**Introduction** Brief repeated sessions of high intensity interval cycling induce changes in skeletal muscle energy metabolism that resemble endurance type training. PGC-1 $\alpha$  is a transcriptional co-activator which through the activation of both nuclear and mitochondrial transcription factors up-regulates mitochondrial biogenesis. At present, there are no studies which have examined the effect of brief repeated sessions of high intensity interval running (HIIR) on mitochondrial biogenesis and endurance performance in players involved in team sports. Therefore the aim of this study was to compare the changes in mitochondrial biogenesis and endurance performance in response to HIIR and endurance running (ER) in Gaelic football players. **Methods** Fourteen club level Gaelic football players (mean  $\pm$  SD; age 21.7  $\pm$  2.3 yr; BMI 24.2  $\pm$  1.2 kg.m<sup>2</sup>; VO<sub>2</sub>max 55.1  $\pm$  4.9 ml.kg<sup>-1</sup>•min<sup>-1</sup>) were randomly assigned to an ER or HIIR group. Both groups undertook 6 training sessions over a 2 week period. ER involved 50 min of continuous running at 75% VO<sub>2</sub>max. The HIIR group performed 3 sets of 3 x 110 m shuttle sprints with a 20 s recovery period between each sprint, and a 5 min recovery period between sets. Muscle biopsies were taken before and after training. Western blot analysis was used to measure the protein content of p38 MAPK, AMPK, PGC-1 $\alpha$ , Tfam and OXPHOS subunits. Maximal activities of CS and  $\beta$ -HAD were determined spectrophotometrically. Endurance performance was evaluated by measuring the time to exhaustion at 110% vVO<sub>2</sub> max before and after the 6 exercise session. **Discussion** Training resulted in a significant increase in protein content of AMPK (p<0.05) and COX I-IV (p<0.05) subunits in the HIIR group, whereas PGC-1 $\alpha$  (p<0.05) and COX V subunit (p<0.05) increased in both groups. There was no increase in Tfam protein content in either group post training. Compared to baseline glycogen, ATP and PCR concentration increased (p<0.05) in the HIIR group only. The activity of CS and  $\beta$ -HAD were significant higher (p<0.05) than baseline in both groups following the 6 training sessions. Endurance performance increased in both the HIIR (p<0.05) and ER (p<0.01) group in response to training. Compared to 6 sessions of ER, HIIR induced a similar improvement in endurance performance and a more pronounced increase in mitochondrial biogenesis. **References** Little J.P, Safdar A., Wilkin G.P., Tarnopolsky M.A., Gibala M.J. ### ORAL L-ARGININE MODULATES BLOOD LACTATE AND INTERLEUKIN-6 AFTER EXERCISE IN HIV-INFECTED MEN

Alves, G.N.1, Tavares, A.M.V.1, Vieira, P.J.C.1, Sprinz, E.2

*1:Exercise Pathophysiology Research Laboratory and Cardiovascular Division 2: Division of Internal Medicine, Clinical Hospital of Porto Alegre - Porto Alegre, Brazil*

**Introduction** The acute administration of L-arginine (L-arg), a nitric oxide (NO) precursor, reduces lactate (LAC) concentration after exercise in healthy individuals. Lower concentration of L-arg may enhance the action of some inflammatory cytokines in HIV-1 infected patients. We tested the hypothesis that acute L-arg administration may reduce post-exercise blood LAC and inflammatory cytokines levels in HIV-infected patients. **Methods** Ten HIV-infected men performed 2 maximal incremental cardiopulmonary exercise tests, separated by one week. Thirty minutes before each test, patients received oral placebo (Plcb) or 20g of L-arg. Blood LAC, tumor necrosis factor alpha (TNF-alpha), interleukin-6 (IL-6), and interleukin-10 (IL-10) were measured before and up to 60 min after exercise. **Results** L-arg administration had no significant effect on peak heart rate, peak oxygen uptake, and peak respiratory exchange ratio. Compared to Plcb, L-arg administration reduced maximal post-exercise blood LAC from 8.7 $\pm$ 0.6 to 6.9 $\pm$ 0.4 mmol/L (p < 0.05). L-arg administration had no significant effect on TNF-alpha or IL-10 concentrations, but increased post-exercise IL-6 (Plcb = 19  $\pm$  3 pg/ml; L-arg = 63  $\pm$  8 pg/m; p < 0.05). **Discussion** There is solid evidence indicating that the elevation of IL-6 in response to exercise may exert anti-inflammatory effects, by blocking TNF-alpha (Pedersen, 2011; Pedersen and Febbraio, 2005; Stevens et al., 2000). Our data suggest that, in HIV-1 positive individuals, L-arg supplementation is needed for the manifestation of the anti-inflammatory effects of acute exercise. Further studies should be conducted to test the hypothesis that chronic L-arg supplementation may improve the anti-inflammatory effects of exercise training. **In conclusion**, in HIV-1 infected men, acute administration of L-arg reduces post-exercise blood LAC and increases IL-6 levels, suggesting the activation of the L-arg-NO pathway, with possible anti-inflammatory consequences. **References** Pedersen BK. ### IS-PM03 Oxygenation and fatigue in humans: unravelling the mechanisms \*

#### NUCLEOTIDES, THE KEY TO HEALTH AND PERFORMANCE?

Hellsten, Y.

*University of Copenhagen*

ATP is a nucleotide of exceptional importance in the body, both for basal cellular functions and for exercise performance. It is the only directly usable energy source for muscle contraction and many other energy demanding functions, but it is also a very important signaling molecule. During short-term, high intensity exercise the rate of ATP utilization within the skeletal muscle cells may exceed the rate of regeneration from ADP, with a consequent acute reduction in intracellular ATP levels. Moreover, a small fraction of the acutely degraded ATP is lost from the muscle as inosine and, if intense exercise is repeated frequently over a period of time, an accumulated loss can occur leading to lowered resting ATP stores. Such reduced ATP levels could, in theory, affect performance, although existing data do not directly support this. Extracellular ATP levels have been proposed to affect muscle contractility and the activity of Na<sup>+</sup>/K<sup>+</sup> pumps that are essential for removal of extracellular K<sup>+</sup>, and thus for development of fatigue. In the muscle interstitium extracellular ATP may primarily originate from secretion from the skeletal muscle cells, but factors controlling such release remain to be identified. In plasma, ATP is a potent

vasodilator and sympatholytic compound and is believed to be important for the control of proper oxygen delivery to skeletal muscle. Plasma ATP originates primarily from secretion from erythrocytes and endothelial cells and if this secretion is impaired, oxygen supply may be inadequate and limit performance. This is believed to occur in lifestyle diseases such as Type II diabetes.

### **BRAIN OXYGENATION AND FATIGUE: ROLE OF PAO<sub>2</sub> AND CAO<sub>2</sub>?**

Calbet, J.

*University of Las Palmas de Gran Canaria*

A rapid increase of oxygenation relieves fatigue during maximal exercise in severe acute and chronic hypoxia. Since this effect is almost instantaneous and it is observed only during exercise with a large muscle mass it has been postulated that this phenomenon indicates that during whole body exercise in severe acute hypoxia fatigue is predominantly caused by a central mechanism linked to insufficient brain oxygenation. The fatigue relieving effect of oxygenation has been observed when the level of hypoxia during the exercise was high (P<sub>IO<sub>2</sub></sub><86 mmHg) but not in moderate hypoxia (P<sub>IO<sub>2</sub></sub>=104 mmHg). At high levels of hypoxia, when the PaO<sub>2</sub> lies in the rectilinear region of the oxygen dissociation curve of the hemoglobin (ODC), an increase of PaO<sub>2</sub> causes a proportional elevation of SaO<sub>2</sub> improving both the pressure driving the diffusion of O<sub>2</sub> from the capillaries to the mitochondria and the delivery of oxygen. However, during exercise in the flat upper region of ODC an increase of PaO<sub>2</sub> elicits a smaller improvement in SaO<sub>2</sub>. If the ergogenic effect of oxygenation is more dependent on PaO<sub>2</sub> than SaO<sub>2</sub> then it should be present regardless of the change elicited in SaO<sub>2</sub>. Using near-infrared spectroscopy, transcranial Doppler, assessment of blood gases, and novel experimental approaches to manipulate swiftly brain blood flow and PaO<sub>2</sub> we will show that at moderate to high levels of hypoxia PaO<sub>2</sub> appears to play a dominant role.

### **OXYGENATION AND TRAINING**

Lundby, C.

*University of Zürich*

Altitude training in the form of Live High – Train Low was first demonstrated effective in increasing athletic performance in the late 1990s and since then numerous studies have either confirmed this or reported no effects. A meta analysis on the topic suggest an approximately 1% increase in performance following LH<sub>TL</sub>, which is obviously not to be neglected when it comes to exercise performance in elite athletes. However the scientific gold-standard design of a double blind, placebo controlled, cross-over trial has never been conducted on LH<sub>TL</sub> and most studies have not made use of truly elite athletes. Thus previous studies should be met with some skepticism. Although the underlying mechanisms for performance gains have been debated since LH<sub>TL</sub> was first launched, it now seems safe to say that a hypoxia induced increase in hemoglobin mass is a prerequisite for LH<sub>TL</sub> also to increase performance. A recent analysis suggests that the erythropoietic response to LH<sub>TL</sub> may depend on the initial nHb value, i.e. a person with an already high nHb will not respond to the hypoxic stimulus as much (or at all) as a person with an initial low nHb. This questions the added value of LH<sub>TL</sub> for truly elite endurance athletes. Furthermore the analysis demonstrated that much more time is required to increase nHb with continuous altitude acclimatization than what is currently recommended for LH<sub>TL</sub>. Thus the rationale to recommend LH<sub>TL</sub> to elite athletes may not be as clear as previously expected.

### **IS-PM08 Limits to performance during short-term and prolonged exercise in the heat sponsored by Aspetar**

---

#### **CARDIOVASCULAR LIMITS DURING EXERCISE IN A HOT ENVIRONMENT**

González-Alonso, J.

*Brunel University*

Understanding what factors limit human performance is one of the most fascinating and complex scientific challenges in Sport Science. Multiple experimental approaches have been and continue to be employed to address this fundamental question depending on the paradigm used. In physiology, a classic approach is to investigate whether a single or several key physiological variables correlate closely with functional processes leading to fatigue. The heart, the brain and the muscles all generate and process numerous regulatory signals to adjust the supply of oxygen, substrates and blood flow to the local demand in the locomotor muscles. A myriad of research endeavours have tried to establish the relative contribution of these organs to fatigue and examine whether regulatory failure in one or all of these organs underpins fatigue. A major focus of this presentation lies on the circulatory limitations to exercise performance in hot environments, particularly the involvement of the heart, brain and muscles. Blood flow can limit the intensity and duration of exercise via its effect on the supply of oxygen and substrates and thus tissue metabolism. Over the years, it has become increasingly evident that blood flow to the active skeletal and respiratory muscles and the brain does not increase linearly with elevations in local metabolic demand produced by increases in exercise intensity or are maintained stable during strenuous constant load exercise. Cardiac output and blood flow to the active muscle and brain either decline during constant load high intensity exercise to exhaustion (which simulates the circulatory and energy requirements of middle distance events) or level off at submaximal intensities during incremental exercise to exhaustion (e.g., Mortensen et al. 2008; González-Alonso et al. 2008; Vogiatzis et al. 2009). At the heart level, coronary blood flow might also be compromised when cardiac output is impaired owing to diminished stroke volume. Thus, findings over the last decade shed new light on the physiological mechanisms of fatigue during short intense and prolonged exercise typical of many sports by indicating that exhaustion during exercise in hot environments is preceded by restrictions in the provision of essential oxygen and substrates to the active muscles and brain, thereby impacting upon local metabolism in the organs with limited functional oxygen reserve. Although addressing the precise contribution of each organ system warrant further investigation, the significant global circulatory strain prior to fatigue during both prolonged exercise and intense exercise in hot environments support the hypothesis that events in active muscles,

the heart and the brain are all contributing to some extent to the physiological processes leading to fatigue. References González-Alonso J et al. (2008). *J Physiol* 586, 45-53. Mortensen SP et al. (2008). *J Physiol* 586, 2621-2635. Vogiatzis I et al. (2009). *J Physiol* 587, 3665-3677.

### **METABOLIC LIMITATIONS DURING PROLONGED EXERCISE IN A HOT ENVIRONMENT**

Mora-Rodríguez, R.

*University Castilla-La Mancha*

In this talk I will discuss how exercise in the heat alters substrate utilization during prolonged submaximal exercise in comparison to similar exercise in a thermoneutral environment. Also, if heat acclimation, external cooling, or rehydration corrects the shift towards increased reliance on carbohydrate metabolism and what are the implications for performance in a hot environment. Exercise in the heat often results in increased intramuscular glycogen utilization rates (1) a concomitant reduction in fat oxidation and increased blood and muscle lactate accumulation. Lowering of intramuscular glycogen stores is one important cause of fatigue during prolonged exercise. However, glycogen depletion has not been deemed as an important cause of fatigue during prolonged exercise in the heat. At the point of fatigue, during time to exhaustion testing, glycogen concentration remains above 300 mmol/kg dry wt (2). Furthermore, carbohydrate supplementation during exercise in the heat does not delay fatigue (3). Unlike muscle glycogen, blood glucose utilization does not seem to be altered by exercising in a hot environment (4). The possible mechanisms by which exercise in the heat stimulates glycogen phosphorylase activity will be briefly presented. Among those; a) stimulation of anaerobic glycolysis due to a decreased O<sub>2</sub> delivery secondary to reduction in muscle blood flow with severe dehydration, b) hormonal stimulation due to the increased circulating epinephrine concentrations, c) a direct effect of elevated muscle temperature (Q10) on the enzymes. Heat acclimation reduces muscle glycogen use and epinephrine concentration but the decrease is not completely explained by a shift towards fat oxidation or increased blood flow. In addition, external cooling and prevention of dehydration help to reduce glycogenolysis rate during prolonged exercise in the heat. 1. Febbraio, M. A., R. J. Snow, C. G. Stathis, M. #### **IS-PM11 Muscle mass regulation in humans: relative importance of protein synthesis and protein breakdown \***

##### **PROTEIN IN PROMOTING ADAPTION WITH EXERCISE TRAINING**

Phillips, S.

*McMaster University*

Muscle hypertrophy requires the balance of muscle protein turnover to favour net protein accrual. The stimulus of resistance exercise is a potent stimulator of the process of muscle protein synthesis (MPS); however, muscle protein breakdown (MPB) is also stimulated and net muscle protein balance does not become positive and protein accretion promoted until protein is consumed. Protein consumption after resistance exercise has been unequivocally shown to result in MPS being greater than MPB for a prolonged period of time, whereas protein consumption during and prior to resistance exercise appears of equivocal benefit. Different types of protein can also impact the MPS response and the collective evidence shows that proteins rich in leucine that are rapidly digested provide the most robust stimulus to MPS. Sustaining the MPS response after resistance exercise does not appear to require sustained aminoacidemia, although further work remains to be done in this area. How different types of exercise affect which proteins are being made following exercise is an area of ongoing investigation, however, evidence suggests that myofibrillar protein synthesis is strongly driven by resistance exercise and is nutritionally responsive. In other words protein augments the MPS response. It is far less clear if the same is true of aerobic exercise, which with training begins to stimulate MPS but confined more to the mitochondrial fraction; however, such stimulation does not appear to require or be stimulated by protein provision. Recent evidence surrounding how protein ingestion can influence adaptation, through practical protein consumption strategies will be discussed.

##### **CATABOLISM: IMMOBILISATION AND INFLAMMATION**

Murton, A.J.

*University of Nottingham*

The unintended loss of muscle mass can have significant consequences on an individual's quality of life, incidence of fall-related fractures, and their chance of survival following subsequent disease or illness. Reports of increased expression of the ubiquitin ligases MAFbx/atrogen-1 and MuRF1 mRNA in animal models of cachexia, along with the ability of proteasome inhibitors to block the muscle atrophy that typically develops in these models, has led to the idea that muscle protein breakdown (MPB) via action of the ubiquitin-proteasome system (UPS) represents the predominant mechanism by which muscle atrophy occurs in many cases (Lecker et al., 2004). However, recent work in humans has questioned the idea of a common muscle atrophy "programme" that centres on the idea of enhanced MPB. Following leg-immobilisation, where a 5% loss of quadriceps muscle mass is typically observed after just 14 days of immobilisation (Jones et al., 2004), consistent increases in ubiquitinated proteins and UPS components are only observed in the first few days (<3 days). More prolonged periods of disuse have resulted in inconsistent observations with regards to expression of UPS components

(Murton et al., 2008). In contrast, the suppression of muscle protein synthesis (MPS) is consistently observed in humans during limb-immobilisation and moreover, appears of a magnitude that can fully account for the atrophy observed, suggesting it is the principle mechanism responsible for the loss of muscle mass. The role of MPB in the aetiology of inflammatory-based cachexia is equally unclear. Expression of the cytokines TNF-alpha and IL6 is enhanced in the majority of inflammatory-based diseases, and are known to individually elicit muscle atrophy when administered in vivo; mechanistic evidence suggests that both TNF-alpha and IL6 can suppress MPS and activate UPS-mediated MPB. However, studies in humans demonstrate clearly that chronic expression of either cytokine does not necessitate an enhancing effect on the UPS. Indeed, we have found that systemic increases in IL6 and TNF-alpha in conjunction with increased intramuscular IL6 mRNA expression, are observed in cachectic non-small cell lung cancer patients, and yet muscle 26S proteasome activity and MAFbx/atrogen-1 and MuRF1 mRNA levels remain unchanged compared to healthy age-matched controls (A. Murton et al, unpublished observations). Collectively, these observations serve to illustrate our rudimentary understand of the molecular mechanisms that elicit muscle catabolism during disuse or disease in humans, but it is clear that a "one size fits all" mechanism for the loss of muscle mass is an inappropriate over simplification. Jones et al., (2004) FASEB J. 18: 1025-7. Lecker et al., (2004) FASEB J. 18: 39-51. Murton et al., (2008) Biochim Biophys Acta. 1782: 730-43.

## AGEING SARCOPAENIA: EXERCISE AND NUTRITIONAL INTERVENTION

Atherton, P.

*University of Nottingham*

Exercise and dietary protein intake, independently, and synergistically stimulate muscle anabolism. Mechanistically, nutrient-mediated increases in muscle protein synthesis (MPS) are initiated after amino acid (AA)-transport into muscle cells, whereupon leucine activates the mechanistic target of rapamycin complex-1 (mTORC1), independently of proximal insulin signalling. Exercise also activates mTORC1 independently of proximal insulin signalling via mechano/chemo-transduction processes. Subsequent downstream signalling enhances translational initiation via activation of mTORC1 cognate substrates (e.g. p70S6K1) culminating in polyribosome formation and increased MPS. In terms of kinetics, muscle is only briefly receptive to the anabolic effects of essential AA (EAA) (~2 h), thereafter displaying tachyphylaxis. This has been termed "muscle-full" as muscles can intrinsically sense excess AA, and divert them toward oxidation. Nutrient intake also provides a second route for anabolism, via insulin-mediated suppression of muscle protein breakdown (though this occurs via poorly defined mechanisms). Superimposing exercise onto nutrition markedly delays the "muscle-full" state to facilitate physiological adaptation in accordance to the demands imposed e.g. resistance vs. endurance exercise. In terms of ageing, it has been shown that these anabolic effects of exercise and nutrition are blunted- a phenomena termed 'anabolic resistance'. Discovering the physiological level(s) at which this blunting is mediated and determining the contribution of age-related inactivity are important foci in managing the impact of sarcopaenia. In addition, the discovery of novel strategies to enhance the anabolic effects of exercise and nutrition (e.g. regimens, nutra-ceuticals) remains a hotly pursued avenue. Finally, the application of systems biology approaches has produced new insight into the effects of exercise on molecular networks associated with ageing. These analyses have revealed that exercise is not simply the 'reverse' of ageing. Moreover, the application of unbiased genome-wide approaches have led to discoveries that provide novel information on, and challenge accepted paradigms of exercise adaptation yielded through reductionist approaches.

#### EFFECT OF ACUTE ISOMETRIC BILATERAL LEG EXTENSION EXERCISE ON BRACHIAL AND COMMON FEMORAL ARTERY FLOW-MEDIATED DILATATION

Howland, L.J.1, Wiles, J.D.1, Coleman, D.A.1, Swaine, I.L.1

*1: Canterbury Christ Church University*

Introduction Flow-mediated dilatation (FMD) is an endothelium-dependant and nitric oxide specific index of endothelial function. The chronic effects of exercise on endothelial function and improvements in FMD have been well established (Tinken et al., 2010). The impact of acute exercise on FMD remains inconclusive. The aim of this study was to investigate the effect of acute isometric bilateral leg extension exercise performed at two different intensities on brachial (BA) and common femoral artery (CFA) FMD. Method 11 healthy male participants visited the laboratory for six visits. High intensity, low intensity exercise and control conditions were performed twice at random. High and low exercise intensity were calculated from an Incremental Isometric Exercise Test (Devereux et al., 2011). BA and CFA FMD were measured pre and 5 minutes post exercise for each of the conditions. The absolute change in BA and CFA FMD was expressed as a percentage (%) and raw (mm). Doppler Ultrasound was used to measure FMD. Edge-detection, wall tracking software was used for analysis. During each exercise bout Doppler Ultrasound was used to measure CFA blood flow and artery diameter. Results There was a significant difference in absolute change BA FMD% between high (mean change -4.23%) and low (2.77%) exercise intensities ( $p=0.033$ ). There was a significant difference in absolute change BA FMD (mm) between high (-0.02mm) and (0.01mm) low intensities ( $p=0.035$ ). No significant differences existed in absolute change CFA FMD% or FMD (mm) between high and low intensities ( $p=0.856$  and  $p=0.741$ ) respectively. Blood flow and shear rate were analysed during exercise contractions and upon release. A significant time by intensity interaction was evident ( $p=0.02$  and  $p=0.014$ ) with significantly higher antegrade blood flow and antegrade shear rate upon release in the high condition. There was no significant main effect or time by intensity interaction evident ( $p>0.05$ ) with retrograde blood flow and retrograde shear rate. Normalisation of FMD to the shear rate stimulus is ongoing. Discussion Results demonstrate that absolute BA FMD% and FMD (mm) are significantly reduced after a high intensity bout of exercise is performed, which coincides with research utilising alternative modes of acute exercise (Llewellyn et al., 2012). The increases in blood flow and shear rate were greater throughout exercise, when compared to more widely researched exercise modes (Gonzales et al., 2011). This research may provide further insight into how the specific exercise stimulus may cause different acute responses in endothelial function, perhaps promoting isometric exercise training as an efficient alternative to improve resting blood pressure. This research could potentially inform future exercise prescrip-

tion for training studies which ultimately aim to improve cardiovascular health. Devereux et al (2011). Journal of Sports Sciences. 29(7). Gonzales et al (2011). Appl Physiol Nutr Metab. 36. Llewellyn et al (2012). Acta Physiol, 205. Tinken et al (2010). J Physiol, 5003-5012.

### EFFECTS OF DAWN SIMULATION ON MARKERS OF SLEEP INERTIA AND POST-WAKING PERFORMANCE IN HUMANS

Thompson, A.I, Jones, H.I, Gregson, W.I, Atkinson, G.2

*1.Liverpool John Moores University 2. Teesside University*

Introduction "Sleep inertia" is a transient state between sleep and feeling fully awake. Individuals typically report symptoms of grogginess, disorientation, decreased motor control and lower cognitive and physical performance. Artificial dawn simulation, mediated by a device which gradually increases the light intensity prior to waking, has been proposed as a method to reduce these symptoms. Therefore, the effects of a simulated dawn during the last 30 minutes of sleep on the subsequent dissipation of sleep inertia, and, for the first time, improvements in simulated work and physical performance were examined. Methods Eight participants, who reported particular difficulty with morning waking (Munich chronotype questionnaire) were recruited. Participants completed, in a random order, a control (C) and a dawn simulation (DS) trial. The DS trial involved a sigmoidal increase in light intensity from 0.1 to 300 lux (Body Clock Active 250, Lumie, UK), which started 30 minutes prior to waking from 8 hours of nocturnal sleep. Subjective ratings of sleep quality (10 cm VAS) and sleepiness (KSS) were measured alongside mathematical and reaction time tasks (Vienna Test System, A2340, Vienna, Austria) at 5, 30 and 75 min after waking at habitual workday times. Physical performance was measured 35 min post waking using a self-paced 4-km cycling time-trial. Data were analysed using two-factor within-subjects (trial x time) generalized estimation equations, with trial-order as a covariate in the model. Time-trial and sleep quality data were analysed using paired t-tests. Data are described as mean±SD. Results After waking in the DS condition, perceived sleep quality was 1.2±0.9 (P = 0.01) points higher compared with C. Ratings of sleepiness were significantly lower in DS compared with C (3.5±1.2 vs. 4.1±1.1, P = 0.04) throughout the testing period. Cognitive performance (mathematical and reaction time) improved in both trials as time-awake increased (P < 0.0005). On average, participants completed a greater number of additions in DS compared with C (70±15 vs. 67±17, P = 0.03). Reaction times were also faster in DS compared with C (0.81±0.07 vs. 0.86±0.06 s, P < 0.0005). The self-paced cycling time-trial was completed, on average, 21.4 s (4.7%) quicker in DS than C (95% CI of the difference: -1 to 43 s, P = 0.07). Conclusion These data provide novel insight into the interactions between phototherapy and performance. For the first time we have demonstrated that gradually increasing light exposure during the last 30 minutes of habitual sleep can decrease subjective sleepiness and improve both cognitive and physical performance soon after waking. These outcomes have implications for both athletic and general populations.

### POST-EXERCISE ELECTROCORTICAL ALTERATIONS INDUCED BY DIFFERENT RECOVERY INTERVENTIONS

De Pauw, K., Roelands, B., Tellez, H.F., Knaepen, K., Meeusen, R.

*Vrije Universiteit Brussel*

Introduction Comprehensive data are available on the effect of different recovery interventions on cycling performance and physiological parameters (Barnett, 2006). However the interplay between recovery and brain functioning might add supplementary information on the effectiveness of a specific recovery intervention. Therefore, we investigated the impact of three different recovery interventions on subsequent cycling performance in the heat and their effect on electrocortical activity. Recovery specific changes will be associated with electrocortical alterations reflecting regional brain processing. A higher activation of frequency band beta (12-30Hz) after exercise has been linked to a greater cortical activation (Moraes, 2007; Nielsen 2003). Methods After a max test and familiarization trial, 9 trained male subjects (22.7±3.4yrs) performed 3 experimental trials in the heat (30°C; RH 43.7±5.6%). Each trial consisted of two exercise tasks separated by 1h. The first one was a 60min constant load trial (55% of Wmax), followed by a 30min simulated time trial (TT1). The second one comprised a 12min simulated time trial (TT2). After TT1 active recovery (AR; cycling at 80W), passive rest (PR; sitting on a comfortable chair) or cold water immersion (CWI; until sternum, water temperature: 15°C) was applied for 15min. We obtained 3min EEG datasets pre and post an exercise task. EEGlab was used to process the datasets (1-45Hz, Notch, ICA). Discrete Fourier transform calculated the absolute power spectrum ( $\mu V^2$ ) for each 4s segments. A normality test, Friedman tests and Wilcoxon Signed-rank tests were conducted (p<0.05). Results CWI resulted in faster TT2 performance when compared to PR (4.2%) and AR (4.7%). The absolute power spectrum pre TT2 did not significantly differ between the recovery interventions. After CWI,  $\beta_2$  power significantly increased at FP1 (p=0.028) [FP2: (p=0.051)] and AR significantly increased  $\beta_2$  power at F3, Fz, F4 and Cz (p<0.039) post compared to pre TT2. PR showed no significant differences post compared to pre TT2. Discussion CWI induced increased prefrontal activation after TT2, which influences information processing and psychological variables like attention and arousal. AR increased  $\beta_2$  power activation at aforementioned electrode sites after TT2 indicating increased information processing at frontal and somatosensory brain areas. We postulate that there exists a link between the absolute  $\beta_2$  power at specific brain areas and the effectiveness of a recovery intervention. References Barnett. ### MODEST FOOD RESTRICTION STIMULATES INCREASES IN APPETITE THAT DO NOT OCCUR IN RESPONSE TO AN EQUIVALENT EXERCISE-INDUCED ENERGY DEFICIT.

Deighton, K., Douglas, J., Pryke, H., Stensel, D.J.

*Loughborough University*

Introduction Weight loss is the result of a sustained negative energy balance, which is typically achieved by decreasing food intake and/or increasing physical activity. Research suggests that appetite, energy intake and plasma acylated ghrelin concentrations increase in response to a daily energy deficit of ~4820 kJ when induced via food restriction but not when achieved via exercise (King et al., 2011). The present study investigated whether such contrasting responses occur with smaller, more practical energy deficits induced by exercise and food restriction. Methods Twelve healthy male volunteers (mean (SD); age 24 (5) years, body mass index 23.8 (2.7) kg.m<sup>-2</sup>, maximum oxygen uptake (VO<sub>2</sub> max) 55.4 (9.1) mL.kg<sup>-1</sup>.min<sup>-1</sup>) completed three 8 h trials separated by one week in a counterbalanced Latin Square design. Participants arrived at the laboratory at 8 am after an overnight fast. Standardised test meals were provided at 1 h and 4 h. Appetite ratings and plasma acylated ghrelin concentrations were measured throughout each trial. Food intake was monitored from an ad libitum meal at 7 h. Thirty min of continuous cycling exercise at 64.5 (3.2) % of VO<sub>2</sub> max was performed from 0-0.5 h during the exercise trial (Ex-Def), which induced an energy deficit of 1469 (256) kJ. An energy deficit of 1478 (275) kJ was induced in the food restriction trial (Food-Def) by deducting the net energy cost of exercise from the energy provided at the standardised test meals. No energy deficits were induced during the control trial (Con). Results The appetite delta AUC was significantly higher in Food-Def than Ex-Def from 0-1 h (P =

0.012), 4-7 h ( $P = 0.018$ ) and for the entire 8 h trial (0-8 h;  $P = 0.009$ ). However, energy intake at the ad libitum meal did not differ between trials ( $P = 0.634$ ; Con 4376 (1634); Food-Def 4481 (1846); Ex-Def 4217 (1850) kJ). Acylated ghrelin delta AUC was elevated in Con relative to Ex-Def and Food-Def from 0-1 h ( $P = 0.049$ ) but did not differ between trials during any other time periods. Closer inspection of the data revealed large individual differences in plasma acylated ghrelin profiles. Discussion An acute energy deficit of ~1478 kJ stimulated increases in appetite when achieved via food restriction but not when induced via exercise. Appetite appeared to be unrelated to changes in plasma acylated ghrelin concentrations, which adds to the current debate regarding the importance of ghrelin in the physiological regulation of appetite (Lippl et al., 2012). Ad libitum energy intake did not differ between trials and may need to be monitored in a free-living environment. References King JA, Wasse LK, Ewens J et al. ### CARDIAC FUNCTION AND LEFT VENTRICULAR MECHANICS IN MEN AND WOMEN AT REST AND DURING EXERCISE

Nio, A.Q.X., Stöhr, E.J., Meah, V., Stembridge, M., Shave, R.

*Cardiff Metropolitan University*

**Introduction** During incremental exercise, cardiac output (Q) increases similarly in men and women. However, women have been suggested to depend on a larger end-diastolic volume (EDV) and men on a smaller end-systolic volume (ESV) during peak supine exercise. Furthermore, sex differences in the underpinning left ventricular strain and twist ('LV mechanics') have not been examined. The aim of this study was to compare LV function and the underlying mechanics in men and women at rest and during exercise. We hypothesised that a similar Q will be attained via different LV mechanics in men and women during exercise. **Methods** 12 healthy men (mean±SD; age 23±3 y; body fat 17±5%; VO<sub>2</sub>peak 43±7 mL/min/kg) and 13 healthy women (age 23±4 y, body fat 30±4%; VO<sub>2</sub>peak 35±6 mL/min/kg) completed four consecutive 4-min stages of exercise at 10, 30, 50 and 70% supine cycling peak power (Wpeak). Heart rate (HR), Q, stroke volume (SV), EDV, ESV, isovolumic relaxation time (IVRT) and LV mechanics were assessed using echocardiography. Q, SV, EDV and ESV were allometrically scaled to fat free mass for statistical analysis. Data were analysed using mixed ANOVA and post-hoc t-tests with Bonferroni correction ( $\alpha=0.05$ ). Relationships were assessed using Pearson's product-moment correlation. **Results** With exercise, HR, Q, SV and EDV increased, and ESV decreased. EDV tended to differ between men and women across exercise ( $p=0.06$ ). Peak basal radial strain remained unchanged but the peaks of all other parameters of LV mechanics (basal and apical radial and circumferential strain and strain rates, rotation and rotational velocities, and LV twist and untwisting velocity) increased with exercise. IVRT was shorter in women at 50 (men 61±10; women 52±12 ms) and 70% Wpeak (men 57±12; women 46±10 ms;  $p<0.05$ ). A shorter IVRT during exercise was related ( $r^2=0.68$ ;  $p<0.01$ ) to a greater uncoupling of peak diastolic rotation velocities (i.e. longer time interval between peak basal and apical rotational velocity). At 70% Wpeak only, this uncoupling of peak regional rotational velocities was more pronounced in women than men (21±15 vs. 6±10% of diastole;  $p<0.05$ ). **Discussion** This is the first study to examine sex differences in LV mechanics during exercise. Whilst the results of the present study suggest that Q in men and women at moderate intensity exercise (70% Wpeak) may be generated by different underlying mechanics, they clearly demonstrate that cardiac function and mechanics are similar in men and women at rest and during low intensity exercise. Whether the uncoupling of peak diastolic basal and apical rotational velocity in women at 70% Wpeak hastens development of the intra-ventricular pressure gradient for mitral valve opening, shortens IVRT and enables maintenance of EDV requires further investigation.

### PACING AND TECHNIQUE OF TALENTED SPEED SKATERS: PERSIST TO THE END.

Stoter, I.K., Hettinga, F.J., Otten, E., Stam, A., Elferink-Gemser, M.T., Visscher, C.

*University Medical Center of the University of Groningen*

**Introduction:** Speed skating is an intriguing time trial sport in which maintenance of technique is of great importance to retain velocity. It is therefore important to incorporate technique in choosing an adequate pacing strategy. The present study investigates technical variables, underlying push-off effectiveness and aerodynamics, and pacing in relation to the performance of talented speed skaters. It is hypothesized that talented speed skaters who out-perform other talented speed skaters are better able to maintain low body angles for an effective push-off and aerodynamics at the end of the race, when they have to cope with fatigue. Furthermore, the results might reveal a performance determining factor defining talents in speed skating. **Methods:** Lap-times, knee, hip, trunk and push-off angles per lap (0-300m, 300-700m, 700-1100m and 1100-1500m) were measured during an official 1500m time trial in 45 (international speed skating talents. Based on end-times (ET), the talents were divided in a fast talent group (FTG), including eight male ( $ET < 115.5s$ ) and eleven female ( $ET < 129s$ ) talents, and a slower talent group (STG), including thirteen male ( $ET > 116.5$ ) and thirteen female ( $ET > 130s$ ) talents. A repeated measures ANOVA was used to find differences in lap-times and body angles between the FTG and STG. A multiple regression analysis was used to find the determining technical factors of speed skate performance. **Results:** Lap-times, knee, hip and push-off angles increased over the race, whereas trunk angles decreased. A between subject effect was found for lap-times, knee, hip and push-off angles. Post-hoc tests showed that FTG had lower lap-times in lap 4 (mean±SD: 33.0±2.1° vs 34.7±2.2°) and lower knee, hip and push-off angles during lap 3 (mean±SD: 108.7±5.0° vs 113.0±5.2°, 62.6±5.1° vs 67.6±6.3° and 57.2±2.8° vs 60.1±2.5° resp.) and lap 4 (mean±SD: 109.4±4.5° vs 114.9±5.6°, 63.6±4.1° vs 69.0±7.7° and 58.0±2.6° vs 60.6±3.5° resp.) than STG. Trunk angle profiles were similar for FTG and STG. Multiple regression analyses showed that knee and hip angles in lap 3 were determining for performance. **Conclusion:** The present study showed that technique (in particular knee and hip angles) is most important for performance at the end of the race for talented speed skaters. The faster talents seem to be better able to pace themselves, limiting increase of knee, hip and push-off angles at the end of the race and simultaneously perform a faster final lap with respect to the slower talents. The results emphasize the importance of maintaining technique when fatigued for the performance of talented speed skaters and could be useful for talent development.

**IS-BN01 What the dynamics of team sports tell us about collective behaviours****INTER-TEAM DYNAMICS IN SOCCER: EVIDENCE FROM SMALL-SIDED GAMES AND FULL-SIZED MATCHES**

Frencken, W.

*Hanze University of Applied Sciences*

Positional data is available in team sports like soccer. Each player's positional data can be used to calculate geometrical configurations that quantify the inter-team dynamics during competition. The main aims of this presentation are to introduce these performance measures that quantify the inter-team dynamics, discuss evaluations thereof in small-sided training games and full-sized matches, and to demonstrate that pitch size manipulations constrain interactive team behaviour. I will discuss a series of experimental and observational studies involving youth, adult and (non) elite-standard soccer players (Frencken et al., 2011; 2012; 2013). In the first experiment, the surface areas and centroid positions of two teams are discussed as geometrical measures that could provide a basis for descriptions of interaction processes between two teams. It will be demonstrated that approximately half of all goal-scoring opportunities and goals display changes in the relative longitudinal position of the centroids of both teams, often characterized by crossings thereof. Based on these observations, a follow-up experiment involved calculations of the absolute differences between the longitudinal or lateral centroid positions of the teams (inter-team distances). Critical match periods were extracted from periods of high variability in longitudinal and lateral inter-team distances in one elite-standard soccer match and subjected to further video analysis. Most critical match periods were associated with events in which the ball was passed longitudinally or laterally and players of one of the teams collectively changed running direction. In order to demonstrate that teams adapt their interactive behaviour to specific task constraints and that previously observed findings need to be interpreted carefully, the effect of task modifications on pattern development of longitudinal and lateral inter-team distances and the surface area difference were evaluated in four small-sided soccer games with different pitch dimensions. It was demonstrated that pitch size manipulations of length and width indeed affect teams' spatio-temporal interaction patterns. Additionally, a crossover effect was observed, meaning that changes in pitch length or width also initiate a response in teams' interactive behaviour in lateral and longitudinal directions. The presentation will conclude with suggestions for future research and clear practical implications for coaches and sports scientists. **PAIRED BEHAVIORS IN RUGBY UNION: THE COMPLEMENTARITY BETWEEN STABILITY AND VARIABILITY**

Passos, P.

*Technical University of Lisbon*

**Introduction** The aim of this study was to describe the attackers' behavior in a 2 vs. 1 situation in rugby union (i.e., two attackers vs one defender). To succeed the attackers must create an interpersonal synergy i.e., the support player must maintain an adjustable angular position with regard to the ball carrier position. This synergy will drive the attackers to a coordination pattern that enables them to avoid the defender and keep running with the ball to the try line. The behavior of one player regulates the behavior of the other in a type of reciprocal compensation (Riley et al., 2011). However decreasing interpersonal distance to the defender may disturb this interaction and attackers must adjust their behaviors to keep decreasing the distance to the score line (Passos et al., 2011). **Methods** Twenty-four under-16 rugby union players with national level experience performed 65 trials on a field with 5 m width and 22 m depth. The trials were videotaped at 25 Hz. TACTO 8.0 software was used to digitize players' positions on the playing field (Fernandes & Malta, 2007). To describe the attackers' behavior we analyzed the following variables over time: i) players distance to the try line; ii) angle between support player and ball carrier; iii) attackers running line velocity. **Results** The data reveal that the position of the ball carrier and support player were strongly correlated ( $0.8 < r < 1$ ) regarding the distance to the try line. As a coordinative variable we used the angle between support player and the ball carrier. Values close to 0 degrees signify that ball carrier and support player are almost side by side, which is a desirable relative position to receive a pass from the ball carrier. This angle initially tends to increase, and close to the moment of the pass, tends to stabilize or decrease. This pattern was stable across trials. During each trial attackers running line velocity was continuously changing. **Discussion** To manage the relative position with the ball carrier the support player needs to manage his own running line velocity which results in continuous fluctuations of both players running line velocity. Therefore the synergy can be described with the angle between support player and ball carrier as a performance variable, which remains within a suitable range to succeed due to variability of attackers running line velocity. **References** Fernandes O, Malta P. **TEAM COORDINATION IN BASKETBALL: WHAT CAN VARIOUS LEVELS OF ANALYSIS REVEAL ABOUT INTERPERSONAL DYNAMICS?**

Bourbousson, J.

*Nantes University*

**Introduction** In team sports, the understanding of the cognitive processes that underlie actions of players has been historically focused on the characterization of the information processing and perceptual skills of performers. Besides of the valuable results obtained, recent research has proposed that the cognitive processes underlying actions of players in team sports should be investigated using alternative approaches, especially those allowing more substantial emphasis on the interpersonal relations between players and teams over time in

which actions and decisions are embedded. Actually, new directions are explored by researchers, notably focusing on team coordination and trying to reveal the processes by which teammates and opponents interact and give rise to the team game dynamics. In this context, amongst the main approaches that emerge (i.e., eco-dynamics approach, course-of-action approach) we will argue that some "multi-level" investigations could deepen our understanding of how does collective intelligence emerge. Especially, we will illustrate two lines of empirical investigation. A multi-level approach of decision making in team sports First, one can observe in eco-dynamics approach a focus (a) on the dyadic level of analysis (attacker/defender relationship), and (b) on the inter-team level of analysis (Team A/Team B relationship). These levels of analysis sign a willingness to embed the decision making processes in local interactions on the one hand, and to consider the inter-team relationship as a dynamic state emerging from local interaction and that may be investigated in itself. However, an investigation of the links between these various levels of description may deepen our understanding of the informational constraints that support actions and their dynamics. A study conducted within basketball will serve to illustrate a multi-level approach of decision making in team sports. A Social Network Analysis of intra-team connectedness Second, recent years have seen some attempts to use social networks approaches in various team coordination investigations. We will argue for the specific use of Social Network Analysis (SNA) to account for various level of description (individual, dyadic, triadic, collective), particularly the use of heuristic variables like centrality, reciprocity, transitivity, and density. A simultaneous description and comparison of the respective dynamics of each variable could point out some bottom-up and top-down phenomena, thus offering a way to discuss about circular causality and slaving principles in teams (i.e., emergence and downward causation). A study that adopted the course-of-action framework within basketball will serve to illustrate a multi-level description (i.e., SNA) of the dynamics of intra-team cognitive connectedness. We assume that methodological concerns and directions could be extended to various empirical data. Together, these two lines of research will serve us to conclude about the need for a more multi-level view of collective intelligence in sport's teams.

### IS-BN04 Cyclic sports: energetics, evaluation and constraints \*

#### INTER-LIMB COORDINATION IN SWIMMING: EFFECT OF EXPERTISE

Seifert, L.

*University of Rouen*

In this talk the inter-limb coordination of elite and sub-elite swimmers are discussed with a view to informing coaches of the similarities and differences between these groups. In the past it has been reported that the inter-limb coordination should show an opposition mode, i.e. a propulsive continuity between the propulsion of one limb and those of the other limb, in order to minimize the intra-cyclic velocity variations. However, the research of our centre of research highlighted the fact that the inter-limb coordination mode adopted by the swimmers corresponds to three types of constraint defined by Newell (1986): organismic, task and environmental constraint. The skill level of the swimmers, the specialty, the gender, the handedness and the breathing laterality act as organismic constraints; the imposed race pace, the stroke frequency, the number of strokes, the breathing frequency and pattern could be consider as task constraints while the active drag and his correspondent velocity relate to the environmental constraints. Inter-limb coordination was found to vary from catch or glide coordination mode to superposition mode, showing that the opposition mode is only the best "theoretical" mode and the glide mode is not a technical mistake. Therefore it is advised for coaches to don't consider an ideal coordination mode in the absolute but to teach the swimmers in different ways when developing coordination. This talk presents new information based on recent scientific research conducted at the CETAPS. The variables of interest were: average swim speed, stroke length, stroke frequency, intra-cyclic velocity variations, breathing laterality, relative duration of arm and leg stroke phases, time gap between propulsive actions assessed by total time gap (TTG) in the simultaneous strokes and by index of coordination (IdC) in the alternate strokes. Interesting findings emerged that have implications for the both elite and sub-elite swimmers should be coached.

#### A LASER SYSTEM AS A TOOL FOR ASSESS PERFORMANCE IN REAL-TIME IN SPORTS

Ferro, A.

*Faculty of Physical Education and Sports Science. Polytechnic University of Madrid, Spain.*

The biomechanical analysis of the sports technique remains an essential tool to achieve performance improvements. After twenty years of experience offering biomechanical support to high-level athletes, using photogrammetric technique, findings seem to point to immediacy and reliability as key to obtaining valuable biomechanical information. Based on this, we developed a kinematic analysis system of real-time movement applying laser technology, Biolasersport (Ferro & Floria, 2010; Ferro, 2012). The system could be used both in competition and in training conditions in all those sporting events in which straight movements are essential. The system is to feature a two-axes motorized device that will allow to track athletes' movements. In addition, kinematic analysis software has been developed to allow the coach to evaluate the performance of the athlete in real-time. On top of all the above, a video camera capture the images that will be annexed aiming to facilitate the data interpretation provided by the laser system. We expect that the set of modules could be a novel and useful technological tool. There are some works where the system laser was used to obtain data, however, there are few studies that demonstrate the validity and reliability of the system to determine the velocity in sprint (Bezodis, Salo, & Trewartha, 2012; Dickwatch et al. 1994; Harrison et al., 2005). The validity and reliability of the system was assessed. The laser sensor type 1 (LDM301, Jenoptik, Germany) was used to record positions of the subjects to 2000 Hz. The data were analyzed using DSL-30 routine created with DasyLab v.10.0. A Photogrammetry-2D system with a high-speed camera (Exilim High Speed EX-F1, Casio) and a double photocell (Polifemo Light, Microgate, Italy) with an electronic stopwatch (Microgate, Italy) Racetime2 were used. The correlation coefficients obtained were higher than 0.86 regarding to photogrammetry and higher than 0.92 regarding to photo-cells. The laser system showed excellent test-retest reliability for average and maximum velocities with a coefficient of correlation intraclass (ICC) between 0.7-0.9 (Ferro et al., 2012). The system has been used in different sports and environments conditions, indoor and outdoor. All in all, it is our aim to introduce a brand new technological tool for biomechanical analysis to support both coach and athlete improving their achievements. References Bezodis, N. E., Salo, A. I. ## ECONOMY AND EFFICIENCY IN CYCLIC SPORTS

Zamparo, P.

*University of Verona*

For cyclic sport activities (on land and in water) energy expenditure can be accurately measured when the energy cost (C) of that form of locomotion is known. C depends on the speed (v) and the mode of locomotion and is calculated by the ratio:  $E'/v$  where E' is metabolic power (derived from aerobic and anaerobic energy sources). For a given form of locomotion, and at a given speed, C depends also on the factors that affect mechanical work (W<sub>tot</sub>) and locomotion efficiency (e<sub>L</sub>). In cyclic sports e<sub>L</sub> defines the ability to transform net muscle force into the "minimum" external work necessary to move (Cavagna, 1988) and can be considered as the product of two main components: muscle efficiency (e<sub>m</sub>) and transmission efficiency (e<sub>T</sub>):  $e_L = e_m \cdot e_T$ . Transmission efficiency (in aquatic locomotion it is known as propelling efficiency: e<sub>P</sub>) is the ratio between the "minimum" external work and total mechanical work (W<sub>tot</sub>) and accounts for all the energy dissipation 'outside' the involved muscles. When the whole mechanical energy flux is known, and when the metabolism is aerobic, muscular efficiency (e<sub>m</sub>) cannot exceed a value of 0.25-0.30; this efficiency depends on the fibre's type composition, on contraction length and speed and on the type of contraction (concentric or eccentric) (e.g. Minetti 2004). Transmission efficiency could range from 0 (no "external work" production such as in isometric contractions) to 1 (when all the work generated by the muscles is utilized to produce "external work"). Thus, e<sub>L</sub> will range from 0 to about 0.3. In cycling e<sub>L</sub> is close to 0.25 and this indicates that in this form of locomotion e<sub>m</sub> is nearly maximal and e<sub>T</sub> is close to 1. In elite swimmers e<sub>P</sub> could be as high as 0.35-0.40 but this value is reduced in children, masters and unskilled swimmers (e.g. as low as 0.10-0.20) (Zamparo et al. 2011). In rowing and kayaking e<sub>P</sub> is larger: it could be as high as 0.65-0.75, depending on the speed and on the level of skill (e.g. Pendergast et al. 2003). Since  $e_L = e_m \cdot e_P$ , in swimming it is possible to estimate e<sub>m</sub> based on measured e<sub>L</sub> and e<sub>P</sub>. As shown by Zamparo and Swaine (2012) the so calculated efficiency turns out to be of about 0.20-0.25 and corresponds to the efficiency (sometimes indicated as gross, overall or mechanical efficiency) that can be calculated by measuring energy expenditure (metabolic input) and mechanical power (mechanical output) by means of a land based swimming ergometer (Zamparo and Swaine 2012). ### IS-SH04 The impact of sport for all policies on elite sporting success

#### DOES MORE MONEY IN EQUAL MORE MEDALS OUT? AN INTERNATIONAL COMPARISON IN 15 COUNTRIES, RESULTS OF THE SPLISS 2.0 STUDY

De Bosscher, V., Van Bottenburg, M., Shibli, S., Westerbeek, H.

*Free University Brussels/ Utrecht University*

**INTRODUCTION** International competition in elite sport has increased in such way that more nations invest strategically in the development and planning of elite sporting success. In the beginning of the 21st century Hogan and Norton (2000) found a linear relationship between public money spent and total medals won by Australia since the 1980s. The past decade however is characterized by an escalating global sporting arms race, with increased public funding and diminishing return of investment (ROI) in terms of medals won at the Olympics (De Bosscher et al., 2008). **AIM** The aim of this study is to analyze the relationship between (public) funding and international success in summer and winter sports. **METHODS** Using the SPLISS (Sports Policy factors Leading to International Sporting Success) framework, researchers in 15 countries, who took part in a large-scale study named SPLISS 2.0, collected data on the national public funding for sport and elite sport, overall (since 2000) and sport by sport (2010). Data were analysed using descriptive statistics and Pearson correlations. **RESULTS** The results revealed that funding is highly correlated ( $r > 0.9$ ) with success (Olympic Games, World championships – top three and top eight places) both in winter and summer sports. Three countries in summer sports (Australia, the Netherlands and France) and in winter sports (Switzerland, Canada, Flanders) performed above the average: they won relatively more medals (2009-2012) than what they invested, compared to the other sample countries. However, despite increasing expenditures in all nations except from Spain and Switzerland, success in the sample nations did not increase to the same extent: it even decreased for summer sports in Australia, Portugal, Belgium and for winter sports in France, Australia, Belgium and Estonia. Increased success (along with increasing investments) was noticed especially in Japan, the Netherlands and Brazil. **DISCUSSION** While the best predictor of output appears to be the absolute amount of funding allocated to elite sport, the results show evidence of an escalating global sporting arms race. Nations have to invest more, simply to keep ahead of the competition and standing still means going backwards. In elite sport the rules of the game are dictated by what rival nations are doing, not on the basis of what an individual nation is doing now compared with what it did in the past. However, although a minimum amount of funding seems necessary for success, elite sport success is the result of the way the resources are invested in a blend of factors. **REFERENCES** De Bosscher, V., Bingham, J., Shibli, S., van Bottenburg, M., & De Knop, P. (2008). A global sporting arms race: An international comparative study on sports policy factors leading to international sporting success. Aachen, Germany: Meyer & Meyer. Hogan, K & Norton, K 2000, 'The 'price' of Olympic gold', *Journal of Science and Medicine in Sport*, vol. 3, pp. 203-218.

**THE IMPACT OF SPORT FOR ALL POLICIES ON ELITE SPORTING SUCCESS**

Dijk, B., van Bottenburg, M., de Bosscher, V., Westerbeek, H., Shibli, S., Kärmeniemi, M.

*Utrecht University*

Although it is often assumed that the scale of sport participation is a condition for elite sporting success, the literature on this subject is inconclusive (Green, 2005; Green & Houlihan 2005; Sotiriadou, Shilbury & Quick 2008; De Bosscher & Van Bottenburg 2011). The relationship between sport for all and elite sport is not that straightforward. Many people practice a sport without any desire to attain a higher level, and increasingly on an informal, non-competitive basis. It also appears to be possible to build high performance programs without relying on a broad participation base, making use of highly developed system-related talent identification and development processes (Green 2005). Unfortunately, there is a dearth of empirical analyses of this relationship, primarily due to a lack of internationally comparable data (De Bosscher et al. 2008; De Bosscher & Van Bottenburg 2011). This paper contributes to filling this gap in the literature, based on the SPLISS 2.0 study, to what extent national sport policies directed towards sport participation determine their elite sporting success, and which policy aspects are most crucial in that respect. The SPLISS 2.0 study elaborates on earlier studies in which a nine-pillar model was developed which identified key sports policy factors that influence the international success of nations (De Bosscher et al. 2008). From January 2011 onwards, researchers from 15 nations collected data following this pillar model and measured 126 critical success factors. Pillar 3 (sport participation) consists of 16 questions, measuring 12 critical success factors. Six levels of analysis were distinguished: 1) the organization of sport at schools; 2) the level of non-organized sport participation; 3) the level of sport participation in clubs; 4) the level of sport participation in competitions; 5) the national policy to improve total quality management in sports clubs; 6) the national policy to improve the quality of talent development in sports clubs. At the time of this abstract submission, the final results could not be calculated yet. However, preliminary findings revealed interesting results. First, in general, the relationship between national policies directed towards sport participation and national sporting success appeared to be rather weak. Second, the relationship was found the weakest with respect to national policies towards total quality management in sport clubs, the level of unorganized sport participation, and the organization of sport at schools, and the strongest with respect to the level of organized sport participation and sport participation in competitions. These findings suggest that sport policies directed towards broadening the participation base are only of secondary importance in explaining differences in elite sporting success between nations, and that such policies are most effective from an elite sport perspective if they lead to more organized sport participation.

**NEW INSIGHTS TO MEASURING THE PERFORMANCE OF NATIONS IN THE OLYMPIC GAMES**

Shibli, S.

*Sheffield Hallam University*

In the London 2012 Olympic Games 204 nations took part and the majority (115) left empty handed. It would be inappropriate to label the majority of participating nations as 'failures' which raises the question 'are there any non-medal based measures of performance that enable nations to demonstrate the effectiveness of their elite sport development systems?' If sporting talent was distributed evenly across the globe, one Olympian would be produced for around every 700,000 people. This statistic legislates against small nations even attending the Olympic Games let alone having a chance of medal success. In order to deliver Jacques Rogge's 'real universality' the reality is that many nations are offered 'wild card' places to enable them to take part. By contrast large and dominant nations have limits on how many medal winning opportunities they can contest. For these reasons, there needs to be a degree of expectation management concerning what it is reasonable to expect a nation to achieve. This paper is concerned with conceptualising non-medal based measure of performance as a first step in helping to set performance and expectation parameters. The research is primarily desk research involving the secondary analysis of existing data and where necessary the construction of data tables from different sources. A significant breakthrough in the capability to analyse performance in the Olympic Games is provided by the Infostrada Podium Performance database. The results reveal that athletic talent is not distributed evenly across the globe and that some nations are more efficient at producing Olympians than others. For example, the Cook Islands with a population of 20,000 was able to send 8 athletes to London 2012, a ratio of 1 Olympian per 2,500 people. By contrast, Bangladesh with a population of 147 million sent five athletes to London 2012, a ratio of one Olympian per 29.4 million people. If we extend the measurement of success from medals to finalists (top eight) we find that in London 2012 the majority of nations (115) register at least one top eight place. Furthermore this is a trend that has been on an upward trajectory since the low of 72 nations in the post-boycott era. Finalists who do not win medals are awarded 'diplomas' for their achievements and thus a new measure of performance that would be relevant to most participating nations would be number of diplomas won. For the 89 nations that do not achieve a diploma there are other contextual measures of performance that may be of value. These include measures such as the number of athletes posting: season's best performances; lifetime best performances and national records. These are all positive outcomes that indicate that athletes were prepared to peak performance for the most important event of their year. Overall the results point to the need for a framework whereby nations can be realistic about their performance expectations and can draw positives from lower levels of achievement than medal winning success.

**16:20 - 17:50****Invited symposia****IS-SH09 Towards a theory of sports coaching****TOWARDS A THEORY OF COACHING: THE LEARNING ORDER**

Jones, R.L.

*Cardiff Metropolitan University*

The principal facet or helix within the coaching 'course of action' is that to do with learning. This reflects interpretations of athlete learning, and takes into account that the 'core business' of coaching is athlete understanding, improvement and performance. Within this dimension, it is recognised that coaches (generally although not always) decide what needs to be learned, how, by whom and by when. This learning needs to be reached (and evidenced) before further learning, or learning something new, can be engaged with. Coaches have

their own cues for 'reading the learning of athletes', and make decisions on the basis of them. However, athletes may have their own learning 'cues' too, which they use to assess their own progress. Naturally such processes sometimes collide. The negotiation (inclusive of inevitable contextual power relations) evident here comprises the 'learning work' of coaching.

### **'TOWARDS A THEORY OF COACHING: THE TEMPORAL ORDER'**

Mesquita, I.

*Faculty of Sport -University of Porto*

The temporal order relates to how time impacts on events and situations within the coaching trajectory. The temporal order in this respect is both predictable and unpredictable. Events in terms of the temporal order are also experienced differently by participants. For example, for the busy coach with a hectic schedule, meeting athletes and listening to their concerns, the time may pass slowly. On the other hand, the opportunity to talk is likely to have been eagerly awaited by the athletes for whom the time passes quickly. An aspect to consider under this facet then, is how the social actors involved in coaching experience time-passing, in addition to how they cooperate or fight against given or alternative schedules to fill such time.

### **TOWARDS A THEORY OF COACHING. PART 1: THE SECURITY ORDER**

Ronglan, L.T.

*Norwegian School of Sport Sciences*

The purpose of this symposium is to present a conceptualisation of coaching as a number of inter-related helices encased in a general progressive 'course of action'. The significance of the project lies in the need to organise coaching around new, largely phenomenologically derived concepts in what remains a largely unexplored terrain. As a basis for future theoretical development, this presentation proposes a conceptual trajectory as an analytical device to bring together the disparate perspectives of those involved in coaching. The three principal facets which comprise the trajectory (and which will form the basis of the symposium) include, 'the insecurity order', 'the learning order' and 'the temporal order'. The context and the interactions of coaching are inherently ambiguous (Jones & Wallace, 2005, 2006). It is a context which induces anxiety, excitement and nervous expectation; conditions which are sometimes generated although more-than-often tempered or alleviated by coaches (intentionally or unintentionally). When the tasks associated with providing security are neglected or badly done, the security order is badly affected. Such work associated with developing or providing such security can be sub-divided into (1) interaction work, (2) trust work, (3) awareness context work, (4) rectification work (which also comprises 'face'work), and (5) identity work.

##### **TRACKING CAREER PERFORMANCE OF SUCCESSFUL TRIATHLETES**

Malcata, R.M., Pearson, S., Hopkins, W.G.

*Auckland University of Technology*

Introduction: Tracking the progression of an athlete's performance is important in elite sport. For sports with simple, objective outcome measures and stable performance environments, determining progression is reasonably simple; however tracking of performance is more problematic for sports with large environmental effects. The purpose of this study was therefore to develop career performance trajectories for elite triathletes, investigating separately the progression of swim, cycle, run and overall performance times while accounting for confounding factors. Methods: Performance times of 337 female and 427 male triathletes competing in 419 races of the World Championships (including Junior and Under-23), World Series, World Cup, European Championship and Olympic Games between 2000 and 2012 were obtained from triathlon.org. Athletes were categorized Top if they finished in the top 16 at a World Championships or Olympic Games between 2008 and 2012. A mixed linear model accounting for race distance (Sprint, Olympic), type of competition, calendar-year trend, athlete's category and clustering of times within athletes and races, was used to derive athletes' individual quadratic performance trajectories. These trajectories provided estimates of age of peak performance and predicted outcomes at the 2012 London Olympic Games. Results: By markedly reducing the scatter of individual race times, the model produced well-fitting quadratic trajectories that were suitable for comparison of athletes' performance progressions. The trajectories for top-16 athletes showed different patterns depending on phase. Trajectories also differed more among women than among men. Ages of peak overall performance were  $28.4 \pm 2.3$  years and  $28.2 \pm 3.4$  years for men and women, respectively, while ages of peak performance for individual phases differed by up to two years. High correlations between observed and predicted placing at the Olympics for men (0.78; 90% confidence interval 0.67-0.85) and women (0.61; 0.4-0.76), represent slightly better prediction than typical race placing in the year of the Olympics. Conclusions: Differences between athletes' trajectories will help to identify athletes' strengths and weaknesses. The wider range of trajectories among women should be taken into account when trajectories are used to select athletes or to set performance targets. Trajectories offer a small advantage over usual race placing for predicting Olympic performance, with potential refinements of the model identified to further improve these predictions.

##### **BODY MASS MANAGEMENT OF FEMALE CYCLISTS: TRENDS IN THE PELOTON**

Haakonssen, E.1,2, Martin, D.1, Burke, L.1, Jenkins, D.2

*1: AIS (Canberra, Australia), 2: UQ (Queensland, Australia)*

Introduction A number of Australian and International female cyclists have resorted to unsafe practices in order to manipulate body mass. No known studies have reported the perceptions of female cyclists towards their body mass as it relates to performance. Methods

Entrants in the Australian National Championship Women's Road Race (n=31) completed a short questionnaire that sought to identify their current body mass; seasonal fluctuations in body mass; perceived optimal body mass; their level of consciousness towards body mass manipulation; techniques used to manipulate body mass and the regularity of their menstrual cycle. Results All but one respondent believed that female cyclists are a 'weight conscious population'. On a 0-10 scale (0 = 'never'; 10 = 'more than once every hour') female cyclists reported being conscious about wanting to change their body mass on average 'once a week' (mean  $\pm$  stdev,  $5\pm 3$ ) and 19% reported being conscious 'more than once a day'. 58% reported that their body mass was not optimal for current competition. Perceived ideal body mass for competition was  $1.3\pm 1.4$  kg less than their actual present mass ( $57.1\pm 5.0$  kg) and 71% reported their lowest body mass was 'beneficial' or 'extremely beneficial' for performance. There was a  $5.4\pm 3.1$  kg difference between the highest and lowest reported body mass for the previous 12 mths. 71% reported reducing body mass in the previous 12 mths ( $-2.3\pm 1.1$  kg). 35% reported that their coach or director had been dissatisfied with their body mass. 16% had previously been diagnosed with eating disorder. The most common weight loss techniques selected were '1 reduced food intake throughout the day' (n=24); '1 avoided foods high in fat' (n=20); and '1 avoided foods high in sugar' (n=19). Five athletes reported skipping meals; 6 performed long rides (>2hrs) without eating; 3 avoided post training meals and 7 increased total training duration. Ten cyclists reported having an irregular menstrual cycle in the previous 12 months and nine reported that their menstrual cycle had ceased for >3 months. Discussion The results suggest that elite Australian female cyclists are indeed a weight conscious population and in many cases are dissatisfied with their body mass coming into major competition. Self reported body mass fluctuated significantly (~5 kg). It appears weight loss was brought about by a range of techniques – most commonly by reducing energy intake and avoiding foods high in fat and sugar. Some athletes resorted to more extreme measures such as skipping meals (n=5), purging (n=2) and wearing excessive clothes or plastic wraps while training (n=1). Almost a third of cyclists reported menstrual dysfunction which may be a symptom of low energy availability (Loucks et al., 2011). References Loucks A, Kiens B, Wright H. (2011). *J Sports Sci*, 29(S1), S7-15.

### ANALYSIS OF OFFENSIVE GAME SITUATIONS IN TEAM HANDBALL BY MEANS OF ARTIFICIAL NEURONAL NETWORKS

Schrapf, N., Tilp, M.

*Institute of Sports Science*

Introduction Analysis of game situations are important for the development of successful game tactics and the planning and controlling of training. Since focus on single action analysis only gives restricted insight into tactical behavior, Carling (2008) suggested analyzing action sequences. Therefore, the aim of the present study is to classify sequences of game actions in team handball to identify offensive behaviors. Methods For this study 6 games from the EHF EURO Men 18 in Hard (Austria) were analyzed. Each game was captured by 8 cameras. Subsequently, all shots and up to 5 passes prior the shot were annotated with custom-made software. Every annotation includes the ground position of the ball carrier and the position of the receiving player for every pass-action. In total 3212 actions were recorded. These single actions generated 612 action sequences which were then analyzed by an artificial neuronal network software (Perl, 2002). In order to obtain suitable entropy, data was enlarged by duplicating to a quantity of 3060 datasets with a noise of 15%. To minimize unwanted learning effects due to the duplication, datasets were also permuted. Subsequently, action sequences were used to train the neuronal network with a dimension of 400 neurons. Each neuron represents a pattern in action sequence. Hereafter, similar neurons are grouped to clusters which represent similar offence play behavior. Results With a similarity resolution, which defines selectivity between similar and dissimilar neurons, of 70% the network recognized 32 clusters. Ten network neurons, containing 34 action sequences (5,6%), could not be classified to a cluster. Summarizing, the net identified 42 different offensive strategies (32 clusters and 10 single neurons) of the different teams. Discussion The analysis revealed the potential to identify offensive patterns in team handball by means of artificial neuronal networks. Expert review of the recognized patterns shows a promising accordance with the original data of the action sequences. However, results have to be taken with care due to the data preprocessing including the enlargement of the original datasets. The next step will be the detection of preferred offensive tactics of single teams. Moreover, with the integration of data about goal success, successful offensive tactics can be identified. Another future goal is to integrate defensive behavior in order to determine effective offensive tactics in relation to the opponent's defense tactic. ### EFFECTS OF LOW-VOLUME HIGH-INTENSITY INTERVAL TRAINING ON POWER OUTPUT IN ADULTS: A META-ANALYSIS

Weston, M.1, Batterham, A.M.1, Taylor, K.1, Hopkins, W.G.2

*Teesside University (Middlesbrough, UK). 2AUT University (Auckland, New Zealand)*

Background Many basic activities of daily living are dependent on muscle power. Power training can improve mobility-related outcomes. Here, we present a meta-analysis on the effect of low-volume high-intensity interval training on lower extremity power output. Methods A search of five literature databases yielded 14 utilisable interval-training studies meeting the eligibility criteria: adults; 30-s Wingate assessed pre and post intervention; intervention period of at least 2 weeks; repetition duration 30 s; work/rest ratio <1; and exercise intensity maximal or near maximal. The total of 19 mean effect estimates on peak power in training and control groups were converted to percent changes for a novel mixed-model meta-analysis that included the usual between-study random effect and a within-study random effect to account for studies with control groups. The fixed effects in the model included type of study (controlled, uncontrolled), subject characteristics (sex, pre peak power) and training parameters (number of exercise sessions, work/rest ratio). With only 15 available effect estimates, mean power was analysed with a standard meta-analysis. Effects were weighted using percent standard errors from exact p-values or from estimated errors of measurement. Probabilistic inferences were based on standardized thresholds for small, moderate and large changes (1.4, 4.6 and 9.2% for peak power; 1.4, 4.3, and 8.5% for mean power) derived from between-subject SDs for pre peak and mean power. Results The meta-analysed effect on peak power of an average interval-training protocol (12 sessions, 0.12 work/rest ratio) in a controlled study was an unclear but possibly small increase in peak power of 2.9% (90% confidence limits  $\pm 6.2\%$ ) in active, non-athletic subjects with a pre peak power of 11.6 W/kg. There was a likely moderate increase in peak power of 7.2% ( $\pm 4.0\%$ ) in uncontrolled studies. Study and subject characteristics had the following possibly small effects: 2.2% ( $\pm 6.6\%$ ) for subjects with peak power lower by 6 W/kg; 0.6% ( $\pm 6.1\%$ ) for each 3-fold increase in number of sessions; 1.5% ( $\pm 4.0\%$ ) for each 4-fold increase in work/rest ratio; and 3.0% ( $\pm 16.1\%$ ) for females. Unexplained variation in peak power effects between studies was typically  $\pm 4.2\%$ . There was a possibly moderate enhancement in mean power of 5.2% ( $\pm 4.2\%$ ) compared with controls. Conclusions Low volume high-intensity interval training produces small to moderate improvements in the peak and mean power output of active, non-athletic subjects, with

greater benefit for the less fit. More studies are needed to clarify the effects of changing the parameters of this efficient form of training, to clarify the effects in women, and to examine the effects in older populations.

### EARLY IMPROPER MOTION DETECTION IN GOLF SWING

Stancin, S., Djordjevic, S., Tomazic, S.

*University of Ljubljana*

**Introduction** Performing the golf swing is a demanding process involving the whole psychophysical system (Nesbit and Serrano, 2005; Hayne, 2009; Leadbetter, 2000; Jacobs and Bowden, 1998; McLaughlin and Best, 1994). Ideally, led with the desire to achieve the same shot outcome, a particular golfer would in multiple trials perform his or hers golf swing completely identically. Due to swing motion comprehensiveness, realistically, some deviations from the desired motion are always present. Not all of these swing motion deviations are detrimental to performance and as such unacceptable. **Methods** Measurements were performed on a professional golfer using his hybrid club. Swing data were collected using a wearable 3D motion sensor comprising gyroscopes and accelerometers produced by TMG-BMC Ltd. The sensor was positioned on the golfers leading arm, i.e., the left arm for a right handed player. All swing observations were labelled according to performance. Performing the Principal Component Analysis (PCA) on the reference observations of properly performed swings, the basis of acceptable motion deviations was established. Using this basis, motion deviations in observations of other swings were examined. **Results** The results obtained for the considered example show improper swing motion in the early phase of the swing, i.e., the first part of the backswing. Similar behaviour of unacceptable deviations in the time domain indicates typical improper motion in the associated swings. **Discussion** The analysis is made under the assumption that the reference set of properly performed swings encompass all acceptable deviations of proper golf swing motion. Swing performance evaluation is achieved individually and the presence of improper motion is explored with reference to that player's properly performed swings. The potential benefit of such early detection of improper swing motion conducted on an individual basis is in providing valuable assistance for the performance improvement process. **References** Nesbit, S.M.; Serrano, M. ### OP-BN01 Biomechanics [BM] 1

#### PRELIMINARY STUDY: ELECTROMYOGRAPHICAL CHANGES IN BAREFOOT AND SHOD RUNNING, BEFORE AND AFTER A FATIGUING 10KM RUNNING TRIAL

Tam, N., van Pletzen, L., Albertus-Kajee, Y., Astephen Wilson, J.L., Noakes, T.D., Tucker, R.

*University of Cape Town*

**Introduction:** Barefoot running has been proposed as the most natural, efficient and safest way to run. Biomechanical differences have been explored between barefoot and shod running. The neuromuscular responses of the lower limb musculature during running in the barefoot and shod conditions have not been fully explored and may reveal certain subtleties in control and adaptation. Further, an aim was describe if difference existed between conditions as a result of fatigue. The aim of this study is to provide insight into the differences in muscle activity of the lower limb between barefoot and shod running both before and after a 10km fatiguing trial. **Methods:** Fifteen recreational runners who were had a 10km race time below 50 minutes participated. First participants performed a 10km familiarization time trial on a treadmill. During the second visit participants ran down a 40m runway and over a floor embedded force plate at 4.3min/km. This was performed seven times in both the shod and barefoot condition. These were conducted prior to and post a run at 10km race pace for 10km. EMG activity was recorded using a telemetric EMG system. The following lower limb muscles were recorded: Vastus lateralis (VL), Biceps femoris (BF), Tibialis anterior (TB) and lateral gastrocnemius (LG). The raw EMG signal was filtered using a 50Hz notch filter. The signal was then filtered a second time using a 15-500Hz band pass filter. The data were smoothed using route mean squared analysis (RMS), calculated as a 50ms-moving window. Thereafter, data were segmented into pre-activation, defines as 100ms prior to initial ground contact, and ground contact, defined between initial ground contact and toe off as determined by a force plate. **Results:** During pre-activation conditional differences were found in TA and LG activity. Lower TA activity and higher LG activity was observed in the barefoot when compared to the shod condition. Further, lower LG activity was found in the barefoot condition when compared to shod. Lastly, increased activity at the end of the fatiguing trial was seen in TA activity and lower activity in BF and VLO during ground contact. **Discussion :** Increased TA activity and decreased LG activity during pre-activation prior to ground contact in the shod condition is indicative of an adjusted running style. These differences in activity may be reflective of the muscular preparation prior to initial ground contact as shod runners tend to land in greater dorsiflexion. With greater dorsiflexion in the shod condition a reduced LG activity was expected. Decreases in VLO and BF activity during ground contact appear to be a result of fatigue and maybe due to muscle rotation, decreased muscle firing rate and recruitment. Conversely, increased TA activity was found during ground contact over time. These difference as a result of fatigue maybe due to muscle size and function. Lower LG activity in the barefoot condition during ground contact maybe indicative of the different biomechanics employed to propel the body during running in the two-different conditions.

## GENDER DIFFERENCES IN FORCE APPLICATION DURING OFFENSIVE AND DEFENSIVE AGILITY MOVEMENTS

Spiteri, T., Wilkie, J.L., Nimphius, S.

*Edith Cowan University*

**Introduction** It is well-established gender differences exist as a result of physical and anthropometrical characteristics (McLean et al., 2004) that have been shown to influence change of direction (COD) performance. COD ability is a physical attribute excluding the cognitive requirements more relevant to sport performance termed agility. Thus athletes often change direction in response to a stimulus with the intent to rapidly exit the COD, termed post-stride velocity. The combination of cognitive and physical abilities required for a faster agility performance may result in an altered force profile produced by each gender that is representative of differences within gender. **Methods** Twenty-four male and female athletes performed six unilateral isometric back squats on a force plate, followed by twenty-four agility trials. COD movements were performed at a 45° angle in response to movements of a human stimulus in offensive (opposite direction) and defensive (same direction) as the stimulus. The COD step was performed on an in ground force plate (Kistler, Type9290AD, Australia), with peak braking and propulsive force and relative braking, propulsive and total impulse measured across stance phase for the dominant leg. Reaction time (RT) during the COD was assessed using a high-speed video camera. Post COD stride velocity of the athlete after the COD was measured using a 12 camera, 250Hz Vicon motion analysis system (Oxford Metrics Ltd., Oxford, UK). **Results** Males demonstrated significantly greater lower body strength, greater braking and propulsive force, impulse and a faster RT to the stimulus, enabling a faster post-stride velocity to be achieved compared to female subjects, during offensive and defensive trials. **Discussion** Increased braking force as observed for males has been identified to contribute to the storage and utilization of elastic energy (Hunter et al., 2005) enabling an increased propulsive force output, improving propulsive ability. Faster running speeds have been attributed to increased lower body strength (Brughelli et al., 2008), to rapidly apply greater amounts of force throughout the movement. Additionally, increasing the time to prepare the body for upcoming movements by reducing RT, can also enable increased force and impulse to be produced (McBride et al., 2008). In conclusion, the greater strength, RT and subsequent increased force application during the plant phase was present in males that also had significantly faster post COD stride velocities. **References** Brughelli M, Cronin J, Levin G, Chaouachi A. ## UNWEIGHTING STATE AS A PREPARATORY MOVEMENT SHORTEN THE SIDESTEP INITIATION FOR BASKETBALL PLAYERS IN 1-ON-1 BASKETBALL SITUATION

Fujii, K.1,2, Yoshioka, S.3, Isaka, T.3, Kouzaki, M.1

*1. Kyoto University (Kyoto, Japan), 2. Japan Society for the Promotion of Science (Japan), 3. Ritsumeikan University, (Shiga, Japan).*

**Introduction** In basketball, the preparatory motion of a defensive motion should be small and involve landing on both feet for strict time and motion constraints. We thus proposed the movement creating an unweighting state, where the body weight of a player is instantaneously decreased during standing before sidestepping. First, we examined the effect of creating unweighting state the experiment where defenders react to the LED stimulus by sidestepping (experiment-1). Second, we investigated the effect on real basketball 1-on-1 defending (experiment-2). In the two experiments, we hypothesized that the defender's preparatory motion creating the unweighting state improves basketball 1-on-1 defending, i.e., sidestepping. **Methods** In experiment-1, ten basketball players performed a two sidestep and reach task reacting to the LED stimulus with and without the voluntary, continuous vertical fluctuation movement. In experiment-2, the same ten players performed dribble 1-on-1 game with basketball. In both experiments, the motions of the players were captured and their ground reaction forces (GRFs) were measured. Movement initiation time and lateral peak velocity were calculated based on trunk lateral velocity, according to the rule of basketball. **Results & Discussion** The results in experiment-1 indicated that the preparatory movement shortened the time of defenders' sidestep initiation (301 vs. 314 ms) and reaching performance (883 vs. 910 ms) but did not increase their peak vertical GRF or movement velocity. The mechanism of the improvement was estimated to be the following: in the preparation phase, the voluntary vertical body fluctuation created the force fluctuation; around the direction signal, the unweighting state can shorten the time required to initiate the sidestepping; around the initiation phase, the dropping down of the body and weighting state can contribute to the reaching performance. In experiment-2, the results demonstrated that the unweighting state shortened the defender's movement initiation relative to the dribbler's and made defended in 70.2 % probability, whereas the weighting state did in 17.5 %. Additionally, the results showed that the hopping, in which the players were in the air more than 100 ms, provided stably high peak velocity but variably change vertical GRFs. The hopping would be undesirable for preparatory motion of defending in basketball 1-on-1 situation. Consequently, it suggests that creating unweighting state but not hopping in attacker's movement initiation would be effective to defend the dribbler in basketball 1-on-1.

## ENERGETIC COST OF LOCOMOTION AND BIOMECHANICAL ASPECTS OF THE DOUBLE POLING TECHNIQUE

Zoppirolli, C.

*University of Verona*

**Introduction** Double poling technique (DP) is extensively used during cross-country skiing races. During DP, the propulsion is generated by synchronized actions of upper limbs and trunk, and transmitted to the ground through the poles. The aim of this study was to analyze the relationship between the energetic cost (EC) and the biomechanics of DP. It has not been widely studied so far, despite the importance of DP in skiing performance (Stöggl et al., 2006). It's knowledge should be important in improving skiing efficiency. **Methods** Eight high level (HL) and eight recreational (R) skiers performed a DP trial on a treadmill, using roller skies and poles. EC was measured at steady state and synchronized biomechanical measurements were acquired, for at least 20 consecutive cycles, during the last minute. Inclination of the poles respect to horizontal plane ( $\alpha$ ), vertical position of centre of mass (COMz) and body inclination respect to the vertical ( $\theta$ ) were monitored at the start of poling phase (on), instant of peak force (p), end of poling phase (off). Integral of poling force, peak poling force, cycle time and poling time were also considered. ANOVA test for repeated measurements was performed to assess the group effect on families of variables. When  $P < 0.05$ , Holm-Bonferroni post-hoc was applied. Biomechanical variables were entered in a stepwise multiple regression analysis to determine the more predictive variables of EC. **Results** HL showed lower EC ( $P = 0.000$ ), higher  $\alpha$ -on and  $\alpha$ -p ( $P < 0.05$  in all cases), higher COMz-on, COMz-p and COMz-off ( $P < 0.05$  in all cases), more pronounced  $\theta$ -p ( $P < 0.05$ ) and higher force integrals ( $P < 0.05$  in all cases).  $\theta$ -p for HL and  $\theta$ -on for R were the only variables able to predict EC ( $R = 0.78$ ,  $P = 0.23$  and  $R = 0.73$ ,  $P = 0.38$ , respectively). In HL,  $\theta$ -p was positively related to force integrals, peak of propulsive force and cycle time ( $P < 0.05$  in all cases), while  $\theta$ -on in R was

not further related to any biomechanical parameter. Discussion DP is an arm-based locomotion, far from the typical legged human locomotion. HL showed lower EC, higher force integrals, a different use of poles and centre of mass.  $\theta$  during the first part of the poling phase was the best predictor of EC. It probably allows to partially load the poles with body weight, permitting an energy-saving mechanism for the muscles involved in the poling movements. HL athletes can maintain a pronounced  $\theta$  for long time during the poling phase, influencing force exertion and cycle timing. R athletes cannot manage  $\theta$  for long time, losing a full benefit of an advantageous use of centre of mass. Our study demonstrated that biomechanical strategies are important to economize DP skiing. References Stöggl T, Lindinger S, Müller E. (2006). *Med Sci Sports Exerc*, 38: 586-91.

### **LOCOMOTION ADAPTATION WITH AGE - CHANGES IN JOINT MOMENTS AND POWERS DURING WALKING, RUNNING AND SPRINTING**

Kulmala, J.P., Korhonen, M., Kuitunen, S., Suominen, H., Heinonen, A., Avela, J.

*University of Jyväskylä*

**Introduction** In old age, muscular force declines. This has been linked to altered joint kinetics during gait where elderly people are known to have reduced joint moments and powers of the ankle but increased effort from the hip joint (1). However, the age-related changes in joint kinetics during more demanding activities like running and sprinting are not well documented. Therefore, the aim of this study was to examine age-related changes in lower extremity kinetics during walking, running and sprinting. **Methods** Young (Y, n=13, age 26±6 years), middle-aged (M, n=13, 61±5 years) and old (O, n=13, 78±4) men with power trained background participated in this study. Inverse dynamics was used to compute joint moments and powers during the stance phase of walking (1.6 m/s), running (4 m/s) and sprinting (maximal speed). **Results** During walking, O had 21% lower concentric ankle power compared to Y (P<0.05). During running O demonstrated 36% lower ankle moment (P<0.001), and 32% less eccentric and 38% less concentric ankle power compared to Y (P<0.05, P<0.001). However, hip power during early stance phase of running was 42% higher in O compared to Y (P<0.05). During sprinting, O showed 27% and 16% lower ankle moment compared to Y and M (P<0.001, P<0.05), respectively. Ankle eccentric power showed 53% and 31% lower values (P<0.001, P<0.01) and ankle concentric power 55% and 23% lower values for O compared to Y and M (P<0.001, P<0.01), respectively. In addition, Y showed 36% and 33% higher hip power during early contact compared to O and M (P<0.05, P<0.05), respectively. No between groups differences observed at the knee joint level. **Discussion** To the best of our knowledge, this is the first study to examine age-related changes in joint kinetics across the whole range of locomotion from walking to sprinting. The main findings shows that during walking and running the deficit of the ankle moment and power generation became larger with age but can be compensated by increasing muscular output of the hip joint. However, during sprinting, young individuals are able to generate significantly greater hip moment and power compared to middle-aged and elderly people. Interestingly, knee kinetics showed only minor changes between age groups. These findings suggest that age-related declines in human locomotion are mainly a result of reduced muscular output of the ankle rather than hip or knee. **References** 1) DeVita et al. 2000. *J Appl Physiol* 88: 1804-1811.

### **RUNNING PERFORMANCE ON DIFFERENT SURFACES IN ELITE AND AMATEUR ORIENTEER ATHLETES**

Hébert-Losier, K., Holmberg, H.C.

*Mid Sweden University*

**Introduction** Training for and competing in orienteering involves a wide variety of differing terrains and the ability to run fast on different surfaces may therefore be a key determinant of performance. This study was designed to test the hypothesis that the elite orienteer athletes run faster in the forest than amateur orienteer athletes, at both short and long distances. **Methods** Eight elite male and eight amateur male orienteer athletes ran on a road, on a path and in a forest twice on two separate days. The first day, each athlete ran 2 km as fast as possible on each surface (in a random order) with 15-min recovery between surfaces. A global positioning system with a heart rate (HR) monitor was used to track each athlete. On the second day, every athlete sprinted 20 m through timing gates on each surface (in a random order) with 2-min rest between sprints. The 2 km and 20 m mean velocity was compared between groups and surfaces. **Results** At both short and long distances, the elite athletes were faster than the amateurs on all surfaces (P ≤ 0.01). Despite similar % HR max across orienteer groups and running surfaces (P ≥ 0.527), the between-group differences in 2 km velocity was greatest in the forest (75s•km<sup>-1</sup>), less on the path (54s•km<sup>-1</sup>), and least on the road (43s•km<sup>-1</sup>), due to the change in surface having a greater influence on amateurs (P < 0.001). A similar pattern in the between-group differences was observed for the 20 m sprint velocity (forest: 0.72 m•s<sup>-1</sup>, path: 0.64 m•s<sup>-1</sup>, road: 0.47 m•s<sup>-1</sup>). The difference in sprint velocity from road to path was greater in the amateur than the elite group (P = 0.05), but the change in sprint velocity from path to forest and road to forest was similar in both groups (P ≥ 0.141). **Discussion** Not only did the elite orienteer athletes, as expected, run faster than the amateurs on all three surfaces; the elites also maintained a faster 2 km velocity on the path and in the forest. Furthermore, the elite athletes kept a faster sprinting velocity than the amateurs on the path vs. the road, but both groups demonstrated similar changes in velocities when sprinting in the forest vs. path or road. The probable explanation for this latter finding is that the maximal sprint velocity in the forest is limited by the risk of fall or injury. Further, short sprints in a forest are rare in orienteer competitions given that winning times range from 12 to 105 min and that the athletes run while consulting maps or compasses. Nonetheless, the elite athletes demonstrate a distinct ability to run fast on various surfaces, thus highlighting the value of integrating regular off-road sessions in training for orienteering. Further, at the elite level, monitoring running performance on various surfaces as described here might prove beneficial for assessment and adjustment of training.

#### **BETROOT JUICE AND EXERCISE: THE PHARMACOKINETIC-PHARMACODYNAMIC AND DOSE-RESPONSE RELATIONSHIPS**

Wylie, L.J.1, Kelly, J.1, Bailey, S.J.1, Blackwell, J.R.1, Skiba, P.F.1, Winyard, P.G.2, Jeukendrup, A.E.3, Vanhatalo, A.1, Jones, A.M.1

1: SSHS (Exeter, United Kingdom), 2: PCMD (Exeter, United Kingdom), 3: GSSI (Barrington IL, USA)

**Introduction** Dietary supplementation with beetroot juice (BR) containing ~ 5-8 mmol of inorganic nitrate (NO<sub>3</sub><sup>-</sup>) has been shown to increase plasma nitrite concentration ([NO<sub>2</sub><sup>-</sup>]), to lower blood pressure and the O<sub>2</sub> cost of submaximal exercise, and to improve exercise tolerance (Bailey et al., 2009). However, the dose-response relationship between ingested BR and physiological effect has not been investigated. The purpose of the present study was to investigate the NO<sub>3</sub><sup>-</sup> dose-response effect on the aforementioned variables when NO<sub>3</sub><sup>-</sup> was administered as NO<sub>3</sub><sup>-</sup>-rich BR. **Methods** In a balanced crossover design, ten healthy males ingested 70, 140 or 280 ml of concentrated BR (containing 4.2, 8.4 and 16.8 mmol NO<sub>3</sub><sup>-</sup>, respectively) or no supplement. Blood pressure was measured and venous blood samples were obtained at rest, and 1, 2, 4, 8, 12 and 24 h post-ingestion. Subsequently, on six separate occasions, subjects completed moderate-intensity and severe-intensity cycle exercise tests 2.5 h post-ingestion of 70, 140 and 280 ml BR, or NO<sub>3</sub><sup>-</sup>-depleted BR as placebo (PL; containing <0.12 mmol NO<sub>3</sub><sup>-</sup>). Pulmonary O<sub>2</sub> uptake (VO<sub>2</sub>) was measured during all exercise tests and the severe-intensity exercise bouts were continued until the limit of tolerance. **Results** Following acute BR ingestion, plasma [NO<sub>2</sub><sup>-</sup>] increased in a dose-dependent manner (~220-654 nM) whilst systolic blood pressure (SBP) and mean arterial pressure (MAP) declined dose-dependently (SBP; ~5-10 mmHg and MAP; ~2-5 mmHg) up to a dose of 140 ml, with the peak changes occurring at ~2-4 h. Compared to PL, 70 ml BR ingestion did not alter the physiological responses to exercise. However, ingestion of 140 and 280 ml BR reduced the steady-state VO<sub>2</sub> during moderate-intensity exercise by 1.7% (P=0.06) and 3.0% (P<0.05), respectively, whilst time-to-exhaustion was extended by 14% and 12% (both P<0.05), respectively, compared to PL. **Discussion** The results of this study indicate that, while plasma [NO<sub>2</sub><sup>-</sup>] and the O<sub>2</sub> cost of moderate-intensity exercise are improved dose-dependently with NO<sub>3</sub><sup>-</sup>-rich BR, there is no further reduction in SBP or MAP or improvement of exercise tolerance after ingesting BR containing 16.8 compared to 8.4 mmol NO<sub>3</sub><sup>-</sup>. These results provide important practical information which may underpin the potential use of NO<sub>3</sub><sup>-</sup> supplementation for improving cardiovascular health in the wider population, and for enhancing exercise performance in athletes. **References** Bailey SJ, Winyard P, Vanhatalo A, Blackwell JR, DiMenna FJ, Wilkerson DP, Tarr J, Benjamin N, Jones AM. #### **EFFECT OF TWO BUFFERING AGENTS ON REPEATED SPRINTS DURING INTERMITTENT EXERCISE PERFORMED UNDER HYPOXIC CONDITIONS**

Saunders, B.1,2, Sale, C.2, Harris, R.C.3, Sunderland, C.2

1: USP (São Paulo, Brazil), 2: NTU (Nottingham, UK), 3: Junipa Ltd (Newmarket, UK)

**Introduction** Repeated sprint ability (RSA) is considered an important aspect of team sport performance and increased RSA has been associated with increased H<sup>+</sup> buffering capacity (Rampinini et al., 2009). When exercise is performed at altitude, there is an earlier reliance on anaerobic glycolysis due to the higher relative intensity for an absolute level of work (Levine et al., 2008), which leads to an increase in both muscle and blood lactate accumulation (Wolfel et al., 1991), resulting in a concomitant rise in H<sup>+</sup>, which would place an increased reliance on the buffering systems of the body to maintain performance. Therefore, the aim of this study was to investigate the separate and combined effects of sodium bicarbonate and β-alanine supplementation on repeated sprint performance during simulated match play performed under hypoxic conditions. **Methods** Study A: 20 recreationally participants performed two main trials following acute supplementation with either sodium bicarbonate (0.3 g/kg B/M) or placebo (maltodextrin). Study B: 16 recreationally active participants were assigned to either a placebo or β-alanine (6.4 g/day for 4 weeks, 3.2 g/day for 1 week) for 5 weeks, and performed one main trial prior to supplementation (with maltodextrin) and two following supplementation (with sodium bicarbonate and with maltodextrin). Main trials consisted of 3 sets of 5 x 6 s repeated sprints performed during a football specific intermittent treadmill protocol under hypoxic conditions equivalent to 2500 m altitude (15.5% O<sub>2</sub>). Mean power output (MPO) and peak power output (PPO) were recorded as the performance measures. Data are presented as mean ± 1SD. **Results** Study A: Overall MPO was lower with sodium bicarbonate than placebo (P = 0.02, 539.4 ± 84.5 vs. 554.0 ± 84.6 W), although there was no effect of sodium bicarbonate on MPO or PPO across the 90 minutes (all P > 0.05). Study B: There was no clear effect of β-alanine supplementation, or co-supplementation with sodium bicarbonate, on MPO or PPO, although there was a trend towards higher MPO with sodium bicarbonate when combining both supplementation groups (P = 0.07, post hoc P = 0.03). **Discussion** Despite previous research suggesting an association between increased buffering capacity and improved RSA, the current investigation showed that sodium bicarbonate and β-alanine supplementation, separately and combined, did not improve 5 x 6 s repeated sprint performance throughout simulated games play under hypoxic conditions. **References** Levine et al. (2008). *Scand J Med Sci Sport*, 18(1), 76-84. Rampinini et al. (2009). *Appl Physiol Nutr Metab*, 34, 1048-1054. Wolfel et al. (1991). *J Appl Physiol*, 70, 1129-1136.

#### **EFFECTS OF COMBINED SUPPLEMENTATION OF DIETARY NITRATE AND L-ARGININE ON PHYSIOLOGICAL RESPONSES, SPRINT AND ENDURANCE PERFORMANCE**

Bucher Sandbakk, S.1, Sandbakk, Ø.1, Peacock, O.2, James, P.3, Wisløff, U.1, Böhle, N.4, Tjønnå, A.E.1

*Department of Circulation and Medical Imaging*

**INTRODUCTION:** Nitric oxide is produced by nitric oxide synthases (NOS) during the catalysis of L-arginine to L-citrulline (NOS dependent) and due to ingestion of nitrate-rich foods via the reduction of nitrate to nitrite (NOS independent). Increased NO bioavailability may enhance oxygen and nutrient delivery to active muscles, thus improving tolerance to physical exercise and recovery mechanisms. However, studies on highly trained populations are sparse and show several discrepancies. The current study examined the effects of acute inges-

tion of dietary nitrates and combined supplementation of nitrates and L-arginine on sprint and endurance running performance, as well as on exercise economy, lung function and blood pressure. METHODS: A randomized cross-over, double-blinded design tested the effects of placebo, 614 mg potassium nitrate and 614 mg potassium nitrate + 6 g L-arginine supplementations in nine elite cross country skiers (69 ml/min/kg VO<sub>2</sub>max). After standardization of nutrition and exercise the subjects were tested for blood responses, blood pressure, lung function, submaximal running at 10 km/h and 14 km/h at 1 % incline, and 200 m and 5 000 m running performance. RESULTS: Plasma nitrite concentrations were higher after nitrate (328 ± 107 nmol/L) and nitrate + L-arginine (319 ± 54 nmol/L) supplementations compared with placebo (149 ± 64 nmol/L, p<0.001). There were no differences in 200 m or 5000 m time-trial performances, lung function or physiological responses during submaximal running between placebo and treatment. CONCLUSIONS: The significantly increased plasma nitrate and nitrite concentrations in the treatment conditions relative to placebo are consistent with previous studies. However, acute ingestions of dietary nitrate or combined nitrate + L-arginine did not enhance 200 m or 5000 m running time-trial performances, exercise economy or lung function in endurance trained cross-country skiers compared to placebo treatment. These findings contrasts studies on untrained subjects, but is supported by studies on elite endurance athletes. Thus training status seems to be an important factor linked to the ergogenic effect of increased NO.

### PROTEIN-LEUCINE INGESTION FOLLOWING INTENSE ENDURANCE EXERCISE STIMULATES A REGENERATIVE INFLAMMATORY TRANSCRIPTOME IN SKELETAL MUSCLE

Rowlands, D., Nelson, A., Raymond, F., Metairon, S., Mansourian, R., Leikis, M., Hayes, M., Faulkner, J., Clarke, J., Moore, D., Stellingwerff, T.

*Massey University*

Introduction Dietary protein and leucine intake following exercise modulates skeletal muscle gene expression, increases protein synthesis, and in some circumstances can lead to enhanced subsequent endurance performance, relative to low protein ingestion. The effect of protein-leucine dose on the transcriptome-directed molecular programme guiding acute-phase skeletal muscle regeneration and recovery after endurance exercise, however, is unknown. Methods In a crossover, twelve trained men completed 100 min of high-intensity cycling prior to ingesting a total of 70/15/180/30 g protein/leucine/carbohydrate/fat (15LEU), 23/5/180/30 g (5LEU) or 0/0/274/30 g (CON) beverages across 4 servings during the first 90 min of a 240-min monitored recovery period. Biopsies from the vastus lateralis were taken 30 and 240 min into recovery and messenger RNA was analysed by Illumina microarray. Gene selection contrasts were interrogated using Ingenuity Pathway Analysis software. Results The top functional modular network in the 15LEU-5LEU dose contrast at 30 min was proinflammatory, centred on interleukin (IL)-1-Beta programming increased leukocyte migration and differentiation, and extracellular-matrix protein gene expression. Furthermore, the 5LEU and 15LEU vs CON feedings promoted cytoskeleton and increased cell viability with a myogenic signature at 30 min. By 240 min, however, in both 5LEU and 15LEU vs CON, and with dose response, an IL6 centred anti-inflammatory and promyogenic transcriptome dominated, with inhibition of NF-Kappa-Beta and SMAD pathway activity guiding expression indicative of decreased leukocyte migration, increased immune and muscle cell apoptosis, and cell metabolism. The transcriptome suggests protein-leucine feeding upregulated an early-phase regenerative programme reflecting wound-healing biology. Conclusions Ingesting a supplement containing 23 g of protein and 5 g of leucine following exercise simulated an early inflammatory transcriptome common to skeletal muscle regeneration biology that was more evident with the 3-fold higher protein-leucine dose. These findings suggest the higher quantity of protein-leucine ingested over the 90-min period post-exercise may better stimulate an inflammatory promyogenic molecular response influencing skeletal muscle recovery processes following strenuous training. ### DOES SODIUM BICARBONATE LOADING IMPROVE FIRE FIGHTER PERFORMANCE

Williford, H., Smoak, L., Esco, M., Reilly, E., Pugh, S., Walker, A.

*Auburn University Montgomery*

Introduction Fire fighter performance is often evaluated by a simulated job performance task (FFJPT). The purpose of the FFJPT is to quantify fire fighter physical fitness in order to meet criterion job standards. Highly fit fire fighters can perform the FFJPT in less than 2 min. Because of the anaerobic nature of the task, it was hypothesized that sodium bicarbonate loading may improve FFJPT performance times. Methods Nine male fire fighters who were part of a FFJPT competition team participated in the study. Their characteristics were: height (183.73 cm, weight 79.98 kg, age 25.1 yrs., and years' fire fighting experience 2.8 yrs.). Each fire fighter performed the FFJPT as fast as possible. The FFJPT consisted of a stair climb, hoist, forcible entry, hose drag, and dummy drag. Times were recorded for experimental and placebo trials with and without sodium bicarbonate ingestion. The experimental trial consisted of a 20 oz. drink mixed with 0.3 g/kg of sodium bicarbonate. The drink was taken one hour before starting the trial. Performance times were recorded and blood lactate (BL) was measured immediately post exercise, and 2.5, 5.0, and 10.0 min. post exercise. A paired T-test was used to evaluate differences in dependent variables (p < 0.05). Results The mean time to complete the task during the placebo trial was 2.8 min compared to 2.6 min for the experimental trial. There was a mean 17 sec improvement in performance (p = 0.007) for the experimental trial. The blood lactate values were respectively significantly higher for all post exercise trials p < 0.05. Other investigations with athletes have also shown increased BL values with sodium bicarbonate loading with improved performance times. Table 1. Blood Lactate (mean±SD) Placebo (mmol) Experimental Trial (mmol) Pre Test 1.5 ± 0.5 1.3 ± 0.5 Immediate Post 9.9 ± 4.1 12.9 ± 3.4 2.5 min post 11.5 ± 1.7 15.1 ± 2.1 5.0 min post 11.0 ± 3.1 14.8 ± 1.5 10.0 min post 11.3 ± 1.5 14.6 ± 1.8 Conclusion Results of the investigation indicate that sodium bicarbonate loading may improve fire fighter job performance. The negative effects of the trial were gastrointestinal discomfort. Further study is needed related to appropriate sodium bicarbonate dosages related to performance times.

**DOES PHYSICAL TRAINING INFLUENCE THE INCRETIN EFFECT?**

Lund, M., Dalby, S., Hartmann, B., Helge, J., Holst, J., Dela, F.

*University of Copenhagen*

## Introduction

It is well-known that insulin secretion in response to an oral or intravenous stimuli is lower in endurance trained athletes (T) compared to sedentary people (UT). The mechanism behind, however, is not fully described and might differ between ways of administration. Incretin hormones (glucagon like peptide-1 (GLP-1) and glucose-dependent insulinotropic peptide (GIP)) are stimulated by nutrients in the small intestine and increase the glucose induced insulin release. We have shown that GLP-1 (higher fasting value) and GIP (lower postprandial release) adapts to physical training (Lund et al. unpublished data). Whether this is followed by a change in  $\beta$ -cell sensitivity to the incretins is unknown. Our aim was to measure and compare the incretin effect, defined as the difference in insulin release during an oral and intravenous glucose test with matched plasma glucose levels, in T and UT. Methods Ten T and ten UT (VO<sub>2</sub>max: 67±2 and 46±2 ml/min/kg; age: 25±1 and 25±1 yrs; BMI: 22±1 and 23±1 kg/m<sup>2</sup>, respectively) healthy men were included. Subjects reported to the lab twice, separated by at least 48 h, after an overnight fast. Day 1 subjects ingested 75 g of glucose dissolved in 300 ml water (OGTT) and plasma glucose was measured every fifth minute for 3½ h. Day 2 glucose was infused intravenously (IIGI) to match the plasma glucose levels during the OGTT at any given time. Blood for insulin measurements, were drawn twice at baseline and at 15, 30, 45, 60, 90, 150 and 210 minutes both test days. Results Glucose concentration (4.9 vs. 4.9 mM, p=0.74) was similar, but insulin concentration (27 vs. 42 pM, p=0.048) lower at baseline in T compared to UT, respectively. There was no difference in glucose AUC between test days in UT (OGTT: 1255±32 vs. IIGI: 1266±24 mM • 210 min, p=0.36) or T (OGTT: 1184±16 vs. IIGI: 1192±15 mM • 210 min, p=0.18), but glucose AUC was lower in T vs. UT both test days (OGTT: p=0.03 and IIGI: p=0.007). Also insulin concentration during the OGTT (T: 21387±1104 vs. UT: 35735±4597 pM • 210 min, p=0.007) and IIGI (T: 9894±714 vs. UT: 16795±2119 pM • 210 min, p=0.006) was lower in T vs. UT. The incretin effect calculated as: (AUCOGTT - AUCIIGI)/AUCOGTT) • 100% for incremental insulin values (70±4 and 67±3%) was similar in T vs. UT, respectively. Discussion With a lower insulin release during both tests in T compared to UT, our data confirms the well-known relationship between insulin secretion and physical training. The incretin effect was similar in both groups. This is a novel finding and in contrast to what could be expected given the markedly different insulin release in T compared to UT. Moreover with a similar incretin effect and an expected lower GIP release in T compared to UT it follows that in endurance trained athletes the GIP sensitivity of the  $\beta$ -cell must be increased.

**SMALL-SIDED GAMES TRAINING ARE AS EFFECTIVE AS TRADITIONAL CYCLE ERGOMETRY AT REDUCING CLINICAL RISK FACTORS ASSOCIATED WITH THE DEVELOPMENT OF DIABETES AND CARDIOVASCULAR DISEASE**

Mendham, A.E., Duffield, R., Coutts, A.J., Marino, F., Bishop, D.J.

*Charles Sturt University*

Introduction The majority of research investigating the potential for exercise to reduce clinical risk factors associated with diabetes and cardiovascular disease has used continuous exercise (Hays et al., 2006; Hutchison et al., 2012). The present study sought to examine whether small-sided games (SSG) could be an effective alternative to traditional continuous exercise training. Methods Thirty middle-aged, sedentary, men (48.6±6.6 y) were randomly assigned to a cycle ergometry (n=11), SSG (n=10), or control group (n=9). Participants in both exercise groups trained 3 d/wk for 8 wk, while control participants maintained normal activity and dietary patterns. All participants completed pre- and post-intervention testing: dual-energy x-ray absorptiometry scan, incremental exercise test, resting oral glucose tolerance test (OGTT) and a resting muscle biopsy. Plasma glucose and insulin concentrations were measured in a fasted state and throughout the 2 h OGTT. Total content of proteins associated with mitochondrial biogenesis, and glucose and insulin signaling were analysed via western blotting. Results In response to the OGTT, the control group exhibited no changes, yet both cycling and SSG groups showed a decline in the area under the curve (AUC) for glucose, whilst only SSG showed a decline in the AUC for insulin (P<0.05). There were no significant changes in proteins associated with mitochondrial biogenesis, glucose or insulin signaling (P>0.05). However, there was a trend for an increase in PGC-1 $\alpha$  (effect size (ES) ± confidence interval: 0.49±0.62), P53 (ES 0.47±0.55) and GLUT4 (ES 0.57±0.65) within the SSG group and for mitochondrial complex I (P<0.05; ES 1.0±0.67) and IV (P<0.05; ES 1.1±0.77) within the cycling group. Participants in both exercise groups decreased total body fat mass (%) and intra-abdominal fat mass (kg; P<0.05). Additionally, peak oxygen consumption improved by 19% in both exercise groups (P<0.05). Discussion This study showed that both cycling and SSG improved aerobic capacity, body composition, and blood biochemistry in relation to glucose regulation. However, such changes were not reflected within the skeletal muscle proteins associated with mitochondrial biogenesis, or glucose and insulin signaling. While the underlying mechanisms need to be further investigated, SSG training in sedentary middle-aged populations was as effective as traditional cycle ergometry by reducing clinical risk factors normally associated with the development of chronic diseases. **TWO WEEKS OF PHYSICAL INACTIVITY REDUCES THE MITOCHONDRIAL RESPIRATORY CAPACITY IN YOUNG AND ELDERLY HEALTHY MEN**

Gram, M., Vigelsoe, A., Yokota, T., Nørregaard, J., Wiuff, C., Kuhlman, A.B., Helge, J.W., Hey-Mogensen, M., Dela, F.

*Xlab*

Introduction The effect of physical inactivity on mitochondrial respiratory capacity in human skeletal muscle is largely unknown. The purpose of this study was to investigate the effect of physical inactivity and subsequent aerobic training on mitochondrial respiratory capacity in young and elderly healthy men. Methods 17 young (Y) (23±1 yr (mean±SEM); 48±1 ml O<sub>2</sub>/min/kg) and 15 elderly (E) (68±1 yr; 33±2 ml O<sub>2</sub>/min/kg) male subjects had one leg immobilised for two weeks using a DonJoy cast. This was followed by six weeks (20 sessions) of

supervised cycle ergometer training (86±1% of maximal heart rate). The daily physical activity level was monitored with a three-axis accelerometer before, during and after immobilisation. Muscle biopsies (v. lateralis) were obtained after immobilisation in the immobilised leg (IMMO), in the non-immobilised control leg (CON) and after training in the immobilised leg (TR). Mitochondrial respiratory rate was determined in permeabilised fibers during state 2 using glutamate and malate as complex I linked substrates (GM2), state 3 after addition of ADP (GM3) which was followed by addition of succinate for dual electron input into complex I and II (GMS3) and finally state 4 after addition of oligomycin to inhibit the ATP synthase (4o). Statistical differences were tested using a two-way ANOVA with repeated measures. Results During immobilization the physical activity level decreased ( $P < 0.001$ ) similarly in both Y (31±9%) and E (37±9%) after which it returned to baseline during the training period. After immobilisation, mitochondrial respiration in CON vs. IMMO decreased ( $P < 0.05$ ) similarly both in Y (GM3: 40±5 vs. 33±3; GMS3: 72±7 vs. 59±5 and 4o: 25±3 vs. 20±2 pmol/sec/mg) and in E (GM3: 37±2 vs. 30±2; GMS3: 75±5 vs. 60±3 and 4o: 23±2 vs. 19±1 pmol/sec/mg), respectively. After training, mitochondrial respiration in IMMO vs. TR increased ( $P < 0.05$ ) in Y (GMS3: 60±5 vs. 92±5 and 4o: 20±2 vs. 38±3 pmol/sec/mg) and in E (GMS3: 61±3 vs. 79±5 and 4o: 19±1 vs. 30±2 pmol/sec/mg), but interestingly there was no effect of training on GM3 in either group (Y: 32±3 vs. 35±4 and E: 31±2 vs. 29±2 pmol/sec/mg). After training, there was no difference in mitochondrial respiration between TR vs. CON in E, while TR was significantly higher than CON in Y ( $P < 0.05$ ). Conclusions We conclude that 1) immobilisation decreases mitochondrial respiration to an equal extent in young and elderly subjects. 2) Retraining after immobilisation have an augmented effect on mitochondrial respiration in young compared to elderly subjects. 3) In contrast to all other respiratory measures, state 3 respiration using glutamate + malate, did not increase with training in either young or elderly subjects.

### ACTN3 GENE POLYMORPHISM: ASSOCIATION WITH AEROBIC FITNESS

Pasqua, L.A.1, Artioli, G.G.1, Bueno, S.1, Damasceno, M.V.1, Lancha Jr, A.H.1, Lima-Silva, A.E.2, Bertuzzi, R.1

1: USP (São Paulo, Brazil), 2: UFAL (Maceió, Brazil)

**Introduction** Genetic polymorphisms have been highlighted as important determinants of physical performance traits. Among them, the R577X polymorphism of the ACTN3 gene, which results in a complete absence of  $\alpha$ -actinin-3 in subjects with XX genotype, has been extensively investigated in relation to sports performance. Association studies observed a higher frequency of the XX genotype among endurance athletes. Additionally, findings in animal models showed a more efficient oxidative metabolism in ACTN3 knockout mice. However, the relationship between the XX genotype and aerobic fitness in humans remains unknown. Thus, the aim of the present study was to verify the association between the XX genotype of the ACTN3 gene and physiological parameters related to aerobic fitness. **Methods** One hundred and fifty male healthy subjects performed a maximal incremental running test to determine maximal oxygen uptake (VO<sub>2</sub>max) and the speeds in which ventilatory threshold (VT) and respiratory compensation point (RCP) were attained. DNA samples were obtained from mouthwashes and subsequently analyzed by PCR reaction. The subjects were divided in terciles based on the analyzed variables. The genotype frequencies were compared through chi-squared test between the first (T1) and third terciles (T3), which represent the two "end-points" for each variable (the lowest and highest values, respectively). Results In relation to VT, T1 (8.8 ± 0.9 km.h<sup>-1</sup>) was significantly lower than T3 (11.3 ± 0.5 km.h<sup>-1</sup>;  $p < 0.05$ ). The XX genotype showed a lower frequency for VT in T1 (16.7%) and a higher frequency in T3 (41.7%,  $p < 0.05$ ), accounting for 32.4% of the observed difference. Similarly, when the individuals were divided by the RCP values, T1 was significantly lower than T3 (12.0 ± 0.8 km.h<sup>-1</sup> vs 15 ± 1.1 km.h<sup>-1</sup>;  $p < 0.05$ ). It was found a higher frequency of the XX genotype for RCP in T3 (52.8%,  $p < 0.05$ ), accounting for 16% of the difference. No differences were observed for the VO<sub>2</sub>max terciles. **Discussion** Our results show that XX subjects have a greater probability to attain the VT and RCP at higher speeds, suggesting that these subjects may sustain higher running speeds in lower exercise intensity domains. It could result in higher oxidation of lipid acids, saving muscle glycogen and delaying the onset of fatigue during prolonged exercises. Therefore, this could be one of the mechanisms that may explain the advantage of the XX genotype to endurance performance suggested in previous studies of association.

### INVESTIGATION OF COL3A1, COL6A1 AND COL12A1 POLYMORPHISMS WITH ANTERIOR CRUCIATE LIGAMENT RUPTURE IN TWO INDEPENDENT POPULATIONS

O'Connell, K.1, Ficek, K.2, Leonska-Duniec, A.3, Maciejewska-Karlowska, A.2, Sawczuk, M.2, Stepien-Slodkowska, M.2, O'Cuinneagain, D.4, Merwe, W.4, Posthumus, M.1, Cieszczyk, P.3, Collins, M.1,5

**Introduction** The exact aetiology of ACL ruptures remains unknown however, a number of extrinsic and intrinsic risk factors, including a genetic component, have been identified (Griffin et al., 2006). The primary aim of this study is determine if an independent association exists between COL3A1 rs1800255 and COL6A1 rs35796750 and risk of ACL ruptures. The secondary aim of the study was to determine if any gene-gene interactions, between these variants and other previously associated variants (Ficek et al., 2012; Posthumus et al., 2009; Khoschnau et al., 2008; Posthumus et al., 2010) are associated with risk of ACL rupture. **Methods** 334 Caucasian participants were recruited for the South African cohort for this study. 122 participants with ACL ruptures and 212 participants with no history of ACL injury were recruited as controls. 234 male Polish participants were recruited for the Polish cohort of this study. 91 participants with ACL ruptures and 143 participants with no history of ACL injury were recruited as controls. Participants were genotyped for COL3A1 rs1800255, COL6A1 rs35796750 and COL12A1 rs970547. Results Significant, but opposite, associations were identified between COL3A1 rs1800255 and ACL injury risk in the male South African and Polish participants. No significant associations were identified for COL6A1 rs35796750 and COL12A1 rs970547. The major COL1A1 rs1800012, COL3A1 rs1800255 and COL12A1 rs970547 inferred haplotype, G+G+A, was significantly ( $p=0.016$ ) over-represented in the combined ACL group when compared to the combined CON group. **Discussion** The novel main finding of this study was a significant interaction between the COL1A1 rs1800012 G/T, COL3A1 rs1800255 G/A and COL12A1 rs970547 A/G variants and risk of ACL injury. **PLASMA ADIPOKINE CONCENTRATIONS IN PREPUBERTAL CHILDREN WITH DIFFERENT LEVELS OF CARDIORESPIRATORY FITNESS AND PHYSICAL ACTIVITY**

Llorente-Cantarero, F.J.1,2, Gil-Campos, M.2, Olza, J.3, Muñoz-Villanueva, M.C.4, Aguilera, C.M.3, Pérez-Navero, J.L.2

1: UCO (Cordoba); 2: URSH (Cordoba); 3: UGR (Granada); 4: IMIBIC (Cordoba).

**Introduction** Physical activity (PA) and cardiorespiratory fitness (CRF) could be protective against low-grade inflammation. Therefore, the aim of this study was to assess some adipokines and inflammation biomarkers in prepubertal healthy children with different levels of fitness and physical activity. **Methods** 132 healthy prepubertal children (78 boys/54 girls) aged between 7-12 years were recruited from local schools. Children were divided into two groups (equal or high fitness (HF) group, and low fitness group (LF) according to the 20-meter shuttle run test. Moreover, to estimate practice of exercise, participants were observed while engaged in an after-school program and answered a questionnaire. So, children were assigned either to the regular physical activity group (PAG) or to the sedentary group (SG). Anthropometric parameters and the following plasma adipokines were measured: leptin, resistin, adiponectin, tumor necrosis factor alpha, hepatic growth factor, interleukin 6 (IL-6), IL-8, macrophage chemoattractant type-1 (MCP1), nerve growth factor, and plasminogen activator inhibitor-1. **Results** After adjustment for BMI, age and sex, the LF group showed higher leptin levels and lower IL-6 levels as compared to the HF group. In relation to PA, adiponectin and MCP1 levels were higher in the SG as compared to the PAG but after adjustments, only MCP1 remained significant. When boys and girls were compared, no differences were found. **Discussion** CRF and PA may influence plasma adipokine levels regardless of BMI, age and sex, already in prepubertal healthy children. Sedentary and low fitness groups of prepubertal children show some changes in inflammatory cytokines comparing to the group of physically active children. At present, the potential anti-inflammatory role of CRF and PA in children is not yet clear. However, the role of risk factors during childhood on the development of cardiovascular diseases later in adulthood should be further analyzed. Whereas genetic and early programming features have been associated with low-grade inflammation in young people 1, an active lifestyle and a desirable CRF may attenuate its effects 2. It has been indicated that PA may have an indirect role through CRF and body fat, which are health determinants. The present study contributes to establish the groups with health risk in childhood that may be re-evaluated in later ages and that could benefit from scheduled physical activity programs. 1: Labayen I, Ortega FB, Sjöström M, Ruiz JR. *J Pediatr* 2009;155:673-7. 2: Martinez-Gomez D, Eisenmann JC, Wärnberg J, Gomez-Martinez S, Veses A, Veiga OL, Marcos A. *IJO* 2010;34:1501-7.

**18:00 - 19:30****Oral presentations****OP-PM05 Health and Fitness [HF] 1****STRENGTH, AEROBIC AND COGNITIVE EXERCISE TO IMPROVE EXECUTIVE FUNCTION**

Eggenberger, P.1, Schumacher, V.2, Angst, M.1, Holenstein, S.1, Theill, N.2, de Bruin, E.D.1

1: ETH Zurich, 2: University of Zurich

**Introduction** Different studies have demonstrated that cognitive functions improve to a greater extent in participants following combined strength and aerobic training than aerobic training alone (Colcombe and Kramer, 2003). Furthermore, neglecting the training of cognitive functions might be one reason for the absence of effects in fall prevention programs (de Bruin et al., 2011). Since executive functions (EF) are important in relation to falls in elderly (Mirelman et al., 2012), we hypothesized that cognitive function improves more when strength-aerobic training is combined with cognitive training and that training attention affects EF more than training working memory. **Methods** 69 elderly (79+-5.6 years) were randomly assigned to one of three groups; AEROBIC (strength-aerobic training only) DANCE (strength-aerobic and attention training) MEMORY (strength-aerobic and working memory training). They performed two one-hour training sessions per week for three months. To identify differences in EF between groups the Trail Making Test (TMT parts A & B; Arbuthnott and Frank, 2000; Sanchez-Cubillo et al., 2009) was assessed pre- and post-intervention and analysed with planned contrasts. Results Planned contrasts revealed that cognitive performance of the groups with combined training (DANCE and MEMORY) improved significantly more compared to the control group (AEROBIC): TMT B-A  $t(66) = 1.78$ ,  $p < .05$  & TMT B/A  $t(66) = 1.93$ ,  $p < .05$ , training type (attention vs. memory) was not different, TMT B-A  $t(66) = -.43$ ,  $p = .34$  (one-tailed) & TMT B/A  $t(66) = -.28$ ,  $p = .39$  (one-tailed). **Discussion** This study indicates an advantage of the combination of strength-aerobic with cognitive training over strength-aerobic training alone. Both combined training groups demonstrated similar performance developments over three months and similar transfer effects to performance in the TMT. These findings encourage further examination of the effect of exercise type and intensity on cognition and clinically relevant outcomes. **References** Colcombe S, Kramer AF (2003). *Psychological Science*, 14(2), 125-130. de Bruin ED, Reith A, Doerflinger M, Murer K (2011) *J Nov Physiother*, 1(104). **SPONTANEOUS PHYSICAL ACTIVITY, AEROBIC PHYSICAL EXERCISE AND CORTISOL TO DEHYDROEPIANDROSTERONE SULFATE RATIO IN POST-MENOPAUSE**

Di Blasio, A., Izzicupo, P., D'Angelo, E., Bucci, I., Ripari, P., Napolitano, G.

Chieti-Pescara University

**Introduction** Both aging and menopause are influencing factors of the increase of cortisol (C) and the decrease of dehydroepiandrosterone sulfate (D-S) plasma values. As the combination of these hormonal modifications has negative cardio-metabolic effects on health, the aim of our study was to investigate the effects of both spontaneous physical activity (SPA) and aerobic physical exercise on C to D-S ratio (C/D-S) in order to prevent and/or to treat the related cardio-metabolic diseases. **Methods** Fifty post-menopausal women (57.22±4.78 yrs), not involved in a physical exercise program, have been recruited and investigated for plasma values of C, D-S, insulin and glucose, together with body composition, blood pressure and aerobic fitness. Daily physical activity (DPA) of participants has been objectively recorded (SenseWear Pro3 Armband, BodyMedia) for seven consecutive days. After basal

measurements, participants walked at moderate intensity 4 days/wk, for 13 weeks, under controlled supervision. At the end of the training period, all measurements were repeated. To detect the presence of any SPA modification (i.e. increase or decrease) during the training period, DPA was recorded 10 days prior to the end of the training, and included both training days and non-training days. Results C/D-S has been shown positively correlated with age, years of menopause, insulin resistance and blood pressure. Also when controlled for the effect of the age, C/D-S did not show relationships with body composition and DPA. C/D-S variation has been shown correlated only with the total volume of the physical exercise (VPE) that participants reached ( $r=-0.435$ ,  $p=0.02$ ). Indeed, when participants were gathered according to tertiles of VPE, the first tertile ( $VPE < 123.13$  min/wk) did not modify C/D-S, the second tertile ( $123.13 < VPE < 159.34$  min/wk) had a quite significant reduction of C/D-S ( $p=0.08$ ) while the third tertile ( $VPE > 159.34$  min/wk) significantly reduced it ( $p=0.02$ ). No effects of SPA modification have been detected on C/D-S variation. Discussion In the absence of aerobic physical exercise, SPA of post-menopausal women does not seem able to influence C/D-S, probably because its characteristics did not adequately stimulate the body. Indeed, C/D-S variation has been shown correlated only with the VPE, independently from the modifications of both SPA and others investigated variables. Our results underline the importance of the practice of moderate intensity aerobic physical exercise and also confirm the importance to totalize at least 150 min/wk of exercise because only participants in the third tertile significantly reduced C/D-S. This result also suggests that C/D-S variation is volume-dependent.

### **TWITCH AND M-WAVE POTENTIATION INDUCED BY MAXIMAL VOLUNTARY CONTRACTIONS OF THE QUADRICEPS: DIFFERENCES BETWEEN OVER-THE-MUSCLE AND FEMORAL NERVE STIMULATION**

Rodriguez-Falces, J., Maffioletti, N., Place, N.

*Public University of Navarra*

**TWITCH AND M-WAVE POTENTIATION INDUCED BY MAXIMAL VOLUNTARY CONTRACTIONS OF THE QUADRICEPS: DIFFERENCES BETWEEN OVER-THE-MUSCLE AND FEMORAL NERVE STIMULATION** Rodriguez-Falces J (1), Maffioletti NA (2), Place N (3) (1) PUN, (Pamplona, Spain), (2) SC, (Zurich, Switzerland), (3) UG, (Geneva, Switzerland). Introduction It is well known that twitch force, as evoked by a single electrical stimulus, increases after a brief muscle contraction. This phenomenon is normally referred to as "potentiation" (Brown and von Euler, 1938). Potentiation is also the name given to the enlargement of the maximal M-wave observed following a conditioning contraction. Single electrical stimulation can be applied transcutaneously by using large electrodes placed over the muscle belly (over-the-quadriceps stimulation), while smaller stimulating electrodes could also be positioned over a major peripheral nerve (femoral nerve stimulation). The aim of this study is to investigate differences in twitch and M-wave potentiation in the quadriceps femoris when electrical stimulation is applied over the quadriceps muscle belly versus the femoral nerve trunk. Methods M-waves and mechanical twitches were evoked using over-the-quadriceps stimulation and femoral nerve stimulation between 48 successive isometric maximal voluntary contractions (MVC) from 10 young, healthy subjects. Potentiation was investigated by analyzing the changes in M-wave amplitude recorded from the vastus medialis (VM) and vastus lateralis (VL) muscles and in quadriceps peak twitch force. Results Potentiation of twitch, VM M-wave, and VL M-wave was greater for femoral nerve than for over-the-quadriceps stimulation ( $P<0.05$ ). M-wave potentiation tended to be greater for VL than for VM ( $P=0.087$ ). Despite a 50% decrease in voluntary force, M-waves during the 48 intermittent MVCs were greater than the M-wave at rest. Twitch potentiation was maximal at 15-20 s from the onset of the fatiguing protocol, after which the twitch underwent a steady decrease. Discussion With the assumption that full MU recruitment was achieved with both stimulation geometries, differences in the type of MU activated or number of MUs by femoral nerve vs. over-the-quadriceps stimulation can hardly account for the above differences in twitch potentiation. Although the enhanced electrogenic  $Na^+-K^+$  pumping is traditionally suggested as the main mechanism underlying M-wave potentiation, other factors (such as synchronization in the activation of muscle fibres and muscle architectural properties) might significantly influence the magnitude of M-wave enlargement. ### **DIFFERENCES IN THE MITOCHONDRIAL CONTENT OF DIFFERENT FIBRE TYPES IN THE LEG AND ARM MUSCLES OF ELITE CROSS-COUNTRY SKIERS**

Ørtenblad, N.1,2, Holmberg, H.C.2, Schrøder, H.D.3, Saltin, B.4, Nielsen, J.1

*1University of Southern Denmark (Odense, Denmark), 2Mid Sweden University (Östersund, Sweden), 3Odense University Hospital (Odense, Denmark), 4University of Copenhagen (Copenhagen, Denmark)*

Introduction Although it is generally believed that the MHC isoforms determine the metabolic profile of a muscle fibre, the relationship between these isoforms and the mitochondrial volume may vary (Handschin 2010), and arm and leg muscle differences has been proposed (Plomgaard et al. 2006). The aim here was to characterize this relationship between mitochondrial volume and MHC isoform in the limbs of elite cross-country skiers exceptionally training in both limbs. Methods Ten male elite cross-country skiers participated in the study, mean ( $\pm$ SD) age  $22 \pm 1$  yrs and  $\dot{V}O_2\max$   $72 \pm 2$  ml  $kg^{-1}$   $min^{-1}$ . Muscle biopsies were taken from arm (m. triceps brachii) and leg (m. vastus lateralis) muscles. Muscle segments were prepared for transmission electron microscopy (TEM) and the volume content of mitochondria were estimated by point-counting. Fibres were classified as type I or II based on a combination of z-line width and mitochondria content. Whole muscle MHC was determined by electrophoresis by with the average of 3 biopsies. Results The mitochondrial volume was higher in type I than in type II fibres. Although there were no clear significant difference between the fibre types of arms and legs (type I:  $0.126 \pm 0.01$  (leg) and  $0.128 \pm 0.01$  (arm) and type II:  $0.058 \pm 0.01$  (leg) and  $0.072 \pm 0.01$  (arm)  $\mu m^3$  per  $\mu m^3$  fibre volume), there was a strong tendency ( $P=0.05$ ) towards a higher mitochondrial volume in type II fibres in the arms vs. legs. The leg muscles contained predominantly MHCI ( $57 \pm 3\%$ ), whereas MHCIa dominated in the arms ( $63 \pm 2\%$ ). Despite this difference, there was no difference in the mitochondrial volumes of the leg and arm muscles, when weighing the mitochondrial content by the MHC distribution ( $0.0950 \pm 0.006$  (leg) vs  $0.0950 \pm 0.008$  (arm)  $\mu m^3$  per  $\mu m^3$  fibre volume). This conclusion was supported by the observation that the activity of citrate synthase, a definitive biomarker for mitochondria, was the same in both the arm and legs ( $118 \pm 6$  (leg) vs  $111 \pm 10$  (arm)  $\mu mol/g$   $dw/min$ ) in the muscles. Discussion Despite an overweight of MHC II fibres in the arms compared with the legs the two muscles have similar total mitochondria content and CS activity. Discrimination between fibre types indicates that the MHC II fibres of the arm muscles are more oxidative than found in the legs. Thus, the MHC phenotypes are clearly different between arm and leg muscles in these highly trained athletes, who have endurance-trained arm and leg muscles. ### MAXIMAL HEART RATE AND PERFORMANCE INCREASE WITH INTERMITTENT OXYGEN SUPPLEMENTATION DURING EXHAUSTIVE WORK IN ELITE ATHLETES

Gullstrand, L.1,3, Boberg, O.1, Fränberg, O.2, Larsson, Å.1, Lindberg, T.3, Lindholm, P.1

*Swedish Sports Confederation*

**Introduction** Inspiration of oxygen (O<sub>2</sub>) during exercise is known to increase peak work load (Bannister, 1954, Perry et al., 2005). Recent studies on pulmonary shunting during exercise suggest that O<sub>2</sub> per se could close these shunts and thus increase arterial PO<sub>2</sub> (Lovering et al., 2008). We hypothesized that a small increase in intrapulmonary PO<sub>2</sub> (5-10kPa) would suffice to get the performance enhancing effect of oxygen. We also hypothesized that intermittent supplementation of 10-20 L/min of O<sub>2</sub> to inspired air could yield this increase without using premixed gas in athletes ventilating 150-300 L/min. **Methods** 19 endurance trained, competitive male athletes were tested on an ergometer cycle in a blinded cross-over design on two separate occasions. Tests were done on two sub-maximal workloads (160 and 240W) and thereafter during a VO<sub>2</sub>max test with increasing workload by 22.5W/min until exhaustion. Measurements included VO<sub>2</sub>max (air), heart rate, SpO<sub>2</sub> etc. O<sub>2</sub> or air was added intermittently to the inspired air in one exercise protocol ending with air and the other with oxygen. O<sub>2</sub> was added at 10-20 L/min by an apparatus developed by Oxelate™, Stockholm, Sweden. **Results** Max workloads were 438.8 (50.6) W (Mean, SD) with air and 453.4 (49.7) W with O<sub>2</sub>,  $p = 2.8 \times 10^{-6}$ . Maximal heart rate were 188 (9.1) beats/min with air and 190.9 (9.7) with O<sub>2</sub>,  $n=17$ ,  $P = 9.7 \times 10^{-5}$ . VO<sub>2</sub>max (air) was 5.09 (0.66) L/min. End-tidal FO<sub>2</sub> was 21.38 (0.72) % at maximal workload with O<sub>2</sub> addition. **Discussion** These data suggest that intermittent supplementation of O<sub>2</sub> is enough to increase work performance and maximal heart rate in highly trained athletes. It also shows that maximal heart rate may be increased by a small increase in inspired PO<sub>2</sub> during maximal exercise. Using this kind of equipment may enable athletes to reach training intensities unattainable in normoxia in their regular training. The developed apparatus offers an easy to handle device for regular hyperoxia training. As this study measured acute responses, long term training effects of various forms (such as training frequency) of intermittent hyperoxia remains to be investigated. **References** Bannister R, Cunningham D. *J Physiol (London)* 1954; 125:118-137. ### HEAVY HIP EXTENSION STRENGTH TRAINING AND VOLUNTARY MOVEMENT RHYTHM IN CYCLING

Sardroodan, M., Madeleine, P., Voigt, M., Hansen, E.A.

*Aalborg University*

**Introduction** Freely chosen cadence (FCC) during submaximal cycling has been suggested to represent an innate voluntary movement rhythm, under primary influence of central pattern generators (Hansen & Ohnstad, 2008). Thus, FCC may be a good reflection of central pattern generator movement rhythm output. A period of heavy leg strength training, involving both hip flexion and extension exercise, has been reported to cause recreationally active subjects to reduce their FCC during submaximal cycling (Rønnestad et al., 2012). The changed rhythmic movement behaviour was observed after 4 weeks of training, where it was first measured. But, perhaps the change occurs even earlier, in response to neural adaptations. In this on-going study, we specifically investigate the early effect of hip extension strength training on voluntary leg movement rhythm represented by FCC. **Methods** At present, 7 recreationally active individuals have completed the entire study protocol. Four have performed strength training intervention consisting of standing hip extension in 2 sessions/week for 4 weeks. In each session, three 5RM-10RM-sets were performed with each leg. Three have acted as controls. Cycling was performed as 5 min bouts at 100 W, on an SRM ergometer. **Results** The preliminary data indicated, as expected, that strength (one repetition maximum, 1RM) in the training group increased. Thus, 1RM in the applied training exercise in the training group was  $40.1 \pm 10.3$  kg at pre-intervention and  $56.8 \pm 12.8$  kg at post-intervention, as average values for the two legs. For comparison, 1RM for the control group was  $48.3 \pm 2.5$  kg at pre-intervention and  $53.6 \pm 5.9$  kg at post-intervention. An indication of a reduction of FCC was seen in the training group that pedaled at  $85 \pm 9$  rpm at pre-intervention and  $71 \pm 4$  rpm at post-intervention. The change in FCC appeared to occur already after 1 week of training where it tended to decrease to  $72 \pm 9$  rpm. For comparison, FCC in the control group appeared to be unchanged from  $75 \pm 5$  rpm at pre-intervention to  $82 \pm 9$  rpm at post-intervention. **Discussion** The preliminary analysis indicated that FCC decreased as a result of heavy hip extension strength training already after 1 week of training. This indicates that neural adaptations rather than e.g. morphological changes can explain the changed movement rhythm. The training may have increased the efficacy of the neuromuscular activation resulting in reduced requirement of common descending supraspinal drive during the submaximal cycling at a constant preset power output. Such an adaptation could cause a reduced voluntary movement rhythm output reflected in a lower FCC. **References** Hansen EA, Ohnstad AE (2008) *Exp Brain Res*, 186, 365-73. #### OPTIMAL JAMAR DYNAMOMETER HANDLE POSITION TO ASSESS MAXIMAL ISOMETRIC HAND GRIP STRENGTH IN EPIDEMIOLOGICAL STUDIES

Trampisch, U., Franke, J., Hinrichs, T., Platen, P.

*Ruhr-Universität Bochum*

**Introduction** Hand grip strength measured by a hand dynamometer is an indicator of general muscle strength and is an easily accessible parameter of physical fitness in epidemiological studies. In some studies, a subject's grip strength has been defined to be the maximal grip strength achieved from measurements taken at several different dynamometer handle positions. However, little is known about the influence of these different positions on the measured grip strength. The aim of the study was to identify the best of all handle positions in order to determine one standard handle position that could be used to assess the maximal grip strength of subjects with only one single measurement. **Methods** Grip strength was assessed with a hand dynamometer (Jamar Plus; Sammons Preston, Rolyon, Bolingbrook, IL). 50 participants were included. Each participant's grip strength was measured 3 times in each of 5 different handle positions with each

hand. The single positions differed by means of the width of the grip between 3.5 cm to 8.7 cm. The best position for each participant was defined as the position at which they achieved their individual maximal grip strength. Results The mean ( $\pm$  standard deviation) age of the 50 participants (21 [42%] men, 29 [58%] women) was 41 ( $\pm$  13, range 23-68) years. Mean maximal grip strength was 43.7 ( $\pm$  12.4) kg for all participants; 55.0 ( $\pm$  10.2) kg for men and 35.4 ( $\pm$  5.2) kg for women. Handle position 2 (width 4.8 cm) was the best position for 70% of participants. The mean difference between the grip strength achieved by each participant at handle position 2 and that achieved at each participant's best position was 0.80 ( $\pm$  1.78) kg. Discussion The assessment of grip strength with the Jamar Plus dynamometer is easier and faster if a single, standard handle position is used rather than multiple different positions. Our results show that measurements taken at a single medium-wide standard handle position are sufficiently accurate to assess grip strengths for different subjects. Furthermore, only one measurement in a single, standard handle position also reduces fatigue and increases the comparability of results between subjects. We therefore recommend handle position 2 of the Jamar Plus dynamometer as the standard position for measuring grip strength with this instrument.

### EFFECT OF STRENGTH AND HIGH-INTENSITY TRAINING ON JUMPING, SPRINTING AND INTERMITTENT ENDURANCE PERFORMANCE IN PREPUBERTAL SOCCER PLAYERS

Ferrete, C., Requena, B., Suarez Moreno-Arrones, L., Saez de Villarreal, E.

UNIVERSITY OF PABLO DE OLAVIDE

Introduction Soccer is a sport with participants spanning from childhood to old age. High-intensity movements (i.e., sprinting, jumping or cutting) and low-intensity movements (jogging or standing) occur in varying lengths depending upon an array of factors (i.e., playing position, skill level, style of play, tactical strategies) (Implellizzeri et al 2006). High-intensity actions such as sprinting or vertical jumping are integral elements for success in soccer and therefore need to be trained as part of a periodized youth training program (Hoff et al 2004). No study has analyzed effects occur (<10 yr) and long-term training intervention (>24 wks) in prepubertal. The aim of this study was to examine the effects of an in-season, low-impact (low-volume) strength and high-intensity training program on physical performance among prepubertal soccer players. Methods We examine the effects of a 26-week on-field combined strength and high-intensity training on physical performance in the competitive phase. Twenty-four players between 8-9 years were randomly assigned to 2 groups: control (C) (n=13) (only trained soccer), and experimental group (S) (n=11). Both groups performed the identical soccer training program, while the S group also performed combined strength and high-intensity training before soccer training. The 15-m sprint time (sec), countermovement vertical jump (CMJ) displacement (cm), Yo-Yo intermittent endurance test (Yo-YoE) (m), and Sit & Reach flexibility (cm) were measured before (baseline) and after 9 (T2), 18 (T3) and 26 weeks (post-test) of training. Results There were no significant differences between the groups in any of the variables tested at baseline. After 26 weeks significant improvements were found in CMJ (6.72%; ES = 0.37), Yo-YoE (49.57%; ES = 1.39), and Flexibility (7.26%; ES = 0.37) variables for the S group. Conversely, significant decreases were found in CMJ (-10.82%; ES = 0.61) and Flexibility (-13.09%; ES = 0.94) variables in C group. A significant negative correlation was found between 15m sprint time and CMJ ( $r=-0.77$ ) and Yo-YoE ( $r=-0.77$ ) in S group. Discussion Training intervention used (2 days per week, squats, different type of jumps, sprints exercises) improves jumping performance. Furthermore, the intermittent endurance and hip-flexibility performance were significantly enhanced. These results tend to agree with most of previous studies performed in young soccer players (Chelly et al 2009, Stone et al 2006). Specific combined strength and high-intensity training in prepubertal soccer players for 26 weeks produced a positive effect on performance qualities highly specific to soccer. Therefore, we propose modifications to current training methodology for prepubertal to include strength and high-intensity training for athlete preparation in this sport. ### EFFECT OF A TYPICAL IN-SEASON WEEK ON STRENGTH JUMP AND SPRINT PERFORMANCES IN NATIONAL-LEVEL FEMALE BASKETBALL PLAYERS.

Calleja-González, J., Delextrat, A., Trochym, E.

FACULTY OF SPORTS SCIENCES. UNIVERSITY OF THE BASQUE COUNTRY. LONDON METROPOLITAN UNIVERSITY. LONDON. UNITED KINGDOM.

AIM: The aim of this study was to investigate the effect of a typical in-season week including four practice sessions and one competitive game on strength, jump and sprint performances in national-level female basketball players. METHODS: Nine female basketball players (24.3 $\pm$ 4.1 years old, 173.0 $\pm$ 7.9 cm, 65.1 $\pm$ 10.9 kg, 21.1 $\pm$ 3.8% body fat) participated in ten testing sessions, before and immediately after practices and game (five pre- and five post-tests). Each session involved isokinetic peak torque measurements of the quadriceps and hamstrings of the dominant leg at 60°·s<sup>-1</sup>, countermovement jump (CMJ) and 20-m sprint. Fluid loss and subjective training load were measured during each practice session, while the frequencies of the main movements performed during the game were recorded. A two-way ANOVA was used to assess the effect of each practice/game and the effect of the day of the week on performances, and the relationship between performance variations and variables recorded during practices/game were analyzed by a Pearson correlation coefficient. RESULTS: Individual sessions induced significant decreases in lower limb strength (from 4.6 to 10.9%,  $P<0.05$ ), CMJ (12.6% to 19.6%,  $P<0.05$ ) and 20-m sprint (1.3% to 7.3%,  $P<0.05$ ). Performances returned to baseline before the subsequent pre-test session, except on day 3. CONCLUSION: These impairments in performance highlight that coaches should plan conditioning programmes based on repeated sprint and repeated jump ability, and monitor the recovery of their players' strength, sprint and jump capacities following specific sessions. ### COMPARISON OF DYNAMIC AND STATIC STRETCHING WARM-UP ON JUMPING, SPRINT AND AGILITY RUN PERFORMANCE

Atan, T., Unver, S., Kose, B.

Ondokuz Mayıs University

Introduction Warm-up is one of the most important elements for an exercise program. The purpose of this study was to compare the dynamic and static stretching within a pre-exercise warm-up on jumping, sprint and agility run performance. Methods Thirty male subjects (age 22.00 $\pm$ 1.98 years) attending Physical Education and Sports Department participated the study. Subjects were required to visit the laboratory on 3 occasions, each separated by 48 hours. In the first visit, participants were taken to the laboratory in order to perform

static jump test, 20m sprint test and Illinois Agility Run test to become familiar with the procedure. After 48 hours, these performance test were applied either after dynamic or static stretching warm-up. The order of the 2 conditions was selected randomly to prevent an order effect. Paired t test was used for the statistical analysis. Results Jump power values were found  $3912.80 \pm 770.44W$  after dynamic warm-up and  $3898.26 \pm 1039.49W$  after static warm-up. There was no significant difference among warm-ups for the static jump performance ( $p > 0.05$ ). 20 m sprint speed values were  $6.31 \pm 0.32m/sec$  and  $6.30 \pm 0.36m/sec$  for the dynamic and static stretching warm-up respectively. No significant differences were found between two warm-up stretching for the sprint performance ( $p > 0.05$ ). Illinois Agility Running times were found significantly different between dynamic ( $24184.33 \pm 1172.57ms$ ) and static ( $24792.13 \pm 1504.73ms$ ) stretching warm-up ( $p < 0.01$ ). Discussion Little and Williams's (2006) study supported our finding that they found no significant difference among warm-ups for the jumping performance too. But in the study of Gelen (2008) results showed that, static stretching performed after aerobic exercises of mild intensity was found to hinder vertical jump performance, while dynamic warm-up was found to have a positive effect. No significant difference was found between dynamic and static stretching for sprint performance. Conversely, our results are different to the results of Fletcher and Jones's study (2004). Their main finding was a significantly faster sprint time when active dynamic stretching was incorporated into a warm-up, with significantly slower sprint times observed for subjects employing either static active or passive stretching regimes (Fletcher and Jones 2004). In our study the agility running performance was better after dynamic warm-up than static warm-up. This finding coincides with the results of a previous study. Data from the study by Little and Williams (2006) indicate that the dynamic-stretch protocol produced significantly faster agility performance than did the static stretch protocol. ### CHANGES IN MUSCLE SIZE AND STRENGTH IN RESPONSE TO RESISTANCE TRAINING WITH MODERATE AND HIGH INTENSITIES IN YOUNG WOMEN

Alegre, L.M.1, Aguado, X.1, Rojas-Martín, D.1, Csapo, R.2

*University of Castilla-La Mancha*

1 University of Castilla-La Mancha, Biomechanics Laboratory, Toledo, Spain 2 University of California San Diego, Department of Radiology, San Diego, USA Introduction: Heavy-load resistance training is generally recommended as an important tool to develop and maintain muscle mass and strength, thereby promoting physical fitness and quality of life in healthy adults (1). As compared to heavy resistance training, few studies have investigated the effects of training with moderate loading intensities. The aim of this study was to analyse the changes in knee extensor strength and muscle size in response to resistance training at two different intensities, but similar overall training load. Methods: Fifteen women (age,  $21.7 \pm 2.7$  yrs; mass,  $58.5 \pm 6.8$  kg; height,  $164.6 \pm 5.4$  cm) participated in a 10-week knee extensor strengthening program. One leg (intensity leg, IL) was trained at increasing training intensity [50-80% of one repetition maximum (1RM)], with constant volume throughout the intervention period. The contralateral leg (volume leg, VL) was trained at constant intensity (50% of 1RM), but the number of repetitions was adjusted during the programme to match the mechanical work performed by the IL. At baseline and after training, isokinetic dynamometry was utilised to assess dynamic and isometric strength of the knee extensor muscles. In addition, vastus lateralis and rectus femoris muscle thicknesses were assessed at several locations by ultrasonography. Results: Both measures of isometric and dynamic strength (IL: 10.2-16.2%,  $P < 0.05$ ; VL: 10.1-14.4%,  $P < 0.05$ ) as well as muscle thicknesses (IL: 7.3-12.0%,  $P < 0.05$ ; VL: 7.9-11.0%,  $P < 0.05$ ) increased significantly during the training programme. However, no between leg differences in the training responses were found, although the gains in muscle thickness were larger in the IL by trend. Discussion: The present study shows that, when matched for overall training load, different resistance training protocols provoke comparable gains in muscle strength and size in a group of untrained, healthy young women. The lack of significant differences between training legs in spite of the different intensities may be attributed to a number of factors: 1) The hormonal and genetic environment was the same for the IL and VL. 2) Crossover training effects could have affected the strength gains of both legs (2). 3) A greater overall training load and longer training period could have brought about significant between leg differences. In conclusion, when a 10-wk resistance training programme is matched for training load in healthy young women, different protocols may lead to similar gains in muscle strength and size. ### STRENGTH TRAINING MAY ENTAIL A LOWER OVERLOAD RISK TO KNEE AND ANKLE. AN INFRARED THERMOGRAPHY STUDY

Fernández-Cuevas, I.1, Gómez Ruano, M.1, Kück, M.2, Marins, J.3, Gómez Carmona, P.1, Sillero-Quintana, M.1

*Technical University of Madrid (Universidad Politécnica de Madrid)*

Introduction Skin temperature (T<sub>sk</sub>) has been measured by Infrared Thermography (IRT) during and immediately after exercise (Merla et al., 2010). Depending on the type of exercise and intensity, T<sub>sk</sub> over muscle and joint areas changes, indicating the activation of these areas and the assimilation of workload (Čoh & Širok, 2007). The aim of this study was to analyse differences on the T<sub>sk</sub> response after strength and endurance training. Methods 14 physically active males (age:  $21.44 \pm 2.64$  yrs; height:  $1.78 \pm 0.04$  m; weight:  $73.23 \pm 7.63$  Kg) performed both an endurance [45' treadmill running at moderate intensity (60-75% MHR)] and a strength training [4 sets of 10 repetitions (70% of 1RM) for four exercises involving leg and pectoral]. T<sub>sk</sub> was recorded before the exercise, immediately after, and once every hour during the 8-hour post-exercise period, using an infrared camera (FLIR T335) under controlled conditions. T<sub>sk</sub> from Abdominal, Thigh, Knee and Ankle Region of Interest (ROI) were obtained by TernoTracker® software and for tympanic temperature a ThermoScan® PRO-4000 was used. ANOVA multivariate analyses of repeated measures with training as inter-subject factor were carried out to find significant differences between both trainings. Results: ANOVA multivariate analyses revealed significant differences between strength and endurance training depending on the considered area. Tympanic, and muscle ROI results were not significant ( $p > 0.05$ ). However, the results for Knee and Ankle T<sub>sk</sub> showed significant differences ( $p < 0.001$ ) between both trainings. Knee and Ankle T<sub>sk</sub> in endurance training increased immediately after exercise, before dropping continuously in the following hours. Nevertheless, T<sub>sk</sub> results of Knee and Ankle ROI in strength training underwent the opposite evolution. Discussion: Our results support the influences of exercise on T<sub>sk</sub>, which could be an indicator of the workload assimilation (Čoh & Širok, 2007). We found similar T<sub>sk</sub> evolution in muscle areas, but a significant difference in knee and ankle responses to the endurance and strength training. IRT has been used as injury prevention tool by detecting asymmetries and significant warmer T<sub>sk</sub> values (Hildebrandt et al., 2012). T<sub>sk</sub> reached higher values after endurance training for these ROI. Thus, strength training could entail a lower overload risk for Knee and Ankle areas. References •Čoh, M., & Širok, B. #### PHYSIOLOGICAL AND BIOMECHANICAL ANALYSIS OF THE ARM SWING IN ROLLER SKI SKATING

Hegge, A., Ettema, G., De Koning, J., Sandbakk, O.

*VU University Amsterdam*

PHYSIOLOGICAL AND BIOMECHANICAL ANALYSIS OF THE ARM SWING IN ROLLER SKI SKATING Hegge, AM.1, Ettema, G.2, De Koning, J.1, Sandbakk, O.2 1: VU (Amsterdam, the Netherlands), 2: NTNU (Trondheim, Norway) Introduction In sports such as jumping and running, it has been demonstrated that the arm movement contributes to enhanced performance. These improvements are mainly explained by higher ground reaction forces resulting in an increased take-off velocity of the body's center of mass. Although the upper body movement is regarded highly important for cross-country skiing, with poling demonstrated to enhance skiing performance, the influence of the arm swing has not yet been investigated. In order to understand the contribution of the arm swing in cross-country skiing with the skating technique, the present study compared the G4 leg-skating technique using a pronounced arm swing (SWING) with leg-skating using locked arms (LOCKED) when roller ski skating on a treadmill. It was hypothesized that the arm swing supports the leg work which would enhance the propulsive forces, lead to longer cycle lengths and reduce the metabolic costs. Methods Sixteen male elite cross-country skiers (age 24±4 years, body mass 74.4±7.6 kg, VO<sub>2</sub>max 71.5±3.8 ml•min<sup>-1</sup>•kg<sup>-1</sup>) completed six 4-minute sub-maximal exercise tests in SWING and LOCKED at low, moderate and high speeds. Ventilatory variables were assessed by open-circuit indirect calorimetry and three-dimensional kinematics analyzed using the Qualisys Pro Reflex system. Kinetic variables were measured using roller skis instrumented with full bridge strain gauges. Results SWING generally demonstrated a higher total force impulse and higher peak force at all speeds, with a significant effect of speed on these differences (all P<0.05). Cycle length was longer for SWING at the highest speed (P<0.05). The flexion-extension movement of the legs was more pronounced for SWING with differences between the strong side and weak side legs here. For LOCKED the flexion-extension movement did not differ between the legs. The oxygen consumption was higher for SWING at low and moderate speeds (both P<0.05), while the blood lactate concentration was similar. At the high speed, blood lactate concentration was lower for SWING (P<0.01), while the oxygen consumption was independent of technique. Conclusions Taken together, the arm swing provides the possibility to use a greater flexion-extension movement of the legs and increases the total force production in roller ski skating. Although skiing at a deeper position with LOCKED compensated the reduced ski forces by improved force effectiveness and similar cycle lengths at the two lowest speeds, SWING led to longer cycle lengths and reduced the metabolic stress when skiing at the highest speed.

#### BIOMECHANICALLY RELEVANT EVENTS IN FIGURE SKATING SINGLE JUMPS CAN BE DETERMINED BY UNIAxIAL ACCELERATION DATA

Schäfer, K., Alt, W.

*University of Stuttgart*

Introduction To optimize technique in sports, precise capture of biomechanical relevant events by performance diagnostics procedures is essential. In figure skating, it is challenging to identify events like toe-pick, release of glide leg, take-off and landing in single jumps. Video-based procedures are used for this intention as state of the art (Albert & Miller, 1996; King et. al., 2004). However, accuracy and usability of these procedures is limited. Therefore the purpose of this study is to validate a new method to determine biomechanically relevant events in single jumps by uniaxial acceleration data. Methods Uniaxial accelerometers (Analog Device ADXL78, 37g) were mounted at both skates heels parallel to the leg axis. 13 competitive figure skaters executed 6 proper trials of each single jump. Acceleration data were sampled (3kHz) and jumps were simultaneously recorded by high speed digital camera (Casio Exilim EX-F1, 300Hz). Raw and low pass filtered acceleration data (50Hz) were used to identify events by means of local signal characteristics. Acceleration event time data were correlated (Pearson) with reference data of the high speed video analysis for parallel test validation. Results Events toe-pick and landing are clearly identifiable in raw acceleration data for all jumps (r=0.996-0.999, p=0.000). Take-off event can already be identified by raw data analysis (r=0.990-0.998, p=0.000). Using low pass filtered data provides higher capability for exact take-off identification (r=0.994-0.998, p=0.000). Event release of glide leg event can also be identified by raw data analysis (r=0.972-0.991, p=0.000), using low pass filtered data leads again to higher reliability (r=0.973-0.994, p=0.000). Discussion Acceleration data provide high capability for valid and reliable identification of biomechanical relevant events in figure skating jumps. Using information from raw and filtered data enhances assessing comfort. Further development of this method for real time event detection is possible and offers new opportunities for technique training. References Albert, W. J., & Miller, D. I. (1996). #### AERODYNAMIC DRAG COEFFICIENT OF MODERN SOCCER BALLS

Asai, T., Kazuya, S.

*Inst. of Health and Sports Sciences*

Introduction We conducted a steady-state analysis (Asai and Kamemoto, 2011) of the newest soccer ball—the Adidas Tango 12 (32 panels)—and conventional soccer balls—the Adidas Roteiro (32 panels), Adidas Teamgeist II (14 panels), and Adidas Jabulani (8 panels)—through a wind tunnel experiment, and we clarified the drag coefficient (Cd) and critical Reynolds number. A simple 2D flight trajectory simulation was conducted based on the drag coefficient, and the effects of the drag characteristics on the flight distance and flight trajec-

tory were examined. Methods We measured the aerodynamic forces acting on different types of balls in a low-speed wind tunnel having a  $0.7 \text{ m} \times 0.7 \text{ m}$  rectangular cross section (turbulence level:  $\leq 1\%$ ). Four full-sized official FIFA soccer balls were tested: the conventional balls—the Adidas Roteiro (smooth surface with 32 pentagonal and hexagonal panels, used at UEFA Euro 2004), the Adidas Teamgeist II (small protuberances with 14 panels, used at the 2008 Beijing Olympic Games), and the Adidas Jabulani (small ridges or protrusions with 8 panels, used at the South Africa 2010 FIFA World Cup)—and the newly designed ball—the Adidas Tango 12 (small grip texture with 32 panels, used at UEFA Euro 2012 and the 2012 London Olympic Games). Results The critical Reynolds number of the Roteiro, Teamgeist II, Jabulani, and Tango was  $\sim 2.2 \times 10^5$  ( $C_d = \sim 0.12$ ),  $\sim 2.8 \times 10^5$  ( $C_d = \sim 0.13$ ),  $\sim 3.3 \times 10^5$  ( $C_d = \sim 0.13$ ), and  $\sim 2.4 \times 10^5$  ( $C_d = \sim 0.15$ ). The critical Reynolds number obtained for the Roteiro was the same as that reported by Asai et al. (2007). The standard  $C_d$  values for the Tango 12 and the Jabulani in the supercritical regime were  $\sim 0.18$  and  $\sim 0.15$ , respectively. The average  $C_d$  in the subcritical regime was  $\sim 0.47$ , which was slightly larger than that of the Jabulani ( $\sim 0.44$ ). Discussion Because the Tango 12 has a smaller critical Reynolds number than the Jabulani, it is inferred that the former has lesser aerodynamic resistance than the latter in the medium-speed region ( $11 < U < 19 \text{ m/s}$ ), the near-critical region for the former. The former has greater aerodynamic resistance than the latter in the high-speed supercritical region ( $20 < U < 29 \text{ m/s}$ ). The flight trajectory simulation (Goff and Carré, 2009) suggested that the Tango 12, one of the newest soccer balls, has less air resistance in the medium-speed region than the Jabulani and can thus easily acquire large initial velocity in this region. It is considered that the critical Reynolds number of a soccer ball, as considered within the scope of this experiment, depends on the extended total distance of the panel bonds rather than the small designs on the panel surfaces. ### LANDING TECHNIQUE DOES NOT EXPLAIN THE INJURY DISCREPANCY BETWEEN ELITE AND SUB-ELITE VOLLEYBALL PLAYERS

Janssen, I.1,2,3, Steele, J.R.1, Munro, B.J.1, Brown, N.A.T.2

1: BRL University of Wollongong (Wollongong, Australia), 2: AIS Movement Sciences (Canberra, Australia), 3: NOC\*NSF (Papendal, Netherlands)

Introduction Patellar tendinopathy is the most common overuse knee injury incurred in volleyball (Ferretti et al., 1990) with prevalence in elites athletes more than three times that of their sub-elite counterparts (Lian et al., 2005). It remains unknown, however, whether this discrepancy is a result of between-skill level differences in jump landing technique. Therefore, the purpose of this study was to investigate whether landing technique was moderated by skill level when landing from a lateral block jump. Methods Eight elite male and eight sub-elite male volleyball players, anthropometrically matched, performed a volleyball-specific lateral stop-jump movement. Three-dimensional landing kinematics (250 Hz), kinetics (1,500 Hz), and neuromuscular activation patterns of the gluteus maximus, biceps femoris, semitendinosus, rectus femoris, vastus medialis, and medial gastrocnemius (1,500 Hz) were collected during each trial. Peak patellar tendon force and the patellar tendon force loading rate were also calculated. Independent t-tests ( $p \leq 0.05$ ) with a Bonferroni correction identified whether any between-skill level differences in landing technique were evident. Results Elite volleyball players generated similar patellar tendon loading as the sub-elite players during landing. There were no significant between-skill level differences found in any of the landing kinematic variables. Furthermore, no significant differences in the onset or peak activation of the lower limb muscles relative to the time of the peak patellar tendon force were observed. Discussion This study revealed that the landing technique of elite and sub-elite volleyball players did not significantly differ, and thus technique differences do not explain the discrepancy in patellar tendinopathy prevalence. As patellar tendinopathy is an overuse injury (Richards et al., 1996), it is probable that high jumping and landing volume is the critical factor in developing the injury. Elite volleyball programs are recommended to reconsider performing a high volume of jumping at each training session, particularly for players who perform a high number of lateral stop-jumps, such as middle blockers. Interventions designed to modify the frequency of landings rather than trying to alter landing technique per se are recommended as a possible strategy to reduce patellar tendinopathy prevalence in volleyball players. ### MOVEMENT PATTERNS OF RUGBY UNION PLAYERS PERFORMING SCRUMMAGING AGAINST A SCRUM MACHINE: THE EFFECT OF PLAYING LEVEL AND ENGAGEMENT CONDITION

Trewartha, G., Preatoni, E., England, M., Stokes, K.A.

University of Bath

Introduction The scrum is an important element of rugby union from a performance perspective but has also attracted attention from an injury potential perspective. Little is known about the characteristics of expert technique or the effect of modifying the method of scrum engagement on players' technique. Therefore, our aim was to analyse the movement patterns of rugby union forwards performing scrums against a scrum training machine, taking into account playing level and engagement condition. Methods Thirty-four forward packs ( $n=272$  participants), ranging in playing level from Under 18 age group to Senior International teams, performed repeated scrum trials against an instrumented scrum machine (contact forces measured in three directions at 500 Hz) under five different engagement conditions, designed in part to modify the biomechanical loading experienced by players. Player's whole-body (CM motion), segment (trunk alignment) and joint (ankle-knee-hip) motions were reconstructed in the transverse and sagittal planes via video analysis (Vicon Motus v9.0) at 50 Hz. Results Engagement speeds ranged from 2.3 m/s (U18) to 3.0 m/s (Elite Club) between playing levels in the 'Base' engagement condition, and from 1.8 m/s ('FoldIn') to 2.9 m/s ('Base') between engagement conditions for the International level. 'FoldIn' engagement significantly reduced the maximum value of a combined kinetic/kinematic measure (trunk angle deviation multiplied by peak force) by approximately 50% compared with all other engagement conditions. Assessing player's joint actions in the sagittal plane uncovered few significant differences between playing levels due to within-group variability, but moderate effects were observed for professional players to have more flexed knee and hip joints at movement onset and to more closely maintain a horizontal trunk position throughout all phases of the scrum. Discussion Previous research has not found strong associations between player technique (joint angles) and performance (force production) during the sustained phase of scrummaging (Quarrie & Wilson, 2000; Wu et al., 2007). Our study confirmed that there were not obvious differences between playing levels in sagittal plane motions through all stages of the scrum including the engagement phase, although this was partly due to within-group variability. Modifying the engagement condition to introduce a 'FoldIn' engagement meant the same kinematics (body alignment) were executed in the presence of reduced forces, and there-

for the injury potential was considered to be reduced. References Quarrie K, Wilson B. (2000). *J Sports Sci*, 18, 237-246. Wu, W, Chang, J, Wu, J, Guo, L (2007). *J Strength Cond Res*, 21, 251-258. Acknowledgement Funded by the International Rugby Board

### DIALECTICAL COMPLEXITY APPROACH TO A CONTESTING ATHLETE IN TEAM SPORTS

Lebed, F.1,3, Bar-Eli, M.2,3

1: Kaya Academic College of Education in Beer-Sheva, 2: Ben Gurion University of the Negev, 3: Zinman College of Physical Education and Sport Sciences at the Wingate Institute in Netanya

**Introduction** In the sport sciences, many studies have addressed questions of complexity, for the most part in two often overlapping fields: (a) motor control and learning and (b) behavioural studies focusing on performance analysis in games. Both fields use a dynamical systems perspective for the interpretation of lab and field research data. While it may be relatively easy to accept this approach in the case of motor control and movement coordination studies (Glazier and Davids, 2009), the dynamical systems approach framework appears too narrow for the performance analysis of human behaviour in all the personal, mental, and social contexts that accompany skill performance (Lebed, 2013). **Methodology** The focus of our study is the phenomenon of 'complexity' in human systems acting in extreme conditions of sport contest in team sports. This aspect of a wider study (Lebed and Bar-Eli, 2013) is presented as an interdisciplinary review which (a) develops a complexity perspective on individual and team performance; (b) is methodologically based on the idea of dialectics as a framework for complexity studies. **Discussion** According to the dialectical view, a person engaged in a physical contest constitutes a unique instance of two correlated and coordinated complex systems. The first is the dynamical system that perceives, moves, and flexibly adapts to changing internal and external conditions of motor action. The second is the specific person's mental system, endowed with free will and therefore relatively independent of and unpredictable in terms of environment. We consider the transactional coordination of these two systems to be the 'dialectical complexity' of physically contesting humans. The suggested view makes it possible: (1) to explain both athletes' reactive actions in acute situations of time limit and their planned proactive activity permanently perturbing an opposing complex system; (2) to construct a complete complex framework for individual performance. Such a framework includes: a model of reactive individual performance, a model of proactive construction of mental action, their dialectical complementarity, and a view of individual performance in the context of environment. #### AN ANALYSIS OF HERDING BEHAVIOURS IN BASKETBALL AS A FUNCTION OF SKILL LEVEL

Chow, J.Y.1, Tay, C.S.H.1, Chaturvedi, I.2, Lee, M.C.Y.1, Kee, A.Y.H.1

*Nanyang Technological University*

**Introduction** It is common to observe how beginners demonstrate herding behaviours in such a territorial game (Button et al., 2011). Variation in stretch indices, geometric centers of teams and analysis of randomness of players' behaviours using dynamic Bayesian networks (DBN) during basketball game play can be potentially useful variables to quantify herding behaviours. The aim of this study is to examine the extent of herding behaviours in basketball as a function of skill level and also confirm the suitability of the analytical variables used for this investigation. **Methods** Two games (beginners and skilled) of basketball were captured with a CCTV and players' trajectories determined with an A-Eye software (Barris, 2008). A total of 48 plays for both games (20 for beginner and 28 for skilled) were further analysed to ascertain level of randomness of players' interactions from their trajectories using the DBN with Markov chain Monte Carlo (MCMC) approach. Geometric centres and stretch indices of teams were also established from the identified plays to examine the extent of herding behaviour indicators. Results The correlation probability for interaction between players was significantly lower in skilled games (-7636.4±1229.9) than in beginner games (-6839.9±1519.9), indicating greater randomness in the skilled games. Difference in randomness of winning team from the losing team was found to be much larger in skilled games (-346.03±7947.53) than in beginners (-146.87±3528.64). Speed behaviour of teams prior to a shot was less correlated for the skilled games (83.07±20.01 for beginners and 71.5±17.04 for skilled). Average stretch index was lower in beginners (3.75±0.74) compared to skilled players (5.68±3.5). **Discussion** There is greater randomness for the skilled games and the game dynamics is more complex. The lower stretch indices for the beginners' teams in their games also suggest that the beginners tend to herd near to each other. Findings from this study shows that herding behaviour is more predominant in the beginners' game and the variables used to capture this herding behavior would be relevant to determine the extent of such behaviour, which has useful implications for determining changes in game play behaviours of players as a function of effective practice. #### FAMILIAL, SOCIAL, AND ENVIRONMENTAL FACTORS IN THE DEVELOPMENT OF ELITE AUSTRALIAN CRICKETERS

MacMahon, C., Weissensteiner, J.

*Swinburne University of Technology; \*Australian Institute of Sport*

Previous research characterises elite athletes by a favourable socio-developmental background (Bruce et al., 2012; Hopwood et al., 2012), with effective support structures (Weissensteiner, 2009). Little work has investigated support beyond parents and siblings, including extended family, mentors and peers, or the types of support provided, such as emotional, technical, financial, and informational. A large-

scale online survey collected information on player development in Australian cricketers. This analysis presents the data for the elite male cohort, between the ages of 17 and 35 (N = 81). Just under 50% of the sample indicated that their father was a significant source of all types of support and commonly played competitive cricket (32% at community level, 10% at elite level). Twenty six per cent of fathers had also coached cricket, whether from community up to elite levels. Although a significant source of financial and emotional support, only two players indicated that their mother played competitive cricket. Thirty per cent of the sample indicated that supportive extended family members played cricket, with 14% at community, and 11% at elite level. Supportive mentors who played at elite levels were relatively frequent (38%) and commonly provided emotional, informational and technical support. Similarly, over 50% of the sample identified supportive peers who commonly acted as fellow participants in developmental play and practice, with 46% of these having competed at elite levels. Siblings also provided support as fellow participants and played cricket at community level, with three reported to have played at an elite level. Notably, 41% of the sample indicated they deliberately changed community level clubs to improve their chances of playing at higher levels. None of the participants cited that their parents were the main decision makers in the move, showing autonomous decision making. Those who changed clubs cited opportunity specific to higher levels of competition (64%), better coaching (58%), better playing opportunities (49%), and better training facilities (46%). Only 24% indicated having friends in the new team was a catalyst for changing clubs. The findings from this study demonstrate the breadth of support (sources and type) required to complement the development of elite athletes. While receiving strong support from multiple sources, these elite performers took ownership, sought better developmental opportunities and were relatively autonomous in their decision making specific to their career planning/strategy. These findings support current results in the literature which characterise elite athletes as highly self-regulated (Mathews et al., 2012). Discussion will focus on potential links between support and self-regulation.

### DIFFERENT LEVEL OF TASK VARIATION IN LEARNING A GOLF PUTTING SKILL

Schmidt, M., Hennig, M., Jaitner, T.

*TU Dortmund University*

**Introduction** Many theories such as Schema theory, Contextual Interference or Differential learning propose that varying the task during skill acquisition provokes superior performance in motor learning. However, empirical evidence is mostly based on a comparison of task variation to either blocked or null training. Only few analyze the effects of different amounts of variability on sports skill learning (e.g. Beckmann et al., 2010). The aim of this study was to investigate motor learning of golf putting by systematically increased contextual interference (CI) in comparison to two different protocols following the Differential Learning (DL) approach (Frank et al., 2008). **Methods** 33 students (12 female/21 male) with no prior experience in golf completed eight training sessions within four weeks and performed an overall of 288 puts. Subjects were randomly assigned to three groups: Group CI (n=12) trained with increasing CI, group DL (n=11) and DL+ (n=10) practiced according to the DL approach with high variability including random variations of initial position, amplitudes, movement dynamics and balls. The DL+ group also varied clubs. All subjects passed pretest, posttest and two retention tests (one week, respectively three weeks after posttest). Each test consisted of 10 trials of defined putting length and three transfer tests with different floor material. Average hit ratios were determined for each subject and analyzed group wise by ANOVA. **Results** For the hit ratios over all tests, ANOVA revealed a significant main effect for time only ( $p < .05$ ;  $\eta^2 = .381$ ). Hit ratios improved significantly between pre and posttest, but did not differ for the CI, DL and DL+ group. From post to retention tests performance remained at the same level, with no difference between groups. For the transfer task, no overall effect was found, but post hoc analyses showed that independent of group performance improved significantly between the first and the second test ( $p < .05$ ). **Discussion** Practicing the golf put with contextual interference as well as by differential learning leads to better performance after a 4-week-training period but motor learning seems not be effected by the amount of task variation. Concordant to Beckmann et al (2010) long term learning effects are supported by stable performance in the retention tests of this study whereas for drill learning decreases in performance after the acquisition phase were reported. Performance in the transfer task was comparable low at posttest but the follow up improvements might indicate a high adaptability to differing conditions due to variable training. Further studies are needed to provide deeper insight on these aspects. **References** Beckmann H, Winkel C, Schöllhorn WI (2010). *Int J Sports Psychol*, 41: 5-10. ### COACHES PERSPECTIVES UPON MOTOR DEVELOPMENT WHEN SELECTING TALENTED YOUNG SOCCER PLAYERS

Roas, T., Dalen, T., Aune, T.K., Ingvaldsen, R.P.

*Nord-Trøndelag University College*

**Introduction** The hunt for future top soccer players involves attempts of early selection of the talented children and exclusion of the less talented children (Unnithan et al., 2012). Here we ask, what are the criteria and thinking behind this? Our hypotheses and hope is that there should be a kind of theoretical foundation for this selection process i.e., that some kind of academic perspectives on motor development should underlie the argumentation for the proper selection. Perspectives on motor development can be divided in predeterminedistic and probabilistic epigenesis (Gottlieb, 2000). The purpose of this study was to explore whether this is reflected in top-level coaches' perspectives on motor development when selecting soccer players at a young age. **Method** Four top-level coaches from Norwegian elite soccer teams participated in a semi structured interview, containing both a set of questions and an open conversation concerning motor development and selection. **Results** The coaches were convinced that they could select the right players at an early age (7-12 years). There was, however, no consensus for the criteria for such an early selection. The coaches' were in general leaning to a predeterminedistic understanding of children's development with a clear understanding of some kind of talent as a constant factor in the process over time. One coach saw some problems in this approach, and had a more dynamic view of development, similar to the probabilistic epigenetic perspective. **Discussion** Selection of young soccer players is influenced by coaches understanding of motor development. The results showed that the coaches' understanding is dominated by a predeterminedistic epigenetic perspective. This can lead to early selection of players, with a great risk of choosing wrong (false-positives), or overlooking future elite players (false-negatives). From a probabilistic epigenetic perspective this early selection might be a problem, as a later selection, would increase the probability of choosing the right talent. The results indicate that coaches' perspectives on development influence their will to select players at an early age. Selecting wrong players at an early age can weaken the pool of potential elite players in the future (Reilly & Williams, 2003). **References** Gottlieb G (2000). *Environmental and Behavioral Influences on Gene Activity*. **ON THE STRIDE RATE CHOICE IN RUNNING**

Hansen, E.A., Sardoodian, M., Madeleine, P., Voigt, M.

*Aalborg University*

Introduction Despite considerable amounts of research, key aspects of movement control in running remains to be clarified. It is e.g. unknown what factor(s) that influence an individual's freely chosen stride rate (FCSR). It has been suggested that humans choose stride rates to minimize their energy turnover (Alexander, 2002). However, this may be questioned (Dean, 2013). Further, the literature only provides a single, fair ( $r=0.68$ ), correlation between the energetically optimal and the FCSR during running, for a group of recreational runners (Cavanagh and Williams, 1982). An alternative explanatory approach is to consider the FCSR as a resultant rhythmic movement output from the nervous system including the key element of central pattern generators (Zehr, 2005). The aim of the present study was to test the hypothesis that FCSR during running is highly correlated with FCSR during another form of locomotion namely walking. Methods Recreationally active individuals (11 males and 4 females, age:  $25\pm 8$  years, body mass:  $73.2\pm 11.1$  kg, and height:  $181\pm 8$  cm) walked and ran on a motorised treadmill at 4.0 and 8.4 km per hour, respectively. For each participant and locomotion form, FCSR, as well as contact phase and swing phase durations (in s), were averaged across the two legs from data obtained by contact sensors mounted on the participants' feet. Results The individual FCSR ranged from 53-62 and 72-89 strides per min during walking and running, respectively. In accordance with the hypothesis, there was a high correlation ( $y=1.7x-20.5$ ,  $r=0.89$ ,  $p<.0001$ ) between FCSR during walking (x) and running (y). There was no significant correlation ( $y=-34.4x+88.7$ ,  $r=0.23$ ,  $p=.41$ ) between contact phase duration (x) and FCSR during running (y). The correlation ( $y=-75.6x+117.4$ ,  $r=0.77$ ,  $p=.0008$ ) between swing phase duration (x) and FCSR during running (y) was high. Discussion Although walking and running are distinct in terms of e.g. musculoskeletal loading and energy transfer, these are still related forms of locomotion e.g. with respect to the primary muscles recruited by the nervous system to execute the movements. We found that the FCSR during walking and running were highly correlated. An interpretation of the present results can be that walking and running share some common frequency generating elements in the nervous system. That may support a hypothesis of stride rate during running to being predominantly based on a central motor pattern in contrast to being predominantly based on feedback-dependent optimisation of e.g. energy turnover as previously suggested. **18:00 - 19:30****Oral presentations****OP-BN04 Biomechanics [BM] 4****THE INFLUENCE OF 6 WEEKS OF MAXIMAL ECCENTRIC PLANTARFLEXOR TRAINING ON MUSCLE-TENDON MECHANICS.**

Kay, A.D.1, Richmond, D.1, Talbot, C.1, Mina, M.A.2, Blazevich, A.J.3

*1: UoN (Northampton, UK), 2: UoD (Derby, UK), 3: ECU (Perth, WA)*

Introduction Resistance training can influence muscle-tendon properties including strength, flexibility, stretch tolerance and muscle-tendon stiffness; however the specific influence of eccentric-only training is unknown. Therefore, the aims of the present study were to examine the effects of a 6-week maximal eccentric resistance training programme on isometric plantarflexor moment (MVC), dorsiflexion range of motion (ROM), stretch tolerance (peak passive moment), muscle and tendon stiffness and running economy. Methods Thirteen recreationally active men (age =  $20.0 \pm 0.9$  yr, mass =  $75.9 \pm 8.5$  kg, height =  $1.8 \pm 0.1$  m) volunteered for the study after giving written informed consent; ethical approval was granted from the University of Northampton. Training was performed twice weekly for six weeks and consisted of 5 sets of 12 repetitions of 3-s maximal eccentric contractions at  $10^\circ \cdot s^{-1}$  from  $20^\circ$  plantarflexion to  $10^\circ$  dorsiflexion. Maximal isometric plantarflexor moment, dorsiflexion ROM, stretch tolerance, and muscle, tendon and muscle-tendon unit (MTU) stiffness were measured using isokinetic dynamometry, real-time ultrasound and 3D motion analyses before and after the training. Running economy (VO<sub>2</sub>) was determined at a running speed equating to 70%VO<sub>2</sub>max using online gas analysis. Repeated measures t-tests were used to determine significant differences between pre- and post-training data, significance accepted at  $p<0.05$ . Results A significant increase in plantarflexor MVC (47.1%;  $p<0.01$ ), dorsiflexion ROM (41%;  $p<0.01$ ) and stretch tolerance (108%;  $p<0.01$ ) was found after training, while no change was found in MTU stiffness (passive moment at the same joint angle) using dynamometry (2.5%;  $p>0.05$ ). Analysis of ultrasound data revealed a significant decrease in muscle stiffness (20.6%;  $p<0.05$ ) and increase in tendon stiffness (27.7%;  $p<0.01$ ). These mechanical changes were not sufficient to influence running economy (0.5%;  $p>0.05$ ). Discussion While the training-induced increase in plantarflexor strength was expected, the substantial increases in ROM, stretch tolerance and tendon stiffness, and the reduction in passive muscle stiffness, were important and novel findings. Interestingly, when measured during passive stretch, MTU stiffness remained unchanged while tendon stiffness increased and muscle stiffness decreased. These disparate findings have clear implications for testing methodologies, and indicate that imaging techniques must be utilised in order to examine the effects of interventions on specific tissues. As the training clearly enhanced the capacity of the muscle to tolerate both tissue loading and deformation, which are commonly associated with muscle strain injury, these data have clear implications for both muscular performance and injury risk.

**DOES MUSCLE ACTIVATION ALTER SYNERGISTIC MUSCLE BEHAVIOR?**

Finni, T., Cronin, N.J., Mayfield, D., Lichtwark, G.A.2, Cresswell, A.G.

*Neuromuscular Research Center, Department of Biology of Physical Activity, University of Jyväskylä, Finland*

Few human studies have reported on the possible intermuscular force transmission by observing the relative movements between muscles. Bojsen-Moller et al. (2010) showed that force may be transmitted between the triceps surae muscles in vivo. Tian et al. (2012) further estimated that the magnitude of force that is transmitted between the passive soleus and gastrocnemius muscles is in the order of few Newtons (<5N). This small force probably has very little functional relevance. However, when muscles are activated, intermuscular force transmission may also be greater. Lieber et al. (2000) suggested that activation of a muscle changes the stiffness of the collagen network

surrounding the muscle, which could then influence shear at the interface with other muscles. This study tested the hypothesis that selective activation of a muscle changes the behavior of adjacent muscles, reflecting intermuscular force transmission. 11 volunteers were positioned in an isokinetic dynamometer (Biodex) with the knee joint aligned to the ergometer's rotational axis. The ankle was kept in a constant neutral position by a stirrup attached to the dynamometer lever. A force transducer attached to the stirrup measured plantarflexion torque. Lateral gastrocnemius (LG) and soleus (SOL) muscle fascicles were imaged using ultrasonography at proximal and distal locations. Using transcutaneous electrical stimulations to the LG, we first identified the maximal intensity that produced an M-wave in LG but not SOL. 20 degree knee extension stretches (20deg/s) were elicited from knee angles of 30, 50, 70 and 90 deg. At each angle the stretches were first applied passively and then during LG stimulation. Two consecutive recordings were done in each condition. Brief contractions of the plantarflexors preceded each stretch protocol to minimise thixotropic effects. Differences in muscle fascicle length changes during the passive and active stretches were compared with a three factor ANOVA (muscle\*joint angle\*condition) with Bonferroni –corrected pairwise comparisons. SOL and LG fascicles responded differently to the stretch ( $p < 0.001$ ). An interaction between muscle, joint angle and condition was found and differences were localized to LG at 70 and 90 deg angles reflecting less stretch in the active vs. passive condition ( $p < 0.05$ ). This difference is likely due to excessive slack in the muscle-tendon unit at small knee joint angles. Activation of LG did not change SOL fascicle behavior leaving the hypothesis unsupported. References Bojsen-Møller et al 2010 J Appl Physiol 109(6):1608-18 Lieber et al 2000 Cells Tissues Organs 166(1):48-54 Tian et al 2012 J Appl Physiol 113(4):517-23

### STANCE LIMB KINETICS OF OLDER MALE ENDURANCE RUNNING PERFORMANCE

Diss, C.E.1, Gittoes, M.J.R.2, Tong, R.J.2, Kerwin, D.G.2

1: University of Roehampton (London, UK), 2: Cardiff Metropolitan University (Cardiff, UK)

**Introduction** Clear health benefits are evident for older adults who maintain participation in exercise and physical activity (Tarpennig et al., 2004). The isolated effects of disuse and ageing on athletic performance have however been difficult to differentiate. Biomechanical studies examining ageing in athletic activities have typically recruited untrained older adults (Wang, 2004), and have focused on extending insight into injury aetiology (Fukuchi et al., 2008). Exposure to regular athletic training may contribute to a reduced rate of decline in distance running performance. Therefore the aim of this study was to develop an understanding of the age-based, lower limb kinetics of running performances of male endurance athletes for the purpose of assisting in the development of customised coaching and training strategies for master athletes. **Methods** Six running trials were performed by each of 24 male endurance athletes, who were distinguished by three distinct age groupings (S32: aged 26 to 32 years, M50 aged 50 to 54 years, M60+: aged 60 to 68 years). Lower limb coordinate and ground reaction force data were collected using a nine camera infra-red system (Vicon 612, 120 Hz) synchronized with a force plate (Kistler, 1080 Hz). Lower limb kinetics including joint stiffness measures and step characteristics were determined and compared for each age grouping. Results A slower horizontal (mean±SD S32 =  $4.13 \pm 0.54$  m·s<sup>-1</sup>; M60+ =  $3.34 \pm 0.40$  m·s<sup>-1</sup>,  $p < 0.05$ ) running velocity was associated with significant ( $p < 0.05$ ) decreases in step length and vertical ground contact force at amortization between the M60+ and S32 athletes. The M60+ athletes simultaneously generated a 32 % and 42 % reduced ( $p < 0.05$ ) normalised ankle joint moment at amortization when compared to the M50 and S32 athletes. While a similar ankle and hip joint stiffness during pre-amortization was evident between groups, the M60+ athletes exhibited a substantially reduced (72%,  $p < 0.05$ ) knee joint stiffness during the respective phase when compared to the S32 athletes. **Discussion** The age-based reduction in the ankle moment was partially attributed to decreased lower leg muscular force generation which has previously been associated with age (Wang, 2008). As a function of ageing the knee joint demonstrated a decline in the ability to tolerate applied stretching during the stance phase of running. Therefore, joint-specific (particularly for the ankle and knee) coaching strategies customised to athlete age are warranted to maintain or enhance dynamic performance in master athletes. ### AGE-RELATED FASCICLE-TENDON INTERACTION IN REPETITIVE HOPPING

Hoffrén-Mikkola, M.1, Ishikawa, M.2, Avela, J.1, Komi, P.V.1

University of Jyväskylä

1: Department of Biology of Physical Activity, University of Jyväskylä, Finland. 2: Osaka University of Health and Sport Sciences, Japan. **Introduction** Recent studies suggest that increasing age influences the fascicle-tendon interaction during walking (Mian et al. 2007) and jumping (Hoffrén et al. 2007). However, these studies examined only one exercise intensity (walking speed / dropping height) that was the same in absolute terms for both age groups. Because neural activation and therefore also fascicle-tendon interaction are intensity-specific in a non-linear fashion (Finni et al. 2001) and neuromuscular capacities of the young and the elderly are totally different, measuring only one exercise intensity may have influenced the interpretations. Therefore, the object of the present study was to examine occurrence and possible reasons for the age-specific behavior of fascicles and tendons and their interaction during hopping with different intensities. **Methods** Nine young and 24 elderly subjects performed repetitive hopping with maximal effort as well as with 50%, 65%, 75% and 90% intensities. During hopping joint kinematics and ground reaction forces were measured together with recordings of ultrasound images of both the fascicle and the muscle-tendon junction part of the gastrocnemius medialis muscle (GaM). **Results** The results showed that fascicle behavior during the braking phase of hopping was clearly age-specific in nature with more fascicle shortening in the young ( $p < 0.001$ ). In addition, the fascicle shortening increased in young subjects with increasing hopping intensity ( $p < 0.05$ ). At the instant of ground contact the elderly subjects demonstrated decreased fascicle length with increasing hopping intensity ( $p < 0.01$ ). Thereafter in the braking phase, the elderly showed much smaller changes in fascicle length as compared to the young. In contrast to the fascicles, the GaM outer tendon did not show major age-specific differences in stretching and shortening amplitudes during hopping although the peak tendon forces were clearly lower in the elderly ( $p < 0.001$ ). **Discussion** These results suggest that GaM outer tendon behavior is not influenced greatly with increasing age. It is further suggested that when aging modifies the fascicle-tendon interaction, it is primarily due to the age-specific difference in the fascicle level. This notion poses a question that as compared to the young, the elderly individuals may have a different fascicle behavior for optimal stretch-shortening cycle locomotion such as hopping. ## RAPID STRETCHING OF THE ACTIVATED AGEING MUSCLE INDUCES FAVORABLE MECHANICAL, MORPHOMETRIC, AND HORMONAL CHANGES

Váczai, M.1, Bogner, P.2, Kőszegi, T.1, Ambrus, M.1, Nagy, S.2, Perlaki, G.2, Orsi, G.2, Tóth, K.2, Hortobágyi, T.3

1: PTE (Pécs, Hungary), 2: PDK (Pécs, Hungary), 3: UG (Groningen, The Netherlands) Introduction In young populations stretch-shortening cycle (SSC) training has been used for about 50 years to improve athletic performance, and has been shown to increase explosive strength, power, elastic energy storage and reutilization (Sáez-Sáez de Villarreal et al., 2010), and muscle fiber cross-sectional area (Malisoux et al., 2006). We tested the hypotheses that (1) SSC training can induce favorable mechanical, morphometric, and hormonal changes in the ageing muscle, and that (2) the magnitude of these changes is different after SSC vs. eccentric training. Methods Sixty to seventy-year old physically active males performed either SSC (n = 8) or slow velocity eccentric (n = 8) quadriceps training contractions on Multicont II dynamometer 2 to 3 times per week for 10 weeks. Total work performed in the two groups was identical. The SSC training comprised contractions with high peak torque and low duration, while the eccentric training contractions were characterized by lower peak torque and longer duration. Maximal isometric torque, rate of torque development (RTD), eccentric impulse, and quadriceps cross-sectional area (CSA) were evaluated, and serum testosterone and cortisol responses to an acute resistance exercise were measured before and after the training program. Ratio of positive SSC work and pure concentric work was measured to assess elastic energy storage and reutilization. Results All mechanical variables improved uniformly after the two training regimens, except RTD, which improved only after SSC training. Quadriceps CSA increased more after eccentric vs. SSC training. Resting testosterone and cortisol were unchanged, but acute reductions in testosterone to cortisol ratio (induced by the acute resistance exercise) was smaller after both trainings. Conclusions SSC training is effective in improving various mechanical properties of the ageing muscle, however, except explosive strength, it was not superior to eccentric training. Eccentric training induced greater hypertrophy than SSC did, indicating that duration vs. peak torque in the contraction is more favorable stimulus. Acute testosterone to cortisol changes indicate favorable hormonal adaptations in both trainings. We conclude that SSC training is effective in the treatment of sarcopenia in healthy, physically active elderly. References Sáez-Sáez de Villarreal E, Requena B, Newton RU. (2010). *J Sci Med Sport*, 13, 513-522. Malisoux L, Francaux M, Nielens H, Theisen D. (2006). *J Appl Physiol*, 100, 771-779.

## COMPARATIVE ANALYSIS OF THE RHYTHMIC STRUCTURE FOR THE 400 METRES HURDLES EVENT AT THE WORLD CHAMPIONSHIPS OF DAEGU 2011 AND BARCELONA JUNIOR 2012

López, J.L.1, Padullés, J.M.2, Tugores, F.3, Álamo, J.M.4, Rovira, N.3, Portas, A.3, Leal, S.3

1: *Universitat de Vic-GREAF (Vic, Spain)*, 2: *INEFC- SSRG UB (Barcelona, Spain)*, 3: *UVic (Vic, Spain)*, 4: *UB (Barcelona, Spain)*

Introduction Rhythmic structure (or stride pattern) on the 400 metres hurdles event can be defined as the number of strides an athlete takes between the hurdles. It's connected to the choice of the lead leg, which can have an impact on the final results achieved. Methods Purpose: To analyse the rhythmic structure in the 400 metres hurdles event at the IAAF World Championships, Daegu 2011 and Junior Barcelona 2012. The study sample was made up of all the 159 athletes participating at the 400 metres hurdles in both championships: 34 men and 38 women in Daegu; 51 men and 36 women in Barcelona. All the races were recorded using 5 Casio Exilim F1 high speed cameras placed in different spots along the stands. The images were analysed using Kinovea 0.8.4 software. The values analysed were the number of strides to the first hurdle, between hurdles, from the last hurdle to the finish line, lead leg at each hurdle, number of hurdles on the curve taken with left-leg lead, stride pattern repetition during the 3 races for the finalists, hurdle in which there is a pattern change and the number of rhythmic structures changes in both championships. Results Men: Daegu and Barcelona respectively, 63.18 % and 49.40 % of them used a left-leg lead (63.8 % and 51.21 % on the curve). Women: 51.86 % and 53.89 % (54.3 % and 58.13 %). At Daegu, there were 33 different stride patterns for men and 40 for women. At Barcelona, there was only one repetition of the stride pattern during the preliminary rounds, semi-final and the final for men. All the rhythmic structures used at the women's final round were different. None of the finalist women at both championships used the same stride pattern during the 3 races, and only 2 finalist men in Daegu and 1 in Barcelona did it. At the Junior championship, both men and women changed their stride pattern mainly on the 6th hurdle (the 7th in Daegu). Finalists in Barcelona changed their stride pattern less often than athletes at the preliminary and semi-final rounds. Discussion There are significant differences between the times achieved and the total number of strides in both championships ( $p < 0.05$ ). Junior athletes are advised to improve their strength in order to get a better take-off ability, as well as a better hurdle clearance technique. There are numerous well differentiated rhythmic structures in both championships. There are major differences ( $p < 0.05$ ) between the lead leg of choice during the whole event and the lead leg used on the curve by men and women at the final. Over 90% of the athletes, both men and women, change their stride pattern during the race at least once.

#### ANTICIPATORY REGULATION DURING REPEATED SPRINTS IS BASED ON LOCOMOTOR MUSCLE FATIGUE

Billaut, F.1,2, Hibbert, A.2, Zois, J.2

1: *Institut national du sport du Québec (Montréal, Canada)*, 2: *College of Sport and Exercise Science, Victoria University (Melbourne, Australia)*

Introduction Factors influencing pacing or avoidance strategies have not been well examined during intermittent exercise. We previously reported the adoption of pacing strategies based on the knowledge of the number of sprints to be performed consecutively (Billaut et al., 2011). Here, we further tested the hypothesis that performance is determined by a mechanism of anticipatory regulation for the avoidance of excessive locomotor muscle fatigue. Methods Nine subjects performed four trials in random order, involving one (S1), two (S2), four (S4) or six (S6) sets of five 5-s sprints (power self-selected) with 25 and 120 s of rest between sprints and sets, respectively. Mechanical work

and total electromyographic intensity (summed quadriceps electromyograms, RMSsum) were calculated during every sprint. Peripheral muscle fatigue was assessed via pre- to post-exercise change in potentiated quadriceps twitch force ( $\Delta Q_{tw,pot}$ ). Voluntary activation (VA) was used to quantify completeness of quadriceps activation. Results Work performed in the first sprint (7.8%) and first set (5.2%) was lower in S6, compared to S1 ( $P < 0.05$ ). Average work performed across all sets was lower in S4 (9.1%) and S6 (12.3%), compared to S1 ( $P < 0.05$ ). Work done in the last set was not different between S4 and S6 ( $P = 0.99$ ). RMSsum data followed a similar pattern. Astonishingly,  $\Delta Q_{tw,pot}$  was not different across the four trials ( $\sim 40\%$ ,  $P = 0.55$ ). VA was more reduced in S4 (5.8%) and S6 (8.3%) than S1 ( $P < 0.05$ ). Discussion Results show that the decrease in performance during repeated sprints is not directly linked to energy stores. Rather, based on projected "finishing points" and afferent feedback, athletes regulate exercise intensity and hence metabolic rate to ensure the rate at which peripheral muscle fatigue develops is similar in all trials, so the organism can anticipate and avoid excessive fatigue. This supports the concept of integrative central regulation of effort (Marino et al., 2011). References Billaut F, Bishop DJ, Schaefer S, Noakes DT (2001). *Med Sci Sports Exerc*, 43(4), 665-672. ### RESIDUAL FORCE ENHANCEMENT – A BENEFICIAL MUSCULAR PROPERTY?

Hahn, D., Seiberl, W., Paternoster, F., Schwirtz, A.

*Technical University of Munich, Faculty of Sport Science*

**INTRODUCTION** Although the phenomenon of residual force enhancement (RFE) is well known and has been systematically observed from single sarcomeres to in vivo human muscles, its relevance for everyday movements performed with submaximal efforts remains unclear. Therefore, the aim of this study was to investigate the idea of RFE being a more effective and energy saving muscular property during an everyday like submaximal multi-joint leg extension. **METHODS** Subjects ( $n = 13$ ) performed bilateral isometric (100° knee flexion) and stretch contractions (80-100° knee flexion at 60°/s with subsequent isometric contractions) in a motor driven legpress dynamometer at submaximal efforts of 30% vastus lateralis (VL) EMG (EMG-control) and 30% Fmax (force-control), respectively. Further, subjects performed purely isometric and stretch contractions at 50% force-control until time to failure. External reaction forces were measured by 3D force plates and activity of 9 lower leg muscles was assessed using EMG. Kinematics were analysed by a VICON system and inverse dynamics served for calculating ankle, knee, and hip joint torques. Visual feedback of VL EMG or external reaction force was given to control submaximal efforts. **RESULTS** For EMG-control we found no differences in VL activity between isometric and stretch contractions but significant RFE at the level of external reaction forces and joint torques. During isometric contractions after stretch, forces and joint torque exceeded the purely isometric references up to 22% and were present for up to 22s post stretch. For force-control preliminary results showed no differences in external reaction forces between contraction types but vice versa to EMG-control, less muscular activity was required to produce the given force of 30% Fmax during the isometric contraction after stretch. After stretch, activity of knee extensor and plantar flexor muscles was reduced up to 38% and 48% compared to the purely isometric contractions. The time to failure contractions showed that after stretch a given force of 50% Fmax could be maintained longer than during an isometric contraction without preceding stretch. **DISCUSSION** Although former studies demonstrated the existence of RFE for submaximal contractions, this is the first study to show RFE to occur during an everyday like multi-joint leg extension performed with submaximal effort. In the light of being beneficial for everyday movements the finding of reduced activity after stretch when producing a given force might be more important than the ability of generating higher forces during EMG-control. Further high correlations between time to failure and muscular O<sub>2</sub>-consumption suggest the mechanisms underlying RFE to be energy saving. **ACKNOWLEDGEMENTS** This work was funded by the German Research Foundation (SCHW1169/3-2) – www.dfg.de.

### NEUROMUSCULAR RECRUITMENT AND COMMON DRIVE OF THE KNEE EXTENSORS FOLLOWING ACUTE ACCENTUATED ECCENTRIC LOAD

Hunter, A.M., Pahar, M., Balshaw, T.G.

*University of Stirling*

**Introduction** Resistance exercise performed with overload of the eccentric phase (AEL) can lead to superior strength gains compared to constant load (CL) exercise (Hortobagyi et al., 2001). Initially, strength adaptations occur from increases in neural drive (Selvanayagam et al., 2011); therefore, it is possible that acute altered neural responses could contribute to this stimulus. Our aim was to investigate motor unit recruitment and common drive (CD) (motor unit discharge rate) following AEL in comparison to CL protocols at 2 different eccentric velocities (4 or 2 seconds). **Methods** Ten healthy males attended the laboratory on 4 separate occasions in random order to perform a maximal isometric voluntary contraction (MVC) followed by a 10 second submaximal trapezoid contraction (70% of MVC)(TRAP) during which high density EMG (De Luca and Hostage., 2010) recorded firing rates of motor units from the vastus lateralis (VL). CD was then analysed from the 3-second plateau phase of the TRAP with the greatest reliability. Then, the participants either did CL (2s), AEL (2s), CL (4s) or AEL (4s). AEL and CL consisted of eccentric load at 120% and 85% of 3RM respectively. All conditions consisted of a concentric load of 85% of 3RM which consisted of 3 x 3, and then MVC and TRAP was repeated. Global EMG was also recorded from the VL during these contractions and was normalised to baseline dynamic strength tests. **Results** For all interventions no alterations were shown in MVC following exercise, also no differences occurred in concentric velocity between conditions. Normalised EMG amplitude (RMS) was significantly ( $p < 0.01$ ) greater in the eccentric phase in AEL vs. CL for both fast (f) and slow (s) contractions [AEL:  $193.7 \pm 6.5\%$  f  $192.7 \pm 6\%$  s CL:  $145.3 \pm 5\%$  f  $135.4 \pm 5\%$  s]. No differences were observed between conditions for CD. For all conditions peak cross-correlation histogram frequency appeared in the range of 0.6 to 0.7 and no differences were shown for maximum and mean peak cross-correlation coefficients ( $p > 0.05$ ). **Discussion** Despite the additional load maximal force capacity of the knee extensors was maintained following AEL. Although there was an increase in motor units recruited during the eccentric phase of AEL there was no alteration in common drive following the intervention. This has therefore demonstrated that AEL increases motor unit recruitment but not in residual common drive in response to a heavier load. Thus, it is likely that neuromuscular responses in the eccentric phase of AEL are responsible for superior adaptations previously reported. ### ANKLE DESTABILISATION DEVICE FOR INJURY PREVENTION OR REHABILITATION IN SPORTS

Paizis, C., Fautrelle, L., Baroudi, A.R., Deley, G., Babault, N.

*University of Burgundy*

**Introduction** Numerous epidemiological studies demonstrated that lateral ankle sprain (LAS) is a recurrent problem in athletes (Hootman et al. 2007). Further to LAS, residual symptoms could arise and about 70% of the athletes who suffered from acute LAS develop chronic ankle instability (Hertel 2002). At the muscular level, evertor muscles strength is an essential factor in order to ensure ankle stability (Wilkerson et al. 1997). In this study, we proposed to investigate the modulation of the EMG activity of 6 ankle muscles (on the right and left leg) when wearing an ankle destabilisation device (ADD) in different situations. We hypothesized that ADD would significantly modify the amplitude of the EMG pattern of the ankle muscles, especially in peroneal muscles. **Methods** Twelve healthy active subjects without previous history of neuromuscular disease or acute LAS volunteered for the experiment. Subjects were required to walk forward and backward, on both sides and in circles, with or without the ADD. They were then asked to maintain unipodal equilibrium with a Freeman board. Kinematics and surface electrical activities were recorded on six muscles of both legs, namely the tibialis anterior, peroneus longus, peroneus brevis, gastrocnemius lateralis, gastrocnemius medialis and soleus. EMG activity recorded during each experimental condition was normalized by the EMG activities recorded during a maximal voluntary isometric contraction. **Results** Electromyographic recordings showed a significantly increased activity during dynamic equilibrium but also when wearing ADD during normal walk forward and backward, circle walking in both directions ( $P < 0.05$ ). **Discussion** Our findings evidenced that walking in different conditions with ADD generates a significant increase in electromyographic activity of tibialis and both peroneus muscles, and therefore suggest that ADD are a valuable resource for functional strength training, sensory-motor rehabilitation and prevention of the ankle injury. **References** Hootman JM, Dick R, Agel R. ### REDUCED TYPE IA AFFERENT FEEDBACK DOES NOT INFLUENCE QUADRICEPS MAXIMAL AND EXPLOSIVE ISOMETRIC FORCE PRODUCTION IN MAN

Fry, A., Folland, J.P.

*Loughborough University*

**Introduction** The role of afferent feedback in maximal motor tasks remains poorly understood. Whilst it has been suggested that a reduced efficacy of the  $\gamma$ -loop following tendon vibration may impair maximal voluntary force, the limited previous studies have been equivocal in their findings. Furthermore, the effect of vibration, and attenuation of the  $\gamma$ -loop, on explosive force production is unknown. The aim of this study was to investigate the role of afferent feedback in maximum and explosive isometric force production of the quadriceps, using a prolonged tendon vibration to attenuate the Ia afferent- $\alpha$ -motoneuron pathway. **Methods** Eighteen healthy males ( $21 \pm 2$  years) performed a series of voluntary and evoked isometric unilateral knee-extensor contractions pre and post two separate 30-min intervention trials of: infrapatellar tendon vibration (80 Hz) and quiet sitting (control), 7 days apart. Participants performed six explosive and two maximal force contractions to assess volitional function, and supramaximal twitch and octet responses were evoked to assess the contractile properties of the muscle-tendon complex. The efficacy of the Ia afferent- $\alpha$ -motoneuron pathway was determined by assessing the H-reflex ( $H_{max}:M_{max}$  ratio of the vastus medialis) at rest, at the start and end of each series of volitional and evoked contractions, pre and post intervention (i.e. at four time points). Participants remained seated in a strength testing chair throughout the trials, with knee and hip angles of  $120^\circ$  and  $105^\circ$ , respectively. Force was measured via a strain gauge strapped perpendicular to the tibia, and surface EMG was recorded from six sites over the quadriceps and two over the hamstrings. **Results** Post-intervention  $H_{max}:M_{max}$  was 60% lower in the vibration trial vs. control, and remained 38% lower at the end of the post-intervention measurements (t-test, both  $P < 0.01$ ). In contrast, no trial  $\times$  time interactions were found for either maximum force (ANOVA,  $P = 0.92$ ) or explosive force (at 50, 100 and 150 ms after force onset; ANOVA, all  $P \geq 0.36$ ), or their corresponding mean agonist EMG amplitude (ANOVA, all  $P \geq 0.23$ ). Evoked responses were also unchanged following vibration (ANOVA, all  $P \geq 0.39$ ). Individual  $H_{max}:M_{max}$  depression did not correlate to changes in either maximum or explosive force (Spearman's Rank, all  $P \geq 0.54$ ). **Discussion** The reduction in H-reflex demonstrated that the vibration stimulus effectively attenuated the homonymous Ia afferent- $\alpha$ -motoneuron pathway for the duration of the post-intervention measurements. However, voluntary maximal and explosive force production remained unchanged. Therefore, Ia afferent feedback does not appear to contribute significantly to either maximal or explosive isometric force production of the quadriceps.

### TORQUE-ANGLE RELATIONSHIPS OF THE ELBOW FLEXORS AND EXTENSORS IN HEALTHY FEMALES

Pencheva, N., Kokova, M., Dencheva, S.

*South-West University*

**Introduction** The aims of this study are: (1) to obtain knowledge of the isometric torque-angle relationship of the elbow flexors and extensors; (2) to explore the impact of the elbow angle on the neuromuscular activity of the biceps brachii – long head (BB-LH) and triceps brachii – long head (TB-LH) by recording sEMG activity; and (3) to evaluate the correlations between the isometric flexor or extensor torque and RMS of the muscles tested. **Methods** Maximal isometric torque of flexors and extensors were measured (Biodex System 4) over a wide range of angles (15-150°) in ten females ( $21.2 \pm 1.4$  years). Agonistic EMG activity and the level of coactivation for BB-LH and TB-LH were also measured. The curve fitting and statistics were performed by Prism software. **Results** The isometric torque-angle curves of flexors and extensors were modeled with 4th order polynomial function. The maximal torque of flexors ( $28.0 \pm 7.5$  Nm) was generated at 90-105° position, while that of extensors ( $28.9 \pm 6.7$  Nm) at 60-75°. The flexors/extensors torque ratio was lower, equal or higher than 100% in the angular positions of 15-75°, 90° or 105-150° respectively. Agonistic EMG activity level of the BB-LH, as RMS, was correlated to measured torque of flexors, within the range of 75-150° (Spearman's  $r = 0.82$ ), while that of TB-LH did not correlate with extensor's torque. The antagonist activity for both muscles was low and did not result angle-dependent. **Discussion** In this study we found that the skew part (tail) of the non-linear, asymmetric torque-angle curve of flexors is situated in the left part of the measured range, while that of extensors, in the right one. These findings and the respective agonistic RMS-angle curves for BB-LH and TB-LH, seem to correspond at some extent to the force-length and to the moment arm-angle relationships (Ada et al., 2003; Pinter et al., 2010). However, the lack of correlation between extensor torque and activity of TB-LH can be explained by lower isometric functional capacity of the long head, which according to Murray et al. (2000) has shorter moment arm, as compared with that of BB-LH. Although, we found low and independent of elbow angle antagonistic activity of both muscles, it is hard to predict the size of crosstalk and the degree of underestimation of the maximal elbow torque, especially for extensors. **References** Ada L, Canning CG, Low ShL. #### THE MEDIATION OF MASTERY ORIENTED CLIMATE BETWEEN COACH INITIATED PROSOCIAL FEEDBACK AND PROSOCIAL BEHAVIOR IN SPORTS

Wagnsson, S., Patriksson, G., Lindwall, M., Strahlman, O., Nyberg, C.

*Institution of health sciences*

**Introduction** Sport involvement has the potential both to improve and to inhibit youth's moral attitudes and behaviour. However, whether the path of development is positive or negative is largely dependent on the structure of their sport environment. Since coaches are one of the most salient socialization agents, variations in coaching approaches are thought to influence the direction of youth moral development. We therefore hypothesized that coach initiated prosocial feedback (CIPF) would positively be related to self-reported prosocial behavior (PB). Moreover, since variations in perceived motivational climate have shown to be associated with character building qualities, we hypothesized that different aspects of motivational climate would mediate the relation between CIPF and PB. **Methods** Longitudinal data were collected at two occasions (1 year between T1 and T2) including 808 Swedish youth sport participants (60% boys and 40% girls; M=13.9 years at baseline). The CIPF scale (T1) included five items (e.g., "My coach/coaches use to talk with us about the importance to obey rules"). Moreover, shortened versions of Perceived Motivational Climate in Sport Questionnaire-2 (Newton, Duda & Yin, 2000) and Prosocial Tendencies Measure (Carlo & Randall, 2002) were used to measure PMC (at T2) and PB (at T2) respectively. Mediation analyses with bootstrapping approach was conducted using the INDIRECT macro for SPSS. **Results** The path between CIPF and mastery oriented climate (MMC) was positive and significant ( $B=.10$ ,  $SE=.03$ ,  $p<.05$ ), as well as the path between MMC and PB ( $B=.21$ ,  $SE=.04$ ,  $p<.01$ ). Moreover, both the total effect ( $B=.09$ ,  $SE=.03$ ,  $p<.01$ ), and direct effect ( $B=.07$ ,  $SE=.03$ ,  $p<.05$ ), of CIPF on PB were significant. More importantly, the bootstrap analyses demonstrated significant indirect effects ( $\alpha\beta=.02$ ,  $SE=.01$ ,  $p<.05$ ) showing a mediating effect of MMC in the relationship between CIPF and PB. Significant paths for performance oriented climate (PMC) were only found in relation to PB ( $B=-.17$ ,  $SE=.04$ ,  $p<.01$ ). However, the indirect effect of PMC was not significant. **Discussion** Results from this study show that sport may have beneficial effects on youth's moral behaviour, both directly (i.e., having coaches discussing and promoting prosocial behaviors), and indirectly by influencing a MMC. Moreover, results indicate that endorsing a PMC will reduce youth's tendencies to act in a prosocial manner. Our study also highlights the important role of the coach when forming a sport environment that either facilitates or debilitates youth's moral development. **References** Carlo G, Randall BA. (2002). *J Youth Adolesc*, 31, 31-44. Newton M, Duda J L, & Yin Z. (2000). *J Sports Sci*, 18, 275-290.

#### QUALITATIVE ANALYSIS OF A SELF-DETERMINATION THEORY-BASED INTERVENTION IN SCHOOL TO PROMOTE PHYSICAL ACTIVITY

González-Cutre, D., Montero-Carretero, C., Beltrán-Carrillo, V.J., Sierra, A.C., Cervelló, E.

*Centro de Investigación del Deporte. Universidad Miguel Hernández de Elche*

**Introduction** Interventions to promote physical activity and its associated benefits are necessary from early ages, being the school and excellent environment to achieve this goal (Biddle et al., 2004). Self-determination theory (SDT) has been useful for the development of motivational strategies applicable to this type of interventions (Fortier et al., 2012). The purpose of this study was to analyze, from a qualitative perspective, the effects of a school-based intervention centered in satisfying the basic psychological needs for autonomy, competence and relatedness, and to develop positive motivation for the promotion of physical activity in adolescents. **Methods** The intervention was carried out with students in the last course of secondary school (15-16 years old), through a teaching unit in physical education (PE) for the promotion of physical activity and health (15 sessions); a voluntary extracurricular physical activity program of 6 months (three sessions of one hour per week); and three meetings with parents. The PE intervention and the physical activity program were conducted by two different teachers with training in the use of motivational strategies based on SDT. To analyze the intervention effects, a content analysis was carried out with the data coming from the following qualitative techniques: two focus groups with the students who showed the highest assistance rate to the physical activity program; a focus group with parents; and the research diary of the teacher of the physical activity program. **Results** The results showed the adolescents' satisfaction of basic psychological needs during the intervention, highlighting the need for relatedness. Furthermore, intrinsic motivation and identified regulation in PE and in the extra-curricular physical activity program was observed. The intervention produced the following positive effects: enjoyment and satisfaction, learning and personal improvement, and in some cases physical activity adherence. The effects were associated to the use of different motivational strategies. **Discussion** This study provides support for the use of SDT to design and implement interventions to promote physical activity (Fortier et al., 2012). Some strategies related to the intervention effectiveness were identified: students' participation in the decision making process; autonomy support for the participation in physical activity; novelty and variety in tasks; positive feedback centered in personal improvement; music use; teachers' involvement and caring climate. **References** Fortier MS, Duda JL, Guerin, E, Teixeira PJ (2012). *Int J Behav Nutr Phys Activ*, 9, 20. ## MOTIVATION IN ADOLESCENTS' PHYSICAL ACTIVITY OF TWO EUROPEAN COUNTRIES

Aibar, A.1,2, Zaragoza, J.1, Generelo, E.1, Nicaise, V.3, Paillard, T.2, Bois, J.E.2

<sup>1</sup>University of Zaragoza (Huesca, Spain) <sup>2</sup>University of Pau and Countries of Adour (Tarbes, France) <sup>3</sup>University Claude Bernard (Lyon, France)

**Introduction** Self-determination theory (SDT; Ryan & Deci, 2000) has become a usual theoretical approach in order to understand the motivational factors that influence physical activity (PA; Teixeira et al., 2012). However, there remain some inconsistencies according to the relations between specific SDT constructs and PA (Teixeira et al., 2012). This study was aimed to improve the knowledge of motivational factors' impact on adolescent's PA of two European countries (France and Spain). **Method** The sample consisted of 806 adolescents (51% Spanish) with a mean age of 14.33±0.73 years. Objective PA was measured during a 7-day period by the GT3X accelerometer and subjective PA by the Assessment of PA Levels Questionnaire. The Sport Motivation Scale was used to measure PA motivation. After confirmatory factor analysis, four motivational latent variables (intrinsic, identified, introjected and external regulation) were included. A structural equation model (SEM) was built where motivational variables predicted subjective PA, which in turn predicted objective PA. Gender and age served as control variables. A multi-group analysis for testing measurement invariance across groups (Spain-France) was conducted. Mplus Version 6.1. was used to conduct all analysis. **Results** The SEM revealed good fit to the proposed model ( $\chi^2(325, N=806) = 988.47, p<.001$ ; CFI= .91, TLI: .89, RMSEA=.071, SRMR=.061). The subjective PA was found to positively predict objective PA. Whilst intrinsic and introjected motivation were significant predictors of subjective PA, external motivation showed a negative association. Relations between latent variables and observed variables were invariant across countries. **Discussion** More intrinsic levels of motivation were found to predict subjective PA (Barbeau et al., 2009). Despite the introjected regulation showed also positive associations, the strength of this association were lower compared to intrinsic regulation. Agreeing with the current literature (Teixeira et al., 2012), a negative association between external regulation and PA was revealed. These findings support the premises of SDT (Ryan & Deci, 2000). **References** Barbeau, A. Sweet, S.N. & Fortier, M. (2009). ## EXPLORING STIGMATISATION OF EATING DISORDERS IN SPORT

McArdle, S., Meade, M.M., Moore, P., Madigan, S., MacManus, C.

1: DCU (Dublin, Ireland), 2: UJJ (Jordanstown, Ireland), 3: MMU/ISIS (Manchester, England; Dublin, Ireland), 4: IIS (Dublin, Ireland), 5: IIS (Dublin, Ireland)

**Introduction** Recent studies have shown that stigma is the most significant perceived barrier to help seeking for young athletes (Gulliver, Griffiths, & Christensen, 2012). Stigmatising attitudes towards individuals with eating disorders have been found to exist in the general population and in more targeted populations such as professionals working in mental health care (Roehrig & McLean, 2010; Thompson-Brenner, Satir, Franko & Herzog, 2012). Little is known about the beliefs or attitudes of support staff working in the sport context towards eating disorders. Identifying the nature of stigmatizing attitudes associated with eating disorders in support staff is important in informing the implementation of initiatives targeted at stigma reduction. The aim of this study was to explore stigmatizing attitudes towards athletes with eating disorders amongst support staff in sport. **Methods** A mixed methods design using both quantitative and qualitative methods was employed. One hundred and fifty coaches, sport nutritionists, sport dieticians, physiotherapists and strength and conditioning coaches were recruited to complete an on-line survey. Participants read four vignettes describing athlete specific cases of Anorexia Nervosa, Bulimia Nervosa, Depression and Burnout and answered questions assessing stigma toward athletes with these four problem areas. Follow-up qualitative interviews were conducted with 15 support staff specifically targeted at exploring stigmatising attitudes towards athletes with eating disorders. **Results** While many of the attitudes expressed by service providers and coaches were generally positive, some negative attitudes were also apparent. Qualitative interviews allowed further exploration of stigmatizing attitudes in sport personnel and the ways in which stigma extended into language use and behaviour. **Discussion** Results support the need to adopt a system approach to target stigma reduction towards eating disorders in sport. Support staff need to be aware of the subtle ways stigma influences their language and their approach to working with athletes with eating disorders. **References** Gulliver, A., Griffiths, K. M., & Christensen, H. (2012). Barriers and facilitators to mental health help-seeking for young elite athletes: a qualitative study, *BMC Psychiatry*, 12, 157. Roehrig, J. P., & McLean, C. P. (2010). ## MOTIVATION, BODY WEIGHT CONTROL AND PHYSICAL EXERCISE: EVALUATION BETWEEN MEN AND WOMEN

Rosa, J.P.P.1,2, Lira, F.S.1,2, Lima, G.H.O.2, Silva, E.A.1,2, Rodrigues, D.F.1,2, Lemos, V.A.1,2, Tufik, S.1,2, De Mello, M.T.1,2

Universidade Federal de São Paulo

**Introduction:** Adherence to a regular physical exercise programme involves a number of factors that might influence the adoption and maintenance of the regular practise of physical activity. This study evaluated body weight control and its effect on the levels of motivation. **Methods:** 39 volunteers (16 men's and 23 women's) who were grouped by BMI into normal weight (NW n=16), overweight (OW n= 15) and obese (OB n=8) groups. A Bod Pod® device was used to establish the body mass of each participant with means Age (years) 34.2±8.77, Height (cm) 166.46±8.64, Weight (kg) 68.59±24.30 and BMI (kg/m<sup>2</sup>) 24.62±8.09. Level of motivation to begin a programme of physical exercise were assessed via a translated version of the BREQ-2 (Markland D, Tobin VA ,2004) and IMPRAF-54 (Barbosa MLL, Balbinotti AAM., 2006). **Results:** Male participants tended to have greater body weights (p<0.01), heights (p<0.01), amotivation scores (p<0.01) and competitiveness scores (p<0.01) compared with females. Females exhibited a higher percentage of body fat (p<0.01) than males. Comparisons among the participants according to the BMI group (NW,OW,OB) to which they belonged. Significant positive correlations between BMI and the stress control (r=0.30; p<0.05) and competitiveness (r=0.40; p<0.05) dimensions of the IMPRAF were found, as was a significant negative correlation between BMI and the health dimension of the IMPRAF (r=-0.36; p<0.05). There were also positive correlations between the body fat percentage, stress control (r=0.39; p<0.05) and competitiveness (r=0.45; p<0.05) dimensions of the IMPRAF. The external regulation scores from the BREQ-2 were negatively correlated with the IMPRAF stress control scores (r=-0.41; p<0.05), and the BREQ-2 scores for introjected and intrinsic regulation were positively correlated with the IMPRAF competitiveness (r=0.39; p<0.05) and stress control scores (r=0.42; p<0.05) **Discussion:** Males were less motivated by external influences, females had a stronger tendency to let emotional matters affect their level of involvement in physical exercise programmes. Cognitive-behavioural strategies are needed to increase and maintain the frequency or intensity of an exercise regimen, regardless of BMI (Dalle Grave et al.,2011). These strategies are

necessary because the regular practise of physical activity can result in countless physical and mental benefits for human beings.(De Mello et al., 2005). References: Markland D, Tobin VA. ### **CONSIDERING TEMPORAL EVOLUTION OF DEPRESSIVE SYMPTOMATOLOGY: A LONGITUDINAL STUDY INVOLVING PHYSICAL ACTIVITY**

Vachon, H.1, Thomas-Ollivier, V.1, Sauvaget, A.2, Vanelle, J.M.2, Fortes-Bourbousson, M.1

1: UFR STAPS, Université de Nantes, 2: CHU, Nantes

**Introduction** Numerous studies highlight the effect of physical activity (PA) on depressive symptoms (for a review, see Mead et al., 2008). However, most of these studies only compared changes of psychological variables before and after PA programs. Such nomothetic approaches are limited to precisely characterize the role of PA on psychological functioning (Ninot et al., 2005). To go beyond, the Ecological Momentary Assessment (Shiffman et al., 2008) permits to assess within-subject psychological variations in the individual life's context and so to capture psychological variations due to exercise as soon as they occur. Because depressive symptomatology refers to a large spectrum, five psychological dimensions strongly implicated in depressive disorder were assessed: global self-esteem, rumination, anxiety, quality of life and depression. The purpose of this study is to identify the temporal evolution of depressive symptomatology when individuals are submitted to constraints in everyday life and to investigate the effect of a PA program. **Methods** Three groups participated to this study: control subjects without physical activity (GC; n=8), depressed patients without physical activity (GD; n=8) and depressed patients with physical activity (GDPA; n=8). All subjects self-evaluated through a short questionnaire assessing self-esteem, rumination, anxiety, quality of life and depression, twice a day during three months. GDPA participated to supervised exercises (active walking) for a one-hour session three times per week, during three months. Analysis of variance was performed on descriptive statistics (mean, SD, range), probability of acute change (PAC), and mean square successive difference (MSSD). **Results** Supervised physical activity is in progress and results of GDPA will be presented at the ECSS conference. Significant differences between GC and GD were observed for the five dimensions regarding mean ( $p < 0,001$ ), standard-deviation (pDep;Rum;Anx $< 0,001$ ; pGSE;QoL $< 0,05$ ), MSSD ( $p < 0,001$ ; pGSE $< 0,05$ ) and PAC ( $p < 0,001$ ; pGSE $< 0,05$ ). **Discussion** The effect of PA will be discussed through two orientations. First, we will identify if groups are different only when considering psychological variable levels (e.g. self-esteem means) or also for criteria considering temporal variability. Second, we will discuss if PA affects each variable in similar way or if some psychological dimensions are more influenced. **References** Mead, G.E., Morley, W., Campbell, P., Greig, C.A., McMurdo, M., and Lawlor, D.A. #### **EFFECTS OF SHORT-TERM EXERCISE-TRAINING ON TISSUE DOPPLER INDICES OF LEFT VENTRICULAR DIASTOLIC FUNCTION IN OVERWEIGHT AND OBESE INDIVIDUALS.**

Millen, A.M.E., Norton, G.R., Avidon, I., Woodiwiss, A.J.

*University of the Witwatersrand*

**Background:** Exercise training has consistently been shown to be unable to improve obesity-associated decreases in left ventricular (LV) diastolic function as assessed using chamber rather than myocardial function measurements. However, the effect of exercise training on LV diastolic myocardial function as assessed using Tissue Doppler Imaging (TDI) is uncertain. **Methods:** In the present study in 32 overweight (n=11) or obese (n=21), sedentary or recreationally active men and women (30–57years), we aimed to assess the effect of 6 weeks of exercise training either preceded (n=16) or followed (n=16) by a 6 week control period on TDI-derived parameters of LV diastolic function ( $e'$ ,  $e'/a'$  and  $E/e'$ ) (echocardiography). **Results:** Baseline measures of diastolic function were comparable with those noted in overweight and obese participants from a community sample (n=245) and 56% (n=18) had baseline  $e'$  values (early diastolic abnormalities) that were below the lower 95% confidence intervals of a lean and healthy cohort (n=60) of the community sample. Exercise training increased peak oxygen consumption from  $27.4 \pm 4.9$  to  $29.4 \pm 5.8$  mL.kg<sup>-1</sup>.min<sup>-1</sup> ( $p=0.0001$ ); but had no effect on body mass index ( $p=0.99$ ). No changes in TDI indices of LV diastolic function were observed after exercise training in all participants ( $e'$ :  $p=0.74$ ,  $a'$ :  $p=0.98$ ,  $e'/a'$ :  $p=0.85$ ;  $E/e'$ :  $p=0.26$ ), in participants with abnormal  $e'$  values (n=18) ( $e'$ :  $p=0.99$ ,  $a'$ :  $p=0.96$ ,  $e'/a'$ :  $p=0.91$ ;  $E/e'$ :  $p=0.97$ ) or in obese participants only (n=21) ( $e'$ :  $p=0.67$ ,  $a'$ :  $p=1.00$ ,  $e'/a'$ :  $p=0.78$ ;  $E/e'$ :  $p=0.11$ ). **Conclusion:** Exercise training alone, despite producing an improved cardiorespiratory fitness is unable to improve obesity-associated decreases in LV diastolic myocardial function.

#### **CARDIORESPIRATORY FITNESS AND RISK OF SUDDEN CARDIAC DEATH IN NORTH AMERICAN MEN AND WOMEN. A PROSPECTIVE STUDY**

Jiménez-Pavón, D., Artero, E.G., Lee, D.C., España-Romero, V., Sui, X., Pate, R., Church, T., Lavie, C.J., Moreno, L.A., Blair, S.N.

*University of Zaragoza*

**INTRODUCTION** Sudden cardiac death (SCD) is recognized as a relevant cause of death within the general population. Moreover, a good cardiorespiratory fitness (CRF) level is associated with lower risk of all-cause mortality in adults. However, little is known about the association of CRF and SCD. The present study was conducted (1) to examine the relation between CRF and SCD in a large population of adults. (2) To study the specific roles of hypertension, obesity and health status on the previous relationship. **METHODS** The current report is based on prospective data from the Aerobics Center Longitudinal Study (ACLS). A total of 55,456 individuals (13,507 women) with a mean age of 44.2 years, whose baseline examination took place between 1974 and 2002 were included in the study. The CRF was

assessed by a maximal treadmill test using a modified Balke protocol and categorized as low, moderate and or high according to gender- and age-specific distributions of maximal exercise duration from the ACLS population. The baseline assessment included an extensive physical examination and an array of clinical measurements such as age, sex, body mass index, physical activity, current smoking, alcohol intake, hypercholesterolemia, diabetes mellitus, hypertension, abnormal electrocardiogram, cancer and parental history of cardiovascular disease. Cox proportional hazard regression was used to estimate hazard ratios, 95% confidence intervals according to CRF categories after adjustments for the baseline assessment. RESULTS There were 109 deaths from SCD (average follow-up of 14.7 years). An inverse risk of SCD was found across CRF levels after adjustments for potential confounders. Participants in the middle and upper CRF levels had 43% and 48% significantly lower risk of SCD, respectively, compared with those in the lower level in the multivariate-adjusted model ( $p < 0.001$ ). The risk of SCD was 14% lower per 1-MET increase in the fully-adjusted model. Those participants identified as hypertensive, overweight or unhealthy and with moderate or high CRF levels had lower risks of SCD that ranged from 59% to 72% compared with those with the same medical conditions and low CRF. DISCUSSION The risk of SCD in men and women can be significantly attenuated by ensuring moderate to high CRF, and this benefit is independent of other risk factors. A highlight is that in particularly vulnerable groups such as hypertensive, obese or unhealthy individuals this protective effect of CRF may substantially lower the risk of SCD. CRF testing should be considered for SCD risk screening in asymptomatic men and women.

### RELATIONSHIP BETWEEN CARDIO-RESPIRATORY FITNESS, PHYSICAL ACTIVITY AND ARTERIAL STRUCTURE AND COMPLIANCE IN CHILDREN

Böhm, B., Elmenhorst, J., Müller, J., Barta, C., Oberhoffer, R.

*Technische Universität München*

OBJECTIVE: Atherosclerosis can begin early in life [1] with endothelial dysfunction, arterial stiffening and wall thickening, whereas functional impairment is considered to be the earliest detectable manifestation. Evidence suggests that exercise enhances endothelial function in subjects with impaired function [3], also demonstrated in obese children, where exercise training enhances NO-mediated vasodilatation [2]. However, the complex mechanism between cardio-respiratory fitness, physical activity, endothelial function and structure is not yet fully understood in healthy children and investigations on possible relationships are rare. METHODS: 119 children (53 girls) with median age of 12.3 years; (interquartile range (IQR) 11.9 – 12.9 years) and median body mass index standard deviation score of 0.06 (IQR -0.93 – 1.18) were examined. Children had high-resolution ultrasound sonography (ProSound, Hitachi/Alokal) on the A. carotis communis measuring intima-media thickness (cIMT), arterial compliance (AC) and stiffness ( $\beta$  index). Flow-mediated dilatation (FMD) was measured at the A. brachialis using a continuous eTRACKING mode, analyzing changes in blood flow velocity and arterial diameter at baseline, after 5 minutes of ischemia and 3 minutes after vasodilatation. Cardio-respiratory fitness was tested by a symptom limited pulmonary exercise test on a bicycle ergometer (Ganshorn Medical). Physical activity was assessed using GT3x accelerometer (Actigraph, USA). RESULTS: Physical fitness (peak  $\text{VO}_2$ ) was inversely correlated to carotid ( $r = -0.246$ ,  $p = 0.012$ ) and brachial ( $r = -0.208$ ;  $p = 0.036$ ) stiffness indices. Time in sedentary lifestyle was inversely correlated to carotid AC ( $r = -0.210$ ;  $p = 0.034$ ); time in high intensive activity levels was negatively correlated with the brachial stiffness index ( $r = -0.286$ ;  $p = 0.004$ ). No significant relations between cIMT and physical fitness as well as physical activity exposed. Regarding brachial endothelial function girls revealed higher ( $p = 0.004$ ) arterial stiffness and lower arterial compliance ( $p = 0.004$ ) than boys. Furthermore, girls spent less time ( $p = 0.001$ ) in moderate activity than boys. CONCLUSIONS: This research is suggestive of the fact that cardio-respiratory fitness and physical activity are associated with arterial function but not with arterial structure. Girls seem to be at higher cardiovascular risk than boys due to less physical activity, demonstrating higher arterial stiffness and lower compliance. Further research need to clarify the mechanisms of early arterial (dys)-function and the impact of exercise intensity on them. ### EFFECT OF EXERCISE AND PHYSICAL ACTIVITY COUNSELLING ON CARDIOVASCULAR RISK FACTORS

Mann, S., Beedie, C., Allgrove, J., Jimenez, A.

*University of Greenwich*

Background: Little research has examined fitness centres as hubs for community interventions aimed at increasing physical activity (PA) and reducing cardiovascular (CV) risk. The present study aimed to assess the effectiveness of fitness centre based interventions; unstructured (FREE) / structured exercise (STRUC) and physical activity counselling (PAC). Methods: Participants ( $n = 105$ , 73 female) were recruited for either PAC ( $n = 18$ -age= $44.5 \pm 4.96$ ) or fitness centre based exercise (FREE= $44$ -age= $42.5 \pm 4.89$  STRUC= $43$ -age= $43.39 \pm 4.27$ ). Participants underwent assessments measuring; predicted maximal aerobic capacity ( $\text{VO}_{2\text{max}}$ ), body composition, blood pressure (BP), cholesterol profile, resting heart rate (RHR) and muscular strength (predicted one-rep max (1RM)), before and after a 12 week intervention period. Participants received accelerometers. Results: Significant ( $P < 0.05$ ) improvements were found in systolic-BP (PAC: 132 – 129 vs FREE: 130 – 125 vs STRUC: 137 – 130 mmHg), body fat mass (PAC: 34.32 – 32.06 vs FREE: 28.48 – 26.73 vs STRUC: 32.85 – 30.85 kg), total cholesterol (PAC: 4.97 – 4.68 vs FREE: 4.46 – 4.35 vs STRUC: 4.85 – 4.82 mmol/L, RHR (PAC: 80 – 71 vs FREE: 71 – 67 vs STRUC: 78 – 73 bpm) and leg press strength (PAC: 91 – 126 vs FREE: 90 – 135 vs STRUC: 93 – 140 1RM kg) in all three groups. Significant differences were found between groups in chest press (PAC: 40.93 – 41.84 vs FREE: 43.77 – 48.45 vs STRUC: 39.01 – 48.89 1RM kg), lat pull down (PAC: 50.94 – 56.5 vs FREE: 54.68 – 61.15 vs STRUC: 52.08 – 60.82 1RM kg), and diastolic-BP which improved significantly in STRUC only (PAC: 80 – 80 vs FREE: 74 – 74 vs STRUC: 83 – 79 mmHg). Weekly energy expenditure increased significantly in all three groups; STRUC was the only group to produce a significant correlation between week and energy expended ( $r = 0.91$   $P < 0.01$ ). Conclusion: Fitness centre based interventions increased the PA levels of participants and improved CV risk factors. Fitness centres may be able to provide community hubs to increase PA and reduce CV risk.

### LONG-TERM EFFECT OF A PHYSICAL ACTIVE LIFESTYLE ON ARTERIAL STIFFNESS IN SAPALDIA 3

Endes, S., Caviezel, S., Dratva, J., Schindler, C., Schaffner, E., Gaspoz, J.M., Rochat, T., Kuenzli, N., Probst-Hensch, N., Schmidt-Trucksass, A.

*Institute of Exercise and Health Sciences*

Introduction: Lack of physical activity (PA) is one condition that is associated with increased arterial stiffness, and consequently with increased risk of cardiovascular events. Therefore, this study aimed at analysing the association between PA at baseline and arterial stiffness assessed by the cardio-ankle vascular index (CAVI) after a mean follow-up time of 8.34 yrs. Methods: CAVI was measured in the second follow-up of the Swiss Cohort Study on Air Pollution and Lung and Heart Diseases in Adults (SAPALDIA 3) using a VaseraVS-1500

vascular screening system (Fukuda Denshi) in supine position after 15 min of rest. A short questionnaire about PAs of the last 7 days was administered within SAPALDIA 2 to classify the subjects' PA level at baseline (inactive: <150 min getting out of breath and <2-3 hrs sweating per week due to PA; moderate: either ≥150 min out of breath or ≥2-3 hrs sweating; vigorous: both ≥150 min out of breath and ≥2-3 hrs sweating). The analyses involved ANOVA and multivariable regression models and included 1776 persons aged 49-81 yrs (868 males, 908 females, 63.4±7.9 yrs) with a normal ankle brachial index (0.9≤ABI≤1.3). Results: The PA groups did not significantly differ regarding the cardiovascular risk factors adjusted for in the final regression model: age, sex, BMI and systolic BP (of SAPALDIA 2 and 3) and baseline HDL cholesterol. The PA level at baseline was significantly associated with CAVI in SAPALDIA 3 with 8.56 (SD 1.1) in those with vigorous activity versus 8.68 (SD 1.09) among the inactive (p=0.005). CAVI did not differentiate between the PA levels "moderate" and "inactive" (p=0.388). Discussion: A physically active lifestyle may slow down or reduce arterial stiffening in an ageing population in the long-term if performed with a vigorous intensity. Future analyses will focus on changes of PA over time in association with CAVI and the promotion of cardiovascular health.

#### REMOTE EFFECTS OF OCCLUSION TRAINING ARE ASSOCIATED WITH ELEVATIONS IN SALIVARY TESTOSTERONE

Beaven, C.M., Kilduff, L.P., Cook, C.J.

*Mid Sweden University*

Purpose: To examine the effects of moderate load resistance exercise with and without intermittent blood flow restriction (BFR) on strength, power and repeated sprint ability, along with acute and chronic levels of salivary hormones. Methods: In a cross-over design, twenty male semi-professional rugby union athletes were randomly assigned to a lower-body BFR intervention (an occlusion cuff inflated to 180 mmHg worn on the proximal thighs during all exercise sets) or a control intervention that trained without BFR. Experimental sessions were performed three times a week at the same time of day for three weeks with 5 sets of 5 repetitions of bench press, leg squat and pull-ups performed at 70% of 1-repetition maximum. Saliva was collected before and after the first experimental training session of each week. Strength and power, as well as repeated sprint performance was assessed prior to, and at the conclusion of the experimental period. Results: Significantly greater improvements in bench press (5.4 vs 3.3 kg), squat (7.8 vs 4.3 kg), leg power (168 vs 68 W), maximum sprint time (0.03 vs 0.01 s) and repeated sprint performance maintenance (1.01 vs 0.28%) were observed following the BFR intervention. Salivary testosterone (Effect Size: 0.84 to 0.61) and cortisol concentrations (ES: 0.65 to 0.20) were acutely elevated following the BFR intervention sessions compared to the controls; however the cortisol increase was attenuated across the training block (p=1.12x10<sup>-5</sup>). Baseline salivary testosterone was also significantly elevated across the 3 week training blocks with BFR training compared to the controls (p=0.0284). Exercise-induced elevations in testosterone were correlated to performance improvements for leg squat strength (r=0.68; p=0.0005), bench press strength (r=0.45; p=0.0233), and countermovement jump power production gains (r=0.46; p=0.0201). Conclusions: BFR training was shown to improve the rate of strength training gains and fatigue resistance in trained athletes, possibly allowing greater gains from lower loading which could be of benefit during high training loads or in competitive seasons. The clear improvement in bench press strength resulting from lower-body occlusion suggests a systemic effect of BFR training. It is of interest to note that there was an association between adaptation and alterations in acute and chronic salivary testosterone levels that could speculatively provide a simple correlative marker of the adaptive response.

#### EFFECTS OF EXERCISE-INDUCED ARTERIAL HYPOXEMIA ON CATECHOLAMINE RESPONSE TO MAXIMAL EXERCISE

Durand, F., Guezennec, C.Y.

*Performance Health and Altitude Laboratory*

Introduction Many athletes show significant exercise-induced arterial hypoxemia (EIAH) at maximal exercise. EIAH was primarily associated with an excessively widened alveolar to arterial PO<sub>2</sub> difference, which was not sufficiently compensated by hyperventilation (Hopkins 2006). Ventilatory response was insufficient to compensate for the underlying excessive alveolar to arterial O<sub>2</sub> difference (Durand et al. 1998). Elsewhere hypoxia increases sympathetic system activity via hypoxia-induced stimulation of the carotid chemoreceptor. This enhanced catecholamine response participate to hypoxia induced hyperventilation during physical exercise. It could be hypothesized that a reduced catecholamine response to intensive exercise could be involved in the mechanism of EIAH. Methods Twenty males endurance-trained subjects (mean age 26±1.2yr) divided in two group, one group (n=10) of athletes without exercise induced hypoxemia (HTN), one group (n=10) of athletes with a previously identified exercise-induced hypoxemia (HTH) performed an incremental exercise on ergocycle until exhaustion (30 w.min<sup>-1</sup>). Blood samples were drawn from brachial artery before the test and at the end of last load. The training volume was of 12.7±0.6 h. weeks<sup>-1</sup> in HTN and 16.3 ± 1.1h.weeks<sup>-1</sup> in HTH. Results The athletes reached same maximal oxygen consumption (62.2 ± 1.9 vs 63.8 ± 1.6 ml.min<sup>-1</sup>.kg<sup>-1</sup>) and same maximal ventilation (161 ± 4.5 vs 156.4 ± 1.6 L.min<sup>-1</sup>) with slightly lesser maximal power in HTH without statistical significance (360 ± 12 vs 343 ± 10 W). Blood gases analysis evidence a significant fall (p≤0.05) in PaO<sub>2</sub> of 16 ± 1.5 mmHg from rest to maximal exercise in HTH and higher PaCO<sub>2</sub> (p≤0.05) at the end of exercise (32.5 ± 1.2 vs 36 ± 1.6 mmHg). Plasma catecholamine assays evidences lesser increase at the end of exercise in HTH compared to HTN (Epinephrine 1203 ± 214 vs 1863 ± 355; Norepinephrine 5132 ± 708 vs 7565 ± 785.09 pg.ml<sup>-1</sup>). The difference remain after 5 min of recovery. Discussion These data evidence that EIAH is associated with a reduced sympathetic response to exercise. This could be responsible for an impaired ventilation/perfusion ratio at pulmonary level (Barman 1998) by the ways of an action on pulmonary circulation which need more investigations. The lesser catecholamine response observed here could be due to a possible overreaching in HTH athletes which is sustained by the lesser maximal power in spite of same aerobic capacity and greater training volume in HTH. ### THE EFFECT OF PROLONGED ERYTHROPOIETIN EXPOSURE AND ENDURANCE TRAINING ON INTRAMYOCYLLULAR LIPID CONTENT IN YOUNG UNTRAINED INDIVIDUALS

Christensen, A., Nielsen, J., Nellemann, B., Vestergaard, P.F., Stødkilde-Jørgensen, H., Jørgensen, J.O.L., Christensen, B.  
*University of Southern Denmark*

**Introduction** It is well known that aerobic training increases the content of mitochondria and intramyocellular lipid (IMCL) within skeletal muscle (Hoppeler 1986). Recent studies indicate that recombinant human erythropoietin (EPO) may activate mitochondrial biogenesis (Carraway et al. 2010) and increase fat oxidation (Hojman et al. 2009). In the present study, we aimed to investigate the effect of EPO and endurance training on IMCL content of untrained individuals. We hypothesized that EPO and training would lead to increased IMCL content and that there would be an additive effect of the two interventions on IMCL content. **Methods** Young (range: 18-35 years), non-smoking, untrained men were randomly assigned to 1 of 4 groups: 1) placebo (PL) (n=8), 2) EPO (E) (n=8), 3) placebo and training (PLT) (n=8), and 4) EPO and training (ET) (n=7). Training consisted of supervised ergometer cycling for 40 min at 65% of maximal watt 3 times pr. week for 10 weeks. The EPO groups were given 40 µg rHuEPO (Darbepoietin alpha) for the first 3 weeks and 20 µg the last 7 weeks. IMCL of the anterior tibial muscle was assessed by <sup>1</sup>H magnetic resonance spectroscopy (Madsen et al. 2012). Data was log-transformed before analysis and values are presented as % of baseline (geometric means) and 95% confidence interval for the means. Results EPO treatment increased hematocrit by 12% in E and 13% in ET. There were no additive effect of EPO and endurance training (P = 0.32) or main effect of EPO (P = 0.80) on IMCL content (PL: 87% (60-127); E: 101% (59-170) ; PLT: 151% (90-256) ; ET: 116% (64-209)). However, endurance training tended to increase IMCL (PL and E: 93% (70-124); PLT and ET: 134% (94-189); P = 0.09). **Discussion** Our findings suggest that prolonged EPO exposure has no major effect on IMCL content in sedentary controls or any additive effect on endurance training-mediated increase in IMCL content as assessed by <sup>1</sup>H magnetic resonance spectroscopy. Thus, any effect of EPO on IMCL is less pronounced or different compared to the effect of endurance training. However, considerations of fiber phenotypes and subcellular localization of IMCL should be considered for a complete evaluation of the effect of EPO on IMCL content. **References** Carraway et al. (2010). *Circ Res*, 106(11),1722–1730 Hoppeler H. (1986). *Int. J Sports Med.*, 7,187-204. Hojman P et al. (2009). *Plos One*, 4,6,e5894 Madsen et al. ### TESTOSTERONE BUT NOT PROTEIN SUPPLEMENTATION INFLUENCES THE MAINTENANCE AND GROWTH OF SKELETAL MUSCLE FOLLOWING IMMOBILIZATION

Hanson, E.D., Betik, A.C., O'Connor, M., Truong, J., Hayes, A.  
*Victoria University*

**Introduction** The loss of testosterone with aging or as a consequence of prostate cancer treatment has adverse effects on muscle mass and function. Protein supplementation and resistance training both have been used to mitigate these declines. However, studies are lacking that combine these complementary therapies in hypogonadal populations and that examine the mechanism(s) responsible for hypertrophy in the absence of testosterone. Using immobilization and subsequent reloading as a model of resistance exercise, this study examined the effects of testosterone and protein supplementation on muscle mass and function as a means of reducing the side effects of androgen deficiency. **Methods** Fischer 344 male rats underwent castration or sham surgery and were allowed to recover prior to unilateral hind limb immobilization (Childs 2003). With immobilization and throughout the study, animals were randomized to receive a high protein diet (50%) with branched chain amino acids (150mg/kg/d) added to their drinking water or standard chow (20% protein). Following 10d of immobilization, casts were removed and the animals underwent limb reloading for 0, 6, or 14d before muscles were stimulated *ex vivo* to assess force production. **Results** Body mass was significantly lower in castrated animals following surgery. Immobilized muscle mass was significantly lower in extensor digitorum longus (EDL, -7.8%), gastrocnemius (-20.8%), plantaris (-17.2%), and soleus (-27.7%). Castration also decreased muscle mass (-5%) but there was no effect of diet. Immobilized muscle mass increased with reloading but was not completely restored. Force production (stimulated at 10-100 Hz) was reduced in both EDL (-21.4 to -26.0%) and soleus (-45.4 to -74.7%) with immobilization but only soleus force recovery was influenced by castration over the time course of the study with no influence of diet. **Discussion** Recent work in humans suggests that load-mediated muscle hypertrophy may be independent of testosterone (West 2010, Hanson 2012), which contradicts previous findings (Galvao 2006, Kvorning 2006). The group differences in total body and muscle mass and greater force declines with immobilization in castrated animals support the hypothesis that testosterone is important for maintaining skeletal muscle but similar mass and force measurements in sham and castrated rats after 14d of reloading suggests testosterone-independent hypertrophy. The lack of dietary influence on muscle mass is contradictory to previous findings (Baptista 2010, Yamamoto 2010), although this may be related to differences in dose and models of atrophy. **References** Childs, TE, Spangenburg EE, et al. ### EFFECTS OF SHORT-TERM SIMVASTATIN TREATMENT ON MITOCHONDRIAL FUNCTION AND APOPTOSIS IN PRIMARY HUMAN SKELETAL MYOTUBES

Kwak, H.B.  
*Inha University*

**Introduction** Statins (3-hydroxy-3-methylglutaryl coenzyme A reductase inhibitors) are cholesterol-lowering drugs widely used in the treatment of cardiovascular disease (Koh et al., 2011). However, statins also cause adverse side effects in skeletal muscle ranging from fatigue to fatal rhabdomyolysis. Recently, we found that long-term (48 h) treatment of simvastatin induced cell death due to impaired mitochondrial respiration and oxidative stress leading to mitochondrial apoptotic signaling in primary human skeletal muscle cells (Kwak et al., 2012). The purpose of this study was to determine the effects of short-term (24 h) simvastatin treatment on mitochondrial respiration, H<sub>2</sub>O<sub>2</sub> emission, apoptotic signaling, and morphological changes in differentiated human skeletal myotubes. **Methods** Primary myoblasts isolated from vastus lateralis in lean male (N=6) were grown and differentiated to myotubes (6 days), and then incubated in differentiation media (0.1% DMSO) with or without simvastatin (5 µM) for an additional 24 hours. The myotubes were harvested and permeabilized by digitonin (3 µg/10<sup>6</sup> cells) for determination of mitochondrial respiration and H<sub>2</sub>O<sub>2</sub> emission. In addition, markers of apoptosis (cell numbers, Bax and Bcl-2) and MnSOD protein levels were measured in primary human skeletal myotubes. **Results** After 24 hour incubation, simvastatin treated myotubes (STM) were not changed in morphology and total cell numbers compared with control. In permeabilized cells supported by palmitoyl-carnitine/malate (PCM, complex I and II substrate), basal respiration rate (non-ADP-

stimulated, state 2) was similar between STM and control. However, maximal ADP-stimulated (state 3) oxygen consumption rate showed lower trends ( $P=0.08$ ) in STM supported by PCM. Mitochondrial  $H_2O_2$  emission rate was not affected by short-term STM compared with control. Similarly, 24 h treatment of simvastatin did not have significant effects on the protein levels of Bax, Bcl-2, and MnSOD in primary human skeletal myotubes. Discussion Long-term (48 h) treatment of simvastatin impaired maximal ADP-stimulated mitochondrial respiration, induced mitochondrial oxidative stress, and increased mitochondrial-mediated apoptotic signaling and cell death in primary human skeletal myotubes (Kwak et al., 2012). However, these data demonstrated that short-term (24 h) treatment of simvastatin did not induce atrophy and cell death that is primarily associated with the impairment of mitochondrial function and the activation of mitochondrial apoptosis in primary human skeletal myotubes. #### LACK OF A PHYSIOLOGICAL ROLE FOR ERYTHROPOIETIN IN HUMAN SKELETAL MUSCLE

Christensen, B.1,2, Nellemann, B.1, Thorsen, K.4, Pedersen, S.B.1, Ørnstrup, M.J.1, Jørgensen, J.O.L.1, Jessen, N.3,4  
*1,3,4 Aarhus University Hospital, 2 Aarhus University*

Background: Erythropoietin (Epo) is considered a pleiotropic hormone, but the presence of Epo receptor (Epo-R) in human skeletal muscle tissue has been debated, mainly due to a lack of specificity of the Epo-R antibodies used to identify Epo-R's in skeletal muscle tissue (1). In addition, we have previously shown no activation of the signalling pathways downstream of the Epo-R (2), further questioning a physiological role for Epo in human skeletal muscle tissue. Aim: The aim of the current study was to thoroughly evaluate Epo's prolonged effects on skeletal muscle; large-scale analysis of mRNA expression was performed by gene array analysis. Furthermore, a new and highly sensitive antibody evaluated Epo-R expression in human skeletal muscle tissue. Methods: Human skeletal muscle biopsies from two clinical studies were used to investigate; 1) gene expression in relation to prolonged treatment with rHuEpo (study A) evaluated by gene array, 2) Epo-R presence determined by western blotting using a new and sensitive antibody (A82, Amgen)(study B). In study A, nine healthy men received one weekly s.c. injection with rHuEpo for 10 weeks (Darbepoietin- $\alpha$ , Aranesp, Amgen); biopsies were collected before and after treatment. In study B, biopsies were collected from ten healthy young men under basal conditions. Results: When correcting for multiple testing, no significant changes in skeletal muscle gene expressions after a prolonged period of rHuEpo treatment were found. Therefore, Epo-R expression was evaluated. Unlike previous studies, with a new and sensitive antibody, A82, it was not possible to identify Epo-R's in human skeletal muscle tissue. Conclusion: In conclusion, prolonged rHuEpo treatment does not affect gene expression in human skeletal muscle, and a physiological role of Epo-R in skeletal muscle is unlikely. #### EFFECT OF "FUNCTIONAL FOOD" SUPPLEMENTATION ON MUSCLE GROWTH AND STRENGTH INDUCED BY 12 WEEKS OF RESISTANCE EXERCISE IN ELDERLY MEN

Hellelid, K.J., Bjørnsen, T., Salvesen, S., Berntsen, S., Stea, T.H., Lohne-Seiler, H., Paulsen, G.

*University of Agder*

**Introduction** Lack of dietary protein and micronutrients is often found amongst elderly. The aim of the present study was to investigate the effect of a mixed supplementation on muscle growth and strength after 12 weeks of strength training in elderly men. **METHODS** Thirty-three elderly males (60 – 81 yrs old) were included to either a supplemented group (N=16) or a placebo group (N=17) in a double blinded randomized placebo controlled trial. Muscle growth was assessed as changes in lean mass with DEXA and thickness of rectus femoris, vastus lateralis and arm flexors (brachialis and biceps brachii) with ultrasound imaging. Strength was measured as 1RM in leg press, knee extension and scott curl. A four day validated 18-page pre-coded food diary was completed. The supplementation was based on natural antioxidant-rich pomegranate juice with 22 g of carbohydrates, enriched with marine omega-3 fatty acids (900 mg), 15 µg vitamin D and 9 g whey protein isolate + 2 g of leucine and were administered twice daily. All participants conducted resistance exercise 3 times a week, following an undulating periodized program: 2/wk 8-10RM (1 min inter-set rest periods), 1/wk between 3-5RM (2 min rest) or 13-15RM (45 sec rest). The load was weekly adjusted, and the volume increased progressively throughout the 12 weeks of resistance exercise. Data was analyzed using non-parametric tests. **RESULTS** The supplemented group (mean±SD, 112g±39) had significantly higher protein intake at baseline compared to the placebo group (86g±20)(p=0.02), but not post. 1RM increased in the range of 15-20% in supplemented and placebo groups during 12 weeks of resistance exercise (p<0.001); no group differences were identified. Lean body mass increased for both the supplemented group (2.2 kg (median with 95% confidence intervals) (0.9-2.9)) and the placebo group (2.2 kg (1.5-3.3)) after 12 weeks of resistance training (p<0.01). However, the rectus femoris thickness increased more in the placebo group (16.2% (12.8-24.1)) than the supplemented group, (11% (4.1-17)) (p<0.05), while no significant differences between group were found for arm flexors and vastus lateralis thickness. **DISCUSSION** A mixed supplement with omega-3 fatty acids and whey protein did not have any additional effects on the adaptations to resistance exercise in elderly men. This might be due to an already sufficient intake of such nutrients, or insufficient levels of proteins in the supplementation to stimulate further muscle growth. Note: The Smartfish@ company partly financed this study.

#### A SIMPLE 45 SECOND SQUAT TEST CAN ACCURATELY PREDICT VO2MAX: PRELIMINARY RESULTS

Sartor, F., Bosio, A., Bonomi, A., Kubis, H.P.

*Philips Research*

**Introduction** VO<sub>2</sub>max is an important parameter to determine the functional capacity of the cardio-respiratory system. Its direct determination via maximal exercise testing may result not always feasible to perform, in particular in subjects with increased risk of cardiovascular diseases. Thus we have validated a simple and short sub-maximal test which does not require any type of equipment other than a heart rate (HR) monitor and a metronome and can be performed by anybody with no lower limbs limitations. **Methods** Eight male cyclists (Age: 19 ± 2 yrs; Height: 177 ± 7 cm; Weight: 65.4 ± 4.5 kg; Body Fat %: 8.36 ± 2.00%) underwent a Ruffier-Dickson test. This consisted of resting supine for 5 min, then standing up, and once the HR was stable, performing 30 squats in 45 s following a metronome set at 80 bpm. Once the squatting exercise was completed the participants laid down supine to recover for 3 min. HR was recorded throughout. After 3 min when HR ≤ initial resting HR the participants underwent a Vo<sub>2</sub>max test on the cycle ergometer. Body fat % was estimated via plicometry. **Results** The cyclists had a mean VO<sub>2</sub>max of 4.36 ± 0.44 L/min, 67.2 ± 6.2 mL/kg/min. Their VO<sub>2</sub>max significantly correlated with their height (r = 0.746, p = 0.03), and slope of HR increase during the squats (r = 0.705, p = 0.05). The best VO<sub>2</sub>max prediction via multiple linear regression showed high r = 0.977 and adjusted r<sup>2</sup> = 0.892, and small inaccuracy, Standard Error of Estimate (SEE) = 0.145 L/min, SEE% = 3.3. Eq.1: VO<sub>2</sub>max (L/min) = -2.489 + (0.0436 \* height (cm)) + (1.458 \* Slope Sq HR) - (0.00234 \* Recovery DeltaHR120 (bpm)) - (0.170 \* Fat %). If body fat % via plicometry is not available VO<sub>2</sub>max can be still predicted accurately using Eq.2: VO<sub>2</sub>max (L/min) = -1.788 + (0.0317 \* height (cm)) + (1.812 \* Slope Sq HR) - (0.00834 \* Recovery DeltaHR120 (bpm)); r = 0.812, adjusted r<sup>2</sup> = 0.405, SEE = 0.340 L/min, SEE% = 7.8. **Discussion** We have developed a model (Eq.1), which can accurately (3% error) predict VO<sub>2</sub>max in young male athletes from a simple 45s squat test. Although body fat % increases the prediction accuracy, if not available the accuracy of an alternative model (Eq.2) (7.8% error) is still in line with other sub-maximal tests (e.g. 9% Astrand-Rhyming cycling test, 11.4% Ebbeling treadmill test, 8% McArdle step test). We are currently testing more sedentary individuals to see whether these results can be generalized. Although these are preliminary results on only 8 participants and the error might increase when a large sample is considered, this 45s squat test seems to be very promising.

#### ASSOCIATION BETWEEN MOTOR COMPETENCE AND PHYSICAL ACTIVITY. A LONGITUDINAL STUDY IN CHILDREN

Lopes, V.P., Sousa, J.F.D., Rodrigues, L.P.

*Polytechnic Institute of Braganca*

**Introduction:** The aim of this study was to analyze the influence of motor competence on children's physical activity levels (PA). Motor skills proficiency and coordination levels were studied as predictors of children's PA levels during 4 years. **Methods:** This longitudinal study took place between 2009 and 2012, with a sample of 98 children. At the beginning of the study the sample was composed of 24 children with

six years old, 40 children with seven years and 34 children with eight years, who were followed over 4 consecutive years, performing annual assessments of anthropometric variables, PA, motor coordination and fundamental motor skills. Pedometer was used as an objective instrument for assessing PA, test of Körperkoordination Test für Kinder (KTK) to assess motor coordination and test of Gross Motor Development (TGMD-2) to assess the fundamental movement skills, composed by objects control skills and locomotor skills. For data analysis we used the hierarchical or multilevel modeling, in order to determine the predictors of PA through five successive adjustment models. Results: The children's PA levels significantly decreased over time. At baseline the girls had a PA level significantly lower than boys. The magnitude of the differences in PA levels between boys and girls has not changed significantly over the observations. Motor coordination levels and proficiency in object control skill were not predictors of PA, whereas the proficiency in locomotor skills was the only significant predictor of PA. There were a large percentage of children who did not comply with the minimum recommendations in the number of daily steps and this situation tends to worsen with increasing age, especially in girls. Conclusions: The locomotor motor skills were a significant predictor of children's PA levels along 4 years.

### EXERCISE HYDRATION KNOWLEDGE OF SINGAPOREAN YOUTH COACHES AND PHYSICAL EDUCATION TEACHERS

Chia, M., Mukherjee, S., Huang, S.H.

*National Institute of Education, Nanyang Technological University, Singapore*

Introduction Dehydration has deleterious effects on sport performance and contributes to heat-related illnesses. Singapore youth athletes are at a greater risk of dehydration-associated ailments due to the tropical climate, especially when training outdoors. Coaches and Physical Education (PE) teachers must possess adequate hydration knowledge to ensure optimal performance and sports safety in the youth athletes. The present study examines the exercise hydration knowledge of Singapore coaches and PE teachers. Methods 193 coaches (Beginning coaches n=129, certified coaches n=64) and 164 PE teachers (Beginning teachers n= 102, graduating teachers n=62) participated in the study. Participants completed a questionnaire based upon ACSM and NATA guidelines on fluid replacement for athletes (Casa et al. 2000; Sawka et al. 2007). The questionnaire consisted of pre-exercise, during-exercise and post-exercise hydration knowledge sections. Adequate hydration knowledge was accepted as a score of 80% and above (Ransone and Dunn-Bennett 1999). Results 70.3% of participants were coaching youth athletes. Average knowledge scores were: beginning coaches (BC)-61.76±12.36%; certified coaches (CC)-68.09±12.30%; beginning PE teachers (BT)-62.46±10.24%; graduating PE teachers (GT)-67.01±9.46%. There was a significant difference in the passing rates between BC and CC (BC-3.1% vs CC-17.2%,  $p < .05$ ). The difference in passing rates between BT and GT was not significant (BT-5.9% and GT-11.3%,  $p = < .05$ ). Even at 80th percentile, none of the groups attained passing scores. At 90th percentile, only the CC and GT attained passing scores. Discussion Results showed that the majority of coaches and PE teachers in Singapore have inadequate hydration and fluid replacement knowledge and they were largely unfamiliar with the NATA and ACSM guidelines on fluid replacement. The lack of adequate exercise hydration knowledge among coaches and PE teachers puts the health and well-being of youth exercising in the hot and humid climate of Singapore at risk. It is important to bridge current hydration knowledge gaps among coaching and PE practitioners and step up education programmes to empower youths with appropriate exercise hydration knowledge. Future studies focusing on coaches' education on hydration and fluid replacement are essential. References Casa DJ, Armstrong LE, et al. (2000). *Journal of athletic training* 35(2): 212-224. ### COMPARING HEART RATE MONITOR AND ACCELEROMETER TO DETERMINE ENERGY EXPENDITURE

Dyrstad, S.I, Hausken, K.2

*University of Stavanger*

Introduction Heart rate monitors are an accurate tool to measure heart rate response to physical activity. It has also become a common tool to measure energy expenditure. During the last 15 years accelerometers have become one of the most common objective methods to assess physical activity. Understanding how different tools measure physical activities differently is important in order to compare methods and interpret data correctly. The purpose of the study was therefore to compare the estimation of energy expenditure from heart rate monitors and accelerometer in interval running and zumba (a Latin dance-inspired fitness program). Methods A total of 26 sports students (15 females) with a mean age of 21.8±2.4 (SD) years, wearing both heart rate monitor and accelerometer, carried out two different training sessions: A 45 min interval running session containing 12 min warmup, 4x4 min running, 90-95% of max heart rate, with 3 min jogging, 70% of max heart rate between each interval, and 5 min cooldown. Zumba 60 min containing 5 min warmup, thereafter 50 min zumba, and 5 min cooldown. Polar RS 100 monitors with belts were used to measure the participants' heart rates. The participants measured their maximal and resting HR by a standardized protocol. ActiGraph GT3X was used to measure the participants' accelerometer counts, collected in 60-second epochs. The equations by Hiilloskorpi et al. (1999) and Sasaki et al. (2011) were used to determine the participants' activity energy expenditure from heart rate monitors and accelerometers, respectively. Results The mean vector magnitude counts per minute (cpm) were 8612±1101 cpm and 6704±1424 cpm for interval running and zumba, respectively. The mean working intensity in % of maximal heart rate was 82.5±3.3 % and 74.9±10.7 % for interval running and zumba, respectively. The mean energy expenditure during the running session was 11.51± 2.29 kcal/min and 9.26±1.86 kcal/min estimated by heart rate monitors and accelerometers, respectively ( $p < 0.0001$ ). Corresponding energy expenditure for zumba were 9.86± 2.68 kcal/min for heart rate monitors and 7.22± 1.73 kcal/min for accelerometers ( $p < 0.0001$ ). Discussion The main finding is the documentation of the large differences in the estimation of energy expenditure between heart rate monitor and accelerometer. Heart rate monitors estimated 24% and 37% higher energy expenditure in kcal/min than accelerometers in interval running and zumba, respectively. A greater difference during zumba could be explained by the fact that the participants perform large upper body movements not recorded by the accelerometer. energy expenditure during exercise. *Int J Sports Med* 1999; 20: 438-443. Sasaki JE, John D, Freedson PS. Validation and comparison of ActiGraph activity monitors. *J Sci Med Sport* 2011; 14: 411-416.

### HEART RATE VARIABILITY THRESHOLD PREDICTS LACTATE THRESHOLD IN WORLD-CLASS ROAD CYCLISTS

García-Tabar, I., Sánchez-Medina, L., Aramendi, J.F., Ruesta, M., Ibañez, J., Gorostiaga, E.M.

*Studies, Research and Sports Medicine Centre, Government of Navarre*

**Introduction** The vagal withdrawal of the heart, defined as the heart rate variability threshold (HRVT), and the blood lactate threshold (LT) have been observed to occur at similar relative exercise intensities (Chwalbinska-Moneta et al., 1989; Tulppo et al., 1996). However, the validity of the HRVT to estimate the LT in homogeneous groups of athletes with very high aerobic capacities has not been examined yet. **Methods** Twelve male professional world-class road cyclists performed a continuous maximal graded cycling test. Blood lactate concentration ([La-]), heart rate and RR intervals were monitored. The LT was defined as the workload corresponding to an elevation in [La-] of 0.2 mmol•l<sup>-1</sup> (Weltman et al., 1987). HRVTs were determined from the standard deviation of the instantaneous beat-to-beat RR intervals (SD1). Workloads associated with SD1 values of 1 ms above the lowest SD1 (SD1Tlow), and 3 ms and 0.5 ms above the SD1 value of the first exercise intensity at which there was a decrease in SD1 < 0.5 ms (SD1T0.5) or < 2.5 ms (SD1T2.5) were established. Results The LT and SD1Tlow were not statistically different and were strongly correlated ( $r = 0.88$ ;  $P < 0.001$ ). HRVTs robustly correlated with percentages of peak aerobic power (% Wpeak) ( $r = 0.94-0.97$ ;  $P < 0.001$ ) and percentages of peak heart rate (% HRpeak) ( $r = 0.87-0.95$ ;  $P < 0.001$ ) at which these thresholds occurred. **Discussion** A lower magnitude of correlation ( $r = 0.82$ ) between visually identified LTs and HRVTs has been previously reported in a heterogeneous (coefficient of variation, CV, of ~25%) group of male and female subjects (Karapetian et al., 2008). The present results indicate that the LT could be accurately and objectively estimated from the SD1Tlow in a homogeneous group (CV of Wpeak = 4.3%) of male world-class cyclists. A novel finding was the extremely large relationships observed between the SD1Tlow and the % Wpeak and % HRpeak at which SD1Tlow occurred. SD1T0.5 and SD1T2.5, two other mathematically determined HRVTs measurable during a non-fatiguing incremental test, also correlated with the LT, % Wpeak and % HRpeak at which these HRVTs occurred. **Conclusion** The LT can be accurately predicted from SD1 values during a maximal or submaximal, non-invasive, low-cost, incremental exercise test in world-class road cyclists. The LT might be coincidental with the vagal withdrawal of the heart. **References** Chwalbinska-Moneta, J., Robergs, R. A., Costill, D. L., & Fink, W. J. (1989). *J Appl Physiol*, 66, 2710-2716. ### RELATIONSHIP BETWEEN HEART RATE RECOVERY AND LACTATE THRESHOLDS IN ELITE SOCCER PLAYERS

Baumgart, C., Hoppe, M.W., Freiwald, J.

*University of Wuppertal*

**Introduction** In elite soccer players, the ability of the cardiovascular system to recover after high-intensity activities (HRrec) is mentioned as an important prerequisite (Stone & Kilding, 2009). Especially among practitioners, there exist an underlying believe that HRrec is related to aerobic endurance performance factors, such as lactate thresholds. With this in mind, the aim of this study was to investigate the relationships between HRrec and lactate thresholds in elite soccer players. **Methods** 122 male German soccer players from the 1st to 4th level (age 24±4 years, BMI 23.6±1.6 kg/m<sup>2</sup>) performed an incremental test on a 400 m tartan track to determine running velocities at 2 and 4 mmol/l blood lactate (v2 and v4). HRrec was defined as the decrease in heart rate from the end of the test to 10, 30 and 60 seconds after exhaustion. Additionally, HRrec was quantified relative as a percent of maximum heart rate (HRrec%). Descriptive statistics were calculated after checking for normality with the Kolmogorov-Smirnov test. Pearson product-moment correlation coefficients (r) were used to investigate the relationship between HRrec, HRrec%, v2, and v4. Statistical significance was set to  $p < 0.05$ . **Results** In elite soccer players, the assessed mean±SD values for HRrec, HRrec%, v2, and v4 were v2: 12.2±1.2 km/h; v4: 14.2±0.9 km/h; HRrec10: 2±1 bpm; HRrec30: 12±4 bpm; HRrec60: 32±8 bpm; HRrec10%: 1.3±0.8 bpm; HRrec30%: 6.1±2.2 bpm; and HRrec60%: 16.8±4.6 bpm, respectively. No correlations were found between HRrec values, v2, and v4 (all  $r < 0.13$ ,  $p > 0.05$ ) as well as between HRrec% values, v2, and v4 (all  $r < 0.15$ ,  $p > 0.05$ ). **Discussion** The results of this study revealed that v2 and v4 were not related to HRrec and HRrec% in elite soccer players. It is well known that endurance trained athletes have greater HRrec than sedentary individuals. Ostojic, Stojanovic, and Calleja-Gonzalez (2011) demonstrated a relationship between maximum oxygen uptake and HRrec only 10 and 20 seconds after exhaustion in young male soccer players, but not for 30 to 60 seconds. Anyway, the present study shows that elite soccer players possess high aerobic endurance performance factors do not possess faster heart rate recovery after exhaustion. **References** Ostojic, S. ### CARDIOVASCULAR EFFECTS OF PASSIVE LOWER LEG VIBRATION

Gholoum, M., Edmond, T., Woods, S., Ball, D., Thin, A.G.

*Heriot-Watt University*

**Introduction** Whole body vibration (WBV) has been used as a novel form of exercise for both physical training and rehabilitation applications. WBV exercise at lower frequencies (<60 Hz) for short periods has been reported to have beneficial effects on the human musculo-skeletal system (Torvinen et al., 2002). WBV has also been observed to increase muscle blood flow (Kersch-Schindl et al., 2001). Whether this is a secondary effect in response to skeletal muscle activation or a separate effect on the cardiovascular system is not known. However, the potential for WBV to produce shear-stress is of interest for its angiogenesis inducing potential. The aim of this study was to investigate the potential vasodilatory effects of vibration independent of muscle activation by applying it in a passive manner. **Methods** Eighteen (9 male) healthy young adults aged (mean±SD) 22.0±2.3 years, height 1.72±0.09 m, body mass 70.1±13.0 kg were recruited to the study. Skeletal muscle activation was avoided by having subjects lie in a supine position on supporting foam mats with their lower legs resting on the vibrating platform (Nemes, Bosco System). Subjects visited the lab on two separate occasions and vibration and control treatments were applied in a randomised order. Vibration consisted of three 60 s bouts with 10 s between (40 Hz, 3 mm amplitude, 6.8 g RMS acceleration). Lower leg blood flow (LLBF) was measured using venous occlusion plethysmography (Hokanson System). Brachial blood pressure (BP) was measured using an automated monitor (Tango+, SunTech Medical) and ankle systolic BP measured manually in duplicate. Baseline measurements were made following 15 min of supine rest. All measurements were then made immediately after treatment and repeated at 3 min intervals thereafter. Data were analysed using repeated measures mixed model ANOVA. **Results** Mean

( $\pm$ SEM) LLBF at baseline was  $2.2\pm 0.1$  ml/100ml/min. After vibration LLBF was increased relative to the control values by  $+31.0\pm 7.9$ ,  $+6.2\pm 5.2$ ,  $+6.1\pm 6.6$ , and  $+9.9\pm 5.2$  % at 1, 4, 7, and 10 min respectively ( $P<0.05$ ). Mean ankle-brachial pressure index at baseline was  $1.01\pm 0.01$  and was reduced by  $-0.8\pm 2.9$ ,  $-6.5\pm 3.3$ ,  $-3.5\pm 3.7$ , and  $-0.6\pm 2.1$  % at the same respective time points relative to the control values ( $P<0.05$ ). Discussion The results of this study provide evidence for body vibration having cardiovascular effects independent of skeletal muscle activation. This means that WBV may be of use in helping to enhance blood flow during warm-up and/or recovery routines. Furthermore, the most likely mechanism underlying the vibration-induced increase in blood flow is increased shear stress, which may have potential as a novel training stimulus and therefore warrants further investigation. ### EFFECTS OF A MULTISTAGE SHUTTLE RUN 15 METERS TEST ON HEART RATE, LACTATE AND RATING OF PERCEIVED EXERTION IN BEACH HANDBALL PLAYERS

Bago Rascon, P., Saez de Villarreal, E.

*Pablo de Olavide University*

Introduction Until 2016, beach handball will not be an Olympic event, and information on the physical characteristics and the physiological demands of elite players is limited. Beach handball is a sport that places high physiological demands on players (dry beach sand, ground deformation, intermittent nature of the game) (Billat, 2003). To run or any type of movement in dry sand races may result in an increase of 1.6 times the energy cost (Lejeune et al., 1998). The involvement of anaerobic glycolysis is the main pathway of energy production. The aims of this study are to determine the relevance of lactate as performance limiter, the relationships between heart rate (HR), rate of perceived exertion (RPE) and lactate as predictors of the level of effort and the adaptation of the Course-Navette test for beach handball. Methods We examined the response of three variables (HR, blood lactate and RPE) in dry sand beach in beach handball players through an adapted Course-Navette and the maximum speed test (15 m). 12 players aged  $21.4\pm 3.87$  years, weight of  $79.68\pm 13.87$  kg, height of  $1.78\pm 0.07$  meters and B.M.I. of  $26.24\pm 4.52$  were subject to two tests conducted in dry sand. Their profile on the beach handball experience comes with  $7.17\pm 2.86$  years in the sport;  $26.42\pm 11.34$  games played in the summer season of 2010 and  $6.46\pm 1.71$  hours per week training in conventional handball. Results The maximum speed obtained in the speed test was 2,49 sec, with an average of  $2.77\pm 0.19$  sec. Regarding lactate results, the baseline value was  $2.51\pm 1.49$  mmol/l, post-exercise  $11.06\pm 2.66$  mmol/l and after 3 recovery minutes  $13.49\pm 2.49$  mmol/l. The average HR during testing was  $177.9\pm 7.02$  bpm, the percentage of intensity on the theoretical maximum heart rate was  $95.70\pm 3.12$ %. The maximum RPE level was recorded at  $17.42\pm 1.08$  according to the Borg 15 degrees scale. Discussion The results show a clear relationship between the intensity of the HR, increased blood lactate concentration and subjective feelings of fatigue a beach handball player. Previous authors have found a similar blood lactate levels after high intensity training (Billat, 2003). The progressive running test on 15m round-trip of 10 minutes maximum duration was a valuable tool for obtaining data in HR, blood lactate and self-perceived effort. Test results show that physical work in sand for beach handball requires very high intensities heart rate ( $\sim 90$ %). These data are consistent with other studies in real game situation in beach football (Castellano and Casamichana, 2010). The results yield evidence that the Beach Handball is a mixed performance sport with high participation of anaerobic metabolism and the consequent production of lactic acid. The outcomes may help coaches and sport scientists formulate better guidelines and recommendations for athlete assessment and selection, training prescription and monitoring and preparation for competition.

### MONITORING RECOVERY DURING THE IN-SEASON COMPETITIVE PHASE IN ELITE SOCCER PLAYERS

Thorpe, R., Strudwick, A., Buchheit, M., Atkinson, G., Drust, B., Gregson, W.

*Liverpool John Moores University*

Introduction Balancing the stress of training and competition with sufficient recovery is a fundamental challenge in the training process. Therefore, knowledge about the effectiveness of non-invasive monitoring tools for assessing recovery status in athletes is paramount (Meeusen et al., 2006). Recovery markers should be sensitive to daily variability in training load, but research on elite team sport players is lacking (Buchheit et al., 2013). Therefore, our aim was to quantify the relationships between daily training load and a range of recovery indices in elite soccer players during the in-season competitive phase. Methods Training load (RPE-TRIMP, heart rate, total and high-intensity distance and the number of accelerations), perceived ratings of fatigue, muscle soreness, sleep quality, counter-movement jump height (CMJ), post-exercise heart rate recovery (HRR%) and heart rate variability (LnMSSD) were measured daily in 10 elite soccer players across a 14-day period during the in-season competitive period. Within-subjects stepwise multiple regression models were used to evaluate the influence of fluctuation in training load markers on fluctuation in recovery indices. Results Variability in fatigue ( $r=0.40$ ) and muscle soreness ( $r=0.38$ ) were correlated to variability in total high-intensity distance and total distance covered measured on the previous days respectively ( $P<0.001$ ). Variability in sleep quality was correlated to the most training load markers; these being RPE-TRIMP ( $r=0.24$ ;  $p=0.02$ ), total distance ( $r=0.33$   $p=0.01$ ) and high intensity distance ( $r=0.42$ ;  $p<0.001$ ). Variability in HRR% and LnMSSD were correlated to time above 80% HRmax ( $r=0.27$ ;  $p=0.04$ ) and the number of high accelerations ( $r=0.31$ ;  $p=0.03$ ) respectively. Correlations between variability in CMJ performance and all training load markers were negligible and not statistically significant. Discussion Perceived ratings of wellness, particularly sleep quality, along with heart rate recovery and heart rate variability were reasonably sensitive to daily fluctuations in training load experienced by elite soccer players. Therefore, these particular indices show the greatest promise for simple, non-invasive assessment markers of recovery status of elite soccer players during the in-season competitive phase. ## TRAINING IN HYPOXIA: DOES IT IMPROVE SEA-LEVEL PERFORMANCE?

Rodríguez, F.A.

*Institut Nacional d'Educació Física de Catalunya, University of Barcelona*

After more than four decades of research on the topic –many think that the few years before Mexico 1968 Olympics were the real beginning of it–, and more than 500 publications reported in PubMed and over 4,000 in Google Academics, altitude training effects on sea-level performance is a matter of live controversy. The first and only published meta-analytic review on this topic concluded –perhaps arguably by some– that the “enhancing protocols by appropriate manipulation of study characteristics produced clear effects with all protocols (3.5-6.8%) in subelite athletes, but only with [‘living high-training high’] LHTH (5.2%) and [‘living high-training low’] LHTL (4.3%) in elite athletes.” It also concludes that “in elite athletes, enhancement was possible with natural LHTL (4.0%; +/-3.7%), but unclear with other protocols”. Something definitely changed our views after the milestone work of Levine & Stray-Gundersen (1997). However, even the referenced paper summary includes expressions like ‘poor reporting’, ‘placebo, nocebo and training-camp effects’, ‘possible’, or ‘unclear’. On a very recent article (Lundby et al., 2012), a well recognised group of experts conclude that “Given that few studies have utilised appropriate controls, there should be more scepticism concerning the effects of altitude training methodologies”, and advocate for “well-controlled studies that will enhance our understanding of the mechanisms and potential benefits of altitude training”. Therefore, controversy is served and perhaps ready to go on for a few more years. In this critical review, new results from a recent international research project which involved 65 elite swimmers from eight nations in four continents will be summarized and put into perspective. The aim will be to stimulate the debate and to emphasise some of the crucial aspects surrounding the controversy, such as the extrapolation from physiological variables to actual sports performance and how realistic it is to conduct robust ‘gold standard’ experiments –such as randomized, double blind, controlled trials– immersed in the complex ‘ecological nest’ of elite sport. ## OXYGEN: A POSSIBLE TREATMENT FOR OBESITY?

González-Muniesa, P.1,2, Quintero, P.1,3, Martínez, J.A.1,2

*1. University of Navarra, 2. Carlos III Health Research Institute, 3. Pontificia Universidad Católica de Chile*

Oxygen is indispensable for cell metabolism, and in turn, tissue oxygenation is essential for all normal physiological functions in most living creatures. Diseases as relevant as cancer, respiratory dysfunctions, and others, such as obesity (Trayhurn and Wood, 2004), are related with a poor tissue oxygenation. On the other hand, several studies have reported that appetite suppression and body weight loss are frequently observed at high altitude. Based on these findings, it has been hypothesized the possible applicability of hypoxia and hyperoxia for the treatment of obesity and related disorders (Quintero et al, 2010). Hyperoxia treatment (95% O<sub>2</sub>, 48 h) on mature murine adipocytes (3T3-L1) seems to produce an inflammatory response probably related to the release of ROS and the upregulation of pro-inflammatory adipokines, such as IL-6 and MCP-1. On the other hand, hyperoxia may have an indirect effect on insulin sensitivity due to the upregulation of PPAR- $\gamma$  signaling as well as a possible modulation of both glucose and lipid metabolic markers, which is in agreement with Goossens and collaborators (Goossens et al, 2012). An intermittent hypoxia treatment was then tested (8% O<sub>2</sub>, 4 weeks of cycle hypoxia) on Wistar rats where a significant weight gain decrease was found compared to the normoxia group, unfortunately this loss was mainly of muscle tissue. At the moment, we are performing a trial with an acute hypoxia (15% O<sub>2</sub>) on obese patients practicing 2h of exercise simultaneously to the exposure to low oxygen levels (Urdampilleta et al, 2012). This project is funded by the EXPLORA Subprogramme, MICINN, Spain (SAF2010-11630-E). This new strategies may be useful and practical for clinical applications in obese patients. References 1. ## BRISK WALKING INCREASES BONE MINERAL DENSITY IN CART-PATIENTS

Bonato, M., Bossolasco, S., Galli, L., Mandola, S., Pavei, G., Testa, M., Bertocchi, C., Galvano, E., Balconi, G., Lazzarin, A., Merati, G., La Torre, A., Cinque, P.

*Università degli Studi di Milano, San Raffaele Scientific Institute*

Introduction In the general population, moderate intensity aerobic activity reduces the risk of obesity, cardiovascular disease, diabetes and may prevent bone loss. We evaluated the effects of brisk walking, with or without strength exercise, on bone mineral density in HIV-infected treated persons. Methods Thirty-four HIV-infected, cART-treated, sedentary subjects with were enrolled in a 12-week exercise program, consisting of 3 outdoor sessions/week of 60 min walking at 65-75% of HR (heart rate) max  $\pm$  30 min circuit training at 65% of 1-

RM (Repetition Maximum). Subjects were examined at baseline (BL) and 12 weeks (W12) by 6-minute walking test (6MWT), 1-RM test; and by dual energy X-ray absorptiometry (DEXA) to evaluate lumbar spine and femoral bone mineral density, and t- and z-scores, in addition to morphometric (BMI, waist, hip and leg circumference) and bloodexamination (cytometry, fastingtotal, HDL and LDL cholesterol, tryglicerides, glucose, insulin; AST/ALT, ALP, gGT, creatinine, CPK, HbA1c; CD4+ and CD8+, plasma HIV-RNA). Differences between BL and W12 were tested by Wilcoxon-signed rank test. Results Thirty-two of 34 (94%) participants completed the 12-week program with a median adherence of 64% (IQR 56-77). They were 25M, 7F; median 48 y-o, IQR 44-54. Twenty patients were enrolled in the 'walk' group and 12 in the 'walk and strength' group. At W12, participants showed significant improvement of distance by 6MWT ( $p<0.0001$ ), and of performance in all strength exercises (crunch  $p=0.0015$ , lat machine  $p=0.001$ , chest press  $p=0.0029$ , leg extension  $p=0.0303$ , sitting calf  $p=0.0015$ , leg press  $p=0.0024$ ). DEXA spine z-score improved significantly in the whole group ( $p=0.0222$ ) and in the walk strength group ( $p=0.0469$ ), and femoral z-scores in the 'walk' only group ( $p=0.0319$ ). At W12 BMI, waist circumference, and LDL were also significantly improved in the whole group, whereas no significant changes were observed for the other variables. Discussion The above 12-week program of brisk walking, with or without strength exercise, improved fitness and bone density in HIV-infected treated subjects, in addition to some morphometric variables and serum LDL. This kind of moderate intensity exercise might help control the long-term consequences of cART on bone metabolism. References Gregory et al 2009 Am J Lifestyle Med

### EXERCISE AUGMENTATION COMPARED TO USUAL CARE FOR POSTTRAUMATIC STRESS DISORDER. A RANDOMISED CONTROLLED TRIAL: RESULTS FROM THE REAP TRIAL

Rosenbaum, S.1,2, Tiedemann, A.1, van der Ploeg, H.P.3, Sherrington, C.1

1 The George Institute for Global Health (Australia) 2 St John of God Healthcare (Australia) 3 EMGO Institute for Health and Care Research (Netherlands)

Introduction People with posttraumatic stress disorder (PTSD) are more likely to suffer from poor physical health (Boscarino, 2004) and are less likely to be physically active (de Assis et al., 2008). Exercise can potentially improve both the primary psychiatric diagnosis and physical health simultaneously. To date no randomised controlled trials (RCTs) have evaluated the impact of exercise on PTSD symptoms. This study aimed to investigate the impact of a 12-week exercise program as an augmentation to usual care for PTSD patients. Methods An assessor-blinded RCT was conducted among participants with a DSM-IV diagnosis of PTSD recruited from St John of God Hospital (Australia) ( $n=81$ ; mean age 47.9 (12.1), 84% male). Participants were randomized to receive usual care ( $n=42$ ) or exercise augmentation in addition to usual care ( $n=39$ ). The intervention comprised resistance training and a pedometer-facilitated walking program. The primary outcome was PTSD symptoms, obtained through the Posttraumatic stress disorder Check List –Civilian version (PCL-C), a 17-item self-report measure. Scores range from 17- 85, with at least a 5-point change considered significant. Secondary outcome measures assessed depression and anxiety, waist circumference, physical activity and sleep quality. Linear regression analyses were conducted. Results 58 participants (72%) completed primary outcome follow-up assessments. The intervention group significantly improved compared to the control group for PTSD symptoms, (mean difference = 5.39, 95% CI 0.26 to 10.52,  $p=0.04$ ), however, the significant between-group difference was lost when missing data were imputed. There were significant between-group differences on the secondary outcomes at follow-up: depression ( $N=51$ ) (mean difference= 17.44, 95% CI 5.95 to 28.93,  $p=0.004$ ), waist circumference ( $N=37$ ) (mean difference = 3.56, 95% CI 0.17 to 6.95,  $p=0.04$ ) and sleep quality ( $N=55$ ) (PSQIA) (mean difference = 2.46 95% CI 0.07 to 4.86,  $p=0.04$ ). Mean adherence was 7 supervised sessions (range 1-11). Discussion This study provides preliminary evidence that exercise may be effective in reducing both PTSD and depressive symptoms, as well as improving body composition and sleep quality in PTSD patients. High proportion of participant loss-to-follow-up is a limitation of this study. This trial has important clinical implications and supports the inclusion of exercise programs within PTSD treatment facilities. References Boscarino, J. A. (2004). ### CONCENTRIC AND ECCENTRIC TORQUE IN COPD PATIENTS VS. HEALTHY CONTROL

Rinaldo, N., Coratella, G., Lanza, M., Schena, F.

University of Verona

Introduction Presence of muscle wasting is common in Chronic Obstructive Pulmonary Disease (COPD) patients across all disease stages (Seymour J.M., 2010) but eccentric (ECC) contraction results greater compared to healthy control (HC) subjects (Mathur S., 2007). The aim of our study is to outline a description of COPD strength performances as a function of contraction modalities and velocities. Methods Thirty-five COPD males (mean FEV1=64.76±20.08% of predicted; FEV1/FVC= 57.35±13.56% of predicted; age 67.21±4.7 years) and 25 HC males (FEV1= 115.06±17.43% of predicted; FEV1/FVC=101.87±6.62% of predicted; age 65.15±5.69 years) performed isokinetic knee extensors concentric (CONC) and ECC torque at 30 and 210 deg/s. Vastus lateralis muscle architecture, 6MWT and 1RM Leg press were performed. One way ANOVA and Pearson coefficient were used to detect significant differences between groups and correlation between variables. Results HC was significantly better in FEV1 ( $p<0.001$ ), FEV1/FVC ( $p<0.001$ ), 6MWT ( $p<0.001$ ) and 1RM Leg press ( $p<0.05$ ). Only CONC 30deg/s peak torque was significantly higher in HC compared to COPD ( $p<0.05$ ). No differences resulted in muscle architecture, fast CONC and ECC torque. Significant differences between groups ECC/CONC peak torque ratio (30 deg/sec  $p<0.001$ ; 210 deg/sec  $p<0.01$ ). Significant correlations were found between FEV1 and 6MWT (0.719  $p<0.001$ ), 1RM Leg press (0.449  $p<0.001$ ), peak torque contraction at 30 deg/sec (0.427  $p<0.01$ ; 0.280  $p<0.05$ ), at 210 deg/sec (0.285  $p<0.05$ ; 0.276  $p<0.05$ ) and ECC/CONC peak torque ratio at both velocities (-0.562  $p<0.001$ ; -0.292  $p<0.05$ ). Same results were observed between FEV1/FVC and parameters assessed. Discussion COPD patients showed lower health related parameters and performed lower CONC contraction compared to healthy controls. Interestingly, COPD preserved ECC contractions and fast CONC torque. ECC contraction seems to involve fast twitch motor units (Duchateau J., 2008) and COPD hypoxia leads fiber shift towards IIX fibers (Gosker H.R., 2002). Therefore, COPD males seem to develop favorable profile to minimize strength loss likely due to neural-muscular modification. References Mathur S. et al. **CHANGES IN WALKING STEPS DURING PREGNANCY. A MULTI-ETHNIC POPULATION-BASED STUDY**

Richardson, K.R.1, Jennum, A.K.1,2, Moerkrid, K.2,3, Sletner, L.2,3, Birkeland, K.I.2,3, Berntsen, S.4

*Norwegian resource centre for women's health |Department for women's- and children's health Faculty of Medicine; University of Oslo 3 Dep. of Endocrinology, Obesity and Preventive Medicine; Oslo Univer*

Introduction: Pregnant women without medical contraindications are recommended to spend 30 minutes or more in moderate to vigorous intensity physical activity (PA) on most, if not all days of the week. However, most epidemiological research typically employ subjective reports of PA. The aims of the present study are (1) to describe PA change operationalised as objectively recorded daily steps in early gestation and gestational week (GW) 28, and, (2) to investigate the association between core set variables and steps in GW 28. Methods: Prospective data from a multi-ethnic cohort from Oslo/Norway (n=823) of pregnant women consisting of 40.8% from Western countries, 24.3% from South Asia, 15.3% from Middle East and 19.6% from other countries. Steps were recorded by the activity monitor SenseWear™ Pro3 Armband in early gestation (< 20 weeks) and in GW 28. Covariates in multiple linear regression analysis were steps in early gestation, BMI, pregnancy-induced emesis, subjective health, ethnicity, education, occupation, age and parity, while steps in GW 28 was the dependent variable. Results: Step data from 528 women with valid recordings from both visits were analysed. The ethnic group mean values for daily steps in early gestation ranged from 7183 to 9185, and Western women walked significantly more steps compared to all other ethnic groups (p<0.001). The percentage drop from early gestation to GW 28 ranged from 4.1% to 9.0%, and it was most pronounced for women from other countries and Western countries. In absolute terms, significant reductions were only seen in women from other countries (p=0.02) and Western countries (p<0.000). Ethnicity (p=0.01), occupation (p=0.04) and parity (p=0.03) were all significantly associated with steps at GW 28 but not after adjusting for steps in early gestation. Steps in early gestation explained 33% of the variance in steps at GW 28 (coefficient with 95% confidence intervals; 0.56 (0.49, 0.63) steps (p<0.001)). Discussion: Steps dropped markedly between early gestation and GW 28 across ethnic groups. Steps in early gestation was an important predictor for steps in GW 28, also after adjusting for other covariates, such as subjective health. Women with few steps in early gestation are at risk for low PA throughout pregnancy and interventions to promote PA in pregnancy should be tailored to their needs.

**08:30 - 10:00****Oral presentations****OP-BN07 Biomechanics [BM] 7****UNSTEADY HYDRODYNAMIC FORCES ACTING ON A ROBOTIC HAND AND ITS FLOW FIELD**

Takenoya, F.1,2, Hirako, T.2, Ota, E.2, Kageyama, H.3, Yamamoto, N.4, Ryushi, T.5, Shioda, S.2

*University of Tsukuba, 1:Hoshi Uni. 2: Showa Univ. 3: Kiryu Univ. 4: Japanese Red Cross Hokkaido College. 5: Daito Bunka Univ.*

Introduction Although an unsteadiness in the flow field during swimming must be considered (Matsuuchi et al. 2009), a quasi-static approach using the coefficients of drag and lift obtained under steady flow conditions has been the mainstream scientific method to predict fluid forces. Therefore, we attempted to directly measure the hydrodynamic forces, the pressure distribution, and the flow field around a hand by using a robotic arm and PIV. The advantages of using a robotic arm are that the obtained data are highly reproducible and that the experimental parameters (e.g., angle of attack and velocity of the hand) are computer controllable. At the first stage, we selected relatively simple hand motions to investigate systematically the effects of angle of attack, relative velocity, and acceleration for generating hydrodynamic force. By investigating the interactions among these data, we aimed to clarify the mechanism of generating unsteady force during swimming. Methods The robotic arm consisted of the trunk, shoulder, upper arm, forearm, and hand, and it was independently computer controllable in five degrees of freedom. The robotic arm was fixed above the flume with a two-dimensional (2D) load cell (LSM-B-SAI Kyowa). The elbow-joint angle of the robotic arm was fixed at 90°, and the arm was moved in semicircles around the shoulder joint, perpendicular to the water surface. Two-component PIV was used for flow visualization around the hand. Eight pressure sensors (PS-05KC KYOWA) embedded in the hand model to measure the pressure distribution on its surface. The data of the forces by the load cell and pressure acting on the hand by the pressure sensors were sampled at 200 Hz and stored on a PC. Results and Discussion When the maximum resultant force acting on the hand was observed, a pair of counter-rotating vortices appeared on the dorsal surface of the hand. A vortex attached to the hand increased the flow velocity, which led to decreased surface pressure, increasing the hydrodynamic forces. This phenomenon is known as the unsteady mechanism of force generation (Dickinson and Gotz, 1993). We found that drag force was 72% greater and that lift force was 4.8 times greater than values estimated under steady flow conditions. Measurement of a flow field has revealed that the behavior of certain kinds of vortices generated by unsteady hand movement plays an essential role in generating high hydrodynamic force. It is presumable that swimmers receive the benefits of this unsteady hydrodynamic force. Further studies are necessary to consider and analyze data obtained in realistic situations and reproducible by the robotic arm. In this way, a real swimming stroke pattern can be analyzed, making it possible to confirm the most efficient stroke technique. **FASTER DISTANCE RUNNERS HAVE MORE COMPLIANT ACHILLES TENDONS**

Oda, T.1,2, Toyoda, Y.1, Hisano, T.1, Kusumoto, K.1, Kunimasa, Y.3, Sano, K.3, Ishikawa, M.3

*1: HUTE (Hyogo, Japan), 2: RIKEN (Saitama, Japan), 3: OUSU (Osaka, Japan)*

Introduction Previous work suggested that superior running economy would be a key factor of the great successful in distance running (Saltin et al. 1995). The running economy and performance would be significantly influenced by mechanical properties of muscle and tendinous tissues, but detailed information has been limited. In this study, we determined the indices of stiffness and Young modulus on both tissues in plantar flexors of distance runners, and then examined the effect of the variables on running performance and running kinematics. Methods Dependent on best official record of 5000m, high performance group (HPG: 14:33±0:21: 10 subjects) and normal performance group (NPG: 16:08±0:26: 10 subjects) with similar age, body height, and weight, were set for the experiment. Morphological parameters of lower limb (e.g. length of segments, muscle and tendinous tissues and their cross sectional areas) were measured. Then,

Stiffness Index defined as the slope of relation between torque and lengthening of tissues, and Young Modulus Index as the index of material property were determined. The lengthenings of tissues were evaluated by B mode ultrasound images, during passive dorsiflexion for muscle tissues, and during isometric voluntary contractions for tendinous tissues. Two-dimensional kinematic analysis of race pace running was also applied with high speed VTR. RESULTS AND DISCUSSION Morphological variables related to length and cross sectional area have no significant difference between HPG and NPG. The mechanical properties related to only tendinous tissues showed significant differences between HPG and NPG. The Stiffness Index and Young Modulus Index of tendinous tissues of HPG were more compliant by 40% ( $p < 0.01$ ) and by 41% ( $p < 0.01$ ) than those of NPG, respectively. However, no significant difference was observed in Induces of muscle tissue. The difference of not only Stiffness Index but also Young Modulus Index in tendinous tissues imply the difference in its material properties between HPG and NPG, which is originated in biomaterial composition like collagen type. In addition, HPG and NPG did not demonstrate significant difference in many kinematic variables such as joint angle changes and step frequencies, while HPG showed 8% larger step length, 12% shorter contact time, and 32% faster maximal angular velocity of plantar flexion in late contact phase significantly ( $p < 0.05$ ). These results in the present study imply that compliant tendon affects effective elastic energy re-use and muscle-tendon interaction, and, thus, contributes to higher power output by ankle joint especially in late contact phase. ## MEASUREMENT OF THE AERODYNAMIC DRAG OF TEXTILES WITH A NOVEL DEVICE

Schindelwig, K., Hasler, M., Van Putten, J., Knoflach, C., Nachbauer, W.

*University Innsbruck*

Introduction In the past years, high speed sports such as speed skating, cycling and skiing were extensively studied from the aerodynamic point of view (Chowdhury et al., 2010; Oggiano et al. 2009). A number of authors previously studied how surface roughness affects the drag of cylinders. The acquisition of the drag data was always carried out in wind tunnel experiments. One important drawback of wind tunnel measurements is the high costs. In this study results of a novel measurement device allowing exact and economic studies are presented. Method The linear measurement system primarily consists of a 25 m long guidance beam and a cylinder with a height of 60 cm and a diameter of 15 cm mounted on a carriage. The carriage runs on the beam on a guideway on four rollers and is moved by a high torque electro motor via light fibre cables. The linear guidance system is located in a cooling chamber that can be adjusted in the range of  $-30^{\circ}\text{C}$  to  $30^{\circ}\text{C}$ . The distance from the cylinder to the carriage is 40 cm. The horizontal forces between the carriage and the cylinder are measured with two load cells and the position of the carriage is determined by an inductive length measuring system. The cylinder was covered with 2 different textiles. The drag force on the cylinder was measured at velocities from 5 to 20 m/s with a step size of 1 m/s with the linear measurement system and in an aeroacoustic wind tunnel (Audi, Ingolstadt, Germany). Every textile was tested 10 times at each speed with the linear measurement system to also assess the reliability of the system and 2 times in the wind tunnel. Results There is a good agreement between the wind tunnel data and the linear measurement system. The mean range of the 10 linear measurements is  $\pm 3.6\%$ . The reliability of the linear system was high with a correlation of 0.92. The range of the calculated  $c_d$  value at the different velocities was  $\pm 2.4\%$  with the linear system. In the wind tunnel experiments drag forces at the relevant velocities were in the range of  $\pm 10\%$ . Discussion The results of this work show that it is possible to determine the drag coefficient exactly with the new system. Especially at low velocities it is advantageous compared to automotive wind tunnels given the large velocity range required for the latter. Therefore in future it will be possible to analyze the effects of textile surfaces on the drag coefficient with a new, exact and economic method. References Chowdhury, Alam F, Subic A. (2010) *Proc. ## THE EFFECT OF PLAYING LEVEL AND ENGAGEMENT METHOD ON FORCES GENERATED IN RUGBY SCRUMMAGING

Preatoni, E., Stokes, K.A., England, M., Trewartha, G.

*University of Bath*

Introduction The scrum is an important phase of the rugby union game. During the scrum, players experience very peculiar biomechanical demands (high forces coupled with unstable balance) and repetitive mechanical stresses (Milburn, 1990; Preatoni et al., 2013), which may be a factor for both acute injuries and chronic degeneration of the spine. Since physical condition and technique likely play a fundamental role for both performance and injury prevention, the aim of this study was to analyse the effects of playing level and engagement conditions on forces generated in scrummaging. Methods Force measures were analysed as a function of: 6 playing levels (International, Elite, Community, Academy, Women and School), and 5 different engagement conditions (Hit&Hold, 3-Stage, FoldIn, 7+1 and 5+3). The different engagement conditions were designed in part to modify the loading conditions on players. Thirty-four teams participated in the study and performed 4-8 machine scrummaging trials for each of the 5 engagement conditions. A commercial scrum machine (Dictator, Rhino Rugby, UK), equipped with a bespoke force measurement system (Preatoni et al., 2012) measured the compression, lateral and vertical forces generated by the scrum pack. A set of parameters was selected to analyse applied forces in the subsequent phases of the engagement, from initial shock absorption to the sustained push. A mixed design ANOVA was used to assess main effects between and within groups and the playing level-engagement condition interaction. Results During the shock-absorption phase: (i) peaks of force (in all three directions) were lower in the FoldIn engagement than in the other conditions, and (ii) International and Elite teams produced higher peak compression forces than the other categories. For example, peak compression force ranged between 8.6 (2.0) kN for International and 4.2 (0.8) kN for School in the FoldIn engagement, and between 16.5 (1.4) kN for International and 8.7 (0.1) kN for Women in the Hit&Hold. Sustained compression force ranged between 8.53 (0.69) kN (International, 5+3) and 4.37 (0.15) (Women, 3-Stage), with greater sustained push for International and Elite, and the FoldIn engagement producing higher sustained compression force than the other conditions (significant for 3-Stage and 5+3). Discussion This study provides a more comprehensive picture of the influence of playing levels and engagement conditions on contemporary scrummaging biomechanics. It also informs practitioners and governing bodies about biomechanical factors that may influence performance and injury prevention. References Milburn PD. (1990). *J Sports Sci*, 8, 47-60. **THE EFFECTS OF GRADED SLOPES AND WALKING SPEED ON LOWER EXTREMITY MUSCLE ACTIVITY**

Gierlinger, G., Christian, J., Schwameder, H.

*University of Salzburg*

Introduction Walking on graded slopes requires exertion of greater forces across lower extremity joints. In the course of walking downwards, the knee joint absorbs up to 70 percent of the total negative work. This work is predominantly performed by the leg extensor M. quadriceps which is also expressed in the increasing tractive patella tendon and quadriceps force. When walking uphill, the rates of the performed work are equally balanced by the ankle, knee and hip joint (Schwameder et al., 2005). Despite increased attention to effects of inclination on human gait during the last years, many questions remain unresolved. On this account, this study has the main purpose of shedding further light on the muscular response to walking on various inclination levels and increased walking speed. Methods Twenty-six healthy male students with average age, height and weight of 25.4 ( $\pm 2.5$ ) years, 178.9 ( $\pm 6.5$ ) cm and 75.4 ( $\pm 9.2$ ) kg respectively, volunteered to complete this study. All participants were instructed to walk up and downhill on a treadmill at 4, 8 and 12 degrees and at walking speeds of 1.0 and 1.3m/s. Muscle activity was recorded of tibialis anterior (TA), soleus (SO), medial gastrocnemius (GA) and vastus (VA), medial (SM) and lateral hamstring (BF), rectus femoris (RF) as well as gluteus maximus (GL). Gait characteristics were obtained with Novel® Pedar insoles. Data was processed with a custom written Matlab® code and statistically analysed applying one-way ANOVA with repeated measures (Bonferroni,  $\alpha=0.05$ ). Results Significant differences were observed between ascending and descending inclination levels for all muscles regarding both mean activity and burst duration. During upslope walking, the mean activity of all muscles significantly and progressively increased from 4 to 12 degrees. GA revealed a significantly delayed activity onset and consequently decreased burst duration. With regard to BF, VA, RF and GL a significantly delayed offset and therefore increased burst duration was detected. However, when walking downwards the activity of BF set on significantly earlier while VA and RF revealed a tremendous increase in burst duration. The mean activity of VA and RF increased significantly at -8 and -12 compared to walking level. Between the walking speeds no significant differences were observed whether in terms of burst duration nor mean activity. Discussion The findings of the present study are in accordance with previously done research (Lay et al., 2007). It can be concluded that the extensor muscles namely SO, RF, GL, GA and VA responded most to the increase in inclination. TA, SM and BF however, served as co-contractors of the respective joints. When walking downhill, only the knee extensors absorbed the downwards moving body while the early onset of GA and BF evidently increases knee joint stability. **BIOMECHANICAL DETERMINANTS OF LONG-STANDING ADDUCTION-RELATED GROIN PAIN IN FOOTBALL PLAYERS.**

Kloskowska, P.1, Morrissey, D.1, Alty, J.2, Graham, J.1, Malliaras, P.1, Woledge, R.1

*1: Queen Mary University of London, 2: Reading FC*

Background: Long-standing adduction-related groin pain (LSARGP) is common (Weir et al., 2011b). In football LSARGP accounts for 12%-16% of all injuries (Ekstrand and Hilding, 1999, Werner et al., 2009). It is associated with high recurrence and prolonged time off sport (Weir et al., 2011a). Muscle activation and kinematic strategies in LSARGP are not well understood. The aim of this research was to better understand the kinematics and muscle activation in professional and amateur footballers with LSARGP. Methods: 20 professional (10 unilateral pain) and 19 male amateur (9 unilateral pain) footballers were recruited. Surface electromyography (sEMG) and 3D motion capture (CodaMotion) were applied during standing hip flexion (SHF). Analysis focused on gluteus medius (GM) versus adductor longus (AL) muscle activation ratio and kinematics of the hip joint in early, middle and end phase of SHF while standing on a symptomatic leg. Results: GM vs AL ratio was significantly ( $p<0.01$ ) decreased in amateur but increased ( $p=0.02$ ) in professional symptomatic athletes compared to matched control groups. Kinematic analysis of professionals with LSARGP showed increased abduction compared to control group, while symptomatic amateurs were more internally rotated and flexed compared to control group. Discussion: Opposite results in symptomatic professionals and amateurs might be explained by differences in rehabilitation. Professionals have access to treatment that might be focused on gluteal muscles, whereas amateurs may not all have rehabilitation and adopt alternative strategies to maintain pelvic stability. The results might also be explained by study limitations as participants were not matched nor controlled for symptoms chronicity or level. These findings have implications for rehabilitation of athletes with groin pain. References: EKSTRAND, J. & HILDING, J. 1999. *Department of Internal Medicine*

Skeletal muscle responds to physical activity with altered gene and protein expression profiles. Repetitive physical activity ultimately leads to morphological and functional adaptations in skeletal muscle. The aim of this study was to determine the currently unknown effects of training status on skeletal muscle transcriptional responses to a bout of acute endurance exercise. Trained ( $VO_{2max} \geq 57$  ml/min/kg BW) and untrained ( $VO_{2max} \leq 47$  ml/min/kg BW) male study participants performed an exhaustive bout of high intensity cycling exercise (60

minutes at 80% VO<sub>2</sub>max). Muscle biopsies were taken from the vastus lateralis at rest, 30 minutes and 3h after exercise. Global mRNA expression profiling by microarray analysis (Affymetrix Human Gene 1.0 ST Array) revealed that expression of the nuclear hormone receptor (NR) family NR4A subgroup, Nurr77 (NR4A1) and Nor-1 (NR4A3) was significantly induced by the acute cycling bout in both T and UT. The NR4A family of orphan nuclear receptors regulates the expression of fiber type specific metabolic and structural genes. Nurr77 expression increased 4.3-fold ( $p < 0.01$ ) and 3.5-fold ( $p < 0.01$ ) compared to the resting state 30 minutes after exercise in T and UT, respectively. Nurr77 expression continued to increase in UT at 3h (6-fold vs. rest,  $p < 0.001$ ), while transcript levels dropped slightly in T (2.1-fold vs. rest,  $p < 0.05$ ). The highest gene induction in this study was measured for Nor-1 at 3h post-exercise (T= 32-fold vs. rest; UT= 52-fold vs. rest,  $p < 0.001$ ). Nor-1 responds to  $\beta$ -adrenergic signaling and reduces myostatin (Mstn) expression. Expression of the  $\beta$ -2 adrenoreceptor (ADRB2) was elevated 2.1-fold vs. rest ( $p < 0.01$ ) in both T and UT muscle 30 minutes post exercise. Mstn expression was 2.6-fold ( $p < 0.01$ ) higher at rest in UT vs. T and expression decreased only in UT after exercise (3.1-fold vs. rest UT 3h,  $p < 0.01$ ). Results suggest that the NR4A family rapidly respond to acute exercise in T and UT skeletal muscle to regulate metabolic and structural genes important for exercise recovery and adaptation. Mstn expression was only perceptible to elevated Nur77 and Nor-1 expression in UT muscle, which suggests that the responsiveness of Mstn to acute exercise is dependent on training status.

### RECOMBINANT ERYTHROPOIETIN TREATMENT ENHANCES MITOCHONDRIAL FATTY ACID OXIDATION IN HUMAN SKELETAL MUSCLE.

Guadalupe Grau, A.1, Plenge, U.2, Belhage, B.2, Dela, F.1, Helge, J.W.1

Erythropoietin (EPO) is a hypoxia-induced hormone released by the renal cortex, where it promotes proliferation and differentiation of erythroid progenitor cells, regulating its number in the peripheral blood and thus increasing oxygen carrying ability of blood. Therefore, recombinant erythropoietin (rhEPO) treatment is widely used, albeit not legally, to enhance endurance exercise capacity. Parallel to these effects, an increase in resting energy expenditure (REE), as well as whole body fat oxidation (FAO) has been attributed to EPO. Skeletal muscle plays a role in REE, and is one of the main tissues responsible for fatty acid metabolism. This led to our hypothesis that a rhEPO-mediated increase in oxygen facilitation to the muscle increases mitochondrial FAO and could explain, at least in part, an increase in systemic REE and FAO. Methods. Human EPO was administered by muscular injection (5000 IU IM once weekly) in 6 healthy volunteers over 8 weeks, titrating the rhEpo dosage to maintain haematocrit level at ~50%. Oral iron (100 mg) supplementation was also given daily. Body composition was measured by DXA. Subjects performed two graded cycle ergometer exercise tests where VO<sub>2</sub>max, and maximal fat oxidation (MFO) were measured.  $\beta$ -hydroxy-acyl-CoA-dehydrogenase (HAD) and citrate synthase (CS) enzyme activity were measured fluorometrically. Mitochondrial respiration was measured in saponin permeabilized muscle using the following substrate-titration protocol: 2 mM Malate + 0.2 mM Octanoyl + 5 mM ADP + 10mM Pyruvate + 10 mM Glutamate/ + 10 mM Succinate. Results. As expected, rhEPO significantly increased blood haematocrit to 51%, and VO<sub>2</sub>max (from 54 $\pm$ 3 to 58 $\pm$ 3 ml·kg<sup>-1</sup>·min<sup>-1</sup>,  $P < 0.05$ ) without any exercise intervention. MFO and was not increased after rhEPO treatment, despite the higher intensity and duration of the exercise test. CS activity remained unchanged whereas HAD activity significantly increased after rhEPO ( $P < 0.05$ ). Maximal fatty acid mitochondrial capacity (MGPS3) was 1.4 fold higher after rhEPO treatment (from 59.5  $\pm$  10.6 to 82.7  $\pm$  20.8 pmol · s<sup>-1</sup> · mg<sup>-1</sup>  $P < 0.01$ ). Conclusion. Skeletal muscle mitochondrial respiratory and fat oxidation capacity is markedly higher after EPO treatment. Whole body MFO was not increased after rhEPO treatment, despite the higher intensity and duration of the exercise test. Our results suggest that the oxygen delivery capacity was not limiting the magnitude of maximal systemic fat oxidation. These findings may partially account for the enhancement of submaximal endurance performance.

### INVOLVEMENT OF OXIDATIVE STRESS IN PROSTATE CANCER PROGRESSION: A PREVENTIVE EFFECT OF PHYSICAL ACTIVITY AND/OR POMEGRANATE JUICE?

Guéritat, J., Lefevre-Orfila, L., Vincent, S., Delamarche, A., Rannou-Bekono, F., Rebillard, A.

*EA 1274,*

Introduction Prostate cancer (PC) is the most common form of cancer affecting men in the Western world. Various studies suggest a decrease of PC evolution with exercise or antioxidants but the association of these two strategies has never been investigated. We hypothesize that oxidative stress is a key regulator factor of PC. In this context, we suppose that the potential decrease of oxidative stress (OS) induced by pomegranate juice (PJ) consumption alone, running training alone or the associated strategies could delay the development of PC. The objectives of this project are (1) to identify the effect of PJ and/or physical activity on PC progression in a rodent model; (2) to determine the molecular mechanisms involved in this prevention. Methods Forty male Copenhagen rats with subcutaneous prostate tumor are divided into four groups: (1) control, (2) daily consumption of pomegranate juice PJ, (3) daily running on a treadmill (training), (4) PJ + training. Each week, tumor growth is evaluated using a sliding caliper. Four weeks after the various treatments, the rodents are sacrificed. The tumors are resected and frozen. Muscles (EDL, soleus, gastrocnemus and tibialis) are removed as well as blood and urine. The levels of antioxidant vitamins, antioxidant enzyme activities, lipid peroxidation, carbonylated proteins and DNA oxidation are investigated and the signaling pathways are identified. Data are compared by analysis of variance (ANOVA) and the degree of significance is set at  $p < 0.05$ . Results PJ consumption alone or training alone decreases prostate tumor growth in the Copenhagen rat ( $p < 0.05$ ) but the association of the two strategies is not also effective. Indeed, tumor volume doubling time is respectively of about six days for control and PJ+ training, whereas it is of eight days for PJ alone or training alone. We observe a significant difference of reduced GSH and vitamin A between PJ and control groups ( $p < 0.05$ ). Moreover, training increases significantly GPx activity vs control and PJ groups ( $p < 0.05$ ). The combination of PJ and training inhibits antioxidant adaptations induced by each treatment. Discussion Although none study has demonstrated the benefits of both PJ and training, urologists recommend consumption of food antioxidants associated with physical exercise as chemoprevention for active monitoring PC patients. However our innovative study shows for the first time that combined effects of PJ and training may inhibit antioxidant adaptations and could prevent the modulation of redox-dependent signaling pathways involved in the prostate tumorigenesis.

### CIRCULATING MICRORNAS SPECIFIC FOR SKELETAL AND/OR CARDIAC MUSCLE ARE ENHANCED AFTER AN IRONMAN TRIATHLON RACE

Wessner, B., Berkowitsch, B., Laaber, O., Bachl, N., Tschan, H.

*University of Vienna*

**Introduction:** MicroRNAs (miRNAs) have been shown to mediate adaptation to exercise by influencing many physiological processes [1,2]. Besides their specific abundance within different tissues, significant levels of miRNAs were detected in serum where they are remarkably stable [3]. It is assumed that muscle-specific miRNAs could serve as diagnostic markers for cardiac damage but the influence of mechanical stress due to exercise is questioned [4]. Therefore, the aims of this study were to investigate whether circulating levels of skeletal and cardiac muscle-specific miRNAs are detectable after extreme exercise and to correlate them with biochemical markers of skeletal and cardiac muscle damage. **Methods:** 18 male triathletes (age:  $40 \pm 9$  y, BMI:  $23 \pm 2$  kg/m<sup>2</sup>) participating at the Ironman Austria agreed to donate blood 1d before, immediately as well as 1 and 7d after the race (finishing time:  $11.8 \pm 1.1$ h). Total RNA was isolated from serum using the miRNeasy Serum Kit (Qiagen). After reverse transcription, miR-133a, -206, -208b, and -499-5p levels were quantified by qRT-PCR. Creatine kinase (CK), myoglobin (MYO), high sensitive troponin (hs-TNT), and NT-proBNP were determined on a COBAS 8000 system. Repeated measures ANOVA was used to detect differences between pre and post values and Pearson's correlation analyses served to describe correlations between single markers. **Results:** Muscle-specific miRNAs were highly enhanced directly after completing the race (miR-133a: 32-fold, miR-206: 61-fold, miR208b: 41-fold, miR-499-5p: 13-fold;  $p < 0.001$  for all comparisons). In general, levels decreased 24h thereafter but still were significantly higher than pre-race levels (miR-133a: 10-fold, miR-206: 10-fold, miR208b: 28-fold, miR-499-5p 12-fold;  $p < 0.001$  for all comparisons). 7d post-race all miRNAs returned to baseline levels. Markers for skeletal muscle damage peaked immediately (MYO: 35-fold,  $p < 0.001$ ) or 1d (CK: 21-fold,  $p < 0.001$ ) post-race. Cardiac stress markers (NT-proBNP, hs-TNT) were significantly enhanced immediately after the Ironman. Correlation analyses revealed high and significant correlations between muscle-damage markers and miRNAs. **Discussion:** This is one of the first studies revealing that intense exercise such as an Ironman triathlon causes increases in circulating muscle-specific miRNAs and that these increases are highly correlated to common markers of muscle-damage. It has to be proven whether they could serve as new diagnostic markers to clearly discriminate between skeletal (miR-206) and cardiac muscle damage (miR-208b). **References** [1] McCarthy J et al (2011). *Exerc Sport Sci Rev* 39(3):150-4. ### GENES ENCODING PROTEOGLYCANS ARE ASSOCIATED WITH THE RISK OF ANTERIOR CRUCIATE LIGAMENT RUPTURES

Mannion, S.1,2, Mtintsilana, A.1, van der Merwe, W.4, O'Cuinneagain, D.4, Collins, M.1,3, September, A.V.1

*1 UCT Human Biology (Cape Town, South Africa), 2 UCT Human Genetics (Cape Town, South Africa), 3 MRC (Cape Town, South Africa), 4 SSOC (Cape Town, South Africa)*

**Introduction** Anterior cruciate ligament (ACL) ruptures are one of the most detrimental injuries sustained in sports. Multiple risk factors, including genetic factors, are associated with the injury (September et al., 2007; 2012). Proteoglycan content is lowered in ruptured ACL tissue in comparison to non-ruptured controls (Young et al., 2011). Genes encoding proteoglycans thus form candidate genes to be investigated for an association with ACL injury risk. The aim of this study was to investigate whether sequence variants within the ACAN, BGN, DCN, FMOD and LUM proteoglycan genes are associated with risk of ACL injury. Aggrecan is a major structural constituent of cartilage, while the small leucine rich proteoglycans are important for collagen fibrillogenesis. **Methods** A case-control genetic association study was conducted. In total, 210 participants with surgically diagnosed ACL ruptures and 234 control participants without any history of ACL injury were genotyped for the following single nucleotide polymorphisms using standard PCR based methods: ACAN rs2351491, rs1042631, rs1516797; BGN rs1126499, rs1042103; DCN rs13312816, rs516115; FMOD rs7543148, rs10800912; and LUM rs2268578. Statistical analysis determined whether genotype or allele frequencies differed significantly between cases and controls. **Results** The GG genotype of ACAN rs1516797 was significantly overrepresented in ACL participants ( $p = 0.042$ , OR=2.018, 95% CI 1.015-4.015) when compared to controls. For BGN rs1126499 the TT genotype was overrepresented in ACL participants ( $p = 0.032$ , OR=1.515, 95% CI 1.037-2.215) while the CT genotype was overrepresented in controls ( $p = 0.004$ , OR=0.470, 95% CI 0.277-0.796). The AA genotype of DCN rs516115 was significantly overrepresented in female ACL participants ( $p = 0.022$ , OR=2.279, 95% CI 1.120-4.636) and interestingly the GG genotype was absent in female ACL participants ( $p = 0.008$ , OR=0.063, 95% CI 0.004-1.096). No other significant genotype or allele associations were noted. **Discussion** Preliminary evidence suggests that ACAN rs1516797, BGN rs1126499 and DCN rs516115 are associated with ACL injury risk. This novel study highlights the potential role of proteoglycans in ACL ruptures. **References** September AV, Schwellnus MP, Collins M. *Br J Sports Med* 2007;41:241-6. The contribution of skeletal muscle, as a main determinant of activity-induced metabolic adjustments, to improved aerobic fitness with skiing is not understood. We hypothesized that adjustments in aerobic capacity in the main knee extensor muscle, m. vastus lateralis, but not capillary-mediated glucose uptake would explain the improved VO<sub>2</sub>max with skiing. **Methods** 28 healthy elderly subjects (age  $67.5 \pm 2.9$  years) entered a supervised 3-months downhill ski-training program including an average of 28.5 days of guided skiing. Anthropometric measures were carried out before and after training, including the measure of VO<sub>2</sub>max, glucose and lipid handling and muscle thickness. Biopsies of vastus lateralis muscle were analysed from 19 subjects (10 males, 9 females) whom completed the training. Cryosections were prepared and capillary density was determined using lectin-based morphometry. Total protein was extracted and subjected to the analysis of the concentration of markers of respiratory chain components (INDUFA9, SDHA, UQCRC1,

ATP5A1) and the mediator of contraction induced glucose transport, GLUT-4, using SDS-PAGE based immunoblotting with commercially available antibodies. Statistical significance of changes was assessed with a one tailed paired T-test at a p-value of 5%. Results VO<sub>2</sub>max was increased by 7%, and the HOMA2 index for insulin resistance, but not plasma glucose (p=0.23), decreased by 21% with ski training. A trend for an increase in the concentration of respiratory chain complexes III (UQCRC1; +60%) and V (ATP5A1, +32%) and capillary density (+12%) was noted. GLUT-4 protein (p=0.49) were not altered. None of measured metabolic proteins correlated with VO<sub>2</sub>max at either stage of training. Discussion The observations indicate that recreational downhill ski training has a borderline effect on muscle's aerobic capacity but leaves glucose uptake capacity unaffected. The disconnection between changes in local aerobic capacity and glucose uptake after downhill skiing remains to be explored. References Dela F, Niederseer D, Patsch W, Pirich C, Müller E, Niebauer J. Glucose homeostasis and cardiovascular disease biomarkers in older alpine skiers. *Scand J Med Sci Sports* 21 S1: 56-61, 2011.

**Introduction.** After intense exercise, the athlete's immune response is characterized by suppressed neutrophil function and increased lymphocyte death, resulting in immunosuppression [1,2]. The purpose of this study was to measure necrosis and apoptosis of lymphocytes (DNA fragmentation, surface expression of CD95 and phosphatidylserine) and ROS release in athletes prior to and after a competitive futsal match. **Methods.** Blood samples were taken from 16 futsal players (19±1 yrs, 68±6 kg, 51±2.6 ml•kg<sup>-1</sup>•min<sup>-1</sup>) before and immediately after a futsal match. Lymphocytes were isolated from the players' peripheral blood using Histopaque®. Lymphocyte necrosis, expression of CD95 and phosphatidylserine, DNA fragmentation and ROS production in lymphocytes were assessed using a flow cytometer. **Results.** The futsal match induced lymphocytosis and apoptotic death of lymphocytes, as indicated by phosphatidylserine externalization (9.5-fold), CD95 expression (1.5-fold), and DNA fragmentation (1.1-fold). In addition, after the futsal match, lymphocytes spontaneously released higher amounts of ROS (3.6-fold). **Discussion.** Our results demonstrate that playing futsal induces lymphocyte apoptosis. During a futsal match, lymphocytes are exposed to pro-apoptotic signals that include augmented levels of inflammatory cytokines and ROS, which elicit changes at the molecular level, leaving lymphocytes more susceptible to both intrinsic and extrinsic pathways for apoptosis. In the extrinsic pathway for apoptosis, the activation of death receptors such as CD95 causes recruitment and oligomerization of the adapter molecule FAS-associated protein with the death domain within the death-inducing signaling complex. Also during apoptosis, membrane asymmetry is lost and phosphatidylserine translocates to the external leaflet of the cell surface, and the cells undergo DNA fragmentation. **References.** [1] de Moura NR., Cury-Boaventura MF., Santos VC., Levada-Pires AC., Bortolon J., Fiamoncini J., Pithon-Curi TC., Curi R., Hatanaka E. #### SALIVARY HORMONAL PROFILE IN RELATION WITH BONE-MUSCLE ACTIVITY OVER A CYCLING STAGE RACE

Lombardi, G.1, Lanteri, P.1, Corsetti, R.2, Grasso, D.1, Di Bernardo, C.1, Colombini, A.1, Graziani, R.3, Banfi, G.1,4

*I.R.C.C.S. Istituto Ortopedico Galeazzi*

1: IRCCS Istituto Ortopedico Galeazzi (Milano, Italy), 2: Liguigas-Cannondale (Pordenone, Italy), 3: CEDAL (Gallarate, Italy), 4: University of Milano (Milano, Italy) **Introduction** Cycling stage races are strenuous performances affecting the homeostasis of many tissues, such as bone (Lombardi et al., 2012; Lombardi et al., IN PRESS) and muscles (Colombini et al., 2012). Although explored, the hormonal changes supporting this response is not fully elucidated. Serially measuring the hormonal levels allows a more accurate profiling; this opportunity could be reached with the use of saliva, since salivary steroid hormones are known to reflect type, duration and intensity of exercise (Gatti and De Palo, 2011). **Aim** of the study was to determine the temporal changes and the reciprocal relationship of salivary steroid hormones, bone-muscular markers and the metabolic effort, during a cycling stage race. **Methods** Nine pro-cyclists participating in 2012 Giro d'Italia were recruited; daily anthropometrical features and power output/energy expenditure were recorded. Diet was kept constant. Saliva was collected at days -1,4,8, 12, 14, 19, 23; blood and urine were collected at days -1, 12 and 23. Salivary cortisol, DHEA, testosterone and estradiol, serum LDH, AST and CK activities and urinary calcium and phosphorous were measured. Plasma volume changes were determined. **Results** While cortisol remained constant, testosterone significantly decreased at day 4, estradiol and DHEA increased in the first part of the race to then returned to basal levels. Salivary hormones levels were not correlated with plasma volume shifts. LDH, CK, and AST increased over the race as well as the urinary excretion of calcium and phosphorous. Correlations were found between DHEA and estradiol and the indexes of metabolic effort and the bone-muscular markers. **Discussion** The present findings on muscular and bone activations are consistent and confirmed those previously published (Lombardi et al., 2012; Lombardi et al., IN PRESS; Colombini et al., 2012). The known co-activation of bone and muscle (Zofkova, 2008) is related to the power output and the energy expenditure and seems to be sustained by the changes in DHEA and estradiol. Saliva represents a useful tool to allow a serial monitoring in the athlete's hormonal asset even during competitions. We confirm the presence of an hormonal co-regulation of bone and muscle metabolic activities driven by the metabolic effort. **References** Lombardi G, Lanteri P, Graziani R, et al. ### THE EFFECTS OF NAC SUPPLEMENTATION ON REDOX STATUS IN PEOPLE WITH G6PD DEFICIENCY

Jamurtas, A., Liakos, Y., Theodorou, A.A., Zalavras, A., Deli, C.K., Fatouros, I.G., Koutedakis, Y.

*University of Thessaly*

**Introduction** Glucose 6 phosphate dehydrogenase deficiency (G6PD) is the rate limiting step in the pentose phosphate pathway that results in the formation of NADPH which is the driving power for the recycling of glutathione. N-acetylcysteine (NAC) has been used to prevent the decline of glutathione under oxidative stress conditions (Vats et al., 2008) and hypothetically could be efficient under conditions where glutathione levels are reduced such as in G6PD deficiency. Therefore, the purpose of this study was to examine the effects of NAC supplementation on redox status in people with G6PD deficiency. **Methods** Ten young people (8 males and 2 females) with G6PD deficiency (D) and 10 matched controls with normal levels of the enzyme (N) participated in the study. All subjects received NAC (600 mg per day) for 14 days. Before and after supplementation blood was collected from all participants. Reduced (GSH) and oxidized glutathione (GSSG), thiobarbituric reactive substances (TBARS), bilirubin and uric acid were assessed. Results G6PD levels were 150 times higher in N compared to D ( $N = 9.27 \pm 1.9$  U/g Hb vs.  $D = 0.62 \pm 0.55$  U/g Hb). There were differences in GSH for group ( $F_{1,9} = 6.25$ ,  $p < 0.05$ ) and time ( $F_{1,9} = 11.73$ ,  $p < 0.005$ ) with N showing significantly higher levels before ( $N = 3.36 \pm 0.86$   $\mu\text{mol/g Hb}$  vs.  $D = 2.75 \pm 0.55$   $\mu\text{mol/g Hb}$ ) and after ( $N = 3.80 \pm 0.90$   $\mu\text{mol/g Hb}$  vs.  $D = 2.98 \pm 0.50$   $\mu\text{mol/g Hb}$ ) supplementation compared to D. No group X time interaction was found for GSH. No significance for group ( $F_{1,9} = 2.22$ ,  $p = 0.17$ ), time ( $F_{1,9} = 0.009$ ,  $p = 0.93$ ) or group x time was observed for GSSG levels. GSH/GSSG ratio was not significant for group ( $F_{1,9} = 0.19$ ,  $p = 0.67$ ) but approached significance for time ( $F_{1,9} = 4.205$ ,  $p = 0.07$ ). No significance for group, time or group x time was observed for TBARS, bilirubin or uric acid levels. **Discussion** These results indicate that short term supplementation with NAC can alter GSH levels in G6PD deficient individuals with no changes in lipid peroxidation or antioxidant indices. Further research is needed in order to examine the effects of longer supplementation with NAC on redox status and the response of these individuals following a stressful condition such as exercise. **References** Vats P, Singh VK, Singh SN, Singh SB (2008). Glutathione metabolism under high altitude stress and effect of antioxidant supplementation. *Aviat Space Environ Med* 2008; 79: 1106 – 11.

### MUSCLE FIBRE TYPE DOES NOT EXPLAIN POOR MUSCLE STRENGTH IN MCARDLE PATIENTS

Kohn, T.A., Noakes, T.D., Rae, D.E., Rubio, J.C., Santalla, A., Lucia, A.

*University of Cape Town, Hospital 12 de Octubre, Pablo Olavide University, European University of Madrid*

**Introduction** Previous research showed that McArdle patients had a higher surface electrical activity (as measured by electromyography (EMG)) at the same relative workload compared to healthy individuals (2). This suggested that more fibres were activated to fulfil the required work. As muscle fibre type plays an important role in overall muscle function, with type IIa and IIx fibres associated with generating more force than type I fibres, it was hypothesized that McArdle patients would have a predominance of type I myosin heavy chain (MHC) isoforms and less MHC IIa and IIx isoforms compared to healthy individuals. **Methods** Muscle biopsies were obtained over a 10-year period from male and female patients diagnosed with glycogen storage myopathy V (McArdle disease). Nine biopsies from the biceps brachii (BB) (+ 3 healthy controls) and 8 from the vastus lateralis (VL) (+10 healthy controls). These samples were analysed for myosin heavy chain isoform content using SDS-PAGE. The latter provides a relative measure of muscle fibre type. Data (mean  $\pm$  SD) were analysed using a non-parametric one-way ANOVA. Results In all the samples analysed, all three MHC isoforms were found, namely MHC I, MHC IIa and MHC IIx. No difference in isoform expression was found between McArdle and control VL (MHC I:  $33 \pm 19$  vs.  $43 \pm 7\%$ ; MHC IIa:  $52 \pm 9$  vs.  $40 \pm 7\%$ ; MHC IIx:  $15 \pm 18$  vs.  $17 \pm 9\%$ ). Similarly, the BB isoform content did not differ significantly between the two groups (MHC I:  $33 \pm 14$  vs.  $29 \pm 12$ ; MHC IIa:  $46 \pm 17$  vs.  $39 \pm 5$ ; MHC IIx:  $21 \pm 13$  vs.  $32 \pm 14\%$ ). **Discussion** This study evaluated whether a difference in muscle fibre type existed between patients diagnosed with McArdle disease and healthy participants. The results showed that the proportion of isoforms expressed in VL and BB are similar to muscle groups from healthy individuals and thus, cannot explain the higher EMG activity recorded. Furthermore, atrophy of muscle fibres from McArdle patients was only reported for type I fibres (1). Therefore, it is speculated that McArdle disease may also affect the contractile apparatus of the skeletal muscle. **References** 1. Felice KJ, Grunnet ML, Sima AA. ### THE EFFECT OF SOCCER TRAINING AND EXERCISE ON DNA STABILITY AND OXIDATIVE STRESS STATUS

Baralic, I.1, Djordjevic, B.2, Andjelkovic, M.1, Dikic, N.1, Kotur Steviljevic, J.2, Sopic, M.2, Antic, T.1, Vukasinovic-Vesic, M.1, Radojevic-Skodic, S.3

*1: Sports Medicine Association of Serbia, 2: Faculty of Pharmacy, University of Belgrade, 3: School of Medicine, University of Belgrade*

**Introduction** The purpose of the current study was to determine whether soccer exercise is able to cause oxidative stress and DNA instability. Also, we sought to investigate if adaptive response will be developed during 90 day training period and to what extent. **Methods** 14 male elite soccer players, members of soccer team "Teleoptik" participated in the study. Blood samples were collected at the onset of the study and after 90 days of regular training in pre-exercise and post-exercise conditions. We used comet assay to investigate leukocyte DNA stability. The results were presented as DNA score and percent of cells with medium and high damage. Oxidative stress was estimated through blood levels of superoxide anion ( $\text{O}_2^{\bullet-}$ ), total oxidative status (TOS), total antioxidative status (TAS), sulphhydryl groups (SH) and redox balance. The effect of time and exercise and of the combined factors (interaction) on each parameter was analyzed using ANOVA repeated-measures, with time (onset of the study vs. end of the study) and exercise (pre-exercise vs. post-exercise) as the two within-subject factors. Results DNA score did not change significantly in response to soccer exercise. Soccer exercise induced significant increase in the percent of cells with medium and high damage ( $p < 0.05$ ), but only at the beginning of the observational period. However, this parameter, as well as DNA score decreased significantly after 90 days of training period (main time effect,  $p < 0.05$  and  $p < 0.001$ , respectively).  $\text{O}_2^{\bullet-}$  levels increased as a result of regular soccer training over the 90 days (main time effect,  $p < 0.001$ , respectively). Soccer players experienced significant increase in  $\text{O}_2^{\bullet-}$  levels in response to exercise at the end of the study (main exercise effect,  $p < 0.01$ ; exercise x time effect,  $p < 0.05$ ). Following 90 days of regular training, TOS and redox balance significantly decreased (main time effect,  $p < 0.001$ ). There was significant time and exercise interaction effect ( $p < 0.01$ ), since we noticed increase in TOS levels post-exercise at the end of the study, but no change at the beginning. We observed a remarkable decrease in TAS in response to exercise both at the beginning and at the end of the study (main exercise effect,  $p < 0.001$ ). Total SH groups content at rest increased significantly after 90 days of regular training (main time effect,  $p < 0.01$ ). **Discussion** Soccer players are exposed to increased levels of oxidative stress at the beginning of the training season, which might compromise DNA stability and decrease capacity of antioxidant defense. However, regular soccer

training can have a protective effect due to upregulation of antioxidant defense system, causing lower oxidative stress and DNA damage, despite increased production of free radicals. Fisher-Wellman K, Bloomer RJ. (2009). *Dynamic Med*, 8, 1-25.

### **BLOOD LACTATE KINETICS AND MUSCLE POWER FOLLOWING ONE SESSION OF HIGH INTENSIVE INTERVAL TRAINING AND HIGH INTENSIVE TRAINING IN YOUNG AND ADULT MALE ATHLETES**

Engel, F., Stockinger, C., Härtel, S., Bös, K.

*Karlsruher Institute of Technology*

**Introduction** Recovery from High Intensive Interval Training (HIIT) and High Intensive Training (HIT) is faster in children than in adults but the exact mechanisms for the difference in recovery remain unclear (Ratel et al., 2006). However, recovery of blood lactate kinetics and muscle power following HIIT and HIT in trained boys remains relatively unknown. The present study aimed to determine the recovery from HIIT and HIT on blood lactate kinetics and performance in young and adult male athletes. **Methods** Twenty-one trained boys (11.5±0.8 years) and 19 trained men (29.6±4.8 years) performed (a) four consecutive Wingate Anaerobic Tests (HIIT) and (b) one single Wingate Anaerobic Test (HIT). Blood lactate concentration (BLC) was measured after each of the four Wingate Anaerobic Tests in HIIT and after HIT and for 30 minutes of recovery in both tests. The individual BLC recovery curves were fitted to a biexponential time function:  $LA(t) = LA(0) + A1(1 - e^{-\gamma_1 t}) + A2(1 - e^{-\gamma_2 t})$ , where  $\gamma_1$  and  $\gamma_2$  describe the abilities to exchange lactate between the previously active muscle and the blood and to eliminate lactate from the organism, respectively (Freund and Zouloumian, 1981). Performance was measured throughout both tests. **Results** In both tests peak BLC was significantly lower in boys (HIIT: 12.2±3.6 mmol/l; HIT: 8.7±1.8 mmol/l) than in men (HIIT: 16.1±3.3 mmol/l; HIT: 11.5±2.1;  $p < 0.01$ ). Higher  $\gamma_1$  and  $\gamma_2$  values were observed in boys in both tests ( $p < 0.01$ ). Decrease of performance from 1st to 4th Wingate Anaerobic Test in HIIT was lower in boys than in men ( $p < 0.01$ ). **Discussion** It was concluded that both abilities, the faster lactate exchange and the better elimination of lactate from the organism, in boys while and after HIIT and HIT leads to diminished peak BLC. The better lactate removal in boys subsequent to HIIT and HIT represents a faster recovery following HIIT and HIT. The faster recovery enables the boys to a better efficiency to maintain muscle power during HIIT. The fast lactate removal shown in boys in the present study is most likely one mechanism for the fast recovery after HIIT and HIT in children that remained undefined by Ratel et al. (2006). **References** Freund H, Zouloumian P (1981). Lactate after exercise in man. *Eur J Appl Physiol Occup Physiol* 46:121–176. Ratel S, Duché P, Williams CA (2006). #### **JOINING UP THE DOTS: WHO ARE THE BEGINNING TEACHERS?**

Queirós, P., Batista, P., Ferreira, A.M.

*University of Porto / Faculty of Sport*

**Introduction** To understand how the pre-service teachers turn themselves into teachers and how they develop their professional identity during the practicum is not an easy task. It is important to uncover the transformations that occur during the practicum, namely the linkage between structure and agency (Giddens, 1984). Trying to better understand how the pre-service teachers developed their professional identity the aim of this study is to describe the main characteristics of a group of 4 pre-service teachers in the beginning of their practicum. **Methods** Data collection The data collection resulted from a participant observation made between 21st September 2012 and 5th February 2013 in a practicum group of Physical Education pre-service teachers that works in a secondary public school of Porto, Portugal. The researcher developed an ethnographic study and stays 4 days each week in the school with the group of pre-service teachers observing their classes, staff reunions, collective and individual seminars and other school activities. During the observation period field notes were taken and informal interviews were done in order to clarify some specific situations or uncover particular meanings attributed by the pre-service teachers. **Data analysis** The concept of metaphors (based on the field notes and in the informal interviews) was used to outlining the initial profile of each pre-service teacher. Tannehill and MacPhail (2012) stated that "generally, we think of a metaphor as a figure of speech or something that we use to replace 'normal' words in order to help others understand or enjoy our message." (p. 3) A different metaphor for each pre-service teacher was used to inform the readers about the type of teachers I (as researcher) interpret them as beginning teachers. **Results and Discussion** Although they all work within the practicum group, the pre-service teachers tend to expose different characteristics, which can define them as novice teachers. These different features are related to their personal beliefs, values and teaching perspectives. Even though, there are also some characteristics that are common to all pre-service teachers. In fact, the pre-service teachers mostly tend to act based in what they think the cooperating teacher expect, just applying what is prescribed. Understanding agency as the capacity to act independently and to take responsibility for our actions (Giddens, 1984), it is noticeable that in the earlier stage of the practicum the structure wins. **Acknowledgements** This study is part of a project funded by the Foundation for Science and Technology (FCT) with the following reference: PTDC/DES/115922/2009. **References** Giddens A. (1984). *The Constitution of Society*, Stanford, CA: Polity. Tannehill D, MacPhail A. (2012). #### **THE HIDDEN LEARNING OBJECTS IN PE – PROBLEMATIC OR NOT?**

Redelius, K., Öhman, M., Quennerstedt, M.

*The Swedish School of Sport and Health Sciences*

Throughout its history Physical Education (PE) has been regarded as a 'practical' subject, with a focus on doing gymnastics, sport or play. Students generally think that the subject is important, but they have a hard time stating what they should learn in PE, and that does not only apply to students. Teachers too have difficulties articulating what the students are supposed to learn (Redelius, Fagrell & Larsson, 2009); (Quennerstedt, Öhman, Ericsson, 2008). The aim was to scrutinize how teachers frame the teaching in terms of whether the make

the purpose and the learning outcomes explicit to their students or not. Central questions were: What aspects of learning do teachers articulate and highlight before the lessons? What aspects of learning do teachers articulate and highlight in the teaching, when presenting the content of the lesson to students? Methods The theoretical framework in which this study is grounded is a socio-cultural perspective on teaching and learning (Lave & Wenger, 1991). The participants were teachers and students from three secondary and three upper secondary schools in Sweden. The schools were located in three different cities spread out from north to south. In all, six PE-teachers and about 150 students participated in the study. At each school, at least three PE lessons were videotaped (in total 24 PE-lessons). In addition, six PE teachers and 24 students were interviewed. Results The analysis reveals that two of the teachers are both quite clear about the aims, purposes and outcomes of the lessons and they also communicate this to their students, two teachers express the aims, purposes and outcomes of the lessons in the pre interviews, but they did not communicate this to their students. The third group of teachers had difficulties in communicating learning outcomes with both in interviews and in front of the students. Discussion In the study the socio-cultural perspective was used as a way to direct our attention towards how teachers situated and framed the lesson by communicating the purposes, aims and learning outcomes of the PE-lessons. The results show that if students are to understand what they are supposed to learn in PE, then teachers must communicate the learning goals to students. References Lave, J., & Wenger, E. (1991). *Situated learning: Legitimate peripheral participation*. Cambridge, MA: Cambridge University Press Quennerstedt, M., Öhman, M., Ericsson, C. ### **EFFECTS OF A SHORT-TERM SERVICE LEARNING EXPERIENCE ON PHYSICAL EDUCATION PRESERVICE TEACHERS' CULTURAL COMPETENCY AND TEACHING SKILLS.**

Peralta, L.R., O'Connor, D., Cotton, W.G., Bennie, A.

*The University of Sydney*

Introduction Although service learning has the potential to address school and community needs while providing valuable learning experiences that enhance preservice teachers' culturally responsive pedagogical skills (Buchanan, Baldwin, & Rudisill, 2002), not one service learning experience (SLE) has focused on preservice physical education (PE) teachers and Australian Indigenous students. Hence, the purpose of this study was to investigate the effects of a community and school-based service learning experience (SLE) on preservice PE teachers' cultural competency. Methods A mixed methodology approach was utilised. Final year preservice teachers enrolled in a core unit of study (n=56; age 21.9[8.3] years; 10.7% from low SES) were invited with 98% consenting to participate in a 6-week service learning experience. Measures included baseline and follow-up reflective journals (individual [n=55] and group [n=18]), multicultural teaching competency scales (n=55) and a follow-up focus group interview (n=8). Results Findings revealed that there were statistically significant increases in cultural competency (p=0.000), multicultural knowledge (p=0.000), and skills (p=0.000) from baseline to follow-up. Qualitative analyses identified that preservice teachers were more able to appreciate cultural differences, challenge existing stereotypes, use a student-centred teaching style and design culturally relevant pedagogies and activities, set high expectations and link theory and practice, as a result of their participation in the SLE. Discussion These findings provide evidence that there are benefits such as improved cultural competency and teaching quality, and broadened perspectives through bridging the theory and practice divide, for preservice teachers experiencing service learning opportunities with Indigenous Australian youth. References Buchanan, A. M., Baldwin, S. C., & Rudisill, M. E. (2002). Service learning as scholarship in teacher education. *Educational Researcher*, 31(8), 30-36.

### **THE SOCIAL CONSTRUCTION OF PEDAGOGIC DISCOURSE IN PHYSICAL EDUCATION AND SCHOOL SPORT POLICY DURING A DECADE OF CHANGE IN ENGLAND, 2000-2010**

Jung, H., Pope, S., Kirk, D.

*Institute for Sport and Physical Activity Research*

Over the past decade in the UK, the rise in salience to government of PE and school sport-related policy interventions has been remarkable for the wide-ranging array of objectives that these interventions have been expected to realize (Phillips, 2008). In light of increasing government intervention and interest in physical education and school sport, we analyse and evaluate the Physical Education, School Sport and Club Links (PESSCL) strategy which is one of the most significant sport policies in 2000s. Drawing on Basil Bernstein's (1990,1996) theory of the social production of pedagogic discourse, the primary aim of this presentation is to identify the physical cultural discourses that have informed the PESSCL strategy and its implementation in terms of sport organisation between 2000 and 2010. We have conducted a documentary analysis (Halperin & Heath, 2012), analyzing discourses embedded in PE and school sport policy documents (n=9) and adapted grounded theory approach (Glaser, & Strauss,1967) in order to conceptualize how notions of physical culture are produced and reproduced across primary and recontextualizing fields in which specific agents and agencies operate. This is combined with conducting semi-structured interviews (n=8) with these agencies and an analysis of the outputs of various media (n=467). We identify a number of physical cultural discourses within these policy and other documents and sources, including discourses of health and obesity, good citizenship and volunteering, and elite sport development with a particular concern for the London 2012 Games. Moreover, we discover evidence, consistent with Goodson's (1990) thesis about the social construction of school subjects, of struggles and contestation among vying groups, in this case between agencies such as Youth Sport Trust and Sport England to take the lead in implementing government policy (ie. PESSCL). In conclusion, we question whether there is any connection between government policies, commissioned evaluation reports (eg. by Ofsted, TNS-BMRB and the Loughborough Partnership), and the practice of forms of physical education and school sport. ## PE TEACHERS' CONSTRUCTIONS OF SOCIAL AND BODILY DIVERSITY AND THEIR INFLUENCE ON TEACHING PROCESSES IN MULTI-CULTURAL PE CLASSES IN SECONDARY SCHOOLS IN THE NETHERLANDS

Van Doodewaard, C.L., Knoppers, A.E.

*Windesheim, university of Applied Sciences, Zwolle*

Introduction Over the years Dutch Physical Education (PE)-classes have become more ethnically mixed (Statistics Netherlands, 2009a) and diversity in behavioral and physical competences has increased (Statistics Netherlands, 2009b). This is placing greater demands on PE teachers (Bax, et al., 2010). Purpose of this project is to gain insight in the way PE teachers (re)construct social and physical differences in multicultural (MC) classrooms and how these constructions influence teaching processes of inclusion and exclusion. We use a social constructionist perspective to investigate the nature of the interactions between teachers and students that reflect cultural traditions and general patterns of action (Grenier, 2007). Research questions are: How do PE teachers construct diversity? Which strategies do PE teachers use to manage diversity in the gym? How do these constructions and strategies inform processes of inclusion and exclusion in PE classes? Methods Thirteen semi-structured and video stimulated interviews were conducted with PE teachers of MC classrooms. We used qualitative data analysis software to analyze the interviews. The outcomes were discussed and confronted with research literature. Results Four meta themes emerged from the data: relating to students, dealing with cultural identities, engaging in leadership, and assessing performance. Results indicated that PE teachers developed close ties with their students. It seems that they construct a set of deviations in maintaining and releasing classroom rules to include MC students. Moreover, they use these constructions in connection to the cultural backgrounds of students. Thereby, they construct appreciation and acceptance for building an own identity as very important. Discussion Teachers' pedagogical aims seem to conflict with their constructions about managing student behavior in relation to authority themes and assessing students learning improvements. The model for pedagogic discourse of Evans and Davies (2004) seems useful to describe the tensions and constructions, which influence inclusion and exclusion processes of students. For theory development and PETE it is advised to pay attention to the role that modes and constructions seem to play on (deviations from) social and physical standards for the learning opportunities of students. ## FACTORS INFLUENCING PARENTS'S INVOLVEMENT IN A SCHOOL-BASED INTERVENTION FOR THE PROMOTION OF PHYSICAL ACTIVITY AND HEALTHY EATING

Beltrán-Carrillo, V.J., Sierra, A.C., González-Cutre, D., Cervelló, E., Montero-Carretero, C.

*Universidad Miguel Hernandez*

Do not insert authors here Introduction School-based interventions are common and efficient strategies for the promotion of healthy lifestyles among youth (Story et al., 2009). Parents' involvement in this kind of interventions is considered crucial for their effectiveness (Golley et al., 2010), but achieving parents' participation is not an easy matter. This qualitative study analyzes the factors influencing parents' participation in the activities addressed to them as part of a 6-month school-based intervention for the promotion of physical activity and healthy eating. Methods The intervention with parents consisted of three meetings (theoretical presentation and debate) and a trekking day trip with parents and pupils. These activities were addressed to the parents of 104 pupils aged 14-16 years old and belonging to the same school centre. The data for this study came from the research diary of the person in charge of the fieldwork, who took notes of the events and conversations she attended during the activities with the parents. Four focus groups with pupils and a focus group with parents also served as sources of qualitative data for this study. The data were analyzed with the support of the software Nvivo, following a conventional content analysis (Hsieh and Shannon, 2005). Results The parents' attendance to the different activities was low (5-8 parents). A lack of communication between pupils and parents was a barrier for their participation, although the attendance to the last meeting remained low (17 parents) after a direct contact with parents by phone. Work and family duties were identified as other barriers for their participation in the different activities, but according to some parents and pupils, many parents did not participate because of a lack of interest. However, parents who took part in the activities were satisfied with them, especially with the trekking day trip, and asked for longer interventions in their children's school. Discussion New technologies could favour the direct contact with parents in this kind of interventions. More socially interactive activities could increase parents' attendance and help to create a collaborative social network for a real promotion of healthy lifestyles at school. This social network composed by parents, pupils, researchers and teachers, and based on strong social links between the different agents, needs time to be built. According to these findings, only long-term interventions lasting several years could obtain this purpose. References Golley RK, Hendrie GA, Slater A, Corsini N. (2010). *Obes Rev*, 12, 114-130. ### THE INTERRELATION OF SPORT PSYCHOLOGY AND SPORT SCIENCES IN THE PREPARATION OF ELITE PERFORMERS.

Fink, C., Balague, G.

*University of Illinois at Chicago, YSC Sports*

Introduction It is understood that sport psychology plays an important role in the preparation of elite level athletes. What has not received enough attention is the need for sport psychology interventions to incorporate information from the other sport sciences. A sport psychologist who is unaware of specific exercise physiology, biomechanics, and/or training principles risks designing interventions that may

actually interfere with performance. Interactions of Sport Psychology and Sport Sciences: The body of the presentation will describe the ways in which the specific requirements of the training phase, such as the physiological demands or biomechanical elements of the task, must be considered when determining the psychological needs of the athlete and possible interventions. A psychologist without knowledge of the various components of sport sciences may mistake the response to heavy training loads as clinical depression, thus wrongly pathologizing a situation. Interventions widely used in sport psychology, such as imagery and visualization must be considered within the context of the training phase. Often, sport psychology training is done only during the beginning of the season because of time constraints. Asking the athlete to create a multi-sensory image of the actions required at peak competitive time is contrary to the information being registered at the muscular level during the heavy conditioning phase (i.e., training phase). Therefore, it is likely that the intervention will not be helpful or learned correctly. Biomechanical knowledge of the demands of the movement is also important when working with an athlete on a centering routine or a focal point identification. For instance, in some sports, choosing a focal point on the ground may make the athlete lower his or her head at the beginning of a motion that requires a straight posture to be effective. Specific examples of all of these situations in a variety of sports will be presented. Discussion The importance of integrating the sport psychologist within the sport scientists and coaching team will be discussed. The presentation will also discuss identifying some of the specific needs of the athlete-sport psychologist relationship that also need to be protected, such as confidentiality. Implications for the training of sport psychologists will be highlighted and the idea of an integrated working model discussed.

### **IDENTITY FORMATION IN PROFESSIONAL YOUTH TEAM FOOTBALL ENVIRONMENTS**

Mitchell, T.O.I., Nesti, M.S., Richardson, D.J., Littlewood, M.A.

*University Centre Doncaster & Liverpool John Moores University*

Introduction Practitioners, such as coaches, play a significant role in influencing the working environment created and also in determining the ideal player characteristics (Identity). A strong, flexible sense of self may be most suitable for young players to meet their potential and maximise chances of progression (Nesti & Littlewood, 2009). Football environments have been characterised as; dominant, authoritarian and masculine (Parker, 2001). Such features may not facilitate the development of a strong, flexible identity. The aim of this study was to gain a critical understanding of ideal player characteristics required for progression to professional status and to understand organisational strategies influencing such characteristics. Methods Nineteen (N = 19) youth development practitioners from 10 (N = 10) English professional football clubs undertook semi-structured interviews exploring perceptions of ideal player characteristics. Interviews were transcribed verbatim and exposed to notions of content analysis (Strauss & Corbin, 1998). Discussion Practitioners required players to have a deep self belief, be mentally resilient, have their own agenda and possess emotional stability. Such notions resonate to the work of Erikson (1968) on Identity, and more specifically, knowing who and what you are as an individual. Practitioners employed strategies to promote such characteristics whilst acknowledging some ideal characteristics were predetermined and beyond the influence of the club. Traditional notions of conformity, discipline and professionalism remain prevalent increasing risk of Identity foreclosure (Pepitas, 1978) which may inhibit development of a strong sense of self. Practitioners must be aware that at critical moments, such as transition, such foreclosure can increase psychological discomfort (Nesti, 2004). This may ultimately reduce chances of progression into first team environments. References Erikson, E.H. (1968) *Identity: Youth and Crisis*. New York: Norton. Nesti, M.S. ### **BREAKING WAVES: THE WITHIN-CAREER TRANSITIONS EXPERIENCED BY A HIGH PERFORMANCE ADOLESCENT SWIMMER.**

Lyons, D., MacPhail, A.

*University of Limerick*

Introduction An athletic career is determined by developments within sporting, psychological, psychosocial and academic/vocational domains (Wylleman & Lavallee, 2004). Within-career transitions are turning phases in the course of an athletic career (Stambulova, Alfermann, Statler, & Côté, 2009). Alongside transitions that can be expected, such as the move from junior to elite-level sport, athletes also face less predictable transitions such as the loss of a coach. The aim of this study is to explore the within-career transitions experienced by an adolescent high performance swimmer, Kelli, as she made the transition from school to university. Methodology This exploratory case study employed a life history methodology. The study began with the use of a retrospective life history grid (adapted from Côté, Ericsson, and Law, 2005) to trace Kelli's development in sport. Over the next two years data from qualitative interviews and observations were collected to gain an insight into Kelli's life, her choices, decisions and their consequences. The results were analysed using a constant comparative method of inductive data coding. Findings During the two years of the study Kelli experienced a number of transitions both planned and unpredicted across all the domains of her athletic career including the move from junior to senior level sport, the loss of a coach, a change of club, the move from school to university, injury and the maturation from adolescence into young adulthood. Kelli's micro-system consisting of herself, her parents, coaches and peers, and their interaction, were the main facilitators in her successful negotiation of the transitions experienced. As Kelli had made decisions on her future academic life based on her swimming goals the loss of her coach and the subsequent move to a new club resulted in her changing her choice of university and programme of study. Negotiating multiple transitions concurrently was a major source of stress for Kelli. Conclusion Using in-depth case studies to explore the transitions experienced by talented young athletes can help us understand the complexities of athletes' decision making and the ultimate consequences that play out. Macro levels, contextual factors such as the sports system, cultural factors and education policy played a significant role in how Kelli, and her parents, coach and peers made decisions that impacted on her athlete career. These contextual factors need to be considered when designing programmes for young talented athletes to facilitate development, reduce talent loss and maximise athletes' potential. ## A QUALITATIVE EXPLORATION OF ATHLETES' EXPERIENCES OF A THREE TIER POST OLYMPIC DEBRIEFING PROGRAMME.

Moore, P.1, McArdle, S.2, Lyons, D.3

1: MMU/IIS (Manchester, England; Dublin, Ireland), 2. DCU (Dublin, Ireland), 3. IIS (Dublin, Ireland)

**Introduction** The challenges of the Post Olympic Games transition process has been well documented (McCann, 2000). Despite this very little attention has been given to the development and evaluation of post Games psychological support services. To support Irish Olympians and Paralympians in the post Games transition process, the Irish Institute of Sport (IIS) developed a three Tier debriefing programme. This programme included supportive contact with athletes three to four days after their event, an individual debrief and/or athlete led support groups four to five weeks post the games and follow-up psychological support if requested or agreed by the athlete. Given the lack of research on psychological interventions targeted at the post Games transition process (both within and end of career), the aim of this study was to conduct a process evaluation on the IIS debriefing programme. **Methods** Employing a qualitative study design, a purposive sample of 10 Irish Olympic athletes (4 females and 6 males) who participated in the IIS programme were recruited to participate in semi-structured interviews. The topic guide focused on examining participants' overall experience of the programme as well as their views on programme implementation and structure. A thematic analytic approach was employed to identify key themes in the data. **Results** Athletes reported that they had no clear expectations for the debriefing programme but were positively surprised by the experience. In this regard they suggested that more effective communication was required to encourage greater uptake of the support and acknowledged the challenges associated with reaching the Olympic cohort. Perceived benefits experienced included changes in mood (e.g., increased positive affect, decreased anxiety) and increased motivation. All of the athletes indicated that the normalisation of their cognitive and emotional responses in the post Olympic period was one component of the programme that had significant utility. Timing of initial contact by service providers was a prevalent theme with most athletes agreeing that enough time should be allowed for reflection and emotional recovery before discussing their Olympic experience. **Discussion** These findings contribute to the existing literature by elucidating the importance of post-Games psychological support and specific challenges to effective engagement and therefore have implications for future service delivery and implementation. **References** McCann, S. C. (2000). Doing sport psychology at the really big show. In M. B. Anderson (Ed.), *Doing Sport Psychology* (pp. 223-234). Champaign, IL: Human Kinetics.

## THE MOTHER'S PSYCHOLOGICAL SUPPORT IN HIGH LEVEL SPORT

Palomo, M., Ruiz, L.M., García, V.

*Universidad de Castilla La Mancha*

**Introduction** The research on the role of the family in the sport has recently determined how parents play a vital and varied support in sport development, holding different roles in it (Wolfenden and Holt, 2005). In a concrete way the family psychological support provided to children athletes has been defined in the literature as a positive attitude to sport key to the enjoyment of the sport itself (Camire, Trudel and Forneris, 2009), other authors have defined it as a support related to motivation given to the children for sports (Keegan, Harwood, Spray and Lavallee, 2009) or that family being considered as the first source of encouragement (Kesend, 1991). **Aim:** Therefore, the objective of this research was to define the role and counseling of the mother in the reach of the high level of young athletes. **Method:** To that end 20 high-level athletes and 17 of their mothers were interviewed. We used a qualitative methodology, inductive, based on technical and typical procedures of Grounded Theory (Corbin and Strauss, 2008). **Results:** The results establish that psychological support as an assistance provided by the mother to her child athlete referred to mind control and reach the maximum potential and performance in their sport, set in an attitude for success. Psychological Support category consists, in turn, of four dimensions: General Psychological Support, refers to how the mother helps from a mental point of view and in a global mode in order to make sure her child is in top condition and reaches the maximum athletic performance. It is a support based on mood, confidence, giving freedom, stay positive ... Psychological Support for the competition, is the assistance provided by the mother referred to counseling focused on the competition. Psychological Support in High Level, is the support of the mother during a particular stage of the sport development. Adolescence Psychological Support, the support at this stage is focused on helping in a difficult period, in which the doubts, fears and worries are constant. **Conclusion:** In general it can be concluded that the mother helps her child from the psychological point of view showing different ways and periods in which such support varies, modifies or increases its intensity depending on the needs of the young athlete.

## MOTIVATIONS OF MASTERS SURF LIFESAVERS

Reddan, G.

*Griffith University*

**MOTIVATIONS OF MASTERS SURF LIFESAVERS** **Introduction** An understanding of the reasons people participate in sport and exercise is fundamental to the promotion of a healthy lifestyle. Attitudes to physical activity and competition have changed significantly, resulting in the development of masters' games competitions. The aim of this study was to determine the factors that motivate masters surf lifesavers to participate in competition. **Methods** The Motivations of Marathoners Scales (Masters, Ogles & Jolton (1993) consider four general categories: physical health motives; social motives; achievement motives; and psychological motives. The Scales were modified (Ogles and Masters, 2003) and forwarded to all competitors throughout Australia. 142 responses were received – 114 male and 28 female. These were divided into young (30-49) and old (50+) competitors, with 78 and 64 in each respective category. Means and standard deviations were used to identify the most important motives for competition, as well as for each age group and gender. **Results** General Health Orientation was considered the most important motive for participation. These items focused on improving one's health, prolonging life and becoming more physically fit. The second most important motive cited was Affiliation. The items denoting this motive including socializing with friends and sharing a group identity. The old competitors indicated General Health Orientation to be the most important motive. Personal Goal Achievement was considered the second most important motive, with Affiliation rated third by this age group. The younger competitors similarly rated General Health Orientation as the most important, but not to the same degree. Interestingly, this group rated Affiliation second and Personal Goal Achievement third from the nine scales. Differences were demonstrated between the old and young competitors in regards to the importance of Personal Goal Achievement and Self-Esteem. Female competitors rated Affiliation as the most important motive, followed closely by General Health Orientation and Personal Goal Achievement. Males rated General Health Orientation as clearly the most important motive, ahead of Affiliation and Life Meaning. Significant differences between the genders were found only in the rating of Life Meaning. **Discussion** Although ageing causes inevitable physical changes, physical activity associated with sports competition for older adults becomes even more important (Cox & Reed, 2007). This research indicates

specific motives that are considered most important for participation. Leaders of activity programs need to match this diversity to ensure wide participation and a satisfying experience for all participants. ##### SPORT SCIENCE IN EUROPE: FIRST STEPS IN A "SCIENCE STUDIES <1>, <2>" RESEARCH PROJECT

Camy, J.

*University Claude Bernard, Lyon*

Our purpose is to present a research project framework and some preliminary results on "Sport Science as an academic discipline in a European context". Science studies is an interdisciplinary research area that seeks to situate scientific expertise in a broad social, historical, and philosophical context. It is concerned with the history of scientific disciplines, the interrelationships between science and society, and the alleged covert purposes that underlie scientific claims. In Sport Sciences, Historians (5), (6), (7) and philosophers (3), (4), have already paved the way, underlying multiple national and international ideological and institutional conflicts between different theories, movements and professional bodies. We intend here to introduce and illustrate four key topics belonging to the science studies area : - The definition of the field of sport science as it has been controversially discussed by players: which object (sport, exercise, physical activities...)? Which relations with existing disciplines? Which specificity for Sport Science? Which paradigms to mobilize? - The outcomes of sport science, analysis of the "products" such as presentations in Sport Science Congresses and publications in related Journals and the ways they are evaluated; - The community of sport scientists, a systematic approach of the individual "producers" (where do they come from and how do they build their professional careers?) and of the institutional framework into which they operate (research teams and institutions, scientific societies...); - The research activities frameworks (research production processes), the way research activities are planned, financed and organized, the operational cooperation with field players (such as the "sport and physical activities stakeholders") and decision makers... That framework will be put under discussion as well as each of its components. ##### COACHES' ALTERNATIVE DEFINITIONS OF THEIR PROFESSIONAL SUCCESS

Dumitriu, D.

*National School of Political Sciences and Public Administration*

**Introduction** An important part in the dynamics of sport social field is built around the relationship between the representational sphere and the corollary sphere of action. How we perceive things is important and, moreover, is the mere input for how we act. Therefore, the way sport actors define and relate to the competitive framework becomes decisive in explaining their professional practices and level of engagement in sport acts. Focusing on the representational pole of this cognitive-action dyad, the main aim of this study is to lay stress on the way Romanian handball coaches define professional success. What or who brings coaches their success? Is coaches' professional success based solely on the winning-losing track record? When can we speak of successful coaching career? These are the guiding lines that settle the research framework for the present study. **Methods** The research design of this case study combines a qualitative exploration of Romanian handball coaches' social representations upon professional success with a quantitative approach meant to highlight the level of convergence and the dominant positions inside handball coaches' community. Thus, the 23 in-depth interviews and the survey conducted on a 118 handball coaches' sample should be understood in terms of methodological complementarity. **Results** While the quantitative results place success mainly in relation to the task goal orientation and the passion trigger beyond sport engagement, the qualitative approach brings out a more contextualized definition of professional success, providing alternative paths in reaching it: from a result oriented definition of professional success, to a pedagogic-formative framing of success. **Discussion** Both the quantitative and the qualitative approaches converge in laying emphasis on the team-dependency condition of coaches' success. This success' component that seems to be off coaches' control, works also as a self-esteem protective mechanism, leaving room for an endless problematization of success. To sustain this convenient value of coaches' limited responsibility towards their own professional success, the qualitative research brings out a significant duality in terms of public discourse and actual convictions of Romanian handball coaches. The public pressure associated with the moral and social desirability standards makes coaches embrace a soft definition of success, favoring the task goal orientation as a rational response to the perceived social expectations. However, results and track records remain coaches' ultimate proof of success, acting as the most powerful success indicator both in and outside the sport professional community. **Note:** The author of this study is beneficiary of the Doctoral Scholarships for a Sustainable Society Project, co-financed by the European Union through the European Social Fund, Sectoral Operational Programme Human Resources and Development 2007-2013

**SPORT ATTITUDES AND MOTIVATIONAL CLIMATE IN TWO CONTRASTING FOOTBALL CLUBS**

Domingues, M., Gonçalves, C.E.

*Faculty of Sports Science, University of Coimbra*

**Aim:** To investigate the relationship between perceived motivational climate, sportspersonship, social-moral functioning and team norms in a sample of young male Portuguese football players as well as to verify possible contextual factors mediating that relationship. **Design:** It was expected that motivational climate of the social club would be associated with lower levels of social-moral functioning, sportspersonship and the perceptions of team norms that would approve of illegitimate behaviors in football. Alongside this, a more mastery-oriented climate by the POC was hypothesized to be beneficial with respect to social-moral functioning, sportspersonship and morally constructive team norm perceptions. **Method:** A cross-sectional study of 125 male football players (aged 13–17 years) was conducted in which players responded to a questionnaire measuring different dimensions of social-moral functioning namely sportspersonship behaviors and team norm perceptions. The players also responded to their perception of coaches motivational climate regarding a more mastery oriented or inversely, a more performance dictated sporting climate. **Results:** Results show consistent higher scores both in SAQ and PMCSQ-2 in POC youth athletes with clear task orientation and a more pro-social acceptance of sport, importance of personal improvement, cooperation and collective sense. SOC and POC showed similar results in ego orientation which might be conducive of different intricate ego orientations. **Conclusion:** The findings illustrate the importance of studying motivational climate in contrasting sporting environments in order to provide an understanding of social-moral functioning and social-moral team norms in youth football and also a way to determine interpersonal relations that are key to establish a good climate.

**PHYSICAL EDUCATION TEACHER EDUCATION IN FINLAND – FOUNDATION BUILT FOR HIGHER EDUCATION IN THE 1960'S**

Lahti, J.

*University of Jyväskylä*

**INTRODUCTION** Physical activity is an important part of Finns' lives. Finland ranks among the top nations in sport participation. Elite sport is also socially significant in the Finnish society. Finland is one of the few countries in Europe where qualified physical education teachers are required to have a master level education. This dates back to 1963 when physical education teacher education (PETE) became an academic discipline at the University of Jyväskylä, which still is the only place in the country with higher PE teacher education. This paper is a part of the doctoral study that examines the changes and developments of the PETE in its 50 years' history in Finland. This presentation scrutinizes the first decade of the PETE in Finland. The aim is to search for the underlying starting points of the content formation of PE teacher education. This will be conducted in the framework of historical research. **DATA and METHOD** The data consists of the official and public resources; documents of the curriculum criteria and interviews of the key persons in the development of PETE in Finland. Legislation concerning education together with archive materials, magazine and newspaper articles are also important sources of research material. The data is analyzed with the method of document analysis. **RESULTS** In 1963 when the PETE started, the curriculum was rather practically oriented. At that time students usually graduated in three years, whereas now, PE teachers study approximately five years. In the very beginning, PETE was based on the guidelines of a committee report by the government. In addition, the content of the curriculum was influenced by individual staff members of the Department of Education. Especially at the early stages of PE education in Jyväskylä the pioneers of educators had an important role in shaping the curriculum. **DISCUSSION** University of Jyväskylä is the only place in Finland where PE teachers are educated. This brings both advantages and challenges. On one hand, Jyväskylä holds a nationwide educational task which is supported by public resources. On the other hand, with its monopoly position as the only PETE unit in the country, there is a risk that "healthy" competition with quality improvements is scarce. Historical analysis of the foundation and the first decade of PETE in Finland become interesting not only because of the curricula changes with their societal linkages during the 50 years' of education. The first decade of PETE serves research attention also as it brings to light facts, persons and incidences that have had substantial and long term consequences in the way sport and physical activity are taught, participated and valued in a society that is one of the most physically active in the whole world.

**08:30 - 10:00****Oral presentations****OP-PM44 Sports Medicine [SM] 5****BENEFITS OF FIFA 11+ PROTOCOL DURING FIVE SEASONS, A PRELIMINARY STUDY IN YOUNG PROFESSIONAL SOCCER PLAYERS**

Olla, S.1,2,3, Scorcu, M.1,2, Piras, F.1,2, Cugia, P.1,2, Angius, L.3,4

*1:F.M.S.I., Cagliari, Italy; 2:Cagliari Calcio S.p.a., Cagliari, Italy; 3:Laboratory of Sport Physiology, University of Cagliari, Italy; 4:School of Sport and Exercise Sciences, University of Kent, UK*

**Introduction and aims:** Football as most of the team sports involves alternation of low and high phases of running intensity. As consequence, a higher increase of injuries is present during match or training. According to this, technical and medical staff work to prevent the onset and the increment of injuries. Numerous protocol of prevention have been proposed to reduce the amount of injuries. The aim is to monitor the application of FIFA 11+ protocol in a young professional football academy during five seasons. **Methods:** a sample of 820 young-players aged between 10-21 years old, was monitored during five Italian championship seasons (from 2007/08 to 2011/12) both during training and match sessions. FIFA 11+ protocol was applied only during the first four season except during the last (2011/12). All the injuries were examined by the medical staff and subsequently classified according to: number of injury, role and condition. A one-way analysis of variance (ANOVA) were used to check differences between each seasons. Significance was set at  $p < 0,05$ . **Results:** the total amount of injuries during the five seasons was 380 (81, 80, 75, 60 and 84). The case report shows a greater incidence in defenders compared to midfielders, strikers and goalkeepers ( $32.00 \pm 7.25$ ,  $20.20 \pm 4.66$ ,  $16.40 \pm 4.39$  and  $7.40 \pm 3.05$ ). Number of injuries during

training was (61, 65, 56, 45 and 51) while during match was (20, 15, 19, 15 and 33). Discussion: Defenders and midfielders were the most affected roles because of the higher density of players in those areas of the pitch. Interestingly this analysis shows a progressive decline of the total number of injury through each season except for the 2011/12. Same decline has been found during training sessions. Results indicates that application of the FIFA 11+ protocol is able to reduce the onset of injury. On the contrary when the protocol was not used, an increment has been observed. In conclusion we can affirm that prevention strategies are important to preserve the physical integrity of players. References: 1. Backous DD, Friedl KE, Smith NJ, et al. *Am J Dis Child* 1988;142(8):839-42; 2. Koutoures CG, Gregory AJ. *Pediatrics* 2010;125 (February (2)):410-4.

### **INJURIES IN GERMAN ELITE MEN'S HANDBALL - VIDEO ANALYSIS OF MATCH INJURIES**

Luig, P., Klein, C., Henke, T.

*Ruhr-Universität Bochum*

Introduction: Elite Men's Handball is undoubtedly a physically demanding team sport with intense body contact and highly intermittent running stressing the athlete's cardiovascular, metabolic and musculoskeletal systems. The first two German national leagues promote themselves as best leagues of the world and are home to numerous international top players. However, among German professional sports handball ranks absolutely high in national injury statistics. This fact endangers game operations of the clubs through steadily increasing insurance rates. Methodology: Registered injuries from the insurer's injury database as well as resulting costs and disabilities are analyzed for three consecutive first and second league seasons (2010-2013). Moreover, identifiable match injuries are assessed through video analysis to objectify the circumstances and situations that frequently lead to injuries. Gathered information will be used to reveal key areas for prevention and to tailor targeted counter-strategies for elite clubs, coaches and athletes. Results: During the first two seasons (2010-2012) 3,732 injuries were registered causing direct medical costs of 4.25 million and 33,000 days of disability. 65 % of injuries need medical treatment only, 35 % cause time-loss (disability). Each player sustained 2.4 injuries per season (0.9 time-loss injuries/season). Injury incidence in league games was 63.7 injuries/1000h (23.7 time-loss injuries/1000h). Knee (12.9 %), ankle (11.6 %) and shoulder (9.5 %) were most frequently affected. Most severe injuries were knee injuries that, on average, induced 52 days of disability and 3,250 costs, followed by hand injuries (49 days, 1,500) and shoulder injuries (38 days, 1,500). Preliminary results of the video analysis show that single-leg landings from jump shots or blocks and side-cutting moves in "1 on 1"-situations, with or without contact, provoke lower extremity injuries. By contrast most upper extremity, trunk and head injuries are caused by direct physical impact through opposing players, falls and ball hits. Discussion: Men's handball on elite level bears a high injury risk. As the primary goal of professional athletes is to maximize performance, preventive measures can best be integrated as standard components in sport-specific performance enhancement programmes and warm-up routines. This includes technique training for crucial handball movement patterns that typically lead to match injuries in both contact and non-contact situations. It is essential to have injury prevention modules included on all levels of athletes' and coaches' education to increase the chances of sustainable inclusion of injury prevention measures in training and coaching. Moreover, federations, clubs and coaches are certainly in charge to protect their athletes best possible. Sufficient preparation and regeneration, especially prior to and after major international events, is of highest priority.

### **DO ELITE RUGBY PLAYERS WITH REPEATEDLY INJURED HAMSTRINGS DEMONSTRATE ALTERED GLUTEAL-HAMSTRING RECRUITMENT PATTERNS WHEN SPRINTING?**

Brett, A.N., McGuigan, M.P.

*University of Bath*

Introduction Acute hamstring injuries are the most prevalent muscle injuries in sport, and recurrence figures remain high. Gluteal-Hamstring recruitment has been proposed as a potential risk factor for hamstring injury susceptibility (Jonkers et al., 2003), and delayed activation of gluteus maximus was demonstrated in hamstring injured vs non injured legs during a single-leg stance (Sole et al., 2011). No recent research has addressed activation and recruitment patterns during sprinting, the main provocative event in many hamstring injuries. The aim of this study was therefore to investigate the timing and magnitude of activation of gluteal and hamstring muscle groups during sprinting in elite rugby players, with and without a history of hamstring injury. Methods A two-way repeated measures design assessed the effect of injury on gluteal activation delay and the magnitude of activation, at different phases of the sprint. Two groups of elite rugby players were used: a control group with no previous history of hamstring injury (n=9); and a hamstring-injured group who had a history of more than one hamstring strain but were currently fit for selection (n=6). EMG signals from gluteal and hamstring muscles were recorded at 1000Hz using Myontec Pro EMG shorts (Myontec, Finland), during three maximal 50m sprints on an outdoor artificial grass surface. EMG data were analysed for the relative timing of the onset of the gluteal muscles compared to the hamstring muscles and the average rectified EMG (AREMG) over a stride for both muscle groups during the acceleration, maximal velocity and deceleration phases of the sprints. Results When considering all phases of the sprint together there were no significant differences in outcome measures between the hamstring injury and control groups. However, there were large effect sizes for a greater delay in gluteal activation onset (d = 0.88) and greater gluteal AREMG (d = 0.93) in the hamstring injury group compared to the control. Discussion Although there were no significant differences between the two groups, the large effect size for a delay in gluteal activation in the hamstring injury group provides some support to the hypothesis, and suggests that the question warrants further investigation with a larger sample size. The large effect size for a greater mean gluteal AREMG in the hamstring injured group compared to the control group suggest that professional rehabilitation and return to play programmes, with a strong gluteal re-education emphasis may have been effective in increasing gluteal activation, but not in initiating this prior to the hamstrings. ### **PROPENSITY OF CONTACT EVENTS TO CAUSE INJURY IN RUGBY UNION**

Stokes, K.A., Roberts, S.P., England, M., Trewartha, G.

*University of Bath*

Introduction Approximately 80% of all injuries sustained during rugby union matches are associated with contact events. Typically, injury incidence rate is reported per unit of time (e.g., per 1000 player hours), but expressing incidence rate per contact event gives an indication of the relative risk of each type of event. The aim of this study was to determine the propensity of specific contact events to cause injury in rugby union. Methods Injury data were reported by medical staff at participating English community level rugby clubs in the 2009/10 (n=46), 2010/11 (n=67), and 2011/12 (n=76) seasons. Injury diagnoses for any injury resulting in an absence from full participation in match

play for one match or more from the day of the injury were recorded using the Orchard Sports Injury Classification System. Injury severity was estimated based on the number of matches missed (accurate to one week / match). Injury data for all seasons were combined for analyses. 30 community rugby matches were filmed and the number of contact events (tackles, collision tackles, rucks, mauls, lineouts and scrums) was recorded using match analysis software (SportsCode Pro, Sportstec, Australia). Significant differences were assumed where 95% confidence intervals (CI) did not overlap. Results There were 370 (95% CI; 364-378) contact events per match of which 141 (137-145) were tackles, 115 (111-119) were rucks and 32 (30-33) were scrums. Tackles resulted in the greatest injury incidence rate [2.3 (2.2-2.4) injuries/1000 events] and severity [16 (15-17) matches missed/1000 events]. Being tackled resulted in a higher incidence rate [1.3 (1.2-1.4) injuries/1000 events] than tackling [1.0 (0.9-1.1) injuries/1000 events]. Collision tackles (illegal tackles involving a shoulder charge) were associated with an incidence rate of 15.0 (12.4-18.3) injuries/1000 events and severity of 83 (68-101) matches missed/1000 events which were higher than any other event. Additional analysis of the scrum in the 2011/12 season showed that collapsed scrums accounted for only 5% of all scrums, but the injury incidence rate was 2.9 (1.5-5.4) injuries/1000 events compared with 0.6 (0.4-0.8) injuries/1000 events for scrums that did not collapse and the severity was 22 (12-42) matches missed/1000 events compared with 3 (2-5) matches missed/1000 events. Discussion Continued focus on injury prevention in the tackle is required through coaching of effective technique when both making tackles and being tackled. In addition, the results support strict enforcement of existing laws in relation to illegal collision tackles. Furthermore, given that the scrum is a relatively controllable phase of contact, further attempts should be made to reduce the frequency of scrum collapses. ## THE ANALYSIS OF MOTOR SKILLS, FUNCTIONAL MOVEMENT AND PREVENTION OF INJURY IN ELITE YOUNG SOCCER PLAYERS

Zalai, D., Bobák, P., Csaki, I., Hamar, P.

*Semmelweis University*

Introduction Over the course of past few years soccer players have progressed tremendously in terms of physical performance. During a competitive game players frequently perform activities that require rapid development of force such as sprinting and fast change in direction (Sporis, 2011). The increasing demand for players has emphasized the importance of motor skills, quality of functional movements and injury prevention. The purpose of this study was to examine the characteristics and impact of motor skills, functional movements on performance and establish risk factors for injuries among elite young soccer players. Methods The participants (N=60) were tested by Functional Movement Screen™ (FMS) system, that determined the muscle strength, flexibility, range of motion, coordination, proprioception and identified athletes limitations and functional asymmetries in movement patterns that are considered to be the most significant risk factors for injury (Kiesel, 2007). Findings in motor skills were analyzed further in relation to players position during a game. Goalkeepers (GK), defenders (DEF), midfielders (MID), and forwards (FW) were investigated regarding their lower limbs explosive strength (LLES) for the horizontal and vertical plane, and the sprint ability (SA) in 5, 10 and 30 meter. Results We have found statistically significant correlations between test LLES ( $r=0,584$ ) and test SA on 5m and 10m ( $r=0,797$ ) in relation to players anthropometric parameters (height,  $185,4\pm 5,65$ cm; weight,  $82,8\pm 6,76$ kg; BMI,  $24,08\pm 1,27$ ). Findings in DEF showed significant differences concerning sprint ability in 10 and 30 meters ( $p<0,05$ ) compare to other groups. The FMS (mean score,  $15,47\pm 1,93$ ) tests have not established substantial link to the anthropometric variables ( $r=-0,236$ ) and sprint abilities ( $r=-0,143$ ), but 41% of players examined demonstrated movements asymmetry and limitations. Discussion The observations made by this study emphasize the importance of timely and detailed evaluation and selection of football players at the beginning of their academy training. It has also verified the incidence and type of functional asymmetry in player's movement patterns. Athletes with lower limb asymmetry have an increased risk to develop non contact injury (Kiesel, 2008). This has also been demonstrated in a previous milestone study by FIFA F-Marc that revealed the non contact nature of injuries in 54% of cases. References Kiesel K, Plisky P, Voight ML. ## Invited symposia

### IS-PM02 ACSM Exchange symposium: Exercise - Thermoregulation \*

#### HEAT TRANSFER FROM SKIN TO ENVIRONMENT IN HYPERTHERMIC HUMANS

Havenith, G.

*Loughborough University*

This second invited presentation of the ECSS-ACSM exchange will look at the heat transfer outside the body, i.e. from the skin outwards, and at recent insights in this process. Starting from the classical heat balance approach, which mostly treats the body as a uniform surface, the presentation will look at regional variation in dry and evaporative heat transfer across the body, linking heat transfer to local body movements, local blood flow and to the local generation of sweat. Body heat loss and sweat production maps produced in the last few years have improved the modelling of heat exposure and have also contributed to the design of sex-specific garments, incorporating the information obtained. Finally the role of clothing and protective gear in this heat transfer will be discussed and the effect they have on heat strain. Promises made in innovative clothing fabrics will be briefly addressed too.

#### INTERNAL HEAT TRANSFER IN EXERCISING HUMANS

Kenney, W.

*Penn State University*

The first in a sequence of two presentations, this invited lecture discusses metabolic heat (M) generation and its requisite transfer from working muscle to the skin. M can be extremely high in exercise, sport, and work scenarios due to intensity of effort and inefficiency of external work produced. Adiabatic exercise would limit exercise duration to minutes in most circumstances, illustrating the need for

convective transfer of heat to the skin. Convective heat transfer is a function of (1) specific heat of blood, (2) the core-to-skin temperature gradient, and (3) skin blood flow, and only the latter is physiologically regulated. Active cutaneous vasodilation involves sympathetic cholinergic co-transmitter release. Further, nitric oxide (NO) bioavailability is a downstream requirement for full reflex cutaneous vasodilation. In older exercising subjects, as well as those with vascular dysfunction (hypertension, hypercholesterolemia) NO-mediated dilation is reduced, with the potential consequence of attenuated heat loss.

##### **PERSISTENCE OF EXERCISE ADAPTATIONS AFTER ONE MONTH OF DETRAINING IN METABOLIC SYNDROME PATIENTS**

Hamouti, N., Ortega, J.F., Fernández-Elías, V.E., Mora-Rodríguez, R.

*University of Castilla-La Mancha*

**Introduction:** High-intensity aerobic interval training is associated with the removal of some of the factors that constitute the metabolic syndrome (MetS) (1). However, it is unclear which of the adaptations are long-term maintained and which are less persistent after exercise training cessation. The STRRIDE study revealed that, after 2 weeks of detraining, the training-induced improvements on insulin sensitivity (2) and HDL-c (3) in sedentary overweight adults persist when exercise is intense enough. To our knowledge, training cessation beyond 2 weeks has not been explored yet in MetS patients. **Material and methods:** Forty-eight sedentary MetS patients (22 men and 26 women, 52±8.8 yrs old) underwent 16 weeks of 3 days per week of supervised cycle-ergometer high-intensity aerobic interval training (HIAIT). Training sessions were composed of 4x4 min bouts of pedaling at 90% HRmax interspersed by 3 min at 70% HRmax. MetS factors, blood metabolites, cardio-respiratory (VO2max) and metabolic (maximal fat oxidation, MFO) fitness and insulin resistance (HOMA-IR) were measured when subjects were sedentary and at 48 h and 33 days after the final training bout. **Results:** Waist circumference was reduced with training (2.4 cm) and remained at trained values after 33 days of detraining. Systolic, diastolic blood pressure and HDL-c improved with 4 months of training (13±3; 12±8% and 12±10% respectively, P<0.05) and returned to the 3 months of training values with detraining. In contrast, the gains in HOMA-IR, VO2max and MFO were almost completely lost after 33 days of detraining. **Conclusions:** Training improvements on body composition were held after 1 month of detraining. The blood pressure and HDL-c improvements decreased with detraining at a rate of 1 to 1 (i.e., 1 month of detraining, cancels out the last month of training). However, insulin sensitivity and cardio-metabolic fitness evaluated during exercise decreased with detraining at a rate of 1 to 3 (i.e., 1 month of detraining cancels out 3 months of training). Surprisingly, some important training adaptations that reduce the risk of cardiovascular diseases (i.e., blood pressure and HDL-c) were persistent to 33 days of detraining. 1. Tjonna AE, et al. ##### **CDC34+ CIRCULATING PROGENITOR CELLS AFTER DIFFERENT TRAINING METHODS**

Niño, O., Javierre, C., Blasi, J., Balagué, N., Aragonés, D., Corral, L., Miguel, M., Gaitán-Peñas, H., Viscor, G., Ventura, J.L.

*University of Barcelona*

**Introduction** Circulating progenitor cells (CPC) are bone marrow-derived cells that are mobilized to the circulation and incorporated in the sites of injury. Exercise is a powerful mediator of hematopoiesis but the CPC increases and their schedule after different types of exercise are contradictory. Moreover, there is a lack of studies comparing different training methods, including resistance, in the possible changes in CPC concentrations. **Methods** Forty-three healthy male subjects physically active, (age 21.2 ± 2.4 years) were randomly distributed in four different training groups: aerobic (AET), resistance (RET), mixed (MIX) and control (CON). They were trained for six weeks except the control group. Peripheral blood samples were collected by puncture of an antecubital vein and CD34+ CPC analysed according to a previously described method (Viscor G), in different days: pre-training, post-training and three weeks after finishing the training period. **Results** No significant CPC differences were observed between the different training groups, but with a tendency to higher values post training and a big dispersion intra and intergroups. We detected an inverse lineal relationship between the % of post-training CPC changes and the pre-training values (R=0.826, F=189.8, p<0.001). In the CPC values 3 weeks after training this inverse relationship was maintained but at lower extent (R=0.566, F=52.2, p<0.001). **Discussion** The different training methods applied in this study do not seem to be able to increase the CPC concentration in a stable form. The way differences in individual responses seem to influence the global training response. **References** Asahara T et al (1997) *Science* 275:964-967 Koutroumpi Met al (2012) *World J Cardiol* 4:312-326 Viscor G et al (2009) *J Transl Med.* Oct 29; 7:91

##### **AEROBIC AND ANAEROBIC THRESHOLD RESPONSES TO A TRAINING PERIOD WITH DIFFERENT STIMULUS**

**Introduction** The purpose of this study was to evaluate the changes in the aerobic respiratory threshold (T1) and in the anaerobic respiratory threshold (T2) after different training types: aerobic (AET), resistance (RET) and both (MIX). **Methods** Forty-three healthy subjects physically active, (age 21.2 ± 2.4 years) were distributed in four randomized training groups: AET, RET, MIX and CON and they were trained during six weeks except the CON (control group). Three evaluations were conducted: pre-training, post-training and three weeks after finishing the training period, and included workload and metabolic-respiratory data in a graded exercise test until exhaustion. **Results.** A/ With regard to the evolution of T1 we observed changes in the MIX group between the 1st and the 2nd evaluation of workload (1st: 84.1 ± 36.8 W; 2nd: 127.8 ± 29.4 W, p=0.024) and between the 1st and the 2nd evaluation of % of the maximal workload (1st: 30.7 ± 12.1; 2nd:

43.2 ± 11.1 %W, p=0.048). In addition, in the AET group % of maximal workload showed statistical differences between the 2nd and the 3rd evaluation (2nd: 32.8 ± 9.2; 3rd: 38.6 ± 6.6 %W, p=0.049). B/ Moreover, when the evolution of T2 was analyzed, changes in the MIX group respect to: the workload between the 1st and the 2nd evaluation (1st: 221.2 ± 34.2 W; 2nd: 255.1 ± 20.9 W, p=0.002), the 1st and the 3rd evaluation (3rd: 257.9 ± 19.2 W, p=0.002) and % VO<sub>2</sub>max between the 2nd and the 3rd evaluations (2nd: 78.8 ± 10.6; 3rd: 86.7 ± 4.07, p=0.04) were found. The AET group showed differences in %VO<sub>2</sub>max between the 2nd and the 3rd evaluation (2nd: 79.1 ± 6.4; 3rd: 86.3 ± 5.6, p=0.002). In the RET group the changes appeared at workload between the 1st and the 2nd evaluation (1st: 211.2 ± 25.8 2nd: 229.2 ± 23.6 W, p=0.042) and between the 1st and the 3rd evaluation (3rd: 228.2 ± 26.4 W, p=0.023). CON group showed changes in the workload between the 1st and the 3rd evaluation (1st: 251.9 ± 36.4 W; 3rd : 273.9 ± 36.0 W, p=0.001) and the 2nd and the 3rd (2nd: 252.0 ± 36.4 W, p=0.006), % workload between the 1st and the 3rd (1st: 81.5 ± 3.8 ; 3rd: 89.9 ± 3.2, p=0.002), between the 2nd and the 3rd (2nd: 83.1 ± 5.5 ; 3rd: 89.9 ± 3.2, p=0.003), %VO<sub>2</sub>max between the 1st and the 2nd evaluation (1st: 80.4 ± 8.1; 2nd: 89.2 ± 6.9, p=0.004) and between the 1st and the 3rd (3rd: 91.0 ± 4.7, p=0.001). Discussion MIX training, under the conditions of the present study, seems to produce greater and more lasting improvements in both thresholds. ### MONITORING WORKLOAD DURING A TRAINING PROGRAM IN A WEIGHT LOSS INTERVENTION IN BREAST CANCER SURVIVORS.

Guillamó, E.1,2, Travier, N.3, Oviedo, G.4, Roca, A.1, Delicado, M.C.1, Niño, O.1, Cos, F.2, Agudo, A.3, Barbany, J.R.1, Javierre, C.1

*University of Barcelona*

Introduction Exercise intensity is an important parameter in exercise programs. As part of a study, in breast cancer (BC) survivors, to promote weight loss through a dietary intervention and a physical exercise program, we propose to design a test to control and adjust the training intensity of each participant along the intervention. Methods Forty two BC survivors (women aged 54.8±8.6 years) overweight and obese, started an intervention with an exercise program, including 5 weekly sessions for 12 weeks (two sessions in the laboratory and the other three at the participant's home). Aerobic exercise combined with strength training were the main components of this physical exercise program. Aerobic exercise was completed cycling and doing aerobics choreography sessions. The test to control the intensity was carried out cycling. The test was integrated into the training sessions. It consisted of two cycles of 8 and 6 minutes, cycling at an intensity of 13-14 on a rate of perceived exertion. Heart rate (HR) and workload were registered every two minutes. Values of the last four minutes of the second cycle of exercise were used to calculate the participant's capacity in each test. This result was assimilated to 70% of the maximum capacity of the participant and used to schedule work intensities for each participant during the next sessions. This test was performed at weeks 3, 5, 7, 9 and 11. Results An increase in power output achieved was observed in the 5 tests (week 3: 80.1 ± 24.5 W, week 5: 84.0 ± 27.4 W, week 7: 88.0 ± 28.3 W, week 9: 90.5 ± 31.5 W and week 11: 93.9 ± 30.2 W), being different from those observed at the beginning from week 7, 9 and 11 (p <0.05). Changes in HR were not monitored during the physical test. Discussion The test carried out two series of 8 and 6 minutes cycling at an intensity chosen by the subject, later introduced as training load in the program. This test seems to be a good method to assess workloads required during the exercise program. The HR for these workloads could be a parameter to complete the information about the best power output requested during the physical program. Future research is needed to confirm these results. #### IS-PM15 Can exercise damage the heart \*

##### CARDIAC SCREENING BEFORE MARATHON?

Scherr, J.

*Technical University Munich*

It is well known that participation in regular, moderate-intensity exercise reduces mortality and cardiovascular and malignoma-associated morbidity. However, it is still an object of debate whether intense and prolonged exercise (such as marathon running and the associated training) results in an in- or decrease in mortality because the reports of marathon-related sudden cardiac death, especially in the lay press, are increasing. Therefore, in the last few years, a discussion has been raised whether pre-marathon participation screening should be performed, with some even arguing that they be mandatory. Furthermore, if screening is to be performed, the extent of screening is currently being discussed controversially, even within expert cardiovascular societies. The World Health Organization (WHO) published several criteria in 1968 which have to be met to justify a pre-participation screening procedure. In accordance to these criteria, the currently discussed pros and cons regarding several potential examination modalities used for pre-participation screening of marathon runners (resting-ECG, exercise testing, echocardiography) are presented with a special focus on different subgroups.

##### DOES MARATHON INCREASE INCIDENCE OF SUDDEN DEATH?

Halle, M.

*Technical University Munich*

Numbers of participants in city marathons have continuously increased over the last decades. This is observed for males and females alike. Interestingly the age >40 years of the participants has also steadily increased from 26% in 1980 to 46% in 2010. This has a substantial impact on the the number (7-fold increase) and cause of sudden cardiac deaths as coronary heart disease is becoming significantly more prevalent and a major cause of exercise induced death beyond the age of 35 years. These fatal events occur mostly during the end of the race beyond mile 22nd. Mechanisms and underlying causes for these events differ substantially. Genetic disease including myo-

cardial hypertrophy, conduction problems, myocarditis of coronary heart disease are mostly found in autopsies. Therefore, understanding the short-term and long-term effects of long-distance endurance sports is mandatory and should lead to a more sophisticated medical screening in leisure time and elite athletes alike in order to reduce the incidence of sudden cardiac deaths during marathon running.

### EVIDENCE FOR CARDIAC STRAIN DURING A MARATHON

George, K.

*Liverpool John Moores University*

Over the last three decades a range of studies have assessed two linked and controversial concepts; (1) exercise-induced cardiac fatigue and, (2) exercise-induced cardiac damage. Whilst these topics were initially developed and assessed in an academic setting there has now been cross-over into the lay press. This has raised substantial awareness and debate within the endurance sports world as to the safety of marathon training and competition for all participants. Both concepts have been studied in a range of endurance-based activities but a significant amount of evidence has been derived from "marathon studies". Marathon racing is exceptionally popular with the number of participants worldwide still growing. One interesting facet of marathon races is that the participants range from the elite to the "weekend warriors" often running for charity. Consequently the marathon (and other similar events) provides a relatively heterogeneous "laboratory" to study the impact of acute endurance exercise on the heart. The structure of this review covers a range of topics related to marathon racing studies of cardiac fatigue and damage. Firstly, we will define exercise-induced cardiac fatigue and damage and detail a number of technical approaches to assess both concepts. We will then assess the available evidence for cardiac fatigue and damage associated with marathon performance. This evidence base will be critically analyzed in relation to the limitations of field-based marathon studies. The impact of personal characteristics such as age and training status will also be examined. Finally, we will look at ongoing technical developments and where this field will progress to in the future. As a consequence of this broad debate we will attempt to draw some conclusions as to the clinical relevance of any change in cardiac function or biomarkers observed after running a marathon.

### IMMUNONUTRITION SUPPORT FOR ATHLETES: BENEFIT OR HAZARDS?

Nieman, D.

*Appalachian State University, North Carolina*

Prolonged and intensive exercise has transient but significant, wide ranging effects on the immune system. The exercise-induced immune perturbations and associated physiologic stress are associated with an elevated risk of acute respiratory infections (ARI), especially during the 1-2 week period following competitive endurance races. Immunonutrition support for athletes is an active area of research endeavor, and this lecture will summarize the efficacy of various nutritional products in countering exercise-induced immune dysfunction, oxidative stress, and inflammation. The value of using immunonutrition support for athletes has been questioned because blocking the transient oxidative stress, inflammation, and elevations in stress hormones following heavy exertion potentially interferes with important signaling mechanisms for training adaptations. Another viewpoint is that even the most effective immunonutrition support systems only partially block exercise-induced physiologic stress indicators, analogous to the beneficial use of ice packs to reduce swelling following mild injuries. In the end, the value of immunonutrition support for athletes during periods of heavy exertion and competitive races will be evaluated by whether or not the athlete has improved recovery, lowered ARI, reduced muscle damage and soreness, and enhanced overall athletic performance.

### IS-PM04 Mitochondrial structural organization, dynamics and function

#### SKELETAL MUSCLE MITOCHONDRIAL NETWORKS – STRUCTURAL ORGANIZATION AND ADAPTATIONS TO PHYSICAL ACTIVITY / INACTIVITY

Dahl, R., Larsen, S., Helge, J.W., Dela, F., Prats, C.

*The Panum Institute, University of Copenhagen*

The mitochondria are highly dynamic organelles that continuously adjust to cellular demands. The morphology of a mitochondrion is not always the classically accepted ellipsoid shape. In most cells, mitochondria are formed by highly interconnected tubular mitochondria. Mitochondria undergo frequent morphological changes, altering the mitochondrial network organization. Reorganization of mitochondrial networks is the result of coordinated processes of mitochondrion fusion and fission, which ensures the proper distribution of mitochondria to fulfill cellular energetic requirements. Dysregulation of mitochondria fusion and fission results in bioenergetic deficiencies and/or production of damaging reactive oxygen species (Park & Choi, 2012). Changes in mitochondrial network organization have been described in a variety of diseases, such as diabetes and obesity (Bach et al., 2003; Makino et al., 2010; Sebastian et al., 2012). The complexity and shape of skeletal muscle mitochondria networks is fiber type dependent. We have developed an immunohistochemical technique to perform 3D reconstructions of skeletal muscle mitochondria networks in human single muscle fibers. The results show that in type I muscle fibers mitochondria are complex interconnected tubular shaped, while in type II muscle fibers the structural organization of mitochondrial network was more diverse; from individual ellipsoid mitochondrion with few connections to tubular interconnected mitochondrial networks. Two percent of type I muscle fibers contained ellipsoid-shaped mitochondrion. Interestingly, in both type I and type II fibers the different morphological variants could be found within the same muscle fiber. Thus, skeletal muscle fibers present both profusion state mitochondria (ellipsoid) and profusion phenotype mitochondria (tubular interconnected) in different fiber types, which have different energetic demands. This makes skeletal muscle the optimal tissue to investigate the regulation processes regulating mitochondria fission and fusion. The effect of one leg immobilization on mitochondrial network organization and the implications of skeletal muscle mitochondrial network organization and dynamics on the currently used methods to assess mitochondrial function will be discussed. ### MITOCHONDRIAL FUNCTIONAL ADAPTATION TO EXERCISE TRAINING

Dela, F.

*University of Copenhagen*

The effect of physical activity and inactivity per se on muscle mitochondrial respiratory capacity per mitochondrion in humans is largely unknown. What is well-known is the several fold increase in skeletal muscle mitochondrial content that occurs in response to (primarily) aerobic training. In this sense the respiratory capacity is enlarged, but whether there is a qualitative adaptation of mitochondrial respiration in response to training is less well studied. The effect of physical inactivity is even less studied, and given the fact that physical inactivity is associated with the prevalence of type 2 diabetes and some types of cancer and is an independent predictor of mortality, there is clearly a need. It is possible that the detrimental effects of physical inactivity are mediated through a lack of adequate muscle oxidative capacity.

### ROLE OF MITOCHONDRIAL FUSION PROTEINS ON MUSCLE METABOLISM

Zorzano, A.

*IRB Barcelona - University of Barcelona - CIBERDEM*

Mitochondrial fusion and fission are key processes regulating mitochondrial morphology. Mitochondrial fusion is catalyzed by Mfn1, Mfn2 and OPA1 in mammalian cells whereas mitochondrial fission is operated by Drp1, Fis1 and Mff proteins. Mfn2 protein seems to play a specifically complex role in mitochondria. It regulates mitochondrial morphology, and in addition, it also controls endoplasmic reticulum morphology and function. Mfn2 expression is exquisitely regulated in skeletal muscle. It is up-regulated in skeletal muscle response to chronic exercise and upon cold exposure. In contrast, Mfn2 is repressed in muscle from high-fat fed mice or in obese or in type 2 diabetic individuals. Changes in Mfn2 expression have a marked impact on mitochondrial metabolism. Skeletal muscles obtained from Mfn2 KO mice show a reduced respiratory control ratio, which occurs in the absence of significant changes in state 3 and state 4 oxygen consumption. Mfn2-ablated soleus muscles also show reduced glucose oxidation, and reduced expression of some OXPHOS subunits. Additional evidence indicating that Mfn2 deficiency causes mitochondrial dysfunction comes from studies in muscle cells in culture. The content of hydrogen peroxide was also enhanced in skeletal muscle upon Mfn2 depletion or in Mfn2-silenced muscle cells. These results occurred in the presence of a normal anti-oxidant defense. Skeletal muscle Mfn2 KO mice also show susceptibility to develop insulin resistance in response to a high fat diet or to aging. In keeping with this, a defective insulin signaling is detected in Mfn2-deficient mice treated with a HFD in response to in vivo insulin administration. Mfn2 knockdown muscle cells also show an impaired capacity to respond to insulin. In all, available data indicate that Mfn2 regulates metabolism and insulin signaling in skeletal muscle, and it may contribute to the pathophysiology in obesity and type 2 diabetes.

### IS-BN07 New trends in motor learning

#### ROBOTICS AS A TOOL TO UNDERSTAND HUMAN MOTOR LEARNING

Stein, T.

*Karlsruhe Institute of Technology*

In 2010 Wolpert and Flanagan gave an overview of how robotics advanced research in neuroscience. Based on this work I will focus in my talk on the question of how robotics advanced research in human motor learning and how research in the field of human motor learning could benefit from robotics in the future. In the seminal experiment of Shadmehr and Mussa-Ivaldi (1994) subjects grasped the end of a robotic device while performing 2D point-to-point reaching movements in the horizontal plane. Meanwhile the device could apply forces to the subject's hand. Numerous experiments have shown that subjects can learn to compensate for the novel dynamics, thereby restoring their movements to normal after a short training period. This compensatory adjustment in motor output is thought to reflect a change in the neural representations related to the dynamics of the musculoskeletal system and external objects. The robotic devices used in these experiments can simulate objects with novel dynamical properties in real time (Wolpert & Flanagan, 2010). In the first part of my talk I will present the classic experimental design of motor adaptation experiments and the underlying theoretical considerations. Based on this, I will give a brief overview of current research topics and findings in the field of motor adaptation. In addition to their use in motor adaptation tasks, robotic devices could also be valuable for research in other fields, such as skill acquisition in sports (Reinkensmeyer & Patton, 2009). However, the upper limb movements occurring in sports take place in 3D space. Moreover, the forces occurring during sports movements are much greater than the forces occurring in the previously described motor adaptation experiments. At the moment the relationship between motor adaptation and skill learning in sports is far from clear (Yarrow et al., 2009). In the second part of my talk I will concentrate on the topic robotics and skill learning. I will present new robotic devices that can be used to investigate skill learning in more natural movement tasks (Bartenbach et al., 2013). Based on these developments, I will present ideas on how the existing experimental designs need to be enhanced to be able to investigate skill learning with robotic devices. **IMPLICIT MOTOR LEARNING: A NEW TREND OR AN OLD ATTRIBUTE?**

Masters, R.

*University of Hong Kong*

An important distinction that arises from cognitive approaches to learning is between conscious and unconscious aspects of human behavior. Much human interaction with the environment takes place at a non-conscious level of awareness, yet humans display a pervasive tendency to acquire not only procedural knowledge but also declarative knowledge when learning motor skills. Usually, this knowledge is accrued by explicit hypothesis testing during an extended trial-and-error process of resolving a motor problem. Instructions from an agent (such as a coach) may add to the quantity of declarative knowledge that is accrued. The ability to test hypotheses and to store and manipulate information that can be used to make motor responses is made possible by the information processing capabilities of the brain. Implicit motor learning tries to discourage hypothesis testing about motor responses or to disrupt storage of information that can be used for hypothesis testing, thereby limiting the amount of declarative knowledge that is accumulated during learning. While it is unlikely that any form of human motor learning is purely implicit or explicit, implicit motor learning techniques appear to augment the role of non-conscious processes in motor performance and thus reduce potential destabilization of automatic movement by conscious thought processes.

**INFLUENCE OF SLEEP ON CONSOLIDATION IN MOTOR LEARNING**

Van der Werf, Y.

*Netherlands Institute for Neuroscience*

Sleep enhances memory for learned skills. Typically, humans acquire motor skills by forming a motor memory through performance. Motor skills can also be learnt through observation. We investigated whether sleep aids learning by action observation, and whether the enhancement of the motor memory depends on the time of observation relative to sleep. Our results show that sleep is necessary for the enhancement of a motor skill by prior observations. This effect happened only if sleep occurs within a limited time window upon observation. The results indicate that observed activity might undergo sleep-dependent re-activation leading to consolidation and subsequent enhancement of motor programs, possibly through a mechanism involving the human mirror neuron system.

**10:20 - 11:50****Oral presentations****OP-PM17 Neuromuscular Physiology [NP] 4****MECHANICAL PROPERTIES OF THE RECTUS FEMORIS MUSCLE IN PROFESSIONAL FOOTBALLERS FROM START TO MID-SEASON**

Warner, M.1, Mullix, J.1, Gimpel, M.2, Stokes, M.1

*(1): Faculty of Health Sciences, University of Southampton, UK. (2): Southampton Football Club, Southampton, UK.*

Introduction Quadriceps' strain is the second most common injury in football players, accounting for 5% of all injuries (Ekstrand et al., 2011). Musculoskeletal screening tests are important to help avoid overtraining and injury (Gabbe et al., 2004). However, measurements of muscle are often made using subjective palpation and observational techniques. Novel technology enables objective measurement of tone and mechanical properties of muscle using a hand-held device (MyotonPRO), and has recently been used to examine thigh muscles in young males (Mullix et al., 2012). The present study aimed to quantify the stability of mechanical properties of the rectus femoris (RF) muscle in professional football players from start to mid-season. Method Nine English Premier League male football players (aged 22-30 years) were studied at the start and mid-way through the season. The MyotonPRO device (Myoton Ltd, London) applied brief mechanical impulses to the resting RF muscle belly on the dominant side, eliciting damped oscillations, which were recorded via the device's accelerometer. Parameters of non-neural tone (frequency), elasticity (logarithmic decrement) and stiffness (N/m) were calculated automatically. None of the participants suffered an injury during the study period. A paired-samples T-test assessed for statistical differences between the two testing sessions. Results There were no significant differences in the mechanical parameters tested between the start and mid-season ( $p > 0.05$ ; tone  $15.9 \pm 0.6$  to  $15.6 \pm 0.7$  Hz; stiffness  $277.7 \pm 11.4$  to  $283.3 \pm 15.7$  N/m; elasticity  $1.3 \pm 0.1$  to  $1.3 \pm 0.2$  decrement). On average there was only a -0.5% change in muscle tone, 3.4% in stiffness, with an 8.3% change in elasticity. Discussion These preliminary data suggest that the mechanical properties of the RF muscle remained constant during the first-half of a football season in players that had not suffered an injury. Monitoring changes in these parameters over the course of a season may provide an indication of injury risk. Further studies are warranted to develop large databases of normal reference values in professional footballers and to document abnormal parameters in injured muscles. **METABOLIC AND NEUROMUSCULAR FATIGUE IN HEALTHY WOMEN DURING A WINGATE TEST**

Kokova, M., Pencheva, N., Kitanoska, D.

*South-West University*

Introduction The reasons for the anaerobic fatigue, the power limitation factors and the factors that could improve performance have been studied mostly on trained subjects. Such data on untrained subjects especially females are scarce and insufficient. The aim of this study is to evaluate the heart rate responses, blood lactate and glucose concentration changes, sEMG RMS and MPF profiles of six muscles involved in cycling as factors for the anaerobic performance and fatigue in healthy untrained women. Methods Nine women ( $24.0 \pm 3.4$  years) performed a 30-s Wingate cycling test (load 0.075W/kg). Lactate and glucose levels were determined before and after the test. The sEMG activity of the following muscles of the right lower limb : vastus lateralis (VL), rectus femoris (RF), semitendinosus (ST),

biceps femoris (BF), lateralis gastrocnemius (GL), and tibialis anterior (TA) was recorded before, during, and after the test. EMG analysis included RMS and  $\Delta\%$ MPF determination. Results The values of the calculated anaerobic parameters were: maximum anaerobic power  $2163 \pm 787$  W, relative anaerobic power  $5.7 \pm 1.4$  W/kg, total anaerobic power  $1454 \pm 466$  kg-m/min and coefficient of anaerobic fatigue  $55.9 \pm 16.9$  %. Heart rate values (bpm) were: during warm-up -  $160 \pm 24$ , end of test -  $170 \pm 11$ , and recovery -  $180 \pm 15$ . Lactate levels increased from  $2.1 \pm 0.7$  to  $11.0 \pm 2.3$  mmol/l, while glucose levels remained statistically unchanged ( $4.5 \pm 0.9$  to  $4.2 \pm 0.6$ ). RMS values (normalized) at the beginning and at the end of the test were as follows: VL  $1.19 \pm 0.37$  and  $1.25 \pm 0.52$ ; RF  $1.28 \pm 0.19$  and  $1.46 \pm 0.39$ ; ST  $1.17 \pm 0.17$  and  $0.99 \pm 0.34$ ; BF  $1.12 \pm 0.18$  and  $1.16 \pm 0.51$ ; GL  $1.11 \pm 0.17$  and  $0.83 \pm 0.17$ ; and TA  $0.95 \pm 0.16$  and  $0.96 \pm 0.34$ .  $\Delta\%$ MPF values were: VL -  $5.2 \pm 12.7$ ; RF  $+0.9 \pm 21.9$ ; SM  $-7.4 \pm 4.2$ ; BF  $-12.5 \pm 11.8$ ; GL  $-3.6 \pm 10.6$ ; TA  $+7.9 \pm 18.4$  %. Discussion The results demonstrate a low anaerobic performance of the tested subjects. The fact that heart rate values rise significantly after the test indicates oxygen debt which is common for anaerobic tests (Weinstein et al., 1998). The significant change in lactate concentration ( $p=0.002$ ) clearly shows the metabolic origin of fatigue under the tested conditions, although glucose levels reveal a lack of exercise-induced hypoglycemia. Moreover, no significant changes occurred in RMS and MPF (Gerdle et al., 2000, Öberg, 1995) showing that the neuromuscular fatigue is not a limiting factor for performance. ### NEUROMUSCULAR FATIGUE INDUCED BY REPEATED WINGATE TESTS

Place, N., Girard, S., Ivarsson, N., Cheng, A.J., Neyroud, D., Mekideche, A., Truffert, A., Westerblad, H.

*University of Geneva*

Introduction It has recently been suggested that leaky ryanodine receptor (RyR) channels (Ca<sup>2+</sup> release channel in the skeletal muscle) might account for the reduced force generating capacity (i.e. muscle fatigue) after prolonged exercise in humans (Bellinger et al. 2008). As peripheral fatigue predominates after high intensity exercise (Place et al. 2009), the present study was designed to test the hypothesis that muscle fatigue following a strenuous, high intensity exercise, will be mainly of peripheral origin, because of altered RyR function. Methods Eleven healthy males ( $27 \pm 7$  yrs,  $VO_{2max}$   $52 \pm 8$  ml.min<sup>-1</sup>.kg<sup>-1</sup>) were recruited to perform 6 Wingate tests (duration 30 s, 0.7 N.m.kg<sup>-1</sup>) on a cycle ergometer, with 4 min recovery between each repetition. Neuromuscular function of the dominant quadriceps muscle was investigated before and immediately after exercise and consisted in measurement of maximal voluntary contraction (MVC) force, voluntary activation level (VAL, twitch interpolation technique), M-wave properties of the superficial knee extensors as well as potentiated doublet amplitude at 100 Hz (PS100). During neuromuscular testings, subjects were seated on a chair equipped with a force transducer with a knee angle of 90° and supramaximal electrical stimuli were delivered over the femoral nerve. A muscle biopsy was collected from the non-dominant vastus lateralis muscle before and about 10 min after the last Wingate test to analyse eventual changes at the RyR level. Results MVC force was considerably reduced after the repeated Wingate tests ( $-40.8 \pm 5.2\%$ ,  $P < 0.01$ ). A small but significant reduction in VAL was also observed ( $-7.3\% \pm 3.7\%$ ,  $P < 0.05$ ). PS100 was decreased by  $38.6 \pm 7.6\%$ , with only minor changes in M-wave properties for vastus lateralis muscle. Muscle biopsies are in the process of analysis. Conclusion This exercise induced considerable muscle fatigue, as evidenced by the large decrease in MVC force. Although VAL -common index of central fatigue- slightly decreased, the large reduction in PS100 seems to indicate that peripheral (muscular) mechanisms mainly account for the impaired maximal force generating capacity. Further, as muscle excitability seems to be relatively well preserved after the exercise, as revealed by the M-wave properties, it seems that processes distal to muscle action potential were impaired (Place et al. 2009). We hypothesize that impaired RyR function, resulting in impaired Ca<sup>2+</sup> handling, explains our findings. The analysis of muscle samples will allow to test our hypothesis shortly. References Place et al. *Clin Exp Pharmacol Physiol* 36(3):334-9, 2009 Bellinger et al. *Proc Natl Acad Sci* 105(6):2198-202, 2008

### FUNCTION OF THE VASTUS LATERALIS MUSCLE FIBERS DURING A RAPID KNEE EXTENSION

Ogiso, K., Naruse, K.

*Kogakkan University*

Introduction Shortening of the muscle fibers and increase in pennation angle (PA) contract the pennate muscle. Force generated by the muscles is transmitted to the tendons and finally attain a motor task by rotating the joints. However, the muscle fiber behavior does not seem to be uniform during the contraction, because irregular filament overlaps (Brown and Hill, 1991; Edman and Tsuchiya, 1996), regional differences in strain of the aponeurosis (Kinugasa et al., 2008) and asymmetry in fascicle cross-section deformation (Kinugasa et al., 2012) have been observed. Unexpected and rapid movement we often experience may make the muscle fiber contraction more irregular. The present study was designed to examine function of the vastus lateralis muscle fibers (VL) during a rapid maximal knee extension. Methods Eighteen male subjects performed a 10-consecutive isokinetic knee extension (90 deg/s) that comprised 7 passive and 3 maximal voluntary contractions (MVC) twice. They were asked to relax their muscles and exert MVC as quickly as possible only when a light turned on at 60 deg of the knee joint angle (0 deg = full extension) in the 3rd, 6th and 9th repetitions (C1) or 3 times in random order (C2). VL-EMG activity was monitored to check relaxation before the light stimulus. A point (P) where a fascicle arose from the deep aponeurosis and PA were measured on ultrasonic images of VL. Results The time course of active shortening after the light stimulus was different from that of passive shortening. PA and muscle thickness sharply increased about 200ms after the light stimulus in active shortening, especially near point P. The increase in PA was significantly larger in C1 than in C2. Premotor reaction time, electromechanical delay and total reaction time were also significantly shorter in C1 than in C2. Discussion VL contracted at MVC just as if the fascicle bit on the deep aponeurosis tightly, which was made quicker and larger by expecting the light stimulus. This markedly differs from the fascicle movement during isometric and slow isotonic contractions. Conduction velocity of the action potential becomes gradually slow near the tendon (Iwata, 1983; Kusama, 1987). Therefore, the biting movement might result from wave summation near the deep aponeurosis, which might lead to irregular behavior of the muscle-tendon complex. This may explain why most of muscle strain injuries occur at myotendinous junction (Garrett, 1990). References Brown LM, Hill I (1991) *J Muscle Res Cell Motil*, 12(2): 171-182. **10:20 - 11:50****Invited symposia****IS-BN03 Biomechanical human-environment interaction****THE EFFECT OF DIFFERENT SKI-SNOW INTERACTION MODES ON THE HUMAN BODY**

Kröll, J., Spörri, J., Müller, E., Schwameder, H.

*University of Salzburg*

In order to turn and regulate speed, a skier must manipulate the orientation and loading pattern of the skis to generate adequate reaction forces from the snow surface. Therefore, a deeper understanding of this ski-snow interaction is an essential component for equipment development. The overall ski performance is primarily affected by the side cut and the torsional and bending stiffness of the skis. Consequently the tuning of these properties may be essential for performance, comfort and injury prevention issues. The principle influence of different ski-snow interaction modes can be demonstrated by theoretical considerations. Hence, the first part of the talk will deal with theoretical models of ski-snow interaction mechanics which already have been described and tested using numerical simulations and physical models. However those models only superficially account for the effect of different Ski-Snow interaction modes on the human body. In order to better understand the effect of different ski-snow interaction modes on the human body it is necessary to consider experimental data from in vivo field studies as well. Therefore, empirical data from an intervention study will then be presented. The aim of this study was to quantify the evolution of total external and internal loads of elite athletes arising from different ski equipment designs under simulated competition conditions. Based on the recent changes of FIS equipment rules, ski side cut radii with 27m (GS 27) were compared against ski side cut radii with 35m (GS 35). Ski ground reaction forces (Pedar Insoles), kinematics (IMU Sensors) and muscle activity (EMG) were determined simultaneously. Comparing GS35 and GS27, force distribution alters forces in a manner that the outside leg forces decrease substantially with GS35 towards the end of the turn. However, an opposite behavior was observed on the inside leg where forces increased slightly at the end of the turn. From a neuromuscular perspective, one would expect that the alterations in external load are directly reflected in the leg extension muscle group. However, the neuromuscular alterations are only partially linked to external load, but in some cases are closely linked to functional aspects of the used ski. This can be observed in the tibialis anterior muscle where an increased activity on both inside leg and outside leg can be observed during the GS35 trial which is seen as "less functional" in a carving ski function. For the final part of the talk, the influence of the theoretical and in vivo approaches will be related along with the potential and limitations to our ski-snow interaction understanding.

**ESTIMATING AND ADJUSTING FOR EFFECTS OF ENVIRONMENTAL FACTORS IN SPORT RESEARCH**

Hopkins, W.G.1, Hume, P.A.1, Hollings, S.C.1, Hamlin, M.J.2, Spencer, M.3

*1: AUT University (Auckland, New Zealand). 2: Lincoln University (Christchurch, New Zealand). 3: Norwegian School of Sport Sciences (Oslo, Norway).*

Environmental and other venue-related factors (e.g., weather, surface conditions, altitude) can have important effects on performance, injury and related dependent variables. As such, they are also nuisance variables that modify the dependent variable in studies of other factors affecting performance or injury. Appropriate inclusion of environmental factors in a linear model not only provides estimates of the effects of the environment but also improves the precision of estimates of other effects and adjusts them to chosen values of the environmental factors. When the environment differs between but not within athletes (e.g., single performances by different athletes at different venues), the effects of environmental differences can be estimated with a covariate in a traditional ANOVA linear model. Such models require hundreds of athletes on each level of the environmental variable to estimate effects with sufficient precision for adjusting outcomes of the main dependent variable. When the environment differs within athletes (e.g., multiple performances by the same athletes at different venues), the changes in the environment are represented by a covariate that changes within each subject. Such within-subject covariates cannot be included in ANOVA models, but mixed linear models allow for them and thereby usually provide adequate precision with smaller sample sizes. There are several options to specify covariates in linear models. A simple linear effect is specified with a numeric covariate. A potentially non-linear effect should be investigated by parsing the covariate either into quantiles or other appropriate subgroups, then specifying the covariate as a nominal variable and estimating the means and differences between means of the different levels. The covariate can also be specified as a quadratic or higher-order polynomial, especially when the aim is to estimate the value of the covariate that maximizes or minimizes the main dependent variable. It is also possible to specify two discontinuous linear effects (e.g., one slope over a low range and another over a high range of an environmental variable) by interacting dummy variables with covariates representing the two linear effects; the transition value of the covariate can then be found by iterative analysis. Non-linear mixed models are another option with such data. Some of these analyses will be illustrated with data from recent studies of the effects of environment on performance of track-and-field athletes and downhill skiers.

**GROUND-SHOE-FOOT INTERACTION TO BIOMECHANICS OF THE MUSCULAR-SKELETAL SYSTEM IN LOCOMOTION**

Brüggemann, G.P., Willwacher, S.

*German Sport University Cologne*

In human locomotion like running the ground shoe foot interaction is frequently used to distinguish between running styles. Runner's striking behavior has been shown to affect the mechanical loading conditions of the lower extremity during the braking phase of stance. Barefoot running leads to a more plantar flexed striking behavior of the, which could be a strategy to reduce local pressures underneath the heel during the initial contact phase or to decrease the tibia and knee joint acceleration during initial stance. Changing the hardness of the surface or the midsole of a shoe affects the contact area as well as the time during which the impact energy is absorbed. Consequently, running on soft surfaces like natural grass has been shown to reduce peak plantar pressures underneath the foot, the peak impact force or at least the rate of impact force. A soft running surface might therefore allow for the maintenance of a more dorsi-flexed foot strike pattern in the absence of soft cushioning materials underneath the heel. Most published studies on barefoot and shod running or on running biomechanics in general did not alter the material properties of the running surface and therefore fail to clarify possible

interactions between footwear and surface conditions. Competitive as well as recreational running is regularly performed on surfaces with different mechanical properties. A recent study investigated the effects of running shoes and surface conditions on the striking behavior and lower leg biomechanics in the sagittal and frontal planes of movement of male and female runners. Gender effects occurred mainly in shank and thigh frontal plane orientation and knee flexion angle. On harder surfaces and when running barefoot, subjects tended to land with a more plantar flexed foot position and ankle angle as well as a more vertical shank alignment. Different adaptation strategies to running surfaces were observed between barefoot and shod conditions. It seems that touchdown behavior is adapted to compensate for the force distributing and energy absorption potentials of distinct surface by shoe combinations. If the combined compliance of the shoe plus surface combination exceeds a certain level, touchdown kinematics seem to be adapted to improve joint stability during early stance. The surface shoe foot strongly interacts with the biomechanics of the muscular skeletal system at least with that of the lower extremity in human locomotion. Running habits (barefoot or shod) might play a role in this interaction but it is not finally understood.

### IS-SH06 Ethico-legal perspectives on justice in sport

#### PRIVACY VS. ANTIDOPING POLICIES

Nicolás, P.

*University of País Vasco*

Introduction The antidoping controls necessarily include medical analyzes and obtaining data concerning the health. It is needed also the availability of the athletes to undergo screening. The legal framework for the collection and use of personal data in Spain is primarily established in the Organic Law 15/1999, which states that data collection should be proportional to the legitimate aim pursued. It also establishes that health data may only be collected and processed and transferred when for reasons of general interest is required by a law or when the subject gives her express consent. Methods To examine the legal basis and legitimacy of the establishment of antidoping controls and the mechanisms that have been articulated in this context (Law 7/2006 of 21 November on the protection of health and the fight against doping in sport and other development regulations), it is necessary to analyse whether these measures are proportionate in relation to the legitimate aims pursued. This test requires a balancing of the interests and rights involved: privacy and data protection, health protection and interest relating to the sport in general. Another issue directly related to this, concerns the fairness of the publication of the results of the analysis, either by public institutions or media. Discussion and results Spanish legislation corresponds to international standards. The incorporation of these measures into our legislation has raised litigation in court and doctrinal discussion as well as a critical report of the General Attorney. The legislation is in the process of reform and the trend to increase control mechanisms does not appear to decrease. References Agencia Mundial Antidopaje. Código Mundial Antidopaje. 2009. #### VALUE PLURALISM IN SPORTS: JUSTICE AND CHEATING

Tamburrini, C.

*University of Stockholm*

Sports games are regulated by a number of rules which determine how the game should be played. Some of them are constitutive, in the sense that they create the game. Others are merely regulatory, as they tell sport practitioners which actions are permitted and which actions are to be abstained from when performing the game. Particularly regulatory rules are open to different interpretations, depending on how the game is understood by different actors (sport practitioners, sport officials, sports experts and journalists, the public, to cite some of them). On grounds of this, it is often affirmed that, besides the formally written rules of a game, there is "an unofficial systems of conventions which determines how the official rules of the game will be applied in various concrete circumstances". This informal system of conventions is usually called "the ethos of the game". (D'Agostino, Fred, "The Ethos of the Game", 1981). In this presentation, I will first argue that, besides this traditional ethos of the game, there is a wider normative framework that evolves directly from how the game is practiced by sportspersons. This enlarged sport ethos rests on a notion of value pluralism and is highly receptive to the influence of ethical relativism, at least in one of its forms. Finally, I will raise the question of the normative relevance to be given to this enlarged, practitioners-based sport ethos.

#### LUCK EGALITARIANISM, JUSTICE AND SPORT

Pérez Triviño, J.L.

*Pompeu Fabra University*

If we used the Rawlsian strategy to propose the principles of justice in a well-ordered society, in other words, the original position, to design the principles that must govern sport practices, which would be these? My purpose here is not so ambitious. I will reduce my goal to examine which should be the paper of the luck in sport. As it is well known, Rawls was concerned also by luck with his known appeal

to the natural lottery and the idea that some factors of social disadvantage must be socially compensated. Other authors have tried to explain and offer a list of factors that prevent that in the sport win always the best athlete. Dixon pointed out several of these circumstances: the refereeing errors, cheating, gamesmanship, the inferior performance by superior athletes and the bad luck. My aim will be to analyse the paper that should be attributed to the luck in sport unlike the social scheme and which luck factors have to be compensated in an athletic competition.

##### CONTESTED BODIES – CONFLICTS AND CONTROVERSIES ABOUT DRESS CODES AT INTERNATIONAL SPORT COMPETITIONS

Pfister, G.

*University of Copenhagen*

In spring 2011, the International Badminton Federation decided to make skirts mandatory for female players, obviously, to increase the glamour quotient in this sport and to attract a larger audience. Bikinis in beach volleyball and increasingly “stunning” attire in tennis seemed to have enhanced the public interest in these sports. At the same time, sport organizations from Islamic countries demand that Muslim women be allowed to compete in all sports and events wearing the hijab. A third party in the struggle about the dress code is the Atlanta Plus Committee and its supporters who addressed the IOC in 2010 with the demand to exclude NOCs who force female athletes to wear “restrictive garments” such as the hijab. In this paper I will explore the arguments and reasons as well as the political and ideological background of the various initiatives and groups involved in the “battle” about the bodies of female athletes. In addition, I will approach the dress issue from the perspectives of various groups of women. Drawing on constructivist concepts of gender, religion and ideology, sport and taste, I will try to unpack the politics and policies of the dress codes as well as the open and hidden meanings of the body presentations. ##### THE TRANSNATIONAL FLOW OF BODY CULTURES: THE GLOBALIZATION OF MODERN YOGA IN THE 20TH CENTURY.

Vertinsky, P.

*University of British Columbia*

Modern transnational yoga has increasingly become understood as a predominantly Anglophone phenomenon in spite of its Asian inspirations - one of the first and most successful products of globalization. Now one of the fastest growing health and fitness activities, said to be ‘oxygen for the modern soul,’ modern yoga can be found everywhere among the affluent, educated and especially women. This paper will discuss how interest in yoga thought and practices began to grow in the late 19th century as the result of an ongoing dialogical exchange between modern body culture techniques originating in the West and the various discourses of modern Hindu yoga that circulated throughout the nineteenth century. It will focus especially upon the feminization of hatha yoga as it was reframed and incorporated into female physical culture practices in the West during the 20th century and examine claims about some of the risks and benefits which have flowed from this classic example of Hobsbawm’s ‘invention of traditions.’ As Anne Harrington reminds us in relation to the history of mind-body medicine, eastward journeys rarely take us into another world for they are located within colonial cultural discourses and narratives that have already established themselves as familiar. They simply take us deeper into ourselves.

##### CHALLENGING THE NORM? PHYSICAL IMPAIRMENT, ACTIVE AGING AND SPORTING BODIES

Knoppers, A., Van Amsterdam, N.

*University of Utrecht*

The purpose of this paper is to explore how discursive practices of active aging and physical disability overlap and (re)produce gendered hierarchies in the valuing of athletic and physically active bodies. More than 100 years ago the bodies of women, the ‘elderly’ and those with visible physical impairments were considered to be unsuited for participation in elite sport. The normal sporting body was young abled and male. Currently, the increasing attention paid to and visibility of elite women’s sport and events such as the Paralympics and Senior Games suggest that the acceptance of athletic bodies has expanded to include a diversity of bodies beyond that of the young abled male. Such global events have expanded opportunities for individual athletes to participate in sport and in that sense can be seen as emancipatory and as challenging existing hierarchies in valued bodies. Yet normative sport discourses often implicitly represent both old age and physical impairment in negative terms. We argue that dominant discursive practices of active ageing and physical disability have similar subtexts related to gender, ability, health, sport and meritocracy. Together these subtexts (re)produce body hierarchies that continue to normalize the sporting body towards that of the young abled male.

### OP-PM02 Adapted Physical Activity [AP] 2

#### PARENTAL SOCIO-ECONOMIC POSITION AND BEHAVIOR INFLUENCING HABITUAL PHYSICAL ACTIVITY AMONG 6-YEAR OLD CHILDREN. A REPRESENTATIVE COMMUNITY STUDY

Aspvik, N.P.1, Wichstrøm, L.2

*Norwegian University of Science and Technology*

**Introduction** High socio-economic position (SEP) has been shown to be an important determinant of health and physical activity (PA) in adults, whereas results for children and adolescents are less consistent (Kolle 2009, Kelly et al., 2006). There is also a dearth of studies concerning other parental determinants of child PA. Therefore, the aim of this study was 1) to examine the extent to which how parent's SEP is related to young children's PA, 2) identify the mediators of parental SEP, and 3) identify parental characteristics associated with child PA. **Methods** The participants is a representative sample of 6-year olds living in the city of Trondheim, Norway (N=680). Children wore the ActiGraph accelerometer GT3X for 7 consecutive days to obtain objective assessment of physical activity. PA was measured as mean counts per minute. Data were considered valid if a child had at least 3 d of at least 480 min•d<sup>-1</sup> (Kolle 2009). Determinants of PA were collected through questionnaire. Data were subjected to a path analysis using Mplus. **Results** Parents' level of education, income and job position (SEP) had no direct significant effect on their child's PA. Nevertheless, there was an effect of mother's education on the child's PA, which was mediated through time spent outdoors with the child. Furthermore, parent self-reported physical activity was not correlated with child PA. **Discussion** Finding parental SEP to have no direct effect on their 6-year-old children's PA is in accordance to other studies of young children (Kelly et al. 2006, Riddoch et al. 2007), but in contrast to studies on older children/adolescents (Mo et al. 2005). It may be that parents' SEP first and foremost is associated with organized physical activities, which is a small contributor to overall PA in young children than in older children. The amount of time parents spend outdoors together with their child strongly influence child PA, a finding corroborated by other findings (Hinkley et al., 2008). This may be due to the fact that children are 2.5 more active when outside than when inside (Cooper et al., 2010). The present findings thus strongly suggest that facilitating parents going outside with their children may increase young children's PA. **References** Cooper, A.R. et al. *International Journal of Behavioral Nutrition and Physical Activity* 7 (2010). Hinkley, T. et al. *American Journal of Preventive Medicine* 34, 435-441 (2008). Kolle E. (2009). Dissertation from the Norwegian school of sport sciences. Oslo. Kelly L.A. et al. (2006). *Arch Dis Child*, 91(1), 35-38. Riddoch C.J. et al. (2007). *Arch Dis Child*, 92:963-969. Mo F. et al. (2005). *International Journal of Adolescent Medicine and Health*, 17(1): 49-56.

#### POSITIVE INFLUENCE OF ACOUSTIC FEEDBACK FOR ADAPTIVE ELITE ATHLETES IN ROWING

Schaffert, N., Mattes, K.

*University of Hamburg*

**Introduction** Rhythmic information provided audibly as acoustic feedback (AF) supports the timing of movement-execution subliminally (Thaut, 2005) based on the physical characteristics of sounds and movements and their time-based-inseparability. Particularly in high performance technique training, time-critical structures are of crucial importance for the precision of successfully executed movements. An online AF-concept for elite athletes has previously been described and empirically investigated during on-water rowing training (WRT) sessions. Assuming beneficial effects for visually-impaired athletes (VIA), AF was implemented into the direct preparation for the Paralympics with the German National Adaptive Rowing Team (ART). The investigation aimed at optimizing the boat run and enhancing athletes' perception for executing the rowing movement. **Methods** The coxed mixed four (LTA4+) (N=6) was accompanied during WRT-sessions with Sofirow (AF-system). Boat acceleration (aB) was measured (MEMS-acceleration sensor  $\geq 125\text{Hz}$ , 1% accuracy,  $\pm 2\text{g}$ ), parameter-mapping-based sonified (audibly converted) and provided online to ART and their coach. Statistical analysis considered two different training intensities (TI) at stroke rate (sr)  $\pm 19.6$  strokes/min. (EXA 1) and  $\pm 22$  strokes/min. (EXA 2). AF was presented in 500-m-blocks (with and without AF) alternately. Standardized questionnaires examined AF's functionality and athletes' perception of it. **Results** Analysis of variance showed significantly increased mean boat velocities (vB) with AF compared to sections without AF for EXA 1 (F1.8=7.59;  $p=0.00$ ;  $\eta^2 p=0.43$ ) and EXA 2 (F1.1=5.92;  $p=0.38$ ;  $\eta^2 p=0.46$ ). Intra-cyclical analysis revealed qualitative changes within the aB-time trace. AF was perceived from ART as a supportive training-aid, providing important functional information about the boat run independently from vision. **Discussion** The results show how AF can affect the mean vB immediately in WRT of ART providing relevant information as well for VIAs by supporting the movement execution and enhancing the feeling for the rowing cycle (rc). Audible presentation of the information from the captured-data, made it directly and intuitively intelligible for ART. The sound reflected the rhythm of rc by providing detailed information of its characteristic phases, yielding to improved crew synchronization. Results reinforced previous findings with elite athletes and were consistent with initial assumptions, showing that AF provides assistance for ART in terms of enhancing their perception for rc more effectively. AF enables access for VIAs to the existing visually-based biomechanical analysis by providing the information audibly. The AF-concept has been integrated into the WRT of ART in preparation for the Paralympics and World Championships. **References** Thaut, M.H. (2005). *Rhythm, music and the brain: Scientific Foundations and Clinical Applications*. New York: Routledge Chapman & Hall.

#### UPPER BODY TRAINING AND EXERCISE: LOW INTENSITY HAND CYCLING

Hettinga, F., Monden, P.G., van der Woude, L.H.V.

*University Medical Center Groningen/ University of Groningen*

**Purpose:** How to optimally train the upper body is a particularly relevant question for those in a wheelchair. Though ACSM guidelines can be used as a basis to train the upper body, risks on overuse injuries are present when training at too high intensities too soon. Early in their rehabilitation process, patients with traumatic injuries are usually not familiar with arm propulsion, and care must be taken with prescribing adequate training. Therefore, the purpose of this study was to determine whether lower intensity (30%HRR) handcycling training improves physical capacity and whether this is perceived as achievable (low perceived discomfort and effort) in untrained able-bodied women. **Methods:** 19 able-bodied, untrained healthy females (age 18-23) were included. Nine participants received handcycling

training (experimental group (EG); 7 weeks, 30% HRR, 30 min per session, three times per week) and 10 received no training (control group (CG)). All subjects performed an incremental pre- and post-test performed on an add-on handbike on a motor driven treadmill. Peak values for oxygen uptake (VO<sub>2</sub>), peak power output (PO), ventilation (VE), heart rate (HR), and submaximal values for mechanical efficiency (ME) at 41W, as well as HR and VO<sub>2</sub> (at 55W) were assessed during both tests. Local perceived discomfort (LPD) and rate of perceived exertion (RPE) were measured. Results: The TG showed an improvement in PO<sub>peak</sub> (pre: 81.1 ± 11W; post: 97.4 ± 11.3W) and HR<sub>peak</sub> (pre: 182 ± 11 bpm; post: 188 ± 11 bpm) in comparison with the CG. Also improvements for submaximal ME (pre: 12.7 ± 0.7; post: 16.6 ± 1.7), VO<sub>2</sub> (pre: 1148 ± 117 ml/kg/min; post: 955 ± 133 ml/kg/min), VE (pre: 37.6 ± 6.1 l/min; post: 28.3 ± 4.5 l/min) and HR (pre: 163 ± 15 bpm; post: 154 ± 12 bpm) were found. The participants scored on average low on RPE (7.1 ± 0.5; very very light) and LPD (3.4 ± 1.6; no discomfort) during the training sessions. Conclusion: Low intensity handcycling training resulted in an increased PO<sub>peak</sub>, while LPD and RPE during the training sessions were very low. Also, literature has shown that handcycling is less straining and requires lower peak forces compared to handrim propulsion. Low intensity handcycling training thus seems to improve physical capacity with a relatively low risk on shoulder injuries. However, VO<sub>2peak</sub> did not increase and fitness thus did not seem to improve. Lastly, at submaximal level, ME increased after low intensity training. This allows greater mobility and possibilities in 'daily life' sub-maximal exercise intensities. It thus seems that, in particular early in the rehabilitation process, when risks on injuries are high, low intensity handcycling training provides interesting opportunities in pursuing a healthy lifestyle.

### REAL-TIME ANALYSIS OF HEART RATE INTENSITY AND MOTOR T-PATTERNS IN EXERCISE PROGRAMMES FOR THE ELDERLY: A MULTILEVEL MIXED METHODS DESIGN

Saüch, G., Castañer, M., Prat, Q., Hilenó, R., Camerino, O.

*INEFC-University of Lleida*

**Introduction** People in Western society are living longer and this raises the need to reconsider the content of exercise programmes for the elderly. With the aim of obtaining information that would help optimize these programmes we used a mixed methods design to analyse heart rate intensity and patterns of motor behaviour, simultaneously and in context. **Methods** Eight female participants (age: 81±4.02 years) were studied over a period of 50 min each. Using the mixed methods design known as Multilevel Triangulation (Camerino et al., 2012) we collected and triangulated: a) quantitative data obtained from heart rate monitors (Polar RS800), tabulated according to the Classification of Exercise Intensity of the American College of Sports Medicine (ACSM, 2011); b) qualitative data on patterns of motor behaviour, organized according to the category system set out in OSMOS (Castañer et al., 2009) and sequentialized (into T-patterns) by means of THEME 6.0; and c) qualitative data derived from a content analysis (using NVIVO 0.8) of participants' answers to open-ended questions about their levels of fatigue. **Results** Regarding the relationship between motor skills (locomotion [LOC], stability [ST]) and HR categories (light [LIG], moderate/vigorous [MV]) the chi-squared test yielded a value of 1.68 (p>0.05). In the analysis of adjusted residuals there were no Z scores >1.96 (p<0.05), although values close to this (Z=1.3, p>0.05) were detected between LOC and LIG, and between ST and MV. Analysis of the T-patterns detected by THEME showed that stability skills are used when HR shifts to MV, after having made use of locomotion skills. The qualitative data derived from the open-ended questions corroborated these findings. **Discussion** Heart rate intensity was directly related to the pattern of motor behaviour, namely locomotion, manipulation and stability (Castañer et al., 2009), as well as to the capacities of resistance, strength and speed. The study confirms the utility of mixed methods designs for evaluating, in context, the heart rate intensities associated both with specific patterns of motor behaviour and with perceived fatigue among participants. We believe that research of this kind can help to ensure that exercise programmes for the elderly are physiologically tailored to the heart rate intensities recommended by the ACSM. **References** ACSM (2011). *Med Sci Sports Exerc*, 43(7), 1334-1359. ### INFLUENCE OF ANATOMICAL PLACEMENT OF ACCELEROMETERS ON PREDICTION OF PHYSICAL ACTIVITY ENERGY EXPENDITURE IN WHEELCHAIR USERS

Nightingale, T.E., Walhin, J.P., Thompson, D., Bilzon, J.L.J.

*University of Bath*

**Introduction** Physical activity energy expenditure (PAEE) is inherently difficult to measure in free-living conditions, particularly in populations where movements and movement patterns are atypical, such as manual wheelchair users. The aim of this study was to (i) assess the mechanical reliability of the Actigraph GT3x+ (Actigraph, USA) accelerometer and (ii) assess the influence of its anatomical placement on PAEE estimation in manual wheelchair users. **Methods** Mechanical reliability: Ten GT3x+ units were attached to a multi-axis shaker table. A testing schedule which comprised various acceleration conditions to replicate a range of physiological movements was conducted along each of the three measurement axes. Human validity: Eleven manual wheelchair users (mean ± SD: 34 ± 11 years, time since injury: 13 ± 15 years, body fat: 25 ± 13 %) completed five activities; deskwork and wheelchair propulsion (2, 4, 6, 8 km.hr<sup>-1</sup>). A GT3x+ accelerometer was worn on the right wrist, upper arm and waist. The relationships between physical activity counts (PAC) from each unit and metabolic rate (Cosmed K4b2, Italy) were subsequently assessed and bias ± 95 % limits of agreement (LoA) calculated. **Results** Mechanical reliability: CV ranged from 0.2 to 4.7 % (intra-unit) and 0.9 to 5.2 % (inter-unit) in all axes. ICCs were 1.0 for all stages in each axis. The absolute bias ± 95 % LoA values within units were 0.4 ± 4.1 counts.5 s<sup>-1</sup>, -0.1 ± 4.6 counts.5 s<sup>-1</sup> and 0.3 ± 4.2 counts.5 s<sup>-1</sup> for x, y and z axes respectively. Human validity: PAC at each anatomical location were significantly (p < .01) associated with metabolic rate (wrist; r = .96, upper arm; r = .91, waist; r = 0.73). The SEE for each correlation was 2.88, 4.15, and 6.89 KJ.min<sup>-1</sup> for wrist, upper arm and waist respectively. Using the generated regression equations the absolute bias ± 95 % LoA values were 0.46 ± 5.71 KJ.min<sup>-1</sup>, 0.33 ± 8.18 KJ.min<sup>-1</sup> and -0.03 ± 13.56 KJ.min<sup>-1</sup> for wrist, upper arm and waist respectively. **Discussion** The findings of the mechanical reliability testing demonstrate that the Actigraph GT3x+ is a reliable tool for assessing accelerations within the physiological range of interest. Of the three anatomical locations considered, a wrist-mounted accelerometer provides the most valid prediction of PAEE in manual wheelchair users. Future studies should assess the validity of such devices and anatomical positions for predicting PAEE during more complex representative daily activities performed by manual wheelchair users.

**"CALCIAPENSIERI" PROJECT: AN ADD-ON TREATMENT IN THE MANAGEMENT OF SUBJECTS WITH SCHIZOPHRENIA**

Battaglia, G.1,2, Alesi, M.1, Inguglia, M.3, Roccella, M.1, Caramazza, G.2, Bellafiore, M.1,2, Palma, A.1,2

1: University of Palermo, Italy; 2: Regional Sports School of CONI Sicilia, Italy. 3: Local Health of Palermo, Italy.

**Introduction** If physical activity is a pivotal component of good health for everyone, there is an increasing emphasis on its importance for psychiatric patients affected from schizophrenia, Alzheimer's dementia, major depressive disorder (Knochel et al. 2012). The aim of this study was to investigate the effects of soccer practice on the self reported health quality of life (SRHQL) and sports performance (SP) in psychotic subjects. **Methods** Eighteen schizophrenic male patients were randomized into either a trained (TG) and control group (CG). TG was trained for 12 weeks by two soccer training sessions/week. CG did not perform any regular sports activity during experimental period. Anthropometric measurements, SRHQL, personal time records in 30-meter sprint test (30-mST) and slalom test running with ball (STB) were evaluated before and after the experimental period. SRHQL was assessed using SF-12 questionnaire measuring physical (PCS-12) and mental (MCS-12) component summary scores. **Results** After the training period, TG showed a relevant reduction by 4.6% in body-weight (BW) and body mass index (BMI) compared to baseline. On the contrary, CG showed an increased BW and BMI by 1.8% from baseline to post test. Moreover, at 12 weeks we found that control patients increased significantly their BW than trained ones ( $\Delta= 5.4\%$ ;  $p<0.05$ ). After the training period, comparing baseline TG's SF-12-scores to post-test results, we found an improvement by 10.5% and 10.8% in PCS and MCS respectively. In addition, 30-mST and STB performances of TG improved significantly ( $p<0.05$ ) from baseline to post-test compared to CG. **Discussion** Soccer practice appears to be able to improve psychophysical health in schizophrenic subjects (Pringle, 2009). Indeed, our study showed that programmed soccer physical activity could reduce antipsychotic medication-related weight gain and improve SRHQL and SP in psychotic subjects. To sum up, the results of this study suggest some interesting implications on the educational and clinical field on the psychiatric rehabilitation. We suggest that it might be worth looking further into the need to plan multifaceted interventions aimed at combining traditional pharmacologic treatments and alternative behavioural methods such as physical activity. **References** Knochel, C, Oertel-Knochel V, O'Dwyer L, Prvulovic D, Alves G, Kollmann B, Hampel H. ### OP-PM41 Sports Medicine [SM] 2

#### **ANKLES BACK IN CONTROL: BRACES VERSUS NEUROMUSCULAR EXERCISES FOR THE SECONDARY PREVENTION OF ANKLE SPRAINS**

Janssen, K.W., van Mechelen, W., Verhagen, E.A.L.M.

*EMGO+ VUmc Amsterdam*

**Introduction** Ankle sprains are the most common sports and physical activity (PA) related injury. There is extensive evidence that there is a twofold increased risk for injury recurrence for at least one year post injury. Recurrences result in about 50% of all cases in chronic complaints requiring prolonged medical care. Therefore, ankle sprain recurrence prevention is essential. Evidence shows that despite different working pathways, braces and neuromuscular training (NMT) are both effective in reducing ankle sprain recurrence risk. We aimed to evaluate the preventive effectiveness of the combined use of braces and neuromuscular training (NMT) against the individual use of either braces or NMT alone. **Methods** This study was designed as a three-way randomized controlled trial with one year follow-up. Adult active sports participants who had sustained a lateral ankle sprain within the preceding two months were eligible for inclusion. After participants finished ankle sprain treatment by means of usual care they were randomized to one of three study groups. Participants in group 1 received an eight week NMT program (Hupperets et al, 2009); participants in group 2 received a sports brace (Aircast A60) to be worn during all sports activities for the duration of one year; and participants in group 3 received a combination of the NMT program and a sports brace to be worn during all sports activities for the duration of eight weeks. The primary outcome measure was injury rate of ankle sprain recurrences, which was registered prospectively through monthly follow-ups. **Results** 384 athletes with an ankle sprain were included and randomly assigned to the three intervention groups. Injury rate of ankle sprain recurrences was 29% for the NMT group, 18% for the brace group and 20% for the combination group. The OR for having a recurrent injury was 1,96 (95% BI 0,85-3,22) for the NMT group compared to the brace group and 1,64 (95% BI 0,67-2,32) for the NMT group compared to the combination group. **Discussion** Current findings indicate braces to be at least equally effective, and potentially superior to NMT. The accumulating evidence on the effectiveness of bracing supports the use of bracing as a (cost) effective secondary preventive measure for ankle sprains (McGuine 2011). In our practical RCT adherence to the different interventions was mediocre (Full adherence: NMT 45%, sports brace 23% and combination 28%). There seems to be more public support for the use of NMT in sports but the support for brace use is often lacking. Therefore we advise future research to focus on the implementation of the effective preventive measures for ankle sprains. **References** McGuine et al. *Am J Sp Med* 2011;39(9):1840-8. Hupperets et al. *BMJ* 2009;339:b2684.

#### **MORPHOLOGICAL CHARACTERISTICS OF THE FOOT WITH JONES FRACTURE IN UNIVERSITY SOCCER PLAYER**

Fujitaka, K.1, Otuki, S.2, Takemura, M.3, Okubo, M.4, Tanaka, Y.5

1: Osaka Sangyo university of Graduate School, 2: Osaka Sangyo University, 3: Hyogo College of Medicine, 4: Biwako Seikei Sport College, 5: Nara Medical University, Orthopedic surgery

**Introduction** The purpose of this study was to investigate morphological characteristics of the foot with Jones fracture in university soccer players. **Methods** Male university soccer players were investigated. Radiographs of 12 feet (injury group) of 11 players with Jones fracture and those of 10 normal feet (control group) of 10 players were compared. Anterior-posterior non-weightbearing foot radiographs were taken for all subjects. Radiographs of injured feet in the injury group and those of a non-dominant leg (The player itself used the dominant leg as the leg of the side which is found in soccer and kicks a ball) in the control group were analyzed. The lengths of the first metatarsal and fifth metatarsal were measured. In addition, the angle between the axes of the first and fifth metatarsals (M1M5 angle)

was measured. The axis of each metatarsal was a line that connected the mid-point of the proximal and distal ends of its metaphysis (Y. Tanaka et al., 1995). The ratio of the first metatarsal length to the fifth metatarsal length (length ratio of the fifth metatarsal) was calculated. Mann-Whitney test was performed to compare differences between the two groups. Results In comparing the length ratio of the fifth metatarsal, the injury group ( $1.35 \pm 0.10$ ) was significantly greater than the control group ( $1.25 \pm 0.05$ ) ( $p < 0.05$ ). The values of the M1M5 angle were  $24.1 \pm 2.7^\circ$  in the injury group and  $24.4 \pm 4.8^\circ$  in the control group. There was no statistical significance. Discussion The fifth metatarsal is longer than the first metatarsal in the foot with Jones fracture. There is a possibility that rotational stress and stress from the lateral side may increase in the foot with the long fifth metatarsal. In addition, stress may concentrate on the plantar side of the fifth metatarsal base during contraction of the toe flexors. References Tanaka, Y., Takakura, Y., Kumai, T., Samoto, N., Tamai, S. (1995). J. Bone and Surg, 77(2), 205-213.

## **SPORTS INJURIES AMONGST UNIVERSITY PHYSICAL EDUCATION STUDENTS – A PROSPECTIVE EPIDEMIOLOGICAL INVESTIGATION**

Mukherjee, S.

*National Institute of Education*

**Introduction** The university physical education (PE) programme is rigorous and exposes the students to increased risks of sports injuries. The higher risk of injuries in the university PE students is a concern as it can adversely affect their teacher training and also interfere with their professional career in the long term. Therefore, keeping the PE programme safe by minimising the injury risks should be of prime concern to the programme organisers and the institute. This study was a prospective epidemiological investigation of sports injuries in university PE students. **Methods** 327 students from different PE programmes participated in the study. Sports-related injuries during a 12 week semester were reported once every three weeks on an injury registration form. The form was adapted from the NCAA injury surveillance system (Dick et al., 2007). Injuries sustained during intramural (curriculum sports lessons and voluntary practice) and extramural sports participation were documented. Severity of injuries was classified based on absenteeism and medical attention. **Results** A total of 82 injuries were documented during the 12 week semester. The students in the first semester of the PE programmes sustained the majority (70%) of injuries. 55% of the 82 injuries were sustained during the intramural activities and 45% during extramural participation. Male and female students sustained 70% and 30% of the injuries respectively. 79% were new injuries, 16% were recurrent and 5% were aggravations of pre-existing injuries. Lower limb was the most commonly injured part (49%) followed by the upper limb (28%) and the head and face (12%). Ankle was the commonest body part to be injured (18%) followed by the knee (16%) and fingers (13%). Sprain was the commonest type of injury (29%) followed by contusion (15%) and muscle-tendon strain (11%). Of the injuries sustained during curriculum sports lessons, majority of injuries were sustained on artificial turf (44%) and cement (31%) surfaces. Contact with another player was the cause of 29% of the injuries while contact with equipment caused 23% of the injuries. With regard to medical attention, 68% injuries were classified as mild, 27% as moderate and 5% as severe injuries. In terms of absenteeism, 76% injuries were mild, 23% moderate and 1% was severe injury. **Discussion** Injury prevention programmes are critical for safety in training and safeguarding professional careers of university PE students. This study provides useful information on epidemiology of sports injuries in university PE students. Evidence from the present study can be used to identify the modifiable risk factors to develop and implement injury prevention strategies to minimize the risk of injuries in university PE students. Future studies on elucidation of intrinsic and extrinsic risk factors and implications of intervention programmes in this population are desired. Reference Dick R, Agel J, Marshall SW (2007). Am J Sports Med, 42, 173-182.

## **EPIDEMIOLOGY OF INJURIES IN MIXED MARTIAL ARTS: A SYSTEMATIC REVIEW WITH META-ANALYSIS**

Lystad, R.P., Gregory, K., Wilson, J.

*Macquarie University*

**Introduction** Mixed martial arts (MMA) is an increasingly popular sport that involves unarmed, full contact contest with minimal rules. Graphic images of caged combatants often evoke visceral responses, and medical associations have repeatedly called for an outright ban on MMA tournaments (White, 2007; Ball & Dixon, 2011). Despite safety concerns, no epidemiologic evidence-synthesis is currently available. Thus, the aim of this systematic review was to provide pooled estimates of incidence, severity, injury patterns and risk factors for injury in MMA. **Methods** Studies were identified by electronic searching of PubMed, Scopus, CINAHL, EMBASE, AMED and SPORTDiscus databases. Eligibility and quality were assessed independently by two reviewers, and relevant epidemiologic data were subsequently extracted and compiled. Random-effects models were used to obtain weighted incidence rate (IR), injury proportion (IP), incidence rate ratio (IRR) and odds ratio (OR) estimates with 95% confidence intervals (CI). Heterogeneity was evaluated with Cochran's Q and  $I^2$  statistics. **Results** The searches returned 2,248 citations (1,416 unique), of which only six studies were eligible for inclusion. Pooled estimates suggested the overall IR and concussion IR to be 226.6 [CI 184.5, 278.2] and 21.5 [CI 9.2, 50.1] per 1000 exposures, respectively. No studies reported on injury severity. The most commonly injured anatomical region was the head/neck (61.2%) followed by the upper limb (21.9%). Common types of injury included laceration (29.4%), fracture (12.2%) and concussion (10.2%). Losing fighters had significantly greater risk of injury compared to their winning counterparts (IRR 2.20 [CI 1.56, 3.11]; OR 2.59 [CI 1.96, 3.43]). **Discussion** The IR in MMA is higher than in other popular combat sports, perhaps with the exception of professional boxing (Zazryn et al, 2003). While the IP of head injuries in MMA is smaller than in professional boxing, it is far greater than in other popular combat sports. The dearth of injury severity data in MMA precludes any comparison with other sports. The conclusions about pooled estimates in this review are limited by heterogeneity, which is most likely owing to the low number of included studies and differences in methodology (e.g. operational injury definitions and data collection methods). The scarcity of quality data underscores the urgent need for more epidemiologic research upon which evidence-informed decisions concerning the regulation of MMA can be made. References Ball CG, Dixon E. The consensus statement on mixed martial arts: emotion, not evidence-based. Can J Surg 2011;54:e1-e2. White C. Mixed martial arts and boxing should be banned, says BMA. ## AN ANALYSIS OF HOW TWO DIFFERENT FRONT FOOT POSITIONS INFLUENCE PELVIC ROTATION AND LOWER EXTREMITY MOTION IN THE TENNIS BACKHAND GROUNDSTROKE

Iwamoto, S.1, Fukubayashi, T.2, Hume, P.3

1: Toyo University (Tokyo, Japan), 2: Waseda University (Tokyo, Japan), 3: AUT (Auckland, New Zealand)

**Introduction** When a tennis player steps forward to hit a backhand groundstroke in closed stance, modifying the direction of the front foot relative to the net may reduce the risk of ankle injury and increase performance. This study evaluated the relationship between pelvic rotation and lower extremity movement during the backhand groundstroke when players stepped with toes parallel to the net (Level) or with toes pointed towards the net (Net). **Methods** Eighteen high school competitive tennis players ( $16.8 \pm 0.8$  years, all right-handed) performed tennis court tests comprising of five maximum speed directional runs (Michikami, 2004) to the court intersection line to hit an imaginary ball with forehand or backhand swings. This study analyzed the front stepping foot contact phase (FSFCP) of backhand groundstroke (BHGS). Based on the data collected, researchers classified the participants as either Level or Net. Using data from the FSFCP, positions of the landmarks were manually digitized using a motion analyzer (Frame-DIAS, DKH, Japan) and then three dimensional coordinates were calculated using a direct linear transformation method (Abdel-Aziz and Karara, 1971). **Results** For both groups, forefoot values increased during the early phase of FSFCP, leveled off during the middle phase, and then decreased during the late phase. However, those values for the Level group changed less than the Net group and were always negative. The foot values for both groups were initially positive, and became negative at approximately 25% FSFCP. The max rotational velocity of pelvis and the max acceleration of pelvis rotation for the Net group was in the first half of FSFCP. However, max rotational velocity of pelvis for the Level group was in the second half of FSFCP. **Discussion** Fong et al. (2007) point out that plantar flexion and supination are the injury mechanisms of inversion ankle sprain. This study suggests that the direction of the front stepping foot in BHGS may influence the risk of inversion ankle sprain. According to the results, after approximately 25% FSFCP for both groups, the foot angle is negative which means that the ankle is in planter flexion. As for the movement of the forefoot, the Net group showed a pattern of supination-pronation-supination during FSFCP, and the Level group, while displaying a similar pattern, was only in supination of various degrees during FSFCP. **References** Abdel-Aziz and Karara, (1971). ##### WHITHER SPORT SCIENCE? THE CHALLENGE OF UNDERSTANDING LIVING MOVEMENT

Scott Kelso, J.A.

Florida Atlantic University & The University of Ulster, N.Ireland

Sport Science is an applied field that draws its concepts, methods and tools from other disciplines that do not have the word 'science' in their names such as physics, chemistry, biology and so forth. Consider 'Testing Ronaldo'. The focus is primarily on measurement and different ways to capture various aspects of what makes Ronaldo a great footballer. Interesting though it is, lacking is a broad framework of ideas with which to interpret and integrate findings from the many different levels and scales of observation involved in typical sports settings. At each level of complexity, from the cellular to the social who are the players, what are their properties and what are the rules of the game? How do we go about it? A first step is to identify significant units on a chosen level. Due to the tremendous degeneracy of living things, where the same outcome may be produced by different combinations of elements, evidence suggests that the significant units are context-dependent coordinative structures. In such level-independent coordinative structures different elements are ordered in space and time sometimes recruiting new pathways to serve a particular function. Perturbing them in one place may produce a remote effect somewhere else. All the parts of the coordinative structure are weakly interacting, often bidirectionally coupled and interdependent. Over the last 25 years or so, theory and experiments on a variety of different systems at neural, behavioral and social levels reveal that WICS (Weakly Interacting Coordinative Structures) are truly emergent. They are collective states whose spatiotemporal dynamics prove to be extremely rich, including interesting transient regimes that are neither fully ordered nor disordered in space and time. Collective states and their dynamics can span old 'splits' and dichotomies that science has created: the separation of animal and environment, sensory and motor, perception and action, structure and function, even mind and matter. It may be that sport science, rather than being viewed as an applied interdisciplinary field of study, is at the core of something physics (the science of inanimate matter and motion) has left virtually untouched, namely animate, living movement. Though in some cases, such as the HKB model and its extensions, it has proved possible to derive collective states at one level from (nonlinear) interactions between component processes at another, evidence suggests an alternative or at least complementary picture: namely that the laws of collective states in living things --coordination dynamics-- are sui generis. That is, coordination dynamics deals with collective behaviors that emerge from and depend on more microscopic levels, but may not be deducible from them. This does not mean that sport science or the life sciences in general should not try to understand the relationships between different levels of observation. Rather, the task is to come up with lawful descriptions that allow us to understand collective, emergent behavior at all levels and to respect the autonomy of each.

##### CHOREOGRAPHIC THINKING TOOLS

Delahunta, S.

Coventry University

How might we develop new ways of augmenting movement creativity in dance? Can we better connect intellect, imagination and the physical body and enrich their relationship? The dance field is already rich in choreographic expertise that is constantly seeking new means of movement related innovation. Can a scientific understanding of the organisation of the mind provide clues and ideas that can be put into practice in this field? This presentation will outline some of the challenges that need to be addressed and specific illustrations

of current studio practices and tasks. The illustrations will focus on research on the use of multiple forms of imagery in movement creation being explored in R-Research (the research arm of Wayne McGregor | Random Dance).

#### A COMPARISON OF TECHNIQUES TO INDICATE ACUTE HYDRATION STATUS AND THE EFFECT OF SAMPLE STORAGE ON MEASUREMENTS

Carter, J.M., Rollo, I., Randell, R.K., Jeukendrup, A.E.

*Gatorade Sports Science Institute*

**Introduction** The importance of adequate hydration for physical and cognitive performance is well known (Sawka et al., 2007). There is a need for assessing hydration status non-invasively, but many techniques using urine analysis, although in widespread use, are not always supported by appropriate validation studies (Carter et al., 2012). Therefore, the present study compared two non-validated methods (Osmocheck, Vitech Scientific Ltd, UK; Urine Reagent Strips, IND Diagnostic Inc, Canada) with a criterion measure and other commonly used techniques. In addition, the stability of urine samples at different storage temperatures was determined. **Methods** Three sequential daily midmorning urine and saliva samples were provided by 13 male athletes (age:  $25 \pm 4$  yr) and analysed for: urine specific gravity (Usg); urine colour (Ucol); urine reagent strip (Urs); saliva osmolality (Sosmo); urine osmolality determined by a handheld refractometer (Uochek). All were compared using regression analysis against the criterion measure of urine osmolality determined by freezing point depression osmometry (Uosmo – Advanced Osmometer 2020; Advanced Instruments, USA). Urine samples were subsequently stored at a range of temperatures (20 °C; 3 °C; -20 °C; -80 °C) for 10 days before being re-analysed and compared to baseline values using a repeated measures ANOVA. **Results** All measures, apart from Sosmo ( $p=0.10$ ), correlated well with Uosmo ( $p<0.0001$ ): Uochek  $R^2=0.94$ ; Usg  $R^2=0.94$ ; Ucol  $R^2=0.75$ ; Urs  $R^2=0.46$ ; Sosmo;  $R^2=0.07$ . The proportion of samples correctly identified as mildly-to-significantly dehydrated ( $>700$  mOsmol/kg;  $\geq 1.020$  Usg; Sawka et al., 2007) was as follows: 100% (Uochek); 96% (Usg); 93% (Ucol); 82% (Urs); 68% (Sosmo). Samples remained stable regardless of storage conditions, with no significant difference from baseline values ( $p>0.05$ ). **Discussion** Urine analysis is a common method to assess body water status in young adult male athletes. The results of the present study confirm that the Osmocheck handheld refractometer and Atago Master-Sur refractometer (Japan) are both strongly associated with urine osmolality, as measured by freezing point depression osmometry. Urine colour remains an adequate and easy-to-use field technique, while urine reagent strips may be used as a marker of hydration when more sensitive methods are unavailable. Finally, if immediate analysis is not possible, urine samples remain stable for at least 10 days at a range of ambient temperatures. **References** Carter, JM, Loney, T, Blacker, SD, Nicholson, GF, Wilkinson, DM. #### EFFECTS OF PREVIOUS INGESTION OF COCONUT WATER ON FLUID BALANCE AND PHYSICAL PERFORMANCE IN THE HEAT

Laitano, O., Menezes, E.S., Marins, D.M., Reis, G.S.

*Federal University of Vale do Sao Francisco, Petrolina*

**Introduction:** It is well established in the literature that exercise in the heat impairs physical performance largely due to dehydration. Therefore, drinking strategies that may counteract this impairment on performance are warranted. Coconut water (CW) is a natural drink found in the coconut and due to its composition may improve performance. However, CW is usually hypertonic which may cause gastrointestinal distress if consumed during exercise. Thus, the aim of the present study was to assess the effects of previous ingestion of CW on fluid balance and aerobic performance in the heat. **Methods:** To achieve this, eight physically active men were recruited (age  $23 \pm 3$  years, height  $176 \pm 6$  cm, body mass  $78 \pm 7$  kg) and performed three time to exhaustion trials on a cycle ergometer in the heat ( $34 \pm 1^\circ\text{C}$ ) ingesting either of the three drinks in a randomized fashion: a) plain water (PW), b) flavored drink (FD), and c) CW. **Results:** There was a greater time to exhaustion in the CW session (PW = 1121 s; FD = 1141 s; CW = 1366 s;  $p=0.029$ ). Likewise, participants had a higher maximal heart rate in the CW session when compared to the other trials (PW =  $183 \pm 5$  bpm, FD =  $184 \pm 8$  bpm, and CW =  $189 \pm 8$  bpm;  $p<0.05$ ) followed by a reduced urine output after the CW ingestion (PW  $214 \pm 85$  ml, FD  $267 \pm 90$  ml, and CW  $161 \pm 73$  ml,  $p<0.05$ ). **Discussion:** The greater time to exhaustion observed with the CW ingestion might be related to the greater hydration capacity, as observed by the reduced urine output. Also, this might have an impact in the cardiovascular limit achieved during the CW trial as shown by the greater maximal HR when compared to plain water and favored drink. **Conclusion:** In conclusion, the results demonstrated that previous ingestion of coconut water improved physical performance in the heat and provided a higher hydration capacity in comparison to plain water and flavored drink.

#### INTAKE OF MACRONUTRIENTS AND FLUIDS DURING AN ULTRA-ENDURANCE BICYCLE RACE: AN OBSERVATIONAL FIELD STUDY

Konrad, M., Karner-Rezek, K., Wallner, D., Simi, H., Knechtle, B.

*FH JOANNEUM*

**Introduction** Ultra-endurance bicycle events are becoming increasingly popular but offer various physiological challenges. The competitors can expect to face extreme nutrient demands and a variety of practical challenges to achieve their fluid and fuel replacement goals. In particular the ingestion of the right amounts and the recommended mix of multiple transportable carbohydrates (CHO) during ultra-endurance bicycle events leads to higher oxidation rates of exogenous CHOs and thus to a higher rate of total CHO-oxidation. The performance in ultra-endurance events is associated with the ingestion of the right mix of CHOs during the race in a dose-dependent manner (1). The aim of this study was to compare the subject's carbohydrate intake during an ultra- endurance race with the recommenda-

tions (2). Methods An observational field study was conducted during the 1188 km Race around Slovenia. The nutritional intake was recorded by using a standardized food-log. All of the foods and fluids consumed were weighted and recorded. Each of the 6 athletes had to provide his own race provisions and to rely on a support crew to meet the planned nutritional intake. Anthropometric data are based on self-reports of the subjects. All the food-logs were calculated with DGE-PC software. Results The energy and fluid intake of six male finishers (age  $36,5 \pm 9,1$  years; weight  $76,8 \pm 8,8$  kg; height  $181 \pm 7,0$  cm; BMI  $23,3 \pm 1,4$  kg/m<sup>2</sup>;  $21,6 \pm 8,0$  average training hours per week; weekly training distance of  $595,8 \pm 296,0$  km; with  $6,6 \pm 3,4$  years of experience in ultra-cycling and no nutrition-related diseases) was  $72,52 \pm 12,71$  MJ and  $29,78 \pm 7,65$  l of fluids in total, respectively. Of the total caloric intake,  $72,0 \pm 11,9$  % derived from carbohydrates,  $15,4 \pm 11,2$ % from fat,  $13,8 \pm 2,9$ % from protein. The average energy intake in solid form was  $14,3 \pm 13,2$ %, the energy intake in form of liquids  $85,7 \pm 13,2$ %. Per hour the subjects consumed  $1,52 \pm 0,27$  MJ and drank  $0,62 \pm 0,12$  l of fluids. The CHO intake per hour was  $68,4 \pm 15,5$ g. Discussion The recommendations of 90 g of CHO per hour (2) in endurance events lasting 2,5 h or more could not be reached by any competitor, thus a CHO intake plan is crucial even for experienced cyclists. The guidelines for fluid intake are highly individual (3) and not evaluated. Therefore, the nutrition plan has to be carefully designed and to contain a fair amount of liquids over time. To the competitors it was important to alternate between sweet forms and savory choices of carbohydrates. ### POST-EXERCISE REHYDRATION: EFFECT OF BEER CONSUMPTION ON FLUID BALANCE

Wijnen, A., Steennis, J., Catoire, M., Wardenaar, F., Mensink, M.

*Wageningen University*

Introduction Among amateur team-based sports, it is common to drink moderate to large amounts of alcoholic beverages, mainly beer, after training or competition. Alcohol is known to increase urine output, which could interfere with adequate rehydration after exercise. Only a few studies addressed the effect of alcohol on rehydration after exercise (Shirreffs; Hobson). Results suggested that the diuretic effect of alcohol is blurred when the body is dehydrated. Beer contains - besides alcohol - water, carbohydrates and a small amount of electrolytes. The final consequences of beer consumption for rehydration and fluid balance are not completely clear. Therefore, we assessed the effect of beer consumption, with a range of alcohol content, on fluid balance after exercise-induced mild dehydration. The rehydration capacity of the beers was compared with isotonic sports drink and water. Methods Ten healthy males were included in this cross-over intervention study (age  $24.7 \pm 5$  yrs, body weight  $75.9 \pm 3.1$  kg,  $VO_{2max}$   $57.7 \pm 6.4$  ml/kg/min). Each subject underwent five experimental conditions: non-alcoholic beer, 2% alc beer, 5% alc beer, an isotonic sports drink and water. They exercised until mild dehydration, i.e. 1% body mass reduction ( $\sim 750$  mL). Thereafter, in random order, one of the experimental beverages was consumed, in an amount equal to 100% of their sweat loss. Up till 5 hours after the last consumption urine was collected at regular intervals. Urine output was measured, and fluid balance was calculated. Results Beverage consumption clearly affected urine output. After 1 hour, urine production was significantly higher for 5% beer compared to the isotonic sports drink ( $308 \pm 148$  mL vs  $101 \pm 70$  mL;  $p < 0.01$ ). At the end of the 5-hour observation period fluid balance was negative for all conditions, with the poorest balance for 5% beer ( $-606 \pm 178$  mL,  $\sim 19\%$  rehydration) and the best balance for the isotonic sports drink ( $-452 \pm 252$  mL,  $\sim 40\%$  rehydration). Non-alcoholic beer, 2% beer and water respectively resulted in a fluid balance of  $-495 \pm 229$  mL (31%),  $-534 \pm 289$  mL (32%) and  $-499 \pm 193$  mL (33%). Conclusion Beer with an alcohol content of 5% had a negative impact on fluid balance and rehydration after exercise. While low alcoholic beer (2%) and non-alcoholic beer led to a comparable fluid balance as plain water, indicating that the diuretic effect of a low dose of alcohol is limited. Drinking an isotonic sports drink, however, appeared to be the best option for rehydration. References Shirreffs, S.M. and R.J. Maughan, *J Appl Physiol.*, 1997. 83(4): p. 1152-1158. ### EFFECT OF GREEN TEA EXTRACTS SUPPLEMENTATION ON FATTY ACID OXIDATION AND MOLECULAR MECHANISM INVOLVED IN GLYCOGEN SYNTHESIS IN EXERCISED HUMAN SKELETAL MUSCLE

Cheng, I.S., Chen, H.W., Lai, H.P., Liu, H.C.

*National Taichung University of Education*

Introduction In Taiwan, green tea has been habitually consumed as one of the most popular beverages. Green tea contains GTEs of polyphenolic flavonoids known as tea catechins (TC), which comprise epigallocatechin gallate (EGCG), epicatechin gallate, and gallic acid. In human and animal studies, green tea extract (GTE) has been shown to increase the proportion of whole body fat utilization by activating PPAR $\gamma$  and increases CPT1 expression (Dulloo et al., 1999; Venables, Hulston, Cox, & Jeukendrup, 2008). Little study is regarding to whether GTE administration is expected to cause metabolic consequence in turn to result in improvement of glycogen synthesis in exercised human skeletal muscle. The purpose of this study was to demonstrate the effect of green tea extracts supplementation on fatty acid oxidation and molecular mechanism involved in glycogen synthesis in exercised human skeletal muscle. Methods Eight male athletes (aged  $22 \pm 0.6$  years) will be participated in this crossover designed study, and served as placebo and GTE trials (130 mg GTE/day for 8-week). Then, subjects will be crossed-over again with separation of 8 weeks. On the day of the experiment, a single bout of 60-min cycling exercise at 75 % ( $VO_{2max}$ ) will be performed and subjects consume a carbohydrate meal (2 g carbohydrate/kg body weight, 80 % carbohydrate, 8 % fat, 12 % protein) immediately after exercise. Biopsied muscle samples will be obtained from vastus lateralis immediately and 3 h after exercise. Simultaneously, blood sampling and gas analysis will be performed before and after exercise. Results The significant glycogen synthesis were shown in GTE trial compared to placebo trial in exercised human skeletal muscle ( $p < .05$ ). Yet, all parameters which included blood glucose, NEFA, glycerol and serum insulin or RER, carbohydrate oxidation rate and fat oxidation rate were no significantly different between GTE and placebo trials. Discussions The results of this study concomitant with the evidences in animal study that GTE enhance the glycogen synthesis after exercise (Murase, Haramizu, Shimotoyodome, Tokimitsu, & Hase, 2006). Therefore, the molecular mechanisms underlying on muscle glycogen synthesis with GTE supplementation will be examined in next four months. The study showed that GTE significantly influenced metabolic consequence, which in turn affects the glycogen re-synthesis in exercised human skeletal muscle. We suggested that GTE could be as ergogenic aid to athletes who are training for competitions. References Dulloo, A. G., Duret, C., Rohrer, D., Girardier, L., Mensi, N., Fathi, M., . . . **EFFECT OF DEHYDRATION ON BASKETBALL SKILL PERFORMANCE IN FEMALE PLAYERS**

Brandenburg, J.

*University of the Fraser Valley*

Introduction Basketball is characterized by repeated bouts of high-intensity effort and requires the execution of complex sport-specific motor skills. Thus, players are at risk for developing dehydration and experiencing dehydration-related decrements in skill performance. In experienced male players, dehydration reduced basketball skill performance (Baker et al.). Whether skilled female players are similarly affected by dehydration is unknown. Thus, the purpose was to examine the effect of dehydration, induced by simulated game play, on shooting accuracy, agility, and perception of effort (RPE) in female basketball players. Methods Participants were 10 female basketball players (174.4 ± 7 cm; 21 ± 1 y; 78.3 ± 13 kg) from a nationally ranked university team. Participants completed a 40-min simulated game on 2 different days. During one game, players ingested water at a rate to match fluid losses (EUH) where as no fluid intake was permitted during the other game (DEH), with the order randomized. Prior to each game, urine samples were collected to ensure players started adequately hydrated. To determine the degree of dehydration (% loss in body mass), body mass was assessed before and immediately after each game. Body mass was also monitored regularly during EUH to ensure fluid ingestion matched fluid losses. Throughout both games RPE were monitored. Shooting performance (2- and 3-point jump shots) and agility (using the T-test) were assessed following each game. Paired sample t-tests were performed to examine if differences between EUH and DEH were significant and effect sizes (ES, Cohen's d) were calculated to determine the magnitude of the differences. Results Pregame urine specific gravity for EUH equaled 1.009 ± 0.007 and was 1.008 ± 0.007 for DEH. The degree of dehydration was significantly greater in DEH (1.3 ± 0.3%) than in EUH (0 ± 0%). Players made 68.8 ± 9% and 63.8 ± 12% of 2pt shots in EUH and DEH, respectively (p=0.07, ES = 0.46). In EUH, players made 49.2 ± 13% of 3pt shots while 47 ± 14% were made in DEH (p=0.45, ES = 0.16). There were no differences in the time to complete the T-test (EUH= 10.3 ± 0.5 s; DEH= 10.2 ± 0.6 s). RPE was significantly higher during DEH (15.2 ± 1.2) than in EUH (14.6 ± 1.3) (p=0.02, ES = 0.5). Discussion The modest degree of dehydration experienced by female players during simulated game conditions did not affect 3pt shooting accuracy as well as agility. Regarding 2pt shooting performance, the moderate effect size and a EUH vs. DEH difference (5%) that approached significance suggest 2pt shooting accuracy experiences a meaningful decrement as a result of dehydration. Dehydration also increased the perception of effort, and practically, these greater feelings of fatigue may translate into a drop in playing intensity. Baker et al. 2007. *Med Sci Sports Exerc*, 39, 1114-23.

**BEER AS A SPORTS DRINK? MANIPULATING BEER'S INGREDIENTS TO REPLACE LOST FLUID.**

Desbrow, B., Murray, D., Leveritt, M.

*Griffith University*

Purpose: To investigate the effect of manipulating the alcohol and sodium content of beer on fluid restoration following exercise. Method: Seven male volunteers exercised on a cycle ergometer until 1.96±0.25% body mass (mean±SD) was lost. Participants were then randomly allocated a different beer to consume on four separate occasions. Drinks included a low alcohol beer (2.3% ABV) [LightBeer], a low alcohol beer with 25 mmol.L<sup>-1</sup> of added sodium [LightBeer+25], a full strength beer (4.8% ABV) [Beer] or a full strength beer with 25 mmol.L<sup>-1</sup> of added sodium [Beer+25]. Volumes consumed were equivalent to 150% of body mass loss during exercise and were consumed over a 1h period. Body mass and urine samples were obtained before and hourly for 4h after beverage consumption. Results: Significantly enhanced net fluid balance was achieved following the LightBeer+25 trial (-1.02±0.35 kg) compared to the Beer (-1.59±0.32 kg) and Beer+25 (-1.64±0.28 kg) treatments. Accumulated urine output was significantly lower in the LightBeer+25 trial (1477±485 mL) compared to the Beer+25 (2101±482 mL) and Beer (2175±372 mL) trials. Conclusion: A low alcohol beer with added sodium offers a potential compromise between a beverage with high social acceptance and one which avoids the exacerbated fluid losses observed when consuming full strength beer.

**EFFECT OF ARG1+ AND MULTI MACA FOOD SUPPLEMENTS ON SPORTSMEN'S PHYSICAL AND FUNCTIONAL CAPACITY**

Milasius, K., Dadeliene, R.

*Lithuanian Educational Science University*

Introduction Preparing athletes it is important to have scientifically based recommendation about consumption possibilities of concrete nutrition and food supplement. Therefore the aim of the present study is to determine the effect of food supplement ARG1+ and ARG1+ in combination with Multi Maca on physical and functional capacity of athletes to work in various energy production zones. Methods Thirty-six physically active men were randomly divided into three groups. First group (E1) subjects took the supplement ARG1+ 10g/day for 20 days. Second group (E 2) subjects took the supplement ARG1+ 10g/day and Multi Maca 2 tablets/day for 20 days. Third group (C) subjects consumed lactose as a placebo. Subjects performed two testing sessions. We tested single muscle capacity power, anaerobic alactic muscle power and aerobic capacity. Heart rate was assessed at rest, after standard physical load and after 60s recovery period. Results Supplementation of ARG1+ in combination with Multi Maca more effectively influenced cardiovascular system capacity and aerobic capacity than supplementation ARG1+. Use of ARG1+ and ARG1+ in combination with Multi Maca has not significant influences on athletes' single muscle capacity power, anaerobic alactic muscle power, absolute and relative maximal moment muscle capacity. These data of the group E1 subjects increased more than group E2 subjects. However, in comparison of groups E1 subjects and E2 group subjects with group C subjects after supplements consumption these data had significant differences. Discussion We have found that food supplement ARG1+ has more appreciable influence on increasing single muscle capacity power and anaerobic alactic muscle power than ARG1+ in combination with Multi Maca. As reported by Álvares et al., 2011, dietary supplements, containing L-arginine, helps to increase muscle strength, their recovery after anaerobic and aerobic exercise. The results of our study show the influence of dietary supplements ARG1+ and ARG1+ in combination with Multi Maca to aerobic capacity of young sportsmen. These results generally comply with the results of previous studies (Bailey et al., 2010). Our and Fahs et al. (2009) studies did not show any significant increases in cardiovascular system functional capacity. References Álvares T, Meirelles C, Bhambhani Y, Paschoalin V, Gomes P. (2011). L-Arginine as a potential ergogenic aid in healthy subjects. *Sports Med*, 41(3), 233-248. Bailey S, Winyard P, Vanhatalo A, Blackwell J, DiMenna F, Wilkerson D, Jones A. (2010). ### FLUID INTAKE HABITS AMONG BRAZILIAN HIGH-SCHOOL WRESTLERS

Capitani, C.D.1, Viveiros, L.2, Moreira, A.3, Zourdos, M.C.4, Vidal, J.A.A.1, Aoki, M.S.3

1-University of Campinas, Limeira, Brazil; 2-Brazilian Olympic Committee, Rio de Janeiro, Brazil; 3-University of Sao Paulo, Sao Paulo, Brazil; 4-Florida Atlantic University, Boca Raton, USA

**Introduction** Traditionally, competitive wrestlers have applied various methods to lose weight quickly to fit a particular weight class. These methods include different exercise modes, accompanying by fasting and dehydration practices. It is reasonable to postulate that dehydration practice resulting in rapid short-term weight loss may cause deleterious effects on performance, however, there is little information regarding the fluid intake by young wrestlers during training and prior to competition. Therefore, the aim of this study was to describe the hydration and fluid intake practices among Brazilian high-school wrestlers. **Methods** Thirty-one high-school wrestlers, female (n=16; 13±2 yrs) and male (n=15; 13±2 yrs) agreed to participate in the study. Immediately following the official weigh-in, which was conducted 24h prior to the competition, subjects answered a hydration and fluid intake habits questionnaire. The standardized questionnaire was composed by 8 multiple-choice questions. Subjects completed the questionnaire in less than 10 minutes in a private room where only the investigator was present. **Results** Of the 31 respondents 81% reported that they had previously received educational information regarding proper hydration habits, while 82% agreed that hydration habits are important to health and performance. The most popular liquids for hydration were water, soft drinks and sports drinks, which were ingested by 96%, 25%, and 22% of respondents, respectively. Additionally, most of the athletes attested that they are concerned about fluid intake during training (51%) and competition (62%). Finally, regarding the time of ingestion, 45% of subjects reported ingestion of liquid before they get thirsty, while 41% reported waiting until after thirst sets in to drink. **Discussion** The majority of athletes seem to recognize the importance of proper fluid intake during training and competitions to optimize performance, and also acknowledge receiving educational information regarding proper hydration habits. Despite these factors, a significant amount of respondents still demonstrated poor choices of liquid ingestion (i.e. soft drinks) and inappropriate timing of fluid intake (i.e. after thirst occurs). Ultimately, coaches and parents should engage in educational programs in order to promote improved fluid intake habits to benefit health and performance in young wrestlers.

### 'EFFECTS BETWEEN A DRINK MILK AND ISOTONIC IN REHYDRATION AFTER EXERCISE'

Astudillo, S., Castro, M., Jorquera, C.

*Universidad Mayor*

**Introduction** One of the principal variable ones in the sports performance is the dehydration. Opposite to this decrease of electrolytes, we can meet a hyponatremia faced, and not only to affect the performance of the sportsman, but also to affect the health of this one. In conditions of rest an individual loses about 95,9 ml/h and in conditions of long exercise it can manage to lose 1.321 ml/h. The study that we have carried out tries to confirm the rehydrating capacity of two drinks, a drink isotónica, opposite to a lacteal drink descremada, to understand and to take up office which is the most suitable drink later to a session of exercise. **Methods** The sample corresponded to 14 males, with an average of age of 23 years, with an average stature of 1,74 cms. one to which lacteal descremada was managing the affairs for the tipsy rehydration flavor chocolate and to another group drink was supplied him isotónica. There has been applied the capture of sample of simple urine to be analyzed by means of the MINI ISE, automatic analyzer of electrolytes, the analyzed electrolytes were sodium and potassium. Also the gravity was evaluated it specifies in urine. **Results** The comparison between the sodium in urine, later to the exercise and the sodium in urine later to the rehydration with lacteal drink descremada, finding very significant differences  $p < 0,007$  evaluating to  $p < 0,05$ . The comparison between the potassium in urine, later to the exercise and the potassium in urine later to the rehydration with drink isotónica, not being significant differences  $p < 0,64$  evaluating to  $p < 0,05$ . The subjects that they re-hydrated with drink isotónica retained 25 % of the quantity of ingested drink and the subjects that descremada re-hydrated with lacteal drink retained 71 % of the ingested drink. **Discussion** The recommendations for a drink re-hydrate, are orientated to the quantity of electrolytes and carbohydrates and not always the value has relation with the quality. When proteins join him to these solutions the retention of liquid can improve for better the assimilation of the electrolytes, for end milk them it transforms in an excellent option as sports drink. ### BODY COMPOSITION CHANGES AND EATING BEHAVIOR IN RECREATIONAL MALE IRONMAN TRIATHLETES

Ghiani, G., Lantini, T., Marongiu, E., Tocco, F., Degortes, N., Concu, A.

*University of Cagliari*

**Introduction** Ironman triathletes appear to profit from low body fat (Knechtle et Al. 2011). The aim of this study was to investigate eating habits and body composition in a group of recreational male Ironman, who were in the preparing season for an imminent competition. They trained for about 20 hours/week. **Methods** Five recreational male Ironman triathletes participated in the study. Each of them completed a food frequency questionnaire (FFQ) to assess their usual diet (Fidanza et Al.,1995) and attended a small interview, so that their daily physical activity level (PAL) was determined. PAL was obtained by dividing Total Energy Expenditure by Base Metabolic Rate (Black et al. 1995). For each subject Fat Mass percentage (FM%) was detected twice by mean of plicometry: eight and one weeks before the competition (Durnin and Womersley, 1974). Dietary recommendations were given to each of them in order to correct their diet as to perfectly fit their needs in term of calories and nutrients. **Results** Processing of the FFQ emphasized that energy requirements were not fulfilled. In detail, their PAL was about 2, but there was more than 1000 Kcal difference between average intake and average needs, mostly from calories derived from complex carbohydrates, so that their diet was adjusted to fit their needs. In the second detection, made one week before the race, each participant modified his body composition reducing his FM%. **Discussion** Results of the present investigation show that the dietary status of our sample of triathletes lacked both in term of food quantity and quality. Taking into account that Ironman competition highly recruit the energetic sources of athletes, it is possible to speculate that they may take advantage from a correction of their eating habit by a proper dietary counseling. **References** Knechtle B, Knechtle P, Rüst CA, Rosemann T (2011) *J Sports Sci*, 29(13):1373-80. ## FOOD DISORDERS IN ATHLETES OVER 10 YEARS OLD OF ANTIOQUIA SKATING AND GYMNASTIC LEAGUES, COLOMBIA

Quiroz, O.

*INDEPORTES ANTIOQUIA*

Introduction Athletes, who require low weight and fat percentage, have been recognized as a population with an increased risk of Eating Behavior Disorders (EBD). This is more difficult in women growth and development stages, with psychophysical changes that make them vulnerable to present EBD or inadequate response to desired body image, having impact on their health. Studies in Antioquia, in Medellin adolescent women, 2003, showed a prevalence of 17.7% and 33.3% EBD at risk of suffering. The study was conducted in the Department of Nutrition for Sports Medicine Indeportes Antioquia, Colombia, through the application of EAT-26 questionnaire. Methods: 37 athletes were surveyed, all of them over 10 year's old, practicing figure skating, rhythmic gymnastics and artistic women in the city of Medellin. We searched literature on the subject. The pilot study was developed and carried out test EAT 26. Analysis of the results was socialized with staff of Department's Leagues. Statistical analysis was made with Epi-Info 6.04. Results: The EAT-26 average was 18 • 8 points. 13 athletes (35%) had a score greater than or equal to 20, which implies risk of a EBD. The average age of 16.2 • 3.3 years in athletes at risk of EBD was higher than those who didn't have, that was 13.7 • 3.0 years. BMI was higher for athletes at risk: 20.7 • 2.6 units, compared with athletes who didn't have EBD risk: 18 • 8.2 units. There was a prevalence 35% of risk within 37 athletes tested. Ten of the 13 people with risk of EBD were women. No significant differences that relate to the type of sport practiced with the risk of EBD. Conclusion Obtained data with EAT 26 test are a contribution to the characterization of the population at risk of EBD related to nutrition. ## WEIGHT LOSS PRACTICES OF GERMAN ATHLETES IN OLYMPIC WEIGHT CLASS SPORTS

Braun, H.1,2, Werkner, J.2, Koehler, K.1,2, Mester, J.2, Thevis, M.1, Schaenzer, W.1

*German Sport University Cologne*

Introduction Rapid weight loss is a common method in weight class sport. To limit negative consequences on health and performance athletes are advised not to exceed bodyweight >3% of competition weight. Furthermore, young athletes are discouraged to use rapid weight loss methods (Sundgot-Borgen et al. 2011). To our knowledge data on weight loss practices of German athletes don't exist. Therefore, the aim of this study was to examine weight loss practices of German athletes in Olympic weight category sports. Methods & Subjects A closed-ended questionnaire was developed based on the questionnaire used by Oppliger et al. (2003). In June 2012 the questionnaire was sent per Email as an online version to athletes and coaches. Finally, 106 athletes answered the questionnaire (Judo n=33, Boxing n=27, Wrestling n=34, Taekwondo n=12). Subjects were grouped into adult (A: ≥18 yrs, n=58) and young (Y: <18 yrs, n=48) athletes. Results Asking the athletes at which age they started to apply weight loss methods, we found the young athletes started significant earlier (age: 12.9 ±4.6 yrs; p<0.001) compared to the adults (15.1±5.3 yrs). Regarding the past season 90% of young athletes (A: 93%) reported to make weight, whereas 52% (A: 74%) stated a weight loss >3% with respect to their competition weight. The frequency of weight loss in young athletes was found to be 4.7±4.0 times (A: 6.3±4.7; p=0.07) in the past season. The weight loss methods young athletes were using at minimum 3-4 times per week were: increased training 33% (A: 47%), dieting 25% (A: 55%), sweat suits 19% (A: 41%) and fluid restriction 15% (A: 17%). Young athletes named coaches (50%), parents (23%), team staff (17%), teammates (17%) (A: 41% coaches, 21% team staff, 21% teammates), whom influences them largely regarding weight loss methods. Discussion In contrast to recent recommendation on rapid weight loss, we found a large number of young athletes using questionable weight loss methods regularly. Furthermore, half of the young athletes reported to cut weight >3% of bodyweight. The young athlete in this day seems to start earlier using rapid weight loss methods than in the past. Therefore, it is important to elucidate coaches and parents about the risks of weight loss methods and include sports dietitians in a long term weight loss strategy. However, to approve the data and to identify possible sports specific differences a study with a larger number of participants should be done in the future. #### EFFECT OF AEROBIC EXERCISE IN SKELETAL MUSCLE REVASCULARIZATION AND FIBER TYPE CHANGES.

Moretto, D.1, André, A.1,3, Lopes, A.4, Paiva, A.4, Pinto-Pereira, S.1, Fontes-Ribeiro, C.A.1,2, Tavares, P.1,2

*1-Faculty of Sport Sciences and Physical Education, 2-Faculty of Medicine -IBILI, University of Coimbra. 3-Coimbra College of Health Technology. 4-Portuguese Institute for Blood and Transplantation.*

Introduction It has been demonstrated that aerobic exercise may change skeletal muscle fiber type. However, the mechanisms underlying this change are still controversial. Nevertheless, an association between an increase in muscle capillaries and circulating endothelial progenitor cells (EPCs) has been reported, being nitric oxide and VEGF probably implicated on the above mechanisms. This work aimed to study after aerobic exercise the relationship of changes of skeletal muscle fiber type with increased number of capillaries, taking into account nitric oxide synthases (NOS) and VEGF levels. The exercise influence over EPCs as well as their relationship with NOS and VEGF were also studied. Methods An animal model was used. All the animals' experiments and treatments were in agreement with the na-

tional and international guidelines regarding the experimental use of animals. Eighteen male Wistar rats (with about 250 g) performed an aerobic training for 8 weeks in a treadmill; a control group without training was also used. At the end of this period the training efficiency was assessed. Blood was collected from the jugular vein, being all the animals sacrificed by anesthetic overdose after this. The soleus muscle was removed and stored for further analyses. To evaluate the soleus muscle fiber type a myosin-ATPase staining was performed. EPCs were determined on whole blood samples by flow cytometry using anti-CD45, -CD34, -CD133 and -CD146 antibodies. The expression of the NOS isoforms was assessed by western-blotting using the antibodies against iNOS and cNOS (Santa Cruz). The serum VEGF concentration was quantified by an ELISA commercial kit (R & D systems). Results The results showed that the aerobic training increased the number of type I fibers and decreased the type II fibers number. In the soleus muscle these changes were associated with increased iNOS and principally cNOS. By using the biomarkers for EPCs in an undifferentiated state (anti-CD34+ and anti-CD133+) no differences were observed (related to control). However, the percentage of cells with biomarkers for the endothelial phenotype (anti-CD146+, anti-FLK1+) decreased in the trained group. In addition, in comparison with controls an increase in the capillaries/fiber type ratio was observed, as well as an increase in the serum VEGF concentration. Discussion These results suggest that aerobic exercise promotes the exchange of fibers type II to type I in rat soleus muscle. This fiber exchange was associated to an increase in muscle revascularization. Thus, the decrease in blood differentiated EPCs may indicate an increase of EPCs mobilization into skeletal muscle. This seems to be supported by the increase in muscle blood flow and C:F ratio, which could be regulated by nitric oxide and VEGF. Support: FCT, Strategic Project (Ref: PEst-C/SAU/UI3282/2011), and COMPETE.

### PERCEIVED EXERTION DURING DIFFERENT SET CONFIGURATIONS IN BENCH PRESS AND ITS RELATIONSHIP WITH BLOOD PRESSURE AND POWER OUTPUT

Mayo, X., Iglesias-Soler, E., Carballeira, E., Sánchez-Otero, T., Castro-Gacio, X.

*UDC (A Coruña, Spain)*

Introduction Interest in the use of ratings of perceived exertion to regulate resistance exercise has increased in recent years. OMNI-RES is a newly scale developed specifically to resistance exercise, and different studies have demonstrated that OMNI-RES is able to distinguish among protocols with different volumes and intensities (Lagally & Robertson, 2006). However, differences in the set design were not largely studied. The aim of the present study was to evaluate the differences between three different protocols with the same total volume and intensity, but with different set configuration. Methods 9 healthy subjects (24.0±1.5 y; 173±7 cm; 67.6±9.2 kg) performed 5 sets to failure with the load of 10RM and with 180 seconds between sets (failure session, FS). On separate days in a counterbalanced order, subjects performed the same volume but with the repetitions clustered in groups of 5 (i.e. 5[10]; Sánchez-Medina et al., 2011) (5S) or with rests between each repetition (1S). The total rest of the FS, 720 seconds, was distributed between each group of 5 repetitions or each repetition. OMNI-RES with memory anchoring procedures for the active muscles was obtained at the end of each set or coincident repetition. Systolic blood pressure (SBP) was measured at the same time than OMNI-RES and Power output (PO) was recorded for each repetition. Results Friedman's test with Friedman post-hoc analysis was realized to compare OMNI-RES. Mean OMNI-RES was higher in FS in comparison with 5S and 1S (8.44±1.19; 6.66±0.84; 6.22±1.23, respectively;  $p < 0.01$ ). In the OMNI-RES coincident after the first set of FS, FS was higher than 1S ( $p < 0.05$ ). At the end of all sets, higher values for FS were also observed in comparison with 5S and 1S ( $p < 0.01$ ). Mean BP and PO were analysed using repeated measures ANOVA followed by post-hoc Bonferroni tests. Higher values in FS was observed for BP among protocols ( $p < 0.05$ ) but post-hoc analysis only showed a tendency between FS and 5S ( $p = 0.077$ ) and between FS and 1S ( $p = 0.093$ ). PO in FS was lower than both 5S and 1S ( $p < 0.01$ ). A positive correlation was observed between Mean OMNI-RES and Mean BP for FS (Spearman's  $\rho = 0.69$ ,  $p < 0.05$ ) whereas a negative correlation was found for 1S (Spearman's  $\rho = -0.88$ ,  $p < 0.01$ ). Discussion FS elicited a greater perceived exertion response than 5S and 1S while PO was lower in FS than in 5S and 1S. These results indicate that OMNI-RES could be used to monitor sessions with different set configuration. In addition, correlations between OMNI-RES and BP suggest that perceived exertion could be used to control BP responses in weight exercise. Surprisingly, different type of correlations were found in relationship with the set configuration. Further studies must be carried out to define the relationship between these two variables. Lagally KM & Robertson RJ (2006) *J Strength Cond Res*, 20(2), 252-6. Sánchez-Medina L & González-Badillo JJ (2011). *Med Sci Sports Exerc*, 43(9), 1725-34.

### SEX AND AGE DIFFERENCES ON LIPID PROFILE CHANGES AFTER INTERVENTION OF WEIGHT LOSS: THE PRONAF STUDY.

Romero Moraleda, B., Peinado, A.B., Morencos, E., Gutierrez, J., Benito, P.J., Calderón, F.J.

*Faculty Physical Activity Science and sport. Universidad Politécnica de Madrid*

Introduction Cardiovascular disease (CVD) is markedly more common in men than in women [1, 2]. In both sexes, CVD risk increases with age, but the increase is sharper in women [3]. Clinical trials have already shown the relevant role of healthy habits as balance diet, no smoke and regular physical activity to protect and decrease CVD risk [4, 5]. However, there are few studies that compare men and women response of the lipid profile to a weight loss intervention. Objective The aim of this study was to compare men and women response of the lipid profile to a weight loss intervention. The secondary aim was to determine if aging influences also on the effect of weight loss on the lipid profile. Methods One hundred and eighty (96 women and 84 men) overweight and obese participants aged 18–50 years participated in a weight loss intervention program based on diet and exercise (PRONAF Study). The intervention period was 22 weeks (3 times/wk of training for 22 weeks and 2 weeks for pre and post evaluation). All subjects followed a hypocaloric diet (25-30% less energy intake than the daily energy expenditure estimated by accelerometry). Multivariate analysis of variance (MANOVA) was used to compare for sex and age and differences in baseline and post-training values. Bonferroni's post-hoc test was employed to locate specific differences. To analyze the gender and age specific interaction the sample was classified by sex and age into responders or no-responders group. Results: There were significant differences between men and women to HDL levels. Women decreased HDL concentrations significantly. Men obtained a significant increase for HDL values. In baseline, LDL values showed differences between men and women ( $p = 0.001$ ). For TG concentrations there were significant differences between men and women in baseline and trend to significant in post-training ( $p = 0.001$ ;  $p = 0.082$ ). TC showed significant differences between men and women in baseline ( $p = 0.013$ ). After intervention, men and women showed a significant decreased to TC. Discussion When the response on lipid profile is compared by sex after weight loss intervention in our study, men achieved a better change than women. In the literature, we found reviews and epidemiological studies that try to explain the gender-specific differences to lipid profile abnormalities treatment. Due to fat distribution there is different response on lipid profile in men than in women [1, 6]. In conclusion, men achieved a positive greater change on lipid profile than women. Moreover, the favorable lipid profile response decreases with increasing age.

### REDUCTIONS IN RESTING BLOOD PRESSURE AFTER ISOMETRIC EXERCISE TRAINING ARE NOT RELATED TO SHEAR STRESS.

Smith, J., Willes, J., Swaine, I., Coleman, D.  
*Canterbury Christ Church University*

**Introduction** The training stimulus responsible for blood pressure reductions after isometric training remains equivocal. It has previously been suggested that increased exposure to shear stress during isometric exercise may mediate endothelial adaptations, similar to that seen in dynamic exercise training. This may lead to a reduced peripheral resistance and thus a lower resting blood pressure (McGowan et al, 2007). However the role of shear stress in isometric training induced blood pressure reductions remains uninvestigated. The purpose of this study was to train participants at two intensities that either elicited a high or low shear stress stimulus to determine the role of conduit femoral artery shear stress in blood pressure reductions after an isometric leg training intervention. **Methods** 35 male normotensive participants (age = 23.79 ± 6.30 yrs, height = 180 ± 5.71 cm, mass = 75.70 ± 11.11 kg) were allocated to one of three groups: high shear stress (HI), low shear stress (LO) or control (CON). The HI and LO groups undertook an 8 week training programme of 4 x 2 minute bilateral-leg isometric contractions, 3 times per week. Mean shear rate (MSR), peak shear rate (PSR) and change in shear rate ( $\Delta$ SR) were used as an estimation of shear stress, and was measured using doppler ultrasound during training intervention in the common femoral artery. Resting systolic (SBP), diastolic (DBP) and mean (MAP) blood pressure parameters were measured at baseline, mid-point (4 weeks) and post-training (8 weeks). **Results** Repeated measure ANOVA demonstrated that the changes in SBP after training were not significant in any group. There were significant differences in DBP for the LO group pre-mid, mid-post and pre-post ( $P < 0.05$ ). Significant differences in MAP were observed in the LO group pre-mid and in the HI group mid-post ( $P < 0.05$ ). However correlation coefficient analysis revealed no significant correlations between these sub-group blood pressure reductions and MSR, PSR, and  $\Delta$ SR ( $P > 0.05$ ). **Discussion** These results suggest that training according to different levels of shear stress in the common femoral artery does not provide a strong training stimulus for reductions in resting blood pressure after isometric leg exercise intervention. Although shear stress is accepted as an important training stimulus in dynamic exercise, these findings indicate that shear stress might not be the main stimulus for reductions in resting blood pressure after isometric training. **References** McGowan, C.L., Levy, A.S., McCartney, N., MacDonald, M.J. (2007). *Clin Sci*, 112, 403-409.

### GREATER VISCOSITY AND SMALLER ELASTICITY OF CENTRAL ARTERY IN RESISTANCE-TRAINED YOUNG MEN

Kawano, H., Gando, Y., Asaka, M., Ise, R., Higuchi, M.  
*Waseda University*

**Introduction:** Arterial mechanical characteristics include both elastic and viscous properties. Arterial elastic property, such as dynamic arterial compliance, beta-stiffness, and pulse wave velocity, are often used for assessment of vascular health, and arterial elasticity is attenuated by resistance training, leading to increases in risk of cardiovascular diseases. On the other hand, arterial wall viscosity is a source of energy dissipation, considering viscosity as an energy-dissipating phenomenon during mechanical transduction (conversion of cardiac pulsatile energy into arterial elastic energy). It remains unclear, however, whether arterial wall viscosity is affected by habitual resistance training. Accordingly, the purpose of the present study is to compare elasticity and viscosity of central artery between resistance-trained and sedentary men. We hypothesized that if resistance-trained men have less elasticity of artery, there is greater viscosity in them. **Methods:** Twelve resistance-trained (age, 21.0 ± 2.7 yrs; height, 167.6 ± 5.9 cm; body weight, 75.2 ± 12.2 kg) and 12 sedentary control peers (age, 22.3 ± 1.8 yrs; height, 174.3 ± 5.6 cm; body weight, 65.7 ± 8.9 kg) were participated in this study. All resistance-trained men had been performing moderate to high-intensity 'full-body' resistance training involving large muscle groups. All subjects were normotensive (< 140/90 mmHg), non-obese and smoker, and free of overt chronic diseases as assessed by medical history, physical examination and complete blood chemistry and haematological evaluation. All participants were measured as follows; static and dynamic compliance, beta-stiffness index, and wall viscosity in carotid artery. **Results and Discussion:** Resistance-trained men had smaller static arterial compliance and carotid beta-stiffness index compared with sedentary control men ( $P < 0.05$  for both), but not statistical difference in dynamic arterial compliance ( $P = 0.0655$ ), which suggests habitual resistance training may induce dysfunction of elastic artery. On the other hand, carotid arterial wall viscosity in resistance-trained men is greater than control peers (1700 ± 548 vs 1296 ± 355 mmHg·s/mmHg,  $P < 0.05$ ). This result indicates that chronic resistance training augments to dissipate pulsatile energy from heart, leading to less elasticity of central artery. **Conclusion:** The present study first examined the impact of resistance training-induced arterial stiffening on wall viscosity carotid artery, and found that there were greater wall viscosity and smaller elasticity of artery in resistance-trained men compared with sedentary young men.

### 7 DAYS ISCHEMIC PRECONDITIONING IMPROVES LOCAL AND SYSTEMIC ENDOTHELIAL FUNCTION AND MICROCIRCULATION IN HEALTHY HUMANS

Jones, H., Hopkins, N.D., Bailey, T.G., Green, D.J., Cable, N.T., Thijssen, D.H.J.  
*Liverpool John Moores University*

**Introduction:** Ischemic preconditioning (IPC) is able to protect tissue against ischemia-induced injury within and beyond the ischaemic area. We examined the hypothesis that daily exposure to IPC leads to improvement in endothelial function and skin microcirculation in the arm exposed to IPC, but also in the contra-lateral arm. Given that late phase of protection from IPC has been shown to be evident for up to 4 days, we hypothesised that improvements in vascular function would remain for 7 days following the daily IPC intervention. **Methods:** Thirteen healthy young males (age 22.5 ± 2.5 yrs; BMI 22.8 ± 1.0 kg/m<sup>2</sup>) completed a 7-day IPC-intervention, consisting of daily exposure of the arm to an IPC protocol (4x5-min at 220 mmHg with 5 min deflation). Bilateral assessment of brachial artery endothelial function (flow-mediated dilation (FMD)) and forearm microcirculation (cutaneous vascular conductance (CVC) calculated from skin flux (laser-Doppler) and blood pressure at rest and during local heating) was performed before (pre) and after 7 days of IPC (post). Bilateral assessment allowed for examination of the local (i.e. intervention-arm) and remote (i.e. contralateral-arm) effect of IPC. Since the late phase of protection from IPC extends up to 4 days, we repeated tests 8 days following cessation of the intervention (post+8). FMD and forearm microcirculation were also examined in a no intervention group (control) of 8 healthy males (age 26.0 ± 4.8 yrs; BMI 26.4 ± 2.0 kg/m<sup>2</sup>), on two occasions separated by 15 days. Differences over time and between arms were analysed using repeated measures general linear models. Data are presented as mean ± SD. **Results:** Brachial artery FMD increased during the 15 day protocol ( $P = 0.03$ ). FMD was significantly elevated at Post+8 (7.0 ± 1.6%) when compared to pre (5.2 ± 1.5%;  $P < 0.01$ ). Forearm resting CVC also increased during the protocol ( $P = 0.006$ ). CVC was elevated at Post+8 (0.16 ± 0.04 mV/mm Hg) when compared to pre (0.13 ± 0.04 mV/mm Hg) ( $P = 0.01$ ). No interaction

between IPC arm and time were evident ( $P > 0.05$ ), indicating similar changes in both the IPC and contralateral arm. The IPC-intervention did not effect CVC-responses to local heating in either arm ( $P > 0.05$ ). No significant changes were evident in the control group across the 15 day time period in FMD or CVC. Conclusion: These data indicate that daily exposure to 7-days of IPC leads to local (IPC arm) and systemic (contra-lateral arm) improvements in brachial artery endothelial function and resting skin microcirculation that remains after cessation of the intervention and beyond the late phase of protection. These novel findings may have clinical relevance, as our data suggest local and systemic potency for the IPC-stimulus to improve endothelial function in small and large arteries both acutely and chronically.

### ACUTE RESPONSES OF HEART RATE VARIABILITY AFTER BLOOD FLOW RESTRICTION EXERCISE

Chacon-Mikahil, M.P., Souza, L.C., Bonganha, V., Souza, G.V., Ferreira, M.L.V., Andrade, M.P.C., Rocha, J., Cavaglieri, C.R., Ugrinowitsch, C., Libardi, C.A.

*State University of Campinas*

Introduction Resistance exercise with high-intensity (RE-HI) ( $> 70\%$  1-RM) has been recommended to increase in skeletal muscle mass. It is suggested that high-intensity resistance training may induce orthopedic and cardiovascular problems (1). On the other hand, resistance exercise low intensity (e.g.  $20\%$  1-RM), with restriction of blood flow (RE-RBF) seems to promote increased muscle mass similar to RE-HI (2). Although the RE-RBF promotes a lower stress on joints, and its efficacy is well established (3), little is known about its effect on the cardiovascular system, especially in autonomic function after exercise. One way to measure the cardiovascular stress is the measuring behavior of heart rate variability (HRV) after exercise. Indeed, sympathetic hyperactivity or reduced cardiac vagal tone (4) after exercise may represent a greater cardiovascular risk (5) and underlie ischemic heart disease and the pathogenesis of malignant ventricular arrhythmias and sudden cardiac death. Therefore, the purpose of the present study was to determine the effect of the RE-HI and RE-RBF in the sympathetic and parasympathetic balance by the HRV analyses. Methods Fifteen middle-age men ( $47.6 \pm 5.28$  y,  $76.81 \pm 10.95$  kg,  $1.74 \pm 0.08$  m), non-physically active performed 3 sets of 10 at  $80\%$  1-RM (RE-HI) and 3 sets of 15 at  $20\%$  1-RM (RE-RBF) in leg press, with the session randomized, counterbalanced order with 72h between session. The rest intervals between sets were 1 min. The cuff pressure used during the RE-RBF was determined as  $50\%$  of the necessary pressure for complete blood flow restriction in a resting condition. Autonomic measures were made before and during 60min after session. Random coefficient growth curve analysis allowed comparison between slopes during the 60 minute recovery for R-R interval, RMSSD, SDNN, LF, HF and LF/HF ratio. Results The random coefficient growth curve analysis identified greater increase post-exercise in LFnu for RE-HI compared to RE-RBF ( $P = 0.004$ ). The RE-HI also showed greater reduction in HFnu compared to RE-RBF ( $P = 0.004$ ). In addition, there was a tendency for higher LF/HF ratio for RE-HI ( $P = 0.059$ ). No differences between slopes for R-R interval, RMSSD, SDNN. Discussion The results suggest that sympathetic hyperactivity and greater reduction cardiac vagal tone after RE-HI may represent a greater cardiovascular risk compared RE-RBF. These results may be important especially for aging people and patients with various disorders, seen that the RE-RBF may promote increased skeletal muscle mass similar to RE-HI (2), but with less cardiovascular stress as seen by the sympathetic and parasympathetic modulation in the HRV analyses. ### EFFECTS OF ENDURANCE TRAINING ON THE INTERNAL CAROTID AND VERTEBRAL ARTERY BLOOD FLOW RESPONSES TO GRADED DYNAMIC EXERCISE

Yoneya, M.I, Sato, K.I, Ooue, A.I, Hirasawa, A.2, Sadamoto, T.1

*1: Japan Women's College of Physical Education, 2: Toyo University*

Introduction Blood supply to the brain originates from the internal carotid artery (ICA) and vertebral artery (VA). Our recent study has demonstrated that there appear to be different in blood flow responses to dynamic exercise between ICA and VA (Sato and Sadamoto 2010). In addition, because endurance training attenuates the increase in cerebral metabolic rate and rating of perceived effort (RPE) during submaximal exercise (Seifert et al. 2009), it is hypothesized that endurance training affects distribution of ICA and VA blood flow during dynamic exercise. The purpose of the present study was, therefore, to assess the effect of endurance training on ICA and VA blood flow during graded dynamic submaximal exercise. Methods Twelve healthy women [ $20 \pm 1$  yr,  $163 \pm 5$  cm,  $54 \pm 3$ kg, and peak oxygen uptake ( $VO_{2peak}$ ):  $35.8 \pm 4.8$  ml/kg/min] participated in this study. The subject performed interval cycle training 4 days a week for 4 weeks, and each training lasted  $\sim 40$  min (exercise intensity:  $30 - 90\%VO_{2peak}$ ). The graded cycling exercise before (Pre) and after (Post) training at workloads corresponding to  $30\%$ ,  $50\%$  and  $70\%VO_{2peak}$  with each loads lasting 5 min. The measurements of ICA and VA blood flow were carried out during the exercise by ultrasonography. Results Endurance training caused  $9.0 \pm 6.3\%$  increase in  $VO_{2peak}$ . The ICA and VA blood flow responses from rest to  $30\%$  and  $50\%VO_{2peak}$  exercise was not change between before and after training. However, the change in ICA blood flow from rest to  $70\%VO_{2peak}$  exercise was increased after training (Pre  $\Delta 81 \pm 33$  vs. Post  $\Delta 117 \pm 58$  ml/min), while VA blood flow significantly decreased (Pre  $\Delta 55 \pm 27$  vs. Post  $\Delta 38 \pm 20$  ml/min). Discussion The change in blood flow from rest to  $70\%VO_{2peak}$  exercise was different between ICA and VA in the present study. The ICA blood flow increases despite the decrease in VA blood flow after training, indicating that anterior and posterior cerebral circulation differently adjusted to the endurance training. These contrasting results are probably due to different responses of the vascular bed in the territories supplied by the ICA and VA. In addition, the cerebral  $CO_2$  reactivity and/or neurometabolic demand may be changed by training. References Sato K & Sadamoto T (2010). *J Appl Physiol* 109, 864-869. ### ACUTE CARDIOVASCULAR RESPONSES TO RESISTANCE AND AEROBIC BLOOD-FLOW RESTRICTION EXERCISE

Warmington, S.A., May, A., Brandner, C.R., Kidgell, D.

*Deakin University*

Introduction Low-load resistance exercise with blood-flow restriction (BFR) increases muscle strength and hypertrophy (1). However, for safety in 'clinical' use it is important to understand the cardiovascular responses to BFR exercise that have only been examined in comparison with similar light-load exercise without BFR and not high-load resistance exercise (2). Similarly, the cardiovascular responses to aerobic BFR exercise (walking, cycling) have not been compared with high-intensity aerobic exercise (3, 4). Therefore, the aim of this study was to measure the cardiovascular stress of both resistance and aerobic BFR exercise compared with equal-intensity and high-intensity non-BFR exercise. Methods Participants ( $n=14$ ) completed two exercise trials in a randomized crossover design. Each trial comprised 3

exercise bouts completed in order (light-intensity [LI]; LI+BFR; high-intensity [HI]). Each bout comprised 4 sets. Rest between sets was 1-min, and rest between bouts was 10 min. The exercise for one trial was a seated 45 degree inclined double-led press (LP) where intensity was 20% 1 RM for the LI and LI+BFR bouts (30, 15, 15 and 15 repetitions), and 80% 1 RM for the HI bout (8 repetitions per set). The other trial was treadmill exercise (TM) where intensity was 4 km/hr for the LI and LI+BFR bouts, and 80% VO<sub>2</sub>max for the HI bout. All TM sets were 2 min. CO, SV and HR were measured prior to each bout, and during set 2 and 4. BP was measured immediately following set 2 and 4. Results Typical responses were observed for all variables (BP, HR, SV, CO) in all bouts over time (rest-to-exercise) in both TM and LP. For the TM LI+BFR bout sBP, HR, SV and CO were lower than HI but similar to LI. In LP, BP was generally similar between LI and HI bouts. However, for the LI+BFR bout, despite sBP being similar MAP and dBP were higher than in HI. CO was lower in the LI+BFR bout compared with HI but similar to LI, while HR was between LI and HI. SV in the LI+BFR bout was not different to LI or HI. Discussion These data show that the cardiovascular stress of BFR resistance exercise is more similar to traditional high-intensity resistance exercise while aerobic BFR exercise is more akin to light-intensity aerobic exercise. This suggests aerobic BFR exercise to be more suitable in 'clinical' populations than BFR resistance exercise to maintain/increase muscle mass and functional capacity. References 1. Wernbom M, et al. ### **BRIEF CYCLING EXERCISE DOES NOT ALTER THE COMPLIANCE OF SUPERFICIAL AND DEEP VEINS IN RESTING UPPER ARM**

Ooué, A., Kobayashi, Y., Sato, K., Yoneya, M., Sadamoto, T.

*Japan Women's College of Physical Education*

**Introduction** Venous vessels have a large elasticity and compliance. Prolonged cycling exercise decreased venous compliance of forearm, which is caused by sympathetic venoconstriction that indicates an elevation of venous vessel tone (Fortney et al. 1983). The increase in sympathetic nerve activity (SNA) during prolonged exercise is caused by both exercise-induced factors (central command and reflex neural control from exercising muscle) and the unloading of cardiopulmonary which is due to the decrease in central blood volume with the increase in sweating and skin blood flow. However, the increase in SNA related to only the former one does not alter venous compliance during static exercise. Thus, it is hypothesized that brief dynamic exercise, which causes the increase in SNA related to the exercise-induced factors, does not change the venous compliance. To test our hypothesis, we assessed the venous compliance from pressure-cross sectional area (CSA) of vein curve during brief cycling exercise (Halliwill et al. 1999). In addition, we measured compliance of superficial and deep veins in resting upper arm, because the function and structure are different between both veins. **Methods** In 14 young subjects, the venous compliance was evaluated during resting (REST) and a 5-min cycling exercise at two loads with 35% (EX35) or 70% (EX70) of peak oxygen uptake. CSA in a superficial basilic vein and a deep brachial vein was measured by ultrasound technique during gradual deflation in the pressure (P) of cuff being inflated to 60 mmHg at 1 mmHg/s to provide a uniform pressure in the vein for the CSA measurement. The relation curve of  $CSA = \beta_2 \times (P)^2 + \beta_1 \times (P) + \beta_0$  was determined in each vein and thereafter the venous compliance equation was obtained as the compliance =  $\beta_1 + 2 \times \beta_2 \times (P)$ . **Results** Cuff pressure-superficial venous CSA curve shifted to downward according to exercise intensity. Cuff pressure-deep venous CSA curve during EX70% was also lower than that during REST. However, compliance of both superficial and deep vein did not differ among conditions. **Discussion** Cuff pressure-CSA curves of superficial and deep veins during exercise were lower than those during REST, indicating an elevation of venous vessel tone during exercise. However, compliance of both veins was not changed by the exercise. This result suggests that brief dynamic exercise, which causes the increase in SNA due to central command and reflex neural control from exercising muscle, induces the venoconstriction but it does not alter the venous compliance of both superficial and deep veins. **References** Fortney SM, Wenger CB, Bove JR, Nadel ER. ### **BLOOD FLOW RESTRICTED LOW-LOAD RESISTANCE EXERCISE INDUCES TYPE 1 FIBRE SPECIFIC CHANGES IN HEAT SHOCK PROTEINS AND GLYCOGEN CONTENT IN HUMAN SKELETAL MUSCLE**

Cumming, K.T., Wernbom, M., Paulsen, G., Raastad, T.

*Norwegian School of Sport Sciences*

**Introduction** Heat shock proteins (HSP) have been identified as important chaperones for repair and stabilisation of stressed and damaged proteins (1). It appears that HSP70 expression increase after both damaging- and non-damaging muscle contractions, whereas the small HSP  $\alpha$ B-crystallin seems to be more specifically responsive to muscle damaging exercise (2). Furthermore, submaximal isometric contractions have been shown to increase mostly HSP70 in type 1 fibres (3). In blood flow restricted resistance exercise performed with low loads the first part of the work is covered by mainly type 1 fibre recruitment. However, when each set is performed to failure, both fibre types will be recruited at some stage (4). It is therefore intriguing to study whether there are fibre type differences in the HSP response after blood flow restricted exercise. **Methods** Nine young healthy subjects performed unilateral knee-extensions at 30 % of 1RM. One leg was exercised with partial blood flow restriction (BFRRE) induced by a pressure cuff (90-100 mm Hg), while the other leg was exercised with normal blood flow (free-flow). The exercise consisted of 5 sets to failure in the BFRRE leg (45 sec rest between sets) and the corresponding number of repetitions in the free-flow leg. Muscle biopsies were sampled from m. vastus lateralis at pre, 1h, 24h and 48h post exercise. Muscle biopsies were cut in 8  $\mu$ m thick cross sections and stained against HSP70,  $\alpha$ B-crystallin and myosin heavy chain 1. Glycogen content was visualised with PAS-staining. **Results** Type 1 fibres showed significantly higher HSP70 and  $\alpha$ B-crystallin staining intensity at baseline than type 2 fibres. Relative to pre exercise values, a significant increase in HSP70 staining intensity was seen in type 1 fibres at 24 and 48 hours post exercise in the BFRRE leg. These changes in staining intensity were significantly larger than in the free-flow leg. Fibres displaying high staining intensities against HSP70 showed low glycogen content, most prominent at 48 hours post exercise.  $\alpha$ B-crystallin staining intensity was not significantly altered in any leg compared to pre exercise values. **Conclusion** Immunohistochemical analysis demonstrated that BFRRE performed to fatigue induced an increase in HSP70 staining intensity in type 1 fibres at 24 and 48 hours post exercise, as previously shown after submaximal isometric contractions (3). Although strenuous low-load BFRRE recruits both fibre types (4), our study demonstrates that the type 1 fibres are more stressed during this type of exercise, probably because of more fatigue than in the type 2 fibres. Interestingly, glycogen content was very low in the stressed type 1 fibres 48 hours after exercise. **Reference list** 1) Noble (2008). *Appl Physiol Nutr Metab*, 33: 1050-1065. 2) Morton (2008). *Sports Med*, 39: 643-662. 3) Tupling (2007). *J Appl Physiol*, 103: 2105-2111. 4) Krstrup (2009). *Scand J Med Sci Sports*, 19: 576-584.

## TEMPORARY IMPACT OF BLOOD DONATION ON PHYSICAL PERFORMANCE AND HAEMATOLOGICAL PARAMETERS IN WOMEN

Stangerup, I.1, Kramp, N.L.1, Ziegler, A.K.1, Dela, F.1, Magnussen, K.2, Helge, J.W.2

*University of Copenhagen*

Purpose: No former studies have examined how blood donation influences physical performance in women and whether being a female athlete is compatible with donating blood. The aim of this study was to clarify how  $\text{VO}_2\text{peak}$ , time trial (TT) performance and haematological parameters are affected in women with normal iron stores (P-ferritin  $>40\mu\text{g/L}$ ) and women with low iron stores (P-ferritin  $12\text{--}35\mu\text{g/L}$ ) following a standard 450ml blood donation and when they can expect to be back to their physical performance level again. Methods:  $\text{VO}_2\text{peak}$  measured by an incremental cycle ergometer test, performance in a 3km treadmill TT and blood parameters were measured at baseline, 3, 7, 14, 21 and 28 days after blood donation in 14 women with normal iron stores and 6 women with low iron stores. Anthropometrics were measured at baseline and day 28. Results: Mean age was  $34.1 \pm 2.2$ . Mean body weight was  $62.0 \pm 1.2$ . There was no difference between the two groups in anthropometrics at baseline or at day 28. Body fat decreased 3.2% otherwise anthropometrics did not change in the study period.  $\text{VO}_2\text{peak}$  was reduced by 6.9% from  $2951 \pm 79$  at baseline to  $2758 \pm 71$  mL/min 3 days after blood donation and remained below baseline through the study period ( $P < 0.001$ ). TT performance was attenuated by 5.6% from baseline ( $868 \pm 28$ s) to ( $917 \pm 26$ s) at day 3. Blood haemoglobin (B-Hgb) declined ( $P < 0.001$ ) 6.4% from  $8.4 \pm 0.1$  to  $7.9 \pm 0.1$  mmol/L from baseline to day 3, respectively. Both TT and B-Hgb were recovered 14 days after blood donation ( $P < 0.001$ ). There was no difference in  $\text{VO}_2\text{peak}$ , TT and B-Hgb between the two groups at baseline or in response to blood donation. Plasma ferritin (P-ferritin) at baseline was  $66 \pm 7$  in the women with normal iron stores and  $28 \pm 3\mu\text{g/L}$  in the women with low iron stores. P-ferritin dropped to a nadir of 65% 28 days after blood donation in the group with normal iron stores, whereas P-ferritin in the group with low iron stores remained unchanged in response to blood donation. Conclusion:  $\text{VO}_2\text{peak}$  was not fully recovered 28 days after a blood donation despite of the normalization of B-Hgb and TT performance 14 days after blood donation. Since iron plays a key role in muscle mitochondrial enzymes and respiratory proteins, low iron availability might explain the observed dissociation between recovery in B-Hgb and  $\text{VO}_2\text{peak}$ . Female athletes should expect more than 28 days to recover from blood donation before entering competition. Female athletes being blood donors should be advised to take iron supplementation to prevent iron depletion, deficiency or anemia and to secure optimal physical performance.

## EFFECT OF KINESIOLOGY TAPE ON FOREARM BLOOD FLOW

Woodward, K.A.1, Unnithan, V.B.1, Bateman, S.J.1, Hopkins, N.D.2

*1: Staffordshire University, UK, 2: Liverpool John Moores University, UK*

Introduction Kinesiology tape (KT) reportedly has several therapeutic effects including correction of joint misalignment, pain reduction, lymphatic flow facilitation and enhanced peripheral blood flow. Evidence to support such claims is insufficient, and the mechanisms through which KT exerts its effects are unknown. This study aimed firstly to determine whether KT affects skin blood flow (SkBF), and secondly, to establish whether SkBF effects are mediated by a nitric oxide (NO) endothelial response. Methods Baseline and maximal thermally stimulated SkBF responses were assessed using laser Doppler flowmetry in 13 healthy, elite, adolescent male soccer players ( $14.7 \pm 0.6$  yrs, Tanner stage 3-5). Participants completed two experimental trials; during trial 1 the arm was taped at the volar aspect of the dominant forearm, using a single 15cm strip of Kinesio® Tex Gold™ applied with 10% stretch. Forearm SkBF was measured on the volar aspect of the forearm, within the taped area (KT), and also in the collateral area, 3cm lateral to the taped area (control 1). During trial 2 no tape was applied to either site (NKT and control 2). Trials were performed within 7 days, in a randomised crossover design. SkBF, measured in perfusion units (PU) and mean arterial pressure, recorded at 5-minute intervals throughout the testing protocol, were used to calculate cutaneous vascular conductance (CVC). Maximum CVC (CVCmax) was identified and data was subsequently expressed as a percentage of this value (%CVCmax). Results There was no significant difference for baseline SkBF between KT ( $11.09 \pm 5.46$ PU) and NKT ( $9.53 \pm 3.94$ PU), or %CVCmax between KT ( $11.68 \pm 5.49\%$ ) and NKT ( $9.21 \pm 3.22\%$ ). Similarly, no significant difference was identified for maximal SkBF between KT ( $118.36 \pm 73.46$ PU) and NKT ( $113.23 \pm 51.80$ PU), or CVCmax between KT ( $1.50 \pm 0.91$ PU/mmHg) and NKT ( $1.54 \pm 0.77$ PU/mmHg). Finally, there were no significant differences between KT and control 1 for baseline SkBF ( $11.09 \pm 5.46$ PU and  $12.37 \pm 9.33$ PU) and %CVCmax ( $11.68 \pm 5.49\%$  and  $11.73 \pm 7.04\%$ ), or for maximal SkBF ( $118.36 \pm 73.46$ PU and  $111.29 \pm 40.29$ PU) and CVCmax ( $1.50 \pm 0.91$ PU/mmHg and  $1.42 \pm 0.48$ PU/mmHg) respectively. Discussion These findings suggest that in a population of healthy, elite, trained adolescent males, KT is not associated with increased forearm SkBF either at the taped site or collateral area. It is therefore, unlikely, that any therapeutic effects of KT are mediated through an upregulation of the cutaneous circulation. Further investigation is warranted into the effects of KT on alternative vascular beds and the mechanisms by which such effects, if any, are achieved.

## EFFECT OF BLOOD FLOW RESTRICTION TIMING IN ENHANCING INTRAMUSCULAR METABOLIC STRESS DURING RESISTANCE EXERCISE

Okita, K., Takada, S., Suga, T., Kadoguchi, T., Sato, T., Morita, N., Taniura, T., Horiuchi, M., Kinugawa, S., Tsuitsui, H.

*Hokusho University*

Background/aim: In recent years it has been reported that increases in muscle size and strength equivalent to those with high intensity load can be achieved even with low intensity loads (20–40% of 1 repetition maximum, RM) using blood flow restriction (BFR) together with resistance training (Abe T. Clin Physiol Funct Imaging 2012). However, there is a possibility that continuous BFR will markedly increase blood pressure and induce the development of blood clots (Manini TM. Exerc Sport Sci Rev 2009, Nakajima T. Int J KAATSU 2006). There are also reports showing a high rating of perceived exertion (Wernbom M. J Strength Cond Res 2006). Therefore, the aims of this study were to investigate the efficacy and timing of intermittent BFR procedures during low-intensity resistance exercise. Methods: Seven healthy men performed 3 sets of 1-min unilateral plantar flexion (30 repetitions) with 1-min intervals under 4 different conditions: low intensity resistance exercise (L, 20% 1-RM) without BFR (L-noBFR), L with BFR during rest periods (L-reBFR), L with BFR during exercise periods (L-exBFR), and L with continuous BFR during both exercise and rest periods (L-conBFR). Based on the results of this experiment, additional moderate intensity resistance exercises (40% 1-RM) with intermittent BFR (M-reBFR and M-exBFR) were performed in four of the seven subjects. Intramuscular metabolic stress, defined as phosphocreatine depletion and intramuscular pH decrease, was evaluated by  $^31\text{P}$ -magnetic resonance spectroscopy. Results: Phosphocreatine depletion and intramuscular pH decrease in L-conBFR were significantly greater than those in L-noBFR, L-reBFR and L-exBFR ( $p < 0.05$ ), while those changes in L-reBFR and L-exBFR were equal and tended to be greater than those in L-noBFR. By contrast, those changes in M-reBFR and M-exBFR were similar to those in L-conBFR. Subject's exertion after BFR during exercise was lower in L-reBFR and L-exBFR than in L-conBFR, and was tended to be lower in L-reBFR than in L-exBFR.

Conclusion: In low intensity resistance exercise with BFR, continuous BFR can successfully increase muscular metabolic stress and might be the most effective method when the goal is improved muscle strength and size. However, an equivalent metabolic load can also be obtained with intermittent BFR exercises by increasing the exercise load. Regarding subject's exertion, moderate intensity with rest periods BFR could be useful method and applicable to resistance training.

### BETA-ALANINE IMPROVES JUMP PERFORMANCE AND AFFECTS ENERGY METABOLISM DURING HIGH INTENSITY EXERCISE IN JUNIOR ALPINE SKIERS

Vogt, M., Gross, M., Bieri, K., Bellwald, A., Weisskopf, R., Hoppeler, H.

*University of Bern*

Introduction: Competitive alpine skiing is a very high intensity sport which taxes muscular strength and aerobic as well as anaerobic energy supply systems of the athletes to the max. Improvements in high intensity performance, muscle buffer capacity and muscle contractility were shown after beta-alanine supplementation in humans and animals (1, 2). It was hypothesized that beta-alanine supplementation of alpine skiers improves performance and affects their muscle energy metabolism. Methods: 11 male junior alpine skiers agreed to participate in this double blinded study (age:  $19.5 \pm 1.2$  y; height:  $179 \pm 4.8$  cm; body weight:  $76.5 \pm 5.5$  kg). They were randomly assigned to beta-alanine (Bal: 4.8g beta-alanine/day) or placebo group (Pla). Before and after the 5-week supplementation phase, exercise tests were performed to assess jump performance (counter movement jump: CMJ) as well as high intensity exercise performance (90s high-box jump: HB90) and energy metabolism (90s high intensity fixed-load cycling test: CLT). Muscle biopsies were taken from M. vastus lateralis to determine buffer capacity. Results: Maximal power output during CMJ was improved in Bal ( $+7 \pm 3\%$ ,  $p=0.01$ ) but not in Pla ( $+1 \pm 3\%$ ,  $p=0.57$ ; between group effect:  $p=0.03$ ). Performance during the last third of HB90 was increased in Bal only ( $+7 \pm 4\%$ ,  $p=0.02$ ) but not in Pla ( $0 \pm 12\%$ ,  $p=1.00$ ; no between group effect:  $p=0.28$ ). Fatigue-index was in a tendency improved for Bal from  $-13\%$  to  $-7\%$  ( $p=0.06$ ) and declined non-significantly in Pla from  $-4\%$  to  $-11\%$  ( $p=0.25$ ; between group effect:  $p=0.03$ ). Spirometric measurements in CLT showed small effects of beta-alanine on high-intensity metabolism. Namely, developments in the oxygen deficit (Bal:  $-2.5 \pm 7.5\%$ ; Pla  $+6.6 \pm 2.8\%$ ;  $p=0.05$ ) and aerobic energy contribution (Bal:  $+1.3 \pm 2.9\%$ ; Pla:  $-2.1 \pm 1.3\%$ ;  $p=0.06$ ) were in tendency different between the groups. Muscle buffer capacity did not change in either group. Discussion: We show for the first time, that well trained competitive alpine skiers can increase explosive strength of their leg muscles when supplemented with beta-alanine. Together, improved performance during the last third of the HB90 and small metabolic shifts during the CLT indicate, that beta-alanine might positively affect aerobic energy supply during high intensity exercise. Beta-alanine's effects on intramuscular calcium sensitivity and turnover might possibly explain these results. References: 1. Everaert I, et al. #### THE SAME EQUATION CAN BE USED FOR BOTH SEXES TO PREDICT RESTING ENERGY EXPENDITURE IN JAPANESE ATHLETES

Murata, H.1, Oshima, S.1, Yoshida, A.1, Torii, S.2, Higuchi, M.2, Taguchi, M.2

1: Graduate School of Sport Sciences, Waseda University (Saitama, Japan), 2: Faculty of Sport Sciences, Waseda University (Saitama, Japan)

Introduction It is important to know a total energy expenditure (TEE) for determination of energy requirement. Though REE is needed to know TEE, it is difficult to measure an actual REE. Therefore, some estimation equations of REE have developed. Currently, the equation for athletes published by Japan Institute of Sports Science (JISS equation,  $REE(kcal/day)=28.5 \times FFM(kg)$ ) have widely used to estimate REE of athletes in Japan. However, this equation was not established based on the measured REE (REEm) of athletes. In our previous study, it was found that estimated REE (REEe) by JISS equation was significantly different from REEm. On the other hand, REEe by Taguchi's equation ( $REE(kcal/day)=27.5 \times FFM(kg)+5$ ) was similar to the REEm of female athletes. The purpose of this study was to examine whether the estimation equation developed for female athletes can be used to predict REE for male athletes. Methods Sixty collegiate male athletes (48 football players and 12 swimmers) were participated in this study (height  $174.2 \pm 5.7$ cm, body weight (BW)  $80.3 \pm 11.5$ kg, and fat free mass (FFM)  $67.2 \pm 7.1$ kg). REE was measured by indirect calorimetry using Douglas bag technique, and body composition was estimated by dual energy X-ray absorptiometry. The REEe was calculated from Taguchi's equations based on a FFM and JISS equation. Paired t-test, estimation error, total error and systematic error by Bland-Altman plots were used for analysis. Results REEe by Taguchi's equation was not significantly different from REEm for male athletes. Whereas REEe based on the JISS equation for male athletes was significantly different from REEm. There is a high correlation between REEm and REEe from Taguchi's equation ( $r = 0.76, p < 0.001$ ). Bland-Altman analysis of Taguchi's equation did not show any systematic error. Discussion It was found that Taguchi's equation for Japanese female athletes can be used to male athletes. Most of predicted equations of REE are based on metabolic rate per body weight (BW). In previous studies, it was suggested that REE are more highly correlated with FFM than BW. Sexual difference exists in body composition that male individual generally have larger FFM than female. Metabolic rates per FFM remove the influence by a sexual difference in body composition. Taguchi's equation uses FFM as variable not BW. Therefore, this study suggested that Taguchi's equation can be used for male athletes. In conclusion, this study suggested that Taguchi's equation can be used to predict REE not only for female athletes but also for male athletes. ## INFLUENCE OF REGULAR TRAINING ON RESPIRATORY SYSTEM ADAPTATION

Mitic, N.1, Popovic, Lj.1, Radic, I.1, Miric, D.2, Djokic, T.1

*Medical Faculty, Kosovska Mitrovica*

Introduction Among many physiological adjustments during exercise, respiratory adaptation seems to be one of the most complex. It is well known that aerobic exercise can increase oxygen consumption by 10-20 folds in whole body, and 100-200 folds in working muscles, increasing the demand for gas exchange. The ventilatory response to exercise is well documented but mixed results have been reported for the 'airways response' (Silverman et al, 2005). Expiratory flow limitation can lead to an inability for increasing alveolar ventilation and together with diaphragmal fatigue are common in endurance trained athletes, resulting in diminished endurance exercise performance. The aim of this work was to examine the effect of regular training on respiratory function parameters. Methods Experiment included 30 regular trained sportsmen and 30 sedentary students. Spirometry measurements were obtained in both groups at rest and included ventilatory parameters (forced vital capacity-FVC, forced expiratory volume in 1 second-FEV1, FEV1/FVC ratio) and air flow parameters (peak expiratory flow-PEF, forced expiratory flow: FEF-25-75, FEF25, FEF50, FEF75). Results Estimated results in sportsmen group were (% of predicted value): FVC=105,9%; FEV1=106,3%; FEV1/FVC=101,2%; PEF=97,2%; FEF-25-75=102,2%; FEF25=90,1%; FEF50=96,4% and FEF75=88,5%. Similar results were obtained among sedentary students: FVC=101,5%; FEV1=101,8%; FEV1/FVC=101,7%; PEF=92,8%; FEF-25-75=99,6%; FEF25=90,4%; FEF50=93,7% and FEF75=86,7%. Discussion It is clear that results didn't show significant difference between any of examined parameters pointing that there were no changes in respiratory function in rest between trained people and sedentary one. Similar results were found by (Boutellier et al, 1992). The efficiency of the respiratory system presents significant limitation factor of the body's ability to perform exercise. Effect of the increased work of breathing, respiratory muscle fatigue and dyspnea point to the importance of respiratory muscle training. Conclusions Sportsmen under regular training in state of rest showed no significant difference in respiratory function parameters compared to sedentary healthy persons.

## YOGA PRACTICE HAS MINOR INFLUENCE ON RESPIRATORY FUNCTION AT REST IN MEN AND WOMEN

Zaicenkoviene, K., Stasiulis, A.

*Lithuanian Sports University*

Introduction Yoga breathing (pranayama) is an important part of health and spiritual practices (Brown R.P, Gerbarg PL.,2009). Yoga induces long-term changes in respiratory function and control (Bernardi L. et al., 2007). Yogic practices are low intensity exercises within lactate threshold and has the potentiality to train the respiratory system in such a way that it helps an individual to cope with the respiratory demand (Ray et al., 2011). Methods Pulmonary function was measured by means of the gas analyzer „Oxycon Mobile“ (Germany) before and after 6 month yoga training in men (YPM) (n=11) (age - 30,8 (7,06), BMI - 25,6 (2,6)) and women (YPW) (n=11) (age - 28,9 (6,86), BMI - 22,5 (2,3)) practicing yoga and control subjects (n=22) of similar age. Results Pulmonary function measures forced expiratory flow rate (FEF) 75/85 (L/s) (p = 0,036), forced vital capacity inspiration (FVC IN) (L) (p = 0,014), forced inspired volume in one second (FIV1) (L) (p = 0,045) were significantly higher in yoga practicing than in control women group, and vital capacity (VC MAX) (%) (p = 0,018), forced expiration volume in one second (FEV1) (%) (p = 0,041), forced expiratory flow rate (FEF) 25% (L/s) (p = 0,017), FVC IN (L) (p = 0,002) in practicing yoga men, than in non practicing yoga men group. They also demonstrated higher values of maximum voluntary ventilation (MVV) (L/min) (p = 0,068) and forced vital capacity (FVC) (L) (p = 0,050). After 6 month of yoga practicing we found higher FEF50% (L/s) (p = 0,003), in women group and VCMAX (%) (p = 0,028) in men group. We also found tendency to increase of VCMAX (L) (p = 0,053), peak inspiration flow (PIF) (L/s) (p = 0,051), FVC IN (L) (p=0,061), FIV1 (L) (p = 0,064) indexes in men and PIF (L/s) (p = 0,072), FVC IN (L) (p= 0,076) in women. Conclusions Yoga practise seems, to have minor influence on respiratory function at rest in men and women of middle age. ## PEAK VO2 IN YOUNG SWIMMERS DURING A TREADMILL INCREMENTAL TEST UNTIL EXHAUSTION

Rodrigues Ferreira, M.A.1,2, Mendes, J.1,2, Fernandes, R.2, Fernando, C.1, Vences Brito, A.M.2

*1: University of Madeira (Funchal, Portugal); 2: Sport Sciences School of Rio Maior, Polytechnic Institute of Santarém (Rio Maior, Portugal)*

Introduction Children's participation in competitive sports often begins at an earlier age, undergoing through training and competition process (Armstrong & McManus, 2011). Therefore, it's important to understand the physiological responses to exercise and training in young athletes. The aim of this study was to analyze the Peak VO2 in pubertal swimmers and compare it with participants not involved in any regular sport practice. Methods In the study 20 young male were evaluated: 10 young swimmers (age, 14.0 ± 1.33 yr.; height, 169.91 ± 7.71 cm; weight, 55.83 ± 9.09 kg; tanner's stage, 3.9 ± 0.32), with an average of 4.3 ± 1.77 years of training practice and competition; and 10 participants not involved in any regular sport practice (age, 14.0 ± 1.25 yr.; height, 165.32 ± 6.22 cm; weight, 64.87 ± 16.35 kg; tanner's stage, 3.9 ± 0.32). Peak VO2 was measured directly (Cosmed K4b2, Rome, Italy), during a continuous progressive treadmill protocol (Modified Balke) where the participants ran until exhaustion (volitional fatigue or maximum criterion was achieved). Normality (Shapiro-Wilks test) and homogeneity (Levene's test) were satisfied for a significance level of .05. To compare the groups, the Student's t test (two-tailed) was used (Statistical Package for Social Sciences, version 17.0), with a significance level of p < 0.05. Results Young swimmers shown higher relative Peak VO2 (75.91 ± 7.75 vs. 55.45 ± 10.03 ml • kg<sup>-1</sup> • min<sup>-1</sup>) compared with the group of young boys not involved in any regular sport practice (p = 0.000). Discussion It was observed a significantly higher relative Peak VO2 in young swimmers and that may be due to the differences in sport practice between the groups. A high Peak VO2 is essential for elite performance in many sports (Armstrong, Tomkinson, & Ekelund, 2011), and the results of the present study were in agreement with improvement of aerobic performance following a period of training in young swimmers (e.g., Faude et al., 2008). Peak VO2 is an important variable for coaches and is also required to access this parameter from sport specific tests. Surely it will be useful for young people to practice regular sport or physical activity in order to achieve a healthier lifestyle. ### PEAK VO<sub>2</sub> AND PEAK POWER OUTPUT IN YOUNG SOCCER PLAYERS

Rodrigues Ferreira, M.A.1,2, Mendes, J.1,2, Rebelo-Gonçalves, R.3, Fernandes, R.2, Fernando, C.1, Vences Brito, A.M.2  
1: *Uma (Funchal, Portugal)*; 2: *ESDRM-IPS (Rio Maior, Portugal)*; 3: *FCDEF-UC (Coimbra, Portugal)*

**Introduction** Children's morphological and functional specialization has concerned the investigators for the past years (Malina, Bouchard, & Bar-Or, 2004). Therefore, the aim of this study was to analyze the evidence of the metabolic specialization in pubertal soccer players. **Methods** Ten young male soccer players (age,  $14.1 \pm 0.88$  yr.; height,  $171.37 \pm 9.02$  cm; weight,  $60.77 \pm 9.84$  kg; tanner's stage,  $3.7 \pm 0.48$ ) participated in the study, with an average of  $6.7 \pm 2.7$  years of experience. An incremental treadmill test to exhaustion (Modified Balke) was used to assess Peak VO<sub>2</sub>, with direct gas analysis, breath-by-breath (Cosmed K4b2, Rome, Italy). To assess Peak Power Output, participants performed the Wingate Anaerobic Test (Monark 894E), with a resistance of 75 g/kg (7.5% of body weight). Statistical analysis was carried out with Statistical Package for Social Sciences, version 17.0. The data was presented as means and standard deviation, and correlations were made (Pearson Correlations) in order to determine the relationships between the Peak VO<sub>2</sub> and Peak Power Output. **Results** The absolute and relative Peak VO<sub>2</sub> was  $3748.57 \pm 659.02$  ml • min<sup>-1</sup> and  $61.66 \pm 3.93$  ml • kg<sup>-1</sup> • min<sup>-1</sup>, respectively. The absolute and relative Peak Power Output was  $517.4 \pm 83.02$  W and  $8.56 \pm 0.89$  W • kg<sup>-1</sup>, respectively. Results showed a strong correlation between absolute Peak VO<sub>2</sub> and Peak Power Output ( $p = .778$ ), but no correlation between relative Peak VO<sub>2</sub> and relative Peak Power Output ( $p = -.346$ ). **Discussion** It was observed that the players who achieved the best results in absolute Peak VO<sub>2</sub> also achieved better performance in absolute Peak Power Output, although no relationship was found in relative to body mass. Those results were in agreement with results of non-athletes (Falk & Bar-Or, 1993) and shown that these young soccer players were not metabolic specialized. The issue of metabolic specialization in young athletes is still unclear, but the results may suggest that the metabolic specialization begins in late puberty. Further studies should take into account allometric scaling to evaluate the physiological performance of young soccer players. **References** Falk B, Bar-Or O (1993). *Pediatr Exerc Sci*, 5, 318-331. ### DIVING RESPONSE IN ELITE DIVERS AFTER A ONE-WEEK DIET AND OVERNIGHT FASTING

Marongiu, E., Tocco, F.1, Migliaccio, G.M.2, Olla, S.1, Palazzolo, G.1, Sanna, I.1, Roberto, S.1, Ghiani, G.1, Pusceddu, M.1, Crisafulli, A.1

*University of Cagliari*

**Introduction.** It is well known that the nutritional status may affect performance. In competitive apnoea it is important to limit metabolism to minimise oxygen consumption and improve apnoea duration. Hence, many elite divers fast before performing apnoea. Lipid metabolism exerts two different effects during apnoea: by one hand it may increase oxygen consumption, on the other hand it may improve performance because it reduces splanchnic filling and the relative amount of carbon dioxide (CO<sub>2</sub>) produced. Therefore, fasting can delay respiratory contractions and prolong the total duration of the breath hold (Lindholm P et al., 2007). Thus, in our opinion, an overnight fasting after a short dietary period could reduce splanchnic filling without inducing an excessive increment in metabolism, thereby improving the diving response. **Methods.** We studied 8 healthy elite divers on two separate trials: (A) three dived to 10-20-30 meters deep, three hours after the normal breakfast, and (B) three dived at the same depth, but after following a specific diet and overnight fasting. Measurements have been performed through an impedance cardiograph contained inside an underwater torch, to assess hemodynamic parameters such trans-thoracic fluid index (TFI), stroke volume (SV), heart rate (HR) and cardiac output (CO), during static and dynamic apnoea (Tocco F et al., 2013). Before and at end of each test we collected blood pressure (MBP), arterial O<sub>2</sub> saturation (SaO<sub>2</sub>), blood glucose (Glu) and blood lactate (Bla) data. **Results.** Preliminary results show that overnight fasting causes an improvement in time of static apnoea at 10-20-30 meters with respect to the same trials after breakfast, probably because of an ameliorated cardiovascular response. In detail, a significant increment in static apnoea duration at 10 meters was found (mean time was  $57.7 \pm 22.8$  sec after fasting and  $40.0 \pm 25$  sec after breakfast,  $p < 0.05$ ). Besides, during dives at 30 meters, mean SV values after fasting were higher than after breakfast ( $+64.6 \pm 61\%$  and  $-1.1 \pm 21.7\%$  respectively,  $p < 0.05$ ). **Conclusion.** Data seem to indicate that diet followed by overnight fasting improves the diving response, and that dietary manoeuvres may have an important application in improving diving response via SV and CO changes during static and dynamic apnoea. **References** Lindholm P, Conniff M, Gennser M, Pendergast, D, Lundgren C. **Purpose:** We developed a tandem-bicycle ergometer. Two subjects can share for one load with one braking pist type using the tandem-bicycle ergometer. We have reported that the tandem-bicycle ergometer is suitable to give an equal load to two subjects during sub-maximal exercise (Onodera S. et al., ECSS 2012). Thus time, we performed a maximal incremental test, and we tested whether the tandem-bicycle ergometer can give equal load to two subjects to exhaustion. **Methods:** The subjects were sixteen males. Their age, height and body mass were  $25 \pm 7$  years,  $173 \pm 7$  cm, and  $71 \pm 10$  kg (mean  $\pm$  SD). All subjects signed the informed consent forms prior to participation in this study. First, the subjects performed incremental exercise until exhaustion using a single-bicycle ergometer (SIN). Cardiorespiratory variables (peak oxygen uptake (VO<sub>2</sub> peak) and peak heart rate (HR peak)) were recorded during exercise. Next, the incremental exercise using a tandem-bicycle ergometer was carried out in two different conditions: former saddle (FOR) and rear saddle (REA). The subjects, who have almost the same peak oxygen uptake (VO<sub>2</sub> peak), were selected for the exercise using a tandem ergometer. The coefficient of variations (CV) for each variable at exhaustion was calculated between trials, e.g., SIN vs. FOR and SIN vs. REA. **Results:** VO<sub>2</sub> peak and HR peak in the SIN trial were  $43.8 \pm 8.7$  ml/kg/min and  $189 \pm 7$  bpm. In the FOR and REA trials, VO<sub>2</sub> peak and HR peak were  $44.7 \pm 7.4$  ml/kg/min and  $192 \pm 12$  bpm (FOR), and  $44.1 \pm 9.3$  ml/kg/min and  $191 \pm 8$  bpm (REA), respectively. There were no significant differences among the trials. The CV for VO<sub>2</sub> peak was  $6.1 \pm 4.6\%$  (SIN vs. FOR) and  $5.5 \pm 3.6\%$  (SIN vs. REA). The CV for HR peak was  $2.7 \pm 2.7\%$  (SIN vs. FOR) and  $2.5 \pm 1.8\%$  (SIN vs. REA). **Discussion:** It was reported that circadian change in VO<sub>2</sub> peak is 3-10%, and that changes in intra-individual difference are 5.5%. These data in the previous studies are quite comparable for the results in the present study. In con-

clusion, it is suggested that the tandem-bicycle ergometer is suitable to give an equal load to exhaustion from the viewpoint of cardiorespiratory responses of two subjects. [The Ministry of Education, Culture, Sports, Science and Technology, Grant-in-Aid for Scientific Research (24500686)]

### THE COMPARISON OF ACUTE RESPONSE OF LUNG FUNCTION INDICES TO AEROBIC AND ANAEROBIC EXERCISES IN AIR POLLUTION

Alibakhshi, E.1,2, Aminian Jazi, A.1, Sobhani, V.2, Parastesh, M.3

1: UB (Barcelona, Spain), 2: BMSU (Tehran, Iran), 3: AU (Arak, Iran)

**Introduction** While aerobic activity is one of the keys to a healthy lifestyle, air pollution and exercise can be an unhealthy combination. This is especially true if you have asthma, diabetes, heart or lung conditions, or lower respiratory disease. Even when you're not exercising, exposure to air pollution can cause health problems. But with the combination of air pollution and exercise, the potential health problems are increased. This thesis project aims at studying the effect of aerobic and anaerobic exercises on lung function in polluted weather. **Methods** In this study 20 healthy men with the age range of 22.4 , 4 were randomly divided into the experiment group (10 participants) and the control group. Initially, the experiment group had one session of aerobic exercised (lasing for 20 minutes with the intensity of 50 revolves in a minute and power of 100 watt). Then after a three- week break ,in polluted air, these participants did the anaerobic exercise (lasting for 21 minutes with the intensity of 70 revolves in a minute and with the power of 285 watt for one minute and a two- minute break for 7 times) on the ergometer bicycle. The same kind of exercise was done by the control group but in healthy clean air. The experimental and control groups were successively exposed to healthy (PSI=60) and unhealthy (PSI=150) weather. Lung function tests were run before the exercises, right after the exercises (the first post-test) and 24 hours after the exercises (the second post-test). Results The findings of this study showed that aerobic exercise in unhealthy polluted air resulted in the reduction of FEV1, FVC and FEF25-75% indexes in the first and second post-tests significantly ( $P<0.05$ ). Following anaerobic exercises in polluted air, a significant decrease was observed in FVC and FEF25-75% indexes in both the first and second post-tests ( $P<0.05$ ). Yet, in comparison to anaerobic exercises, FEV1 and FEF25-75% indexes in the first and second post-tests and FEV1 and FVC indexes in the second post-tests underwent a greater reduction ( $P<0.05$ ). **Discussion** While physical exercise in polluted weather caused a reduction in the lung function indicators (FEV1, FVC and FEF25-75%) in the first and second post-tests, it seemed that anaerobic exercises in polluted weather reduced (FEV1 and FEF25-75% in the first and second post tests and FEV1/FVC in the second post test to a far lesser extent. **References** 1. ### HIGHER CARDIORESPIRATORY FITNESS ATTENUATES ARTERIAL STIFFENING ASSOCIATED WITH THE ESTROGEN RECEPTOR-BETA POLYMORPHISM IN HEALTHY WOMEN

Hayashi, K.1, Iemitsu, M.2, Murakami, H.3, Sanada, K.2, Kawano, H.4, Gando, Y.4, Tanaka, N.3, Miyachi, M.3

1: Kokugakuin University (Kanagawa, Japan), 2: Ritsumeikan University (Shiga, Japan), 3: National Institute of Health and Nutrition (Tokyo, Japan), 4: Waseda University (Saitama, Japan)

**Introduction:** Epidemiological and animal studies have suggested that the reduction of estrogen secretion after menopause results in acceleration of arterial stiffening and cardiovascular diseases (Meyer et al., 2009). Action of estrogen via estrogen receptor-beta (ESR2) has an anti-atherosclerotic effect in vessels (Villablanca et al., 2009). Additionally, gene polymorphisms of ESR2 are associated with cardiovascular disease risks. Habitual exercise brings higher cardiorespiratory fitness and results in the improvement of arterial stiffening and cardiovascular disease risks. However, the effect of cardiorespiratory fitness on the relationship between genetic variation of ESR2 and arterial stiffness remains unclear. **Purpose:** The aim of present study was to clarify the effects of cardiorespiratory fitness on the relationship between ESR2 gene polymorphism and arterial stiffness in Japanese women. **Methods:** Five hundred eighty-eight healthy women (18-84 yr old) participated in a cross-sectional study. ESR2 (rs1271572, G>T; transposition in the promoter region) polymorphism was determined by real-time PCR with Taqman probe. Arterial stiffness was measured by brachial-ankle pulse wave velocity (baPWV), and cardiorespiratory fitness was evaluated by peak oxygen uptake. Subjects were divided into high-cardiorespiratory fitness (High-fit) and low-cardiorespiratory fitness (Low-fit) groups based on the median value of peak oxygen uptake in each gender and decade. **Results:** High-fit subjects had lower baPWV value than in Low-fit subjects (High-fit;  $1225\pm 224$ , Low-fit;  $1292\pm 284$  cm/sec, mean $\pm$ SD,  $p<0.05$ ). The baPWV value of individuals with the TT genotype of ESR2 was significantly higher than those with the TG and GG genotypes (GG;  $1244\pm 267$ , GT;  $1273\pm 264$ , TT;  $1328\pm 305$  cm/sec). In the Low-fit subjects, baPWV value was significantly higher in individual with TT genotype ( $1387\pm 364$  cm/sec) than in individuals with the GT ( $1293\pm 280$  cm/sec) and GG ( $1255\pm 246$  cm/sec) genotypes. However, there were no such differences in High-fit subjects (GG;  $1234\pm 285$ , GT;  $1252\pm 247$ , TT;  $1256\pm 235$  cm/sec). **Conclusion:** These results revealed that the higher cardiorespiratory fitness may attenuate the change in arterial stiffness that is associated with ESR2 gene polymorphism (rs1271572) in the healthy Japanese women. **References:** Meyer MR, et al., (2009) Cardiovascular research, 83, 605-610. ### ASSESSMENT OF HEART RATE, PULMONARY AND MUSCULAR V'O<sub>2</sub>-KINETICS OF UPPER AND LOWER BODY EXERCISE DURING DYNAMIC MODERATE WORK RATE CHANGES

Drescher, U., Loosen, D., Baak, B., Essfeld, D., Hoffmann, U.

German Sport University Cologne

**Introduction** During dynamic work rate changes the kinetics of heart rate and pulmonary V'O<sub>2</sub> can be measured by ECG and gas exchange easily. Muscular V'O<sub>2</sub> kinetics can be non-invasively estimated by using time-series analysis in combination with a physiological model, comprising the time delay and the distortive effects of the cardio-dynamic phases between muscular and pulmonary level (Hoffmann et. al., in press). Using the mentioned non-invasive approach, we compared the kinetics of upper (Up: arms/torso) and lower body (Lo: legs) exercise for heart rate (HR), pulmonary (V'O<sub>2</sub>pulm) and in particular for calculated muscular oxygen uptake (V'O<sub>2</sub>muscl). **Methods** 11 male volunteers (age:  $24 \pm 2$  years; height:  $184 \pm 8$  cm; weight:  $79 \pm 7$  kg;  $relV'O_{2peak}(Up)$ :  $37.8 \pm 5.0$  ml $\cdot$ min $^{-1}$  $\cdot$ kg $^{-1}$ ;  $relV'O_{2peak}(Lo)$ :

$56.1 \pm 7.4 \text{ ml}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$ ) were subjected to pseudo random binary work rate (WR) changes on a leg cycle ergometer (30 W, 80 W) and an arm cranking exercise device (20 W, 50 W). HR was measured beat-to-beat by ECG,  $\dot{V}O_{2\text{pulm}}$  was determined breath-by-breath, and  $\dot{V}O_{2\text{musc}}$  was estimated by the method of Hoffmann et al. (in press) for Up and Lo. Given a linear, time-invariant, first order system the peak of the cross correlation function (CCF) of WR and a second parameter (e. g. HR,  $\dot{V}O_{2\text{pulm}}$ ,  $\dot{V}O_{2\text{musc}}$ ) indicates the kinetic responses of this parameter (Hpeak, Ppeak, Mpeak). Higher peaks denote faster system responses. Accordingly, for Up and Lo the kinetic responses for HR (Up\_Hpeak, Lo\_Hpeak),  $\dot{V}O_{2\text{pulm}}$  (Up\_Ppeak, Lo\_Ppeak) and  $\dot{V}O_{2\text{musc}}$  (Up\_Mpeak, Lo\_Mpeak) were calculated. Differences between the kinetic responses were statistically analyzed applying a two-way ANOVA (parameter x exercise model) for repeated measurements. Results Significant differences were found between Up\_Mpeak ( $0.341 \pm 0.062$ ) and Lo\_Mpeak ( $0.414 \pm 0.046$ ;  $p=0.018$ ;  $n=11$ ). In addition, there were no significant differences between Up\_Hpeak ( $0.465 \pm 0.183$ ) and Lo\_Hpeak ( $0.457 \pm 0.075$ ;  $p=0.895$ ;  $n=11$ ), as well as between Up\_Ppeak ( $0.312 \pm 0.090$ ) and Lo\_Ppeak ( $0.351 \pm 0.072$ ;  $p=0.316$ ;  $n=11$ ). Discussion It can be speculated that there could be differences between upper and lower muscular  $\dot{V}O_2$  kinetics due to different characteristics of the specific upper and lower body musculature from daily activities. Furthermore, the influence of the individual training status, muscle fiber composition, and enzyme activity, remain to be clarified. The study was funded by the DLR (Deutsches Zentrum für Luft- und Raumfahrt), Germany (FKZ 50WB0726). References Hoffmann U, Drescher U, Benson AP, Rossiter HB, Essfeld D (in press).

### SYMMETRIC CARDIOVASCULAR DYNAMICS GENERATE ASYMMETRIC RESPIRATORY $\dot{V}O_2$ RESPONSES TO ON- AND OFF-STEP CHANGES IN WORKLOAD

Hoffmann, U., Drescher, U., Mookerjee, S., Eßfeld, D.

*German Sport University Cologne*

**Introduction** Muscular  $\dot{V}O_2$  kinetics ( $\dot{V}O_{2\text{musc}}$ ) are frequently estimated on the basis of respiratory  $\dot{V}O_2$  ( $\dot{V}O_{2\text{resp}}$ ) responses to step changes in workload. A typical approach to account for the distorting effects of cardiac output (CO) dynamics and venous return is to discard the initial response of about 20 s ("cardiogenic phase") before data fitting. **Methods** In this study we investigated, by means of a mathematical model, the influence of CO dynamics, muscle perfusion, venous volume and venous volume distribution on respiratory  $\dot{V}O_2$  as well as the effect of discarding the first 20 s of  $\dot{V}O_{2\text{resp}}$  on the quality of  $\dot{V}O_{2\text{musc}}$  estimation. **Results** The results show marked asymmetries between on- and off  $\dot{V}O_{2\text{resp}}$  kinetics and substantial errors in  $\dot{V}O_{2\text{musc}}$  estimates in particular for the off-kinetics. Discarding cardiogenic phases only partly compensates for the distortion of muscular  $\dot{V}O_2$  generated by the transport through the venous system. Within the parameter settings chosen, errors in the estimate of  $\dot{V}O_{2\text{musc}}$  time constants were up to 90% for off-kinetics and up to 40% for on-kinetics. **Discussion** The simulations suggest, that major improvements in estimated muscular  $\dot{V}O_2$  kinetics can only be obtained if the values of the relevant distorting parameters (muscle perfusion, venous volume and venous volume) are known. These values would allow a backward computation of muscular  $\dot{V}O_2$  dynamics from respiratory  $\dot{V}O_2$  data. **References** Barstow TJ and Mole PA. ### GROUND'S SLOPE AFFECTS THE VENTILATORY EFFICIENCY IN SKYRUNNERS DURING A RACE SIMULATION AT ALTITUDE

Mandolesi, G.1, Mossuto, G.1, Spiridonova, M.1, Telli, R.2, Marchetti, A.3, Rosa, S.3, Roi, G.S.4, Cogo, A.1

1: *University of Ferrara (Italy)*, 2: *University of Milano (Italy)*, 3: *University of Bologna (Italy)*, 4: *Isokinetic (Bologna, Italy)*

**Introduction** Skyrunning is the discipline of running in the mountains above 2000 m where the slope can exceeds 30%. During races at altitude the ventilatory request increases due to the combined effect of exercise and hypoxia. It is well known that a deeper and lower ventilation (VE) is more efficient in terms of gas exchanges. We aimed to analyse the ventilation, the thoraco-abdominal coordination and the oxygen saturation (SpO<sub>2</sub>) in skyrunners during a race simulation. **Methods** 14 athletes (12M; age 34-60) run from 2030m to 2804m wearing an inductive plethysmography system (Lifeshirt) equipped with a pulse-oximeter and GPS (Garmin). We evaluated ventilation (VE), tidal volume (VT), ventilatory pattern (VE/VT) and phase angle (PhA), index of thoraco-abdominal coordination. **Results** Subjects run 6.2 kilometers, mean speed 1.6m/s. Values at rest and during the ascent are respectively: SpO<sub>2</sub> (%) ( $94.8 \pm 1.2$ ;  $85.2 \pm 3.2$ ) VE (L/min) ( $20.3 \pm 4.3$ ;  $128.6 \pm 29.3$ ), VE/VT ( $22.4 \pm 3.9$ ;  $52.3 \pm 8.4$ ). The relationship between the slope (S) and PhA is represented by a quadratic curve. As S increases >30% a significant increase in PhA is observed ( $p < 0.01$ ), index of worsening thoraco-abdominal coordination. The increase in PhA is significantly related to an increase in VE/VT ( $r = 0.4^*$ ) which in turn affects SpO<sub>2</sub>. In fact the correlation between VE/VT and SpO<sub>2</sub> is highly significant ( $r = -0.69$ ). The low SpO<sub>2</sub> is associated to a lower race speed ( $r = 0.33^*$ ).  $*p < 0.01$  **Discussion** Our data evidence that in skyrunners the slope of ground negatively influences the thoraco-abdominal coordination, mostly when slope is >30%. The increase in slope is also related to a decrease in SpO<sub>2</sub> through a change in ventilatory pattern toward a less efficient breath. These factors negatively influence the speed performance. **References** Casaburi R, Porszasz J, Burns MR, Carithers ER, Chang RS, Cooper CB. (1997). *Am J Respir Crit Care Med*, 155, 1541-1551. ### EFFECTS OF VARYING RAMP PROTOCOLS ON PEAK POWER AND MAXIMAL OXYGEN CONSUMPTION: A VALIDATION OF MORTON'S MODEL

Ferretti, G., Sivieri, A., Moia, C., Perini, R., Adami, A.

*University of Brescia, IT, and University of Geneva, CH*

**Introduction** In ramp protocols, the peak power attained at the end of the test ( $w'_{\text{peak}}$ ) does not correspond to the  $w'_{\text{max}}$  of a classical Astrand-type test. On this basis, Morton (2011) proposed a model of  $w'_{\text{peak}}$  that included critical power (CP) and anaerobic capacity as constants, and the mean ramp slope as variable. He validated his model using experimental data from a previous study (Morton et al., 1997), with continuous linear ramp increments. Yet most ramp tests foresee discrete step ramp increments, in which power is increased by a given amount at a given fixed time which may vary from 15 to 300 s. The aim of this study was to test Morton's model of  $w'_{\text{peak}}$  in ramp tests, with invariant step increment and increasing step duration. **Methods** 16 men performed six ramp tests with 25 W increments up to exhaustion. Step duration was: 15, 30, 60, 90, 120 and 180 s.  $\dot{V}O_{2\text{max}}$  and  $w'_{\text{peak}}$  were identified as the highest values reached during each test. An Astrand-type test with 50 W increments, 5-min duration steps, 6-min recovery between steps, was also performed,

in which  $\dot{V}O_2\max$  and  $w\max$  were established from plateau in the  $\dot{V}O_2$  versus power relationship.  $\dot{V}O_2$  and ventilatory variables were measured by metabolic cart. Lactate and heart rate (HR) were also measured. The results were fitted into Morton's model. Results  $\dot{V}O_2\max$  was the same in all tests. In contrast,  $w\text{peak}$  was lower the longer the step duration, with differences being significant among all step durations. All  $w\text{peak}$  obtained in the various ramp tests were significantly different from the  $w\max$  of the Astrand-type test. At the end of the test, no differences were observed for HR, except for the two shortest protocols (15 and 30s ramps), during which a significantly lower HR was reached compared with the longest ramp test. No differences were found for the peak  $[La]_b$  values among the various ramp tests. When  $w\text{peak}$  was analysed within Morton's model, an excellent fitting was found, yielding mean CP equal to  $198.08 \pm 37.46$  W and anaerobic capacity equal to  $16.82 \pm 5.69$  kJ. Further developments of Morton's model provided a univocal relation between CP and  $w\max$ . Discussion Present validation of Morton's model authorizes estimating CP and  $w\max$  from any type of ramp test, provided  $w\text{peak}$  and ramp slope are known. Thus, there is no further need of establishing lactate threshold or performing long protocols like the Astrand-type when training powers are to be set. References Morton RH. ## A COMPARISON OF THE PHYSIOLOGICAL RESPONSES TO MAXIMAL OXYGEN UPTAKE TESTS ON MOTORISED AND NON-MOTORISED TREADMILLS

Evans, W.J., Ditroilo, M., Abt, G.

*University of Hull*

**Introduction** Maximal oxygen uptake ( $\dot{V}O_2\max$ ) is considered to be the criterion measure of cardiorespiratory fitness (ACSM, 2010). A non-motorised treadmill (NMT) may better simulate the physical stress of the training environment and/or be better suited for testing team sport players. However it is unknown if the NMT allows the exerciser to reach  $\dot{V}O_2\max$ . The aim of the study was to examine the physiological responses to  $\dot{V}O_2\max$  test protocols on motorised and non-motorised treadmills. **Method** Sixteen males completed one continuous incremental test to exhaustion on a motorised treadmill (Cosmos) and two incremental tests on an NMT (Woodway Force 3) in a randomised order. Participants completed the motorised treadmill test using a step protocol that increased by  $1 \text{ km}\cdot\text{h}^{-1}\cdot\text{min}^{-1}$  at a gradient of 1% (MOT-CONT). The first NMT trial mirrored the motorised treadmill protocol (NMT-CONT) with the second NMT trial using an intermittent step protocol also increasing by  $1 \text{ km}\cdot\text{h}^{-1}\cdot\text{min}^{-1}$ , but alternating between higher and lower speeds ( $2 \times 15 \text{ s}$  blocks per minute - NMT-15). Heart rate was measured in the final 15 s of each stage. Expired air was measured by a breath-by-breath system (Oxycon). Data were analysed using the effect size statistic and 90% confidence intervals (Hopkins, 2009). **Results** The mean (SD)  $\dot{V}O_2\max$  ( $\text{mL}\cdot\text{kg}^{-1}\cdot\text{min}^{-1}$ ) were MOT-CONT 46 (7), NMT-CONT 46 (7), NMT-15 45 (7). The mean difference as an effect size for MOT-CONT vs. NMT-CONT (ES = -0.03; 90%CI -0.12 to 0.09) and MOT-CONT vs. NMT-15 (ES = -0.16; 90%CI -0.37 to 0.05) were both trivial. The mean (SD) peak speeds ( $\text{km}\cdot\text{h}^{-1}$ ) were MOT-CONT 15.1 (1.5), NMT-CONT 10.3 (0.9), NMT-15 13.8 (1.0). The mean difference in peak speed as an effect size for MOT-CONT vs. NMT-CONT was very large (ES = -3.71; 90%CI -4.13 to -3.29). The mean difference in peak speed as an effect size for MOT-CONT vs. NMT-15 was moderate (ES = -0.87; 90%CI -1.35 to -0.38). The mean (SD) HR<sub>peak</sub> ( $\text{beats}\cdot\text{min}^{-1}$ ) were MOT-CONT 186 (7), NMT-CONT 178 (9), NMT-15 183 (7). The mean difference as an effect size for MOT-CONT vs. NMT-CONT was large (ES = -0.84; 90%CI -1.10 to -0.59) and for MOT-CONT vs. NMT-15 was small (ES = -0.38; 90%CI -0.63 to -0.13). **Discussion**  $\dot{V}O_2\max$  can be successfully achieved on an NMT when using the same protocol as used on a motorised treadmill. However, the peak speed achieved is reduced by approximately one third and with a large reduction in HR<sub>peak</sub>. When an incremental protocol is performed intermittently on the NMT the same  $\dot{V}O_2\max$  can be achieved together with smaller reductions in peak speed and HR<sub>peak</sub> compared to a motorised treadmill protocol. **References** Thompson (2010). ## AN INNOVATIVE PROCEDURE FOR THE ANALYSIS OF $\dot{V}O_2$ KINETICS WITHOUT DATA PRE-TREATMENT

Bringard, A.

*University of Geneva*

**Introduction** The study of pulmonary gas exchange dynamics at the onset of exercise is constrained by the low time resolution due to breathing frequency and the low signal-to-noise ratio. Off-line interpolation was proposed to artificially increase the time resolution, but it may induce data distortion. The aim of this study was to propose and evaluate a new approach to the problem of poor time resolution in the analysis of breath-by-breath  $\dot{V}O_2$  kinetics. **Methods** A set of noiseless bi-exponential  $\dot{V}O_2$  kinetics (Barstow and Molé, 1987), mimicking transitions from rest to moderate exercise, were simulated by Monte-Carlo method. This provided a set of exact data, which we used as reference data. The parameters were randomly selected from intervals that cover the range of physiological values for this intensity domain. Then, each of these kinetics was sampled 10 times with non-uniform sampling time, mimicking breathing patterns during rest-exercise transition, and was subjected to 3 different pre-treatment procedures. The linear (Hughson et al, 1993) and step (Lamarra et al, 1987) pre-treatment methods consisted, respectively, of linear and step 1-s interpolations of each repetition. Then the average value was calculated for each second, resulting in an "averaged transition", to which bi-exponential fitting was applied. Our method (called none) needed no interpolation: the data of the 10 repetitions were pooled together as if they were from the same transition. Bi-exponential fitting was applied to the pooled data. For all methods, data were compared with the exact values. The confidence intervals were estimated by bootstrap using the bias corrected and accelerated percentile method. **Results** Phase I time constant ( $\tau_1$ ) data lying exactly on the identity line were more numerous with the none than with the linear and the step methods. With the none method, the identity line stayed within the confidence intervals for  $\tau_1$  but was below the lower confidence interval curve for the step and the linear methods, indicating that both overestimated  $\tau_1$ . **Discussion** The better performance of the none method is due to the fact that the linear and step methods introduce a "filter-like" effect (interpolation followed by data averaging) that affect the data. This kind of pre-treatment is not present in the none method. By definition, a filter affects the time constants of an exponential response. We conclude that the none method should be used instead of the linear and step methods, when the rapid phase of  $\dot{V}O_2$  kinetics is to be analysed. **References** Barstow TJ, Molé PA. **PHYSIOLOGICAL ADAPTATIONS OF AN 8-WEEK RECREATIONAL SOCCER PRACTICE AND RUNNING TRAINING IN UNTRAINED WOMEN**

Ortiz, J.G., Fernandes da Silva, J., Guglielmo, L.G.A., Diefenthaler, F.

*Universidade Federal de Santa Catarina*

**PHYSIOLOGICAL ADAPTATIONS OF AN 8-WEEK RECREATIONAL SOCCER PRACTICE AND RUNNING TRAINING IN UNTRAINED WOMEN** Introduction Soccer is a potential element to induce physiological adaptations and improved performance for all types of people (Randers et al., 2010). Physiological indices are references to identify the effects of training in many sports (Impellizzeri et al., 2006). Thus, the purpose of the present study was to compare physiological adaptations of an 8-week recreational soccer practice and running training in untrained women. Methods Twenty-six untrained women were separated in two groups: soccer (SG) and running group (RG). Participants performed three times per week training during eight weeks. The soccer sessions consisted of ordinary eight-a-side matches on a 50 x 30 m artificial grass field. The aerobic training sessions consisted of continuous and interval training at low intensity and high intensity running on a motorized treadmill. Maximal incremental running test to determine maximum oxygen uptake (VO<sub>2</sub>max), lactate threshold (LT) and onset of blood lactate accumulation (OBLA) was performed before and after the intervention period. Data were evaluated by two-way analysis of variance on repeated measurement ( $p < 0.05$ ). Effect size (ES) was calculated, in which values of 0.2, 0.5 and  $> 0.8$  were considered small, moderate and large, respectively. Results After eight weeks of training VO<sub>2</sub>max increased from  $37.0 \pm 6.4$  to  $41.4 \pm 6.0$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in SG ( $p < 0.05$ ; ES:0.7) and from  $36.5 \pm 6.2$  to  $42.2 \pm 5.5$  ml.kg<sup>-1</sup>.min<sup>-1</sup> in RG ( $p < 0.05$ ; ES: 1.0); speed at LT increased from  $6.1 \pm 0.7$  to  $6.7 \pm 0.9$  km.h<sup>-1</sup> in SG ( $p < 0.01$ ; ES:0.8) and  $6.0 \pm 0.8$  to  $7.0 \pm 1.2$  km.h<sup>-1</sup> in RG ( $p < 0.01$ ; ES:0.8); speed at OBLA increased from  $7.2 \pm 1.1$  to  $8.1 \pm 1.5$  in SG ( $p < 0.01$ ; ES:0.6) and  $7.1 \pm 1.1$  to  $8.4 \pm 1.1$  km.h<sup>-1</sup> in RG ( $p < 0.01$ ; ES:1.2). Discussion The main novel finding of the present study is that soccer training lead similar improvements to aerobic training performed at LT and OBLA intensities, generating significant changes in the metabolic and aerobic capacity. These results are in agreement with previous studies that investigated both indices (McMillan et al. 2005; Impellizzeri et al. 2006). Moreover, the improvement in VO<sub>2</sub>max (11 and 14% in SG and RG, respectively) is in agreement with a similar study, in which improved 15 and 10% in SG and RG, respectively (Bangsbo et al., 2010). Thus, the intensity of training conducted during physical exercise is key aspect for improvement of physiological indices. References Bangsbo J, Nielsen J, Mohr M, et al. (2010). **LACTATE TURN POINTS, CRITICAL LACTATE CLEARANCE AND CONSTANT LOAD CYCLE ERGOMETER EXERCISE**

Hofmann, P.1, Mueller, A.1, Tschakert, G.1, Groeschl, W.1, Wallner, D.2, Burgsteiner, H.2

*1: University of Graz 2: University of Applied Science Graz, Austria*

**LACTATE TURN POINTS, CRITICAL LACTATE CLEARANCE AND CONSTANT LOAD CYCLE ERGOMETER EXERCISE** Introduction According to the lactate shuttle theory (Brooks 2002), two turn points (LTPs) and three phases of lactate metabolism may be detected during incremental (Hofmann and Tschakert 2011) and constant load exercise. Aim of our study was to validate LTPs by constant load ergometer exercise (CE) below and above the pre-determined LTPs in a heterogenous group of subjects. Methods 23 healthy male and female subjects (age:  $36.0 \pm 13.2$  yrs; body mass:  $67.4 \pm 9.0$  kg; VO<sub>2</sub>max:  $49.5 \pm 9.7$  ml.kg<sup>-1</sup>.min<sup>-1</sup>) performed maximal cycle ergometer exercise (IE) (20/40W start; 15/20W.min<sup>-1</sup> increments). The first (LTP1) and the second (LTP2) lactate turn points were determined by linear regression break point analysis. CE tests (30 min) were performed at 5% (or 10%) Pmax below and above LTP1 and LTP2 in all subjects. Heart rate (HR) and gas exchange variables were determined and blood lactate concentration (La) was determined at rest, at the end of every workload step (IE), every 5 min in CE as well as during 3 and 6 min of active and passive recovery. Results: Power output in IE was  $261.0 \pm 59.8$  W at Pmax,  $179.9 \pm 46.1$  W at LTP2 ( $68.9 \pm 3.2$  % Pmax) and  $89.7 \pm 32.0$  W at LTP1 ( $34.4 \pm 6.8$  %Pmax). Subjects worked at  $76.8 \pm 29.4$  W (LTP1-),  $102.9 \pm 34.6$  W (LTP1+),  $162.6 \pm 41.1$  W (LTP2-) and  $184.0 \pm 44.8$  W (LTP2+) which were  $28.7 \pm 6.6$  %Pmax (LTP1-),  $38.7 \pm 6.6$  %Pmax (LTP1+),  $62.1 \pm 3.5$  %Pmax (LTP2-) and  $70.5 \pm 5.0$  %Pmax (LTP2+) as well as  $39.9 \pm 7.9$  %VO<sub>2</sub>max (LTP1-),  $49.3 \pm 7.0$  % VO<sub>2</sub>max (LTP1+),  $76.4 \pm 5.6$  % VO<sub>2</sub>max (LTP2-) and  $88.0 \pm 6.9$  % VO<sub>2</sub>max (LTP2+), respectively. La was  $12.44 \pm 2.25$  mmol.l<sup>-1</sup> (max),  $3.58 \pm 0.71$  mmol.l<sup>-1</sup> (LTP2) and  $1.21 \pm 0.41$  mmol.l<sup>-1</sup> (LTP1). Subjects completed 30 min of CE up to LTP2- and stopped earlier with increasing work load (LTP2+:  $22.0 \pm 7.8$  min). Mean La values were sign. Different during CE at  $0.83 \pm 0.02$  (LTP1-),  $1.21 \pm 0.04$  (LTP1+),  $4.96 \pm 0.09$  (LTP2-), and  $7.54 \pm 0.07$  (LTP2+). 16 of 23 subjects presented a lactate steady state at 5% below LTP2 and 7 subjects showed a steady state at 10% below LTP2. Discussion According to the lactate shuttle theory (Brooks 2002), two distinct turn points and three phases of lactate metabolism, detected during IE (Hofmann and Tschakert 2011) were also found for CE. LTPs distinguished the lactate curve into different metabolic domains, were significantly related to the CE lactate response and define and discriminate the main metabolic trainings zones "low", "moderate" and "vigorous" for constant load exercise training. **IS THERE A RELATION BETWEEN CHANGES IN TRAINING PERFORMANCE AND AEROBIC OR ANAEROBIC CAPACITY DURING TWO-WEEK HIGH-INTENSITY INTERVAL TRAINING?** Introduction High-intensity interval training is a time-efficient strategy for promotion of health by physical exercise (Gibala et al. 2012). We investigated whether the changes in training intensity between the six training sessions over the period of two weeks of high-intensity interval training (HIT, Wingate protocol) are related into the changes in aerobic fitness (VO<sub>2</sub>max) and anaerobic capacity (blood lactate).

Methods 13 healthy sedentary middle-aged men (age  $48 \pm 5$  years and BMI  $25.8 \pm 2.9$ ) trained six HIT sessions within two weeks using Monark 894 E ergometer. A session consisted of 4  $\times$  6  $\times$  30 s maximal sprints (Wingate protocol) with 4 min rest between the sprints. The amount of training was increased after every second session (4 $\rightarrow$ 5 $\rightarrow$ 6 sprints). The Monark anaerobic test software 3.0.1 with the ergometer provided detailed information of the different parameters related to training intensity during the sprints and we selected peak (PEAK) and average (AVG) power and power drop (DROP) to be the most representative parameters of the training load. As the amount of sprints differed, we took only the first four sprints from every session for the analysis. The subjects did also VO<sub>2</sub>max test (cycle ergometry, start intensity 50 W, increased 30 W every two minutes until to the volitional fatigue) before and after the training. One subject abandoned the study due to personal reasons. Results VO<sub>2</sub>max improved by 6.2 % (from  $34.0 \pm 3.7$  to  $36.2 \pm 4.5$  ml/kg/min  $p=0.005$ ) and blood lactate 28.6% (from  $10.8 \pm 1.7$  to  $13.8 \pm 2.7$  mmol/l  $p<0.001$ ) after the training. Average power in the sprints increased during the training period and this was especially due to increase in power in the third and fourth sprint (about 10%). Power drop in the sprints decreased during the training intervention (from about 58 at the first training session to 51 % at the last training session,  $p<0.05$ ). Peak power remained unchanged. We found no correlation between the changes in the training data with VO<sub>2</sub>max or blood lactate improvements. Discussion Both aerobic fitness and anaerobic capacity were improved by HIT training, but these changes cannot be predicted by the changes in the training performance. ### EXHAUSTIVE CYCLING EXERCISE TERMINATES EARLIER FOLLOWING PRIOR UPPER BODY EXERCISE DESPITE LESS QUADRICEPS MUSCLE FATIGUE

Johnson, M., Williams, N., Hannah, R.

*Nottingham Trent University*

Changes in the metabolic milieu of locomotor muscles during heavy exercise may elicit inhibitory feedback to the central nervous system, thereby influencing the magnitude of central motor drive to prevent the degree of peripheral muscle fatigue and/or sensory perception exceeding a "critical" individual level [1]. Whether exhaustive exercise terminates due to reaching a critical level of peripheral fatigue per se or an intolerable level of sensory perception remains unknown. Therefore, we aimed to differentiate these influences by examining the effects of a pre-existing metabolite accumulation, achieved using prior upper body exercise, on cycling exercise capacity, effort perception, and locomotor muscle fatigue. Eight males performed 3 constant power cycling tests at 85% Wmax (mean (SD): 272 (26) W). Cycling was performed to exhaustion without (C) or with (AC) prior arm-cranking exercise (8  $\times$  1 min bouts, interspersed by 30 s rest intervals, at an intensity of 1.0-1.5W/kg body mass), or without prior exercise and for an equal duration to that achieved during AC (ISO). Arm-cranking was followed by a 6 min rest period prior to cycling. Blood lactate concentration ([La]) was measured before (PRE-CYC) and after (POST-CYC) cycling. Rating of perceived exertion (RPE) for leg discomfort was measured following 3 min of cycling and POST-CYC. Peripheral muscle fatigue was assessed via changes in potentiated (using maximal voluntary contractions) quadriceps twitch force (QTF) obtained via electrical stimulation of the femoral nerve. Cycling time to exhaustion during AC and ISO (4.33 (1.10) min) was 38% shorter than during C (7.46 (2.79) min) ( $P<0.01$ ). PRE-CYC [La] was higher during AC (9.3 (1.9) mmol/L) compared to C and ISO (pooled mean: 0.7 (0.3) mmol/L) ( $P<0.01$ ), whereas POST-CYC [La] differed between all trials (C: 11.5 (3.0) mmol/L; AC: 13.9 (2.4) mmol/L; ISO: 9.2 (2.6) mmol/L) ( $P<0.05$ ). Following 3 min of cycling RPE during C (3.6 (1.3)) and ISO (3.7 (1.4)) were similar, whereas both were lower compared to AC (6.0 (1.5)) ( $P<0.05$ ). POST-CYC RPE during C (7.9 (2.0)) and AC (8.6 (1.7)) were similar, whereas both were higher compared to ISO (4.6 (1.8)) ( $P<0.01$ ). QTF was unchanged after arm-cranking. The decrease in QTF following C (-38%) was greater than the similar decreases observed after AC (-26%) ( $P<0.01$ ) and ISO (-24%) ( $P<0.05$ ). In summary, compared to C the voluntary termination of exhaustive cycling during AC was associated with less quadriceps muscle fatigue but the same level of RPE. We thus attribute the reduced exercise capacity during AC to the attainment of a critical level of sensory perception resulting from metabolite accumulation, rather than a critical level of quadriceps muscle fatigue per se. ### EFFECTS OF TWO CYCLING LEG EXERCISES ON MAXIMAL POWER: COMPARISON BETWEEN THE WINGATE AND THE FORCE-VELOCITY TESTS

Jaafar, H., Rouis, M., Attiogbe, E., Vandewalle, H., Driss, T.

*Université Paris Ouest Nanterre La défense*

Introduction Maximal power output on cycle ergometer depends on both pedaling velocity and braking force. It can be estimated from the force-velocity relationship (Pmax, Vandewalle et al., 1987) or by measuring the highest mechanical power (Ppeak) produced during an all-out Wingate test (Bar-Or, 1987). However, in order to be valid indicator of anaerobic fitness, the testing protocol must consider the resistance at which force is produced to achieve a maximal power output. Thus, the aim of this study was to compare maximal power measured by the force-velocity test (FVT) and by the Wingate test (WT) performed with two different loads among two groups with different anaerobic fitness. Methods Two groups of healthy males according to their individual training histories and physical fitness participated in this study. They consisted of ten active subjects (AS,  $22.7 \pm 1.4$  years,  $78.9 \pm 6.6$  kg and  $1.85 \pm 0.05$  m) and ten recreational subjects (RS,  $22.9 \pm 1.7$  years,  $73.3 \pm 10.4$  kg and  $1.81 \pm 0.06$  m). After a familiarization session, they performed randomly on three separate occasions a FVT according to the protocol proposed by Vandewalle et al. (1987) and two WTs with different loads, 8.7% (WT8.7%) according to the table optimization of Bar-Or (1987) and 11% (WT11%) of body mass (BM) on Monark cycle ergometer. Data were analyzed by ANOVA (group  $\times$  test) with repeated measures. Results Pmax values (W.BM-1) obtained from FVT were  $15.60 \pm 1.45$  and  $12.05 \pm 0.55$  W.kg<sup>-1</sup>, respectively for AS and RS. Ppeak values (W.BM-1) measured during the WT11% were  $14.95 \pm 1.09$  and  $11.98 \pm 0.72$  W.kg<sup>-1</sup>, respectively for AS and RS, and during the WT8.7% were  $13.58 \pm 0.96$  and  $11.40 \pm 0.70$ , respectively for AS and RS. Significant main effects of group, test and group by test interaction were found ( $p < 0.001$ ). Discussion In both groups, Ppeak measured during WT8.7% was significantly lower than Ppeak WT11% and Pmax. Consequently, a braking force 8.7% of BM underestimates maximal power and is not an optimal load, even in subjects with a low anaerobic level. In RS, Ppeak WT11% and Pmax were almost equal due to the similarity of the force and velocity values corresponding to maximal power in the FVT and WT. However, Pmax in AS was significantly higher than Ppeak WT11%, which corresponded to an underestimation of maximal power in WT using 11% of BM. Indeed, maximal power is occurred at optimal velocity and braking force (Hintzy et al., 1999; Vandewalle et al., 1985). Consequently, the load optimization should take into account not only age, individual body build, and composition, but anaerobic fitness as well. Our study suggested that FVT results in more sensible and individualized test for assessment of maximal mechanical power. References Bar-Or O (1987). *Sports Med*, 4(6), 381-394. ## DOES MAXIMAL POWER OUTPUT ON A CYCLE ERGOMETRE DEPEND ON RATE OF FORCE DEVELOPMENT AND MUSCULO-TENDINOUS STIFFNESS OF THE PLANTAR ANKLE FLEXOR MUSCLES?

Majidi, R., Lambertz, D., Jaafar, H., Vandewalle, H., Driss, T.

*Université Paris Ouest Nanterre La Défense*

**Introduction** The rate of force development depends on muscle fibre type. Furthermore, several studies suggested differences in the elastic behaviour of fast and slow muscles and were in favour of a negative relationship between stiffness and the percentage of fast fibres. Some results in single fibres or isolated muscles and in humans suggest that stiffness could be higher in the subjects with high percentage of slow fibres, i.e. the less powerful subjects. In this case, Pmax would be negatively correlated with musculo-tendinous stiffness while being positively correlated with MRTD. The aim of the present study was to verify if high MRTD and high indices of stiffness of the series elastic component of the plantar flexors were obtained in the most powerful subjects. **Methods** Twenty-one male physical education students ( $79.8 \pm 9.7$  kg,  $1.83 \pm 0.08$  m) participated in this study. Maximal power on a cycle ergometre (Pmax BM-1) was computed from the results of the force-velocity tests according to the protocol proposed by Vandewalle et al. (1985). The torque during a maximal voluntary contraction (TMVC) and musculo-tendinous stiffness (MTS) of the plantar flexors were studied by means of an ankle ergometre and quick release method (Lambertz et al. 2001). During the same session, maximal rate of torque development (MRTD) was measured according to the protocol of Sahaly et al. (2001). MTS was determined at 20, 40, 60 and 80% TMVC (S0.2, S0.4, S0.6 and S0.8). MTS was also predicted at 30% TMVC (S0.3) and 50% TMVC (S0.5) by interpolations of S0.2, S0.4 and S0.6. The relationship between Pmax, MRTD, TMVC and MTS has been tested by Pearson product-moment correlation (r), and linear regression analysis. The coefficient of determination ( $r^2$ ) was used to predict the proportion of the variance (fluctuation) of Pmax that is predictable from other variables (MRTD and MTS). **Results** Pmax BM-1 was significantly and positively correlated with MRTD related to body mass ( $r = 0.460$ ;  $P_{\text{max BM-1}} = 11.2 + 0.62 \text{ MRTD BM-1}$ ,  $P < 0.05$ ) but the positive correlation between Pmax BM-1 and TMVC did not reach the significance level ( $P > 0.05$ ). Pmax BM-1 was significantly and positively correlated with the stiffness at S0.4 ( $P_{\text{max BM-1}} = 10.7 + 0.94 \text{ S0.4 BM-1}$ ) and S0.5 ( $0.44 \leq r \leq 0.45$ ,  $P < 0.05$ ) but not with stiffness at S0.2, S0.6 and S0.8 ( $P > 0.05$ ). **Discussion** The results of the present study suggested that maximal power output during cycling is significantly correlated with the level of musculo-tendinous stiffness which corresponds to torque range around peak torque at optimal pedal rate. However, the low coefficient of determination ( $r^2 = 0.203$ ) between Pmax BM-1 and S0.4 BM-1 or S0.5 BM-1 suggested that Pmax BM-1 largely depended on other factors than the musculo-tendinous stiffness of the only plantar flexors. **References** Lambertz D, Pérot C, Kaspranski R, Goubel F (2001). *J Appl Physiol*, 90(1), 179-88. ## SPECIFICS OF MUSCLE ELECTRIC ACTIVITY DURING ARCHERY SHOOTING

Buchatskaya, I.N., Pukhov, A.M., Gorodnichev, R.M.

*Velikiye Luki State Academy of Physical Education and Sports*

**Introduction:** The research goal was to study specifics of muscle electric activity when shooting arch. **Methods:** Eight highly-qualified archers underwent the study, each doing 10 shooting sessions of 3 shoots. Registering and analysis of shoot kinematic parameters was done with the help of the "Qualisys Track Manager" 3D video-analysing system (Sweden), electromyography - with the help of the 16-channel ME6000 myograph and MEGAWIN software. **Results:** 12 "leading" muscles were determined out of 32 ones under study, the former had a high electromyographic amplitude and significant activity changes at various shoot stages. It became clear that on the group average (1st session, 46 %) the first to activate were the upper left dorsal fascicles of the trapezius muscle, those were also the first to stop contracting in the course of the shooting exercise. By the end of the exercise (10th session) the upper left dorsal fascicles of the trapezius muscle were the first to activate only in 31 % together with the upper right dorsal fascicles (31%), which attests to the fatigue process at the end of the shooting session. Electrical activity of the right extensor carpi ulnaris muscle and the left flexor carpi radialis muscle were at highest at the moment of the arrow release, which attests to a programmed control of the muscles at this particular stage. The EMG of the upper right dorsal and lower left dorsal fascicles of the trapezius muscle at the stage of "post-strengthen" showed sporadic high amplitude rises combining with low amplitude action potential, the latter fact speaks of the corrective-mechanism principle. It was found out that out of all the shoots the "successful" ones amounted to 63% and, respectively, 37 % to the "unsuccessful". A statistically valid direct dependence of the success was determined, based on the increase of average group amplitude values of the EMG of the following muscles - lower right dorsal fascicles of the trapezius muscle, posterior fascicles of the right deltoideus muscle, flexor carpi radialis muscle of the right hand, extensor carpi ulnaris muscle of the left hand. On the whole, the total electric activity of the mentioned muscles would increase by 28,6% compared with "unsuccessful" results. The latter fact attests to the dependence of the success on a higher electrical amplitude of the muscles under study.

## BLOOD LACTATE AFTER COMPETITIVE FREE DIVING AND SYNCHRONIZED SWIMMING EVENTS

Rodríguez-Zamora, L.1,2, Engan, H.K.2,3, Lodin-Sundström, A.2, Iglesias, X.1, Rodríguez, F.A.1, Schagatay, E.2,4

*1: INEFC-Barcelona Sport Sciences Research Group, UB (Barcelona, Spain), 2: Department of Engineering and Sustainable Development, Mid Sweden University, Östersund, Sweden. 3: LHL Health Röros, The No*

**Introduction** Analysis of sports involving apnea is essential for the understanding of how dives with different levels of exertion and apneic durations lead to changes in the net lactate accumulation (NLA). The aim was to describe lactate accumulation during competition performances in different free-diving and synchronized swimming (SS) disciplines. **Methods** Volunteers were 43 free apnea divers and 34 synchronized swimmers competing at an elite level. Disciplines investigated were static apnea (STA), dynamic apnea with-(DYN) and without fins (DNF), deep diving disciplines constant weight with-(CWT) and without fins (CNF), and free immersion using upper body work (FIM). Competitive SS events included solo, duet and team routines. The blood lactate concentration (La) was measured at rest before (rLa), and 3 minutes after (La3post) dives and routines executed in competition. **Results** For the entire group of athletes the average rLa was  $1.8 \pm 0.7$  mmol/L and La3post was  $6.0 \pm 2.1$  mmol/L ( $p < 0.001$ ). La3post was lower after STA ( $2.5 \pm 0.9$  mmol/L) than in all other disciplines ( $p < 0.05$ ). It was also higher after CNF ( $7.6 \pm 1.8$  mmol/L) than after DYN ( $6.2 \pm 2.1$ ), DNF ( $6.2 \pm 2.2$ ), and all SS events (solo  $6.3 \pm 2.0$  mmol/L, duet  $5.8 \pm 1.4$  mmol/L and team  $5.8 \pm 1.7$  mmol/L),  $p < 0.05$  in all cases. CWT ( $7.6 \pm 1.7$  mmol/L) showed higher La3post values than SS duets ( $5.8 \pm 1.4$  mmol/L,  $p < 0.05$ ) and teams ( $5.8 \pm 1.7$  mmol/L,  $p < 0.01$ ). **Discussion** The lowest La3post observed in STA is explained by the lack of work. CNF seems to represent the greatest hypoxic stress due to the whole body being at work and likely the full development of the diving response during the free-fall phase of the deep dive to keep O<sub>2</sub> conservation at its maximum (Schagatay, 2011). Relatively moderate La3post in SS events despite intense exertion suggests that lactate is used as an energy source due to intermittent breathing pattern

in accord with the "lactate shuttle" hypothesis (Brooks, 1991), but apnea-related peripheral vasoconstriction may play a role as well in limiting lactate clearance in the active muscles and subsequent lactate oxidation during recovery (Rodríguez-Zamora et al., 2012). Our results suggest that NLA is influenced by 1) the type, intensity, and duration of work, 2) the magnitude of the diving response developed, and 3) by the apneas' duration. ### SHORT-TERM EFFECTS OF DIFFERENT HIGH-INTENSITY INTERVAL EXERCISE PROTOCOLS IN ADULTS

Wiewelhoe, T., Fernandez-Fernandez, J., Kappenstein, J., Ferrauti, A.

*Ruhr-University Bochum, Faculty of Sport Science*

**Introduction** Over the last years, a huge number of different high-intensity training (HIT) protocols were published with the aim of improving aerobic and anaerobic capacity. Most of them have been shown to be superior in improving athlete's performance comparing to traditional endurance training. However, the prescription of different HIT protocols with regard to intensity, number of intervals, work-to-rest-ratio and movement pattern has yet to be evaluated. Therefore the aim of this study was to compare the acute effects of five different HIT protocols on the physiological, neuromuscular and psychological parameters of adults. **Methods** Nine trained male subjects participated in five different training protocols (P1: 4x4 min; P2: 7x2 min; P3: 2x10x30 s; P4: 3x9x15 s; P5: 4x6x5 s) with similar total work output (~26 min) but different work-to-rest-ratio (from 2:1 to 1:6). Measurements included blood lactate (La), blood pH, creatin kinase (CK), perceived exertion (RPE and Session-RPE), total quality recovery (TQR), delayed onset muscle soreness (DOMS), heart rate (HR) and counter movement jump (CMJ), which were taken pre, during and post-training. **Results** Significant differences ( $p < 0.05$ ) were found in mean La between P4 and P2 (5.37 vs. 10.01 mmol•L<sup>-1</sup>) as well as between P4 and P5 (5.37 vs. 10.19 mmol•L<sup>-1</sup>). Blood pH was significantly different ( $p < 0.05$ ) between P4 and P5 (7.38 vs. 7.27). Rate of perceived exertion (RPE and Session-RPE) differed significantly between P4 and P1 (2.9 and 3.1 vs. 5.7 and 6.1) and also between P4 and P2 (2.9 and 3.1 vs. 5.7 and 6.1). Significant differences for mean HR were found between P3 and P5 (168 vs. 149 beats•min<sup>-1</sup>). No differences between protocols or pre and post-training were found for CK and CMJ. Moreover, there were no differences between protocols in TQR and DOMS. **Discussion** Although the present results show differences between HIT protocols, all induced relatively high physiological and perceptual demands. The magnitude of the physiological and perceptual responses in all protocols is similar to previously research conducting HIT interventions, which is associated with physical performance improvements. Overall, the results show no great differences between HIT protocols even though intensity, number of intervals, work-to-rest-ratio and movement pattern differed significantly between protocols. Furthermore, the evaluation of different HIT interventions (e.g., mid and long-term) and their effects on the physiological and performance characteristics of team sport athletes warrants future studies. **References** Burgomaster, K. ### MENSTRUAL CYCLE PHASES EFFECTS ON ANAEROBIC POWER AND REACTION TIMES

Aras, D., Sahin Ozdemir, N.

*Ankara universitesi*

**MENSTRUAL CYCLE PHASES EFFECTS ON ANAEROBIC POWER and REACTION TIMES AU-SCH P EDUC SPORT (Ankara, Turkey)** **Introduction** Although menstruation is a universal phenomenon experienced by almost all women it has been assumed that, women's mental performance capacity and physical work capacity is impaired prior and during menstruation (Gamberale, 1975). It is still poorly understood and has been discussing effects of menstrual cycle (MC) on athletic performance (Dawson and Reilly, 2009). The purpose of this study determine effects of menstrual cycle phase on anaerobic power and reaction time of college athlete. **Methods** Nine female students from the School of Physical Education have voluntarily participated in this study. Mean age 22.22 year ( $\pm 1.39$ ), mean body height 165.20 cm ( $\pm 6.09$ ), mean body weight 57.28 kg ( $\pm 9.41$ ) and mean body fat 26.47 % ( $\pm 3.66$ ) has been found for the participant. Body compositions were measured by Avis 333 plus (Korea) and parameters about anaerobic power as; Peak Power (PP), Average Power (AP), Minimum Power (MP) and Power Drop (PD), were determined by Wingate Test (WanT) with Monark Peak Bike ergometer. Visual (VRT) and auditory (ART) reaction times were determined by Newtest (Finland) for both left and right hand. Resting heart rates (RHR) were recorded after ten min rest with lying position by Polar F 11 (FINLAND). All measurements were repeated for each participant at follicular, ovulation and luteal phases of menstruation. For statistical significance alpha value set as 0.05. After the test of normality, mean differences of normally distributed parameters were compared with Repeated Measures ANOVA and abnormally distributed parameters were compared by Friedman tests. **Results** Results obtained from participants during three phases of MC is as follows; RHR 71.22 ( $\pm 11.53$ ), 71.00 ( $\pm 10.86$ ), 79.87 ( $\pm 7.01$ ), VRT for right hand.186 ( $\pm .031$ ), .182 ( $\pm .021$ ), .184 ( $\pm .021$ );for left hand 193 ( $\pm .055$ ), .183 ( $\pm .021$ ), .183 ( $\pm .020$ ); ART for right hand.161 ( $\pm .017$ ), .169 ( $\pm .018$ ), .166 ( $\pm .023$ ) and for left hand.169 ( $\pm .019$ ), .175 ( $\pm .021$ ), .166 ( $\pm .014$ ) msec. Anaerobic powers test results was recorded as follows; for PP i 7.78 ( $\pm 1.35$ ), 8.32 ( $\pm 1.08$ ), 8.23 ( $\pm 1.14$ ); for AP 5.48 ( $\pm .57$ ), 5.72 ( $\pm .50$ ), 5.62 ( $\pm .69$ ) and for MP i3.38 ( $\pm .91$ ), 3.00 ( $\pm .95$ ), 2.67 ( $\pm 1.31$ ) and PD is 56.61 ( $\pm 13.02$ ), 64.08 ( $\pm 10.22$ ), 68.22 ( $\pm 14.44$ ) w/kg. The only difference has recorded between on luteal and follicular phases auditory left hand reaction time results. **Discussion:** The results of this study indicated that menstrual cycle has no effect on anaerobic power and visual and auditory reaction time. Despite significant differences on auditory reaction time of left hand, this result can interpreted as coincidence. **References** Gamberale F, Strindberg L, Wahlberg I. (1975). *Scand J Work Env Hea*, 1(2):120-127. Dawson E, Reilly T. (2009). *Biol Rhythm Res*, Vol. 40, No. 1, 99-119.

### BETA-ALANINE SUPPLEMENTATION AFFECTS SUPRAMAXIMAL EXERCISE METABOLISM BUT NOT INTERVAL TRAINING EFFECTIVENESS

Gross, M.

*University of Bern*

**Introduction:** Sporting events lasting 1 to 4 minutes require intensities that exceed the limits of the aerobic capacity; fatigue is partly due to metabolite accumulation caused by substrate-level phosphorylation and insufficient aerobic energy supply. Thus, enhancing performance capacity is possible by improving the response time and maximal rate of aerobic energy production or by counteracting metabolite accumulation. Thus, we hypothesized that 1) high-intensity interval training (HIT), by enhancing aerobic energy contribution, and  $\beta$ -alanine supplementation, by increasing acid buffering capacity via muscle carnosine, would discretely and positively affect physiological

mechanisms important for supramaximal exercise, and 2) that HIT would have greater benefits when performed directly after supplementation. Methods: Seventeen active men performed an incremental cycling test for aerobic capacity and a 90-second supramaximal (110 % VO<sub>2</sub>max) cycling test at three time points: before and after oral supplementation with 3.2 g/d β-alanine (n=7) or placebo (n=9), and after an 11-d HIT block (9 sessions, 4 × 4 min maximal cycling), which followed supplementation directly. Aerobic energy contribution was estimated from the ratio of O<sub>2</sub> consumption to the O<sub>2</sub> deficit, while biopsies from m. vastus lateralis were taken before and immediately after the supramaximal cycling test to address metabolic mechanisms. Subjects also completed stress-recovery questionnaires weekly and logged all training throughout the study. Results: Supplementation with β-alanine improved subjective state and stress-recovery balance, especially during HIT, and slightly increased aerobic energy contribution during 90 s cycling at 110% VO<sub>2</sub>max (1.4 ± 1.3 %, effect size 0.53), concurrent with reduced oxygen deficit and muscle lactate accumulation (-23 ± 30 %, e.s. 0.87), but had no effect on pH disturbance during exercise, buffering capacity or incremental cycling parameters. The HIT block improved buffering capacity (8 ± 11 %, e.s. 0.57), glycogen storage (30 ± 47%, e.s. 0.56) and peak cycling power output slightly (4 ± 4 %, e.s. 0.29), but did not affect VO<sub>2</sub>max or supramaximal exercise mechanisms. Moreover, there were no differential training effects of HIT when performed following β-alanine supplementation. Conclusions: Contrary to our hypothesis, β-alanine had only minor effects on supramaximal exercise mechanisms whereas HIT had none. However, β-alanine may benefit subjective parameters and perceived stress-recovery balance during intense training phases, while HIT blocks are probably useful in sports involving repeated sprints, where glycogen depletion and acidosis limit performance.

### MAXIMAL MEAN POWER OF TRACK AND ROAD SPRINT CYCLISTS DURING WORLD CLASS RACES

Menaspà, P., Martin, D.T., Flyger, N., Quod, M., Beltemacchi, M., Abbiss, C.R.

*Edith Cowan University*

Introduction. Sprint cyclists have the ability to produce very high power outputs for relatively short durations (i.e. 1-30 s). Within track cycling, sprinters are required to produce these high power outputs over short durations (20-60 s), whereas, road race sprint specialists will produce high power outputs at the end of a long ride (up to ~7 hours). As a result, the physiological demands of track and road races are extremely different. However, the peak power (PP) and maximal mean power (MMP) of track and road sprinters has not been extensively reported. Thus, the aim of this study is to describe PP and MMP achieved by these specialists during world class races. Methods. Four world class track sprinters (TRACK) and three successful professional road sprinters (ROAD) participated in this study. Data were collected from flying events at track World Cup or Championship, and during World Tour road races. Anthropometric characteristics, cadence at PP and absolute (W) and relative (W/kg) PP and MMP for 10, 20 and 30 s were determined and compared between TRACK and ROAD using independent sample T-test. Significance was established at P<0.05. Results are presented as means ± SD. Results. Age and stature were not statistically different between TRACK (age, 23±3 y; height, 183±9 cm) and ROAD (age, 26±3 y; height, 176±3 cm). TRACK was heavier than ROAD (89.0±3.8 vs. 72.0±1.7 kg). Absolute PP and MMP for 10, 20 and 30 s were higher in TRACK (2027±136, 1592±102, 1336±75 and 1129±86 W, respectively), compared with ROAD (1358±168, 1174±149, 944±80 and 843±63 W). Relative PP and MMP for 10, 20 or 30 s were not different between TRACK (22.8±0.8, 17.9±0.9, 15.0±0.6 and 12.7±0.5 W/kg) and ROAD (18.8±2.1, 16.3±1.8, 13.1±1.1 and 11.7±0.6 W/kg). Cadence at PP was higher in TRACK, compared with ROAD (128±6 vs. 109±6 rpm). Discussion. Despite a similar age and height, TRACK was considerably heavier than ROAD. As expected, the absolute power output of TRACK was significantly higher than ROAD. Although the physiological demands of track and road sprinting is extremely different, PP and MMP relative to body weight were not different. Further research should compare power relative to coefficient of drag (CdA), which could explain typically observed differences in sprint speed (~72 vs. ~65 km/h, for TRACK and ROAD, respectively). This study presents novel data which will assist sport scientists and coaches in the preparation of athletes by providing a better understanding the demands of world class track and/or road sprint performances.

#### RELATIONSHIP BETWEEN ILLNESS-SPECIFIC SELF-EFFICACY, DEPRESSION AND THE LEVEL OF PHYSICAL ACTIVITY OF COPD- PATIENTS

Müller, K., Brammer, N., Wagner, P.

*Leipzig University*

Introduction Among Patients with Chronic Obstructive Pulmonary Disease (COPD), physical activity (PA) is the strongest predictor for mortality (Waschki et al., 2011). Consequently, the maintenance of PA on a long-term basis does play an essential role in COPD-disease management. However, there is a lack of instruments to assess illness-specific self-efficacy. Together with a validation of a German version of Wigal's et al. (1991) "COPD-Self-Efficacy Scale", the purpose of the present study is to investigate the correlation between the illness-specific self-efficacy and the patient's level of activity as well as their psychological health. Methods For the present cross sectional study data giving evidence about the physical activity level (FFkA) of in- and out- patients with COPD (N=160; male: 68,6%; Age: M=67.3, SD=10.3) have been generated. Next to socio-demographic data, we also collected the illness-specific self-efficacy with the help of the first German version of the "COPD-Self-Efficacy Scale" (Müller et al., 2013; α = .984) as well as the level of depression using the HADS-D. Results The results indicate a total time of physical activity of 9.8 hours per week (SD= 8.8), however 30.6% of the patients show too little physical activity. Physically active participants reach higher values regarding the illness-specific self-efficacy (F(2,153)=8.21, p<.001). There is a low correlation between the total physical activity and the level of depression (r=-0.261, p<.01). Additionally, calculations indicate a middle correlation between levels of depression and illness-specific self-efficacy (r=-0.453; p<.001). For further interpretations, multivariate analysis will follow. Discussion Depending on the factors illness-specific self-efficacy and symptoms of depression, COPD- patients show different levels of physical activity. Interventions aiming on changing these factors can increase the level of physical activity and therefore essentially contribute to a successful disease management on a long-term basis. ## BENEFITS OF EXERCISE IN SELF IMPROVEMENT IN ELDERLY PATIENTS WITH CARDIOVASCULAR DISEASES

Simeao, A.

*Universidade de Évora*

**Introduction** Physical Exercise (PE) seems positively influence the functional autonomy. The aim of this study was to investigate the benefits of a program to improve the EF functional autonomy in elderly patients with cardiovascular diseases. **Methodology** A total of 39 seniors, including 28 women and 11 men, mean age 77 years, were subjected to a 90-day EF program. The program consisted of sessions fine and gross motor control, individual counseling, gait training and sensory stimulation. These sessions were held for 5 days a week with a duration of 55 minutes each. This study consisted of two phases: the first, before running the program, and the other end after application. At such times, various measures were taken kinanthropometric (resting HR, maximal HR, systolic blood pressure, diastolic blood pressure, BMI, weight, test March 6 minutes Rikli & Jones) and performed a functional assessment of activities of daily living (IADL's) with scale application Lawton (1969). The comparison between the behavior of variables kinanthropometric autonomy and total 'score' in IADL assessed'S (Scale Lawton, 1969) at the beginning and at the end was done by t test for related samples. **Results** When comparing the 'score' of Autonomy at the beginning and end found a statistically significant increase of the values of autonomy, having seen an average increase of 7 (95% CI: 5.4 to 7.7). We also found statistically significant differences between the measures kinanthropometric the initial and final moments, when there was an average decrease in the following variables: 4.8 bpm in resting HR (95% CI: 1.2 - 8.3) and 1.1 HMG in systolic BP (95% CI: 1.5 - 2). It was also observed an average increase of 81.5 m in Test 6 Mins Walking (95% CI: 61.9 to 101.1). **Discussion of Results** The results of the study suggest that the comparison of the initial and final time kinanthropometric measures, an average decrease of 4.8 bpm (95% CI: 1.2 - 8.3) and resting HR in systolic BP of 1.1 HMG (95% CI: 1.5 - 2). Second, Michel (1) (2001) the EF has a positive impact on hypertension. It was also observed an average increase of 81.5 m in Test 6 Mins Walking (95% CI: 61.9 to 101.1). In the study by Sousa (2) et al. (2010) sought to compare the level of functional ability and practice of EF in adults and the elderly with chronic diseases were statistically significant differences in the re-test Test March 6 min, where there was an increase in the number of meters traveled. The results obtained in the 'Score' of autonomy through the Lawton Scale (1969), we observed a statistically significant increase in the values of autonomy, having been an average increase of 7 (95% CI: 5.4 to 7.7). In the study by Correia (3) et al. (2010) found statistically significant improvement in functional capacity in elderly patients with diabetic disease practitioners EF. In this context, it appears that this program EF was effective for the improvement of autonomy in IADL'S in locomotor capacity and cardiovascular endurance.

## THE IMPORTANCE OF VO2MAX, WORK EFFICIENCY & ANAEROBIC ENERGY TURNOVER IN TRAINING-INDUCED INCREASE IN EXERCISE CAPACITY AMONG CARDIO PATIENTS

Mikkelsen, A.L.1, Petersen, A.K.1,2, Laustsen, S.1,2, Nielsen, O.B.1, Overgaard, K.O.1

1: AU (Aarhus, DK), 2: AUH (Aarhus, DK)

**Introduction** Based on a pilot study showing that the increase in exercise capacity with training in cardio patients often is larger than what can be explained by increased VO2max, our aim was to analyse the relative contributions of the VO2max, work efficiency and anaerobic energy turnover to the training-induced increase in exercise capacity. **Methods** In 93 patients, VO2 and power output was measured during an incremental ramp-test (8-12 min) performed on a bicycle ergometer to exhaustion before (1) and after (2) an 8-w exercise rehabilitation program. Maximal power output (MPO) was taking as an estimate of exercise capacity, and VO2peak as VO2max. Work efficiency (WE) in W/mL O2 was determined as the slope between power output and VO2 in the interval between 25 % of MPO and power output at RER 1 using regression analysis. The anaerobic energy turnover (AET) was calculated as MPO - (WE x VO2peak). The contribution of increased VO2peak to the increased MPO after the 8-w exercise program was calculated as [VO2peak(2) - VO2peak(1)] x WE(1), contribution from work efficiency as [WE(2)-WE(1)] x VO2peak(1), and contribution from anaerobic energy turnover as AET(2)-AET(1). **Results** Preliminary results from 14 subjects showed that before the rehabilitation program, MPO and VO2peak were 123 ± 22 W and 1520 ± 340 mL O2/min, and increased by 12 ± 7 and 13 ± 10 % (P < 0.0003), respectively, when tested after the rehabilitation program. Determinations of VO2peak, WE and AET indicate that both improved VO2peak and improved WE contributed to the increase in MPO (P < 0.01 and P < 0.06, respectively). There were, however, large inter-subject variations in their relative contributions. Thus, the increased VO2peak and increased WE accounted for 44 ± 53 and 56 ± 102 %, respectively, of the increase in MPO. The rehabilitation program had no effect on AET. **Discussion** The results suggest that increased VO2max and increased WE are equally important for the improved MPO after training in cardio patients. Other studies show that a significant part of the increase in WE with endurance training is related to mechanisms that are independent on the specific exercise task, including decreased motor discharge rate in submaximal contractions (Vila-Chã et al., 2009) and more economical fibre Ca2+ handling (Majerczak et al. 2008). Since this indicate that increased WE transfers to exercise tasks outside the test laboratory, our study point to MPO as a better predictor for improvements of physical function after cardiac rehabilitation than VO2max. **References** Majerczak J., Karasinski J., Zoladz J.A. (2008). *J. Physiol. Pharmacol.*, 59, 589-602 Vila-Chã C., Falla D., Farina D. (2010) *J. Appl. Physiol.* 109, 1455-1466

## THE EFFECT OF ENDURANCE TRAINING IN A GROUP OF CARDIAC PATIENTS ALSO PERFORMING STRENGTH TRAINING.

Sveen, O.1, Hanssen, K.E.1, Skaug, A.1, Johansen, E.2, Jensen, J.2

*1Østfold College, Faculty of Education 2Norwegian School of Sport Sciences*

**Abstract** ECSS, Barcelona 2013 The effect of endurance training in a group of cardiac patients also performing strength training. **Introduction** In cardiac rehabilitation the main focus has been on endurance training. Combination of strength training has recently been suggested. So far, the effect of training with combined endurance and strength training on maximal oxygen uptake has not been studied extensively in overweight cardiac patients. **Aim:** The aim of this study was to investigate whether intensified training consisting of two strength training session with heavy loads and two high intensity interval spinning weekly increased maximal oxygen uptake more than a moderate training consisting of two endurance training sessions with moderate intensity and one circuit training session weekly. **Methods** Thirty coronary patients (aged: 50-72 years; 23 males and 6 females) were recruited from Fredrikstad Cardio-Club (Club for cardiac

patients after hospital treatment) and stratified and randomly assigned to intensified training or continuation of normal training. During 10 weeks of intervention, the control group (CON) exercised 45 minutes aerobic training two days a week and one day of strength circle training. The endurance training sessions had three high intensity periods where heart rates should reach 95 % of maximal heart rate. The group performing intensified training (INT) exercised four days a week: two aerobic exercises (spinning) of 60 minutes and two days of strength training. Endurance training was performed as interval of 2-3-4-5-4-3-2- min with 2 min rest between intervals (Pyramid training) with intention to obtain heart rates higher than 90 of maximal heart rate. Strength training was performed twice a week with 8 RM to 12 RM. Results The group continuing with 3 weekly training sessions (CON) increased maximal oxygen uptake from  $29.7 \pm 1.3$  and  $30.9 \pm 1.2$  ml/kg/min ( $p < 0.05$ ) during the 10 week intervention. The group performing intensified training increased maximal oxygen uptake from  $30.9 \pm 1.0$  to  $32.4 \pm 1.2$  ml/kg/min ( $p < 0.05$ ). There was no difference in the increase in maximal oxygen uptake between groups. The increase in peak watt during maximal oxygen uptake similar in both groups. Discussion: Intensified training improved maximal oxygen uptake significantly similarly to the group performing moderate intensity endurance training. However, the group with intensified training performed two strength training sessions weekly and showed a large increase in strength. Importantly, cardiac patients are able perform high intensity strength and endurance training with improvement in both parameters. Conclusion: Inclusion of strength training to a group of cardiac patients does not impair the improvement in maximal oxygen uptake when two sessions of high intensity interval training sessions are performed weekly for 10 weeks.

### THE EFFECT OF STRENGTH TRAINING IN A GROUP OF CARDIAC PATIENTS ALSO PERFORMING ENDURANCE TRAINING.

Hanssen, K.

*Norwegian School of Sciences, Østfold College, Faculty of Education*

**Introduction** In cardiac rehabilitation the main focus has been on endurance training. However, combination of strength training has recently been suggested to be superior to endurance training alone to improve health in middle-aged subjects. **Aim:** The aim of this study was to investigate whether intensified training consisting of two strength training session with heavy loads and two high intensity interval spinning weekly increased strength more than a moderate training consisting of two endurance training sessions with moderate intensity and one circuit training session weekly. **Methods** Thirty coronary patients (aged: 50-72 years; 23males and 6 females) were recruited from Fredrikstad Cardio-Club (Club for cardiac patients after hospital treatment) and stratified and randomly assigned to intensified training or continuation of normal training. During 10 weeks of intervention, the control group (CON) exercised 45 minutes aerobic training twice a week and one day of circuit training. The intensified training group (INT) exercised four days a week: two sessions with high intensity spinning and two sessions with strength training. Strength training was performed as three sets of eight exercises (leg press, leg curl, leg extension, chest press, pull down, curl, crunches, back; performed in machines). Load was in the first 2 weeks 12 RM; 10 RM in week 3-6, and 8 RM in week 7-10. **Results** Maximal strength in chest press increased from  $23.3 \pm 3.0$  kg to  $27.9 \pm 3.4$  kg (19.7 %;  $p < 0.05$ ) in CON and from  $26.7 \pm 2.0$  kg to  $32.9 \pm 2.2$  kg (23.2 %;  $p < 0.05$ ) in INT. Maximal strength in leg press increased from  $110.8 \pm 8.9$  kg to  $125.4 \pm 9.5$  kg (13.2 %;  $p < 0.05$ ) in CON and from  $107.9 \pm 8.1$  kg to  $162.0 \pm 8.4$  kg (50.1 %;  $p < 0.05$ ) in INT. Intensified training increased muscles strength more than CON ( $p < 0.05$ ). Maximal oxygen uptake increased similarly and significantly in both groups (~ 4 %). **Discussion/Conclusion** Discussion: Strength training in machines improved strength in both arms and legs. Circuit training also increased muscles strength in arm and legs, but was less effective than training in machines to improve strength in leg muscles. The fact that strength in leg muscles increased by more than 50 % highlights the importance of heavy strength training to induce muscle hypertrophy. It is also noteworthy that the large increase in strength was possible although two weekly spinning sessions were performed to maintain endurance capacity. **Conclusion:** Strength training with weights increased leg strength much more than circuit training whereas the increase in arm strength was similar. Importantly, it is possible to increase muscle strength in leg muscles even though two sessions of high intensity endurance training is performed.

### EFFECT OF WATER IMMERSION IN PATIENTS WITH STABLE CARDIAC DISEASE

Saito, K.1,2, Takagi, Y.1, Saito, T.1, Yuguchi, S.2, Matsuo, T.2, Aritaka, S.2, Komuro, K.2, Yoshitaka, H.2, Sakaguchi, T.2, Hiraoka, A.2, Kita, T.2, Morisawa, T.3, Onodera, S.4

*1: Graduate school, Kawasaki University of Medical Welfare, 2: The Sakakibara Heart Institute of Okayama, 3: Hyogo University of Health Sciences, 4: Kawasaki University of Medical Welfare*

**Background** Water exercise would be one of the most effective techniques for adopted persons. However the influence of water immersion on cardiac function has been controversial. The purpose of this study was to clarify the physiological effect of patients with cardiac disease in water. **Methods** Six male patients (age :  $72.2 \pm 2.9$  years, BMI :  $22.5 \pm 1.5$  kg/m<sup>2</sup>) with stable cardiac disease were involved in this study (3 patients with non-ischemic cardiomyopathy, 2 patients with history of previous coronary artery bypass grafting, 1 patients with ischemic cardiomyopathy, mean left ventricular ejection fraction (LVEF) :  $48.5 \pm 11.6\%$ ). Beta-blockers and diuretics were used in all patients. Evaluation out of water was during a stable ambient temperature of thirty degree Celsius. Evaluation in water immersion to the level of axilla was during water temperature of thirty-one degree Celsius. In both conditions, patients were evaluated while sitting the chair after five minutes of rest. Blood pressure, heart rate and thermal sensation were monitored. Transthoracic echocardiography was performed to evaluate E and A wave velocity, left ventricular stroke volume (LVSV). **Results** In five patients, water immersion significantly increased E wave velocity (from  $0.69 \pm 0.35$  m/sec to  $0.85 \pm 0.30$  m/sec,  $p = 0.021$ ), and LVSV (from  $37.4 \pm 29.2$  ml to  $42.2 \pm 32.3$  ml,  $p = 0.043$ ), except one patient with non-ischemic cardiomyopathy (LVEF=38%) who showed decrease in those values. There were no significant changes in blood pressure, heart rate or thermal sensation. **Discussion** Water immersion has beneficial hemodynamic effects in patients with stable cardiac disease in terms of enhanced diastolic filling leading to an increase in LVSV. However, patients with severe heart failure could show negative hemodynamic responses and those hemodynamic variations might be masked in patients using antihypertensive medication. **Conclusions** Although careful consideration is required for patients with severe heart failure, water exercise is a useful therapy in patients with stable cardiac disease.

## BLOOD FLOW RESTRICTED TRAINING IMPROVES MUSCLE POWER AND GAIT SPEED IN A 74 YEAR-OLD MALE WITH SPORADIC INCLUSION BODY MYOSITIS: A CASE REPORT

Jørgensen, A.N.1, Nielsen, J.L.1, Frandsen, U.1, Aagaard, P.1, Diederichsen, L.2  
*Odense University Hospital, University of Southern Denmark*

**Introduction** Sporadic inclusion body myositis (sIBM) is an idiopathic inflammatory myopathy, which is a systemic disease that result in substantial muscle weakness and skeletal muscle inflammation. sIBM is mostly observed in patients of +50 years of age, and it is characterized by a progressive loss in skeletal muscle mass and a resulting reduction in muscle strength of 5-15% per year in both distal and proximal muscles, particularly affecting hands and thighs (1–3). In comparison, healthy adults typically experience a loss of muscle strength of 0.5-1.5% per year from the age of 60-65 years (5). Currently no effective treatment of sIBM is known. The purpose of this study was to investigate how a patient with sIBM would tolerate and respond to low-load resistance exercise with concurrent partial restricted blood supply to the working muscles (BFRE). **Methods** Twelve weeks of BFRE training (2 sessions per week). Training consisted of unilateral- leg press, knee extension and seated calf rise, with a load equalling 25RM. The patient was tested before (Pre), at 6 wks (Mid), and after 12 wks of training (Post). Testing consisted of a series of functional tests and maximal unilateral knee extension power (Nottingham Power rig). Results Calf raise training loads increased by 75% and total training volume increased by 146%/163% (left/right leg). Leg press training loads increased 33% and 40% with gains in total training volume of 47%/70% (right/left leg). No pre-to-post changes in self-chosen 10m walking speed and Timed Up & Go (3m) were observed. In contrast, 10m maximal walking speed increased by 19% (7.9s to 6.4s). At Pre, leg extension power was 40% lower in the left compared to right leg (0.49W/kg vs. 0.82W/kg). Post training, knee extension power for the right leg remained unaltered, but increased in the left leg by 47% (0.72W/kg) and was only 12% lower than the right leg. **Conclusion** BFRE was well tolerated by the present sIBM patient, and led to substantial improvements in mechanical muscle function and maximal gait speed. Further, a reduced limb-asymmetry in maximal muscle power was observed, which is known to reduce the risk for falls (4). **References** 1. Cox F & Reijnen M. *Rheumatology* : 1153–1161, 2011. 2. ## ACTUAL TEMPERATURE DURING AND THERMAL RESPONSE AFTER WHOLE-BODY CRYOTHERAPY IN CRYO-CABIN

Fonda, B., Savic, M., Sarabon, N.  
*S2P, Ltd.*

**Introduction** Whole-body cryotherapy involves exposing minimally dressed participants to very cold air (injecting liquid nitrogen with temperature -195 °C), either in a specially designed chamber (cryo-chamber) or cabin (cryo-cabin), for a short period of time. It has been widely used in sport to improve athletes' recovery (Banfi et al., 2010). The aim of this study was to examine the actual temperature of the air in the cryo-cabin at different locations throughout the cabin next to the subject's body. Additionally, we monitored skin temperature before and for 60 minutes after the cryo-cabin session. **Methods** Twelve subjects completed one 3-minute cryo-cabin session. Air temperature measured next to the skin was assessed during the session. Temperature sensors were placed on the middle of the tibia, middle of the thigh, lateral to the belly button and over the sternum. Skin temperature was monitored before, 3 min after and every 10 min for 60 minutes after the session with thermal imaging of the whole body from front and back. **Results** There was a statistically significant interaction (time x position) for temperature among the different body parts during the WBC ( $p = 0.000$ ), and for skin temperature among different body parts after the cryo-cabin session ( $p = 0.000$ ). Statistically significant time effects during and following cryo-cabin session were present for all body parts. **Discussion** We showed that atmospheric temperature in the cryo-cabin is substantially different from the one reported by the manufacturer. Manufacturers should pay attention on temperature sensors placement for displaying the temperature inside the cabin. This would be particularly important for clinical use when adjusting the temperature for specific therapeutic purposes such as recovery after strenuous exercise. Thermal response after cryo-cabin session is similar to the response observed after the cryo-chamber session reported in previously published studies (Westerlund et al., 2003). This could be of practical value as cryo-cabins are less expensive and easier to use compared to cryo-chambers. **References** Banfi, G., Lombardi, G., Colombini, A. & Melegati, G., 2010. *Sports Medicine*, 40, 509-517. Westerlund, T., Oksa, J., Smolander, J. & Mikkelsson, M., 2003. *Journal of Thermal Biology*, 28, 601-608.

## HIGH INTENSITY INTERVAL TRAINING IN CARDIOVASCULAR REHABILITATION

Nebel, R.  
*medicos.Osnabrueck*

**Purpose:** Interval training has a century long history in sports training, in the last decade High Intensity Interval Training (HIIT) as a special form of polarized training has come into the focus of scientific research. The effects on cardiovascular, respiratory and peripheral (muscle) systems have led physicians to consider its application in patients in cardiac rehabilitation (CR). A number of different protocols is currently used by different study-groups. The objective of this review is to report the effects and safety of HIIT in patients with cardiovascular diseases as coronary artery disease (CAD), metabolic syndrome (MBS), Diabetes mellitus type 2 (DM2), chronic heart failure (CHF) and with chronic obstructive lung diseases (COLD). **Methods:** We performed a non-systematic PubMed review using the keywords 'high-intensity interval training', 'exercise', 'interval training', 'coronary artery disease', 'coronary heart disease', 'metabolic syndrome', 'diabetes mellitus type 2', 'chronic heart failure', 'chronic obstructive pulmonary disease' and 'chronic obstructive lung disease'. Randomized and non-randomized interventional clinical trials, articles concerning basic science research, physiological research published in English were included. **Results:** HIIT protocols in general appear safe and often better tolerated by patients in CR than low- to moderate-intensity high-volume training (HVT) protocols. A large amount of recent studies gives detailed knowledge about the underlying specific physiological central and peripheral responses and adaptations to HIIT. Avoiding 'all-out' protocols like the Wingate-Test, in stable and selected patients it is a time-efficient (and therefore most motivating) strategy inducing substantial clinical improvements - often superior to those achieved by HVT - including beneficial effects on important prognostic factors like exercise capacity, peak oxygen uptake, left ventricular function, skeletal muscle and endothelial function, as well as improving quality of life. **Conclusions:** HIIT as a form of polarized exercise appears to be a safe and effective alternative for the rehabilitation of patients with CAD, DM2, MBS, CHF and also COLD. Due to its time-efficiency and variety of feasible protocols adjusted to a patient's individual fitness (in or after CR) it may also assist in improving adherence and maintenance to regular physical exercise. Still, randomized and larger interventional studies including clinical end-points are necessary to improve safety, indications and contraindications for this therapy in different populations.

## EVALUATION OF THE EFFECTS OF AN AEROBIC EXERCISE PROGRAM ON QUALITY OF LIFE AND CREATINE KINASE IN PATIENT WITH MCARDLE'S DISEASE: A CASE REPORT

Crege, D., Ferreira, R.C.M., Quaggio, M.C.

*Universitary Center Padre Anchieta*

**Introduction** McArdle disease (MAD) is a rare autosomal recessive metabolic myopathy that leads to myophosphorylase deficiency. Normally, the disease symptoms appear in the second or third decades of life. Subjects with this syndrome presents myoglobinuria, muscle pain, early fatigue, leg cramps and exercise intolerance that directly reflects on quality of life (Moustafa, et al., 2013). The aim of this study was to analyze the effects of an aerobic exercise program on quality of life and creatine kinase (CK) serum concentrations in a patient with MAD. **Methods** A 21 years old man with MAD diagnostic participated of an aerobic exercise program. The exercises were performed in treadmill, 2 times a week, for 40 minutes per session, during 8 weeks. The initial exercise intensity was determined calculating 60% of heart rate reserve. VO<sub>2</sub> was evaluated by indirect measurement, before and after the 8 weeks of the program. Every exercise session, 2 blood samples, before and after exercise, were collected to analyze CK. This procedure was performed before starting the program and every 15 days. To evaluate quality of life, Medical Outcomes Study 36-Item Short Form Health Survey (SF-36) was applied 2 times. Results Initial VO<sub>2</sub> - mL x kg (-1) x min (-1) - was 12.6 and after the eight weeks increased to 16.0. Before initiating the exercise program, the CK serum concentrations was 846 U/L. As described before, in four days, blood samples were collected before (BS) and after every exercise session (AS). 15 days (after initiating exercise): BS – 714; AS – 785 U/L; 30 days: BS – 654; AS – 706 U/L; 45 days: BS – 586; AS – 598 U/L; 60 days: BS – 863; AS – 868 U/L. The SF-36 results showed increases in 5 of the 8 domains analyzed, demonstrating that quality of life was improved at the end of the program. **Discussion** Our results showed that moderated aerobic exercise can improve VO<sub>2</sub> values in patients with MAD, after 8 weeks, as occurs with individuals that practice regular exercise activity. CK is useful as an indirect marker of muscle damage. During the eight weeks, the CK serum concentrations, before initiating exercise sessions, reduced compared to first analysis performed, except for the last analysis. We believe that the reason for this increase, is due before the last exercise session, according to patient report, he did not sleep during the night and went straight to the gym. These results corroborates with literature, that showed reduction in CK in patients with MAD that performed different exercises programs, suggesting reduction in muscle damages, which collaborates to the management of other symptoms of MAD, resulting in better quality of life for the patient. **References** Moustafa S., Patton DJ., Connelly MS. (2013). *Heart Lung Circ*, 18.

##### SOMATOTYPING OF THE SWISS JUNIOR AND ELITE NATIONAL JUDO TEAM - A DESCRIPTIVE STUDY

Clijssen, R.1,2,3, Spieser, L.1, Rucker, A.M.L.1, Cabri, J.1, Clarys, P.2

*1. University College Physiotherapy „Thim van der Laan“, Switzerland 2. Vrije Universiteit Brussel, Belgium 3. SUPSI Landquart, Switzerland*

**Objective** To establish the anthropometrical characteristics and the hand grip strength of the Swiss junior and elite judo national team. **Methods** 24 members, 19 males (23.01 ± 4.91 years) and five females (19.95 ± 2.02 years), were measured. The following anthropometric measurements were carried out: body size, body weight, skinfolds (subscapular, biceps, triceps, supraspinal, abdominal, calf) bicondylar humerus and femur breadths, upper arm and calf circumferences, body fat % (Tanita scale). Based on these measurements BMI and determination of somatotypes were calculated. In addition, the handgrip strength was measured. The anthropometric measurements were carried out in accordance with ISAK guidelines. **Results** There were anthropometric differences between the Swiss male juniors and elite male judokas in muscular components and between the Swiss athletes and the athletes of the reference studies. The mean somatotype of the male judokas was 2.2 ± 0.8 for the endomorphy, 6.0 ± 0.9 for the mesomorphy and 2.0 ± 0.7 for the ectomorphy. The mean somatotype was balanced mesomorph. The mean handgrip strength of male judokas was 47.4 ± 6.7kg. The mean somatotype of female judoka was 3.7 ± 1.2 for the endomorphy, 4.9 ± 0.7 for the mesomorphy and 1.5 ± 0.3 for the ectomorphy. The mean somatotype was mesomorphic endomorph. The mean hand grip strength of the female judoka was 27.0 ± 3.1kg. **Conclusion** Somatotyping and handgrip strength values indicate the importance of muscularity in judo performance. All results are in agreement with the literature. **References** Degotte F, Jouanel P, Bègue RJ, Colombier M, Lac G, Peguinot J M, Filaire E. ##### SPORT SPECIFIC ADAPTATIONS IN THE SHOULDER IN ADOLESCENT ELITE HANDBALL PLAYERS. A RANDOMIZED CONTROLLED TRIAL

Asker, M.1, Skillgate, E.1,2

*1. Scandinavian College of Naprapathic Manual Medicine 2. Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden*

**INTRODUCTION:** Handball includes repetitive overhead motions in the shoulder girdle (1). Sports related adaptations in the shoulder girdle in adolescent elite tennis and baseball players are associated with shoulder injuries (2-3). Knowledge is missing regarding prevalence of such adaptations and about possible treatment strategies in adolescent elite handball players. The aim of this study was to 1. Investigate whether adolescent elite handball player have a shorter pectoralis minor muscle (PM) and decreased internal rotation (IR) in the glenohumeral joint on their dominant side compared with the non-dominant side, and 2. To evaluate the effect of soft tissue manipulation (STM) combined with self-stretching (SS) on such adaptations. **METHODS:** Two-hundred and fifty-one adolescent Swedish elite handball players, 160 boys, aged 15.5 (± 0.9) and 92 girls aged 15.3 (± 0.9), were screened for PM length, shoulder posture and glenohumeral joint rotation mobility using a digital caliper and a goniometer. Sixty five shoulders from 33 adolescent elite handball players, 16 boys aged 15.4 (± 0.9) and 17 girls aged 15.4 (± 0.9), were randomized to either STM and SS of the PM or placebo treatment in form of SS of the

upper part of the pectoralis major muscle. PM length and SP was measured right before and after treatment. Perceived mobility in the shoulders was measured direct after treatment and after 14 days. RESULTS: The players showed a significantly shorter PM (0,9 cm 95% CI 0,5-1,1), a gleno-humeral internal rotation deficit (11,2 degree 95% CI 9,0 - 13,0) and a more rounded SP on the dominant side (0,8 cm 95% CI 0,7-1,1). The index group showed a significantly greater increase in PM length than the control group (0,5 cm 95% CI 0,2 to 0,7) after treatment, but there were no significant differences in SP. DISCUSSION: Adolescent elite handball players have shoulder adaptations in form of shorter PM and poorer internal rotation in their dominant side compared with the non-dominant. SMT and SS may increase the length of PM, especially on the dominant side. To evaluate long lasting effects and the clinically relevance, further studies is needed. 1. ### AWARENESS OF GENITAL EXAMINATION IN MALE ELITE SOCCER PLAYERS

Mónaco, M.1,2, Til, L.1,3, Avendaño, E.1, Verdugo, F.4,5, Montoro, B.1,6, Drobic, F.1,3

(1) Medical Services FCBarcelona. (2) XARXA Saniària i Social Santa Tecla, ABS El Vendrell (Tarragona, Spain). (3) GRSANE CAR– CST (Barcelona, Spain) (4) School of Medicine, University of Chile. (5)

INTRODUCTION: The consensus regarding the medical exam prior to sports participation recommends performing examination of the genitals. The literature references about this topic are scarce. In sports there is no awareness about the importance of genital exploration at Pre-Participation Physical Examination (PPE). It may be due to abnormal findings at genital examination do not affect sport performance, and they are not usually life threatening diseases for athletes. The incidence of genitourinary abnormalities is low. The genital examination in young patients is a simple, fast, and routine procedure. It is important for diagnosis of testicular diseases like varicocele, testicular hydrocele, cryptorchidism, etc. Therefore, early detection and treatment are important for prognosis and fertility in adulthood. Varicocele and cryptorchidism are the most common disorders in this age group. The subclinical varicocele in young athletes seems to progress faster, compared to non-athletes, which may lead to changes in the quality of semen and therefore problems with fertility. These findings highlight the importance of performing a genital examination, at least until the patient has completed puberty. OBJECTIVE: To describe the incidence of genital abnormalities in adolescent athletes METHODS: During PPE protocol we examined 280 elite football players between the 2010-2011 and 2011-2012 seasons, boys ages 7-17. Evaluated by the same physician, who palp and measured: both testicles and spermatic cord before and after the Valsalva maneuver. RESULTS: No athlete refused to be examined. Of 280 players evaluated, ages 7 to 17 years old, fifteen genital anomalies were detected, representing 5.36 cases /100 subjects (confidence interval 95% (2,70-8,01), and nine of them (3.2%) had clinical varicocele (VC) representing 3.21 cases / 100 subjects (confidence interval 95% (1,14-5,29). Only two (13%) of the 15 athletes affected had prior knowledge of their pathology, and 13 (87%) were unaware of their abnormality. All patients were referred to their pediatricians to confirm the diagnosis and one of them required early surgery. CONCLUSION: The preventive health exam at pediatric age is the time to detect abnormalities to prevent adulthood consequences. In Spain, there is no regular medical control during late puberal or post-puberal time, and it's unusual the genital examination at PPE. Although this study shows a low incidence of genital abnormality in our population, only 13% were aware of it prior to our assessment, 87% were unaware of their abnormality. These findings demonstrate that the genital examination of the pediatric population is practical, simple and effective to identify genital abnormalities undetected by pediatric health checks or to appear afterwards. Further research is required to determine whether sport predisposes to genital abnormalities and emphasize the genital examination at PPE as comprehensive health strategy

### WAIST CIRCUMFERENCE IS A BETTER PREDICTOR OF MOTOR ABILITY IN KINDERGARTNERS THAN BMI

Hoffmann, S.1, Brendel, C.2, Simon, P.2

1: University of Bayreuth; 2: Johannes Gutenberg-University of Mainz

Introduction Recent data indicate that prevalence of childhood overweight especially increases around the age of school entry (Hoffmann et al., 2012). Parallel to an increase in childhood obesity, motor abilities (MAs) have deteriorated by an average of 10% (Bös, 2003). Little is known about the relationship between anthropometric measurements and MA at pre-school age (De Toia et al., 2009), and published data were only related to BMI. Therefore, the aim of the present study was to analyse whether waist circumference (WC) predicts significantly to MA in kindergartners. Methods Data of 764 subjects aged 3-6 years were obtained from a cross-sectional health study conducted in Mainz, Germany. BMI and WC-SDS were calculated relative to international proposed values (Cole et al., 1992). MA was collected with multiple test items to determine the MAs of coordination, speed strength, muscular endurance, and speed (Bös et al., 2004; De Toia et al., 2009). Adjusted for covariates (SES, parental BMI, media time), correlation analysis and logistic regression were conducted to estimate the effect of WC on MA. Results Below-average motor abilities (BAMA) were found in 46.0%. No relationship to BMI has been observed ( $p=0.247$ ). Children with BAMA had significantly higher WC compared to the reference group (OR: 1.56, 95% CI: 1.16-2.11;  $p=0.004$ ). The risk decreases with age (0.54, 0.42-0.71;  $p<0.001$ ) and higher physical activity levels (0.58, 0.42-0.78;  $p<0.001$ ). Discussion Overall, WC is a more specific predictor to determine abdominal obesity in children than BMI (Savva et al., 2000). Furthermore, our findings suggest that altered WC appeared to be linked to measurements of MA already in kindergartners. We therefore propose that WC is a better predictor of MA than BMI. ## BASKETBALL TRAINING EFFECTS ON GROWTH AND DEVELOPMENT OF YOUNG GIRLS

Antic, T., Dikic, N., Andjelkovic, M., Vukasinovic-Vesic, M., Baralic, I.

*Sports Medicine Association of Serbia*

**Introduction** Growth and development are influenced by a variety of genetic and external factors. Only favorable environmental conditions will lead to the full expression of genetic potential without jeopardizing maturation. Considering the obvious impact of physical activity on children's health status the objective of this study was to assess the influence of basketball training on growth and development of young girls in the period of 18 months. **Methods** Girls were divided into two groups: research group (RG) consisted of 25 girls who played basketball 5-8 hours per week at beginner level (age  $13,86 \pm 0,89$ ) and control group (CG) of 25 girls who were not involved in any sports (age  $13,90 \pm 0,74$ ). Anthropometric and body composition measurements, together with functional and motor tests were performed. Somatic growth was assessed by height, weight, body mass index, arm span and body fat percentage (FAT%). Functional capacity tests included the evaluation of aerobic endurance (AE)-VO<sub>2</sub> max obtained by maximal test on a treadmill and anaerobic endurance (ANE)-300 yards test. Following motor skills were tested: static power (SP)-dynamometry, repetitive power (RP)-push-ups, sit-ups, explosive power (EP)-vertical jump, flexibility (F) and agility (A)-T test. The questionnaire regarding the menstrual status was filled out by both groups. All measurements were performed at the beginning of the study and after 18 months. Student T test was used for statistical analysis. **Results** Initial measurements: There was no statistically significant difference between two groups in terms of anthropometry (APM), FAT%, SP, EP and F ( $p > 0.05$ ). On the other hand, statistically significant difference was found regarding AE and ANE, as well as RP and A ( $p < 0.01$ ). Menarche was reported at average age of  $12.04 \pm 1.06$  for RG, and  $12.3 \pm 1.26$  for CG. The average period between two menstrual cycles was  $29.0 \pm 2.9$  days for RG and  $30.9 \pm 5.26$  days for CG. Measurements after 18 months period: No statistically significant difference between RG and CG was obtained regarding APM, FAT% and F ( $p > 0.05$ ). Statistically significant difference between two groups existed in terms of AE and ANE, SP, RP, EP and A ( $p < 0.01$ ). No changes in menstrual status were observed. Within RG there was significant increase in AE, SP and EP compared to the initial tests ( $p < 0.01$ ). All measurements in the CG showed an insignificant increase after 18 months ( $p > 0.05$ ). **Conclusion** Moderate level of basketball training has no negative effects on somatic growth and menstrual status of young girls. Moreover, this type of physical activity has beneficial influence on growth and development in general, as it is associated with cardiovascular benefits and favorable changes and improvements in motor skills which are important for adequate maturation of young girls.

## IMPACT OF CERTAIN MUSCLE GROUPS FUNCTIONAL STATE ON THE YOUNG BASKETBALL PLAYERS EFFECTIVENESS

Mekhdieva, K., Domanov, S.A., Blyakhman, F.A.

*URAL FEDERAL UNIVERSITY*

**Introduction** The HUBER® MOTION LAB (LPG Systems, France) is a multifunctional device for musculoskeletal system functional state evaluation and neuromotor rehabilitation, and it has "real-life situation" advantages for sports training application (Couillandre A. et al., 2008). The aim of this study was to determine possible correlation between functional state of specified muscle groups obtained with the HUBER use and the game effectiveness of young basketball players. **Methods** Eleven basketball players of the URFU Student Basketball team (MSBL) underwent the examination of musculoskeletal functional state with the HUBER use during training period before the MSBL game. All players signed the consent for study participation. The following parameters of musculoskeletal system functional state were determined: maximum pushing and pulling force right (MFRpush and MFRpull) and left (MFLpush and MFLpull), coordination, pushing and pulling muscle endurance (Epush and Epull), reaction rate. Furthermore, the indices of cardiorespiratory system during stress test with treadmill (Schiller AG, Switzerland) use were determined as well. Evaluation of effectiveness was based on game statistic indices monitoring. As a result, the number of effective actions (EFF) and points per game (PPG) were calculated. The statistic software package IBM SPSS was used for statistical analysis. **Results** On average, the players had  $21.8 \pm 0.6$  years,  $198.5 \pm 7.4$  cm height and  $93.4 \pm 11.3$  kg body weight. We found close correlations between EFF and MFRpull ( $r=0.61$ ,  $n=11$ ,  $p < 0.05$ ); EFF and MFLpull ( $r=0.63$ ,  $p < 0.05$ ); EFF and Epush ( $r=0.62$ ,  $p < 0.05$ ); PPG and MFRpull ( $r=0.61$ ,  $p < 0.05$ ); PPG and MFLpull ( $r=0.62$ ,  $p < 0.05$ ); PPG and Epush ( $r=0.66$ ,  $p < 0.05$ ). No significant correlations between EFF or PPG and any parameter of cardiorespiratory system function were found. **Discussion** The research has mainly an assessed value because of limited number of sportsmen examination. Perhaps, the lack of correlation between the cardiorespiratory system parameters and game effectiveness ones is the reason of little number of observations. Meanwhile, we found out that the player effectiveness depended on the indices, characterizing pulling, e.g. involving mainly posterior surface muscles, flexors of upper limbs, hips and shins. On the contrary, the pushing force indices didn't impact significantly on EFF and/or PPG. At the same time, the increase of Epush resulted in the increase of EFF and/or PPG. We concluded that the pushing muscle endurance is the most important determinant of young basketball player effectiveness than the pushing muscle maximum force. **References** Couillandre A., Duque Ribeiro M.-J., Thoumie P., Portero P. ## OSTEOGENIC EFFECT IN PRE-PUBERTAL ATHLETES PRACTICING DIFFERENT IMPACT-LOADING SPORTS

Cavedon, V.I., Milanese, C.I., Piscitelli, F.I., Zancanaro, C.I

*I: School of Exercise and Sport Sciences, University of Verona*

**Introduction** Physical activity involving weight bearing or jumping is beneficial per se to bone mineral accrual in children. However, there is large evidence that sports involving high-impact loading (i.e., generated ground reaction forces greater than or equal to 3 times body weight) tend to produce a better overall osteogenic response than sports without impact loading (i.e., generated ground reaction forces = 0 times bodyweight). The aim of this study was to compare the effect of different impact loading sports on bone quality and body composition of pre-menarcheal athletes. **Methods** Thirty pre-menarcheal girls (aged  $11.1 \pm 1.33$ (SD)) participating in volleyball (VOLLEY,  $n=10$ ) and artistic gymnastics at high (HGYM,  $n=10$ ) and low (LGYM,  $n=10$ ) intensity training underwent total body DXA analysis. Body composition (bone mineral content (BMC), fat-free soft tissue mass (FFST), fat mass (FM), and %FM) was assessed by dual-energy X-ray absorptiometry (DXA) at the total body and regional (arms, legs, trunk) level as well as specific axial skeleton sites (thoracic and lumbar spine, pelvis). Normality of data was assessed with the Kolmogorov-Smirnov test. Comparison of the three groups of pre-menarcheal athletes was performed with univariate ANOVA taking "group" as the within-subjects factor. Post-hoc analysis used Bonferroni's correction for multiple comparisons. Statistical analysis was performed with SPSS v.16. Differences were considered significant when  $P \leq 0.05$ . **Results** After adjusting for body size, total body composition measurements were all significantly ( $p < 0.01$ ) different in the three groups of pre-menarcheal athletes. VOLLEY had lower BMC and FFST, and greater FM and %FM vs. both HGYM and LGYM. The main difference between LGYM and HGYM was greater %FM in the former.

Similar results were found at the regional level (but for similar BMC in the legs) and at lumbar spine and pelvis. Linear regression analysis showed that a model using FFST mass as the independent variable is able to explain more than 90% of variance in total body less head BMC in the whole group of impact loading athletes, whereas introducing %FM in the model did not improve its predictive power. Discussion The findings of this study provide evidence that greater bone mineral accrual takes place in pre-menarcheal impact loading athletes participating in artistic gymnastics vs. volleyball and the dose of impact loading activity mainly affect %FM; moreover, results suggest that BMC in the weight-bearing skeleton is strongly.

### VARIABLE PARAMETERS OF BODY COMPOSITION OF YOUNG HOCKEY PLAYERS

Rylova, N.1,2, Khafizova, G.1

*Volga Region State Academy of Physical Culture, Sport and Tourism (Kazan, Russia)*

**Introduction** Body composition is the result of long-term adaptation to the effects of specific training loads, and it reflects different priorities of energy mechanisms (aerobic, mixed, anaerobic). Accordingly, the level of labile body components, and their ratio may be considered as markers of different types of training. In the case of individual analysis it allows to evaluate indirectly the level of general physical fitness, adequate balance between physical work and recovery, and to focus on the priority of physical effects (Portal et al. 2010). The aim of the study was to evaluate the level of body fat and muscle mass in young male hockey players. **Methods** We examined nine young hockey players (1 group, main). Various anthropometric measurements were evaluated (weight, height, circumferences and skinfold thicknesses). The following anthropometric indices were derived from the obtained data: fat mass (FM, kg), relative FM (%), muscle mass (MM, kg), relative MM (%). For this we used modified by Lutovina et al. (1970) anthropometric equations of Mateika. The results were then compared with the literature data (young male hockey players, 2 comparison group; Abramova 2010). Groups of young athletes were matched by the following parameters: body weight ( $31.37 \pm 4.5$  kg and  $28.4 \pm 4.5$  kg, respectively), height ( $134.3 \pm 5.75$  cm and  $131.4 \pm 5.7$  cm) and duration of sports experience ( $3.25 \pm 1.16$  years and  $2.7 \pm 1.5$  years, respectively), age (all of young athletes were 8 years old). **Results** The two groups of young athletes showed similar measurements of the following anthropometric characteristics: relative FM ( $17.13 \pm 7.17\%$  vs.  $13.8 \pm 8.6\%$ ,  $P > 0.05$ ), MM ( $12.07 \pm 3.96$  kg vs.  $12.7 \pm 2.1$  kg,  $P > 0.05$ ). Moreover, first group of athletes had higher fat mass ( $5.53 \pm 2.79$  kg and  $3.5 \pm 1.9$  kg,  $P < 0.03$ ), and lower percentage of muscle mass ( $38.35 \pm 11.48\%$  vs.  $44.8 \pm 1.8\%$ ,  $P < 0.02$ ) in comparison with the second group. **Discussion** Low levels of muscle mass and medium level of fat mass corresponded to the age of young hockey players, and pointed to the low exercise tolerance of children, especially to high intensity work. So, planning of training process should be in accordance with the age and the level of physical fitness of children. **References** Portal S. Body fat measurement in elite adolescent volleyball players: correlation between skinfold thickness, bioelectrical impedance analysis, air-displacement plethysmography, and body mass index percentiles / S. ### ANTHROPOMETRY, MATURITY AND PERFORMANCE IN YOUNG SOCCER PLAYERS DIVIDED IN AGE-QUARTILES

Gil, S.M.1, Badiola, A.1, Bidaurrazaga-Letona, I.1, Zabala-Lili, J.1, Santos-Concejero, J.1, Gravina, L.2, Lekue, J.A.3, Granda, C.1

*University of the Basque Country (UPV/EHU)*

**1**Department of Physical Education and Sport, University of the Basque Country, UPV/EHU. **2**Department of Nursing, UPV/EHU. **3**Athletic Club de Bilbao **Acknowledgements** This study was partially supported by a grant from the Basque Government (UE09+/07) **Introduction** The presence of the Relative Age Effect (RAE) has been widely reported; however, its underlying causes have not yet been clearly determined. The aim of this study was to analyze if anthropometry, maturity and performance were different amongst older and younger soccer players born in the same year. **Methods** Eighty-eight young soccer players, all born in 2001, participated in the study (age  $9.75 \pm 0.30$ , range: 9.16-10.37). Anthropometric measurements, performance tests (30m sprint, 30m agility, Yo-yo IT test, CMJ, hand dynamometry) and the estimation of the maturity status were carried out (Mirwald et al., 2002). Also, to estimate an overall performance, a SCORE was calculated summing up the results (z-scores) of the performance tests. The 75th, 50th and 25th percentiles (Pc) of the chronological age were calculated. According to these Pc, four groups (quartiles) of players were obtained: Q1= players whose age was above Pc 75th (they were the eldest), Q2 (Pc50-75), Q3 (Pc25-50) and Q4= age below Pc 25th (the youngest). Measurements were compared amongst the groups of players of the four age-quartiles. Mean  $\pm$  standard deviations are shown and the differences were assessed using a Student t-test or a U-Mann-Whitney test and also Cohen's d. **Results** Most players (65.9%) had been born in the first half of the year. Older players were taller (Q1:  $140.85 \pm 5.58$  vs. Q4:  $137.13 \pm 4.51$  cm,  $p < 0.05$ ), had longer legs (Q1:  $66.10 \pm 2.81$  vs. Q4:  $64.11 \pm 2.99$  cm,  $p < 0.01$ ) and a larger fat-free mass (Q1:  $29.54 \pm 3.32$  vs. Q4:  $27.37 \pm 2.78$  kg,  $p < 0.05$ ). Maturity offset was closer in the older boys (Q1:  $-3.50 \pm 0.36$  vs. Q4:  $-3.93 \pm 0.23$  kg,  $p < 0.05$ ); however age at peak height velocity was similar. Older boys performed better ( $p < 0.05$ ) in velocity (Q1:  $5.07 \pm 0.27$  vs. Q4:  $5.37 \pm 0.42$  s) and agility (Q1:  $5.89 \pm 0.38$  vs. Q4:  $6.24 \pm 0.42$ ) and particularly in the overall SCORE of performance (Q1:  $2.03 \pm 3.55$  vs. Q4:  $-1.66 \pm 3.41$ ,  $p < 0.01$ ). Older players also performed better in the Yo-yo IR1 (Q1:  $626.66 \pm 285.49$  vs. Q4:  $470.47 \pm 216.85$  m) and the CMJ (Q1:  $29.56 \pm 3.13$  vs. Q4:  $27.10 \pm 3.25$  cm) but the differences were not statistically significant; however, the effect size was medium to large ( $d = 0.616$  and  $0.771$ , respectively). **Conclusion** Older players were taller and displayed a better performance which may underlie the RAE through a selection of soccer players towards the outstanding players. **References** Mirwald RL, Baxter-Jones AD, Bailey DA, Beunen GP. An assessment of maturity from anthropometric measurements. *Med Sci Sports Exerc.* 2002, 34, 689-94

### FLUID INTAKE AND SWEAT RATE OF YOUNG ELITE BASKETBALL PLAYERS

Vukasinovic Vesic, M.1, Dikic, N.1,2, Andjelkovic, M.1, Antic, T.1, Turner, R.2, Stokes, R.2, Gunter, H.2

*Sports Medicine Association of Serbia, FIBA Europe*

**Introduction** FIBA Europe, as active International Federation in fields of sports medicine, supplementation and anti-doping, has decided to monitor hydration of basketball players on the one major European competition. The aim of this study was to determine sweat rate and fluid intake of young elite basketball players. Sweat rates depend principally on factors such as the environmental conditions, choice of clothing or exercise intensity and they also vary greatly between individuals. Exercise can elicit high sweat rates and substantial water and electrolyte losses during sustained exercise, particularly in warm-hot weather. **Method** Ninety-six basketball players of eight national teams were assessed during the official FIBA Europe U20 Championship Division B. In order to determine sweat rate and fluid intake we measured body mass of all players before and after one game, the quantity of consumed fluid and urine output during the game, as well

as temperature and humidity in the sports hall. Results Players age was  $19\pm 0.79$  years. After the game body mass loss was  $0.9\pm 0.7$  kg, percentage of dehydration  $0.99\pm 0.7\%$ , total fluid intake  $1868\pm 816$  ml (range 435 – 3987) and sweat rate  $2.7\pm 0.9$  L/h (range 5.54 - 1.16). Urine output during the game was  $55\pm 61$  ml. Ambient temperature was  $30\pm 2^\circ\text{C}$  and humidity  $55\pm 4\%$  on average. We found statistically significant correlation between sweat rate and: Usg ( $p<0.05$ ), Uosmol ( $p<0.01$ ), body mass loss ( $p<0.01$ ), FI ( $p<0.01$ ), BSA ( $p<0.01$ ) and percentage of dehydration ( $p<0.01$ ). Discussion Most of the athletes failed to match sweat losses during the game and they were significantly dehydrated. Recommendations for fluid and electrolyte replacement must be carefully considered and monitored in basketball players to promote safe hydration. Players, as well as coaches and team doctors, should receive encouragement and educational information about suitable hydration strategies.

### **BENEFICIAL EFFECTS OF EXERCISE TRAINING IN CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS**

Roschel, H., Prado, D.M.L., Benatti, F.B., De Sá-Pinto, A.L., Hayashi, A.P., Gualano, B., Pereira, R.M.R., Sallum, A.M.E., Bonfá, E., Silva, C.A.

*University of Sao Paulo*

**Introduction** Exercise training has emerged as a promising therapeutic strategy to counteract physical dysfunction in adult systemic lupus erythematosus. However, no longitudinal studies have evaluated the effects of an exercise training program in childhood-onset systemic lupus erythematosus (C-SLE) patients. **Objective** To evaluate the safety and the efficacy of a supervised aerobic training program in improving the cardiorespiratory capacity in childhood-onset systemic lupus erythematosus (C-SLE) patients. **Methods** Nineteen physically inactive C-SLE patients were randomly assigned into two groups: trained (TR,  $n=10$ , supervised moderate-intensity aerobic exercise program) and non-trained (NT,  $n=9$ ). Gender-, BMI- and age-matched healthy children were recruited as controls (C,  $n=10$ ) for baseline (PRE) measurements only. C-SLE patients were assessed at PRE and after 12 weeks of training (POST). Main measurements included exercise tolerance and cardiorespiratory measurements in response to a maximal exercise (i.e.: peak  $\text{VO}_2$ , chronotropic reserve [CR], and the heart rate recovery [ $\Delta\text{HRR}$ ] (i.e. the difference between HR at peak exercise and at both the first [ $\Delta\text{HRR1}$ ] and second [ $\Delta\text{HRR2}$ ] minutes of recovery after exercise). **Results** The C-SLE NT patients did not present changes in any of the cardiorespiratory parameters at POST ( $p>0.05$ ). In contrast, the exercise training program was effective in promoting significant increases in time-to-exhaustion ( $p=0.01$ ;  $\text{ES}=1.07$ ), peak speed ( $p=0.01$ ;  $\text{ES}=1.08$ ), peak  $\text{VO}_2$  ( $p=0.04$ ;  $\text{ES}=0.86$ ), CR ( $p=0.06$ ;  $\text{ES}=0.83$ ), and in  $\Delta\text{HRR1}$  and  $\Delta\text{HRR2}$  ( $p=0.003$ ;  $\text{ES}=1.29$  and  $p=0.0008$ ;  $\text{ES}=1.36$ , respectively) in the C-SLE TR when compared with the NT group. Moreover, cardiorespiratory parameters were comparable between C-SLE TR patients and C subjects after the exercise training intervention, as evidenced by the ANOVA analysis ( $p>0.05$ , TR vs. C). SLEDAI-2K scores remained stable throughout the study. **Conclusion** In conclusion, this study demonstrated for the first time that a three-month supervised moderate-intensity aerobic exercise training program can be safe and effective in ameliorating the cardiorespiratory capacity and the autonomic function in C-SLE patients. These findings stress the potential role of exercise training in the management of C-SLE, strengthening previous evidence of the beneficial effects of exercise in other pediatric rheumatic diseases.

### **ACL INJURY RISK IN FEMALE BASKETBALL PLAYERS DURING MATURATION**

Otsuki, R., Fukubayashi, T.

*Waseda University*

**Introduction** Anterior cruciate ligament (ACL) injuries are frequently seen in basketball players, especially in girls during maturation. Biomechanical factors such as knee valgus motion have been associated with ACL injuries. Understanding when young female athletes increase biomechanical ACL injury risk factors may help identify the optimal timing to implement injury prevention program. Therefore, the purpose of this study was to evaluate ACL injury risk in female basketball players during puberty. **Methods** Ninety-two female basketball players between 9 and 17 years old participated in the study. They were classified based on maturation stages: early pubertal, middle pubertal, late pubertal, and post pubertal. ACL injury risk was evaluated using a newly developed ACL injury risk prediction algorithm (Myer et al., 2010), which consists of measurements of tibia length, weight, quadriceps/hamstring ratio, two-dimensional knee valgus motion and knee flexion range of motion during a drop vertical jump. ACL injury risk (probability of high knee abduction moment), knee valgus motion and knee flexion range of motion were compared among four subject groups. **Results** Early pubertal stage demonstrated smaller knee valgus motion than middle and post pubertal stages ( $p<0.05$ ). Similarly, knee flexion range of motion was greater in early pubertal stage when compared with late and post pubertal stages ( $p<0.01$ ). ACL injury risk was significantly lower in early pubertal stage compared with other stages ( $p<0.01$ ). **Discussion** In this study, height and weight were significantly increased between early and middle pubertal stages. Following this rapid growth, knee valgus motion was significantly increased. This finding supported previous studies that reported increased knee valgus angle in late and post pubertal females (Hewett et al. 2004). This study also found that knee flexion angle was decreased following the growth spurt. Decreased knee flexion angle during landing is commonly observed during actual ACL injuries (Koga et al., 2010) and might be a risk factor of ACL injury. These biomechanical factors, as well as a rapid increase in height and weight, contributed to increased ACL injury risk. The results of this study suggested that early pubertal stage might be the important time period. Implementation of injury prevention program during this period might be needed. **References** Myer G, Ford K, Khoury J, Succop P, Hewett T. (2010). *Clinic Biomech*, 25, 693-699. ### **EFFECTS OF ROPE JUMPING ON PHYSICAL FITNESS IN CHILDREN WITH ADHD**

Lin, W.S.1, Su, C.T.2, Yang, A.L.1

*1:Taipei Physical Education College; 2:Fu Jen Catholic University*

**Introduction** As one of the most prevalent pediatric disorders, attention deficit hyperactivity disorder (ADHD) is characterized by a persistent pattern of inattention and/or hyperactivity-impulsivity. Recently, the concerns of problems of physical performance in children with ADHD have been raising. However, studies that explored the physical performance, such as physical fitness, and the effects of exercise intervention in this population (Hopkins et al., 2009; Verret et al., 2012) remained insufficient. Thus, the purposes of this study were to (1) compare the physical fitness between typically developing children and children with ADHD; (2) evaluate the influences of the long-term rope jumping intervention on physical fitness in children with ADHD. **Methods** We recruited 30 children, including 20 children with ADHD and 10 matched typically developing children (normal group), to participate in this study. The recruited children with ADHD were randomly assigned into control (ADHD-CON) and exercise (ADHD-EX) groups. Participants in the ADHD-EX group performed an eight-weeks exercise intervention, i.e. rope jumping, for 30 minutes per day, 3 days per week. Physical fitness assessment included height, weight, body

mass index, waist-hip ratio, body fat, sit and reach test (flexibility), sit-up test for 1 minute (muscle endurance), standing long jump (instantaneous power), and 3-min step test (cardiorespiratory endurance). The assessment was conducted for 3 groups at the baseline and for 2 ADHD groups at the end of the intervention. Results Our results indicated poorer physical fitness in the ADHD groups compared with the normal group, including sit and reach test, sit-up test for 1 minute, and standing long jump. After eight weeks of exercise intervention, height and weight were increased and waist-hip ratio was reduced in the ADHD-EX group in comparison with the ADHD-CON group. Also, body fat increased significantly in the ADHD-CON group, but remained the same for the ADHD-EX group. The performance for tests of sit and reach, standing long jump, and sit-up for 1 minute in the ADHD-EX group were significantly greater than the ADHD-CON group. Discussion This study confirmed the problems of physical fitness for children with ADHD. Our findings suggested that eight-weeks rope jumping could improve parts of physical fitness for children with ADHD, including height, weight, waist-hip ratio, body fat, flexibility, muscle endurance, and instantaneous power. #### DIPLOMA IN MOUNTAIN MEDICINE PROGRAM IN JAPAN

Natsui, H., Masuyama, S., Kamikomaki, N.

*Japan Women's College of Physical Education*

Introduction Diploma in Mountain Medicine (DiMM) program in Japan started in May/2010. This diploma is based on Union Internationale Des Associations D'alpinisme Medical Commission (UIAA-MedCom), International Commission for Alpine Rescue (ICAR), and International Society of Mountain Medicine (ISMM). This program is operated by Japanese Society of Mountain Medicine (JSMM), in co-operation with Japan Mountaineering Association and National Mountaineering Training Center Japan. Methods This program includes 6 clusters, 1 ; Utsunomiya cluster (various medical problems in Japanese mountains), 2 ; Tateyama cluster (mountaineering techniques in summer), 3 ; Matsumoto cluster (pre-hospital evaluation and care), 4 ; Tokyo cluster (basic theory), 5 ; Yatsugadake cluster (mountaineering techniques in winter), and 6 ; Sapporo cluster (rescue technic in mountain and snow activity in Japan). In order to complete the courses, it needs 3 steps; pre-examination paper before each cluster, participation in each cluster, and terminal examination after each cluster. All clusters must be completed within 5 years. Results In May 2010, opening of DiMM program in Japan started 35 registered doctors, and it grew up to 102 doctors (23 female, 79 male) at the end of 2012. Doctors come from various specialties, such as sports medicine, cardiology, neurology, psychology, orthopedics, brain surgery, gynecology, plastic surgery, anesthesiology, emergency medicine, and dentist. Only 9 doctors have been authorized as International Diploma in Mountain Medicine on November 2012. Discussion This DiMM program started in Europe (Austria, France, Germany, Italy, Spain, Switzerland, and UK) from 1998, 3500 doctors registered this program. On the other hand, JSMM joined DiMM program from 2010, 102 doctors registered and only 9 doctors were authorized. It is expected to create more DiMM doctor in Japan.

#### ESTABLISHING SPORT PSYCHOLOGY TRAINING WITHIN ATHLETIC TRAINING CURRICULA

Schoen, C., DiCredico, L., Murphy, J.

*Salem State University*

Context: Despite the requirement that accredited university AT clinical curriculum in the United States includes psychosocial strategies and referral techniques, many AT programs do not schedule sport psychology courses in their curriculum. The purpose of this study was to demonstrate a demand for a course designed specifically to offer coursework covering currently accepted theory-based practices from sport psychology in the area of injury rehabilitation. Design: A three day workshop for 30 athletes training students (ATS) currently placed in clinical internships at area high school and university sites was developed to cover sport psychology principles, psychology of the injured athlete and counseling techniques. The workshop was conducted by the university's sport psychology professor and a licensed social work counselor. At the start of the workshop we asked with open-ended questions what ATS' current perception of sport psychology was and how it can be used in rehabilitation situations. Additionally, we obtained baseline data measuring how often they had used sport psychology techniques in the past, and how often they had ever worked with a sport psychology consultant (SPC) or referred an athlete to one before. This data will be used at a later time to demonstrate competency and proficiency of psychosocial intervention and referral techniques. Results: Using content analysis of the open-ended responses concerning importance of using sport psychology techniques during rehabilitation, our results confirmed what has been reported in similar studies. ATS mostly admitted that they did not know enough sport psychology to use them adequately in rehabilitation while at the same time overwhelmingly reporting that sport psychology techniques are important or very important for the success of rehabilitation. Conclusions: Our findings support studies published in athletic training journals calling for instituting curriculum covering sport psychology principles. Specific content areas that need to be included in these curricula include motivation techniques, establishment of social supports systems and most importantly training ATS to treat athletes holistically with emotional awareness and regulation strategies.

#### RISK FACTORS FOR SPORTS CONCUSSION: A SYSTEMATIC REVIEW

Mc Fie, S.1, Abrahams, S.1, Patricios, J.2, Posthumus, M.1, September, A.V.1

*1. University of Cape Town, 2. Morningside Sports Medicine and Sports Concussion, Johannesburg*

Introduction Concussion is a common sports injury with approximately 1.6-3.8 million sport-related concussions reported in the US annually. Identifying risk factors may assist in preventing these injuries. This systematic review aims to identify such risk factors. Methods Three electronic databases; ScienceDirect, PubMed and Springerlink, were searched using the keywords "RISK FACTORS" or "PREDISPOSITION" in conjunction with "SPORT" and "CONCUSSION" (including truncated forms). The database search was limited to articles published be-

tween 1980 and 2012. Inclusion and exclusion criteria were independently evaluated by two of the authors. Reference lists of relevant studies were screened for additional articles using the same selection method. Only articles with a level of evidence of I, II and III were included (Obremskey et al., 2005). The level of certainty, as previously defined (Sawaya et al., 2007), for each risk factor was determined. Briefly, a high level of certainty was given if the research provided a good risk estimate and produced consistent findings. Moderate certainty was assigned when available evidence was sufficient to determine that there is risk, but confidence estimate was constrained by study quality. Low certainty was given when there was insufficient evidence of risk. Results Sixty nine articles were selected for appraisal. A history of concussion was the only risk factor with a high level of certainty. All 14 studies, including 8 prospective studies, showed that athletes sustaining more than 1 previous concussion had an increased risk of a subsequent concussion. Risk factors with a moderate level of certainty included playing position, sex and match play. Defensive players and forwards were high risk playing positions in American football and ice hockey, respectively. Generally a higher concussion risk was observed for males, across ages and sports, except for soccer in which females often had a higher risk. Concussion proportion was greater in games compared to training in 6 of the 7 studies. The use of protective equipment, age, genetics and playing environment had a low level of certainty. Conclusion Although several risk factors were identified in the appraised studies, poor study methodology limited estimation of concussion risk. Prospective cohort design and consistent measures of risk should be employed in future research.

### **EFFECT OF 1-YEAR RUGBY TRAINING AND PARTICIPATION IN MATCHES ON THE SCORES OF THE CONCUSSION ASSESSMENT TOOL**

Otomo, M.1, Torii, S.2, Otuka, S.1, Iwanuma, S.2, Saho, Y.2, Fukubayashi, T.1

1: *Graduated School of Sport Sciences, Waseda University*, 2: *Faculty of Sport Sciences, Waseda University*

**Introduction** Sport-related concussion attracted attention of sports medical personnel in recent years. Therefore, Japan rugby association has recommended the measurement of baseline testing using the assessment tool of concussion at the start of the season. Purpose of this study was to research the effect of 1-year rugby training and participation in matches on the scores of the concussion assessment tools (SCA). **Methods** Subjects are adult male rugby players in Japan. To examine differences in SCAs at baseline testing between 2011 and 2012 season, concussion assessment used included the Standardized Assessment of Concussion (SAC), Balance Error Scoring System (BESS), Trail Making Test form A and B (TMT) and Symbol Digit Modalities test (SDM) (Tamerah and Michael, 2009; P McCrory et al., 2009). In addition, we counted the number of matches, playing time, the number of impact and tackle in each player of 2011 season matches, investigating the relationship of SCAs and these match data. **Results** There was no significant difference between SCAs in 2011 and 2012, except for TMT improved. Also, there were no significant correlations between SCAs and each parameter of match data. **Discussion** Improvement of TMT scores was considered to be learning effect. However, it is considered that it is more effective to use objective neuropsychological tests (eg: SAC, BESS) than using pencil and paper tests (eg: TMT) for concussed athletes (Tamerah and Michael, 2009). In addition, no significant difference was found on comparison between 2011 and 2012 season on the scores of SCAs. One of the reasons was that the player who injured concussion was only one. Another reason was that players of this team engaged to the prevention training of concussion by wrestling. Moreover, it means that training and matches of rugby has no effect on SCAs in 1 season. But there is a style of play in each team. Therefore this result may be special result of this team. As the playing style is different between teams, these results may limited to this team. **Conclusion** During 2011 season, only one player had concussion. Very low incidence of concussion and practice of prevention training for concussion recommended would decrease the effects of rugby participation on SCAs. **References** Tamerah N, Michael S. (2009). *Journal of Athletic Training*, 44(4), 405-409. P McCrory, W Meeuwisse, K Johnston, J Dvorak, M Audry, M Molloy, R Cantu. (2009). *British Journal of Sports Medicine*, 43(suppl 1), i76-i84.

### **DIURNAL PROFILES OF Pedometer-DETERMINED PHYSICAL ACTIVITY IN OLDER PRIMARY HEALTH CARE PATIENTS**

Bloch, A., Hinrichs, T., Platen, P., Moschny, A.

*University of Bochum*

**Purpose** Although the benefits of regular physical activity (PA) are widely known, many older adults are insufficiently physically active. In order to design appropriate PA programs for older people, it is important to better understand their PA behaviour. Therefore, the aim of this study was to analyse the diurnal profiles of PA in a sample of adults aged 70 years and over. **Methods** 213 older (70+), chronically ill and mobility restricted primary health care patients were recruited via their general practitioner. Participants wore a pedometer (Omron Walking Style Pro HJ-720IT-E2) on six consecutive days and documented whether or not they had worn the device for the whole day. Only participants who wore the pedometer on at least 2 workdays (Monday-Saturday) and on a Sunday with a minimum of 300 steps per day were included in the analysis. Mean steps per day (d) and per hour (hr) were analysed descriptively for all participants as well as stratified by gender and age group (<80/80+ years). **Results** A total of 149 primary health care patients (74.5% women) with a median age of 80 (range 70-94) years were included in the analysis. The overall PA averaged 3267±1901 steps/d (men: 3037±1688 steps/d, women: 3346±1969 steps/d; <80 years: 3721±2017 steps/d, 80+ years: 2819±1675 steps/d). Participants walked 3340±1879 steps on workdays and 2890±2687 steps on Sundays. Analyses by gender and age group showed the same trend. Looking at diurnal profiles, there were two peaks at 10-11 am (373±318 steps) and at 15-16 pm (316±336 steps) interrupted by a period of lower PA with a low point at 13-14 pm (230±241 steps). The same profile was observed in male (10-11 am: 385±297 steps; 13-14 pm: 254±257; 15-16 pm: 281±365 steps) and in female participants (10-11 am: 368±326; 13-14 pm: 161±170; 15-16 pm: 328±326 steps) as well as in younger adults (10-11 am: 425±364 steps; 13-14 pm: 246±218; 15-16 pm: 382±378 steps). For adults aged 80+ years peaks were less prominent and the PA level was more evenly distributed throughout the day. **Conclusion** This study is the first to analyse diurnal profiles of pedometer-determined PA in older adults. The overall PA level was rather low, with distinct gender- and age group-related differences. Considering diurnal profiles, PA was highest late in the morning, followed by a second peak in the afternoon. A better understanding of PA in the course of the day helps to adjust offers of PA/exercise programmes to preferred PA phases of older adults in order to more successfully increase their PA.

### **TIME OF DAY, ENVIRONMENT LUMINOSITY AND PHYSICAL EXERCISE ON INFLAMMATORY PARAMETERS OF SWIMMING RATS**

Beck, W., Scariot, P.P.M., Dos Reis, I.G.M., Gobatto, C.A.

*University of Campinas*

**Introduction** Forced swimming for rats has been extensively used in sport sciences investigations, however, the chronobiological control is usually neglected. Since the circadian rhythm is mainly controlled by light/dark cycle, the environmental luminosity and time of day

should be investigated in order to avoid additional stress. So, we aimed to analyze inflammatory parameters in animals submitted to a time to exhaustion swimming trial (TE) at lactate minimum intensity under two environmental luminosities during sleep and wakefulness period. Methods At 45 days-old, 84 rats were housed under 12/12 h light-dark cycle in standard (SI) or experimental (EI) illumination. The daylight was equal for both (560-595nm; <60lux), however, from 18:00h to 06:00h SI was maintained in total darkness while EI under constant red light (>600nm; <15lux). These groups were further subdivided according time of day, being assessed at 12:00h or 20:00h. After two weeks of water and swimming adaptation, the animals were submitted to lactate minimum test (90 days-old) and to TE 48h after. Were collected blood samples immediately after TE in order to determine the C-reactive protein (CRP), lymphocytes (Lymp), neutrophils (Neutr) and monocytes (Mono). Analysis of variance were used with  $p < 0.05$  to luminosity, time of day and exercise effects. Results At 12:00 h, Lymp (7550.14/mm<sup>3</sup>), Mono (861.86/mm<sup>3</sup>) and Neutr (2872.61/mm<sup>3</sup>) were higher ( $p < 0.01$ ) in relation to 20:00 h (5347.67/mm<sup>3</sup>, 498.81/mm<sup>3</sup> and 1992.62/mm<sup>3</sup>, respectively), remained only CRP unaltered by time of day (3.11µg/mL for 12:00 h and 3.21µg/mL for 20:00 h;  $p = 0.23$ ). EI increases Lymp (SI = 5984.63/mm<sup>3</sup>; EI = 6913.19/mm<sup>3</sup>;  $p = 0.01$ ), Mono (SI = 523.40/mm<sup>3</sup>; EI = 837.29/mm<sup>3</sup>;  $p < 0.01$ ) and decreases Neutr (SI = 2678.70/mm<sup>3</sup>; EI = 2186.53/mm<sup>3</sup>;  $p < 0.01$ ), while CRP do not suffer alteration in function of this main effect (3.21µg/mL for SI and 3.11µg/mL for EI;  $p = 0.22$ ). Solely the exercise increases CRP concentration (3.05µg/mL for control and 3.26µg/mL for exercise;  $p = 0.01$ ), also leading to high count on Lymp (5269.47/mm<sup>3</sup> and 7628.34/mm<sup>3</sup>;  $p < 0.01$ ), Neutr (2084.25/mm<sup>3</sup> and 2780.97/mm<sup>3</sup>;  $p < 0.01$ ) and Mono (621.27/mm<sup>3</sup> for control and 739.41/mm<sup>3</sup> for exercise, respectively;  $p = 0.04$ ). Discussion While SI and 20:00 h groups had normal Lymp, Mono and Neutr counts, EI and 12:00 h groups showed increased counts, expressing worse experimental conditions. Our results confirm the acute characteristic of CRP, being modulated only by exercise effect. We postulate that luminosity and time of day should be controlled for all animal models investigations to avoid mistaken interpretations on experimental results, once the studied white blood cells counts could be associated to modulations on physiological parameters. Supported by FAPESP-Proc. 2011/13226-1

### EFFECTS OF LOW-INTENSITY PULSED ULTRASOUND EXPOSURE ON SKELETAL MUSCLE REGENERATION AFTER CARDIOTOXIN-INDUCED DAMAGE IN THE MOUSE MODEL.

Sakamoto, M., Horiuchi, T., Hiraguchi, T., Tadano, C., Takahira, N.

*School of Allied Health Sciences, Kitasato University*

Effects of low-intensity pulsed ultrasound exposure on skeletal muscle regeneration after cardiotoxin-induced damage in the mouse model. Sakamoto, M.1, Horiuchi, T. 1, Hiraguchi, T.1, Tadano, C.2 Takahira, N.1. 1: Kitasato University (Sagamihara, Japan), 2: Toho University School of Medicine(Tokyo, Japan) Introduction Low-intensity pulsed ultrasound (LIPUS) has non-thermal effects and it has been shown to induce biological activities related to tissue repair. Although there are several studies on the effect of therapeutic ultrasound on bone, tendon and ligament injuries (Khanna A, et al), information on the therapeutic application of LIPUS for muscle injuries is insufficient( Rantanen J, et al, Shu B, et al). The purpose of this study was to examine the effects of LIPUS exposure on the regenerative process of injured muscle using immunohistochemistry in a mouse model. Methods Female ICR mice were used in this study. These mice were divided into the control group (N=5), muscle injury (injury) group (N=25) and LIPUS exposure after muscle injury (LIPUS) group (N=25). To induce muscle injury, cardiotoxin was injected into the left tibialis anterior (TA) muscle. LIPUS was initiated 3 hours after injury to the left TA muscle and it was applied once daily in the day that followed until sacrifice. LIPUS was performed under the following conditions: 10 min/day, frequency of 3 MHz, intensity of 0.5W/cm<sup>2</sup>, 20 % duty cycle. TA muscles were excised after 2, 3, 5, 7 and 10 days after injury. Frozen cross sections were reacted with anti-desmin antibody (a marker of myogenic cell). Nuclei were stained with DAPI. Sections were observed to identify the expression of desmin-positive mononuclear cells. And, fiber cross sectional area (FCSA) was measured in injured part at 10 days after injury. The results were analyzed using 1-way analysis of variance. If statistical significance was achieved ( $p < 0.05$ ), multiple comparisons were performed using Tukey's method. Results Desmin-positive mononuclear cells were detected at 3 days after injury in both the injury group and the LIPUS group. The mean FCSA was no significant difference between the injured group and the LIPUS group. Regarding the size distribution of FCSA, it tended to differ between injured group and LIPUS group. In LIPUS group, the number of myofibers with FCSA > 2800 µm<sup>2</sup> was larger compared with the injured group. Discussion In this experiment, mean FCSA was similar in both the injured group and the LIPUS group at 10 days after muscle injury. However, the number of larger myofibers tended to increase in the LIPUS group compared with the injury group. Thus, it seems likely that exposure with LIPUS had a beneficial effect on the injured muscle. Reference Khanna A, et al. ### DIFFERENTIAL SENSORI-MOTOR MODULATIONS ON THE LOAD COMPLIANCE DURING MAINTAINING CONSTANT FINGER FORCE OR POSITION

Kirimoto, H., Tamaki, H., Onishi, H., Suzuki, M., Matsumoto, T., Yotani, K.

*Niigata University of Health and Welfare*

Introduction When an individual performs a submaximal static contraction, there are two different load types either to produce a constant force by pulling against a noncompliant restraint (force task) or to maintain a constant limb angle while supporting an equivalent isoinertial load (position task). Despite each subject exerting a similar net muscle torque during the two tasks, referring to the Newtonian mechanics (the force outputs are the same and the joints are still), previous work has reported that time to failure, which occurs when the participant is no longer able to match the task criterions, is briefer for the position task than for the force task. The aim of this study was to determine whether sensorimotor modulations on the load compliance during maintaining constant finger force or position are different Methods Ten healthy subjects contracted the right first dorsal interosseus muscle by abducting their index finger 90 seconds either to produce a constant force against a rigid restraint by 10 degree (force task) or to maintain a constant position against a constant load of 20% of maximum contraction (position task). Visual feedback was provided during both tasks. Somatosensory evoked potentials (SEPs) were recorded from the C3' (2 cm posterior to C3) by stimulating either right ulnar or median nerve at the wrist while subjects kept contraction. In addition, the motor evoked potentials (MEPs) and the silent period (cSP) to the transcranial magnetic stimulation were recorded. Results The amplitudes of P45 reduced significantly during isometric contraction of both force and position tasks. The reduction of amplitude of P45 was significantly larger during position task than force task only when ulnar nerve but not median nerve was stimulated. The duration of the cSP in force task was significantly longer than position task. However, the amplitude of MEPs did not differ between tasks. Discussion These results suggest that the position task causes more inhibitory effect on somatosensory cortex compared with the force task. Larger gating effect in the position task could imply that the task to maintain the position of the index finger while supporting a constant load requires more proprioceptive information from the group Ia afferents with which the enhanced gating of

centripetal mechanism occurs. Shorter duration of the cSP in position may be attributable to lower levels of presynaptic inhibition of Ia afferents. These results suggest that there is a more rapid recruitment of the motor unit pool and a briefer time to task failure when supporting a compliant load. ### STATIC AND DYNAMIC POSTURAL CONTROL IN ANKLE SPRAIN COPERS

Steib, S.1, Zech, A.2, Pfeifer, K.1

1: University of Erlangen-Nuremberg (Erlangen, Germany), 2: University of Hamburg (Hamburg, Germany)

**Introduction** Approximately every third person suffering an ankle sprain develops long term functional impairments (Hiller et al., 2011). Studying those who successfully return to preinjury levels of sports activity while having no injury recurrences or feelings of instability (ankle sprain copers) may help to gain a better understanding of underlying mechanisms (Hertel and Kaminsky, 2005). The aim of this study was a) to compare static and dynamic postural control abilities between copers and noninjured controls and b) to evaluate correlations between measures of static and dynamic postural control. **Methods** 32 athletes with a long-term history of ankle sprain (coper, age:  $23.8 \pm 3.2$  years; time since injury:  $21.3 \pm 13.2$  months) but no residual symptoms or subjective instability were compared with 30 athletes without a history of lower extremity injury (control group; age:  $24.4 \pm 3.3$  years). They completed two measures of postural control: (static) centre of pressure sway velocity (vCOP) in single-leg-stance and (dynamic) the 'star excursion balance test' (SEBT) in four reach directions (anterior, medial, lateral, posterior). Differences between groups were determined with independent t-tests. Effect sizes were calculated as Hedge's g. The relationship between both dependent variables was measured by using the Pearson product-moment correlation coefficient. Results Sway velocity in single-leg-stance did not differ significantly between groups (control group =  $2.39 \pm 0.60$  cm/s; coper =  $2.65 \pm 0.65$  cm/s;  $p = .128$ ). Significant group differences existed for mean SEBT in anterior (ES =  $-0.64$ ;  $p = .016$ ) and lateral (ES =  $-0.52$ ;  $p = .046$ ) direction. No significant correlation was found between vCOP and mean SEBT ( $r = -.005$ ;  $p = .966$ ) among all participants. **Discussion** Although seemingly recovered, postural control deficits appear to exist in ankle sprain copers. The lack of correlation between static and dynamic measures indicates that they rely on different aspects of sensorimotor control. Dynamic measures of postural control seem to be more sensitive in detecting long term deficits. References Hertel J, Kaminsky TW. (2005) *J Orthop Sports Phys Ther*, 35(5), A2-6. ### EFFECTS OF NORDIC HAMSTRING EXERCISE ON THE HAMSTRING MUSCLE ATROPHY AND WEAKNESS AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION

Nomura, Y., Kuramochi, R., Fukubayashi, T.

Waseda University

**Effects of Nordic Hamstring Exercise on the Hamstring Muscle Atrophy and Weakness after Anterior Cruciate Ligament Reconstruction** Nomura, Y. 1, Kuramochi, R. 2, Fukubayashi, T. 3 1: Graduate School of Sport Sciences, Waseda University, 2: Chukyo University School of Health and Sport Science, 3: Faculty of Sport Sciences, Waseda University **Introduction** Atrophy of the semitendinosus (ST) muscle after harvesting the ST tendon for anterior cruciate ligament reconstruction (ACLR) has been reported (Makihara et al.2006). This morphological change could be reasonably a factor causing torque deficits in deep knee-flexion. However, the way to prevent this problem remains controversial. Moreover, previous study showed that the ST peculiarly responded to knee-eccentric flexion tasks among hamstring muscles (Kubota et al., 2007). This study aimed to evaluate the effects of Nordic Hamstring exercise (NH), a partner exercise focusing the eccentric phase - on atrophy of the ST and strength deficit after ACLR. **Methods** Twelve athletes (7 males and 5 females, age:  $19.1 \pm 1.4$ yr) who underwent unilateral ACLR ( $19.0 \pm 15.8$  months postoperation) were divided into either a control group or an NH group. The exercises were conducted 22 sessions during a period of eight weeks. Two sessions were conducted each week for the first two weeks, then three sessions per week for the remaining six weeks. Before and after the training period, hamstring muscle strength was measured as isometric maximal torque on a Biodex dynamometer. And hamstring muscle volume was evaluated using MRI for biceps femoris long head, biceps femoris short head, ST, semimembranosus, gracilis. Then we compared pre and post measurements in each two groups. **Results** Before the training period, deep knee-flexion torque and the ST muscle volume of the ACLR limb were smaller compared with these of the normal limb in both groups. In the post NH group, isometric knee-flexion torque and muscle volume of the ST, biceps femoris short head and gracilis were observed to have increased significantly. In the control group, there was no statistical difference between pre and post measurements. **Discussion** The results suggest that Nordic Hamstring exercise is an effective method to improve muscle atrophy and weakness induced by ACLR in the knee-flexor muscles, especially the fusiform muscle. Moreover, it is obvious that ST muscle can function and be enhanced even after harvesting its tendon. Nevertheless, since the control subjects were not demanded any training program, we do not know the difference between eccentric exercise and concentric exercise such as hamstring curl. ### EFFECTS OF DIFFERENT TRAINING PROGRAMMES ON ANTHROPOMETRIC OUTCOMES AND BLOOD LIPIDS IN OVERWEIGHT/OBESE SUBJECTS: A SYSTEMATIC REVIEW AND META-ANALYSIS

Schwingshackl, L.1, Strasser, B.2, Hoffmann, G.1

1: University of Vienna; 2: University of Health Sciences and Technology UMIT

**Introduction:** Physical exercise is an integral part of obesity management. However, it still remains a matter of debate which kind of training programme (aerobic (AET), resistance (RT) or combined training (CT)) is the most efficacious. The aim of this study was to compare the efficacy of AET, RT and CT on anthropometric as well as blood lipid outcome parameters. **Methods:** Electronic searches for randomized controlled trials (RCTs) were performed in MEDLINE, EMBASE and the Cochrane Central Register of controlled trials with no restrictions to language and calendar date. Inclusion criteria were: Body Mass Index (BMI)  $\geq 25$  kg/m<sup>2</sup>, supervised exercise training and a minimum intervention period of 8 weeks. Outcomes of interest included: weight, waist circumference, waist-to-hip ratio, fat mass and blood lipids. Pooled effects were calculated using an inverse-variance random effect meta-analysis, following the guidelines of the Cochrane Collaboration (1). Begg's and Egger regression tests were performed to detect publication bias (2,3). **Results:** Overall, 27 studies enrolling 1381 participants met the inclusion criteria and were considered for meta-analysis. As compared with RT, AET resulted in a significantly more pronounced reduction of body weight [weighted mean differences (WMD):  $-0.99$  kg (95% CI  $-1.85$  to  $-0.13$ ),  $p = 0.02$ ], and waist circumfer-

ence [WMD: -0.82 cm (95% CI -1.51 to -0.13),  $p=0.02$ ], respectively. Moreover, HDL-cholesterol increase turned out to be more prominent following AET [WMD: 1.71 mg/dl (95% CI 0.34 to 3.07),  $p=0.01$ ]. When comparing CT with RT, WMD in change of body weight [-1.67 kg (95% CI -2.32 to -1.01),  $p<0.00001$ ], waist circumference [-1.51 cm (95% CI -2.31 to -0.71),  $p=0.0002$ ], and fat mass [-1.59 mg/dl (95% CI -2.51 to -0.67),  $p=0.0007$ ] was in favour of combined training, respectively. Results of Begg's and Egger test indicated no hint for publication bias. Discussion: The present systematic review and meta-analysis indicate that some of the anthropometrical as well as blood lipid data seem to be more affected by AET and CT as compared to RT. However, further studies are necessary to estimate the effectuality of the different training programs in the setting of obesity management. References 1. Higgins JPT, Green S (2008). ### **INTERMITTENT HYPOBARIC HYPOXIA AND ELECTRICAL MUSCLE STIMULATION INFLUENCE IN CIRCULATING PROGENITOR CELLS LIBERATION IN PATIENTS WHO SUFFERED A TRAUMATIC BRAIN INJURY**

Conde, L., Guillamó, E., Blasi, J., Juncadella, M., Gaitán-Peñas, H., Corral, L., Javierre, C., Ventura, J.L., Viscor, G.  
*Barcelona University*

Introduction: severe traumatic brain injured (TBI) patients may have long term physical and psychological sequelae. A previous study showed an increase of circulating progenitor cells (CPC) after Intermittent hypobaric hypoxia (IHH) and electrical muscle stimulation. Increase of CPC may contribute to neurogenesis and TBI patients recovery. The objective of this study is to improve physical or psychical sequelae of patients who suffered a TBI with a program of IHH sessions and electrical muscle stimulation and measure CPC in peripheral blood. Methods: a program of IHH and electrical muscle stimulation 3 days (3 hours/day) per week during 12 weeks were carried out in the intervention group (IG),  $n=6$ , and a day of cognitive activities 1 day (1 hour/day) per week during 12 weeks were done in the control group (CG),  $n=5$ . Physical stress test, neuropsychological tests and circulating progenitor cells (CPC) were measured before and after the program. IHH were applied in the hypobaric chamber of Barcelona University simulating an altitude of 4.500m during 2 hours and at the same time two sessions of 20 minutes of electrical muscle stimulation were applied with the Compex Vitality® vascular capillarization program, in quadriceps and abdominal muscles. CPC were measured nine times before, during and after the program. Results: in the IG there was an increase in workload of the physical stress tests, but there were no changes in psychological tests and CPC. There were no changes in physical stress tests, psychological tests and CPC in CG. Discussion: the IHH and electrical muscle stimulation, under the conditions of the current study, did not increase CPC in peripheral blood in TBI patients, nor any changes in psychological tests. Only the workload increased in physical stress tests compared to CG. This may be because it was an insufficient intensity stimulus or perhaps a different inter-individual answer in CPC liberation. #### **EFFECTS OF WEIGHT LOSS ON THE DYNAMICAL MARKS OF CENTRE OF GRAVITY IN DIFFERENT BMI, BODY FAT PERCENTAGE AND WAIST HIP RATIO CATEGORIES**

Szablics, P.1, Szabó, S.1, Dvorák, M.1, Orbán, K.1, Balogh, L.1, Molnár, A.H.1, Béres, S.3, Pintér, Z.2, Pósa, A.2, Kupai, K.2, László, F.1,2, Varga, Cs.2  
*University of Szeged*

Introduction: It is known that the quality and dynamical marks of movement deteriorate due to obesity and overweight. The movement dynamics is also improved by recreational training (Katzmarzyk and Lear, 2012). We investigated the recreational training-induced changes in body composition and dynamical marks of centre of gravity (CG) in case of simple movements like crouch and jump. Methods: 50 participants (age: 20-70 years) took part in our study. They did 60 minute long recreation trainings two times a week for 3 months on 60 percent of maximal heart rate. The movement analysis (APAS 3D system) was performed in the beginning and at the end of training program. Participants crouched and jumped in front of a camera. We analysed the position, velocity and acceleration of CG. Changes of body weight, fat and muscle mass were determined by InBody230. Participants were divided into normal (N), overweight (OW) and obese (O) groups based on their initial BMI, BF % and WHR (Gallagher et al., 2000). Statistical analysis: simple 't' test. Results: We detected significant decrease of body weight in the OW and the O groups at the BMI and WHR categories. This change was significant in all groups at the BF% categories. The decrease of fat mass was significant in the N and the OW groups at every three categories. We observed significant increase in lifting of CG in case of jump in every three groups at the WHR categories, in the OW and the O groups at the BMI categories, and in the N and the OW groups at the BF% categories. The increase of CG velocity was significant in the N body type group at the BMI categories, in the OW group at the BF% and WHR categories. In case of crouch the sinking of the CG was significantly enhanced in the OW group at the BF% and WHR categories, and the sinking velocity of the CG was increased in the O group at the BMI, BF% and WHR categories. Discussion: Our results suggest that low intensity recreational training optimizes the body composition and the dynamics of movement. The most effective among was detected in the OW people based on the different categories. Comparing the BMI, BF% and WHR categories, the detected changes were similar at the body composition, but the detected changes at the dynamic of the movement were different, because the BF% and WHR categories distinguish between the fat mass and the muscle mass. ## EFFECT OF 24-WEEKS OF BIODENSITY TRAINING ON BONE MINERAL DENSITY AND LEAN MUSCLE QUANTITY AND STRENGTH IN HEALTHY AND OSTEO-PENIC/-POROTIC ADULTS

Rockey, S.1, Moynes, R.1, Skinner, J.2, Conviser, J.3, Smith, D.1

(1) University of Wyoming (2) Indiana University (3) JMC Associates

**Introduction** The age-related decline in skeletal muscle mass and strength, collectively known as sarcopenia, are well-documented (Doherty, 2001; Roubenoff, 2001). Sarcopenia is associated with a higher likelihood of less than optimal bone mineral density and osteoporosis (Verschuere et al. 2013). bioDensity is a novel resistance training (RT) approach that employs a one session per week high-intensity (maximal-voluntary contraction) routine using four limited-range static exercises to achieve a near total body RT program - Chest Press (CP), Leg Press (LP), Core Pull (Core), and Vertical Lift (VL). Methods Healthy and osteopenic/porotic adults (N=116; 21-80 years) were recruited and assigned to complete 36-weeks of bioDensity RT. At baseline, 12-, 24-, and 36-weeks the following assessments will be made: 1) bone mineral density, lean body mass, fat mass (DEXA); 2) change in bioDensity-quantified force production; 3) upper (push-up) and lower (vertical jump) body bilateral ground reaction forces (dual force plates); and 4) 5-component fitness assessment. Changes between baseline and follow-up assessments were determined (RMANOVA) for the entire sample and across tertiles of age and bone health (normal, osteopenic, and osteoporotic). Results Presently, 116 participants are actively training and 12-week follow-up testing has been completed in 2 participants (due to the start date of the intervention November 2012). Ninety-eight participants will have completed 24-week follow-up testing by June 10, 2013. Body composition, ground reaction force, and 5 component fitness assessment data are not yet available. However, for bioDensity force production at 8-weeks in 73% of the sample: CP increased 6.3%; LP increased 7.1%; Core was stable (0.5% change); and VL 6.8%. Discussion With exception of the Core exercise, these increases in maximal-voluntary force production resulting from 8-weeks of bioDensity RT are encouraging and may be associated with improvements in functional upper and lower body power and health promoting adaptations to bone mineral density and lean muscle mass. 12- and 24-week findings will elucidate whether the time-sparing and low-volume approach of bioDensity RT elicits significant and meaningful body composition and functional changes important to the prevention or attenuation of osteoporosis and sarcopenia (Sundell, 2011). ## EFFECTS OF A 3-MONTHS VIGOROUS PHYSICAL ACTIVITY INTERVENTION ON EATING BEHAVIOR AND BODY COMPOSITION IN OBESE ADOLESCENTS

Martin-Garcia, M.1, Bryant, E.2, Plaza-Carmona, M.1, Fernandez-Rodriguez, M.3, Gonzalez-Vergaz, A.3, Garcia-Cuartero, B.3, Ara, I.1

UNIVERSITY OF CASTILLA-LA MANCHA

1GENUD Toledo Research Group, Univ. of Castilla-La Mancha, Spain; 2Division of Psychology, Univ. of Bradford, UK; 3Department of Pediatrics, Hospital Severo Ochoa, Spain. **Introduction** The Three Factor Eating Questionnaire (TFEQ) is associated with weight loss and less successful weight maintenance following weight loss intervention in adults (Bryant et al., 2012): the relationship in children is unclear. Previous evidence has shown that, despite having a lower % body fat, those children who perform more vigorous physical activity (VPA) have a higher energy intake (Gutin, 2008). Thus, the aim of this study was to analyze the effects of a short-term VPA intervention on eating behavior and whether those effects are related to the body composition changes. **Methods** Twenty three obese adolescents (Tanner 3-4) participated in this study. Thirteen were ascribed to the active group (13.6±0.3 yr, 30.1±0.8 kg/m<sup>2</sup>) and 10 to the control group (13.2±0.4 yr, 30.4±0.6 kg/m<sup>2</sup>). Body composition was assessed in all participants pre and post the VPA intervention / control condition, using dual energy X-ray absorptiometry (DXA). Adolescents' eating behavior was determined with a shortened 21-item version of the TFEQ (TFEQ-R21) that includes 3 main factors: uncontrolled eating (UE), cognitive restraint (CR) and emotional eating (EE) (Cappelleri et al., 2009). The intervention included 3 hours of VPA per week of recreational games for 3 months. **Results** Although no significant changes were found, TFEQ-UE and TFEQ-EE scores decreased 8% and 6% respectively in the active group, while no changes in the control group were found. In the active group, whole body fat mass decreased by 6% (36.1±1.3 kg vs. 34.1±1.6 kg, pre and post respectively, p>0.05), and total lean mass increased by 3% (41.6±2.2 kg vs. 42.7±2.2 kg, p>0.05). No significant correlations between the 3 factors of TFEQ-R21 and changes in body composition were found. **Discussion** Despite the changes in body composition (decrease in fat mass and increase in lean mass) found in the active group after a short-term VPA intervention, TFEQ scores were similar after the intervention and no correlation between eating behavior and body composition changes were found. Eating behaviors and body composition changes after a longer VPA intervention need further investigation. References Bryant EJ, Caudwell P, Hopkins ME, King NA, Blundell JE. ## BODY COMPOSITION IN TENNIS PLAYERS AND MAXIMAL OXYGEN INTAKE: A LONGITUDINAL STUDY WITH CHILDREN.

Rey López, J.P., Berdejo del Fresno, D., Santiin Medeiros, F., Moraes, A.C., Barbosa de Carvalho, H.

University of Sao Paulo

**Introduction** Tennis is an anaerobic predominant activity requiring high levels of aerobic conditioning to avoid fatigue and aid in recovery between points. Body composition is often measured in young tennis players but it is unclear if it is a useful predictor of a better cardiorespiratory fitness. The aim of this study is to examine the association between: I) Anthropometric measures and maximal oxygen intake (VO<sub>2</sub>max); II) Dual x-ray absorptiometry (DXA) and VO<sub>2</sub>max. **Methods** 7 children (3 boys and 4 girls, age = 10.83 ± 0.39) from the high-performance tennis center from the Aragon Tennis Federation (Spain) were measured twice during a whole season (baseline-10 months later) (Berdejo del Fresno et al. 2010). Body composition (whole lean, bone and fat mass) by DXA (Explorer, Hologic Corp.) and by anthropometry (height, weight, waist circumference). VO<sub>2</sub>max was estimated by Leger et al. (1984) using the 20 meter shuttle run test. A linear regression analysis was performed (adjusting by age) between baseline body composition and VO<sub>2</sub>max at the end of the season. A significance level was considered when p values were <0.05. Statistical analyses were performed using STATA 12.1. **Results** No significant mean differences in VO<sub>2</sub>max (ml/kg/min) were found during the season (baseline: 54±3, 10months: 55±3). In the regression model,

body composition at baseline by DXA was not statistically associated with VO<sub>2</sub>max values at the end of the season: Standardized  $\beta$  (95% CI): 0.56 (-0.28-1.19); -0.55 (-1.02-0.24); 0.46 (-1.60-9.24) for lean mass, fat mass and bone mass respectively. Similarly, anthropometric measurements were not associated with VO<sub>2</sub>max values.  $\beta$  (95% CI): -0.27 (-0.67-0.28); -0.34 (-63.4-25.7); -0.05 (-0.60-0.57) for weight, height and waist circumference respectively. Discussion Our results show that in children who regularly train for competitive reasons (our sample around 12 hours per week) body composition is not a predictor of VO<sub>2</sub>max changes during a whole season. Therefore, we suggest that in pubescent tennis players changes in VO<sub>2</sub>max are more likely due to hematological variables (Hemoglobin, Hematocrit changes) as has been found in soccer players (Hansen et al. 2004). In summary, in competitive tennis children players' body composition analyses are not justified as a way to predict aerobic performance. Nonetheless, the study of body composition in athletes by DXA should be promoted to monitor changes in bone mass during growing years. ### **BODY COMPOSITION CHANGES AFTER 4 MONTHS OF HIGH-INTENSITY AEROBIC INTERVAL TRAINING IN METABOLIC SYNDROME PATIENTS.**

Cruces, C., Fernández-Eliás, V.E., Ortega, J.F., Hamouti, N., Mora-Rodríguez, R.

*Universidad de Castilla-La Mancha*

Introduction and purpose: Sedentary lifestyle in obese individuals can develop into many health conditions, particularly cardiovascular diseases. Four months of a 3-week intense pedaling program (70% VO<sub>2</sub>max; 40 min) lowers trunk fat and tends to reduce leg fat in obese, type II diabetic patients [1]. The purpose of our study is to determine if high-intensity aerobic interval training could also reduce trunk fat in a larger sample of obese subjects with metabolic syndrome. Subjects: Forty-eight obese men and women aged between 31 and 68 years volunteered to participate in this study. Participants were defined as having MetS according to the criteria of the International Diabetes Federation [2]. Methods: Nude body weight was obtained using a  $\pm$  0.05 kg sensitive scale (WildCat; Mettler, Toledo, USA). Waist circumference was measured to the nearest 0.1 cm using a plastic tape (Figure Finder Tape Measurement, LaCrosse, WI, USA) 2 cm below the lower rib while subjects rested their arms along their bodies. Whole body percent body fat, trunk and leg fat and fat-free mass was determined using DEXA scanning, using a total body scan mode; Lunar iDXA (GE Medical Systems Lunar, Madison, WI 53718 USA). The analyses were performed using encore TM 2008 software version 12.30.008. Results: Body weight decreased by 1.2 $\pm$ 0.4 kg after 4 months of training (P=0.003). Waist circumference was also reduced by 4.1 $\pm$ 0.45 cm (3.9% reduction; P=0.000). Fat-free mass was maintained during the exercise program (51.5 $\pm$ 1.4 vs. 51.2 $\pm$ 1.4 kg, P=0.12). Fat mass decreased by 0.9 $\pm$ 0.3 kg after 4 months of training (P=0.006). However, due to the concomitant loss of body weight, percent body fat was reduced only by 0.5% (38.7 $\pm$ 0.01 to 38.2 $\pm$ 0.01; P=0.033). Most of the 0.9 kg of fat loss, belonged to trunk fat that declined from 18.5 to 17.7 (i.e., 0.77 $\pm$ 0.25; P=0.03). Leg fat mass was reduced by only 89 $\pm$ 0.05 gr which was not significant (P=0.06). Conclusions: An intense aerobic exercise program with a frequency of 3 sessions per week during 4 months, results in measurable losses of waist circumference and body weight. Approximately, 75% of the reduction in body weight could be accounted by losses of body fat. Most of the fat loss in this exercise program belonged to abdominal fat (86%). Thus, high-intensity aerobic interval training meets the objective of reducing abdominal fat which is associated with a risk reduction of developing cardiovascular diseases. References: 1. ### **VALIDITY OF SELF-REPORTED ANTHROPOMETRIC VALUES USED TO ASSESS BODY MASS INDEX IN PHYSICALLY ACTIVE ADULTS**

Theodoropoulou, E., Karteroliotis, K.

*National and Kapodistrian University of Athens*

Introduction Large scale studies frequently used self-reported weight and height to assess Body Mass Index (BMI). However, self-reported anthropometric values were subject to measurement errors (Spencer et al., 2002; Stommel & Schoenborn, 2009). Specifically, men and women underreported their weight, overestimated their height and consequently, underestimated their BMI. Thus, the purpose of the current study was to examine the differences between self-reported and measured anthropometric values in a sample of Greek physically active adults. Methods The participants were 684 volunteers, 206 men and 478 women, ranging in age from 18 to 65 years (39.2 $\pm$ 13.5 yrs), who regularly participated in various exercise programs in the Sport Facilities of the Municipality of Athens. First, the participants completed questions about their body weight and height. Second, the anthropometric measurements were carried out by trained personnel in accordance with Heyward and Stolarczyk recommendations (1996). Weight was measured to the nearest 100 gr by a calibrated scale and height in bare feet to the nearest cm by a stadiometer. BMI was calculated as weight (kg) divided by height (m) squared. A series of paired t tests were conducted to explore the differences between self-reported and measured anthropometric values. Results The results showed that according to self-reported BMI, 69.3% of the participants were normal weight, 23.6% were overweight and 4.6% were obese. Based on measured BMI, 58.6% of the participants were normal weight, 31.6% were overweight and 8.3% were obese. Men underestimated their weight (t(203)=-11.2, p<0.01) and overestimated their height (t(202)=18.5, p<0.01). Women underreported their weight (t(476)=-18.6, p<0.01) and BMI (t(475)=-7.8, p<0.01) and overestimated their height (t(475)=30.2, p<0.01). Additionally, the overweight subgroup underestimated weight (t(212)=-11.7, p<0.01) and BMI (t(213)=-12.7, p<0.01) and overestimated height (t(212)=20.0, p<0.01). Similarly, the obese subgroup underreported weight (t(50)=-6.5, p<0.01) and BMI (t(50)=-10.9, p<0.01) and overestimated height (t(50)=10.2, p<0.01). Discussion The results of this study demonstrated significant differences between self-reported and measured anthropometric values, showing that self-reported data were subject to measurement errors. Large scale studies should use more valid procedures for overweight and obesity assessment. References Heyward VH, Stolarczyk LM. (1996). Applied body composition assessment. Human Kinetics, USA. ### ASSOCIATION OF FEMORAL NECK BONE MINERAL DENSITY WITH BODY COMPOSITION AND GRIP STRENGTH

Tachiki, T.1, Kitagawa, J.1, Takahira, N.1, Iki, M.2, Tamaki, J.2, Kajita, E.3, Sato, Y.4, Kagamimori, S.5, Kagawa, Y.6, Yoneshima, H.7

1: Kitasato Univ. Graduate School of Medical Science, 2: Kinki Univ., 3: Nagoya Univ. Graduate School of Medicine, 4: Jin-ai Univ., 5: Univ. of Toyama, 6: Kagawa Nutrition Univ., 7: Shuwa General Hospital

**Introduction** Osteoporosis reduces quality of life in the elderly because of bone fracture (Copland, 1999). Femoral neck fracture is critical in elderly women, as they will require primary nursing care or, at worst, become bedridden. Therefore, it is very important to study the factors associated with femoral neck bone mineral density (FNBMD). Optimum body mass, good muscle strength, and physical activity have beneficial effects on FNBMD. Because body mass can be divided into fat mass and lean tissue mass, the factors associated with FNBMD need to be determined by analyzing fat mass and muscle mass separately. In this cross-sectional study, we investigated the associations among grip strength (GS) as an indicator of whole-body strength, FNBMD, and body composition in postmenopausal Japanese women. **Methods** This research was part of the Japan Population-based Osteoporosis (JPOS) study. The subjects were 304 women aged 54 to 91 years (mean  $70.8 \pm 7.7$  years). All subjects had undergone natural menopause more than 10 years previously, and none had abnormalities in bone metabolism. FNBMD, fat mass, and appendicular lean soft tissue mass were measured by dual-energy X-ray absorptiometry. Total-body skeletal muscle mass (TBSM: Kim, 2002) and fat mass index (FMI: fat/height<sup>2</sup>) were then calculated. GS was measured with a digital hand dynamometer. **Results** FNBMD was significantly correlated with age ( $r = -0.34$ ,  $P < 0.01$ ), TBSM ( $r = 0.42$ ,  $P < 0.01$ ), FMI ( $r = 0.31$ ,  $P < 0.01$ ), and GS ( $r = 0.34$ ,  $P < 0.01$ ). GS was not significantly correlated with FMI ( $r = 0.06$ ,  $P = 0.30$ ), but it was significantly correlated with TBSM ( $r = 0.55$ ,  $P < 0.01$ ). Multiple linear regression analysis showed that FNBMD was significantly associated with age ( $\beta = -0.27$ ,  $P = 0.01$ ), TBSM ( $\beta = 0.16$ ,  $P = 0.01$ ), FMI ( $\beta = 0.22$ ,  $P = 0.01$ ), and GS ( $\beta = 0.12$ ,  $P = 0.04$ ). **Discussion** This research suggests that FMI and TBSM have the same degree of influence on FNBMD. The association of FMI with FNBMD could be affected by the presence of aromatase in fat (Riancho, 2007). Because GS as well as TBSM were associated with FNBMD, both muscle strength and muscle mass must be maintained and improved. We intend next to perform a longitudinal study of the effects of GS and TBSM on FNBMD. **References** Copland CA et al. (1999) *Int J Epidemiol*, 28, 241-246. Kim K et al. ### RELATIONSHIPS AMONG BODY MASS INDEX, BODY IMAGE AND PHYSICAL PERFORMANCE IN ITALIAN ADOLESCENTS

Spiga, F., Di Michele, R., Merni, F., Ceciliani, A., Semprini, G., Brasili, P., Toselli, S.

*University of Bologna*

**Introduction** The prevalence of weight status disorders and body dissatisfaction is continually increasing in adolescents from European countries (Sanchez Cruz et al, 2013) (Eisenberg, Neumark-Sztainer, & Paxton, 2006). Physical capacities are related to body size. In particular, the weight status affects some motor and strength performances (Graf et al, 2004). Little is known, however, on how one's physical fitness affects the perception of his/her own body image. The objective of the present study was to determine the interrelationships among body mass index, body image perception and motor performance in Italian second grade school students. **Methods** The sample included 61 adolescents (35 boys and 26 girls) from Bologna, Emilia-Romagna, Italy, aged 16-17 years. Height and weight were measured and BMI was calculated. Body image perception was assessed using Body Silhouette Charts (Collins, 1991). Physical assessments included a standing broad jump, hand grip dynamometer test, sit and reach flexibility test, gross motor skill test, and shuttle run endurance test. **Results** The BMI was similar in girls (21.4 kg/m<sup>2</sup>, SD: 2.0) and boys (22.4, kg/m<sup>2</sup>; SD: 2.9). However, girls overestimated their actual figure, and showed a higher body dissatisfaction, as revealed by a larger difference between their desired and perceived body image. Boys performed better than girls in the standing broad jump, dynamometer, and shuttle run tests, while girls had a higher flexibility. When controlling for gender, BMI was negatively related to performance in the standing broad jump and gross motor skill tests. When controlling for both gender and BMI, performing better in the standing broad jump and shuttle run involved a thinner body perception. **Discussion** Self-perception of body image is affected, apart from the actual body size, even by one's aerobic and explosive strength capacity. Therefore, improving physical fitness may contribute to reduce body dissatisfaction in adolescents, by means of both loss of weight and change of perceived body image. **References** Sanchez Cruz et al. ### SECULAR TREND IN ANTHROPOMETRIC MEASUREMENTS OF ATHLETES SPECIALIZING IN SPEED SKATING

Godina, E., Bobarykin, N.

*Russian State University of Physical Education, Sports, Youth and Tourism*

**Introduction** Studies of secular changes in different populations remain one of the most important research topics in human biology. Manifestations of a secular trend include changes in morphological characteristics for children and adults. While a lot of data is known for general populations, not many studies deal with the same subject for professional sportsmen. In our previous publications secular changes in the free wrestlers have been studied (Godina and Kolomeichuk, 2012). The aim of the present paper is to follow secular changes in speed skaters for the last 40 years. **Methods** In 2011/12, 74 athletes specializing in speed skating were investigated in Moscow according to the standard anthropometric protocol. All were of high sports qualification (Master of Sports or Master Candidate), 18-24 years old. The results were compared with archive data on speed skaters from the previous generation (Gladysheva et al., 1979). Anthropometric program included about 30 measurements; body mass index (BMI) and body mass components were calculated. Statistical analysis was performed with STATISTICA 6.0, 8.0 packages. **Results** There are noticeable changes in main body dimensions in modern speed skaters as compared with their counterparts from the previous years. While stature remained practically the same, as well as biacromial and pelvic diameters, body weight and BMI significantly decreased (weight: 73.5 kg in 1979 vs 70.5 in 2012; BMI: 23.8 vs 22.9 correspondingly), leg length increased, chest and some other body circumferences decreased. There is a significant increase in bone component, measured as elbow and knee breadth (e.g., knee breadth: 91 mm in 1979 vs 100 mm in 2012). The hand grip strength in 2012 athletes showed significant decrease. **Discussion** In our previous study it was shown that secular changes in free style wrestlers could be connected with their typical morphological structure and adaptation to specific sports activity (Godina, Kolomeichuk, 2012). The comparison of body dimensions in high qualification speed skaters examined in 1979 and in 2012, revealed that modern athletes express the tendency towards leg length increase, elbow and ankle breadth, as well as decrease in all circumferences of the body. The increase in leg length is part of the general secular trend (Bogin and Varela-Silva). The changes in bone mass shown in this study could

be associated with the cardinal change of skates' model in the middle of the 1990's and with the techniques of run. The decrease in BMI, some body circumferences and hand grip might demonstrate the trend to asthenic body build, which was found in some modern populations (Godina, 2011). ### **DOES BODY MASS INDEX AFFECT ARREST TECHNIQUE PERFORMANCE ON NORWEGIAN POLICE UNIVERSITY COLLEGE STUDENTS?**

Jenssen, O., Dillern, T.

*The Norwegian Police University College*

**INTRODUCTION** Police officers tend to increase their body mass during their occupational career. (Boyce, Jones, Schendt, Lloyd, & Boone, 2009; Sørensen, Smolander, Louhevaara, Korhonen, & Oja, 2000). This can cause health issues but it can also affect police officers ability to perform occupational tasks such physical confrontation and arresting struggling suspects. Our aim with this study is therefore to investigate if body mass index (BMI) affects results in arrest amongst Norwegian Police Students. **METHODS** 19 males and 10 females participated in the study. BMI was calculated as kg/m<sup>2</sup>. The World Health Organization (WHO) categories are used to categorize BMI. Arrest technique (AT) results are gathered as physically performed tests, evaluated and given points from experienced instructors. The test performed was seizing technique, teamwork 2 against 1, release techniques and self defence techniques. Descriptive statistics as mean, SD is used. T-test is used to compare gender and BMI classifications. Significance level was set to P<0.05. **RESULTS** Mean BMI for the subjects was 24.1(±1.9) Males: BMI 25.0 (±1.5). Females: BMI 22.4 (±1.2), results presented as means (±SD). 57.9% of the males was classified normal weight and 42.1% classified overweight. All females classified as normal weight. The normal weight group performed better in all AT test, and also the final AT score summarized from all tests. A significant better performance was found for the self-defence technique (P<0.042). P-levels for the seizing technique (P<0.066) and the total AT score (P<0.067) **DISCUSSION** The tendencies that higher BMI levels has a negative effect on performance in arrest technique raise a concern regarding the police officers capability to safely perform occupational tasks as arresting suspects and self-defence. Especially if these students development in BMI follow the trend with increasing BMI during the occupational career. **REFERENCES** Boyce, R. W., Jones, G. R., Schendt, K. E., Lloyd, C. ### **RELATIONSHIP BETWEEN PRACTICE, BODY COMPOSITION AND PERFORMANCE IN MALE UNDERGRADUATE TRIATHLETES**

Elvira, L., Drehmer, E., Blasco, E., Moratal, C., Vera, F., Salvador, T.

*Facultad de CC. de la Actividad Física y del Deporte Universidad Católica de Valencia*

**INTRODUCTION** Triathlon practice has increased during the last decade. According to the CSD, since 2000 the number of associated triathletes has quadrupled in Spain. As a consequence of this development, the number of scientific studies has increased in this field. There are studies which analyze body composition in triathletes (Martínez, Cejuela, Urdampilleta, Gallar, & Soriano, 2011); some show a relationship between the percentage (%) of body fat mass and the total performance time (Knechtle, Knechtle, & Rosemann, 2011; Knechtle, Wirth, Rüst, & Rosemann, 2011). Moreover, other studies analyze the relationships between the volume of training and performance (Knechtle, Wirth, Baumann, Knechtle, Rosemann, & Oliver, 2010). The main goal of this study was to analyze the relationship between practice, different body composition variables and final performance in male undergraduate triathletes. **METHODS** 41 male triathletes participating in the University Championship of Spain in 2012 were analyzed by 4 composition variables (BMI, %fat, %bone, %muscle mass), 2 practice variables (years of practice, practice index) and 1 performance variable (final line time). The instruments used for anthropometric data collection were a Skinfold caliper, a paquimeter and a height meter Holtain, and a Tanita BC-418 balance. To obtain practical data, subjects completed a Health Behavior Inventory designed by our research group and ChampionChip system was used to record the time. Data processing was conducted by descriptive analysis, normality was analyzed by Shapiro-Wilk test, and a correlative analysis was performed. **RESULTS** Significant correlation was observed between the final line time and (%) body fat (p=.003), BMI (p=.030), index of practice (p=.019) and years of practice (p=.045), these last were negative **DISCUSSION** The results show that the best times in finish line are related to highest index of practice, replicating the data obtained with women in the Knechtle et al., (2010) study, and with more years practicing triathlon. The best final line times also were related to %fat and BMI lower than the others, coinciding with results obtained by Knechtle, Knechtle, et al. (2011) and Knechtle, Wirth, et al. (2011). **REFERENCES** Knechtle, B., Wirth, A., Baumann, B., Knechtle, P., Rosemann, T., & Oliver, S. ### **PHYSICAL PERFORMANCE IN YOUNG MEN AT SWISS ARMY RECRUITMENT 2006 TO 2012**

Wyss, T., Jimmy, G., Mäder, U.

*Swiss Federal Institute of Sport Magglingen SFISM*

Several studies have demonstrated decreases in aerobic fitness levels in young Scandinavian and Swiss men between 1980 and 2000 [1-3]. The aim of the present study is to describe the development of physical fitness in young Swiss men in the new millennium. Therefore, data of the compulsory Swiss Army recruitment were analysed. In 2006 a new physical fitness test was implemented at the recruitment and physical performances of 218'939 male conscripts (19.9 ±1.0 y) have been measured in the past seven years. The fitness test battery contained a progressive endurance run (PER) to measure aerobic endurance capacity, a trunk muscle strength test (TMS) to assess trunk muscle fitness, a standing long jump (SLJ) and a seated shot put (SSP) to determine the muscle power of the lower and upper extremities, respectively, and a one-leg standing test (OLS) to quantify balance [4]. In addition, body height and mass were measured and a self-report physical activity questionnaire (adapted ipaq short) was administered. ANOVA with Bonferroni post-hoc tests was applied to compare results between calendar years. Only SLJ decreased constantly from 2.33m in 2006 to 2.30m in 2012 (p<.001). Results for all other performance tests did not change over time (mean values and SD between years: 6.47 ± 0.01m in SSP, 123.34 ± 1.37s in TMS, 45.81

$\pm 0.64s$  in OLS and  $14.10 \pm 0.07\text{km/h}$  in PER). Body mass index increased about 1.5% from 23.07 in 2006 to 23.41 in 2012 ( $p < .001$ ). The physical activity questionnaire showed, that the ratio of conscripts classified as trained increased constantly from 41.5% in 2006 to 47.0% in 2012. The trend of decreasing aerobic fitness, investigated in young European men between 1980 and 2000 was not confirmed between 2006 and 2012 in young Swiss men. No relevant changes in physical fitness were seen in that time period. The decreasing SLJ performances are most likely explained by an increase in body mass of about 1kg in seven years. 1. ##### EFFECTS OF SOCIAL OCCUPATIONS IN EXERCISE REHABILITATION RESPONSES OF FRENCH ELDERLY

Leprêtre, P.M., Bréchat, P.H., Lebreton, C., Bellanger, M., Rivière, D., Regnard, J., Lonsdorfer, J., Vogel, T.

*UFR-STAPS, Université de Picardie Jules Verne*

Introduction Controversial results on exercise training on senior health status may be explained by fitness, gender, exercise modalities (Mian et al. 2007). It has been also shown that environmental variables could also explain a part of difference in physical and mental health between rural and urban senior (Philipps et al. 2012). Objective To examine the links between geographical areas, social classification of occupations (SPC), aerobic and health related quality of life (HRQoL) responses to exercise training in middle-aged and aged population, 148 on 232 mixed subjects (ranged from 50 to 85 years) engaged in 9 weeks of twice-a-week interval training (IWEP). HRQoL was assessed with a French version of SF-36 questionnaire. The independent variables were gender, age, socio-economic status and size of town. Ordinal regression models were fitted to assess the association of physical training benefits (i.e aerobic capacity) with sociodemographic factors. Results A significant training-induced difference was observed in aerobic capacity ( $+ 43.6 \pm 29.9 \%$ ) and all components of HRQoL in whole population: physical, functioning and role, bodily pain, general and mental health, vitality, emotional role and social functioning dimensions. Lower was endurance before training, greater was the increase in aerobic capacity with training. Our results also showed significant relationship between changes in aerobic capacity with exercise training, SPC and disease status. Only living in an urban area of Northeast of France was related with aerobic changes due to physical activity; there were no difference among genders. Conclusion Based on the present data, IWEP may have potential to promote aerobic capacity and the all HRQoL dimensions in middle-aged and aged subjects whatever their geographical areas and social classification of occupation. ##### WAIST CIRCUMFERENCE AND GRIP STRENGTH ARE MORE STABLE AT 6, 8 AND 10 YEARS OF OBSERVATION

Matsudo, S.M.M., Araujo, T., Raso, V.2,3

*1Physical Fitness Research Center, CELAFISCS, Brazil, 2 Bandeirante University of Sao Paulo, UNIBAN, 3 Western University, UNOESTE, Brazil*

PURPOSE: To examine the stability of body composition and functional capacity in physically active older women at 6, 8 and 10 years of observation. METHODS: We measured body composition (body mass index, total body adiposity and waist circumference), physical function (body balance, flexibility, grip strength, and usual walking) in 157 physically active older women at three different moments apart 6 (age:  $64.9 \pm 1.1$  vs  $70.7 \pm 1.1$  years-old; BMI:  $27.4 \pm 0.5$  vs  $27.7 \pm 0.5 \text{ kg}\cdot\text{m}^2$ ), 8 (age:  $66.7 \pm 0.9$  vs  $74.6 \pm 0.9$  years-old; BMI:  $27.3 \pm 0.5$  vs  $26.9 \pm 0.7 \text{ kg}\cdot\text{m}^2$ ) and 10 YEARS (age:  $65.3 \pm 0.7$  vs  $75.2 \pm 0.7$  years-old; BMI:  $27.2 \pm 0.5$  vs  $27.2 \pm 0.5 \text{ kg}\cdot\text{m}^2$ ) from baseline. RESULTS: Our multiple regression analyses demonstrated that total adiposity (6 YEARS: adjusted  $R^2 = .49$ ,  $P = .001$ ; 8 YEARS: adjusted  $R^2 = .52$ ,  $P = .001$ ; 10 YEARS: adjusted  $R^2 = .37$ ,  $P = .001$ ), waist circumference (6 YEARS: adjusted  $R^2 = .37$ ,  $P = .001$ ; 8 YEARS: adjusted  $R^2 = .67$ ,  $P = .001$ ; 10 YEARS: adjusted  $R^2 = .58$ ,  $P = .001$ ), grip strength (6 YEARS: adjusted  $R^2 = .35$ ,  $P = .001$ ; 8 YEARS: adjusted  $R^2 = .59$ ,  $P = .001$ ; 10 YEARS: adjusted  $R^2 = .64$ ,  $P = .001$ ), flexibility (6 YEARS: adjusted  $R^2 = .63$ ,  $P = .001$ ; 8 YEARS: adjusted  $R^2 = .45$ ,  $P = .001$ ; 10 YEARS: adjusted  $R^2 = .44$ ,  $P = .001$ ), body balance (6 YEARS: adjusted  $R^2 = .29$ ,  $P = .001$ ; 8 YEARS: adjusted  $R^2 = .26$ ,  $P = .003$ ; 10 YEARS: adjusted  $R^2 = .25$ ,  $P = .001$ ), usual walking (6 YEARS: adjusted  $R^2 = .15$ ,  $P = .022$  mediated by age and body mass index; 8 YEARS: adjusted  $R^2 = .14$ ,  $P = .036$  mediated by age; 10 YEARS: adjusted  $R^2 = .09$ ,  $P = .037$ ) were significantly predicted by respective variables at baseline regardless of age (unless for usual walking at 6 and 8 YEARS) and body mass index (unless for usual walking at 6 YEARS). CONCLUSION: Our data permit to conclude that the stability of waist circumference and grip strength appears to be proportionally direct to the years of observation. Nevertheless, the explained variance of body balance and usual walking seems to be more dependent of external variables rather than physical activity regardless of observation period.

##### WALKING TIME AS A KEY FACTOR FOR THE MAINTENANCE OF PHYSICAL FITNESS IN NON-INSTITUTIONALIZED ELDERLY PEOPLE

Gómez-Cabello, A., Vicente-Rodríguez, G., Pedrero-Chamizo, R., Rodríguez-Marroyo, J.A., Olivares, P.R., Luzardo, L., Aznar, S., Villa, J.G., Gusi, N., Espino, L., Gonzalez-Gross, M., Casajús, J.A.

*GENUD Research Group. University of Zaragoza*

Introduction: the aging process is accompanied by several changes, such as a decrease in physical fitness. Low levels of physical fitness are associated with increased risk of several diseases, disabilities and also higher risk of mortality [1]. Aims: to examine whether an active

behavior (walk more than 1 hour per day [1 h•d-1]) is associated with lower risk of having low levels of physical fitness in a representative sample of non-institutionalized Spanish elderly people. Methods: a total of 3136 people  $\geq 65$  years of age, members of the cohort of the multi-center EXERNET Study [2], were included in this report. Balance, lower- and upper-body strength and flexibility, agility, walking speed and aerobic endurance were assessed with specific tests (adapted from the Senior Fitness Test Battery and Eurofit Testing Battery for adults). Self-reported hours walking per day were recorded by questionnaire. Binary logistic regression analysis was used to study the association of walking time with low levels of physical fitness by sex, using as reference for each test the 20th percentile of the normative values in Spain [3]. Results: in both, men and women, walking more than 1 h•d-1 was associated with lower odds of having low levels of physical fitness in most of the tests compared with those walking less than 1 h•d-1 (all  $p < 0.01$ , except for strength of left arm and walking speed in men and upper-body flexibility in both genders). Specifically, the risk of having low physical fitness levels in the tests mentioned above was reduced up to 60.4% in men and 51.5% in women. Moreover, the highest prevalence of low physical fitness were found in those who spent walking less than 1 h•d-1 compared with those who spent walking more than 1 h•d-1 (all  $p < 0.05$ ). Conclusion: time spent walking has a positive influence on physical fitness in elderly people. An active lifestyle should be encouraged in the older population in order to contribute to a good health during the aging process. References: 1. Erikssen G. Sports Med 2001. 2. Gomez-Cabello A et al. Obes Rev 2011. 3. Pedrero-Chamizo R et al. Arch Gerontol Geriatr 2012.

### **RELATIONSHIP BETWEEN PHYSICAL FITNESS AND PARTICIPATION IN SOCIAL ACTIVITIES IN JAPANESE COMMUNITY-DWELLING OLDER PEOPLE.**

Haeuchi, Y., Honda, T., Matsuo, E., Nofuji, Y., Kumagai, S.

*kyushu university*

Introduction Participation in social activities (SA) has been indicated as one of the important factors for successful aging 1). Similarly, regular exercise has been suggested as an enhancing factor of physical and mental health through the maintenance or improvement of physical fitness (PF) in older adults. However, older people don't always engage in regular exercise 2). Furthermore, although both factors are important in older people, little is known about the relationship between PF and participation in SA. Therefore, we aimed to investigate the relationship between PF and SA in Japanese community-dwelling older people. Methods A total of 1746 Japanese community-dwelling older people aged 65 years or older were involved in this study. We assessed the following types of PF: grip strength, knee extension strength, five-times-sit-to-stand, one foot balance with eyes open, and 5 meter gait speed. Also, participation in the following SA was asked by questionnaire with a binary manner (yes/no): local event or festival, senior citizen's club, paid work, community activity, independent group activity, volunteer activity, religious activity, cultural lesson, and association of commerce and industry. We also asked participants if they engage in regular exercise. In order to exclude the effect of regular exercise to PF, participants were divided into two groups: exercise and non-exercise group. SA were categorized into 4 category based on the number of participation: (1)none, (2)one or two, (3)three or four, and (4)five or more. We examined the trend of each PF score according to SA category in both exercise and non-exercise group. Adjusting factors for the trend analyses were gender, age, body mass index (BMI), and instrumental activity of daily living (IADL). Results In exercise group, participants categorized into groups with greater number of SA tend to have higher scores in all of the five PF indexes ( $p$  for trend  $< 0.05$ ). Similarly, in non-exercise group, participants categorized into groups with greater number of SA tend to have higher scores in all of the five PF indexes ( $p$  for trend  $< 0.05$ ). Discussion This study showed that older people participating in greater number of SA showed higher PF. Furthermore, this result was indicated in both exercise and non-exercise groups. Since the categories of SA in this study may include various types of physical activity with different intensities, future study should investigate them. References 1) Robert B.T, Leedine L et al. Definition of successful aging by elderly Canadian males:The Manitoba follow-up study. Gerontologist (2003).43,735-744. 2) Iain KC, Linda I et al. ### **LET'S DANCE:A PROGRAM FOR OLDER ADULTS USING LIVE MUSIC TO ENHANCE MOBILITY AND PHYSICAL ACTIVITY**

Le Navenec, C., Rosling, L., Hirst, S.

*University of Calgary*

The purpose of this presentation is two-fold: (1) to disseminate the research findings of a scooping study about the contribution of various type of music (e.g., dance, marches, other) for enhancing /maintaining mobility and physical activity among older adults in a residential centre; and (2) to compare those findings to a short descriptive case study of the Let's Dance program at Langara Residential Centre in Vancouver, Canada. This interdisciplinary program (involving nursing, physiotherapy, rehab assistants, and volunteers) is designed to improve/maintain walking, gait, and physical activity through use of live music (piano playing by the music therapist) What is unique about this program is that the music used is based on the participant's taste, and is structured to support, match, and encourage each person's walking style and ability. When not walking, the other participants are offered percussion instruments so that they may accompany rhythmically the resident who is walking Based on the staff's observations of so many smiles on everyone's faces, and sounds of laughter, this is indeed a "moving experience" that enhances not only mobility but also personhood well-being for all the participants, including the staff. If time permits, a concluding discussion will address how 'frontline' line residential staff are indeed engaging in knowledge translation (KT) ; i.e., informing their clinical practice with research findings about a creative way to promote mobility and mood enhancement of older people in residential settings.

### **PROMOTING FUNCTIONAL FITNESS PROGRAMS FOR THE ELDERLY FOR AN ACTIVE AGEING**

Honório, S.1, Batista, M.1, Martins, J.2, Cardoso, J.2, Dias, M.1, Honório, G.3

*Higher School of Education, Torres NOvas-Portugal*

Introduction In order to improve the quality of life for seniors and their remaining physical capacities, we intend to establish differences in physical fitness among older adults with physical activity programs and systematic non-active elderly evaluated by Fullerton Battery Tests. Methods The sample consisted of 62 elderly aged between 58 and 90 years old, with 37 males and 25 females, from the district of Santarém - Portugal. This Battery Tests were applied, contains 10 exercises that assess the fitness of these individuals. They were also evaluated according to their Gender, Age Group, Programs / Practices for Physical Activity and BMI. It was applied for statistical comparison techniques and non-parametric correlation. Results We found that on the gender variable, this was not determinative of the results obtained in Battery Fullerton because men showed better results in just two variables; Individuals from younger age are the ones with the best performing tests; Older people who practice physical activity, fulfilling a regular schedule, the best-performing activities assessed by

the battery, and individuals with higher BMI perform in a more effective activities. Discussion We inferred this way that regular physical activity and systematic programs reveal a positive and functional factor, and a greater ability to perform daily tasks, as assessed by tests that promote and maintain active aging.

### THE STRENGTH IN MIDDLE-AGED ADULT WOMEN PRACTITIONERS OF DIFFERENT PHYSICAL EXERCISE PROGRAMS

Araujo, P., Filippetto, M.C., Peirau, X.

*Instituto Nacional de Educación Física de Catalunya /INEFC-Lleida*

**Introduction** The physical exercise is an important agent in the improvement and maintenance of the health and of the physical condition (American College of Sports Medicine, 7th ed., 2006). It acts in the reduction of the chronic illnesses risk factors and in the decrease of the effects of the osteoporosis, common in middle-aged adult women. Within the developed physical abilities, strength stands by its prophylactic in the risk of falls and fractures, frequent in this population. The aim of the study was to evaluate the strength in women practitioners of two different programs of physical exercise. **Methods** Initially was applied the IPAQ questionnaire (International Physical Activity Questionnaire) for the amount of physical activity performed by the sample  $N = 43$  women aged between 44 and 57 years, divided into aquatic fitness practitioners, practitioners of neuromuscular stimulation mechanic and non-practitioners systematic physical exercise. Exercise programs had the duration of 12 weeks and we evaluate the strength before and after (pre and post test). We measured the peak of isometric force of the lower body coupling the Muscledab® system to a machine of Leg Press. The system consists of a load cell and a computer-readable recording the variation of force versus time with unsurpassed resistance and absence of motion. **Results** The strength of women practitioners aquatic fitness, neuromuscular stimulation mechanic and non-practitioners physical exercise ( $n = 17, 13, 13$ ) has not presented significant variation ( $p = 0.92, 0.71, 0.58$ ). **Discussion** The programs of physical exercise have been geared towards a maintenance perspective and health promotion, so the not decreased strength is considered a positive factor. Emphasize the importance of maintaining the strength for this population as a factor favouring overall fitness, improving functionality in activities of daily living (Caspersen, Powell & Christenson, 1985) and contributing to the prevention of falls (Matsudo, 2002). **References** American College of Sports Medicine (7th ed) (2006). ### EFFECTS OF A PHYSICAL EXERCISE PROGRAM IN THE FUNCTIONAL FITNESS AND BODY COMPOSITION OF AN ELDERLY POPULATION

Martins, A.1, Raimundo, A.1,2, Pereira, C.1,2

*1: UE (Évora, Portugal), 2: CIDESD (Portugal)*

**Introduction** Exercise is a key mean for the maintenance of health, functional capacity, quality of life and independence in the elderly, being recommended the performance at least 3 sessions/week(1). Although many elderly adhere to these recommendations, the absenteeism can be an impediment to exercise benefits. This study aimed analyze the effects of a 3 months exercise program (3 sessions/week; 50-60'; 50-60%HRmax.), accounting for absenteeism, in elderly women. **Methods** Participants were 44 women, equal or >60 yrs, clustered into 3 groups: Experimental 1 (E1: 20-59% sessions;  $n:13$ ; age:  $69,3 \pm 6,9$  yrs); Experimental 2 (E2: equal or >60% sessions;  $n:15$ ; age:  $70,9 \pm 5,6$  yrs); Control (C: 0% sessions;  $n:16$ ; age:  $68,7 \pm 9,2$  yrs). Anthropometry and DXA assessed body composition. Clinical analysis determined the lipid profile. Functional Fitness Test assessed physical fitness. POMS-SF questionnaire assessed the Mood States. The variation between pre post intervention (post-pre values) were computed for all variables. Comparisons between groups were performed by ANOVA and Bonferroni post hoc test or by Kruskal-Wallis and Pair Wise Wilcoxon tests. The level of significance was set at  $p < 0.05$ . **Results** There were significant differences between groups concerning variation in upper ( $p = .001$ ;  $E2 > C$ ) and lower strength ( $p = .009$ ;  $E2 > C = E1$ ), lower flexibility ( $p = .020$ ;  $E2 > C$ ), aerobic endurance ( $p < .001$ ;  $E2 = E1 > C$ ) and speed/agility/balance ( $p < .001$ ;  $E2 = E1 > C$ ) and confusion ( $p = .027$ ;  $E2$  60%HRmax to improve these parameters. This study highlights the usefulness of programs adopting an active lifestyle through exercise because proved that exercise have benefices in physical fitness and mood state even with a high absenteeism. **References** 1 ACSM (2009). *Med Sci Sports Exerc*, 1510-1530. 2 Barata T (2003). ### INBODY 720 COMPARED TO DEXA FOR THE ASSESSMENT OF BONE MINERAL CONTENT, FAT%, FAT MASS, FAT FREE MASS, AND LEAN BODY MASS IN ELDERLY MEN

Lohne-Seiler, H.1, Bjørnsen, T.1, Hetlelid, K.1, Salvesen, S.1, Stea, T.H.1, Paulsen, G.2, Berntsen, S.1

*1University of Agder, Kristiansand, Norway, 2Norwegian School of Sport Sciences, Oslo, Norway*

**Do not insert authors here** **Introduction** Aging is characterized by a progressive atrophy of muscle tissue, increased fat mass and loss of bone mass. Bioelectrical impedance analysis (BIA) is a non-invasive, transportable and relatively inexpensive method for measuring body composition and hence extensively used by health professionals. However, few studies have examined the validity of the BIA based instrument Inbody 720 in the elderly. We aimed to compare InBody 720 to DEXA (Dual Energy X-ray absorptiometry) for the assessment of bone mineral content (BMC), fat%, fat mass (FM), fat free mass (FFM), and lean body mass (LBM) in elderly men (60-80 years). **Methods** The present study is a part of the SARA-study, a double-blinded randomized placebo-controlled study evaluating the effect of whether large dosages of antioxidants can affect adaptation to resistance training in elderly men. Forty five men ( $68.6 \pm 6.2$  yrs) were included in the present study. Analysis were based on the tests performed at baseline which were completed within a week. Data were analyzed as follows: paired-samples t-test, Bland-Altman plots with limits of agreements, and intra-class correlations (ICCs), two-way mixed model, with 95% confidence intervals (CIs). **Results** Mean differences and limits of agreements from the Bland-Altman plots were: BMC:  $0.21 \pm 0.38$  kg ( $p = 0.001$ ), fat%:  $-3.0 \pm 2.7\%$  ( $p < 0.001$ ), FM:  $-1.7 \pm 2.4$  kg ( $p < 0.001$ ), FFM:  $1.5 \pm 2.7$  kg ( $p = 0.001$ ), and LBM:  $1.2 \pm 2.7$  kg ( $p = 0.003$ ), percentage changes were 6.0, -11.0, -8.1, 2.3, and 2.1%, respectively. The ICCs were: BMC: 0.54 [95% CI: 0.29-0.72] ( $p < 0.001$ ), fat%: 0.92 [95% CI: 0.85-0.95] ( $p < 0.001$ ), FM: 0.96 [95% CI: 0.92-0.98] ( $p < 0.001$ ), FFM: 0.92 [95% CI: 0.85-0.95] ( $p < 0.001$ ), and LBM: 0.91 [95% CI: 0.84-0.95] ( $p < 0.001$ ). **Discussion** These results indicate that InBody 720 seems to overestimate BMC, FFM and LBM compared to DEXA and underestimate fat% and FM. Fat%, FM, FFM, and LBM assessed with InBody 720 explained more than 90% of the variance in fat%, FM, FFM, and LBM assessed with DEXA. On the other hand BMC assessed with InBody 720 explained only 54% of the variance in BMC assessed with DEXA. Our results are in agreement with other studies (Völgyi et al., 2008; Holteberg 2010) however these studies are includ-

ing younger individuals. In conclusion it seems that InBody 720 is a valid method for the determination of fat%, fat mass, fat free-, and lean body mass in elderly men. References Holteberg, K. (2010). Master thesis, NSSC. Völgyi E, Taylavsky FA, Lyttikäinen A, Suomien H, Alén M, Cheng S. (2008). *Obesity*, 16(3), 700-5.

### DOES FITNESS LEVEL INFLUENCE URINARY INCONTINENCE AND SLEEP QUALITY IN AGED WOMEN?

Moreno-Vecino, B.1, Vila-Maldonado, S.1, Alcázar, J.1, Marfín-García, M.1, Mata, E.1, Arija-Blázquez, A.1, Ara, I.

*University of Castilla-La Mancha*

1: GENUD "Growth, Exercise, Nutrition and Development" TOLEDO Research Group, University of Castilla-La Mancha, Toledo, Spain; Introduction Urinary incontinence (UI) and poor sleep quality (SQ) are highly prevalent in women after menopause (1). In addition, fitness level is dramatically reduced with advanced age (2). Very few studies have been conducted in order to investigate the interactions between fitness levels, UI and SQ. Thus, the aim of this study was to analyze the relationships between the mentioned factors in aged women. Methods A total of 174 women (age:  $74.3 \pm 5.5$  yr, body mass index:  $30.1 \pm 3.8$  kg/m<sup>2</sup>) completed a battery of physical fitness tests including static balance, lower body strength, agility/dynamic balance, walking velocity and aerobic endurance (2). The ICIQ-SF questionnaire and Cervantes Scale (for UI) (3, 4) and Jenkins Scale (5) (for SQ) were used. Participants' physical fitness tests were graded according to normalized percentile values for Spanish elderly (2) to correct the effect of age. Additionally, a fitness index (FI) was calculated splitting subjects into low fitness (LF) and high fitness (HF) level groups for those corresponding to the 1st and 4th quartile respectively. Results UI variables (i.e. frequency and amount of urine leaks, never leaks urine, urge UI, stress UI and number of times that urinates during the night) showed significant worse values in the LF compared to the HF group (all  $p < 0.05$ ). Significant correlations between frequency of urine leaks, amount of urine leaks, number of times that urinates during the night and FI were found (range:  $-0.18$  to  $-0.26$ ,  $p < 0.05$ ), whereas no correlation between SQ variables and fitness level was present. Discussion An inverse association between moderate physical activity and UI exist (6), maybe due to maintaining body weight, reducing intra-abdominal fat and/or other potential mechanisms such as the strengthening of the pelvic floor muscles (7). Furthermore, our findings support that lower physical fitness is strongly associated with higher UI values in aged women. Therefore, physical fitness seems to play an important role in quality of life in aged women further than the typical associations with a better performance in movement tasks. References 1. ### MAXIMAL FAT OXIDATION IN TRAINED YOUNG AND MIDDLE-AGED MALE TRIATHLETES DURING RUNNING AND CYCLING

Beck, T.N.1, Dela, F.1, Helge, J.W.1

*Copenhagen University*

Objective: This cross-sectional study investigated the effect of exercise mode and aging on the maximal fat oxidation capacity in well trained young and middle aged male triathletes. Methods: Two groups of well trained male subjects (8 young triathletes [ $28 \pm 1.6$  y,  $VO_{2\max}$ :  $69.7 \pm 2.5$  ml/min/kg] and 10 middle aged triathletes [ $53.2 \pm 2$  y,  $VO_{2\max}$ :  $58.7 \pm 2$  ml/min/kg]) performed two graded exercise tests to exhaustion; one test on cycle ergometer and the other on a treadmill. The stage duration in both trials was 3 minutes and gas exchange measurements (Oxycon Pro, Jaeger) and venous blood was sampled at the end of each stage. Plasma lactate and free fatty acid (FFA) concentrations were determined using commercially available assays. Fat oxidation rates were calculated using stoichiometric equations. Results: Maximal fat oxidation was significantly higher in running compared with cycling in well trained middle aged men ( $0.62 \pm 0.04$  vs.  $0.46 \pm 0.03$  g \* min<sup>-1</sup>;  $P = 0.002$ ), but not in young men ( $0.84 \pm 0.09$  vs.  $0.720 \pm 0.02$  g \* min<sup>-1</sup>;  $P = 0.1$ ), respectively. The relative work intensity which elicits Fatmax, was different between cycling and running in trained middle aged men ( $46.4 \pm 2.7$  vs.  $60.7 \pm 2.4$  %  $VO_{2\max}$ ;  $P < 0.001$ ), but not in trained young men ( $57.4 \pm 2.6$  vs.  $63.3 \pm 3.8$ ;  $P = 0.215$ ). The relative work intensity which elicits Fatmax was different between groups in cycling but not in running (24 %;  $P < 0.001$  and 5.7 %  $P = 0.274$ ). In both trained middle aged ( $P = 0.073$ ) and trained young men ( $P = 0.011$ ) lactate concentrations were higher in cycling than running. During both cycling and running in trained young men there was an (83 and 29 %) reduction plasma FFA concentrations from baseline values at ( $685 \pm 85$  and  $537 \pm 117$  μmol L<sup>-1</sup>, respectively) and in trained middle aged an (12 and 3 %) reduction in plasma FFA concentrations from baseline values at ( $347 \pm 44$  and  $406 \pm 48$  μmol L<sup>-1</sup>, respectively) until exhaustion. Conclusions: In both middle aged and young male trained triathletes maximal fat oxidation was 35 % and 17 % higher doing treadmill compared with cycle exercise, respectively, whereas the intensity which elicits maximal fat oxidation in the two exercise modes was only different in the middle aged and not the young triathletes. The higher venous plasma lactate concentrations during cycling compared to running implies a higher muscle glycogen turnover and supports the observed lower maximal fat oxidation during cycling. Interestingly the plasma FFA was reduced and not increased though the graded exercise protocol.

### EFFECTS OF MOTOR PLAY INTERVENTION ON PHYSICAL ACTIVITY IN JAPANESE PRESCHOOL-AGED CHILDREN AND THE RELATIONSHIP BETWEEN THE EFFECTS AND MOTOR ABILITY

Ikeda, T.1, Ikeda, T.2, Aoyagi, O.3

*1Fukuoka Prefectural University, 2Nishi-kyusyu University, 3Fukuoka University*

Introduction Recently, children's physical activity (PA) has tended to decrease in many countries (Dollman et al., 2005). This study aimed to estimate the effects of intervention on the amount of PA for Japanese young children by supporting their motor play and evaluate the

durability of these effects. Furthermore, this study clarified the relationships among the amount of PA, the effects of intervention, and children's motor ability (MA). **Methods** Subjects were 31 preschoolers (14 boys, 17 girls) at two preschools. PA was measured using a 3-axis accelerometer (Power-Walker EX-300) worn between 9 a.m. and 2 p.m. As a control (T1), children wore the accelerometer for three days in a week (Mon., Wed. and Fri.). For the intervention (T2), children were supported in motor play with university students for 60 minutes in the morning, during which they wore the accelerometer. For the post intervention period (T3), the accelerometer was also worn for three days (same days of the week). MA was evaluated using the following items: potato-race, grip strength, sits-and-reach, long distance throwing, standing broad jump and side jump. Principle component analysis was used to calculate a general MA score. To compare the mean PA (T1-T3), two-way layout and repeated measures ANOVA and the Bonferroni test were used. Results The mean PA of each time differed significantly according to ANOVA ( $F(2, 60)=9.82, p<.001$ ), and there was no interaction of gender or each time ( $F(1, 30)=.47, p=.449$ ). PA for boys was larger than PA for girls ( $F(1, 30)=7.05, p<.05$ ). A multiple comparison test revealed a significant difference in PA between T1 and T2 (T1=5971.5 steps

### COMPARISON OF SUMMER AND WINTER PHYSICAL ACTIVITY OF SENIOR CITIZENS IN THE REYKJAVIK CAPITAL AREA

Oskarsdottir, N.1, Arnardottir, N.1, Koster, A.2, VanDomelen, D.3, Brychta, R.4, Eiriksdottir, G.5, Sverrisdottir, E.5, Gudnason, V.5, Johannsson, E.1, Harris, T.3, Chen, K.4, Sveinsson, T.1

1: UI (Iceland), 2: MU (The Netherlands), 3: NIA (USA), 4: NIDDK (USA), 5: IHA (Iceland).

1: UI (Reykjavik, Iceland), 2: IHA (Kopavogur, Iceland), 3: NIA (Bethesda, Maryland, USA); 4: MU (Maastricht, The Netherlands), 5: NIDDK (Bethesda, Maryland, USA), 6: UI (Laugarvatn, Iceland), 7: USD (Odense, Denmark). **Introduction** Regular physical activity (PA) has various health benefits both physically and mentally. Seasonality may play a role in PA patterns, and Iceland has a unique dark-light cycle difference between winter and summer. The objective of this study was to examine the difference between summer and winter in PA of older Icelanders living in the capital area. **Methods** The research was conducted in cooperation with the Icelandic Heart Association (Harris et al., 2007, Arnardottir et al., 2012). Among participants who had one week of free-living measurements by a hip-worn accelerometer during the summer months, 219 volunteered to repeat another session during the opposite dark-light cycle (winter). Overall, 142 people (87 women and 55 men) finished at least four valid days of PA measurements during both sessions. The levels of PA was categorized as sedentary < 100 counts/min, low-light 100-759 counts/min, light-moderate 760-2019 counts/min, and moderate-vigorous >2020 counts/min. Results Significantly more time was spent in summers at the low-light PA level (178 vs 161 min,  $p<0.001$ ), and the light-moderate level (30 vs 22 min,  $p<0.001$ ). However, subjects recorded significantly more sedentary time in the winter as compare to summer (10.4 vs 10.2 h,  $p=0.02$ ) and less wear-time (13.5 vs 13.8 h,  $p=0.002$ ). Very limited time was spent in moderate-to-vigorous PA in either seasons (7 vs 6 min,  $p=0.19$ ) with women spending less time than men on average (5 min vs 9 min,  $p=0.01$ ). The differences in seasonal wear-time and low-moderate PA were significantly higher for men than women ( $p=0.03$  and  $p=0.02$ ). The difference in PA between seasons was not related to age or body weight. **Discussion** The seasonal difference in PA patterns in this unique population showed the environmental influences on habitual PA in older populations and underscores the necessity of taking season into account in analysis. Future studies should examine the feasibility and effectiveness of different interventions to increase of PA all year long. **References** Harris TB, Launer LJ, Eiriksdottir G, et al. ### ANALYSIS OF VARIATIONS IN CENTRE OF PRESSURE IN STANDING POSITION IN YOUNG SUBJECTS WITH DOWN SYNDROME AFTER A DANCE TRAINING PROGRAMME

Massó, N., Gutiérrez, L., Rey, F., Costa, L., Casals, S.

*Universitat Ramon Lull*

**Introduction:** People with Down Syndrome (DS) show slow motor performance, long reaction times and anomalies in COP (centre of pressure) control (Galli M. et al. 2008; Cabeza-Ruiz R. et al. 2011; Rigoldi et al. 2011). Nevertheless, they can improve with training (Debū, 2004). Thus, our purpose is to analyze COP control differences between groups and possible changes before and after a dance training programme during 18 weeks. **Methods:** 11 young people with DS aged  $20.5 \pm 1.3$  and 11 non-DS aged  $20.2 \pm 2.0$  were analyzed. We registered bipedal standing position in closed eyes and open eyes conditions during 30 seconds. The following parameters relative to COP were taken from platform (AMTI- SGA6-4): sway area, A-P (anteroposterior) and M-L (mediolateral) displacement, and also maximum displacement excursion. Differences were compared between both groups using Mann-Whitney U test. Wilcoxon Test was applied to compare differences between open and closed eyes in both groups. All of them were registered before and after training programme, and changes pre-post training were analyzed using Anova Test. **Results:** In open eyes condition we found significant pre-training differences between groups in COP sway area ( $p<.000$ ), A-P ( $p<.000$ ) and M-L displacement ( $p<.005$ ) and maximal displacement excursion ( $p<.001$ ). In contrast, post-training results did not show significant differences between groups in A-P and maximal displacement excursion. In closed eyes condition differences were found in pre-training sway area and M-L values. And, post-training results were different in all parameters. Intragroup pre-post changes did not show any variation except sway area in closed eyes condition of control group. Nevertheless, DS group showed a better reduction in A-P displacement in open eyes condition in comparison with control group ( $p<.018$ ). **Discussion:** According to previous literature, we found that people with DS show worse COP control than non-DS in open and closed eyes conditions. Also, we can conclude that a dance-based training programme can improve some parameters relative to COP control in open eyes condition. **References:** Cabeza-Ruiz R. et al. ### EFFECT OF TWO ENDURANCE TRAINING METHODS ON PHOSPHOCREATINE KINETICS IN CHILDREN

Slopianka, M.1, Kappenstein, J.1, Ferrauti, A.1, Müller, K.2, Zange, J.2,3

1: RUB (Bochum, Germany), 2: DLR (Cologne, Germany), 3: University of Cologne (Cologne, Germany)

**Introduction** Several studies showed similar positive adaptations on the oxidative capacity comparing high-intensity intermittent (HIT) with continuous endurance training (CT) in children (Williams et al., 2000; McManus et al. 2005; Baquet et al., 2010). However, studies measuring the effects of endurance training on phosphocreatine (PCr) kinetics are only available in adults, suggesting a faster PCr recovery after a training intervention (Jones et al., 2007; Forbes et al., 2008). The aim of the present study was to compare the effects of HIT and moder-

ate-intensity continuous training (CT) on PCr kinetics in children. Methods 36 children (9.5±1.1 yrs, 141±8 cm, 35±8 kg, muscle mass 48±6%, VO<sub>2</sub>max 54±9 ml/kg/min) participated in the study. A 3-group experimental design was applied comparing the PCr kinetics after 10 weeks (2 training sessions per week) of HIT with CT, by means of <sup>31</sup>P-magnetic resonance spectroscopy (31P-MRS). Both training modalities were compared with a non-exercising control group (CG). The exercise test consisted of a dynamic plantar flexion protocol (8 bouts of 30-s exercise interspersed by 20-s recovery) followed by 5 min of passive recovery, measuring the energy-rich phosphates during and post-exercise. Results Results were calculated using a multi factor ANOVA (main factors were group [HIT, CT, CG] and training [pre-post]). No significant differences for the main factors group and training as well as no interactions were found for average PCr at the end of exercise contractions and post-exercise PCr recovery time constant (τ) (P > 0.5). Conclusion The results obtained in the present study suggest that ten weeks of two different endurance training modalities (HIT and CT) don't affect the PCr kinetics during and after a high-intensity intermittent exercise protocol in children. Therefore, it seems that in order to specifically train endurance in children, coaches and physical trainers should wait until the age at peak height velocity. For practical reasons both training methods seem to be suitable, although children show clear preferences for high intensity intermittent bouts of exercise under natural conditions (i.e., short runs with changes of direction). ### INDIRECT ASSESSMENT OF AEROBIC CAPACITY OF OBESE ADOLESCENTS: INTEREST OF A SHORT INTERMITTENT, PROGRESSIVE AND MAXIMAL RUNNING TEST.

Rey, O.1,2,3, Nicol, C.1, Rossi, D.4, Mercier, C.S.5, Vallier, J.M.2,3, Maïano, C.6

1 - ISM (Marseille, France), 2 - LAMHES (Nice, France), 3 - LAMHES (Toulon, France), 4 - Lycée Raynouard (Brignoles, France), 5 - AJO@ (Sanary, France), 6 - Lab. Cyberpsychologie (Gatineau, Canada)

Introduction This study examined the validity of a progressive intermittent running test (15-15; entitled Spartacus) to indirectly assess the aerobic capacity of obese adolescents in comparison with the Shuttle run test. Methods The participants were 43 obese adolescents (33 girls and 10 boys) aged 13.7 ± 1.4 years old, with a mean IMC of 31 ± 5. Both tests were performed at the 3.8th ± 1.5 month of their stay for combined diet and exercise training in a health care centre. The two tests were performed at a three week interval. Differences according to the « test », « sex » and the interaction « test X sex » have been assessed for maximum heart rate (HRmax), final running speed, total and net running durations, and perceived exertion (Borg's scale RPE 6-20). Results MANOVA analysis did not reveal any significant inter-test differences for HRmax (193 vs. 196 ± 9 bpm) and RPE (16 ± 2). As compared to the Shuttle test, however, the Spartacus resulted in a 20% increased final running speed (11.5 vs. 9.4 km.h<sup>-1</sup>) and a 3.3 times longer total running duration (17.3 vs. 5.3 min) for a 1.7 times longer net exercise duration (8.7 vs. 5.3 min) (p<0.001). The results were neither influenced by the « sex » nor by the "test X sex" interaction. Discussion The Shuttle test includes repeated braking and accelerating actions from lower limb extensor muscles, which are known to affect runners, and in particular obese ones (Bovet et al. 2007). As expected, the aerobic capacity indirectly assessed by the Shuttle run test was significantly lower than when using the Spartacus test. The mean values of HRmax give support to the maximal involvement of the adolescents in both tests. This is not attenuated by the observed HRmax-REP uncoupling, which is commonly reported for this age group (Gros Lambert and Mahon 2006). Conclusion The Spartacus test allowed obese adolescents to reach a similar psycho-physiological state effort while producing an increased aerobic performance in both speed and duration. Although requiring additional validation, the Spartacus test might contribute to the individual planning of short intermittent exercises, and thus to the prevention of cardiovascular risks associated with obesity. ### THE EFFECT OF WII FIT® BALANCE GAME ON THE BALANCE ABILITY OF CHILDREN WITH HEARING IMPAIRMENT

Hsu, T.Y., Ko, B.J., Kuei, W.L.

National Taichung University of Education

Introduction As a result of the impairment of their inner ears or premature growth, the capability of balance for children who are hard of hearing is malfunctional. However, the capability of balance is essential for the human body to maintain its own stability in our daily life. A poor ability of balance will affect our everyday life as well as the quality of learning. Therefore, this study aimed to explore the effect of a six-week Wii Fit game of balance training on the static and dynamic ability of balance for hearing-impaired children. Methods The subjects of this study were 14 hearing-impaired children and 7 normal, unimpaired children. The hearing-impaired ones were further divided into 7 experimental-group children and 7 regular-activity children, whereas the normal-hearing ones were divided into 7 control-group children. With the experimental group, the Wii Fit game of balance training was conducted 3 times per week, 45 minutes per session for 6 weeks. The regular-activity group and the control group ones just live their lives the way they normally do with their regular routines. This experiment utilizes a force plate and thin sensor strip to measure the SLECLL(Single-leg Eyes Closed Left Leg) and the SLECRL(Single-leg Eyes Closed Right Leg) balance abilities of these two groups' subjects, as well as to time the test of "timed up-and-go" Afterwards, the BTS Bioengineering-Sway software was used to gather the parameters of the subjects' characteristics of balance control. After the data were analyzed and processed, the Wilcoxon signed ranks test of nonparametric statistics and the Kruskal-Wallis one-way analysis of variance ranks(H-test) of nonparametric statistics were undergone to compare the result of the pre-test and the post-test, as well as to compare the variations among the groups. Results The collected data indicate that, with the comparison of the pretest and the posttest between the experimental group and the control group, the timing of the SLECLL and of the SLECRL, as well as the time of the "timed up-and-go", have both reached a remarkable variation of p< .05. Of all the collected data, a significant progress has shown. Discussion The Wii Fit game of balance training can effectively enhance the ability of body balance for the hearing-impaired children. During the process of the training, it's not only fun-filled but also safe, so this is a highly recommended exercise. References An, M. H., Yi, C. H., Jeon, H. S., Park, S. Y. (2009). **Introduction** Aging-related reduced spinal mobility can interfere with the execution of important functional skills and activities in elderly women. However there is a lack of studies about the effects of range of motion exercises on flexibility outcomes in older populations and a lack of consensus regarding the prescription of stretching exercises for older adults (ACSM, 2009). For these reasons the purpose of this study was to examine the extent to which spinal extension and flexion could be improved in a population of older women participating in a 8-week flexibility training program. **Methods** Thirty female volunteers were cluster randomized into either a control group [CG] (n: 13; age: 69.69±7.94 years; height: 1.57±0.06 m; weight: 68.42±8.18 kg, BMI: 27.88±2.81) and a trained group [TG] (n: 17; age: 68.35±6.04 years; height: 1.54±0.06 m; weight: 64.78±10.16, kg, BMI: 27.28±3.08). TG was trained for 8 weeks by two sessions/week. In particular, every trained session included: a warm up period (~15 min), a training period (~60 min) including specific exercises to train spinal flexibility, cool down period (~15 min). CG did not perform any structured physical activity during the experimental phase. All data were acquired before and after the experimental period. Spinal ranges of motion (ROM) were measured using SpinalMouse® (Ildiag, Volkerswill, Switzerland), which is an electronic computer-aided device that measures sagittal spinal ROM and inter-segmental angles non-invasively using the so-called surface technique. Each angle was measured three times in a neutral standing (nS) position, maximum bending (maxB) position, and maximum extension (maxE) position, and average data were used. **Results** Results indicated a significant improvement in spinal mobility in the trained group compared to the control one, and virtually no measurable change in the control group. In particular, we found a significant increase of thoracic ROM from nS position to maxB one ( $p < 0.05$ ) in TG than CG after the training period compared to baseline. Instead we did not show any significant difference of sagittal spinal ROM from nS position to maxE one ( $p > 0.05$ ). **Discussion** This study shows that used training program can improve the spinal flexibility in female older adults. We suggested, in agreement with Miyakoshi et al. (2007), that an increase in spinal ROM had positive effects on quality of life and that deterioration of back muscle strength could be the most important factor decreasing spinal ROM in elderly people. **References** Miyakoshi N, Hongo M, Maekawa S, Ishikawa Y, Shimada Y, Itoi E. (2007). Osteoporosis Int 18:1397–1403.

## MAY BE ASSESSED THE INDEPENDENCE IN SENIORS WITH HELP OF BODY COMPOSITION?

Bunc, V., Hráský, P., Skalská, M.

Faculty of P.E. and Sports Charles University

**Introduction** The importance of physical activity as an element of healthy living for older adults is important mainly for their independence and self-serving. Physically active older adults can reduce or prevent functional declines linked to aging through improved cardiovascular functioning, reduced risk of osteoporosis, reduced risk of falling, and reduced loss of muscle mass and strength. Surveys such as the Behavioral Risk Factor Surveillance System, however, show that only one third of people age 65 years and older participate in regular sustained physical activity. Therefore, ways older adults can modify their behaviors or leisure lifestyles to be more active are critical to promoting their muscle state. An effect of physical exercise in humans may be assessed by body composition (BC). Like a decisive parameter for independency assessment may be used the relationship between extracellular (ECM) and body cell mass (BCM). The aim of this study was to verify BC assessment in female seniors by whole body BIA analysis and verify if the BC parameters may be used like a predictor of their independency. **Methods** In a group of healthy non-active senior women (n=23, age=70.1±4.8 years, BM=70.3±5.9 kg, height=161.9±2.0 cm, percentage of body fat (%BF)=37.5±5.1%) were determined by DEXA method. These data were used for the prediction equation calculation that was used by BIA analysis. The measurement itself was performed in a tetrapolar configuration of electrodes. The BIA was used in a group of healthy senior women (n=79, age=70.7±4.3 years, BM=69.9±7.9 kg, height=161.0±2.8 cm, %BF=37.9±4.8%, TBW=46.0±2.3% of BM, ECM/BCM=0.98±0.03). **Results** The exercise time in active seniors spent per week ranged between 90-250 min (mean 156.8±48.9 min). According to data from non active group the influence of the resting activities should be neglected. The mean energy output was 3970±960 kJ. A highly significant dependence of peak oxygen uptake on ECM/BCM was found:  $VO_{2peak}.kg^{-1} (ml.kg^{-1}.min^{-1}) = -43.165 * ECM/BCM + 67.765$ ;  $r = 0.911$ ,  $p < 0.005$ ,  $SEE = 1.68 ml.kg^{-1}.min^{-1}$ ,  $TEE = 1.93 ml.kg^{-1}.min^{-1}$ . The relationship ECM/BCM increased significantly with the age. The following linear dependence was established:  $ECM/BCM = 0.021 * age (years) + 0.412$ ;  $r = 0.898$ ,  $p < 0.005$ ,  $SEE = 0.04$ ,  $TEE = 0.05$ . **Discussion** If we evaluate their daily regime it may be determine that the  $ECM/BCM < 1$  may be use like a morphological criterion of senior's independence. We may conclude that for the BC assessment and thus for evaluation of an actual state of seniors and predispositions of their independence may be use the BIA analysis if the senior's prediction equation was used with the reproducibility about 2% of absolute values of measured variables. The study was supported by the grant Czech Ministry of Education MSM 0021620864

## TWO WEEKS OF ONE LEG IMMOBILISATION DECREASES HDL CHOLESTEROL IN YOUNG AND ELDERLY HEALTHY MEN

Noerregaard, J., Gram, M., Vigelsoe, A., Wiuff, C., Reihmane, D., Helge, J.W., Dela, F.

University of Copenhagen

**Background:** Previous studies have shown that bed rest significantly reduces high-density lipoprotein cholesterol (HDL-c). However, the impact of inactivity and possibly of age on the HDL-c concentration where only a limited muscle mass is affected, is not well established. **Objective:** To investigate and compare the lipid profile in young (Y) and elderly (E) healthy males after two weeks of one-leg immobilisation and six weeks of aerobic retraining. **Methods:** 17 Y (23±1 yr; 48±1 ml O<sub>2</sub>/min/kg) and 15 E (68±1 yr; 33±2 ml O<sub>2</sub>/min/kg) male subjects had one leg immobilised using a Don Joy cast for two weeks. This was followed by six weeks (20 sessions) of supervised aerobic cycle training (86±1% of maximal heart rate). The plasma lipid profile was measured overnight fasted at baseline, after immobilization and after retraining. The daily activity level was monitored with a three-axial accelerometer during the intervention. On the three days prior to each blood sampling, subjects were asked to eat a high carbohydrate diet. Data are Mean ± SEM. **Results:** Immobilisation decreased the daily activity level ( $P < 0.001$ ) for both Y (by 31±9 %) and E (by 37±9%) compared to baseline and during training it was not different from baseline. At baseline E had higher plasma concentrations of total cholesterol (TC) (5.2±0.2 vs. 3.8 ±0.1 mM,  $P < 0.001$ ), low-density lipoprotein cholesterol (LDL-c) (3.5±0.2 vs. 2.3±0.1 mM,  $P < 0.001$ ) and triglyceride (TG) (1.2±0.1 vs. 0.8±0.1 mM,  $P < 0.05$ ) compared to Y. Immobilisation caused a significant decrease in the plasma concentration of TC (4.0±0.1 to 3.8±0.1 mM and 6.0±0.1 to 4.9±0.1 mM), HDL-c (1.4±0.1 to 1.2±0.1 mM and 1.6±0.1 to 1.4±0.1 mM), TG (0.9±0.1 to 0.8±0.1 mM and 1.3±0.1 to 1.0±0.1 mM) and LDL-c (2.2±0.1 to 2.1±0.1 mM and 3.7±0.1 to 3.4±0.1 mM) in Y and E, respectively. Training increased ( $P < 0.05$ ) plasma HDL-c concentration back to baseline (1.2±0.1 to 1.3±0.1 mM and 1.4±0.1 to 1.6±0.1 mM) in Y and E, respectively. After training plasma TC concentrations remained ( $p < 0.05$ ) below baseline (3.7±0.1 vs. 4.0±0.1 mM and 5.3±0.1 vs. 5.5±0.1 mM) in Y and E, respectively. Plasma LDL-c and TG concentrations were not affected

by training. The Y and E subjects responded similarly to the intervention. Conclusion: Despite the possibility to ambulate freely and encouragement to stay habitually active the immobilisation of one leg was sufficient to decrease the HDL-c concentration. This reduction occurred irrespective of age. Our findings emphasise the marked effects of physical inactivity in both young and elderly and highlights the prolonged recovery period needed to recover the HDL-c to baseline levels.

### ASSOCIATION OF BRAIN ANATOMY WITH PHYSICAL ACTIVITY IN OLDER ICELANDERS

Arnardottir, N., Koster, A., Van Domelen, D., Brychta, R., Caserotti, P., Eiriksdottir, G., Sverrisdottir, J., Sigurdsson, S., Johannsson, E., Chen, K., Gudnason, V., Harris, T., Launer, L.

1: UJ (Reykjavik), 2: IHA (Kopavogur), 3: NIA (Bethesda, Maryland), 4: MU (Maastricht), 5: NIDDK (Bethesda, Maryland), 6: SDU (Odense), 7: UJ (Laugarvatn)

**Introduction** The brain atrophies with age, which is reflected in reduction in white (WM) and gray matter (GM) and in increased white matter lesions (WML). This change in the brain has been associated with reduced cognitive ability. The aim of this study is to examine how MRI-derived brain atrophy measurements in a 5-year period, is associated with physical activity (PA) in an older population. **Methods** PA was measured in the second phase of the Age, Gene/Environment Susceptibility (AGES II- Reykjavik study) (Harris et al., 2007) from April 2009 to June 2010. Among many other measurements, all participants had a second MRI as a follow-up to their first MRI 5 years prior (AGES-Reykjavik study). We examined the relative volume of WM, GM and WML and their changes over 5 years. The participants wore an accelerometer (Actigraph GT3X) at the right hip for one complete week in a free-living setting (Arnardottir et al., 2013). PA is expressed as total counts of activity/day and average minutes/day >760 counts/min (HLH-PA), and sedentary time is expressed as <100 counts/min. In total, 361 participants had complete PA measured in AGESII and both MRI measurements in AGES and AGESII. Results The mean age of the participants was 79.2 (SD=4.5 years) (at AGES III). After adjusting for age, sex and brain infarctions, both 5-year change in GM (beta=0.17, p=0.001) and baseline GM (beta=0.17, p=0.002) predicted time spent in both PA categories. Baseline WM predicted PA (beta=0.14, p=0.014) but not the 5-year change in WM. However, the 5-year change in WML predicted only HLH-PA (beta=-0.12, p=0.017) but not baseline WML. Conversely, the 5-year change in GM (beta=-0.13, p=0.015) and baseline WM (beta=-0.13, p=0.029) predicted sedentary time. Adjustments for baseline PA according to questionnaire did not change the above relationships. **Discussion** The results suggest that brain atrophies negatively affects PA in older adults. However, the causality is unclear as PA has positive effects on cognitive functions (Smith et al., 2010) and the older adults with more PA may slow the changes in the brain anatomy. **References** 1. ### ELECTROENCEPHALOGRAPHIC CHARACTERISTICS OF DIFFERENT MOVEMENT PARAMETERS DURING A COMPLEX SENSORIMOTOR TASK

Hülsdünker, T., Mierau, A., Goldmann, J.P., Strüder, H.K.

*German Sport University Cologne*

**Introduction** Movement quality is a key determinant for success in many different sports. However, until now only little is known about the central mechanisms of movement control. The currently available literature on cortical processes associated with movement is limited to simple movements with small muscular activity. Considering the motor requirements of many daily life tasks as well as in sports, these movements are not representative and control processes may differ significantly in more complex movements which usually involve a larger muscle mass and are more dynamic. **Methods** Twelve male subjects were asked to perform 30 counter-movement jumps, respectively. EEG was recorded over sensorimotor areas of the cortex and spectral power was analyzed using band-pass-Filter. Alpha, beta and gamma frequency bands were defined based on individual frequency characteristics. The entire period of movement was further subdivided into different segments based on the ground reaction force. For statistical analysis log-transformed electrical power values were calculated for the electrodes overlying the functional leg/foot region of the primary motor cortex. Results We found a desynchronization (ERD) in the alpha and beta frequency bands before movement onset while the gamma frequency band remained unchanged. During movement execution beta and gamma power increased significantly with maximum values within the segment prior to toe off. After landing, beta power decreased to baseline level within one second while gamma power remained elevated for about two seconds. These effects revealed broad band characteristics rather than narrow reactive frequencies. **Discussion** The present study provides first insights into the electrocortical characteristics of a complex whole-body movement task. Our results suggest common processes in the primary sensorimotor cortex preceding simple and complex movements that are reflected by the alpha and beta ERD. However, during actual movement execution significant differences were present when compared to the literature on simple isolated limb movements reflected by the beta ERS during movement and the absence of a beta ERS after movement offset. The combined beta and gamma changes during jumping were interpreted to reflect different feedback processing and binding of information based on the 'binding by synchronization' hypothesis.

### COMPARISON OF LOWER LIMBS TORQUE PRODUCTION IN PARKINSON DISEASE

Vieira, A., Fischer, B.L., Homem, R.C.P.P., Akira, V., Resende, L.C., Tavares, D.P., Paulista, H.R., Bottaro, M., Lima, R.M., Oliveira, R.J.

*Universidade de Brasília*

One of the earliest manifestations of Parkinson's Disease (PD) is the clinical condition characterized by more pronounced unilateral impairment, which cause a decrease in functional capacity and disability. By the way, few studies have examined the effects between this

characteristic and lower limbs torque production in this population. **PURPOSE:** To evaluate the differences in torque production between the more involved lower limb (MILL) and less involved lower limb (LILL) in PD subjects. **METHODS:** 41 PD subjects ( $67 \pm 13.79$  years,  $161 \text{ cm} \pm 0.64 \text{ cm}$ ,  $70.7 \pm 13.97 \text{ kg}$ ), evaluated by the UPDRS (section 3), stages 1 to 3 of Hoehn and Yahr scale, were submitted to a concentric isokinetic knee extension (Biodex System 3 Isokinetic Dynamometer) using a protocol composed of one warm up set (10 repetitions at  $120.\text{s}^{-1}$ ) and two evaluation sets (4 repetitions at  $60.\text{s}^{-1}$ ) with one minute interval after each set. **RESULTS:** One-way ANOVA did not demonstrated significant differences between MILL and LILL for absolute peak torque ( $\Delta = 14 \text{ N/m}$ ;  $\Delta\% = 8.68\%$ ;  $p = 0.5864$ ), average torque ( $\Delta = 9.9 \text{ N/m}$ ;  $\Delta\% = 9.3\%$ ;  $p = 0.5139$ ) and relative peak torque ( $\Delta = 4.5\%$  of bodyweight;  $\Delta\% = 2.41\%$ ;  $p = 0.5864$ ). **CONCLUSION:** Our results demonstrated that despite subjects with PD have more pronounced unilateral impairment, the torque production between MILL and LILL are equal.

### EFFECT OF A 103-KM MOUNTAIN TRAIL-RUNNING RACE ON CORTICOSPINAL VOLUNTARY ACTIVATION AND EXCITABILITY

Temesi, J.1, Rupp, T.2,3, Arnal, P.J.1, Martin, V.4, Verges, S.2,3, Millet, G.Y.1,3

1 Université de Lyon, Saint-Etienne, France, 2 Université Joseph Fourier, Grenoble, France, 3 INSERM U1042, Grenoble, France, 4 Université Blaise Pascal, Clermont-Ferrand, France

**Introduction** The well-established central deficit in ultra-endurance running races (Millet et al. 2011) is poorly understood. The use of transcranial magnetic stimulation (TMS) in parallel with peripheral nerve stimulation provides greater insight into the source of these central changes. The aims of this study were to determine the presence and magnitude of corticospinal and peripheral voluntary activation deficits after completion of a mountain trail-running race and whether there are simultaneous changes in corticospinal excitability and intracortical inhibition. **Methods** Neuromuscular function was evaluated before and after a 103-km mountain trail-running race ( $20:25:30 \pm 3:28:55$ ) in 27 experienced endurance trail runners (15 men, 12 women;  $43 \pm 9$  years;  $66 \pm 11 \text{ kg}$ ;  $\text{VO}_2\text{max}: 56 \pm 6 \text{ ml}\cdot\text{min}^{-1}\cdot\text{kg}^{-1}$ ). Subjects performed maximal voluntary isometric contractions (MVC) of the knee extensors with electrical stimulation of the femoral nerve (single and paired 100-Hz stimuli) delivered at rest and during MVC to evaluate peripheral voluntary activation (VAp) and maximal vastus lateralis (VL) M-wave. TMS was also delivered during sets of voluntary isometric contractions at 100, 75 and 50% MVC to calculate estimated resting twitch, cortical voluntary activation (VAc), motor-evoked potential (MEP) amplitude and cortical silent period (CSP) duration in VL. MEPs were normalized to maximal VL M-wave. Variables were analyzed by paired t-test with significance at 0.05. **Results** There was a 37% decrease in MVC post-race ( $P < 0.001$ ), coinciding with decreased VAc (92 to 78%) and VAp (91 to 67%) (both  $P < 0.001$ ). There was a significant correlation between  $\Delta\text{VAp}$  and  $\Delta\text{VAc}$  ( $r = 0.83$ ;  $P < 0.001$ ). VL MEP amplitude at 100% MVC was increased post-race ( $P < 0.05$ ). There were no differences in MEP amplitude at 50 or 75% MVC nor in CSP duration at any contraction intensity pre- to post-race ( $P > 0.05$ ). **Discussion** The changes in cortical and peripheral VA indicate a serious inability of the corticospinal pathway to maximally drive the muscles after an endurance mountain trail-running race. This was not explained by changes in intracortical inhibition. Increased corticospinal excitability was observed post-race during maximal contractions but not during submaximal effort at the same relative intensity as pre-race, suggesting a hypothetical link between increased corticospinal excitability and decreased VA at maximal effort. **References** Millet GY, Tomazin K, Verges S, Vincent C, Bonnefoy R, Boisson RC, Gergele L, Feasson L, Martin V. (2011) PLoS One, 6, e17059.

### ACTION DIRECTION OF MUSCLES DURING MULTI-DIRECTIONAL ACTIVITIES IN 3-DIMENSIONAL FORCE SPACE

Hagio, S., Kouzaki, M.

Kyoto University

**Introduction** The central nervous system is expected to activate the relevant muscles based on their mechanical actions to produce the desired endpoint force (Kuo, 1994). The torques, however, are generated on complicated interaction among neighboring muscles, so it is required to examine the net contributions of muscles to endpoint forces (referred to as 'action direction [AD]') in various configurations. In this study, we estimated the ADs of muscles during multi-directional voluntary isometric force-generating tasks in 3-dimensional force space. **Methods** Each subject lay on their left side on a bed with the right leg supported horizontally by a sling. The knee and hip joint were applied with the angles of  $90^\circ$  from full extension. Isometric endpoint forces surrounding the right ankle were produced for 10 s at two different intensities (20 N and 40 N) in each of 32 different directions in 3-dimensional space, which were composed of three force vectors referring to anatomical hip adduction-abduction, knee extension and hip flexion directions, respectively. The subjects viewed the desired force as a target on a visual display. Surface electromyograms (EMGs) were recorded from quadriceps muscles. The AD is based on a cross-correlation of each rectified EMG and force component. According to three correlation coefficients, which peak time lag was defined from 0 to 200 ms, the AD in the 3-dimensional space was determined across each trial. **Results** The ADs of vastus lateralis (VL), vastus medialis longus (VML) and vastus intermedius (VI) as mono-articular knee extensors, dominated not only knee extension but hip flexion torques and were furthermore not corresponding to each other despite functionally similar muscles. Additionally, the ADs of the knee extensors containing the rectus femoris (RF) as bi-articular muscle showed not only the directions on sagittal plane but either medial or lateral direction. Interestingly, variability of ADs for all muscles was also observed across each trial. **Discussions** The contribution of off-axis torques or misalignment of functionally similar muscles might come from the complex interaction between each muscle and bi-articular muscle, RF (Nozaki et al., 2005), or the neighboring muscle based on the different characteristics in their architecture (Akima et al., 2000). The variability of ADs was suggested to be involved with the change of the interaction among muscles depending on desired endpoint forces and make it possible to generate flexible forces in a high degree of freedom. **References** Akima H, Kubo K, Kanehisa H, Suzuki Y, Gunji A, Fukunaga T. (2000). Eur J Appl Physiol, 82: 30-38. Kuo AD. (1994). Hum Move Sci, 13: 635-663. Nozaki D, Nakazawa K, Akai M. (2005). J Neurophysiol, 93: 2614-2624.

### POTENTIATION OF ELECTROMYOGRAPHIC ACTIVITIES OF THE PLANTAR FLEXOR BY ANTAGONIST CONDITIONING CONTRACTION AND JUMP

Kamimura, T.1, Muramatsu, K.2

1:Tokyo University of Social Welfare, 2:Health Science University

**Introduction** Preceding antagonist conditioning contraction (ACC) has been shown to potentiate agonist contraction force, electromyography (EMG) activity, and other agonist outputs (Sale, 1986). Previously, we showed that the rate of rise of EMG activity was increased by isometric ACC (Kamimura et al, 2009). However, the neural influence on muscle activities of plantar flexors in dynamic ACC has not been

clarified. In addition, whether plantar flexor activities in loaded conditions were affected by ACC was not clear. The purpose of this study was to examine whether plantar flexor activities were potentiated by the dynamic ACC in a standing position and to clarify the involvement of neural factors. Methods Twelve male subjects performed three experimental trials five times for each: plantar flexion in a standing position (control), plantar flexion immediately after dorsi flexion in a standing position (ACC), and continuous jump at toe. The plantar flexion in control and ACC trials was done maximally. In the ACC trials, the plantar flexion was done immediately after maximal dorsi flexion of less than one second. Surface EMG signals were recorded from the gastrocnemius medialis, and integrated EMG (iEMG) and median power frequency (MdPF) of the EMG signals during the plantar flexion phase were calculated. To calculate the rate of the EMG amplitude development (RED), the absolute values of EMG amplitude signal were numerically filtered and differentiated. The statistical analysis was done using Kruskal-Wallis and Steel-Dwass tests. Results The magnitude of iEMG during plantar flexion phase in jump trial was significantly larger than that of control, whereas that in ACC trial was not. In contrast, the value of MdPF in ACC trial, but not in jump trial, was significantly larger than that of control. Both the values of RED in ACC and jump trials were significantly larger than that of control. No significant difference was observed between the RED of jump and ACC trials. Discussion Among the three EMG activities of the plantar flexor tested in this study, RED was potentiated in both ACC and jump trials, suggesting involvement of neural factors in the potentiation. However, iEMG was potentiated only in jump trial, whereas MdPF was potentiated only in ACC trial. It was suggested that the proprioceptive stretch reflex might primarily contribute to the potentiation in jump trial, whereas other neural factors such as Golgi tendon organ reflex originated from antagonist muscles might be involved in the potentiation observed in ACC trial. Reference Sale DG. (1986). Human Muscle Power. 289–307. Champaign, IL: Human Kinetics. Kamimura T, Yoshioka K, Ito S, Kusakabe T. (2009). Human Movement Science. 28, 407–414.

### PREFRONTAL CORTEX OXYGENATION AND ELECTROCORTICAL ACTIVITY DURING INCREMENTAL BICYCLE EXERCISE

Abeln, V., Schneider, S., Knicker, A., Vogt, T., Hollmann, W., Strüder, H.K.

*German Sport University Cologne*

Introduction Decreased prefrontal cortex (PFC) oxygenation was postulated to reflect impaired PFC function contributing to central mediated fatigue during high intensity exercise. In hypoxia, oxygenation saturation within the PFC is known to be reduced and assumed to go along with decreased brain activity playing a role in earlier occurring fatigue. Near-infrared spectroscopy (NIRS) has mainly been used for the examination of PFC oxygenation situation, which is supposed to reflect neural activity indirectly, however so far no exercise study exists investigating hemodynamic (NIRS) and electro cortical activity (EEG) synchronously to shed light on their correlation. Methods Eight sport students commenced an incremental bicycle exercise test at 50 Watts (W) increased by 50 W at any five minutes under normoxic and hypoxic (12.7 kPa PIO<sub>2</sub>) conditions respectively. Before, during and after exercise EEG and NIRS recordings of the left and right PFC Brodmann area (BA) 10 and 46 were performed synchronously. ANOVA for repeated measures was used to compare mean EEG and NIRS values of the last twelve minutes of exercise to pre and post exercise as well as between conditions and hemispheres. Results Under normoxic conditions, higher absolute workload (231.3± 37.2 W), and relative PFC oxygenation (oxygenated- (O<sub>2</sub>Hb): 8.82± 9.57; deoxygenated- (HHb): 3.04± 3.19) were observed, whereas hypoxic conditions resulted in earlier exhaustion (200± 26.7 W) and reduced PFC oxygenation (O<sub>2</sub>Hb: -1.49± 3.02; HHb: 6.56± 3.05). Hemodynamic parameters increased remarkably with exercise intensity (p< .001) and differed between conditions (O<sub>2</sub>Hb: p< .001; HHb: p=.021) and hemispheres (O<sub>2</sub>Hb: p=.047). For EEG cortical source density within PFC BA10 and BA46, higher values during compared to pre and post exercise (p< .001) and an interaction between hemisphere and condition (BA10 p=.007; BA46 p=.017) indicating a shift of electro cortical activity from left towards right hemispheric activation from normoxia to hypoxia were revealed. No correlation between NIRS and EEG but between NIRS and heart rate were found. Discussion The results shed light on the correlation between two different methods for brain imaging during high-intensity exercise and emphasize that transferability of results between methods need to be done with caution. NIRS signal is supposed to be predominated by systemic hemodynamic changes during exercise overlaying changes attributable to neural activity. Reduced performance in hypoxia was accompanied by lower left-sided and higher right-sided PFC activity. Results are discussed in relation to the proposed frontal asymmetry model.

### SPECIFIC FEATURES OF EXCITABILITY OF CENTRAL AND PERIPHERIC PARTS OF NEUROMUSCULAR SYSTEMS OF ATHLETES IN THE TRAINING CYCLE

Mikhailova, E.

*Velikiye Luki State Academy of Physical Education and Sports*

Introduction Investigation of the mechanisms of neuronal adaptation of central and peripheral sections of neuromuscular systems of athletes under the influence of training and competitive loads is of great importance for practical sports. Methods and subjects 8 (males) middle - distance runners (ages 18 -21) took part in the research. Motor-evoked potentials (MEP) of leg muscles by transcranial magnetic stimulation (TMS), posterior root-muscle reflexes (PRM-reflex) of these muscles by electrical stimulation of the spinal cord at T11-T12 and M-wave were registered at rest. Single stimulus (1ms long) were used for the stimulation. Thresholds and amplitudes MEP m. soleus, m. tibialis anterior, m. gastrocnemius were analysed. Results Thresholds and maximum amplitude MEP have been changed during the training cycle. The most significant changes occurred in the competitive period. Thresholds of MEP under TMS were raised before the competitions and were decreased after them, thresholds of PRM-reflex had opposite changes. The amplitude of MEP under stimulation of motor cortex and amplitude of PRM-reflex increased before the competitions and reduced after them. The amplitude of M-wave varied insignificantly. Conclusion. There are the processes of the specific neuronal adaptation, under the influence of a focused training, which were more pronounced at the supraspinal and spinal levels. The results of the study can be used in practice of sports to control the efficiency of the training, and to evaluate degree of adaptation to muscle work. ### ESTABLISHING CRITICAL TORQUE DURING AN INCREMENTAL TEST OF INTERMITTENT ISOMETRIC KNEE EXTENSIONS

de Ruijter, C.J., Mallee, M.I.P., Leloup, L.E.C., de Haan, A.

*MOVE Research Institute Amsterdam, VU University Amsterdam*

For every exercise there is a critical intensity above which output can not be maintained for a long time (30-60 min) without progressive fatigue. Establishing this critical exercise intensity is time consuming and difficult to perform as it involves a series of exhausting exercise

tests performed at different intensities and days (e.g. Burnley, 2009). However, during muscle function testing, strenuous exercise may be problematic for fragile subjects and patients. Moreover, also in healthy individuals the occurrence of central fatigue may affect estimated critical torque. Recently de Ruiter et al. (2012) showed that during 5 min bouts of sub maximal isometric knee extensor contractions (3s with 2s rest in between), the highest torque level during which EMG and muscle oxygenation remained stable (fatigue threshold, FT) was related to aerobic training status (VO<sub>2</sub>-max). In that study bouts of different intensities were applied in random order, with the risk of inducing early fatigue that may affect the test outcome. We hypothesize that the FT can also be established during an incremental test and that this FT signifies a critical exercise intensity that can be sustained for at least 30 min with ratings of perceived exertion (RPE)<8. Starting at 25% MVC (3s with 2s rest in between, 90 deg knee angle), for 10 subjects (~25yr, 6 male) torque was increased in steps of 5 % MVC every 5 minutes until failure. In each subject, the ratio of rectified surface EMG (mean values of the 3 superficial knee extensor muscle heads) over Torque Time Integral (TTI) was averaged over 6 consecutive contractions and values were subsequently expressed as a percentage of the first value at 25% MVC. The highest intensity for which EMG/TTI did not increase more than 10% during the 5 min (linear regression) was defined the fatigue threshold. FT (mean±sd) was reached at 39.0 ± 6.1% MVC (RPE: 5.8±1.8), which was 15.5 ± 5.0 % MVC below torque failure. With two additional measurements on different days and in a double blinded set up, for 5 subjects sustainable torque (ST; 30min completed with RPE<8) was subsequently found to be the same as FT, while for the others ST was 5% MVC higher than FT. We conclude that during repetitive isometric contractions a critical intensity, at which torque can be sustained for 30 minutes with limited signs of fatigue, can objectively be established using a sub maximal incremental test that does not require participants to go all out. ### INTERACTION OF CENTRAL AND PERIPHERAL FACTORS DURING REPEATED SPRINTS AT DIFFERENT LEVELS OF ARTERIAL SATURATION

Billaut, F.1,2, Kerris, J.P.2, Rodriguez, R.F.2, Martin, D.T.M.3, Gore, C.J.3,4, Bishop, D.J.2

1: INS Québec (Montréal, Canada), 2: Victoria University (Melbourne, Australia), 3: AIS (Canberra, Australia), 4: Flinders University (Bedford Park, Australia)

**Introduction** We investigated the effects of arterial hypoxemia on muscle recruitment, functional performance and the development of peripheral locomotor muscle fatigue during repeated-sprint exercise (RSE). **Methods** In a single-blind, randomised and cross-over design, ten team-sport male athletes performed two RSE (fifteen 5-s cycling sprints with 25 s of rest; power self-selected) in normoxia and in acute moderate hypoxia (FIO<sub>2</sub> 0.138). Mechanical work, total electromyographic intensity (summed quadriceps electromyograms, RMSsum) and muscle (vastus lateralis) and pre-frontal cortex near-infrared spectroscopy (NIRS) parameters were calculated for every sprint. Blood lactate concentration ([Lac-]) was measured throughout the protocol. Peripheral quadriceps fatigue was assessed within 45 s post-exercise via changes in potentiated quadriceps twitch force ( $\Delta Q_{tw,pot}$ ) pre- versus post-exercise in response to supra-maximal magnetic femoral nerve stimulation. The central activation ratio (QCAR) was used to quantify completeness of quadriceps activation. **Results** Compared with normoxia, hypoxia reduced arterial oxygen saturation (-13.7%, P=0.001), quadriceps RMSsum (-13.7%, P=0.022), QCAR (-3.3%, P=0.041), and total mechanical work (-8.3%, P=0.019). However, the magnitude of quadriceps fatigue induced by RSE was similar in the two conditions ( $\Delta Q_{tw,pot}$ : -53.5% and -55.1%, P=0.71). Performance reduction in hypoxia occurred despite similar metabolic (muscle NIRS parameters and [Lac-]) and functional (twitch and M-wave) muscle states. **Conclusion** These results suggest that quadriceps muscle recruitment and cycling performance during intermittent, short sprints may be regulated to limit the development of quadriceps muscle fatigue. This finding supports the role of the interaction between muscular perturbations and neural adjustments in the regulation of high-intensity, whole-body exercise.

### EFFECTS OF FINGERTIP LIGHT TOUCH ON HUMAN WALKING ON THE GROUND

Kimura, T.1, Otsuka, M.1, Taki, C.1, Konishi, K.1, Sanada, K.1, Kouzaki, M.2, Shiozawa, N.1

1:Ritsumeikan University (Japan), 2:Kyoto University (Japan)

**Introduction** Previous studies have shown that fingertip light touch to a fixed surface substantially reduces postural sway during quiet standing (Jeka and Lackner, 1994), due to an enhanced somatosensory feedback (Kouzaki and Masani, 2008; Kimura et al., 2012). To further shed light on this additional feedback, we examined the effects of the fingertip light touch on the posture of walking on the ground. **Methods** Twelve young subjects (20-26 yrs) volunteered for two experiments. In Exp 1, they walked straight for 16 m at their comfortable velocity, in a measurement room. In the light touch trial, the subject lightly (less than 2.0 N) touched a handrail, with his/her index finger of the right hand. A force transducer attached on the fingertip measured the touch force online. The experimental conditions with and without light touch (LT and CON) were conducted. Also, in each experimental condition, the eyes-open (EO) and eyes-closed (EC) trials were performed. The four trials were, respectively, repeated three times, in pseudo-random order. A triaxial-accelerometer was attached on the subject's back. The height of the accelerometer was adjusted to the third lumbar vertebra. A pair of foot switches was attached on the soles of the feet. As the Exp 1 eliminated the effect of fingertip tactile sensation, the additional experiment was performed (Exp 2). The handrail in the Exp 1 was replaced by a water way, positioned at about the same height as the handrail. The subject dipped the index finger into the water during walking, in a manner similar to that employed in the Exp 1, while the force transducer on the fingertip had been removed. **Results and Discussion** In the Exp 1, the average number of footsteps in the 16 m was not different between LT and CON trials. On the other hand, it was found that, in each of the EO and EC conditions, the LT significantly reduced the average amplitude of the acceleration of the third lumbar vertebra in the mediolateral direction (P<0.05). Also, in the Exp 2, the light touch to the water significantly reduced the average amplitude of the mediolateral acceleration (P<0.05). In the Exp 1, the additional feedback of the body orientation may be accounted for mainly by the proprioception of upper limb. And, in the Exp 2, the effect of the finger tactile sense was also confirmed. These results suggest that the somatosensation, including the proprioception and the tactile sense, can enhance the postural stability during normal walking on the ground, as well as the quiet standing. **References** Jeka JJ, Lackner JR. **UNILATERAL LEG PRESS FATIGUE INFLUENCES INTRACORTICAL EXCITABILITY IN NONEXERCISED HAND MUSCLES**

Takahashi, K., Maruyama, A.

*Kumamoto National College of Technology*

Objective It has recently been demonstrated that exhaustive unilateral fatiguing exercises not only affects the motor area innervating exercising muscles but also the ipsilateral motor area innervating nonexercised muscles. The aim of this study was to examine whether exhaustive unilateral leg press exercise affects intracortical excitability of the motor cortex representation of nonexercised hand muscles. Methods Two experiments were performed. In the first experiment, 8 subjects performed an intermittent right leg press exercise composed of 3 bouts of 5-min leg presses at 50% maximal voluntary contraction, each separated by a 2-min period of rest and followed by a 30-min period of recovery. Single- and paired-pulse transcranial magnetic stimulation (TMS) were applied to evoke responses in the non-exercised right first dorsal interosseous (FDI) muscle before and immediately after each bout of exercise; TMS was also applied during recovery. Inhibitory (3 ms) and facilitatory (10 ms) interstimulus intervals were randomly intermixed with the test stimulus. In the second experiment, 6 subjects underwent TMS to the left FDI muscle by using the same experiment design as experiment 1. Results Short-interval intracortical inhibition (SICI) of the right and left FDI muscle gradually decreased with the exercise time, and was maximal 5 min into the recovery period. Intracortical facilitation (ICF) also gradually decreased with the exercise time; however, it was unchanged during the recovery period. The rate of change of both SICI and ICF in the right FDI muscle was larger than that in the left FDI muscle. Conclusions Exhaustive unilateral leg press exercise influences the intracortical excitability of the motor area innervating the right and left FDI muscles. Furthermore, our findings suggest that it induces more significant change in the ipsilateral hand muscle than the contralateral hand muscle.

**EFFECT OF PRESSURE INTENSITY OF GRADUATED ELASTIC COMPRESSION TIGHT ON MUSCLE FATIGUE DURING RUNNING**

Miyamoto, N., Kawakami, Y.

*Waseda University*

Elastic compression garments such as tights and stockings are widely used for the improvement of sports performance. Although previous studies have examined the effect of wearing compression garments during submaximal running exercise on oxygen consumption, blood lactate level and time to exhaustion, the findings are not consistent. One of the possible reasons for the inconsistent findings is the pressure intensity exerted by the compression garments. It has been shown that the elastic compression garment with adequate pressure can relieve a decline in muscle force generating capacity (i.e., muscle fatigue) during repetitive muscle contractions (Miyamoto et al. 2011). They suggested the smaller accumulation of metabolites such as inorganic phosphate and proton as possible mechanisms for the reduced muscle fatigue. However, it remains unclear. The purpose of the present study was to examine the effect of pressure intensity of elastic compression tight on the extent of muscle fatigue of the thigh muscles during running, by using magnetic resonance (MR) T2-weighted imaging which is sensitive to accumulation of lactate, inorganic phosphate, and proton. Methods Eleven subjects performed three treadmill tests consisting of 4.5-min warm-up and 30-min running at 12 km/h on separate days; two kinds of elastic compression tights (one (LOW) with  $1.08 \pm 0.20$  kPa at 50% regions of the thigh length and the other (HIGH) with  $1.94 \pm 0.44$  kPa at the same regions, respectively) and non-elastic compression tight as a control (CON). Before and after the exercise, MR-T2 images of the thigh were recorded without the tights (TE: 25, 50, 75, 100 ms; TR: 2000 ms; Matrix:  $256 \times 256$ ; FOV:  $240 \times 240$  mm; Slice thickness: 10 mm; Gap: 20mm). From each image, the T2 values of four knee extensors (vastus lateralis, vastus medialis, vastus intermedius, rectus femoris), three knee flexors (short and long heads of the biceps femoris, semitendinosus, semimembranosus), two hip adductors (adductor magnus and longus) were computed. For T2 values of each muscle, separate 2-way ANOVAs with repeated measures (time (before, after)  $\times$  condition (CON, LOW, HIGH)) and post-hoc tests were performed. Results and Discussion In almost all knee flexors and hip adductors, the T2 values were significantly increased after the 30-min running at 12 km/h. For the biceps femoris, semimembranosus, adductor magnus, and adductor longus, 2-way ANOVAs revealed significant condition  $\times$  time interaction, and post-hoc tests showed that the T2 values after running in HIGH condition were significantly smaller than those in CON conditions. These results indicate that wearing an elastic compression tight with adequate pressure intensity during running can relieve the accumulation of metabolites. **14:00 - 15:00****Mini-Orals****PP-PM69 Training and Testing [TT] 4****TRAINING RECOMMENDATIONS FOR THE DEVELOPMENT OF TORQUE, POWER AND ACCELERATION IN MEN AND WOMEN BASED ON MULTIVARIATE STRUCTURAL EQUATION MODELS**

Heazlewood, I., Boutagy, A.

*Charles Darwin University*

Do not insert authors here Introduction Structural equation modeling (SEM) is analogous to multiple regression but is a more powerful statistical method as it can evaluate the modeling of more complex interactions, nonlinearities, correlated independent variables, measurement error, correlated and uncorrelated error terms and multiple latent independents or factors, each measured by multiple indicators (Hair et al., 2010; Arbuckle, 2009; Heazlewood & Boutagy, 2010). Research aim was to evaluate using structural equation modelling more complex relationships between strength-torque, power and sprint acceleration in both genders. Methods The sample was physically fit males (n=32) and females (n=28). The exogenous variables in the model were isokinetic peak torque (N.m) at isokinetic speeds of 60os-1, 180os-1 and 300os-1 using leg extension/flexion. The endogenous variables were vertical jump (flight time (s)), peak vertical height (m) and jump contact time (s) and 10m (s) acceleration sprint. Isokinetic torque, power, work and fatigue index were measured using a HUMAC NORM - CYBEX 340. Statistical analysis was AMOS 18 software (Arbuckle, 2009) to solve the structural equations and path mod-

els. Results It was observed the relationship for jump height to sprint time is significantly more important for males (coefficient = -.82) than for females (coefficient = -.47). The path coefficients from peak torque are more significant for males at 600s-1, however peak torque at 1800s-1 and 3000s-1 were similar for gender. The significant indirect effect is the peak torque leg extension for 600s-1 on 10m sprint performance mediated via the vertical jump for males, whereas in females this effect was not significant. Analysis assessing the congruence between the two path models indicated significant difference between genders. This was attributed to the significant direct effect between vertical jump height and 10m sprint in males and the gender difference for the indirect effect of peak torque leg extension for 600s-1 on 10m sprint. Discussion Different interactions between strength-torque, power and acceleration ability were evident between genders. The significant indirect path of isokinetic peak torque for leg extension for 600s-1 influencing 10m acceleration ability via power ability in males when contrasted with this non-significant path in females has implications for training. Males should gain improvement from both high resisted strength training coupled with specific jump power training to enhance acceleration whereas females would gain more by training with power and sprint acceleration activities. ### **THE ISAF AEROBIC FITNESS TEST. A TRIAL INTO THE VALIDATION OF A CARDIO-RESPIRATORY ENDURANCE TEST FOR FOOTBALL PLAYERS**

Jemni, M., Vahedi, A.

*University of Greenwich*

Introduction & Objective The intermittence and the random nature of football games make any specific physiological assessment quite harder comparing to any "cyclic" sports. This study is part of a series of investigations within the process of a new aerobic fitness test validation: the "ISAF aerobic fitness test" (International Science And Football Association). It aims to compare the cardio-respiratory and metabolic variables between two gradually increasing maximal tests: a random and a standardised one that contain specific football skills Method 22 male football players took part in this stage [23.3 (4.4) yrs, 80.1 (9.2) kg, 180 (1) cm]. Each subject performed two trials based on the YoYo test: a standardised test and a randomised one. Running speed increased every 2 min. Footballers performed selected skills signalled by audio stimulus while running, either in standard order or randomised during two different occasions (running forward & backward, jumping, changing directions, ball work). Gas exchange (VO<sub>2</sub>; VCO<sub>2</sub>) and heart rate (HR) were continuously measured using portable gas analyser (MetaMax). Blood lactate (BL) before and after the test was also measured using Analox Lactate analyser. Data were compared using a one-way ANOVA for repeated measures followed by a post hoc Fisher for cell-to-cell comparison. Results and discussion Sharp linear increase of the HR and VCO<sub>2</sub> have been noticed at the start of both tests. HR continued to slightly increase until exhaustion reaching maximal values around 190 bpm with no significant difference between the trials. VO<sub>2</sub> showed a more obvious linear increase during the randomised test compared to the standard one, reaching significantly different values around 45 and 35 ml/kg/min respectively (p<.05). The rate of the expiratory ratio (RER) was significantly higher during the randomised test compared to the standardised one (p<.05), reaching 1.47 and 1.19 respectively. Maximal BL was average around 4 mmol/l, with no difference between the trials. Conclusion Both trials have led to the footballers' maximal cardiovascular abilities. They have however affected them differently from the respiratory system point of view, with a clear difference between the VO<sub>2</sub> maxs achieved. The metabolic response seems nevertheless quite reduced within both tests. Note: the results above are the very early stage of data collection; we are currently continuing the investigations and more footballers are being tested. More work will be done within the validation process including variation and reliability assessment within each trial and reproducibility. References Kemi, O. J., Hoff, J., Engen, L. ### **STAR EXCURSION BALANCE TEST AND SINGLE-LEG DROP JUMP TEST FOR THE ANALYSIS OF DYNAMIC STABILITY: WHAT IS THE RELATIONSHIP BETWEEN THEM?**

Borao, O., Corbi, F., Planas, A., Beltrán, J.V.

*INEFC/UdL (Lleida)*

Introduction Several analysis tools have been described to evaluate balance in humans. Among these tools, we highlighted two dynamic tests widely used in sport injury prevention: the Star Excursion Balance Test (SEBT) and a single-leg drop jump (SLDJ) test on a force platform. We have hypothesized that there could be a relationship between both tests. In this study, we evaluated the relationship between the SEBT and the force platform in terms of dynamic balance. Methods Fifteen male subjects were evaluated (age 14.9±0.915, height 181.025±8.97, weight 67.34±11.83). Six attempts were recorded in the posterior-medial (PM) and posterior (P) directions for the SEBT, and 3 attempts for the drop jump test from a 20cm high landing on a portable extensometric force platform (MuscleLab 4000TM), sampled at 100Hz. Different variables related to the centre of pressure (COP) were assessed: anterior/posterior COP displacement, middle/lateral COP acceleration and anterior/posterior COP acceleration. One-minute rest was given between every test. During the landing test, subjects were instructed to let themselves drop (without jumping) with their hands on their waist. Kendall's tau and Spearman's rho were used to analyse the correlation. Results Measurements for PM direction correlated with the anterior/posterior COP displacement, the acceleration of the COP middle/lateral and anterior/posterior were significant (p=0.029/p=0.047/p=0.029) (p=0.039/p=0.023/p=0.039) and for P direction correlated with the anterior/posterior COP displacement, the acceleration of the COP middle/lateral and anterior/posterior were significant (p=0.015/p=0.042/p=0.015) (p=0.046/p=0.046) except for P direction correlated with the acceleration of the COP middle/lateral (p=0.064) Discussion We used the SEBT PL and P directions as they seem to have more impact on the dynamic balance (Olmsted et al., 2002), and we compared the results to the test platform (Ross, Guskiewicz and Yu, 2005). According to our results, we can suggest that the longer the measurement the participants got on the SEBT, the better dynamic stability was observed on the platform test for the anterior/posterior displacement of COP and the anterior/posterior acceleration of the COP. Despite the relative small sample size, we can suggest the possibility of evaluating balance using the SEBT, which is an easy, economic and reliable tool instead of other expensive items, especially when the institution cannot afford it. ## VO<sub>2</sub> PEAK MEASURED DURING 200 M IS NOT DIFFERENT FROM THAT CALCULATED WITH A NEW MODEL AFTER A 200-M MAXIMAL SWIM

Chaverri, D.1, Iglesias, X.1, Barrero, A.1, Schuller, T.2, Štrumbel, B.3, Hoffmann, U.2, Rodríguez, F.A.1

1: GRCE, INEFC-Barcelona, Universitat de Barcelona (Spain), 2: Institut für Physiologie und Anatomie, Deutsche Sporthochschule Köln (Germany), 3: University of Ljubljana (Slovenia)

**Introduction** Measuring V<sub>O</sub>2 during swimming is a complex and cumbersome procedure. Backward extrapolation (BE) is often used for estimating V<sub>O</sub>2 during exercise, but error can derive from a delay at the onset of the V<sub>O</sub>2 recovery curve. We aimed to compare direct peak V<sub>O</sub>2 during an incremental test with estimated values after a free 200-m maximal swim using a new modelling procedure. **Methods** 12 elite swimmers performed an incremental test (IT) composed by 3x200 m at increasing submaximal speeds, followed by an all-out 200-m swim. V<sub>O</sub>2 was measured bxb using a portable gas analyser (K4 b2, Cosmed, Italy) connected by a respiratory snorkel. HR was measured from RR intervals (CardioSwim, Freelap, Switzerland). Peak V<sub>O</sub>2(IT) was the average of the last 20 s during the 200-m maximal swim. On a separate session, all swimmers performed a free all-out front crawl 200 m swim and gases were collected during 30 s using a Hans-Rudolph 7400 oro-nasal mask immediately afterwards. Peak vV<sub>O</sub>2(200) was the post-exercise 20-s average calculated using a mathematical model (Schuller et al., 2013). In short, virtual V<sub>O</sub>2 at time (t) of recovery [vV<sub>O</sub>2(t)] is calculated using the peak HR during the last 10 s of the swim [HR(t)] and the 1-s interpolated value at (t) [IHR(t)], multiplied by the 1-s interpolated V<sub>O</sub>2 at (t) [V<sub>O</sub>2(t)], according to:  $vV_{O2}(t) = HR(t) / HR(t) \cdot V_{O2}(t)$ . Differences between direct and estimated peak V<sub>O</sub>2 were assessed using a paired t-test and Pearson's coefficient (r) was used to examine correlation. **Results** Peak V<sub>O</sub>2(IT) (mean 3296 ±SD 629 ml•min<sup>-1</sup>) was not different from vV<sub>O</sub>2(200) (3313±651) (mean diff.=17 ml•min<sup>-1</sup>, p=0.74). Both parameters were highly correlated (r2=0.97) and the standard error of the estimate was low (SEE=170 ml•min<sup>-1</sup>). **Discussion** Montpetit et al. (1981) showed that peak V<sub>O</sub>2 estimated by BE method was not different from V<sub>O</sub>2 peak during an incremental swimming test using Douglas bags. Frequently, a delay of the V<sub>O</sub>2 recovery curve occurs and BE overestimates peak V<sub>O</sub>2 (Rodríguez, 1996). In our study no significant differences were found between directly measured peak V<sub>O</sub>2 during an incremental test and that calculated using the new model based on post-exercise V<sub>O</sub>2 measures and HR kinetics. **References** Montpetit RR, Léger LA, Lavoie JM, Cazorla G. ## VALIDITY OF PEAK V<sub>O</sub>2 AFTER A MAXIMAL 400-M FREE SWIMMING TEST USING A NEW MODEL BASED ON POST-EXERCISE MEASUREMENTS AND HEART RATE KINETICS

Chaverri, D.1, Iglesias, X.1, Schuller, T.2, Barrero, A.1, Štrumbel, B.3, Hoffmann, U.2, Rodríguez, F.A.1

1: GRCE, INEFC-Barcelona, Universitat de Barcelona (Spain), 2: Institut für Physiologie und Anatomie, Deutsche Sporthochschule Köln (Germany), 3: University of Ljubljana (Slovenia)

**Introduction** A mathematical model based on heart rate (HR) and post-exercise V<sub>O</sub>2 measurements for estimating peak V<sub>O</sub>2 at the end of a swimming exercise has been recently implemented (Schuller et al., 2013). We aimed to ascertain the validity of direct V<sub>O</sub>2 measurements during an incremental 200-m test with modelled peak V<sub>O</sub>2 after a free 400-m maximal swimming test. **Methods** 17 elite swimmers performed 3x200 m at increasing submaximal speeds, followed by a maximal 200-m front crawl swim. V<sub>O</sub>2 was measured bxb using a portable gas analyser (K4 b2, Cosmed, Italy) connected by a respiratory snorkel. HR was measured from RR intervals (CardioSwim, Freelap, Switzerland). Peak V<sub>O</sub>2(200) was the average of the last 20 s during the 200-m swim. On a separate session, all swimmers performed an all-out front crawl 400 m swim and respiratory gases were collected during 30 s at the immediate recovery with a Hans-Rudolph 7400 oro-nasal mask. Peak vV<sub>O</sub>2(400) was the immediate post-exercise 20-s average calculated using the mathematical model proposed by Schuller et al. (2013). In short, virtual V<sub>O</sub>2 at time (t) of recovery [vV<sub>O</sub>2(t)] is calculated using the peak HR during the last 10 s of the swim [HR(t)] and the 1-s interpolated value at (t) [IHR(t)], multiplied by the 1-s interpolated V<sub>O</sub>2 at (t) [V<sub>O</sub>2(t)], according to:  $vV_{O2}(t) = HR(t) / HR(t) \cdot V_{O2}(t)$ . Differences between peak V<sub>O</sub>2(200) and vV<sub>O</sub>2(400) were assessed using a 2-tailed paired t-test, and correlation was examined using the Pearson's coefficient (R). **Results** V<sub>O</sub>2(200) (mean 3551±SD 657 ml•min<sup>-1</sup>) was not different from vV<sub>O</sub>2(400) (3535±631) (mean diff.=17ml•min<sup>-1</sup>, p=0.70). Correlation was very high (R2=0.93) and the standard error of the estimate was low (SEE=180 ml•min<sup>-1</sup>). **Discussion** Peak V<sub>O</sub>2 during an incremental test can be estimated from HR kinetics and recovery V<sub>O</sub>2 measured after a maximal 400-m test using the modelling procedure by Schuller et al. (2013). It has been shown that V<sub>O</sub>2 attained after a maximal 400-m swim does not differ from V<sub>O</sub>2max measured at maximal incremental tests on the treadmill or the cycle ergometer in competitive swimmers (Rodríguez, 2000). Therefore, we propose the testing and modelling procedure, using a maximal 200-m test with continuous HR and post-exercise V<sub>O</sub>2 measures, as a valid method for estimating V<sub>O</sub>2max in competitive swimmers. **References** Rodríguez FA. (2000). *J Sports Med Phys Fitness* 40(2), 87-95. Schuller T, Rodríguez FA, Iglesias X, Barrero A, Chaverri D, Hoffmann U. (2013) 18th ECSS Annual Congress, Barcelona.

## THE EFFECTS OF A SINGLE INTAKE OF POLYPHENOLS EXTRACTS® ON EXERCISE ENDURANCE AND RECOVERY IN HEALTHY SUBJECTS: A CONTROLLED, RANDOMIZED, CROSS-OVER, DOUBLE-BLIND STUDY VERSUS PLACEBO

Deley, G., Babault, N., Guillemet, D., Allaert, F.A.

Faculty of Sport Sciences

**Introduction** Exercising involves adaptations of all the systems of the body (pulmonary, cardiac, muscular and vascular) and this requires an increase in peripheral blood flow and a vasodilation. Among the various mediator of this vasodilation, nitric oxide (NO) is one of the most important.1 Supplements such as polyphenols are, therefore, thought to be an interesting ergogenic aid.2 To date, most of the studies regarding the effects of polyphenols investigated several weeks supplementation and vascular or blood parameters.3 The present work therefore aimed to study the effects of an acute intake of polyphenol (Vinitrox®) on physical performances. **Methods** 48 physically active men (31±6 yrs) were included in this study, composed of 3 experimental sessions interspersed with at least 7 days. During the first experimental session, subjects performed a maximal test on an ergocycle to determine their maximal aerobic power. During the 2 other testing sessions, subjects realized an endurance test at 70% of their maximal power and time to exhaustion was measured. The preceding evening and 1 hour before the endurance test, volunteers had to absorb either 2 capsules with 250mg Vinitrox® each or 2 placebo capsules according to randomization. **Results** In comparison with the placebo, there was a significant 2.5 min increase of the maximal duration of the endurance with Vinitrox® (P<0.05) corresponding to a 9.7±6.0% increase. Moreover, the maximal perceived exertion was reached 2.7 min later (+12.8±6.8%, P<0.05) with Vinitrox® than with placebo. **Discussion** As a conclusion, the results of the

present study showed beneficial effects with Vinitrox® for athletes looking for performance. Indeed, Vinitrox® appears to enhance endurance (i.e., capacity to maintain an intense effort) and delay maximal effort perceived exertion. Several mechanisms could account for these effects, and this, through its action on NO production. NO might increase muscle perfusion thanks to a direct vasodilation on vessels smooth muscle cells and to an inhibition of the adrenergic vasoconstriction.<sup>4,5</sup> This hyperemia would result in an increased oxygen availability to muscle cells allowing a greater and longer aerobic utilisation of glycogen. ### HANDBALL GOALKEEPER TRAINING FOR COMPETITION AND FOR SHOOTING ANTICIPATION

Sá, P.1,2, Gomes, A.R.3, Saavedra, M.4, Pimenta, N.1,2, Fernández, J.J.4

1 ISMAI (Portugal), 2 CIDESD (Portugal), 3 Universidade do Minho (Portugal), 4 Universidade da Coruña (Spain)

**Introduction** The importance of knowledge held by experts has been increasingly valued. Researchers can benefit if they focus on athletes who represent successful models, because these athletes have a complex knowledge inherent to the performance of their activity (Gomes & Cruz, 2006). The objectives of this study are to understand how goalkeeper's experts prepare the competition and what 'tools' they use to more accurately and earlier anticipate the shots. **Methods** Eight male international level goalkeeper experts participated in this research. All participants were submitted to tape-recorded semi-structured interviews, and the software QSR 6 was used to help the categorizing data. At the time of the interviews, all participants were competing at the highest level, they were from five different nationalities and they were also considered as one of the best in the world in their position. **Results** During preparation for competition, one of the most relevant tools used was observing opponents playing videos. This observation allowed athletes to understand opponent's actions, and therefore they could later anticipate their movements during competition. It was evident that goalkeepers use as shooting anticipation references: shooter corporal references; defenders actions; the impulse, trajectory and shooter laterality; along with their knowledge of opponent's actions. **Discussion** It becomes necessary and relevant that goalkeeper's preparation has its starting point on the characteristics of the competitive activity (Pascual, 2008). Games preparation is crucial and goalkeeper's main sources of information are: observing opponents' previous games and gaming experience between the same opponents. Shooter study and analysis, more specifically their finishing location predilections and their athletic qualities should lead the goalkeeper to capture information in order to anticipate the ball trajectory. It seems that pre-indicators information analysis can be a good basis on how to found a possible change in handball goalkeeper training methodology. If the goalkeeper is able, through training, to understand and to interiorize significant signs that the involvement of the shot gives, it will facilitate a spatiotemporal anticipation, while ensuring a high percentage of success in its anticipation. ### RELATIONSHIP BETWEEN BALANCE MEASURES AND PERFORMANCE OUTCOMES IN YOUTH AND ADULT TEAM ATHLETES

Zech, A.1, DeLorant, M.1, Fischer, S.1, Steib, S.2

1University of Hamburg; 2University of Erlangen-Nuremberg

**Introduction** Lower extremity injuries in team sports occur most frequently in the youth population aged 10 to 16. This has been explained with the lower skill level and physical performance in the less experienced, younger players (Peterson et al 2000). The objective of this study is to determine whether balance measures, that have been shown to be associated with an increased injury risk, differ between the youth and adult team athlete population. Furthermore, the relationship between balance and performance outcomes will be compared between both age groups. **Methods** Twenty-seven youth (14±1 years) and twenty-one adult (27±1 years) team athletes (soccer, hockey) without previous lower extremity injuries volunteered for participation. They performed the star excursion balance test (SEBT) and the balance error scoring system (BESS) in order to assess balance. Physical performance was measured by using the 30m sprint, standing long jump and agility (T-Test) tests. Differences between both age groups were analyzed by using ANOVA. Pearson product-moment correlation coefficients were calculated between maximum reach distances of the SEBT and BESS error scores as well as sprint time, jump distance and T-test time. **Results** Performance and balance outcomes differed significantly between both age groups. Young athletes demonstrated shorter jump distances ( $p=0.021$ ) and longer T-Test times ( $p=0.046$ ), as well as smaller SEBT reach distances ( $p<0.001$ ) and higher BESS error scores ( $p<0.001$ ). In both age groups, significant correlations ( $p<0.001$ ) were found among all performance outcomes (between  $r=-0.66$  and  $r=-0.83$ ). Performance and balance outcomes showed no significant correlation in adult athletes. In youth athletes, the BESS error score correlated negatively with jump distance ( $r=-0.50$ ;  $p=0.011$ ). **Conclusions** Youth athletes demonstrated lower scores in the balance and performance measures compared to adult athletes. This finding indicates that postural control is not fully developed in the age of 13 to 15 years which may contribute to the enhanced injury risk. The lack of correlations between most performance and balance variables in both groups also questions the hypothesis that the skill level and physical performance may contribute to postural or sensorimotor control impairments and thus, an increased injury risk. ### DEVICE-BASED CONTROL FOR ON-WATER TRAINING AND ROWING RACES

Schaffert, N.1, Mattes, K.1, Gehret, R.2, Schroeter, S.2

1 University of Hamburg; 2 BeSB GmbH Berlin

**Introduction** Biomechanical diagnostics in rowing performance and technique has been conducted for many years in the German Rowing Association (DRV) using mobile measuring systems, capturing relevant data for a functional training structure (Mattes, 2012). The disadvantage in its routine daily use by coaches is the complexity of the systems which require professional installation. Accrow was developed in cooperation with movement scientists from the University of Hamburg, to provide an easy-to-use measuring-, testing and analyzing device to determine important factors of the boat motion (BM) in on-water training (WRT) and rowing races (RR), by providing sport specific design and device-requirements, and engineers from BeSB GmbH Berlin, producing the hard- and software. Accrow provides clear analysis of WRT and RR and facilitates the answering of numerous training questions. **Methods** Accrow measures and stores the boat's position and acceleration data during the rowing trip with 4-Hz-GPS (0.25% measuring error 2000m) and MEMS-acceleration

sensor 50Hz (1% accuracy,  $\pm 2g$ ) and transfers the data wireless (WLAN) in real time to an operation system (notebook or iOS device). Accrow-Live provides the coach an online data-visualization during the WRT. The evaluation software Regatta analyses the measured data and calculates different rowing-specific evaluation routines: intensity analysis for WRT, RR-profile (500-2000m) and rowing start (1.-15. rowing stroke). Rowing stroke (RS) detection proceeds on the basis of the boat acceleration (aB). For each RS, Regatta calculates the mean boat velocity (vB), stroke frequency (SF), propulsion per RS (sB), total distance traveled (sGPS) and the driving time per section (tsection). Results Accrows results are well suited for analyzing and optimizing WRT and 2000-m-RRs including its main phases (start, max. and pick-up aB, max. vB., transition phase and final-sprint) by specifying the main details of external training load (vB, SF, sB), volume (sGPS, number of strokes) and time duration (tsection). Data analysis refers to RS as well as to sB and the results were described on the basis of specialized experiences in biomechanical and physiological performance diagnostics in race rowing (tabular form and graphically) for the documentation of WRTs. Discussion Accrow analyses BM according to scientific criteria and provides a precise measuring for the performance diagnostic or for scientific studies by describing the external training intensity. In combination with results from the internal training load of physiological related performance studies (e.g. lactate-step-tests), the device facilitates the daily training routine of rowing coaches. It was validated with elite athletes from DRV and successfully implemented into the biomechanical diagnostic of the German National Rowing Team for the World Championships and Olympics. ## RELATIONSHIP BETWEEN MAXIMAL ISOMETRIC STRENGTH IN UPPER AND LOWER LIMBS AND BALL VELOCITY IN THE TENNIS SERVE

Baiget, E.2, Corbi, F.2, Fuentes, J.P.3, Fusté, A.4, Fernandez-Fernandez, J.5

1: UVic (Vic, Spain), 2: INEFC-Lleida, UDL (Lleida, Spain), 3: UEx (Cáceres, Spain), 4: FCT (Barcelona, Spain); 5: Faculty of Sports Science, Ruhr-University Bochum (Germany).

**Introduction** The tennis serve is a highly complex stroke because of the reliance on multiple body segments to produce power through properly timed rotations and complex coordinated muscular activations, as well as the most important from a strategic standpoint (Girard et al., 2007; Elliot, 2003). Therefore, strength levels in muscles related to the serve performance seem to be an important issue. The aim of this study was to analyse the relationship between isometric strength levels in different upper and lower limb movements and serve velocity in competitive tennis players. **Methods** Twelve male competitive tennis players (mean  $\pm$  SD; age:  $17.2 \pm 1.0$  years; height:  $180.1 \pm 6.2$  cm; weight:  $71.9 \pm 5.6$  kg) participated in the study. Measurements were conducted using a strain gauge (500N) connected to a portable MuscleLab™ system, and included maximal isometric voluntary contraction (100 Hz) of the wrist flexion/extension, elbow flexion/extension, and shoulder internal/external rotation, in the dominant side, as well as leg and back extension. A radar gun (Stalker ATS 4.02, EJA) was used to measure serve velocity (i.e., best of twelve serves (six to each side)). The relationship between quantitative variables was established with a linear correlation analysis, by calculating the Pearson's linear correlation coefficient (r). A multivariate analysis was carried out using a multiple regression model (stepwise method). Results None of individual quantitative variables analysed was significantly correlated with serve velocity in any of the analysed movements. Individual correlations were found for wrist ( $p=0.076$ ) and elbow ( $p=0.08$ ) flexion/extension. Results obtained from the multivariate analysis showed that the highest relationship ( $R^2=0.484$ ) was established between serve velocity and wrist flexion/extension, shoulder flexion and internal rotation, and knee extension. Discussion The lack of relationship between strength variables analysed and serve velocity could be due to the complexity of the tennis serve motion. The serve requires a combination of limb and joint movements in order to summate and transfer forces from the ground up through the kinetic chain and out into the ball (Pugh et al., 2003). Multivariate correlation suggests that in order to be efficient in the tennis serve, isolated strength is not the only determinant factor, and the total body perspective is just as important as the individual segments alone (Kovacs & Ellenbecker, 2011). Effective servers maximally utilize their entire kinetic chain via the synchronous use of selective muscle groups, segmental rotations, and coordinated lower extremity muscle activation. ## RELATION BETWEEN METABOLIC AND PSYCHOLOGICAL RESPONSES AS A SIMPLE METHOD TO DETERMINE THE LEVEL OF EFFORT IN HIGH INTENSITY EXERCISES

Galdeano Llinares, P.1, Suárez-Parra, I.1, Barba-Moreno, L.1, Alarcón-Torrecillas, S.1, González-Hernández, J.M.2, Jiménez-Reyes, P.1

1: Catholic university of San Antonio, Murcia, España; 2: UAX (Madrid)

**Introduction** The intensity of the exercises along with the speed of execution are the key factors to estimate the mechanical power output generated. Several studies have attempted to measure the intensity of effort through metabolic responses such as blood lactate and ammonia concentrations. Given the complexity of the measure has been validated a scale of rating of perceived exertion (RPE) (Borg scale). This RPE scale has been used to measure the resistance exercise intensity (low intensity) hitherto only Lauren et al (2010) have used the RPE at submaximal sprint. Thus, we tried to correlate the RPE scale with acute effects in high intensity sprints. **Methods** Eighteen high level sprinters (age  $23.1 \pm 4.4$  yr, body mass  $73.7 \pm 4.6$  kg, height  $177.6 \pm 5.9$  cm; body fat  $9.6 \pm 2.9\%$ ) took part in this study. Three sessions for 40, 60 and 80m performed at highest possible speed up to lose 3% of speed with 4, 6 and 8 minutes rest between sets (same ratio work/recovery for different DT) separated by a week were performed. Psychological (i.e. RPE) and metabolic responses (i.e. blood lactate and ammonia concentrations) were measured pre-exercise, during exercise each repetition performed and post-exercise. Results RPE pre-post session were significant for all sprint workouts analyzed and highly correlated to metabolic responses (Lact-RPE40/60/80m  $r = 0.86, 0.8, 0.83$ ) (Amn-RPE40/60/80m  $r = 0.84, 0.79, 0.81$ ). The speed losses produced in the successive sprints presented a high relation between the distances and RPE responses. The fatigue, measured as RPE increment, is strongly correlated to lactate ( $r = 0.83$  average), and ammonia ( $r = 0.82$  average). Discussion Through different studies it has observed that exist a relation between RPE and strength trainings (Naclerio, F., Barriopedro, I., Rodríguez, G., 2009). In addition the high correlations found between psychological (RPE) and metabolic (lactate and ammonia) measures of fatigue support the validity of using RPE to objectively quantify metabolic fatigue during sprint training. The results of this study show that, indicating or using the values of RPE in different moments or at the end of each serie, it is possible to monitor the intensity of successive sprints. ## EFFECTS OF SIX WEEKS OF MEDICINE BALL TRAINING ON THROWING VELOCITY, PRECISION AND SHOULDER ISOKINETIC STRENGTH IN FEMALE HANDBALL PLAYERS

Raeder, C., Fernandez-Fernandez, J., Ferrauti, A.

*Ruhr-University Bochum*

Introduction Handball is a high-intensity impact intermittent sport game which requires an optimal combination of maximum intensity efforts in a short period of time, where players jump, run, and throw the ball at a high velocity, followed by low intensity or rest moments. Throwing performance is an important key skill for success in competitive handball, with the effectiveness of a shot primarily affected by two aspects: throwing velocity and precision. To the best of our knowledge there is no information evaluating the impact of medicine ball training on throwing velocity in handball. Medicine ball training ensures the opportunity to closely mimic the powerful actions and specific movement patterns relevant for success. Therefore the aim of the study was to investigate the effects of medicine ball training on throwing velocity, precision and shoulder strength in female handball players. Methods Twenty-eight 4th division female handball players (18-26 years of age) were randomly allocated into a training group (TG; n=15) and a control group (CG; n=13). TG performed supervised shoulder injury prevention (i.e., elastic tubing) and medicine ball training programs (throws that all illustrate handball-specific movement patterns), finishing with a throwing protocol using a regular handball. CG performed the supervised shoulder injury prevention program and the throwing protocol with a regular handball. Players trained three times a week, for a total of six weeks. Pre and post-measurements included throwing velocity, throwing precision and isokinetic peak torques of shoulder internal (IR) and external rotation (ER) at 90°/s and 180°/s. Results There was found a significant group x time interaction in throwing velocity ( $p=0.000$ ) with a significant increase in throwing velocity ( $p=0.000$ ) of 14% and 3.7% for both TG and CG, respectively. Precision did not change ( $p=0.144$ ) from pre to post-training, both for TG and CG. There was a significant group x time interaction ( $p=0.023$ ) for concentric IR at 180°/s for the dominant arm with a significant increase in concentric IR of 15% in TG, whereas no changes occurred in CG. Discussion The study showed that six weeks of a combined strength training (i.e., shoulder injury prevention, medicine ball training and handball throwing) can elicit significant improvements in the performance variables analyzed (throwing velocity and shoulder strength) in female handball players, while throwing precision remained unaffected. Medicine ball exercise training seems to be a useful and inexpensive strength training strategy in enhancing functional performance by closely mimic sport-specific movement activities. ## ANALYSIS AND COMPARISON OF LACTATE AND ANAEROBIC THRESHOLDS OF PROFESSIONAL AND ELITE CYCLISTS IN A 20-WEEK PERIOD

García, I., Arratibel, I., Cámara, J.

*UPV Universidad del País Vasco*

INTRODUCTION. Improving lactate and anaerobic thresholds (LT and IAT, respectively) is considered crucial to the performance in the road cycling (I). Cyclists with high values of LT and IAT have a high potential for success in this sport (I). The aim of the study was to compare the evolution of LT and IAT in elite and professional cyclists in a 20-week period. METHODS Thirty-two cyclists participated in this study, 19 elite level ( $20.5 \pm 1.9$  years) and 13 professional level ( $24.2 \pm 1.1$  years). During the period of study (20 weeks) the participants performed 3 tests; during the 1st (T1), 10th (T2) and 20th (T3) weeks, corresponding respectively to the preseason, beginning of the competitive period and the competitive period. During testing 3 variables were measured; heart rate, blood lactate and power. The exercise protocol for LT and IAT determination started at a workload of 100 W and 50 W increments every 3 minutes until exhaustion performed on a cycle ergometer. RESULTS The LT and IAT values increased during the 20-week period in both groups. These increments were observed in absolute power (T1: 140 + 31 W; T2: 155 + 33 W; T3: 166 + 35. W LT elite), percentage of Wmax (T1: 44 + 6 %Wmax; T2: 48 + 3 %Wmax; T3: 50 + 3 %Wmax LT professional) and power relative to body mass (T1: 2,0 + 0,3 W•kg<sup>-1</sup>; T2: 2,3 + 0,4 W•kg<sup>-1</sup>; T3: 2,5 + 0,4 W•kg<sup>-1</sup> in LT elite) (T1: 3,1 + 0,4 W•kg<sup>-1</sup>; T2: 3,5 + 0,5 W•kg<sup>-1</sup>; T3: 3,7 + 0,5 W•kg<sup>-1</sup> IAT elite) values for  $p<0,05$ . Professional cyclists showed significantly higher absolute (T1: 215 + 41 vs. 246 + 25 W; T2: 239 + 43 vs 268 + 27 W, 3°: 245 + 41 vs 277 + 27 W IAT) and relative (T1: 3,14 + 0,40 vs 3,56 + 0,51 W•kg<sup>-1</sup>; T2: 3,55 + 0,47 vs 4,10 + 0,26 W•kg<sup>-1</sup>; T3: 3,67 + 0,47 vs 4,24 + 0,34 W•kg<sup>-1</sup> IAT) values for  $p<0,05$  in both thresholds. No statistical differences using heart rate criteria were observed. DISCUSSION During the 20-week period absolute (W) and relative (%Wmax and W•kg<sup>-1</sup>) values of both thresholds increases, Lucia described the same in previous study (2). In the present study, LT and IAT values of professional cyclists are higher than the previously observed in elite cyclists (3). In addition, these differences were maintained during 20 weeks. It is proposed the need and the importance of analyzing the thresholds in relative values for body mass and maximum power, because the differences between the two groups suggested that at the same absolute intensity the biological status of each group could be different. ## THE ACUTE EFFECT OF WHOLE BODY VIBRATION ON REPEATED SHUTTLE-RUNNING IN YOUNG SOCCER PLAYERS

Padulo, J.1,2, Ibba, G.1, Di Giminiani, R.3, Chamari, K.2, Attene, G.1, Bishop, D.4, Migliaccio, G.M.1

1: CONI -Italian Regional Olympic Committee, Sardinia (Italy), 2: National Centre of Medicine and Science in Sport, Tunis (Tunisia), 3: University of Aquila (Italy), 4: Victoria University (Australia).

Introduction In this study we hypothesized that whole body vibration (WBV) improves the repeated sprint ability (RSA) performance and reduces the fatigue. To test our hypothesis we studied the acute effect of WBV, which could represent a new field training method (ecological validity), on time performance variables and blood lactate concentration during the RSA. Therefore, the aim of this study was to investigate the acute effects of WBV on RSA (Impellizzeri et al., 2008). Methods Seventeen male soccer players ( $16.71 \pm 0.47$  yrs) performed three RSA tests in different days (Randomized crossover study). RSA (1,2,3) test was performed with 6 maximal 40m shuttle-sprints (20+20m) with a change of direction of 180° separated by 20-s of passive recovery. The second RSA (RSA2) test was done with WBV "Power Plate pro5" was applied during the recovery periods to evaluate the effect of WBV (45 Hz - 2.2 mm). The studied variables were: best time (BT), worst time (WT), total time (TT), blood lactate (BLa) and the fatigue index (FI). Result ANOVA with repeated measures showed no effect between RSA1 and RSA3, while there were significant differences in TT= (RSA2 <0.92% ( $p<0.05$ ) vs. RSA1; RSA2 <1.71% ( $p<0.005$ )).

vs. RSA3],  $Bl_a = [RSA2 > 20.39\%$  ( $p < 0.001$ ) vs. RSA1;  $RSA2 > 12.82\%$  ( $p < 0.001$ ) vs. RSA3],  $WT = [RSA2 < 2.35\%$  ( $p < 0.005$ ) vs. RSA1;  $RSA2 < 3.51\%$  ( $p < 0.0001$ ) vs. RSA3], and  $Fl = [RSA2 < 29.38\%$  ( $p < 0.0001$ ) vs. RSA1;  $RSA2 < 69.11\%$  ( $p < 0.0001$ ) vs. RSA3]. When compared individual sprints, WBV showed a significant effect at the 5° sprint:  $RSA2 < 2.29\%$  ( $p < 0.005$ ) vs. RSA1;  $RSA2 < 2.95\%$  ( $p < 0.0001$ ) vs. RSA3, and the 6° sprint:  $RSA2 < 2.75\%$  ( $p < 0.01$ ) vs. RSA1;  $RSA2 < 4.09\%$  ( $p < 0.0001$ ) vs. RSA3. Discussion In conclusion, by using WBV during the recovery periods of a RSA test, we demonstrated that most of the time performance variables were improved. Further studies are needed to explain the physiological mechanisms behind these improvements and also to see whether chronic use of WBV during training might improve the on-field RSA performance. #### EFFECTS OF HEAVY STRENGTH TRAINING ON UPPER-BODY STRENGTH, POWER AND SPRINT PERFORMANCE IN ICE SLEDGE HOCKEY

Sandbakk, Ø.1, Hansen, M.1, Rønnestad, B.R.2, Ettema, G.1

*(1) Norwegian University of Science and Technology, (2) Lillehammer University College*

**INTRODUCTION:** Ice sledge hockey is a popular paralympic team sport where players rely entirely on their upper-body to propel themselves rapidly across the ice surface. These isolated and repetitive poling movements provide a good model for examining upper-body sprint ability, and the subsequent requirements for upper-body maximal strength and power. Therefore, the purpose of the present study was to investigate the relationship between upper-body maximal strength, power and sprint performance in ice sledge hockey, as well the effects of six weeks of maximal strength training on these variables. **METHODS:** Eight ice sledge-hockey players from the Norwegian national team performed 30-m maximal sprint on ice and 1 repetition maximal (1RM) strength and peak power in the bench pull (BP) and pull-down (PD) exercises before and after six weeks with heavy strength training. Strength training was standardized the last month before the intervention period started and a stable level in 1RM during this period was shown. In the intervention period, the athletes performed three weekly sessions of heavy strength training; each session included two warm-up sets and three sets with 6-8 RM for pull-down, pull-over and front-pull exercises. Each lift was performed with maximal effort. **RESULTS:** 30-m sprint time correlated with 1RM and peak power for BPu ( $r = 0.86$  and  $0.62$ , respectively) and PD ( $r = 0.97$  and  $0.78$ , respectively) at pre-test (both  $P < 0.05$ ). From pre- to post-test there was significant improvements for 30-m sprint time ( $6.63 \pm 0.54$  vs  $6.47 \pm 0.50$  s), 1RM in BPu ( $77.2 \pm 13.4$  vs  $79.4 \pm 13.7$  kg), and 1RM and peak power in PD (1RM:  $92.6 \pm 12.5$  vs  $101.3 \pm 9.7$  kg, peak power:  $556.6 \pm 104.8$  vs  $642.3 \pm 126.0$  W) (all  $P < 0.05$ ). Peak power for BPu did not change ( $515.6 \pm 81.4$  vs  $536.2 \pm 94.6$  W). When correlating the changes in sprint and strength performances from pre- to post-test, there were significant correlations between 30-m sprint time and 1RM for BPu ( $r = 0.59$ ) and PD ( $r = 0.60$ ) (both  $P < 0.05$ ). **CONCLUSIONS:** The strong associations between 1RM strength, peak power and sprint ability found in this study support the general view that maximal strength and power are key components for sprint performance. Here, we show this for highly upper-body trained athletes, and additionally reveal that short-time heavy strength training can improve maximal strength, power, and sprint performance significantly in such populations. The correlation between changes in 1RM strength and in sprint performance lead further support to our conclusion that upper-body maximal strength training is advantageous for improving sprint performance.

#### A NEW WAY TO QUANTIFY TRAINING LOAD IN SPORT: THE "Z-INDEX"

Zabala, M., Morente-Sánchez, J.

*Faculty of Sport Sciences - University of Granada*

**A NEW WAY TO QUANTIFY TRAINING LOAD IN SPORT: THE "Z-INDEX"** Zabala, M.1,2 & Morente-Sánchez, J.1 1 Faculty of Sport Sciences, University of Granada (Spain) 2 Spanish Cycling Federation, Madrid (Spain) Introduction Training load is an important issue related to adequately apply the optimum stimulus to get the best work-recovery relationship to improve performance. In some middle-long distance sports like cycling or running, some indexes in relation to the time spent working are used as Heart Rate (TRIMP) [1], RPE (Foster) [2], relative Power output in cycling (TSS -Training Stress Score-) [3], or Time/km in running (multiplying them by time in minutes or seconds). The aim of this study was to integrate those indexes that describe the same event from different but complementary perspectives (physiological, physical, and perceptual perspectives) to create a more complete index of training load. Methods Twelve under-23 elite road cyclists, and 14 recreational triathletes, (mean age:  $19.67 \pm 1.12$  years, and  $27.67 \pm 3.12$  years, respectively) participated in the study. Training was monitored during a total of  $20 \pm 2$  training sessions measuring TRIMP, Foster, and TSS or time/km x min. Then a new score was got weighting each value in a scale from 0-10 (Log10) and then getting the average of the indexes multiplied by 10 to get a final score in %: for cyclists, the so-called "Z-Index" =  $[(\log_{10} \text{ of TRIMP} + \log_{10} \text{ of Foster} + \log_{10} \text{ of TSS}) / 3 * 10]$ , and for runners, "Z-Index" =  $[(\log_{10} \text{ of TRIMP} + \log_{10} \text{ of Foster} + \log_{10} \text{ of (Time/km x min)}) / 3 * 10]$ . Descriptive and correlation statistics was carried out. Results Values in % of daily, weekly or monthly training loads were calculated in relation to the training plan and sessions. The relation of the subjective plan and the later training load showed that sometimes the proposed training load was less or more than the one measured after the workouts (10 to 20% difference, correlation of  $r = 0.80^{**}$ ). When relating the different conventional indexes to the Z-index, significant and high correlations were found in cycling ( $r = 0.75^{**}$  for TRIMP,  $r = 0.79^{**}$  for Foster,  $r = 0.81^{**}$  for TSS), and running ( $r = 0.80^{**}$  for TRIMP,  $r = 0.79^{**}$  for Foster,  $r = 0.80^{**}$  for km/time x min). All the athletes stated that the new index was "easy, useful, and practical". Discussion Z-index is a very easy to understand value calculated taking into account the most feasible indexes that can be got from training using specific variables for each sport - cycling or running- and that could be used in Swimming adapting the formula from running but using the specific units (e.g. time in seconds / 25-50-100m). This index can be somewhat elitist, but there are many athletes nowadays that can afford GPS devices, powermeters, or just a chronometer. More research is needed to validate and develop the original formula. References 1. Manzi V. et al. *Am J Physiol Heart Circ Physiol* 2009; 296, H1733-40. 2. ## EFFECTS OF RESISTED SLED TOWING ON ACCELERATION SPRINT KINEMATIC IN SOCCER PLAYERS. A PILOT STUDY

Cánovas, J.F.1, Martínez-Valencia, M.A.1, Márquez, G.1, Del Cerro, N.1, Alcaraz, P.E.1

1: UCAM (Murcia, Spain), 2: UCLM (Toledo, Spain)

**INTRODUCTION** Weighted sled towing is a popular resisted sprint training methods. Several researches have shown acute effects on sprint kinematics during a sled towing exercise, in athletes such as sprinters and rugby players (Cronin et al., 2008; Lockie et al., 2003, Alcaraz et al., 2008). However, to our knowledge no one has been carried out in soccer players. The purpose of this study was to analyze the effects that increasing loads have on running kinematics during a sled towing exercise with soccer players. **METHODS** Seven semi-professional soccer players ( $23.07 \pm 2.25$  years;  $1.77 \pm 0.07$  m;  $77.6 \pm 5.8$  kg) with previously sled-towing training experience performed 4 x 20-m sprints (unloaded, 15, 20 and 25% of their body mass) from a standing start. The order for the trials was randomized and a 3-min rest period was allocated. First five meters were recorded with a high speed video camera (Casio Exilim EXFH20, Casio Computer, Tokyo, Japan) operating at 210 fps. The camera was placed at 90° angle to the direction of the sprinting, a distance of 15 m from the middle of the athlete's lane and it was mounted on a rigid tripod at a height of 1.3 m. Open-source software (Kinovea-v0.8.15) was used to analyze the data. The kinematic variables taken into account for the analysis were: stride length (SL), stride frequency (SF), contact time (CT) and flight time (FT) performed in first five meters of sprint. Repeated-measures ANOVA were used to compare the four sprint conditions. **RESULTS** As expected, both velocity and SL decreased significantly for all loaded situations when comparing with unloaded sprint ( $p < 0.01$  for all trials). CT increased significantly only between unloaded and 25% Bm ( $p = 0.005$ ). No significant differences were found for nor FT either SF. **DISCUSSION** Data suggested that variables most affected by load were SL and CT. Particularly CT has only affected with high loads (25% Bm). In fact, one study (Alcaraz et al., 2012) reported that CT increased significantly after a 4-weeks sled towing training in sprinters. However, SF and FT were not affected significantly by the external load. These results are consistent with previous studies (Lockie et al., 2003, Cronin et al., 2008, Alcaraz et al., 2008). When we use sled towing training method in soccer players, must be considered that SL decreases when an external load is added, and CT may be modified by a load of 25% of Bm or above. **REFERENCES** Alcaraz PE, Palao JM, Elvira JL, Linthorne NP. ## RESULT OF AN INDIVIDUALIZED CYCLING TRAINING PROGRAM THROUGH POWER METERS

Fernández-Montilla, J.A., López-Grueso, R., Sarabia, J.M., Aracil, A., Guillén, S., Pastor, D., Moya, M.

GIAFIS, Sports Research Centre, Universidad Miguel Hernández de Elche (Spain)

**Introduction** The theoretical framework for quantifying the training proposed by Dr. Coggan (Allen and Coggan, 2010) parts of the biparametric models theory applied to cycling and bike segment in triathlon. The aim of the study was to evaluate the influence that an individualized training program at different percentage of functional threshold power (FTP) Methods Fourteen triathletes (aged  $38.12 \pm 6.37$  years) were divided into two groups (Control -C- and Experimental, -E-) and developed six weeks of planned workouts, with a pre and post-test in both cycle ergometer (Monark ergomedic 839) and field tests (Powertap, CycleOps, Madison, USA). The program focuses on the critical pedaling power with normalized power (NP) and decreasing by 30% the intensity factor (IF), developing a working method based on the and training stress score (TSS) on the basis of an individualized FTP for each subject (E) versus usual training group (C). The variables evaluated were: maximal oxygen uptake (VO<sub>2</sub>max), time to exhaustion (tExh), power generated at the second ventilatory threshold (wVT<sub>2</sub>), lactate threshold (LT) on a cycle ergometer test, and volume in kilometers (Vkm), absolute and relative power generated in the FTP field test (wFTP and w/kgFTP). **Results** The average values show no significant differences between both groups in the different tests and variables assessed at the pre y post- tests. However, a beneficial trend (in favor of experimental group) is clearly marked in all of them: wFTP (C:  $256.6 \pm 22.4$  to  $260.0 \pm 16.9$  w vs E:  $236.0 \pm 19.3$  to  $248.0 \pm 25.0$  w), w/kgFTP (C:  $3.34 \pm 0.32$  to  $3.33 \pm 0.27$  w/kg vs E:  $3.53 \pm 0.21$  to  $3.67 \pm 0.20$  w/kg), tExh (C:  $14.71 \pm 1.08$  to  $14.89 \pm 1.43$  min vs E:  $12.29 \pm 1.89$  to  $13.50 \pm 1.86$  min), wVT<sub>2</sub> (C:  $267.9 \pm 12.2$  to  $271.4 \pm 17.3$  w vs E:  $239.3 \pm 19.3$  to  $260.7 \pm 24.4$  w), wLT (C:  $200.0 \pm 0.0$  to  $204.2 \pm 19.0$  w vs E:  $158.3 \pm 34.0$  to  $170.8 \pm 43.0$  w), w/kgLT (C:  $2.60 \pm 0.08$  to  $2.60 \pm 0.27$  w/kg vs E:  $2.42 \pm 0.53$  to  $2.63 \pm 0.73$  w/kg) and lactate production at LT kgLT (C:  $2.23 \pm 0.37$  to  $1.95 \pm 0.61$  mM vs E:  $2.12 \pm 0.60$  to  $2.32 \pm 0.73$  mM). The decline in VO<sub>2</sub>max had a negative trend less marked in the experimental group also (C:  $55.1 \pm 2.1$  to  $54.0 \pm 2.2$  ml/kg/min vs E:  $55.4 \pm 3.5$  to  $55.0 \pm 3.9$  ml/kg/min,  $p = 0.088$ ). **Discussion** For group C which was training a larger volume at different IF and not individualized %UPF (but the same NP) is not guaranteed performance improvement. This group even manifests a negative trend, while group E, with relatively lower but personalized volumes, shows a slight improving trend, although not significant. **References** Allen H, Coggan A. ## THE EFFECT OF DIFFERENT WARM-UP PROTOCOLS ON PAP IN SPRINTERS – A PILOT STUDY

Gonzalez Hernandez, J.1, Ortega-Becerra, M.A.2, Cuadrado-Penafiel, V.3, Alarcon-Torecillas, S.4, Galdeano-Llinares, P.4, Jimenez-Reyes, P.4

1: UNIVERSITY ALFONSO X EL SABIO (Madrid, Spain), 2: UPO (Seville, Spain), 3: UJA (Jaén, Spain), , 4: UCAM (Murcia, Spain)

**Introduction** It is known that different types of pre-conditioning activity (PCA) (squat, CMJ and sprint running), as well as different levels of intensity and volume, have a different effect on the function of the neuromuscular system. Therefore, it is likely that different content and, as a result, different intensity of warm-up will influence different mechanisms of the neuromuscular function after different warm-up protocols (WUP). The aim of this study was to examine Postactivation Potentiation (PAP) effects induced by different warm-up protocols based on 1) jump with extra loads from light to heavy and 2) squats from light to heavy weight. **Methods** Ten high level sprinters (age  $21.1 \pm 2.2$  yr, body mass  $70.3 \pm 3.2$  kg, height  $180.6 \pm 5.1$  cm; body fat  $7.9 \pm 3.3\%$ ) took part in this study. Two different PCA were designed and two different WUP was assigned to each one of these two PCA, and after that, athletes were separated by groups. Each group corresponded each one of the 2 different PCA designed. PCA were squat (SQ) with 80% 1RM and other with 40% 1RM, and CMJ with loads of 100% of body weight (BW) and 50% of BW. PAP effect was verified on CMJ and sprint performance in 0, 4, 6, 8 and 10 minutes after each WUP and group. **Results** The main result of this study was that CMJ height increased significantly 4 min after the PCT with 80% 1RM in SQ and 100% BW in CMJ. The percentage increase, based on the pre and post means, was 3.7% (significant) in CMJ performance with 80% 1RM vs 40% 1RM (an increase of 0.5%, ns), and, a reduction of 2.4% (significant) in sprint time performance with 80% 1RM vs 40% 1RM (a reduction of 0.1%, ns). In CMJ with loads, the percentage increase, based on the pre and post means, was 3.4% (significant) in CMJ performance with 100%-BW vs 50%-BW (an increase of 0.3%, ns), and, a reduction of 2.7% (significant) in sprint time performance with 100%-BW vs 50%-BW (a reduction of 0.4%, ns). **Discussion** According to Mitchell & Sale (2011), CMJ performance increased significantly 4 min after a similar load than they used in his study (80% 1RM vs 5RM). In addition to this, in our study, a load of 100% of BW in

CMJ increased CMJ performance 4 min after too. Likewise, in our study, sprint performance improved in these protocols. The mechanism of PAP increases rate of force development (RFD) (Baudry & Duchateau, 2007) and the shortening velocity attained under load (Baudry & Duchateau, 2007); therefore, PAP may have contributed to the increase in CMJ height in our study, as same than Mitchell & Sale (2011).

### ACUTE EFFECTS OF STATIC STRETCHING ON PLANTAR FLEXORS MUSCULAR AND TENDINOUS STIFFNESS

Babault, N., Paizis, C., Opplert, J.

*UFR STAPS Dijon*

**Introduction** Although widely used during warm-up, static stretching has been suggested to alter the muscle-tendon unit stiffness and consequently passive resistance (Behm et al. 2011). However, the effects on the tendon and muscles fascicles stiffness and their origins are still equivocal (Kay and Blazevich, 2009). The aim of the present study was therefore to examine the acute effects of static stretching in dorsiflexion on the gastrocnemius medialis and Achilles tendon passive stiffness. Since the "dose effect" has never been clearly determined, we also assessed the kinetics of all these parameters at several time points of the stretching protocol. **Methods** 11 male subjects underwent 10 repetitions of 30-s static, passive dorsiflexion stretching, on an isokinetic dynamometer. Passive torque, musculo-tendinous junction (MTJ) displacement, pennation angle and gastrocnemius medialis (GM) muscle fascicles length have been measured during the 1st, 5th and 10th stretching movement. Muscle and tendon stiffness indexes have been determined from the relation between passive torque variation and variations of the MTJ displacement and fascicles length. **Results** GM and Achilles tendon stiffness indexes were significantly decreased during the 5th ( $-25.9 \pm 10.1\%$ ;  $-22.3 \pm 16.9\%$ ,  $P < 0.05$ ) and 10th stretching movements ( $-32.4 \pm 8.4\%$ ;  $-29.4 \pm 14.4\%$ ,  $P < 0.05$ ). Although passive torque variation was significantly decreased for both the 5th and 10th stretch ( $-12.5 \pm 7.4\%$ ;  $-6.8 \pm 6.7\%$ ,  $P < 0.05$ ), the MTJ displacement, fascicles length and pennation angle variations were not modified. **Discussion** These results suggest that 5 x 30-s of static stretching could alter the muscle-tendon unit's mechanical properties and therefore significantly decrease muscle and tendon stiffness. Alterations of the elements responsible of force production and transmission such as actin-myosin bridges, titin, viscosity or muscle fibres recruitment, could be responsible of this decrease. Sports requiring strength, power or speed should therefore use very short duration of static stretching or even totally exclude them before competition. **References** Behm DG, Chaouachi A (2011) A review of the acute effects of static and dynamic stretching on performance. *Eur J Appl Physiol.* 111: 2633-51. Kay AD, and Blazevich AJ (2009) Moderate-duration static stretch reduces active and passive plantar flexor moment but not Achilles tendon stiffness or active muscle length. *J Appl Physiol.* 106:1249-1256.

### EFFECT OF SPEED TRAINING IN YOUTH SOCCER PLAYERS

Mathisen, G.

*University of Tromsø*

**Introduction** Sprint and agility performance is crucial in many sports like soccer. There are few studies about training effect in children and youth in sprint distances shorter than 30 m, and in agility performance. Earlier studies have shown conflicting results regarding the effects of sprint training programs in this age, but recent studies have found that appropriate training stimulus may lead to enhances sprint and agility performance. However, more research is needed to find out the effectiveness in methods of sprint and agility training in youth. Therefore, in the recent study we wanted to examine a high-intensity short-burst exercise program on 13-year-old male soccer players. **Method** A training group of 14 male soccer players, mean age ( $\pm$  SD) 13,5 years ( $\pm$  0,24) followed an 8 week intervention program, one hour per week, and a group of 12 male soccer players of corresponding age, mean age 13,5 years ( $\pm$  0,23) served as control group. The intervention consisted of short burst linear sprints, or mostly sprints with change of direction (agility) with maximal effort in 2-6 seconds, and interspersed with recovery periods lasting from 1-1,5 minutes. Each session consisted of 30-40 sprints. Pre- and post-tests assessed 10 m linear sprint, 20 m linear sprint and agility performance. The agility test course was a 20 m standardized course. Electronic timing gates were used to record split and completion times (Brower Timing System, USA). Differences between groups were tested with one way analyze of variance, and Pearson product moment correlation  $r$  were used to evaluate the relationship between linear sprint and agility performance test measures (SPSS 19.0). **Results** Results showed significant improvement in agility performance, pre 8,23 s ( $\pm$ 0,34) to post 7.69 s ( $\pm$  0,34) ( $p < 0.01$ ), and significant improvement in 0-20 m linear sprint, pre 3,54 s ( $\pm$  0,17) to post 3,42 s ( $\pm$  0,18) ( $p < 0,05$ ). In 0-10 m sprint the participants showed improvement, pre 2,02 s ( $\pm$  0,11) to post 1,96 s ( $\pm$  0,11) (n.s). Correlation between 10 m sprint and agility was  $r = 0.53$  ( $p < 0,01$ ), and between 20 m linear sprint and agility performance  $r = 0.67$  ( $p < 0,01$ ). **Discussion** The major finding in the study is the improvement in agility performance. The participants showed a smaller, but significant improvement in 0-20 m linear sprint, and also improvement in 0-10 m linear sprint, not significant. The control group showed no significant improvement. Another interesting finding is the correlation between linear sprint (10 m and 20 m) and agility performance, indicating a stronger relationship in sprint and agility at this age than have been found among adults. These findings suggest that organizing the training sessions with short burst high-intensity activities lasting 2-6 sec, interspersed with adequate recovery time, may result in improvements in both linear sprint and especially agility at this age among young soccer players. **References** Venturelli M, Bishop M, Pettene L. Sprint Training in Preadolescent Soccer Players. *Int J Sports Physiol* 2008; 3: 558-562

### TRAINING EFFECT ON ROS PRODUCTION PROFILE IN MASTER SWIMMERS DETERMINED BY ELECTRON PARAMAGNETIC RESONANCE

Mrakic-Spota, S.1, Porcelli, S.1, Bellistri, G.1, Montorsi, M.2,1, Gussoni, M.3, Vezzoli, A.1

*IBFM-CNR*

1: Istituto di Bioimmagini e di Fisiologia Molecolare, CNR, (Segrate, Italy), 2: Univ. Telematica S. Raffaele, (Rome, Italy), 3: Dipartimento di Fisiopatologia Medico Chirurgica e dei Trapianti, Unimi (Milan, Italy) **Introduction** Exercise induces an increase in free radicals production in human skeletal muscle. The amount of production depends on the intensity of exercise, with higher amount of free radicals and, consequently, oxidative cellular damage generated by strenuous exercise. Electronic Paramagnetic Resonance (EPR) is the only non-invasive technique available to detect and quantitate Reactive Oxygen Species (ROS) concentration. **Methods** Ten masters swimmers (males, mean age  $30 \pm 5$  ys; weight  $78.6 \pm 5.1$  kg; height  $1.82 \pm 0.47$  m) underwent to 6 weeks of low-volume high-intensity training. Peak oxygen consumption ( $VO_{2peak}$ ) was evaluated by an incremental arm-ergometer test until exhaustion. At rest and after incremental exercise, time course of ROS generation was determined in 50  $\mu$ l capillary blood by means of a recently developed EPR micro-invasive method (Mrakic Spota et al., 2012), both before (PRE) and after (POST) training period. **Results**  $VO_{2peak}$  significantly increased after

training ( $37.2 \pm 4.7$ ,  $40.8 \pm 5.5$  in PRE and POST respectively). At the end of exercise, a significant increase ( $p < 0.05$ ) of ROS production was observed both in PRE and POST. As for training effects: 1) ROS resting values recorded in POST were significantly ( $p < 0.001$ ) lower (-20%) than in PRE and, 2) the increase of ROS blood concentration at the end of exhaustive exercise was lower (+10 vs +16%) in POST than in PRE respectively. Discussion Strenuous aerobic exercise increases ROS resting production, as demonstrated in our previous study (Mrakic Sposta et al., 2012) and others studies with different athletes (Bailey et al., 2004, 2007). A good training scheduling, although characterized by high intensity regimen, reduces ROS production values at rest and after an exhaustive exercise. This results could be due to a more efficient mitochondrial respiratory chain or antioxidant capacity. Indeed a variance analysis indicate an inverse correlation ( $r^2$  value = 0.58,  $p < 0.05$ ) between ROS rate production and  $VO_{2peak}$ . ## PHYSICAL PERFORMANCE AND MORPHOLOGICAL CHARACTERISTICS OF YOUNG ATHLETES IN THE STATE OF PARANÁ – BRAZIL.

Dourado, A.C.1,3, Osiecki, R.4, Roman, E.R.1, Busto, R.M.3, Stanganelli, L.C.R.3, Daros, L.B.2

1:State of Paraná Secretariat of Sports, 2: Center-West of Paraná University (Paraná-Brazil), 3: State University of Londrina (Paraná-Brazil), 4: Federal University of Paraná (Paraná-Brazil)

Introduction The control of sports performance of young athletes by means of morphological, physiological, biomechanical and genetic evaluations is essential for following up their improved performance, long term training organization and sport life style, aiming at positive results in sports modalities and tests. Therefore, the objective of this study was to identify the characteristics of body composition, velocity, potency of lower limbs and aerobic potency of young athletes in the State of Paraná – Brazil. Method The data obtained in this study refer to 180 athletes (N=102 male and N=78 female), average age between 11 and 18 years old, under systematic training and from 19 sports modalities. For their physical performance and morphological characteristics, the following tests and items were used: body composition – plethysmographic (Bodpod); velocity in 30m – photoelectric sensors (Multisprint); potency of lower limbs – applied in 3 types of different jumps: Squat Jump/SJ – Countermovement Jump/CJ – Countermovement Jump with the aid of arms/CJF (thrust mat - Multisprint); aerobic potency – treadmill test with start speed of 8 km/h, and progressive increases of 1km/h at every 1 minute, and the subject being tested until showing signs of exhaustion, controlled by ergospirometer (K4b2). For the presentation of results, descriptive statistics with measures of central tendency was used (average and standard deviation and frequency). Results In both genders, the following values were found for the male athletes (102) and female athletes (78) respectively: height  $174.6\text{cm} \pm 0.109$  –  $162.0\text{cm} \pm 0.203$ ; weight  $69.81\text{kg} \pm 16.06$  –  $57.65\text{kg} \pm 17.45$ ; % slim mass  $81.04 \pm 26.06$  –  $68.27 \pm 29.72$ ; % fat mass  $11.13 \pm 11.20$  –  $21.93 \pm 20.25$ , speed 30meters  $3^{\circ}74\text{s} \pm 1.77$  –  $3^{\circ}76\text{s} \pm 2.27$ ; SJ  $31.67\text{cm} \pm 8.36$  –  $27.31\text{cm} \pm 27.19$ ; CJ  $34.68\text{cm} \pm 9.19$  –  $26.83\text{cm} \pm 7.23$ ; CJF  $40.50\text{cm} \pm 11.03$  –  $31.49\text{cm} \pm 8.59$ ; aerobic potency  $VO_{2max}$   $42.40\text{ml.kg.min} \pm 12.11$  –  $37.78\text{ml.kg.min} \pm 13.76$ , maximum cardiac rate  $187\text{bpm} \pm 41.16$  –  $188\text{bpm} \pm 39.85$ . Discussion In this present study, the values for morphological variables and physical performance of both genders were coherent and similar to the values found in other studies (Hoff, 2005; Bosco, 1993) There was also a predominance of more athletic results from male subjects, favoring their physical and sports performance despite the fact that all the young athletes had been grouped from 19 different sports modalities (Malina, 2001). HOFF, J. Journal of Sports Sciences, v 23, n 6, p. 573-582, 2005. Bosco, C.. *Atleticastudi*. Roma. Vol. 6. 1993. p. 361-371. Malina, R. M., 2001. Am. J. Hum. Biol. 13, 162–172.

## INDICATORS IN LENGTH OF THE LOWER LIMBS, BODY COMPOSITION AND RELATIONSHIP WITH NEUROMUSCULAR PERFORMANCE IN UNDER 15 SOCCER PLAYERS

Franciscon, C.A., Spigolon, L.M.P., Medeiros, E.M., Gongora, A., Borin, J.P.

*Desportivo Brasil Participações Ltda*

Introduction Currently the information obtained in the training of young players, especially in the category U15, seeks to identify aspects involved in sports performance, especially in detection and promotion of sporting talent, but dismiss the influence of relationships and various biological components, which can assist in understanding and targeting of sports preparation. Thus, this study aims to identify the relationship of the length of the lower limbs (CMMII) and indicators of body composition with neuromuscular performance indicators. Methodology 30 athletes participated in the U15 category ( $14.79 \pm 0.48$  years,  $176.88 \pm 6.01$  cm,  $64.06 \pm 6.41$  kg) with experience of two years of training. We measured the CMMII, the percentage of muscle mass (% MMusc) (Martin et al,1990) and body fat percentage (BF%) (Faulkner,1968). Neuromuscular performance was evaluated using a forward sprint, with distances of 10, 20 and 30m (T10M, T20M and T30M), (Svensson, Drust,2005) by means of photocells (SpeedTestFit-Cefise®) placed every 10m. The potent force lower limb was assessed by the countermovement jump (CMJ) (JumpTest-Cefise®). It is the normality of the data, of Shapiro-Wilk and then the Pearson correlation test, with significance level of  $p < 0.0001$ . Results There were no significant correlations between CMMII, indicators of body composition (%BF, CMMII and MMusc%) and neuromuscular performance (CMJ, T10M, T20M and T30m). Discussion Even with the non-significance of the data, one must consider that: i) the neuromuscular performance is related to maturational changes and morphofunctional (Mirwald et al,2002); ii) influence of organization of sessions and content of training, especially regarding the biomotors capacities (Gomes,2002); iii) the assessment of speed and potent force, intra and intermuscular coordination are influenced by the process of training and type of muscle fibers. This information shows the importance of following the young athlete facing the process of sports preparation, besides considering the various biological components associated with monitoring the response of sporting performance. **EFFECTS OF MATURATION AND BODY MASS ON MATCH RUNNING PERFORMANCE IN HIGHLY-TRAINED UNDER 15 SOCCER PLAYERS**

Buchheit, M., Simpson, B.M., Di Salvo, V., Mendez-Villanueva, A.

*ASPIRE*

**Introduction** In youth soccer, players in the same age group often present variations in maturation (Malina 2000). More mature players are taller and heavier, and outperform less mature players in most of physical performance tests (Malina 2000). Whether this physical advantage translates into greater match running performance is however unknown. Recent data have shown that increases in physical capacities are not consistently followed by increases in game physical activities (Buchheit 2012). The aim of the present study was to examine match running performance in highly-trained U15 soccer players differing in either maturation or body mass. **Methods** Thirty six highly-trained U15 soccer players ( $14.4 \pm 0.4$  yr,  $0.2 \pm 0.7$  yr from peak height velocity [APHV]) from an elite academy were involved. Maximal sprinting (MSS) and aerobic (MAS) speeds were measured via field tests. Match running performance was analysed with GPS (GPSport, 1 Hz) during 19 international friendly games. Total distance covered (TD), distance  $>16$  km/h, peak game speed (GS) and the number of high-intensity actions ( $>19$  km/h, HIA) were collected. The 16 less mature players (the 4 less mature central-defenders, full-backs, midfielders and wingers) were compared with the 16 more mature players, both in terms of physical capacities and match running performance. Similar comparisons based on body mass were also performed. Between-group differences were analyzed for practical significance using magnitude-based inferences. **Results** Compared with the less mature players (APHV:  $-0.3 \pm 0.3$  yr), more mature players ( $+0.9 \pm 0.4$  yr) were almost certainly taller (Cohen's  $d=+1.56$ ) and heavier ( $+1.42$ ), have almost certainly faster MSS ( $+0.98$ ) and possibly faster MAS ( $+0.33$ ). During games, they covered likely greater distances  $>16$  km/h ( $+0.51$ ), reached likely faster GS ( $+0.52$ ) and performed almost certainly more HIA ( $+0.74$ ). In contrast, TD was possibly lower ( $-0.15$ ). All other differences were unclear. **Discussion** In accordance with previous findings (Malina 2000), soccer players advanced in maturity were physically advantaged compared with their less mature counterparts. We showed however, for the first time, that these advantages are also beneficial for match running performance. The magnitude of the between-group differences was however lower for match activities than for physical performance. This extends previous findings suggesting that technical and tactical demands likely regulate (at least partially) match running activities independently of physical capacities (Buchheit 2012) and maturation. These results have important implications for the identification and selection of young players. **References** Buchheit M et al. *Int J Sport Med* 2012, 34:40-8 Malina RM et al. *J Sports Sci* 2000, 18:685-93

**THE COMBINATION OF PLYOMETRIC AND BALANCE TRAINING IMPROVES SPRINT AND SHUTTLE RUN PERFORMANCES TO A GREATER DEGREE THAN PLYOMETRIC-ONLY TRAINING WITH CHILDREN**

Chaouachi, A.1, Ben Othmen, A.1, Hammami, R.1, Chamari, K.1, Drinkwater, E.J.2, Behm, D.G.3

*Tunisian research laboratory Sports Performance Optimisation*

**Introduction** Since balance is not fully developed in children and studies have shown functional improvements with balance only training studies (Behm et al. 2010), a combination of plyometric and balance activities might enhance static, dynamic balance and power. It was the objective of this study to compare the effectiveness of plyometric only (PLYO) with combined balance and plyometric (COMBINED) training on balance and power measures in children. **Methods** Before and following an 8-week training period, testing assessed lower body strength (1 repetition maximum leg press), power (horizontal and vertical jumps, triple hop for distance, reactive strength, leg stiffness), running speed (10m and 30m sprint), static and dynamic balance (Standing Stork Test and Star Excursion Balance Test), and agility (shuttle run). Subjects were randomly divided into two training groups (plyometric,  $n=14$  and plyometrics and balance,  $n=14$ ) and a control group ( $n=12$ ). **Results** Results based on magnitude-based inferences and precision of estimation indicated that the balance and plyometric training group was considered likely to be superior to the plyometric group in leg stiffness (91% likely), 10-meter sprint (84% likely) and shuttle run (80% likely). The difference between the groups was unclear in eight of the 11 dependent variables. **Discussion** While plyometric only training provided beneficial effects for static balance, combined training enhanced to a greater degree activities such as 10m sprints and shuttle runs. Whereas PLYO training was as effective as COMBINED training for static balance tests, COMBINED training produced better results for 10m sprint and shuttle run times as well as leg stiffness. The inherent balance challenges associated with plyometric training are sufficient to adequately improve static balance measures, while the greater stability or balance challenges of high speed sprinting and change of direction running (shuttle) may be enhanced with the addition of balance training to plyometric exercises. The increased leg stiffness scores found with the combined training may also have contributed to the greater improvement in sprint and shuttle run performance. As balance is less well developed in youth, coaches and athletes should consider adding or replacing some of their jumping, hopping, bounding and other similar training activities with balance activities. Considering that the COMBINED training group performed half as many jumping actions as the PLYO group, such COMBINED training could also be an important consideration for reducing the volume of jump training. This reduction in jump training volume with the replacement of balance and landing exercises might help to alleviate the overtraining effects of excessive repetitive activity. **References** Behm DG, Drinkwater EJ, Willardson JM and Cowley PM. ## MECHANICAL DETERMINANTS OF ACCELERATION AND MAXIMAL SPRINTING SPEED IN HIGHLY TRAINED YOUNG SOCCER PLAYERS

Buchheit, M.1, Samozino, P.2, Mendez-Villanueva, A.1, Glynn, J.1, Simpson, B.M.1, Al Haddad, H.1, Di Salvo, V.1, Morin, J.B.2

*1Aspire (Doha, Qatar) 2Exercise Physiology Lab (Saint-Etienne, France)*

**Introduction** Both acceleration (Acc) and maximal sprinting speed (MSS) are important for success in elite soccer. Understanding their specific mechanical determinants is pivotal to design optimal training programs. To date however, research was focused on non locomotor-specific determinants, and/or vertical force application capability, which limits field applications. The aim of the present study was to examine, in highly-trained young soccer players, the mechanical and horizontal determinants of Acc and MSS (Samozino 2013). **Methods** 86 soccer players (14.1±2.4 yr) from an elite academy performed a 40-m sprint to assess Acc (10-m sprint time) and MSS (best 10-m split) (Buchheit et al. 2012). Speed was measured with a 100-Hz radar (Laveg 300C, Jenoptik, Germany). Horizontal Force/Velocity profile, theoretical maximal velocity (V0), horizontal force (F0) and horizontal power (Pmax) were calculated (Samozino 2013). Within each age group, players were classified as High Acc/Fast MSS (>2% faster than group mean), medium (between -2 and +2% of group mean), and Low/Slow (>2% slower than group mean). Results Acc and MSS were very largely correlated (-0.79, 90%CL[-0.85;-0.71]). The determinants ( $r^2=0.84$ [0.78;0.89]) of Acc were V0 (partial  $r$ :-0.80 [-0.86;-0.72]) and F0 (-0.57[-0.68;-0.44]); those of MSS ( $r^2=0.96$ [0.94;0.97]) were V0 (0.96[0.94;0.97]) and Pmax (-0.73[-0.80;-0.63]). When comparing High/Med vs. Low/Med, High/Med have likely greater F0 (Cohen's  $d$ : +0.8[0.0;1.5]), V0 (+0.6[-0.1;1.3]) and Pmax (+0.9[0.2;1.7]), and a likely more Force-oriented profile (-0.8[0.1;1.6]). When comparing High/Fast vs. High/Med, High/Fast have an almost certainly faster V0 (+2.1[1.5;2.7]) and a likely greater Pmax (+0.6[-0.1;1.3]), with no clear differences in either F0 (-0.0[-0.7;0.6]) or Force/velocity profile (0.2[-0.4;0.9]). **Discussion** Present results confirm the specificity of Acc and MSS capabilities (Little and Williams 2005; Mendez-Villanueva et al. 2011). They show however for the first time that their mechanical horizontal determinants differ. The magnitude of the relationship with V0 is greater for MSS than Acc, and while a horizontal Force-oriented profile is likely beneficial for Acc, MSS may be more exclusively dependent on V0 and Pmax. These results might suggest the need for individualizing training contents based on players' mechanical profile and on field requirements. **References** Buchheit M et al. *Int J Sports Physiol Perform* 2012, 7:76-8. ## LOW- AND HIGH-VOLUME STRENGTH TRAINING INDUCES SIMILAR NEUROMUSCULAR ADAPTATION AND IMPROVEMENT ON MUSCLE QUALITY IN ELDERLY WOMEN.

Pinto, R.S., Radaelli, R., Botton, C.E., Wilhelm, E.N., Gaya, A., Brown, L.E., Bottaro, M.

*Federal University of Rio Grande do Sul*

The aim of present study was to compare the effects of low- and high-volume strength training on strength, muscle activation and muscle thickness (MT) of the lower- and upper-body, and on muscle quality (MQ) of the lower-body in older women. Twenty apparently healthy elderly women were randomly assigned in two groups: low-volume (LV, n=11) and high-volume (HV, n=9). The LV group performed one-set in each exercise, and the HV group performed three-sets in each exercise, twice weekly during 13 weeks. MQ was measured by echo intensity obtained by ultrasonography (MQEI), strength per unit mass (MQST), and strength per unit mass adjusted by an allometric scale (MQAS). After the training period, it was observed a significant increase ( $p \leq 0.01$ ) in knee extension 1-RM ( $31.8 \pm 20.5\%$  for LV and  $38.3 \pm 7.3\%$  for HV) and in elbow flexion 1-RM ( $25.1 \pm 9.5\%$  for LV and  $26.6 \pm 8.9\%$  for HV) and in isometric maximal strength for lower-body ( $p \leq 0.05$ ) and for upper-body ( $p \leq 0.001$ ), with no difference between groups. The maximal electromyographic activation for both groups increased significantly ( $p \leq 0.05$ ) in the vastus medialis and biceps brachii, with no difference between groups. All MT of the lower- and upper-body increased similarly in both groups ( $p \leq 0.001$ ). After training period, similar improvement in MQEI ( $p \leq 0.01$ ), MQST, and MQAS ( $p \leq 0.001$ ) for both groups was observed. The results of present study showed low- and high-volume strength training promoted similar effects on neuromuscular adaptations of lower- and upper-body, and on MQ of the lower-body in elderly women.

## JUNIOR SUCCESS – THE WAY TO THE TOP?

Hoffmann, A., Wulff, J.

*Institute for Applied Trainings Science*

**Introduction** The talent promotion system in Germany is based on the assumption that performance development follows a progressive trend with a linear and normative ascent from junior to senior competition levels (Deutscher Sportbund, 2006). The underlying model hardly considers other trajectories, e. g. of lateral recruits or late bloomers. This investigation aims to examine the competitive transition from junior elite to senior elite level in selected sports. **Methods** Junior World Championship (JWC) participation of elite athletes in boxing, pole vault, rowing and triathlon (participants in Olympic Games and/or World Championships) was analysed retrospectively using Fisher-Freeman-Halton exact test. Comparisons of age when entering elite competition level were conducted between JWC-participants and Non-JWC-participants, using t-test for independent samples. **Results** Data in the examined sports don't provide evidence for the assumption of a normative transition from junior to senior competition success. Between 10% (male boxing, U17 JWC) and 61% (male triathlon) of the elite athletes participated in JWC. Associations between ranking in JWC and success in Olympic Games and/or World Championships differed considerably from sport to sport. In all sports under review, those athletes who didn't take part in JWC, entered the elite level at an significantly older age. **Discussion** According to Gulbin et al. (2013) and Schumacher et al. (2006), results implicate that the generalised assumption of participation in international junior competitions as a prerequisite for elite success isn't sustainable. Even this 'coarse-grained' view onto athlete development shows, that talent selection and promotion systems are needed to allow for different trajectories of performance development, depending both on the specificity of the sport and the circumstances of the individual (e. g. high-achiever, late-bloomer or lateral recruit). Further research is required to identify successful trajectories including key points and possible catalysts and obstacles more in-depth. **References** Deutscher Sportbund (Hrsg.). ## TECHNICAL-TACTICAL PERFORMANCE OF SUB-13 FUTSAL PLAYERS: TRAINING GAME X OFFICIAL GAME

Milisteid, M., Saad, M., Nascimento, J.V.

*State University of Midwest (Paraná)*

**Introduction** The technical and tactical skills in team sports are understood as decisional-perceptual-motor strategies of players in the match, trying to solve the inherent game problems. The proper domain of technical and tactical actions is necessary to obtain success in team sports such as futsal. Thus, the aim of the study was to compare the technical-tactical performance of U-13 Futsal players in training game and official competition game. **Methods** 14 players participated in the research from two separate teams in the state of Santa Catarina. The Instrument of Assessment Individual Technical-Tactical Performance in Futsal (Saad, 2012) was used to analyze the components adaptation (A), decision making (DM) and efficacy (E) of technical-tactical actions of each player in different game environments. Data collection involved the complete filming of game and transcript data in training situation and the official competitive situation. Resorted to inferential statistical analysis to compare the performance achieved by players in each component evaluated using the test T for independent samples, assuming a value of  $p \leq 0.05$ . **Results** The data in this study showed that the level of technical-tactical performance of the players investigated in game situation-training were significantly higher in all variables (A = 78.9 x 71.3; DM = 79.4 x 66.5; E = 78.8 x 64.7). **Discussion** The results demonstrate that the competitive environment, where external constraints are present, has negative effects on technical-tactical performance of young futsal players. Also, confirm that the technical and tactical actions in team sports are determined by the interaction between cognitive, coordinative and psychological capacities, being the latter, most requested in the competitive environment (Greco, 2006; Canyon, 2009). Thus, the evidence found point to the need of the young athlete training at competitive situations, favoring the development of their cognitive, psychological and coordinative abilities. It is also recommended that the competition is perceived by coaches as an authentic environment for long term athletes formation. **References** GRECO, PJ (2006) Knowledge tactical-technical: pendulum model of behavior and action in team sports. *Rev. ## REVISITING CRITICAL POWER MODEL

Tsai, M., Thomas, S.

*University of Toronto*

A well-established model, Critical Power, has been extensively used in numerous endurance sports to characterize an individual's work performance; anaerobic work capacity (AWC) and critical power (CP). A linear relationship between total work and time to fatigue was observed and can be described mathematically by  $Work = AWC + CP \cdot time$  (Monod 1957). A mathematical equivalent model,  $Power = AWC/time + CP$ , can be derived from the traditional model and has been a popular model used in research. The model makes an assumption that all types of athlete have the same responses when it comes to power and time to fatigue, however recent study showed different observation (Bundle 2012). Therefore, we proposed a modified CP model with an introduction of a relationship variable,  $n$ , to allow the freedom to describe the relationship between power and time for different types of athlete.  $Power = AWC/time^n + cp$ . **Methods** Ergometer testing results (power outputs for 1 minute, 1km, 2km, and 6km) were obtained from 31 senior (24.89yrs  $\pm$  0.78), 33 U23 (20.8yrs  $\pm$  1.47), 23 junior (16.35yrs  $\pm$  1.03) athletes. Out of the 87 athletes, 57 were male (20.89 yrs  $\pm$  2.92) and 30 were female (19.03 yrs  $\pm$  3.34). The data were fitted using nonlinear regression model on the proposed modified CP model to determine the relationship between power output and time to fatigue for each individual. Analysis of variance with Tukey correction for type I error was used to compare the means of the relationship variable  $n$  between 3 competitive categories (senior, U23, and junior) and also between sex (male, female). **Results** The relationship variable,  $n$ , were 0.4721, 0.4841, and 0.3359 for the senior, U23, and junior athletes respectively. There were significant difference between the junior athletes when compared to the senior ( $p < 0.001$ ) and U23 ( $p < 0.000$ ) athletes, however there were no significant difference between the senior and U23 athletes ( $p = 0.930$ ). There were also no differences in responses for male and female to performance and time to fatigue. **Discussion** In all three categories, the relationships were shown to be significantly different from the inverse relationship suggested by the traditional model. The senior and U23 athletes appeared to have different response to power and time to fatigue than junior athletes indicating the years of training may have altered their physiology to accommodate specific rowing performance needs. The next phase of the study will be to examine the power-time relationship between more extreme types of athletes (sprint or endurance) and across different sports. We hypothesize there will be a significant difference in power-time relationship between sprint and endurance athletes and this relationship parameter will be consistent across the different sport. **References** Monod H, Scherrer J. (1957). *Soc boil Fil*, 151(7): p.1358-62 Bundle MW. (2012). *Exerc Sport Sci.* 40(3):p.174-82

## COMPARISON OF THE SPIKE VELOCITY BETWEEN DIFFERENT GROUPS OF VOLLEYBALL PLAYERS

Đurković, T., Marelić, N., Rešetar, T.

*Faculty of Kinesiology, University of Zagreb*

**Introduction** Spiking efficacy is one of the key factors for success of one volleyball team. The fact that one team wins most of the points in the set/match with the spike (Bellendier, 2003; Marelić et al., 2005) makes this element very interesting for analysis. Besides technical – tactical diversity the key factor on high competitive level is the spiking velocity. The aim of this study was to compare the spiking velocity among three different groups of volleyball players. **Methods** Nineteen senior male volleyball players were divided into three different groups according to their quality: G1 (national team members), G2 (premiere league players) and G3 (second league players). Each volleyball player performed three spikes. Spiking velocity was measured using STALKER PRO radar in km/h. The means and SE were calculated for each tested group. Results between the groups were compared using ANOVA (Tukey HSD post – hoc test). Results Significant differences in spiking velocity were found ( $p < 0.05$ ). Using Tukey post-hoc test significant differences were found between all three groups ( $p < 0.05$ ). The speed of the spike increases according the level of the tested group (G1: 106.3 $\pm$ 5.83, G2: 97.5 $\pm$ 2.81, G3: 90.9 $\pm$ 2.96). **Discussion** The obtained results are almost identical to the previous results obtained on similar samples (Christopher, 2001; Coleman et al., 1993; Forthomme et al., 2005). Considering the importance of a spike in the structure of points scored during a set/match it may be concluded that the spiking velocity may represent important criteria in the selection process in volleyball especially at the top level. **References** Bellendier J. ### **MAXIMAL AEROBIC CAPACITY IN THE WINTER OLYMPIC ENDURANCE DISCIPLINES: CURRENT OLYMPIC MEDAL BENCHMARKS**

Tønnessen, E., Hem, E., Leirstein, S., Haugen, T., Seiler, S.

*The Norwegian Olympic Sports Program*

**Introduction:** Maximal oxygen uptake (VO<sub>2</sub> max) is a key performance parameter in winter Olympic endurance sports. Since 1990, the Norwegian Olympic Training Center has served as a standard testing facility for a large number of athletes across a broad range of performance levels, including multiple medal winners in cross-country skiing, biathlon, Nordic combined and speed-skating. The aim of this study was to generate Olympic medal benchmarks for VO<sub>2</sub> max in these disciplines. **Methods:** We identified male and female athletes who either won medals or ended in 4-8th place in winter Olympic Games or World Championships in the period 1990-2012. All identified athletes tested VO<sub>2</sub> max at the Norwegian Olympic Training Center within the same year of the actual competition. The treadmill testing procedures, described in Tønnessen et al. (2012) were consistent throughout the entire period, making all data comparable. **Results:** For the medal winning athletes, the following relative VO<sub>2</sub> max values (mean: 95 % CIs) for men were observed: cross-country skiing (85: 79-90) mL x min<sup>-1</sup>x kg<sup>-1</sup>(n=16), biathlon (80: 76-84) (n=9), Nordic combined (77: 74-80) (n=8) and speed-skating (74:69-80) (n=8). For the female medalists, the following VO<sub>2</sub> max values were observed: cross-country skiing (71: 63-80) mL x min<sup>-1</sup>x kg<sup>-1</sup> (n=11), biathlon (65: 60-71) (n=8). VO<sub>2</sub> max did not distinguish medal winners from athletes who ended in 4th-8th place for any of the disciplines. **Discussion:** This study provides concrete benchmark values for VO<sub>2</sub> max Olympic medal level performance in typical winter Olympic endurance disciplines. High VO<sub>2</sub> max is necessary but not sufficient in itself to deliver peak performance. Less complex disciplines seem to achieve higher values than more complex sports. World class female athletes achieve 16-19 % lower relative VO<sub>2</sub> max values than their male counterparts. The present results update the VO<sub>2</sub> max values presented by Saltin & Åstrand in 1963 and can serve as guidelines for future elite athletes. **References:** Tønnessen E, Hem E, Leirstein S, Haugen T, Seiler S. *Int J Sports Physiol Perform*. 2012 Oct 30. #### **TREADMILL VS OVERGROUND RUNNING. INFLUENCE OF THE EXHAUSTIVE RUNNING ON PLANTAR PRESSURE**

Lucas-Cuevas, A.G., García-Pérez, J.A., Pérez-Soriano, P., Llana-Belloch, S., Aparicio, I.

*University of Valencia*

**Introduction** Properties of different surfaces may provoke biomechanical modifications in running gait. Although the use of treadmills is becoming ever commoner (Wank et al., 1998), the differences produced when running on a treadmill vs overground (Wank et al., 1998; Hong et al., 2012) may call into question the use and validity of the treadmill as equipment used in research, training, and rehabilitation. Furthermore, how the runner's fatigue can affect the comparison between treadmill and overground running is unknown to date. Therefore, the aim of this study was to analyse under pre- and post-fatigue conditions the effect of the surface (treadmill vs overground) on plantar pressures. **Methods** Twenty-seven recreational runners (17 men, 10 women) participated in the study. On different days, the runners ran on a treadmill and overground at two different speeds (S1=3.33 m/s, S2=4.00 m/s), before and after a fatigue protocol consisting of a 30-min run at 85% of their individual maximal aerobic speed. Contact time (CT), peak pressure (PP), and relative load (RL) were analysed under 9 foot zones of the left foot using a Biofoot® in-shoe plantar pressure device. **Results** Treadmill running (compared to overground running) increases CT (7.70% in S1 - 9.91% in S2), modifies the pressure distribution (RL) and reduces PP (25.98% in S1 - 31.76% in S2), especially under the heel, medial metatarsals, and hallux. Moreover, on both surfaces, fatigue (S2) led to a reduced PP on the lateral heel and hallux (15.96% - 16.35%, respectively), and (S1) increased RL on the medial arch (9.53%). There was no significant interaction between the two factors analysed (surface and fatigue). **Discussion** Running on a treadmill compared to running overground significantly modifies the contact time as well as the magnitude and distribution of plantar pressures. On both types of surfaces, the runner's fatigue increases the relative load on the medial arch and reduces the peak pressure under the lateral heel and hallux. The effect of each surface on plantar pressure seems to be independent of the runner's fatigue state, given that no significant interaction was found between the two factors. The aforementioned surface effects should be taken into account when interpreting the results of studies that use the treadmill in their experimental protocols and when prescribing physical exercise on a treadmill. **References** Wank V, Frick U, Schmidbleicher D. #### **COMPARISON OF MORPHOLOGICAL CHARACTERISTICS OF HIGH-RANK FEMALE JUDOKAS OF VARIOUS WEIGHT CLASSES**

Elipkhanov, S., Nemtsev, O.

*Adyge State University*

**Introduction** Data on morphological features of judokas of various weight categories are often used to select athletes and determine the course of their training. Such studies have been done mainly for male judokas (Franchini, Nunes, Moraes & Del Vecchio, 2007 et al.). Yet, morphological features of female judokas still remain poorly researched. So the aim of this study was to compare the lengths and circumferences of body segments, skinfolds, and body fat percentage of high-rank female judokas of various weight classes. **Methods**

Twenty-three Russian female judokas (Masters of Sports of Russia and Masters of Sports of Russia of International Class) took part in the investigation. Morphological characteristics of 11 judokas of lighter weight classes (under 52, 57, and 63 kg) and 12 judokas of heavier weight classes (under 70 and 78 kg) were compared. Measurements were taken in accordance with ISAK guidelines. Body fat percentage was calculated from the measurements of four skinfolds (Jackson, Pollock & Ward, 1980). One-way analysis of variance was used to examine statistical differences of data. Results No significant differences in lengths of upper arms, forearms, hands, thighs, and shins were found for the judokas of both groups ( $p > 0.05$ ). Yet, heavier judokas appeared to have significantly larger lengths of feet ( $p < 0.01$ ). Circumferences of neck, thorax at forced inspiration, arm relaxed, forearm, mid-thigh and calf were significantly larger in case of heavier judokas ( $p < 0.01-0.001$ ). No significant differences in hand circumferences were found ( $p > 0.05$ ). Eight skinfolds proved to be significantly larger in case of heavier judokas (triceps, forearm, subscapular, chest, abdominal, thigh, medial calf:  $p < 0.05-0.01$ ). Body fat percentage was significantly larger for judokas of heavier weight classes ( $p < 0.01$ ). Discussion The absence of significant differences in the lengths of body segments between female judokas of lighter and heavier weight classes (except for feet) has shown that there is no need to rely on these characteristics when selecting athletes of different weight categories. Significantly larger circumferences of most body segments, larger skinfolds and body fat percentage of heavier judokas might result in lower mobility and deficiencies in competitive performance. Big values of body fat in judokas of heavier weight classes might be the consequence of their insufficient competitive readiness, and thus might be viewed upon as a reason to adjust their training processes. ### KETTLEBELL SNATCH TRAJECTORY OF ELITE LEVEL KETTLEBELL SPORT ATHLETES

Ross, J.I, Lorenzen, C.I, Wilson, C.I

*1: Australian Catholic University*

Introduction The first Kettlebell or Girevoy Sport (GS) competition was held in Russia in 1948. The competition has a ten minute time limit per set and the aim is to perform as many repetitions as possible within that period. Interest in the sport has developed only recently in the West, leading to a paucity of research on the sport in English language scientific journals. The 'snatch', is considered the most technical event in GS and was the focus of this research. The aim was to document kettlebell trajectory and variation during the snatch when performed by elite GS athletes. Method Four elite GS athletes (age =  $38.25 \pm 6.9$  years, body mass =  $90.5 \pm 16.7$ kg, height  $180.3 \pm 7.7$ cm) completed a set of 16 repetitions of the kettlebell snatch with a 32.1kg kettlebell. Kettlebell trajectory was captured with the VICON motion analysis system (at 250 Hz) and analysed with VICON Nexus (1.7.1). Four points in the sagittal plane were noted to identify the the point at which the kettlebell trajectory changed from forwards to backwards, or backwards to forwards. At these four points means, standard deviations, absolute error and radial error (RE) were measured in the sagittal and frontal planes. This was used to ascertain a measure of consistency from trial to trial. Additionally, the distance between the midpoints of the upwards and downwards phases in the sagittal and frontal planes were recorded. Results The trajectory of the kettlebell, followed a 'C' shape in the sagittal plane, and had a larger radius on the upwards phase than the downwards phase of the snatch. There was a mean distance between upwards and downwards phases at the midpoint of 72mm in the sagittal plane and 24mm in the frontal plane. The mean peak speed occurred during the upwards phase, and was  $4.03 \pm 0.20$  m s<sup>-1</sup>, whilst measuring  $3.70 \pm 0.30$  m s<sup>-1</sup> during the downwards phase. Mean RE for the sagittal and frontal planes was  $22 \pm 6$  mm. Discussion Three dimensional motion analysis was used in this case study to document the athletes kettlebell snatch kinematics. Despite some differences, there were three major commonalities. A 'C' shape trajectory was shown during the downwards and upwards phases of the snatch. Relative to the upwards phase, the 'C' shape of the downwards phase followed a narrower trajectory. The larger radius during the upwards phase and the slower mean peak speed during the downwards phase, may reduce force placed on the finger flexors. Additionally, at the four points of the kettlebell snatch there was low movement variability. A consistent path for each repetition may have been used to reduce extraneous movements, increasing efficiency. References Tikhonov V, Suhovey A, Leonov D. (2009). ### A NOVEL PROTOCOL FOR ASSESSING SKATING PERFORMANCE IN ICE HOCKEY

Kendall, M., Zanetti, K., Hoshizaki, T.B.

*University of Ottawa*

Introduction: In ice hockey, the ability to skate swiftly and with skillful precision is most predictive of players' proficiency in the game<sup>1</sup>. Prior research aiming to understand the patterns and mechanics of skating has focused on measuring kinetic and kinematic variables at play during the movement<sup>2,3</sup>. While force plates have long been the gold standard for the measurement of force output, their use is limited to a laboratory environment and thus a simulated skating environment for the athlete. The purpose of this study was to establish a novel protocol for evaluating ice hockey skating performance through direct in-skate measures. Methods: Five competitive-level hockey players completed three skating acceleration trials from rest on a regulation ice hockey rink. Tekscan Inc. insoles were placed into a hockey skate equipped with a novel technology designed to optimize force transfer and control (NS), followed by participants' own skates (OS). Peak plantar force, impulse, and center of force (COF) variance (A-P and M-L axes). Results/Discussion: Significantly higher vertical plantar force and impulse were found in the NS condition when compared to the OS condition for all participants ( $p \leq 0.05$ ). COF variance and A-P COF displacement were also significantly greater for the NS condition. Maximization of dynamic stability while skating is crucial to achieve high plantar force and impulse. Impulse in particular has been identified as an important performance parameter in sprinting sports as well as skating<sup>4,5</sup>. Acting to optimize dynamic stability, the higher COF variance indicates a greater ability to move the body through the stance phase of skating with control while a greater range of force distribution in the A-P axis may indicate an increased ROM at the ankle joint. Thus, the results of this study show that direct measurement of these dynamic variables may be important indicators in evaluating skating performance in ice hockey as it relates to skate design or skill development. ## TRUNK MUSCLE ACTIVITY AND BODY ALIGNMENT DURING A HANDSTAND POSTURE

Okubo, Y., Kaneoka, K., Matusnaga, N., Hasebe, K., Tanaka, Y.

*Saitama Medical University*

**Introduction:** Handstands are frequently performed by competitive gymnasts and divers. Muscle activity and body alignment of a handstand posture differ from those of a standing posture because an individual's center of mass is controlled by their upper extremities. The purpose of this study was to clarify trunk muscle activity and body alignment during handstand posture in gymnasts. **Methods:** Seven male collegiate gymnasts who have been practicing gymnastics for more than 10 years participated in this study. Electromyographic (EMG) and body alignment data were synchronously measured during static handstand and standing postures. EMG data were obtained for the rectus abdominis (RA), external oblique (EO), internal oblique (IO), thoracic erector spinae (TES), lumbar erector spinae (LES), and rectus femoris (RF) muscles and normalized with respect to the amplitude of the maximum voluntary isometric contraction (%MVC). The angles of thoracic kyphosis, lumbar lordosis, pelvic tilting, and the hip joint in the sagittal plane were collected using 2 motion analysis system cameras. Each %MVC and alignment data were compared between experimental tasks (handstand vs. standing) by using a paired t-test ( $p < 0.05$ ). **Results:** The RA, EO, and RF activity levels during the handstand were  $6.5 \pm 4.2$  %MVC,  $6.4 \pm 5.1$  %MVC, and  $3.5 \pm 2.2$  %MVC, respectively, and were significantly higher than the values while standing. On the other hand, the LES activity during the handstand ( $1.6 \pm 1.2$  %MVC) was significantly lower than that during standing ( $4.7 \pm 3.6$  %MVC). The anterior pelvic tilting angle ( $18.2 \pm 8.6^\circ$ ) and the hip extension angle ( $11.2 \pm 5.8^\circ$ ) during the handstand were greater than those while standing. **Discussion:** These results indicated that the anterior surface muscles (RA, EO, and RF) were activated as antigravity muscles to maintain the handstand posture. In contrast, the LES muscles were activated as antigravity muscles while standing. Moreover, the alignment data showed greater angles of anterior pelvic tilting and hip extension during the handstand than while standing. Gautier et al, (2009) reported that expert gymnasts could maintain a handstand posture with less hip extension displacement than amateur gymnasts. The findings of the current study suggest that the abdominal and hip flexion muscles involved in the maintenance of a straight handstand posture in expert gymnasts.

## NEURO-MECHANICAL RESPONSES TO A 4-WEEK NORDIC HAMSTRING EXERCISE TRAINING PROGRAMME

Ditroilo, M.1, Wang, D.2, De Vito, G.2, Delahunt, E.2

*(1) University of Hull (UK); (2) University College Dublin (Ireland)*

**Introduction** Hamstring strains are prevalent in many sports with sprinting, jumping and kicking actions (Orchard et al, 1997). The use of eccentric exercise in the prevention and rehabilitation of hamstring injuries has been advocated by numerous authors (e.g. Brockett et al, 2004). The Nordic hamstring exercise (NHE) is a popular eccentric exercise; however there is a paucity of information available regarding the biomechanical adaptations to this type of training. Accordingly, the aim of this study was to investigate the kinematic and muscle activation adaptations to a 4-week eccentric hamstring training programme. **Methods** Ten male university students (age:  $20.4 \pm 1.9$  years) were recruited and invited to visit the laboratory on three occasions (TS1, TS2, TS3), 4 weeks apart. During each laboratory visit the participants performed two sets of five repetitions each of the NHE and maximal eccentric voluntary contraction (MEVC) of the knee flexors on an isokinetic dynamometer (30deg/s) whilst knee angular displacement and electrical activity (EMG) of biceps femoris were measured. The first 4-week control period was followed by a 4-week intervention period during which the participants underwent 2 training sessions per week of up to 4 sets of 6 repetitions of the NHE. **Results** Following the training intervention, the peak knee angular velocity was significantly reduced ( $63.4$  vs  $83.2$  deg/s,  $p < 0.05$ ) whereas the angle at peak velocity increased ( $53.5$  vs  $43.0$  deg,  $p < 0.05$ ) during the performance of the NHE. Similar significant trend was observed for peak EMG ( $0.150$  vs  $0.322$  mV,  $p < 0.05$ ) and angle at peak EMG ( $72.5$  vs  $63.6$  deg,  $p < 0.05$ ). Interestingly, while there was no significant change in MEVC following the training intervention ( $174.9$  vs  $168.2$  Nm), the neuro-mechanical efficiency was significantly increased on TS3 ( $1427.2$  vs  $878.7$  Nm/mV,  $p < 0.05$ ). **Discussion** A reduction in the knee peak angular velocity, along with an increase in the angle, mean that the forward fall is broken more efficiently, which can potentially be attributed to an enhancement in eccentric muscular contraction. MEVC did not improve and this finding conflicts with the results of Iga et al (2012). However the increase in neuro-mechanical efficiency can be ascribed to an improved contractile state of the musculature, where the concurrent activation of less motor units generated the same amount of external force. Notably, this is mirrored by reduced EMG amplitude during the performance of the NHE, which can be again an indication of improved efficiency. **References** Brockett CL et al. ## THE EFFECT OF HOLDING A LACROSSE STICK AND ANTERIOR CRUCIATE LIGAMENT INJURY ON THE LATERAL TRUNK ROTATION DURING CUTTING MOVEMENT

Takebayashi, Y.

*Waseda University*

**【Introduction】** Each lacrosse player always carries a lacrosse stick (crosse) in a game. Holding a crosse restricts the mobility of their arm, and their trunk should be requires larger movement to their trunk for compensation. The lacrosse player with anterior cruciate ligament (ACL) injury performs an unusual motion associated with knee instability and deficit in somatosensory system. Thus, the trunk movement of the lacrosse player with ACL injury is assumed to be larger than that of the uninjured player. The purpose of this study was to determine the effect of carrying a crosse and ACL injury on lateral trunk rotation during cutting movement. **【Methods】** Ten male collegiate lacrosse players (injured group: five players, control group: five players) were voluntarily participated in this study. Subjects were instructed to run diagonally backward right and quickly change direction to turn left ( $70^\circ$ ) to the initial direction. They performed two trials in both holding and not holding a crosse conditions, then their motions were recorded by three high-speed cameras at 300 fps. From the obtained movies, bilateral anterior superior iliac spines (ASISs) and acromia were digitized in three-dimension. The trunk rotation angle was defined as the orientation of the line connecting between bilateral acromia relative to the line connecting between bilateral ASISs (positive values indicate that right acromion rotates to forward). The range of the trunk rotation and the mean rotation angles of the trunk were calculated during the contact phase of cutting movement. **【Results and Discussion】** The ranges of trunk rotation were not different between in holding a crosse condition (injured group:  $28.3 \pm 4.2^\circ$  and control group:  $30.2 \pm 5.5^\circ$ ) and in not holding a crosse condition ( $30.0 \pm 11.1^\circ$  and  $31.8 \pm 17.4^\circ$ ). Although the mean rotation angles of the trunk in the control group were similar in both conditions, those in the injured group were tended to be larger in holding a crosse condition ( $9.9 \pm 4.1^\circ$ ) than in not holding a crosse condition ( $6.6 \pm 8.5^\circ$ ) ( $p = 0.09$ ). Thus, it is indicated that the range of lateral trunk rotation during cutting movement with a crosse in the injured group was totally shifted to left side compared with that in the control group. These results suggested that the subjects in the injured

group made their trunk rotate to the next direction prior to the cutting movement in order to reduce the load on the injured knee. Further studies are needed to confirm the motion prior to the cutting movement.

### THE EFFECT OF INSTRUCTION ON THE NON-THROWING ARM ON THE 3D ARTHROKINEMATICS OF TRUNK AND UPPER LIMB IN A TEAM HANDBALL PENALTY THROW.

Serrien, B., Blondeel, J., Bosmans, K., Baeyens, J.P.

*Vrije Universiteit Brussel*

**Introduction.** This abstract presents preliminary results in an ongoing study. The team-handball penalty throw has only once been studied in an interventional design in which the instructions on throwing velocity or accuracy were the independent variables and the kinematics the dependent(1). The purpose of this study was to analyze the effect of instructions on the throwing technique to the ball velocity and kinematics of other joints. Based on another study, that found that players with a constraint on the non-throwing arm threw slower and had other kinematical parameters(2), we tested if an instruction regarding the non-throwing arm could increase the ball release speed (BRS). **Methods.** Three-dimensional kinematics of 2 male subjects (students at the Topsportschool Vlaanderen, 17 years old) were measured using a 6 camera motion analysis system at 250Hz (VICON Nexus) and kinematic parameters were calculated using a Finite Helical Axis approach (FHA). We measured 3 trials for the penalty shot (PS) without any instructions and afterwards 3 trials for a penalty shot (PS.2) with the instruction to use their non-throwing arm actively during the acceleration phase ("active backward pull of the non-throwing arm"). Subjects did not know that after the initial trials, there would follow an instruction, nor were they informed as to why this instruction was given. The throws with highest BRS of both shots were used for analysis. **Results.** For subject 1, we observed a similar BRS after instruction (PS: 25.6m/s, PS.2: 25.2m/s), but for subject 2 there was a decrease discernible (PS: 21.65m/s, PS.2: 20.96m/s). Subject 1 showed consistently higher mean angular velocities (MAV's) in the PS.2 for all calculated variables (shoulder internal rotation, elbow extension, pelvis internal rotation, upper thorax internal rotation, trunk flexion, trunk internal rotation) and a shorter acceleration phase, but no higher BRS. Subject 2 showed no such pattern in MAV's or acceleration phase. **Discussion.** It was hypothesized that the momentum created by the non-throwing arm would help the trunk reach higher rotational velocities, but based on these preliminary results we cannot agree with our initial hypothesis. Further data processing on other subjects is ongoing and will lead to more insight. **References** (1)van den Tillaar & Ettema (2008) Instructions emphasizing velocity, accuracy or both in performance and kinematics of overarm throwing in experienced handball players. *Perceptual and Motor Skills*. 97: 731-742 (2)Kazuyuki & Yuichi (2004) Effects of non-throwing arm on trunk and throwing arm movements in baseball pitching. *Int. ### DETERMINATION OF THE FRICTION COEFFICIENT OF CROSS COUNTRY SKIS ON A NOVEL LINEAR TRIBOMETER

Hasler, M., Schindelwig, K., Van Putten, J., Knoflach, C., Nachbauer, W.

*University of Innsbruck*

**Introduction** In skiing competitions, besides aerodynamic drag, the frictional force between ski and snow is the most important performance-limiting material factor. National ski federations and ski producers have been carrying out reams of gliding tests in the field. Outdoor tests however are affected by changing environmental conditions (Nachbauer et al., 1996) and the influence of the test skier. Laboratory measurements up to now were of limited significance due to design restrictions of the measurements devices (Ducret et al., 2005; Kuroiwa, 1977). In this study, laboratory snow friction measurements of complete cross country skis at sports specific velocities are presented. **Method** A novel tribometer was developed which is based on linear movement. It consists of a guidance beam (25 m), a carriage and a trough for snow or ice. The carriage runs on the beam and is pulled via light fibre cables by a high torque electro motor. In the first section the carriage carrying ski and measurement equipment is accelerated. In the measurement section the speed is kept constant and frictional force is measured. Afterwards the carriage is decelerated. In the study, a vertical force of 420 N was applied to the ski by springs. Two stone grinded cross country ski with a roughness of 40 µm (ski A) and 15 µm (ski B) were tested. Eight test series were performed at the speed of 2.5 and 5 m/s at temperatures of -4°C and -8°C for both skis. Additionally one series was carried out at -8°C and 2.5 m/s to check repeatability. One test series consisted of 30 runs, starting on a fresh snow track. The friction coefficient was calculated by dividing horizontal friction force by the vertical force and averaging the values over the measuring track. **Results** The friction coefficient of ski A at 2.5 m/s was 0.041 (-4°C) and 0.047 (-8°C). Ski B showed friction coefficients of 0.051 (-4°C) and 0.055 (-8°C). Results at 5 m/s were similar. The measurement value deviation within one test series was lower than 3%. Two test series carried out under the same conditions but on different tracks differed by 5%. **Discussion** The measurement device in the current setup is a valuable tool for evaluating friction differences between skis. Results are in agreement with findings in the literature (Bäurle et al. 2006; Kuroiwa, 1977). Due to the complicate and demanding assessment of the snow surface properties, direct comparisons are not possible. **References** Bäurle, L., Szabo, D., Fauve, M., Rhyner, H., Spencer, N.D., 2006a. ### TEMPORAL CHARACTERISTICS OF THE EMG PATTERNS DURING CYCLING USING DIFFERENT ANGLE SCALE NORMALIZATION METHODS

Fonda, B., Sarabon, N., Grey, M.J., Li, F.X.

*University of Birmingham*

**Introduction** Muscle activity during cycling is generally studied from a representative ensemble-averaged EMG profile obtained over consecutive cycles, with time-scale normalisation for comparison across different trials. The abscissa is typically expressed as a percentage of the duration of the complete crank cycle, based on a single position in the cycle. However, because crank speed is not constant throughout the cycle, Hug (2011) suggested interpolating between multiple crank position detection points. This notion has not yet to be specifically tested. The aim of this study was to test if the number of crank position measurements affects the calculation of the temporal characteristics (onset, offset, and peak occurrence) of the EMG patterns. We hypothesised that these temporal characteristics would be different for crank positions measured at a single angle or interpolated between 4, and 360 crank positions. **Methods** 8 trained cyclists completed a constant-cadence 5-min cycling trial at 65% maximal aerobic power. Muscle activity patterns of the vastus medialis, vastus lateralis, rectus femoris, biceps femoris, gastrocnemius lateralis, tibialis anterior and soleus muscles were recorded using surface EMG. Raw EMG traces were bandpass filtered (20-450Hz) and smoothed with a RMS moving average (25ms window). Ensemble-averages

were calculated from 50 cycles. Onset, offset, activity duration, peak activity were analysed. On a rescaled EMG pattern according to 1 measurement point (0°), interpolating between 4 measurement points (0°, 90°, 180°, 270°), and between 360 measurement points. Differences among the number of measurement points were analysed with 2-way repeated measure ANOVA (muscles (7) x method (3)). Results No statistically significant main effects were found among the used methods to analyse the EMG pattern for onset ( $p = 0.052$ ), offset ( $p = 0.241$ ), and peak occurrence ( $p = 0.623$ ). Discussion This is the first study testing the effect of crank position detection on muscle activity patterns. The results do not confirm our hypothesis. A single crank angle detection point is sufficient to produce a representative EMG pattern during cycling at constant cadence. The present study is of practical value for future cycling research, and suggests that continuous measurement of the crank position is not required. References Hug, F. (2011). *J Electromyogr Kinesiol*, 21(1), 1-12.

### THE USE OF SOFTBALLS AS TEACHING METHOD OF TENNIS

Dorst, L.M.1, Bachinski, L.2, Colombo, M.2, Dorst, D.G.B.3

1: FAG (Cascavel, Brasil) e Secretaria de Estado do Esporte (Curitiba, Brasil) 2: FAG 3: FAG e UNICAMP (Campinas, Brasil)

Introduction With the popularization of tennis in the last years, new training strategies are appearing that contributed to this growth and, among these strategies, the training with lower pressure balls, that are slower, favoring the movement levels which, in theory, would be more successful (Ishizaki, 2008). The aim of the following study was to verify if the low pressure balls (soft balls) provide better results when compared if the normal-pressured balls in the learning process. Methods 8 students, between 10 and 12 years old and in an initial level of learning, were selected. They were divided in two groups (G1 and G2). G1 trained with the low pressure balls and G2 used normal-pressured balls, according to the International Tennis Federation. The training method was the same for both groups. For the G1 group, every two classes the type of ball changed, following the sequence: red balls, orange, green and regular ones. G2 used only regular balls. The movements were recorded in sagittal plane, in the first class and when a new type of ball was used. Each class lasted 50 minutes for 4 weeks. The forehand cinematic was measured by bi-dimensional videography (60 Hz), through the variables sustentation base size (SBS), elbow bending angle (EBA), inferior members positioning (IMP), movement conclusion (MC) and court delivery (CD). To analyze the data it was used median descriptive statistic and standard deviation. Results The SBS variable for the G1 group presented development in technical positioning, increasing the size. G2 developed during classes, increasing the size. However, the base increase brought a bigger variation. For the EBA variable neither groups showed technical evolution. Regarding to the IMP, MC and CD, there was improvement in G1 with the classes. For the G2 group, the variables IMP and MC didn't show any development, not improving their positioning. In the CD variable, there was an evolution as the weeks went by. Discussion Training with low pressure balls was more successful, while the ones who trained with regular balls stayed the same in the two first aspects, improving only in the delivery. Analyzing the high and continuous improvement of group G1, we can see that the soft balls, having less pressure, increase the time between hitting the ground and getting to the student, making it easy to move around and to prepare for the hit. ### BALL-FOOT INTERACTION IN IMPACT PHASE OF KNUCKLE SHOT

Hong, S., Asai, T.

*University of Tsukuba*

BALL-FOOT INTERACTION IN IMPACT PHASE OF KNUCKLE SHOT Introduction There are many kicking techniques in soccer, all kicks represent almost same impact time of 1/100 second at the impact between a ball and a foot. Also, such a very short impact time decides the direction of a ball after the interaction between the ball and the foot, but there are still no clear answers for the complex mechanical interaction occurred at the moment of impact between the ball and the foot. Moreover, it is easy to find the non-spinning or low-spinning soccer balls in recent soccer games in which the trajectory of balls represents a characteristic of swing that is called as a knuckle shot or knuckle ball as an unsteady phenomenon (Hong and Asai, 2011; Hong et al., 2010). However, there are virtually few knuckle shot studies on the kicking motions or ball impact characteristics; as a result, the mechanisms of this shot have not been elucidated, possibly because this phenomenon occurs at extremely high speeds. Moreover, there are relatively few soccer players who can intentionally perform knuckle shot, and even among them, most have low success rates (Hong et al., 2011). Methods We used high-speed video cameras to compare the knuckle shot with the curve shot and straight shot, and investigated the swing characteristics of the kicking leg. Furthermore, the impact process of the kicking foot was analysed, elucidating the technical mechanism of the knuckle shot. Results & Discussion Results revealed flexion of the ankle joint in an approximate L-shape at impact, similar to that of the curve shot, and ball impact with a posture closer to that of the curve shot than to that of the straight shot was observed. The curve shot was considered a kicking motion with greater lateral motion than the straight shot, and the knuckle shot was considered to have a swing motion closer to the straight shot than to the curve shot. The ankle joint in the curve shot had greater lateral motion than the other shots, but was comparatively smaller in the knuckle shot. Hip external rotation in the knuckle shot exerted greater external rotation torque of the hip joint ( $61.2 \pm 8.1 \text{ N}\cdot\text{m}$ ) than the other shots ( $37.7 \pm 3.8 \text{ N}\cdot\text{m}$ ,  $51.8 \pm 7.7 \text{ N}\cdot\text{m}$  for the straight shot, and curve shot), and the tendency to impact with the heel pushed out towards the inside of the foot was considered. Furthermore, the angle of attack in the knuckling shot ( $4.3 \pm 1.3^\circ$ ) was smaller than those in the straight and curve shots ( $20.2 \pm 3.7^\circ$  and  $35.1 \pm 0.9^\circ$ , respectively) and was believed to be a factor for balls with smaller rotational frequencies. ### BIOMECHANICAL PARAMETERS OF VERTICAL JUMPS IN VOLLEYBALL AND BEACH VOLLEYBALL PLAYERS: COMPERATIVE ANALYSIS

Michalski, R., Busko, K., Mazur-Rozycka, J., Gajewski, J.

*Institute of Sport*

Introduction The aim of this study was a comparison of jumping abilities between two similar sport disciplines: volleyball and beach volleyball. Assuming that the differences of playground in both disciplines results in different jumping technique and energy expenditure [1], we found it reasonable to examine and identify the differences in mechanical parameters of vertical jumps between both groups. Methods 20 volleyball and 17 beach volleyball male players took part in the experiment. Descriptive statistics of the examined groups is as follows: body height ( $190,0 \pm 5,3$  and  $197,6 \pm 6,9$  cm), body mass ( $80,0 \pm 5,94$  and  $88,1 \pm 10,1$  kg), age ( $18,5 \pm 2,8$  and  $17,9 \pm 1,2$  years) and training experience ( $6,6 \pm 2,7$  and  $6,0 \pm 2,4$  years) respectively for beach volleyball and volleyball players. All the relevant biomechanical parameters were computed from the recorded ground reaction force developed by subjects on the force plate. All subjects performed

countermovement jumps (CMJ) and akimbo countermovement jumps (ACMJ), which are commonly used to describe jumping abilities of athletes. ANOVA (with Tukey post hoc test) procedures were employed for data processing ( $p < 0,05$ ). Results Both examined groups differed significantly in respect to body mass and body height. The ACMJ test revealed significant difference in height of jump, in favor to beach volleyball players ( $0,455 \pm 0,05$  vs  $0,423 \pm 0,06$ m). On the other hand, the CMJ test showed that the both groups differed in countermovement depth ( $0,456 \pm 0,06$  vs  $0,389 \pm 0,06$ m), developed maximal ground reaction force ( $1228,3 \pm 303,5$  vs  $1456,0 \pm 229,7$ ) and maximal and average power output ( $2927,5 \pm 569,1$  vs  $3392,8 \pm 491,9$ N and  $1338,6 \pm 248,0$  vs  $1622,8 \pm 347,5$ N). No significant differences were observed for height of jump and relative power output (maximal and average power in relation to body mass). Discussion The presented results suggest that the beach volleyball players may attain better jumping abilities. Assuming that training of both disciplines is focused on power output and height of jump, the observed differences in jumping mechanics might be a result of playing and training on a different playground. Bishop [3] claimed, that differences in plyometric training performed on firm ground and on sand are caused by the lower ground reaction force developed on sand. Differences in jumping mechanics are supposedly related to the mechanism of stretch – shortening cycle. Acknowledgements: The study was supported by Ministry of Science and Higher Education. ### BETWEEN DECEPTION AND VERIDICALITY: A PRINCIPAL COMPONENT ANALYSIS ON BASKETBALL PASSES

Peng, S.E., Liu, Y.T.

*National Taiwan Normal University*

Introduction Deception is an effective tactic popularly used in basketball games of all levels. While the offensive players are trying to deceive the opponents, the defenders must detect the movement of deception in order to make the appropriate defense. Experimental works have shown that kinematics of movement are the source of the deception (Shim and Carlton, 1997) although experts were able to detect the veridical information from being deceived (Sebanz and Shiffrar, 2009). Principal Component Analysis (PCA) has been shown to be able to reduce the complex multi-segment movements to fewer dimensions, therefore the purpose of the study was to use PCA to examine the differences in the movement kinematics between the deceptive and veridical movements of basketball passes. Methods University basketball players served as the performers to make deceptive (fake passes) and veridical (true passes) motions. The GypsyGyro 18 motion digitizing system (120Hz) was used to capture the 3D kinematics of 17 joints, yielding a total of 51 dimensions of the movement data. Both position and velocity data were submitted for PCA. Results PCA on both position and velocity data show reduction of the number of principal components in the deceptive condition. The velocity data further show differences in the content of the components between the deceptive and veridical motions. The distinct slow-down of movements of the upper limbs were differentiated from the general forward motion of the majority of the body segments in the deceptive passes. Discussion The results of PCA on the movement velocity data provide useful information in distinguishing the deceptive vs. veridical motion. The results of this study may apply to the training of performing and detecting deceptive passes in basketball. Future studies with PCA will extend the scope of movements to other sports where deceptive motions play an important role in offensive tactics. References Sebanz N, Shiffrar M. (2009). ### RELATIONS BETWEEN GROUND REACTION FORCES AND THROWING PERFORMANCE IN EXPERIENCED AND NOVICE HANDBALL PLAYERS

Boudolos, K.1, Rousanoglou, E.1, Noutsos, K.2, Bayios, I.2

*1Sports Biomechanics Lab-Department of Sports Medicine & Biology of Exercise, 2Department of Sport Games,*

Introduction Throwing performance (ThrP) differences in experienced (EP) and novice (NP) players are of particular interest (Wagner et al., 2010) for the NP's technical optimization. The ground reaction forces (GRF) during a shot is associated with the energy transferred from lower to upper extremity (Oliver and Plummer, 2011). However there is lack of data about the relations between GRF and ThrP. The study aimed to identify the GRF- ThrP relations in EP and NP. Methods Fifteen EP and 15 NP ( $24.9 \pm 2.9$  and  $21.7 \pm 0.9$  yrs) did 3-step (3SS) and jump shots (JS). The ball throwing velocity (Thr-Vel) and throwing accuracy (Thr-Acc) were used to assess ThrP (measured with a laser system and an electronic coordinate system, respectively, Bayios et al., 1998). The GRF-time curve during contact phase was recorded (Kistler-9281, 250Hz) to determine the parameters of contact time ( $t_{\text{contact}}$ ) and the maximum GRF ( $F_{\text{max:N-BW}}$ ), the time to peak ( $t_{\text{peak}}$ )  $F_{\text{max}}$  ( $\text{ms} \cdot \%t_{\text{contact}}$ ) and total impulse ( $\text{Imp:N} \cdot \text{s} \cdot \text{BW} \cdot \text{s}$ ) for the vertical ( $F_z$ ), anterior-posterior ( $F_y$ ) and lateral ( $F_x$ ) components, respectively. T-test was used for the differences between EP and NP and the Pearson coefficient for the significance of the GRF-ThrP relations (SPSS 13.0,  $p < 0.05$ ). Results The EP had better Thr-Vel and Thr-Acc in 3SS and JS ( $p < 0.05$ ). The significant GRF differences between EP and NP were not the same in 3SS and JS (3SS: EP>NP: $F_{\text{ymax}}$ , EPNP: $F_{\text{zmax}}$ ,  $F_z$ -Imp). In 3SS the NP had a non-consistent pattern of GRF peaks and dips. The GRF-ThrP relations were significant only in 3SS and only for Thr-Vel ( $p < 0.05$ ). In EP, Thr-Vel was negatively related to  $t_{\text{peak}}$ - $F_{\text{ymax}}$  & Imp- $F_x$  ( $r = -.52$  &  $-.62$ ). In NP Thr-Vel was related negatively to  $t_{\text{contact}}$  &  $t_{\text{peak}}$ - $F_{\text{ymax}}$  ( $r = -.66$  &  $-.74$ ) and positively to  $F_{\text{ymax}}$  (N - BW) ( $r = .65$  -  $.61$ ). The Thr-Acc relations with GRF were not significant ( $p < 0.05$ ). Discussion The GRF-pattern differences reveal a non-consistent force production during the 3SS in the NP which possibly highlights a technical weakness in energy transfer to the throwing upper extremity (Oliver and Plummer, 2011). The overall dissimilar pattern of GRF-ThrP relations in EP and NP is possibly associated to the shortage of technical optimization in EP and underline the necessity to identify the differences between EP and NP so as to improve the training schedule (Wagner et al., 2010). **THE LUMBAR SPINE HAS AN INTRINSIC SHAPE THAT IS MAINTAINED THROUGHOUT FLEXION AND EXTENSION**

Pavlova, A.V.1, Meakin, J.R.2, Cooper, K.3, Barr, R.J.1, Aspden, R.M.1

*1 University of Aberdeen, 2 University of Exeter, 3 The Robert Gordon University*

Introduction: We have previously shown that the lumbar spine has an intrinsic shape which is maintained from sitting to standing and lying supine (1) and the magnitude of muscle forces to stabilize the spine depend on the intrinsic shape (2). The effect of intrinsic shape on movement patterns, especially during load-bearing, is unknown. This study investigates the change in spinal shape throughout a range of flexion and extension postures. Methods: Thirty healthy adults (15 males and 15 females) aged 20-52 years were recruited. Sagittal images of the lumbar spine were taken using a positional magnetic resonance imager (Fonar 0.6T Upright) with participants adopting six postures: seated extension, neutral standing, standing with 30°, 45°, 60° and full 'hanging' flexion. Active shape modelling (ASM) of the lumbar spine (L1 to S1) was used to analyse variations in spinal shape. ASM is a statistical model that uses principal components analysis to identify and quantify independent 'modes' of variation in shape. Results: ASM showed that 89.5% of the variation in the shape of the spine could be explained by the first two modes; describing the overall curvature or 'curviness' of the spine (M1, 85.3% of total variance) and the distribution of curvature or 'evenness' of the spine (M2, 4.2% of total variance). Within each of the first ten modes, scores were strongly and significantly correlated between all six postures ( $r = 0.4 - 0.97$ ,  $P < 0.05$ ), showing that intrinsic shape was maintained when changing postures. Mode scores were significantly different between postures ( $P < 0.001$ , first two modes) and pairwise comparisons revealed that the spine was most even in seated extension and had the most uneven curvature at 35° flexion ( $P < 0.05$ ). Discussion: We have extended our previous research and shown that the intrinsic shape of the lumbar spine is maintained throughout a wide range of postures from extension through to full flexion. This allows us to characterise and group individuals according to their spinal shape for analysis of motion with confidence that their intrinsic shape is maintained in the sagittal plane. Future research will use these results to investigate the effects of intrinsic spinal shape on movement and load-bearing activities. Knowledge of an individual's intrinsic posture could be important in sporting activities such as throwing and lifting. References: 1. Meakin JR, Gregory JS, Aspden RM, Smith FW, Gilbert FJ. **START-UP TIME AND GAIT SPEED OF OLDER ADULTS DURING LOADED WALKING**

Kong, P., Chua, Y.H.

*Nanyang Technological University*

Introduction The safety of older pedestrians in road crossing has received considerable attention in many countries. In the calculation of signal timings required for pedestrians to safely cross the road, both start-up time and gait speed need to be considered. This study investigated the start-up time and gait speed in older adults under loaded conditions that reflected their daily activities. Methods Thirty-two older adults (age = 69.4 (7.0) yrs) and 20 young controls (age = 23.1 (2.0) yrs) walked under four conditions: 1) unloaded, 2) pushing a stroller loaded with 10 kg, 3) pulling a shopping cart loaded with 15 kg, and 4) carrying two shopping bags each loaded with 2 kg. Upon a pedestrian crossing signal turned from red to green with an audible cue, participants walked at their comfortable pace for 10m. Start-up time was determined from video analysis, while gait speed measured by timing gates. Mixed model Analyses of Variance with repeated measures were used for statistical analyses. Results Start-up times were slower in the stroller and shopping cart conditions compared with walking unloaded and with shopping bags ( $P < .001$ ). Loading reduced walking speed, with the shopping cart being the slowest, followed by the stroller and then the shopping bags ( $P < .001$ ). Young controls reduced their speeds more substantially while handling the stroller/cart than older participants ( $P < .001$ ). Discussion Age and loading independently caused a compromise in start-up time and walking speed. Older adults were slower in starting up than their younger counter-parts, which is in agreement with a previous field study in the US (Knoblauch et al., 1996). While carrying shopping bags did not affect the start-up time, longer time was needed to initiate a stroller and a shopping cart. This is related to the extra friction that needs to be overcome to initiate motion due to the increase in load and surface contact area with the ground. In parallel with previous findings, our older participants walked slower than the young controls (e.g. Knoblauch et al., 1996; Langlois et al., 1997; Romero-Ortuno et al., 2010) but surprisingly they walked considerably faster than the older populations of similar age in other countries. A compromise in walking speed was observed in all loaded conditions. Young controls may lack experience in handling a stroller or shopping cart and therefore reduced their speed more substantially than older participants in these conditions. **EFFECTS OF STABILITY DEMAND ON THE POSTURAL CONTROL OF CHRONIC LOW BACK PAIN PATIENTS**

Garcia-Gil, M.1, Busquets, A.1, Angulo-Barroso, R.M.1

*1: INEFC-Barcelona, Sport Sciences Research Group, Institut Nacional d'Educació Física de Catalunya, Universitat de Barcelona, (Spain).*

Introduction Multiple studies have investigated upright postural control in patients with chronic low back pain (CLBP) by means of analyzing the center of pressure (CoP) excursion under different conditions. A recent review indicated that the majority of studies support worse balance control in CLBP (Rube et al, 2011). However, it seems that results depend on the type of variable measured and the conditions of assessment. We hypothesized that patients with CLBP, when placed under a higher stability demand, would demonstrate better CoP parameters than healthy adults. Methods Participants were 44 adults divided into 23 patients with CLBP (age mean 41.04, SD 11.04 years, 52.38% male) and 21 healthy adults (H) (age mean 34.75, SD 13.045 years, 56.52% male). Subjects were instructed to maintain quiet stance for 30 seconds in 2 different conditions: stable (SS) and instable surface (IS). Three trials were conducted in each condition. The center of pressure (CoP) was calculated with the use of a force platform (Kistler 9281EA) sampling at 500Hz and filtered with a cutoff frequency of 10Hz. The variables analyzed were path length (LEN), maximal displacement (MXD), mean velocity (MVe) and peak velocity

(PkVel) of the CoP in the anterior/posterior (AP) and medial/lateral (ML) directions. All variables were normalized to each individual base of support. 2 (groups) x 2 (conditions) ANOVAs with repeated measures on conditions were conducted for each variable. Results As expected, results confirmed worse postural control in IS than SS condition for all variables in both directions (all  $p < 0.01$ ). The IS condition yielded larger CoP displacements and velocities than the SS condition. Significant group effects were observed only for LEN in AP ( $p < 0.03$ ) and MXD in AP ( $p < 0.04$ ) in the SS condition. MXD in AP was significantly reduced in patients with CLBP (mean =0.106, SD=0.04) compared to H group (mean =0.077, SD=0.035). Similarly, LEN in AP was shorter in CLBP (mean =0.687, SD=0.27) than in H (mean =0.924, SD=0.42). Discussion Contrary to our hypothesis, these results suggest that subjects with CLBP may control balance at a similar level than healthy adults despite the increased stability demand. However, the shorter displacement of the CoP may be related to a decreased utilization of the hip strategy probably as a result of an increased activity of lumbo-pelvic muscles (Mok et al, 2004). Increased activity of the trunk muscles has been reported in subjects with CLBP, which may compromise the capacity to maintain equilibrium and limit trunk and hip motion. ### GAIT ANALYSIS BASED ON A SINGLE INERTIAL SENSOR: RELIABILITY OF GAIT PARAMETERS

Hamacher, D., Hamacher, D., Törpel, A., Schega, L.

*Otto-von-Guericke-Universität Magdeburg*

Introduction The advantages of gait analyses in patients with different disorders are diversified and well-known. The equipment, that is deemed the gold standard to conduct kinematic gait analyses, are camera-based motion tracking systems. However, the expense, the required time and the need for a laboratory makes these systems inefficient in clinical practice (Reininga et al., 2012). Gait analyses by inertial sensors, which are feasible in a clinical setting, offer the potential to minimize these costs. Therefore, the aim of this study was to examine the inter-day and intra-day reliability of gait parameters using a single inertial sensor. Methods Gait data of 19 healthy elderly subjects (5 male, 19 female, age:  $71 \pm 4$  years) were captured twice within the first day (m1) and also after seven days (m2). A wireless inertial motion tracker (MTw, Xsens) was fixed on the subjects' forefeet. Then, kinematic data was captured while the subjects were walking five times up and down a level hallway (distance 25 m) with their preferred walking speed. By means of a specifically designed algorithm, the inner-person averages of stride velocity (v), minimum foot clearance (mfc), stride length (sl), stance time and swing time as well as the corresponding measures of variability (coefficient of variation, CV) were calculated. Intra-day differences and inter-days differences were rated using the intraclass coefficient (ICC), the bias and the Limits of Agreement (LoA, Bland & Altman, 1986). Results Regarding average values, an ICC of 0.93-0.99 has been found for the intra-day data. Additionally, a low bias (e. g. sl: 0.001 m-0.002m, mfc: 0,000 m-0.001 m) and small LoA (e. g. sl: 0.026 m-0.047 m, mfc: 0.001 m-0.004 m) have been observed. In variability measures, the ICCs ranged from 0.600 to 0.958 (except for v in the m2 comparison, ICC: 0.484) with a bias of 0.01%-0.37% and a LoA of 0.36%-3.94%. Concerning inter-day reliability, analyses yielded ICCs ranging from 0.86 to 0.97 for average values and from 0.35-0.83 for CV. In particular, the comparison of the second gait data in m1 vs. m2 showed high ICCs for CV sl (0.83), CV mfc (0.82) and CV v (0.70) in variability measures. Discussion The results showed excellent reliability for all average parameters in both intra-day and inter-day reliability. While the intra-day reliability indicated good to excellent reliability of the variability measures, inter-day reliability ranges from poor for CV st to excellent for CV mfc and CV sl. Thus, to analyze average values as well as CV mfc and CV sl, the proposed system is suitable in a clinical setting. References Bland JM, Altman DG (1986). *Lancet*, 1, 307-310. ### JOINT COUPLING IN GAIT WITH ACTIVE SUPINATION OR PRONATION OF THE HINDFOOT

Vareka, I., Svoboda, Z., Janura, M.

*University Hospital Hradec Kralove; Palacky University Olomouc, Czech Republic*

Introduction The coupling of leg joints during walking was discussed widely in the past. There are various opinions - from the "Root biomechanics" [1] to denial of it [2]. This dispute inspired us to test the effect of active (hind)foot supination or pronation on gait kinematics of the ankle, knee and hip and to search for differences between natural and modified walking. Methods Thirty young healthy subjects completed trials of natural gait (NG), gait in active supination (SG) of the hindfoot and in active pronation (PG). The 3D kinematics (Vicon) and dynamic plantography (Footscan) were used to analyse the gait. The mean curves of joint motion were calculated for each gait type in the knee (sagittal, frontal, transversal) and hip (transversal). Differences among the gait types were estimated by a sign test at level  $p < 0.05$ . Results At the knee in SG, the flexion was reduced at FootFlat (FF) as well as during MidStance (MSI), Propulsion (PP) and Acceleration (AC). Varosity was stressed at the Heel Strike (HS), FF, MSt and valgosity was reduced during PP and AC but not at MidSwing (MSw). The external rotation was stressed at FF and PP. At the knee in PG, the flexion was stressed at HS and MSt but reduced during AC. The valgosity was stressed at HS, FF and MSt but not during PP. The internal rotation was stressed at HS, FF and MSt, at the start of Swing Phase and during MSw. Hip rotations in artificial gait are shifted to the external rotation in PG as well as in SG. Discussion The results are in agreement with "Root biomechanics" - the (hind)foot pronation is coupled with (relative) tibia internal rotation and (relative) knee flexion and the supination is coupled to (relative) tibia external rotation and relative knee extension, when the leg is working under load, which means in a closed chain. The differences between "artificial" and natural gait during the swing phase, which means in an open chain, are results of muscle synergy, but the central control must respect the (joint) anatomy as well as biomechanical principles. The movements of the hip and pelvis are more complicated due to pronounced influence of the opposite leg and trunk motion. References 1. Michaud TC. (1997). *Foot Orthoses and Other Form of Conservative Foot Care*, Thomas C. Michaud, Newton, Massachusetts. 2. Kirby KA. (2009). *Podiatry Today*, 31: 32-39.

### HOW DO NORMAL PEOPLE WALK: INVESTIGATING NORMAL GAIT USING A FORCE APPLIED TREADMILL ON FLAT SURFACES

Jessel, A., Harris, S., Aqil, A., Manning, V., Gibbs, V., Andrews, B., Cobb, J.

*Imperial College London*

Introduction Normal variation of the gait cycle was investigated using a force applied treadmill. Similar assessments have been previously conducted but with fewer patients and using alternative methods. The use of a force applied treadmill has been recognised to be appropriate in the assessment of physiological gait. By use of 3D software, graphical demonstration of the gait cycle at variable speeds can be observed. The left and right strides were measured and assessed on a comparative basis. The aim therefore, is to highlight the

consistent symmetry of the gait cycle at increasing speeds for a large group of asymptomatic subjects. Methods 74 asymptomatic subjects were required to walk on a force applied treadmill enabling digital measurements to be recorded in order to plot individual gait curves. Ground reaction forces (GRF) were recorded at 100HZ over 10 seconds at 4km/hr, and then at increments of 0.5 km/hr until the subjects were comfortable with a top walking speed, all at a flat (0%) gradient. The aim was to reach a top speed without running, pain or discomfort. Walking speed was normalised to height using a formula suggested by Hof – the square root of the Froude number. A normalised speed of less than 8km/hr was considered the maximum. The raw data was extrapolated and plotted against % stride on the X axis, normalised force on the Y axis and Hof normalised speed on the Z axis. A software programme written in C++ enabled us to manipulate the data to demonstrate the actions of the feet at increasing speeds. Results The average gait curves for asymptomatic individuals walking on a flat surface have been represented graphically in a 3D manner. The use of a force applied treadmill accurately reflects forces experienced when walking on flat surfaces. There is a near identical representation between left and right strides throughout the gait cycle. This symmetry is maintained through increasing speeds, despite an amplitude increase of the overall curve. However, a difference during the push off phase between both feet is evident. Conclusions This is the first instance which exhibits gait symmetry of large numbers of asymptomatic individuals at high walking speeds. The graphs generated have been able to provide an expectant set of data when assessing gait. Its true application can be seen by allowing us to compare function of this normal gait to symptomatic patients with osteoarthritis, for example, in the future. ### THE INFLUENCE OF GAIT VELOCITY, GENDER AND AGE ON PLANTAR PRESSURE OF SENIORS UNDER DT CONDITIONS

Wollesen, B., Mattes, K.

*University of Hamburg*

Introduction In a study, which was conducted to identify falls risks of older adults, the dual-task (DT) paradigm was used during a treadmill walk. Biomechanical gait variables like plantar pressure (pp) should be used to explain gait variability under these DT conditions. These test situations need a fixed gait velocity (v) to be standardized, which might influence gait behavior. In addition there might be other confounding factors like gender and age on the plantar pressure. Therefore, this preliminary study examined the effects of gait velocity (v), gender and age on pp to identify the amount of confounding effects on the internal validity. Methods N=58 seniors (n=41 women: 72.3 ± 6.3 y, 162.6 ± 17.2 cm, 71 ± 21.7 kg; n=17 men: 72.0 ± 4.7 y, 172.7 ± 24.9 cm, 81.7 ± 8.4 kg) were included. They were divided into three age groups (A1: n=8, 60.5 ± 3.5 y; A2: n=38, 70.0 ± 2.7 y; A3: n= 13, 78.5 ± 3.1 y). The pP (maximum pressure (px)) and gait kinematics (stride length (s), cadence (f) and stride time (t)) for the whole foot in three sections (heel (h), midfoot (mf) and forefoot (ff)) were analyzed walking barefooted on the treadmill (h/p/cosmos, FDM-T, 100Hz) in two different walking speeds (v= 3.5 and 4.5km/h). An ANOVA with repeated measures and additional determination of effect sizes ( $\eta^2$ ) as well as a partial correlation analyses (control variable: body mass) was done using SPSS 16. Results An increase of v was accompanied with a significant raise of s with a large effect size ( $p = .00$ ;  $\eta^2 = .82$ ) and an increased f ( $p = .02$ ;  $\eta^2 = .09$ ). Maximum plantar pressure px raised in all three observed foot sections (pxh, pxmf, pxff;  $p = .00$ ,  $\eta^2 = .12 - .49$ ). The age groups differed for s and f significantly with a small effect size ( $p = .04 - .05$ ,  $\eta^2 = .11$ ); the steps differed in their stride time structure. The pp distribution was only significant for pxff ( $p = .03$ ;  $\eta^2 = .13$ ). The heavier men walked under comparable f with increased s and increased vertical forces ( $p = .00 - .02$ ;  $\eta^2 = .11 - .22$ ) without significant changes in px. When the body mass was partialled out there was a positive correlation between pxff and age ( $r = .34^*$ ). Discussion The results confirmed findings by Chung & Wang (2011). Most values of pp were determined by gait velocity but not influenced by interactions of age and gender. Moreover the body mass has an important impact on plantar pressure. With rising age a larger s and f is needed to manage the same gait velocity. These changes are accompanied with an increased maximum of the plantar pressure. Future studies on plantar pressure should be arranged the fixed gait velocity in percentage of the individual preferred speed (Chung & Wang, 2011) as well as the analysis of the gait velocity in relation to individuals body mass to control confounding factors on the internal validity. In addition, for DT walking the differences between preferred and fixed gait speed have to be controlled to assign the DT effects.

### COMPARISON OF GAIT KINEMATICS OF ELDERLY PRACTITIONERS OF EXERCISE, NOT PRACTICING AND NOT-PRACTICING OBESE

Dorst, L.M.1, Hetkowsky, T.3, Santos, C.H.N.3, Marafon, R.C.3, Ferreira, C.R.3, Dorst, D.G.B.2, Roman, E.P.2, Ribeiro, R.R.2

1:Faculty Assis Gurgacz (Cascavel, Brazil) and Secretary of State for Sport (Curitiba, Brazil) 2:Faculty Assis Gurgacz and UNICAMP (Campinas, Brazil) 3:Faculty Assis Gurgacz

Introduction It is estimated that 85% of the population over age 65 complain of imbalance, instability and falls that come from the loss of mass and strength leading to decreased ability to promote rapid joint torque necessary for activities of daily living (Pedrinelli et al., 2009). The objective was to analyze the gait kinematics of elderly-exercising, non-practicing and non-practicing obese. Methods Sample, 23 seniors, were divided into group A, 8 elderly not practicing physical exercises, group B, 6 elderly practitioners and group C, 9 elderly and obese non-practicing. We used the International Physical Activity Questionnaire version/short. BMI was calculated using height and weight. The kinematics gait was measured by two-dimensional videography (60 Hz), temporal variables through the double support (IAD/2AD), single support (AS/RIGHT – AS/LEFT), step (TP/RIGHT – TP/LEFT), balance (FB/RIGHT – FB/LEFT), and total cycle (TPASS), and the spatial variables, stride length, cycle and walking speed. The SPSS stored the data. The test of normality Shapiro Wilk identified the variables were parametric. One way ANOVA comparing variables between groups and Post Hoc Bonferroni test showed differences between groups. The Student T-test (5%) groups compared with the adult gait. Results There are significant differences in gait 2AD time between groups B and C, duration of AS/RIGHT and time FB/LEFT between groups A and C. In comparison with adult gait (Rose and Gamble, 1998) there are significant differences, with higher values for time 1 and 2AD and lower values for AS Right/Left and FB Right/Left for groups A and C. Group B showed superior value for time to IAD and lower for AS Right and FB Left. Discussion There is a significant difference between the groups, especially between group C and others. In the groups A and B there is no significant difference, that due to the similarity in BMI. Compared with the march of the march groups of adults, differences were found for all groups, but group C, a greater number of variables, justifiable, because it has greater mass, loss of strength and power, which generate uncertainty in the realization of march, adopting it, compensatory mechanisms to produce walking safer and more stable. ## DIFFERENCES OF STRIDE CHARACTERISTICS IN BAREFOOT VERSUS SHOD SPRINTING AND ITS RELATIONSHIP WITH REACTIVE LEG STRENGTH IN CHILDREN

Hasegawa, H.1, Hasegawa, A.2, Mochizuki, K.2, Nakamura, R.2, Nishiyama, K.2

1:Sports Science Ryukoku University, 2: S&C Sports Science Technology

**Introduction** There is a hypothesis that modern sports shoes can contribute to weak feet during childhood (Lieberman, 2012). However, there are few studies to investigate the effects of the shoes on the physical abilities in this generation. The aim of this study was to compare the stride characteristics between barefoot and shod sprinting and its relationship with lower leg strength in children. **Methods** 546 healthy children (367 boys and 179 girls) aged 4 -15 yrs performed 10m sprints in barefoot and with shoes. Sprint time was measured by a timing gate. Contact time (Tc), flight time (Tf), step-length (SL), step-frequency (SF) and step-velocity (Vstep) were measured by photoelectric cells arranged 0.003 m above the floor with 0.01 m interval by 1000 Hz sampling frequency. 152 children out of all subjects were filmed with 600 fps to identify foot strike pattern. Repeated rebound jump (RJ) and counter movement jump (CMJ) were tested with three-axial accelerometer to measure jump height (JH-R), contact time (Tc-R), reactive strength (RS), and stiffness (Stiff) for RJ, and jump height (JH-C), power (Pw), force (F), and velocity (V) for CMJ. Paired t-test was used to compare the sprints in barefoot and shod. Comparison of values obtained in the subjects group who ran faster in barefoot (BF group) and in shod (SH group) was performed using independent samples t-test. **Results** Sprint time in barefoot was shorter than in shoes. Tc was shorter in barefoot than shod sprinting. Children adopted shorter SL in barefoot sprinting than in shoes. SF was higher in sprinting barefoot than in shoes. Vstep at the first step was slower in barefoot than in shoes, however, at the last step, Vstep was faster in barefoot than in shoes sprinting. Higher percentage of rear-foot strike (RFS) was observed than mid-foot strike (MFS) and fore-foot strike (FFS) in shod sprinting. In contrast, RFS decreased, and MFS and FFS increased in barefoot sprinting. BF group used shorter Tc, longer SL, and higher SF than SH group in barefoot sprinting. BF group showed higher RS, Stiff, JH-C, and V than SH group. **Discussion** These results confirm previous report that adolescents who grew up wearing shoes mostly used RFS when shod running, but adopt FFS or MFS when barefoot running (Lieberman et al., 2010). Increased percentage of FFS and MFS in barefoot sprinting appears to induce more elasticity produced in arch and Achilles tendon, which affects positively to sprint performance than shod sprinting in children. **References** Lieberman D.E., Venkadesan M., and Werbel W.A. et al. (2010), *Nature*, 463, 531-535. Lieberman D.E. (2012), *Exerc. Sport Sci. Rev.*, 40 (2), 63-72.

## EFFECT OF CUSTOM-MADE AND PREFABRICATED INSOLES ON PLANTAR PRESSURE AND KINEMATIC PARAMETERS DURING RUNNING

Lucas-Cuevas, A.G., Pérez-Soriano, P., Llana-Belloch, S., Macián, C., García-Pérez, J.A.

University of Valencia

**Introduction** Running involves contacting the ground 600 times per kilometer (Guo et al., 2006). Even though those impact forces are below the injury threshold, the fatigue of the athlete may reduce the ability of the biological structures to deal with that accumulative loading. Orthoses have been proved to effectively reduce impact forces (Creaby et al., 2011). However, there is a controversy whether custom-made insoles are more effective in reducing impact forces compared to prefabricated insoles. Therefore, this study aimed to compare the effect of different orthoses on kinematic and plantar pressure parameters during running. **Methods** Forty recreational runners (21 men, 19 women) participated in the study. Kinematic (contact time and stride rate) and plantar pressure (mean peak pressure [Px] and Pressure-Time Integral [PTI]) were analysed under three insole conditions (control [CI], prefabricated [PI], custom-made [CMI]) in 9 foot areas at 12km/h before and after a 15-min fatigue run with Biofoot@IBV/Valencia instrumented insoles. **Results** No difference in the plantar pressure and kinematic parameters analysed was observed due to the fatigue state. However, regarding the insole condition, CMI decreased Px under the hallux by 45%, and by 31% and 54% under the medial and lateral heel compared to CI. PI also led to reductions of Px under the toes (35%), lateral (31%) and medial (31%) arch compared to CI. When comparing both study insoles, CMI decreased Px under the medial heel by 31% and PTI under the lateral heel by 53% compared to PI. Finally, the insole conditions did not modify any of the kinematic parameters measured. **Discussion** The use of orthoses (both custom-made and prefabricated) decreased plantar loading under different foot areas (hallux, toes, foot arch and heel) compared to the control condition. In long distance races, where the accumulative effect of the impact forces can be harmful for the body structures, even a slight reduction in plantar pressure at each foot strike may suppose a significant decrease in the overall stress experienced by the foot and the observed loading reduction may involve a better pressure distribution without modifying the individual kinematic running pattern and lead to a lower injury occurrence in long distance races. **References** Guo LY, Su FC, Yang CH, Wang SH, Chang WL, Lin HT. (2006). Effects of speed and incline on lower extremity kinematics during treadmill jogging in health subjects. *Biomedical Engineering*, 18:73-79. Creaby MW, May K, Bennell KL. (2011). ## SUBJECTIVE MONITORING TOOL FOR LOWER LIMB COMFORT AMONG HABITUALLY SHOD RUNNERS DURING A MINIMALIST SHOE TRANSITION PROGRAMME

Venter, R.E., Schutte, K.

Stellenbosch University

**Introduction** Controversy exists around minimalist shoes (MS) which have been suggested as a means to either reduce, or potential to enhance risk of running-related injury. Monitoring of the initial transition period may be essential to help support the former notion (Rothschild, 2012). While previously applied to football players, the Lower Limb Comfort Index (LLCI) is a subjective scale that has been developed as a tool for clinicians and athletes to monitor the wellbeing of the lower limb at multiple anatomical areas (Kinchington et al., 2010). Identifying areas with the most potential for discomfort could help approximate mileage increments and predict and prevent MS running-related injury from occurring. Thus, the primary aim of this study was to determine changes in LLCI in runners undergoing a supervised MS transition programme. **Methods** Ten experienced shod male runners underwent a supervised seven-week MS (Vibram Fivefingers) transition programme. The MS training consisted of progressive increases in running mileage which started at ~ 11% to 22%, and ended at ~ 52% - 132% of the participants' usual shod training distance, recorded using global positioning system. No instruction was provided on running technique. The LLCI was used to record perceived lower limb comfort immediately prior to every training session. Each bilateral anatomical area (foot, ankle, calf-Achilles, shin and knee), was subjectively scored on a scale from 0-6 (0 = extreme discomfort; 6 = extreme comfort). **Results** T-tests showed that shin area had statistical and practical improvement in perceived comfort from start to end of the transition period (P = 0.04; Effect size (ES) = 0.96). The calf-Achilles (CA) area showed a similar trend, but only improved practically (P = 0.07; ES = 0.96). The rest of the LLCI items (feet, ankles, knees) had negligible to small practical improvements in perceived comfort (P >

0.05; ES = 0.1 - 0.17). ANOVA's showed that the calf-Achilles area had significantly more discomfort in comparison to all other anatomical areas ( $P < 0.05$ ) throughout the intervention. Discussion The CA area was found to have a significantly lower perceived comfort rating over the entire intervention period in comparison to all other LLCI areas. Runners should be aware of this significant CA discomfort during the MS transition, but should also acknowledge that CA comfort may improve with more MS experience. This could indicate positive adaptation in response to the new mechanical loads. Other areas of the LLCI (foot, ankle, and knee) may be less affected by MS training, possibly due to a redistribution of loads or kinematic adaptations. ### THE EFFECT ON BAREFOOT STANDING BALANCE TEST OF WEARING MBT AFTER 8 WEEKS TRAINING

Ying Fang, L., Chi Huang, H.

*Hsin Sheng College of Medical Care and Management*

**Introduction** The "bare foot concept" is a new fashion of shoes. More and more concepts tend health, body shape, shock-absorbing and increase exercise performance. The Masai barefoot technology (MBT) was designed to improve walking balance with its unstable soles. The unstable soles could change the posture control, muscle activation and balance just like "wobble board training". Shoes with unstable soles could provide more balance training effect in life via walking weekdays. MBT is a new kind of shoes in Asia in Taiwan, so the purpose of our study is to investigate the effect of standing balance during 8 weeks wearing with MBT shoes. **Methods** There were 18 females volunteers in our study. All of them never have any experience with MBT, Reebok Easy-Tone and Sketchers Shape-up shoes. The participants have to do balance test before wearing MBT, and back to do the same test through 8 weeks. Every participant needed to complete tests in a Kistler force plate: both feet closed-eyes 10 seconds and single leg closed-eyes standing as possible as they can, the most time is 10 seconds. All the data would be collected and calculated as posture sway displacement, sway velocity, sway area and one-leg standing time. After pretest, they wear MBT 8 hours per day, 5 days per week at least. **Results** The both feet closed-eyes standing showed some significant differences in A-P sway (pre 2.30 cm vs. post 1.80 cm), sway velocity (pre 0.045 cm/s vs. post 0.036 cm/s) and sway areas (pre 6.41 cm<sup>2</sup> vs. post 1.58 cm<sup>2</sup>) before and after 8-week wearing MBT. But M-L sway (pre 3.09 cm vs. post 1.16 cm) only showed decline, on significant differences. The single leg closed-eyes standing time showed some significant differences in dominant leg and non-dominant leg before and after 8 weeks. Both were standing longer than pretest (dominant: 6.25 seconds vs. 8.22 seconds; non-dominant: 7.32 seconds vs. 8.91 seconds). **Discussion** This study participants continue every day through the 8 weeks wearing unstable shoes training, MBT shoes significant progress in the post-test results of most value dropped significantly improve the long time wearing MBT shoes can really affect bare foot balance control ability, special curved soles design can actually improve the balance standing capacity, also need a long time to adapt. The sway velocity after 8 weeks training, bare foot test significantly slower than the pre-test results. That showed participants in the eyes closed case gradually stabilized control the degree of shaking of the torso. The single leg standing test showed there were more improve in non-dominant leg. That would because it was more difficult to maintain balance in non-dominant, cause to more training effect. But the dominant legs standing time also have significant extension after 8 weeks. This results Nigg et al. (2006) findings consistent through the 12 weeks of training can effectively enhance the balance standing time; increase of the time standing on one foot to improve balance control ability, are one of the important methods to reduce the risk of falls.

### EVALUATION OF RISK FACTORS FOR ACL INJURY IN HIGH LEVEL MALE FOOTBALL PLAYERS

Ferrer-Roca, V.1, Linde, X.2, Gasol, X.2, Domínguez-Castrillo, O.1,3, Turmo, A.1,2

*1: GRSANE, Centre d'alt rendiment (CARI); 2: RCD Espanyol; 3: INEFC Barcelona, UB;*

**Introduction** Anterior Cruciate Ligament (ACL) injury is one of the most serious time-loss injuries in football. Preventing knee injuries is an important goal, and to accomplish that, the specific intrinsic risk factors must be identified. The purpose of the present study is to evaluate dynamic knee valgus and lower limb strength imbalance in high level football players during the preseason. **Methods** Thirty-five high level football players (24.3 ± 3.8 years; 75.2 ± 5.4 kg; 180.02 ± 3.89 cm) were tested during the first week of the preseason. All players signed and informed consent form prior to participation. Three vertical drop jumps were captured by a video movement analysis system (Peak Motus, Version 9.2.0; USA) with 3 digital cameras at 150Hz and two force platform (Kistler Instrument 9281B; Switzerland) at 900Hz. Frontal plane knee angle, knee flexion angle and vertical force were measured during the landing. Relative lower limb imbalance was calculated: (stronger - weaker) / stronger × 100. Intraclass correlation coefficient (ICC) was determined to assess test-retest reliability and a level of 0.05 is considered statistically significant. **Results** The ICC1.1 values were 0.92 for the knee flexion angle, 0.68 for the knee frontal angle and 0.82 for both eccentric and concentric impulse. There were significant differences between the stronger and weaker legs in eccentric impulse (32.4 Ns; CI 95% 22.9 – 41.8 Ns  $p < 0.05$ ) and concentric impulse (32.4 Ns; CI 95% 22.9 – 41.8 Ns  $p < 0.05$ ). Additionally, 31.4% of the subjects obtained a lower limb strength imbalance higher than 15%. During the vertical drop jump 24.2% of the players landed with a valgus knee alignment. Furthermore, 14.2% of the subjects obtained a frontal plane knee valgus angle higher than 20°. **Discussion** Findings of the present study are particularly significant because valgus loading appears to be an important component of the ACL injury. In the "return to sport" process the greatest acceptable imbalance should be about 15%. Less than a 10% deficit implies to normal knee function (Kvist, 2004). Furthermore, an increased in valgus knee motion at the knee suggests altered muscular control of the lower extremity in the frontal plane (ligament dominance) (Hewett et al; 2010). Results of the present study suggested that the vertical drop jump test is a good tool to identify ACL injury intrinsic risk factors in high level male football players in order to introduce the necessary preventive measures. #### EVALUATION OF EXERCISE PROGRAM: HIGH INTERVAL AEROBIC TRAINING COMBINED WITH SMALL SIDED GAMES

Rodríguez-Fernández, A.I, Sánchez-Sánchez, J.2, Rodríguez-Marroyo, J.A.1, Villa, J.G.1

1 *Institute of Biomedicine, University of León.* 2 *Pontifical University of Salamanca.*

**INTRODUCTION** The Small sided games (SSG) reproduce what happens in a soccer game, are tasks based on the training through the game, altering the game's features, areas, spaces, and adapted rules involving fewer players (Hill-Haas et al., 2011). The aim of this study is to assess changes in performance after an exercise program for 8 weeks consisting of a combination of high-intensity aerobic training and SSG in young soccer players. **METHODS** The young soccer players were divided in three groups. Control group (GC) (n=10), Specific Training (GEl) (training only with the ball) (n=9) and Intervention (GASG) (n=9): 2x4' 85% HRmax + 2x4' SSG 85% HRmax with 3 min recovery, performed twice per week for 8 weeks. After 24 h without exercise realized an: incremental running test in laboratory (start at 8 km/h with increased 1 km/h every 1 min so that exhaustion) with electrocardiograph, on a motorized treadmill (Cosmos® Pulsar 4.0), expired gases were analyzed (Medisoft®). 48 hours after RSA test of 8x30 m sprints with 25 s of active recovery, analyzing: total time (TT), mean time (MT) and best time (BT) and 2 index of fatigue: decrement (%DEC), and differences between best and worst sprint (CHANGE). 48 h after a Maximal Multistage 20-m Shuttle Run Test **RESULTS** After intervention GASG improve significantly your VO<sub>2</sub>max in 7.4% (p=0.012) from 52.37(±2.38) to 56.25(±2.87) speed anaerobic threshold in 15.8% (p=0.006) from 11.87(±0.99) to 13.75(±1.16) km/h and improve significantly TT (3.60%), MT (3.13%) and TM (3.60%). GEl group improve significantly TT (2.05%), MT (2%) and TM (2%). The GC did not obtain significant improvements in the analyzed values. VO<sub>2</sub>max was significantly correlated between lab test and field test was (r=0.554 p=0.005). **DISCUSSION** In this study, group GASG improvements obtained similar to those of other studies (Impellizzeri et al., 2006) which compared the general and specific training. The improvements were higher than other studies (Ferrari Bravo et al., 2008) using a similar protocol but without the ball. Furthermore GASG and GEl improvement significantly in absolute values in RSA test (MT, TT, and TM). Several studies show the relationship between aerobic capacity of subjects and test performance in RSA (Pyne et al., 2008). Therefore the SSG combination of high-intensity aerobic training has proven useful for increasing performance in soccer, because get similar improvements to other less specific protocols. **REFERENCES** Ferrari Bravo, D. et al. (2008). *Int J Sports Med*, 29(8), 668-674. Hill-Haas, S. et al. (2011). *Sports Med*, 41(3), 199-220. Impellizzeri, F. M. et al. (2006). *Int J Sports Med*, 27(6), 483-492. Pyne, D. B., et al. #### THE DIAGNOSIS IN COMBAT SPORTS - THE IDENTIFICATION OF THE BODY WEIGHT PLACEMENT IN AN EXPERIMENTAL SITUATION

Lopes, H., Fernando, C., Prudente, J., Vicente, A.

*University of Madeira, University of Beira Interior, CIDESD*

**Introduction** The relative position of the center of mass (CM) to the support base (SB) is critical for performance in combat sports. The coach's ability to recognize the placement of the CM without constant laboratory support is of great importance in terms of diagnosis in ecological context when aiming to optimize a personalized learning process (Lopes et al., 2012). The objective of this study is to identify the ability to diagnose the placement of the body weight by Sports Science university students with different levels of knowledge. **Methods** We have created an experimental situation where 46 Sport Science university students (mean age 23.7 years, 23 from 2nd year and 23 from 3rd year), had to look at 20 images (slides with 5 seconds interval between them), and identify the percentage by weight which was placed in the left of each subject who appeared on the image (20%, 40%, 60%, 80%). The images used were the result of an experimental situation which we've requested that each subject should put a previously defined percentage of their weight on a dynamometer (20%, 40%, 60%, 80%). In the 20 selected images each of the four weight percentages were performed five times. **Results** The success rate of the students was of 38.7% (38.1% 2nd year and 39.3% 3rd year), and from the four possible weight percentages participants had greater success identifying the placement of 80% of the weight (total of 40.3%, 40% 2nd year and 40.6% 3rd year) and 20% (total of 39.8% being 39.1% in the 2nd year and 40.5% in the 3rd year). There were no significant differences between students of the 2nd and 3rd years, or between different percentages of weight placements. **Discussion** Whereas the probability of properly prescription increases with the better the diagnosis, the results show that the ability to diagnose the placing of body weight in the situation analyzed was not very high (38.7%). The ability to use a variable with the importance of the CM / SB without laboratory support can however be trained so that it can promote optimization of personalization in the learning process. **References** Lopes, H., Fernando, C., Vicente, A., Simões, J., Prudente, J. (2012). *Edição Coisas de Ler*. pp. 83-92.

#### MONITORING THE EFFECT OF METHODOLOGICAL AND DIDACTICAL ACTION ON IMPROVING THE BACKSTROKE SWIMMING TECHNIQUE AT STUDENTS' EDUCATION

Götz, J.K., Faßbender, J., Sperling, W., Hartmann, U.

*Universität Leipzig, Faculty of Sport Science*

**Introduction** The elementary swimming education of sports students at the University of Leipzig is based on improving the swimming techniques. Through methodical series the propulsive effective use of body surfaces and the coordination of partial movements are pursued to a total movement of backstroke. This leads in particular to a streamlined body position. **Aim** The aim of this study was to evaluate the improvement of sports students swimming backstroke under the conditions of implementation of educational content within one semester. **Methods** In this study took part 17 students with different technique levels. At test week 1 (T1, at the beginning of the semester), test week 2 (T2, after the methodical series to learn and improve the backstroke technique) and at test week 3 (T3, at the end of the semester), it was measured the swimming time of 50 m backstroke at maximal speed (t50max) and the swimming times of 4x50 m backstroke at moderate intensity (t4x50) with a passive break of one minute. Also maximal lactate values, the heart rate and the individual technique levels were determined after 4x50 m backstroke. The subjective quality rating of the swimming technique was based on a

point system. Results After 4x50 m backstroke at self-selected moderate intensity at T1 the maximal lactate was  $11.2 \pm 3.5$  mmol/l and the heart rate was  $155 \pm 22$  beats/min. The heart rate was similar at T1, T2 and T3. Significant improvement occurred for t4x50 paralleled T1 to T3 with an absolute advance of  $3.69 \pm 4.30$  s. The maximal lactate level after 4x50 m backstroke in moderate velocity was significantly lower at T3 compared to T1 with an absolute reduction of  $2.55 \pm 3.71$  mmol/l. The t50max decreased significantly from T1 to T3 with a difference of  $4.61 \pm 4.74$  s. The subjective quality rating of the backstroke technique showed a progress at T3. Conclusion After one semester of elementary swimming education the improvement of the backstroke technique was not only shown by better subjective rating but also by significant reduction in t50max and in t4x50 and in a significant decrease of maximal lactate values after 4x50 m backstroke.

## RELATIONSHIP BETWEEN BODY MASS INDEX AND PHYSICAL FITNESS IN YOUNG SWIMMERS

Kostoulas, I., Nikolaidis, P.T.

*Hellenic Army Academy*

**Introduction** While the relationship between body mass index (BMI) and physical fitness in the general population has been studied extensively since the obesity epidemic began, there is still little information about this relationship in sport populations. Therefore, the aim of this study was to examine the association between BMI with physical fitness components in young swimmers. **Methods** Twenty-nine female (age  $13.8 \pm 0.9$  yr, weight  $52.1 \pm 8.3$  kg, height  $1.59 \pm 0.08$  m) and 36 male competitive swimmers ( $14.1 \pm 1.1$  yr,  $58.4 \text{ kg} \pm 12.2$  kg,  $1.67 \pm 0.10$  m) were examined for body composition and physique, and they performed the physical working capacity in heart rate 170 bpm, sit-and-reach, handgrip and Wingate anaerobic test (WAnT). T-test was used to examine sex differences. **Results** Partial correlations adjusted for the effect of age were computed between BMI and physical fitness components. Results The female swimmers were lighter ( $-6.3$  kg (-11.6;-1.0), mean difference (95% CI)), shorter ( $-0.08$  m (-0.12;-0.03)), more endomorph ( $1.3$  (0.6;2.1)), with higher BF (5.6% (3.2;7.9)) and lower fat free mass ( $-8.1$  kg (-11.8;-4.5)), had higher flexibility (6.9 cm (3.6;10.3)), lower handgrip strength ( $-0.18$  kg.kg<sup>-1</sup> weight (-0.28;-0.09)), lower PWC170 in both arms ( $-0.43$  W.kg<sup>-1</sup> (-0.65;-0.21)) and legs ( $-0.53$  W.kg<sup>-1</sup> (-0.86;-0.19)), and lower Ppeak ( $-1.62$  W.kg<sup>-1</sup> (-2.14;1.09)) and Pmean ( $-1.48$  W.kg<sup>-1</sup> (-2.03;-0.93)) than their male counterparts. No sex difference was found with regard to BMI ( $20.6 \pm 2.3$  vs.  $20.8 \pm 2.9$  kg.m<sup>-2</sup>). BMI was correlated with handgrip strength in female and male swimmers ( $r = -0.41$ ,  $p = 0.035$ ;  $r = -0.47$ ,  $p = 0.006$ , respectively), while in the latter group, it was also correlated with mean power ( $r = -0.49$ ,  $p = 0.016$ ) and fatigue index of WAnT ( $r = 0.57$ ,  $p = 0.004$ ). BMI was correlated with percentage of body fat in female and male swimmers ( $r = 0.70$ ;  $r = 0.72$ ,  $p < 0.001$ , respectively), fat mass ( $r = 0.78$ ;  $r = 0.88$ ;  $p < 0.001$ ) and fat-free mass ( $r = 0.52$ ;  $r = 0.72$ ,  $p < 0.001$ ). BMI was correlated with endomorphy ( $r = 0.68$ ;  $r = 0.77$ ,  $p < 0.001$ ), mesomorphy ( $r = 0.83$ ;  $r = 0.69$ ,  $p < 0.001$ ) and ectomorphy ( $r = -0.93$ ;  $r = -0.92$ ,  $p < 0.001$ ). **Conclusions** Based on these findings, it is concluded that BMI is associated with both physique and physical fitness components, and these associations are sex-dependent. Although the abovementioned significant correlations do not imply causality between BMI and physical fitness, it is reasonable to support that a higher BMI is associated with lower particular components of physical fitness. Consequently, exercise and nutrition interventions should also focus on achieving an optimal BMI.

## RUNNING ECONOMY AND LEG ANTHROPOMETRY OF ELITE KENYAN MIDDLE- AND LONG-DISTANCE RUNNERS

Mooses, M.1, Jürimäe, J.1, Wondimu, D.2,3,4, Pitsiladis, P.2,3,4

*1: University of Tartu, 2: Addis Ababa University, 3: University of Glasgow, 4: Moi University*

**Introduction** Kenyan middle- (MD) and long-distance (LD) runners have dominated distance running for more than 40 years. Previously this dominance has been attributed to superior running economy which has been proposed to be result of slim body shape. However, middle- and long-distance runners use different training volumes and intensities which lead to different adaptation in aerobic performance parameters and also in running economy. The aim of this study was to find whether leg anthropometry explains differences in running economy between top performance level middle- and long-distance runners. **Methods** VO<sub>2</sub>max and running economy were determined on an outdoor running track in 13 Kenyan MD ( $24 \pm 5$  yrs;  $60.1 \pm 5.6$  kg; IAAF score:  $988 \pm 62$  p) and 19 LD ( $26 \pm 5$  yrs;  $54.0 \pm 4.4$  kg; IAAF score:  $997 \pm 88$  p) runners using a Metamax 3B portable gas analyser. Kenyan athletes' testing was conducted in Eldoret, Kenya (altitude 2200 m a.s.l.). In total 4 girths and 5 lengths (Centurion Kit, Rosscraft, Canada) were recorded according to the protocol recommended by the International Society for Advancement of Kinanthropometry. The Achilles tendon moment arm was determined as described elsewhere (Scholz et al., 2008). **Results** Despite similar VO<sub>2</sub>max in Kenyan MD and LD runners ( $69.2 \pm 5.4$  vs.  $66.1 \pm 5.0$  ml/kg/min), a superior running economy at 16 km/h was found in LD runners compared to Kenyan MD runners ( $55.1 \pm 2.4$  vs.  $58.1 \pm 2.5$  ml/kg/min,  $p < 0.01$ ). In spite of similar body height, middle distance runners have significantly higher body mass and BMI ( $19.8 \pm 1.3$  vs.  $18.4 \pm 1.1$ ). From anthropometrical indices, long-distance runners presented significantly smaller thigh ( $48.2 \pm 2.5$  vs.  $50.6 \pm 2.2$  cm) mid-thigh ( $46.0 \pm 2.1$  vs.  $48.8 \pm 1.4$  cm), calf ( $32.5 \pm 2.8$  vs.  $35.0 \pm 1.8$  cm) and ankle ( $19.6 \pm 1.1$  vs.  $21.2 \pm 1.3$  cm) circumferences and shorter achilles tendon moment of arm ( $3.83 \pm 0.36$  vs.  $4.27 \pm 0.39$  cm) compared with middle-distance runners. Linear regression did not reveal important relation between running economy and leg anthropometry nor achilles moment arm in neither of the groups. **Discussion** Present findings in general support the notion of a better running economy in long-distance runners compared with middle-distance runners. However differences in leg anthropometry and body mass do not explain differences in elite level Kenyan middle- and long-distance runners economy. **References** Scholz M, Boobert M, van Soest A, Clark J, van Heerden J (2008). Running biomechanics: shorter heels, better economy. *J Exp Biol* 211, 3266-3271.

## THE DECISION MAKING COSTS: EFFECTS IN THE HEART RATE

Fernando, C., Vicente, A., Prudente, J., Lopes, H.

*University of Madeira, University of Beira Interior, CIDESD*

**Introduction** Walking in an irregular route that involves permanent adaptations to the terrain requires constant adjustments of the sportsman gait. These adjustments involve a process of collecting information, its interpretation and consequent assembly of the appropriate strategies to the desired skill, i.e. a decision making. There are several studies on the variation of energy cost depending on the terrain slope, the load carried, walking speed, etc., nevertheless the effect of the need to adapt, and thus the cost of the decision-making, is not well known. With this study we aim to understand what are the effects on the heart rate (HR) when a person faces a situation where there is continuous need to decide where to put the feet on the terrain to progress. **Methods** We've used a treadmill (BH Impulse) where we've put several spots along the mat to constrain the person's gait. Each subject performed two situations. A first situation (1) where walked on the treadmill for 10 minutes (min.) without any restriction, except the variation of the treadmill speed every 2 min. as follows: 2'-4.5km/h, 4'-5km/h, 6'-4km/h, 8'-5km/h, 10'-4.5km/h. In the second situation (2) the speed variation was maintained as in the first (1) but

subjects could not step the spots on the treadmill. We've used a HR monitor (Polar) to measure the HR every 30 seconds throughout each situation. The sample consisted of 20 subjects with a mean age of 25 years, 13 male and 7 female. Half of the group (10) started the first situation (1) and only after 60 min. performed the second situation (2); the other group half had the reverse procedure. Results Between both situations (2) and (1) there was a change in the HR average of 43 beats per minute (bpm) (45%). The maximum HR variation was of 153bpm and the minimum of 97bpm. The highest average variation between the two situations happened at 7.30 min and the lowest at 0.5 min.. Discussion The results showed that the constant need for decision-making implies a cost that reflects on the individual HR. This cost (45% of HR, in average) is higher than the cost identified by the increased terrain slope in 14% (Brito, J. Moreira, A. & Reis, V., 2004) where there was an average increase of 39% of the HR. We can than assume the importance of considering this factor when we need to prepare individuals for trekking activities where adaptation to terrain is crucial for the success of their performance (Fernando, C., Lopes, H. & Vicente, A. 2011). ## EXPLORING THE CONSTRAINTS-LED TABLE TENNIS TRAINING PROGRAM

Chuang, K.L., Liu, Y.T.

*National Taiwan normal university*

EXPLORING THE CONSTRAINTS-LED TABLE TENNIS TRAINING PROGRAM Chuang, K-L., Liu, Y-T. NTNU, (Taipei, Taiwan) Introduction The competitive table tennis is a fast-paced sport where the best of the five games of 11 points determines the winner of a match. Therefore, it is crucial for players to tune up the condition in a short period of time for the best performance in the match. In addition, for the collegiate division B table tennis matches in Taiwan, a rally usually finishes within 4 strokes. As a consequence, a successful service and service return becomes key to scoring a point. Based on the constraint-led approach (Newell, 1986; Davids et al., 2008), a training program that aims for these specific goals should be able to help improve the match performances of the players. Thus the purpose of the study was to develop such effective table tennis training program. Methods Seven members of a collegiate division B table tennis team participated in the study. In addition to the game scores of each match, notational analyses were performed on the first 4 strokes of all points in all matches from an inter-collegiate table tennis competition. Based on the recorded data, a Constraint-Led Training Program (CLTP) was developed to help improve the success rate of service and service return, as well as the reduction of the warm-up decrement effect. CLTP was implemented 40 min each practice session, 2 sessions a week for 8 weeks. At the end of the 8 weeks training, a notational analysis was performed again for another inter-collegiate table tennis competition. Data recorded from the 2 competitions were compared using paired t-tests. Results The paired t-test result on the outcome of the first 2 strokes (service and service return) shows significant difference between the 2 competitions:  $t(6)=2.716$ ,  $p<.05$ . However, the first game score ratio was not significantly different between competitions:  $t(6)=.174$ ,  $p=.867$ . These results indicate that the focus of CLTP on the service and service return was effective and reflected on the performances in the competition, whereas the goal of reducing the warm-up decrement effect was not as successful as expected. Discussion The results of the study demonstrate the importance of performance feedback in developing training programs and the necessity of assessing the training program in real competitions. The training programs of competitive sports should take into consideration the actual competition situations and develop training drills that reflect in the competitions. Future studies will continue to combine the research with sports training practice to implement a scientific training program. References Davids K, Button C, Bennett S. (2008). ## PROFILE OF TRAINING HABITS OF WORLD CLASS PROFESSIONAL SURFERS

Moreira, M.1, Hasser, C.2, Peixoto, C.1

*1 Univ Tecn Lisboa, Fac Motricidade Humana, 2 Leopold-Franzens-Universität Innsbruck, Fakultät für Psychologie und Sportwissenschaft*

Introduction Compared to other sports, training methodology is still a rather new concept for surfers. For this reason a difference between training schedules and organization of practice sessions can be found among them. This work is an attempt to create a profile of training habits of world class professional surfers and further find reappearing patterns in the execution of practice sessions. Methods In order to receive information about the trainings behavior of professional surf athletes (n=40 average of 25 years old) to further find common behavioral patterns and derive suggestions to improve the efficiency of training sessions a questionnaire was designed. Data has been collected during the Surf World Championships in Ericeira and it is limited to 35 questions to allow a shorter response time of about 10 minutes. To reply to the questionnaire the athletes (from 5 different countries) could choose between various categories of answers. The Bravais-Pearson correlation coefficient and Chi-Square test were used as statistical methods. Results The surf athletes practice on average 4 times per week with an average time of 120 minutes. Given the time it takes to prepare for the session, and time amount of time consumed by paddling, this is a reasonable practice time. The questionnaire shows that with an increasing number of practice sessions also the length of the practice sessions increases. 33,3% of the athletes have a coach. 61,5% stated to follow their professional career without a coach. Of those athletes with a coach, 60% stated the coach is doing nothing but observing their training session. Only 28,2% are being corrected during or after the practice sessions. No further relation between the age of the athlete and the presence of a coach during practice sessions could be found. 79,5% of the athletes watch surf videos focusing mainly on technique. 51,3% watch surf videos of themselves in order to analyze their performance. This habit is independently from the age of the athletes. Surfers listed Bottom-turn, Cutback, Snap, Tube and Floater to the maneuvers they execute most frequently. The list of the five maneuvers that are most desired consists of Airs, Tubes, Airs with rotation Reverse Airs and Floaters. The missing technique, the dependence on the right quality of waves, and the risk of injuries were listed as the reason why the athletes don't perform these maneuvers. Discussion Since coaching is a relatively new concept in the competitive surfing world, training characteristics, if existing, still vary among surfers. In order to help them on their progress to be a top professional surfer, and to stay there, it is advisable to adapt existing training methods from other sports to the surfing sport.

## EVALUATING THE REBOUND VELOCITY OF SQUASH RACQUETS

Sharp, G.D., Clohessy, C.M., Du Plessis, F., Mothibi, H.N., Stretch, R.A.

*Nelson Mandela Metropolitan University*

Introduction Squash is a racquet-based sport played with the ball speed an important factor, particularly in club players where the greater the ball velocity the more likely the opponent may be to make an error. Ball speed is dependent on a player's physical ability and the

equipment used. Therefore, the aim of the research was to develop a method for assessing the rebound velocities of a selection of squash racquets used by club level squash players, whilst simultaneously evaluating the rebound velocity based on different racquet brands and string tensions. Methods Three racket types, based on the purchase price (well priced racquet (WPR), medium priced racquet (MPR), higher priced racquet (HPR)) were assessed at two string tension (manufacturers' string tension (MST), re-strung tension setting of 30lbs (RST)). A pre-heated squash ball (40 °C) was dropped from a height of 1.44 meters on to a stationary racquet so that impact would occur at the centre of the racquet. Ball impact was filmed using a high speed camera. The ball speed (m/s) for each rebound was calculated from the bounce height and the video frame time. Analysis was performed using videographics with statistical assessment using Statistica version 10. Results The results of the study indicated that there were differences in rebound velocities for different racquets and string tensions for different MST and RST respectively (MPR = 0.363 m/s and 0.378 m/s; WPR = 0.250 m/s and 0.360 m/s; HPR = 0.350 and 0.322). The medium priced racquet's rebound velocity was greatest for both string tensions. Discussion The MPR rebound velocity was the fastest of the three racquets while the variability of the rebound velocity was the smallest for the HPR indicating that a player who prefers a faster game (higher speed) may compensate for some loss of control (more variability) and would thus prefer the MPR to the HPR. The restringing of the racquets indicates a nominal improvement in rebound velocity for MPR and WPR, but this may come at a consistency cost and therefore it may be advantageous to replace racquet strings when purchasing a new racquet. The mean rebound velocity for the WPR with MST racquet versus all other racquets is considerably smaller and supports the thought that the racquet requires restringing if a player prefers more speed. This study proposes a video graphical method for assessing the rebound velocity of a pre-heated squash ball on a squash racquet, while the statistical evaluation of the rebound velocity of the racquets evaluated indicates that there are measurable differences in the rebound velocity based on different racquet brands and different string tensions.

### A LONGITUDINAL EXAMINATION OF HOW ATHLETES PREPARE, COPE AND REFLECT UPON DEVELOPMENT

Algar, L., MacNamara, A.

*University of Limerick*

**Introduction** Every athletic challenge, whether expected or not, has the potential to be a crisis, or a beneficial experience depending on the individual's perception, management and support (Sinclair & Orlick, 1993). Given the complex nature of talent development, it makes sense that coaches are aware, anticipate and prepare athletes in advance of developmental challenges by clarifying support resources and coping strategies (Tamminen & Holt, 2012). The aim of this study was to examine how athletes utilised support in preparation and in management of seasonal challenges, and whether retrospective learning outcomes were achieved in the process. **Methods** A semi-structured qualitative interview design (retrospective and quasi-longitudinal) was used to gather data from purposefully sampled group developmental (n=3) and high performance (n=3) swimmers. To triangulate the data the athlete's coaches (n=2) were also recruited. Five stages of interviews were conducted one-on-one between September and August of the following year. Analysis was conducted using ATLAS TI (version 5.0.66) to inductively explore the interview transcripts (Patton, 2002). Raw data codes (quotations) emerged from the interviews and filtered into themes that best captured the substance of the group of codes (Miles & Huberman, 1984). **Results** Lack of a clear performance strategy was identified as a major source of organisational stress for both athletes and coaches. Injury and illness emerged as the most unexpected challenge, causing a 'shock-wave' like disruption to goals and life style management. Athletes that coped best demonstrated autonomous pre-empted management by maintaining a clear relationship with their coaches, revising their performance plan, and setting realistic goals. Pressure to perform well at competition and achieve qualification times and standards emerged as the only significant competition challenge experienced by athletes. This was dealt with by using mental skills, such as self-talk, imagery, focus triggers or relaxation as part of their pre-race routine. Throughout the season athletes reflected instinctively but did not purposefully utilise reflective practice techniques for learning. **Discussion** Evidence from this study suggests that the athletes tend to utilise their support resources during times of disorder as opposed to pre-empting stressors. Establishing comprehensible communication pathways throughout a sport system and the strategic use of reflective practice for learning can help athletes and coaches prepare for, manage, and benefit from developmental challenges. **References** Sinclair D.A., & Orlick T., 1993, Positive transitions from high-performance sport, *The Sport Psychologist*, 7(2), 138 - 150 Patton M.Q. *Qualitative research and evaluation methods*, 3rd edn. ### ANTHROPOMETRY AND PHYSICAL PERFORMANCE IN YOUNG SOCCER PLAYERS ACCORDING TO THEIR MATURITY STATUS AND CHRONOLOGICAL AGE

Bidaurrazaga, I., Lekue, J.A., Amado, M., Gil, S.M.

*Faculty of Physical Activity and Sport Sciences*

**Introduction** In young soccer players there is a considerable variation in size and performance due to age and maturity (Valente-dos-Santos et al., 2012). Therefore, maturation may have an impact on talent identification and selection processes in favor of early maturing athletes. **Methods** 41 elite soccer players of the Athletic Club of Bilbao participated in this study. The following measurements were taken at the beginning of the season: -Anthropometry: height, sitting height, weight, six skinfolds, diameters and perimeters. Body composition was calculated. -Performance tests: velocity (15m), agility (Barrow's test), Yo-yo IT level 1, CMJ, handgrip. -Skeletal age (SA) was calculated using the Tanner-Whitehouse II method to divide players into 3 maturity groups: early (EM), average (AM), late (LM). -Age at peak height velocity (APHV) (Mirwald et al., 2002). -Birth-dates: BQ1 (January-March), BQ2 (April-June), BQ3 (July-September), BQ4 (October-December). SPSS v17 was used for: means and standard deviations, chi squared tests, Student's t-test and U-Mann-Whitney test. **Results** Mean chronological age was 12.06±0.68 (range 10.91-13.19 years), mean SA was 11.98±1.00 (range 10.00-14.50 years) and mean age range for APHV was 13.4 to 15.2 years. Regarding SA: 8 (19.5%) players were LM, 24 (58.5%) AM and 9 (27%) EM. We found significant differences (p<0.01) in SA (year) [13.07 (EM) - 11.87 (AM) - 11.06 (LM)], APHV (year) [13.86 (EM) - 14.37 (AM) - 14.52 (LM)], SkF (mm) [69.10 (EM) - 46.35 (AM) - 47.86 (LM)]; (p<0.05 to 0.01) in BMI [19.15 (EM) - 17.52 (AM) - 17.43 (LM)] and fat% [11.57 (EM) - 9.48 (AM) - 9.43 (LM)]; (p<0.05) in the agility test (s) [11.50 (EM) - 11.19 (AM) - 11.23 (LM)] and in Yo-yo IT level 1 (m) [920 (EM) - 1117.50 (AM) - 1320 (LM)]. 36.6% of the players were born in BQ1, 24% in BQ2, 22% in BQ3 and 17.1% in BQ4 (p<0.05). None of the LM players had been born in BQ4. **Discussion** AM was the most representative group, whereas LM and EM were equally distributed. The literature shows a balance between these two maturity groups until 13-15 years-old. LM players had significantly less fat and outperformed their mature peers in the agility test and Yo-yo IT level 1 test. In fact, studies had already reported that late maturing players remain in their sport by outperforming their early mature counterparts (Deprez et al., 2012). Nevertheless, none of the LM players were born in the last quarter of the year. Thus, we can say that it seems that late born and late maturing players are systematically excluded from selection processes in soccer. **References** Valente-dos-Santos J et

al. (2012) *Int J Sports Med* 33, 773-80 Mirwald RL et al. (2002) *Med Sci Sports Exerc* 34, 689-94 Deprez D et al. (2012) *Int J Sports Med* 33, 987-93

### RELATIONSHIP BETWEEN ARMS AND LEGS ANAEROBIC POWER IN YOUNG SWIMMERS: EFFECTS OF SEX AND AGE

Kostoulas, I., Nikolaidis, P.T.

*Hellenic Army Academy*

**Introduction** While the importance of maximal anaerobic power (Pmax) for swimming performance has been well established, there is little information with regard to the relationship between arms and legs Pmax. The aim of the present study was to examine the effect of age and sex on the ratio of Pmax between arms and legs in adolescent swimmers. **Methods** Seventeen girls (age 14.7±1.8 yr, body mass 56.5±11.5 kg, height 1.62±0.08 m, BMI 21.5±3.2 kg.m<sup>-2</sup>, BF 22.8±5.7% and fat free mass 43.1±6.0 kg) (M±SD) and 28 boys (14.6±1.4 yr, 58.2±10.4 kg, 1.68±0.09 m, 20.6±2.4 kg.m<sup>-2</sup>, 14.5±4.1%, 49.5±8.4 kg, respectively) all members of competitive swimming clubs, performed the Force-velocity test (Vandewalle et al., 1985) for both arms and legs (arm cranking and cycle ergometer Monark, respectively), which consisted by four maximal sprints, each lasting 7 s, against incremental braking force interspersed by 5-min break. Compared with other anaerobic measures, this test provides additional information about the constituents of power, i.e. force (F0) and velocity (v0). **Results** The correlations between arms and legs ranged from r=0.45 (F0) to r=0.64 (Pmax) in girls, and from r=0.40 (F0) to r=0.72 (v0) in boys. In legs, boys had higher values of Pmax (709±210 vs 565±162 W), Pmax expressed in relative to body mass values (rPmax, 12.2±2.0 vs 10.0±2.1 W.kg<sup>-1</sup>) and v0 (191±21 vs 166±14 rpm, p<0.05), while no differences were found for F0 (148±40 vs 136±37 N) and v0/F0 (1.37±0.36 vs 1.31±0.38 rpm.N<sup>-1</sup>). In arms, boys had higher values of Pmax (272±90 vs 188±76 W), rPmax (4.7±1.0 vs 3.3±1.1 W.kg<sup>-1</sup>) and v0 (153±32 vs 125±18 rpm, p<0.01), while no differences were found for F0 (72±22 vs 59±20 N, p=0.06) and v0/F0 (2.36±0.97 vs 2.31±0.78 rpm.N<sup>-1</sup>). However, no sex difference was found with regard to the ratios of Pmax (p=0.06), F0 and v0 between arms and legs. There was direct relationship between age and Pmax of legs (r=0.64 in girls; r=0.43, p<0.05 in boys) and arms (r=0.56, r=0.57, p<0.05 respectively), while there was not any significant association between age and the ratios of mechanical characteristics of upper and lower limbs. **Conclusions** The moderate to large correlations between arms and legs suggest that while arms F-v characteristics accounts for the 20.3-41.0% in girls and 16.0-51.8% in boys of legs variance, the largest proportion of variance remains unexplained. Although the sex differences in Pmax, we found that the ratio of Pmax, F0 and v0 between arms and legs was similar in boys and girls, which indicates a common training effect of swimming. These findings emphasize the need for separate evaluation of arms and legs' F-v characteristics on a regular basis and the consideration of these measures in training design. **References** Vandewalle H, Peres G, Heller J, Monod H (1985). *Eur J Appl Physiol* 54:222-229.

### VALUES IN PHYSICAL EDUCATION CLASSES: DIFFICULTIES FOUND

Freire, E., Miranda, M.L.

*São Judas University*

**Introduction** Values are contents of Physical Education classes disseminated consciously or unconsciously by both students and teachers. Although there is a lot of talk about the relationship between Physical Education and building of values, we know little about how it occurs in the day to day of the classes and how they appear in the curriculum framework. To liaise the building of values does not depend only of the Physical Education teacher's wish, competence or good will as many factors interfere and difficult the intervention of the teacher. Research showed that it is difficult to some teachers to implement the building of values. The objective of this study was to understand what makes difficult the work of the teachers who want to use the Physical Education classes as a space for building the systems of values of their students. **Methods** The Critical Hermeneutic is the epistemological basis of this qualitative study in which the intervention of three teachers, intentionally chosen, was observed. **Results** Difficulties were identified in relation to infrastructure and material resources available in the school; to the school team's culture notion of physical education, values and attitudes; to the physical education classes themselves; to the relationship with the students; and to the teachers' emotional state. **Discussion** Some difficulties are external to the teachers as they result from the school's structure and organization. Others, however, are related to the teachers' beliefs about the possibilities of stimulation of the students to build values in the school. Two teachers understand that it is their responsibility to make a space for the building of moral values in their classes. This could be considered as a form of illusion, used unconsciously by the teacher in a try to make sense of her practice (Bourdieu, 1983). This belief has resulted in unreal expectations, incoherence between speech and practice and, in the case of the sample of this study, in the feeling of frustration or impotence. To break up with this illusion is essential so that the teacher could adopt a critical perspective, recognizing himself as a social agent with possibilities and limits in his practice, as does one of the investigated teachers. This teacher, unlike the other two, understands that the building of moral values should diffuse through her classes as well as the other school subjects. **References** BOURDIEU, P. Esboço de uma teoria da prática. In: ORTIZ, R. Pierre Bourdieu: sociologia. São Paulo: Ática, 1983. p.46-81.

### ELEMENTARY SCHOOL STUDENTS' PERCEPTIONS OF PHYSICAL EDUCATION COURSE

Avsar, Z., Saglam, M.

*Uludag University, Anadolu University*

**Introduction** PEC is very important for social, psychological and physical development of elementary school students therefore, the purpose of the present study is to investigate elementary school students' perceptions of PEC. **Methods** The study was designed as a descriptive study and the study sample included elementary school students (N=408). Data regarding students' expectations on PEC were collected with a questionnaire, and content analysis was performed on the gathered data. **Results** Results revealed that students per-

ceived PEC as crucial to their physical development. Most students liked the course as it provided them a chance to be sportive, and they disliked being forced to run for a long time and skipping class. Students suggested that schools needed course-related equipment, gyms, locker rooms and showers for the efficacy of PEC. Discussion in the present study, it was realized that especially boys want to play football and girls want to play volleyball. Hill and Cleven (2005) also found out that football is the most important sport for boys and volleyball for girls. Students think PEC help their body and muscle development and improve their health and help them grow taller and fitter. Students say that PEC's offer a possibility to learn every kind of sport, PEC's help students to provide their movement need and PEC's cause them to gain the habit of doing sports regularly. Bailey (2006) also specified PEC's effect on doing sports regularly. Most students said "I like PEC, there is no point that I dislike". Furthermore, they state that they like PEC since it provides possibilities for students to do sports, play with the ball, be free and PEC is an enjoyable course. They don't like PEC when they run for a long time, there is no teacher and they do nothing, when they have to do the exercise that they don't like at all and when they do the same exercise all the time. Hill and Cleven (2005) also specified in their study that most of the students said the most favorite course was PEC for them. In another study, it is pointed out that the least liked point in PEC's is short lesson time (Rice, 1988). Students mostly said that they need a sports hall or sports room and a shower and enough equipment for each student. Couturier, Chepko and Coughlin (2007) also specified that students don't join the PEC because of some problems such as lack of showers. Supaporn and Griffin (1998) emphasized that students enjoy the PEC more if they have enough equipment and if they do not have to wait for their turns. References Bailey, R. (2006). *Journal of School Health*, 76 (8). Couturier, L.E., Chepko, S. and Coughlin, M.A. (2007). *Physical Educator*, 64 (3). Hill, G. and Cleven, B. (2005). *Physical Educator*, 62 (4). Rice, P. ### 15-17 YEARS TEENAGERS THAT ENGAGED AND NOT ENGAGED IN AFTER SCHOOL ACTIVITIES FEATURES OF ANXIETY

Tilindiene, I.

*Lithuanian Sports University*

Introduction Anxiety is undefined or imaginary danger sign. The survey about the influence of anxiety on the learning process: learning organization, knowledge testing and evaluation. B. Henker and etc. (2002) states that anxious teenagers feel angry, became sadder, often feels tired, also feel less happy than their peers. More anxious less interact with peers, rarely engage in recreational activities, focuses on the achievement, have more eating disorders, use more tobacco. Methods 208 people participated in the research: 56 % of boys and 49 % of girls. The questionnaire „Teenager Anxiety Assessment“ was given to the participants of the research, which includes thirty situations of anxiety. Results The overall girls and boys engaged in after school activities and not engaged levels of anxiety in differ ( $\chi^2(1)=6,82$ ;  $p<0,05$ ). Girls, not engaged in after school activities anxiety intensity level a little bit increased, male anxiety intensity level increased slightly. Respondents anxiety level indicators involved in after school activities are lower. Girls that not engaged in after school activities anxiety associated with group work rate is slightly increased and associated with interpersonal relationships and self-esteem-related anxiety levels - normal ( $\chi^2(2)=4,21$ ;  $p>0,05$ ). Boys that involved in after school activities anxiety associated with teamwork and self-esteem levels are slightly increased. Anxiety associated with interpersonal relationships - level is normal. Extracurricular activities not engaged in all three types of boys anxiety levels slightly increased ( $\chi^2(2)=5,01$ ;  $p<0,05$ ). References Henker, B., Whalen, C., Jamner, L.D., Delfino, R.J. ### SLEEPING TIME AND STUDENTS' PHYSICAL ACTIVITY: IN PHYSICAL EDUCATION CLASSES, SCHOOL SPORTS AND EXTRA-CURRICULAR SPORTS

Botelho, G.1, Ferrão, A.2, Aguiar, M.2

1: CERNAS/ESAC/IPC (Coimbra, Portugal), 2: UTAD (Vila Real, Portugal)

Introduction Physical education plays a major role in the development of young people. It is an integral part of the total education of any child or adolescent and is closely linked to other creative and learning experiences and skills acquisition. Complementarily, extra-curricular sports are also important to increase the physical activity practice of adolescents. On the other hand, sleeping time is also an important dimension to consider since there are evidences that it facilitates memory processes. The purpose of this study was to assess the school physical activity inside physical education classes or school sports and extra-curricular sports patterns of 9-14 year old Portuguese adolescents. Methods A new questionnaire entitled "Questionnaire to Assess Physical Activity and Sedentarism, QAPAS" based on two previous questionnaires, QAPACE (Barbosa et al., 2007) and HBSC (2001-02) was developed and applied. Participants of this school-based cross-sectional study were a random sample of 1403 students, aged 9-14 (mean age: 10.64±0.76, 50.0 % males and 49.9 % females, with 0.1 % providing no answer) from 7 public schools of the municipality of the city of Viseu. Data analysis was performed using SPSS software v. 20.0. Results The great majority of adolescents (91.7%) follow the WHO recommendations for the sleeping time. Girls sleep more time in average than boys and the differences between gender were statistically significant ( $p<0.001$ ). The adolescents with the highest BMI values sleep less than the others, but a statistically significant difference was not found. Taking into account the practice of physical education classes, 98.4% of adolescents stated that they attend classes and follow the curricular programme in full. Only 28.4% of adolescents are engaged in school sports activities, with the indoor football (42.3%) being the most popular sport. On the other hand, 39.8% of adolescents practice sports in extra-school organizations or associations, and swimming (39.2%) and football (24.8%) are the most popular sports. Discussion The sleeping time reported by adolescents, in general, does not present a deficit, with the girls sleeping, in average, more time. The results showed that the frequency of attendance of physical education classes is near to 100 %. The other school sports offers presented a lower attendance. This situation needs to be analysed carefully by the National Curriculum Developing Authority. Despite the importance of the physical education classes, the promotion of sport activities inside the school must be increased and supported, not only by the teachers, but also by the parents and community. **PHYSICAL ACTIVITY AND PEER RELATIONSHIPS AT SCHOOL AMONG FINNISH STUDENTS IN GRADES 4–5 AND 7–8**

Haapala, H.1,2, Hirvensalo, M.2, Laine, K.1, Laakso, L.2, Tammelin, T.1

*1: LIKES - Research Centre for Sport and Health Sciences (Jyväskylä)*

**Introduction** The Finnish school system has been acknowledged for students' learning success, but the proportion of students liking school is fairly low (OECD, 2010; Currie et al., 2012). Students with good peer relationships tend to like school more, and students' social relationships affect school well-being (Konu & Koivisto, 2011). The Finnish core curriculum for basic education emphasises a learning environment that supports interaction among students, guiding them towards team work and a positive atmosphere (National Board of Education, 2004). Participation in physical activity (PA) provides possibilities for social interaction and peer relationships. This study investigated whether students' PA within and around a school day was associated with peer relationships at school by school level and sex.

**Methods** The data were obtained from the baseline measurements of the Finnish Schools on the Move programme's pilot phase in autumn 2010, targeting enhanced PA in the school setting. The data were collected with a questionnaire in 11 local projects (19 schools) across the country from 579 students from grades 4–5 (boys 53%) and 884 students from grades 7–8 (boys 49%). Statistical analysis was made using two-way ANOVA. Results Both boys and girls reported better peer relationships at school in grades 4–5 compared to grades 7–8 ( $p=.001$ ). Students who had at least 3–4 days with over 60 minutes of moderate-to-vigorous physical activity (MVPA) per week had better peer relationships compared to those with 0–2 days of MVPA ( $p<.026$  for girls,  $p<.040$  for boys). Boys who participated in sports clubs often reported better peer relationships than those who never ( $p<.001$ ) or sometimes ( $p=.048$ ) participated. Peer relationships at school were better among students who took part in PA at recess sometimes ( $p<.001$ ) and often ( $p<.001$ ) than among those who never took part.

**Discussion** Peer relationships at school were better in grades 4–5 than in grades 7–8. Because more physically active students reported better peer relationships, PA could be a tool for enhancing peer relationships at school. In particular, PA at recess seems to be a potential context within the school day for social interaction with peers.

**COMPARATIVE STUDY REGARDING THE ATTITUDE OF PUPILS IN PRIMARY AND SECONDARY SCHOOLS TOWARD THE EXTRACURRICULAR SPORTS ACTIVITIES**

Stanescu, M., Vasile, L., Stanescu, R.

*National University of Physical Education and Sport, Bucharest*

**Introduction** The adult's healthy lifestyle bases are laid during the childhood, by involving the individual into different forms of physical exercise practice. School assumes more and more often the role of modeling pupils' attitudes through educational offers including extracurricular sports activities. Methods In our study, we used the 10 item questionnaire-based inquiry, administered to 210 pupils in primary and secondary cycles, from Bucharest. The main variables pursued were pupils' involvement into extracurricular sports activities, performance sports practice, pupils' time budget structure, social factors supporting pupils' involvement in these activities. These variables were analyzed in relation to pupils' age and number of physical education lessons per week. Results The obtained results illustrate significant differences among the elementary school pupils, as compared to the secondary school pupils, as for their attitude toward the practice of extracurricular sports activities; even pupils desire to participate in the compulsory lessons, there is a significant difference on their preference for some sports contents/branches. This difference was analyzed in relation to the age. Other variables, although they didn't show significant differences, represent important landmarks for the application of educational methods destined to optimize pupils' attitude toward the extracurricular sports activities.

**Discussion** Our study results show that the time allotted to extracurricular sports activities counts about 4 hours/week, in elementary school pupils, and 2.5 hours/week, in secondary school pupils. According to Blair (2004), physical exercises should be daily practiced for at least 30 minutes. At the same time, we can ascertain that parents' involvement in the creation of an attitude favorable to physical exercise practice is very important. This was also highlighted by A. Wagner et al. (2004). The paper also includes discussions regarding children's implication in the practice of different sports branches, during their leisure time. The results obtained by us partially confirm the specialty literature data (Sunnegardh et al., 1985).

**EDUCATION IN VALUES IN PHYSICAL EDUCATION CLASSES: ANALYSIS OF A PROJECT FOR THE AUTONOMY OF THE STUDENTS**

Molina, F.F.1, Freire, E.1,2, Miranda, M.L.1

*1: São Judas University; 2: Mackenzie Presbyterian University*

**Introduction** Although there is much discussion about the possibility of building values in Physical Education classes, we know little about how this building occurs in the routine of classes. Frequently teachers try to reinforce positive attitudes and to inhibit those considered as negatives and in doing so they use strategies of submission, stimulating heteronomous behavior in their pupils. The objective of this study was to analyze the use of a pedagogical project aimed to stimulate the moral autonomy of students and to identify the vision of both teacher and students regarding the project. Methods A qualitative approach with a case study research was conducted in a private school. The sample was composed by 56 students and a Physical Education teacher. The education in values was used in 34 classes and information was gathered through observation and interview. In this project the teacher made a panel with the expected attitudes during the classes trying to stimulate the reflection about the behavior rules. The students assumed roles of responsibility and the use of dialogue to solve conflicts emerged in the classes was stimulated. Results The students' critical understanding was stimulated during the experiment with the possibility of discussing their own attitudes, their colleagues' and also the teacher's. The perception about the results are different among students and teacher. Students appreciate the teacher's initiative and compare the actual classes to the ones of past years. The evaluation of the teacher evolves during the project. In the beginning, her perception is that the students are changing and actively participating in the proposed activities. Nevertheless, in her final interview, she is disappointed and recognizes that attitudes generating exclusion of the less skilled are still in course.

**Discussion** The adopted strategies were adequate to reach the objectives of the Project. It is also true the need for a re-thinking of the time and way for building rules so that students do not see this process as some-

thing theoretical or external to Physical Education classes. Also the process of choice of the teams for the games should be changed. Although it is a resource that allow students to assume responsibility, peers' pressure limits the freedom of the person who makes the choices and, consequently, the responsibility about his own acts.

### THE JOINT ACTIVITY IN A TEACHING AND LEARNING SEQUENCE OF RUGBY. A DESCRIPTIVE ANALYSIS

López-Ros, V., Llobet, B.

*University of Girona*

**Introduction** Social constructivism shows how teacher and learners are in a joint activity around a specific content in which they exert mutual influences (e.g. Rovegno & Dolly, 2006). It also displays how the teaching and learning process responds to the way in which this joint activity organization evolves (e.g. Coll, Onrubia & Mauri, 2008). Several studies in sports initiation show how this joint activity is, its evolution, and its characteristics (e.g. López-Ros, in press). In the present paper we analyse the joint activity and its evolution in a rugby initiation sequence of three sessions. **Methods** We used interpretative methodology in accordance with the model and units of analysis employed in other researches (e.g. Coll, Onrubia & Mauri, 2008). Data collection was based on video and audio recording. The units of analysis are the segments of interactivity (SI) obtained from the transcription and video analysis of the sessions. We describe their characteristics and evolution through the three sessions of this teaching and learning sequence. **Results** We found six types of SI according to their instructional function: Activity Organization (SIAO), Guided Practice (SIGP), Autonomous Practice (SIAP), Discussion (SID), Recapitulation (SIR) and Transition (SIT). The number of SI for each session remains quite stable (32, 35 and 35). In relation to the percentage of time of the SI in each session, there is a decrease of SIAO in the last session (19.7, 22.1 and 13.3), the SIGP remains similar in all the sessions (59.9, 63.7 and 58.6) and the SIAP increases in the third session (8.3, 4.7 and 13.0). **Discussion** Joint activity organization is partially unpredictable and appears on the fly (Durand, 2001). Its analysis using segments of interactivity gives an image of its evolution in relation to the cession of the learning responsibility and control from the teacher to the students (Coll, Onrubia & Mauri, 2008). In our sequence we highlight the decrease of the organization segments and the increase of the autonomous practice that could be an evidence of this transfer of control to the learners in accordance with other works (López-Ros, in press). **References** Coll, C, Onrubia, J & Mauri, T (2008). ### "SPORT FOR ALL" SCHOOL PROGRAMME - A NEW WAY OF ORGANIZING AND PRACTICING CHILDREN'S SPORT?

Carlman, P., Augustsson, C., Olin-Scheller, C.

*Department of Health Sciences*

**Introduction** This study focuses on organized "Sport for All" activities, offered in cooperation between schools and sport clubs; targeting children aged 7-12. In Sweden there has been an increasing implementation of these kinds of sport activities for children in the past fifteen years. But, although the great will to implement these programmes, there is a lack of knowledge on the logic underpinning these activities. The present study investigates the logic of the practice revealed when children and engaged adults (teachers, sport leaders and management) describe their experiences of a Sport for All Programme in school (SAP). **Methods** This study has a case study design. Fifteen single interviews were conducted with the programme manager, three school teachers, two sport club leaders and nine children (five girls and four boys aged 9-10). The data were categorized based upon the core themes of the interviews (Silverman, 2010). In this study, Bourdieu's (1990) as well as Lave and Wenger's (1991) theoretical models are used as an analytic tool to study the Sport for all - programme as a "childing practice" with a focus on the participants agency (Alanen, 2001; James & James, 2003) in relation to the context of the logic of practice in an SAP. **Results** The result analysis shows that the organization and the practice of the activities are noticeably related to conventionally organized sport. Further, it also prove to be a new way of organizing and practicing children's sport - with its own logic. **Discussion** The history of sport has contributed to a conscious and unconscious idea of the meaning and function of competitive sport. The absence of organized competition, less intensive activities, more flexibility and variation in the SAP, challenge this dominant hegemony, especially in children's sport. When the adjusted and developed "Sport for All" initiatives are implemented, sport will be offered in a new context with other meanings and functions compared to conventionally organized sport. Consequently, the SAP concept calls for a new way of approaching children's sport, and new demands on those who organize and lead the activities. **References** Alanen, L. ### THE SWIMMING FULLY-CLOTHED IN ELEMENTARY SCHOOLS IN JAPAN

Fujiwara, Y., Fujitsuka, C., Kimura, K., Yonetani, S.

*Kawasaki university medical and welfare*

**Introduction:** Children have much chance touching water. Pool, pound, lake and a road following make children fun, pleasure and adventurous. However, water could be dangerous. Lots of disaster at sea and pool in Japan was reported rather than other countries. The swimming class in Japan has been based on Government Course Guidelines. It includes contents about playing in water in grade 1 and 2, floating and swimming in grade 3 and 4, and swimming in grade 5 and 6. The swimming fully-clothed is entrusted to each schools, not required content. The aim of present study was to investigate the actual conditions concerning swimming fully-clothed of elementary schools in Japan. **Methods:** We created original questionnaires survey for the elementary schools, and mailed them to 513 elementary schools of Shikoku where is around the sea in 2012. The survey contained the following questions. Q1: Does your school have the class of swimming fully-clothed? - Yes or No. Q1-1: Which grade does it have? Q1-2: Where does it have? Q1-3: How many times does your school have it in a year? Q1-4: What is the purpose? Q1-5: How to teach it? Q1-6: Who is the leading teacher? Q2: Have you have the instruction of swimming fully-clothed before? -Yes or No. Q3: Why not having the class of swimming fully-clothed? **Results:** 256 schools completed the questionnaires and return to researchers. The percentage of Q1 that it was YES was 49.6 % (n=127). Q1-1 was 48.0%, 47.2%, 55.1%,

60.0%, 78.7% and 87.4% from in grade 1 to grade 6 respectively. The percentage of Q1-2 was pool (99.2%) and river (0.8%). Q1-3 was once (81.1%), twice (15.7%) in a year. Q1-4: The purpose was guarding one's life (98.4%), learning to rescue (28.3%), and understanding nature (10.2%). Q1-5 was floating with fully-clothed (96.1%), floating with goods (88.2%), and swimming with fully-clothed (86.6%). Q1-6 was teacher (58.3%), fireman (16.5%), maritime safety staff (6.3%), and swimming coach (2.4%). Q2 was YES (79.3%) and NO (18.8%) before learning of swimming fully-clothed. Q3: Half of schools answered that they cannot make safe environments, keep sanitation of the pool, have enough instructors and set aside enough time. Discussion: Schools instructing children the swimming fully-clothed were less than half in Shikoku area around the sea. In order to increase the number of schools instructing the swimming fully-clothed, teachers should have chances to learn how to instruct, and also need to make safe environments.

### **DECISION MAKING PROCESSES OF PRIMARY SCHOOL PHYSICAL EDUCATION TEACHERS TO IMPROVE INCLUSION OF FEMALE IMMIGRANTS**

Nieva Boza, C., Lleixà Arribas, T.

*University of Barcelona*

In recent decades, physical education has undergone important social and cultural change. In the Baix Llobregat area (2010-2011), 9.3% of the students registered were foreigners, mainly from Latin America and the Magreb. This immigration has changed the working environment in primary education classrooms. In reference to cultural diversity, authors such as Capllonch, Godall & Lleixà (2007), and Soler, Gonzalo & Prat (2012), state that in the area of physical education, teachers can improve the inclusion of immigrant students, since it is an area characterized by socializing, with intrinsic motivation, which encourages participation among students of both genders. This paper shows the second set of results of a PhD research that analyzes the decision-making processes of primary school physical education teachers regarding inclusion of female immigrants, a minority group with its own peculiarities. METHODS This paper is focused on the results of a questionnaire filled in by 87 teachers. Analyzed variables include teacher's knowledge, immigrant female student characteristics, decision making processes, etc. RESULTS Student characteristics: 77% of teachers state that immigrant female students participate in all kind of activities and they do it together with the rest of the class. 75% of teachers consider that these students have mainly hygiene and health needs, and they need affection. Teacher expectations: 53% of teachers recognize that immigrant female students participate in all of the five content areas, although this participation is different in some of them. Teachers believe that the most difficult physical contents for these students are hygiene and health, and body expression. According to Dagkas (2006), there are different notions in Islamic culture about body and gender that influence physical education classes. In conclusion, teachers perceive some differences between these students and the rest of the class. Therefore, it is recommended to implement training programmes for teachers that include contents such as inclusion, coeducation and knowledge about other cultures, in order to improve these students inclusion. In fact, authors like Pastor, González, Cuevas and Gil (2010) state that the training offered by public administration is insufficient to approach cultural realities. ### **INCLUSIVE PHYSICAL EDUCATION IN SERBIA: CURRENT SITUATION AND PROSPECTS**

Djordjic, V., Tubic, T.

*University of Novi Sad*

Introduction The main strategic orientation in Serbia is the inclusive approach in education, which provides every student with equal rights and availabilities of education (Law on the Fundamentals of the Education System, 2009). Although education of disabled children in Serbia still goes on in three routes: special schools for disabled students, special classes within regular schools and inclusive classes within regular schools, the number of disabled students enrolled in regular education is growing. Since physical education has potential to be one of the most supportive and active pieces in inclusion process in schools (Rouse, 2009), the study was conducted aiming to define current situation and prospects of inclusive physical education in Serbia. Methods The secondary and primary data analyses were combined in order to get a comprehensive insight in current status and future perspectives of inclusive physical education in Serbia. Results According to current data, 1,570 (5.44%) children with disabilities were enrolled in 38% of regular primary schools in Serbia: 258 (0.82%) children with physical disabilities and 1,312 (4.62%) children with developmental disorders (intellectual and communicative). Around one fifth of teaching staff attended additional trainings for inclusive teaching. However, the lack of pre- and in-service training oriented toward inclusive physical education exists, as well as adequate professional support. Material resources for inclusive teaching are unsatisfactory: almost 37% of schools do not possess proper indoor facilities while quality and quantity of equipment is insufficient. Class size in Serbian schools, comprising 30 do 34 students, is inconvenient for inclusive teaching. Personal or teaching assistant is an option, yet not widely used. As for the teachers' attitudes toward inclusive physical education, most of them reported moderately positive attitudes (Djordjic, 2012). Discussion Radical educational reform in Serbia requires further development of systemic support to operationalization of proclaimed principles of equity and inclusion. Considering inclusive physical education, main lines of actions include: quality pre- and in-service training of teaching staff, adequate provision of material resources and professional support, as well as development of inclusive culture in broader societal context. ### **STRONG AND WEAK POINTS IN PHYSICAL EDUCATION WHEN ATTENDING TO IMMIGRANT STUDENTS: THE TEACHER'S VOICE IN A MULTICULTURAL SCHOOL**

Flores Aguilar, G.1, Prat Grau, M.1, Soler Prat, S.2

*1. Universitat Autònoma Barcelona 2. INEFC Barcelona*

Introduction Over recent years, Catalan public schools have seen a progressive increase in their students' cultural diversification. To face the challenge of educating citizens capable of living harmoniously in such a plural society, physical education (PE) may well be an excel-

lent tool for fostering respect, tolerance and exchange between different cultures (UNESCO, 1978). This study aims to "give voice to the PE teacher" who has years of experience in multicultural contexts. With this, we aim to ascertain those points considered to be strong and weak within this subject when attending to immigrant students. In this way, we also hope to analyse the manner in which PE and sport contribute to the social cohesion and inclusion of students at school. Methods The interpretative orientation of this educational research has allowed us to develop a multiple case study consisting of 12 cases: 7 women and 5 men, with more than five years' work experience, belonging to 10 schools whose immigrant student population exceeds 50%. Semi-structured interviews and non-participant observation were the techniques used in the study. For results analysis, the NVivo programme (eighth edition) was used to analyse content. Results On the basis of PE teachers' opinion, some of the strong and weak points in PE that have been identified are: Strong: imitation diminishes students' language problems; students tend to be motivated with respect to the subject and its content; there is more relationship and interaction amongst students. This favours the socialisation and inclusion of newcomers, and helps in breaking prejudices and stereotypes through education in values (respect, tolerance, etc.); and PE may increase the students' personal safety, confidence and self-respect, particularly that of those with greater abilities. Weak: greater student-student contact may facilitate greater conflict; there are many female students who are highly unmotivated, particularly amongst Asians; the negation of the body promoted by certain families creates significant dilemmas amongst immigrant students; verbal explanations create difficulties of comprehension for those students who are not fluent; and the universality of certain sports diminishes students' motivation for participating in other less well-known sports activities. Discussion PE may well be a privileged tool with which to attend to immigrant students (Soler, 2004), always providing that PE teachers act in a constructive manner so as to limit the subject's weak points and in order to take advantage of the opportunities that it offers for students' inclusion and cohesion. ### PE TEACHERS' PERCEPTIONS ON THE SIGNIFICANCE OF CAPACITIES FOR TEAM AND INDIVIDUAL SPORTS IN 6-8 YEAR OLD HIGH SPORT POTENTIALS

Platvoet, S., Elferink-Gemser, M., Niet, M., Visscher, C.

*HAN University of Applied Sciences*

Introduction According to physical education (PE) teachers a high sport potential can be identified in the setting of PE by six capacities; work attitude, developmental-, motor-, creative-, interpersonal-, and intellectual capacity (Platvoet et al., 2012). The predictive value of identifying high sport potentials in some sports may be higher than in other sports as there might be a different number of essential performance components (Vaeyens et al, 2008). Therefore, the relative significance of each capacity for different types of sports needs to be clarified. The aim of this study was to determine the relative significance of the six capacities for team versus individual sports. Method 134 primary PE teachers with experience as trainer/coach (n= 68 team sports, n= 66 individual sports) filled a questionnaire with statements on a five point scale constructing the six capacities. Independent sample t-test were used to determine differences in relative significance of each capacity. Effect sizes were calculated to determine if effects were substantive. Results All subscales had sufficient internal consistencies (Cronbach's  $\alpha = .70$  to  $.86$ ). For individual sports ( $M = 4.31$ ,  $SE = 0.08$ ) the relevance of motor capacity is significantly higher than for team sports ( $M = 4.01$ ,  $SE = 0.07$ ;  $t(131) = 2.86$ ,  $p < 0.05$ ). The effect size is small ( $r = 0.24$ ). Interpersonal capacity has a significantly higher relevance for team sports ( $M = 3.80$ ,  $SE = 0.08$ ) than for individual sports ( $M = 3.05$ ,  $SE = 0.08$ ;  $t(126) = -6.64$ ,  $p < 0.05$ ) with a large effect size ( $r = 0.51$ ). Also for intellectual capacity the relevance for team sports ( $M = 3.28$ ,  $SE = 0.09$ ) is significantly higher than for individual sports ( $M = 2.80$ ,  $SE = 0.09$ ;  $t(126) = -3.67$ ,  $p < 0.05$ ) with a medium-sized effect ( $r = 0.31$ ). For the other three capacities no significant differences were found ( $p > .05$ ) and effect sizes were all small. Discussion In the perceptions of PE teachers motor capacity, interpersonal capacity, and intellectual capacity have a significant different relevance for the identification of high sport potentials in individual and team sports. This can be explained by the different performance demands of team and individual sports and confirms statements of Vaeyens et al., (2008) that the relative components may have a different impact on performance in different sports. A next step will be to develop an instrument based on the capacities that PE teachers can use to identify high sport potentials for different kind of sports. #### COMPARING ORGANIZATIONAL INTERVENTIONS TO ENHANCE PERFORMANCE IN ELITE SPORT

Wagstaff, C.R.D., Hanton, S., Fletcher, D.

*University of Portsmouth, Cardiff Metropolitan University, Loughborough University*

Introduction This study intended to contribute to the growing body research on positive organizational psychology in sport (POPS). The purpose of this research was to compare the perceived effectiveness of two intervention approaches aimed at improving organizational functioning in an Olympic National Sport Organization. Specifically, we compared the utility of adopting one-to-one (e.g., coaching) or organization-wide (e.g., educational workshop) interventions to facilitate optimal performance through enhancing emotion ability and regulation strategy use. Methods We examined the data from a recent action research intervention in an Olympic sport organization, which comprised two intervention approaches. The first intervention approach involved delivering educational workshops to individuals fulfilling a range of roles (i.e., board of directors, chief executive officer, heads of performance and development, staff, national coaches and team managers, club coaches, national talent academy athletes) across the organization over a 6-month period. The second intervention involved providing one-to-one coaching to national managers for 3 months. Data regarding the perceived effectiveness of the interventions were collected from three national managers who completed both interventions and involved analyzing participant daily diaries, a researcher's log, and social validation interviews. Results Whilst data analysis procedures indicated that both intervention approaches were effective at improving individual, team, and organizational functioning, participants perceived the one-to-one coaching

intervention approach to be more effective. Specifically, participants perceived the educational workshops to be effective for learning emotion regulation strategies (i.e., techniques) for use in building and maintaining interpersonal relationships. However, they perceived the coaching intervention to be more effective at developing emotion abilities (e.g., intelligent selection and use of emotion regulation strategies) for optimal intrapersonal and interpersonal outcomes. Discussion The findings indicate generic workshop interventions may have utility for educating participants about emotion regulation strategies, with the use of more ideographic, solution-focused coaching more beneficial for facilitating an understanding of when and how to use these strategies for optimal relational outcomes in sport organizations. Hence, it would appear that, where possible, applied practitioners should match intervention approaches to their intended outcomes.

## RELATIONSHIP OF SPORT PARTICIPATION AND SELF-PERCEIVED ACADEMIC COMPETENCE

Tubić, T., Đorđić, V.

*Faculty of Sport and Physical Education*

**Introduction** The notions that sport participation negatively influence academic achievement has currently been by far overcome. However, previous findings suggest that there is low to moderate relationship between academic and sports achievement (Bradley et al., 2013; Donaldson and Ronan, 2006). The purpose of this paper was to study the relations between sport participation and academic competence from the aspect of social perception; we were interested whether the participants of both genders differed in self-perception of academic competence depending on their sports participation (individual and team), as well as whether and to what extent sports duration and/or level of sports engagement contributed to the obtained differences. **Methods** The sample included 786 college students, 366 males and 420 females. Out of the total sample, 253 students were not engaged in sport, 182 were engaged in individual sports and 351 in team sports. Within the category of sportsmen, 124 students have been engaged in sports up to three years, 75 up to five years, and 334 for more than five years. Concerning the level of sports engagement, 319 students were at local-level, 134 national, and 80 international. The research applied the subscale of self-perception of scholastic competence from the questionnaire Self-perception Profile for College Students (Neeman and Harter, 1986). **Results** Univariate GLM results confirmed that there was statistically significant effect of duration/level mutual interaction of sports engagement on self-perception of scholastic competence among subjects of different gender and sports engagement ( $F=5.39$ ;  $p= .01$ ). Considering the effects of individual factors on the dependent variable, female students had significantly higher scores on academic competence than the males ( $F=10.52$ ;  $p= .01$ ), whereas other obtained differences were not statistically significant. **Discussion** It is possible to explain the relationship between sports engagement and perceived scholastic competence in terms of the effect of essential underlying factors of both types of activities, such as increasing motivation i.e. task orientation, cooperation, as well as the experience of satisfaction leading to success in general. In addition, sport participation helped students build discipline, organize time and develop self-confidence, which can positively affect self-perception of academic competence. **References** Bradley J, Keone FK, Crawford S (2013). ## UNDERSTANDING INSPIRATION IN SPORT: ATHLETES PERCEPTIONS

Dodds, S., Mc Cullough, D.

*Roehampton University*

**Introduction** An event such as the Olympics can inspire athletes to emulate the success of their sporting heroes and achieve a feat once thought of as impossible. Whilst inspiration has been researched within the mainstream psychology literature (Thrash & Elliot, 2003, 2004) the concept has received little research attention within the sport psychology literature. The aim of the present research therefore, was to define inspiration in sport and explore athletes' understanding of inspiration by ascertaining what inspires them to participate and compete. **Method** An IPA (Smith & Osborn, 2008) approach was employed to gain athletes' subjective experiences of inspiration. Six sprinters (4=male, 2=female) were purposefully sampled and participated in a semi-structured interview (Patton, 1987) to explore early and current experiences of inspiration. Interviews were transcribed and analysed in line with IPA guidelines. **Results** Data analysis revealed four super-ordinate themes addressing the antecedents of inspiration: 1) the role of influential people 2) a strong desire to succeed 3) continued commitment towards goals and 4) the role of positive and negative emotions. It emerged that many antecedents of inspiration occurred during the participants' early experiences in childhood which had a continual impact throughout the athletes' lives. Particularly, the latter two sources of inspiration became more prominent during current experiences. **Discussion** These findings reveal key sources of inspiration for athletes and the importance of these in initiating motivation. Findings also assisted in the development of the first sport specific 'working' definition of inspiration presented within the sport psychology literature. As such, more research needs to be conducted across various sports and standards to build upon this definition, whilst also providing a greater insight into what factors contribute to inspiration and hence, motivation within athletes. **References** Patton, MQ. ## INTERNAL TASKS HIDDEN IN ATHLETIC PERFORMANCE PROBLEMS IN COLLEGE ATHLETES: ANALYSIS BY THE LANDSCAPE MONTAGE TECHNIQUE

Katsuhiko, K.1, Daisuke, T.2, Kaori, E.3

*1)Hokkaido university of education., 2)Japan Institute of Sports Sciences., 3)University of Tsukuba*

**Introduction** The purpose of this study is to examine the feature of internal tasks hidden in athletic performance problems in college athletes by using the Landscape Montage Technique (LMT). In psychological supports for athletes, they consult about the troubles related to the athletic performance. For example, when they are playing a game, they say that "I can't demonstrate my ability", "I lost the eagerness for my sport", and "I can't decide at the crucial moment", etc. It is often their performance are not enough progressed by giving the psychological skill training corresponding with their performance problems they mentioned. Therefore, it is important in psychological support to grasp their problems as not only their performance but also internal tasks even if they mention only their performance. **Methods** The study asked 30 colleges athlete to answer the questionnaire: Diagnostic Inventory of Psychological-Competitive Ability for Athletes (DIPCA), and to draw the Landscape Montage Technique (LMT). By answering DIPCA, this study let them notice their abilities and

then write the abilities they need. The aim of the creation of LMT was to identify the internal tasks that they hold. Results This study considered the relationship between the contents of athletic performance problems that they identified from the results of DIPCA and the features of LMT that they drew. In particular, it analyzed paying attention to the reference of 'I have no confidence in my performance'. As a result, the difference was looked at by depiction of a way and a person. Discussion The result of this study indicated that there are various internal tasks in the background that they said 'I have no confidence in my performance' or "I can't decide at the crucial moment". The characteristics are summarized in the following two points. 1) Depiction that the road is interrupted is considered to be an expression with an indefinite meaning which tackles an activity. 2) Depiction of a person like a stick figure was considered to be an expression in the state where it is difficult to an athlete's own ability.

### **ATHLETES' JUSTICE PERCEPTIONS OF COACHES' LEADERSHIP- ANTECEDENTS AND CONSEQUENCES**

Huang, L.W., Liao, C.M., Tien, C.Y., Chao, Y.C., Hsieh, Y.S., Chieh, C.C., Liang, F.W., Liu, C.H.

*National Taiwan Sport University*

**Introduction** The importance of team members' justice perceptions of their leaders has been well documented in organizational psychology. In sport, however, how and why athletes perceive their coaches' behaviors as being just and what consequences will athletes' justice perceptions of their coaches bring about have not been systematically studied. The purpose of this study was to conceptualize athletes' perceptions of justice by exploring the antecedents and consequences of justice perceptions via interviewing elite athletes. In addition, interview data were analyzed based on the three different values (equity, equality, and need) used as the basis for distributive justice proposed by Deutsch (1975) to examine possible situational specificity. **Methods** Nine athletes were interviewed by the first author either individually or in a focus group. The athletes were from college level or above (mean age 21.56, 5 males and 4 females) with 4 from Taekwondo, 2 from basketball, 2 from track and field, and 1 from baseball. Interviews were taped, transferred into qualitative data, and analyzed following the standard protocol of content analysis. **Results** Content analysis revealed that justice perception is multidimensional, consisting of distributive justice, procedural justice, voice, interpersonal justice, and informational justice. Antecedents of athletes' justice perception were categorized into 7 characteristics of coaches, including caring about the athletes, open-mindedness, emotional control, patience, coaching ability, attribution of athletes' performance, and motivation. Athletes also indicated that their perceived justice would influence their trust and satisfaction of the coach, coach-athlete relationship, as well as team cohesion. In addition, athletes reported that the basis for evaluating justice was situational specific. The rule of equity was essential in deciding starting lineups (the more the contribution, the more the playing time); the rule of need should be followed in practice (the needier gets more instructions); and finally, the rule of equality should be applied in finance-related issues and social activities. **Discussion** The findings of this study support the notion proposed in organizational psychology that justice perception is multidimensional in nature. In sport, athletes' justice perception of their coaches' behaviors comes from various sources. Coaches who are more open-minded and willing to give more chances to athletes are more likely to be perceived as fair. Athletes emphasized that perceived justice influenced their relationship with coaches and team cohesiveness. However, athletes appear to use different rules to evaluate their coaches' behaviors across situations. Coaches should apply different strategies accordingly for having their athletes perceive them as just. **References** Deutsch, M. (1975). Equity, equality, and need: What determines which value will be used as the basis for distributive justice? *Journal of Social Issues*, 31, 137-149.

### **STUDENT-ATHLETES' TIME COMMITMENT TO ATHLETICS AND ACADEMICS: AN EXPLORATORY STUDY IN TAIWAN**

Yang, C.H., Liao, C.M.

*National Taiwan Sport University*

**Introduction** Student-athletes play two roles and the roles of student and athlete are usually conflicting in nature. In the USA, to ensure that student-athletes can keep a balance between student and athlete's duty, National College Athletic Association (NCAA) has limited the time for student-athletes engaging in athletically related activities to a maximum of 20 hours per week in-season and 8 hours per week off-season (NCAA, 2011). A survey showed that most of the student-athletes in the USA followed this NCAA rule and were satisfied with their time commitment in sports (Ayers, Pazmino-Cevallos, & Dohose, 2012). In Taiwan, no regulation has been set by the authority to limit student-athletes' time engagement in athletically related activities. How much time do student-athletes spend on athletic and academic activities, and how their time commitments influence their psychological and social development, have not been systematically studied. In this study, we interviewed university student-athletes from Taiwan to explore their perceptions of the time they spend to lay the basis for future studies regarding the antecedents and consequences of time commitment of student-athletes. **Method** Eight university student-athletes were interviewed by the first author individually. They were from the highest college level (6 males and 2 females) with 3 from swimming, 3 from handball, 1 from badminton, and 1 from table tennis. Interviews were taped, transferred into qualitative data, and analyzed following the standard protocol of content analysis. **Results** Results showed that training hours varied according to sports. Swimmers and badminton players trained around 12 and 15 hours per week, while table tennis and handball players trained more than 21 and 25 hours per week. The long training hours for table tennis and handball players were because they trained two times a day. In terms of academic activities, they spent 14 to 22 hours per week depending on how many course hours they took. All interviewees reported that they were satisfied with their time commitments. **Discussion** It appears that some of the university student-athletes may spend too much time in sport training, and some even train twice a day. Although there is no time regulation for student-athletes in Taiwan, training over 20 hours per week is certainly an issue of concern in assuring a quality education. It is also worrying that all interviewees in our study are satisfied with their time allocation despite long training hours. Athletic achievement seems to be overly-emphasized and academic duty be neglected. This may result in maladaptive career and identity development. **References** Ayers, K., Pazmino-Cevallos, M., & Dohose, C. (2012). The 20-Hour Rule: Student-Athletes Time Commitment to Athletics and Academics. *Virginia Journal*, 33(1), 22-26. National Collegiate Athletic Association. (2011). 2011-12 NCAA Division I Manual. (2011-12) Indianapolis, IN: National Collegiate Athletic Association.

### **DEVELOPING AND MAINTAINING PURPOSE IN YOUNG ATHLETES**

Jones, M.I., Parker, J.K., Fiander, M.

*University of Gloucestershire*

A growing body of literature suggests that purpose plays a significant role in the development of positive young people. Damon, Menon, and Bronk (2003) defined purpose as a stable and generalized intention to accomplish something that is at once meaningful to the self and of consequence to the world beyond the self. Despite this growth in research, scholars and practitioners know little about young

people with purpose, particularly young people who spend significant time in a sporting context. Young people spend large amounts of leisure time participating in sports activities, and sport provides a salient context for positive youth development (Larson, 2000). Therefore, study of purpose in sport is warranted. The aims of this study were to examine the kinds of noble purposes inspiring today's young, and how young people have been introduced to these purposes. We adopted a qualitative description methodology (Sandelowski, 2000) and purposefully sampled eight members of the same university rugby team from the UK. All participants were aged 18-25 years. We conducted an iterative cycle of data collection and analysis, whereby each interview was collected and analyzed before conducted the next interview. We audio recorded and transcribed each interview verbatim. We then used a thematic analysis procedure in line with Sandelowski's (2000) recommendations. Results revealed that not all the participants were living a purposeful life (i.e., they were not engaging in activities that were meaningful to the self and of consequence to the world beyond the self). Of those young people who described living or searching for a purposeful life, the most common types of purpose to search for and find were forming intimate relationships, becoming a teacher/ coach, and having a family. Participants described social agents (e.g., parents, peers, and teachers) in developing a sense of purpose. Current findings correspond with Erikson's stages of psychosocial development, which suggest that young adulthood (e.g., ages 18-30 years) is about love (intimacy vs. isolation) and middle adulthood is about care (generativity vs. stagnation). Exploring both the content of young athlete's purpose as well as the ways in which they work in pursuit of purpose can help individuals increase the likelihood of maintaining respective purposes over time. Toward a psychology of positive youth development. *American Psychologist*, 55, 170-183 Sandelowski, M. (2000) Focus on research methods: Whatever happened to qualitative description? *Research in Nursing & Health*, 23, 334-340

### A STUDY OF LIFE SKILLS ACQUISITION FOR UNIVERSITY ATHLETES

Hatta, N., Shimizu, Y., Daigo, E.

*Kanagawa University*

**Introduction** One of the prevalent problems in university sport clubs is athletes' maladjustment to teams and dropout from clubs. In order to enhance the university athletes' adjustment to atmosphere and interpersonal relationships in the club activities, psychological factors based on life skills need to be explored. A number of studies in the field of sports psychology have been conducted to examine the influence of sports experience on acquisition of life skills. However, there are few studies that have focused the psychological effects on negative factors such as stressor. The purpose of this study is to clarify the relationship among life skills acquisition, athletes' stressor, sport commitment and sport enthusiasm. **Methods** The subjects of 272 college athletes (Male=228, Female=44, mean age=19.9, SD=1.15) were asked answer a questionnaire composed of socio-demographic question items, Sport Life Skill Scale (SLSS), Sport Stressor Scale (SSS), Sport Commitment Scale (SCS) and Sport Enthusiasm Scale (SES). Previous studies developed SLSS, SSS, SCS and SES, and confirmed the reliabilities and structural validities of each scale. Correlation analysis and covariance structural analysis were conducted to examine the relationships among each scale. **Results** The result of correlation analysis showed that both 'SCS' and 'SES' are positively associated with the subscales of "SLSS" (both 'Personal Skills' and 'Individual Skills'). The result also showed that 'SES' is positively associated with "SSS" ( $r = 0.12, p < 0.05$ ). Covariance structural analysis showed that the path coefficients between 'SCS' and "SLSS" and between "SCS" and "SLSS" were statistically significant, but other coefficients in the structural equation model were not statistically significant. **Discussion** The results suggested that athletes with high sport commitment and enthusiasm enhance their life skills in ordinary college life and sport club activities. The results imply that sport club activities for university athletes promote their life skills even if the activity level is high and practices are recognized severe. Future research with larger sample size and the sample of ordinary university students will be needed in order to explore effective life skills acquisition. **References** Naoki HATTA, Yasuo SHIMIZU, Eiji DAIGO (2013). ### PSYCHOLOGICAL PREPARATION OF BRAZILIAN GYMNASTS PARTICIPATING IN OLYMPIC GAMES

Schiavon, L., Paes, R.R., Toledo, E.

*State University of São Paulo*

**PSYCHOLOGICAL PREPARATION OF BRAZILIAN GYMNASTS PARTICIPATING IN OLYMPIC GAMES** **Introduction** This paper is part of a research on the sports career of all the Brazilian gymnasts who participated in Olympic Games (OG) in Women's Artistic Gymnastics (WAG), from 1980 to 2004, which objective was to register and analyze this process of formation (Schiavon, 2009). This paper will cover the psychological preparation of the gymnasts. **Method** This qualitative research used the Oral History method, with the techniques of "oral testimonial" and crossed analysis (Thompson, 2002) with non-structured interviews (Laville and Dionne, 1999). **Criteria:** Brazilian gymnasts participating in OG till 2004 (WAG). **Subjects:** 10 gymnasts (100% of the universe) since the first Brazilian participation in OG in 1980. For a better analysis, the gymnasts were divided in three groups: "pioneers" (1980-1992), "transition" (1996-2000) and "new generation" (2004). **Results and Discussion** In the generation of the "pioneer" gymnasts it was verified that there was not enough or continuous support from sports psychology professionals. When they happened, they were very specific and without continuity. The "transition" and "new generation" groups obtained psychological support only when the trainings were transferred to the Artistic Gymnastics (AG) Excellence Center. Many times, coaches themselves take care of the gymnasts "psychological issues" because there is no structure or financial conditions to hire a professional. In other cases, this is an option, as they consider that they know better their gymnasts (Arkaev and Schilin, 2004). Nevertheless, often these coaches do not know how to deal with some emotional situations emerging from trainings and competitions. Many gymnasts are afraid to talk with their coaches, and this is a cultural trait in the AG, specially stimulated by both the inflexible behavior of the coaches (Gervis and Dunn, 2004) and by their childlike handling of the gymnasts. Together these aspects could generate an insurmountable barrier and a threat to the emotional wellbeing of elite young athletes, and could even jeopardize the results. **References** Arkaev L, Suchilin N. ### **RHYTHMIC GYMNASTS' REFLECTIONS ON COPING AND SOCIAL SUPPORT FOLLOWING A MISTAKE AT AN OLYMPIC GAMES: THE IMMEDIATE AND LONG-TERM AFTERMATH**

Magnisali, V., Mc Cullough, D.

*Roehampton University*

**Introduction** Making a mistake during competition can be a stressful experience for an athlete (Nicholls et al., 2009). However, little research has focused on the psychological impact of making a mistake during an Olympic Games. This was the purpose of the present investigation. Specifically, this study aimed to explore retired Olympic rhythmic gymnasts' reflections of coping and social support immediately after the mistake occurred and the long-term aftermath. **Method** Semi-structured interviews (Patton, 1987) were conducted with a purposeful sample of eight retired Greek Olympic rhythmic gymnasts. These were transcribed verbatim and analysed using Interpretative Phenomenological Analysis (IPA, Smith & Eatough, 2007). **Results** Athletes' feelings immediately after the mistake related to disappointment, sadness, anger, guilt, enhanced motivation, worry about the coaches' reaction and fear of another mistake. Problem-focused, emotion-focused, avoidance coping and no coping were reported during this time with emotional, esteem and informational support being highlighted as fundamental in helping the athletes cope. In terms of the long-term aftermath, some gymnasts had changed their perception of the mistake from negative to positive overtime, but a few still had strong negative feelings. Problem-focused, emotion-focused and avoidance coping were utilised over time with emotional and esteem support being perceived as important for coping effectively. **Discussion** Findings indicated that coaches' negative informational support can influence the way in which gymnasts coped with the immediate and long-term aftermath of a mistake. The majority of athletes' perceptions changed over time through the use of a combination of coping strategies, which reflects previous studies (Poczwardowski & Conroy, 2002). Moreover, perceived social support from family, friends and fans was identified as a crucial coping factor (Rees & Hardy, 2000). Two main implications arise from this study: (a) Enhancing coaches' awareness of how their support can affect athletes' ability to cope effectively; (b) The important role of significant others in helping athletes cope more effectively immediately after making a mistake at a major competition and over time. **References** Nicholls, AR, Jones, CR, Polman, RC, Borkoles, E. ### **EXAMINING THE DEVELOPMENT ENVIRONMENTS OF ELITE YOUTH SOCCER ACADEMIES IN ENGLAND: THE PLAYERS' PERSPECTIVE**

Mills, A., Maynard, I., Butt, J., Harwood, C.

*Sheffield Hallam University*

**EXAMINING THE DEVELOPMENT ENVIRONMENTS OF ELITE YOUTH SOCCER ACADEMIES IN ENGLAND: THE PLAYERS' PERSPECTIVE** **Introduction** While the development and eventual success of a gifted young soccer player is considered to be influenced by a variety of psychological and behavioural factors (cf. Mills, Butt, Maynard & Harwood, 2012); few would dispute that it is also shaped by their environmental experience (Reilly, Williams & Richardson, 2003). Despite this, scant research exists regarding the environments that are created for developing players. The purpose of the present study was to examine elite youth players' perceptions of the quality of their development environment at a crucial stage in their progression to the professional level. **Method** With institutional ethics approval, the Talent Development Environment Questionnaire (TDEQ; Martindale, et al. 2010) was used to survey 50 elite youth soccer players aged 16-18 (m 17.1,  $\pm$  s = 0.6 years). The players were recruited from the academies of a range of elite English Premier League clubs. In the analysis, the internal consistency of the TDEQ's factors was established and the mean subscale scores were calculated for each factor. Subsequently, all individual item mean scores were ranked by proportion of agreement. **Results** Overall, players reported that their environment emphasised long-term development, had effective communication, and robust support networks. Specific strengths included: Varied and individualised development plans and access to a wide-range of support professionals. Areas for improvement related to: Opportunities to train with senior players; interest shown in life outside of sport; and discussing players' well-being. **Discussion** The results suggest that the development environments of elite youth academies are perceived to be of a good quality. However, while academies appeared strong in areas related to organisation, planning, and coaching; they were not as strong in areas related to players' socio-emotional needs. From an applied perspective, the findings underline the need for academies to pay close attention to the psychosocial environments they create for players at a critical stage in their development. **References** Mills, A., Butt, J., Maynard, I., & Harwood, C. (2012). Identifying factors perceived to influence the development of elite football academy players in England. *Journal of Sport Sciences*, 30, (15), 1593-1604. (2003) Identifying talented players. In: Science and Soccer II (Eds. T. Reilly and A.M. Williams), pp. 307-326. London: Routledge.

### **DEVELOPMENT OF A "PERFORMANCE TRANSITION" PROGRAMME FOR OLYMPIC AND PARALYMPIC ATHLETES TO SUPPORT GAMES' READINESS AND RECOVERY.**

Moore, P.1,2, Lynch, K.1, Sheridan, D.1, Lyons, D.1

*1: Irish Institute of Sport (Dublin, Ireland), 2: Manchester Metropolitan University (UK)*

**Introduction** Research into athlete career transitions has predominantly focused on transitions into and out of elite sport with less attention on within-career transitions (Wylleman & Lavallee, 2004). Similarly, whilst the in-games and post-games experiences of athletes have been well documented, little has been written regarding the pre-games period. For those charged with providing support to athletes there is a relatively sparse evidence base in the preparation for the Olympic games. The aim of this paper is to outline the development stages in the process of designing a holistic transition-based model for support services to Olympic and Paralympic athletes in the preparation for the London Games. **Methods** One year prior to the London Olympics, the Irish Institute of Sport (IIS), in partnership with the performance directors of sports aspiring to qualify athletes for the Games, identified an athlete pool of 219 potential Olympic (155) and Paralympic (64) athletes. Between September and December 2011, athletes were surveyed by interview (in person, skype or telephone) to build a profile of potential Olympians in the year before the Games. The survey addressed four areas – qualification pathway; training, funding, lifestyle and health status; support services used; and perceived critical performance factors. **Results** 201 athletes responded to the survey invitation (92%). Three qualification pathways were identified; via standards (ie athletics); via direct competition and elimination (ie boxing, sailing) and via ranking points (ie triathlon, pentathlon). At the end of the data collection period, 22 Olympic athletes and 34

Paralympic athletes had achieved qualification status. This represented around one third of the final Olympic team and two thirds of the final Paralympic team. 67% of athletes were carded (funded). 40% classified themselves as full-time athletes, 37% as full-time plus part-time education or employment and 23% as full-time in education or employment. 25% of athletes indicated that they had no plans or were deferring planning until after the Games. Of the full-time athletes, 48% had no plans for after the games. Critical performance factors identified by athletes most frequently were physical (104), technical (73), mental (63) and lifestyle (31). Discussion Based on the profiles generated, sport and athlete-specific interventions were developed. Of particular interest was the lifestyle profile relating to post-games planning. Identification of "at-risk" profiles (full-time, no post-games plans) allowed for early intervention and specific preparation for the post-games support. Wylleman, P., & Lavallee, D. (2004). A developmental perspective on transitions faced by athletes. *Developmental sport and exercise psychology: A lifespan perspective*, 507-527.

#### EFFECTS OF PROGRESSIVE FATIGUE AND EXPERTISE ON SELF-TALK CONTENT IN RUNNING: AN AMBULATORY ASSESSMENT APPROACH

Nieuwenhuys, A., Veltman, L.J., Braakman-Jansen, L.M.A., Davis, P.A.

*Behavioural Science Institute, Radboud University Nijmegen*

**Effects of Progressive Fatigue and Expertise on Self-Talk Content in Running: An Ambulatory Assessment Approach** Arne Nieuwenhuys (1)\*, Laurens J. Veltman (2), Louise M.A. Braakman-Jansen (2), & Paul A. Davis (3) (1) Behavioural Science Institute, Radboud University Nijmegen, The Netherlands (2) Institute for Behavioral Research, Twente University, The Netherlands (3) Department of Sport Development, Northumbria University, United Kingdom  
**Introduction** In this study we investigated how progressive fatigue differentially affects self-talk use (nr. of statements) and content (instructional, motivational, positive, negative) in recreational and competitive runners, by using a new ambulatory assessment method called "PsyqRun" – a smartphone application that enables online assessment of psychological states and variables (e.g. self-perceived exertion, self-talk) during exercise. **Methods** 42 participants (20 recreational runners, 22 competitive runners) performed a strenuous running exercise in which they attempted to reach a maximal distance over eight 2-minute intervals. Self-perceived exertion (RPE) and self-talk were assessed at the end of every interval by using the PsyqRun application. Heart rate was measured continuously with a heart rate monitor. **Results** RPE scores and heart rate measurement confirmed that fatigue systematically increased as a function of exercise interval. Under high levels of fatigue (i.e., at later intervals) participants generally reported more self-talk statements than under low levels of fatigue (i.e., at earlier intervals). More specifically, with increasing fatigue, participants' use of positive and motivational self-talk strongly increased at the cost of instructional self-talk, which strongly decreased. Finally, a marginally significant effect of expertise ( $p = .058$ ) indicated that competitive runners used more instructional self-talk than recreational runners – also under high levels of fatigue. **Discussion** Using modern smartphone technology, the current study was the first to provide an online assessment of fatigue and self-talk in running. Findings indicated that participants actively focused on their running technique at the start of the exercise (e.g., "keep running smoothly") but shifted to self-motivation and perseverance during later intervals, when they became more fatigued (e.g., "just one more interval!"). These results are consistent with research on fatigue and attentional focus and indicate that – with increasing fatigue – runners' thoughts and attention are automatically drawn inwards towards the monitoring of internal states and processes. Finally, it is suggested that by using more instructional self-talk, competitive runners may be able to maintain a more efficient running technique, also under high levels of fatigue. Further development of the PsyqRun application should clarify this matter, by relating the assessment of self-talk to objective measures of running technique and performance.

#### EXERCISE-INDUCED FATIGUE CHANGES THE WIDTH AND DIRECTION OF ATTENTION FOCUS

Aragonés, D.1, Marbà, J.1, Hristovski, R.2, Balagué, N.1, Tenenbaum, G.3

*1: INEFC Barcelona (Spain), 2: Ss. Cyril and Methodius University, Skopje (Rep. of Macedonia), 3: Florida State University (USA)*

**Introduction** Research has reported a shift from the dissociative to the associative mode of attention as a function of workload accumulation (Balagué et al., 2012; Tenenbaum, 2001). However, the effects of exercise-induced fatigue on the width and direction of thought contents have yet to be investigated. The aim of this study was to examine the effects of a constant-power cycling exercise performed until voluntary exhaustion on the width (broad/narrow) and direction (internal/external) of attention focus. **Methods** Twelve physically active participants previously familiarized with the experimental procedures performed twice a constant-power cycling exercise at 80% of their maximum workload until voluntary exhaustion. The first aimed at establishing their intrinsic dynamics of attention focus. The second required participants to impose and maintain any Task-Unrelated Thought (TUT) and report back about changes in their thought contents by using a key word. After the test they were interviewed in order to describe more precisely those thoughts, which were classified as IB (internal/broad), EB (external/broad), EN (external narrow) or IN (internal/narrow). Time spent in each of these thought subcategories and the entropy of thought dynamics throughout the trial were calculated and compared by non-parametric repeated measures Friedman ANOVA. **Results** All participants started the second test with thoughts classified as IB. The Friedman ANOVA revealed a significant effect of exertion time on IB ( $X^2(12, 4) = 35.41, p < .0001$ , decreasing probability), and IN ( $X^2(12, 4) = 28.60, p < .0001$ , increasing probability). The Friedman ANOVA applied to the entropy change showed a significant effect of exertion time on the entropy of thought dynamics,  $X^2(12, 5) = 32.9, p < .0001$ . **Discussion** Although no specific TUT subcategory (IB or EB) was required by researchers, all participants started the second test with IB. However, it could not be maintained when effort accumulated and EB, EN and IN were emerging and stabilizing. This produced a dominant metastable thought dynamics with switches between the different thought subcategories. As fatigue developed, IB (which requires more active degrees of freedom), lost its stability, whereas stability was gained by IN. Minor changes were noticed in EB and EN. In conclusion, the width and direction of attention focus was changed according to the reduction of active degrees of freedom as voluntary exhaustion approached. **References** Balagué, N., Hristovski, R., Aragonés, D., & Tenenbaum, G. (2012). *Psycho Sport Ex.*, 13(5), 591-597. Tenenbaum, G. (2001). *Handbook of sport psychology* (pp. 810–820). New York, NY: Wiley.

### **META-STABLE SPATIO-TEMPORAL DYNAMICS OF TOPOLOGICALLY DEFINED AREAS OF PERCEIVED DISCOMFORT DURING CYCLING AND RUNNING UNTIL VOLITIONAL EXHAUSTION**

Slapsinskaite, A.1, Balagué, N.2, Hristovski, R.3

*LUHS (Kaunas, Lithuania), 2. INEF(Barcelona, Spain), 3 University of Ss Cyril and Methodius (Skopje, Macedonia)*

**Introduction** The aim of this study was to unravel the spatio-temporal dynamics of topologically defined areas of perceived body discomfort in trained participants while cycling and running at constant high intensity until voluntary exhaustion. **Methods** Eleven students (7 males, 4 females),  $M=20.83$ ,  $SD=1.27$  years old, previously familiarized with the experimental tasks participated voluntarily in the study. They performed a constant cycling and running exercises, respectively, at an intensity corresponding to  $RPE=15$  (Borg's RPE 6-20 scale) until voluntary exhaustion. During both exercises they self-monitored and reported the locations of pain, discomfort/strain according to a scoring template for pain drawing (Margolis et al. 1986) every 15s. These locations were transformed in time ordered binary vectors containing the topological configurations for each time interval. A hierarchical principal component (PC) analysis of these vectors was performed to obtain the temporal structure and dynamics of discomfort perceptions. **Results** Maximum number of obtained primary PC by HPCA was 7 and the minimum was 3 in both tasks. The average proportion of explained variance by the set of PCs was 90.56% and 92.00% for the cycling and the running task, respectively. Each primary component obtained the largest projections of temporal vectors containing topological information about the active areas. These primary components were correlated, so a higher order structure was revealed. For most of the participants only one general PC was obtained in both tasks, signifying a highly correlated perceptual dynamics. Component scores revealed that in both tasks areas 17 and 18 (left and right quadriceps area) were predominantly active as well as the area 49 (left knee joint) specific in the cycling task. Toracal discomfort was only detected in the running task. Other areas were making temporary motifs and were idiosyncratically distributed among participants. **Discussion** The dynamics of body discomfort areas showed a clear metastable behavior characterized by intermittent integration and segregation of distinct topologically defined communities. These communities almost invariably contained a few persistent areas which were active over the whole period of exercise. These areas were the skeleton of the globally correlated activity of topologically local discomfort perceptions. We further hypothesize that this metastable dynamics is formed by a cooperative action of peripheral afferent information coming from active body regions during the exercise and the attention focus of participants. **References** Margolis, R.B., Tait, R.C. & Krause, S.J. (1986). Pain, 24, 57-65.

### **THE FLUCTUATING DYNAMICS OF THE RATING OF PERCEIVED EXERTION CHANGES WITH EXERCISE INTENSITY**

Aragonés, D.1, Aguirre, C.1, Hristovski, R.2, Balagué, N.1, Tenenbaum, G.3

*1: INEFC Barcelona (Spain), 2: Ss. Cyril and Methodius University, Skopje (Rep. of Macedonia), 3: Florida State University (USA)*

**Introduction** Recent research has shown that changes in the rating of perceived exertion (RPE) have a dominant fluctuating dynamics (alternating increased and decreased perceptions) during constant-power cycling (Aragonés et al., submitted). The aim of this study was to compare the RPE dynamics at different constant-power cycling intensities (from somewhat hard to extremely hard). **Methods** 51 voluntary physical education students (27 males and 24 females), previously familiarized with the experimental procedures and randomly assigned to 4 groups, performed a constant-power cycling exercise until voluntary exhaustion at different intensities corresponding to 13, 15, 17 and 19 on the Borg's RPE 6-20 scale. RPE changes, reported when occurring, were recorded during the trials. The individual time series of increases/decreases reports were divided into non-overlapping temporal windows and the percentages of RPE increases were calculated for each window. The differences were analyzed by means of non-parametric repeated measures Friedman ANOVA. Effect sizes (Cohen's  $d$ ) were computed to demonstrate means' differences where effects reached accepted significance level. **Results** The Friedman ANOVA showed a fluctuating dynamics during the whole trial in the RPE 13 group ( $X^2(13, 4) = 6.72$ ,  $p < .15$ ) and a dominant fluctuating dynamics changing to non-fluctuating dynamics (only increased perceptions) close to voluntary exhaustion in the RPE 15 group ( $X^2(12, 4) = 25.29$ ,  $p < .0001$ ). Cohen's  $d$  values were: 0.19, -1.45, and -1.69 for means between the first and third, first and fifth, and third and fifth time window, respectively. A dominant non-fluctuating dynamics was found during the whole trial in the RPE 17 and RPE 19 groups, respectively. **Discussion** Results show that although a fluctuating RPE dynamics was dominant during the somewhat hard (moderate) and hard cycling intensities, the last period in the hard exercise performed until voluntary exhaustion and the whole trial in the very hard and extremely hard cycling exercise were characterized by a non-fluctuating RPE dynamics. **In conclusion**, the RPE fluctuating dynamics changes according to the exercise intensity. **References** Aragonés, D., Balagué, N., Hristovski, R., Pol, R., & Tenenbaum, G. *Psycho Sport Ex.* (submitted)

### **CARDIORESPIRATORY FITNESS IS ASSOCIATED WITH COGNITIVE FLEXIBILITY IN PREADOLESCENT CHILDREN**

Kamijo, K., Bae, S.R., Masaki, H.

*Waseda University*

**Introduction** Recent neuroelectric studies using event-related brain potentials, and in particular the P3 component, have suggested that greater cardiorespiratory fitness is associated with better cognitive control in children (Hillman et al., 2009; Pontifex et al., 2011). The goal of this study was to provide new insights into the association between cardiorespiratory fitness and cognitive flexibility, which is one aspect of cognitive control, by manipulating the probability of trial types during a modified flanker task. **Methods** Preadolescent participants were separated into higher-fit and lower-fit groups according to their performance on a field test of cardiorespiratory capacity. We compared higher-fit and lower-fit children's task performance and the P3 component during a modified flanker task performed under two conditions, in which the probability of congruent and incongruent trials was manipulated, such that in the mostly congruent condition, 70% of trials were congruent and 30% were incongruent, whereas in the mostly incongruent condition, 30% of trials were congruent and 70% were incongruent. **Results** There were no significant differences in fitness between the groups on task performance measures. Neuroelectric data indicated larger P3 amplitude for the higher-fit group relative to the lower-fit group, replicating previous findings (Hillman et al., 2009; Pontifex et al., 2011). Further, planned comparisons revealed that higher-fit children had larger P3 amplitude relative to lower-fit children in the mostly incongruent condition, whereas no group difference was observed in the mostly congruent condition. **Discussion** It has been suggested that when most trials are incongruent, adult participants would be biased toward adopting a proactive control strategy to optimize task performance within the environment, which reduces conflicts with increased and sustained lateral prefrontal cortex activation (De Pisapia and Braver, 2006). Based on this theory, the larger P3 amplitude observed in the higher-fit group for the mostly incongruent condition might reflect a strategic shift from bottom-up reactive control to top-down proactive control. These data suggest that greater cardiorespiratory fitness is associated with an increased flexibility in the modulation of cognitive control networks involving the prefrontal cortex. **References** De Pisapia N, Braver TS. ### **DON'T BELIEVE YOUR EYES! THE IMPACT OF VISUAL ILLUSIONS ON QUIET EYE, KINEMATICS**

Vine, S., Wood, G., Wilson, M.R.

*University of Exeter*

Introduction: Research has shown that prior performance can influence subsequent perceptions of target size. For example, Witt et al. (2008) found that golfers who performed well made larger target size estimates. This phenomenon has been labelled action-specific influences on perception (Witt & Proffitt, 2008) and similar findings have been reported in a number of targeting tasks (e.g. Cañal-Bruland et al., 2010). The current study will attempt to explore if the relationship between action-specific perception and performance is bi-directional. We aim to extend previous research (Witt et al., 2012) revealing that the Ebbinghaus illusion can influence performance in golf putting, by exploring potential underlying explanations for this effect. Method: Thirty participants (mean age of 20.40 years, SD = 3.36) putted to identically sized target holes that appeared smaller or larger depending on the size of surrounding 'flanker' circles (Ebbinghaus illusion). Task appraisal was assessed using the cognitive appraisal ratio (CAR, Tomaka et al., 1993); Gaze control (quiet eye; QE) was assessed using an ASL eye tracker (ASL; Bedford, MA); Putter head acceleration was assessed using an accelerometer (LIS3L06AL, ST Microelectronics; Geneva, Switzerland); Performance was assessed as distance from the hole (cm). Results: Results indicated that the illusion was effective in facilitating differences in perceived target size [4.20cm vs. 3.83cm,  $p = .003$ ] and that perceiving the hole as bigger lead to more accurate putting [24.51cm vs. 27.29cm,  $p = .027$ ]. These performance differences were underpinned by changes in task appraisal, gaze control and kinematics. Specifically, when participants perceived the target to be bigger they perceived the demands of the task to decrease [4.80 vs. 5.03,  $p = .05$ ], displayed longer QE dwell durations [294ms vs. 213ms,  $p = .004$ ] and increased putter head acceleration [2.57 ms<sup>-2</sup> vs 2.41 ms<sup>-2</sup>,  $p = .042$ ]. Discussion: This research is the first to explore mechanisms underlying how and why perceptions of target size can influence subsequent performance. Perceptually bigger targets appear to improve performance by reducing the demands of the task, and improving the gaze control and motor control of the performer. Such enquiry may eventually lead to the formulation of interventions designed to help when action-specific influences on perception become counterproductive. References: Cañal-Bruland. et al. (2012). ### **ENHANCING COMBAT SPORT DECISION-MAKING WITH AN IMPLICIT PERCEPTUAL TRAINING PROGRAM : EFFECT ON VISUAL SEARCH STRATEGY**

Milazzo, N.1, Farrow, D.2, Fournier, J.1

*1. INSEP - French Institute of Sport, 2. Victoria University & Australian Institute of Sport*

In combat sports, perceptual-cognitive abilities are indispensable in order to adapt one's actions before contact with the opponent's strike (Wilk, McNair, & Feld, 1983). Video-based perceptual training has shown a number of advantages for the optimization of these skills (Hopwood, Mann, Farrow, & Nielsen, 2011). Recently, a growing number of studies have suggested the benefits of implicit learning during video perceptual training. The present study demonstrates the effect of implicit video perceptual training on performance in the laboratory, on the field and on visual-search behavior in elite Karate athletes. Twelve elite athletes volunteered to take part in perceptual training over 12 sessions. Athletes were split into a placebo group and an implicit learning group. During video training, participants were required to place themselves in the role of one of the two fighters on screen. When the screen was then occluded, participants had to mime the move that they would have made had they been in the fight situation that they were observing. In order to facilitate implicit learning, the results of the sequences were not disclosed and no instructions were given during or after the training sessions. In addition, participants were required to process a secondary task simultaneously (counting in two's aloud). The placebo group had to hit targets on a dummy as soon as they lit up. Results indicated a significant increase in decision accuracy for the implicit learning group from pre-test to post-test compared with the placebo group. Furthermore, a change in eye movement behavior was observed post-test for implicit group only. Indeed, results highlight for this group a significant decrease in the mean number of visual fixations per sequence from pre-test to post-test. Analysis of means of fixation locations for both groups indicate that participants tended to fix their eyes on the upper-body. This study shows the effectiveness of implicit video training session on decision-making in karate. We hypothesize that participants learned to identify and interpret environmental cues in order to better understand the situation. In addition, as the results for eye movements have shown, it is also likely that the performance increase was a result of more effective visual search behavior of the participants, who were better able to read the kinematic information coming from their opponent's movement. ### **KEEP YOUR EYE ON THE BALL? EXAMINING THE IMPORTANCE OF QUIET EYE LOCATION.**

Vine, S., Lee, D., Uiga, L., Wilson, M.R.

*University of Exeter*

Introduction: Research has established the benefits of QE training (QET) for the acquisition and resilient performance of targeting skills (Vine et al., 2012). In this experiment we manipulated QE location in putting, to explore how QET aids performance. If the QE provides visual information required for planning and execution (Moore et al., 2012), then adjusting its location should have an adverse effect on performance. Methods: 33 novices (mean age = 22.82, SD =2.98) performed putts in one of 3 groups. All groups followed a QET intervention (as Moore et al., 2012) but the location of the QE varied. Group 1 were asked to fixate the back of the ball (ball); group 2 a paper ball placed on the green 45cm above the ball (above); and group 3 a paper ball placed on the green 45cm in front of the ball on the putting line (front). Participants performed 40 baseline putts (B) from 10 feet, followed by 320 training putts, 80 retention putts (R) to assess learning, and 20 pressure putts (P) to assess resilience against anxiety. Anxiety was manipulated via financial incentives and assessed using the mental readiness form (MRF-3, Krane, 1994). Performance was measured as distance from the hole (cm). Gaze was measured

using an ASL mobile eye tracker. Performance and QE data were subjected to a 3 group vs. 3 condition (B, R, P) ANOVA. Anxiety data were subjected to paired sample t-tests (R vs. P). Results: Performance: ANOVA revealed a significant main effect for condition [ $F(2,60) = 37.36, p < .001$ ], but no group [ $F(2,30) = 1.27, p = .30$ ] or interaction [ $F(4,60) = .31, p = .87$ ] effect. All groups improved from B to R ( $p < .001$ ) and remained robust at P ( $p = .97$ ). QE: ANOVA revealed a significant main effect for condition [ $F(2,54) = 126.44, p < .001$ ], but no group [ $F(2,27) = .83, p = .45$ ] or interaction [ $F(4,54) = 1.16, p = .34$ ] effect. All groups displayed longer QE at R ( $p < .001$ ), which remained stable at P ( $p = .93$ ). Anxiety: Anxiety was higher at P compared with R ( $p < .001$ ). Conclusion: Fixating the ball may not be crucial to achieving the benefits of QET. There are 2 potential explanations for this finding. (1) QE training simply promotes an external focus of attention (Wulf et al., 2007); (2) the above and front groups were able to use peripheral vision to gain appropriate target information. Future research could examine putter head acceleration to establish if movement variability increases when QE location is changed. References: Krane V. (1994). ## EYE-TRACKING INVESTIGATION OF ELITE GOLFERS IN FIELD SITUATIONS

Fournier, J., Bernier, M.

*INSEP - French Institute of Sport & University of Caen*

Most published studies on gaze-analysis are based on indoor putting. Gaze strategies of golfers on the field are unknown partly for technical reasons. Eye tracking devices were used indoors to prevent conflict between sunlight and the infrared light used to create corneal reflection in order to track the gaze. In addition, most studies involve a task of repeated putting. In these cases, judging the slope of a green (reading the green) is not taken into consideration, as the task consists of putting on a flat, artificial green: a mat, with an artificial continuous light. All shots are identical from one try to the next, so no information other than the distance and the smoothness of the mat is needed. In contrast, the present communication reports observation of gaze strategies of golfers putting in their natural setting. The participants were 12 elite junior golfers, alternating identical putts (same hole) and different putts (different holes) on a grass putting green. Gaze was recorded using the 2012 SMI tracking glasses connected to a portable recording unit, allowing outdoor gaze monitoring. Results showed that the pre-shot routines (duration, number of practice swings) were different across putts and across golfers. Gaze strategies were also different across golfers and across putts. When repeating the same putts, golfers took less time and fewer looks at the hole and ball trajectory compared to putting in different holes each time. Hence, regardless of the gaze training intervention (Vine, Moore, & Wilson, 2011), it seems urgent to explore the ability to read the green in real life settings. Vine SJ, Moore LJ and Wilson MR (2011) Quiet eye training facilitates competitive putting performance in elite golfers. *Front. Psychology* 2:8. doi: 10.3389/fpsyg.2011.00008

## WHEN THREAT DUE TO PHYSICAL ENGAGEMENT IMPROVES OUT-GROUP ATTITUDES : THE IMPORTANCE OF THE CONTEXT IN INTERGROUP RELATIONS

Rull, M.

*1 : Normandie Université, France ; 2 : UNICAEN, CESAMS, F-14032, France*

Introduction One main stake in physical education and in the policies of social integration through sport is to improve intergroup attitudes. Theoretical models only explain intergroup relations by intergroup emotions and cognitions (Allport, 1954; Fiske et al., 2002). However, affiliation under threat (e.g., Schachter, 1959) assumes that a shared threat improves interpersonal relations. We expect that an intergroup contact under shared threat, nevertheless independent of intergroup emotion and cognition, improves intergroup attitudes. Methods Thirty-six pupils of traditional classes who were inexperienced climbers (18 girls and 18 boys) ( $M = 14.03$  years old,  $SD = 1.31$ ) participated with two disabled pupils from a special education class in the same climbing exercise that took place under threat (at the top of the climbing area) or in control condition (bottom of the climbing area). Judgments of warmth ( $\alpha = .87$ ), positive behavioral intentions ( $\alpha = .86$ ) towards special education pupils (Fiske et al., 2002) and implicit out-group attitudes (Corcoran et al., 2009) were measured. Results The threatening context improved judgments of warmth ( $F(1, 34) = 16.48, p < .0001$ ), positive behavioral intentions ( $F(1, 34) = 38.71, p < .001$ ) and implicit attitudes ( $F(1, 34) = 18.70, p < .001$ ) towards special education pupils. Besides the threatening context decreased negative behavioral intentions ( $F(1, 34) = 9.18, p < .004$ ) towards special education pupils. Discussion This study shows the prosocial dimension of body commitment at implicit and explicit levels of intergroup attitudes. Physical activities and more consistently risky sports appeared as efficient vectors of policies of social integration and struggle against discrimination. From a more theoretical perspective, these results provide evidence that the context and more specifically the physiological and psychological states it carries are neglected in the models which explain the building and evolution of intergroup relations. ## THE EFFECT OF PHYSICAL EXERCISE IN HYPOXIA CONDITION IMPROVES REACTION TIME

Lemos, V.A.1,2, Bittar, I.G.L.2, Caris, A.V.1, Silva, E.A.1,2, Rosa, J.P.P.1,2, Santos, R.V.T.2,3, Lira, F.S.1,2, Antunes, H.K.M.2,3, Tufik, S.1,2, De Mello, M.T.1,2

*1: UNIFESP (São Paulo, Brasil), 2: CEPE (São Paulo, Brasil), 3: UNIFESP (Santos, Brasil)*

Introduction Although hypoxia condition impairs the reaction time, some studies show that physical exercise in normoxia condition can improve reaction time. The aim of this study was to evaluate the influence of acute exercise on reaction time in hypoxia condition equivalent to 4500-m for 29 hours. Methods Thirty-eight healthy men were enrolled in this study, randomly divided into four groups: (Hypoxia  $n = 10$ , Normoxia  $n = 10$ , Exercise in Normoxia  $n = 10$  and Exercise in Hypoxia  $n = 8$ ). The mean values were: age (years) - ( $23 \pm 8$ ), body mass (kg) - ( $71 \pm 7$ ), height (m) - ( $1.76 \pm 0$ ), BMI (kg/m<sup>2</sup>) - ( $22 \pm 9$ ) and VO<sub>2</sub> peak (ml/kg/min) - ( $47 \pm 4.2$ ). The reaction time was evaluated using the Vienna Test System (Schuhfried, 1998), in all groups. In the groups that performed the sessions of exercise, the test was applied on the first day before the first session and after a night's sleep it was reapplied after the second exercise session of 60 minutes at 50% VO<sub>2</sub> peak- ml/kg/min. The groups hypoxia and exercise in hypoxia were exposed in hypoxic condition in Colorado Altitude Training™/12 CAT-Air Unit). Statistical analyzes were conducted using the Mann-Whitney U test with Bonferroni correction, the level of significance was set at  $p \leq 0.016$ . Results There was a significant improvement in reaction time ( $p = 0.0005$ ) in the hypoxia exercise group when compared

with the hypoxia group. In the hypoxia group there was a significant worsening on reaction time ( $p = 0.0005$ ) when compared with normoxia group. The exercise in normoxia group presented a significant improvement on reaction time ( $p = 0.003$ ) when compared with normoxia group. Discussion These results are similar to experimental conditions performed at sea level (Davranche et al., 2009). This study shows that even in conditions of hypoxia, which impairs reaction time, (Pettrassi et al., 2012), can be reversed by exercise performed under these conditions. This association may occur due the effect of exercise on improving sleep quality (Youngstedt et al., 1997), which might improve reaction time. Thus, we suggest that exercise, in hypoxia condition, can improve the reaction time; however further studies are needed to better understand the mechanisms involved. #### FEATURES OF SPORTS ORGANIZATION BRANDING STRATEGY FORMATION

Valantiniene, I., Kromalcas, S.

*Lithuanian Sports University*

Introduction In recent years, scientists actively creates and develops brand-building models in an effort to fill in the missing gaps in sports branding strategy theory. In the modern world sport organizations are focusing more on the marketing strategies of implementation and purposeful image. Many researchers of this field, studying the marketing process emphasises that investing in brand awareness is purposefully and long. Well and carefully chosen organizations branding strategy – the real value of the organization, which influences the success of the organization, while at the same time increasing the value to the organization. Branding strategy provides organizations with the formation of the market value added, which enhances and ensures reliability and competitive advantage. Methods – systematic, comparative and logical analysis. Results Sports branding concepts analysis by macro level revealed that in the literature dominates two main provisions: some theorists states that this activity is designed to create, maintain or change people's attitude towards certain sports, others opinion includes the development of design, planning and communication delivery name and identity, in order to form or manage reputation. The analysis proposed by the authors of branding concepts, it can be said that there is no consensus on sports branding and brand development concepts of consumption. Done sports organizations branding models and their elements revealed, that most of the models have clearly defined the elements, but they are often intermittent nature; unclear design consistency; sports brand development models are not sufficiently detailed and informatively analyzed a limited amount of the factors often impose final sports branding actions that leads sports brand development models incompleteness and limited practical use. #### HOW DOES ADVERTISING THROUGH SPORT WORK? EVIDENCE FROM MONTENEGRO.

Popovic, S.1, Bjelica, D.1, Jaksic, D.2, Georgiev, G.3

1: *University of Montenegro (Niksic, Montenegro)*, 2: *University of Novi Sad (Novi Sad, Serbia)*, 3: *Ss. Cyril and Methodius University (Skopje, Macedonia)*

Introduction The first purpose of this study was to compare consumers' attitudes towards advertising through sport with their attitudes towards advertising in general. The second purpose of this study was to analyze the relationships between beliefs about and attitude towards advertising through sport, mostly due to the reason that it was expected that companies should profit from the use of sport as an advertising medium and the identification of specified beliefs influencing to positive attitudes would enhance advertising strategies. Methods The data was collected from randomly selected 433 stakeholders in Montenegro (male: 217; female: 216) during the spring semester of 2010. The system of variables consist 45 items, modeled by seven-point Likert scale, of attitudes and beliefs about and 6 demographic items that were modified from Pyun (2006) original items to fit each area. The factor analysis were employed to take the best item of each question, while Wilcoxon Signed Ranks Test was used to test consumers' attitudes towards advertising through sport with their attitudes towards advertising in general. Then, Optimal Scaling Method was employed to reveal the relationships between beliefs about and attitude towards advertising through sport. Results The customers' attitudes towards advertising through sport were significantly more positive than their attitudes towards advertising in general, while all beliefs, except materialism significantly influenced attitude towards advertising through sport. Discussion The current findings support the authors' hypothesis that the consumers' attitudes toward advertising through sport in Montenegro are significantly more positive than advertising in general. These findings were consistent with the previous evidences (Mittal, 1994; Schlosser et al., 1999; Pyun et al., 2012). However, this study that recruited whole Montenegro's population didn't show consistent findings with the previous studies that were conducted using college students as a research sample (Pyun & James, 2009, 2011; Pyun et al., 2012), mostly due to the reason this study found much more advertising beliefs significantly influenced consumers' attitude towards advertising through sport. The authors believe these findings were caused because the sample covered whole population, but it could be also caused, due to the reason that the generalisability of results could vary from one population to other populations. Anyway, these findings with certainty provide a cornerstone for understanding the growth of consumers' attitude towards advertising through sport in Montenegro. ### **PROFILE OF SKI RESORTS CONSUMERS: A CUSTOMER SATISFACTION APPROACH**

Miragaia, D., Martins, M.

*University of Beira Interior*

**Introduction** The global ski destination market is highly significant, involving around 80 countries worldwide with an annual total of approximately 400 million skier visits (Vanat, 2010). Identifying the attributes most valued by tourists generates a tool for developing strategies able to enhance the competitiveness of that tourist destination (Kyle, Theodorakis, Karageorgiou, & Lafazani, 2011). Therefore, the propose of this study is to analyze the degree of satisfaction with the services provided by a ski resort. Methods A questionnaire adapted from Hudson and Shephard (1998), was applied to 200 tourists (57.5 % male; 42.5 % female) in the ski resort Serra da Estrela (Portugal). To determine de consumer profile, a factor analysis was done to identify the satisfaction factors, used subsequently in cluster analysis. Results Five factors were identified with the preferences of different consumer segments discriminated through the identification of five clusters. Significant differences between clusters were found as regards: gender ( $X^2 = 10.75$ ,  $P < .05$ ); reason for the journey ( $X^2 = 13.14$ ,  $P < .05$ ); length of stay ( $X^2 = 28.72$ ,  $P < .05$ ); and experience in other winter sports resorts ( $X^2 = 26.16$ ,  $P < .05$ ). Discussion The main reason for visiting the ski resort was for leisure/holidays (77%), making understandable the trend to appreciate attributes ranging beyond specific ski attributes. On the other hand the trend demonstrated by visitors who never experienced other resorts and demonstrated their completely satisfaction about the resorts services, must be carefully analyzed. This information must therefore be taken into account by managers who should identify what proportion of a season's clients display these characteristics as they may prove less demanding. We also conclude that this destination is visited mostly by consumers aged between 20 and 40, who live near the resort and stay only 1-day, indicating the need to attract consumers staying for longer periods of winter sports practice and consequently consuming accommodation and restaurant services and thereby contributing to developing regional tourism. We would also emphasise that the means attributed to the different factors related to levels of satisfaction vary between 2.50 and 2.72. This fact suggests the opportunity for greater improvement in a set of attributes that would drive improved consumer satisfaction with intervention in aspects able to boost destination competitiveness. (2011). *Journal of Park and Recreation Administration*, 28(1), 1-15. Vanat, L. (2010). Overview of the key industry figures for alpine resorts. (pp. 56). Genève.

### **UNIFYING SPORT SCIENCE WITHIN HIGH PERFORMANCE SPORT: REFLECTIONS ON BEST PRACTICE FROM CANADA, AUSTRALIA NEW ZEALAND AND QATAR.**

Patrick, T., Hatcher, D.

*Aspetar Orthopaedic & Sports Medicine Hospital*

**Introduction** Many have argued for the need to integrate appropriate sport science and medicine support into training in order to facilitate enhanced performance (e.g. Smith & Norris, 2000; Tuffey Riewald, 2002). While there is ample evidence within the literature pertaining to the efficacy of sport science interventions (e.g. Burkett & Mellifont, 2008) and on the research needs for elite coaching practice (Williams & Kendall, 2007), little has been written on the nature of effective sport science service delivery as it pertains to enhancing coaching practice and athletic performance. Methods Dorgo (2009) acknowledged, "that most aspects of the participant's practical knowledge were developed through field experience, real-life practices, and other professionals" (p. 17). Given the author's collective experience totaling over 50 years working in high performance environments as part of National Sport Institutes in Canada, Australia, New Zealand and Qatar, key themes that emerged as part of several learning conversations together eventuated into the emergence of important characteristics of effective integration. Results and Discussion When sport science integration was optimal, a shared philosophy existed amongst the coaches, athletes and sport scientists. This process often required a series of discussions where all team members shared their personal and professional perspectives from which they grounded their practice. Frequent interaction and effective communication were also essential components. Whenever possible, team members achieved and maintained an interdisciplinary form of interprofessional collaboration. A coach driven approach was adopted and respected. As Petosa (1996) stated "the effectiveness of the performance enhancement program is dependent on the coaches' acceptance and confidence in the program" (p. 64). It was also important for sport science teams to slowly and purposefully integrate team members into the program (Smith & Norris, 2000). Finally, the implementation of practically relevant knowledge became one of the most important outcomes for sport science teams to achieve. References Dorgo, S. (2009). ### **INVESTIGATING THE SPORT PARTICIPATION LEGACIES OF THE LONDON 2012 OLYMPIC GAMES: CAN THE OLYMPIC GAMES INCREASE SPORTS PARTICIPATION IN UNPOPULAR SPORTS?**

Pappous, S., Camps, A.

*INEFC- KENT UNIVERSITY*

Research scholars are currently questioning the possible effects that Mega-Sport Events might have in increasing the sport participation of the host population at a grass root level. One of the most prominent key pledges set out from the organisers of the 2012 Games was to make the UK a world-leading sporting nation and to increase sport participation. However evidence for the effect of the Games on sustained participation and health legacies in sport is open to doubt. Research does not offer clear results to argue that Mega-Sport Events increase long-term sport participation. There is much anecdotal evidence based on "mega events" and their assumed positive effect upon grass roots participation for the host nation, although there is scarce empirical evidence to support it. This study is a contribution to the lack of empirical evidence of the long term influence of such a mega event. Sport England has administered a standardised survey, the Active People Survey (APS) annually since 2005 which would act as a suitable tool to analyse the effects of the London 2012 Olympic Games in decades to come. This research project will utilise the APS data as secondary data to assess the number of Judo and Fencing participants prior to the Games. Judo and fencing have being targeted for a measure of a boost in grass roots participation because both

sports are relatively unpopular Olympic sports in UK (0.1% of people that are active participate in those two Sports (AP2, 2008)) so any changes of participation as a percentage would be greater, and more identifiable. Objective: The aim of this project is to investigate whether the grass root participation of two unpopular sports in UK (Judo and fencing) in the county of Kent has noticeably changed following the London 2012 Olympics in comparison to 2005 after the Olympics were announced to be held in London. Methodology: The participant sample to be used in this research comprises of coaches and managers of Judo and Fencing clubs. This is a multi-disciplinary study using a mixture of quantitative and qualitative research and both primary and secondary data. The qualitative data consisted of recorded semi-structured interviews with coaches and managers. The quantitative data are based on an analysis of the membership rates of the participants since from 2005 till 2013.

### **SPORTS AID – WHAT IS NORWEGIAN SPORTS AID ORGANIZATIONS TRUE MOTIVATION FOR THEIR DONATIONS?**

Moen, A.

*Norwegian University of Science and Technology*

**Introduction** Norwegian aid to countries in Africa, especially south of Sahara, goes all the way back to the 1950s with the Norwegian Peace corps (Fredskorpset, 2012). Back then they focused on aid to hunger-crisis or post-war reparations. This thesis is going to look closer at the two biggest sports aid organizations in Norway today – Right to Play and Norwegian Sports Organizations aidprogramme – Sports Peace corps. The aim here is to look closer at the motives behind their aid and who benefits from this. Methods I chose to use qualitative method, both interviewing and document analysis (Rapley, 2007; Tjora, 2010; Widerberg, 2005) and people from the organizations were interviewed. Because of long distances they were interviewed by phone. The analyzed documents were political documents and the guidelines from both of the organizations. Results Sports Peace Corps representatives repeatedly said that they had to do things Norads way to make sure they got financial aid. When Spc wright their recommendation letter they have a recipe for what it should say. Rtp on the other hand are not willing to change their visions or goals just to please Norad. Both Rtp and Spc works with local partners and their grassroots-projects. The difference between the two is that Rtp is doing it for the kids growing up in underdeveloped countries, while Spc is doing it for the Norwegian volunteers who go to Africa and their cultural experiences. They want the teenagers to learn about themselves first and foremost, almost like a cultural and spiritual experience that they can talk about when they get back to Norway. **Discussion** The research shows big differences between the two organizations. Rtp works for the recipients in Africa, while Spc works for the teenagers that go to Africa. Which one is better than the other? They both work in the hopes of a better world. They both work with local partners in the countries they go to. On the other hand, both organizations gets economic aid from Norad, and it is obvious that Norad has a lot of power through their donations to sports aid. This might be fair regarding the millions they donate to aid every year. **References** Fredskorpset. (2012). Fredskorpset, <http://fredskorpset.no/no/Fredskorpset/>. Retrieved 08.03.12 Rapley, Tim. ### **SPORT AS A FOUNDATION FOR THE CONCEPT OF REGIONAL DEVELOPMENT: A CASE STUDY FROM THE CZECH REPUBLIC**

Schwartzhofová, E., Skoumal, J.

*Palacky University*

**Introduction:**The new political-economic position within the framework of the new regional structure of the Czech Republic has lead, among other things, to an increase in regional disparities. The dynamic growth of sports tourism effectively contributes to improving the situation of regions with structural problems. In economically weak regions sports tourism has served a so-called "multiplier effect" in contributing to their development. In the strategic management of the regions, support for sport can significantly contribute to the development of tourism and thus to the development of the region. For a client to choose a destination, the secondary offering – infrastructure – must also be suitable. Every city and region today includes a conception for sports, as well as a conception for tourism development, in its strategic development plan. The main objective of this conception is the modernization, renovation, construction, operation or maintenance of sports and recreational facilities. This paper deals with the issue of sport as a basis for regional tourism development. The aim is to ascertain the extent to which the regions take advantage of tourism as a tool for regional development in their programs using the specific example of the Olomouc region. This region was chosen for its diverse sports and tourism potential, determined by its natural conditions. The region has both flat terrain suitable for summer sports and mountains suitable for winter sports. Grant programs supporting sports connected with tourism are also an important instrument of regional policy. Currently, the main sources of funding for individual activities in the Czech Republic are EU structural funds. The operational objective is also to analyze operational programs aimed at financing the planned activities and projects within these strategies. **Methods:**The foundation of this study based on an analysis of regional policy for the development of sport and tourism consisted of the four strategic documents. We have chosen a qualitative approach for our basic understanding of the problems. The study and content analysis of documents provided the data, through which the link between tourism and regional development was then interpreted. These documents form the only data base for the study. In analyzing the documents we used our own system of classifying information into categories, based on which the text was searched for occurrence of the given categories. **Discussion:**In examining the indicators listed above, it was confirmed that the supported projects in the field of sport analyzed are clearly in line with the available strategies pertaining to the given territory, which the region fully supports in accordance with its established goals and priorities. Projects receiving support in the areas observed have a positive impact on the region, its citizens and potential visitors (tourists). The area of sports and leisure is addressed in all the strategic documents examined.

### **THE REVENUE OF SPORTS CLUBS IN EGYPT - A COMPARATIVE STUDY WITH GERMAN NON-PROFIT SPORTS CLUBS**

Zoromba, M.

*Sport Economics and Sport Management*

**Introduction** Non Profit Sports clubs are some of the main social bodies concerned with the sporting activities in the Arab Republic of Egypt (Al-Kholy, 1995). These Sports clubs undertake to promote different sports and develop the teams representing Egypt in the local, regional, continental and international Olympic competitions (Abdel Maksoud, 1997). The German Olympic Sports Confederation (GOSC) states that there are more than 90,000 sports clubs comprising over 27 million memberships (GOSC, 2009). Finance plays an important role in the fulfillment of planned targets in sports clubs. The Egyptian sports clubs examined in the course of this study especially the

revenue sources. Meanwhile, different sports clubs were entered into the revenue sources presented and compared with German sports clubs and their revenue sources. Methods This study was undertaken in two parts. -The document analysis of the annual reports (2009-2010) to the Directorates of Youth and Sport of the biggest four cities in Egypt (Cairo, Alexandria, Giza and Port-Said) n=120. -The data source is the Sport Development Report (Breuer, 2007), which is a nationwide panel survey of non-profit sports clubs in Germany (2005/06) (n=2964). Results Not every sports club in both countries is using all possible sources of revenue. The majority of German and Egyptian sports club received membership fees (99%/100%), donations (80%/60%) and subsidies (62%/88%). There are also a few sports clubs which have different sources of income. 0.7% of German sports clubs get revenue through broadcasting rights and 3.3% through borrowing. In Egypt, the borrowing and its own business association were used in about 8% and 4.17% of the sports clubs. The other sources of income are here at levels between 10.83% and 46.67%. Discussion Sports clubs in both countries have several different unused opportunities that could enhance the internal funding sources. The membership fees and revenues - despite their significance as steady resource and differentiation from one sports club to another - are not sufficient to cover annual total costs of sport clubs. This basically has its origin in the system that sport clubs use for collecting their fees. References Abdel Maksoud, I. (1997). Sport und Tourismus. Kairo: Dar Al-Fikr Al-Arabi. Al-Kholy, A. (1995). ## STATE ECONOMIC REGULATION OF SPORTS IN RUSSIA

Beskrovnaya, V., Medvedev, A., Povareshchenkova, Y.

*Velikiye Luki State Academy of Physical Education and Sports*

Introduction. Modern economic research pays more and more attention to the activities of the state. State role strengthening finds its reflection in an increase of the state expenses and significant expansion of direct legal regulation of the economic life. The state support of physical education and sports is carried out by two principal methods: • direct financing of various activities and • by creating favorable conditions for sports organizations and facilities. Methods. The basis of the studies is provided by a systemic approach to the sports development as well as by methods of economic and institutional analysis, the structural and statistical analysis, socio-economic planning and prognostics. We used complex scientific approaches, such as hypothetical, deductive, abstract-logical, structural-functional, comprehensive and systemic. Results. When analyzing the model of the state physical education and sports regulation in Russia, the following is to note: • market mechanisms only insignificantly act in the regulation of physical education and sports; • the structure of the state sports governing is stable and focused on the state support provision; • physical education and sports in Russia are financed by the federal, regional and local budgets; • in 2001-2012 physical education and sports were financed in an increasing mode; annual budgetary allotments are increased; • the state carries on a paternalism policy in the physical education and sports sphere; • the basic expenses are sport events financing, maintenance of sport teams and sports universities expenses. Discussion. So, the sports sphere state regulation in Russia is based on the federal, regional and local budgets, and the state policy of paternalism in the physical education and sports area is of a tremendous importance. Sports finance analysis in Russia allows it to conclude that in the latest decade the state only gave a priority to some fields of international competition sportsmen training to a search of investments, maintenance and support of some sporting infrastructures and to international sport cooperation

## ECO-COUNTERS. STEP-FREQUENCY ANALYSIS FOR THE DESIGN OF A SPORTS-TOURIST PATH

Ingles, E., Funollet, F., Fuster, J.

*INEFC*

Introduction The main objective of the international project "FFCF: Making on the Frontier a Path Towards Education" (presented in the 07-13 POCTEFA: Operational Programme of Territorial Cooperation Spain-France-Andorra, and with an overall budget of 2,846,772) was to revitalize the territories involved (Alt Urgell, Andorra and Ariège). One of the main actions of the project was to create a path to link these territories and to give relevance to their values. Thus, the aim of this study is to evaluate the step-frequency of the path before its promoting and marketing and to evaluate the design of the route. Method 4 eco-counters were placed in 4 strategic points along the path to gather the step-frequency data (Pettebone et al., 2010). The eco-counters consist of a slab 10 cm underground, sensitive to micro pressure variations, that can discern steps, connected to a hidden counter that collects them. Thus, the method used was the re-counting of the pressures on these 4 eco-counters (Sep11-Sep12). Results The first control point (Bescaran, Cat) has a step-frequency much lower than the rest (5.7%), and it only exists in the summer season (Jun-Au). The only point frequented during the winter season (Dec-Mar) is the one in Coll de les Cases (And). The two points located in Andorra collect 80% of the total frequency. Considering the amount of hikers who have gone through the 4 control points, the maximum step-frequency estimation is 282 steps (Sep11-Sep12). Discussion It has been difficult to estimate the number of hikers going over the full path, because the route is still being tested and not completely operational: unlabelled sections, accommodations far from the points of arrival and departure, etc. We have observed that at the point of Port de Rat (And), which had been studied previously (2009), the step-frequency has not increased since the development of the path (Marquilló, 2012). This fact together with the low frequency detected in controls 1 and 4 suggest the need of promotion of the path and improvement of the signposting. Conclusions Eco-counters are a useful tool for the study of the step-frequency of a natural area (Bates et al., 2007) and, more specifically, of the suitability of a path route. We have been able to evaluate the usage of the path and therefore the efficiency of the actions undertaken for its preparation. The data has helped us to design improvements and strategies of promotion. The eco-counters can also provide data about the impact caused by erosion and pollution. **ENERGY INTAKE AND DISTRIBUTION OF MACRONUTRIENTS IN THE DIET OF ADOLESCENT SWIMMERS**

Julian Almarcegui, C., Gomez-Cabello, A., Gonzalez-Aguero, A., Gomez-Bruton, A., Matute-Llorente, A., Casajus, J.A., Vicente-Rodríguez, A.

UNIVERSIDAD DE ZARAGOZA

**Introduction** In adolescents, both total energy intake (EI) and macronutrients seem to have an important role to ensure a good bone development (Vicente-Rodríguez et al., 2008). Adolescent swimmers are required to consume a high amount of calories due to their high energy expenditure (Slattery KM et al., 2012). Therefore, we aimed to evaluate whether energy intake of adolescent swimmers is adequate in relation to their physical activity levels and to describe the distribution of macronutrients in their diet. **Methods** Twenty adolescent swimmers (11 females;  $14.68 \pm 1.73$  y) participated in the study. A 24 h dietary recall was performed by using the Helena-DIAT (Dietary Assessment Tool). CESNID table of food composition was used to calculate EI, carbohydrates, proteins and lipids. Total energy expenditure was estimated as resting energy expenditure plus the physical activity level of each participant expressed by the metabolic equivalent value plus the thermogenic effect of food. Spanish recommendations of macronutrients for the general population (50-55% of the total energy of the diet should be carbohydrates, 30-35% fats and 10-15% proteins) were taken into account to compare with the diet of adolescent swimmers. **Results** Forty five percentage of swimmers were over and 55% under EI. 95%, 77% and 82% of the participants did not comply with carbohydrates, proteins and lipids recommendations, respectively. **Conclusion** Adolescent swimmers did not follow the recommended calorie intake in terms of total energy expenditure. Macronutrients intake of adolescent swimmers diet is not well-distributed according to dietary recommendations for the overall Spanish population. Further studies should be focused on consequences of a poor diet in performance and health of adolescent swimmers and the design of interventions to achieve dietary guidelines. **References** Vicente-Rodríguez G, Ezquerro J, Mesana MI, Fernández-Alvira JM, Rey-López JP, Casajús JA, Moreno LA. (2008). J Bone Miner Metab, 26, 416-424. Slattery KM, Coutts AJ, Wallace LK. (2012). J Sports Med Phys Fitness, 52, 501-5.

**COMPARATIVE ANALYSIS OF ANTHROPOMETRIC IN DIFFERENT POSITIONS IN BRAZILIAN YOUTH SOCCER PLAYERS**

Sousa, S., Rodrigues, E.Q., Cintra Filho, D.A.

Londrina State University

In soccer there are positions that differ both in game tactical aspect as in motor applications, as the players' anthropometric profile can be different depending on the position the player acts on the field. Thus, it is essential to investigate anthropometric profile, because what are differences between playing position? **Methods:** 50 young soccer players were divided into five groups, group 1: 9 central defenders (age  $15.2 \pm 0.4$ ; body mass  $73.4 \pm 7.8$ ; height  $1.82 \pm 0.0$ ); group 2: 8 external defenders (age  $15.5 \pm 0.5$ ; body mass  $73.4 \pm 7.8$ ; height  $1.77 \pm 0.0$ ); group 3: 17 midfielders (age  $15.2 \pm 0.4$ ; body mass  $66.3 \pm 6.8$ ; height  $1.75 \pm 0.0$ ); group 4: 12 forwards (age  $15.3 \pm 0.4$ ; body mass  $68.7 \pm 12$ ; height  $1.75 \pm 0.0$ ) and group 5: 4 goalkeepers (age  $15.0 \pm 0.0$ ; body mass  $80.5 \pm 7.7$ ; height  $1.84 \pm 0.0$ ). They were analyzed skinfold thickness, which were subjected to analysis of skinfold calf, thigh, suprailliac, abdominal, subscapular and triceps for subsequent calculation of fat weight, lean weight and fat percentage, using the equation of Faulkner (1968). Statistical analysis was performed using the Shapiro-Wilk normality and for analysis of variance (ANOVA) with extension to the Post Hoc Tukey test for multiple comparisons. In all cases the level of significance was pre-set for  $P < 0.05$ . SPSS 17.0 was used. **Results:** The main differences were related to % fat and fat weight (FW) between goalkeepers (G5) x external defenders ( $p = 0.04$ ) and defenders x external defenders ( $p = 0.01$ ). **Discussion:** The group 5 (G5) showed more differences for % fat and fat weight (FW) between groups, ie in this case the goalkeepers have more fat, especially that side (G2) and midfielders (G3). Group 1 similarly showed differences in % fat and FW, but only 2 differences between G1 (central defenders) and G2 (external defenders), in this case the quarterbacks have more fat than the external defenders. As explanation, the study LAGO-PENAS et al (2011) in a study of young footballers aged similar study that goalkeepers and defenders showed higher fat percentage as well as in absolute (FW), which corroborates with this study. In the search GIL et al (2007) only in the goalkeepers % fat and were superior differently from the present study it was observed compared to forwards. **References** FAULKNER, J. A. **DO I TRAIN TO LOSE BODY WEIGHT IF I AM ALREADY FOLLOWING A DIET?**

Rojo-Tirado, M.A.1, Benito, P.J.1

Technical University of Madrid

**Introduction** Most studies have described how the weight loss is when different treatments are compared (1-3), showing that there are no statistical differences between them when the diet is included. The aim of this study was to compare the effect of training added to a calorie restriction on the body weight (BW) loss. **Methods** Eighty-five people, with BMI  $25-34.9 \text{ kg} \cdot \text{m}^{-2}$ , aged from 18 to 50 years, participated in the study during 6 months. Two types of treatments were randomly assigned: combined strength + endurance training group (SE,  $n=46$ ), and physical recommendations group (C,  $n=39$ ). All participants followed a 25-30% calorie restriction diet. A Student's t test was used to compare the BW loss in both groups. Probability level for statistical significance was set at  $\alpha=0.05$ . **Results** The BW loss was similar for both groups in kg ( $t_{83}=1.302$ ;  $p=0.196$ ) and in percentage ( $t_{83}=-1.224$ ;  $p=0.224$ ). The BW loss was for SE group  $-9.37 \pm 3.58 \text{ kg}$  ( $-10.51 \pm 3.58 \%$ ) and for C group  $-8.15 \pm 5$  ( $-9.27 \pm 5.64$ ). **Discussion** Although weight loss was similar in both groups, we suggest that any weight loss program should include exercise because it maintains the FFM, contributing to the body's overall energy expenditure rate (4), and has greater cardiometabolic health benefits (3). All body weight loss would be due to fat mass loss if exercise is included. However,

since exercise cannot produce a 25% caloric restriction by itself (approximately 120 min for women and 90 min for men would be required), a daunting task today (5), it would be desirable to combine diet and exercise. ### **THE EFFECTS OF AN EXERCISE INTERVENTION ON DIETARY INTAKE DURING THE MENSTRUAL CYCLE IN WOMEN SUFFERING FROM PREMENSTRUAL SYNDROME**

Hillier, S.E.1, Craven, R.P.1, Venables, M.C.1,2, Wheeler, S.J.1

*Oxford Brookes University*

Introduction Energy and carbohydrate (CHO) intake are reported to increase during the luteal phase of the menstrual cycle in women with premenstrual syndrome (PMS) (Wurtman et al., 1989). The current study investigated whether energy and macronutrient intake, particularly that of non-milk extrinsic sugars (NMES), was affected by a moderately intensive exercise regime in women with PMS; both over the entire menstrual cycle and between cycle phases. Methods Twenty-five sedentary women, suffering from moderate PMS symptoms, were recruited to a randomised control trial spanning four menstrual cycles, the first serving as a baseline followed by three cycles of intervention. Participants were randomised into either an exercise (EX) group (n=13), which included three supervised 30-minute moderate-intensity exercise sessions per week (70-80% HR max) or a control (CON) group which included a 90-minute, one-to-one meeting once per week (n=12). Dietary intake was assessed by a 24-hour dietary recall interview once per week during each cycle. Venous blood samples were collected three times per week during Cycle 1 and 4 to determine menstrual cycle phase according to plasma estradiol and progesterone concentrations. Results There was no difference in energy intake or macronutrient intake as a proportion of total energy intake (%TEI) between menstrual cycle phases at baseline (Cycle 1). Further, there was no difference in energy intake (2487 vs. 2457 kcal) or macronutrient intake (%TEI) (Protein: 14.4% vs. 14.6%; Fat: 35.1% vs. 34.5%; CHO: 48.5% vs. 49.4%; NMES: 17.4% vs. 16.1%), as a result of the exercise intervention (EX vs. CON). However, over the three cycles of the intervention period, CHO intake was lower during the luteal phase in the EX group, as compared to the menstrual (45.5% vs. 50.1%,  $P<0.05$ ) and follicular (45.5 vs. 49.9%,  $P<0.05$ ) phases. No difference was found between menstrual cycle phases in the CON group. There was no difference in plasma estradiol or progesterone concentrations between Cycle 1 and 4, in either group. Discussion CHO intake during the luteal phase is reduced following moderately intensive exercise over three cycles. However, overall energy intake does not change. Previous evidence suggested that CHO intake may increase during the luteal phase and as such the findings of this study are unexpected and require further confirmation. References Wurtman J, Brzezinski A, Wurtman R, Laferrere B (1989). *Am J Obstet Gynecol*, 161, (5), 1228-1234

### **PHYSICAL FITNESS AND BODY COMPOSITION OF OTAGO ADOLESCENTS.**

Black, K.

*University of Otago*

It was recently shown that over a third of New Zealanders aged 15-18 years were overweight or obese (1). Poor physical fitness and obesity have been identified as independent risk factors for cardiovascular disease. Habits formed during adolescence continue into adulthood (2). This cross sectional study aimed to describe the relationship between fitness and body composition of adolescents aged 15-18 in Otago, New Zealand. Ethical approval was obtained from the University of Otago Human Ethics Committee. Body composition was measured using segmental bio-electrical impedance and students completed the multistage fitness test, which was used to calculate  $VO_2\max$  (3). Linear regression analysis was undertaken and was adjusted for age, gender and school as these have been shown to affect fitness. In total 269 students participated in both the body composition and fitness testing. Of these 79 % were classed as normal weight with the remaining students classed as overweight (16 %) or obese (4 %). The mean estimated  $VO_2\max$  was 46.3 (6.7) mL/kg/min, it was higher in males than females (48.9(7.0) and 43.2(5.6) mL/kg/min ( $p<0.01$ )). There was a significant association between all of the body composition measures (BMI z-scores and fat-to-lean mass ratio) and  $VO_2\max$ . The females had similar  $VO_2\max$  values to previous studies amongst European populations; in comparison the males had lower  $VO_2\max$  values than their Spanish counterparts (4). BMI was slightly higher than previously reported for European adolescents (4). There was a strong association between body composition and fitness in adolescent females, which was weaker in boys. It is not possible from this study to determine whether fitness influences body composition or vice-versa. However, the low fitness seen in the boys in combination with associations between fitness and body composition suggests initiatives to tackle weight should also focus on fitness. Funding This study was funded by the National Heart Foundation of New Zealand, Lottery Health Research New Zealand and the University of Otago.

### **CONTROLLED NUTRITION INTAKE AFTER WORKOUT IMPROVES LEAN BODY MASS AND MENTAL STATE OF HIGH SCHOOL BASEBALL PLAYERS IN SUMMER SEASON**

Konishi, K., Moriya, M., Abe, C., Taki, C., Kimura, T., Sanada, K., Ebi, K.

*Ritsumeikan University*

Introduction A young athlete requires sufficient energy intake, not only for the increased energy expenditure, but also for the adequate growth. A high school baseball player shows much more energy expenditure (1). It is practically known that the substantial decrease of the lean body mass occurs in the summer season because of the negative energy balance. The summer season is important for them, as the national high school baseball championship is held. Accordingly, it is necessary to develop the nutrition education that appropriately controls their nutrient intakes for the summer season. The purpose of this study was, therefore, to examine the effects of controlled nutrition intake after workout on the physical and mental functions of the high school baseball players during the summer season. Method Seventy-seven high school baseball players participated in this study for 4 months. The subjects in intervention group (n = 34) were regularly provided controlled nutrition intake after the workout and received the nutrition education. On the other hand, the subjects in control group (n = 43) were only with the nutrition education. In each group, the body composition (height, body mass, % body fat), nutrient intakes, and mental states (profile of mood states, POMS) were measured before, during, and after the intervention. Results The

results showed that the lean body mass in the intervention group significantly increased at 6 and 8 weeks (8wk and 6wk) after the start of the nutrition instruction ( $P < 0.05$ ). On the other hand, the lean body mass in the control group at 8wk was significantly lower than that at 6wk ( $P < 0.05$ ). The energy intake and carbohydrate intake were significantly increased only in the intervention group ( $P < 0.05$ ). Furthermore, the results of the POMS showed that, in the control group, the tension-anxiety score significantly increased ( $P < 0.05$ ) and the fatigue score unchanged. In contrast, in the intervention group, the tension-anxiety score tended to decrease and the fatigue score significantly increased after the intervention ( $P < 0.05$ ). Discussion These results suggest that the controlled nutrition intake after workout, in addition to the nutrition instruction, prevents the lean body mass decrease in the high school baseball players during summer season. This effect can be accounted for by the increase of carbohydrate intake. The effect of the intervention on the mental state was also observed.

### IMPACT OF AN INTERVENTION ON POSTPARTUM WEIGHT RETENTION

Kurashima, C.H., Benicio, M.H.D., Takito, M.Y.

*School of Physical Education and Sport of University of Sao Paulo*

**Introduction** Women of childbearing age are at risk for weight gain because of biological and behavioral reasons, and the development of obesity has important implications, as diabetes and hypertension (Schmitt et al, 2007). In pregnant women, excessive weight gain is linked with greater postpartum weight retention and longer-term effects on obesity risk (Nehring et al, 2011). The objective of this study was to evaluate the impact of an intervention program on postpartum weight retention (PPWR). **Methods** Healthy pregnant women were monitored from early pregnancy until 1-year postpartum. Seventy nine women in the intervention group (IG) received individual counseling by professional nutritionists at gestational and postpartum period about diet and physical activity. One hundred-six women in control group (CG) receive routine care of health service. PPWR was analyzed using hierarchical mixed models analysis. Results One year postpartum, the average weight retention was 2.44kg in CG and 3.09kg in IG, however there was no difference between groups ( $p > 0.05$ ). There were difference between nutritional status, overweight and obese women had 9.44kg and 23.62kg more than normal weight women, respectively ( $p < 0.05$  for both). Postpartum women in IG who gained weight higher than recommended gestational weight gain by IOM (2009) retained 7.41kg more than did women who gained weight below/within the guidelines ( $p < 0.05$ ). Breastfeeding, physical activity and other lifestyle factors (having partner, parity) haven't been related to PPWR. Discussion Only nutritional status and gestational weight gain (GWG) did – Nehring et al (2011) meta-analysis showed that GWG in accordance with the IOM recommendations could help to reduce long-term postpartum weight retention. On the other hand, studies aiming to reduce GWG through lifestyle changes have inconclusive results. Gardner et al (2011) meta-analysis showed that dietary and/or physical activity change programmes produced a significant gestational weight gain reduction. Streuling et al (2010) suggests that weight monitoring was associated with effective interventions – inform participants of their weight, raising their awareness of weight gain could change behaviour. Not sharing weight information, as happened in the present study, would not be expected to influence behaviour. References Gardner B, Wardle J, Poston L, Croker H. (2011). *Obes Rev*, 12(7):e602-20. ### NUTRITIONAL INTAKE, BODY COMPOSITION AND RISK FACTORS FOR DISORDERED EATING IN MALE ATHLETES

Schneider, C., Baldissera, G., Meyer, E., Stenzel, L.

*Federal University of Health Sciences of Porto Alegre*

**Introduction** Achieving and maintaining the desired body shape for a sport involves eating control practices to adjust the body to the requirements and demands of competitive sports environments. Participation in sports that require a low body fat percentage or low body weight has been described as a risk factor for the development of eating disorders. Therefore, the aim of this study was to evaluate food intake, body composition and the presence of risk for developing eating disorders in men practicing sports with aesthetic ideals. **Methods** Fifty adult males participated in this cross-sectional study. Practiced sports were ballet, jazz, contemporary dance, gymnastics and figure skating. Food intake was analyzed using a Food Frequency Questionnaire. We employed three self-report questionnaires in eating disorders research in their translated and validated Brazilian Portuguese versions: Eating Attitudes Test (EAT-26), Bulimic Investigatory Test of Edinburgh (BITE), and Body Shape Questionnaire (BSQ). Body fat was assessed by seven skinfold measures. Statistical analyses were performed using SPSS 20.0 at a 0.05 significance level. Results are presented as mean  $\pm$  SD. Results Participants were 24.9  $\pm$  8.2 y, 68.7  $\pm$  9.1 kg, 1.74  $\pm$  0.08 m, and 9.5  $\pm$  4.5% body fat. Forty-six percent were below the reference values of body fat to the sport practiced. Daily energy expenditure was 3285  $\pm$  665 kcal and daily energy consumption was 3205  $\pm$  1240 kcal. Nutrient intake was above the recommendation for proteins (46%) and lipids (52%), and below the recommendation for carbohydrates (44%), calcium (56%), magnesium (52%) and vitamin A (92%). Positive results for EAT-26, BITE and BSQ have been verified in 6%, 30% and 20% of the athletes, respectively. An association was detected between body image dissatisfaction and disordered eating behavior ( $r = 0.677$ ;  $p < 0.001$ ). Discussion We found an association between body image dissatisfaction and disordered eating behavior that was found in previous study (Milligan and Pritchard, 2006). As well as in Canadian athletes (Lun et al, 2009), some athletes presented food consumption below recommendation. Opposite to Petri et al (2008), the pattern observed in the present study suggests that maintaining low body fat levels is not associated with an increased time spent with exercise, nor the restriction of energy intake. References Milligan BA, Pritchard M (2006). *Ath Ins*, 8,32-46 Lun V, Erdman KA, Reimer RA (2009) *Clin J Sport Med*, 19,405-411 Petrie TA, Greenleaf C, Reel J, Carter J (2008) *Psychol Men Masc*, 9,267-277

### EFFECT OF MIXTURE OF BAS ON EXERCISE PERFORMANCE OF JUDOISTS

Sukhov, S., Ivanov, A.

*National Research and Practical Centre of Physical Culture*

**Introduction** At intensive physical loads, there arise multiple deficits, while the use just of one or two biologically active supplements (BAS) cannot address all objectives for generating an optimum metabolic background needed for advancing the certain physical capacities. Goal of the study was to assess the effect of a mixture of BAS on exercise performance of judoists. **Methods** Twenty-five elite judoists (12 athletes – experimental group, 13 athletes – control group) have been examined. Both groups were coached with the same program and catered in the same canteen. Pedagogic testing was performed. Determination of maximum oxygen consumption ( $VO_{2max}$ ), anaerobic threshold (AT) by blood lactate concentration, exercise performance (PWC 130, 150, 170 and max.) at veloergometry, complete blood

count were performed. Athletes of experimental group were administered a mixture of 7 BAS for 8 weeks. After completion of BAS intake, the both groups were tested again. Results Intake of BAS mixture resulted in improvement of muscle-strengthening exercises – chin-up on horizontal bar – 10 times for speed exercise (11.78 sec – at the first examination, 10.26 sec – at the second examination) and for the number of times (30.75 and 34.7, respectively), as well as a test for special endurance – number of back throw fighting dummy (in 5 minutes has increased by 2). No positive dynamic of tests was noted in the control group. Besides the numbers, the quality of back throws was assessed by a five-grade scale. In experimental group, the quality of back throws has improved slightly (from  $4.75 \pm 0.08$  to  $4.83 \pm 0.07$  points), while in the control group it stayed on the same level. No change of  $VO_{2max}$  was noted in both groups. In the experimental group the exercise performance at different heart rate tended to increase while in the control group its has decreased slightly at heart rates 130, 150 and 170 bpm, and did not change at the maximal heart rate. In the experimental group, after intake of BAS, there was noted the increase in red blood cell count from  $4.47 \pm 0.12$  to  $4.93 \pm 0.17 \cdot 10^{12}/l$ , hemoglobin concentration from  $142.1 \pm 3.1$  to  $150.9 \pm 3.4$  g/l. While the control group showed a slight decrease of erythrocytes and hemoglobin. AT shows better than  $VO_{2max}$  the processes occurring in the body at middle and submaximal physical loads. The experimental group demonstrated growth of AT from  $140.1 \pm 3.9$  to  $149.3 \pm 3.4$  bpm. No change of AT was noted in the control group. Conclusion Intake of mixture of BAS by judoists had a positive effect on their exercise performance. No positive dynamics was noted in the control group.

### **PATTERNS OF WEIGHT LOSS OF YOUNG WRESTLERS DURING THE BRAZILIAN NATIONAL HIGH-SCHOOL GAMES**

Capitani, C.D.1, Viveiros, L.2, Moreira, A.3, Zourdos, M.C.4, Vidal, J.A.A.1, Aoki, M.S.3

1-University of Campinas, Limeira, Brazil; 2-Brazilian Olympic Committee, Rio de Janeiro, Brazil; 3-University of Sao Paulo, Sao Paulo, Brazil; 4-Florida Atlantic University, Boca Raton, USA

**Introduction** The aim of this study was to evaluate the weight loss patterns of Brazilian wrestlers during the national high-school games. **Methods** Thirty-one high-school wrestlers, female ( $n=16$ ;  $13 \pm 2$  yrs) and male ( $n=15$ ;  $13 \pm 2$  yrs) agreed to participate in the study. First, subjects were weighed 24 h prior to competition at the official weigh-in. Immediately following the official weigh-in the athletes answered a standardized weight loss questionnaire. The next day, immediately prior to the first competitive match, the athletes were submitted to a pre-match weigh-in. Additionally, sodium, potassium, chloride, hematocrit and hemoglobin were measured immediately before the first competitive match (24h after the official weigh-in) by STAT Blood Gas Analyzer (iSTAT® Abbott, USA). Results A significant weight gain was detected from the official weigh-in to the pre-match weigh-in (Females:  $+2.7 \pm 1.4$ kg and Males:  $+1.5 \pm 0.9$ kg) ( $p < 0.05$ ). Weight loss practices were employed by 42% of the subjects and they have started to reduce their weight for wrestling competitions before the age of 13 ( $12.1 \pm 1.3$  yrs). The majority of athletes, reported side effects (61.5%) and 46.2% said that these side effects negatively altered performance. The most common methods employed by wrestlers to produce a rapid reduction in weight included: increased amount of exercise (84.6%) and reduced food intake per meal (84.6%). Sodium, potassium, chloride, hematocrit and hemoglobin were in the normal range at the pre-match weigh-in compared to the reference levels. **Discussion** The results demonstrate that the high-school wrestlers gained weight from the official weigh-in to the pre-match weigh-in just 24 h later. These results suggest that wrestlers likely lost a significant amount of weight in a short period of time prior to the official weigh-in. Rapid weight loss prior to competition has become part of the culture of wrestling and the athletes are resistant to change, despite reporting negative side effects on performance. Interestingly, immediately prior to competition, the athletes achieved normal levels of electrolytes and hydration. However, preventative measures are needed to discourage wrestlers from continuing to practice rapid weight loss, especially at such young age. Moreover, educational programs should be developed with coaches and parents aiming to preserve high school wrestlers' health and performance.

### **SPORTS NUTRITION: SUPPLEMENT AND PRODUCT USE IN THE DUTCH GENERAL POPULATION**

Wardenaar, F.1, Ceelen, I.1, Witkamp, R.2, Mensink, M.2

1: HAN University of Applied Sciences (Nijmegen, NL), 2: Wageningen University (Wageningen, NL).

**Introduction** Nutritional supplements and sports nutrition products (e.g. drinks, bars or shakes) are widely used among (elite) athletes; estimations range from 44% up to 100%, depending on age, type of sport and level of the athletes investigated (Molinero & Márquez, 2009). Information from the recreationally-active part of the general population is limited. Therefore, as part of the Dutch National Sport Investigation (NSO 2012) we investigated the self-reported consumption rate of nutritional supplements and sport products in relation to age, sex and sports participation in the Dutch general population. **Methods** The objective of the NSO is to gain insight into sports participation, level of physical activity and the attitude towards sports-related topics of the Dutch general population aged 15 to 80 years. In a representative sample (1647 subjects), 5 questions were asked about nutritional supplement and sports nutrition products use, and self-reported knowledge about this topic. Chi-square test was used to determine differences between sexes and subgroups for age and participation level. Level of significance was set on  $P \leq 0.05$ . Results Response rate was 62% ( $n=1015$ ). 727 individuals (72%) indicated to be active in sports during the last 12 months. Among them, 5.8% used supplements to improve performance, while 21.6% used sports nutrition products before, during or after exercise. Supplements and products were used more frequently by men than women (suppl: 8.8% vs. 2.7%, products: 29.5% vs. 13.6%,  $p < 0.05$ ). Both, supplement and product use was more prevalent in younger people, and those being a member of a sports club; while use of sports nutrition products, but not supplements, was more common in people more regular active in sports. General knowledge about nutrition and sports was considered sufficient in 41% of the population. Remarkably no sex difference was seen for this question, while specific knowledge about 'nutritional supplements and performance' and 'use of sport specific nutrition' was more frequently reported to be sufficient in men than women (26.9% vs. 15.8% and 29.3 vs. 17.6% respectively,  $p < 0.05$ ). Again, younger age, higher sports participation and being a member of a club were associated with better self-reported knowledge. **Conclusion** The use of nutritional supplements and sports nutrition products in the Dutch general population is lower than previously reported intake in recreational and elite athletes. A typical consumer of nutritional supplements and sport nutrition products is a young (< 35 years) male, frequently active in sports (> 1 time/week), and member of a club. References Molinero, O. and Márquez, S. *Nutrición Hospitalaria* 2009;24(2):128-134

## EFFECT OF NUTRITION INTERVENTION PROGRAM IN HANDBALL ATHLETES: CONSEQUENCES ON ANTIOXIDANT STATUS

Molina-López, J.1, Molina, J.M.2, Chiroso, L.J.2, Sáez, L.1, Florea, D.I.1, Planells, E.1

*1Department of Physiology, Institute of Nutrition and Food Technology, University of Granada; 2Department of Physical Education and Sports, Faculty of Sports Sciences, University of Granada. Spain.*

**Introduction** The signalling function of ROS also plays a role in mediating the physiological adaptations gathered from regular exercise. The regular training induced adaptations in blood antioxidant capacity and the following attenuated exercise-induced oxidative stress have been clearly demonstrated in adult athletes. To study the effect of nutrition education and polymineral supplementation (Mn, Zn, Cu and Se), on total antioxidant power (PAO) levels in sports performance in a population of elite athletes. **Methods** Longitudinal study of 14 professional handball players > 18a, with intense intermittent training and nutrition education for 2 months, were supplemented with 50% RDAs for Cu, Zn and Se; and 100% RDA for Mn. Training variables were monitored: load, intensity and perceived exertion (RPE). Mineral intake and PAO levels were recorded by 72 h reminder Nutriber® software, and Paglia and Valentine method, respectively. All controls were performed at baseline, after 2 month with supplementation, and after another 2 month without supplementation. Results 7.1% and 35.7% of subjects were initially below the RDA for Se and Cu for healthy population, respectively. Mn, Cu, Zn and Se intake were significantly increased ( $p < 0.05$ ) following supplementation being no influenced by nutritional education. Zn plasma level was significantly correlated ( $r = -0.83$ ) with Cu in plasma. Zn ( $r = -0.66$ ), Mn ( $r = -0.81$ ) and Cu ( $r = -0.80$ ,  $r = -0$  to 75) plasma levels were significantly correlated with PAO after supplementation ( $p < 0.05$ ). PAO increased significantly from baseline ( $p < 0.001$ ) at final of experimental period. **Discussion** The maintenance of the redox balance might partly result from the integrative effect of augmentation of individual antioxidant in adaptation to chronic exercise. Such adaptive endogenous processes in athletes might be associated with their habitual intakes of antioxidant nutrients. Elite athletes should be monitored by a clinical-nutritional follow up to avoid deficiencies that alter antioxidant status in critical situations, so supplementation may be necessary to optimize athletic performance. **References** Tong TK, Lin H, Lippi G, Nie J, Tian Y (2012). *Oxid Med Cell Longev.* 1-7. ## THE INFLUENCE OF CHANGING LIFESTYLE IN OBESITY: 'WEIGHT LOSS CHALLENGE' APPROACH

Andjelkovic, M., Dikic, N., Mikovic, N., Vesic Vukasinovic, M., Antic, T., Baralic, I.

*Sports Medicine Association of Serbia, Belgrade, Serbia*

**Introduction** The primary objective of this study was to investigate the effects of programmed moderate intensity exercise and dietary regime on the reduction of body weight and body fat in obese people, as well as reducing cardiovascular risk factors. The advantage of nonpharmacologic 'Weight Loss Challenge' approach in treatment of obesity is in joining groups according to the similarity of body weight (BW), health status, body shape and nutritional habits with aim to train and respect diet, with constant medical support. **Methods** Inclusion criteria for this pilot intervention study was BMI  $\geq 30$ . Measurements and tests conducted at the beginning and at the end of the program that lasted three months were: anthropometry, waist circumference, body composition, blood pressure (TA), ergospirometry, blood and biochemical analyses, three-day diet record, Beck Depression Inventory (BDI), Pittsburgh Sleep Quality Index (PSQI) and International Physical Activity Questionnaire (IPAQ). Three basic components were complied: 1) special diet regime using meal replacement, 2) nutrition education and workshops in club and 3) programmed moderate physical activity three times/week. Weekly control were conducted by physician. Results 13 individuals (6 male and 7 female), aged  $46.2 \pm 12.0$  yr had average BMI  $36.6 \pm 5.8$  kg/m<sup>2</sup>, mean BW  $109.0 \pm 24.9$  kg and body fat percentage (F%)  $38.2 \pm 6.6$  at the start of program. The most common comorbidity was metabolic syndrome (80%) and hypertension (50%). Half participants had PSQI category 'poor sleepers'. BDI at start registered moderate and severe depression in three patients. Average VO<sub>2</sub> max ( $21.6 \pm 4.7$  ml/kg/min) indicates a low oxygen consumption. All participants had insufficient or low levels of physical activity according to IPAQ. At the end of program there was a statistically significant difference ( $p < 0.05$ ) for: body weight ( $106.5 \pm 24.3$ kg), BMI ( $35.6 \pm 5.5$ ), body fat mass ( $2.5 \pm 21$ .1kg), F% and fat mass in both arms. Systolic TA were significantly lowered for  $21.8 \pm 11.9$  mmHg and diastolic for  $20.7 \pm 12.0$  mmHg. Fat free mass did not change. **Discussion** The multidisciplinary program, which involves moderate physical activity, dietary regime with meal replacement, regular medical supervision and behavior modification lead to a greater reduction in BW without consequences on health status. Treatment caused a significant change in the body composition, morphological and nutritional status in obese people. This pilot study requires further evaluation and follow-up data of additional participants resulting certain recommendations. **References** Lagerros YT, Rössner S. (2013) *Therap Adv Gastroenterol.* Jan; 6:77-88

## THE NUTRITIONAL SITUATION OF VICTIMS OF THE NORTH-EASTERN JAPAN EARTHQUAKE

Sugiura, K.1, Yamauchi, T.1, Sakai, K.2, Uenishi, K.3

*1: Rikkyo Univ., 2: Josai International Univ., 3: Kagawa Nutrition Univ.*

**Introduction** The enormous earthquake off the coast of North-Eastern Japan on March 11, 2011 and the ensuing massive tsunami devastated a wide area of the North-Eastern coastal area of Japan. The number of dead and missing currently stands at over 19,000, with over 390,000 buildings either completely or partially destroyed. At the peak, there were over 400,000 evacuees who were forced to live in temporary housing units for a prolonged period of time. Food deliveries for evacuees who moved into temporary housing units in the autumn of 2011 were ended and the victims given their privacy. However, as a result it became difficult to gauge their health, or to measure their dietary, nutritional or exercise intakes behind the closed doors of their temporary housing units. Therefore, this research investigated nutritional intakes and physical activity of two groups of elderly housewives: the first residing in temporary housing units and the second in their own original houses, lived in a Kesenuma Oshima Island (population 3,478, with 1,127 homes and an area 9.05km<sup>2</sup> as of March 2008), Miyagi Pref., Japan. **Methods** The subjects of the study were 11 elderly housewife victims (4 residing in temporary housing units, aged  $79 \pm 2$  yrs, height  $146.5 \pm 2$ cm, weight,  $45.8 \pm 7.8$ kg and BMI  $21.2 \pm 3.0$ ; and 7 residing in their original houses, aged  $50 \pm 4$  yrs, height  $158.9 \pm 4.4$ cm, weight  $62.6 \pm 6.9$ kg, and BMI  $24.8 \pm 2.5$ ). Both the groups' nutritional intakes and total energy expenditure were measured in February 2012, and the comparisons made between them, as well as with the 2010 dietary reference intakes (DRIs) of a Japanese person. **Results** The group residing in temporary housing units had an average intake of  $1402 \pm 237$ kcal per day, compared to  $1933 \pm 381$ kcal the group living in their own houses ( $p < 0.05$ ). The temporary housing unit group consumed  $1495 \pm 295$ kcal, compared to  $2127 \pm 198$ kcal of the own housing group ( $p = 0.231$ ). Protein, calcium and iron intakes of the temporary housing unit group were significantly lower than own housing group. The food intake of the temporary housing unit group was 300kcal lower compared to the DRIs for people over 70; and they also consumed 200kcal less. Calcium and vitamin intakes were also found to be insufficient. **Discussion** Since

the subjects in the temporary housing unit group are elderly, they have a heightened risk of developing Locomotive syndrome. It is therefore vital that they have access to adequate nutrition, exercise and health information and support. Since the research was carried out in winter, there is a high likelihood that they were unable to get enough exercise or buy enough food. In light of this, after a year of retrieving adequate health and information support, a second investigation was carried out in February 2013, with the results to be discussed.

##### THE EFFECTS OF A FORMAL EXERCISE TRAINING PROGRAMME ON HORMONE CONCENTRATIONS AND BODY COMPOSITION IN PREVIOUSLY SEDENTARY AGING MEN.

Hayes, L., Grace, F., Sculthorpe, N., Herbert, P., Ratcliffe, J., Kilduff, L., Baker, J.

*London Metropolitan University, University of the West of Scotland, University of Wales, Swansea University*

Alteration in body composition, physical function, and substrate metabolism occur with advancing age. These changes may be attenuated by exercise. This study examined whether twenty eight, previously sedentary males ( $62.5 \pm 5.3$  years of age; body mass of  $89.7 \pm 16.4$  kg) adhering to the ACSM minimum guidelines for aerobic exercise for six weeks would improve exercise capabilities, body composition and hormone profiles. After six weeks of adhering to the guidelines, salivary testosterone and  $vo_{2max}$  (absolute and relative) increased ( $p < 0.05$ ), whilst body fat percentage and body mass decreased ( $p < 0.05$ ). Peak power output, fat free mass and cortisol values were not significantly different. Interestingly, salivary testosterone correlated inversely with body fat percentage ( $R^2 = .285$ ,  $p = 0.011$ ). These results suggest that despite previous inactivity, older males can achieve improvements in cardiorespiratory fitness, body composition and anabolism by adhering to simple lifestyle changes.

##### THE INFLUENCE OF MENSTRUAL STATUS UPON POST EXERCISE HYPOTENSION IN ENDURANCE ATHLETES

Nakamura, M., Saito, Y., Eguchi, K., Suzuki, N., Takahashi, H.

*Japan Institute of Sports Sciences*

**【Introduction】** Previous study demonstrated that buffering of post exercise hypotension (PEH) appears to be enhanced in the late follicular phase and midluteal phase where estrogen concentrations are known to be elevated in eumenorrheic female (Esformes et al., 2005). However, the impact of menstrual status upon PEH has not been evaluated. Exercise-associated amenorrhea and oligomenorrhea are in a state of estrogen deficiency compared with eumenorrhea. Thus, it is possible that the PEH may be different between eumenorrheic and non-eumenorrheic (including oligomenorrhea and amenorrhea) athletes. Therefore, in the present study we investigated the temporal pattern of cardiovascular recovery from an acute bout of exercise in female endurance athletes, in two groups of eumenorrhea and non-eumenorrhea. **【Methods】** Eighteen healthy female athletes volunteered for this study and signed an informed consent in accordance with Ethics Committee of the Japan Institute of Sports Sciences. The subjects were divided into two groups based on their menstrual status: ten eumenorrheic athlete (EA,  $19.0 \pm 0.7$  years) and eight menstrual disorders athlete (DA,  $18.2 \pm 0.4$  years, 5 were amenorrhea and 3 were oligomenorrhea). EA group was studied on follicular phase and DA group was studied on an arbitrary day. In the supine position, arterial blood pressure (BP), heart rate (HR), cardiac output (CO), total peripheral resistance (TPR) and spontaneous baroreflex sensitivity (SBRs) were determined before and after 15, 30 and 60 minutes after a graded cycling to exhaustion.

**【Results】** There was no difference in estrogen concentration between EA and DA groups (EA,  $26.1 \pm 12.4$  pg/ml; DA,  $25.4 \pm 11.1$  pg/ml). Systolic BP was reduced in post-exercise compared with pre-exercise ( $p < 0.05$ ) in both groups, and the degree of change was higher in DA than EA groups ( $p < 0.05$ ). Diastolic BP and mean BP were reduced in post-exercise compared with pre-exercise ( $p < 0.05$ ), but the degree of change was not different between the two groups. There was no group difference in TPR reduction after the exercise. We found no significant differences in index of SBRs between pre-exercise and post-exercise phases in both groups. **【Conclusion】** PEH was observed in eumenorrheic and non-eumenorrheic athletes. However, the pattern of PEH was different between eumenorrheic and non-eumenorrheic athletes. **【References】** Esformes, J., Norman, F., Sigley, J. and Birch, K. ##### ENDOCRINE RESPONSES DURING DIFFERENT MICROCYCLES IN PROFESSIONAL BASKETBALL PLAYERS: A FOUR-YEARS FOLLOW-UP STUDY.

Schelling, X.1, Calleja-González, J.2, Torres, L.3,4, Terrados, N.5,6

*1: Fundació Privada Foment del Bàsquet (Manresa, Spain); 2: UPV-EHU (Vitoria-Gasteiz, Spain); 3: GREAF (Vic, Spain); 4: INEFC (Spain); 5: Unidad Regional de Medicina Deportiva del Principado de Asturias*

**Introduction** The aim of this study was to investigate differences in anabolic-catabolic balance depending on week's structure (including training sessions and one competitive game, two-games or non-game) throughout four consecutive seasons in professional basketball players. **Methods** Thirty-five male players from the same team, with regular training and competition in Spanish 1st Division (ACB) volunteered to take part in this study (age:  $27.0 \pm 4.2$  yr; height:  $195.7 \pm 7.4$  cm; weight:  $93.7 \pm 10.1$  kg). A gathering of consecutive detailed blood samples were collected to analyze different blood parameters in relation to seasonal changes depending on type of microcycle (training and game exposure). Blood samples were collected every 4-6 weeks during regular season (277 total samples). **Results** Cortisol was significantly lower after two-games microcycle ( $0.470 \mu\text{Mol/L}$ ) in comparison with one-game microcycle ( $p=0.000$ ,  $\Delta: 0.34$ ). Moreover, the variation of testosterone-to-cortisol ratio was significantly higher after no-game microcycle ( $+12.2\%$ ) compared to one-game microcycle ( $+0.3\%$ ) ( $p=0.006$ ,  $\Delta: 0.27$ ). **Conclusion:** Regular blood samples reveal significant changes that may be related to training and game pattern week. No-game microcycle, but with regular training, stimulates anabolism. These results highlight that regular analyzes of blood samples could be an important method to monitoring training and competition process to optimize training/competition load for better adaptation, but sampling has to be regular and a database has to be build for each individual player. **References** 1. ### EFFECT OF 48H ULTRA MARATHON RUN ON BIOACTIVE SPHINGOLIPIDS LEVELS IN PLASMA AND ERYTHROCYTES

Górski, J.1, Baranowski, M.1, Kłapcińska, B.2, Waśkiewicz, Z.2, Sadowska-Krępa, E.2

1: *Medical University of Białystok (Białystok, Poland)*, 2: *Academy of Physical Education (Katowice, Poland)*

**Introduction** The bioactive sphingolipids, i.e. sphingosine-1-phosphate (S1P), sphingosine (SPH), sphinganine (SA), sphinganine-1-phosphate (SA1P) and ceramide (CER) are present in human plasma. The most powerful is S1P that binds to plasma membrane receptors and activates G protein. S1P exerts strong cardioprotective, immunoregulatory, pro-proliferative and anti-apoptotic effects. The main source of plasma S1P are red blood cells (RBC). Previous studies showed that muscular work affects metabolism of sphingolipids in skeletal muscles. The aim of this study was to investigate effects of 48h ultra-marathon run on bioactive sphingolipids levels in plasma and RBC. **Methods** Seven runners aged 35-59yrs volunteered to provide blood samples before the run, after 24 and 48h running and after 1 and 2 days of recovery for analyses of bioactive sphingolipids by HPLC and of routine biochemical indices. The runners were allowed free intake of food and beverages during the run. Results Blood glucose and lactate levels were stable throughout the race, free fatty acids increased ~4-fold after 24h and almost 3-fold after 48h running, and returned to normal during recovery. Plasma S1P (pmol/ml) decreased ( $P<0.05$ ) from  $233.5\pm30.6$  pre-run; to  $153.5\pm35.1$  after 24 h,  $121.7\pm22.6$  at the finish, and to  $115.9\pm13.9$  and  $120.7\pm17.7$  after 1 and 2 days of recovery. Plasma levels of SPH and SA were not affected by the run although SPH decreased after 24h and SA after 48h rest ( $p<0.05$ ). The level of SA1P decreased after 48h running and during recovery ( $p<0.05$ ). Plasma CER level remained stable during the event. The level of S1P in RBC was fairly stable during the run but it increased after 24h rest ( $p<0.05$ ). 24h running led to a significant ( $p<0.05$ ) increase in SA1P in RBC, which returned to baseline thereafter. The level of SPH in RBC rose only in the 2nd day of recovery ( $p<0.05$ ), while SA and CER contents were not affected by the run. **Discussion** It is known that S1P and SA1P are not taken by any cell. Prolonged 48h running reduced S1P and SA1P contents in plasma, but not in RBC. Therefore, the decrease in plasma contents of these sphingolipids was most likely due to their enhanced breakdown in this blood compartment. The drop in the plasma S1P has certainly blunted its cardioprotective and other effects both during the run and in the recovery. **References** Błażnio-Zabielska AU, Zabielski P, Baranowski M, Górski J. ### RELATIONSHIP BETWEEN ANDROGENS AND CORTICOSTEROIDS IN PLASMA AND URINE IN PRE AND POSTMENOPAUSAL WOMEN AFTER 6 MONTHS OF AEROBIC TRAINING.

Maynar, M., Robles, M.C., Crespo, C., Llerena, F., Toribio, A.F.

*University of Extremadura*

**Introduction:** The postmenopausal period is associated with an estrogen and androgens deficiency and a corticosteroids increase. These hormonal alterations could be responsible for the increased morbidity. Physical activity could have an important regulating effect on female hormonal metabolism, although not necessarily the same in pre or postmenopausal women. **Purpose:** To evaluate the effect of 6 months of aerobic exercise on relationship between androgens and corticosteroids levels in plasma and urine in pre and postmenopausal women. **Method:** 20 premenopausal (PRE) ( $45.56 \pm 4.06$  years) and 20 postmenopausal (POST) ( $52.27 \pm 3.80$  years) women, all sedentary, were studied before and after a supervised 6 months exercise training program based on aerobic dance (60- 70% maximal heart rate, 60 min/day, 3 days/week). Before and after the program, anthropometric data and VO2 max were measured and overnight fasting urines and plasma samples were collected and analyzed by gas chromatography/mass spectrometry (GC/QMS). Steroids values were expressed as  $\mu\text{g steroid/g creatinine (cr)}$ . The data was analyzed by one-way ANOVA and by repeated measures. **Results:** Both groups improved their VO2 max after the aerobic exercise program ( $32.59\pm6.0$  before vs  $37.60\pm8.2$  ml/min/kg after exercise in PRE  $p<0.01$ ;  $31.84\pm6.0$  before vs  $36.94\pm6.3$  ml/min/kg after exercise in POST  $p<0.01$ ). Important differences were observed between relationship androgens/corticosteroids in plasma and urine in both groups in basal values (Table 1). After the exercise program, no changes in plasma and urinary levels were observed in premenopausal women. However, the aerobic exercise caused a significant increase in urinary relationship DHEA+androstenedione/glucocorticoids in postmenopausal women (Table 2). **Conclusion:** Pre and postmenopausal women presented important differences in the basal levels. In postmenopausal women, the elevation of the relationship androgens /glucocorticoids could bring health benefits, because it could indicate a reduction in glucocorticoid levels, reducing the risk of diseases such as obesity, diabetes, cardiovascular disease and depression.

### IVGTT BUT NOT OGTT DETECTS INSULIN SENSITIVITY IMPROVEMENTS AFTER A BOUT OF EXERCISE IN HEALTHY MEN

Ortega, J.F., Fernández-Eliás, V.E., Hamouti, N., Mora-Rodríguez, R.

*University of Castilla-La Mancha*

**Introduction:** Euglycemic hyperinsulinemic clamp (EHC) is the gold standard method to assess insulin sensitivity (IS). However, few researchers can carry it out since it requires costly and complex equipment. In addition, the infusion of insulin is not risk free and it requires trained hospital staff to avoid complications and to obtain accurate measures (1). Exercise science professionals, that cannot implement EHC, are in need of an affordable and simple diagnosis test to gauge the effects of exercise interventions on insulin actions. This index, besides of valid, must be highly reproducible since otherwise the benefits of exercise could remain hidden underneath the variability of the measurement. To our knowledge, there is a scarcity of data comparing the reliability and response to exercise of technically and economically affordable IS indices. **Purpose:** To compare the reproducibility and post-exercise response of two glucose tolerance tests to estimate IS, with different routes of glucose administration; i.e., oral (OGTT) vs. intravenous (IVGTT). **Methods:** Ten healthy moderately-fit young men ( $\text{VO2peak}$ :  $45.4\pm1.8$  mL•kg<sup>-1</sup>•min<sup>-1</sup>; age  $27.5\pm2.7$  yrs) underwent four OGTT's and four IVGTT's in different days after a standardized dinner and overnight fast. One of the OGTT and one of the IVGTT were carried out right after 55-min of cycle-ergometer exercise at 60%  $\text{VO2peak}$ . Matsuda's insulin sensitivity index (MISI) was calculated from OGTT (2-hour blood sample collection). Tura's calculated IS index (CSI) (2) was calculated from IVGTT (50-min blood sample collection). Coefficient of variation (CV) and intraclass reliability (ICR) were used to assess absolute and relative within-subject reproducibility, respectively. Improvements in IS after exercise were evaluated using one-way repeated measures ANOVA. **Results:** After exercise, MISI improved 29% without reaching statistical significance ( $P=0.182$ ) due in part to its low reproducibility (CV  $16\pm3$  %; ICR 0.846). However, CSI improved by 50% after exercise ( $P<0.001$ ) and showed better

reproducibility (CV  $13 \pm 4\%$ ; ICR 0.955). Calculated sample sizes based on observed IS differences (rest vs. post-exercise) showed that 7 subjects were required for detecting the effects of exercise when using CSI while 81 when using MISI. Conclusions: At rest, CSI is more reproducible than MISI in healthy young men. Our data suggest the preferential use of IVGTT to assess the beneficial effects of exercise on IS, at least in a young and moderately-fit non-diabetic population. References 1. Muniyappa, R., et al. *Am J Physiol Endocrinol Metab.* (2008). 2. Tura A. et al. *Diabetologia* (2010).

### **SPRINT INTERVAL EXERCISE INCREASES INSULIN SENSITIVITY ABOVE CONTINUOUS EXERCISE OF HIGH AND LOW INTENSITY**

Ortega, J.F., Fernández-Eliás, V.E., Hamouti, N., Mora-Rodriguez, R.

*Universidad of Castilla-La Mancha*

**Introduction:** The American College of Sports Medicine and the American Diabetes Association recommend at least 150 min•week<sup>-1</sup> of moderate-vigorous aerobic exercise for type 2 diabetic patients (1). Sprint interval exercise (SIE) is a time-efficient strategy to induce similar health benefits and training adaptations than continuous endurance exercise (2). However, it is unclear if SIE has similar effect on insulin sensitivity (IS) than typically recommended continuous exercise. **Purpose:** To compare the immediate and short-term effects of continuous exercise vs. SIE on glucose and fat metabolism. **Methods:** Ten young, healthy and physically active men underwent three exercise trials in a random and counter-balanced order separated by at least four days: a) continuous exercise for 60 min at 45% VO<sub>2peak</sub> (CLow), b) continuous exercise for ~35 min at 80% VO<sub>2peak</sub> (CHigh), or c) SIE consisting in 4 all-out 30-s sprints interspersed with 4.5-min of active recovery. CLow and CHigh were matched for energy expenditure while during SIE 32% less energy was expended. IS calculated from 50-min intravenous glucose tolerance test (CSI index (3)) was measured at rest, immediately post-exercise (IPE), and 24-h and 48-h after each trial. Muscle glycogen use was measured IPE from vastus lateralis. Plasma free fatty acids (FFA) were measured before each IS assessment. Two-way (time•exercise model) repeated measures ANOVA was used to determine differences and Pearson coefficient for correlations. **Results:** During exercise, total carbohydrate oxidation was higher during CHigh ( $P < 0.05$ ). Glycogen use was different from rest in both CLow and CHigh ( $P < 0.05$ ) but not after SIE. Fat oxidation and IPE circulating FFA were higher in CLow ( $P < 0.05$ ). Although CSI increased IPE in all trials, SIE was higher than CLow and CHigh (133%, 75% and 70%, respectively;  $P < 0.05$ ). CSI enhancement persisted up to 48-h after CLow and CHigh but only up to 24-h after SIE. CSI improvements did not correlate with energy expenditure, glycogen use, substrates oxidation and blood FFA concentration. **Conclusion:** SIE is superior to CHigh and CLow on immediately post-exercise IS improvements. However, continuous exercise maintains the effects longer. The lack of correlation between energy or muscle glycogen expenditure and substrates oxidation with IS suggests that other factors are important mediators of post-exercise insulin sensitivity enhancement. ### **PHYSICAL TRAINING PREVENTS INSULIN RESISTANCE BY ACTIVATING THE AMPK PROTEIN IN SKELETAL MUSCLE**

Evangelista, F.S.1, Silva, R.C.1, Higa, T.S.2, Fonseca-Alaniz, M.H.3

*1School of Arts, Science and Humanities, University of Sao Paulo; 2School of Physical Education and Sport, University of Sao Paulo; 3Heart Institute-Medicine School, University of Sao Paulo*

**Introduction:** The adaptation of skeletal muscle induced by physical training (PT) has been associated with the prevention of insulin resistance (IR). We investigated the role of AMP-activated protein kinase (AMPK)/acetyl CoA carboxylase (ACC) pathway behind this response. **Methods:** Male C57BL/6J mice were assigned into chow-fed controls (C, n=8), cafeteria diet (CAF, n=8), chow-fed trained (TR, n=8), and cafeteria diet plus trained (CAF-TR, n=8). PT was performed simultaneously with diet and consisted of 8-wk running session of 60 min, 5 days/wk. Exercise tolerance (ET) was determined by graded treadmill test, intraperitoneal insulin tolerance test (ITT), insulin, leptin and adiponectin levels were measured after PT. The weight of skeletal muscles, fiber type, capillary number and density, and the content of muscle lipids were determined. The expression of AMPK, AMPK phosphorylation at  $\alpha$ -Thr172 (p-AMPK), ACC and ACC phosphorylation at Ser 79 (p-ACC) in skeletal muscle were determined by Western blot. **Results:** After PT, TR and CAF-TR increased ET, CAF showed hyperinsulinemia and insulin resistance compared to TR and CAF-TR. Leptin did not differ among groups, but adiponectin was decreased in CAF compared to C group and increased in TR and CAF-TR compared to C and CAF groups. The weight and the content of fiber type 1, 2a and 2b in soleus, plantaris and gastrocnemius muscles did not differ among groups. Capillary number and density did not differ, but the content of muscle lipids in the soleus was decreased in TR compared to CAF-TR. AMPK expression was higher in CAF-TR compared to C, CAF and TR, p-AMPK increased in CAF-TR compared to C, ACC and p-ACC increased in CAF-TR compared to C and CAF groups. **Discussion:** The metabolic potential of skeletal muscle is largely modulated by the activity of AMPK (McGee & Hargreaves, 2010). Although the PT has been associated with morphological changes in skeletal muscle (Burr et al., 2010), our results showed that PT prevented IR by activating the AMPK/ACC pathway which was associated with increased adiponectin level but not with change in skeletal muscle morphological phenotype. Increases in adiponectin are associated with improved insulin sensitivity and glucose homeostasis (Yamaguchi et al., 2002). References: Burr JF, Rowan CP, Jamnik VK, Riddell MC. ### **NEUROPEPTIDE W MODULATED OF FOOD INTAKE BY STRESS RESPONSE AND VOLUNTARY EXERCISE IN MOUSE**

Takenoya, F., Hirako, T., Ota, E., Kageyama, H., Yamamoto, N., Ryushi, T., Shioda, S.

*Hashi University School of Pharmacy and Pharmaceutical Science*

**Introduction** Neuropeptide W (NPW), which was isolated from the porcine hypothalamus, which belong to the G protein-coupled receptor family. Centrally administered NPW is known to suppress feeding behaviour and promotes to secret adrenocorticotropin hormone (ACTH) and corticosterone. However, the target neurones of this action have not been clarified. The present study aimed to determine features of the NPW-mediated neuronal feeding pathway in rat. Moreover, generally voluntary wheel running reduces the activation of HPA axis to stimuli. Therefore, we studied to clarify the effect of infusion of by stress response and voluntary exercise in mouse. **Methods** To clarify the neuronal interaction between NPW-containing neuron and stress response and suppress feeding regulate peptide of corticotropin-releasing hormone (CRH) neuron. NPW i.c.v. injection with or without CRH antagonist pretreatment. Mouse were icv infusion of the vehicle and NPW (2 n mol) once a day. Body weight, food intake, water intake and locomotor activity were measured 24 hours later. Moreover compared it was the voluntary exercise and none by DAB staining of c-Fos positive cell in rat hypothalamus. **Results** NPW axon terminals

were found to make synapses on CRH immunoreactive cell bodies and dendritic processes in the PVN. Suppress feeding behaviour of NPW were canceled by CRH antagonist pretreatment. Mouse did not affect Body weight, food intake, water intake and locomotor activity milage with voluntary excise by NPW icv infusion. Voluntary wheel running canceled the NPW-induced anorexia and c-FOS decreases in the PVN. Discussion These results suggested that NPW mediated neuronal feeding pathway via CRH neurons in hypothalamus of the mouse. Moreover, the voluntary exercise stimulated the HPA axis and influence the feeding regulation in the mouse. References [1]Shimomura Y, Harada M, et al. (2002) *J Biol Chem* 277, 35826-35832. ### **CARDIORESPIRATORY ADAPTATION AND HORMONAL RESPONSES TO ENDURANCE EXERCISE IN FEMALE CROSS-COUNTRY SKIERS**

Zebrowska, A., Kochanska-Dziurawicz, A.

*Academy of Physical Education*

**Cardiorespiratory Adaptation and Hormonal Responses to Endurance Exercise in Female Cross-country Skiers**  
Introduction Competitive cross-country skiing is one of the most demanding sports disciplines. It requires a high maximal oxygen uptake, fast force production and ability to resist fatigue (Carter et al., 2001, Widdowson et al., 2009). During short uphill skiing, finishing burst and during new sprint skiing, the energy demand exceeds maximum oxygen uptake and, consequently, anaerobic energy production has been found to have an important role in cross-country skiing performance. The purpose of our study was to compare serum catabolic and anabolic hormones concentrations in relation to cardiorespiratory performance of elite female cross-country skiers of the Polish National World Cup Team. Methods We investigated the response of testosterone (T), growth hormone (GH), cortisol (C), steroid hormone binding globulin (SHBG), insulin-like growth factor (IGF-1), insulin-like growth factor binding protein-3 (IGFBP-3), and some anabolic-catabolic indexes, i.e.: T/C, T/SHBG, and IGF-1/IGFBP-3 to maximal aerobic exercise in twelve female cross-country skiers (mean age: 22±2 years). In all subjects M-mode and two-dimension Doppler echocardiography were analyzed before exercise. Pulmonary ventilation and oxygen uptake (VO<sub>2</sub>) were measured continuously during the exercise (Oxycon; Jaeger, Germany). Results The elite female skiers demonstrated high level of aerobic performance (VO<sub>2</sub>max: 55.6 ± 2.8 ml/kg/min. The maximal exercise test induced an increase in post-exercise GH (p<0.001), and T (p<0.01) and SHBG (p<0.01) concentration. Significant differences of IGF-1/IGFBP-3 and T/SHBG were seen between the resting and post-exercise levels. The results indicate differences in myocardial parameters depending on training status, and suggest a beneficial effect of endurance training on heart muscle function (Wernstedt et al., 2002). No significant associations were observed in left ventricular mass and anabolic hormones levels. Left ventricular mass and stroke volume correlated with VO<sub>2</sub>max (p<0.01). Conclusions We conclude that hormone changes following endurance training were different in female athletes, which may have both metabolic and hypertrophic implications [1, 2, 3]. Greater IGF-1/IGFBP-3 and T/SHBG elevation after exercise might suggest that both total and free fractions of these hormones may play an important role in adaptive mechanism and enhanced exercise performance of female athletes. The obtained results indicate differences in myocardial contractility parameters depending on training overload, and suggest a beneficial effect of endurance training on heart muscle function. 1. ### **EFFECTS OF ACUTE EXERCISE ON CYTOKINE AND IMMUNO-ENDOCRINE RESPONSES IN DIFFERENT AMBIENT TEMPERATURES**

Gagnon, D.D., Gagnon, S.S., Rintamäki, H., Karhu, T., Kyröläinen, H., Herzig, K.H.

*University of Jyväskylä*

**Introduction** Acute exercise and ambient temperature are both stressors that modulate the immune and endocrine systems. It is known that both systems communicate bi-directionally through hormone and cytokine production (Haddad et al., 2002). Much work has been done investigating the effects of exercise and heat stress on the immune-endocrine system whereas little is known regarding the effects of exercise and cold. Therefore, this study examined the effects of combined exercise and cold exposures on cytokine and immune-endocrine functions. Methods Nine healthy males with normal body weight, dressed in shorts and t-shirts, completed 6 exercise trials on separate days. They walked or ran (50% and 70% of maximal oxygen consumption (VO<sub>2</sub>max), for 60-min on a treadmill in a climatic chamber set at 22°C (Neutral, NT), 0°C (Cold, CD), or at 0°C following a low-intensity shivering cooling period (Cold-Shivering, CS). Leukocyte counts and subsets, catecholamines (epinephrine and norepinephrine), ACTH, cortisol, and cytokines were measured pre and post exercise. Results Leukocyte and granulocyte counts increased during exercise and were greater at 70% VO<sub>2</sub>max. Lymphocyte and monocyte counts were greater in NT compared to CD at post. ACTH and cortisol increased in NT and at 70% VO<sub>2</sub>max but remained unchanged in CD, CS and at 50% VO<sub>2</sub>max. Norepinephrine was also greater in NT and at 70% VO<sub>2</sub>max. Regarding cytokines, IL-1b, IL-7, IL-13, IP-10, MCP-1, MIP-1b, PDGF-bb, RANTES, VEGF, and IFN-g concentrations were greater in NT compared to CD (p < 0.05). Greater concentrations of IL-1b, IL-10, IL-13, MIP-1b, PDGF-bb, VEGF, and IFN-g were observed at 70% compared to 50% VO<sub>2</sub>max (p < 0.05). Finally, IL-1b, IL-13 and PDGF-bb concentrations were greater in CS as compared to CD (p < 0.05). Discussion During exercise, the immune and endocrine systems responded more strongly in the neutral ambient temperature indicating an immuno-suppressive effect from the cold. Exercise intensity also affected the endocrine-immune response as the 70% VO<sub>2</sub>max condition induced stronger cytokine and hormonal responses. Shivering in the cold also produced a stimulatory immune response compared to cold alone. In conclusion, exercising in a cold environment without the simultaneous presence of shivering suppresses immune-endocrine responses associated with exercise and heat stress during low and moderate exercise intensities. ### **ENDURANCE TRAINING AND INSULIN THERAPY ARE BOTH REQUIRED TO OBTAIN THE FULL THERAPEUTIC BENEFIT ON OXIDANT STRESS AND GLYCEMIC REGULATION IN DIABETIC RATS**

Groussard, C., Malarde, L., Le Douairon-Lahaye, S., Zguira, M.S., Vincent, S., Lemoine-Morel, S., Gratas-Delamarche, A.

*M2S Laboratory (Rennes, France).*

**Introduction** In type 1 diabetic subjects, hyperglycaemia-induced oxidant stress (OS) is a central mechanism in the onset and development of diabetic complications (Brownlee 2001). This study aimed to assess the effects of an endurance training program and insulin therapy,

alone or in combination, on glycaemic regulation, oxidant stress markers, and the antioxidant system in diabetic rats. Methods Forty male Wistar rats were divided into diabetic (D), insulin-treated diabetic (D-Ins), diabetic trained (D-Tr), or insulin-treated diabetic trained (D-Ins+Tr) groups. An additional healthy group served as a control group. Insulin therapy (Lantus, insulin glargine, Sanofi) and endurance training (a treadmill run of 60 min/day, 25 m/min, 5 days/week) began one week after diabetes induction by streptozotocine (45 mg/kg) and continued for 8 weeks. At the end of the protocol, blood glycaemia and fructosamine levels were evaluated, and skeletal muscle OS markers (CML, isoprostanes, GSH/GSSG) and the antioxidant system (SOD and GPx activity, ORAC) were measured. Results Diabetic rats exhibited altered glycaemic regulation and higher OS markers but no antioxidant system modifications. Insulin treatment improved the pro-antioxidant status and fructosamine levels but failed to correct glycaemia. Endurance training decreased OS markers without improving antioxidant enzyme activity. Endurance training and insulin therapy in combination extended insulin action, leading to decreased glycaemia in the D-Ins+Tr group. Moreover, endurance training, when associated with insulin treatment, exerted antioxidant effect by increasing SOD activity. Conclusion Our results demonstrate that a combination of insulin treatment and endurance training potentiates their respective effects on glycaemic regulation and oxidant status. ## CYTOKINE RELEASE FOLLOWING CONTINUOUS AND INTERVAL EXERCISE OF CONTRASTING VOLUME

Cullen, T., Thomas, A., Webb, R., Hughes, M.

*Cardiff Metropolitan University (UK)*

**Introduction** The cytokines interleukin-6 (IL-6) and interleukin-10 (IL-10) are known to play a role in metabolism and immune function during periods of stress. The responses of these cytokines have been well characterized in the context of long duration aerobic exercise (Petersen and Pedersen 2005). However responses to shorter, high intensity interval training (HIT) remains unknown. The aim of the current study was to characterize the response of the cytokines IL-6 and IL-10 to high intensity interval exercise, and to evaluate the sensitivity of these measures to variations in exercise intensity. **Methods** Five male and five females (mean SD  $VO_{2peak} = 49.1 \pm 4.5$  ml kg<sup>-1</sup> min<sup>-1</sup>) completed three exercise tests on a cycle ergometer: LOW (35 min, 50%  $VO_{2peak}$ ), MODERATE (5 X 2 min, 80%  $VO_{2peak}$  interspersed with 5 min relative recovery at 50%  $VO_{2peak}$ ) and HIGH (5 x 4 min, 80%  $VO_{2peak}$  interspersed with 3 min relative recovery at 50%  $VO_{2peak}$ ). Exercise tests were performed in a randomized and counterbalanced order with each test separated by a minimum of three days. IL-6 and IL-10 concentration were determined from blood samples taken pre and immediately post exercise. **Results** The average oxygen uptake during each bout was  $50.4 \pm 4.6\%$   $VO_{2peak}$  (LOW),  $59.3 \pm 3.1\%$   $VO_{2peak}$  (MODERATE) and  $69.2 \pm 2.2\%$   $VO_{2peak}$  (HIGH). The end test blood lactate was  $1.4 \pm 0.6$  mmol (LOW),  $3.0 \pm 1.4$  mmol (MODERATE) and  $5.8 \pm 3.2$  mmol (HIGH). Compared to pre-exercise IL-6 increased significantly in all 3 conditions: 1.4±0.32 fold (P<0.01) (LOW), 1.95±0.80 fold (P<0.01) (MODERATE), 2.7±1.51 fold (P<0.01)(HIGH). The increase in IL-6 was significantly greater in the HIGH protocol than the LOW protocol (P=0.04), and showed a trend towards significance when compared to the protocol MODERATE (P=0.11). IL-10 showed no significant change from pre to post in any of the exercise protocols. **Discussion** This study demonstrates that IL-6 release is sensitive to short duration aerobic exercise lasting 35 minutes and that the response to HIT style exercise (HIGH) is greater than that of steady state moderate intensity exercise. It is possible that with a larger sample size a statistically significant difference would have been observed between the MODERATE and HIGH protocols. While previous studies have shown that IL-10 does increase as a result of longer durations of exercise (Cox et al., 2007) this study suggests that IL-10 is not sensitive to exercise intensity during exercise lasting 35 minutes. #### THE IMPACT OF PARACETAMOL ON THERMOREGULATORY RESPONSES DURING EXERCISE

Veltmeijer, M.T.W.1, Eijsvogels, T.M.H.1,3, Netea, M.G.2, Van der Meer, J.W.M.2, Hopman, M.T.E.1

*1,2 Radboud University Nijmegen Medical Centre, Nijmegen, the Netherlands, 3 Hartford Hospital, USA*

**INTRODUCTION** Exercise typically results in elevation of core body temperature (CBT), which may lead to a decreased exercise performance and/or the development of heat-related illnesses. While the role of inflammatory cytokines in the induction of fever is clearly established, their pyrogenic effect during exercise has not been studied extensively. The aim of this study was to examine whether exercise leads to upregulation of the hypothalamic set-point by the production of inflammatory mediator prostaglandin E2 (PGE2) based on an increased release of interleukin-6 (IL-6). We hypothesized that blocking PGE2 production with paracetamol would result in a lower CBT during exercise compared to the use of a placebo. **METHODS** A randomized double-blind cross-over design was applied in which 11 healthy subjects (52±5 years, BMI 25.2±2.6) were administered 1000 mg paracetamol or placebo on two separate days. After 30 minutes of rest, subjects performed 30 minutes of continuous treadmill exercise with speed adjusted to maintain 85% of their maximal heart rate. Subsequently, subjects continued with 30 min of intermittent exercise keeping running speed constant and alternating 2 minutes of running at a 10% incline and 2 minutes at a 0% incline. IL-6 plasma levels were determined from venous blood samples drawn immediately before and after the test. CBT was measured continuously using a wireless telemetry system. **RESULTS** Running speed did not differ between the paracetamol (8.4±0.7 km/h) and placebo (8.6±0.5 km/h) condition (p=0.07). Baseline IL-6 levels were similar (4.1±3.6 vs. 3.8±1.9 pg/mL, p=0.68), increased significantly (p=0.03), and were similar in both conditions post-exercise (5.2±4.4 vs. 5.3±3.4 pg/mL, p=0.86). Baseline CBT did not differ between the paracetamol (37.0±0.3 °C) and placebo (37.1±0.3 °C) condition (p=0.29), and increased significantly in all subjects (p<0.001). Although the course of CBT increase during exercise was not different between the conditions (p=0.10), peak CBT was slightly but significantly lower in the paracetamol (38.9±0.4 °C) compared to the placebo (39.1±0.4 °C) condition (p=0.04). **CONCLUSION** The significant rise of plasma IL-6 demonstrates a similar stimulus for PGE2 production in both conditions. Interestingly, we found a significantly lower peak CBT after administration of paracetamol, indicating that part of the elevated CBT during exercise is due to PGE2 release. These results suggest that the exercise-induced elevation in CBT may be partially due to an upward shift of the hypothalamic set-point, with the remainder of the temperature rise being caused by a hyperthermic response.

### EFFECTS OF TIME OF DAY ON REPEATED SPRINT ABILITY ON A NON-MOTORISED TREADMILL.

Pullinger, S.A., Brocklehurst, E., Iveson, R., Waterhouse, J.M., Burniston, J., Doran, D., Edwards, B.J.

*Research Institute for Sports and Exercise Sciences,*

Time-of-day differences in short-term anaerobic sprint performance (<6s) in trained males have been well established, with improved performance evident in the evening (Racinais et al., 2004; Souissi et al., 2004). This diurnal variation is attributed to motivational, peripheral and central factors, and possibly higher core and muscle temperatures observed in the evening (Edwards et al., 2013). What has received little attention is the possible diurnal variation in repeated sprint ability (RSA) a fundamental variable in team-sports games. The purpose of the present study was to investigate whether, in team-sport trained subjects, a daily variation in RSA (assessed on a non-motorised treadmill) exists. Sixteen healthy active males (mean  $\pm$  SD: age, 20.8  $\pm$  2.2 yrs; body mass, 78.7  $\pm$  10.5 kg; height, 1.78  $\pm$  0.6 m) completed the study, which was approved by the local University Ethics Committee. The subjects were familiarized with the techniques and protocol and then completed two experiment sessions (separated by at least 48h) counterbalanced in order of administration: morning (07:30h) and evening (17:30h) sessions. Rectal (T<sub>rec</sub>) and muscle (T<sub>m</sub>) temperatures were measured after the subjects had re-learned for 30min at the start of the protocol and during a 5-min active warm-up at 10km.h<sup>-1</sup>. Each session comprised of 3 task-specific warm-up sprints at 50, 70 and 80% maximum and 10 x 3s sprints with 30s recovery between each of them, performed on a non-motorised treadmill (Woodway Force 3.0, Waukesha, WI, USA). Distance covered (m), peak power output (W), average power output (W), peak velocity (km.h<sup>-1</sup>) and average velocity (km.h<sup>-1</sup>) were measured in all sprints. Heart rate (HR), thermal comfort (TC), rating of perceived exertion (RPE) and effort (on a 0-10 scale: 0 meaning no effort and 10 maximal effort) were recorded throughout. Data were analysed using General Linear Models with repeated measures. Resting T<sub>rec</sub> and T<sub>m</sub> values were higher at rest in the evening than in the morning (by 0.44°C and 0.47°C respectively,  $p < .05$ ). Total distance covered, peak power, average power, peak velocity and average velocity over the ten sprints all showed significantly higher values in the evening compared to the morning (an average range of 3.2-7.6%,  $p < .05$  in all cases). All subjects reported maximal values for RPE for each sprint. In summary, in this population of motivated subjects, effects of time of day were seen in all measures of RSA indicative of performance, in general agreement with past research. Both T<sub>rec</sub> and T<sub>m</sub> values also showed significant diurnal variation. This diurnal variation in RSA could potentially be attributed to a combination of motivational, peripheral and central factors, as well as the higher rectal and muscle temperatures observed in the evening. Key words: Rectal and Muscle temperature, RSA, diurnal variation.

### THE EFFECT OF EXTREME ENVIRONMENTAL CONDITIONS ON THE DECISION MAKING PERFORMANCE OF ON FIELD REFEREES AND GOAL LINE OFFICIALS

Watkins, S.1, Fitch, N.1, Aldous, J.1, Mauger, A.R.2, Castle, P.1, Brewer, J.1, Taylor, L.1

1. University of Bedfordshire, UK, 2. University of Kent, UK

Introduction UEFA cup competitions are international in nature and as a result are played in a diverse set of climatic conditions, eg Moscow (-5 oC) and Madrid (+30 oC). It is currently unknown how these environmental conditions impact the decision making ability of on-field soccer referees (REF) and soccer goal line officials (GLO) and how such conditions combine with the differing movement patterns of REF and GLO. Methods 24 physically active males were randomly split into 2 groups (n=12), group 1: REF; group 2: GLO. Both groups were exposed to 3 environmental conditions: cold (-5 oC, 50%RH); temperate (18 oC, 50%RH); hot (30 oC, 50%RH) for 90 min with a 15 min half time break following 45 min exposure. Throughout 90 min exposure REF carried out an intermittent sprint protocol (Drust, Reilly et al. 2000) where as GLO were allowed only small lateral movements. Decision making performance was assessed using the PSYCHE software package (Vigilance and Dual Task) (Hope, Woolman et al. 1998). Traditional environmental physiology measures were also recorded (Rectal and Skin temperature, Heart rate, Thermal Sensation). Results reported as percentages of change and qualitative interpretations of effect size. Results 1st 45 min Exposure: REF negative responses during the dual task increased by 33% in the heat compared to temperate (ES: 0.8, Large). Negative responses of GLO increased during cold exposure when compared to temperate by 86% during the vigilance task (ES: 3.2, Large) and 94% in the dual task (ES: 1.2, Large) when compared to temperate condition. 2nd 45 min Exposure: The negative responses of REF increased by 17% in the heat compared to temperate for both vigilance and dual tasks. GLO negative responses increased by 90% during the vigilance task and 69% during the dual task when compared to scores in temperate conditions. Discussion A greater number of errors in decision making were observed in GLO in-line with reductions in endogenous temperatures and thermal comfort when exposed to cold. In contrast, heat exposure induced an increase in REF endogenous temperatures leading to reductions in thermal comfort and decision making performance. Such findings may have implications on the use of GLO in future tournaments and the implementation of goal line technology. References Drust, B., T. Reilly, et al. (2000). ### INFLUENCE OF COMPETITION ON PERFORMANCE AND THERMOREGULATION DURING EXERCISE IN THE HEAT

Corbett, J.

*University of Portsmouth*

Introduction It is suggested that the reduced power during self-paced exercise in the heat represents a form of behavioural thermoregulation to avoid a critical rise in body temperature (Marino, 2004). However, it has recently been shown that performance is improved when participants believe they are competing against another athlete compared to exercise alone (Corbett et al., 2011), although this study used short duration exercise in temperate conditions. The present study examined the effect of competition on performance and thermoregulation during prolonged exercise in a hot environment. Method Six physically active males undertook a 20 km preliminary cycling time trial (TT) (15°C, 50% R.H.) and three 20 km experimental TTs in a balanced order: (15°C & 50% R.H [15SOLO]; 30°C & 50% R.H [30SOLO]; 30°C & 50% RH 'head to head' competition [30HH]). During 'solo' trials an avatar of the participant cycling on a virtual 20 km course (constructed with Velotron 3D software) was displayed enabling them to gauge their progress. During HH competitions participants were separated by a screen and avatars of both were generated on the racecourse, although the competitor performance was actually generated by the software using the preliminary trial data obtained under cooler conditions; the participants were not aware of this deception. Performance times and aural temperature (T<sub>aural</sub>) were recorded. For safety, trials were terminated if T<sub>aural</sub> >39°C. Where this occurred the shortest distance completed before termination in any trial was defined as the 'endpoint' across all trials for that participant. Repeated measures ANOVA and post-hoc T-tests were used to examine between-trials differences. Results Endpoint times were 2097 $\pm$ 381 s, 2125 $\pm$ 384 s, and 2059 $\pm$ 396 s for 15SOLO, 30SOLO and 30HH, respectively. Endpoint times for 30HH were faster than

either 15SOLO or 30SOLO ( $P < 0.05$ ). Endpoint Taural was  $37.2 \pm 0.4^\circ\text{C}$ ,  $38.1 \pm 0.5^\circ\text{C}$ ,  $38.5 \pm 0.3^\circ\text{C}$  for 15SOLO, 30SOLO and 30HH and was different between all conditions ( $P < 0.05$ ). Discussion Performance was improved in HH competition in hot conditions relative to the same exercise performed alone in the same ambient conditions, or performed alone under cooler conditions. The higher Taural in 30HH indicates that HH competition may encourage participants to override thermal cues which might otherwise be used to regulate performance, although this hypothesis requires further investigation given that performance was not significantly impaired in 30SOLO relative to 15SOLO. The improved performance in HH competition in a warm environment is consistent with the concept of a physiologic reserve (Corbett et al., 2011). ### TRAINING WITH HEAT DISSIPATION COMPRESSIVE T-SHIRT: THERMOREGULATORY AND CARDIOVASCULAR EFFECTS.

Leoz, I., Aguado-Jimenez, R.

*Universidad Pública de Navarra*

Introduction: It is well known that hyperthermia causes fatigue, in other words, endurance can be impaired in hot compared with temperate climates (1,2). To prevent hyperthermia some of the strategies that have been used over the years are rehydration and ventilation (3). Nowadays new strategies as cooling vest or heat dissipation clothes are becoming important to prevent heat stroke. One of these strategies, heat dissipation compressive T-shirt (X-Bionic Energy Accumulator) is the one we use in this research. The aim of this study was to know the utility of the heat dissipation clothing, to prevent hyperthermia during moderate intensity training. Methods: 16 subjects were recruited for this study. All the subjects performed two randomized protocols separated each other by a minimum of 7 days: Control group (Control) and compressive T-shirt (experimental). They exercised at 60% of maximum oxygen consumption ( $\text{VO}_2\text{max}$ ) on a cycle ergometer for 30 min maintaining the same cadency in a thermoneutral environment ( $25^\circ\text{C}$ ) (4). Skin (Thermocouple), rectal (YSI), tympanic and forehead temperature were measured every 5 minutes. HR,  $\text{VO}_2/\text{VCO}_2$  (Vacumed) and body weight were also measured. Results: 1. Weight Loss: Control vs. experimental ( $0.36 \pm 0.2$  vs.  $0.24 \pm 0.2$  L)  $P < 0.05$ . It shows that compressive T-shirt allows you to lose less body fluid. 2. Heart Rate: Control vs. experimental at min. 30 ( $147.1 \pm 21$  bpm vs.  $143.6 \pm 25.6$  bpm)  $P = 0.07$ . HR is reduced at the end of the protocol wearing compressive T-shirt. 3.  $\text{VO}_2$ : Control vs. experimental at min. 30 ( $2.2 \pm 21$  L/min vs.  $1.8 \pm 25.6$  L/min)  $P > 0.05$ . Data shows tendency to reduce  $\text{VO}_2$  during experimental protocol. 4. Skin Temperature: Control vs. experimental at min. 30 ( $32.9 \pm 0.5^\circ\text{C}$  vs.  $33.8 \pm 1.6^\circ\text{C}$ )  $P > 0.05$ . Result shows tendency to increase skin temperature when wearing compressive T-shirt. 5. Rectal Temperature: Control vs. experimental at min. 30 ( $38.2 \pm 0.6^\circ\text{C}$  vs.  $37.9 \pm 0.5^\circ\text{C}$ )  $P > 0.05$ . Result shows tendency to reduce rectal temperature when wearing compressive T-shirt. Discussion: Heat dissipation compressive T-shirt allows you to prevent dehydration, reducing HR, which is reflected in the same way in a smaller aerobic necessity. At the same time, this clothing reduces the increase of rectal temperature, probably due to a better heat dissipation of temperature through the skin, considering that plasma volume might not be so reduce. ### THERMOREGULATION AND TEMPERATURE PERCEPTION IN SUBJECTS SUBMITTED TO 30-HOURS OF EXERCISE AND SLEEP DEPRIVATION

Mikulski, T.1, Bogdan, A.2, Zwolinska, M.2, Ziemba, A.1

*1 Mossakowski Medical Research Centre, PAS, Warsaw, Poland. 2 Central Institute for Labour Protection – National Research Institute, Warsaw, Poland.*

Introduction Participants of outdoor ultra-endurance events lasting more than 24 hours often perceive temperature inadequately in latter stages of exercise. Thus, the aim of the present study was to compare the core temperature and temperature perception in subjects submitted to prolonged exercise combined with complete sleep deprivation. Methods Core temperature was measured with a single use, swallowed sensor (Vital Sense, USA) in ambient temperature of  $19^\circ\text{C}$  at rest for 30 min and during graded exercise test to exhaustion in 11 endurance trained men before (B) and immediately after (A) 30 hours of prolonged exercise (simulated adventure race) combined with complete sleep deprivation. Perception of temperature was evaluated using a 6 grade ASHRAE thermal sensation scale. Subjects were dressed in standardized, single layer of cycling shorts and T-shirt. Results Core temperature increased during rest period already in 10th min and remained elevated for 30 min in both trials (trial B from  $36.96 \pm 0.04^\circ\text{C}$  to  $37.07 \pm 0.05^\circ\text{C}$  in 10th min ( $p < 0.05$ ) and to  $37.14 \pm 0.06^\circ\text{C}$  in 30th min ( $p < 0.01$ ); trial A from  $36.99 \pm 0.06^\circ\text{C}$  to  $37.08 \pm 0.06^\circ\text{C}$  in 10th min ( $p < 0.05$ ) and to  $37.18 \pm 0.08^\circ\text{C}$  in 30th min ( $p < 0.01$ )). There were no differences in core temperature between trials B and A. Perception of temperature was significantly "colder" in trial A than B ( $-1.7 \pm 0.2$  vs.  $-1.0 \pm 0.2$ ,  $p < 0.001$ ). Exercise induced increase in core temperature and maximal temperature at exhaustion were similar in both trials B and A. Discussion Sitting in thin clothes in ambient temperature below comfort stimulates cold receptors on the skin surface leading to induced thermogenesis and limited skin blood flow. Therefore, in moderately cold environment enhanced heat production and decreased heat loss can produce increase in core temperature, what probably have happened in both experimental trials. Definitely different perception of temperature after prolonged exercise and sleep deprivation may reflect the impaired function of overstrained nervous system, probably in cortex, whereas rear part of hypothalamus governing maintenance of the heat functions correctly. Thermoregulation during exercise worked properly, as it is handled by hypothalamus with simple reflexes.

### EFFECTS OF A HOT AND HUMID ENVIRONMENT ON DRUMMING PERFORMANCE – A CASE STUDY.

Smith, M., Draper, S.

*University of Chichester & University of Gloucestershire*

Hot and humid environments have been shown to impair health and performance in military (Adolph et al., 1947), occupation (Wilkinson et al., 2007) and sport (Chan et al., 2008) settings. Anecdotal evidence from professional drummers report heat stress when performing at hot and humid venues [personal communications: Clem Burke, drummer Blondie (2011) and Mark Richardson, drummer Skunk Anansie (2012)]. The aim of this study was to investigate the thermal challenge of drumming during a live performance at an indoor venue. The participant was a volunteer professional drummer (punk rock band UKSUBS: 27yr, 1.80m and 76.5kg). All data acquisition took place at the 100 Club (London, UK). Environmental temperature ( $^{\circ}\text{C}$ ) and relative humidity (%) were measured using a USB sensor and

data logger (Lasca EL USB2+, Lasca Electronics Ltd, Salisbury, UK). Core temperature was measured using a gastrointestinal pill (HQ Inc, Palmetto, USA) consumed 3hr prior to the performance. Body mass was recorded pre- and post-concert to estimate sweat rate (Seca 880 scales, Birmingham, UK). Heart rate was measured using short-range telemetry (Polar S810i, Kempele, Finland). The concert lasted 62min, comprising 22 songs. During the concert air temperature increased from 25 to 34°C and relative humidity from 68 to 84%. Body mass decreased by 2.6%, equating to a sweat rate response of 2.0L.hr<sup>-1</sup>. Peak core temperature increased from 37.4°C at baseline to 39.0°C after 30min, when 500ml of chilled water was consumed. Heart rate ranged between 115-208b.min<sup>-1</sup> with an average for the whole performance of 195b.min<sup>-1</sup>. It is evident from the data that small indoor venues pose a significant thermal challenge to the drummer. Therefore, drummers should adopt an appropriate fluid replacement strategy to reduce the risk of impaired performance and health.

### **A COMPARATIVE STUDY OF TOTAL SWEAT LOSS , BODY TEMPERATURE AND SWEAT CONCENTRATIONS OF AFTER EXERCISE OF TRAINED AND UNTRAINED ADULTS <18-20> YEARS OLD.**

Mathkor, F.

*college of physical education*

Introduction Eccrine sweat glands play a clear and vital role in our ability to survive heat stress and maintain remarkably constant homeothermic conditions under thermal loads (Quinton PM 1983) , on the other hand the physical loads are playing an important role for sweat secretion and they regulated the active of cells, physiological systems and glands especially in sweat glands which result to physiological adaptations to exercise and improving the ability of the athletes for exercised in a hot environment and decrease the injury risk of many heat disease methode Six Male well-trained athletes from different sport events, (age 19.1 ± 4.6 years; mass 76.4 ± 6.9 kg; peak oxygen consumption 5.10 ± 0.85 l min<sup>-1</sup>; mean ± s.d first exercise a continuous (75)watts at (10) minutes after (5) minutes for worm up and second exercise a continuous (100) watts at (8) minutes at 30°C (50% relative humidity) . Results sweat concentrations and body temperature were generally greater, at the first exercise: total sweat loss(0.22 ±0.139),( 0.685±0.268) (p<0.01)respectively, body temperature difference (1.97 ±0.456) ( 1.4±0.26) (p<0.05) respectively and sweating concentrations of phosphate(1.935±0.441)(3.94±0.625) respectively (p<0.01) , sodium (93.24±4.634)(71.553±2.436)(p<0.01) and chloride(37.53±3.547)(22.834±6.677) (p<0.01) respectively during trained group compared to the untrained group, and the second exercise : total sweat loss(0.20 ±0.805),( 0.60±0.171) (p<0.01)respectively, body temperature difference (1.93 ±0.36) ( 1.52±0.43) (p<0.05) respectively and sweating concentrations of phosphate (1.721±0.214) (3.45±0.752) respectively (p<0.01) , sodium (87.34±2.511) (64.942±2.732) (p<0.01) and chloride (47.22±2.87) (20.655±4.330) (p<0.01) respectively during trained group compared to the untrained group Discussion The sweat phosphate concentration was decreased in the trained group compared to the untrained group because of the role of physical training which enhances the decrease of sweat phosphate to rise the function of sweat glands to product high energy compounds inside the sweat glands tissues (fadhel k. mathkor 1997 ) .the same result has been shown for sodium and chloride concentrations in the trained group compared to the untrained group these results are agree with the (fadhel k. mathkor 1997; fukumoto T. et. al 1988; Kirk , JM. 1992; Michal E. Bergeron 1995. Knowledge of sweat production might also be valuable specially when comparison of these data showed that the sweat ions may be as indicated to comparative between trained and untrained group and should take the concentration of sweat such as sodium

### **INFLUENCE OF PASSIVE HYPERTHERMIA ON ARM CRANKING ENDURANCE CAPACITY AND ISOKINETIC TORQUE OF EXERCISED AND NON-EXERCISED MUSCLE GROUPS**

Otani, H.1, Kaya, M.2, Shirato, M.3, Goto, H.4, Tsujita, J.5

*1; Himeji Dokkyo University (Japan), 2; Hyogo University of Health (Japan), 3; Mejiro University College (Japan), 4; Loughborough University (UK), 5; Hyogo College of Medicine (Japan)*

Introduction: It has been reported that hyperthermia elicits the reduction in isometric force production in the exercised and non-exercised limb following cycling exercise. However, the effects of hyperthermia on arm cranking endurance capacity and isokinetic force production of exercised and non-exercised muscles following arm-crank exercise are poorly understood. The aim of this study was to examine the effect of passive hyperthermia on arm cranking endurance capacity and isokinetic torque of exercised (elbow flexors) and non-exercised (knee extensors) muscle groups. Methods: Eight healthy males were immersed to the upper chest in water at 36 degrees C (control) or 40 degrees C (hyperthermia) for 30 min, and then exercised on an arm cranking ergometer at 60% of maximal oxygen uptake until voluntary exhaustion in a 25 degrees C and 50%RH environment. Pre- and post-immersion and immediately following the exercise, subjects performed two series of isokinetic shortening and lengthening maximal voluntary contractions (MVCs) of the elbow flexors and knee extensors: one series of single MVCs and one series of 25 endurance MVCs. Electromyography (EMG) was recorded with surface electrodes over the biceps brachii and vastus lateralis during isokinetic MVCs. Rectal temperature, skin temperature, heart rate, skin blood flow and blood pressure were recorded at rest and during exercise. Results: Rectal temperature at the end of immersion was 37.1 ± 0.3 degrees C (± SD) and 38.1 ± 0.3 degrees C in the control and hyperthermia trials, respectively. During arm-crank exercise, time to exhaustion was less in the hyperthermia trial than in the control trial (control 52 ± 12 min; hyperthermia 41 ± 13 min, P < 0.01). There was no difference in rectal temperature at exhaustion between trials (control 37.7 ± 0.3 degrees C; hyperthermia 37.8 ± 0.4 degrees C). At post-immersion, peak torque for shortening single MVC of the elbow flexors (control 56.4 ± 13.1 Nm; hyperthermia 42.1 ± 7.1 Nm, P < 0.01) and integrated EMG at biceps brachii (control 79.7 ± 18.9%; hyperthermia 57.7 ± 9.2%, P < 0.05) were lower in the hyperthermia trial than in the control trial. Conclusion: This study demonstrates that passive hyperthermia elicits significant reductions in arm cranking endurance capacity and isokinetic torque for shortening single MVC of the elbow flexors. This decrement in isokinetic elbow flexion torque is accompanied by a lower integrated EMG. However, no statistically differences in isokinetic torque of exercised and non-exercised muscle groups following arm-crank exercise are apparent between trials.

### **DO WELL-TRAINED ENDURANCE ATHLETES BENEFIT FROM A FABRIC WITH IMPROVED EVAPORATIVE PROPERTIES?**

Born, D.P., Lindner, N., Sperlich, B.

*University of Wuppertal*

Introduction While thermoregulation can limit performance when exercising in the heat clothing itself presents a layer of insulation thereby impeding heat dissipation (Gavin 2003, Sports Med). It was shown, that synthetic fabrics have higher moisture transfer capacities in comparison to cotton thereby retaining less moisture and diminishing the rise in body temperature and humidity during submaximal exercise in untrained individuals (Dai et al. 2008, Eur J Appl Physiol). Therefore, we hypothesised that wearing shirts made of a synthetic

fabric with improved evaporative properties would reduced body temperature, humidity, cardio-respiratory and metabolic strain thereby improving performance in well-trained endurance athletes. Methods 6 male, well-trained endurance athletes volunteered for this study ( $71.7 \pm 5.4$  kg,  $177 \pm 6$  cm,  $9.5 \pm 2.9\%$ ,  $62.0 \pm 4.0$  ml/min/kg). The exercise protocol consisted of a submaximal running effort for 30min running at 70% of  $VO_{2peak}$  followed by a ramp test to voluntary exhaustion and a recovery period of 10min walking. All participants performed two trials in a climatic chamber ( $30.3 \pm 0.7^{\circ}\text{C}$ ,  $36.4 \pm 9.1\%$  RH,  $1.0$  m/s air flow) wearing a synthetic fabric (91% polyester, 9% lycra) and a cotton shirt in a randomized order. During the trials  $VO_2$ , VE, and HR were measured continuously with an open breath-by-breath analyzer (ZANN600, Oberthulba, Germany). Body temperature and humidity was determined using adhesive temperature sensors, an ingestible sensor pill (Mini Mitter Co., Inc., Bend, OR) and humidity sensors (MSR, Glatfbrugg, Switzerland). Capillary blood samples were taken in 5min intervals and analysed using amperometric-enzymatic determination of lactate (Eppendorf, Hamburg, Germany). At the same time points the subjects rated their perceived exertion (BORG's scale) and sensation of humidity on a 4-point likert scale from 1 (dry) to 4 (wet). Results While changes in body mass were unaffected ( $p=0.17$ ), gain in shirt mass was lower in the synthetic fabric ( $p<0.01$ ). During recovery, the synthetic fabric reduced core ( $p<0.01$ ) and skin temperature ( $p=0.02$ ). Humidity between shirt and skin was reduced during all three time points at the chest ( $p\leq 0.04$ ) and back ( $p\leq 0.01$ ). Cardio-respiratory and metabolic measures ( $p\geq 0.20$ ) as well as perceived exertion remained unchanged ( $p\geq 0.46$ ). Sensation of humidity was reduced during recovery only ( $p=0.04$ ). Although thermoregulation was improved, statistical analysis did not reveal any improvements in performance of well-trained endurance athletes due to the synthetic fabric ( $p=0.28$ ). Discussion & Conclusion Under hot environmental conditions, thermoregulation was improved due to a synthetic fabric in well-trained endurance athletes. However, performance was unaffected.

### IMPAIRED COGNITIVE FUNCTION FOLLOWING MATCH-PLAY TENNIS IN THE HEAT

Herrera, C.P., Gaoua, N., Racinais, S., Knez, W.L., Girard, O., Christian, R.J., Periard, J.D.

*Aspetar - Qatar Orthopaedic & Sports Medicine Hospital*

Introduction Success in match-play tennis requires both physical strength and the mental capacity to anticipate, react and make split second decisions. During matches, the repetition of high-intensity efforts over several hours leads to the development of fatigue, which is manifested by alterations in neuromuscular function. However, it remains unknown whether match-play tennis results in impaired cognitive function and the extent to which this may be exacerbated by playing in a hot environment, or influenced by hydration status. Methods Eleven competitive male tennis players (ITF rank 2-3) undertook three matches separated by 72 hrs. Each match consisted of 20 min of effective play, separated in two 10 min segments. One match was played in a control, temperature environment (CON:  $22^{\circ}\text{C}$  and 70% RH) and the remaining two were played in hot environments ( $\sim 36^{\circ}\text{C}$  and 35% RH); Based on the first match in the heat (HOT), an individualized hydration regimen was developed and implemented during the second match (HYD). Executive function (OTS with 2 level of complexity: OTS-4 and OTS-6), sustained attention (RVP, Rapid Visual Processing), and reaction time (CRT, Choice Reaction Time) were assessed before (PRE) and after (POST) match-play using the Cambridge Neuropsychological Test Automated Battery (CANTAB). Results OTS: the overall mean latency to first response was significantly shorter after match play (PRE: 10.9s, POST: 9.3s,  $p=0.02$ ). The overall mean latency to correct response was significantly shorter after match play (PRE: 11.6s, POST: 9.9s,  $p=0.01$ ), and the complex task (PRE: 34.5, POST: 26.3,  $p=0.01$ ), but not the simple task (PRE: 7.3, POST: 6.0,  $p=0.11$ ). There was a main effect of condition on the number of correct problems solved (range 0-4) on the complex task only (CON: 3.5, HOT: 2.8, HYD: 3.2; pair-wise comparisons were: HOT vs. HYD ( $p=0.01$ ), HOT vs. CON ( $p=0.03$ ), and HYD vs. CON ( $p=0.13$ ). There were no significant main effects on all measures of RVP and CRT. Discussion This study demonstrates a paradoxical effect of match-play tennis in the heat on cognitive function. While athletes had faster response rates and no change in simple cognitive function, complex cognitive function was impaired after match-play in the heat. Further research is needed to confirm whether an individualized hydration strategy attenuates cognitive impairment after match-play tennis in the heat.

### EVALUATION OF THE MUSCLE ARCHITECTURE OF THE RAT GASTROCNEMIUS MUSCLE AFTER AEROBIC TRAINING

André, A., Moretto, D., Fontes-Ribeiro, C.A., Tavares, P.

*University of Coimbra*

Do not insert authors here Introduction Human activity requires a movement or at least a muscle contraction, either for walking or running or other functions. This enormous diversity of muscle functions is reflected by its size and shapes. The maintenance of skeletal muscle architecture is essential for its contraction and performance. One of the parameters that is considered in the muscle architecture is the pennation angle. In pennate muscle the fiber are obliquely inserted into the tendon or in the deep aponeurosis, and because this arrangement is termed pennate. In this type of muscles the fibers are shorter than those in a fusiform belly, because they pull on the tendon or aponeuroses at an certain angle. The force developed by this muscles, which depends on the cross sectional area of all fibers, is increase proportionately. In previous works we demonstrated that aerobic exercise changes skeletal muscle fiber type that changes the skeletal muscle architecture. Thus, the aim of this study was to investigate the alterations in muscle architecture with aerobic exercise. Methods To perform this work an exercise animal model was used. All the animals' experiments and treatments were in agreement with the national and international guidelines regarding the experimental use of animals. Eighteen male Wistar adults' rats ( $\sim 250$  g) were used. The animals were divided in two groups: a control and an exercise group. The exercise group performed an aerobic training for 8 weeks in a treadmill. At the end of this period the training efficiency was assessed by a resistance/velocity test. After training, an ultrasound analysis of the medial gastrocnemius muscle was taken (GE, Hologic E; 12 MHz transducer). The evaluation of the gastrocnemius was based in the measurements of the pennate angle, between the deep aponeuroses and the fascicle of the muscle. Then, the medial gastrocnemius muscle, laterally and in its antero-posterior face, was measured with a caliper rule. The gastrocnemius muscle was removed, weighted and stored for further analyses. Results The exercise group under aerobic training for 8 weeks showed a good performance. Concerning muscle architecture parameters no changes were observed in the pennation angle, muscle weight or on the thickness of the muscle. Moreover, no changes were observed in the ultrasound analysis of muscle measurements. Discussion Our results showed no changes in muscle architecture despite the slight change in fiber type and increase in performance. These findings suggest that aerobic training for eight weeks increases muscle rats performance without changing gastrocnemius architecture.

**CONFIGURATIONS OF FOOTBALL MATCH PLAY AND THEIR IMPACT ON CARDIOVASCULAR STRESS**

Gupta, S., Goswami, A.

*University of West Indies, FMS*

Do not insert authors here Introduction Heart rate (HR) has been used as an index of physiological strain in footballers during game and is closely correlated to the work-rate profiles. Workload of players can also change with configurations or systems of play, such as, 4-4-2 or 4-3-3. Methods VO<sub>2</sub>max, HRmax and HR at anaerobic threshold (HRAT) of footballers (N=20) were determined in laboratory. Finally, HR of the players was measured during selection matches. The first two matches were played between two common teams of equal skill and fitness status. The first match was played in configuration known as 4-3-3 (i.e., 4 defenders [D], 3 midfielders [M], 3 forwards [F]) while 4-4-2 was the formation of the second match. HR of 7 players of different playing positions (1 G, 2 D, 3 M, and 1 F) was recorded in the first game. In the second match also, HR of 7 players (1 G, 1 D, 3 M, and 2 F) was recorded, of which 3 M were common to the first match. The third match was played between two other teams. A total of 9 players (3 each of D, M, and F) were studied in the third match. Maximum Heart Rate Reserve (MHRR) was calculated using the formula (ACSM 1987):  $MHRR = [Exercise\ HR - Resting\ HR] \times 100 / [HRmax - Resting\ HR]$  Results In both the systems, mean HR of the M were almost identical (169.4±13.8 beats/min and 170.3±14.1 beats/min respectively). MHRR is highest on the M (75.2±2.2%) followed by F (73.1±3.5%), D (65.9±4.2%) and G (28.5±0.4%). Outfield footballers played majority of the time in the aerobic zone (76±5.9%, 79.8±4.1%, and 92.5±3.3% of the total time of play in F, M and D respectively), but G played almost completely in the aerobic zone. Discussion HR-VO<sub>2</sub> relationship shows that outfield players were exercising at an average of 71 to 76% and with a mean value of 74% of their VO<sub>2</sub>max, whereas G utilized about 44% of their VO<sub>2</sub>max. Systems of play in football game have been expected to alter the work rate profile of a player (Reilly and Thomas, 1976; Mendez-Villanueva A, 2013). In the match, which employed the 4-3-3 team formation, 3 M were supposed to take the major workload in the midfield against 4 M in the team configuration of 4-4-2 system of play, and thus total workload may be expected higher in the midfielders in 4-3-3 system. But results suggest that workload on the M in both the configurations of play were identical. Probably, the excess load on the 3 M, played in 4-3-3 system was distributed by other outfield teammates. Aerobic process plays the predominant role for energy supplement in football game. References American College of Sports Medicine position statement (1978). Med Sci Sports Exerc, 10:vii-x. **PEDAL FORCE AND METABOLIC STRESS RESPONSES TO DIFFERENT PEDAL RATES DURING CYCLING**

Migita, T.1, Tokui, M.2, Hirakoba, K.3

*1:Kurume University, 2:Kyushu Kyoritsu University, 3:Kyushu Institute of Technology*

Introduction External power output (EP) for pedaling cycle ergometer is estimated by product of load to wheel inducing mainly by developed tension of exercising muscle and pedal rate (PR) depending on muscle contraction velocity. It has been thought that the pedal force (PF) would be unchanged at a constant load even if the PR is changed. To our knowledge, there have been no assessments as to the PF with changing PR. Therefore we assessed PF, which reflects the developed tension of leg muscle, and physiological responses to three different pedal rates during constant-load cycling exercise, and investigated the associations with physiological variables. Methods Ten healthy male volunteers (mean±SD: age, 21.1±0.3 yr; height, 169.6±3.9 cm; weight, 66.7±8.4 kg) performed a load-incremental cycling exercise and three trials of constant-load cycling exercise. The load-incremental exercise test started at 0.5 kp for 2 min, followed by an increase of 0.5 kp every 2 min at a constant pedal rate (60 rpm) until the exhaustion point. After the test, the subjects performed three tests at different pedal rates (40, 80, and 120 rpm) during constant-load exercise (1.0 kp) for 6 min. The order of three trials with 40, 80, and 120 rpm of pedal rates was carried out at random. Oxygen uptake (VO<sub>2</sub>) and PF were measured during all exercise tests, and the comparisons of these values for three different pedal rates were made by using an average of 30 sec between 4 min 30 sec and 5 min. Blood lactate accumulation above rest ([ΔLa]) was measured during constant-load exercise with three pedal rates. Results and Discussion During constant-load (1.0kp) exercise, EP was increased according to an increase of pedal rate. It is not surprising because EP is controlled by load to wheel and/or PR. As a result, VO<sub>2</sub> and [ΔLa] also showed higher values with an increase of pedal rate. Furthermore, despite the same load to wheel of cycle ergometer, greater peak value of PF was observed with an increase of PR, which is mainly interesting finding because we hypothesized that only increase of PR could not affect exerted tension of leg muscles, assuming that a constant load is maintained. Conversely, integral of PF per one cycle was lower value with an increase of PR. As a result of greater peak PF and lower integral of PF per one cycle, integrated value of PF for 30 sec was increased with an increase of PR. These results suggest that extremely high pedal rate dependent on muscle contraction velocity affects an exerted tension of muscle and metabolic stress during cycling exercise.

**INFLUENCE OF HIGH-INTENSITY AEROBIC TRAINING ON EXERCISE-INDUCED GROWTH HORMONE RESPONSE, ABDOMINAL AND ECTOPIC FAT.**

Sasaki, H., Morishima, T., Hasegawa, Y., Mori, A., Ijichi, T., Kurihara, T., Goto, K.

*Ritsumeikan University (Shiga, Japan)*

Introduction The enhancement of growth hormone (GH) secretion is considered to be important to prevent obesity, because GH has a powerful lipolytic effect. Although exercise is a potent stimulus for GH secretion, obese people show lower exercise-induced GH response. A previous study (Salvadori et al., 2010) suggested that moderate aerobic exercise training may be an effective tool to augment GH response. Considering that the magnitude of GH response depends on exercise intensity, high-intensity aerobic training would be more beneficial for improving exercise-induced GH response. Furthermore, growing evidences suggest that fat accumulation in abdominal as well as non-adipose tissue (ectopic fat) attenuates GH secretion. Therefore, the purpose of this study is to investigate the

effects of high-intensity aerobic training on exercised-induced GH secretion, abdominal and ectopic fat accumulation. Methods Twenty-four sedentary men were randomized to either high-intensity aerobic training (HT) group or low-intensity aerobic training (LT) group. The HT group performed intermittent exercise (10x1min with 30s rest between sets) at 85% of  $\dot{V}O_2\text{max}$ . The LT group performed continuous aerobic exercise (lasting 22min) at 45% of  $\dot{V}O_2\text{max}$ . Each training session was conducted 3days per week for 4weeks. Before and after the training period, hormonal and metabolic response to an acute exercise, abdominal fat area, intramyocellular and hepatic lipid contents were determined. Results Acute exercise significantly increased GH concentrations in both groups ( $P < 0.05$ ). However, these responses were not significantly different between before and after the training period in either group. Visceral fat area (evaluated by MRI), hepatic and intramyocellular lipid contents (evaluated by  $^1\text{H-MRS}$ ) did not change after the training period in either groups. Discussion The present results were not consistent with previous findings (Salvadori et al., 2010) that demonstrated moderate intensity aerobic training augmented exercise-induced GH response. In the present study, intramyocellular and hepatic lipid contents did not change before and after the training period in either group. We consider that the lack of abdominal and ectopic lipid content would be a reason why high-intensity aerobic training did not change the magnitude of exercise-induced GH secretion. In conclusion, 4week of high intensity aerobic training did not change exercise-induced GH response, abdominal fat area or ectopic lipid content in healthy sedentary men. References Salvadori A, Fanari P, Marzullo P, Codecasa F, Tovaglieri I, Cornacchia M, Walker G, Brunani A, Longhini E. (2010). Clin Endocrinol (Oxf), 73(4), 491-496.

### GPS-DERIVED RUNNING LOADS AND INJURY RISK IN ELITE AUSTRALIAN FOOTBALLERS

Colby, M.1, Dawson, B.1, Heasman, J.2, Rogalski, B.2, Gabbett, T.J.3

1 The University of Western Australia; 2 West Coast Eagles Australian Football Club; 3 School of Exercise Science, Australian Catholic University

Introduction An upward trend in injury prevalence in the last decade in Australian football (Orchard et al. 2012) has prompted great interest in the multifactorial aspects of injury prevention. Coaches and sport scientists often attribute training overload as an important (although largely preventable) cause of injury (particularly soft tissue). The purpose of this study was to investigate the relationship between overall physical workload measures (derived from GPS data) and injury risk in elite Australian football players across an entire season. Methods Forty-six elite Australian footballers participated in this study. GPS data and intrinsic injury incidence was monitored across pre-season and in-season (18 matches) phases. A multiple regression model was used to compare cumulative (1-, 2-, 3-, 4-weekly loads) and absolute change (from the previous-to-current week) in workloads between injured and uninjured players for all GPS-derived variables: total distance; V1 distance (total distance above individuals' aerobic threshold speed); V2 distance (total distance above an individual's anaerobic threshold speed); force load; velocity load and relative velocity change. Consistent with previous research (Rogalski et al. 2012), odds ratios (OR) were reported against a reference group of the lowest training load range. Results During pre-season, 3-weekly total distance (between 73721 and 86662 m, OR= 5.489,  $p=0.008$ ) and 3-weekly sprint distance (>1453m, OR= 3.667,  $p=0.074$ ) were most indicative of greater intrinsic injury risk. Higher in-season cumulative loads showed the strongest relationship with intrinsic injury risk. In particular, 3-weekly force load (> 5397 AU, OR=2.530,  $p=0.031$ ), 4-weekly relative velocity change load (>102 AU, OR= 2.244,  $p=0.035$ ), and 2-weekly V2 distance (>4431 m, OR= 3.091,  $p=0.016$ ) were associated with a greater risk of intrinsic injury. No differences in intrinsic injury risk between years of AFL experience and GPS load data were seen, although 7+ year players had the highest injury incidence. Discussion From an injury prevention perspective, these findings support the careful management of running load variables (GPS) in AFL players, in order to reduce injury risk. In particular, cumulative workloads should be closely monitored; with 3-weekly running loads most indicative of a greater injury risk across both phases of the season. ### THE EFFECT OF PLANNED OVERREACHING AND SUBSEQUENT SHORT-TERM DETRAINING ON SPRINT PERFORMANCE

Hasegawa, Y., Ijichi, T., Morishima, T., Sasaki, H., Fujioka, M., Hamaoka, T., Goto, K.

Ritsumeikan University

Do not insert authors here Introduction In a previous study, a significant increase in resting intramuscular phosphocreatine (PCr) level has been shown by 14 sessions of daily high-intensity sprint training (Parra et al., 2000). However, sprint performance did not improve after the training period. The finding suggests that overreaching was occurred due to the insufficient recovery from the accumulated fatigue of daily training. We hypothesized that consecutive exercise training would enhance sprint performance dramatically when short-term detraining period was provided following the last session of the exercise training. Therefore, the purpose of this study is to investigate the effect of the training program consisting of planned overreaching and subsequent short-term detraining on sprint performance. Methods 24 physically active men participated in 18 days of sprint training program. They were divided into two groups; OR-DT (12 days daily training + 6 days detraining), or CON (12 days training with a rest day every 3 days). Power output during maximal pedaling was recorded in each training session. Resting intramuscular PCr concentration was determined using magnetic resonance spectroscopy ( $^31\text{P-MRS}$ ). Resting blood samples were collected to evaluate changes in blood hormone concentrations over the training period. Result Peak power output during 30s maximal pedaling significantly increased after 6 days of detraining period in OR-DT compared to pre-training value ( $P < 0.05$ ), whereas no change was observed in CON. Average power output significantly increased after detraining in OR-DT ( $P < 0.05$ ), but CON showed a significant increase throughout the whole training period ( $P < 0.05$ ). Intramuscular PCr concentration significantly increased after 12 days of daily training in OR-DT and it was maintained after the detraining period ( $P < 0.05$ ). However, no change was observed in CON. Serum leptin concentration significantly increased after detraining period in OR-DT when compared to the values of Day-6 and Day-12 ( $P < 0.05$ ). Discussion In contrast to the present findings, previous study using 14 days successive training sessions (Parra et al., 2000) failed to improve sprint performance, despite the large increase in resting PCr level and enzyme activities. This is probably because of insufficient recovery from accumulated fatigue. Based on this finding, training program for OR-DT was designed to set 6 days of detraining period following the 12 days successive sprint training. Consequently, a significant increase in power output was found after the detraining period. Increased intramuscular PCr concentration and recovery from accumulated fatigue may be related to the improvement of this sprint performance. Reference Parra, J., et al., Acta Physiol Scand, 2000. 169(2): p. 157-65.

## DIFFERENCES IN HEART RATE RESPONSE BETWEEN FAST AND SLOW SUPERMOTO RACE RIDERS

Morosi, C., La Torre, A., Sartor, F.

*Philips Research*

**Introduction** Supermoto racing is a sport performed by different riders from different categories, also as training for other competitions (e.g. Motogp, Moto2 and Superbike athletes). The highest percentage of practicing and competing for this sport is located in Europe and North America. Anecdotally it requires fitness condition, riding experience, off-road skills. However not much is known about the responses in heart rate (HR) during supermoto racing. The aim of this study was to investigate HR response during a 12 lap supermoto race in national race riders, on the racing track, without the off-road part. **Methods** Sixteen supermoto race drivers (Means  $\pm$  SDs, Age:  $29 \pm 9$ ; BMI:  $23.0 \pm 2.4$ ; Years of experience with supermoto:  $4 \pm 3$ ) performed 12 laps on an international circuit 1200 m long in Italy. Mean temperature and humidity during the race were  $31.6 \pm 0.5$  °C and  $53.5 \pm 2.0\%$  respectively. Heart rate of the race drivers was monitored throughout the 12 laps. **Results** The mean HR in the 16 supermoto race drivers during the 12 lap race simulation was  $168 \pm 16$  bpm. The peak HR was  $177 \pm 15$  bpm, which corresponded to 94% of the HRmax. We found a positive relationship between the best racing performance (fastest lap time) and the mean HR over the whole duration of the race ( $r=0.747$ ,  $p<0.001$ ,  $n=16$ ). Fastest lap time also positively correlated with the peak HR ( $r=0.722$ ,  $p<0.01$ ,  $n=16$ ) and the peak HR% of HRmax ( $r=0.642$ ,  $p<0.01$ ,  $n=16$ ) over the whole duration of the race. When the fastest 5 supermoto race drivers were assigned to the fast group (F group), and the remaining 11 to the average to slow group (AtS group) we found that mean and peak HR were significantly higher in the AtS group than in the F group (Mean HR:  $174.917 \pm 12.363$  (bpm) vs.  $154.556 \pm 13.256$  (bpm),  $p = 0.010$ ; Peak HR:  $182.846 \pm 11.052$  (bpm) vs.  $163.553 \pm 15.782$  (bpm),  $p = 0.013$  respectively). **Discussion** We have found that the faster supermoto race drivers have a lower mean as well as peak HR than slower drivers. This could be due to the fact that the HR rising due to cognitive causes in faster drivers is less than in the slower drivers. Alternatively it could be that the cardio-respiratory fitness of the faster race drivers is higher than in the slower drivers. Understanding what determines the difference in HR that we have found between fast and slow race drivers can be crucial to improve racing performance. It is still to be determined whether training in this sport should focus on improving cognitive skills such as reaction times and attentiveness or aerobic capacity.

## EFFECTS OF ACTIVE ORTHOSTATIC TASK ON HEART RATE VARIABILITY IN SOCCER PLAYERS.

Somlev, P., Uzunova, G., Pavlova, E.

*National Sports Academy "Vassil Levski"*

**Introduction** For the evaluation of autonomic cardiac regulation heart rate variability (HRV) is usually determined in supine position. Standing or active orthostatic task (AOT) has been used to induce changes in HRV to obtain additional data about cardiac regulation in athletes (1). Studies with HRV during AOT, evaluating athletes from sports with both aerobic and anaerobic training such as soccer, are scarce. Aim of this investigation was to assess the differences in HRV parameters between active and former soccer players in supine position and after standing. **Methods** In the study participated 12 active soccer players (age= $21.6 \pm 1.4$  years) and 14 former soccer players (age= $21.8 \pm 2.5$  years). The active players were studied during competitive season. In supine position after 20 min of rest RR intervals of each subject were recorded for 5 min with Polar S810i heart rate monitor. After that subjects actively stood up (AOT) and data were collected for 5 min from 3th to 8th minutes in upright position. With Kubios HRV 2.0 software were obtained mean heart rate (Mean HR) and HRV indices: Mean RR, SDNN, RMSSD, pNN50%, LF and HF power in absolute and normalized units (ms<sup>2</sup> and nu), and LF/HF ratio. Cardio-respiratory fitness was assessed with PWC170 cycle ergometer test. **Results** There were no differences in physical work capacity between both groups. During supine rest Mean RR, SDNN, RMSSD, pNN50%, LF ms<sup>2</sup> and HF ms<sup>2</sup> were significantly higher ( $p<0.05$ ) in active players than in former players. Active players also demonstrated lower Mean HR at rest. During AOT in both groups there were significant increase ( $p<0.05$ ) in Mean HR, LF nu and HF/LF ratio and significant decrease ( $p<0.05$ ) in Mean RR, RMSSD, pNN50%, HF ms<sup>2</sup> and HF nu. After standing SDNN, RMSSD, pNN50% and LF ms<sup>2</sup> remained significantly higher in active players than in former players, but there were no statistical differences between the groups in Mean HR, Mean RR, and HF ms<sup>2</sup>. There were no differences between the groups in LF nu, HF nu and HF/LF ratio during both supine and standing positions. **Discussion** These results indicate that active players have an increased parasympathetic influence on heart rate in supine position in comparison with former players. In both groups AOT induces identical changes in HRV indices, showing decrease of vagal activity and increase of sympathetic activity. Active standing eliminates some differences in HRV between active and former players, established in supine rest. The study shows that HRV during AOT does not provide additional information about the characteristics of cardiac autonomic regulation of active players in comparison with former players. **References** 1. ## RELIABILITY OF HEART RATE VARIABILITY UNDER RESTING CONDITIONS

Schumbera, O., Fernandez-Fernandez, J., Simola, R., Wiewelhoe, T., Ferrauti, A.

*Ruhr-University Bochum, Faculty of Sports Science*

**Introduction** Heart rate variability (HRV) is used for the evaluation and assessment of the cardiac autonomic regulation. Its usefulness has been reported not only in experimental research, but also as a diagnostic tool for athletes. Although the methodology of HRV measurement has been extensively used, the reliability and reproducibility of parameters, particularly for short-term recordings (2-20 min) seems to be insufficient and inadequate. Therefore the aim of this study was to investigate the reliability of three different testing procedures under resting conditions. **Methods** Ten healthy male subjects (mean  $\pm$  SD, age:  $33.4 \pm 10.0$  years; weight:  $80.3 \pm 5.8$  kg; height:  $183.7 \pm 5.3$  cm) participated in the study. Measurements included heart rate (HR; Polar RS800cx) after waking up in the morning, in three different situations: (a) 3 min in supine position + 3 min in standing position; (b) 3 min in sitting position + 3 min in standing position, and (c) 2 min sitting + 3 min standing. Each subject performed 4 tests over a one-week period. Absolute reliability was assessed by the standard error of measurement (SEM) and the relative reliability by the intraclass correlation coefficient (ICC). Data obtained and computed from the RR-intervals were indices in the time (MeanRR, SDNN, RMSSD and NN50) and the frequency domain (Low-Frequency, High-Frequency and Low-/High-Frequency). **Results** Protocol 1 (3 min in supine and standing position) showed significant ( $p<0.05$ ) and high correlations of the HRV indices SDNN (ICC=0.878), RMSSD (ICC=0.958), NN50 (ICC=0.954), Low-Frequency (ICC=0.924), High-Frequency (ICC=0.924) and Low-/High-Frequency (ICC=0.873). Protocol 2 and protocol 3 show also good correlation for the different HRV indices, except for SDNN (ICC= 0.263-0.962), whereas both measurements show similar results for the absolute (RMSSD SEM=6.84/6.25) and relative reliability (RMSSD ICC=0.938/0.934). **Discussion** Comparing the three different short-term protocols of heart rate variability, protocol 1 (3 min in supine and standing position) shows the highest and the best correlations for almost every index of the time and the frequency domain. The frequency domain indices (Low-Frequency, High-Frequency and Low-/High-Frequency), which are commonly used for short-term recordings, showed high reproducibility, although an effect of a controlled breathing rhythm improves the reliability of the HRV indices,

which was previously reported in the literature. Summarizing protocol 1 is the most appropriate measurement for short-term HRV under resting conditions for healthy subjects. ### COMPARISON OF THE HEART-TYPE FATTY ACID-BINDING PROTEIN WITH THE HIGH SENSITIVE CARDIAC TROPONIN T IN HEALTHY RUNNERS

Le Goff, C., Melon, P., Brevers, E., Fillet, M., Kaux, J.F., Chapelle, J.P., Cavalier, E.  
*University Hospital of Liège*

Background: Heart-type fatty acid-binding protein (H-FABP) is a low molecular weight protein involved in the intracellular uptake and buffering of long chain fatty in the myocardium. It is an early marker for acute coronary syndrome. Troponin T (TnT) is a component of the contractile apparatus of the striated musculature. Cardiac TnT is a cardio-specific, highly sensitive marker for myocardial damage. The aim of our study was to compare the results obtained with the H-FABP and the highly sensitive cardiac troponins (hsTnT) and to test their cardio-specificity in healthy runners. Methods: Twenty three runners (marathon) were enrolled. We drew samples at three times: just before (T0), just after (T1), and three hours after the end of the race (T3). H-FABP was determined with a Randox immunoturbidimetric assay and hsTnT with a Roche electrochemiluminescence immunoassay, both on Cobas 6000. A linear regression was calculated to observe if there is any correlation between the two biomarkers. Values above the 95th percentile for H-FABP (2.5ng/mL) and the 99th percentile for hsTnT (14ng/L) were considered as positive. Results: At T0, none of the subjects were positive for hsTnT but 35% were positive for H-FABP; at T1, 83% for hsTnT and 100% for H-FABP; at T3, 83% for hsTnT and 96% for H-FABP. At T0, the regression equation was  $H-FABP_{T0} = 3.9454 - 0.1001 \times hsTnT_{T0}$ ; at T1:  $H-FABP_{T1} = 51.838 - 1.7026 \times hsTnT_{T1}$ ; at T3:  $H-FABP_{T3} = 47.977 - 1.6193 \times hsTnT_{T3}$ . No correlation was observed between the two biomarkers at the different time. Conclusions: We observed a significant increase of H-FABP and hsTnT in runners. These markers are independent to each other. These values could biologically correspond to a heart ischemia. However, we suggested that exercise-induced cardiac hsTnT and H-FABP release is not a marker of exercise-induced pathology but likely a physiologic response to effort or an exercise-induced cardiac remodelling.

### CHANGES IN HEART RATE VARIABILITY AFTER A QI GONG SESSION IN AN ELDERLY PEOPLE GROUP

Calvo, E.1, Niño, O.2, Alamo, J.M.2, Javierre, C.2, Cutillas, B.1, Falcó, A.1  
*Universitat de Barcelona*

Introduction Qi Gong is a physical activity that combines slow body movements, coordinated breathing and mental focus search. Several authors have suggested that one or more of these components of Qi Gong, as Tai Chi Chuan, have a positive impact on the heart autonomic control (Audette et al., 2006; Jahnke et al., 2010). The aim of the study was to quantify the changes in heart rate variability (HRV) during a session of Qi Gong, monitoring the relative intensity of the specific exercise. Methods Descriptive Study. Ten healthy subjects physically active, (age  $62 \pm 2$  years), (3 men and 7 women) performed a session of Qi Gong during 90' with heart rate monitoring beat by beat. Polar Team 2 (Polar, Finland) heart rate monitor was used to recode HRV through the R-R interval. HRV parameters were obtained with Polar Precision Performance software. Two evaluations of heart rate variability in supine rest position were conducted during 10': pre-training and post-training, spectral analysis of HRV (high-frequency, low-frequency power as well as high- and low-frequency power in normalized units) as a measure of autonomic control of the heart, were done (Pichon et al., 2004). Student's t-tests for paired samples was used to evaluate differences between before and after Qi Gong session. Results The relative intensity respect theoretical maximal heart rate was of  $61 \pm 4$  %. At the begin of the session, RR was  $783.8 \pm 86.5$  ms and in post-training evaluation was  $776.5 \pm 112.6$  ms, without differences. HF % showed statistical decreases between before and after training analysis ( $21.0 \pm 8.7$  to  $12.4 \pm 2.7$ ,  $p < 0.05$ ). Discussion A single session of Qi Gong increase the heart parasympathetic activity, a positive effect respect the studied group. Despite the relatively moderate intensity activity during the session of Qi Gong (about 60% of the theoretical maximum heart rate), there is an immediate effect on parasympathetic activity. This fact is particularly relevant in people of this population group because presenting major risk of high blood pressure, musculoskeletal and endocrine disorders. Immediate positive results obtained with a simple Qi Gong session, we recommend further studies of the cardiac effects at medium and long term of this moderate physical activity. ### THE EFFECT OF TAI CHI TRAINING ON AUTONOMIC RE-ACTIVITY AND BODY KINETICS DURING A MOCK BOXING ROUND IN SOCCER PLAYERS: A FEASIBILITY STUDY

Rauch, H.G.L., Smit, S., Karpul, D., Noakes, T.D.  
*University of Cape Town*

Introduction Very rapid movement execution in athletes is best done subcortically; with cortical modulation only necessary for movement modifications. However, rapid movement execution is usually associated with sympathetic up-regulation, which may increase cortical modulation at the expense of subcortically regulated central pattern generators (CPGs) (Rauch et al., 2013). This study quantified the effects of a 10 session Tai Chi training program designed by a Tai Chi Master on heart rate variability (HRV) and on the ability to maintain optimal joint angles during a 2 min boxing sparring performance (box) round in professional soccer players; and further to access if these two variables were correlated. Methods Fourteen professional soccer players aged  $18 \pm 3$  years were recruited and randomly assigned to either a Tai Chi group (TAI) – who completed 10 sessions of Tai Chi training over 4 weeks - or a control group (CON). All participants underwent 45 min of box training and individually completed a 2 min familiarisation box round, and the next day, a pre intervention 2 min box round. Participants' heart rates were recorded telemetrically (at 1000Hz) and markers for 3D camera analysis were placed at appropriate distances on each participant's head, back, arms, hands, hips, legs and feet to continuously monitor their joint angles during the 2 min box rounds. Results The delta heart rates in the post vs. pre box rounds correlated with the delta (LF+HF) power values in the participants' cardiac spectrograms ( $R^2 = 0.93$ ,  $p < 0.000$ ). There was a positive correlation ( $R^2 = 0.76$ ,  $p < 0.01$ ) between the inter-foot angles of participants and the log of their cardiac (LF+HF) spectral power values during the pre training box round. After the Tai Chi training program the inter-foot angles of participants in the post box round were negatively correlated to the log of their delta cardiac (LF+HF)

spectral power values ( $R^2 = 0.70$ ,  $p < 0.02$ ). Discussion The significant correlation between delta heart rates and HRV values in the post vs. pre box rounds showed that cardiac (LF+HF) spectral power was an excellent marker for cardiac vagal modulation during the box rounds. Participants who demonstrated greater cardiac vagal modulation during the pre box round had wider inter-foot angles (more on the back-foot), but during the post box round, the participants who demonstrated greater vagal modulatory improvements had more parallel inter-foot angles (more on the front-foot). This provides evidence that Tai Chi training facilitated vagal modulatory control over the heart and enabled those participants who were more front-footed to also be more centred (ANS balanced) during the post box round. ### METHODOLOGICAL CONSIDERATIONS OF HIGH-INTENSITY INTERVAL EXERCISE IN CARDIAC REHABILITATION

Tschakert, G.1, Pichlhoefer, P.1, Kroepfl, J.1, Mueller, A.1, Harpf, H.2, Traninger, H.2, Wallner-Liebmann, S.3, Hofmann, P.1  
 1Karl-Franzens-University Graz (Graz, Austria) 2Center for Ambulatory Rehabilitation Graz (Graz, Austria) 3Medical University Graz (Graz, Austria)

Introduction Aerobic high-intensity interval exercise (HIIE) is successfully applied in the field of cardiac rehabilitation (Gibala et al. 2012). However, the optimal prescription of aerobic HIIE in heart disease patients is still unclear. The aim of this study was to compare acute metabolic and cardiorespiratory responses during short and long HIIE to moderate continuous exercise (CE). Methods 8 patients undergoing phase III cardiac rehabilitation (7 males, 1 female; age:  $63.0 \pm 9.4$  yrs; ht:  $174.1 \pm 4.6$  cm; wt:  $83.6 \pm 8.7$  kg), treated with  $\beta$ -blocking agents, performed a maximal symptom-limited incremental exercise test (IET). Subsequently, the participants performed three various exercise tests matched by mean load ( $P_{mean}$ ) which was set 20 % below the second lactate turn point (LTP2): 1) short HIIE with peak workload durations ( $t_{peak}$ ) of 20 sec, peak workloads ( $P_{peak}$ ) equal to  $P_{max}$  from IET, recovery workloads ( $P_{rec}$ ) 10 % below the first lactate turn point (LTP1), and a calculated recovery duration ( $t_{rec}$ ); 2) long HIIE ( $t_{peak}$  4 min,  $P_{peak}$  corresponding to the power output at 85 %  $HR_{max}$  from IET,  $t_{rec}$  3 min,  $P_{rec}$  calculated); 3) CE with a target workload equal to  $P_{mean}$  of both types of HIIE. Sessions took 28 min and were randomly assigned and interspersed by at least 2 days. For statistical analysis, repeated measures ANOVAs with Fisher's-LSD (least significant difference) were used. Results In long HIIE,  $HR_{peak}$  ( $124.0 \pm 24.9$  b/min) was significantly higher than in CE ( $111.3 \pm 18.0$  b/min;  $p < 0.05$ ) and by trend higher than in short HIIE ( $116.3 \pm 22.8$  b/min;  $p = 0.08$ ).  $HR_{peak}$  in long HIIE was also markedly higher compared to HR at LTP2 from IET ( $111.7 \pm 17.7$  b/min). Significantly higher peak  $VO_2$  values were found in long HIIE ( $1.9 \pm 0.6$  l/min) compared to short HIIE ( $1.6 \pm 0.4$  l/min) and CE ( $1.5 \pm 0.3$  l/min) ( $p < 0.05$ ). Mean and peak  $La$  values were significantly higher during long HIIE (mean:  $4.8 \pm 2.6$ ; peak:  $5.5 \pm 2.9$  mmol/l) than during short HIIE (mean:  $3.4 \pm 1.7$ ; peak:  $3.9 \pm 2.0$  mmol/l) and CE (mean:  $3.2 \pm 1.6$ ; peak:  $3.6 \pm 1.7$  mmol/l) ( $p < 0.05$ ). Between short HIIE and CE, no significant difference could be found for any parameter. Discussion Acute metabolic and peak cardiorespiratory responses during short aerobic HIIE were significantly lower compared to long HIIE and similar to CE despite considerably higher peak workload intensities in short HIIE. Therefore, short intervals may be associated with lower health risks than long HIIE. The training effects elicited by short HIIE have to be proven in randomized controlled training studies. ### PREVALENCE AND CORRELATIONS OF DEPRESSION, ANXIETY AND PHYSICAL CAPACITY OF PATIENTS WITH OCCUPATIONAL RESPIRATORY DISEASES

Müller, K.1, Kotschy-Lang, N.2, Wagner, P.1

1: Leipzig University, 2: Rehabilitation Clinic Falkenstein

Introduction The prevalence of depression (10-60%) and anxiety (11-45%) is higher for patients with Chronic Obstructive Pulmonary Disease (COPD) than for patients with cardiac insufficiency. Further, current research results indicate that symptoms of depression seem to be significant determinants for exacerbation and days of hospital stay as well as for a worse physical capacity (Spruit et al., 2010). However, there is a lack of studies concerning the specific illness-characteristics of COPD. Consequently, the purpose of the present study is to analyze prevalence and correlations of depression and anxiety with physical capacity of patients with occupational respiratory diseases. Methods During a rehabilitation process in the clinic of occupational diseases in Falkenstein (Germany), 243 patients with occupational respiratory diseases (Age:  $M=71.51$ ;  $SD=9.13$ ) participated in the study. At the beginning (T1) and at the end (T2) of the clinical stay, data giving evidence about levels of depression and anxiety (BDI-II, HADS-D) have been collected with the help of a questionnaire and the physical capacity has been assessed using the six minute walking distance (6MWD). Results At T1, 26.4% of the patients show clinical relevant depression values and 18.2% have clinical relevant anxiety values. The results indicate that the correlation between the 6MWD and the levels of depression depends on the occupational diseases ( $r = -0.332$  to  $-0.708$ ,  $p < 0.01$  to  $0.001$ ). Further, the mean anxiety values differ depending on occupational disease ( $F(4.237) = 3.860$ ,  $p < 0.01$ ). Additionally, for patients with low 6MWD-values ( $< 326.30$ m), there are significant differences regarding depression ( $F(1.234) = 32.210$ ,  $p < 0.001$ ) and anxiety ( $F(1.234) = 3.396$ ,  $p < 0.05$ ). At T2, the 6MWD-values increase and the depression-values significantly decrease for the total of participants. Discussion The present results concerning prevalence of depression and anxiety in patients with occupational respiratory diseases confirm the current state of research regarding COPD. Since there is a correlation between the physical capacity, depression, and anxiety, increasing the factor of physical capacity can decrease the psychological symptoms of COPD-patients. In future, intervention studies including a control group and a follow up with additional objective parameters are necessary to further investigate causal relationships among the above mentioned determinants. References Spruit, MA, Watkins, ML, Edwards, LD, Vestbo, J, Calverley, PMA, Pinto-Plata, V, Celli, BR, Tal-Singer, R, Wouters, EFM. (2010). ## EFFECT OF MUSIC THERAPY ON BRAIN FUNCTION AS ASSESSED BY LEVELS OF BRAIN-DERIVED NEUROTROPHIC FACTOR

Taniura, T., Okita, K., Takada, S., Sato, T., Morita, N., Sawada, E.

*Graduate School of Hokusho University*

Background and aims: In various types of rehabilitation, effects on psychological and nervous functions much more difficult to objectively assess than effects on the body. Brain-derived neurotrophic factor (BDNF) is a nerve growth factor that plays central roles in the survival, growth, and maintenance of neurons (Sakuma K. J Biomed Biotechnol 2011). BDNF has been reported to be associated with learning, memory, cognitive function, and depression (Leibrock J. Nature 1989, Barde YA. J Biomed Biotechnol 1990, Huang EJ. Annu Rev Neurosci 2001). The possibility has also been suggested that blood BDNF represents a biomarker for memory and cognitive function (Laske C. J Neural Transm 2005). We investigated the effect on serum BDNF of music therapy, as higher function rehabilitation, made with the purpose of improving brain function. Methods and results: Conventional blood biochemical parameters (blood profiles, lipids, glucose metabolism, and uric acid), serum BDNF, and State-Trait Anxiety Inventory (STAI) scores to assess mental function were measured before and after music therapy in 13 patients with mild dementia (age range, 71-103 years). Music therapy was implemented with six programs consisting of singing and playing simple instruments. Music therapy sessions were 60 min each, with two sessions a week for 4 weeks, oriented to achievement of a task. At the final session, nearly all subjects had achieved the tasks. After intervention, no changes in conventional parameters or STAI were seen, but serum BDNF levels were significantly increased compared to baseline ( $16,798 \pm 1588$  pg/mL vs.  $19,410 \pm 1507$  pg/mL,  $P < 0.05$ ). Conclusion: These findings suggest that effects of music therapy on brain function may be reflected in increased BDNF levels and the utility of interventional methods for the maintenance of brain function from a new perspective, and at the same time suggest possibilities for methods of objectively evaluating art therapy, which has so far been difficult.

## THE INFLUENCE OF SPORTS CLIMBING ON SELF-EFFICACY, SELF-ESTEEM AND DEPRESSION IN PATIENTS WITH MULTIPLE SCLEROSIS

Kern, C., Mayer, C., Bischoff, C., Oberhoffer, R.

*Technische Universität München*

Purpose Multiple Sclerosis (MS) is a chronically, progressive disease with a highly social-medical importance. In Germany about 130.000 adults suffer from MS. Even though research on immunomodulation drugs is increasing, there is still no cure to MS. Following Turner et al. (2009) a key-point to enhance psycho-social constitution and quality of life in patients with MS is the facilitation of physical activity. The aim of this study was to investigate if sports climbing (SC) improves self-efficacy, self-esteem and depression in patients with MS. Methods This study consisted of 27 patients (17 females), mean age  $45.8 \pm 7.2$  years, randomized into SC-group ( $n=12$ ) and control-group (CG) ( $n=15$ ). The SC-program consisted of 20 sessions over 2 hours for duration of 6 months. Inclusion-criteria are 'range 1-6.5 on the Expanded Disability Status Scale (EDSS)' and 'assured diagnoses of MS'; exclusion-criteria are 'attendance in less than 18 sessions' or 'relapse during intervention'. Data were collected pre and post intervention for self-esteem (Multidimensionale Selbstwertkala, Schütz/Sellin), self-efficacy (Skala zur allgemeinen Selbstwirksamkeit, Jerusalem/Schwarzer) and depression (Allgemeine Depressionsskala, Hautzinger). Self-reports were used to detect alterations of their physical and mental condition. Results EDSS score in SC-group ( $n=10$ ) decreased significantly from  $4.6 \pm 1.7$  to  $4.1 \pm 2.1$ ,  $p=0.068$ , whereas no changes occurred in CG ( $n=14$ , EDSS  $4.2 \pm 1.7$ ,  $p=0.157$ ). Significant changes could be demonstrated in self-efficacy over time, whereas self-esteem and depression did not reveal significant improvements. The mean value for self-efficacy increased in SC-group from  $25.9 \pm 6.49$  to  $28.7 \pm 4.52$ , significant over the time period ( $p = 0.005$ ), whereas results in CG also increased slightly from  $28.0 \pm 6.42$  to  $29.0 \pm 6.18$ , but not significant over time period  $p = 0.107$ . The mean value in self-esteem did not change significantly in the SC group pre  $51.4 \pm 9.63$ , post  $53.6 \pm 13.1$ ; neither in CG pre  $52.5 \pm 11.55$ , post  $51.36 \pm 10.13$ . For depression both groups ( $n = 18$ ) showed similar, not significant results: SC group pre  $15.5 \pm 12.6$ , post  $10.38 \pm 8.47$ ; CG pre  $14.7 \pm 11.96$  post  $10.1 \pm 6.88$ . Results from self-reports revealed that all of the patients with MS felt "better" after climbing. Conclusions Patients with MS can psychologically benefit from a SC-intervention. Self efficacy, as a more predictive value for short-time changes, showed significant improvements over time. Subjective self-report was over all positive. Further research should elucidate psychologically long term effects of SC on patients with MS, especially for self-esteem and depression.

## FUNCTIONAL PERFORMANCE AT RETURN TO PLAY FOLLOWING ACUTE INVERSION ANKLE SPRAIN AMONG COMPETITIVE COLLEGIATE BASKETBALL PLAYERS

Uematsu, D.1, Suzuki, H.2, Nagano, Y.3, Fukubayashi, T.4

*1: Waseda University, 2: Niigata University of Management, 3: Niigata University of Health and Welfare, 4: Waseda University*

Introduction Previous studies have shown that functional performance tests (FPTs) that stress the lateral aspect of the ankle are able to detect functional performance deficits among the chronically unstable ankles. No study, however, has examined the FPTs' effectiveness to detect the functional deficits at return-to-play phase of acute inversion ankle sprains among competitive athletes. Method Nineteen collegiate basketball players with an acute inversion ankle sprain (height =  $173 \pm 9.05$  cm, mass =  $67.4 \pm 10.11$  kg, age =  $19.5 \pm 1.35$  years, days lost due to injury =  $11.01 \pm 8.01$  days), and a control group of 19 gender and leg dominance matched collegiate basketball players (height =  $173 \pm 10.27$  cm, mass =  $67.0 \pm 9.71$  kg, age =  $20.1 \pm 1.54$  years) participated in the study. The participants completed two FPTs; Square hop test (SQ) and Side Hop test (SH). For the time measurement, the means of 2 trials for each FPT were recorded (in seconds). After completing each FPT, the subjects were asked to rate the perceived pain, instability and difficulty on the 10cm VAS (in cm) (VAS score). One-way factorial ANOVA was performed to identify time differences for each FPT among the injured (Injured), uninjured (Uninjured) and control (Control) limbs. Kruskal-Wallis one-way analysis and Mann-Whitney U Test were performed to identify significant differences of the VAS scores among the groups. Alpha for all analyses was set at  $p < .01$ . Results No significant difference of the time measurements was found among the groups for SQ ( $p=.729$ ), or SH ( $p=.131$ ). For the VAS scores of SQ, the self-reported pain of the Injured ( $1.3 \pm 1.92$ ) was significantly higher than the Control ( $0.47 \pm 0.21$ ),  $p=.006$ , while the self-reported instability of the Injured ( $1.9 \pm 1.64$ ) was also significantly higher than the Uninjured ( $0.5 \pm 0.98$ ),  $p=.003$ , and Control ( $0.2 \pm 1.06$ ),  $p<.001$ . For the VAS scores of SH, the self-reported pain of the Injured ( $1.8 \pm 1.82$ ) was significantly higher than the Uninjured ( $0.2 \pm 0.67$ ),  $p=.003$ , and Control ( $0.2 \pm 0.54$ ),  $p<.001$  while the self-reported instability of the Injured ( $2.6 \pm 1.98$ ) was significantly higher than the Uninjured ( $0.24 \pm 0.70$ ),  $p<.001$ , and Control ( $0.31 \pm 1.04$ ),  $p<.001$ . No significant differences were found for the self-perceived difficulty among the groups for the SQ ( $p=.156$ ) or SH ( $p=.073$ ). Conclusions Based upon the self-reported pain and instabilities, the FPTs were able to effectively detect functional deficits among competitive basketball players at return-to-play phase following acute inversion ankle sprains.

### WALKING ECONOMY AND REHABILITATION INDEX OF SELF-SELECT SPEED IN TRANSFEMORAL AMPUTEES

Peyre-Tartaruga, L.A., Tartaruga, M.P., Bona, R., Figueiredo, P., Gomenuka, N., Bonezi, A., Storniolo, J.L.L., Ribeiro, J.P.  
UNIVERSIDADE FEDERAL DO RIO GRANDE DO SUL

**Introduction** In healthy subjects, the self-selected walking speed (SSWS) corresponds to the lowest cost of transport (CT) or most economical walking (Saibene & Minetti, 2003). This study tested the hypothesis that SSWS in amputee would not be the most economical speed, which is often called the optimal walking speed (OWS), when compared with healthy controls. Furthermore, was also tested a rehabilitation index (RI) (Figueiredo et al., 2013), which could be assist in the rehabilitation of individuals with walking limitations. **Methods** Ten transfemoral amputees (30.3±4.7 years old, 73.3±15.0 kg, 1.78±0.1 m) and ten healthy controls (23.1 ± 2.9 years old, 71.6±6.5 kg, 1.78±0.06 m) were compared. Both groups were submitted to a walking cost protocol on the treadmill at the SSWS, at 2 speeds below and 2 speeds above (Figueiredo et al., 2013). The RI was calculated based on the Froud Number equation (Farley & Ferris, 1998), based in leg length and was called RI theoretical (RI<sub>the</sub>), and the quadratic equation (Daijro et al., 2008), based in gas analyzer and was called RI experimental (RI<sub>exp</sub>). For both RI's the closer to 100% this result gets the closer to OWS will the subject be. Comparisons between amputee and control characteristics were carried out with an unpaired t-test and were used repeated measures ANOVA to verify the influence of walking speed. **Results** Amputee's patients had a lower SSWS than healthy controls (2.95±0.41 vs 4.0±0.3; p <0.05). Among the 5 speeds, the control was most economical in SSWS. For the amputees, the SSWS was less economical than the higher speeds. Controls presented higher RI than amputees, where RI<sub>exp</sub> was 98.4±0.05 vs 79.83±0.05; p <0.05, and RI<sub>the</sub> was 84.8±0.06 vs 73.08±0.04; p <0.05, respectively. **Discussion** We confirm our hypothesis and the amputee's patients chose a SSWS with a higher CT unlike of the healthy individuals. The mechanisms responsible for this choice are not readily apparent from our data. Both the theoretical and the experimental RI values were closer to 100% in the control group, which may indicate that these subjects are walking closer to their OWS. With this finding we suggest that the theoretical RI may be a simple and easy method for every usage to establish a goal for rehabilitation. **References** Farley CT, Ferris DP. ### SELF SELECT SPEED OF TRANSFEMORAL AMPUTEES: ECONOMY AND PENDULAR MECHANISM

Peyré-Tartaruga, L.A., Tartaruga, M.P., Bona, R., Figueiredo, P., Gomeñuka, N.A., Bonezi, A., Storniolo, J.L.L., Ribeiro, J.P. (in memoriam)

*Exercise Research Laboratory, Universidade Federal do Rio Grande do Sul*

**Introduction** The lower limb mass and loss of muscle function result at lower self-select walking speed (SSWS) in above-knee amputees (TF) when compared to non-handicapped. The mechanisms underlying the choice of SSWS in amputees have not been well defined. Recovery that represents the pendular mechanism (Cavagna & Kaneko, 1977), in physical handicapped subjects, such as TF, is lower than non-handicapped (Saibene & Minetti, 2003) suggesting that this energy expenditure minimization system may be altered and this may influence the SSWS (Detrembleur et al., 2005). The aim of this study was to test the influence of walking speed in pendular mechanism and cost of transport (C) in TF and control group. **Methods** Ten traumatic unilateral TF (30.3±4.7 years old, 73.3±15.0 kg, 1.78±0.1 m) performed treadmill level walking with prostheses at five speeds (SSWS 2.95 ±0.46 km.h<sup>-1</sup>, two speeds below were 2.44 ±0.46 km.h<sup>-1</sup> and 1.94 ±0.46 km.h<sup>-1</sup>; their speeds above were 3.42 ±0.46 km.h<sup>-1</sup> and 3.63 ±0.10 km.h<sup>-1</sup>) and ten healthy controls (23.1 ± 2.9 years old, 71.6±6.5 kg, 1.78±0.06 m) on average, the SSWS was 3.96 ±0.25 km.h<sup>-1</sup>; their two speeds below were 2.98 ±0.14 km.h<sup>-1</sup> and 1.98 ±0.25 km.h<sup>-1</sup>, and their speeds above were 4.96 ±0.25 km.h<sup>-1</sup> and 5.97 ±0.28 km.h<sup>-1</sup>. 18 anatomical reflective markers were used to every speed and they were videotaped (50 Hz) 3D during the last minute. Routines in Matlab 6.3 (Mathworks, Inc, USA) were developed for the data analysis. We used the method proposed by Cavagna and Kaneko (1977) for calculation of recovery and C. Were used repeated measures ANOVA. **Results** C was higher in the amputees. The controls presented the smallest economy of walk in the first speed of the protocol. In contrast, the amputees presented the lowest C at speeds above their SSWS. For recovery, the control group, the largest change occurred between the mechanical energies in the intermediate speeds. This optimization was already at the highest speed of walking in this protocol for the amputees **Discussion** According to our starting hypothesis, we found that the C of TF is minimal; in other words, the greatest economy of walking is presented above SSWS (higher walking speed during protocol on treadmill). Similarly, the conversion between mechanical energy (potential and kinetic) during one step (recovery) showed the maximum value at the higher walking speed performed during the trials. Therefore, the energetic optimal speed of amputees is above the freely chosen speed. **References** Cavagna GA, Kaneko M. (1977). *J Physiol*, 268, 467-481. Saibene F, Minetti AE. ### WHAT ARE THE DIFFERENCES IN PHYSICAL STRAIN AND MECHANICAL EFFICIENCY BETWEEN A LEVER PROPELLED WHEELCHAIR AND A HAND RIM PROPELLED WHEELCHAIR?

Monden, P.G., Hettinga, F.J., Van der Woude, L.H.V.

*University of Groningen, University Medical Center Groningen, The Netherlands*

**Purpose** In those in a wheelchair, handrim (HA) propulsion is straining for the shoulder joint with a low mechanical efficiency. Therefore, the Aspire Centre for Disability Sciences developed the NuDrive (ND), which is a unidirectional lever propelled wheelchair system that can be added to an ordinary HA wheelchair. Literature suggests that lever propelled wheelchairs are more efficient and less straining due to the cyclic movement and the involvement of a greater muscle mass. **Methods** Nine able bodied participants (21,3 ± 1,2 yrs) without wheelchair experience participated in this study. The participants performed a submaximal test with- and without the ND in a randomised order. Submaximal testing was performed on a motor driven treadmill (constant velocity: 0.56 m/s; inclination: start 0% and +1% per 3 minutes). Respiratory and metabolic parameters (oxygen uptake (VO<sub>2</sub>), heart rate (HR) & ventilation (VE)) were measured by a gas analyser on the 0% and 4% condition. Power output (PO) was calculated by a drag test before every test. Mechanical efficiency (ME) was calculated as the ratio between PO and metabolic power (P<sub>met</sub>). **Results** No differences in ME, HR and PO (0% condition, HA-ND: ME 4.7-4.4%, HR 73-81bpm, PO 10.5-11.2W; 4% condition, HA-ND: ME 8.6-8.1%, HR 84-82bpm, PO 27.5-28.7W) were found between ND and HA propulsion for all conditions. However, higher values for ND were found for VO<sub>2</sub> (0%-4% condition: 14% - 24%) and VE (0% - 4% condition: 12% - 20%). **Conclusion** ND-propulsion induced a greater physiological strain (i.e. increased VO<sub>2</sub> and VE) probably explained by the greater mass (3 kg added) of the ND system. This results in a higher required PO at a similar % and velocity. ME of both ND and HA was similar in the present study. In earlier literature, bidirectional lever systems were used while the ND is a unidirectional lever system. Con-

sequently, shorter push times are possible for the ND, possibly being less efficient. It has to be kept in mind though that learning effects may have a great influence on ME. In ND propulsion, it is essential to move in a straight line forwards-backwards. Any deviations in left-right direction result in activating the brake mechanism or shifting gears. This movement is not intuitive, and might require a different and more extensive learning process than HA propulsion. Future studies should incorporate these learning aspects. Besides this, the ND could provide variety in propulsion mode and could be suitable for people with very low active muscle mass, and should be evaluated for different patient groups.

### **THE EFFECT OF ALPINE SKIING ON LEG MUSCLE STRENGTH ASYMMETRY IN PARTICIPANTS WITH TOTAL KNEE ARTHROPLASTY**

Pötzelberger, B.1, Raschner, C.2, Maurer, S.3, Fink, C.3, Scheiber, P.1, Müller, E.1

*1University of Salzburg; 2University of Innsbruck; 3Sportsclinic Innsbruck, OSM Research Foundation*

**INTRODUCTION** Total knee arthroplasty (TKA) is one of the most common surgery interventions for end stage knee osteoarthritis. The annual incidence of TKA is on average 175 procedures per 100 000 population (1). It has been demonstrated that force deficits (asymmetry) between operated (OP) and non operated (NOP) legs exist (2), which may persist for years after TKA, and are associated with functional limitations (3). In alpine regions, skiing is an extremely popular leisure-time activity for individuals of all ages. An increase in functional performance through skiing was found in elderly without TKA (4). The purpose of this study was to investigate if a 10 wk skiing intervention reduces asymmetry in leg strength and in force distribution during skiing. **METHODS** Thirteen participants (2 ♀, 11 ♂; 66±4 yrs.; 2.1±1.1 yrs. post OP) with unilateral TKA and intermediate skiing skills underwent a 10 wk (30 skiing days) guided skiing intervention. Pressure insoles (Novel, Germany) were used to determine the kinetic data (mean GRF) during skiing on a defined course pre and post intervention. The maximal isometric leg strength (120° knee angle) was measured unilaterally on both legs using a leg press during pre and post intervention. Paired sample t-tests ( $p < .05$ ) were used for statistical analyses. **RESULTS** Asymmetry in ground reaction forces while skiing between OP and NOP leg was found, neither in pre nor in post test. Maximal isometric leg strength was significantly lower in OP leg compared to NOP leg in pre (OP 12.6±4.35; NOP 14.2±3.6 N/kg) ( $p = .031$ ) and post test (OP 14.1±3.6; NOP 15.3±2.9 N/kg) ( $p = .020$ ). Improvements in leg strength were determined in the OP leg ( $p = .006$ ) but not in the NOP leg ( $p = .051$ ). Asymmetry between dominant and non dominant leg strength could be significantly reduced from 15.8±10.6 to 8.7±8.8 % ( $p = .012$ ). **DISCUSSION AND CONCLUSIONS** Interestingly, the existing leg strength asymmetry in the lab test did not occur during alpine skiing as it was found in gait analyses (3). Even though alpine skiing is a bilateral training, a significant improvement in leg strength was found only in the OP leg. However, based on the classification of dominant vs. non dominant leg, the results showed that leg strength asymmetry was reduced. This potentially plays a beneficial role to reduce increased fatigue rate, fall risk and limitation of mobility. **REFERENCES** (1) Kurtz SM, et al. ### **RELATIONSHIPS BETWEEN SELF-PERCEIVED KNEE FUNCTION AND INDICES OF MUSCULOSKELETAL PERFORMANCE IN AN ACL-RECONSTRUCTED POPULATION**

Gleeson, N.1, Shepherd, J.2, Bailey, A.3, Yates, C.1, Minshull, C.2

*Queen Margaret University Edinburgh*

**Introduction** Rupture of the anterior cruciate ligament (ACL) is a potentially career-threatening injury for sports performers, invariably requiring reconstructive surgery to restore knee function (1) and considerable rehabilitative temporal and fiscal costs. Two-thirds of patients have not returned to competitive sport within 12 months of surgery (1). Knee joint function is usually evaluated from a combination of clinical assessment and patient perceptions obtained from rating scales and questionnaires. Limited research has focused on how these inventories in an ACL-reconstructed population relate to objective measures, which is the focus of this study. **Methods** 31 patients (27 males, 4 females) were selected randomly from those presenting with arthroscopically verified unilateral ACL rupture. Patients underwent a standardised rehabilitation and were assessed at pre-, 6 weeks, 12 weeks, 24 weeks and 48 weeks following surgery. Knee extensor (KE) and flexor (KF) peak force (PF) and rate of force development (RFD), ACL laxity (LAX) and single leg hop for distance were assessed. Perceptions of knee function were obtained using the IKDC Subjective Knee Evaluation form (IKDC) and performance profiling (PP). Relationships between self-perceived and objective measures were calculated for the injured limb expressed as a percentage of the corresponding value for the non-injured limb to produce a limb symmetry index (2). **Results** Anticipated patterns of altered musculoskeletal performance were evident following surgery. Knee laxity significantly improved (56.5%) from pre-surgery to 6 weeks. Following impairment to most indices of performance (injured limb) over this same time-period (e.g. KE PF: 35.3%; KF PF: 26.9% decrease), continual improvements to each index was observed at all time-points thereafter ( $p < 0.001$ ). Increases in PP ( $p < 0.001$ ) and IKDC ( $p < 0.001$ ) scores indicated progressively improved perceived knee function. A lack of significant concomitant and latent correlations between indices of perceived and objective outcomes were evident throughout most of the rehabilitation, although at 48 weeks moderate concomitant correlations were observed with various indices (e.g. hop: 0.45; KERFD: 0.57;  $p < 0.001$ ). **Discussion** Discrepancies between self-perceived and actual function may reflect a lack of efficacy of the self-reported inventories, or possibly a misplaced level of confidence in the capabilities of the reconstructed knee. Both of which might prompt overly cautious approaches to rehabilitation. **References** 1. Ardern et al. (2011) *Br J Sp Med*, 45: 596-606. 2. Thomee et al. ### **THE RELATION BETWEEN THE PERFORMANCE OF TRANSITION PHASE OF SIT-TO-WALK TASK AND STRENGTH COMPONENTS IN PARKINSON'S DISEASE PATIENTS**

Pelicioni, P.H.S., Pereira, M.P., Lahr, J., Altarugio-Junior, J.L., Rodrigues, M.M.L., Morais, L.C., Gobbi, L.T.B.

*Universidade Estadual Paulista*

**Introduction** The Parkinson's disease (PD) is characterized by bradykinesia, rigidity, tremor and deficit balance. This symptom leads PD patients to a poorer performance in activities of daily living (ADL) as rising up from a chair and walking. To perform ADL muscular strength is required. It is known that PD patients are weaker than healthy pairs, however there is the need to investigate other strength components, as the rate of force development (RFD) in these subjects (Stevens-Lapsley et al., 2012). It is also important to determine if these variables play an important role in ADL, as the transition phase of sit-to-walk (STW). Therefore, the aim of this study was to analyze the differences between the performance of PD patients and healthy subjects on STW task (Kerr et al., 2004), mainly in transition phase (TP) and on force production. We also analyzed the RFD in 50, 100 and 200 ms after the force onset and the correlation between force varia-

bles to task performance and to clinical measures (only for the PD group). Methods Participated 12 PD patients and 12 healthy subjects (CG). The subjects were instructed to walk as fast as possible to answer a telephone (positioned at 3m apart) after hearing its signal. To analyze the TP, we captured subjects' movements with a digital camera and the task was defined as between the ring signal and the first step toe off. The isometric knee extension strength was measured using a leg-press through a force cell. Results Student t-test showed differences between groups in: TM ( $p=0,029$ ), PF ( $p=0,009$ ), RFD-50ms ( $p=0,002$ ), RFD-100ms ( $p=0,003$ ) and RFD-200ms ( $p=0,008$ ). The Pearson correlation showed correlations for PD (TMxUPDRS II -  $r=0,721/p=0,008$ ; and TMxHY -  $r=0,660/p=0,02$ ) as for CG (TMxRFD-50ms -  $r=-0,601/p=0,039$ ; TMxRFD-100ms -  $r=-0,606/p=0,037$ ; TMxRFD-200ms -  $r=-0,629/p=0,028$ ). Discussion PD patients showed a poorer performance on TP and on strength variables. However, the correlation tests failed to point a relation between PD clinical characteristics and force production. These results demonstrate: i) the TP performance of PD patients is more influenced by disease characteristics than to force production, whereas in CG, it is highly influenced by these variables; ii) the strength test could not be sensitive to PD characteristics, (as no correlation between RFD and clinical signs – as bradykinesia – was found) and should be replaced on further studies. Finally, this slowness could explain the poorer performance on TM. References Kerr A et al. (2004). Clin Biomech, 19, 385-390. Stevens-Lapsley J et al. (2012). ### **CHRONIC EXERCISE INFLUENCE ON THE AMPHETAMINE-DEPENDENT BEHAVIOUR AND DOPAMINE IN STRIATUM, FRONTAL CORTEX AND HIPPOCAMPUS IN THE RAT**

Fontes Ribeiro, C., Pereira, F.C., Silva, A.P.

*Faculty of Medicine*

**Introduction** The dopaminergic mesocorticolimbic and nigrostriatal systems are involved in drug addiction. However, there is little information about the effect of exercise on addiction and on the synthesis, metabolism and action of dopamine (DA) in the presence of amphetamines. This work aimed to verify the influence of exercise on addiction using an amphetamine (AMPH)-induced conditioned place-preference (CPP) in rats, and to determine DA and respective metabolites in striatum, frontal cortex and hippocampus. **Methods** Adult male Sprague-Dawley rats were randomly separated in two groups: one with and another without exercise (8 weeks running program in a treadmill, with increasing intensity). The CPP test was performed in both groups. There were three phases: 1st- Pre-conditioning: free access to both compartments, 20 min sessions with registration of the time spent in each compartment; 2nd- Conditioning: 8 consecutive days (45 min sessions) in the alternated compartments (4 days of 2 mg/kg AMPH alternated with saline injections); 3rd- Test day: free access to both compartments, 20 min sessions with registration of the time spent in each compartment. Animals were sacrificed 24 h after the last AMPH or saline, and striatum, hippocampus and frontal cortex were dissected for DA and metabolites measurement by HPLC-ECD. **Results** Since in the pre-conditioning phase none of the animals presented preference for a compartment, all the animals were used. Rats without exercise showed preference for the compartment associated with AMPH, an effect which did not occur with the animals with training. Amphetamine decreased striatal DA content and turnover from trained and untrained rats. Training reduced and increased DA content in frontal cortex and hippocampus, respectively. **Discussion** Exercise may prevent the AMPH-seeking behaviour but not changes the AMPH impact on striatal DA. Exercise may alter DA dynamics in the frontal cortex and hippocampus which may be correlated with addiction.

### **EFFECT OF EARLY IMPLEMENTATION OF ELECTRICAL MUSCLE STIMULATION TO PREVENT MUSCLE WEAKNESS IN PATIENTS AFTER ANTERIOR CRUCIATE LIGAMENT RECONSTRUCTION**

Hasegawa, S., Kobayashi, M., Arai, R., Ichihashi, N., Moritani, T.

*Kyoto University*

**Introduction** Following anterior cruciate ligament (ACL) reconstruction, restricted weight bearing and immobilization results in thigh and calf muscle atrophy and weakness. Electrical muscle stimulation (EMS) is available as a training tool to prevent muscle weakness and atrophy, but there are currently no reports in which EMS was started during the early rehabilitation stage after surgery. The purpose of this study was to assess the effect of EMS on prevention of muscle atrophy in patients during the early rehabilitation stage after ACL reconstruction using the wave form of 20Hz exponential pulse. **Methods** Twenty patients with acute ACL tears were divided into two groups. The control group (CON group) participated in only the usual rehabilitation program. In addition to this protocol, the electrical muscle stimulation group (EMS group) received EMS training from the 2nd post-operative day to 4 weeks after the surgery. The muscle thicknesses of the rectus femoris (RF), vastus intermedius (VI), vastus lateralis (VL), and calf (CA) muscles were measured as well as knee extensor muscle strength before the operation and at 4 weeks and 3 months after surgery. **Results** Muscle thickness of VL and CA increased significantly 4 weeks after surgery in the EMS group, while it decreased significantly in the CON group. The decline of knee extension strength was significantly less in the EMS group than in the CON group at 4 weeks after the surgery, and the EMS group showed greater recovery of knee extension strength at 3 months after surgery. **Discussion** There have been some controversial findings regarding the effects of EMS following ACL reconstruction. Lieber et al. demonstrated that 50 Hz neuromuscular electrical stimulation and voluntary muscle contraction treatments, when performed at the same intensity, are equally effective in strengthening skeletal muscle that has been weakened by surgical repair of the ACL. On the other hand, Snyder-Mackler et al. reported that quadriceps strength averaged at least 70% of the strength on the uninvolved side in patients treated with high-intensity electrical stimulation (either alone or combined with low-intensity electrical stimulation), 57% in patients treated with high-level active exercise, and 51% in patients treated only with low-intensity electrical stimulation. Our present results confirmed significant efficacy of EMS training following ACL surgery, but differ from previous studies on some points. Our current data indicated that EMS training not only prevented muscle atrophy following ACL reconstruction, but also resulted in VL and CA hypertrophy, which have not been reported previously. We believe these different results are caused by differences in the start timing of EMS, the EMS protocol, and the electrodes. **References** Lieber RL, Silva PD, Daniel DM. (1996). ### **EFFECT OF A PREPARATION PROGRAM AFTER SURGERY ON REPEATED ANTERIOR SHOULDER DISLOCATION**

Alibakhshi, E.1,2, Aminian Jazi, A.1, Sobhani, V.2

*1: UB (Barcelona, Spain), 2: BMSU (Tehran, Iran)*

**Introduction** A fall onto an outstretched arm or a collision on the playing field often leads to an acute anterior shoulder dislocation for high school- and college-age athletes. The diagnosis is usually made by history and physical exam. Despite immobilization, supervised

rehabilitation, and gradual return to full activity, dislocation recurrence ranges from 60% to 94% in patients younger than 25. The purpose of this study was to review the effect of a mobilization exercise and strengthening program with dynamic splint on prevention of repeated shoulder dislocation in professional athletes. Methods In this retrospective quasi experimental study, 18 athletes with mean age of 25 years suffering from repeated anterior shoulder dislocation with effective trauma were reviewed in a mobilization and strengthening program with dynamic splint of shoulder. The results were evaluated by Constant Shoulder Score (CSS), descriptive analysis, and t- test ( $P < 0.05$ ). Results The decreased range of motion in shoulder joint in abduction and external rotation in comparison with healthy shoulders was 36 degrees. The training program had a significant effect on reduction on repeated anterior shoulder dislocation. In radiology, 3 cases of premature arthritis which had restriction in external rotation were observed. Discussion Rate of instability after mobilization and strengthening program with dynamic splint was low but due to the restriction that dynamic splint induces in external rotation of shoulder joint, this program should be done by professional athletes in a way that in the final stages of the training program splints are used less. ### MOTOR ABILITY AND DEPRESSIVE SYMPTOMS ARE RELATED AFTER ISCHEMIC STROKE

Yoshida, H.M.1, Lima, F.O.2, Avelar, W.M.2, Li, L.M.2, Fernandes, P.T.1,2

*State University of Campinas - UNICAMP*

**Introduction** Motor impairment is one of most common deficit after ischemic stroke. It is estimated that 80% of patients remain with some motor deficit (1). Other common difficulty is a depression, which has a negative impact in patient's life. Depressive symptoms are estimated between 10-78% in post-stroke patients (2). Motor impairment and depression affect directly the quality of life in stroke patients (3). **Objective** Verify the relationship between motor ability and depressive symptoms after ischemic stroke. **Methods** We evaluated patients with first anterior circulation unilateral ischemic stroke. Motor function was appraised by Fulg-Meyer Motor Scale (FMMS). Depressive symptoms were evaluated by Beck Depression Inventory (BDI). We also got general information as: age, sex, stroke lateralization, NIHSS. A linear regression model was used to assess the independent factors associated with motor impairment. **Results** We performed an evaluation in 58 patients (36 men;  $62.4 \pm 12.9$  years; 35 had a left sided ischemic stroke). The median time to evaluation was 178 (IQR 118-397) days, median NIHSS at the time of evaluation was 2 (IQR 0-4), mean FMMS was  $92.8 (\pm 25)$  and mean BDI score was  $11 (\pm 7.2)$ . After adjusting for BDI score, stroke lateralization, sex, age and NIHSS, only depressive symptoms ( $\beta = -0.84$ ,  $p = 0.04$ ) and NIHSS ( $\beta = -4.3$ ,  $p < 0.001$ ) were independently associated with motor function. There was a strong trend for women to have better motor function ( $\beta = 9$ ,  $p = 0.09$ ). **Discussion** The relationship between motor impairment and depression could be explained by Kim and colleagues (2005) (4) that found motor dysfunction affecting mobility and self-care. It influences mood, consequently, depression could be manifested. Our result also collaborates to the Van de Port and Colleagues (2007) (5), who found the relationship between motor impairment and depression in chronic post stroke patients, emphasizing an association between post stroke depression and post stroke fatigue. **References** 1.Barker W. #### BLOOD PRESSURE RESPONSES TO DIFFERENT TRAININGS.

Niño, O.1, Alamo, J.M.1, Aragonés, D.2, Balagué, N.2, Cos, F.2, Guillamó, E.1,2, Ventura, J.L.1, Javierre, C.1

*University of Barcelona*

**Introduction** The purpose of this study was to evaluate the values of blood pressure at rest and at submaximal exercise after different training modalities: aerobic (AET), resistance (RET) and mixed (MIX). **Methods** Forty-three healthy male subjects physically active, (age  $21.2 \pm 2.4$  years) were randomly distributed in four different training groups: AET, RET, MIX and control (CON). They were trained for six weeks except the control group. Before (1st day), after training period (2nd day) and three weeks after the training (3rd day) the subjects were evaluated in the cycle ergometer during 6 minutes with a constant workload corresponding to 60% of maximal aerobic power. **Results** Blood pressure decreased in the three training groups. A/ At rest: systolic blood pressure (SBP) between the 1st and the 3rd day in the AET group ( $10.1 \pm 5.6$  mmHg), in the RET group ( $8.9 \pm 5.0$  mmHg) and significantly in the MIX group ( $19.1 \pm 7.2$  mmHg) ( $p = 0.038$ ); diastolic blood pressure (DBP) ( $9.9 \pm 4.3$  mmHg) ( $p = 0.049$ ) and mean blood pressure (MBP) ( $12.4 \pm 5.0$  mmHg) ( $p = 0.043$ ) in the MIX group. B/ At exercise, the AET group showed differences between the 1st and the 3rd day for: SBP ( $18.7 \pm 5.2$  mmHg) ( $p = 0.003$ ), DBP ( $7.6 \pm 3.1$  mmHg) ( $p = 0.035$ ) and MBP ( $12.4 \pm 3.2$  mmHg) ( $p = 0.004$ ); the RET group showed differences between the 1st and the 2nd day for SBP ( $17.6 \pm 6.0$  mmHg) ( $p = 0.016$ ), DBP ( $7.8 \pm 2.3$  mmHg) ( $p = 0.009$ ) and MBP ( $11.3 \pm 3.5$  mmHg) ( $p = 0.010$ ) and between the 1st and the 3rd day for SBP ( $25.8 \pm 8.4$  mmHg) ( $p = 0.013$ ), DBP ( $11.3 \pm 4.1$  mmHg) ( $p = 0.022$ ) and MBP ( $16.7 \pm 5.7$  mmHg) ( $p = 0.017$ ) and the MIX group showed differ-

ences between the 1st and the 2nd day in DBP ( $6.8 \pm 2.4$  mmHg) ( $p=0.021$ ) and between the 1st and the 3rd day SBP ( $16.2 \pm 4.4$  mmHg) ( $p=0.006$ ) and MBP ( $11.4 \pm 5.0$  mmHg) ( $p=0.043$ ). Discussion The blood pressure response to resistance training or to mixed training can be at least as effective as aerobic training, with positive effects lasting 3 weeks after finishing the exercise program. Mixed training seems to provoke a bigger decrease at rest. References Cornelissen VA, Buys R, Smart NA, Buys R. (2013) J.Hypertens. (ahead of print). ### CHANGES OF BIOCHEMICAL AND CARDIOVASCULAR SYSTEM FUNCTIONAL PARAMETERS OF MIDDLE-AGED MEN OF DIFFERENT PHYSICAL ACTIVITY DURING EXERCISE

Cesnaitiene, V.J., Siniciene, J.

*Lithuanian sports university*

Introduction In the middle age, most of the time people spend on profession, household needs, child care that affect their lifestyle and at the same time and physical activity. The aim of the study was to establish how physical activity and age effects on cholesterol and glucose levels in the blood, heart, and circulatory system function of middle-aged men during increasing physical load. Methods In the research participated 95 Lithuanian soldiers. Participants were divided into low, medium and high physical activity groups to evaluate physical activity level. Biochemical blood tests were carried out (blood glucose level, cholesterol amount in the blood), recorded and measured electrocardiogram (ECG), calculated heart rate (HR) and blood pressure (BP) during the rest time. Participants did exercise test to determine exercise capacity and changes of cardiovascular systems function with measured standardized load. Results. Cholesterol of physically inactive reserached participants was 80 mmol / l higher than physically active - 50 mmol / l. Glucose in the blood of physically inactive participatns are 68 mmol / l - physically active - 31,3 mmol / l. Heart rate of physically inactive participants rised much faster than medium and high physical active participants ant they earlier reached the sub-maximal heart rate. Both systolic and diastolic blood pressure during exercise came faster for physically inactive participants than physical active, regardless to physical activity level for all participants blood recovered after 8 minutes. Conclusions: The results of the study showed that physical activity in the middle age has a positive effect on biochemical and cardiovascular functional parameters during and after exercise. The only cardiovascular rate - systolic blood pressure was significantly higher of older research participants than younger, all other parameters researched age had no effect. References Booth, F. ### THE INFLUENCES OF ACUTE EXERCISE ON ENDOTHELIUM-DEPENDENT VASORELAXATION AND ANTIOXIDANT ACTIVITY IN POSTMENOPAUSE WITH HYPERTENSION

Lin, H.Y.1, Su, C.T.2, Yang, A.L.1

*1:Taipei Physical Education College; 2:Fu Jen Catholic University*

Introduction Menopause-related estrogen deficiency increases the risk of cardiovascular disease, which could be further aggravated by the presence of hypertension. Regular exercise has been reported to improve cardiovascular function and antioxidant activity. However, whether acute exercise influences endothelium-dependent vasorelaxation and antioxidant activity in postmenopause with hypertension remains unclear. Therefore, the aim of this study was to investigate the influences of a single bout of exercise on endothelium-dependent vasorelaxation and antioxidant activity in postmenopausal hypertensive rats. Methods Four-month-old female spontaneously hypertensive rats were divided into three groups: (1) the sham-operated control group (sham); (2) the ovariectomy without exercise group (OVX); and (3) the ovariectomy with exercise group (OVX+EX). A single bout of exercise was conducted by treadmill running at moderate intensity for 1 hour in the OVX+EX group. Rat thoracic aortas were isolated for the measurement of the endothelium-dependent (acetylcholine, ACh) and endothelium-independent (sodium nitroprusside, SNP) vasorelaxation by the organ bath system. The serum levels of antioxidant and oxidant activities, such as catalase and thiobarbituric acid reactive substance (TBARS), were also evaluated. Results The single bout of exercise significantly improved ACh-induced vasorelaxation in the OVX+EX group compared with the OVX group ( $p<0.05$ ). However, there was no significant difference in the SNP-induced vasorelaxation among three groups. Furthermore, the single bout of exercise significantly increased the catalase activity ( $p<0.05$ ), but not TBARS level, in the OVX+EX group compared with the OVX group. Discussion Our results indicated that a single bout of exercise could acutely improve endothelium-dependent vasorelaxation and antioxidant activity in postmenopausal hypertensive rats. It implicated that exercise would ameliorate the cardiovascular function in the population of postmenopause with hypertension. Since our study only explored the influences of a single bout of exercise, further studies would be encouraged to examine the effects of long-term exercise intervention for this population. ### THE EFFECTS OF ACUPUNCTURE ON TISSUE-BLOOD VOLUME

Kaneko, Y.1,2, Kime, R.1, Takagi, S.1, Murase, N.1, Osada, T.1, Katsumura, T.1, Kihira, A.2, Uehara, A.2, Furuya, E.2, Sakamoto, A.2

*1: TMU (Tokyo, Japan) 2: Kuretake College of Medical Arts & Sciences (Tokyo, Japan)*

[Objective] Acupuncture is widely used for musculoskeletal disorders such as low back pain, shoulder pain, knee pain or osteoarthritis in complementary and alternative medicine. It is considered as one of the reasonable referral option for chronic pain (Vickers, et al. 2012). Acupuncture may help athletes who complain of their injuries by reducing the pain. One of the physiological effects of acupuncture is increasing blood circulation and it may help to ease pain or fasten the recovery from injuries (Kubo et al. 2011). The aim of this study was to examine the effects of acupuncture on tissue-blood volume in both local and distant area at the same time. [Methods] Subjects were 10 healthy male. Near Infrared Spectroscopy (NIRS, HB-14, ASTEM Co.,Ltd.) were used to detect Oxyhemoglobin (OxHb), Deoxyhemoglobin (DxHb), Total hemoglobin (ToHb), and Tissue-Oxygen Saturation (StO2). The probes of NIRS were placed on the right and left side of erector spinae at S1 level (RS1, LS1), the right side of erector spinae at L4 level (RL4), and the belly of gastrocnemius on the right (RG). Subjects lay on their belly and rested. The acupuncture needle (0.25\*50mm, SEIRIN Co.ltd.) was inserted into right side of erector spinae at S1 level,

then manipulated for 1 minute and left for 9 minutes. Subjects kept rested after removal of needle for 10 minutes. OxHb, DxHb, ToHb, and StO<sub>2</sub> at rest (Pre) and after the acupuncture stimulation (Post) were evaluated. [Result] At RS1 where the needle were inserted, OxHb was increased from 39.8±11.7µM to 43.9±12.8µM (p<0.01). No change was observed in DxHb (8.0±4.1µM to 7.9±4.5µM). ToHb was increased from 47.8±14.1µM to 51.8±15.5µM (p<0.01). StO<sub>2</sub> was increased from 83.8±6.0% to 85.4±6.1% (p<0.01). At LS1 OxHb was increased from 30.6±9.6µM to 32.7±10.5µM (p<0.01). No change was observed in DxHb (7.6±3.7µM to 7.6±3.9µM). ToHb was increased from 38.2±13.0µM to 40.3±14.1µM (p<0.01). StO<sub>2</sub> was increased from 80.9±5.2% to 82.0±5.1% (p<0.05). At RL4 OxHb was increased from 36.1±7.8µM to 41.0±9.2µM (p<0.01). No change was observed in DxHb (8.5±4.4µM to 8.9±3.6µM). ToHb was increased from 44.1±11.0µM to 49.8±12.3µM (p<0.01). StO<sub>2</sub> was increased from 81.2±5.1% to 82.8±4.2% (p<0.01). At RG OxHb was increased from 77.7±34.2µM to 80.7±36.6µM (p<0.05). DxHb was increased from 27.4±7.7µM to 28.7±7.4µM (p<0.05). ToHb was increased from 105.2±40.3µM to 109.2±42.3µM (p<0.01). There was no change in StO<sub>2</sub> (72.8±4.9% to 72.4±5.5%). [Conclusion] The different effects of acupuncture on tissue-blood volume were observed in local and distant area. These results indicate that the acupuncture stimulation may affect differently to local and distant area such as by axon reflex and by segmental effects. [References] Vickers et al. (2012) Arch Intern Med. 2012;172(19):1444-1453. Kubo et al. (2011) Int J Sports Med. 2011 Oct;32(10):807-13.

### THE EFFECT OF MUSIC TYPE IN CARDIOPULMONARY CAPACITY DURING AEROBIC EXERCISE

Chou, T.Y., Ko, H.T., Hu, C.Y., Lin, H.T.

*Department of Sports Medicine*

Introduction Favorite music can make one delight, however, displeasure music may become the source of the stress. Previous studies showed that music can affect human automatic nervous system and change one's blood pressure and heart rate (Potteiger et al., 2000). Therefore, listening music during exercise may affect exercise performance. The purpose of this study was to discuss the effect of music type in cardiopulmonary function during cycling. Methods Seven male college students without any cardiopulmonary system syndrome were recruited in this study. Before testing, the subjects were asked to have a Physical activity Readiness Questionnaire (PAR-Q) to make sure the subjects could afford the testing. During the test, the pulmonary gas exchange system was used to record the cardiopulmonary parameters during cycling. The subjects were asked to keep at rest for five minutes and doing cycling at 30W resistance, 60 rpm pedaling rate for warm up for four minutes. After warm up, the resistance increased to 60W and the subjects' heart rate must reach 75% maxima heart rate within one minute. During data collection, the resistance maintained at 60W and subjects were asked to keep at 75% maximum heart rate with free pedaling rate for fifteen minutes. The data still keep record for five minutes after cycling. Two different types of music with light music and heavy metal music were tested and the tempo in two types of music is 134 beats/min. Results During the rest, the heart rate is significant higher in listening the heavy metal music than in light music. During cycling, the averaged Rf, VE, VO<sub>2</sub> and VCO<sub>2</sub> are higher in listening heavy metal music than in light music, however not reached significant difference. After exercise, the VE, VO<sub>2</sub> and VCO<sub>2</sub> recovered faster in first minute significantly when listening the heavy metal music (heavy metal music: VE=18.2%±0.1, VO<sub>2</sub>=37.9%±0.1, VCO<sub>2</sub>=43.3%±0.1; light music: VE=27.8%±0.1, VO<sub>2</sub>=36.1%±0.1, VCO<sub>2</sub>=35.5%±0.1). In the second minute after exercise, only the recovering percentage of heart rate is much significant faster in listening the heavy metal music (heavy metal music HR=22.3%±0.03, light music HR=19.8%±0.04, P=0.03). Discussion From our results, the heavy metal music may stimulate more sympathetic nervous system that could increase heart rate and respiratory system. In the recovery phase, the heavy metal also have similar stimulation outcome that could enhance recovery after exercise. In this study, the exercise intensity is not very high, the heavy metal music could inspire someone, and stimulate sympathetic nervous system. If listening heavy metal music in higher intensity exercise, it may be a pressure and would not help for exercise. Listening music could change the physiological condition during exercise, and listening the heavy metal music after exercise could recover faster. References Potteiger JA, Schroeder JM, Goff KL. (2000). Percept Mot Skills, 91, 848-854.

### EFFECTS OF A COMMUNITY-BASED EXERCISE PROGRAM IN CLINICAL BLOOD PRESSURE OF PATIENTS WITH TYPE 2 DIABETES: DIABETES EM MOVIMENTO® PILOT STUDY

Mendes, R., Sousa, N., Reis, V., Themudo Barata, J.

*University of Trás-os-Montes e Alto Douro*

Introduction One of the major complications of type 2 diabetes is systemic arterial hypertension, that leads to an increase in morbidity and mortality of diabetic patients. Regular exercise is widely recommended as a non-pharmacological strategy to control type 2 diabetes and also to control blood pressure levels and reduce cardiovascular risk. This study aims to analyze the effects of a community-based group exercise intervention in clinical blood pressure of patients with type 2 diabetes. Methods This was a longitudinal study design. Twenty-three individuals with type 2 diabetes (diagnosed at 7.43 ± 5.23 years; 12 men and 11 women; age 60.17 ± 7.85 years old; glycated hemoglobin 7.13 ± 1.40 %; fasting glucose 155.67 ± 50.51 mg/dl; body mass index 30.38 ± 4.64 kg/m<sup>2</sup>; waist circumference 105.20 ± 11.73 cm; clinical systolic blood pressure 131.35 ± 14.33 mmHg; clinical diastolic blood pressure 78.90 ± 10.04 mmHg) treated with oral antihypertensive agents (with same drugs and dosages for at least 3 months), underwent a community-based group exercise program with 23 weeks duration. Exercise sessions were held three times per week on non consecutive days (Mondays, Wednesdays and Fridays) with a duration of around 70 minutes and were supervised by exercise professionals. Sessions consist of five phases: 1) Warm up (5 min), which included brisk walking; 2) aerobic exercise (30 min), which included walking at different speeds, relay races, obstacle and stairs courses; 3) resistance exercises (20 min) performed with chairs, dumbbells, fitness balls and bodyweight exercises; 4) agility training (10 min) consisting of reduced, simplified and adapted team ball games; and 5) cool down / flexibility (5 min) through static and dynamic stretching exercises. Clinical blood pressure was determined before and after exercise program (pre and post-test). Results Exercise program dropout was 26.09 % (N = 6) and exercise adherence was 70.79 ± 19.73 %. No changes occurred in type and dosages of antihypertensive drugs between pre and post-test. Student's t test for paired samples identified significant differences in systolic blood pressure (133.00 ± 14.21 mmHg vs. 122.71 ± 11.98; t = 4.036; p = 0.001) and diastolic blood pressure (78.65 ± 10.44 mmHg vs. 68.92 ± 8.02; t = 4.278; p = 0.001) between pre and post-test. Conclusions Community-based group exercise programs are effective interventions to control blood pressure levels and cardiovascular risk in patients with type 2 diabetes. Trial funding and registration Diabetes em Movimento® is funded by Portuguese Foundation for Science and Technology with reference SFRH/BD/47733/2008 and is registered in Current Controlled Trials with reference ISRCTN09240628.

## PREVALENCE AND FACTORS ASSOCIATED WITH THE CO-OCCURRENCE OF CARDIOVASCULAR RISK BEHAVIORS IN ADOLESCENTS

Barros, M., Brito, A., Hardman, C., Barros, S.

*Universidade de Pernambuco*

The aim of this study was to analyze the prevalence and factors associated with the co-occurrence of cardiovascular risk behaviors in adolescents. A cross-sectional study was performed with a representative sample of adolescent high school students from state public schools in Pernambuco, Brazil (n= 4,207, 14-19 years old). Data were obtained using a self-reported questionnaire. The co-occurrence of cardiovascular risk behaviors was established based on the sum of five behavioral risk factors (low physical activity, sedentary behavior, low consumption of fruits/vegetables, alcohol consumption and tobacco use). The independent variables were gender, age group, time of day attending school, school size, maternal education, occupational status, skin color, geographic region and place of residence. Data were analyzed by ordinal logistic regression with proportional odds model. Approximately 10% of adolescents were not exposed to cardiovascular risk behaviors, and 58.5% reported being exposed to at least two health risk behaviors simultaneously. It was observed a higher likelihood of co-occurrence of cardiovascular risk behaviors among adolescents in the upper age (17-19 years) category (OR= 1.17; P<0.01), with higher maternal education (OR= 1.21; P<0.01), and that reported living in the driest region of the state of Pernambuco (OR= 1.39; P<0.001). Adolescents who reported having a job (OR= 0.86; P=0.04) and residing in rural areas (OR= 0.78; P=0.001) had a lower likelihood of co-occurrence of risk behaviors. Findings suggest that the prevalence of co-occurrence of cardiovascular risk behaviors in this group is high, particularly among older adolescents, whose mothers had a higher schooling level e among those who reported having no job, residing in urban areas, and in the semiarid region.

## COMPARISON OF OXYGEN CONSUMPTION IN RATS DURING UPHILL AND DOWNHILL TREADMILL EXERCISE TESTS

Sirvent, P., Chavanelle, V., Ennequin, G., Caillaud, K., Montaurier, C., Morio, B., Boisseau, N., Richard, R.

*AME2P - EA 3533*

**Introduction** The study of the physiological adaptations of skeletal muscle in response to eccentric (ECC) contraction is based on protocols in which exercise intensities are determined relative to the concentric (CON) reference exercise (as percentage of the CON maximal oxygen consumption, or VO<sub>2</sub>max) (Lastayo et al., 2000, Lastayo et al., 2003). In order to use similar exercise protocols in rats, we compared the VO<sub>2</sub> values during uphill (CON) and downhill (ECC) running tests, using variable slopes. **Methods** VO<sub>2</sub> (using a breath-by-breath device) was measured in 15 Wistar rats during incremental treadmill running exercises (initial speed 15 cm/sec, increment of 5 cm/sec every 3 min) with different slopes: level (0%), positive (+15% incline: CON+15%) and negative (-15% incline: ECC-15%; and -30% incline: ECC-30%). **Results** The VO<sub>2</sub> plateau (VO<sub>2</sub>max) was reached in nine exercise tests (89.82±2.32 mL•kg<sup>-1</sup>•min<sup>-1</sup>; mean rat weight: 447±7 g). Similar VO<sub>2</sub> values were obtained in the ECC-30% and CON+15% running conditions at the three target speeds (15, 25 and 35 cm/sec). Conversely, VO<sub>2</sub> values were 1.5 to 2 times lower (p<0.05) in the ECC-15% than in the CON+15% condition (CON+15% VO<sub>2</sub>/ECC-15% VO<sub>2</sub> ratios of 1.86, 2.05 and 1.65 at the three target speeds, respectively). **Discussion** Thus, during ECC treadmill exercise it is necessary to double the slope (ECC-30%) to obtain similar VO<sub>2</sub> levels than during CON exercise with 15% positive incline. The CON VO<sub>2</sub>/ECC VO<sub>2</sub> ratio can be useful for designing animal research protocols particularly to study the effects of ECC and CON exercise in ageing populations or with cardiovascular and respiratory diseases. **References** LaStayo PC, Ewy GA, Pierotti DD, Johns RK, Lindstedt S (2003). *J Gerontol A Biol Sci Med Sci*, 58, 419-424. ## THE RELATIONSHIP OF EXERCISE-INDUCED CARDIAC TROPONIN T RELEASE AND LEFT VENTRICLE MASS IN ADOLESCENT ATHLETES

Nie, J.1, Kong, Z.2, Lin, H.3, Tong, T.4, Shi, Q.1

*Macao Polytechnic Institute*

1: MPI (Macao, China). 2: UMAC (Macao, China). 3: LNU (Dalian, China). 4: HKBU (Hong Kong, China). **Introduction** Although regular exercise training reduces cardiovascular disease risk, recent studies have documented elevations in cardiac troponin (cTn) consistent with cardiac damage after bouts of exercise in apparently healthy adults (Shave et al., 2010) and adolescents (Nie et al., 2011). At present, the mechanism(s) and clinical significance of exercise-induced cTn release remains understood. It has been proposed that cTn release following exercise is related to, or an adjunct of the messenger cascade responsible for the physiologically hypertrophied heart (Shave et al., 2007). The objectives of the present study were to determine left ventricle mass (LVM)-associated differences in the cTn response to exercise. We hypothesize that the magnitude of cTn responses to a bout of prolonged exercise would be significantly lower in athletes with more training experience and more pronounced cardiac hypertrophy. **Methods** Cardiac troponin T (cTnT) was assessed before and 4 hours after a single 21-km run (R1) at maximal sustainable pace in eleven healthy adolescent athletes (15.3±1.3yr). LVM was examined echocardiographically before run. After one year of intense endurance training (80-120 km/wk on a 7 days/wk basis), these athletes were studied again at same run (R2), using an identical test protocol. **Results** cTnT was undetectable before R1 and R2 but was elevated after R1 (median, range: 0.06, 0.02-0.08 ng/ml) and R2 (median, range: 0.05, 0.03-0.37 ng/ml) (R1 vs. R2 P>0.05). Resting LVM was elevated after one year of training (R1 vs. R2: 177±57 vs. 205±72g, P<0.05). Post-exercise cTnT was not correlated with LVM in R1 (r=0.18, P>0.05, n=11), R2 (r=-0.01, P>0.05, n=11) and combined R1 and R2 (r=0.09, P>0.05, n=22). **Discussion** In the current study we observed that during recovery from a 21-km run cTnT was elevated in adolescent athletes and LVM was significantly increased after one year of endurance training. However, a surprising finding of the investigation is that in contrast to what we expected, no inverse relationship between cTnT release and LVM has been found in present study. This approach to longitudinal study on the relationship between exercise-induced cTnT release and LVM has not been investigated before, which adds to the novelty of the current study. These findings support the contention that exercise-induced cTnT release and cardiac hypertrophy are likely mediated by independent phenomenon. \*The study was supported by a research grant from Macao Polytechnic Institute (RP/ESEFD-01/2012). **References** Nie J, George K, Tong TK, Gaze D, Tian Y, Lin H, Shi Q (2011). *Current Medicinal Chemistry*, 18, 3452-3456. ### EFFECT OF ACUTE INTENSIVE EXERCISE ON SALIVARY ALPHA AND BETA DEFENSINS, AND SECRETORY IGA IN YOUNG MALE SUBJECTS

Hanaoka, Y., Shimizu, K., Suzuki, S., Oikawa, S., Kimura, F., Akama, T., Kono, I., Miyamoto, T.

*University of Tsukuba*

**Introduction** In the field of athletics, the risk of upper respiratory tract infection (URTI) is one of the most important problems in athletes. Human neutrophil protein 1-3 (HNPI-3) and human beta-defensin 2 (hBD2) have anti-virus activity and are related to susceptibility to URTI. However, there is little information of HNPI-3 and hBD2 in response to exercise. The aim of this study was to examine the effect of acute intensive exercise on salivary HNPI-3, hBD2 and secretory immunoglobulin A (SigA). **Methods** 8 healthy young male subjects ( $23.4 \pm 0.6$  years) participated in this study. The subjects performed exercise experiment (exercise on a cycle ergometer at 75%  $\text{VO}_2\text{max}$  for 60 min) and control experiment (non-exercise). Saliva samples were collected before exercise (7:30 AM), immediately following (8:30), 1 h (9:30), 2 h (10:30), 3 h (11:30), and 24 h after the bout of exercise. The HNPI-3, hBD2 and SigA concentrations were measured by the enzyme linked immunosorbent assay (ELISA). The total protein concentration was determined by the Pierce 660nm Protein Assay. The HNPI-3, hBD2 and SigA data were expressed as relative to total protein concentration (HNPI-3/TP, hBD2/TP, SigA/TP, respectively). **Result** In the exercise experiment, salivary hBD2/TP was significantly decreased during the period from immediately following to 2 h after the exercise ( $p < 0.05$ ). Salivary SigA/TP was significantly decreased during the period from immediately following to 24 h after the exercise ( $p < 0.05$ ). Salivary HNPI-3/TP did not show significant change during the study period. Additionally, in the control experiment, salivary SigA/TP was significantly decreased at 2 h and 3 h ( $p < 0.05$ ). While HNPI-3/TP and hBD2/TP did not show significant change during the study period. **Discussion** In this study, mucosal immune system mediated by hBD2 and SigA might be impaired by acute intensive exercise. Additionally, SigA secretion might have a circadian rhythm. These findings may contribute to development of markers to oral immunity in athletes. Further study is required to determine relationship between variation in immune markers and susceptibility to URTI in athletes. **In conclusion**, salivary hBD2 and SigA secretions seem to be decreased by acute intensive exercise. **Reference** Davison G, Allgrove J, Gleeson M. ### RIDING A MOTORCYCLE OR RACING A MOTORCYCLE: DIFFERENCES IN OXYGEN CONSUMPTION, HEART RATE, BLOOD LACTATE; A PILOT STUDY.

D'Artibale, E.1, Tessitore, A.2, Lupo, C.2,3, Capranica, L.2

*University of Hawai'i at Hilo*

1: University of Hawai'i at Hilo (Hilo, USA), 2: University of Rome Foro Italico (Rome, Italy), 3: University of Turin (Turin, Italy). **Introduction** Riding a motorcycle requires human motor skills (Stella et al 2002). Racing with a motorcycle requires physical efforts measured by high intensity Heart Rate (HR) and Blood Lactate (BLa) (D'Artibale et al 2008). No data are published regarding the physiological differences between an amateur rider and a regular racer. This is a pilot study aimed at comparing differences in physical load suffered by an amateur motorcyclist and a road race motorcycling rider. **Methods** An amateur motorcyclist (28 yrs, 1.72 mt, 60 Kg) and a regular licensed road racing rider (35 yrs, 1.70 mt, 68.7 Kg) volunteered for this study. A portable pulmonary gas exchange analyzer (K4b2, Cosmed) was used to collect data while participants were asked to separately ride the same bike (600cc) in the same private track (2.5 Km) at a constant comfortable pace for 40 min. HR was also recorded (Team System, Polar) while riding. A portable BLa analyzer (Accutrend, Roche) was used to investigate differences in peak BLa concentrations after riding. Ratings of perceived exertion (RPE) were recorded immediately after the ride using the original Borg scale (Borg, 1998). **Results** Amateur rode 62.4 Km at 93.7 Km/h average speed. Rider rode 87.4 Km at 131.2 Km/h (+40%) average speed. While riding, average oxygen consumption ( $\text{VO}_2$ ) was four times the baseline for the amateur (20 ml/min/Kg) and was seven times the baseline for the rider (21 ml/min/Kg). Amateur's HR was 121 bpm average (63%  $\text{HR}_{\text{max}}$ ), with a peak of 137 bpm (71%  $\text{HR}_{\text{max}}$ ). Rider's HR was 142 bpm average (77%  $\text{HR}_{\text{max}}$ ), with a peak of 161 (87%  $\text{HR}_{\text{max}}$ ). BLa peak after riding was 2.1 mmol/l for the amateur and 2.8 mmol/l for the rider. Rider's RPE values were 15% lower than amateur. **Discussion** Riding a motorcycle or racing with it requires different oxygen consumptions, unlike physical loads. Road racing motorcycling has been shown to require physical effort, whereas riding as a motorcyclist seems to require smaller effort. Previous studies showed a higher cardiac load and BLa during official competitions (D'Artibale et al 2006). The differences between amateur's performance and racer's performance could be enhanced when considering their competitive environment. Further data are needed to clarify the physiological responses to those two different intensities of riding a motorcycle. Motor sports is a field that would benefit from sports sciences and training (Klarica 2001). **References** D'Artibale E, Tessitore A, Capranica L; (2008); *JouSportSci.* D'Artibale E, Tessitore A, Tiberi M, Capranica L; (2006); 11th ECSS. ### ASSOCIATION BETWEEN LEFT ATRIAL FUNCTION AND EXERCISE CAPACITY IN THE VERY ELDERLY ATHLETES

Nogami, Y., Seo, Y., Atsumi, A., Yamamoto, M., Ishizu, T., Ajisaka, R., Aonuma, K.

*University of Tsukuba*

**Introduction:** Exercise training is associated with left ventricular (LV) functional changes in athlete. The previous study was suggested that the left atrial (LA) functional change in young athletes could estimate athlete's heart remodeling. Therefore, the purpose of this study was to evaluate whether LA function in very elderly athletes affected exercise capacity or not. **Methods:** Thirteen well-trained athletes and fourteen sedentary subjects were enrolled. We divided into four groups, seven very elderly athletes ( $90 \pm 5$  years, EA group), six young athletes ( $21 \pm 2$  years, YA group), six elderly sedentary ( $77 \pm 5$  years, ES group), and eight young sedentary ( $43 \pm 10$  years, YS group). All subjects underwent a cardiopulmonary exercise testing (CPX). We measured LV and LA function using ultrasound echocardiography before CPX. LV and LA volume were measured by biplane Simpson method. Systolic LV and LA longitudinal function were assessed by systolic global longitudinal strain (GLS), peak GLS rate (GLSRs), LA strain (LAS), and LAS rate (LASR) with 2D speckle tracking imaging. Diastolic longitudinal function was assessed by mitral annular velocity ( $E'$ ) with tissue Doppler imaging. The index of exercise capacity was assessed by peak oxygen uptake ( $\text{peakVO}_2$ ). **Results:**  $\text{PeakVO}_2$  in YA was significantly higher compared to other three groups ( $48.8 \pm 3.7$  vs.  $29.4 \pm 4.5$  (YS),  $19.3 \pm 4.3$  (EA),  $18.1 \pm 6.0$  (ES) ml/kg/min,  $P < 0.01$ ). However, there was no difference between EA and ES, although age in EA was older than ES.  $E'$  in young groups was higher than those in elderly groups ( $19 \pm 3$  (YA),  $13 \pm 2$  (YS) vs.  $7 \pm 2$  (EA),  $8 \pm 2$  (ES) cm/sec,  $P < 0.01$ ), however there was not significantly difference between EA and ES. LA volume index was significantly larger in athletes groups compared to sedentary groups ( $31.5 \pm 4.3$  (YA),  $34.3 \pm 10.9$  (EA) vs.  $19.1 \pm 3.3$  (YS),  $17.6 \pm 4.9$  (ES) mL/m<sup>2</sup>,  $P < 0.01$ ). LASR in ES was significantly higher than those in other three groups ( $2.7 \pm 0.8$  vs.  $1.5 \pm 0.3$  (YA),  $1.5 \pm 0.3$  (YS),  $1.1 \pm 0.5$  (EA) 1/sec,  $P < 0.01$ ). On the other hand, GLS and

GLSRs were no difference in four groups. Discussion: Normally, peakVO<sub>2</sub> was decreased with aging. However peakVO<sub>2</sub> in very elderly athletes could be maintained more young age level in this study. LA volume in athletes was larger than sedentary, additionally LASR in EA was maintained at a young LA longitudinal functional level. Then, it was suggested that LA volume and function may be an important factor to maintain the exercise capacity.

### COMPARISON OF AORTIC STIFFNESS AFTER EXERCISE BETWEEN 2 DIFFERENT EXERCISE PROTOCOLS IN ELDERLY SUBJECTS

Nogami, J.1,2, Nogami, Y.2, Naruto, T.2, Otsuki, T.3, Maeda, S.2, Ajsaka, R.2

1:Teikyo Heisei University(Chiba, Japan), 2:University of Tsukuba (Tsukuba, Japan), 3: Ryutsu Keizai University (Ryugasaki, Japan)

Introduction Age-associated change in the structure and function of arteries increases the risk of cardiovascular disease. It has been reported that moderate aerobic exercise decreases arterial stiffness in young humans (Kingwell, et al., 1997, Hefferman et al., 2007). However, it has been unclear whether the different exercise protocols influence the effect of exercise on arterial stiffness in elderly humans. The purpose of this study was to investigate the effect of exercise on aortic stiffness with 2 different exercise protocols in elderly subjects. Method Healthy elderly subjects performed a 15min of cycling exercise with 50% peak VO<sub>2</sub> (trial 1) and symptom-limited ramp-protocol exercise (trial 2). Brachial-ankle PWV (ba PWV), heart rate (HR) and blood pressure (BP) were measured at baseline, 30min, and 60min after the exercise. All measurements were performed in a quiet and air conditioned room at the same time of the day in the morning. Results **【Trial 1】** The exercise HR was 108.9 beats/min and % HR max was 69.4%. The % peak VO<sub>2</sub> was 56.6% during the exercise, and there were no significant changes in ba PWV after the exercise. **【Trial 2】** The peak HR was 131.2 beats/min and %HR max was 86.6%. The % peak VO<sub>2</sub> was 158%. The ba PWV significantly decreased at 30min after the exercise (P<0.05). On the other hand, the BP at 30 min after exercise was not different from that at baseline. Conclusion The present study showed that ba PWV significantly decreased after symptom-limited exercise, whereas there were no significant changes after moderate intensity exercise in elderly subjects. Although the underlying mechanism is still unknown, the results in the present study support that aortic stiffness could decrease as a result of aerobic exercise even in elderly subjects, however, the effects are dependent on exercise protocol References Kingwell, B. A., Berry, K. L., Cameron, J. D., Jennings, G. L., and Dart, A. M. (1997). *Am J Physiol* 273, H2186-2191. Hefferman, K. S., Jae, S. Y., Echols, G. H., Lepine, N. R., and Fernhall, B. ### CENTRAL BLOOD PRESSURE VERSUS PERIPHERAL BLOOD PRESSURE AT REST, INCREMENTAL EXERCISE AND RECOVERY IN A YOUNG FEMALE AND MALE COHORT

Garrett, A.1, West, D.2, Shelford, A.2, Chard, G.2, Kipps, N.2, Baber, N.2, McEniery, C.3

University of Hull1; University of Hertfordshire2; University of Cambridge3

INTRODUCTION: Arterial stiffening causes increased systolic pressure and predominantly affects pressure in the central arteries. Measurement of central blood pressure (CBP) may provide more useful information than the traditional peripheral blood pressure (PBP) measure, as a marker of hypertension. The purpose of this study was to determine CBP versus PBP in a young, female and male cohort at rest, incremental exercise and recovery. METHOD: Ethical approval was obtained for 20, white, caucasians; females (n=10; age 20.1±0.6 yrs; height 167.8±5.5 cm; body mass 66.2±12.4 kg; resting cardiac output 6.0±1.0 L; VO<sub>2</sub>peak 2.1±0.6 L.min<sup>-1</sup>) and males (n=10; age 20.4±1.9 yrs; height 179.9±5; bodymass 72.9±9.2 kg; resting cardiac output 9.2±2.9 L; VO<sub>2</sub>peak 3.1±0.6 L.min<sup>-1</sup>). Participants performed a VO<sub>2</sub>peak on a cycle ergometer. CBP, PBP, augmentation index (AIx) and pulse wave velocity (PWV) were measured at rest, during incremental exercise, exhaustion and one hour of recovery using a SphygmoCor®. A sphygmomanometer was used to measure PBP. Cardiac output was measured by CO<sub>2</sub> rebreathing (Innocor®). RESULTS: There was a difference between resting systolic central blood pressure (SCBP) and resting systolic peripheral blood pressure (SPBP) in females (102 vs 110 mmHg; p=0.001) and males (107 vs 126 mmHg; p=0.001). During exercise at 50% max heart rate there was a difference between SCBP and SPBP in females (118 vs 151 mmHg; p=0.007) and males (116 vs 139 mmHg; p=0.001). Similarly, this was reported at 30 mins recovery from maximal exercise in females (88 vs 103 mmHg; p=0.006) and males (106 vs 127 mmHg; p=0.003). DISCUSSION: The results of this study indicates that central blood pressure provides different and potentially better measures than the more established peripheral blood pressure, which is traditionally used as a marker of hypertension in a young female and male cohort. Therefore, current methods used to identify cardiovascular risk factors in young people should be revised to provide more accurate information.

#### THE INFLUENCE OF EXTRACURRICULAR AEROBIC EXERCISE EXPERIENCE ON PSYCHOLOGICAL WELL-BEING IN MALE UNIVERSITY STUDENTS

Nakahara-Gondoh, Y.1, Nagamatsu, T.1, Sensui, H.1, Fujiwara, S.2, Fujimoto, T.2

1:Meiji Yasuda Life Foundation of Health and Welfare, 2: Tohoku University

Introduction Psychological research has made it increasingly clear that exercise can be of tremendous benefit. In fact, aerobic exercise has been shown to improve psychological well-being (Gondoh et al., 2009). However, few studies have demonstrated the improvement of psychological well-being as a result of extracurricular exercise, particularly aerobic sports. The purpose of the present study was to examine the effect of extracurricular aerobic exercise experience on psychological well-being. Methods Subjects in the present study comprised young male university students. Subjects who regularly participated in extracurricular aerobic exercise were assigned to the athlete group (n= 50), and those who seldom participated in extracurricular aerobic exercise were assigned to the non-athlete group (n= 53). Maximal oxygen uptake (VO<sub>2</sub>max) was measured during performance of an exercise task on a bicycle ergometer. Psychological scales relating to development of identity (IDS) (Simoyama et al., 1992), self-acceptance (SAS) (Sawazaki, 1993) and depression (CES-D)

(Shima et al., 1985) were also used to assess psychological well-being. Results The athlete group had significantly higher VO<sub>2</sub>max, IDS and SAS scores than the non-athlete group. No significant difference in CES-D score was observed between the two groups. Discussion Our results suggest that extracurricular aerobic exercise experience promotes psychological well-being, particularly the formation of positive feelings. VO<sub>2</sub>max levels were higher in the athlete group than in the non-athlete group. Generally, higher VO<sub>2</sub>max levels have been known to be associated with a lower prevalence of lifestyle-related disease. Therefore, higher aerobic ability may lead to more positive feelings in everyday life. On the other hand, individuals who have a relative absence of positive feelings may not be interested in exercise. This results in a lack of exercise experience. In addition, it is thought that extracurricular aerobic exercise experience induces positive changes in the physiological mechanism underlying psychological well-being. However, the details involving this influence were unclear in this study. Therefore, clarification of this physiological mechanism should be a focus in future studies. ## EXERCISE AT THE OFFICE: HOW TO MAINTAIN WORKING PERFORMANCE OF EMPLOYEES

Wollseiffen, P.1, Schneider, S.1, Peters, T.2, Strüder, H.1

1: German Sports University Cologne, 2: University of Applied Science Bonn-Rhein Sieg, Germany

Introduction: Psychiatric diseases have reached one of the top positions for absenteeism in Europe in 2012 and are still increasing. The diagnosis Burnout with its exhaustion syndroms turns to be the most present and cost-intensive disease for national economies and health insurances. This entails tremendous economic damage in the loss of production in companies. Breaks to interrupt the working time are known to support health care and working safety. For the individual employee they also offer job satisfaction and might reduce the rate of disease. Recent studies have shown that exercise is accompanied by a decrease in (pre-) frontal cortex activity, which might be related to an increase in cognitive performance. This study examined the influence of different types of breaks on the cognitive performance and related cortical activity of office-based employees. Methods: Female and male office workers were randomly assessed into four different interventions (N= 4\*10) and one control group (N=10). Interventions were applied after a predetermined work rate of 2 hours and consisted of exercise (1) boxing on a punching bag for 3 min (2) lying in a massage chair for 20 min, (3) riding on a bicycle for 20 min (4) having a standard break for 20 min. The control group kept on working for 20 min without any break. Cognitive performance was assessed using two mental tests followed by a profile of mood state to assess individuals perceived physical, motivational and psychological state. In addition, before and after the interventions an EEG was recorded, using a three lead dry system, to explore related neurophysiological changes. Results: A significant increase could be obtained in cognitive performance from pre to post intervention after boxing compared to standard break and massage chair ( $p < .05$ ). Perceived psychological state was significantly improved after the standard break compared to all other interventions ( $p < .05$ ). Alpha-2-activity was significantly increased after boxing ( $p < .01$ ) and biking ( $p < .05$ ) compared to standard break and no break. Discussion: The positive effect of a three minute boxing intervention on cognitive performance is mirrored by an increase in perceived psychological state as well as a decrease in prefrontal cortex activity, expressed by an increase in alpha-2 activity. Although perceived psychological state was increased after the standard break (which might be due to social interactions), this is neither reflected in cortical activity nor cognitive performance. With respect to the fact that also bike activity resulted an increase in prefrontal alpha-2 activity a positive effect of exercise on neuro-cognitive performance can be stated. Further research is necessary to distinguish between effects of time and exercise preferences. Health and economic benefits may result from brief physical activity breaks and help to maintain work-place performance, job satisfaction and finally reduce the loss of production.

## RELATIONSHIP BETWEEN DAILY PHYSICAL ACTIVITY AND DAYTIME SLEEPINESS IN UNDERGRADUATE STUDENTS

Shimamoto, H.1, Naito, T.2, Tanida, K.3, Shibata, M.3

1, 2: Osaka University (Osaka, Japan), 3: University of Hyogo (Akashi, Japan)

Introduction Insufficient sleep is known to be linked to mental and physical health problems, and the quality of nocturnal sleep is closely correlated with daily physical activity. However, the relationship between physical activity and magnitude of daytime sleepiness is not well known. In this study, we investigated the relationship between these 2 elements in undergraduate students. Methods A total of 1146 undergraduate students participated in this study (615 men and 531 women; age [mean  $\pm$  SD], 18.9  $\pm$  1.1 years). They were asked to answer a questionnaire to assess their life style, such as the frequency of exercise, duration of physical activity, past exercise habits, etc. Magnitude of daytime sleepiness was evaluated using the Japanese version of the Epworth Sleepiness Scale (JESS) (Takegami et al., 2009). We measured the level of physical activity in 274 students (177 men and 97 women) using an accelerometer (Lifecorder (Lc), Kenz, Nagoya, Japan). The subjects were asked to wear the Lc on the right-side waist continuously for the experimental period (median, 9 days) except while bathing. The Lc measured the daily number of steps (steps/day), 24-hour energy expenditure (kJ/day), and energy expenditure during exercise (kJ/day). To eliminate the influence of the menstrual cycle on the magnitude of daytime sleepiness, timing for evaluation using the JESS for each subject was randomly selected during the duration of accelerometer experiment. Results In all subjects, the magnitude of daytime sleepiness was significantly higher in women than in men ( $p < 0.05$ ). A significant relationship between daytime sleepiness and the indices of physical activity was observed only in women ( $r = -0.27$ ,  $p < 0.05$ ). Discussion In this study, we found that the magnitude of daytime sleepiness was higher in women than in men. Furthermore, there was a significant negative correlation between the magnitude of daytime sleepiness and physical activity level only in the female subjects. Our results suggest that for female students, improvement of daytime sleepiness will be effective for increasing physical activity, but this will not be applicable for male students. Thus, we need to use different strategies to increase the physical activity level for male and female students. References Takegami M, Suzukamo Y, Wakita T, Noguchi H, Chin K, Kadotani H, Inoue Y, Oka Y, Nakamura T, Green J, Johns MW, Fukuhara S (2009) *Sleep Med*, 10, 556-56

## THE PHYSICAL CHARACTERISTICS AND THE RELATIONSHIP BETWEEN MUSCLE QUALITY AND PHYSICAL FUNCTION IN THE COMMUNITY-DWELLING OLDEST OLD POPULATION

Osawa, Y.1,2, Oguma, Y.1, Sumida, S.2, Harada, N.2, Abe, Y.2, Takayama, M.2, Hirose, N.2, Arai, Y.2

1.The JSPS research fellow, The University of Tokyo, 2. Keio University

Introduction The oldest old ( $\geq 85$  year-old) account for 7% of the population  $\geq 65$  year-old (4). As age-related physical changes, muscle mass and physical function decrease after 60s, as well as the increase in muscle attenuation lowers muscle quality. Previous studies

reported the correlations between muscle quality and muscle strength or aerobic performance independent of muscle thickness (MT) (1, 3). However, it is not clear the physical characteristics and the relationship between muscle quality and physical function in the oldest old population. Therefore, the present study investigated the physical characteristics based on sarcopenia criteria and the relationships among echo intensity (EI) and physical function in the community-dwelling oldest old population. Methods One hundred eight  $\geq 85$  year-old individuals (F, 58; M, 50; 88-92 year-old) participated in the present study. We measured body height, weight, lower extremity circumference, and skinfold thickness as morphological characteristics. The EI and MT of anterior thigh were measured using B-mode ultrasound as the indices of muscle quality and quantity, respectively. In addition, the participants performed hand grip strength, chair rising, open-eyes one-foot balance, and time up and go tests for physical function evaluation. Results Of the participants, 44% and 86% participants were categorized as sarcopenia based on lower extremity circumference and hand grip strength, which were reported in the European Working Group on Sarcopenia in Older People, respectively (2). Significant correlations were observed between EI and hand grip strength ( $r=-0.33$ ,  $p=0.001$ ), and chair rising ( $r=-0.21$ ,  $p=0.03$ ), and time up and go test ( $r=0.22$ ,  $p=0.02$ ), respectively. Significant partial correlations were found between EI and hand grip strength ( $r_{xy.z}=-0.21$ ,  $p=0.04$ ), and time up and go test ( $r_{xy.z}=0.22$ ,  $p=0.03$ ) after controlled by gender. In addition, significant correlation was observed between EI and MT ( $r=-0.70$ ,  $p<0.001$ ). Discussion It should require circumspection to apply the sarcopenia criteria to the oldest old population. Muscle quality assessed by EI would contribute to physical function irrespective of gender. Muscle quality would be more closely related to muscle quantity in the oldest old population compared with the relationship in the young old population ( $r=-0.33$ ) (3). ### QUALITY OF LIFE PERCEPTION AND EXPERIENCES IN ELDERLY LEISURE

Marinho, A.1, Santos, P.M.2, Hallal, P.C.3, Mazo, G.Z.1

1: CEFID/UEDESC (Santa Catarina, Brazil), 2: CDS/UFSC (Santa Catarina, Brazil), 3: UFPel (Rio Grande do Sul, Brazil)

QUALITY OF LIFE PERCEPTION AND EXPERIENCES IN ELDERLY LEISURE Introduction Populations are aging virtually worldwide, and thus means of measuring how the elderly are living in these extra years (i.e., quality of life- QOL) is of growing importance (OMS, 2005). In addition, it is necessary to consider aspects that may be related to QOL perception by the elderly, such as leisure experiences. Therefore, the objective of this study was to analyze the relationship between elderly individuals' leisure activities and their QOL perception. Methods An exploratory descriptive investigation with a quantitative approach was carried out. A sample of 141 elderly individuals from a university extension program in Florianópolis, Brazil participated in the study. A form including information on general characteristics, a leisure experience questionnaire and QOL questionnaires from the World Health Organization (WHOQOL-BREF and WHOQOL-OLD) were used. Spearman's correlation coefficient and multiple linear regression analysis were applied. A significance level of 5% was adopted in all tests. Results According to the general evaluation (WHOQOL-BREF) and the evaluation specifically for elderly individuals (WHOQOL-OLD), the elderly individuals' QOL perception was considered good: 74.5+15.2 and 93.1+10.2, respectively. The general evaluation domains resulted in the following means: 73.7+16.1 (social relations), 70.7+12.6 (environment), 66+9.3 (psychological) and 62+9.7 (physical). The components of the specific evaluation resulted in the following means: 73+14.7 (social participation), 73+17.6 (functioning of the senses), 72.8+17.1 (intimate life), 72.3+14.1 (participation in past, present and future activities), 70.5+15.5 (autonomy) and 70.3+23.7 (death and dying). Leisure experiences are more frequent when linked with intellectual, touristic, physical, social, manual, artistic and virtual leisure interests, respectively. Except for the virtual experiences, all were significantly associated with QOL perception, with a correlation ranging from weak ( $r=0.166$ ) to moderate ( $r=0.388$ ) and a linear relation with coefficients varied from 0.04 to 1.85. Discussion Investigating QOL involves the subjective perceptions closely related with living conditions and daily experiences (Fleck, 2008). The highest frequency of leisure experiences among this sample was associated with better QOL perception, which underscores the fundamental importance of providing leisure opportunities for the elderly. ### THE CROSS-SECTIONAL STUDY OF THE RELATIONSHIPS AMONG HOUSEHOLD PHYSICAL ACTIVITY, LOCOMOTIVE PHYSICAL ACTIVITY AND METABOLIC SYNDROME RISKS FACTORS

Okumatsu, K., Aoki, M., Watanabe, S., Sato, K., Kurihara, T., Otsuka, M., Fujioka, M., Fujita, S., Hamaoka, T., Sanada, K. *Ritsumeikan University*

Although previous studies have investigated the relationship between physical activity and metabolic syndrome risk, there is no report whether household physical activity, locomotive physical activity related to metabolic syndrome risks factors. PURPOSE: The purpose of this study was to investigate whether household physical activity, locomotive physical activity, and physical inactivity time were associated with physical fitness and/or metabolic syndrome risk factors in young and elderly men. METHODS: Healthy Japanese young male ( $n=29$ ) aged 18-28 yrs and Japanese old male ( $n=19$ ) aged 60-82 yrs participated in the study. Metabolic syndrome risk factors and physical fitness level were measured. Measurements of physical fitness included Body height, weight and abdominal girth were measured in all subjects. Body composition was measured using Dual-energy X-ray absorptiometry (DEXA), and  $VO_2\max$  were measured using breathe-by breathe gas analysis. The abdominal visceral and subcutaneous fat areas were measured by magnetic resonance imaging (MRI). The household physical activity, locomotive physical activity, and physical inactivity time were determined by a tri-axial accelerometer (active style pro HJA-350IT). RESULTS: The physical inactivity time and locomotive physical activity time in young men were significantly higher than those in elderly men ( $p<0.001$ ). On the other hand, the household physical activity time in elderly men was significantly higher than that in young men ( $p<0.001$ ). The physical inactivity time was positively correlated with percent body fat in young men ( $p<0.05$ ). The locomotive physical activity (Mets  $\cdot$  h) was negatively correlated with percent of body fat ( $p<0.05$ ) and abdominal visceral fat area ( $p<0.05$ ) in young men. In addition, moderate-vigorous intensity locomotive physical activity (Met  $\cdot$  h) was negatively correlated with percent of body fat ( $p<0.05$ ). The household physical activity (Mets  $\cdot$  h) and the light intensity household physical activity (Met  $\cdot$  h) were negatively correlated with HbA1c in elderly men. CONCLUSION: These findings suggest that the increase of household physical activity and decrease of physical inactivity may have a positive influence in the maintenance of physical fitness and prevention of metabolic syndrome.

### EFFECT OF EXERCISE ON DEPRESSION LEVEL

Çiçek, G.1, Imamoglu, O.2, Atan, T.2, Yamaner, F.1, Aslan, V.2

1 : University of Hitit, School of Physical Education and Sports, (Corum/Turkey) 2 : University of Ondokuz Mayıs, Yasar Dogu Physical Education and Sports Department (Samsun-Turkey)

**Introduction** Depression can be used as a concept which can include many features from normal, temporary and momentary feeling to a symptom of an illness or a psychiatric disorder (Alper et al.,1997). The aim of this study was to search the effect of exercise on depression level in terms of men and women who do not do exercise or who do exercise for a healthy lifestyle. **Methods** Beck Depression Inventory was applied to total 605 subject between the age of 18 and 45 composed of 230 female and 375 male who do not exercise or do the exercise at different levels for health. Independent sample t and chi-square tests were used to determine the statistical differences. **Results** In our study, 22.48 percent of the persons who responded to our survey are the ones who do not do the exercise, 44.13 percent of them are the ones who exercise between 1 and 3 hours a week and 33.39 of them exercise for more than 4 hours. When the Depression scores were analysed, the average score of the ones who do not exercise is 13.18 while that of the ones who exercises a little or much is 8.93. More depressive symptoms were found in the people who do not exercise than those who do. According to the gender, no meaningful difference could be found between depression level ( $p>0.05$ ). **Discussion** Generally, the point prevalence of the depressive symptoms in the society is varying between 13 and 20 percent (Oztürk 2004). In the USA, the average Beck Depression Inventory score among university students is reported as 7.6 (Oliver and Paul 1995). When the score is between 0 and 10 in Beck Depression Inventory, it is said that depression does not exist (Cıgırkçı, 2007). In our study, the people who do not exercise have more depressive symptoms than those doing exercise. According to the result of the study, it has been observed that doing weekly exercise and lengthening the duration of it decrease the level of depression. Therefore, to decline the depression level of people and to increase their life quality, the habit of doing regular exercise should be accelerated. **References** Alper Y, Bayraktar E, Karacam O. ### RELATIONSHIP BETWEEN SCREEN TIME, PHYSICAL ACTIVITY AND BARRIERS TO EXERCISE IN 16-17 YEARS-OLD CATALAN GIRLS.

Arumi Prat, I., Puig-Ribera, A., Wasley, D., Martori, J.C.

*Universitat de Vic, Cardiff Metropolitan.*

**Introduction:** In Spanish context TV viewing and computer use are sedentary behaviours highly prevalent in 17 years old (2.21 hours/day), on the other hand majority of the girls between 14-17 years old exercise less than two days a week (79%) (Roman, B et al., 2006). While evidence suggests that external barriers have a stronger influence than internal barriers for being physically active among the youth (Daskapan, A et al., 2006), little is known about how the amount of time spent on screen activities influences teenagers' physical activity (PA) levels and perceptions of barriers for being active. Therefore, the aim of the present study is to observe how a specific sedentary pattern prevails among 17 years old girls and relate this pattern with PA levels and perceived barriers to exercise. **Methods:** All secondary schools from Osona (Barcelona) were invited to participate in the study with 12 out of 16 responding. In total 342 girls (95% response rate) completed a survey evaluating the barriers and benefits for PA (version of barriers and benefits scale) and sitting time (Active Where? Questionnaire). Assignment to activity level group was based on time spent sitting in front of screen using tertile splits. Chi Square tests and one way ANOVA were used to analyse differences between groups. **Results:** Girls spend on average 2.8 hours during a normal weekday and 3.9 hours Saturday and Sunday in front of a screen (computer, TV and videogames). Girls in the high sedentary group ( $\geq 3$  hours week day and  $\geq 3.5$ h Saturday and Sunday) perceived significantly more barriers to PA, and were significantly less active than girls in the low sedentary group ( $p \leq 0.007$ ). A common barrier among all three groups to not engage in PA was the lack of time linked to too much school work, although this barrier was significantly more highlighted among high sedentary group girls. In addition, this group reported a lack of energy or being interested in other things as other main barriers for being physically activity. **Discussion:** This specific sedentary pattern among girls is significantly related to their levels of PA and their perceived barriers to exercise. Addressing perceptions about the demands implicit in being active would appear to be a target to address the low levels observed in Spanish girls. **References:** Roman, B., Serra, L., Ribas, L., Pérez, C., Aranceta, J. (2006). Apunts. Medicina de l'esport. Vol. 41, pp. 86-94. Daskapan, A., Handan, E., Eker, L. (2006). Journal of Sports Science and Medicine. Vol. 5, pp. 615-620.

### SITTING TIME AND MVPA OF TWO INTERNATIONAL SAMPLES. COMPARATIVE STUDY

Varela-Mato, V., Clemes, S.

*Loughborough University*

**Introduction:** It has been observed that time spent at university in undergraduate study is often associated with a decline in physical activity (PA) levels. University students spend large amounts of time sitting, which has been associated with numerous health risks. Sedentary behaviours and lack of PA represent separate and distinct risk factors for non-communicable diseases. This study examined PA and sitting time and its relationships according to gender and university. **Methods:** Data were collected via 2 processes, an online questionnaire from 138 (104 Females, 34 males) students from Loughborough University (Group 1), UK, and from 119 (14 females, 105 males) students at Vigo University (Group 2), Spain. PA was assessed using the IPAQ short version and converted into MET-minutes/week and sitting time data were reported as minutes/weekday. A t-test, a one-way ANOVA and ANCOVA tests examined any differences between PA and sitting time reported between genders and the influences of light activity in sitting time and MVPA. **Results:** The mean sitting time on a weekday for the two groups, Group 1 ( $M= 246.8$ ,  $SD 274.39$ ) and Group 2 ( $M= 129$ ,  $SD 190$ ), was significantly different,  $p<0.001$ . Females reported higher levels of sitting time per weekday ( $M= 235$ ,  $SD 279.6$  vs.  $M= 155.4$ ,  $SD 206.8$ ,  $p<0.001$ ). Walking time was similar for both groups,  $p>0.05$ . Levels of light activity didn't show a significant effect on the amount of time spent sitting, although it was positively associated with MVPA,  $p= 0.001$ . Group 1 showed significant higher levels of MVPA, (2858 METs-min/Week vs. 394.4 METs-min/Week,  $p< 0.001$ ). Gender differences within groups were found not to be significant ( $p >0.05$ ). **Conclusion:** It seems that sitting time worked as a compensatory behaviour to high levels of MVPA, as Walking was similar in both groups. Future interventions are needed to increase MVPA and reduce sitting time to promote a healthier lifestyle.

## THE COMPARISON OF THE HEALTH RISKS OF WOMEN AGE BETWEEN 40-49 WHO WERE ATHLETES AND WHO WERE NEVER DONE ANY SPORTS IN THEIR PAST

Odabas, I.1, Bulgan, C.1, Kahya, D.1

*Halic University*

Introduction: Physical activities are most important behaviour to reduce diseases and injuries and in many study supported that physical exercises can be a medicine for health (Haskell et al. 2007; Ainsworth et al, 2000; Kesaniemi et al, 2001). The purpose of this study was to evaluate of risks related to the health of women ages between 40-49 years who were active athletes in the past and who were never done any sports. Method: Eighty eight women volunteered to participate in this study. Subjects' mean±SD for age were 45.1 ±2.4 years. 42 of them were licensed athletes in the past (Group 1) and the other 46 women had no any experience in sports (Group 2). This study was a kind of cross section study and the groups were provided from 4000 adults who were registered Private Fitness Club in Istanbul. It was asked risk factors related by their health before when they started to the activities. Also family history, own diseases/injuries and consumption of cigarette and alcohol information were collected in addition to Framingham risk factors. All data results were analysed by using SPSS program (version 18.0; SPSS, Inc., Chicago, IL). Frequency analyses were done and Anova was used for calculated to differences between the groups. Results: There is no any significant differences between the average of height, weight, fat percentage, lean body weight, systolic and diastolic pressure of two groups. However, there were significant differences between sum of trunkskinfold thicknesses and sum of extremite skinfold thicknesses of groups. It was found that group 1's thicknesses were less than group 2. Additionally, total cholesterol and blood glucose average values were found higher in group 2. When it was evaluated according to the risks of disease and habits; 24.4 % of women from group 1 had no any risk, but 21.5 % of in total rate, there were 5 different risk factors were found in group 2. Lastly it were found that in group 1, 34% of women smoke cigarettes, 31.7 % drink alcohol and 41.5 % using medicine regularly; in group 2, 40.4% of women smoke cigarettes, 36.2 % drink alcohol and 66 % using medicine. Discussion: In conclusion, It was found that no any physical differences between the groups but alcohol and cigarette consumption and medicine usage therefore total risk scores were higher in a group that had physical inactivity. According to Haskell et al. 2007, participation in aerobic and muscle-strengthening physical activities provides additional health benefits and results in higher levels of physical fitness. So we recommend to adults, who wish to improve their personal fitness and further reduce their risk for chronic health conditions and mortality related to physical inactivity, should exceed the minimum recommended amount s of physical activity. ## SEDENTARY TIME AND PHYSICAL ACTIVITY AFTER CHILDBIRTH

Takito, M.Y., Romero, S.C.S., Romero, A., Kurashima, C.H.

*School of Physical Education and Sport of University of Sao Paulo*

Introduction Decreasing levels of physical activity during pregnancy (Domingues et al. 2008; Tavares et al. 2009) and after childbirth are related to morbidity and obesity increase. It's important to recommend women to increase their physical activity levels. The objective was identifying changes in leisure physical activity after intervention during pregnancy in postpartum women. Methods One historical cohort Control Group (CG) (n=112) and one Intervention Group (IG) (n=79) were follow. All women were asked about physical activity habits and socioeconomic and behavioral variables in three moments (at the end of pregnancy, 6 and 12 months after childbirth). Chasan-Taber et al. (2004) questionnaire was used to measure physical activity. Data was analyzed using linear mixed model for longitudinal unbalanced data. Results The average age of participants was 27 years (range 19-40 years). Nutritional status was 65.4% normal weight and 29.3% excess weight (BMI≥25kg/m<sup>2</sup>). Regarding physical activity, there were no significant changes in energy expenditure, domestic activities and occupational mobility between groups. Conversely, leisure physical activity were significant higher in IG (p=0.03). However, physical activity during leisure time has very little contribution of total energy expenditure. Noteworthy is the fact that the intervention group have greater time in sedentary activities (p = 0.02). Other related factors were the presence of partner (in leisure physical activity), and work (on sedentary activities, locomotion and energy expenditure). Discussion Alleged impediments to exercise in postpartum are: concern about compromising the mother-child relationship, lactation and/or financial hardship (Derbyshire et al., 2008). Thus, the physical activity patterns of women raising their babies are changed, leading to an extended period of reduced physical activity and increased sedentary activities, transforming into a sedentary lifestyle. Physical activity during leisure time may had been increased twelve months postpartum, due to lower dependency of the child and likely regular sleep with decreased breastfeeding, allowing more available time. The results indicate compensatory effect of physical activity during leisure activities with the increase of sedentary ones. The recommendation to rise physical activity during leisure time showed unsatisfactory result since it represents negligible increase in total energy expenditure and resulted in increased sedentary time. ## INTERRUPTING SEDENTARY TIME IN AN EIGHT HOUR WORKING DAY

Frick, F., Froböse, I., Wallmann-Sperlich, B.

*Institute of Health Promotion and Clinical Movement Science*

INTRODUCTION There is growing evidence that sedentary behaviour increases the risk for morbidity and mortality regardless of the time spent performing physical activity. Occupational sitting represents the major source of sedentary behaviour in adults. A mainly sedentary lifestyle leads often to a negative energy balance which is related with overweight and obesity. Office workers are of high risk for prolonged sitting and it is of interest to minimise the amount of time spent being sedentary. The aim of the present study was to investigate the energy impact of interrupting office working days through hourly physical activity interruptions. METHODS On two consecutive days eight participants (3 male / 5 female; Ø age: 25,3 ± 2,1 years; Ø BMI: 22,7 ± 1,0 kg/m<sup>2</sup>) simulated an eight hour working day. On working day one the participants did activities in sedentary posture for eight hours. On working day two sedentary time of eight hours was interrupted with hourly staircase walking breaks. Total energy expenditure, active energy expenditure and METs were measured by the SenseWear Armband. The differences in the energy expenditure of the two days were compared. RESULTS The average total energy expenditure in an eight hour working day of interrupted sedentary time was 120 cal higher than total energy expenditure of uninterrupted sedentary time (980 ± 160 cal vs. 860 ± 170 cal; p<0,05). Active energy expenditure was 160 cal higher for interrupted sedentary time

compared to uninterrupted sedentary time ( $250 \pm 50$  cal vs.  $90 \pm 70$  cal;  $p < 0.05$ ). The average Metabolic Equivalents were  $1.8 \pm 0.2$  Met on working day with hourly active breaks compared to  $1.6 \pm 0.2$  Met on working day without hourly interruptions ( $p < 0.05$ ). DISCUSSION & CONCLUSION Energy expenditure increased during an interrupted working day compared to a non-interrupted working day. When extrapolated for a full 40 hour-working week, this data shows that an individual would theoretically expend additional 610 cal per week if they climbing stairs every hour compared with consecutive sitting for the eight hour working day period. This indicates that making active breaks such as climbing stairs could result in beneficial weight control or weight loss. This could be a potential approach for health promotion workplaces.

### OBJECTIVELY MEASURED DAILY PHYSICAL ACTIVITY PATTERN AND SEDENTARY BEHAVIORS IN COMMUNITY-DWELLING OLDER ADULTS

Chen, T., Narazaki, K., Honda, T., Nofuji, U., Matsuo, E., Kumagai, S.

*Kyushu University*

Introduction Physically active lifestyle is essential in healthy aging and sedentary behavior (SED) has been recognized as a risk factor for poor health (Lee et al., 2012). Studies that used accelerometer to monitor PA in older adults were mostly performed with a small sample size of less than 50 samples (Taraldsen et al., 2012). Accurate and validated data is still lacking in older adults. The purpose of this study is to describe the PA patterns in community-dwelling older adults by using a tri-axial accelerometer (TAA). Method Participants of this study were individuals ( $n=1,747$ ) who were 65 years or older and not certified as those requiring nursing care. The PA was assessed with a TAA device (HJA-350IT; Omron Healthcare, Inc., Japan) for 7 days. 1747 Participants with valid TAA data ( $\geq 600$ min/day for  $\geq 4$  days) were included in the analysis. Mean volume of daily total PA ( $>1.5$  METs, TPA, METs.hour/day) as well as daily time spent in sedentary behavior ( $\leq 1.5$  METs; SED, min), locomotive or non-locomotive light PA (1.6 to 2.9 METs; LPA, min), locomotive or non-locomotive moderate-to-vigorous PA ( $\geq 3.0$  METs; MVPA, min) are present by gender and age groups (65~69, 70~74, 75~79, 80~). Results The TPA decreases with age ( $p$  for trend  $< 0.01$ ), while SED increased with age in both genders ( $p$  for trend  $< 0.01$ ). Significant trends were also present that locomotive LPA, locomotive MVPA, non-locomotive LPA and non-locomotive MVPA decreased with age (all  $p < 0.01$ ). Compared with women, men had less average TPA ( $p < 0.01$ ). Compared with women, men had more minutes of SED, locomotive LPA and locomotive MVPA and fewer minutes of non-locomotive LPA and non-locomotive MVPA (all  $p < 0.01$ ). In addition, non-locomotive LPA highly correlated with TPA in both genders (men,  $\rho=0.80$ ,  $p < 0.01$ ; women,  $\rho=0.81$ ,  $p < 0.01$ ) after controlling with wearing time and age. Conclusions This study provides objective physical activity data on a relatively large sample of adults aged 65 years or older. Results showed that daily physical activity decreased with increasing age and non-locomotive LPA can be the main component for the total physical activity level in older adults. Furthermore, women spend more time in non-locomotive PA and are more active than men, while men spend more time in locomotive PA and SED than women. These results allow us to further investigate how PA and SED are related to health outcomes in this cohort. References Lee JM, Shiroma EJ, Lobelo F, Puska P, Blair SN, Katzmarzyk PT. (2012). ### THE PATCH STUDY - A SCHOOL BASED INTERVENTION TO INCREASE PHYSICAL ACTIVITY LEVELS IN PRIMARY SCHOOL CHILDREN

Cunningham, C.1, Breslin, G.1, Murphy, M.1

*University of Ulster*

Introduction The majority of primary-school aged children in Northern Ireland do not meet current recommendations for physical activity (PA) as outlined by the Department of Health (Breslin et al., 2012). Childhood has been identified as an important period to promote active lifestyle habits. Schools offer continuous contact with children and remain the only setting in which interventions aimed at increasing daily PA can be uniformly applied. The aim of this study was to evaluate the effects of the PATCH (Physical Activities To improve Children's Health) school based physical activity intervention on PA levels, body composition and physical self perception in a group of primary school children from Northern Ireland. Methods PATCH is a multicomponent, teacher-led intervention developed to incorporate classroom based PA breaks throughout the school day and to deliver weekly theory lessons on exercise and activity. The 'PA at Home' component involved daily PA homework and monthly parental newsletters to inform parents of the benefits of PA for children's health. Before and after the intervention, participants stature and body mass were measured and BMI calculated. Bone mineral content (BMC), bone mineral density (BMD), lean body mass and fat mass were obtained from a whole body DEXA scan. Resting blood pressure was measured using an automated blood pressure monitor. Physical self perception was assessed with the Children and Youth - Physical Self Perception Profile (CYSPSP). An individually calibrated treadmill test to  $VO_{2peak}$  (pre-intervention) enabled PA intensity cut-points to be calculated for each individual. Habitual PA was measured using a tri-axial accelerometer, pre, mid, and post intervention. Results PATCH participants increased daily moderate-to-vigorous PA (MVPA) and total daily PA by 14 mins and 27 mins respectively, compared to slight decreases of 4 min daily MVPA and 6 min total daily MVPA in the control group (pre to mid-intervention). PATCH participants increased total daily PA by 24 mins pre-to-post intervention whereas controls reduced total daily PA by 21 mins. PATCH participants decreased daily sedentary time by 14 mins (pre to mid-intervention) and 10 mins pre-to-post intervention. Contrastingly, the control group decreased daily sedentary time by 1 min pre to mid-intervention with no further reduction in daily sedentary time pre-to-post intervention. Discussion These findings suggest that the PATCH intervention has the potential to increase daily MVPA and total daily PA and decrease sedentary time in a group of primary aged school children. **SQUARE-STEPPING EXERCISE INCREASES REGIONAL CEREBRAL BLOOD FLOW: A NEAR-INFRARED SPECTROSCOPY STUDY**

Abe, T.1, Hotta, K.1, Tsunoda, K.2, Kitano, N.2, Okura, T.2

1: Ibaraki Prefectural University of Health Sciences, 2: University of Tsukuba

**Introduction:** Decline in cognitive function with aging is inevitable, and it sometimes leads to the need for long-term assistance or care. We developed a novel exercise for maintaining and enhancing physical and cognitive functions called "Square-Stepping Exercise (SSE)" (Shigematsu et al., 2008; Okura et al., 2010). This study tests the hypothesis that SSE would increase regional cerebral blood flow (rCBF). **Methods:** The subjects of the pilot study were 15 college students ( $21.7 \pm 0.5$  years old) in Japan. We used near-infrared spectroscopy (NIRO-200) to measure rCBF of the prefrontal area during normal walking and SSE. We divided the SSE into 3 patterns based on difficulty: 1) basic step, 2) challenge step, which is somewhat difficult and 3) special step which is difficult. The rCBF was measured by both changes in oxygenated hemoglobin concentration (oxy-Hb) and changes in normalized tissue hemoglobin index (nTHI). Each SSE pattern was conducted in three cycles: 1) resting for 30 seconds, 2) memorizing the SSE step pattern and 3) performing the SSE. We used a one-way repeated-measures analysis of variance. **Results:** An increasing level of square stepping difficulty positively associated with a higher level of oxy-Hb of the left brain and a higher level of nTHI in both left and right brains (Trend P values  $<0.05$ ). In the post-hoc tests, oxy-Hb of the left brain during the special step was significantly higher than during the basic step. There were significant differences in nTHI level of the left brain between walking and basic step and in nTHI level of the right brain between walking, basic or challenge steps and special step. **Conclusion:** The levels of oxy-Hb and nTHI increased with increased difficulty of the SSE pattern especially with the special step. Our data suggest that the SSE may be an effective intervention program for activating brain function. **References:** Shigematsu R, Okura T, Nakagaichi M et al. (2008). *The Journals of Gerontology: Series A*, 63(1):76-82. Okura T, Yoon JY, Sanada I et al. (2010). *Journal of Japanese Society for Dementia Care*, 9(3), 519-530.

**RELATIONSHIP BETWEEN OXIDATIVE STRESS AND EXCESS POST-EXERCISE OXYGEN CONSUMPTION IN MODERATE AEROBIC EXERCISE: FOCUSING ON THE DIFFERENCE DURATION AND ENVIRONMENTAL TEMPERATURE**

Kimoto, R.1, Morita, N.2, Tsukamoto, M.3, Uchida, E.4, Takeda, H.5, Kambayashi, I.6

1: Asahikawa National College of Technology, 2: Hokkaido University of Education Iwamizawa, 3: Tokai University, 4: Taisho University, 5: Hokusei Gakuen University, 6: Hokkaido University of Education

**Introduction** Recently, lifestyle diseases and metabolic syndrome have become a social problem. Moderate aerobic exercise is expected to make an effect on prevention and improvement of those diseases. Additionally, more and more people are taking exercise in a hot environment to increase the lipid metabolism. On the other hand, some researchers say the rise in body temperature had a negative influence on body. The purpose of this study was to investigate the relationship between oxidative stress and excess post-exercise oxygen consumption (EPOC) after moderate aerobic exercise (50%VO<sub>2</sub>max). **Methods** Six trained male young volunteers took part in the study after giving a written informed consent. The subjects exercised on separate days for 30 min (30EX), 60 min (60EX), 90 min (90EX) at 20 degrees and 60 min at 32-34 degrees (60EXH) at an identical intensity of 50 % of VO<sub>2</sub>max on a bicycle ergometer. Urine samples were collected before exercise (baseline) and 1.5 hour after exercise (1.5h) for analysing urinary 8-hydroxy-2'-deoxyguanosine (8-OHdG) level as an index of oxidative stress. Cardio-respiratory data and body surface temperature were measured during and 30 min after exercise on a sitting position. The statistical analysis was performed using the following tests: Student's t-test and Pearson's correlation coefficient. **Results** The values of EPOC after each exercise was 151.4 +/- 4.6 ml/kg (30EX), 168.4 +/- 4.5 ml/kg (60EX), 193.7 +/- 10.6 ml/kg (60EXH), and 170.2 +/- 4.1 ml/kg (90EX). The values of urinary 8-OHdG level at baseline and 1.5h were 5.02 +/- 0.91 ng/kg/h and 5.83 +/- 0.47 ng/kg/h (30EX), 8.22 +/- 2.54 ng/kg/h and 10.2 +/- 1.66 ng/kg/h (60EX), 7.65 +/- 1.48 ng/kg/h and 11.3 +/- 4.09 ng/kg/h (60EXH), and 5.76 +/- 0.45 ng/kg/h and 6.71 +/- 0.63 ng/kg/h (90EX). Urinary 8-OHdG level had a low correlation with EPOC (R<sup>2</sup>=0.29). Furthermore, relative value of Urinary 8-OHdG level in 60EXH correlated significantly with EPOC (R<sup>2</sup>=0.60), but there is no definite correlation in 60EX (R<sup>2</sup>=0.08). **Conclusion** The values of 60EXH were peak of EPOC and urinary 8-OHdG level at 1.5h. Therefore, there was some sort of relationship between EPOC and oxidative stress after exercise. Furthermore, it was suggested that the higher environmental temperature, the relationship between oxygen consumption and oxidative stress became strongly.

**THE EFFECTS OF RECREATIONAL PHYSICAL ACTIVITY ON THE LABORATORY LIPID PROFILE VALUES IN DIFFERENT AGE GROUPS AND BMI CATEGORIES**

Orban, K.1,3, Hachbold, N.1, Szalai, Z.2, Szabo, R.2, Berko, A.2, Posa, A.2, Balogh, L.1, Laszlo, F.1,2, Molnar, A.H.1, Varga, C.2

University of Szeged

**Introduction** Nowadays, cardiovascular diseases and their complications are part of widespread diseases in the world of advanced industrial societies. It is well-known that regular physical activity has beneficial effects on cardiovascular risk factors. We investigated the effects of 3-month of recreational type of regular aerobic physical activity done on different "fat" parameters in each BMI categories of different age groups. **Methods** The program was on a voluntary basis, regardless of age or gender anyone can participate, so the sample of the research consisted of 108 persons. The participants took part in different aerobic exercise programs for 3 months at least 3 times per week. At the beginning and at the end of the program, the participants' body composition was analysed by Inbody230 and blood samples were collected. We measured the change of relative body fat, triglycerides, total cholesterol, HDL- and LDL-cholesterol, by age groups (20-29; 30-39, 40-49, >50 years old) comparing these values to the baseline BMI (19-25, 25-30, >30 BMI groups/every age groups) values. **Statistical analysis:** Mann - Whitney U test. **Results** Body fat percentage tended to decrease in all age groups in all BMI categories, and significantly decreased in 20-29 and >50 years old groups. We observed significant decrease of the triglyceride levels

almost everywhere (exception 30-39 years old group). In the case of total cholesterol, the physical activity significantly reduced the initial high values in most categories (exception >50 years old group). It is known that the increase of HDL – cholesterol level has beneficial effects. This trend also appeared as the effect of regular physical education, except for the older age group (>50), where there was no a significant increase in HDL level. The LDL concentration decreased in every group. This reduction was significant except for the older age group (>50). Discussion All the changes in parameters of the study were favourable, so it is supposed that the effects of regular physical activity on body composition and blood lipid profile are clearly positive in every age groups. The cardiovascular risk factors can be significantly reduced by regular recreational physical activity. ## RELATIONSHIPS BETWEEN PHYSICAL FITNESS LEVEL AND HEALTH-RELATED QUALITY OF LIFE IN OBESE ADULTS: A PILOT STUDY.

Annoni, I.1,2, Sforza, C.1, Bruseghini, P.3, Zago, M.1, Galvani, C.2

*Università degli Studi di Milano, Università Cattolica del Sacro Cuore (Milano, Italia)*

1: LAFAL, Dipartimento di Scienze Biomediche per la Salute, Università degli Studi di Milano (Milano, Italia) 2: Laboratorio di Fisiologia Sperimentale, Corso di Laurea in Scienze Motorie, Università Cattolica del Sacro Cuore (Milano, Italia) 3: Corso di Laurea in Scienze Motorie, Università Cattolica del Sacro Cuore (Milano, Italia) Introduction If recent epidemiologic studies suggested that higher levels of physical activity (PA), cardiorespiratory and muscular fitness may offset much of the excess of mortality risk that is associated with overweight and obesity (Blair, 2004; Fogelholm, 2010) and may counteract the adverse cardiovascular profile (Artero, 2012), only PA participation has been linked to health related quality of life (HRQoL) in obese adults (Herman, 2012). Currently, there is insufficient evidence available regarding the relationship between physical fitness level with HRQoL in this special population. Therefore, the aim of the present study was to investigate the impact of cardiorespiratory ( $\dot{V}O_2\max$ ) and muscular (iMVC) fitness on HRQoL in obese adults. Methods 10 obese adults (6 women 4 men, mean age  $27.6 \pm 6.3$  years; BMI  $39.9 \pm 5.8$  kg/m<sup>2</sup>; MVPA  $37.9 \pm 36.6$  min/day;  $\dot{V}O_2\max$   $30 \pm 6$  mL/kg/min; iMVC  $15.2 \pm 2.6$  N/kg) were involved in the study. To assess  $\dot{V}O_2\max$  and iMVC, they performed a maximal treadmill test with indirect calorimetry (Quark CPET, Cosmed, Italy) and a maximal isometric strength test using two force platforms (Twin Plates, Globus, Italy) fixed on a horizontal leg press (Technogym SpA, Gambettola, Italy). HRQoL was measured with the Short-Form 36 Health Status Survey (SF-36v2) that provided the physical (PCS) and the mental (MCS) component summary score. Results The overall average PCS and MCS scores were  $53.6 \pm 6.7$  and  $45.2 \pm 6.9$ , respectively. Regression analysis, adjusted for age and BMI, revealed that neither  $\dot{V}O_2\max$  nor iMVC were related to a higher HRQoL. Only lower BMI was associated with higher vitality, a sub-dimension of MCS (F-value 5.966;  $p < 0.05$ ). Discussion The absence of associations between  $\dot{V}O_2\max$  and iMVC with HRQoL may be due to a higher PCS score when compared with the mean reference values of a population of moderately obese subjects (reference PCS =  $45.99 \pm 12.1$ ), and, in contrast with Doll et al. (2000), a higher PCS score compared with MCS values. In accordance with Fontaine (2001), a higher BMI was associated with a lower vitality score. Future studies are needed to gain a better insight into these findings. ## EFFECT OF WHOLE-BODY VIBRATION EXERCISE ON KNEE FUNCTION IN MIDDLE-AGED AND OLDER JAPANESE WOMEN WITH KNEE PAIN: EXAMINED BY DEGREE OF KNEE PAIN

Tsuji, T., Yoon, J., Aiba, T., Kanamori, A., Okura, T., Tanaka, K.

*University of Tsukuba, Japan*

INTRODUCTION: Strength training is known to be an effective, conservative therapy for middle-aged and older women who suffer from knee pain associated with knee osteoarthritis. Recently, whole-body vibration (WBV) exercise has been gaining attention as a new strength training technique that is both safe and effective. The objective of this study was to investigate the effect of WBV exercise on knee extension muscle strength and power, functional mobility and self-reported knee function at each degree of pain in middle-aged and older Japanese women who suffer from knee pain. METHODS: Twenty-nine subjects who suffer from knee pain were recruited (mean age:  $62.1 \pm 5.5$  years). Using the Western Ontario and McMaster Universities Arthritis Index (WOMAC) pain score, we divided the subjects into 2 groups by knee pain: "mild" ( $n = 16$ ) with a score of  $< 3$  and "moderate/severe" ( $n = 13$ ) with a score of  $\geq 3$ . All subjects participated in WBV exercise programs 3 days/week for 8 weeks. Each session included a 10-minute warm-up period, a 25-minute period of weight-bearing strength training and a 15-minute cool-down period. The strength training exercises were designed to strengthen mainly the quadriceps (e.g. squats and lunge exercises) and other surrounding muscles. All exercises were done using POWER PLATE (POWER PLATE International, London, UK) at a frequency of 30-40 Hz and vibration amplitude of 2.5 mm. We measured isometric peak torque and isokinetic (60 deg/s) mean power of knee extension. The timed-up-and-go test and WOMAC questionnaire were used to evaluate functional mobility and self-reported knee function, respectively. RESULTS: There were no dropouts with all 29 subjects completing the study through the post-test. Participation rate was 95.3%. Peak torque and average power improved significantly in both groups (mild: 3.19 to 4.00 Nm/kg, 1.43 to 1.79 W/kg; moderate/severe: 2.72 to 3.16 Nm/kg, 1.18 to 1.38 W/kg, respectively). We observed significant shortening in the timed-up-and-go test results in both groups (mild: 5.43 to 4.81 s; moderate/severe: 6.20 to 5.43 s). WOMAC total score decreased significantly (improved knee function) in the moderate/severe knee pain group (19.5 to 14.5 points) but not in the mild knee pain group (5.1 to 4.1 points). CONCLUSIONS: An 8-week, three times per week, WBV exercise program was shown to be safe while eliciting a high participation rate in middle-aged and older Japanese women who suffer from knee pain. In addition, our data suggest that the WBV exercise program can improve lower limb muscle strength and power, functional mobility independent of degree of knee pain and self-reported knee function for moderate/severe knee pain.

**WEEKDAY AND WEEKEND PHYSICAL ACTIVITY PATTERNS OF FRENCH AND SPANISH ADOLESCENTS**

Aibar, A.1,2, Bois, J.E.2, Zaragoza, J.1, Generelo, E.1, Paillard, T.2, Fairclough, S.J.3

<sup>1</sup> University of Zaragoza (Huesca, Spain) <sup>2</sup> University of Pau and Countries of Adour (Tarbes, France) <sup>3</sup> Liverpool John Moores University (Liverpool, UK)

Introduction Recent research showed significant differences in Spanish and French adolescents' physical activity (PA; Aibar et al., 2012). To develop a clearer cross-cultural understanding of these findings, the primary purpose of this study was to determine country and gender differences in moderate to vigorous physical activity (MVPA) levels during specific segments of weekdays and weekend days, and to explore the contribution of each segment to PA guidelines. Method Morpho-demographic, socio-economic and PA data were collected in a sample of 829 adolescents (45.0% Spanish; 55.2% females; 14.33±7.3 years) in two twin mid-sized European cities, Huesca (Spain) and Tarbes (France). Actigraph GT3X accelerometers were worn for seven consecutive days to assess adolescents' habitual MVPA for three segments of weekdays (school-travel-, school-, and non-school-time), and weekend days (morning-, afternoon- and night-time). Data were analysed using multilevel modelling. Results The most active segments were non-school-time (29.2±17.5 min) and school-time (25.8±14.2 min) during weekdays, and morning-time (28.2±25.8 min) on weekend days. Except for school-time, Spanish adolescents were more active ( $p < .05$ ) than French adolescents during all segments. Gender was significantly associated with MVPA across all weekday and weekend segments, with boys accumulating more MVPA than girls ( $p < .05$ ). Discussion Out-of-school time (especially weekends) appears to present the greatest potential for targeted PA interventions (Floh et al., 2006), particularly focused on girls and low active boys (Fairclough et al., 2012). Country differences highlight the need to recognize cultural contexts and settings that influence adolescents' PA. Common European-wide strategies may be insufficient to increase MVPA levels if cultural variability is not considered. References Aibar, A., Bois, J.E., Generelo, E., Zaragoza, J., Paillard, T. **STEPS THAT COUNT! Pedometer-measured versus self-reported ambulatory physical activity in relation to current guidelines- A South African adult, employed population.**

Pillay, J.D., van der Ploeg, H., Kolbe-Alexander, T.L., Tomaz, S., van Mechelen, W., Lambert, E.V.

*University of Cape Town*

Background: The association between perceived and objectively measured ambulatory physical activity (PA), with particular reference to current PA guidelines, may be an important factor in determining the extent of uptake and compliance to PA. We aimed to examine this association, with reference to volume, intensity and duration of PA through self-reported and pedometer-measured data. Methods: A convenience sample (N=312, 37±9yrs), recruited from health risk screening events, completed a questionnaire that included information on PA patterns and thereafter wore a pedometer (minimum 3 days; maximum 7 days). Analyses of co-variance (ANCOVA), adjusting for age and gender were used to compare pedometer-determined volume and intensity of steps/day to meeting/not meeting guidelines, self-reported. The extent of agreement between self-reported and pedometer-measured PA was also determined through correlational analyses. Results: Average steps/day of the entire study group were 6,574±3,541; of a total of 312 participants' self-reported data, those meeting guidelines (n=63) accumulated significantly more steps/day than those not meeting guidelines (8,753±4,251 versus 6,022±3,114, respectively;  $p < 0.001$ ). A similar finding was noted when comparing aerobic steps/day in those meeting/not meeting guidelines (1,772±2,020 versus 421±1,140, respectively;  $p < 0.0001$ ). Our data identified that more than half of the group meeting guidelines, self-reported, did not meet guidelines, pedometer-determined. However, participants reporting to meet guidelines were more likely to meet PA guidelines, pedometer-measured (40%), than those that reported not to meet guidelines (8%). Conclusion: Notwithstanding the limitations of both measurement tools in estimating PA patterns, the use of pedometers as an alternative to self-reported measures or accelerometers is an area for consideration.

**INFLUENCE OF WORK EXPERIENCE ON PHYSICAL FUNCTION IN LATER LIFE**

Tsunoda, K.1, Kitano, N.1, Kai, Y.2, Kanamori, S.3, Tsuji, T.1, Mitsuishi, Y.1, Okura, T.1

*1: University of Tsukuba, 2: Meiji Yasuda Life Foundation of Health and Welfare, 3: Juntendo University*

INTRODUCTION Some studies reported that work experience links with subjective health status in later life (Kajitani, 2011), but little is known about associations between work experience and physical function (PF) using objective performance tests. This study investigated whether work experience links with PF in later life. METHODS Our study included 564 community-dwelling older adults (73.3±5.3 years old) in Kasama City, rural Japan. We classified participants' longest work experiences into nine categories: 1) owner of a shop or small company, 2) farmer, 3) self-employed other than shop or small company owner or farmer, 4) manager of a company or public organization, 5) professional e.g. medical doctor, nurse or teacher, 6) clerical worker, 7) factory worker or driver, 8) sales or restaurant staff and 9) unemployed including housewife. For a comprehensive assessment of PF, we calculated a principal component score based on eight performance tests: 1) grip strength, 2) single-leg balance, 3) functional reach, 4) sit-to-stand, 5) timed-up-and-go, 6) habitual walk, 7) hand working and 8) choice reaction time. The principal component score (PF score) was converted into a T score (50±10). To compare PF by work experience, we used the analysis of covariance (ANCOVA) controlling for age, education, equivalent income, current working status, physical activity (physical activity scale for the elderly score) and clinical history. RESULTS The PF scores of both men and women were significantly different with regards to work experience (ANCOVA P values < 0.05). Older men who were farmers (T = 42.4±10.0) or self-employed (T = 43.3±10.4) were more likely to have a low level of PF, whereas, men who were managers (T = 52.6±8.5) or professionals (T = 52.5±9.6) were more likely to have a high level of PF. Older women who were owners (T = 40.0±12.9), managers (44.8±4.7) or farmers (T = 42.8±12.0) were more likely to have a low level of PF, whereas, women who were professionals (T = 52.7±12.0) or clerical workers (T = 55.2±12.0) were more likely to have a high level of PF. DISCUSSION We did not expect to find that men and women who worked as farmers were more likely to be physically frail since habitual physical activity at midlife links with a high level of PF in later life (Tikkanen et al., 2012). However, Fletcher et al. (2011) reported that work with a high physical burden relates to a future, self-reported unhealthy status. Our study supported this negative relationship with PF. **INFLUENCE OF SEX ON STRETCHING EXERCISE -INDUCED REDUCTION IN ARTERIAL STIFFNESS**

Gando, Y., Yamamoto, K., Kawano, H., Hara, R., Muraoka, I.

*Waseda University*

**Introduction:** Arterial stiffness has been identified as an independent risk factor for mortality and cardiovascular disorders. The previous research has shown that poor flexibility is associated with arterial stiffening. Stretching exercise is effective for increasing flexibility. Currently, it is unknown whether arterial stiffness is reduced after one bout of stretching exercise, and moreover whether there are sex specific responses in arterial stiffness. The purpose of this study was to compare arterial stiffness after one bout of stretching exercise between young men and women. **Methods:** Twenty four healthy adults (age  $24 \pm 1$  yrs, 11 men and 13 women) participated in this study. Brachial-ankle pulse wave velocity (baPWV) was calculated from the distance between brachial and post-tibial arteries divided by transit time. The transit time was determined from the time delay between two arterial waveforms. The baPWV was used as index of arterial stiffness. Arterial stiffness measurements were performed during the follicular phase of that individual's menstrual cycle in women. The stretching protocol was performed according the static method. The session consisted of 40 stretches for whole body at the maximum range of motion. The baPWV, systolic blood pressure, and heart rate were measured before and immediately after the stretching exercise as well as 15, 30, 45, 60 minutes after the stretching exercise. **Results:** There was no significant interaction between sex and time for baPWV. However, there were sex effect ( $P < 0.05$ ) and time effect ( $P < 0.05$ ). The baPWV was greater in men compared with women ( $P < 0.05$ ) and reduced at 45 minutes after stretching exercise ( $P < 0.05$ ). There were no significant interactions between sex and time for systolic blood pressure and heart rate. Systolic blood pressure was higher in men compared with women ( $P < 0.05$ ) and increased after stretching exercise, changed this parameter to baseline levels within 15 minutes after stretching exercise. Heart rate was similar in men and women and decreased after stretching exercise, changed this parameter to baseline levels within 30 min after stretching exercise ( $P < 0.05$ ). **CONCLUSION:** These results suggest that stretching exercise acutely decreases arterial stiffness regardless of sex.

**COMBINATION OF  $\alpha$ -GLYCEROPHOSPHOCHOLINE ( $\alpha$ -GPC) INTAKE AND AEROBIC EXERCISE IMPROVES COGNITIVE FUNCTIONS IN HEALTHY OLDER WOMEN**

Yuhaku, A., Sato, K., Fujita, S., Okubo, T., Hamaoka, T., Iemitsu, M.

*Ritsumeikan University*

**BACKGROUND:**  $\alpha$ -Glycerophosphocholine ( $\alpha$ -GPC) contributes to the cognitive improvement of mild to moderate Alzheimer's patients (Moreno DJ, Moreno M. 2003). Additionally, habitual exercise improves the cognitive functions. However, the effect of the combination of  $\alpha$ -GPC and aerobic exercise on cognitive abilities in healthy older adults remains unclear. **PURPOSE:** The purpose of this study was to clarify whether the combination of  $\alpha$ -GPC and exercise improve cognitive functions in healthy older people, especially the short-term and the working memory. **METHODS:** 10 healthy females (60-69 yrs. old;  $M = 65.6$ ) participated in the study. They were administered at  $\alpha$ -GPC 1,000 mg once a day and performed walking training for 8-week aiming for at least 30-min training-session 3 times a week. They received the memory test (Kunimi M. 2007) before and after the intervention. The memory test is divided into the serial recall task, which measures the short-term memory, and the reverse recall task, which measures the working memory. The participants were required to remember the successively -presented four kinds of symbols ( $\circ / \Delta / \times / \square$ ), which varied from the two-symbol conditions (e.g.  $\circ / \Delta$ ) to the five-symbol conditions (e.g.  $\circ / \Delta / \times / \square / \circ$ ). **RESULTS:** The memory test showed that there was no significant difference in the serial recall task. Only the five symbol condition showed a marginally significant improvement in the accuracy rate (pre  $46.0 \pm 31.3\%$  / post  $61.6 \pm 23.9\%$ ;  $p = .096$ ). On the other hand, the reverse recall task showed a marginally significant difference in the three-symbol condition (pre  $76.7 \pm 17.3\%$  / post  $90.7 \pm 10.5\%$ ;  $p = .059$ ) and significant improvement in the four-symbol one (pre  $57.0 \pm 15.8\%$  / post  $73.5 \pm 16.3\%$ ;  $p = .031$ ) and the five-symbol one (pre  $36.8 \pm 23.5\%$  / post  $50.8 \pm 21.5\%$ ;  $p = .011$ ). **CONCLUSION:** These findings suggest that the combination of  $\alpha$ -GPC and aerobic exercise may be effective in improving the cognitive functions, especially working memory, in the healthy older women. It is known that exercise helps to improve the cognitive functions of older people, but longer period of training is usually needed (Voss, et al., 2011). In that point, the combination of  $\alpha$ -GPC and exercise makes possible more rapid improvement of the cognitive functions of older people. **REFERENCES:** (1) Moreno, D. J., Moreno M. **EFFECT OF SUPPLEMENTATION WITH VITAMIN C AND E ON MUSCLE GROWTH AND STRENGTH INDUCED BY 12 WEEKS OF RESISTANCE EXERCISE IN ELDERLY MEN**

Bjørnsen, T., Salvesen, S., Bernsen, S., Hellelid, K.J., Stea, T.H., Lohne-Seiler, H., Paulsen, G.

*University of Agder*

**INTRODUCTION:** Supplementation with antioxidants may be beneficial to accelerate gains in lean mass during resistance exercise in elderly men, due to a reduction in oxidative stress. However, oxidative stress is also important to sufficiently activate redox-sensitive signaling pathways that regulate protein synthesis. To the authors knowledge only a few studies have looked at this issue. Thus, the aim of the present study was to investigate the effect of daily supplementation with high dosage of vitamin C and E on muscle growth and maximal strength during 12 weeks of resistance exercise in elderly men. **METHODS:** Thirty-four elderly males (60 – 81 yrs old) were randomized to either a supplemental group (antiox., 1000 mg of vitamin C and 235 mg of vitamin E per day) ( $N=17$ ) or a placebo group (placebo,  $N=17$ ). Muscle growth was assessed as changes in lean mass with Dual-energy X-ray absorptiometry and thickness of rectus femoris, vastus lateralis and arm flexors (brachialis and biceps brachii) with ultrasound imaging. Strength was measured as 1 repetition maximum (1RM) in leg press, knee extension and scott curl. All participants conducted resistance exercise 3 times a week, following an undulating periodized program: 8-10RM (1 min inter-set rest periods), between 3-5RM (2 min rest) or 13-15RM (45 sec rest). The load was weekly adjusted, and the volume increased progressively throughout the 12 weeks of resistance exercise. **RESULTS:** Median changes in total lean mass and in the legs were significantly increased in the placebo group (3.9% (95% confidence intervals 3.0-5.2); and 4.6% (3.0-5.7);, respectively) compared to antiox. (1.2% (CI 0-3.6);  $p < 0,03$  and 1.7% (1.1-3.4);  $p < 0,02$ , respectively). Similar results were shown in ultrasound images of rectus femoris, as the muscle thickness increased with 16.2% (12.8-24.1) for the placebo vs. 10.9% (9.8-13.5) for the antiox. ( $p=0.01$ ). 1RM increased in the range of 15-21% in antiox. and placebo during 12 weeks of resistance exercise ( $p < 0.001$ ), although not significantly different. Changes in lean trunk and lean arms, as well as for muscle thickness in armflexors and vastus lateralis did not differ significantly between groups. **DISCUSSION:** In response to resistance exercise both groups had a robust increase in lean mass,

muscle thickness and strength. However, supplementation with vitamin C and E did not have any positive effects on the adaptation to resistance exercise in elderly men, but seemed on the contrary to hamper muscle growth.

#### **ACTIVA: A COMMUNITY PROGRAM TO PROMOTE PHYSICAL ACTIVITY**

Manzanares Serrano, A., Meseguer Zafra, M., García Arzac, R.M., Micol Torres, C., Martínez Rocamora, M.D., Lillo García, I.

*Universidad Católica de San Antonio Murcia. Health Center Jesus Marín. Health Center Antonio Gracia*

**Introduction** The comprehensive plan for Physical Activity and Sport (Plan A + D) is a strategy created by the Spanish Government (The Sports Advisory Board) which has, as its objective, to guarantee the whole Spanish population universal access to high-quality and practical sport, thus helping to fight against the high levels of sedentary living and obesity and to promote active and healthy lifestyles. The aim of "Activa" is to improve physical activity through coordination between Primary Care doctors and nurses and Town Councils with the purpose of analysing the effectiveness of therapeutic physical exercise prescription from Primary Care consultations in patients with cardiovascular risk factors. **Methods** The subjects were included on the program on primary care centres by their doctor or nurse. They evaluate the criteria for inclusion and exclusion that people have. The criteria for inclusion in the program were the presence of two or more CVRF (hypertension, lipidic disorders, overweight and smoking) and sedentary lifestyle in people from 35 to 65 years old. The program "Activa" consisted of 30 sessions (10 weeks) of training on strength, flexibility and aerobic endurance, 3 days per week on circuit training. The program is designed and supervised by graduates in Sport Science and Health. The program will be coordinated by Healthcare and Social Policy and the Town Halls of the Region of Murcia. **Results** The program is currently being developed on 16 Town Halls in the Region of Murcia, where it is working in 42 Health Centers with 267 professionals (146 doctors, 107 nurses and 14 graduates in Sport Science). Actually, the program has already formed 82 physical exercise groups, with at least 15 patients in each group. **Discussion** The approach to chronic illness is currently a primary objective in society (Geneau, Stuckler, Stachenko, et al., 2010.). Primary care is the ideal place to initiate preventative strategies such as advice on physical exercise. However, the evidence base is weak and is not conclusive (Pavey, Taylor, Fox, et al., 2011). Some of the benefits of physical exercise are: helps prevent the development of hypertension, reduces childhood and adult obesity, reduces cholesterol and the risk of cardiovascular and cerebrovascular illness, reduces symptoms of depression and anxiety and improves your physical condition: resistance, strength, flexibility, agility, breathing and circulation. **References** Geneau, R., Stuckler, D., Stachenko S., Mckee, M., Ebrahim, S., Basu, S., Chockalinhm, A., Mwatsama, M., Jamal, R., Alwan, A. & Beaglehole, R. #### **CARDIORESPIRATORY FITNESS IS ASSOCIATED WITH INTRAMYOCARDIAL TRIGLYCERIDE IN HEALTH MEN**

Kim, M.K., Kang, H.Y.

*Kyungpook National University*

**Introduction** Previous studies have demonstrated convincing evidence that exercise capacity (maximal cardiorespiratory fitness; VO2peak) is related to health and predicted mortality in middle-aged as well as in older adults (Liu et al., 2012). It has been reported that intramyocardial triglyceride (IMTG) content is associated with lipotoxicity and contractile dysfunction. The aim of this study was to examine the relationship between VO2peak and IMTG. **Methods** We examined the relationship between exercise capacity and cardiovascular risk factors in 20 healthy male subjects (age 30.7 ± 1.6 yr; weight 67.4 ± 1.5 kg; body mass index 22.7 ± 0.4 kg/m<sup>2</sup>; means ± SE). Using a graded maximal cycle ergometric test, VO2peak and exhausted time were assessed. A 2 cm<sup>3</sup> (10 × 10 × 20 mm) volume of interest with was prudently selected to avoid blood contamination within the ventricular septum from cine dynamic images using breath-hold proton magnetic resonance spectroscopy (1H-MRS) techniques. IMTG content was calculated according to the area under curve of each spectrum from water and lipid (Hammer et al., 2008). As novel markers of arterial stiffness, cardio-ankle vascular index (CAVI) was simultaneously measured with blood pressure (Nakamura et al., 2008), and carotid intima-media thickness (IMT) using high-resolution ultrasound imaging was measured at the common carotid artery (O'Leary et al., 2002). **Results** There were no significant relationships between CAVI (r = 0.055), SBP (r = 0.147), DBP (r = 0.258) and pulse pressure (r = 0.258) values against VO2peak. We observed a significant inverse relationship for VO2peak and IMTG (r = -0.512, P for trend < .05). Moreover, VO2peak showed a negative correlation with IMT level (r = -0.584, P < 0.05). **Discussion** Although the results of this study were limited to healthy men, cardiorespiratory fitness showed a strong inverse relationship with intramyocardial fat as an ectopic fat. Moreover, VO2peak may be associated with carotid morphological aspect of the IMT as a surrogate marker for atherosclerosis, but not arterial stiffness, at least in healthy men. These findings suggest that cardiac triglyceride contents and carotid intima-media thickness may be linked to exercise capacity. **References** Hammer S, van der Meer RW, Lamb HJ, de Boer HH, Bax JJ, de Roos A, Romijn JA, Smit JW. #### **EFFECTS OF AEROBIC EXERCISE TRAINING ON PLASMA ASYMMETRIC DIMETHYLARGININE CONCENTRATION AND CENTRAL ARTERIAL COMPLIANCE IN POSTMENOPAUSAL WOMEN**

Tanahashi, K., Akazawa, N., Miyaki, A., Choi, Y., Ra, S.G., Matsubara, T., Higashino, R., Kumagai, H., Oikawa, S., Aijisaka, R., Maeda, S.

*University of Tsukuba*

**Background:** Central arterial compliance decreases with advancing age. Reduction in Central arterial compliance with aging increases the risk of cardiovascular disease. Regular aerobic exercise has a favorable effect on vascular aging. Asymmetric dimethylarginine (ADMA) is an endogenous competitive inhibitor of nitric oxide synthase (NOS), an enzyme responsible for generation of nitric oxide (NO). Plasma concentration of ADMA increases in elderly people and in menopausal estrogen deficient women. However, it is unclear whether regular aerobic exercise decreases plasma ADMA concentration in postmenopausal women. We investigated the effects of aerobic exercise training on plasma ADMA concentration and central arterial compliance in postmenopausal women. **Methods:** Thirty postmenopausal women were divided into two groups, i.e., exercise training group (n = 20) and control group (n = 10). Subjects in the exercise

group completed 12 weeks of aerobic exercise training (65-80% of maximal heart rate, 40-60 min/day, 3-5 days/week). The subjects in the control group were instructed not to change their physical activity level for 12 weeks. Before and after the intervention, we measured plasma ADMA concentration and carotid arterial compliance in all participants. Results: The baseline plasma ADMA concentration, carotid arterial compliance, and most other key dependent variables did not significantly differ between two groups. Plasma ADMA concentration was significantly decreased in the exercise group after the intervention ( $P < 0.05$ ). In the exercise group, carotid arterial compliance was significantly increased after the exercise intervention ( $P < 0.05$ ). There was no change in the parameters tested in the control group. In addition, changes in carotid arterial compliance were correlated with changes in plasma ADMA concentration ( $r = -0.367$ ,  $P < 0.05$ ). Conclusion: We demonstrated that aerobic exercise training significantly decreased plasma ADMA concentration associated with improvement of carotid arterial compliance in postmenopausal women. These data suggest that reduction in ADMA may play an important role in the aerobic exercise training-induced increase in arterial compliance.

##### DOES A SEDENTARY LIFESTYLE MODIFY THE BODY COMPOSITION CHANGES DURING THE AGING PROCESS? A LONGITUDINAL STUDY

Gómez-Cabello, A., Ara, I., González-Agüero, A., Casajús, J.A., Vicente-Rodríguez, G.

*GENUD Research Group. University of Zaragoza*

Introduction: Obesity and sarcopenia are common disorders within the older population and constitutes a large and important health-related problem as they are associated with functional decline, loss of independence, morbidity and increased risk of mortality [1,2]. Aim: To evaluate the evolution of fat mass (FM) and lean mass (LM) through the aging process in a 2 years follow-up study and to clarify whether sedentary lifestyle could be affecting these changes. Methods: A total of 125 non-institutionalized elderly (37 men and 88 women; aged  $73.1 \pm 5.4$  y), members of the cohort of the multi-center EXERNET Project [3] participated in the study. Dual-energy X-ray absorptiometry was used to measure FM and LM of the whole body, trunk, upper and lower limbs in all participants. Lifestyle information was collected through personal interviews using a structured questionnaire. The variables considered in the present study were sex, age and sitting time (sedentary behavior). The evaluations were performed at baseline (2008-2009) and 2 years later (2010-2011). A 2-way repeated measures ANOVA test was performed to determine body composition changes. All the analyses were repeated taking into account the time spent sitting per day in order to test whether a sedentary behaviour could affect this variation. As no sex by time interactions were found, analyses were performed including men and women as a whole. Results: After the 2 years follow-up FM increased and LM decreased at all sites (all  $p < 0.01$ ) in the whole group. The percentage of change during the follow-up ranged from 3% to 5.5% for fat-related variables and from -1.6% to -2.1% for lean-related variables. When the sample was divided by sedentary time, those who spent sitting less than 4 h per day had no changes neither in LM at all regions nor in the FM in the arms. Conclusion: Human aging normally leads to an increase in fat mass and a decrease in lean mass. Sitting time seems to be a determinant factor in this body composition changes. Therefore, a reduction of sedentary behaviors among elderly population should be encouraged in order to guarantee a healthier body composition during the aging process. References: 1. Kopelman PG. ##### 10 000 DAILY STEPS TARGET FOR INFLUENCING THE CARDIOMETABOLIC RISK

Skalska, M., Bunc, V.

*Charles University*

Introduction Physical inactivity is lifestyle behavior associated with high cardiometabolic risk not least due to its contribution to weight gain. The aim of this study was to determine the effectiveness of increase of physical activity by walking for cardiometabolic risk in healthy obese women. Methods The study was carried out in 36 obese fully employed mid-age women (age  $44.1 \pm 9.7$  years). 6 months intervention was based on recommendation 10 000 steps per day. For step's monitoring was used Pedometer Omron HJ-720IT-E2. Women took part in 12 weekly sessions of cognitive behavioral therapy programme, followed by 12 weeks interactive internet support. Results Women walked  $6866 \pm 1944$  steps per day before intervention. They increased by 23% to  $8354 \pm 2112$  steps per day during the intervention ( $p < 0.0001$ ). The initial weight was  $96.5 \pm 18.6$ kg, terminal was  $89.3 \pm 19.4$ kg ( $p < 0.05$ ). The initial waist circumference was  $98.3 \pm 10.0$ cm, terminal was  $95.2 \pm 10.3$ cm ( $p < 0.0001$ ). The body fat percentage decreased from  $40.7 \pm 4.9$  to  $39.3 \pm 5.6$ % ( $p < 0.004$ ). The initial HDL cholesterol increased from  $1.3 \pm 0.4$  mmol/l to  $1.6 \pm 0.3$  mmol/l ( $p < 0.0001$ ). Discussion Exercise intervention can elicit long-term changes only in cases when it gets over certain minimum level which is given by intensity, time, frequency and form of such exercise (Bunc, 2009). A crucial factor for the volume of changes is the start level of evaluation parameters and then changes are the bigger the lower was the start position. One of the methods which has recently gained higher attention and is, of course, more often used in practice, is the evaluation of the number of steps. Here we can find the necessary volume of exercise for the needs of overall physical condition and positive influence of overweight, which is 10000 steps a day (Le Masurier et al., 2003). Changes announced by applied intervention programme were on the level which was mentioned in writing (e.g. Bouchard 2000, Brettschneider a Naul 2007). The results of our study confirm that the increase of physical activity of 23%, with constant energy intake, manifests in the weight reduction, has positive influence on cardiometabolic risk and can be achievable in daily life of obese fully employed mid-age women. ## BODY COMPOSITION, BLOOD PRESSURE AND DIETARY HABITS AMONG YOUNG QATARI MALE ADULTS

Goebel, R.1, Velenczei, A.2, Alsuliman, B.1, Riahi, M.1, Bibi, K.1, Kneffel, Zs.1

1 Qatar University, Sport Science Program. 2 Qatar Foundation, Al-Shaqab

**Introduction:** Due to a rapidly changing lifestyle in Qatar, determinants of non-communicable diseases and linked levels of risk factors have risen. These facts pose a national challenge (1). Information about Qatari adults' (19-30yr.) dietary habits is essential because of the increase in the incidence and prevalence of obesity in Qataris. In 2006, the percentage of Qatari boys who are overweight and obese is 28.6%, and 7.9%, respectively (3). Aim of this study was to determine body composition, blood pressure and dietary habits of the next cohort, those 18-29 yrs old. **Methods:** 80 Qatari male students, 18-29 yrs of age, from Qatar University (QU) participated. Blood pressure (BP) was measured by Omron HEM-780, body composition (body weight and percent of body fat (BF)), were measured by OMRON BF-400. Dietary habits were evaluated using the NHANES Food Frequency Questionnaire. For data analysis, Chi-square test and univariate analyses of variance were conducted using SPSS version 20. **Results:** The mean systolic and diastolic BP was 128.6±1.42 mmHg, 73.32±1.1 mmHg, respectively. The mean arterial pressure (MAP) was 91.74±1.06 mmHg. The mean BF is 23.79±1.19%. 30.77% of the subjects were classified as overweight, 38.46% as obese. The crosstab statistical analyses yielded a difference between fast food (FF) vs. seafood (SF) consumptions ( $p=.007$ ). No statistical difference between vegetables consumption vs. pasta intake occur. However, the subjects' soda consumption was greater than fruit juices ( $p=.05$ ). The BF is expressed by an interaction between salad and SF consumption,  $p=.047$ ,  $\eta^2=.409$ , but these main effects are not qualified by a separate interaction on BF ( $p=.234$ ,  $\eta^2=.181$  vs.  $p=.34$ ,  $\eta^2=.149$ , respectively). No interaction was found between FF, SF or sweets and blood pressure values. **Conclusion:** Obesity is uniformly considered to be the most important factor in developing non-communicable diseases in Qatar (2). Our study supports the results. In our sample, the prevalence of overweight and obesity was higher compared to previously published studies. No correlation between dietary habits and MAP occurred though, due to the wide range of nutrients consumed. High caloric diets are prevalent among QU students. **References:** (1) Al-Thani, Hamad bin Jabor bin Jassim (2008). Qatar National Vision 2030: The Four Development Pillars. ## FOUR-YEARS INCIDENCE OF YOUTH OVERWEIGHT-OBESE. ASSOCIATION WITH DEMOGRAPHIC AND LIFESTYLES FACTORS

Gaya, A.R.1, Reuter, C.2, Gaya, A.3, Burgos, L.1, Possuelo, L.G.2, Pohl, H.H.2, Burgos, M.S.1

University of Santa Cruz do Sul; Federal University of the South of Brazil

**Introduction** Considering premature consequences of obesity, several studies appointed for the public health importance of understand obesity since childhood. Therefore, the aim of this study was to evaluate four-years incidence of youth overweight/obese (OW/OB) and to identify lifestyles and demographic outcomes of youth and their parents associated. **Methods** This is a longitudinal study comprised a randomized sample of 405 schoolchildren and adolescents for both genders aged 7-17 from Santa Cruz do Sul - Brazil. A previously trained research group measured baseline and 3 years after all variables at the University laboratory. Subjects were classified in OW/OB according of an international cut off point. Youth and their parent's lifestyles and demographic variables were measured by an adapted questionnaire. Cardiorespiratory fitness (CRF) was available by a nine minutes walking and run test. Subjects were categorized in CRF healthy and unhealthy zone in agreement with Brazilian parameters. **Results** The cumulative incidence of OW/OB was 23% over a period of four years. The prevalence of both OW/OB was two times more elevated on the second year compared with baseline values (OW: 16.8%-33.3%; OB: 6.7%-15.3%). By poisson regression test: CRF unhealthy youth on baseline and on the fourth year showed a higher risk for keeping and developing OW/OB (Baseline - OR: 2.03; 95% CI: 1.16; 3.55; fourth year - OR: 2.37; 95% CI: 1.52; 3.69); and, youth with mother categorized in OW/OB (OR: 2.92; 95% CI: 1.69; 5.05). Sex, age, birth weight, school localization and variation of CRF did not show significant association with develop our keep over four year on OW/OB group. **Discussion** Approximately half of our sample kept or became OW and OB over a four years period. Mother overweight/obesity and low levels of cardiorespiratory fitness seem important predictors that should be considerate for prevention and treatment of this pandemic disease. Promotion of health through modification of children and their parent's lifestyles could be an important approach. **References** Cole, T. J., Bellizzi, M. C., Flegal, K. M., & Dietz, W. H. ## THE INFLUENCE OF DIETARY BEHAVIOR AND SEDENTARY LIFESTYLE ON BLOOD PRESSURE AND BODY COMPOSITION AMONG YOUNG QATARI FEMALE ADULTS

Kneffel, Zs.1, Al-Bader, H.K.1, Bou Hassine, R.R.1, Velenczei, A.2, Goebel, R.1

1. Qatar University, 2. Qatar Foundation

**Introduction:** Obesity is emerging as a major health problem due to recent dietary habits and sedentary lifestyles in Qatar. The prevalence of, overweight, and obesity was over 23%, among adolescents girls in the country. On the other hand, the adult Qatari population has a high prevalence of hypertension (32.1%)(1,2). The aim of the study was mapping the early signs of hypertension and its connection to the dietary habits, to the inactivity level, and to the body composition of young adult Qatari females. **Methods:** 70 Qatari female students were involved from Qatar University, age between 18-29 yr. Blood pressure was measured by Omron HEM-780, body composition (body weight (BW), % of body fat (BF)), were measured by OMRON BF-400. The dietary habit was evaluated by NHANES Food Frequency Questionnaire (FFQ). To clarify the subjects actual physical activity International Physical Activity Questionnaire (IPAQ) was used. For data analyzes Chi-square test and univariate analyses of variance were used by SPSS version 20. **Results:** The systolic (BPS) and diastolic (BPD) blood pressure mean values were in the normal range (BPS 114±1.44 mmHg and BPD 64±1.16 mmHg). Mean arterial pressure (MAP) was 87.71±1.15 mmHg. Mean BF was 28.82±1.44 and 39.65% of the subjects was overweight or obese. The crosstabs shown significant difference between the seafood vs. fast food (FF) consumption, however no difference was shown between the vegetables and pastas use. In the fluid uptake, soda and 100% fruit juice drinking did not differ from each other. There were qualified by an interaction between FF consumption and total weekly sitting hours (TWH) on BF,  $p = .16$ ,  $\eta^2=.164$ , where the main effects was FF vs. TWH ( $p=.01$ ,  $\eta^2=.245$  vs.  $p=.451$ ,  $\eta^2=.012$ ), but these effects did not qualified by an interaction on MAP ( $p=.256$ ,  $\eta^2=.055$ ). **Conclusion:** Qatar puts

big effort to popularized the regular physical activity in the society to prevent the appearance of non-communicable diseases (hypertension, type-II diabetes) (3). Based on our data 37% of the measured subjects has some weight problem which seems to be generated by their regular eating behavior and with less weight the lack of regular physical activity. These factors didn't shown any interaction to the MAP values, probably because in this age group the different physiological protective mechanisms control well the systolic and diastolic pressure. ### THE EFFICACY OF 12 WEEKS SUPERVISED AEROBIC OR RESISTANCE TRAINING FOR OBESITY MANAGEMENT

Herring, L., Scott, A., Wagstaff, C.

*Loughborough University & University of Portsmouth*

Purpose: This randomised controlled trial (RCT) was designed to assess the effect of a structured 12-week aerobic training (AT) or resistance training (RT) programme on morbidly obese individuals as part of a multidisciplinary weight management programme. Methods: The RCT was undertaken on male & female participants aged between 24 and 68 with a body mass index (BMI) of at least 40kg•m<sup>2</sup> or at least 35kg•m<sup>2</sup> with co-morbidities. Participants were assigned to either the AT (n=12), RT (n=11) or control group (CON) (n=10). AT and RT groups undertook three structured ~60 minute moderate intensity sessions per week, two supervised gym-based and one structured home-based session for 12 weeks. Pre and post intervention, anthropometric, psychological and functional capacity measures were obtained to allow comparisons. A one-way ANOVA was applied to the data. Results: When compared to the CON both exercise interventions elicited improvements in: the incremental shuttle walk test distance [AT [Difference 207.0±123.0 metres, 68.0%, P=0.04], RT [Difference 165.0±183.3 metres, 48.8%, P=0.06], CON [Difference -14.3±38.7 metres, -6.2%]], the triceps skin fold [AT [Difference -9.29±3.33mm, -25.6%, P=0.01], RT [Difference -9.03±5.80mm, -24.9%, P=0.01], CON [Difference 0.50±3.34mm, 1.5%]], self-efficacy to regulate physical activity (P=0.005) and interest/enjoyment physical activity motive (P=0.006). The RT group displayed additional improvements compared to the CON in BMI [RT [Difference -1.02±0.91 kg•m<sup>2</sup>, -2.5%, P=0.033], AT [Difference -0.19±2.70kg•m<sup>2</sup>, -3.9%,P=0.142], CON [Difference -0.31±1.47kg•m<sup>2</sup>, -0.6%]] waist circumference (P=0.022), the competence PA motive (P=0.019), the biceps skin fold (P=0.012) and the medial calf skin fold (P=0.013). No significant differences were displayed between AT and RT. Conclusion: Physiological, functional and psychological measures improved with structured exercise in patients with a BMI of 35kg•m<sup>2</sup> or greater demonstrating RT was at least as effective as AT.

### EFFECT OF RHYTHMIC ACTIVITIES AND CHOREOGRAPHIC WORKS PROGRAM ABOUT THE QUALITY OF LIFE PERCEIVED IN OBESITY OR OVERWEIGHT

Monleón, C., Arborelo, V., Pablos, A., Fargueta, M., Martín, M., Pablos, C.

*Facultad de CC. de la Actividad Física y Deporte, Universidad Católica de Valencia "San Vicente Mártir"*

Introduction Obesity has been provided by different ways (SEEDO, 2000) and is defined as entity where health and well-being are affected by excess of body fat (WHO, 1998). Rhythm programs have been used, for example, with elderly (Granacher et al, 2012), individuals with cancer (Aktas and Ogce, 2005) or Parkinson disease (de Breu et al, 2012). Nevertheless, application not found in these programs with overweight and obese populations. Numerous studies have a relationship with physical activity practice and the improvement of the quality of life (Horacio et al., 2009). Authors such as Muller-Pinget et al. (2012) have emphasized the importance of designing exercises that cause enjoyment and entertainment to assume a program of physical activity in overweight and obesity people. Methods The sample was composed of 32 overweight or obese (7 males and 24 females). To conduct the study, 2 groups were created into a 4 months intervention based with rhythmic and choreographic activities. First group with 9 subjects with obesity Type I (33.1±2.59BMI; 85.86±8.96K; 161±7.37cm) and the second one with Type II obesity integrated by 22 subjects (40.35±3.8BMI; 106.62±15.55K; 161.84±7.99cm). Each individual completed the Health Questionnaire SF-12 and the analyzed variables were Physical Functioning, Role Physical, Bodily Pain, General Health, Vitality, Social Functioning, Role Emotional, Mental Health, Physical Component Scale and Mental Component Scale. Data processing was conducted by descriptive analysis (SPSS v 20.0), by Shapiro-Wilk test and a Wilcoxon test. Results Statistically significant improvements was obtained in the obese group in type II and higher, Vitality variables (t = 1968, p <.05) and Social Functioning (t = 2227, p <.05). Discussion Perhaps, to find improvements in Obese Type I the sample and the performance time should be bigger. According to results of Mohamed et al. (2012), after 12 weeks of intervention Biodanza program for patients diagnosed with fibromyalgia, there were significant improvements in the same components, Social Functioning and Vitality. References Granacher, U., Muehlbauer, T., Bridenbaugh, S. A., Wolf, M., Roth, R., Gschwind, Y., Wolf, I., Mata, R., & Kressig, R. W. (2012). ### MORPHOLOGICAL CHANGES IN THE FOOT OF OBESE CHILDREN AFTER A THREE-MONTH VIGOROUS PHYSICAL ACTIVITY PROGRAMME

Jiménez-Ormeño, E.I, Aguado, X.I, Martín-García, M.2, Delgado-Abellán, L.I, Ara, I.2, Alegre, L.M.I

*Universidad de Castilla-La Mancha, Toledo, Spain*

Introduction Excess weight affects the anthropometric structure of the foot of children (2). Also, long-term adaptations in the foot due to exercise can lead to changes in both the arch index or in the foot morphology of young subjects (1). The aim of this study was to assess the effects of a three-month vigorous physical activity (VPA) programme on the foot morphology of children with obesity. Methods Eighteen children in an experimental group (EG) (12.5±2.0 years; BMI 28.9±3.5 kg/ m<sup>2</sup>) and 11 children in a control group (CG) (11.2±1.9 years; BMI 27.4±2.1 kg/m<sup>2</sup>) participated, all of them diagnosed as overweight or obese. The EG performed a three-month VPA programme aimed primarily to improve aerobic endurance and strength, while the CG did not train. Foot dimensions were measured with a 3D feet digitizer in static standing, and body composition was assessed with dual-energy X-ray absorptiometry, before and after the intervention. Results The EG showed significant decreases in body mass (-2.5%, P = 0.002) and body fat (-4.8%, P < 0.001) after the intervention. There were significant changes in the foot morphology in both groups, mainly in widths, resulting in an increase in all measures except arch

height, which decreased (EG: -1%,  $P = 0.657$ ; CG: -3%,  $P = 0.045$ ), indicating that the foot was made flatter. Discussion The CG showed changes in foot morphology, therefore the changes found in the EG were influenced by growth. The plantar arch should have already been established at these ages; hence the tendency to a flatter foot found in both groups could have been due to their overweight (3). Therefore, despite changes in body composition, it seems like the EG group did not revert the flattening of the foot that could lead to orthopaedic pathologies. To conclude, foot morphology should be an item to control in children with overweight and obesity involved in physical activity interventions in order to avoid future lower limb injuries. ## CHANGES IN VO<sub>2</sub>MAX AFTER A MASSIVE WEIGHT LOSS INDUCED BY GASTRIC BYPASS SURGERY IN OBESE AND TYPE 2 DIABETIC PATIENTS.

Dalby, S., Lund, M., Hansen, M., Helge, J.W., Dela, F.  
*University of Copenhagen*

**Introduction** Morbid obesity is associated with an inactive lifestyle and impaired exercise performance, partly explained by physical discomforts and morbidities associated with overweight. Gastric bypass surgery leads to substantial weight loss, but whether obesity alters lifestyle patterns in morbidly obese is unknown. Our aim was to measure, if substantial weight loss in relation to gastric bypass surgery was associated with an enhanced level of fitness in normal glucose tolerant (NGT) and type 2 diabetic patients (DM2), before and after Roux en Y gastric bypass surgery, as an indication of a more active lifestyle following weight loss. **Methods** 8 DM2 and 15 NGT (age:  $42 \pm 1$  and  $43 \pm 1$  yrs; BMI:  $42 \pm 1$  and  $43 \pm 1$  kg/m<sup>2</sup>; weight:  $129 \pm 5$  and  $122 \pm 5$  kg respectively), were recruited. Subjects reported to the lab four times: Before any weight loss (A), after a diet induced weight loss prior to surgery (B), 4 months (C) and 1.5 years after surgery (D) ( $n = 5$  DM2 and 10 NGT). At each test day a dual Energy X-ray Absorption Scan for determination of body composition was performed, followed by an incremental bicycle test (75W warm-up 2 minutes, increase 25W/min until exhaustion) on a stationary ergometer bicycle, with continuous oxygen uptake measurement. Maximal oxygen uptake (VO<sub>2</sub>max) was determined over a 20 sec period according to the levelling off criterion. Data is presented as mean  $\pm$  SEM and 2-way ANOVA for repeated measurements was used for statistical analysis. **Results** Weight loss was similar in NGT and DM2: A-B:  $5 \pm 1$  kg and  $5 \pm 1$  kg; B-C:  $27 \pm 2$  kg and  $26 \pm 3$ ; C-D:  $11 \pm 3$  and  $10 \pm 2$  kg, respectively. VO<sub>2</sub>max per kg body weight was similar in the two groups at any given time and increased after surgery: NGT: (A:  $22 \pm 1$  vs. C:  $26 \pm 2$  or D  $33 \pm 3$  ml/min/kg, both  $p < 0.05$ ) and DM2 (A:  $20 \pm 2$  vs. C:  $26 \pm 2$  or D  $29 \pm 2$  ml/min/kg, both  $p < 0.05$ ). Absolute values of VO<sub>2</sub>max were similar in both groups and did not change between test days (NGT: A:  $2722 \pm 194$ ; B:  $2744 \pm 229$ ; C:  $2565 \pm 221$ ; D:  $2803 \pm 385$  ml/min; A vs. D:  $p = 0.92$  and DM2: A:  $2456 \pm 253$ ; B:  $2504 \pm 223$ ; C:  $2491 \pm 175$ ; D:  $2355 \pm 157$  ml/min; A vs. D:  $p = 0.61$ ). **Discussion** The substantial weight loss of more than 25 kg body weight due to diet and gastric bypass surgery increased VO<sub>2</sub>max when calculated per kg body weight. However, the absolute maximal oxygen uptake is unaltered by the massive weight loss. Thus gastric bypass surgery does not improve exercise performance or induce regular exercise habits in these previously morbidly obese patients, when they have achieved a new (lower) steady state body weight.

## BODY COMPOSITION OF HUMAN LIMBS BY USING BIA AND MRI

Yoshikawa, M.1, Kurihara, T.1, Taguchi, S.1, Yamauchi, J.2,3, Hashimoto, T.1,3

1. *Ritsumeikan University, Shiga, JAPAN* 2. *Tokyo Metropolitan University, Tokyo, JAPAN* 3. *Future Institute for Sport Sciences, Tokyo, JAPAN*

**Introduction** The modern lifestyle increases the prevalence of metabolic syndrome with increasing intra-abdominal fat in both obese and non-obese individuals. An increase in adipose tissue and decrease in muscle mass may further cause to decrease in peripheral uptake of glucose and insulin resistance. Such metabolic syndrome or sarcopenia contributes to atherosclerosis, causing to reduce blood flow in the limbs, usually the legs. Due to human hands being free from locomotion, legs engage in motor activities. There are a great number of studies with body composition in whole body; however, the chronic metabolic responses or body composition of limbs have seldom been studied. In order to maintain our good health status and understand chronic metabolic responses in our body, it is important to measure and evaluate our body compositions. The bioelectrical impedance analysis (BIA) method is widely used for both clinical and practical fields; however, it is still unclear whether body composition of limbs is equivalently estimated with a whole body composition. On the other hands, magnetic resonance imaging (MRI) offers to accurately and non-invasively assess size and volume of regional muscle and fat. The aim of this study was to investigate body composition of human limbs by using BIA and MRI methods. **Methods** Twenty-two healthy young individuals volunteered and their body compositions were measured by BIA and MRI, respectively. For a measurement of BIA, the eight-contact electrode system (Inbody720, Biospace, Japan) was used. The device can measure segmental impedance at multiple frequencies of 5 body parts (arms, trunk, and legs). For a measurement of MRI, subjects were laid supine on the examination table of a 1.5-T MR system (Signa HDxt, GE Healthcare). The axial images of upper arm and thigh were acquired to measure the cross sectional areas of muscle, fat and bone. The images at the midpoint of the limbs were selected due to that the anatomical cross-sectional area (ACSA) is the largest at this point. **Result & Discussion** The percentage of the fat in upper and lower limbs measured by BIA and MRI were significantly correlated (upper limb:  $r = 0.96$ ,  $p < 0.01$ ; lower limb:  $r = 0.95$ ,  $p < 0.01$ ). However, the values measured by MRI method were larger than those measured by BIA (upper limb,  $26.0 \pm 12.1\%$  for BIA;  $32.1 \pm 14.2\%$  for MRI; lower limb  $23.1 \pm 7.8\%$  for BIA,  $25.2 \pm 11.6\%$  for MRI). The difference was more significant in upper limb as compared to lower limb. The study demonstrated a close relationship between body composition of limbs measured by BIA and MRI. It is suggested that multifrequency whole-body BIA may be useful in the estimation of the whole body and limb composition, but it may be difficult to determine the regional specificities in body composition of limbs.

## SUSTAINED BOUTS OF MODERATE-VIGOROUS PHYSICAL ACTIVITY ARE RELATED TO CARDIOVASCULAR HEALTH IN OVERWEIGHT AND OBESE JAPANESE MEN

Tsujiimoto, T., Sasai, H., Eto, M., So, R., Tanaka, K.  
*University of Tsukuba*

**Introduction:** Whereas greater physical activity (PA) is known to prevent cardiovascular disease (CVD) in overweight and obese adults, the influence of sustained or shorter bouts of PA on CVD risk factors is not well known. Global PA recommendation indicates that PA should be accrued in bouts of at least 10 min for potential health benefits. However, further research is needed to determine the health benefits of PA lasting < 10 min. The objective of this study was to investigate the relationship between moderate-vigorous PA (MVPA), measured in

bouts  $\geq 10$  and  $< 10$ min, and CVD risk factors in overweight and obese Japanese men. Methods: We analyzed a cross-sectional data of 190 men (age = 50.3 years; body mass index = 29.4 kg/m<sup>2</sup>) who underwent objective assessment of PA by a uniaxial accelerometer (Kenz Lifecorder-EX) over 2 consecutive weeks. Total MVPA, MVPA lasting  $\geq 10$  min (MVPA10+), and MVPA lasting  $< 10$  min (MVPA<10) were calculated. Multiple linear regression analysis was applied to assess contributions of different MVPA exposures to individual CVD risk factors, including measures of waist circumference, blood pressure, blood lipid, glucose, and insulin resistance. Results: Greater total MVPA and MVPA10+ were significantly associated with higher HDL cholesterol level ( $\beta = 0.23$  and  $0.29$ , respectively). In contrast, MVPA<10 showed no significant association with any CVD risk factors. Meeting PA recommendation ( $\geq 150$  min/week of MVPA10+) was related to lower waist circumference, triglycerides, insulin level, insulin resistance, and higher HDL cholesterol level (Cohen's  $d > 0.2$ ). Accumulation ( $\geq 150$  min/week) of total MVPA was not related to any CVD risk factors. Conclusions: Our cross-sectional observations confirm a positive association of MVPA with a healthier CVD risk factor profile and indicate that accruing MVPA lasting  $\geq 10$  min may favorably influence CVD risk factors. These results underscore the importance of sustained physical activity as exercise for health benefits in overweight and obese men.

### **CASE STUDY: COULD GPS TECHNOLOGY ASSIST IN DETECTING EARLY SIGNS OF OVERREACHING IN A PROFESSIONAL CRICKET PLAYER OVER A SEASON?**

Opperman, S., Opperman, E., Venter, R.E.

*Stellenbosch University*

Case study: Could GPS technology assist in detecting early signs of overreaching in a professional cricket player over a season? Introduction Global positioning system (GPS) technology has been used extensively in various team sports, however, most research focused on the kinematics of players to determine the demands of a specific sport. We focused on test cricket to try and find indicators that will resonance to triggers to inform coaches of a player's physical state. This is a unique study as no other study tracked a fast bowler over a test season to measure changes in kinematics. A decline in muscle force production has been proposed as a potential marker for overreaching (Mackinnon 2008), which could be related to a reduction in speed. Knicker et al. (2011) mentioned that fatigue is related to a decline in peak velocity, along with altered kinematic components. We tested our hypotheses that the player's maximum speed will decline over the test match season. Methods A professional fast bowler was monitored for five consecutive 5-day international test matches. The player wore a SPI ProXII GPS unit (GPSports, Canberra, Australia) for a total of 147 overs during five matches. The speed of every run-up was recorded during an over (six run-ups) to calculate the average maximum speed per over. This was then used to calculate the average maximum speed per match (AveMax). Secondly the maximum run-up speed per over was recorded, and the average of the maximum speeds per over was then calculated per match for the absolute maximum speeds per over per match (AbsMax). Results A decline in the AveMax, as well as the AbsMax speed of the player over the five consecutive matches were found. Differences in AveMax between the matches were not significant ( $p=0.157$ ) ( $p>0.05$ ). AbsMax, however, showed a significant difference  $p=0.001$  ( $p<0.05$ ) and indicated variability of the maximum speeds of run-ups between matches. The number of wickets taken also declined progressively over the season. Discussion These findings seem to support our theory that accumulated fatigue during a season might be responsible for a decline in maximum power, in this case, maximum speed. This might result in a poor performance and can be detrimental to an athlete's health. If this decline in speed is a result of central or peripheral fatigue, still needs to be investigated. We propose this method used, in this study, to be an alternative method to monitor and manage an athlete's health. We can conclude that GPS is a suitable device to monitor speed of a player during a season and detect changes which might be valuable in managing a player's workload. ### **INGESTION OF ANTIOXIDANT-RICH DATES TO CURE DELAYED ONSET MUSCLE SORENESS**

Zainuddin, Z., Halijah, I., Syazimee, C.H.

*Universiti Teknologi Malaysia*

Antioxidant-rich dates originally cultivated from middle east countries with scientific name "Phonex Dactylifera" are very common among muslims especially in fasting months. It was consumed for more than 100 years. Proven scientifically for its high antioxidant nutrients, ingestions of these dates may assist the recovery of muscle damage. The purpose of this research is to observe the effect of rich antioxidant dates intake during the recovery process following eccentric exercise. Ten healthy male subjects with no history of biceps muscle injury and not participate in specific strength training or exercises were involved in these two experimental sessions. Contralateral arms approach was used in this study. Subjects were randomly assigned to have their arms undergo treatment or control condition. The treatment session consists of exercise induce muscle damage (EIMD) to the biceps via eccentric exercise and seven days recovery monitoring where the subjects daily ingests  $\pm 10$  gram of dates fruits for seven consecutive days. The control session consists of similar EIMD protocol and seven days of recovery monitoring without ingestion of Phonex Dactylifera. The EIMD involved 6 set of exercises and each set consisting ten controlled eccentric contraction repetitions of arm (elbow flexors) with dumbbell weighted 7.5 kg. One minute rest were given between sets. Muscle injury existence were measured through four indirect muscle injury indicators that are upper arm circumference, range of motion (ROM), delayed onset muscle soreness (DOMS) and maximum strength. The indicators were measured one hour after EIMD and followed by day 1,2,3,4 and day 7 after the damage. Subjects were then rested for two weeks between two experimental sessions to avoid the effects of injury between arms. Results indicates that only upper arm circumference showed a significant difference with  $p = 0.05$ , where the control group recorded higher score in circumference. No significant differences were recorded on DOMS, ROM and maximum strength. As a conclusion, dates fruit is only effective in reducing the diameter of the swelling but not effective to lessen DOMS and other indicator of muscle damage

### **THE RELATIONSHIP BETWEEN THE 6MWT AND PSYCHOLOGICAL STATUS IN PEOPLE WITH SCHIZOPHRENIA**

Tortosa-Martínez, J.I, Caus Pertegaz, N.I, Blasco-Lafarga, C.2

<sup>1</sup>Universidad de Alicante (Spain); <sup>2</sup>Universidad de Valencia (Spain)

Introduction: People with schizophrenia are more sedentary than the general population, with only 25% of schizophrenics meeting the minimum recommendation for health of 150 min a week of moderate-intensity physical activity (Faulkner & Carless, 2006). In addition, 25 to 50% of mental health patients experience depressive and/or anxiety symptoms (Buckley et al., 2009). Thus, the aim of this study was to analyse the relationship between physical function and psychological status in schizophrenics. Methods: Fifty hospitalized patients from a

public mental health institution in Spain diagnosed with schizophrenia (DSM-IV criteria), and thirty matched healthy controls, were recruited using convenience sampling. Participants were assessed by the Six-Minute Walk test (6MWT) for physical function, and the DASS-21, which measures the 3 negative affective states of depression, anxiety, and stress over the past week. Results: Schizophrenics had lower levels of physical function as measured by the 6MWT ( $p < 0.001$ ) compared to healthy controls. They also showed significant higher levels of stress ( $p < 0.001$ ), anxiety ( $p < 0.001$ ), and depression ( $p < 0.001$ ). Within the schizophrenics, there was a negative correlation between the 6MWT and the levels of stress ( $p < 0.05$ ) and depression ( $p < 0.05$ ), and a tendency was found for anxiety. After controlling for possible confounding variables (age, years of illness, gender, smoking, and body mass index), a negative correlation was found for anxiety ( $p < 0.05$ ), and the significance and the power of the correlations increased for stress and depression. No correlations were found in the healthy controls. Discussion: As expected, people with schizophrenia walked lower distances in the 6MWT and had higher levels of psychological distress, compared to healthy controls. The poor performance of people with SCZ in the physical test is partially due to high sedentary levels and also other negative lifestyle habits such as a poor diet and high levels of smoking, common in this population (Faulkner & Carless, 2006). Our results confirm the need to increase physical activity in people with SCZ (Vancampfort et al. 2012), since better performance in the test correlated with better psychological status. #### BIOENERGETIC PROFILE OF SWIMMERS WITH LOCO-MOTOR DISABILITY

Junior, V.R., Pelarigo, J.G., Marques, T., Vilas-Boas, J.P., Corredeira, R., Daly, D., Fernandes, R.J.

1 Faculty of Sport, University of Porto, Portugal 2 Centre of Research, Education, Innovation and Intervention in Sport 3 Porto Biomechanics Laboratory (LABIO MEP), University of Porto, 4 Faculty of Kines

Introduction Research involving swimmers with loco-motor disabilities has increased exponentially in the last decade, but little attention has been given to the bioenergetic factors that play a key role in improving sports performance. The aim of this study was to evaluate the bioenergetic variables related to swimming velocity at the individual anaerobic threshold (IAnT) and maximal oxygen uptake (VO<sub>2</sub>max) of swimmers with loco-motor disability. Methods Three male competitive swimmers (a superior limb paralysis, amputee and neuropathy impairment), mean: 24.0yrs; 71.9kg; 1.84m, in functional classes S8 and S9, according to the International Paralympic Committee performed incremental protocol in front crawl until voluntary exhaustion. Steps were repeated 200m swims, at increments of 0.05m.s<sup>-1</sup> with 30s rest intervals. Swimming velocity, ventilatory parameters, and blood lactate response ([La-]) associated to the IAnT and VO<sub>2</sub>max was determined. The IAnT was calculated by the [La-] vs velocity curve modeling method (Fernandes et al., 2011). Results The mean values associated with the intensity of IAnT and VO<sub>2</sub>max were 40.5mL.kg<sup>-1</sup>.min<sup>-1</sup>, 153.0bpm, 2.3mmol.L<sup>-1</sup>, 1.03m.s<sup>-1</sup> and 51.1mL.kg<sup>-1</sup>.min<sup>-1</sup>, 177.7bpm, 6.3 mmol.L<sup>-1</sup> and 1.15m.s<sup>-1</sup>, respectively. The percentage values of IAnT regarding VO<sub>2</sub>max were 79.9% and 89.3% in the VO<sub>2</sub> and velocity domains, respectively. Discussion The bioenergetic profile of loco-motor disability swimmers maintain a similar standard in issues associated to the physiological performance when compared with these reported for non-disability swimmers described in the literature, however, when analyzed the velocities at which the disability swimmers attained the VO<sub>2</sub>max and the IAnT, the motor disability should be recognized as a severe limiting factor to achieve high absolute swimming performances. #### BODY COMPOSITION ASSESSMENT, STATUS NUTRITIONAL AND METABOLIC CHANGES IN INFECTED CHILDREN ANTI-VIRAL THERAPY

Ramalho, L., Gonçalves, E., Samur-San Martin, J., Krahenbühl, T., Barbeta, V., Bertapelli, F., Barbeta, C., Guerra-Júnior, G., Morcillo, A., Silva, M.

Faculty of Medical Sciences – State University of Campinas

Introduction: The advent of antiretroviral therapy (ART) has resulted in increased survival of children and adolescents infected with HIV. However, several adverse effects were found with the use of this therapy. Objective: To evaluate body composition nutritional status, and lipids in Brazilian children infected with HIV, effective ART and the association of these variables with lifestyle, clinical, immunological, virological and therapeutic. Methods: Cross-sectional study with 97 children HIV and 364 healthy. Body composition was measured by anthropometry. Identified the accumulation of abdominal fat by waist circumference (WC) and waist-hip ratio (WHR). Lipodystrophy was identified by clinical evaluation. The clinical and immunological categories defined by CDC. Lipid levels in the serum were defined according to the international standard. We use 24-hour Recommended Dietary Allowances, (RDA), (Recommended Dietary Allowances, 1989). Statistical analysis was performed using SPSS for Windows. Results: The prevalence of short stature in a 25.53%, 22.34% by malnutrition, lipodystrophy by 38.29% and 40.42% in lipohypertrophy in patients. Hypercholesterolemia was associated with the RDA, (OR 1.57, 1.12 to 10.22) and viral load (1.81, 1.20 - 8.70). Patients who were treated with protease inhibitor (PI) showed a higher risk of malnutrition (3.51, CI 1.07 to 11.44) and lipodystrophy (3.5, CI 1.37 to 8.95). The insulin resistance was associated with the use of IP (0.48, CI 0.02 to 0.49) and clinical category C (2.35, CI 1.05 to 31.46). Comparing HIV groups and control, WHR and WC were higher in HIV ( $p < 0.001$ ) and ( $p = 0.011$ ), respectively. HIV patients had a higher risk of short stature (5.33, CI 2.83 to 10.04), malnutrition (4.7, CI 2.44 to 9.06) and small risk of obesity and overweight (0.33, IC 0.14 to 0.78). Discussion: Pediatric patients with ART showed greater involvement in nutritional status and body composition (Buonora et al., 2008). His body and metabolic alterations were associated with the severity of the infection, such as the use of IP, an advanced stage of the disease, the difficulty of virologic control and immunosuppression. References: Recommended Dietary Allowances - 10th Edition - National Academy Press, Washington, D.C. 1989. Buonora S, Nogueira S, Pone MV, Aloé M, Oliveira

### DEVELOPMENT AND EVALUATION OF A NEW ARM CRANK ERGOMETER

Hayashi, S., Arakane, K., Wada, T., Tsuchida, Y., Onodera, S.

*Kwasaki University of Medical Welfare*

**INTRODUCTION:** An arm crank ergometer is the popular devices used in clinical exercise testing or programs of cardiac rehabilitation and training of upper limb for wheelchair users. However, it is speculated that assessment of oxygen uptake is difficult because of mixing muscle exertion of lower limb with arm cranking exercise. Therefore, we have developed a new designed device for arm cranking ergometry. The purpose of this study was to compare oxygen uptake and heart rate (HR) on a new arm ergometer with performance on a conventional arm ergometer. **CHARACTERISTICS:** The new ergometer and a seat unified by one framework. It is possible to adjust height of the seat, and distance to the ergometer in accordance with characteristics of subjects and/or purpose of the exercise. The ergometer has belts in five points (both shoulders, waist on either side and between the leg), and the subject's body is fixed by the belts when the arm cranking ergometry. **METHODS:** Nine healthy Japanese male (age  $22 \pm 3$  yr, height  $172.8 \pm 2.9$  cm, weight  $69.5 \pm 2.1$  kg) participated in arm ergometer test. The arm test began with subjects cranking (60 rpm) at a work rate of 25 watts, and the load was increased until exhaustion. On one testing day subjects performed an incremental arm test using the new ergometer (Fixed condition) while on the other day the subjects completed a same test using conventional ergometer (Control). HR, rating of perceived exertion (RPE) and oxygen uptake were measured at rest and every a minute. Data were analyzed using two-way ANOVA, and presented as mean  $\pm$  SD. **RESULTS and DISCUSSION:** Each subject finished the test using the new ergometer at early phase rather than that using conventional ergometer. Final workload in Fixed condition was lower than that of Control at exhaustion. No significant difference existed in HR between Fixed condition and Control. Oxygen intake 2 and 3 minutes before exhaustion in Fixed condition (2min: 20.9ml/kg/min, 3min: 23.4ml/kg/min) were significantly higher than that of Control (2min: 23.5ml/kg/min, 3min: 25.1ml/kg/min). However, there was no significant difference in peak oxygen uptake between the two tests (Fixed: 28.4ml/kg/min, Con: 29.1ml/kg/min). RPE in Fixed condition was reached 20 (very, very hard) earlier than Control. It is considered that the upper limbs reached the all-out state at an early stage, and it became difficult for exercise to continue. **Conclusion:** We could show that arm cranking test using an adjustable arm ergometer could be monitor heart rate and peak oxygen uptake with accuracy, and measure with shorter time than conventional method.

### PHYSICAL ACTIVITY DURING THE MONTH OF RAMADAAN FASTING

Noorbhai, H.

*University of Cape Town*

The month of Ramadaan incorporates the fasting of Muslims for approximately 12-18 hours of the day. Because it's a month where no drink or food can be consumed during daylight, there has been a lot of speculation regarding the abstinence of exercise and physical activity during Ramadan. There have been myths with regards to a decrease in blood levels and heart function, weakening of the immunity system and syncope when exercising during Ramadan. Research has shown that fasting for 30 consecutive days without exercise results in a regression of strength and fitness. It is imperative that Muslims maintain their exercise routine during Ramadan. Persons with chronic diseases, injuries and complications Persons with the above should take caution when exercising or doing any strenuous workloads during Ramadaan. In particular, persons with Type 1 Diabetes should not exercise at all as this can hinder their glucose levels profusely. Hypoglycemia is the most common problem for Diabetics who exercise and is usually a concern for Diabetics taking insulin or oral medication. However, persons with Type 2 Diabetes can exercise at a low-intensity, but for a maximum of 35 minutes focusing predominantly on aerobic and strength training. Persons with any injuries or complications should also exercise at a low-intensity for a maximum of 30 minutes because your bodies utilise more energy during the recovery phase of injury or pain, especially when fasting. Therefore, not enough energy and glycogen stores will be retained for more than 30 minutes when exercising. In addition, persons with chronic diseases or complications are refrained from consuming medication while fasting. It is therefore difficult to manage sugar levels, cholesterol levels and blood pressure without medication during Ramadaan. Exercise can manage these as well but the above recommendations need to be adhered to when exercising during fasting. Individuals with any chronic diseases, and in particular Diabetes and Hypertension, should consult with their physician first before implementing an exercise routine during Ramadaan. When to exercise After having a moderate exercise session, you will not adequately replenish the glycogen stores that you burnt during exercise, thus resulting in weight loss and dizziness. 90 minutes before sunset would be the ideal time to train because when breaking your fast, you can supplement the energy and glycogen stores lost when exercising. **References** 1. ### THE ROLE OF SOCIAL COMPETENCE IN THE RELATIONSHIP BETWEEN SPORT INVOLVEMENT AND MOTOR PERFORMANCE IN PREADOLESCENT CHILDREN

Hay, J.

*Brock University*

**Background:** Lifestyle habits in childhood are retained in adulthood, emphasizing the importance of developing strong physical activity habits among children. Children with motor impairments have an established activity deficit including lower sport participation (Cairney et al., 2006) while socially competent children are capable of having supportive friendships which aid in adopting active lifestyles (Jago et al, 2011). The inter-relationship of these factors is unknown and we examined the role that social competence (SC) plays in the relationship between motor performance (MP) and sport involvement (SI). **Methods:** We examined data from 1958 sixth grade children (50.2% males) from the Physical Health Activity Study Team study in Ontario, Canada. Sport involvement was determined using the Participation Questionnaire, MP was established with the short form of the Bruininks-Oseretsky Test of Motor Proficiency (BOTMP), and SC using Harter's Self-Perception Scale. Multiple regression models were created by gender adjusting for BMI and SES. Odds ratios (OR) were created with z scores (<0 vs.  $\geq$ 0) used as SI and SC cut offs with BOTMP quartiles as high or low MP (reference= 3rd/4th BOTMP quartile with Harter z

score  $\geq 0$ ). Results: MP and SC are both independent predictors of SI. Children with low MP and low SC were at significantly greater risk of low SI (OR<sub>males(m)</sub>=2.8198; OR<sub>females(f)</sub>=2.4138). Children with low MP and high SC (OR<sub>m</sub>=1.0462; OR<sub>f</sub>=1.4104), or high MP and low SC (OR<sub>m</sub>=1.1226; OR<sub>f</sub>=0.9774) demonstrated no significant risk of low SI. Conclusion: Social competence plays an important role in sport participation during childhood and appears to ameliorate the risk of inactivity associated with low MP. Higher SC in children with low MP removes the risk of low sport participation for both genders. In the development of sport promotion campaigns the role of SC in enhancing sport participation should be considered. This is particularly true for children with poor MP as SC is an important contributing factor in their sport participation. References: Cairney, J., Hay, J., Faight, B.E., Corna, L.M. & Flouris, A.D. Introduction The Paralympic sport has been competitiveness every year, being crucial to evaluate psychobiological aspects of Paralympic athletes. The aim of this study was to assess the psychobiological aspects of Brazilian Paralympic athletes before the London 2012 Paralympic Games. Methods 40 athletes (31 men and 9 women) participants of athletics were evaluated. The questionnaires were used to assess anxiety, mood, sleep and sleepiness, respectively: IDATE, POMS, BDI, Epworth Sleepiness Scale. Results 62% of the athletes had medium level of anxiety-trace -state and 80% of the athletes showed no propensity to depression. In the humor assessment it was found: tension-anxiety  $2.1 \pm 3.8$ ; depression  $3.3 \pm 7.3$ ; anger-hostility  $5.0 \pm 8.2$ ; vigor  $21.5 \pm 5.5$ ; fatigue  $4.3 \pm 5.0$ ; mental confusion  $-0.4 \pm 3.7$ ; total mood disturbance  $-7.3 \pm 28.0$ . Considering sleep quality, 62.5% of the athletes had good sleep, 67.5% presented sleep latency < 20 minutes and 92.5% had sleep efficiency > 85%. Mean total sleep time was  $7.3 \pm 1.2$  hours, 52.5% presented excessive daytime sleepiness and 46.3% were dissatisfied with their own sleep. Sleep latency was higher in athletes with poor sleep quality ( $p = 0.000$ ), total sleep time was shorter in athletes with poor sleep ( $p = 0.005$ ), sleep efficiency was lower in athletes with poor sleep ( $p = 0.000$ ) and total sleep time was shorter for those who had sleep efficiency < 85% ( $p = 0.01$ ). Discussion Most athletes had medium level of anxiety, which according to Halvari and Gjesme (1995) this is associated with better performance during a competition. The athletes showed positive mood states profile and this can lead to a better performance during competition (Bertollo et al., 2009). The athletes did not show propensity to depression, possibly due to the absence of injury (Smith and Milliner, 1994) or dissatisfaction (Wiese and Weiss, 1987) during the period of evaluation. To Walker and Stickgold (2005) sleep is important, if in the adequate quantity and quality, to ensure good performance, cognitive and psychomotor tasks when needed. The control of psychobiological aspects can be decisive to achieve better results in competition. The work of a multidisciplinary team can benefit athletic performance of Paralympic athletes. ### PEAK FAT OXIDATION DURING PHYSICAL ACTIVITIES OF DAILY LIVING – A COMPARISON OF NORMAL WEIGHT AND OVERWEIGHT ADULTS

Grams, L.1, Kück, M.1, Tegtbur, U.1, Nelius, A.K.1, Kerling, A.1

Medical School Hannover

Introduction: Physical inactivity and obesity are risk factors for numerous diseases and strategies to accomplish activity recommendations are needed. These suggest 30 minutes of physical activity per day in moderate (3-6 METs) intensity on most days of the week (Haskell et al., 2007) and can also be reached with exercise bouts throughout a normal day followed by an increase of energy expenditure (EE) and fat loss (Jeppesen and Kiens, 2012). In order to benefit from exercise, it is important from what source the body takes the energy. Fat oxidation rises until a specific maximum at moderate intensity, with further intensity fat oxidation drops again (Jeukendrup and Wallis, 2005). This study aims to find out if healthy adults can reach high fat oxidation up to a maximum (FATpeak) in physical activities of daily living (PADL). Methods: 33 subjects were divided into a normal weight (NW:  $n = 21$ , body fat  $21.6 \pm 6.1\%$ ,  $52 \pm 7$  yrs) and overweight (OW:  $n = 12$ , body fat  $33.1 \pm 6.5\%$ ,  $47 \pm 9$  yrs) group and matched according to gender, age, fat free mass (FFM) and maximal aerobic capacity (VO<sub>2</sub>max). Six PADLs, including REE, PC work, vacuuming, walking, stair stepping and cycling, were tested under controlled conditions using a portable spirometric system. Body composition was measured with Bio Impedance Analysis. Physical activity under free-living conditions was detected with a multi sensor device. Results: Both NW and OW reached FATpeak (NW: Confidence interval 95% 42.56 – 56.37% of VO<sub>2</sub>max, OW: 43.79 – 53.22% of VO<sub>2</sub>max), but showed no significant difference. In all activities except for the last activity with the highest intensity the NW consumed more carbohydrates than the OW. Multiple regressions with FATpeak as dependent variable show that VO<sub>2</sub>max, FFM and physical activity explain 75% of the variance. Conclusion: Results prove that FATpeak can be reached during physical activities of daily living under controlled conditions. Thus behavioral changes that include increased physical activity throughout the day can result in high fat oxidation rates. Furthermore activities like walking and stair stepping can help reaching physical activity recommendations. References: Haskell WL, et al. **THE HEALTH COACH PROJECT - AN INTERVENTIONAL STUDY ON HEALTH PROMOTION IN ELEMENTARY SCHOOL**

Hedström, P., Augustsson, C., Patriksson, G.

*Department of Health Sciences*

Introduction Young school children in Sweden spend today less time taking part in physical activities, compared to what they did 15-20 years ago. Physical activity is a major health component, which can make children maintain or increase their health. Given this background new efforts to meet these inactivity problems among young children are very important. The purpose of this study is to analyze and describe a longitudinal (two years) health coach intervention, focusing on the effects and experiences of expanded physical activities in an elementary school, managed by a health coach. Methods A health coach has been employed on a part time basis in an elementary school, to increase young children's (10-12 years old) physical activity. The research team planned the health coach's activities which were based on earlier research and the theoretical model; Youth Physical Activity Promotion Model (YPAPM) (Welk, 1999). In order to make comparisons, we also selected two control schools where no health coach is employed and no health promotion activities are conducted. In the study, quantitative data has been collected on two occasions over a period of two years (2011-2013: pupils survey n=120, parents survey n=40, pupils pedometers, n=120). In addition to the quantitative data, a qualitative data collection has also been conducted on two occasions (2011: pupils & teachers interview n=30; 2013: pupils, teachers & health coach interview n=32). Results Baseline data (2011) has been collected, and the last data is being gathered under February, 2013. Preliminary analysis has indicated that the implemented health promotion activities, managed by the health coach, attract even those children who usually do not like the PE classes. More data will be analyzed and some central variables from the final data collection will be presented in comparison to baseline data. Discussion Earlier research has shown that a minimum of 60 minutes a day of physical activity are needed for young children to develop good health (Strong, et al. 2005). The regular school curriculum in Sweden is not enough to meet this conditions, and therefore it's of great importance to find new ways to activate all children during the school day. This project has investigated if and to what extent a health coach, as an extra resource in school, can make a difference concerning increased physical activity for young school children. **15:00 - 16:00****Mini-Orals****PP-PM25 Neuromuscular Physiology [PH] 3****THE USE OF FAR INFRARED EMITTING FABRIC RESULTS IN BETTER NEUROMUSCULAR PERFORMANCE**

Souza, T.M.F., Gáspari, A.F., Guimarães, P.S., Felipe, T.I., Rodrigues, G.F.C., Souza, G.V., Chacon-Mikahil, M.P.T., Moraes, A.C.

*University of Campinas*

Introduction: The fabric made from polyamide yarn far infrared emitting (FIRE) to issue far infrared ray when it is heated (e.g. exercise condition). This far infrared ray promotes an increase in mobility of body fluids, breaking the clusters of water molecules and facilitating the clearance of nutrients and metabolic products. This could reduce the oxidative stress, fatigue and improve the performance through the increase in offer of substrate, possibly including ATP concentration, as removal of active muscle metabolic waste. Aim: To assessment the effect of FIRE garment on muscular performance in individuals submitted to muscle damage protocol on isokinetic dynamometer. Methods: Twenty-one volunteers (23.83 ± 3.19 years, 73.60 ± 11.37 kg and 1.75 ± 0.07 m), performed two maximal eccentric exercise bouts on an isokinetic dynamometer composed by 10 sets of 15 repetitions to 210°.s<sup>-1</sup> in synchronism with contact electromyography, using randomly the FIRE garment and Placebo (double blind). Were measured the knee extensor muscle Peak of Torque and Total Work compared between groups (FIRE and Placebo) by repeated measures ANOVA followed by Tukey's Post Hoc test. Results: In the measured variables it were found differences between garments in Peak of Torque (p = 0.035) and Total Work (J) in sets 1 (Placebo = 1966.0 ± 671.4; FIRE = 2275.4 ± 919.9; p = 0.028), 2 (Placebo = 1954.4 ± 779.9; FIRE = 2380.5 ± 747.1; p = 0.000) and 3 (Placebo = 2082.2 ± 845.4; FIRE = 2507.2 ± 613.1; p = 0.000). Discussion: Greater differences between garments in Total Work were found in the first sets of the protocol, when the fatigue process has lesser effect on performance. This finding show a possible action of far infrared on muscular tissue, with no relation to the increase in mobility of body fluids or reduction of acidosis (YU et al., 2006; LEUNG et al., 2011), but exerting an influence on the neuromuscular mechanisms determinants to performance (BENEDICENTI et al., 2008). Conclusion: The FIRE garment was efficient to improve the neuromuscular performance, with better results in eccentric Peak of Torque and Total Work. **ACHILLES TENDON LENGTH EVALUATED BY A TWO-DIMENSIONAL STRAIGHT LINE MODEL IS SERIOUSLY ERRONEOUS: USEFULNESS OF A THREE-DIMENSIONAL CURVED LINE MODEL**

Fukutani, A.1, Ema, R.1, Hirata, K.1, Hashizume, S.1, Wakahara, T.1, Kanehisa, H.2, Kawakami, Y.1

*1: Waseda university (Saitama), 2: National Institute of Fitness and Sports in Kanoya (Kagoshima)*

Introduction The Achilles tendon has a key role in the performance of human movements because it acts as a spring by storing and releasing elastic energy. In a previous study (Hoffrén et al. 2012), the Achilles tendon length change during an ankle joint movement was evaluated as the straight distance between the proximal and distal ends of the Achilles tendon in a two-dimensional (2D) plane in a three-dimensional (3D) space. However, this approach inevitably contains errors in two ways: neglecting the curvature and underestimation caused by the projection from 3D to 2D plane. The purpose of this study was to compare the Achilles tendon length change calculated by 2D straight line model (2D straight) and by 3D curve line model (3D curve). Methods Eight subjects were recruited. After confirming the location of the Achilles tendon from ultrasonographic images, markers were attached on the skin over the Achilles tendon and 3D

coordinates of markers were obtained from video camera images. The Achilles tendon length evaluated by 3D curve was expressed as the sum of distances between adjacent markers. The Achilles tendon length evaluated by 2D straight was obtained by projecting the 3D coordinates of markers onto the sagittal plane of the lower leg and taking the distance between markers attached on both the ends of the Achilles tendon. The Achilles tendon length was determined at dorsiflexion 20° (DF20) and at plantar flexion 20° (PF20), and its length change was calculated by both methods. Results The Achilles tendon length was 182.6 ± 18.6 mm at DF20 and 174.5 ± 17.2 mm at PF20 in 2D straight, and 183.7 ± 18.3 mm at DF20 and 179.6 ± 17.7 mm at PF20 in 3D curve. The extent of Achilles tendon length change calculated in 2D straight (8.1 ± 3.2 mm) was significantly larger than that calculated in 3D curve (4.1 ± 1.5 mm) ( $p < 0.05$ ). Discussion Although the Achilles tendon length was almost similar between the two methods at DF20, its length at PF20 was shorter in 2D straight than in 3D curve. This difference between two methods in PF20 caused the overestimation of Achilles tendon length change in 2D straight compared to that in 3D curve. The measurement error of approximately 4 mm in 2D straight clearly has a substantial effect in the evaluation of the Achilles tendon length change conventionally done in previous studies (e.g., 10-15 mm, Hoffrén et al. 2012). The current results call for a need to determine the Achilles tendon length by 3D curve. References Hoffrén M, Ishikawa M, Avela J, Komi PV (2012). Eur J Appl Physiol, 112(12), 4035-4043.

### CHANGES OF H-REFLEX DURING THE MENSTRUAL CYCLE PHASE

Murata, M.1, Yamaguchi, H.2, Seki, K.3, Takahara, T.4, Onodera, S.5

1:GRADUATE SCHOOL, KAWASAKI UNIV OF MEDICAL WELFARE, 2:KIBI INTERNATIONAL UNIV, 3:UNIV OF MARLETING AND DISTRIBUTION SCIENCES, 4:UNIV OF HUMAN ARTS AND SCIENCES, 5:KAWASAKI UNIV OF MEDICAL WELFARE

**Introduction:**The menstrual cycle phase is phenomenon in woman-specific. A negative association between the menstrual cycle phase and muscle contraction. Muscle contraction was relationship the activity on spinal  $\alpha$ -motoneuron pool, but it was without relation to the menstrual cycle phase. The purpose of this study was to investigate the activity on spinal  $\alpha$ -motoneuron pool excitability was dependent on the menstrual cycle phase.**Methods:**The subject was a healthy Japanese female (age: 25 years) who had regular menstrual cycle phase. Three menstrual cycle phases were defined as menstrual phase (M phase), follicular phase (F phase) and luteal phase (L phase) following the changes in the basal body temperature during a month. The H-reflex was measured twice each phase. Measurement position was in prone posture. H-reflex was elicited in the SOL from the right leg by electrical stimulation with single square pulse of 1ms duration to the tibial nerve in the popliteal fossa. EMG was recorded on the middle surface of the SOL using disposable bipolar electrodes. Mmax was defined as the M-wave at the time of verifying the peak out in amplitude with the increases of stimulus intensity. All the signals were digitized the AD converter with a 10-kHz sampling frequency. The amplitude of maximal H-wave and M-wave potential was measured by obtaining H-reflex / M-wave recruitment curve and calculating Hmax / Mmax. Results & Discussion: The subject of each phase in Hmax / Mmax was showed similar value. The men of Hmax / Mmax were showed similar value in different measurement day. Thus, the Hmax/Mmax was to consider of effect sex differences. However, recruitment curve of pattern were showed the pattern differ by menstrual cycle phase. M phase was showed the Hmax in near the M-wave threshold value and then showed a steep decline of the H-wave. Meanwhile, F phase and L phase was showed the Hmax in late the M-wave threshold value. The men of recruitment curve were no difference pattern and amplitude of changes. From these, the activity on spinal  $\alpha$ -motoneuron pool was to change by menstrual cycle phase.

### RESTING PERIODS OF 1-MIN ARE TOO LONG TO INDUCE A DECREMENT OF THE MEDIAN FREQUENCY DURING AN INTERMITTENT FATIGUE PROTOCOL

Marina, M., Torrado, P., Busquets, A., Angulo-Barroso, R.

INEFC, GRCE-UB (Barcelona, Spain)

**Introduction:** Using superficial EMG, it is usual to observe how the power spectrum is displaced toward lower frequencies when muscles become fatigued (De Luca, 1997). Nevertheless, the distinct results reported in the literature could be explained by the combination of different force intensities, recovery and contraction times, muscle groups, and other non-controlled or non-reported factors (Bystrom and Kilbom, 1990). The aim of this study is to check how much recovery time is too long to induce a decrement of the median frequency during an intermittent fatigue protocol (IFP). **Methods:** 21 road racing motorcycle riders aged 29.1 ± 8.0 years performed an IFP exerting forces of different intensities respect to the maximal voluntary contraction (MVC) against a brake lever attached to a gauge connected to the Muscle-Lab system 4000e (Ergotest Innovation). The sequence of the IFP, as well as the structure that replicated the overall position when the rider is piloting a racing motorcycle coincides with Marina et al. study (2012). A ME6000 electromyography system (Mega Electronics, Kuopio, Finland) was used to register flexor digitorum superficialis (FS) and carpi radialis (CR) median frequency (MF). The MF was normalized with the basal measure (NMF). The NMFs measured from the 30% MVCs (NMF30), preceded by 5 s recovery period, were compared to the ones obtained from the 50% MVC (NMF50), preceded by 1 min rest. A 2x2x2 Anova of repeated measures was used to compare the NMF values between the beginning and the end of the IFP, and to study potential interactions with the two muscles (Carpi radialis -CR- and flexor superficialis digitorum -FS-) and the two intensities that are led by very distant recovery periods (5 s rest for NMF30 and 1 min for NMF50). Results Whereas at the beginning of the IFP we observed bigger CR' NMF30 than CR' NMF50, the opposite was observed at the end of the IFP. In both muscles, NMF30 decreased significantly during the IFP whereas the opposite or maintenance was observed with NMF50 after 1 min rest. Conclusion Our results suggest that 1-min-resting period can be enough to avoid fatigue from the previous contractions using voluntary contractions and IFP. This suggestion is in accordance to previous studies (Kleine et al., 2000; Kamimura and Ikuta, 2001). References: Bystrom, SE., Kilbom, A. (1990). Eur J Appl Physiol 60, 457-466. De Luca, CJ. (1997). ### CORRELATION BETWEEN HANDGRIP STRENGTH AND PARKINSON DISEASE RELATED DISABILITY AND IMPAIRMENT.

Silva, M., Vieira, A., Santos, T., Vidal, S., Silva, M., Tolentino, G., Clael, S., Miranda, A., Sousa, J., Oliveira, R.

Univesidade de Brasilia

**Introduction:** Parkinson Disease is a neurodegenerative condition characterized by substantia nigra dopaminergic neurons death (BRAAK et al., 2003). Searching for a better clinical and functional evaluation of the PD population, it was developed the Unified Parkinson Disease Rating Scale (UPDRS) (MOVEMENT DISORDERS SOCIETY, 2003). On the other hand, this instrument doesn't contemplate the mus-

cular strength on a specific way. A literature review by Cano-de-La-Cuerda et al. (2003) showed that this physical valence is deficient in PD subjects. Thus, instruments that measure muscular strength are necessary on a comprehensive approach. Purpose: To correlate handgrip strength and PD-related disability and impairment. Methods: Activities of daily living and motor exam was evaluated by UPDRS sections II and III, respectively. Handgrip strength was evaluated by a Jamar® hand hydraulic dynamometer. Variable correlation was made through Pearson coefficients of the level of significance set at  $p \leq 0.05$ . Results: Inverse correlations were founded between handgrip strength and UPDRS 2 ( $r = -0.7$ ;  $p = 0.009$ ) and UPDRS 3 ( $r = -0.72$ ;  $p = 0.01$ ). Discussion: The inverse proportional correlation between handgrip strength and II and III UPDRS sections happened by the fact that handgrip strength is a global motor aspect, as activities of daily living and main motor exam tasks. So, the handgrip strength shows to be an efficient and comprehensive tool for the clinical and functional characterization of individual with PD.

## MUSCULAR POWER IS NOT EFFECT DURING MENSTRUAL CYCLE PHASES

Mascarin, N.

*Universidade Federal de São Paulo*

**Introduction** Knowledge about acute decreases in strength during menstrual cycle remains equivocal. Besides variation of muscles strength, others studies also have been done to investigate variation of sprint capacity, aerobic capacity and aerobic endurance in any specific menstrual cycle phase. However, there are no data about muscular power. Therefore, the aim of this study was to verify the effects of menstrual cycle phase (MCP) upon lower limb isokinetic power and vertical jump performance in female soccer players. **Methods** Seventeen female soccer players athletes with regular menstrual cycles volunteered to participate in the study (age:  $22.35 \pm 6.42$ ; height  $165.3 \pm 7.8$ ; weight:  $61.8 \pm 7.7$ ). The phases of the menstrual cycle (luteal and follicular), was determined by monitoring for 3 consecutive months. Isokinetic muscular test, squat jump test and countermovement jump test were measured in 2 consecutive menstrual cycles in the follicular phase and in the luteal phase. Knee flexors and extensors isokinetic power for both lower limbs were measured at  $300^\circ/s$ . Results Mean values for dominant and non dominant isokinetic flexors power were not different from luteal and follicular phase ( $p = 0.89$  and  $p = 0.58$ , respectively). Dominant and non dominant isokinetic extensors power were not different too. Both vertical jump tests, also failed to show significant difference between menstrual cycle phases ( $p = 0.64$  and  $p = 0.61$  for squat jump and countermovement jump, respectively). **Discussion** Results from these studies showed no difference in muscular power between luteal and follicular menstrual cycle phase, neither in isokinetic muscular power, nor in jump tests that depends on muscular power. These results suggested that the changes in female steroid hormones during their menstrual cycle did not affect muscular power. However, these findings were limited to isokinetic power evaluation and jump test measured at 2 different times, and further research examining these variables at multiple times and using other measures of neuromuscular function is needed. **References** Montgomery MM, Shultz SJ, *Journal of Athletic Training* 2010;45 (6):586–593. ## INFLUENCE OF AGING ON FOOT GRIP FORCE

Yamauchi, J.

*Tokyo Metropolitan University*

**[Introduction]** A deterioration of skeletal muscle function is the main consequence of aging. The impairment of neuromuscular function in lower limbs may affect functional movement of daily living and cause a fall after stumbling in elderly individuals (Yamauchi et al. 2009, 2010). Because foot bears body weight as it carry the body through daily activities, it plays an integrative role in controlling the posture and movements. There are numerous studies on muscle functions of lower limbs; however, no studies have demonstrated how foot grip force affects with aging. Therefore, the present study was to investigate the influence of aging on maximum isometric foot grip force generation. **[Methods]** Nineteen healthy young ( $21.1 \pm 1.8$  years old) and 18 healthy elderly ( $66.3 \pm 6.9$  years old) individuals were measured the maximum foot grip force on the dynamometer. For the measurement of maximum isometric foot grip force, subjects exerted force with maximum effort for ~3 seconds on a foot grip dynamometer in either sitting or standing position. Measurements were repeated three times with at least one-minute rest period between bouts, and the highest value among the measurements was used. **[Results and Discussion]** Foot grip forces in the sitting position was significantly lower in elderly than young individuals; however, its in the standing position was not significantly different between elderly and young individuals. The present results indicate that the ability to generate foot grip force in standing position was somehow compensated to maintain higher force in elderly individuals. **[References]** Yamauchi J et al. *Journal of Biomechanics* 42: 2151–2157, 2009. ## SEX DIFFERENCES IN MUSCULAR AND NEUROMUSCULAR FUNCTION FOLLOWING A DOWNHILL RUNNING TASK

De Ste Croix, M.1, Elnagar, Y.O.1, Iga, J.2, James, D.1

*1: University Of Gloucestershire; 2: Wolverhampton Wanderers Football Club*

**Introduction** Increased relative risk of non-contact anterior cruciate ligament (ACL) injury has been attributed to numerous biomechanical, anatomical and neuromuscular factors with females 4 times more likely to suffer a non-contact ACL injury compared with males. The aim of this study was to examine the effects of a fatigue task on sex differences of the functional Hamstring / Quadriceps ratio (FH/Q ratio) and electromechanical (EMD). **Methods** One hundred and ten healthy males ( $n = 55$  age  $29 \pm 5$  yrs) and females ( $n = 55$  age  $27 \pm 6$  yrs) were recruited from the university population. Isokinetic concentric (CON) and eccentric (ECC) torque of the hamstrings and quadriceps were determined in a prone position at 60, 120 and  $240^\circ/s$  with the hip flexed at  $10^\circ$ . Range of movement of the knee joint was  $90^\circ$  with  $0^\circ$  determined as full volitional extension. The FH/Q ratio was determined at 15, 30,  $45^\circ$  and where peak torque (PT) was achieved for each movement velocity. Surface electromyography was recorded from the semitendinosus (ST), semimembranosus (SM) and biceps femoris (BF) of the dominant limb using an 8-channel DelSys EMG telemetry system during the eccentric actions. The electromechanical delay (EMD) was determined as the time delay between the onset of muscle activation (change in activation of  $+15 \mu V$ ) and onset of torque production (9.6 Nm) according to the procedures described by Zhou et al (1995). Each participant performed a 40 min intermittent downhill running protocol consisting of  $5 \times 8$  min bouts on a  $-10\%$  decline at 80% Heart rate max, with 2 min standing rest between each bout. **Results** Irrespective of sex, joint angle or angular velocity, the FH/Q ratio was significantly lower and EMD of hamstring muscles was significantly longer post-fatigue compared to pre-fatigue. Significant interactions between sex and time for the FH/Q ratio and EMD of hamstring muscles were found. The interactions showed a significantly lower FH/Q ratio and significantly longer EMD post fatigue in

females compared to males. Discussion These data suggest that functional stability of the knee is reduced when fatigue is present as both muscular (FH/Q) and neuromuscular (EMD) function is impaired. The impact of fatigue is significantly greater in females compared to males and this may in part contribute to the greater relative risk of non-contact knee injury in females. These data reinforce the need for appropriate pre-habilitation programmes for both males and females to reduce the risk of injury. However, most current conditioning programmes for injury prevention do not focus on fatigue resistance to reduce the impairment to muscular and neuromuscular function and thus there is a need to re-develop injury prevention programmes to focus conditioning on fatigue resistance.

### SEX-RELATED CHANGES IN FORCE AND MUSCULOTENDINOUS ARCHITECTURE FOLLOWING PASSIVE STRETCH

Simpson, C.L., Arefin, S., Smart, R., Harwood, B., Jakobi, J.M.

*University of British Columbia*

**INTRODUCTION** Strength is contingent upon the effective transfer of force from the contractile element of skeletal muscle to passive tendinous structures. Men are typically stronger than women in part because of larger muscle mass, cross-sectional area, and shorter, less compliant tendons (Kubo et al., 2003; Bryant et al. 2008). Stretch may minimize sex-related force differences by attenuating musculotendinous compliance in women. The purpose of this study was to determine whether passive stretch differentially affects maximal voluntary force (MVC) production and musculotendinous architecture in men and women. It was hypothesized that stretch would lessen slack length of the musculotendinous unit in women reducing sex-related strength differences. **METHODS** A 5s plantar flexion MVC was performed prior to, and following, a two minute maximal dorsiflexion stretch. The ankle was positioned at 15° plantar flexion in a custom foot plate attached to the Biodex Dynamometer for each MVC. Passive stretch was achieved by rotating the ankle joint to each subject's maximal stretch (~30° dorsiflexion). An ultrasound probe (GE Logiq E9) was fastened over the plantar flexors at the musculotendinous junction of the medial gastrocnemius and the Achilles tendon. Supramaximal square wave stimuli (200µs pulse width, 66-217mA) were administered prior to, during, and immediately after each MVC. Surface EMG of the agonists and antagonist were recorded. **RESULTS** Voluntary activation (98% vs. 95%) and strength ( $\Delta$ 33%) were higher in men than women and did not change following stretch. Normalized surface EMG of the MVC for the agonists (%M-wave) and antagonist (%MVC) did not differ between men and women. In women ( $\Delta$ 33%), but not men, tendon length increased following stretch. Relaxed fibre length was greater in men than women post-stretch (30%). **DISCUSSION** Contrary to the hypothesis, passive stretch did not affect the difference in strength between men and women. Greater tendon length in women and longer relaxed fibre lengths in men suggest that the absorption of passive stretch was isolated to contractile tissue in men and non-contractile tissue in women. Results demonstrate changes in muscle and tendon following passive stretch are sex-specific and may function to maintain maximal isometric force.

### THE INFLUENCE OF AGE AND MATURATION ON RELATIVE LEG STIFFNESS IN FEMALE YOUTH SOCCER PLAYERS

De Ste Croix, M.1, Priestley, A.1, Deighan, M.1, Lloyd, R.2, Oliver, J.2

*1: University Of Gloucestershire; 2: Cardiff Metropolitan University*

**Introduction** Leg stiffness has been associated with both jumping and running performance in youth athletes as well as associated with injury risk/prevention. Data from boys suggests that leg stiffness increases with age and maturation, however, there are no comparative data on girls. Given the relative increase in ACL risk in females compared to males understanding the age and maturation related changes in leg stiffness is important. The aim of this study was to determine the intra and intersession reliability of determining leg stiffness using a mobile contact mat with female youths, and to explore the influence of maturation on leg stiffness. **Methods** 32 healthy female youth players from 3 age groups (U13, U15 U17y) attached to an FA women's super league football club were recruited for this study. Participants were split into three maturation groups based on estimated maturity offset: Group 1:  $-0.27 \pm 0.56$  (n=11), Group 2:  $1.38 \pm 0.64$  (n=11) and Group 3:  $3.14 \pm 0.49$  (n=10). Participants completed a familiarisation and two testing sessions, requiring four sets of 20 sub-maximal hops at 2.5Hz. Relative leg stiffness (normalised for body mass and leg length) was determined on each test occasion. Reliability statistics included independent sample t-tests, intraclass correlation coefficient and coefficient of variation (CV). To explore maturation effects, a group one-way repeated measures analysis of variance (ANOVA) was conducted. **Results** The contact mat was found to be a reliable method to determine leg stiffness in female youth both between control trials and within trials (CV = 9.5%). A significant main effect for maturation was observed with group 3 demonstrating significantly lower relative leg stiffness than either group 1 or 2 ( $36.6 \pm 6.6$  Vs  $44.6 \pm 5.5$  and  $46.4 \pm 8.8$  respectively). There were no significant differences in leg stiffness between group 1 and 2. **Discussion** The mobile contact mat was deemed a reliable measure of relative leg stiffness in youth female footballers both within and between test sessions. In contrast to data from male youths we did not find a significant increase in leg stiffness with maturation. Our data identified a lower leg stiffness in more mature girls. This reduced stiffness may be due to traditional football training de-sensitising supra-spinal feed forward input and short latency stretch reflexes that are required to regulate greater levels of leg stiffness. However further research is require including non-training control groups to explore the influence of traditional football training on relative leg stiffness.

### POST ACTIVATION POTENTIATION OF THE PLANTAR FLEXORS AT DIFFERENT KNEE ANGLES

Eklom, M.M., Gago, P.R.

*Swedish School of Sport and Health Sciences*

**Introduction** Post activation potentiation refers to the enhanced contractile muscle properties seen after a conditioning maximal voluntary muscle action (MVC) (1). In tasks such as sprint start and jumping, propulsive force is achieved by both the slow twitch Soleus muscle and the fast twitch Gastrocnemius. The contribution of each muscle to plantar flexor torque varies with knee angle (2). To understand how post activation potentiation affects performance in such tasks post activation potentiation of plantar flexors should be compared between different knee joint angles. **Purpose** To investigate differences in post activation potentiation of the plantar flexors between an extended and a flexed knee position. **Methods** Nine power athletes participated in the study. Twitches were evoked by supramaximal stimulation of the tibial nerve in the popliteal fossa before and repeatedly after a 6s conditioning plantar flexor MVC, with the subject lying first prone with an extended knee and then (after 15 min rest) in four point kneeling position, with the knees and hips flexed at 90 degrees. **Results** At 5s after MVC, PT was potentiated by (mean $\pm$ SD)  $67 \pm 18\%$  in the straight versus  $40 \pm 24\%$  in the flexed knee. At 5s after MVC, RTD was potentiated by  $94 \pm 26\%$  in the straight versus  $64 \pm 41\%$  in the flexed knee position. PT and RTD remained potentiated for an equal duration irrespective of knee position. At 5s after MVC, HRT was decreased by  $19 \pm 5.5\%$  in the flexed knee position but increased by  $4 \pm 24.4\%$  in the straight knee position. **Discussion** The finding that RT and RTD were potentiated more in the extended knee than the flexed knee

position suggests that post activation potentiation likely has greater influence on RTD and strength of the plantar flexors in tasks where the knee is extended. Since the duration of potentiation was similar between position, a few minutes of rest after a conditioning MVC the plantar flexors are equally potentiated in both positions. Furthermore, the findings lend support to the notion that post activation potentiation enhances performance of fast twitch muscles more than slow twitch muscles, since in the flexed knee position there is lesser involvement of the gastrocnemii muscles. This study was financially supported by The Swedish Center for Sports Research. ## FACTORS INFLUENCING MAXIMUM ROM AT THE ANKLE JOINT: DIFFERENT RESULTS FROM CROSS-SECTIONAL VS. LONGITUDINAL STUDIES

Blazevich, A.J.1, Waugh, C.M.2, Cannavan, D.3, Fath, F.2, Miller, S.C.4, Kay, A.D.5

*1Edith Cowan Univ. (Aus), 2Brunel Univ. (UK), 3Seattle Pacific Univ. (USA), 4Middlesex Univ. (UK), 5Univ. of Northampton (UK).*

**Introduction** The ability to move through large joint ranges of motion (ROM) is important for the successful performance of activities of daily living and athletic tasks, however the factors affecting ROM are not currently known. Two common approaches to studying these factors are to: (1) compare neuromuscular differences between 'flexible' and 'inflexible' subjects, and (2) determine which neuromuscular factors change temporally with ROM. We have compared the results obtained by these two approaches. **Methods** In study one, 21 healthy men were divided into two groups (flexible, n=11; inflexible, n=10) based on their maximum dorsiflexion ROM (median = 46 deg) measured on an isokinetic dynamometer with the knee straight. Muscle and tendon lengths, passive muscle and tendon stiffness, fascicle length, angle, strain (lengthening) and rotation, peak passive torque (i.e. stretch tolerance), gastrocnemius and soleus EMG records, and H wave amplitudes (maximum and at 10% Mmax) were measured using dual-transducer ultrasound, isokinetic dynamometry, EMG and tibial nerve stimulation procedures. In study two, these measures were obtained in 12 subjects who performed twice daily straight-leg plantarflexion stretches for 3 weeks and 9 subjects who acted as non-stretching controls. Five additional subjects were tested for fascicle length, strain and rotation only, in order to improve statistical power. **Results** In study one, subjects with a greater ROM (flexible) tolerated a greater peak passive torque (48.6%) and exhibited greater fascicle rotation during stretch to 30 deg dorsiflexion (9.7 vs. 5.9%) than inflexible subjects; there was a greater tendon length at stretch termination only due to the greater loads tolerated. There were no differences in H-reflex magnitudes, EMG maximum amplitudes or EMG at stretch termination, but there was a moderate correlation between the angle of EMG onset and maximum ROM ( $r=0.60$ ,  $p<0.05$ ). There were no other between-group differences. In study two, subjects who performed stretching training showed an increased peak passive torque (28.1%), greater fascicle strain measured to 30 deg (27.2%), lower muscle stiffness (-18.0%) without change in tendon stiffness, and a depression of the H reflex measured in plantarflexed and neutral joint positions only. **Discussion** In both studies, the ability to tolerate stretch appeared to be a key factor influencing maximum ROM. However, the later onset of EMG and greater fascicle rotation appeared to be characteristics of more flexible subjects, whilst reductions in fascicle and muscle stiffness were associated with improvements in flexibility with training. Thus, the neuromuscular factors that contribute to between-subject variability in flexibility are largely different to those that are associated with improvements in flexibility with training.

## THE TRUNK MUSCLE STRENGTH AND MUSCLE VOLUME OF BALLET DANCERS

Kuno-Mizumura, M.1, Yokohata, E.1, Kumagawa, D.2, Tanaka, S.3, Takahashi, Y.3, Tsunoda, N.3, Ikegawa, S.4

*1.Ochanomizu University 2.JISS 3.Kokushikan University 4.Jumonji University*

**Introduction** Previous studies have indicated that better balance control in dancers than in control groups (Mouchnino et al., 1992, Crottes et al., 1996, Golomer et al., 1997). However, functional characteristics of trunk muscle for dancers have not been fully elucidated. So the purpose of this study was to investigate isometric isokinetic muscle strength during trunk flexion and extension and their relations to trunk muscle volume for Japanese female ballet dancers. **Methods** Subjects were seven female dancers with ballet training more than ten years as the dance students group and four professional ballet dancers as the professional dance group and nine female university students as the control group. Control subjects had no experience of any dance training and no regular exercise in past three years. This study was divided into two testing. For evaluating muscle volume of the trunk, MRI images were prepared using a 1.5 T MRI scanner (TOSHIBA EXCELART Vantage). Contiguous transverse images with 1.0cm slice thickness were obtained from the seventh thoracic vertebra to the hip joint. Cross sectional area were digitized for psoas major muscle, abdominal rectus muscle, erector spinae muscle, external oblique muscle, and quadratus lumborum muscle. For evaluating isometric and isokinetic muscle strength during trunk flexion and extension, subjects performed trunk flexion and extension on the isokinetic dynamometer (Biodex) at 60 deg./sec, 120deg./sec and 180deg./sec. **Results** There was no significant difference in all trunk muscles among three groups. The peak torque for trunk extension at 60 and 180deg./sec were significantly higher in the professional dance group compared to the controls. Significant higher peak torques were found in both dance groups during trunk flexion at 120 and 180deg./sec compared to the controls. Professional dance group showed significant greater torque/CSA compared to the control during trunk extension at 180deg./sec. For trunk flexion, significant higher peak torque/CSA was found at 120 and 180deg./sec. **Discussion** From the results of this study, it is indicated that ballet dancers would have high strength of the trunk muscles especially for faster isokinetic conditions, although there was no significant difference in muscle volume of the trunk by MRI images. It is also speculated that greater torque of trunk muscle might induced by physiological factors.

## IDENTIFICATION OF MULTI-DIRECTIONAL POSTURAL CONTROL IN HUMANS

Azusa, K., Shota, H., Motoki, K.

*Human and environmental studies, Kyoto-university*

**Introduction** Human bipedal standing is inherently unstable. So even during quiet standing, we must constantly regulate multiple joint torques by controlling a large number of muscles coordinately to keep the body stability. To achieve such complex bipedal standing effectively, it is thought that muscle synergies, which are modular organization formed by muscles activated in synchrony, are contribute to postural control (Torres-Oviedo and Ting, 2007). In this study, we investigated multi-directional postural control from the viewpoint of muscle synergies. **Methods** Five healthy males participated in this study. The subject stood on a force plate with four postural configurations: normal stance, narrow stance, and parallel stance (right foot anterior and left foot anterior). During the tasks, the foot center of pressure (COP) position was measured. Each subject was instructed to gradually shift their position of COP from the original position to the target point by leaning his body around the ankle joint and then to hold the COP position for 10 s. The targets were placed in 12 direc-

tions, which were equally distributed in 30° increments to cover the entire horizontal plane (Imagawa et al., 2013). Surface electromyography (EMG) was recorded from 10 muscles, and raw EMG data were rectified and averaged across 10 s period for each muscle and direction. From them, we generated EMG data matrix, which consisted of 10 muscles × 12 directions for each stances. Then, we extracted muscle synergies and their activation for each direction from the EMG data matrix using nonnegative matrix factorization (NMF) (Lee and Seung, 2001). Results The principal synergies mainly contribute to the fluctuations of anterior-posterior direction, which are mainly composed of soleus, medial gastrocnemius, and tibialis anterior. The synergies activated for medial-lateral postural adjustment were also observed by varying stance configurations, which were dominant for gluteus medius and fibularis longus. Discussion Present results suggest that the synergies were connected to postural strategies (Horak and Nashner, 1986), for example, anterior-posterior “ankle” strategy. Human postural control is low-dimensionally achieved by the contribution of synergies which is related to regulation of each joint torque. References Imagawa H, Hagio S, Kouzaki M. #### **DETERMINANTS OF ACCELERATION AND MAXIMUM SPEED PHASE OF REPEATED SPRINT ABILITY IN SOCCER PLAYERS: A CROSS-SECTIONAL STUDY**

Nikolaidis, P.1, Dellal, A.2, Torres-Luque, G.3, Ingebrigtsen, J.4

*1University of Athens (Greece), 2Medical Excellence Centre FIFA (Lyon, France), 3University of Jaen (Spain), 4University of Nordland (Bodø, Norway)*

**Introduction** Despite the increasing knowledge and interest in the associations of repeated sprint ability (RSA) with anaerobic and aerobic power measures, there is little information about the physical fitness determinants of the acceleration and maximum speed phase of an RSA test. The aim of this study was to examine the anthropometric and physiological factors that influence the acceleration (0-10 m) and maximum speed phases (10-20 m) of an RSA test. **Methods** Thirty-six soccer players were tested for height, body mass, body fat (BF), sit-and-reach test, squat jump (SJ) and countermovement jump (CMJ), Wingate anaerobic test (WAnT), maximal aerobic running speed (MAS), 20 m sprint time and a 10×20 m RSA test. A stepwise regression analysis was performed to investigate variables that predict RSA. **Results** The comparison between groups with different levels of RSA revealed that players with higher RSA had better scores in physical fitness than their counterparts with lower RSA (MAS +1.1 km.h<sup>-1</sup>, +7.1%; SJ +4.5 cm, +14.2%; mean power in WAnT +0.4 W.kg<sup>-1</sup>, +4.6%; 20 m sprint -0.13 s, -4.1%; p<0.05). Sprint time at 0-20 m (Sprint), 0-10 m (Sprint0-10) and 10-20 m (Sprint10-20) were predictor variables of eight out of nine RSA dependent variables. Sprint was the best predictor variable of best time (BT) and mean time (MT), Sprint0-10 time the best predictor of BT0-10 and MT0-10, and Sprint10-20 time the best predictor of BT10-20, MT10-20 and performance decrement at 10-20 m (PD10-20). BF was predictor variable of BT, MT, BT0-10, MT0-10 and performance decrement (PD0-10). MAS was predictor variable of MT, PD0-10, BT10-20 and MT10-20. Other predictor variables included age, CMJ, mean and peak power in WAnT. Very large multiple correlation coefficients were found in the models of BT, MT, BT0-10, MT0-10, BT10-20 and MT10-20, large in the model of PD10-20, and moderate in the models of PD and PD0-10. While Sprint0-10 and Sprint10-20 had similar correlations with BT and MT (0.57

#### **COMPARATIVE MULTIPLE SENSOR APPROACH FOR POWER CALCULATION IN LOADED SQUAT JUMP AND POWER CLEAN**

Cardinale, D.1,2, Nilsson, J.2, Cardinale, M.3

*1: Elite Sports Centre, Swedish Sports Confederation, Bosön, Lidingö, Sweden; 2: The Swedish School of Sport and Health Sciences, Stockholm, Sweden; 3: British Olympic Medical Institute, London, UK*

**Introduction** Power output is a critical component of athletic performance (McGuigan et al., 2012); therefore, strength and conditioning specialists are nowadays employed to help athletes increase the power-generating capacity in specific motor tasks. Due to the widespread need to assess power output in common strength training exercises, the development and validation of various assessment approaches has led to studies aimed at identifying the external optimal load (OL) to maximize power output (Cormie et al., 2007). The aim of this study was to compare conventionally used linear position transducer and force plate based methods with a new methodology for calculation of peak power (PP) and average power (AP) output in conjunction with the load-power relationship. **Methods** Nineteen male elite athletes performed loaded squat jump (LSJ) and power clean (PC) with different external loads to determine the load/power relationship. Nine methods were used simultaneously in data collection: vertical ground reaction force (VGRF), ground reaction force (GRF) i.e. vertical, antero-posterior and medio-lateral reaction force components, 1 linear encoder (1Encoder), 1 linear position transducer (1LPT), 1LPT and VGRF (1LPT+VGRF), 2 linear position transducers (2LPTs), 2LPTs and VGRF (2LPTs+VGRF), 5 linear position transducers (5LPTs), 5LPTs and GRF (5LPTs+GRF; novel method). Power output was calculated for each lift according to the sensor or sensors simultaneously used and the results were compared. **Results** Power output calculated separately with LPTs and GRF method differed significantly from combined methods such as 1LPT+VGRF, 2LPTs+VGRF, and 5LPTs+GRF (novel method). The optimal load in LSJ and PC with respect to PP output was identified at loads between 30 and 50% of their body mass (bm), respectively; and with respect to AP output equal to loads between 85 and 75% of bm, respectively. **Discussion** This study indicates that test methodology influences the results of the power output and the load-power relationship in LSJ and PC exercises. The results of this study suggest the possibility that the combined methods provide a better representation of muscle power generation during dynamic movements involving the non-linear trajectories of the barbell than kinematic or kinetic methods alone. **References** Cormie, P., McBride, J. ## STRENGTH TRAINING PERIODISATION AND PERFORMANCE DEVELOPMENT OF AN ELITE JUDO ATHLETE DURING AN ENTIRE OLYMPIC TRAINING CYCLE

Ullrich, B., Oliveira, S.R.S., Stening, J.

*Olympic training and testing centre of Rheinland-Pfalz/Saarland*

**Introduction** Long-term individual training and testing data of elite judo athletes are rarely published. The main objectives of this work were to monitor the strength training periodisation and the performance diagnostic data of an elite judo athlete during an entire Olympic cycle. **Methods** Based on a regular macrocycle quarterly periodisation the strength training of a male elite judoka (junior world champion 2010; 5th European Championship 2012) was monitored during the Olympic cycle of 2008-2012. The following nonspecific strength training exercises with free weight barbells and machines were used: Snatch/Sn; Clean and Jerk/CJ; Back Squat/BS, Barbell Bench Press/BP, Barbell Bench Pull/BBP, Knee Flexion Curl/KF; Barbell Elbow Curl/B, High Pulley Triceps Extension/T, Lat Pull Down/LP. Training volume was quantified as described by Stone et al. (1982) and varied (maxima to minima) as follows: Sn/396-98, CJ/396-98, Sq/420-84, BP/BBP/KF/B/T/LP/800-120, respectively. Intensity was 50-90% of 1 RM and the weekly duration of strength exercises ranged from 240-300 minutes. Using an isokinetic dynamometer isometric MVC of the knee extensors and flexors and the shoulder internal and external rotators were assessed at the beginning and the end of the yearly winter training period. An incremental laboratory treadmill running test including measurements of VO<sub>2</sub>-kinetics and lactate accumulation was performed at these yearly testing days. **Results** During the 4-years period, the following 1 RPM increases of the exercises were detected: Sq: 50%; BP: 16%; BBP: 28%; KF: 22%; B: 33%; T: 33% and LP: 37%. MVC knee extension moments increased of about 25% and MVC knee flexion moments showed enhancements between 20% and 30% according to body side. MVC of the internal and external shoulder rotators showed large enhancements of about 50% and 60%, respectively. Body weight increases peaked at 11% during the period. Treadmill test performance remained relatively stable during the period and displayed running speeds of 15-16 km/h at the individual anaerobic threshold, maximum speeds of 20 km/h and maximum VO<sub>2</sub>-uptake values of slightly above 60 ml/kg/min. **Discussion** This work presents the training and testing values of an elite judoka during an Olympic cycle. Despite profound gains in absolute strength and without special focus on aerobic training at any time of the period, the athlete's aerobic and anaerobic performance values remained stable at a relatively high level. These data might underline the importance of special genetic and individual talent factors in elite athletic performance. **References** Stone, M, O'Bryant, H, Garhammer, J, McMillan, J, Rozenek, R. (1982). Journal of the National Strength and Conditioning Association, 4, 36-39.

## USEFULNESS OF THE THREE-DIMENSIONAL MOTION ANALYSIS IN KICK START OF SWIMMING

Keita, A., Kurokawa, T., Deguchi, T., Otsuka, D., Shiokawa, M.

*Hiroshima University, Prefectural University of Hiroshima*

**Introduction** Kick start (KS) is the starting technique which swimmers set up their rear leg on a back plate of the starting platform. It is reported that KS can achieve higher performance than the traditional start in the start phase. However, the detailed characteristics of KS movement has not been clarified because the two-dimensional motion analysis (Two-DMA) was used in previous studies. Since the KS involves trunk twisting movements, three-dimensional motion analysis (Three-DMA) is more appropriate for analyzing the KS movement. Therefore, the aim of this study was to gain new KS's data by using the Three-DMA through the comparison with Two-DMA, in order to clarify the movement characteristics of the KS. **Method** Six male university swimmers were asked to perform the KS. The movement of the KS was taken by three digital video cameras on each subject. The real coordinates of captured anatomical landmarks were calculated by Three-DMA using the DLT method. In this study, we defined the two joint angles as the 2D angle (angle on the sagittal plane) and the 3D angle (angle in 3D space). **Result** Average value of each time segment in the movement of the lower limbs were as follows: the time in which knee angle starts extending;  $0.18 \pm 0.03$ s, leaving the starting platform;  $0.65 \pm 0.08$ s as to the rear leg and the time in which knee angle starts flexing;  $0.28 \pm 0.08$ s, starts extending;  $0.60 \pm 0.07$ s, leaving the starting platform;  $0.77 \pm 0.08$ s as to the front leg. In most subjects, the trunk twist angle was soared after the slight decrease in the block phase. In the lower limb movement, the 2D angle and the 3D angle showed a very high positive correlation ( $r = .938$  or more,  $p < 0.01$ ). **Discussion** In the block phase of KS, the knee angle of the rear leg extended without flexion, but the knee angle of the front leg extended rapidly after flexion. And the trunk twist angle was also soared after the slight decrease in the block phase of KS. This results suggest that stretch-shortening cycle (SSC) occurred in the knee extensor of the front leg and the trunk rotator. Bosco et al. (1982) reported that the utilization of the SSC enhanced the performance over that of the pure concentric contraction. Therefore, it was considered that the KS is superior to the usual starting technique in performance of start phase because of the utilization of SSC. It was suggested that Two-DMA can obtain same results in the lower limb movement as Three-DMA, because the 2D angle and the 3D angle showed a very high positive correlation in the lower limb movement. **Reference** Bosco C, Tarkka I, Komi PV (1982) International Journal of Sports Medicine, 3(3):137-140

## THE EVALUATION OF REPRODUCIBILITY OF BALLET LEG POSITION IN ELITE JUNIOR AND SENIOR SYNCHRONIZED SWIMMERS

Komori, Y., Ohnishi, H., Kamiyoshi, M., Kawai, Y.

*Osaka International University*

**Introduction** Synchronized swimming is a competitive sport, which is judged based on synchrony between music and the movements of each swimmer. Synchronized swimming competition includes a figure session and a routine session. All specified 200 figures are constituted from movements of the leg, such as hip extension-flexion movements, in particular, the ballet leg positions (from a back layout position to raise a leg and to keep the hip flexion angle at 90°) that account for 40% of the figures. Therefore, precise control of hip flexion angle is important for synchronized swimmers. The purpose of this study was to examine the evaluation of reproducibility of ballet leg position in elite junior and senior synchronized swimmers. In addition, the relationship between these positions and the physical performance characteristics of synchronized swimmers were also determined. **Methods** A total of 24 elite female synchronized swimmers participated in this study. The participants were divided into the following 2 groups: junior group ( $n = 15$ ; age,  $11.5 \pm 1.5$  years) and senior group ( $n = 9$ ; age,  $17.7 \pm 2.6$  years). The participants performed the ballet leg positions in water and on dry land. The indicators of ballet leg positions, namely, (1) repositioning error (RE) of hip flexion angle and (2) maximal moving distance of the greater trochanter of the femur, were evaluated using an image analyzing system with high-speed underwater video cameras. The indicators of physical performance tests were (1) sculling on double ballet leg position, (2) range of hip motion, and (3) abdominal muscle endurance. **Results** RE for ballet leg position in water was  $3.2 \pm 1.7^\circ$  and  $7.2 \pm 4.3^\circ$  in the senior and junior groups, respectively. RE for ballet leg position on dry land was  $2.9 \pm 3.0^\circ$  and  $5.0 \pm 3.5^\circ$  in the senior and junior groups, respectively. The physical performance tests of sculling, range of hip mo-

tion, and abdominal muscle endurance was greater in the senior group. Conclusions These findings showed that compared to the junior group, the senior group showed better reproducibility of ballet leg position in water. In conclusion, this study suggested that the precise reproducibility of ballet leg position in water correlated with the physical performance characteristics of synchronized swimming, and that sculling, range of hip motion, and abdominal muscle endurance seem to be important indicators. Reference Yamamura, C., et al. (1999). Physical characteristics of well-trained synchronized swimmers in relation to performance scores. *Int J Sports med*, 20 (4):246-251.

### **EFFECTS OF 18-WEEKS IN-SEASON HEAVY RESISTANCE AND HIGH-INTENSITY TRAINING ON THROWING VELOCITY, STRENGTH, JUMPING AND MAXIMAL SPRINT SWIM PERFORMANCE OF ELITE MALE WATER POLO PLAYERS**

Ramos Veliz, R., Requena, B., Saez de Villareal, E.

*UNIVERSITY PABLO DE OLAVIDE*

**Introduction** Water polo (WP) is a sport that places high strength and high-intensity as well as endurance demands on the athlete, with a predominance of sprint swimming and wrestling. The importance of non-swimming activities (e.g., throwing, passing, and wrestling) which account for around 69% of playing time has been previously highlighted (D'Auria 2008; Smith 1998). Competitive performance in WP depends not only on strength, but also on the ability to exert force at the speed required by this discipline. In addition to technical and tactical skills it has been argued that muscular strength and power are the most important factors that give a clear advantage in elite competitions (Smith 1998). Elite WP players who supplemented their normal in-season WP training with an 18-week program of bi-weekly heavy resistance and high-intensity oriented exercises would enhance their muscular strength without compromising other qualities critical to WP performance. **Methods** This study was designed to assess the effects of 18 weeks of bi-weekly (36 sessions) strength and high-intensity training in-season on muscular strength performance of elite WP players. The participants were randomly allocated to undergo an additional program of strength and high-intensity training or only receive usual in-water training. 20-m maximal sprint swim, maximal dynamic strength (1RM) for upper (bench press (BP) and lower (full squat (FS) body, countermovement jump and throwing velocity were measured before and after training. **Results** Baseline-training results showed no significant differences between the groups in any of the variables tested. No improvement was found in the control group, however, meaningful improvement was found in all variables in the experimental group: CMJ (2.38 cm, 6.9%, Effect Size (ES)=0.48), BP (9.06 kg, 10.53%, ES=0.66), FS (11.06 kg, 14.21%, ES=0.67), throwing velocity (1.76 km/h, 2.76%, ES=0.25) and 20-m maximal sprint swim (-0.26 sec, 2.25%, ES=0.29). **Discussion** Specific resistance and high-intensity training in-season enhances the strength output of both upper and lower-body, whether assessed by jumping (6.90%) or swim sprinting (2.25%), 1 RM-BP (10.53%) and FS (14.21%) test, or throwing velocity (2.76%). Other studies have examined the influence of strength training and jump height on overhead throwing velocity of elite WP players (Bloomfield et al 1990; McCluskey et al 2010), but this is the first study to examine gains of jumping and swim sprinting performance, using resistance and high-intensity exercises such as the bench press, military press and pull-ups for the upper-body and full-squat and plyometric exercises for the lower-body. Therefore, we propose modifications to current training methodology for WP players to include strength and high-intensity training for athlete preparation in this sport. **References** D'Auria S, Gabbett, T (2008). *Int J Sports Phys Perfor* 3: 305-319. ### **EFFECTS OF IN-SEASON LOWER BODY HEAVY RESISTANCE AND HIGH-INTENSITY TRAINING ON PERFORMANCE OF ELITE FEMALE WATER POLO PLAYERS**

Ramos Veliz, R., Requena, B., Saez de Villareal, E.

*UNIVERSITY PABLO DE OLAVIDE*

**Introduction** Until 2000, women's water polo (WP) was not an Olympic event, and information on the physical characteristics and the physiological demands of elite female WP players was limited. WP is a sport that places high physiological demands on players (aquatic environment and intermittent nature of the game) (Mujika et al, 2006). To technical and tactical skills it has been argued that muscular strength and power are the most important factors that give a clear advantage in elite competitions (Smith 1998). Elite female WP players who supplement their normal in-season WP training with a 16-week program of bi-weekly heavy resistance and high-intensity oriented exercises for the lower body would enhance muscular strength without compromising other factors critical to WP performance. **Methods** We examined the effect of 16 weeks of lower body strength and high-intensity training on key sport performance measures of elite female players. Twenty-one players were randomly assigned to 2 groups; control group (C) who did in-water training only and a lower body strength group (LBS), who performed strength and high-intensity training sessions (twice per week) in addition to the same in-water training. In water training was conducted five days per week for a total of sixteen weeks. 20-m maximal sprint swim (MSS), lower body strength during 1RM full-squat (FS), countermovement jump (CMJ) and throwing velocity (ThV) was measured before and after the training. **Results** Pre-training results showed no meaningful differences between the groups in any of the variables tested. After sixteen weeks no meaningful improvement was found in any of the variables measured in the C group, however, meaningful improvement was found in the LBS group: CMJ (2.48 cm, 8.66%, Effect Size (ES)=0.85), FS (12.78 kg, 25.11%, ES=2.41), ThV (3.55 km/h, 6.73%, ES=3.22). **Discussion** Elite female WP players can enhance muscle strength and jumping ability by undertaking a 16 week in-season program of strength and high-intensity oriented training involving exercises for lower body (FS, split and loaded and unloaded jump exercises). Such benefits can be realised from only two short training sessions per week during competitive season. Previous authors have found a similar benefit of strength and power oriented training in other sports (McCluskey et al, 2010), but this is the first study involving elite female WP players. It is recommended that WP coaches implement during competitive season strength and high-intensity training to enhance the performance of their players. The outcomes may help coaches and sport scientists formulate better guidelines and recommendations for athlete assessment and selection, training prescription and monitoring and preparation for competition. **References** Mujika I, McFadden G (2006) *Int J Sports Phys Perfor* 1: 27-39. ### **PHYSICAL FITNESS IN MALE TEAM HANDBALL PLAYERS FROM TEAMS WITH DIFFERENT RANKING**

Nikolaidis, P.T.1, Ingebrigtsen, J.2

*1University of Athens (Greece), 2University of Nordland, Bodø, Norway*

**Introduction** Although the physical fitness profile of team handball players according to age, sex and playing position is well documented, there is little information about the components of physical fitness that differentiate players according to their level. Therefore, the aim of this study was to examine possible discriminant physical and physiological characteristics between male team handball players from

elite teams with different league rankings. Methods Participants included players from three teams, A, B and C, which competed in the first league of the Greek championship during the season 2011-2012. Team A finished first, B came second and C came eighth out of eleven clubs. Teams A and B also participated in European Cups, and team A won the European Challenge Cup. The players (n=44) were examined for stature, body mass, percentage body fat, fat free mass (FFM) and performed a sit-and-reach test, physical working capacity in heart rate 170 bpm, squat jump, countermovement jump without and with arm-swing, 30-s Bosco test, handgrip strength test, Force-velocity test and Wingate anaerobic test (WAnT). Results Players from teams A and B were taller (6.1 and 9.2 cm,  $p \leq 0.001$ ), and had higher amount of FFM (6.4 and 5.3 kg,  $p \leq 0.05$ ) compared to those of the lower ranked team (C). Players from team A performed better than players from team C in mean power (0.5 W.kg<sup>-1</sup>,  $p \leq 0.05$ ) during the WAnT, squat jump (5.5 cm,  $p \leq 0.05$ ), countermovement jump without arm-swing (5.5 cm,  $p \leq 0.05$ ) and with arm-swing (6.0 cm,  $p \leq 0.05$ ), and in the 30 sec Bosco test (5.8 W.kg<sup>-1</sup>,  $p \leq 0.01$ ). Also, team A players outperformed team B in the Bosco test (7.8 W.kg<sup>-1</sup>,  $p \leq 0.01$ ). Overall, players from the best ranked team performed better than the lowest ranked team on WAnT, vertical jumps and the Bosco test. Stepwise discriminant analysis showed that stature and mean power during the Bosco test were the most important characteristics in team handball players, accounting for 54.6% of the variance in team ranking. Conclusions For the first time, mean power output (W.kg<sup>-1</sup>) in a 30 sec Bosco test and WAnT, were shown to differentiate between players from higher ranked and lower ranked male elite handball teams. Also, vertical jump performances were better among the players on the best team. Furthermore, higher stature and amount of FFM were found in players from the higher ranked teams. This could indicate that both physiological and physical characteristics can be useful for differentiating between elite male team handball players.

### EFFECTS OF 9 WEEKS OF WHOLE BODY VIBRATION VS. UNSTABLE SURFACE TRAINING ON BALANCE IN POSTMENOPAUSAL WOMEN

Del Cerro, N., Alcaraz, P.E., Marín-Cascales, E., Rubio, J.A.

*UCAM (Murcia)*

Introduction One of the biggest expenses in the health services is caused by hospitalization and intervention of injuries resulting from falls in older people. Thus, it emerges the need to create training protocols focused on one of the main factors that cause falls: loss of balance that leads to functional instability. Therefore, the aim of this study was to study different protocols for improving balance in older people. Methods We conducted a quasi-experimental design intra- and inter-subject with a control group of 39 sedentary postmenopausal women ( $58.8 \pm 1.6$  years,  $73.5 \pm 8.9$  kg,  $1.56 \pm 0.06$  m). The participants were divided according to their BMD at three experimental groups and control group (G4). The experimental groups performed an incremental training, WBV (G1), unstable surface (G2) and floor (G3), for 9 weeks 3 sessions/week. All participants maintained a static position of semi-squat and every 6 times (1-0-5, 100bpm) performed ankle plantar flexion. At the beginning and end of the process static balance was assessed (Romberg test) with and without unstable surface, and dynamic balance (Stepping test) using a force platform. Results Only significant differences were observed between the groups G3 and G4. For static balance, the projection area was reduced without surface in the Romberg test, with values of 0.034 between pre-test and post-test. Concerning the dynamic balance, there were significant differences in the minimum contact time in the Stepping Test, 0.047 between pre-test and post-test. Discussion A decrease in the projection area in static balance (Romberg test without surface) is related to an improvement of the functional stability of the subject, and therefore more effective postural control to any disturbance before the fall (1; 3). Reducing the minimum contact time in dynamic balance (Stepping test) is related to the speed of walk and a more reactive step, and an improved ability to recover any disturbance of the postural stability (2; 4). Therefore, the motor pattern performed during training is indicated as a preventative exercise for fall risk when performed without unstable surface. References 1. Agrawal, Y., Carey, J., Santina, C. ### A COMPARISON OF THE PHYSIOLOGICAL, PHYSICAL AND TECHNICAL DEMANDS DURING BATTLEZONE, TRADITIONAL CRICKET TRAINING AND ONE-DAY CRICKET MATCHES

Vickery, W., Dascombe, B., Duffield, R.

*University of Newcastle; University of Newcastle; University of Technology Sydney*

Introduction Current research suggests that small-sided games allow players to simultaneously develop decision-making and technical ability, along with metabolic conditioning, whilst simulating match conditions (Gabbett et al., 2009). Recently, small-sided games (Battlezone) have been suggested as an alternative to cricket net-based training (Renshaw et al., 2010). However, it is unknown if either training method replicates match demands. This study aimed to compare position-specific physiological, physical and technical demands of Battlezone, traditional cricket training and One-Day matches. Methods Eleven (age:  $22.2 \pm 3.3$  yr, height:  $1.82 \pm 0.06$  m, body mass:  $80.4 \pm 9.8$  kg) amateur, male cricket players completed four Battlezone and four traditional cricket training sessions within respective playing positions with measures of heart rate, blood lactate concentration, rating of perceived exertion and movement patterns taken. Retrospective video analysis was performed to code for technical outcomes. Following this, similar data was collected from 42 amateur ( $23.5 \pm 4.7$  yr,  $1.81 \pm 0.07$  m,  $81.4 \pm 11.4$  kg), male cricket players during One-Day matches. To compare the difference within each playing position between the different formats, one-way repeated measures analysis of variance with Fisher's LSD post hoc ( $p < 0.05$ ) tests were used. Results Main effects were present ( $p < 0.05$ ) between Battlezone, traditional cricket training and One-Day matches within each playing position for physiological, physical and technical measures. Battlezone and traditional cricket training invoked significantly ( $p < 0.05$ ) greater physiological, physical and technical demands within each playing position compared to One-Day matches. Discussion It appears that across all playing positions the physiological, physical and technical demands of Battlezone and traditional cricket training are suitable for replicating the demands of a One-Day match in amateur players. For batsmen, the loads imposed on players during Battlezone greatly exceed that of a match. In regards to the other playing positions, it appears a similar match-appropriate load can be gained from either Battlezone or traditional cricket training. ## HEMOGLOBIN MASS ADDS TO THE PREDICTIVE VALUE OF BODY WEIGHT FOR MAXIMAL OXYGEN UPTAKE IN INTERNATIONAL LEVEL ELITE ATHLETES.

Jørgensen, S.

*Team Danmark*

**INTRODUCTION** In elite athletes, frequent determination of maximal oxygen consumption (VO<sub>2</sub>max) normalized to body weight (BW) is used in analyses of physical capacity during careers and seasons. The test is physically demanding and time consuming. Manipulations of tHb clearly affect VO<sub>2</sub>max and performance. Thus, we investigated if a relative simple measurement of total hemoglobin mass (tHb) in combination with gender and BW would be of predictive value for VO<sub>2</sub>max. **METHODS** In 6 female and 10 male Danish international level elite athletes maximal oxygen uptake was determined using an incremental running test to exhaustion. Within ±XX days, total hemoglobin mass was determined by 2 min carbon monoxide rebreathing. Multiple linear regression with backward elimination was performed using VO<sub>2</sub> max as the dependent variable (SPSS v. 20). The following possible predictor variables were included: gender; BW; height; tHb. Further, it was investigated if VO<sub>2</sub> normalized to BW could be predicted from tHb normalized to BW in combination with gender. The level of significance was set at P<0.05. **RESULTS** VO<sub>2</sub>max was 4.42±0.88 [3.01; 5.82] l x min<sup>-1</sup> (mean±SD [Range]), BW was 72.3±9.4 [54.7; 86.2] kg, blood volume was 6.16±1.29 [4.41;8.19] l and tHb was 827±168 [549;1064] ml. VO<sub>2</sub>max was strongly associated (P<0.001) with BW (R<sup>2</sup>=0.80) with an additional predictive value of tHb (P<0.001) resulting in a model where R<sup>2</sup> reached 0.91. Gender and height did not contribute to the model. The resulting predictive equation was VO<sub>2</sub>max = BW x 0.052 + tHb x 0.002 -1.389. In prediction of VO<sub>2</sub>max normalized to body weight (VO<sub>2</sub>max<sub>rel</sub>) tHb was of predictive value (R<sup>2</sup>=0.68; P<0.001) whereas gender and height was not. The resulting predictive equation was VO<sub>2</sub>max<sub>rel</sub> = 0.031 x tHb + 35.311. **CONCLUSION** The expected strong association between absolute VO<sub>2</sub>max and BW was confirmed. Adding tHb as a predictor variable increased R<sup>2</sup> an additional 11%. This demonstrates that tHb determination is a feasible way to improve VO<sub>2</sub>max estimations without the need for stressing and time demanding testing. The prediction of relative maximal oxygen uptake from normalized tHb was less precise. Future studies should address if the suggested relationship between body weight and tHb can be verified in a larger population of elite athletes. It should also be addressed if seasonal and career variations in VO<sub>2</sub>max is associated with fluctuations in total hemoglobin mass. Do not insert authors here

## BIOMECHANICAL STUDY OF THE EFFECT OF DURATION ON CATCHING AND THROWING MOTION IN THE FIELDING PRACTICE OF BASEBALL

Goro, M., Takashi, K., Keita, A., Kenta, N., Takeshi, U.

*Hiroshima University*

**Introduction:** The change of catching and throwing motion during a long term fielding practice was investigated. **Methods:** One collegiate baseball player participated in a fielding practice in the position of shortstop. One set of the fielding practice lasted for 5 minutes at intervals of 17 seconds, and 10 sets were continuously done. Rest periods between each set were 1 minute. The fielding actions of the subject were recorded by 4 high-speed cameras. Then, after calculating the coordinates of 13 anatomical landmarks and the center of the ball, each parameter of catching and throwing motion were calculated by the three-dimensional motion analysis. The accuracy of the throw was evaluated with the target. **Results:** The accuracy of the throw did not change within the increase in the number of attempts, but the ball velocity significantly decreased (p<0.01). In the catching situation, the knee joint angle of the pivot leg and the step size increased (p<0.01, p<0.05, respectively). In the throwing situation, the shoulder abduction angle, the amount of change of forward trunk tilt and the horizontal mobility speed of waist middle point decreased (p<0.05, p<0.05, p<0.01, respectively). The amount of change of shoulder horizontal adduction and abduction angle increased (p<0.01). The hip joint angle of the step leg at the moment of ball release had the highest correlation with the ball velocity (r=-0.579, p<0.01). **Discussion:** In the catching situation, the catching form with "high waist" was prevented by compensating the decrease in the knee angle with the extension of the step size. In the throwing situation, the number of attempts in this study significantly decreased the ball velocity due to the decrease in the amount of change of the forward trunk tilt, just as same as the result in 5~6 innings pitching done by Murray et al. (2001). Escamilla et al. (2007) also observed the decrease in the forward trunk tilt of the pitcher during the last innings in a game. It was considered that the decrease in the muscular power of leg due to the fatigue caused the decrease in the physical mobility speed toward the direction of the target. It was considered that this fatigue wrecked the interlocking of each segment, and the amount of change of the shoulder horizontal adduction and abduction angle increased as the compensation movement. This movement may become the mechanism of the pathogenesis of disorder. Escamilla RF, Barrentine SW, Fleisig GS, Zheng N, Takata N, Kingsley D, Andrews JR (2007) *Am J Sports Med*, 35, 23-33. ### PP-PM76 Training and Testing [TT] 11

#### SCREENING OF MOTOR PROFICIENCY IN CHILDREN

Fors, E., Ekblom, M.

*The Swedish School of Sport and Health Sciences*

Children with Developmental Coordination Disorder (DCD) have poor motor proficiency unrelated to intellectual or neurological diseases. The most cited prevalence among schoolchildren is 5 - 6%. DCD greatly affects school work, social relations and self-esteem as children incorrectly risks being seen as clumsy and awkward by the environment. Still, many countries are lacking a national screening policy for DCD. To detect children with motor problems and provide adequate support, valid and functional testing and screening methods designed to reflect the linguistic and cultural differences are needed. Developmental Coordination Disorder Questionnaire 2007 (DCDQ'07) is an international survey tool specifically designed to identify children with DCD, which is based on the parents' perception of their own child's motor skills relative to peers. **Purpose** The aim of this study was to evaluate whether a Swedish version of DCDQ'07 can serve as a

screening instrument for detection of children with DCD in Sweden by examining how the classification of DCD via DCDQ'07 is consistent with the classification of DCD via the motor skills test Movement ABC. Method In conjunction with a larger study a Swedish version of DCDQ'07 sent to 4000 randomly selected families in the area of Stockholm. Forty families were contacted. Thirty-four children (8.5 ± 0.6 years) completed the quantitative portion of the Movement ABC chosen as the standard for motor skills. The recommended limits for DCDQ'07 were applied (56/57 for 9 and 10 years). Receiver-operator characteristic curve (ROC graph) was used to identify positive criterion for DCDQ'07. Spearman's Rho was used to test associations between variables. Significance level  $p < 0.05$ . Results A sensitivity of 80%, specificity of 67% and positive predicted value (PPV) of 50% was achieved at cut of values of 56/57. Kappa was just under 0.4. Significant correlations were found between Movement ABC and total score of DCDQ'07 ( $r = -0.61$ ) and between the subcomponents of DCDQ'07 and all subtasks of the Movement ABC except one. Discussion The study showed that the Swedish version of DCDQ'07 exhibits an acceptable validity and can be recommended as one of several steps for early detection of DCD among schoolchildren 8-10 years of age. Cut of values between 48 and 57 are recommended, depending on whether the survey is used in clinical environments or population studies. In populations with known high prevalence of motor problems even lower cut of values should be considered. Perceived and actual motor performance is highly related to the child's school performance and participation in physical activity and thus health. To prevent children with motor problems from developing secondary problems early identification via motor skills screenings such as DCDQ'07 and Movement ABC are necessary. The project was financed and supported by the Promobilia Foundation in Sweden.

### OXYGEN UPTAKE KINETICS AROUND MAXIMAL LACTATE STEADY STATE VELOCITY IN SWIMMING

Almeida, T., Espada, M., Reis, J., Vleck, V., Alves, F.

*Faculty of Human Kinetics, Technical University of Lisbon*

Introduction The upper boundary for the heavy intensity domain is defined as the highest exercise intensity in which oxygen uptake (VO<sub>2</sub>) can be maintained at an elevated but steady-state level. In severe intensity exercise, maximal oxygen uptake (VO<sub>2max</sub>) is attained and signals the imminent termination of exercise (Burnley & Jones 2007). Maximal lactate steady state velocity (MLSSv) is considered to be the best predictor of endurance performance, indicates an exercise-intensity above which the metabolism changes qualitatively (Beneke et al., 2000). VO<sub>2</sub> kinetics provides information related to efficiency and conditioning of several integrated systems (Reis et al., 2012). The purpose of this study was to analyze VO<sub>2</sub> kinetics response around MLSSv in swimming. Methods Twelve male swimmers completed an incremental test composed by 5x250 and 1x200 m front crawl for VO<sub>2max</sub> and the velocity associated to VO<sub>2max</sub> (VVO<sub>2max</sub>) determination. For MLSSv estimation, subjects performed, in random order and different days, 30-min at constant velocity at 87.5, 90 and 92.5% of VVO<sub>2max</sub>. In two complementary days, four 6-min bouts were performed separated by one hour of passive rest between each repetition at 97.5% and 102.5% of MLSSv (two bouts each day). All tests were completed with aquatrainer swimming snorkel®. Results Time delay (td) and time constant (tp) of the primary phase were not significantly different (respectively 10.6 ± 3.8 Vs. 11.0 ± 3.2 s and 19.5 ± 6.8 Vs. 17.7 ± 8.0 s) below and above MLSSv. Contrarily, the amplitude of the primary phase (Ap) was significantly different at infra and supra MLSSv (2931.9 ± 445.6 Vs. 3152.9 ± 406.2 ml.min<sup>-1</sup>). Two swimmers revealed relevant slow component (A'(sc)) at 97.5% (average 31.2 ± 5.6 ml.min<sup>-1</sup>) and seven at 102.5% of MLSSv (average 41.4 ± 21.4 ml.min<sup>-1</sup>). T-test revealed that end-exercise VO<sub>2</sub> at 102.5% MLSSv (3666.8 ± 371.7 ml.min<sup>-1</sup>) was not different from VO<sub>2max</sub> (3767.7 ± 483.9 ml.min<sup>-1</sup>). Discussion VO<sub>2</sub> kinetics seems to be a useful tool to be applied in swimming to diminish the tests used to access MLSSv. Although the designated gold standard indicates an exercise intensity above which metabolism changes qualitatively, td and tp were not significantly different at 97.5 and 102.5% MLSSv. On the other hand, Ap and end-exercise VO<sub>2</sub> values below and above MLSSv were significantly different and end-exercise VO<sub>2</sub> evidenced at supra MLSSv signaled the heralding of the imminent termination of exercise, confirming that MLSSv represents the boundary of the heavy intensity domain. ### RELATIONSHIP OF FORCE METRICS WITH SWIMMING PERFORMANCE IN AGE-GROUP SWIMMERS

Amaro, N., Marinho, D.A., Batalha, N., Morouço, P.

*Polytechnic Institute of Leiria*

Introduction In competitive swimming, performance relies in the good combination of force and technique. The relative contribution of each of these components is still a controversial issue. Therefore, the aim of this study was to verify if force metrics obtained through tethered swimming can be explanatory of free swimming performance. Methods 22 age-group swimmers (male n=14, age: 14.6±1.2years of age, body mass: 53.1±9.0kg, height: 1.66±0.1m; female n=8, age: 13.9±2.1years of age, body mass: 46.3±9.2kg, height: 1.57±0.1m) took part in the study. Each participant performed a 30 s maximal front crawl tethered swimming test (described in detail by Morouço et al., 2011). After normality assumption checked, force metrics (average force – Favg; maximum force – Fmax; and impulse of force – Fimp) were correlated with 50m in-water maximal bout performance (t50). Results Both in male and female swimmers Favg presented strong negative correlations with t50 ( $r = -0.81$  and  $r = -0.95$ ;  $p < 0.01$ , respectively). For the male group, both Fmax and Fimp obtained moderate negative associations with t50 ( $r = -0.63$  and  $r = -0.57$ ;  $p < 0.05$ , respectively). In female swimmers, both Fmax and Fimp attained strong negative relationships with t50 ( $r = -0.91$  and  $r = -0.85$ ;  $p < 0.01$ , respectively). Discussion The higher force metric associated with t50 was Favg for both groups, in accordance with Taylor et al. (2001). These authors stated that only average force was a reliable parameter to estimate swimming performance in age-group swimmers. However, if propulsion occurs along the whole propulsive phase of the stroke cycle (Marinho et al., 2011), integral of force with respect to time should be considered. The lower relationship of Fimp with t50 may suggest that this cohort of swimmers have lack of technique leading to a poor ability to extend the propulsive capacity during stroke. The impulse of force assessment, and respective association with swimming performance, is a feasible methodology to analyze the balance between force and technique in age-group swimmers. ### RUNNING PATTERNS IN ELITE YOUTH FOOTBALL USING GPS DATA

Bowen, L., Case, A., Taberner, M., Wilson, C., Ross, F., Li, F.X.

*University of Birmingham*

Introduction Bearing the importance of sprinting in football, many studies have looked into its characteristics, particularly regarding positional variations. Furthermore, default commercially available GPS systems' outcomes tend to classify a sprint as anything over a certain

speed and a set time, usually one second (Li & Dallaway, 2012). However, there is lack of research analysing the movement patterns pre and post-sprint. In addition, to our best knowledge, changes of direction within a sprint have not been systematically analysed. Therefore, using raw GPS data, this study aims to identify these patterns in elite youth footballers. We hypothesise that there will be substantial differences in the variables tested for gender, age and level. Method Data from 36 elite male footballers (age range 16-21 years) across the current season will be included in the analysis (completed by April). For each player, time-motion analyses are performed using a global positioning system (10Hz) during 5-10 league and cup games. All data above 2m/s are included. Measures consist of maximum speed, average speed, duration and distance in each speed zone and in total across 5 positions: central defenders, external defenders, central midfielders, external midfielders and forwards. Sprints are calculated from the start of acceleration to the end of deceleration. Changes of direction within a sprint are also analysed to determine at what speed most changes of direction occur. Mixed design ANOVA were performed with alpha level set at .05. Results Currently, the majority of the data has been collected and exported from the GPS system. A bespoke program has been created to analyse the data. A small sample from one central midfield player shows a Maximum speed 7.5m/s; average speed 4.5 m/s; distance covered overall 71.2m, in acceleration 36.6m, in sprint 6.2m, in deceleration 28.4; duration overall 13.1s, in acceleration 6.1s, in sprint 1.9s, in deceleration 5.2s. Discussion This is the first study to examine the sprint patterns in more detail, from the beginning of the acceleration to the end of the deceleration. The results will provide coaches information on the optimal sprint training for players in different positions, in terms of distance, duration and acceleration/deceleration time. Additionally, it is rare that football players start sprinting from a standing start within a game, so in order to increase transfer between training and matches, pre and post movement patterns should be taken in to account. References Li, F-X & Dallaway, N (2012). ### **DEVELOPMENT OF THE ESTIMATE OF COMPUTER ASSISTANCE PROGRAM FOR CHECKMARK POSITION BY DIFFERENT BEND RADIUS OF CURVATURE OF DIFFERENT LANES IN 4X100M RELAY**

Hsu, T.Y., Ko, B.J., Luo, C.C.

*National Taichung University of Education*

**Introduction** The set of the checkmark position is affected by the speeds of the incoming and outgoing runners. The speed is divided into two parts, namely the linear speed and the bend speed. According to the scientific theory, the bend speed is affected by the bend radius of curvature and the linear speed, but all three takeover zones cover the bend part, and the different lane has the different bend radius of curvature. Therefore, the bend radius of curvature is recognized as an important factor that may affect the set of the checkmark position, and will be also an important uncontrollable condition that will affect the baton exchange. This study aims to discuss the effect of radius of curvature on the checkmark in different lanes of 4x100m relay and offer appropriate suggestion of checkmark according to the speed of different runners. **Methods** The objects of research were sixteen outstanding players of senior high school and college who had accepted the long-term training in 4x100m relay. The research obtained the interval time of checkmark calculation of each runner in 130m to calculate the interval speed by SPM100. Experimental checkmark was calculated from the interval speed of incoming runner in last 30m and the starting speed of outgoing runner in 30m. Traditional checkmark was the original used distance. The grades were analyzed and tested for significance via paired-sample t-test ( $\alpha = .05$ ). **Results** The grades of experimental checkmark were better than the grades of traditional checkmark ( $p < .05$ ). Therefore, the estimate of computer assistance program for checkmark position by the different bend radius of curvature of different lanes in 4x100 m relay could be applied to the real competitions which can provide the runners and coaches as prompt references, which expect to reduce the possibility of mistakes of baton exchange and let relay process more easily completed. **Discussion** The forecast formula of bend speed developed by Greene in 1985 could be used in present PU track, thus we can apply it to substitute the actual measurement. In 4x100 m relay, some grades of traditional checkmark were better than the grades of experimental checkmark, we found the inferior grade of certain runner caused the decrease of the whole grades. One reason might be that setting the takeover zone in the end resulted in the pressure of outgoing runner easily. Another reason might be the differences between the checkmark and the original habit. **References** Campbell, K.M., Kram, P. R., Chang, Y. H. (1999). ### **THE ADVENTURE RACING ATHLETE: A PHYSIOLOGICAL PROFILE**

Mattsson, C.M., Enqvist, J.K., Ekblom, B.

*Åstrand Laboratory of Work Physiology, The Swedish School of Sport and Health Sciences*

**Introduction:** The aim of this study was anthropometric and physiological characterisation of male and female adventure racing athletes (ARs), and also to compare top and bottom finishers in the Adventure Racing World Championship (ARWC) 2006. **Methods:** The physiological profile was developed from oxygen uptake during submaximal and maximal exercise on treadmill, cycle- and kayakergometers. The characterisation study included 15 male and 9 female ARs. Additional anthropometric measurements were obtained from 128 participants in the ARWC. **Results:** The anthropometrics for male ARs were: [mean (95% confidence interval)] age 33 (32-34) years, height 180 (179-181) cm, body mass (BM) 79.4 (78.1-80.7) kg, body fat 17.1 (16.5-17.7) % of BM. Corresponding values for female ARs were: age 31 (30-32) years, height 165 (163-167) cm, BM 61.6 (59.8-63.4) kg, body fat 24.7 (23.6-25.8) % of BM. The men's peak oxygen uptakes were: running 5.02 (4.82-5.22), cycling 4.99 (4.80-5.18), and kayaking 4.05 (3.84-4.26) L·min<sup>-1</sup>. Corresponding values for the women were: running 3.26 (3.02-3.50), cycling 3.27 (3.05-3.47), and kayaking 2.59 (2.34-2.84) L·min<sup>-1</sup>. The characterized ARs had fractional utilisation in the order: running > cycling > kayaking (best trained in running), indicating that a shift in training regime in favour of kayak training could result in better overall performance. Top male finishers in the ARWC were taller, heavier, had a higher BMI and a trend towards higher body fat than bottom finishers, while there were no such differences among the women. The ARs display a distinct profile, in both anthropometric and physiological aspects, which differs from the specialist athletes'. The ARs have to balance a wide variety of demands, such as sufficient endogenous storage of fat and high ability to carry, against sustained ability to run and perform other BM related tasks.

### BIOPHYSICAL EVALUATION OF A YOUNG SWIMMER ALONG A TRAINING MACROCYCLE

Fernandes, R.J.1,2,3, Sousa, M.1,2, Silva, A.1,2, Sousa, A.1,2, Ribeiro, J.1,2, Pelarigo, J.G.1,2, Marques, M.1,4

1: Faculty of Sport, University of Porto, 2: Centre of Research, Education, Innovation and Intervention in Sport, 3: Porto Biomechanics Laboratory, 4: Leixões Sport Club

**Introduction:** Swimming performance development is based on a complex training process, involving a combination of several variables. Concurrently, it is necessary to monitor training during both the preparatory and competitive periods, once its efficiency is determined by the evaluation of the swimmer's capabilities and needs. Our aim was to observe (and give feedbacks about) the evolution of relevant swimming determinants and performance during the winter macrocycle of the current training season. **Methods:** One international level male juvenile swimmer (15yrs, 1.75m, 64.3kg and 7 units/week training frequency), performed a 7x200m front crawl incremental protocol until exhaustion (0.05m/s increments and 30s intervals, cf. Fernandes et al., 2008) in the final of the general preparatory (6 weeks), specific preparatory (6 weeks) and competitive (3 weeks) training periods. The corresponding averaged training volume and relative intensity values were: 32500, 38063 and 28283m/week, and 75, 77 and 78%, respectively. The anaerobic threshold (vAnT) was calculated by the blood lactate concentration ([La-]) vs velocity curve modeling method. Oxygen consumption (VO<sub>2</sub>) and heart rate (HR) values were obtained during the recovery periods using a portable gas analyzer (Cosmed, Italy). Stroke rate (SR) was registered by a Seiko base 3 chronofrequencemeter and stroke length (SL) was obtained by the ratio between v and SR. Swimming performance was obtained by maximal 200 and 800m front crawl tests. **Results:** Longitudinal data (in the consecutive 3 training periods) were: (i) [La-]AnT: 3.37, 1.80 and 2.30mmol/l and vAnT: 1.38, 1.38 and 1.40 m/s; (ii) [La-]max: 7.6, 8.6, 10.2mmol/l, VO<sub>2</sub>max: 41.4, 52.4, 59.1ml/kg/min, HRmax: 195, 198 and 196 b/min, vVO<sub>2</sub>max: 1.48, 1.54 and 1.59m/s, SRmax: 39.8, 41.1 and 41.0cycles/min and SLmax: 2.61, 2.69 and 2.63m/cycle; 200m: 147, 146, 144s and 800m: 586, 557 and 527s. **Discussion:** As expected, aerobic capacity related parameters, i.e., [La-]AnT and vAnT evolved along the training macrocycle (despite a stabilization in the specific preparatory period), reflexing in a better performance at the 800m test. Furthermore, it is known that after a cycle of "basic" (i.e. aerobic) training, coaches implement a cycle focusing on more intense training areas, particularly developing the swimmers aerobic power, with evident higher values of [La-]max, VO<sub>2</sub>max and vVO<sub>2</sub>max. Nevertheless, the swimmer's SR and SL seem to regress in the competitive period, evidencing eventual biomechanical and coordinative deficiencies in the final stage of the training process. **References:** Fernandes R et al (2008). *Int J Sports Med*, 29(2). **Acknowledgements:** PTDC/DES/101224/2008 (FCOMP-01-0124-FEDER-009577)

### HEART RATE VARIABILITY IN MEN SUBJECTED TO 30-HOURS OF EXERCISE AND SLEEP DEPRIVATION

Dabrowski, J.1, Mikulski, T.1, Kozacz, A.1, Bogdan, A.2, Krzeminski, K.1

1 Mossakowski Medical Research Centre, Polish Academy of Sciences, Warsaw, Poland. 2 Central Institute for Labour Protection – National Research Institute, Warsaw, Poland

**Introduction** Heart rate variability (HRV) is considered to be a factor determining condition of the heart, especially its fatigue and possible overtraining. The aim of the present study was to evaluate the heart rate variability at rest in subjects submitted to prolonged exercise combined with complete sleep deprivation using simple, commercially available tool. **Methods** Heart rate variability was assessed in 11 endurance trained men before (trial B) and immediately after (trial A) 30 hours of prolonged exercise (simulated adventure race) combined with complete sleep deprivation using infrared sensor fitted in BioCardio Mouse (Poland). For evaluation of HRV PNN50 and RMSSD factors were chosen. **Results** Significantly lower values of HRV were observed after 30 hours of prolonged exercise (simulated adventure race) combined with complete sleep deprivation. In trial B PNN50 was 18.3±2.0 vs. 10.6±2.3 in trial A, p<0.001 and RMSSD was 515.7±81.4 vs. 708.6±70.1, p<0.05, respectively. **Discussion** Simple and cheap BioCardio Mouse delivered consistent and reliable results of several factors determining HRV. Automatically generated reports are easy to follow and raw results can easily be used in everyday monitoring of athletes, whereas description and recommendations in extreme case of present study were completely inadequate. Prolonged, 30-hour physical activity combined with total sleep deprivation produced decreased HRV which results from the shift in parasympathetic to sympathetic activity balance.

### DISCRIMINATING CHARACTERISTICS OF UNDER-17 MALE HOCKEY PLAYERS

Pereira, J.1, Vaz, V.1, Valente-dos-Santos, J.1, Cupido-dos-Santos, A.1, Figueiredo, A.J.1, Soles-Goncalves, R.2, Areceres, A.3, Elferink-Gemser, M.4, Malina, R.5, Coelho-e-Silva, M.1

1: FCDEF-UC (Coimbra, Portugal), 2: School of Health and Technology (Coimbra, Portugal), 3: INEF (Coruna, Spain), 4: University of Groningen (The Netherlands), 5: University of Texas (Austin, USA)

**INTRODUCTION:** The objectives of this study were twofold: (i) to profile the experience, size, adiposity and biological maturity characteristics and functional performances of U-17 Portuguese male roller hockey players using both field and laboratory tests; and (ii) to evaluate the contributions of these variables to the discrimination of players by competitive level (international versus local). **METHODS:** Characteristics of 32 international and 41 local U-17 (14.5-16.5 years) roller hockey players were considered in the context of training history, body size, skeletal maturation, and several laboratory (peak O<sub>2</sub>, isokinetic strength of knee extensors and flexors, wingate test) and field performance tests (25-m dash, jumps, sit-ups, 2-kg ball throw, PACER). **RESULTS:** More international (42%) than local (22%) players were advanced in maturity status. International players had slightly less hockey experience (years), but had more practice sessions and match time (minutes) during the season. Local players were shorter and attained better performance in the 25-m dash, while international players performed better in sit-ups, ball throw and 20-m shuttle run. The fatigue index derived from the Wingate anaerobic test was higher among local players, while peak torques of knee extension and flexion were greater in international players. Stepwise discriminant function correctly classified 85% of players by competitive level based on grip strength, ratio of eccentric and concentric knee extension, number of training sessions, playing time and fatigue index. **CONCLUSION:** An interaction between isokinetic strength, anaerobic fitness and training plus game time seemed relevant factors in discriminating international from local level players and by inference in the selection and development of youth roller hockey players.

## PROGRESSIVE RESISTANCE TRAINING AND PROTEIN SUPPLEMENTATION INCREASES PHYSICAL FUNCTION IN INSTITUTIONALIZED ELDERLY

Oesen, S., Halper, B., Hofmann, M., Bachl, N., Wagner, K.H., Wessner, B.

*University of Vienna*

Introduction Von Haehling et al. [1] showed that 5-13% of 60- to 70-year-old and 11-50% of people over 80 years are affected by sarcopenia. Recent observations proved that resistance training is effective up to old age to mitigate the effects of sarcopenia [2,3]. However, most of the studies applied resistance training performed on weight machines which is not practicable for most of seniors. Therefore, we aimed to capture the effect of resistance training using therabands and own body weight on muscle strength and function in elderly institutionalized persons. Additionally, the effect of dietary supplementation enriched with branched chain amino acids was examined. Methods The population of this randomized, observer-blind, controlled intervention study consisted of healthy untrained men (n=14) and women (n=103) aged  $83 \pm 6.0$  years. They were distributed randomly but stratified by sex to one of 3 groups [Cognitive training (CT), resistance training (RT), RT+supplement (RTS)]. Supervised RT was performed twice a week. The supplement (FortiFit, Nutricia) was distributed every morning as well as after training. CT was based on activities with coordinative or cognitive tasks. Pre, during (after 3m) and post (6m) intervention functional tests for strength as well as aerobic capacity were assessed. Tests include isokinetic torque measurements of knee extensors - and flexors, isometric handgrip strength, chair-rise test, maximum walking speed and 6min walking test. Repeated measures ANOVA was used for analysis of group-, time- and interaction effects. Results Baseline values didn't differ in any of the functional parameters. The attendance to training sessions was  $71 \pm 26.5\%$  and did not differ between groups ( $p>0.05$ ). We observed a group-, time- and interaction effect in the chair rise test. The RT improved by 17.2% and 20.1%, the RTS by 7.3% and 16.4% after 3 and 6 months whereas CT did not show improvements. Significant time but not group or interaction effects were detected for isokinetic torque measurements, walking speed and 6 min walking test. Discussion Six months of progressive resistance training with own body weight and therabands is able to improve physical function of the lower limbs as shown by chair rise test. Protein supplementation did not lead to further enhancements. Interestingly, many of the other parameters improved over time regardless of group implying that different types of supervised training and the potential social aspects can lead to improvements in fitness parameters in institutionalized elderly. ## THE EFFECT OF MATURITY ON FUNCTIONAL MOVEMENT SCREEN™ SCORE IN YOUNG SOCCER PLAYERS

Portas, M.D., Parkin, G., Roberts, J., Batterham, A.M.

*Teesside University*

Introduction Knowledge of movement competency in junior athletes informs athletic development and recruitment. The functional movement screen (FMS) is a reliable tool that is used to assess and grade fundamental human movement (Frohm et al., 2012). The aim of this study was to examine the effect of maturity on FMS score in young soccer players. Methods Participants were 914 junior, male soccer players (age 9 – 16 years) from English Football League clubs. Each player was assessed on the FMS by an experienced practitioner. The FMS is a series of 7 tests, each scored 0-3 on a categorical scale, whereby an individual with perfect execution on each test would score a maximum 21. Players were awarded a score that was the sum of all 7 tests (FMS<sub>T</sub>). Age from peak height velocity was estimated from anthropometric measures (Mirwald et al., 2002). Players were subsequently grouped as pre- (n = 665) and post- (n = 249) peak height velocity (PHV). To identify where differences in FMS<sub>T</sub> score existed between groups we separated the screen into 3 parts: FMS<sub>m</sub> (3 movement tests), FMS<sub>f</sub> (2 flexibility tests) and FMS<sub>s</sub> (2 stability tests). Data were modelled using ordinal logistic regression to derive estimates of the probability of having a score  $\geq 14$  for FMS<sub>T</sub>,  $\geq 6$  for FMS<sub>m</sub>, and  $\geq 4$  for FMS<sub>f</sub> and FMS<sub>s</sub>. These cut-points are equivalent to scoring a '2' on each test - 'satisfactory' performance. Results The median (interquartile range) for FMS<sub>T</sub> was 12 (10 to 13). For FMS<sub>T</sub> the predicted probability for a score  $\geq 14$  was: Pre-PHV = 0.15; Post-PHV = 0.40 [Difference = 0.25 (95% confidence interval, 0.20 to 0.30)]. In FMS<sub>m</sub> the predicted probability of a score of  $\geq 6$  was: Pre-PHV = 0.24; Post-PHV = 0.41 [Difference = 0.17 (0.11 to 0.23)]. In FMS<sub>f</sub> the predicted probability of a score of  $\geq 4$  was: Pre-PHV = 0.69; Post-PHV = 0.79 [Difference = 0.10 (0.04 to 0.16)]. In FMS<sub>s</sub> the predicted probability of a score of  $\geq 4$  was: Pre-PHV = 0.10; Post-PHV = 0.48 [Difference = 0.38 (0.32 to 0.44)]. Discussion Maturity status had a substantial effect on functional movement screen performance, with players who were post-PHV being more likely to achieve at least a satisfactory performance than those pre-PHV. Maturity affected the total score and all three sub-components, with the largest effect on stability. Coaches using the FMS to evaluate movement competency of their junior players should take maturity status into account when interpreting results. ## TRAINING IN THE FASTED STATE DOES NOT IMPROVE PERFORMANCE OR FAT OXIDATION IN MILD LEVEL ATHLETES COMPARED TO TRAINING IN THE FED STATE, BUT INCREASES VO<sub>2</sub>MAX

Charlot, K., Pichon, A., Chapelot, D.

*Université Paris 13*

Introduction Training in a fasted state is practiced by many athletes in endurance to improve their performances through increased fat oxidation and spared muscle glycogen. To this day, the demonstrations of these metabolic effects have been unconvincing and performances not significantly modified. One hypothesis is that carbohydrate supplementation during the post-training measurements precluded increased fat oxidation to occur. Thus, we assessed here the effects of endurance training in a fasted state on performance, oxygen uptake and substrate oxidation without carbohydrate supply. Methods Sixteen young healthy male and mild level athletes ( $21.1 \pm 2.3$  y; maximal oxygen uptake or VO<sub>2</sub>max =  $56.3 \pm 3.8$  mL/min/kg) trained on a treadmill during 6 weeks, 3 sessions/week planned on 3 different days, consisting in 2 continuous sessions (40 min at 70% of VO<sub>2</sub>max) and 1 intermittent session (40 min with 8 sets of 2 min at 85 % of VO<sub>2</sub>max). One group trained in a fasted state (FAST, n=8) and one group in a fed state (FED, n=8). Before and after the training period, 4 variables of interest were measured in the fed state: substrate oxidation during a 60 min-steady state exercise at 60 % of VO<sub>2</sub>max, the 3000 m-time trial performance that followed the steady-state, the intensity eliciting the highest fat oxidation (FATmax) and VO<sub>2</sub>max. Results The substrate oxidation during the 60 min steady-state exercise was not altered by training or by the nutritional status. Time to complete the 3000 m trial decreased not differently in FED and FAST (-63 and -108 s, respectively,  $p<0.001$ ). FATmax tended to increase with training ( $p=0.058$ ) without difference between FED or FAST. VO<sub>2</sub>max increased only in FAST ( $56.9$  vs  $61.6$  mL.kg<sup>-1</sup>.min<sup>-1</sup>, +8.1 %,  $p=0.019$ ) although speed at VO<sub>2</sub>max increased by 9 % ( $p<0.001$ ) without difference between groups. Discussion In this study, training

in a fasted state failed to improve fat oxidation, endurance performance or intensity of maximal fat oxidation although tests were conducted without carbohydrate supplementation. Only maximal oxygen uptake was still increased in these mild level athletes when they trained in the fasted but not in the fed state, suggesting a power of training in the fasted state to enhance already high  $\text{VO}_2\text{max}$ . In conclusion, the demonstration of an effect of training in a fasted state on performance is still needed.

### THE EFFECTS OF AEROBIC AND COMBINED AEROBIC AND RESISTANCE EXERCISE TRAINING ON PHYSICAL FITNESS IN YOUNG WOMEN

Batalha, N.1,2, Marmeleira, J.1,2, Dias, J.1

1: UE (Évora, Portugal), 2: CIDESD (Portugal)

**Introduction** There is a lack of studies evaluating the effects of combining different types of exercise in young women. Therefore, the purpose of this study was to evaluate the effects of aerobic training alone or combined with strength training on the physical fitness of young women. **Methods** Sixty-five women (18–28 years old), who were not engaged in any exercise program for at least one year, were randomly assigned to an aerobic training group, a combined training group, or a control group. The aerobic training consisted of indoor cycling sessions and the combined training consisted of indoor cycling and resistance exercise in the first and second half of each session, respectively. Both aerobic and combined exercise programs lasted 8 weeks with a periodicity of 3 sessions of 45 min per week. Assessments were conducted before and after the 8-week intervention period on muscular strength, body composition, bone mineral density and cardiorespiratory fitness. Total fat and bone mineral density (lumbar spine and femoral neck) were determined by dual-energy x-ray absorptiometry (DEXA Hologic QR). Knee and elbow extensor and flexor concentric strength were measured with an isokinetic dynamometer (Biodex System 3) using protocols with angular velocities of  $60^\circ\cdot\text{s}^{-1}$  (3 reps) and  $180^\circ\cdot\text{s}^{-1}$  (20 reps). The YMCA cycle ergometer test was used to estimate  $\text{VO}_2\text{max}$ . Data were analysed using repeated measures ANOVA with Bonferroni post-hoc analysis (level of significance was set at  $p < 0.05$ ). **Results** Knee strength increased significantly for the combined exercise group following training. The post-hoc analysis showed that the combined training group improved in comparison to the aerobic training group in knee flexion peak torque (PT) ( $p = 0.024$ ) and knee flexion PT/body weight ( $p = 0.046$ ) at an angular speed of  $60^\circ\cdot\text{s}^{-1}$ . Significant positive changes of the combined training group in comparison with the control group were also found in knee extension PT ( $p = 0.013$ ), knee flexion PT ( $p = 0.002$ ) and knee flexion PT/body weight ( $p = 0.014$ ) at an angular speed of  $180^\circ\cdot\text{s}^{-1}$ . Finally, after the 8-week training period and also for the evaluation at  $180^\circ\cdot\text{s}^{-1}$ , the combined training group showed better scores than the indoor cycling group in knee flexion PT/body weight ( $p = 0.014$ ). No significant changes were found at follow-up for measures of cardiorespiratory fitness, body composition and bone mineral density. **Discussion** Our results show that 8 weeks of combined training can improve the knee muscular strength of young women. Nevertheless, no other differences were found between groups in measures of physical fitness. Future studies should examine if prolonged training periods would lead to more noticeable differences on the effects of combined and indoor cycling training programs.

#### SEASONAL CHANGES IN BODY COMPOSITION OF A PROFESSIONAL BASKETBALL TEAM IN TURKEY

Ozlem, T., Alp, B.

Health Science Institute

**Introduction** There is a growing interest in improving the performance of athletes. Many of the activities are focused on increasing the physical fitness of athletes with taking into consideration the assessment of their nutritional status and body composition (Rodríguez et al., 2009). Specific athletic events require different body types and weight for maximal performance. Physical abilities are important for basketball players to achieve higher levels of performance. To evaluate these physical abilities, the anthropometric measurements, parameters of the body composition such as the body fat percentage (% fat), fat mass (FM) and fat-free mass (FFM) are often used (Apostolidis et al., 2003). Changes in body composition during a season or in response to specific training and nutrition programs are important for assessment of the athletic performance (Harley et al., 2011; Sallet et al., 2005). The aim of this study is to evaluate the professional basketball players' seasonal body composition changes and present an average data. **Methods** Anthropometric measurements were collected from the players of a first division Turkish basketball team (TBL). Fifteen players (27.3±5 years, 195.7±10.1 cm, and 99.2±11.5 kg) were evaluated by using a bioelectrical impedance analyser (Tanita, BC-418, Japan). First measurements were taken prior to the beginning of the practices and the second ones were noted 18 weeks later in the season. Changes in the body composition of these players during the season were analysed. **Results** A significant decrease in fat mass (2.1 kg,  $p < 0.05$ ) and a significant change in body fat percentage (% 2.24,  $p < 0.05$ ) was measured. Although there is no statistically significant difference in fat-free body mass, a tendency toward a slight increase in FFM was observed (1.05 kg,  $p = 0.29$ ). It is also presented that the average body fat percentage is  $12.63 \pm 4.04$  for the basketball players of a professional Turkish team. **Discussion** Although it is clear that the athletes' body composition and anthropometry will not remain static, but may alter according to the quantity, intensity and type of activity undertaken (Kamble et al., 2012), we believe that the present study provides a valuable baseline data for further investigation of the anthropometry of professional athletes. **References** Rodríguez NR, Di Marco NM, Langley S (2009). *Med Sci Sports Exerc.* 41(3): 709-731 Apostolidis N, Nassis GP, Bolatoglou T, Geladas ND (2003). *J. ### LONGITUDINAL PREDICTORS OF AEROBIC PERFORMANCE IN ADOLESCENT SOCCER PLAYERS

Duarte, J.1, Valente-dos-Santos, J.1, Pereira, J.1, Simões, F.1, Rebelo-Gonçalves, R.1, Severino, V.1, Figueiredo, A.1, Elferink-Gemser, M.1, Malina, R.M.2, Coelho-e-Silva, M.1

*University of Coimbra, Portugal*

Background: The importance of aerobic performance in youth soccer is well established. The aim of the present study was to evaluate the contributions of chronological age (CA), skeletal age (SA), body size, and training to the longitudinal development of aerobic performance in youth male soccer players aged 10 to 18 years. Methods: Players (n=83) were annually followed up during 5 years, resulting in an average of 4.4 observations per player. Decimal CA was calculated, and SA, stature, body weight, and aerobic performance were measured once per year. Fat-free mass (FFM) was estimated from age- and gender-specific anthropometric formulas, and annual volume training was recorded. After testing for multicollinearity, multilevel regression modeling was used to analyze the longitudinal data aligned by CA and SA (Model 1 and 2, respectively) and to develop aerobic performance scores. Results: The following equations provide estimations of the aerobic performance for young soccer players:  $\hat{y}$ (Model 1 [deviance from the null model =388.50;  $P<0.01$ ]) =  $57.75+9.06\times\text{centered CA}-0.57\times\text{centered CA}^2+0.03\times\text{annual volume training}$  and  $\hat{y}$ (Model 2 [deviance from the null model= 327.98;  $P<0.01$ ]) =  $13.03+4.04\times\text{centered SA}-0.12\times\text{centered SA}^2+0.99\times\text{FFM}+0.03\times\text{annual volume training}$ . Conclusions: The development of aerobic performance in young soccer players was found to be significantly related to CA, biological development, and volume of training.

### SPEED AND GRADE INCREMENT DURING CARDIOPULMONARY TREADMILL TESTING: IMPACT ON EXERCISE PRESCRIPTION

Belli, K.C.1,2, Figueiredo, P.1,2, Stein, R.1,2, Ribeiro, J.P.1,2 (in memoriam)

*1: HCPA (Porto Alegre, Brazil), 2: UFRGS (Porto Alegre, Brazil)*

Introduction: Ventilatory thresholds (VT) have been used as reference for exercise prescription (EP). We test the hypothesis that EP, based on VT determined by treadmill cardiopulmonary exercise testing (CPET), could be influenced by the emphasis in speed or grade of the treadmill. Methods: Nine healthy individuals underwent two CPET, followed by two sessions of submaximal exercise, both in randomized order. The protocol based on speed increments (SP) increased the speed in 0.1 to 0.3 Km/h every 15s. The protocol mainly based on grade increments (GP) increased the grade in 1% every 30s and 0.1Km/h every 45s. Each submaximal session lasted 40min, at the intensity corresponding to heart rate (HR) between 1st and 2nd VT. Results: The SP resulted in higher 1st ( $27.5\pm 2.3$  vs  $24.9\pm 1.9$  ml/kg.min;  $p=0.001$ ) and 2nd ( $32.4\pm 2.9$  vs  $29.7\pm 2.1$  ml/kg.min;  $p=0.017$ ) VT, and had no difference on maximal oxygen uptake. The target HR for EP was higher in the SP ( $169\pm 9$  vs  $156\pm 8$  bpm;  $p<0.001$ ). Blood lactate was higher during the submaximal session prescribed with SP ( $6.2\pm 1.6$  vs  $4.6\pm 1.9$  mmol/l;  $p<0.001$ ) remaining stable over the session. Discussion: The oxygen uptake (VO<sub>2</sub>) and HR at VT were higher in the SP when compared to the GP (7% and 8%, respectively). Previous studies have shown that the detection of VT was independent of the rate of increment in power output on cycle ergometer (Ribeiro et al, 1986; Davis et al, 1982; McLellan, 1985). When the treadmill was utilized the results were dependent of the type of increment. One possible explanation for lower VT on the GP is activation of a larger muscle mass with increments in grade (Wall-Scheffler et al, 2010). It is associated with larger oxygen deficit (Sloniger et al, 1997) and larger glycogen depletion (Costill et al, 1974). The GP used in the present study probably resulted in the activation of a larger muscle mass, larger glycogen utilization, and earlier blood lactate accumulation, resulting in a lower VO<sub>2</sub> at 1st and 2nd VT. The EP based on SP modified the target HR between 1st and 2nd VT, and resulted in higher blood lactate on submaximal sessions (8% for heart rate and 2 mmol/l for blood lactate). ### COMPARISON ON ENERGY EXPENDITURE, HEART RATE, AND RATING OF PERCEIVED EXERTION ACCORDING TO VARIOUS BEGINNING SET POINTS OF TARGET EXERCISE INTENSITY WHILE EXERCISING

Lee, H.

*SANGMYUNG UNIVERSITY*

Introduction In general, we always exercise with exercise intensity based on the target HR which was made by HRR. However, there is no standard principle about when we should set the beginning of target HR. If we let the clients exercise without specific settings about this, they don't know about how much exercise volume they had have, and whether they are doing it with accuracy. Therefore, the aim of this study is to compare the differences on energy expenditure, heart rate, and rating of perceived exertion according to various beginning set points of target exercise intensity during aerobic treadmill exercise. Methods 13 healthy university-aged male students volunteered to participate in this research. They determined their 70%HR<sub>max</sub> as target exercise intensity with using HRR, individually. And then, they have performed 30min treadmill aerobic exercise repeatedly. The research design consisted of 3-exercise trails according to approaching points(after 5min,10min and 20min of main exercise) of target HR. It were measured the energy expenditure(EE) and heart rate(HR) with heart check device(Polar, RS800CX), rate of perceived exertion(RPE) with Borg CR10 Scales(1-10), and body composition factors with In body(Biospace, 3.0). Statistical analysis was completed using one-way repeated ANOVA. Results In case of setting at 5min after main exercise, there were the highest values on EE, HR, and RPE among others(10min, 20min). There were significant difference on energy expenditure (TEE), heart rate(THR, MHR, PHR) ( $p<.001$ ,  $p<.01$ ,  $p<.001$ ,  $p<.01$ , respectively), and rating of perceived exertion (MRPE, PRPE) ( $p<.001$ ,  $p<.001$ , respectively), except RHR. Discussion It was reconfirmed that there was a similar trend among TEE, MHR and MRPE (Borg, G. et al., 1983; Borg, G.A.V. 1998) in all of three trials of exercise. There was different on exercise volume according to setting the beginning point of target HR while exercising. Especially, in case of setting the target HR at the finish point while exercising, it was produced the least energy expenditure and performed the most easy among others. Therefore, when we let the clients training the exercise program, we have to set appropriately the beginning point of the target HR based on their physical fitness level and their purpose of exercise (Peter Hofmann et al., 2011). ### INFLUENCE OF EXERCISE TYPE ON GROSS EFFICIENCY: ELLIPTICAL TRAINER VS CYCLING TRAINER

Morio, C., Haddoum, M., Barla, C.

*Oxylane Research*

**Introduction** The elliptical trainer is known as a good mean to develop physical fitness. The increase of energy expenditure when compared to that of a classical cycling trainer can be attributed to the additional use of arms (Mier & Feito, 2006). It is well known that upper limbs are less efficient than lower limbs (Eston & Brodie, 1986). However, there is no information in the literature concerning the efficiency of pedalling on an elliptical trainer. The aim of the present study is to compare metabolic cost and gross efficiency for two different trainers, elliptical and cycling. **Methods** Fourteen subjects (7 men, 7 women) were tested on the elliptical trainer (ET) and the cycling trainer (CT) during two different exercise sessions. Both trainers use magnetic resistance and were previously calibrated on a specific torque/cadence system. For each exercise session, an initial 5 min measurement was taken at rest then a 5 min warm-up protocol was followed prior to exercise. Subjects pedaled at 9 different power outputs (3 resistance levels x 3 cadences) for 3 min each. To avoid fatigue effects, the exercise was split in 3 bouts of 9 min with 3 min rest periods. A Fitmate Pro (Cosmed) recorded oxygen consumption (VO<sub>2</sub>) and heart rate (HR), whereas respiratory exchange ratio was estimated according to Nieman et al (2007). Gross efficiency (GE) was calculated as the ratio between mechanical energy output and human energy expenditure during the last 30 sec of each 3 min period at a different power output. Maximal aerobic power (MAP) was estimated for each subject in both trainer through a linear regression between HR, VO<sub>2</sub> and power output. Results MAP was significantly greater in CT (237±88W) compared to ET (151±51W). Significant positive correlations were found between power output and VO<sub>2</sub> in both CT (r=0.93) and ET conditions (r=0.97). Regarding the large variability in MAP, GE was significantly correlated to the percentage of MAP (r=0.75 in CT and r=0.69 in ET). Logarithmic relationships were found with  $GE=5.9*\ln(\%MAP)+24.5$  in CT condition and  $GE=3.9*\ln(\%MAP)+14.3$  in ET condition. Maximal GE reached at 100% of MAP corresponded to the second coefficient, 24.5% in CT and 14.3% in ET. **Discussion** The originality of the present study was to investigate different metabolic demand of two type of exercise using the relative power output in each condition (%MAP). The results confirmed that metabolic cost of ET was greater than CT at similar %MAP. Gross efficiency was greatly impaired in ET condition. This could be explained through the additional use of arms and the upright position during ET. **References** Eston RG, Brodie DA. (1986). *Br J Sports Med* 20(1):4-6. Mier CM, Feito Y. ### THE RELATIVE AGE EFFECT AND THE INFLUENCE OF THE LEVEL OF PERFORMANCE OF PHYSICAL MOTOR SKILLS ON IT IN ALPINE SKIING

Müller, L., Müller, E., Kornexl, E., Raschner, C.

*University of Innsbruck; University of Salzburg*

**Introduction** The relative age effect (RAE) was recently shown to be present in international alpine skiing for top elite athletes (Müller et al., 2012; Baker et al., 2012). The causes for it still remain unclear and it is unknown at which age category it starts to exist. As a result, the aims of this study were (1) to test the presence of RAE depending on gender and age in young alpine ski racers and (2) to test the influence of the level of performance of physical motor skills on the RAE. **Methods** We investigated 989 participants of the entrance exams of three Austrian ski boarding schools, examined their birth dates and tested three different physical fitness abilities. Chi<sup>2</sup>-tests were used to assess differences between the observed and the expected birth-quarter-distributions, in which an even distribution was assumed. For evaluating the influence of the level of performance of the physical motor skills on the RAE, multivariate, univariate and parameter-free univariate analyses of variance were used. Results A highly significant difference from an equal distribution was shown for the overall sample ( $\chi^2=25.4$ ;  $p<0.001^{**}$ ) and for both male ( $\chi^2=13.8$ ;  $p=0.003^{**}$ ) and female athletes ( $\chi^2=12.9$ ;  $p=0.005^{**}$ ), without a significant gender specific difference. For testing age specific differences, the participants of the entrance exams were divided into two groups: children (9-10 years; n=541) and adolescents (14-15 years; n=448). Both groups showed a significant (children:  $\chi^2=11.0$ ;  $p=0.012^{**}$ ) or a highly significant difference between the expected and the observed birth quarter distribution (adolescents:  $\chi^2=19.9$ ;  $p<0.001^{**}$ ), without age specific differences. The analyses of variance did not show significant differences, which means that the level of physical motor skills does not influence the RAE. **Discussion** Obviously, the RAE in alpine skiing exists from an early age. The results of our study indicate that the level of physical motor skills does not influence the RAE. Therefore, changes in the talent-selection- and talent-development-system are imperative (Lames et al., 2008). Since the level of physical motor skills does not influence the RAE, the causes for it have to be pursued elsewhere. The assessment of the biological age within the talent-selection-systems could be a possible solution. **References** Lames M, Augste C, Dreckmann C, Görsdorf K, Schimanski M. ### RESISTED SPRINT EFFECTS OF THREE DIFFERENT LOADS ACCOUNTING FOR 5%, 12.5% AND 20% OF BODY MASS ON ACCELERATION, VERTICAL JUMP, LOADED VERTICAL JUMP, AND FULL SQUAT.

Bachero-Mena, B., González-Badillo, J.J.

*Pablo de Olavide University*

**Introduction** The optimal resisted load for sprint training has not been established yet, but a resistance reducing the athlete's velocity by more than 10% from unloaded sprinting would entail substantial changes in the athlete's sprinting mechanics (1). The aim of this study was to examine the effects of sled resisted sprint training during 7 weeks with three different loads both on acceleration and strength variables. **Methods** Nineteen young male subjects were divided into three sled loads training groups according to a % of body mass (BM): low load (LL: 5% BM), medium load (ML: 12.5% BM) and high load group (20% BM). During 7 weeks (2 sessions/week), these followed the same training program consisting in sprint accelerations with pull sled. The three loads used caused a mean velocity loss of 5.6%, 10% and 15.5%, respectively as compared to unloaded sprinting. The subjects performed sprint tests (40m) and strength tests (CMJ, JS, and full squat) before and after the 7-week training period. Results Statistical improvements were observed on 20m and 30m for the HL group, and on 40m for the three groups. Likewise, the partial times 10-40m and 20-40m for the LL group, and the partial times 20-30m and 20-40m for the ML group, were improved. Regarding the strength tests, CMJ and full squat for the ML and HL groups, and jump squat (JS) for HL group were improved. **Discussion** Some studies have investigated the effect of resisted sprint training. However, different reasons such as a higher training volume (3) or the use of parallel strength and soccer training sessions (2) make it difficult to directly compare the results of these studies with ours. Sprinting tests results suggest that the improved 40m performance of the HL group is due to a better acceleration phase up to 30m; however, improvements in both LL and ML groups on 40m are fundamentally due to a better

maximum speed phase. The results show that depending on the magnitude of load we use, the effects will be attained in different phases of 40 metres acceleration run. Moreover, sprint resisted training with ML and HL improves vertical jump and leg strength in moderately trained subjects. References 1. Clark KP, Stearne DJ, Walts CT, and Miller AD. ### RELATIONSHIP BETWEEN SPORTS INJURY AND LANDING STEP PATTERN IN MALE LONG-DISTANCE RUNNERS

Tanaka, T., Yoshimura, Y., Yasukawa, M., Oishi, K.

*Chuo University*

Recently, the running form of long-distance runners has been analyzed to prevent sports injuries and to improve performance. The purpose of this study was to investigate the relationship between the incidence of sports injury and the pattern of landing step. We included 23 Japanese collegiate long-distance runners as subjects. A video analysis system was used to check the forms of their lower legs during the landing phase. The duration to first incidence of injury (DFI) for each runner from March 1, 2011, to February 29, 2012, were obtained through structured interviews. On the basis of the video data of the feet during the landing phase, the subjects were divided into 2 groups, i.e., separate step type (SST) and overlap step type (OST) groups. Mean DFI for the SST group ( $254.5 \pm 29.5$  days) was higher than that for the OST group ( $177.5 \pm 35.7$  days). In other words, the incidence of sports injury was lower in the SST group than in the OST group (Kaplan–Meier survival curves and log-rank test;  $p = 0.046$ ). It was suggested that step types during the landing phase influenced the incidence of injury in long-distance runners.

### ALLOMETRIC SCALING OF PEAK OXYGEN UPTAKE IN UNDER-17 MALE ROLLER HOCKEY PLAYERS

Pereira, J.R.1, Vaz, V.1, Valente-dos-Santos, J.1, Duarte, J.1, Simões, F.1, Rebelo-Gonçalves, R.1, Severino, V.1, Cupido-dos-Santos, A.1, Elferink-Gemser, M.T.2, Malina, R.M.3, Coelho-e-Silva, M.J.1

1: FCDEF-UC (Coimbra, Portugal), 2: UMCG, University of Groningen (The Netherlands), 3: University of Texas (Austin, USA)

Background: Peak oxygen uptake (peak VO<sub>2</sub>) is routinely expressed in liters per minute and also by unit of body mass (ml/kg/min) despite theoretical and statistical limitations of using ratios. Allometric modeling is an effective approach for partitioning body-size effects in a performance variable. Methods: The current study examined the relationships among chronological age (CA), skeletal age (SA), total body and appendicular size descriptors with peak VO<sub>2</sub> in male adolescent roller hockey players. Seventy three Portuguese, highly trained male athletes (CA:  $15.4 \pm 0.6$  years; SA:  $16.4 \pm 1.5$  years; stature:  $169.9 \pm 6.9$  cm; body mass:  $63.7 \pm 10.7$  kg; thigh volume:  $4.8 \pm 1.0$  L) performed an incremental maximal test on a motorized treadmill. Results: Exponents for body size descriptors were 2.15 for stature ( $R^2=0.30$ ;  $P<0.01$ ) and 0.55 for thigh volume ( $R^2=0.46$ ;  $P<0.01$ ). The combination of stature or thigh volume with CA or SA and with CA<sup>2</sup> or SA<sup>2</sup> increased the explained variance in peak VO<sub>2</sub> ( $R^2$  ranged 0.30-0.55). The allometric model combining more than one body size descriptor (i.e., stature and thigh volume) in addition to SA and CA<sup>2</sup> was not significant. Conclusions: Results suggested that thigh volume and skeletal age are the main contributors to explain inter-individual variability in aerobic fitness.

### HEART RATE AND GRADED MAXIMAL TEST VALUES TO DETERMINE POSITIONAL RUGBY UNION GAME INTENSITIES OF ADOLESCENT BOYS

Willemse, F., Coetzee, B.

*North-West University*

Heart rate and Graded Maximal Test Values to Determine Positional Rugby Union Game Intensities of Adolescent Boys Introduction The positional demands of high school rugby union games need to be quantified so that appropriate conditioning programs can be compiled (Hartwig et al., 2008). Therefore, the purposes of this study were firstly, to determine the significant positional differences in the heart rate and standard incremental maximal oxygen uptake test values of u/15 high school rugby players and secondly, to determine the significant positional differences in the intensities of u/15 high school rugby union games when making use of heart rates and standard incremental maximal oxygen uptake test values. Methods Twenty-four u/15 rugby union players from a high school in the Potchefstroom area of the North-West Province, South Africa performed standard incremental running tests to the point of exhaustion in the periods between rugby games, to determine the individual heart rate (HR) intensity zones: (1) low intensity zone or LIZ (below ventilatory threshold (VT)); (2) moderate intensity zone or MIZ (between VT and respiratory compensation point (RCP)) and (3) high intensity zone or HIZ (above RCP). Players' HR values were then recorded during several rugby games and categorised according to the HR intensity zones. Descriptive statistics and an independent test were used to describe and determine significant differences between the two positional groups. Results Results of the standard incremental running test showed that the backs obtained a significantly higher average HR at the VT and HRs for the LIZ and MIZ as well as significantly lower average VO<sub>2</sub> at RCP compared to the forwards. With regard to the match analysis related results, forwards and backs spent the highest percentage of match time in the MIZ (60.3% and 57.5%). Forwards spent less time in the LIZ (12.5% versus 26.4%) and more time in the HIZ compared to the backs (27.4% and 17.6%). The average length of each intensity bout were 33 s (forwards) and 51 s (backs) for the LIZ; 70 sec (forwards) and 60 sec (backs) for the MIZ; and 39 s (forwards) and 37 s (backs) for the HIZ. Despite these differences, only total time and relative total time spent in the LIZ obtained significantly lower values for the forwards compared to the backs. Discussion Results of this study seem to suggest that the positional specific intensities of u/15 high school rugby union games can be determined and compared by making use of HRs and standard graded maximal oxygen uptake test values. Furthermore, results showed that the physical match demands of high school backline play are less than the demands of front-line play. References Hartwig TB, Naughton G, Searl J. 2008. Defining the volume and intensity of sport participation in adolescent rugby union players. *Int. J. Sports Physiol. Perform*, 3, 94-106.

## THE COMPARISON OF ARM-LEG AND AGILITY PERFORMANCES OF YOUNG ELITE WRESTLERS WITH ELITE SOCCER PLAYERS

Memiş, U.A., Ayan, S., Yapıcı, H., Ünver, R., Doğan, A.A., Kutlu, M.

*Bulent Ecevit University*

Introduction Wrestling and soccer are highly popular sports that need very markedly different strength from each other. It is well known that speed, strength, endurance, flexibility, balance and agility affect performance in both team and individual sports in which aerobic and anaerobic systems are used consecutively (Calbert et al., 2003). Especially, agility is one of the key elements an athlete must have in order to be successful in competitions (Little, 2007). In recent days strength and power have been assessed by comparing body composition of an athlete and his performance (Wozniak et al., 2006). The aim of this research was comparing agility, anaerobic strength and capacities (arm-leg) of elite wrestlers who compete in Turkish National Team with elite soccer players who compete in professional and amateur soccer teams in Kirikkale. Methods Elite Turkish National Greco-Roman young wrestlers (n=48) and elite professional and amateur (at least 7 years) (n=40) soccer players in Kirikkale participated in this study. Illinois agility run test and Wingate anaerobic (leg and arm) test were conducted. Statistically independent t test was used to assess the comparison. Results Elite Greco-Roman young wrestlers' (N=48) ages were 19±1 years, heights were 172±8.4 cm, weights were 77±18 kg, and professional and amateur soccer players' (N=40) ages were 20±2 years, heights were 178±6 cm, and weights were 73±8 kg. Discussion Significant differences were found between elite wrestlers and soccer players' body weights, heights, percentages of body fat, body mass indexes, anaerobic capacities (leg-arm) and agility scores (p<0.05). No significant differences were found in athletes' ages with sport ages (p<0.05). Results revealed that anaerobic performances and capacities of wrestlers were higher than soccer players. Agility scores of soccer players were found significantly better (p<0.05). Wrestlers were also found more successful in Wingate (cycling) strength test. That result emphasized the importance of test selection and effects of different work out styles (Sands et al., 2004). It is thought that the findings which revealed wrestlers arm and leg anaerobic strength and capacities were higher than those of soccer players, was because of the effects of strength and power trainings specific to wrestling. Findings which showed agility scores of soccer players were higher than wrestlers also suggested that agility trainings of soccer players must be better. Moreover, it is thought that differences in body composition affected sports performance. References 1. SANDS WA, MCNEAL JR, OCHI MT, URBANEK MJ, JEMNI M., STONE MH. (2004). ##### ANTHROPOMETRIC CHARACTERISTICS OF ELITE MONOFIN SWIMMERS: A FIRST APPROACH

Tampaki, M., Theos, A., Kaloupsis, S., Maridaki, M.

*University of Athens*

Introduction Anthropometric characteristics play an important role in performance of swimmers (Saavedra et al., 2010; Strzala et al., 2009). The purpose of the present study was to investigate the anthropometric characteristics of Greek competitive monofin swimmers. Methods Fifteen elite male monofin swimmers, age 20.3 ± 3.5 yrs, all members of the Greek fin swimming national team participated in this study. Anthropometric characteristics such as body mass, body height, the circumferences of the limbs and the thicknesses of skinfolds at the pectoral, mid-axilla, triceps, subscapular, abdominal, suprailiac, front thigh, and medial calf sites were measured. All skinfold thicknesses and circumferences of the limbs were measured on the right side of the body. Based on these data, body mass index (BMI), percent body fat, fat mass, skeletal muscle mass and somatotype (endomorph, mesomorph, ectomorph) were calculated. Results are presented as mean ± SD. Results Mean body mass was 75.6 ± 6.3 kg, body height 178.6 ± 2.9 cm, body mass index 23.7 ± 1.6 kg/m<sup>2</sup>, percent body fat 16.3 ± 5.3 %, estimated fat mass 12.5 ± 4.5 kg and estimated skeletal muscle mass 63.1 ± 5.1 kg. The mean of skinfold thicknesses were: pectoral 6.8 ± 1.8 mm, biceps 7.8 ± 3.3 mm, axilla 8.3 ± 2.4 mm, triceps 12.4 ± 5.5 mm, subscapular 10.5 ± 2.3 mm, suprailiac 10.1 ± 4 mm, abdominal 14.9 ± 4.8 mm, suprailiac mm, thigh 15.3 ± 5.8 mm, calf 12.1 ± 4.7 mm. The mean of somatotype (endomorph, mesomorph, ectomorph) was 2.7 – 5.9 – 2.6. Conclusion The results of the present study suggest that elite male monofin swimmers are more mesomorphic than endomorphic and ectomorphic. References Strzala, M., Tyka, A. (2009). ##### PERFORMANCE AND PHYSIOLOGICAL CHANGES AFTER COMBINED REPEAT SPRINT TRAINING AND SODIUM BICARBONATE SUPPLEMENTATION

Varley, M.C., McKenna, M.J., Anderson, M.J., Stepto, N.K., Aughey, R.J.

*Victoria University*

Introduction A variety of training strategies have been used to enhance sprint performance. Four weeks of repeat sprint training (RST) can improve acceleration and peak and mean sprint velocity. Cellular potassium (K<sup>+</sup>) efflux during muscle contraction may impair membrane excitability and contribute to fatigue. Sodium bicarbonate (NaHCO<sub>3</sub>) ingestion improves K<sup>+</sup> regulation during exercise and may improve repeat sprint exercise (RSE) performance. This study investigated whether chronic NaHCO<sub>3</sub> ingestion during 4 weeks of RST would result in greater improvements in RSE performance and improved K<sup>+</sup> regulation compared to placebo ingestion. Methods Fourteen healthy participants were randomly assigned to experimental (EXP, NaHCO<sub>3</sub> ingestion before RSE) or placebo (CON, calcium carbonate ingestion before RSE) groups. Both groups performed a baseline RSE (3 sets of five, 4-s sprints on a non-motorised treadmill, 25 s rest between sprints and 4.5 min rest between sets). The EXP and CON groups completed twelve RST sessions ingesting either NaHCO<sub>3</sub> or placebo before each session, respectively. Both groups then completed RSE post-training in which they ingested the placebo before exercise.

Performance (acceleration, peak and mean velocity) was recorded in all sessions. Venous blood was sampled before, during and after RSE in all sessions and analysed for venous [K+] ([K+]<sub>v</sub>). Results Following four weeks of RST the CON group had small improvements across all sets in acceleration (6.6 – 7.7%; Effect Size (ES) 0.32 – 0.37) and peak and mean velocity (4.0 – 6.3%; ES 0.33 – 0.51 and 3.8 – 5.8; ES 0.31 – 0.47, respectively). The EXP group had small improvements in acceleration in set 1 and 2 (4.8 – 5.4%; ES 0.20 – 0.22) and peak and mean velocity in set 2 (3.6%; ES 0.24 and 3.8%; ES 0.25). Following four weeks of training there was an increase in [K+]<sub>v</sub> during exercise (P=0.006) however [K+]<sub>v</sub> did not differ between groups. Discussion Repeat sprint training induced small improvements in acceleration and velocity, but these improvements were not enhanced with the addition of NaHCO<sub>3</sub> ingestion. Therefore, whilst RST is recommended to improve acceleration and velocity, the concomitant ingestion of NaHCO<sub>3</sub> is unnecessary. The increase in [K+]<sub>v</sub> following training was unexpected and associated with an improvement in performance. The small rise in [K+]<sub>v</sub> during RSE suggests this variable is unlikely to exert a critical role in fatigue during extremely short maximal sprint efforts.

### RECOVERY KINETICS DURING A 3-DAY FLOORBALL TOURNAMENT

Does, H.T.D., van der Brink, M.S., Lemmink, K.A.P.M.

*Hanze University of Applied Sciences*

Introduction During tournaments, team sport athletes are exposed to high physical loads due to a large number of games played within a few days. To perform well and prevent injuries, recovery in between these games is crucial. To monitor the recovery kinetics the Total Quality of Recovery (TQR) is suggested as a practical and useful tool (Kentta et al, 1998). The purpose of this study was to explore the feasibility and sensitivity of the TQR as a recovery monitoring tool during a 3-day floorball tournament. Methods Eleven elite Dutch female floorball athletes (age:24.3±4.8, length:171.5±9.1, weight:67.6±8.1) participated in a 3-day tournament. Their recovery was monitored with the TQR scale (6-20) (Kentta et al, 1998). All athletes were asked to rate their recovery each morning and every two hours including: 1 hour prior to the game (pre-game), immediately after the game (post-game) and 2 hours post-game. Comparisons were made for the TQR at the beginning and end of the tournament as well as pre- vs. post-game. Results A significant (p<0.05) lower TQR was recorded at the end of the tournament (M=13.2,SD= 1.9) compared to the beginning of the tournament (M=14.8,SD= 1.8). On the first day the pre-game TQR (M=14.6,SD= 2.1) was significantly (p<0.01) higher compared to the TQR two hours post-game (M=12.8,SD= 2.3). The second day the TQR pre-game (M=14.7,SD= 1.3) was significantly (p<0.05) higher compared to post-game (M=13.6,SD= 1.6) and two hours post-game (M=13.8,SD= 1.2). On the last day the TQR pre-game (M=14.5,SD=1.2) was significantly (p<0.05) higher compared to six (M=13.2,SD= 1.8) and eight hours (M=13.2,SD= 1.9) after the game. Discussion The TQR scale seems feasible and sensitive to monitor recovery kinetics in general. Besides, the TQR shows clear individual patterns. On average, recovery seems to go back to pre-game values after two hours the first and second day, while on the third day the recovery is still lower eight hours post- game. However the time of day at which the games were played were different. Earlier research used the TQR in soccer around a regular competition game looking at pre- and post-game and 24-hours post-game or in longer intervals showing higher TQR pre-game compared to post-game just as compared to 24-hours post-game (Kinugasa et al, 2009, Nedelec et al, 2012). More research is needed in recovery kinetics around tournaments and should take into account the time of the day at which the game is played. Besides, recovery-enhancing strategies should be developed to optimize recovery kinetics. References Kentta G., Hassmen P.(1998) *Sports Med*,26(1):1-16. Kinugasa T., Kilding, A.E. ### THE EVALUATION OF BLOOD LACTATE RECOVERY PROCESS USING AN EXPONENTIAL REGRESSION MODEL

Tsunoda, K., Hoshino, H., Sasaki, T., Takeda, H.

*Hokusei Gakuen University*

Introduction Most athletes know that recovery process after high intensity exercise is important to improve sports performance. In our previous study, gas exchange parameters were fitted using exponential regression model (Sasaki and Tsunoda, 2006). Blood lactate concentrations reflect the balance between lactate production and clearance. Failure of oxidative mechanisms can affect both production and clearance of lactate. (Barrie Phypers, et al., 2006). In this study, we applied an exponential regression model to evaluation of blood lactate recovery process after high intensity exercise. The purpose of this study was to clarify the relationship between the gas exchange parameters and blood lactate parameters. Methods Incremental metabolic test: 21 athletes (8 females, 13 males, VO<sub>2</sub>Max: 63.8±8.6 (ml/min/kg)) voluntarily participated in this study. Subjects voluntarily participated in stepwise incremental metabolic test. This test contained 3 min resting, approximately 20 min exercise (Cycling or Running), and 10 min recovery resting. All subjects performed exercise until exhaustion. Gas exchange parameters (VO<sub>2</sub>, VCO<sub>2</sub>, VE and HR) were sampled at 30 sec interval. Blood Lactate was sampled at 3 min interval after exercise (0, 3, 6, 9 and 12 min). An exponential regression model was fitted to each parameter. Exponential regression model:  $F(t) = (A - C) * \exp(-t / B) + C$ , A: Initial amplitude at end of exercise in an exponential function, B: Time-constant (time taken to reach 63% of the final amplitude), C: Final amplitude in an exponential function. Regression analysis was performed, between blood lactate parameters and Gas exchange parameters. Results The responses in all parameters during recovery fitted exponential models highly (e.g. mean value of regression coefficient of Blood Lactate was 0.93). Mean values of time-constant of Blood lactate were about 20-30 times larger than gas exchange parameters (VO<sub>2</sub>: 64.3±16.4, VCO<sub>2</sub>: 101.2±20.6, VE: 109.6± 29.8, HR: 101.1± 27.2, and La: 1881.1±1646.2). The maximum blood lactate at exhaustion was explained by the linear regression equation using time-constant of HR. ( $Y = 0.061 * X + 6.98$ ,  $r = 0.564$ ,  $p < 0.01$ ). Y: Blood lactate (mmol/l), X: time-constant of HR (sec). And, time-constant of Blood lactate was associated with RQ ratio at exhaustion ( $Y = 4738.9 * X - 3822.4$ ,  $r = 0.461$ ,  $r = 0.461$ ,  $p < 0.01$ ). Y: time-constant of Blood lactate (sec), X: RQ ratio (VCO<sub>2</sub>/VO<sub>2</sub>). Discussion The higher concentration of blood lactate caused the slower recovery of heart rate after exercise. RQ is the ratio of CO<sub>2</sub> produced to O<sub>2</sub> consumed. The higher production of CO<sub>2</sub> at exhaustion caused the slower recovery of blood lactate after exercise. References Sasaki, T., and Tsunoda, K. (2006), The estimation of oxygen consumption from heart rate using an exponential equation, *Hokkaido J. Phys. Educ, Hlth, Sports Sci.* 41:27-35 Barrie, Phypers, and JM, Tom, Pierce (2006), Lactate physiology in health and disease, *Continn Educ Anaesth Crit Care Pain* (2006) 6 (3): 128-132.

### TIME COURSE ALTERATIONS IN PHYSIOLOGICAL AND BIOCHEMICAL PARAMETERS DURING 2 WEEKS OF HIGH ALTITUDE TRAINING IN CROSS-COUNTRY SKIERS

Kato, H.1, Satouchi, T.1, Takeoka, H.1, Mimura, T.2, Shimamoto, H.3, Endo, H.4, Takeda, M.1

1: Doshisha Univ. (Kyoto, Japan), 2: Osaka Sangyo Univ. (Osaka, Japan), 3: Osaka Univ. (Osaka, Japan), 4: Univ. Ryukyus (Okinawa, Japan)

**Introduction** Although it has been reported results of pre-post high altitude acclimatization (Dill & Adams, 1971; Levine & Stray-Gundersen, 1997), it has not well been demonstrated that how the endurance athletes adapt to high altitude environment during high altitude training. The purpose of this study was to investigate the time course alterations in physiological and biochemical parameters during 2 weeks of high altitude training in cross-country skiers. **Methods** Collegiate cross-country skiing athletes (8 males, 6 females, 20 ± 1.0 yrs.) were participated. They lived 1 day before exposed to high altitude at sea level for collecting control data and lived and trained for 14 days at 2,200 m above sea level. Resting heart rate (HR), HR, arterial blood oxygen saturation and blood lactate during 3 minutes submaximal cycling exercise at a constant load corresponding to their each 70% HRmax, salivary amylase, urine specific gravity and subjective feeling of physical condition were measured at every morning. Erythropoietin (EPO), red blood cell, hemoglobin (Hb) and ferritin were measured just before altitude training and 48 hours and 14 days after sojourn at 2,200 m. Salivary cortisol and feeling profile were measured at day 2, 8 and 14. 5,000 m running performance test at sea level as an index of endurance performance was conducted pre and post altitude training. One way repeated measure of variance was used for the statistical evaluation. **Results** Supine and standing HR significantly increased at day 2 (vs control) and, after that, gradually decreased during acclimatization process of 2 weeks of high altitude training. Particularly, supine HR was significantly decreased at day 12 (vs. day 2). Likewise, salivary cortisol was significantly increased at day 2 (vs. con) and, after that, significantly decreased at day 14 (vs. day 2 and 8). The other measurements at the every morning were positive changed similarly resting HR. EPO was significantly increased after 48 h at 2,200 m (vs. before altitude training) and significantly returned to the same level with sea level at day 14. Hb was significantly increased day 14 (vs. con, day 2). However, no significant changes were found in other hematological parameters. 5,000 m running time was significantly improved after high altitude training. **Conclusion** This study suggested that it needs for at least 2 weeks to acclimatize to high altitude environment (2,200 m) during high altitude training in cross-country skiers. **References** Dill DB and Adams WC. (1971). *J Appl Physiol*, 30(6), 854-859. Levine BD and Stray-Gundersen J. (1997). *J Appl Physiol*, 83(1), 102-112.

### RECOVERY FROM REPEATED ON-COURT TENNIS SESSIONS; COMBINING COLD WATER IMMERSION, COMPRESSION AND SLEEP HYGIENE INTERVENTIONS.

Duffield, R.1,2, Murphy, A.2,3, Kellett, A.3, Reid, M.3

1. University of Technology Sydney, 2. Charles Sturt University, 3. Tennis Australia

**Introduction** The use of interventions such as cold water immersion (CWI) and compression garments (CG) to assist recovery are popular; while the role of sleep to also aid athlete recovery remains an integral, but rarely researched area. Similarly, combining recovery techniques into a mixed-method protocol, and the application to the prolonged and repeated demands of tennis has not been reported. The current study investigated the effects of combining CWI, CG and a sleep hygiene protocol on physical, physiological and perceptual recovery following on-court tennis sessions. **Methods** In a cross-over design, 8 male high-performance tennis players completed two sessions a day of on-court tennis drill training and match-play, followed by a recovery or control condition. Recovery interventions included a mixture of 15min CWI, 3h of full-body CG and a sleep hygiene protocol performed that night (earlier into bed, reduced ambient light, cool room temperature and sleep eye-masks). Conversely, the control condition involved 15min post-session stretching and self-regulated sleeping patterns. Technical performance (stroke count and error rates), physical performance (accelerometry, counter-movement jump), physiological (heart rate, blood lactate) and perceptual (mood, exertion and soreness) measures were recorded from each on-court session. Measures of sleep quantity and quality were determined via actimetry measures each night. A two-way ANOVA and effect size analyses were used to compare respective conditions. **Results** While stroke and error rates did not differ in the drill session ( $P > 0.05$ ;  $d < 0.20$ ), a large effect for increased time-in-play and stroke-volume were evident in match-play following the recovery interventions ( $P > 0.05$ ;  $d > 0.90$ ). Although accelerometry values did not differ between conditions, ( $P > 0.05$ ;  $d < 0.20$ ), a large effect for CMJ improvement was evident before match-play with recovery ( $P > 0.05$ ;  $d = 0.90$ ). Further, CWI and CG resulted in faster post-session reductions in heart rate and lactate and reduced perceived soreness ( $P < 0.05$ ;  $d > 1.00$ ). Finally, the sleep protocol increased sleep quantity ( $P > 0.05$ ;  $d > 2.00$ ) and also maintained lower perceived soreness and fatigue the next day ( $P < 0.05$ ;  $d > 2.00$ ). **Discussion** Given the increased soreness and fatigue resultant from two tennis sessions a day, post-session mixed-method recovery interventions (CWI and CG) increased time in play and lower-body power and reduced perceived soreness. Further, a sleep hygiene protocol increased sleep quantity and assisted the reduction of perceived soreness. Mixed-method recovery interventions may also be applicable to other athletes required to perform and recover for twice daily sessions.

### THE EFFECTS OF DIFFERENT TRAINING INTENSITIES ON PHYSIOLOGICAL RESPONSES WHEN TRAINING DURATION IS INDIVIDUALISED

Coakley, S.L., Passfield, L.

University of Kent

**Introduction** Numerous studies have compared high intensity training (HIT) to moderate intensity training (MOD), with findings suggesting HIT provides similar or greater physiological benefits. These studies have used standardised training times to set the training interventions. Consequently, the individual differences in one's ability to train at the same relative intensity for variable durations have been ignored. The aim of this study was to compare the physiological effects between MOD and HIT when training durations are individualised. **Methods** The study population consisted of sedentary or recreationally active (training <4h wk) male and female participants ( $n=12$ ; mean ± standard deviation (SD) 29 ± 9 yr; 72 ± 14 kg; 171 ± 9 cm) randomly assigned to either the MOD ( $n=5$ ;  $VO_{2max} = 3.14 \pm 1.01$  l min<sup>-1</sup>) or HIT ( $n=7$ ;  $VO_{2max} = 2.78 \pm 0.49$  l min<sup>-1</sup>) training group. Before and after 4-wks of supervised training we measured  $VO_{2max}$ , maximal aerobic power (MAP), time-to-exhaustion (TTE) and gross efficiency (GE). Training consisted of supervised cycling 4times/wk for 4-wks. The MOD group exercised at 60% MAP for the duration completed in the pre-training time-to-exhaustion test. This consisted of 5 min blocks with 1 min passive rest until the target training duration was complete. The HIT group exercised at 100% MAP with 2 min active (25% MAP) and 1 min passive rest. Participants were encouraged to complete the maximal number of repetitions in the first training session. All participants were encouraged to complete an extra block/repetition after every two training sessions. The effects of training were analysed using a two-way mixed ANOVA (time; training group). All values are reported as the mean ± SD. The level of significance was set at

$P < 0.05$ . Results Average training time per week ( $\approx 2$ h vs. 4.5h) was substantially lower in the HIT compared to the MOD group. TTE ( $+60 \pm 3$  vs.  $50 \pm 35$  %); MAP ( $+10 \pm 7$  vs.  $11 \pm 5$ %) and  $VO_{2max}$  ( $+10.5 \pm 7.5$  vs.  $12.5 \pm 6.7$ %) increased significantly in the MOD and HIT exercising groups following 4-wks of training (main effects;  $P < 0.05$ ). There were no significant changes in GE for either group or time ( $P < 0.05$ ). Discussion No differences are found between MOD and HIT when training duration is individualised at different intensities, despite differences in training volume. These findings further support the contention that HIT is a time-efficient strategy, inducing physiological improvements that are comparable to MOD.

### **STRENGTH OR ENDURANCE FIRST?: EFFECTS OF COMBINED SESSIONS ON ECONOMY AND BIOMECHANICS OF RUNNING**

Taipale, R.S.1, Kyröläinen, H.1, Sorvisto, J.1, Schumann, M.1, Mikkola, J.2, Nummela, A.2, Häkkinen, K.1

*University of Jyväskylä*

**Introduction** Strength is recognized as a necessary component of training for endurance runners but because of the divergent responses and adaptations to strength and endurance training (Hickson 1980), training needs to be carefully planned. As part of an optimal training regimen, or to save time, recreational and elite athletes may perform strength (S) and endurance (E) in the same combined session, but which should be performed first when focusing running performance? **Methods** Recreationally endurance trained men and women ( $M=12$ ,  $W=10$ ) and ( $36 \pm 8$  years) completed two combined loadings: E followed by S (ES) and S followed by E (SE). S focused on the leg extensors, while E consisted of 60min moderate intensity steady-state running. Maximal bilateral isometric force (MVC) and muscle activation (EMG) were measured Pre-Mid-Post ES and SE. Running economy was measured at the beginning and after E. Biomechanical characteristics of running were measured at the beginning, during, and after both E sessions. **Results** A significant decrease in MVC was observed at mid in men after E of ES ( $p < 0.01$ ), while a significant decrease in MVC was observed in both men and women at mid after S of SE ( $p < 0.05$ ). MVC was significantly decreased in men and women at post in both conditions ( $p < 0.05$ ) and men showed a significant decrease in EMG post SE ( $p < 0.05$ ). Running economy was decreased significantly at the beginning of E after S when compared to E performed before S (4 and 3% in men and women, respectively). In men, stride-length shortened significantly ( $p < 0.05$ ) in both ES and SE, but running speed, and stride-rate were statistically unaltered. Braking time was unaltered and push-off time increased slightly, but total contact time remained statistically unaltered in both ES and SE. In women, stride-length, running speed and stride-rate were statistically unaltered while a slight increase in braking time and decrease in push-off time were observed and total contact time remained statistically unaltered in both ES and SE. **Discussion** Performing S immediately prior to E may decrease neuromuscular performance of maximal strength and muscle activation and led to decrements in running economy and selected biomechanical characteristics of running. These findings in combination with our previous study (Taipale & Häkkinen 2013), suggests that performing E prior to S may be better for recreational endurance runners if the main focus of the specific combined training session is on optimizing running performance. **References** Hickson (1980) *Eur J Appl Physiol.* 45:255-263. Taipale & Häkkinen (2013) *PLOS ONE*

### **DIFFERENCES ON VERTICAL JUMPING, SPRINT VELOCITY AND RSA AMONG ELITE SENIOR AND TEEN BASKETBALL PLAYERS**

Balsalobre-Fernández, C.1, Tejero-González, C.M.1, Sánchez, J.2, del Campo-Vecino, J.1

*(1) Autonomous University of Madrid, (2) Strength & Conditioning Coach, Asefa Estudiantes 1st team*

**Introduction** The speed in short sprints, the height in vertical jump and the ability to repeat such efforts are key in basketball (Buchheit, Bishop, & Girard, 2012). However, the differences in these variables between elite senior and teen basketball players are poorly studied. **Purpose** Analyze the differences in the vertical jump, 35-meter sprint, the repeated sprint ability (RAST) and loss of vertical jump among professional and teen basketball players. **Methods** **Sample** The sample consists of two top-level basketball teams. Group A consists of professional basketball players ( $N = 11$ , age =  $24.2 \pm 5.5$  years) and group B consists of elite, teen basketball players from the same club ( $N = 9$ , age =  $15, 2 \pm 0.4$  years). **Variables** The variables analyzed were: Vertical jump height (cm), 35m sprint time (s), vertical jump loss (%), loss of speed in the RAST (%), average power of RAST (W), maximum power of RAST (W) and RAST fatigue index (W / s). **Instrumental** Optojump Infrared Platform (Microgate, Italy) and photoelectric cells Racetime 2 (Microgate, Italy). **Procedure** After a 5 minute warm up, the players performed the tests as follows: (1) counter-movement jump (CMJ) with free arms, (2) repeated sprint test RAST, (3) CMJ with free arms. **Statistical Analysis** T test for independent samples was used, using the IBM SPSS Statistics 20 software. **Results** There were no significant differences in any of the variables studied, except in the average ( $+168W$ ,  $t = 3.8$ ,  $p = 0.003$ ) and maximum power ( $+219,4 W$ ,  $t = 3.2$ ,  $p = 0.005$ ) produced in the RAST, with group A being significantly more powerful than the group B. **Conclusion** Our data indicate that elite teen basketball players have similar values of CMJ, sprint velocity and ability to repeat those efforts than professional players, while these have significantly higher power levels. These results suggest that to reach the highest competitive level in basketball is not necessary to obtain higher values than those achieved in adolescence, but the key would be to maintain the same levels while significantly increasing the body size and weight and muscle power. **References** Buchheit, M., Bishop, D., & Girard, O. (2012). Should We be Recommending Repeated Sprints to Improve Repeated-Sprint Performance? *Sports Medicine*, 42 (2), 169-173.

### **PHYSIOLOGICAL RESPONSES IN REFERENCE TO SURFACE AND IMMERSION IN FIN SWIMMING: A PILOT STUDY**

Lampadari, V.1, Thanopoulos, V.1, Rozi, G.1, Dopsaj, M.2, Ktena, S.1, Gerou, E.3

*1: National & Kapodistrian University of Athens, 2: Faculty of Sport and Physical Education, University of Belgrade 3: Swimming Coach, Panellinos Club of Athens*

**Introduction** Fin swimming is a sport that takes place on the surface of water as well as underwater, with the aid of a fin. Repeated efforts, due to different stops between them, provoke different physiological responses in the muscle (McCartney, 1986; Spiet et al., 1989; Gaitanos et al., 1993; Bogdanis et al., 1995). The aim was to compare two different conditions, swimming immersion and surface, in physiological responses. **Methods** The sample of this study consisted of 8 athletes of competitive level of fin swimming, aged:  $19.0 \pm 1.92$  years, height:  $172.5 \pm 3.59$  cm and weight:  $67.0 \pm 11.15$  kg. The participants swam with maximum intensity 6x100m with two different ways, immersion and surface. The stop between each 100m was 1min. After each experimental condition, lactic acid, oxygen saturation and heart rate were measured. **Results** The results of Manova analysis showed that there are no statistical significant differences between the two conditions of fin swimming in all measured variables. **Discussion** In the present study it was noted that swimming on the surface in comparison to immersion, does not present significant differences according to physiological responses. This fact gives the motive for further research in fin swimming with bigger sample and other variables, such as  $VO_{2max}$ , that may affect performance in this

specific sport. References Bogdanis GC, Nevill ME, Boobis LH, Lakomy HKA, Nevill A. (1995). *J Phys*, 482 (2), 467-480. Gaitanos GE, Williams C, Boobis LH, Brooks S. ### THE RHYTHM OF PLAY IN COMPETITION. A PROPOSAL TO CONTROL THE TRAINING LOAD IN ELITE RUGBY SEVENS

Carreras, D.1, Solé, J.2, Planas, A.1, Vaz, L.3

1: INEFC-Lleida (Spain); 2: INEFC-Barcelona (Spain); 3: CIDESD (Portugal)

**Introduction** The concept of rhythm of play is based on the frequency of alternation between the team role with the ball possession or team role as opposition, in relation to the number of the actions taking place on each role time unit. In this study we set two aims: (i) determine the influence of the rhythm of play in competition at the final score, (ii) propose the rhythm of play in competition as a control of training load on the Spanish team of rugby sevens. **Method** To focus our analysis, we build the following equations: - Rhythm of play = (no possession units + no opposition units) x no total actions / total time ball in play. - Rhythm of possession = no possession units x no possession actions / total time possession role. - Rhythm of opposition = no opposition units x no opposition actions / total time opposition role. **Statistical analysis** based on the multiple linear regression model allows us to analyze the first aim of the study, considering the rhythm of play, rhythm of possession and rhythm of opposition as independent variables, and the points difference at the final score as dependant variable. To analyze the second objective of the study used descriptive statistics (means  $\pm$  standard deviations). **Results** In the determination of the influence of the rhythm of play, rhythm of possession and rhythm of opposition has obtained a statistically significant model  $F(11,3) = 6.639$ ,  $p = 0.015$ . in which the independent variables explained 61% of the variability ( $R^2_{corrected} = 0.606$ ) and the independent variables that violate the null hypothesis are rhythm of possession ( $\beta_{standard} = 1.819$ ,  $t = 4.184$ ,  $p = 0.003$ ) and rhythm of play ( $\beta_{standard} = -1.463$ ,  $t = 3.286$ ,  $p = 0.011$ ). In the observed tournament Spanish team has a rhythm of play of 6.5. The rhythm of possession was 4.5 (11.5  $\pm$  1.9 possession units, of 25.9s  $\pm$  5.2s each one, with 10.1  $\pm$  2.0 possession actions and 57.1s  $\pm$  6.8s pause time); and the rhythm of opposition was 1.7 (11  $\pm$  1.9 opposition units, 20s  $\pm$  1.4s each one, with 3.3  $\pm$  1.2 opposition actions and 57.1s  $\pm$  6.8s, and pause time). **Discussion** The high influence of the rhythm of play, rhythm of possession and rhythm of opposition on the final score gives this proposal a consistency of very high suitability. To control the training load, are multiple options: increasing or decreasing the number of actions to perform in each role time unit; increasing or decreasing the length of role time units, increasing or decreasing the pause time. The best option will depend on the characteristics of the style of play technical staff want to implement. **References** Solé, J. (2002) *Endurance training in team sports, Master of high performance in team sports*. INEFC-Byomedic. Barcelona. Vaz, L.; Carreras, D. & Kraak, W. (2012). ### RELATIONSHIP BETWEEN RUNNING VELOCITY AND SUBJECTIVE SENSATION.

Kenji, Y., Naoya, T., Akiharu, S.

*Kokushikan University*

**Introduction** It has been reported that the stimulation to the foot has important, and barefoot activity has been noted in recent years. In addition, it came to be observed that the children running with barefoot on the school yard. However, we did not understand about the sprinting conditions faster in barefoot and shoes. For this reason, it is considered that it is important to clarify which is about the way leaders can run faster in education. The purpose of this study, it was decided to make the questionnaire and the 50m dash in order to clarify the relationship between the subjective sensation and the running velocity, and comparison of running velocity of barefoot and in shoes. **Methods** Subjects were 133 students (84 males and 49 females) at a university of physical education. Measurements were questionnaire and 50m dash. Measurements were made twice with subjects running a 50m dash barefoot and in shoes. Measurements were made one week apart. Running time was measured every 10m. In the analysis, we calculated the average running velocity and the interval running velocity. The average running velocity was calculated by dividing by the time taken in the distance measured points. The interval running velocity was calculated by dividing by the time taken the distance of each interval. In addition, a questionnaire was completed before and after the measurement. **Results** Both males and females had a significantly faster average running velocity barefoot than in shoes. Both males and females had a significantly faster interval running velocity from 0-10m and from 30-40m barefoot than in shoes. In males, there was a relationship between subjective sensation and faster sprinting condition. There was no such relationship in females. **Discussion** These results revealed that barefoot sprinting is faster because the acceleration at the start. This could have affected the sprint velocity at all measured points. Subjective sensation may be an effective way to select sprinting conditions. **References** Shunichi T. (2007). 50m running with shoes and barefoot-from the viewpoint of running time, running velocity and swing-back velocity of driving leg immediately before foot contact on the ground-. *Doshisha Journal of Health and Sport Sciences*, 45, 37-54. ### PERFORMANCE ANALYSIS OF ELITE GROUP RHYTHMIC GYMNASTICS

Ávila-Carvalho, L., Klentrou, P., Lebre, E.

*Porto University*

The aimed was to analyze, anthropometric characteristics, body composition, age at menarche, training hours volume, sport activity initiation and years of practice of Elite Rhythmic Gymnastics gymnasts and analyze according to the competition performance, the content of the competition routines contributing to high level RG gymnasts and RG group's performance characterization. We studied 84 group gymnasts' characteristics who participated in Portimão 2009 and 2010 RG World Cups, and the 126 group competition routines content from 28 countries that participated at 4 World Cups in Portimão (2007 to 2010). For the gymnasts characteristics analysis\* we calculated body mass index, body fat and lean body mass, the last two estimated from skinfolds thicknesses and circumferences. Age at menarche, age of RG training initiation, years of practice and training volume (daily and weekly) was recorded using a questionnaire. For the routines content analysis, all body and specific groups elements\*\* and apparatus elements\*\*\* recorded on the official forms provided in competitions were analyzed. It was clear that anthropometric characteristics, body composition and age at menarche were not relevant in success competition explanation. However, we concluded that those characteristics were similar for the high level performance gymnasts. The high number of training hours per week (about 42 hours) explained 42% of competition success. Early initiation in RG (6 yrs old) and the high number of years of practice are significantly relevant to achieve the excellence level in RG groups. The age at menarche ob-

served in gymnasts was significantly more delayed in older gymnasts probably due a higher number of years training gymnastics prior to the menarche onset. It was possible to conclude that competition routines content follow a pattern consistent with the high level sports performance. This pattern includes: high number and complexity in exchange difficulties; balance difficulties mostly performed with high amplitude movements and performed on different supports in a dynamic way; jump difficulties mainly performed with rotation; rotation difficulties performed mostly with high technical complexity; higher use of throws criteria (explaining 6% of competition success) than the catches criteria; high use of collaborations with loss of visual contact with the apparatus during its flight explaining 16.5% of competition success. \*Ávila-Carvalho, L., Klentrou, P., Palomero, M. d. ### **DIFFERENCES IN PHYSIOLOGICAL CHARACTERISTICS BETWEEN YOUNG GIRLS PARTICIPATING IN TENNIS AND GYMNASTICS**

Giannopoulos, A., Theos, A., Moustogiannis, A., Ioannidi, V., Maridaki, M.

*National and Kapodistrian University of Athens*

**Introduction** Tennis is a demanding sport because it requires speed, agility, explosive power and aerobic conditioning along with the ability to react and anticipate quickly (Barber-Westin et al., 2010). Gymnastics training develops strength, flexibility, concentration, balance, grace and speed (Carric et al., 2007). The purpose of the present study was to investigate differences in physiological characteristics of young girls participating in different sports. **Methods** A total of thirty eight girls (14 tennis players and 24 gymnasts, age:  $13.5 \pm 0.2$  yrs, weight:  $49.8 \pm 1.7$  kg, height:  $155.7 \pm 1.6$  cm) that had a training experience of more than three years participated in this study. Flexibility (sit and reach test), arm strength (handgrip) and agility (agility T-test) were measured. Differences between the groups were analyzed using t-test. Results are presented as mean  $\pm$  SE. Results In the dominant hand tennis players performed better than gymnasts ( $24.8 \pm 0.9$  kg vs.  $15.5 \pm 1.6$  kg,  $p < 0.001$  respectively) and so did in the non dominant hand ( $21.6 \pm 0.9$  kg vs.  $14.4 \pm 1.3$  kg,  $p < 0.001$  respectively). Dominant and non dominant hand differed also in tennis players ( $p < 0.05$ ) while there was no difference in gymnasts ( $p = 0.59$ ). Significant difference was also observed in agility (Tennis players:  $12.6 \pm 0.8$  sec vs. Gymnasts:  $13.6 \pm 0.3$  sec,  $p < 0.05$ ). On the other hand gymnasts performed better than tennis players in flexibility ( $29.3 \pm 1.5$  cm vs.  $20.6 \pm 1.6$  cm,  $p < 0.001$  respectively). **Discussion** The results of the present study show that tennis seems to improve arm strength, especially the strength of the dominant hand, and agility while gymnastics seems to promote flexibility in girls with the same training experience. **References** Barber-Westin SD., Hermeto A. and Noyes F. ### **EDUCATION TO SEE. AN INQUIRY INTO THE PERFORMANCE IN YOUNG FEMALE VOLLEYBALL ATHLETES.**

Nart, A., Biancalana, V.

*Sezione di Scienze Motorie Università degli Studi di Urbino*

**Introduction** The eye allows encoding and receiving information about movement: it also allows knowing the environment, including space and three-dimensional parameters: therefore it plays a key role in posture. Thus, there is a strong connection between the latter, the visual system and movement. Therefore, the aim of this study was to highlight, through electronic stabilometry in static mode, a correlation, whether or not statistically significant, of any possibility of influencing in an immediate manner the proprioceptive reflexes that link an athlete's extrinsic eye muscles and posture. **Methods** The study was conducted on 18 female volleyball athletes. These were subjected to a Lang test of dominant eye and of hypo-convergence. Then to a stabilometric measurement in upright stance with open and closed eyes both in the cabin and in the open field. After that, to exercises of evocation of the convergence reflexes at close range, with the use of a micro-magnet, and from a distance, using a stereo trainer device. We eventually proceeded to a comparison between the stabilometric recordings in the cabin and in the open field. **Results** There were no statistically significant differences between recordings in the cabin and in the open field. The difference is statistically significant ( $p < .001$ ), however, on behalf of the condition in the open field in the length parameter, which indicates a greater stability of athletes. **Discussion.** The sporting gesture is mostly influenced by the Tonic Postural System, although there are many other factors that contribute to its success. The data confirm that the volleyball athletes are accustomed to an assessment of their surroundings and have a good stability due to the frequent handling of balance or unsteady conditions. **References** Zupan M, Wile A. #### **FORCE PLATFORM VS CONTACT MAT IN THE ASSESSEMENT OF VERTICAL JUMP IN VOLLEYBALL PLAYERS.**

Borràs, X., Balius, X., Drobnic, F.

*Universitat de Vic*

**FORCE PLATFORM VS CONTACT MAT IN THE ASSESSEMENT OF VERTICAL JUMP IN VOLLEYBALL PLAYERS.** Borràs, X.1, 2, Balius, X.2, Drobnic, F.2 1: Uvic (Spain), 2: GIRSANE. CAR (Spain) **Introduction** Vertical jump test is commonly used in volleyball to assess different force manifestations of the lower extremity. Contact mat (CM) and force platform (FP) are two devices used for the assessment (Bosco et al, 1983; Vanrenterghem et al, 2004). Both are considered reliable in recording vertical jump height (Moir et al, 2009; Harman et al, 1990) and show a high correlation coefficient (Roig et al, 2008). With this study we want to give a help to trainers to choose between devices, knowing their advantages and disadvantages. **Methods** Sixteen male, of the Spanish National volleyball team, performed a vertical jump test

consisting of squat jump (SJ), countermovement jump (CMJ), CMJ with arms (CMJa) and spike Jump (SPJ). Jumps were recorded simultaneously in a FP (Kistler) and a CM (ErgoJump System). Results Vertical jump height were calculated by means of flight time (FT) in CM (SJ 41.3cm, CMJ 47cm, CMJa 56.5cm, SPJ 68.6cm) and FP (SJ 39.1cm, CMJ 46.7cm, CMJa 55.9cm) and by means of velocity of take off (V) also in the FP (SJ 36.4cm, CMJ 43cm, CMJa 51.1cm). Correlation coefficient between devices is high (R(FT) 0.998; R(V) 0.970). Discussion CM has a higher portability even compared with the FP brands considered portable and has a lower cost than the FP. The CM allows the assessment all the jumps used in volleyball; FP does not permit the measurement of the SPJ due to reduced dimensions. CM results are immediate while FR data usually needs to be processed before giving height. Power is calculated from force in FP while CM uses prediction equations. Devices show a high correlation coefficient, however, caution has to be taken when comparing heights. CM data is higher than FP values regardless the method used. The flight time method, used in CM, overestimates height (Garcia-Lopez et al, 2005) consequence of the different body position when taking off and landing (Aguado and Gonzalez, 1995). With the FP this problem can be avoided. FP allows to distinguish between the maximum SJ (SJV 38.1•4.6cm) and the "valid" SJ (minimum countermovement). 25% of the experienced players couldn't avoid a small countermovement after 3 attempts. Those jumps were considered valid and make evident the difficulty to differentiate correct SJ. References Aguado X, Gonzalez JL (1995). RED, 9, 17-23. Bosco C, Mognoni P, Luhtanen P. (1983). ### DOES THE POSITION OF BALL CONTACT EXERT A DIFFERENCE ON THE RESULT OF INSIDE SOCCER TRAPPING?

Tahara, R.

*Fukuoka University*

Introduction In soccer, it could be said that trapping, in which the ball is stopped using the inside of the foot, is the most frequently used skill. However, little research has been devoted to ball trapping. The purpose of this study was to clarify that the factor determined the success of inside soccer trapping changes with the position of ball contact. Methods Six experienced male collegiate soccer players and six unskilled players were asked to perform inside trapping 10 consecutive times with the following task. The subjects controlled the ball in front of the foot. The ball kicked at random speeds 7m away from the experimental subjects. The motion of the whole body during trapping was recorded using two high-speed video cameras. And distances between trapping foot and supporting leg (= ball contact position) were determined. The ball was recorded with another camera set on the right side, and the spin rate of the ball was calculated by the method of Jinji et al (2006). Paired t-test and Pearson's product-moment correlation coefficients were used for the statistical processing. The criterion for statistical significance was  $p < 0.05$  for all analyses. Results About the mean ball velocities for after ball impact, experienced players' velocities ( $1.2 \pm 2.5$  m/s) were significant lower than unskilled players' ( $3.5 \pm 4.5$  m/s). About ball contact positions, the experienced players ( $0.25 \pm 0.12$  m) had stopped the ball in the position away from the unskilled players ( $0.07 \pm 0.24$  m). The experienced players ( $70.8 \pm 43.8$  rpm) applied many backspins to the ball rather than the unskilled players ( $-10.2 \pm 70.1$  rpm). There were significant correlations among ball velocity after trapping, ball contact position and ball spin rate. Discussion Since the ball velocity after trapping was low, it can be said that ball control is good at experienced players. In the experienced players, the ball contact position was in front, and there was also much number of backspin rates. Moreover, there were correlations between ball velocity after trapping and spin rate, ball contact position respectively. These results suggested that contact to the ball in front of supporting leg increase the backspin rate, and reduce the velocity of the ball. It was considered that abduction of the hip joint has been made easier by the forward position of the ball contact, and it produces buffer action toward ball impact (Tahara et al., 2012) and the movement to put a backspin. ### THE ANALYSIS OF MUSCLE ACTIVITY PATTERN IN PEDALING MOTION AT THE SUBJECTIVELY APPRECIATED SADDLE HEIGHT OF A SKILLED CYCLIST

Tokuyasu, T., Kushizaki, S., Matsumoto, S.

*Fukuoka Institute of Technology*

Introduction In the setting of mechanical components of a cycle road racer, the saddle height has been considered as the most significant factor to set the other components, because cyclists commonly use binding pedals and shoes to efficiently convert their physical power to the propulsion force of a bicycle. This study aims to evaluate the saddle height based on the statistical analysis of the muscle activity patterns of lower limb of a skilled cyclist. Methods The experimental environment was composed of a cycle ergometer, an electromyography, and a computer, in which the lab-made saddle height control device has been mounted at the saddle part of the ergometer. SEMG signals of lower limb muscles during pedaling motion are used to estimate the activity patterns. The relationship between the the muscle activity patterns and the subjective evaluation against the saddle height of a skilled cyclist was investigated. Results A skilled cyclist clearly recognized the small changes of saddle height that declined by 3mm from 680mm to 650mm. In the results of principal component analysis (PCA) applied to the muscle activity data, the PCA scores concentrated near zero point at the saddle height subjectively appreciated by the skilled cyclist. Discussion The authors have been considering that the subjective evaluation were based on the empirical rule of activating muscles in pedaling motion amassed through longtime training. Then the pedaling motion performed at the saddle height subjectively appreciated, satisfied his motion perceptions empirically constructed. Since the skilled cyclist pedals by keeping balance well the muscle's activity among muscles to avoid the development of regional fatigue, the muscle activity patterns became featureless at the saddle height subjectively appreciated by the skilled cyclist.

### STRIKE INDEX AND SPATIOTEMPORAL PARAMETERS AT DIFFERENT RUNNING VELOCITIES

Mann, R., Malisoux, L., Urhausen, A., Meijer, K., Statham, A., Brunner, R., Gette, P., Theisen, D.

*CRP-Santé*

Introduction When running, higher speed can be achieved by increasing stride length (SL), stride frequency (SF) or both. Increasing SL can lead to overstriding, which has been associated with higher braking forces and elevated injury risk [1]. Adopting a rearfoot strike (RFS) also generates greater impact forces compared to a forefoot strike (FFS) during running [2]. Strike pattern can be measured by the strike index (SI), i.e. the point of contact on the foot sole as a percentage of total sole length. A lower SI value means a more pronounced RFS

pattern. We aimed to explore changes in SI and spatiotemporal parameters under increasing running speed, hypothesising a decrease in SI and an increase in SL. Methods Participants were recreational runners selected from a convenience sample, all having performed an incremental, maximal exercise test on a treadmill. The incline was set to 0° and velocity was increased by 0.5 m/s every 3min. 38 participants (41±9 y, 1.77±0.08m and 77.1±11.5kg) were selected on the basis that they ran at 2.5, 3.0, 3.5 and 4.0 m/s. They were equipped with the Runalyser (TNO Eindhoven, The Netherlands), a pressure-sensitive insole device designed to measure pressure patterns and temporal parameters during running. Intra-subject changes in SI, contact time (CT), flight time (FT), stride time (ST), duty factor (DF, CT/ST), stride length (SL) and stride frequency (SF) were compared using repeated measures analyses of variance. Statistical significance was accepted at  $p < 0.05$ . Results The following significant ( $p < 0.001$ ) decreases were found when running speed increased from 2.5-4.0 m/s: SI [33.4-29.6%], CT [283-231ms], ST [749-693ms] and DF [37.8-33.7%]. SL [1.87-2.77m] and SF [80.3-86.9 strides/min] increased significantly ( $p < 0.001$ ), whereas FT [467-462ms] displayed no significant change ( $p = 0.261$ ). Discussion As hypothesised, runners increased SL with higher running speed, in spite of a significantly higher SF. This resulted in a more pronounced RFS pattern as indicated by the reduction in SI. As a consequence, greater running speeds will increase the risk of overstriding, thereby promoting injury risk through higher braking forces [1]. In how far SI, SL and SF are related to injury remains to be established. References 1. Lohman EB, 3rd, Balan Sackiriyas KS, Swen RW. ### EFFECTS OF ELASTIC TAPING ON PLYOMETRIC JUMPING PERFORMANCE IN KOREAN COLLEGE MALE STUDENTS

Lee, B.K., Shin, J.M.

*SM-UI(Cheonan, S Korea)*

Introduction Some of the recent research focused on applying elastic taping on a body to improve the jumping performance. The results, however, hardly confirm any positive influence the elastic taping may have on the performance (Lin, Huang & Huang, 2011; Murray, 2000). Therefore, the aim of this study is to investigate the effects of knee joint elastic taping on performance and kinematic of lower limbs in plyometric jump. Method Ten healthy college male students were selected and their 3D motion captures were sampled by infrared cameras. The participants were subjected to jump on the force platform with and without the Kinesio tape applied to both knee joints. Vertical ground reaction force (VGFR), center of mass (CoM) of total body, and range of motion (RoM) of the ankle, knee and hip joint were analyzed in the two conditions respectively. A paired t-test was conducted to compare the two groups. This research is based on the raw data from Shin(2013). Result Although there were no statistically significant differences in variables such as peak VGFR, range of CoM, height of CoM, peak velocity of CoM between the two conditions ( $p > 0.05$ ), the variables obtained from the condition with taping produced an increase. Both of the peak times of vertical displacement and of vertical velocity of CoM yielded the differences between the two conditions ( $p > 0.05$ ). There were no statistically significant differences in RoMs of 3D motion of joints between the two conditions ( $p > 0.05$ ), but the group with taping showed an increase except RoM of ab/adduction of hip joint. Discussion and Conclusion In this research, there were no statistically significant differences when the taping is applied to knee joints, but most variables in this research showed a consistent increase in the condition with taping. For instance, amplitude of VGFR was greater after taping. With regards of CoM, range, height, and peak velocity increased to 4.2%, 1% and 1.3%, respectively whereas peak times of height and velocity between two groups showed little change. The magnitudes of RoMs of ankle, knee, and hip joint also showed a little bit of increase in the three dimensional planes with a maximal increase of 3.7° in the flexion/extension of knee joint. Therefore, this research showed the latent positive effects the application of elastic taping has on the enhancement of the performance such as an explosive jumping task. Reference Fu, T. ### THE 3D KINEMATIC EFFICIENCY OF USAIN BOLT'S SPRINTING STRIDE

Antekolovic, L., Bakovic, M., Durkovic, T.

*Faculty of Kinesiology*

Introduction The efficiency of sprinting velocity depend on the optimal proportion of starting phase, acceleration phase, maximal velocity phase and deceleration phase. Maximal velocity is one of the most important factors of sprint (Coh and Dolenc, 2008) and in 100m race it is mostly maintained from 60 m to 90 m. Biomechanical parameters of sprinting performance made on elite sprinters are important for the scientists and coaches. This study is conducted to obtain 3D kinematic parameters of sprinting strides of the top level male sprinter during the 100 m race. Methods The video acquisition was done in competition conditions during the 100 m race in Zagreb, Croatia (IAAF World Challenge Zagreb 2011). The subject of this study was Usain Bolt (height 196 cm; weight 86 kg) a world record holder on 100m and 200m (9.58 sec and 19.19 sec). Three miniDV digital cameras (Sony HDR-HC9E) operating at 50 frames per second filmed space on track between 65 m and 75 m. The space was defined by the cube (180cmx180cmx180cm) placed on track and filmed after the competition. 3D kinematic data calculations were done with APAS (Ariel Dynamics Inc., San Diego, CA) using a 15-segment model of sprinter's body (Dempster, 1955). Results Usain Bolt won this competition with 9.85 sec. His stride lengths of sprinting cycle left-right-left contact (from 63.42 m to 68.92 m of 100 m track) were 278.41 cm and 272.81 cm. The heights of the center of mass (CM) at touchdown (TD), amortization (AM) and takeoff (TO) during left foot support phase were 111.76 cm, 111.62 cm and 115.99 cm. The heights of CM during right foot support phase were 114.63 cm (TD), 113.31 cm (AM) and 115.04 cm (TO). The heights of CM during flight phases were 119.20 cm and 118.51 cm. The AM angles were 144.15° (left) and 131.71° (right). The horizontal projection of CM in braking phase was 21.42 cm on left foot and 14.56 cm on the right foot. In the propulsion phase the projection of CM was 65.36 cm and 65.68 cm. An average horizontal velocity of CM during observed strides was 12.36 m/sec which is 44.50 km/h. Discussion The efficiency and economic of Usain Bolts sprinting performance are confirmed by the 3D kinematic parameters. It can be noticed extremely small vertical CM oscillation during support and flight phases. The horizontal distance between toe and projection of CM at the instant of TD is also very small which helps to minimize velocity loss in the braking phase. The only disproportion is noticed at AM angle values where right knee AM angle is lower than left leg. References Bruggemann GP, Glad B (1990). ## THE INFLUENCE OF HILL'S FORCE-VELOCITY RELATION ON MUSCLE STRESS DURING EXERCISES WITH CONSTANT LOAD AND VELOCITY

Thaller, S., Penasso, H.

*University of Graz*

**Introduction** It is often assumed that by following a fixed protocol for exercise movements (e.g. performing a movement at a given constant velocity with a certain percentage of the 1RM or the maximal isometric force) equal stress is exerted to muscles of different individuals. However, there is a strong dependence on the individual Hill parameters of the muscles involved. Aim of this simulation study is to quantify the differences in muscle activation (MA) for a movement on a vertical leg press taking into account the individual shape of the force-velocity relation of the muscle. **Methods** To show the differences in MA we simulated two knee extension movements on a vertical leg press with two constant velocities  $k_1 = 0.55$  m/s and  $k_2 = 0.8$  m/s. A load corresponding to 70% of the isometric force was first accelerated with a maximal voluntary contraction to reach the velocity-value  $k_{1,2}$  as fast as possible. Then the velocity was kept constant and thus the load was pushed with constant force equal to the weight. We used a model with arbitrary but fixed Hill parameters (cf. Siebert et al., 2007; Thaller et al., 2010) and computed the contraction velocity (CV) as a function of time. Via Hill's force-velocity relation we got the corresponding muscle force for a fully activated muscle. In addition, we calculated the actual muscle force as a function of time according to the constant external force applied to the leg press. Comparing these two forces we got the percentage of MA during the movement in dependence of the force-velocity relation of the muscle involved. **Results** The maximal CV for  $k_1$  and  $k_2$  was 0.24 m/s and 0.36 m/s, respectively. The muscle force first increased, then decreased already during the acceleration phase. The MA started at 70%, went up to 96.3% and 98.2%, then decreased to 32.7% and 49.1% and again increased to 33.6% and 61.3%, respectively. **Discussion** Although both movements were performed at the same submaximal level of 70%, the percentage of MA ranged between more than 90% and less than 40% during the movement. This was not only due to the fact that the knee angle changed and therefore less muscle force for pushing was needed at the end of the movement but also due to the individual force-velocity relations of the muscles. The behaviour of the MA as a function of time crucially depends on the Hill parameters of the muscle. If the optimal contraction velocity ( $v = 0.19$  m/s in this case) is exceeded during the movement, the percentage of MA increases again. Therefore, for assessing the amount of active motor units the individual shape of the force-velocity relation of the muscles involved has to be considered. **References** Siebert T, Sust M, Thaller S, Tilp M, Wagner H. (2007). *Hum Mov Sci.*, 26, 320-341. Thaller S, Tilp M, Sust M. (2010). *Math Comp Model Dyn Syst.*, 16(05), 417-429.

## INDIVIDUALS WITH CURVY OR STRAIGHT LUMBAR SPINES EXHIBIT DIFFERENT MOTION PATTERNS WHEN LIFTING A BOX

Pavlova, A.V.1, Meakin, J.R.2, Cooper, K.3, Barr, R.J.1, Aspden, R.M.1

*1 University of Aberdeen, 2 University of Exeter, 3 Robert Gordon University*

**Introduction:** We have recently used active shape modelling (ASM) to show that the lumbar spine has an intrinsic shape (I) which is maintained throughout flexion and extension. We earlier showed that when the shoulders are axially loaded straighter than average spines tend to straighten while curvier spines curve further (2). The affect of intrinsic shape on dynamic motion and load-bearing is unknown, but could have implications in sport and manual handling occupations where the incidence of low back pain is high despite training and lifting guidelines. **Methods:** This study investigated the effects of different intrinsic shapes on the natural motion patterns of 30 healthy adults during lifting. The lumbar spine was imaged in standing using a positional magnetic resonance imager (Fonar 0.6T Upright). ASM, a statistical model that uses principal components analysis, was used to identify and quantify 'modes' of variation in the shape of the lumbar spine (L1-S1). The main mode of shape variation (M1) describing the overall lumbar curvature was used to group participants into 'curvy' (lordotic) or 'straight' spines by their deviation from the mean shape (M1=0). Three dimensional motion capture (Vicon MX, Oxford Metrics) was used to examine how participants lifted a weighted box (6-15 kg, participant selected) without instruction. **Results:** Straighter spines exhibited higher knee flexion angles ( $r = 0.4$ ,  $P = 0.03$ ) typical of a 'squat' style of lifting. Peak knee flexion negatively correlated with measures of lumbar flexion ( $r = -0.5$  to  $-0.86$ ,  $P < 0.01$ ) and with forward pelvic tilt ( $r = -0.81$ ,  $P < 0.001$ ). Furthermore, in a comparison of the two extreme ends of spinal shape ( $\geq \pm 1$ SD from mean;  $n=8$ ) individuals with straighter spines had significantly higher peak knee flexion ( $U=0$ ,  $P=0.04$ ) and appeared to maintain their lumbo-pelvic posture for a greater proportion of the lift. Curvier spines tended to have more lumbar flexion ( $r=-0.79$ ,  $P=0.02$ ). **Discussion:** These results indicate that individuals with a greater than average lumbar curvature naturally tend to adopt a stooped posture when lifting a load, while those with a straighter lordosis primarily lift by bending at the knees with less flexion of the back. Although further analysis of other shape modes and internal lumbar forces is required, these novel results suggest that the intrinsic shape of the spine affects how we naturally move to pick up a load. This has implications for individualizing lifting guidelines and screening in sports and manual occupations in an attempt to reduce injury risk. **References:** 1. Meakin JR, et al. ## KINEMATICS OF ATHLETE'S CENTER OF MASS IN SPRINTING AT VARIOUS FOOT ABDUCTION IN FIRST FOOT STRIKE

Nemtsev, O.I, Shubin, M.2

*1: Adyge State University (Maykop, Russia), 2: Kuban State University of Physical Education, Sport and Tourism (Krasnodar, Russia)*

**Introduction** The features interaction of foot and ground mostly determine efficiency of high speed run (Bates, 1983; Lee & Piazza, 2009). But now there aren't justified recommendations about optimal of foot abduction in first foot strike in sprinting. So the aim of this study was comparison of kinematic characteristics of athlete's center of mass (CM) in sprinting with forward and outward toes position. **Methods** Four male sprinters were tested for this study (age  $19.3 \pm 2.0$  years, body mass  $71.5 \pm 8.5$  kg, height  $182.8 \pm 7.2$  cm, 100 metres best  $11,23 \pm 0,25$  s). Every participants had two attempts in 50 metres maximal speed running: first attempts with comfortable foot position in first foot strike and second attempts with toes forward. 3-D video analysis (Qualisys, 6 cameras ProReflex with the frame rate 120 Hz) was used for evaluating kinematic characteristics of athlete's CM. The data were filtered with the 2nd order of lowpass filter (10Hz). Were analyzed kinematic characteristics of athlete's CM from takeoff moment of one leg to takeoff moment of other leg. Videotaping performed on 38-42 metres of distance. One-way analysis of variance was used to examine statistical differences of data. **Results** Value of foot angle in first attempt was significantly large than in second attempt ( $19.9 \pm 5.9^\circ$  and  $10.9 \pm 4.4^\circ$ ,  $p < 0.05$ ). However no significant differences ( $p > 0.05$ ) of following characteristics between run with both first foot strike techniques were found: average velocity of CM ( $9.30 \pm 0.35$  and  $9.12 \pm 0.20$  m/s), ground contact time ( $0.098 \pm 0.008$  and  $0.100 \pm 0.007$  s), flight time ( $0.146 \pm 0.014$  and  $0.152 \pm 0.015$  s), horizontal displacement of CM in direction of moving during ground contact time ( $0.83 \pm 0.09$  and  $0.84 \pm 0.08$  m) and during flight time ( $1.27 \pm 0.11$  and  $1.29 \pm 0.11$  m), vertical displacement of CM during ground contact time ( $0.02 \pm 0.00$  and  $0.02 \pm 0.00$  m) and during flight time ( $0.04 \pm 0.01$  and

0.04±0.02 m). Discussion Results of present study haven't shown what foot position toes forward or outward in the first foot strike in maximal speed run is better. Horizontal velocity of CM not increased significantly after decrease of foot angle. At the same time not all participants of this study really completed their task to turn toes forward. It is shown that foot position in first foot strike is strong skill and planting foot with zero angle (neutral position) can be reason of larger changes of kinematic characteristics of CM than in present study. ### NEURAL AND MECHANICAL ADAPTATIONS OF RHYTHMIC MULTI-JOINT COORDINATION DUE TO EXTERNAL INTER-ACTION TORQUE

Stosic, J.

*The University of Queensland*

Rhythmic multi-joint coordination is influenced by the two constraints typical for multi-segmental coordination: interaction torque and multi-joint muscles (muscles that cross two or more joints). Interaction torque emerges in virtually all multi-joint tasks and the neural control also needs to be adjusted to the presence of multi-joint muscles. The effects of interaction torque and multi-joint muscles in multi-joint coordination are hard to discern. Typically, previous research has been focused on only one constraint, while trying to control the effect of another constraint on the studied coordination. In order to address the exclusive role of multi-joint muscles in rhythmic coordination, it is necessary to exclude the influence of natural interaction torque. The aim of the study was to explore how CNS adapts to artificially imposed interaction torques, by looking specifically into behaviour of elbow muscles during rhythmic multi-joint tasks. Elbow joint system with 2 independent degrees of freedom (DOF) of flexion-extension (FE) and supination-pronation (SP) was selected because of negligible influence of natural interaction torque (IT) and suitability to apply IT artificially using a robot motor arm. Subjects (8) were asked to produce in-phase movement pattern (simultaneous flexion-supination followed by extension-pronation), while an external IT was imposed at 90 degrees out of phase (i.e. the supination lagging relative to flexion). Five levels of IT were applied while EMG was recorded from 4 muscles (biceps, triceps, brachioradialis and pronator teres). Onset and half-relaxation time of linear enveloped EMG were analysed to quantify the time shift and the duration of EMG signal for different IT levels. A sine wave of muscular torque produced in the absence of IT and a sine wave of external IT were used to calculate the pattern of net muscle torques exerted in the presence of external IT (i.e. predicted net muscular torques). The results showed that EMG activity was correlated with the predicted net muscular torques. The onset of EMG activity shifted earlier with an increase in the level of IT. Namely, the phenomenon matched with the shift of the predicted net muscular torques, reflecting therefore flexibility of the CNS to adapt to resistive IT while preserving the instructed kinematics. Conversely, the activity pattern of multi-joint muscles (i.e. biceps and triceps) remained unaffected, which was probably enabled by the adaptation of the activity of single-joint muscles. In conclusion, this approach (a system with both a negligible own IT and a possibility to apply additional external IT) offers the way to test multi-joint muscles irrespective of IT which could be important for future rehabilitation purposes.

### 3D PATH OF THE BODY CENTRE OF MASS AND PROPULSIVE MUSCLES LENGTH CHANGE WHEN PEDALLING: RECUMBENT VS. UPRIGHT BICYCLE.

Telli, R., Seminati, E., Minetti, A.E.

*università degli studi di milano*

Introduction: Recumbent bike (RB) is a high performance human powered vehicle allowing man to reach speeds in excess of 130 km/h principally due to aerodynamic drag reduction (Wilson 2004). The change in posture of the rider moves the body centre of mass (BCoM) in a lower position compared to normal bicycle (NB) and also could lead the propulsive muscles to work at different lengths. Here we compared RB and NB at different cadences in terms of muscle length changes, 3D BCoM trajectory, internal and 'eventually additional' external mechanical work (EAEMW). Methods: Four subjects performed one minute of pedalling at different RPM (50, 70, 90, 105) on both bicycles placed on rolls. Lower limbs muscles lengths were estimated with the musculoskeletal modelling software OpenSim 2.4, from 3D kinematic data sampled at 100 Hz with an 8-camera motion capture system (VICON MX, Oxford, UK). 35 reflective markers were placed on subjects body landmark (Plug-In-Gate model) with two additional markers placed in correspondence of the greater trochanter for the evaluation of BCoM position and EAEMW. Results: In RB, when compared to NB, some muscles work nearer their optimal muscle length (from 1 to 12% nearer in RB among NB), while others farther (from 3% to 13%). The advantaged muscles (propulsive signed with P) are: biceps femoris longus (P), rectus femoris (P), vastus lateralis intermedius and medial (P), biceps femoris brevis (P), iliacus (P), psoas (P), semitendinosus (P), tibialis anterior (P), sartorius (P). The disadvantaged muscles: semimembranosus (P), soleus (P), lateral and medial gastrocnemius (P). BCoM 3D trajectory follows an elliptical profile in the sagittal plane (as reported by Minetti 2011), with different major axis inclinations for the two bicycles, but also shows some lateral displacement, the range of which increases with pedalling frequency. Mechanical internal work increased as a power function of pedalling cadence, for both bicycles, while EAEMW was always higher for RB. Discussion: Comparison between the two bikes shows some differences: the EAEMW is higher in RB (+42.13%), while the internal work is slightly lower (-11.63%) (probably due to a different BCoM trajectory), in line with the progressive reduction of internal work in cycling evolution shown by Minetti and collaborators (Minetti et al. 2010). Propulsive muscles in RB work either in a nearer or a farther part of optimal muscle length, likely balancing out the advantage/disadvantage due to the force-length relationships. **15:00 - 16:00****Mini-Orals****PP-BN12 Coaching [CO] 3****RELATIONS BETWEEN LEGS-ONLY AND FULL STROKE SWIMMING IN VARIOUS SWIMMING STYLES**

Leko, G., Šiljeg, K.

*Faculty of Kinesiology*

**Introduction** Some researchers consider that the role of legs in swimming is negligible, especially in front crawl. Most of the research has concentrated on front crawl or breaststroke styles. The purpose of this study was to investigate the relationship between swimming speed achieved using full stroke, and swimming speed achieved using legs-only, in four different swimming styles. **Methods** Sixty-eight well conditioned male swimmers aged 16-18 participated in this study. The subject swam "all-out" 25 m and 100 m distances four times, using each of the four styles (crawl, backstroke, breaststroke and butterfly) starting from the water. Each of the swimming styles was performed on the same day (25 m + 100 m) with a 15 minutes rest period. Two days later, the procedure continued by legs-only swimming, all styles on the same day with 15 minute rest periods. **Results** The statistical analyses were performed using Statistica 10.0. The mean full stroke swimming times (in seconds) were: 100 m crawl = 59.13±3.46, 100 m backstroke = 69.13± 6.04, 100 m breaststroke = 77.65±5.27 and 100 m butterfly = 69.68±6.71. Mean times for 25 meter swims were: 25 m crawl = 13.54±0.60, 25 m backstroke = 15.92±1.11, 25 m breaststroke = 18.49±1.23 and 25 m butterfly = 15.27±1.17. Times for legs-only swimming were: 25 m crawl = 19.50±1.88, 25 m backstroke = 19.99±2.66, 25 m breaststroke = 22.28±1.49 and 25 m butterfly = 20.27±2.47. The results indicated that correlation coefficients between legs-only swimming times and full stroke swimming times across various distances are similar. When comparing different styles it can be noticed that front crawl has the lowest correlation coefficients (0.40 and 0.38 for 100 meters and 25 meters, respectively). The highest correlation coefficient was observed for breaststroke (0.55 and 0.71 for 100 meters and 25 meters, respectively). For butterfly style, the correlation coefficients were 0.59 and 0.54 for 100 meters and 25 meters, respectively) and for backstroke 0.47 and 0.46 for 100 meters and 25 meters, respectively. **Discussion** The results showed that legs-only swimming may be a good indicator of full stroke swimming speed for butterfly and breaststroke styles. In front crawl and backstroke, this influence is less pronounced. Relationships in different swimming distances are similar. **References** Deschodt VJ, Arsac LM, Rouard AH.. **HOW SPORT COACHES IDENTIFY AND DEVELOP TALENT IN CHILDREN AND YOUTH**

Ellingsen, J.E.1, Danielsen, A.G.2

*1 Bergen University College 2 University of Bergen*

**Introduction** Sport coaches' thinking about talent is likely to influence how children and adolescents who participate in leisure sport activity-programs are stimulated (Gagné, 2000). The coaches' thinking may reflect socio-cultural assumptions which can be more or less in discrepancy with research-based knowledge. Therefore, the aim of this study is twofold: (i) to establish research-based knowledge of the criteria used by coaches when identifying the talented child or young person, and (ii) to provide for knowledge and greater understanding of how talent is developed and stimulated in qualified ways. **Methods** Exploratory Interviews (semi-structured) with the research participants (sport coaches) were based on an interview guide designed to ensure both comparability and completeness, using a similar approach as Martindale et al. (2006), adjusted to our study. Six experienced sport coaches were selected, from swimming, gymnastics, and football resp., all training 10- to 15-year old boys and girls. **Results** Three themes emerged: (1) Personal characteristics/psychological factors; (2) Body characteristics; and (3) Social characteristics. The coaches emphasize (1a) talented youth learns things fast; is willing to learn and train; is motivated; (1b) the significance of the coach as a motivator, care person, conversation partner, and role model; and parental support; (2) bodily conditions; (3) the importance of comprehensiveness; variation; motivational climate; and safety, growth, and challenge. **Discussion** Our findings support that the concept and understanding of talent are compound (Abbott & Collins, 2004). The significance of the coach as a motivator and the motivational climate correspond with empirical research based on achievement goal theory and self-determination theory (Duda, 2001; Deci & Ryan, 2000). Our research was limited to coaches' statements. **References** Abbott, A., Collins, D (2004). **THE PARENTAL SUPPORT IN THE CAREER OF BRAZILIAN GYMNASTS PARTICIPATING IN THE OLYMPIC GAMES <1980-2004>: THE GYMNAST'S VIEW**

Schiavon, L.M., Paes, R.R., Toledo, E.

*State University of São Paulo/State University of Campinas*

**THE PARENTAL SUPPORT IN THE CAREER OF BRAZILIAN GYMNASTS PARTICIPATING IN THE OLYMPIC GAMES (1980-2004): THE GYMNAST'S VIEW** **Introduction** This abstract is part of a wider research made about the sports career of all the women Brazilian gymnasts participating of Olympic Games in Artistic Gymnastics, from 1980 to 2004, which objective was to register and analyze this process of formation (Schiavon, 2009). In this poster, we will analyze the parental support in the career of gymnasts. This aspect has been highlighted, many times, as determinant in the preparation of the athletes (Ewing et al, 2002; Cummings, Davies and Campbell, 2000). **Method** In this qualitative research it was used the Oral History method (as there is no available data about some aspects of the modality in Brazil), with

the techniques of "oral testimonials" and crossed analysis (Thompson, 2002), and non-structured interviews (Laville and Dionne, 1999). The selection criteria was: Brazilian gymnasts participating in the Olympic Games till 2004 (GAF). Subjects: 10 gymnasts (100% of the universe), since the first Brazilian participation in Olympic Games in 1980. Results and Discussion It was found that all gymnasts had significant parental support, their families offered a stable structure so they could concentrate on training. The family was often decisive in the process, especially in relation to motivation to continue their daily training and also stimulating them at crucial moments, most important life of a child / athlete. And eight out of the ten gymnasts mentions their parents as the people who know most about their sporting careers, demonstrating complicity and support. From the high incidence of positive aspects in relation to family support, it is possible to conclude that this was an important aspect in the formation of gymnasts, especially because of the peculiarities of the modality (early onset, injuries, risks etc.); and that should be considered, mediated and encouraged by the coaches. ## A STUDY ON THE ADVANTAGES AND DISADVANTAGES OF STUDENT ATHLETES AS FEMALE STUDENTS

Kim, S.H., Kim, J.H.

*Mokpo National University & Andong National University*

**Introduction** The purpose of this study was to understand the difficulties female students had as student athletes. For that purpose, the study set the following research questions: first, what kind of advantages and disadvantages do female students have by doing sports in terms of exercise and instructor? Secondly, what kind of advantages and disadvantages do female students have according to the gender of instructor? **Methodology** The subjects include 140 female students at physical education middle and high schools in G and J Province. Research tool was an open-ended questionnaire. As for data gathering, questionnaires were distributed to the students, who were asked to fill them out. Their answers were classified by item, encoded, and put to inductive category analysis for data analysis. **Results** First, the advantage of being a student athlete as a female student most cited by the respondents was the positive perception of body changes, which was followed by the positive perception of oneself and others. As for disadvantages, the respondents had a relatively high negative perception of their body changes and appearances. Secondly, as for their advantages and disadvantages as female students according to the gender of instructor, many mentioned good sport instructions and more consideration for female students as the advantages of having a male instructor. On the other hand, they experienced such disadvantages as male instructors being difficult to talk to and being unable to understand women. The advantages of female instructors include understanding female students based on good knowledge of women and further having sympathy for them. However, over familiarity with women also had negative aspects as the respondents mentioned privacy violation and excessive meddling as the disadvantages of having a female instructor. **Discussion** In short, the vulnerability of female student athletes due to their female features or physical strength, body changes, and physiological phenomena have negative effects on their athletic life. Student athlete interest in the body and appearance is a type of self-management (Seong Min-gyeong and Jang Yeon-jip, 2006) and can have positive influences on an athlete's satisfaction and performance (Jin Myeong-su, 2012). It is thus required to instruct female students not to have excessive interest in their appearances and, at the same time, form a positive perception of themselves. The research findings also confirm that female student athletes have a considerable amount of difficulty according to the gender of instructor. An instructor has the biggest influence on young student athletes and can cause changes to them (Im Ji-hun, 2008), which means that field instructors need to have a serious contemplation over what to teach them and how to deal with them.

## COACHING AT SWEDISH RIDING SCHOOLS - FROM MILITARY PRACTICE TO A SPORT FOR GIRLS

Thorell, G.

*The Swedish national Equestrian centre*

**Introduction** Equestrian sport in Sweden has a long tradition within the military academy until the end of 1960s, when the equestrian sport became formed by civilians and an increasing number of women began to be educated to riding instructors (Hedenborg, 2009). Today almost 500 riding schools provide education in riding and horse caring and play an important role as a leisure activity, especially among young girls. In Sweden, sport and leisure activities for children are supported by the government and that is why education at riding schools are not exclusively for the wealthy as in many other countries (Forsberg & Tebelius, 2011). Coaching and pedagogics in equestrian sport have traditionally been formed by military commands and instructions, so the aim of this study is to explore riding instructors' experience and perceptions about coaching at riding schools and if there has become a change due to the shift from military to girls. **Methods** A constructivist grounded theory method have been use to collect and analyzed the data material from interviews with ten riding instructors with more than ten years of experience at their riding school. The constructivist approach of grounded theory is based on the scientists who produce knowledge based on the interpretation of the informants' actions and behavior (Charmaz, 2009). Thus, the result can be seen as an interpreted portrait of the studied world, not an exact picture of it. **Results** The result shows that the way to perform the lessons and the language are very much the same as the military tradition but the riding instructors considered that there has been a pedagogical change over time. Today they stressed the importance of listening to the pupils and create new activity besides the traditional riding lessons. **Discussion** This main result is explained by impact of the changing market conditions and increased competition from other sports and interest that the riding instructors adapt their way of coaching. In conclusion this generates a new way of coaching at riding schools with a more individual and social focused form of coaching which shows that there is a development ongoing in Equestrian sport. **References** Charmaz, K. (2009) Shifting the Grounds. J. M. Morse, P. Noerager Stern & J. Corbin (Eds). Developing grounded theory: The second generation. Left Coast Press Inc. Forsberg, L & Tebelius, U. (2011). ## PREPARING AN EXPEDITION - PERFORMING IN UNCERTAIN ENVIRONMENTS

Fernando, C., Lopes, H., Vicente, A.

*University of Madeira, University of Beira Interior, CIDESD*

**INTRODUCTION** When preparing and organizing an expedition it is important to understand how the performance of the participants will be influenced by the conditions in which they will have to act and take decisions. This work continues previous studies (Fernando et al., 2010) with cold, mud and dust, and how these conditions influence decisions, even very simple decisions. To easier compare the results we kept, as possible, the same methodology. Uncertain conditions are present in several sport environments, mainly in Open Spaces Sports and in Environments Adaptation Sports. **METHODS** To a sample of 20 people aging between 21 and 25 years, we presented on a paper a test of 60 arithmetical operations (additions, subtractions, divisions and multiplications), with numbers equal or inferior to 5, distributed randomly. Participants should perform these arithmetical operations with two sorts of objectives: 1- first of all to make no mistakes; 2- to do it as quickly as possible. But in one of the situations participants also have to be aware of a ball in the top of a table that can never fall down. The sample was divided in two groups of 10 and 10, randomly. One group, group A, answered to the test, always the same test, first comfortably sitting at a table, indoors, and then, second, the same test but with a ball on a table at 1 meter distance and having the information that if the ball moves they have to prevent it from touching the floor (it never happens but they don't know) – priority to the test. The other group, group B, did the same situation but in the reverse order. So after doing the second test (with the ball) they had half an hour rest and then answered the same test in the same comfortable situation indoors. We've measured the time of each participant and the total of errors committed by all the members of each group. **RESULTS** Group A - the average time in uncertain conditions was 15% higher than indoors in comfortable conditions. Results showed a much wider distribution in the uncertain conditions situation (with the ball). While in indoors conditions there were practically no errors (less than 3.5% of the total), in uncertain conditions there were 12% of errors. Group B - the average time in uncertain conditions was 19% higher than in the situation with the ball. Results showed a much wider distribution in uncertain conditions (with the ball). While in the situation without the ball there were practically no errors (less than 2% of the total), in uncertain conditions there were 15% of errors. **DISCUSSION** Performance was influenced by uncertain conditions so we must know what to expect and the influence it can have in the activities. This knowledge is an essential tool to organize and plan an expedition because it allows us to define the limits within which this type of activity can occur in order to preserve the safety of sportsmen and ensure their ability to respond to happenings. **REFERENCES** Fernando, C., Vicente, A., Lopes, H. & Almada, F. (2010). 15th ECSS, pp.473-474.

## SOMATOTYPE IN RUNNERS AND PARTICIPANTS IN ADVENTURE RAIDS

Perez Ruiz, J.A., Escaño Lopez, H.

*Universidad de Extremadura*

**INTRODUCTION:** Adventure raids it's a newfangled sport which increased the number of licenses since 1993, year of the founding of the Federation, 975 licenses, at 2011, 18,324 licenses. (Memory 2011, CSD, "<http://www.csd.gob.es/csd/estaticos/asoc-fed/historico-de-licencias.pdf>") It is defined as a multidisciplinary competition designed to test the ability of resistance, navigation and survival of the team in complete autonomy. The teams must complete an extensive orientation tour, in the shortest time possible, overcoming natural difficulties, which are on their way, using only their own forces, without receiving aid, or use motorized means. (FEDO, 2011). The different stages are: career, mountain biking and canoeing. Special tests are normally declines or vertical ascents (abseiling, climbing, Tyrolean traverse, archery, ...). The profile of the participant in raids is varied. In terms of gender we find a 84.2% correspond to men and 15.8% to women. (Baena Extremera. A, 2008) In regard to the age, it reveals that the predominant groups are 20 to 30 years (51.8%) and 31 to 40 years (41.9%) (Baena Extremera. A, 2008) The analysis of athletic performance is an area of Sport Sciences is dependant for the investigation of the current performance of sports or performance in training, in the specific context where it develops (O'Donoghue, 2010). This must be set the factors influencing the performance of objectively determining the selection criteria, which include anthropometric variables. (Bompa, 1987; Kutsar, 1992; Kunst y Florescu, 1971, cited in Bompa, 1987) From decades ago, different studies have made sufficiently clear that anthropometric profile is a very important target for sporting success factor. (Rocha, 1975, cited in Esparza y col., 1993) The study of body composition provides us valuable information about the structure of an athlete at a particular time of the season and on the effect of the training. (Battistini y col., 1996; Villa y col., 2000; Withers y col., 1997; Gambarara y col., 1994). **METHOD:** The measurements will be carried out in adventure Raids Extremadura League competitors. Taking as shown in 20 competitors from different categories and gender. The measuring instruments used to conduct the assessment are skinfold or compass of skinfold thickness, thickness gauges and metal tape. The measurements were carried out in the same place, by the same explorer following all corrections by the Spanish group of Kinanthropometry. (Esparza y col., 1993) The evaluation will take place at the end of the day's competition. Weight, age, and size-related data will be collected through a sociodemographic questionnaire. Anthropometric measures to take are: skin folds (triceps, bicipital, subscapular, suprailliac), perimeter (biceps flexed and leg) and diameters (femur biepicondylar and humerus biepicondylar). The technical measurement error considered as good is set at a maximum of 5% for the folds and a maximum of 3% for diameters and perimeters. (Sillero Quintana M., 2004) ere

**MENTORING CONVERSATIONS IN PHYSICAL EDUCATION- CONTENT AND PROCESSES IN FIELD WORK IN INITIAL TEACHER EDUCATION**

Næsheim-Bjørkvik, G., Helgevold, N., Østrem, S.

*University of Stavanger*

**Introduction** This presentation reports from a study of mentoring conversations in student teachers' field work within initial teacher education (ITE). We ask what affordances can be depicted when studying mentor conversations in Physical education field work. What is at the core in such conversations and how do the mentors and students talk about physical education in question? What do student teachers possibly learn by taking part in such conversations? **Methods** This study is a part of a larger project on students learning, TasS (Teachers as Students) 2012 – 2014, at the University of Stavanger, Norway. The primary objective of this project is to develop a research-based approach to enhance students' teaching in ways that promote pupils' learning and inclusion. Data collection has included focus group interviews with student teachers, mentoring conversations and lessons led by student teachers, all video-recorded. This presentation is based on 12 video recordings related to pre- and post-supervision and lessons led by students in physical education. We have developed a system for observing and quantifying activities in mentoring conversations. Also the observed categories are recorded in a binary form, stating what is "absent" or "present" during the period of observation, a tool that made it possible to get an overview of a complex material. **Results** Our system of observing has made it possible to compare activities and content in mentoring conversations across student groups, mentoring teachers and subjects. It has also been a starting point for more qualitative analyses. Findings show great variation between how these mentoring conversations are developing (what form of conversations; dialogue – monologue, instruction – co-production, information seeking – reasoning), and also to what is spoken about (pupil oriented, subject oriented, task oriented, general pedagogic oriented conversations). At the core of these conversations task oriented topics are dominating, while pupil oriented and subject oriented references are scarce. Attention is focused on student teachers' "doings", and little awareness of pupils' learning can be depicted. Never the less conversations show variations. **Discussion** Our analyses has made it possible to gain insight into students' knowledge of teaching Physical Education. There is reason to suggest that mentoring will not necessarily serve as scaffolds in students' professional development. The interplay between students and mentors and their use of tools seem to be crucial. In the poster presentation variations between conversations related to this interplay will be further discussed. **References** Gibson, J. **MINIMAL GUIDANCE LEARNING FOR PHYSICAL EDUCATION IN A SCOTTISH SECONDARY SCHOOL**

Jakeman, J., Clarkson, K., Lorimer, R.

*1 Oxford Brookes University; 2 Harris Academy; 3 University of Abertay, Dundee*

**Introduction** It has been recognised, that a traditional, linear model of teaching may not necessarily be the most effective in physical education scenarios, where game-play and understanding are as important as the learning of specific skills. However, attempts to alter approaches to teaching are not always forthcoming or well reported. This paper reports on a small-scale teaching intervention, which implemented a minimally guided teaching approach to a six-week handball activity block. **Methods** Two classes of equal age and ability were used in the intervention, based around a handball teaching block. One class followed a normal curriculum, using a traditional teacher-led teaching approach. The other class was given a task brief, and although supervised, was given no assistance from the class teacher. After the six-week block, the classes competed against each other under normal supervision. Teachers provided qualitative analysis of performance, and a small focus group with pupils was completed after the teaching block. **Discussion** During the first session of the intervention, students were provided with access to computer terminals, and used the internet to research the regulations and skills required for handball. During the teaching block, the intervention class teacher noted that participants were continuing to use the internet and other media sources, to develop their understanding of the game. It was also noted that this was not something usually done by students in relation to other sports. Teachers observing the final session of the block reported that individuals from the intervention group demonstrated greater teamwork, organisation and apparent tactical awareness than those in the control group, with no apparent difference in technical skill ability. Students involved in the project reported that although initially they found the task difficult because of the lack of direction, as they became more familiar with the game, they expressed feelings of excitement that they were able to dictate their own learning, and organise their own practice sessions. They also reported that they drew on skills and knowledge from other sports, in order to improve their handball gameplay, which they did not usually contemplate following a teacher-led approach. In this way, the students were able to develop a deeper understanding of the game, demonstrating some criticality in considering, selecting and modifying appropriate concepts from other team games. This case study indicates that a heavily student focused, minimally guided approach may be an effective tool in the development of student ability in some team games.

**CORRELATES OF PHYSICAL ACTIVITY IN PRESCHOOL CHILDREN**

Roettger, K.1, Grimminger, E.1, Kreuser, F.1, Assländer, L.1, Korsten-Reck, U.2, Gollhofer, A.1

*University of Freiburg*

**Introduction:** Physical activity (PA) is important for preschool children's health including their weight status and motor and psycho-social development. PA behaviors are already established in preschool years and track from early childhood into adolescence (Herman et al. 2009). To create well fitted future interventions and public health programs, factors associated with physical activity have to be analyzed. The present study sought to identify multidimensional correlates of preschool children's physical activity. **Methods:** In N=117 preschool children PA was measured over 7 days using accelerometry. Proxy-report diary and physical-activity and spare-time questionnaire were

completed by parents. Anthropometrical data (weight, height, BMI) and socioeconomic data were obtained. Timetables and curricula of two different models of child-care were analyzed. Multi-regression-models were used to identify constructs potentially associated with preschool children's physical activity. Results: Correlates of physical activity were found across all the domains of the potential factors and varied between week and weekend days. On weekday the kind of child-care (open concept vs. desk based), and socio-economic status (SES) had influence on PA. Desk-based teaching versus an open concept in child-care leads to more inactivity ( $p < 0.05$ ) and children with lower SES were more passive in the afternoon if cared at home ( $p < 0.05$ ). A variance of 88% was explained through the regression model ( $R^2 = 0.88$ ) using the PA on weekend as dependant variable. The highest influence on PA on weekend was given by the BMI of the child, the number of brothers and sisters, TV-consumption of parents and child and the family state and income of both parents. Children with a lower BMI, more brothers and sisters, less TV-consumption and with married parents were more active. Additionally the factors high income of the father and lower income of the mother had also a significant influence on PA on weekend. Discussion: PA-affordance seems to be supported by a kind of "traditional higher SES" family background, meaning one adult responsible for promoting PA in context with other children and responsible for observing screen time at home. In child-care "open concepts" with caregivers skilled in PA should be preferred for enhancing PA (Reilly 2010). Herman, K. M., Craig, C. L., Gauvin, L., & Katzmarzyk, P. T. (2009). ### THE IMPLEMENTATION OF PROBLEM BASED LEARNING STYLES TO TEACH THE COACH-ATHLETE RELATIONSHIPS TO UNDERGRADUATE SPORT AND EXERCISE SCIENCE STUDENTS

Rossato, C.J.L.

*Canterbury Christ Church University*

**Introduction** The central components of problem based learning consist of students working in groups to provide a possible solution and that the focus is on the process of problem resolution as well as the actual solution (Savin-Baden, 2003). A meta-analysis by Dochy et al (2003) found that there was a significant and positive effect on student's skills when using problem based learning styles, and that students engage with slightly less knowledge but retain more knowledge and elaborate more on information than those taught traditionally. There was also a positive effect on student skills that was immediate and lasting. **Methods** This study attempted to explore whether problem based learning styles are suited to lecturing Coach-Athlete relationships. Sixty four (39% female, M age=22.64, SD=2.02 and 61% male, M age=24.30. SD=4.86) students attended a lecture on the topic of Coach-Athlete relationships, a problem based learning task was implemented using images of a coach showing a hostile approach and another image of a coach using a friendly approach. These images were used to initiate discussions about the potential problems the scenarios could elicit. At the end of the session students filled out an evaluation sheet regarding their thoughts about the session's ability to aid learning and whether they felt it was preferred over a traditional style of lecturing as well as their enjoyment of the session. **Results** Eight one percent ( $n=52$ ) of participants found the task helpful to aid learning, 65% ( $n=42$ ) participants indicated that using this style of lecture could aid learning more than a traditional approach and 73% ( $n=47$ ) participants enjoyed the task. **Discussion** It maybe useful to use problem based learning styles in lecture sessions to engage students with the topic area of Coach-Athlete relationships. Problem based learning could also be used to help develop transferable skills for those students who want to pursue a career in coaching. Skills such as problem solving and working within a team in a Coach-Athlete environment are invaluable as communication plays an important part in the Coach-Athlete relationship (Philippe and Seiler, 2006). **References** Dochy, F., Segers, M., Van den Bossche, P., & Gijbels, D. ### ANALYSIS ABOUT THE CONCEPTUAL RELATION BETWEEN SPORT AND GYMNASTICS FOR ALL

Toledo, E., Schiavon, L.M., Paoliello, E.

*UNICAMP/UNESP*

**ANALYSIS ABOUT THE CONCEPTUAL RELATION BETWEEN SPORT AND GYMNASTICS FOR ALL** **Introduction** Brazil has expanded, in the last decade, the publications, events and practices of Gymnastics for All (GFA), which can be seen through many indicators, including the artistic and academic production of the six editions of the International Forum of General Gymnastics (FIGG). In this context, we aim to expand our research about the concept of GFA, and their approaches and detachments with the concepts of sport. **Method** This research is characterized as bibliographical and documentary, using the technique of data interpretation (Gil, 2007). Database: Scielo Sport (articles) and CAPES portal (theses and dissertations), with the following keywords: sport, general gymnastics and gymnastics for all. In addition, all Brazilian books that were specific about GFA (4) and all the annals from FIGG (6) that were available in Gimnica Virtual Library, have been researched. **Results and Discussion** Three clear concepts on GFA were found in: Gallardo e Souza (1992 apud Souza, 1997), Santos e Santos (2001) e Ayoub (2003), which comprise it respectively as: manifestation of body culture, gymnastic field and corporal practice. There are not, in any of them, approaches with the classic concept of sport. Some Brazilian authors hold that detachment, to emphasize the cultural, inclusive, creative and autonomous aspects of GFA (Paoliello, 2008; Toledo, 2005), in the opposite direction of a competitive logic and of a gesture standardization, a characteristic of the modern sport. However, that understanding differs, in some ways, from other countries, among them are :Germany (Hartmann, 2003); Japan (Tatsuo, 2012), Hong Kong (Cheung, 2012), that shows the need for further discussions on a national and international level. **References** Ayoub E. **TAXONOMIC AND COMPARATIVE STUDY OF MOTOR PLAY. HOMO LUDENS AND TRANSCULTURALITY**

Bantulă, J., Buscă, B.

*FPCEE Blanquerna Universitat Ramon Llull*

Introduction Play is not a simple human expression of culture, is the main factor for humanity structuring processes (Huizinga, 2000). The culture 'is playing' and finds its essence inside the human play. The man, the most social animal in the world, built himself as a Homo sapiens and faber due to its fun nature. Thus, play takes part in the development process of all societies and draws its history and its personality. Several studies have focused on motor play to describe the how homo ludens express its profile (Henricks, 2008; Pellegrini, 2009; Roopnarine, 2012; Corsaro, 2012). Hence, the main aim of the study was to analyze the internal structure of plays practised by different cultures from Europe, Africa and Center-South America. Methods 546 traditional motor games were analyzed using the COMET taxonomic model (Bantulă, 2012). The distribution of games per country was Catalonia (210), Colombia (101), Morocco (81), Peru (61) and Dominican Republic (93). The model takes into account the presence and the absence of the following factors: teammates and opponents, competition, external materials and space. Results The main finding of the analysis was the coincidence in the nature of the game concept through the different cultures. We could observe that 90% of cases were sociomotor games, 75% were without teammates, 70% were with opponents and 80% were competitive games. Thus, the profile of the recreational behaviour of cultures describes a sociomotor game played without teammates, against opponents in a competition. Besides, the use of external material is an important factor of this profile. From 33% to 66% of the different game catalogues of the different cultures reflects the use of external materials. Furthermore, the use of external materials is linked with sociomotor game (from 70% to 90% of games with opponent uses external materials). On the other hand, the cooperative play was the recreational manifestations with less external materials use (Catalonia 1%, Colombia 10% Morocco 4%, Peru 0% and Dominican Republic 2%). Discussion The important degree of coincidence observed in the different play culture of the countries analyzed contributes to idea that humans play in a similar manner. According to Huizinga (2000), Homo ludens keep a certain isomorphic and transversal behaviour through the different cultures. This finding contributes to the idea that we can study the different cultural manifestations from a transversal point of view. References Bantulă, J. (2012). **MY CONFESSION: NARRATIVE OF A TENNIS COACH**

Kim, J.

*Andong National University*

Introduction The purpose of this study is to analyze my experiences as a tennis athlete and a coach via life history research and narrative method. For this research questions are three. First, what influence do the experiences as an athlete have on the student athlete's life? Second, does tennis coach's contextual life improve him as a professional? Third, what suggestions does the understanding of my experiences make to tennis education context, particularly in relation to athletes and coaches' society? Methods It is not too much to say that tennis accounts for 99% of my life because most of my experiences are tennis related as far as I can remember. Data collected from the third grade in elementary school when I started tennis to a 28-year-old tennis coach were arranged in 'student athlete period' and 'coaching period' respectively. Data consist of self-stories as a coach, the conversations with my students when training, memos with other coaches, pictures and books, were 80 pages, revised and edited over ten times. Data analysis was inductive method. The revision and complement was accomplished by mixing domain analysis and taxonomic analysis. Results and Discussion The results of this study were as follows. First, my abilities as a coach were found. Coach is an educator, not simply a trainer who only controls and demands from his athletes. Second, physical punishment and the verbal abuse should be eliminated when coaching because athletes have been treated only as exercise machines with such violence. Third, the coach as an occupation was found. Will the student athlete be a good coach if he only performs well in matches? It is often the case that the student athlete does not attend classes and only does exercise. Is it proper that the performance is the only requirement for applying to the coach? It is necessary to regard a coach as an educator who teaches and respects students. Therefore, coach as an educator should reflect upon himself and his practices. This study is based on my experience as an athlete and a coach, serves as a useful introduction to anybody who is interested in improving coaching skills and who is inclined to know himself as a coach. The fact that this self-study and makes the life history of a tennis coach meaningful deserves our full attention. References Clandinin, D.J. & Connelly, F.M. **DEVELOPING COACING PEDAGOGY: TEACHING MODEL BASED INSTRUCTION**

Kim, J.

*Andong National University*

Introduction The aim of this paper is explored Sport Education Model (SEM) approach as one means through which this neglect can be addressed, and the goal of coaching integration can be realised. Methods SEM was introduced to a final year class of 19 undergraduate students during a two-hour weekly session over the course of a 15 week semester. This article was to construct and evaluate pedagogical teaching method drawn from tenets of both action research and 'communities of practice' as a means through which the practice-theory gap can be somewhat addressed. The unit in question involved students being introduced to a particular theoretical position with the expectation that they would integrate that theory into their practice in the upcoming week. The students then shared their experiences in structured discussion groups during the following class. Data on student learning were gathered both through on-going observations and focus groups interviews with researcher and students at the end of the unit. Each interview was attended by three or four students and lasted approximately 90 minutes. The data were carefully sifted through by author to identify common themes as inductively analysed. Results In respect of the unit's learning outcomes, the students encouragingly reported that it had 'opened [their] eyes to something new' (Jihey) and that it provided an explicit opportunity to use some theoretical knowledge 'for the first time really, in a practical situation' (Inhwa). There was also some evidence that the students had begun to think differently about coaching as a result of their SEM experience, in addition to developing a better appreciation of the inherent complexity of coaching which relates to the many interrelated

knowledge needed to excel at the activity (Jones et al., 2012). There was also greater recognition of the structural constraints upon coaches' role fulfillment and the subsequent limits of their agency. Problems, however, were also encountered, centering principally on the use of peer assessment and the perceived ambiguity in a couple of the presented scenarios. Discussion Findings revealed that the students were generally stimulated by and, hence, generally positive about the pedagogical approach experienced. This was specifically in terms of better ordering the knowledge they had as well as developing new insights about coaching practice. In conclusion, although it carries the possibility to make some defensive and dismissive, we believe that SEM also possesses the potential to help coaches towards the higher goals of transferable knowledge, considered flexibility, critical reflection and lifelong learning--qualities which recent research suggests comprise effective, holistic coaching practice (Cassidy, 2010; Robert, 2010). Although not unproblematically, the staff were also positive about the unit; citing better and more continuous student engagement as a result of it.

### **ASSESSMENT TOOL FOR PREDICTING THE HEALTHY FITNESS LEVELS IN STUDENTS THROUGH THE BMI AND COURSE-NAVETTE**

Nebot, V., Ros, C., Martín, J., Valverde, T., Bermejo, J.L., Santamaría, R.

*Universidad Católica de Valencia*

**INTRODUCTION** Body Mass Index (BMI) and Course-Navette test (CN), included in the Eurofit battery (Jiménez, A., 2007), are two accessible, reproducible and non-invasive tools available for any teacher. Its use allows the prediction or estimation of the fitness levels in school populations, as the one shown in this study. Furthermore, these resources allow to reach specific goals when planning the Physical Education lessons. The aim of this study is provide a tool for teachers and students for predicting some reference values on their current health status. **METHODS** 46 students, 29 male and 17 female, (expressed on average (standard deviation), 17.0 (0.5) years; 64 (2.1) male weight and 54.17 (1.83) female weight; 1.71 (5.3) male stature and 1.61 (4.2) female stature). All of them completed a questionnaire about extracurricular Physical Activity Habits (PAH), number of days of practice and its duration. The fitness levels were assessed through the CN. The BMI values were obtained following the ISAK protocol. **RESULTS** BMI was higher in male (BMI male:  $21.9 \pm 2.9$  vs. BMI female:  $20.9 \pm 2.7$ ). Also, the mean CN Period (P) and extracurricular PAH percentage values were higher in male (P male:  $8.5 \pm 1.7$  vs. P female:  $4.5 \pm 0.7$ ; PAH male: 78.61 vs. PAH female: 58.8). Results showed a moderate correlation between the BMI and the fitness levels in male ( $r = -0.46$ ), not being significant in female. **DISCUSSION** The assessment tool, applied to a population that does not show a complex morphology disposable in this type of study, as suggested by Molina et al. (2007), presented in the case of male, a correlation between the BMI and the results of the CN ( $r = -0.46$ ). This test is considered as first priority for health within the EUROFIT (Jiménez, A., 2007). These results support the study of Vela et al (2007), who define the BMI as a good fitness indicator given its high correlation with the percentage of body fat ( $r = 0.80$ ). To conclude, this study allows a more effective self-assessment method to design a specific plan, such as a fitness maintenance or improvement, which considers the students' personal needs. **REFERENCES** • Jiménez, A. ### **ENHANCING TEAM WORK COMPETENCE THROUGH SELF AND PEER ASSESSMENT AS PART OF A PHYSICAL ACTIVITY AND SPORTS SCIENCE DEGREE**

Lavega, P., Lasierra, G., Planas, A., Sáez de Ocáriz, U., Salas, C., Ticó, J.

*INEFC-University of Lleida*

**Introduction** One of the proposals of The European Higher Education Area indicates that students should be actively involved in their own learning. Team work competence is not only a very important skill, not only in relation to knowledge for students' personal development but also as preparation for their future employment (Noonan & Duncan, 2005). The aim of the present study was to analyse students' self and peer assessment, as well as the assessment of teachers, regarding four of 4 dimensions of team work competence required by our degree course in physical activity and sports science. **Methods** Participants: 117 first-year students (Mage = 20.15 years [SD 3.28], 26 [18.46%] women, 91 men [81.53%]) on the degree in physical activity and sports science (INEFC, University of Lleida) and 6 teachers. The students had to solve a problem in teams of four. Self and peer assessment of team work competence was performed and assessed by means of rubrics. **Statistical analysis:** In order to assess the four dimensions of team work competence we took the mean of the ratings given by the student and his/her three classmates. The Student's t test was used to compare means for the dependent variables. A repeated measures analysis of variance (ANOVA) was applied. **Results** The differences between self and peer assessments were only statistically significant for one dimension (Identity) of team work competence ( $t = 1.99$ ;  $p = .048$ ; 95% CI [0.0027 - 0.6156]). The results also revealed significant differences between the ratings given by teachers and both self and peer assessments by students ( $F = 38.89$ ;  $p < .0005$ ). **Discussion** A significant difference was only observed in relation to the 'Identity' dimension of team work competence, where self-assessments were better than those given by peers. This finding is consistent with previous studies which have also reported that students tend to overestimate their own performance (Lindblom-Ylänne, Pihlajamäki, & Kotkas, 2006). The finding that teacher ratings were lower than those of students is in line with previous research in this regard (Noonan, & Duncan, 2005). The use of the rubrics favoured the self-regulation of learning, thereby aiding the teaching and learning process in relation to team work competence. These kinds of positive outcome have been previously reported by other authors (Butler, & Hodge, 2001). **References** Butler, S A. & Hodge, S. R. (2001). ### **LEVEL OF PHYSICAL ACTIVITY AMONG CHILDREN IN KINDERGARTEN:**

Weydahl, A., Stokke, A.

*Finnmark University College*

**Introduction** Kindergartens in Norway aim to ensure that all children have their physical activity needs met, and that they experience physical achievement. These factors are claimed to be important for learning, good habits and good health. Guidelines from NASPE

(Education, 2009) points out that preschoolers should be active for at least 60 minutes a day. The scientific research on physical activity among children is limited. According to international research only fifty percent of children are physically active for one hour a day or more (Tucker, 2008). Therefore, the aim of this study was to investigate the level of physical activity among children in Norway and compare different methods for describing level of physical activity. Methods Six kindergartens and 42 children in the north of Norway were involved in the study. Kindergarten staff filled out a questionnaire about the children's activity level at the end of a day of observation, while researchers observed one child throughout the entire day. The children wore a Polar Team2 monitor (Heart rate, HR) and Actigraph GT3X accelerometer (AC) during the observation. Results 16 children did not want to use the equipment. Only 14 children (6 boys and 8 girls) wore the registration equipment for more than 4 hrs (ACmedian: 421 min; HRmedian: 353min). The median age for boys was 38 months, for girls 47 months. HR- and AC-measures showed that the children's activity level through the day was above the recommended 60 min activity. Boys were more active than girls: median activity time boys: 209 min vs. girls 183 min. The same results are found in the staff's questionnaires and the HR-values. Boys are evaluated as more active than girls and their mean HR during the recorded period is higher. The researchers' observation results were "moderate activity", while the post-day evaluations from staff-members showed that they evaluated the activity level in the same child differently. Discussion The children were followed only one day during the fall. The study shows that there is no problem to get children to meet the recommended activity level in kindergartens if the physical environment allows for it. In the kindergartens that we observed the children were allowed to be outside for many hours playing. Observation, mean of the staffs' "end-of-day- evaluations" and monitoring activity level using HR and AC gave the same results. References Education, N. N. A. f. S. a. P. (2009). ### RELATIVE AGE EFFECT IN PHYSICAL EDUCATION: BORN TOO LATE TO GET AN A

Aune, T.K., Dalen, T.

*Nord Trøndelag University College*

Introduction In the beginning of the 1900 century it was described that young people with eminent performance had a tendency to be born early in their year of birth (Kassel, 1929), and subsequent studies have documented the relative age effect (RAE) in both sport (i.e. Musch & Grondin, 2001) and the educational system (Cobley et al., 2009). The students marks in Norwegian physical education (PE) is an evaluation of different competence aims based on the PE curriculum, and there is a distinct difference in the competence aims in secondary school (SS) vs upper secondary school (USS) (Norwegian Ministry of Education and Research, 2012). On the other hand the variability in maturation is larger in SS, whereas the last year of USS the students normally are fully grown. The present study examined PE attainments in Norwegian adolescents in order to identify eventually RAE. Method The study is based on final marks in PE from in the last year of secondary school (15-16 year) (n=1154) and upper secondary school (18-19 year) (n=1010). Month of birth and marks were classified in quartiles, and the mean of the marks for the respective quartiles were calculated. Also the binominal distribution for the mark 6 and 2 were calculated. The marks is ranged with numbers from 1-6, were 6 is the best. Results The results showed a decrease in the mean of the marks for the respective quartiles ( $p < 0.05$ ) for both boys and girls. The binominal distribution showed a higher number of students born in the first two quartiles getting mark 6 ( $p < 0.05$ ), while there were a higher number of student born in the last two quartiles getting mark 2 ( $p < 0.05$ ). Discussion RAE is documented in the present study for the last year of both SS and USS despite of differences in competence aims for SS compared to USS according to the Norwegian PE curriculum. This indicates that traditional ratings of sport performance are commonly used when evaluating attainment in PE in Norwegian samples. Early maturation and physical capacity seem to favor children's attainment in PE at last year for both SS and USS even that it should not be monitored according to the curriculum. ### EXAMINING THE RELATIONSHIP BETWEEN MINDFULNESS AND PAIN CATASTROPHIZING IN RUNNERS

Jones, M.I., Parker, J.K.

*University of Gloucestershire*

Sullivan (2008) suggested that persons experiencing or anticipating pain may avoid painful activities (e.g., high intensity training) and may quit high intensity training when the going gets tough. Recent research has shown that pain catastrophizing can influence the pain experience. Catastrophizing is a process where individuals magnify pain, ruminate on pain, and feel helpless to cope with pain. It is evident that athletes experience catastrophic thinking in relation to pain (Sullivan et al., 2000) and athletes who catastrophize may miss out on potentially useful training regimens (e.g., high intensity training). Researchers have not examined relationships between catastrophizing and other variables that may reveal ways of reducing catastrophic thinking in athletes. Mindfulness, a non-judgmental focus of one's attention on the experience that occurs in the present moment, may be important for reducing perceived pain and may help attenuate catastrophizing. We propose that runners high in dispositional mindfulness will have lower pain catastrophizing. We recruited 228 runners from online running forums, the British Miler's Club email list, and through running clubs in the UK. We asked runners to complete the Pain Catastrophizing Scale, a 13-item measure of catastrophic thinking associated with pain, and the Mindful Attention Awareness Scale, a 15-item measure of individual differences in the frequency of mindful states over time. The PCS yields a total score and three subscale scores assessing rumination, magnification, and helplessness. The MAAS yields a total score, with high scores

reflecting high levels of dispositional mindfulness. Following screening for missing data, normality, and internal reliability, we conducted a 1-tailed Pearson's correlation between the MAAS total score and the PCS subscales and total score. Results revealed significant relationships between MAAS total and PCS total ( $r = -.384$ ,  $p < .01$ ), MAAS and helplessness ( $r = -.395$ ,  $p < .01$ ), MAAS and magnification ( $r = -.325$ ,  $p < .01$ ) and MAAS and rumination ( $r = -.295$ ,  $p < .01$ ). The relationships between mindfulness and pain catastrophizing correspond with findings from clinical studies (e.g., Schutze et al., 2010) and provide preliminary evidence that low mindfulness might be a precursor to pain catastrophizing in athletes, although it is impossible to make causal connections from correlational research. ### INTERMITTENT HYPOXIC TRAINING IMPROVES QUALITY OF LIFE AND SLEEP QUALITY IN THE INACTIVE ELDERLY

Törpel, A., Hamacher, D., Peter, B., Schega, L.

*Otto-von-Guericke-Universität Magdeburg*

**Introduction** Physical exercise has a positive effect on quality of life (QoL) including sleep quality (SQ) (Reid et al., 2010). Intermittent hypoxia promotes first, the proliferation of endogenous neuroprogenitors which leads to an increased number of newborn neurons and second, the expression of brain-derived-neurotrophic factor (BDNF) in the adult hippocampus (Zhu et al., 2010). BDNF expression provokes an anti-depressive effect (Dreimüller et al., 2012) which is positively correlated to subjective QoL. An intervention, coupling intermittent hypoxic training together with physical activity may, therefore, lead to higher improvement of QoL and SQ as compared to an intervention that just includes physical training. **Method** 34 elderly physically inactive people were included in the study and randomly assigned to a control group (CG) or intervention group (IG). During 6 weeks (3 times / 1 hour / week), CG was supplied with a placebo air mixture and IG undertook an intermittent hypoxic training regulated by the same oxygen saturation in the blood (SpO<sub>2</sub>) in each subject. After that, both groups underwent the same strength-endurance exercise programme. QoL was determined with the Medical Outcomes Study Short-Form 36-Item Health Survey (SF12) and SQ has been tested with the Pittsburgh Sleep Quality Index (PSQI) prior and after the intervention. **Result** Regarding QoL, we observed that an interaction effect just failed to become statistically significant ( $F(1.00, 25.00) = 3.96$ ;  $p = .058$ ) in the Mental Component Summary (SF12). However, in SQ an interaction effect has been found ( $F(1.00, 30.00) = 5.89$ ;  $p = .026$ ) which is based on a significant effect in PSQI only in IG ( $t(14) = 2.11$ ;  $p = .011$ ). **Discussion** The current study evaluated the effect of an additional hypoxic training prior to physical intervention. The data of our study suggest that an intermittent hypoxia combined with physical exercise augments the positive effects of exercise on SQ in elderly physically inactive humans. We assume that the hypoxic stimulus was possibly not strong enough to affect QoL in our subjects. Furthermore, it is insufficiently clarified whether the observed result through hypoxic training is caused by physiological adaptation effects or through neurological adaptations. Therefore, further research is recommended. **References** Reid KJ, Baron KG, Lu B, Naylor E, Wolfe L, Zee PC. (2010). *Sleep Med*, 11, 934-40. ### INTERMITTENT HYPOXIC TRAINING AFFECTS COGNITIVE PERFORMANCE IN THE ELDERLY

Hamacher, D., Peter, B., Törpel, A., Schega, L.

*Otto-von-Guericke-Universität Magdeburg*

**Introduction** Physical exercise has a positive effect on cognitive performance (Etner et al., 1997). One reason for this might be the upregulation of brain-derived-neurotrophic factor (BDNF) which improves brain plasticity (Knaepen et al., 2010). Furthermore, intermittent hypoxic training promotes first, the proliferation of endogenous neuroprogenitors which leads to an increased number of newborn neurons and second, the expression of BDNF in the adult hippocampus (Zhu et al., 2010). Therefore, intermittent hypoxia may support synaptic plasticity, process of learning. Hence, intermittent hypoxia might also lead to improved cognitive functioning. This study aims to evaluate to what extent physical activity with a preceded intermittent hypoxic training is more effective than just a strength-endurance programme on measures of cognitive performance in the physically inactive elderly. **Method** Thirty-four elderly physically inactive people who successfully passed a medical exam by a medical doctor and who were between 60 and 70 years of age were randomly assigned to a control group or intervention group. Contrarily to the control group, which was supplied with a placebo air mixture, the intervention group was supplied with an intermittent hypoxic training prior to a strength-endurance exercise programme. The cognitive performance of individuals was examined using the d2-test (measuring attention) and the Number Combination Test (measuring cognitive processing speed) both before and after the exercise programme. **Result** We observed a time x group effect in the performance of the d2-test ( $F(1.00, 32.00) = 4.65$ ;  $p = .034$ ) which is based on a significant improvement over time in the intervention group ( $p = .001$ ). Regarding the Number Combination Test, we did not find any interaction effect ( $F(1.00, 32.00) = 0.21$ ;  $p = 0.649$ ). **Discussion** To the best of our knowledge, the current study provides the first data set indicating that an additional intermittent hypoxic training combined with physical exercise augments the positive effects on cognitive performance in elderly physically inactive humans. This result might be caused by an increased expression of BDNF. From an application stand point, the authors carefully speculate that due to the possible effect which increases cognitive performance, intermittent hypoxia might also be an effective preventive measure for elderly people e.g. prone to diseases like dementia. To strengthen that statement, further research is strongly recommended. **References** Etner JL, Salazar W, Landers DM, Petruzzello SJ, Han M, Nowell P. (1997). *JSEP*, 19, 249-277. ### THE EFFECT OF PHYSICAL EXERCISE IN HYPOXIA CONDITION IMPROVES MOOD

Lemos, V.A.1,2, Bittar, I.G.L.2, Caris, A.V.1, Silva, E.A.1,2, Rosa, J.P.P.1,2, Santos, R.V.T.2,3, Lira, F.S.1,2, Antunes, H.K.M.2,3, Tufik, S.1,2, De Mello, M.T.1,2

1: UNIFESP (São Paulo, Brasil), 2: CEPE (São Paulo, Brasil), 3: UNIFESP (Santos, Brasil)

**Introduction** Although hypoxia condition worsens mood, after the performance of exercise there is an improvement of mood in normoxia condition. However, it was never evaluated the effect of acute exercise, in hypoxia condition, on mood. Thus, the aim of this study was to evaluate the influence of acute exercise on mood state in a condition of hypoxia equivalent to 4500-m for 29 hours. **Methods** Thirty-eight healthy men were enrolled in this study, randomly divided into four groups: (Hypoxia  $n = 10$ , Normoxia  $n = 10$ , Exercise in Normoxia  $n =$

10 and Exercise in Hypoxia  $n = 8$ ). The mean values were: age (years) - ( $23 \pm 8$ ), body mass (kg) - ( $71 \pm 7$ ), height (m) - ( $1.76 \pm 0$ ), BMI ( $\text{kg}/\text{m}^2$ ) - ( $22 \pm 9$ ) and  $\text{VO}_2$  peak ( $\text{ml}/\text{kg}/\text{min}$ ) - ( $47 \pm 4.2$ ). Mood was assessed using the Brunel Mood Scale (Rohlf's et al., 2008), applied on the first day in all groups and reapplied on the second following day, shortly after the exercise session of 60 minutes, 50% of  $\text{VO}_2$  peak ( $\text{ml} / \text{kg} / \text{min}$ ). The groups Hypoxia and Exercise in Hypoxia were exposed in hypoxic condition in Colorado Altitude Training™/12 CAT-Air Unit). The comparisons were performed using ANOVA for repeated measures followed by the Tukey Post Hoc and the level of significance was set at  $p \leq 5\%$ . Results There was a significant improvement in tension ( $p = 0.001$ ) and anger ( $p = 0.001$ ) in the hypoxia exercise group when compared with hypoxia group. In the hypoxia group it was observed significant worsening in tension ( $p = 0.013$ ), anger ( $p = 0.002$ ), fatigue ( $p = 0.008$ ) and vigor ( $p = 0.05$ ) compared with normoxic group. The normoxia group and exercise in normoxia did not differ significantly. Discussion These results are similar to experimental conditions performed at sea level (Herring and O'Connor, 2009). Our results show that even in hypoxia condition, which worsens the mood (Lemos et al., 2012), the exercise can reverse this undesirable effect. This association might be explained due to an increased in serotonin levels, once it can modulate mood (Strüder and Weicker, 2001). Thus, we suggest that physical exercise performed in hypoxia condition can improve the mood state; however more studies are need to better understand the mechanism involved. ### WORKING MEMORY CAPACITY AND PROPENSITY FOR CONSCIOUS MOTOR PROCESSING IN AN INHIBITION TASK

Cosgrove, A., Poolton, J.M., Masters, R.S.W.

*The University of Hong Kong*

Introduction It is known that people differ in their propensity to consciously monitor and control automated movements (also known as "reinvestment"), particularly under pressure or when extensive preparation time is available (e.g., Masters & Maxwell, 2008). While reinvestment generally leads to inferior performance, a high propensity for conscious movement control might be an advantage in a task that requires inhibition. The aim of this study was to investigate the interaction between propensity to consciously control movements (i.e., movement specific reinvestment) and working memory capacity (WMC) when executive supervision of a normally automated task is required. Methods Participants were asked to coordinate a bimanual movement task (index finger movements in the horizontal plane) in an anti-phase movement pattern during a baseline and a distraction condition. They were instructed to keep in rhythm with a metronome while preventing transition from anti-phase to in-phase as the frequency increased. A visual search task was added in a distraction condition and participants were asked to do their best in both tasks. We assessed participant's WMC via the Automated Working Memory Assessment (Alloway, 2007) and administered the Movement Specific Reinvestment Scale questionnaire (MSRS, see Masters & Maxwell, 2008) Results Low scores on the MSRS were associated with better overall performance of the task, although this difference was not significant ( $p = .061$ , partial eta squared = .203). A significant interaction was evident between condition and visual WMC group ( $p < .05$ ). Participants with high visual WMC scores performed worse in the distraction condition compared to the pressure condition. They also performed worse on the secondary task compared to participants with low visual WMC. Discussion A high propensity to consciously control movements was not shown to be beneficial for performance of tasks requiring the inhibition of automated movements. One possible explanation for our findings is that control of finger movements was unlikely to have been supported by underlying declarative knowledge, which is essential for reinvestment. High visual WMC was associated with decreased performance of both tasks in the distraction condition, suggesting that participants with high visual working memory abilities may have utilized visual feedback in the inhibition task more than participants with low visual working memory capacity. ### ATHLETE'S INTERNAL TASKS AND THEIR EXPRESSIONS OF BODY. -CASE STUDY OF PSYCHOLOGICAL SUPPORT WITH JAPANESE ELITE ATHLETE -

Takeda, D.1, Kotani, K.2, Eda, K.3

*1: Japan Institute of Sports Sciences, 2: Hokkaido University of Education, 3: University of Tsukuba*

Introduction The purpose of this study is to illuminate athlete's psychological maturity from a viewpoint of their internal tasks and their expression of body. In Japan, there are two ways to approach psychological support concerning sports and physical activities. These are called Sports Counseling (SpC), and Sports Mental Training (SMT). In this presentation, we introduce a matter which rose from clinical practices of SpC, and discuss athlete's expressions of body through practical cases. Those who practice SpC often experience difficulties in providing support to athletes using approaches like psycho-skill training, which only concerns consciousness and behaviors. They state that we need to pay attention to their inner world or internal tasks which lurk in athletes' seeking psychological support. Especially, the more athletes' performance levels grows, the more confronted they must be with their internal tasks, which are expressed through their performance; their expression of their own body (Nakagomi, 2004; Takeda, 2011). Methods We examined athletes who voluntarily received personal psychological consultation. Materials used in the analysis were the verbatim records of conversations that took place during private sessions. The clinical approach using the case study method was used to analyze the materials. Case & Discussion Case A (Female in her 20's) sought psycho-support after a struggle with movements of her sport. She mentioned that in a certain action, at the later part of the movements, she felt clumsy to the extent where she had to stop. Certified Sport Counselor interviewed with her to get information about her internal task, and identified her task was acquisition of the sense of independence. When her performance changed to higher level, the attitude of people around her also changed, and she stated that was the time she began to question her own existence as an athlete. At a competition, she felt numb in her right leg, and said the experience was a wonder. At a later competition, she achieved her personal best. Psychological sessions were ended when the change in her attitude towards her sport brought performance stability. We approached the case from a psychodynamics perspective, and concluded that the internal task of an athlete was expressed as external changes and through their performance /body. ## PREVENTIVE AND RISK FACTORS FOR BODY DISSATISFACTION IN PORTUGUESE ADOLESCENTS

Coelho, E., Fonseca, S., Pinto, G., Mourão-Carvalho, I.

*University of Trás-os-Montes and Alto Douro*

**Introduction:** The aim of this study was to determine the prevalence of body image dissatisfaction and associate factors in adolescents, separately for females and males. **Methods:** A cross-sectional study including 529 adolescents (53.7% male and 46.3% female) aged 10 to 18 years ( $13.32 \pm 1.59$ ) was done. Body image was assessed using Collins's body image silhouettes and estimated body image dissatisfaction. Height and weight were measure and Cole et al.'s cutoffs were used to define obesity. Lifestyle, socioeconomic status and demographic characteristics of participants were obtained through a constructed questionnaire. Univariate and multiple logistic regression analyses were used. **Results:** The prevalence of body dissatisfaction was 58%. Significant associations were found between body dissatisfaction and gender ( $p < 0.00$ ) and prevalence of obesity ( $p < 0.00$ ). Multivariate logistic regression revealed that the following variables were associated with body dissatisfaction: obesity (OR=6.94; IC95%: 3.86-12.49), more than 4 days by week of sport activities (OR=0.52; IC95%: 0.32-0.84), see tv more than 2 hours by day (OR=2.22; IC95%: 1.25-3.94; OR=2.28; IC95%: 1.35-3.84). Among male adolescents, the variables that had a significant association were obesity (OR=6.46; IC95%: 3.26-12.81) and see tv more than 2 hours by day (OR=2.50; IC95%: 1.13-5.53; OR=3.34; IC95%: 1.57-7.11). Obesity was the only variable that had a significant association with body dissatisfaction (OR=12.55; IC95%: 2.92-53.99) among female adolescents. **Conclusions:** Obesity and hours spending watching tv are risk factors of body dissatisfaction, while sport practice is a preventive factor. It is necessary to considered different interventions for men and women to reduce body image dissatisfaction

## THE RELATIONSHIPS BETWEEN BURNOUT, HEALTH DISORDERS AND PERCEIVED HEALTH IN YOUNG FOOTBALLERS

Castillo, I., Fabra, P., Ródenas, L., García-Merita, M., González, L., Balaguer, I.

*University of Valencia*

Little research in sport has previously studied the effects of burnout on the perceived health of young athletes, although some works have shown the relationship between different dimensions of burnout and physical and psychological health disorders in youths (Reinboth & Duda, 2004). This study pursue two objectives: (1) to analyze the relationship between burnout, health disorders (somatic and psychological), and perceived health in young footballers and (2) to explore the mediational role of health disorders between burnout and perceived health. 725 young male footballers from the Valencian Community Football Federation (Spain) between 11 and 13 years old ( $M = 12.6 \pm .54$  years) completed the Spanish versions of the Athlete Burnout Questionnaire (Raedeke & Smith, 2001) and some items from the Inventory of Health Behaviour in School Children (HBSC; Wold, 1995). Five simple regressions and two hierarchical regressions analyses were performed. The results reported that burnout was a positive predictor of somatic ( $\beta=0.23$ ) and psychological ( $\beta=0.22$ ) disturbances and both health alterations were, in turn, negative predictors of perceived health ( $\beta=-0.21$  and  $\beta=-0.19$ , respectively). In addition, following Baron and Kenny (1986), the regression analysis performed with predictor variable (burnout), mediating variables (somatic and psychic disturbances, separately) and the criterion variable (perceived health), indicated that health disorders, both somatic and psychic, acted as a partial mediators between the burnout and perceived health, with a beta coefficient of burnout significantly reduced by the inclusion of the both mediator variables ( $z=-3.83$ ,  $p < 0.01$ ;  $z=-3.52$ ,  $p < 0.01$ , respectively, according to the Sobel test). The results emphasize the risk of experiencing burnout in sport for the general health of footballers, both regarding symptoms as well as their perception. Research funded by Ministerio de Ciencia e Innovación (DEP2009-12748), Spain. References Baron, R. M., & Kenny, D. A. (1986). ## MUSCLE DYSMORPHIA AND EATING DISORDERS: WEIGHTLIFTERS

González-Marfí, I., Papathomas, A.

*University of Castilla-La Mancha and Loughborough University*

**Introduction** Muscle dysmorphia is characterised by a pathologically distorted perception of muscularity. Those who experience the condition perceive themselves to be significantly less muscular than reality and duly develop increased body dissatisfaction and an obsessive preoccupation with muscle development. Although numerous scholars have speculated on the link between muscle dysmorphia and eating disorders, few studies have explored this relationship empirically (Murray, Maguire, Russell & Touyz, 2011; Murray et al., 2012). The aim of this study was to explore muscle dysmorphia symptoms in weightlifters and assess the impact of an eating disorder on the severity of these symptoms. **Methods** We recruited a large sample of 442 weightlifters (285 male and 157 female) from ten Spanish gymnasiums. Ages ranged from 18 to 63 years ( $M=30.92$ ). Each participant completed a demographic questionnaire composed of 10 items and the Escala de Satisfacción Muscular (ESM; González-Marfí, Fernández, Contreras and, Mayville, 2012). The ESM is a validated 19-item scale designed to assess muscle dysmorphia symptoms. **Results** 4.8% of participants self-reported previously suffering with an eating disorder. We applied an ANOVA to compare ESM scores between the eating disorder group and the non-eating disorder group. This analysis showed significant differences ( $p < .05$ ) for all ESM factors except "Injury". The post-hoc analysis showed weightlifters who had experienced an eating disorder demonstrated higher mean scores for the "bodybuilding dependence", "muscular dissatisfaction", "substance use" and "checking behaviours". **Discussion** This study provides provisional evidence for a relationship between muscle dysmorphia and eating disorders. Given weightlifters with eating disorder experiences demonstrated accentuated muscle dysmorphia symptoms, some degree of shared pathology may be at work. Further research is needed to better understand the complex interplay between these two conditions (Murray et al., 2012). References González-Marfí I, Fernández JG, Contreras OR, Mayville SB. (2012). ## THE EFFECTS OF DIFFERENT TRAINING VOLUME OF RESISTANCE EXERCISE ON COGNITIVE FUNCTIONS IN SEDENTARY YOUNG MEN

Ho, J.Y., Kuo, T.Y., Liu, K.L., Tsai, Y.J., Zeng, Y.S., Kao, S.C., Huang, C.W., Hung, T.M.

*National Taiwan Normal University*

**Introduction** Although regular aerobic exercise has been shown to improve cognitive functions (Kramer et al., 2006), little is known about the effects of resistance exercise, particularly the influence of training volume, on cognitive functions. Therefore, this study aimed to examine the effects of 1 set versus 3 sets of resistance exercises on cognitive performance in sedentary young men. **Methods** Twelve healthy sedentary young men (age  $21.6 \pm 1.7$  yrs, height  $171.7 \pm 5.3$  cm, weight  $68.1 \pm 13.2$  kg) were recruited and participated in three experimental trials in a counter-balanced order separated by one week: (1) performed single set of resistance exercises (SS); (2) performed multiple sets of resistance exercises (MS); (3) rest (Control). The whole body workout consisted of 7 different resistance exercises performed at 10 repetition maximum with 2 minutes of rest between sets and exercises. Cognitive functions were assessed by task switching paradigms with two conditions before exercise and 30 minutes after exercise. The pure task condition required repeated performance on a single task; the mixed-task condition required participants to change rapidly between two different tasks. Task performance measures of reaction times (RTs) were collected and analyzed. Results RTs of pure task significantly decreased in SS and MS after exercise ( $478.8 \pm 47.2$  to  $451.1 \pm 53.5$  ms and  $469.3 \pm 50.7$  to  $448.4 \pm 53.0$  ms, respectively) while RTs remained similar in Control. In addition, RTs of pure task were significantly shorter in MS when compared to Control ( $448.4 \pm 53.0$  vs  $472.3 \pm 59.1$  ms). Within the mixed-task condition, non-switch RTs were shorter in SS and MS but not in Control after exercise and there was no significant interaction for switch RTs. Furthermore, results showed no differences in switch cost (i.e., difference in RTs between non-switch and switch) on RTs for all three trials before and after exercise. **Discussion/Conclusion** Task switching paradigms have been used extensively to evaluate executive control functions such as working memory, inhibition, and mental flexibility (Monsell, 2003). Our findings indicate that greater training volume of resistance exercise enhances cognitive functioning in a simpler cognitive task. However, when the cognitive tasks require greater amounts of executive control, training volume of resistance exercise may not play an important role in improving cognitive functions in sedentary young men. **References** Kramer AF. et al. (2006). *J Appl Physiol*, 101, 1237-1242. Monsell, S. (2003). *Trends Cogn Sci*, 7, 134-140.

## PREVALENCE OF EATING DISORDERS AND PSYCHOLOGICAL PARAMETERS IN ELITE FEMALE GYMNASTS: THEIR RELATION TO BODY IMAGE AND BODY MASS INDEX

Theodorakou, K., Donti, O.

*ATHENS KAPODISTRIAN UNIVERSITY*

**Introduction** There is strong evidence that participation in aesthetic sports, like gymnastics, is an important risk factor for developing eating disorders, particularly in the case of female athletes (Sundgot-Borgen & Torstveit 2004). Previous studies indicated that psychological factors such as anxiety, self-esteem, and disturbed body image are implicated in the etiology of eating disorders (Biro et al., 2006). The purpose of the current study was to examine the relation between the prevalence of eating disorders and trait anxiety, self-esteem, body image and body mass index in elite gymnasts. **Methods** Participants Thirty gymnasts (16 rhythmic and 14 artistic), members of the Greek national team, aged 15-21 years with considerable competitive experience ( $10.70 \pm 2.20$  years) participated in this study. Study design Participants completed the following questionnaires: the Eating Attitudes Test (EAT-26), the State-Trait Anxiety Inventory (STAI), Rosenberg's Self-Esteem Scale (RSE), Body Cathexis and Body Image scales. Results Nine gymnasts had a total score above 20 in EAT-26. Canonical correlation analysis revealed that age and body mass index highly correlated with bulimia and food preoccupation and oral control while trait anxiety and self-esteem had a medium correlation with dieting. **Discussion** Results revealed that 30% of the gymnasts demonstrated disordered eating attitudes, (EAT-26 > 20) underlining the need for sport specialists to ensure gymnasts' well being. Despite previous studies suggesting that body image dissatisfaction and psychological parameters are critical factors for eating disturbances, in this study, body image did not correlate with the subscales of EAT-26 and trait anxiety and self-esteem had a low correlation with only one subscale (dieting). In contrast, age and body mass index highly correlated with the subscales of EAT-26 (bulimia and food preoccupation and oral control) thus being in line with recent research (De Bruin, Oudejans & Bakker, 2007) suggesting that in the context of aesthetic sports long-term training and competitive demands for thinness may affect differently gymnasts' body image and eating disturbances. **References** Biro, F.M., Striegel-Moore, R.H., Franko, D.L., Padgett, J., Bean, J.A. ## PROBABILISTIC DETERMINATION OF OPTIMAL PERFORMANCE ZONES ACROSS FOUR DIFFERENT PSYCHOMOTOR TASKS

Thin, A.G., Ellis, R.M., Warnock, D.

*Heriot-Watt University*

**Introduction** Physiological activation has long been known to be a major determinant of psychomotor performance (Yerkes & Dodson, 1908). While a number of different models of performance have subsequently been developed, none are readily quantifiable. More recently Kamata et al. (2002) developed a probabilistic estimation method to quantify the Individual Zone of Optimal Function (IZOF) model proposed by Hanin (2000). By utilising all available information their approach generates estimates of the likelihood of optimal performance at a given level of activation. The aim of this study was to compare IZOFs for a group of subjects across four different psychomotor tasks varying in type and difficulty. It was hypothesised that the IZOFs would be higher for less demanding tasks. **Methods** Ten subjects (4 male) mean ( $\pm$ SD) age  $20.7 \pm 1.1$  years, height  $1.73 \pm 0.11$  m, body mass  $69.8 \pm 9.9$  kg were recruited. The tasks used were one- and two-handed turning and placing tasks adapted from the Minnesota Dexterity test and two motor racing simulation tasks (F1 2012, Sony Playstation) using easy and hard tracks. Activation was assessed both by heart rate (HR) and galvanic skin response (GSR) recorded continuously and self-reported arousal and pleasure scores at regular intervals (Edmonds et al., 2006). Performance was assessed by elapsed time at specified points during and at the end of each trial. Subjects performed the tasks on separate occasions in a randomised order. Repeated measures ANOVA were used to compare IZOFs between tasks. Results Mean HR ( $\pm$ SEM) at the mid-point of the IZOFs were  $95.5 \pm 3.0$  and  $101.9 \pm 5.0$  bpm for the one- and two-handed turning and placing tasks respectively and were significantly higher compared to the easy ( $83.0 \pm 2.6$  bpm) and hard ( $81.7 \pm 3.3$  bpm) racing tasks ( $p < 0.05$ ). There were no significant differences between

mean GSR or for mean arousal and pleasure scores. Discussion The mean HR for the turning and placing tasks was around 16 bpm higher compared with the driving tasks. Part of this difference (5-10 bpm) can be attributed to the turning tasks being designed to be performed in a standing position whereas the subjects were seated for the driving tasks (MacWilliam, 1933). The absence of any observed differences in the other measures suggests that are not sufficiently responsive to be of use to distinguish between performance levels. In conclusion, the probabilistic approach to determining IZOFs would appear to have significant potential for quantifying the relationship between physiological activation and psychomotor performance, but further work is needed to develop appropriate experimental paradigms and measures. ##### VISUAL BEHAVIORS OF PENALTY KICKERS IN A REAL-PLAY SITUATION

Nagano, T.

*Keio University*

**Introduction** Penalty kicks is decisive role in important competitions such as the World Cup. In previous studies that skilled goalkeepers use more effective visual search strategies than less skilled counterparts has been widely researched. Meanwhile, only a few studies have investigated visual behaviors of penalty kickers (e.g., Nagano et al., 2006; van der Kamp, 2006; Wood & Wilson, 2010). In the first study of penalty kickers, Kuhn (1988) identified two kicking strategies, which were termed keeper-dependent (KD) and keeper-independent (KI). The aim of this study was to investigate visual search behavior of kicker using a KD strategy and KI strategy in a real-play situation. **Methods** Twenty male university footballers volunteered to take part in this study. Participants were fitted with an eye-mark recorder EMR-9 (Inac Image Technology, Inc., Tokyo, Japan) to record the gaze while kicking. Each participant took 5 practice kicks in a "real-play" situation with an experienced goalkeeper, followed by the 20 kicks for a test trial; half of the trials were KD strategy and the other half were KI strategy. An externally positioned digital video camera was located behind of the participants. This view allowed the whole area of the penalty kick to be visible for subsequent analyses. **Results & Discussion** The shooting performances (the number of scoring a goal) for KD strategy were lower than for KI strategy. Regardless of kicking strategies, the number of fixations for high scorers was lower than low scorers. The last fixation durations for KD strategy on the ball were shorter than for KI. Regardless of kicking strategy, last fixation duration for high scorers on the ball were longer than for low scorers. These results suggest that the shooting performance was affected by visual behaviors of a kicker. **Conclusion** We measured the eye movements of penalty kickers in a real-play situation. The visual behaviors of kickers affect the performance. More research is required to understand "how" and "when" penalty kickers decide on their strategy and the direction. **References** Nagano, T. et al. ##### PETTLEP IMAGERY AND SHOOTING ACCURACY IN FOOTBALL: AN EXAMINATION OF DOMINANT AND NON-DOMINANT FOOT PERFORMANCE.

Grills, A., Wakefield, C.

*Myerscough College & Liverpool Hope University*

**Introduction** Imagery has been shown to be beneficial in enhancing the performance of many motor skills. PETTLEP imagery (Holmes & Collins, 2001) provides guidelines on how imagery should be conducted to increase the behavioural matching (Wakefield, Smith, Moran, & Holmes, in press) between imagery and physical execution of a task, thus enhancing the performance increment. The present study investigated the impact of dominant foot PETTLEP imagery on dominant and non-dominant foot shooting performance. **Methods** Twenty three male academy football players (Mean age = 18.26 years, SD = 1.01) were assigned to one of three intervention groups: PETTLEP imagery (dominant foot, video assisted); physical practice group (dominant foot); and a control group (stretching task). The interventions were carried out twice per week for 6 weeks. Pre and post testing consisted of 10 shots at a goal with both dominant and non-dominant feet. Participants took ten shots at goal from a marker which was central to the goal and 20.12metres out from the goal line. The goal was divided into appropriate sections based on the design of Smith, Wright, Allsopp & Westhead (2007), with the sections reflecting the difficulty of the shot. Total scores were collated and taken as a performance measure. **Results** A repeated measures ANOVA for non-dominant foot revealed no significant main effect,  $F(1,20)=.68$ ,  $p=.79$ , and no significant interaction,  $F(2,20)=.026$ ,  $p=.974$ . A repeated measures ANOVA for dominant foot revealed a significant main effect,  $F(1,20)=6.13$ ,  $p=.022$ , and a significant interaction,  $F(2,20)=3.57$ ,  $p=.047$ . Post hoc tests revealed that the PETTLEP imagery group improved significantly from pre test to post test ( $p<.05$ ). No further significant changes were observed. **Discussion** The results indicate that PETTLEP imagery of the dominant foot is not transferable to the performance of non-dominant foot shooting within football. This lack of transferability lends support to the importance of individualising PETTLEP interventions. The results do however suggest that PETTLEP imagery can have positive impact on dominant foot football shooting performance, compared to physical practice and a control task. This is coherent with previous research conducted (Finn, Grills & Bell, 2011; Wakefield & Smith 2011; Wright & Smith, 2009). Future research is needed in order to realise the implications on performance that this use of imagery can have on coaches, athletes and sports practitioners. **References** Finn, J., Grills, A., Bell, D. ## MUTUAL INTELLIGIBILITY AMONG FOOTBALL OFFICIALS DURING MATCH

Boyer, S., Rix-Lievre, G., Recope, M.

*Université Blaise Pascal - Clermont Université*

Introduction: Rix (2005) adopts a non-normative perspective and methodology in order to understand referee's activity in naturalistic context. The concept of judgment act highlights the synthetic cognition of the referee: he shows to - and imposes on - players what is acceptable. More, the referee judgment does not consist in an application of rules to a reality. The rules are a resource. But the referee is a member of a team of officials: the collective functioning of refereeing on pitch has never been studied. Understanding the organizing role of the prescriptions regarding the task partition (official directives, training recommendations...) is not sufficient to grasp the coordination of the individual unfolding activities. So we investigate the mutual intelligibility (Salembier & al., 2004) among officials in order to determine the way each official contributes to produce judgment acts and what operational procedures enable this contribution in match. Method: After 3 professional football games, researcher conducted individual self-confrontation interviews with: the referee, 2 assistant and the replacement referees (n=12). Using video recording of game allows each participant to relate to a particular lived-experience in his match. Researcher confronted the team members' respective perspective concerning: (1) their own actions and radio communications; (2) the perception of other teammates' actions and radio communications. Results: Assistant and replacement referees develop awareness about: - The referee information needs in situ. They focus on the body indications of doubts the referee shows to make judgments acts. It enables them to provide information for the referee judgment act process at the right moment. - The tolerance threshold of the referee for the intensity of the opponents' physical confrontation. Thus they construct a threshold which is compatible with the referee's. By taking into account (or not) the information addressed to him to produce judgment acts the referee validates (or not) - tacitly or explicitly- the relevance of the information delivered by his colleagues. Discussion: The construction of mutual intelligibility of game situations is shaped by two interactive procedures: (1) the awareness towards referee activity that the assistant and replacement referees construct; (2) the episodes of regulation in which the referee validates information relevance (Poizat & al., 2009). From their perspective each official acts on pitch in order to contribute to judgment act process. This contribution requires officials' own understandings of the game to be compatible with each other: partly shared and partly specific. ## PASSION MOTIVES IN OFFICIATING FOOTBALL: DIFFERENCES BETWEEN NORWEGIAN ELITE AND NON-ELITE REFEREES?

Johansen, B.T., Haugen, T.

*University of Agder*

Introduction Johansen & Bjørnstad (2011) found in their study of motives for officiating football among non-elite referees in lower leagues passion as one of three main categories; fitness motives (31 %), passion motives (25 %), and social motives (25 %). One may ask: Do elite football referees see officiating as a passionate activity? Philippe, Vallerand, Andriananrisoa, & Brunel (2009) concluded in their study that elite referees are highly passionate about their officiating. The aim of this study was to compare the role of passion for officiating football between Norwegian elite and non-elite referees. Methods This cross-sectional study was conducted as a part of the "Norwegian Elite Referees in football"-study. A total of 83 (participating rate: 84.7 %) top-ranked referees (73 males and 10 females) from age 20 to 46 (mean age 33.3 years) completed a web based questionnaire (SurveyXact). The referees were asked to report randomly three main reasons or motives for officiating football. The data was analyzed and results were obtained by bracketing, intuiting, and describing the different motives reported and organized into categories of description (Marton, 1995). The different categories of description that emerged were studied and regrouped by two colleagues. Results A total of 249 different motives for being a referee reported were bracketed and grouped, and three main categories emerged; passion motives, 61 % (e.g., simply love football, enjoyment, mental fulfillment, coping of stress), social motives, 26 %, fitness motives, 13 %. A second analysis of the category passion motives revealed two main categories of passion; activity related passion (e.g., enjoyable, excitement, incredible fun), and performance related passion (e.g., handling stressful situations, feeling of success, leadership fulfillment). Discussion Norwegian elite referees are in some extent more passionate in their refereeing than non-elite referees reporting the importance of enjoyment and excitement in officiating. Moreover, several elite referees underlined that they simply love officiating football, and they find conducting this activity incredibly fun and it gives them valuable training in handling stressful situations in their professional occupations and in their lives in general. References Johansen, B.T. & Bjørnstad, J.O. (2011). Motives for being a referee in football (soccer). Proceedings for the 16th Annual Congress of the ECSS, 6th - 9th July, Liverpool-UK, 97-98. ## AWARDING PENALTIES IN SOCCER: DOES TEAM SUCCESS INFLUENCE THE REFEREE?

Erikstad, M., Johansen, B.T.

*University in Agder*

Introduction The fundamental role of the soccer referee is to be an impartial leader of the game, who does not favor one team over the other. Nevertheless, Sutter & Kochen (2004) found in their study that referees are significant more likely to award a penalty to the home team, suggesting that referees are subconsciously influenced by noise created by the home crowd. Social influence theory (i.e., Mucchi Faina, 1996) pinpoint that conformity to the majority is only one of various types of social influences. The aim of this study was to examine the social influence of ability by investigating if team success influences the referee in potential penalty situations in professional Norwegian soccer. Method All 16 teams in the Norwegian Premier League (NPL) 2012 were divided into three categories based on recent success; 2 "highly successful" teams, 3 "some successful" teams, and 11 "less successful" teams. Based on objective match reports in which a team were pre-categorized as "highly successful" had played against a lower categorized team, or two teams in same category had played each other, were examined. Video clips from potential penalties situations identified in the reports (n=98) were edited to reduce potential biases by hiding elements like time, score, sound, order and referees decision. The situations were evaluated individually by an expert panel of three male NPL referees, and their decisions compared to the actual decisions made in game. Results Of the 55 situations including teams in same success category, the expert panel awarded mean number of 28 penalties, while the actual game referees awarded 22 penalties (79% of the expert panel). Of the 22 situations where a highly successful team attacked, the expert panel awarded 9.7 penalties, while the game referees awarded 11 penalties (114 %). Of the 21 situations where a successful team's opponent attacked, the expert panel awarded 7 penalties, while the game referees awarded 1 penalty (14%). Discussion In the games between two teams

rated as equal successful, the actual game referees awarded 79% of the mean number of penalties identified by an expert panel. This difference may be explained by a greater possibility to identify an offence when a situation is seen on video from different angles, zoomed in and in slow motion. However, when a highly successful team attacked, referees in games awarded 114% of penalties identified by the expert panel, while the referees in games only awarded 14% when their opponent attacked. This may indicate that the actual game referees were biased by team success in potential penalty situations in the NPL 2012. References Mucchi Faina, A. (1996). *L'influenza sociale* [Social influence]. Bologna: Il Mulino. Sutter, M., & Kocher, M. G. (2004). ### **ENACTIVE ACCOUNT OF IN SITU MOBILIZATION: THE CASE OF VOLLEYBALL PLAYERS STRONGLY COMMITTED**

Recope, M., Rix-Lievre, G., Boyer, S., Laurin-Landry, D.

*Clermont University*

Introduction: Many studies based on cognitive framework focus on expertise-related differences in sport performance, none on criteria that would be common to the practice of some novices and experts. The defensive mobilization, a key aspect in volleyball (Selinger & Ackermann-Blount, 1987), seems to be one. Our enactive based study, conceiving cognition as a 'teleological constraint' (Weber & Varela, 2002; Laurent & Ripoll, 2009), aims to understand what underlies it. Method: We investigate 12 players regularly and strongly committed, with different levels of expertise (from beginner to highly skilled). Games were filmed and self-confrontation interview were realized. We bring primacy to various types of regularities identifiable about the action as it unfolds in situ. Analysis connects three kinds of regularities, related to: typical behaviors; discriminating circumstances of the game in which they are manifested; feelings and meanings expressed about these behaviors and circumstances. Results: Regularities pointed that there is a common convergence among these various players mobilized, between all of their discriminatory behavior (instantly oriented facing the ball, frequently manifest ready position, instantaneous spurts before giving up sometimes, extended attempts to contact the ball sometimes until fall or impact, frustration manifested when defensive failure occurs); and between these and feelings signified (defensive requirement been generalized, time and space always ever reported to the defending possibility, not reflected and impulsive rushes, prevalence of the defensive need on the bodily discomfort, pleasure felt in defensive success, dissatisfaction about inactive defending partners). Discussion: Despite their different expertise levels, players strongly committed in defense have in common an intrinsic teleology directed by their sensibility to the rally break. While this is at stake for them along the game, their domain of relevant interaction (Weber & Varela, 2002) is large: extremely attentive, they try to anticipate events, to be well positioned to save the ball and to avoid the rally's breaking. This phenomenological assumption about proper world is consistent with Lazarus proposals on appraisal and commitment (2001). We claim the necessity to investigate such dimension to better understand sport performance. References: Laurent E, Ripoll H (2009). ### **ARE THE STAGES OF CHANGE FOR SWIMMING & AQUATIC EXERCISE PROS & CONS QUALITATIVE DISTINCT? : AN ANALYSIS USING A PRECONTEMPLATION STAGE UNIVERSITY STUDENTS OF DECISION BALANCE**

Nishida, J.

*Gunma University*

Introduction Various studies conducted in and out of Japan have indicated the effects of swimming and doing aquatic exercises on the mind and the body. Berger and Owen (1983) examined the effects of swimming and aquatic exercises on transient feelings of university students and suggested that there were significant changes in their feelings, such as depression, anger, energy, and emotional stability. However, the number of university students that swim is 10.6%. The characteristics of university students that do not swim, or do other aquatic exercises were investigated from the perspective of decisional balance in behavior change theory. In a qualitative study, the perceptions regarding the pros and cons of doing these exercises to participants in the precontemplation stage were examined and compared with perceptions of participants in the maintenance stage. Methods Participants were required to recall past experiences of swimming and doing aquatic exercises and to describe three positive and negative things that might have been caused by them. Following Nishida (2011), participants were also required to make self-evaluations about behavior change stages related to swimming and aquatic exercises, with the exception of those conducted as university classes. Results The results indicated certain keywords and among the keywords, those with a frequency of 3 or more were extracted and categorized. The following 10 categories reflected descriptions of participants in the precontemplation stage regarding pros (N=593, 91.0%): improving health and physical strength, dietary effects, increasing muscle strength, stress reduction, improved aerobic capacity, comfort and enjoyment, gross movement, improved swimming, appropriate physical load, and healing effects. The following seven categories reflected the contents of description of participants in the precontemplation stage regarding the cons of swimming (N=535, 82.1%): changing clothes and preparation, physical damage, tiredness and exhaustion, danger, time required, expenses, and exposing the body. Discussion Categories indicated by participants in the maintenance stage were considered to be perceptions of pros of those doing these exercises for an extended period. Such participants considered that their health and physical strength improved, personal development was promoted, opportunities for meeting other people were increased, and life was enriched. On the other hand, participants in the precontemplation stage considered increased muscle strength and improved swimming ability as the main pros. References Berger, B. G. & Owen, D. R. (1983). Mood alteration with swimming- Swimmers really do 'feel better'. *Psychosomatic Medicine*, 45: 425-433. Nishida, J. (2011). Assessment of the pros and cons of swimming & water exercise among university student: Development and validation of a decisional balance scale. *Japan Journal for Health, Physical Education, Recreation, and Dance in Universities*, 8, 13-23.

### **MINDFULNESS TRAINING AND ATTENTION CONTROL IN ELITE SPORT**

Thienot, E.1,2, Dimmock, J.1, Jackson, B.1, Grove, B.1, Bernier, M.3, Fournier, J.4

1: University of Western Australia (Perth, Australia), 2: Western Australian Institute of Sport (Perth, Australia), 3: University of Caen (France), 4: INSEP French Institute of Sport (Paris, France)

In sport, the ability to self-regulate and respond efficiently when facing disruptive stimuli, by allocating the focus of attention to appropriate cues, is an essential prerequisite of success. Mindfulness is defined as a meta-cognitive skill that encompasses self-regulation of attention coupled with an attitude of acceptance towards one's present experience. To date, no studies conducted in sport have tested

the impact of a mindfulness-based intervention on variables associated with attention control. This study was designed to test the impact of mindfulness training (MT) on attention control using sport-specific and non-sport specific tasks. Elite swimmers were tested before and after an assignment to a four-week sport-based MT program ( $n = 15$ ) or to a control condition ( $n = 17$ ). Testing included a balance-task involving visual and audio distractions, a Stroop task, and a swimming task involving visual and audio distractions, as well as a validated instrument assessing the development of mindfulness skills in sport. We expected better post-intervention performances across the tasks among participants who attended MT in comparison to the control group. Two-way (group x time) MANOVAs were conducted for each task. Contrary to expectations, findings did not indicate that the MT provided benefits to attention control across sport and non-sport specific tasks. However, greater engagement in mindfulness practice during the intervention period was positively correlated with performances involving visual and audio distractions (i.e., swimming and balance task) and the development of non-judgmental skill. The nonsignificant multivariate effects may be explained by the lack of practice, but also by the nature of the tasks, the absence of incentive, and/or small sample size. However, this intervention provides an important framework for future sport-based studies, by implementing novel techniques for mindfulness training and incorporating objective measures of the mechanism underlying performance changes.

### **EMPOWERING PROFESSIONAL SOCCER PLAYERS IN SOUTH AFRICA: EVALUATION OF PROJECT ITHUSENG**

Taylor, G.

*Sports Science Institute of South Africa*

Introduction In response to the recognised need for life skills amongst professional soccer/football players in South Africa (SA), Project Ithuseng (meaning "Empower Yourself"), a life skills programme, was implemented by the Sports Science Institute of South Africa (SSISA). The programme was offered to Premier and First Division men's teams, women's national teams and nine top women's clubs. Evaluation of Project Ithuseng included formative, process and outcome evaluation components. Methods Prior to implementation of the programme, a needs assessment questionnaire was administered to all participating players, and seven focus groups were conducted with players ( $n=55$ ). A life skills questionnaire was administered to all participating players pre- and post-implementation. Post implementation, seven focus groups were conducted to assess players' perceptions of the programme ( $n=62$ ) and process evaluation data were collected via key informant interviews ( $n=9$ ). Results Seven Premier and 6 First Division clubs, 13 women's clubs, and 16 men's clubs from other divisions and academy teams completed the programme. Priority issues identified in the formative evaluation were planning for the future, leadership, communication, teamwork, self-confidence, taking responsibility and financial skills. Post-implementation focus groups revealed that Project Ithuseng was generally perceived as beneficial for players, and that fewer implementation challenges were experienced with women's clubs. Most valuable topics identified were finances, nutrition, conflict resolution and time management. The main factor influencing successful implementation was team management buy-in. A paired sample t-test ( $n=123$ ) showed a significant difference between pre- and post-implementation scores on the life skills questionnaire ( $p=0.046$ ). Discussion Evaluation recommendations include offering this programme to academy teams, younger players and other women's clubs, and that, in the interests of sustainability, a second phase is implemented to train soccer stakeholders to take over life skills facilitation. Through encouraging collaboration between soccer stakeholders in SA, Project Ithuseng has created a platform for future work in this area. (The full evaluation paper was published in the International Journal of Sports Science & Coaching. Volume 7.Number 3. 2012.)

### **COMPARISON OF PROBLEM SOLVING SKILLS OF STUDENTS STUDYING AT THE SCHOOL OF PHYSICAL EDUCATION AND SPORTS - AND FACULTY OF ARTS AND SCIENCE**

Unlü, C., Atan, T., Dilican, T., Yamaner, F., Çiçek, G.

*hitit üniversitesi*

INTRODUCTION: The aim of this study was to compare the problem solving abilities of the students between studying at the School of Physical Education and Sports (SPES) and Faculty of Arts and Science (FAS). MATERIALS AND METHODS: In this study, totally 350 students, 176 from SPES and 174 from FAS, participated voluntarily. As a data collecting instrument, Personal Information Form and "Problem Solving Inventory (PSI)" (Heppner and Petersen 1982) have been used in the research. In the adaptation of this scale to Turkey, 6 factors, such as "Hasty Approach," "Thinking Approach," "Avoiding Approach," "Evaluative Approach," "Self-Confident Approach" and "Planned Approach" have been found by Savasir and Sahin (1999). High total score means low problem solving ability of the individual. Mann Whitney-U test and Kruskal-Wallis test was used for the statistical analysis. RESULT: When all students were studied, Hast Approach, Thinking Approach and Evaluative Approach subscale scores and general PSI scores of SPES students were found to be higher than those of FAS students ( $p<0.01$  and  $p<0.05$ ). When the PSI and subscale scores of male students were compared, no statistically meaningful difference could be found between the males of different departments ( $p>0.05$ ). Once the scores of female students were analysed, the Evaluative Approach scores and general PSI scores of SPES students were found to be higher than FAS students' scores ( $p<0.05$ ). While Hasty approach scores of males were higher than females ( $p<0.01$ ), the other scores did show no statistically meaningful difference between genders ( $p>0.05$ ) when the PSI and subscale scores of boys and girls were compared regardless of department. DISCUSSION: In our study SPES students have higher PSI scores and this shows that SPES students have low level of problem solving abilities. Yildiz and et al. (2011) supported our finding that SPES students have high PSI scores. In our study PSI scores did not significantly differ between genders. Some previous studies supported our finding. In the study of Soyer and Bilgin (2010), the university students' perceptions of problem solving skills as adequate or inadequate did not differentiate between genders. Caglayan (2007), in his study, has found that there is not a statistically meaningful difference between PSI approaches of male and female students and that both genders will show an approach in the same way when they face such a situation. ### **ANALYSIS OF NAVIGATION EXPERIENCE IN ORIENTEERING: WHAT IS MEANINGFUL FOR NOVICE ORIENTEERS?**

Mottet, M.

*MIP, Université de Nantes*

Introduction Most previous psychological studies on orienteering have focused on the characteristics of the expert orienteer's activity. They pointed out the importance of the cognitive processes to navigate in a quick and efficient way (Macquet et al., 2012). The aim of this

study was to understand the experience of novices in orienteering from the analysis of the meanings they were building through their navigation. This study was carried out referring to the "course of action" framework in line with the empirical phenomenological psychology perspective (Theureau, 2006). Methods Eight male novices volunteered to participate in the study which took place during an orienteering teaching cycle. Two types of data were gathered: (a) audiovisual recordings made with glasses camera worn by orienteers, (b) verbalizations during self-confrontation interviews. Forty interviews were carried out. The analysis of the data consisted of reconstruct the participants' "courses of experience", which enabled to characterise the various dimensions of their experience during orienteering tasks. Results The analysis showed the fluctuating character of the orienteers' navigation experience. They varied on continuum between two contrasted feelings of doubt and confidence concerning the conviction of their correct location. When they were confident, the orienteers' activity was defined by algorithmic reasoning aiming at solving the navigation problems based on comparing the map and the terrain. When they had a strong doubt (feeling of being lost) the orienteers' reasonings were more erratic, thus taking into account other elements more meaningful to them: (a) the aggressions and obstacles of the forest environment, (b) the feeling of urgency considering their limited time to carry out the task, (c) their being close or far from the others and (d) from emotionally charged man-made features. Discussion These results show that the experience of novices in orienteering does not only consist in some cognitive operations aiming to solve a well-defined navigational problem thanks to map-terrain comparison. This adaptive mode only occurs when orienteers are confident enough. Conversely, in time of doubt, we can notice more complex experiential forms which show the physical, material, social and cultural dimensions of the navigation. In that case, the orienteers seem to be faced with ill-defined problems of navigation that can not be reduced to an algorithmic problem of wayfinding. These results highlight the conception of tasks and practical modalities in orienteering teaching and training. References Macquet, A.-C., Eccles, D. W., Barraux, E.
