(Received 23 March 2013; published 17 May 2013)

We present a global reanalysis of the most recent experimental data on azimuthal asymmetries in semi-inclusive deep inelastic scattering, from the HERMES and COMPASS Collaborations, and in $e^+e^- \rightarrow h_1h_2X$ processes, from the Belle Collaboration. The transversity and the Collins functions are extracted simultaneously, in the framework of a revised analysis in which a new parametrization of the Collins functions is also tested.

1. INTRODUCTION AND FORMALISM

The spin structure of the nucleon, in its partonic collinear configuration, is fully described, at leading-twist, by three independent parton distribution functions (PDFs): the unpolarized PDF, the helicity distribution and the transversity distribution. While the unpolarized PDF and the helicity distribution, which have been studied for decades, are by now very well or reasonably well known, much less information is available on the latter, which has been studied only recently. The reason is that, due to its chiral-odd nature, a transversity distribution can only be accessed in processes where it couples to another chiral-odd quantity.

The chiral-odd partner of the transversity distribution could be a fragmentation function, like the Collins function [1] or the di-hadron fragmentation function [2–4] or another parton distribution, like the Boer-Mulders [5] or the transversity distribution itself. A chiral-odd partonic distribution couples to a chiral-odd fragmentation function in semi-inclusive deep inelastic scattering processes (SIDIS, $\ell N \rightarrow \ell hX$). The coupling of two chiral-odd partonic distributions could occur in Drell-Yan processes ($D-Y$, $hN \rightarrow \ell^+\ell^-X$) but, so far, no data on polarized D-Y are available. Information on the convolution of two chiral-odd fragmentation functions (FFs) can be obtained from $e^+e^- \rightarrow h_1h_2X$ processes.

The $u$ and $d$ quark transversity distributions, together with the Collins fragmentation functions, have been extracted for the first time in Refs. [6,7], from a combined analysis of SIDIS and $e^+e^-$ data. Similar results on the transversity distributions, coupled to the di-hadron, rather than the Collins, fragmentation function, have been obtained recently [8]. These independent results establish with certainty the role played by the transversity distributions in SIDIS azimuthal asymmetries.

Since the first papers [6,7], new data have become available: from the COMPASS experiment operating on a transversely polarized proton (NH$_3$ target) [9,10], from a final analysis of the HERMES Collaboration [11] and from corrected results of the Belle Collaboration [12]. This fresh information motivates a new global analysis for the simultaneous extraction of the transversity distributions and the Collins functions.

This is performed using techniques similar to those implemented in Refs. [6,7]; in addition, a second, different parametrization of the Collins function will be tested, in order to assess the influence of a particular functional form on our results.

Let us briefly recall the strategy followed and the formalism adopted in extracting the transversity and Collins distribution functions from independent SIDIS and $e^+e^-$ data.

A. SIDIS

We consider, at $O(k_1/Q)$, the SIDIS process $\ell p \rightarrow \ell' hX$ and the single spin asymmetry,

$$A_{UT}^{\sin(\phi_h + \phi_S)} = \frac{2 \int d\phi_h d\phi_S [d\sigma^1 \sin(\phi_h + \phi_S)]}{\int d\phi_h d\phi_S [d\sigma^1 + d\sigma^1]}$$

(1)

where $d\sigma^1$ is a shorthand notation for

$$d\sigma^1 = \frac{d^6\sigma}{dxdydzdP_T d\phi_S}$$

and $x, y, z$ are the usual SIDIS variables.
\[
\begin{align*}
    x &= x_B = \frac{Q^2}{2(P \cdot q)} \quad y = \frac{(P \cdot q)}{(P' \cdot \ell)} = \frac{Q^2}{xs} \\
    z &= z_h = \frac{(P \cdot P_h)}{(P \cdot q)}.
\end{align*}
\]

We adopt here the same notations and kinematical variables as defined in Refs. [6,13], to which we refer for further details, in particular for the definition of the

\[
A_{UT}^{\sin(\phi_h + \phi_s)} = \sum_q e_q^2 \int d\phi_h d\phi_s d^2k_\perp \Delta_T q(x, k_\perp) \frac{d(\Delta \hat{\sigma})}{dy} \frac{\Delta N D_{h/q}(z, p_\perp)}{\Delta N D_{h/q}(z, p_\perp)} \sin(\phi_h + \phi_s) \sin(\phi_h + \phi_s),
\]

where \( p_\perp = P_t - zk_\perp \), and

\[
\frac{d\hat{\sigma}}{dy} = \frac{2\pi \alpha^2}{s x y^2} \left[ 1 + (1 - y)^2 \right]
\]

\[
\frac{d(\Delta \hat{\sigma})}{dy} = \frac{d\hat{\sigma}_{q' \rightarrow q'}}{dy} - \frac{d\hat{\sigma}_{q' \rightarrow q'}}{dy} = \frac{4\pi \alpha^2}{s x y^2} (1 - y).
\]

The usual integrated transversity distribution is given, according to some common notations, by

\[
\Delta_T q(x) = h_1(x) = \int d^2k_\perp \Delta_T q(x, k_\perp).
\]

This analysis, performed at \( \mathcal{O}(k_\perp/Q) \), can be further simplified by adopting a Gaussian and factorized parametrization of the transverse momentum dependent functions (TMDs). In particular for the unpolarized parton distribution (TMD-PDFs) and fragmentation (TMD-FFs) functions we use

\[
f_{q/p}(x, k_\perp) = f_{q/p}(x) \frac{e^{-k_2^2/(\langle k_2^2 \rangle)}}{\pi \langle k_2^2 \rangle},
\]

\[
D_{h/q}(z, p_\perp) = D_{h/q}(z) \frac{e^{-p_2^2/(\langle p_2^2 \rangle)}}{\pi \langle p_2^2 \rangle},
\]

with \( \langle k_2^2 \rangle \) and \( \langle p_2^2 \rangle \) fixed to the values found in Ref. [16] by analyzing unpolarized SIDIS azimuthal dependent data:

\[
\langle k_2^2 \rangle = 0.25 \text{ GeV}^2 \quad \langle p_2^2 \rangle = 0.20 \text{ GeV}^2.
\]

The integrated parton distribution and fragmentation functions, \( f_{q/p}(x) \) and \( D_{h/q}(z) \), are available in the literature; in particular, we use the GRV98LO PDF set [17] and the DSS fragmentation function set [18].

Azimuthal angles which appear above and in the following equations.

By considering the \( \sin(\phi_h + \phi_s) \) moment of \( A_{UT} \) [14], we are able to single out the effect originating from the spin dependent part of the fragmentation function of a transversely polarized quark, embedded in the Collins function, \( \Delta^N D_{h/q}(z, p_\perp) = (2p_\perp \cdot z m_n) H_{1}^{L}(z, p_\perp) \) [15], coupled to the transverse momentum dependent (TMD) transversity distribution \( \Delta_T q(x, k_\perp) \) [6]:

\[
\frac{\Delta N D_{h/q}(z, p_\perp)}{\Delta N D_{h/q}(z, p_\perp)} = 2N_q^C(z) D_{h/q}(z) \frac{e^{-p_2^2/(\langle p_2^2 \rangle)}}{\pi \langle p_2^2 \rangle},
\]

For the transversity distribution, \( \Delta_T q(x, k_\perp) \), and the Collins FF, \( \Delta N D_{h/q}(z, p_\perp) \), we adopt the following parametrizations [6]:

\[
\Delta_T q(x, k_\perp) = \frac{1}{2} N_q^T(x)[f_{q/p}(x) + \Delta q(x)] \frac{e^{-k_2^2/(\langle k_2^2 \rangle)}}{\pi \langle k_2^2 \rangle},
\]

\[
\Delta N D_{h/q}(z, p_\perp) = 2N_q^C(z) D_{h/q}(z) \frac{e^{-p_2^2/(\langle p_2^2 \rangle)}}{\pi \langle p_2^2 \rangle},
\]

with

\[
N_q^T(x) = N_q^C x^\alpha (1 - x)^\beta \frac{(\alpha + \beta)(\alpha + \beta)}{\alpha^\alpha \beta^\beta},
\]

\[
N_q^C(z) = N_q^C z^\gamma (1 - z)^\delta \frac{(\gamma + \delta)(\gamma + \delta)}{\gamma^\gamma \delta^\delta},
\]

and \(-1 \leq N_q^T \leq 1, -1 \leq N_q^C \leq 1\). We assume \( \langle k_2^2 \rangle_T = \langle k_2^2 \rangle \). The combination \([f_{q/p}(x) + \Delta q(x)]\), where \( \Delta q(x) \) is the helicity distribution, is evolved in \( Q^2 \) according to Ref. [19]. Notice that with these choices both the transversity and the Collins function automatically obey their proper positivity bounds. A different functional form of \( N_q^C(z) \) will be explored in Sec. II B.

Using these parametrizations we obtain the following expression for \( A_{UT}^{\sin(\phi_h + \phi_s)} \):

\[
A_{UT}^{\sin(\phi_h + \phi_s)} = \frac{P_z}{M_h} \frac{1 - y}{s x y \sqrt{2 \pi}} \frac{e^{-k_2^2/(\langle k_2^2 \rangle)}}{\pi \langle k_2^2 \rangle} \sum_q e_q^2 N_q^T(x)[f_{q/p}(x) + \Delta q(x)] N_q^C(z) D_{h/q}(z)
\]

\[
\frac{e^{-p_2^2/(\langle p_2^2 \rangle)}}{\pi \langle p_2^2 \rangle} \sum_q e_q^2 f_{q/p}(x) D_{h/q}(z)
\]
\[ \Delta^N D_{h_i/q}(z) = \int d^2 p_\perp \Delta^N D_{h_i/q}(z, p_\perp). \]  

(17)

Integrating over the covered values of \( \theta \) and normalizing to the corresponding azimuthal averaged unpolarized cross section one has

\[ R_{12}(z_1, z_2, \varphi_1 + \varphi_2) \]

\[ = 1 + \frac{1}{4 \langle \sin^2 \theta \rangle} \cos(\varphi_1 + \varphi_2) \]

\[ \times \sum_q e_q^2 \Delta^N D_{h_i/q}(z_1) \Delta^N D_{h_i/q}(z_2) \]

\[ = 1 + \frac{1}{4 \langle \sin^2 \theta \rangle} \cos(\varphi_1 + \varphi_2) P(z_1, z_2). \]

\[ R_0(z_1, z_2, \varphi_0) \]

\[ = 1 + \frac{1}{4 \langle \sin^2 \theta \rangle} \cos(2\varphi_0) \]

\[ \times \sum_q e_q^2 \Delta^N D_{h_i/q}(z_1) \Delta^N D_{h_i/q}(z_2) \]

\[ = 1 + \frac{1}{4 \langle \sin^2 \theta \rangle} \cos(2\varphi_0) \]

\[ \times \cos(2\varphi_0) P(z_1, z_2). \]

\[ R_{12}^U \]

\[ = 1 + \frac{1}{4} C(\theta) \cos(\varphi_1 + \varphi_2) P_U \]

\[ R_{12}^L \]

\[ = 1 + \frac{1}{4} C(\theta) \cos(\varphi_1 + \varphi_2) P_L \]

\[ \equiv 1 + \frac{1}{4} \cos(\varphi_1 + \varphi_2) A_{12}^{UL}. \]

\[ \equiv 1 + \frac{1}{4} \cos(\varphi_1 + \varphi_2) A_{12}^{UL}. \]

\[ \equiv 1 + \frac{1}{4} \cos(\varphi_1 + \varphi_2) A_{12}^{UL}. \]

\[ \equiv 1 + \frac{1}{4} \cos(\varphi_1 + \varphi_2) A_{12}^{UL}. \]
\[
\frac{R_0^U}{R_0^L} = \frac{1 + \frac{z_1 z_2}{z_1^2 + z_2^2} C(\theta) \cos (2 \varphi_0) P_U}{1 + \frac{z_1 z_2}{z_1^2 + z_2^2} C(\theta) \cos (2 \varphi_0) P_L} \approx 1 + \frac{z_1 z_2}{z_1^2 + z_2^2} C(\theta) \cos (2 \varphi_0) (P_U - P_L),
\]

\[= 1 + \cos (2 \varphi_0) A_0^{UL}, \tag{24}\]

and similarly for \(R_{12}^U/R_{12}^C\) and \(R_0^U/R_0^C\). Explicitly, one has

\[
P_U = \frac{\sum_q e_q^2 \left[ \Delta N D_{\pi^-/q}^i (z_1) \Delta N D_{\pi^-/q}^i (z_2) + \Delta N D_{\pi^-/q}^i (z_1) \Delta N D_{\pi^-/q}^i (z_2) \right]}{\sum_q e_q^2 \left[ D_{\pi^-/q}^i (z_1) D_{\pi^-/q}^i (z_2) \right]} = \frac{(P_U)_N}{(P_U)_D}, \tag{25}\]

\[
P_L = \frac{\sum_q e_q^2 \left[ \Delta N D_{\pi^-/q}^i (z_1) \Delta N D_{\pi^-/q}^i (z_2) + \Delta N D_{\pi^-/q}^i (z_1) \Delta N D_{\pi^-/q}^i (z_2) \right]}{\sum_q e_q^2 \left[ D_{\pi^-/q}^i (z_1) D_{\pi^-/q}^i (z_2) \right]} = \frac{(P_L)_N}{(P_L)_D}, \tag{26}\]

\[
P_C = \frac{(P_U)_N + (P_L)_N}{(P_U)_D + (P_L)_D}, \tag{27}\]

\[
A^{ULC}_{12}(z_1, z_2) = \frac{1}{4} \frac{\langle \sin^2 \theta \rangle}{1 + \langle \cos \theta \rangle} (P_U - P_{LC}), \tag{28}\]

\[
A^{ULC}_{0}(z_1, z_2) = \frac{1}{\pi} \frac{z_1 z_2}{z_1^2 + z_2^2} \frac{\langle \sin^2 \theta \rangle}{1 + \langle \cos \theta \rangle} (P_U - P_{LC}). \tag{29}\]

For fitting purposes, it is convenient to introduce favored and disfavored fragmentation functions, assuming in Eq. (10):

\[
\frac{\Delta N D_{\pi^-/u,d}^i (z, p_L)}{D_{\pi^-/u,d}^i (z)} = \frac{\Delta N D_{\pi^-/u,d}^i (z, p_L)}{D_{\pi^-/u,d}^i (z)} = 2 N_C^\text{fav} (z) h(p_L) e^{-p_L^2/(\pi p_L^2)} - \frac{\pi (p_L^2)}{\pi (p_L^2)}, \tag{30}\]

\[
\frac{\Delta N D_{\pi^-/u,d}^i (z, p_L)}{D_{\pi^-/u,d}^i (z)} = \frac{\Delta N D_{\pi^-/u,d}^i (z, p_L)}{D_{\pi^-/u,d}^i (z)} = \frac{\Delta N D_{\pi^-/u,d}^i (z, p_L)}{D_{\pi^-/u,d}^i (z)} = 2 N_C^\text{dis} (z) h(p_L) e^{-p_L^2/(\pi p_L^2)} - \frac{\pi (p_L^2)}{\pi (p_L^2)}, \tag{31}\]

with the corresponding relations for the integrated Collins functions, Eq. (17), and with \(\mathcal{N}_C^\text{fav,dis} (z)\) as given in Eq. (12) with \(N_C^\text{dis} = N_C^\text{dis} - N_C^\text{fav,dis}\).

We can now perform a best fit of the data from HERMES and COMPASS on \(A_{12}^{UL} = A_{12}^{UL} \sin (\phi_s + \phi_d)\) and of the data, from the Belle Collaboration, on \(A_{12}^{ULC} = A_{12}^{ULC} \sin (\phi_s + \phi_d)\). Their expressions, Eqs. (14) and (25)–(31), contain the transversity and the Collins functions, parametrized as in Eqs. (9)–(13).

They depend on the free parameters \(\alpha, \beta, \gamma, \delta, N_T^u, N_T^d, N_C^u, N_C^d, M_h\). Following Ref. [6] we assume the exponents \(\alpha, \beta\) and the mass scale \(M_h\) to be flavor independent and consider the transversity distributions only for \(u\) and \(d\) quarks (with the two free parameters \(N_T^u\) and \(N_T^d\)). The favored and disfavored Collins functions are fixed, in addition to the flavor independent exponents \(\gamma\) and \(\delta\), by \(N_C^u\) and \(N_C^d\). This makes a total of nine parameters, to be fixed with a best fit procedure. Notice that while in the present analysis we can safely neglect any flavor dependence of the parameter \(\beta\) (which is anyway hardly constrained by the SIDIS data), this issue could play a significant role in other studies, like those discussed in Ref. [23].

II. BEST FITS, RESULTS AND PARAMETRIZATIONS

A. Standard parametrization

We start by repeating the same fitting procedure as in Refs. [6,7], using the same “standard” parametrization, Eqs. (6)–(13), with the difference that now we include all the most recent SIDIS data from the COMPASS [10] and HERMES [11] Collaborations, and the corrected Belle data [12] on \(A_{12}^{UL} = A_{12}^{ULC}\). Notice, in particular, that the \(A_{12}^{UL} = A_{12}^{ULC}\) data are included in our fits for the first time here. In fact, a previous inconsistency between \(A_{12}^{UL} = A_{12}^{ULC}\) data, present in the first Belle results [21], has been removed in Ref. [12].

The results we obtain are remarkably good, with a total \(\chi^2/\text{d.o.f.} = 0.80\), as reported in the first line of Table I, and the values of the resulting parameters, given in Table II, are consistent with those found in our previous extractions. Our best fits are shown in Fig. 1 (upper plots), for the Belle \(A_{12}^{UL} = A_{12}^{ULC}\) data, in Fig. 2 for the SIDIS COMPASS data and in Fig. 3 for the HERMES results.

We have not inserted the \(A_0\) Belle data in our global analysis as they are strongly correlated with the \(A_{12} = A_{12}^{ULC}\) results,
TABLE I. Summary of the $\chi^2$ values obtained in our fits. The columns, from left to right give the $\chi^2$ per degree of freedom, the total $\chi^2$, and the separate contributions to the total $\chi^2$ of the data from SIDIS, $A_{12}^{UL}$, $A_{12}^{UC}$, $A_0^{UL}$, and $A_0^{UC}$, “NO FIT” means that the $\chi^2$ for that set of data does not refer to a best fit, but to the computation of the corresponding quantity using the best fit parameters fixed by the other data. The four lines show the results for the two choices of parametrization of the $z$ dependence of the Collins functions (standard and polynomial) and for the two independent sets of data fitted (SIDIS, $A_{12}^{UL}$, $A_{12}^{UC}$ and SIDIS, $A_0^{UL}$, $A_0^{UC}$).

being a different analysis of the same experimental events. However, using the extracted parameters we can compute the $A_{12}^{UL}$ and $A_0^{UC}$ azimuthal asymmetries, in good qualitative agreement with the Belle measurements, although the corresponding $\chi^2$ values are rather large, as shown in Table I. These results are presented in Fig. 1 (lower plots).

The shaded uncertainty bands are computed according to the procedure explained in the Appendix of Ref. [24].

We have allowed the set of best fit parameters to vary in such a way that the corresponding new curves have a total $\chi^2$ which differs from the best fit $\chi^2$ by less than a certain amount $\Delta \chi^2$. All these (1500) new curves lie inside the shaded area. The chosen value of $\Delta \chi^2 = 17.21$ is such that the probability to find the “true” result inside the shaded band is 95.45%.

We have also performed a global fit based on the SIDIS and $A_0$ Belle data, and then computed the $A_{12}$ values. We do not show the best fit plots, which are not very informative, but the quality of the results can be judged from the second line of Table I, which shows that although this time $A_0^{UL}$ and $A_0^{UC}$ are actually fitted, their corresponding $\chi^2$ values remain large. This has induced us to explore a different functional shape for the parametrization of $N_q^C(z)$, Eq. (12), which will be discussed in the next subsection.

The difference between $A_{12}$ and $A_0$ is a delicate issue, that deserves some further comments. On the experimental side, the hadronic-plane method used for the extraction of $A_0$ implies a simple analysis of the raw data, as it requires the sole reconstruction of the tracks of the two detected hadrons; therefore it leads to very clean data points, with remarkably small error bars. On the contrary, the thrust-axis method is much more involved as it requires the reconstruction of the original direction of the $q$ and $\bar{q}$ which fragment into the observed hadrons; this makes the measurement of the $A_{12}$ asymmetry experimentally more challenging, and leads to data points with larger uncertainties.

On the theoretical side, the situation is just the opposite: as the thrust-axis method assumes a perfect knowledge of the $q$ and $\bar{q}$ directions, the asymmetry can be reconstructed by a straightforward integration over the two intrinsic transverse momenta $p_{1T}$ and $p_{2T}$, transforming the convolution of two Collins functions into the much simpler product of two Collins moments [6], Eqs. (17) and (18). Instead, the phenomenological partonic expression of $A_0$ involves more complicated kinematical relations and some approximations; the simple final outcome, Eq. (19), holds at $O(k_{1T}/z\sqrt{s})$ and $(p_{1T}/P)$ (where $P$ is the final hadron 3-momentum magnitude) [6]. Thus, on the theoretical side, the partonic interpretation of $A_0$ is a bit less clear.

One should also add that most of the large $\chi^2$ values found when computing $A_0$ from the parameters of a best fit involving SIDIS and $A_{12}$ data (or vice versa) originate from the experimental points at large values of $z_1$ or $z_2$ or both (see, for example, the last points on the left lower panel in Fig. 1). Large values of $z$ bring us near the exclusive

TABLE II. Best values of the nine free parameters fixing the $u$ and $d$ quark transversity distribution functions and the favored and disfavored Collins fragmentation functions, as obtained by fitting simultaneously SIDIS data on the Collins asymmetry and Belle data on $A_{12}^{UL}$ and $A_{12}^{UC}$. The transversity distributions are parametrized according to Eqs. (9) and (11), and the Collins fragmentation functions according to the standard parametrization, Eqs. (10), (12), and (13). We obtain a total $\chi^2$/d.o.f. = 0.80. The statistical errors quoted for each parameter correspond to the shaded uncertainty areas in Figs. 1–3, as explained in the text and in the Appendix of Ref. [24].

simply computed using the parameters of Table II.

dependence of favored and disfavored Collins functions analogous to that of Belle.

an independent new analysis of results of the seems to be confirmed by very interesting preliminary

process limit, where our factorized inclusive approach cannot hold anymore.

B. Polynomial parametrization

In an attempt to fit equally well \( A_{12} \) and \( A_0 \) (keeping in mind, however, the comments at the end of the previous subsection) we have explored a possible new parametrization of the \( z \) dependence of the Collins function. We notice that data on \( A_0(z) \) seem to favor an increase at large \( z \) values, rather then a decrease, which is implicitly forced by a behavior of the kind given in Eqs. (10) and (12) (at least with positive \( \delta \) values).

In addition, an increasing trend of \( A_0(z) \) and \( A_{12}(z) \) seems to be confirmed by very interesting preliminary results of the BABAR Collaboration, which has performed an independent new analysis of \( e^+ e^- \rightarrow h_1 h_2 X \) data [25], analogous to that of Belle.

This suggests that a different parametrization of the \( z \) dependence of favored and disfavored Collins functions could turn out to be more convenient. Then, we try an alternative polynomial parametrization which allows more flexibility on the behavior of \( N_q^C(z) \) at large \( z \):

\[
N_q^C(z) = N_q^C [(1 - a - b) + a z + b z^2],
\]  

with the subfix \( q = \text{fav, dis} \), and \(-1 \leq N_q^C \leq 1\); \( a \) and \( b \) are flavor independent so that the total number of parameters for the Collins functions (in addition to \( M_h \)) remains 4. Such a choice fixes the term \( N_q^C(z) \) to be equal to 0 at \( z = 0 \) and not larger than 1 at \( z = 1 \). Notice that we do not automatically impose, as in Eq. (12), the condition \(|N_q^C(z)| \leq 1 \); however, we have explicitly checked that the best fit results and all the sets of parameters corresponding to curves inside the shaded uncertainty bands satisfy that condition.

We have repeated the same fitting procedure as performed with the standard parametrization. When fitting the combined SIDIS, \( A_{12}^{UL} \) and \( A_{12}^{UC} \) Belle data, the resulting
best fits (not shown) hardly exhibit any difference with respect to those obtained with the standard parametrization (Fig. 1). This can be seen also from the $\chi^2$'s in Table I, where the third line is very similar to the first one. As a further confirmation, the corresponding best fit plots for $N_{C_fav;dis}^{(z)}$, in case of the standard and polynomial parametrizations, plotted in Fig. 4 (left panel) practically coincide up to values of $z$ very close to 1.

The situation is different when best fitting the SIDIS data together with $A_{UL}^{0}$ and $A_{UC}^{0}$; in such a case the polynomial parametrization allows a much better best fit, as shown in Fig. 5, upper plots. A reasonable agreement can also be achieved between the data and the computed values of $A_{12}^{UL}$ and $A_{12}^{UC}$, as shown by the $\chi^2$ values in Table I and by the lower plots in Fig. 5. In this case the polynomial form of $N_{C_fav;dis}^{C}(z)$ differs from the standard one, as shown in the right plots in Fig. 4.

Notice, again, that the large $\chi^2$ values of the computed $A_{12}^{UL}$ are almost completely due to the last $z$ bins, which correspond to the quasi exclusive region. Also, the larger $\chi^2$ values corresponding to SIDIS data are mainly due to a slightly worse description of HERMES $\pi^-$ azimuthal...
moments. The values of the parameters obtained using the polynomial shape of $N^c_{\text{fav}, \text{dis}}(z)$, Eq. (32), are given in Table III.

C. The extracted transversity and Collins functions; predictions and final comments

Our newly extracted transversity and Collins functions are shown in Figs. 6 and 7; to be precise, in the left panels we show $x\Delta_T q(x) = x h_1(q, x)$, for $u$ and $d$ quarks, while in the right panels we plot

$$z \Delta^N D_{h/q}^{\sin(\phi_h + \phi_S)}(z) = z \int d^2 p_\perp \Delta^N D_{h/q}^{\sin(\phi_h + \phi_S)}(z, p_\perp)$$

$$= z \int d^2 p_\perp \frac{2 p_\perp}{zm_h} H_1^{h/q}(z, p_\perp)$$

$$= 4z H_1^{(3/2)q}(z)$$

for $h = \pi^\pm$ and $q = u$. The Collins results for $d$ quarks are not shown explicitly, but could be obtained from Tables II and III.
polynomial parametrization, Eqs. (10), (32), and (13). We and the Collins fragmentation functions according to the shaded areas correspond to the statistical uncertainty on the parameters, as explained in the text and in Ref. [24]. Notice that the $M$ obtained by fitting simultaneously SIDIS data on the Collins asymmetry and Belle data on $A_{12}$ favored and disfavored Collins fragmentation functions, as distributions are parametrized according to Eqs. (9) and (11) and the Collins fragmentation functions according to the polynomial parametrization, Eqs. (10), (32), and (13). We obtain a total $\chi^2$/d.o.f. $= 1.01$. The statistical errors quoted for each parameter correspond to the shaded uncertainty areas in Fig. 5, as explained in the text and in the Appendix of Ref. [24].

TABLE III. Best values of the nine free parameters fixing the $u$ and $d$ quark transversity distribution functions and the favored and disfavored Collins fragmentation functions, as obtained by fitting simultaneously SIDIS data on the Collins asymmetry and Belle data on $A_{UL}$ and $A_{UC}$. The transversity distributions are parametrized according to Eqs. (9) and (11) and the Collins fragmentation functions according to the polynomial parametrization, Eqs. (10), (32), and (13). We obtain a total $\chi^2$/d.o.f. $= 1.01$. The statistical errors quoted for each parameter correspond to the shaded uncertainty areas in Fig. 5, as explained in the text and in the Appendix of Ref. [24].

$N_u = 0.36^{+0.19}_{-0.12}$  $N_d = -1.00^{+0.40}_{-0.00}$  
$\alpha = 1.06^{+0.87}_{-0.56}$  $\beta = 3.66^{+5.87}_{-2.78}$  
$N_{u,d} = 1.00^{+0.00}_{-0.36}$  $N_{u,d} = -1.00^{+0.10}_{-0.00}$  
$a = -2.36^{+1.24}_{-0.98}$  $b = 2.12^{+0.61}_{-1.12}$  
$M_h^2 = 0.67^{+0.38}_{-0.36}$ GeV$^2$

Figure 5 (color online). The experimental data on $A_{UL}^0$, $A_{UC}^0$ (upper plots) and $A_{UL}^{12}$ and $A_{UC}^{12}$ (lower plots), as measured by the Belle Collaboration [12] in unpolarized $e^+e^- \rightarrow h_1 h_2 X$ processes, are compared to the curves obtained from our global fit. The solid lines correspond to the parameters given in Table III, obtained by fitting the SIDIS and the $A_0$ asymmetries with polynomial parametrization, the shaded areas correspond to the statistical uncertainty on the parameters, as explained in the text and in Ref. [24]. Notice that the $A_{UL}^{12}$ and $A_{UC}^{12}$ data are not included in the fit and our curves, with the corresponding uncertainties, are simply computed using the parameters of Table III.

Figure 6 shows the results which best fit the COMPASS and HERMES SIDIS data on $A_{UT}^{\sin(\phi_1+\phi_2)}$, together with the Belle results on $A_{UL}^{12}$ and $A_{UC}^{12}$, using the standard parametrization. The red solid lines correspond to the parameters given in Table II. The shaded bands show the uncertainty region, which is the region spanned by the 1500 different sets of parameters fixed according to the procedure explained above and in the Appendix of Ref. [24]. The blue dashed lines show, for comparison, our previous results [7]: the difference between the solid red and dashed blue lines is only due to the updated SIDIS and $A_{UL}$ data used here, with the addition of $A_{12}$, while keeping the same parametrization. The present and previous results agree within the uncertainty band: one could at most notice a slight decrease of the new $u$ quark transversity distribution at large $x$ values.

Figure 7 shows the results which best fit the COMPASS and HERMES SIDIS data on $A_{UT}^{\sin(\phi_1+\phi_2)}$, together with the
FIG. 6 (color online). The left panel shows (solid red lines) the transversity distribution functions $xh_1^q(x) = x\Delta T q(x)$ for $q = u$, $d$, with their uncertainty bands (shaded areas), obtained from the best fit of SIDIS data on $A_{UT}^{\sin(\phi_s+\phi_3)}$ and $e^+e^-$ data on $A_{12}$, adopting the standard parametrization (Table II). Similarly, the right panel shows the corresponding first moment of the favored and disfavored Collins functions, Eq. (33). All results are given at $Q^2 = 2.41$ GeV$^2$. The corresponding results using the polynomial parametrization, not shown, would almost entirely overlap with those shown here, both for the transversity and the Collins functions. The dashed blue lines show the same quantities as obtained in Ref. [7] using the data then available on $A_{UT}^{\sin(\phi_s+\phi_3)}$ and $A_{12}$.

Belle results on $A_0^{UL}$ and $A_0^{UC}$, using the polynomial parametrization. The red solid lines correspond to the parameters given in Table III. This is not a simple updating of our previous 2008 fit [7], as we use different sets of data (SIDIS and $A_0$ rather than SIDIS and $A_{12}$) with a different polynomial parametrization. In this case the comparison with the 2008 results is less significant. When comparing the results of Figs. 6 and 7, one notices a sizeable difference in the favored ($u/\pi^+$) Collins function, and less evident differences in the transversity distributions.

In Fig. 8 we show, for comparison with similar results presented in Ref. [7], the tensor charge, corresponding to our best fit transversity distributions, as given in Tables II and III. Our extracted values are shown at $Q^2 = 0.8$ GeV$^2$ and compared with several model computations. One should keep in mind that our estimates are based on the assumption of a negligible contribution from sea quarks and on a set of data which still cover a limited range of $x$ values.

All other results are shown at the scale $Q^2 = 2.41$ GeV$^2$. The evolution to the chosen value has been obtained by evolving at leading order the collinear part of the factorized distribution and fragmentation functions. The TMD evolution, which might affect the $k_\perp$ and $p_\perp$ dependence, is not yet known for the Collins function. Consistently, it has not been taken into account for the other distribution and fragmentation functions.

We have not included in our fit some recent results on the SIDIS Collins asymmetry on a neutron target published by the Jefferson Lab Hall A Collaboration at 6 GeV [33]. These results have been obtained from data (4 points) off a $^3$He target, and the extraction of $A_{UT}^{\sin(\phi_s+\phi_3)}$ for a neutron requires some model dependence in order to take into account nuclear effects; the published results have indeed

FIG. 7 (color online). The left panel shows (solid red lines) the transversity distribution functions $xh_1^q(x) = x\Delta T q(x)$ for $q = u$, $d$, with their uncertainty bands (shaded areas), obtained from the best fit of SIDIS data on $A_{UT}^{\sin(\phi_s+\phi_3)}$ and $e^+e^-$ data on $A_0$, adopting the polynomial parametrization (Table III). Similarly, the right panel shows the corresponding first moment of the favored and disfavored Collins functions, Eq. (33). All results are given at $Q^2 = 2.41$ GeV$^2$. The corresponding results using the standard parametrization, not shown, would almost entirely overlap with those shown here for the transversity distribution. The favored Collins function would be smaller and the disfavored one also smaller (i.e., larger in magnitude), with their uncertainty bands still partially overlapping.

FIG. 8 (color online). The tensor charge $\delta q = \int_{-1}^{1} dx [\Delta T q(x) - \Delta T \bar{q}(x)]$ for $u$ (left) and $d$ (right) quarks, computed using the transversity distributions obtained from our best fits, Table II (top solid red circles) and Table III (solid red triangles). The gray areas correspond to the statistical uncertainty bands in our extraction. These results are compared with those given in Ref. [7] (number 2), obtained in Ref. [8] (number 10) and computed with lattice [26] (number 5) or model calculations Refs. [27–32] (respectively, numbers 3, 4 and 6–9).
FIG. 9 (color online). Estimates, obtained from our global fit, for the azimuthal correlations $A_{UL}^{UL}$, $A_{UL}^{UC}$, $A_{UL}$, and $A_{UL}^{UC}$ in unpolarized $e^+e^- \rightarrow h_1h_2X$ processes at BABAR [25]. The solid lines correspond to the parameters given in Table II, obtained by fitting the $A_{12}$ Belle asymmetry; the shaded area corresponds to the uncertainty on these parameters, as explained in the text.

FIG. 10 (color online). Estimates, obtained from our global fit, for the azimuthal correlations $A_{UL}^{UL}$, $A_{UL}^{UC}$, $A_{UL}$, and $A_{UL}^{UC}$ in unpolarized $e^+e^- \rightarrow h_1h_2X$ processes at BABAR [25]. The solid lines correspond to the parameters given in Table III, obtained by fitting the $A_0$ Belle asymmetry; the shaded area corresponds to the uncertainty on these parameters, as explained in the text.
large errors. If we use our extracted transversity distributions and Collins functions, exploiting isospin symmetry and the same model [34] for the nuclear effects as in Ref. [33], we find a negligible Collins asymmetry on a $^3\text{He}$ target, which is in agreement with three out of the four data points of JLab.

As BABAR data on $A_{12}$ and $A_0$ should be available soon, we show in Figs. 9 and 10 our expectations, based on our extracted Collins functions. Figure 9 shows the expected values of $A_{12}^U$, $A_{12}^C$, $A_0^U$, and $A_0^C$, as a function of $z_1$ for different bins of $z_2$, using the parameters of Table II, obtained by fitting the SIDIS and the $A_{12}$ Belle data with the standard parametrization. Figure 10 shows the same quantities using the parameters of Table III, obtained by fitting the SIDIS and the $A_0$ Belle data with the polynomial parametrization.

The Belle (and BABAR) $e^+e^-$ results on the azimuthal correlations of hadrons produced in opposite jets, together with the SIDIS data on the azimuthal asymmetry $A_{UT}^\sin(\phi_0+\phi_2)$, measured by both the HERMES and COMPASS Collaborations, definitely establish the importance of the Collins effect in the fragmentation of a transversely polarized quark. In addition, the SIDIS asymmetry can only be observed if coupled to a nonnegligible quark transversity. The original extraction of the transversity distribution and the Collins fragmentation functions [6,7], has been confirmed here, with new data and a possible new functional shape of the Collins functions. The results on the transversity distribution have also been confirmed independently in Ref. [8].

A further improvement in the QCD analysis of the experimental data, towards a more complete understanding of the Collins and transversity distributions, and their possible role in other processes, would require taking into account the TMD evolution of $\Delta Tq(x,k_L)$ and $\Delta^0 D_{q/q}(z,p_L)$. Great progress has been recently achieved in the study of the TMD evolution of the unpolarized and Sivers transverse momentum dependent distributions [35–39] and a similar progress is expected soon for the Collins function and the transversity TMD distribution [40].
