To date, the combination of CIMAvax-EGF with anti-PD1 therapy has been safe and well tolerated. Enrollment to the phase II portion of this study is ongoing at Roswell Park and is in the process of being expanded to additional U.S. sites.

Keywords: CIMAvax-EGF, anti-PD1, Immunotherapy

Background: Tumour PD-L1 expression is a key predictor of benefit from anti-PD-1 therapy in NSCLC. Clinical factors associated with benefit include smoking status. We explored the additional predictive impact of smoking status added to tumour PD-L1 expression. **Method:** A prospective cohort of 125 patients with advanced NSCLC treated at a single institution with anti-PD-1 therapy and outcome data including treatment response was explored. Ordinal logistic regression was performed to test factors associated with treatment response, including age, sex, ethnicity, pathology, PD-L1 expression (>=1%) and smoking status. **Result:** Median age of the cohort at the time of anti-PD-1 therapy was 65.3 years (range 28-88.2); 55.2% were male, 21.2% were East Asian, 76.8% had adenocarcinoma (11.8% *EGFR* mutant, 15.2% squamous, 8% other). In univariable analysis, smoking status was associated with higher response rate (current versus never smoker: OR 3.73, 95% CI 1.40-9.97, p=0.004; past versus never: OR 1.09; 95% CI 0.52-2.30, p=0.09). Patients with *EGFR* mutant lung cancer were unlikely to respond (OR 0.25; 95% CI 0.07-0.83, p=0.02). In multivariable analysis, smoking remained significantly associated with response in patients with positive tumour PD-L1 expression (current vs. never smoker OR 4.01; 95% CI 1.31-12.27, p=0.01). **Conclusion:** Clinical factors such as smoking status may enrich our ability to select patients with PD-L1 positive lung cancer that respond to immunotherapy.

EP1.04-25 INCREASED PD-L1 EXPRESSION IN MET AMPLIFIED (AMP) ADVANCED NON SMALL CELL LUNG CANCER (NSCLC) PATIENTS (P)

E. Carcereny[1], M. Domenech[1], A. Muñoz[2], L. Angelats[1], A. Plaja[1], C. Erasun[1], C. Sanz[2], A. Estival[1], A. Hernandez[2], S. España[1], T. Moran[1], L. Vilà[3], Y. Garcia[3], E. Dalmau[3], I. Perez[1], A.M. Esteve[1], O. Fernandez[1], M. Manzano[1], J.L. Mate Sanz[2]

[1]*Catalan Institute of Oncology-Badalona; Hospital Universitari Germans Trías I Pujol; B-ARGO; IGTP, Badalona/Spain,* [2]*Hospital Universitario Germans Trias i Pujol, BADALONA/Spain,* [3]*Hospital Parc Taulí, Sabadell/Spain*

Background: MET amp has been reported in a subset of NSCLC p and treatment with crizotinib has proved clinical activity in cases of MET exon 14 alterations and MET amp. Recently, immunotherapy has emerged as a new approach to treat NSCLC. The development and success of programmed cell death 1 (PD-1)/program death-ligand 1 (PD-L1) checkpoint inhibitors has been correlated with PD-L1 status, particularly in NSCLC p whose tumors express high PD-L1 levels by tumor proportion score (TPS) ⩾ 50%. In this study we have reviewed the PD-L1 status in a cohort of advanced NSCLC p with a METamp. **Method:** PDL1 expression has been evaluated in a retrospective cohort of NSCLC p with MET amp and wild type for EGFR, KRAS, BRAF mutations and ALK and ROS1 rearrangements. Overall Survival (OS) was evaluated with Kaplan-Meier curves and groups were compared using log-rank test. Clinical and tumor characteristics, as well as treatment details, were evaluated. MET amp was analyzed by FISH, while PD-L1 status was assessed by immunochemistry by SP 263. antiboby **Result:** A total of 50 p were included, 15 p has high or intermediate Met amp and 35 p had low or negative Met amp. Median age were 66 years old. 39 (78%) p were male, 43 (86%) p were smokers or former smokers, 37 p (74%) were ECOG PS 0-1, 37 p (74%) were stage IV. PD-L1 were negative (< 1%) in 21 p (42%), positive (>1%) in 26 p (52%). PD-L1 highly positive in 18 p (36%). Statistically significant more p had PD-L1 positive (TPS > 1%) in high or intermediate Met amp p versus low or negative (92.9% vs 39.4%; p 0.001). And high or intermediate Met amp p had PD-L1 high expression (TPS > 50%) than negative or low Met amp p (64.3% vs 27.3%; p 0.020). No differences in PD-L1 expression was observed by gender, ECOG PS or smoking status. Median OS was 16.367 m (2.295-30.438). No differences in OS were seen by PD-L1 expression or Met amp status. **Conclusion:** PD-L1 expression in NSCLC p is positively correlated with MET amp, especially in p with PD-L1 > 50%. Our data suggests that MET amp may play a direct role in up-regulating PD-L1 expression in NSCLC p. Additionally, combination therapy targeting MET and checkpoint inhibition should be considered as a potential therapeutic strategy for NSCLC p with high and intemediate MET amp.

Keywords: PD-L1, MET amplification

EP1.04-26 EFFICACY AND SAFETY OF ANTI-PD-1 INHIBITORS IN ELDERLY PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER

Y. Tanaka[1], T. Okano[2], Y. Kudo[1], S. Takeuchi[1], Y. Makino[1], Y. Shimada[1], S. Maehara[1], M. Hagiwara[1], M. Kakihana[1], N. Kajiwara[1], T. Ohira[1], N. Ikeda[1]

[1]*Tokyo Medical University, Tokyo/Japan,* [2]*Nippon Medical School Chiba Hokusoh Hospital, inzai-city/Japan*

Background: Recently, the proportion of elderly patients with advanced non-small cell lung cancer (NSCLC) has increased. However, those patients cannot occasionally continue to receive systemic therapy due to adverse events (AEs) or decreased performance status (PS). There are few reports which address efficacy and safety of anti-PD-1 inhibitors as the second line therapy for such elderly patients. The purpose of this study is to evaluate the efficacy and feasibility of anti-PD-1 inhibitors for elderly patients with advanced NSCLC are controversial. **Method:** We retrospectively evaluated the efficacy and feasibility of anti-PD-1 inhibitors in 14 elderly patients (≥ 75 years old) with advanced NSCLC, comparing with 53 non-elderly patients (< 75 years old). All patients received anti-PD-1 inhibitors as the second line therapy or later. **Result:** Of the 14 elderly patients, 11 patients had PS score 0 or 1. Anti-PD-1 inhibitors included nivolumab in 11 patients and pembrolizumab in 3 patients, and the median courses of anti-PD-1 inhibitors was 7 (1-27). There was no difference in patient background between the elderly group and the non-elderly group. The objective response rate (ORR) was 43% in the elderly group, while the rate was 30% in the non-elderly group (p = 0.33). The median progression-free survival (PFS) was 12.1 and 11.1 months in the elderly and non-elderly group, respectively (p = 0.86). The median overall survival (OS) was 14.3 and 29.6 months in the elderly and the non-elderly group, respectively (p = 0.53). Immune related AEs (irAEs) of grade 2 or higher were significantly observed in 50% of the elderly group, comparing with 17% of the non-elderly group (p = 0.048).

Immune-Related Adverse Events

Age	<75 (%)	75≦ (%)	
Any (≧G2)	9 (17.0)	7 (50.0)	p=0.048
Skin Reaction	0 (0)	2 (14.3)	
Pneumonitis	3 (5.7)	2 (14.3)	(G5 IP:1)
Hepatitis	2 (3.8)	0 (0)	
Colitis	2 (3.8)	1 (7.1)	
Nephritis	0 (0)	0 (0)	
Neuropathy and Myositis	1 (1.9)	1 (7.1)	
Endcrinopathy	1 (1.9)	1 (7.1)	

Conclusion: The anti-PD-1 inhibitors led to good prognosis for the elderly patients with advanced NSCLC while the rate of irAEs was higher. The follow-up or management of irAE should be careful.

Keywords: Anti-PD-1 inhibitor, Elderly patients, immune related adverse event

EP1.04-27 EXPRESSION ANALYSIS OF PROGRAMMED DEATH-LIGAND (PD-L) 1 IN LARGE CELL NEUROENDOCRINE CARCINOMA

T. Sakaue[1], H. Nakaoka[2], M. Okazaki[3], H. Shigematsu[1], H. Izutani[1], Y. Sano[1]

[1]*Ehime University Hospital, Toon City/Japan,* [2]*Ehime University, Toon City/Japan,* [3]*Okayama University Hospital, Okayama/Japan*

Background: Programmed death (PD)-1/PD-ligand-1 (PD-L1) signaling is main target of immune-checkpoint therapy for lung cancer. Since PD-L1 expression level is known as an important indicator for patient selection of PD-1/PD-L1 blockade therapy, immunohistochemical analysis using anti-PD-L1 antibody were largely performed in various lung cancer tissues. However, there was few evidences regarding expression pattern of PD-L1 in large cell neuroendocrine carcinoma (LCNEC). In this study, we aimed to clarify the tissue distribution of PD-L1, and gene expression pattern between PD-L1-positive and negative cells in LCNEC. **Method:** Lung cancer tissues were derived from patients with LCNEC (n=10) and adenocarcinoma (n=8). All tissues were stained with anti-PD-L1 (SP142, Ventana/Roche), CD8 (T lymphocytes), and PD1 antibody using OptiView DAB IHC systems. To investigate the molecular mechanism of overexpression of PD-L1 in LCNEC, we have also performed microarray analysis of PD-L1-positive and -negative cancer cells in the identical LCNEC patient. **Result:** From immunohistochemical staining data, while 25% of adenocarcinoma were PD-L1 positive, 80% of LCNEC were strongly stained by anti-PD-L1 antibody. Invasion of PD-1-positive lymphocytes were also seen around PD-L1 positive lung cancer cells. Microarray data showed that antigen-presenting related genes were dominantly up-regulated in the PD-L1-positive cells. **Conclusion:** Our data concluded that the patients with LCNEC might be targets for immune-checkpoint therapy using anti-PD-1 neutralizing antibody.

Keywords: LCNEC, PD-L1, Immune-checkpoint therapy

EP1.04-28 THE ABSCOPAL EFFECTS OF THE COMBINATION OF RADIOTHERAPY AND GM-CSF FOR PATIENTS WITH METASTATIC THORACIC CANCERS

M. Liu, X. Cai, Y. Zeng

Department of Radiation Oncology, Shanghai/China

Background: An absopal response was defined as distal tumor regression out of irradiated field induced by radiotherapy and mediated by immune system. Golden EB et al reported a benefit with the use of Granulocyte-macrophage colony-stimulating factor (GM-CSF) with local radiotherapy in a subset of chemotherapy or hormone therapy in patients with metastatic solid tumors. However, the contribution of systemic therapy to abscopal effects couldn't be defined. Therefore, we conducted the study aiming to evaluate the abscopal effects of the pure combination of local radiotherapy and GM-CSF in patients with metastatic thoracic cancers. **Method:** Patients who met the following criteria were included for this study: (1) Pathologic confirmation of thoracic cancer by histology; (2) at least three distinct measurable sites of metastatic disease; (3) received at least one line of previous chemotherapy and had stable or progressing disease to the last chemotherapy or refused to receive chemotherapy; (4) received the combination of GM-CSF and radiotherapy; (5) no previous malignancies; (6) no previous immunotherapy. **Result:** A total of 30 consecutive patients who were treated between March 31, 2016 and March 31, 2019 were included in this study. In the 16 patients with lung cancer, 2 partial abscopal responses, 9 stable and 5 progress were observed. In the 10 patients with thymic cancer or thymoma, 2 partial abscopal responses (thymic cancer), 6 stable and 2 progress were seen. Neither of the two patients with esophageal cancer had progressive diseases within 3 months. The patient with tracheal adenoid cystic carcinoma had partial response to the treatment, whereas the other patient with malignant pleural mesothelioma had stable disease. Twenty-four patients (80%) received GM-CSF of 125ug/m2 d8-22, which was the same as Golden EB et al reported. However, 8 patients had high fever (33.3%), 4 patients (16.7%) had edema (Grade 2: 3, Grade 3: 1), 4 patients (16.7%) had dyspnea of Grade 2, and one patient had dermatitis of Grade 3. Another one patient underwent cerebral infarction during the third day of GM-CSF injection. The other 6 patients who had GM-CSF of 70% dosage (87.5ug/m2) had no obvious side effects. No evidence showed that the reduced dosage of GM-CSF may have negative influence on the effect of the treatment. **Conclusion:** In conclusion, pure combination of local radiotherapy and GM-CSF may increase the incidence of abscopal responses, and bring benefits to patients with thoracic cancers except esophageal cancer. Lower dosage of GM-CSF is recommended to Asian patients.

Keywords: GM-CSF, Abscopal effect, radiotherapy

EP1.04-29 KHORANA SCORE: A POTENTIAL NEW BIOMARKER FOR REAL LIFE NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS TREATED WITH IMMUNOTHERAPY

B. Bjørnhart[1,2,3], K. Hansen[2,3], T. Jørgensen[2,4], J. Herrstedt[4,5], T. Schytte[1,2]

[1]*University of Southern Denmark, Odense/Denmark,* [2]*Odense University Hospital, Odense C/Denmark,* [3]*OPEN, Odense Patient Data Explorative Network, Odense C/Denmark,* [4]*Academy of Geriatric Cancer Research (AgeCAre)., Odense/Denmark,* [5]*Zealand University Hospital, Roskilde/Denmark*

Background: PD-L1 tumor proportion score is presently the only biomarker used for selecting incurable NSCLC patients for immune check point inhibition (ICI). Performance score (ECOG) and comorbidities are useful, but no specified guidelines exist in this regard. New objective biomarkers are warranted. Khorana score (KS) is a validated tool used to predict venous thromboembolisms (VTE) in out-patients with cancer prior to chemotherapy. For NSCLC patients undergoing chemotherapy KS has recently been associated with prediction of early mortality and not VTE. KS has not previously been investigated in patients undergoing ICI. **Method:** Retrospective data from 118 incurable advanced/metastatic NSCLC patients treated with ICI in a single center during the period of September 2015-April 2018 was gathered. Baseline platelet count (PC), leucocyte count (LC), and hemoglobin count (HC) were registered. Baseline body mass index calculations were performed as well as KS (a minimum of KS ≥ 1 due the primary lung cancer disease). Based on follow-up data Kaplan Meier curve estimates of overall survival (OS) and progression free survival (PFS) were performed. **Result:** For patient, tumor and treatment characteristics see Table 1. Fourteen percent had known VTE prior to ICI. Two patients died from pulmonary embolisms. KS correlated significantly to OS but not to PFS. A median OS of 18.1 months [CI 12.8-23.4] and 8.4 months [CI 4.3-12-6] was found for groups with KS=1-2 and KS≥3, respectively (log-rank test, p=0.017).

Table 1.

Age, median (years)	66
Interquartile range	[59-71]
PD-L1 tumor proportion score (TPS), n (% of pts)	
< 1%	3 (3)
>=1% but < 50%	16 (14)
>= 50%	80 (68)
NR	19 (15)
ECOG score at baseline, n (% of pts)	
0	31 (26)
1	75 (64)
>=2	12 (10)
Charlsons Comorbidity Index Score, n (% of pts), range	[0-8]
0	35 (30)
1	37 (31)
2	22 (19)
>=3	24 (20)
Khorana Score (KS), median, range, n (%) (n=107)	2 (1-4)
1	51 (43)
2	37 (31)
3	27 (23)
4	2 (2)

Conclusion: Baseline Khorana Score may represent a new clinical applicable prognostic biomarker for incurable NSCLC patients undergoing ICI. A KS ≥ 3 may be a predictor for early mortality but large prospective studies validating or rejecting this are warranted.

Keywords: Biomarker, Checkpoint inhibitors, Non small cell lung cancer

EP1.04-30 RECIST AND IRECIST COMPARISON IN A COHORT OF PATIENTS WITH ADVANCED NSCLC TREATED WITH IMMUNOTHERAPY: PRELIMINARY STUDY

F. García Martínez, M. Fernández-Velilla Peña, P. Cruz Castellanos, J. De Castro Carpeno, A. Pertejo, I. Torres Sánchez

Hospital Universitario La Paz, Madrid/Spain

Background: Nivolumab, Pembrolizumab and Atezolizumab are anti-programmed death-receptor-1 (PD-1) and anti-programmed-death-ligand 1 (PD-L1) immunotherapy agents used in the treatment of advanced non-small cell lung cancer (NSCLC). However, its radiological evaluation is challenging because of atypical patterns of response and immune-related adverse events. This study aims to (i) compare the Response Evaluation Criteria in Solid Tumors (RECIST), version 1.1, with the Immune RECIST (iRECIST) and (ii) explore the association of response patterns and clinical outcome. **Method:** We conducted a retrospective study of previously treated patients with advanced NSCLC who received Nivolumab, Pembrolizumab or Atezolizumab (first and second line). All CT scans were reviewed by two radiologists specialized in immunotherapy evaluation (1 senior, 1 junior). Tumor response was assessed according to both RECIST v1.1 and iRECIST C. **Result:** Were included 39 patients (27 male, 12 female) between November 2014 and December 2018 with advanced NSCLC. Median of age was 64 years (range 43 to 86). 13 patients (33,3 %) were treated with Nivolumab, 18 patients (46,1 %) with Pembrolizumab and 8 patients (20,5 %) with Atezolizumab. Among of 100% of patients included, 35,9 % showed partial response (PR),

20,5% stable disease (SD) with RECIST and iRECIST criteria. 43,6 % of patients showed progressive disease (PD) with RECIST criteria but only 4 of them were confirmed progressive disease (iCPD) with iRECIST criteria (2 truly progressed and died, 1 showed PR with the treatment and 1 reached SD). 8 patients with PD (20,5 %) could not be confirmed with iRECIST, remaining as unconfirmed progressive disease (iUPD), 5 of them because of patient's death, 1 because a change of therapy was performed and 2 because they reached SD within the treatment. The remaining 4 patients with PD presented improvement within the treatment after the initial progression (pseudoprogression). **Conclusion:** In our study, both RECIST 1.1 and iRECIST criteria were valid for measuring the effectiveness of the treatment with Nivolumab, Pembrolizumab and Atezolizumab. No differences were found in the assessment of PR and SD. 13 differences were detected between RECIST and iRECIST in the assessment of PD. RECIST criteria underestimated more the benefit of the treatment compared with iRECIST, but was better detecting true PD resulting in patient's death than iRECIST (which could not always confirm the progression). Given the relatively small number of patients studied, further study is warranted on whether RECIST and iRECIST criteria are equivalent to evaluate new immunotherapy treatment in NSLC.

Keywords: Immunotherapy, RECIST, iRECIST

EP1.04-31 IMMUNOTHERAPY IN ADVANCED NON-SMALL CELL LUNG CANCER PREVIOUSLY TREATED: REAL WORLD DATA

F. Ferreira Pereira, A.R. Lopes, A. Cruz, M. Cassiano, A. Rosinha, C. Oliveira, A. Rodrigues, J. Oliveira, I. Pousa, I. Azevedo, M. Soares

Instituto Português de Oncologia do Porto, Porto/Portugal

Background: Immunotherapy has changed the paradigm of the treatment and prognosis of Non-Small Cell Lung Carcinoma (NSCLC). Pembrolizumab and nivolumab are monoclonal antibodies that blocks PD-1, both approved in advanced NSCLC. The aim of this study was to evaluate the demographic, histological characteristics, response and toxicities of these drugs. **Method:** This is a retrospective cohort of patients with metastatic NSCLC that had been treated with pembrolizumab or nivolumab in our institution, who began treatment until 12.2018. **Result:** 60 patients were included in this study. In pembrolizumab group (N27), 81.5% (22/27) were men, 53.8% (14/26) ex-smokers, median age 68 (45-79). Histologically, 81.5% (22/27) were adenocarcinomas, EGFR negative, one with ALK translocation and 48.1% (13/27) with PD-L1 levels > 50. At diagnosis 66.7% (18/27) was in stage IV. 1st line palliative chemotherapy was platinum/pemetrexed in most patients (59.3% 18/27). 81.5%(22/37) were treated with pembrolizumab in 2nd line. ECOG at the start of pembrolizumab was 1 in 74.1% (20/27). Median number of cycles was 8 (1-34). 42.3% (11/26) had toxicity, grade 3 in 4 patients, the most common being asthenia, anorexia and hypothyroidism. Treatment discontinuation occurred due to clinical deterioration in 33.3% (9/27) or 25.9% (7/27) disease progression. 7 patients (25.9%) maintained treatment. 12 patients die due to NSCLC (mortality: 44.4%). In nivolumab group (N 33), 78.8 % were men (26/33), median age 62 years (46-73), 54.5% (18/23) smokers. Histologically, 69.7% (23/33) were adenocarcinomas, EGFR positive in 2 patients, no ALK translocation and PD-L1 negative in all patients. 60.6% (20/33) were diagnosis in stage IV. 1st line palliative treatment was platinum/pemetrexed in most cases (63.6%, 21/33). 84.8% (28/33) were submitted at least to 2 lines of treatment before nivolumab. 81.8% (27/33) had ECOG1 at the start of nivolumab. Median number of cycles was 9 (1-50). 54.5% (18/33) of patients had toxicity, grade 3 in 5 patients, with asthenia and rash being the most common. Disease progression (42.4%; 14/33) and clinical deterioration (27.3%; 9/33) are the most reason for treatment discontinuation. 21 patients die due to cancer (mortality: 63.6%). At 12 months, progression-free survival was 33.3% in pembrolizumab and 64% in nivolumab. **Conclusion:** Immunotherapy brought higher survival rate to NSCLC, with good tolerability in most cases, maintaining and improving the quality of life. However, given the disparities between responses, acknowledgment of new targets and biomarkers will make the patient selection for immunotherapy more accurate.

EP1.04-32 SUCCESSFUL CORNEAL TRANSPLANTATION IN A PATIENT TREATED WITH NIVOLUMAB FOR METASTATIC NON-SMALL CELL LUNG CANCER

C. Dutra[1], B. Rocha Garcia[1], R. Vieira[2], A.C. Figueiredo[1], Y. Néron[1]

[1]*CEPON, Florianópolis - SC/Brazil,* [2]*CEPON, Florianópolis-SC/Brazil*

Background: Survival improvement in metastatic non-small cell lung cancer has been achieved with the use of checkpoint inhibitors. PD1/PD-L1 pathway is related to immune response and tolerance, so its blockage could predispose to graft rejection. In the pivotal studies of novel immunotherapy, patients submitted to organ transplantation were classically excluded, and scarce data on medical literature exits about graft and patient outcomes in a scenario of use of checkpoint inhibitors in this patientes. **Method:** We report the case of a 58 years old man treated with nivolumab for metastatic non-small cell lung cancer, after received platinum-based doublet chemotherapy, docetaxel and erlotinib and that was submitted to a corneal transplantation during the nivolumab treatment. **Result:** The patient received Nivolumab 3mg/kg intravenously every two weeks and had stable disease accessed by RECIST 1.1 after 54 cycles and keeped ECOG 0 performance status. This man had a previous history of vision impairment on right eye because of bullous keratopathy after vitrectomy for vitreoretinal disorder, whose treatment of choice is corneal transplantation. After multidisciplinary discussion, the nivolumab was stopped 2 weeks before the corneal graft was successfully performed. The patient received systemic corticosteroid treatment with prednisone at 10mg daily dose for 10 days and topical dexamethasone for 45 days after procedure. Nivolumab was initiated 3 weeks later. The patient has currently received 68 cycles of nivolumab, CT scan shows stable disease. In the recent ophthalmologic examinatio, there were no sign of chorneal rejection and ocurred an improvement of visual function on right eye (counts fingers in a 2 metes distance). In the literature, there are with few reports of graft outcomes in a scenario of threatment with chekpoint inhibitors, since this patients were not included in clinical trials. Diverse outcomes are reported ,with a substancial risk of rejection, specially with the use of PD-1/PD-L1 inhibitors in comparison with agents anti -CTLA-4. In our knowledge, this is the first reported case of a graft transplantation during checkpoint inhibitors therapy. **Conclusion:** Immunotheray in this special popullation is usually not recommended and under studied. In a context of immunotherapy, corneal graft transplantation can be associated with favourable outcomes due to devoid of vasculature and lymphatics in this tissue, that can facilitate immunological tolerance. So, although the risk of rejection must be taken into account, the treatment with anti-PD1 could not be considered an absolute contraindication to corneal transplantation, specially in patients with amaurosis, whose the risk of rejection of a graft cannot induce more damage than is already installed.

Keywords: Non-Small Cell Lung Cancer, Immune Checkpoint Inhibitors, organ transplant

EP1.04-33 PEMBROLIZUMAB WITH HIGH PD-L1: WHO ARE NON-RESPONDERS?

F. Shigematsu, Y. Kogure, A. Torii, A. Yamada, A. Ishida, H. Niwa, M. Nakahata, S. Oka, C. Kitagawa, M. Oki, H. Saka

Nagoya Medical Center, Nagoya/Japan

Background: Pembrolizumab is a programmed death-1 (PD-1) blockade which is approved for non-small cell lung cancer (NSCLC). It has been reported that programmed death-ligand 1 (PD-L1) high patients are more effective than low patients to pembrolizumab. It has not been clear what factors decide responsiveness to pembrolizumab in PD-L1 high patients. **Method:** NSCLC patients who had been given pembrolizumab from April 2017 to October 2018 in Nagoya Medical Center and whose PD-L1 tumor proportion score (TPS) was ≥50% were included. A double cancer case was excluded. The non-effective group was made of patients who had stable and progressive diseases, and the effective group was made of patients who had complete and partial response. We compared the non-effective group with the effective group. **Result:** Data were extracted retrospectively from patients' medical records. In total, 34 patients received pembrolizumab. One patient who had double cancer and 7 patients whose PD-L1 TPS was <50% were excluded from this analysis. Twenty-six patients were included. In 26 patients, 19 men (73.1%), 22 current or former smokers (84.6%). The median age was

69 (ranged 48–88). Patients with adenocarcinoma, adenosquamous, squamous, not otherwise specified, and pleomorphic carcinoma were 15/1/ 8/1/1. Stage IIIA, IIIB, IV, and recurrence after surgery were 1/2/16/ 7. Performance status (PS) 0, 1, 2, 3, and 4 were 7/9/7/ 2/1. First, second, and fourth lines of chemotherapy were 18, 7, and 1, respectively. Differences between pembrolizumab effective and non-effective group in gender, smoking history, age, tissue type, proportion of stage IV, and treatment line were not statistically different. In terms of PS, all PS 3 or 4 patients were non-effective. **Conclusion:** In NSCLC PD-L1 high patients treated with pembrolizumab, PS 3–4 might be a factor, which indicated poor response to pembrolizumab.

Keywords: NSCLC, Immune Checkpoint Inhibitors, Pembrolizmab

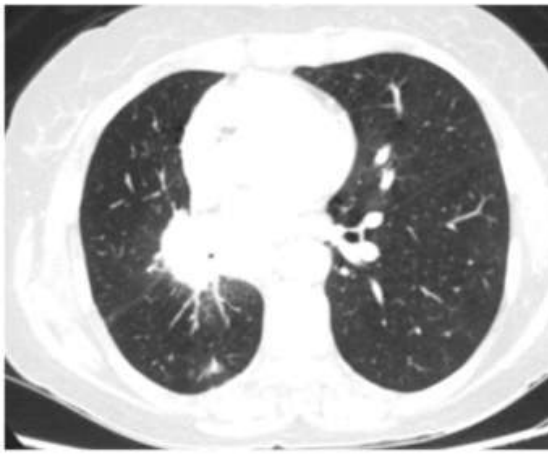
EP1.04-34 IMAGING CHALLENGES IN THE IMMUNOTHERAPY TREATMENT OF NON SMALL CELL LUNG CANCER (NSCLC): PROGRESSION VS. PSEUDO PROGRESSION

C. Dutra, F. Magalhaes, S. Viegas, F. Thomaz

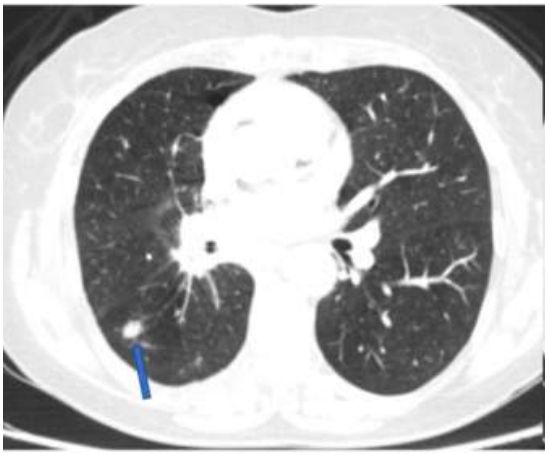
CEPON, Florianópolis - SC/Brazil

Background: Immunotherapy has revolutionized treatment of squamous NSCLC. Along with the superior efficacy physicians have to face new side effects and response criteria. Initial tumor growth or new lesions followed by tumor response is called pseudo progression and can be seen in up to 10 % of patients. **Method:** This education exhibit aims to show how the treatment response was evaluated in a series of cases of the clinical research of our institution using both RECIST and irRECIST, comparing the two methods and the multidisciplinary team consensus with correlation with the clinical status of the patient. Demonstrate the importance of the concept of unconfirmed progression and pseudo progression in the imaging evaluation of these patients. Illustrate with practical cases the diverse treatment outcomes. **Result:**

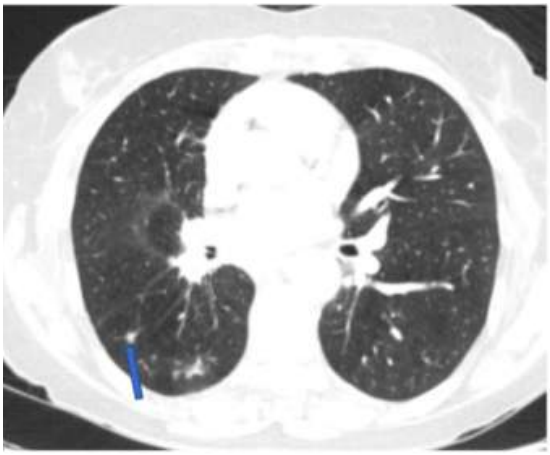
Pseudo Progression



Baseline



Control 1



Control 2

A 65 yo female patiente receive atezolizumab in the second line treatment for NSCLC stage IV, after a pulmonar progression with carboplatin + paclitaxel treatment in first line. PD-L1 was unknown. EGFR and ALK was negative. After 3 cicles of treatment wih anti PD-L1 agent (radiological control 1) the RECIST 1.1 evaluation identified a pattern of progression of disease, becouse there was a new pulmonary nodule. The patient was improving clinically, with weigh gain and cough reduction and in the immune-related response criteria (irRC) a stable disease was the response in that moment, besides the new lesion appearance. She does not have any remarkable side effect with the treatment, thas was susteined becouse of the clinical benefit. In order to get a close follow up of the disease, after 2 months she did a new radiologic evaluation (control 2), that show the involution of that new lesion in the right inferior lobe as well as happen to other pulmonary lesions at the same time, what could be characterized by a pseudoprogression pattern of response. **Conclusion:** We need to take care in the radiologic and clinical evaluation of response in immunotherapy. Besides thrue pseudoprogression pattern ir rare in NSCLC and it is not able to be captured by convencional RECIST evaluation, it need to be reminded. Is necessary to combine clinical evaluation and immune-related response criteria (irRC) in doubtful cases in order do not underestimate the benefit of immunotherapy and prevent premature cessation of treatment.

EP1.04-35 IMMUNOTHERAPY IN NON-SMALL CELL LUNG CANCER (NSCLC) – EXPERIENCES FROM CLINICAL PRACTICE – SWEDEN

H. Koyi[1], J. Isaksson[1], A. Vikström[2], R. Öhman[3], P. Xanthoulis[1], A. Rosberg[2], E. Brandén[1]

[1]*Gävle Hospital, Gävle/Sweden,* [2]*University Hospital, Linköping, Sweden, Linköping/Sweden,* [3]*University Hospital of Skåne/Lund, Lund/Sweden*

Background: Lung cancer is the leading cause of cancer-related mortality worldwide, with NSCLC accounting for over 85% of all cases. Until recently, chemotherapy – characterized by some benefit but only rare durable responses – was the only treatment option for patients (pts) with NSCLC whose tumors lacked targetable mutations. By contrast, immune checkpoint inhibitors have demonstrated durable responses and represent the opportunity of a new treatment approach for pts with NSCLC. **Method:** A chart review was conducted of incident cases of all pts who had been treated with immune check point inhibitor during the last 3 years in 4 hospitals. Data was retrospectively collected: pts characteristics, tumour characteristics, treatment details, tumor stage, adverse events, survival. **Result:** In total, 244 pts, 114 (46.8%) males were given immunotherapy. Mean and median age was 70.11, 72.3 yrs. 219 (89.6%) were smoker or former smoker. 168 (68.9%) with PS 0-1, 61 (24.9%) PS 2. Most of the pts had stage IVA 119(48.6%), IIIB 34 (13.9%), IIIA 31 (12.7%). Adenocarcinoma in 151 (61.6%) and squamous cell carcinoma in 70(29.6%) of the pts. PDL1 < 1% in 30(12.2%), 1-49% in 66(27.3%) and ≥50% in 92 (37.6%). Pembrolizumab was given either as 1st or 2nd line in 120 (49.0%) ,nivolumab as 2nd, 3rd or 4th line in 85 (34.7%) and atezolizumab 31 (12.7%) as 2nd or 3rd line. 76(31.1%) had partial response, 3 (1.2%) complete response, 41 (16.8%) stable disease, 64 (26.2%) progressive disease. 60 (24.5%) still on treatment. Most adverse events (AE) was pneumonitis 13 (5.2%), *colitis 10 (4.1%), Thyroiditis 8 (3.2%).* **Conclusion:** Pembrolizumab has been given mostly in first line treatment due to high PD-L1 but nivolumab or tecentriq most in 2nd or 3rd line. Overall responses was 49.1%. Very few AE mostly pneumonitis and colitis More data will be presented during the conference

EP1.04-36 AGGRAVATION OF DEPIGMENTATION FOR A NSCLC PATIENT WITH PRE-EXISTING VITILIGO USING IMMUNE CHECK POINT (PD-1) INHIBITOR: A CASE REPORT

K. Ma, Y. Cai, Y. Xu, X. Wang, C. Sun, Y. Guo

The First Hospital of Jilin University, Chang Chun/China

Background: Immune checkpoint inhibitors (ICIs) such as anti-PD-1/PD-L1/CTLA4 antibody can enhance the antitumor activity of the immune system by mainly promoting CD8+ T lymphocyte immune function. While, they can also induce immune-related adverse events (irAEs), especially the skin toxicity, such as maculopapular rash, lichenoid reactions, vitiligo and pruritus. However, the effectiveness and safety of ICIs in cancer patients who are also suffered from autoimmune diseases are still unclear. **Method:** In our present report, we described a newly diagnostic non-small cell lung cancer (NSCLC) patient who suffered from the focal vitiligo for about ten years, her vitiligo lesions were localized in eyes and mouth circumference. **Result:** The patient's vitiligo was aggravated rapidly with depigmentation of the whole body skin in just half a year. Meanwhile, lung cancer focus was still in a stable status for over 14 months. The efficacy evaluation is stable disease (SD), but as the treatment time prolonged, the tumor density gradually decreased, suggesting that the immunotherapy continues to benefit. **Conclusion:** Vitiligo, as one kind of autoimmune diseases, should be paid more attention as using with ICIs at the same time. Meanwhile, ICIs may bring more irAEs and more benefit in the pre-existing autoimmune disease population, compared with that normal population.

Keywords: Non-Small Cell Lung Cancer, pd-1, vitiligo

EP1.04-37 BIOMARKERS IN NON-SMALL CELL LUNG CANCER: EXPRESSION OF PD-L1 PROTEIN AND P16 IN SQUAMOUS CELL CARCINOMA HISTOLOGIC SUBTYPE

L. Sua[1,2], J. Lores[1], M. Aguirre[1,2], A. Castro[1], L. Fernandez-Trujillo[1,2]

[1]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia,* [2]*Universidad Icesi, Cali/Colombia*

Background: Squamous cell carcinoma(SCC), 30% of Non-Small Cell Lung Cancer(NSCLC), cigarette is its mayor etiology. >50% NSCLC are diagnosed in advanced/stage, 10–15%EIIIB, 40%E-IV. In terms of survival, NSCLC is heterogeneous and variable. Survival at 5 years is <15%, treatment is not curative. In cancer, the evasion of the immune system and the uncontrolled tumor proliferation is important. The programmed-cell-death-ligand(PD-L1) is a lymphocyteT protein. The union PD-1/PD-L1 inhibits the lymphocyteT's activity. Overexpression of PD/L1 in CD8+lymphocytes inhibits apoptosis, reduces survival. In NSCLC, PD-L1 is a predictor of successful immunotherapy. Inhibition PD:PD-L1 is an effective antitumoral therapy. The p16INK4a intervenes in pulmonary carcinogenesis, localized in chromosome 9p21(locus CDKN2A), its codes suppressor/tumoral proteins:p16INK4a-p14ARF. P16 inhibits D1-dependent quinases4-6(CDK4/6,ciclinaD1) which regulate the retinoblastoma protein through phosphorylation. Dysfunctional p16 inactivates Rb through hyperphosphorilation and progression of the cell cycle. Its expression contributes to the therapeutic response and to survival in NSCLC. We describe the clinical, pathological and survival characteristics in SCC based in expression of PD-L1/p16. **Method:** Descriptive study, 24 patients with SCC, 2009–2013. PD–L1 studied with antibody 22C3 pharmDxkit(Agilent, Santa-Clara, CA,USA) in Autostainer Link/48DAKO® with murine monoclonal antibody(Clone/E6H4™) in BenchMark/Autostainer(Ventana®). PD-L1 was classified with TPS(Tumor/Proportion/Score), high expression TPS>50%, low expression TPS1-49%, or negative TPS=0%. P16(+) with expression >70% in nuclei, tumoral membranes. STATAv.14®, ShapiroWilk, Chi squared, Fisher, t-Student or U/Mann/Whitney were used. Survival with Kaplan-Meier. **Result:** Age 67±14, 63%men. 54% of smokers, 7% had COPD. E-IV54%, E-IIIA25%, E-IIIB13%, E-IIB y E-IIA4%. PD-L1(+) more in smokers (85%)p=0.001. Treatment: palliative/care(25%), chemotherapy/surgery(17%); chemotherapy/radiotherapy/surgery(12%); radiotherapy/surgery(8%), only surgery(4%). PD-L1, high-expression survival 33m, low expression/negative 66m (log-rank test p=0.0041), Figure1: p16(+) in 10(41.6%), survival 36.2m, p16(-) survival 66.8m, p16/PD-L1(-) survival 66.8m, p16/PD-L1(+) survival 36.2m. **Conclusion:** SCC with PD-L1 TPS>=50%, p16(+), smokers with high/tumor/burden had lower survival rates. Immunotherapy against programmed cell death(PD-1) is a promising alternative impacting survival in advanced/metastatic NSCLC.

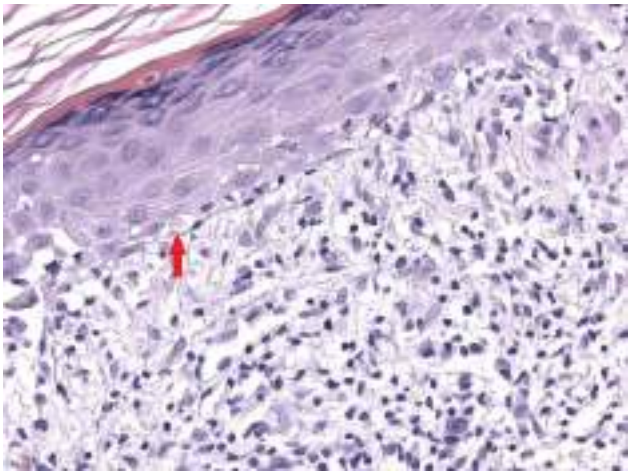
EP1.04-38 A CASE OF LICHENOID REACTION AS LATE AND UNCOMMON IMMUNE-RELATED SKIN TOXICITY DURING NIVOLUMAB TREATMENT

A. Catino[1], R. Filannino[2], L. Fucci[3], D. Galetta[1], M. Guida[2], G. Del Bene[4], V. Longo[4], M. Montrone[1], F. Pesola[4], P. Pizzutilo[1], S. Strippoli[2]

[1]*Thoracic Oncology, Clinical Cancer Centre "Giovanni Paolo II", BARI/ Italy,* [2]*Oncology Unit, Clinical Cancer Centre "Giovanni Paolo II", Bari/Italy,* [3]*Pathology Department, Clinical Cancer Centre "Giovanni Paolo II", Bari/Italy,* [4]*Thoracic Oncology ,Clinical Cancer Centre "Giovanni Paolo II", BARI/Italy*

Background: Immune-checkpoint inhibitors have shown remarkable activity in advanced Non-small cell lung cancer (NSCLC). An increasing number of immune-related skin toxicities has been reported, also heterogeneous and unusual. So, these reports could be useful to manage such events. Lichenoid dermatitis (LD) identifies a group of dermatoses clinically and histologically reminiscent of idiopathic lichen planus (LP). Pharmacologycal, chemical and viral causes agents can induce skin lichenoid reactions. **Method:**

We report the case of a 81-years-old man with stage IV non-small cell lung cancer treated with Nivolumab developing a hitchy, recurrent and polymorphous lichenoid eruption after 36 cycles of treatment (Figure 1). **Result:** A skin biopsy (Figure 2) showed an area of parakeratosis associated to a dense lympho-histiocytic infiltrate of the papillary derma that obscures the basal membrane and causes vacuolization of the basal layer of the epidermidis with an isolated Civattes body (red arrow), (40X, H&E).



The temporary interruption of Nivolumab, together with short and low-dose cycles of corticosteroids repeated for several times due to the wave evolution of the lichenoid reaction, allowed for the partial recovery of the skin toxicity and the resumption of treatment. **Conclusion:** Unlike the classic appearance of lichenoid reactions, this patient showed a more polymorphous lesions as compared to the

EPOSTERS

classic forms. The correct and early recognition of these uncommon effects is useful to optimally manage and safely continue a treatment while achieving a therapeutical response of neoplastic disease

EP1.04-39 IS BODY MASS INDEX A PROGNOSTIC FACTOR IN PATIENTS WITH LUNG CANCER TREATED WITH IMMUNOTHERAPY?

I. Rego[1], F. Pontes[2], A. Chaves[1], E. Jesus[1]

[1]*Portuguese Institute of Oncology, coimbra/Portugal,* [2]*Portuguese Institute of Oncology, Coimbra/Portugal*

Background: Non-small cell lung cancer (NSCLC) is a prevalent disease with high mortality and poor response to traditional cytotoxic therapy. Immune checkpoint inhibitors (ICI) approvals were the landmark in the last years for the treatment of lung cancer. With these treatments, many patients with advanced disease are starting to see durable responses and longer survival rates. Several factors like obesity has been previously investigated for its role in cancer and promoting tumor growth, at least partially by inducing a chronic inflammatory state, but it's unclear how it links to immunotherapy, where inflammation has been linked to treatment response," High Body mass index (BMI) might have a positive impact in the outcomes of patients who are taking PD-1 or PD-L1 inhibitors, according to a recent study. In this study, we aim to determine if the body mass index (BMI) is a prognostic factor in patients treated with immunotherapy **Method:** We retrospectively evaluated the outcomes of 30 patients with NSCLC confirmed histology, aged 18 years or older, treated with anti PD-1/PD-L1 from 2016 to 2018. BMI was stratified unto 2 groups: 1) normal and under-weighted (BMI < 25 kg/ m2) and 2) over-weighted and obese (BMI ≥ 25 kg/ m2). Simple descriptive statistics were created for all covariates. After statistical analyses with Kruskal-Wallis equality-of-populations rank test were related to progression free survival (PFS). **Result:** A total of 30 lung cancer patients were enrolled in this study, divided by gender as 10 female-patients (33,33%) and 20 masculine-patients.(66,67%) The median age was 63 years (youngest 41-year-old and oldest 81 years old). According to histology 20 patients have adenocarcinoma (66,67 %) and 10 patients have squamous tumors (33,33%). Analyzing the mutational status, the majority was EGFR Wild type (WT). The majority of patients involved (43,33 %; 13 patients) were given immunotherapy in the third-line setting or beyond. More than half of patients had over-weighted and obese BMI (group 2 – 56,67% (n=17)). The median follow-up was 86 days (1 quartile 35 days and 3rd quartile 291 days (minimum 5 days, maximum 971 days). The median PFS in group 1 was 98 days (1 quartile 56 days and 3rd quartile 407 days (minimum 28 days, maximum 495 days) and in over-weighted and obese was 74 days (1quartil 26 days and 3rd quartile 127 days (minimum 5 days, maximum 971 days). There were no statistical differences in PFS (p= 0,249) between higher or lower BMI groups (group1 vs. group 2). **Conclusion:** In this single institution cohort, BMI hadn't a significant effect on outcomes of patients with lung cancer receiving anti PD-1/ PD-L1 agents. As a critic to this evaluation we have that is for now a small group of patients and we think it is important to maintain studies in this field as the number of patients under this therapy increases.

EP1.04-40 EXTRA-THORACIC METASTASIS INDICATED WORSE CLINICAL EFFICACY ON IMMUNE CHECKPOINT INHIBITORS IN CHINESE ADVANCED NSCLC PATIENTS

S. Liu[1], A. Xiong[2], X. Li[1], C. Zhao[1], C. Zhou[1]

[1]*Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/China,* [2]*Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China*

Background: Immune checkpoint inhibitors (ICIs) have demonstrated inspiring effectiveness against lots of cancer types, including non-small-cell lung cancer (NSCLC). However, the individual therapeutic response varies and heterogeneous. The purpose of this study was to investigate the association of different metastatic sites with clinical outcomes after ICIs monotherapy in Chinese advanced NSCLC patients. **Method:** We retrospectively analyzed all patients receiving more than two circles of ICIs monotherapy (anti-programmed death 1 or anti-PD-L1) in Shanghai pulmonary hospital from January 2016 to December 2018. Detailed clinical characteristics, metastasis status and progress-free survival (PFS, calculated from the first day receiving ICIs until the disease progressed) was recorded. **Result:** 76 patients were enrolled in this study. 10 of them received immunotherapy in the first-line and 46 of them in the second-line. The rate of extra-thoracic metastasis was 50% (38/76), including brain metastasis (10/38), liver metastasis (11/38), bone marrow metastasis (30/38), adrenal metastasis (4/38), extra-thoracic lymph node metastasis (10/38) and others (5/38). Patients with extra-thoracic metastasis had a significantly shorter PFS than those without (median PFS 4.20 VS 7.10months; hazard ratio [HR] 1.939, 95% CI 1.221-3.389; p=0.0072). In subgroup analysis, patients with brain metastasis, liver metastasis or bone marrow metastasis showed significantly shorter PFS than those without (3.35 vs 4.60m, p=0.0499; 2.50 vs 4.60m, p=0.0007; 3.70 vs 5.80m, p=0.0003 respectively). The disease control rate (DCR) is numerically lower in patients with extra-thoracic metastasis (66.7% vs 80%) comparing with those without, even though not statistically significant. **Conclusion:** The current study suggested that advanced NSCLC patients with extra-thoracic metastasis indicated worse clinical outcomes on ICIs monotherapy and more clinical strategies should be considered to improving treatment efficacy for them.

Background: Immunotherapy (IO) has become a standard of care in NSCLC. Aging is associated with structural and functional changes in the immune system; hence, elderly patients could obtain less benefit from IO. Although randomized clinical trials showed benefit regardless of age, elderly are underrepresented, though its role in this population remains uncertain. **Method:** We conducted a retrospective analysis of patients (pts) with NSCLC treated with IO at six centers between Nov 2013 and Feb 2019. We categorized patients in two groups (≥ 75 and < 75 years old) and evaluated overall response rate (ORR), disease control rate (DCR), progression-free survival (PFS), overall survival (OS) and safety. Correlations were assessed using Fisher's exact tests. Kaplan-Meier was used to estimate survival rates and compared using log-rank testing. Cox proportional hazard models were used to evaluate prognostic factors for PFS and OS. **Result:** A total of 269 NSCLC pts treated with ICIs were included, 49 pts were ≥ 75 years old. Among them, 27 pts (55.1%) were male, 42 (85.7%) current or former smokers and 39 (79.5%) had PS 0-1; baseline brain metastases were present in 5 pts (10.2%). PDL-1 tumor proportion score (TPS) was ≥ 50% in 13/32 pts (41%), 31% received IO in first-line. There were no statistical significant differences in baseline characteristics between both groups. There was similar rate of G3-4 adverse events (18.4% vs. 17.7%, p=1.00) and treatment discontinuation (8.2% vs. 11% p=0.15, respectively) for ≥ 75 and < 75 years respectively. ORR was 18.4% (9/49) vs. 33.2% (73/220) p=0.06, DCR was 47% (23/49) vs. 65.9% (145/220) p=0.01, for ≥ 75 and < 75 years respectively. Median follow-up from IO was 15.9 months [95%CI 12.1 – 19.7]. Median PFS was 3.5 months [95%CI 2.4 – 4.6] vs. 9.8 months [95%CI 7.35 – 12.3] p<0.001 and median OS was 8.7 months [95%CI 5.4 – 12.0] vs. 18.8 months [95%CI 11.8 – 25.8] p=0.008, for ≥ 75 and < 75 years pts respectively. Histology (p=0.032), baseline corticoid treatment (p<0.001), first-line (p=0.004) and G3-4 toxicity (p=0.005) were significantly associated with OS in multivariate analysis. **Conclusion:** In our cohort, immunotherapy demonstrated to be safe for elderly pts showing similar toxicity profile compared to their younger counterparts; however, elderly pts achieve less benefit than younger patients. Further assessment in larger cohorts is warranted, considering the high prevalence of lung cancer among this subset of patients.

EP1.04-42 USING A MULTIPLEXED IMMUNOFLUORESCENCE APPROACH TO COMPARE IMMUNE CELL POPULATIONS IN SUBTYPES OF NON-SMALL CELL LUNG CANCER

A. Juncker-Jensen, V. Reddy, E. Parnell, M. Nagy, J. Kuo, E. Leones, F. Sahafi, N. Hoe, J. William

NeoGenomics, Aliso Viejo/United States of America

Background: Non-small cell lung cancer (NSCLC) accounts for approximately 80-85% of all lung cancer cases, and is characterized by a poor response to chemotherapy and a low survival rate. Treatment targeting the immune checkpoint inhibitor pathway PD-1/PD-L1 has been found to be effective against NSCLC with manageable side effects, but with only 20-25% of patients showing a positive response there is an urgent need for additional immunotherapy options for this group of patients. NSCLC is a very heterogeneous disease with the two most common types being adenocarcinoma (ADCA) accounting for about 70% of all NSCLC cases, and squamous cell carcinoma (SCC) accounting for about 20% of all cases. In a study profiling the molecular signatures of these two NSCLC subtypes the existence of specific molecular networks and subtype-specific differences was reported (1), while a study using flow cytometry to analyze NSCLC on protein level reported the immune cell composition to be fundamentally different in ADCA compared with SCC (2). However, to the best of our knowledge this study is the first of its kind performing an extensive analysis of NSCLS immune cell composition in tissue. 1. Kargl et al. Nature Commun, 2017 Feb 1;8. 2. Daraselia et al. Am J Cancer Res, 2012 2(1). **Method:** In order to perform a comprehensive immunoprofiling of ADCA and SCC we used MultiOmyx™, an immunofluorescence (IF) multiplexing assay that utilize a pair of directly conjugated Cyanine dye-labeled (Cy3, Cy5) antibodies per round of staining. Using a 16-marker panel we have analyzed the proportion of B cells, T cell subtypes, M1/M2-type tumor-associated macrophages, as well as the expression of not only PD-1 and PD-L1, but also of more novel immunotherapy targets LAG-3, TIM-3, ICOS, and OX40 in 20 samples from patients with NSCLC (10 ADCA and 10 SCC). **Result:** While we found LAG-3 expressed mainly on T cytotoxic cells in both subtypes, the overall density of LAG-3 was increased from 130 cells/mm^2 in ADCA to 239 cells/mm^2 in SCC. Likewise, we found the density of TIM-3 to be increased from 413 cells/mm^2 in ADCA to 1100 cells/mm^2 in SCC, while the density of PD-L1 was decreased from 1626 cells/mm^2 in ADCA to 1089 cells/mm^2 in SCC. **Conclusion:** It is our hope that these data will help provide new insights into the biology of ADCA and SCC that can ultimately be used to explore novel immunotherapeutic interventions for lung cancer treatment.

EP1.04-43 THE SIGNIFICANCE OF NY-ESO 1 SEROPOSITIVITY AND INFLUENCE ON NSCLC PATIENTS SURVIVAL

D. Myšíková, B. Kútna, R. Lischke

Faculty Hospital Motol, Prague/Czech Republic

Background: Lung cancer is the leading cause of cancer mortality worldwide. Understanding biological processes of specific antitumor immune response remains of an eminent interest and represents necessity for designing successful antitumor immunotherapeutic strategies. In our previous study published in JTO 2017, we focused on the humoral component of the specific antitumor response and prospectively analysed serum frequencies of antitumor antibodies against NY-ESO-1, Her2/neu and MAGE-A4 antigens in 121 patients with NSCLC. Here it was shown for the first time that tobacco smoking significantly increases the frequency of NY-ESO-1 antibodies in sera of smokers in comparison to ex-smokers and non-smokers. In our current follow-up study, we plan to describe the significance of NY-ESO 1 seropositivity and influence on NSCLC patients survival. We suppose to have data completed during June 2019 (we are waiting for the 5-year observation period). We would like to apply for Late-Breaking Abstract privileges and the opportunity to present these novel promising data. **Method:** Between 2009 and 2014 we prospectively analyzed the serum frequencies of NY-ESO-1 antibodies and corresponding antigen expression in tumors of 121 non-small cell lung cancer (NSCLC) patients undergoing surgery without prior neoadjuvant chemotherapy and compared them with 57 control age-matched patients with no history of malignant disease, each with no sign of malignancy on chest X-ray. In addition to pulmonary X-ray, a panel of tumor markers (CEA, TPA, NSE, SCC, CYFRA 21-1) was used to compare the group of cancer patients and the group of control patients. The complete set of samples for NY-ESO-1 analyses which includes serum, tumoral and non-tumoral tissue was obtained only for 40 patients. Nowadays we are finishing a 5-year observation period after surgery for primary tumor and we plan to complete a statistical analysis of all data by June 2019. We would like to present results of our follow-up study on WCLC 2019. **Result:** We suppose to have data completed during June 2019 and we apply for Late-Breaking Abstract privileges. Thank you for considering our request. **Conclusion:** We suppose to have data completed during June 2019 and we apply for Late-Breaking Abstract privileges. Thank you for considering our request.

Background: Although the introduction of immune checkpoint inhibitors (ICIs) has yielded substantial benefits in terms of survival in the treatment of Non-Small Cell Lung Cancer (NSCLC), the possibility of activation of dormant autoimmune diseases or onset of immune mediated toxicities is a reality. The objective of this study was to explore intrinsic immunological factors associated with poor outcomes. **Method:** In a retrospective cohort study of 48 patients, without any prior medical history of autoimmunity, treated for advanced/metastatic NSCLC with ICI´s were assessed. Determination of HLA-A*02011 as well as acute phase reactants and antiphospholipid antibodies was performed. Additionally, evaluation of survival in a time to event manner was conducted using the Kaplan Meier method and Cox regressions **Result:** Median follow-up was 27.3 months, of the included patients 26 were male (54%) with a median age of 62 years old and there were no individuals with and ECOG performance score >1. Median overall survival (OS) was reached at 22.47 months. When analyzing the presence of the HLA-A*02011 serotype, 6 patients tested positive (12.5%). Additionally, all presented with borderline or abnormal B2glycoprotein IgM and IgG, 2Bmicroglubulin and elevated C reactive protein. Four patients (66%) experienced reactive lymphadenopathy during treatment and all suffered some form of venous thromboembolism. When analyzing OS, this group of patients had a significantly worse outcome (6.53 vs 22.47 months, HR= 4.47, [95%CI 1.47 – 13.61], p<0.001) compared with their counterparts. Overall response rate for the whole was superior for the HLA-A*02011 positive patients achieving 41.4% and 33%, p<0.001, respectively. **Conclusion:** The presence of the HLA-A*02011 could potentially predispose to a paradoxical and pathological activation of the immune system without offering any benefit in terms of tumor control. Larger studies validating these findings are warranted.

Background: The composition of gut microbiota affects antitumor immune responses, as well as preclinical and clinical outcomes following immune checkpoint inhibitors (ICI) in cancer. Antibiotics (ATB) alter gut microbiota diversity and composition leading to dysbiosis, which may influence the effectiveness of ICI. **Method:** We examined patients with advanced non-small-cell lung cancer (NSCLC) treated with anti-programmed cell death ligand-1 mAb monotherapy alone or in combination in three different countries of Latin America. Those receiving ATB within 30 days of beginning ICI were compared with those who did not. Objective response, progression free survival (PFS) and overall survival (OS) were assessed. **Result:** 18 of 140 (13%) NSCLC patients received ATB. The most commonly used ATB were b-lactam or quinolones for pneumonia or urinary tract infections. In NSCLC patients, ATB was associated with 4 cases of primary PD (28.6% versus 31.5%, P=0.818), non-significant decreased PFS (median 2.66 versus 1.94 months, HR 1.63, [95% CI 0.71-3.72], P=0.247) and significantly deleterious OS (median 12.42 versus 2.04 months, HR 2.3, [95% CI 1.08-4.95], P=0.03). In multivariate analyses, the impact of ATB remained significant for OS. **Conclusion:** ATB were associated with reduced clinical benefit from ICI in Hispanic patients with NSCLC. Modulation of ATB-related dysbiosis and gut microbiota composition may be a strategy to improve clinical outcomes with ICI.

Background: Immunotherapy for NSCLMC offers a significant advantage to chemotherapy in selected cases. This benefit starts to disapear as the patients start two progress and requiere change in medication or even chemotherapy. The objective of this study was to compare survival outcomes of patients with advanced or metastatic NSCLC who received immunotherapy at first, second or beyond versus matched patients receiving standard chemotherapy. **Method:** A retrospective multicenter international cohort study of 296 patients with unresectable/ metastatic NSCLC treated with immunotherapy either as first, second, third or fourth line was conducted. A matched comparison with a historical cohort of first line chemotherapy was conducted. **Result:** Median age was 64 years (Range 34-90) and 40.2% were female patients. 91.2% of patients had an ECOG performance score ≤ 1. Immunotherapy as first line was given to 39 patients (13.7%), second line to 140 (48.8%), and as third line and beyond to 108 (37.6%). Median overall survival was 19.9 months (95% CI 14.5-22.7 months) and progression-free survival was 3.73 months (95% CI 2.8-4.2). Factors associated with increased survival included treatment as first-line (p < 0.001), type of response (p < 0.001) and PD-L1 status (p = 0.0039). Compared with the historical cohort, immunotherapy proved to be superior in terms of OS (p= 0.05) but not PFS (p= 0.2). **Conclusion:** Patients who receive immune checkpoint inhibitors as part of their treatment for NSCLC have better OS compared with matched patients treated with standard chemotherapy, regardless of treatment line.

EP1.04-47 CHRONIC AND SEVERE NON-LICHENOID ORAL ULCERS INDUCED BY NIVOLUMAB: DIAGNOSTIC AND THERAPEUTIC CHALLENGE

A.F. Cardona[1,2,3], A. Ruiz-Patiño[2,3], L. Ricaurte[2], L.L. Rojas[3,4], Z.L. Zatarain Barrón[5], F. Barrón[6], O.G. Arrieta[5]

[1]*Clínica del Country, Bogotá/Colombia,* [2]*Molecular Oncology and Biology Systems Research Group (FOX-G), Universidad el Bosque, Bogota/Colombia,* [3]*Fundación para la Investigación Clínica y Molecular Aplicada del Cáncer-FICMAC, Bogota/Colombia,* [4]*Oncology Department, Clinica Colsanitas, Bogota/Colombia,* [5]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [6]*Instituto Nacional de Cancerología, México City/Mexico*

Background: Due to the widespread use of immune checkpoint inhibitors and the growing research efforts in this area, immune mediated toxicity is well recognized. Nonetheless, few severe cases of oral or upper gastrointestinal tract mucosal involvement have been documented. In this case, report we present the case of a patient who developed severe oral ulcers that were refractory to steroidal support. We also developed a few hypotheses regarding the pathological findings and the implications of microbiomal environment seen in this patient. From a therapeutic point of view, a strategy based on the management given to both Behcet´s disease and Graft versus Host Disease is described. **Method:** A 93-year-old male was diagnosed with T2N1M0 squamous cell carcinoma of the pharynx with partially involvement of the base of the tongue. Due to comorbid conditions, hypofractionated radiotherapy (40 Gy) plus cetuximab (loading dose of 400 mg/m2 5-7 days before radiotherapy initiation, followed by cetuximab 250 mg/m2 weekly for 5 doses (total 1.650 mg/m2) was administered. A partial response was achieved. Local progression occurred within 12.4 months. The patient received Nivolumab 200 mg IV q15 days. A complete response after 4 months of initiation was observed. After 10 cycles, multiple painful erythematous ulcers in the buccal mucosa and tongue were seen. No test evidence of herpes virus, mycotic, Ebstein Barr virus or cytomegalovirus infection was found. Treatment with Nivolumab was halted. He was started on sucralfate, magic mouthwash (oral mucoadhesive) a 14 day course of oral prednisone (1 mg/kg q/day) and topical triamcinolone acetonide, with minimal response. Two weeks later, the patient reported progressive dysphagia, severe pain and rapid weight loss (≈8 Kg). Initial blood tests showed a normal white cell count 8.4×109/L (neutrophils 6.87× 109/L, lymphocytes 0.940×109/L, eosinophils 0.5× 109/L) and platelets at 296.000×109/L. Intravenous methylprednisolone 2 mg/kg/day was started without improvement and increased pain. Due to refractory behavior of the oral ulcers and based on the histological findings, a chronic GVHD reaction was considered. **Result:** It was hypothesized that the ulcers were caused by a pathologic immune system reactivity against the oral mucosa. Based on this, oral cyclophosphamide was initiated in a metronomic schedule: 50 mg q/day by 21 days in a regimen of 28 days for 2 cycles. Additionally, and extrapolating the use of colchicine used for Behcet´s disease ulcers, treatment was initiated with a solution of 1 mg in 150 ml q/8h. Shortly after, an almost complete remission of the lesions and optimal pain control was achieved. Simultaneously, metagenomic evaluation of oral microbiome was also performed. High throughput sequencing

of bacterial 16S rRNA was used. A significant reduction in bacterial diversity was observed. The bacterial species most commonly found were Prevotella melaninogenica, Veillonella dispar and an enrichment in the concentration of Prevotella melaninogenica and Haemophilus parainfluenzae was noted. At 3 months of follow up the patient maintains an oncologic complete response with no evidence of new ulcers or other ICIs derived complications. **Conclusion:** In conclusion, treatment of oral lesions as an adverse reaction to ICIs is a therapeutic challenge.

EP1.05 INTERVENTIONAL DIAGNOSTICS/ PULMONOLOGY

EP1.05-01 "LIQUID WITHDRAW" TECHNIQUE IN CT-GUIDED CUTTING NEEDLE LUNG BIOPSY DECREASE INCIDENCE OF COMPLICATIONS: PROSPECTIVE STUDY

X. Wang[1], L. Wang[1,2,3], W. Ren[1,2,3], R. Li[1,2,3], B. Liu[1,2,3]

[1]*Medical School of Nanjing University, Nanjing/China,* [2]*Clinical Cancer Institute of Nanjing University, Nanjing/China,* [3]*Comprehensive Cancer Centre of Drum Tower Hospital, Nanjing/China*

Background: CT-guided percutaneous biopsy is a minimally invasive technique used for obtaining enough tissue samples in the diagnosis of pulmonary lesions and genetic testing related to drug efficacy. The common complications of CT-guided percutaneous lung biopsy include pneumothorax, hemoptysis etc. Coaxial technique makes it much easier to repeat sampling and obtain adequate specimens, still it makes no change to the high incidence of pneumothorax. For all this, it is particularly urgent to find some technique to reduce the incidence of pneumothorax. Basic on the research De Filippoet al. had done about complications of the biopsy technique, we hypothesis that when the inner chuck of coaxial guiding needle was removed and the cutting needle was placed inside the guiding needle, the injection of a small amount of liquid (a mixture of lidocaine and hemocoagulase) through the syringe while withdraw of the guiding needle may help to prevent the incidence of pneumothorax for which close the needle track with liquid. **Method:** From August 24th, 2018 to April 1th ,2019, a total of 32 CT-guided percutaneous transthoracic biopsy procedures performed in 32 patients were retrospectively evaluated. The patients were divided into groups regarding the lesion from pleural surface: <30 mm or ≥30 mm. The rates of complications such as pneumothorax and pneumorrhagia were analyzed. And the complications were graded as mild/very mild, moderate, and severe. Different complications between the two groups were analyzed using Pearson's Chi-squared test for categorical values. **Result:** Pathology results were malignant in 28 patients (17 cases were adenocarcinoma, in which10 patients consented EGFR mutation test), benign in 4 patients.7 cases (21.9%) happened pneumothorax (4 very mild pneumothorax, 2 mild pneumothorax, 1 moderate pneumothorax),13 cases (40.6%) happened pneumorrhagia (12 mild pneumorrhagia, 1 very mild pneumorrhagia). No infection, tumor implantation or aeroembolism happened. And there was no statistically significant between pneumothorax and the depth of lesion to pleural surface (P>0.05). **Conclusion:** Compared to co-axial technique only, CT-guided percutaneous lung biopsy using co-axial combined with "liquid withdraw" significantly reduced the incidence of pneumothorax, which has been confirmed what we found in earlier retrospective study. The new technique provided a more accurate, secure and reliable way to obtain adequate tissue samples in the diagnosis.

EP1.05-02 ENDOBRONCHIAL ULTRASOUND AND TRANSBRONCHIAL NEEDLE ASPIRATION EBUS-TBNA: IN A UNIVERSITY HOSPITAL IN LATIN AMERICA

L. Fernandez-Trujillo[1,2], E. Morales[1,2], J. Lores[2], M. Aguirre[1,2], A. Castro[2], L. Sua[1,2]

[1]*Universidad Icesi, Cali/Colombia,* [2]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia*

Background: Endobronchial Ultrasound and Transbronchial Needle Aspiration (EBUS-TBNA) nowadays it has a primordial role in the workup of malignant and nonmalignant pulmonary disease. It's the most important advancement in pulmonary medicine in the last 20 years.EBUS-TBNA is a minimally invasive technique, well tolerated, cost efficient, for real time visualization of the airways with ultrasound and for sampling the mediastinum and hilum. Its indications: diagnosis, staging, restaging of lung cancer, evaluation of metastatic lesions and non-malignant diseases. It requires multidisciplinary evaluation with image analysis, general condition of the patient, risks and benefits, also close work with pathology, performing a Rapid On-Site Evaluation (ROSE) to improve the diagnostic performance. We describe the EBUS-TBNA in Fundación Valle del Lili a University Hospital of Reference in Latin America. **Method:** Prospective, descriptive study, period June/2015-June/2018. The indications were staging and restaging of lung tumors, diagnosis of lung or mediastinal masses, abnormal ganglia in CT or PET/CT equal or greater than 1cm. 108 patients were evaluated under general IV anesthesia, with a standardized protocol in the endoscopy room. The equipment used was Olympus® bronchoscope + US probe + 22G FNA. **Result:** Average age of 63,5 +/- 12,9, women 53(49%), men 55(50,9%). The quality of the sample was adequate in 105 (97,22%), positive of malignity 63(60%) negative 42(40%), inadequate samples 2(1,8%) and in one case a complete evaluation of the mediastinum was made without evidence of lesions, so no samples were taken. The ganglionary stations most frequently evaluated were 7 40(37%), 11R 22(20,3%), 11L 14(12,9%) and mediastinal mases 11(10,1%). The malignant lesions were non-small cell pulmonary carcinoma (NSCLC) 26(41,2%), metastasis head and neck tumors 10(15,8%), small cell pulmonary carcinoma 9(14,28%). 97,22% of the smears with Diff-Quick staining presented lesion, 5 dips were performed in each station, and immunohistochemistry was made in cellblocks as well as DNA extraction for EGFR mutation studies and EML4/ALK gene rearrangements in 50% of cases of NSCLC and PDL1 in 19,2% of these cases. 10(9,26%) of the series was taken to mediastinoscopy with a 100% correlation with the results of EBUS-TBNA. **Conclusion:** EBUS-TBNA is the recommended technique for lung cancer mediastinal staging. Our results adjust to international results; it is safe, minimally invasive, in many cases an outpatient procedure and a good performance when accompanied with ROSE.

EP1.05-03 THERAPEUTIC BRONCHOSCOPY IN MULTIMODAL THERAPY FOR THE MANAGEMENT OF CENTRAL AIRWAY OBSTRUCTION

L. Fernandez-Trujillo[1,2], E. Morales[1,2], J. Lores[2], M. Aguirre[1,2], A. Castro[2], L. Sua[1,2]

[1]*Universidad Icesi, Cali/Colombia,* [2]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia*

Background: Central airway obstruction may be due to malignant and non-malignant causes. The malignant obstruction of the airway is an important cause of morbidity and mortality in lung cancer. Intervention with therapeutic bronchoscopy decreases symptoms and allows time to employ treatments like surgery/radiotherapy or quimotherapy. In benign pathology prior intubation or complications related to lung/transplantation are common. Patients usually have cough and dyspnea that can progress to respiratory failure. Therapy should be oriented to secure and restore the airway. Best technique choice depends on etiology, type and severity of lesion, technological availability and operators skills. Nowadays, a multimodal therapy is implemented, including different intervention methods for the management. We aimed to describe therapeutic bronchoscopy in Fundación Valle del Lili a University Hospital in Latin America. **Method:** Descriptive retrospective study, April-2013/June-2018. 151 procedures were performed. Symptoms, etiology, localization, severity, diagnosis, type of anesthesia, interventions and complications were analyzed. The device was a therapeutic flexible and rigid bronchoscope Olympus® and specific intervention instruments. **Result:** 56.9+/-16.9-years. 58(38%)women and 93(61,5%)men. Malignant lesions were found in 91(60.26%). Symptoms were cough 122(80.8%), dyspnea 122(80.8%), hemoptysis 51(33.8%) and chest pain 41(27.2%). General anesthesia was used in 147(97.35%), the most common approach was the use of laryngeal mask 112(74,17%) then an endotracheal tube 22(14.57%). In 108(71,52%) a severe airway obstruction was present. 93(61,59%) had an endobronchial mass and 36(23,84%) external compression. Lesion location was: left-stem bronchi 73(48,34%) right-stem bronchi 64(42,38%), trachea inferior 23(15,23%), trachea superior 18(11,92%), carina 18(11,92%), trachea media 11(7,28%) and intermediate bronchus 11(7,28%). Most common malignant etiology was non-small cell lung cancer 39(42,85%), followed by typical/atypical carcinoid tumor 11(12,08%), sarcoma 9(9,89%) and metastatic tumors of gastrointestinal origin 8(8,79%) and head and neck tumors 6(6,59%) among others. Benign pathology was found in 60(39,7%) included granuloma 11(18,33%), stenosis 41(68,3%) which are related in most with airway complications after lung/transplantation and foreign bodies were found in 6(10%). Procedures were debridement 104(68,87%), electrocoagulation 95(62,91%), argon plasma 39(25,83%), stent colocation 5(3,31%), balloon/dilatation 42(27,81%) and cryoprobe 29(19,21%). Multiple interventions were made in various patients. Obstruction resolution was complete for 56(37,09%) and there was residual stenosis in 42(27,81%) or residual mass in 53(35,1). Complications included mild hemoptysis in 8(5,38%) and scaling in the attention room in two cases. No reported deaths associated with the procedure. **Conclusion:** Central airway obstruction is a complex situation that requires multidisciplinary approach. Currently, multimodal therapy is recommended combining different options of intervention, through flexible or rigid bronchoscopy, to achieve optimal results.

Examples of endobronchial lesions.

EP1.05-04 RESULTS AFTER RETROSPECTIVE STUDY ABOUT COEXITENCE BETWEEN BRONCHIAL CARCINOMA AND ACTIVE TUBERCULOSIS IN ENDEMIC AERA

I. Alloubi, R. Marouf

CHU Med VI, OUJDA/Morocco

Background: Morocco is an endemic country of tuberculosis (TB); the coexistence of active pulmonary tuberculosis in patients with lung cancer is not uncommon and may delay the management of bronchial carcinoma. To clarify the features and risk factors of cases with coexistence cancer and active TB, the aim of this study is to evaluate the clinical and radiological features through a retrospective study of cases with establishment of a diagnostic score to overcome conflict situation. **Method:** The medical records of 70 cases between 2008 and 2018 in which lung cancer and active pulmonary tuberculosis are intermingled in the same lobe of the lung were collected using our hospital database. We evaluated demographic data, the ways diagnosis of TB cases, the location of TB and cancer using the serial chest radiographs available for all patients; results of bronchoscopy with sampling for mycobacterial culture were reviewed. The CT findings; size, shape, border and location of the lesions and the possible causes of delay in the diagnosis of lung cancer were analyzed. **Result:** The findings of 70 patients (62 males and 08 females, aged 36-82 years), there are

47 smokers versus 23 never-smokers, in whom pulmonary TB and bronchogenic carcinoma coexisted in the same lobe were analyzed. Fifteen patients had history of tuberculosis. Isolated upper lung field were involved in 75 % patients. Sixty five per cent of cases had respiratory infection symptoms with presence of air-fluid levels in the affected lung with cavitation. Bronchoalveolar lavage (BAL) was performed with the positivity of smears and cultures in all patients. With regards to chest X-ray features, smokers presented with more advanced, and cavitating lung lesions. The average delay in diagnosing lung cancer was 12 (range, 6-18) months, and the causes of this were misinterpretation of lung cancer as active tuberculosis with cavitation in 92% of cases. **Conclusion:** Pulmonary TB and lung cancer may mimic each other especially in the aspect of the clinical and radiological features. We mainly discussed the diagnostic points to detect the coexistence of lung cancer and pulmonary tuberculosis at early stage.

EP1.05-05 THE OPTIMAL SEQUENCE OF BRONCHIAL WASHING AND BRUSHING FOR DIAGNOSIS OF NON-VISIBLE LUNG CANCER DURING NON-GUIDED BRONCHOSCOPY

H.-S. Nam[1], C. Kim[2], M.J. Kim[1], M.H. Park[1], J.H. Lim[1], W.Y. Kim[3], M.K. Lee[1], J.H. Kim[1], L. Kim[1], J.-S. Ryu[1]

[1]*Inha University Hospital, Incheon/Korea, Republic of,* [2]*Jeju National University Hospital, Jeju/Korea, Republic of,* [3]*Incheonsarang-Hospital, Incheon/Korea, Republic of*

Background: The optimum sequence of obtaining bronchial washing and brushing samples in lung cancer patients with non-visible tumor during conventional bronchoscope is uncertain. Recent advanced diagnostic bronchoscopy use only is feasible in a few institutions and can be expensive. The aim of the study was to investigate the diagnostic yield of washing performed after brushing in patients with non-visible tumor during non-guided flexible bronchoscopy (FB). **Method:** We performed a retrospective review of prospectively collected data of suspected lung cancer patients who were performed washing after brushing in non-visible tumor during non-guided FB from 2010 to 2015. Total 166 patients with histologically confirmed primary lung cancer were enrolled in the study. **Result:** The overall diagnostic rate was 52.4 %, and the diagnostic yield of bronchial brushing and washing were 37.3 % and 46.4 %, respectively. We compared the diagnostic yield of brushing with washing using McMemar's test. Washing had a better diagnostic yield, 46.4 % (77/166) vs. 37.3 % (62/166) (p=0.017, kappa index=0.570). Comparison of intra-individual agreements between the positive cytology of brushing or washing and the final pathologic diagnosis were a concordance rate of 89.6 % and 90.3 %, with a kappa value of 0.791 (p<0.001) and 0.801 (p<0.001), respectively. The presence of a bronchus sign, tumor size, and higher standardized uptake value on positron emission tomography scan were predictors of a higher diagnostic yield. **Conclusion:** In institutions where advanced diagnostic bronchoscopy is unavailable, the sequence of washing after brushing in the diagnosis of non-visible lung cancer during non-guided FB may help improving the diagnostic yield.

EP1.05-06 BENEFITS OF 18F-FDG PET/CT-GUIDED CORE-NEEDLE BIOPSY IN NECROTIC OR RECURRENT CHEST TUMORS

V. Voitko[1], V. Sokolov[1], O. Voitko[2], Y. Kmetyuk[3], E. Oliinichenko[2], V. Getman[4]

[1]*Kyiv City Clinical Hospital 17, Kyiv/Ukraine,* [2]*Kyiv City Clinical Oncology Center, Kyiv/Ukraine,* [3]*Clinical Hospital "Feofaniya", Kyiv/Ukraine,* [4]*Shupyk National Medical Academy of Postgraduate Education, Kiev/Ukraine*

Background: In case when we have deal with necrotic chest masses and recurrent tumors histological verification become challenged. This happens because CT and ultrasound imaging don't give us enough information about vital and necrotized part of tumor. CT-guided core-needle biopsy give us possibility to take sample from almost any part of tumor but only with information about density of tissure. On the other hand, ^{18}F-FDG PET/CT give us information about tumor vitality. But usually, ^{18}F-FDG PET/CT performs after morphological verification and we don't use PET/Ct benefits for biopsy. **Method:** We analyzed 6 patients with chest malignancies: 3 with primary mediastinal lymphoma, 1 – recurrent Hodgkin's lymphoma, 1 – lung cancer and 1 thymoma. All of them had had at least non-diagnostic core-needle biopsy followed by non-diagnostic thoracoscopic biopsy (1 patient) of Chamberlain procedure (1 patient). We performed PET/CT in all the patients to define the viable target area for subsequent core-needle biopsy. One patient had the biopsy immediately after PET/CT scanning, using the CT-part of PET/CT scanner for navigation. In 5 patients the biopsies were taken within 1 week after PET/CT scanning under normal CT-control. The imaging data obtained from CT and PET/CT scanning were analyzed and compared using the axial slices and MPR reconstructions with OsiriX MD software. 14G and 16G needles were used for mediastinal and lung tumors respectively. All procedures were performed under local anesthesia on outpatient basis. **Result:** We received tissue confirmation in all cases. No complications occurred during or soon after the biopsy. **Conclusion:** Uptake zone of the radiotracer on ^{18}F-FDG PET/CT image correlates with informative biopsy specimen taken from that part of the tumor. We may recommend performing of ^{18}F-FDG PET/CT prior to the repeated core-needle biopsy to get information on viable and necrotic tumor compounds to define the target areas.

EP1.05-07 EXAMINING ENDOBRONCHIAL ULTRASOUND (EBUS) UTILISATION IN LUNG CANCER DIAGNOSIS AND TREATMENT DELAY. A RESTROSPECTIVE OBSERVATIONAL STUDY

R. Stirling[1], S.W. Khung[2], M. Hew[1], E. Dabscheck[2], D. Keating[2], T. Williams[2]

[1]*The Alfred Hospital, Melbourne/Australia,* [2]*Alfred Hospital, Melbourne/Australia*

Background: Introduction • EBUS has high diagnostic yield in the assessment of mediastinal lymphadenopathy, staging and diagnosis of lung cancer. (1) • FDG PET/CT scans can be used in the initial assessment of hilar and mediastinal nodes, EBUS-TBNA has a higher sensitivity and specificity for staging these lymph nodes in patients with lung cancer. (2) • The provision of high quality EBUS demands that procedures are delivered in a manner which is demonstrably evidence based, effective, equitable, safe, patient-centred and timely. • Timeliness in EBUS provision will ensure a minimum in patient related anxiety and minimal prolongation of the referral to diagnosis and referral to treatment intervals. Objective To examine the impact of EBUS wait time on diagnosis and treatment delay in evaluating lung cancer and mediastinal lymphadenopathy within the Alfred Hospital. **Method:** A retrospective chart review of diagnosed lung cancer patients undergoing EBUS (linear and radial) at the Alfred Hospital between August 2013 and September 2018 was conducted. We recorded the waiting interval between EBUS referral and procedure and examined impact on lung cancer management timeliness from lung cancer referral to lung cancer diagnosis and first treatment based on electronic records. Electronic records were also used to gather baseline patient characteristics. **Result:** 103 EBUS procedures were completed on 96 patients with the below characteristics. Lung cancer referral to diagnosis interval had mean 23.2 days (30.5 SD), diagnosis to treatment interval had mean 24.1 days (21.2 SD), and referral to treatment interval had mean 47.4 days (35.9 SD).

EBUS within one week of EBUS referral, n(%)	70 (79%)
EBUS within two weeks of EBUS referral, n(%)	85 (96%)

EBUS waiting time was compared for lung cancer referral to diagnosis interval (within vs delay of greater than 28 days), and diagnosis to treatment interval (within vs delay of more than 14 days). There was a trend towards diagnosis delay with prolonged wait for EBUS (p=0.052). Significantly, EBUS wait time was greater for delayed referral to treatment interval (more than 42 days), than within 42 days (p=0.012). **Conclusion:** Delay in investigation has the potential to delay key management issues including lung cancer diagnosis and treatment. Prolonged wait for EBUS lead to a trend towards diagnosis delay and significant delay in referral to treatment interval in this cohort. Further assessment of causes in EBUS delay warrants further investigation.

Keywords: EBUS, staging, Timeliness

EP1.05-08 OBTAINING DIAGNOSTIC LUNG BIOPSIES IN SUSPECTED LUNG CANCER PATIENTS

E. Barclay, A. Sharman, R. Booton, R. Duerden, M. Evison

Manchester University NHS Foundation Trust, Manchester/United Kingdom

Background: Lung cancer screening programs will inevitably increase demand for lung biopsies, therefore best practice and standardised investigation pathways need to be well established. This study was designed to determine current practice in obtaining diagnostic lung biopsies in patients with suspected lung cancer. **Method:** A retrospective study of CT-guided lung biopsies and frozen section biopsy procedures performed in 10 hospital trusts over 3 years. All pathology results were reviewed for patients with suspected lung cancer. The number of procedures performed, and the proportion of cancerous, benign and indeterminate findings were ascertained and compared for the two biopsy techniques. Relevant imaging was reviewed (by an experienced interventional thoracic radiologist) to determine whether patients met the criteria for a percutaneous CT-guided biopsy. **Result:** 607 frozen sections and 204 CT-guided biopsies were performed over three years in 10 hospital trusts for suspected lung cancer. Pathology results demonstrated that 23% of frozen sections were benign, 2% were indeterminate and 75% were cancerous. In comparison, 16% of CT-guided lung biopsies were benign, 30% indeterminate, and 54% cancerous. Trends showed a gradual increase in the number of CT guided biopsies over 3 years, and a decrease in the number of frozen sections performed. There was a reduction in indeterminate CT-guided biopsy results and in benign frozen section results over the three-year period. Most patients met the criteria for percutaneous CT-guided biopsy, based on size and location of the lesion and background lung function, yet frozen section biopsy frequently remained the first line approach. **Conclusion:** Advancements in imaging and biopsy techniques promotes percutaneous CT-guided biopsy - the more favourable, less-invasive approach for obtaining lung tissue. However, many patients are still undergoing frozen section biopsies as the first-line option. A review of individual trust pathways is recommended to ensure standardisation of practice and that patients are offered the most appropriate investigation.

EP1.05-09 WELL-DIFFERENTIATED LIPOSARCOMA CAUSING ENDOBRONCHIAL OCCLUSION: A CASE REPORT

L. Fernandez-Trujillo[1,2], E. Morales[1,2], J. Lores[2], M. Aguirre[1,2], L. Sua[1,2]

[1]*Universidad Icesi, Cali/Colombia,* [2]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia*

Background: Endobronchial well-differentiated liposarcoma(WDL) is an uncommon benign entity which corresponds to 0,1-0,5% neoplasms affecting the bronchial tree. 60% patients are men with a median age of presentation of 60-years-old. Smoking and obesity are known risk factors. Its treatment implies resection of the tumor only or part of the lung too. Endobronchial WDL is associated with favorable prognosis, particularly when distant compromise from the lungs is absent. In consequence, timely diagnosis is pivotal. We present the case of a endobronchial occlusion due to WDL. **Method:** Review of the Clinical History. **Result:** 74-years-old man former smoker of 54.8 packs-year, with COPD and family history of gastric and bladder cancer. Attends medical assistance with constant expectorant cough and repeated pneumonias without dyspnea. Chest-CT evidence a great size, exophytic tumoral lesion in left main bronchus, complete ipsilateral atelectasis and mediastinal lymphadenopathies. Bronchoscopy is performed, revealing a mass of tumoral appearance from the left inferior lobe. Mass resection is performed in two times with electrocoagulation and cryoprobe under general anesthesia, leaving permeable the lumen of the main left bronchus and all its segments without complications. Histopathological studies with hematoxylin-eosin stain showed a lesion of mesenchymal origin, compound by different size adipose tissue and fibrous stroma covered by respiratory epithelium. Immunohistochemistry expressed vimentin, within fibrous septa nuclear marker CDK4 was expressed, KI67 of 2% without evidence of mitosis according to pHH3 assessment. Morphological pattern and immunophenotypic expression profile. compatible with WDL. Periodic follow-up evaluations of the airway with bronchoscopy were recommended. **Conclusion:** WDL is a benign but uncommon neoplasm arising at the tracheobronchial tree. Despite its benignity, endoluminal polypoid growth can cause endobronchial occlusion and destruction of distal parenchyma. Cough, progressive dyspnea, hemoptysis and recurrent pneumonia are common clinical manifestations, yet bronchoscopy and histopathologic assessment are essential to confirm diagnosis and avoid irreversible parenchymal changes.

Endoscopic aspect of the mass in the left main bronchus, handled with electrocautery and cryoprobe

EP1.05-10 METASTASIS FROM A PRIMARY MELANOMA OF THE SINONASAL CAVITY: A CASE REPORT

L. Fernandez-Trujillo[1,2], E. Morales[1,2], J. Lores[2], M. Aguirre[1,2], L. Sua[1,2]

[1]*Universidad Icesi, Cali/Colombia,* [2]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia*

Background: Metastatic extension to tracheobronchial tree from non-lung primary neoplasms is a common clinical problem. Endoluminal compromise is estimated to be present in 2-28% of metastatic disease cases. Melanoma's high metastatic potential can affect lung in 71% of cases, turning it into a frequent cause of relapse, however, endobronchial metastases by this entity corresponds to 4,5% of all metastatic lesions from the tracheobronchial tree. Mucosal melanoma (MM) is a rare entity that encompasses 1.3% from all cases of melanoma. Sinonasal cavity and conjunctiva are the most frequent locations. Liver metastasis from primary sinonasal MM has been described but endoluminal airway spread is extremely uncommon. We report the case of primary MM from sinonasal cavity with endotracheal metastasis and severe obstruction of the central airway. **Method:** Review of the Cinic History. **Result:** 47-year-old man with previous diagnosis of nasal melanoma attended the hospital for a FBC indicated due to one month of dyspnea and chest discomfort. His medical history included surgical resection from inferior turbinate lesion with positive borders, followed by adjuvant radiotherapy as part of the therapeutic management for his melanoma. Subsequent PET-CT scan evidenced hypermetabolic lesion in VII hepatic segment and pre-cava adenopathy. On the FBC, a 1-cm tumoral lesion in right nasal fossa was observed in addition to a complex mass located in the fourth tracheal ring, obstructing 90% of the lumen. ICU hospitalization was indicated due to respiratory failure high risk. Complete lesion resection was performed via therapeutic FBC with electrocautery and cryoprobe under general anesthesia. Pathological report: Neoplastic lesion compatible with metastasis of MM with non-mutated BRAF. Chemotherapywasinitiated. **Conclusion:** Primary MM is an uncommon tumor. Although endoluminal airway metastases are extremely rare from primary sinonasal MM, they are a differential diagnosis to consider in a patient with respiratory symptoms within the context of this primary neoplasia.

EP1.05-11 INTEGRATING RADIOLOGICAL FEATURES TO CT GUIDED LUNG BIOPSY RESULTS; THE EXPERIENCE OF AN ARGENTINEAN UNIVERSITY TEACHING HOSPITAL

D. Mansilla, M. Vargas Benitez, C. Gabay, M. Castro

Thoracic Oncology Unit, Instituto Angel H. Roffo, Buenos Aires/Argentina

Background: To analyze the radiological findings and the diagnostic accuracy of percutaneous transthoracic needle biopsies (CT-PTNB) performed for the evaluation of patients with lung lesions derived to our center. **Method:** We describe a retrospective review of 206 consecutive patients undergoing CT- PTNB of lung lesions performed between 2016 and 2019 at a single oncological referral center. Clinico-pathological data, including: age, smoking status, and previous cancer was described. Radiologic lesion´s characteristics on CT; multiple or solitary , location, mean diameter (mm), type (mass^{3}30 mm, nodule < 30mm, other), mean distance to pleura, presence of consolidation, nodule edge, calcifications, presence of radiologic emphysema, ground glass component and PET-CT SUVmax were used to compare with lung biopsy results. The rate and factors associated with complications was also be reported. **Result:** From 105 patients who underwent CT- PTNB and fulfilled inclusion criteria; 85 (81%) had pathologic confirmed cancer diagnosis, 3 (3%) had benign findings and 17 (16%) had inadequate samples for accurate diagnosis. The majority of patients were: male (57%) and the mean age was 63 years (32–88). Lung cancer was the main diagnosis (49/85; 58%) achieved through CT-PTNB; 71.2% of these cases had adenocarcinoma histology and 29% (14/49) had previous cancer diagnosis (35%: breast cancer) being the majority of them smokers (86%). Metastatic lesions (36/85; 42%) were: 44% melanoma-sarcoma, 38%: breast, colorectal, renal and cervix cancer and 18%: lymphoma, cervix, head and neck, lung and urothelial cancer. Primary lung cancer compared to lung metastases showed on CT images: mass presentation (63%vs33%; p=0.002), right superior lobe localization (47% vs 33%; p=0,016), solitary lesion (77% vs 53%; p=0,016), consolidation (22% vs 5%; p=0,033), central calcification (12% vs 0%; p=0,024), emphysema (55% vs 28%; p=0,009), mean major diameter (mm) (61±33 vs 36±24; p=0,000), mean distance to pleura (mm)(32±78 vs 86±12.7; p=0,014) and PET-CT mean SUVmax (8.8±10.63 vs 4.7±6.8; p=0.045). The complication rate of CT- PTNB was 18.5% (half of them practiced through right upper lung lobe , being pneumothorax the most common. Mean distance between pleura to CT- PTNB site was 10.54 vs 3.81 mm in complicated and non-complicated cases, respectively. **Conclusion:** Primary and metastatic lung lesions were safely pathologically evaluated by CT-PTNB. Radiological characteristics of the lesions can help in patient´s initial assessment to predict their nature.

Keywords: lung-nodules GGO

EP1.06 MESOTHELIOMA

EP1.06-01 AMRUBICIN TREATMENT AS PALLIATIVE-INTENDED CHEMOTHERAPY FOR PREVIOUSLY TREATED MALIGNANT PLEURAL MESOTHELIOMA

S. Kawai

Tokyo Metropolitan Cancer and Infectious Diseases Center Komagome Hospital, Bunkyoku Tokyo/Japan

Background: Treatment options for non-naive malignant pleural mesothelioma (MPM) are limited. Few phase II trials have provided evidence for the treatment. Till date, antineoplastic activity has been observed in phase II trials in patients with MPM treated with anthracyclines, doxorubicin, or pegylated-liposomal doxorubicin. However, few studies have reported on these treatments because of severe toxicities. Conversely, amrubicin (AMR) is an anthracycline drug that is commonly used for treating thoracic tumors; therefore, we know that the treatment is generally well tolerated. We performed this phase II trial to determine whether AMR monotherapy is a promising treatment approach for non-chemotherapy naive patients with MPM. **Method:** Non-randomized phase II trial Patients diagnosed with MPM based on the histological and cytological examination of specimens, with disease progression after pemetrexed/platinum, 1–2 prior regimens, age 18–74 years, AMR naïve status, and performance status (PS) 0–2 were enrolled. Patients received 35 mg/m2 AMR (days 1–3) every 3 weeks until tumor progression and had unacceptable toxicities. The primary endpoint was tumor response rate, and secondary endpoints were progression-free survival, overall survival, and toxicity rate. **Result:** From September 2013 to July 2018, five patients with MPM were enrolled, and the treatment responses were evaluated. All subjects in this case series were men with a median age of 65 (range, 49–76) years; the mean number of treatment cycles was 3 (range, 2–11). Stable disease was observed in three patients (60%) and progressive disease in two (40%). The median progression-free survival was 2.4 (range, 1.2–11.2) months, and the median overall survival was 9.1 (range, 6.2–22.0) months. Grade 1/2 toxicities, such as nausea and malaise, were reported in all subjects, and most of the toxicities were controllable. Grade 3/4 neutropenia occurred in four patients (80%), and there was no case of febrile neutropenia. **Conclusion:** Three of our patients achieved stable disease with AMR treatment. These data suggest that AMR is a promising treatment for previously treated MPM in the absence of another treatment. Moreover, AMR is associated with modest toxicities, similar to that in previous reports.

Keywords: malignant pleural mesothelioma, amrubicin, case series

EP1.06-02 ASSOCIATION OF INFLAMMATORY BIOMARKERS WITH OVERALL SURVIVAL IN PATIENTS WITH ADVANCED MALIGNANT PLEURAL MESOTHELIOMA

L. Gutiérrez Sainz, P. Cruz, S. Martínez Recio, I. Esteban, F. Arias Lotto, D. Viñal, J. Villamayor, D. Sanchez Cabrero, O. Higuera, J. De Castro Carpeno

La Paz University Hospital, Madrid/Spain

Background: The inflammation process has been proposed as a mechanism of immunoresistance in patients with cancer, promoting cancer growth and dissemination. Derived neutrophil to lymphocyte ratio (dNLR) greater than 3 and lactate dehydrogenase (LDH) level greater than upper limit of normal (ULN) are associated with poor outcomes in patients with advanced non–small cell lung cancer. The aim of this study is to determine whether pretreatment levels of dNLR and LDH as well as PD-L1 status are associated with overall survival in patients with malignant pleural mesothelioma. **Method:** We conducted a retrospective study, which included all patients with malignant pleural mesothelioma diagnosed in a tertiary referral hospital from December 2009 to March 2019. PDL1 status, complete blood cell counts and LDH levels were collected. A descriptive analysis was carried out, followed by a survival analysis using the Kaplan-Meier estimator. **Result:** We selected 25 patients. No correlation was found between dNLR and LDH levels. 5 patients (20%) had a dNLR greater than 3, of which 3 patients had stable disease and 2 patients received supportive care. Patients with a dNLR greater than 3 had a median overall survival (mOS) of 8,5 months, whereas patients with a dNLR less than 3 had a mOS of 17,0 months, with statistically significant differences (P:0.038). 2 patients (8%) had a LDH level greater than ULN, of which 1 patient achieved

a partial response and 1 patient had stable disease. Regarding the LDH level no difference in overall survival was found. Regarding to the PD-L1 status, 10 (40%) of 25 patients had PD-L1 ≥ 1%, 8 (32%) had PD-L1 < 1% and 7 (28%) had unknown PD-L1. Patients with PD-L1 ≥ 1% had a mOS of 8,5 months, whereas patients with PD-L1 <1% had a mOS of 15,7 months, with no statistically significant association (P> 0.05). **Conclusion:** In our sample, pretreatment levels of dNLR greater than 3 were correlated with worse overall survival in patients with malignant pleural mesothelioma. Furthermore, pretreatment levels of LDH greater than ULN and PD-L1 greater than or equal to 1% could be correlated with worse overall survival, although due to the size of our sample we are not able to conclude statistical significance. Further studies are needed to explore this relationship.

Keywords: Malignant pleural mesothelioma, inflammatory biomarkers, PDL1 status.

EP1.06-03 THE MESOTHELIOMA OUTCOMES, RESEARCH AND EXPERIENCE (MORE) SURVEY. USING REAL WORLD RESEARCH METHODOLOGY

L. Creech, L. Darlison

Mesothelioma UK, Leicester/United Kingdom

Background: Malignant mesothelioma is a locally invasive neoplasm arising from the mesothelial surfaces of the pleural cavity & a smaller number of cases affecting the peritoneum. Annually approximately 2,700 are diagnosed with mesothelioma in the UK with approximately 2,500 deaths.(CRUK 2019) In 2012 Mesothelioma UK (MUK) undertook a patient experience survey enabling MUK to inform healthcare providers what was done well, what could be improved & to demonstrate where there were variations in care. As a primary objective MUK are replicating the 2012 survey to update recommendations representing the patient experience & to circulate these to the mesotheloma community and healthcare providers. A secondary objective will deliver data to support regulatory discussions for new medical interventions. This will include the collection of treatment histories, patient reported outcome measures, NHS resource use & non-medical patient costs. This will provide a comprehensive evidence portfolio, from which the understanding & burden of disease in mesothelioma can be identified/quantified, so that the provision of services for individuals can be deployed. The survey will provide cost effective utility assessments assisting in the approval for new therapeutic interventions. **Method:** The survey is anonymous, prospective, cross sectional & non-interventional. Recruitment of mesothelioma patients is via a number of methods coordinated & led by MUK. The research will collect circa 600 participants over 26 weeks from January to June 2019. Participants are given a survey that includes questions on standard demographics, experience of care (questions adapted from the 2012 Mesothelioma Experience Survey), HRQol and previous/current clinical management. On completion of the survey, the participants are asked to provide consent for the CNS to review /validate the clinical section & the information provided on their clinical management. **Result:** A full statistical analysis plan will be developed and disseminated following completion of the survey and review of the data. **Conclusion:** MUK believes the data being collected using this unique methodology will be the only data of its kind to examine real world patient demographics, occupational histories, treatment pathways, individual experience and the burden of disease.

EP1.06-04 DIFFERENCES IN HEALTH STATE PREFERENCE VALUES FOR MALIGNANT PLEURAL MESOTHELIOMA AND GLIOBLASTOMA MULTIFORME

C. Proescholdt[1], J. Kelly[2]

[1]*Novocure, Root D/Switzerland,* [2]*Novocure, Portsmouth/United States of America*

Background: Malignant pleural mesothelioma (MPM) is an invasive and generally fatal malignancy of the pleura mainly caused by exposure to asbestos fibers. Glioblastoma (GBM) is the most aggressive and similarly fatal form of primary brain cancer in adults. It was recently shown, that both rare cancers are treateable with tumor treating fields (TTFields). Novel cancer treatment modalities are subject to comparative economic evaluation using health state preference values or heath utilities, in addition to clinical trial endpoint data. Utilities have a value range between 0 and 1, with "1" representing a state of perfect health and "0" death. Clinical results of TTFields treatment show a comparable effect on median overall survival (OS) for both MPM and GBM. The EF-23 STELLAR trial in MPM demonstrated a median OS increase of 6.1 months for TTFields treatment compared to historical control. The EF-14 trial showed a median OS increase of 4.9 months in GBM. Differences in health state preference values however, could significantly influence the adoption of a treatment independent of its clinical efficacy and safety in the respective indication. **Method:** We reviewed the structure and results of the trials using TTFields treatment in GBM and MPM from a health economic standpoint. Three health states (stable disease, progressed disease and death) were determined appropriate for both, the EF-14 trial in GBM and for the EF-23 STELLAR trial in MPM. A comprehensive review of the published literature adressing health state preference values or health utilities was performed using a boolean search of the PubMed database. The results were compiled separately for both diseases and then compared to each other. **Result:** Estimates of health states preference values or utilities in GBM all refer to one single publication. Healthy members of the NHS Value of Health Panel (VoHP) rated a total of nine descriptive health state scenarios using the standard gamble method for preference elicitation. There are no published preference values for descriptive health states scenarios or disease states in mesothelioma. Uilities published for MPM were elicited at individual patient level as derived from the EQ-5 questionnaire data collected during the trial. Other publications do not use specific mesothelioma heath state preference values but assume applicability of utilities derived from a non small cell lung cancer (NSCLC) population. **Conclusion:** Although both are rare cancers, health state preference values for GBM and MPM are different. GBM health state preference values are elicited from a single source, while utilities used in MPM are more diverse. Published utilities for GBM allow for use in a health state disease model, while there are no similar published values for MPM. MPM utilities derived from the EQ-5 questionnaire however describe more adequatly the individual utilities and their change during the course of the disease. This difference in structure, elicitation methods and sources of health state preference values in GBM and MPM could lead to disparities in the assessment of cost effectiveness of new treatments like TTFields in different indications, despite similar costs and clinical efficacy.

Keywords: Mesothelioma, TTFields, health state preference value

EP1.06-05 THE BRITISH LUNG FOUNDATION MESOTHELIOMA RESEARCH NETWORK: AN INTERNATIONAL COLLABORATIVE RESEARCH PLATFORM

C. Lenny[1], S. Gray[2], J. Moore-Gillon[3]

[1]*British Lung Foundation, London/United Kingdom,* [2]*Trinity College Dublin, Dublin/Ireland,* [3]*St Bartholomew's Hospital, London/United Kingdom*

Background: The British Lung Foundation's Mesothelioma Research Network (MRN) brings together basic science and clinical researchers in the field of mesothelioma to share knowledge, skills and resources. It aims to facilitate research progress and improve patient outcomes. International researchers are encouraged to join. **Method:** The MRN was launched in October 2017. Success is measured against performance indicators including member numbers and member feedback. Member surveys were conducted in July and December 2018. **Result:** • The MRN has over 130 members ranging from PhD students to departmental heads and includes non-UK based researchers. • In May 2018, 4 early-career MRN members were financially supported to attend the International Mesothelioma Interest Group (iMig) conference. • The first annual MRN Research Day (held June 2018, London, UK) was attended by 85 researchers. Evaluation showed that 85% of responders rated the programme as excellent or good and 86% felt the event would impact positively on their future research. • In the December 2018 members survey: - 77% of responders felt that being a member of the MRN helped them in their work as a researcher and 95% would recommend being an MRN member to a colleague. - 9 responders had contacted other members of the Network to access expertise or resources, and 5 of the 9 felt this contact had formed or could form research collaborations. • In December 2018, a British Lung Foundation collaborative grant call was launched exclusively for MRN members. The award, which will pump-prime new ideas in mesothelioma research, will be made in June 2019. **Conclusion:** A year and a half since launch, the MRN has

established itself as a valued resource for UK researchers. There will be a significant drive to increase international members in 2019. The MRN is supported by the Victor Dahdaleh Charitable Foundation.

Keywords: Mesothelioma, network, collaboration

EP1.06-06 RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES AND NONSTANDARD TREATMENT OF MALIGNANT PLEURAL MESOTHELIOMA IN A GENERAL HOSPITAL

K. Imasaka

Saiseikai Yokohamashi Tobu Hospital, Yokohama-City, Kanagawa/Japan

Background: Malignant pleural mesothelioma (MPM) is a relatively rare disease and there are not many cases at a single institution. However, our hospital is closed to the industrial area, so there were relatively many MPM patients who visited our hospital. On the other hand, MPM is disease with poor prognosis, and its standard treatment is also limited. Only two regimens; cisplatin + pemetrexed and nivolumab are approved as standard treatment in Japan. But in clinical practice, other drugs are also used for various reasons. Therefore, it is necessary to clarify the actual condition including nonstandard treatment. **Method:** We extracted patients of MPM who visited our hospital during the twelve-year period from April 2007-March 2019. And we carried out a retrospective analysis of the both data of patients who received standard therapy only and nonstandard therapy based on the medical records. And more summarized the clinical course, outcome and various factors. **Result:** There were a total of 41 MPM patients, of which 80.5% were male and 19.5% were female, and median age was 72 years old. Sixty-one percent of patients had a history of asbestos exposure. The most common clinical symptom at the first visit was dyspnea (48.8%). In 92.7% patients, pleural effusion was present. Their performance status (PS) at the time of diagnosis was as follows: "0" in 4 cases (9.8%), "1" in 23 cases (56.1%), "2" in 7 case (17.1%), "3" in 7 case (17.1%), and "4-5" in 0 case (0%). By histology of MPM, 17 cases (41.5%) were epithelioid type, 10 cases (24.4%) were biphasic type, 3 cases (7.3%) were sarcomatoid type, and there were 11 other cases (26.8%) (including unknown); classified by the disease stage (IMIG Ver.8), 43.9% patients had "1A", 7.3% patients had "1B", 14.6% patients had "2", 9.8% patients had "3A", 12.2% patients had "3B", and 12.2% patients had "4". Radical surgery could be performed in only 3 cases (7.3%). Chemotherapy was administered in 25 cases (61%), and 16 cases (39%) also received chemotherapy with unapproved drugs and regimens, e.g., pemetrexed only, carboplatin, gemcitabine, vinorelbine, and bevacizumab, etc. The median overall survival (OS) of all patients was 13.8 months. The median OS for patients who received only standard treatment or only palliative treatment was 7.6 months, while the median OS for patients who received unapproved treatment was 16.9 months. The group of patients who received unapproved treatment included 3 cases with PS 2 or more, and also included 47 months of long-term survival cases. **Conclusion:** Although it is data of one general hospital, 41 MPM patients could be extracted and analyzed. Nevertheless, it is difficult to show statistically significant differences due to an insufficient number of cases, and factors such as stage and PS are related. However, it can be said that survival tends to be longer in patients who also received unapproved treatment. We will analyze more cases, including patients under observation, and will report these detailed data at the venue.

Keywords: malignant pleural mesothelioma, nonstandard therapy, overall survival

EP1.06-07 IN VIVO STUDIES OF TUMOR TREATING FIELDS TO UPPER TORSO IN COMBINATION WITH CHEMOTHERAPY SHOW NO ADDITIONAL TOXICITIES

M. Giladi, S. Davidi, M. Munster, R. Schneiderman, N. Kaynan, T. Voloshin, Y. Porat, S. Cahal, E. Kirson, U. Weinberg, Y. Palti

Novocure Ltd, Haifa/Israel

Background: Tumor Treating Fields (TTFields) are low intensity, intermediate frequency alternating electric fields targeting rapidly dividing cells. TTFields (200 kHz) are FDA-approved for the treatment of glioblastoma based on phase 3 studies demonstrating efficacy and a high safety profile. TTFields are currently being tested as a treatment option for other solid tumors in the brain, abdomen, and torso. We evaluated if the safety profile of TTFields is maintained at various frequencies in the upper torso. **Method:** TTFields (150 kHz) were applied for 1-4 weeks using the Novo-TTF 100 system to rat and rabbit torso at 2-3 V/cm, which are intensities and frequencies known to be effective for the treatment of NSCLC and mesothelioma. The safety of TTFields in combination with liposomal doxorubicin and cyclophosphamide or paclitaxel was tested in animals. Throughout the treatment course, all animals underwent daily clinical examination by a certified experienced veterinarian and their body weight was determined on a weekly basis. Extensive blood workup, ECG, and temperature measurements were performed in the rabbit experiments. At the end of treatment, animals were euthanized and an experienced independent pathologist performed histological comparative evaluation of all major internal organs. **Result:** No changes in the following parameters were observed in activity level, food intake, drinking, stools, motor neurological status, and respiration. Further, no changes in weight were observed between the TTFields treated and relevant control groups. No significant changes were observed in complete blood count and differential between TTFields treated animals and relevant control groups. Histological analysis did not reveal any increase in pathological findings in the TTFields treated animal groups. **Conclusion:** These results demonstrate the safety of TTFields application at frequencies of 150 kHz to the torso. No additional toxicities were observed with the combination of TTFields and chemotherapy agents vs chemotherapy agents alone. This work further supports the safety profile of TTFields and offers opportunities for combining TTFields with various chemotherapy agents in lung cancers.

Keywords: Tumor Treating Fields, Safety, In Vivo

EP1.06-08 A RETROSPECTIVE ANALYSIS ON SARCOMATOID MESOTHELIOMA TO IDENTIFY IF CHEMOTHERAPY PROVIDES GREATER OVERALL SURVIVAL COMPARED TO BSC

R. Thomas, S. Daly

Guy's and St Thomas' NHS Trust, London/United Kingdom

Background: Sarcomatoid is the least common, but most aggressive type of mesothelioma (1) accounting for approximately 11% of all malignant pleural mesothelioma (MPM) (2). However, unlike lung cancer which has different treatment depending on histology, Mesothelioma has the same treatment, regardless of cell type (3, 4). Current data suggests patients with Sarcomatoid Mesothelioma have an average of 5.3 months survival from diagnosis. (5). **Method:** Method A retrospective analysis was undertaken on 9 Sarcomatoid Mesothelioma patients diagnosed and treated from March 2017 to November 2018. The aim of the audit was to identify if patients who received chemotherapy had better overall survival when compared to those patients' who received best supportive care (BSC). All of the 9 patients were PS 0/1 at time of diagnosis. 5 patients had platinum doublet chemotherapy 4 patients had best supportive care partly due to age and concerns of the patient about impact of chemotherapy on quality of life. **Result:** 2 patients who received chemotherapy died within 8 months of diagnosis. 2 patients who had BSC died within 5 months of diagnosis. 1 patient had 1 line of chemotherapy and then on PD recruited to PROMISE Trial and received Pembrolizamab. Still on treatment at C20. 3 patients who had chemotherapy are still alive on average 1yr 6 months post diagnosis with continuing stable disease. 3 of the patients who had first line chemotherapy went on to receive 2nd line chemotherapy either in or out of a clinical trial. 2 patients BSC still alive with average 6 months progression free survival. **Conclusion:** The results do suggest that patients who have chemotherapy do have an OS benefit when compared to those with BSC only. Overall patients tolerated chemotherapy well and have gone on to either receive second line oral Vinorelbine or be recruited into a clinical trial. Due to small numbers of patients it would be good to undertake a formal research study in multiple centres to recruit larger numbers of patients to assess if these results are mirrored nationally. It would also be of interest to identify if Sarcomatoid patients are routinely offered chemotherapy as first line treatment or whether the majority of patients are advised to accept BSC only.

Keywords: Sarcomatoid Mesothelioma, chemotherapy, best supportive care, overall survival.

EP1.06-09 MESOTHELIAL TUMORS REGISTRY IN SPAIN: A RETROSPECTIVE MULTICENTER STUDY

P. Cruz[1], S. Martínez Recio[1], X. Mielgo[2], V. Sotelo Peña[2], L.E. Chara[3], I. Nalda Ariza[3], E. Martinez Moreno[4], Y. Lage Alfranca[5], A. Velastegui[6], L. Gutiérrez Sainz[1], J. De Castro Carpeno[1]

[1]*La Paz University Hospital, Madrid/Spain,* [2]*Fundación Alcorcón Hospital, Madrid/Spain,* [3]*Medical Oncology Department. Hospital Universitario Guadalajara, Guadalajara/Spain,* [4]*Virgen de la Salud Hospital, Toledo/Spain,* [5]*Fundación Jiménez Díaz University Hospital, Madrid/Spain,* [6]*Móstoles University Hospital, Madrid/Spain*

Background: Malignant mesothelioma is an unusual tumor associated with poor prognosis. Currently, there are no effective treatments after the progression to the first line. The aim of this study is to analyze the experience in 7 spanish centers. **Method:** We conducted a retrospective analysis including patients with malignant mesotheliomas of 7 centers in Spain. Demographic, clinical and pathological variables, tumor response, progression date and death were collected. **Result:** We enrolled 63 patients with diagnosis of malignant mesothelioma. The average age was 70 years. 73,4% were men and 26,4% women. The most frequent location was the pleural (78,1%) and biopsy was the main diagnostic method (92,2%). 76,6% were diagnosed as epitheloid mesothelioma subtype, whereas sarcomatoid and mixed subtypes were less frequent. Tumor in stage IV was presented at diagnosis in 75 % cases. The most frequent first treatment was chemotherapy, 95,2% of patients received treatment based on platinum doublet with pemetrexed, followed by pemetrexed maintenance. Best response was partial response in 20,6%, stable disease in 41,3%, complete response in 22,2% and progressive disease in 15,9%.The median progression free survival of the sample was 8,8 months, and the median overall survival was 12 months. **Conclusion:** The demographics and baseline characteristics as well as the survival data obtained in our sample are consistent with the previously reported.

Keywords: Malignant mesothelioma, retrospective study.

EP1.06-10 MALIGNANT PLEURAL MESOTHELIOMA DIAGNOSIS: AN 18-YEAR-OLD EXPERIENCE

P. Paglialunga, G. Molins, S. Erzi, R. Cavo Frigerio

Hospital San Juan de Dios de La Plata, LA PLATA/Argentina

Background: Malignant pleural mesothelioma (MPM) is a rare malignant tumour derived from the embryonic mesoderm, whose most frequent location is the pleura. It regularly occurs between the ages of 60 and 80, and it is strongly related to an asbesto exposure. This work compiles the joint experience of both the thoracic surgery and the pathological anatomy services of the General Interzonal Hospital for Acute and Chronic Cases "San Juan de Dios" from the city of La Plata, Argentina. **Method:** A retrospective analysis was carried out in all the patients with a MPM diagnosis registered in the database of San Juan de Dios Hospital, during the time period from January 2000 to December 2018. All diagnoses were performed through pleural biopsies, analized by means of a routine haematoxylin-eosin test and confirmed by an immunohistochemistry study (two positive and two negative indicators). **Result:** 118 cases were analized, and ages ranged from 17 to 89 years (62 years old was the average), 70% were male while 30% female. The biopsy was taken through videothoracoscopy or thoracotomy, except for a case in which Abrams needle was used. In 14% of the cases a second biopsy was necessary to confirm the diagnosis. The histologic patterns were: epithelioid (65%), sarcomatoid (11%), desmoplastic (3%), and biphasic (12%); in 6% of the cases the histologic type was not determined. **Conclusion:** We could observe that most cases apply to men elder than 70 years of age and that the most frequent histologic pattern is the epithelioid one. Moreover, we could see that the average size of the useful sample for diagnosis and the one which did not require a new biopsy sample was 0.8 cm.

Keywords: Mesothelioma, size of pleural biopsies, diagnosis

EP1.06-11 ADVANCED MALIGNANT PLEURAL MESOTHELIOMA: A SINGLE INSTITUTION EXPERIENCE

L. Gutiérrez Sainz, P. Cruz, S. Martínez Recio, I. Esteban, F. Arias Lotto, D. Viñal, J. Villamayor, D. Sanchez Cabrero, O. Higuera, J. De Castro Carpeno

La Paz University Hospital, Madrid/Spain

Background: Malignant pleural mesothelioma is a rare and highly aggressive tumor that typically presents with advanced disease. The prognosis of patients with malignant pleural mesothelioma is poor and there is currently a lack of effective treatment options. The aim of this study is to analyze the experience of our center in the management of this pathology. **Method:** We conducted a retrospective study, which included all patients with malignant pleural mesothelioma diagnosed in a tertiary referral hospital from December 2009 to March 2019. Data regarding baseline characteristics, treatment response and survival were collected. A descriptive analysis was carried out, followed by a survival analysis using the Kaplan-Meier estimator. **Result:** We selected 25 patients. Table 1 summarizes the main sociodemographic characteristics, the histological subtype and the stage.

Table 1	Nº (%)
Sex: Male/Female	19 (76%) / 6 (24%)
Age (years):	71 (51 – 89)
Histology: – Epithelioid mesothelioma – Sarcomatoid mesothelioma – Mixed mesothelioma	22 (88%) 1 (4%) 2 (6%)
Stage: – Stage III – Stage IV	4 (16%) 21 (84%)

22 (88%) of 25 patients received first line chemotherapy with platinum doublet with pemetrexed followed by pemetrexed maintenance and 3 (12%) received palliative care. The proportion of patients who received six cycles of platinum doublet with pemetrexed was 55%. 5 (20%) of 22 patients who received first line chemotherapy with platinum doublet with pemetrexed achieved a partial response, 15 (60%) had stable disease and 2 (8%) experienced disease progression. After a median follow-up duration of 15,17 months, 19 (76%) patients had died. The median progression free survival was 13,1 months (IC 95%: 6,7 – 19,5), and the median overall survival was 15,7 months (IC 95%: 11,3 – 20,0). The major cause of death was cancer in 18 patients (95%) and 1 patient dead of heart disease. **Conclusion:** Demographics and baseline characteristics as well as the survival data obtained in our sample are consistent with the previously reported. Further studies are needed to determine other treatment options to improve the prognosis of these patients.

Keywords: Malignant pleural mesothelioma, retrospective study.

EP1.07 NURSING AND ALLIED PROFESSIONALS

EP1.07-01 EFFECTIVENESS OF THERAPEUTIC MASSAGE FOR TREATING ANXIETY IN SUSPECTED LUNG CANCER PATIENT PRE-BRONCOSCOPIC PROCEDURES

P.R. Santosa[1], R. Sitompul[2], R. Maria[2]

[1]*Persahabatan Hospital, East Jakarta/Indonesia,* [2]*Medical Nursing Surgery Post Graduate Program, Jawa Barat/Indonesia*

Background: Anxiety management rules important aspect during intervention procedures. Suspected lung cancer patients especially in diagnostic bronchoscopy procedures mostly experience mental and emotional problems including stress, anxiet and depression. Massage therapy as complementary and alternative medicines (CAM) are being used to help reduce tension and elicit feeling of calm and deep relaxation. **Method:** Our objective was to assess the effect of massage therapy on suspected lung cancer patients among pre-procedure of bronchoscopy. These are clinical trial placebo-controlled assesing pre and post anxiety quisionaire with massage therapy intervention. **Result:** Twenty eight patient with clinically diagnosed with suspected lung cancer were included in pulmonary ward divided into 14 subjek each massage group and control group. Based on anxiety quisionaire one hour post massage vs one to two hours pre-procedure there had been significantly decreasing anxiety score (p<0,05). Confounding factor are controlled by solo terapist

performing massage. **Conclusion:** Our results indicate that massage is effective to reduce anxiety before interventional procedures. Further well-designed, large studies with longer follow-up periodes are needed for better standard treatment managing anxiety.

Keywords: anxiety, massage, therapy, suspected lung cancer, pre-procedures bronchoscopy.

EP1.07-02 ROLE OF NURSE IN PATIENT CARE DURING IMMUNOTHERAPY TREATMENT THROUGH EXAMPLE OF CANADA AND POLAND

M. Pawlak[1], J. Ksiazek[2]

[1]*Szpital Kliniczny Przemieniania Panskiego Uniwersytetu Medycznego w Poznaniu, poznan/Poland,* [2]*Medical University of Gdansk, Gdansk/Poland*

Background: Immunotherapy is a rapidly growing field and is seen as an active cancer treatment strategy. Administration of immunocompetent drugs does not always take place in a stationary setting, so the level of education of the patient and his family is worth paying attention to. The knowledge of nursing staff plays an important role here. **Method:** The method of participant observation and analysis of the literature was used in the work. The materials utilized are the procedures and standards abided in Princess Margaret Hospital in Toronto, Clinical Hospital no. 1 of Poznan Medical University and the Medical University of Gdańsk. The observations were made during the participation in the Personalized Learning Program in Nursing-Clinical Research at Princess Margaret Hospital in Toronto on 17-21 September 2018, and at Polish centers in 2018. **Result:** Observations confirm that the analysis of the work structure, the functioning of observed centers, the availability of treatment methods and the scope of nurses competence in both countries vary. The level of education presented in Canada can serve as a model to follow for each country, where the method of treatment with immunocompetent drugs is transformed from the level of clinical trials into therapeutic programs. **Conclusion:** Polish Nursing should use the experience of Canadian nurses in the education of patients treated with immunotherapy.

Keywords: Immunotherapy, patient education

EP1.07-03 PREPAREDNESS IN PROMOTING AND SELF-ASSESSMENT OF NURSES ABILITY TO PROMOTE HEALTH AWARENESS IN LUNG CANCER PREVENTION

J. Ksiazek, W. Rzyman, R. Dziedzic, M. Jelitto-Gorska, I. Biadacz

Medical University of Gdansk, Gdansk/Poland

Background: Aim: The aim of this study was to analyze the self-assessment of nurses' knowledge regarding lung cancer, and to verify whether this group of professionals is prepared for promoting lung cancer prevention. Background:Lung cancer constitutes a health and epidemiological problem worldwide. Introduction: The complete elimination of exposure to the components of tobacco smoke is a primary prevention component of vital importance and should constitute extensive educational activities be undertaken by family nurses. However, according to available literature, the level of relevant knowledge represented by nurses remains insufficient. **Method:** This study included 490 nurses from Pomerania province. All the respondents completed the questionnaire verifying their knowledge of the etiology of lung cancer and their preparedness for promoting the prevention of this malignancy and self-assessed knowledge of the problems in question. **Result:** The average level of etiological knowledge of lung cancer was high. Preparedness for promoting health awareness in the prevention of lung cancer represented an intermediate level. The efficacy of screening is determined by its coverage. Nurses can provide a pivotal role in lung cancer prevention provided they are given training and responsibility for these additional duties. **Conclusion:** Many nurses, given appropriate training, have the potential for educating people in the prevention of lung cancer. However, full utilization requires education and reorientation of nurses towards primary prevention, especially in healthcare education. Nursing professionals may require additional training and increases in staffing to adequately respond to the increase in responsibility for patient care. Implications highlight a need for additional training and consultancy to improve knowledge and preparedness of nurses to address concerns in lung cancer prevention.

EP1.07-04 INCOMPLETE FIRST TREATMENT COURSE AND RELATED FACTORS OF SURVIVAL RATE ANALYSIS FOR LUNG CANCER PATIENTS

C.H. Hsu[1], M.H. Lee[2], C.Y. Kuo[2], J.Y. Hung[2], M.Y. Huang[2]

[1]*Nurse, Kaohsiung University Hospital, Kaohsiung/TW,* [2]*Kaohsiung University Hospital, Kaohsiung/TW*

Background: Cancer case managers not only provide clinical care for cancer patients and management, but also make sure patients receive continuous, correct and complete integrated care, in order to have good survival rate.To investigate reasons for lung cancer patients with incomplete treatment course and their survival rate analysis **Method:** The retrospective study enrolled patients with lung cancer from the case manager system according to the international classification disease(ICD-9:162) during 2013~2017 and analyzed the reason of incomplete first treatment course and related factors of survival rate. **Result:** Totally, 1489 lung cancer patients were enrolled in the study. Most of the patients were stage 4 disease, about 68.6%. There were 114 patients who incompleted their first treatment course (7.6%). In these patients, 41 patients(35.9%) were transfered to other hospital; 8 patients (7%) did not want to receive treatment anymore because they felt better; 27 patients (23.6%) refused treatment due to side effects; 36 patients (31.57%) received hospice care due to poor performance, and 2 patients (1.7%) incompleted their treatment due to old age. **Conclusion:** Case management interventions can provide health education of treatment, improvement of side effects, and social resources to the patients. Through the connection of nursing cares, case management can offer continuous follow up and support to reduce incomplete therapy course and increase patient survival rate by helping patients to return to hospital to complete their therapy course.

EP1.08 OLIGOMETASTATIC NSCLC

EP1.08-01 WHOLE-BRAIN RADIOTHERAPY PLUS SEQUENTIAL OR SIMULTANEOUS INTEGRATED BOOST FOR THE TREATMENT OF LIMITED NUMBER OF BRAIN METASTASES IN NSCLC

Q. Dong, M. Yuan

Affiliated Hospital of North Sichuan Medical College, Nanchong/China

Background: There has been no definitive regimens on how to integrate whole brain radiotherapy(WBRT) and local boost for brain metastases(BMs). To compare the therapeutic effect and cerebral cognitive dysfunction in non-small cell lung cancer(NSCLC) patients with limited number of BMs (≤10) treated by WBRT plus sequential integrated boost (SEB) or simultaneous integrated boost(SIB). **Method:** A total of 52 non-small cell lung cancer patients with limited number of BMs who underwent IMRT from January 2013 to December 2016 were retrospectively analyzed. 20 cases in group A were irradiated by WBRT+ SEB (first 3Gy*10Fx for WBRT then 4Gy*3Fx for BMs) and 32 case in group B were irradiated by WBRT+SIB(3Gy*10Fx for WBRT and the same 4Gy*10Fx for BMs). All patients had complete MMSE scores before radiotherapy, at the end of radiotherapy, 1 month after radiotherapy, 3 months after radiotherapy, and 6 months after radiotherapy. The clinical efficacy and differences in cognitive impairment were compared between 2 groups. **Result:** The Cumulative survival rates of 1,2 and 3 years in 52 patients were 52.5%, 28.6% and 14.3%, respectively. The median survival time was 13 months. The Cumulative 1, 2 and 3-year survival rates of group A were 60.0%, 41.1%, 27.4%, respectively. The median survival time was 15 months. The 1,2 and 3-year survival rates of group B were 47.8%, 19.1%, 0%, respectively. The median survival time was 10 months. The effect difference between group A and B was significant (P=0.046). Subgroup analysis revealed that 1, 2 and 3 years survival rate and median survival time of group A were significantly superior to group B, especially to those patients with 1-2 BMs, male or age <60 years old (P<0.05). MMSE scores at the end of radiation and at 1 month after radiation were not significantly different from those before treatment in both group (P>0.05), however, the scores at 3 or 6 months after radiation were lower than before radiation, the difference was significant(P<0.05). There was no significant difference in MMSE scores in the 2 group before radiation, at the end of radiation, at 1 month after radiation and at 6

months after radiation (P> 0.05). The scores of group A at 3 months after radiation was higher than that of group B (P<0.05). Certainly, group A had longer radiotherapy time and more cost than group B (P<0.005). **Conclusion:** For limited number of BMs in non-small cell lung cancer, WBRT+SEB is likely to be better than WBRT+SIB, especially to 1-2 metastases, male or aged <60 years patients. The decline of cognitive function in both groups occurred after 3 months of radiation, and WBRT+SEB group seems to be less impairment of brain cognitive function than that WBRT+SIB group. It is worth further study to verify Which boost scheme will be better.

Keywords: Non-Small Cell Lung Cancer, Brain metastases, Neurocognitive

EP1.08-02 SURGICAL INDICATION FOR POSTOPERATIVE REGIONAL LYMPH NODE OLIGO-RECURRENCE IN NON-SMALL CELL LUNG CANCER

Y. Watanabe[1], K. Takamochi[1], S. Oh[1], K. Suzuki[2]

[1]*Juntendo University School of Medicine, Bunkyo-ku/Japan,* [2]*Juntendo University, Tokyo/Japan*

Background: Currently, evidence-based guidelines for therapy to treat regional lymph node (LN) oligo-recurrence in post-resection non-small cell lung cancer (NSCLC) are limited. We investigated the clinical outcome of surgery for LN oligo-recurrence in post-resection NSCLC. **Method:** From 2008 to 2017, 14 patients received R0 resection for regional LN oligo-recurrence after initial NSCLC R0 surgery. Eligible patients met these criteria: A, no recurrences without regional LN by PET-CT and brain-MRI; B, LN recurrence within 3 regions. We investigated the characteristics of surgically curable NSCLC patients with postoperative regional LN oligo-recurrence, including recurrence-free survival (RFS) and overall survival (OS). **Result:** Ten patients were male and 4 were women. The median age was 69 years (62-86). Pathological findings in initial surgery was as follow; adenocarcinoma in 9, squamous cell carcinoma in 5, pathological stage I in 6, II in 4, and IIIA. The regional number of LN recurrence was as follow; 1 region in 11, 2 regions in 1, and 3 regions in 2. The median number of pathological metastatic LN were 2 (1-8). The median size of LN oligo-recurrence was 19 mm (14-38). All the oligo-recurrence LN had uptake in PET-CT. All the recurrent LN site was out of the dissection range at initial surgery. The median period from the initial surgery to oligo-recurrence was 18.1 months (7.0-66.5). The median operation time was 134 minutes (52-452), and median bleeding volume was 15 ml (2-2593). SVC reconstruction was performed in 1. Postoperative complication was detected in 3 cases; arrhythmia in 2 and graft occlusion in 1. There were no cases of perioperative death. EGFR mutation was detected in 4 cases. After LN dissection, 9 patients were followed up without treatment, and the other 5 patients underwent chemotherapy. Six patients (42.8%) out of 14 were recurrence-free after LD dissection. Compared recurrence-free patients with recurrence patients after LN dissection, pathological only one LN of oligo-recurrence ($p < 0.01$) and EGFR wild type ($p = 0.04$) were significant in the recurrence-free group. LN oligo-recurrence in only one region also tended to be more frequent in the recurrence-free group ($p = 0.09$). Pathological N or stage in initial surgery, size of LN oligo-recurrence, recurrence-free interval after initial surgery were no significant difference between recurrence-free and recurrent group. The median RFS and OS after LN resection in all 14 patients was 24.2 and 66.3 months. The 2-year and 5-year RFS rates after LN resection were 52.7% and 35.2%. Eight patients were recurrence after LN dissection; 4 were locoregional and the others were distant. Of the 8 relapsed patients, only 2 patients survive with EGFR-TKI. **Conclusion:** Surgery for postoperative regional LN oligo-recurrence in NSCLC should be indicated for the patients with only one LN of oligo-recurrence in only one region or EGFR wild type.

Keywords: oligo-recurrence, regional lymph node, Non-Small Cell Lung Cancer

EP1.08-03 RESULTS OF DEFINITIVE TREATMENT IN PATIENTS WITH SYNCHRONOUS OLIGOMETASTATIC NON SMALL CELL LUNG CANCER

S. Duru Birgi, S. Akyurek, E. Gumustepe, B. Bakirarar, S. Gokce

Ankara University Faculty of Medicine, Ankara/Turkey

Background: To evaluate the prognostic factors and outcome of both thoracic radiotherapy (RT) and oligometastasis treatment with curative intent in cases with oligometastatic non-small lung carcinoma (NSCLC). **Method:** We retrospectively evaluated 18 synchronous oligometastatic NSCLC patients who underwent radical treatment in the thoracic and oligometastasis region between 2015 and 2018 in our center. **Result:** The median age of patients was 62 years. Only two of 18 patients had ≥2 organ involvement. Patients' clinical and treatment characteristics are summarized in Table-1 and Table-2. Median follow-up was 7 months. The median overall survival (OS) was 11 months and the median progression-free survival (PS) was 8 months. The one year OS and PS was found 45% and 50% respectively. In the univariate analysis, the localization of oligometastasis (brain vs other distant met) was found as an effective factor on OS. The median survival was found to be 7 months in patients with brain metastasis whereas 18 months in patients with other metastasis. Although treatment type (RT vs surgery) or RT technique applied for oligometastasis (Conformal RT (3DCRT)/IMRT vs Stereotactic RT (SRS/SBRT)) did not cause significant difference on OS in univariate analysis; in the multivariate analysis, the localization of oligometastasis (HR: 7.3, 95% CI 1.33-40.5) and the RT technique applied for oligometastasis (HR: 8.45, 95% CI 1.43- 49.9) were found to be prognostic factors on OS ($p = 0.012$). In the univariate analysis induction chemotherapy (CT) and RT tecnique were statistically significant for PS, but this significance could not be demonstrated in multivarian cox regression analysis.

Table.1: Demographic characteristics of patients and the results in univarian analysis

	Number (%)	p value (OS)	p value (PS)
Age (years) median (min-max) <60 years ≥ 60 years	61.5 (35.0-73.0) 7 (38.9) 11 (61.1)	0.725	0.355
Gender Male Female	16 (89.0) 2 (11.0)	0.786	0.876
Histology Adenocarcinoma SCC	12 (67.0) 6 (33.0)	0.145	0.785
T stage T1 T2 T3 T4 Unknown	3(17.0) 4(22.0) 4(22.0) 6(33.0) 1(6.0)	0.87	0.369
N stage No N1 N2 N3 Unknown	4(22.0) 5(28.0) 8(44,0) 0(0) 1(6.0)	0.169	0.222

Table 2: Treatment characteristics of patients and the results in univarian analysis

	Number (%)	p value (OS)	p value (PS)
RT region Brain Bone Surrenal Liver Other	7 (50) 3 (21) 1 (7) 1 (7) 2 (15)	0.299	0.021
Metastasis number 1 2 3-5	12 (66.0) 3 (17.0) 3 (17.0)	0.393	0.794
Metastatic organ Brain Other Bone Surrenal Liver Multiple Other	7 (39.0) 11(61.0) 3 (17.0) 3 (17.0) 1 (5.0) 2 (11.0) 2 (11.0)	0.031	0.421
Oligometastasis treatment Surgery RT Surgery and RT	4 (22.0) 10 (56.0) 4 (22.0)	0.412	0.534
Oligometastasis RT tecnique SRS/SBRT 1x20 Gy 5x5 Gy 3DCRT/IMRT 3x 10 Gy 3x 15 Gy	4 (28.5) 3 1 10 (72.5) 6 4	0.065	0.468
Thoracic RT Dose 45 60 64-66	4 (22.0) 5 (28.0) 9 (50.0)	0.194	0.536
Induction CT Yes No	11(61.0) 7 (39.0)	0.067	0.044
Concurrent CT No Yes	6 (33.0) 12 (67)	0.084	0.142

Conclusion: Results of treatment with thoracic RT and oligometastasis region in oligometastatic NSCLC seem promising. The localization of the oligometastasis and the technique of RT are important factors.

Keywords: oligometastasis, nonsmall cell lung cancer, treatment

EP1.08-04 LOCAL TREATMENT FOR PATIENTS WITH PULMONARY OLIGO-RECURRENCE OF NON-SMALL CELL LUNG CANCER

Y. Kitamura, W. Nishio, S. Sekii, Y. Fujibayashi, M. Nishikubo, Y. Nishioka, H. Ogawa, S. Tane, K. Tsujino, M. Yoshimura

Hyogo Cancer Center, Akashi-shi/Japan

Background: The concept of oligo-recurrence, which is theoretically curable by definitive local therapy, has been proposed in several cancers. But the efficacy of local therapy for patients with pulmonary oligo-recurrence of non-small cell lung cancer (NSCLC) is unclear. The aim of this study was to investigate the efficacy of local therapy for pulmonary oligo-recurrence of NSCLC. **Method:** We retrospectively analyzed the data on 35 patients who underwent lung resection or radiotherapy for pulmonary oligo-recurrence in our institution, between 2000 and 2016. We evaluated independent risk factors for overall survival and progression-free survival after local treatment for patients with pulmonary oligo-recurrence of non-small cell lung cancer. In this study, pulmonary oligo-recurrence was defined as local recurrences limited within lungs after local or systemic treatment for NSCLC. **Result:** There were 26 men and 9 women with median age of 72 years [interquartile range (IQR), 64-75]. The median follow-up time was 48.8 months [IQR, 16.3-66.7]. Previous therapies for NSCLC were pulmonary resections in 26 patients (74.2%), stereotactic radiosurgery for brain metastasis in 3 (8.6%), radiotherapy for lung tumors in 3 (8.6%), chemoradiotherapy in 2 (5.7%) and chemotherapy (ALK-TKI) in 1 (2.9%). The median progression-free interval between previous therapy and local treatment for oligo-recurrence was 29.0 months [IQR, 16.0-44.5]. Histopathology were adenocarcinoma in 26 patients (74.2%), squamous cell carcinoma in 7 (20.0%), adenosquamous carcinoma and large cell neuroendocrine carcinoma in 1 (2.9 %). Among 21 patients (60.0%) who underwent surgical resection for pulmonary oligo-recurrence, surgical procedures were wedge resection in 11 patients, segmentectomy in 3, lobectomy in 5 and pneumonectomy in 2. Among 14 patients (40.0%) who underwent radiotherapy for pulmonary oligo-recurrence, 11 patients (31.4%) underwent stereotactic body radiotherapy. There were no treatment-related death. Three-year overall survival and progression-free survival were 60.3% and 49.6%. Post-treatment recurrence occurred in 16 (60.4%) patients (local; 6, distant; 2, local and distant; 8). Univariate analyses identified progression-free interval between previous therapy and local treatment for pulmonary oligo-recurrence as independent risk factor for overall survival (HR 0.97 [95% CI 0.95-1]; p=0.039). **Conclusion:** Local therapy for pulmonary oligo-recurrence of NSCLC are feasible and the post-therapeutic survival is acceptable. But there are highly selective patients in our study, further study is needed for curative intent treatment.

Keywords: non-small lung cancer, Oligometastases, local therapy

EP1.08-05 LOCAL NON-SALVAGE RADIOTHERAPY FOR SYNCHRONOUS OLIGOMETASTATIC NSCLC: A MULTICENTER, RANDOMIZED, CONTROLLED, PHASE 2 STUDY

X. Zhu, Z. Zheng, S. Li

The Radiation Oncology Department, Nanfang Hospital, Southern Medical University, Guangzhou/China

Background: Previous studies had suggested that aggressive thoracical treatment, such as surgery, might lead to higher local control rate and better long-term survival in oligometastatic NSCLC. Radiotherapy (RT) is also an effective and less invasive local treatment. Therefore, we assessed the role of addition of aggressive thoracical RT to first-line systemic therapy in patients with synchronous oligometastatic NSCLC. **Method:** Stage IV patients with measurable primary tumor and distant metastases number ≤5, histologically or cytologically confirmed NSCLC and ECOG PS≤2 were included. All enrolled patients had not previously experienced local or systemic antitumor treatment, including surgery (biopsy is allowed), first line chemotherapy, targeted therapy or immunotherapy. Other inclusion criteria included adequate organ function and life expectancy of >3 months. Our study randomized patients at 1:1 ratio to receive systemic therapy plus radiotherapy(RT+) or systemic therapy alone(RT-). First-line regimens recommended by NCCN guidelines are allowed for systemic therapy, including standard platinum-based doublet chemotherapy, targeted therapy, antiangiogenic therapy and immunotherapy. Three-dimensional conformal radiotherapy(3D-CRT) or Intensity modulated radiotherapy(IMRT) to primary thoracic foci or remediable oligometastatic focus should be given no later than disease progression. Randomization was stratified by histological type (squamous cell carcinoma vs. adenocarcinoma), first-line systemic therapy (targeted therapy vs. non-targeted therapy), intracranial metastasis (yes vs. no), number of metastases (1 vs. 2-5) and local stage (I/II vs. III). Primary endpoint of this study is progression-free survival(PFS) based on RECIST v. 1.1 criteria. Secondary endpoint are local tumor control; oligometastatic foci control; thoracic progression-free survival(TPFS); overall survival(OS); toxicity and compliance. The study has 80% power to detect a greater effect of RT+ group in PFS at a 2-sided alpha level of 0.05. Assuming a 10% drop-out rate, randomization of 148 patients was planned. The trial opened in China in November 2017. To date, 14 patients have been randomized and 2 sites in China have activated the trial. Support: 81572279, 2016J004, LC2016PY016, 2018CR033. Clinical trial information: NCT03119519. **Result:** Section not applicable **Conclusion:** Section not applicable

EP1.08-06 POSTOPERATIVE OLIGO-RECURRENCE OF NON-SMALL CELL LUNG CANCER

O. Kawamata

Onomichi Municipal Hospital, Onomichi/Japan

Background: Postoperative recurrences of non-small cell lung cancer (NSCLC) are usually disseminated and systemic. The concept of oligo-recurrence, defined as a small number of new lesions at a distant site theoretically curable by local therapy, has recently been proposed for several cancers. The aim of this study was to clarify clinical features and outcomes of patients with postoperative oligo-recurrence of NSCLC. **Method:** From 364 patients who underwent resection for NSCLC between January 2008 and December 2017 at our hospital. A total of 43 patients who developed recurrence were included in this study. Oligo-recurrence was defined as 1-2 loco-regional or distant recurrence lesions restricted to a single organ. Other recurrences were classified as poly-recurrence. Local therapy included surgery, stereotactic radiotherapy and radiotherapy. **Result:** Oligo-recurrence was identified in 12 (27.9%) patients, mainly as a solitary recurrence (n=11, 91.7%) in regional lymph nodes (n=1), surgical stump (n=2), brain (n=5), lung (n=1), bone (n=2) and liver (n=1). Primary tumor histopathological types included 9 cases of adenocarcinoma, one case of squamous cell carcinoma, one case of pulmonary pleomorphic carcinoma and one case of large cell neuroendocrine carcinoma.The patients with oligo-recurrence had a longer time to recurrence than those with poly-recurrence (median: 23.5 months, 11.0 months). A case of mediastinal lymph node recurrence was performed radiation therapy. A case of surgical stump recurrence underwent lobectomy and other case was performed concurrent chemo-radiotherapy. 4 case of brain metastasis were underwent tumor resection and were performed stereotactic radiotherapy, one case of brain metastasis was performed stereotactic radiotherapy only. A case of lung metastasis underwent wedge resection and was used EGFR-TKI. A case of bone recurrence was performed radiation therapy and was used EGFR-TKI, other case was performed concurrent chemo-radiotherapy. A case of liver metastasis underwent tumor resection. 7 of 12 cases confirmed re-recurrence after local therapy. But 9 patients were alive between 30.4 and 110.0 months after local therapy, whereas three of 5 brain metastatic patients died between 24.9 and 71.8 months. The 5 year overall survival rates after local therapy were 81.5%. **Conclusion:** The presence of oligo-recurrence can predict a favorable prognosis in patients with NSCLC treated with aggressive local therapy.

Keywords: oligo-recurrence, non-small cell lung cancer, local therapy

EP1.08-07 CORRELATION BETWEEN GENETIC PROFILING AND RESPONSE IN DANISH ALK-POSITIVE NSCLC PATIENTS TREATED WITH CRIZOTINIB

L. Melchior[1], E. Santoni Rugiu[1], J. Sørensen[2], J. Bjerregaard[2], E. Urbanska[2]

[1]*University of Copenhagen, Department of Pathology, Copenhagen/Denmark,* [2]*University of Copenhagen, Oncology Clinic, Copenhagen/Denmark*

Background: In 2011 Crizotinib received FDA approval for the treatment of *ALK*-positive NSCLC. Due to large diversity in clinical course of these patients, baseline genomic profiling at diagnostic biopsy was performed to find possible correlations with clinical features. **Method:** We performed a retrospective analysis of 28 consecutive patients receiving Crizotinib for metastatic, immunohistochemistry (IHC)- and fluorescens in-situ hybridization (FISH)-determined *ALK*-positive NSCLC, between September 2011 and DATE. Clinical data were collected by chart review. DNA/RNA genomic profile were performed using the patients' biopsy at the time of diagnosis or at initiation of therapy using targeted next-generation sequencing (NGS) Oncomine™ Focus (ThermoFisher Scientific) and Archer® Solid Tumor (ArcherDx) assays. Baseline clinical features and genetic information were correlated with overall survival and progression free survival. **Result:** The cohort included 15 women and 13 men, median age 56 (range 22-83). Median PFS was 5.2 months (CI 2.9-9.5), median OS was 17.3 months (CI 8.8-33.2). Favorable prognostic factors for both PFS and OS were PS 0-1 vs 2 (n=25), male gender (n=13), never smoking (n=18) and up-front brain metastasis (n=6). Fourteen patients were treated with Crizotinib as 2nd line therapy and had better OS, but similar PFS. Crizotinib-responders (CR+PR+SD) represented 71% and -no responders (PD) 29%. Most patients received further treatment after progression on Crizotinib (68%). The most common *ALK*-fusion-partner was EML4 (64%; of which 50% were variant v1, 28% v2, 22% v3). For 8 patients (28%) no fusion partner was identified. In 7 cases (25%) the FISH-detected *ALK*-rearrangement was not confirmed by IHC and NGS and 4 of them did not respond, 1 case (4%) was FISH-/IHC-positive but NGS-negative and responded. Four of 8 non-responders (all 4 IHC-negative, 3 NGS-negative) showed another *de novo* gene-alteration (in KRAS, ALK or EGFR). Two patients with another fusion-partner: KIF5B(17)-ALK(20) and TEMP3(6)-ALK(20) had an aggressive clinical course after short-term response. In contrast, a patient with pre-existing *ALK*-mutations F1174L and R1275Q, had the longest duration of treatment with Crizotinib (2.5 years). Patients with EML4 fusion-partner (n=18) were prone to achieve better OS than the others. Rebiopsies at progression for 8 patients showed different TKI-resistance mechanisms. **Conclusion:** *ALK*-positive NSCLC represents a heterogenous disease, which in most cases can be encapsulated by ALK-TKI. Although this small cohort does not allow to draw unambiguous conclusions, it does indicate that the efficacy of treatment may vary with different *ALK*-fusion-partners. Moreover, *ALK*-positive NSCLC should be validated and classified by NGS-testing at baseline to optimize the choice of ALK- TKI.

Keywords: ALK positive NSCLC, DNA-NGS, RNA-NGS

EP1.09 PATHOLOGY

EP1.09-01 SUITABILITY OF QUBIT RNA IQ TO DETERMINE THE RNA QUALITY OF FFPE SAMPLES IN CANCER GENOMIC MEDICINE

M. Souda[1], E. Udo[1], B. Furusato[2], J. Fukuoka[2], M. Masutani[2], H. Ikeda[2], K. Ashizawa[2]

[1]*Nagasaki University Hospital, Nagasaki/Japan,* [2]*Nagasaki University Graduate School of Biomedical Sciences, Nagasaki/Japan*

Background: Nucleic acid evaluation of formalin-fixed, paraffin-embedded (FFPE) samples by next-generation sequencing (NGS) is essential in cancer genomic medicine. In this study, our aim was to examine the suitability of the Thermo Fisher Scientific Qubit RNA IQ Assay to evaluate RNA quality by using pigments selectively binding to large or small RNAs, and rapidly measuring fragment percentages with a fluorophotometer. **Method:** RNA was extracted from FFPE samples (n = 35) prepared in clinical settings. DV200 (low: 30-50%, medium, 50-70%, high: > 70%) and RNA IQ (low-high: 1-10) values, which are recommended as indicators of RNA quality, were determined and the correlation between them was examined. By using NGS analysis to obtain the overall percentage of aligned reads (%) and comparing this to the RNA IQ values (15 samples), the suitability of RNA IQ as a tool for RNA quality evaluation was determined. **Result:** The correlation coefficient (*r*) between DV200 and RNA IQ values was 0.72, indicative of a strong correlation. However, a scatter diagram revealed that 4-7 samples used to determine the RNA IQ values accounted for 11.4% of the DV200 values (< 30%) that were not recommended for use as NGS samples. In the scatter diagram showing the overall percentage of aligned reads (%) and the RNA IQ levels, the correlation coefficient between aligned reads (> 50%) and RNA IQ levels > 4 was 0.54, representing a moderate correlation. However, RNA IQ values > 4 accounted for 33.3% (false-positive rate) of the aligned reads (< 50%). **Conclusion:** NGS analysis demonstrated a high false-positive rate for RNA IQ values. Therefore, further optimization is needed prior to utilizing this method as an indicator of RNA quality for FFPE samples in cancer genomic medicine.

EP1.09-02 EXPRESSION OF INTRATUMORAL GFPT2 IN LUNG ADENOCARCINOMA

Y. Jin, Y. Inoue, H. Shimada, T. Hara, K. Shimaya, Y. Sakakibara, N. Inase, K. Yamanaka, O. Matsubara

Hiratsuka Kyosai Hospital, Hiratsuka Kanagawa/Japan

Background: Cancer cells exhibit abnormal proliferation and require large amounts of nutrients. In cancer tissues, the observed changes in metabolism are associated with an altered metabolic pathway. Moreover, an elevated uptake of glucose has been demonstrated in proliferating cancer cells. Glutamine fructose-6-phospate aminotransferase 2 (GFAT2) - coded by the glutamine-fructose-6-phosphate transaminase 2 (*GFPT2*) gene – is a metabolic enzyme involved in the hexosamine biosynthesis pathway (HBP). In normal cells, the glucose used for the HBP is in small amounts. However, in cancer tissues, the activation of the HBP influences tumor progression. In this study, we investigated the expression of *GFPT2* in the tumor microenvironment of lung adenocarcinoma. **Method:** The expression of*GFPT2* in tumor cells and cancer-associated fibroblasts was examined through immunohistochemistry in 31 patients with surgically resected adenocarcinoma. Histopathological subtype, tumor stage, other clinicopathological conditions, and survival rate were compared with the level of *GFPT2* expression. **Result:** Expression of *GFPT2* in tumor cells and cancer-associated fibroblasts was detected in 87% of patients. In the tumor microenvironment, the expression of *GFPT2* was significantly lower in patients with AIS and MIA versus that observed in patients with invasive adenocarcinoma. Notably, overexpression of *GFPT2* in the tumor microenvironment was associated with a poor-5-year survival rate. **Conclusion:** Activation of the HBP is implicated in the development of lung adenocarcinoma. This result may be helpful in predicting worse prognosis, and the HBP may carry therapeutic potential in this setting.

Keywords: lung adenocarcinoma, GFPT2, hexosamine biosynthesis pathway

EP1.09-03 INTEROBSERVER VARIABILITY STUDY OF PD-L1 IMMUNOSTAINING IN NON-SMALL CELL LUNG CANCER

Y.-D. Choi

Chonnam National University Medical School, Gwangju/Korea, Republic of

Background: Pathologic assessment of programmed cell death ligand 1 (PD-L1) immunohistochemical staining now have been used for treatment of non-small cerll lung cancer in advanced stage. But, due to misinterpretation or unspecified staining pattern, interpretation of PD-L1 staining may be difficult. This study was to investigate interobserver variability between three different pathologists to see if the staining can be safely assessed in practice. **Method:** PD-L1 immunostaining (SP263 and SP142) was performed in representative sections of 70 adenocarcinoma cases and 58 squamous cell carcinoma cases which surgically resected at the chonnam National University Hwasun Hospital, Republic of Korea between 2013 to 2015. Three pathologists individually evaluated the percentage of positive tumor cells, scoring each sample applying cutoff levels used in clinical practice: < 1% positive tumor cells (score 0), 1–4% (score 1), 5–9% (score 2), 10–49% (score 3), and >50% positive tumor cells (score 4). **Result:** Three pathologists were in

agreement in 121 of 128 (94.5%) of scored cases in the SP263 test and 109 of 128 (85.2%) in the SP142 test. In 26 remaining cases, at least two pathologists were in aggrement of scored cases. Weighted kappa value for interobserver variability between pathologists was respectively 0.892 in the SP263 test and 0.837 in the SP142 test. The number of differently classified cases was significantly higher for the ≥1% cutoff value than every other cutoff value. Also, a significantly better agreement between pathologists was seen using ≥50% as cutoff. No statistically significant differences were seen between adenocarcinoma and squamous cell carcinoma. **Conclusion:** Interobserver agreement remains an important challenge, and the ≥1% cutoff value seems to be problematic. But, this may be overcome by training, longer experience and optimization of cutoff value.

Keywords: PDL1, Non-Small Cell Lung Cancer, Interobserver

EP1.09-04 GATA-3 EXPRESSION IS A POOR PROGNOSTIC MARKER IN RESECTED NON-SMALL CELL LUNG CARCINOMA

N. Yanagawa, S. Shiono, M. Endo, K. Suzuki, K. Hayasaka

Yamagata Prefectural Central Hospital, Yamagata/Japan

Background: GATA transcription factors play a wide role in determination of cell differentiation and control of cell proliferation and movement. GATA binding protein-3 (GATA-3) is a member of the GATA family and it plays decisive roles in the differentiation and maintenance of normal luminal cells and the development of Th2 lymphocyte. Decreased GATA-3 expression is associated with poor prognosis in breast cancer. On the other hand, GATA-3 expression correlates with poor prognosis in peripheral T cell lymphoma. However, the correlation of GATA-3 expression with non-small cell lung carcinoma (NSCLC) remains unclear. The aim of this study is to examine the clinicopathological and prognostic value of GATA-3 expression in surgically resected NSCLC. **Method:** A total of 842 NSCLC were examined. The male:female ratio was 515:327; the age range was between 38 and 85 years of age and the mean age was 71 years. Pathological stage's ratio (0:I:II:III) was 37:553:151:101. Adenocarcinoma:Squamous cell carcinoma:Others' ratio was 602:200:40 in histology. Adjuvant chemotherapy was performed in 188 patients. The follow up duration was from 0.4 months to 168.7 months and the mean duration was 61.9 months. Tissue microarray was constructed and GATA-3 expression was analyzed using immunohistochemistry (clone L50-823, F. Hoffmann-La Roche, Ltd., Basel, Switzerland). The GATA-3 staining percentage in tumor cells were classified as follows: (Negative, 0-9%; Positive, 10%≤). The status of GATA-3 staining was correlated with clinicopathological backgrounds, molecular features and patient outcome. **Result:** The status of GATA-3 staining was as follows: Negative, 808 (96%); Positive, 34 (4%). GATA-3 expression status was associated with sex, smoking history, pathological stage, histology, pleural invasion, p53 protein expression, MIB-1 labeling index and *EGFR* mutation. Both overall survival (OS) and recurrent-free survival (RFS) were significantly worse in the patients with positive expression of GATA-3 in comparison with those with negative expression of GATA-3 (5-year OS, 55.7% vs. 74.8%, p=0.006; 5-year RFS, 51.5% vs. 66.8%, p=0.016, respectively). In multivariate analyses adjusting for sex, year, smoking history and pStage, positive expression of GATA-3 was found to be an independent predictive factor of both OS (HR=1.76, 95%CI: 1.02-3.05; p=0.042) and RFS (HR=1.66, 95%CI: 1.01-2.74; p=0.046). **Conclusion:** GATA-3 expression is correlated with poorer prognosis for both OS and RFS in resected NSCLC. Therefore, the evaluation of GATA-3 expression by immunohistochemistry is a potentially useful prognostic marker for postoperative period.

Keywords: GATA-3, NSCLC, prognosis

EP1.09-05 CORRELATION OF ROS1 (D4D6) IMMUNOHISTOCHEMISTRY WITH ROS1 FISH ANALYSIS IN LUNG ADENOCARCINOMA: IS IHC A RELIABLE SCREENING TOOL?

S. Sharma, A. Dewan, L. Kini, M. Bhardwaj, S. Kumar, D. Sharma, B. Yadav, R. Pandey, K. Gogai

CORE Diagnostics, Gurgaon/India

Background: ROS1 gene rearrangement in the lung adenocarcinomas is a one of the targetable non- overalapping genomic alterations (1-3%) besides, EGFR mutation, KRAS mutation, ALK fusion, and many others in patients with non small cell lung carcinomas. Lung adenocarcinoma that exhibit ROS1 gene rearrangement, respond to the targeted inhibitor, crizotinib. Various techniques such as Fluorescent in situ hybridization(FISH), immunohistochemistry(IHC), next generation sequencing and RT Polymerase chain reaction are used to detect ROS1 mutations. We evaluated the correlation between ROS1 IHC and FISH analysis considering FISH as the gold standard method to determine the utility of IHC as a screening method for lung adenocarcinoma. **Method:** Twenty-nine lung adenocarcinoma patients were retrospectively analyzed for ROS1 rearrangement. Each case underwent IHC and FISH analysis. ROS1 IHC was performed using D4D6 antibody clone on Ventana Benchmark platform. A positive and a negative control were run with each case. The analysis was based on H score system that calculates a score from 0 to 300 according to both the intensity of tumor cells (cytoplasmic) staining and the percentage of cells stained. FISH analysis was performed on the tumor area marked on Hematoxylin and Eosin stained slides. Dual colour break apart probe was used and the hybridization pattern was considered positive when > 15% of the tumor cells scored showed a gene rearrangement involving the ROS1 gene. **Result:** Among a total of 29 cases, 17 cases were positive by IHC and FISH analysis (true positive) while seven cases were negative by both the techniques (true negative). Four cases were positive by IHC but were negative on FISH analysis (false positive by IHC) and one case was found to be negative on IHC but positive by FISH analysis (false negative). Subsequently various indicators were calculated as shown in table 1.

Indicator	Value	95% Confidence interval
Sensitivity	94.44%	72.71% to 99.86%
Specificity	63.64%	30.79% to 89.07%
Positive likelihood ratio	2.6	1.18 to 5.72
Negative likelihood ratio	0.09	0.01 to 0.62
Positive predictive value	80.95%	65.86% to 90.35%
Negative predictive value	87.50%	49.74% to 98.02%
Accuracy	82.76%	

Conclusion: 1. ROS1 IHC using antibody D4D6 has high sensitivity but the specificity of detection of ROS1 gene rearrangement is low. 2. All cases that are positive by ROS1 IHC, should be confirmed by FISH testing and this stands as a reliable and economic approach to screen ROS1 positive lung adenocarcinomas.

Keywords: ROS1, immunohistochemistry, FISH, screening

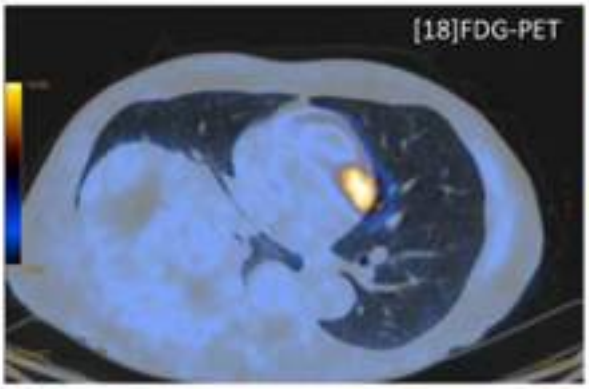
EP1.09-06 AN UNUSUAL DIAGNOSTIC CASE OF HYPOGLYCEMIA: A DIFFERENT PERSPECTIVE OF THE DOEGE-POTTER SYNDROME

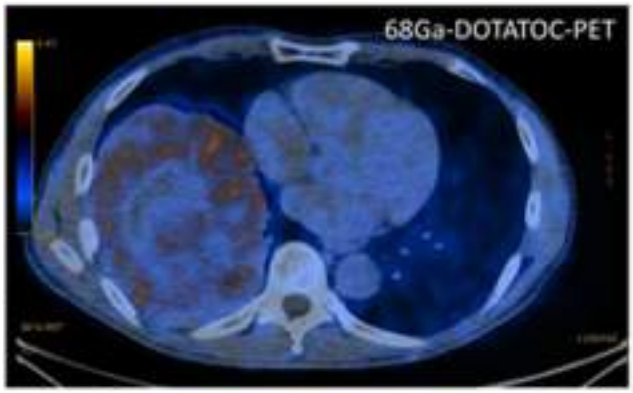
S. Congiu[1], M.T. Migliano[2], D. Giunta[1], G. Dolci[1], A. Gramenzi[2], V. Vicennati[3], M.G. Pirini[4], V. Ambrosini[5], F. Trevisani[2], N. Daddi[1]

[1]*U.O.Chirurgia Toracica - Pad. 23, Bologna/Italy,* [2]*Internal Medicine, Bologna/Italy,* [3]*Endocrinology, Bologna/Italy,* [4]*Pathology, Bologna/Italy,* [5]*Nuclear Medicine, Bologna/Italy*

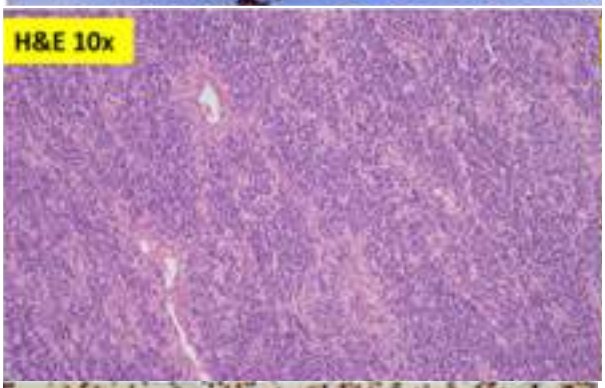
Background: Solitary fibrous tumor (SFT) is an uncommon type of mesenchymal tumor that can occur anywhere in the body. A typical molecular feature is a NAB2-STAT6 fusion, that enhances cellular proliferation. Symptoms are often related to the mass effect exerted by the tumor, but paraneoplastic syndromes can occur. Among them the Doege-Potter syndrome, characterized by refractory hypoglycemia, occurs in <5 % of cases. **Method:** A 60 years-old

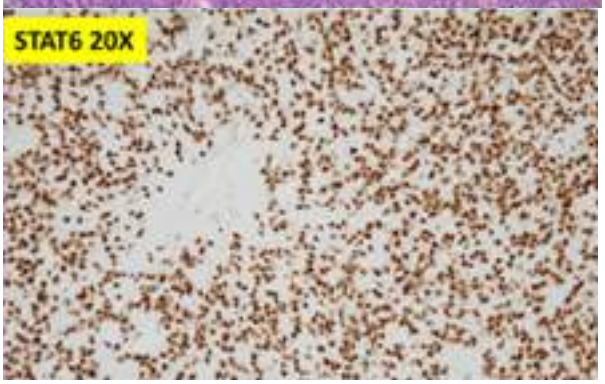
male patient was admitted to the hospital because of a recent severe recurrent hypoglycemia and an episode of syncope during his tennis play. No clinical history of co-morbidities were identified at the time of E.R. admittance. Blood tests were performed and endogen insulin, C-peptide and ACTH levels were below the lower limit, serum cortisol was low-normal. Ca125.5 and NSE were slightly elevated. Total body CT-scan revealed, in the right lung, a large mass (cranio-caudal extension 17 cm) dislocating the adjacent structures. While [18]FDG-PET was almost negative (SUVmax=2.6) the 68Ga-DOTATOC-PET showed faint focal uptake in patchy areas of the tumor (SUVmax=3.6). During diagnostic workup, hypoglycemia was treated with steroid administration.





Result: The patient underwent surgical resection, through a right-sided postero-lateral ribs "bellows" spreading thoracotomy, for a 17x16cm sessile lesion originating from the visceral pleura of the middle lobe of the lung. The tumor cells did not express neuroendocrine(chromogranin), nervous(PS100), but showed CD34+ and STAT6+ cells, with a Ki-67<10%, confirming the diagnosis of SFT. Hypoglycemia resolved after tumor removal, coherently with the Doege-Potter syndrome. At 12 months from surgery the patient is alive with no evidence of disease.





Conclusion: Hypoglycemia can be the single symptom of malignant tumors, frequently seen with insulinomas, but in our case, it was associated with an SFT, a tumor with uncertain biological behaviour. Surgical resection of the tumor is the mainstay of treatment.

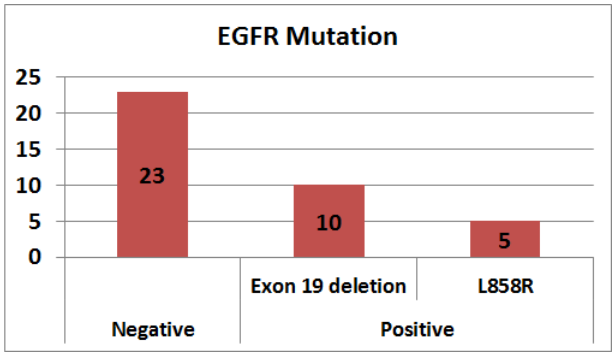
Keywords: Pleura, Doege-Potter syndrome, solitary fibrous tumor

EP1.09-07 DETECTION OF EGFR MUTATION BY AUTOMATED AND RAPID QPCR BASED BIOCARTIS IDYLLA™ SYSTEM IN LUNG CANCER PATIENTS

S. Sharma, L. Kini, R. Katara, S. Pandey, V. Kumar, R. Pal

CORE Diagnostics, Gurgaon/India

Background: Detection of EGFR mutations in subset of Non-small cell lung carcinoma (NSCLC) has significantly changed the therapeutic management strategies in lung cancer. The Biocartis Idylla™ EGFR detection system is used for the qualitative detection of EGFR mutations (exon 18 (G719A/C/S), exon 20 (T790M, S768I), exon 21 (L858R, L861Q) mutations, exon 19 deletions and exon 20 insertions). The system is unique as it covers the entire process from sample to result with an integrated sample preparation, followed by real time PCR amplification and detection of the targeted sequences. We present the data of series of 38 NSCLCs tested on this system with discussion on the advantages and disadvantages of the assay system. **Method:** A series of thirty-eight patients of NSCLC from July 2018 to March 2019 were included in the study. An H and E stained slide was prepared from the Formalin fixed paraffin embedded (FFPE) block to document the tumor content in each case. A cut off of 10-15% tumor content was set. About 10 sections were cut with a thickness of 10 micron. Using a new razor blade, the FFPE tissue sections were scrapped onto wet filter papers. Finally, the cartridges are loaded. The Idylla™ EGFR specific software (EGFR TTP) automatically analyzes the obtained PCR data. The test includes an integrated sample processing controls to verify adequate completion of the sample to the result process. The clinical and demographic data of these cases was analysed. **Result:** The median age of the population was 66 years. Male to female ratio was 1.5:1. Of total 38 cases, 15 were positive for EGFR mutation (39.4%). 10 cases were positive for Exon 19 deletion (66.6%) and 5 cases were positive for L858R mutation (33.3%).



Conclusion: 1. The Idylla™ mutation assay has an edge over conventional EGFR detection system of detecting 51 mutations and indels *versus* 21 mutations and indel. 2. Turn around time of this assay is average of 4 to 5 hours as compared to 12-48 hours of the conventional assay. 3. The system gains appreciation for minimum requirement of high end expertise required for the testing and interpretation of the results, making it valuable to reach to the masses and provide rapid treatment base for lung cancer patients. 4. The disadvantage of this system is the non-availability of extracted DNA for additional testing.

Keywords: Non small cell lung carcinoma, EGFR, IdyllaTM

EP1.09-08 PLASMA CIRCULATING FREE TUMOUR DNA IN ADVANCED LUNG ADENOCARCINOMA: EGFR TKI-NAÏVE

N. Soeroso, H. Taufik, S. Tarigan

Universitas Sumatera Utara, Universitas Sumatera Utara Hospital, Medan, Sumatera Utara/Indonesia

Background: Molecular testing of tumour samples is therefore mandatory in routine clinical practice. Tumour DNA is also present as cell-free molecules in blood, which is therefore a very useful and convenient source of tumour DNA. Circulating tumour DNA (ctDNA) consists of short, double-stranded DNA fragments that are released into the circulation by tumour cell. With the advent of newer molecular platforms, ctDNA can be detected with high sensitivity and specificity in plasma. Aim of this study is to assess diagnostic accuracy of plasma circulating free tumour DNA (ctDNA) in advanced lung adenocarcinoma (EGFR TKI-Naïve) in several hospitals in Medan, Indonesia. **Method:** This was a cross-sectional study whose subjects were patients with adenocarcinoma obtained from histopathology and / or cytology and examined for EGFR mutations from plasma ct-DNA. Data analysis used *chi square test* and *fisher exact test*. **Result:** One hundred data have been collected, with male are 71 (71.0%), and 29 are female (29.0%). Found 20 mutations, single mutations from 19 tissue biopsies, del exon 19 as many as 12 cases (60.0%), deletion mutations in Exon 21 (L858R) 6 cases (30.0%), 1 case Exon L861Q (5.0%) and del Exon 19 and 21 L861Q double mutations 1 case (5.0%). From plasma ctDNA examination EGFR mutations were found 15 cases, del Exon 19:12 cases (80.0%), del Exon 21 (L858R) 3 cases (20.0%). Plasma ctDNA for detection of EGFR mutations has a sensitivity of 45.0%, specificity of 92.5%. It's means, all patients with EGFR (+) mutations, ctDNA managed to detect 45% of cases, while 55% of cases detected mutations (-). Then, all patients detected EGFR (+) mutations based on ctDNA, only 60% of cases have EGFR (+) mutations when examined by tissue will be EGFR (-) mutations. The positive predictive value of ctDNA is 60%. **Conclusion:** Plasma ctDNA can be used to detect EGFR mutations but cannot replace tissue biopsy as the gold standard.

Keywords: EGFR mutation, EGFR TKI-Naïve, lung adenocarcinoma

EP1.09-09 SURGICAL CASES OF PULMONARY PLEOMORPHIC CARCINOMA AT OUR INSTITUTION

H. Masuda[1], H. Arai[1], Y. Mishina[1], S. Nakamura[1], K. Shiino[1], K. Okudela[2], T. Iwasawa[1], M. Tajiri[1], M. Masuda[3]

[1]*Kanagawa Cardiovascular and Respiratory Center, Yokohama/Japan,* [2]*Yokohama City University Graduate School of Medicine, Yokohama/Japan,* [3]*Yokohama City University School of Medicine, Yokohama/Japan*

Background: Pulmonary pleomorphic carcinoma (PC) is rare with an incidence of 0.1% to 0.4% of all lung cancers. Because of its rarity, its exact characteristics are still unknown and standard treatment strategies have not been established. **Method:** The clinical features and prognosis of 19 surgical cases (1.5%) with PC among 1,247 cases of all resected lung carcinoma from August 2007 to September 2018 at Kanagawa Cardiovascular and Respiratory Center were retrospectively analyzed. **Result:** A total of 19 cases, 16 males (84.2 %) and 3 females (15.8 %) with a median age of 71±9.4 (range: 52-83) years was included in the analysis. The median of the brinkman index was 1060±662.8 (0-3000). Coexisting lung diseases included 1 case of chronic obstructive pulmonary disease (COPD) and 5 cases of interstitial pneumonias (IP). Tumors were located in the upper lobes in 10 cases and in the lower lobes in 9 cases. The median size of the tumors was 28 ± 22.9 (10-100) mm in diameter. The surgeries comprised 5 wedge resections, 2 segmentectomies, and 12 lobectomies, including 3 combined wedge resections, 2 combined angioplasties, and 1 double sleeve lobectomy. The epithelial components of PC were 11 adenocarcinomas, 5 squamous cell carcinomas (SQC), and 3 large cell carcinomas. There were 9 cases in stage I (IA1: 3, IA2: 3, IA3: 2, IB: 1), 4 in stage II (IIA: 2, IIB: 2), and 6 in stage III (IIIA: 5, IIIB: 1). All of the cases were followed-up, and the median follow-up period was 1124 ± 1066 (195-3845) days. After 5 years, 11 cases were alive (including 2 relapsed cases) and 8 cases had died (6 died from PC). The overall survival rate was 50.3% at 5 years in all cases. In univariate analysis, PC with both a SQC component and lymph node metastasis had a poor prognosis with a significant difference in the 3-year survival rate (component; SQC vs non SQC: 26.3% vs 73.7%, p=0.024) and in the 5-year survival rate (lymph node metastasis; positive vs negative: 36.8% vs 73.2%, p=0.026). In multivariate analysis, a SQC component (p=0.011) and lymph node metastasis (p=0.016) were independent prognostic factors indicating a poor OS. On the other hand, 8 of the 9 cases with a non SQC component and no lymph node metastasis were still alive. **Conclusion:** We found that PC generally had a poor prognosis even in surgical cases. A SQC component and lymph node metastasis were prognostic factors indicating a poor overall survival.

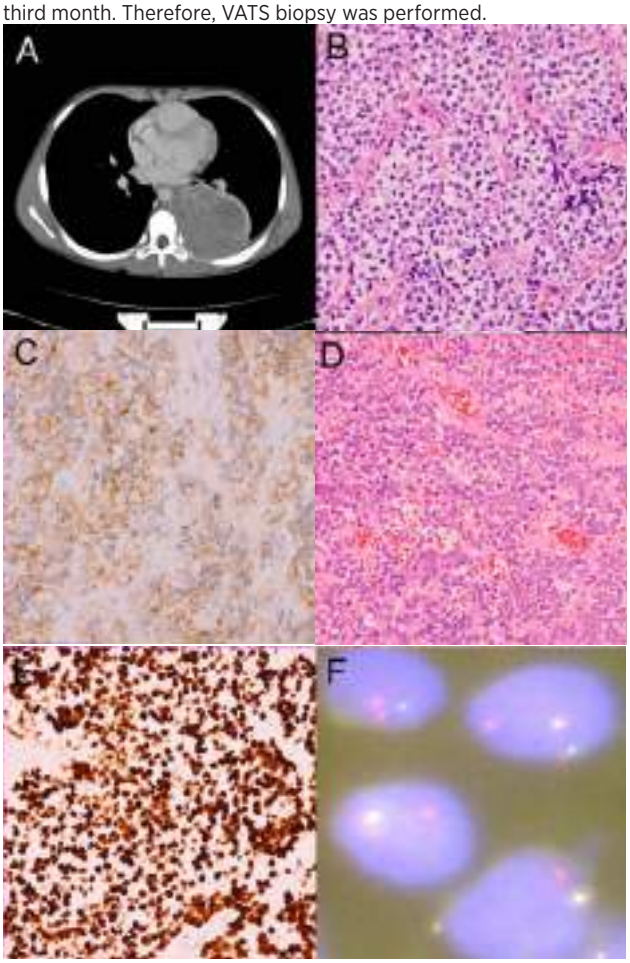
Keywords: pulmonary pleomorphic carcinoma, epithelial component, Lymph node metastasis

EP1.09-10 A DIAGNOSTIC PITFALL IN POSTERIOR MEDIASTINAL TUMOR: EXPRESSION OF CD117 IN ATYPICAL EWING SARCOMA MASQUERADING AS CLASSIC SEMINOMA

Y.-L. Huang, Y.-L. Chang, C.-T. Wu

National Taiwan University Hospital, Taipei/Taiwan

Background: Ewing sarcoma is a rare malignancy and occurs most commonly in metaphyseal-diaphyseal portion of long bones in children or young adults. Atypical Ewing sarcoma refers to unusual alterations at cell morphology and immunoprofile associated with atypical clinical presentation mimicking carcinomas, lymphomas, or other sarcomas, but still harbors *EWSR1* rearrangement. We recently encountered a case of atypical Ewing sarcoma involving the posterior mediastinum, which was initially misdiagnosed as seminoma based in part on CD117 expression by immunohistochemistry. **Method:** This 11-year-old boy without any systemic disease has been suffered from intermittent chest pain for months. CT scan showed a huge left thoracic tumor (7 cm, Fig 1A), centralized in the posterior-medial portion of mediastinum with adjacent rib destruction. The radiological findings were compatible with malignant neurogenic tumor or germ cell tumor. Microscopically, it showed tumor cell nests with oval nuclei, conspicuous nucleoli and abundant clear cytoplasm (Fig 1B). Immunohistochemically, the tumor cells revealed strong positivity for CD117 (Fig 1C). Based on the above findings, seminoma was diagnosed. A carboplatin-based regimen for malignant germ cell tumor, JEB (carboplatin, etoposide and bleomycin), was given and he finished two cycles. The tumor had initially decreased in size (4.5 cm) for the first two months but progressed again (7 cm) in the third month. Therefore, VATS biopsy was performed.



Result: Microscopically, it showed compact tumor cells in sheets, lobules or focal cord-like pattern with frequent necrosis, similar to the tumor cells seen in previous biopsy regarding both growth pattern and cell morphology. However, it also contained cells with high N/C ratio, finely dispersed chromatin (Fig 1D) and brisk mitotic activity (up to 24 mitoses per 10 HPFs) which were different from the cells of classic seminoma and prompted the consideration of atypical Ewing sarcoma and other small blue round tumors. After thorough immunohistochemical study, the tumor cells were positive for CD99 and NXK2.2 (Fig 1E), but also focally positive CD117. Fluorescent in situ hybridization demonstrated unbalanced *EWSR1* rearrangement (Fig 1F), confirming the diagnosis of atypical Ewing sarcoma. **Conclusion:** Atypical Ewing sarcoma could be present as a huge mediastinal mass with only partial rib destruction as well as strong CD117 expression, giving a false impression of primary mediastinal tumor and misdiagnosed as seminoma. Pathologists should always keep in mind this rare but lethal disease in the differential diagnosis. IHC of CD99 and NKX2.2 or even molecular test for *EWSR1* rearrangement would help pathologists make the right diagnosis.

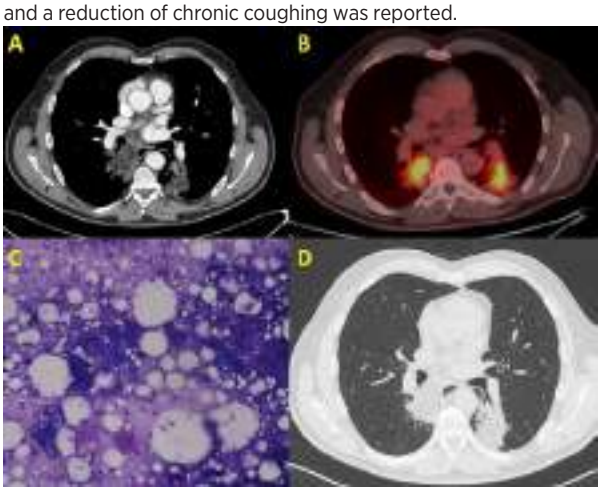
Keywords: Seminoma, EWSR1 Rearrangement, Atypical Ewing sarcoma

EP1.09-11 LIPOID PNEUMONIA RESEMBLING BILATERAL LUNG CANCER: BE AWARE OF NASAL DECONGESTANTS!

C. Braggio[1], G. Bocchialini[1], L. Ventura[1], P. Carbognani[1], M. Tiseo[1], L. Gnetti[2], M. Rusca[1], L. Ampollini[1]

[1]*University Hospital of Parma, Parma/Italy,* [2]*University Hospital of Parma, PARMA/Italy*

Background: To describe a case of bilateral exogenous lipoid pneumonia mimicking lung cancer in a patient affected by obstructive sleep apnea syndrome treated with decongestants mineral oils. **Method:** A 57 year-old male patient was referred to our surgical department for an incidental finding of a bilateral pulmonary mass during a chest X-ray made for chronic coughing. His past medical history was unremarkable; he was an everyday smoker with a 80pack/years and he was affected by obstructive sleep apnea syndrome. A chest CT and CT/PET scans was subsequently done and revealed the presence of a both pulmonary consolidations of the lower lobes bilaterally with increase in uptake of FDG (Fig. 1A-B): mediastinal lymph node was normal, no other lesions was found. Morphology of the lesions was strongly suspect for non small cells lung cancer, so the patient underwent a CT-guided lung biopsy. **Result:** A percutaneous CT-guided lung biopsy was done in the right lower lobe. The histological examination was consistent with pulmonary adenocarcinoma with signet-ring cell features (Fig.1C): therefore, the patient was addressed to conventional chemotherapy. At that point, a multidisciplinary discussion was done: a careful revision of the chest CT-scan was carried out and focal areas of fat attenuation within the lung consolidations were observed. According to that finding, a diagnosis of lipoid pneumonia was hypothesized. A more careful questioning about patient's medical history revealed the use of daily nasal decongestants during the last 4 years due to chronic rhinitis secondary to OSAS: the drug was composed of mineral oils. A further blind revision of the histological tissue samples was requested and confirmed the diagnosis of exogenous lipoid pneumonia. The patient was invited to discontinue the nasal oil decongestant. No other pharmacological treatment was started. Six months later, a chest CT-scan was performed but no significant changing of the pulmonary consolidations were observed (Fig. 1D). Currently, the patient is well and a reduction of chronic coughing was reported.



Conclusion: Exogenous lipoid pneumonia is a rare condition that might be misdiagnosed with lung cancer; for this reason it should be considered in the differential diagnosis of pulmonary consolidations, especially when occurring bilaterally. A precise medical history could be resolutive.

EP1.09-12 LUNG CANCER IN KENYA: QUANTIFICATION OF THE PROBLEM

F. Asirwa[1], A. Kalebi[2], H. Kibet[1]

[1]*Ampath_ICI Kenya, ELDORET/Kenya,* [2]*Lancet, Nairobi/Kenya*

Background: Objective As part of MLCCP to establish a baseline of lung cancers in Kenya. **Method:** s Setting I: A Retrospective review of lung cancer diagnosis at Eldoret Cancer registry 1995-2017; 310 analyzed. Setting II: All those with lung masses at radiology unit from 2014- 2018 ;78 lung masses noted. Setting III: Data from a large private laboratory group- 514 cases that were biopsied, 279 malignant vs 235 others. **Result:** s Setting I: 310 lung malignancies. Primary lung 102 (32.9%). M: F was 1:1. Mean age, and range in years was 60.3±1.2 and 29-98. NSCLC 81.4% and SCLC 18.6%. Adenoca 62.7%, SCC 21.7%, large cell carcinoma 6.0%. Staging on 18 patients, 14 had stage IV disease. Age 55-74 accounted for 61.7% Setting II: From Rad unit Biopsies done mainly by CT-guidance (31/73), Ultrasound guidance (20/73), bronchoscopy (19/73) and Thoracotomy (3/73). Of 78 cases, 50 (64.1%) were malignancies. Lung cancer had 34 of the 50. Mean age 57.1 range 32-84 yrs with median 61. Males were 21 (67.8%) and females were 13 (38.2 %) NSCLC was 83.4% and SCLC was 17.6%. Adenoca accounted for 82.14% of NSCLC. Clinical data was available on 10 of the 34 cancer patients and indicated Stage IV in 80% of them. Setting III: Of the 279 malignant cases from the private lab facility, Primary lung cancer had 209 patients (74.9%). Other metastatic cancers;Metastatic carcinoma 4.7%, CUP 4.3%, Neuroendocrine 3.6%, Carcinoid tumor 1.8%, sarcoma, spindle cell tumor, lymphoma and others. M:F 116 (55.5%) vs 86 (41.2%). 61 av. age at diagnosis, range 23-94 yrs. NSCLC was 91.8% of all cases, SCLC was 8.2%. In NSCLC, Adenocarcinoma 129 (61.7%), SCC 20% and others 20% Others-TB, Pna, Aspergillosis, Benign tumors, Fibrosis, Bronchiolitis Obliterans etc. **Conclusion:** High index of suspicion, education and training is needed to improve diagnostics in Lung cancer in Kenya. Bio-banking of tissue and more research i.e Evaluation of mutations; EGFR, ALK, ROS1, MET, BRAF, HER2, PDL1, MAPK, PI3K signaling pathways may be useful to define mechanisms of drug sensitivity and potential molecular targets in our setting. There is a need to fully characterize, optimally treat and measure outcomes of lung cancer in Kenya. *MLCCP is a Multi-National Lung Cancer Control Program with Dr. Asirwa the overall PI for Kenya, Tanzania, Swaziland and South Africa. Funding for the program has been provided by Bristol Myers Squib Foundation (BMSF) *MLCCP Team is the Team for this Kenya Program Component

EP1.09-13 CLINIC-PATHOLOGICAL AND MOLECULAR FEATURES OF PD-L1 ANALYSES IN ADVANCED NSCLC: A REAL LIFE SINGLE CENTER EXPERIENCE

F. Tabbò, L. Righi, G. Rota, S. Cappia, A. Rigutto, S. Izzo, S. Novello, M. Volante

University of Torino, Orbassano/Italy

Background: Programmed death ligand 1 (PD-L1) immunohistochemistry (IHC) is the most rapid, less expensive and routinely applied predictive assay for treatment with immune checkpoint inhibitors (ICI) in advanced non small cell lung cancer (NSCLC). We analyzed a real-life single center activity of PD-L1 characterization together with pathological features, molecular status determination and patients' clinical response to ICI. **Method:** From January 2017 to July 2018 all advanced NSCLC tumor tissue analyzed for PD-L1 expression and molecular status determination in the Pathology Unit of San Luigi Hospital, Orbassano (Turin) were selected. PD-L1 analysis was performed using 22C3 PharmDX on Dako Autostainer, while ALK rearrangement was assessed by FISH and EGFR mutations by direct pyrosequencing. Furthermore in a majority of cases (60%) a 22-gene panel was evaluated by Ion Torrent PGM™ Next Generation Sequencing (NGS). The PD-L1 IHC assay results were analyzed with cut-off values of >50% (strong positive), 1-49% (weak positive), and <1% (negative). Clinical data of response to ICI were acquired for 65 patients. **Result:** 510/532 (96%) cases were adequate for PD-L1 determination and molecular analyses; 169 (33%) were histological, 269 (53%) core biopsies and 72 (14%) cytological samples; 375 (74%) were from primitive lesion, while 135 (26%) were from metastatic sites. Of the 22 inadequate samples for PD-L1 analysis half of them were cytological specimens. PD-L1 was strong positive in 91 (18%) cases, weak positive in 137 (27%) cases and negative in 285 (56%) cases. Specimens with higher expression (>50%) derived preferentially from histological samples (e.g. surgical specimens) and from external hospitals referred to our Central Hub. EGFR and ALK positive cases were more frequently PD-L1 negative or weak positive (13% and 2%, respectively), although not reaching statistical significance. Instead, KRAS and TP53 mutated cases were significantly associated with negative or weak positive PD-L1 expression (14% and 22%, chi-square p=0.0006 and p=0.01, respectively). Among the 65 patients with clinical data of response to ICI, 37/65 (57%) were responders (partial response + stable disease) while 28/65 (43%) had progressive disease. No significant differences in terms of clinic-pathological or molecular features were found between these two groups, maybe due to the limited number of cases. **Conclusion:** Our analyses suggest that integration of PD-L1 testing in the pathological and molecular characterization of advanced NSCLC is feasible with a very high adequacy, enabling a wide ICI administration to these patients.

Keywords: Adequacy, molecular analyses, PD-L1

EP1.09-14 BEST PRACTICE SESSION ON LUNG CANCER MOLECULAR DIAGNOSTICS IN THE NETHERLANDS TO ENHANCE TESTING PROPORTIONS NATIONWIDE

C. Kuijpers[1,2], M. Van Den Heuvel[3], A. Van Lindert[2], R. Damhuis[4], S. Willems[1,2]

[1]*Foundation PALGA, Houten/Netherlands,* [2]*University Medical Centre Utrecht, Utrecht/Netherlands,* [3]*Radboudumc, Nijmegen/Netherlands,* [4]*Netherlands Comprehensive Cancer Organisation (IKNL), Utrecht/Netherlands*

Background: Adequate and timely testing for genetic alterations in lung cancer is necessary to consider targeted therapy. Previously, we demonstrated that in the Netherlands molecular testing was suboptimal in 2015, as 25% (EGFR and/or KRAS and ALK) to 50% (ROS1) of patients were not tested according to the guidelines, and notable variation between laboratories was present. Results were fed back to individual laboratories. In a best practice session, we aimed to identify a process for best possible flow and highest possible testing proportions. **Method:** We invited pathologists, molecular biologists, pulmonologists, and technicians from six laboratories/hospitals with highest testing proportions to join a best practice session. Ultimately, four laboratories, two academic and two non-academic, joined. Following a questionnaire, we discussed their work flow and why they think their laboratory/hospital performs well. **Result:** We identified several stimulatory factors for molecular testing: 1. discuss all metastatic lung cancer patients at multidisciplinary meetings; 2. dedicated/specialized professionals; 3. short communication lines and clear agreements; 4. work culture of critical openness and honesty; 5. awareness and feedback on performance; 6. comprehensive request by the pulmonologist of all genes to be tested; 7. to obtain sufficient tumor tissue: a. perform CT-scan earlier in process, making it possible to collect larger biopsies in case a metastasis is detected, and b. embed cytological material. Costs, without reimbursement, were seen as a prohibitive factor. **Conclusion:** Several elementary steps (such as good communication) to improve adequate molecular testing were revealed. Initiatives will be taken to implement the outcomes nationwide, by starting a dialogue with health care professionals at a regional level.

EP1.09-15 UNUSUAL MALIGNANCIES OF LUNG-EXPERIENCE FROM A TERTIARY CARE CENTRE OF EASTERN INDIA

S. Mishra, S. Das Majumdar, M. Kar, S. Patra, D. Parida

All India Institute of Medical Sciences, Bhubaneswar/India

Background: Carcinoma lung accounts for 12.3% of all malignancies globally and is the leading cause of deaths due to malignancies.Pathologically,among various types of lung carcinomas;adenocarcinoma,squamous cell carcinoma,small cell and large cell carcinoma are the common varieties encountered.However there are certain uncommon variants of malignancies arising in lung which require distinct diagnostic and management approach and hence pose a challenge to the oncologist.Hereby we present our experience with some of these unusual pathologic variants of lung malignancies with relevant literature review. **Method:** A retrospective

analysis was done from the hospital records of patients visiting at a tertiary cancer hospital of eastern India between June 2013 to December 2018. All patients with biopsy or cell block proven diagnosis of lung malignancies were included in the study. Common pathological types of lung carcinoma such as adenocarcinoma,squamous cell carcinoma and small cell carcinoma were excluded from the study. **Result:** Among a total of 216 lung malignancies presented during this time period, six patients presented with unusual pathological variants such as: synovial sarcoma,lymphoma(diffuse large B cell lymphoma),neuroendocrine carcinoma,mucoepidermoid carcinoma,basaloid squamous cell carcinoma and adenosquamous carcinoma(one case from each pathological type). All six patients in the study were male with age range 31-74 years(median-49 years). Out of these six cases,laterality was evenly distributed i.e three cases had malignancies on left lung whereas in other three cases right lung was involved. Three patients had distant metastasis during presentation(synovial sarcoma, adenosquamous carcinoma and DLBCL) whereas other three patients were nonmetastatic at presentation. The presentation,histopathological diagnosis and immunohistochemistry,treatment received and followup of the patients are briefly summerised in the table. Among these six patients,one has died(adenosquamous carcinoma),one has lost followup and four patients are on followup (range-2-24 months).

Conclusion: Unusual malignancies of lung pose a diagnostic and therapeutic challenge to the oncologist in clinical practise owing to paucity of relevant data and insufficient studies. However they are treated according to the specific histopathologic subtype and stage of presentation. More studies are needed to be conducted regarding this subgroup of malignancies and their management

EP1.09-16 A CASE OF PULMONARY PRIMARY ENTERIC ADENOCARCINOMA DIAGNOSED PREOPERATIVELY

T. Tachibana[1], T. Omori[1], O. Uchida[1], H. Takahashi[1], N. Ikeda[2]

[1]*Tokyo Medical University Hachioji Medical Center, Tokyo/Japan,* [2]*Tokyo Medical University, Tokyo/Japan*

Background: Pulmonary primary enteric adenocarcinoma(PEA) is a extremely rare subtype of lung cancer, which is defined in the new edition of 2015 WHO classification. Its histopathological and immunohistochemical feature is close to colorectal carcinoma, and it is important to distinguish between PEA and metastasis from colorectal carcinoma. In the paper, we present a case of PEA diagnosed before surgery. **Method:** Case report **Result:** A 72-year-old male was attending our hospital for rheumatoid arthritis, Thirty eight mm nodule in diameter was pointed out at the right S^9 lung area by follow-up CT of interstitial pneumonia. The patient was refered to our department and TBLB was performed. Histopathological examination revealed that the tumor formes ducts composed of tall columnar cells. Immunohistochemical stains demonstrated positive for CK20, Cdx-2 and negative for CK7, TTF-1 and NapsinA. These findings were suggested metastatic colorectal carcinoma of the lung. However, additional clinical examinations, including FDG-PET/CT, gastroscopy and colonoscopy, did not reveal any existance of tumor elsewhere. The CEA level was 20 ng/ml. The patient was given a diagnosis of primary lung cancer, Pulmonary primary enteric adenocarcinoma staged as cT2aN0M0 stageIB was considered and right lower lobectomy with systemic lymph node dissection was performed. Final histopathological findings of the tumor was same as colorectal carcinoma. Immunohistochemical examinations were also the same as TBLB specimens. The final diagnosis was PEA and the staged as pT2aN0M0 stageIB. **Conclusion:** PEA is difficult to confirm histopathologically or immunohistologically, and it is necessary to deny the existence of gastro intestinal carcinoma. At present, treatment of PEA should be conducted as primary lung cancer, including operation. It is thought that the biologic and clinical feature of PEA becomes crear by accumulation of more cases.

Keywords: Pulmonary primary enteric adenocarcinoma, histopathologically, immunohistologically

EP1.09-17 SPANISH LUNG CANCER BIOMARKER TESTING REGISTRY (LUNGPATH): DESCRIPTIVE ANALYSIS FOCUS IN ALK TRASLOCATION RESULTS

J. Martin Lopez[1], L. Aduz Alexandre[2], S. Gatius Caldero[3], A. Navarro Gonzales[4], P. Saiz Lopez[5], C. Gomez Bellvert[6], C. Camacho García[7], L. Melgar[8], E. Costa Navarro[9], I. Abdulkader Nallib[10], C.A. Vasquez Dongo[11], M. Saiz Camin[12], A. Yagüe Hernando[13], L. Atienza Cuevas[14], L. Pijuan[15], T. Hernández Iglesias[16], A. Martinez Pozo[16], C. Salas Anton[1]

[1]*Hospital Universitario Puerta de Hierro, Madrid/Spain,* [2]*Fundacion Jimenez Diaz, Madrid/Spain,* [3]*Hospital Arnau de Vilanova, Lleida/Spain,* [4]*Hospital General Universitario de Valencia, Valencia/Spain,* [5]*Hospital Universitario de Burgos, Burgos/Spain,* [6]*Hospital Son Espases, Palma/Spain,* [7]*Complejo Hospitalario Insular Materno-Infantil, Gran Canaria/Spain,* [8]*Hospital Nuestra Señora de la Candelaria, Santa Cruz de Tenerife/Spain,* [9]*Hospital Universitario de Alicante, Alicante/Spain,* [10]*Hospital Clínico Universitario de Santiago de Compostela, Santiago de Compostela/Spain,* [11]*Hospital Universitari Josep Trueta, Girona/Spain,* [12]*Hospital Universitario de Cruces, Barakaldo/Spain,* [13]*Hospital San Pedro, Logroño/Spain,* [14]*Hospital del Mar, Cádiz/Spain,* [15]*Parc de Salut Mar, Barcelona/Spain,* [16]*SEAP, Madrid/Spain*

Background: Oncogenic ALK gene rearrangements are found in approximately 4% of non-small cell lung cancer (NSCLC). Treatment options such as ALK tyrosine kinase inhibitors lead to improved progression free survival and overall survival. Thus, biomarker testing on pathology specimens is an essential requirement to properly treat lung cancer (LC) patients. *LungPath* is an on-line tool developed by the Spanish Society of Pathology (*SEAP*) with free and voluntary participation of differents Departments of Pathology to registry, monitor and trace biomarker results in clinical practice. After initial data reclutation step, first objective is to realize a descriptive analysis of *LungPath* focusing on ALK traslocation testing. **Method:** Descriptive analysis of the *LungPath* registry. Biomarkers determinations of LC patients were collected from March 2018 to January 2019, from 38 Spanish Departments of Pathology. **Result:** Based on this real clinical practice database, 19.332 biomarkers were tested over a total of 4.773 samples from LC patients. Small lung biopsies (60%), surgical resection specimen (16,3%) and cell block cytology (10,7%) were the mainly used samples in addition to fine needle aspiration cytology (5,1%), blood (2,5%) and other non lung biopsies (5,4%). NSCLC accounts for 95,1% of cases, principally adenocarcinoma (66%), squamous cell carcinoma (SCC) (19%), NOS (not otherwise specified, 6,1%), large cell neuroendocrine carcinoma (3,7%) and large cell carcinoma accounting for 0,3%. In non-squamous samples, ALK traslocation was one of the most frequently analyzed biomarker (80,1%), on the other hand, in SCC, ALK traslocation was shortly analyzed (53,1%), being PD-L1 expression the main biomarker realized (73,6%). From the adenocarcinoma samples were ALK was tested the positivity rate was 3,4%, whereas, 2,4% were not valit determinations due to several reasons. Used techniques plus further information has also been analyzed. **Conclusion:** Development of central biomarker databases, such as Lungpath, provide an opportunity to registry clinical practice data and in the future could be an useful tool to monitor, correlate results between different centers and improve the available knowledge regarding biomarkers in LC. According the international guidelines, EGFR mutation and ALK traslocation should be tested in all advanced NSCLC overall in lung adenocarcinoma. ALK traslocation was one of the main biomarkers tested in our database with 3,4% traslocation rate, similar with the literature reports.

Keywords: ALK, Targeted therapy, Biomarker

EP1.09-18 COMPARISON OF SAMPLE TYPES WITH SUCCESS RATES OF NEXT-GENERATION SEQUENCING

K. Yamane, T. Sakamoto, Y. Terutya, M. Yanai, N. Kinosita, K. Yamaguchi, H. Makino, M. Kodani, T. Igishi, A. Yamasaki

Tottori University Hospital, Yonago/Japan

Background: Precision medicine based on driver oncogenes is now developed for non-small cell lung cancer.Recent approval of next-generation sequencing(NGS)-based companion diagnosics has increased the need for use of high-quality specimens for diagnosis. **Method:** From December 2013 to May 2018,88 patients who were enrolled in a nation-wide genome screening, LC-SCRUM-Japan,from our institution were examined for the success rates of genetic analysis according to sample types. NGS analysis, NGS Ion Seq™,Oncomine Comprehensive Assay™,was performed using DNA and RNA extracted from lung cancer specimens. **Result:** The success rates of DNA and RNA analyses were 100% (88/88 cases) and 80% (70/88), respectively. Of the 88 samples analyzed, 85 (97%) were tissues and three (3%) were pleural effusions. The success rates of RNA analysis in the 85 tissue samples were 49/64 (77%) in bronchoscopic byopsy, 11/11(100%) in operation, 5/6(83%) in Percutaneous biopsy and 3/4(75%) in others. Of the 64 bronchoscopic samples, the success rates were 74% (20/27) in EBUS-TBNA, 90% (9/10) in EBUS-GS (large diameter), 69% (11/16) in EBUS-GS (small diameter) and 82% (9/11) in direct vision biopsy. In the 88 cases analyzed, a total of 55 actionable gene alterations (20 KRAS mut, 7 MET amp/mut, 6 EGFR mut, 5 RET fus, 5 ALK fus, 4 PIK3CA mut, 2 ERBB2 mut, 2 ROS1 fus, 2 FGFR1 amp, 1 BRAF mut, 1 FGFR3 fus) were detected in 50 cases (57%). Twelve of the 50 (14%) were registered in ongoing clinical trials of targeted drugs. **Conclusion:** All the samples were available for DNA analysis of the NGS. The success rates of RNA analysis were lower in samples obtained from EBUS-TBNA and EBUS-GS (small diameter), suggesting that the success rates depend on the sample size.

Keywords: NSCLC, Next-generation sequencing, sample size

EP1.09-19 MOLECULAR TESTING IN BRONCHIAL ADANOCARCINOMAS: RETROSPECTIVE ANALYSIS OF PARARFFINE BLOCKS ABOUT 100 PATIENTS IN EASTERN MOROCCO

I. Alloubi[1], S. Afqir[2], H. El Attar[3]

[1]*CHU Med VI, OUJDA/Morocco,* [2]*CHU Oujda, OUJDA/Morocco,* [3]*Annasr Pathology Center, CASABLANCA/Morocco*

Background: The search for mutations in lung cancer has become a standard in the current management of this pathology; even more immunotherapy takes up more space in the therapeutic arsenal against this disease; in our department of thoracic surgery we became aware of this evolution; in this work which follows the creation of the electronic registry of lung cancer in our region which was also retained in the work presented at the IASLC summit in Tangier, Africa **Method:** This is a retrospective study of 100 patients treated between 2009 and 2017 in our center; only four patients benefited from this research (only EGFR mutation) in this period; the authors retrospectively screened all others patients who were diagnosed with stage IIIA through IV adenocarcinoma. We repredited the carefully preserved paraphine blocks. we present through this study the epidemiological profile of EGFR mutations; ALK; KRAS; as well as looking for PD-1 and PD-L1 checkpoints. The goal is to know the rate of these mutations in a region with a high incidence of 90% metastatic lung cancer. **Result:** Molecular testing was possible in 94.9% of the parrafine blocks obtained by excisional biopsy. Our results are being developed; preliminary observations shows the PD-L1 high expression rate was not associated with EGFR, ALK or KRAS molecular alterations. Higher stage (IV) was associated with higher PD-L1. The various proportional cut-offs used to interpret the results can be summarized in this study, which can be reproducibly assessed. **Conclusion:** To our knowledge this is the first epidemiological study of genetic mutations of lung cancer; with a significant number of patients in a region of high incidence of this metastatic disease; our results will make it possible to change the management towards targeted therapeutics and immunotherapy.

EP1.09-20 SOMATIC VARIANTS INTERPRETATION AND CLASSIFICATION IN LUNG ADENOCARCINOMA PATIENTS FROM A TARGETED GENE PANEL IN A MOLECULAR DIAGNOSTIC SETTING

I. Arora, P. Viola

Pathology, Imperial College Healthcare NHS Trust, London/GB

Background: The key driver mutations of lung adenocarcinoma are well described, and several targeted therapies have been developed. Personalized medicine with the availability of rapid and actionable clinical NGS-based genomic profiling has become a reality. But, as the molecular data continue to expand, we face a challenge to reliably estimate the pathogenicity of the identified variants. Thus, the aim of the present study is to interpret and classify somatic variants generated from next-generation sequencing of lung adenocarcinoma patients' samples in routine molecular diagnostic laboratory. **Method:** Variant call format files generated from next-generation sequencing of 150 lung adenocarcinoma patients'

samples, using Ion torrent hotspot panel of 50 oncogenes covering 207 amplicons, during a three year period (2014-2017) at Department of Molecular Pathology, Hammersmith Hospital, Imperial College Healthcare NHS Trust, were retreived from the database. The variant classification and interpretation was done by an in-house generated bioinformatics pipeline based on the clinical and biological relevance of variants, levels of evidence available in the literature and *in-silico* pathogenicity prediction tools score. **Result:** A total of 125 VCF files were available from the 150 lung adenocarcinoma patients' samples. Variant annotation of the these files for the 50 cancer panel genes resulted in altogether 26,9180 variants. Application of variant filtering parameters to all the variants resulted in 117 unique variants. We classified these 117 variants into 3 categories: variants of strong clinical significance in lung cancer (55, 47%), varaints of potential clinical significance (19, 16%) and variants of unknown significance (43, 36.7%) which were further categorized into possible pathogenic (37) and unlikely pathogenic (6) based on their *in-silico* predicted pathogenicity scores and their effect on protein function. **Conclusion:** By using this classification system, we could classify 47% of variants as of strong clinical evidence and 16% variants of potential clinical significance in our cohort of lung adenocarcinoma cases. The VUS were further characterized into possibly pathogenic (31.6%) and unlikely pathogenic (5%), thus providing a structure and value to the interface between the oncogenic variants and non-oncogenic variants.The classification system proposed in the study is simple, robust and can be applied to a range of cancer panels in a clinical laboratory and will help in reducing the turn-around time to analyse and report variants. The variants identified in the study can be used to build an in-house database of VUS and the potential clinical significance of these variants could be assessed by correlating with patients' histopathological and clinical data.

Keywords: somatic variants, lung adenocarcinoma, Next-generation sequencing

EP1.09-21 SARCOMATOID CARCINOMA OF THE LUNG. ANALYSIS OF THE TUMOR IMMUNE-MICROENVIRONMENT AND SURVIVAL OF A CASE SERIES

A. Koumarianou[1], A. Liakea[2], E. Tsagari[3], E. Kefalidi[3], J. Duran[1], T. Raptakis[3], P. Foukas[2], P. Tomos[3]

[1]*Attikon University General Hospital, Athens/Greece,* [2]*Laiko University Hospital, Athens/Greece,* [3]*Attikon University Hospital, Athens/Greece*

Background: Sarcomatoid carcinoma is a poorly differentiated non-small-cell lung carcinoma that comprises 3 subtypes i)the pleomorphic including different components such as squamous cell carcinoma, adenocarcinoma, or undifferentiated non-small-cell carcinoma and at least 10% spindle and/or giant cells; ii)the spindle cell consisting only of spindle cells and iii)the giant cell. The study aimed to assess the presence of immune cells in tumoral environment and the survival of patients (pt) with these tumors **Method:** Formalin-fixed paraffin-embedded tissues of pt treated with surgery for sarcomatoid carcinoma from 2009-2014 were retrieved and centrally revised and restaged. PAS diastase staining and immunohistochemistry with CK7, p63 and vimentin were performed to identify epithelial and mesenchymal components. The presence of tertiary lymphoid structures, plasma cells and necrosis were assessed. Clinical data were collected from patients' files regarding adjuvant treatment (chemotherapy, radiotherapy) and survival. Institutional Review Board, Ethical Approval and patient's signed informed consent were obtained. **Result:** Ten pt of median age 74 (59-80) years, were treated with pneumonectomy (1 pt) upper (4pt) or lower (5pt) lobectomy for pleomorphic (8pt) or giant cell (2pt) sarcomatoid carcinoma. Squamous or adenocarcinoma components were each present in 4 pt. Visceral pleural involvement was present in 5pt and parietal in 1 pt. TNM staging and the composition of tumor microenvironment are shown in Table 1. Tumor spread through airspace was present in 3 pt and lymphovascular invasion in 5 pt. At the time of the analysis, only 2 pt were alive, the median time to recurrence was 11.5 months and the median survival was 1.8 years

Patient number	Staging WHO 8TH Edition	Plasma Cells	Tertiary Lymphoid Structures	Pattern of Necrosis
1	pT3N0 (IIB)	Absent	Focal Aggregates	Diffuse
2	pT4N1 (IIIA)	Small	Primary Follicles	Focal
3	pT2N1 (IIB)	Absent	Focal Aggregates	Diffuse
4	pT2N0 (IIA)	Small	Primary Follicles	Diffuse
5	pT2aN2 (IIIA)	Absent	Focal Aggregates	Focal
6	pT1cN0 (IA3)	Small	Focal Aggregates	Diffuse
7	pT2aN2 (IIIA)	Absent	Primary Follicles	Focal
8	pT1cN0 (IA3)	Absent	Focal Aggregates	Diffuse
9	pT1cN0 (IA3)	Intermediate	Primary Follicles	Diffuse
10	pT4N0 (IIIA)	Absent	Focal Aggregates	Diffuse

Conclusion: Sarcomatoid carcinoma represents a rare disease with an aggressive clinical course and a poor prognosis even in stage IA3 treated with combination therapies. The exact mechanisms whereby the formation of tertiary lymphoid structures occurs and their function remain elusive. Studying these changes could reveal new ways for modulating immune responses to prolong the survival of these pt.

EP1.10 PREVENTION AND TOBACCO CONTROL

EP1.10-01 SOCIODEMOGRAPHIC CHARACTERISTICS AND PERCEPTIONS OF TOBACCO WORK AND HAZARDS IN A RURAL COMMUNITY OF NIGERIA

U. Ofonakara[1], O. Ekesi[2], T. Kotey[3]

[1]*Federal Teaching Hospital Abakaliki, Abakaliki/Nigeria,* [2]*Madona University, Okija/Nigeria,* [3]*Lagos University Teaching Hospital, Lagos/Nigeria*

Background: Introduction One of the major preventable causes of death is tobacco use and tobacco workers are exposed to a lot of hazards including physical, chemical, psychosocial and biological hazards but unfortunately many are unaware of these hazards. The aim of this study was to determine the Socio-demographic characteristics and perception of tobacco work and hazards in a rural community of Nigeria. **Method:** Methodology A cross-sectional descriptive study was carried out among 326 tobacco workers selected using a two-stage sampling method. Data was collected using anonymous pre-tested interviewer-administered questionnaires adapted from the Global Adult Tobacco Survey. Odd ratios and 95% confidence intervals were computed and P values of < 0.05 were considered statistically significant. **Result:** s Of the 326 respondents ,4(1.2%) were between 11-20 years, 52 (16.0%) between 21-30 years, 70 (21.5%) between 31-40 years, 88 (27%) between 41-50 years, 61 (18.7%) between 51-60 years, 28 (8.5%) between 61-70 years ,13 (4.0%) between 71-80 while 10 (3.1%)between 81-90.The age range of respondents was 20-70 years with a mean of 42.18 ± 15.412 years. Also, 264(81.0%) were males and 62(19.0%) were females. For marital status, 83 (25.5%) were single, 183(56.1%1.5%) married, 5 (1.5%) divorced, 51(15.6%) widowed while 4 (1.2%) were separated. Also, 113 (34.7%) had only primary education, 135(41.4%) had secondary education, 28 (8.5%) had tertiary education while 50 (15.3%) had no formal education. Only about half, 175 (49.9%) knew that tobacco is dangerous to health, 250 people (76.7 %%) were aware that tobacco is associated with tooth decay while 65 (19.8 %) were aware that it is associated with lung cancer. Age (p<0.0001), male gender (p<0.0001), and lower educational attainment (p<0.0001) were associated with a poor perception of the relationship between tobacco and lung cancer. **Conclusion:** Efforts targeted at raising

tobacco workers' awareness of the health effects of tobacco especial lung cancers are needed in rural communities. Programs should be directed at young males with lower levels of education.

Keywords: Perception, Tobacco work, Hazards

EP1.10-02 RISK FOR OCCURRENCE OF LUNG CANCER AMONG EXPOSED TO PROFESSIONAL AGENTS: A CASE-CONTROL STUDY

I. Pavlovska, B. Tausanova, B. Zafirova

Institute of Epidemiology and Biostatistics, Medical Faculty, Skopje/North Macedonia

Background: Lung cancer (LC) is the most frequent disease worldwide, but, with great differences among different regions. About 5% of the lethal cases, caused by cancer, are determined by the exposure to some substances, present at the working place. The most important cancerogenes for occurrence of professional cancer are ionizing radiation and various chemical and physical agents. For purposes of this study was used classification of the professional cancerogenes according to the International Agency for Research on Cancer (IARC). The exposure to carginogenes from group I (established) and 2A (probable) is taken into account.The aim of this investigation is to observe the eventual causal accociations among the professional exposure and the occurence and distribution of the lung cancer. **Method:** This was a case-control study. It comprised 185 patients with LC and matched controls with no malignant diseases. By calculating the odds-ratios, the risk factors that play a role in the disease onset, have been estimated. Statistical significance of the examined variables as risk factors has been defined with confidence intervals. **Result:** Professional exposure was present in 127 (68,6%), individuals with LC. Most of them were exposed on established (77,2%), and the others (22,8%) on probable cancer agents.The greatest part from the exposed was with more than 20 years at the same working place (established-72,4%;probable-69%). In the diseased group there was total of 124 actual smokers. Out of them, professionally exposed were 89 (71,8). Exposed to established cancer agents had 1,12% (95%CI, 0,70<OR<1,75), times greater risk to become ill from LC, compared to the non-exposed ones. Various are professions in individuals with LC. Greater frequency of the disease was registered in: constructors (present in 18,9% from the total exposed of the professional cancer agents), farmers (17,3%), transport workers (drivers, tractor drivers) (15,0%), mechanicals (8,7%).The most exposed were the farmers, in whom the average timeduration of the exposure was 36,36±9,04 years. The greatest part of the diseased farmers, transport workers and mechanicians had more than 30-year period of working. Transport workers had 2,50 (95%CI, 1,01<OR<6,15), while the mechanicians had 2,31 (95%CI, 0,76<OR<7,07), times non-significantly greater risk to become ill from LC in relation to non-exposed individuals. **Conclusion:** In order to the determined role of some professional cancer agents in occurrence of LC, prevention of this disease means several activities, among which are:complete elimination of the agents present at the working place, decrease of its concentration as well as the decrease of the exposition to the agent.

EP1.10-03 LEVEL OF AWARENESS OF VARIOUS ASPECTS OF LUNG CANCER AMONG COLLEGE STUDENTS IN INDIA: DO WE NEED TO MAKE YOUTH AWARENESS AN IMPORTANT AGENDA?

A. Shankar[1], S. Roy[2], D. Saini[2], A. Dubey[2], M. Khanna[2]

[1]*DRBRAIRCH, All India Institute of Medical Sciences, NEW DELHI/India,* [2]*Indian Society of Clinical Oncology, Delhi/India*

Background: Lung cancer is one of the most common causes of cancer mortality among men in India and incidence is increasing, but actually, they are largely preventable diseases. In India, advanced stage at the time of presentation is responsible for high mortality and morbidity and early detection is the only way to reduce it. The purpose of this study is to know the level of awareness of various aspects of lung cancer among college students to ensure prevention and early detection. **Method:** This assessment was part of Pink Chain Campaign—a campaign on cancer awareness. During the cancer awareness events in 2017–2018 at various colleges in Delhi, pre-test related to lung cancer was followed by awareness programme. Post-test using the same questionnaire was conducted at the end of interactive session, at 6 months and 1 year. **Result:** A total of 2571 out of 3200 students participated in the study (overall response rate was 80.3 %). Mean age of the study population was 19 years (range 17-21 years). There was a significant increase in the level of knowledge regarding lung cancer at 6 months, and this was sustained at 1 year. Among students who were just asked yes or no question, 229 students (8.9 %) were smokers and 423 students (16.4 %) were alcoholics. Internet and Newspapers were sources for knowledge in 72 % of students, whereas approximately 29 % of students were educated by TV and Magazines regarding various aspects of lung cancer. Post awareness at 6 months and 1 year, Pink Chain Campaign was the major source of knowledge related to lung cancer in more than 90 % of students by continuous and timely update on subject. Post awareness at 6 months and 1 year, there was a significant change in alcohol and smoking habits. Major reasons for not going for check-up were ignorance (52.9 %), fear (24.2 %) and lethargic attitude (29.4 %) initially, but over time, lack of time, lethargic attitude and hesitation became important factors after knowing various aspects of lung cancer. **Conclusion:** Knowledge of lung cancer due to smoking was known to most of the students but students were not well aware about environmental determinants of lung cancer. Overall awareness of risk factors, sign and symptoms, screening modalities of lung cancer has improved in a year along with practices related to smoking and alcohol, but there was not much improvement in people undergoing regular check-ups. To inculcate safe practices in the lifestyle of people, awareness programmes Such as the Pink Chain Campaign should be conducted more widely and frequently.

Keywords: Lung cancer. Awareness campaign. College students

EP1.10-04 CHARACTERISTICS OF SMOKER PATIENTS WITH LUNG CANCER IN THE LUNG CANCER

J. Rauseo López, J. González Ruiz, M. Hernández Mezquita, R. Cordovilla Pérez, J. Cascón Hernández, V. Guevara Velázquez, M. Rosales Dedios, M. Bartol Sánchez, A. Pascual Rodriguez, M. Barrueco Ferrero

Hospital Universitario de Salamanca, Salamanca/Spain

Background: It is already known that tobacco has hamrful effects, however in Spain there is a significant population of smokers. Our aim is to study the characteristics of a sample of smokers and former smokers with lung cancer, evaluated in the Lung Cancer Unit (LCU). **Method:** Retrospective study with prospective data. All patients were included according to their smoking history in the LCU between 2010-2017. Variables, such as age, sex, histopathology, pack-year index (PYI), COPD, pulmonary emphysema, Charlson index, TNM, death and survival in months were included. Statistical analysis by statistical program SPSS 20.0. **Result:** We studied 108 smoker patients with an average age of 69.78 ± 10.738, 81.5% men and 18.5% women, 24.1% with COPD, and 42.6% with emphysema. The most frequent histopathologic finding was of adenocarcinoma (ADC) with 34.3%, followed by squamous carcinoma (SC) with 21.3%. 56.8% of men died with a PYI average of 44.26 ± 26.137, and a median survival of 9.00 months (95% CI 4.77-13.22) compared to 52.4% of women who died with a PYI average of 17.67 ± 16,889 and a median survival of 13.00 months (95% CI 0-34.60). The most common histopathology among smokers was ADC followed by SC. The distribution in smokers with PYI <20 was as follows: ADC 42.9% and SC 28.6%; with a PYI between 21 and 40 was ADC 36.7% and SC 23.3%; and in those with PYI> 40, ADC 25.0% and SC 22.7%. Similarly, those with a PYI less than 21, (57.1%) died with a median survival of 13.00 months (95% CI 0-30,531), most of them with a Charlson index lower than 3 (84.7%) and a TNM stage 3 or 4 (61.6%); with a PYI between 21-40, 50% died with a median survival of 8.00 months (95% CI 4.11-11.88), most with a Charlson index less than 3 (81.4%) and a TNM stage 4 (37.5%); and with a PYI greater than 40, 56.8% died with a median survival of 13.00 months (95% CI 7.17-18.72), most of them with a Charlson index less than 3 (80.7%) and a TNM stage 3 (38.4%). **Conclusion:** The most common lung cancer is ADC in all cases. The male population is the most affected with a higher mortality and a lower median survival. Mortality is similar in the PYI sections studied, where most had TNM stage ≥ 3, while the survival in these same groups was variable.

Keywords: Lung cancer, smokers, Tobacco

EP1.11-01 SCREENING AND EARLY DETECTION

EP1.11-01 LUNG CANCER SCREENING AND CANADA'S INUIT: A MISSED OPPORTUNITY

C. Bornais, C. Roberts, P. Wheatley-Price, T. Asmis, C. Dennie, D. Maziak, G. Nicholas, G. Barton, E. Alie, T. Greene

The Ottawa Hospital, Ottawa/Canada

Background: Inuit peoples account for 0.2% of Canada's population. Lung cancer rates in this population are disproportionately high for both genders with Canada's Inuit having the highest incidence of lung cancer in the world. Outcomes are also poor with median survival for all stages combined in Nunavut being approximately 10 months. Lung cancer screening with low dose CT scan is being implemented in many countries, and a pilot program exists in Ontario, Canada. However, the screening model may not be appropriate for the Inuit. **Method:** A literature review was performed regarding lung cancer screening, specifically with reference to the Inuit. **Result:** Several challenges must be considered for implementation of lung cancer screening with the Inuit population. The Prostate, Lung, Colorectal and Ovarian Screening Trial model (PLCO[M2012]) is the risk prediction model used in the Ontario Lung Cancer Screening Pilot for People at High Risk. This requires individuals to be between ages 55-74 and to have smoked daily for at least 20 years during their life. The average life expectancy among Inuit is 72 years, compared to 82 years for Canadians overall. Using this model where the average life expectancy is lower than the upper limit of eligibility restricts its applicability. Smoking rates among this indigenous group are approximately 3 times higher than the rest of Canada, which indicates a clear need for screening where a higher proportion of the population would be eligible. Nunavut is a vast land area of around 2 million square kilometres, with a population of approximately 35,000. The logistics of providing screening in remote communities only connected by air travel is therefore daunting. Other dominant health issues among the Inuit of Nunavut are high rates of tuberculosis, therefore screening CT scans may be further complicated by higher false positive scans requiring established algorithms for management of all abnormal scans. With the Inuit population growing faster than the rest of Canada, yet experiencing a reduced lifespan as compared to other Canadians, there is an opportunity to address the inequity that may be created with the current eligibility model used for screening in Ontario. Furthermore, current recruitment strategies and eligibility assessments are not well suited to this group's unique background. **Conclusion:** The current PLCO risk prediction model used in Ontario may not offer the best benefit for screening in this population while careful thought about how this group is recruited is also required to minimize barriers experienced by this vulnerable population.

Keywords: Screening, Indigenous

EP1.11-02 IMPLEMENTATION PLANNING OF LUNG CANCER SCREENING IN CHINA

Y. Cheng[1,2], M. Davies[2], D. Liu[1], W. Li[1], J. Field[2]

[1]*West China Hospital, Sichuan University, Chengdu/China,* [2]*University of Liverpool, Liverpool/United Kingdom*

Background: Lung cancer is the leading cause of cancer-related deaths in China, with approximately 690,000 lung cancer deaths estimated in 2018; this has increased about fivefold from the mid-1970s. Lung cancer low-dose CT (LDCT) screening in smokers was shown to improve the survival in the US National Lung Screening Trial and more recently in the European NELSON trial. However, the predominant risk factor smoking contributes to a lower fraction of lung cancers in China than in Europe and the US. Therefore, it is necessary to establish Chinese-specific screening strategies. **Method:** To curate data on Chinese lung cancer screening programmes, we searched four Chinese and four English databases, and other sources including references in papers, policies or news from government websites and personal communications with principal investigators. We reviewed the current evidence for the implementation of lung cancer screening in China to generate Chinese-targeted recommendations. **Result:** There are 23 associated programmes completed or ongoing in China since the 1980s, mainly after 2000; and one has recently been planned. Municipal or city-level screening programmes are increasing, particularly after two central government-supported feasibility programmes: the Rural Cancer Screening Programme in 2009 and the Cancer Screening Programmes in Urban China in 2012. Some institutes have established collaborations with international lung cancer screening research groups, i.e. I-ELCAP and NELSON. Most of the programmes targeted community-based high-risk urban residents. Generally, their entry criteria are not smoking-stringent but involve other risk factors, e.g. second-hand smoking, family history of cancer, occupational exposures and air pollution. Some programmes have reported their preliminary results, which demonstrated a different high-risk subpopulation of lung cancer in China and the potential importance of risk-based selection. Evidence concerning LDCT screening implementation is mainly based on randomised controlled trials outside China, which indicates population recruitment, screening protocol and nodule management need more delicate considerations. In addition, LDCT screening programmes combining tobacco control would produce more benefits. Targeting populations to support cost-effectiveness will be important, especially in China where almost half of the lung cancer sufferers are non-smokers. **Conclusion:** In China, the high-risk subpopulation eligible for lung cancer screening has not as yet been confirmed, as all the risk parameters have not yet been determined. Though evidence on best practice for implementation of lung cancer screening has been accumulating in other countries, further research in China is urgently required, as China is now facing a lung cancer epidemic.

EP1.11-03 DIAGNOSTIC EVALUATION OF PATIENTS WITH SOLITARY PULMONARY NODULES IN A TERTIARY REFERRAL CENTER

A. Athanasopoulou[1], I. Gkiozos[1], V. Skouras[1], D. Apostolou[2], V.-V. Kaminitios[2], P. Nikolopoulos[2], R. Trigidou[2], D. Grapsa[1], E. Kokkotou[1], K. Syrigos[1]

[1]*National and Kapodistrian University of Athens, Athens/Greece,* [2]*Sotiria Athens General Hospital, Athens/Greece*

Background: Management of patients with Solitary Pulmonary Nodules (SPN) is primarily targeted at achieving an early diagnosis and treatment of all malignant nodules. We herein aimed to assess the adherence of pulmonologists to current clinical practice guidelines for SPN evaluation in a tertiary referral center for thoracic diseases. **Method:** The medical records of 64 patients with SPN, diagnosed and treated at Sotiria Hospital for Chest Diseases from January 2017 to September 2018 were retrospectively reviewed. Following analysis of the clinical features and imaging characteristics of all cases, the probability of malignancy was evaluated, and the management approach followed by pulmonologists was compared to the approach suggested by issued guidelines. **Result:** We observed a tendency by pulmonologists to monitor all SPN irrespective of size, density and likelihood of malignancy and reassess them at an earlier time than recommended by guidelines. Use of PET/CT in solid nodules > 8 mm of very low (50%) and high (80%) probability of malignancy was also observed, despite lack of a clear indication of PET/CT in the above patients' groups. Conventional bronchoscopy was performed in 81% of patients with a SPN of > 8 mm with intermediate and high probability of malignancy, even though this is not typically recommended. A low-dose protocol was applied in the majority of SPN cases monitored by computed tomography, in accordance with guidelines. Malignancy was diagnosed in 42/64 patients. **Conclusion:** Pulmonologists in real-world practice may adopt a more "aggressive" management approach towards patients with SPN, so as to exclude the possibility of an underlying malignancy.

Keywords: solitary pulmonary nodule, early diagnosis, guidelines

EP1.11-04 LOW DOSE LUNG CT SCREENING IN FIRST RESPONDERS IN THE PHOENIX METRO AREA: A FEASABILITY STUDY

V. Shukla[1], S. Brandman[2], M. Petersen-Incorvaia[3], K. Kalkbrenner[3], J. Denogean[1], P. Prichard[1]

[1]*Vincere Cancer Center, Scottsdale/United States of America,* [2]*Simon Med, Scottsdale/United States of America,* [3]*City of Phoenix, Arizona/United States of America*

Background: United States Preventative Task Force recommends annual lung cancer screening with low dose computed tomography (CT) in adults ages 55-80, who have a thirty pack year history of smoking and are currently smoking or quit within the past 15 years. Thirty percent of all lung cancers diagnosed in United States are due to occupational exposure, with a vast majority diagnosed in first responders. No occupational specific guidelines exist for lung cancer screening with low dose CT for first responders. **Method:** November 1, 2018-March 21, 2019 low dose lung CTs were performed on a 144 first responders. Age ranges from 40-76, Gender: 116 Males and 28 Females. The average years of exposure was 23 yrs. Patients were screened at various Simon Med Radiology locations in Arizona with various CT scanners. The CT dose index ranged (CTDI vol) ranged from 1.6-2.6mGy. No contrast was used. **Result:** 40 lung nodules identified: 1 anterior mediastinal mass, 2.1x1.5cm which was removed in a 42 year-old and found to be an epithelioid thymoma. Lung-RADS screening follow-up was used even though a lot of the patients did not meet age criteria. The remainder of the lung lesions classified as follows: Lung-RADS (LR) 1:4, LR2:28, LR2s:1, LR3:4, LR4A:2 **Conclusion:** This study demonstrates value for LDCT as a screening modality for first responders. First responders are often diagnosed with lung cancer earlier than smoker for various reasons and therefore screened earlier in this study. The very early results are promising and ongoing follow-up will likely lead to further diagnoses of early lung cancer. This is a small study and warrants further investigation on a larger scale.

Keywords: lung, Screening, Firefighter

EP1.11-05 INTEGRATION OF LOW DOSE COMPUTED TOMOGRAPHY (LDCT) FOR LUNG CANCER SCREENING IN THE NATIONAL CANCER PROGRAM IN INDIA: A FEASIBILITY STUDY

J. Meena, A. Pandey

Geetanjali Medical College & Hospital, Udaipur/India

Background: Lung cancer is the commonest cause of cancer-specific mortality in India. It is difficult to screen and often misdiagnosed due to non-specific symptoms. However, improvement is likely with the advent of low-dose computed tomography (LDCT) screening recommendations by U.S. Preventive Services Task Force and American Cancer Society. Notably, specialists are concerned due to false-positive rate (up to 25%), radiation exposure and unnecessary invasive procedure, etc. Therefore it's pertinent to study the feasibility of LDCT integration in the national cancer program. **Method:** A descriptive online survey was developed for medical and surgical specialists using Google survey tool. Google platform was selected for its wide outreach and use by specialists in northern India. The survey period was 1 month and included items for lung cancer screening, LDCT awareness, the feasibility of its integration in the National cancer program, etc. The survey adopted a stratified sampling strategy for representation, and data collected were completely anonymous. **Result:** A total of 530 completed responses were collected. Majority specialists (60.37%) were from the private sector, employed at academic institutions (64.15%). The mean work experience was 7.83±5.64 years with an average of 34.47±8.73 lung cancer patients attended. Most had specialized in internal medicine (26.41%), pulmonology (20.75%) and general surgery (18.86%). Although 71.69% practiced smoking cessation counselling and 25.47% counted it as a potential benefit of LDCT screening, only a few (6.98%) were formally trained in it. Most cited early detection (78.67%) and false positive results (50.94%) as potential benefit and harm of LDCT, respectively. Almost half (52.83%) erroneously suggested LDCT screening in the smoking history of 20 to 30 pack-years & age 40 to 55 years. Poor patient knowledge (55.28%) and denial of cancer risk (36.03%) were quoted as primary causes of refusal for screening. Only a few (24.33%) specialists were aware of the National cancer program, but many (80.75%) favored integration of LDCT screening for reducing lung cancer-related mortality. Poor finances and logistics (67.92%), and human resource (38.11%) were identified as potential barriers. Provision from health budget (39.62%) and social insurance (22.64%) were the preferred funding options. **Conclusion:** In the present study a favorable attitude towards the inclusion of LDCT in national cancer program was observed among specialist doctors. However, the study also highlights potential barriers including financial and human resources to its integration warranting operational research. At the same time study also illustrate poor awareness of lung cancer screening protocols and inept smoking cessation counselling for which training should be formalized.

Keywords: ldct, Screening, Lung cancer

EP1.11-06 DESIGN AND IMPLEMENTATION OF AN INTEGRATED LUNG CANCER PREVENTION AND SCREENING PROGRAM USING A MOBILE CT IN BRAZIL

R. Chiarantano[1], F. Vazquez[1], R. Haikel Junior[1], L. Ferreira[1], M. Da Costa[1], L. Leal[1], P. De Marchi[1], M.C. Meinberg[2], A. Franco[2], L. Almeida[1], E. Mauad[1], R. Reis[1]

[1]*Barretos Cancer Hospital, Barretos/Brazil,* [2]*Municipal Health Secretary, Barretos/Brazil*

Background: Lung cancer is a high-ranking cause of cancer deaths in Brazil. Low dose computerized tomography screening national guidelines has not yet been established, and public primary prevention and tobacco control programs have an inconsistent coverture, especially among the most deprived. The Cancer Prevention Department of Barretos Cancer Hospital has a large tradition in the use of mobile units to reach out and conduct cancer screening in underserved Brazilian populations. This study aims to design an integrated lung cancer prevention and early detection program using a mobile CT unit to reach high-risk lung cancer population. **Method:** The study is placed in Barretos, Brazil, with an estimated population of 120,000 inhabitants. Tobacco cessation intervention and LDCT screening will be offered in partnership between the municipal health system and Barretos Cancer Hospital. Every smoker seeking health assistance and those identified in active surveys in the community would be offered tobacco cessation support. High-risk individuals matching USPTF criteria will be offered LDCT using a mobile CT unit. **Result:** Nineteen tobacco cessation teams were formed in different public primary health unities throughout the city. Patient information are stored in a web-based databank (RedCap) and shared between teams. Screening flow was coordinated by municipal health office and Barretos Cancer Hospital. The CT mobile unit is intended to be placed near primary health care centers. It was estimated 3,376 eligible participants. A comprehensive epidemiological questionnaire will be asked, in addition with blood and sputum samples collection for further cancer biomarker studies. Those with symptoms of suspected lung malignancy or poor clinical condition would be excluded from screening. Nodules detected in LDCT screening will be managed under ACR Lung-Rads criteria. A multidisciplinary team will be available to discuss doubtful cases, diagnosis and treatment strategies. Two reports are generated for each LDCT screening exam and sent back to primary care teams, one with educational purposes and another with technical information. Primary care teams were trained, being responsible to manage non-cancer conditions eventually detected on screening. A direct line of communication was set between primary care teams, radiologists and multidisciplinary team. **Conclusion:** Tobacco cessation and lung cancer screening in high-risk individuals have to be integrated. Since Brazilian health assistance in public system is fragmented, it is imperative to design a coordinated flow and establish communication channels between primary care teams, radiologists and multidisciplinary team. There was good feedback by primary care teams and patients about the impact of screening in the tobacco cessation process.

Keywords: Mobile CT, Tobacco Cessation, lung cancer screening

EP1.11-07 DEVELOPMENT OF A CHROMOSOME INSTABILITIES IN PLASMA CELL-FREE DNA ASSAY FOR EARLY LUNG CANCER DETECTION AND TREATMENT RESPONSE MONITORING

Z. Qian[1], Y. Yang[2], W. Yin[3]

[1]*Prophet Genomics Inc, San Jose/United States of America,* [2]*Shanghai Pulmonary Hospital, Shanghai/China,* [3]*Dartmouth Collage, Hanover/United States of America*

Background: Chromosomal instability (CIN) is one of the hallmarks of cancer. Tumor cells keep shedding DNA into blood stream which provides an opportunity for CIN analysis. Here we present a retrospective study to investigate the potential of CIN in plasma cell-free DNA (cfDNA) as a minimal-invasive biomarker for early cancer detection and cancer treatment responses monitoring. **Method: Method:** To characterization the baseline data of CIN in cfDNA, 171 plasma samples were collected since June 2017. 35 was from non-cancer individuals. 136 was from cancer patients. cfDNA was extracted and sent to low-coverage genome sequencing on the Illumina X10 platform, followed by chromosomal instability (CIN) analyses by a customized workflow Ultrasensitive Chromosomal Instability Detector (UCAD). **Result:** Increased plasma cfDNA CIN was observed along with disease progression. In lung cancer, cfDNA CIN increased along with the development of lesions, from adenocarcinoma in-situ, minimal invasive adenocarcinoma, invasive adenocarcinoma (P=0.034) to relapsed cancer (P<0.01). The sensitivity of early lung cancer detection was 30.7%, 37.5%, 45.5%, 50.0% and 98.1% for AIS, MIA, IAC, SCC and relapsed lung cancer, at a specificity of 75%. In primary lung cancer, cfDNA CIN decreased after curative therapies. And cfDNA CIN significantly increased after disease relapsed (P<0.01). And cfDNA levels did not show statistical differences regarding metastases sites. **Conclusion:** Conclusions: cfDNA CIN can help early cancer detection and treatment response monitoring.

Keywords: CIN, UCAD, cfDNA

EP1.11-08 ULTRA-HIGH-RESOLUTION CT TO PROJECT THE DETAILED COMPONENTS IN NODULES; FAT COMPONENTS IN PULMONARY HAMARTOMAS

D. Takenaka[1], A. Higashida[1], C. Tanaka[1], E. Matsushiro[1], T. Hashimoto[1], H. Maeda[1], S. Sakamoto[1], Y. Ohno[2]

[1]*Hyogo Cancer Center, Akashi/Japan,* [2]*Fujita Health University School of Medicine, Toyoake/Japan*

Background: The purpose of this study was to evaluate the utility of the detailed matrix of ultra-high-resolution CT (UHRCT) to detect the detailed attenuation heterogeneity in pulmonary hamartoma which contains fat component. **Method:** Seven consecutive patients (three males, four females; 48-73 y.o.) with pulmonary hamartoma who underwent UHRCT were enrolled retrospectively. Each patient's hamartoma was diagnosed by using bronchoscope, surgical therapy or follow up study. All CT studies were performed by using ultra-high-resolution CT machine (Aquilion Precision; Canon Medical Systems, Otawara, Japan). All CT examinations were performed with 160-detector row CT scanner; 120kVp, auto-mAs, 1792 channels, collimation 0.25 mm x 160 rows, 1024 matrix. Conventional high-resolution CT (HRCT) images were reconstructed with 1mm slice, 1mm interval, 512 x 512 matrix. Ultra-high- resolution CT (UHRCT) images were reconstructed with 0.25 mm slice, 0.25 mm interval, 1024 x 1024 matrix. The CT densities of each hamartoma were measured by placing ROI at the longest diameter of the nodule on CT image. The lowest densities in the nodule were statistically compared between on HRCT and UHRCT by using paired t-test. P value less than 0.05 was considered to be significant. **Result:** The average minimum densities of hamartomas on HRCT and UHRCT were -39.1 and -65.0, respectively (p = 0.092). **Conclusion:** The lowest densities of hamartomas were lower on UHRCT than on HRCT, not significantly. The UHRCT's smaller voxel may reveal the detailed heterogeneity in the nodule to detect fat component of hamartoma.

Keywords: Ultra-high-resolution CT, pulmonary nodule, Hamartoma

EP1.11-09 EVALUATION OF SEVEN-AUTOANTIBODY PANEL TEST IN EARLY DETECTION OF LUNG CANCER IN ROUTINE CLINICAL PRACTICE

N. Chang, J. Zhang, T. Yang, S. Wu

Department of Pulmonary Medicine, Department of Pulmonary Medicine, Xijing Hospital, Fourth Military Medical University, Xi'An/CN

Background: There is an increasing incidence of pulmonary nodules due to the promotion and popularization of low-dose computed tomography (LDCT) screening for potential populations with suspected lung cancer. However, high rate of false-positive and concern of radiation-related cancer risk of repeated CT scanning remains major obstacle to its wide application. Here, we aimed to investigate the clinical value of a non-invasive and simple test, named 7 autoantibodies (AABs) assay (P53, PGP9.5, SOX2, GAGE7, GUB4-5, MAGEA1 and CAGE), in distinguishing malignant pulmonary nodules from benign ones in routine clinical practice. **Method:** 152 patients with malignant lung diseases and 151 with benign pulmonary diseases were identified. The serum levels of the 7-AABs were tested by Enzyme-linked Immunosorbent Assay (ELISA). The primary goal was to assess the sensitivity, specificity, false positive rate (FPR) and positive predictive value (PPV) of the 7-AABs panel in detection of lung cancer. **Result:** The serum levels of AABs (including PGP9.5, GAGE7, GBU4-5 and MAGEA1) in malignant group were significantly higher than that in benign group. The sensitivity and specificity of the 7-AABs panel test were 46.1% and 82.9% in whole group, and 35.3% and 70.0% in cases with pulmonary nodules. Comparing to 7-AABs panel test or LDCT screening plus multiplane reformation (MPR) alone, the combination of 7-AABs panel and LDCT screening+MPR improve the PPV (70.6% vs 89.5%; P < 0.001) and reduce the FPR (21.1% vs 30.0%; P < 0.001) in patients with pulmonary nodules. **Conclusion:** The 7-AABs panel may be a promising method for early detection of lung cancer. It would be a valuable diagnostic tool to distinguish malignant pulmonary nodules from benign ones.

Keywords: lung cancer,screening,LDCT,seven-autoantibody panel

EP1.11-10 CREATING A COMPREHENSIVE LUNG CANCER SCREENING PROGRAM TO DIAGNOSE EARLY STAGE LUNG CANCERS

K.A. Braithwaite, J. Schneider

NYU Winthrop Hospital, Mineola/United States of America

Background: Objective: The goal was to create a comprehensive lung cancer screening program at our Cancer Center that integrates evidence-based results as a way to identify early stage lung cancers in the high risk population of our community. Literature review: Lung cancer is the third most common type of cancer diagnosed in the United States, but it is the leading cause of cancer deaths (U.S. Cancer Statistics Working Group, 2018). Lung cancer is most often diagnosed at late stages which have low survival rates. The National Lung Screening Trial (NLST) was an NCI funded trial which determined that screening with low dose CT as compared to chest radiograph would reduce mortality by 20% in high risk populations (Team, 2011). Screenings for breast and colorectal cancer has been associated with improved patient outcomes and sets a precedent for implementing responsible lung cancer screening in high risk populations (Mulshine & D'Amico, 2014). **Method:** A comprehensive screening program was designed with a nurse coordinator as the main point person to ensure all screenings had follow up tracking completed. The screening program was designed to function in cooperation with the Hospital Comprehensive Lung Cancer Program as needed based on screening results. Program protocol were set up to include timely result reports to referring physician with clear follow up recommendations and result letters to screening patients. A tracking system was put into place to ensure the necessity of follow up scans are communicated to the patients and completed. **Result:** Since the start of our program in October 2012, we have performed 933 initial scans, 647 annual scans and 172 short-term follow up scans. We have diagnosed 13 lung cancers, 3 renal cancers, 1 thyroid cancer, 1 melanoma, 2 thymoma, and 1 breast cancer recurrence. **Conclusion:** We have found lung cancer screening to be an effective method of diagnosing early stage lung cancers in high risk populations.

Keywords: screening program

EP1.11-11 FAMILIAL LUNG CANCER: A CALL FOR ACTION

V. Sacramento[1], M. Felizardo[1], P. Calvinho[2], R. Madureira[1], S. Furtado[1]

[1]*Hospital Beatriz Ângelo, Loures/Portugal,* [2]*Hospital Santa Marta, Centro Hospital Lisboa Central, Lisboa/Portugal*

Background: Lung cancer (LC) is the most deadly of all cancers mostly due to the fact that the disease is often detected at an advanced stage with less effective treatment options. While 80% of lung cancers can be directly attributable to tobacco smoking, the disease has been increasing in non smokers raising awareness to other risk factors that could be screened for and controlled in order to achieve higher rates of early stage diagnosis. **Method:** A retrospective analysis of the electronic records of LC patients followed in our district hospital between May 2012 and December 2018 was conducted. Patients with family history of cancer were selected and their demographic characteristics, smoking status, co morbidities and LC characteristics were analyzed. **Result:** A total of 524 patients were followed, 33 of whom with a positive family history of cancer (20 men and 13 women, median age of 61.7years old at diagnosis +- 12.8 years). Only 9 were never smokers and 63.6% (21) were diagnosed following the investigation of symptoms. The majority (24) had an adenocarcinoma subtype (3 EGFR mutations, 1 ALK translocation and 2 HER2 amplification were identified). Twenty patients (60.6%) had a family history of LC and the most frequent family member affected were parents (father: 14; mother: 11) and siblings (11). Cancer affected at least 2 family members of 15 patients. At the time of diagnosis 19 of the 20 patients with LC family history had an ECOG Performance Status of 0-1 and 8 (40%) had advanced stage disease. We found no significant difference in stage at diagnosis, smoking status or symptoms at diagnosis between patients with and without a LC family history of malignancy (p=0,120, p=0,117 and p=0,814 respectively). **Conclusion:** Studies demonstrating evidence of familiar aggregation of LC suggest a possible genetic susceptibility to this malignancy. Identification of individuals at particularly high risk of lung cancer due to this type of susceptibility would contribute to early detection and possibly to prevention through targeted and intense anti-smoking efforts. Perhaps due to the small dimension of our study population, our patients were not diagnosed in early stages of the disease despite a positive family history of lung cancer. This raises the question whether this particular group of people should be selected for specific cancer screening to allow for the possibility of curative treatments.

Keywords: Lung cancer, familiar aggregation, early diagnosis

EP1.11-12 LUNG CANCER SCREENING: IMPLEMENTATION IN A MULTI-STATE, COMMUNITY-BASED SETTING

C. Wilshire, S. Anton, C. Henson, L. Horslen, C. Fuller, B. Mccall, K. Spiegel, J. Rayburn, A. Carlson, C. Gilbert, J. Gorden

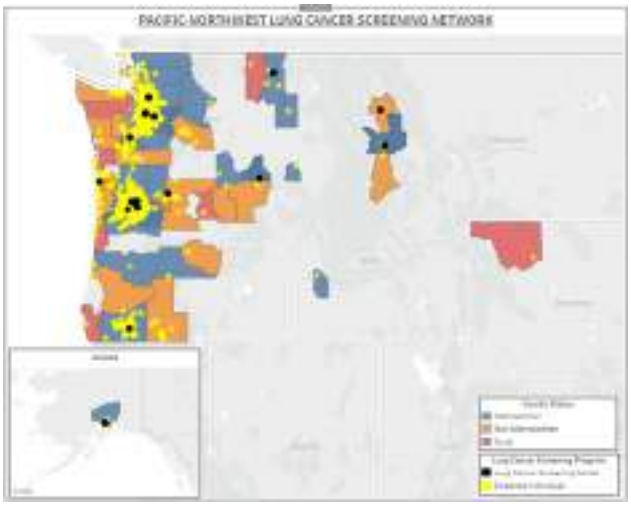
Swedish Cancer Institute, Seattle/United States of America

Background: The benefits of lung cancer screening (LCS) was largely proven in academic centers, and while implementation in the Veterans Health Administration has been reported, little data has been published on the broader community experience. We aimed to describe the LCS implementation experience in a multi-state, community-based healthcare network. **Method:** We reviewed individuals who were referred for LCS between 01/01/2012-03/31/2017 within our community-based network of 12 LCS programs spanning 22 LCS sites in Alaska, Montana, Oregon and Washington. One of the programs is considered centralized (shared decision making, evaluation and management occur at a single site) and 11 are considered decentralized (shared decision making, evaluation and management occur in geographically diverse community care settings with support from a central LCSP coordinator). 2013 Rural-Urban Continuum Codes from the United States Department of Agriculture were used to determine metropolitan/non-metropolitan/rural status. **Result:** Data collection is complete for 4,820 of the total 6,451 individuals, of which 9% (450/4,820) were excluded for being outside the age and smoking history LCS criteria range. A further 908 were excluded for other reasons. Thus, the preliminary results of 3,462 individuals are included here. Characteristics of the individuals are shown in the table. Of the 22 LCS sites 82% (18) were located in metropolitan areas, 18% (4) in non-metropolitan areas and none in rural areas. The distribution of screened individuals and LCS centers within the healthcare network are shown in the figure.

FACTOR	% (Number)
DEMOGRAPHICS	
Median age, years (IQR)	64 (60-69)
Gender, male:female	56%:44% (1,930:1,532)
Race	
White	87% (3,018)
Non-white	13% (444)
Current smoker on program entry	57% (1,974)
Median tobacco pack year history (IQR)	41 (35-50)
Median income by county, USD (IQR)	$65,965 ($54,102-$75,302)
Residential location	
Metropolitan	92% (3,204)
Non-metropolitan	7% (231)
Rural	<1% (19)
Unknown	<1% (8)
Median distance to screening site, miles (IQR)	7 (4-14)
INITIAL LOW-DOSE CT SCAN	
Individuals with Lung RADS 4	7% (232)
Individuals with at least one nodule >6mm	26% (905)
Median size of largest nodule, mm (IQR)	8 (6-12)
PULMONARY NODULE INTERVENTIONS	
All individuals that underwent a procedure	4% (128/3,462)
Individuals with positive nodules that underwent a procedure	14% (128/905)
Pulmonary resections	55% (71/128)
Malignant	92% (65/71)
Benign	8% (6/71)
Major postoperative complications	13% (9/71)
ATTRITION*	
Individuals that underwent attrition	17% (588)
Median time to attrition, months (IQR)	15 (12-21)
Nodule on first scan	46% (273/588)
Median size of largest nodule, mm (IQR)	5 (4-7)
Smoking on program entry	61% (360/588)

IQR, 25th-75th interquartile range; *Attrition defined as declining further screening or lost to follow-up.

EPOSTERS



Conclusion: Screening in the community setting remains in metropolitan areas. Positive findings on the initial scan are common; however, intervention rates are low. Retention for screening also remains high.

Keywords: Lung cancer screening, Community-based lung cancer screening, Multi-state lung cancer screening

EP1.11-13 LUNG CANCER SCREENING PROTOCOL BY USING LOW DOSE COMPUTERIZED TOMOGRAPHY IN COMBINATION WITH DIGITAL TOMOSYNTHESIS: 4 YEARS FOLLOW UP RESULTS

N. Triphuridet[1], S. Vidhayakorn[2], A. Worakitsitisatorn[2], N. Chuengkhlay[2]

[1]*Chulabhorn Royal Academy, Bangkok/Thailand,* [2]*Chulabhorn Hospital, Bangkok/Thailand*

Background: Annual Low-dose computerized tomography (LDCT) screening for lung cancer is currently a standard protocol recommendation. However, LDCT has limitations in its high rate of false positive results, accumulation of radiation exposure, and relatively high cost. Using LDCT in combination with Digital Tomosynthesis (DT) may be an alternative screening protocol for lung cancer. **Method:** A lung cancer screening protocol using LDCT yearly alternate with DT in normal LDCT finding and abnormal finding that stable or decreased after annual LDCT for 2 years in solid and part-solid nodule has been performed in 634 former or current heavy smoker since July 2012 at Chulabhorn Hospital, Thailand. **Result:** At initial screening of LDCT, 196 (30.9%) had normal lung finding and 438 (69.1%) had abnormal finding. During annual follow up, 187 and 156 cases who had initial normal LDCT underwent DT screening on 1st and 3rd year of follow up, and no lung cancer was diagnosed within the 4 years follow up period. Meanwhile, among 271 participants who had stable or decreased lung lesions and underwent DT on 3rd year follow up, 3 lung cancers was diagnosed on 4th year follow up. Two lung cancers were early stage and one was stage 4, which represented as a new solid nodule, new solid component and new endobronchial lesion on LDCT finding, respectively, while DT could not detected the new solid component of part solid nodule. **Conclusion:** LDCT in combination with DT would be an alternative protocol for lung cancer screening particularly in normal lung lesion.

Keywords: Low-dose CT, Digital tomosynthesis, lung cancer screening

EP1.11-14 KNOWLEDGE AND PERSPECTIVES OF INDIAN MEDICAL PRACTITIONERS TO LUNG CANCER: A REGIONAL SAMPLE SURVEY

J. Meena, A. Pandey

Geetanjali Medical College & Hospital, Udaipur/India

Background: Lung cancer leads cancer-associated mortality figures in India. According to various cancer registries, It's a pervasive problem with incidence expected to rise to 67,000 new cases per year by 2020. Especially concerning are limited health resources to tackle this problem in terms of specialty centers and trained staff. Adding to woes are poor knowledge, and practices among general practitioners (GPs) pertaining to lung cancer screening and referral. Thereby putting an additional burden on the constrained Indian health care system as a majority of cases are diagnosed at advanced stages leading to poorer prognosis and high treatment costs. **Method:** A descriptive online survey was developed and pilot tested for GPs with Bachelor degree in Medicine & Surgery (MBBS) using Google survey forms. Google platform was selected for its wide outreach and use by GPs in northern India. The survey was done over 1 month period and included items related to etiopathology and diagnosis of Lung Cancer. The survey adopted a stratified sampling strategy for representation, and data collected were completely anonymous. **Result:** A total of 2674 complete responses were collected. Majority of GPs were in the private sector (67.68%) with a mean work experience of 8.93±6.70 years. An average of 10 (10.45±7.10) Lung cancer cases were attended by GPs with majority presenting with non-resolving cough and/or hemoptysis (66%). Most common risk factors reported were cigarette smoking (93.27%) and exposure to chemicals (74.49%). Only a quarter of GPs identified lung cancer mortality being the highest (29.09%) with attribution to smoking (23.60%). Only 69.10% GPs advocated Lung cancer screening for current and past smokers. Only 30.89% GPs affirmed that a substantial reduction in mortality (95%) can be achieved by timely and proper screening. Only a quarter (25.46%) GPs reported low dose CT Scan (LDCT) as best modality lung cancer screening. 1943 (72.66%) GPs reported tissue sample biopsy as a method of diagnosis followed by CT scan (58.18%). Histopathology (85.48%) and molecular markers (74.49%) were frequently reported to guide therapeutic decision making. **Conclusion:** Based on the survey, It can be concluded that knowledge of Indian GPs for Lung cancer is deficient in wake of high disease burden. Poor suspicion and detection of lung malignancy at early stages devoid patients of better prognosis and outcomes. Therefore it is recommended that sensitization workshops and training of GPs in opportunistic cancer screening and referral protocols be done.

EP1.11-15 LUNG CANCER SCREENING PROGRAM WITH LOW-DOSE CT IN GREEK POPULATION

K. Domvri[1], T. Kontakiotis[1], G. Lazaridis[2], D. Spyratos[1], E. Eleftheriadou[1], K. Porpodis[1], K. Tsiakitzis[3], S. Lampaki[1]

[1]*Aristotle University of Thessaloniki, Pulmonary Department, Thessaloniki/Greece,* [2]*Aristotle University of Thessaloniki, Department of Clinical Oncology, Thessaloniki/Greece,* [3]*Gen Hospital of Thessaloniki "G. PAPANIKOLAOU", Pharmacy Department, Thessaloniki/Greece*

Background: The majority of lung cancer patients are at an advanced stage at the time of diagnosis, when curative treatment is no longer feasible. On this basis, we performed screening with low-dose CT in patients with high risk of lung cancer development. **Method:** From Feb 2015 to Feb 2019, 500 patients were recruited in the study. Patients were screened for lung cancer with low-dose CT according to European Union position statement expert group. **Result:** Group A consisted of patients <55 years old (25%) including 80% of current smokers (30 ± 5 pack years) and 15% of overweight subjects. Group B consisted of patients >55 years old (75%) including 65% of current smokers (40 ± 8 pack years) and 9% of overweight subjects. Former smokers were divided into three groups, those who quit a) 15 years ago (48%), b) 10 years ago (29%) and c) 5 years ago (23%). Concomitant diseases of the whole population included hypertension (27%), diabetes mellitus (19%), COPD (24%), coronary disease (12%) and prior cancer (1%). Hypertension, diabetes mellitus and COPD were correlated with smoking in the population studied ($p<0.05$). Findings (nodules > 10mm) were observed in 13% of patients in Group A and in 8% of Group B. One patient in Group

A and one patient in Group B were diagnosed with squamous cell carcinoma and adenocarcinoma respectively. After screening, 13% of the whole population started low fat diet whereas 20% of the whole population refused follow up. Interestingly, 80% of the whole screened population agreed for an annual low-dose CT and 21% of this population quit smoking through screening period (p<0.05). **Conclusion:** Screening with low-dose CT offers a tool for the early detection of lung cancer that can save lives for those at high risk and might significantly improve the low survival rates for this disease. European countries should take into consideration the implementation of lung cancer screening programs as a preventive care strategy. The value of the screening test in lung cancer patients remains to be further elucidated.

Keywords: screening, lung cancer, low-dose CT

EP1.11-16 COMPARISON OF THREE DIAGNOSTIC MODALITIES FOR LUNG NODULES

S.K. Hwang, S. Bae, S. Lim

Ulsan University Hospital, University of Ulsan, College of Medicine, Ulsan/Korea, Republic of

Background: Lung cancer screening and computed tomography (CT) have increased the detection of lung nodules. However, the diagnosis and selection of diagnostic modality are difficult for small nodules. The objective of this study was to determine the appropriate modality for lung nodule diagnosis. **Method:** We reviewed 446 consecutive cases that underwent radial endobronchial ultrasound (EBUS), percutaneous needle aspiration (PCNA), or surgical resection for the diagnosis of lung nodules (≤3cm) from February 2017 to January 2019. The patients underwent contrast-enhanced chest CT in our hospital before each examination. We performed retrospective data collection and analysis. **Result:** Radial EBUS was performed in 120 (27%) cases, of which 73 had a proper diagnosis; PCNA was performed in 151 (34%) cases, of which 131 had a proper diagnosis; surgical resection was performed in 175 (39%) cases, of which 172 had a proper diagnosis. We detected malignancy, benign nodules, and atypical cells in 290 (65%), 139 (31%), and 17 (4%) cases, respectively. The mean sizes measured on CT were 20, 19.7, and 12.1 mm in PCNA, radial EBUS, and surgical resection, respectively (p<0.001). The lung lobe with nodules (p=0.762) was not statistically different among the modalities. Radial EBUS was preferred for centrally located nodules (55/120; 45.8%; p<0.001). Surgical resection showed many portions of ground-glass opacity nodules (p<0.001). PCNA was attempted in peripherally located or solid lung nodules (p <0.001). The failure of diagnosis with PCNA, radial EBUS, and surgical resection occurred in 20 (13.2%), 47 (39.2%), and 3 (1.7%) cases, respectively (p <0.001). **Conclusion:** Surgical resection is preferable for small lung nodules and ground-glass opacity nodules; PCNA is preferable for peripherally located and solid nodules; radial EBUS is preferable for centrally located nodules. It is important to select the diagnostic modality based on the characteristics of each nodule.

EP1.11-17 THE IMPACT OF OCCUPATIONAL EXPOSURE ON DETECTION OF EXTRA-NODULAR AND EXTRAPULMONARY LESIONS IN LDCT FROM A PILOT SILESIAN STUDY

S. Szablowska-Siwik[1], E. Wachula[2], W. Bulska-Bedkowska[1], D. Czyzewski[3], M. Adamek[3]

[1]*Department of Oncology, School of Medicine with the Division of Dentistry in Zabrze , Medical University of Silesia, Katowice/Poland,* [2]*Department of Oncology, School of Medicine with the Division of Dentistry in Zabrze, Medical University of Silesia, Katowice/Poland,* [3]*Department of Thoracic Surgery, School of Medicine with the Division of Dentistry in Zabrze , Medical University of Silesia, Zabrze/Poland*

Background: Smoking and additional exposure to occupational factors such as coal dust, can cause changes in the lungs and also in other organs. **Method:** We did the comparative analysis of the prevalence and nature of extra-nodular lesions and extra-pulmonary findings seen in low-dose computed tomographies (LDCT) done in 533 participants of the Pilot Silesian Study of Early Lung Cancer Detection. The study cohort consisted of miners (n=59) and people without occupational exposure (n=474). Statistical analysis was performed using Statistica 13.0 PL. Statistical significance was set at a p value below 0.05. Distribution of variables was evaluated by the Shapiro-Wilk test. The two groups were compared with the U Mann-Whitney test in case of non-normal data distribution. Chi-square test was used. **Result:** The value of 'pack-years' for miners was statistically higher than for people without occupational exposure (M: 37 v 30, p=0.01). Emphysema was more often found in the group of miners (44,07 % v 31,50 %, p = 0.05). COPD was also diagnosed more often in people exposed to coal dust than without occupational risk (45,76 % v 32,07 %, p=0.035). Extrapulmonary findings were reported in 86,44 % of miners and 62,45 % of people without occupational exposure (p=0.00027). Degenerative changes in the skeleton, osteoporosis, calcification in vessels were found statistically more frequently in miners. **Conclusion:** Long-term smoking, exposure to coal dust, physical work could contribute to a faster development of COPD and osteoarticular diseases.

Keywords: occupational exposure, LDCT (low dose computed tomography), lung cancer screening

EP1.11-18 FOLLOW-UP AND RECURRENCE AFTER SURGERY IN PATIENTS WITH NON-SMALL-CELL LUNG CANCER

F. Martelo, M. Felizardo, M.O. Fernandes, M. Pantarroto, M. Grafino, J. Eurico Reis, A. Catarino, A. Ribeiro, C. Loewenthal, R. Vieira, F. Mascarenhas

Hospital da Luz Lisboa, Lisboa/Portugal

Background: Lung cancer is one of most common cause of cancer death in the world. Surgery is a potentially curative intervention in early stages of non-small-cell lung cancer (NSCLC), although some patients develop recurrence. Identification of factors related to recurrence is essential to reduce it. **Method:** The objectives of this study were to evaluate the follow-up of patients with early stage NSCLC who undergoing surgical resection, as well as, the factors related to recurrence. We retrospectively evaluated patients with early-stage NSCLC (stage 0-II) who underwent surgical resections between January 2015 and December 2017 at Hospital da Luz – Lisboa. Patients were evaluated at a multidisciplinary lung cancer tumour board team meeting and followed according to international guidelines. We characterised demographic, clinical and radiological features, surgical procedure, histology and follow-up. The mean and standard deviation were shown; the T-student and Fisher tests were used; P value ≤0.05 was considered significant. **Result:** There were included 46 resected NSCLC: 41 (89.1%) adenocarcinoma (ADC) – 25 invasive ADC, 11 ADC in situ (Tis) and 5 minimally invasive ADC; 4 (8.7%) epidermoid and 1 (4.2%) pleomorphic carcinoma. Twenty-seven (58.7%) were female and 29(63.0%) were current or former smokers; mean age was 63.1±9.3 years old (37-82). We underwent 30 (65.2%) lobectomies, 13 (28.3%) anatomic segmentectomies, 2 (4.3%) wedge resections and 1 (2.2%) bilobectomy, all with mediastinal lymph node dissection. No major complications were reported. Regarding surgical stage, 11 (23.9%) were stage 0, 26 (56.5%) Ia, 7 (15.2%) Ib, and 2 (4.3%) IIa. Thirty-nine (84.8%) patients were in follow-up or died due to non-lung cancer cause (1 case). The follow-up was 28.7±8.5 (12-47) months. Recurrence was documented in 4 (8.7%) patients; the time of recurrence development was 14.8±9.2 (4-26) months; Second primary lung cancer occurred in 3 6.5%) patients. Comparing recurrence and follow-up groups, there was only difference regarding age (73.0±7.8 vs 62.4±9.1; p=0.032) - gender (p=1.0), smoking history (p=0.621), nodule characteristics (solid vs sub solid) (p=0.140), lung resection (lobar vs sublobar) (p=0.297) and stage (stage 0/I vs stage II) (p=1.0). All Tis lesions were in follow-up. **Conclusion:** In this group with resected early-stage NSCLC, most of the patients were in follow-up and the age was the only factor associated to NSCLC recurrence. Although low recurrence documented, it is essential to perform more accurate patient selection ensuring a radical cure. Probably other variables, as molecular/genetic parameters, can help to identify those with high-risk recurrence and the liquid biopsy can be useful in the detection of lung cancer recurrence.

Keywords: non-small-cell lung cancer, Follow-up, Recurrence

EP1.11-19 SURVEILLANCE WITH PET/CT AND CTDNA OF LUNG CANCER PATIENTS AFTER COMPLETION OF DEFINITIVE THERAPY; A RANDOMIZED TRIAL

K. Skougaard[1], K. Guldbrandsen[2], O. Østrup[2], U. Bødtger[3], M. Frank[3], T. Schytte[4], B. Sorensen[5], T. Rasmussen[6], O. Gerke[7], J. Søgaard[7], B. Rychwicka-Kielek[8], Z. Saghir[9], G. Persson[10], B. Fischer[2,11]

[1]*Herlev Hospital, Herlev/Denmark,* [2]*Rigshospitalet, Copenhagen/Denmark,* [3]*Næstved Hospital, Næstved/Denmark,* [4]*Odense University Hospital, Odense C/Denmark,* [5]*University Hospital of Aarhus, Aarhus N/Denmark,* [6]*Aarhus University Hospital, Aarhus/Denmark,* [7]*University of Southern Denmark, Odense/Denmark,* [8]*Aalborg University Hospital, Aalborg/Denmark,* [9]*Gentofte Hospital, Gentofte/Denmark,* [10]*Herlev-Gentofte Hospital University of Copenhagen, Herlev/Denmark,* [11]*Kings College London, London/United Kingdom*

Background: Even after treatment with curative intent lung cancer patients have a high risk of relapse. Patients are currently followed with CT. However, after surgery and especially radiotherapy CT has limited accuracy potentially delaying the diagnosis of a relapse. There is a scarcity in evidence regarding the most efficient follow-up interval as well as maging method. Together with CT the use of PET/CT for follow-up has been increasing and there is a need for improved understanding and perhaps questioning of the role of imaging in surveillance. Relapse of tumour activity can also be reflected by shedding of tumour DNA (ctDNA) into the blood stream. Studies have shown increase in circulating ctDNA months before standard radiologic assessment. Blood sampling and subsequent analysis of ctDNA therefore represent a promising minimally-invasive strategy to assess genomic tumour material and follow its changes. The purpose of this on-going clinical trial is to improve early detection of lung cancer relapse enabling more patients to receive definitive treatment of their relapse, ultimately leading to improved survival. **Method:** This national, randomized trial compares two strategies for surveillance of patients with non-small cell lung cancer treated with curative intent (figure 1): standard follow-up +/- imaging with FDG PET/CT. Primary endpoint is frequency of treatable relapse and secondary endpoints includes survival and quality of life, number and type of invasive procedures, adverse events and type of treatment after verification of relapse, as well as use of healthcare resources. Based on samples collected during this randomized trial we will evaluate if monitoring patients with ctDNA enable us to track cancer evolution and detect early signs of relapse, as well as exploring potential new stratification of patient cohort with focus on high-risk and low-risk groups. Hereby, designing an optimal surveillance strategy for individual patients.

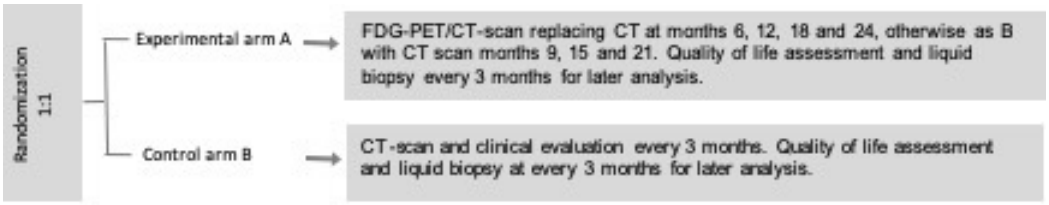

Figure 1: Overview of the SUPE_R trial

Result: The trial has been starting gradually since end-2018 and is now including patients in 4/5 Danish regions. The study aims to include 750 patients by 2021. In order to obtain baseline blood sample for ctDNA patients are included both prior to treatment (by April 2019 n=61) and 3 months after treatment (only patients in complete remission, n=25). **Conclusion:** SUPE_R will provide the scientific basis for implementing new ways for surveillance of patients with lung cancer as well as provide knowledge transferable to other groups of cancer patients. This is the first study considering bioinformatics and methodological aspects of liquid biopsies and relating them directly to imaging and clinical benefits for the patients.

Keywords: Surveillance, PET/CT, ctDNA

EP1.11-20 A PANEL OF LIQUID BIOMARKERS FOR EARLY RESPONSE CAPTURING OF NSCLC THERAPIES IN ADVANCED STAGES

F. Janke[1,2], M. Schneider[1,3], S. Wrenger[4,5], S. Dietz[1,2], T. Muley[1,3], G. Heussel[3,6], C.-P. Heussel[1,3,6], C. Da Silva[7], F. Bozorgmehr[1,3], S. Janciauskiene[4,5], H. Sültmann[1,2], M. Meister[1,3]

Background: CT scans are the gold standard to measure treatment success of Non-Small Cell Lung Cancer (NSCLC) therapies. In recent years, liquid biopsies became an adequate diagnostic tool especially in advanced disease stages. **Method:** Here, we investigated very early tumor response of patients receiving chemotherapy or targeted therapies using a panel of already established and explorative liquid biomarkers. Blood samples from patients were taken at baseline and day + 1 for the chemotherapy cohort (n = 25) and at baseline, day +7 and +14 for the targeted therapy cohort (n = 25). DNA mutational load, a panel of 17 microRNAs, glycodelin, glutathione disulfide, glutathione, soluble caspase-cleaved keratin 18 (M30 antigen) and soluble keratin 18 (M65 antigen) were measured using serum and plasma from patients. Baseline and first follow-up CT scan were evaluated by an experienced radiologist and correlated with biomarker data. **Result:** In the majority of patients a decrease in glycodelin abundance as well as mutational load coincided with clinical response as assessed by CT scan. Consequently, an increase of these biomarkers implicated progressive disease. Among the measured miRNAs, miR-103, miR-628-3p, and let-7e showed largely similar behavior within individual patients upon treatment initiation. The abundance of these miRNAs increased in responding patients and in a subset of patients experiencing tumor progression. Similar observations were seen for the apoptosis markers while the best results were obtained with the detection of M65. **Conclusion:** Taken together, several investigated biomarkers showed high potential for an early response capturing in defined NSCLC cohorts.

Keywords: NSCLC, Biomarker, Early Response Capturing

EP1.11-21 LUNG CANCER SCREENING PILOT IN ISRAEL

S. Shilo[1], S. Verner[1], L. Ipale-Zvi[1], I. Luria[2], L. Guranda[2], A. Agbarya[2], D. Shaham[3], N. Peled[2]

[1]*The Israel Lung Cancer Foundation, Rehovot/Israel,* [2]*ASSUTA Medical Center, Tel-Aviv/Israel,* [3]*HADASSAH Medical Center, Jerusalem/Israel*

Background: Lung cancer kills more people than any other cancer, both in Israel and worldwide. In israel 2000 die from the disease each year where the prevalence of smoking is 22.5% above age 21. There is not yet a national lung cancer screening program in Israel, therefore the Israeli Lung Cancer foundation (ILCF) initiated and funded in cooperation with Assuta Medical centers, a pilot program, ILCF-A, calling participants at risk to come and get checked. The activity took place during the international Lung Cancer awareness month, November 2018. **Method:** A call for free lung cancer screening was published and promoted on Facebook. People who enlisted filled a questionnaire to evaluate eligibility for screening, which was age 55–74 years, 30 pack-year of smoking history and current smokers or ones who quited within 15 years. There was only a screening arm and LDCT was performed for all subjects. CT reporting and management was performed using LUNGRADS. **Result:** Overall 90 subjects were eligible and underwent screening of which, 45% were women and 55% men. The average age of subjects was 63 and the average pack years was 45. Most of the subjects were current smokers. In one third of the subjects, nodules were not detected., when detected, average size of nodules was 3.25 mm. Of all subjects, eight were classified with positive results. Four with LUNGRAD score of 3 are under LDCT follow-up. Of the four who had LUNGRAD score of 4, One subject was diagnosed with stage 1 Lung Cancer and had a successful surgery, two subjects were found to be healthy by PET-CT and Bronchoscopy and 1 is still under investigation. Lung Cancer detection rate was 1.11% and FP rate was 7.7%. **Conclusion:** The ILCF-A trial provided evidence that Lung Cancer Screening in Israel is beneficial. In addition, raising awareness and calling the public to come get screened via digital media has an impact. Despite the limitation of this small study, results of cancer detection rate and FP rates were comparable with NLST and NELSON trials. Although the smoking rate of women in Israel is more then half then that of men (12% compared with 27%), their responsiveness for undergoing screening was as high. Based on this promising evidence, Lung Cancer National Screening program in Israel is recommended and feasible.

Keywords: Screening, Awareness, Pilot study

EP1.11-22 INCORPORATING GENETIC COUNSELING INTO THE THORACIC ONCOLOGY UNIT: A PILOT PROJECT IN THE REAL WORLD

G. Pacheco Cuéllar, K. Campos-Gomez, J.J. Valdéz-Andrade, S. Campos-Gomez

Thoracic Oncology Unit, Centro Oncologico Estatal Issemym, Toluca de Lerdo/Mexico

Background: Lung Cancer (LC) is the 6th cause of cancer death in Mexican population. Genetic counseling (GC) in LC is not often offered in the Oncology departments in Mexico. CG is a process including education, genetic cancer risk evaluation, guidance about Genetic Testing (GT), and psychosocial support. Germline mutations in *ATM, TP53, BRCA2, EGFR*, and *PARK2* cause a small percentage of LC; those patients (pts) could have benefits such as identify the genetic etiology, adjust surveillance, direct therapy, calculate transmission risk and even struggle with stigma. There are no clear criteria to refer LC pts to CG/GT. We started a GC service to identify which pts would benefit of GT. Herein, we describe our pilot project **Method:** We reviewed medical records (MR) and offered GC to the new LC pts from Sept2018-Feb2019. The main objectives were: identify patterns of hereditary cancer syndromes, and analyse pedigrees of pts carrying the *EGFR* T790M mutation prior to treatment. We collected clinical, familial and demographic variables through the CG session. We reviewed the liquid biopsy results for *EGFR, ALK* and *ROS*. CG also included supportive measures and recommendations for GT according to the personal and family history (FH). No germline testing was available. **Result:** 79 cases were reviewed (66 MR and 13 CG sessions) Mean age was 61.54y (range 26-88). 45(57%) were females. 57% (45) were smokers. 40(50.6%) had positive FH. 8 had at least 1 member with LC, notably 1 had 3 relatives with LC. 21(26.58%) had at least 2 relatives with Cancer. Two pts had 7 and 10 relatives with CA. *EGFR* was mutated in 16 (20.25%), but T790M prior to therapy was found on 2 pts; they had no FH of LC. 3 tested positive for *ALK*, none tested positive for *ROS*. Pts with FH tended to be younger (p=0.046). 10 (12.65%) pts meet criteria for GT according to FH for breast, ovarian, prostate and colon cancer; 1 of those relatives tested negative for *BRCA1&2* for Ovarian CA. **Conclusion:** We think that implementing this service could increase the awareness of the potential use of GC in LC. Our sample is small, nonetheless we could identify at least 10 pts who would benefit of GT: multigene testing would be needed at least for these pts. Recognise the cases with hereditary background could bring many advantages to pts and their families. We expect to offer GT to LC pts and eventually, measure the potential advantages against stigma.

EP1.11-23 PROTOCOL FOR A RANDOMIZED CONTROLLED TRIAL OF FDG-PET-CT IN FOLLOW UP OF STAGE II-IIIA NSCLC POST TREATMENT

R. Stirling[1], M. Voskoboynik[2], J. Holland[3], J. Zalcberg[4]

[1]*Respiratory Medicine, The Alfred Hospital, Melbourne/Australia,* [2]*Medical Oncology, The Alfred Hospital, Melbourne/Australia,* [3]*Department of Epidemiology and Public Health Medicine, Monash University, Melbourne/Australia,* [4]*Department of Respiratory Medicine, The Alfred Hospital, Melbourne/Australia*

Background: Early stage Non-Small Cell Lung Cancer (NSCLC) accounts for some 70% of all lung cancer and, although curative treatment may be an option, the 5 year survival remains poor at just over 50%. If cancer recurrence or new disease following initial treatment could be detected earlier, especially whilst still asymptomatic, overall survival may be improved by enabling the earlier use of modern effective salvage therapies. Currently, there is limited evidence, and no consensus in Australia or internationally, on the most effective surveillance strategy following curative treatment. Hence, there is a critical need for a prospective study to examine whether a modern approach to surveillance imaging with PET-CT to detect NSCLC recurrence or new disease earlier and whilst still asymptomatic will not only improve survival but is cost effective. **Method:** We propose a randomised controlled trial of systematic PET-CT for follow up of patients treated with curative intent for stage II-IIIA NSCLC at hospitals across Australia. Patients will be randomised to either usual care or systematic PET-CT 6 monthly over 3 years and followed for 5 years. Patients with new or recurrent disease will be referred for treatment to their usual clinical team and treatment details collected. The primary outcome of this study will be overall survival. Secondary outcomes include, 1. Detection rate for new tumours and a/symptomatic recurrence 2. Number/type of investigations used in the control arm. 3. Number/type of investigations used in the evaluation of new problems. 4. False positive/negative detection rate. 5. Cost effectiveness analysis. 6. Patient experience. Study design is a 2 arm trial with 1:1 randomisation to routine PET-CT surveillance added to usual care (or usual care alone), commencing 6 months after surgery or curative radiotherapy. The study will be stratified by centre, stage, curative therapy and ongoing smoking status. **Result:** Section not applicable **Conclusion:** The study results will define for each stage of disease, whether active surveillance with PET-CT added to usual care prolongs survival compared to usual care. It will also allow for collection of real-word data to understand of what constitutes usual care such that the mortality from the commonest cause of cancer death in our community.

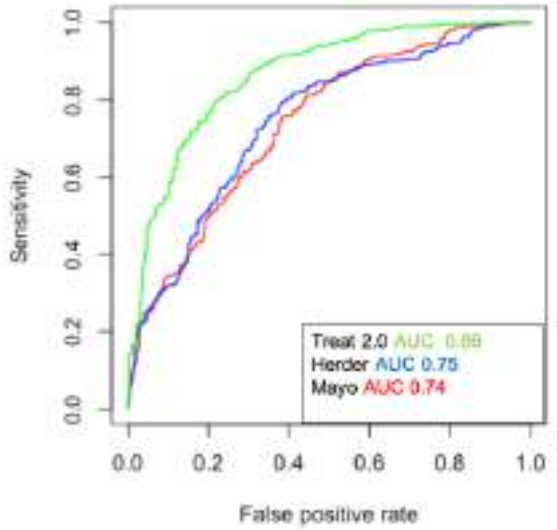
EP1.11-24 THE TREAT MODEL 2.0: PREDICTING LUNG CANCER IN PATIENTS SEEKING CARE IN HIGH-RISK CLINICS

M. Shipe[1], A. Maiga[1], S. Deppen[1], V. Welty[1], J. Blume[1], M. Aldrich[1], C. Montgomery[1], A. Dickerson[1], J. Crockett[1], L. Vaszar[2], C. Williamson[3], S. Regis[4], B. Mckee[3], J. Isbell[5], O. Rickman[6], R. Pinkerman[7], E. Lambright[1], J. Nesbitt[1], P. Massion[6], E. Grogan[1]

[1]*Vanderbilt University Medical Center, Nashville/United States of America,* [2]*Mayo Clinic, Scottsdale/United States of America,* [3]*Thoracic Surgery, Lahey Hospital and Medical Center, Burlington/United States of America,* [4]*Lahey Hospital & Medical Center, Burlington/United States of America,* [5]*Memorial Sloan Kettering Cancer Center, New York/United States of America,* [6]*Vanderbilt University Medical Center, Nashville/United States of America,* [7]*Tennessee Valley Healthcare System, Nashville/United States of America,*

Background: Appropriate risk-stratification of indeterminate pulmonary nodules (IPNs) is necessary to estimate the best diagnostic strategy. Validated models for patients with high-risk IPNs are poorly calibrated. We sought to expand our previous Thoracic Research Evaluation And Treatment (TREAT) model into a more generalized, robust model for lung cancer prediction, the TREAT 2.0. **Method:** A total of 1402 patients with known or suspected lung cancer were used to recalibrate the TREAT 1.0 model. Clinical data and patient demographics were retrospectively collected from six clinics located in four U.S. states. Six datasets were divided into 3 clinical groups: patients who presented to a pulmonary nodule clinic (n=375), patients who presented to an outpatient thoracic surgery clinic (n=553) and patients who presented for surgical resection (n=474). A logistic regression model using multiple imputation was developed and validated. Model variables included age, body mass index, gender, smoking pack-years, size of nodule, spiculation, growth over time, location in upper lobe, prior cancer history, pre-operative FEV1, pre-operative symptoms, FDG-PET positivity, and clinical group. The discrimination and calibration of the TREAT 2.0 model was estimated and compared to two other common models for lung nodules, the Mayo Clinic and Herder models. **Result:** Lung cancer prevalence was as follows: pulmonary nodule clinic 42%, thoracic surgery clinic 73%, and surgical resection cohort 90%. The strongest predictors of cancer were clinical group, age, nodule growth, PET positivity, and smoking pack-years. The median TREAT 2.0 area under the receiver operating curve (AUC) for the imputed dataset was 0.86 (95% confidence interval (CI), 0.86-0.87) and the Brier score was 0.13. The TREAT 2.0 model had better accuracy ($p < 0.001$) (Figure 1) and calibration than the Mayo Clinic (AUC =0.74 95% CI: 0.74-0.75; Brier score=0.21) or Herder models (AUC=0.75; 95%CI: 0.74-0.75 and Brier score=0.19).



Conclusion: The TREAT 2.0 model is more accurate and better calibrated than the Mayo Clinic or Herder models in patients presenting with nodules at high risk for lung cancer. Nodule calculators such as the TREAT 2.0 that account for variation in lung cancer prevalence with a variable for clinical group may improve generalizability and increase use in clinical practice.

EP1.12 SMALL CELL LUNG CANCER/NET

EP1.12-01 DOES PCI STILL HAVE A ROLE IN LIMITED SCLC?

I. Yehonatan, D. Geffen, O. Belochitski, K. Lavrenkov, I. Goldstein, I. Shelef, L. Roisman, N. Peled

Soroka University Medical Center, Beer-Sheva/Israel

Background: Prophylactic cranial irradiation (PCI) has long been an integral part of treatment protocols for limited stage small cell lung cancer (SCLC). PCI stands for "prophylactic" while it may be not really prophylactic, rather therapeutic for un-detectable brain disease. **Method:** A survey of 39 questions was conducted on the online platform "Survey Monkey" for practicing oncologists, radiotherapists, pulmonologists and thoracic surgeons. The aim of this survey is to establish a practice baseline for a future multicenter study of overall survival (OS) benefits of PCI versus MRI follow-up in limited SCLC. **Result:** 41 respondents participated from 14 European countries (26 oncology centers) and from 4 US radiotherapy centers: medical oncologists (31%), radiation oncologist (25%), pulmonologists (34%). Brain imaging at diagnosis of SCLC is performed by MRI in 83% and CT with contrast in 49%. Brain follow up after chemotherapy is performed by MRI in 49%, CT with contract in 41%, and no imaging in asymptomatic patients in 20%. PCI is recommended to 67% of patients and performed immediately after the last chemotherapy in 37%, or 2 months after chemotherapy in 49%. The most important criteria whether patient needs PCI are performance status and response to chemotherapy. The most common schedule of PCI is 25Gy in 10 fractions, 41% of respondents. In case of a single brain metastasis after PCI the 1st choice of treatment is SRS, in 93%. Regarding the role of PCI 46% of respondents think that PCI prevents brain metastases from occurring, and 54% think that PCI treats occult brain metastases. **Conclusion:** The lack of clinical trials about PCI for limited SCLC patients is undisputed. Our survey shows practice patterns to PCI for patients with limited SCLS depends on Institution and/or specialty. These results establish a practice baseline for a multicentral trial of PCI versus MRI observation, and 93% of our respondents agreed to take part in this trial.

EP1.12-02 SCLC TREATMENT UPTAKE AND SURVIVAL OUTCOMES: A 2-YEAR COMPARISON BETWEEN 2 TERTIARY REFERRAL CENTERS IN ALBERTA, CANADA

A. Elegbede[1], F. Hao[1], M. Dean[1], A. Gibson[1], D. Bebb[2]

[1]*University of Calgary, Calgary/Canada,* [2]*Alberta Health Services, Calgary/Canada*

Background: Although the guideline recommend treatment for small cell lung cancer (SCLC) has not changed for several decades, real world evidence on patterns of practice and outcome are scarce. We compared two similar sized cancer care centers in the province of Alberta over a two-year period for experiences with both extensive stage (ES) and limited stage (LS) SCLC diagnoses, treatment and survival outcomes **Method:** Retrospective analyses were conducted on the clinical data of SCLC patients retrieved from the Glans-Look Lung Cancer database. All SCLC patients diagnosed between 2015 and 2016 at the Tom Baker Cancer Centre (TBCC), Calgary and Cross Cancer Institute (CCI), Edmonton were included. The characteristics of patients seen at the two institutions were compared using the Fisher Exact test. The overall survival (OS) outcome based on guideline recommended 1st and 2nd line SCLC treatments as well as treatment location was estimated with Kaplan Meier survival analysis and multivariate Cox Proportional Hazard model. **Result:** Between 2015 and 2016, 105 SCLC patients were diagnosed at the TBCC, Calgary and 243 at CCI, Edmonton, Alberta. Patient characteristics were similar for both centers. 66% (69/105) of SCLC were ES at TBCC as opposed to 78% (189/243) in CCI ($p = 0.024$). Overall, treatment uptake rates in TBCC compared to CCI were as follows: 1st SCLC treatment (chemotherapy, surgery, radiotherapy) rate 88% (92/105) versus 86% (208/243), prophylactic cranial irradiation (PCI) 27% (28/105) vs. 37% (89/243) and 2nd line chemo- and or radio-therapy 33% (35/105) vs. 30% (74/243). 6% (2/36) of LS patients at TBCC compared to 28% (15/54) at CCI had surgery ± adjuvant as their 1st treatment. More ES patients at CCI received chemo & thoracic RT (32 vs.19%, 61/189 and 13/69) as well as PCI (31 vs.16%, 58/189 and 11/69) than those at TBCC. OS at CCI versus TBCC was not statistically different for all SCLC patients (11 vs. 10 months, $p = 0.217$; HR = 1.278, 95% CI: 0.978 -1.671, $p = 0.072$) nor when we stratified patients by LS or ES. **Conclusion:**

Despite subtle variation in the uptake of PCI, surgical resection of peripheral LS, management patterns for SCLC patient, including the uptake of second line treatment were consistent between the two geographically separate centers. It is reassuring that similar survival outcomes can be achieved in the real world setting by the adoption of standard practices across a single health administered jurisdiction.

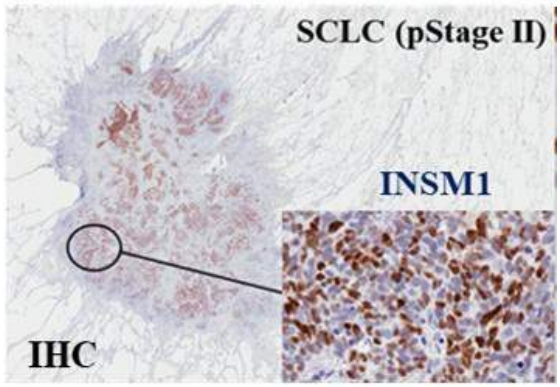
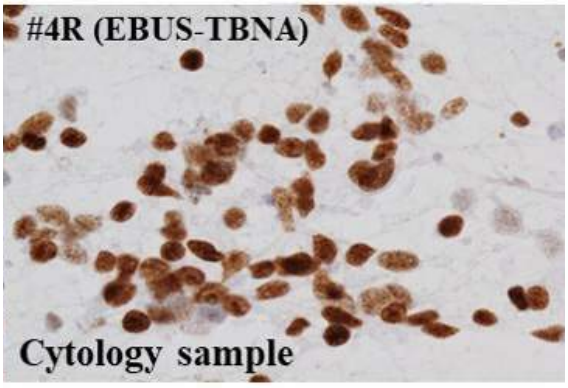
EP1.12-03 THE SIGNIFICANCE OF INSM1 EXPRESSION IN SMALL CELL LUNG CANCER

K. Fujino[1], Y. Motooka[1], R. Matsushima[1], T. Ito[2], M. Suzuki[1], K. Yasufuku[3]

[1]*Kumamoto University Hospital, Kumamoto/Japan,* [2]*Kumamoto University, Kumamoto/Japan,* [3]*University Health Network, Toronto/Canada*

Background: We previously demonstrated that INSM1 expressed in NE tumors (NETs) exclusively and INSM1 is a highly sensitive and specific immunohistochemical (IHC) marker in NETs, such as small cell lung cancer (SCLC). In the present study, we investigated 1) diagnostic performance of INSM1 in the diagnosis of SCLC in various types of samples 2) the association of INSM1 with clinical course. **Method:** We evaluated INSM1 as an IHC marker in 384 formalin-fixed paraffin-embedded lung cancer samples (291 surgically resected samples (90 SCLCs and 201 NSCLCs) and 55 CT-guided biopsy samples (25 SCLCs and 30 NSCLCs)), in 50 cytology samples (25 SCLC metastatic lymph nodes and 25 NSCLCs) obtained by endobronchial ultrasound-guided transbronchial needle aspiration. The mRNA expression levels of INSM1 was examined using qRT-PCR in 37 SCLCs and 40 NSCLCs. We evaluated the association of INSM1 expression (IHC and qRT-PCR data) with clinical course. **Result:** INSM1 was expressed in 94% of formalin-fixed paraffin-embedded SCLC samples (109/115) and in 92% of cytology SCLC samples (23/25). Whereas, 4 out of 231 formalin-fixed paraffin-embedded NSCLC cases (1.7%) had weak expression of INSM1 and none of the cytology NSCLC samples were positive. The mRNA level of INSM1 was significantly higher in SCLCs including in two cases who were INSM1 negative with IHC. No association between IHC positivity and mRNA expression level of INSM1 with evaluated clinical features including overall survival was observed. **Conclusion:** Our study suggests INSM1 is a reliable IHC marker for SCLC in various types of clinical samples. There was no association between INSM1 and clinical courses in the present study.





Keywords: Lung cancer, SCLC, INSM1

EP1.12-04 CAN PROPHYLACTIC CRANIAL IRRADIATION REDUCE NEUROLOGICAL SYMPTOMS IN PATIENTS WITH SMALL CELL LUNG CANCER?

T. Boskovic, N. Secen, S. Vitorovic, M. Sevo, T. Culibrk, D. Bokan

Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica/Serbia

Background: The central nervous system is the usual site of metastasis in patients with small cell lung carcinoma (SCLC). Despite advances in combined treatment modalities, it's the main cause of morbidity in these patients. High prevalence of brain metastases, combined with the poor intracranial penetration of most chemiotherapy regimens used, led to development of prophylactic cranial irradiation (PCI), a preventive radiotherapeutic treatment, which has been shown to be effective in reducing the incidence of brain metastases. Earlier studies showed that patients who had PCI, had reduced rate of symptomatic brain metastasis at one year (14.6% vs 40.4%) and had slightly better overall survival. In Institute for pulmonary diseases of Vojvodina, there are around 1200 newly diagnosed patients with lung cancer in each year, of which around 200 patients (14%) have SCLC. PCI is now routinely administered to patients with SCLC, after a complete/partial response to initial treatment. **Method:** This was a retrospective study conducted at the Institute for Pulmonary Diseases of Vojvodina, Serbia, which included patients diagnosed with SCLC in this institution, between October 2015 - October 2017. The patients were divided into two groups, one who received PCI after complete/partial answer to systemic therapy and chest irradiation, total of 34 patients. The control group consisted of 30 patients, who also had good answer to systemic therapy and chest radiation therapy, but didnt receive PCI. **Result:** In this study, significantly higher percentage of patients in the PCI group (84.8% vs 40.0%) didn't develop neurological symptoms (p= 0.000). In the group of patients who received PCI, only 5 out of 34 (14.7%) developed CNS symptoms, an average of 10 months after completing the PCI. In the control group, 60% (18/30) of patients experienced neurological symptoms, on average 11 months after diagnosis. Data analysis found that patients in PCI group were 8.4 times less likely to develop neurological symptoms. Also, it was confirmed that overallsurvival was better for patients who received PCI after systemic and irradiation treatment, the mean OS of patients in the PCI group was 19.0 months, compared to the control group where it was 15.4 months. **Conclusion:** The authors strongly believe that PCI should remain a standard of care for patients with SCLC, after response to initial treatment. If not only for prolonging the overall survival, but also because it improves the quality of life in these patients by reducing the neurological symptoms.

Keywords: SCLC, brain, irradiation

EP1.12-05 IS THERE A ROLE FOR MEDIASTINAL LYMPH NODE DISSECTION IN PULMONARY CARCINOIDS?

D. Niyogi, G. Karimundackal, C.S. Pramesh, S. Jiwnani

Tata Memorial Hospital, Mumbai/India

Background: Pulmonary carcinoids are slow growing tumours with surgery being the mainstay of treatment. Histology(typical/atypical) and nodal status are known prognostic markers. In light of the results of the ACOSOG Z0030 trial, the role of mediastinal lymphnode dissection in surgery for NSCLC is being questioned. This question becomes more pertinent in pulmonary carcinoids, where nodal positivity is known to adversely impact survival and surgery is the only curative treatment option. **Method:** We performed a retrospective analysis of a prospectively maintained database of surgery in pulmonary carcinoids. Data regarding histology, type of surgery, imaging, nodal status, margin status and follow up were captured from the database and where missing, from the electronic medical records. Statistical analysis was performed using SPSS version 20 for Mac. **Result:** 141 patients with pulmonary carcinoid tumours treated with curative intent in a single center from August 2004 to February 2017 were included. 108 (76.6%) were typical carcinoids and 29 (20.6%) were atypical carcinoids. 4 patients were not classified. 120 (86.42%) patients underwent mediastinal nodal sampling or systematic clearance. The median survival in patients undergoing lymphnode dissection was 66 months, where as it was 53.5 months in those who did not(p = 0.43). Twenty (16.66%) patients were node positive. Node positivity rate in typical carcinoids was 11.11%, while that in atypical carcinoids was 27.58% After a median follow up of 57 months, 115 (81.6%) patients are alive and

disease free, 10 (7.1%) are alive with disease, 6 (4.3%) have died due to disease, 6 (4.3%) have died due to other causes. Estimated 5 yr survival in patients with typical carcinoids is 96.9% while that of patients with atypical histology is 67.8%. (p<0.001) Patients with positive nodes had an estimated 5 yr survival of 80.5% while that in node negative patients was 95.37%. (p=0.12). **Conclusion:** In our series, the node positivity rate was higher than reported in literature and this could be seen in both patients with typical and atypical histology. Nodal positivity also showed a trend towards decreased survival showing that it is an important prognostic factor. Lymphnode dissection showed a trend towards improved survival, though not statistically significant. The lack of statistical significance could be attributed to the fewer number of cases in the study and the lower number of events. In view of the relatively low morbidity of the procedure and the lack of any other curative treatment option we suggest that systematic lymph node dissection be performed for all cases of pulmonary carcinoids. A randomized study to answer this question appears unlikely.

Keywords: pulmonary, carcinoid, atypical

EP1.12-06 NEW TREATMENT OPTION FOR ES-SCLC: PATIENT CHARACTERISTICS AND USE OF AN ATEZOLIZUMAB REGIMEN IN THE REAL-WORLD SETTING

Hoffmann-La Roche Ltd, Basel/Switzerland,* [15]*Virginia Cancer Specialists Research Institute, Fairfax/United States of America*

Background: Results from the Phase III IMpower133 study (NCT02763579) were previously made public. Based on improvements in overall survival in patients with extensive-stage small cell lung cancer (ES-SCLC) who received atezolizumab plus carboplatin and etoposide (IMpower133 regimen) vs chemotherapy administered in the 1L setting, the NCCN added this regimen to its guidelines (category 1, preferred) on October 10, 2018. Accordingly, some providers began implementing this regimen in their clinical practice, creating a unique opportunity to characterise its early and broad use in a real-world setting. **Method:** Patients with ES-SCLC who started treatment within 90 days of initial diagnosis and had a confirmed administration of atezolizumab with carboplatin or cisplatin and etoposide (atezo regimen) on or after September 25, 2018, were included from the de-identified Flatiron Health electronic health records–derived database, representing > 280 US cancer clinics (≈ 800 sites of care). Treatment data were analysed through April 30, 2019. Broad use was defined as treatment with the atezo regimen outside of several main clinical trial restrictions (ECOG PS ≥ 2, abnormal laboratory values, cisplatin use or as 2L treatment). Frequencies and percentages are reported. Monthly uptake was defined as the percentage of ES-SCLC patients starting 1L therapy each month who were treated with the atezo regimen. **Result:** Uptake of the atezo regimen increased from 10% in October 2018 to 46% in February 2019 (before FDA approval on March 18, 2019) and 66% in April 2019 (after FDA approval); 143 patients were identified, 92% of whom had ES-SCLC at initial diagnosis (Table). The atezo regimen was used broadly among 46% of patients (18% with ECOG PS ≥ 2, 18% with an abnormal laboratory value, 1% on cisplatin, 17% as 2L ES-SCLC treatment). The median time from ES-SCLC diagnosis to start of the atezo regimen was 16 days for 1L patients and 78 days for 2L patients. Patients treated with the atezo regimen in the 1L were administered atezolizumab at a median of 8 days after start of chemotherapy; those treated in the 2L were typically administered atezolizumab immediately at the start of the line. **Conclusion:** This real-world analysis demonstrates the broad use of the atezo regimen, with nearly half of patients treated outside of several main IMpower133 trial restrictions. Further, a rapid uptake of the regimen even before FDA approval underscores its impact on changing clinical practice and the high unmet need of this patient population.

Table. Characteristics of Patients Treated With the Atezolizumab Plus Carboplatin/Cisplatin and Etoposide Regimen in Routine Clinical Care

Patients, n	143
Treated prior to FDA approval (March 18, 2019), n (%)	101 (71)
Median age at ES-SCLC diagnosis (IQR), years	67 (61, 73)
Aged ≥ 65 years at ES-SCLC diagnosis, n (%)	90 (63)
Female, n (%)	71 (50)
White, n (%)	100 (70)
Smoking history, n (%)	137 (96)
Stage at initial diagnosis, n (%)	
LS	7 (5)
ES	132 (92)
Unknown	4 (3)
ECOG PS, n (%)a	
0 or 1	76 (53)
2+	26 (18)
Unknown	41 (29)
Radiation therapy, n (%)b	14 (10)
LS setting, n	7
ES setting, n	7
Regimen, n (%)	
Atezolizumab, carboplatin, etoposide	141 (99)
Atezolizumab, cisplatin, etoposide	2 (1)
Line of therapy of atezo regimen in ES setting, n (%)	
1L	119 (83)
2L	24 (17)
Median time from ES-SCLC diagnosis to start of line of therapy containing atezo regimen (IQR), days	
1L	16 (11, 26)
2L	78 (59, 98)
Median time from ES-SCLC diagnosis to first administration of atezo within line (IQR), days	
1L	24 (14, 27)
2L	78 (59, 98)
Abnormal baseline laboratory value, n (%)c	26 (18)

1L, first line; 2L, second line; atezo, atezolizumab; ECOG, Eastern Cooperative Oncology Group; FDA, US Food and Drug Administration; IQR, interquartile range; LS, limited stage; PS, performance status. a ECOG PS value closest to within −30 to +7 days of treatment start. b Includes radiation therapy to chest following initial diagnosis of SCLC, including concurrent radiation therapy with systemic chemotherapy, chemotherapy followed by radiation therapy, up-front palliative radiation therapy to the chest or for superior vena cava syndrome. c Abnormal values defined as those not meeting the following definitions: absolute lymphocyte count ≥ 500/μL, lymphocyte count ≥500/μL, absolute neutrophil count ≥ 1500 cells/μL, platelet count ≥100,000/μL, hemoglobin ≥ 9.0 g/dL, aspartate aminotransferase ≤ 5 × upper limit of normal (ULN), alanine aminotransferase ≤ 5 × ULN, alkaline phosphatase ≤ 5 × ULN, serum bilirubin ≤ 1.25 × ULN, serum creatinine ≤ 1.5 × ULN, serum calcium ≤ 12 mg/dL.

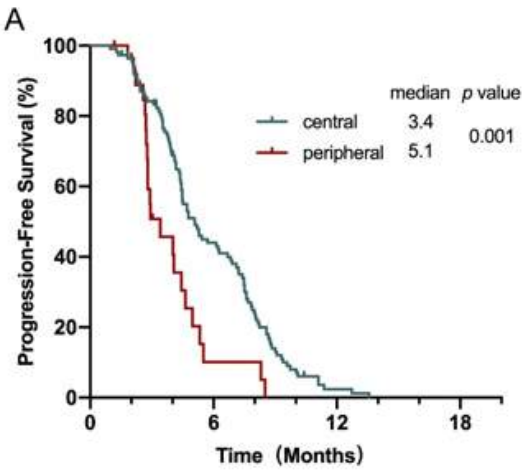
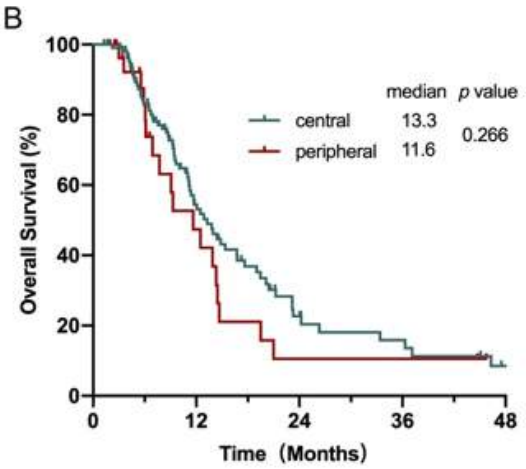
EP1.12-07 HIGH DISCREPANCY OF CHEMOTHERAPY OUTCOMES BETWEEN PATIENTS WITH PERIPHERAL AND CENTRAL SMALL CELL LUNG CANCER

S. Mao[1], Q. Liu[1,2], Y. Liu[1,3], F. Zhou[4], S. Yang[1], Y. Wang[2], X. Yu[2], F. Wu[5], Y. He[6], X. Chen[6], C. Su[1], S. Ren[7], C. Zhou[1]

[1]Shanghai Pulmonary Hospital, Shanghai/China, [2]Shanghai Pulmonary Hospital, Shanghai/China, [3]Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China, [4]Shanghai Pulmonary Hospital, Tongji University School of Medicine, SHANGHAI/China, [5]Tongji University, Shanghai/China, [6]Shanghai Pulmonary Hospital, Tongji University, Shanghai/China, [7]Shanghai Pulmonary Hospital, Thoracic Cancer Institute, Tongji University School of Medicine, Shanghai/China

Background: Previously we found that imaging central and peripheral LCNEC has distinct clinicopathologic features and survival. As LCNEC and SCLC are all neuroendocrine tumor, this study further investigated whether imaging tumor location impact the outcome of first line chemotherapy in patients with small cell lung cancer extensive disease. **Method:** Patients with ES-SCLC diagnosis between May 2014 and September 2015 in Shanghai Pulmonary Hospital, Tongji University were included. Contrast enhanced CT scans were reviewed retrospectively for tumor location (central or peripheral) and imaging features. The clinical characteristics and outcomes of chemotherapy were collected and compared. **Result:** 140 patients were identified with a median age of 64, 89.3%, 76.4% and 98.6% were male, smokers and ECOG PS 1 respectively. Among them, 135 received etopside based chemotherapy and 5 received irinotecan based chemotherapy.111 (79.3%) had central-type and 29 (20.7%) had peripheral-type SCLC. The patients characteristics were similar between the central and peripheral subgroups. Peripheral subgroup showed less marginal GGO (65.5% vs 84.7%, p=0.02), obstructive pneumonia (48.3% vs 80.2%, p=0.001), obstructive atelectasis (3.4% vs 40.5%, p<0.001) and effusion (37.9% vs 61.3%, p=0.011) than central tumors. Peripheral subgroup had lower ORR (44.8% vs 73%, p=0.004) and DCR (79.3% vs 92.8%, p=0.042). The median PFS was 4.6 months in the entire cohort and peripheral subgroup had significantly short PFS than central one (median PFS: 3.4 vs 5.1 months, p=0.001, figure A). The median OS was 12.9 months and peripheral subgroup had numerally short OS (median 11.6 vs 13.3 months, p=0.266, figure B).





Conclusion: Central type tumors account for most of SCLC, while patients with peripheral tumors had a significantly lower ORR, shorter PFS and OS after the first line chemotherapy than central type.

EP1.12-08 PROGRAMMED DEATH-LIGAND 1 AND HUMAN LEUKOCYTE ANTIGEN CLASS I EXPRESSION IN VARIOUS NEUROENDOCRINE TUMORS OF THE LUNG

Y.B. Han, H.J. Kwon, E.-S. Kim, H. Kim, J.-H. Chung

Seoul National University Bundang Hospital, Seongnam/Korea, Republic of

Background: Pulmonary neuroendocrine tumors (PNETs) encompass a broad spectrum of tumors including typical carcinoid (TC) and atypical carcinoid (AC) tumors, small cell lung carcinoma (SCLC) and large cell neuroendocrine carcinoma (LCNEC) with important pathological, biological and clinical differences. Recently, FDA grants Atezolizumab regimen for use in combination with carboplatin and etoposide for the frontline treatment of patients with extensive stage SCLC. The aim of this study was to investigate Programmed death-ligand 1(PD-L1) and Human leukocyte antigen (HLA) class I expression patterns in PNETs. **Method:** PD-L1 and HLA class I expression was evaluated by immunohistochemistry in a total of 37 resected lung neuroendocrine tumors using tissue microarray. Correlations between the expression of HLA class I/PD-L1 and clinicopathologic features and prognostic significance were analyzed. **Result:** Of the 37 patients enrolled in this study, 32 patients (86.5%) were male and the median age was 66 years (range, 35–81 years), and 28 patients (75.6%) were current or ex-smokers. The pathologic stage (AJCC 8th) in the patients at presentation was IA(including IA1, IA2, IA3) in 11 patients (24.3%), IB in 4 patients (10.8%), IIA in 1 patients (2.7%), IIB in 4 patients (10.8%), IIIA in 10 patients (27.0%), IIIB in 4 patients (10.8%), and IVA in 1 patients (2.7%). Histologically, 6 patients (16.2%) were diagnosed TC, 5 patients (13.5%) with AC, 9 patients (24.3%) with SCLC, and 17 patients (45.9%) with LCNEC. Positive PD-L1 expression in tumor cells was 29.7% (11/37, 1% cut-off), and the numbers (proportions) of positive PD-L1 expression according to histologic subtypes were as follows; TC/AC/SCLC/LCNEC, 2(33.3%)/2(40.0%)/1(11.1%)/6(35.2%). HLA class I expression was reduced in 86.5% (32/37). The numbers (proportions) of reduced HLA class I expression according to histologic subtypes were as follows; TC/AC/SCLC/LCNEC, 5(83.3%)/5(100%)/8(88.9%)/14(82.4%). In survival analysis, (median overall survival (OS); 56 months) there was no significant difference in OS according to PD-L1 and HLA class I expression status. However, two cases with HLA(+)/PD-L1(+) showed more unfavorable survival curves and three cases with HLA(+)/PD-L1(-) showed a tendency of more favorable clinical course. **Conclusion:** Lung NETs shows frequent HLA class I reduction and variable PD-L1 expression. Although this is a preliminary study including small number of NETs, the finding that NETs with HLA(+)/PD-L1(-) showed favorable clinical course suggests immune microenvironment might be one of the important biomarker for NETs of the lung.

Keywords: Pulmonary neuroendocrine tumors, Programmed death-ligand 1, Human leukocyte antigen class I

EP1.12-09 EGFR-MUTANT ADENOCARCINOMA TRANSFORM INTO SMALL-CELL LUNG CANCER: REAL OR NOT

Y. Zhang, R. Li, L. Jiang

West China Hospital of Sichuan University, Chengdu/China

Background: Small-cell transformation is well known as one of the acquired resistance mechanism to EGFR-tyrosine kinase inhibitors (TKIs), nevertheless we recently found an interesting phenomenon that most small-cell transformations actually are combined small-cell lung cancer before TKI treatments rather than pure adenocarcinoma. **Method:** We retrieved 13 patients with former pathological diagnosis of adenocarcinoma before TKI therapies from 1,082 cases with SCLC component and compared the previous biopsy results of the these cases. All the previous adenocarcinomas slides were gathered and were reviewed one by one carefully again by an advanced pathologist. **Result:** All patients were stage IV EGFR-mutant adenocarcinomas and treated with EGFR-TKIs before SCLC transformation diagnosed.

After their disease progress, re-biopsy were performed to identify resistance mechanism. Previous pathology showed only one patient was diagnosed with combined SCLC mixed with adenocarcinoma before TKI, the rest 12 cases were pathologically diagnosed of pure adenocarcinoma and identified as small-cell transformation. We amazingly found that 9 of 12 patients actually contained very few SCLC component when we reviewed these cases, varying from less than 1% to 5%. Dubious SCLC components were found in two patients. Only one patient was a real small-cell transformation and we didn't find any SCLC mixture on previous adenocarcinoma sections. In conclude about 75% (9/12) of cases originally diagnosed with small-cell transformation were actually pseudo-small-cell transformation. Combined SCLC with very few SCLC components were prone to be misdiagnosed into pure adenocarcinoma. **Conclusion:** Most metastatic lung cancers were diagnosed with small biopsy, in which the potential mixture of SCLC was much more easily to miss, so the pseudo-small-cell transformation may be more common than estimate in real world. It's worth noting that careful review again of the previous adenocarcinoma sections is essential before diagnosis of small-cell transformation.

Background: LCNEC is an aggressive, biologically heterogenous carcinoma which can be molecularly characterized as SCLC-like and NSCLC-like. Accurate distinction of molecular subset is of major clinical relevance since it may guide treatment choices in LCNEC. Here we determined the genomic characteristics of the two LCNEC subsets in a Chinese cohort to clarify their correlations with traditional lung cancer histologies. **Method:** FFPE samples from 31 LCNECs were sequenced using a 520-cancer-related gene panel, with an average sequencing depth of 1385X. Comparative mutational analysis was conducted between NSCLC-like LCNECs from our cohort and adenocarcinomas from TCGA dataset **Result:** Despite similar clinical features in terms of stage and age at diagnosis, NSCLC-like (42%, 13/31) and SCLC-like (32%, 10/31) subsets from LCNEC displayed distinct molecular characteristics. NSCLC-like subset harbored significant higher mutation frequencies of *STK11, KEAP1* and *FAT3* (53.8%, 38.5% and 38.5%, p=.007, .046 and .046), while SCLC-like subset was characterized by highly mutated *RB1* (100%, p<.001) and *PTEN* (50%, p=.007). Compared with TCGA adenocarcinomas, NSCLC-like LCNEC displayed more frequent mutations in *TP53*, *STK11*, *APC*, *KMT2D* and *SMARCA4* (76.9%, 53.8%, 30.8%, 30.8% and 23.1%; p=.043, .004, .045, .005 and .049). In addition, potential targetable alterations were present in 46.2% (6/13) pts of NSCLC-like subset. For those advanced stage pts, 2/5 NSCLC-like and 5/5 SCLC-like pts received relevant chemotherapy according to their molecular characteristics. The clinical outcomes of these pts are still under follow-up. **Conclusion:** This study demonstrates the distinct molecular features between NSCLC-like and SCLC-like subsets, and highlights the predominant genomic similarity and separate entities between NSCLC-like LCNEC with adenocarcinoma. Given the evidence that genomic profiling may aid in informing treatment decisions for pts with LCNEC, our study indicates that, based on accurate molecular typing, 46.2% NSCLC-like pts may benefit from potential targeted therapy and the rest of them may be more suitable to receive NSCLC-chemotherapy

EP1.12-11 EFFECT OF TREATMENT MODE ON PROGNOSIS OF RESECTABLE LIMITED-STAGE SMALL CELL LUNG CANCER

F. Teng, J. Li, P. Xing, X. Hao

National Cancer Center/National Clinical Research Center for Cancer/Cancer Hospital, Chinese Academy of Medical Sciences and Peking Union Medical College, Beijing/China

Background: The optimal choice of post-operative treatment mode for resectable limited-stage small cell lung cancer (SCLC) is controversial in clinical practice. Different treatment modes may have different effects on prognosis of small cell lung cancer after resection. **Method:** Data from a total of 122 patients with limited-stage SCLC undergoing operation were collected at our Cancer Hospital from 2012 to 2016. Clinical and pathological features, and treatment modes (including surgical methods, postoperative adjuvant radiotherapy and chemotherapy, prophylactic brain radiotherapy, etc.) were compared in small cell lung cancer after resection .The survival outcomes among different factors were analyzed by Kaplan-Meier method, and the survival differences among different factors were compared by log-rank method. Multivariate cox regression analysis was used to explore independent prognostic factors. **Result:** The median follow-up time was 54.23 months. Among 122 patients, the 1-, 3- and 5-year overall survival (OS) rates were 95.08%, 75.14% and 63.79%, respectivly. The 1-, 3- and 5-year recurrence-free survival (RFS) rates were 80.99%, 66.62% and 61.86%, respectively. Recurrences were diagnosed in 56 (45%) patients, including 22 (39%) with brain metastasis, 15 (27%) with intrapulmonary recurrence, 7 (13%) with bone metastasis, 6 (11%) with hepatic metastasis, and 6 (11%) with other metastasis. Operation patterns affected OS. 116 patients received lobectomy and 6 patients received pneumonectomy. Median OS of these two groups were 68.37 and 35.37 months, respectively (p = 0.028). The T stage affected the postoperative OS. The median OS of T1,T2,T3 were 65.87, 71.29 and 29.92 months, respectively (p = 0.021). The disease-free survival (PFS) and OS of patients receiving adjuvant chemotherapy or combined with radiotherapy were longer than those receiving surgery only. The median PFS of adjuvant chemotherapy group, chemotherapy and radiotherapy combination group, and simple surgery group were 69.01,53.87 and 19.37 months, respectively (p=0.002). Accordingly, the median OS were 70.6, 65.56 and 30.8 months (p=0.002). Patients with postoperative prophylactic cranial irradiation (PCI) had a longer OS than those without PCI (62.28 vs. 78.84 months, p=0.028). **Conclusion:** As for patients with resectable limited-stage SCLC,the 5-year survival rate of patients with surgery is higher than those without. Lobectomy is the optimal surgery mode, and adjuvant chemotherapy combined with prophylactic cranial irradiation after operation can significantly prolong the OS.

Keywords: small cell lung cancer, surgery, Chemotherapy

EP1.12-12 FACTORS ASSOCIATED WITH SURVIVAL OUTCOMES AMONG RELAPSED SCLC DIAGNOSED AT A CANADIAN CANCER CENTRE

A. Elegbede[1], F. Hao[1], M. Dean[1], A. Gibson[1], D. Bebb[2]

[1]*University of Calgary, Calgary/Canada,* [2]*Alberta Health Services, Calgary/Canada*

Background: The 5-year survival rate for small cell lung cancer (SCLC) is only 7%. This poor survival is partly accounted for by sparse management options for the high proportion of patients developing disease progression or recurrence after their initial treatment (Koinis et al. 2017). Clinical guidelines recommend 2nd line chemotherapy only for SCLC patients who relapse ≥90 days after their 1st line treatments. This study examined factors predicting favorable survival outcomes among relapsed SCLC patients seen at the Tom Taker Cancer Centre, Alberta Canada. **Method:** Retrospective analyses were conducted on clinical data of SCLC patients retrieved from the Glans-Look Lung Cancer database. All SCLC patients diagnosed between 2010 and 2016 who completed ≥ 4 cycles of 1st line platin doublets or single-agent etoposide and then relapsed during or after their initial treatments were included. The characteristics of patients relapsing ≥90 versus <90 days were compared using the Fisher Exact test. The overall survival (OS) was estimated using the Kaplan Meier survival and multivariate Cox Proportional Hazard model. **Result:** 190 SCLC patients were identified, of which 68% were extensive stage (ES), 57% were female, and 98% were smokers (Ex or current), with a median age of 67 at diagnosis. Most patients relapsed in ≥90 days:

57/60 (95%) for Limited stage (LS) and 102/130 (79%) for ES (p = 0.003). 48% of LS and 45% of ES received 2nd line systemic treatment (2L). In ES, receiving 2L cisplatin/etoposide was associated with better survival compared to not receiving 2L (HR=0.426, p=0.016) and having a longer relapse interval (≥90 days) was also associated with better survival (HR=0.539, p=0.015). Stratifying by relapse intervals, receiving 2L was associated with better survival in both the ≥90 (445 vs 286 days, p = 0.049) and <90 days (301 vs 219 days, p = 0.059) strata. In LS, favorable OS was associated with initial thoracic radiation (RT) receipt (HR=0.237, p=0.024) and no distant metastases (DM) at relapse (HR=0.257, p=0.005). Also of note, 83% LS and 21% ES had RT (p < 0.001) and at relapse, 52% LS and 92% ES had distant metastases. **Conclusion:** The median OS in relapsed SCLC is low but is at least improved with 2L receipt in relapsed ES patients irrespective of the time to relapse (≥90 or <90 days). Hence, more effective therapy is required for these patients.

Keywords: Small Cell Lung Cancer, 2nd Line Chemotherapy, Overall Survival

EP1.12-13 CONSOLIDATION RADIOTHERAPY IN EXTENDED DISEASE SMALL CELL LUNG CANCER: SINGLE CENTER EXPERIENCE

K. Stanič, J. But-Hadžić, M. Vrankar

Institute of Oncology, Ljubljana/Slovenia

Background: Consolidation radiotherapy in extended disease small cell lung cancer (ED-SCLC) showed improved 2 year overall survival (OS) in patients who responded to chemotherapy according to the results of CREST trial and many centers included this treatment in local guidelines. **Method:** We retrospectively reviewed medical records of patients with small cell lung cancer (SCLC) treated at the Institute of Oncology Ljubljana from January 2010 to December 2014. Median follow up was 65 months. We compared median overall survival (mOS) of patients with ED-SCLC treated with chemotherapy (ChT) only and those treated with ChT and consolidation radiotherapy (RT). We also compared mOS of patients treated with different consolidation doses. **Result:** Out of 703 patients 411 (58.5%) had ED-SCLC and were included in our analysis. Of those 59 patients received only best supportive care (BSC), 66 patients had RT only, 113 had ChT only and 173 patients had combination of ChT and RT. Median OS of patients who had either BSC or RT only was poor, 1.86 and 2.42 months, respectively. Patients who had any form of additional chest irradiation had significantly better mOS than patients with ChT only (9.9m vs 7.6m, p=0.002). Consolidation radiotherapy was delivered to 76 patients. Patients with consolidation RT had significantly longer mOS compared to patients with ChT only, 11.1 months (CI 10.1-12.0) vs 7.6 months (CI 6.9 - 8.5), p<0.001. They also had longer 1-year OS (44% vs 23%) as well as 2-year OS (10% vs 5%). Different fractionation schemes were used for consolidation RT. Patients with 45 Gy (in 18 fractions) had better mOS compared to lower doses 30-36Gy (in 10-12 fractions), 17.2 months vs 10.3 months, p=0.03. Patients with higher dose of consolidation RT had better 1-year OS (68%) than those with lower dose (30%) and also better 2-year OS (18% vs 5%). **Conclusion:** Consolidation RT improved mOS in ED-SCLC as compared to ChT only. Higher dose of consolidation RT (45Gy) had greater impact on survival than lower doses (30-36Gy).

Keywords: SCLC, consolidation radiotherapy, chemoradiotherapy

EP1.12-14 MULTIPLE PRIMARY MALIGNANT NEOPLASMS IN PATIENTS WITH SMALL CELL LUNG CANCER. THE EXPERIENCE OF OUR CENTER

M. Vaslamatzis, T. Tegos, N. Alevizopoulos, M. Pavlakis, K. Karagiorgou, E. Patila, K. Gioti, D. Exarchos, C. Zisis

Evangelismos General Hospital, Athens/Greece

Background: Treatment and, mainly, modern diagnostic tools during the first diagnosis of the disease and follow-up, seem to improve survival in patients with small cell lung cancer (SCLC) and thus increase the number of patients diagnosed with multiple primary malignant neoplasms. **Method:** The aim of this retrospective study was to estimate and report the incidence of multiple primary malignant neoplasms and discuss the clinical characteristics of this subgroup of patients with SCLC. The study includes all patients consecutively admitted between 1/1983 -3/2019 at the Department of Medical Oncology, Evangelismos General Hospital, Athens, Hellas. **Result:** Five hundred fifty eight patients [386(69%) men, 172(31%) women, 285(51%) with limited and 273(49%) with extended disease] were included in the study. Median age was 63 (33-87)years, median ECOG was 2 (0-4) and median time of follow-up was 18+ (1+ - 696+) months. Three hundred ninety six (71%) had a short period of follow-up ≤24 months (group A), while 162 had a period of follow-up >24 months (group B). Multiple primary malignant neoplasms were detected in 23(4%) patients, 20(5%) men and 3 (2%) women (p<0.05), synchronous in 11(48%) and metachronous in 12(52%) patients, p=NS. The second malignant neoplasms were lung adenocarcinoma, squamous cell lung carcinoma, colon adenocarcinoma, bladder transitional cell carcinoma, head and neck squamous cell carcinoma, prostate adenocarcinoma, NHL, and thyroid follicular carcinoma in 7, 5, 4, 3, 2, 1 and 1 cases respectively. In the group of the 285 patients with limited disease 16(6%) multiple primary malignant neoplasms were observed in relation to 7/273(2.5%) of the patients with extensive disease (0.01< p<0.05). The multiple primary neoplasms were 12/396(3%) and 11/162(7%), p <0.05 in patients of the groups A and B respectively. **Conclusion:** 1. Development of multiple primary malignant carcinomas in patients with SCLC, does not seem to be a rare phenomenon. 2. The great majority of the multiple primary carcinomas (lung adenocarcinomas, squamous cell lung carcinomas, bladder transitional cell carcinomas, head / neck carcinomas) is smoking dependent. 3. The risk was higher in males, in patients with limited disease and in those surviving more than 24 months.

Keywords: Multiple Primary Malignant Neoplasms, SCLC, Second Primary Neoplasms

EP1.12-15 ONCOLOGIC TREATMENTS AND OUTCOMES FOR SMALL-CELL LUNG CANCER PATIENTS WITH BRAIN METASTASES

Background: Brain metastases (BM) are common in patients with small-cell lung cancer (SCLC), and are associated with short survival. Few data are available on this specific population of patients with SCLC and BM, as they are usually excluded from prospective randomized clinical trials. **Method:** We present data on all patients diagnosed with BM from SCLC from the Cancer Register of the Hospital Universitari Dr. Josep Trueta during 2013–2017. Age, gender, and treatment in patients were recorded. Data cut-off for survival analysis was 28th March 2019. **Result:** We identified 50 patients with SCLC and BM. Median age: 66 y (range: 48–82 y); male: 39 (78%). Synchronous BM were observed at the diagnosis of primary lung cancer in 33 (66%) patients. Impact of treatments on median overall survival (mOS) is summarized in Table 1. Only 1 patient received brain surgery (with an OS of 6.5 months). One-third of patients (34%) received best supportive treatment as unique treatment. The 1-year OS was 18% in our study.

Table 1

Treatment	%	mOS (without treatment)	mOS (with treatment)	p-value
Brain radiotherapy	52 %	1.4 m	9.1 m	< 0.000001
Chemotherapy	50 %	1.5 m	6.9 m	=0.003
Brain radiotherapy and chemotherapy	34 %	1.6 m	10.7 m	=0.000331

EPOSTERS

Conclusion: Our real-world data reinforce the need for better therapies to improve the prognosis of patients with SCLC and BM.

Keywords: SCLC, brain metastasis, brain radiotherapy

EP1.12-16 CD47 EXPRESSION AND PROGNOSIS IN PATIENTS WITH SMALL CELL LUNG CANCERCD47 EXPRESSION AND PROGNOSIS IN PATIENTS WITH SMALL CELL LUNG CANCER

N. Hernandez-Pedro[1], M. Orozco-Morales[2], A. Aviles-Salas[1], L. Cabrera-Miranda[2], L. Ramírez-Tirado[2], P. Barrios -Bernal[2], O.G. Arrieta[2]

[1]*Instituto Nacional de Cancerología, Mexico city/Mexico,* [2]*Intituto Nacional de Cancerología, Mexico City/Mexico*

Background: CD47 is an integral membrane protein expressed in all cells. CD47 present two opposing roles in cell survival. CD47 can interact with signal-regulatory protein-α (SIRP-a) on macrophages, prevents phagocytic clearance. Besides, CD47 signaling through the thrombospondin-1 limits self-renewal and suppresses expression of the stem cell transcription factors cMyc, Sox2, Oct4, and Klf4 in non-transformed cells. Data on the clinical significance of CD47 expression in patients with small cell lung cancer remain limited. **Method:** Forty-five naive patients with small cell lung cancer diagnosis were evaluated. Tumor samples obtained by biopsy or surgical resection, were collected for CD47 evaluation. Tumor samples were scored according to the fraction of stained cells at each intensity. The staining intensity of the cell membrane was scored within a scale ranging from 0-3. To determine the prognostic and predictive biomarkers of CD47, patients were stratified according to a cutoff point. This cutoff was optimized as a function of overall survival (OS) using the X-tile and Cutoff Finder software **Result:** Preliminary results showed that CD47 was present in 26.7% of population. We stratified the CD47 in two cohorts: CD47 positive-negative and a score of CD47>80. The CD47>80 was present mainly in patient with more than 60 years old (35% vs. 8.0%, p=0.024). Longer overall survival was associated with ECOG-PS 0-1 (20.2 vs. 6.9 p=0.001), disease stage IIIB (49.4 vs. 8.0, p=0.020), absent of CNS metastases (14.1-6.8, p=0.016) and absent of pleural effusion (16.2 vs. 6.99, p=0.002). Interestingly, patient with CD47 positive present better OS (10.8 vs. 6.99, p=0.485) but not reaching significance and patient with a score of CD47>80 have better OS (14.0 vs 9.2, p=0.296). **Conclusion:** Immune checkpoint CD47 expressed on the surface of tumor cells allows them to escape immunosurveillance. We previously reported that high CD47 expression was associated with the presence of somatic EGFR mutations in patients with NSCLC. In these patients, high CD47 expression was an independent prognostic factor of worse progression-free survival. Recent studies have indicated that the signal-regulatory protein (SIRP)α–CD47 pathway regulate a phagocytosis checkpoint in macrophages and other innate immune cells. In contrast, in this report we found that high CD47 expression was associated with <60 years old patient and better overall survival. Previously, studies in small cells lug cancer express high levels of CD47 and the blocking of CD47 enhances phagocytosis inhibits tumor growth. CD47 have a dual role, when interact with SIRPα avoid clearance of cells, but it interacts with thrombospondin 1 inhibits cell cycle progression and induces senescence in endothelial cells. Previous studies have shown that the protein TSP1 is as potent inhibitor of angiogenesis and its antiangiogenic activity is mediated by its receptors, CD36 and CD47. In conclusion CD47 have different function according to the ligand, and is a potential biomarker in cancer

Keywords: CD47, immune checkpoints, small-cell lung cancer

EP1.12-17 NEUROENDOCRINE MARKER STAINING PATTERN CATEGORIZATION OF SMALL-SIZED PULMONARY LARGE CELL NEUROENDOCRINE CARCINOMA

K. Minami[1], Y. Tanaka[1], T. Okamoto[1], N. Shimizu[1], T. Doi[1], H. Ogawa[2], D. Hokka[1], N. Jimbo[1], W. Nishio[2], M. Yoshimura[2], T. Itoh[1], Y. Maniwa[3]

Background: Pulmonary large cell neuroendocrine carcinoma (LCNEC) is categorized as high-grade neuroendocrine carcinoma and is known to be associated with shorter survival than that of other non-small cell lung cancers. Radical therapies for these tumors are considered to have limited applicability to small-sized cases because of their rapid growth and early metastasis. The study aim was to identify subgroups with good or bad prognosis in patients with small-sized LCNEC (sLCNEC) that were based on immunostaining patterns with neuroendocrine markers. **Method:** From January 2001 to December 2017, of all patients with surgically resected LCNEC, we selected patients whose pathological tumor sizes were ≤30 mm in diameter (defined as small-sized tumors) and who underwent complete anatomical resection with hilar and mediastinal lymphadenectomy. We classified patients with sLCNEC into 2 subgroups based on immunostaining patterns with 3 neuroendocrine makers (chromogranin A, synaptophysin, and neural-cell adhesion molecule). **Result:** Forty-eight patients with sLCNEC were enrolled in this study. Of 48 patients with sLCNEC, 21 were categorized as the small-sized triple-positive group (sTP), whose patients were positive for the 3 neuroendocrine markers, and 27 patients were categorized as the small-sized non-triple-positive group (sNTP), whose patients were not positive for all 3 neuroendocrine markers. Table 1 shows cliniopathological characteristics among sNTP and sTP. The percentage of lymph node metastasis was significantly lower in sNTP than in sTP (11% and 48%, respectively, $P< 0.01$). There was no significant difference in overall survival, but recurrence-free survival (RFS) and tumor-specific survival (TSS) were significantly poorer in sTP than in sNTP (Fig 1). Multivariate analysis using 6 clinical factors (age, sex, surgical procedure, pN status, histology, and adjuvant chemotherapy) revealed that sTP were independent prognostic factors for poorer RFS and TSS than those of sNTP.

Table 1

Cliniopathological characteristics among sNTP and sTP.

Charasteristics	sLCNEC			*P* value

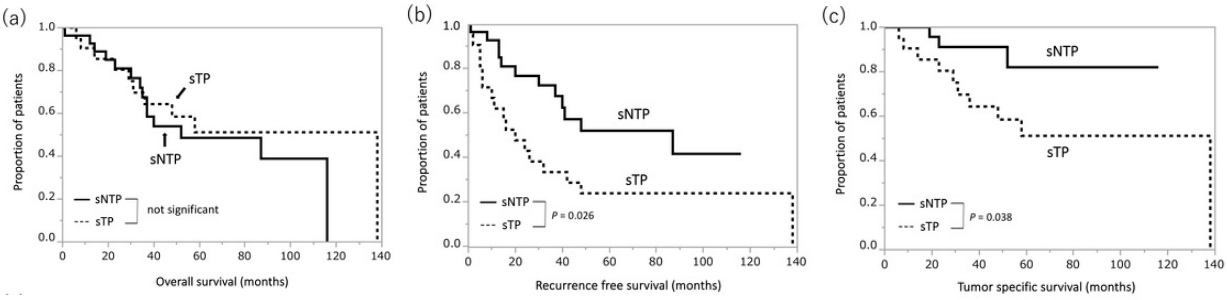
Values are presented as n (%) or mean.
sLCNEC: small-sized LCNEC patients,
sTP: small-sized LCNEC patients who were positive for all 3 neuroendocrine markers (synaptophysin,chromogranin A and NCAM),
sNTP: small-sized LCNEC patients who were positive for 1 or 2 of 3 neuroendocrine markers.
*: $P < 0.05$, **: $P < 0.01$.

Fig 1



Conclusion: The sNTP subgroup had good prognosis and the sTP subgroup had poor prognosis.

EP1.12-18 NET-001: A PHASE II STUDY OF ABI-009 IN METASTATIC NEUROENDOCRINE TUMORS OF THE LUNG OR GASTROENTEROPANCREATIC SYSTEM

R. Ramirez[1], M. Matrana[1], S. Satti[1], R. Griffin[1], B. Voros[2], A. Mohammed[1], R. Thiagarajan[2], J.P. Boudreaux[2], E. Woltering[2]

[1]*Ochsner Clinic Foundation, New Orleans/United States of America,* [2]*Louisiana State University Health Sciences Center, New Orleans/United States of America*

Background: Neuroendocrine tumors (NETs) are a heterogeneous group of malignancies with limited systemic treatment options. Preclinical evidence has shown that the PI3K/AKT/mTOR signaling pathway plays a central role in the pathogenesis and progression of NETs. Clinical studies with the mTOR inhibitor, everolimus, demonstrated its safety and efficacy in the treatment of NET, however, patients will ultimately progress. A novel mTOR inhibitor, ABI-009 (albumin-bound rapamycin nanoparticles, *nab*-rapamycin), has a favorable safety profile and evidence of efficacy in patients with solid tumors and offers promise for NETs. A preclinical study showed significantly greater antitumor activity and prolonged survival with ABI-009 compared with equal weekly dosing of oral rapamycin and oral everolimus. This preclinical study demonstrated superior efficacy of ABI-009 to oral mTOR inhibitors and suggest that ABI-009 may result in disease control after everolimus failure. The goal of this phase II pilot study is to evaluate the utility of ABI-009 in NETs to warrant a full phase II clinical study. **Method:** This pilot phase II trial is a prospective, open-label, single arm, single center trial evaluating the efficacy and safety of ABI-009 in patients with gastroenteropancreatic or lung NETs who have undergone prior treatment with everolimus. Patients with unresectable, metastatic grade 1 and 2 NETs of the gastroenteropancreatic system or lung who have progressed or have been intolerant to everolimus will be eligible for inclusion in this study. The study will enroll 10 patients with Eastern Cooperative Oncology Group (ECOG) performance status of 0-1. ABI-009 will be administered intravenously at 100 mg/m^2 on days 1 and 8 of a 21-day cycle. Patients will be treated until disease progression. Tumor response will be assessed by computerized tomography scan at baseline then every 9 weeks for 1 year, then every 12 weeks thereafter until progression. The primary endpoint is disease control rate at 6 months measured by RECIST 1.1. Currently, 3 of the planned 10 patients have been enrolled. ClinicalTrials.gov Identifier: NCT03670030. **Result:** Section not applicable **Conclusion:** Section not applicable

Keywords: neuroendocrine tumors, mTOR inhibitor, ABI-009

EP1.12-19 CHARACTERISTICS OF PATIENTS WITH SMALL-CELL LUNG CANCER IN THE REAL-WORLD: A SYSTEMATIC REVIEW

A. Golozar[1], M. Faure[2], A. Bergamasco[3], K. Chen[2], T. Arredondo-Bisonó[3], Y. Moride[2,3,4]

[1]*AstraZeneca, Gaithersburg/United States of America,* [2]*YOLARX Consultants, Montreal/Canada,* [3]*YOLARX Consultants, Paris/France,* [4]*Faculty of Pharmacy, Université de Montréal, Montreal/Canada*

Background: Patients with poor performance status (PS) ≥2 are generally underrepresented in clinical trials. Describing patients' characteristics outside clinical trials setting would help better characterize unmet needs. This study aimed to assess the characteristics of SCLC patients, overall and according to sub-types; extensive-stage (ES) and limited-stage (LS). **Method:** A systematic review of observational studies was conducted using MEDLINE and Embase databases between January 1998 and October 2018. Pragmatic searches of the grey literature were conducted to identify additional sources. Studies reporting epidemiological data on SCLC were independently screened, adjudicated and data were abstracted by two assessors, with conflicts resolved by a third. **Result:** Of the 2,418 sources identified, 394 were reviewed in depth and 140 were retained. An additional 28 sources were identified through pragmatic searches yielding a total of 168. Median age at diagnosis (reported in 32 studies) ranged from 54 to 74 years. Sex distribution was reported in 86 studies, with a male predominance irrespective of stage. Eastern Cooperative Oncology Group PS was reported in 30 studies. The majority of studies were hospital-based (n=28, 93%) and data mainly originated from medical records or chart review (22, 73%). PS was assessed at baseline or at the time of diagnosis in 26 studies. Twenty-three (77%) studies reported poor PS status for ≥25% of the SCLC population, with six reporting poor PS in ≥50% of the SCLC population. The proportion of SCLC patients with poor PS ranged from 14% to 88%. Findings were heterogeneous across studies due to the variability in thresholds used to define the categories, study setting and inclusion of both LS- and ES-SCLC patients for reporting. For studies reporting PS by stage (n=4), the proportion of patients with poor PS ranged from 13% to 53% in ES-SCLC and 11% to 12% in LS-SCLC. **Conclusion:** A significant percentage of patients with SCLC outside clinical trials present with a poor PS. LS-SCLC patients have a better PS. Prevalence of poor PS was higher for ES-SCLC and the reported figures are higher compared to non-small cell lung cancer.

EP1.12-20 RETROSPECTIVE STUDY ABOUT THE IMPACT OF METASTATIC SITE IN SMALL CELL LUNG CANCER

D. Sanchez Cabrero[1], P. Cruz[2], P. Perez[2], S. Martinez[2], O. Higuera[1], A. Pertejo[1], I. Esteban[1], L. Gutierrez[1], J. Villamayor[1], D. Viñal[1], J.L. Torres[1], J. Ramón[1], J. De Castro Carpeno[1]

[1]*University Hospital La Paz, Madrid/Spain,* [2]*University Hospital La Paz, MADRID/Spain*

Background: Small cell lung cancer (SCLC) is a very aggressive type of lung cancer. It is characterized by a high cellular proliferation and an early development of widespread metastases (nearly 70% of patients presents macroscopic metastases at diagnosis). SCLC spread mainly to bone, brain and liver. In extensive disease, metastatic involvement of the liver, bone and central nervous system seems to have a worse prognosis comparing with other sites, though the studies are quite inconclusive. **Method:** We conducted a descriptive and retrospective study including all patients diagnosed with metastatic SCLC between January 2012 and December 2018. A Kaplan Meier survival analysis (log-rank analysis) was carried out to study the impact of the metastatic involvement (depending on the localization) at diagnosis and at recurrence. **Result:** Of the 58 patients included, 58.6% presents liver involvement at diagnosis. These patients present a worse overall survival (OS), with a mean of 1.9 months, and a clear trend to worse progression-free survival (PFS, with a mean of 5.6 months (P=0.56). Bone involvement was presented in 41.4% of the patients. No difference was observed neither in OS (with a median of 6 vs 7.9 months) nor PFS (3.9 vs 3.3 months). Lastly, only the 19% present brain metastases at diagnosis, and it didn't show significant differences in OS (8.3 vs 6.7 months) but it did in SLP (2.6 vs 5 months). When the tumor relapses, it usually does in multiple localizations (51.3%) and the main organ involved is the lung (78.3%). It didn´t show any difference in prognostic between sites. **Conclusion:** SCLC is a very aggressive tumor. Due to its biological behavior, a large proportion of the patients presents an advanced staged at diagnosis. In extensive disease, the number of organ sites involved is related to prognosis, but it´s not clear which localizations have a greater impact on survival rates. In our studies, liver and bone metastases are related to worse prognosis and short survival. Surprising, in our series, brain metastases don´t seem to impact in patient's prognosis. When the tumor relapses, tumor extent (limited vs extensive) is a factor that affects the prognosis. However, in our experience, there are not clear differences between one or another, all of them related to poor prognosis. More studies will be needed to be able to clarify the prognostic impact of the metastases site, both at diagnosis and relapse.

Keywords: SCLC, metastases, prognostic

EP1.12-21 TREATMENT PATTERNS AND PROGNOSTIC FACTORS IN SMALL-CELL LUNG CANCER PATIENTS IN ISRAEL – REAL WORLD ANALYSIS OF A HEALTH SERVICES DATABASE

S. Sharman Moser[1], J. Bar[2], I. Khan[3], K. Ofek[3], R. Cohen[3], N. Khandelwal[4], V. Shalev[1], G. Chodick[1], N. Siegelmann-Danieli[5]

[1]*Maccabi Institute For Research & Innovation, Tel Aviv/Israel,* [2]*Chaim Sheba Medical Center, Tel HaShomer, Ramat Gan/Israel,* [3]*Abbvie Inc., Hod Hasharon/ Israel,* [4]*AbbVie Inc., North Chicago/United States of America,* [5]*Maccabi Healthcare Services, Tel Aviv/Israel*

Background: Small-Cell Lung Cancer (SCLC) is an aggressive smoking-associated malignancy, with rapid growth and early metastatic dissemination that accounts for 10-15% of all lung cancers. Data on current epidemiology and clinical aspects of the disease in Israel are lacking. In this observational study, we analyzed treatment patterns and prognostic factors in patients with SCLC in Maccabi Healthcare Services (MHS), a public integrated care organization in Israel. **Method:** Patients with newly diagnosed, histologically confirmed SCLC who initiated systemic anti-cancer treatment between 2011 to 2017 were identified from the MHS cancer registry. Their demographic, clinical and treatment data were retrospectively analyzed. **Result:** 235 SCLC patients were identified; 61% male, median age 64 years (IQR: 58, 70), 95% ever smokers, 62% had extensive stage disease (ES), 11% had brain metastases and 60% had 0-1 ECOG performance status (PS), all at treatment initiation. First-line treatment was platinum-etoposide regimen for the whole cohort. 107 of 235 patients (46%) continued to 2nd-line therapy and 29 patients (12%) received 3rd-line regimen. Median overall survival (OS) for the study population was 11.8 months. Patients with limited stage disease (LS) had a significant longer survival than those with ES (23.5 vs 9.1 months, P<0.001). In a multivariable model for all-cause mortality, males had a HR of 1.59 (95% CI 1.14-2.21, P=0.006) compared to females, and patients with ES had a HR of 4.76 (95% CI 1.37-16.49, P=0.014) compared to LS. Additionally, risk of death increased significantly with ECOG PS at presentation (ECOG PS 2 vs 0-1, HR=1.49 (95% CI 0.93, 2.40), ECOG PS 3-4 vs 0-1, HR=3.29 (95% CI 1.10, 9.84)). For LS disease, female sex and concurrent chemo-radiation were associated with significantly longer survival. Median survival after initiation of 2nd line was significantly longer for those re-challenged with platinum-based regimen compared with those switched to topotecan: 9.1(95% CI 6.1-12.1) vs. 4.5 months (95% CI 3.3-5.7), P=0.001. Results were not affected by platinum sensitivity (i.e. interval from end of first-line to beginning of second line ≥3 months). A multivariable model considering 2nd line patients and incorporating age, sex, stage, PS and brain metastasis at diagnosis confirmed these results. **Conclusion:** Overall survival for SCLC patients in a real world setting was found to be similar to those reported in clinical trials. Extent of disease, sex and PS were significantly associated with prognosis. Re-challenge of platinum-based doublet was associated with longer OS compared to switching to topotecan treatment.

Keywords: SCLC, First line treatment

EP1.12-22 THE EXPRESSION AND PROGNOSTIC ROLES OF PD-L1, PAPR1 AND DLL3 IN SMALL CELL LUNG CANCER

X. Fu, T. Tian, M. Liu, Z. Ruan, X. Liang, K. Nan, Y. Yao

The First Affiliated Hospital of Xi'an Jiaotong University, Xi'an/China

Background: Small cell lung cancer (SCLC) is an aggressive high-grade neuroendocrine tumor with limited treatment. Recently chemotherapy combined with anti-PD-L1 therapy was approved for SCLC. PARP1and DLL3 inhibitor are under clinical trials but the data revealed that these agents benefit a proportion of SCLC patients. Which patient can benefit from anti-PD-L1, PARP1 and DLL3 inhibitor therapy and whether combination of these agents can improve the survival of SCLC are unknown. We aim to examine the expression and prognostic roles of PD-L1, PARP1 and DLL3 and to analyze the correlation between them and clinicalpathological factors. **Method:** All protocols were approved by the Ethics Committee of Xi'an Jiaotong University and informed consent was signed. FFPE samples were obtained from Department of Pathology at The First Affiliated Hospital of Xi'an Jiaotong University from 2011 to 2018. SCLC was confirmed in all patients by surgical pathology and graded by AJCC TNM staging system. The expression of PD-L1, PARP1 and DLL3 were detected by immunohistochemistry as previously described. The association between PD-L1, PARP1, DLL3 and clinicalpathological characteristics was performed by $\chi 2$ test. The survival curves were analyzed by the log-rank test and Cox proportional hazards model. **Result:** Except for CYFRA21-1 and DLL3, no correlation between PD-L1, PARP1 and DLL3 and clinicalpathological factors were noticed (Table 1).

Table 1. Correaltion between PD-L1, PARP1, DLL3 and clinialpathological factors in SCLC patients

NSE high	10	17			21	6			11	16		
Unknown	6	8	3.04	0.22	12	2	0.79	0.49	4	10	1.73	0.42
TNM stage												
TNM stage 1-2	10	13			13	10			6	17		
TNM stage 3-4	7	12	0.19	0.66	16	3	3.73	0.05	9	11	1.69	0.19

We also demonstrated that PD-L1 predicts poor prognosis (HR=0.26, *P*=0.01), while either PARP1 or DLL3 has no correaltion with prognosis in SCLC patients (HR=0.40, *P*=1.39 and HR=0.07, *P*=1.29 respectively). Interestingly, we found SCLC patients with negative PD-L1 and PARP1, negative PD-L1 and DLL3 performed the best survival (Figure 1).

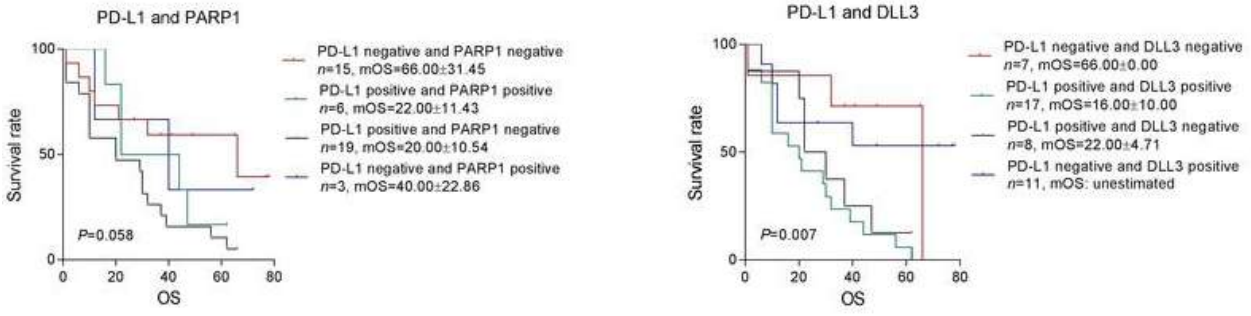

Figure 1. Overall survival of SCLC patients with different expression patterns of PD-L1 and PARP1, PD-L1 and DLL3.

Conclusion: PD-L1 is a negative prognositc factor in SCLC. Different expression pattern of PD-L1 and PARP1, PD-L1 and DLL3 lead to significantly different prognosis in SCLC.

Keywords: PD-L1, PARP1, DLL3

EP1.12-23 SURGERY IS ASSOCIATED WITH FAVORABLE OUTCOME IN PATIENTS WITH EARLY STAGE SCLC – RETROSPECTIVE INSTITUTIONAL EXPERIENCE

T. Klikovits, K. Sinn, E. Gschwandtner, N. Kasbauer, S. Taghavi, W. Klepetko, M.A. Hoda

Medical University of Vienna, Vienna/Austria

Background: Small-cell lung cancer (SCLC) is characterized by rapid growth, early metastases and dismal outcome. Only few patients are diagnosed in early stages and thus might be candidates for potentially curative treatment. However, the value of surgery within multimodal treatment of early stage SCLC remains under debate. The aim of this study was to evaluate long-term outcome in patients with early stage SCLC undergoing curative intent surgery. **Method:** Eligible patients with SCLC who underwent curative intent surgery at the Medical University of Vienna between 2006 and 2016 were retrospectively analyzed focusing on treatment modalities and long-term outcome. **Result:** A total of 31 patients were included (male, n=20 (65%); median age 63.9 years). Clinical TNM-8 staging at diagnosis was stage I in 20 (65%), stage II in 5 (16%) and stage IIIA in 6 (19%) patients. 4 patients (13%) received induction chemotherapy. Sublobar resection was performed in 14 (45%) patients whereas 9 (29%) underwent lobectomy, 4 (13%) bilobectomy and 4 (13%) pneumonectomy. 24 (77%) patients received adjuvant treatment (chemotherapy, n=17 (55%); radiotherapy, n=1 (3%), chemoradiotherapy, n=5 (16%); PCI: n=8 (26%)). Median overall survival (OS) of all patients was 43.5 months, 3-years OS 58% and 5-years OS 42%, retrospectively. Patients undergoing sublobar resection had decreased median OS compared to patients undergoing lobectomy/bilobectomy/pneumonectomy (25.5 vs. 89 months, p=ns). Importantly, patients with TNM-8 stage I undergoing adjuvant chemotherapy had significantly improved OS compared to patients without adjuvant treatment (median OS 44 vs. 12 months, p=0.01). **Conclusion:** This institutional experience shows good long-term outcome after adequate surgical resection followed by adjuvant treatment in selected patients with early stage SCLC. Our data indicate that sublobar resection should be avoided, however, well designed prospective trials are required to define the optimal treatment modalities in these patients.

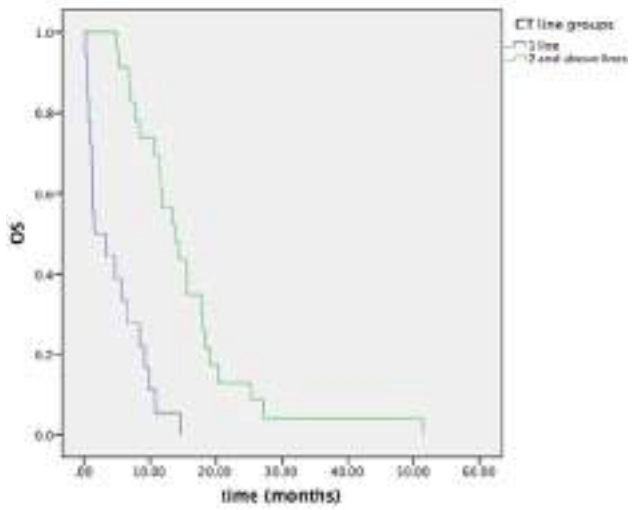
Keywords: SCLC, surgery, multimodality treatment

EP1.12-24 EFFICACY OF CHEMOTHERAPY IN SMALL CELL LUNG CANCER: SECOND LINE AND BEYOND

B. Ozturk, S. Bayram

Health Sciences University, Antalya Education and Research Hospital, Antalya/Turkey

Background: Small cell lung cancer (SCLC) is aggressive neuroendocrine carcinoma; despite of chemo sensitivity at first line, almost all cases will be relapsed in 10-12 months. In the absence of checkpoint inhibitors, chemotherapy (CT) is single choice for refractory pts. **Method:** A single center, retrospective analysis was performed to assess the survival data of 2nd line and beyond CT in the pts with SCLC. The patients' characteristics were recorded. Kaplan meier survival rates were calculated. **Result:**



A total of 52 (Female/Male:14/38) pts were evaluated. Median age was 64±7(range:47-77) years. Median follow-up was 9 (range:0-51) months. ECOG PS were 0,1 and 2 (9,34 and 9 pts), respectively. At the time of diagnosis, 15 (28.8%) pts were limited, 37 (71.2%) pts were extensive stage. Brain metastases were observed in 8 (15.4%) pts. 14 pts with limited stage disease were received chemoradiotherapy. Profilactic cranial radiation was administered all responders. Platinum and etoposid (PE) combination was the first line CT regimen. ORR was 61.6% (CR:46.2%, PR:15.4%). 31 pts were received 2nd line CT. Irınotekan (16 pts), topotecan (6 pts), PE (6 pts), platin-paclitaxel (5 pts) were 2nd line CT regimens. 5 pts were received 3rd, 2 pts were received 4th line CT. Median OS was 8.5±1.9 (95%CI:4.8-12.2) months for all pts. Median OS 14±3.8 (95%CI:6.4-21.5) and 6.9±1.9(95%CI: 3-17) months, for limited and extensive stage, respectively. Median PFS (for first line therapy) were 8.8, 7.7 and 8.1 months for limited, extensive and all pts. For second line treatment, median PFS was 5 months. For pts who had received 2 and above line CT, median OS was 14±2 (95%CI:10-17.8) months (Fig1). 5 pts were received 3rd line CT, 2 of 5 pts were survived 25 and 51 months. 14 (34%) pts had achieved 1 year and longer survival. Most of these 14 pts were limited stage and platinum-sensitive and had received at least 2 lines CT (13/14 pts). **Conclusion:** Despite of high response rates, prognosis is still poor in SCLC. Because of high tumor mutation burden, adding immunotherapy to CT had improved survival. However, some pts cannot be reached immunotherapy in the worldwide. In the absence of checkpoint inhibitor for some countries, with 2-3 line CT regimens (platin based, irinotecan/topotecan and paclitaxel agents), the pts could be survived ≥12 months. Irinotecan and topotecan seems most effective agents for refractory pts. Median PFS for the pts received 2nd line CT was 5 months and it was similar to literature.

Keywords: small cell lung cancer, chemotherapy

EP1.12-25 COMPARISON IN THERAPEUTIC OF OPERATION COMBINED WITH CHEMOTHERAPY AND WITH PD-1 AND PD-L1 INHIBITORS FOR STAGE 2 SMALL CELL LUNG CANCER

Y. Zhang

The First Hospital of Lanzhou University, Lanzhou/China

Background: The treatment of small cell lung cancer has always been a comprehensive treatment based on chemotherapy. In recent years, the surgical treatment has certain positive effects on the OS and PFS of early small cell lung cancer. Studies on the treatment of small cell lung cancer by surgical treatment combined with chemotherapy have reported positive effects. As the application of pd-1 and pd-l1 inhibitors in non-small cell lung cancer has been approved by FDA, the treatment of pd-1 and pd-l1 inhibitors in small cell lung cancer still needs to be studied. In particular, the study of surgical treatment combined with pd-1 and pd-l1 inhibitors in the treatment of small-cell lung cancer is still a new field, and there is no authoritative report at present. **Method:** 115 cases patients with IIA-IIC small cell lung cancer were divided into three groups. Group B: lobectomy + lymph node dissection combined with EP; Group C: lobectomy + lymph node dissection combined with pd-1 / pd-l1 inhibitors. The length of hospital stay, blood routine, blood biochemistry, complications, bone marrow suppression, OS, PFS and DFS were observed in the three groups. **Result:** Group A: the average hospitalization time of 53 patients was 2-3 days, including 3 patients with fever, 21 patients with fatigue, 4 patients with diarrhea and 2 patients with skin rash, 1 patient died, and 30 patients with abnormal blood routine examination. Average DFS4.2-5.8 months, PFS 2.1-2.7 months, OS 6.4-9.3 months; Group B: the average hospitalization time of 46 patients was 10-21 days, including 10 patients with fever, 27 patients with fatigue, 2 patients with diarrhea and 3 patients with rash, and 41 patients with abnormal blood routine examination. Mean DFS7.7-8.3 months, PFS3.4-6.7 months, OS9.4-12.3 months; Group C: the mean hospitalization time of 16 patients was 10-27 days, including 12 patients with fever, 9 patients with fatigue, 1 patient with diarrhea and 2 patients with rash, and 14 patients with abnormal blood routine examination. Average DFS7.1-8.9 months, PFS 3.7-6.1 months, OS 10.1-11.1 months. **Conclusion:** Chemotherapy alone is an effective treatment for small cell lung cancer, especially for advanced small cell lung cancer. Surgical treatment combined with chemotherapy can prolong OS and DFS in early small cell lung cancer. Surgical treatment combined with PD-1/PD-L1 inhibitors also has certain effect, which is one of the possible treatments.

EP1.12-26 RETROSPECTIVE STUDY ABOUT THE IMPACT OF BRAIN METASTASES AND CRANIAL IRRADIATION IN SMALL CELL LUNG CANCER

D. Sanchez Cabrero[1], P. Cruz[2], S. Martinez[2], P. Perez[2], A. Pertejo[1], O. Higuera[1], L. Gutierrez[1], J. Villamayor[1], D. Viñal[1], I. Esteban[1], J.L. Torres[1], J. Ramón[1], J. De Castro Carpeno[1]

[1]*University Hospital La Paz, Madrid/Spain,* [2]*University Hospital La Paz, MADRID/Spain*

Background: Small cell lung cancer (SCLC) is a very aggressive type of lung cancer. Due to this behavior, it presents early development of metastases. Brain metastases (BM) are very common and are related with a great impact on both survival and quality of life. Prophylactic cranial irradiation (PCI) is used for patients without detectable brain metastases, improving survival and decreasing the incidence of brain relapses (BR). Cranial irradiation (CI) for affected patients are usually used in patients with clinical BM, but its benefits are less clear. **Method:** We conducted a descriptive and retrospective study including all patients diagnosed with SCLC tumor between January 2012 and December 2018 (both localized and metastatic). We study the impact of PCI and CI in both patients with/without BM at diagnosis. A Kaplan Meier survival analysis (log-rank analysis) was carried out to study the overall survival and the impact of the radiotherapy treatment. **Result:** Of the 98 patients included, 60.2% presents extensive-stage, while 39% were locally advanced. Of the advanced stages, only 18.4% presented brain involvement at the diagnosis. 34.7% of the patients received RT at the diagnosis (37.5% PCI and 50% of the patients with BM received CI). Over the course of the disease, 35.1% of the patients present BR. 67.6% of the patients treated with RT at diagnosis (both PCI and CI) relapsed in the brain, meanwhile, the 54.8% in the group without RT (no significant differences). However, in the RT group, 69.5% of patients relapse outside the brain (mainly the lung). Chemosensitive didn´t show any relation with the incidence of BR (30.4% RT group vs. 35.7% in no-RT group). Overall, there were no significant differences in survival (p 0.19) between the group treated with RT (both PCI and CI) and the group which didn´t. **Conclusion:** SCLC presents early dissemination. Brain is one of the main organs involved. PCI for patients without detectable BM decrease the incidence of brain relapses and improve survival. The impact of CI is less clear in patients that already have BM. Surprisingly, in our series, we didn´t find any difference with PCI or CI in overall survival and BR. A high proportion of the patients in both groups (with/without BM at diagnosis) didn´t receive radiotherapy, due to a very poor clinical status (which can may lead to bias). More studies will be needed to be able to clarify the prognostic impact of these metastases and the effectiveness of this treatment nowadays.

Keywords: SCLC, brain, radiotherapy

EP1.12-27 PROPHYLACTIC CRANIAL IRRADIATION IN SMALL CELL LUNG CANCER - IS IT STILL AN ENIGMA?

S. Pathy, A. Thimmarayappa, P. Malik

All India Institute of Medical Sciences, New Delhi/India

Background: Small cell lung cancer accounts for 15% of lung cancer burden and is characterized by widespread metastases. Brain is a susceptible site of relapse hence prophylactic Cranial Irradiation (PCI) has been used. Patients of Small cell lung cancer (SCLC) are more prone to develop brain metastasis. However the efficacy of PCI in treating SCLC has not been clear and various randomized studies demonstrated conflicting results. There exists a controversy regarding the benefit from PCI in SCLC with time to develop brain metastases (BM) and progression free survival (PFS). In the current study we studied the benefit of PCI in time to develop BM and PFS. **Method:** Medical records of patients of SCLC treated between June 2016 – June 2018 were evaluated. Clinical presentation, evaluation, treatment details and outcome were recorded. Case records of incomplete workup or treatment, not eligible for radical treatment were excluded. Eligible patients received a median of 3 cycles of EP chemotherapy followed by thoracic radiation therapy (TRT) and PCI. **Result:** Fifty patients of SCLC were registered during the study period. The distribution as per histology and stage include, Limited stage 22, Extensive stage 28, 20 were metastatic and 30 were non metastatic .Eight patients received best supportive care ,15 patients received thoracic RT and PCI and 9 patients received PCI alone . The median follow-up was 10.8 months (6 – 26 months). 7 out of 15 patients had progression and 6 (40%) of them developed BM. The median time to develop BM was 10.2 months (6.7 -27.5 months). The median PFS was 11.2 months (6- 28 months). **Conclusion:** This study shows the contemporary line of management in SCLC. The time to develop BM and median PFS was comparable with existing literature. PCI benefits all stages of SCLC in terms of time to develop BM and PFS benefit.

EP1.12-28 ANTICANCER EFFECTS OF IMIPRAMINE, REPOSITIONED DRUG, FOR SMALL CELL LUNG CANCER

K.U. Kim, S.M. Koo

Soon Chun Hyang University Hospital, Seoul/Korea, Republic of

Background: Drug reposition is one of the blue oceans on discovery of new drugs. Anticancer new drugs by reposition are also vigorous mining area by *in vivo*, *in vitro* and *in silico*. Treatment of small cell lung cancer (SCLC) is restricted due to lack of chemotherapeutic agents. Imipramine, a challenging drug for SCLC was discovered by *in silico* reposition recently. We tried imipramine to the patients who diagnosed SCLC after 1st line chemotherapy **Method:** From July of 2013 to December of 2015, patients who diagnosed SCLC were enrolled. All of them were treated 1st line combination chemotherapy, platinum and etoposide and some of them were done radiotherapy to main lesion. After chemotherapy or combined radiation therapy, imipramine was prescribed 25-75mg according to patient's tolerance alternately. **Result:** Fifteen patients were participated, 6 (40%) of them were limited, 9 (60%) of them were extensive stage, but more limited stage in imipramine group compare to not prescribed group (4 to 2). All of them were smokers, 12 were man (80%), mean age was 64.6. Classified by TNM stage, stage 3 was 8, stage 4 was 7. There were no differences of age, performance status, cancer stage, chemotherapy and radiation. Amount and duration of imipramine, the prescribed group, was mean 55 mg, and 9 month. Survival of two groups was imipramine prescribed group, 22 ± 6.3 month, and not prescribed group 13.0 ± 2.8 month. (P=0.105) **Conclusion:** Trial of imipramine is one of the promising agent to control or maintenance of neuroendocrine tumor, especially SCLC.

Keywords: small cell lung cancer, Drug reposition, Antidepressant

EP1.12-29 RETROSPECTIVE STUDY ABOUT SMALL CELL LUNG CANCER: OUR EXPERIENCE IN A SPANISH HOSPITAL

D. Sanchez Cabrero[1], P. Cruz[2], S. Martinez[2], P. Perez[2], O. Higuera[1], A. Pertejo[1], I. Esteban[1], L. Gutierrez[1], J. Villamayor[1], D. Viñal[1], J.L. Torres[1], J. Ramón[1], J. De Castro Carpeno[1]

[1]*University Hospital La Paz, Madrid/Spain,* [2]*University Hospital La Paz, MADRID/Spain*

Background: Incidence of small cell lung cancer (SCLC) has been decreased during the last decades. This neoplasm appears almost exclusively in smokers and it is characterized by aggressive biology and early development of metastases. Due to this aggressiveness, a large proportion of patients present a poor performance status at the time of diagnosis. Though the tumor is initially highly responsive to therapies, most of the patients will relapse after treatment. The prognosis is generally poor, even in limited stage disease. **Method:** We conducted a descriptive and retrospective study including all patients diagnosed with SCLC tumor between January 2012 and December 2018 (both localized and metastatic forms were included). A Kaplan Meier survival analysis (log-rank analysis) was carried out to study the overall survival. **Result:** diagnosed in advanced stages (60.2%), while 29.6% were locally advanced and only 8.2%, localized. In metastatic stage, the main organ affected was the liver (35.7%), followed by the bone (24.5%). Only 12% presented brain metastases at the diagnosis. The vast majority were smokers (68.4%) or ex-smokers (27.6%), with only one patient that had never smoked. The 78.4% of the patients received chemotherapy (36.7% with concomitant radiotherapy). After the initial treatment, up to 55.4% of the patients recurred, mainly involving various localizations (50%). Only 39% received a second line of chemotherapy, and 24% a third line. At the end of the study, 84.6% of the patients had died (median of 19.7 months since diagnosis). Log-rank analysis (Kaplan-Meier estimates) showed significant differences (p<0.05) between tumor

stages and platinum-sensitive status. On the contrary, there wasn´t significant difference related to sex, smoke status, type of recurrence or type of chemotherapy chosen in second line. **Conclusion:** SCLC is heavily related with smoke. Most of them exhibit an aggressive behavior, with an advanced stage at diagnosis (in our study, up to 60.2%, and 29.6% locally advanced). Thought usually presents high chemosensitivity, most of the patients recur. At this point, the prognosis is poor, with a low benefit with the treatment, in our series regardless of the drug. Unlike the previous series, we haven´t seen a worse outcome related to sex or smoke status. More studies will be needed to be able to clarify the prognostic impact of factors such as the smoke status, sex, type of relapse or second line treatment.

EP1.12-30 CLINICOPATHOLOGICAL FEATURES AND SURVIVAL OF LUNG NEUROENDOCRINE TUMORS

M. Galvez Nino, R. Ruiz, J. Moreno, K. Roque Perez, N. Valdivieso, M. Olivera, E. Ferrer, V. Rojas, E. Amorin, J. Montes, L. Mas

Instituto Nacional de Enfermedades Neoplasicas, Lima/Peru

Background: Lung neuroendocrine tumors (NETs) are a heterogenous group of malignances classified into four histological types, being small cell lung cancer (SCLC) the most frequent and mortal. Due to the rarity of the disease, limited clinical data is available for NTEs. Herein we aim to describe the epidemiology, clinical features and survival of this group of neoplasms. **Method:** This is a retrospective analysis of patients diagnosed with lung NETs between 2010 and 2014 at Instituto Nacional de Enfermedades Neoplasicas (INEN) in Lima, Peru. Demographic characteristics, possible predisposing factors, histological type and stage were collected from clinical files. Survival analysis was calculated with Kaplan-Meier method. Prognostic factors were analyzed with Cox regression method. **Result:** We identified 69 patients with lung NETs, which corresponds to the 2.8% of lung cancers diagnosed in the same time period. Median age at diagnosis was 62 years and 59.4% of patients were male. Possible risk factors described were smoking history (50%) and familiar history of cancer (23.2%). Mean time from onset of symptoms to diagnosis was 3 months. Frequent symptoms at diagnosis were cough (75%), chest pain (59%), dyspnea (50%), weight loss (49%), hemoptysis (28%), hyponatremia (19.6%) and superior vena cava syndrome (13.8%). Between NETs, SCLC was the most common histological type (82.8%), followed by typical carcinoid (12.1%) and large cell neuroendocrine carcinoma (5.2%). Almost all patients (91.8%) had unresectable disease at diagnosis (21.3%, stage III; 70.5% stage IV) according TNM classification. Among SCLC, 60.4% had an extensive disease according to the IASLC classification, with extra thoracic compromise in bone (25.6%), brain (23.1%), suprarenal gland (21.1%) and liver (15.8%). The preferred systemic treatment was cisplatin/etoposide (93%) in the metastatic setting. The median overall survival for all histological types was 6.7 months (range 4.1 – 9.2) (Differences by histological grade in Table 1). Among clinical factors, weight loss at diagnosis emerged as a prognostic factor associated with survival of high-grade NETs (HR 3, 95% CI 1.6 – 5.5).

	I	II	III	IV	mOS
Carcinoids	40%	0%	30%	30%	87m (40.4 – 133.6)
High-grade NETs	8.8%	0%	21.1%	70.2%	4.5m (2.6 – 6.4)

Conclusion: Lung NETs have a heterogenous clinical presentation with unresectable disease at diagnosis in almost all cases. SCLC is the most frequent histology, however, this proportion regarding of the total cases of primary lung neoplasms is markedly lower than what is reported in the literature, probably to our lower frequency of smokers. The survival of this group of patients is poor in comparison to other series being weight loss at diagnosis an important prognostic factor in this series.

EP1.12-31 RESPONSE RATES AND OVERALL SURVIVAL IN BRAZILIAN PATIENTS DIAGNOSED WITH SMALL CELL LUNG CARCINOMA

L. Araujo, V. Alencar, T. Bartelli, V. Lima, D. Nunes, E. Dias-Neto

CIPE- AC Camargo Cancer Center, Sao Paulo/Brazil

Background: Despite its relative low incidence when compared to other lung tumors, small cell lung carcinoma (SCLC) is the most aggressive lung cancer subtype. About 30% of patients diagnosed with SCLC do not respond to first line chemotherapy and disease relapse usually occurs within 6 months. **Method:** Here, we evaluate clinical and treatment-related data of patients diagnosed with SCLC that attended the Clinical Oncology service at A.C.Camargo Cancer Center (ACCC - IRB approval 2445/17). **Result:** Between the year 2000 to 2017, 92 individuals were diagnosed with SCLC in the ACCC. The median age at diagnosis was 65, (varying from 32-86), with a slightly higher frequency in males (55.4%). Complete clinical and demographic information was available for 57 cases (62%), which encompassed patients from 2005 to 2017. The median age at diagnosis and male/female ratios were the same for this subset. Most patients were smokers (87.7%), presented co-morbidities (68.4), were diagnosed with extensive disease (78.9%) while 22.8% had brain mets at diagnosis, a common metastatic site of SCLC. Familial history of cancer was identified in 29 cases (50.9%). The overall survival (OS) of this cohort was 26.75 months, ranging from 1.3 month to 309 months. All but one patient underwent first line chemotherapy, and the most commonly used regimen was the combination of Cisplatin (CDDP) and Etoposide (VP-16) (73.7%), followed by the combination of Carboplatin and Etoposide (14%). Complete response was observed for 8.7% of patients and partial response in 38.6%. Stable disease and disease progression were respectively observed in 5.2% and 17.5% (33% were not classified) of patients. Second and third line treatments were respectively given to 45% and 22.8% of patients. Additionally, along with chemotherapy, 43.8% of the patients received radiotherapy; overall survival was similar for patients treated with chemotherapy alone (477 days) versus chemotherapy plus radiotherapy (386 days) (p=0.57, one-way ANOVA). No differences in OS were seen for patients receiving distinct chemotherapy regimens (p=0.38, Kruskall Wallis test) and response to first-line therapies was not capable to predict overall survival (p=0.15). As expected, patients with limited stage disease presented a trend towards better OS as compared to extensive disease (70.7 x 27.3 months) (p=0.08). **Conclusion:** We intend to evaluate genetic variants in these patients' tumor samples to investigate mechanisms that could influence outcomes and predict response.

EP1.12-32 CLINICO-PATHOLOGICAL FEATURES OF SMALL CELL LUNG CANCER IN ALBANIAN PATIENTS

D. Xhemalaj[1], P. Kapisyzi[1], S. Bala[1], H. Hafizi[1], F. Gradica[2], E. Hila[1], J. Tula[1], A. Andoni[1], M. Krushova[1]

[1]*University Hospital, Tirane/Albania,* [2]*University Hospital "Shefqet Ndroqi", Tirane/Albania*

Background: Lung cancer is the leading cause of cancer-related death in the world. Small cell lung cancer (SCLC) is an aggressive type of lung cancer and accounts for 15% of all lung cancer cases. Progress in the survival rate of SCLC is poor with a 5-year survival rate of only 5-10%, depending on tumour stage at presentation. **Method:** Purpose of this study was to describe.1- the main characteristics of small cell lung cancer and overall survival of these patients. All patients with SCLC were evaluated in the main university hospital for lung diseases. Demographic, clinical, histological characteristics were reviewed. **Result:** 153 patients diagnosed with sclc between 2015 and 2018 were included. this counts 5.8 % of all lung cancer patients (n=2598) .The mean age was 62,2 +/- 4,0 years, with the majority being men (93%). 88.2 % of patients had a smoking history. 12% of them were presented with liver metastasis. The median overall survival was 6,1 months after the diagnosis. Twelve patients had a previous familiar cancer history. At diagnostic, the most frequent symptoms were cough (65%) and dyspnea (51,3%). The mean time between the first symptoms and diagnosis was 123 +/- 89 days. **Conclusion:** Small cell lung cancer is an agressive tumor with low overall survival because albanian patients come later to the health

care profesionists and are heavy smokers. Policies for smoking cessation should be strengthened and a lung cancer screening program should be initiated.

EP1.12-33 PROGNOSTIC ANALYSIS OF SURGERY VS. CONSERVATIVE THERAPY WITH CHEMOTHERAPY IN STAGE OF LIMITED DISEASE SMALL CELL LUNG CANCER

A. Berber[1], D. Wehde[1], M. Lavae-Mokthari[2], A. Akil[2], G. May[1], S. Fischer[2], N. Dickgreber[1]

[1]*Mathias Spital Rheine, Rheine/Germany,* [2]*Klinikum Ibbenbüren, Ibbenbüren/Germany*

Background: The current standard of care for limited disease small-cell lung cancer (SCLC) consists of combination chemotherapy and thoracic radiotherapy during the early cycles of chemotherapy. Unfortunately, the prognosis is poor and the long-term survival is limited. The 5-year overall survival rate of SCLC reaches 5%. Furthermore, the role of surgery as a part of multimodality treatment with curative intent remains controversial. Here we investigate the long-term survival benefit of patients with limited disease SCLC following surgery combined with chemotherapy compared to those without surgery. **Method:** In this retrospective analysis was analyzed all the patients with limited disease small-cell lung cancer from our hospital database. Between January 2010 and May 2015, all patients with limited disease small-cell lung cancer were retrospectively enrolled and data retrospectively analyzed. Patients were grouped for multimodality treatment with chemotherapy and surgery consisting of primary tumor resection and systematic lymph node dissection (Group 1) versus chemoradiotherapy alone (Group 2). Survival time was defined as the frame of the date of diagnosis to the time of death. Deaths from other causes are censored. The primary endpoint for this analysis was the survival time. **Result:** A total of 47 patients were included. About 16 Patients received treatment in the main focus with surgery (group 1), 31 patients had treatment without surgical treatment (group 2). In group 1 with surgical treatment 4 patients of 16 died within the first 16 months. The minimal survival time was 13 months and the maximum was detected at 48 months. The median survival time was discovered at 13 months, the arithmetic mean was 23 months. The standard deviation from the mean was 3,94. In the group without surgery 11 patients of 31 died. In this group the minimal survival time was 1 month and the maximum survival time was determined at 43 months. The median survival time was founded at 10 months, the arithmetic mean at 17 month. The standard deviation from the mean was detected at 16,08. **Conclusion:** One of the leading cause of death from cancer around the world is small cell lung cancer. The characteristics of rapid growth and early metastasis, is still an intractable problem for the treatment of small lung cancer. In addition only few patients are diagnosed in early stages, so that a surgical treatment can be considered. If we compare the patients who had surgical treatment with patients without surgery, we see that the group with surgical treatment seems to have a longer median survival time. The surgery seems to be safe and an important component of the multidisciplinary treatment.

EP1.12-34 SMALL CELL LUNG CANCER REVEALED BY CHOROIDAL METASTASIS: CASE REPORT

M. Rahli

Beni Messous Hospital, ALGER/Algeria

Background: Ocular metastasis sit preferentially in the choroid, a vascularized membrane located between the sclera and the retina. Lung cancer is the second cancer provider of ocular metastasis after breast cancer. Choroidal metastasis are rarely indicative of primary neoplasia and are part of a generalized cancer. **Method:** We experienced a 70-year-old man, an ex-smoker (45 packs/year) which showed a decrease in visual acuity of the right eye. Physical examination was remarkable for just a exophtamia. The ophthalmological report revealed a retinal detachment and a choroidal tumor process of the right eyeball. The chest CT scan showed a central right pulmonary mass measured 80X50X47 mm and associated with three right superior lobar nodular formations and ipsilatetal mediastinal lymphadenopathy. Using a flexible bronchoscopy, we found a reduction of the superior right lobby caliber by an infiltrated mucous. **Result:** The bronchoscopic biopsy was performed, and the tumor was found to be small cell lung cancer, classified T4N3M1 according to The eight IASLC classification. The patient had benefit of chemiotherapy combining "Cisplatin and Etoposid" with radiotherapy of the right eyeball. After three curs of chemotherapy and radiotherapy we note a regression of the exophtamia, the radiological control was demand. **Conclusion:** The research primary cancer will be done quickly to allow for the therapeutic management. Chemotherapy and radiotherapy remain the treatment of choice for limited extension and improved patient survival.

EP1.12-35 COMPARISON OF LONG TERM RESULTS BETWEEN MATCHED CHEMORADIOTHERAPY AND SURGERY FOR LIMITED STAGE SMALL CELL LUNG CANCER

M. Chen, X. Hu, M. Chen

Zhejiang Cancer Hospital, Hangzhou, Zhejiang/China

Background: The role of surgery in patients with SCLC is undefined. Our study was conducted to compare the long term results of chemoradiotherapy with surgical treatment for limited stage SCLC. To compare the efficacy of chemoradiotherapy or surgery for limited-stage small cell lung cancer (SCLC). **Method:** A retrospective analysis was performed on 138 patients with limited-stage SCLC who received surgery (69 patients) or chemoradiotherapy (69 patients) between January 2000 and September 2016 in Zhejiang Cancer Hospital. Patients of the chemoradiotherapy group were selected by using 'pair-matched case-control' methodology from a cohort of 503 patients who received chemoradiotherapy. **Result:** The major prognostic factors including T, N stage, treatment duration, age, gender, and whether or not received prophylactic cranial irradiation were well balanced between two groups. The median overall survival (OS) time and 5-year OS rate were 37.1 months and 45.0% in surgical group versus 45.0 months and 45.0% in chemoradiotherapy group (P=0.846). The median progression-free survival (PFS) time and 5-year PFS rate were 27.1 months and 37.8% versus 36.2 months and 40.0% respectively in the two groups (P=0.610). The 5-year OS rate (62.3% vs. 40.1%, P=0.038) and 5-year PFS rate (80.1% vs. 40.1%, P=0.048) in surgical group were significantly higher than those of chemoradiotherapy group in patients with stage I disease. While the 5-year OS rate (41.2% vs. 50.6%, P=0.946), 5-year PFS rate (64.7% vs. 42.1%, P=0.280) of surgery for stage II SCLC were comparable to chemoradiotherapy. As for stage III SCLC, compared with the surgical group, the chemoradiotherapy group had a better 5-year OS trend (25.1% vs. 47.6%, P=0.220). **Conclusion:** Surgery could confer survival benefit in patients with p-stage I disease, but not in patients with p-stage II and III disease.

Keywords: surgery, chemoradiotherapy, small cell lung cancer

EP1.12-36 TREATMENT OUTCOMES AND RISK FACTORS OF LIMITED-STAGE SMALL CELL LUNG CANCER PATIENTS TREATED WITH CHEMORADIOTHERAPY

T. Hayakawa[1], I. Soda[1], A. Sekiguchi[1], S. Kawakami[1], M. Kubota[1], H. Mitsufuji[1], S. Igawa[1], T. Fukui[1], K. Naoki[1], K. Hayakawa[2], H. Ishiyama[1]

[1]*Kitasato University, School of Medicine, Sagamihara (Kanagawa)/Japan,* [2]*National Hospital Organization Disaster Medical Center, Tachikawa (Tokyo)/Japan*

Background: The aim of this study was to report clinical outcomes and prognostic factors in limited- stage small cell lung cancer (LD-SCLC) patients treated with chemoradiotherapy (CRT). **Method:** Data on 107 LD-SCLC patients who received CRT between September 2000 and March 2017 were analyzed retrospectively. The median age of the patients was 66 years (range 42–85 years); 79 (73.8%) patients were male and 28 (26.2%) were female. Seventy-four (69.2%) patients received concurrent CRT (CCRT) with 45 Gy in 30 twice-daily fractions (n=52) or with 54–60 Gy in 27–30 once-daily fractions (n=22). The other 33 patients received sequential CRT (SCRT) with 54–60 Gy in 27–30 once-daily fractions. Prophylactic cranial irradiation was administered to 35 (32.7%) patients. Cisplatin/etoposide or carboplatin/etoposide were mainly selected as chemotherapy regimens. Survival rates were estimated using the Kaplan-Meier method, and univariate and multivariate analysis was performed using the log-rank test and Cox proportional hazard model, respectively. **Result:** Median follow-up duration

was for 28.6 months (range 1.6–147.2 months). Three-year overall survival, progression-free survival and cause-specific survival rates were 51.1%, 38.8% and 51.5%, respectively. On univariate analysis metastatic lymph node status (N0 vs N≥1) and timing of CRT (CCRT vs SCRT) were detected as significant prognostic factors for overall survival (3-year overall survival: 100% vs 48.2%, *p*=0.02; and 56.6% vs 37.7%, *p*=0.04, respectively). On multivariate analysis, however, these factors did not reach statistical significance. **Conclusion:** Treatment outcomes in LD-SCLC patients suggested metastatic lymph node status and timing of CRT as prognostic factors for overall survival.

EP1.12-37 HIGHER CONSISTENCY OF MUTATIONS BETWEEN TUMOR DNA AND CTDNA IN SMALL-CELL LUNG CANCER COMPARED TO NON-SMALL CELL LUNG CANCER

H. Ma[1], C. Li[2], J. Ma[2], H. Wang[2], F. Lou[2], S. Cao[2], Y. Zhu[1], L. Tong[1], Q. Zhang[1], X. Wang[1], T. Wang[1], W. Chang[1]

[1]*The Affiliated Traditional Medical Hospital of Xinjiang Medical University, Urumqi/China,* [2]*AcornMed Biotechnology Co., Ltd., Beijing/China*

Background: Small-cell lung cancer (SCLC) is an aggressive neuroendocrine lung tumor representing 15% of lung cancers, patients with SCLC usually have a poor prognosis and limited treatment options. This is primarily due to the lack of adequate tumor tissues to assess and delaying therapy to repeat biopsies is often not possible. Circulating cell-free tumor DNA (ctDNA) based test for EGFR mutations in patients with Non-small cell lung cancer (NSCLC) has been approved by US Food and Drug Administration, however, whether it is feasible to perform genomic profiling of ctDNA from SCLC patients still have been lacking. SCLC is characterized by early hematogenous spread, we hypothesized that ctDNA sequencing in SCLC is more comprehensive as a promising biomarkers than that in NSCLC. **Method:** To analyze the consistency of gene mutation sites between tumor DNA and perepheral blood ctDNA in patients with lung cancer (SCLC and advanced NSCLC), and further explore the feasibility of ctDNA as a clinical tool in SCLC. Paired tumor and blood samples were obtained from systemic treatment naïve patients with SCLC and advanced NSCLC. DNA was sequenced by target-capture deep sequencing of 808 previously annotated genes related to solid tumors. **Result:** During February 2017 to April 2018, 8 SCLC and 119 advanced NSCLC patients were enrolled from 3 centers. A total of 256 somatic variations were detected in tumor DNA and ctDNA. TP53 and RB1 are the most frequently mutated genes in SCLC patients and mutations occurred most frequently in NSCLC were *EGFR*, *TP53*, *KRAS, ALK*. In matched tumor DNA and ctDNA, we observed significant higher concordance of mutations in SCLC (90%) compared to NSCLC (65%). Furthermore, the variant allele frequency (VAF) of shared mutations in SCLC highly correlated to each other (r=0.68). In addition, a subset of mutations was exclusively detected in ctDNA, indicating that the genomic landscape derived from ctDNA reflects that from SCLC to a certain degree. **Conclusion:** Taken together, our data showed the potential advantage of sequencing ctDNA in SCLC over than that in NSCLC to reveal the global genomic landscape. SCLC ctDNA analysis will be used as a powerful research tool that can shed light on this poorly understood disease and could also provide clinical information that benefits patients.

EP1.12-38 RETROSPECTIVE ANALYSIS OF IMMUNOTHERAPY UTILIZATION IN ADVANCED SMALL CELL CARCINOMA AT AN ACADEMIC CANCER CENTER

E. Bertino, C. Presley, G. Otterson, D. Owen, K. He, D. Carbone, T. George

The Ohio State University, Columbus/United States of America

Background: Small-cell carcinoma (SCC) is an aggressive neuroendocrine carcinoma which commonly originates in the lung (SCLC). In contrast to non-small cell lung cancer (NSCLC), immunotherapy (IO) utilization has been limited for SCLC. Nivolumab was approved as a single agent in 2018 for third-line therapy. In 2019, the IMpower133 trial led to approval of first-line chemo-IO (atezolizumab plus carboplatin and etoposide) for extensive-stage SCLC. Despite these approvals, there is limited data about experience utilizing IO in SCC outside of clinical trials, including patterns of care, survival, and incidence of brain metastases. We therefore conducted a retrospective review of IO utilization at an academic cancer center in the United States. **Method:** Institutional pharmacy database was used to perform an unstructured data collection of medical record numbers based on SCC diagnosis and IO treatment codes between January 1, 2008 and October 1, 2018 at The Ohio State University Medical Center. Patient data was then abstracted from the electronic medical record. Variables included demographics, co-morbidities, stage, metastatic sites (including brain), treatment history (including chemotherapy, IO and radiation), and treatment response. Survival from the start of IO to death and median overall survival (OS) from diagnosis to death were calculated. **Result:** Forty patients, 17 women and 23 men, were eligible for evaluation. The median age was 64 years (30-91 yo); 36 patients were current/former smokers. At diagnosis, most were extensive-stage (65%). Common metastatic sites at diagnosis included brain (20%), bone (35%) and liver (33%). Overall, 22 patients (55%) developed brain metastases over the course of disease. Median line of IO was 2nd line (range 2nd-5th line); nivolumab-ipilimumab was the most common regimen (43%), followed by nivolumab (38%), then pembrolizumab (20%). Patients received an average of 4 cycles of IO (range 1-35). Nine patients were treated on clinical trial. Median survival after IO was 4.2 months and median OS of 17.3 months. Median survival for patients with brain metastases was 2.2 months vs. 10.3 months without (P=.01). Most patients had no durable response to IO; however, responses were observed in 7 patients (1 CR, 6 PR) and 8 patients had stable disease.

Table 1: Treatment Summary	
Treatment	**Patients – no.**
Chemotherapy – any line	
Carboplatin	28
Cisplatin	15
Etoposide	40
Topotecan	19
Irinotecan	23
Paclitaxel	11
Gemcitabine	1
Immunotherapy	
Nivolumab-ipilimumab	17
Nivolumab	15
Pembrolizumab	9
Radiation Therapy	
Radiation (non-CNS site)	36
Radiation (CNS)	24
Type of CNS radiation	
Prophylactic Cranial Irradiation	8
Whole brain radiation (therapeutic)	16
Gamma knife/stereotactic radiation	6

Conclusion: This retrospective review describes our experience utilizing IO in advanced SCLC at our academic institution. Although treatment patterns are changing with first-line IO, this data reflects the variability of patient responses. Several patients had prolonged responses, indicating potential areas of further investigation. This data will also be used to evaluate IO activity in CNS disease.

EP1.12-39 SURVIVAL AND PROGNOSTIC FACTORS IN PATIENTS WITH SMALL-CELL LUNG CANCER: A SYSTEMATIC REVIEW OF OBSERVATIONAL STUDIES

M. Faure[1], A. Golozar[2], A. Bergamasco[3], K. Chen[1], T. Arredondo-Bisonó[3], Y. Moride[1,3,4]

[1]*YOLARX Consultants, Montreal/Canada,* [2]*AstraZeneca, Gaithersburg/United States of America,* [3]*YOLARX Consultants, Paris/France,* [4]*Faculty of Pharmacy, Université de Montréal, Montreal/Canada*

Background: With limited advances in the management of small-cell lung cancer (SCLC) within the past thirty years, SCLC still imposes a substantial burden. Identification of prognostic factors help optimize development of appropriate treatment strategies. As part of a larger systematic review, this study aimed to describe survival and prognostic factors in SCLC. **Method:** A systematic review of observational studies was conducted using MEDLINE and Embase over the period 01 January 1998-17 October 2018. Pragmatic searches of the grey literature, including conference abstracts and proceedings, were also conducted to identify additional sources. Search outputs were independently screened, adjudicated and abstracted by two assessors independently, with conflicts resolved by a third. **Result:** Of the 2,418 sources identified in the literature, 394 were retained for full text review, out of which 140 were included. In addition, 28 were identified through pragmatic searches yielding a total of 168 sources. Data mainly originated from Asia-Pacific (51; 42.2%), North America (30; 24.8%) and Europe (29; 24%). Eight different measures of survival were used across 121 studies (102 overall, 40 limited-stage [LS]-SCLC and 42 extensive-stage [ES]-SCLC): median overall survival (OS) was the most commonly reported, followed by 1- and 5-year survival rates. A total of 71/102 (69.6%) studies on SCLC, 19/40 (47.5%) on LS-, and 17/42 (40.5%) on ES-SCLC reported median OS. In SCLC, the median OS ranged from 4.6 to 29.1 months, while it ranged from 10 to 47 months in LS-SCLC and from 4 to 14.2 months in ES-SCLC. Survival trend was reported in three studies using data from SEER registries with a general trend towards an increase in survival rate when 2- and 5-year survival rates were reported. When reported (one source), no improvement in OS trend was noted. Chemotherapy, radiation therapy, prophylactic cranial irradiation, performance status, age and sex were among prognostic factors identified in both stages of SCLC. **Conclusion:** SCLC survival rate is low yet variable with significantly lower rates in ES-SCLC and minimal changes in survival trend. Significant variability exists in measurement and reporting SCLC survival and survival trend, thus hampering comparability of findings, syntheses of findings and clinical decision-making.

EP1.12-40 NEUROENDOCRINE TUMORS OF THE LUNG: CLINICO-PATHOLOGICAL CHARACTERIZATION AND FOLLOW-UP OF PATIENTS TREATED AT AN ARGENTINEAN UNIVERSITY HOSPITAL IN THE LAST 10 YEARS

A. Giorlando, C. Gabay, M. Bonet, L. Thompson, M. Castro

Thoracic Oncology Unit, Instituto Angel H. Roffo, Buenos Aires/Argentina

Background: Neuroendocrine tumors (NETs) comprise a heterogeneous group of malignancies that arise from neuroendocrine cells throughout the body, most commonly from the lungs and gastrointestinal tract. Histological characteristics and clinical behaviour define lung NETs, which are classified into four groups: typical (TC) and atypical carcinoids (AC), large-cell neuroendocrine carcinoma (LCNC) and small-cell lung cancer (SCLC). The identification and differentiation of TCs from ACs or LCNECs and SCLC is essential for treatment options and prognosis. **Method:** We performed a retrospective review of patients with lung NETs treated in our institution in the last decade. We analysed histological confirmed primary lung NETs cases. Demographics, clinical characteristics, imaging, treatment and outcome are described for this patient population. **Result:** A total of 91 patients with lung NETs were included; 28/91 (30.8%) were lung carcinoids (TC:14 and AT: 14) and 63/91 (69.2%) were high grade lung NETs (SCLC: 54 and LCNC: 9). Comparing low and high grade NETs groups of patients, we could identify differences in the following variables: mean age at diagnosis (51±14 vs 61 ±9 years, p=0.000), mean time from the beginning of symptoms to achievement of pathologic diagnosis (10.5±15.9 vs 3.9 ± 2.6 months, p=0.002), ECOG^{3}2 (14% vs 42%, p=0.001), smokers (57% vs 95%, p=0.000), median % of Ki67 expression (4%, (1-30%) vs 50%, (20-90), p=0.000), history of inflammatory lung disease (18% vs 32%, p=0.028) and presence extra-thoracic disease at diagnosis (47% vs 68%, p=0.000). No statistically differences between groups were observed in: sex, family history of lung cancer, second diagnosis of cancer and body mass index at diagnosis. Functioning carcinoid syndrome was observed in 10% (3/28) of patients with lung carcinoids. For the entire cohort, the median overall survival (OS) was 19 months (IC95%: 14-24 months). The five year OS for patients with lung carcinoids was 62% and 13% for high grade NETs. **Conclusion:** In our series of lung carcinoids we observed a high frequency of: atypical carcinoids, advanced disease at presentation and smoking history. However, the 5-year overall survival is the expected for this population. More knowledge is needed about this entity in South American countries.

Keywords: SCLC NET

EP1.13 STAGING

EP1.13-01 MULTIPLE LUNG NODULES: HISTOPATHOLOGIC, MOLECULAR AND CLINIC APPROACH OUTCOMES

M.L. Dalurzo[1], N. Minatta[2], M. Labanca[1], P. De La Iglesia[1], J. Oliver[1], D. Smith[1], H. Diaz[1], F. Jauk[1]

[1]*Hospital Italiano Buenos Aires, Buenos Aires/Argentina,* [2]*Hospital Italiano de Buenos Aires, Buenos Aires/Argentina*

Background: Distinguishing multiple primary lung cancers from intrapulmonary metastases in patients with synchronous multifocal lung carcinomas can be challenging. Histologic and molecular features, in conjunction with clinical and radiological information, can all be tools to assist with staging of multiple nodules. **Method:** Retrospective descriptive study. Patients diagnosed with multiple lung nodules and underwent surgery between 07/2011 - 2/2018 were included Pathologists trained in lung cancer performed the histological diagnosis of each of the nodules according to WHO 2015 classification and comprehensive histologic assessment analysis and, subsequently, a molecular analysis by Oncomine Focus Assay panel in Ion PGM platform was made. We also carried out clinical and demographic analyzes. **Result:** A total of 22 patients were retrospectively studied Median Age: 67,5 years old (r 39-79). Non smokers: 6/22 (27,7%) patients. 13/22 (59%) pts men. 95,5% was staging with PET before surgery/mediastinoscopy, 6 of them reported mediastinal lymph node involvement by PET but only mediastinal involvement was evidenced in the biopsy in 1 case. 6 cases showed 2 nodules in same lobe, 12 cases showed 2 or more nodules in same lung but in different lobe, 2 cases bilateral nodules, (2 of 4 required sequential surgery). 21/22 mediastinoscopy before surgery, Segmentectomy, lobectomy or both were the most frequent surgeries. The lobe most frequently affected was the right upper lobe (alone or combined) followed by the left lower lobe. There were no cases of neoadjuvant treatment and 6 patients required adjuvant chemotherapy. The decision to perform adjuvant was evaluated in the tumor board. 4/22 relapses (sites of relapses: nodes, bones, lung). One of them had performed adjuvant treatment. Despite a high rate of sub-lobar surgeries, the incidence of local relapse was low (1 case lung and 3 mediastinal nodes). With a median follow-up of 19 months there was only one death and 4 relapses. The combination of WHO 2015 classification and CHA criteria improves the accuracy of synchronous or metastatic tumors. The addition of molecular testing is useful to define discrepancies in challenging cases. **Conclusion:** Decisions regarding post-surgery treatments were not defined by molecular biology. Both the TNM and the histological concordance between the nodules were the main determinants to make a therapeutic decision. Gene panels could help make decisions based on these finding. Being able to address and differentiate early stages vs. intrapulmonary metastatic disease can have a prognostic impact and help predict the outcome and guide the therapy.

EP1.13-02 NEGATIVE PREDICTIVE VALUE OF EBUS-TBNA FOR MEDIASTINAL STAGING OF NON-SMALL CELL LUNG CANCER

N. Anagnostopoulos[1], K. Cholidou[1], D. Ampazis[1], D. Grapsa[1], R. Trigidou[2], V. Vitsas[1], G. Stratakos[1], P. Bakakos[1], I. Gkiozos[3]

[1]*National and Kapodistrian University of Athens, Athens/Greece,* [2]*Sotiria Athens General Hospital, Athens/Greece,* [3]*Oncology Center of Biomedical Research and Education, Athens/Greece*

Background: Mediastinal staging must precede surgery in patients with resectable non-small cell lung cancer (NSCLC). According to current guidelines, minimally invasive techniques, such as endobronchial ultrasound with transbronchial needle aspiration or/and biopsy (EBUS–TBNA/B), represent the preferred first-line approach for mediastinal staging, before performing mediastinoscopy. We herein aimed to evaluate the negative predictive value (NPV) of EBUS-TBNA in a tertiary referral center and correlate NPV with primary tumor features and other clinicopathological variables. **Method:** We retrospectively studied the medical records of 20 patients with resectable NSCLC, submitted, from January 2017 to January 2018, to EBUS-TBNA in the Department of Interventional Pulmonology of the first Pulmonology Clinic of Sotiria Athens General Hospital; EBUS-TBNA had been performed prior to surgical resection of the primary tumor and surgical lymph node staging in all patients. The EBUS-TBNA results were correlated with surgical staging. **Result:** Among all lumph node stations sampled, there were 46 with negative EBUS-TBNA results. Post-operatively, 6 EBUS-TBNA negative lymph nodes were re-staged as positive. The remaining 40 EBUS-TBNA negative nodes were true negative, as confirmed by surgical staging. NPV of EBUS-TBNA was 87%, and thus within the range of previously published results. Among cases with negative EBUS-TBNA results, a statistically significant correlation was observed between low NPV (false negative EBUS-TBNA) and T3 tumor size (> 7cm), pre-bronchoscopy N2 disease, presence of necrosis within the primary tumor, and microscopic vascular invasion (p-value <0.05 in all cases). **Conclusion:** Patients with T3 tumors (>7cm), N2 disease before the performance of EBUS-TBNA, and those with tumor necrosis or microscopic vascular invasion may be at greater risk for false negative EBUS-TBNA results. Given the small sample size of our study and its retrospective study design, it must be emphasized that these findings are highly preliminary and must be confirmed in larger prospective series.

Keywords: Non-Small Cell Lung Cancer, EBUS-TBNA, mediastinal staging

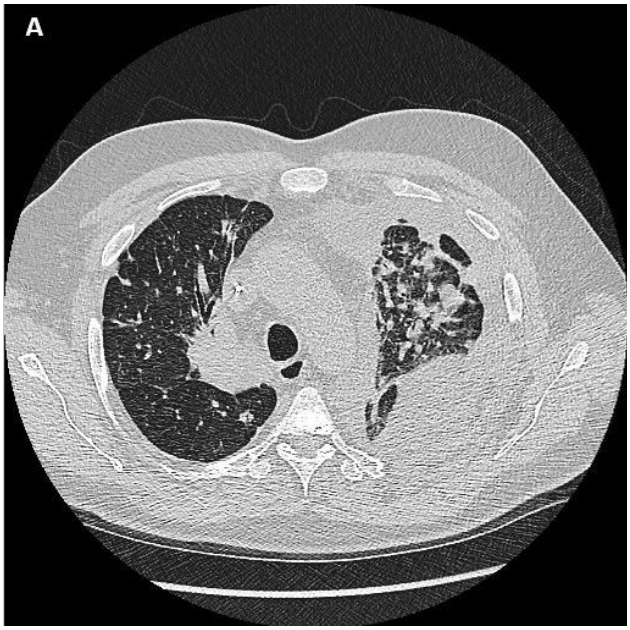
EP1.14 TARGETED THERAPY

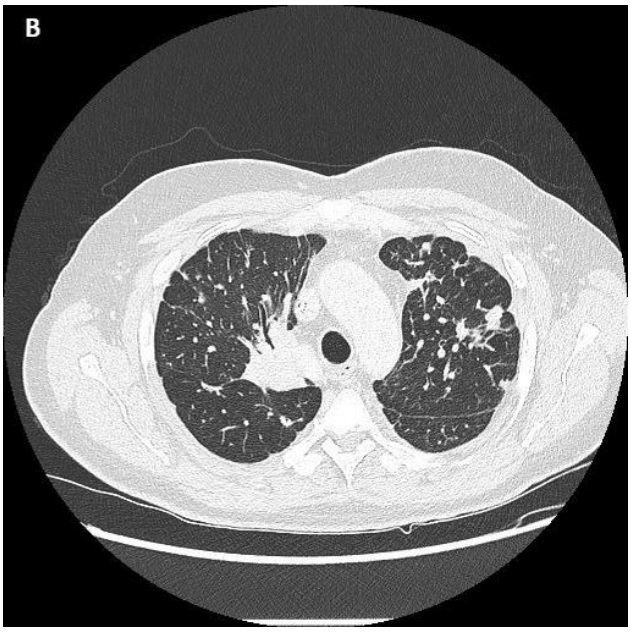
EP1.14-01 MAJOR THERAPEUTIC RESPONSE TO T-DM1 IN METASTATIC LUNG ADENOCARCINOMA WITH HER2 MUTATION

G. Berardi, A.C. Toffart, J. Pinsolle, D. Moro-Sibilot, M. Giaj Levra

CHU Grenoble, La Tronche/France

Background: The *HER2* exon 20 mutation is described in 1-5% of patients with Non-small cell Lung cancer, and at the moment no targeted agents are approved in Europe. However, the use of conjugated antibodies such as trastuzumab and ado-trastuzumab emtansine (T-DM1) has shown promising results. **Method:** We describe the case of a major response to T-DM1 in fourth line treatment in a patient with metastatic adenocarcinoma and *HER2* mutation. **Result:** A 60-year-old male, former smoker (3 packs/year), presented to the emergency room in 2016 for dyspnoea. A bilateral pleural and compressive pericardial effusion with tamponade requiring pericardial drainage were discovered. A lung adenocarcinoma with *HER2* mutations was diagnosed. He benefited from two successive treatment lines between September 2016 and September 2017 (carboplatin- paclitaxel and bevacizumab followed by bevacizumab maintenance until progression, then pemetrexed for two cycles). At this time, he developed a new disease progression as a recurrence of tamponade requiring surgical drainage and a third line with docetaxel and trastuzumab was started for twelve cycles. After eight months, he presented an acute respiratory failure due to the recurrence of pericardial and pleural effusions, requiring a pleural drainage (Fig.1A). After discussion at the multidisciplinary meeting, a fourth line of treatment with T-DM1 in compassionate has been proposed. After three cycles, we observed an excellent clinical response, with disappearance of dyspnoea, resumption of normal daily activity. The radiological evolution was also very favourable (Fig.1B). The patient benefited from other six months of treatment before getting a new progression. **Conclusion:**





In this case T-DM1 showed a major clinical and radiological benefit despite its use in fourth line. Other clinical reports and phase II trials confirmed promising results with targeted agents already used in breast cancer. Several studies are exploring the efficacy of these agents, opening up new hopes.

EP1.14-02 COMPARATIVE EFFICACY OF FIRST-LINE CERITINIB AT A DOSE OF 450MG WITH FOOD AND ALECTINIB IN ADVANCED ALK+ NSCLC

F. Liang, D. Shen

Fudan University Shanghai Cancer Center, Shanghai/China

Background: Anaplastic lymphoma kinase (ALK) rearrangement occurs in approximately 3% to 7% of patients with non–small cell lung cancer (NSCLC), and the clinical data have demonstrated the success of therapeutic approaches targeting the ALK protein in this patient population. Ceritinib and alectinib were both second generation of ALK inhibitors that approved as first-treatment for

ALK+ NSCLC. Ceritinib is initially approved at the recommended dose of 750 mg/day fasted (ceritinib 750-mg fasted). Ceritinib at a dose of 450 mg with food (ceritinib 450-mg fed) compared to ceritinib 750-mg fasted showed consistent efficacy and less gastrointestinal toxicity in the Ascend 8 trial. Although a previous cross-study indirect study compared the efficacy of ceritinib 750-mg fasted with alectinib, the efficacy of ceritinib 450-mg fed compared with alectinib is unknown. **Method:** Progression-free survival of ceritinib 450-mg fed was indirectly compared with that of alectinib using a Bucher anchor-based indirect comparison approach using ceritinib 750-mg fasted as the common anchor. The comparative efficacy of alectinib vs ceritinib 750-mg fasted was obtained from matching-adjusted indirect comparison(MAIC) and the comparative efficacy of ceritinib 450-mg fed vs ceritinib 750-mg fasted was estimated using reconstructed individual patient-level data from Ascend-8 trial. The corresponding 95% CI of HR for ceritinib 450-mg fed vs alectinib was calculated using the standard errors of the HRs of alectinib vs ceritinib 750-mg fasted and ceritinib 450-mg fed vs ceritinib 750-mg fasted. **Result:** The HR of alectinib vs ceritinib 750-mg fasted in the MAIC was 0.78 (95% CI 0.50-1.23). The estimated HR of ceritinib 450-mg fed vs ceritinib 750-mg fasted was 0.71(95% CI 0.41-1.23). In the anchor-based indirect comparison, HR of ceritinib 450-mg fed vs alectinib was 0.91(0.45-1.85). **Conclusion:** In the cross-study indirect comparison, the efficacy of ceritinib 450-mg fed was comparable with alectinib with numerically lower hazard of progression or death. However, results from indirect comparison can be limited by unobserved or unmeasured confounding. Head-to-head randomized phase III trials are needed to formally compare the efficacy of ceritinib 450-mg fed vs alectinib

Keywords: ALK, Ceritinib, alectinib

EP1.14-03 DRIVER GENES AS PREDICTIVE INDICATORS OF BRAIN METASTASIS IN PATIENTS WITH ADVANCED NSCLC: EGFR AND ALK AS WELL AS RET GENE MUTATIONS

H. Wang[1], Z. Wang[1], J. Ma[1], G. Zhang[1], M. Zhang[1], X. Zhang[1], H. Li[1], X. Zheng[1], Z. Ma[2]

[1]*The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, zhengzhou/China,* [2]*The Affiliated Cancer Hospital of Zhengzhou University, Henan Cancer Hospital, Zhengzhou/China*

Background: Brain metastasis is a cause of disease progression and death in lung cancer patients, and is also one of the most common metastatic sites of lung cancer. Non-small lung cancer (NSCLC) accounts for about 80% of all lung cancer patients, and adenocarcinoma has become the main subtype of NSCLC in recent years. A retrospective analysis verified the role of gene mutations in brain metastasis in patients with non-small lung cancer (NSCLC). **Method:** The clinicopathological data of 552 patients who received driver genes detection for lung cancer in the Affiliated Cancer Hospital of Zhengzhou University/Henan Cancer Hospital from January 2015 to June 2017 were collected; NGS was used for gene detection. The driving genes for detection were EGFR, ALK, KRAS, ROS-1, BRAF, ERBB2, RET and c-MET, which were eight lung cancer driving genes recommended in NCCN guidelines. All the tests were carried out in the Center of Molecular Pathology in the Affiliated Tumor Hospital of Zhengzhou University. **Result:** Of the 552 patients with advanced NSCLC, 153 (27.7%) had brain metastases. Univariate analysis showed that age (*P* = 0.008), gender (*P* = 0.016), smoking history (*P* = 0.010), lymph node metastasis (*P* = 0.003), and three driver genes: positive EGFR mutation (*P* = 0.001), positive ALK gene fusion (*P* = 0.021) and positive RET gene fusion (*P* = 0.003) were factors influencing the incidence of brain metastasis. Logistic multivariate regression analysis revealed that only positive EGFR mutation (*P* = 0.012), positive ALK gene fusion (*P* = 0.015), positive RET gene fusion (*P* = 0.003), pathological type (*P* = 0.009), lymph node N2–3 metastasis (*P* = 0.000) and a younger age (*P* = 0.000) were independent risk factors for brain metastasis. In addition, a ROC curve was plotted with the above factors with AUC=0.705 (P=0.000). **Conclusion:** EGFR mutation, ALK gene fusion and RET gene fusion in advanced NSCLC patients play roles in brain metastasis as positive driver genes.

EP1.14-04 VALIDATION OF NEW TARGETS INTERFERING AT PHOSPHATIDYLETHANOLAMINE PRODUCTION AGAINST NSCLC

S. Fernandes Teixeira[1], L. Inata Mambelli[1], B. Kawamura[2], J. Marzagão Barbuto[1], E. Suavinho Ferro[1], A. Ferreira[2]

[1]*Institute of Biomedical Sciences of University of Sao Paulo, Sao Paulo/Brazil,* [2]*University of Sao Paulo Medical School, Sao Paulo/Brazil*

Background: Besides all medicine advancements, lung cancer is still the leading cancer-related cause of death worldwide. In this scenario, our group validate new targets to drug development focusing in interfering at phosphatidylethanolamine (PE) production as a breakthrough strategy, once PE has been previously described as increased in Non-Small Cell Lung Cancer (NSCLC) tumors. Two critical points in PE production should be highlighted: ethanolamine cellular uptake and the enzyme responsible for the limiting step of the main route of PE synthesis, CTP:phosphoethanolamine cytidylyltransferase (Pcyt2). Therefore, this study aimed to evaluate *in vitro* modulation of Pcyt2 enzyme and ethanolamine cellular uptake in A549 cells to validate the therapeutic potential of these targets for NSCLC treatment. **Method:** Pcyt2 was silenced in A549 cell line by CRISPR-Cas9-Mediated technology using 4D-Nucleofector™ System, followed by sorting using FACSAria II and confirmation of Pcyt2 protein depletion by Western blotting. Cellular sensitivity to meclizine (a Pcyt2 inhibitor) and isopropanolamine (an ethanolamine uptake inhibitor) was assessed by MTT assay. The proliferation capacity was evaluated by plotting cell growth curves and Colony Forming Units (CFU) assay. Cells were fixed in ethanol overnight in freezer, stained with 7-Aminoactinomycin D and analyzed by flow cytometry using BD LSRFortessa. All statistical data are expressed as mean ± standard deviation (SD) and were analyzed by one-way ANOVA followed by the Tukey's test using GraphPad Prism software, version 7. **Result:** Initially, A549 cells Pcyt2 knockout (KO) cells were established and confirmation in three different passages by Western Blotting. KO cells were resistant to meclizine ($p<0.001$) and more sensitive to isopropanolamine ($p<0.05$) than wild-type (WT) cells. Only WT cells proliferate more when cultured in media with ethanolamine supplementation ($p<0.01$), which is related to the S-phase arrest ($p<0.05$). KO cells showed proliferation changes which were not affected by meclizine treatment both in clonogenic and cell cycle assays. This data is closely related to the reduction of pRb expression and the increase of p21 expression in KO cells. On the other hand, WT cells were arrested in G0/G1 phases and their proliferation capacity was reduced (34% less colonies, $p<0.01$) after meclizine treatment. **Conclusion:** Pcyt2 modulation in A549 cells both genetic and pharmacological showed the decrease of cancer cells proliferation and viability. On the other hand, supplementation of ethanolamine increase cellular proliferation. Altogether, these preliminary results confirm the importance of PE for cell metabolism and division which is an exciting starting point to deeply evaluate Pcyt2 potential as a target for NSCLC treatment.

EP1.14-05 CLINICAL CHARACTERISTICS OF OSIMERTINIB RESPONDER IN NON-SMALL CELL LUNG CANCER PATIENTS WITH EGFR-T790M MUTATION

T. Yamada[1], A. Yoshimura[1], T. Takeda[2], S. Shiotsu[3], O. Hiranuma[4], Y. Chihara[5], J. Uchino[1], K. Takayama[1]

[1]*Kyoto Prefectural University of Medicine, Kyoto/Japan,* [2]*Japanese Red Cross Kyoto Daini Hospital, Kyoto/Japan,* [3]*Japanese Red Cross Kyoto Daiichi Hospital, Kyoto/Japan,* [4]*Otsu City Hospital, Otsu/Japan,* [5]*Uji-Tokushukai Medical Center, Kyoto/Japan*

Background: Osimertinib is a mutant-selective EGFR inhibitor that is effective against non-small cell lung cancer (NSCLC) patients with the *EGFR*-T790M mutation, who are resistant to EGFR-tyrosine kinase inhibitors (EGFR-TKIs). However, the factors affecting response to osimertinib treatment are unknown. **Method:** In this retrospective study, 27 NSCLC patients with the *EGFR*-T790M mutation were enrolled at 5 institutions in Japan. **Result:** Among several parameters tested, the progression-free survival (PFS) associated with the initial EGFR-TKIs was positively correlated with the PFS after osimertinib treatment (p = 0.021). The median PFS following osimertinib treatment and the overall survival (OS) were longer in patients who responded to osimertinib than in those who

did not (17.7 months versus 3.5 months, p = 0.009 and 24.2 months versus 13.5 months, p = 0.021, respectively). A multivariate analysis demonstrated that the PFS with initial EGFR-TKIs was significantly related to the PFS with osimertinib treatment (p = 0.035), whereas osimertinib response was significantly related to the PFS and OS with osimertinib treatment (p = 0.016 and p = 0.006, respectively). **Conclusion:** Our retrospective observations indicate that PFS following the initial EGFR-TKI treatment and the response rate to osimertinib might be promising predictors for effective osimertinib treatment in NSCLC patients with the *EGFR*-T790M mutation.

Keywords: Osimertinib, Biomarker, EGFR-T790M mutation

EP1.14-06 CLINICAL APPLICATION OF AN APPROPRIATE SIZE NGS PANEL IN ADVANCED NON-SMALL CELL LUNG CANCER MANAGEMENT: PERSONAL EXPERIENCE

K.-C. Tung[1], C.-H. Lin[2], S.-C. Chen[3], K.T. Tan[1], Y.-T. Liu[1], Y. Chao[3], C.-M. Tsai[3]

[1]*ACT Genomics, Co. Ltd., Taipei/Taiwan,* [2]*Cathay General Hospital, Taipei/Taiwan,* [3]*Taipei Veterans General Hospital, Taipei/Taiwan*

Background: Precision medicine plays an important role in patients with advanced non-small cell lung cancer (NSCLC). The targeted genes, EGFR, BRAF, ALK, and ROS1, have become as a standard genetic test in NSCLC. Using multi-gene next-generation sequencing (NGS) technology is an efficient approach compared with the conventional genetic test that can identify hundreds of genetic information simultaneously. In this study, we share our clinical experience of using an appropriate size NGS test in Taiwan NSCLC patients. **Method:** The formalin-fixed, paraffin-embedded (FFPE) were collected from 100 patients with advanced NSCLC. 94 patients had received at least one treatment and six patients were treatment-naïve. The FFPE samples were profiled using a medium size NGS panel on the Ion Torrent system. The single nucleotide variants (SNV) and small InDels were detected in 35 or 40 genes, as well as copy number variations (CNVs) in 14 or 22 genes. The gene fusion status was evaluated by an RNA fusion test in 4 genes. **Result:** In total, the alternation of FDA-approved biomarkers was identified in 70.0% (70/100) patients. Other genetic alterations, including suggested biomarkers in NCCN guideline (ERBB2 mutations and CNVs, MET exon 14 alterations and RET fusions), and other potential actionable mutations (EGFR exon 20 insertions and CNVs, BRAF rare mutations, KRAS mutations and CNVs, ALK CNVs, MET CNVs, mTOR pathway, and cell cycle pathway alternation) were detected in 60.0% (60/100) patients. The co-occurred potential genomic alterations were discovered in 60.7% (37/61) of patients who had EGFR mutations at diagnosis. 78.3% (18/23) patients with post third generation EGFR TKI therapy had at least a co-occurring potential actionable alterations with EGFR mutation. In patients with wild type EGFR and ALK or unknown-status at diagnosis, the targeted alternation was detected in 51.4% (19/37), and 21.6% (8/37) were FDA-approved biomarkers. Furthermore, we report two cases who responding to the targeted drugs followed the NGS testing results. One case had a potentially actionable alteration co-occurred with EGFR mutation and the other had a rare BRAF mutation. **Conclusion:** The data reported here suggest that using genetic test by an appropriate size and cost-effective NGS panel for NSCLC patients at disease diagnosis or disease progression could identify more mutations other than FDA-approved biomarkers for targeted drug selection.

Keywords: Targeted therapy, NSCLC, NGS

EP1.14-07 EFFICACY AND SAFETY OF ALK INHIBITORS IN ALK-REARRANGED NON-SMALL CELL LUNG CANCER: A SYSTEMATIC REVIEW AND META-ANALYSIS

D. Breadner, S. Shanmuganatjan, G. Boldt, P. Blanchette, J. Raphael

London Regional Cancer Program, London/Canada

Background: First and second generation ALK inhibitors were shown to delay disease progression and improve tumour response in ALK-rearranged advanced non-small cell lung cancer (NSCLC) patients. While a significant progression free survival (PFS) improvement has been consistently reported, no overall survival (OS) benefit was shown in randomized trials. We conducted a systematic review and meta-analysis to assess the efficacy and safety of ALK inhibitors compared to chemotherapy (ALK vs. chemo) and 2nd generation ALK inhibitors compared to 1st generation ALK inhibitors (ALK 2G vs. ALK 1G). **Method:** The electronic databases PubMed and EMBASE, were searched for relevant randomized trials. Pooled hazard ratios (HR) for overall survival (OS) and progression free survival (PFS), and pooled risk ratios for objective response rates (ORR) and grade 3 or higher toxicity were meta-analyzed using the generic inverse variance and the Mantel-Haenszel methods. To account for between-studies heterogeneity, random-effect models were used. Subgroup analyses compared PFS by gender, smoking status, brain metastases, race and age. **Result:** Six trials were included in the analysis of ALK vs. chemo and four in the analysis of ALK 2G vs. ALK 1G. Treatment with ALK inhibitors improved OS compared to chemotherapy (HR: 0.84, 95%CI 0.72-0.97) while a trend toward a better OS was seen with ALK 2G vs. ALK 1G without reaching statistical significance (HR: 0.64, 95%CI 0.36-1.16). PFS was improved with ALK vs. chemo and ALK 2G vs. ALK 1G (HR: 0.44, 95%CI 0.35-0.44 and HR: 0.38, 95%CI-0.29-0.51, respectively). Similarly, ORR was improved with ALK vs. chemo and ALK 2G vs. ALK 1G (RR: 2.68, 95%CI 1.89-3.81 and RR: 1.16, 95%CI 1.08-1.24, respectively). The risk of grade 3 or higher toxicity did not differ between treatments (RR 1.08, 95%CI 0.88-1.33 and RR 0.77, 95%CI 0.56-1.06, respectively). Overall the PFS benefit of ALK vs. chemo and ALK 2G vs. ALK 1G was homogenous across all subgroups with a greater degree of benefit within never-smokers when treated with ALK vs. chemo (*p* for subgroup differences=0.03). **Conclusion:** This meta-analysis is the first, to our knowledge, to report an OS improvement with the use of ALK vs. chemo. A trend toward a better OS was also seen with ALK 2G vs. ALK 1G and this is likely because of crossover effects and limited OS follow-up. Longer follow up and further research are warranted to directly compare ALK inhibitor sequences and to understand the outcomes of 2nd generation ALK inhibitors as initial therapy.

Keywords: ALK, Targeted therapy, advanced NSCLC

EP1.14-08 IRREVERSIBLE SEVERE CARDIOTOXICITIES EXCEPT FOR QTC INTERVAL PROLONGATION ASSOCIATED WITH OSIMERTINIB

K. Kunimasa, M. Kimura, T. Inoue, M. Tamiya, K. Nishino, F. Imamura, T. Kumagai

Osaka International Cancer Institute, Osaka/Japan

Background: QTc interval prolongation is a known and warning cardiotoxicity associated with Osimertinib. The final summary on the safety profile of Osimertinib (AstraZeneca plc) reports that severe cardiotoxicities except for QTc interval prolongation are 0.8 % (29/3578 patients) and alerts us to such adverse events. Here, we report irreversible severe cardiotoxicities associated with Osimertinib except for QTc interval prolongation. **Method:** We reviewed the medical records of EGFR-mutated Non-Small Cell Lung cancer patients who were treated with Osimertinib at Osaka International Cancer Institute between March 2016 and January 2019. We checked cardiotoxicities associated with Osimertinib based on the medical records. **Result:** We enrolled 123 patients treated with Osimertinib into this study. The median age was 69 (range: 33-86) years. Of 123 patients, 40 (32.5%) were male, all cases except one were adenocarcinoma, EGFR mutation profile was Ex. 19 del/ L858R/ de novo T790M/ others(G719S, L861Q); 62 (50.4%)/ 56 (45.5%)/ 3/ 2. Osimertinib treatment line was 1st line; 23 (18.7%), 2nd line; 30 (24.4%), 3rd line; 18 (14.6%), ≧4th line; 41 (33.3%), 11 pts; switching from other EGFR-TKI during 1st line. Severe cardiotoxicities (CTC-AE Gr.3≧) were observed in 5 pts (4.1%); acute myocardinal infarction (1), irreversible congestive heart failure due to systolic dysfunction (1), exacerbation of tricupid regurgitation (1), decreasing ejection fraction (EF) (2). QTc interval prolongation was observed only in one patient (Gr.1). Histopathological analysis of a myocardial biopsy from one patient with decreased EF (Gr.3) revealed inflammatory cells infiltration into cardiomyocytes. Intriguingly, afatinib switched from osimertinib overcame osimertinib induced cardiomyopathy in the patient. **Conclusion:** We experienced severe cardiotoxicities associated with Osimertinib at a higher frequency (4.1%) than reported before. Considering some patients were forced to quit their chemotherapy due to severe cardiotoxicities. We should pay attention to not only QTc interval prolongation but also other cardiotoxicities in administrating Osimertinib in the clinical setting. Afatinib could be an alternative to Osimertinib for overcoming Osimertinib-induced cardiotoxicities.

EP1.14-09 CHARACTERIZATION OF ACTIONABLE BRAF^{V600E} AND CO-MUTATIONS IN NON-SMALL CELL LUNG CANCER (NSCLC) PATIENTS

P. Sanvarinda[1], S. Oranratnachai[2], S. Detarkom[2], N. Iemwimangsa[2], N. Trachu[2], P. Incharoen[2], W. Chantratita[2], T. Reungwetwattana[2]

[1]*Faculty of Science, Mahidol University, Bangkok/Thailand,* [2]*Faculty of Medicine Ramathibodi Hospital, Mahidol University, Bangkok/Thailand*

Background: Targeting activated-mutations in NSCLC offers unique benefit that outperforms other cancers. Multiplex Next Generation Sequencing (NGS) platform provides opportunity for detection of low-frequency actionable-mutations such as *BRAF* ^{V600E}, which was previously reported in 1-2% of NSCLC and correlated with poorer response to chemotherapy. In this study, we used the NGS platform to determine the prevalence and characteristics of *BRAF* ^{V600E}-mutated NSCLC. **Method:** Tissue archive of stage I-IV NSCLC from Ramathibodi and Phramongkutklao Hospitals during 2012-2015 was retrieved for DNA extraction. Samples were analyzed by NGS with Lung Cancer Panel 45 Genes on Ion Torrent system. Variants from NGS with coverage of higher than 1000X and ≥3% alternate variant frequency were considered as positive. The cutoff-point was validated by Real- time PCR. Clinical data correlation was analyzed. **Result:** Of the 159 FFPE-samples, 16 samples (10.1%) with BRAFV600E mutation were identified. The median age was 66.6 years old. Majority of the patients were female (81.3%) and never-smoker (75%). Seven patients had early stage and 9 patients had stage III-IV disease. Co-mutations with BRAFV600E were found in 13 patients. EGFR mutation was the most common co-mutation (62.5%) follow by co-mutation with KRAS (37.5%), MET exon14 splice-site (18.8%), and PIK3CA (6.3%) (Table1). Advanced-stage patients with KRAS and MET exon14 splice-site co-mutations with BRAFV600E had worse survival (10.4, 10.4 months) compared to patients with EGFR co-mutation (41.1 months). Survival of patients with single BRAFV600E is better than patients with other co-mutations (not reach vs 60.5 months) in all stages. Table 1: Baseline characteristics of 16 patients with BRAFV600E mutation and their co-mutated gene including palliative treatment in stage IV patients

Conclusion: Our data demonstrated high prevalence of *BRAF* ^{V600E} and coexisting-actionable mutations. *BRAF*^{V600E}-mutated NSCLC are common in female and never-smoker. Co-mutations with other actionable-mutations patients showed worse survival compared to single *BRAF*^{V600E} patients. Integrating the sensitive multiplex NGS method into the clinical practice will help broaden the opportunity for superior treatment efficacy in the future.

EP1.14-10 INVESTIGATION OF MECHANISMS OF ACQUIRED RESISTANCE TO AFATINIB WITH PLASMA DNA IN NON-SMALL CELL LUNG CANCER PATIENTS

N. Sueoka-Aragane[1], T. Nakamura[1], C. Nakashima[1], K. Iwanaga[2], H. Umeguchi[3]

[1]*Saga University Hospital, Division of Respiratory Medicine, Saga/Japan,* [2]*Division of Respiratory Medicine, Saga-Ken Medical Centre Koseikan, Saga/Japan,* [3]*Department of Respiratory Medicine, Karatsu Red Cross Hospital, Saga/Japan*

Background: Afatinib, the 2nd generation epidermal growth factor receptor tyrosine kinase inhibitor (EGFR-TKI) has been evidenced better efficacy compared to 1st generation EGFR-TKI by phase III studies, but the problem is to acquire resistance approximately one year after treatment. The detail mechanisms of acquired resistance to afatinib has not clarified, although T790M was also detected at time to acquired resistance. Recently, the 3rd generation EGFR-TKI, osimertinib has been approved as the first line setting. As for the mechanisms of acquired resistance to osimertinib as 1st line, various kinds of pathway beside EGFR contributed, suggesting difficulty to select next treatment strategy after osimertinib. Considering how to use 1st, 2nd and 3rd approximately, it has been reported that longer PFS was shown among the patients who were treated with osimertinib following afatinib, compared to 1st generation EGFR-TKI. Based on these evidences, we hypothesize that mechanisms of acquired resistance to afatinib may be less genetic alterations compared to osimertinib, and these alterations could be limited to EGFR pathway, resulting in EGFR-TKI sequencing, from afatinib to osimertinib showed better prognosis. Because the concept of tumor evolution showed that the number and kind of genetic alterations were increased after treatment modifications, comprehensive assay system is indispensable for evaluation of acquired resistance. Moreover, non-invasive assay system such as liquid biopsy is needed since distant metastases are often observed in advanced lung cancer patients. Guardant360™, a high sensitive digital sequencing system with plasma DNA has been developed by Guardant Health, enable to detection of SNV of 73 genes, in/del of 23 genes, amplification of 18 genes, and fusions of 6 genes. The assay system enables us to detect 0.03% allele fraction. The purpose of this study is to clarify mechanism of acquired resistance to afatinib with liquid biopsy to determine best EGFR-TKI sequencing. **Method:** Study Design Prospective observational study Primary objective To determine mechanisms of acquired resistance to afatinib with plasma DNA Target sample size 40. We are planning to compare with the results of patients who acquired resistance to osimertinib with liquid biopsy performed in FLAURA. So far, 29 patients acquired resistance to afatinib, and we collected these blood samples. Sample preparation Collection of samples 1. before afatinib treatment and at PD to afatnib 2. collection of 5ml blood with sodium citrate collection tube Genomic examinations NGS is performed in Guardant Health. **Result:** This study had finished enrollment and under analysis now. **Conclusion:** Comprehensive analysis are needed to clarify the mechanisms of acquired resistance to afatinib to facilitate consideration of the best sequence of EGFR-TKI.

Keywords: Afatinib, Acquired resistance, EGFR-TKI sequencing

EP1.14-11 REAL-LIFE DATA OF OSIMERTINIB IN PRETREATED PATIENTS WITH ADVANCED NON-SMALL CELL LUNG CANCER HARBORING EGFR T790M MUTATION

C. Alfaro Autor, A. Romero, V. Calvo De Juan, F. Franco, E. Sánchez Romero, N. Ortiz Cortes, S. Sanz Moreno, A. Rodríguez Festa, R. Serna Blasco, M. Barquín Del Romo, M. Provencio

Hospital Puerta De Hierro Majadahonda, Majadahonda (Madrid)/Spain

Background: Several clinical trials have demonstrated the efficacy and safety of osimertinib in pretreated patients with advanced non-small cell lung cancer (NSCLC) harbouring EGFR T790M resistance mutation. However, clinical real-world data on patient characteristics and efficacy of the drug is limited. **Method:** We reviewed the medical records of T790M mutation-positive lung cancer patients treated with osimertinib between May 2016 and February 2019 in our institution. We calculated progression-free survival (PFS) and overall survival (OS) from osimertinib initiation. **Result:** The study included 22 patients with a mean age of 59.6 years. 59% (13/22) were female and 100% had adenocarcinoma histology. We had an unusual high frequency of tobacco use in our series as 40.9% (9/22) of our patients were smokers (3/22) o former-smokers (6/22), with a mean of 35 pack-year (sd, 28.5). 45.5% (10/22) had exon 21 L858R mutations, whereas 54.5% (12/22) harboured exon 19 deletions (19del). One patient simultaneously had an exón 19 deletion and exon 20 S768I mutation. Osimertinib was used in second, third and fourth line in 50% (11/22), 27% (6/22) and 23% (5/22) of patients, respectively. All patients had liquid biopsy blood samples obtained prior to the start of the treatment, and T790M mutation could be detected in 86.4% (19/22), with a mean mutant-allele fraction of 4,11% (standard deviation 8.65, min 0, max 37.7). T790M was detected only in tissue in 2 patients and exclusively in cerebrospinal fluid in 1 of them. At the time of starting osimertinib, patients had a median of 3 metastatic sites (min 1, max 6), being the most frequent locations the lung (73%), the bone (64%), the pleura (59%), the central nervous system (23%) and the peritoneum (14%). Median follow-up duration was 10 months (IQR, 4.7-22.67). To the date, 63% (14/22) have experienced progression of the disease. Median PFS in our series was 8.9 (95% CI, 4.9-17.9) months, whereas median OS since osimertinib initiation was 18.2 (95% CI, 8.8-NE) months. Regarding to toxicity, 12 patients referred adverse events, 82.6% of which were mild (G1), being the most frequent toxicities neutropenia (9%), diarrhoea (9%), hypertransaminasemia (9%) and asthenia (9%). Only 1 G3 event was recorded (asymptomatic hyperamilasemia). **Conclusion:** The efficacy of osimertinib in real-world practice was similar the observed in clinical trials, with a favourable adverse effect profile. Liquid biopsy is an effective non-invasive method to assess the presence of the T790M resistance mutation prior to the start of osimertinib.

EP1.14-12 KRAS EXON 2 MUTATION - A RESISTANCE PATHWAY TO 1ST AND 2ND GENERATION EGFR TKIS

M. Moskovitz[1], Y. Fisher[2], M. Wollner[3], Y. Zohar[2]

[1]*Rambam Health Care Campus, Haifa, Israel/Israel,* [2]*Rambam Health Care Campus, Haifa/Israel,* [3]*Rambam Health Care Campus, Haifa, Israel/Israel*

Background: The most common resistance pathway to first and second generation epidermal growth factor receptor tyrosine kinase inhibitors (EGFR TKIs) in advanced non-small cell lung cancer (aNSCLC) is acquired EGFR T790M mutation. Other resistance mechanisms composed of amplifications of MET, HER-2 and small cell transformation. Acquired KRAS mutation is known as resistance mechanism to 3rd generation EGFR TKIs, but not to 1st or 2nd generation. **Method:** Patients with EGFR positive NSCLC had molecular profiling done upon resistance to 1st or 2nd generation EGFR TKIs, done by next generation sequencing on FFPE tissue or cfDNA from plasma including EGFR exons 19, 20, 21, KRAS exon 2 and BRAF exon 15. Treatment outcomes and prognosis data were taken from the medical records. **Result:** Fifty-three EGFR positive NSCLC patients had molecular profiling done upon resistance to 1st or 2nd generation EGFR TKIs since August 2017, of them 48 had KRAS exon 2 mutation tested. Six (12.5%) patients had KRAS exon 2 mutation, found on plasma in 5 patients and in tissue in 1 patient. Of the 6 patients, the original EGFR mutation was found in 3 patients (50%), and 2 had concurrent EGFR T790M mutation. One patient had KRAS mutation on the initial EGFR testing, although had prolong response to EGFR TKIs. All patients responded to 1st line EGFR TKIs. Upon progression- the 3 patients tested positive for EGFR T790M mutation were treated with osimertinib, although only 1 patient with concurrent KRAS and EGFR T790M mutation responded, and 2 patients with no EGFR T790M mutation were treated with chemotherapy with progressive disease. **Conclusion:** We found acquired KRAS mutation as resistance mechanism for EGFR TKIs in 12.5% of patients with EGFR positive NSCLC treated with 1st or 2nd generation EGFR TKIs. The patients with NSCLC tested positive for KRAS as resistance mechanism for EGFR TKIs were characterized by poor response to either TKIs or chemotherapy. Therefore, testing for KRAS exon 2 mutation is advised upon disease progression during EGFR TKI therapy.

EP1.14-13 EGFR MUTATION IN LUNG ADENOCARCINOMA: REAL WORLD STUDY FROM A SINGLE INSTITUTE

G. Wang, C. Zhang, W. Shang, J. Li, H. Sun, Z. Yu, H. Liu

Liaoning Cancer Hospital & Institute, Shenyang/China

Background: To investigate the EGFR mutation in lung adenocarcinoma of real world. **Method:** Patients diagnosed lung adenocarcinoma and performed EGFR mutation analysis in Liaoning Cancer Hospital & Institute from June 2014 to April 2018 were collected retrospectively. Gender, age, EGFR mutation status of patients were analyzed. **Result:** There were 779 patients included in the study. Of all patients, 365 were male, 414 were female, median age was 60 years-old (range 29-80). EGFR mutation analysis showed that there were 417 mutation cases, 362 were negative, the overall mutation rate was 53.5%. For male patients, the mutation rate was 37.0% (135/365), and 68.1% for female patients (282/414). Seven hundred and sixty-one patients had one EGFR mutation type, 17 had two types, and 1 had three types. The most common type of EGFR mutation was Exon 21 L858R (204/436, 46.8%), and the second common was Exon 19 deletion (175/436, 40.4%), other mutation types were significantly less, including Exon 20 insertion (20/436, 4.6%), Exon 18 G719X (19/436, 4.4%), Exon 20 S768I (10/436, 2.3%), Exon 21 L861Q (5/436, 1.1%). Primary resistance of T790M mutation were found in 3 patients (0.7%), however, all the 3 cases had two types of mutations besides T790M mutation (2 Exon 19 deletion and 1 Exon 21 L858R). **Conclusion:** The overall EGFR mutation rate was over 50% in our institution, and higher in female patients, about 70%. The most common mutations were Exon 21 L858R and Exon 19 deletion, and other mutation types were rare. Finally, T790M mutation often combined with the other type of EGFR mutations.

Background: Tumor initiating cells (TICs) are responsible for causing chemotherapy resistance and tumor relapse, but the mechanisms have not been elucidated. This study aims to explore the role of mucin 1 (MUC1) in chemotherapy resistance of TICs and its clinical significance. **Method:** The relationships between expression of MUC1 and clinical outcomes were analyzed by multiple databases. The MUC1 expression and function in chemoresistant TICs were investigated *in vitro* and *in vivo* through gain-of and loss-of function strategies. The potential downstream targets of MUC1 were analyzed using chromatin immunoprecipitation and luciferase reporter assay. The prognostic value of MUC1 signaling was evaluated using IHC. **Result:** High expression of MUC1 positively related with poor outcome of cancer patients. Elevation of MUC1 in chemoresistant cancer cells concomitant with TICs enrichment. Mechanistically, MUC1 induces the expansion of TICs population through activation of EGFR, which augments interleukin-6 (IL-6) transcription. Inhibition of EGFR-IL-6 signaling significantly abolishes expansion of chemoresistant TICs. Furthermore, coadministration of EGFR inhibitor overcomes the resistance of TICs to paclitaxel both *in vitro* and *in vivo*. Analysis of cervical cancer patients reveales that the expression of MUC1, EGFR and IL-6 are considerably increased after chemotherapy, showing a positive correlation between the expression of MUC1, EGFR and IL-6. Consistently, mining TCGA datasets uncovered a significant positive correlation between activation of MUC1-EGFR-IL-6 signaling pathway and poor disease-free survival in chemo-treated cervical cancer patients. **Conclusion:** MUC1 confers chemotherapy resistance of TICs through EGFR-mediated transcriptional regulation of IL-6.

EP1.14-15 REAL WORLD CLINICAL EXPERIENCE OF THE GALICIAN LUNG CANCER GROUP: AFATINIB IN PATIENTS WITH EGFR POSITIVE MUTATION

S. Agraso Busto[1], V. Varela[2], N. Fernandez[3], X.L. Firvida[4], L. Santome[5], J. Afonso[6], C. Azpiarte[7], N. De Dios Alvarez[1], J. Garcia[8], B. Campos[3], M.C. Areses[9], D. Pereiro[1], M. Lazaro[1]

[1]*Complexo Hospitalario Universitario de Vigo, VIGO/Spain,* [2]*Hospital Clinicio Universitario Santiago de Compostela, SANTIAGO DE COMPOSTELA/Spain,* [3]*Hospital Lucus Augusti, LUGO/Spain,* [4]*Complexo Hospitalario Universitario De Ourense, OURENSE/Spain,* [5]*Hospital Povisa, VIGO/Spain,* [6]*Complexo Hospitalario Universitario de Ferrol, FERROL/Spain,* [7]*Complexo Hospitalario de Pontevedra, PONTEVEDRA/Spain,* [8]*Hospital Clinico Universitario Santiago de Compostela, SANTIAGO DE COMPOSTELA/Spain,* [9]*Complexo Hospitalario Universitario de Ourense, OURENSE/Spain*

Background: Treatment with tyrosine kinasa inhibitors has been a revolution for the patients with non-small cell lung cancer and EGFR positive mutation, especially in patients with exon 19 deletions. Afatinib seems one of the best options of treatment. **Method:** Retrospective study on patients from differents hospitals in Galicia (Spain) diagnosed of metastasic lung adenocarcinoma with EGFR positive mutation who have received first line treatment with afatinib between July 2015 and September 2018 were included. Main objective was to compare our clinical experience concerning response rate, progression free survival and toxicity with published data. **Result:** 45 caucasians patients were included in our analysis (33 women, 12 men). Median age was 71.2 years (range 39-91 years) and 29 patients had never smoked. Exon 19 deletion was the most common mutation (41 patients, 91.1%). The objective overall response was 68.9% (95% CI: 82.4-55.3), complete responses were observed in 6 patients (13.3%) and partial responses were found in 25 patients (55.6%). Stable disease was observed in 8 patients (17.8%) and disease progression in 1 patient (2.2%), 5 patients have not been reevaluated (11.1%). Median progression free survival (PFS) was 27 months (95% CI: 14.8-39.1) and overall survival was not reached. Common adverse events grade 3/4 were mucositis and skin toxicity in 11 patients (24.4%) and diarrhea in 6 patients (13.3%), respectively. The dose was reduced in 28 patients (62.2%) and treatment was discontinued in 8 patients (17.8%) owing to adverse events. **Conclusion:** Median PFS in our patients is 15 months longer than the information retrieved from differents studies with similar response rates and toxicity. This might be due to a majority of population with exon 19 deletion which, according to published data, seems to benefit more from afatinib than from other EGFR mutations.

EP1.14-16 USE OF DIGITAL DROPLET PCR FOR DETECTING EGFR T790M RESISTANCE MUTATION IN PLASMA AT PROGRESSION ON TKI THERAPY

M. Jönsson[1], M. Planck[1,2], C. Reuterswärd[1], I.-M. Nilsson[2], M. Carlsson[2], A. George[1], L. Saal[1], J. Staaf[1], S. Isaksson[1]

[1]*Division of Oncology and Pathology, Lund/Sweden,* [2]*Skåne University Hospital, Lund/Sweden*

Background: Therapy surveillance is a corner stone in advanced lung cancer clinical management. Due to the ease of sampling, analysis of tumor derived circulating DNA in plasma for treatment monitoring and decision making is desirable. Patients with tumors harboring a sensitizing *EGFR* mutation benefit from targeted therapy using tyrosine kinase inhibitors (TKIs). Unfortunately, the majority of patients develop resistance towards the initially administered TKI either through intrinsic mechanisms of *EGFR* or mutations of additional genes such as amplification of *MET*. Osimertinib can be administered at disease progression due to the resistance mutation T790M in *EGFR*. In this study we used liquid biopsy at progression after TKI treatment to assess mutational status of sensitizing and T790M mutations. In some cases, a tumor biopsy was analyzed in parallel as part of clinical management. **Method:** Six 10 ml Streck Cell free BCT® tubes were collected and plasma was isolated. Cell free circulating DNA was purified and used in an ultra-sensitive ddPCR assay IBSAFE (George et al, manuscript in preparation). Both the sensitizing *EGFR* mutation and T790M was analyzed. In some cases, a solid biopsy was analyzed in the clinic in parallel to our plasma analysis. Patient outcome data will be collected from patient files. **Result:** Eighteen of 25 patients tested positive in plasma for the previously known sensitizing *EGFR* mutation (72%). Twelve of 25 tested positive in plasma for T790M mutation (48%). Among plasma samples positive for the sensitizing mutation, 67% were also positive

for T790M. The minor allele frequency (MAF) fraction of T790M in comparison to the sensitizing mutation varied extensively from 0.01% to 90% and also the MAF compared to total DNA varied (0.005% to 23%). Updated clinical follow up data will be presented. **Conclusion:** For a subset of patients were a tumor biopsy is not feasible, a liquid biopsy could provide information about the mutational status. As the MAF vary considerably and can be very low, a highly sensitive assay such as the IBSAFE ddPCR assay, capable of confirming a mutation at a MAF as low as 0.005% is advantageous. Further, a large plasma input volume may aid in identifying patients positive for mutations at a low MAF. Updated clinical follow up data will be discussed.

Keywords: plasma, EGFR, ddPCR

EP1.14-17 ACQUIRED T790M MUTATION IN PATIENTS FAILING TREATMENT WITH FIRST OR SECOND-GENERATION EGFR-TYROSINE KINASE INHIBITORS

C.K. Liam[1], C.S. Chai[2], M.E. Poh[1], D.B.L. Ong[3], P.L. Cheah[3], Y.K. Pang[1], G.F. Ho[4], A. Alip[4]

[1]*Department of Medicine, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia,* [2]*Department of Medicine, Faculty of Medicine and Health Science, University Malaysia Sarawak, Kota Samarahan/Malaysia,* [3]*Department of Pathology, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia,* [4]*Department of Clinical Oncology, Faculty of Medicine, University of Malaya, Kuala Lumpur/Malaysia*

Background: The majority of patients with epidermal growth factor receptor (*EGFR)*-mutant advanced non-small cell lung cancer (NSCLC) develop resistance to first- or second-generation *EGFR*-tyrosine kinase inhibitor (TKI) after a median treatment period of 12 months. This study aimed to determine the prevalence and predictors of acquired *T790M* mutation as a resistance mechanism among these patients. **Method:** This was a retrospective study of patients with sensitising *EGFR*-mutant advanced NSCLC who experienced disease progression (PD) while on first- or second-generation *EGFR*-TKI treatment and underwent investigations to determine the resistance mechanisms in University of Malaya Medical Centre from 1st January 2015 to 31st December 2017. **Result:** Of 87 patients, acquired *T790M* mutation was detected in 55 (63.2%) patients at PD. *T790M* mutation was significantly more frequent in patients who achieved partial response (PR) as the best response (p = 0.008) or had new lung metastasis (p = 0.048); and significantly less frequent in patients who developed new symptomatic brain metastases (p = 0.021). Patients with *exon 19* deletion were more likely to acquire *T790M* mutation compared to those with *exon 21 L858R* point mutation (p = 0.077). In multivariate analysis, PR with *EGFR*-TKI treatment was a significant independent predictor of acquired *T790M* mutation (p = 0.021) while having new symptomatic brain metastases (p = 0.034) or new lymph node metastases (p = 0.038) were significant independent predictors against acquired *T790M* mutation. **Conclusion:** Acquired *T790M* mutation was a common resistance mechanism leading to first- or second-generation *EGFR*-TKI treatment failure. Patients with tumours harbouring *exon 19* deletion mutation were more likely to acquire *T790M* mutation. A best tumour response of PR to *EGFR*-TKI treatment was an independent predictor of acquiring this resistance. This information is helpful to clinicians in the early prognostication and management planning for patients with *EGFR*-mutant NSCLC.

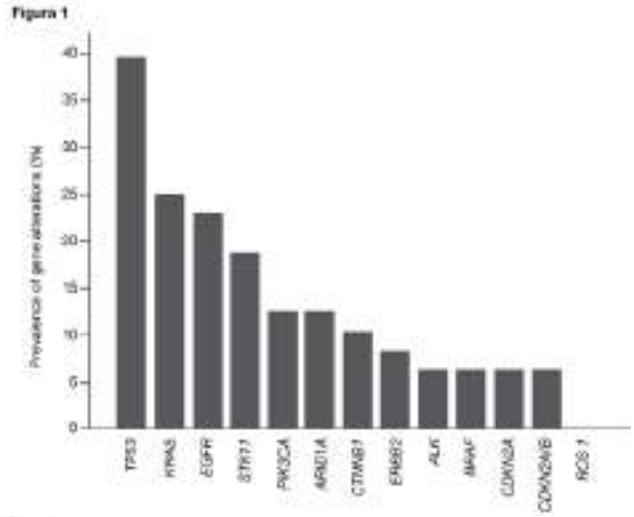
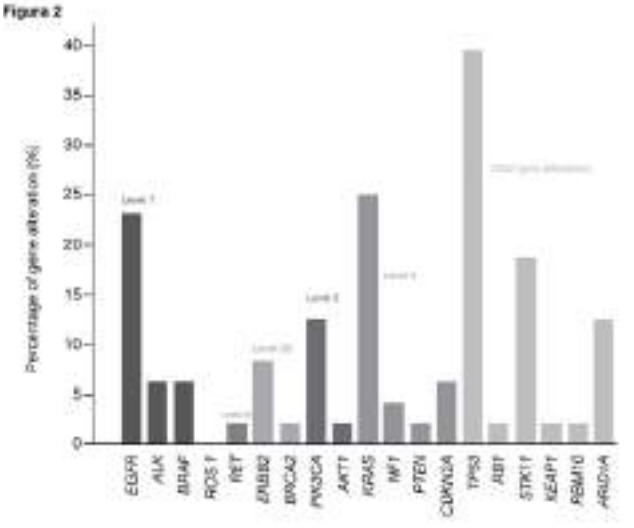
EP1.14-18 NGS-MOLECULAR CHARACTERIZATION OF LUNG ADENOCARCINOMAS FROM HISPANIC PATIENTS: LEVEL OF EVIDENCE FOR THERAPEUTIC ACTIONABILITY

O.G. Arrieta[1], R. Gerson[2], C. Blanco[2], J. Alexander Meza[3], A. Silva[4], S. Rivera Rivera[4], C. Zuloaga Fernández[5], M. Lazaro[6], E. Kazakova[7], A. Villa[8]

[1]*Instituto Nacional de Cancerologia, Mexico City/Mexico,* [2]*ABC Medical Center, Mexico City/Mexico,* [3]*Unidad de Cancerología, Guadalajara/Mexico,* [4]*Instituto Mexicano del Seguro Social (IMSS), Mexico City/Mexico,* [5]*ANKER Oncología Global, Mexico City/Mexico,* [6]*Hospital General de Mexico, Mexico City/Mexico,* [7]*Roche, Mexico City/Mexico,* [8]*Universidad Nacional Autónoma de México, Mexico City/Mexico*

Background: Several studies have shown that NSCLC genomic background among Hispanics differs from other populations, therefore genotyping tumors in order to assess their molecular profile is adamantly needed in the current era of targeted therapy. Panel-detected oncodriver mutations can drive therapeutic approaches, and can help classify the information in order to propose strong evidence-based interventions in treatment guidelines. In this study we sought to understand the landscape of genomic drivers in a cohort of patients with lung adenocarcinoma of Hispanic ancestry. **Method:** Tumor samples were collected from 48 patients with lung adenocarcinoma from march 2017 until march 2019. Samples were submitted for testing to Foundation Medicine and hybrid capture NGS was performed. **Result:**





A total of 282 samples were sent for evaluation, among which 48 (17%) with lung adenocarcinoma were tested by FoundationOne (FO) in tumor tissue. Among the patients included, 54.2% were men and 79.2% were >50 years of age. Most patients had a previous negative report for *EGFR* and *ALK* (in tumor tissue). Results for tumor mutation burden (TMB) were obtained from 48 (100%) samples. Median TMB was 4 mutations/Megabase (m/Mb). High TMB (>10 m/Mb) was identified in 9 (18.8%) samples. The most frequently detected alterations were in *P53*, *KRAS* and *EGFR* genes (Figure1). In terms of the level of evidence for therapeutic actionability, level-1

was 33.5 %, level-2 was 12.5%, level-3 14.6% and level-4 37.5%. (Figure 2). **Conclusion:** Despite an initial assessment of actionable alterations (EGFR and ALK), through a NGS-approach we were able to detect a high amount of genomic alterations linked to a high-level of evidence for therapeutic actionability (33.5%), possibly due to higher sensitivity and a higher number of genes tested in the panel, increasing therapeutic options in this molecular-driven era. This research work was conducted with the support of Roche Foundation Medicine.

Background: Afatinib is an irreversible ErbB family blocker that improves progression-free survival (PFS) of advanced EGFR-mutant lung adenocarcinoma, comparing with chemotherapy. However, afatinib leads to more adverse events than first-generation EGFR inhibitors. Hence, exploration of optimal afatinib initial dose and its efficacy and safety for Asian patients has drawn extensive attention. **Method:** We retrospectively investigated advanced NSCLC patients treated with afatinib from February 27, 2017 to October 30, 2018. Demographic and clinical information, survival data and adverse events were collected and evaluated. **Result:** A total of 60 patients were included into this study. Thirty-nine (65%) patients received afatinib as first-line treatment. Median PFS for first-line afatinib treatment was 15.64 months [95% confidence internal (CI), not reached] and median OS has not been reached. When including age, sex, smoking history, baseline brain metastasis status, afatinib starting dose and mutation types into a multivariate COX regression analysis, PFS of patients with common sensitive EGFR mutations only was significantly longer than that of patients with uncommon mutations [hazard ratio (HR), 0.256; 95%CI, 0.080-0.823; p=0.022]. No significant difference was observed in median PFS between patients treated with a starting dose of 40mg and 30mg (11.18 vs. 5.25 months, p=0.060). The incidence of all grades rash/acne (92.5% vs. 61.1%, p=0.011) and paronychia (82.5% vs. 50.0%, p=0.010) of 40mg group was significantly higher than that of 30mg group.

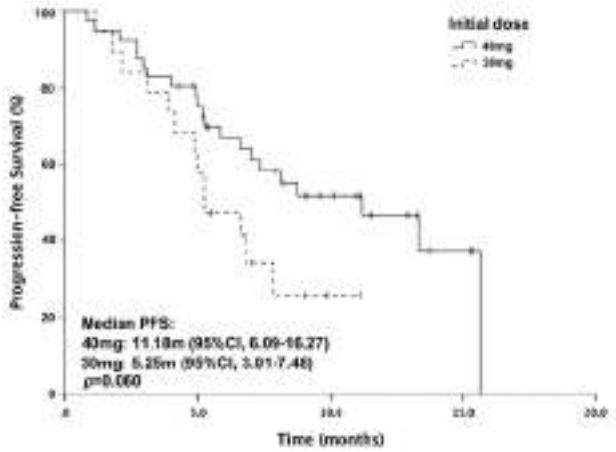

Table 1. Afatinib-Related Adverse Events

Adverse events	All Patients N=58		Afatinib 40mg N=40		Afatinib 30mg N=18		
	N	%	N	%	N	%	p
Diarrhea	50	86.2	36	90.0	14	77.8	0.402
≥Grade 3	6	10.3	5	12.5	1	5.6	0.736
Rash/acne	48	82.8	37	92.5	11	61.1	0.011
≥Grade 3	2	3.4	2	5.0	0	0.0	1.000
Paronychia	42	72.4	33	82.5	9	50.0	0.010
≥Grade 3	2	3.4	2	5.0	0	0.0	1.000
Stomatitis/ mucositis	41	70.7	29	72.5	12	66.7	0.652
≥Grade 3	0	0.0	0	0.0	0	0.0	-
Dry skin	22	37.9	16	40.0	6	33.3	0.628
≥Grade 3	0	0.0	0	0.0	0	0.0	-
Pruritus	9	15.5	7	17.5	2	11.1	0.818
≥Grade 3	0	0.0	0	0.0	0	0.0	-

Conclusion: First-line afatinib treatment is beneficial to advanced lung adenocarcinoma with sensitive EGFR mutations. Initial dose and baseline brain metastasis status do not impact PFS significantly.

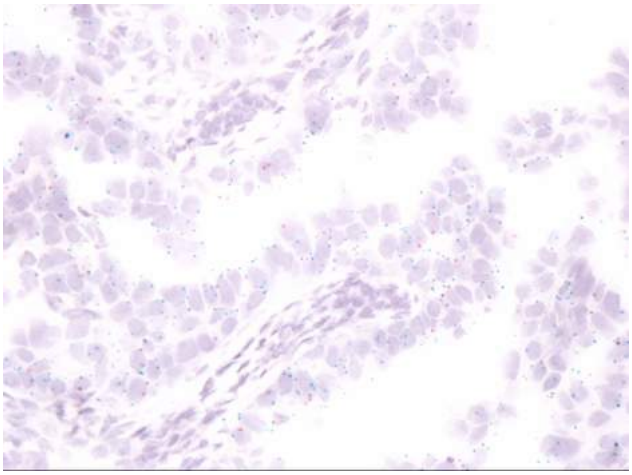
EP1.14-20 EGFR T790M MUTATED CELLS ARE NOT A NEW EMERGING SUB-CLONAL POPULATION IN LUNG ADENOCARCINOMA AFTER THE TREATMENT OF TARGETED THERAPY

X. Shi, S. Wu, Y. Liu, X. Liu, H. Wang, L. Zhang, Z. Liang, X. Zeng

Peking Union Medical College Hospital, Beijing/China

Background: EGFR TKI targeted therapy has improved prognosis for lung adenocarcinoma patients. Almost all patients inevitably develop acquired resistance to these agents, mainly through EGFR T790M mutation. Lung adenocarcinoma patients retained the sensitive mutation and simultaneously acquired the T790M resistance mutation. Whether the acquired T790M mutation is in a newly formed cell groups, or they co-exist with the sensitive mutation in the same cell remained unknown. **Method:** RNA *in situ* hybridization (ISH) methods were employed to examine EGFR T790M and L858R mutations. EGFR L858R mtation probe was labelled with blue color and T790M was labelled with red color. EGFR mutations were also assessed using PCR methods. **Result:** s of RNA ISH and PCR analyses were identical in the majority of examined tissues. We observed that the T790M and L858R mutations co-expressed in the same cell in both the primary and acquired resistance tissue samples. For the two cases with tissues available following third generation TKI therapy, we observed that the T790M mutation disappeared in the repeated biopsy specimen.



EPOSTERS

Conclusion: The EGFR sensitive mutation is a trunk and drive mutation, while T790M is a gatekeeper mutation that can appear or disappear under the pressure of TKI therapy. EGFR T790M mutation isn't a new emerging cell clone and co-existed with the sensitive mutation in the same cell.

Keywords: EGFR, T790M, lung adenocarcinoma

EP1.14-21 IMPLEMENTING PRECISION MEDICINE IN A COMMUNITY CANCER CENTER TO IMPACT OUTCOMES IN LUNG CANCER

E. Hassen[1], A. Khomani[2]

[1]*Spartanburg Regional Health System, Spartanburg/United States of America,* [2]*Gibbs Cancer Center, Spartanburg/United States of America*

Background: With the majority of cancer patients being treated at community cancer centers, it is important to recognize the need for implementation of a Precision Medicine program in community-based oncology programs (Levit et al, 2019; Madhavan et al., 2018; Davis et al, 2018). Increasing indications for targeted therapies and immunotherapies drive the need for molecular testing so patients receive personalized treatment to impact quality outcomes (Gagan & Allen, 2015; Freedman et al., 2018). **Method:** Retrospective review of Precision Medicine program and use of molecular testing. **Result:** The Precision Medicine program was established October 2016 recognizing the need for structure and administrative support. Several key committees were formed including: Steering Committee with administrators and medical staff; Scientific Advisory Board for approval of genomic test; and Operations Committee for review, approval, and accountability, which are responsible for promoting and implementing Precision Medicine. A Precision Medicine team was formed to educate, expand testing availability, and establish policies and procedures within the healthcare system. The Scientific Advisory Board has reviewed and approved genomic test based on scientific validation. The multidisciplinary Lung Advisory Board has evaluated NCCN and College of American Pathologist guidelines to approve lung biomarker reflex testing for lung cancer patients. Currently PD-L1, *EGFR*, *BRAF*, *ROS1*, and *ALK* are reflexed for diagnosis of lung adenocarcinoma, and for squamous cell lung, PD-L1 is reflexed. Since January 2017, 2% *ALK* positive, No *ROS1*, 3% for *BRAF*, and 10% for *EGFR* mutations. PD-L1 combined positivity of high and low expression has been >41%. The population reviewed has an 85% current or past smoker rate. Next-generation sequencing (NGS) is physician ordered, and has increased utilization, 164 in 2017 to 225 in 2018, and trending to over 300 in 2019. For patients with NSCLC stage III and IV, about 20% have NGS. Education and recognition of limited tissue has led to increased use of liquid biopsy, 1 in 2017, 5 in 2018, to 21 in the first quarter of 2019, with lung cancer being 45% of cases. **Conclusion:** A Precision Medicine program provides education, resources, and processes to the healthcare system and multi-disciplinary team to ensure appropriate genomic testing is used to guide personalized medicine and quality outcomes. The approval of reflex testing for non-small cell lung cancer diagnosis allows identification of key targetable mutations for treatment decisions.

EP1.14-22 AMPLIFICATION AND OVEREXPRESSION OF MET IN BRAIN METASTASES OF NON-SMALL CELL LUNG CANCER

N. Akyurek, C. Ercan, O. Ekinci

Gazi University Medical School, ANKARA/Turkey

Background: Non-small-cell lung carcinoma (NSCLC) with *MET* amplification may respond to c-MET inhibitors. **Method:** We investigated *MET* gene amplification status by fluorescence in-situ hybridization (FISH) and c-MET protein expression by immunohistochemistry of 42 NSCLC brain metastases (34 adenocarcinoma, 4 squamous cell carcinoma, 4 NSCLC-NOS). **Result:** We found *MET* gene amplification in 7/42 (21.6%) and c-MET protein expression in 9/42 (21%) of evaluable brain metastasis. There was no correlation between the presence of *MET* gene amplification and c-MET protein expression ($p<0.1$, Chi square test). One patient with *MET* amplification also had *EGFR* mutation. Three patients with c-Met overexpression had *ALK* rearrangement. **Conclusion:** c-MET overexpression and *MET* amplification are commonly found in brain metastasis of NSCLC and may represent a promising therapeutic target.

Keywords: MET, NSCLC, driver mutation

EP1.14-23 COMPARISON OF MOLECULAR TESTING USING VARIOUS SPECIMENS FOR NON-SMALL CELL LUNG CANCERS

T. Ohira, Y. Kudo, Y. Makino, Y. Shimada, S. Maehara, H. Masaru, M. Kakihana, T. Okano, N. Kajiwara, N. Ikeda

Tokyo Medical University, Tokyo/Japan

Background: The effectiveness of various molecular target drugs such as EGFR-TKI for non-small lung cancers came to be shown. So we performed a genetic tests to make plan for suitable therapy individually. For the cases that an operation was carried out for the lung cancer, I inspected the usefulness of the liquid biopsy. The somatic cell variation rate of detection in blood was low, and, in the relatively early non-small-cell lung cancer patient targeted for the operation, the tumor volume was shown in the rule factor when it was. I examined it including the lung cancer case that moved an object as well as an early case this time. **Method:** Patients provided written informed consent for use of the samples were participated in this prospective research. EGFR mutation was examined using blood, a liquid cytological specimen, biopsy specimen. These patients was suspected lung cancer and bronchoscopy was performed. We collected blood, the cytodiagnosis specimen using liquid fixed vial for Cellprep and biopsy specimen. I examined EGFR mutations by three kinds of specimens using Cobas EGFR variation detection kit v2.0. We compared results of EGFR mutation, **Result:** One-hundred fifty-eight patients were registered to this study. Among those patients, 77 patients with matched set of samples were enrolled to this study. EGFR mutation rates in tissue, cytology, and plasma were 37.7, 29.9 and 16.9 %, respectively. Overall agreement rate of the cytology specimens and the plasma specimens against the tissue samples were 87.0 and 75.3%, respectively. All eightT790M mutation positive cases were perfectly matched between tissue and cytology specimens. **Conclusion:** We previously reported that detection of mutations in cfDNA of patients with disease at stage IA or IB or at T2a or lower is difficult. Tumor volume is a determining factor for the feasibility of mutation detection with cfDNA. In this study, advanced lung cancer patients were included. Biopsy specimen were the most feasible sample for detecting mutations. Since high specificities were confirmed in both cytology and plasma specimens, the results are reliable if the mutation results were positive. Choosing cytology or plasma specimens for EGFR testing can be the considerations for the patients who have difficulties in collecting tissue samples in the real world setting.

Keywords: Lung cancer, EGFR mutation, liquid biopsy

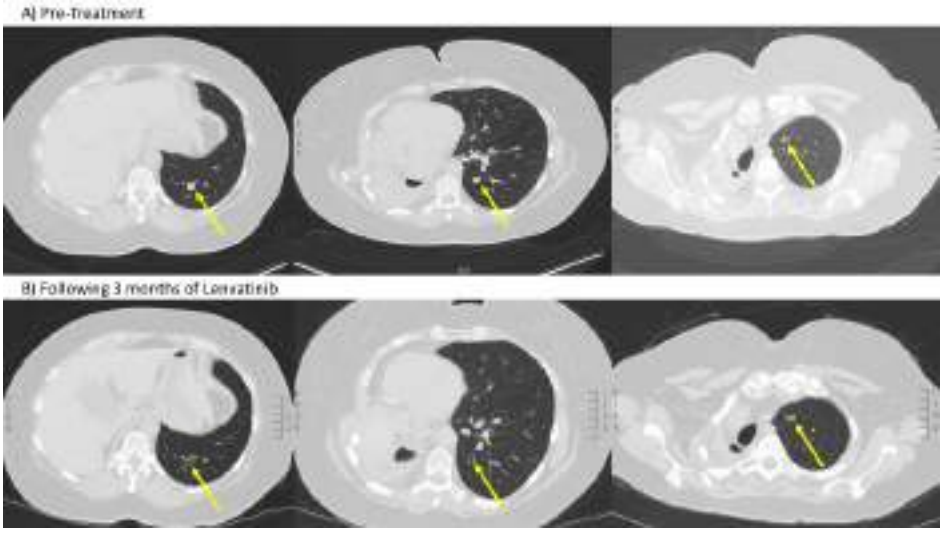
EP1.14-24 LENVATINIB FOR RECURRENT METASTATIC ADENOID CYSTIC CARCINOMAS (ACC) OF THE LUNG

L. Al Rabadi, K. Tolba

Oregon Health & Science University, Portland/United States of America

Background: Adenoid cystic carcinoma (ACC) is a rare malignant neoplasm that frequently originates from the salivary glands of the head and neck, but may also arise in the mainstem bronchus and major airways. The tumor is characterized by a tendency for both local and distant recurrences. Surgical resection remains the mainstay of treatment and radiotherapy is offered in select cases. Palliative systemic chemotherapy offers only modest benefit and is minimally effective. In preclinical studies, ACC has been shown to overexpress the oncogene MYB, which is involved in cell proliferation, apoptosis, differentiation and in upregulation of several growth and angiogenetic factors contributing to the autocrine activation of the FGFR and VEGFR-mediated angiogenesis. Two phase II studies have demonstrated that targeting salivary gland ACC with Lenvatinib, an oral multiple kinase inhibitor targeting VEGFR-1-3, FGFR-1-4, RET, c-KIT, and PDGFR, produced objective partial responses and tumor stabilization. Here we present a case of a patient treated with primary pulmonary ACC treated with Lenvatinib. **Method:** A 62-year-old female underwent a right pneumonectomy for a localized endobronchial ACC of the right lung followed by post-

operative radiotherapy for microscopic involvement of the resection margins. Two and a half years after primary therapy, she was noted on surveillance imaging to have multiple lung nodules in her left lung concerning for recurrent metastatic disease. Subsequently, she initiated palliative therapy with Lenvatinib 24mg daily. **Result:** Tumor assessment by chest CT performed three months after start of Lenvatinib revealed partial response per RECIST V1.1 criteria with interval cavitation of several pulmonary nodules reflecting treatment response. She experienced the typical adverse events associated with Lenvatinib, including CTCAE V4.05 grade 3 hypertension that was managed with three anti-hypertensive medications and grade 3 diarrhea, which required dose reduction.



Conclusion: Consistent with other early phase clinical trials of Lenvatinib in salivary gland ACC, Lenvatinib may exert therapeutic activity in primary pulmonary ACC as has been demonstrated in this case.

EP1.14-25 DEVELOPMENT OF NEW LUNG CANCER THERAPIES BASED ON GENE-EDITING TECHNOLOGIES

J.C. Álvarez Pérez[1,2], J. Martin-Padron[1,3], A. Arenas[1,2], M. Rodríguez[1,2], P. Medina[1,2]

[1]*GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Regional Government, Granada/Spain,* [2]*Department of Biochemistry and Molecular Biology I, University of Granada, Granada/Spain,* [3]*Department of Biochemistry and Molecular Biology III and Immunology, University of Granada, Granada/Spain*

Background: Genome editing has enriched our understanding of mechanisms of the human pathology. Genome editing took a significant advance with the recent development of the CRISPR-Cas9 technology. CRISPR is an acronym for: Clustered Regularly Interspaced Short Palindromic Repeats and it is an adaptation of a prokaryotic functional system. It uses a single guide RNA to direct Cas9 activity to a specific part of the genome, therefore, this system can be used for gene editing and regulation. Cancer is a genetic disease where some DNA-damaged cells begin to divide without stopping and spread into surrounding tissues. Interestingly, in some tumors there is a dependency of a single oncogenic activity (oncogene addiction). This phenomenon indicates that mutations in key oncogenes (driver mutation) are able to drive carcinogenesis and maintain the tumor phenotype. Suggestively, if we can prevent or disrupt these mutations, we can difficult carcinogenesis or damage an established tumoral phenotype **Method:** We seek out for using Crispr-Cas9 technology to target driver mutations and evaluate its therapeutic and preventive value. To develop a proof of concept, we focused on *KRAS* gene which represents the most frequently mutated family across all cancer types. About one-third of human lung adenocarcinomas, the most prevalent form of lung cancer, carry *KRAS* mutations. Most of these mutations are located on codon 12; the mutations *KRAS* c.34G>T (G12C) and *KRAS* c.35G>A (G12D) are the most frequent and important ones. **Result:** We designed specific targeting strategies using HiFiCas9 nuclease which induced *KRAS* G12C and G12D edition while leaving KRAS WT untouched. Disruption of these *KRAS* mutations with the specific gRNA-guided-CRISPR-Cas9 decreases viability and proliferation of mutated cells such as H23 and A427. The generation of a transgenic mouse expressing Crispr-Cas9 designed to target these mutations will allow us to test the potential cancer-resistant phenotype. **Conclusion:** Crispr-Cas9 can be engineered to specifically target single nucleotide oncogenic mutations of *KRAS*. Edition of *KRAS* oncogenic mutations G12C and G12D led to a reduction in the viability of mutated lung adenocarcinoma cell lines.

EP1.14-26 UNCOMMON EGFR MUTATIONS SENSITIVE TO FIRST-GENERATION EGFR-TKI, ICOTINIB

D. Yue[1], B. Sun[1], B. Zhang[1], N. Li[2], R. Lin[2], T. Wang[2], C. Wang[1]

[1]*Tianjin Medical University Cancer Institute and Hospital, Tianjin/China,* [2]*Repugene Technology Inc., Hangzhou/China*

Background: The first-generation EGFR-TKIs are the standard of care for non-small cell lung cancer patients withEGFR activating mutations. Patients with EGFR L858R (p.L858R) or exon 19 deletions are the most prevalent subgroup sensitive to EGFR-TKIs. Previous reports showed that the minority of lung cancer patients with rare EGFR mutations still achieved clinical benefit with EGFR-TKIs. Here, we profiled the landscape of gene mutations in lung cancer patients who responded to Icotinib (a first- generation EGFR-TKI approved in China) treatment without classic EGFR activating mutations. **Method:** We performed a comprehensive sequencing study by a NGS-based panel on a cohort of eleven lung adenocarcinoma patients without common EGFR sensitive mutations and receiving Icotinib treatment in a previous clinical trial (ICOGEN, NCT01040780). The pre-treatment FFPE tissues from all eleven patients were sequenced using a 500-gene panel. **Result:** Six patients responded to Icotinib treatment including three patients with partial response (PR) and three patients with stable disease (SD). The other five patients showed immediate disease progression (PD) after the treatment of

Icotinib. Rare EGFR mutations in the EGFR tyrosine kinase domain, including EGFR mutations W731C (exon 19), M793I (exon 20), and V845L (exon 21), were detected in the PR and SD groups but not in the PD group. EGFR somatic mutation M793I has been detected in the lung tissue of a patient according to the COSMIC record (COSM1716335). In the PR and SD groups, ERBB2 I655V and JAK2 R215Q were identified as potential mutations which could relate to Icotinib sensitivity.

Mutation Information

Gene	p.HGVS	COSMIC ID	P1 (PR)[a]	P2 (PR)[a]	P3 (PR)[a]	P4 (SD)[a]	P5 (SD)[a]	P6 (SD)[a]
EGFR	p.W731C	-	-	5.7%	-	-	-	
EGFR	p.M793I	COSM1716336	-	-	-	-	6.8%	
EGFR	p.V845L	-	2.9%	-	-	-	-	
ERBB2	p.I655V	COSM4000121	-	95.5%	21.5%	-	54.1%	47.5%
JAK2	p.R215Q	COSM275614	1.3%	6.7%	1.0%	-	25.3%	-

a-patient ID and best clinical response per RESIST criterion in the parenthesis.

Conclusion: This study uncovered potential new biomarkers predicting the clinical benefit to Icotinib. With further validation and evidence, it may expand the current patient populations which benefits from the first-generation EGFR-TKIs.

Keywords: icotinib, rare EGFR mutations, gene panel

EP1.14-27 RETROPERITONEAL PSEUDOTUMOR INDUCED BY CRIZOTINIB TREATMENT FOR CMET EX14 SKIP MUTATION NCSLC

R. Gillis[1,2], A. Tiganas[2], Y. Refaley[3], N. Andew[4], N. Peled[1,2]

[1]*Ben Gurion University of the Negev, Beer Sheva/Israel,* [2]*Soroka Medical Center, Beer Sheva/Israel,* [3]*Soroka University Medical Center, Beer Sheva/Israel,* [4]*Rabin Medical Center, Petach Tikva/Israel*

Background: MET-exon-14-skipping(METex14) mutations have been described in 0.6-7% of non-small-cell-lung-carcinomas(NSCLC). METex14 enhance MET receptor pathway signalling through increasing MET protein stability. Patients with NSCLC harboring METex14 mutations may respond to MET tyrosine-kinase-inhibitors(TKI) such as crizotinib. A.E. Drilon et al presented in the Profile-1001 study that crizotinib also demonstrated clinical activity in NSCLC with MET amplification and further data were associated with METex14 skip mutation. **Method:** A 63-year-old, non-smoking, female presented with right-upper-lobe (RUL) mass, Lymphangitis spread and bilateral mediastinal nodal involvement (figure 1). Lung adenocarcinoma (TTF1(+), PDL>20%) was diagnosed. The patient refused radiation nor chemo-therapy and therefore treated by pembrolizumab (KeyNote-042). Upon the presence of CMET ex 14 skip mutation detected on ctDNA (Gaurdnat360™), crizotinib was started with a significant response that allowed a RUL lobectomy with free surgical margins (R0), 4 months later (pT1aN0M0). Following the surgery, she has continued crizotinib therapy and a retroperitoneal pseudotumor was seen on the 9th months post-surgery (figure 2). Needle biopsy indicated a fibrocollagenous tissue, bundles of striated muscle and mixed acute and chronic inflammation without malignant cells. Considering the pathological report, a cyst drainage was performed (figure 3) and crizotinib treatment continued in a lower dose of 250 mg X 1 with no evidence of disease until this report. **Result:** Crizotinib has been shown to act clinically as a targeted selective inhibitor of ALK activity in NSCLC. It is a multi-kinase inhibitor of c-MET and ROS1 oncogenic tyrosine kinase. C-MET receptors are normally present in renal tubular epithelium. Previous publications have described complex renal cyst development as a side effect of crizotinib treatment[iv] [v]. It is not clear yet whether its target of c-MET may explain the crizotinib relation to pseudotumors and renal cysts development. Therefor cases of renal cysts should be registered and reported as rare side effects of crizotinib treatment. **Conclusion:** "Section not applicable"

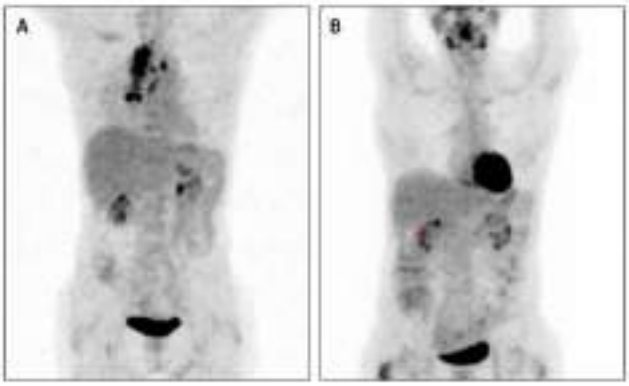

Figure 1: (A) The patient's PET-CT demonstrates right upper lobe mass with multiple mediastinal nodes (02/2017). (B) The Patient's PET-CT post crizotinib treatment present complete response (08/2018).

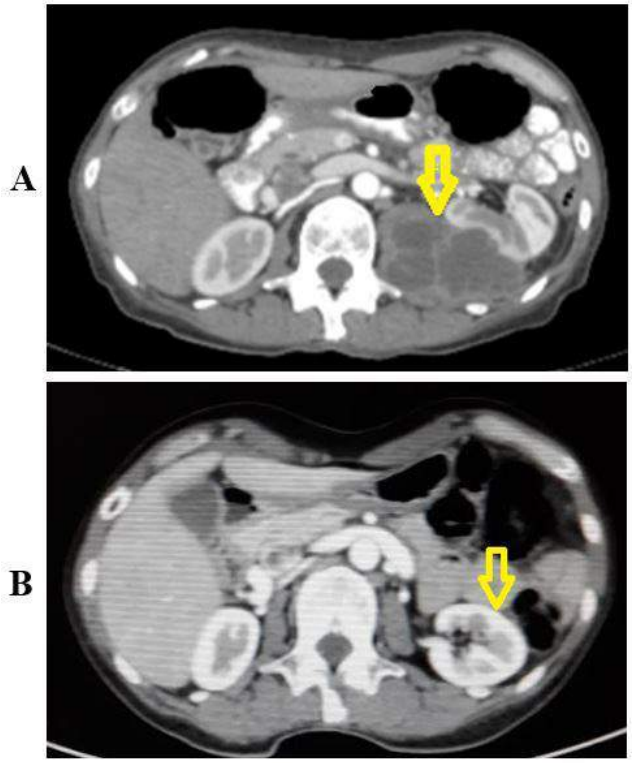

Figure 2: (A) Computed Tomography demonstrates left renal pseudotumor cysts before drainage. **(B)** Normal Computed Tomography after cysts drainage.

EP1.14-28 A DELPHI CONSENSUS ON TKI SEQUENCING IN TREATING ADVANCED EGFR-MUTATED NON-SMALL CELL LUNG CANCER (NSCLC)

T. Wehler[1], V. Hirsh[2]

[1]*EVK Hamm, Hamm/Germany,* [2]*McGill University, Montreal/Canada*

Background: Epidermal growth factor receptor (EGFR) tyrosine kinase inhibitors (TKIs) are standard of care for first-line therapy in patients with EGFR mutation-positive (EGFR M+) non-small cell lung cancer (NSCLC). However, many patients with EGFR M+ NSCLC eventually acquire resistance to first and second generation TKIs, which commonly occurs with the onset of a T790M mutation.[1,2,3,4] Due to the different resistance mechanisms caused by first- and second-generation TKIs versus third-generation TKIs, and the subsequent availability of targeted treatment options, the sequence of TKIs in EGFR M+ NSCLC must be considered. Previous studies have shown the effectiveness of afatinib followed by osimertinib in delaying later chemotherapy, but there is not yet agreement on wider use of this sequencing strategy. The aim of this survey was to establish a global

expert consensus on TKI sequencing strategies in EGFR M+ NSCLC. **Method:** The global panel (7 expert oncologists) reached consensus by a modified Delphi approach (e-surveys). The panellists voted on each statement: disagree, agree, agree with changes (consensus defined as ≥85% agree). Statements without consensus were refined as per suggested changes (through freeform answers to the 'agree with changes' option) and re-voted on. Voting was electronic. The project was funded by Boehringer Ingelheim, who had no role in the development of the Delphi questions or the voting process. **Result:** The panel reached consensus that it is important to consider the sequencing of treatments when deciding which EGFR TKI to choose for a patient with advanced EGFR M+ NSCLC, and that optimising TKI sequencing may delay the need for chemotherapy. When choosing the appropriate TKI, the panel reached consensus that a treatment sequence which extends survival, without compromising quality of life, is an important factor when treating patients with advanced EGFR M+ NSCLC. The panel also reached consensus that the sequential strategy of afatinib followed by osimertinib is a viable option to prolong the chemotherapy-free period, in particular for the 75% of patients with an Exon 19 deletion (del19) who acquire T790M mutations after first-line treatment.[2,5] **Conclusion:** The survey confirms the importance of considering the sequencing of treatments when deciding which TKI to choose for patients with advanced EGFR M+ NSCLC, and provides an expert consensus view on the treatment priorities for this patient population. EP1.14-29 MUTATIONAL LANDSCAPE IN LUNG CANCER PATIENTS BY TARGETED NEXT-GENERATION SEQUENCING AND DIFFERENCES BY GENDER IN SPANISH POPULATION

B. Jimenez Munarriz

Hm Sanchinarro, MADRID/Spain

Background: Personalized treatment with matched therapies according to genomic alterations improve treatment outcome in advanced NSCLC and some genomic alterations are linked to sex. Next Generation Sequencing (NGS) is reliable tool for genomic profiling. We aim to search clinical and pathological differences by sex in NSCLC patients with a comprehensive genomic profile by NGS. **Method:** We retrospective assess clinical-pathological and molecular characteristics of 73 stage I-IV lung cancer patients and NGS at baseline. NGS was performed in 67% by Oncomine ™, 30% by OCA v3 and 2% by Foundation One. **Result:** The cohort included: 49% of females (F), the mean age was 63 years (40-85), 90% stage IV, 91% adenocarcinoma, followed by squamous cell carcinoma (9.5%) and small cell (2%). Former smoker were reported in 74% and 80% of male (M) and females, respectively. Primary tumor lung biopsy was the main source of sample for NGS in 90% of cases. The majority of somatic genomic alterations were mutations (64% M *vs*. 78% F), followed by CNV (19% M *vs*. 11% F) and rearrangements (17% M *vs*. 11% F). In both genders KRAS mutation (mut) was the most common (M vs. F) (27% vs. 28%), and wild-type tumors was reported in 20% and 9%, respectively. Regarding actionable drivers, there was a higher incidence of *EGFR* mut (18% *vs*. 9%), *ALK* rearrangements (6% *vs*. 4%) and *HER 2* mut (6% vs 4%) in F vs M, respectively. As contrary *BRAF* mut (4% *vs*. 3%), and *RET* rearrangements (4% *vs*. 0%) were more frequent in M. Baseline brain metastases in patients with *EGFR and BRAF* mut was similar regardless of sex (50% and 0%), whereas in *ALK* and *HER2* were more frequent in F (50% F vs. 0% M). Twenty-nine percent of patients received personalized treatment according to these results. **Conclusion:** NGS can identify a significant proportion of therapeutically relevant driver alterations in LC leading personalized treatment. Some clinical features were found by gender in our population probably related to genomic differences linked to sex.

Keywords: Lung cancer, NGS, Gender

EP1.14-30 CEREBROSPINAL FLUID FOR LIQUID BIOPSY IN LEPTOMENINGEAL METASTASES OF EGFR-MUTANT NON-SMALL-CELL LUNG CANCER – A CASE REPORT

R. Natal, M. Oliveira, J. Costa, A. Amaral, R. Gomes, L. Ferreira

Local Health Unit of Guarda, Guarda/Portugal

Background: Leptomeningeal metastases (LM) occur in 3-4% of non-small-cell lung cancer patients, especially in 9.4% of those with an epidermal growth factor receptor (EGFR) mutation. EGFR tyrosine kinase inhibitors (TKIs) markedly prolong survival, but LM remain a devastating complication. Since leptomeningeal lesions are difficult to access, resulting in a poor understanding of the resistance mechanisms of LM, greater efforts have been made to trace the evolution of the tumor genome in accessible body fluids including plasma and cerebrospinal fluid (CSF). **Method:** "Section not applicable" **Result:** Case report: The presented clinical case refers to a 69-years-old female, PS 0, with a new right lower lobe nodule submitted to wedge resection surgery. Pleomorphic adenocarcinoma, staging IIB (pT3N0M0), and adjuvant chemotherapy with carboplatin and vinorelbine was done (4 cycles). Eight months after surgery, CT and PET-CT showed relapse with local and distant metastasis, staging IV (rT3N3M1b), EGFR mutation positive, initiating second-line therapy with erlotinib during 31 months, with complete response. By that time she initiated neurologic symptoms with headache and dysarthria. Head CT and MRI didn't revealed any lesions, and there was no evidence of relapse in thoracoabdominal CT. A lumbar puncture (LP) was performed and CSF was sent to cytology (negative for neoplastic cells). Liquid biopsy with CSF and peripheral blood to search for the T790M mutation were both negative. Multidisciplinary decision was to maintain erlotinib, and was oriented to consultation of psychiatry and neurology. Three months later she had another predominant neurologic episode of disorientation, aggression and aggravated dysarthria. Head CT showed progression with multiple foci of leptomeningeal uptake in both cerebral hemispheres, confirmed by MRI. A new LP was performed and infectious etiologies were excluded; cytology was negative and repeated liquid biopsy of CSF and blood were negative for the T790M mutation. Erlotinib dose was increased to 600mg. Ten days after discharge, she returned with diffuse diarrhea and uncontrollable vomiting ending up dying a day later. **Conclusion:** This case highlights the worse prognosis when LM exists and a high correlation between the onset or worsening of neurological symptoms and the development or progression of LM, before imaging; the use of CSF for liquid biopsy to search for T790M mutation, more than one time by the possibility of spatiotemporal heterogeneity; and also is in agreement with the existing literature that the EGFR T790M occurrence in CSF is relatively rare, potentially explained by the low exposure level of first-generation EGFR TKIs in CSF.

Keywords: Cerebrospinal fluid liquid biopsy, leptomeningeal metastases, epidermal growth factor receptor tyrosine kinase inhibitors

EP1.14-31 RETROSPECTIVE STUDY ABOUT EGFR MUTATIONS IN LUNG CANCER: OUR EXPERIENCE IN A SPANISH HOSPITAL

D. Sanchez Cabrero[1], P. Cruz[2], J. Miranda[1], O. Higuera[1], A. Pertejo[1], J. Ramón[1], J.L. Torres[1], L. Gutierrez[1], J. Villamayor[1], D. Viñal[1], I. Esteban[1], J. De Castro Carpeno[1]

[1]*University Hospital La Paz, Madrid/Spain,* [2]*University Hospital La Paz, MADRID/Spain*

Background: Mutations in the epidermal growth factor receptor (EGFR) tyrosine kinase are observed in approximately 15% of lung adenocarcinomas and usually occur in nonsmokers. The detection of these mutations can be detected either in liquid biopsies or solid tissue biopsies. EGFR mutations are a predictive biomarker for high response and longer survival (both progression-free and overall) with tyrosine kinase inhibitors (TKIs), namely gefitinib, erlotinib, afatinib and osimertinib. **Method:** We conducted a descriptive and retrospective study including all patients diagnosed with EGFR mutations between January 2007 and September 2018 (both locally advanced and metastatic forms were included). **Result:** Of the 67 patients, the mean age was 67.2 years. The majority were adenocarcinoma (82.5%), with only 7.9% of squamous and 6.4% large cell carcinoma. The main mutations registered were exon 21 deletion (41%) and exon 19 deletion (4.9%). Only 24.6% had history

of smoking. 71.6% of patients present stage IV disease at diagnosis. The main organ involved was the bone (45.8%), followed by the lung (44.1%) and brain (25.4%). Also 13.6% presents pleural, 10.2% liver, 5.1% adrenal and 5.6% lymph node involvement. 84.1% of the patients were treated with TKIs (erlotinib 49.2%, gefitinib 16% and afatinib 19%) while 16% were treated with chemotherapy. With first line treatment, 94.7%presented disease control (41.8% partial response, 41.9% stable disease and 11% complete response). With a mean of 23.6 months, 56.9% of them progressed, mainly involving the lung (28.6%) and the bone (20.6%). Only 9.5% presented brain progression. At the end of the study, 34% had died (overall survival´s mean of 27.5 months). **Conclusion:** In patients with oncogenic driver mutations in EGFR, treatment with TKIs results in a better outcome than standard chemotherapy. This mutation predicts sensitivity to EGFR (our study shows up to 94.7% presents some type of response). Also, this response is longer (23.6 months in our experience) and better tolerated than chemotherapy. Overall survival of these patients is longer too, in our series, round to 27.5 months of overall survival, and mainly related to the tumor stages. More studies will be needed to be able to clarify the prognostic impact of factors such as the smoke status, sex, type of relapse or second line treatment.

Keywords: NSCLC, EGFR, characteristics

EP1.14-32 PATTERN OF EGFR MUTATIONS AND RESPONSE TO FIRST GENERATION EGFR TKIS IN PATIENTS OF METASTATIC LUNG CANCER AT A TERTIARY CARE CENTRE IN INDIA

S. Saldanha, L. D, L. Jacob, S. Babu, L. N, R. H, R. Lakkavalli, A. Thottian

Kidwai Cancer Institute, Bangalore/India

Background: EGFR gene mutations, ALK and ROS1 gene rearrangements represent the most common targetable lesions in the era of TKIs for treatment of metastatic lung cancer. Use of TKIs improves overall survival compared to cytotoxic chemotherapy in these patients. The objective of the study was to identify the prevalence and pattern of EGFR mutations and their response to TKIs in Indian patients. **Method:** Histopathologically confirmed cases of metastatic lung adenocarcinoma diagnosed between 2016 to 2018 at Kidwai Cancer Institute, Bangalore were reviewed for their EGFR mutation, ALK and ROS1 gene rearrangement status. DNA was extracted from formalin fixed paraffin embedded tissue and tested for EGFR hotspot mutations (Exon 19 deletions, exon 20 insertions and substitution mutations G719X, S768I, T790M, L858R and L861Q in exons 18, 20 and 21 of the EGFR gene) using ARMS real-time PCR. ALK and ROS1 rearrangement was tested using IHC with primary antibody ALK D5F3 and ROS1 D4D6 respectively. **Result:**

Complex EGFR mutations			
PATIENT ID	**EGFR MUTATION**	**TREATMENT**	**PFS (MTHS)**
51	EXON 19 DEL + T790M	Chemotherapy	6
1626	EXON 19 DEL + L858R	Gefitinib	6
164	S768I + L858R	Gefitinib	2
208	L858R + T790M	Chemotherapy	3
229	EXON 19 DEL + T790M	Chemotherapy	4

A total of 240 patients underwent testing. EGFR mutations were detected in 31.6% (n =76) and ALK and ROS1 rearrangement in 7% (n=17) and 1.25% (n=3) of the patients. The most common EGFR mutation was exon 19 deletions (e19 del) (n=44; 57.9%) followed by L858R mutation in exon 21 (n=23; 30.3%). Double EGFR mutations was seen in 5 patients (6.6%) and 3 patients had L861Q mutation. One patient had upfront T790M mutation. Median age was 54 years (range 35 -78 years). Male to female ratio was 0.9. 43.45% (n=33) were never smokers. Gefitinib was advised in 50 patients (65.8%), Erlotinib in 21 patients (27.6%) and rest were treated with chemotherapy. Median PFS in patients with e19 del, L858R and other mutations was 11, 12 and 4 months respectively. **Conclusion:** The prevalence of EGFR mutations in our studies are similar to those reported from other parts of India, lower than that from other Asian countries and higher than that from Western countries. E19 del and L858R mutations respond favourably to TKIs, but complex mutations do so poorly. Use of TKIs other than Gefitinib and Erlotinib need to be explored in these cases to improve outcomes.

EP1.14-33 INTESTINAL METASTASIS FROM PRIMARY ROS1-POSITIVE LUNG ADENOCARCINOMA PATIENTS RESPONDING TO CRIZOTINIB

H. Chen[1], Y. Zhu[1], X. Li[1], L. Wu[1], K. Du[1], W. Wang[2], C. Xu[3], M. Fang[2]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China*

Background: Small intestinal metastases from primary lung cancer are rare. Such patients have a poor prognosis. Early diagnosis of small intestinal metastases is difficult because of the low incidence of clinically apparent symptoms. The standard treatment for small intestinal metastases has not been established. **Method:** A 69-year-old Chinese man presented for evaluation of a tumor in the right lower lung and mediastinal lymph node enlargement on clinical examination. The clinical stage was cT2N2M0 (stage IIIA). Histologic examination of the tumor revealed lung adenocarcinoma. **Result:** He received two chemotherapy regimens. However, the disease progressed. He had bloating after chemotherapy and decreased flatus. An abdominal CT scan showed an intestinal effusion with local intestinal obstruction. Medical treatment was ineffective; hence, he underwent a diagnostic laparoscopy. The pathologic evaluation suggested an intestinal metastatic adenocarcinoma from the primary lung cancer. Based on an real-time PCR assay, the tumor had a ROS1 fusion and responded well to crizotinib. The progression-free survival was 7 months. **Conclusion:** Physicians must be aware of the possibility of intestinal metastases from primary lung cancer. With an accurate diagnosis and thorough evaluation, patients may benefit from targeted therapy.

Keywords: lung adenocarcinoma, ROS1, small intestine

EP1.14-34 ADVANCED NSCLC TREATED WITH GEFITINIB OR ERLOTINIB FOR FIVE YEARS OR LONGER - UPDATED DATA FROM THE RETROSPECTIVE SLOVAKIAN STUDY

P. Berzinec[1], P. Kasan[2], J. Mazal[3], I. Andrasina[4], A. Cipkova[5], G. Chowaniecova[1], M. Martak[2], M. Urda[3], M. Vesela[2], I. Jancokova[6], I. Kuliskova[7], L. Plank[8]

Safarik University, Kosice/Slovak Republic,* [5]*East Slovakian Cancer Institute, Kosice/Slovak Republic,* [6]*Outpatient Oncology Department, Prievidza/Slovak Republic,* [7]*University Hospital, Martin/Slovak Republic,* [8]*Martin's Biopsy Center Ltd., Martin/Slovak Republic*

Background: Median PFS in the key phase III trials with gefitinib or erlotinib for advanced NSCLC with EGFR sensitizing mutations was less than 12 months. There are only a few data about the treatment results and toxicity of long-term treatment lasting 5 years or over. Purpose of this study was to find patients treated with either gefitinib or erlotinib for at least 5 years and to evaluate the treatment results in this group of patients. **Method:** Retrospective multicentre study, approved by the Ethics Committee of the Specialised Hospital of St Zoerardus Zobor, Nitra. All thoracic oncology centres in Slovakia were involved. For this update also the other hospitals and oncology outpatient departments were asked to participate. Data regarding patients were obtained from the databases of participating institutions and patient files. Descriptive statistics was used for the data analysis. **Result:** At the IASLC WCLC 2018 we presented data about seven patients included in the study. Here we present the data about another two patients, and updated data about the previously found seven patients. Characteristics of patients and the treatment results are summarised in the Table. Median PFS in this exceptional group was not reached, but it will be over 80 months. There was only one patient with the decreased dose of erlotinib (from 150 to 100 mg QD) due to skin toxicities. All the other patients had the common and manageable grade I – II toxicities only, and there were no unexpected drug-related AEs. Table: Patients characteristics and treatment results

Gender (M/W)	Age (yrs)	Smoking status	PS	Histology, Cytology	NSCLC stage	EGFR mutation	Treatment line/TKI	Response	PFS (mo)
W	72	Ex	2	AC	IV	Del 19*	1st/gefitinib	SD	67
W	53	Smoker	1	AC	IV	NK	1st/erlotinib	SD	112+
W	58	Never	1	AC/SQ	IIIB	NK	2nd/erlotinib	PR	94+
W	69	Never	1	AC	IV	NK	2nd erlotinib	SD	87+
W	72	Never	1	AC	IV	Del 19	2nd erlotinib	PR	75+
W	59	Never	1	AC	IV	L858R	1st/erlotinib	PR	72
M	64	Never	1	AC/SQ	IV	NK	2nd/erlotinib	PR	108+

W	50	Never	1	AC	IV	Del 19	1st/gefitinib	PR	66

*Del 19 and T790M

Conclusion: The treatment was safe and effective in our group of patients with advanced NSCLC treated with gefitinib or erlotinib for over 5 years. The NGS analysis of the available samples will be done after approval of the submitted Protocol by the Ethics Committee.

EP1.14-35 SQUAMOUS CELL CARCINOMA TRANSFORMATION AFTER ACQUIRED RESISTANCE TO OSIMERTINIB

C.-L. Chiang, Y.-C. Yeh, C.-H. Chiu

Taipei Veterans General Hospital, Taipei/Taiwan

Background: Osimertinib is a third-generation epidermal growth factor receptor - tyrosine kinase inhibitor (EGFR-TKI) for the management of NSCLC carrying *EGFR* T790M mutation after acquired resistance to prior EGFR-TKI and is now the preferred therapy in the front-line. The resistance mechanism of osimertinib, including histologic transformation had been reported, mostly small cell carcinoma. **Method:** Here we a patient with lung adenocarcinoma with uncommon EGFR H835L +L833V + T790M mutation who developed progressive lung atelectasis after acquired resistance to osimertinib. Bronchoscopic biopsy over the endobronchial tumor was done and the pathology report showed squamous cell carcinoma. **Result:** Mutation analysis of the squamous cell carcinoma performed by next generation sequencing (FoundationOne® CDx) was performed and reveled complex genomic alteration including EGFR H835L, L833V and T790M mutation, TP53 mutation and mTOR amplification. Squamous cell transformation after acquired resistance to osimeritinib was diagnosed. Then the patient was treated with a mTOR inhibitor, everolimus (5mg /day) plus osimertinib. One month after treatment an initial tumor response was observed, however, a progression occurred after 3 months of treatment.

Specimens for sequencing	Surgical specimen	CT-guided lung tumor biopsy	Endobronchial biopsy
EGFR mutation profile	L833V & H835L	L833V & H835L&T790M	L833V & H835L & T790M
Cell type	Adenocarcinoma	Adenocarcinoma	Squamous cell carcinoma
Other genetic alteration			PDL1 0% MTOR amplification STK11 loss CDKN2A/B loss FANCA loss JUN amplification PMS2 R534fs*3 TP53 R175H

Conclusion: Squamous cell transformation is a rare manifestation of osimertinib resistance, further research is need to investigate the underlying mechanism of this histologic change and discover the proper treatment strategy.

EP1.14-36 SUICIDE GENE THERAPY DIRECTED BY MICRORNA ACTIVITY

A. Arenas[1,2], I. Coira[1,2], M. Rodríguez[1,2], E. Rufino-Palomares[2], J. Lupiañez[2], M. Cuadros[1,3], P. Medina[1,2]

[1]*GENYO. Centre for Genomics and Oncological Research: Pfizer / University of Granada / Andalusian Regional Government, Granada/Spain,* [2]*Department of Biochemistry and Molecular Biology I, University of Granada, Granada/Spain,* [3]*Department of Biochemistry and Molecular Biology III and Immunology, University of Granada, Granada/Spain*

Background: Lung cancer is one of the most prevalent types of malignancies worldwide, accounting for 1.6 million deaths every year. Despite last efforts, the overall survival rate at five years after diagnosis is under 15%. Therefore, new approaches are needed to improve the current clinic. Suicide gene therapy is an interesting technology which consists in expressing a toxic gene into tumor cells. The most studied suicide gene system is the Herpes Simplex Virus Thymidine Kinase (HSV-TK) that converts the non-toxic prodrug ganciclovir (GCV) into a guanosine analog, promoting cell apoptosis. However, there are problems regarding the expression of the toxic gene in non-tumor cells, which would cause unwanted cell death. MicroRNAs (miRNAs) have been revealed as one of the most important families of gene expression regulators, acting at a posttranscriptional level by binding messenger RNAs (mRNAs) and blocking protein translation. Alterations in the expression levels of these miRNAs in carcinogenesis have been largely described in the literature, being some of them biomarkers in the diagnosis of cancer. The aim of this work is to improve the selectivity of the HSV-TK suicide gene therapy to target exclusively tumor cells, taking advantage of the alterations in the expression of miRNAs in lung cancer. **Method:** We have constructed a plasmid that expresses the HSV-TK mRNA under the control of an artificial 3'-UTR containing binding sites for different members of the let-7 family, a miRNA family whose expression is frequently lost during lung cancer development. Thus, we could direct the expression of the toxic gene preferably in tumor cells where the levels of let-7 are low, allowing the expression of the HSV-TK. To determine the ability to direct the expression of the suicide gene on this system, we used a lung cancer cell line and a non-tumor, lung tissue one. Both lung cancer and non-tumor cell lines were infected with lentiviruses containing the plasmid construction and then cell viability assays, competitive cell growth assays by immunofluorescence and apoptosis assays were performed to check for differences between the GCV-treated and untreated cells. **Result:** Our preliminary results suggest that miRNA expression can selectively drive the expression of the HSV-TK in lung cancer cells due to their low let-7 expression values, resulting in a decrease of cell viability in lung cancer cells compared to non-tumor cells after treating them with GCV. Ectopically overexpressing let-7 into the lung cancer cells blocked the cell viability decrease caused by the GCV, meaning that our artificial 3'-UTR with binding sites for let-7 is working. **Conclusion:** According to our results, we have successfully directed the expression of a suicide gene to tumor cells using miRNA activity. Thanks to that, our HSV-TK/GCV suicide gene therapy model adds an extra layer of safety by preventing off-target cell death. Differential miRNA expression between tumor and normal

tissues could be used to direct the expression of a gene of our choice to the tumor tissue, which could be an interesting approach and a potential tool to treat this disease.

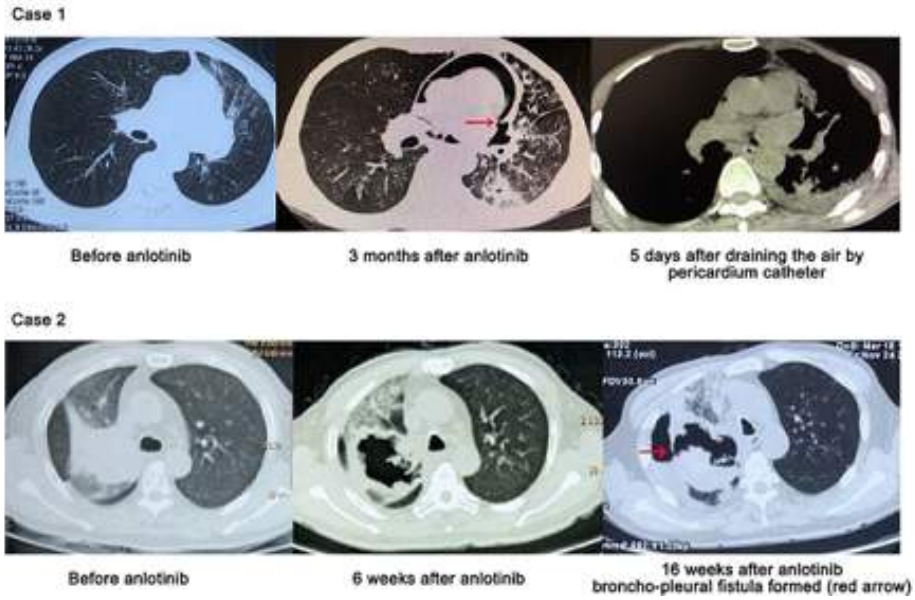
Keywords: miRNA, suicide gene therapy

EP1.14-37 ANLOTINIB-INDUCED BRONCHO-PERICARDIAL/PLEURAL FISTULA IN PATIENTS SUFFERING FROM LUNG CANCER (FIRST REPORT)

P. Deng, C. Hu, Y. Li, H. Yang, X. Chen, J. Tan

Xiangya Hospital of Central South University, Changsha/China

Background: Anlotinib is an small molecule inhibitor of multiple receptor tyrosine kinases, with inhibitory effects on tumor angiogenesis, and approved in China for treatment of patients with non-small cell lung cancer (NSCLC) who have undergone progression after≥2 lines of chemotherapy. The occurrence of bronchial fistula related to anlotinib has not been reported yet. We presented 2 cases of NSCLC patients with bronchial fistula after treatment with anlotinib. **Method:** Case 1: A 69-year-old male diagnosed central squamous cell lung carcinoma(CSCLC) of the left (stage IV) on July 2018, who refused chemotherapy but treated with anlotinib for 3 months, aggravated with short breath, with CT indicating broncho-pericardial fistula. After catheter was set into pericardium and drained for 5 days, CT showed significant reduction of gas and pericardium partially conglutinated. Case 2: 63-year-old male diagnosed CSCLC of the right (EGFR 19del) in 2016, with a history of diabetes, who successively received 2 lines of chemotherapy, target therapy, radiotherapy, shifted to anlotinib in August 2018 for 4 months, then aggravated with coughing pyohemosputum and fever, with CT indicating broncho-pleural fistula. After performed a closed thoracic drainage and anti-bacterium therapy, the patient improved and drainage decreased.



Result: Two cases developed bronchial fistula during the treatment of anlotinib alone, suggesting that the adverse effects mainly related to the antiangiogenics effect of it and causing ischemic necrosis. Other possible factors include: ①central lung cancer, ②squamous cell carcinoma, ③cachexia, ④multi-line treatment, ⑤long diameter of tumor≥5cm) and cavity formation, ⑥radiotherapy, ⑦accompanied with underlying diseases easy to complicated with infection, such as diabetes.

Conclusion: Although the incidence of bronchial fistula caused by anlotinib in NSCLC is extremely rare, it seriously affects the quality of life and overall survival of patients. Therefore, we need to use it selectively and make a close observation of the high-risk patients.

Keywords: Anlotinib, Broncho-pericardial/pleural fistula, Lung cancer

EP1.14-38 PROLONGED SURVIVAL IN A CASE OF NSCLC WITH RECURRENT BRAIN METASTASIS - A CASE REPORT

S. Das Majumdar[1], S. Mishra[1], S. Dhar[1], P. Mishra[1], S. Mohapatra[2], D. Parida[1]

[1]*All India Institute of Medical Sciences, Bhubaneswar/India,* [2]*Prolife Diagnostics, Bhubaneswar/India*

Background: Carcinoma lung remains the most common cause of cancer related deaths in men globally.Approximately 10 percent of newly diagnosed patients with advanced non-small cell lung cancer (NSCLC) have brain metastases. Presence of brain metastases is associated with very poor prognosis with decreased survival and compromised quality of life in patients even after intensive treatment with multimodal approach.Though the survival varies according to performance status and presence of other prognostic factors, the survival in non small cell lung cancer with brain metastasis has increased to some extent in last two decades(median survival ranges between 7 -12 months in various studies).Hereby we present our experience with a case of adenocarcinoma lung with brain metastasis on presentation who has received multiple lines of treatment approach and leading a happy and hearty life after 8 years(96 months) of diagnosis. **Method:** Section not applicable **Result:** CASE REPORT A 45 year old nonsmoker male presented with constant headache with memory loss and on evaluation was found to have a SOL in the left temporal region with few other small lesions at other sites in brain along with right lung mass and was diagnosed as primary lung cancer with brain metastasis.CT guided biopsy of the lung mass showed adenocarcinoma lung.EGFR and ALK were non mutated.He received palliative whole brain radiotherapy followed by four cycles of chemotherapy with pemetrexed and carboplatin regimen.Received EBRT to right lung mass. Developed relapse after one year and underwent surgery.After six months,he developed recurrence at brain,for which surgical excision of the brain lesion(metastatectomy) was done followed by reirradiation to brain. Again he developed brain recurrence following which he received six cycles of Pemetrexed and Carboplatin followed by six cycles of maintenance Inj Pemetrexed.Again developed brain recurrence after one year which was surgically resected out following which he received Tab Erlotinib+ Tab Temezolamide. Recurrence of brain lesion was again encountered after four months for which he received six cycles of Inj Bevacizumab+ Nab-Paclitaxel + Carboplatin. Evaluation with whole body PET-CT scan and MRI brain showed complete metabolic response at primary site(lung) and partial response at brain. Then he received maintenance Inj Bevacizumab for six cycles. Then after one year,on recurrence in brain with surgical excision of the tumor and subsequent evaluation it was found that he had T790M mutation and hence was planned for Tab Osimertinib. He

is on Tab Osimertinib since last 26 months. Recent evaluation was done two months back in form of whole body PET-CT scan and MRI brain which showed complete response at both primary(lung) site and brain.Patient is doing fine till date with a followup period of 96 months since upfront presentation with brain metastasis. **Conclusion:** Treatment approach for NSCLC has seen a paradigm shift in last few years with the increased role of targeted therapies which has improved the survival.Hence biopsy and identifying the druggable targets have become of prime importance in managing lung malignancies.Metastatectomy and target oriented approach has always proven to be beneficial in oligometastatic settings.

EP1.14-39 BRG1 DEFICIENT CELLS ARE SENSITIVE TO THE INHIBITION OF SPECIFIC LYSINE DEMETHYLASES (KDMS) IN LUNG CANCER

A. Vilarrubí Porta[1], J. Alburquerque-Béjar[1], D. Trastulli[1], P. Llabata[1], E. Pros[1], A. Villanueva[2], O. Romero[1], M. Sanchez-Cespedes[1]

[1]*Cancer Epigenetics and Biology Program-PEBC (IDIBELL), L'Hospitalet de Llobregat/Spain,* [2]*ICO-IDIBELL, Hospitalet de Llobregat/Spain*

Background: The standard treatment of non-small cell lung cancer (NSCLCs) is surgery. New therapeutics, such as tyrosine kinase inhibitors or immunotherapy may improve survival, but these treatments are only effective in small cohorts of patients. Thus, hopes of improving survival of lung cancer patients are related to the advent of novel therapeutic strategies. The classic epigenetic research focuses in the reversion of gene promoter DNA hyper methylation or histone code modifications, using a battery of unspecific drugs addressed to modify the global epigenetic code in cancer cells. In our previous work, we identified frequent inactivating mutations in the epigenetic gene BRG1 (about 20% of NSCLC), which were mutually exclusive with amplifications in the MYC oncogenic family. Unfortunately, BRG1-mutant cancer cells were also not able to respond to certain epigenetic therapies whereas cancer cells carrying MYC amplification, which are BRG1 proficient, appear to be highly sensitive to these combinations of treatments. These results show that MYC amplification could be used as a prognostic biomarker for a specific personalized therapy. In this project we observed that the mutational status of BRG1 directly correlates with the expression levels of several Lysine methyltransferases (KMTs) and Lysine demethylases (KDMs) in cancer cells. We also found that inactivating mutations in KDMs and KMTs tend to be mutually exclusive with inactivating mutations in BRG1, mutations in other SWI/SNF members and mutations in MYC oncogenic genes. Thus, we focused on targeting histone-modifying enzymes, in BRG1 proficient or deficient lung cancers cell lines. **Method:** For this propose we integrate state of the art technology like genome-wide chromatin modification and transcriptome analysis, using human cell lines and preclinical models for lung cancer, including in vivo models of mice such as xenografts, subjected at different concentrations of histone deacetylase inhibitor (HDACi), lysine demethylase inhibitor (KDMi) and EZH2 inhibitor (EZH2i) to design a personalized epigenetic treatment with high efficacy and low toxicity. **Result:** Our results showed that BRG1 deficient cells are not sensitive to HDACi, displaying an unexpected increase in some epigenetic marks after treatment that correlates with a global enrichment of repressive marks and EZH2 occupancy at gene promoter in BRG1-mutant cells. Otherwise, BRG1 directly regulates KDMs expression in lung cancer and demonstrates that inactivating mutations in BRG1 sensitizes cancer cells to the lysine demethylase inhibitor (KDMi). However, EZH2i seems to reverse KDMi activity in the absence of BRG1, exposing an interesting and determining role of this histone lysine methyltransferase in the sensitization of BRG1 deficient cancer cells to the KDMi. **Conclusion:** The results will be of great value for the stratification of lung tumors according to their genetic or epigenetic background for tailored treatments, opening the possibility to use BRG1 mutations as a potential Biomarker for personalized epigenetic target therapy in cancer. The development of an epigenetic-based therapeutic prediction model will hopefully set the basis for future treatment of lung cancer as well as of other epithelial cancers.

Keywords: Epigenetics, Target therapy, BRG1

EP1.14-40 LOCALLY ADVANCED DESMOIDE TUMOR: RESPONSE TO SORAFENIB: CASE REPORT

A. Iraqi[1], O. Omran[1], N. Benchakroun[2]

[1]*CHU Ibn Rochd, CASABLANCA/Morocco,* [2]*CHU Ibn Rochd, casablanca/Morocco*

Background: Desmoid tumors or deep fibromatoses are malignant connective clonal tissue tumors that do not metastasize, but are at high risk of local recurrence and are associated with morbidity and mortality. There is still no standard for treatment, however the reactions of patients with desmoid tumors with Sorafenib are promising. The objective of this work is to highlight the contribution of sorafenib in the treatment of desmoid tumors. **Method:** Our study is a case report conducted in the oncology department of IBN ROCHD CHU of Casablanca, focusing on the analysis of the Sorafenib response in patient with locally advanced desmoid tumor. **Result:** Our case is a 60-year-old patient with no comorbidities who had presented in 2012 a left dorsal parietal mass, he was operated on, the histopathological examination concluded to a desmoid tumor. He presented in 2015 a tumor recurrence for which he was again operated and put under Celecoxib for one year, after the clinical and radiological progression, he was put under Tamoxifen, for 2 years. Currently, he presents a tumor increase. In fact he has a posterior dorso lumbar parietal mass, measuring clinically about 15 cm, very painful, the initial thoracic CT scan as well as the MRI of the soft tissues showed left lateral vertebral parietal mass, hypodense coming into contact with the last 3 ribs without bone lysis, measuring 12 * 11 * 7 cm. The surgery was considered dilapidated by the surgeons, the decision was to put the patient under Sorafenib 400 mg per day, the assessment after two months found an excellent clinical and radiological response, with a total disappearance of pain and 50% decrease in the size of the initial injury on the chest CT scan. **Conclusion:** This case study allowed us to support the efficacy of Sorafenib, currently being tested (Study Alliance A91105) in the treatment of recurrent or locally advanced desmoid tumors.

Keywords: Desmoid, Sorafenib

EP1.14-41 CASE SERIES: LUNG NEUROENDOCRINE CARCINOMA WITH EGFR MUTATION

J. Zaini[1], S. Andarini[2], A. Putra[2], E. Syahruddin[2]

[1]*Faculty of Medicine Universitas Indonesia / Persahabatan Hospital, Jakarta/Indonesia,* [2]*Faculty of Medicine Universitas Indonesia / Persahabatan Hospital, JAKARTA/Indonesia*

Background: Lung Neuroendocrine Tumor derived from neuroendocrine cells in the lung and could be classified as well differentiated (low-grade typical carcinoids [TCs] and intermediate-grade atypical carcinoids [ACs]) and poorly differentiated (high-grade large cell neuroendocrine carcinoma or SCLC). Little is known about EGFR mutation in LCNET although EGFR mutation were frequently found (about 40%) in Indonesia NSCLC population. **Method:** We reviewed 3 cases from our hospital of large cell neuroendocrine tumor (LCNET) with EGFR mutation testing available. Clinical data and therapeutic responses were retrospectively evaluated. **Result:** Case#1 was a 53 years heavy smoker male with shortness of breath since 6 months, stg 4 T4N3M1a/pericardial effusion, Trans-thoracal Core biopsy showed LCNEC and harboring EGFR mutation in Exon 18 G719S. He was given Gefitinib, but the diseased progressed within 2 months and continued with Platinum based regimen with survival of 9 months. Case#2 was a 64 years old heavy smoker male with shortness of breath and chronic fatigue since 6 months, stg IV T3N3M1a, biopsy from neck lymph nodes showed LCNEC and harboring EGFR mutation in Exon 19 INS/DEL. He was given Erlotinib, but the diseased progressed within 2 months and refused to be given chemotherapy, with survival of 5 months since diagnosis. Case#3 was a 48 years old Non Smoker male with shortness of breath and chronic cough since 3 months, stg IIIB T4N3M0, biopsy from supraclavicular lymph nodes showed LCNEC and harboring EGFR mutation in Exon 21 L858R and L861Q. The disease remain stable for 13 months with Erlotinib, and followed by platinum based chemotherapy thereafter. He survived 20 months after diagnosis. **Conclusion:** De-novo EGFR mutation were found in LCNEC, but the response of the TKI is variable.

Keywords: Lung Neuroendocrine Tumor, EGFR mutation, tyrosine kinase inhibitor

EP1.14-42 DE NOVO EMERGENCE OF ISOLATED CNS T790M MUTATION AS A MECHANISM OF RESISTANCE TO FIRST GENERATION EGFR-TKI ERLOTINIB

L. Al Rabadi, K. Tolba

Oregon Health & Science University, Portland/United States of America

Background: A 57-year-old female never-smoker presented in 07/2009 with persistent cough and hemoptysis. Diagnostic imaging studies revealed 5.5-cm left upper lobe/hilar mass with mediastinal adenopathy, CT-guided biopsy revealed a TTF-1 positive pulmonary adenocarcinoma. Brain MRI identified a solitary 4mm metastatic lesion in the left superior precentral gyrus. Given her respiratory symptoms and hemoptysis, she proceeded with a platinum doublet and concurrent EBRT. Follow-up imaging revealed partial response. Tumor mutational analysis became available during radiation therapy and revealed an EGFR exon-19 deletion; she subsequently started treatment with erlotinib 150mg daily. Imaging performed six months after starting erlotinib revealed resolution of her residual lung disease and left precentral gyrus brain metastasis and she continued erlotinib for the next 7-years until 03/2017, when she presented with headaches and ataxia. Brain MRI identified a new 3.9cm left cerebellar mass, as well as reappearance of the left precentral gyrus lesion (Figure 1). Resection of the cerebellar mass identified metastatic lung adenocarcinoma with molecular analysis revealing the same exon-19 deletion plus T790M resistance mutation. Repeat PET/CT imaging failed to identify extracranial disease (Figure 2). She received post-operative stereotactic radiosurgery to the involved sites and started therapy with osimertinib 80mg daily. At the time of this writing, she remains in remission almost 10 years after initial diagnosis of metastatic NSCLC. This report presents an unusual clinical scenario, where visceral disease achieved durable remission on erlotinib while an isolated T790M acquired resistance mutation emerged de novo in the CNS. T790M often emerges as a resistance mechanism under selective pressure from early-generation EGFR-TKI. However, due to low BBB penetrance of 1st/2nd generation EGFR-TKI at standard dose, erlotinib concentration that frequently drives the de novo development of T790M mutation in visceral organs is rarely achieved in CNS metastases. In rare occasions where T790M is detected in the CNS, it is often metastatic from a distant visceral organ. In our patient, low concentration of erlotinib in the CNS might have created a permissive environment for the development of drug-tolerant "persister" cells that remained dormant for several years before eventually acquiring *de novo* T790M-mutation. The latter enabled accelerated growth of CNS metastatic disease in the presence of continuous treatment with erlotinib.

Figure 1.

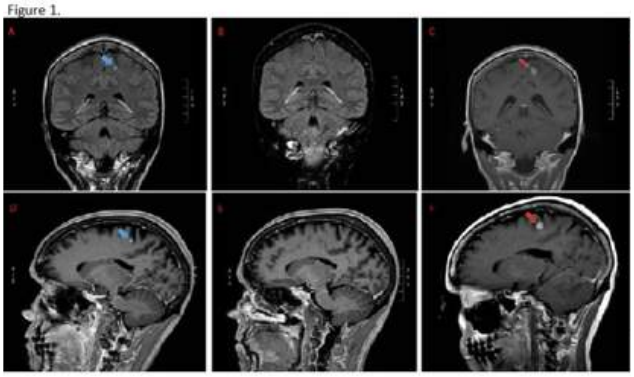

Figure 2.

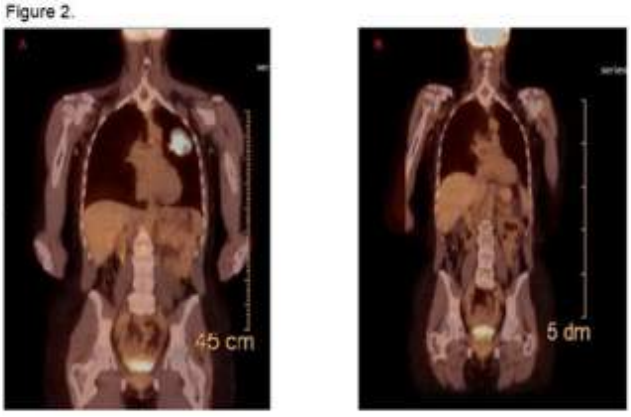

Method: Section not applicable **Result:** Section not applicable **Conclusion:** Our case report illustrates a real-life example of how spatiotemporal differences in the tumor micro-environment could give rise to intra-tumor heterogeneity and shape response to therapy.

Keywords: CNS metastases, EGFR exon 19 deletion, T790M

EP1.14-43 THE SAFETY OF FIRST-LINE AND SUBSEQUENT MONOTHERAPY OF PD-1/PD-L1 INHIBITORS IN NSCLC: A META ANALYSIS

Y. Yang, Z. Xie, P. Pang, N. Wang, H. Liang, L. Zhao

Guangzhou Medical University, Guangzhou/China

Background: With the application of PD-1/PD-L1 inhibitors for non-small cell lung cancer (NSCLC), some agents (pembrolizumab, nivolumab, atezolizumab and durvalumab) were approved not only in subsequent but also first-line therapy. However, the spectrum of side effects in different therapy time might exist heterogeneity. In this meta-analysis, we assessed and compared the safety of PD-1/PD-L1 inhibitors in first or subsequent line therapy, and the systemic-specific spectrum of treatment-related adverse events (trAEs) were summarized. **Method:** A comprehensive search of online databases was performed. Incidence and its 95% CI were chosen to assess safety outcomes. The incidence of trAEs were calculated, including discontinuation and death results. Besides, the most common trAEs and system-specific trAEs of nivolumab and atezolizumab in subsequent therapy were also collected based on Common Terminology Criteria for Adverse Events (CTCAE) 4.0. **Result:** In total, 13 studies (3180 patients) were included. First-line therapy was associated with more frequent high-grade trAEs and withdrawal rates compared with subsequent line therapy (20.9% vs 14.1%, p=0.000; 8.3% vs 5.1%, p=0.000), while no significantly statistical difference existed according to any grade trAEs or deaths rates (18.9% vs 13.9%, p=0.985; 0.3% vs 0.5%, p=0.554). Basing on CTCAE 4.0, the common system-specific trAEs of first-line and subsequent therapy were semblable, no matter in any grade or high-grade trAEs. For the detailed trAEs, the common trAEs of first-line and subsequent therapy were similar including fatigue, diarrhoea, nausea and the like. However, in the high-grade trAEs, first-line therapy focused more on liver disorders (1.85%), and subsequent therapy was associated with more gastrointestinal disorders (1.73%). **Conclusion:** The incidence of high-grade trAEs and withdrawal rates in first-line therapy were higher than in subsequent therapy, possibly because of the different sensitivity and response of the major organs and immune system to PD-1/PD-L1 inhibitors. Besides, the differences of the common high-grade trAEs may be related to the uneven distribution of targets in various organs. These findings indicate that clinicians should pay more attention to heterogeneous side effects when prescribe PD-1/PD-L1 inhibitors in different time of therapy. Further perspective trials and data are warranted to confirm this conclusion and improve clinical medication guidance.

Keywords: NSCLC, PD-1/PD-L1 inhibitors, treatment related adverse events

EP1.14-44 LUNG ADENOCARCINOMA WITH A RARE BRAF V600E K601_W604DEL MUTATION RESPONDED TO DABRAFENIB PLUS TRAMETINIB TREATMENT: A CASE REPORT

J. Shimizu, Y. Horio, T. Hida, Y. Yatabe

Aichi Cancer Center Hospital, Nagoya/Japan

Background: *BRAF* V600E mutation can be detected in 1% of lung adenocarcinomas, and far more rarely, complex mutations in addition to BRAF V600E have been reported. **Method:** Case presentation: A 42-year-old man was diagnosed with advanced lung adenocarcinoma with stage cT1cN3M1c stageIVB. *BRAF* V600E mutation was found with in-house molecular testing, so we submitted the same specimen to be analyzed with Oncomine Dx Target test for reimbursement of the subsequent treatment. However, the result was negative for BRAF V600E. **Result:** The patient was treated with pembrolizumab (first-line therapy) and then carboplatin, pemetrexed and bevacizumab (second-line therapy). Nevertheless, the disease was progressed, so dabrafenib plus trametinib were used for the third line therapy. One month later CT scan showed a partial response. A subsequent

study showed that the V600E mutation accompanied K601_W604 deletion, three bases after the V600E point mutation. **Conclusion:** Our clinical experience suggested that some tumors with compound BRAF mutations, such as *BRAF* V600E K601_W604 del mutation, could respond to dabrafenib plus trametinib treatment, and that rare compound mutations, like this case, may not be detected with the conventional amplicon sequencing, particularly when the additional alterations are acquired at the positions adjacent to hotspots.

Keywords: braf, K601_W604 deletion, dabrafenib plus trametinib

EP1.14-45 ROS1-ADGRG6: A NOVEL ROS1 ONCOGENIC FUSION VARIANT IN LUNG ADENOCARCINOMA AND THE RESPONSE TO CRIZOTINIB

X. Li[1], C. Xu[2], S. Xu[3], W. Wang[4], J. Ye[5], Y. Zhu[1], T. Ge[6], M. Fang[4], T. Lv[7], Y. Song[7]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Ningbo Medical Center Lihuili Eastern Hospital, Ningbo/China,* [4]*Zhejiang Cancer Hospital, Hangzhou/China,* [5]*Sanmen People's Hospital of Zhejiang, Taizhou/China,* [6]*Ningbo Medical Center Lihuili Hospital, Ningbo/China,* [7]*Jinling Hospital, Nanjing/China*

Background: *ROS1* rearrangements are validated driver genes in non-small cell lung cancer (NSCLC) and have been identified in a small subset (1%-2%) of patients with NSCLC. To date, 18 different fusion genes of *ROS1* in NSCLC have been identified. The ALK inhibitor, crizotinib, exhibits therapeutic efficacy against *ROS1*-rearranged NSCLC. In addition to immunohistochemistry, real-time PCR, and fluorescence *in situ* hybridization, next-generation sequencing (NGS) technology represents a novel tool for *ROS1* detection that covers a wide range of fusion genes. **Method:** A 55-year-old female with stage IV was detected with a novel *ROS1* fusion afther treated with gefitinib due to detection of an *EGFR* mutation (L858R). Histological examination was consistent with lung adenocarcinoma. **Result:** A NGS assay showed that the tumor had a novel *ROS1-ADGRG6* rearrangement generated by the fusion of exons of 1-33 of *ROS1* on chr6: q22.1 to exons of 2-26 of *ADGRG6* on chr6: q24.2. The predicted ROS1-ADGRG6 protein product contained 3075 amino acids comprising the N-terminal amino acids 1-1853 of *ROS1* and C-terminal amino acid 1-1222 of *ADGRG6*. The patient had a favorable tumor response to crizotinib. **Conclusion:** *ROS1-ADGRG6* is a novel *ROS1* fusion gene in NSCLC detected by NGS and should be considered in *ROS1* detection assays.

Keywords: lung adenocarcinoma, NGS, ROS1 rearrangement

EP1.14-46 THE KIF5B-RET FUSION AS A NOVEL MECHANISM OF ACQUIRED EGFR TYROSINE KINASE INHIBITOR RESISTANCE IN LUNG ADENOCARCINOMA

Y. Zhu[1], W. Wang[2], C. Xu[3], Q. Zhang[3], W. Zhuang[3], K. Du[1], G. Chen[3], M. Fang[2], T. Lv[4], Y. Song[4]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China,* [4]*Jinling Hospital, Nanjing/China*

Background: Lung cancer is a common malignancy and a leading cause of cancer deaths worldwide. Non-small cell lung cancer (NSCLC) is the most common type of lung cancer. And most NSCLC patients with epidermal growth factor receptor (EGFR) mutations respond well to the treatment with epidermal growth factor receptor tyrosine kinase inhibitors (EGFR-TKIs). Unfortunately, almost all patients with effective EGFR-TKIs therapy eventually develop drug resistance in about 1 year. The most common mechanism of acquired resistance to first-generation EGFR-TKI treatment is the development of the *T790M* mutation in exon 20 of the *EGFR*, which occurs in almost one half of cases of acquired resistance. **Method:** In this case report, we present a 72-year-old male non-smoker patient with an *EGFR* exon 19 deletion diagnosed with lung adenocarcinoma (LADC), who initially responded to first-generation EGFR-TKI treatment, but developed acquired resistance, and was shown to have gene detected by the next generation sequencing. **Result:** Repeated liquid biopsy showed the *KIF5B-RET* fusion gene by next generation sequencing. Therefore, cabozantinib was added to the treatment, and stable disease (SD) was achieved. Unfortunately, the patient did not acquire long-term benefits and the progression-free survival (PFS) was only 2 months **Conclusion:** Our results suggested that the *KIF5B-RET* fusion gene is a possible novel cause of acquired resistance to first-generation EGFR-TKIs.

EP1.14-47 LUNG ADENOCARCINOMA WITH CONCURRENT KRAS MUTATION AND ALK REARRANGEMENT RESPONDING TO CRIZOTINIB

Y. Zhu[1], W. Wang[2], C. Xu[3], X. Li[1], W. Zhuang[3], K. Du[1], G. Chen[3], M. Fang[2], T. Lv[4], Y. Song[4]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China,* [4]*Jinling Hospital, Nanjing/China*

Background: Chromosomal translocation resulting in the fusion between the echinoderm microtubule-associated protein-like 4 (EML4) gene and the anaplastic lymphoma kinase (ALK) gene has been considered as a novel oncogenic fusion in a subset of non-small cell lung cancer (NSCLC), mostly in non-smokers with adenocarcinoma. EML4-ALK translocations are commonly reported to be mutually exclusive with EGFR or KRAS mutations. **Method:** We reported a rare case of 47-year-old female was diagnosed with lung adenocarcinoma and treated with three cycles of chemotherapy. A biopsy acquired after disease progression revealed concurrent *KRAS* mutation and *ALK* translocation by a NGS assay. **Result:** Based on molecular findings, treatment was initiated with crizotinib in September, 2016. After 2 months of therapy, the patient achieved a partial response. Afterwards, the patient was further administrated with crizotinib for 9 months with a stable disease before tumor progression. **Conclusion:** A further understanding of the molecular biology with multiple oncogenic drivers will promote the optimal treatment for NSCLC.

Keywords: ALK rearrangement, KRAS mutation, lung adenocarcinoma

EP1.14-48 EFFICACY AND SAFETY OF AFATINIB PLUS APATINIB COMBINATION THERAPY FOR A LUNG ADENOCARCINOMA PATIENT WITH HER-2 V659D MUTATION

K. Ma, C. Sun, Y. Xu, X. Wang, Y. Guo

The First Hospital of Jilin University, Chang Chun/China

Background: In lung cancer,several literature report the rare transmembrane domain mutations occur in V659D of Her-2 may be effective for afatinib. This is a successful case of a lung adenocarcinoma patient with a novel Her-2 V659D mutation but unsatisfactory efficacy with afatinib treated with afatinib plus apatinib. **Method:** A 73-year-old Chinese man with a heavy-smoking history came to our hospital due to"Intermittent cough"in eary March 2017. He was diagnosed with stage IB(T2aN0M0)lung adenocarcinoma by pathology of left upper lobectomy in 29th Mar 2017(Fig.1). An HER-2 mutation(V659D mutation)was detected in the surgical specimen by Next-generation sequencing (mutation abundance is 44.6%).

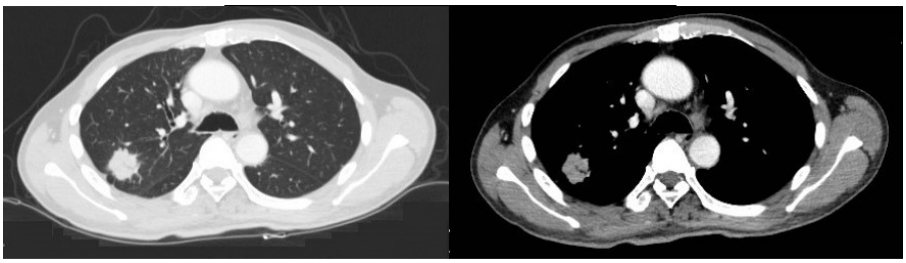

Fig.1 Preoperative pulmonary CT revealed a right pulmonary nodule

Recurrence of lung cancer occurred after 16 months on 30th July 2018. Pulmonary CT revealed multiple nodules in both lungs(Fig.2). The patient had no intention of chemotherapy. Daily oral doses of 40mg of afatinib were given on 31st July 2018. Twenty-two days later, a CT scan revealed the bilateral pulmonary nodules were slightly smaller, however cough symptoms were worse than before(Fig.3). On 23rd Agu 2018, considering the efficacy and side effects, he started taking afatinib(reduced to 30mg)combined with apatinib(500mg/day). The chest CT scan revealed the metastases continued to shrink after 1 month, and necrotic cavities appeared in the middle of the lesions(Fig.4). Cough symptoms improved obviously. Therapeutic evaluation was stable. He had no progression of the disease for months.

Fig. 2 Pulmonary CT revealed multiple nodules in both lungs

Fig. 3 The bilateral pulmonary nodules were slightly smaller, and the curative effect was evaluated as SD. New patchy shadows in the left lower lobe of the lung are more likely to be inflammatory.

Fig. 4 Bilateral pulmonary nodules shrank , and necrotic cavity appeared in the lesions. The curative effect was evaluated as SD. The patchy shadow of the left lower lobe disappeared.

Result: On 21st Feb 2019, lung CT indicated enlargement of bilateral pulmonary nodules and new lesions suggesting disease progresses. Progression-free survival is 6.1 months. As for the side effects, he had two-grade rash on the face, three-grade oral mucositis with afatinib monotherapy. And he had one-grade rash on the face, two-grade oral mucositis and two-grade hand-foot syndrome in the combined treatment of afatinib and apatinib. **Conclusion:** Afatinib combined with apatinib is a safe therapeutic method for rare mutation of HER-2 V659D that can increase the efficacy.

Keywords: Her-2 rare mutation, Combined targeted therapy, lung adenocarcinoma

EP1.14-49 A PHASE IIIB OPEN-LABEL STUDY OF AFATINIB IN EGFR TKI-NAÏVE PATIENTS WITH EGFRM+ NSCLC: EXPLORATORY BIOMARKER ANALYSIS

J. Wang[1], J. Zhao[2], H. Bai[3], X. Wang[3], Y. Wang[2], J. Duan[3], H. Chen[2], Z. Xue[4], S. Meng[4], Y. Tian[4], A. Cseh[5], D.C. Huang[6], Y. Wu[7]

[1]*Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China,* [2]*Beijing Cancer Hospital, Beijing/China,* [3]*Molecular Oncology, Department of Medical Oncology, National Cancer Center/Cancer Hospital, Chinese Academy of Medical Sciences & Peking Union Medical College, Beijing/China,* [4]*Boehringer Ingelheim (China) Investment Co., Ltd, Shanghai/China,* [5]*Boehringer Ingelheim Rcv Gmbh & Co. Kg, Vienna/AT,* [6]*Boehringer Ingelheim Taiwan Limited, Taipei/Taiwan,* [7]*Guangdong Lung Cancer Institute, Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou/China*

Background: The safety and efficacy of EGFR TKIs in patients with *EGFR* mutation-positive (*EGFR*m+) NSCLC have previously been demonstrated. Here, we present results of a biomarker analysis from a subset of patients in a Phase IIIb study of afatinib in EGFR TKI-naïve patients with locally advanced/metastatic *EGFR*m+ NSCLC. The aim was to explore the relationship between tumor mutation type, and patients' response to afatinib in terms of efficacy and tolerability. **Method:** Patients with EGFR TKI-naïve *EGFR*m+ NSCLC received 40 mg/day afatinib until lack of clinical benefit (determined by investigator). The primary endpoint was incidence of serious adverse events (SAEs). Secondary endpoints were number of patients with drug-related AEs, and time to symptomatic progression (TTSP). Further endpoints included progression-free survival (PFS). For biomarker analysis, peripheral blood samples were collected during scheduled visits from patients entering the study at Beijing Cancer Hospital. DNA extracted from samples collected at Visit 3 and baseline was analyzed for *EGFR* and pre-specified non-*EGFR* mutations, respectively, using an amplification-refractory mutation system. **Result:** In total, 64 patients were included in the biomarker analysis. Baseline characteristics: Chinese, 100%; female, 70.3%; mean age, 57.4 years; *EGFR* mutations: L858R, 50%; Del19, 42.2%. All patients experienced ≥1 drug-related AE, most commonly (grouped terms; any grade/≥3): diarrhea (n=63/9, 98.4%/14.1%) and rash or acne (n=52/5, 81.3%/7.8%). SAEs were reported for 15 patients (23.4%), most commonly cerebral infarction (n=3, 4.7%), malignant neoplasm progression, CNS metastases (both n=2, 3.1%). Median TTSP was 13.5 months (95% CI: 10.9, 18.0). At baseline, 19 of 42 patients analyzed (45.2%) had additional non-*EGFR* mutations; 17 (89.5%) progressed/died. Median PFS was 8.1 months in these patients, versus 12.5 months for patients with EGFR-only mutations (HR, 1.72; 95% CI 0.88, 3.36; p=0.1054). At Visit 3, mutation status had changed from *EGFR*m+ to *EGFR* mutation-negative in 33 of 40 patients analyzed (82.5%). Of these, 29 (87.9%) progressed/died; median PFS was 11.0 months versus 5.5 months for patients who remained *EGFR*m+ (HR, 1.25; 95% CI: 0.47, 3.30; p=0.6556). **Conclusion:** In this analysis, safety data were consistent with the known safety profile of afatinib. Median PFS was twice as long in patients who became *EGFR* mutation-negative compared with those who remained *EGFR*m+; however, the difference was not statistically significant. There was no significant difference in PFS for patients with additional non-*EGFR* versus those with *EGFR*-only mutations. This exploratory analysis suggests that afatinib has clinical benefit for patients with *EGFR*m+ NSCLC across all the subgroups assessed.

EP1.14-50 THE EFFECTIVENESS OF THE COMBINED THERAPY OF OSIMERTINIB AND VEMURAFENIB IN A PATIENT WITH COEXISTANCE OF EGFR AND BRAF MUTATION

K. Ma, M. Sun, X. Wang, Y. Xu, C. Sun, Y. Guo, S. Qiu

First Hospital of Jilin University, Changchun/China

Background: With the widely application of gene detection techonology in lung cancer, more rare genetic alterations are indentified, including the coexistance of double driver mutations. The coexistance of EGFR and BRAF mutations in lung cancer is rare and its treatment strategy has not been systemetically explored. Synergistic inhibition of the tumour cells by EGFR-TKI combied with BRAF inhibitor has been proved in a vitro trail. If there's clinical benefit of the combined tharepy targeting EGFR and BRAF pathways is unclear. **Method:** We present an adenocarcinoma lung cancer patient harboring 19 exon deletion and T790M mutation of EGFR who progressed on osimertinib with an emergence of BRAF VE600 mutation. The treatment of single-agent vemurafenib is effective for the metastatic leision but make the primary leision progession. Given the progression of primary leision the was noted, osimertinib was added to vemurafenib for treatment. **Result:** During the first week of combined therapy of osimertinib and vermurafenib with oral dose of 80 mg qd and 960mg bid respetively, the patient developed intolerable palpitation and fatigue (grade 3), which were related to drugs. Therefore, the dose of vemurafenib was reduced to 960mg qd, and osimertinib was taken with the original dose (80mg qd). Subsequently, aboved adverse events were obviously relieved (grade 1). After three months of combined therapy, the size of the priamry leision reduced significantly and the patient achieved a partial reponse, suggesting the the effectiveness of the combined therapy of osimertinib and vemurafenib. Currently, the follow-up of the patient is ongoing https://cpaper.ctimeetingtech.com/wclc2019/submission/mediafiles/view?id=1295&type=mediafile **Conclusion:** This case provides an example of the successful treatment of the combination of vemurafenib and osimertinib, and highlights the potential value of BRAF inhibitor combined EGFR-TKIs in the treatment of advanced lung cancer harboring BRAF mutation and EGFR mutation.

Keywords: Combined Therapy, BRAF mutation, EGFR mutation

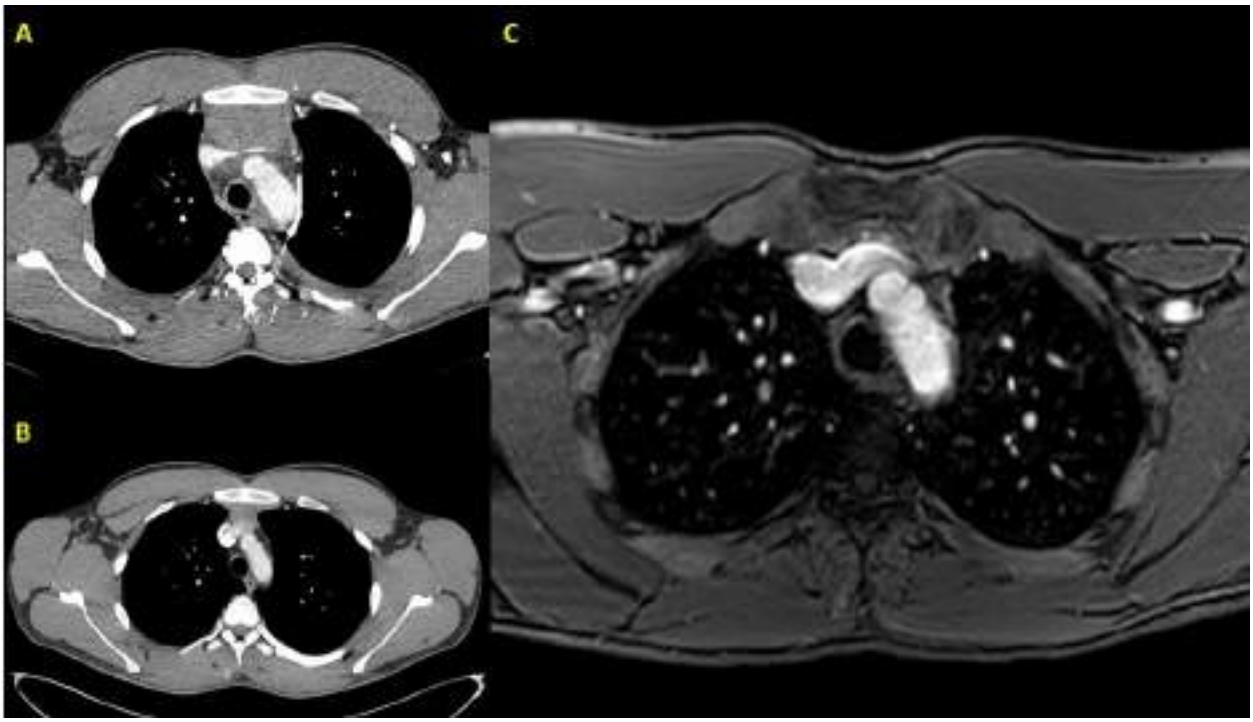
EP1.15 THYMOMA/OTHER THORACIC MALIGNANCIES

EP1.15-01 SPONTANEOUS MEDIASTINAL HEMATOMA RESEMBLING MEDIASTINAL TUMOR IN A HAEMOPHILIAC PATIENT

C. Braggio, G. Bocchialini, L. Ventura, M. Rusca, P. Carbognani, L. Ampollini

University Hospital of Parma, Parma/Italy

Background: To describe an extremely rare case of spontaneous mediastinal hematoma secondary to a thymic cyst bleeding and its surgical treatment in a patient with haemophilia A. **Method:** A 22-year-old male was admitted to the Emergency Department for chest pain, fever and haematuria arisen four days before. He was a heavy smoker with a previous diagnosis of haemophilia A (factor VIII deficiency). Vital signs showed tachycardia (110 beats per minute) and fever (37.5°C); physical examination showed a superior vena cava syndrome with oedema of the neck and the left harm. Hematological examination revealed only a prolonged clotting time compatible with his hemophilic disorder. A chest X-ray was performed and a mediastinal widening was revealed. A subsequent chest CT-scan showed a mediastinal mass of 77x35x85mm with compression of the left subclavian vein and superior vena cava (Fig. 1A). A suspect of lymphoma was posed and a surgical biopsy was planned. **Result:** Through a right uniportal VATS, the anterior mediastinal pleura was incised to reach the mass, and suddenly 400ml of hematinic liquid leaked out and multiple biopsies of the remnant mediastinal tissue were performed. A mediastinal hematoma was then suspected. Post-operative chest X-ray showed a reduction of the mediastinal widening. A chest CT scan performed a few days later revealed an impressive reduction of the mass (Fig. 1B). Histological examination was consistent with a thymic cyst surrounded by a large amount of haemorrhagic and inflammatory tissue. A chest MRI at 3 and 6 month after surgery demonstrated a gradual and complete reduction of the mediastinal mass (Fig. 1C).



Conclusion: Spontaneous mediastinal hematoma is a very rare condition that could radiologically be misdiagnosed with a mediastinal tumour. A suspect must be posed in patients with bleeding disorders presenting with a mediastinal widening.

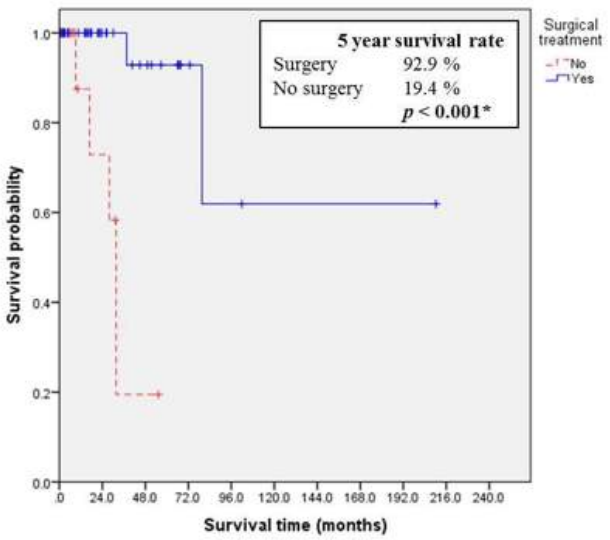
Keywords: mediastinum, mediastinal cancer, mediastinal hematoma

EP1.15-02 THYMIC EPITHELIAL NEOPLASM: A 15-YEAR EXPERIENCE TREATMENT IN RAJAVITHI HOSPITAL, THAILAND

K. Maneenil[1,2], S. Sa-Nguansai[1,2], V. Kaewchoung[2]

[1]*College of Medicine, Rangsit University, Bangkok/Thailand,* [2]*Rajavithi Hospital, Bangkok/Thailand*

Background: Due to the rarity and indolent natural history of thymic tumors, the prospective randomized trials have been lacking. Surgery is the primary treatment for localized disease and chemotherapy may be indicated in advanced disease. We performed a retrospective review of all cases over a 15-year period at our institution. **Method:** We retrospectively evaluated all patients who were diagnosed as thymoma and thymic carcinoma during 2003-2017 at Rajavithi hospital. Clinical characteristics, staging, treatment, and outcomes were collected and analyzed. **Result:** Thymic epithelial neoplasms were identified in 60 patients: 52.0% male with a median age 56.5 years (range, 22-83 years), 87.0% with Eastern Cooperative Oncology Group performance status of 0 to 1. Paraneoplastic syndromes were presented in 21.7%. The distribution by WHO histologic classification was A, 3.3%; AB, 8.3%; B1, 25.0%; B2, 15.0%; B3, 15.0%; C, 1.7%; and thymoma unclassified, 31.7%. The majorities (55%) of patients were stage 1-3. Of 40 patients who underwent operation, 47.5% underwent R0 resection. Nineteen patients received adjuvant radiation and 5 patients received adjuvant chemotherapy. Palliative chemotherapy and radiation were given in 12 and 7 patients, respectively. The overall response rate to palliative chemotherapy was 10/12 (83.3%) with majority (75.0%) of patients received carboplatin plus paclitaxel. After a median follow-up of 26.8 (1-180) months, 53 (88.3%) patients remain alive. Median overall survival (OS) was 79.6 months with OS rate at 5-year being 73.6%. Ability to received surgical resection was the only significant (p = 0.003) prognostic factor on multivariate analysis. Figure Kaplan-Meier curve for overall survival in thymic malignancy patients (N=60), comparison by the ability to receive surgical treatment



Conclusion: Although surgical resection is the mainstay of treatment, it remains clear that these tumors are chemo-sensitive diseases. Traditional cytotoxic agents remain the standard of care in patients with advanced disease. Multidisciplinary approach should be offered in all patients.

Keywords: THYMOMA, thymic tumors, Chemotherapy

EP1.15-03 SMARCA4-DEFICIENT THORACIC MALIGNANCIES: A UNIFYING GENETIC ABERRATION ACROSS TUMORS OF DIVERGENT DIFFERENTIATION

A. Nambirajan[1], R. Parshad[1], A. Goyal[1], S. Mittal[2], D. Jain[2]

[1]*All India Institute of Medical Sciences, NEW DELHI/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Mutations in ATPase-dependant chromatin remodelling units are one of the most common genetic alterations observed in human cancer. Germline mutations in *SMARCA4* encoding for Brg-1 protein, a subunit of the SWI/SNF chromatin modifier unit, are well recognised as the causative genetic event in rhabdoid tumor predisposition syndromes that occur in infants and young children. In recent years, somatic mutations in *SMARCA4* have been increasingly identified in many adult-onset malignancies ranging from well differentiated carcinomas to poorly differentiated high grade sarcomas in a variety of anatomical sites, including thorax. Documentation of such tumors is essential to our understanding of the pathogenesis and possible mechanisms of therapeutic targetting. **Method:** Case 1: A 60-year-old male smoker presented with chronic emphyema thoracis of non-tubercular etiology which was treated by intercostal drainage. He had repeated episodes of blockade of chest drain over the next 6 months and eventually a thoracic window was surgically created. Five months following thoracotomy, patient presented with a mass growing at the site of the thoracic window. No other masses in the lung parenchyma or mediastinal lymphadenopathy was seen. Patient underwent an excision of the granulation tissue-like mass. Formalin fixed paraffin embedded sections were subject to microscopy and immunohistochemistry for vimentin, CD34, MIC2, p53, SALL4, pan-cytokeratin (AE1/AE3), EMA, p40, TTF-1, cytokeratin-7, Hepar-1, desmin, myogenin, CD31, S100, Melan-A, HMB-45, GATA-3, calretinin, WT1, INI-1, brg-1 and hematolymphoid markers. Case 2: A 58-year old male smoker presented with hemoptysis and cough. On evaluation, an endobronchial mass was identified and was excised. Formalin fixed paraffin embedded sections from excised tumor mass was subject to microscopy and immunohistochemistry for cytokeratin 7, cytokeratin 19, epithelial membrane antigen, chromogranin, synaptophysin, cytokeratin 20, CD117, TTF-1, NUT1, Her2neu, GATA3, p40, S100, INI-1 and brg-1. **Result:** Case 1: Microscopy revealed a tumor centred in the soft tissue of the chest wall ulcerating the overlying skin. No lung parenchymal involvement was seen. The tumor was arranged in sheets composed of monomorphic large tumor cells with abundant eosinophilic cytoplasm and prominent nucleoli showing frequent mitoses and foci of necrosis. No squamous or glandular differentiation was seen. Tumor cells were only immunopositive for vimentin, CD34, MIC2, p53, and SALL4, very focally immunopositive for CK (AE1/AE3) and showed retained INI-1 protein expression. Brg-1 expression was lost in tumor cells leading to a diagnosis of SMARCA4-deficient thoracic sarcoma. Case 2: Microscopy revealed a high grade tumor arising from the main bronchi with parenchymal and tracheal extension ulcerating the overlying squamous epithelium. Tumor cells were arranged in lobules with peripheral palisading and central necrosis. The tumor cells were large with frequent cytoplasmic clearing and frequent mitoses. Tumor cells were immunopositive for CK-7, CK-19, EMA, CG while were negative for others. INI-1 was retained while brg-1 was lost leading to a diagnosis of SMARCA4-deficient carcinoma. **Conclusion:** Two independant studies have delineated SMARCA4-deficient thoracic sarcomas and SMARCA4-deficient lung carcinomas as distinct clinicopathological entities. Despite a unifying genetic alteration, these tumors appear to show varied histomorphology and immunoprofiles. Long term follow-up and molecular analysis of such tumors is necessary.

Keywords: SMARCA4, lung, chest wall

EP1.15-04 HUGE INTRA THORACIC MESENCHYMAL TUMORS. ABOUT 19 CASES

W. El Aamadi

Ibn sina University Hospital Center, Lot attanmia n temara Morrocco/Morocco

Background: Mesenchymal tumors represent a heterogeneous group of tumors, which may be benign or malignant and are developed from supportive tissues: connective, vascular, nervous or adipose tissues. They often reach large volumes making their care very difficult. **Method:** Our work consists of a retrospective study of 19 cases, collected in the department of thoracic surgery of Rabat; over a period of 7 years from January 2011 to December 2018. The purpose of this work is to update the diagnostic approach of this type of tumor, and also their anesthetic and surgical management. **Result:** We counted 19 cases including 12 women and 7 men, with an average age of 49 years. Dyspnea and chest pain are the main symptoms found in all our patients. All the patients received an X-ray and thoracic CT scan, 13 patients underwent a transparietal biopsy and were inconclusive in 3 patients. The surgical approach was a posterolateral thoracotomy for 16 patients, a mean lobectomy completing tumor resection was performed on one patient. The average size of the operative pieces was 16 cm. In operation 5 patients presented hemodynamic instability, 12 patients required a transfer to the intensive care unit in the immediate postoperative. The anatomopathological study of operative specimens returned to solitary fibrous tumor (8 patients) Neurogenic tumors (4 patients) Teratoma (2 patients) Liposarcoma (1 patient) Metaplastic thymoma (1 patient) Synoviosarcoma (1 patient) Pneumoblastoma (1 patient)) fibromatosis (1 patient). **Conclusion:** The diagnosis of an intra-thoracic mesenchymal tumor is very difficult, but it must in no way delay surgical management as long as it is possible.

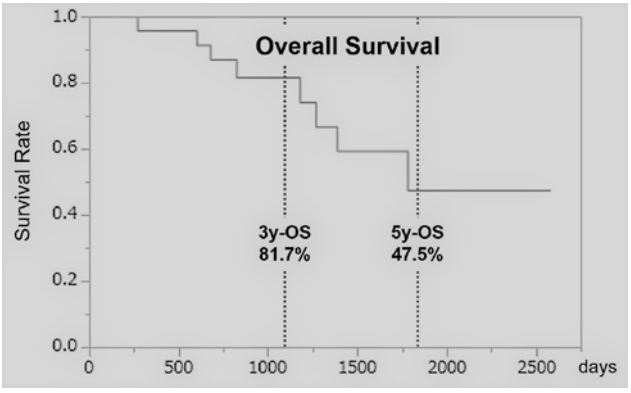
Keywords: Huge, mesenchymal tumors, Intra-thoracic

EP1.15-05 SURGICAL OUTCOMES OF PULMONARY METASTASECTOMY FOR HEAD AND NECK CANCER: A SINGLE INSTITUTIONAL RETROSPECTIVE STUDY

T. Ochi, H. Wada, T. Yamamoto, J. Morimoto, Y. Sakairi, H. Suzuki, T. Nakajima, I. Yoshino

Chiba University Graduate School of Medicine, Chiba/Japan

Background: Pulmonary metastasis is often observed during clinical course of head and neck cancer (HNC). Five-year survival rate after pulmonary metastasectomy of HNC has been reported to be around 60%, however, proper indication of metastasectomy remains unclear. We aimed to clarify clinicopathological features and surgical outcomes of HNC patients who underwent with pulmonary metastasectomy. **Method:** A total of 25 patients underwent pulmonary metastasectomy at Chiba University Hospital during from January 2011 to December 2016. Prognostic factors related to overall survival after pulmonary metastasectomy were retrospectively examined using the univariable Cox proportional hazard models. **Result:**



Median follow-up period was 39.5 ±22.5 months. Mean age of the patients was 64.5 ±13.4 years, and they included 23 males. Primary lesions arose in pharynx in 12 patients, oral cavity and nasal cavity and paranasal cavity in 6, larynx in 4, and salivary gland in 3. Seventeen patients were diagnosed as stage IV due to tumor size and/or lymph node metastasis in the first presentation. Primary lesions were resected in 19 patients, and chemotherapy and/or radiation therapy were added in 15 out of these patients. The mean tumor diameter of pulmonary metastases was 15.4 ±10.3 mm. A single pulmonary nodule was detected in 15 patients and double in 6, triple in 3 and four in 1 patient, respectively. Among the 40 lesions, partial resection was selected for 30, segmentectomy for 7, lobectomy for 3. Squamous cell carcinoma was the most predominant (76%). Recurrent site after pulmonary metastasectomy was most frequently observed in the lung (72%). Eight patients survived without recurrence, 10 patients survived with recurrent disease, and others died of the diseases. After pulmonary recurrence, 3 patients underwent repeated metastasectomy, and eventually achieved cancer free status for 4.43

±1.64 years. Following pulmonary metastasectomy, 6 patients were suffered from other cancers. Three- and 5-year survival rates were 81.7% and 47.5%, respectively. In the univariate analysis, disease free survival (< 140 days) and age (< 60) were independent predictors of poor prognosis. **Conclusion:** Surgical treatment for pulmonary metastasis of HNC can offer favorable survival. The number of cancer-bearing patients after pulmonary metastasectomy is increasing possibly due to the advance of novel chemotherapy. It is important to provide a careful observation considering that the most frequent site to redevelop recurrence after pulmonary metastasectomy is the lung and that other organ cancers often arise in those patients.

Keywords: metastasectomy, head and neck cancer, pulmonary metastasis

EP1.15-06 ASKIN TUMOR: A CASE REPORT

A. Moumen, S. Boubia, N. Idelhaj, A. Fatene, M. Ridai

University Hospital Ibn Rochd, Casablanca/Morocco

Background: Askin's tumor is a rare highly malignant tumor that originates from the soft tissue of the chest wall, rarely in the lung. It is observed with predilection in the young subject and still raises many questions about his own individualization and his links with Ewing's sarcoma. **Method:** We report the case of child Y. I, 12 years old, who had left chest pain with dyspnea stage 1 6 months before his admission **Result:** The chest CT objectified 2 contiguous formations of the left chest base (30mm and 92mm) with peripheral calcification that contrasted homogeneously with a left pleural effusion. After a multidisciplinary meeting, a biopsy was indicated and its examination found an aspect of round cell tumor proliferation infiltrating muscle tissue and expressing intensely anti CD99 Ac, in favour of a primary peripheral neuro-ectodermal tumor (PNET) Askin type. The patient was then referred to haematology where he received 6 cycles of neo-adjuvant chemotherapy (VIDEprotocol). The thoracic CT evaluation showed a regression of the 2 formations with a slight thickening in the mid-arc of the 9th left rib. The patient therefore benefited from a one-piece resection of the left lateral arches of Co8, Co9 and Co10. The post-operative history was simple. The patient left the ward the fourth day after the surgery. The anatomopathological examination of the resected piece concluded that there was a residual site compatible with the Askin tumour representing 10 to 50% of the tumor mass and evaluated as grade II of Huvos and Rosen with the presence of necrotic and fibrohyaline changes. The resection was complete. After an adjuvant chemotherapy and 8 months before surgery, the patient is regularly followed in consultation and shows no sign of recurrence. **Conclusion:** The therapeutic management of Askin's tumor is not yet well codified and patients are most often treated on a case-by-case basis. All decisions should therefore be taken within the framework of a multidisciplinary meeting.

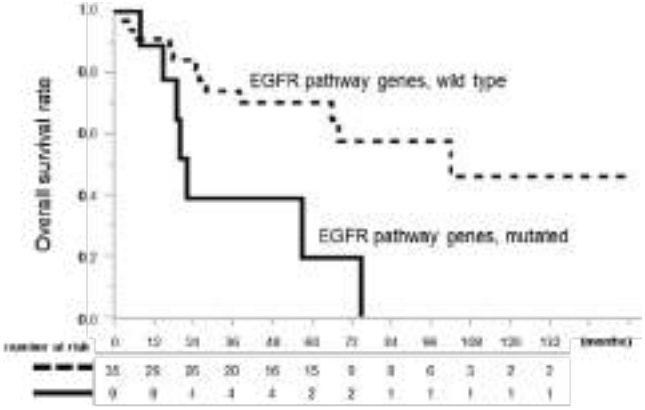
Keywords: askin tumor, surgical treatment

EP1.15-07 A MUTATIONAL ANALYSIS OF EPIDERMAL GROWTH FACTOR RECEPTOR PATHWAY GENES IN THYMIC CARCINOMA

T. Sakane, K. Okuda, K. Yokota, T. Tatematsu, K. Endo, R. Nakanishi

Graduate School of Medical Sciences, Nagoya City University, Nagoya/Japan

Background: Thymic carcinoma is rare and usually has a fatal outcome. In many malignancies, gene mutations in the epidermal growth factor receptor (EGFR) signaling pathway are important for predicting a patient's prognosis and as targets in molecular-targeted therapy. However, these mutations have not been well analyzed in thymic carcinoma. **Method:** We examined a large cohort of thymic carcinoma and looked for gene mutations in the EGFR pathway genes; *RAS* family, *EGFR*, *PIK3CA*, *AKT1*, and *BRAF* using a highly sensitive single-base extension multiplex assay, SNaPshot assay. **Result:** Among 54 thymic carcinoma cases, 13 (24.1%) showed 14 mutations: *RAS* family mutations in 10 cases (18.5%; KRAS in 6 [11.1%], HRAS in 3 [5.6%], and NRAS in 1 [1.9%]), *EGFR* in 2 (3.7%), *PIK3CA* in 1 (1.9%), *AKT1* in 1 (1.9%), and *BRAF* in 0. All of these mutations were of the missense type, and mutations were mutually exclusive in all cases except in one case that harbored *HRAS* and *AKT1* mutations. A prognostic analysis focusing on squamous cell-type thymic carcinoma cases (n=44, 9 mutation-positive cases) showed that the overall survival (OS) was significantly shorter in patients with EGFR pathway mutations than in those without in a univariate analysis (median OS time, 22 months vs. 102 months; p=0.0173) (Figure 1). Subsequently, EGFR pathway mutations were selected as an independent factor for a poor overall survival (p=0.0389).



Conclusion: In the present study, gene mutations in the EGFR pathway in thymic carcinoma were found more frequently than in previous studies. Gene mutations in the EGFR pathway may be associated with a poor prognosis in thymic carcinoma patients. Therapeutic significance of the gene mutations in thymic carcinoma should be further clarified.

Keywords: gene mutations, EGFR pathway, Thymic carcinoma

EP1.15-08 ASSOCIATION OF PERIOPERATIVE CHEMOTHERAPY WITH SURVIVAL IN THYMIC MALIGNANCIES

K. Parikh, U. Durani, S. Funni, J. Inselman, G. Goyal, K. Leventakos, N. Duma, S. Yadav, R. Go, A. Mansfield

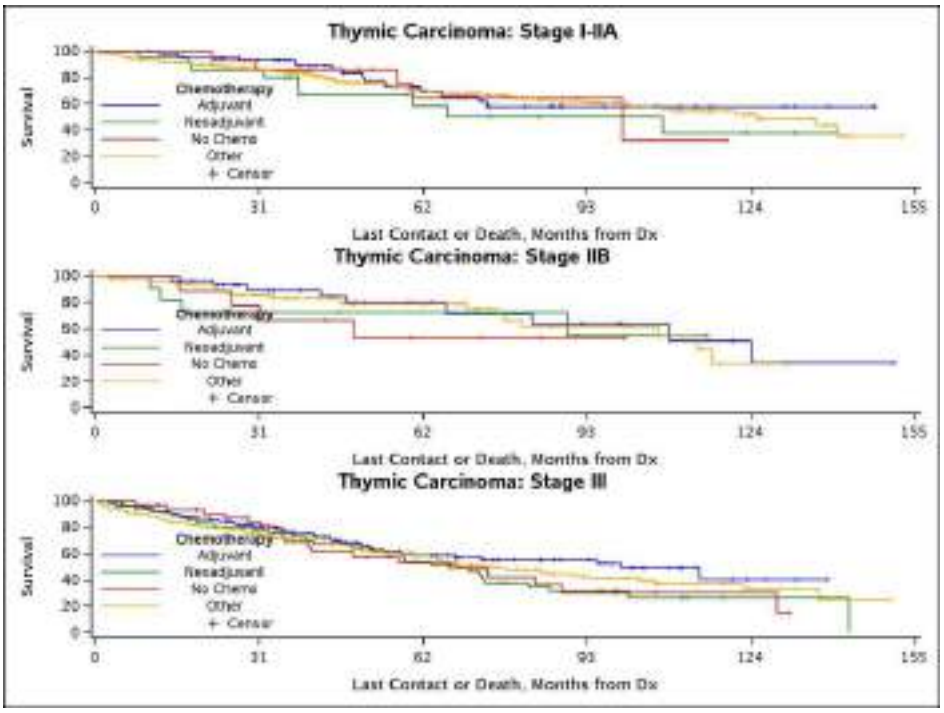
Mayo Clinic, Rochester/United States of America

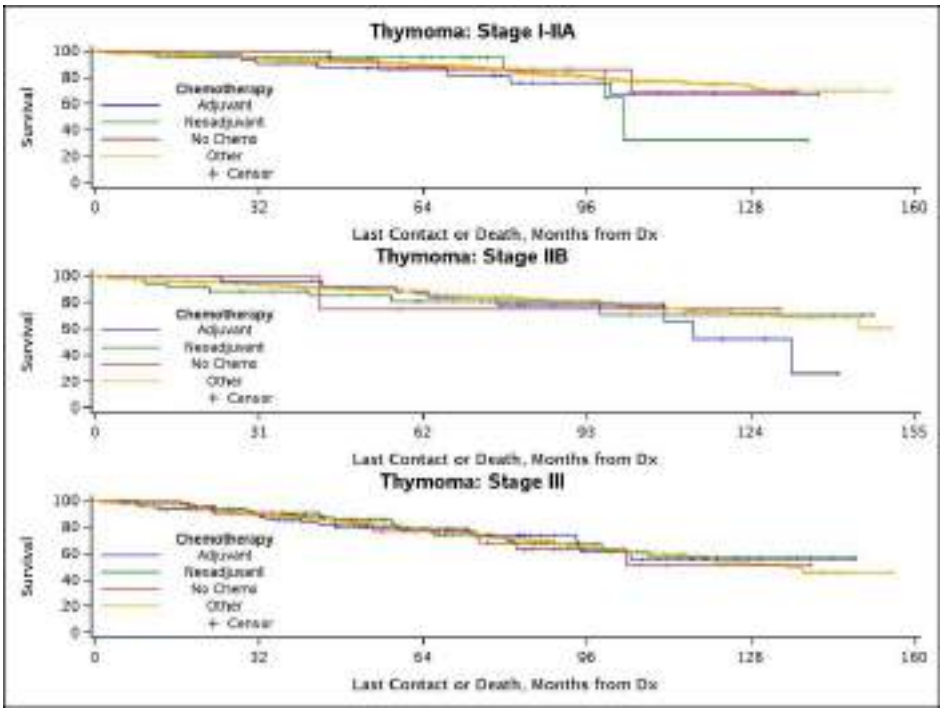
Background: Patterns of perioperative chemotherapy utilization and its association with survival in thymic malignancies are largely unknown. **Method:** We queried NCDB from years 2004-2014 and identified 3,788 patients with non-metastatic thymic carcinoma (TC) and thymoma who received surgery. We compared patients who received perioperative chemotherapy to those who didn't and used a Cox proportional hazards model to determine predictors of mortality. **Result:** 764 patients (20%) received chemotherapy: 287(38%) neoadjuvant (NAC), 347(45%) adjuvant (AC), and 130(17%) unspecified. 184(24%) had TC; the rest had thymoma. Patients who didn't receive chemotherapy (N=3024) had older age (median 62 vs 47, P<0.01) and earlier stage (51% versus 24% stage I-IIA, P<0.01). In multivariable analysis, patients who received AC versus no chemotherapy had a similar overall survival(OS); however, NAC predicted a worse OS. For separate thymoma and TC subsets, median OS did not differ between those who received AC and those who didn't in either group. AC did not improve OS for patients with R1/R2 margins (114 months, 95%CI 94-NR vs 131 months, 95%CI 118-NR)

Characteristic	Hazard ratio for mortality (95% confidence interval)[1]
Age	1.03 (1.03-1.04)
Thymoma vs. TC	0.50 (0.43-0.58)
Charlson-Deyo score>0	1.40 (1.21-1.63)
Chemotherapy None Adjuvant Neoadjuvant Unclassified	1 1.13 (0.89-1.44) 1.77 (1.37-2.27) 1.60 (1.16-2.19)
Masaoka-Koga Stage I-IIA IIB III Unknown/other	1 1.08 (0.88-1.34) 1.59 (1.34-1.90) 2.71 (2.01-3.65)
Radiation	0.78 (0.67-0.91)
Positive margin	1.55 (1.33-1.81)

[1]Model included sex, academic center, insurance, and race/ethnicity

EPOSTERS





Conclusion: Chemotherapy in the perioperative setting was not associated with improved OS in either TC or thymoma. Prospective controlled studies are needed to determine the role of perioperative chemotherapy in thymic malignancies.

Keywords: thymic carcinoma chemotherapy NCDB, thymoma chemotherapy NCDB

EP1.15-09 SURGICAL RESECTION OF PULMONARY METASTASES FROM HEPATOBILIARY AND PANCREATIC CANCERS

R. Sugimoto, T. Hayashi, N. Sakao, H. Shigematsu, Y. Sano

Ehime University Hospital, Toon City/Japan

Background: Hepatobiliary and pancreatic cancers account for 22% of all cancer deaths in Japan. Although these cancers have had a high mortality rate and have been poorly responsive to chemoradiation therapy, the survival of patients have been gradually improved with recent advances in diagnosis and treatment. Pulmonary metastases derived from hepatobiliary and pancreatic cancers have been a rare event and the management in such patients remains controversial. The aim of this study is to review our experience of pulmonary resection for metastatic hepatobiliary and pancreatic cancers, and to assess the feasibility of pulmonary metastasectomy. **Method:** Clinical data of 7 patients who underwent pulmonary resection for metastatic hepatobiliary and pancreatic cancers from April 2010 to March 2019 at Ehime University Hospital were retrospectively reviewed. Disease-free interval was defined as the time between operations for the primary cancer and the metastatic lesion. **Result:** The median follow-up period was 61 (range, 7 to 110) months. Primary diseases of these patients were hepatocellular carcinoma in 2, cholangiocarcinoma in 1, gallbladder cancer in 2 and pancreatic cancer in 2. There were 5 men and 2 women with mean age of 69 (range, 47 to 82) years. The median disease-free interval was 19 (range, 6 to 59) months and one patient with solitary metastasis was treated by lobectomy, the other 6 patients (3 solitary, 3 multiple) were treated by wedge resection. 5 surgeries were operated by VATS and the other 2 were operated by thoracotomy. There were 3 patients with incomplete resection. Additional treatments after metastasectomy were performed in 4 patients. Although no surgical complications and operative mortalities occurred, 2 patients died of primary diseases. Recurrence after pulmonary metastasectomy developed in 1 of 4 patients without incomplete resection. The longest survivor was still alive more than 5 years without recurrence after lung resection and the median survival period was 45 months. **Conclusion:** Surgical resection of pulmonary metastases from hepatobiliary and pancreatic cancers are feasible and the postoperative survival is acceptable. But there are highly selective patients in our study, further study is needed to evaluate the efficacy of pulmonary metastasectomy.

Keywords: hepatobiliary and pancreatic cancer, metastatic lung tumor, pulmonary metastasectomy

EP1.15-10 SURVIVAL IMPACT OF NON-SURGICAL TREATMENT IN THYMIC EPITHELIAL TUMOURS: A RETROSPECTIVE STUDY

S. Ridai, N. Benchakroun, Z. Bouchbika, H. Jouhadi, N. Tawfik, S. Sahraoui, A. Benider

CHU Ibn Rochd, casablanca/Morocco

Background: The management of thymic epithelial tumours, although poorly defined due to their rarity, remains multidisciplinary in order to offer patients multimodal treatment with surgery as the therapeutic pillar. Our main objective is to highlight the impact of non-surgical treatments on the overall survival and the progression free survival of patients treated for these tumours at the Mohamed VI center. **Method:** We carried out a monocentric, descriptive and retrospective study using databases from the oncology, the thoracic surgery and anatomopathology departments of the Ibn Rochd University Hospital in Casablanca. We identified all patients with thymoma or thymic carcinoma whose histological diagnosis was made on a biopsy or a surgical excision piece between July 2006 and February 2016 After exclusions, 42 patients were identified and we used a farm sheet to specify for each patient, epidemiological data, data related to histological type, Masaoka-Koga staging and progress under treatment (complete or partial response, stabilization or progression) For our analysis, we used Microsoft Office, Excel 2007 and Kaplan Meier Software to assess overall ans progression free survival. **Result:** 42 cases of thymic epithelial tumours were reported between 2006 and 2016 with apredominance of type B1 in patients aged between 25 and 77 years. The radiological assessment carried out before treament showed that 9.5% of the diseases were metastatic from the outset, while the others had an intra – thoracic locoregional extension Half of the patients were resectable from the outset, wich made it possible to perform primary surgery leading to carcinological resection with generally simple post-operative outcomes. In our series, CAP D1 = D21 chemotherapy was the preferred regimen to be indicated as a pre operative treatment to reduce the size of the tumor and increase its resectivity rate in 11 patients (26,2% of cases). This chemotherapy was indicated as adjuvant treatment in 06 cases of incomplete resection (14,3% of cases) Two patients (4,8% of cases) received first chemotherapy followed by exclusive radiation therapy at 66 Gy while more than 25% received a post-operative radiation therapy at variable doses ranging from 50-54Gy for R0 tumours or microscopic disease to 60-70Gy for macroscopic disease. The overall and progression free survivals at 22 months were 94,6% and 68,4% respectively. The prognostic factors are, in univariate analysis, the performans status, the histological type, the Masaoka-Koga stage and the quality of surgical resection. The multivariate analysis could not be performed due to a lack of statistical power, due to the small number of patients and the retrospective nature of the study. **Conclusion:** The thymic epithelial tumours treatment is a real challenge given the absence of randomized prospective studies on this subject Surgery remains the mainstay of management but neo-adjuvant and or adjuvant treatments can be considered in case of poor prognostic factors in order to reduce the risk of recurrence or death from the disease.

Keywords: Adjuvant, neoadjuvant, thymic epithelial tumors

EP1.15-11 OUTCOMES OF THYMOMA AND DETERMINANTS OF SURVIVAL: 16 YEARS EXPERIENCE OF A TERTIARY CANCER CENTER

N. Ak[1], A. Toker[2], S. Bayraktar[3], B. Özkan[4], M. Ülker[4], N. Dağoğlu[1], S. Karaman[1], E. Kaba[2], F. Ferhatoğlu[1], E. Aydın[1], E. Kaytan Sağlam[1], E. Nezih Oral[1], G. Yegen[4], Y. Eralp[1], A. Aydiner[1]

[1]*Istanbul University, Institute of Oncology, İstanbul/Turkey,* [2]*Istanbul Florence Nightingale Hospital, İstanbul/Turkey,* [3]*Memorial Sisli Hospital, Istanbul/Turkey,* [4]*Istanbul University, Faculty of Medicine, İstanbul/Turkey*

Background: We aimed with this study to explore the demographics and clinical outcome of patients with thymoma. **Method:** A total of 203 patients with thymoma (Masaoka stage II-IV) treated from 2002-2018 were included in this retrospective analysis. IBM-SPSS statistical software version 20 for Windows (IBM, NY) was used for analysis. Survival analysis were estimated by the Kaplan–Meier method and compared by the log-rank test. $p<0.05$ was considered statistically significant. Cox-regression tests used for multivariate analysis. **Result:** Male:female ratio was 105:98 with median age 49 years (Range 11-77). At presentation, patients with stage II, III and IV disease were 90, 67 and 45, respectively. A total of 123 patients(60,6%) had myasthenia gravis, and 56,1% of these patients had presented with myasthenia related symptoms. Majority of the patients were operated with sternotomy(n=103), and mean hospital stay was 8,34 days (Table 1). A total of 76 patients had received adjuvant radiotherapy, and 31 patients and 35 patients had received adjuvant and neoadjuvant chemotherapy, respectively. At mean follow-up of 218,6 months(95%CI:201,8-235,3), 5-year and 10-year OS rates were 93,8% and 89,2%. 30 patients had recurrence after surgery, and 5-year and 10 year DFS rates were 76,5% and 68,3%. Masaoka-Koga stage($p<0.0001$), postoperative hospital stay more than 10 days($p=0,004$) and needing neoadjuvant chemotherapy($p=0,003$) were significant effects on DFS. Among patients who had given neoadjuvant chemotherapy, comparing cisplatin with etoposide or doxorubicin based combinations did not change DFS($p=0,34$) or OS ($p=0,48$). Adjuvant radiotherapy and chemotherapy also have no survival effect on DFS and OS. On univariate analysis, age($p=0.013$), Masaoka-Koga stage($p=0.001$), postoperative hospital stay more than 10 days($p=0,006$) and having recurrence($p=0,013$) were significant effects on OS. Stage ($p=0,001$) and age ($p=0.007$) retained its prognostic significance on multivariate analysis (Table 2).

EP1.15-12 PREDICTIVE VALUE OF PERCENTAGE OF KI 67 EXPRESSION IN BRONCHOPULMONARY CARCINOID TUMORS

A. Patané[1], G. Guma[2], W. Astorino[3], M. Rosenberg[1]

[1]*Hospital de Rehabilitación Respiratoria María Ferrer /Instituto Médico Alexander Fleming, Buenos Aires/Argentina,* [2]*Hospital de Rehabilitación Respiratoria María Ferrer, Buenos Aires/Argentina,* [3]*Instituto Médico Alexander Fleming, Buenos Aires/Argentina*

Background: Introduction The determination of Ki67 has not been shown to be useful in the diagnostic discrimination between typical (CT) and atypical (CA) carcinoid tumors. However, the biological behavior of these tumors is not homogeneous. Objective: to establish a Ki67 cut-off point for carcinoid tumors and to determine its prognostic implications in overall survival and disease-free survival in both histological subtypes. **Method:** Material and **Method:** retrospective cohort on 106 patients with diagnosis of carcinoid tumor (OMS 2015) surgically trated. The% of cells expressing Ki 67 was determined manually by two pathologists specialized in the use of a rabbit monoclonal antibody prediluted anti Ki67 (Clone MIB-1). Ki67-positive nuclei were quantified in 2000 consecutive tumor cells in the areas of highest activity (HOT SPOT) at a magnification of 40X. The comparison of continuous variables was made according to its distribution and the categorical variables with the Chi2 test or Fisher's exact test. To evaluate the association between Ki-67 expression and the occurrence of events, logical regression analysis was performed and ROC curves were constructed to evaluate global predictive capacity as per histological subtype, identifying the best cut-off point using the Youden index. Once this point was identified, the regression analysis was repeated using Ki-67 as a dichotomous variable (equal or greater than the cut-off point versus lower). All tests are two-tailed and a value of p <0.05 was considered statistically significant. The analysis was carried out with the program R: A Language and Environment for Statistical Computing version 3.5.1 (Vienna, Austria) **Result:** The data of ki-67 were available in 63/106 patients (59.4%). 40 (65.6%) CT and 23 (34.4%) CA. The 60.3% (n = 38) were women, the average age was 43.7 (SD 15.4) years, 25 (28.8%) were smokers. The median of ki-67 was 0.86 (RIQ 0.50 - 3.25). The presence of lymph node metastases N2 (12.8% vs 38.1%, p = 0.045), recurrence rate (2.5% vs 19%, p = 0.044) and mortality (0 vs 28.6%, p = 0.005) were significantly higher in the group of the CA. The median of ki-67 between the CTs was 0.63 (RIQ 0.44 - 1-93) vs 2.00 (RIQ 0.65 - 4.00) in CA (p = 0.005).The Ki-67 value was not significantly associated to mortality (p = 0.546), nor to risk of relapse, analyzing the entire population (p = 0.489), nor by histological subtype (CT p = 0.677 vs CA p = 0.202). The best cut-off point of Ki-67 on the ROC curve in patients with CA was 1.18. Using this value as a predictive variable, there was no significant association between% Ki-67 and mortality (p = 0.077), but a marginal association with the frequency of relapses (p = 0.054). **Conclusion:** Although we have not been able to demonstrate predictive association between KI 67 and mortality, this could be due to the small number of observed events. In the AC subgroup, the marginal association between relapse frequency and Ki 67 values> = to 1.18 presents clinical relevance and future analyzes are required to determine the real predictive value of this variable.

EP1.15-13 PROGNOSIS OF COLORECTAL CANCER CASES THAT UNDERWENT LUNG AND LIVER METASTASECTOMY AND THERAPEUTIC OUTCOMES OF BRAIN METASTASIS

T. Fujita, M. Kataoka, K. Suemori, D. Okutani, K. Watanabe, H. Kawai, S. Harita

Okayama Saiseikai General Hospital, Okayama/Japan

Background: The resectability is often debated in cases of lung and liver metastases. Further, we had reported previously that the incidence of brain metastasis is significantly higher in colorectal cancer with lung metastasis than cases with liver metastasis (lung: 7.7%, liver: 1.6%). We compared and investigated the therapeutic outcomes of cases of lung, liver and brain metastasis. **Method:** Between 2002 and 2013, we retrospectively studied the prognosis of 90 cases of colorectal cancer cases that underwent lung metastasectomy, and 148 cases that underwent liver metastasectomy. The course of treatment in 8 cases of subsequent brain metastasis was also evaluated. **Result:** The 5-year survival rate (5-SR)for 90 cases of lung metastasectomy overall was 66.7%. 63 cases were initial metastasis and the 5-SR was 66.7%. Out of these, there were 7 cases of synchronous metastasis with a 5-SR of 57.1%, and 56 cases of metachronous metastasis with a 5-SR of 67.9%, indicating no significant difference. The regions of secondary recurrence after lung resection were as follows: lung: 28 (cases), liver: 7, brain: 3, mediastinal lymph nodes: 5, other: 5. The 5-SR for 148 cases of liver metastasectomy overall was 54.7%. 141 cases were initial metastasis and the 5-SR was 55.3%. Cases who underwent lung metastasectomy had a significantly higher survival rate (p=0.0068). Out of these, 70 cases were synchronous metastasis with a 5-SR of 35.7%, and 71 cases were metachronous metastasis with a significantly higher 5-SR of 67.9% (p=0.011). The regions of secondary recurrence after liver resection were as follows: lung: 47 (cases), liver: 66,brain: 2, abdominal lymph nodes: 9, dissemination: 6, other: 7. While there were 5 cases of subsequent brain metastasis after lung resection, no subsequent brain metastasis was found after liver resection. All but one of the 8 cases of brain metastasis after lung resection were treated with surgery or CyberKnife. The total survival period was 1141 - 3848 days (median: 1913.5 days), and the survival period after detection of brain metastasis was 15 - 852 days (median: 401 days). In addition, all cases were experiencing associated symptoms when brain metastasis was detected, and only one patient was undergoing regular examinations to detect brain metastasis. **Conclusion:** While appropriate surgical intervention is recommended in cases of lung metastasis and metachronous liver metastasis,it is debatable in cases of synchronous liver metastasis. Cases of lung metastasis should give attention to brain metastasis and recieve early detection and intervention.

Keywords: lung metastasis of colorectal cancer, Liver metastasis, brain metastasis

EP1.15-14 MEDIASTINAL LYMPH NODE DISSECTION THROUGH MEDIAN STERNOTOMY IN THYROID CARCINOMA

Y. Yamada[1], J. Maeda[1], T. Hoshino[1], T. Yokota[1], T. Uruno[2], S. Ikeda[1]

[1]*Mitsui Memorial Hospital, Tokyo/Japan,* [2]*Ito Hospital, Tokyo/Japan*

Background: Recurrent cervical and mediastinal lymph node metastasis after the surgery of thyroid carcinoma is frequently reported. Generally, surgery is the best treatment but there is still no established standard surgical procedure. In our hospital, we perform the operation through median sternotomy. **Method:** Surgical procedure for recurrent cervical and mediastinal lymph node metastasis after thyroid carcinoma varies throughout each institute. Recently, reports of the usage of VATs in these cases are increasing. We report 2 resected cases of cervical and mediastinal lymph node metastasis after thyroid cancer which underwent dissection through median sternotomy. **Result:** A 68-year-old Japanese man underwent left thyroid lobectomy for poorly differentiated thyroid cancer in September 2009. The follow-up CT in 2014 showed a multiple mediastinal lymph node metastases. Therefore, the patient underwent mediastinal lymph node dissection through median sternotomy. Pathological findings showed metastasis in 24 of the 42 lymph nodes. During outpatient follow-up, CT revealed a recurrent mass lesion in the vincinity of the right subclavian artery and common carotid artery. Although I131 was administered, the mass did not respond. Therefore surgery therapy was required. The second operation was cervical incision. The pathological findings showed consistent recurrence. The patient was discharged from the hospital on postoperative day 4. The second patient was a 58-year-old Japanese man who had been treated by subtotal thyroidectomy in May 2008. The patient noticed a gradual increase of a mass near his right lower jaw from 2011. As a result of further examination, mediastinal lymph node metastasis was suspected. The patient underwent mediastinal lymph node dissection through median sternotomy and neck collar incision. Pathological findings showed metastasis in 9 of the 31 lymph nodes. Pathological findings revealed metastasis of papillary thyroid carcinoma. The patient was discharged from the hospital on postoperative day 13. **Conclusion:** Recent reports of recurrent cervical and mediastinal lymph node metastasis after thyroid carcinoma suggests using VATs, which may have less complications. In our hospital, the possibility of micrometastases is also considered in cases of post-operative lymph node recurrence. Therefore, we completely resect the mediastinal lymph nodes by median sternotomy approach. We have been promoting mediastinal

lymph node dissection for lung cancer surgery at our center, but we would like to report the significance of mediastinal lymph node dissection for recurrence cases after thyroid carcinoma.

Keywords: mediastinal lymph node metastasis,median sternotomy,thyroid carcinoma

EP1.15-15 SINGLE-CENTER RETROSPECTIVE ANALYSIS OF OPERATED THYMOMAS

A.R. Costa, R. Barata, J. Silva, J. Eurico Reis, P. Calvinho

Santa Marta Hospital, Lisboa/Portugal

Background: Thymoma is the most common thymic neoplasm. In the majority of cases, patients are asymptomatic and the diagnosis is incidental. Surgery is the gold-standard treatment whenever possible. The objective of this study was to evaluate retrospectively the surgical outcomes in patients with stage Masaoka-Koga I to IVa thymomas at our department. **Method:** A review of 50 cases of thymomas submitted to surgical excision at our Thoracic Surgery Department was made by accessing their clinical records, in a six-year period, from January 2012 to December 2018. **Result:** From the 50 patients, 38% were males, with an average age of 58 years old, ranging from 15 to 85. In a relatively high percentage of patients, the thymic malignancy was accidentally found in a CT-scan. 24 of the cases were associated with Myasthenia Gravis. All the patients had a CT-scan prior to surgery but just 3 had done a PET-CT scan that seemed to be reserved to those of a higher stage. The histological diagnosis was done by CT-controlled biopsy in 14 cases and in the rest the diagnosis was done by the analysis of the extracted specimen. There were 4 type A thymomas, 12 type AB, 5 type B1, 17 type B2, and 10 type B3, one sclerosing thymoma and one micronodular thymoma with lymphoid stroma. The majority (54%) were in Masaoka-Koga stage II. There were 11 patients at stage I, 9 at stage III and only 3 at stage IV. Only 3 patients did neoadjuvant treatment, 21 patients had adjuvant radiotherapy, 2 patients had adjuvant chemotherapy and 3 had both. The surgical approach was sternotomy in 76% of cases, videothoracoscopy in 18%, thoracotomy in 2%, sternotomy plus thoracotomy in 2%, hemiclamshell in 2%. In all cases was done an en bloc resection, which in some involved lung resection (16), pericardial resection (9), vascular resection (8) and diaphragm resection (1). There was no surgical mortality, but 10 patients had phrenic nerve paralysis and 2 had a myasthenic crisis. The mean of hospital stay was 7 days (+- 8), comprising between 2 and 56 days. After a mean follow-up of 29 months (+- 20 months), there were 2 disease-related deaths and 4 recurrences (2 pleural, one diaphragmatic and one lung and mediastinal). The time to recurrence ranged from 4 to 74 months. There was a 100% survival rate at the post-operative period and overall survival at 5 years of 81%. Regarding the Masaoka classification, the 5-year-survival rate was shown to be of 100% in stage I, 96% in stage II, 44% in stage III and 100% in stage IV. On the other hand, the analysis by the WHO classification showed a 5-year-survival of 100% in thymoma A and AB groups, 40% in thymoma B1 group, 75% in thymoma B2 group and 67% in thymoma B3 group. **Conclusion:** Even though thymic malignancies are rare tumors, thymomas are commonly approached by the Thoracic Surgeon. Surgical resection is the mainstay of treatment, but a multimodality approach is crucial in specific cases.

Keywords: thymoma, surgery, survival

EP1.15-16 TWO CASE REPORT OF MALIGNANT TRACHEAL TUMORS

M. Rahli

Beni Messous Hospital, ALGER/Algeria

Background: Primary malignant tumors of the trachea are rare and uncommon, they represent less than 0.01% of adult tumors and about 0.2% of respiratory ones. They are malignant 90% of the time, with squamous cell carcinoma being the most frequent (50–66%) followed by adenoid cystic carcinoma (10–15%). **Method:** The first case report concerns a 42 years old man with no medical history, that consulted in our unit with cough, wheezing and shortness of breath, the chest computerized tomography (CT) showed a distal tracheal mass with axophytic extension without carinal involvement, the ascertain size was 34 mm × 40 mm. Neither mediastinal lymphadenopathy nor obvious invasion to surrounding structures was noted. During the flexible bronchoscopy, we found tracheal tumor partially blocking. the anatomopathology study of the biopsy reported a squamous carcinoma. The second report is about a 20 years old female with an allergic rhinitis history, who consulted with a dyspnea and vigorous cough persisting for more than year. During this this period the symptoms were attached to asthma and were treated by an association inhaled corticosteroid-beta 2 sympathomimetic. The neck and chest CT showed an endotracheal mass of 26 mm diameter originating from the anterior wall, occluding 70% of the trachea. The bronchoscopy confirmed the same analysis and showed an easy bleeding to the touch. The biopsy revealed an adenoid cystic carcinoma. **Result:** The Multidisciplinary decision (pulmonologist, thoracic surgeon, oncologist and anesthesiologist) advised for a surgical resection for the two patients. The first patient underwent surgery with five tracheal rings resection and end-to-end anastomosis after tree neo-adjuvant chemotherapy with modified 5-fluorouracil and cisaliplatin. A chest CT will be done in 3 months and an endoscopic control in 12 months. The second patient had benefited also from a reaction with end to end anastomosis followed by radiotherapy. After 3 years no tumor recurrence has occurred. **Conclusion:** Careful clinical evaluation, tomography and endoscopic examination are essential for the confirmation and staging of primary tracheal tumors. Surgery remains the best treatment to achieve a long-term survival.

EP1.15-17 GIANT THYMOLIPOMA IN A YOUNG WOMAN: A CASE REPORT

L. Fernandez-Trujillo[1,2], E. Morales[1,2], J. Lores[2], M. Aguirre[1,2], L. Sua[1,2], M. Velasquez[2]

[1]*Universidad Icesi, Cali/Colombia,* [2]*Fundacion Valle del Lili Hospital Universitario, Cali/Colombia*

Background: Thymolipoma is a benign mediastinal tumor composed by adipose tissue and thymic tissue. It is a rare mediastinal tumor, presenting predominantly between 20-40 years, without predilection for a specific gender. Its clinical presentation is variable, from asymptomatic cases to thoracic pain and recurrent respiratory infections. We describe the case of a young female, asymptomatic, with an incidental finding of a mediastinal mass posteriorly diagnosed*as a* thymolipoma. **Method:** Review of the Clinic History. **Result:** A 21-year-old female, previously healthy, presents with a recent history of community acquired pneumonia with radiological alterations in x-rays. She denies respiratory or systemic symptoms; physical exam she has decreased breaths sounds in the bases. Chest CT-scan: a large mass in the anterior mediastinum, extending to the left hemi-thorax, with adipose tissue, surrounding the cardiomediastinum without infiltrating it. Surgical excision is performed describing a large (39x22x8cm) lobulated mass weighing 3378grs with a fatty appearance, encapsulated and with scarce hemorrhagic areas, collapsing the left lung. Histopathology: a mesenchymal lesion composed of mature adipose and thymic tissue, with Hassall´s corpuscles and immunohistochemistry compatible with an encapsulated thymolipoma. **Conclusion:** Thymolipomas are identified typically in the management of other medical conditions. They are associated with chromosomal alterations such as rearrangement of the cytogenetic bands, loss of chromosomal material or supra-numeric chromosomes. Four categories have been proposed for its classification: lipoma with thymic tissue combined adipose and thymic neoplasm, adipose tissue replacement of a thymoma and replacement of a hyperplasic thymus; being the first type the one we found on our patient. Surgical excision is curative, without complications and there are no descriptions of malignant transformation. A few case reports on the literature have associated it with myasthenia gravis, particularly in elderly patients with small masses. Within the differential diagnosis the lipoma, the liposarcoma and the thymic hyperplasia have to be taken into account.

A. Chest radiograph showing bilateral basal opacity with displacement of mediastinal structures to the left. B. H & E staining reveals mature thymic and adipose tissue. C. ST-Scan with anterior mediastinum-dependent lesion extending to the lug bases and occupying them with fat content with soft tissue density. D. Appearance of the thymolipoma at the time of the surgical approach

Keywords: Thymolipoma, Thoracic surgery

EP1.15-18 AN 18-YEAR SINGLE-CENTER EXPERIENCE ON 76 GIANT MEDIASTINAL TUMOR RESECTIONS

X. Shi, X. Dong, X. Liu, D. Lu, S. Feng, K. Cai

Nanfang Hospital, Guangzhou/China

Background: Giant mediastinal tumors are often case reported in sparse and can be difficult for surgical removal. The purpose of this study was to make a comprehensive review of the relevant clinical data in our center, aiming to upgrade our current understanding of the disease. **Method:** A retrospective review of medical record was conducted at our single institution from 2001 to 2019. The preoperative, postoperative characteristics and survival data were retrieved. The patients under 16 years old were excluded. The descriptive statistical analysis and Kaplan-Meier analysis were R-3.5.0. **Result:** A total of 76 patients with mediastinal tumors over 10cm underwent surgery in this period were summarised: the median age is 44; the maximum tumor diameter ranges from 10cm to 35cm; the surgical approaches include median sternotomy, lateral thoracotomy, and with or completed by minimally invasive procedure; the blood loss in surgery ranges from 100ml to 3000ml; average postoperative the hospitalization is 30 days. The average overall survival is 39 months. **Conclusion:** With careful preoperative evaluation, our results indicate that surgical management of giant mediastinal tumor is safe and recommended. Patients with a benign or less aggressive malignant tumor who received surgery have a favorable outcome in terms of long-term survival.

Keywords: Giant mediastinal tumors, Thoracic surgery, surgical outcome

EP1.15-19 PRIMARY ENDOBRONCHIAL HYALINISING CLEAR CELL CARCINOMA PRESENTING IN ASSOCIATION WITH ACTIVE PULMONARY TUBERCULOSIS

A. Nambirajan[1], P. Sharma[2], M. Sharma[1], S. Kumar[2], D. Jain[2]

[1]*All India Institute of Medical Sciences, NEW DELHI/India,* [2]*All India Institute of Medical Sciences, New Delhi/India*

Background: Hyalinising clear cell carcinoma (HCCC) is a rare tumor of putative salivary gland origin that most commonly presents as an oral submucosal lesion in middle aged to elderly adults. With a characteristic histomorphology of infiltrating cords and nests of clear tumor cells set in a hyalinised stroma, these tumors frequently harbour *EWSR1:ATF1* fusions, the latter serving as a useful diagnostic marker in differentiation from other clear cell-rich tumors. Only four cases with primary pulmonary origin have been previously reported, all of which were incidentally detected small (<3 cm) intrabronchial masses in non-smoking middle aged men. We report the fifth case in a 44-year-old non-smoker who presented with hemoptysis and was found to harbour a 3.5 cm intra-bronchial HCCC in association with active pulmonary and mediastinal tuberculosis. **Method:** A 44-year-old male, non-smoker, presented with 2 episodes of hemoptysis. On imaging, a heterogeneously enhancing FDG-lobulated soft tissue mass was noted within the left lower lobe bronchus with lobar collapse. FDG avid nodular lesions were also seen in the left lower lobe parenchyma with enlarged aortopulmonary window and bilateral hilar lymphnodes. No pleural effusion was seen. There was no evidence of any metastatic lesions. He underwent an endobronchial biopsy from the left main bronchus followed by left lower lobectomy and mediastinal lymphadenectomy. Formalin fixed paraffin embedded tumor sections were subject to special stains for detection of acid fast bacilli and fungi, immunohistochemistry for p40, TTF-1, chromogranin, synaptophysin, epithelial membrane antigen, smooth muscle actin, S100 and smooth muscle myosin heavy chain, and fluorescence-in-situ hybridisation for 22q12 locus using the Vysis *EWSR1* dual color, break apart rearrangement probe. **Result:** Microscopic sections from the endobronchial biopsy revelaled a subepithelial tumor arranged in nests, cords and trabeculae within a densely hyalinised stroma. Tumor cells were monomorphic with clear to eosinophilic cytoplasm and occasional mitoses. Left lower lobectomy specimen showed a grossly circumscribed solid tumor in the wall of the left main bronchus abutting the cartilage and demarcated from adjacent lung parenchyma by a thin fibrous capsule. Tumor cells were immunopositive for p40, epithelial membrane antigen, while were negative for TTF-1, and myoepithelial markers. FISH revealed presence of EWSR1-re-arrangement in tumor cells, confirming the diagnosis of HCCC. Numerous mililary parenchymal and pleural nodules with necrotic caseous material containing acid fast bacilli were also seen, consistent with tuberculosis. Further work-up did not reveal presence of tumor elsewhere ascertaining a primary lung origin. Patient was started on anti-tubercular therapy and adjuvant radiotherapy/chemotherapy was not given. Patient is currently on follow-up **Conclusion:** From the limited numbers reported, primary pulmonary HCCCs appear to be indolent slow growing neoplasms with an excellent outcome after surgical excision. The differential diagnoses include the commoner squamous cell carcinomas with clear cell change, clear cell adenocarcinomas, mucoepidermoid carcinomas, metastatic clear cell renal cell carcinoma, and myoepithelial neoplasms. Knowledge of its typical histomorphology aided by prudent immunohistochemistry and demonstration of *EWSR1* gene rearrangement or more specifically, EWSR1:ATF1 fusion transcripts should lead one towards the correct diagnosis.

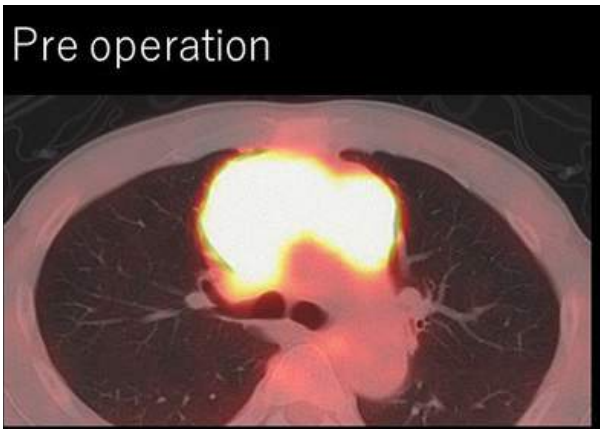
Keywords: hyalinising clear cell carcinoma, bronchus, Tuberculosis

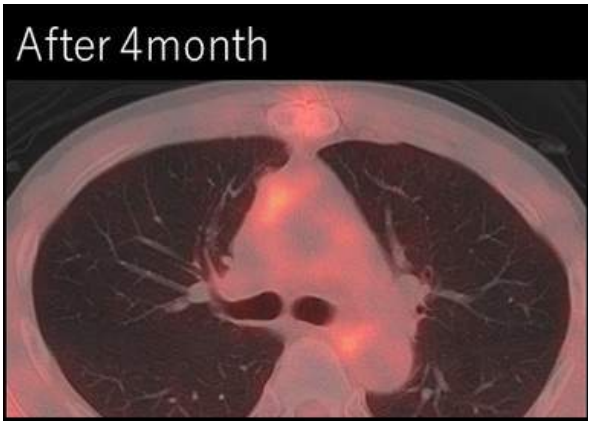
EP1.15-20 GOOD CONTROL BY RE-ADMINISTRATION OF CARBOPLATIN AND PACLITAXEL AGAINST UNRESECTABLE THYMIC CARCINOMA

A. Uchibori, D. Kato, N. Takeda, T. Takeda

Japanese Red Cross Kyoto Daini Hospital, Kyoto/Japan

Background: Many chemotherapy regimens have been administered for unresectable and recurrent thymic carcinoma. However, hightly effective standard regimens have not yet been developed. Although carboplatin-based chemotherapy is considered one of the effective options for thymic carcinoma, carboplatin can be used to treat thymic carcinoma up to only 4–6 cycles following guidelines. In addition, there is no scientific evidence for the usefulness of chemotherapy when thymic carcinoma relapses. **Method:** A 48-year-old man who had an abnormal shadow on a chest radiograph obtained during a medical checkup was referred to our hospital. Chest computed tomography (CT) showed a mass measuring 9.3 cm in the anterior mediastinum. Positron emission tomography (PET)-CT showed significant abnormal uptake with a standardized uptake value of 24.5, and there was no evidence of metastasis. We performed median sternotomy, but found pleural dissemination in the right thoracic cavity. We then only obtained a biopsy. Pathologically he was diagnosed with thymic carcinoma. We administered carboplatin and paclitaxel for up to 6 cycles, combined with radiotherapy (60 Gy/30 fr). Six months later, abnormal uptake on PET-CT almost disappeared. However, one year after the chemoradiotherapy, PET-CT showed recurrence of thymic carcinoma. Therefore, we decided to administer the same regimen again for up to 13 cycles. **Result:**





After re-administration, PET-CT showed markedly decreased accumulation and regression of thymic carcinoma. No severe adverse effects were observed. We have subsequently continued monotherapy containing paclitaxel, and until currently there is no evidence of relapse 23 months after surgery. **Conclusion:** Carboplatin has no limitations on its cumulative dose according to its drug package insert, unlike in the case of anthracycline, and the total dose is only limited on the basis of increased side effects regardless of its antineoplasmatic effect. We herein report a case of re-administering carboplatin against unresectable thymic carcinoma beyond the dose suggested by guidelines and achieving good progress.

Keywords: Thymic carcinoma, carboplatin and paclitaxel, Re-administration

EP1.15-21 THYMIC EPITHELIAL TUMORS: REVIEW OF CLINICAL AND PATHOLOGICAL FINDINGS AND PROGNOSTIC FACTORS FOR THE SURVIVAL

A. Moumen, S. Boubia, N. Idelhaj, A. Fatene, M. Ridai

University Hospital Ibn Rochd, Casablanca/Morocco

Background: Considered as a very rare malignances (0,15 cases per 100.000), thymic epithelial tumors are also the most commun tumor of the anterior mediastinum. Their treatment is based on multidisciplinary management. The basis of the treatment is a complete surgical and carcinological resection. In locally advanced tumors, neo-adjuvant chemotherapy can be performed. In the case of invasive tumors or incomplete resection, adjuvant radiotherapy is usually recommended. **Method:** We conducted a monocentric, descriptive and retrospective study based on the medical record of 32 patients who underwent surgery for a thymic epithelial tumors in the department of thoracic surgery in the university hospital Ibn Rochd, Casablanca, Morocco. The aim of this study is to review the clinical and pathological findings and also to determine which factors independently predict survival after surgical resection. **Result:** The average age was 48 years and the sex ratio was 0. 88. Of the 32 cases, 32,4% had symptoms consistent with myasthenia gravis. Surgical resection was performed either by sternotomy, thoracotomy or VATS. It was complete in 87,5% of cases. 3 patients (9,4%) received neoadjuvant chemotherapy to reduce tumor size before the surgery. Post-operative radiotherapy was indicated in 31. 2% of patients. We have experienced only one death due to the disease in our series and 2 patients were lost to the follow-up. After an univariate analysis, prognostic factors were: the histological type, the Masaoka-Koga stage and the extent of surgical resection. No multivariate analysis could be done due to small numbers of patients. **Conclusion:** Thymic epithelial tumors present specific problems from anatomical pathology to therapeutic strategy. Their optimal care is still poorly defined because of their rarity and of the resulting difficulty to conceive large clinical trials. Meanwhile, ITMIG, UICC and AJCC are trying to develop a consensus on easier and more universal classification, based on the TNM, to help improve the management.

Keywords: thymic epithelial tumors, prognostic factors, surgery

EP1.15-22 PRIMARY EPITHELIAL - MYOEPITHELIAL CARCINOMA OF THE LUNG WITH UNEXPECTED AGGRESSIVE ONSET

S. Ricciardi[1], G. Alì[2], E. Marrama[1], A. Nesti[1], P. Dini[2], V. Aprile[2], G. Fontanini[1], M. Lucchi[1]

[1]*University of Pisa, Pisa/Italy,* [2]*Azienda Ospedaliero-Universitaria Pisana, Pisa/Italy*

Background: Epithelial-myoepithelial carcinoma (EMC) is the rarest sub-type of primary salivary gland type neoplasms of the lung. It usually arises from the salivary glands in the trachea or main bronchi and it is generally classified as a low-grade tumour, but because of its rarity and the unknown malignant potential, the treatment of choice has not been established. **Method:** A 50-year old Hispanic woman, with no history of previous malignancies or comorbidities, arrived at our institution with cough and dyspnoea. A chest CT showed a lesion of left upper lobe (LUL) bronchus, associated to complete atelectasis of left lung, pleural effusion and two inhomogeneous pleural masses just over the diaphragm. PET/CT revealed increased FDG uptake in LUL and in pleural lesions. Fiberbronchoscopy showed a mass originating from left upper bronchus that occluded left main bronchus. The biopsy of the neoplasm revealed pulmonary EMC. The cytological examination of pleural effusion was negative for neoplastic cells. After cardio-respiratory complete assessment and tumour board evaluation, the patient underwent left pneumonectomy, systematic lymphadenectomy and removal

of two solitary lesions respectively located on parietal pleural and on diaphragm en-block with portion of muscle (repaired with non-absorbable running suture) by thoracotomy

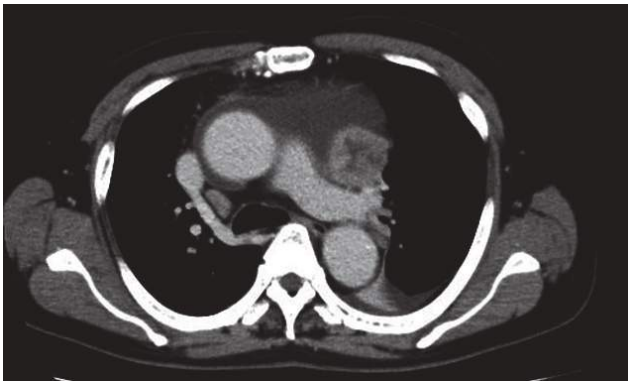
Result: The postoperative course was uneventful (hospitalization: 10 days), however two weeks after discharge the patients was readmitted with pleural effusion and fever. The patient underwent a left thoracentesis (amicrobic, no malignant cells) and a fiberbronchoscopy (regular bronchial suture). After 7 days the patient was discharged. Histopathology confirmed R0 resection of EMC (7x5.5x4 cm), and two solitary metastases on parietal pleura and diaphragm. Ki 67 was <30%. Patient underwent adjuvant chemotherapy, was alive and free of disease 32 months after surgery. **Conclusion:** Primary EMC of the lung is an extremely rare neoplasm with an unpredictable biological behaviour. The surgical resection represents the gold standard if a complete resection can be reached

EP1.15-23 CARDIAC TAMPONADE CAUSED BY A TYPE A THYMOMA: A CASE REPORT

T. Sakai[1], Y. Yamauchi[1], F. Yokote[1], Y. Saito[1], H. Uehara[1], K. Saito[2], Y. Sakao[1], M. Kawamura[1]

[1]*Teikyo University School of Medicine, Itabashi/Tokyo/Japan,* [2]*Teikyo University School of Medicine, tokyo/Japan*

Background: Thymomas, the commonest neoplasm of the anterior mediastinum, are characteristically asymptomatic for prolonged periods. Most patients with disseminated disease have significant signs and symptoms such as chest pain or discomfort, dyspnea, and superior vena cava syndrome. Hemorrhagic pericardial tamponade is an uncommon initial manifestation and it is particularly rare for a thymoma to present with pericardial tamponade. We here present a 73 year-old man who was admitted to our institution with fever and shortness of breath and diagnosed with hemorrhagic pericardial tamponade resulting from a Type A thymoma. **Method:** The patient presented to our emergency department in a stable condition and reported no previous trauma or muscular weakness. Chest computed tomography (CT) showed a cardiac effusion, an anterio-superior mediastinal 40×39×38 mm mass and enlarged mediastinal lymph nodes (image)



After a hemorrhagic pericardial effusion had been drained, PET-CT performed to further investigate the mediastinal mass showed increased uptake in the mediastinum and right gluteus maximus

muscle. Examination of a needle biopsy from the right gluteus maximus muscle mass revealed schwannoma. We therefore suspected the mediastinal mass was a metastatic schwannoma and performed VATS thymectomy combined with partial pericardiectomy. **Result:** Histopathological evaluation of the operative specimen revealed a Type A thymoma that was T3 (cardiac) M1aN0 pStage IVa and Masaoka-Koga stage III. The tumor had invaded the cardiac structures. The patient was discharged on the eighth postoperative day. Radiation therapy (50Gy/25Fr) was started three months later. A chest CT taken 9 months postoperatively did not reveal any metastasis. **Conclusion:** We here present a remarkable case of Type A thymoma extending into the pericardium and causing cardiac tamponade that was successfully resected after evacuating a hemorrhagic pericardial effusion.

Keywords: Type A thymoma, Pericardial tamponade

EP1.15-24 VIDEO-ASSISTED THORACOSCOPY APPROACH FOR RADICAL THYMOMA RESECTION

K. Kurowski[1], J.M. Corcoles Padilla[2], J. Matuszek[3]

[1]*Thoracic Surgery Dpt. Hospital Universitario del Vinalopo Elche, Spain, Torrevieja, Alicante/Spain,* [2]*Hospital Universitario Vinalopo Elche, Elche (Alicante)/Spain,* [3]*Hospital Universitario de Torrevieja, ALACANT/Spain*

Background: Thymoma is the most common neoplasm of the anterior mediastinum, accounting for 20-25% of all mediastinal tumors and 50% of anterior mediastinal masses. the mean age of patients is 52 years. No sexual predilection. The main treatment is complete surgical resection. Minimally invasive thymectomy (MIT) for thymic tumors remains good opcion in both early and advanced stages, minimizing surgical trauma, improving post-operative course and recovery and pain redusing. **Method:** The aim of this study was to review our experience with VATS surgery for thymoma radical and extended resection. We reviewed data from all MIT cases from December 2009 to February 2019. Patients data was collected regarding demography, perioperative management and clinical outcomes. **Result:** A total of 16 VATS thymectomies were performed in the last 10 years, from December 2009 to February 2019. The median age was 52 years (range: 27 – 83 years) with fimale to male ratio of 1/,1,3.The main pathologic diagnosis was Thymoma and Thymic carcinoma (13%) with 5 % associated with myasthenia gravis (MG). The mean tumor size was 4,09 cm (range: 3 to 11 cm). Figure 1.CT- scan image showing a 11 cm giant anterior mediastinal Thymoma, successfully resected by 2 portal VATS access of the left hemithorax.

Mean blood loss and operative time were significantly lower in the video-assisted thoracoscopic surgery versus open surgery.There was no 30-day mortality. Reoperation was not required. Lenght of hospital stay 3,5 days (range 2 -9 days). Mean follow up was 20 months, with no tumor recurrence. **Conclusion:** Unilateral and bilateral VATS approaches have demonstrated good long-term oncologic and neurologic results with low complication rates. Reduced blood loss, operative time and earlier hospital discharge.

Keywords: mediastinum, minimally invasive surgery, THYMOMA

EP1.15-25 A RARE CASE OF METASTATIC LEIOMYOMA OF THE LUNG

F. Luiz, A.B. Abrahão, E. Silva, C. Bognar, M. Monteiro, R. Moreira, T. Padua

Américas Oncologia, São Paulo/Brazil

Background: Leiomyoma is the most common benign uterine tumor. Atypically, it can show with metastatic disease. Lungs are the most frequent metastatic site. Although the benign, metastatic leiomyoma (MLM) has an indolent growth pattern and it may induce pulmonary symptoms and decrease the quality of life. **Method:** We present a case of a 63-year-old woman, former smoker with a past medical history of hysterectomy and bilateral salpingo-oophorectomy due to leiomyoma in 1994. In 2015, the patient showed with a dry cough, chest pain and no fever. Chest X-ray revealed multiple non-specific bilateral pulmonary nodules. Chest and total abdominal CT scans were performed for further evaluation, which confirmed multiple well-circumscribed bilateral pulmonary nodules measuring up to 26mm and 31mm in the right and left lung respectively. No other suspected neoplastic lesions were found. Afterward, she underwent a thoracoscopic resection and pathology determined the neoplastic proliferation of smooth cells favoring the diagnosis of MLM. Tumor markers, including CEA, CA 19.9, CA 125, CA 15.3 and AFP were regular. Patient's symptoms have improved, and she has started a clinical follow-up alternating chest X-ray with chest CT scan every six months. Four years later, lung nodules have increased, measuring up to 37mm (Figure 1). She underwent a lung CT scan-guided biopsy and final pathology showed mesenchymal neoplasia of smooth muscle cells, with a proliferation of spindle cells, with no atypia, absence of necrosis and mitoses. Positive immunohistochemical staining for desmin and smooth muscle actin positive with negative staining for CD34, S100 protein and DOG 1 (Figure 2). **Result:** She remains asymptomatic, and the medical oncology team decided to maintain clinical follow-up with a chest CT scan. Despite the increase of the lesion, the patient was asymptomatic and maintained a follow-up in our service. **Conclusion:** Although MLM is a rare condition, it should be considered in the differential diagnosis in women with a past medical history of uterine leiomyoma. Accurate histopathological and immunochemistry analysis are necessary for the final diagnosis. Due to the slow growth of pattern, most of the patients can be followed with no active specific treatment. There are few similar cases described in the literature and the is no standard treatment in this scenario. Further studies are warranted to evaluate the best treatment option for these patients.

Keywords: spindle cells, immunochemistry analysis, metastatic leiomyoma (MLM)

EP1.15-26 CARDIO MEDIASTINAL TUMORS - DIAGNOSIS AND TREATMENT IN TWO OF OUR CASES

F. Gradica[1], L. Lisha[1], D. Argjiri[1], A. Cani[1], F. Kokici[1], E. Prifti[2], A. Pere[2], F. Gradica[3], D. Lala[4], D. Xhemalaj[1], G. Quadir[5]

[1]*University Hospital "Shefqet Ndroqi", Tirane/Albania,* [2]*University Hospital Center "Mother Theresa", Tirane/Albania,* [3]*Public Pharmacy Service, Tirane/Albania,* [4]*Stomatology, Tirane/Albania,* [5]*National Contra Cancer Center Beijing China, Ch/China*

Background: Malignant cardiac tumors are very rare. Although they are clinically diagnosed and diagnoses very quickly ,but in some cases it is very difficult to diagnose or are diagnosed in the late stages. Objective: To analyze our rarly two cases for diagnosis and treatment in delayed diagnoses for cardiac primary tumor invadation in mediastinum and pericardium tumor wih myocardial and mediastinal invasion in the other case. The diagnosis is based on the clinical history, echocardiography in two cases, and, sometimes, computerized tomography and magnetic resonance imaging, FNAB and mediastinotomy . **Method:** In two cases the diagnosis is based on the clinical history, echocardiography in two cases, and, computerized tomography and magnetic resonance imaging, FNAB and mediastinotomy . **Result:** Patient A. 66 years old ,male patient the diagnosis was established with trans-thoracic biopsies of myosarcoma-derived mass, treated by oncologist and cardiologists.While patient B is a 45 year old female with a pericardiac tumor,with huge pericardial effusion and effusion in the sinister pleural cavity. Liquid cytology with malignant cells. Was performed left mediastinotomy, pericardiotomy ,biopsy of intrapericardial mass, pericardial window and drainage pleural sinister. Biopsy results in pericardial sarcomatous mesothelioma with myocardial and mediastinal invasion. Macroscopically hemorrhagic effusion in pericardial and left pleural cavities. Very large tumor and

quite intrapericardial hemorrhagic disease. **Conclusion:** Malignant cardiac tumors are very rare and early stage diagnosis and adequate treatment is difficult.

Keywords: Malignant cardiac tumor ,pericardial effusion ,pleural effusion.

EP1.15-27 ONE CASE OF MUCINOUS CARCINOMA OF THYMUS CAUSED BONE MARROW METASTASIS

T. Omori[1], H. Takahashi[1], T. Tachibana[1], O. Uchida[1], H. Hirano[1], Y. Ishikawa[1], N. Ikeda[2]

[1]*Tokyo Medical University Hachioji Medical Center, hachioji-si/Japan,* [2]*Tokyo Medical University Hospital, shinjyuku-ku/Japan*

Background: Primary mucinous adenocarcinoma of the thymus is extremely rare neoplasm. Most thymic carcinomas metastasize to the mediastinal lymph node, pleura, pericardium and diaphragm. And distant metastasis to the extrathoracic organs such as liver, bone or kidney is considered rare. In this case, mucinous carcinoma of the thymus caused bone marrow metastasis and multiple bone metastasis is very rare. **Method:** Case report **Result:** A 51-year-old man. He was pointed out fecal occult blood test positive by medical checkup, and he was diagnosed the sigmoid colon cancer. After undergoing surgery for colon cancer, he was admitted to our hospital for treatment of mediastinal tumor. An anterior mediastinal tumor was pointed out by preoperative examinations. Computed tomography (CT) showed a tumor with maximum diameter of 55mm at the anterior mediastinam, including calcification and contrast effect and swollen lymph node. Thymoma or thymic cancer were suspected, so we surgical resection of mediastinal tumor and lymph node dissection were performed. Result of frozen section diagnosis was adenocarcinoma with mucinous component. Pathological findings showed that most of the tumor was a mucin component, and atypical cells with a small duct formed inside the mucin, signet ring cells were found. Immunohistochemistry, the neoplastic cells were positive for CK7 and CK20. Based on these features, diagnosis of this tumor was mucinous adenocarcinoma of thymus. Pathological stage was T2N1M0 stageIII. Two months after operation, radiation was performed at anterior mediastinum and one week after radiation compression fracture of lumbar vertebra was present. And five months after operation, pancytopenia was present. Examination of bone marrow aspiration biopsy was performed, and the cancer cells were detected. Bone marrow metastasis originated from thymic cancer was diagnosed as a result of comparing pathological features of the colon cancer and thymic cancer. Primary thymic adenocarcinoma is very rare and about 2.7% of all thymic carcinoma. Furthermore, only 16 cases have been reported and there have been no reported cases of thymic mucinous carcinoma caused bone marrow metastasis. **Conclusion:** In this paper, we report a very rare and valuable case with consideration of some literature review.

Keywords: Thymic carcinoma, mucinous adenocarcnioma, bone marrow metastasis

EP1.15-28 SURVIVAL OF THYMOMA IS EXTENSIVE IN LATIN-AMERICAN PATIENTS: RESULTS FROM OVER 10 YEARS OF EXPERIENCE (CLICAP-LATIMUS)

Background: Thymomas are a group of rare neoplasm of the anterior mediastinum. Due to their low incidence, large cooperative studies are required to evaluate outcomes. The objective of this study is to present the results and experience in treatment of this pathology in Latin-America. **Method:** A retrospective multicenter cohort study was conducted by The Latin-American Consortium for the Investigation of Lung Cancer (CLICaP). Patients with histologically proven thymomas between 1997 and 2018 were included in the analysis. Variables including clinical, pathological and therapeutic outcomes were registered in a centralized manner. **Result:** A total of 105 patients were included. Median age at diagnosis was 54 years old (20-84), and with 60% (n = 38) of the included patients were female. Only 11% (n=7) of the patients had an ECOG performance score >1. Twenty-four patients (22.9%, 95%CI 14.8-30.9) presented with pulmonary or distant metastatic involvement with a median of 2 metastatic sites. Furthermore, 21.9 % of patients (n=23, 95%CI 13.9-29.8%) concurrently presented myasthenia gravis. Surgery was performed in 55 patients (52.3%, 95%CI 42.8 – 61.9%), comprising of 15 tumorectomies, 37 thymectomies and 5 biopsies achieving an R0 resection rate of 78% (95%CI 67.3-89.1%). Adjuvant treatment in the form of either chemotherapy, radiotherapy or both was offered to 3(5%), 7(12.7%) and 5(9%) patients, respectively. Disease progression was documented in 10 cases (9%, 95%CI3.9-15.1%) of which 6 (60%) were locoregional, 1 (10%) distant progression and 3 (30%) both locoregional and distant. Median overall survival (OS) was estimated at around 139.5 months (95%CI 86.1-NA). Cox regression indicated that OS was significantly improved by resection (139.5 vs 25.7 months, HR 4.17 [95%CI 12.6-17.8 months]). **Conclusion:** Survival in patients with thymomas continues to be very favorable, especially in patients who receive adequate local control. The benefit of adjuvant treatment in this setting remains unclear.

Dexeus University Hospital, barcelona/Spain,* [17]*Hospital Vall d´Hebron, Barcelona/Spain*

Background: Thymic carcinoma is a rare tumor that represents a clinical challenge, especially in resource limited settings. The objective of the present study was to characterize patients who presented this disease in Latin-America. **Method:** From 2014 until 2018, a multinational Latin-American cooperative retrospective cohort study was performed. Patients with histologically confirmed thymic carcinoma were included. Clinical, pathological and treatment variables were collected across 7 participating nations. **Result:** A total of 31 patients were included. Median age at diagnosis was 58 years old (34-69), 48% (n=15) of individuals were women with all but 2 patients (6.5%) achieving an ECOG performance score <2. All patients debuted with Stage IV disease; 24 patients (66%, [95%CI 62-92%]) as stage IVa and 7 as stage IVb (33%, [95%CI 7-37%]) with a median LDH level of 396.5 U/L (153-1529 U/L) and a median of 2 metastatic sites. 13 (41.9%, [95%CI 25-59%]) patients received preoperatory treatment consisting of chemotherapy (n=8, 42%) and chemoradiotherapy (n=5, 16%). Among these patients only 4 (12.9%) were subjected to surgery, two of which underwent a tumorectomy

and 2 a thymectomy. 28 (90%, [95%CI 79.9-100%]) received palliative chemotherapy either with sunitinib (n=7, 25%) or cytotoxic agents. Median overall survival (OS) was reached at 20.2 months (95%CI 19-NA months). Patients who received preoperative treatment had a significantly prolonged OS (17.6 vs 26 months, HR 2.93 [95%CI 1.04-8.27 months], p = 0.03). **Conclusion:** Thymic carcinoma constitutes an aggressive disease that is often diagnosed in advanced stages. These results suggest that multimodal treatment can be beneficial even in locally advanced cases. Larger clinical trial validating these conclusions are warranted.

EP1.15-30 RESECTION ANASTOMOSIS OF MALIGNANT TUMORS OF THE TRACHEA

L. Belliraj, M. Lakranbi, Y. Ouadnouni, M. Smahi

University Hospital Hassan II, Fes/Morocco

Background: Primary malignant tracheal tumors is a rare entity, making only 0.2% of all respiratory tract tumors. Due to their insidious development, their clinical symptom is often late, after a significant reduction of tracheal diameter, which delays the diagnosis that is often misdiagnosed for late asthma. The dominant histological type is adenoid cystic tumor. Wide tracheal resection allowing the release of airways, is the treatment of reference. **Method:** This work is a retrospective study of a series of 7 patients admitted for tracheal stenosis at the department of thoracic surgery of the University Hospital Hassan II of Fes, for a total of 7 years from December 2010 to December 2017. **Result:** There were 6 men and 1 woman, with a mean age of 43 years, 3 of whom were smokers. Dyspnea was the main symtom. All patients received thoracic CT. 6 cases underwent bronchial fibroscopy, the most frequent appearance of which was a tumoral process in 4 patients, most often in the middle part of the trachea in 3 patients, obstructing tracheal diameter almost all in 6 patients. Treatment was surgical with intubation across the operative field in all patients, including 3 resection anastomosis and 4 plasty (V-plasty lateral resection, Kergin-type plasty, Mattey-type tracheobronchial anastomosis, and a V-resection enlarged to carena). The most common histological type was adenoid cystic carcinoma in 2 patients, squamous cell carcinoma in 2 patients, adenocarcinoma in 1 patient, and atypical carcinoid-type neuroendocrine tumor in 1 patient. 2 patients received adjuvant treatment. The follow-up was simple in 6 of our patients who all had postoperative fibroscopy within 9 days on average (8 to 16 days), two deaths, one post-operative death unrelated to tracheal surgery on D4, and a second follow-up to complications of post-radiation tracheal stenosis. The average follow up is 32 months. There was one death at 8 months following post-radiation tracheal stenosis and distant relapse by cervical lymph node metastasis in one patient at 5 years after surgery. He benefited from cervical lymph node dissection + Radiotherapy. He is still alive with controlled disease. **Conclusion:** Despite advances in tracheal surgery, primary malignant tracheal tumors still have an unfavorable prognosis. Endoscopic or radiation disobstruction is a therapeutic alternative for nonoperable tumors.

EP1.16 TREATMENT IN THE REAL WORLD - SUPPORT, SURVIVORSHIP, SYSTEMS RESEARCH

EP1.16-01 A SPANISH INITIATIVE TO KNOW THE UNMET NEEDS OF WOMEN WITH LUNG CANCER: "CIRCULOS PROGRAM"

R. Garcia Campelo[1], F. Vazquez Rivera[2], X.L. Firvida[3], M. Lazaro[4], S. Vazquez[5], D. Isla[6], M. Majem[7], J. De Castro Carpeno[8], N. Viñolas[9]

[1]*Hospital Universitario A Coruña, A Coruña/Spain,* [2]*Complejo Hospitalario Universitario De Santiago de Compostela, Santiago de Compostela/Spain,* [3]*Complexo Hospitalario Universitario De Ourense, Ourense/Spain,* [4]*Complexo Hospitalario Universitario de Vigo, Pontevedra/Spain,* [5]*Lucus Augusti University Hospital, Lugo/Spain,* [6]*Hospital Clinico Universitario Lozano Blesa, Zaragoza/Spain,* [7]*Hospital de la Santa Creu i Sant Pau, Barcelona/Spain,* [8]*Hospital Universitario La Paz, Madrid/Spain,* [9]*Clinic Hospital, Barcelona/Spain*

Background: The personal and family impact of an oncological disease can only be adequately understood and managed from a biopsychosocial perspective. Lung cancer experience has a profound impact on the well-being of both patient and family caregiver and is largely influenced by communication within the family environment. Lung cancer impact can be especially significant when women are affected. **Method:** The objective of this study was to develop an informative program for women with lung cancer, implementing the development of strategies in order to get a deepening knowledge of their perceived needs. Additionally, we aimed to define and design new useful resources that may help other women with lung cancer. A qualitative research allowed to collect data on the experiences in the circle of women and their families, and the identification of the needs and the coping resources used of the participants. The collection of these data was what led to the development of the tools used to develop the support strategies. **Result:** A total of 10 women with lung cancer from Galicia (Spain) participated in 7 sessions. At the personal and psychological level in the women circle, needs were related to improve medical information they get from their physicians, share information and experiences with women in the same situation, more holistic-human care, and the need for more supporting groups. About the social and labor environment, they expressed concern about the social stigma associated with lung cancer, and the culpability for having smoked as well as the concern related to the interruption of working life. The family environment also expressed the need for emotional support and preparation for families and caregivers to be able to support the patient, the need to provide them with strategies to improve the situation, and the need to overcome initial isolation through working groups. Regarding resources, women´s circle was mainly focused on occupying time with new activities, humor and not stigmatizing the disease and the professionals who assist them. **Conclusion:** "Círculos program", even being a pilot program, show the benefits of a more humane approach to the treatment of lung cancer in women, with a better understanding of patients and families needs. More similar programs should be done in order to improve the quality of life of these patients and their transit through this disease.

EP1.16-02 PROACTIVELY IMPROVING THE MANAGEMENT OF IMMUNE-RELATED ADVERSE EVENTS (IRAES) IN A COMMUNITY CANCER PROGRAM

L. Dobrea[1], E. Esposito Nguyen[1], J. Maurice[1], M. Carandang[1], D. Boyd[1], S. Haimowitz[2], L. Gracie-King[3], J. Kim[4]

[1]*St. Joseph Hospital, St. Joseph Health, Orange/United States of America,* [2]*Real CME, New York/United States of America,* [3]*Axis Med Education, Fort Lauderdale/United States of America,* [4]*Q Synthesis LLC, Langhorne/United States of America*

Background: As more patients with lung cancer are being treated with immune checkpoint inhibitor (ICI) therapy in community settings, there is a pressing need to properly identify and manage immune-related adverse events (irAEs). Promptly and correctly identifying and managing irAEs can be challenging since clinicians may lack knowledge about irAEs. Furthermore, patients may not know when to report symptoms. For these reasons, an educational research project supported by a grant from Genentech was developed to assess how cancer clinicians may improve the identification and management of irAEs. **Method:** The cancer care team at St. Joseph Hospital Orange (SJO) reviewed 30 patient charts (9 lung cancer, 21 other types of cancers) in early 2018 and assessed the documentation of different types of irAEs, the grading of symptom severity, and how often irAEs led to a visit to an urgent care, ER, or inpatient hospital visit. 37% of patients developed a suspected irAE; the severity of symptoms was documented in 57% of charts; 27% of patients developed irAEs that required care in an ER or hospital. In July 2018, members of the cancer care team held a workshop to discuss their findings and identify opportunities to improve the identification and management of irAEs. Using Plan-Do-Study-Act (PDSA) cycles for improvement, the team at SJO developed and implemented the following process changes: 1) a patient education video explaining irAEs (made in English and Spanish) that is delivered by infusion nurses when patients start ICI therapy; 2) continued use of immunotherapy wallet cards for patients; 3) improving awareness among infusion nurses about irAEs; 4) updates to survivorship care plans to highlight how delayed irAEs may occur after active cancer treatment is completed. **Result:** The project remains ongoing at the time of abstract submission. The patient education video was approved by the oncology council and launched in Jan 2019. The infusion nurses report that patients who watch the video are highly engaged and asking questions about irAEs. Changes to the survivorship care plans were finalized at the end of 2018 and were focused on patients receiving ICI therapy for curative intent (eg,

adjuvant melanoma and lung cancer). **Conclusion:** Since serious irAEs may occur at any time, a proactive approach is required to improve the identification and management of irAEs and ensure optimal patient outcomes. This project demonstrates how one community cancer center developed feasible interventions based on identified needs.

Keywords: Side Effect managment, Immunotherapy

EP1.16-03 TRIAL OF COST-EFFECTIVENESS ANALYSIS OF LUNG CANCER SURGERY-ANALYSIS IN STAGE IIIA LUNG CANCER

T. Miyoshi

Yuai Memorial Hospital, Koga City/Japan

Background: Currently, lung cancer treatment is being treated according to lung cancer treatment guidelines. Most of the guidelines so far have been prepared after studies using the EBM method have been made about treatment effects and disadvantages. On the other hand, recent clinical research has come to examine the QOL of patients and the cost-effectiveness of treatment in chemotherapy, but there has not been any report on the cost-effectiveness of surgical treatment for cancer. We examined the cost-effectiveness of surgical treatment for lung cancer. **Method:** Based on the results of lung cancer treatment at home and abroad, survival time was extracted for each stage, and from this group, surgery was performed at stage IIIA (+ S group) and not performed (-S group) Group data were used. Expenses used domestic data with reference to treatment costs in the United States. Chemotherapy was based on commonly used medications for non-small cell lung cancer. Decision analysis was used for cost-benefit analysis, and effects were calculated from survival rate and quality-adjusted survival year (QALY) using the incremental cost-effectiveness ratio (ICER) as an index. **Result:** If QALY after 5 years is calculated using the life-or-death only QOL score, the ICER of +S group is approximately 5.64 million yen, and the cost-effectiveness is generally superior. If QALY is obtained from the survival curve, the ICER of +S group after 1 year is 4.97 million yen, and the cost utility analysis is even better. **Conclusion:** In this study, performing surgery on patients with stage IIIA lung cancer was also useful in terms of cost-effectiveness. In the future, it is necessary to analyze the cost-benefit analysis of the QALY and the new treatment cost due to deterioration of QOL at relapse and relapse by long-term simulation using Markov model.

Keywords: surgery, cost-effectiveness analysis, Stage IIIA lung cancer

EP1.16-04 REAL WORLD CLINICAL OUTCOMES FOR METASTATIC NON-SMALL CELL LUNG CANCER (MNSCLC) AT IRST ITALY

M. Altini[1], I. Massa[1], W. Balzi[1], N. Gentili[1], F. Foca[1], V. Danesi[1], S. Manunta[1], F. Ejzykowicz[2], S. Chandwani[3], M. Burgio[1], P. Cravero[1], A. Verlicchi[1], G. Bronte[1], L. Crino[1], A. Delmonte[1]

[1]*Istituto Scientifico Romagnolo per lo Studio e la Cura dei Tumori (IRST)-IRCCS, Meldola/Italy,* [2]*Merck & Co., Inc., New Jersey/United States of America,* [3]*Merck & Co., Kenilworth/United States of America*

Background: This study sought to evaluate the real word clinical outcomes concerning overall survival (OS) for patients in first-line treatment for metastatic non-small cell lung cancer (mNSCLC) prior to the availability of immunotherapies in any line. **Method:** Patients who received systemic anti-cancer treatment for mNSCLC at IRST between Jan2014-Jun2017 with a minimum follow-up of six months were included. The clinical dataset was obtained from data registered in electronic health records maintained during clinical practice. OS was defined as the interval from start of first-line therapy until death or follow-up end, whichever occurred first. Death information was detected from mortality register. OS was estimated using the Kaplan-Meier method stratified by type of first-line treatment. **Result:** Among the 428 first-line patients analyzed, 64.5% were over 65 years old and 62.6% were men (Table 1). A total of 79.0% patients had non-squamous histology whereas 15.0% had squamous histology, with the remaining 6% other histologies. EGFR mutation was detected in 15.7% and ALK translocation in 8.4% of patients. In the first-line the majority (57.0%) of patients received platinum-doublet (mainly platinum+pemetrexed) while single agent chemotherapy was administered in 23.8%, whereas 10.0% received targeted therapy. Conversely overall 9.0% were enrolled in clinical trials, while 0.2% received Immunotherapies. Median OS was 19.9 months (95%CI:9.2-21.7) with targeted therapy, 8.5 months (95%CI:4.8-13.6) for patients enrolled in clinical trials, 6.4 months (95%CI:5.8-7.6) with platinum-doublet and 4.4 months (95%CI:3.7-5.7) with single agent chemotherapy. A total of 34.5% of first-line patients continued to receive second-line treatment.

Table 1. Patient characteristics and real-world overall survival by type of first-line treatment for metastatic NSCLC, Jan 2014 to June 2017, IRST-Italy

Characteristics	Overall N=428	Platinum doublet N=244	Single agent chemo N=102	Targeted therapy N=43	Immuno therapy N=1	Clinical trial N=38
Age >65 years	276 (64.5)	121 (49.6)	99 (97.1)	33 (76.7)	1 (100.0)	22 (57.9)
Men	268 (62.6)	155 (63.5)	75 (73.5)	14 (32.6)	0 (0.0)	24 (63.2)
Current/former smoker	310 (72.4)	188 (77.0)	69 (67.6)	21 (56.8)	1 (100.0)	31 (81.6)
Squamous histology	63 (15.0)	37 (15.6)	19 (18.8)	1 (2.3)	0 (0.0)	6 (15.8)
Stage IV at diagnosis	335 (78.5)	189 (77.8)	75 (73.5)	38 (88.4)	0 (0.0)	33 (86.8)
ECOG PS ≥2	70 (17.3)	30 (12.7)	28 (29.8)	12 (30.8)	0 (0.0)	0 (0.0)
EGFR mutant*	51 (15.7)	2 (1.0)	1 (0.9)	38 (88.4)	0 (0.0)	10 (28.6)
ALK translocated*	21 (8.4)	10 (4.1)	5 (10.9)	3 (8.6)	0 (0.0)	3 (9.7)
Real world overall survival #						
Median (95% CI)	6.4 (5.8-7.5)	6.4 (5.8-7.6)	4.4 (3.7-5.7)	19.9 (9.2-21.7)	-	8.5 (4.8-13.6)
6 months rate (95% CI)	52.1 (47.2-56.7)	53.6 (47.2-59.7)	36.6 (27.1-45.5)	74.4 (58.6-84.9)	-	60.5 (43.3-74.0)

*Done only for 358 patients with not squamous histology
Data cutoff: Dec 2017

Conclusion: In this analysis prior to the introduction of immunotherapies for NSCLC, OS was similar to real world OS in the published literature. The survival was worse in the single agent chemotherapy group while it is superior in platinum doublets group. Overall survival was longest in patients treated with targeted therapy.

EP1.16-05 REAL WORLD OUTCOMES OF ADVANCED NSCLC PATIENTS WITH LIVER METASTASES

J. Law[1], C. Pettengell[2], L. Chen[2], L. Le[1], M. Sung[1], S. Aviv[2], S. Lau[3], A. Sacher[1], D. Merritt[4], P. Demarco[4], N. Leighl[1]

[1]*University Health Network, Toronto/Canada,* [2]*Pentavere, Toronto/Canada,* [3]*Princess Margaret Cancer Centre, Toronto/Canada,* [4]*Roche Canada, Mississauga/Canada*

Background: Patients with advanced lung cancer represent a heterogenous population with varying patterns of metastasis. Those with liver metastases may represent a unique cohort with differential response to therapy, including immunotherapy in NSCLC. Novel Natural Language Processing (NLP) and Artificial Intelligence (AI) technology enables automated extraction of real-world data to examine these populations at greater scale than current manual chart abstraction processes, helping clinicians make more informed treatment decisions. **Method:** Patients diagnosed with stage IIIB/IV lung cancer who received first-line systemic therapy at the Princess Margaret Cancer Centre between 2015 and 2018 were reviewed using the DARWEN™ NLP and AI data abstraction platform developed by Pentavere. Data extracted include tumour histology, patient age, sex, ECOG performance status, smoking status, biomarker status, PD-L1 expression, sites of metastases, treatment details and survival. **Result:** Of 615 patients with accessible electronic pathology records, 540 (87.8%) had NSCLC and 333 (54.1%) received systemic therapy. In those patients treated with first-line therapy (immunotherapy 10.2%, targeted therapy 30.9%, chemotherapy 62.7%), 27.3% (91/333) had liver metastasis at any point from baseline to end of follow up (median follow up 8 months). 280 patients had NSCLC and received systemic therapy and were included in subsequent analysis. Of these, 69 (24.6%) had liver metastases at any point and overall survival was worse in those patients 544 vs 715 days (p=0.006). Liver metastases were more commonly seen in those with more metastatic sites (OR: 1.42, 95% CI: 1.19-1.70, p= < 0.001). By contrast, those with *EGFR* mutant lung cancer were less likely to develop liver metastasis (OR: 0.45, 95% CI: 0.23-0.87, p=0.02). Using Cox regression analyses, after controlling for age, sex, baseline performance status, baseline smoking status, first line treatment, total number of metastatic sites and baseline LDH, presence of liver metastasis remained significantly associated with worse survival (HR: 1.78, 95% CI: 1.14-2.76, p=0.01). Elevated baseline LDH, a known poor prognostic factor, was also associated with worse overall survival (HR: 1.58, 95% CI: 10.6-2.35), p=0.02). No differential effect by type of therapy was seen. **Conclusion:** The presence of liver metastases confers worse prognosis in advanced non-small cell lung cancer patients. This effect was observed irrespective of treatment type and highlights the need for additional treatment options which are efficacious in this patient population. Larger cohort studies may help identify patients with liver metastases that may benefit from specific therapeutic strategies in the future. NLP and AI technologies like DARWEN™ can rapidly generate population-based datasets and provide clinicians with timely access to previously unavailable information on treatment patterns and outcomes which can lead to improved care.

Keywords: Real world evidence, AI, Liver metastasis

EP1.16-06 REAL WORLD DIAGNOSIS AND TREATMENT OUTCOMES IN PATIENTS WITH EGFR-MUTANT METASTATIC LUNG CANCER

T. Li, W. Ma, E. Tian, Q. Li

University of California Davis Comprehensive Cancer Center, Sacramento/ United States of America

Background: We recently showed that lung cancer incidence and mortality rates have steadily decreased in California between 1990 and 2014. Improvements in overall and yearly survivals were most pronounced for Asian and female patients, and for patients with adenocarcinoma after 2004, when molecularly targeted therapy was introduced (Pan et al., ASCO 2018). The objective of this study was to determine the impact of molecular diagnosis and targeted therapy on survival by time interval, gender, race/ethnicity, and smoking status in patients with EGFR-mutant metastatic lung cancer. **Method:** This retrospective study included consecutive cases from patients with locally advanced or metastatic EGFR-mutant NSCLC seen at an academic clinic between 2009 and January 2018 with follow up through February 2019. Allele-specific PCR was used before 2014 (Cohort 1, N=94)) and FoundationOne® was used after 2014 (Cohort 2, N=101). Kaplan-Meier curves were estimated for overall survival and stratified by smoking status, gender, and race/ethnicity. Relative survival rates were calculated for 1 year, 2 years and 5 years. **Result:** A total of 83 and 88 patients with metastatic lung cancer who received ≥1 EGFR TKI were identified in Cohort 1 and 2, respectively. Table below summarizes demographic characteristics, median overall, 1-year, 2-year and 5-year survivals for each cohort. Relative to cohort 1, all cohort 2 subgroups saw improvements in survival. Improvement was most pronounced for never smoker, female, asian and white patients. Survival rates among both cohorts were significantly higher than that of all patients in California during the same periods.

EGFR TKI-Treated Patients	Cohort 1 (N=83)	Cohort 2 (N=88)	HR (95% CI)
Age (mean ± SD) (years)	58.7 ± 11.7	67.2 ± 14.3	
Median Overall Survival (months)	33.5	45.3	0.6 (0.39-0.80)
1-year survival rate (%)	91.5%	93.9%	
2-year survival rate (%)	64.3%	79.5%	
5-year survival rate (%)	16.1%	43.2%	
Never smoker: No. Patient (%)	52 (62.7%)	54 (61.4%)	
Median survival (months)	32.5	60.2	0.4 (0.27-0.71)
Female: No. Patient (%)	51 (61%)	54 (61%)	
Median survival (months)	31.6	78.8	0.4 (0.27-0.71)
Male: No. Patient (%)	32 (39%)	34 (39%)	
Median survival (months)	31.6	78.8	0.8 (0.27-1.39)
White: No. Patient (%)	59 (71.1%)	52 (59.1%)	
Median survival (months)	37.9	45.3	0.55 (0.35-0.87)
Asian: No. Patient (%)	21 (25.3%)	26 (29.5%)	
Median survival (months)	34.4	80.0	0.50 (0.22-1.06)

Conclusion: Advances in the diagnosis and treatment for patients with EGFR-mutant lung cancer have increased patient survival times. Further study is needed to determine the causes of gender and ethnicity differences.

Keywords: Survival, EGFR-mutant lung cancer, treatment outcome

EP1.16-07 NATIONAL, OBSERVATIONAL, MULTICENTRIC STUDY IN STAGE III NON-SMALL CELL LUNG CANCER PATIENTS IN TURKEY: STONE TRIAL

C. Onal[1], A. Demiral[2], B. Atalar[3], D. Yalman[4], S. Gul[5], P. Hurmuz[6], P. Erpolat[7], S. Akyurek[8], T. Berber[9], O. Guler[1], C. Umay[2], F. Sert[4], N. Dagoglu[10], G. Yaprak[5], E. Karahacioglu[8], S. Duru Birgi[11], E. Kaytan Sağlam[12]

Background: In this national, non-interventional study, our aim is to collect stage III non-small cell lung cancer (NSCLC) data derived from medical records in nationwide to capture and consolidate information of treatment patterns, treatment effectiveness and patient outcomes in the real-world setting. This study was carried out with the collaboration of Turkish Society for Radiation Oncology. **Method:** Patients newly diagnosed with primary stage III NSCLC between 01 January 2013 and 31 December 2017 included. A total of 556 patients from 10 hospitals in Turkey were included in this study. Patient characteristics, initial treatment modalities, chemotherapy regimens, overall (OS) and local progression free survival (LPFS), failure patterns and secondary treatments after recurrence for recurrent patients were analyzed. **Result:** Median age was 63 years (range, 56-69 years). 488 patients (%87.8) were male and 68 patients (%12.2) were female. Histopathological type was adenocarcinoma in 197 patients (%35.4), squamous cell carcinoma in 291 patients (%52.3) and others (Large Cell Carcinoma, mixed and unknown) in 68 patients (%12.3). 385 patients (%69.2) received definitive/curative therapy, 23 patients (%4.1) received palliative, 33 patients (%5.9) received adjuvant and 63 patients (%11.3) received neoadjuvant oncological treatment. 54.8% of patients received concomitant chemoradiotherapy, 22.1% of patients received concomitant chemoradiotherapy+ adjuvant chemotherapy, 12.2% of patients received only radiotherapy and, 10.8% of patients received sequential chemotherapy followed by radiotherapy. 75 patients (13.4%) underwent curative resection as primary treatment and, 33 (5.9%) of them received adjuvant chemoradiotherapy and/or radiotherapy. The 2- and 3-year of OS were 57%, and %43, respectively. 2- and 3-year of PFS were %38 and %25, respectively. **Conclusion:** To our best knowledge, this is the first national study representing valuable information about real-life data in stage III NSCLC population in Turkey.

Keywords: national study, Non-Small Cell Lung Cancer, Real world data

EP1.16-08 BEHOBIAMEDIOPULMON: PUTTING FACE AND RUNNING SHOES ON PATIENTS WITH LUNG CANCER

J. Zabaleta[1], B. Gaspar[2], I. Etxeberria[3], M. Cruzado[4], B. Aguinagalde[1], I. López[1], A. Fernandez-Monge[1], J. Izquierdo[1], F. Hernando-Trancho[5]

[1]*Donostia Universitary Hospital, Donostia/Spain,* [2]*AEACAP, Valencia/Spain,* [3]*CD Fortuna, Donostia/Spain,* [4]*Diputación Foral de Gipuzkoa, Donostia/Spain,* [5]*Hospital Clínico San Carlos, Madrid/Spain*

Background: As lung cancer is one of the most lethal in Europe, it has little presence in the media and social networks. To change this dynamic, a campaign to support lung cancer patients using the hashtag #behobiamediopulmon was planned, where the final event was the participation of patients with lung cancer in the most famous half-marathon in Spain: Behobia-San Sebastián. **Method:** Joining forces between the Spanish Association of Lung Cancer Victims (AEACAP), the organization of the Behobia-San Sebastian and the local government of Gipuzkoa; And with the support of the main scientific societies that treat this pathology (SECT: Spanish Society of Thoracic Surgery, SEPAR: Spanish Society of Pneumology and Thoracic Surgery, SEOM: Spanish Society of Medical Oncology and SEOR: Spanish Society of Radiation Theraphy), it was decided to carry out a campaign of visibility of lung cancer patients. **Result:** During 2018 different actions were carried out: solidary running training (300 participants), children´s race (180 children), charity market, online sale of shirts, creation of a specific song (the protagonists of the videoclip were four patients), production of a documentary-film about lung cancer (presented at a round table with the participation of the daughter of Johan Cruyff). Broadcast of the videoclip in the football matches that Real Sociedad and SD Eibar played at home until the day of the race. In the Behobia-San Sebastian, 3 patients operated on for lung cancer at Donostia Universitary Hospital runned accompanied by 300 people (among them stand out soccer players like Xabi Prieto and Xabi Alonso; musicians of La Oreja de Van Gogh, the journalist Juan-Ramon Lucas or Susila Cruyff). Impact achieved: 3 different national newscast spoke about #behobiamediopulmon, 10 times in regional newscast, 18 radio interviews and 14 newspaper interviews. In YouTube 800,000 reproductions of the song “Sólo si lo hacemos juntos”, 1300 reproductions of the documentary-film #datupaso, Instagram profile (@behobiamediopulmon) with 1000 followers, Prize to the charitable cause with the highest collection in the Behobia-San Sebastian 5000€, solidarity training fund 6600€. **Conclusion:** By joining forces it is possible to perform an action that provides visibility to patients with lung cancer. Joining sport and health, we are able to create a very positive message that reaches to the newly diagnosticated patients, inspiring confidence and life expectancy. The race represents the metaphor of their situation, where patients try to reach the goal, with their ups and downs along the way, accompanied by family, friends and health personnel.

EP1.16-09 DELAYS IN CARE OF LUNG CANCER: A MOROCCAN PUBLIC HEALTH PROBLEM

N. Benchakroun[1], S. Ridai[2], Z. Bouchbika[1], H. Jouhadi[1], N. Tawfik[1], S. Sahraoui[1], A. Benider[1]

[1]*CHU Ibn Rochd, casablanca/Morocco,* [2]*CHU Ibn Rochd, Casablanca/Morocco*

Background: For several years, lung cancer, which is responsible for one in five cancer deaths, has been considered the leading cause of cancer death. In Morocco, in 2018, 6488 new cases of lung cancer were reported for both sexes and all ages with 22,9% of all new cases of male cancer (Globocan) It’s a real public health problem The delay between the different therapeutic sequences has a real impact on survival, which makes it’s optimization a real public health issue. The aim of this work was to describe the care pathway for patients treated for lung cancer at the Mohamed VI Center, as well as the different treatment delays in our context. **Method:** To do this, we conducted a monocentric, retrospective study in patients treated for lung cancer between January 2012 and November 2017 at the Mohamed VI Cancer treatment Center. To study this period and obtain significant results, we referred to the statistical rules and retained one month pey year, one year out of two, for a total of six months spread between January 2012 and November 2017 Using the oncology department’s database, we identified all patients with histologically confirmed lung cancer and a usable archived record that was summarized in a farm with pre-established responses coded as numerical variables. The key point of this study was the study of the time between the appearance of the first clinical signs and the initiation of the different therapeutic sequences discussed in a multidisciplinary meeting. **Result:** During the study period, 125 cases of lung cancer were collected. The average age was 57,6 years The average consult time also called patient time was 3.92 months. As for the delays related to the health system there are:An average diagnostic time of 63,5 days A therapeutic delay of 67,9 days on average An average overall delay of 216,3 days The time to diagnosis was therefore close to that recommended by the littérature, while the consultation, treatment and overall time to diagnosis were longer which significantly affects the survival curve **Conclusion:** In several countries, delays in care and access to care services, considered as indicators of system performance, have become a priority in public health policies. The establishment of more specialized oncology and radiation oncology centers should help to reduce them A subsequent reassessment of these delays, after correction, will male it possible to assess the evolution of the quality of the managementof this cancet at the Mohamed VI center

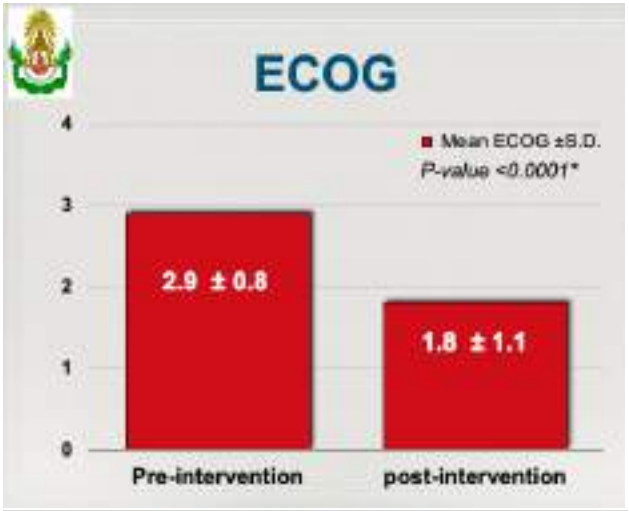
Keywords: Lung cancer, delays, access to care

EP1.16-10 DIFFERENTIATION OF PERFORMANCE STATUS AFTER TUMOR DEBULKING IN MALIGNANT CENTRAL AIRWAY TUMOR VIA RIGID BRONCHOSCOPY

P. Aungkajornkul[1], V. Wongsrichanalai[2], N. Prasongsook[1]

[1]*Phramongkutklao Hospital, Bangkok/Thailand,* [2]*Phramongkutklao Hospital, bangkok/Thailand*

Background: Bronchogenic carcinoma patients havebeen suffered from cancer and its complications. The aim of cancer treatment is for prolonged survival and symptomatic control. Novel multimodality treatment can be relieving symptoms and improve patients' performance status (PS). Malignant central airway obstruction is the most harmful complication that increases morbidity, mortality and decreases PS. Rigid bronchoscopy with tumor resection plays pivotal roles for resolve these problems **Method:** Retrospective Observational study enrolled cancer patients who had beensuffered from malignant central airway obstruction that undergo Rigid bronchoscopy with tumor debulking in Phramongkutklao Hospital during January 2014 – October 2018 **Result:** 64 cancer patients were included in this study. 37(60.7%) were older than sixty. 36 (59%) were male and 38 (62.3%)had primary lung cancer in origin. 30 (49.2%)had left main bronchial obstruction 24(39.3%) had right main bronchial obstruction and 15(24.6%) had thetracheal obstruction. Most of patients 43(70.5%) had intraluminal obstruction and degree of obstruction were grade 4 39(63.9%). Pre-intervention ECOG 2-4 group were 23(37.7%), 24(39.3%) and 14(23%) respectively. Mean pre- intervention ECOG was 2.9±0.8 After rigid bronchoscopy with tumor debulking mean ECOG was decreased to 1.8 ±1.0. 46 of 64 (90.2%) had clinical improvement after successful procedure. 37 (72.5%) had 6-month survival and 33(64.7%) had 1-year survival after successful procedure, compared with 2(20%) and 1(10%) in unsuccessful procedure. 43(95.6%) had opportunity to received other treatment such as chemotherapy, targeted therapy, etc. after ECOG status was improve



Conclusion: Rigid bronchoscopy with tumor debulking improves performance status, increases survival and increases opportunity for other new multimodality treatment in cancer patients who had malignant central airway obstruction.

Keywords: Malignant central airway obstruction, tumor debulking, ECOG

EP1.16-11 IMMUNOTHERAPY IN NSCLC: REAL WORLD EXPERIENCE IN A PERUVIAN POPULATION

T. Runciman[1], C. Aliaga[1], O. Rua[1], D. Ponce De Leon[2], C. Carracedo Gonzales[1]

[1]*Aliada, lima/Peru,* [2]*Ricardo Palma, lima/Peru*

Background: Checkpoint inhibitors drugs, have achieved positive results above chemotherapy in 2nd line and 1st line for specific populations with lung cancer. Nowadays, investigations continue studying biomarkers which could be useful as predictive factors of response as if inflammatory markers might have some role. **Method:** The study design included patients with non-small cell lung cancer (NSCLC) that receivedimmunotherapy with "Pembrolizumab" or "Nivolumab" in two private cancer centers of reference since January 2015 until January 2018. The adverse effects were evaluated by medical oncologists and classified by CTCAE v 4.0. The response were assessed by RECIST criteria. Furthermore, inflammatory markers results were obtained from blood work performed before immunotherapy started. All patients that received at least one dose of immunotherapy were taken into analysis. **Result:** A total of 158 patients with lung cancer were diagnosed in that period, only 18 patients were assessed, the mean age was 62, and the vast majority had adenocarcinoma. The mean number of cycles was 27 (2-52). The ORR was of 28%, 80% had partial response (PR) and 20% had complete response (CR). Thirty-nine percen had stable disease (SD) while 33% had progressive disease (PD). The median of time to achieve a response was of 11.5 weeks. The response according to the PD-L1 expression was stratified, founding clinical benefit in all the groups. The time to progression since immunotherapy was 15weeks. One case was reported as unconfirmed progressive disease by week 10. Markers of inflammation analyzed showed Neutrophil-lymphocyte rate (NLR) and Platelet-lymphocyte rate (PLR) means were 4.37 (1.42 – 21.6) and 270.19 (93.1-650.7)respectively. The values obtained according to response found that the group that progressed to therapy had 4.23 NLR and 343.9 PLR. The group who had clinical benefit, had 4.39 NLR and 229.9 PLR. 33% of the population present toxicity, from which 83% was graded G1-2 and 17% G3-4. **Conclusion:** A high PLR might be associated with an unfavorable prognosis although more studies are needed. This is the first study in Peruvian population that shows results of immunotherapy in lung cancer.

Keywords: Inmunotherapy, NSCLC, Markers of inflammation

EP1.16-12 RIGHT VS LEFT LUNG CANCER – PROGNOSTIC IMPLICATIONS

T. Khalid[1], T. Mahgoub[2], N. O'Leary[2], O. Grady[1], M. Martin[1], A. Yousif[1]

[1]*Sligo University Hospital, Sligo/Ireland,* [2]*University Hospital Limerick, Limerick/Ireland*

Background: Lung cancer is one of the leading causes of death in the developed world. In Ireland alone there are over 2,500 new cases of lung cancer every year. Several studies set to determine prognostic factors that may play a role in optimising the management of patients with lung cancer. One of the factors currently being studied is the location of lung cancer. The interest in this prognostic factor was partially due to the reported implications of tumour 'sidedness' in colon cancer. We conducted a retrospective study to assess if tumour 'sidedness' impacts overall survival in a population of Irish patients with non-small cell lung cancer. **Method:** In this study we selected patients with a diagnosis of non-small cell lung cancer (stage I – stage IV) who received systemic therapy at Sligo University Hospital between 2011-2018. The cut-off date for inclusion was the 1st of March 2019. The primary end point was overall survival. The study was reviewed by the ethics board of Sligo University Hospital who approved data collection and waived consent for this study. **Result:** A total of 76 patients were identified. Of them 41% (n=31) were females and 59% (n=45) were males. 70% (n=53) had a right-sided

EPOSTERS

lung cancer and 30% (n=23) had a left-sided lung cancer. There were 3 patients with stage I disease, 13 patients with stage II disease, 26 patients with stage III disease and 34 patients with stage IV disease. Median overall survival for all stages was 19.0 ± 5.0 months (95% CI 9.2-28.8) for right lung cancers and 15.0 ± 7.4 months (95% CI 0.6-29.4) for left lung cancers. For stage III lung cancers median overall survival was 34.0 ± 6.7 months (95% CI 20.8-47.2) for right lung cancers and 13.0 ± 4.0 months (95% CI 5.2-20.8) for left lung cancers. For stage IV lung cancers the median overall survival was 12.0 ± 1.5 months (95% CI 9.0-15.0) for right lung cancers and 13.0 ± 13.4 months (95% CI 0.0-39.2) for left lung cancers. **Conclusion:** We did not observe a significant difference in outcome between right-sided and left-sided lung cancers when assessing patients of all stages combined or for the stage IV sub-group. However, in stage III lung cancer, patients with right lung tumours seem to have a better outcome than patients with left lung tumours. Our data are limited by the fact that this is a single institute study with only a modest number of patients, 76 in total. A larger study will be required to assess if the trend observed holds true, the factors behind it and how it may contribute to optimising the management of lung cancer.

Keywords: NSCLC, Right Vs Left, Prognostic Implication

EP1.16-13 CHARACTERISTICS AND CLINICAL OUTCOMES IN PATIENTS WITH NON-SMALL CELL LUNG CARCINOMA IN FUNDACION SANTA FE DE BOGOTA: 42 MONTHS EXPERIENCE

A.V. Ospina Serrano, L.E. Pino Villareal, J.M. Segovia Gomez, I.C. Triana Avellaneda

Hospital Universitario Fundacion Santa Fe De Bogota, Bogotá/Colombia

Background: The source of information available about lung cancer caracteristics and clinical outcomes in Colombia are poor. **Method:** Observational, descriptive study of a cohort of patients with non small cell carcinoma (NSCL) treated at Fundacion Santa Fe de Bogota (FSFB). We followed patients from August 2015 to January 2019 (42 months) and analyzed clinical and epidemiological characteristics, progression free survival (PFS), overall survival (OSm) and treatment related complications. **Result:** Forty-eight patients were included. 56.2% stage IV, 16.6% stage III, 8.3% stage II and 18.75% stage I. Stage IA (44%) received management with surgery, stage IB (56%) were treated with surgery and adjuvant therapy no patients progressed or died. In stage II all were IIA and received management with surgery and adjuvant therapy, 25% progressed and died OSm 26m and PFS 10m. In stage III group, IIIA (62.5%) treated with surgery and chemo-radiotherapy, 40% progressed PFS 12m, and OSm has not been reached. In stage IIIB (37.5%) received chemo-radiotherapy, 33% progressed PFS 8m and OSm has not been reached. In stage IV, the group without PDL-1 expression and negative for oncogenic addiction (22.5%) received treatment with chemotherapy OSm was 16.9m and PFS 7.5m. EGFR positives (41.9%) received target therapy, OSm was 25.8m and PFS 13.1m. The patients with ALK rearrangement (9.6%) were treated with target therapy OSm was 16m and PFS 12.6m. For PDL-1 >50% (12.9%) all received monoagent immunotherapy OSm was 11m and PFS 10m. For PDL-1 1-49% (12.9%) PFS was 28m and OSm has not been reached, they were treated with inmunotherapy plus chemotherapy. In relation with grade 3 toxicity with adjuvant chemotherapy was 10% diarrhea, 10% kidney failure, 10% hematotoxicity, 10% decompensation of heart failure previously diagnosed. In metastatic disease 7% with chemotherapy had kidney failure, 7% emesis, 7% diarrhea and 7%% hyporexia. Patients with target therapy 17% had diarrhea and 11% hepatotoxicity, 5% hematotoxicity, 5% dermatological complications. 9% with bevacizumab presented hemoptysis and 6% of patients with immunotherapy had autoimmune colitis. Hypothyroidism was the most frequent complication with the immunotherapy 37%. **Conclusion:** We had important proportion of stages I-II (27%). Recurrent disease was more frequent in stage III as had been described. Factors like cigarette, nutritional status and ECOG were no statistically significant for the survival. In metastatic setting the highest OS and PFS was for the group with PDL-1 expression between 1-49%, treated with chemotherapy plus immunotherapy.

Keywords: Colombia, metastatic lung cancer, Real world experience

EP1.16-14 EFFICACY OF FIRST-LINE CONTINUOUS MAINTENANCE OF PEMETREXED THERAPY FOR LUNG ADENOCARCINOMA WHEN ADMINISTERED AT ROUTINE OR EXTENDED INTERVALS

Y. Wang, Y. Huang, D. Hu, L. Chen, R. Zhang, S. Cheng, G. Wu, X. Dong

Cancer Center, Union Hospital, Tongji Medical College, Huazhong University of Science and Technology, Wuhan/China

Background: Lung cancer is the most common cancer and the leading cause of death due to cancer worldwide , The benefit of maintenance therapy with pemetrexed with or without antiangiogenesis inhibitors has been observed in previous studies. However, continuous maintenance therapy with the pemetrexed-antiangiogenesis combination has rarely been evaluated in the real world setting. In real life, patients may not receive maintenance therapy or may receive delayed maintenance therapy (stopping interval of >21 days) owing to many factors. The purpose of this study was to obtain real-world data on the maintenance of local progressive and metastatic non-squamous non-small cell lung cancer (NSCLC) in first-line patients treated with or without pemetrexed antiangiogenesis, and to evaluate the effect of extended interention on clinical outcomes.

Method: 168 patients with stage IIIB or IV lung adenocarcinoma who had not been treated previously received pemetreplatin-induced chemotherapy with or without anti-angiogenesis inhibitors (bevacizumab or rh-endostatin) every 3 weeks for a course of 4-6 weeks.The efficacy and safety of 112 patients without progression after induction chemotherapy were analyzed. **Result:** 70 of the 112 patients received continuous maintenance therapy, with or without an anti-angiogenesis inhibitor, until the disease progressed.42 patients did not receive continuous maintenance therapy.The median duration of maintenance therapy was 4(range 1-26);The median interval of each maintenance treatment cycle was 40 days (ranged from 21 to 77 days).The optimal objective efficiency of maintenance group and non-maintenance group was 48.6% and 33.3%, respectively.At an average follow-up of 14.6 months, the median progression-free survival was 11.5 months (95% CI: 9.8 -13.2 months) and 6.8 months (95% CI :5.4-8.2 months,p < 0.001), and the median overall survival was 40.1 months (22.5 - 57.7 months) and 18.0 months (10.4-25.6 months,p = 0.001) in the maintenance and non-maintenance groups, respectively.The most common grade 3-4 adverse event in both groups was neutropenia (18.6% vs. 19.0%). **Conclusion:** prolongation of maintenance time is feasible, and for patients without progression after first-line induction therapy for lung adenocarcinoma, continuous maintenance therapy with or without combination of pemetrexed with anti-angiogenesis is essential for survival benefits.

Keywords: lung adenocarcinoma, continuous maintenance therapy, pemetrexed

EP1.16-15 SUBCLINICAL INTERSTITIAL LUNG DISEASE IS A RISK FACTOR FOR RADIATION PNEUMONITIS IN PATIENTS WITH LUNG CANCER AFTER THORACIC RADIATION THERAPY

F. Li[1], S. Liang[2], H. Wu[1], Y. Xu[1], M. Chen[3]

[1]*Shanghai Pulmonary Hospital, Tongji University School of Medicine, Shanghai/China,* [2]*Cancer Hospital Affiliated to Guangxi Medical University, Nanning/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China*

Background: Previous studies reported that patients with subclinical interstitial lung disease were more susceptible to developing radiation pneumonitis after thoracic stereotactic body radiotherapy or thoracic 3-dimensional conformal radiotherapy. The present study aimed to evaluate the incidence and predictors of RP after TRT in patients with lung cancer with or without preexisting subclinical interstitial pulmonary disease. **Method:** Patients with lung cancer between May 2016 and August 2018, who were treated with thoracic intensity-modulated radiation therapy in our institutions, were prospectively analyzed. Statistical analysis was performed using SPSS software 22.0 for Mac. Univariate and multivariate analyses were used to assess the correlation of subclinical interstitial lung disease with radiation pneumonitis and risk factors of radiation pneumonitis. A P value < 0.05 was considered statistically significant. **Result:** A total of 123 patients with lung cancer were prospectively analyzed. The median follow-up time was 13.9 months. Radiation

pneumonitis was observed in 30, 18, 2 and 1 patient with grades 1, 2, 3 and 5 radiation pneumonits, respectively. No patient suffered from ≥grade 4 radiation pneumonitis. The incidence of ≥grade 2 radiation pneumonitis was 17.1%. Mean lung dose, V10, V20, V30 and subclinical interstitial lung disease before radiotherapy were associated with an increased incidence of ≥grade 2 radiation pneumonits in univariate analysis. Subclinical interstitial lung disease and mean lung dose were significantly associated with ≥grade 2 radiation pneumonits in multivariate analysis (*P*=0.022, *P*=0.018, respectively). **Conclusion:** Preexisting subclinical interstitial lung disease and mean lung dose are predictors of ≥grade 2 radiation pneumonits.

Keywords: Radiation pneumonitis, Lung cancer, interstitial lung disease

EP1.16-16 PEMBROLIZUMAB AS FIRST THERAPEUTIC LINE IN NON-SMALL CELL LUNG CANCER – THE EXPERIENCE OF A PORTUGUESE TERTIARY HOSPITAL

N. China Pereira, A. Mendes, D. Reis, M. Dias, D. Coutinho, T. Costa, E. Silva, S. Campainha, S. Conde, A. Barroso

Centro Hospitalar Vila Nova de Gaia/Espinho, E.P.E., Vila Nova de Gaia/ Portugal

Background: Pembrolizumab is a humanized monoclonal antibody against PD-1 that has antitumoral activity in NSCLC. It is currently approved by the EMA for the treatment of patients with advanced NSCLC with PD-L1 expression ≥50%. **Method:** A retrospective study was performed in patients with advanced NSCLC proposed for first-line treatment with pembrolizumab. These patients were recruited at our Thoracic Tumor Unit between June 2017 and December 2018. An epidemiologic characterization of patients was performed and a progression-free survival (PFS) was analysed through the Kaplan-Meier method. **Result:** Twenty-two patients were included, with one being excluded due to the presence of synchronous tumor lesions. The majority of patients were male (90,5%), with a mean age of 63±13 years and 85.7% were smokers or former smokers. At the start of immunotherapy, 23.8% had a PS0 and 76.2% had a PS1. The most frequent histology was adenocarcinoma (57.1%), followed by squamous cell carcinoma (33.3%), and the majority of patients were in stage IV (95.2%). The median of PD-L1 expression was 80% (IQR 30). Partial remission was achieved in 47.6% of patients, stable disease in 28.6%, and 23.8% of patients had progressive disease. The median PFS was 10.0 months. Adverse effects were documented in 28,6% of patients, namely hypothyroidism, colitis, hepatitis and sialadenitis. Only one was classified as grade 3 according CTCAE, leading to interruption of the drug. **Conclusion:** The PFS obtained in our study was similar to that described in literature (10.3 months). As we can observe the safety profile of pembrolizumab was also good. Thus, pembrolizumab is increasingly being shown as a well-established drug in 1st line for advanced NSCLC with PD-L1 expression ≥50%.

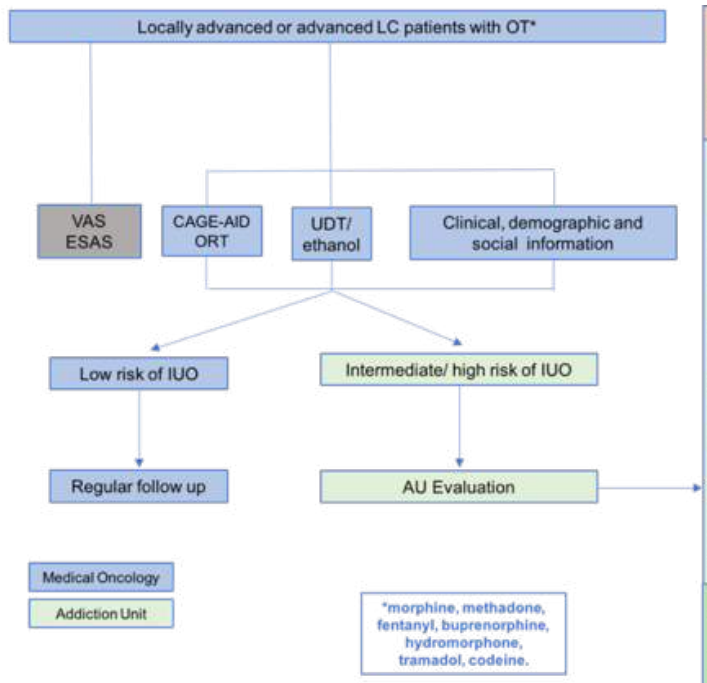
Keywords: advanced NSCLC, progression-free survival, Pembrolizumab

EP1.16-17 MANAGEMENT OF INAPPROPRIATE USE OF OPIOIDS (IUO) IN PATIENTS (P) WITH LUNG CANCER (LC)

T. Moran[1], P. Zuluaga[2], M. Domenech[1], A. Estival[1], E. Carcereny[1], L. Angelats[1], A. Plaja[1], C. Erasun[1], R. Muga[2], D. Fuster[2]

[1]*Catalan Institute of Oncology-Badalona; Hospital Universitari Germans Trías I Pujol; B-ARGO; IGTP, Badalona/Spain,* [2]*Hospital Universitari Germans Trías i Pujol, Badalona/Spain*

Background: Pain represents one of the main symptoms in patients (p) with lung cancer (LC). Currently, the molecular classification and targeted therapies and immunotherapy for LCp yield a prolonged survival in some p. In this context, analgesia with opioid therapy (OT) requires special caution. The prevalence of IUO LCp is unknown and its assessment is suboptimal. There is no current recommendation to assess IUO risk in cancer p, other than in long cancer survivors with chronic pain. Several scales are validated for the screening of aberrant OT-behaviors. The Addiction Unit (AU) role could be key in the evaluation and minimization of the IUO risk (Fig.1) STUDY DESIGN:Prospective study for the evaluation of IUO risk in LCp. P with intermediate/high risk of IUO will be referred to the AU for evaluation and follow-up (Fig.1) OBJECTIVES:Determine if screening scales are capable of detecting the risk of IUO in LCp. Reduce the impact of IUO in LCp by assessment and follow-up in the AU. VARIABLES: Main: To determine if the Cut down-Annoyed-Guilty-Eye opener (CAGE-AD) and Opioid Risk Tool (ORT) scales are able of detecting the risk of IUO in LCp. Secondary: Determine if the urine and blood drug testing (DT) reinforces the information of such scales. Determine the risk reduction of IUO after the intervention of the AU. **Method:** ELIGIBILITY CRITERIA (Fig.1) SCALES:The MO team will use the following scales for the IUO risk assessment: CAGE-AID, ORT. Visual Analogic Scale (VAS) and Edmonton Symptom Assessment Scale (ESAS) will be used for pain evaluation. LABORATORY: DT (urine/ blood ethanol) ASSESSMENT OF IUO RISK: Proposed timeline and strategies at the AU are summarized in Fig.1. SAMPLE SIZE:Study will include 45 p in a 1-year period. Approved by IRB-Hospital Germans Trias in Pujol, Nov, 23th2018 (UIO-pulmon 2018)



AU, Addiction Unit; CAGE: Cessation-Annoyed-Guilty-Eye opener; ESAS, Edmonton Symptom Assessment Scale; IUO, inappropriate use of opioids; LC, lung cancer; ORT, Opioid Risk Tool; OT, opioid therapy; p, patients; UDT, urine drug testing; VAS, visual analogic scale

Result: Section not applicable **Conclusion:** Section not applicable

Background: Approximately 10-16% of non-small cell lung cancer (NSCLC) cases have the EGFR mutation. Studies have shown that EGFR tyrosine kinase inhibitors (TKIs) significantly prolong progression-free survival (PFS) in patients with advanced NSCLC in comparison to those treated with platinum-based chemotherapy doublets. Our aim is to perform a real world analysis of patients treated with TKI as first line therapy at the Hospital of Leon (CAULE). **Method:** We retrospectively reviewed a total of 74 patients diagnosed with EGFR mutation positive NSCLC between March 2011 to June 2018 in the CAULE. Data was obtained from their medical records. The impact of comorbidities and smoking status on the survival rate were evaluated, in addition to the PFS and overall survival (OS) outcomes in patients treated with first line TKI. The follow-up schedule for computed tomography (CT) imaging was realized every 8 to 12 weeks. **Result:** A total of 74 patients were included in the study, out of which 55 were treated with a first line TKI. Exon 19 deletion was the most prevalent mutation subtype accounting for 53% of cases. 67% of patients were women. The average age was 69 years old. 44% had metastasis to more than 2 sites at the time of diagnosis; 6 patients had brain metastasis, 4 of which received prior whole brain radiotherapy, 1 surgical treatment, and 1 didn't receive local treatment. 22% of patients had no medical comorbidities (including cardiovascular, pulmonary, neurological or psychiatric history). Results revealed that the presence of comorbidities had no statistical significance when analyzing its impact on survival outcomes (HR=0.85, 95%CI 0.37-1.83 p=0.64). Similar results were obtained when non-smokers (71%) were compared to smokers or former smokers, suggesting that smoking had no statistical significance when analyzing survival data (HR=0,94 95%CI: 0.43- 2.02 p=0.87). 50% (n= 28) of patients were treated with first line gefitinib, 32% (n=18) with erlotinib and 10% (n= 6) with afatinib. There was no statistical significance in survival rates amongst patients treated with gefitinib vs afatinib or erlotinib (HR=1.6 P=0.56 95%CI 0.84-3.2). When analyzing best response to treatment, 63% of patient had a partial response, 20% demonstrated stable disease and 10% had progression of disease. Median OS was 31 months (95%CI: 20,5-31,4 months) and the PFS was 17 months (95%IC 13,9-20,6 months). 30% were alive at the time of analysis. The main cause of death was disease progression. **Conclusion:** This real-world analysis of the data gathered from the Hospital of Leon confirms that treatment with TKI is beneficial for patients diagnosed with EGFR mutation positive NSCLC. In fact, our OS outcomes are similar than those reported in clinical trials. We have not observed significant differences amongst TKI treatment options, nor was there an impact on global survival rates in patients with underlying medical comorbidities. Given the prevalence of EGFR mutation positive lung cancer, more clinical data is required in order to expand scientific evidence and determine the best driver mutation therapy option based on patient's profile.

Keywords: EGFR mutation, TKI first line, comorbidities

EP1.16-19 EXPECTED YEARS OF LIFE LOSS AND SURVIVAL OUTCOME IN NON-SMALL CELL LUNG CANCER PATIENTS IN RAJAVITHI HOSPITAL

S. Sa-Nguansai, P. Tienchaiananda, S. Payapwattanawong, S. Laohavinij

College of Medicine, Rangsit University, Bangkok/Thailand

Background: To determine expected years of life loss (EYLL) that was the burden of disease parameter of all stages non-small cell lung cancer (NSCLC) patients, survival outcomes in advanced NSCLC patients and association between clinical prognostic factors and survival outcomes in advanced diseases. **Method:** This retrospective cohort study was conducted by reviewing 305 eligible all stages NSCLC patients treated at Oncology Unit, Department of Medicine, Rajavithi hospital from 2011 to 2015. The iSQoL statistical package was used to evaluate EYLL compared to the reference Thai population. For advanced NSCLC patients, univariate and multivariate analysis were used to determine prognostic factors associated with survival

outcomes. **Result:** Total 305 patients were included for EYLL analysis. From survival extrapolation, corresponding EYLL of stage I, II, III, and IV NSCLC patients were 9.20, 15.61, 18.03, 20.23 years, respectively. Male patients had EYLL less than female patients (18.81 years vs 20.70 years). In advanced NSCLC, 261 patients were included in survival and prognostic factors analysis. The median overall survival was 6.08 months. The clinical parameters associated with poor survival outcomes in multivariate analysis were male gender (HR 1.71; p = 0.017), presentation with cough or hemoptysis (HR 1.81; p < 0.001), significant weight loss (HR 1.80; p < 0.001), SVC obstruction (HR 1.98; p = 0.019), pathological fracture (HR 2.16; p = 0.002), symptomatic brain metastasis (HR 2.05; p = 0.005), pericardial metastasis (HR 1.88; p = 0.015), adrenal metastasis (HR 1.58; p = 0.011), and not received palliative chemotherapy (HR 6.18; p < 0.001).

Figure: Expected years of life loss (EYLL) of non-small cell lung cancer patients by different staging. The difference of life expectancy between non-small cell lung cancer patients and the sex- and age-matched referents were represented in the shadowed area

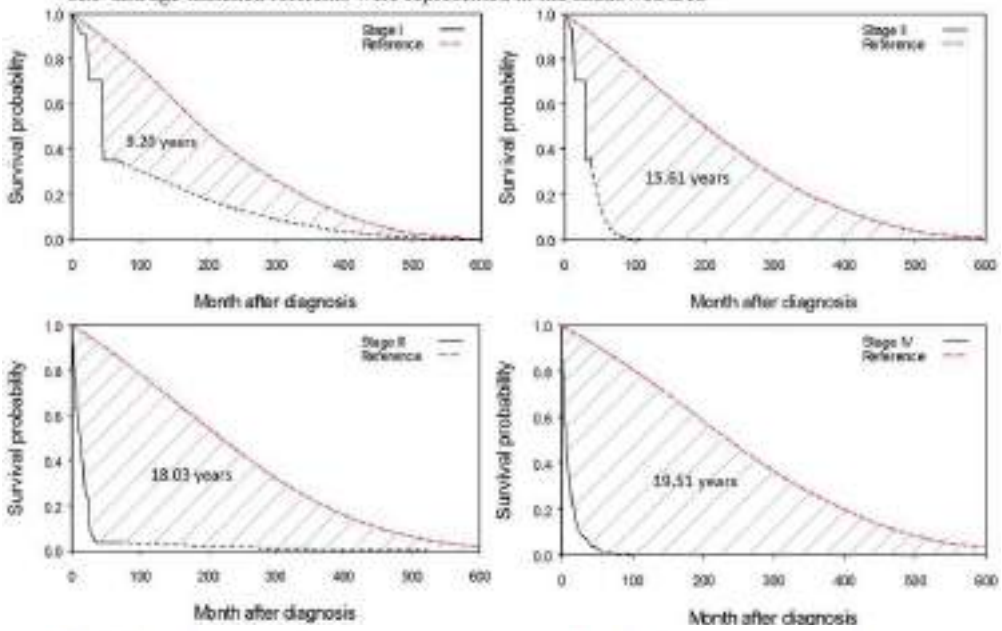

Table: Multivariate analysis of factors related to overall survival outcome in advanced non-small cell lung cancer patients

Variables		Crude HR			Adjusted HR

No		4.44	3.38 – 5.82	< 0.001	6.18	4.16 – 9.18	**< 0.001***

Abbreviations: HR, hazard ratio; ECOG PS, Eastern Cooperative Oncology Group performance status; SVC syndrome, superior vena cava syndrome; CMT, chemotherapy.
[a] Weight loss ≥ 5% in 6 months.

Conclusion: Diagnosis and treating patients with NSCLC as early as possible would be save more life-years from 18 – 20 years in advanced disease to 9 – 15 years in early stage disease. In advanced NSCLC patients, palliative chemotherapy was the most important factor related to better survival outcomes.

EP1.16-20 PEMBROLIZUMAB - SUBSEQUENT LINES IN NON-SMALL CELL LUNG CANCER: THE EXPERIENCE OF A TERTIARY HOSPITAL

N. China Pereira[1], A. Mendes[2], D. Reis[1], M. Dias[1], D. Coutinho[1], T. Costa[1], E. Silva[1], S. Campainha[1], S. Conde[1], A. Barroso[1]

[1]*Centro Hospitalar Vila Nova de Gaia/Espinho, E.P.E., Vila Nova de Gaia/Portugal,* [2]*Centro Hospitalar Vila Nova de Gaia/Espinho, E.P.E., Porto/Portugal*

Background: Pembrolizumab is currently approved for the treatment of metastatic NSCLC, with PD-L1 expression ≥1% and with progressive disease during or after treatment with chemotherapy. **Method:** A retrospective study was conducted in patients with metastatic NSCLC with ≥ 1% of PD-L1 expression, proposed for subsequent therapeutic lines with pembrolizumab. Patients were recruited in our Thoracic Tumor Unit between June 2017 and December 2018. An epidemiology characterization of patients was performed and progression-free survival (PFS) was analyzed throw a Kaplan-Meier method. **Result:** Fourteen patients were included. The majority of patients were male (85.7%), with a mean age of 65±11 years, and 78.6% of them were smokers or former smokers. The observed PS was: PS0 in 7.1% and PS1 in 92.9%. The most prevalent histologies were adenocarcinoma (71.4%) and squamous cell carcinoma (28.6%), with the majority of patients in stage IV (78.6%) at the time of initiation of pembrolizumab. The median of PD-L1 expression was 60% (IQR 50). Mutations and translocations (KRAS and BRAF) were present in 38.5% of these patients. Partial disease remission was achieved in 28.6% of patients, stable disease in 50.0%, and 21.4% of patients progressed. The median PFS was 8.0 months. Adverse effects were documented in 28.6% of patients, namely hypothyroidism (28.6%) and hepatitis (7.1%). Only one patient developed grade 3 adverse effect that led to drug interruption. **Conclusion:** The PFS obtained in our study was twice as large as that described in the literature (3.9 months), although due to the small number of patients it was not possible to divide in subgroups of PD-L1 expression. However, the high median of PD-L1 expression in our study may explain in part the results obtained. The authors intend to show that pembrolizumab in 2nd line is an effective drug and should be considered in patients with high expression of PD-L1.

Keywords: Pembrolizumab, second line, advanced NSCLC

EP1.16-21 FREQUENCIES AND PROGNOSIS OF NON-SMALL CELL LUNG CANCERS COMPLICATED WITH SYNCHRONOUS/METACHRONOUS MULTIPLE PRIMARY CANCERS

T. Honda, R. Ochiai, T. Haruyama, M. Ishihara, T. Sakamoto, S. Tanzawa, S. Ota, Y. Ichikawa, K. Watanabe, N. Seki

Teikyo University School of Medicine, Tokyo/Japan

Background: Recently, opportunities to diagnose multiple primary cancers have been increasing due to the progress of diagnostic technology, resulting in the difficulty in treatment decisions. Therefore, we examined the frequencies, background, and prognosis of non-small cell lung cancers (NSCLC) complicated with synchronous/metachronous multiple primary cancers. **Method:** Between 2013 and 2017, we retrospectively examined the medical charts in patients with NSCLC who had never experienced cancers before. We classified such NSCLC patients into the following three groups: (1) single primary NSCLC group (SPN), showing no other cancers during the follow-up period, (2) synchronous NSCLC group (SN), showing other cancers diagnosed within 2 months from the first NSCLC diagnosis, and (3) metachronous NSCLC group (MN), showing other cancers diagnosed after 3 months or more from the first NSCLC diagnosis. **Result:** Among 1350 cases enrolled, the frequencies of SPN, SN, and MN groups were 88.6% (1196 cases), 8.3% (112 cases), and 3.1% (42 cases), respectively. Background factors such as age, sex, performance status, smoking history, clinical stage, EGFR mutation, EML4-ALK fusion gene, ROS-1 gene, PD-L1 expression, and the number of affected cancers were adjusted using Cox proportional hazards model analysis. In SN group, NSCLC (32 cases), colon cancer (20 cases), and gastric cancer (12 cases) were commonly observed. Similarly, in MN group, NSCLC (17 cases), colon cancer (4 cases), and gastric cancer (4 cases) were commonly observed. The median survival times of SPN, SN, and MN groups were 24.0 months, 42.1 months, and not reached, respectively ($p < 0.001$). Regarding the prognostic factors, the hazard ratios [HR] of SN and MN groups toward SPN group were 0.98 (95% confidence interval [CI]; 0.71 to 1.36, $p = 0.91$) and 0.38 (95% CI; 0.22 to 0.66, $p < 0.001$), respectively. The other prognostic factors were 75 years old or older (HR; 1.46, 95% CI; 1.24 to 1.72, $p < 0.001$), male (HR; 1.56, 95% CI; 1.26 to 1.94, $p < 0.001$), performance status 3-4 (HR; 3.88, 95% CI; 3.09-4.82, $p < 0.001$), smoking history (HR; 1.44, 95% CI; 1.12 to 1.84, $p = 0.01$), and clinical stage IIIB-IV NSCLC (HR; 4.37, 95% CI; 3.62 to 5.30, $p < 0.001$). **Conclusion:** In patients with NSCLC who had never experienced cancers before, synchronous/metachronous multiple primary cancers could be often observed. However, their coexistence might not adversely affect the prognosis of firstly diagnosed NSCLC.

Keywords: single primary lung cancer, synchronous cancer, metachronous cancer

EP1.16-22 PEMETREXED, PLATINUMIN COMBINATION WITH BEVACIZUMAB FOR CHINESE PATIENTS WITH ADVANCED LUNG ADENOCARCINOMA CANCER: A REAL WORLD STUDY

X. Chen

Affiliated Hangzhou First People's Hospital, Zhejiang University School of Medicine, Hangzhou/China

Background: Bevacizumab and platinum based chemotherapy have been standard treatment for advanced non-squamous non-small cell lung cancer. Otherwise, the chemotherapy protocol is often paclitaxel and carboplatin, and pemetrexed combination with platinum are also generally used in our clinical practice. Thus, the aim of this present study is to evaluate the efficacy and safety of cisplatin or carboplatin+pemetrexed combination with bevacizumab followed by maintenance pemetrexed and bevacizumab for Chinese chemotherapy-naïve patients with advanced lung adenocarcinoma cancer in real word. **Method:** A total of 44 chemotherapy-naïve patients with advanced lung adenocarcinoma cancer were administered pemetrexed (500 mg/m2), cisplatin(60mg/m2)/carboplatin (AUC, 5.0 mg/ml/min) and bevacizumab (7.5 mg/kg) intravenously every three weeks for up to six cycles. Maintenance PB was administered until disease progression or unacceptable toxicity. The endpoints were objective response rate (ORR), progression-free survival (PFS) and safety. **Result:** 44 advanced lung adenocarcinoma cancer patients were enrolled and median age was 61 years. 33 patients were males, 24 were never smokers, the ECOG performance status of 42 patients were 0 and 1. The status of epidermal growth factor receptor mutation, ALK and ROS1 fusion were all negative in 26 patients. EGFR mutation, ALK or ROS1 fusion positive and unkown were 10, 2 and 6 patients respectively. The median cycles of induction therapy and maintenance were 4.2 (95% confidence interval, 2-7) and 3.7 (95% confidence interval, 0-22).The median PFS was 7.4 months. The ORR, SD and DCR were 63%, 32 % and 95% respectively. The grade 3 or 4 toxicities were neutropenia (8%), anemia (1%), fatigue (1%). **Conclusion:** The combination of the bevacizumab, pemetrexed, and platinum demonstrated activity with acceptable toxicity in patients with advanced lung adenocarcinoma cancer regardless of drive gene status.

Keywords: Bevacizumab, pemetrexed, platinum, lung adenocarcinoma cancer

EP1.16-23 THE EFFICACY OF S-1 IN THE THIRD OR MORE THAN LINE TREATMENT OF ADVANCED NON-SMALL CELL LUNG CANCER PATIENTS

C. Lin[1], W. Wang[1], Y. Zhu[2], K. Du[2], W. Wang[3], C. Xu[4], M. Fang[3]

[1]*Jiangshan People's Hospital, Quzhou/China,* [2]*Zhejiang Rongjun Hospital, Jiaxing/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Fujian Cancer Hospital, Fuzhou/China*

Background: S-1 as the third generation of fluorouracil derivate with well safety and low toxicity, presented some efficacy in lung cancer treatment. The aim of this study was to evaluate the efficacy of S-1 treatment in advanced non-small cell lung cancer (NSCLC) in a real world. **Method:** We explored the efficacy of S-1 in advanced NSCLC patients with previously treated from 2015 to 2018 in Jiangshan People's Hospital, Zhejiang Rongjun Hospital and Zhejiang Cancer Hospital. Platinum or the third-generation chemotherapy drugs could be combinedly used. Clinical response was assigned every cycle according to Response Evaluation Criteria in Solid Tumors

(RECIST) version 1.1. Survival analysis and univariate survival analysis were performed by the Kaplan-Meier method. **Result:** 158 patients were included in the research. These patients received S-1 treatment were as a third-line or more-line therapy, including 63 patients S-1 monotherapy, the other 95 patients combined regimens. All 158 NSCLC patients had therapeutic evaluation. Six patients were partial response (PR), and 51 patients were stable disease (SD), then an overall response rate (ORR) was 3.80% and a disease control rate (DCR) was 36.08%. Median progression-free survival (mPFS) was 1.94 months (95%CI 0.56-10.98), no difference between monotherapy and combined group (DCR 30.16% *vs* 40.00%, P>0.05), the liver metastasis showed poorer PFS (1.29 months *vs* 1.92 months, P<0.05). **Conclusion:** S-1 presented some activity in advanced NSCLC treated with more than third lines of treatment. The addition of other drugs cannot improve efficacy. S-1 monotherapy can be used as a choice for heavily-treated patients.

EP1.16-24 OVERCOMING APPOINTMENT DELAY IN RADIOTHERAPY: A SINGLE INSTITUTION EXPERIENCE

M. Ait Erraisse, F.Z. Abboud, K. Hassouni

University Hospital Hassan II, Fez/Morocco

Background: Delay to access to radiation therapy in developing countries is challenging and compromising the cancer prognosis. In our department, we have one linear accelerator for a whole region in the country. We treated about 50 to 60 patient a day and appointments were for more than 3 months. The medical and psychological impact on patients was important. Our objective was to shorten this delay. **Method:** The radiotherapy treatment delivery was to treat 50 to 60 patients from Monday to Friday as the majority of radiation therapy departments. Treatments started at 8 AM to finish at about 7 to 8 PM. The idea was to treat more patients and quickly. Therefore, actions were taken on three main situations: 1st Before radiotherapy, we had to shorten the time from the first consultation to the first radiotherapy fraction. 2nd during radiation, we extended treatment period to above 8 PM.and 3rd concerns fractionation regimens. **Result:** The hospital executive decided to transform the oncology hospital to an emergency hospital with the possibility to treat 24/7. With this way, we could treat up to 100 patient a day or more. we also treat on weekends especially palliative patients. Concerning the patient workflow, patients were seen immediately when they arrive at the department, and if the medical file is complete and ready to radiation, CT scan simulation was done within a week, contouring, dosimetry, and validation with safety checks were done within 3 days. and finally, when possible, we chose hypo-fractionated regimens. The appointment time started to drop from more than 3 months to almost 2 weeks. **Conclusion:** In developing countries, access to radiotherapy is a real problem. The number of linear accelerators per capita is very low. Therefore delays are very long. This kind of approach, if sufficient human resources, could solve the problem while waiting for a second and maybe other machines.

Keywords: Delay - Radiotherapy - Emergency hospital

EP1.16-25 INVESTIGATING THE SYSTEM IMPACT OF REPORTING MULTIDISCIPLINARY CARE MEASURES FOR CANCER SERVICES IN NSW

K. White

University of New South Wales, Sydney/Australia

Background: Multidisciplinary cancer care to facilitate the provision of patient centred and evidence-based care is considered best practice internationally. The Cancer Institute New South Wales (the Institute), the government cancer control agency for the state of New South Wales (NSW) in Australia, has supported multidisciplinary care development and sustainability since 2006. In 2016, measures were developed and reported on by all local health districts across NSW to further understand the practices of different multidisciplinary team meetings (MDT). The measures focused on lung cancer and communication from the MDT to the general practitioner following the MDT meeting. The aim of this study was to identify system level changes and quality improvement activities initiated in the NSW cancer system as a result of reporting on these measures. **Method:** Focus group discussions were used to generate a synergy of ideas from stakeholder respondents regarding the way in which multidisciplinary care and multidisciplinary team meetings operated and how the measures were being used. The participants included NSW Cancer Registry Program Managers and Cancer System Innovation Managers. Content analysis was undertaken using Framework Analysis. **Result:** Two focus groups were held with a total of 17 participants. Five primary themes emerged: use of the oncology medical information system (OMIS); documentation in the MDT; awareness of the measures; relationships; and current and future measures. Some of the key findings included that reporting on the measures expedited the development of the OMIS and improved documentation directly into the OMIS during the MDT. Some challenges that emerged were implementing change in processes and documentation when the MDT sat outside of cancer services governance structures. **Conclusion:** This study has identified that the reporting of performance measures has expedited the development of electronic documentation and data extraction from the MDT, identified barriers and facilitators to MDT data collection and supported MDT improvement activities across NSW. The Institute will continue to work with the NSW cancer control system on the development of new measures to continue the development of multidisciplinary care through the use of MDTs state wide, to ensure all people with a cancer diagnosis in NSW have their care overseen by an MDT.

EP1.16-26 PREHABILITATION FOR LUNG CANCER PATIENTS RECEIVING RADICAL RADIOTHERAPY

P. Rose[1], A. Myres[2], G. Rodger[3], S. Harrow[1], K. Moore[1], M. Omand[1]

[1]*Lung Team, The Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom,* [2]*Physiotherapy, The Beatson West of Scotland Cancer Centre, Glasgow/United Kingdom,* [3]*Quit Your Way Smokefree Hospital Service, Queen Elizabeth University Hospital, Tf/United Kingdom*

Background: Radical radiotherapy with or without chemotherapy is recommended in patients with stage I to III lung cancer who are unsuitable for, or decline surgery. Treatment options are influenced by a patient's performance status, thoracic symptoms and co-morbidities. There is increasing evidence in other fields such as surgery, that prehabilitation has the potential to optimise patient's health prior to starting treatment, reduce treatment related toxicities and increase the opportunity for further treatment options. To investigate the therapeutic potential of prehabilitation, the Beatson West of Scotland Cancer Centre inititated a multidisciplinary prehabilitation clinic for patients with lung cancer embarking on radical radiotherapy. **Method:** Patients from the West of Scotland embarking on a radical dose of radiotherapy with or without chemotherapy were invited to attend the prehabilitation clinic 2 to 3 weeks prior to starting treatment. Their National Early Warning Score (NEWS), Malnutrition Universal Screening Tool (MUST) score, Karnofsky Status, Distress Themometer score, Godin Leisure-Time Exercise Questionnaire (GLTEQ); 30 second chair to stand test (CST) and smoking status were measured at prehabilitation (time point 1) and again during the first week of radiotherapy (time point 2). **Result:** Between May 2019 and July 2019 49 patients were eligible to attend the prehabilitation clinic. 78% attended clinic, 8% were not invited, 6% could not attend due to hospital admission and 8% declined. The range of dose and fractionation schedules varied but included 40 Gy in 15 fractions (N=9), 45 Gy in 30 fractions (N= 1), 55 Gy in 20 fractions (N=17) or 54 Gy in 36 fractions (N=11). 34% of patients received their radiotherapy concurrent with chemotherapy. Twenty-two patients (58%) were current smokers, 15 (68%) of whom engaged with smoking cessation. 13 current smokers (59%) remained smoke free during treatment, with 2 continuing to smoke. MUST, NEWS, Karnofsky Status and Distress scores were available for 15 patients who had commenced treatment. No statistically significant changes were noted in these measurements between time point 1 and two 2 (P = 0.49, 0.27, 1 and 1.53 respectively). However, significant improvements in the GLTEQ (p = 0.008) and CST (p = 0.008) between the two time points were observed for the 8 patients who completed these tests. **Conclusion:** Due to the small sample size conclusions cannot be drawn about the impact of this prehabilitation service as yet. The uptake of smoking cessation and physical activity are encouraging. Over time, data will be available from the Common Toxicity Criteria and the FACT-L to measure its effectiveness.

EP1.16-27 OBSERVATIONAL STUDY TO INVESTIGATE THE IMPLEMENTATION RATE OF RE-BIOPSY IN EGFR-TKI-RESISTANT PATIENTS (NLCTG1602)

K. Koyama[1], K. Nozaki[2], S. Shoji[2], J. Koshio[3], Y. Hayashi[4], D. Ishikawa[5], T. Miyabayashi[6], M. Okajima[7], T. Ota[8], T. Tanaka[9], N. Matsumoto[10], T. Abe[11], K. Sato[12], S. Miura[1], H. Tanaka[1], K. Ichikawa[2], R. Kondo[2], S. Watanabe[2], T. Kikuchi[2]

[1]Niigata Cancer Center Hospital, Niigata City/Japan, [2]Niigata University Graduate School of Medical and Dental Sciences, Niigata/Japan, [3]Nagaoka Red Cross Hospital, Nagaoka/Japan, [4]Nagaoka Chuo General Hospital, Nagaoka/Japan, [5]Sado General Hospital, Sado/Japan, [6]Niigata City General Hospital, Niigata/Japan, [7]Saiseikai Niigata Hospital, Niigata/Japan, [8]Shibata Hospital - Niigata Prefectural Hospital, Shibata/Japan, [9]Niigata Prefectural Central Hospital, Joetsu/Japan, [10]Nishi-Niigata Chuo National Hospital, Niigata/Japan, [11]Shinrakuen Hospital, Niigata/Japan, [12]Tsuruoka Municipal Shonai Hospital, Tsuruoka/Japan

Background: In EGFR-TKI treatment, cannot perform re-biopsy in all cases for recurrent style and involvement. In the case that only cytodiagnosis can gather, we cannot perform an examination for T790M by the Cobas method even if we can obtain a specimen.The examination of plasma is useful, but the case which cannot but provide the next treatment as we cannot confirm a resistant mechanism may often occur by the true clinic because we cannot detect all resistance. **Method:** Examine the rate of use of re-biopsy in the EGFR-TKI-resistant case of the EGFR mutation in the gene-positive progress non-small cell lung cancer and histological diagnosis and rate of agreement of the T790M mutation detection by the Cobas method of the cytodiagnosis prospectively. <subjects>Treated by EGFR-TKI, and do the case that an effect was able to continue with primary registration, and do it with the second registration when treatment was resistant, and do the laboratory procedure and results with registration when there are a recurrence point, PS, use or nonuse of re-biosy. We added up the liquid as re-biosy after July, 2017. **Result:** Start registration of this study in February, 2017, and 197 primary registration, second registration completion become 127 cases as of January, 2019.We conducted the interim analysis in 80 second registration in October, 2018. The Re-biopsy rate of use was 74/80 = 92.5%.The re-biopsy success rate was the whole, and 79.7%, the T790M positive rate were 41.9%.By the specimen distinction, the histological diagnosis, the cytodiagnosis, the re-biopsy success rate and the T790M positive rate by the examination of plasma were 92.3% /56.4%, 83.3%/8.3%, 56.5%/34 .8%, respectively. It is during data cleaning work and is going to report end results now at the general meeting. **Conclusion:** Section not applicable

EP1.16-28 ALK TRANSLOCATED PATIENTS: SURVIVAL IN AN UNSELECTED POPULATION

B. Núñez-García, R. Gómez-Bravo, J.C. Sánchez, B. Cantos, M. Méndez, A.M. Morito, M. Blanco, V. Calvo, M. Provencio

Hospital Puerta de Hierro, Majadahonda/Spain

Background: Lung cancer is the leading cause of death from cancer in our environment. About 5% have ALK translocation, which is more frequent in young, Asian women and non-smoking patients. In the last years, multiple treatments have been developed for patients with ALK translocation, improving prognosis and reaching overall survivals (OS) of more than two years. **Method:** A cohort of 34 patients diagnosed of non-small cell lung cancer with ALK translocation were retrospectively analyzed in our center between 2008-2018. Baseline demographics characteristics were described. OS was calculated as the main objective. **Result:** Patients were followed a median of 47 months (IQR 30-203). Median age was 59 years (IQR 36-83), being 47% male and 53% female. 44% were never smokers and 58% had any comorbidities. At diagnosis, 83% were symptomatic and the most frequent metastases were bone ones (32%). Complete baseline characteristics are shown in Table 1. Median OS was 32 months (IQR 15-78). 1-year, 2-year and 3- year survival was 75%, 69% 49.9% respectively. Kaplan-Meier curve is shown in Figure 1. **Conclusion:** The ALK translocation and targeted treatments have led to a dramatic improvement in overall survival in clinical trials confirmed in our series.

Keywords: OS, NSCLC, ALK mutation

BASELINE CHARACTERISTICS	PATIENTS (N = 34)	
Gender	16 (47%) male, 18 (53%) female	
Age at diagnosis	59 years (IQR 33-83)	
Smoking habit	15 (44%) never smokers 19(59%) smokers (15 (44%) former and 4(12%) current)	
Smoking Pack year	16 (RIQ 10-39)	
Symptoms at diagnosis	6 (17%) → asymptomatic. Cough→12 (35%) Pain →5 (15%) Others→ 1 (2%) headache, dysphonia, low back pain, asthenia)	Weight loss →5 (15%) Dysnea→ 4 (12%)
Comorbidities	11(32%) → no comorbidities HTA → 9 (26%) Heart disease. →3 (9%) DM → 2 (6%)	DL 8 (24%) COPD → 2 (6%) Vasculopathy→ 2 (6%)

EP1.16-29 CLINICAL CHARACTERISTICS AND OUTCOMES OF POSTOPERATIVE EMPYEMA FOLLOWING LUNG SURGERY

K. Kameyama[1], S. Okada[1], M. Shimomura[1], H. Tsunezuka[1,2], S. Ishihara[1], S. Ikebe[1], T. Furuya[1,2], N. Ishikawa[1,2], S. Kitaoka[1,2], J. Shimada[1], M. Inoue[1]

[1]*Kyoto Prefectural University of Medicine, Kyoto/Japan,* [2]*Kyoto Prefectural University of Medicine, Kajii-cho, Kamigyo-ku/Japan*

Background: Postoperative empyema prolongs hospital-stay durations and may lead to mortality. However, clinical risk factors for postoperative empyema have been insufficiently investigated. This study explored the relevant characteristics and outcomes of postoperative empyema after lung surgery. **Method:** A retrospective study of 16 cases of postoperative empyema after lung surgery between April 2008 and December 2018 was conducted. The inclusion criteria were patients who had fever and bacterial pleural effusion confirmed by culture within the first 30 postoperative days. Preoperative patient characteristics, operative findings, and postoperative course were evaluated. **Result:** There were eight cases of empyema with fistula (six with pulmonary fistula and two with bronchopleural fistula) and eight without fistula. Patients included 15 men and one woman. Median (range) age, body mass index, and Brinkman index were 68 (20-84) years, 22.9 (14.5-27) kg/m2, and 650 (0-2320), respectively. Nine patients were operatively diagnosed with primary lung cancer (p-stage I, three cases; p-stage ≥II, six), six with metastatic lung cancer, and one with pneumothorax. Co-morbidities included chronic obstructive pulmonary disease (COPD) (eight cases; incidence, 50%); diabetes mellitus (five cases; 31%), and history of preoperative chemotherapy (seven cases; 44%). Operative procedures were as follows: two pneumonectomies, five lobectomies, two segmentectomies, six wedge resections, and one bulla suturing. Surgical approaches included 12 thoracoscopic surgeries and four open thoracotomies. Median (range) operative time and bleeding volume was 219 (92-739) minutes and 21 (0-1400) g, respectively. Surgery-to-empyema-onset duration was 12 (4-30) days. Before empyema onset, postoperative complications developed in 14 cases (88%) as follows: four, surgical-site infection; four, prolonged pulmonary air leak; two, pneumonia; two, bronchopleural fistula; one, both prolonged pulmonary air leak and surgical-site infection; and one, both pneumonia and surgical-site infection. Organisms cultured from empyema cases included *Staphylococcus aureus* (12 cases; MRSA, one), oral resident bacteria (three), and others (one). Postoperatively, five cases required treatment with antibiotics only; five, both antibiotics and chest drainage; and six, surgery with the aforementioned treatments. Surgical procedures for empyema included thoracoscopic debridement and/or pleural irrigation (four cases) and fenestration (two cases). The hospital-stay duration after first surgery was 30 (12-99) days. There were no postoperative mortalities. **Conclusion:** Diabetes mellitus, preoperative chemotherapy, and COPD could be significant risk factors for postoperative empyema. Infecting organisms associated with postoperative empyema were related to preceding postoperative complications. Therefore, emphasis on controlling factors that contribute to pulmonary and surgical-site infection and pulmonary air leak is important to prevent postoperative empyema.

Keywords: postoperative empyema, Postoperative complication, lung surgery

EP1.16-30 BENIGN EMPTYING OF THE POST-PNEUMONECTOMY SPACE

F. Leite, G. Paupério

Instituto Português de Oncologia do Porto, Porto/Portugal

Background: Whenever a sudden drop in intrapleural effusion occurs after a major pulmonary resection, a bronchopleural fistula is suspected. It often presents with a productive cough due to oral expulsion of pleural fluid as the fistula allows direct communication between the thoracic space and bronchus. An empyema usually follows due to contamination of bacterial flora from the bronchus into the aseptic pleural space. Still, rarely a sudden drop in the pleural fluid occurs in a stable patient, usually with a benign evolution. **Method:** Section not applicable **Result:** A 67 year old man with an adenocarcinoma of the left upper lobe, cT2,N2,Mx, was submitted to a left pneumonectomy due to invasion of the lower lobe and proximity to the hilum. The patient made an uneventful recovery, but on the 13th postoperative day, presented respiratory failure with need for invasive ventilation, but hemodynamically stable. CT-scan showed a pneumonia spanning the entire right upper and lower lobes. On 15th day, Chest X-ray showed a sudden drop on the normal pleural effusion level, with no worsening of the ventilatory or hemodynamic status and no visible loses. No fistula of the bronchial stump was identified on bronchoscopy, and CT-scan showed an empty left pleural cavity. The patient's condition worsened and he died on the 63rd day. **Conclusion:** This rare entity was first described in 2011 by Merritt et al. in a subset of patients who presented inconsistently with a sudden drop in the pleural fluid level following pneumonectomy and coined the term benign emptying of the post-pneumonectomy space (BEPS). These same authors presented the largest series of confirmed BEPS, with seven cases, with, to the best of our knowledge, no more than 20 cases described. Several mechanisms were proposed to explain this entity. Kanakis et al. theorise the existence of a transient bronchopleural fistula that closes spontaneously. This causes the negative pleural pressure to equalize that of the atmosphere, the hydrostatic balance to be reversed and fluid to be absorbed through the parietal pleura. Another possible explanation is a defect in the diaphragm, either congenital, a porous diaphragm syndrome, or created at the time of the surgery, being more likely when an extrapleural pneumonectomy is performed. Similarly, a less-than-watertight chest wall closure, would allow the fluid to enter the soft tissues of the chest wall. Finally, Gervez-Zapata et al. described a case of a drop in air–fluid level likely due to severe dehydration. Given the case of a septic patient with a sudden drop in the intrapleural effusion level, and even in the setting of a contralateral pneumonia, the hypothesis of a bronchopleural fistula could not be warded of. Still, upon review, the patient was stable, ventilating well and had had no vomits. Bronchoscopy and CT scan showed no fistula, and the surgical team had not seen or caused any diaphragmatic lesion. The question that should be asked is at what point is a wait and watch approach valid? The authors believe that even though BEPS is a diagnosis of exclusion, this point is just before a surgical reexploration.

Keywords: Pleural effusion, BEPS, Postpneumonectomy

EP1.16-31 DISENFRANCHISED GRIEF TOOLS USED IN THE TREATMENT OF BEREAVEMENT, ARE USED IN THE THERAPY OF CANCER PATIENTS

A. Kapah

Soroka Medical Center, Ber Sheva/Israel

Background: In the last decade, treatment for bereavement evolved. Jorst (1988) said that mourning occurs when we grieve for the death of our beloved people, but similarly we can mourn the end of a marriage, termination from work, disability, illness, premature delivery, etc. The bereavement experience is characterized by tremendous emotional difficulty, deep sorrow, pain, helplessness, lack of control, disappointment, anger frustration, etc. (Robin, Malkinson, and Witztom 2016), which can lead to depression, and even major dysfunction. People who are dealing with cancer, experience a great sense of loss i.e: loss of self-perception, loss of dreams and expectations, and loss of control in their life. These personal emotional experiences often are not fully spoken about, and there is a large gap between the patient's inner feelings and the perception of their family and friends The reaction of the family and friends is normally encouraging, strengthening, and providing hope for the cancer patient. It is for this reason, there is great difficulty for the family to perceive negative reactions such as deep sorrow, depression, lack of appetite, dysfunction, anger, helplessness from the patient. These reactions stimulate severe responses in both the family and the therapist, especially when there is a major gap between the physical condition of the patient and their emotional response. (For example, the patient has been informed that he is ill, but he has no symptoms, and yet he is currently dysfunctional due to his personal bereavement). The goal of the intervention is to help the patient and his family by the understanding that the patient is dealing with a real loss. This understanding enables emotional processing, as well as reducing the gap between the patient and his family **Method:** During therapy, we use the same tools that are used in the field of bereavement, for example, the use of the 'Two Track Model of Bereavement ', the four truths of the Buddha, the acquisition of the concept of "self-compassion" and techniques for distraction and relaxation. These tools enable normalization, acceptance of the situation, and a discussion of existential questions that arise. **Result:** In families where these tools of bereavement were used, a

reduction was seen, in the gap between the patient and his family. The family became more empathetic, the patient became calmer in the understanding of himself. Thus, the patient was more willing to participate in social functions vs social isolation. **Conclusion:** Treating cancer patients and families, as those who deal with real loss, enables them to better manage and understand their situation appropriately, and enables us (therapists) to be more empathic and target precisely the appropriate treatment for them.

EP1.16-32 PERCENTAGE OF ALK REARRANGEMENT AS A RESPONSE PREDICTOR IN NON-SMALL CELL LUNG CANCER TREATMENT

M. Oliveira, R. Natal, J. Costa, R. Gomes, A. Amaral, L. Ferreira

Local Health Unit of Guarda, Guarda/Portugal

Background: The presence of the Anaplastic Lymphoma Kinase (ALK) fusion oncogene defines a subgroup of non-small cell lung cancer (NSCLC) with clinical and pathological characteristics. It is estimated that 4 to 7% of patients have this rearrangement and it may be detected in the tumour using fluorescence in situ hybridisation (FISH), immunohistochemistry (IHC), and reverse transcription polymerase chain reaction of cDNA. As we walk to a more personalised treatment in NSCLC, we need to search every day for more predictors of response to our newer therapies, such as ALK inhibitors. Our study aimed to correlate the percentage of ALK rearrangement found as a predictor of response in NSCLC ALK-positive treatment. **Method:** Designed a retrospective study with NSCLC ALK rearrangement patients in a peripheral Hospital from the last six years. Collected demographic data, histology, disease stage, the percentage of ALK rearrangement detected by FISH, lines of treatment, the response rate (RR) evaluated by RECIST 1.1 criteria, the progression-free survival (PFS) and the overall survival (OS) in patients under ALK inhibitors. Results are presented as medians and range for non-normally distributed continuous variables and as number/total for categorical data. Statistical analysis was performed using U-Mann-Whitney test, considering a significance level of 5%. **Result:** Eight patients diagnosed with NSCLC ALK-positive, male (4/8), aged 64 (28-85) years, most common histology pattern was adenocarcinoma (6/8), followed by adenosquamous (2/8), mainly in stage IV (6/8) and 2 in stage IIIB, where the most frequent distant metastasis was pleural (4/6), followed by bone (2/6) and pulmonary (1/6), none of the patients had brain metastasis. All ALK-positive with % of rearrangement 68 (18-100), PD-L1 positive, but under 50%, in 1/8 patients with no other mutation found. First line therapy was mainly platinum-based chemotherapy (6/8), followed by ALK inhibitor Crizotinib (2/8). As second-line therapy, all used ALK inhibitors, mainly Crizotinib (5/7) and then Ceritinib (2/7). In third line therapy, there was only one patient with Ceritinib. RR of the patients to the first line therapy was progression disease (5/8), partial response (2/8) and stable disease (1/8). RR in the second line therapy was progression disease (4/6), stable disease (1/6) and partial response (1/6). RR in the third line was progression disease. PFS was 5,5 (2-31) months, and when we used ALK inhibitors as first line, the PFS improved to 19 months. OS was 17 (5-53) months, and with ALK inhibitors as first line was 25 months. We found that there is no statistical correlation between the percentage of ALK rearrangement and the PFS, OS or the response rate in our patients, whatever the line of therapy. Nevertheless, there is an improvement in RR, PFS and consequently in OS among patients with ALK inhibitors in first line. **Conclusion:** Besides our negative results with the the percentage of ALK rearrangement, we found in our sample an improvement in the RR, PFS and OS in patients that made in first line, ALK inhibitors rather than platinum-based chemotherapy, which is compatible with the literature and the use of ALK inhibitors in first line in NSCLC ALK-positive patients.

EP1.16-33 QT PROLONGATION IN AN EGFR 19 DELETION LUNG ADENOCARCINOMA PATIENT FROM ICOTINIB TREATMENT

L. Wu[1], H. Chen[1], X. Li[1], Y. Zhu[1], K. Du[1], W. Wang[2], C. Xu[3]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Zhejiang Cancer Hospital, Hangzhou/China,* [3]*Fujian Cancer Hospital, Fuzhou/China*

Background: An increasing number of tyrosine kinase inhibitors (TKIs) are available for the treatment of non-small cell lung cancer (NSCLC). QT prolongation is one of the known, but relatively rare, adverse events of several TKIs (e.g. osimertinib, crizotinib). Screening for QT prolongation in (high risk) patients is advised for these TKIs. When a QT prolongation develops, the physician is challenged with the question whether to (permanently) discontinue the TKI. **Method:** In this perspective, we report on a patient who developed a QT prolongation during icotinib (a first-generation epidermal growth factor receptor [*EGFR*]-TKI) treatment. **Result:** On discontinuation of icotinib, he developed a symptomatic disease flare, not responding to subsequent systemic treatment. The main aim of this perspective is to describe the management of QT prolongation in stage IV *EGFR* 19 deletion mutation NSCLC patients. We also discuss the ethical question of how to weigh the risk of a disease flare due to therapy cessation against the risk of sudden cardiac death. A family history of sudden death and a prolonged QT interval might indicate a familiar long QT syndrome. **Conclusion:** We have summarised the current monitoring advice for TKIs used in the treatment of lung cancer and the most common druge TKI interactions to consider and to optimise TKI treatment in *EGFR* mutation patients.

Keywords: QT prolongation, lung adenocarcinoma, icotinib

EP1.16-34 SURVIVAL ANALYSIS OF ICOTINIB FOR BRAIN METASTASES IN EGFR MUTATED NON-SMALL CELL LUNG CANCER

Y. Zhu[1], C. Xu[2], W. Wang[3], L. Wu[1], H. Chen[1], X. Li[1], C. Xu[4], W. Zhuang[2], K. Du[1], M. Fang[3]

[1]*Zhejiang Rongjun Hospital, Jiaxing/China,* [2]*Fujian Cancer Hospital, Fuzhou/China,* [3]*Zhejiang Cancer Hospital, Hangzhou/China,* [4]*Nantong Tumor Hospital, Nantong/China*

Background: Survival and treatment options are limited for patients with brain metastases arising from non-small cell lung cancer (NSCLC). The aim of this study is to investigate the efficacy and survival analysis icotinib treatment for brain metastasis in non-small cell lung cancer patients with *EGFR* mutation. **Method:** We retrospectively reviewed NSCLC patients with brain metastases who were treated with icotinib, and the survival rate was calculated by Kaplan-Meier method and log-rank test was used to compare the survival rates. Univariate and multivariate factors for survival were analyzed by COX proportional hazards regression model. **Result:** 116 cases of rain metastases in *EGFR* mutated non-small cell lung cancer were female, less than 60 years old and non-smoking patients predominant; COX multivariate analysis found that histologic subtype and EGFR gene subtype were independent prognostic factors for these patients. **Conclusion:** Icotinib showed promising efficacy in NSCLC patients with brain metastases. PFS and OS was longer in patients with adenocarcinoma than in those with a non-adenocarcinoma subtype. PFSand OS was longer in patients with *EGFR* common mutations than *EGFR* uncommon mutations.

Keywords: Non-Small Cell Lung Cancer, brain metastasis, icotinib

EP1.16-35 SURVIVAL OF PATIENTS WITH SMALL CELL LUNG CANCER AT A CANCER HOSPITAL IN THAILAND, 2007-2016

S. Sukauichai

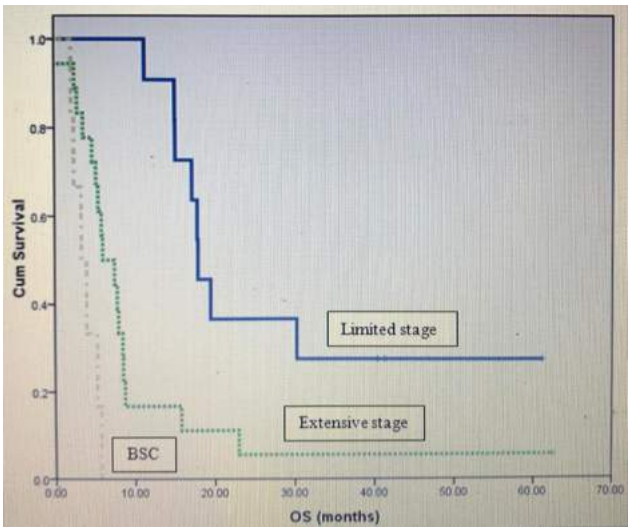
Chonburi Cancer Hospital, Chonburi/Thailand

Background: To determine survival of small cell lung cancer (SCLC) patients treated at Chonburi Cancer Hospital (CCH), Thailand. **Method:** The researcher conducted this retrospective study by review medical records of SCLC patients treated at CCH from Jan, 2007-Dec, 2016 and follow up until Dec, 2018. **Result:** This study enrolled 35 patients with median follow up time 7.9 months. The median age of patients was 61.0. Patient characteristics were male (82.9%), history of smoking (91.4%), clinical SVC obstruction at initial treatment (28.6%), ECOG 0-1 (57.1%), ECOG 2-4 and no record ECOG (42.9%).

Treatment		Concurrent chemo +definitive TRT	Sequential chemo +definitive TRT	Sequential chemo +palliative TRT	Palliative chemo.	BSC +/- TRT	Total N=35
Stage	Limited	4	4	3	0	1	12
	Extensive	1	3	3	11	5	23

BSC; best supportive care, Chemo; chemotherapy, TRT; thoracic radiotherapy

Treatment modality was shown in the table. The first two most common chemotherapy as first-line regimen was cisplatin/etoposide (n=18) and carboplatin/etoposide (n=10). Treatment response was CR 10.3%, PR 44.9%, SD 10.3%, PD 3.4 % and NA 31%. Prophylaxis cranial irradiation (PCI) was done in one patient. Overall survival (OS) of the patient received systemic chemotherapy and/or radiotherapy with limited and extensive stage was 17.77 (95%CI;15.22-20.32)(n=11) and 5.94 (95%CI; 2.60-9.23) (n=18) months, respectively, and those of patient received supportive care was 3.28 (95%CI;1.43-5.13) (n=6) months.



Conclusion: The OS of the limited stage SCLC patients at our hospital was comparable to landmark studies. Nevertheless, the small number of the patient received PCI and most received treatment as sequential chemo-radiation.

Keywords: Survival, small cell lung cancer, real world

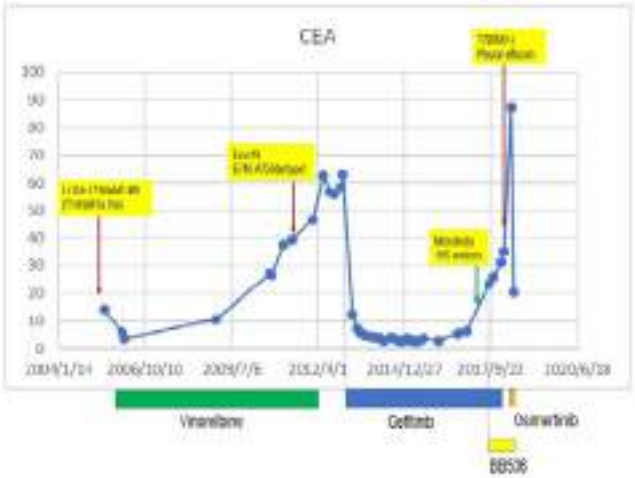
EP1.16-36 A GOOD INTESTINAL BACTERIAL ENVIRONMENT CAN REDUCE THE SIDE EFFECTS OF TYROSINE KINASE INHIBITORS AND ENHANCE THEIR ANTI-CANCER EFFECTS

J. Shimada, S. Okada, H. Tsunezuka, M. Shimomura, S. Ishihara, M. Inoue, Y. Naito

Kyoto Prefectural University of Medicine, Kyoto/Japan

Background: We live in symbiosis with a huge number of microorganisms. Recently, analysis of intestinal bacterial layer has been analyzed in detail in the clinical field by the development of 16S next-generation sequencer. Furthermore, in the lung cancer

region, various tyrosine kinase inhibitors are being administered based on gene mutations of EGF receptor of lung cancer. In this case, an elderly female patient with EGFR gene mutation who was p-stage IVa at the time of surgery was appropriately treated with anticancer agents after surgery and a long-term survival of 14 years after surgery was obtained with a good intestinal bacterial environment. **Method:** The case was a 78-year-old woman at the first treatment in 2004. There was a tumor in the left S4, pleural effusion was positive, and numerous pleural disseminations were observed during surgery (stage Iva). She was treated with vinorelbine alone, taking into consideration her age. The treatment was successful with caution for hematopoietic disorders. She was treated at home, but in October 2011, she observed an increase in CEA and confirmed that the focal gene mutation was the exon 19 deletion E746-A750 deletion type 1. Then, she had multiple systemic metastasis when CEA rose to 63.0ng/mL, gefitinib was introduced in January 2013. Gefitinib responded dramatically, then CEA dropped to 2.8ng/mL and metastases also became CR with dermatitis as an adverse effect. Although she had paronychia in her extremities, she had no gastrointestinal symptoms such as diarrhea and constipation, and her appetite was good. Since there were no digestive tract symptoms at all, analysis of the intestinal flora was analyzed by the next-generation sequencer. **Result:**



The next-generation sequencer has detected no microbiota-disturbing bacteria and balance-regulating bacteria such as Ficarra, fragilis, bifidobacterial, lactic acid bacteria, and equal-producing bacteria. Respiratory distress appeared in November 2017 and a large pleural effusion was noted in the left thoracic cavity. At the same time, CEA rose to 25.9 ng/mL. After genetic mutation check of the pleural effusion, the T790M mutation was confirmed. At this point CEA had risen to 87.4 ng/mL. At this time, Osimertinib was administered, and CEA decreased to about 1/4 to 20.3 ng/mL in two weeks. There were no digestive tract symptoms such as diarrhea and vomiting constipation, and the appetite was also a normal amount. **Conclusion:** A good intestinal bacterial environment can reduce the side effects of tyrosine kinase inhibitors and enhance their anti-cancer effects.

Keywords: Microbiota, tyrosine kinase inhibitor, Bifidobacterium

EP1.16-37 CORRELATION OF SERUM ALBUMIN AND CRP LEVELS WITH CHEMOTHERAPY TOXICITY IN PATIENTS OF METASTATIC LUNG CANCER

S. Saldanha, L. N, L. D, L. Jacob, S. Babu, R. H, R. Lakkavalli, A. Thottian

Kidwai Cancer Institute, Bangalore/India

Background:significant proportion of patients of lung cancer present with metastatic disease. Chemotherapy is often offered as first line treatment if patients does not have driver mutations in a specific targetable oncologic pathway and is fit to receive systemic therapy. Systemic inflammation associated with advanced cancer is often regarded as one of the factors for poor prognosis in lung cancer patients. High level of CRP and low levels of albumin are regarded as markers of systemic inflammation and prior studies have shown poor survival in such patients. It has also been shown that systemic inflammation alters the metabolism of chemotherapeutic agents resulting in either treatment failure or increased toxicity, both of which can lead to poor outcomes. This study aims to identify if increased systemic inflammatory response leads to enhanced toxicity with chemotherapeutic agents used in palliative setting in patients of metastatic lung cancer, and in turn poorer survival. **Method:** Trial design Objectives • Primary objective – Correlating chemotherapy toxicity with patients' baseline albumin and CRP levels • Secondary objective - Correlating CRP and Albumin levels with PFS and OS Materials and Method: • Study Design - Patients with a tissue diagnosis of lung cancer will be prospectively enrolled in the study after informed consent. All clinically relevant details will be entered in a clinical proforma. • Site and duration of study - Kidwai Cancer Institute; June 2018 to Dec 2019 • Sample size – All patients meeting the inclusion criteria between the study time period will be included Inclusion Criteria: • Patients of Metastatic Biopsy Proven Lung Cancer • Age 18 – 80 • Planned for chemotherapy with a platin Doublet • Albumin > 2.0 Exclusion Criteria • Presence of targettable driver mutations • Any other Synchronous / Metachronous cancer • Any other uncontrolled medical comorbidities **Result:** Statistical Analysis The Mann-Whitney U test and the $\chi 2$ test will be used to determine statistically significant differences *1/10/2019 #337: Correlation of Serum Albumin and CRP Levels with Chemotherapy Toxicity in Patients of Metastatic..* https://cpaper.ctimeetingtech.com/elcc2019/submission/preview/print?publication_id=337 2/2 Kaplan-Meier method will be used to assess survival curves; Log-rank test to evaluate the statistical

significance of differences and Cox proportional hazards model for multivariate analysis of the effect of clinicopathological factors on survival. **Conclusion:** This study aims to identify if increased systemic inflammatory response leads to enhanced toxicity with chemotherapeutic agents used in palliative setting in patients of metastatic lung cancer, and in turn poorer survival.

EP1.16-38 PULMONARY INFILTRATES IN PATIENTS TREATED WITH ANTI-PROGRAMMED DEATH-1/PROGRAMMED DEATH LIGAND 1 THERAPY

A. Okada, K. Ota, K. Horimoto, T. Ibaraki, S. Murakami, H. Takenaka, S. Choh

Saiseikai Suita Hospital, Suita, Osaka/Japan

Background: Interstitial lung disease (ILD) is one of the fatal toxicities of anti-programmed death-1 (PD-1)/programmed death ligand 1 (PD-L1) monoclonal antibodies (mAbs). Some possible risk factors are indicated like male, smoker, and previous history of interstitial pneumonia, but clinical, and radiologic features are not well known. **Method:** Patients who received anti-PD-1/PD-L1 monotherapy were identified at our hospital from March 2016 to October 2018. We identified the patients who developed pulmonary infiltrates after PD-1/PD-L1 therapy, cases with confirmed malignant lung infiltration were excluded. We retrospectively analyzed their clinical and radiological features. **Result:** Of 77 patients who received anti-PD-1/PD-L1 mAbs, pulmonary infiltrates developed in 10. The clinical and radiologic features are shown in Table 1,2.

Table.1 Baseline characteristics of 10 patients with pulmonary infiltrates related to immune checkpoint inhibitors.

Conclusion: Pulmonary infiltrates associated with anti-PD-1/PD-L1 mAbs showed variable onset and clinical, and radiologic appearances. Sometimes it is difficult to identify whether it is ILD or infection. Most ILD cases were successfully treated with corticosteroids, but rarely, ILD worsened despite treatment. Thus, careful monitoring including imaging examinations is important to preventing the worsening of ILD.

Keywords: pd-1/pd-l1, pulmonary infiltrates, ILD

EP1.16-39 PROSPECTIVE EPIDEMIOLOGICAL STUDY OF METASTATIC NON-SMALL CELL LUNG CANCER (NSCLC) IN LATIN AMERICA – LATINO LUNG (LACOG 0116)

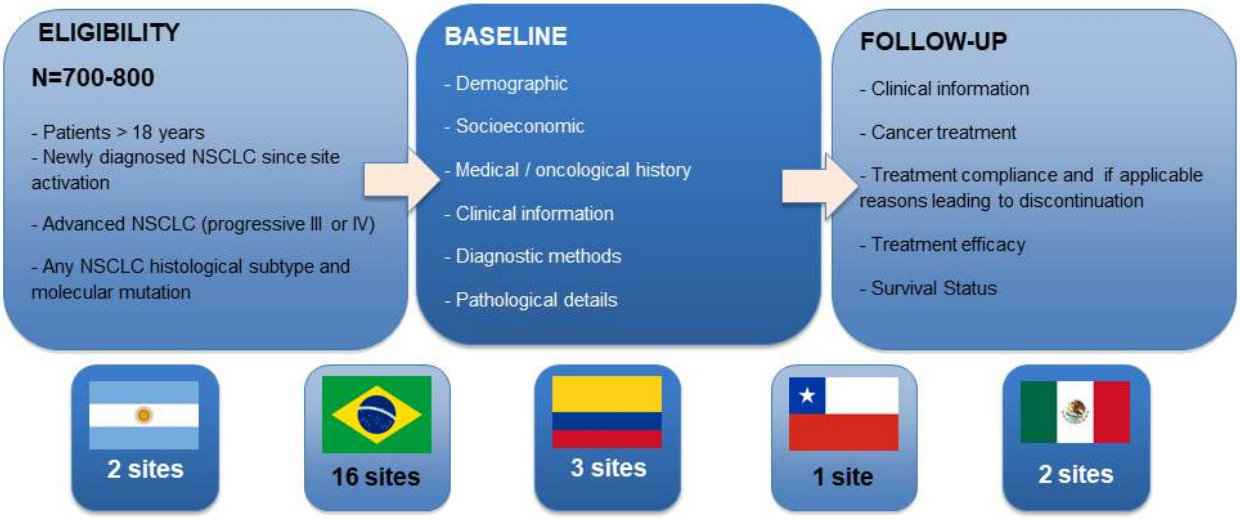
Background: Non-small cell lung carcinoma (NSCLC) is the main cause of cancer-related death in Latin America. Nonetheless, there is insufficient information regarding its epidemiology, treatment and outcomes in the region. The goals of this study are to describe disease characteristics, treatment patterns and survival for advanced NSCLC in Latin America. **Method:** LACOG 0116 LATINO Lung is a prospective cohort study aiming to include approximately 800 patients with advanced stage NSCLC (stage III/IV at diagnosis or distant relapse of early-stage disease) from 24 sites in Brazil, Argentina, Mexico, Colombia and Chile. All consecutive newly diagnosed patients seen at each site will be invited to participate. Data on socioeconomic and demographic characteristics, medical/ oncologic history and clinical-pathological characteristics will be collected at baseline. Thereafter, patients will be followed every 6 months for 3 years in order to gather information regarding treatment patterns and sequencing, reasons for treatment discontinuation, response to treatment, disease progression and overall survival. Data will be collected during medical visits or telephone calls and by medical charts review. Primary endpoint is to estimate the overall survival. Descriptive analysis of treatments and outcomes are planned. Multivariable regression methods will be applied to assess possible independent prognostic or predictive factors. **Result:** As of April 3rd, 2019, 107 patients have been included, all of them within 16 sites in Brazil. Currently, there are 2 sites from Argentina, 2 from Mexico, 3 from Colombia and 1 from Chile awaiting regulatory approval to begin enrollment. Recruitment is planned to last until December 2019, when the estimated sample size will be achieved.



Conclusion: LACOG 0116 LATINO Lung is the first Latin American lung cancer prospective cohort study that will generate real-world data on NSCLC. The study may identify gaps and inequities in a diverse population of NSCLC in Latin America and consequently raise the need for improvement and individualized approach of lung cancer care in the region.

EP1.16-40 COMMUNICATING WITH LUNG CANCER PATIENTS IN EASTERN EUROPEAN COUNTRY: TOPICS OF INTEREST

T. Kovacevic[1,2], B. Zaric[1,2], D. Bokan[1,2]

[1]*Faculty of Medicine, University of Novi Sad, Novi Sad/Serbia,* [2]*Institute for Pulmonary Diseases of Vojvodina, Sremska Kamenica/Serbia*

Background: Sincere and open communication about comprehensive lung cancer (LC) care is often avoided both by physicians and patients. Knowing the patients' points of interest is of great importance for better provision of treatment and further planning of care. Aim of this pilot study was to assess the importance of selected topics for LC patients in order to provide a pathway for improvement of communication with patients. **Method:** This prospective pilot study was conducted at the Institute for Pulmonary Diseases of Vojvodina, Serbia within a one Month period. Consecutive patients with advanced lung cancer in ECOG performance status 0-1 were included in this study regardless of lung cancer type and therapy regimen. Patients filled a questionnaire with 50 selected topics of interest and grading them based on importance using a on 5 point Likert scale. Topics were divided into following sections: diagnosis and prognosis, therapeutic options, care, rehabilitation, supportive and palliative care, psycho-oncology and spirituality. In the last question patients were asked to decide on length or quality of life (QoL). **Result:** The total number of subjects included in this prospective study was 78. Out of total, 66.7% were male and 33.3% female. Average age of subjects was 64 (46-78). Section with topics about diagnosis and prognosis was rated with highest and the one about supportive and palliative care with lowest scores. We observed that topics of highest interest were the goal of therapy, effects of therapy and whether the cancer is curable. Among others most subjects in this study were willing to know more about duration of life when on therapy, how therapy will be applied and should they (and how) change life habits. Least important topics were ones about influence of therapy on sexual life, supportive and palliative care and accommodation in the nursing homes and palliative care units. Out of total, 53.8% of subjects chose quality over duration of life, 15.4% gave priority to life length and the rest (30.8%) could not decide. There were no differences between gender and age. **Conclusion:** Advance communication skills should be equal with other (technical) medical skills. Comprehensive cancer care of LC patients starting from the diagnosis, promoting supportive and palliative care through open communication should be of great importance for all involved parties: patients and their family members and medical staff. Acknowledging important topics and introducing topics of interests for advanced cancer care planning can improve the QoL of LC patients.

Keywords: Communication, Lung cancer, Palliative medicine

EP1.16-41 LUNG LOBECTOMY FOR ELDERLY PATIENTS OVER 85 YEARS OLD IS A RISK OF A COMPLICATION AND LONG-TERM HOSPITALIZATION COMPARED WITH SUBLOBAR RESECTION

K. Nakata[1], K. Suzawa[1], S. Toyooka[1], K. Araki[1], S. Miyauchi[1], A. Miura[1], M. Okazaki[2], H. Yamamoto[1]

[1]*Okayama University Hospital, Okayama/Japan,* [2]*Okayama University, Okayama/Japan*

Background: The increased number of elderly patients with non-small lung cancer underwent lung resection, though the clinical outcome has remained unclear. In this study, we reviewed the postoperative complications and clinical outcome after lung resection in elderly patients over 85 years old with lung cancer, defied as "very elderly patients". **Method:** Among patients who underwent lung surgery for non-small cell lung cancer (NSCLC from 2012 to 2019 in our institute, a total 24 patients were enrolled for this retrospective study. **Result:** During the study period, 24 elderly patients (mean age, 87.3) underwent lung resection, consisting of 14 female and 11 male, 19 adenocarcinomas and 5 non-adenocarcinomas, and 19 c-Stage 0: 1, IA: 16, IB: 3, IIA: 2, IIB: 1, IIIA:1[KS1] (based on UICC 7th edition), and 12 sublobar surgery (6 wedge resections and 6 segmentectomies) and 12 lobectomy. Perioperative complications were observed in 8 patients, and the average hospitalization days are 23.4 days. Next, patients were Stratified by the surgical procedure. The clinical stage is, in limited resection group,cStage 0: 1, 1A: 8, 1B: 3, otherwise in lobectomy group, cStage1A: 8, 1B: 0, 2A: 2, 2B: 1, 3A:1[KS2]. The procedures underwent complete video assisted thoracic surgery are 6 in sublobar resection, 3 in lobectomy. Average operation time is 168 minutes in limited resection, 207 minutes in lobectomy, and blood loss is 48.8 ml and 67.5 ml, respectively. No perioperative mortality was observed within 30 days after surgery. There are more complications in lobectomy group than in limited resection group (50.0%, 25.0%), although the p value was not significant (p = 0.22). [KS3] The patients need HOT after surgery is one in limited resection, two in lobectomy. Especially the frequency of onset of arrhythmia requiring treatment is high, 33.3%, in lobectomy group and one case needs implanting a pacemaker. On the other a patient in lobectomy group onsets appendicitis after thoracic surgery and the patient is proceeded appendectomy. The average hospitalization days in lobectomy group, 32.5 days, are longer than in limited resection group, 14.3 days.(p = 0.20) **Conclusion:** Lung lobectomy in very elderly patients is associated with postoperative complications and prolonged hospitalization compared with sublobar surgery.

EP1.16-42 PHARMACEUTICAL FOLLOW-UP PROGRAM FOR PATIENTS WITH DRIVER MUTATION IN NON-SMALL CELLS LUNG CANCER

G. Moreira[1], C.G. Ferreira[2], T. Montella[1], J. Vasconcellos[1], I. Gonçalves[1]

[1]*Grupo Oncoclinicas, Rio de Janeiro/Brazil,* [2]*Oncoclinicas Institute, Rio de Janeiro/Brazil*

Background: Lung cancer has faced important changes in its recent history. With the improvement of main genetic mutations and its discovery evidences, the target-therapy oriented to specific molecular groups have revolutionized that kind of tumour. Those recent discoveries made possible oral drugs administration procedures at anti-lung cancer treatment. Compared to intravenous therapy, the oral medicine administration brought several benefits, which include the treatment in the comfort of patient's home. However, its use can be frequently associated with some concerns as: treatment adherence, medical conciliation, collateral effects and drug cost. The purpose of this paper is to describe the best practices of follow-up lung cancer patient service model while making use of oral drugs in the household environment. **Method:** This article presents a multidisciplinary team's expertise acting in an oral chemotherapy program, managed by pharmacists between april of 2016 and march of 2019. All patients had driver mutations at non-small lung cancer cells and were being treated at a private medical clinic. **Result:** We developed a service program named as *Projeto Droga Oral (Oral Drug Project)* (Figure 1), in order to contribute to the better management of interdisciplinary team while handling the above mentioned patients. A total number of 77 persons where identified and 9 different drugs where applied: Afatinib, Alectinib, Brigatinib, Ceritinib, Crizotinib, Erlotinib, Gefitinib, Lorlatinib and Osimertinib.

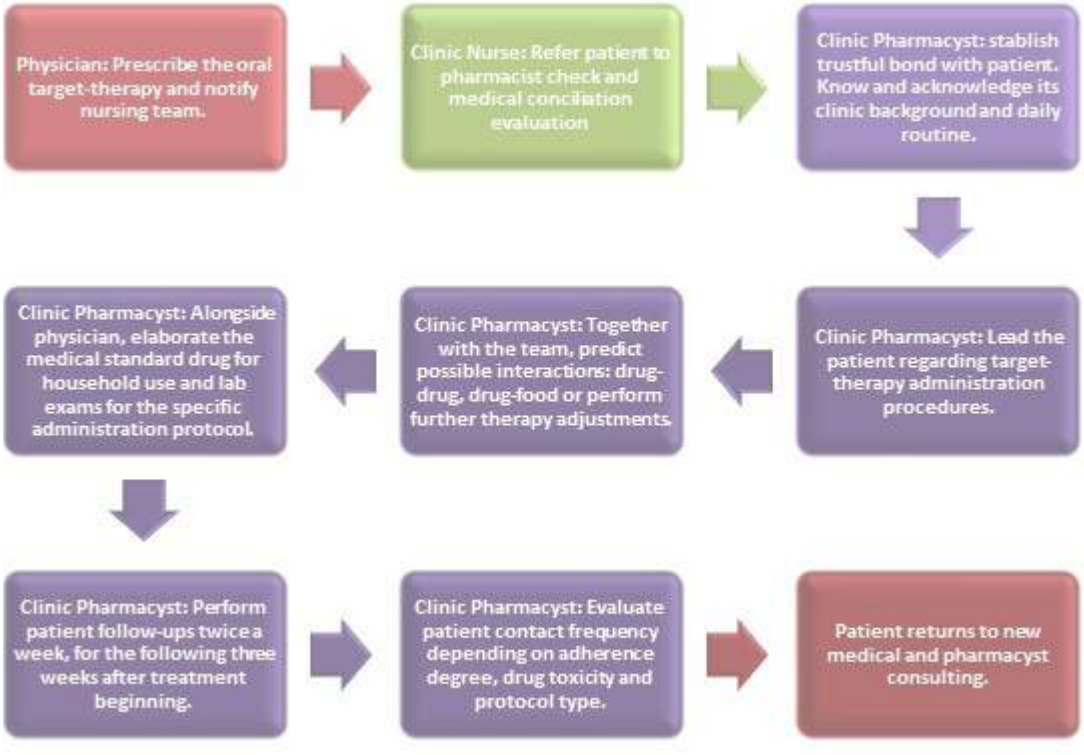

Figure 1: Service flowchart for *Oral Drug Project* Of the mentioned patients, 53% presented drug-drug and 43% drug-food interactions. 95% of all interventions where accepted by multidisciplinary team. No hospitalizations due to drug intoxication were registered and only 2% needed to suspend treatment definitely due to 3rd degree of non-manageable toxicity. 56% presented 1st or 2nd degree of toxicity and prematurely managed. All toxicities were identified and there were no patient abandonment during treatment. **Conclusion:** The *Oral Drug Program* is a key factor to guarantee patient correct follow-ups and treatment success. The development of a support program for the patient and caregiver during the administration of target-therapy at household environment granted the main benefits: quality of life improvement, better therapeutic control, better patient adherence and caregiving management, early problem identification related to the drug use, reduction of hospitalization costs and collateral effects. To ensure the project implementation success, institutional protocol and conduct standardization is mandatory as well as qualified workforce participation and correct patient education about his or her treatment plan.

Keywords: multidisciplinary team, target-therapy, Pharmaceutical follow-up

EP1.16-43 COMBINED PROGNOSTIC VALUE OF CYFRA 21-1 AND CEA IN OVERALL SURVIVAL OF PATIENTS WITH III-IV CLINICAL STAGE NSCLC

C.J. Flores, A. Aguilar, L. Mas, D. Enriquez, J.M. Gutierrez, L. Schwarz, C. Vallejos

Oncosalud - AUNA, Lima/Peru

Background: Despite great advances in diagnostics and treatment, lung cancer still represents a fatal disease worldwide. Most biomarkers that have been described are not reliable neither applicable in clinical practice, however higher mortality has historically been associated to disease burden and blood biomarkers as CYFRA21-1 and CEA. Our aim was to evaluate the combined prognostic value of two known biomarkers (CEA and CYFRA21-1) among patients with III-IV clinical stage NSCLC in a private Peruvian institution (Oncosalud - AUNA). **Method:** We analyzed data of 117 patients with III-IV clinical stage NSCLC, treated at Oncosalud-AUNA between 2011-2014 (Lima - Peru). The clinical-pathological data were collected from digital medical records. Tumor biomarkers (CYFRA 21.1 and CEA) were collected from blood routine test. Optimal cutoff value of CYFRA 21.1 (<3.3 and >3.3) and CEA (<9 and >9) were calculated using the maximally selected rank statistics. OS was determinate using Kaplan-Meier method and survival curves comparison were performed using log-rank or Breslow test. Cox model was used for multivariate analysis. **Result:** The median age was 67 years (range: 40-84) and 49% of patients were women. The 22.4% had ≥2 ECOG scale, and 74.4% were CS IV, and the most frequent site of metastasis was bone (36%) and brain (22%), and adenocarcinoma (82.9%) was the most common histology. The 90.6% of patients received chemotherapy with or without radiotherapy and 9.4% have TKI as front-line of treatment. The median follow-up was 60 months (95%CI: 4.8-5.1), median survival was 1.4 months (95%CI: 1.1 - 1.7), and two and 5 years survival rate were 37% and 18.6%, respectively. The median survival for monotherapy -based treatment was 5.7 months and 17.2 months for combined treatment. In univariate analysis, ≥2 ECOG scale (p = 0.004), IV CS (p = 0.023), NLR >3.6 (p = 0.003), CYFRA 21.1 >3.3 ng/mL (p < 0.001) and CEA > 9 ng/mL (0.045) were associated with poor survival. Age, sex and LMR do not show significant effect. In the Cox model, high values of NLR (HR: 1.6, 95%CI: 1.1 - 2.5), CYFRA 21.1 (HR: 2.4, 95%CI: 1.4 - 4.1) and CEA (HR: 1.9, 95%CI: 1.1- 2.6) was associated with poor prognosis. The high values of CYFRA 21.1 or CEA increment the risk of death by 4 times more than in those with low values (HR: 4.3, 95%CI: 2.1-9.0). **Conclusion:** Patients with combined values of CYFRA 21.1>3.3 and CEA > 9 were associated to high risk of death in our cohort, combined treatments were associated to longer survival.

EP1.16-44 SURVIVAL AND PROGNOSTIC ASSOCIATION OF NON-SMALL CELL LUNG CANCER WITH BRAIN METASTASES AFTER WBRT: A MULTICENTRE STUDY

M. Shuayb[1], M.S.J.R. Shahi[2], M.S. Reza[3], A.M.M. Shariful Alam[2], X. Dong[1]

[1]*University of British Columbia, Vancouver/Canada,* [2]*Ahsania Mission Cancer General Hospital, Dhaka/Bangladesh,* [3]*Square Hospitals Ltd., Dhaka/Bangladesh*

Background: Forty percent of intracranial tumors are metastatic, arising most commonly from lung. To our knowledge, no data is available on prognosis factors of the survival of non-small cell lung cancer (NSCLC) patients with brain metastases in Bangladesh. This study aims to determine overall survival (OS) and identify prognosis factors in NSCLC patients with brain metastases after whole brain radiation therapy (WBRT). **Method:** The study retrospectively investigated histologically proven NSCLC patients with brain metastases at two tertiary hospitals in Bangladesh from January, 2013 to April, 2018. A total of 62 patients were eligible who received 30 Gy (3 Gy per fraction) of WBRT. The primary end point was OS and the secondary endpoint was prognostic association with various factors including patient age and gender, tumor histology, Karnofsky performance status, pleural effusion, primary not controlled, extracranial metastases, the number of brain metastases, surgical resection and diagnosed initially with brain metastases or developed brain metastases later. RTOG Recursive Partitioning Analysis (RPA) was used to categorize the patients. Survival was calculated by Kaplan-Meier method and compared by Log-rank test. Prognostic association was evaluated with Cox proportional hazards model analysis. **Result:** Mean survival of the entire cohort was 5.76 months (95% CI: 4.69 – 6.84 months). Patients with brain metastases at diagnosis or developed brain metastases later during disease progression had a statistically similar mean survival (6.18 months vs. 5.49 months; P = 0.422). Among the 62 patients, 16.1%, 30.6% and 53.2% were RPA Class I, II and III respectively. Mean survival differed significantly among the three classes (Class I: 9.10 months, Class II: 6.68 months, Class III: 3.64 months; P = 0.00). Individual prognostic factors were not found to be associated with survival difference except, single vs. multiple brain metastases (P = 0.042) and primary controlled or not (P = 0.026). **Conclusion:** The study reported survival time of NSCLC patients with brain metastases undergo WBRT, and indicated that higher RPA classes, primary not controlled and greater numbers of brain metastatic lesions are the three prognostic factors of poor survival for this cohort. Our results may help clinicians in patient counseling, treatment selection and designing future clinical trials.

EP1.16-45 THE USE OF PROPENSITY SCORE MATCHING TO ANALYZE THE EFFECTIVENESS OF MEDICAL PROCEDURES ON THE EXAMPLE OF SURVIVAL OF PATIENTS WITH LUNG TUMORS

E. Nojszewska[1], A. Sielska[1], S. Szafraniec-Burylo[2], A. Śliwczyński[3]

[1]*Warsaw School of Economics, Warsaw/Poland,* [2]*Institute of Mother and Child, Warsaw/Poland,* [3]*University of Humanities and Economics in Lodz, Warsaw/Poland*

Background: Cancer diseases are among the most common causes of mortality in Poland, with the highest mortality caused by cancers of the trachea, bronchi and lungs (C33 and C34). Simple comparison of the appropriate median survival rates for groups of patients receiving different treatments would require the assumption of high similarity of the characteristics of the patients, what usually cannot be assumed. The Propensity Score Matching method used among others to assess the effects of treatment addresses this problem. The propensity score vector is defined as the probability of being treated. **Method:** Using the Propensity Score Matching method, the impact of the disease stage was estimated as a conditioning variable on the survival of patients undergoing surgery due to squamous cell lung tumors, registered in the database of the Institute of Tuberculosis and Lung Diseases in Warsaw, Poland. The resulting variable in the study is the change in survival calculated in days for two surgical procedures, that is thoracotomy and VATS. In order to ensure comparability of results obtained for both procedures, the analysis included patients with tumors smaller than 55 mm. 10803 patients who have undergone thoracotomy and 1167 patients who have undergone VATS were identified in the database. Only those stages for which number of observations was at least 1000 were analyzed. The calculations were made using the Matching package in R Software. **Result:** In the case of thoracotomy, stages IIA, IB, IIB were associated with prolonged survival (325, 63 and 124 days respectively), whereas patients in stages IVA, IIIA and IIIB survived accordingly 340, 217 and 453 days shorter. For VATS, only patients in stage IIIA survived for considerably different time than other patients – 329 days shorter. **Conclusion:** Propensity Score Matching method confirmed findings from simple comparisons of the appropriate median survival rates.

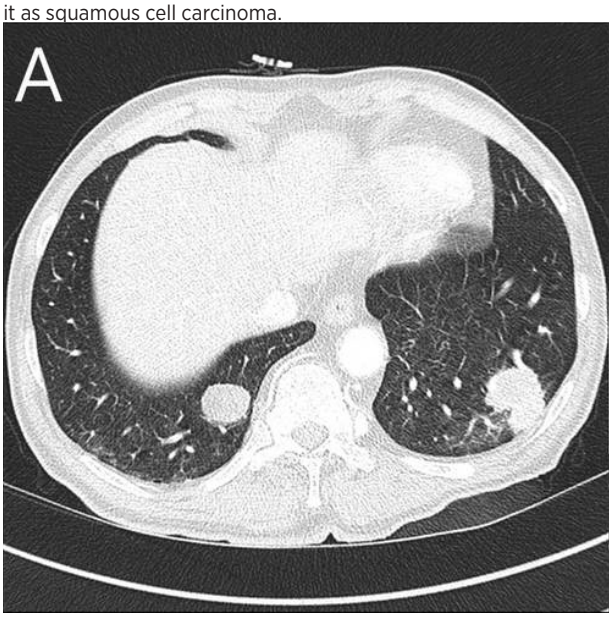
EP1.17 TREATMENT OF EARLY STAGE/LOCALIZED DISEASE

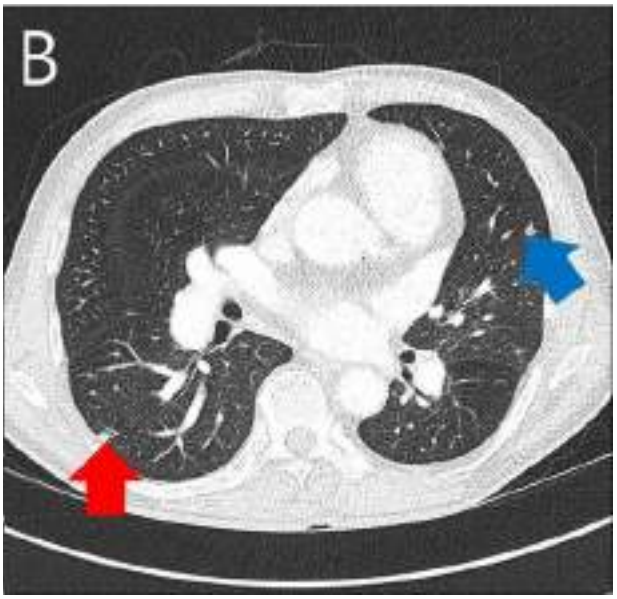
EP1.17-01 SURGICAL RESECTION OF SYNCHRONOUS QUADRUPLE PRIMARY LUNG TUMORS PRESENT AS THREE-DIFFERENT CANCERS AND ONE BENIGN MASS

Y. Lee, S.K. Hwang, G.S. Kim, H.J. Cha

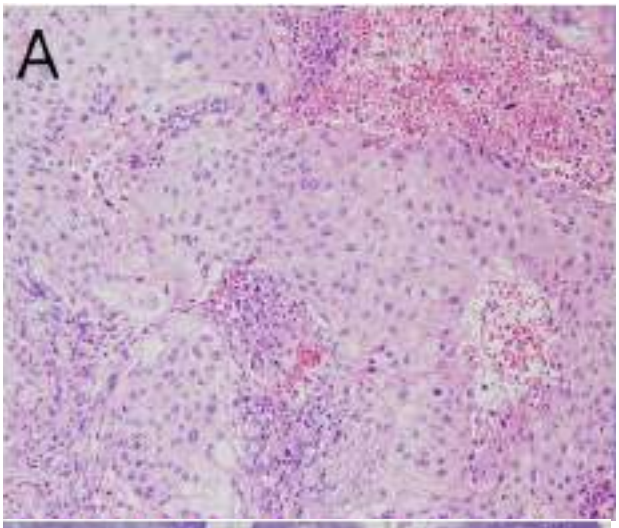
Ulsan University Hospital, University of Ulsan, College of Medicine, Ulsan/ Korea, Republic of

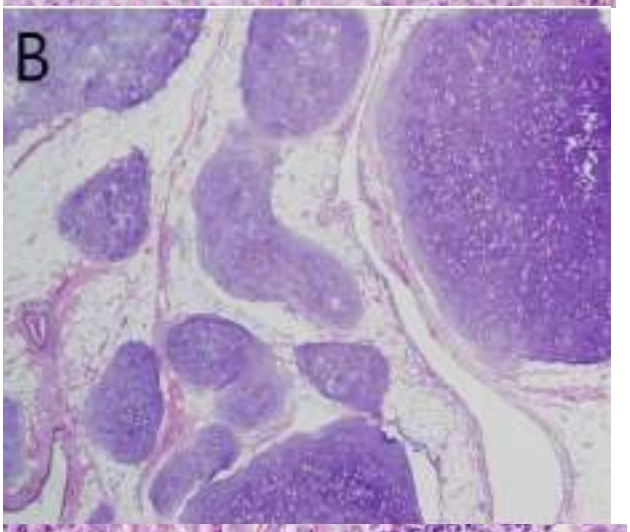
Background: Synchronous triple lung cancer is uncommon and little is known, making it difficult to establish proper guidelines or treatment strategies. In this report, we describe a 70-year-old male with three synchronous independent and histologically different primary cancers and one benign hamartoma. **Method:** Chest CT showed a 30 mm-sized lobulated lung mass in posterior basal segment of the left lower lobe (tumor 1) (Figure 1A). In addition, there were another 26 mm-sized well defined solid nodule in the right lower lobe (tumor 2) (Figure 1A). Two sub-centimeter nodules were also presented in superior segment of the right lower lobe (tumor 3) (Figure 1B) and the lingular segment of the left upper lobe (tumor 4) (Figure 1B). A transthoracic percutaneous needle aspiration biopsy performed on the 30 mm-sized nodule in the left lower lobe revealed it as squamous cell carcinoma.

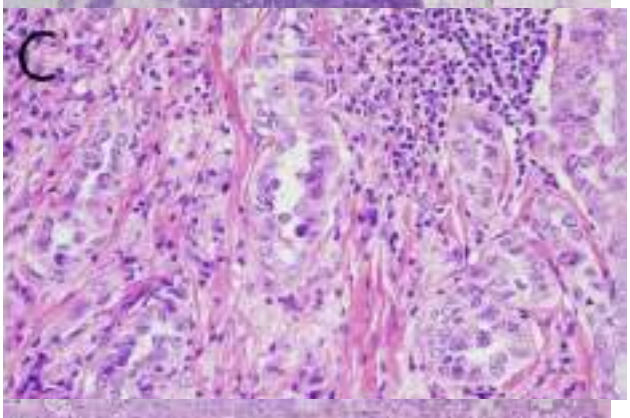


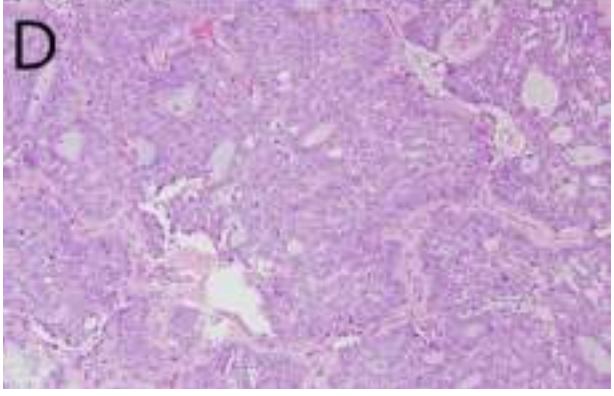


Result: During the right side surgery, intraoperative frozen biopsy of tumor 2 and tumor 4 were reported as chondroid hamartoma and adenocarcinoma, respectively. As we already knew that the left side tumor was squamous cell carcinoma, we decided to continue left side surgery with mediastinal lymph node dissection. The final results of the pathological examination of tumor 1 showed squamous cell carcinoma of pT2bN1M0 (Figure 2A), stage IIB. Tumor 2 was diagnosed as chondroid hamartoma (Figure 2B). Small nodules located in the right lower lobe (tumor 3) and left upper lobe (tumor 4) were 6 mm-sized adenocarcinoma with visceral pleural invasion (pT2aNx) (Figure 2C) and 7 mm-sized adenoid cystic carcinoma (pT1aN0) (Figure 2D), respectively. There was no recurrence during the 3-year follow-up period.









EPOSTERS

Conclusion: Appropriate preoperative staging work up including HRCT and percutaneous needle aspiration biopsy can allow timely detection of synchronous multiple lung cancer, offer proper surgical strategy, and give the possibility of implementing potentially curative treatment for patients conventionally misdiagnosed or considered as metastasized.

Keywords: synchronous tumor, lung cancer, chondroid hamartoma

EP1.17-02 ARTIFICIAL INTELLIGENCE IN THE QUALITATIVE STUDY OF PULMONARY NODULES BY ANALYZING THE GENETIC MAP AND IMAGING DATA OF LUNG ADENOCARCINOMA

Y. Zhang

The First Hospital of Lanzhou University, Lanzhou/China

Background: Artificial intelligence is the most influential technology for the future and the hottest research and technology at present. Lung cancer is the most common malignant tumor with the highest morbidity and mortality. By analyzing the genetic characteristics and imaging of patients with lung adenocarcinoma, this study aims to analyze the pulmonary nodules in the susceptible population to find the most characteristic. Gansu province is an economically backward province in northwest China, with a poor environment, poor living conditions, low level of medical and health services, mainly rural population, per capita income less than 5,000 yuan, and a high incidence and mortality of lung cancer and esophageal cancer. Most patients come to the hospital for treatment are in the middle and late stage of lung cancer, and often miss the best time for treatment. Even if they come to the hospital for treatment, there is no good effect, and bring huge economic burden and family burden. The early diagnosis and treatment of lung cancer is particularly important. Artificial intelligence for lung cancer and population census is an economical, convenient and accurate technology, which will bring huge benefits to people's health. **Method:** In this study, the imaging data of diagnosed lung adenocarcinoma patients with pulmonary nodules and the gene sequencing and mutation point of pathological specimens were studied by artificial intelligence, and the lung cancer genes identified by NICC were compared with deep learning to produce relatively complete learning software. The software was used to select the selected sample population of people with high risk of lung cancer regions, and then the postoperative pathology of pulmonary nodules highly suspected of lung cancer was input into the database, and the preoperative diagnosis of AI was compared and studied to optimize the software. **Result:** It is hoped that this study can develop a set of artificial intelligence software with high accuracy and sensitivity, and then carry out early diagnosis and treatment of lung cancer in high-risk groups. Provide research basis for the genetics of lung adenocarcinoma and the early invasion characteristics of lung adenocarcinoma. **Conclusion:** This study could develop a set of artificial intelligence software with high accuracy and sensitivity, and then carry out early diagnosis and treatment of lung cancer in high-risk groups. Provide research basis for the genetics of lung adenocarcinoma and the early invasion characteristics of lung adenocarcinoma.

EP1.17-03 NEW APPROACH TO COMPLETE VIDEO-ASSISTED THORACOSCOPIC LOBECTOMY IN T2 AND T3 NON-SMALL CELL LUNG CANCER

M. Kato

Hiramatsu Hospital, Ogi City/Japan

Background: The advantages of complete video assisted thoracoscopic surgery(c-VATS) include less postoperative pain and early cosmetic benefit because of the small incision recured. If large tumors can be successfully removed without need for a long thoracic incision or extensive costal rib resection, c-VATS may be performed in patients with stage II or III NSCLC. We herein repot our experience with a novel c-VATS technique that involves removal of resected lung tissu from an abdominal incision in patinets with T2 and T3 NSCLC. **Method:** Fifteen patients with T2 and T3 NSCLC who underwent surgical treatment. Five patients underwent c-VATS lobectomy, and 10 patients under went hybrid VATS(h-VATS), which is performed mainly by direct visualization using video assistance. The tumour large perpendicular was 60 to 140mm in the c-VATS group and 52mm to 82mm in the h-VATSgroup. **Result:** *Surgical procedure.* For lobectomy, the ports were placed in the 3rd, 5fh, and 7th intercostal spaces on the anterior axillary line for the operator and camera pole and in the 6th and 8th intercostal spaces on the infrascapular line for the assistant. An abdominal skin incision of <5cm was then created just below the xiphoid in Fig1. A forceps was inserted through this incision into the intrapleural cavity through the preperitoneal space to remove the resected lung tissu by grabbing the endocatch bag. the resected lung tissue was remoed with the forceps through this route.

Comparison between c-VATS and h-VATS groups. Significantly fewer patients in the c-VATS than h-VATS group developed severe pain in Table1. Fig.1

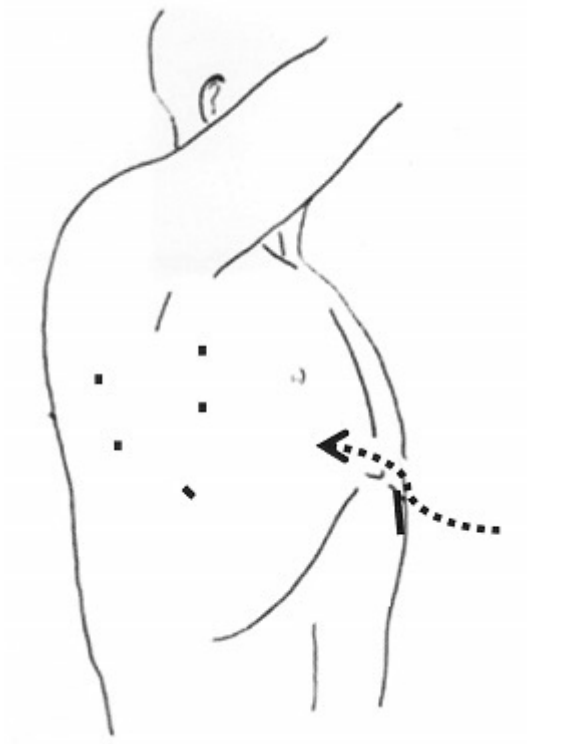

Table 1

	Pain control		
	Yes	No	Total
New procedure	1	4	5
Previous procedure	8	2	10
Total	9	6	15
p-Value	0.025*		

*Calculated by the Chi-squared test.

Conclusion: The present study suggests that the indications for c-VATS lobectomy in patients with T2 and T3 NSCLC can be expanded by implementation of our approach, which involves removal of the free lobe through an abdoninal incision.

EPOSTERS

EP1.17-04 PNEUMONECTOMY SHOULD BE AVOIDED IN PATIENTS WHO DO NOT REACH THE DISTANCE OF 500 METERS IN 6-MINUTE WALKING TEST DUE TO HIGH EARLY MORTALITY

T. Marjanski[1], D. Wnuk[2], R. Dziedzic[1], M. Ostrowski[1], W. Sawicka[2], W. Rzyman[1]

[1]*Medical University of Gdansk, Gdańsk/Poland,* [2]*Medical University of Gdansk, Gdansk/Poland*

Background: Pneumonectomy is required in less than 10% of patients operated for lung cancer. This type of surgery is performed ultimately because of its debilitating character, high morbidity, and mortality. Previously estimated values of the 6-minute walking test (6MWT) performed preoperatively helps to identify high risk of postoperative complications, increased early mortality and worse long term results in patients undergoing lobectomy for lung cancer. The aim of the study was to validate the value of 500 meters in 6MWT differentiating risk of complications in patients undergoing pneumonectomy. **Method:** Between January 2009 and January 2018 1618 patients were operated in the Thoracic Surgery Department. All of the patients were accepted for resection based on a standard evaluation protocol. Additionally, on the day before the surgery, patients performed 6MWT. 141 patients underwent pneumonectomy, but 16 patients did not undergo 6MWT due to different reasons. Finally, 125 patients entered the analysis. The cut-off value of 6MWT – 500 meters was defined in previously published papers in patients requiring lobectomy. This value was validated in the current study in patients who underwent pneumonectomy. **Result:** There were 93 men and 32 women with a mean age of 63 years. All patients underwent pneumonectomies due to primary lung cancer. The cut-off value of 500 meters identified patients with increased 90-day mortality [17.9% vs. 3.5% odds ratio (OR) 6.271 95% confidence interval (CI) 1.528-25.739 p=0.005], and first-year mortality (30.7% vs. 11.6% OR 3.378 95%CI 1.310-8.709 p=0.009), while 30-day mortality (10.3% vs. 2.3% OR 4.800 95%CI 0.840-27.418 p=0.055) fairly reached statistical significance. Patients who covered distance shorter than 500 meters had increased risk of atrial fibrillation (35.9% vs. 16.3% OR 2.880 95%CI 1.207-6.870 p=0.015) and cardiac complications (38.4% vs. 19.8% OR 2.537 95%CI 1.100-5.849 p=0.026). The rates of pulmonary complications, general complications, and duration of postoperative stay did not differ between the study populations. **Conclusion:** Patients who do not reach the distance of 500 meters in 6MWT have a high risk of cardiac complications and early postoperative death after pneumonectomy.

EP1.17-05 UNIPORTAL VIDEO-ASSISTED THORACOSCOPIC SURGERY LOBECTOMY AND SEGMENTECTOMY FOR EARLY STAGE LUNG CANCER

R. Hu

Hangzhou First People's Hospital, Hangzhou/China

Background: With the extensive application of imaging techniques such as HRCT in general and the potential adoption of low-dose spiral CT screening for high-risk former smokers. It is likely that a greater number of small lung cancers will be detected. Uniportal VATS lobectomy and segmentectomy for small-sized lung cancer has been accepted. **Method:** We retrospectively analyzed for 180 patients who underwent Uniportal VATS lobectomy and segmentectomy between January 2018 and December 2018 at our hospital.We reported our uniportal experience, the surgical technique, the extent of lymph node dissection and decision-making of uniportal VATS lobectomy and segmentectomy for small-sized lung cancer. **Result:** 180 patients of early stage lung cancer underwent intended uniportal VATS included 120 lobectomies and 60 segmental resections. The mean operation time was 120.2±40.5 minutes. Chest drain duration was 2.1±0.8 days. The total amount of lymph node stations sampled or dissected were 8.0±0.7. There were no deaths 30 days after surgery. **Conclusion:** Uniportal Video-assisted Thoracoscopic Surgery Lobectomy and Segmentectomy was safe and feasible for early stage lung cancer.

Keywords: Early Stage Lung Cancer, Video-assisted thoracoscopic surgery (VATS)

EP1.17-06 RETROSPECTIVE REVIEW OF INITIAL EXPERIENCE OF ROBOT-ASSISTED LEFT UPPER LOBECTOMY FOR LUNG CANCER IN AN ATTEMPT TO STANDARDIZE ITS PROCEDURE

A. Yamamoto

Kansai Rosai Hospital, Hyogo/Japan

Background: Left upper lobectomy (LUL) is high risk because the incidence of pulmonary artery injury is the most frequent than the other lobes. In Japan, lobectomy by robot-assisted thoracoscopic surgery (RATS) has been accepted by the national insurance since April 2018, many institutes still avoid LUL by RATS. We retrospective reviewed our first 8 cases of RATS-LUL and the results were compared with LUL by video-assisted thoracoscopic surgery (VATS) in an attempt to standardize the procedure of RATS-LUL. **Method:** We have started RATS with da vinci Si since September 2018, and the system was switched to Xi in March 2019. Twenty-six RATS were performed until March 2019 including 23 lobectomies. Nine LUL were found but one was performed for benign disease, therefore 8 cases were included in this study as RATS-LUL group. Twenty-eight LUL by VATS were performed from April 2015 to March 2019, were also included in this study as VATS-LUL group. Two groups were compared statistically and the procedure of RATS-LUL in 9 cases was retrospectively reviewed by the videoin an attempt to standardize its procedure. **Result:** No significant difference was found in sex, age, clinical and pathological stages, nodal dissection between the groups. The average operative time (min), console time (min, RATS only), bleeding (g) in RATS-LUL and VATS-LUL were, 142 (127-226), 102 (58-171), 36 (0-165), and 116 (57-166), not available, 74 (0-391), respectively. The operative time was significantly longer in RATS-LUL (p=0.0156). The duration of chest drainage was significantly shorter (p=0.0294) in RATS-LUL (median 1 day) than in VATS-LUL (median 2 days). By the video review, A3 was transected before bronchial transection in VATS-LUL, however, in all cases of RATS-LUL, A3 was transected after bronchial transection. **Conclusion:** RATS-LUL took longer operative time than VATS-LUL but its extension time was only 26 min. RATS-LUL also showed a shorter duration of drainage than VATS-LUL. In our institute, bronchial transection before A3 transection was the de facto standard.

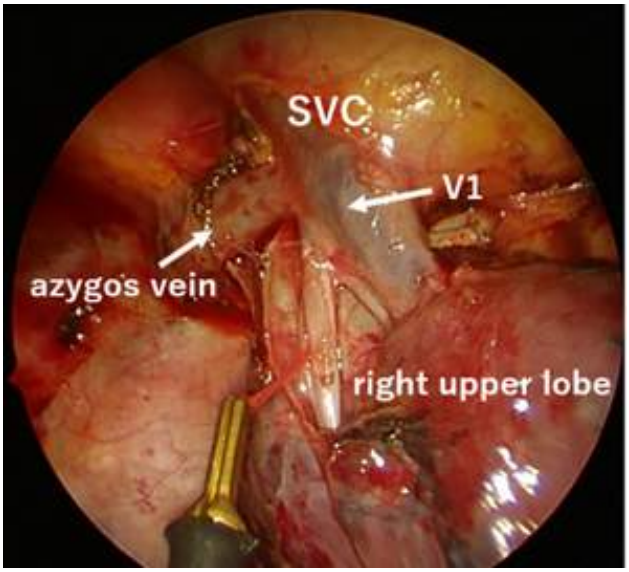
Keywords: robot-assisted thoracic surgery, robot-assisted thoracoscopic surgery, video-assisted thoracoscopic surgery

EP1.17-07 PARTIAL ANOMALOUS PULMONARY VENOUS CONNECTION FOUND DURING A LOBECTOMY FOR LUNG CANCER

F. Yokote, Y. Yamauchi, T. Sakai, Y. Saito, H. Uehara, Y. Sakao, M. Kawamura

Teikyo University School of Medicine, Itabashi/Tokyo/Japan

Background: Partial anomalous pulmonary venous connection (PAPVC) is an uncommon congenital anomaly and asymptomatic in most cases. According to previous reports, PAPVC found during a lobectomy for lung cancer is rare. **Method:** A 76-year-old man who was asymptomatic, was referred to our hospital for an abnormal shadow found in the right upper lobe of the lung on computed tomography (CT) scan. A preoperative thoracic plane CT showed a small nodule in the right lobe. The contrast-enhanced CT for evaluating vascular system was not tested due to his renal dysfunction. **Result:** Right upper lobectomy and mediastinal node dissection was performed without any surgical complications. An irregular vascular access was found intraoperatively that the one of superior pulmonary vein (V1) didn't drain into the left atrium but the superior vena cava. The pathological diagnosis of the right lung tumor was adenocarcinoma, pT1bN0M0 stgeIA-2. The postoperative course was uneventful and echocardiography after surgery showed normal cardiovascular activity.



Conclusion: It is possible that PAPVC of a single anomalous pulmonary vein with an intact atrial septum may not be clinically important. However, when the PAPVC is located in a different lobe, major lung resection (especially pneumonectomy) for lung cancer can result in fatal acute right heart failure due to increased shunting through the PAPVC. Therefore, the preoperative discovery of asymptomatic PAPVC may be very important for patients with planned lung resection. We must carefully interpret the findings of the existing architectural structure, including pulmonary artery, vein, or bronchus, as well as a lung tumor on the CT.

Keywords: Partial anomalous pulmonary venous connection, PAPVC

EP1.17-08 GOOD SURVIVAL IN FEMALES UNDERGOING SURGERY WITHOUT ADJUVANT CHEMOTHERAPY FOR STAGE THREE LUNG CANCER: A REVIEW OF OUR 12-YEAR EXPERIENCE

J. Chen, H. Muthiah

National University Hospital Singapore, Singapore/Singapore

Background: Lung cancer is a major disease in Singapore. Anatomical surgical resection is the treatment of choice for early lung cancer. No study on outcome of surgery on early lung cancer has been reported in a mixed Asian population. We aim to review the outcome of patients with early lung cancer who underwent surgery in our tertiary centre. **Method:** We performed a retrospective cross-sectional study on all patients who underwent lung resection between 1st January 2006 and 31st December 2017. Information collected included patient's age, gender, race, stage of disease and outcome data. Those with a diagnosis of primary lung cancer were included whilst those whose surgery was not for curative intent were excluded. **Result:** 404 patients are included in our study. The mean age is 62.9 years with the modal age group between 60 and 69 years old. Females are significantly younger than males (mean 61.6 years vs 64.0 years, p = 0.019). 76.6% (n = 310) are early disease (Stage 1 or Stage 2) and 20.0% (n = 81) are late disease (Stage 3). Overall survival is significantly higher in early than late disease and in females than males. In female patients with Stage 3 disease, there is no significant difference in 1-year survival between early (97.3%) and late (89.7%) (p = 0.177) disease. Those aged between 70 and 79 years has a significantly higher mortality at 3 years (27.3%, odds ratio 3.73 (1.0 – 13.5, CI 95%)). There is no significant difference in 3 year mortality between early and late disease in females younger than 60 years old (87.5% vs 77.8%, p = 0.303). T3/T4 disease patients have better survival rates than N2 disease patients. All female patients with T3/T4 disease are still alive at 5 years even in those without adjuvant chemotherapy. In females with N2 disease, 3 and 5-year survival is also higher in patients with partial or no adjuvant chemotherapy but this is not statistically significant. The use of adjuvant chemotherapy is also associated with a significant higher rate of recurrence (53.5% vs 16.1%, p = 0.001) in all patients with Stage 3 disease, especially in female patients (68.2% vs 18.2%, p = 0.009). In females with N2 disease, the recurrence rate is significantly higher in those who had adjuvant chemotherapy (68.4% vs 25.0%, p = 0.049). For those with T3/T4 disease, there is no recurrence in patients who did not have any adjuvant chemotherapy but this is not statistically significant. **Conclusion:** Our study demonstrate that female patients with early lung cancer present earlier and have significant higher survival rates than males. Even in patients with stage 3 disease, there is good survival benefit up to 3 years post-surgery for patients aged 60 years old and below. Three and five year survival are better in female patients with N2 disease who did not have or did not complete their adjuvant chemotherapy than those who did. The use of adjuvant chemotherapy is also associated with a higher rate of recurrence, especially in females with N2 disease.

EP1.17-09 SURVIVAL ANALYSIS OF 911 PATIENTS WITH SURGICALLY RESECTED LUNG CANCERS

J. Zhang[1], N. Chen[2], J. Qi[1], Q. Liu[1], B. Zhou[1], X. Qiu[1]

[1]*China Medical University Lung Cancer Center, The First Hospital of China Medical University, SHENYANG/China,* [2]*Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, SHENYANG/China*

Background: To summarize the treatment results of surgically resected lung cancers. **Method:** Survival analysis was conducted in 911 cases of lung cancers surgically resected during the period of April 2000 to July 2010; 577 (63.3%) were male, 334 (36.7%) female; aged 16 to 85 years-old (middle 60); 455 (49.9%) were smokers. **Result:** Lobectomy and lymph node dissection were undergone. The1, 3, 5, 10-years survival rate for this group of resected lung cancers was 81%, 62%, 53% and 43%, respectively; the middle survival time was 85.5 months. Univariate analysis revealed that gender, smoking status, histology and pathological stages (pTNM stages), tumor size (T factor), lymph nodes' metastasis (N factor), and postoperative adjuvant chemo-radiation therapy were important prognostic factors affecting the postoperative survival significantly (P<0.05). The1, 3, 5, 10-year survival rate for this group of resected stage I (336 cases) lung cancers was 94%, 79%, 75% and 62%, respectively, the middle survival time 132 months; stage II (234 cases): 78%, 60%, 48% and 32%, respectively, the middle survival time 64 months; stage III (242 cases): 69%, 45%, 33% and 24%, respectively, the middle survival time 33 months (P=0.000). The1, 3, 5, 10-years survival rate for resected adenocarcinoma (491 cases) was 85%, 65%, 53% and 39%, respectively, the middle survival time 84 months; squamous cell carcinoma (315 cases): 79%, 60%, 53% and 45%, respectively, the middle survival time 91 months; adenosuamous carcinoma (17 cases): 82%, 58%, 58%, and none, respectively, the middle survival time 78 months; small cell lung cancer (43 cases): 64%, 44%, 33% and none, respectively, the middle survival time 32 months (P=0.011). The1, 3, 5, 10-years survival rate for those who received adjuvant chemo or chemo-radiation therapy (319 cases) was 87%, 73%, 67% and 64%, respectively, the middle survival time 132 months; who did not receive adjuvant chemo or chemo-radiation therapy (592 cases): 78%, 57%, 46% and 36%, respectively, the middle survival time 57 months (P=0.000). **Conclusion:** Pathological stages and postoperative chemo-radiation therapy are independent prognostic factors for surgically resected lung cancers. Surgically resected early stage lung cancers have much better prognosis; postoperative adjuvant chemo-radiation could improve prognosis of surgically resected lung cancers. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05, 17-230-9-71)

EP1.17-10 FIRST RESULTS OF THE BRONCHIAL CANCER REGISTRY OF THE THORACIC ONCOLOGY INTERGROUP (IGOT) OF CASABLANCA, MOROCCO

S. Waguaf, S. Boubia, N. Idelhaj, M. Ridai

Thoracic Surgery Department, CHU Ibn Rochd, CASABLANCA/Morocco

Background: Primary bronchial cancer is the leading cause of cancer deathwith an estimated incidence of 1.6 million new cases per year and a mortality rate of 1.4 million per year. In Morocco, according to the Casablanca Cancer Registry, itaccounts for 22.1% of all cancers. The objective of this work is to describe the epidemiological, clinical, pathological and therapeutic characteristics of patients diagnosed with primary bronchial cancer. **Method:** This is a descriptive

retrospective study of a series of 74 cases, conducted by the Thoracic Oncology Intergroup (IGOT) of the Ibn Rochd University Hospital Center in Casablanca from January 2016 to October 2018 and which met the inclusion criteria. All records of patients diagnosed with primary bronchial cancer were retained based on histopathological examination of operative specimens. **Result:** The majority of patients were diagnosed in the later stages of the disease:stage I and II :9,3%, stage III:16% and the stage IV:73,7%. We were able to operate only 6.3% of the 9.3% resecable which is 74 patients. There were 56 men (76%) and 18 women (24%) with a sex ratio calculated at 3.11. The average age was 58.5 years, with age extremes ranging from 24 to 82 years. 35% of our patients had histological confirmation at the time of the diagnosis carried out by the flexible bronchoscopy or the scanno-guided biopsy puncture. Occupational exposure was not noted in our patients. 65% of our patients were smokers. The medical pathological antecedents were tuberculosis in 10% of cases, arterial hypertension in 10% of cases, diabetes in 8% of cases and chronic obstructive pulmonary disease in 4% of cases. Neoplastic antecedents were lung cancer in 4% of cases, digestive cancer in 4% of cases, breast cancer in 3% of cases, cancer of the Otorhinolaryngology sphere in 6% of cases. The average consultation time exceeded three months in 80% of cases. The symptomun derlying the consultation was chest pain in 46% of cases. The radiological lesions were preferentially located at the level of the right lower lobe. The PET-Scan was performed in 65% of the cases and the respiratory functional exploration in 93% of the cases. Neoadjuvant chemotherapy was necessary in 32% of cases and neoadjuvan tradiotherapy in 19% of cases. The treatment was surgical. Surgical approache was postero lateral thoracotomy in 21 cases (28%) and video-assistedt horacic surgery (VATS) in 53 cases (72%). Conversion to thoracotomy was necessary in 9 cases. The interventions performed were 63 lobectomy (85%) and 11 pneumonectomy (15%).The average size of the tumor was 5.5 cm (0.5-12 cm). The predominant histological type was adenocarcinoma in 64% of cases. On the evolutionary level, in the short term, the operative follow-up was simple in 80% of the cases. The other cases had various complications. The main complication recorded was prolonged bubbling in 3.2% of cases. **Conclusion:** The very low level of stage I and II at the time of diagnosis requires sensitization on the interest of screening and early diagnosis so that patients can benefit from endoscopic treatment.

Keywords: VATS, thoracotomy, bronchial cancer

EP1.17-11 NON-SMALL CELL LUNG CANCER SURVIVAL: GENDER INEQUALITY AFTER LUNG RESECTION?

M.T. Tsukazan[1], A. Vigo[2], J. Rios[3], A. Schneider[3], J.R. Schmitt[3], T. Lima[3], R. Ruszkowski[1], P.A. Schulze[1], J. Figueiredo Pinto[1]

[1]*PUCRS Medical School, Porto Alegre/Brazil,* [2]*Universidade Federal do Rio Grande do Sul, Porto Alegre/Brazil,* [3]*Hospital Sao Lucas da PUCRS, Porto Alegre/Brazil*

Background: Gender has been reported as a predictor factor for non-small cell lung cancer survival. Economical status has also been associated with poor prognosis. The objective of this study was to evaluate weather gender or public versus private healthcare assistance is prognostic variables after lung anatomical resection. **Method:** Retrospective analysis of patients with non-small cell lung cancer (NSCLC) surgically resected between January 2008 and December 2013 in a single institution. Gender and type of healthcare system used were evaluated for five-year survival analysis using Kaplan-Meier and log-rank test, as well as by means of Cox proportional hazards regression, adjusted and non adjusted for propensity scores. **Result:** In our study, 300 patients underwent lung anatomical resection for NSCLC, 141 (47%) were women, mean age 63.8 years (10.43), 195 (65%) were from public healthcare system, 254 (84.7) had lobectomy, 145 (48.3%) had adenocarcinoma. Five-year survival for women was 56.1% and men 42,4% (log-rank p=0.003). Five-year survival for public healthcare was 46.0% and private 54.4% (log-rank p=0.133). Female gender was a prognostic factor predicting better survival. However, that was not confirmed after adjusting for propensity scores: HR 1.28 (95%CI 0.91-1.81) for 60-month survival. Public healthcare assistance had no survival difference with patients with private healthcare, HR 1.15 (95% CI 0.80-1.66). **Conclusion:** After adjusting, female gender is not an independent prognostic factor predicting better survival for lung cancer. Patients with lower economic status (public healthcare) treated within the same institution and group of surgeons had no difference in five-year survival compared to patient with access to private healthcare.

Keywords: Gender, Survival, Lung cancer

EP1.17-12 MULTIMODAL AGGRESSIVE MANAGMENT FOR ASKIN' TUMOR: RESULTS AND PROGNOSIS ABOUT 3 CASES

I. Alloubi[1], S. Afqir[2], A. Sbai[2]

[1]*CHU Med VI, OUJDA/Morocco,* [2]*CHU Oujda, OUJDA/Morocco*

Background: Peripheral primitive neuroectodermal tumor (pPNET) is a highly aggressive small round cell tumor belonging to PNET/Ewing sarcoma family. Askin's tumor is a rare entity of neuroectodermal pathology that starts from the soft parts of the chest wall. It is observed with predilection in the young subject. Herein; We discuss follow up of three cases after multimodal therapy. **Method:** We report the case of three patients aged respectively 18; 20; 60 years; whose main symptom in consultation is the appearance of a thoracic parietal mass gradually increasing in size and painful. The general condition was completely preserved in all three patients; and the clinical examination is without abnormalities apart from clubbing in the person aged on a past of smoking. Imaging revealed the presence of a thoracic parietal tumor, the largest of which was 15 X 10X 6 cm without signs of locoregional or distant extension with weak contrast. The histological diagnosis was made on a transparietal mass biopsy with a conclusive immuohistochemical study in favor of a PNET tumor (Askin'tumor) **Result:** Management was multimodal with 6 aggressive chemotherapy cycles, followed by extensive carcinologic resection surgery and radiation therapy on the tumor bed. We deplore the loss of a patient after distant recurrence in 8th month; the other two patients remain alive after 25 and 36 months of progression without recurrence. **Conclusion:** Askin's tumor is a bone or extra-bone tumor that is histologically similar to Ewing's sarcoma and PNET, which is characterized by its thoracic location. These three tumors appear to represent different forms of the same entity. They present the same specific chromosomal translocation (11q24-22q12) and, in immunohistochemistry, the same expression of the MIC2 oncogene (CD99) and of the translocation-related FLI-1 protein. The diagnosis is often made at the late stage of locoregional or remote invasion. The treatment is mainly based on surgery and radiotherapy and postoperative chemotherapy to reduce recurrence. The prognosis is unfavorable with a survival at 2 years not exceeding 40% after treatment. Pulmonary metastases are frequently observed even a few years after surgery.

EP1.17-13 OPERATED STAGES I-IIIB NSCLC AMONG YOUNG INDIAN COHORTS - CLINICAL PROFILE AND OUTCOMES

J. Saikia, P. Malik, K. Madan, D. Jain, S. Bharati, M. Gowda, S. Nandi, S.V.S. Deo, S. Kumar

Dr Brairch, All India Institute of Medical Sciences, New Delhi/India

Background: Lung cancer is the third highest cause of mortality in India. Young lung cancers are on a rise and the characteristics of operable NSCLC among these group needs evaluation. We aim to compare the differential risk factors of Indian young NSCLC patients compared to the older group who underwent resection. **Method:** A retrospective analysis of NSCLC patients operated from May 2012 to December 2018 at DR.BRAIRCH, All India Institute of Medical Sciences, New Delhi, India. Patients were divided into two groups, group (Gp)-YON includes young patients (defined as age 50 years or less) and Gp-OLD includes those older than 50 years. Factors analysed were demographics, histology, stage, disease free survival(DFS) and overall survival(OS) rates. **Result:** A total of 143 patients of NSCLC underwent resection (including those post neoadjuvant chemotherapy). Gp-YON includes 37 (26%) and Gp-OLD 106 (74%) patients. Significant differences were observed between Gp-YON vs GP-OLD among non-smokers 40% vs 26% (p=0.025). Young females were higher in number 27% vs 18% but was insignificant (p=0.229). Other factors between the two groups like performance status(ECOG-2) 5% vs 4% (p=0.297), histologic subtypes(p>0.05)-squamous cell carcinoma(49% vs 55%), adenocarcinoma(38% vs 43%) and NSCLC(not otherwise specified) (2% vs 4%) did not reach statistical significance. The distribution of cases in various stages

were stage IA(13% vs 18%), IIA (24% vs 17%), IIB (18% vs 16%), IIIA 35% vs 36%) and IIIB (10% vs 13%). Stage for stage evaluation was insignificant(p>0.05). Family history, FEV1, intraoperative blood loss, postoperative complications, chest tube drainage and postoperative hospital stay were also insignificant (p>0.05). Distant metastases was lesser in Gp-YON (27% vs 16%, p=0.046). Median follow up was 40.7 months (95%CI 29.7-47.2).The median DFS in Gp-YON (23.3 months, 95% CI: 17.1-28.5) was higher than Gp-OLD (13.6 months, 95% CI: 10.1-15.3). Median OS in Gp-YON (38months, 95% CI: 32-45) was also higher than Gp-OLD (24months, 95% CI: 19-27). Only independent adverse prognostic factor was NACT(neoadjuvant chemotherapy) (HR,2.254, CI:0.98-5.15,p=0.050). **Conclusion:** The number of young operable lung cancer is increasing in India (26%). Non-smokers contribution is significant. Incidence among young females is slightly higher. Patients receiving NACT has an adverse prognosis. Histologic type has no predilection to young age. No survival difference among young compared to old with respect to TNM substages. Distant metastases is lesser in young. Short-term follow up shows that overall young patients have a better DFS and OS as observed from our study.

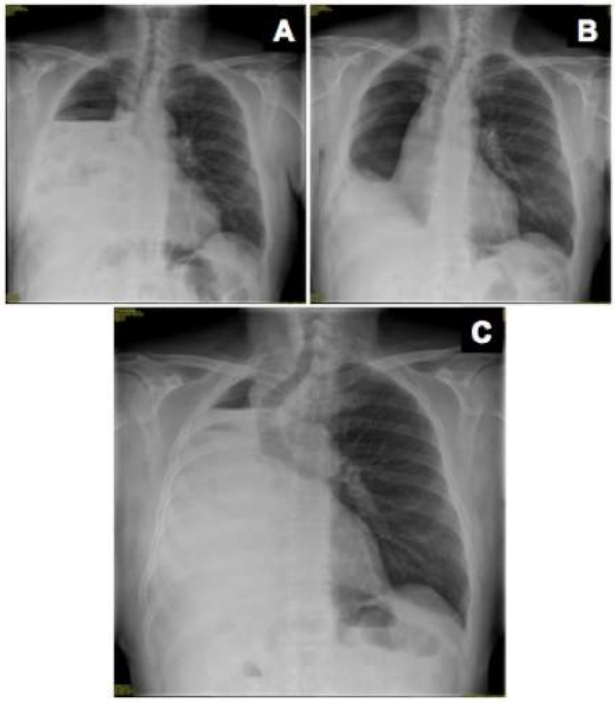
Keywords: NSCLC, young, India

EP1.17-14 LESS IS MORE: AN UNUSUAL CASE OF BENIGN EMPTYING OF THE POST - PNEUMONECTOMY SPACE

G. Bocchialini, C. Braggio, L. Ventura, M. Pagani, P. Carbognani, M. Rusca, L. Ampollini

University Hospital of Parma, Parma/Italy

Background: To describe an unusual case of benign emptying of the post-pneumonectomy space. **Method:** A 68-years-old man presented to our clinic with a large swelling located on the previous thoracotomy increasing at Valsalva maneuvers. One month before he underwent right pneumonectomy for lung adenocarcinoma. He was discharged on the seventh post-operative day uneventfully. Patient denied any history of chest trauma, fever, neither productive cough nor vomica. Chest X-Ray showed a drop of the air-fluid level within the post-pneumonectomy space. Suspecting of a broncho-pleural fistula (BPF), patient underwent a flexible fiberoptic bronchoscopy which showed a regular bronchial stump. A chest CT-scan revealed an empty right hemithorax associated with an air collection in the subcutaneous tissues. No pleural puncture was performed, in order to avoid any contaminations of the pleural cavity. A BPF was ruled out; a watchful waiting approach without surgical intervention or antimicrobial therapy was decided. A roentgenogram 10 weeks later showed the almost refill of the pleural cavity and at physical examination the swelling was dramatically decreased. At chest CT-scan 3 months later the post-pneumonectomy space was completely filled by fluid associated with an overexpansion of the residual lung. After one year the patient is healthy and disease-free. **Result:** Patient's presentation meets the clinical and laboratory criteria of Benign Emptying of the Postpneumonectomy Space (BEPS) (afebrile, normal WBC, no fluid expectoration, negative bronchoscopy, negative pleural culture if performed). Among the hypotheses about the pathogenesis of BEPS we advocated the valve-like mechanisms of "occult bronchopleural fistula", which was large enough to let enter only air into the postpneumonectomy space although arresting the passage of pleural effusion to the airways. A spontaneous healing of the micro-fistula was maybe the underlying mechanisms of the refilling of the thoracic cavity. BEPS seldom occurred after pneumonectomy although it should be considered during differential diagnosis of a sudden drop of the pleural fluid especially in asymptomatic patients, in order to avoid unnecessary invasive procedures.



Conclusion: Benign emptying of the postpneumonectomy space should be considered when facing with a sudden drop of the pleural fluid in asymptomatic patients in order to avoid unnecessary invasive procedures.

Keywords: pneumonectomy, Lung cancer, bronchopleural fistula

EP1.17-15 COMPARISON OF LONG-TERM OUTCOME OF WEDGE RESECTION, ANATOMICAL SEGMENTECTOMY AND LOBECTOMY IN STAGE I-II NON-SMALL CELL LUNG CANCER

K. Sinn, E. Gschwandtner, A. Steindl, S. Taghavi, W. Klepetko, T. Klikovits, M.A. Hoda

Medical University of Vienna, Vienna/Austria

Background: In patients with early stage non-small cell lung cancer (NSCLC) lobectomy is still considered the treatment of choice, whereas sublobar resection is more frequently performed in patients with reduced lung function and high perioperative risk. We investigated long term outcome of patients undergoing either lobectomy or anatomical segmentectomy or wedge resection for early stage NSCLC. **Method:** In this retrospective cohort study patients with early stage NSCLC who underwent either lobectomy or anatomical segmentectomy or wedge resection at our center between 2006 and 2018 were analyzed. Primary endpoint was overall survival (OS) and disease-free survival (DFS). **Result:** 383 patients with peripherally located stage I or II NSCLC (TNM 8) who underwent curative intent surgery were identified. Patients undergoing neoadjuvant or adjuvant treatment or with centrally located tumors were excluded. 325 patients (84.8%) received lobectomy, 26 patients (6.8%) anatomical segmentectomy and 32 patients (8.4%) wedge resection. Pathological stage was IA 221 (57.7%), IB 93 (24.3%), IIA 48 (12.5%), IIB (3.9%). Histology revealed adenocarcinoma in 285 (74.4%), squamous cell lung cancer 98 (25.6%). There was no significant difference regarding OS and DFS between all three groups. Interestingly, in patients with tumors larger than 2cm there was also no significant difference in OS and DFS between all groups. **Conclusion:** The relevance of sublobar resection in early stage NSCLC patients is still controversial. In our cohort study the long-term outcome of anatomical segmentectomy and wedge resection was comparable to outcome after lobectomy. However, well-designed prospective randomized studies are necessary to confirm the value of sublobar resections for stage I and II NSCLC.

Keywords: segmentectomy, Wedge, Sublobar

EP1.17-16 ULTRA-SMALL LUNG CANCER (≤0.5CM) IS FACING DILEMMA SITUATION OF OVER-RESECTION

J. Zhang[1], N. Chen[2], B. Zhou[1], X. Qiu[1]

[1]*China Medical University Lung Cancer Center, The First Hospital of China Medical University, SHENYANG/China,* [2]*Department of Logistic Management, College of Economics and Management, Liaoning University of Traditional Chinese Medicine, SHENYANG/China*

Background: Lung cancer is increasing rapidly in China. More and more ground-glass opacity (GGO) nodules, micro-small pulmonary nodules (micro-SPN, ≤1.0cm), and ultra-small pulmonary nodules (ultra-SPN, ≤0.5cm) are being detected, most are not malignant, some are atypical adenomatous hyperplasia (AAH), but some are indeed early stage lung cancer, either adenocarcinoma in situ (AIS) or minimally invasive adenocarcinoma (MIA). Limited resection is reasonable for these micro-small lung cancer (micro-SLC, ≤1.0cm), and ultra-small lung cancer (ultra-SLC, ≤0.5cm), but we always face the dilemma situation that the patients prefer to ask for lobectomy instead of limited resection, no matter what the postoperative pathology will be, a MIA, AIS or just an AAH. For some patients, especially those with family cancer history suffer more mental pressure than others. On the other hand, we face the dilemma situation that when surgery performed at early stage, ultra-SPN stage, the result will be ultra-SLC, AIS, or AAH; when follow-up finds GGO nodules growing up, emerging with malignant signs, it will enter into micro-SPN stage, we may need to cut more lung tissues, the result will become micro-SLC, MIA; when enter into SPN (≤2.0cm) stage, it may become SLC (≤2.0cm), invasive lung adenocarcinomas (ILA). **Method:** Video-assisted thoracoscopic surgery (VATS) and minimally invasive small incision, muscle- and rib-sparing thoracotomy (miMRST) were performed. Case 1: male, aged 60 in 2015, a peripheral ultra-SPN, GGO nodule, 0.3X0.3cm in right upper lobe; it became 0.5X0.3cm in Jan 2018, *VATS* wedge resection was performed. Case 2: female, aged 59 in 2013, an ultra-SPN, GGO nodules, 0.5X0.3cm in right middle lobe; the patient omitted it until it became 0.8X0.6cm in Nov 2016, VATS wedge resection was performed. Case 3: male, aged 55 in 2016, an ultra-SPN, GGO nodules, 0.5X0.4cm in lingular segment, segmentomy was advised; the patient refused; it became 1.0X0.8cm in Jan 2019, lingular segmentomy with lymph node sampling was advised, but the patient insisted on asking for lobectomy, instead of limited resection (both his brothers suffered from lung cancer). miMRST was performed for case 3. **Result:** The patients recovered quickly from mini-invasive surgery. The final pathology was AIS, or MIA. Case 1: the frozen pathology was AAH; the postoperative pathology was AIS. Case 2: the frozen pathology was AAH; the postoperative pathology was MIA. Case 3: the frozen pathology was AAH; the postoperative pathology was MIA. No adjuvant treatment needed. Follow-up shows no recurrence and metastasis. **Conclusion:** Certain GGO nodules progress rapidly, surgery should be performed at much earlier stage, ultra-SPN stage, ultra-SLC stage might be of first choice. For Case 1: if the surgery was done earlier, the final result might be AAH, instead of AIS. For Case 2, 3: if the surgery was done earlier, especially at ultra-SPN stage, the postoperative pathology should be AAH, AIS, instead of MIA. To perform surgery at much earlier stage could help save much more lung tissues, to achieve a much better prognosis for micro-SLC and ultra-SLC patients. (This study was partly supported by Science Foundation of Shenyang City, China, No. F16-206-9-05, 17-230-9-71).

EP1.17-17 FEASIBILITY STUDY ON THE CENTRAL OF MASSIVE LESION IN NON-SMALL CELL LUNG CANCER WITH HIGH-DOSE RADIOTHERAPY

J. Li

Fujian Medical University Cancer Hospital, Fujian Cancer Hospital, Fuzhou/China

Background: Radiotherapy of the massive lesion in Non-small cell lung cancer remains a great challenge because of the dose limitation due to the normal tissue damage. This study aims to explore the potential feasibility, adding high dose for the central of massive lesion in NSCLC and the surface of massive lesion is conventional dose. **Method:** Patients with massive lesion in NSCLC (tumor volume>500cm^3) who required radiotherapy were enrolled in this study. In the first course of radiotherapy ,the Dose of tumor is divided into 3 parts, PTV of tumor was received 200cGy/F×10 times, the surface of tumor was received 250cGy/F×10 times, The central of massive lesion(delineated by reducing a 3D margin of 1-2 cm from surface of tumor) was received 400cGy/F×10 times. In the second course, GTV should be decreased when tumor shrinked and PTV was received 200cGy/F×15-20 times. The dose did not gived to th surface and central of massive lesion. **Result:** 7 patients with massive lesion in lung cancer was treated with intensity-modulated radiotherapy (IMRT). In the first course, the tumor volume in 6 patients was reduced. After second course, 7 patients were PR. The significant reduction in GTV of one patient (1560cm^3 to 565.25cm^3) .No obvious treatment-related complications occurred during the treatment. **Conclusion:** There was significant reduction in tumor volume and no obvious treatment-related complications by adding high dose for the central of massive lesion in NSCLC. This method is worth to further study.

Keywords: radiotherapy, massive lesion, Non-Small Cell Lung Cancer

EP1.17-18 NEUTROPHIL COUNT IS NON-PROGNOSTIC IN EARLY STAGE LUNG CANCER TREATED WITH SABR: RETROSPECTIVE ANALYSIS FROM A SINGLE UK CENTRE COHORT

K. Mactier, A. Horne, T. Evans, A. Price, S. Campell, F. Little, I. Phillips

The Edinburgh Cancer Centre, Western General Hospital, Edinburgh/United Kingdom

Background: Stereotactic body radiotherapy (SABR) has become the non-surgical treatment of choice for stage I and II lung cancer patients. The small number of treatment fractions required and the favourable toxicity profile means SABR is being utilised in frailer population groups, who are more likely to have other life-limiting conditions. Elevated neutrophil count has previously been shown to associated with poorer overall survival across all lung cancer stages. However, there is a relative paucity of evidence for this relationship for in early, opposed to locally advanced, disease. We aimed to determine if neutrophil count was associated with poorer outcome in our SABR cohort. **Method:** A database was kept of all patients undergoing lung SABR at the Edinburgh Cancer Centre between 2013-2015. Neutrophil counts from up to three months prior to first radiotherapy fraction were obtained from the Scottish Clinical Information Store. Patient outcome data was extracted from the electronic patient records. Statistical analysis was undertaken using Microsoft Excel and SPSS v25.0 (IBM). **Result:** One hundred and forty-eight patients were included in the sample. Eight-one patients (54.7%) were female, mean age 74.1 years (s.d. 8.6, range 52-93). Patients were followed-up for a mean of 1.36 years (range 0.17-4.07 years). Full blood counts were available for ninety-six patients. There was no significant difference in neutrophil count between patients who were alive or dead at the end of follow-up: median (interquartile range) 5.40 (3.40-6.40) *vs.* 6.35 (3.85-8.85), $p = 0.657$. Neutrophil count was also not associated with progression-free survival: median (interquartile range) 5.41 (4.41-6.41) *vs.* 5.86 (3.86-7.86), $p = 0.835$. **Conclusion:** Our findings suggest that pre-treatment neutrophil count is non-prognostic in early stage lung cancer treated with SABR. This contrasts with findings from two other single centre series. Our findings may be attributable to the small tumour size in our cohort.

Keywords: SABR, neutrophils, prognosis

EP1.17-19 ROBOTIC-ASSISTED THORACIC SURGERY FOR EARLY STAGE LUNG CANCER: TEN YEARS' SINGLE INSTITUTION EXPERIENCE

D. Galetta, M. Casiraghi, L. Spaggiari

European Institute of Oncology, Milan/Italy

Background: Less invasive surgical resection for early stage lung cancer is gaining popularity. We analyzed the short- and long-term outcomes of robotic-assisted thoracic surgery (RATS) for early stage non-small cell lung cancer (NSCLC). **Method:** We retrospectively reviewed 339 patients who underwent RATS for clinical stages I ($n = 318$) or II ($n = 21$) NSCLC from November 2006 to December 2016 and we analyzed long-term survival by Kaplan-Meier method. **Result:** Twenty-nine patients underwent segmentectomy, 307 lobectomy,

and 3 pneumonectomy. Conversion occurred in 22 patients (6.5%): 15 (4.4%) due to technical issues, 4 (1.2%) for oncological reasons, and 3 (0.9%) for bleeding. The median number of N1 and N2 stations resected was 2 and 3, respectively, and the median number of N1 and N2 lymph nodes resected was 9 and 6, respectively. Median operative time was 192 minutes for lobectomy, 172 minutes for segmentectomy, and 275 minutes for pneumonectomy. Median length of hospital stay was 5 days (2-191). The most common postoperative complication was prolonged air leak (12.1%). Major complications occurred in eight patients (2.4%). The 30-day and 90-day operative mortality was 0% and 0.3%, respectively. Two and 5-year cancer-specific survival rate was 96.1% and 91.5%, respectively. Five-year survival rate was 96.2% for patients who underwent segmentectomy, and 89.1% for lobectomy. All three patients who underwent pneumonectomy were alive at 5 years with no disease. **Conclusion:** Besides the well-known short-term outcomes showing very low morbidity and mortality rates, mediastinal lymph node dissection during RATS adequately assesses lymph node stations detecting occult lymph node metastasis and leading to excellent oncologic results. However, these results await longer follow-up studies.

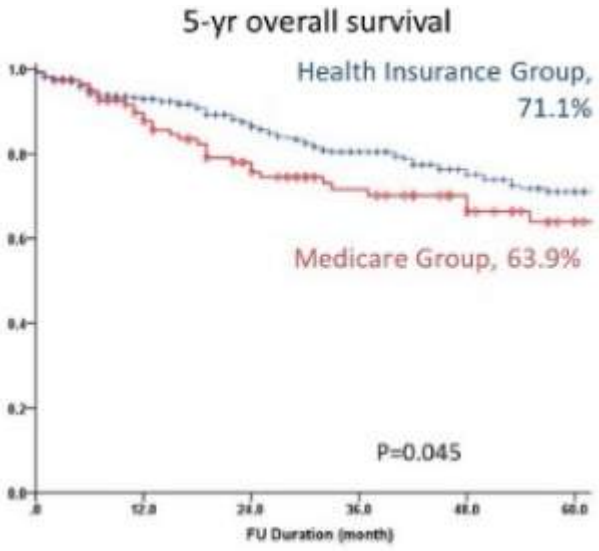
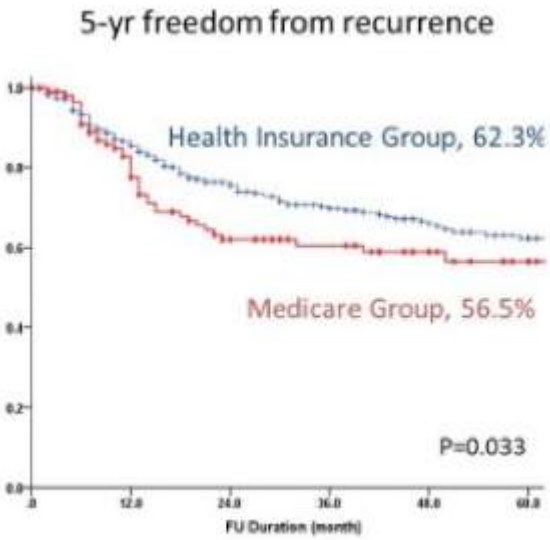
EP1.17-20 INFLUENCE OF INSURANCE STATUS ON SURVIVAL OF PATIENTS WITH NON-SMALL CELL LUNG CANCER UNDERWENT SURGICAL TREATMENT

Y. Hwang[1], H.J. Moon[2], M.S. Shin[2]

[1]*Seoul National Bundang Hospital, Seongnam-si/Korea, Republic of,* [2]*SMG-SNU Boramae Medical Center, Seoul/Korea, Republic of*

Background: Insurance coverage was an important determinant of access to care and was on potential cause of disparities in lung cancer care outcomes. The aim of the study was to clarify the association between National Health Insurance Status (Health insurance vs Medicare) and survival of patients with non-small cell lung cancer (NSCLC) who underwent surgical treatment. **Method:** Among 544 patients who underwent surgical resection for primary NSCLC from January 1997 to July 2017, 116 patients (21.3%) were in the Medicare Group. Data were analyzed to identify the clinical manifestation and to compare the postoperative and oncologic outcomes between two groups. **Result:** There was no significant different in distribution of pathologic stage (p=0.89). The rates of squamous cell carcinoma were significantly higher in the Medicare group (43.9% vs 30.9%, p=0.03). Minimally invasive surgical approach was performed more in the Health insurance group (67.3% vs 56.9%, p=0.04). In the Healthy insurance group, the median length of hospital stay was significantly shorter (8 days vs 11 days, p=0.01). Although postoperative mortality rates were not different between two groups (1.7% vs 2.1%, p=0.79), the incidence of postoperative complications was non-significantly higher in the Medicare group (35.1% vs 29.8%, P=0.29). The 5-year overall survival and freedom from recurrence were significantly lower in the Medicare group (63.9% vs 71.1%, p=0.045, 56.5% vs 62.3%, p=0.033, respectively). (Figure. 1)





Conclusion: Socioeconomic status based on National Health Insurance service could have a bad influence on overall survival in patients with surgical treated lung cancer.

EP1.17-21 EARLY STAGE NSCLC (ES-NSCLC) 5-FRACTION STEREOTACTIC BODY RADIATION THERAPY (SBRT) 3-YEAR PATTERNS OF FAILURE

R. Krochmal[1], N. Aghdam[1], S. Kataria[1], M. Pernia[2], C. Hall[3], T. O'Connor[3], L. Campbell[1], S. Suy[1], S. Collins[1], J. Lischalk[1], E. Anderson[1], B. Collins[1]

[1]*Georgetown University Hospital, Washington/United States of America,* [2]*Metropolitan Hospital Center, New York/United States of America,* [3]*Cornell University, Ithaca/United States of America*

Background: SBRT is an effective treatment for ES-NSCLC. Five fraction approaches have been advocated to limit treatment induced toxicity. In this report, we evaluate 3-year patterns of failure for an institutional 5 fraction protocol. **Method:** Medically inoperable patients were treated with frameless robotic SBRT. PET/CT was completed for staging and at 6 month follow up intervals. A tumor was considered central if it was located within 2 cm of the proximal bronchial tree (PBT). **Result:** From December 2010 to December 2015, 50 patients with biopsy proven ES-NSCLC (stage I - 31; stage II – 19) with median age of 75 were treated to 50 Gy in 5 fractions. Thirty-nine tumors were peripheral and 11 were centrally located. The majority of peripheral tumors were adenocarcinoma (73%) and the majority of central tumors were squamous cell carcinoma (73%). At median follow up of 36 months, local control, regional control, distant metastasis free survival (DMFS) and overall survival (OS) were 88%, 92%, 83% and 52% for all patients. Local control for peripheral tumors was significantly better than central tumors (94% vs. 60% p-value=0.018). Squamous tumors constituted 60% of local failures despite making up 40% of the entire cohort. Conversely, 12% of peripheral adenocarcinoma failed regionally comprising the only regional failures in this series. DMFS (88% vs. 81% p-value=0.445) and OS (46% vs. 54% P=0.421) were not different for central and peripheral tumors. **Conclusion:** Acceptable outcomes are achievable for central and peripheral inoperable ES-NSCLC patients treated with 5-fraction SBRT alone. However, future trials should consider the addition of systemic therapy to reduce the risk of locoregional and distant failures.

EP1.17-22 IN STAGE I NON-SMALL CELL LUNG CANCER, ABUTTING ADJACENT STRUCTURES IS A POSSIBLE PROGNOSTIC FACTOR

S. Choi[1], D. Cho[1], S. Yoon[2], J. Yoon[2]

[1]*St. Vincent Hospital, Suwon/Korea, Republic of,* [2]*Seoul St. Mary's Hospital, Seoul/Korea, Republic of*

Background: In TNM staging system, tumor which invades directly adjacent lobe does not change its T status. But there are some papers that emphasize, adjacent lobe invasion should be classified as T3. Here, we report our analysis of clinical characteristics and prognosis of abutting stage I non-small cell lung cancer (NSCLC). **Method:** Non-small-cell lung cancer (NSCLC) which does not exceed three centimeters was enrolled. All patients underwent curative surgical resection from October 2008 to April 2017. We divided the patients into two groups. Abutting group comprised of tumors, which abutted adjacent structures (interlobar fissure, parietal pleura, mediastinal pleura, pericardium, and diaphragm) and non-abutting group was not. We compared patient demographics, surgical procedures, pathologic status, and recurrence rate. Finally, we compared overall survival using Kaplan Meier survival curves. **Result:** Non-small-cell lung cancer (NSCLC) which does not exceed three centimeters was enrolled. All patients underwent curative surgical resection from October 2008 to April 2017. We divided the patients into two groups. Abutting group comprised of tumors, which abutted adjacent structures (interlobar fissure, parietal pleura, mediastinal pleura, pericardium, and diaphragm) and non-abutting group was not. We compared patient demographics, surgical procedures, pathologic status, and recurrence rate. Finally, we compared overall survival using Kaplan Meier survival curves.

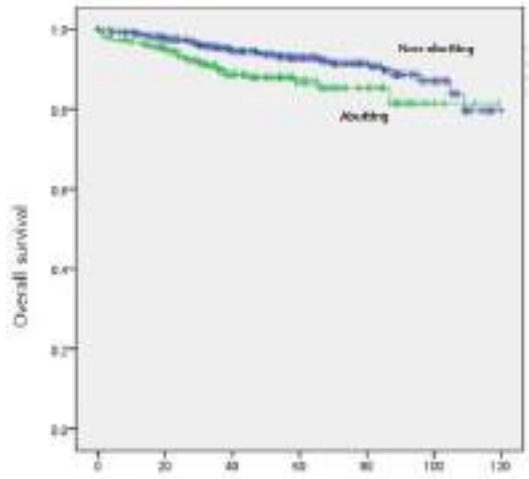

Figure 1. Kaplan-Meier survival curves for overall survival (p<0.01)

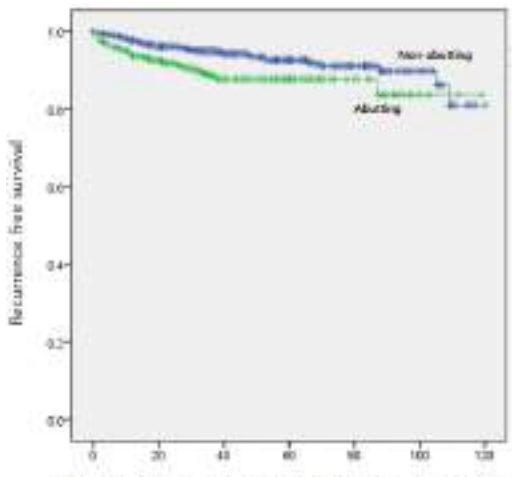

Figure 2. Kaplan-Meier survival curves for recurrence free survival(p<0.01)

Conclusion: In stage I NSCLC which does not exceed three centimeters, abutting to the adjacent structures could be an unfavorable factor in prognosis after curative surgical resection. Further study should be conducted.

EP1.17-23 OMENTOPEXY FOR POST-PNEUMONECTOMY BRONCHOPLEURAL FISTULA IN PATIENTS WITH NON-SMALL CELL LUNG CANCER AFTER SALVAGE RADIOTHERAPY

S. Choi, D. Cho, H.S. Park, G. Heo, Y. Chang

St. Vincent Hospital, Suwon/Korea, Republic of

Background: Preoperative chemotherapy or radiotherapy could affect bronchial mucosa blood flow and also the normal healing process of bronchial stump after surgical resection. Otherwise, bronchopleural fistula (BPF) is the worst and time consuming complication in lung cancer surgery. Pneumonectomy is reported as a high risk surgery of BPF. Here, we report our successful treatment experience of BPF using omentum after salvage radiotherapy in NSCLC patient. **Method:** Retrospective medical chart review **Result:** A sixty-four years old male patient who had a history of chronic obstructive pulmonary disease diagnosed as squamous carcinoma in left upper lobe, clinical stage of T2aN1M0. Because interlobar artery invasion was suspicious, the patient was treated with radical radiotherapy. After 6600cGy of radiotherapy, the lesion showed marked response. Thus we decided to perform curative surgical resection, pneumonectomy. The patient had discharged in postoperative day 11 and the pathologic report was ypT1aN0M0. But after 1 week from discharge, the patient readmitted and complained of dyspnea and profound sputum. In bronchoscopy, fistula was seen. We performed the second operation. Due to hard fibrosis, direct closure of bronchial stump was not possible. Thus, we covered the stump site with omental flap in multilayers. The patient discharged uneventfully and now in disease free status almost after 2 years from initial operation.

Figure1. CT shows bronchial wall disruption and air fluid level in left hemi-thorax. Bronchoscopy shows small fistula hole in bronchial stump.

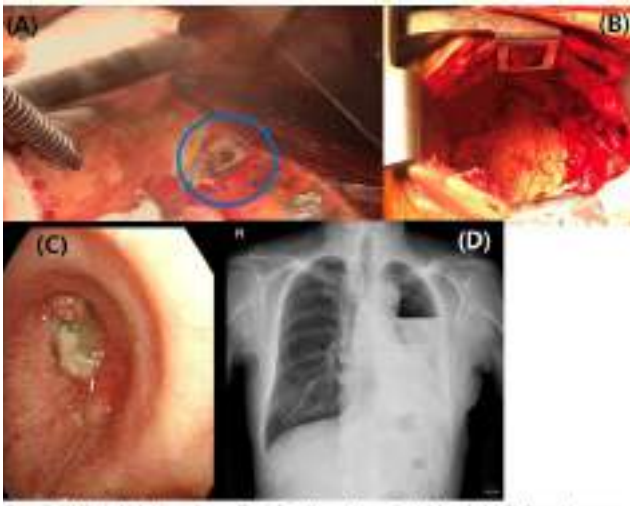

Figure2. (A) Bronchial stump shows disruption(Bronchotomy view), blue circle. (B) Omentum was sutured to peri-stump tissues, double layered. (C) Previous opening has closed with omentum. (D) Uneventful postoperative chest x-ray.

Conclusion: Neoadjuvant radiation therapy and pneumonectomy are risk factors for post-operative BPF. Direct closure with buttressing biocompatible flap is the treatment of choice. But if direct closure is not possible, double-layered omentopexy could be an alternative treatment strategy.

EP1.17-24 BIOLOGICALLY EFFECTIVE DOSE WAS ASSOCIATED WITH OVERALL SURVIVAL IN STEREOTACTIC BODY RADIOTHERAPY FOR LUNG TUMORS

O. Tanaka[1], N. Funaguchi[1], S. Toyoshi[1], T. Taniguchi[1], K. Ono[1], Y. Kunishima[1], Y. Masui[1], M. Matsuo[2]

[1]*Asahi University Hospital, Gifu/Japan,* [2]*Gifu University Hospital, Gifu/Japan*

Background: To evaluate factors associated with overall survival (OS) in inoperable lung cancer cases treated with stereotactic body radiotherapy (SBRT). SBRT delivers precise concentric radiation to a tumor. It is well established that local control depends on the biologically effective dose (BED) delivered, with BED10 of ≥100 as a significant predictor of local control. **Method:** From 2013 to 2016, 22 patients with inoperable lung cancer treated with SBRT who could be followed up until their time of death were retrospectively enrolled. Data on Sex, age, dose (Gy), number of fractions, BED (α/β = 10), pathology, tumor location, performance status, and background lung disease were collected. The median total dose at the isocenter was 50 Gy, and median BED was 120 Gy. We compared OS in groups with BED of ≥120 Gy ("high-BED"; n = 14) and BED of <120 Gy ("low-BED," n = 8). **Result:** Overall, 1-year OS was 48%. In the univariate analysis, the number of fractions, BED, and pathology were significantly associated with OS. The high-BED group showed better OS, with 1- and 2-year OS of 64% and 21%, respectively, compared with 25% and 0% for the low-BED group (p = 0.04). No adverse event of grade 3 or higher occurred. **Conclusion:** For these inoperable lung cancer cases treated with SBRT, BED was significantly associated with OS. The poor of OS rate in our series might be associated with that all the tumors were inoperable.

EP1.17-25 RADIO-GUIDED LOCALIZATION OF SMALL LUNG NODULES

S. Garcia-Reina[1], E. Fernandez-Araujo[1], S. Lafuente[1], V. Margeli[1], I. Nogueira[1], M. Lacambra[2], C. Martinez-Barenys[1], P. Lopez De Castro[1]

[1]*Hospital Universitari Germans Trias i Pujol, Badalona/Spain,* [2]*Hospital Mutua de Terrassa, Terrassa/Spain*

Background: The widespread use of computed tomography and the obligation of early diagnosis and treatment of small lung nodules have increased in recent years. There are few localization techniques, ROLL seems one of the safest and most effective. The purpose of this study is to report our experience. **Method:** We have retrospectively reviewed all patients with undetermined lung nodule that underwent radio-guided localization. The aim of the study was to evaluate the efficacy of the ROLL for the diagnosis and treatment of small lung nodules. The morning of the surgery, Tc99 macroaggregated albumin was injected guided by computer tomography. Afterwards a SPECT-CT was performed to check the correct localization of the tracer and the patient was brought into the operating room. During the surgery a gamma probe connected to a gamma ray was introduced and the lung surface scanned. After detecting the higher value area, a lung resection was performed and the lung is rescanned to check the residual activity (less than 10%). **Result:** Between November 2011 and February 2019, 30 patients (22 male and 8 female) underwent radiotracer injection followed by lung resection surgery in our institute. Mean age was 66,3 years (range 52 to 76 years). The main complication was pneumothorax (9 patients, 30%), but no patient required chest drainage. There was one non-complicated aortic puncture. There were no other complications. The mean nodule size was 9,07mm +/- 4,35mm and the mean visceral pleural distance was 19,6mm +/-16,27mm. By radiology characteristics, 16 were ground glass opacities, 10 solid nodules and 4 partially solid nodules. The lesions were well detected in 100% cases. They were resected by wedge resection in all the cases. The final pathologic diagnosis confirmed 12 lung adenocarcinoma (6 lepidic growth adenocarcinoma, 3 adenocarcinoma in situ, 2 solid adenocarcinomas, 1 minimally invasive adenocarcinoma), 12 lung metastasis, 2 atypical adenomatous hyperplasia, 2 inflammatory nodules, 1 squamous carcinoma and 1 hamartoma. Clean margins were obtained in 28 patients (93,3%). There were not intraoperative and postoperative complications secondary to the procedure. **Conclusion:** The radio-guided localization is a simple, easy and safe procedure for the diagnosis and treatment of small lung nodules. There were not problems of radiotracer lung diffusion and misplacement.

Keywords: Lung cancer, surgery, Radio-guided

EP1.17-26 SPONTANEOUS RIGHT CONTRALATERAL TOTAL PNEUMOTHORAX IN BULLOUS LUNG AFTER LEFT PNEUMONECTOMY FOR LUNG CANCER

F. Gradica[1], L. Lisha[1], D. Argjiri[1], A. Cani[1], F. Kokici[1], S. Gradica[2], A. Lala[2], K. Gradica[2], L. Shpataraku[1], G. Quadir[3]

[1]*University Hospital "Shefqet Ndroqi", Tirane/Albania,* [2]*Public Pharmacy Service, Tirane/Albania,* [3]*National Contra Cancer Center, Beijing/China*

Background: Introduction: The spontaneous contralateral pneumothorax after pneumonectomy is very rare and with a high death rate. Objective: To introduce a patient with spontaneous total pneumothorax in the right hemithorachal post-pneumonectomy with dg.:cancer bronchial. The treatment alternatives are controversial. **Method:** Involved a 52-year-old man with non-small-cell lung cancer (NSCLC) who underwent left pneumonectomy after induction chemoradiotherapy on 2015.One year after surgery 2016 he had total right pneumothorax was treated by pleural drainage. Two(2) years after surgery 2018, he had recureent pneumothorax and was treated with chest tube drainage and pleurodesis with autolog blood. He was discharged and no pneumothorax recurrence occurred for one year. **Result:** After one year he had total pneumothorax right side and severe respiratory insuficience .He came to our hospital 3 hour after right Pneumothorax was started.O2SAT 60 %.Imediatly was treated with right chest tube drainage and airlack was stoped but for safety reason was discharged with Heimlich valvul after pleurodesis with povidion jod(BETADINE) .Heimlich valvul was get out after 10 days.The clinical status of patient is good. **Conclusion:** Although management of pneumothorax after pneumonectomy is challenging, surgical intervention may be useful and necessary especially when there is high risk of recurrent pneumothorax.

EP1.17-27 DEVELOPMENT OF TITANIUM ALLOY VASCULAR MIRROR FORCEPS FOR UNIPORTAL VATS

J. Shimada, K. Ito

Kyoto Prefectural University of Medicine, Kyoto/Japan

Background: During lung surgery after the elderly or chemotherapy, blood vessel walls of blood vessels, including pulmonary arteries and micro vessels of soft tissues become fragile. For this reason, it may lead to bleeding during peeling operation with forceps. In order to reduce tissue damages in manipulation at the time of tissue detachment, we have developed a "Mirror ™" forceps with OFFSET of the groove position at the tip in industry and university co-creation and launched it in Japan in 2016. However, when an electric scalpel is used in the distal end portion, minute roughness occurs on the surface of the forceps. In order to solve this problem, we began developing technology to make Uniportal VATS forceps by Electropolishing as a titanium alloy. **Method:** A steel material with a diameter of 5 mm of a titanium alloy material used for the tip of a forceps was cut out and physically polished with # 600 to 1200 diaphragm as a pretreatment for electrolytic polishing. As an electrolytic polishing condition, a comparative test was carried out by using an electrolytic bath of 50% ethylene glycol water with sodium chloride, voltage of 10, 25 and 35 V intermittently applied voltage and time of 3 minutes 10 minutes.

Result: Polishing at 25 V for 3 minutes caused less pitting corrosion (roughening of metal surface) on the surface of the titanium alloys. **Conclusion:** By adopting state-of-the-art Electropolishing at the "last 1 mm" part where the surgical instrument contacts, the patient, it has improved the precision of the surface finishing work.

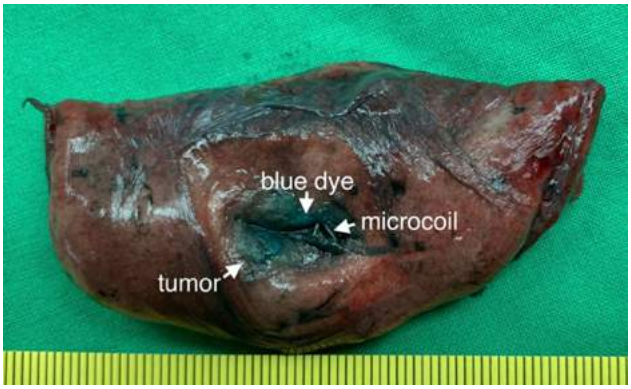
Keywords: Mirror forceps, Uniportal VATS, Electrolytic polishing

EP1.17-28 ELECTROMAGNETIC NAVIGATION-GUIDED PREOPERATIVE LOCALIZATION FOR SMALL MALIGNANT PULMONARY TUMORS

P.-K. Hsu, Y.-C. Wu

Taipei Veterans General Hospital, Taipei/Taiwan

Background: Surgical removal of non-visible, non-palpable small pulmonary nodules is sometimes challenging during video-assisted thoracoscopic surgery (VATS) and preoperative nodule localization is of paramount importance for precise resection. We reported our experience of preoperative localization using the SPiN thoracic electromagnetic navigation system. **Method:** The inclusion criteria include: 1. Patients with highly suspicious malignant pulmonary nodules according to persistent or progressive nature on follow-up CT scans, or history of extrathoracic malignancy. 2. Target nodule size less than two centimeters. 3. Presumed to be non-visible and non-palpable during VATS according to surgeon`s judgement. 4. Patients who received electromagnetic navigation for preoperative localization. As the SPiN system allows for both transbronchial (endobronchial) and transthoracic (percutaneous) routes, the optimal approach was decided according to the location of target nodule.The preoperative localization and thoracoscopic resection were performed in the same operation room by the same team. The successful localization was defined as successful identification of target tumors during VATS procedure without palpation. **Result:** From Jun 2018 to March 2019, a total of 30 patients with 35 nodules were included. Thirty-one percutaneous and five endobronchial approaches were performed. One patient received both approaches for the same tumor. Three patients received both percutaneous and endobronchial approaches for multiple targets localization. The mean nodule size was 9.6 ±3.5 mm. The materials used for marking included dye (n = 18), micorcoil (n = 4), indocyanine green (ICG, n = 2), microcoil + dye (n = 8), and microcoil + ICG (n = 3). There was no localization-related adverse event. Successful localization was achieved in 27 of 30 (90.0%) patients and 32 of 33 35 (91.4%) nodules. In three patients, localization failed as dye extravasation in the pleural cavity without any stains in the subpleural parenchyma. The pathological diagnosis included metastatic tumors (n = 6), primary pulmonary squamous cell carcinoma (n = 2), and primary pulmonary adenocarcinoma (invasive adenocarcinoma, n = 9; minimally invasive adenocarcinoma, n = 12; adenocarcinoma in situ, n = 6).



Conclusion: We reported our experience of electromagnetic navigation-guided transbronchial and transthoracicpreoperative localization for small malignant pulmonary tumors. Lessons from failed cases were learned and localization techniques were modified to improve successful localization rate.

Keywords: electromagnetic navigation, localization, VATS

EP1.17-29 EVALUATION OF THE INFLUENCE OF REMOVED LYMPH NODES DURING VATS-LOBECTOMY IN THE GROUP OF PATIENTS WITH EARLY STAGE OF NSCLC ON LONG-TERM RESULTS

D. Dziedzic, G. Wojciech, R. Piotr, R. Langfort, T. Orlowski

National Institute of Chest Diseases, Warsaw, Poland, Warsaw/Poland

Background: Numerous controversies are caused by the smaller number of acquired lymph nodes (LN) during VATS-lobectomy (VATS-L) compared to the classic thoracotomy (TORA-L) and the potential impact on long-term results of treatment in the oncological aspect. The aim of the study was to determine the number of LN removed during VATS-L and compare it to TORA-L in the group of patients with pT1N0 stage and to determine distant experiences in both groups. **Method:** The study was based on data from the National Registry of Lung Cancer. In the first stage, the number of removed nodes in the whole group was analyzed with the cN0 feature including 18199 TORA-L and 2685 VATS-L in stages I and II. In the next stage, in the group of patients in the pN0 stage (9864-TORA-L and 2001-VATS-L), the differences in the number of removed nodes in particular types of lobectomy were determined using the Mann-Whitney test and correlated with the survival curves using the log-rang test **Result:** In the entire examined group, the median of removed nodes was higher in the TORA-L 13 group compared to VATS-L-10 (p <0.0001). In the TORA-L group, the change in grade from N0 to N1 and N2 was found in 11.1% and 7.7% of patients respectively, and in the VATS-L group in 8.8% and 5.7% (p <0.001). In the group of patients with pT1N0, the median of removed nodes for TORA-L and VATS-L were respectively 11 and 9 (p <0.001). The biggest differences concerned the nodes of the groups: 2L, 3, 4L, 7 and 8. In the division into individual lobectomy types, the differences of the removed LN were related to the groups: LDL-2L, 5,6,7,8; LDP-3, LGL-2L, 4L, 8.9; LGP-3, 4R, 7,8,12. 3- and 5-year survivors in the VATS-L group were 84% and 77%, respectively, and were significantly better in comparison to TORA-L: 76% and 67% (p <0.001). **Conclusion:** The long-term results in the early-stage NSCLC in the group of patients treated with VATS are significantly better than in the group treated classically despite the smaller number of removed lymph nodes during the operation. In the absence of the possibility to clearly determine the required number of lymph nodes, lymphadenectomy during VATS-lobectomy should meet the same criteria as for thoracotomy.

Keywords: Early lung cancer, VATS-lobectomy, Limphadenectomy

EP1.17-30 EXPERIENCE OF UNIPORTAL VIDEO-ASSISTED THORACOSCOPIC SURGERY IN A JAPANESE GENERAL HOSPITAL

F. Ishiguro, H. Takenaka, N. Kawasaki, K. Shigemitsu

Ogaki Municipal Hospital, Ogaki, Gifu/Japan

Background: The role of multiport video-assisted thoracoscopic surgery (M-VATS) is widely recognized for performing major pulmonary resections. Alternatively, uniportal VATS (U-VATS) is a novel upcoming approach and several institutions around the world have been reported its beneficial effects. We have been performing U-VATS since November 2018. The aim of this study is to evaluate the effectiveness, safety and analyzing short-term results of U-VATS compared with M-VATS. **Method:** A total of 76 patients underwent anatomical pulmonary resection via U-VATS or M-VATS procedures in our institution between June 2018 and March 2019. The general clinical data and perioperative data were retrospectively compared and analyzed between the two groups. **Result:** The two groups were similar in terms of clinicopathological features. Thirty-seven patients underwent U-VATS anatomical pulmonary resections (29 lobectomies and 8 segmentectomies) between November 2018 and March 2019. And 39 patients underwent M-VATS anatomical pulmonary resections (31 lobectomies and 8 segmentectomies) between June 2018 and October 2018. The mean wound length was 4.2cm in U-VATS group. U-VATS showed shorter operative time (124 vs. 152 min, P<0.01) and less postoperative pain at 24 hours (Numerical Rating Scale 0 vs. 1, P<0.01) than those with M-VATS approach. There was no statistical difference in the blood loss (5 vs. 5 g, P=0.07), duration of chest drainage (2 vs. 2 days, P=0.09), total number of dissected lymph nodes (6.3±3.9 vs. 5.6±4.6, P=0.63) and postoperative complications (4 vs. 6, P=0.48) in U-VATS vs. M-VATS. Prolonged air leak was the most common complications in both

groups. In U-VATS group, 1 case was converted to two port VATS due to the failure for stapler pass across the superior pulmonary vein. There was no intraoperative and thirty-day mortality. **Conclusion:** U-VATS is feasible and safe approach, and may be a less invasiveness alternative to M-VATS because of its effectiveness reducing operative time and postoperative pain.

EP1.17-31 30 DAYS MAJOR MORBIDITY AND MORTALITY AFTER LUNG CANCER SURGERY. OUTCOMES OF FIVE YEARS IN A SINGLE CENTER EXPERIENCE

F. Caushi[1], D. Xhemalaj[1], I. Skenduli[1], S. Bala[1], R. Isufi[1], A. Mezini[1], H. Hafizi[2], O. Nuredini[1], A. Hatibi[1], A. Cani[3]

[1]University Hospital "Shefqet Ndroqi", Tirana/Albania, [2]University Hospital, Tirane/Albania, [3]University Hospital "Shefqet Ndroqi", Tirane/Albania

Background: Lung cancer is the leading cause of cancer-related death in the world. Surgery offers the best potential cure, but as in any surgery there are some complications that will be minimized with the improvement of surgical practice and treatment protocols. The aim of this study was to clarify the level of service we are providing in order to improve it and to add more information in the global database on the Thoracic Morbidity and Mortality classification system for patients undergoing lung resection. **Method:** This is a retrospective study that included all patients who underwent lung resection in our department from January 2011 to January 2015. The parameters examined were postoperative mortality thirty days and postoperative complications. Both patients were evaluated prior to surgery according to the Karnofsky score and the intervention was performed by postero-lateral thoracotomy. **Result:** There were 216 patients who were operated on for lung cancer in which 37 (17%) of them underwent pneumonectomy meanwhile the rest lobectomies, bilobectomies and anatomical segmentectomies. The average age was 62.4 years (± 12SD). 12% of patients were women and 88% males. 79% were smokers and 21% non-smokers. According to TNM classification, 10.2% of cases were in the first stage, 44% in the second stage, 21.3% in the third stage and 5.6% in the fourth stage. 40.4% of cases had another illness (cardiovascular disease 24.2%, COPD 11.8%, diabetes mellitus 3.7% and other diseases 0.6%). 17% of patients had complications 30 days after surgery and only 2.3% died. As for pneumonectomy, the complication rate was 24% and the mortality rate was 8%. The main complications that have been observed were 19 cases of empyema, 4 cases of broncho-pleural fistula, 4 cases of pneumonia, 3 cases of prolonged air loss, 3 cases of heart attack and in 4 cases different complications were observed. 2 of mortality occurred due to a heart attack, in 2 cases occurred due to severe pneumonia and in one case a vascular accident occurred during the operation. Hospital stay was 8.5±3 days. **Conclusion:** In our specialty, the complication rate following a surgical operation is a parameter very often used to check the quality level provided by health professionals. Our results show average mortality and morbidity after lung cancer surgery. However, patients with reduced lung capacity and undergoing pneumonectomy should be treated with the utmost care, since they run a considerable risk of major complications or death during the first 30 days after surgery.

EP1.17-32 LONG-TERM OUTCOMES OF PULMONARY RESECTION FOR LUNG CANCER PATIENTS WITH CHRONIC KIDNEY DISEASE

Y. Yamamoto, R. Kanzaki, T. Kanou, N. Ose, S. Funaki, M. Minami, Y. Shintani

Osaka Univiersity Graduate School of Medicine, Suita-City, Osaka/Japan

Background: The increasing prevalence of chronic kidney disease (CKD) may hinder the perioperative management and postoperative follow-up of lung cancer. To our knowledge, this study is the first to evaluate the surgical outcomes of surgery for non-small cell lung cancer (NSCLC) in patients with CKD as a preoperative comorbidity. **Method:** Among 671 patients who underwent surgery for NSCLC between 2007 and 2014 at our hospital, 55 (8%) had CKD and we retrospectively analyzed the surgical outcomes of these patients. **Result:** Most patients with CKD were elderly and male. Patients with CKD had a higher frequency of smoking habit, cardiovascular disease, and pulmonary diseases, and a notably lower pulmonary function, resulting in receiving limited pulmonary resection. There were no marked differences in the frequency of surgical complications between patients with and without CKD (p = 0.16). Squamous cell carcinoma was more frequently diagnosed in patients with CKD than in those without it. The 5-year disease-free survival rates in patients with and without CKD were 60.0% and 69.7% (p = 0.06), respectively, and the 5-year overall survival rates were 68.9% and 80.0%, respectively, showing significant differences (p = 0.01). The rate of receiving supportive care was higher in patients with CKD when recurrence observed. **Conclusion:** CKD is associated with a poorer overall survival in patients who undergo lung cancer resection for recurrent disease. As patients with CKD tend to have a poor respiratory function, thoracic surgeons should carefully select the resection type to balance the therapeutic benefit and invasiveness.

Keywords: Lung cancer, surgery, chronic kidney disease

EP1.17-33 PREDICTORS OF AIR-RELATED COMPLICATION AND RE-INTERVENTION AFTER PLEURAL DRAINAGE TUBE REMOVAL IN DIGITAL THORACIC DRAINAGE SYSTEM USE

Y. Lee

Taipei Veterans General Hospital, Taipei/Taiwan

Background: After digital drainage system coming onto the market, a number of its advantages have been reported. The objective of this paper is to review the patient's outcome and illustrate the risk factor of postoperative complications and potential of re-intervention needed after pleural drainage tube removal. **Method:** The study population included patients with pre-operative pulmonary function test within 3 months underwent video assisted thoracoscopic or open lung resection surgery and were subsequent managed with digital chest drainage system in our institution between March 2016 and July 2018. **Result:** A total of 497 patients were included, 182 (36.6%) had air-related complications (subcutaneous emphysema, pneumothorax or prolonged air leak) and 23 patients (4.6%) required reintervention because of progression of complications, including re-drainage (n=16) and re-operation (n=7). Patients have higher complication rates in male (56% versus 41.3% years; p=0.001), older age (61.2 versus 57.8 years; p=0.017), with previous smoking history (38.5% versus 18.1%; p<0.001) and chest surgery history (19.2% versus 12.4%; p=0.039), lower FEV1 value (91.47% versus 96.03%; p=0.01), presence of initial air leak (42.3% versus 23.5%; p<0.001) and longer duration of drainage tube placement (6.8 versus 3.9 days; p<0.001), especially prolonged air leak (95%CI: 5.91–19.12; OR: 10.63, p < 0.001). Within above, patients have higher potential of re-intervention due to air-related complication in presence of male (69.6% versus 45.6% years; p=0.024), previous smoking history (52.2% versus 24.3%; p=0.003), initial air leak (78.3% versus 28.1%; p<0.001) and longer drainage tube remaining day (10.4 versus 4.7 days; p=0.002). **Conclusion:** This study demonstrates higher risk of air-related complication after thoracic surgery and subsequently managed with digital chest drainage system, including male sex, old age, previous smoking and chest surgical history, lower forced expiratory volume (FEV1%), initial air leak noted at recovery room and higher proportions of remaining day. Higher potential risk of re-intervention after drainage tube removal are male, previous smoking history, intial air leak and longer tube day. Especially, prolonged air leak had the highest risk with the occurrence of air-related complications and longer tube duration day is significantly associated with higher risk of re-intervention after drainage tube removal, especially over 5 days.

Keywords: digital thoracic drainage system, Post-operative complication

EP1.17-34 ASSOCIATION BETWEEN THE NUMBER OF RESECTED LYMPH NODES AND LONG-TERM SURVIVAL IN N0 NON-SMALL CELL LUNG CANCER: DATA FROM A CHINESE LARGE COHORT

H.-X. Yang, M.-Z. Yang, J.-S. Cai, J. Yang, S. Li, H. Long, J.-H. Fu, L.-J. Zhang, P. Lin, X. Wang, T.-H. Rong

Sun Yat-Sen University Cancer Center, Guangzhou/China

Background: We aim to investigate the impact of the numbers of resected total lymph nodes (TLNs) and mediastinal lymph nodes (MLNs) on long-term survival in patients with node-negative (N0) non–small cell lung cancer (NSCLC) using a large cohort. **Method:** Patients with N0 NSCLC who underwent R0 resection between 2001 and 2014 were included. Scatter plots of hazard ratios (HRs) from Cox proportional hazards model against the numbers of resected TLNs and MLNs were depicted and curves were fit using a LOWESS smoother. Cut-off points for the optimal numbers of resected lymph nodes were further determined by Chow test. Kaplan–Meier method was used to compare the overall survival (OS) between groups divided by the cut-off points. **Result:** A total of 2,444 patients were included in this study and adenocarcinoma accounted for most of the cases (adenocarcinoma: 1,522/2,444, 62.3%; squamous-cell carcinoma: 784/2,444, 32.1%; others: 138/2,444, 5.6%). Mean numbers of resected TLNs and MLNs were 19.4 ± 11.0 (median: 17) and 12.1 ± 8.6 (median: 10). Cox regression analysis suggested that the increasing numbers of resected TLNs/MLNs were independent factors favoring OS in adenocarcinoma (TLNs: HR = 0.983, 95% confidence interval [95% CI] 0.971 to 0.996, $P < 0.01$; MLNs: HR = 0.983, 95% CI 0.968 to 0.999, $P = 0.034$). Curves of HRs against resected numbers of TLNs/MLNs with Chow test suggested that 17 resected TLNs and 12 resected MLNs were optimal cut-off points for prolonged OS in adenocarcinoma. Furthermore, both the cut-off points were confirmed by OS comparison (5-year OS: 84.2% [≥17 TLNs] vs. 77.9% [<17 TLNs], $P = 0.02$; 84.4% [≥12 MLNs] vs. 78.9% [<12 MLNs], $P = 0.04$) and Cox regression model (TLNs: univariate HR = 0.754, 95% CI 0.593 to 0.959, $P = 0.021$, multivariate HR = 0.712, 95% CI 0.556 to 0.914, $P < 0.01$; MLNs: univariate HR = 0.769, 95% CI 0.598 to 0.988, $P = 0.040$, multivariate HR = 0.730, 95% CI 0.560 to 0.952, $P = 0.020$). However, the numbers of resected TLNs/MLNs were not associated with OS in non-adenocarcinoma (TLNs: HR = 0.998, 95% CI 0.987 to 1.009, $P = 0.756$; MLNs: HR = 1.000, 95% CI 0.986 to 1.015, $P = 0.988$). **Conclusion:** The number of resected lymph nodes associated with OS in N0 lung adenocarcinoma patients. At least 17 TLNs and 12 MLNs are required to be resected to warrant the long-term survival in these patients.

EP1.17-35 CBCT RADIOMICS MAY PREDICT SHORT-TERM SBRT EFFECT IN EARLY STAGE LUNG CANCER PATIENTS

L. Hou[1], C. Zhou[1], Y. Xu[2], Y. Meng[1], C. Yu[1], F.-M. Kong[1], H. Yang[1]

[1]*Radiation Oncology Institute of Enze Medical Health Academy, Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China,* [2]*Affiliated Taizhou Hospital of Wenzhou Medical University, Taizhou/China*

Background: This study aimed to determine whether radiomics features can be obtained from cone-beam CT (CBCT) through the linac based onboard-imaging systems. **Method:** Thirty consecutive patients with early stage lung cancer treated with stereotactic body radiation therapy (SBRT) (Total dose:50-60Gy, Fraction:5-8) were included. CBCT scan were performed before delivery of each SBRT treatment. Diagnostic CT scan before Radiation Therapy (diagnostic CT) and follow-up CT at one month after radiotherapy (follow-up CT) were analyzed. Primary tumors were delineated manually and modified on diagnostic CT, CBCT and follow-up CT. Tumor size on diagnostic CT and follow-up CT were used to calculate the reduction rate. The primary endpoint was average daily tumor reduction rate. Radiomics features were extracted from first fraction CBCT (CBCT first), last fraction CBCT (CBCT last) and diagnostic CT by Imaging Biomarker Explorer (IBEX) software. Radiomic features were selected using correlation coefficient and LASSO dimensionality reduction based on R. **Result:** A total of 222 radiomics features were obtained from CBCT first, CBCT last and diagnostic CT of each patient. Based on correlation coefficients>0.70 and with LASSO dimensionality reduction, 5, 4 and 5 features were selected in diagnostic CT, CBCT first and CBCT last, respectively. Comparing the features in three CT subsets, two features were same between diagnostic CT and CBCT first, three features were the same between diagnostic CT and CBCT last. Two features are common in all three CT imaging sets. (Table 1)

Table 1 Different characteristic values of different CT radiomics be predicted SBRT reduction rate.

Images	diagnostic CT	CBCT first	CBCT last
Feature	Inverse Variance	Inverse Variance	Inverse Variance
	Percentile	Percentile	Percentile
	Complexity	Cluster Shade	Cluster Shade
	Correlation	Max3D Diameter	Correlation
	Inverse Diff Moment Norm		Information MeasureCorr1

Conclusion: A few radiomics features may be robust to the noise in daily CBCT images which are often considered of poor quality. Study with larger sample size are needed to verify this interesting finding.

Keywords: Radiomics, Cone-beam CT (CBCT), Stereotactic body radiation therapy (SBRT)

EP1.18 TREATMENT OF LOCOREGIONAL DISEASE - NSCLC

EP1.18-01 EFFECTIVENESS OF VIDEO-ASSISTED SURGERY AND PRE-OPERATIVE MULTI-DISCIPLINARY SUPPORT FOR PRESERVING RESPIRATORY FUNCTION

M. Kataoka, D. Okutani, H. Kawai, K. Watanabe, S. Harita, M. Baba, T. Okutani, T. Fujita, K. Suemori

Okayama Saiseikai General Hospital, Okayama/Japan

Background: Evaluation of post-operative respiratory function after lung resection is very important because it greatly affects the quality of life (QOL). **Method:** The predicted post-operative lung VC was calculated according to the number of 42 sub-segments of the lung. The % predicted post-operative VC (%PR) was defined as (number of resected segments)/42 × 100. The % real reduction (%RR) was defined as (pre-operative VC- post-operative VC)/ (pre-operative VC) ×100. Furthermore, we defined %PR-%RR as the index of post-operative reduction of respiratory function (RI).Using RI, we investigated the differences in respiratory function between 22 cases of open-thoracic surgery and 96 cases of thoracoscopic surgery and among 3 different pre-operative support groups, namely, no preoperative support (Non; 39 cases), pre-operative rehabilitation support (Reha; 20 cases), and multi-disciplinary support (Multi; 59 cases). Pre-operative rehabilitation support is coaching for respiratory rehabilitation provided to patients by the rehabilitation physicians and physical therapists at our outpatient clinic. In addition to rehabilitation support, multi-disciplinary support was provided by a multi-disciplinary team consisted of an anesthesiologist, a nutritionist, a pharmacist, a medical social worker, and a nurse. **Result:** The %PR for lobectomy was 9.31 and that of segmentectomy was 2.48; there was a significant difference between them (*p = 0.0151*). The average RI for open-thoracotomy and video-assisted thoracotomy was -0.80 and 9.16, respectively. Pulmonary function was significantly preserved in patients with thoracoscopic surgery compared with that in patients with open-thoracic surgery (*p = 0.00221*). With respect to pre-operative support, the average RI for the Non, Reha, and Multi groups was 5.31, 8.79, and 11.61, respectively. There were significant differences among the three groups (*p = 0.00991*). **Conclusion:** It is difficult to evaluate the respiratory function after lung resection, because the resected lung volume and pre-operative respiratory function may vary among patients. To reduce the fluctuation according to the resected lung volume in each case, the ratio of predicted % reduction and real % reduction (RI) was used to compare the preserved degree of respiratory function for each classified group. The comparison of RI, calculated from the pre-operative and 1-year post-operative VC, proved the preservation of respiratory function by thoracoscopic surgery and pre-operative support.

Keywords: lung resection, evaluation of respiratory functional loss, multi-disciplinary support

EP1.18-02 PATTERN OF POSTOPERATIVE RECURRENCE AND CLINICAL VALUE OF ADJUVANT RADIOTHERAPY IN COMPLETELY RESECTED STAGE III/N2 EGFR-MUTANT NSCLC

J. Ni, T. Guo, Y. Li, Z. Zhu

Fudan University Shanghai Cancer Center, Shanghai/China

Background: The pattern of postoperative recurrence among patients with stage III/N2 EGFR-mutant non-small cell lung cancer (NSCLC) is seldom reported. Moreover, the clinical value and optimal candidate of postoperative radiotherapy (PORT) for stage III/N2 NSCLC is still controversial. **Method:** Consecutive patients who underwent curative resection and were pathologically confirmed EGFR-positive stage III/N2 NSCLC at Fudan University Shanghai Cancer Center from January 2007 to December 2017, were retrospectively enrolled. Serial imaging scans of each patient were intensively examined and the initial recurrence sites were categorized into five groups: thoracic recurrence, brain recurrence, neck recurrence, abdominal recurrence, and bone recurrence. Recurrence-free survival (RFS) were estimated by Kaplan-Meier curves. The Cox proportional hazards model was applied to estimate the association between RFS and clinic-pathological parameters (including age, sex, tumor size, TNM stage, tumor differentiation, tumor histology, lymphovascular invasion, visceral pleural invasion, and EGFR mutation subtypes), as well as a panel of routinely used immunohistochemical markers (including Her2, Ki67, TTF-1, CK20, CK7, CK5/6, p53, RRM1, NapsinA, p40, syn, Bcl-2, CDX2, ERCC1 and p63). **Result:** Ninety-one patients were identified, all of whom received adjuvant chemotherapy and 28 of whom received PORT. After a median follow up of 28 (range, 6-103) months, disease recurrence occurred in 62 patients. Thirty-six (58.1%) patients had thoracic recurrence, 15 (24.2%) had bone recurrence, 14 (22.6%) had brain recurrence, 9 (14.5%) had neck recurrence, and 8 (12.9%) had abdominal recurrence. Nineteen patients had multiple sites of initial recurrence. In terms of thoracic recurrence, initial relapse at the resection margin occurred in 1 patients and relapse in the mediastinal or ipsilateral hilar lymph nodes was observed in 11 patients. Ki67≥45% and positive expression of ERCC1 were identified as independent predictors of postoperative recurrence in multivariate analysis. Of note, PORT was not significantly associated with RFS in the whole population (p=0.877). However, among the 62 patients who had at least one of the independent predictors of postoperative recurrence (ie: Ki67≥45%, expression of ERCC1), PORT (n=22) significantly prolonged RFS (p=0.043). **Conclusion:** The majority of patients with stage III/N2 EGFR-mutant NSCLC developed their initial recurrence in the thorax. Patients with Ki67≥45% and/or positive expression of ERCC1 have a significant higher risk of postoperative recurrence, who may be the potential candidate for PORT.

EP1.18-03 OUTCOME OF SURGICAL RESECTION FOR INVASIVE MUCINOUS ADENOCARCINOMA: EXPERIENCE AT A SINGLE INSTITUTION

S. Omura, N. Motoi, Y. Yoshida, K. Nakagawa, S. Watanabe

National Cancer Center Hospital, Tokyo/Japan

Background: Invasive mucinous adenocarcinomas are new histological type which was determined by WHO classification 4thedition. The aim of this study was to investigate the outcome of surgical treatment for the patients with invasive mucinous adenocarcinoma who underwent surgery in our institution. **Method:** Between 2010 and 2013, We identified 68 patients with invasive mucinous adenocarcinoma who underwent surgical resection. We measured the distance of tumor cell size and mucinous size, and their clinical and pathological data were retrospectively reviewed. Overall survival (OS) rates were compared using a log-rank test and survival curves were plotted using the Kaplan–Meier method. **Result:** Participants comprised 31 men and 37 women, ranging in age from 46 to 83 years (median, 67 years). Median observation period in the survivors was 5.1 years. T classification of group oftumor cell size was T1/T2/T3,4=42/17/9 cases, and group of mucinous size was T1/T2/T3,4=38/17/13 cases. The 5-year overall survival rate for group oftumor cell sizewere T1/T2/T3,4=94.3/88.3/60.5%, and group of mucinous size were MS:T1/T2/T3,4=94.1/85.7/70.0%(5Y-OS tumor cell size / mucinous size:p=0.02/p=0.147, 5Y-RFS tumor cell size / mucinous size:p=0.04/p=0.237). **Conclusion:** Our result indicated that to determine T classification, we should measure the distance of tumor cell size instead of mucinous size.

Keywords: invasive mucinous adenocarcinoma, surgery

EP1.18-04 DO TUMOR-RELATED FACTORS PREDICT POSTOPERATIVE PULMONARY COMPLICATIONS IN PATIENTS UNDERGOING CURATIVE SURGERY FOR LUNG CANCER?

R. Litvinyak[1], N. Lukavetskyy[2], I. Hipp[1]

[1]*Lviv State Oncologic Regional Treatment and Diagnostic Center, Lviv/Ukraine,* [2]*Danylo Halytsky Lviv National Medical University, Lviv/Ukraine*

Background: The purpose of the present study is to identify preoperative risk factors related to pulmonary complications with a focus on tumor-related factors. **Method:** The authors conducted a retrospective review of the clinical records of all patients operated at the thoracic department of the Lviv State Oncological Regional Treatment and Diagnostic Center in 2010-2011. Tumor-related factors (histological type of lung cancer, tumor localization, TNM classification, past medical history of different cancer types) were analyzed. Postoperative pulmonary morbidity was defined as: respiratory failure, atelectasis, air leak more than 7 days, prolonged intubation (>72hours), pleural effusion, pleural empyema, chylothorax, and pneumothorax. The study included patients meeting the following criteria: age under 70, absence of neoadjuvant chemo- and/or radiotherapy, benign lung lesions, lung metastases, and non-curative lung resection. Logistic regression was performed using IBM SPSS Statistics 22 program. The result was considered statistically significant when p<0.05. **Result:** 144 patients underwent surgery for primary lung cancer at our institution. Lobectomy was performed in 36.1%, pneumonectomy – in 59%, lung resection – in 4.9% of patients. Histological examination showed that 84 patients had squamous cell carcinoma, 31 patients – adenocarcinoma, 6 patients – large cell carcinoma, 6 patients – small cell carcinoma, 8 patients – NET and 9 patients – other histological types. 12 (8.3%) patients had a medical history of a different type of cancer. The 30-day postoperative mortality rate was 3.47%, postoperative morbidity was 36.8%. The analysis showed that presence of a different type of cancer in past medical history (p<0.05) remained a significant risk factor for respiratory morbidity after lung cancer surgery while the presence of NET reduces the risk of postoperative pulmonary complications (p<0.05). **Conclusion:** Presence of a different type of cancer in past medical history constitutes a significant risk factor for respiratory postoperative morbidity in lung cancer patients. Patients with NET have a lower risk of postoperative pulmonary complications. We suggest that this result requires confirmation by further research

Keywords: lung cancer, postoperative pulmonary complication, risk factors

EP1.18-05 DO WE HAVE BETTER CHOICE FOR INOPERABLE LUNG CANCER PATIENTS WITH GOOD PERFORMANCE STATUS? CONCURRENT VERSUS SEQUENTIAL CHEMO-RADIOTHERAPY

N. Wu[1], X. Li[1], S. Li[1], S. Yan[1], Y. Wang[1], X. Wang[2], Y. Yang[1]

[1]*Peking University Cancer Hospital & Institute; Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/China,* [2]*Key Laboratory of Carcinogenesis and Translational Research (Ministry of Education), Beijing/China*

Background: Lung cancer has hitherto been the commonly life-threatening disease, adjuvant treatment regimens are being explored when tumors are beyond the indication of surgery. Concurrent chemo-radiotherapy is nowadays recommended when compared with sequential chemo-radiotherapy for overall survive benefits during treatment at the cost of increased acute esophageal toxicity. **Method:** Studies are searched from the public database (PubMed, EMBASE, Medline, Cochrane library. Data were analyzed by calculating pooled hazard ratio(HR) for survival and dichotomous variables with risk ratio(RR) for toxicities. Survival benefits (OS and PFS) was regarded as primary outcome, and toxicities was the second outcome. Data consolidation was reflected through forest plots with the bias were evaluated through the tools

of risks of bias. **Result:** 8 studies contained 1223 patients were finally included in this meta-analysis. There were no significant benefits in concurrent chemo-radiotherapy on the two groups' overall survival (HR,0.92; 95% CI, 0.81 to 1.04; p=0.18). Concurrent chemo-radiotherapy performed better in progression-free survival comparing with sequential chemo-radiotherapy (HR,0.83; 95% CI, 0.73 to 0.95; p=0.007). Concurrent chemo-radiotherapy increase the esophagitis and thrombocytopenia (grade 3-4), with (RR 4.49; 95% CI, 3.18 to 6.33; p<0.0001) and (RR 1.55; 95% CI,1.01 to 2.39; p=0.04), respectively. Whereas the two groups performed little significant difference in pulmonary toxicities (RR 0.83; 95% CI, 0.64 to 1.08; p=0.18). **Conclusion:** 8 studies contained 1223 patients were finally included in this meta-analysis. There were no significant benefits in concurrent chemo-radiotherapy on the two groups' overall survival (HR,0.92; 95% CI, 0.81 to 1.04; p=0.18). Concurrent chemo-radiotherapy performed better in progression-free survival comparing with sequential chemo-radiotherapy (HR,0.83; 95% CI, 0.73 to 0.95; p=0.007). Concurrent chemo-radiotherapy increase the esophagitis and thrombocytopenia (grade 3-4), with (RR 4.49; 95% CI, 3.18 to 6.33; p<0.0001) and (RR 1.55; 95% CI,1.01 to 2.39; p=0.04), respectively. Whereas the two groups performed little significant difference in pulmonary toxicities (RR 0.83; 95% CI, 0.64 to 1.08; p=0.18).

EP1.18-06 RESULTS OF CYTOREDUCTIVE WEDGE RESECTION OF THE PRIMARY SITE IN MULTIDISCIPLINARY TREATMENT OF STAGE III NON-SMALL CELL LUNG CANCER

M. Toda, A. Yamamoto, T. Iwata

Kansai Rosai Hospital, Inabasou, Amagasaki/Japan

Background: In patients with stage III non-small cell lung cancer (NSCLC), radical lung resection for curative intent sometimes can not be performed because of the highly local invasiveness of the tumor and/or the patient' poor general condition. In such cases, combination of radiation therapy, chemotherapy, and sometimes additional immunotherapy is considered. We have performed surgical excisional biopsy by wedge resection for primary site of the lung tumor not only with the diagnostic purose, but also with the intent of cytoreduction and sometimes narrowing the later irradiation range to reduce the risk of radiation pneumonitis (RP). The aim of this study was to determine the results of this cytoreductive wedge resection (CWR) retrospectively, exploring the risk of RP and progression-free survival (PFS). **Method:** We analyzed the medical records of 64 patients who were diagnosed clinical stage III NSCLC at our hospital between October 2012 and May 2018. The patients were divided into three groups according to the diagnostic method (42 patients were radical resection group, 10 patients were CWR group, and 12 patients were biopsy group that was including the patients diagnosed by surgical incisional biopsy and the primary tumor remained). The relationships between clinicopathological characteristics and the diagnostic method, and PFS among the three groups were investigated. **Result:** They were aged between 47 and 88 years (average 70.9), and 41 were men. Thirty-seven patients had adenocarcinoma, 19 had squamous cell carcinoma, and 8 had other. No significant difference was found in age, smoking index, performance status, adverse events in chemoradiotherapy among the 3 groups. In the biopsy group, men and squamous cell carcinoma were significantly more compared with the other 2 groups. PFS was not significantly different between the radical resection group and the CWR group but the biopsy group was significantly associated with shorter PFS (median 552 days, 533 days vs. 360 days, p = 0.01). The incidence of RP was 25% in the CWR group and 57% in the biopsy group (p = 0.20). **Conclusion:** The CWR group showed no inferiority upon PFS compared with the radical resection group. The CWR group showed more than a half rate of RP compared with the biopsy group however this was not statistically significant. It was suggested that the surgical removal of the primary tumor could reach the PFS that is not inferior to the radical resection, and also might reduce the risk of RP compared with the biopsy group.

Keywords: cytoreductive wedge resection, stage III non-small cell lung cancer, Radiation pneumonitis

EP1.18-07 EVALUATION OF PATIENT OUTCOMES USING HAEMATOLOGICAL BIO-MARKERS IN PATIENTS UNDERGOING CHEMORADIATION FOR NON SMALL CELL LUNG CANCER

A. Horne, K. Mactier, T. Evans, H. Hayhurst, I. Phillips, A. Price, S. Campell, F. Little, A. Tufail, K. Maclennan

The Edinburgh Cancer Centre, Western General Hospital, Edinburgh/United Kingdom

Background: Baseline haematological markers have potential to prognosticate the outcomes of patients undergoing chemoradiation for NSCLC (1)(2). We aimed to evaluate progression free survival (PFS) and overall survival (OS) from all patients with NSCLC receiving radical Cisplatin/Vinorelbine chemoradiation in 2017, based on absolute neutrophil count (ANC) and Neutrophil-Lymphocyte Ratio (NLR). **Method:** Patients identified by interrogating the local chemotherapy and radiotherapy prescribing databases. We included all patients whose intended treatment was radical radiotherapy (60Gy/30 fractions over 6 weeks), with 4 cycles of concurrent Cisplatin and Vinorelbine. We recorded patient and tumour characteristics alongside baseline ANC and NLR. Kaplan Meier Survival Analysis was used to compare Progression Free Survival (PFS) and Overall Survival (OS). Previous studies in locally advanced lung cancer has shown outcome differences comparing groups ANC of 8 and NLR of 5. We used a log rank test to differentiate between these cohorts with a pre-test p value of 0.05. **Result:** 50 patients were identified. Median age was 64 years old (range 42-78). 56% were male and 44% female. 11 patients (22%) were ECOG performance status (PS) 0, 38 patients (76%) PS 1 and 1 patient (2%) PS 2. No patients were PS 3 or 4. 10 patients(20%) had an ANC<8, 40(80%) had ANC >8 (Range 1.37-20.94). PFS (ANC<8 vs ANC>8, 115 weeks vs 34 weeks, p=0.005) and OS (130 weeks vs 34 weeks, p=0.047). 10 patients (20%) had a NLR>5, 40 (80%) had NLR<5 (Range 0.81-19.39). PFS (NLR <5 vs NLR >5, 101 weeks vs 32 weeks, p=0.053) and OS (130 weeks vs 59 weeks, p=0.132).

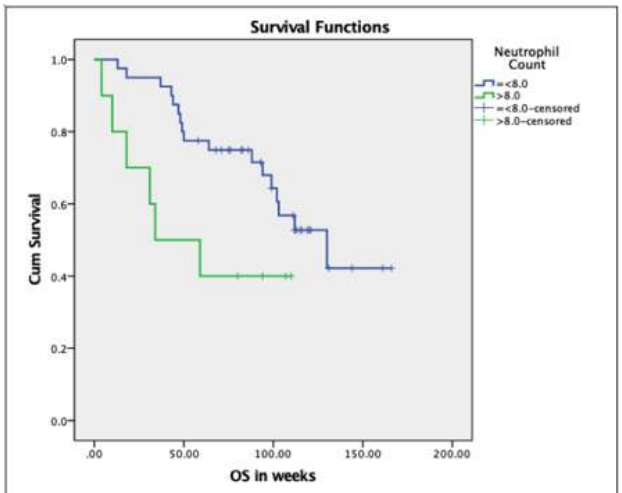

Figure 1: Kaplan Meier survival curve of patients with normal or high pre-treatment neutrophil count. Log Rank Significance = 0.047.
Median OS Neut =<8.0 = 130 weeks. (95% CI 86.904-173.096)
Median OS Neut >8.0 = 34 weeks. (95% CI 0.00 – 77.386)

Conclusion: The sample selected shows a statistically significant association between baseline neutrophil count and overall survival in patients receiving chemo-radiotherapy for NSCLC. This suggests that these haematological baseline characteristics can help risk stratify patients. Further understanding of NLR is required as the sample showed no statistical significance between the two groups although this may be in part due to relatively small sample size. EP1.18-08 PULMONARY LOBECTOMY AND COMPLETION PNEUMONECTOMY FOR IPSILATERAL LUNG CANCER AFTER RADICAL RESECTION

M. Okazaki, K. Suzawa, K. Miyoshi, S. Otani, H. Yamamoto, S. Sugimoto, M. Yamane, T. Oto, S. Toyooka

Okayama University Hospital, Okayama/Japan

Background: Ipsilateral reoperation such as lobectomy and completion pneumonectomy after radical resection of lung cancer is a high-risk operation. We evaluated outcomes after these operations in our hospital. **Method:** We retrospectively reviewed the records of 27 patients who underwent ipsilateral lobectomy or completion lobectomy for new primary lung cancer or recurrence after pulmonary lobectomy or bi-lobectomy between 1998 and 2017. **Result:** 9 patients underwent completion lobectomy, of which 4 were right and 5 were left, and 18 patients underwent lobectomy. Mean operative time was 308.7±27.4 minutes, and mean blood loss was 706.9±254.3mL. Blood loss was significantly higher in completion pneumonectomy patients as compared to lobectomy patients, whereas operative time was not different between the operations. There was no perioperative mortality, but intraoperative complications were seen in 4 cases (14.8%), which were 2 pulmonary artery injury, superior venous cava injury and azygos vein injury. Perioperative morbidity was seen in 8 cases (29.6%), and postoperative bronchopleural fistula occurred in one case. Fourteen patients had Pathological stage IA disease, 6 had IB, and 5 stage II or over. As clinical outcome, 5-year overall survival rate was 71.1%. **Conclusion:** Pulmonary lobectomy or completion pneumonectomy for ipsilateral lung cancer after radical resection were performed in 27 patients without perioperative mortality. Our results strongly suggests that this strategy is a meaningful option for new or recurrent ipsilateral lung cancer.

Keywords: completion pneumonectomy, reoperation, ipsilateral

EP1.18-09 ANALYSIS OF THE ROLE OF POSTOPERATIVE RADIOTHERAPY IN PATHOLOGICAL N2 NON-SMALL CELL LUNG CANCER WITH PROPENSITY SCORE MATCHING

J. Li[1], L. Su[2]

[1]*Fujian Medical University Cancer Hospital, Fujian Cancer Hospital, Fuzhou/China,* [2]*Fujian Cancer Hospital & Fujian Medical University Cancer Hospital, Fuzhou/China*

Background: N2 non-small cell lung cancer (NSCLC) is a heterogeneous disease. For operable patients with postoperative N2 non-small cell lung cancer, the optimum adjuvant treatment strategy is still in dispute. Our aim was to assess the efficacy of conbine postoperative chemoradiotherapy (POCRT) or postoperative chemotherapy(PCT)alone following surgery in pathological N2 non-small cell lung cancer using propensity score matching, and to explore the factors influencing the prognosis. **Method:** Between 2004 and 2014, a total of 175 patients fulfilled the inclusion criteria. The initiation of PCT started later than 2 weeks after the operation. The regimens of PCT in the present study included a cisplatin-based regimen and were administered for at least 2 cycles. POCRT was executed sequentially or sandwiched with PCT with three-dimensional conformal radiotherapy(3D-CRT) or intensity-modulated radiotherapy technique(IMRT). The prescription dose to clinical target volume (CTV) was 50 (range 44-60) Gy, Data were analyzed using SPSS version 24.0. Survival curves were produced using the Kaplan-Meier estimator method and compared with the log-rank test. Univariable and multivariable analyses of clinical characteristics. All available patient and tumor variables were compared using the $\chi 2$ test. Propensity score matching (PSM) analyses were used to compensate for differences in baseline characteristics between the POCRT and PCT groups to confirm the survival difference. The survival of the two groups was followed up and the effect of postoperative radiotherapy was analyzed. **Result:** The median survival time was 57 vs 40 months in the POCRT and PCT groups, and the 1, 3 and 5-year OS rates in the POCRT and pCT groups were 98.3 vs. 86.1%, 71.7 vs.53.0% and 45.7 vs. 39.0%, respectively (P=0.019). Exploratory subgroup analysis found that compared with PCT, POCRT improved OS in patients with squamous cell subtype (P=0.010), no lymphovascular invasion (P=0.006), pN2a (P=0.006) or total number of metastatic lymph nodes ≤7 (P=0.016). Following PSM, a total of 113 events were identified in both the POCRT and PCT groups, with 60 and 53 patients in each group, respectively. There was no significant difference in the general clinical data between the two groups after matching. The median survival time was 57 vs 63 months in the POCRT and PCT groups after matching, and the 1, 3 and 5-year OS rates in the POCRT and PCT groups were 98.3 vs. 92.5%, 71.7 vs. 64.2% 和 45.7 vs. 50.7% respectively, with no significant difference (P=0.463). Following PSM, the survival differences between POCRT and PCT in the various subgroups were not statistically significant, except in patients with squamous cell lung cancer (P=0.010), there was also a trend toward an increase in the overall survival of pN2-NSCLC with pN2a (P = 0.196) or total number of metastatic lymph nodes ≤7 (P=0.367). **Conclusion:** Univariate and multivariate analyses indicated that T stage, total number of MLNs and POCRT were independent factors affecting OS. POCRT following complete resection clearly demonstrated superior survival compared with pCT. And POCRT may be specifically recommended to N2 patients with squamous cell lung cancer, particularly those with limited nodal involvement and T4 disease.

EP1.18-10 BILATERAL MEDIASTINAL LYMPHADENECTOMY IS ASSOCIATED WITH BETTER SURVIVAL IN STAGE IA-IIIB NON-SMALL CELL LUNG CANCER

A. Turna[1], H. Kara[1], M. Agkoç[2], B. Sözen[1], M. Işcan[1], E. Erşen[1], K. Kaynak[1]

[1]*İstanbul University-Cerrahpaşa Cerrahpasa Medical School, İstanbul/Turkey,* [2]*Istanbul University Istanbul Medical School, Istanbul/Turkey*

Background: Studies have shown that, mediastinal lymph node dissection improves survival in non-small cell lung cancer. However, the role of bilateral lymph node dissection is yet to be elucidated. The aim of this study was to analyze the impact of bilateral mediastinal lymphadenectomy on survival in operable and inoperable non small-cell lung cancer (NSCLC) patients. **Method:** Between May Between March 2010 and December 2017, 1344 patients with potentially operable non-small cell lung cancer were evaluated. Of those 560 patients(41.7%) underwent video-assisted mediastinoscopic bilateral mediastinal lymphadenectomy(VAMLA) including removal of upper paratreacheal, lower paratracheal, subcarinal lymph node dissection via cervical incision, As the preference of surgeon, 510 patients(37.9%) underwent mediastinoscopic biopsy before planned operation. Of 1344 patients, 801(59.6%) were found to have no mediastinal lymph nodal involvement after bilateral lymphadenectomy or mediastinoscopy. Of those, 690 patients(51.3%) underwent anatomical lung resection. The patients who had negative VAMLA/mediastinoscopy results underwent anatomic pulmonary resection and systematic lymph node dissection/systematic sampling. **Result:** The 5-year survival rate in all patients was 44% for bilateral lymphadenectomy patients and 35.1% for patients who had unilateral mediastinal lymphadenectomy patients(p=0.001). Among the patients who had pulmonary resection (pstage IA-IIIA), The 5-year survival was 88% for BML patients and 61% for patients who had mediastinal lymph node sampling(P=0.02). By multivariable analysis, BML was associated with better survival (odds ratio, 0.64; 95% confidence interval, 0.27-0.83; P=0.02). After propensity matching of two groups, BML provided independently better survival (odds ratio; 95% confidence interval, 0.34-0.82; P=0.03) **Conclusion:** ML was associated with improved survival in resectable (pIA-IIIA) or non-resectable (pIIIA-IIIB) NSCLC patients.

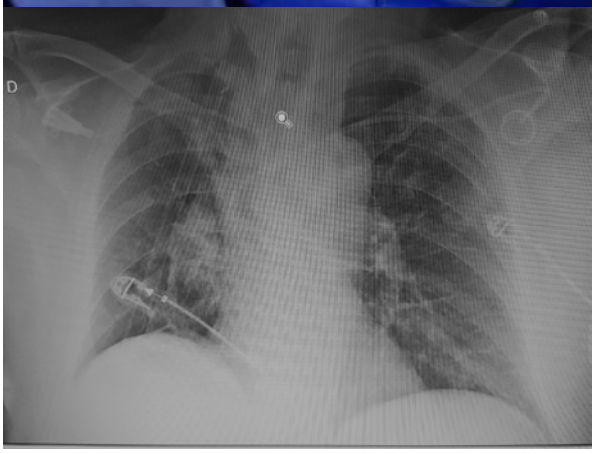
EP1.18-11 PANCOST TUMOR: FEASIBILITY OF MINIMALLY INVASIVE APPROACH

D. Brandao[1], F. Brito[2], M. Balieiro[3], E. Ponzio[1]

[1]*Thorax CMI, Brasília/Brazil,* [2]*Hospital de Base DF, Brasília/Brazil,* [3]*Hospital dos Servidores do Estado RJ, Rio de Janeiro/Brazil*

Background: Surgery for Pancoast tumors is one of the most challenging procedures in thoracic oncology. Completeness of resection and preservation of vital structures plays major role in survival and post operative quality of life. Classical posterior approach (Shaw-Paulson) and anterior (Dartevelle) are well defined

in literature, offers excellent exposure, and have been used for many decades, but is there a safe and less invasive surgical procedure for these patients? **Method:** Patient information and surgical notes of patients treated by our group with a hybrid-minimmaly-invasive approach were reviewed. **Result:** We performed two hybrid-minimally invasive pancost tumor resection in 2019. One patient was male. Both had squamous cell carcinoma at the rigth upper lobe with invasion the first two ribs, shoulder/arm pain and Horner syndrome. One was treated with induction chemoradiotherapy and other had upfront surgery. Procedure has been carried out with 4 incisions: A) posterior 10cm vertical incision betwen the medial border of scapula and spine, from fourth rib up to the base of the neck; B) anterior 3cm over the 4th intercostal space; C) 12mm trocar at 7th anterior axillary line for camera; D) 12mm trocar at 8th posterior axillary line for stapling. VATS rigth upper lobectomy with lymphadenectomy was performed by sequential stapling of upper lobe vein, arterial branches, bronchus and fissure at last. Then the chest wall resection "en bloc" with rigth upper lobe, first and second ribs, ligation of the T1 root of brachial plexus, scalene muscles insertions and soft tissues below the C 8 root and subclavian artery adventicia. Mean operative time was 270'. Frozen sections from surrounding margins were negative. Patients had uneventfull recoveries and were discharged on 5th and 6th post operative days with oral analgesics.



Conclusion: The Hybrid-minimally invasive approach is feasible and offer the advantage of less surgical trauma and probably earlier recovery.

EP1.18-12 THE NEUTROPHIL AND PLATELET TO LYMPHOCYTE RATIOS AND GLASGOW PROGNOSTIC SCORE AS A PREDICTOR FOR RELAPSE AFTER STEREOTACTIC RADIATION FOR LUNG CANCER

J. Berg[1], M. Lindberg[1], M. Bengtson[1], O.T. Brustugun[2], Å. Helland[2]

[1]*Vestfold Hospital Trust, Tønsberg/Norway,* [2]*Cancer Genetics, Oslo University Hospital - the Norwegian Radium Hospital, Oslo/Norway*

Background: Chronic inflammation plays an important role in lung carcinogenesis. The neutrophil-to-lymphocyte (NLR), platelet-to-lymphocyte ratios (PLR) and modified Glasgow Prognostic Score (mGPS) have been associated with overall mortality and PLR greater than 250 with non-local failures in non-small cell lung cancer (NSCLC) patients. We hypothesised that NLR, PLR and mGPS were higher in patients developing non-local failures within the first year after stereotactic body radiation therapy (SBRT) than in those without non-local failures. **Method:** Medically inoperable stage I NSCLC patients were included in a prospective, observational, single centre study from February 2014 until December 2017. Follow up included physical examination, CT scans and blood samples at baseline, 6 weeks, 3, 6, 9 and 12 months after SBRT. Most patients took baseline blood samples within mean 7 days before treatment. Differences in NLP, PLR and mGPS between the groups (with and without non-local failures) were calculated using Mann-Whitney-Wilcoxon U-test. **Result:** We included 46 patients with median age 75 years, of which 67% were men. Comorbidities were common, and 80% had chronic obstructive pulmonary disease (COPD). Six patients were diagnosed with non-local failures within the first year of follow-up. Multiple metastases were identified in the mediastinum (2 patients), contralateral lung (2 patients) and in the liver and bone (2 patients).

Marker	Non-local failures (n=6)	Without non-local failures (n=40)	P-value
NLR	3.3	3.5	0.83
PLR	246	158	0.35
mGPS	0.67	0.33	0.27

Conclusion: Our study found no statistically significant association between increased NLR, PLR, mGPS and the identification of non-local failures within the first year after SBRT. This is a relatively small cohort of patients, and the patients suffered from serious chronic medical comorbidities such as COPD, chronical renal and cardiac disease. These medical conditions can also influence NLR, PLR, mGPS and can explain our finding.

EP1.18-13 REVIEW OF PREOPERATIVE EXAMINATION

F. Hoshi[1], A. Sakurada[2], M. Noda[2], T. Sado[2], Y. Matsuda[2], H. Oishi[2], H. Notsuda[2], T. Hirama[2], S. Eba[1], H. Yabuki[2], M. Katahira[2], Y. Suzuki[2], K. Abe[2], K. Sato[2], H. Katsumata[2], H. Oshio[2], T. Yamada[2], Y. Okada[2]

[1]*Aomori Prefectural Central Hospital, Aomori/Japan,* [2]*Institution of Development, Aging and Cancer, Tohoku University, Sendai/Japan*

Background: Before lung resection, it is necessary to perform various preoperative examinations to determine the indication for surgery. In our department, lung blood flow scintigraphy is performed on all cases scheduled for lung resection, and predicted post operation (ppo)%FEV1 and ppo%DLCO, are calculated based on lung function tests and scheduled surgery. Both have a cut-off value of 40%, and if the case has less than 40%, change to surgery with less lung volume loss. However, the large number of cases have no difference between left and right lung blood flow ratios. Even if the difference is large, almost all cases have organic lung abnormalities which are detected by CT easily. In addition, even if there is a large dissociation in the left-right difference in pulmonary blood flow, it is very rare that the predicted value after surgery is less than 40% in normal respiratory function patients. In recent years, most institutions do not perform pulmonary blood flow scintigraphy as preoperative examination, and it may be necessary to examine the significance of lung blood flow scintigraphy as preoperative examination. **Method:** Of the cases in which lung blood flow scintigraphy was performed as a preoperative examination for lung resection in our department from January 2010 to December 2018, we selected the cases who has the blood flow ratio between the left and right lungs has more than doubled difference and doesn't have detectable organic abnormality and history of lung resection. **Result:** Nineteen out of 1570 cases were extracted. The blood flow of the right lung was more than twice that of the left lung in 18 cases. 19 cases have 12 men and the average age is 73.6 ± 6.9. There were 13 cases undergoing planned surgery, 3 cases that could not be resected due to the progress of the tumor, 1 case refusing the operation, and only 2 cases changed treatment based on the result of scintigraphy. One case treated by radiation therapy and another was treated by PDT. **Conclusion:** It is suggested that lung blood flow scintigraphy may not be necessary in cases who have normal pulmonary function and have no organic abnormalities.

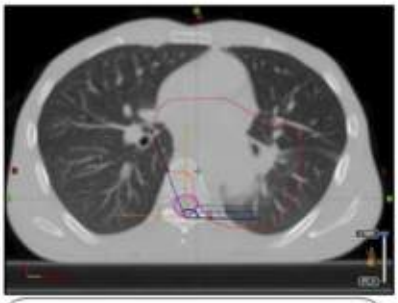
EP1.18-14 ALGORITHM FOR DECIDING RADIOTHERAPY TECHNIQUE IN STAGE III NON-SMALL CELL LUNG CANCER

N. Das, R. Kapoor, A. Sood, A. Oinam, R. Miriyala, N. Singh

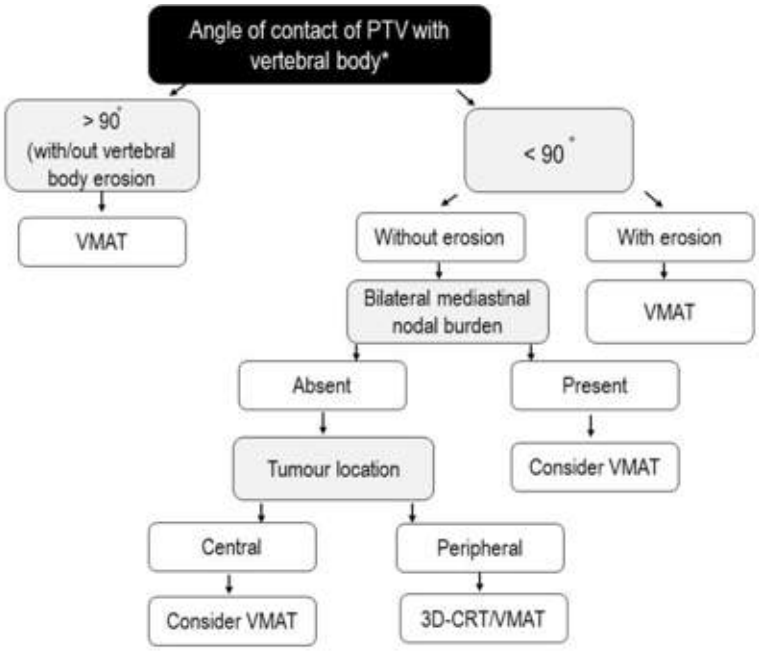
Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh/India

Background: Concurrent chemoradiotherapy has shown superior survival outcomes in inoperable, Stage III non-small cell lung cancer (NSCLC) with good performance status. Usage of 3-dimensional conformal radiotherapy (3D-CRT) technique is commonest with intensity modulated radiotherapy (IMRT) gaining popularity owing to its ability to spare normal tissues. In our study we analysed the tumour and nodal characteristics of patients to predict which technique maybe beneficial by generating optimised plans of both 3D-CRT and volumetric modulated arc radiotherapy (VMAT), a type of IMRT. **Method:** A total of 27 Stage III NSCLC patients underwent PET-CT (in the treatment position) co-registered treatment planning using either 3D-CRT or VMAT. The total prescription dose was 60 Gy in 30 fractions over 6 weeks with concurrent cisplatin based chemotherapy. Retrospectively alternate treatment plans were generated to obtain two sets of plans (3D-CRT and VMAT) of each patient for dosimetric comparison. The tumour and nodal characteristics and treatment technique were analysed to identify predictive factors limiting total dose delivery. The angle of contact of the PTV with the circumference of the vertebral body was calculated for patients where the tumour or nodal mass was in contact with the vertebral body (Figure 1).

Figure 1



*Angle of contact: angle subtended by the lines joining the extreme extents of the PTV on the vertebral body to the midpoint of a horizontal line joining the transverse process . Here angle of contact >90 degrees



Result: Of the 27 patients enrolled, 6 patients could not be planned to the complete dose of 60 Gy in a single phase by 3D-CRT. Dose limiting factors were high spinal cord doses due to vertebral body erosion (2 out of 6) and bilateral bulky mediastinal lymphadenopathy (4 out of 6). Alternate VMAT plans for these patients could achieve the dose constraints in all but the two patients with vertebral body erosion. Differences in the normal tissue doses of bilateral normal lungs, esophagus, heart and spinal cord were compared between both techniques to ascertain statistical significance. **Conclusion:** The spatial location of the tumour and nodal burden rather than the volume limited the maximum dose delivered. For tumours with vertebral body contact of more than 90 degrees, VMAT should be used. With gross vertebral body erosion, even VMAT falls short if the PTV includes the spinal cord. In view of high patient volume and limited resources, VMAT is not an economical option for all patients. A simple clinical algorithm is outlined (Figure 1) which will help select patients who will best benefit from VMAT.

Keywords: NSCLC, Treatment algorithm, 3D-CRT versus IMRT

EP1.18-15 SURGICAL RESULTS OF PRIMARY MUCOEPIDERMOID CARCINOMA OF LUNGS: A 9 YEARS' EXPERIENCE

T.M. Tsai, M.-W. Lin, H.-H. Hsu, J.-S. Chen

National Taiwan University Hospital, Taipei/Taiwan

Background: Pulmonary mucoepidermoid carcinoma is a rare salivary-gland type lung cancer and accounts for 0.1%–0.2% of all primary lung malignancies. The optimal treatment of pulmonary mucoepidermoid carcinoma is not well determined. The aim of this study was to examine the surgical outcomes for the pulmonary mucoepidermoid carcinoma in our institution. **Method:** From January 2010 to December 2018, we performed a retrospective review including all patients with primary pulmonary mucoepidermoid carcinoma of lung who underwent pulmonary resections in our institutions. The patients'demographic, clinical, and survival data were analyzed. **Result:** A total of 3124 primary lung cancer patients underwent surgical resections by the same surgical team during the 8-year study period. 8 cases (0.25%) patients who were diagnosed with primary mucoepidermoid carcinoma of the lung were analyzed in this study. The patients' characteristics are shown in Table 1. The median age of all patients was 57 year-old (range: 22-75 year-old). Cough is the most common symptom (5 cases, 62.5%). 7 cases had a low-grade tumor, and all the cases were completely resected thoracoscopically. Two cases were resected by wedge resection because peripherally located, and two cases required bronchial reconstruction. There was no adverse effect after the operation. One case recived adjuvent chemotherapy due to nodal invasion. However, this case had disease progression with patella bone metastasis 5 months after opeartion. The other cases were free of malignancy with a median follow-up of 27.2 months.

Table 1. Patients' demographic's data.

Age	Sex	Tumor Size (cm)	pTMN	p-Stage	Grade	Tumor Location	Surgical Procedure	Outcome
22	F	2	T1aN0M0	IA	Low	RLL, peri bronchial	Lobectomy	Disease Free
72	M	2.8	T2aN0M0	IB	Low	LLL, peripheral	Wedge	Died of cardiac disease 5 years after surgery
27	M	2.5	T1bN0M0	IA	Low	LLL, endobronchial	Lobectomy	Disease Free
75	F	1	T1aN0M0	IA	Low	LLL, peripheral	Wedge	Disease Free
53	F	2.8	T2aN0M0	IB	Low	LLL, bronchial	Sleeve Lobectomy	Disease Free
67	F	3.6	T2aN1M0	IIA	High	RUL, peri bronchial	Sleeve Lobectomy	Died due to bone metastasis 5 months after surgery
49	F	2.2	T1bN0M0	IA	Low	RUL, peri bronchial	Lobectomy	Disease Free
49	M	2.2	T1bN0M0	IA	Low	LLL, endobronchial	Lobectomy	Disease Free

Conclusion: Complete surgical resection of a mucoepidermoid carcinoma of lungs can be atributed to a long-term survival in patients. For an elederly patient with a peripherally located tumor, wedge rsection with mediastinal lymphnode dissection could be an alternative treatment.

EP1.18-16 SURGERY FOR LOCALLY ADVANCED LUNG CANCER INVADING THE SPINE AFTER CHEMORADIOTHERAPY

K. Matsuda[1], K. Kaseda[2], K. Masai[3], K. Asakura[2], T. Hishida[2], H. Asamura[3]

[1]*Keio University, School of Medicine, Tokyo/Japan,* [2]*Keio University School of Medicine, Tokyo/Japan,* [3]*Keio University, Tokyo/Japan*

Background: Treatment for locally-advanced lung cancer invading the spine remains challenging, and multimodality treatment should be considered. The aim of this study was to clarify surgical outcomes following induction chemoradiotherapy (CRT) for lung cancer invading the spine following chemoradiotherapy. **Method:** We retrospectively reviewed clinical and pathological data of locally-advanced lung cancer patients with vertebral invasion, in who we have performed total or partial vertebrectomy after induction CRT between 2011 and 2017. **Result:** A total of 4 patients were extracted. All patients were diagnosed as cT4N0M0 disease based on chest computed tomography (CT) and positron emission tomography (PET)-CT, and vertebral invasion was evaluated by chest computed tomography (CT) and magnetic resonance imaging. The histologic type included adenocarcinoma in 3 patients and squamous cell carcinoma in one patient, respectively. Average dose of radiation was 50 Gy. Total vertebrectomy was performed in 3 patients and transverse-process resection in one patient. Average Median operation time and blood loss were 800 minutes and 878 ml, respectively. In all 4 cases, complete R0 resection was performed. There was no perioperative and in-hospital death, and complication occurred in one patient. Median follow-up period was 39 months (range, 16-63 months), and median overall survival time and relapse free survival time were 39 months (range, 16-63 months) and 29months (range, 7-63 months). **Conclusion:** The current preliminary result indicated that lung cancer surgery combined with vertebrectomy after induction CRT was feasible. Although our series were small, this multimodal treatment strategy might be a option for cT4N0M0 lung cancer invading to the spine. Further study should be conducted to confirm the current result with a large sample size.

Keywords: locally advanced lung cancer, surgery after chemoradiotherapy, invading the spine

EP1.18-17 PRE-RADICAL RADIOTHERAPY PLASMA EGFR DNA LEVELS IN LUNG CANCER PATIENTS MAY PREDICT FOR EARLY DISEASE PROGRESSION

B.S.H. Chia, W.L. Nei, K.W. Fong, S.P. Yap, K. Chua, C. Yip, W.L. Ng, T.R. Siow, M.-H. Tan

National Cancer Centre Singapore, Singapore/Singapore

Background: Circulating cell-free tumour DNA is an alternative method to detect for and monitor sensitising EGFR mutations in metastatic lung adenocarcinoma. The clinical utility of plasma EGFR (pEGFR) DNA is increasing but there is limited data for its use in early stage patients. We performed a pilot prospective study to test for and monitor pEGFR DNA in lung cancer patients planned for radical lung radiotherapy (RT). **Method:** Patients with biopsy proven lung adenocarcinoma harbouring sensitising EGFR mutations that were referred for radical lung RT were recruited in our centre. Patients who tested positive on baseline plasma (Pre-RT) sample would be monitored at 1 month post-RT. Detection of pEGFR p.E746_A750del, p.L858R and p.T790M was performed by mutation-specific quantitative PCR. The protocol was later updated to allow the use of next-generation sequencing, LiquidMARK™ Lung assay. Patients baseline characteristics, tumour and treatment details were recorded. Follow-up data was collected prospectively. **Result:** From April 2017 to August 2018 a total of 9 patients (3 Stage IA/B, 1 IIB, 3 IIIA and 2 IIIC) were enrolled. All were PET staged. 8 underwent radical lung radiotherapy (3 SBRT, 5 chemo-radiotherapy). 3 patients had detectable baseline pEGFR. These patients had stage IIIA/C disease at diagnosis. None of the 4 Stage I/II patients had a detectable pEGFR DNA. Gross tumour volume did not correlate with pEGFR detection rate (GTV range 9.1cc - 124.9cc). Median follow-up was 300 days (range 196-404 days). Of the 3 patients with positive pEGFR DNA mutations, 1 defaulted treatment, 1 had a positive post-RT blood test and 1 refused 2nd blood test. These patients had distal metastatic relapse shortly after RT while patients with an undetectable baseline pEGFR DNA remained disease free on last follow-up. On analysis, a positive baseline pEGFR DNA predicted for early disease progression (Median time to progression 99.5 days vs NR, p=0.004). **Conclusion:** Our study was terminated due to poor recruitment. In early stage I/II lung cancers, pEGFR DNA was not detectable suggesting limited utility of this test in these patients. Detection rate was higher in stage III patients. Detection of baseline pEGFR DNA in patients with treatable lung cancers appears to have a negative prognostic value and could suggest evidence of micro-metastatic disease. This test may be a useful biomarker to guide treatment and follow-up in locally advanced patients and should be explored in larger studies.

Keywords: Plasma EGFR DNA, prognostic, Locally advanced Lung adenocarcinoma

EP1.18-18 BODY SHAPE AND TISSUE COMPOSITION INFLUENCES UNIFORM DISTRIBUTION OF TUMOR TREATING FIELDS INTENSITY DELIVERED TO THE LUNGS

N. Urman, Z. Bomzon, H. Hershkovich, U. Weinberg, E. Kirson, Y. Palti

Novocure Ltd, Haifa/Israel

Background: Tumor Treating Fields (TTFields) are low intensity, alternating electric fields in the intermediate frequency range that disrupt mitosis. TTFields are approved for the treatment of glioblastoma. A Phase 3 study investigating the efficacy of TTFields in Non-Small Cell Lung Cancer is ongoing [LUNAR NCT02973789]. TTFields are delivered through two pairs of transducer arrays placed on the patient's skin. Since the efficacy of TTFields increases with intensity, identifying factors that influence field intensity in the lungs is beneficial to understand how body shape and tissue composition influence the field intensity. We present a computer-simulation-based study investigating the effect of body size, shape, and composition on TTFields distribution in the lungs. **Method:** This study was performed using the Sim4Life software package and realistic computational phantoms: female (ELLA), male (DUKE), and obese male (FATS). Various array layouts were placed on the models, and the distribution of TTFields within their lungs were calculated and compared. **Result:** For all models, uniform field distributions within the lungs were obtained when the arrays were axially-aligned with the parenchyma as much as anatomically possible. The layouts that generated the highest average field intensities were those in which one pair of arrays delivered an electric field from the anterolateral to the posterior-contralateral aspect of the patient and the second pair inducing the field from the anterior-contralateral to the posterolateral aspect of the patient. In all models, these layouts led to average field intensities in the lungs above the therapeutic threshold (>1 V/cm). The highest field intensities were seen in DUKE's lungs and the lowest field intensities in FATS's lungs. Analysis suggests that field attenuation was caused primarily by layers of fat. Hence, the lower field intensities in the lungs of ELLA and FATS can be largely attributed to the thick layers of fat present in FATS and the fatty tissue in ELLA's breasts. **Conclusion:** This study provides insights into how TTFields distribution in the lungs is influenced by body composition. These findings will help to optimize the placement and design of transducer array placement for the treatment of lung cancers.

EP1.18-19 PATIENTS WITH UNRESECTABLE STAGE III NON-SMALL CELL LUNG CANCER ELIGIBLE TO RECEIVE DURVALUMAB IN CLINICAL PRACTICE

K. Furuhashi, O. Hataji, Y. Nakamura, Y. Suzuki, T. Sakaguchi, K. Ito, K. Fujiwara, Y. Nishii, O. Taguchi

Matsusaka Municipal Hospital, Matsusaka-city, Mie/Japan

Background: Durvalumab has been reported to significantly prolong progression-free survival and overall survival in patients with stage III unresectable non-small cell lung cancer (NSCLC) after chemoradiotherapy, compared with placebo. The aim of this retrospective study is to evaluate the eligibility of patients with unresectable stage III NSCLC able to receive consolidation therapy with durvalumab in clinical practice based on the PACIFIC study criteria. **Method:** From January 2011 to May 2018, electronic data were collected from patients diagnosed with unresectable stage III NSCLC treated with definitive chemoradiotherapy. A total of 81 patients were identified. Of these, 73 were treated with platinum-based chemotherapy based on the criteria of the PACIFIC study. **Result:** Radiation pneumonitis of any grade occurred in 54 patients (73.9%) who received definitive chemoradiotherapy. Of these, 12 (16.4%) developed radiation pneumonitis of grade 2 or more within 42 days after chemoradiotherapy and would be excluded from durvalumab treatment. Two patients (2.7%) developed other pneumonitis, 7 patients (9.6%) showed poor performance status, and 3 patients (4.1%) displayed disease progression at initial assessment. After considering overlapping cases mentioned above, 22 patients (30.1%) were ineligible to receive durvalumab by the criteria utilized in the PACIFIC study. **Conclusion:** In clinical practice, approximately 70% of patients with unresectable stage III NSCLC would be eligible to receive consolidation therapy with durvalumab.

Keywords: chemoradiotherapy, durvalumab, Non-Small Cell Lung Cancer

EP1.18-20 SLEEVE LOBECTOMY FOR CENTRALLY LOCATED NON-SMALL CELL LUNG CANCER: INITIAL SHORT-TERM RESULTS FROM A SINGLE INSTITUTE IN NORTHEAST CHINA

H. Liu, Y. Ma, Z. Yu, C. Zhang, G. Wang, H. Liu, G. Wang

Liaoning Cancer Hospital & Institute, Shenyang/China

Background: To evaluate the feasibility and short-term outcome of sleeve lobectomy for centrally located non-small cell lung cancer in Northeast China. **Method:** Clinical data of 69 patients who underwent sleeve lobectomy in the Department of Thoracic Surgery of Liaoning Cancer Hospital & Institute from November 2016 to February 2019, were retrospectively collected. Operative strategies, duration of postoperative drainage, postoperative hospital stay, complications and follow-up data were recorded. Simple bronchoplasty or angioplasty without any sleeve resection was excluded in this study. **Result:** 14 of the 69 patients received neoadjuvant chemotherapy because of N2 disease. Nine underwent bronchial and arterial sleeve lobectomy (double sleeve resection), 6 bronchial sleeve resection and partial resection of pulmonary arterial wall (angioplasty), 2 arterial sleeve resection and partial resection of bronchial wall (bronchoplasty), 2 arterial sleeve resection only, 50 bronchial sleeve resection only., Simple sleeve resection was achieved in 57 cases,

and extended sleeve resection in 12 cases. Of the extended cases, two were classified as Okada type B, 2 Okada type C, 5 Okada type D, 2 with complex anastomosis between left main stem bronchus with superior and basal bronchus, 1 with anastomosis between trachea and right middle lobe bronchus. There was 1 perioperative death (1.4%), which was highly suspected of myocardial infarction. There was neither anastomotic fistula nor symptomatic stricture, which needed treatment thereof. Surgical margin status was R0 in 50 patients (72.5%), R1 in 18 patients (26.1%), and R2 in 1 patient (1.5%). The median time of postoperative drainage was 7 days (3-33 days), median time of postoperative hospital stay was 11 days (6-39 days). Major complications occurred in 14 patients (21.5%), including 2 with chylothorax, 7 pneumonia, 3 pleural effusion, 1 air leak, 1 heart failure. Atelectasis necessitated endoscopic sputum clearance in 16 patients. Pathology showed squamous cell carcinoma in 50 patients, adenocarcinoma in 16, adenosquamous carcinoma in 2, and large cell carcinoma in 1 patient. Two patients were in stage IA2, 2 in stage IA3, 12 stage IB, 2 stage IIA, 34 stage IIB, 12 stage IIIA,and 5 stage IIIB. The median follow-up duration was 14 months (0-25months), with the follow-up rate of 97.1%. All patients are alive except for one death. The local-recurrent rate was 1.4% (1/69), and the distant metastasis rate was 7.2% (5/69). **Conclusion:** Sleeve lobectomy is a safe and reasonable procedure for surgical treatment of centrally located non-small-cell lung cancer. It has the advantages of expanding operation indication, avoiding pneumonectomy, preserving more pulmonary function, and improving postoperative quality of life.

Keywords: sleeve lobectomy, bronchoplasty, arterioplasty

EP1.18-21 SURGICAL TREATMENT FOR LUNG CANCER IN TWO PATIENTS WITH SITUS INVERSUS

E. Matsuda, Y. Mouri

Saiseikai Imabari Hospital, Imabari/Japan

Background: Situs inversus is congenital recessive condition with a prevalence of 1to 2 in 10000 people. All organs of chest and abdomen locate at opposite side. Cardiac and vascular anomalies are frequent in patients with situs inversus compared to the general population. There are few reports of resected cases of lung cancer with situs inversus. In such cases, additional technical difficulties during operation should be expected. The risk of situs peri-operative cardiovascular complications in patients with situs inversus is higher. We report two cases of lung cancer in patients with situs inversus who underwent video assisted thoracoscopic surgery. **Method:** Case 1. A medical check showed abnormal shadow in left lower lobe in 72-year-old man. Chest CT revealed tumor, 3.5cm diameter, in left lower lobe and situs inversus. Squamous cell carcinoma was confirmed by transbronchial biopsy. Chest three-dimensional computed tomography showed that pulmonary artery corresponded to the usual right side pattern. Left lower lobectomy was performed successfully after induction chemotherapy. Case 2. A medical check showed abnormal shadow in left upper lobe in 70-year-old woman. Chest CT revealed tumor, 1.5cm diameter, in left upper lobe and situs inversus. Chest three-dimensional computed tomography showed that pulmonary artery corresponded to the usual right side pattern. Thoracoscopic surgery was performed. Upper pulmonary vein was injured during dissecting procedure of hilar. Left upper lobectomy was completed after repair of upper pulmonary vein. Adenocarcinoma was confirmed by postoperative pathological examination. **Result:** We performed operation for lung cancer in two patients with situs inversus successfully. Diagnosis of situs inversus can be confirmed using chest three-dimensional computed tomography. **Conclusion:** Anatomical resection is optimal surgical treatment for lung cancer. However anatomical resection of lung is associated with an increased risk of peri-operative complications in such patients who have stractual anomalies of lung, heart and mediastinum. Situs inversus is rare. Pre and intraoperative attention should be paid for vascular anomalies to avoid intraoperative injuries and complications. Chest three-dimensional computed tomography should be performed before surgery to detect anomalies of pulmonary artery and vein.

EP1.18-22 A RANDOMIZED PROSPECTIVE STUDY COMPARING CONCOMITANT CRT USING PACLITAXEL-CARBOPLATIN AND ETOPOSIDE-CISPLATIN IN LOCALLY ADVANCED NSCLC

S. G Y

Post Graduate Institute of Medical Education and Research, Chandigarh/India

Background: Several randomized trials and meta-analyses have established that the best survival can be achieved in patients with locally advanced NSCLC with concurrent CRT instead of the sequential approach. Most of the studies used cisplatin based regime along with radiation. However, due to the higher toxicity of this treatment, this is generally given to patients with minimal or no comorbidities, and who are relatively young. In this study, we have compared different CCT regime along with RT in inoperable locally advanced non-metastatic NSCLC. **Method:** In this study, 36 patients were enrolled. In study arm patients were treated with concomitant CCT using Injection cisplatin 20 mg/m2/day iv days 1-5 & days 29-33 and Injection etoposide 50 mg/m2/day iv days 1-5 & days 29-33 along with EBRT to a total dose of 60 Gy in 30#, starting day 1 of chemotherapy, @ 2Gy/# & 5#/week using CO-60 machine. In study arm patients were treated with concomitant CCT using Injection paclitaxel 50mg/m2 i/v every Monday and Injection carboplatin AUC2 i/v every Monday along with EBRT to a total dose of 60 Gy in 30# starting day 1 @ 2Gy/# & 5#/week using CO-60 machine. In both the arms spinal cord off was done after 44Gy. QOL was evaluated and recorded weekly using the EORTC QLQ–LC13 questionnaire. Improvement/deterioration in any scale was analysed between the baseline score and the score at treatment completion or 1st follow-up, whichever was higher. **Result:** When the response rates at 1st follow-up were assessed, CR was obtained in 2 patients in the control and 2 patients in the study arm. PR was obtained in 11 patients in the control arm(61.1%) and 13 patients in the study arm(72.2%). There were 2 patients in the control arm and 1 in the study arm who were found to have disease progression at 1st follow up and they were statistically insignificant. When grade >III toxicities are analysed, the total number of events in the control arm were 3(16.7%) and in the study arm were 5(27.8%), which is statistically insignificant and the OS was similar. Both, the improvement in the 5 major symptoms and worsening / appearance of 4 symptoms, shows equal quality of life in both control and study arm Both, the improvement in the 5 major symptoms and worsening / appearance of 4 symptoms, shows equal quality of life in both control and study arm **Conclusion:** This study has attempted to address the topic of different chemotherapeutic agents in combination with radiotherapy for the definitive treatment of stage III_A and III_B (unresectable) non-small cell lung cancer. The response rates, disease progression and overall survival are similar between study and the control arm. The other two endpoints namely the toxicity profile and quality of life are also similar between the two arms. Since we are not only treating the disease but treating the patient as a whole, due consideration must be given to toxicities as well as quality of life. However larger study with longer follow up are needed to establish the comparability of these two regimens.

Keywords: concurrent chemoradiotherapy, Non-Small Cell Lung Cancer, Quality of life

EP1.18-23 IS SALVAGE LUNG RESECTION NECESSARY AFTER DEFINITIVE CHEMORADIATION THERAPY FOR STAGE IIIA(N2) NON-SMALL CELL LUNG CANCER?

A. Turna[1], H. Melek[2], M. Agkoç[3], C. Gebitekin[2], H. Turna[4], F. Dinçbaş[5], S. Erturan[5], G. Aydın[5], K. Kaynak[1]

Background: A combination of platinum-based chemotherapy and definitive radiotherapy is the standard of care for Stage III (N2) NSCLC patients who have single or multiple lymph node metastasis. However, the role of salvage lung resection in patients with residual disease without lymph node metastasis is yet to be identified. **Method:** Between January 2011 and December 2018 103 eligible patients who had pathologically proven in two university hospital clinics, stage IIIA/N2 non-small-cell lung cancer and were prospectively recorded. Those in the chemoradiotherapy group

received three cycles of neoadjuvant chemotherapy (AUCx2 carboplatin and docetaxel 85 mg/m[2] docetaxel) and concurrent radiotherapy with 61.2-64.0 Gy in 34 fractions over 3 weeks followed by surgical resection. Also, a group of patients who had definitive chemoradiotherapy who did not undergo surgery was compared with the surgical group. **Result:** A total of 103 patients were analyzed, of whom 75(72.8%) received chemoradiotherapy followed by surgical resection and 28(27.2) had chemoradiotherapy only. Median overall survival was 49 months (95% CI 8.0–58.0) in the chemoradiotherapy + surgery group and 33.0 months (95% CI:7.5–90.4) in the chemotherapy group (p=0.423). One patients died in the surgery group within 30 days(0.9%) after surgery. Complication rate in all patients and the patients who underwent pneumonectomy after chemoradiation were not statistically significantly different compared to those who had undergone resectional surgery without oncological therapy(p=0.321, p=0.08 respectively) **Conclusion:** Pulmonary salvage resection after definitive chemoradiotherapy is safe and surgical resection after chemoradiotherapy did not seem to provide better survival in histologically proven N2 stage IIIA non-small cell lung cancer.

Keywords: stage IIIA, definitive chemoradiotherapy, salvage resection

EP1.18-24 NOVEL TECHNIQUE - MINI PORT THORACOSCOPIC APPROACH AND ENHANCED RECOVERY AFTER SURGERY FOR TREATMENT OF LUNG CANCER

L. Wentao[1], N. Toleska Dimitrovska[2]

[1]*Shanghai Chest Hospital, Shanghai/China,* [2]*University Clinic for Thoracic and Vascular Surgery - Skopje, Skopje/North Macedonia*

Background: In the last two decades, thoracic minimal invasive surgical approaches gain in the treatment of lung cancer. Mainly, because they are less invasive and they provide shortened hospital stay. With new anesthesia protocols which are incoporated in Enhanced Recovery After Surgery (ERAS) protocol, they are one of the most important points in the treatment of lung cancer. New mini video-assisted thoracoscopic surgical approach and enhanced recovery after surgery approach are safe for the patients and decreases hospital stay of the patients.

Method: In our study were inroled 100 patients who undergone surgery for lung cancer. All of them were treated with a new minimal invasive approach - mini Video Assisted Thoracic Surgery (VATS). The approach is less traumatic of all other previous described and used minimal invasive thoracoscopic procedures because it consists of only two small ports (mini ports), 1cm each. One port we use for the camera and the other port for applying the instruments in the thoracic cavity. We didn't use additional ports. Also, this minimal invasive approach is more cosmetic than all other previosly used minimal invasive thoracic approaches which is important for most of the patients. All of the patients undergone general anesthesia with endotracheal double-lumen tube. They all had lobectomy (or segmentectomy) with locoregional lymphadenectomy. Twenty to fifty minutes after extubation all of the patients were doing some easy exercises in the operating room (OR) and were walking from the OR to their room in the Department. **Result:** Because of the new minimal invasive surgical approach, less-invasive surgical treatment and anesthesiology protocol incorporated in ERAS protocol, none of the patients who undergone this type of treatment had complications in the postoperative period. Also, all of the patients were discharged on the 2nd (some of them 3rd) postoperative day. Their recovery was faster, they had shorter hospital stay, without any complications, and they had less needs for analgesics in the postoperative period. **Conclusion:** Our new multimodal approach (anesthesiological and surgical) showed that described less invasive surgical approach as well as treatment, and adequate anesthesiologic technique incorporated in ERAS protocol are the key for adequate treatment as well as early recovery of the patients treated for lung cancer. Also, postoperative complications and hospital stay were decreased a lot. Also, the patients were more satisfied in the postoperative period because of their extremely early recovery after surgery as well as shortened hospital stay.

Keywords: mini port VATS, ERAS, lung cancer

EP1.18-25 DEFINITIVE RADIOTHERAPY IN LUNG CANCER – A GLIMPSE OVER THE NARROW WINDOW

S. Pathy, A. Thimmarayappa, P. Malik, S. Kumar

All India Institute of Medical Sciences, New Delhi/India

Background: Lung cancer is one of the leading global malignancies. Locally advanced NSCLC (LA-NSCLC) comprises of a significant proportion of patient burden. Despite advances in the treatment definitive radiotherapy is delivered only to a small proportion of patients. The current study was carried out to analyze various factors associated with change of curative treatment plan to palliative treatment at a tertiary cancer Centre **Method:** Medical records of patients of LA-NSCLC lung cancer treated between June 2016 to June 2018 were evaluated. Clinical presentation, evaluation, treatment details and outcome were recorded. Patients who were not eligible for radical treatment were excluded. All patients were taken for radical treatment but could not receive definitive radiotherapy were analyzed **Result:** Of 67 patients of LA-NSCLC 8 patients that were non metastastic were planned for upfront palliative intent.25 patients needed change in their treatment plan to palliative treatment. Majority of them were ≥ 65years. Median number of chemotherapy cycles was 2 (0-6). Patients were assessed after 2 cycles of chemotherapy for concurrent chemoradiation as our institute practice. Patients were assessed at the end of 2nd chemotherapy. Reasons for ineligibility was noted and categorized into patient, tumor and treatment factors. Factors for change in treatment plan were divided as (i) Patient related factors included, treatment defaults, poor compliance, financial and social reasons, ECOG performance status at the end of chemotherapy, comorbidities, which accounted for 30.3%. (ii)Tumor related factors included, disease progression, poor response to chemotherapy, which accounted for 54.5%. (iii)Treatment factors included ,risk of toxicity due to large volume disease, volume not able to cover in one radiotherapy portal, poor respiratory reserve, which added up for remaining 15.2% of patients. Palliative radiotherapy to primary tumor alone was delivered in 25 patients, 5 patients received palliative radiotherapy to primary and brain2 patients received palliative radiotherapy to bone and I received radiation to brain alone. The median time to diagnose and stage was 0.65months (0.06 to 3.6 months). Median time to start chemotherapy was 0.8 months (0.16 to 7.3 months). **Conclusion:** Eligibility for definitive radiotherapy is a dynamic decision which need to be reviewed at every stage of treatment. Timely radical intervention need not necessarily translate into radical radiotherapy. Feasibility of definitive radiotherapy pass through a narrow window and multiple factors play pivotal role in it.

Keywords: Advanced lung cancer, treatment patterns, Non small cell lung cancer

EP1.18-26 TREATMENT PATTERNS AND CLINICAL OUTCOMES IN LOCALLY ADVANCED NON SMALL CELL LUNG CANCER: EXPERIENCE FROM TERTIARY CARE CENTRE

S. Pathy, A. Thimmarayappa, P. Malik

All India Institute of Medical Sciences, New Delhi/India

Background: Lung Cancer comprises a significant global cancer burden.About two-thirds patients with non small cell lung cancer, present in advanced/metastatic stage, of which the locally advanced group account for 30%.Combined modality approach with definitive chemoradiation is feasible in only a small proportion of patients. Several factors play a role in deciding the treatment and outcome In developing countries access to cancer centres and waiting period for oncological intervention and radiation therapy also significantly affect the management.The current study evaluates the demographic profile, treatment pattern, outcome and Radiotherapy practice and patient care at a tertiary care academic medical institution. **Method:** Archives patients of locally advanced Non Small Cell lung cancer(LA-NSCLC) treated at our centre between, June 2016-June 2018 were included in our study. Clinical, demographic characteristics, treatment patterns, outcomes was recorded. Radiotherpy practice and patient care process including integration of radiation therapy with other specilities,waiting time, compliance to treatment was documented. Case records with incomplete work up or treatment was excluded. Univariate and multivariate analysis of factors on survival and overall survival was analysed. **Result:** 174 patients were treated during the study period. The distribution as

per histology include Squamous cell carcinoma 54, Adenocarcinoma 108, Others (adenosquamous,poorly differentiated) 12. The median age was 57 years(35-84) with male preponderance .Only 67 patients belonged to locally advanced group and remaining 107 presented with metastastic disease. 59 patients of LA-NSCLC group were planned for definitive chemoradiation comprising of two cycles of induction chemotherapy followed by concurrent chemoradiation. 34 patients eventually underwent the planned treatment.The reason for conversion to palliative radiotherapy included disease progression during induction chemotherapy(18),poor performance status(7),large volume disease and risk of toxicity with radical dose ,defaulters(3). Median follow up was 11 months (range 0.7-29), overall survival 9.4 months(range 1.7-44.8). Median overall treatment time was 44 days.Progression free survival 8.9 months(range 1.6-28.6). Time to start any oncological intervention was 1 month(0.1-4.3) and time to start radiotherapy was 2.1 months(0.1-5.4). Adherence to treatment was 91.2%.Age ≥65 and performance status ≥2 were significant for overall survival in univariate analysis but did not confer any significance in multivariate analysis. **Conclusion:** The study concludes that more than 60%of patients with Non small cell lung cancer present with metastatic disease. Only about a third are suitable for definitive chemoradiation and eventually only 20% undergo the planned treatment. Adherence to treatment is good in definitive setting

Keywords: Non small cell lung cancer, treatment patterns, overall time

EP1.18-27 STUDY OF FIVE CASES RESECTED PULMONARY PLEOMORPHIC CARCINOMA - IMMUNE CHECKPOINT INHIBITORS ARE IMPROVED THE PROGNOSIS?

O. Kawamata

Onomichi Municipal Hospital, Onomichi/Japan

Background: Pulmonary pleomorphic carcinomas are rare malignant tumors, poor prognosis, and no standard treatments have been established. A previous study reported that pulmonary pleomorphic carcinomas expressed high levels of programmed death ligand-1 (PD-L1), suggesting the potential efficacy of immune checkpoint inhibitors in these tumors. **Method:** We retrospectively reviewed the clinical records of 5 patients with pulmonary pleomorphic carcinoma who had a surgical resection from January 2014 to December 2018 at our institution. The characteristics, histological parameters, PD-L1 expressions, treatment and outcome of 5 patients were studied. **Result:** There were 4 male and 1 female. The average ages were 77.4 years (range, 69-84 years). At pathologic analysis, one of 5 was stage IA3, one was IIB, two were IIIA, and one was IVA. PD-L1 was highly expressed in all patients (70-90%). Three patients of 5 relapsed within one year after surgery. Two patients (case 3, 4) were no recurrence and were alive for 39 months, 24 months after surgery. Case 1 was confirmed mediastinal lymphnode recurrence at 3 months after surgery and performed radiation therapy. This case is alive for 53 months after recurrence. Case 2 was confirmed pleural dissemination and chest wall recurrence at 10 months after surgery and was treated with cisplatin, docetaxel plus bevacizumab at first line treatment, carboplatin, gemcitabine plus bevacizumab at second line, and nivolumab at third line. This case is alive for 51 months after recurrence. Case 5 was confirmed multiple liver metastasis and chest wall recurrence at one month after surgery and was treated with pembrolizumab at first line treatment. This case is alive for three months after recurrence.

case	1	2	3	4	5
sex	male	male	male	female	male
age	82	69	79	73	84
pstage	IVA	IIB	IA3	IIIA	IIIA
PD-L1 (22C3)	90	90	70	80	90
recurrence	yes	yes	no	no	yes

Conclusion: We thought that immune checkpoint inhibitors are improved the prognosis of pulmonary pleomorphic carcinoma.

Keywords: pulumonary pleomorphic carcinoma, PD-L1, immune checkpoint inhibitors

EP1.18-28 NEOADJUVANT THERAPY AMONG PATIENTS UNDERGOING RESECTION FOR NON-SMALL-CELL LUNG CANCER: A SINGLE INSTITUTION EXPERIENCE

L. Gutiérrez Sainz, P. Cruz, J. Villamayor, S. Martínez Recio, I. Esteban, F. Arias Lotto, D. Viñal, D. Sanchez Cabrero, O. Higuera, J. De Castro Carpeno

La Paz University Hospital, Madrid/Spain

Background: Lung cancer is the leading cause of cancer deaths worldwide. Surgery alone results in poor overall survival in patients with stage III non-small cell lung cancer (NSCLC). Neoadjuvant therapy offers the ability to treat micrometastatic tumor cell dissemination preoperatively and increased resectability due to tumor regression. The aim of this study is to analyze the experience of our center and to identify clinical and pathological characteristics related to greater relapse-free survival (RFS). **Method:** We conducted a retrospective study, which included all patients with NSCLC treated with neoadjuvant therapy follow by surgery in a tertiary referral hospital from April 2013 to March 2019. Data regarding clinical and pathological characteristics, treatment response, type of surgery and survival were collected. **Result:** We selected 10 patients. Table 1 summarizes the main sociodemographic characteristics, the histological subtype, the stage, the regimens of neoadjuvant therapy and the types of surgery.

Table 1	**Nº (%)**
Sex: Male/Female	6 (60%) / 4 (40%)
Age (years):	62 (44 – 77)
Performance status: – 0 – 1	6 (60%) 4 (40%)
Smoking: – No – Yes	1 (10%) 9 (90%)
Weight loss before diagnosis: – High (≥5%) – Low (<5%)	1 (10%) 9 (90%)
Histology: – Squamous cell carcinoma – Adenocarcinoma – Large-cell cancer	3 (30%) 6 (60%) 1 (10%)
Stage: – Stage IIIA – Stage IIIB	6 (60%) 4 (40%)
Node status: – N0 – N1 – N2	3 (30%) 1 (10%) 6 (60%)
ALK translocation: – No – Yes – Unknown	8 (80%) 0 (0%) 2 (20%)
EGFR mutation: – No – Yes – Unknow	8 (80%) 0 (0%) 2 (20%)
Percentage of PD-L1 at diagnosis: – < 1% – 1 – 49% – ≥ 50% – Unknow	5 (50%) 1 (10%) 2 (20%) 2 (20%)
Neoadjuvant therapy regimens: – Platinum – pemetrexed – Platinum – vinorelbine – Platinum – paclitaxel – bevicizumab – Platinum – vinorelbine – gemcitabine – Platinum – paclitaxel – nivolumab	5 (50%) 1 (10%) 1 (10%) 1 (10%) 2 (20%)
Types of surgery: – Lobectomy – Bilobectomy – Pneumonectomy	6 (60%) 1 (10%) 3 (30%)
Percentage of PD-L1 after neoadjuvant therapy: – < 1% – 1 – 49% – ≥ 50% – Pathological complete remission – Unknow	2 (20%) 1 (10%) 4 (40%) 2 (20%) 1 (10%)

Regarding tumour response rates after neoadjuvant chemotherapy, 2 (20%) of 10 patients achieved a complete response and 8 (80%) achieved a partial response. Furthermore, 5 (71%) of 7 patients with mediastinal lymph node involvement achieved a nodal downstaging. Using the Wilcoxon signed-rank test, there are statistically significant differences in the stage of the patients before and after the neoadjuvant chemotherapy (Z: -2,82, p:0,005). After a median follow-up duration of 38 months, 5 (50%) patients had relapsed. The median RFS was 22 months (IC95%: 2–41). We did a *multivariate logistic regression analysis, in which* no statistically significant associations were found between clinical and pathological characteristics studied and the RFS (p>0,05). **Conclusion:** Neoadjuvant therapy followed by surgery should be considered as standard treatment for a selective group of patients with stage III of NSCLC, in our sample all patients yielded excellent results. In the *multivariate analysis* no statistically significant associations were found due to the small size of our sample.

Keywords: non-small cell lung cancer, neoadjuvant therapy.

EP1.18-29 SURVIVAL OF PATIENTS WITH NON-SMALL CELL LUNG CANCER THAT HAS SINGLE STATION LYMPH NODE METASTASIS OF 4R OR 10R AFTER SURGICAL TREATMENT

A. Ucvet, O. Samancilar, S. Yazgan, S. Gursoy

Dr.Suat Seren Chest Diseases and Thoracic Surgery SUAM, Izmir/Turkey

Background: The effect of single station 4R or 10R lymph node metastasis on survival in patients that had right upper lobectomy because of non-small cell lung cancer is investigated. **Method:** The survival of patients that were operated on due to non-small cell lung cancer that were applied right upper lobectomy between November 20076 and March 2018 and had single station 4R or 10R lymph node metastasis are compared. The patients with perioperative mortality and incomplete resection are excluded. **Result:** There were a total of 30 patients (25 men and 5 women) with a mean age of 60,5±8,9 (range 47-77) in the study population Ten patients had preoperative chemotherapy and/or radiotherapy. Seven-teen patients had single station 4R and 13 patients had single station 10R metastasis. The 5-year survival of patients with 4R and 10R metastasis were 39.8% and 53.8% respectively (p=0.33). **Conclusion:** Altough patients with right upper lobectomy that had single station 10R lymph node metastasis has a relatively better survival than patients with 4R metastasis the difference is not statistically significant. Surgeons should name the lypmh node stations 10R and 4R during lymph node dissection carefully that can sometimes be very challenging because of the localization of the lymph nodes.

EP1.18-30 A CASE OF RESECTED PRIMARY LUNG CANCER WITH INTERLOBAR DISSEMINATION

D. Kato, A. Uchibori, N. Takeda, T. Takeda

Japanese Red Cross Kyoto Daini Hospital, Kyoto/Japan

Background: Primary lung cancer with pleural dissemination is at least diagnosed as Stage IVa, and it is considered that there are no surgical indications. This is because the presence of pleural dissemination indicates that the cancer cells exist in the entire pleural cavity, and radical resection is impossible. However, if pleural dissemination is observed in a limited space, we could consider the case as one of locally advanced lung cancer and perform radical resection as an exception of the current staging system. **Method:**

A 71-year-old man was referred to our hospital because of an abnormal shadow on chest radiography. He was diagnosed with adenocarcinoma of the right upper lobe and cT2aN0M0 stage IB (Union for International Cancer Control (UICC) 8th edition). We planned to perform right upper lobectomy. There were sporadic trabecular adhesions in the right pleural cavity. Although lobulation was relatively favorable, we could not recognize the interlober surface between the upper and middle lobes until after interlobar adhesilolysis. In other words, the interlober space was packed. There were diffuse nodules between the upper and middle lobes suspected of interlobar disseminations. Intraoperative frozen-section diagnosis yielded a pathological diagnosis of pleural dissemination. The pleural effusion cytology showed negative findings. Therefore, we considered the diagnosis to be of locally advanced lung cancer, and upper and middle lobectomy was performed. **Result:** Pathologically, the patient was finally diagnosed with papillary invasive adenocarcinoma and pT2aN0M1a Stage IVa (UICC 8th edition), and subsequently, we administered adjuvant chemotherapy, which is in progress. **Conclusion:** We performed radical right upper and middle lobectomy for locally advanced lung cancer, which showed interlobar pleural dissemination. This kind of dissemination could be treated like interlobar T3.

Keywords: Lung cancer, local advanced, interlobar dissemination

EP1.18-31 MINIPORT VIDEO-ASSISTED THORACIC SURGERY TECHNIQUE - A NEW MINIMAL INVASIVE APPROACH FOR TREATMENT OF LUNG CANCER: CASE REPORT

L. Wentao[1], N. Toleska Dimitrovska[2]

[1]*Shanghai Chest Hospital, Shanghai/China,* [2]*University Clinic for Thoracic and Vascular Surgery - Skopje, Skopje/North Macedonia*

Background: When multiportal VATS lobectomy was first developed in the 1990s, it has been changed through years. Since the first VATS anatomical resection (lobectomy) for lung cancer 20 years ago, the approach has been modified from approach with four ports, three ports, two ports and one additional and uniportal approach which skin incision is about 3-5 cm long. After all these modified approaches, we modified an approach which is least invasive of all the others mentioned above and most cosmetic. In this article we will describe our approach with use of only two small ports and steps for performing lobectomy of the left uper lobe for lung cancer with lymphadenectomy. **Method:** Patient is positioned in a right lateral decubitus position. The hands are placed in the almost "prayer" position and the left arm is slightly supported on an arm holder. As soon as the double lumen endotracheal tube is confirmed to be in the correct position, ventilation is switched to the contralateral lung to optimize deflation of the lung that is going to be operated. Suction can be used if the lung does not deflate. The respiratory rate can also be increased to 20 breaths/min or more in order to reduce the tidal volume and hence the degree of the of mediastinal excursion due to ventilation which provides more stable operating field. The surgeon and the assistant stand in the front part of the patient (the surgeon on the cranial part and the assistant on the caudal part, on the right side of the surgeon) with the screen directly across them and the scrub nurse stands obliquely opposite. Incision: only two small (mini) ports are used in this approach. The skin incisions of the ports are not bigger than 1 cm. The incision of the first port is located in the 8th intercostal space at the posterior axillary line. This port we will use to insert the 30 degree camera. After the incision is done by electrocautery, we place the camera in the left chest cavity. By that, we can explore the chest cavity and see where is the best location for the second port. The second port's incision is done on the 4th intercostal space in the posterior axillary line. After the incision is done and intercostal muscle is devided by electrocautery, we place the wound retractor. Afterwards, we try to localise the tumor using the suction tube or sometimes grasper. The disection starts from the anterior side **Result:** With this type of approach any type of lung resection is feasible. **Conclusion:** This approch is safe, less traumatic and more cosmetic for the patients comparing to other approaches.
